

At the same timepoint blood flow by dynamic MRI was decreased in post-clamp wild type kidneys vs R4OX. WT and R4OX tissue- AngII levels were elevated in a sub-vasoconstrictive range in kidneys after 12 and 18hrs; confirmed by isolated perfused-kidney technique. By cytokine screen, AngII stimulated VSMC to secrete macrophage chemoattractant, RANTES. RANTES expression increased further when RGS4 expression was suppressed. AngIIR2 (AT2) inhibition decreased RANTES expression in RGS4-depleted cells implicating Gα protein activation in an AT2-RGS4-dependent pathway. Specificity of RGS4 function in VSMC was confirmed with VSMC-specific RGS4-/- that showed high macrophage density by T2 MR imaging compared to Tg and non-Tg. MΦ localized to the above region of blood flow disturbance. Tissue AngII in knockouts was also elevated at 12 and 18 hours but in a non-vasoactive range.

**Conclusions:** We conclude that RGS4 expression, specific to renal VSMC, inhibits AngII-mediated oxidative stress and macrophage recruitment during reperfusion injury.

### Regulatory T Cells Promote Renal Protection from Ischemia-Reperfusion Injury through Programmed Cell Death 1 (PD-1) Interactions with PD-L1 and PD-L2

Katarzyna Jaworska, Joanna Ratajczak, Brian K. Stevens, Liping Huang, Mark D. Okusa, Gilbert R. Kinsey. *School of Medicine, Div of Nephrology, UVA, Charlottesville, VA.*

**Background:** Regulatory T cells (Tregs) exert anti-inflammatory effects through diverse contact-dependent and -independent mechanisms. We have recently shown that Tregs protect against ischemia reperfusion (IR) injury and PD-1 expression on Tregs is required for their protective effect. We hypothesized that Treg PD-1 engagement by its ligands PD-L1 and PD-L2 promotes suppression of post-ischemic renal inflammation and dysfunction.

**Methods:** Naïve C57Bl/6 (WT) mice were injected with monoclonal blocking antibodies to PD-L1 or PD-L2 or isotype control antibodies 24 hr prior to bilateral renal ischemia followed by 24 hr reperfusion. In further experiments, WT Tregs were injected 6 hr after antibodies and 18 hr prior to IR.

**Results:** In a model of mild kidney IR (24 min ischemia) that does not result in significant renal dysfunction in isotype control antibody-treated mice (plasma creatinine (PCr) level: 0.5±0.1 vs. sham: 0.4±0.1) blockade of PD-L1 or PD-L2 prior to IR caused a significant reduction in renal function (PCr: 1.4±0.2 and 1.5±0.2, respectively) with enhanced acute tubular necrosis (ATN) and distinct patterns of inflammation in the kidney measured by flow cytometry, immunofluorescence microscopy and ELISA. Blocking both ligands simultaneously resulted in additive potentiation of renal inflammation and injury (PCr 2.4±0.1). As previously published, adoptively transferred WT Tregs offered near-complete protection from moderate renal IR (26 min ischemia) in the absence of PD-1 ligand blocking antibodies. In mice undergoing IR (24 min ischemia) in the presence of PD-L1 or PD-L2 blockade we observed moderate renal dysfunction (PCr: 1.5±0.2; 1.8±0.2, respectively) and adoptive transfer of WT Tregs in these mice did not protect from injury (PCr: 1.5±0.3 and 1.9±0.1, respectively), ATN or inflammation in the kidney.

**Conclusions:** These results suggest PD-L1 and PD-L2 have distinct and additive roles in protection from ischemic kidney injury and adoptively transferred Tregs must interact with both PD-L1 and PD-L2 to offer protection from kidney IRI.

## FR-PO058

### Effect of Endotoxemia on the Expression of the $PGE_2$ Synthetic System, and of Prostaglandin EP Receptors in the Kidney of the Mouse

Klaus Höcherl, Katharina Mederle, Hayo Castrop, Frank Schweda. *Univ of Regensburg, Institute of Physiology, Regensburg, Bavaria, Germany.*

**Background:** Sepsis is one of the leading causes of acute kidney injury (AKI). The present study was undertaken to characterize the biosynthetic pathway of prostaglandin (PG) $E_2$ and to examine the role of $PGE_2$ in the pathogenesis of endotoxemia-related AKI.

**Methods:** Male C57BL/6 mice, 8-10 wk old, were used. Endotoxemia was induced by the injection of lipopolysaccharide (LPS; 3 mg/kg; i.p.). The mRNA and protein levels were measured by q-RT-PCR and by immunoblotting, respectively. $PGE_2$ levels were determined by assay kits. Glomerular filtration rate (GFR) was determined by FITC-sinistrin clearance in conscious mice.

**Results:** LPS caused a time-dependent increase in renal COX-2 expression, whereas COX-1 expression was decreased. Endotoxemia increased the expression of mPGES-1, but not of mPGES-2 or cPGES. This was paralleled by an increase in tissue $PGE_2$ concentration. The COX-1 inhibitor SC-560 (20 mg/kg; i.p.) and the COX-2 inhibitor SC-236 (10 mg/kg; i.p.) decreased basal tissue $PGE_2$ levels. However, only pretreatment with SC-236 attenuated the LPS-induced increase in tissue $PGE_2$ concentration. Inhibition of COX-2 did not alter basal GFR, but augmented the LPS-induced decline in GFR. LPS caused an induction of the mRNA for the prostaglandin EP4 receptor, whereas the abundances of the prostaglandin EP1 and EP3 receptors were decreased. The mRNA expression of the EP2 receptor was not altered in response to LPS. In addition, $PGE_2$ exerted a dual effect on renal vascular tone, inducing vasodilatation at lower concentrations and vasoconstriction at higher concentrations in kidneys of control mice. In kidneys from endotoxemic mice, the vasodilatory component was more pronounced, whereas the vasoconstriction at higher $PGE_2$ concentrations was absent.

**Conclusions:** Our data provide evidence that an activation of the COX-2 / mPGES-1 synthetic pathway is responsible for the increased renal formation of $PGE_2$ in response to LPS. Our data further suggest that the vasodilatory effect of $PGE_2$ is enhanced in response to endotoxemia. Thus, agonism of EP2 and/or EP4 receptors may provide a basis for the treatment of sepsis-induced AKI.

### Regulatory T Cells Recruited to the Kidney by *N,N*-Dimethylsphingosine Ameliorate Lipopolysaccharide-Induced Acute Kidney Injury

Koeun Lee,[1] Sang Heon Suh,[1] Chang Seong Kim,[1] Joon Seok Choi,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Jongun Lee,[2] Soo Wan Kim.[1] *[1]Internal Medicine, Chonnam National Univ Medical School, Kwangju, Korea; [2]Physiology, Chonnam National Univ Medical School, Kwangju, Korea.*

**Background:** Regulatory T cells (Tregs) induce immunologic tolerance and prevent inflammatory diseases. The present study was aimed to examine whether Tregs recruited to the kidney by N,N-dimethylsphingosine (DMS), a sphingosine kinase inhibitor, prevents lipopolysaccharide (LPS)-induced kidney injury.

**Methods:** Mice were treated with LPS (20 mg/kg, i.p.) with or without DMS (0.4 mg/kg, i.p.). The degree of apoptosis was assessed by terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining. The expression of cyclooxygenase-2 (COX-2), inducible nitric oxide synthase (iNOS), endothelin-1 (ED-1), and Foxp3 was determined by immunoblotting and/or immunohistochemistry, while mRNA level of proinflammatory cytokines, chemokines, adhesion molecules, and Foxp3 was measured by real-time PCR. Using flow cytometry analysis, we investigated the expression of $CD4^+$ $CD25^+$ Tregs in the mice spleen and kidney.

**Results:** Plasma creatinine level was increased after LPS injection for 12 h compared with controls, which was attenuated in pretreatment with DMS. LPS treatment resulted in the elevation of both bax/bcl-2 ratio and number of TUNEL-positive cells in the kidney, which was counteracted by DMS pretreatment. The expression of COX-2, iNOS, and ED-1 was increased in LPS group, which was counteracted by DMS. DMS pretreatment also ameliorated LPS-induced increased mRNA expression of proinflammatory cytokines, chemokines, adhesion molecules,Administration of LPS upregulated $CD4^+$ $CD25^+$ Tregs in the spleen, while downregulated the cells in the kidney DMS cotreatment induced $CD4^+$ $CD25^+$ Tregs both in the spleen and kidney. The mRNA and protein levels of Foxp3 in the kidney were decreased in LPS group, which was prevented by DMS treatment.

**Conclusions:** In conclusion, it is supposed that DMS exerts its protective effects against LPS-induced kidney injury by suppression of apoptosis and inflammation in the kidneys, where modulation of Tregs by DMS might be involved in the underlying mechanisms.

**FR-PO060**

**Efficacy of C-C Chemokine Receptor 2 (CCR2) Antagonists CCX140 and CCX872 in a Mouse Model of Ischemia-Reperfusion Injury** Juan C. Jaen, Matthew J. Walters, Zhenhua Miao, Robert D. Berahovich, Jay P. Powers, Karen Ebsworth, Linda Ertl, Pirow Bekker, Thomas J. Schall. *ChemoCentryx Inc., Mountain View, CA.*

**Background:** Ischemia-reperfusion injury (IRI) is one of the most common causes of Acute Kidney Injury (AKI). In humans, IRI reflects poor renal perfusion in connection with major cardiothoracic surgery, such as coronary artery venous bypass grafting, and myocardial infarction. The CCR2 chemokine receptor is believed to regulate recruitment of circulating monocytes to the tubulointerstitial space in response to IRI-induced upregulation of the CCL2 chemokine by injured proximal tubular epithelial cells. We describe here the effects of 2 clinical-stage CCR2 inhibitors (CCR2-I) in a mouse model of renal IRI.

**Methods:** CCX872 was evaluated in male C57Bl/6 wt mice. Due to the high selectivity of CCX140 for human CCR2, CCX140 studies were performed in mice in which the mouse CCR2 coding region was replaced with the human CCR2 coding region (hCCR2KI). Mice underwent concurrent surgical clamping of both renal arteries for 45 min. Drug administration was initiated the day prior to surgery and continued until sacrifice 24 hrs later. Sham-operated animals were used as negative controls. Assessments included body weight, serum creatinine (sCRE) and BUN levels, histological assessment of tubular damage, and number of renal leukocytes.

**Results:** CCR2-I treatment significantly reduced sCRE, tubular damage and inflammatory cell infiltration in wild-type and hCCR2KI mice. sCRE: 1.47 and 2.02 mg/dL, CCX872 and vehicle control, respectively; $p<0.05$; Tubular Damage (% tubules): 41 and 62, CCX872 and vehicle control, respectively; $p<0.0001$; Total Leukocytes: 1,538 and 12,820 cells/kidney, CCX872 and vehicle control, respectively; $p<0.01$). Similar results were obtained with CCX140 using transgenic hCCR2KI mice.

**Conclusions:** Robust protection against AKI in a mouse model of IRI was obtained by prophylactic administration of either of two clinical-stage CCR2 inhibitors, one of which, CCX140, is currently being studied in two Phase-2 trials in subjects with T2D diabetic kidney disease. Thus, CCR2 inhibition may represent a novel therapeutic modality in the treatment of human AKI.

**FR-PO061**

**A Novel $S1P_1$ Agonist Protects Endothelial and Epithelial Cells and Preserves Renal Function in Acute Kidney Injury Models without Sustained Lymphopenia or Cardiovascular Effects** Bruno Poirier,[1] Véronique Briand,[1] Sylvain Ribeyro,[1] Marie-claire Philippo,[1] Alice Raffenne-devillers,[1] Catherine Cadrouvele,[1] Emilie Cornaire,[1] Isabelle Boitel-barbosa,[1] Florence Derdinger,[1] Michel Pelat,[1] Philippe Prigent,[1] Christine Girardot,[1] Jean-pierre Bidouard,[1] Valérie Fleury,[1] Philippe Beauverger,[1] Yi Shi,[4] Sylvie Lemarinel,[4] Meghan Clements,[2] Anna Zuk,[2] Souad Naimi,[4] Dieter Kadereit,[3] Matthias Schaefer,[3] Hartmut Ruetten,[3] Christina Soubrane,[1] Bérangère Thiers,[1] Alexandre Jagerschmidt,[1] Pierre Rosenzweig,[1] Ashfaq Parkar,[1] Steven R. Ledbetter,[2] Philip Janiak.[1] *[1]Tissue Protection and Repair Unit, Sanofi R&D, Chilly-Mazarin, France; [2]Tissue Protection and Repair Unit, Sanofi Genzyme, Framingham, MA; [3]Diabetes BU, Sanofi R&D, Frankfurt 65926, Germany; [4]SCP Biologics, Sanofi R&D, Vitry-sur-Seine, France.*

**Background:** We describe a novel $S1P_1$ agonist, $S1P_1$AGT, which is distinguished from the class of lymphopenic $S1P_1$ functional antagonists for multiple sclerosis.

**Methods:** $S1P_1$AGT was evaluated in cellular and in vivo models of AKI.

**Results:** $S1P_1$AGT does not desensitize $S1P_1$, which translates to an absence of sustained lymphopenia, and does not show any significant effect on heart rate and AV conduction. $S1P_1$AGT protected renal tubular epithelial cells from tunicamycin-induced apoptosis, inhibited the increase in VCAM, ICAM and P/E-selectins in TNFa-stimulated endothelial cells, and induced survival pathways (pAkt/pErk). In the setting of renal ischemia-reperfusion in rats, $S1P_1$AGT showed almost complete preservation of renal function and consistently reduced tubular necrosis, diminished renal inflammation, maintained endothelial barrier integrity and limited capillary rarefaction. The preservation of renal function was further confirmed in two separate mouse models of AKI induced by glycerol or tunicamycin.

**Conclusions:** $S1P_1$AGT displays endothelial protective effects which is in contrast to $S1P_1$ functional antagonists which are endothelial-damaging. The observed endothelial protective effects of $S1P_1$AGT, coupled with its epithelial protective and anti-inflammatory effects, represent a new and exciting approach for AKI treatment.

**FR-PO062**

**Natural IgM Protects against Renal Ischemia Reperfusion Injury by Altering Dendritic Cell Function** Peter I. Lobo, Kailo H. Schlegel, Liping Huang, Amandeep Bajwa, Mark D. Okusa. *Dept of Med/CIIR, Univ of Virginia, Charlottesville, VA.*

**Background:** We have shown in prior studies that natural IgM, especially IgM that binds to autologous leukocytes (IgM-ALA), protects against Renal IRI. These studies explore the mechanisms by which protection is conferred. Damage-associated molecular patterns (DAMPS), released following renal ischemia, activate Dendritic cells (DC), which present these autoantigens (especially glycolipids) to NK and NKT cells, initiating the inflammatory process resulting in magnified injury. As we observed high binding of natural IgM on DCs compared to other leucocyte population, we examined if the protective effect of IgM is mediated at the DC stage.

**Methods:** To test the effect of IgM on DC activation, cultured C57BL6 (B6) Bone Marrow Dendritic Cells (BMDC) were activated with LPS after pretreatment with either purified natural polyclonal murine IgM from serum, murine IgG, isotype murine IgM (lacking binding to mouse cells), or albumin. After 24 to 48 hours incubation, supernatant was taken for cytokine, and the BMDCs examined via flow cytometry. The effect of IgM on DC function was tested by I.V transfer of $5x10^5$ pre-treated BMDC into B6 mice given Renal IRI 24 hours later.

**Results:** IgM inhibited LPS induced TNFa secretion (from 7,150 pg/mL to 3,750 pg/mL) as well as decreasing the up-regulation of CD40 by approximately 40%. We observed no effect of IgM on BMDC expression of CD80, CD1d, MHC class II or on LPS induced TLR4 downmodulation. IgM+LPS pretreated DCs conferred significant protection against IRI compared to both control IRI or transfer of LPS treated DCs. Kid damage was evaluated by both plasma creatinine and histology.

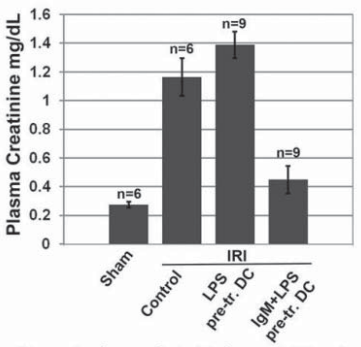

Figure 1 shows that 24 hr. post-IRI, mice receiving BMDC treated with IgM were protected from Renal IRI (p= 0.0006 for Control IRI vs IgM+LPS treated BMDC). This protection appeared to be IL-10 mediated, as an IL-10 neutralizing antibody given at time of IRI abolished the protective effect of IgM. Other experiments showed that pretreatment of BMDC with albumin, isotype IgM, or IgG conferred no protection. The effect appeared specific to DCs, as IgM pre-treatment and transfer of T or B cells did not protect.

**Conclusions:** These studies indicate that Natural IgM, especially IgM-ALA, can provide an innate regulatory mechanism by its effect on DCs.

**Interleukin 17A Drives Acute Kidney Injury through the Recruitment of Innate Effector Cells** Shaun A. Summers,[1] Amy J. Chan,[1] Oliver M. Steinmetz,[2] A. Richard Kitching,[1] Stephen R. Holdsworth.[1] *[1]Nephrology and Medicine, Monash Health and Monash Univ, Melbourne, Victoria, Australia; [2]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Acute kidney injury (AKI) is a major cause of morbidity and mortality. Clinical and experimental data demonstrate that cytokines and leukocytes promote renal inflammation and injury. We sought to define the role of Interleukin (IL)-17A in cisplatin induced AKI.

**Methods:** We administered cisplatin (15mg/kg) to C57BL/6 wild type (WT) mice and measured kidney inflammation and injury. For reconstitution studies, CD4+ T cells were isolated using magnetic beads and injected into RAG1-/- mice, which lack adaptive immune cells.

**Results:** Kidney mRNA expression of IL-17A increased significantly after cisplatin treatment. Compared to WT mice treated with cisplatin, functional (serum urea: WT 72.2±10.7 vs. IL-17A-/- 28.2±8.2mmol/L, $P<0.01$) and histological injury (Injury score [0-4]: WT 3.3±0.2 vs. IL-17A-/- 1.0±0.2, $P<0.001$) were decreased in IL-17A-/- mice. While interstitial neutrophil recruitment (1.8±0.1 vs.1.0±0.1, cells/high power field, $P<0.001$) decreased in the absence of IL-17A, CD4+ T cell recruitment remained intact. Pre-emptive administration of anti-IL-17A antibodies to WT mice attenuated renal injury, serum urea (control antibodies: 54.6±10 vs. anti-IL-17A 25.9±11.2mmol/L, $P<0.05$). Neutrophil depletion prior to cisplatin treatment did not significantly reduce renal injury, which only decreased after additional IL-17A neutralization in neutrophil deficient mice. Depletion of both neutrophils and natural killer T cells significantly protected from AKI, but injury was not further reduced after additional anti-IL-17A treatment, linking these cells with IL-17A induced AKI. While reconstitution of RAG1-/- mice with CD4+ T cells prior to cisplatin treatment increased renal injury, there was no difference after reconstituting with WT or IL-17A-/- CD4+T cells, demonstrating that IL-17A- producing CD4+ T cells did not enhance AKI. Mice deficient in gammadelta T cells were not protected from AKI.

**Conclusions:** IL-17A drives AKI and represents a new therapeutic target.

**Alpha-Lipoic Acid Attenuates Lipopolysaccharide-Induced Kidney Injury**
Sang Heon Suh,[1] Koeun Lee,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Soo Wan Kim,[1] Chang Seong Kim,[1] Joon Seok Choi,[1] Jongun Lee.[2] *[1]Depts of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [2]Depts of Physiology, Chonnam National Univ Medical School, Gwangju, Korea.*

**Background:** Kidney is one of the major target organs in sepsis, while effective prevention of septic acute kidney injury has not yet been established. We investigated the protective effect of α-lipoic acid (LA) on lipopolysaccharide (LPS)-induced kidney injury.

**Methods:** Two groups of rats were treated with LPS (20 mg/kg, i.p.), one of which being co-treated with LA (50 mg/kg), while the control group was treated with vehicle alone. Human renal proximal tubular epithelial cells (HK-2 cells) were cultured with or without LPS (10 μg/ml) in the presence or absence of LA (100 μg/ml) for 3 hours prior to LPS treatment.

**Results:** Serum creatinine level was increased in LPS-treated rats, which was attenuated by LA co-treatment.LPS treatment increased both cleaved caspase-3 expression and the number of terminal deoxynucleotidyl transferase dUTP nick end labelling-positive cells in the kidney, which was counteracted by LA. Protein expression of inducible nitric oxide synthase and cyclooxygenase-2 detected by immunoblotting and/or immunohistochemical staining, along with mRNA levels of pro-inflammatory cytokines detected by real time polymerase chain reaction, was increased in the kidney with LPS administration, which was ameliorated by with LA treatment. LA also protected LPS-induced tubular dysfunction, preserving type 3 $Na^+ / H^+$ exchanger and aquaporin 2 expressions in the kidney. Suppression of LPS-induced expression of cleaved caspase-3 by LA was also observed in HK-2 cells. 4', 6-diamidino-2-phenylindole staining also revealed heavy staining in HK-2 cells treated with LPS, which was prevented by LA. Increased protein expression of phospho-extracellular signal-regulated kinases 1/2 and c-Jun N-terminal kinases by LPS treatment was attenuated by LA pretreatment in HK-2 cells, while p38 was not affected by either LPS or LA treatment.

**Conclusions:** LA treatment attenuates LPS-induced kidney injury by suppression of apoptosis, inflammation, and renal tubular dysfunction.

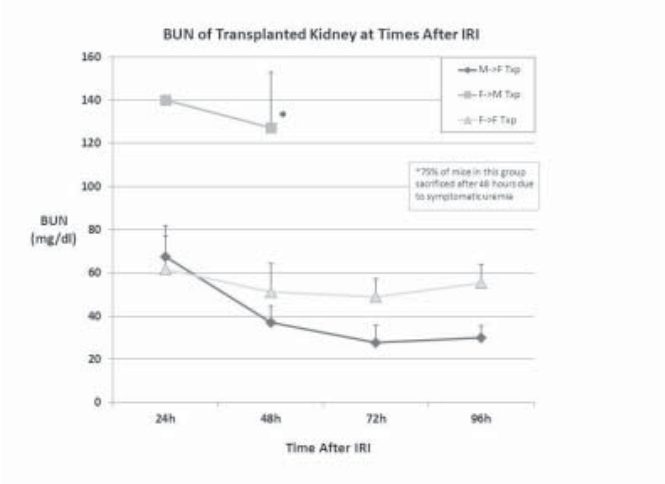
## FR-PO065

**Gender Differences in Murine Ischemia Reperfusion Tolerance Is Extrinsic to the Kidney Itself: Lessons from Transplantation**
Matthew H. Levine,[1] Zhonglin Wang,[1] Tricia Bhatti,[2] Wayne W. Hancock.[2] *[1]Surgery, Univ of Pennsylvania, Philadelphia, PA; [2]Pathology, Childrens Hospital of Philadelphia, Philadelphia, PA.*

**Background:** Gender differences are well described in murine basic renal ischemia reperfusion injury (IRI) models, with females being more tolerant of injury. Whether these differences are driven by differences in the kidney's resistance to IRI or whether they are due to differences in the host response to IRI are not known.

**Methods:** We utilized a syngeneic murine renal transplant model with male and female kidneys being transplanted into male and female recipients and then, after recovery, undergoing subsequent renal IRI by standardized 25 minute renal IRI protocol. Confirmatory cold ischemia renal experiments were performed with the same four groups, after storage of kidneys at 4 degrees C in UW solution for duration noted below and then subsequently transplanted with standardized transplantation times.

**Results:** Syngeneic kidneys transplanted into across genders with subsequent renal IRI showed that kidneys of both genders had similar and enhanced tolerance to IRI in a female host. Conversely, kidneys of both genders tolerated renal IRI equally poorly in a male host, with most mice euthanized in this group by 48 hours due to renal insufficiency.



Subsequent experiments demonstrated that male recipients of either gender kidneys after 18 hours of cold ischemia could not survive more than 48 hours after native nephrectomy due to renal insufficiency. Conversely, female recipients of either gender kidney tolerated 24 hours of cold ischemia and native nephrectomy with near total survival.

**Conclusions:** We conclude that female mice have significantly enhanced tolerance of renal IRI relative to males and that this tolerance is largely extrinsic to the kidney itself and is rather driven by gender differences in the inflammatory repsonse to IRI.

*Funding:* NIDDK Support

## FR-PO066

**Recombinant Alkaline Phosphatase Modulates Inflammation and Injury in Two Rat Models of AKI**
Can Ince,[1] Bulent Ergin,[1] Andrea Van van Elsas.[2] *[1]Translational Physiology, Academic Medical Center, Amsterdam, Zuid Holland, Netherlands; [2]AM Pharma, Bunnik, Netherlands.*

**Background:** Purified bovine alkaline phosphatase (AP) has shown intriguing clinical activity treating acute kidney injury in sepsis patients (Heemskerk et al. 2009, Crit. Care Med. 37: 417-23; Pickkers et al., 2012, Crit. Care 23: R14). A recombinant alkaline phosphatase was designed by swapping the crown domain from intestinal AP with that derived from placental AP enzyme generating a stable human chimeric called recAP.

**Methods:** To study its activity and mode-of-action in models of acute kidney injury (AKI), a single i.v. dose of 1000 U/kg recAP was administered to instrumented Wistar rats (7 per group) within 30 min. after ischemia-reperfusion (I-R) or LPS injection to induce AKI, and compared to saline (n=7). Systemic and local hemodynamics as well as kidney oxygenation were assessed for the duration of the experiment (3 h post-treatment). A control group underwent surgery and insertion of various probes without AKI induction.

**Results:** Saline treated animals developed mild (I-R model) or severe AKI (LPS model). Systemic hemodynamics was unaffected by recAP, however renal vascular resistance improved in the I-R model (control 2424 ± 370 dyn/s/cm2, 4314 ± 1182 in the saline group vs 2905 ± 1246 after recAP treatment) and renal blood flow significantly improved in the LPS model (control 5.02 ± 1.30 mL/min, saline 8.35 ± 2.98, recAP 6.28 ± 1.89, $p<0.01$). By immunohistochemistry, RecAP modulated inflammatory markers iNOS, IL-6 ($p<0.001$), as well as peroxidation marker MDA ($p<0.001$) in the LPS model. Compared to saline, recAP treatment reduced the number of infiltrating MPO+ leukocytes in the cortical peritubular areas ($p<0.05$). Moreover, recAP reduced expression of renal injury markers L-FABP, NGAL ($p<0.001$) and pro-apoptic Bax ($p<0.01$).

**Conclusions:** In conclusion, in rat AKI recAP demonstrated immediate pharmacological effect which included suppression of acute inflammation in the afflicted kidney and inhibition of tissue injury. This study provides first evidence that recAP is an active protein therapeutic in two rat models of AKI.

## FR-PO067

**Protective Effect of Cilostazol and Probucol on Inflammatory Kidney Injury**
Peng He,[1] Harukiyo Kawamura,[1] Kunimasa Yan,[2] Minoru Takemoto,[1] Koutarou Yokote.[1] *[1]Clinical Cell Biology and Medicine, Chiba Univ Graduate School of Medicine, Chiba, Japan; [2]Dept of Pediatrics, Kyorin Univ School of Medicine, Tokyo, Japan.*

**Background:** The aim of this study is to clarify the protective effect of a combination of cilostazol (CSZ) and probucol (PBC), both of which are prescribed for cardiovascular diseases and exhibit anti-inflammatory properties on inflammatory kidney injury.

**Methods:** In vivo, we employed lipopolysaccharide (LPS) induced acute renal inflammation model mice. In brief, after pretreatment with CSZ, PBC aloneor in combination with each other (CSZ/PBC), mice were intraperitoneally injected with LPS. After 24 h, urinary albumin levels were measured by ELISA and expression of MCP1 in glomeruli was analyzed by immunostaining and real-time PCR. In vitro, we treated cultured podocytes with LPS (100 ng/mL) in the presence or absence of CSZ, PBC or CSZ/PBC and then we estimated activation of MAP kinase by immunoblotting, activation of NFκB by immunostaining and reactive oxygen species (ROS) by dihydroethidium (DHE) staining.

**Results:** In mouse glomeruli and cultured podocytes, LPS-induced albuminuria and MCP1 upregulation were considerably suppressed by CSZ/PBC. Among the native cells of glomeruli, podocytes expressed most of MCP1 compared with endothelial and mesangial cells. In cultured podocytes, CSZ and PBC suppressed LPS-induced NFκB activation and MCP1 expression, while the combination of them showed an additive suppressive effect. CSZ increased intracellular cAMP levels and PKA activation which in turn suppressed ERK activation and MCP1 expression downstream. On the other hand, PBC lowered LPS-induced NFκB activation and MCP1 expression by reducing LPS-induced activation of NADPH oxidase and intracellular ROS production.

**Conclusions:** In a LPS-induced acute renal inflammatory mouse model, we confirmed that both CSZ and PBC showed anti-inflammatory effects through different mechanisms. Moreover, the combination of these two drugs had a stronger protective effect on LPS-induced renal dysfunction and glomerular inflammation. This study indicated that combination of CSZ and PBC could be a prospective treatment for inflammatory kidney diseases.

## FR-PO068

### CXCR2 Knockout Mice Are Protected against Dextran Sulfate Sodium-Colitis Induced Acute Kidney Injury and Inflammation

Punithavathi Vilapakkam Ranganathan, Calpurnia Jayakumar, Ganesan Ramesh. *Vascular Biology Center, Georgia Regents Univ, Augusta, GA.*

**Background:** Organ cross-talk exists in many human diseases and in animal models. Recent study had demonstrated that inflammatory mediators can cause acute kidney injury (AKI) and neutrophil infiltration in the mouse model of acute colitis. However, the chemokines and their receptors that mediate distant organ effects in colitis are unknown.

**Methods:** We examined the hypotheses that KC-CXCR2 pathway mediates DSS-colitis induced AKI. Colitis was induced in 8-week old wild-type (WT) and CXCR2 knockout mice by feeding them with 3.5% DSS in drinking water for a period of 8 days. Animals were sacrificed 2 days after removal of DSS. Kidney function was monitored by measuring serum creatinine. Some mice received recombinant KC (100ng/animal) to determine whether exogenous administration of KC exacerbates acute kidney injury. Inflammation and immune cell infiltration were quantified by immunostaining, RT-PCR and ELISA.

**Results:** WT mice developed severe colitis with DSS treatment which was associated with inflammatory cytokine and chemokine expression and neutrophil infiltration in the colon. DSS-colitis in WT was accompanied by acute kidney injury (serum creatinine: 0.4±0.03mg/dl) and enhanced expression of cytokine (TNFa) and chemokines (MCP-1, IP-10 and KC) in the kidney. However, CXCR2 knockout mice were protected against DSS-colitis as well as acute kidney injury (serum creatinine: 0.2±0.02mg/dl). Moreover, the expression of cytokines and chemokines and neutrophil infiltration was significantly and completely blunted ($p<0.001$ vs. WT) in CXCR2 knockout mice in colon and kidney. Administration of recombinant KC exacerbated DSS-colitis induced acute kidney injury (0.6±0.03 mg/dl, $p<0.05$ vs. vehicle treated).

**Conclusions:** Our results suggest that KC and its receptor CXCR2 are critical and major mediators of organ cross talk between colon and kidney in DSS induced colitis and neutralization of CXCR2 will help to reduce the incidence of acute kidney injury due to ulcerative colitis and crohn's disease in humans.

## FR-PO069

### Genetic Deletion of Semaphorin 3A Render Resistance to Ischemia Reperfusion Induced Inflammation and Acute Kidney Injury in Mice

Punithavathi Vilapakkam Ranganathan, Calpurnia Jayakumar, Ganesan Ramesh. *Vascular Biology Center, Georgia Regents Univ, Augusta, GA.*

**Background:** Recent studies show that guidance molecules that are known to regulate cell migration during development may also play an important role in adult during normal and pathological state. One such molecule called semaphorin 3A (sema3A) is known to be expressed in the kidney and its patho-physiological role in the kidney is unknown.

**Methods:** To test the hypothesis that sema3A is a mediator of ischemia reperfusion of the kidney by increasing epithelial cell apoptosis. Ischemia reperfusion injury in the kidney was induced by clamping renal pedicle for a period of 35 minutes followed by 24hr of reperfusion in sema3A knockout (KO) and C3H control mice. Kidney function, inflammation, immune cell infiltration and apoptosis were quantified by measuring serum creatinine, immunostaining, RT-PCR, ELISA and TUNEL assay. Some wild-type received sema3A pathway inhibitor or sema3A blocking peptide 2hr before renal pedicle clamping to determine the effect of pharmacological inhibition of sema3A pathway on ischemic acute kidney injury (AKI).

**Results:** C3H mice subjected to ischemia reperfusion developed severe renal dysfunction as compared to sema3A KO mice (serum creatinine: 1.7±0.1 vs. 1.0±0.1 mg/dl, $p<0.01$), which was associated with histological alteration, neutrophil infiltration, increased cytokine and chemokine expression and excretion in urine. These changes were minimal in sema3A KO mice with ischemia reperfusion. Moreover, ischemia reperfusion induced extensive apoptosis in renal epithelial cells which was significantly suppressed in sema3A KO mice. Similarly, administration of sema3A inhibiting peptide or sema3A signaling inhibitor LOXblock-1 protected kidney against ischemia reperfusion induced AKI. Consistent with *in vivo* pathogenic role of semaphorin 3A, addition of semaphorin 3A to kidney epithelial cells *in vitro* increased cisplatin induced apoptosis.

**Conclusions:** Our data suggests that sema3A play a pathogenic role in acute kidney injury through increasing epithelial cell apoptosis and sema3A inhibition may provide protection against human AKI.

### Depletion of $CD25^+$ T Regulatory Cells Reverses Protection against Ischemic Renal Injury in Heat Shock Factor-1 Knock-Out Mice

Rajasree Sreedharan, Shaoying Chen, Dipica Haribhai, Calvin B. Williams, Scott K. Van Why. *Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

**Background:** We previously reported that Heat Shock Factor-1 knock-out (HSF-1 KO) mice, are protected against ischemic renal (IR) injury compared with Heat Shock Factor-1 wild type (WT). Further, HSF-1 KO mice have altered T cell infiltration immediately following IR, with significantly fewer $CD4^+$ and $CD8^+$ cells infiltrating HSF-1 KO kidneys than WT kidneys following IR. Our goal was to determine whether T regulatory cells play a role in the protection against IR injury seen in HSF-1 KO mice.

**Methods:** We compared T regulatory cells ($Foxp3^+/CD25^+$) in HSF-1 KO and WT kidneys in the sham condition and after reperfusion following 45 minutes ischemia by flow cytometry. The effect of depletion of T regulatory cells on IR injury was studied by subjecting HSF-1 KO mice to IR (45 minutes with 24 hours reflow) after treatment with PC61 anti-CD25 antibody or vehicle control group.

**Results:** There are significantly more $Foxp3^+$ T regulatory cells in sham operated kidneys of HSF-1 KO mice compared with WT ($p=0.02$). Early in reperfusion after renal ischemia, $Foxp3^+$ did not change in HSF-1 KO kidneys, but increased by 50% in WT kidneys. Treatment of HSF-1 KO mice with PC61 antibody significantly depleted the renal $Foxp3^+CD25^+$ cells when compared with vehicle control group in sham ($p=0.008$) and following IR insult ($p=0.01$). PC61 treatment did not affect serum creatinine compared to vehicle control group in sham operated HSF-1 KO mice. However PC61 treatment (causing depletion of intra-renal $CD25^+$ T regulatory cells) resulted in higher serum creatinine in HSF-1 KO than in vehicle treated HSF-1 KO following IR injury (0.89 mg/dL vs 0.48 mg/dL respectively).

**Conclusions:** Higher endogenous levels of renal T regulatory cells play a role in the protection afforded to HSF-1 KO mice against IR injury.

### Detailed Analysis of Double Negative (CD4-/CD8-) T Cells during AKI

Maria Noel Martina Lingua,[1] Samatha Bandapalle,[2] Sanjeev Noel,[2] Abdel Hamad,[1] Hamid Rabb.[2] *[1]Pathology, Johns Hopkins Univ, Baltimore, MD; [2]Nephrology, Johns Hopkins Univ, Baltimore, MD.*

**Background:** Double negative (DN) T cells lacking CD4 and CD8 have recently been described to be a resident kidney immune cell (*J Leuk Biol* 2008). The role of these cells in kidney and how they mediate immune responses are unknown. We hypothesize that DN T cells are innate T cells involved in regulating early immune response in kidney and have a suppressive function on cytokine production, potentially protecting kidney from injury.

**Methods:** Purified T lymphocytes from mice were analyzed for expressing surface markers and cytokines secretion. B6 wild type mice and acute kidney injury mice model were used. Surface and intracellular staining were done and analyzed with flow cytometry technology.

**Results:** Double negative T cells comprise a major population in kidney in the steady state (30%). This percentage shows a rapid and transient expansion early after IRI, increasing after 3h of ischemia up to 60% and decreasing after 24h to 10%. DN T cells showed an activated phenotype in the kidney, expressing markers like CD44 and CD69, and also higher level of co-stimulatory molecules like CD28 and CD40-L compared to CD4+ and CD8+ in kidney. DN T cells exhibit a unique cytokine secretion profile: in steady state express IL-17, IL-10, IFN-y, IL-4 (60%, 10%, 5% respectively) after in vitro stimulation with PMA/ion in, while in ischemic kidneys they increased IL-10 – IL-17 (18%, 68% respectively) secretion and decreased IL-4 (1%). They also express the transcription factor ROR-y up to 20% in steady state.

**Conclusions:** Our data shows that resident kidney double negative T cells produce a distinct cytokine profile during steady state. After AKI, DN T cells have a significant change in cytokine profileincluding a change in transcription factor ROR-y. DN T cells are a newly identified resident kidney cell that can improve our understanding of immune mediated kidney diseases including AKI, glomerulonephritis and transplant rejection.

### The Role of Toll-Like Receptors and Reactive Oxygen Species in the Development of Lupus Nephritis

Altaf-M Khan,[1] Jerome L. Maderdrut,[2] David H. Coy,[2] Eric E. Simon,[1,3] Vecihi Batuman.[1,3] *[1]Medicine, Section of Nephrology & Hypertension; [2]Peptide Research Laboratory, Tulane Univ School of Medicine, New Orleans, LA; [3]Veterans Affairs, SLVHCS, New Orleans, LA.*

**Background:** Lupus nephritis is a common and serious manifestation of systemic lupus erythematosus (SLE). We have explored the role of Toll-like receptors (TLRs) and reactive oxygen species (ROS) in the development of kidney disease in a mouse model of SLE.

**Methods:** We used the female New Zealand Black/New Zealand White (NZB/NZW) F1 hybrid (lupus-prone) mouse, which spontaneously develops SLE-like pathology, as a model for lupus nephritis. NZW mice served as the controls. Mice (n = 4) were euthanized at 22, 29 or 41 weeks (wk) of age, and blood and kidneys were harvested to assess renal function and pathology.

**Results:** Serum creatinine and cystatin C levels and mRNA levels of the genes for the kidney injury biomarkers KIM-1 and Nogo-B1 increased significantly in lupus-prone mice at 22 wk compared to controls and continued to rise through 41 wk. The mRNA levels of the genes for inflammatory cytokines (IFN-γ, MCP-1, TNF-α, and TGF-β1) and TLR2, TLR4, TLR6, TLR7, and TLR9 were significantly up-regulated in lupus-prone mice at 41 wk compared to controls at 41 wk. Activation of TLRs was propagated through MyD88-dependent but not TRIF-dependent signaling pathways. The messages for ROS-generating enzymes (iNOS, Nox2 and Nox4), for pro-apoptotic genes (FADD-1, Fas-1 and Aifm-1), and for the marker genes for monocyte/macrophage/neutrophil infiltration (CD11b, CD68 and MPO) were significantly increased, while the messages for the anti-apoptotic proteins Bcl-2 and Ube2v1 (a TLR effector protein) were significantly decreased at 41 wk in lupus-prone mice compared to controls. The protein levels for proinflammatory cytokines in the kidneys of lupus-prone mice increased significantly between 22 wk and 41 wk.

**Conclusions:** Lupus-prone mice develop renal pathology as early as 22 wk and could be a good model to study the role of innate immunity in lupus nephritis. These data suggest that modulation of TLR pathways and ROS suppression could be useful strategies for the treatment of lupus nephritis.

**Depletion of Macrophage Ameliorates Glycerol-Induced Acute Kidney Injury in Mice** Seong Eun Yun, Eunjin Bae, Yeojin Kang, Hyun Seop Cho, Se-Ho Chang, Dong Jun Park. *Internal Medicine, Gyeongsang National Univ Hospital, Republic of Korea.*

**Background:** The roles of macrophage in rhabdomyolysis mice model have not been well organized. This study was conducted to elucidate the relative contribution of renal macrophages to the development of acute kidney injury (AKI) by glycerol injection into mice.

**Methods:** The macrophages were depleted by liposomal encapsulated clodronate (LEC). Mice were distributed into four groups: control group (liposomal vehicle 100 *u*l, intravenously 24 hour prior to and just before glycerol injection), LEC group (LEC 100 *u*l, intravenously 24 hour prior to and just before glycerol injection), Gly (50% glycerol (10 ml/kg)), and Gly plus LEC. On day 24 hour, renal function, histology, flow cytometry for macrophages, Western blot and renal tissue immunohistochemistry were assessed.

**Results:** Glycerol injection increased serum creatinine and blood urea nitrogen (BUN) 24 hours after injection. LEC injections (100 *u*l/mouse via tail vein) administered 24 h prior to and just before glycerol injection prevented the deterioration of renal function and also tubular damages 24 hours after glycerol injection. Renal macrophages represented by $CD45^+CD11b^+Ly6c^+F4/80^+$ or $CD45^+CD11b^+Ly6c^+$ cells were significantly decreased by pretreatment of LEC in both normal and myoglobin injured kidney. LEC injection decreased apoptotic death of the tubular epithelial cells by decreasing pro-apoptotic caspase-9 protein and increasing anti-apoptotic Bcl-2 protein expression. LEC administration also attenuates activation of ERK and p53 expression 24 hr after glycerol administration. NF-kB, MCP-1, and ICAM-1 were also decreased in the damaged tubular epithelial cells by LEC injection. iNOS and COX-2 expression were decreased in LEC plus glycerol group, compared to glycerol only group.

**Conclusions:** These results support the hypothesis that depletion of macrophages is effective in prevention of renal dysfunction by abrogating apoptosis and attenuating inflammation in glycerol-induced AKI mice model.

**FR-PO074**

**PKC-α Offers Protection against Programmed Necrosis in Renal Proximal Tubules through Maintaining Functional MPT Pore** Grazyna Nowak. *Pharmaceutical Sciences, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** We have shown that necrosis, but not apoptosis, is the mechanism of cell death in renal proximal tubular cells (RPTC) injured by oxidant. RPTC necrosis is preceded by mitochondrial membrane hyperpolarization and bioenergetics failure. PKC-α activation prevents mitochondrial hyperpolarization, reduces mitochondrial dysfunction and ATP deficits, and decreases necrosis in oxidant-injured RPTC. Overexpression of the inactive mutant of PKC-α induces mitochondrial membrane hyperpolarization in non-injured RPTC.

**Methods:** To determine specific mechanisms of oxidant-induced RPTC necrosis, monolayers were treated with inhibitors of three different pathways of regulated necrosis and cell viability was assessed following exposure to a model oxidant, tert-butylhydroperoxide. In some experiments, PKC-α was overexpressed and RPTC lysis assessed following TBHP exposure.

**Results:** TBHP induced 43% RPTC death at 24h after the exposure. Pretreatment of RPTC with cyclosporine A (inhibitor of cyclophilin D) offered no protection at concentration of 1 μM (41% lysis) and exacerbated cell lysis at higher concentrations (58% lysis). Iron chelation by deferoxamine and inhibition of ferroptosis by ferrostatin prevented TBHP-induced RPTC death (4% lysis). Necrostatin-1, an inhibitor of necroptosis, decreased RPTC lysis to 12% of controls. Overexpressing PKC-α in RPTC decreased oxidant-induced necrosis to 22% and this protective effect was reversed by cyclosporine A and PKC inhibitor, Go6976. Ferrostatin and deferoxamine augmented PKC-α-mediated protection against oxidant-induced injury (13% and 5% cell lysis, respectively).

**Conclusions:** These results demonstrate that oxidant-induced RPTC necrosis is iron-dependent and its major mechanism is through ferroptosis. Necroptosis is an additional mechanism involved in RPTC death. However, the opening of the mitochondrial permeability transition pore (MPTP) and loss of $\Delta\Psi_m$ are not mechanisms that mediate oxidant-induced programmed necrosis in RPTC. The protective effects of PKC-α are mediated through maintaining functional MPTP and preventing mitochondrial membrane hyperpolarization.

**FGF/FGFR2 Signaling Protects against Tubular Cell Death and Acute Kidney Injury** Zhuo Xu, Weichun He, Junwei Yang, Chunsun Dai. *The Center for Kidney Disease, the Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

**Background:** Fibroblast growth factors (FGFs) are heparin-binding proteins involved in a variety of biological processes, including cell proliferation, differentiation, survival and angiogenesis. However, the role and mechanisms of FGFs/FGFR signaling in tubular cell survival and AKI need further investigation.

**Methods:** In this study, Ischemia/reperfusion or cisplatin injection was used to induce AKI in mice. A mouse model with tubule specific deletion of FGFR2 (Tubule-FGFR2-/-) was generated.

**Results:** In the kidneys with ischemia/reperfusion injury (IRI), the expression of FGFs including FGF2, FGF7, FGF10, FGF12, FGF13, FGF18, and FGF22 were up-regulated. In addition, phosphorylated ERK1/2, a downstream signaling of FGFR was also elevated in the IRI kidneys. To further explore the role of FGF signaling in tubular cell survival and AKI in mice, a mouse model with tubular cell specific FGFR2 gene disruption was generated by using Cre-LoxP system. The knockouts were born normal and no obvious kidney dysfunction was found within four months after birth. Specific deletion of FGFR2 in tubular cells in mice aggravated the tubular cell death as well as AKI induced by IRI or cisplatin. In cultured NRK-52E cells, recombinant FGF2 protein could induce Erk1/2 phosphorylation and inhibit cisplatin-induced cell death. PD98059, a specific MEK 1/2 inhibitor, abolished Erk1/2 phosphorylation and partly reversed the protective effect of FGF2 in ciaplatin-induced cell death.

**Conclusions:** Together, this study indicates that FGF/FGFR2 signaling is important for protecting against tubular cell death and AKI, which is partly through ERK1/2 signaling activation.

**FR-PO076**

**Propidium Iodide Is Cheating on Necrosis Detection: A Multiphoton Microscopy Study** Matthias Hackl,[1] Andreas Linkermann,[2] Bernhard Schermer,[1] Thomas Benzing.[1] *[1]Dept II of Internal Medicine and Center for Molecular Medicine Cologne, Univ of Cologne, Cologne, Germany; [2]Clinic for Nephrology and Hypertension, Christian-Albrechts Univ, Kiel, Germany.*

**Background:** There is an ongoing debate, if apoptosis or necrosis is the more prevalent form of cell death after ischemia-reperfusion injury. Propidium iodide (PI) staining has been used as a marker of necrotic cells in many studies. Intact cell membranes prevent the entry of PI into viable cells. PI has been successfully used to detect necrotic nuclei *in vivo* in the heart, the eye and the brain. Here we tested if PI is a reliable marker of cell necrosis in the kidney *in vivo*.

**Methods:** 6 wk old C57BL6 mice were anaesthetized, an arterial catheter was placed and the left kidney was exteriorized for *in vivo* multiphoton microscopy. 30μg PI was injected during the acquisition of a time lapse movie. Blood vessels and nuclei were labeled by the injection of 70kDa Texas red dextrane and 150μg Hoechst 33342 respectively. Lucifer Yellow was injected to visualize tubular fluid handling. To stop tubular flow the left ureter was ligated three times with 6-0 silk and the animals imaged 2-7 days later.

**Results:** In healthy and uninjured kidneys a considerable amount of PI was taken up by tubular cells. Time-lapse imaging demonstrated that the nuclei turned red 30-60 minutes after the injection of PI into the circulation. Colabelling with Hoechst 33342 and studies of tubular handling of filtrate showed that only proximal tubular cells (PTC) take up PI. The uptake of PI was markedly reduced 3-7 days after an unilateral ureteral ligation, while Hoechst 33342 staining was unaltered. Imaging of liver and gut showed no uptake in these organs. After the induction of damage with the laser beam some cells immediately took up PI.

**Conclusions:** Our data clearly demonstrates that PI is taken up by viable PTC from the tubular fluid. Distal tubular cells, glomerular cells, the liver and the gut do not show uptake of PI, demonstrating that this uptake is restricted to PTC. Although cells with membrane damage may show a faster PI uptake than viable PTC, the use of PI as a marker for necrotic cells *in vivo* is limited by the false positive nuclei of viable PTC.

**FR-PO077**

**SUMOylation Occurs in Acute Kidney Injury and Plays a Cytoprotective Role** Chunyuan Guo, Zheng Dong. *Dept of Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA.*

**Background:** SUMOylation is a mechanism of post-translational modification where Small Ubiquitin-like Modifiers (SUMO) are covalently attached to target proteins to regulate their localization, stability and functions. SUMOylation has been demonstrated during hypoxia, oxidative, genotoxic and metabolic stresses, suggesting an important role of this modification in cellular stress response. However, it is largely unclear if SUMOylation contributes to the pathogenesis of kidney diseases, such as acute kidney injury (AKI).

**Methods:** We examined protein SUMOylation in two experimental models of AKI: cisplatin nephrotoxicity and renal ischemia-reperfusion in vitro and in vivo. In addition, we examined the regulation of SUMOylation during cisplatin treatment of cultured rat kidney proximal tubular cells (RPTC) by two ROS scavengers and a pharmacological p53 inhibitor. We further examined the role of SUMOylation during cisplatin treatment of RPTC cells by using ginkgolic acid (GA), a pharmacological inhibitor of the E1-activating enzyme in SUMOylation.

**Results:** We have demonstrated dramatic increases of protein SUMOylation in both experimental models of AKI. Cisplatin-induced SUMOylation in RPTC cells was partially suppressed by N-acetylcysteine and dimethyurea (two ROS scavengers), supporting a role of oxidative stress in the activation of SUMOylation. In addition, SUMOylation by SUMO-2/3, but not SUMO-1, was partially suppressed by pifithrin-alpha, a pharmacological inhibitor of p53, supporting a role of p53 in SUMOylation by SUMO-2/3. Pretreatment with GA suppressed SUMOylation during cisplatin incubation and importantly, GA enhanced apoptosis.

**Conclusions:** Taken together, the results demonstrate the first evidence of SUMOylation in AKI which may result from oxidative stress and p53 signaling and suggest that SUMOylation may play a cytoprotective role in kidney tubular cells.

**Two Independent Pathways of Regulated Necrosis Mediate Ischemia-Reperfusion Injury** Andreas Linkermann,[1] Jan Hinrich Braesen,[2] Maurice Darding,[3] Ana Belen Sanz,[4] Jan O. Heller,[1] Ricardo Weinlich,[5] Alberto Ortiz,[4] Henning Walczak,[3] Joel M. Weinberg,[6] Ulrich Kunzendorf,[1] Stefan Krautwald.[1] *[1]Clinic for Nephrology and Hypertension, Christian-Albrechts-Univ, Kiel, Schleswig-Holstein, Germany; [2]Institute for Diagnostic Histopathology and Cytopathology, Pathology Hamburg-West, Hamburg, Germany; [3]Centre for Cell Death, Cancer and Inflammation (CCCI), Cell Death and Inflammation Laboratory, Univ College London, Cancer Institute, London, United Kingdom; [4]IIS-Fundacion Jimenez Diaz, U Autonoma de Madrid, Redinren, FRIAT, Madrid, Spain; [5]Dept of Immunology, St. Jude Children's Research Hospital, Memphis, TN; [6]Div for Nephrology, Univ of Michigan Medical Center, Ann Arbor, MN.*

**Background:** Regulated necrosis (RN) may result from cyclophilin D (CypD)-mediated mitochondrial permeability transition (MPT) and receptor-interacting protein kinase 1 (RIPK1)-mediated necroptosis, but it is unclear whether there is one common pathway in which CypD and RIPK1 act in or if separate RN pathways exist.

**Methods:** Here, we demonstrate that necroptosis in ischemia-reperfusion injury (IRI) in mice occurs as primary organ damage, independent of the immune system, and that mice deficient for RIPK3, the essential downstream partner of RIPK1 in necroptosis, are protected from IRI.

**Results:** Protection of RIPK3-ko mice was significantly stronger than of CypD-deficient mice. Mechanistically, analysis of cisplatin-induced AKI and hyperacute TNF-shock models in mice suggested the distinctness of CypD-mediated MPT from RIPK1/RIPK3-mediated necroptosis. We therefore generated novel CypD-RIPK3 double-deficient mice that are viable and fertile without an overt phenotype and that survived prolonged IRI which was lethal to each single knockout. Combined application of the RIPK1 inhibitor necrostatin-1 (Nec-1) and the MPT inhibitor sanglifehrin A (SfA) confirmed the results with mutant mice.

**Conclusions:** The data demonstrate the pathophysiological co-existence and co-relevance of two separate pathways of RN in IRI and suggest that combination therapy targeting distinct RN pathways can be beneficial in the treatment of ischemic injury.

**Cdk2-Dependent Phosphorylation of Bcl-xL Promotes Cisplatin-Induced Renal Cell Death *In Vitro* and *In Vivo*** Peter M. Price,[1,2] Adel Tarcsafalvi,[1] Nang San Hti Lar Seng,[1] Judit Megyesi.[1,2] *[1]Univ AR Med Sci; [2]VA Med Ctr.*

**Background:** Expression of $p21^{WAF1/Cip1}$ *in vitro* and *in vivo* protects kidney cells from cisplatin cytotoxicity by inhibiting on Cdk2 activity. Similarly, inhibition of Cdk2 activity also protects from cisplatin-induced cytotoxicity.

**Methods:** *C*ultured mouse proximal tubule cells were exposed to cisplatin at 25 μM. Mice were administered cisplatin at 20 mg/kg body weight and were either wild-type (129/Sv), p21-transgenic, or DN-Cdk2 transgenic. Transgenes were induced specifically in kidney proximal tubules by implantation of testosterone pellets. Bax activation was assessed by a conformation-specific antibody. Bcl-xL and phosphomimic Bcl-xL were purified by Ni-affinity chromatography to His-tagged Bcl-xL. Specific phosphorylation of Bcl-xL by Cdk2 was by analogue-sensitive Cdk2/cyclin A. Localization of the Bcl-xL phosphorylation site was by MS/MS analysis.

**Results:** We show that after cisplatin exposure, Cdk2 activity is upregulated, that Cdk2 phosphorylates Bcl-xL, a pro-survival Bcl-2 family member, and that phosphorylated Bcl-xL has a lower affinity to bind and inhibit Bax, a pro-apoptotic Bcl-2 family member. There are several possible mechanisms proposed to explain Bax activation, which results in Bax-mediated MOMP and eventual cell death. A common factor in these hypotheses is the prevention of Bax activation by virtue of its binding to pro-survival Bcl-2 family member proteins, such as Bcl-xL. We provide evidence that Bcl-xL is phosphorylated by Cdk2 at a previously unreported site in the protein, and also that Bcl-xL phosphorylation after cisplatin exposure is dependent on Cdk2 *in vitro* and *in vivo*. Previous studies showed that Bcl-xL phosphorylation can cause dissociation of Bax/Bcl-xL heterodimers. The interaction of Bcl-xL and Bax prevents the structural change necessary for Bax activation, which is required for Bax oligomerization in the mitochondrial membrane and subsequent MOMP, caspase activation, and cell death.

**Conclusions:** We propose that Cdk2 phosphorylation of Bcl-xL interferes with Bax retrotranslocation, resulting in Bax accumulation on mitochondrial membranes, Bax activation, MOMP, and subsequent cell death.

**FR-PO080**

**Nephron-Specific Kidney Injury Molecure-1 Overexpression Induces Tubular Damage and Kidney Failure in Transgenic Zebrafish** Wenqing Yin, Said Movahedi Naini, Dirk M. Hentschel, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Mammalian Kidney injury molecule-1 (KIM-1) is upregulated after kidney injury in proximal tubular cells, and serves as a highly sensitive and specific biomarker for acute kidney injury. KIM-1 is also upregulated in many subjects with chronic kidney disease. KIM-1 functions as a phagocytic receptor which mediates the uptake of apoptotic bodies as well as oxidized lipids. Data from our laboratory suggests that prolonged expression of KIM-1 in mice is maladaptive. Here, we characterized zebrafish KIM-1 (zKIM-1) family members, and studied the effect of zKIM-1 overexpression on the zebrafish pronephros.

**Methods:** We cloned zKIM-1 and related family members and compared biochemical and functional aspects with that of human KIM-1 (hKIM-1) using PCR, western blotting, in situ hybridization (ISH) and immunostaining. We created two zebrafish models of KIM-1 overexpression in the pronephros employing the cdh17 promoter. In one case the expression was constitutive. In the other case a cdh17:$Cre^{ERT2}$ transgenic fish line was created that allowed for tamoxifen-induced overexpression of KIM-1 in nephrons initiated at 72 hr post fertilization (hpf).

**Results:** As with hKIM-1, zKIM-1 was not expressed in healthy nephrons, and was markedly upregulated after gentamicin-induced injury. zKIM-1 also showed a conserved phagocytic activity comparable to hKIM-1. Tissue-specific constitutive overexpression of zKIM-1 in the pronephros under cdh17 promoter control caused pericardial edema, reduced GFR and a higher mortality with defects apparent by 48 hpf. Histologic examination revealed kidney tubular damage in nephrons overexpressing zKIM-1. Cre-mediated overexpression of zKIM-1 initiated at 72hpf caused a similar kidney maladaptive phenotype marked by tubular damage, edema and higher mortality.

**Conclusions:** zKIM-1 has high structural and functional similarities to hKIM-1. KIM-1 overexpression in the pronephros of the zebrafish results in tubular damage and kidney failure. Enhanced prolonged expression of KIM-1 in human proximal tubules may have maladaptive consequences due to KIM-1-mediated in phagocytosis of tubular components.

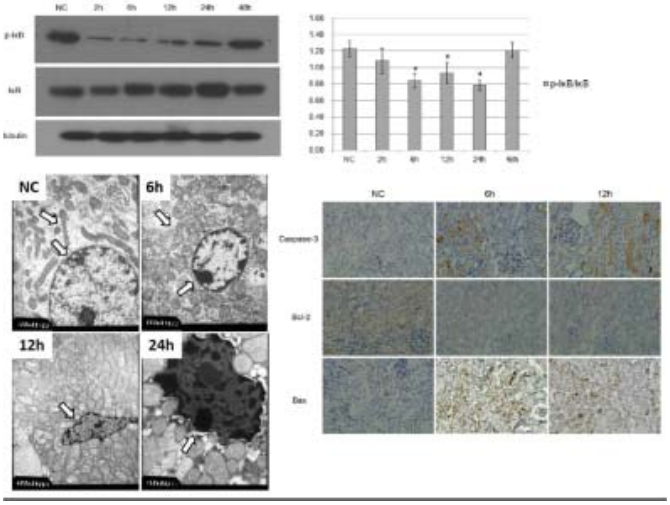
**FR-PO081**

**Melittin Induced Acute Kidney Injury through TNF-α/NF-κB/Mitochondria Dependent Apoptotic Pathway** Ling Zhang, Ping Fu. *West China Hospital of Sichuan Univ, China.*

**Background:** Mechanism of acute kidney injury (AKI) following multiple bee stings is not clear. Melittin, a main component of bee venom, can induce apoptosis in many cell types. We aimed to investigate the mechanism of melittin induced apoptosis in renal tubular epithelial cells through TNF-α/NF-κB signaling pathway.

**Methods:** AKI model was established by injecting melittin (4.0 μg/g) through the caudal veins of BALB/c mice (n=60). AKI was defined as creatinine (Cr) increased over 2 fold of that in control group. Blood and kidney samples were collected at 0h, 2h, 6h, 12h, 24h and 48h. Cr, urea nitrogen and hemoglobin were measured by Abbott i-STAT blood-gas analyzer. Creatine kinase was measured by immunochemiluminometric assays. Serum TNF-α was measured by ELISA method. Apoptosis of renal tubule cells was detected by TUNEL staining and transmission electron microscope. Expression of caspase-3, caspase-8, caspase-9, Bcl-2, Bax, and cytochrome c was detected by RT-PCR and/or immunohistochemical method. Expression of IκB and p-IκB was detected by Western Blot.

**Results:** AKI was diagnosed at 6h after injection of melittin (Cr: 1.1±0.3 mg/dl at 6h vs. 0.4±0.1 mg/dl at 0h, $p<0.05$). Serum TNF-α level increased significantly since 2h after injection. Apoptosis was detected since 2h, and was most notable at 12h. Western Blot showed that p-IκB/IκB ratio was significantly decreased in melittin group during 6h to 24h, indicating that NF-κB signal pathway was inhibited. RT-PCR showed that the Bcl-2/Bax ratio was significantly lower in melittin group than control group, indicating that the mitochondrial dependent apoptosis pathway was activated.



**Conclusions:** We successfully established melittin induced AKI in mice. Melittin might induce mitochondrial dependent apoptosis in renal tubular epithelial cells through activating TNF-α and inhibiting NF-κB signaling pathway.

**FR-PO082**

**DNA Damage Response in Renal Ischemia-Reperfusion and ATP-Depletion of Renal Tubular Cells** Zhengwei Ma, Zheng Dong. *Dept of Cellular Biology & Anatomy, Georgia Regents Univ, Medical College of Georgia, Augusta, GA.*

**Background:** Renal ischemia-reperfusion leads to acute kidney injury (AKI) that is characterized pathologically by tubular damage and cell death, followed by tubular repair, atrophy and interstitial fibrosis. Recent work suggested the possible presence of DNA damage response (DDR) in AKI. However, the evidence is sketchy and the role and regulation of DDR in ischemic AKI remain elusive.

**Methods:** In this study, DDR was studied in kidney tissues during ischemia-reperfusion in mice and renal proximal tubular cells (RPTC).

**Results:** We detected DDR in kidney tissues during ischemia-reperfusion in mice, as shown by increased expression of γH2AX and phosphorylation of ATM, Chk2 and p53. DDR was also induced In vitro during "reperfusion" of RPTC after ATP-depletion. DDR in this model was abrogated by supplying glucose (generate ATP via glycolysis), indicating that the DDR depends on ATP depletion. The DDR was suppressed to various extents by the ATM inhibitor Ku55933, the antioxidant N-acetylcysteine, the general caspase inhibitor z-VAD and overexpression of Bcl-2.

**Conclusions:** In conclusion, DDR occurs during renal ischemic AKI in vivo and ATP-depletion injury in vitro. ATM is a sensor in this DDR, which involves oxidative stress and apoptosis.

**Rictor/mTORC2 Protects against Cisplatin-Induced Tubular Cell Death and Acute Kidney Injury** Jianzhong Li, Weichun He, Junwei Yang, Chunsun Dai. *The Center for Kidney Disease, the Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiansu, China.*

**Background:** The mammalian target of rapamycin (mTOR) plays a critical role for cell growth and survival in many cell types. While substantial progress has been made in understanding the abnormal activation of mTORC1 in the pathogenesis of kidney disease, little is known about mTORC2 in kidney disease such as acute kidney injury (AKI).

**Methods:** Here a mouse model with tubule specific deletion of Rictor (Tubule-Rictor-/-) was generated and NRK-52E cell, a rat proximal tubular cell line, was used.

**Results:** The knockouts were born normal and no obvious kidney dysfunction or kidney morphologic abnormality was found within 2 months after birth. Cisplatin-induced AKI was generated in the mice and ablation of the Rictor in the tubular cells exacerbated cisplatin-induced AKI compared to those in the control littermates. Tubular cell apoptosis, Akt phosphorylation (Ser473) as well as autophagy were induced in the kidneys from the control littermates with cisplatin-induced AKI. Less cell autophagy or Akt phosphorylation and more cell apoptosis in the knockout kidneys were identified compared with those in the control littermates. In cultured NRK-52E cells, Rictor siRNA transfection sensitized cell apoptosis to cisplatin while reduced cisplatin-induced autophagy. Finally, metformin could abolish cell death induced by Rictor siRNA and cisplatin admininstration.

**Conclusions:** This study suggests that endogenous Rictor/mTORC2 protects against cisplatin-induced AKI, which is probably mediated by promoting cell survival through Akt signaling activation and autophagy induction.

**Rapamycin Prevents LPS-Induced Endothelial Cell Dysfunction** Giuseppe Castellano,[1] Alessandra Stasi,[1] Margherita Gigante,[1] Angelica Intini,[1] Paola Pontrelli,[1] C. Divella,[1] Claudia Curci,[2] Massimo Papale,[3] Enrico Fiaccadori,[4] G. Grandaliano,[2] Loreto Gesualdo.[1] *[1]DETO, Univ Bari, Bari, Italy; [2]Consorzio Carso, Univ Bari, Bari, Italy; [3]Med and Surg Sciences Dept, Univ Foggia, Foggia, Italy; [4]Clin and Exp Med Dept, Univ Parma, Parma, Italy.*

**Background:** During sepsis-induced acute kidney injury, LPS activates renal endothelial cells (ECs) resulting in cellular dysfunction. Aim of our study was to investigate the effects of LPS on ECs and the role of Rapamycin (Rp) in the modulation this pathogenic process.

**Methods:** Renal ECs were stimulated with LPS (4μg/ml) and Rp was used at 5nM. ECs were analyzed by MTT cell viability assay, FACS and western blot.

**Results:** We found that LPS did not induced apoptosis but a significant increase in ECs proliferation (.597 ± .03 vs basal .469 ± .004, p= .04; MTT assay). Moreover, LPS significantly decreased specific ECs markers such as CD31 (46.53% ± 9.65 vs basal p=.03) and VE-cadherin (15.2% ± 4.35 vs basal p=.001). On the contrary, LPS up-regulated markers of ECs dysfunction such as N-cadherin (81.51% ± 4.51 vs basal p=.002), Vimentin (71.34% ± 4.82 vs basal p=.01) and FSP-1 (64.66% ± 6.08 vs basal p=.01). Treatment with Rp normalized EC proliferation rate, without induction of apoptosis even in presence of LPS. Interestingly, the addition of Rp abrogated the LPS-induced ECs dysfunction by restoring the high expression of CD31 (R+LPS: 82.06% ± 3.4 vs LPS p=.01 ) and VE-cadherin (R+LPS: 55.33% ± 4.7 vs LPS p=.0003) and the low expression of N-cadherin (R+LPS:4%±2.1 vs LPS p=.0002), Vimentin (R+LPS:33,26%±4.1 vs LPS p=.03) and FSP-1 (R+LPS:9.83%±4.87 vs LPS p=.01). By western blot analysis, we observed that LPS induced a progressive and time dependent phosphorylation of ERK that was hampered by Rp treatment (R+LPS 60': .40±0.01 vs LPS 60' :1.15±0.32 p=.01).

**Conclusions:** Our study demonstrates that LPS caused EC dysfunction by activating EC proliferation and promoting phenotypic changes by ERK pathway. The inhibition of EC dysfunction by Rp may be a possible therapeutic strategy to preserve ECs during sepsis-induced acute kidney injury.

**FR-PO085**

**Protective Effects of Citrate in a Rat Model of Ischemic Acute Kidney Injury** Anja H. Bienholz,[1] Jonas Reis,[1] Frank Petrat,[1] Herbert De Groot,[1] Joel M. Weinberg,[2] Andreas Kribben,[1] Thorsten Feldkamp.[1,3] *[1]Univ Duisburg-Essen, Germany; [2]Univ of Michigan; [3]Christian-Albrechts-Univ Kiel, Germany.*

**Background:** Like other citric acid cycle metabolites, citrate can reverse the fatty acid-mediated energetic deficit impairing recovery of isolated proximal tubules subjected to hypoxia/reoxygenation at concentrations reached during clinical use as an anticoagulant for renal replacement therapy. In the present studies we used a rat model of ischemia/reperfusion (I/R)-induced AKI accompanied by intensive biomonitoring to assess renal protection by citrate in vivo.

**Methods:** I was induced in rats by bilateral clamping (40min) followed by R (3h). Citrate was infused at three different concentrations (in mmol/kg/h: 0.3; 0.6 and 1) continuously for 60min before and 45min after I. Normoxic and I/R control group received 0.9% NaCl. Ionized plasma calcium concentrations were kept stable by calcium gluconate infusion. Effects were assessed by biomonitoring, blood/plasma parameters and renal ATP.

**Results:** Renal I led to a drop in mean arterial blood pressure (end of I: 62±3 vs 85±2mmHg; p<0.01), a progressive rise in creatinine (end of R: 1.29±0.08 vs 0.49±0.04mg/dl; p<0.001) and a decrease in ATP (4.5±0.1 vs 9.0±0.4nmol/mg protein; p<0.001) in comparison to the normoxic control group. Citrate infusion stabilized blood pressure during I in concentration dependent fashion reaching statistical significance in the 1mmol/kg/h citrate group. Serum osmolarity was not changed during the experiment. Infusion of 1mmol/kg/h citrate lowered creatinine (1.04±0.04 vs 1.29±0.08mg/dl; p<0.05) and increased ATP (5.8±0.2 vs 4.5±0.1nmol/mg protein; p<0.05) at 3h of R compared to the I/R control group.

**Conclusions:** Citrate has protective effects in I-induced AKI, possibly by both beneficial cardiovascular effects and by directly limiting the energetic deficits. These data provide further rationale favoring the use of citrate in renal replacement therapy and encourages us to pursue citrate infusion with maintenance of stable calcium levels as a therapeutic treatment for AKI. They also indicate the importance of assessing hemodynamics in studies of protective maneuvers in renal I/R models.

**Arginase2 Is Up-Regulated in Renal Tubular Cells of AKI and Regulated NO In Vitro and In Vivo** Koji Ogata, Tatsuki Matsumoto, Kazu Hamada, Yoshinori Taniguchi, Yoshiko Shimamura, Kosuke Inoue, Taro Horino, Yoshio Terada. *Kochi Univ, Japan.*

**Background:** Arginase (AGase) is an enzyme that breaks down L-arginine and ornithine to urea, and was identified as nitric oxide (NO) metabolism-related factor. AGase2 is expressed constitutively in normal kidneys. However, because the biological role for AGase2 in acute kidney injury (AKI) is poorly understood, we studied the expression/modulation mechanism and role of AGase2 axis, and the aging effects.

**Methods:** To clarify the role of AGase2 in AKI, we used a rat ischemia/reperfusion (I/R) AKI model and cultured renal tubular cells (NRK-52E cells). To examine the effects of AGase2 in NO system, we used AGases2 expression vector and siRNA. Moreover, to assess aging effects, we also studied AGase2 expression in aged mice (42- and 87-week-old).

**Results:** Western blot analysis showed that AGase2 expression was increased at 12-48 h after I/R. The renal expression of AGase1 is very weak and not changed by I/R. Immunohistological examination revealed that AGase2 expression was increased in proximal tubules. In vitro AGase2 expression was also increased in NRK-52E cells under hypoxic stimulation. Overexpression of HIF-1α and Arnt resulted in increased AGase2 expression. When increased AGase2 under hypoxia was suppressed by AGase2 siRNA, phosphorylation of eNOS (Ser-177) was increased. Overexpression of AGase2 in NRK-52E cells resulted in suppressed phosphorylation of eNOS. Finally, AGase2 expression was significantly increased in 42- and 87-week-old aged mice, and showed further increase after AKI, in addition to the reduction of phosphorylation of eNOS.

**Conclusions:** In summary, AGase2 is up-regulated in renal tubular cells under AKI and hypoxic conditions. AGase2 might play a pivotal role on AKI pathogenesis via NO modulation by break down arginine and suppress eNOS activity. Furthermore AGase2 might be critical for aging-related AKI pathogenesis.

**FR-PO087**

**Inhibition of PKCδ Protects against Cisplatin-Induced Renal Tubular Cell Apoptosis by Activation of Autophagy through Directly Inhibition of AKT/mTOR Signaling** Zheng Dong.[1,2,3] *[1]The Second Xiangya Hospital, Central South Univ; [2]Dept of Cellular Biology and Anatomy, Medical College of Georgia, Georgia Regents Univ; [3]Charlie Norwood VA Medical Center, Augusta, GA.*

**Background:** Inhibition of PKCδ protects against cisplatin-induced acute kidney injury (AKI); however, the underlying mechanism remains[ensp]unclear. Autophagy has recently been recognized as an important mechanism of kidney protection. We hypothesized that inhibition of PKCδ may provide renoprotection by increasing autophagy.

**Methods:** In this study, we examined the role and signaling pathway of PKCδ in autophagy regulation during cisplatin treatment of renal proximal tubular cells (RPTC).

We further determined if the protective effect of PKCδ inhibitors depends on autophagy using renal proximal tubule–specific Atg7 knockout (PT-Atg7-ko) mice.

**Results:** PKCδ was activated rapidly by cisplatin in RPTC. After activation, PKCδ was shown to directly interact with Akt, resulting in Akt phosphorylation at serine-473. Consequently, Akt phosphorylated and activate mTOR, a major negative regulator of autophagy. Consistently, dominant negative and genetic inhibition of PKCδ during cisplatin treatment blocked mTOR activation, enhancing autophagy for cell survival. Rottlerin, a pharmacologic inhibitor of PKCδ, showed significant protective effect during cisplatin-induced AKI in mice, which was markedly abrogated in PT-Atg7-ko mice.

**Conclusions:** This study revealed a new signaling pathway mediated by PKCδ and Akt in the regulation of mTOR and autophagy. Moreover, it demonstrates the involvement of autophagy in the renoprotective effect of PKCδ inhibitors in AKI.

## FR-PO088

**Targeted Deletion of p53 from Proximal Tubules Protects against Ischemia-Reperfusion and Cisplatin-Induced Acute Kidney Injury** Zheng Dong.[1,2,3] *[1]The Second Xiangya Hospital, Central South Univ, Changsha; [2]Dept of Cellular Biology and Anatomy, Medical College of Georgia, Georgia Regents Univ; [3]Charlie Norwood VA Medical Center, Augusta, GA.*

**Background:** A role of p53 in acute kidney injury (AKI) has been suggested for over a decade but it remains controversial. Inhibition of p53 protects against AKI in rats, but it exacerbates ischemic AKI in mice as shown by recent work. One intriguing possibility is that p53 in different cell types in kidneys may have distinct or opposing roles: while tubular p53 may mediate injury in AKI, leukocyte p53 is renoprotective by limiting inflammation and inflammatory damage.

**Methods:** Test of this possibility requires the use of tissue or cell type specific p53-knockout models.

**Results:** Here we generated proximal tubule–specific p53 knockout mice, which were shown to be significantly resistant to both ischemic and cisplatin nephrotoxic AKI as indicated by renal function and histological analyses.Tubular apoptosis and associated gene expression were also attenuated.

**Conclusions:** Thus p53 in kidney tubules plays a general injury role in AKI.

## FR-PO089

**Valproic Acid, a Class I Histone Deacetylase Inhibitor, Protects Early Renal Function in the Renal Ischemia Reperfusion Injury Model** Elerson Costalonga, Andressa Daron, Filipe M. Silva, Irene L. Noronha. *Nephrology Div, Univ of Sao Paulo.*

**Background:** Ischemia reperfusion injury (IRI) is a major contributor to acute kidney injury (AKI). At present, there are no effective therapies to ameliorate injury or accelerate recovery after AKI. Histone deacetylases (HDACs) are a large family of epigenetic regulators, which catalyze the removal of acetyl groups from histones. Histone modifications have been shown to play a role in renal repair after IRI. The aim of the study was to analyze whether the valproic acid (VPA), a classe I HDAC inhibitor, could prevent renal IRI.

**Methods:** Male Wistar rats(250–300 g; n=24) were divided into three groups: **SHAM**: rats subjected to sham surgery; **IRI**: rats undergoing bilateral ischemia for 45 min; **IRI+VPA**: rats treated with VPA at 300 mg/kg twice daily 2 days before bilateral IRI. Blood urea nitrogen (BUN), serum creatinine(SCr), fractional excretion of sodium(FENa) and potassium(FEK), renal histology, number of interstitial macrophages (MØ)(immunohistochemistry), and TNF-α expression in the kidney tissue(real time PCR) were assessed 48 hours after IRI. The histopathological evaluation of the cortical acute tubular necrosis(ATN) used a grading scale of 0 to 5.

**Results:** VPA significantly attenuated renal dysfunction after ischemia, characterized by a decrease in BUN, SCr, FENa, and FEK in the IRI+VPA group compared with IRI. Kidney sections of the IRI+VPA group showed significantly lower ATN score with a marked reduction in the number of MØ, compared with the IRI group. Reduction of TNF-α mRNA levels was also observed.

| | SHAM | IRI | IRI+VPA |
|---|---|---|---|
| BUN(mg/dL) | 13±2 | 145±66* | 39±25# |
| SCr(mg/dL) | 0.3±0.05 | 2.7±1.6* | 0.5±0.2# |
| FENa(%) | 0.2±0.1 | 4.9±2.8* | 0.5±0.2# |
| FEK(%) | 22±8 | 129±56* | 17±4# |
| ATN Score | 0 | 2.3±0.9* | 1.1±0.4# |
| MØ(cells/mm$^2$) | 17±8 | 172±43* | 40±15# |
| TNF-α(mRNA level) | 1±0.1 | 2±0.2* | 1.4±0.1# |

*p<0.001 vs SHAM; #p < 0.001 vs IRI

**Conclusions:** These preliminary data suggest that HDAC inhibitors could prevent renal dysfunction and inflammation associated with IRI.

## FR-PO090

**ERK-Mediated Suppression of Cilia in Cisplatin-Induced Tubular Cell Apoptosis and Acute Kidney Injury** Shixuan Wang,[1] Zheng Dong.[1,2] *[1]Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA; [2]Medicine/Renal, Second Xiangya Hospital, Changsha, Hunan, China.*

**Background:** In kidneys, each tubular epithelial cell contains a primary cilium that protrudes from the apical surface. Ciliary dysfunction was recently linked to acute kidney injury (AKI) following renal ischemia-reperfusion. Whether ciliary regulation is a general pathogenic mechanism in AKI remains unclear. Moreover, the ciliary change during AKI and its underlying mechanism are largely unknown.

**Methods:** We examined the change of primary cilium by immunofluorescence and its role in tubular cell apoptosis and AKI induced by cisplatin, a chemotherapy agent with notable nephrotoxicity.

**Results:** In cultured human proximal tubular HK-2 epithelial cells, cilia became shorter during cisplatin treatment, followed by apoptosis. Knockdown of Kif3a or Polaris (cilia maintenance proteins) reduced cilia and increased apoptosis during cisplatin treatment. We further subcloned HK-2 cells and found that the clones with shorter cilia were more sensitive to cisplatin-induced apoptosis. Mechanistically, cilia-suppressed cells showed hyperphosphorylation or activation of ERK. Inhibition of ERK by U0126 preserved cilia during cisplatin treatment and protected against apoptosis in HK-2 cells. In C57BL/6 mice, U0126 prevented the loss of cilia from proximal tubules during cisplatin treatment and protected against AKI. U0126 up-regulated Polaris, but not Kif3a, in kidney tissues.

**Conclusions:** It is suggested that ciliary regulation by ERK plays a role in cisplatin-induced tubular apoptosis and AKI.

## FR-PO091

**Epidermal Growth Factor Receptor (EGFR) Inhibition with Erlotinib Attenuates Cisplatin-Induced Nephrotoxicity in Rats** Yukihiro Wada, Masayuki Iyoda, Kei Matsumoto, Yuki Shindo-Hirai, Yoshihiro Kuno, Taihei Suzuki, Ysutaka Yamamoto, Saitou Tomohiro, Ken Iseri, Takanori Shibata. *Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Japan.*

**Background:** The effects of blocking the EGFR in acute kidney injury (AKI) are controversial. We investigated the renoprotective effect of erlotinib, a tyrosine kinase inhibitor that can block EGFR activity, on cisplatin (CP)-induced AKI.

**Methods:** CP nephrotoxicity (CP-N) was induced in 6-week-old male Sprague-Dawley (SD) rats (n=28) by intraperitoneal injection of CP (7 mg/kg) on day 0. Groups of animals were given either erlotinib (CP+E, 20 mg/kg, n=14) or vehicle (CP+V, n=14) daily by oral gavage from day -1 to day 3. Five SD rats were used as normal control (NC). All rats were sacrificed on day 4. In addition, we analized the effects of erlotinib in signaling pathways that are involved in CP-N by using human renal proximal tubular cells (HK-2).

**Results:** Compared to the NC rats, the CP+V rats exhibited marked AKI characterized by deterioration of renal function, severe tubulointerstitial (TI) damage, and increase in renal cortical mRNA expressions for proinflammatory cytokines, fibrogenic genes, and pro-heparin-binding EGF-like growth factor. Compared to vehicle, erlotinib treatment significantly prevented BW loss and increased urine volume. Erlotinib significantly improved renal function (sCr: 1.6 ± 0.3 vs. 0.8 ± 0.2 mg/dL, p<0.01) and ameliorated TI injury (the number of casts/HPF: 2.0 ± 0.7 vs. 0.7 ± 0.1, p < 0.01). PCNA-positive and TUNEL-positive cells were significantly reduced by erlotinib. Furthermore, renal cortical mRNA for TGF-β and Bax/Bcl-2 ratio were significantly reduced in CP+E rats compared to CP+V rats. Additionally, we observed that erlotinib significantly reduced the phosphrylation of ERK1/2, which was induced by CP in HK-2.

**Conclusions:** Our study shows that erlotinib attenuates the CP-induced AKI by degradation of tubular cell apoptosis and proliferation. The inactivation of ERK1/2 is likely one of the fundamental factors involved in apoptosis reduction. These results strongly suggest that erlotinib is useful for preventing AKI in patients receiving chemotherapy including CP.

## FR-PO092

**Truncated DNase I Acts as Dominant-Negative Inhibiting Kidney Cell Death Induced by Cisplatin** Alexei G. Basnakian,[1,2] Dmitry D. Zhdanov,[1] Tariq Fahmi,[1] Alena Savenka.[1] *[1]Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, John L. McClellan Memorial Veterans Hospital, Little Rock, AR.*

**Background:** DNA fragmentation, generally regarded as the hallmark biochemical event of apoptosis, is the attribute and important mechanistic step in many cell death modes that occurs in in vivo and in vitro models of kidney injury. DNA fragmentation induced by cisplatin toxicity to the kidney was shown to be mediated by deoxyribonuclease I (DNase I) in association with endonuclease G (EndoG). The latter, however, was later shown to induce alternative splicing of DNase I. The current study was aimed to determine the role of the alternatively-spliced truncated DNase I, delta4DNase I, generated by EndoG.

**Methods:** Real time RT-PCR, western blot, TUNEL assay, Annexin and flow cytometry.

**Results:** Our study demonstrated that cisplatin intoxication induced delta4DNase I in mouse kidneys. The DNase I isoform was shown to be expressed in many other mouse organs, and it was associated with low nuclear endonuclease activity. Recombinant delta4DNase I completely lacked endonuclease activity, and its actin-binding activity was also strongly diminished. The overexpression of delta4DNase I downregulated mRNA and protein expression of native DNase I and other apoptotic endonucleases in rat kidney tubular epithelial NRK-52E cells. It also suppressed total DNase activity in the cells, and provided protection against cisplatin toxicity measured by TUNEL assay or Annexin V/PI assay followed by flow cytometry.

**Conclusions:** This study identified a new native mechanism of kidney tubular epithelial cell protection by DNase I inactivation, which potentially can be applied in future therapies of cisplatin/toxic acute kidney injury.

**Epoxyeicosatrienoic Acids Increase Intrarenal Reoxygenation and Prosurvival Signaling and Protect against Renal Ischemia/Reperfusion Injury** Uwe Hoff,[1] Gordana Bubalo,[1] Maximilian Blum,[2] Mandy Fechner,[1] Ye Zhu,[1] Andreas Pohlmann,[2] Jan Hentschel,[2] Karen Arakelyan,[3] Erdmann Seeliger,[3] Bert Flemming,[3] Wolfgang Schneider,[2] Michael Rothe,[4] Thoralf Niendorf,[2] John Falck,[5] Wolf-hagen Schunck,[2] Duska Dragun.[1] *[1]Nephrology and Intensive Care Medicine, Campus Virchow-Klinikum, Center for Cardiovascular Research, Charité, Berlin, Germany; [2]Max-Delbrueck Center for Molecular Medicine and Berlin Ultrahigh Field Facility (B.U.F.F.), Berlin, Germany; [3]Institute of Physiology, Center for Cardiovascular Research, Charité, Berlin, Germany; [4]Lipidomix GmbH, Berlin, Germany; [5]Southwestern Medical Center, Univ of Texas, Dallas, TX.*

**Background:** Imbalances in cytochrome P450 (CYP)-dependent eicosanoids play a central role in ischemic acute kidney injury (AKI). We previously reported that inhibition of 20-hydroxyeicosatetraenoic acid (20-HETE) ameliorated ischemia/reperfusion (I/R)-induced AKI Now, we hypothesized that enhancement of epoxyeicosatrienoic acid (EET) actions may offset 20-HETE actions and contribute to cellular protection during immediate reperfusion.

**Methods:** Studies were performed in male Lewis rats that underwent right nephrectomy before 45-min clamping of left renal pedicle.

**Results:** CYP-eicosanoid analysis with liquid chromatography tandem mass spectrometry (LC-MS/MS) revealed pronounced postischemic 20-HETE release, yet only minor release of protective EETs. Therefore, we applied a synthetic EET agonist by intrarenal injection 5 min before ischemia. Continuous in vivo MRI monitoring in a 9.4 T MR-scanner showed markedly improved medullary reoxygenation after EET agonist application as assessed by T2* . EET-agonist treatment initiated fast rephosphorylation of key survival signaling PI3K dependent Akt (Thr308) and mTORC2 dependent Akt (Ser473) together with inactivation of pro-apoptotic GSK-3β, paralleled by reduced tubular apoptosis. Renal function was almost completely preserved upon EET intervention.

**Conclusions:** We demonstrate that EETs are responsible for induction of key survival mechanisms and improved intrarenal reoxygenation early after I/R. Renoprotective EET agonists offer a promising new option for prevention and treatment of ischemic AKI.

*Funding:* Government Support - Non-U.S.

**FR-PO094**

**Protein Kinase C-α Phosphorylates $F_0F_1$-ATPase and Contributes to Recovery of $F_0F_1$-ATPase Activity in Injured Renal Proximal Tubular Cells** Grazyna Nowak, Diana Bakajsova. *Pharmaceutical Sciences, Univ of Arkansas for Medical Sciences.*

**Background:** We have shown that overexpression of active PKC-α in mitochondria alleviates decreases in $F_0F_1$-ATPase activity and ATP content and promotes recovery of mitochondrial function in oxidant-injured renal proximal tubular cells (RPTC). This study tested if mitochondrial PKC-α interacts with $F_0F_1$-ATPase, changes its phosphorylation, and improves $F_0F_1$-ATPase recovery from injury.

**Methods:** Wild-type PKC-α (wtPKC-α) and inactive PKC-α mutant (dnPKC-α) were overexpressed in primary cultures of RPTC to increase their levels and cells were exposed to the model oxidant, *tert*-butylhydroperoxide (TBHP) or hypoxia. PKC-α was immunoprecipitated from mitochondria following RPTC injury and associated proteins and their phosphorylation were identified.

**Results:** Proteomic analysis demonstrated association of PKC-α with subunits α, β, and γ of $F_0F_1$-ATPase. The association of these subunits was predominantly with the active PKC-α in injured and non-injured RPTC. Overexpressing wtPKC-α maintained, whereas overexpressing dnPKC-α decreased, association of α, β, and γ subunits with PKC-α in mitochondria of injured RPTC. RPTC overexpressing wtPKC-α had increased levels of mitochondrial phospho-proteins. Proteomic analysis revealed increased levels of phosphorylated subunits α, β, and γ, which suggested that PKC-α is involved in their phosphorylation. Immunocapture of $F_0F_1$-ATPase and immunoblotting using phospho-(Ser) PKC substrate antibody showed phosphorylation of serine(s) present in PKC consensus site(s) on the γ subunit of $F_0F_1$-ATPase. Further, this phosphorylation increased in response to overexpression of wtPKC-α, but not dnPKC-α. Phospho-proteomic analysis of the immunocaptured γ subunit demonstrated phosphorylation of $Ser^{146}$ (TH**S**DQFLVTFK) of the γ subunit. $F_0F_1$-ATPase activity and ATP content decreased to 59% and 60% of controls, respectively, in injured RPTC. Overexpressing wtPKC-α, but not dnPKC-α, restored $F_0F_1$-ATPase activity and ATP content.

**Conclusions:** We conclude that active PKC-α associates with $F_0F_1$-ATPase in injured mitochondria, phosphorylates γ subunit, improves $F_0F_1$-ATPase activity, and promotes recovery of ATP content in injured RPTC.

*Funding:* NIDDK Support

**FR-PO095**

**The Injured Kidney Releases Factors into the Circulation That Cause Increased Mitochondrial Membrane Potential and Increased Anti-Oxidant Gene Expression *In Vitro* and *In Vivo*, Contributing to the Pathophysiology of Uremia** Jon D. Ahlstrom,[1] Florian Toegel,[3] Zhuma Hu,[1] Ping Zhang,[1] Christof Westenfelder.[1,2] *[1]Depts of Medicine, Univ of Utah and VA Medical Centers, Salt Lake City, UT; [2]Depts of Physiology, Univ of Utah and VA Medical Centers, Salt Lake City, UT; [3]Dept of Medicine, Brigham and Women's Hospital, Boston, MA.*

**Background:** Our laboratory has previously shown in animal models and in a Phase I Clinical Trial that Mesenchymal Stem Cells (MSCs) are a safe and effective therapy for acute kidney injury (AKI). It is well recognized that the changes in the "milieu interne" that result as a consequence of tissue injury adversely affect the function of distant organs, together leading to the multisystem manifestations of the "uremic syndrome". Largely unstudied and poorly understood is the impact that the kidney injury environment has on therapeutically administered MSCs, renal cells, or on other tissues and organs *in vivo*.

**Methods:** To characterize the response of cells exposed to a kidney injury environment, we treated cultured normal rat kidney cells (NRK, proximal tubular) or rat MSCs in 10% serum obtained from F344 rats 24 hrs post either 50 min IRI-AKI, bilateral nephrectomy (NPHX, uremic control without kidney injury) or SHAM controls. To verify these results *in vivo*, we also examined the mitochondrial function and gene expression of various organs from F344 rats following IRI-AKI, NPHX, or SHAM surgeries.

**Results:** The exposure of cell types to 10% AKI serum for 48 hours caused, compared to incubation with NPHX or SHAM animal sera, increased mitochondrial membrane potential (TMRE), up-regulation of anti-oxidant genes (catalase, HO-1), and increased reactive oxygen species activity (CM-H2DCFDA activity). Similar results were also observed in organs studied *in vivo* such as the kidney, heart, liver, and lung.

**Conclusions:** The mitochondrial and oxidative stress produced by yet to be identified factors, potentially electrophiles, released into the circulation by injured kidney tissue has the capacity to adversely affect kidney cells, other organs, and MSCs administered to treat AKI.

**FR-PO096**

**Oxygen-Sensing Prolylhydroxylase 1 (PHD1) in Acute Kidney Injury** Almut Grenz,[1] Raechel Peralta,[2] Uladzimir Shabeka,[1] Eunyoung Tak,[1] Sue Murray,[2] Shuling Guo,[2] Gene Hung,[2] Holger Eltzschig.[1] *[1]Anesthesiology, UC Denver, Denver, Aurora, CO; [2]ISIS Pharmaceuticals, Carlsbad, CA.*

**Background:** Acute kidney injury (AKI) due to ischemia is one of the most common complications with no treatment. Limited oxygen availability results in inhibition of three oxygen-sensing prolyl hydroxylases (PHD1-3) with subsequent stabilization of hypoxia-inducible factors (HIFs). Activation of HIF results in a transcriptionally regulated response that re-programs cellular metabolism towards hypoxia adaptation. *Thus, we hypothesize that genetic deletion or pharmacologic inhibition of PHDs mediates kidney protection from ischemia.*

**Methods:** Mice were studied in an ischemic model of AKI by utilizing a hanging weight system. Renal function was determined by inulin clearance, serum creatinine, urinary NGAL and KIM-1, renal cytokine levels, myeloperoxidase and histology.

**Results:** To pursue our hypothesis, we first treated wild type mice with a non-selective PHD inhibitor (DMOG, dimethyloxallyl glycine) before renal ischemia (30 min). Mice with DMOG treatment showed attenuated kidney injury. We then further characterized that the protection is specifically associated with PHD1but not PHD2 or PHD3 by utilizing gene-targeted mice (PHD1-3 KO mice). To confirm our findings in PHD1-/- mice, we explored a drugable approach using PHD1 specific antisense inhibitors (ASO1 and ASO2) which can reduce 90% and 60% kidney PHD1 RNA respectively in WT mice following systemic treatment. Interestingly, in the ischemic reperfusion model, both compounds showed comparable kidney protection as in PHD1-/- mice. To further elucidate cell type specificity of protection, we utilized conditional mice with depletion of PHD1 in tubular epithelia or endothelial cells. Indeed, mice with genetic deletion of PHD1 in tubular cells showed kidney protection from ischemia.

**Conclusions:** These studies identify tubular PHD1 inhibition or genetic depletion as key in protection from AKI due to ischemia. Furthermore, newly designed PHD1 inhibitors showed protection from AKI. If translatable from mice to human, these data have important therapeutic implications.

**FR-PO097**

**Stanniocalcin-1 Inhibits Renal Ischemia/Reperfusion Injury via an AMPK-Dependent Pathway** Jenny S. Pan,[1] Luping Huang,[1] Tatiana Belousova,[1] Qiang Tong,[2] David Sheikh-Hamad.[1] *[1]Nephrology Div, Dept of Medicine; [2]Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX.*

**Background:** Acute kidney injury (AKI) is common and is associated with increased morbidity, mortality, and development/progression of chronic kidney disease. Inflammatory, hypoxic and oxidative stresses play central roles in the pathogenesis of ischemic AKI; but while the pathogenesis is better defined, therapeutic options remain limited. We previously showed stanniocalcin-1 (STC1) suppresses superoxide generation through induction of mitochondrial uncoupling proteins (UCPs), and overexpression of STC1 in mice inhibits ROS and confers resistance to ischemia/reperfusion (I/R) kidney injury. Our observations reveal increased AMPK activity in STC1 transgenic (Tg) kidneys, and we hypothesize that STC1 protects from I/R kidney injury via AMPK activation.

**Methods:** We subjected wild-type (WT) and STC1 Tg mice to bilateral I/R kidney injury (clamping of renal pedicles for 30 min), concomitant with AMPK inhibition using compound C (CC; single IP injection at 20 mg/kg).

**Results:** Kidney baseline activity of AMPK correlated with the expression of stanniocalcins; with the highest activity in STC1 Tg, followed in decreasing order by WT, STC1 knockout (KO) and STC1/2 double KO. I/R in WT kidneys increased AMPK activity and expression of STC1, UCP2 and sirtuin-3 (SIRT3) proteins. AMPK inhibition with CC before I/R abolished AMPK activation and diminished SIRT3 and UCP2 expression without affecting STC1 protein expression. Moreover, the kidneys displayed increased production of superoxide and $H_2O_2$, and worse morphological changes. Pretreatment of STC1 Tg mice with CC restored susceptibility to I/R kidney injury characterized by: decreased creatinine clearance and urine output; morphological changes similar to those observed in WT kidneys after I/R; and increased ROS production. As observed in WT mice, AMPK inhibition in STC1 Tg mice attenuated UCP2 and SIRT3 expression at baseline and after I/R.

**Conclusions:** The data suggest that: 1) STC1 is critical for AMPK activation in the kidney; and 2) STC1-induced protection from I/R kidney injury and expression of UCP2 and SIRT3 are AMPK-dependent.

## FR-PO098

**Development of Novel Nrf2 Activator to Treat Acute and Chronic Kidney Disease** Sanjeev Noel,[1] Samatha Bandapalle,[1] Rajesh Thimmulappa,[2] Shyam Biswal,[2] Hamid Rabb.[1] *[1]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]School of Public Health, Johns Hopkins Univ, Baltimore, MD.*

**Background:** Oxidative stress induced by ischemia reperfusion (IR) participates in the development of AKI and its progression to CKD. Transcription factor Nrf2, is critical for the induction of antioxidant response during ischemic injury and therefore an attractive therapeutic target for pharmacological augmentation of antioxidant response in kidney diseases. Novel Nrf2 activators such as Trifluoromethyl 2'methoxychalcone (TMC) are needed which could be more potent and safer than bardoxolone.

**Methods:** Primary (RPTEC) and immortalized (HK-2) renal epithelial cells were treated with 5μM TMC for 6, 12 and 24h or 2.5, 5, and 10μM, TMC for 24h. Nrf2 activity was assessed by measuring HO-1 and NQO1 expression by qPCR and western blotting along with NQO1 enzyme activity. C57BL/6 male mice were treated with 40, 200 and 400mg/kg TMC for 6 or 24h to examine Nrf2 activity in mouse kidney.

**Results:** In comparison to vehicle, TMC treatment (5μM) resulted in significant ($p<0.01$) increase in *HO-1* gene expression at 6h (relative fold change (RFC) =1.2±0.3 vs 10.6±1.0) and 12h (RFC=1.0±0.02 vs 3.7±0.04) and showed a significant increase after 24h following 5 ($p=0.03$) and 10μM ($p<0.01$) TMC treatment in RPTEC cells (RFC=1.1±0.2 vs 2±0.2 and 7.3±0.2 respectively). Western blot analysis revealed 2.6, 3.4 and 3.6 fold increase in HO-1 protein expression in RPTEC cells following 2.5, 5 and 10μM TMC treatment respectively in comparison to vehicle. Similar observations were made for HO-1 expression in HK2 cells. *Ho-1* gene expression in mouse kidney increased significantly ($p<0.01$) after 200 and 400mg/kg oral TMC administration in comparison to vehicle at 6h (RFC=2.0±0.3 and 1.9±0.2 respectively) but returned to baseline at 24h. We observed significant increase in NQO1 expression and activity under these experimental conditions in HK2, RPTEC cells and mouse kidney.

**Conclusions:** These data demonstrates that TMC increases Nrf2 activity in renal epithelial cells and mouse kidney and appears to be a promising novel Nrf2 activator that merits evaluation for AKI and CKD treatment.

**Crosstalk between p53-Sestrin2 and Hypoxia-BNIP3 (Bcl-2/Adenovirus E1B 19kDa-Interacting Protein3) Pathways in Regulating Autophagy, Mitophagy and Apoptosis in Renal Tubular Cells in Acute Kidney Injury** Masayuki Ishihara,[1] Madoka Urushido,[2] Kazu Hamada,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Taro Horino,[1] Mikiya Fujieda,[3] Yoshio Terada.[1] *[1]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan; [2]Center for Innovative and Translational Medicine, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan; [3]Dept of Pediatrics, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan.*

**Background:** Little is known of the signaling pathways that regulate cell viability during acute kidney injury (AKI). We reported that hypoxia-Bcl-2/adenovirus E1B 19kDa-interacting protein 3 (BNIP3) and p53-sestrin2 pathways induced autophagy during AKI. The aim of this study is to investigate the crosstalk of two pathways during AKI.

**Methods:** We used rat ischemia/reperfusion (I/R) injury and cultured renal tubular cells (NRK-52E) as in vivo and in vitro models of AKI. We used TUNEL staining to evaluate apoptosis under oxidative stress in vitro AKI model. We transfected control siRNA or siRNA specific for BNIP3 and sestrin2, and measured LDH release following exposure of cells to hypoxic or oxidative stress.

**Results:** The expressions of BNIP3 and sestrin2 were upregulated after I/R. NRK-52E cells exposed to hypoxia showed increased expression of BNIP3 mRNA and protein. Sestrin2 mRNA and protein expression was upregulated following exposure to oxidative stress. Apoptosis was reduced by overexpression of sestrin2, and slightly reduced by BNIP3. These data are in accordance with the results of both the caspase 3 assay and Western blot analysis of cleaved caspase 3. Under hypoxic conditions LDH release was increased by BNIP3 siRNA and slightly increased by sestrin2. On the other hand, under oxidative stress, LDH release was increased by transfection with sestrin2 siRNA.

**Conclusions:** In summary of these data, both BNIP3 and sestrin2 induce autophagy. However, two molecules play some different role in apoptosis and cell death according to stress condition. These data the 2 autophagy-promoting signaling pathways regulate cell viability in different ways may be due to cell types or experimental condition.

## FR-PO100

**Structure and Function of the Polycystin-1 PLAT Domain** Yaoxian Xu,[1] Andrew J. Streets,[1] Peter J. Artymiuk,[2] Mike P. Williamson,[2] Albert C. Ong.[1] *[1]Academic Nephrology Unit, Univ of Sheffield, Sheffield, United Kingdom; [2]MBB, Univ of Sheffield, Sheffield, United Kingdom.*

**Background:** The PLAT (named after Polycystin-1, Lipoxygenase and Alpha Toxin) or LH2 (Lipoxygenase Homology 2) domain is located in the 1st intracellular loop of polycystin-1, the protein product of *PKD1*, the gene mutated in 90% of Autosomal Dominant Polycystic Kidney Disease (ADPKD) patients. This signature domain is found in all PC1 paralogues and shows evolutionary conservation in orthologues down to nematodes. PLAT has been predicted to be a lipid-binding domain based on homology to the lipoxygenases although little has been reported about its structure or function.

**Methods:** Nuclear Magnetic Resonance (NMR) studies of the polycystin-1 PLAT domain have resulted in assignment of 90% of its amino acid residues, which has allowed us to calculate a model of its structure. PLAT adopts a beta-sandwich fold composed of two four-stranded beta sheets, and is thus similar in structure to homologous domains in lipoxygenases.

**Results:** Lipid blot assays show that PLAT binds selectively to certain phospholipids, in particular phosphatidyl serine (PS) and phosphatidyl inositol 4-phosphate (PI4P). Using NMR, we have shown that these lipids have adjacent but different binding sites. We have also identified the binding site for calcium, and demonstrated that binding to PS is calcium dependent. In addition, we have identified a protein/protein interaction site, which is on the opposite face to the lipid binding interface. We also demonstrate that phosphorylation at a predicted protein kinase A (PKA) phosphorylation site dramatically internalizes the basolateral membrane-localized isolated PLAT domain and full length PC1 in kidney epithelial cell lines. Phosphorylation here abolishes the ability of PLAT to bind to PI4P, as predicted from the structure.

**Conclusions:** Based on these results, we propose a model for the function of PLAT, in which PLAT binds to specific membrane lipids, in a calcium- and PKA-dependent manner; binding controls the orientation of PLAT and thus the way in which it interacts with partner proteins. These interactions appear to be critical for the location and function of PKD1 and downstream effectors.

## FR-PO101

**Cleavage of PC1 Is Dependent on the Unfolded Protein Response (UPR) Effector Xbp1** Sorin V. Fedeles,[1] Seung H. Lee,[1] Rachel Gallagher,[1] Ann-hwee Lee,[2] Stefan Somlo.[1] *[1]Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Lab. and Exp. Medicine, Weill Cornell, New York, NY.*

**Background:** The unfolded protein response is a cellular mechanism that is activated when unfolded proteins accumulate in the ER, with Xbp1 being its most conserved effector. Active Xbp1s translocates to the nucleus and activates transcription of chaperones and proteins involved in ER-associated degradation. (ASN, 2011 TH-OR125) we have shown that Sec63, one of the ADPLD genes, and Xbp1 interact genetically in a polycystin-1 (PC1) dependent manner. In the current work we investigated the molecular underpinnings of the Sec63-Xbp1-Pkd1 interaction.

**Methods:** We examined processing of PC1 in kidney tubule cell lines isolated from mice carrying the ImmortoMouse and $Pkd1^{F/H}$-BAC transgenes in addition to inactivating mutations in Sec63 alone (SKO) or in Sec63 and Xbp1 together (DKO). We also analyzed kidney tissues from $Pkd1^{F/H}$-BAC SKO ($Sec63^{fl/fl}$;Ksp-Cre) and DKO ($Sec63^{fl/fl}$;$Xbp1^{fl/fl}$;Ksp-Cre) mice.

**Results:** Full length PC1 (PC1-FL) is cleaved at the GPS to yield the extracellular N-terminal fragment (PC1-NTF) and the intramembranous C-terminal fragment (PC1-CTF). The levels of PC1-CTF were reduced in SKO-$Pkd1^{F/H}$-BAC cells while they were almost completely absent in DKO cells where a concomitant increase in PC1-FL was observed, suggestive of a defect in GPS cleavage. Lysates from DKO-$Pkd1^{F/H}$-BAC mice exhibited further reduction in PC1-CTF beyond that seen in SKO-$Pkd1^{F/H}$-BAC kidneys. Re-expression of Sec63 in the DKO cells completely restored PC1-CTF while overexpression of XBP1 partially restored PC1-GPS cleavage in a dose dependent manner. Thus, activated XBP1s can compensate for Sec63 deficiency to promote PC1-GPS cleavage. XBP1s overexpression can also restore PC1 processing in $Prkcsh^{-/-}$;$Pkd1^{F/H}$-BAC cells suggesting that the effect of XBP1s on PC1-GPS cleavage is not limited to Sec63 null cells. Finally, the ER chaperone ERdj4, a XBP1s transcriptional target, modestly increased PC1-CTF levels in DKO cells.

**Conclusions:** The most conserved effector of the UPR response, XBP1, can modulate the cleavage of PC1 and this may represent a potential therapeutic avenue for PC1-misense mutant backgrounds.

## FR-PO102

**Functional Role of GPS Cleavage for Polycystin1 Biogenesis and Trafficking**
Feng Qian,[1] Almira Kurbegovic,[2] Hangxue Xu,[1] Hyunho Kim,[1] Julie Cruanes,[2] Marie Trudel.[2] *[1]Medicine, Univ of Maryland School of Medicine, Baltimore, MD; [2]Institut De Recherches Cliniques De Montreal, Montreal, Canada.*

**Background:** Autosomal dominant polycystic kidney disease is characterized by formation of renal cysts and caused mainly by mutations in PKD1, which encode polycystin-1 (PC1). PC1 is regulated in part by post-translational modifications via cleavage at the extracellular juxtamembrane GPS motif. We previously showed that this cleavage is frequently disrupted in ADPKD patients. $Pkd1^{V/V}$ mice homozygous for a "knock-in" missense change at cleavage site express a non-cleavable Pc1 ($Pc1^{V}$) and develop distal tubular cystic kidneys postnatally, leading to death by 1-month of age.

**Results:** Herein, we characterize the molecular composition of endogenous Pc1 resulting from GPS cleavage by various biochemical strategies. We show that GPS cleavage generates a previously unrecognized complexity of endogenous Pc1 products. Two distinct forms of cleaved Pc1 molecules are produced along with a small amount of uncleaved Pc1 ($Pc1^{U}$) in postnatal developing kidneys and other tissues: (1) heterodimeric $Pc1^{cFL}$ in which NTF is non-covalently associated with CTF; (2) $Pc1^{deN}$ in which NTF becomes detached from CTF. Both cleaved products traffic past the Golgi to substantial extents whereas $Pc1^{U}$ is restricted to the ER. Importantly, GPS cleavage is not a prerequisite for Pc1 trafficking. Only $Pc1^{deN}$ is found at the cell surface of renal epithelial cells. We have also analyzed the function of $Pc1^{deN}$ for kidney development by BAC-transgenic expression of a NTF fragment in $Pkd1^{V/V}$ mice. We then examined the molecular mechanism of $Pc1^{deN}$ biogenesis and trafficking using Pkd1 mutant mice with mutations in CTF. We show that proper $Pc1^{deN}$ trafficking requires intact CTF and propose a model in which $Pc1^{deN}$ is derived from $Pc1^{cFL}$.

**Conclusions:** Our data demonstrates that GPS cleavage is a critical regulator of Pc1 biogenesis and CTF plays a crucial role in Pc1 trafficking for all Pc1 products. This study thus provides novel insights into the complexity of Pc1 biogenesis and trafficking with functional roles in a cell type- and stage-dependent manner.

## FR-PO103

**PKC-Zeta Phosphorylates Polycystin-1 and Modulates Its Regulation of STAT3 Activity**
Nicholas Doerr,[1] Yidi Wang,[1] Markus M. Rinschen,[2] Jeffrey Talbot,[1] Alexis V. Gibson,[1] Bernhard Schermer,[2] Thomas Weimbs.[1] *[1]Univ of California Santa Barbara; [2]Univ of Cologne, Germany.*

**Background:** Mutations in the gene coding for polycystin-1 (PC1) cause autosomal-dominant polycystic kidney disease. We have previously shown that STAT3 is aberrantly activated in ADPKD and that PC1 regulates STAT3 activity by a dual mechanism. Here, we tested the ability of several kinases to bind PC1 and regulate PC1-mediated STAT3 activity.

**Methods:** Protein interactions were determined by co-IP. Phosphorylation of PC1 by PKC-zeta was examined in HEK293T cells and specific phosphorylation sites were determined by mass spectometry. Phosphorylation results were confirmed by *in vitro* kinase assays. Regulation of STAT3 activity was measured by luciferase reporter assay. Expression of PKC isoforms in ADPKD and mouse models was determined by western blot analysis.

**Results:** We found that atypical PKC (PKC-zeta) interacts with the cytoplasmic tail of PC1. We identified three sites within the PC1 tail that are phosphorylated by PKC zeta. The interaction between PC1 and PKC-zeta is enhanced by expression of the scaffold protein p62/SQSTM1, which was also found to bind the PC1 tail. PKC-zeta decreases the activation of STAT3 by membrane-anchored PC1 but promotes the activation of STAT3 by the cleaved, soluble PC1 tail, suggesting that it acts as a regulatory switch. Regulation of PC1-mediated STAT3 signaling is specific as PKC zeta does not alter IL6-induced STAT3 signaling nor PC1-mediated AP1 signaling. This signaling switch is likely dysregulated in the disease as PKC-zeta expression is decreased and STAT activation is increased in ADPKD kidneys and a PKD1 mouse model.

**Conclusions:** These data demonstrate a novel interaction between PKC-zeta, p62 and PC1. PKC-zeta binds and phosphorylates the PC1 tail and regulates its activation of STAT3. Whether PKC-zeta activates or represses STAT3 signaling depends on the state of proteolytic processing of PC1. Therefore together PKC-zeta and PC1 may serve as critical regulators of STAT3 signaling in the kidney and the pathogenesis of ADPKD.

## FR-PO104

**Polycystin-1 Accelerates Degradation of Polycystin-2 via the Aggresome Pathway**
Valeriu Cebotaru,[1] Liudmila Cebotaru,[2] Feng Qian,[3] William B. Guggino.[4] *[1]Johns Hopkins Univ; [2]Johns Hopkins Univ; [3]Univ of Maryland; [4]Johns Hopkins Univ.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is an inherited disorder that presents with renal cysts. Mutations in PKD1 or PKD2 genes lead to ADPKD. Polycystin-1 (PC1) and polycystin-2 (PC2) are gene expression products of PKD1 and PKD2 respectively. Up-regulation or down-regulation PC1 or PC2 leads to polycystic kidney disease in mice suggesting that polycystins must be regulated within a functional window to avoid cyst formation. We have shown previously that PC1 regulates PC2 expression (un-published data). Here we further investigated the regulation of the PC2 degradation pathway by PC1. Misfolded and unfolded proteins are refolded by chaperones. Proteins that cannot be refolded usually end up degraded by proteasomes. Proteins that are not degraded by proteasomes precipitate as aggresomal particles and are transported by Histone deacetylase 6 (HDAC6) towards the aggresome for degradation.

**Methods:** We used MDCK cells that were stably transfected with an expression system where expression of full length PC1 or PC1-R4227X mutant can be induced by tetracycline.

**Results:** We found that inhibition of the aggresome degradation pathway with tubacin, a specific HDAC6 inhibitor, led to an up-regulation of PC2 expression when PC1 was overexpressed. Importantly, tubacin had no effect on PC1 expression. In addition we found that HDAC6 does interact with PC2 in control MDCK cells where PC1 expression has not been induced. Over-expression of PC1 not only decreased expression of PC2, but also greatly reduced the interaction of HDAC6 and PC2. On the other hand, PC1 does not interact with HDAC6, suggesting that PC1 accelerates the aggresomal degradation of PC2 via a second messenger that requires the presence of the C-terminal tail of PC1. Consistent with this concept is the observation that over-expression of the PC1-R4227X mutant, that lacks the last 76 amino acids, did not decrease PC2 expression, nor did it decrease the interaction between PC2 and HDAC6.

**Conclusions:** We have now uncovered a new pathway that explains how PC1 regulates PC2 expression via the aggresome degradation pathway.

## FR-PO105

**Different Patterns of Pkd1 Deficiency Lead to Heart Dysfunction and Fibrosis in Mice**
Bruno E. Balbo, Andressa Godoy Amaral, Jonathan Mackowiak Fonseca, Vera Mc Salemi, Luiz F. Onuchic. *Nephrology, Univ of São Paulo, Brazil.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is a systemic disorder associated with cardiovascular manifestations, including hypertension (SAH) and ventricular hypertrophy. Although fibrosis impacts on kidney disease progression, its role in ADPKD cardiac phenotype remains uncertain.

**Methods:** Cardiac and renal phenotypes were analyzed in two *Pkd1*-deficiency mouse models: 10-13-wk-old noncystic $Pkd1^{+/-}$(HT) and its wild-type controls (WT); and 20-23-wk-old cystic $Pkd1^{cond/cond}$:$Nestin^{Cre}$(CY) and its noncystic controls ($Pkd1^{cond/cond}$, NC). Heart function and kidney cystic index (CI) were evaluated by high-resolution ultrasound.

**Results:** The HT and CY mice displayed lower fractional shortening (FS) and ejection fraction (EF) than their controls, findings consistent with systolic dysfunction (FS: 20.5±1.2 *vs* 28.8±1.9; 23.6±2.4 *vs* 31.8±1.8, $p<0.05$; EF: 42.3±2.2 *vs* 55.9±3.0; 47.2±4.3 *vs* 60.3±2.7, $p<0.05$). The myocardial performance index was also elevated in the HT and CY groups, expressing worsening of global ventricular function. In another study, we have shown that HT mice were not hypertensive at this evaluated age, while CY had SAH. No difference in BUN, serum creatinine ($S_{Cr}$), Na, K, fractional excretion of Na ($FE_{Na}$) and $FE_K$ were detected between HT and controls. CY mice presented lower $S_{Cr}$ than NC animals and a CI of 6.9% (IQR:4.1-9.5). A higher fibrosis index (FI) was observed in HT and CY cardiac tissue compared with their controls (0.84 *vs* 0.30%; 0.22 *vs* 0.01%, $p<0.01$), as well as higher apoptosis. Higher FI and increased cell proliferation rates were detected in HT and CY kidneys compared with their controls.

**Conclusions:** Our results demonstrate that two distinct profiles of *Pkd1* deficiency lead to heart dysfunction and fibrosis in mice. The absence of SAH in HT mice suggests the development of a primary cardiomyopathy associated with decreased polycystin-1 activity. Our findings suggest, on the other hand, that CY mice develop a cardiomyopathy based on two components: primary *Pkd1* deficiency and cardiac damage secondary to SAH. Our data provide significant insights into human ADPKD heart disease and prove useful for future investigations.

*Funding:* Government Support - Non-U.S.

## FR-PO106

**Over-Expression of the Polycystin 1 C-Terminal Tail Leads to Disappearance of Acetylated α-Tubulin**
Nikolay P. Gresko, Michael J. Caplan. *Cellular and Molecular Physiology, Yale Univ School of Medicine, New Haven, CT.*

**Background:** Autosomal dominant polycystic kidney disease is caused by mutations in the genes encoding polycystin-1 and 2 (PC1 and 2). PC1 is a massive multi-spanning membrane protein that is localized in part to the primary cilium in polarized epithelial cells. The primary cilium is composed of an axoneme containing 9 pairs of parallel microtubules. The tubulin monomers in these microtubules are modified through acetylation on lysine 40. This modification is controlled by the activities of acetylating and deacetylating enzymes and may contribute to the stability of cilia-associated microtubules. PC1 is subject to several cleavages that release various C terminal fragments. One of these fragments appears to include the 200 amino acids of the PC1 C terminal tail (CTT) and contains a functional nuclear localization sequence (NLS). We find that over-expression of a construct corresponding to the C terminal 200 amino acid residues of PC1 (P200) results in a dramatic reduction in tubulin acetylation.

**Methods:** Ciliated LLC-$PK_1$ cells were transfected to express P200 or a version of P200 lacking the NLS (p200ΔNLS). LLC-$PK_1$ cells transfected with an empty vector served as controls. Tubulin acetylation was assessed using anti-acetylated tubulin antibodies in western blot (WB) and immunofluorescence (IF) analyses.

**Results:** IF reveals that the cilia of control LLC-PK1 cells label brightly with anti-acetylated tubulin. Acetlyated tubulin is also detected by WB in lysates prepared from control cells. In contrast, P200 expression reduces the abundance of acetylated tubulin below the limits of detection of both the IF and WB assays. Interestingly, expression of p200DNLS significantly increases acetylated tubulin levels. Perhaps surprisingly, cilia appear to be structurally normal in the acetylated tubulin-deficient P200-expressing $LLCPK_1$ cells, as revealed through both light and electron microscopic analysis.

**Conclusions:** Over-expression of P200, but not of P200DNLS, results in dramatically decreased tubulin acetylation. Tubulin acetylation is not essential for the development or structural integrity of the primary cilium.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## FR-PO107

**Polycystin-1 Regulates Actin Cytoskeleton Organization and Directional Cell Migration through a Novel PC1-Pacsin 2-N-Wasp Complex**

Gang Yao,[1] Vy Nguyen,[1] Kristina A. Roberts,[1] Ayumi Takakura,[1] Markus Plomann,[2] Jing Zhou.[1] *[1]Harvard Center for Polycystic Kidney Disease Research, Brigham and Women's Hospital, Boston, MA; [2]Center for Biochemistry, Univ of Cologne, Cologne, Germany.*

**Background:** Formation of a tubule with defined length and lumen diameter is a fundamental step for epithelial and endothelial cells to make many vital organs. Autosomal dominant polycystic kidney disease (ADPKD), the most common life-threatening monogenic disease that manifests itself in cyst formation in multiple epithelial organs, is the result of the loss of control of tubule lumen size. One of the prerequisites for proper tubulogenesis in vitro and in vivo is directional cell migration.

**Methods:** In this study, we utilized yeast two-hybrid screens, biochemistry, cell biology, and live cell imaging to discover proteins that interacts with ADPKD protein polycystin-1 (PC1) and to study the consequence of the identified interaction.

**Results:** Yeast two-hybrid screens using the C-terminus of PC1 as bait, identified Pacsin 2, a cytoplasmic phosphoprotein that has been implicated in cytoskeletal organization, vesicle trafficking, cell intercalation during gastrulation, and more recently in kidney tubule development, and repair of ischemia-reperfusion injured kidneys. PC1 C-tail binds to a 107-residue fragment containing the a3 helix of the F-BAR domain of Pacsin 2. Pacsin 2 expression and localization are altered in *Pkd1* targeted kidneys. Kidney epithelial cells deficient in either PC1 or Pacsin 2 migrate at a slower speed with reduced directional persistency, and exhibit defects in lamellipodium formation and tubulogenesis in 3-dimentional (3D) collagen gels. We further demonstrate that PC1, Pacsin 2, and N-Wasp are in the same protein complex, and both PC1 and Pacsin 2 are required for N-Wasp/Arp2/3-dependent actin remodeling.

**Conclusions:** Our study suggests that PC1 modulates actin cytoskeleton rearrangements and directional cell migration during tubule development and regeneration through the Pacsin 2/N-Wasp/Arp2/3 complex, which consequently contributes to the establishment and maintenance of the sophisticated tubular architecture.

## FR-PO108

**Polycystin Signaling Is Required for Lymphatic Development**

Patricia Outeda Garcia,[1] Gregory G. Germino,[2] Terry J. Watnick.[1] *[1]Dept of Medicine, Div of Nephrology, Univ of Maryland, School of Medicine, Baltimore, MD; [2]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD.*

**Background:** Edema is a universal feature of all *Pkd1* and *Pkd2* targeted alleles reported in the literature to date and has been variably attributed to vascular fragility and/or cardiac defects. Since the lymphatic system plays a critical role in tissue fluid homeostasis, we speculated that a defect in the lymphatic vasculature might contribute to edema in *Pkd* mutant embryos.

**Results:** We harvested E14.5 $Pkd^{-/-}$ embryos and controls (WT) and performed whole mount staining of dorsal skin with the lymphatic endothelial cell (LEC) marker, Lyve1. We found that both $Pkd1^{-/-}$ and $Pkd2^{-/-}$ mice exhibited a more dilated and disorganized lymphatic network with decreased branching. Next, we focused on an earlier stage of lymphatic development and stained sections from the jugular area of E11.5 embryos with the LEC marker, Prox1. At this stage Prox1 positive LECs were budding from the dorsolateral aspect of the cardinal vein in both mutant and wild type embryos. In wild type embryos LECs were found in a narrow, restricted dorsolateral area. In contrast, in $Pkd^{-/-}$embryos the distribution of Prox1 positive cells appeared to be more random. We found that the area of distribution of Prox1 positive cells in the dorsolateral aspect of the cardinal vein was significantly increased in $Pkd^{-/-}$ embryos, suggesting an abnormality in polarized cell migration. We used a cell culture system to show that both *Pkd1* and *Pkd2* depleted endothelial cells have an intrinsic defect in directed migration that may contribute to the *in vivo* phenotype.

**Conclusions:** Our work establishes a role for polycystins in lymphatic development and identifies a new signaling pathway that is involved in lymphangiogenesis.

## FR-PO109

**The Role of Phosphorylation in Polycysytin-2 Trafficking and Channel Activity**

Yiqiang Cai,[1] Ivana Y. Kuo,[2] Hongzhi Quan,[1] Kathryn Stone,[3] Ke Dong,[1] Xin Tian,[1] Ming Ma,[1] Seung H. Lee,[1] Jian Chen,[1] Barbara E. Ehrlich,[2] Stefan Somlo.[1] *[1]Internal Medicine, Yale Univ School of Medicine, New Haven, CT; [2]Pharmacology, Yale Univ, New Haven, CT; [3]WM Keck Biotechnology Resource Laboratory, Yale Univ, New Haven, CT.*

**Background:** Loss of polycystin-2 (PC2), a cation channel, results in autosomal dominant polycystic kidney disease (ADPKD). PC2 has been localized to cilia and is abundantly expressed in the endoplasmic reticulum (ER). Our previous studies have shown that PC2 is constitutively phosphorylated at residue $Ser^{812}$, and that loss of phosphorylation at $Ser^{812}$ results in a 10-fold decrease in sensitivity to $Ca^{2+}$ activation of PC2 but has no effect on PC2 localization at the ciliary membrane (Cai et al, 2004).

**Methods:** We identified additional phosphorylation sites in PC2 by phosphoproteomic analysis of TiO2 enriched immunoprecipitated PC2 prepared from either cultured epithelial cells stably overexpressing PC2 or from native mouse kidney tissues. Cultured renal epithelial cells stably overexpressing the PKD2 cDNAs with combinations of the mutations in the identified phosphorylation site(s) were examined for PC2 function. The functional assays examined the effects of PC2 phosphorylation on: 1) the association of PC2 with PC1 or with itself; 2) PC2 ciliary trafficking; 3) stabilization of PC1-CTF by PC2; and 4) cellular Ca2+ transient activity of PC2.

**Results:** A total of 3 Ser phosphorylation sites were identified in PC2. Loss of phosphorylation or pseudophosphorylation mutations at these sites had no effect on the association of PC2 with PC1 or PC2 itself, nor on the stabilizing effect of PC2 on the PC1-C terminal fragment.Loss of phosphorylation at one site resulted in increased ciliary expression of PC2. Loss of phosphorylation at another site resulted in higher baseline cytosolic Ca2+ in unstimulated cells likely effecting the ER channel activity of PC2.

**Conclusions:** Phosphorylation of PC2 plays a role in regulation of PC2 channel activity and trafficking to cilia. Understanding the molecular basis for the regulation of PC2 phosphorylation may enhance understanding the mechanism of cyst growth in ADPKD.

*Funding:* NIDDK Support

## FR-PO110

**Sorting Nexin 3 Regulates the Trafficking and Surface Localization of Polycystin-2**

Shuang Feng, Andrew J. Streets, Albert C. Ong. *Academic Nephrology Unit, Univ of Sheffield, Sheffield, United Kingdom.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD), is caused by mutations in *PKD1* (85%) or *PKD2* (15%). Although the ADPKD proteins, polycystin-1 (PC1) and polycystin-2 (PC2) have been shown to form a receptor-ion channel complex, the surface expression of PC2 appears to be regulated by protein phosphorylation and interaction with key adaptor proteins.

**Methods:** To identify additional regulators of PC2 sorting and trafficking, we conducted a yeast-2-hybrid (Y2H) screen using the PC2 C-terminal domain as bait. Here, we report a functional interaction between PC2 and two isoforms of sorting nexin 3 (SNX3). The SNXs are a family of proteins first identified in yeast which share a Phox (PX) domain with affinity for PtdIns(3)P and which regulate endosomal sorting. In mammals, 30 SNXs have been identified. The retromer complex comprises two subcomplexes: a trimer (Vps26-29-35) which functions as a cargo-selective adaptor and a membrane deforming subcomplex consisting of a sorting nexin (SNX) heterodimer. In mammals, there are two distinct mammalian retromer complexes distinguished by either a SNX-BAR heterodimer or by monomeric SNX3.

**Results:** We identified a new SNX3 isoform (102aa, isoform 5) as a new binding partner to the C-terminus of PC2. This isoform lacks the PX domain present in the classical SNX3 isoform (162aa, isoform 1). In-vitro binding studies confirmed that this interaction was direct. Unexpectedly, we found that SNX3-162 could also bind to PC2 indirectly via the retromer complex; PC2 binds to VPS35 directly via its N-terminal domain. The localization of both isoforms was distinct with SNX3-102 expressed in clathrin-coated vesicles where it binds to AP2 whereas SNX3-162 is expressed in early endosomes where the retromer complex is expressed. Knockdown of both SNX3 isoforms in polarized kidney cells resulted in a two fold increase in surface PC2 expression by biotinylation.

**Conclusions:** Our results reveal for the first time that PC2 internalisation and recycling is regulated by a new SNX3 isoform as well as a SNX3-retromer complex. Since SNX3 expression can be modulated by different drugs, this could represent a potential new target for patients with ADPKD.

**Deletion Mutant of *Pkd1* and *Pkd2* Gene Cause Cyst Formation in Transgenic Medaka**

Yasunobu Ishikawa,[1] Saori Nishio,[1] Tomotsune Miyamoto,[1] Sekiya Shibazaki,[1] Hisashi Hashimoto,[2] Yuko Wakamatsu,[2] Tatsuya Atsumi.[1] *[1]Medicine II, Hokkaido Univ, Sapporo, Hokkaido, Japan; [2]Bioscience and Biotechnology Center, Nagoya Univ, Nagoya, Aichi, Japan.*

**Background:** Autosomal dominant polycystic kidney disease is the most common monogenic disorder resulting in cystic kidneys and liver. Several genetic mechanisms probably contribute to the phenotypic expression of the disease. A two-hit mechanism has been proposed to explain how cysts develop. However, the dominant pattern of inheritance would argue for a gain of function, haploinsufficiency, or a dominant negative mechanism. We established four different transgenic medaka models to investigate whether a dominant negative mechanism can cause cyst formation.

**Methods:** We cloned the medaka *Pkd1* and *Pkd2* genes by homology search. Next we generated 4 transgenic medaka models named as *Pkd1* EF1α, *Pkd2* EF1α, *Pkd1* Tet-On and *Pkd2* Tet-On that expresses translation elongation factor 1 subunit alpha (EF1α) promoter linked to deleted exons 6-27 in *Pkd1* or exons 12-15 in *Pkd2* respectively. In lines *Pkd1* Tet-On and *Pkd2* Tet-On, we used the Tet-On system that induces gene expression upon doxycycline (DOX) administration. We carried out a series of analyses including gene expression by real time PCR, histology, cell proliferation and apoptosis in Medaka at specific time points of 1, 2, 3, 4 and 5 months of age .

**Results:** Pkd1 gene expression in the Pkd1 transgenic medaka ranged from 2- to 5-fold increase relative to Pkd1 endogenous levels from control medaka arbitrarily set at 1. Pkd2 expression levels in Pkd2 transgenic medaka ranged from 3- to 60-fold relative to Pkd2 endogenous levels from control medaka arbitrarily set at 1. All four models developed kidney cysts, however both Pkd1 EF1? and Pkd1 Tet-On showed very small and fewer cysts compared with Pkd2 EF1? and Pkd2 Tet-On. Proliferating Cell Nuclear Antigen positive cells increased in cyst lining cells of all models. But the overall number of apoptotic nuclei seen in low power fields in cystic kidneys was very low and did not differ significantly among all models.

**Conclusions:** Overexpression of of *Pkd1* and *Pkd2* deletion mutants in medaka results in cyst formation via a dominant negative mechanism.

## FR-PO112

### Biochemical Analysis of the ADPKD *PKD2-D511V* Patient Mutation

Alexis Hofherr, Michael Kottgen. *Div of Nephrology and General Medicine, Univ Medical Centre Freiburg, Freiburg im Breisgau, Baden-Württemberg, Germany.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common lethal monogenetic disorder in humans. Mutations in the *PKD2* gene account for approximately one out of four cases. *PKD2* encodes the transient receptor channel polycystin-2 (TRPP2), a non-selective $Ca^{2+}$-permeable cation channel. There are multiple types of mutations causing ADPKD. The Mayo ADPKD Mutation Database lists a total of 268 unique *PKD2* mutations, including 77 frame-shift, 42 non-sense and 37 splice mutations as well as 26 substitutions. However, rather little experimental data investigating the disease mechanism of these mutations is available.

**Methods:** Here we analyze the biochemical properties of the pathogenic missense variant *PKD2-D511V*, which has been previously characterized as a channel-dead mutant. Cellular expression systems and a *Drosophila melanogaster PKD2* knock-out model are used for *in vitro* and *in vivo* studies, respectively.

**Results:** The *D511V* mutation causes significantly reduced (-85.2%) TRPP2 expression levels compared to wild-type protein in heterologous expression systems. The mutant protein is degraded in lysosomes. Treatment with the lysosomotropic agent chloroquine increases TRPP2 protein levels 14.6-fold, whereas incubation with the proteasome inhibitor MG132 has no effect. Notably, incubation of cells expressing TRPP2-D511V with an FDA-approved small molecule results in a significant rescue of reduced expression levels. To investigate the pathogenic mechanism of the *D511V* mutation *in vivo*, we introduced the corresponding mutation into the *D. melanogaster PKD2* homolog (*Amo-D627V*). This transgene does not rescue the *PKD2* knock-out phenotype and protein expression is likewise reduced compared to wild-type TRPP2 *in vivo*.

**Conclusions:** In conclusion, the *D511V* mutation seems to cause TRPP2 protein instability, which can be rescued by small molecules *in vitro*. Future studies will have to show whether this chemical rescue of protein instability results in increased TRPP2 function *in vivo*. The *D. melanogaster* model mimicking *PKD2-D511V* will be a valuable tool to test this hypothesis.

### Roles of PKD2 mRNA 3'UTR in Its Translational Regulation

Wang Zheng, Jungwoo Yang, Xing-Zhen Chen. *Physiology, Univ of Alberta, Edmonton, Canada.*

**Background:** Mutations in PKD2 account for 10% autosomal dominant polycystic kidney disease (ADPKD) which is associated with elevated cell proliferation, apoptosis and de-differentiation, and affects over 10 million people worldwide. Either lose- or gain-function of PKD2 is pathogenic, indicating that the PKD2 protein level needs to be tightly regulated into a narrow range. However, how PKD2 steady-state level is regulated remains largely unclear. Here we reported two fragments in PKD2 mRNA 3' untranslated region (3UTR) that respectively mediate up- and down-regulation of PKD2 translation.

**Methods:** Dual luciferase assay was used to identify functional domains in PKD2 mRNA 3UTR which can regulate PKD2 translation in HEK and HeLa cells. Biotin-RNA pull down and mass spectrometry were used to identify protein partners that bind with these domains.

**Results:** By dual luciferase assays, we firstly found that PKD2 mRNA 3UTR significantly inhibits luciferase translation. We then divided the full-length 3UTR into two overlapping fragments and found that the first fragment strongly inhibits, while the second fragment stimulates, luciferase translation. We then narrowed down the inhibitory fragment to nt 691-1044 which was named 3FI and the stimulatory fragment to nt 1056 – 1129 which was named 3FS. Consistent with this, deletion of 3FI or 3FS from full-length 3UTR resulted in an increased or decreased luciferase activity, respectively. We then confirmed inhibitory/stimulatory effect of 3FI/3FS on luciferase and PKD2 expression by Western blotting. Using biotin-RNA pull down in combination with mass spectrometry, we isolated interacting partners of 3FI or 3FS. We are confirming the interaction between some identified potential partners and 3FI/3FS.

**Conclusions:** Two fragments (3FI and 3FS) in PKD2 mRNA 3UTR respectively inhibit and stimulate PKD2 translation and these regulations are presumably through RNA-binding proteins that interact with 3FI or 3FS. These translational regulations may provide novel insights into the mechanism of ADPKD pathogenesis. Supported by CIHR and AIHS (to XZC) and AITF (to WZ).

### Regulation of Endoplasmic Reticulum Polycystin-2-Dependent Ca Signaling

Qian Wang,[1] Jungwoo Yang,[1] Wang Zheng,[1] Richard Zimmermann,[2] Xing-Zhen Chen.[1] *[1]Dept of Physiology, Univ of Alberta, Edmonton, Canada; [2]Dept of Medical Biochemistry and Molecular Biology, Saarland Univ, Homburg, Saarland, Germany.*

**Background:** Polycystin-2 (PC2), is a Ca permeable cation channel mutated in ~15% of the autosomal dominant polycystic kidney disease (ADPKD). PC2 mainly localizes in the endoplasmic reticulum (ER) membrane, but also presents in the plasma membrane and the primary cilium. The ER-resident PC2 was suggested to be an intracellular Ca release channel, but it is still controversial as to how PC2 regulates intracellular Ca concentration. In this study, we report the function of PC2 in the ER membrane and the regulation by its binding partners including filamin-A and PERK.

**Methods:** Ca imaging was used to measure the cytoplasmic Ca concentration. siRNA and shRNA were used for gene knockdown (KD).

**Results:** Here, we used cultured HEK, HeLa and mouse collecting duct (MCD) cell lines. We first showed that over-expression of PC2 in HeLa cells reduces Ca release from the ER in response to thapsigargin (Tg) treatment. Conversely, KD of PC2 by siRNA increased ER Ca release and the increased Ca response correlated with PC2 KD efficiency, indicating the specificity of PC2 siRNA. Our previous study showed that filamin-A, a large cytosolic actin-binding protein, physically interacts with PC2 and reduces its channel activity in a lipid bilayer system. Interestingly, HeLa cells with stable filamin-A KD showed a decreased response to Tg treatment, which can be rescued by KD of PC2. This is probably due to the fact that loss of inhibition on PC2 channel function in filamin-A KD cells increases the ER Ca permeability and leads to a lower ER Ca concentration, which results in reduced Ca release from the ER in response to Tg treatment. We are also obtaining data on the effect of PERK (pancreatic ER eIF2α kinase) on PC2-dependent Ca signaling.

**Conclusions:** ER-resident PC2 functions as a Ca channel, which reduces luminal Ca content thereby decreasing Ca release from ER lumen to cytoplasm upon Tg treatment. Filamin-A reverses these processes through inhibiting PC2 channel function. Our finding provides in vivo evidence on the regulation of ER PC2 channel function.

## FR-PO115

### Polycystins Regulate Collagen Secretion in Polycystic Kidney Disease

Stephanie Le Corre, Iain A. Drummond. *Nephrology Div, Massachusetts General Hospital.*

**Background:** Mutations in Polycystins account for Autosomal Dominant Polycystic Kidney Disease (ADPKD), the most frequent heritable human genetic disease. ADPKD is characterized by the presence of multiple cysts in both kidneys but is also associated with vascular aneurysm, cardiac valve defects and abdominal wall hernia; these pathologies are linked to extracellular matrix defects.

**Results:** We have modeled ADPKD in zebrafish by polycystins mutation or knockdown and shown that the strong dorsal axis curvature mutant/morphant phenotype was caused by overproduction collagen II alpha1 protein in the notochord sheath. Indeed, *col2a1* knockdown rescued dorsal axis curvature in polycystin-deficient embryos. Surprisingly, overproduction of notochord collagens was not due to over-expression of *col2a1*, *col9a2*, or *col27a1* mRNA (qRTPCR). Instead, over-accumulation of collagen protein is more likely linked to enhanced collagen secretion or reduced degradation. One of the major post-translational modification of collagen is the cross-linking mediated by lysyl oxydase enzymes. We found that collagen type II cross-linking and expression of lysyl oxidase enzymes were not affected in polycystin2-deficient embryos. *MMP1*, *MMP9* and *MMP14* expression (qRTPCR) is increased in polycystin 2-deficient embryos. Therefore, collagen type II accumulation is not due to a defective cross-linking or a lack of degradation. Collagen secretion from the endoplasmic reticulum to the Golgi apparatus is mediated by the COPII complex (Coat Protein complex) that is made of Sec proteins. We found that *Sec23* and *Sec24* are upregulated in polycystin1 and polycystin2-deficient embryos (qRTPCR). Interestingly, when we knockdown *Sec24d* we are able to partially rescue the dorsal axis curvature observed in polycystin2-deficient embryos.

**Conclusions:** Our results support a model where Polycystins 1 and 2 are involved in the regulation of extracellular matrix secretion. A similar mechanism may contribute to disease pathogenesis in human ADPKD patients. Our project represents a re-examination of poorly understood ECM defects in polycystic kidney disease and may lead to the discovery of new therapeutic targets.

**FR-PO116**

**Ciliary Defects in Induced Pluripotent Stem Cells from Patients with Polycystic Kidney Disease and Ciliopathies** Benjamin S. Freedman,[1] Albert Q. Lam,[1,2] Jamie L. Sundsbak,[3] Rossella Iatrino,[1,4] Xuefeng Su,[1] Sarah J. Koon,[3] Maoqing Wu,[1] Peter C. Harris,[3] Jing Zhou,[1,2] Joseph V. Bonventre.[1,2] *[1]Harvard Center for PKD Research, Renal Div, Dept of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA; [3]Mayo Translational Polycystic Kidney Disease (PKD) Center, Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [4]Nephrology Div, Policlinico Universitario di Modena, Italy.*

**Background:** Induced pluripotent stem (iPSCs) are a powerful new technology for investigating human disease in diverse cell types. We tested the potential of iPSCs to reveal ciliary defects specific to polycystic kidney disease (PKD) or related ciliopathies.

**Methods:** Fibroblasts from patients with autosomal dominant (ADPKD) and autosomal recessive PKD (ARPKD), or the ciliopathies Bardet-Biedl Syndrome (BBS) and Meckel Syndrome (MKS), were retrovirally reprogrammed into iPSCs, sequenced for mutations, and compared to cells from healthy patients for PKD-related defects.

**Results:** PKD iPSCs elaborated primary cilia and expressed endogenous polycystin-1 (PC1), polycystin-2 (PC2), and fibrocystin/polyductin at levels similar to healthy controls. However, in ADPKD iPSCs or derived somatic epithelial cells, PC2 was detectable in cilia at only 25-50% of the frequency seen in ARPKD and healthy control lines. Unique *PKD1* heterozygous mutations were identified in fibroblasts from all three ADPKD patients, and iPSCs from two of these. A possible "second hit" was found at the mutation site in iPSC lines from one patient. Overexpression of wild-type PC1, but not a carboxy-terminal truncation mutant, increased endogenous ciliary PC2 ~3-fold in ADPKD iPSC-derived hepatoblasts or cultured mouse kidney cells. Neither BBS nor MKS iPSCs exhibited reduced ciliary PC2. However, MKS iPSC cilia were elongated two-fold and displayed curled ends.

**Conclusions:** PC1 enhances PC2 trafficking to cilia. Reduced ciliary PC2 may represent an early and highly penetrant metric of ADPKD, while other ciliopathies may have distinct ciliary phenotypes. iPSCs may provide novel mechanistic insights into the cellular pathophysiology of kidney disease.

**Fluid Shear Stress (FSS)-Mediated mTORC1 Regulation Is Aberrant in Cystic Epithelial Cells** Robin L. Maser,[1] Darren P. Wallace,[1] Xiangyi Lu.[2] *[1]Kidney Inst, Univ of Kansas Med Ctr, Kansas City, KS; [2]Inst of Environmental Health Sciences, Wayne State Univ, Detroit, MI.*

**Background:** Mammalian target of rapamycin complex 1 (mTORC1) is a major regulator of cell growth, division and metabolism. In autosomal dominant polycystic kidney disease (ADPKD), mTORC1 activity is increased and is thought to play a role in disease pathogenesis, but the underlying mechanism(s) is incompletely understood. For example, FSS has been shown to modulate mTORC1 by a primary cilium-dependent, but polycystin-2/calcium-independent mechanism, while polycystin-1 can inhibit mTORC1 via pathways independent of FSS. Since amino acid (AA) sufficiency is required for mTORC1 activation by all stimuli, we examined the relationship between FSS and AA-stimulated mTORC1 in both normal and cystic renal epithelial cells to uncover additional mechanisms of mTORC1 regulation.

**Methods:** Mouse inner medullary (IMCD3) and cortical (M1) collecting duct cell lines, and primary epithelial cells from a normal human (NHK) and an ADPKD kidney were grown under primary cilium-generating conditions. Cultures were subjected to either static or FSS (0.75 dyn/cm$^2$) conditions under a treatment regime that involved preconditioning in medium containing 1% serum, followed by a period of glucose- and AA-starvation. Starved cells were either lysed (-AA), or stimulated by addition of AA (+AA), and then lysed. Levels of phospho (p)- and total (t) p70 S6 kinase (S6K), an mTORC1 kinase substrate, were quantified by Western blot to determine relative mTORC1 activity.

**Results:** Under static conditions, +AA increased pS6K/tS6K levels in both mouse and human renal epithelial cells as compared to -AA. With FSS, +AA increases in pS6K/tS6K levels were significantly suppressed in M1 (61%; n=7; p<0.001), IMCD (77%; n=5; p<0.005), and NHK (54%; n=4; p<0.005) cells relative to static+AA levels. In contrast, FSS was unable to effectively suppress AA-activated mTORC1 in the human ADPKD cells (102%; n=3; p=0.470).

**Conclusions:** These studies reveal a FSS-dependent pathway of mTORC1 regulation that is aberrant in cyst-lining epithelial cells from an ADPKD kidney, and suggest that multiple mechanisms exist to modulate mTOR activity in renal epithelial cells.

**FR-PO118**

**mTORC1 and 2 Signaling in Polycystic Kidney Disease** Kameswaran Ravichandran,[1] Iram Zafar,[1] Zhibin He,[1] Adam E. Mullick,[2] Charles L. Edelstein.[1] *[1]UC Denver; [2]ISIS Pharmaceuticals.*

**Background:** We have previously reported that Pkd2WS25/- mice, an orthologous model of human PKD, treated with a mTOR kinase antisense oligonucleotide (ASO) that inhibits both mTORC1 and 2 have a normalization of kidney function and a dramatic decrease in cyst volume density.The aim of the study was to determine the effect of combined mTORC1 and 2 inhibition on mTOR signaling in in vivo and in vitro models of cyst growth.

**Methods:** Pkd mice and wild types (WT) were treated with an mTOR (mTOR) or scrambled (SCR) ASO 50-100 mg/kg/wk IP from 4 to 16 weeks of age. In vitro, to inhibit both mTORC1 and 2, type 1 MDCK cells in which Rictor the functional component of mTORC2, was silenced using plasmid based shRNA vector, were treated with sirolimus a mTORC1 inhibitor.

**Results:** On immunoblot, the mTOR ASO resulted in a significant decrease in pS6, pAktser473 and pSGK1. On densitometry, the phospho/total protein ratio in PKD mice treated with SCR vs. mTOR ASO was 2.4±0.6 Vs 0.78 ± 0.3 for pS6 (p<0.05), 1.9 ± 0.3 Vs 0.9 ± 0.2 for pAktSer473 (p<0.05), 2 ± 0.6 Vs 0.5± 0.19 for pSGK1 (p<0.05). On PCNA staining the number of PCNA positive cells in normal tubules was 9 ± 0.5 in SCR and 2.7 ± 0.5 in mTOR ASO (p<0.01) and per cyst was 1.9 ± 0.2 in SCR and 0.8 ± 0.1 in mTOR ASO (p<0.01). On TUNEL staining the number of TUNEL positive cells in normal tubules was 3.6 ± 0.6 in SCR and 1.2 ± 0.1 in mTOR ASO (p<0.01) and per cyst was 4.4±1.3 in SCR and 1.4 ± 0.2in mTOR ASO (p<0.01). In MDCK cells, combined mTORC1 and 2 inhibition resulted in a complete inhibition of pAktSer473 on immunoblot. To determine the role of mTORC2-mediated production on pAkt Ser473, Akt1 was overexpressed in mTORC2 inhibited cells. Over-expression of Akt1 reversed the decrease in cyst size. On day 10 the cyst size (μm) was 251.4±6.5 in WT cells, 135.6 ± 7.2 in Rictor -/- cells and 216.5 ± 7.3 in Rictor -/- cells+Akt1.

**Conclusions:** Combined inhibition of mTORC1 and 2 results in a significant decrease in pAktSer473 both in in vivo and in vitro models of cyst growth. Ultimately mTOR inhibition decreases cyst growth in vivo by decreasing proliferation and apoptosis of both normal and cystic tubular cells.The role of Akt1 in cyst growth merits further study.

*Funding:* Other NIH Support - 5RO1DK074835-04

**FR-PO119**

**Angiiotensinogen Inhibition Slows Cyst Growth in an Orthologous Model of Human Polycystic Kidney Disease** Kameswaran Ravichandran,[1] Iram Zafar,[1] Adam E. Mullick,[2] Zhibin He,[1] Charles L. Edelstein.[1] *[1]UC Denver; [2]ISIS Pharmaceuticals.*

**Background:** Renal cyst enlargement is associated with the activation of both circulating and intra-renal renin-angiotensin-aldosterone (RAAS) system. Angiotensin converting enzyme (ACE) inhibitors together with Angiotensin receptor blockers (ARB) are being tested in humans with PKD in HALT-PKD studies. Angiotensin is derived from its precursor molecule Angiotensinogen (AGT) which is primarily expressed in the liver, however renal AGT expression may also contribute to renal cystic disease. AGT is the only precursor for all angiotensin metabolites, which are the key effectors of RAAS. AGT inhibition is regarded as a novel therapy for hypertension in kidney disease. The aim of the study was to determine the effect of angiotensinogen inhibition in polycystic kidney disease.

**Methods:** An AGTantisense oligonucleotide (ASO) that inhibits both liver and renal AGT mRNA expression was injected at 50mg/kg/wk dose i.p. once weekly in PKD2WS25mice (an orthologous model of human ADPKD involving mutation of the Pkd2 gene) from 4 to 16 weeks of age. A scrambled (SCR) ASO that was similar to the AGT ASO but lacked antisense activity was used as a control.

**Results:** The 2K/TBW ratio in PKD mice treated with SCR Vs. AGT was 2.45 ± 0.31 vs. 1.54 ± 0.11 (p<0.01). The BUN in PKD mice treated with SCR vs. AGT was 46.71± 4.5 vs. 33.85 ± 3.3(p<0.01).The cyst volume density in PKD mice treated with SCR vs. AGT was 37.64 ± 5.7 vs. 21.97 ± 2.9 (p<0.01). The kidney weight in PKD mice treated with SCR vs. AGT was 0.66±0.08 vs. 0.47±.06 (p<0.01). The AGT treatment did not alter the body weight in PKD mice. The body weight in PKD mice treated with SCR vs. AGT was 27.28±1.6 vs. 29.42 ± 2.2 (NS).

**Conclusions:** In Summary, 1) Angiotensinogen inhibition resulted in significant decrease in kidney weight, 2K/TBW ratio and the cyst volume density in PKD mice,2) Angiotensinogen inhibition improved the kidney function. In conclusion the role of angiotensinogen inhibition at the precursor level in cyst growth merits further study.

**FR-PO120**

**A Novel LBK-1 Activator Inhibits mTOR Signaling and Proliferation of Human ADPKD Cells** Gail Reif, Archana Raman, Bailee Lynn Slack, Cibele S. Pinto, Bhaskar Chandra Das, Darren P. Wallace. *Kidney Institute, Kansas Univ Medical Center, Kansas City, KS.*

**Background:** In autosomal dominant polycystic kidney disease (ADPKD), elevated mTOR activity contributes to the aberrant proliferation of cyst-lining epithelial cells. Stimulation of AMP-activated protein kinase (AMPK), an energy sensor that regulates cell growth, inhibits mTOR signaling and cell proliferation. AMPK also phosphorylates CFTR $Cl^-$ channels and inhibits $Cl^-$-dependent fluid secretion. Recently, AMPK activation was shown to inhibit mTOR and cyst growth in PKD animals. Liver kinase B1 (LKB1) is a tumor suppressor that directly phosphorylates and activates AMPK; and mutations that cause a loss-of-function of LKB1 are associated with elevated mTOR activity and cancer. Our goal was to determine if AMPK stimulation using a novel LKB1 activator inhibits $Cl^-$ secretion and mTOR-mediated proliferation of human ADPKD cells.

**Methods:** We designed and synthesized a small molecule LKB1 activator BIT-11 by incorporating an oxadiazole moiety into a unique 3-substituted 2H-chromene derivative. The effects of BIT-11 on phosphorylated AMPK (P-AMPK) and S6 kinase (P-S6K), a downstream target of mTOR, were determined by western blot analysis. To test the drug's effect on $Cl^-$ transport, ADPKD monolayers were incubated in the absence and presence of BIT-11 and then treated with forskolin, a cAMP agonist. Changes in $Cl^-$ transport were measured by short circuit current. For *in vitro* cyst growth assays, ADPKD cells were seeded within a collagen matrix and treated with EGF and forskolin ± BIT-11, and total surface area of cysts per well was calculated from individual cyst diameters.

**Results:** BIT-11 caused a concentration-dependent increase in P-AMPK/AMPK levels in ADPKD cells. BIT-11 (1 μM) decreased P-S6K/S6K and the rate of ADPKD cell proliferation, consistent with inhibition of mTOR signaling. The drug also inhibited cAMP-induced anion secretion across ADPKD cell monolayers and significantly reduced *in vitro* cyst growth.

**Conclusions:** AMPK activation with small molecule LKB1 activators, such as BIT-11, may be a therapeutic approach to reduce mTOR activity, cell proliferation and $Cl^-$-dependent fluid secretion in ADPKD.

## FR-PO121

**Evaluation of Selective Inhibitors of Nuclear Export for the Treatment of ADPKD** Robert H. Weiss,[1] Hiromi Inoue Wettersten,[1] Matthew Tan,[1] Michael Kauffman.[2] *[1]UC Davis; [2]Karyopharm.*

**Background:** Capitalizing on the recent excitement in the ADPKD field with the connection between cancer and PKD, we have extended our RCC therapeutic innovations to evaluate the role of pharmacologic inhibitors of nuclear export to cystic disease characterized by uncontrolled RTE cell proliferation. We previously showed study that blockade of Exportin 1 (XPO1), also known as chromosome region maintenance protein 1 (CRM1), by a Selective Inhibitor of Nuclear Export (SINE) attenuates renal cell carcinoma (RCC) growth by confining p53 and p21 proteins to the nucleus and thus decreasing their degradation (J Urol. 2013, 189:2317). Given that low p21 levels are characteristic, and perhaps pathogenic, for PKD and may lead to increased proliferation and apoptosis of RTE cells (BMC Nephrol. 2007, 8:12), we asked whether SINE XPO1 antagonists attenuate key cell cycle regulatory proteins and exert salutary effects in ADPKD.

**Methods:** Immortalized human ADPKD cells (WT9-12 and WT9-7), human primary ADPKD cells, primary normal human kidney cells (NHK), mouse ADPKD cells ($pkd1^{v/v}$), and control mouse kidney cells were incubated with the SINE XPO1 inhibitors, KPT-251 and -330, and cell viability assay, cell cycle analysis, apoptosis assay, immunoblotting, immunofluorescence, and PCR were performed.

**Results:** Both KPT-251 and KPT-330 caused cell cycle arrest at G1/S and led to apoptosis in all ADPKD cell lines tested. While XPO1 inhibitors attenuated XPO1/CRM1 protein levels in ADPKD cells as was seen in RCC cells, the inhibitors did not affect p53 and p21 protein levels in ADPKD cells in vitro but decreased levels of the cell cycle-relevant proteins CDK4 and 6.

**Conclusions:** We introduce a novel therapeutic approach to the treatment of ADPKD, based on our earlier findings in RCC, using SINEs. These compounds attenuate key cell cycle regulatory proteins, and decrease proliferation, in human ADPKD cells. In vivo studies examining the efficacy of these XPO1 inhibitors in cyst growth and renal function preservation are currently underway; these studies have the potential to revolutionize ADPKD treatment.

## FR-PO122

**Downregulating Hedgehog Signaling Attenuates Renal Cystogenesis in Mouse Models of Cystic Kidney Disease** Pamela Vivian Tran,[1] George Talbott,[2] Annick Doan,[2] Damon T. Jacobs,[1] Luciane M. Silva,[1] Michael P. Schonfeld,[1] Anindita Chatterjee,[1] Mary Prysak-gehrke,[2] David Beier.[2,3] *[1]Anatomy and Cell Biology and the Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS; [2]Genetics Div, Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [3]Center for Developmental Biology and Regenerative Medicine, Seattle Children's Research Institute, Seattle, WA.*

**Background:** Mutations associated with renal cystic diseases reside in genes encoding proteins that localize to primary cilia. These cystoproteins can disrupt ciliary structure or cilia-mediated signaling, although molecular mechanisms connecting cilia function to renal cystogenesis remain unclear. The ciliary gene, *Thm1*, negatively regulates Hh signaling and is most commonly mutated in ciliopathies.

**Methods:** We examined renal cystogenesis in a *Thm1* conditional knock-out (cko) mouse, generated using a ubiquitous, tamoxifen-inducible Cre recombinase.

**Results:** *Thm1* deletion at E17.5 caused cystic kidney disease in adult mice, with elevated cAMP and increased proliferation. To determine if proliferation initiates *Thm1* cko renal cystogenesis, we examined kidneys at earlier time points. At P15, *Thm1* cko renal tubular dilations were evident and proliferation levels were high but similar to levels in wild-type kidneys. At P20, proliferation was markedly reduced in wild-type medullas, but not in *Thm1* cko kidneys. These data suggest that proliferation alone is insufficient to initiate renal cystogenesis and that the ciliary defect may keep the kidney in a developmental state. In *Thm1* cko cystic kidneys, expression of Hh signaling genes was upregulated. Importantly, transcripts of Hh target genes were also increased in *jck* and *Pkd1* cko cystic kidneys. To determine a functional role for enhanced Hh activity in renal cystogenesis, we are genetically downregulating Hh signaling in these mouse mutants. Preliminary data suggest that ablation of *Gli2*, the main transcriptional activator of the Hh pathway, attenuates *Thm1*, *jck* and *Pkd1* cystic kidney disease.

**Conclusions:** Thus enhanced Hh activity may play a general role in renal cystogenesis and may present a novel potential therapeutic target.

**Inhibition of Macrophage Migration Inhibitory Factor Delays Renal Cyst Growth in ADPKD** Li Chen,[1,2] Xia Zhou,[1,2] Katherine Swenson-Fields,[2,3] Xiaogang Li.[1,2] *[1]Dept of Internal Medicine; [2]Kidney Institute; [3]Dept of Anatomy and Cell Biology, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Macrophage migration inhibitory factor (MIF) can stimulate tumor cell proliferation, suppress apoptosis, facilitate invasion of the extracellular matrix and promote angiogenesis. Elevated levels of MIF have been found in the urine of ADPKD patients. However, the cellular origin of MIF in ADPKD and the potential contribution of this factor to disease progression have not been determined.

**Methods:** MIF expression was assessed in the kidneys and cells from Pkd1-deficient mice by RT-PCR and immunoblot analysis. The contribution of MIF to proliferation and proliferative signaling pathways was determined following treatment of cystic renal epithelial cells with either MIF siRNA or its inhibitor, ISO-1, in vitro. Then the functional effect of MIF on renal cyst growth was tested by treating Pkd1 conditional knockout mice with ISO-1.

**Results:** MIF was upregulated in Pkd1 mutant renal epithelial cells and tissues of Pkd1 conditional knockout mice vs Pkd1wild type mice. Furthermore, MIF was secreted and could be detected in the cyst fluid of $kd1^{flox/flox}$:Ksp-Cre mice and $Pkd1^{flox/flox}$:Pkhd1-Cre mice. Knockdown of MIF with siRNA or inhibition of MIF with ISO-1 in Pkd1 mutant renal epithelial cells: 1) decreased cystic renal epithelial cell proliferation as analyzed by the MTT assay; and 2) decreased the expression of Cyclin D1, phospho-Stat3, and phospho-S6, which are aberrantly upregulated and are known to contribute to cystic epithelial cell proliferation in ADPKD. These results suggest that MIF promotes cystic renal epithelial cell proliferation potentially through activation of these pathways. We also found that treatment with ISO-1 decreased monocyte chemoattractant activity in ADPKD cyst cell conditioned medium (CM). Most importantly, the administration of ISO-1 to $Pkd1^{flox/flox}$:Ksp-Cre mice delayed cyst growth and improved renal function.

**Conclusions:** Inhibition of MIF produces a potent anti-proliferative and anti-monocyte chemotactic effect in cystic renal epithelia and CM respectively, and delays cyst formation. These results support MIF as a potential therapeutic target in ADPKD.

**Effects of 2-OH Estradiol and Bicarbonate Loading on the Development of Polycystic Kidney Disease (PKD) in the PCK Rat** Xiaofang Wang, Hong Ye, Christopher James Ward, Vicente E. Torres. *Mayo Clinic.*

**Background:** 2-OH estradiol (2-OHE) alleviates PKD in Han:SPRD cy/+ rats by an undefined mechanism associated with up-regulation of P21 and mTOR inhibition (AJP Renal Physiol 302:F636, 2012). Since 2-OHE inhibits soluble adenylyl cyclase (SAC) *in vitro* and bicarbonate loading markedly aggravates PKD in PCK rats, likely by activating SAC (unpublished observation), we sought to determine whether 2-OHE administration would be protective in this *Pkhd1* model and prevent the detrimental effect of bicarbonate.

**Methods:** Four groups of PCK rats (10M and 10F per group) were treated with vehicle or 2-OHE (10 μg/kg/hr) via osmotic pumps and given water or 200mM sodium bicarbonate to drink between 3 weeks and sacrifice at 10 weeks of age. Linear regression analysis was used to assess the effect of treatment comparisons adjusted for gender.

**Results:** In PCK rats 1) 2-OHE modestly inhibited SAC and PKD development without affecting renal cAMP levels; 2) Bicarbonate loading markedly increased renal SAC activity, cAMP levels and PKD severity; 3) 2-OHE did not reduce cAMP levels or prevent the bicarbonate induced aggravation of PKD, possibly because of insuficient SAC inhibition; 4) 2-OHE stunted growth and had no effect on liver cystic disease.

## FR-PO125

**COX-2 Inhibition in the PCK Rat** Xiaofang Wang, Hong Ye, Katharina Hopp, Peter C. Harris, Vicente E. Torres. *Mayo Clinic.*

**Background:** Cyclooxygenase (COX)-2 is up-regulated in the kidneys of Han:SPRD cy/+ rats and COX-2 inhibitors have a protective effect in this model (AJP Renal Physiol 293:F821, 2007; Mol Biol Rep 39:7743, 2012). Furthermore, antagonists of two PGE2 GsCPRs, EP2 and EP4, inhibit cAMP signaling in human and/or murine tubular epithelial cells and *in vitro* cystogenesis (AJP Renal Physiol 293:F1622-F1632, 2007; Prost & Lipid

Med 98:11, 2012). We sought to quantify renal mRNA expression of COX isozymes, PGE2 synthases (PGEs), and EP receptors and renal PGE2 levels in PCK compared to wild-type rats; and the effect of the COX-2 inhibitor celecoxib (CXB) on the development of PKD in this *Pkhd1* model.

**Methods:** mRNA expression was quantified using real-time PCR. Four groups of PCK rats (1 control, C, and 3 treatment groups fed 250, 500 and 1000ppm CXB in powdered chow, 10M and 10F per group) were studied between 3 weeks and sacrifice at 10 weeks of age. Linear regression analysis was used to assess the effect of treatment comparisons adjusted for gender.

**Results:** COX-1, -2, mPGEs-1, -2, cPGEs, and EP-1-4 mRNAs and PGE2 levels were significantly increased in PCK compared to wild-type kidneys. CXB administration was associated with relatively higher kidney volumes in both genders and blood pressures in male rats only (Table). Despite significant reductions in tissue PGE2, cAMP levels remained unchanged. CXB had no detectable effect on the liver cystic disease.

| | Body Wt (g) | Kidney Wt (% BWt) | Cyst Vol (ml) | Fibrosis Vol (ml) | Renal PGE2 (pg/mg prot) | Syst BP (mmHg) | Pl Creat (mg/dl) |
|---|---|---|---|---|---|---|---|

## FR-PO126

**Multi-Target Treatment in ADPKD** Yang Liu,[1] Johannes Loffing,[2] Alexandre Arcaro,[3] Andreas L. Serra.[1,4] *[1]Institute of Physiology, Univ of Zürich, Switzerland; [2]Institute of Anatomy, Univ of Zurich, Switzerland; [3]Dept of Clinical Research, Univ of Bern, Switzerland; [4]Div of Nephrology, Univ Hospital Zürich, Switzerland.*

**Background:** Targeting the mammalian target of rapamycin (mTOR) by mTOR inhibitors showed only a 30 to 50% reduction of kidney growth in polycystic kidney disease (PKD) animal model. The mTOR inhibitor treatment was proven futile in randomized clinical trials of ADPKD patients. A dual-negative feedback loop has been recently described in human cancer: treatment with mTOR inhibitor results in a hyperactive IRS-1/PI3K pathway lead to the pro-proliferative ERK and Akt pathway. We hypothesized that blockage mTOR in PKD lead to an upregulation of PI3K-dependent pathway rendering the polycystic kidney partial resistant to the anti-proliferative action of mTOR inhibitors.

**Methods:** We assessed the effect of mTOR inhibitor and placebo treatment in human and animal PKD on the activation status of the mTOR, PI3K/Akt and PI3K/ERK pathways in vitro and in vivo. Next we compare the effect of single-target mTOR and NVP-BEZ235, a multi-target mTOR/PI3K inhibitor, on PKD progression in Han:SPRD rats low and high dosage (NVP-BEZ235 15 and 50 mg/kg/day), and early and late treatment initiation in Pkd1 conditional knock-out mice (from D12 to 35 as early treatment, from D21 to 35 as late treatment).

**Results:** Continuous mTOR inhibitor treatment triggered a dual-negative feedback loop *in vitro*, in ADPKD patients and Han:SPRD rats. Multi-target mTOR/PI3K treatment prohibited these feedback loops and blocked completely PKD progression while single-target mTOR had only modest effects on PKD progression. Biomolecular studies revealed that the multi-target mTOR approach depressed the PI3K-dependent pathway dual feedback loop causing blockage of the mTOR and PI3K/Akt pathway, and ultimately blocking the pro-proliferative PI3K/ERK pathway.

**Conclusions:** mTOR inhibitors cause an upregulation of pro-proliferative PI3K-dependent singling pathways whereas mTOR/PI3K inhibitor treatment prevented these circumventions resulting in a complete normal renal function of morphology of PKD animal models suggesting an innovative effective therapeutic strategy for ADPKD.

## FR-PO127

**Combination Therapy with Tolvaptan and Pasireotide Has Enhanced Efficacy in the *Pkd1* R3277C Model** Katharina Hopp, Xiaofang Wang, Hong Ye, Cynthia J. Hommerding, Peter C. Harris, Vicente E. Torres. *Mayo Clinic.*

**Background:** Animal and human studies have identified elevated levels of cAMP as a basic defect in Autosomal Dominant Polycystic Kidney Disease (ADPKD). Further, indirect targeting of AC6 has been shown as an effective means to lower cAMP levels and slow the rate of cyst growth by using two therapeutics, tolvaptan and pasireotide, that act through antagonizing the stimulatory V2R or stimulating the inhibitory SSTRs, respectively.

**Methods:** Here, we utilize the *Pkd1* R3277C mouse model, which genetically and phenotypically mimics human ADPKD, to test the value of a combined treatment. Both drugs (tolvaptan, 0.1% via food; pasireotide, 10μg/hr/kg via osmotic pump) were administered over a 5-month period, starting at 1 month. Statistical analyses were performed by 2-Way ANOVA and a Tukey HSD post-hoc test.

**Results:** At 6 months the %KW/BW was 1.9±0.2 in the control (C, n=22), 1.7±0.2 in the tolvaptan (T, n=21), 1.6±0.1 in the pasireotide (P, n=18), and 1.4±0.2 in the T+P groups (B, n=20), highlighting a significant reduction of %KW/BW upon treatment (p=1.4E-9). Pairwise comparisons showed the greatest significance for the combined treatment (C vs: T, p=1.0E-2; P, p=2.3E-4; B, p=5.5E-10) with a marked additive effect over single treatments (B vs: T, p=1.9E-4; P, p=1.8E-2). Both treatments reduced cyst volume (μl, C: 91.8±38.1, T: 71.9±34.2, P: 50.4±20.6, B: 32.5±16.2), with significance of C vs P (p=1.8E-4), T vs B (p=3.2E-4) and C vs B (p=5.4E-8). Further, cAMP levels (pmol/mg protein) were significantly reduced to WT levels by the combined treatment (C: 4.5±1.5, T: 4.1±1.3, P: 3.9±1.4, B: 3.3±0.6, WT: 3.3±0.9; C vs B, p=1.7E-2). No significant differences were found between treatment with tolvaptan/pasireotide or males/females.

**Conclusions:** The strengths of this study are the use of an orthologous model with slowly progressive renal cystic disease and long-term treatment. Further, this study shows for the first time an additive effect between tolvaptan and pasireotide, reinforcing the central role of AC6 and cAMP in ADPKD pathogenesis and the likely benefit of combination therapy for ADPKD patients.

*Funding:* NIDDK Support

## FR-PO128

**Aliskiren Ameliorates Cyst Progression by Suppressing the Intrarenal Renin-Angiotensin System Activity in Autosomal Dominant Polycystic Kidney** Tasuku Nakagaki,[1] Saori Nishio,[1] Yasunobu Ishikawa,[1] Sekiya Shibazaki,[1] Akira Nishiyama,[2] Stefan Somlo,[3] Hiroyuki Kobori,[2] Tatsuya Atsumi.[1] *[1]Internal Medicine II, Hokkaido Univ Graduate School of Medicine, Sapporo, Hokkaido, Japan; [2]Dept of Pharmacology, Kagawa Univ School of Medicine, Kagawa, Japan; [3]Dept of Internal Medicine, Yale Univ School of Medicine, New Haven, CT.*

**Background:** Hypertension is a well-recognized complication of autosomal dominant polycystic kidney disease (ADPKD) and is significant independent risk factor for progression to end stage of renal disease. Involvement of the renin-angiotensin system (RAS) has been postulated, but no consistent relationship has been found between blood pressure and plasma renin activity.

The purpose of this study is to examine the effects of antihypertensive drugs for *Pkd1* conditional knockout mice and to evaluate the participation of intrarenal RAS in this model.

**Methods:** We generated *Pkd1* conditional knockout mice carrying the Cre transgene under the control of the *Mx1* promoter (*Pkd1* $^{flox/flox}$*;Mx1-Cre* mice). All mice were injected with polyinosinic-polycytidylic acid (pI:pC) to induce the expression of Cre recombinase and to inactivate *Pkd1* at 2 weeks of age. To evaluate the effects of antihypertensive drugs, *Pkd1* $^{flox/flox}$*;Mx1-Cre* mice were treated by osmotic mini-pumps with amlodipine or olmesartan or aliskiren, or vehicle for 12 weeks. Blood pressure was measured by the tail-cuff method. Kidney weight to body weight ratio (KW/BW),and renal cystic index were used to assess efficacy of treatment. Intrarenal RAS activity was examined by measurement of urinary angiotensinogen (AGT) excretion and immunohistochemistry for renin, angiotensin II, and AGT in the kidneys.

**Results:** Blood pressure was almost similar among the treatment groups. There was no difference in KW/BW and renal cystic index, between amlodipine, olmesartan and vehicle. Aliskiren treatment significantly reduced the KW/BW, renal cystic index, BUN, urinary albumin excretion, and intrarenal RAS activity.

**Conclusions:** These studies suggest RAS inhibition with aliskiren may be effective in slowing cyst growth by suppressing the intrarenal RAS activity in ADPKD.

## FR-PO129

**H2-Relaxin Modulates Expression of Fibrosis-Related Genes in Normal and Cystic Human Renal Epithelial Cells** Heather Hilary Ward,[1] Paul C. Grimm,[2] Angela Wandinger-ness.[3] *[1]Internal Medicine, Nephrology Div, Univ of New Mexico, Albuquerque, NM; [2]Pediatric Nephrology, Stanford Univ, Stanford, CA; [3]Pathology, Univ of New Mexico, Albuquerque, NM.*

**Background:** In autosomal dominant polycystic kidney disease (ADPKD), renal inflammation, abnormal extracellular matrix (ECM) deposition, and fibrotic progression are concurrent with cyst growth and collectively destroy renal architecture, resulting in irreversible loss of kidney function. To date, the opportunity to circumvent these additional factors that promote the loss of renal function has been insufficiently studied.

**Methods:** We used computer-assisted quantification of picrosirus red staining and real-time PCR to evaluate the effect of H2-relaxin on matrix metabolism in cystic kidneys and specific renal cell types.

**Results:** We demonstrate that administration of H2-relaxin in the Cy/+ rat model of ADPKD decreased expression of genes that regulate ECM synthesis and degradation, and these data correlated with trends of decreased renal interstitial matrix content. Relaxin acts directly on fibroblasts and endothelial cells, but little is known about relaxin-mediated signaling in epithelia. In vitro, real-time PCR data showed that human ADPKD renal epithelia expressed abnormal levels of ECM components in the absence of other fibrotic drivers. When normal and ADPKD renal epithelia were incubated with H2-relaxin in the presence of a fibrotic stimulus (TGFβ1), H2-relaxin differentially inhibited up regulation of matrix-synthesis genes, tissue inhibitors and mesenchymal markers in normal and ADPKD epithelia. In contrast, expression levels of genes related to ECM synthesis and degradation were strongly up regulated upon TGFβ1 stimulation in normal and ADPKD renal epithelia, when compared to respective vehicle-treated control cell types.

**Conclusions:** These studies provide the first detailed mechanistic analyses of the utility of relaxin for dissecting fibrotic mechanisms in renal epithelia. Pinpointing the mechanisms underlying fibrosis in ADPKD has important implications for identifying effective therapies, such as H2-relaxin, to prevent or reverse the process of fibrosis in ADPKD patients.

## FR-PO130

**Pyrrolidine Dithiocarbamate Reduces Kidney Enlargement and Proteinuria in Experimental Polycystic Kidney Disease** Michelle Ta,[1] Padmashree Rao,[1] Mayuresh Korgaonkar,[2] Sheryl L. Foster,[2] Anthony Peduto,[2] David C. Harris,[1] Gopala K. Rangan.[1] *[1]Centre for Transplant & Renal Research, Westmead Millennium Institute, Sydney, Australia; [2]Brain Dynamics Centre, Westmead Millennium Institute, Australia.*

**Background:** The proinflammatory transcription factor family, nuclear factor (NF)-kB, is upregulated in experimental PKD, and NF-kB inhibition reduces cyst growth in *Pkd1*$^{-/-}$ murine kidney explants. To determine the *in vivo* effects of NF-kB, we hypothesised that pyrrolidine dithiocarbamate (PDTC, a NF-kB inhibitor) reduces disease progression in rodent PKD.

**Methods:** Male LPK rats (*Nek8/NPHP9* ortholog with diffuse collecting duct dilatation) received i.p.i of either vehicle (V) or PDTC [40mg/kg once (x1), or twice daily (x2)] from postnatal wks 4 until 11. Total kidney volume (TKV) was assessed by 3D MRI at wk 5 and 10.

**Results:** PDTC reduced proteinuria by 66%, but did not alter renal dysfunction (Table). By serial MRI, the relative within-rat increase in TKV was 1.3-fold greater in V vs PDTC (p=0.010). PDTC also attenuated 2KW:BW ratio by 25% and interstitial CD68+ cells (x1 only), but not %cyst area, Ki67+ cells or interstitial fibrosis.

| | Lewis+V N=3 | Lewis+PDTC(x2) N=4 | LPK+V N=9 | LPK+PDTC(x1) N=8 | LPK+PDTC(x2) N=9 |
|---|---|---|---|---|---|

## FR-PO131

**Phosphodiesterase 1A Rescue of Renal Cystogenesis and Examination of Additional PDEs in Zebrafish** Caroline R. Sussman, Christopher James Ward, Amanda Christine Leightner, Peter C. Harris, Vicente E. Torres. *Mayo Clinic.*

**Background:** Substantial evidence indicates the importance of elevated cAMP in polycystic kidney disease (PKD). Preclinical and clinical trials have shown the feasibility of therapies (vasopressin V2 receptor antagonists and somatostatin analogs) acting on G protein coupled receptors to inhibit Adenylyl Cyclase activity and production of cAMP.

**Methods:** To test whether modulating cAMP hydrolysis also affects renal cystogenesis, we have altered activity of the Phosphodiesterase, PDE1A, in zebrafish embryos by injecting morpholinos and RNA. We have additionally examined the involvement of cAMP/PKA signaling in zebrafish cystogenesis using the PKA inhibitor, H89. Finally, we have analyzed the expression of additional PDEs in zebrafish by RT-PCR.

**Results:** We have previously shown that *pde1a* morpholinos induce renal cysts, hydrocephalus, and body curvature in zebrafish embryos, and that PDE1A depletion aggravates body curvature phenotypes from morpholino-induced Polycystin-2 (PC2) depletion. We show here that human *PDE1A* RNA partially rescued PDE1A and PC2-depletion phenotypes (renal cysts, hydrocephalus, and body curvature). In addition, the PKA inhibitor, H89, partially rescued the formation of renal cysts, hydrocephalus, and body curvature in *pde1a* morphants. Besides *pde1a*, 2 day post-fertilization zebrafish embryos also expressed clear orthologs to human *pde1c, pde3a, pde3b,* and *pde4c*.

**Conclusions:** These data are consistent with previous data from PDE1A loss of function studies, providing further evidence of an integral role of PDE1A in renal cystogenesis in zebrafish. Data are consistent with PDE1A effects downstream of PC2 and upstream of PKA, and indicate the utility of zebrafish for analysis of additional PDEs. In addition, these data suggest a role for zebrafish in evaluating PDE-targeted therapy for PKD.

## FR-PO132

**Intravenous Renal Cell Therapy for Autosomal Recessive Polycystic Kidney Disease in Rats** Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Medicine, IUMS, Indianapolis, IN; [2]Medicine, VAMC, Indianapolis, IN.*

**Background:** Polycystic kidney disease (PKD, including ADPKD1, ADPKD2, ARPKD) is a group of diseases with overlapping phenotypes and are not curable. They are enhanced by renal injury which accelerates progression to ESRD, and then the only hope to get off of dialysis is kidney transplantation, but the need for organs to transplant exceeds supply.

**Methods:** We have introduced intravenous renal cell transplantation (IRCT) in rats as a future alternative to kidney transplantation, and tested the hypothesis that IRCT with Serum Amyloid A protein (SAA) expressing normal adult renal cells improves structure and function in PKD by coordinating the re-orientation of adjacent host PKD cells.

**Results:** We tested this idea in the PCK rat, an orthologus model of ARPKD. We included four rat groups starting with surgery at 6 weeks of age and IRCT at 6, 8, and 10 weeks of age, termination was at 26 weeks of age: AS, were sham operated and given SAA negative cells, n=7. BS, were sham operated and given SAA positive cells, n=7. AI, had unilateral renal ischemia for 50 min and given SAA negative cells, n=8. BI, had unilateral renal ischemia for 50 min and given SAA positive cells, n=8. We followed renal function and structure with Dynamic Contrast Enhanced CT. Donor cells were found in abundant numbers on the cyst walls and damaged tubules, but not outside the kidneys. SAA positive "B" cells improved function and structure.

| | AS | BS | AI | BI |
|---|---|---|---|---|
| Kidney Weight (g) | 2.60±0.07 | 2.18±0.14* | 3.11±0.05 | 2.8±0.10§ |
| Albuminuria (g/g creat) | 1.93±0.14 | 1.26±0.11* | 2.40±0.16 | 1.42±0.13§ |
| BUN (mg/dl) | 24±0.6 | 19±0.6* | 29±1.5 | 23±0.3§ |
| Cyst Volume (ml) | 0.43±0.02 | 0.26±0.07* | 0.57±0.11 | 0.36±0.02§ |
| GFR (ml/min) | 1.08±0.05 | 1.28±0.08* | 0.97±0.09 | 1.32±0.09§ |
| *p<0.05 vs AS, §p<0.05 vs AI | | | | |

**Conclusions:** IRCT is an effective means to retard cyst development and progression (all "B" groups significantly different than corresponding "A" groups) in the PCK and has a great potential for PKD therapy.

## FR-PO133

**Abnormal Upregulation of Notch3 Pathway in Polycystic Kidney Disease** Madhulika Sharma,[1] Trisha Home,[1] Lynn Magenheimer,[1] Gail Reif,[1] Brenda S. Magenheimer,[2] Robin L. Maser,[2] Darren P. Wallace,[1] James P. Calvet.[2] *[1]Internal Medicine (Nephrology and Hypertension), Univ of Kansas Medical Center, Kansas City, KS; [2]Biochemistry and Molecular Biology, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Aberrant proliferation of tubular epithelial cells is a hallmark of polycystic kidney diseases (PKD). Despite recent advances, a better understanding of the molecular mechanisms involved in cyst development is needed. Notch signaling plays an important role in cell proliferation and differentiation and has a key role in kidney development and in kidney diseases. However its role in PKD is not yet defined. We hypothesized that Notch signaling may be an important pathologic feature of autosomal dominant (ADPKD) and autosomal recessive (ARPKD) PKD.

**Methods:** Immunohistochemistry (IHC) was performed in kidney paraffin sections obtained from CPK mice (a model ARPKD) and Pkd1 null/HoxB7 conditional mice (a model of ADPKD) at one and two weeks of age. These mice develop rapidly progressive cystic disease and by 20 days of age the mice die due to end stage renal disease. We also obtained kidney sections from ADPKD patients undergoing a nephrectomy. We used commercially available antibodies for Notch1, Notch2, Notch3 and Notch4 (Notch receptors); Jagged1, Jagged2, Delta like1, Delta like3 and Delta like4 (Dll4) (Notch ligands); and Hes1 and HeyL (Notch targets). Signals from IHC were quantified using Image J Analysis. Comparisons were made with littermate controls or with normal human kidney samples.

**Results:** Notch3 was found to be distinctly upregulated in the cystic epithelia of all the models of PKD tested. Upregulation of Notch3 expression correlated with disease progression in CPK mice. Among the ligands, Dll4 expression was most significantly upregulated in the cystic epithelium. In addition both Hes1 and HeyL targets of Notch pathway were found to be significantly upregulated in the cystic epithelium of CPK, Pkd1null/HoxB7 mice and ADPKD patients.

**Conclusions:** Upregulation of the Notch signaling pathway in ADPKD and ARPKD suggests that small molecule inhibitors of this pathway may have therapeutic potential in the PKD setting.

## FR-PO134

**Paricalcitol Attenuated In-Vitro Cyst Formation, Phenotype Transition and Apoptosis of ADPKD Cyst-Lining Epithelial Cells** Hyun-soo Shin, Yea-Jin Choi, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi, Duk-Hee Kang. *Div of Nephrology, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea.*

**Background:** Recent data demonstrated the reno-protective effect of vitamin D analogs via anti-inflammatory, immunomodulatory and anti-fibrotic effects. Polycystic kidney disease (PCK) is the most common inherited disease characterized by multiple cysts formation accompanied by renal fibrosis. However, there have been no studies investigating whether vitamin D imposes any effect on cyst formation, growth & renal fibrosis in PCK.

We aimed to examine the effect of active vitamin D analog, paricalcitol on in-vitro cyst formation as well as phenotype transition and apoptosis of cyst-lining epithelial cells.

**Methods:** 3D culture system of forskolin-treated Madin-Darby canine kidney (MDCK) cells was used to examine the effect of paricalcitol (20 nM) on cyst development. Effect of paricalcitol on TGF-β (10 ng/ml)-induced phenotype transition and apoptosis of ADPKD cyst-lining epithelial cells (WT9-12 cell) was also evaluated with an assessment of phosphorylation of p38 and ERK1/2 MAPK, GSK-3β and nuclear translocation of β-catenin.

**Results:** Paricalcitol significantly inhibited forskolin-induced cyst formation of MDCK cells with an attenuation of both ERK1/2 MAPK activation and GSK-3β phosphorylation. Paricalcitol also inhibited TGF-β-induced expression of vimentin and fibronectin in WT9-12 cells with an amelioration of p38- and ERK1/2 MAPK activation, GSK-3β phosphorylation and nuclear translocation of β-catenin. Paricalcitol protected ADPKD cyst-lining cells from TGF-β-induced apoptosis with down-regulation of Bax, Cytochrome C, cleaved caspase-3 and -9.

**Conclusions:** Paricalcitol ameliorated cyst formation, pro-fibrotic phenotype transition and apoptosis of renal tubular cells, which can be one of the therapeutic options targeting early and late mechanisms of renal disease progression in PCK.

## FR-PO135

**Macrophage-Cyst Cell Interaction in ADPKD Promotes Production of Fibrogenic Factors** Katherine Swenson-Fields, Jacqueline D. Peda, Sally M. Salah, Brad M. Davis, Darren P. Wallace, Timothy A. Fields. *The Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** In polycystic kidney disease (PKD), the destructive compression of parenchyma responsible for loss of kidney function is driven by both expanding cysts and fibrosis. We have shown that interaction between cyst epithelial cells and macrophages (MΦs) promotes cyst cell proliferation and expansion. MΦs are known to promote fibrosis in chronic kidney disease and thus are likely to do so in PKD. However, the specific contribution of MΦ/epithelial cell interactions to the creation of a pro-fibrotic environment in PKD has not been examined. In this study we co-cultured MΦs with primary human epithelial cells isolated from either PKD cysts or non-cystic kidneys to generate conditioned media (CM), which was assessed for fibrogenic effects on renal fibroblasts.

**Methods:** RAW 264.7 cells (mouse MΦ-like line) or MΦ-differentiated THP-1 cells (human monocytic line) were co-cultured with PKD cyst cells or collecting duct cells from non-cystic kidneys (NHK) either directly or in transwells (0.4 um pores). CM was collected and incubated with NRK-49F cells (rat renal fibroblast line), and the effects on cellular morphology and the production of fibrogenic markers [type-I collagen (COL1A1) and smooth muscle actin (SMA)] were assessed.

**Results:** CM from co-culture of MΦs and either PKD cells or NHK cells but not CM from any cell-type alone induced dramatic morphological transformation in fibroblasts. Fibroblasts treated with co-culture CM displayed a bipolar or stellate morphology with markedly elongated cellular extensions, which was similar to but distinct from that produced by TGFβ treatment. Also, treated cells accumulated in nodular foci. These effects were observed whether the MΦ-epithelial cell co-culture was direct or via transwell. Immunoblots showed COL1A1 was induced specifically by treatment with co-culture CM or with TGFβ. However, myofibroblast marker SMA was induced only by TGFβ.

**Conclusions:** Interaction between MΦs and renal tubule epithelial cells results in production of fibrogenic factors. This interaction may be a viable therapeutic target in PKD and other chronic kidney diseases.

## FR-PO136

**Amphiregulin, an Epidermal Growth Factor Receptor Ligand, and BRP39 in the Pathogenesis in Cystic Kidney Fibrosis** Seung H. Lee,[1] Sung Hyun Son,[2] Sorin V. Fedeles,[1] Rachel Gallagher,[1] Stefan Somlo.[1] *[1]Dept of Internal Medicine, Section of Nephrology, Yale Univ, School of Medicine, New Haven, CT; [2]Dept of Internal Medicine, Section of Nephrology, BHS Han Seo Hospital, Busan, Republic of Korea.*

**Background:** Fibrosis plays an important role in the progression of polycystic kidney disease (PKD). Dysregulated EGFR signaling has also been implicated in the pathogenesis of PKD.We sought to determine whether there may be an inter-relationship between fibrosis signaling pathway, EGFR activation and mediators of the fibrotic/inflammatory response in PKD.

**Methods:** Fibroblast cells (NIH3T3) and kidneys from an ADPKD orthologous gene model ($Pkd1^{fl/fl}$;Pkhd1-Cre) were used to examine mRNA and protein levels of TGF-β1 targets (PAI-1, SMAD2), EGFR ligands amphiregulin (AR) and HB-EGF, EGFR downstream effectors Akt and ERK and the marker of tissue fibrosis/inflammation BRP39 by quantitative PCR (qPCR) and semi-quantitative Western blot.

**Results:** TGF-β1 activation of NIH3T3 cells resulted in increased AR expression and activation of EGFR targets p-Akt and p-ERk and associated fibroblast cell proliferation. The proliferative response to TGF-β1 was inhibited by EGFR inhibitor AG1478. We next examined P24 kidney tissues from cystic $Pkd1^{fl/fl}$;Pkhd1-Cre and non-cystic controls for evidence of up-regulation of these fibrosis related pathways. Cystic kidney tissue at P24 showed up-regulation of the TGF-β1 targets PAI-1 and AR and the fibrosis and inflammatory disease marker BRP39 by qPCR.

**Conclusions:** The data support further testing of the hypothesis that TGF-β1 mediated fibrosis in PKD may in part be mediated by amphiregulin and EGFR signaling and by the inflammatory mediator BRP39. These pathways may prove to be reasonable therapeutic targets for treating renal fibrosis in ADPKD.

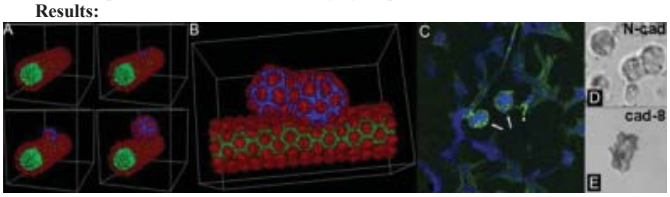
## FR-PO137

**Computer Model of Renal Cyst Formation** Julio M. Belmonte,[1] Sherry G. Clendenon,[1] James A. Glazier,[1] Robert L. Bacallao.[2] *[1]Physics/Biocomplexity Institute, Indiana Univ, Bllomington, IN; [2]Medicine, Indiana Univ, Indianapolis, IN.*

**Background:** Recently we have shown that ectopic cadherin-8 expression can initiate cyst formation. We utilized a 3D multi-cell simulation of renal tubules to investigate mechanisms behind this observation. Our model predicts that loss of cell-cell adhesion in a single cell suffices to trigger cysts and the pattern differs from contact-inhibition changes.

**Methods:** CompuCell 3D is an open source simulation environment for running multicell simulations. The program numerically solves matricies that model cell-cell, cell-ECM adhesion and cell/volume constraints. Cell adhesion was analyzed over a continuum of values and predictions confirmed by hanging drop assay.

**Results:**



**PKD simulation**. (**A**) Starting from a stable tubular structure we model cadherin-8 phenotype by changing macroscopic properties of the microinjected cell (blue cell in panel). Increased surface tension between wild type and cadherin-8 expressing cell leads to deactivation of contact-inhibition, proliferation and formation of a single ectopic cyst. (**B**) 3D view of a similar simulation showing two formed cysts. (**C**) Images of cysts (arrows) stained for cadherin- 8(green) (**D-E**) Hanging drop asays show (**D**) compacted spheres of N-cad expressing cells and (**E**) loosely associated sheets of cadherin-8 expressing cells. The prediction that cadherin 8 decreased cell-cell adhesion in renal epithelial cells was confirmed in hanging drop assays. Cadherin 8 transfected HK-2 cells had fewer cell aggregates and aggregate size was decreased compared to N-cadherin transfected cells.

**Conclusions:** in silico modeling of renal cyst formation makes discrete predictions about cell cell adhesion properties that are confirmed by cell-cell adhesion assays. This approach allows for rapid identification of biological pathways that alter normal epithelial morphogenesis pathways.

## FR-PO138

**Microbiology and Outcomes of Central Line Associated Blood Stream Infections (CLABSI) in Chronic Hemodialysis Patients** LaTonya J. Hickson, Kirandeep K. Khangura, Muhammad Rizwan Sohail, Patricia J.M. Best, Robert C. Albright, Larry M. Baddour, Rodney L. Thompson. *Nephrology, Infectious Disease, Cardiology, Mayo Clinic.*

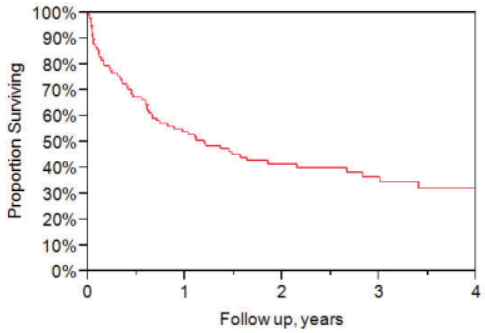
**Background:** Infections are the second most common cause for hospitalization in chronic HD patients. CLABSIs remain a major health concern and focus of quality improvement programs. However, CLABSIs continue to occur in select groups.

**Methods:** Review of baseline characteristics and outcomes of CLABSIs at a single tertiary care center.

**Results:** From 01/2007-06/2012, 99 chronic HD patients were treated for CLABSIs. CLABSIs were equally distributed over the 4.5 years; range 16-20/year. Mean age was 62±17 years, 52% male, and 77% Caucasian. Diabetes (55%), coronary artery disease (57%), and heart failure (64%) were frequent comorbidities. Others included: immunosuppression (24%), intracardiac device (22%), joint arthroplasty (15%), and prosthetic heart valve (10%). Diabetes was the main (28%) renal failure cause. The majority (94%) had tunneled central venous catheters (CVC) and few had temporary CVCs (6%). The most common pathogens are shown.

| | Prevalence |
|---|---|
| coagulase-negative staphylococci | 22% |
| *Enterococcus* species | 14% |
| methicillin-sensitive *Staphylococcus aureus (SA)* | 11% |
| methicillin-resistant *SA* | 9% |

CVCs were removed in 78% with salvage attempted in others. At index hospitalization, infective endocarditis (IE) was confirmed (5 patients) or suspected (6). Over a 6-month period, 2 were later diagnosed with IE. A second CLABSI occurred in 23 patients within 12 months. Overall survival rate was reduced at 6 (67%) and 12 months (47%).



**Conclusions:** Chronic HD patients hospitalized with CLABSI have a high prevalence of comorbidities that complicate decision-making. Even with being high risk, few patients developed IE from CLABSI. Better prediction tools to identify those at highest risk for CLABSI despite modern infection prevention protocols merit further investigation.

## FR-PO139

**Risk of Catheter-Related Bloodstream Infections in Elderly Patients on Hemodialysis** Mariana Murea, Kimone M. James, Gregory B. Russell, Anthony J. Bleyer, John M. Burkart, Barry I. Freedman. *Wake Forest School of Medicine, Winston- Salem, NC.*

**Background:** Elderly patients are more likely to require tunneled central vascular catheters (TCVC) for dialysis than younger patients. Unfortunately, there is little data on the risk of catheter-related bloodstream infections (CRBSI) in this population.

**Methods:** We collected data regarding CRBSI on prevalent and incident adult patients undergoing HD solely via TCVC at 9 Wake Forest Outpatient Dialysis centers between 2005 and 2007. Subjects who had a TCVC for <21 days were excluded. Cox proportional hazards regression analysis was performed with an event defined as CRBSI and censoring for death, end of study, or CRBSI no longer needed.

**Results:** 374 adult (age < 75 years) and 90 elderly (age ≥75 years) subjects of mean±SD age 54.8±12.3 and 81.3±4.9 years, dialysis vintage 1.8±3.3 and 1.5±2.9 years (p=0.47), and race distribution (European-American, African-American, other) 43.8%, 51.9%, 4.3%, and 73.3%, 26.7%, 0%, respectively (p<0.0001) were evaluated. CAD and CHF were more prevalent in elderly (51.1% and 48.9%) vs. adult patients (27.0% and 26.5%), p<0.001; while diabetes, HTN, and PVD had similar prevalence between groups. Mean total at-risk catheter-days were 272±243 in adults and 318±240 in the elderly. There were no significant differences in catheter site, use of anti-microbial catheter lock solutions, and bacterial culture results between groups. 208 total CRBSI events occurred (190 in adults, 18 in elderly), with CRBSI incidence per 100 catheter-days 0.20±0.46 in adults and 0.06±0.16 in elderly, p<0.0001. Using Cox regression analysis adjusted for sex, ethnicity, diabetes, catheter site and antimicrobial catheter lock solution, the hazard ratio (HR) for CRBSI in the elderly vs. adults was 0.33, (95% CI 0.20-0.54; p <0.0001). Risk of CRBSI declined by 11% per each 5 year age increment (HR, 0.89, 95% CI, 0.85-0.93, p<0.0001).

**Conclusions:** Elderly patients on HD using TCVC are at a significantly lower risk of CRBSI than younger patients. These results suggest that TCVC may be a more suitable option in elderly patients if permanent vascular access is problematic.

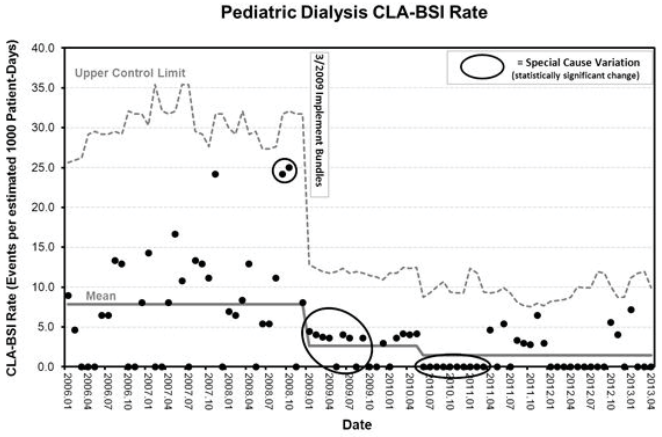
## FR-PO140

**Reduction in Catheter Associated Blood Stream Infections in a Pediatric Dialysis Unit** Kera E. Luckritz,[1] Maureen M. Shanley,[1] Theresa A. Mottes,[2] Matthew Niedner.[3] *[1]Pediatric Dailysis, Univ of Michigan, Ann Arbor, MI; [2]Center for Acute Care Nephrlogy, Cincinnati Children's Hospital, Cincinnati, OH; [3]Pediatric Critical Care, Univ of Michigan, Ann Arbor, MI.*

**Background:** Hemodialysis (HD) is the most common dialysis modality in children with a tunneled catheter as the vascular access in >75% of patients. The USRDS 2012 report cites a central line-associated bloodstream infection (CLABSI) incidence of 14.5% among pediatric patients. CLABSI can lead to morbidity including hospitalization and access failure, making prevention a priority in this population.

**Methods:** A CLABSI eradication team of pediatric nephrologists, dialysis/apheresis nurses, an infection control practitioner, a physician assistant who specializes in dialysis catheter insertions and an administrator was established. A bundle of evidence-based best practices was developed for the care of dialysis catheters and exit sites. A checklist of 10 steps was used as a tool to prompt desired practices and capture self-auditing process measures. Audits were performed with an "all or none" compliance methodology. Only trained dialysis/apheresis nurses who received 1:1 education regarding the accessing procedure from a member of the CLABSI team were allowed to access dialysis catheters. Audits were completed over 18 months and results were reviewed monthly by the team with feedback from the staff on challenges to compliance. After each infection, a root cause analysis was performed. Follow up communication with the dialysis staff emphasized lessons learned, preventability and patient impact.

**Results:** In the first 3 months, self-reported and observed compliance were 32% and 41% respectively, which rose to 82% and 67%. CLABSI rates are shown in a control chart, with statistically significant special cause variation patterns circled.



CLABSI rates fell from 7.9 to 2.6 per 1000-patient-days (66% reduction), and after a year of ongoing quality improvement work with rising compliance, rates dropped further to 1.5 per 1000-patient-days (81% reduction).

**Conclusions:** Minimizing the number of personnel accessing HD catheters and standardizing the technique with constant monitoring and feedback can reduce CLABSI rates.

## FR-PO141

**Fibrin Sheath Disruption during Catheter Exchange: Association with Bacteremia and Catheter Patency** Amanda M. Valliant, Muhammad K. Chaudhry, Alexander S. Yevzlin, Brad C. Astor, Micah R. Chan. *Univ of Wisconsin Hospitals and Clinics, Madison, WI.*

**Background:** Tunneled dialysis catheters are the most common form of vascular access among incident dialysis patients in the United States. Fibrin sheath formation is a frequent cause of late catheter dysfunction requiring an exchange procedure with balloon disruption of the fibrin sheath. It is unknown whether fibrin sheath disruption is associated with increased incidence of bacteremia or catheter failure.

**Methods:** We reviewed all tunneled dialysis catheter exchange procedures at the University of Wisconsin between January 2008 and December 2011. The primary outcome was incidence of bacteremia, defined as positive blood cultures within 2 weeks of the procedure. Catheter failure, requiring intervention or replacement, was examined as a secondary outcome. Baseline characteristics examined included diabetic status, gender, race and age.

**Results:** A total of 163 procedures were reviewed; 67 (41.1%) had fibrin sheath disruption and 96 did not. There was no difference in the prevalence of bacteremia among those with (3/67; 4.5%) and those without fibrin sheath disruption (3/97; 3.1%; p=0.65). Fibrin sheath disruption was not significantly associated with the risk of catheter failure (adjusted hazard ratio [AHR] = 1.34; 95% confidence interval [CI]: 0.87-2.10; p=0.18). Diabetes was associated with greater risk of catheter failure (AHR = 1.88; 95% CI: 1.19-2.95; p=0.006), whereas higher age was associated with a lower risk of catheter failure (AHR per 10 years = 0.83; 95% CI: 0.72-0.96; p = 0.01).

**Conclusions:** This study demonstrates for the first time, to our knowledge, that there is no significant association between fibrin sheath disruption and bacteremia or catheter patency. These results are encouraging given the large numbers of patients utilizing tunneled catheters for initial hemodialysis access and the known rates of fibrin sheath formation leading to catheter failure.

## FR-PO142

**MRSA and MSSA Carriage in a Cohort of Haemodialysis Patients: Prevalence, Eradication and Short Term Outcomes** Nadia Sarween, Anna Price, Jyoti B. Baharani. *Renal Medicine, Birmingham Heartlands Hospital, Birmingham, United Kingdom.*

**Background:** Haemodialysis (HD) patients with Staphylococcus aureus *(S.aurues)* bacteraemia have an increased risk of adverse outcome including death, compared to bacteraemia caused by other pathogens. Nasal colonisation of MRSA has been shown to increase the risk of subsequent endogenous infection with the organism in dialysis patients.

We performed a retrospective study in chronic haemodialysis patients to estimate the prevalence of *S.aureus* nasal carriage (for both MSSA and MRSA), to define patient groups at risk of colonisation and to look at the short-term outcomes following a decolonisation programme.

**Methods:** All established HD patients (666) were screened 4 monthly for 24 months (between June 2009 and May 2011)**.** At least two swabs; from the nose and access site were taken. Those with a positive result completed a course of decolonisation treatment. Data was gathered retrospectively using hospital electronic records and the renal unit data base for up to a period of 18 months following the date of the initial swab. Statistical analysis was performed using SPSS.

**Results:** The prevalence of colonisation with *S.aureus* was 47.7% (MRSA 9% MSSA 91%). 59% were male and median age was 65 years. 18.9% were in the high-risk co-morbidity group using Charlson Index. After decolonisation treatment 34% remained

successfully eradicated (eradicators). There was a significantly higher incidence of positive blood cultures in the non-eradicators (23%) compared with the eradicators (2%) but no difference was found in age, incidence of diabetes, co-morbidity score or number of hospital admissions between the two groups. 40% of patients died within 18 months without a difference in death rates between the two groups.

**Conclusions:** Decolonisation therapy was successful in eradicating carriage with *S.aureus* in 34% of our patients. Those that recolonised or remained colonised had a higher rate of bacteraemia with MSSA/MRSA compared to those that sucessfully eradicated. These patients are not easily identified from their demographics or co-morbidities. We would based on our findings advocate routine surveillance and aggressive attempts at eradication of *S.aureus* carriage in HD patients.

## FR-PO143

**Reduction of Catheter-Related Bloodstream Infections (CRBSI) after Implementation of an Endoluminal Catheter Colonization Surveillance Culture Protocol in Hemodialysis** Patricia Brañas,[1] Enrique Morales,[2] Francisco Rios,[1] Fernando Chaves.[1] *[1]Microbiology, Hospital 12 de Octubre, Madrid, Spain; [2]Nephrology, Hospital 12 Octubre, Madrid, Spain.*

**Background:** The colonization of the inner catheter lumen is the first step in the pathogenesis of most CRBSI. The aim of the study was to analyze the results of a protocol established in our hemodialysis (HD) unit, based on surveillance cultures (SCs), to prevent CRBSI.

**Methods:** Prospective study (April 2011-April 2012) in HD patients (pts) with tunnel cuffed central venous catheters (TCCs). Endoluminal colonization was assessed every 15 days by SCs: mixture of heparin (~ 2 mL) and blood (~ 3 mL) extracted from the TCC just before connecting the pts. SCs were inoculated into aerobic culture bottles and incubated 5 days (BacT/Alert, Biomerieux). Based on the microorganism and the time to positivity (TTP), an algorithm was designed: Group 1 (negative): continue surveillance; Group 2 (Coagulase-negative Staphylococcus [CoNS], TTP>14 hours): draw a new SC in a week. If the result was repeated, antibiotic lock therapy (ALT) was indicated (vancomycin or daptomycin 5 mg/mL, 2 weeks); Group 3 (CoNS, TTP<14 hours): ALT; Group 4 (other microorganism, any TTP): diagnosis of CRBSI and management according to guidelines.

**Results:** We included 104 pts with 129 TCCs. 56 pts were male and the median age was 73.0 (IR:54.5-80.0). The Charlson comorbidity index adjusted for HD was 7.0 (IR: 6.0-9.0), and the TCC vintage was118 days (IR:18-364). The most common causes of renal impairment were diabetic nephropathy (26.9%) and renal vascular disease (22.1%). The median of follow up was 262.5 days (IR: 135-365). A total of 1734 SCs were collected (median/pt: 18 [IR:10-24]) and 100 (5.8%) were culture positive. According to the protocol TCC colonization was detected in 28 occasions: 19 from groups 2 and 3, and 9 from group 4. Six pts carrying 7 TCCs had 7 CRBSI. The rate of CRBSI was 0.27/1000 catheter-days (1.65/1000 catheter-days in 2008).A total of 25 TCCs were removed, 11 for infection and 14 from other causes.

**Conclusions:** SCs, based on easily accessible samples, may contribute to reduce CRBSI in HD pts. Thereby, ALTs would be restricted to pts at high risk of CRBSI.

## FR-PO144

**Sustained Infection Reduction in Outpatient Hemodialysis Centers Participating in a Prevention Collaborative** Sarah H. Yi,[1] Stephanie L. Booth,[2] Virginia R. Bren,[2] Gemma Downham,[2] Sally Hess,[2] Karen Kelley,[2] Mary E. Lincoln,[2] Curt Lindberg,[2] Heather Weirich,[2] Alexander Kallen,[1] Priti Patel.[1] *[1]Div of Healthcare Quality Promotion, Centers for Disease Control and Prevention (CDC); [2]Steering Committee for the CDC Dialysis Bloodstream Infection Prevention Collaborative.*

**Background:** We reported previously reductions in bloodstream infections (BSIs) and access-related BSIs in a group of outpatient hemodialysis centers after implementation of a package of BSI prevention interventions. We sought to assess sustainability of these reductions, and to assess trends in intravenous (IV) antimicrobial use.

**Methods:** In 2009, 17 outpatient hemodialysis centers joined a CDC-sponsored collaborative project to prevent BSIs. Centers implemented CDC's Core Interventions for BSI Prevention, and reported BSIs, access-related BSIs, IV antimicrobial starts, and monthly patient census by vascular access type per CDC's National Healthcare Safety Network protocol. Up to 12 months of baseline and 36 months of intervention data were analyzed. Segmented regression analysis was used to assess initial change from baseline at intervention start and monthly rate changes during the intervention.

**Results:** The table contains actual and modeled rates.

| Measure | Pooled rates | | Modeled changes during intervention | | | |
|---|---|---|---|---|---|---|
| | | | Initial | | Monthly | |
| | Baseline | Intervention | Change | *P*-value | Change | *P*-value |
| BSI[a] | 1.09 | 0.83 | -24% | .16 | -0.71% | .36 |
| Access-related BSI[a] | 0.73 | 0.43 | -52% | <.0001 | -0.12% | .85 |
| IV antimicrobial start[a] | 4.38 | 3.36 | -17% | .22 | -0.67% | .25 |
| CVC use[b] (%) | 31.8 | 24.7 | -14.5%[c] | .02[d] | | |

[a]Count per 100 patient-months.
[b]Percent of patients with central venous catheter (CVC).
[c]Actual.
[d]Wilcoxon signed-rank test.

Using the modeled baseline trend, an estimated 147 of 298 expected access-related BSIs were prevented during the intervention.

**Conclusions:** Centers demonstrated an early drop in access-related BSIs that persisted through intervention month 36. Access-related BSIs may be preventable through implementation of and adherence to recommended prevention practices; improvements may be maintained at least three years after adoption.

*Funding:* Other U.S. Government Support

## FR-PO145

**Revision versus Exchange of Malfunctioned Tunneled Dialysis Catheters for Hemodialysis Lowers Infection Rate** Jackson Wang,[1] Tuan A. Nguyen,[1] Andrew I. Chin,[1,2] Jamie L. Ross.[1] *[1]Div of Nephrology, Univ of California Davis, Sacramento, CA; [2]Div of Nephrology, VA Healthcare Northern California, Mather Field, CA.*

**Background:** Malfunctioned catheter is defined as blood flow rate of <300 ml/min achieved in dialysis and not responding to tissue plasminogen activator. There are 2 methods of fixing a malfunctioned tunneled dialysis catheter (TDC): exchange vs revision. Exchange procedures involve TDC removal and exchange over a wire, using the same exit site and venotomy site, where diagnostic imaging or intervention are generally not performed. Revision procedures involve placement of a new TDC using the previous venotomy site and creating a new tunnel and exit site. The majority of revisions usually include diagnostic imaging and intervention in the central circulation if needed.

**Methods:** The choice of procedure was physician preference. A retrospective single review of 70 patients who underwent 97 TDC replacements from 2010 to early 2012 because of catheter malfunction. Endpoints of the study were either infection or malfunction within 30 days of the procedure.

**Results:** There were a total of 41 exchanges and 56 revisions out of the 97 procedures performed. There were 8 infections (documented by positive blood culture) in the exchanges (19.5%) and 1 in the revision group (1.8%). The need for an additional procedure due to malfunction was 10 in the exchange (24.4%) and 10 (17.8%) in the revision group.

| | TDC Exchanges (n = 31) | TDC Revisions (n = 56) | p-value |
|---|---|---|---|
| Infections (positive blood culture) within 30 days | 8 (19.5%) | 1 (1.8%) | 0.003 |
| Additional Procedures within 30 days | 10 (24.4%) | 10 (17.8%) | 0.432 |

**Conclusions:** Compared to an exchange, revision of a malfunctioned TDC resulted in lower infection rate and trended towards a lower malfunction rate within 30 days after the initial procedure. While the revision procedure may require more time and effort, the lower rate of subsequent infections may justify this approach to malfunctioning TDCs in hemodialysis patients.

*Funding:* Clinical Revenue Support

## FR-PO146

**Recirculation in Reverse Flow with a Split-Tip versus Symmetrical Tip Hemodialysis Catheter** Hariprasad S. Trivedi,[1] Tushar J. Vachharajani,[2] Nand K. Wadhwa,[3] Mark Vannorsdall,[4] Jean Lee,[5] Klemens B. Meyer.[6] *[1]Medical College of Wisconsin; [2]W. G.(Bill) Hefner VAMC; [3]Stony Brook Univ Med Ctr; [4]Maine Health; [5]Temple U; [6]Tufts Med Ctr.*

**Background:** When blood flow is low during hemodialysis (HD) line reversal is often undertaken, which can lead to high recirculation (RC). Catheter (C) tip design is considered a key factor that affects RC. We compared RC with a split-tip versus symmetrical tip C.

**Methods:** A prospective trial of split-tip and symmetrical tip tunneled C performance included a pre-planned ultrasound blood flow sub-study. Consenting adult chronic HD subjects were randomized to either: 1. A symmetrical tip catheter, Covidien's Palindrome™ catheter with side slots; 2. A split-tip catheter, Bard® Hemosplit® catheter. In 206 subjects ultrasound dilution velocity measurement was used to capture blood flow rates (BFR) and RC during week 1, 5 and 11 after C insertion. BFR and RC, and arterial (AP) and venous pressures (VP) were recorded in both forward flow (FF) and after line reversal at flow rates of 350, 400, and 450 mL/min, between 30 and 90 minutes following initiation of HD. The primary objective of the sub-study was RC in reverse flow (RF).

**Results:** Median RC in RF was 3.8% in the split-tip C and 3.2% in the symmetrical tip C (P=0.096). The following additional variables were analyzed. 1) RC in FF flow was higher in the symmetrical tip C (median 3.7 versus 0, P<0.0001); 2) The symmetrical tip C had a higher mean BFR during week 5 at all three pump settings (all $P \leq 0.038$) but no different at other measurements; 3) The difference between the prescribed and actual BFR was -20.4±25.9 vs. -9.8±21.1, split-tip vs. symmetrical tip C (P=0.018) during week 5 at setting of 350 mL/min and no different at all other measurements; 4) All measurements showed higher AP in the split-tip C (all $P \leq 0.03$) except during the week 11 setting of 450 mL/min (P = 0.9); 5) VP was higher in the split-tip C at pump settings of 350 and 400 mL/min during all weeks and at pump setting of 450 mL/min during week 1 (all $P \leq 0.032$).

**Conclusions:** There was no statistically significant difference in recirculation after line reversal between a split-tip and symmetrical tip HD catheter.

## FR-PO147

**Comparison of a Split-Tip versus Symmetrical Tip Hemodialysis Catheter**
Hariprasad S. Trivedi,[1] Tushar J. Vachharajani,[2] Nand K. Wadhwa,[3] Mark Vannorsdall,[5] Jean Lee,[4] Klemens B. Meyer.[6] *[1]Medical College of Wisconsin; [2]W. G.(Bill) Hefner VAMC; [3]Stony Brook Univ Medical Ctr; [4]Temple U; [5]Maine Health; [6]Tufts Med Ctr.*

**Background:** In a multi-center, randomized, open-labeled trial we compared the performance and longevity of a split-tip versus symmetrical tip hemodialysis (HD) catheter (C).

**Methods:** Adult subjects requiring chronic HD scheduled to receive a tunneled C for vascular access were considered for the trial. Key study criteria included a patent internal jugular vein and absence of active infection. Eligible and consented subjects were randomized in a 1:1 ratio to either: 1. A symmetrical tip catheter, Covidien's Palindrome™ catheter with side slots; 2. A split-tip catheter, Bard® Hemosplit® catheter. Subjects were followed until study completion which was defined as 35 weeks after catheter placement, study catheter removal, or death. The primary end-point was "time to catheter-induced complication or TCIC" defined as time to first incidence of intervention for malfunction due to thrombosis, poor flow requiring administration of tissue plasminogen activator (tPA), mechanical problems requiring surgical/radiological intervention, catheter displacement, or failure due to catheter related blood stream infection.

**Results:** 15 US centers enrolled 601 subjects of whom 568 had at least one post-baseline visit measurement for the primary end-point. Mean age was 59.4 ±14.8 years, 51.6% were female, 52.8% were African American, 8.3% were of Hispanic/Latino ethnicity. The most common cause of end-stage renal disease was type 2 diabetes mellitus (38.6%). 89 subjects completed the full 35 week follow-up. The most common cause of early termination was C removal. 42% (n= 252) subjects met the primary endpoint. The median TCIC for the symmetrical C group was 148 days and for the split-tip C group was 213 days. The 2 groups did not differ statistically in the composite primary end-point (log-rank test P=0.2).

**Conclusions:** There was no difference between a split-tip versus symmetrical tip hemodialysis catheter in time to catheter-induced complication comprised of a composite of important mechanical, thrombotic and infective complications.

*Funding:* Pharmaceutical Company Support - Covidien

## FR-PO148

**Exchange from Non-Tunneled to Tunneled Hemodialysis Catheter with over the Guidewire Can Be Performed without Increasing Complication Risk**
Hoon Suk Park, Kyungyoon Chang, Hyung Wook Kim, Bum-Soon Choi, Cheol Whee Park, Chul Woo Yang, Dong Chan Jin. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** Exchange from non-tunneled hemodialysis (HD) catheter to tunneled HD catheter over the guidewire using previous venotomy has advantage that it does not require new venipuncture so that it can prevent additional injury to vessel wall. Several previous studies demonstrated its safeties, but concerns that it can be associated with infection and bleeding prevent it from being chosen rather than de novo placement. Therefore, we investigated its safeties in our center.

**Methods:** Twenty five patients who started initially HD with non-tunneled catheter and then received catheter exchange procedure into tunneled catheter and 110 patients who initially received de novo placement of tunneled HD catheter within the same period were respectively assigned to exchange and de novo placement groups. Catheter survival, immediate and long term complication rates were compared.

**Results:** Catheter exchange into tunneled catheter was performed at 10±3 days after initial insertion of non-tunneled catheter. Immediate complication rates including exit site bleeding, bruise and hematoma were comparable (26.3 % in exchange group vs. 23.7 % in de novo placement group, p = 0.8). Long term complication rates including catheter dysfunction and catheter related infection (5.3 % in exchange group vs. 8.8 % in de novo placement group, p = 0.61) and catheter survivals (p = 0.7) were also comparable between 2 groups.

**Conclusions:** Exchanging procedure over the guidewire from non-tunneled to tunneled catheter was comparable with de novo placement of tunneled catheter in complication rates and catheter survival, in spite of merit in avoiding unnecessary additional vessel wall injury. Therefore it should be firstly considered in the cases where replacement non-tunneled catheter with tunneled one is required.

## FR-PO149

**Multi-Disciplinary Approach to Peripherally Inserted Central Catheter Avoidance in Hospitalized CKD Patients: A Single Center Experience**
Mireille El Ters,[1] Gauri Bhutani,[1] Amy Mahon,[2] Amy W. Williams,[1] Marie C. Hogan.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Nursing, Mayo Clinic, Rochester, MN.*

**Background:** The use of PICCs in chronic kidney disease is highly discouraged by several renal societies. Recent data show strong association of prior PICC with lack of functional arterio-venous fistula(AVF);however efforts at PICCs avoidance are so far ineffective.

**Methods:** 1.Creating an electronic alert of patients with ↓eGFR (<30 ml/min, CKD-EPI) at time of PICC order, stating the reason for its avoidance and providing alternate access (small bore internal jugular) with link to educational material.2.Education to nephrologists,dialysis nurses,hospitalists and intensivists in form of a lecture detailing the impact of PICCs on AVF success. We compared proportion of patients with ↓eGFR among 550 consecutive patients receiving PICC before (March 2010) and after the intervention (April 2013) using Fisher's exact test. We queried the electronic alert system to determine its effectiveness in reducing PICC prevalence in the target population.

**Results:** The proportion of patients with ↓eGFR receiving PICC before and after intervention was not statistically significantly different,except for a trend to a lower proportion of end stage renal disease patients after intervention. Of the 567 PICC requests during April 2013, 83 (14.6%) caused the alert to appear, leading 11 requests (13.3%) to be discontinued. The commonest reported indication for PICC despite the alert was need for central access,with ICU providers being commonest (23/30,76%).

| Intervention (Dec 2012) | Before (n=275) | After (n=275) | p value |
|---|---|---|---|
| All patients with eGFR < 30 ml/min | 35 (12.7%) | 30 (10.9%) | 0.51 |
| CKD | 17 (6.2%) | 16 (5.8%) | 0.99 |
| AKI | 18 (6.5%) | 14 (5.1%) | 0.58 |
| ESRD | 11 (4%) | 3 (1.1%) | 0.054 |

**Conclusions:** Despite educational measures on the impact of PICCs on future AVF there remains a continued reliance on PICC lines in our center in the CKD population especially in the critical care setting. Future efforts will concentrate on continued education of patients, critical care physicians and hospitalists and promotion of alternative small bore internal jugular lines.

## FR-PO150

**Decreasing the Incidence of Dialysis Catheter Infections Using Evidence Based Strategies**
Catherine C. Wells, Steven Wagner, Iasmina Craici, Mary Alice Luckett, Luis A. Juncos. *Dept of Medicine, Div of Nephrology, Univ of Mississippi, Jackson, MS.*

**Background:** Hemodialysis (HD) Catheter associated infections have recently become a focus for attention in outpatient HD quality control due to their role in morbidity and mortality. However, there are still no specific guidelines for inpatient HD catheter infection prevention. Additionally, since 2008 CMS payments are reduced for every incidence of preventable vascular catheter associated infection. Therefore, we implemented a Quality Improvement Project (QIP) to develop a protocol intended to reduce the burden of HD catheter associated infections.

**Methods:** The first intervention, performed in October 2009, was comprehensive education of all inpatient HD nurses based on the NKF KDOQI guidelines as well as limiting handling of HD catheters to HD nurses when possible. Nurses were taught using a slide presentation with pre- and post-testing, delivered via Healthstream online education system to ensure compliance. After education, audits of practice were conducted to ensure compliance. In Quarter 1 of 2010, a similar Healthstream slide presentation with post-testing was delivered to all hospital nurses. Education was repeated as indicated throughout the project. Chi Squared Trending test was used to evaluate significance; $p < 0.05$ was considered a significant reduction in hospital acquired infections.

**Results:** Quarterly evaluation of hospital acquired HD catheter infections from June 2009 to September 2012 fell from 25% to 3% ($p < 0.0001$). Annual incidence of HD catheter infections present on admission fell from 17% to 6%. At least 7 targeted infection prevention interventions were conducted during this time period, using the principles of the NKF KDOQI guidelines and restricting catheter use to HD nurses when possible.

**Conclusions:** Hospital-wide nurse education based on existing guidelines intended for outpatient HD catheter infection prevention, in addition to minimizing use of HD catheters by non-dialysis staff can successfully reduce the incidence of hospital acquired HD catheter infections. This was a QIP and required ongoing interventions to maintain the decline in hospital acquired infections.

## FR-PO151

**Multidetector CT Angiography in the Evaluation of Catheter-Related Central Venous Stenoses in Hemodialysis Patients**
Yuliang Zhao, Tianlei Cui, Ling Zhang, Ping Fu. *Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan Province, China.*

**Background:** Multidetector CT angiography (MDCTA) is widely available in evaluating vascular tree, but its correlation with digital substraction angiography (DSA) in demonstrating catheter-related central venous stenoses among hemodialysis patients remains to be clarified. This study aims to compare MDCTA with DSA in the evaluation of catheter-related central venous stenoses in hemodialysis.

**Methods:** During 24 months, a total of 25 chronic hemodialysis patients with suspected catheter-related central venous stenoses were examined by MDCTA and 3-D image reconstruction, while subsequent DSA served as gold standard. The presence, site and number of stenoses or occlusions were accessed. According to the reduction in vessel lumen, the stenoses were classified as insignificant (<50%), significant (>50%) and occlusion. We calculated the sensitivity, specificity, accuracy, odds ratio (OR), positive predictive value (PPV), negative predictive value (NPV), positive likelihood ratio (PLR) and negative likelihood ratio (NLR) for MDCTA as an alternative to DSA.

**Results:** 115 vascular segments in 25 patients were analyzed. MDCTA detected 22 significantly stenotic or occluded central veins. DSA verified 19 of them and demonstrated 25 additional ones.

| | | DSA | | |
|---|---|---|---|---|
| | | Significant stenoses/Occlusions | Insignificant stenoses | Total |
| MDCTA | Significant stenoses/Occlusions | 19 | 3 | 22 |
| | Insignificant stenoses | 25 | 68 | 93 |
| | Total | 44 | 71 | 115 |

MDCTA has a high specificity (95.8%) in diagnosing central venous stenoses as compared with DSA, but its sensitivity is low (43.2%). The PPV, NPV, PLR, NLR were 86.4%, 73.1%, 10.2, 0.59 respectively. The diagnostic OR is 17.2, with 75.7% accuracy.

**Conclusions:** MDCTA has a high specificity in detecting catheter-related central venous stenoses. Positive findings by MDCTA are helpful to clinical diagnosis. However, MDCTA might not be reliable in ruling out stenoses for its low sensitivity.

## FR-PO152

**Ethanol versus Heparin Catheter Locks for Cuffed Central Venous Catheters in Hemodialysis Patients: A Single-Center Randomized Controlled Trial** Xiaomeng Sun, Hong Liu, Bi-cheng Liu. *Institute of Nephrology, Southeast Univ, Nanjing, China.*

**Background:** Tunnelled central venous catheter use is significantly limited by the frequent occurrence of catheter-related bacteraemias (CRBs), which results in significant attributable morbidity and mortality. In this trial, we studied the efficacy and safety of 70% ethanol lock for the prevention of CRBs in hemodialysis patients with a tunnelled central venous catheter.

**Methods:** A randomized, prospective, controlled study was undertaken. Hemodialysis patients with tunnelled catheter were randomised assigned to receive 70% ethanol lock once a week and standard heparin locks for other dialysis days *vs* thrice per week heparin locks. CRBs and catheter dysfunction were recorded.

**Results:** From January 1, 2013 to June 1, 2013, 22 patients (aged 50 - 85 years) were enrolled. A total of 1484 catheter days were observed in the ethanol lock arm and 1568 catheter days in the heparin lock arm from trial entry. There was no significant difference in patient's age, gender, age of dialysis, the primary disease between the two groups. For ethanol locks, the incidence of CRBs per 1000 catheter days was 0.67 (1/1484), compared to 1.28 (2/1568) for heparin locks. Catheter dysfunction occurred at a rate of 0.67 (1/1484) vs 0.64 (1/1568) per 1000 catheter days in the heparin and ethanol groups respectively. No adverse symptoms attributable to ethanol occurred.

**Conclusions:** Our preliminary results suggested there was a trend towards a reduced rate of CRBs in a 70% ethanol lock without resulting in catheter dysfunction. However, these results should be confirmed with a larger trial.

## FR-PO153

**The Stuck Catheter—A Hazardous Twist to the Meaning of Permanent Catheters** Venkat Sainaresh Vellanki, Cynthia B. Bhola, Charmaine E. Lok. *Toronto General Hospital and the Univ of Toronto, Toronto, Canada.*

**Background:** Permanent central venous catheters (CVC) use is associated with significant complications that often require their rapid removal. Tunneled CVC's can usually be easily removed after dissecting out the retention cuff. However, a less often described complication is resistant removal of the CVC due to adherence of the CVC to the vessel wall which mandates use of invasive interventions for removal. The aim of this study is to describe the occurrence of the "stuck catheter" phenomenon and its consequences.

**Methods:** We performed a retrospective review from July 2005 to June 2013 at a single academic based HD center of all removed tunneled CVC's to determine the incidence of stuck catheters, the type of intervention needed to remove them and subsequent follow up. Data was retrieved from a prospective vascular access database and verified manually against patient charts.

**Results:** During the study period there were 1908 CVC removed in 923 patients. There were 16 cases (1.73%) of stuck CVC's (0.031/1000 days) needing interventional radiology (IR) or surgical intervention for removal. Clinical characteristics: 7 men (47%), 4 diabetic (27%), etiology of ESKD - 3 SLE, 1 ANCA vasculitis, 3 had secondary hyperparathyroidism needing parathyroidectomy. Catheter characteristics: 75% were in the right internal jugular vein, the mean CVC duration was 51.1 months (range 11-144). Three CVC could not be removed from the vessel, thus were embedded into the facial planes / mediastinum. The rest of the CVCs required dissection and traction by IR except 1 required surgical sternotomy. The two embedded catheters had 34 and 53 months of uneventful follow up. The other became infected with a fungal organism and the patient consequently died from infectious complications.

**Conclusions:** Our series demonstrated that 1.7% of hemodialysis patients with permanent catheter insertion were complicated by a vessel embedded catheter that required removal by IR or surgery. Prolonged catheter vintage could be a predisposing factor. Permanent catheter use should be avoided if possible to avoid complications, including this rare but important complication.

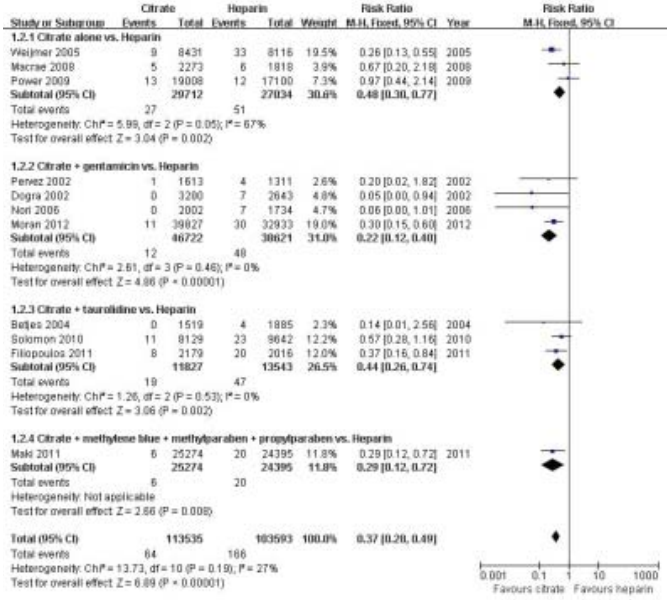
## FR-PO154

**Citrate versus Heparin Lock for Hemodialysis Catheter: A Systemic Review and Meta-Analysis of Randomized, Controlled Trials** Yuliang Zhao,[1] Ling Zhang,[2] Ping Fu.[3] *[1]Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan Province, China; [2]Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan Province, China; [3]Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan Province, China.*

**Background:** Citrate solution has been suggested as an effective and safe catheter lock in hemodialysis. However results from studies comparing citrate with heparin locks remain inconclusive.

**Methods:** We collected from PubMed, Ovid, the Cochrane Library, Web of Science databases and major nephrology journals. A systemic review and meta-analysis was performed of all eligible randomized controlled trials.

**Results:** 13 randomized controlled trials (1770 patients, 221064 catheter-days) met the inclusion criteria. Pooled analyses found that Citrate locks could significantly reduce the incidence of catheter related bloodstream infection (RR=0.37, 95%CI=0.28-0.49, *P*<0.001). Subgroup analysis showed citrate alone, citrate + gentamicin, citrate + taurolidine were all superior to heparin lock in the prevention of catheter related bloodstream infection (*P*=0.002, <0.001, =0.002 respectively).



Incidence of exit site infection(RR=0.67, 95%CI=0.47-0.95, *P*=0.03) and bleeding episodes (RR=0.47, 95%CI=0.30-0.74, *P*=0.001) were significantly lower in patients receiving citrate lock, while both groups were similar in terms of catheter removal for poor flow (*P*=0.91), thrombolytic treatment (*P*=0.77), all-cause death (*P*=0.21), catheter thrombosis (*P*=0.93), mean catheter duration (*P*=0.20), catheter related bloodstream infection-free catheter survival (*P*=0.22) and catheter-related readmission (*P*=0.51).

**Conclusions:** Citrate lock is better than heparin lock in the prevention of catheter-related infections and bleeding episodes, while both lock solutions show similar efficacy in preserving catheter patency. Our meta-analysis suggests wider applications of citrate lock in hemodialysis.

## FR-PO155

**Geographic Disparities in AV Fistula Placement in Patients Approaching Hemodialysis** Wajih A. Syed,[3] Bhanu K. Patibandla,[2] Akshita Narra,[1] Varun Chawla,[1] Yael Vin,[1] Tammy Hod,[1] Alexander S. Goldfarb-Rumyantzev.[1] *[1]BIDMC; [2]St. Vincent Hospital; [3]Metrowest Medical Center.*

**Background:** Arterio-venous fistula (AVF) is the preferred access for hemodialysis. However in the US, the number of patients starting HD with AVF is still relatively low. Several factors associated with AVF placement have been identified (e.g., age, sex, race, co-morbidities). In this project we hypothesized that geographic location of patient residence might be associated with the probability of AVF placement as the first access for initiation of hemodialysis.

**Methods:** We used the data from the USRDS database (2005-2008) linked to Medicare claims (2003-2008). Logistic regression was used to estimate specific characteristics of population associated with the AVF as first access placed or attempted for hemodialysis initiation. Our primary variable of interest was the geographic location and the multivariate model was adjusted for age, sex, race, BMI, primary cause of ESRD, duration of pre-ESRD nephrology care, comorbidities, employment status, substance abuse, and income. Geographic location of the patient residence was determined using the data collected by the RUCA project and divided population into metropolitan, micropolitan, and rural categories.

**Results:** Patients (n=111,953) identified from the USRDS data base with linked Medicare claims were examined. Rates of fistula placement in the metropolitan, micropolitan and rural population were 18.5%, 22.4% and 21.6% respectively. In comparison, patients who received catheter as the first access were 81.5%, 77.6% and 78.4% respectively. The odds ratio of AVF placement as a first hemodialysis access in the rural and metropolitan population compared to the micropolitan population were 0.96 (0.90-1.03) and 0.75 (0.71-0.79) respectively.

| Odds of having AVF as first access placed or attempted pre-dialysis compared to a catheter | | |
|---|---|---|
| | **OR (95% CI)** | **P value** |
| **Geography** | | |
| Rural | reference | |
| Urban | 0.76 (0.73-0.80) | 0.03 |
| Unknown | 0.49 (0.42-0.57) | <0.001 |

**Conclusions:** Our results indicate geographic disparities in AVF placement with decreased rates of AVF as the first access created in the metropolitan and rural populations compared to the micropolitan populations.

## FR-PO156

### Factors Predicting Failure of AV "Fistula First" Policy in the Elderly

Tammy Hod,[1] Bhanu K. Patibandla,[2] Yael Vin,[1] Robert S. Brown,[1] Alexander S. Goldfarb-Rumyantzev.[1] *[1]BIDMC; [2]St. Vincent Hospital.*

**Background:** An arteriovenous fistula (AVF) is the preferred access for HD. The goal of this study was to identify factors associated with AVF failure in the pre-dialysis period in an elderly HD population.

**Methods:** We used USRDS + Medicare claims data to identify incident HD patients ≥67 year old from 01/01/05 to 12/31/08 with first pre-dialysis access placed being an AVF (n=20,360; 76.2±6.02 year old, 58.5% males). AVF failure, defined as failure of using the AVF for the first outpatient dialysis, was used as the outcome. Logistic regression model was used to identify factors associated with AVF failure.

**Results:** Of patients who had an AVF placed pre-dialysis, 48% initiated dialysis using the AVF and 52% using a catheter or an AVG. The following variables were found to be associated with AVF failure when an AVF was created at least 4 months pre-HD initiation: age ≥67 yr, female gender, black race, prior history of diabetes mellitus, cardiac failure and shorter duration of pre-ESRD nephrology care. Odds ratio for AVF failure for the entire cohort showed similar findings.

| | Entire study population (n=20,360) | | 'Early' AVF placement group (n=11,258) | |
|---|---|---|---|---|
| | Odds Ratio (95% CI) | P Value | Odds Ratio (95% CI) | P Value |
| Age at ESRD onset | 1.01 (1.00-1.01) | 0.006 | 1.01 (1.00-1.02) | 0.003 |
| Female (vs male) | 1.55 (1.46-1.65) | <0.001 | 1.69 (1.55-1.83) | <0.001 |
| Black (vs white) | 1.33 (1.22-1.45) | <0.001 | 1.41 (1.26-1.58) | <0.001 |
| Diabetes | 1.20 (1.09-1.33) | 0.0003 | 1.22 (1.06-1.39) | 0.005 |
| Congestive Heart Failure | 1.30 (1.22-1.39) | <0.001 | 1.26 (1.15-1.37) | <0.001 |
| Pre-ESRD care | | | | |
| >12 months | Reference | | Reference | |
| 6-12 months | 1.24 (1.15-1.33) | <0.001 | 1.31 (1.18-1.43) | <0.001 |
| <6 months | 1.27 (1.16-1.39) | <0.001 | 1.22 (1.07-1.38) | <0.001 |
| Zero | 4.17 (3.58-4.86) | <0.001 | 4.09 (3.35-5.00) | <0.001 |

**Conclusions:** In an elderly HD population, there is an association of older age, female gender, black race, diabetes, cardiac failure and shorter duration of pre-ESRD care with predialysis AVF failure. These results might help to identify populations at risk in order to assure adequate AVF maturation or AVG creation as primary access.

## FR-PO157

### Optimal Time for AVF Placement in the Elderly. "The Earlier the Better"–A Myth or a Truth?

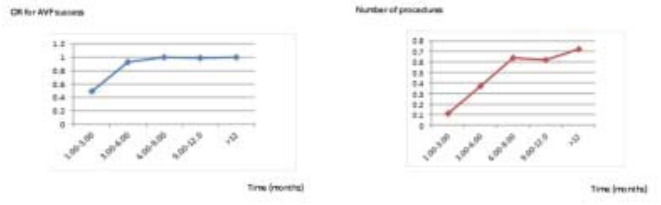
Tammy Hod,[1] Bhanu K. Patibandla,[2] Yael Vin,[1] Robert S. Brown,[1] Alexander S. Goldfarb-Rumyantzev.[1] *[1]BIDMC; [2]St. Vincent Hospital.*

**Background:** AVF is the preferred access for hemodialysis (HD). However, many AVFs fail to mature or develop stenosis/thrombosis prior to starting dialysis, especially in the elderly. That results an undesirable increased incidence of catheter use.

**Methods:** We used USRDS + Medicare claims data to identify incident HD patients ≥67 year old from 01/01/05 to 12/31/08 with first pre-dialysis access placed being an AVF (n=17,511; 76.1±6.0 year old, 58.3% males). AVF success is defined as using the AVF for the first outpatient dialysis. Our second outcome was the number of pre-dialysis vascular access procedures. Time between AVF placement and dialysis start was our primary variable of interest. Using a logistic regression model we further analyzed subgroups divided by gender, race, presence/absence of diabetes and CHF.

**Results:** Of patients who had an AVF placed pre-dialysis, 54.9% initiated dialysis using the AVF and 45.1% using a catheter or an AVG. The OR for success increased with longer time from AVF creation to HD initiation between 1-3, 3-6 and 6-9 months (OR of 0.49, 0.93 and 1) but stabilized after that so creation of AVF more than 6-9 months from the first HD session was not associated with a higher AVF success rate. The number of procedures increased with longer times between AVF placement and dialysis start. This trend was also present in the subgroups studied.

| Time (months) | OR for success (95% CI) | P Value | Procedures Mean (SD) | P Value |
|---|---|---|---|---|
| 1-3 | 0.49 (0.44-0.53) | <0.001 | 0.11 (0.64) | <0.001 |
| 3-6 | 0.93 (0.85-1.02) | 0.005 | 0.37 (1.38) | |
| 6-9 | 1 (0.90-1.11) | <0.01 | 0.64 (2.08) | |
| 9-12 | 0.99 (0.88-1.11) | 0.006 | 0.62 (1.82) | |
| >12 | 1 | | 0.72 (2.11) | |



**Conclusions:** We suggest that placing an AVF more than 6-9 months in advance of HD initiation in the elderly might be counterproductive as it is not associated with better AVF maturation, but might lead to greater number of access procedures.

## FR-PO158

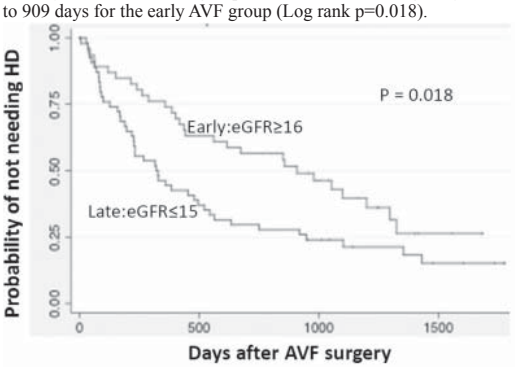
### Early versus Late Arteriovenous Fistula Creation in Pre-Dialysis Patients

Mardiana Lee, Matthew A. Roberts, Maree S. Ross-smith, Jason Chuen, Peter F. Mount. *Austin Health, Australia.*

**Background:** Optimal timing of arteriovenous fistula (AVF) surgery in pre-dialysis CKD patients is uncertain. Current guidelines recommend creation of an AVF in preparation for hemodialysis (HD) when the estimated glomerular filtration rate (eGFR) is 15-30 ml/min/1.73m$^2$.

**Methods:** We reviewed records of all CKD patients who had a first AVF creation for future HD at Austin Health from 01/01/2007-31/12/2009 and obtained follow-up data until 31/12/2011. Survival analysis was performed for the primary outcome of time from AVF creation to first need for HD.

**Results:** 100 patients had a first AVF created with a median eGFR at the time of AVF surgery of 15 ml/min/1.73m$^2$. Patients were classified as having had an early AVF if eGFR was ≥16 (n=46) or a late AVF if eGFR was ≤15 (n=54). The mean age was 63.7+13.7 years, 49 had diabetes and 39 were female. Over 2-5 years follow up 81% (44/54) of late AVF and 63% (29/46) of early AVF patients required HD (P=0.04). Median time to starting HD was 479 days. In the late AVF group median time to starting dialysis was 321 days compared to 909 days for the early AVF group (Log rank p=0.018).



At 3, 6 and 12 months respectively, 20%, 44% and 56% of patients with eGFR≤15 had needed HD compared to 11%, 20% and 26% with eGFR≥16. A dialysis catheter was required at HD commencement in 11% (5/44) of patients from the late AVF group and 24% (7/29) of patients from the early AVF group (P=0.20). Additional vascular access procedures prior to the need for HD were required for 35% of late AVF and 39% of early AVF patients.

**Conclusions:** A higher risk of AVF non-use was observed in patients having AVF surgery with an eGFR ≥16, whilst the rate of catheter use at HD start remained low in patients having AVF surgery with an eGFR ≤15. These data suggest that strict adherence to current guidelines might lead to AVF creation earlier than is clinically optimal for many patients.

## FR-PO159

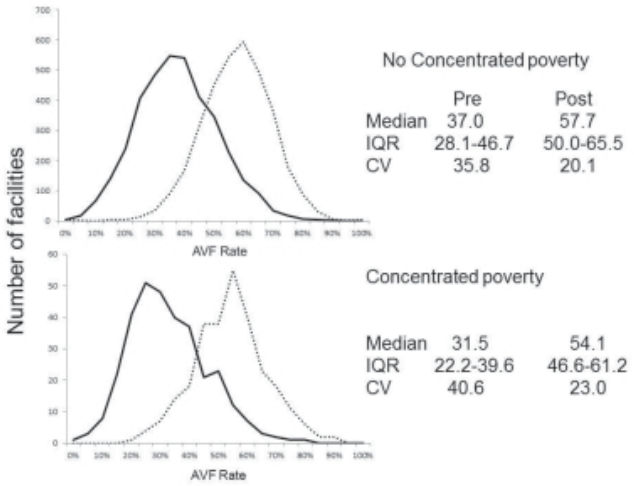
### Comparable Rates of Improved Arteriovenous Fistula Use Were Observed in Poor Communities during the Fistual First Breakthrough Initiative

William M. McClellan, Sumit Mohan, Janet R. Lynch, Edwin D. Huff. *For Fistual First Data Committee.*

**Background:** The Fistula First Breakthrough Initiative (FFBI) is a population-based intervention by the Centers for Medicare & Medicaid Services (CMS) to increase arteriovenous fistula (AVF) use. Variations in AVF have been noted among individual hemodialysis centers. This study examines the relationship between county-level poverty and baseline use and rates of improvement in facility AVF use.

**Methods:** This was a retrospective analysis of AVF use in 3,485 dialysis centers treating dialysis patients. Monthly data collected by the ESRD Networks was used to estimate rates of AVF use among prevalent adult hemodialysis patients. We calculated facility-specific slopes of prevalent AVF use over the study period. Counties with centers were categorized by the presence or absence of concentrated poverty and AVF slopes were compared between the two poverty groups after controlling for baseline case-mix factors.

**Results:** The Figure shows the proportion of a hemodialysis center's patients with a prevalent AVF was lower in counties that were part of a cluster of concentrated poverty than in other counties [difference (95% CI) = -8.4% (-10.3,-6.0 )].The slope of increased AVF use among centers was independent of county poverty and higher in those centers with lower baseline AVF use.The inverse association between the slope and lower baseline AVF use, which occurred more frequently in counties with concentrated poverty, resulted in substantial attenuation of poverty-associated disparities in AVF use at the end of the study illustrated by the narrowing of the differences between the two county categories interquartile ranges and coefficients of variation of the mean slopes (Figure).



**Conclusions:** Improvement rates of AVF use among hemodialysis centers were not significantly associated with poverty within the county where it is located.

## FR-PO160

**Choice of Permanent Vascular Access for Dialysis in Elderly Patients (> 75 yo): A Multicenter Observational Study** Maurizio Gallieni,[1] Marcello Napoli,[2] Andrea Bandera,[2] Decenzio Bonucchi,[2] Antonio Granata,[2] Monica Spina.[2] *[1]Ospedale San Carlo Borromeo, Milano; [2]Scientific Committee, Vascular Access Study Group, Italian Society of Nephrology, Roma, Italy.*

**Background:** Currently, patients over 75 yo represent about 30% of the dialysis population in Italy. Median age at start of dialysis in Italian patients rose from 62.8 years in 1999 to 67.2 years in 2009. A concomitant increase in the prevalence of central venous catheters (CVC) was observed. This observational study aimed at better defining the status of vascular access and the clinical policies of Italian nephrologists in elderly dialysis patients.

**Methods:** In 31 dialysis units which spontaneously adhered to this observational study, data were collected regarding all permanent vascular access interventions (AV fistula, CVC, grafts) performed between Jan 2009 and Dec 2011 in a large cohort of elderly dialysis patients (over 75 years old). Both incident and prevalent hemodialysis patients were included.

**Results:** In 1346 patients (811 males, 60.3%), 1584 access interventions were recorded. Mean (±SD) age was 81.0±4.6 years. Comorbidities included diabetes mellitus (25%), heart disease (34%), cancer (13%), central or peripheral vascular disease (35%). In the total population, the chosen procedure was an AV fistula for 51,3% of patient, for 45,2% the insertion of a tunnelled CVC and for 3,5% a graft. Gender was a relevant factor in determining outcome: females had higher chances of having a CVC as dialysis access (54.4 vs. 39%, $p < 0.005$) and conversely lower chance of having an AV fistula (42.1 vs. 57.5%, $p < 0.002$), while grafts were similar (3.6 vs. 3.5%, p: ns). Presence of one or more comorbidities did not affect the patient distribution for dialysis access type. Among the 836 AV fistula interventions, 163 cases (19.5%) of early failure were recorded. None of the specific comorbidities affected AV fistula early failure, but the concomitant presence of 3 comorbid factors was associated with higher chances of early failure ($p < 0.01$).

**Conclusions:** In almost half of patients older than 75 years a tunnelled CVC is the dialysis access of choice. Elderly females, but not diabetics, are more likely to receive a tunnelled CVC.

## FR-PO161

**A Non-Invasive Approach to Evaluation of Biofilm Burden in Hemodialysis Patients** Amy B. Pai,[1] Adinoyi O. Garba,[1] Jonathan Waldman,[2] Shaker Mousa.[3] *[1]Pharmacy Practice, Albany College of Pharmacy and Health Sciences, Albany, NY; [2]Medicine, Nathan Littauer Hospital, Gloversville, NY; [3]Pharmaceutical Research Institute, Rensselaer, NY.*

**Background:** Central venous catheters (CVCs) are rapidly colonized with Gram-positive bacteria that form intraluminal biofilm. Currently, there are no clinical assessments to detect biofilm in catheters. Lipoteichoic acid (LTA) is Gram-positive bacterial cell wall component that activates the toll-like receptor-2 resulting in transcription of pro-inflammatory cytokines. This pilot study evaluates relative concentrations of LTA in catheter aspirate, plasma and urine of hemodialysis patients.

**Methods:** Eligible patients had tunneled CVCs being used for dialysis access. Catheter aspirate from both ports was collected prior to dialysis initiation. Venous blood (plasma) from the dialysis circuit was collected 30 min after dialysis initiation. Urine was collected from non-anuric patients. Demographic, laboratory, infection and catheter data were collected. LTA concentration in aspirate, plasma and urine was measured by ELISA. For comparison, endotoxin concentration (ET, i.e. Gram-negative cell wall component) was measured by limulus amebocyte lysate (LAL) assay.

**Results:** Twenty-six patients were enrolled in the study. Baseline demographics included; median dialysis vintage 1.2 years (range 0.3 to 10) and mean (SD) duration of catheter use was 85(54.7) days. The median (range) concentration of LTA (ng/mL) and ET (EU/mL) in catheter aspirate was 2.7 (1.5-8.1) and 0.9 (0.23 to 35), respectively. In 10 (38%) of patients, plasma concentration of LTA after 30 minutes of dialysis was on average 7 fold higher ($p<0.001$) than the aspirate concentration. Plasma ET concentrations [median (range)] 0.7 (0.3 to 5.7) were on average lower than catheter aspirate ET. LTA and ET were also detected in all urine samples.

**Conclusions:** These data show that CVCs are likely colonized with Gram-positive and Gram-negative organisms. Systemic concentrations of LTA markedly increased in nearly half of the patients, suggestive of catheter biofilm instability after dialysis initiation. Biofilm as a source of inflammation should be further investigated.

*Funding:* Private Foundation Support

## FR-PO162

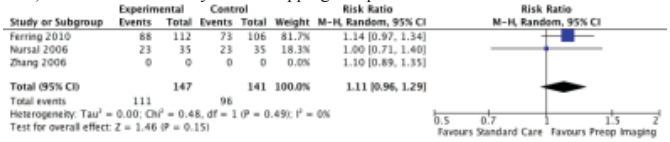
**Preoperative Hemodialysis Vascular Access Evaluation: A Cochrane Systematic Review** Sarah Daisy Kosa,[1] Ahmed A. Al-jaishi,[2] Louise M. Moist,[2] Charmaine E. Lok.[1] *[1]Toronto General Hospital and the Univ of Toronto, Toronto; [2]London Health Sciences Centre, London, Canada.*

**Background:** The high risk of arteriovenous fistula (AVF) failure to mature (FTM) and non-suitability for hemodialysis (HD) (20-60%) limits their greater use. Preoperative vascular access assessment by radiologic imaging (vessel mapping) may help identify vessels most suitable for AVF creation and may improve AVF maturation and use.

**Aim:** To compare the outcomes of preoperative vessel mapping vs. none (standard care) among adult HD patients requiring AVF creation.

**Methods:** We systematically searched for RCTs in the Cochrane Renal Group's specialised register, Cochrane Central Register of Controlled Trials (RCTs), MEDLINE, EMBASE and article refereencess without language restriction. Two reviewers assessed abstract and study inclusion, study quality and extracted data. Dichotomous outcomes were expressed as risk ratios (RR) and continuous outcomes as mean differences with 95% confidence intervals (CI). Outcomes were pooled using a random effects model.

**Results:** We screened 235 abstracts; 8 went to full text abstraction, and 3 were included in the meta analysis. A greater proportion of AVFs were mature at 6 months with vessel imaging (3 studies, 356 patients: RR 1.17, 95% CI 1.00 to 1.36); however, the proportion of AVF s successfully created (3 studies, 356 patients: RR 1.02, 95% CI 0.94 to 1.12) and the proportion of AVF s used for dialysis (2 studies, 288 patients: RR 1.11, 95% CI 0.96 to 1.29) were not increased by vessel mapping compared with standard care.



The proportion of patients requiring a catheter access and the rate of interventions needed to maintain patency did not differ between 2 groups.

**Conclusions:** We cannot recommend routine vessel mapping over standard care without imaging based on the current evidence. Uncertainty surrounds the benefits and there is a paucity of high quality data.

*Funding:* Clinical Revenue Support

## FR-PO163

**The Association of Pre-Dialysis Nephrology Care Intensity and Vascular Access at Hemodialysis Initiation** Vanessa Grubbs,[1] Bernard G. Jaar,[2] Jessica M. Ameling,[2] Raquel Greer,[2] Patti Ephraim,[2] Kerri L. Cavanaugh,[3] L. Ebony Boulware.[2] *[1]UCSF; [2]Johns Hopkins Univ; [3]Vanderbilt.*

**Background:** Despite the 2005 Fistula First Initiative, most patients initiating hemodialysis (HD) in the US continue to do so with catheters. While catheters are often thought the result of emergency initiation among patients with little or no pre-dialysis nephrology care, the role of the intensity of this care in achieving permanent vascular access (ateriovenous fistula or graft, AVF/AVG) has not been explored.

**Methods:** We conducted a retrospective chart review of 76 patients who received nephrology care in academically affiliated public hospital or private practice settings prior to initiating HD between 10/1/2011 and 9/30/2012. Using multivariable logistic regression adjusted for age and insurance, we examined the association of nephrology clinic visits within 6 months of initiating HD with provider action (pre-dialysis referral for AVF/AVG creation) or patient action (completion of at least one step—i.e. evaluation by a vascular surgeon, vein mapping or vascular surgery—toward AVF/AVG use at initiation).

**Results:** Patients' mean age at HD initiation was 60.7 (SD 14.3) years. 30.3% (n=23) had only Medicaid insurance and 18.4% (n=14) were uninsured. 29.0% (n=22) initiated with AVF/AVG. Of the remaining 71.0% (n=54) who initiated with catheter, 48.1% (n=26) had documented pre-dialysis referral for AVF/AVG creation. Among those referred, 69.2% (n=18) completed at least one action step toward AVF/AVG. Only 16.7% (n=9) of catheter patients missed any scheduled nephrology visit. Compared to catheter patients with 0-1 nephrology visits within 6 months of initiation (33.3%), those with 2-3 visits (37.0%) were similarly likely to have provider or patient action [odds ratio 4.0 (95% CI 0.8-20.2), p=0.09 or 3.9 (0.9-17.0), p=0.07], respectively, but those with 4+ visits (29.6%) were more likely to have provider and patient action [OR 6.9 (1.4-35.2), p=0.02 and 6.4 (95% CI 1.1-36.1), p=0.04], respectively.

**Conclusions:** More intense pre-dialysis nephrology care is associated with more provider and patient action toward permanent vascular access at hemodialysis initiation.

## FR-PO164

**Barriers to Timely Dialysis Access Creation: South Texas University Health System Experience** Christina Mehanni, Faraz M. Khan, Padam Hirachan, Jonathan A. Gelfond, Shweta Bansal. *Div of Nephrology, Univ of Texas Health Sciences Center at San Antonio, San Antonio, TX.*

**Background:** An arteriovenous fistula (AVF), graft (AVG) and peritoneal dialysis catheter are the recommended accesses to start dialysis therapy, however, about 80% patients in the US start dialysis using a catheter. We assessed the rate of suboptimal dialysis start (defined as initiation of dialysis with a catheter) with the aim to identify barriers to timely access creation at the University Health System in San Antonio.

**Methods:** Charts of consecutive incident dialysis patients were reviewed from January 2010 to December 2012. A total of 154 patients were identified.

**Results:** Mean age ± SD of study population was 52.4 ± 13 years, 47% were males and 82% were Hispanics. End stage renal disease was attributed to diabetic nephropathy in 75% patients. Suboptimal starts occurred in 80% of the patients (19% had an immature AVF or AVG at the time of initiation). Patient's demographics, medical history and lab parameters were not different between the suboptimal and optimal start groups. Ninety-two percent patients in the optimal group were seen by a nephrologist for >6 months compared to 66% patients in the suboptimal group (p=0.003). Physician and nurse pre-dialysis education was noted for 86% and 84% patients, respectively in optimal starts versus 33% and 28%, respectively in the suboptimal starts (p<0.001). Among the suboptimal starts, lack of regular health care prior to initiation (40%) and patient related delays (36%) were major barriers to timely access creation. Wait times (median [IQR] in days) to nephrology consult (90[48, 169]), vascular mapping (23[12, 49]), surgery consult (41[27, 62]) and access creation (44[23, 106]) were same between the two groups. On multivariate regression analysis, care by a nephrologist for > 6 months was the only predictor for an optimal start (OR=13, 95% CI 2.3-72).

**Conclusions:** Initiation of dialysis with suboptimal access is common in our system. Lack of regular health care prior to initiation and patient related delays were the major barriers to timely access creation, which are partly modifiable. This study provides the opportunity to test methods to prevent suboptimal starts.

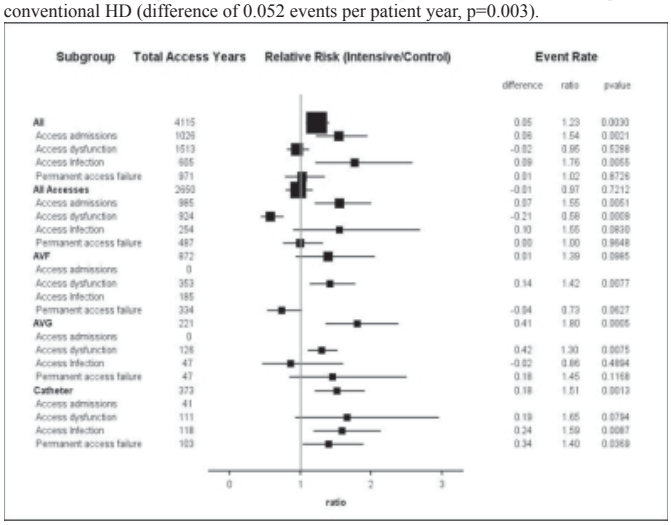
## FR-PO165

**Vascular Access Vulnerability in Intensive Hemodialysis: A Significant Achilles' Heel?** Tom Cornelis,[1] Len A. Usvyat,[2] Peter Kotanko,[2] Yuedong Wang,[3] Karel M.L. Leunissen,[1] Frank Van der Sande,[1] Jan Tordoir,[1] Jeroen Kooman.[1] *[1]Maastricht Univ Medical Center, Maastricht, Netherlands; [2]Renal Research Institute, New York; [3]Univ of California - Santa Barbara, Santa Barbara.*

**Background:** Frequent hemodialysis (HD) may be associated with an increased risk of vascular access complications as compared to conventional HD, especially for arteriovenous fistulas (AVF) and grafts (AVG) due to the increased cannulation frequency. Studies addressing vascular access outcomes in frequent HD so far have shown conflicting results.

**Methods:** We searched Medline and Embase for all trials looking at vascular access outcomes in frequent HD as compared to conventional HD.

**Results:** Nineteen studies met the inclusion criteria; 3 studies used a randomized design, 11 studies were prospective cohort studies, and 5 studies were retrospective cohort studies. The overall vascular access event rate (including access admissions, access dysfunction, access infection and permanent access failure) was higher in intensive HD as compared to conventional HD (difference of 0.052 events per patient year, p=0.003).



Event rates in the AVF group did not differ by HD intensity (conventional 0.155; intensive 0.161; difference 0.006, p=0.099). The overall event rates in the AVG (0.61 in conventional; 1.015 in intensive HD) and catheter (0.36 in conventional; 0.539 in intensive HD) group were higher than in the AVF group. Also, vascular access event rates were higher in intensive as compared to conventional HD patients for both the AVG (difference 0.405, p=0.001) and the catheter (difference 0.179, p=0.001) group.

**Conclusions:** Vascular access is the Achilles' heel also in intensive HD predominantly with AVG and catheters. Therefore, a Fistula First strategy is recommended also for intensive hemodialysis.

## FR-PO166

**Be Careful of Central Venous Stenosis in Chronic Dialysis Patients with a Well-Functioning Arteriovenous Fistula** Mingli Zhu,[1] Yaxue Shi,[2] Yucheng Yan,[1] Zhaohui Ni.[1] *[1]Renal, Renji Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China; [2]Vascular Surgery, Renji Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

**Background:** It is not clear whether patient who is dialyzing with a well-functioning vascular access may be presence of venous stenosis. The aim of this study is assessment of venous stenosis/occlusion by digital subtraction angiography (DSA) in chronic hemodialysis patients with an ipsilateral well-functioning native AVF.

**Methods:** The data were comprised of prevalent hemodialysis patients with a well-functioning mature autogenous radio-cephalic forearm AVF in our single center by 7/31/2012. Total 54 patients were met the criteria of well-functioning AVF defined as adequate delivery of dialysis, no difficulty in cannulation, and no abnormal physical findings. All patients signed informed consents. We performed angiography examinations for these patients. Positive case was defined as any abnormality of relevant vein which was presence of stenosis, occlusion, or collateral branch.

**Results:** Of all 54 eligible patients, 30 (55.5%) were male, the median dialysis vintage was 7.74 (4.2, 12.38) years. The average of blood flow and venous pressure during dialysis session were 247.7±25.98 ml/min and 125.15±27.82 mmHg, and the mean URR and spKt/V were 77.33±4.61% and 1.83±0.27, respectively. Among 54 patients, 21 (39%) were detected positive cases by the angiography. 13 of 54 (24%) had mild central venous stenosis (stenosis <50% diameter with or without collateral branch), one of 54 (2%) had severe central venous stenosis (stenosis >50% diameter), 6/54 (11%) had upper arm vein system occlusion or stenosis, another one had anastomoty stenosis. No significant difference was observed between positive cases and negative cases (including BMI, BSA, hemoglobin, albumin, gender, primary disease, blood flow, venous pressure, URR and spKt/V, p>0.05).

**Conclusions:** The frequency of venous lesion is not low in hemodialysis patients with a well-functioning AVF. Although we don't recommend treating these cases by intervention approach immediately, we suggest to draw attention to these positive results and perform surveillance of access constantly.

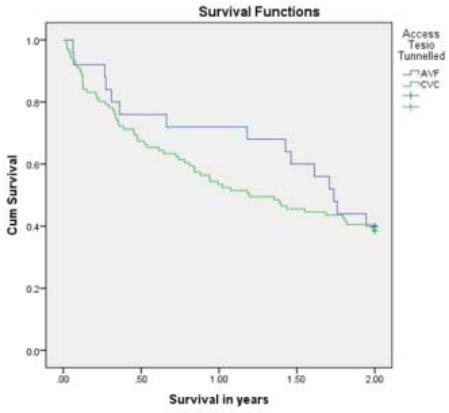
## FR-PO167

**Vascular Access Critical for Prolonged Survival in the over 80 Starting Haemodialysis** Adam Daniel Jakes,[1] Poonam Jani,[3] Archie Lamplugh,[2] Victoria L. Allgar,[3] Sunil Bhandari.[2] *[1]Leeds Teaching Hospitals NHS Trust, United Kingdom; [2]Renal Unit, Hull and East Yorkshire Hospital NHS Trust, United Kingdom; [3]Hull York Medical School, United Kingdom.*

**Background:** Initiating dialysis in patients over 80 years old carries a poor prognosis, but little is known about the most efficient vascular access method in this age group. The creation of an arteriovenous fistula (AVF) is both time consuming and expensive, requiring surgical insertion. A tunnelled central venous catheter (CVC) is a cheaper alternative and requires no surgical intervention but carries a higher risk of infection. We examined whether the creation of an AVF or CVC affected mortality for these patients.

**Methods:** Vascular access and survival data from patients within East Yorkshire was collated using regional databases. Patients must have started elective dialysis over the age of 80 years and received haemodialysis in hospital.

**Results:** 126 patients were included, with 101 initially being dialysed using a CVC and 25 by AVF. 78(62%) were male. The median age of starting dialysis was 82.7(IQR: 81.6-84.5) years and was similar in both CVC and AVF groups; 82.9(81.8-84.7) and 82.0(81.0-82.8) respectively. The median survival was 1.22(1.08-1.35) years, with patients using a CVC surviving 1.17(1.02-1.33) years compared with those using an AVF; 1.40(1.11-1.68) years (p=0.584). The mortality of patients using a CVC at 1 year was 47(47%) in contrast to an AVF; 7(28%), but this was not significant (p=0.094) and after 2 years the survival curves converged. Mortality at 2 years was; CVC 62(61%) and AVF 15 (60%)(p=0.899).



**Conclusions:** There was no statistical difference in survival associated with choice of vascular access for dialysis in elderly patients. Therefore a joint decision between patient and clinician should be considered, encompassing patient preference, fitness for surgery and realistic prognosis related to therapy.

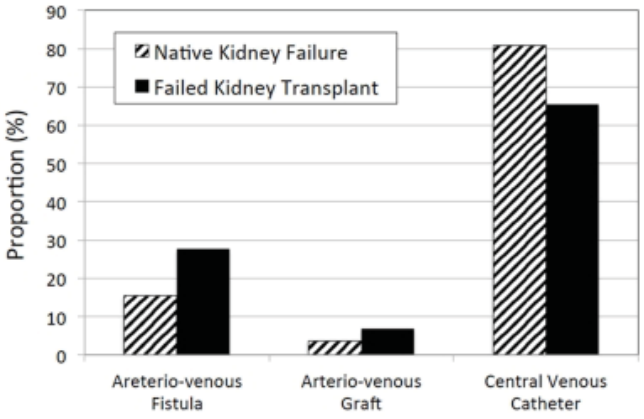
## FR-PO168

**Initial Vascular Access Type in Failed Renal Transplant Recipients** Micah R. Chan,[1] Ahmed I. Al-Absi,[1] Janet Bellingham,[2] Maureen J. Wakeen,[1] Alexander S. Yevzlin,[1] Brad C. Astor.[1] *[1]Nephrology, Univ of Wisconsin, Madison, WI; [2]Transplantation, Univ of Wisconsin, Madison, WI.*

**Background:** Permanent hemodialysis vascular access is crucial for ESRD patients and in those with failed renal transplants,as central venous catheters (CVC) are associated with greater risk of infection and mortality than arterio-venous fistulae (AVF) or arterio-venous grafts (AVG). As renal transplant patients are closely followed by transplant physicians,it would be expected that they have a higher prevalence of AVF/AVG at the time of hemodialysis initiation than those with native kidney failure.

**Methods:** We examined data from USRDS on 16,728 patients with failed renal transplant and 509,643 patients with native kidney failure who initiated dialysis between 1/1/2006 and 9/30/2011.

**Results:** At the initiation of dialysis, 27.7%(n=4,636) of patients with a failed transplant started with an AVF, 6.9%(n=1,146) started with an AVG, and 65.4% (n=10,946) started with a CVC. Conversely,80.8%(n=411,997) patients with native kidney failure initiated dialysis with a CVC (p<0.001).



Among those with failed transplant,predictors of CVC included female(adjusted [OR]=1.74; 95%[CI]: 1.63, 1.87),white race(OR=1.31; 1.22, 1.41), lack of referral to a nephrologist(OR=2.03; 1.74, 2.37), diabetes(OR=1.13; 1.05, 1.22),peripheral vascular disease(OR=1.30; 1.15, 1.47). Factors associated with lower odds of CVC use included public insurance(OR=0.76; 0.71, 0.81),current employment(OR=0.87; 0.80, 0.95),and having a prior failed transplant(OR=0.91; 0.85, 0.99).

**Conclusions:** Central venous catheters are used in more than half of failed renal transplant patients. This group of patients usually are being followed closely by transplant physicians before developing ESRD after a failed transplant,but the relatively low prevalence of AVF/AVG in this group at the initiation of dialysis needs to be investigated more thoroughly.

## FR-PO169

**MicroRNA-30 Family InhibitsCalcineurin Signaling in Podocytes** Junnan Wu, Wanfen Zhang, Shaolin Shi, Zhi-hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing Univ School of Medicine, Nanjing, China.*

**Background:** Calcineurin signaling has recently been implicated in the injury of podocytes. Several reagents, including TGF-beta, Lipopolysaccharides (LPS) and puromycinaminonucleoside (PAN), can induce calcineurin signaling in podocytes, but the underlying mechanisms are unknown.We have recently found that miR-30 members are abundantly expressed in podocytes, but all downregulated by TGF-beta, LPS or PAN, leading to podocyte injury. Thus, miR-30s may protect podocytes by inhibiting calcium-calcineurin signaling, and downregulation of miR-30s by TGF-beta, LPS or PAN would enhance calcineurin signaling, leading to podocyte injury.

**Methods:** Conditionally-immortalized human podocyte cell line treated with TGF-beta, LPS or PAN,PAN-treated rats, and the biopsies of FSGS patients were used for the study. miR-30 target validations were performed by luciferase reporter assay and western blotting.

**Results:** We treated podocytes with TGF-beta, LPS or PAN, and found an increase of calcineurin activity, accompanied by downregulation of miR-30s and upregulations of calcineurin signaling components (PPP3ca and NFATc3, which are the predicted miR-30 targets) in the cells. However, exogenous miR-30 expression that sustained the overall level of miR-30s in the podocytes prevented the increase of calcineurin activity and upregulation of PPP3ca and NFATc3 in the treatment of TGF-beta, LPS or PAN. In PAN-treated rats, upregulation of PPP3ca and NFATc3 and downregulation of miR-30s were also observed in the podocytes. However, transferring exogenous miR-30a to the podocytes of the rats prevented the upregulation of PPP3ca and NFATc3 and ameliorated podocyte injury. Calcineurin (PPP3ca)upregulation was also found in the podocytes of FSGS patients, in which miR-30s were downregulated. Finally, luciferase reporter assays confirmed that PPP3ca and NFATc3 are the direct targets of miR-30s inpodocytes.

**Conclusions:** miR-30s inhibit calcineurin signaling in podocytes by directly targeting calcineurin signaling components. Downregulation of miR-30s and the consequent upregulation of calcineurin signaling may be an alternative mechanism by which TGF-beta, LPS or PAN damages podocytes.

*Funding:* Government Support - Non-U.S.

## FR-PO170

**The Paracrine Function of Myofibroblast Was Regulated by miRNA-21 in 5/6 Nephrectomy Mice** Yiwen Li. *ZheJiang Province Hospital.*

**Background:** Myofibroblast is very importment to maintain the normal cardiac function and the cardiac remodeling in pathologic condition. Our provious study found that the paracrine dysfunction of myofibroblast may be responsible for the left ventricular remodeling in uremic cardiopathoy. However, the mechanism of paracrine disregulation of myofibroblast is unknown.

**Methods:** CRF was induced in adult male mice by 5/6 nephrectomy. The mice were killed at 12 weeks after operation. Myofibroblast was derived from sham mice and 5/6 nephrectomy mouse. miRNA-21 was analysized by PCR. IL-1ß, IL-6, TNF-α,TGF-ß.were analysized by ELISA. p-AKT, p-ERK1/2, and p-STAT5 were analysized by west bloting. In the in vitro study, normal medium, and medium with uremic patients serum were used for the myofibroblast culture.

**Results:** Myofibroblas driverd from 5/6 nephrectomy mice showed a significant increased expression of miRNA-21 accompany increasing the concentration of IL-1ß, IL-6, TNF-α,TGF-ß in medium. The uremia patient serum increased the expression of miRNA-21 in normal cultured myofibroblas accompany increasing the expression of p-AKT, p-ERK1/2, and p-STAT5. Inhibited the miRNA-21 expression by siRNA significant reduced the overexpression of p-AKT, p-ERK1/2 and p-STAT5 caused by uremic serum. In same time the concentration of IL-1ß, IL-6, TNF-α,TGF-ß were also decreased in medium.

**Conclusions:** The current study elucidated that myofibroblast paracrine function was regulation by miRNA-21 through p-AKT, p-ERK1/2 and p-STAT5 signals pathways in 5/6 nephrectomy mice.

## FR-PO171

**Number and Function Impairment of Resident c-kit+ Cardiac Stem Cells in Mice with Renal Dysfunction Caused by 5/6 Nephrectomy** Yiwen Li. *ZheJiang Province Hospital.*

**Background:** Cardiac stem cell (CSC) dysfunction exists in various kinds of cardiovascular diseases, and may be responsible for the insufficient regeneration of cardiac myocytes and coronary vessels. However, whether chronic renal failure (CRF) affected CSC is unknown.

**Methods:** CRF was induced in adult male mice by 5/6 nephrectomy. The mice were killed at 12 weeks after operation. C-kit+ CSC numbers was evaluated by flow cytometer. Apoptosis and DNA damage of C-kit+ CSC in the control and CRF mice was analyzed by immunohistochemistry. In the in vitro study, normal medium, and medium with uremic rat serum were used for the CSC culture.

**Results:** CSC counts attenuated significantly in the chronic renal failure model, whereas apoptosis cells and 8-OHdG-positive cells significantly increased. CSC derived form 5/6 nephrectomy mice heart showed an impaired anti-oxidant potential. In the cultured cells, CSCs subjected to uremic rat serum showed a higher frequency of TUNEL stain-positive and 8-OHdG-positive cells. The uremia rat serum reduced the expression of hepatocyte growth factor (HGF) and vascular endothelial growth factor (VEGF) in CSC.

**Conclusions:** The current study elucidated that CSC number and function disorders existed in mice with chronic renal insufficiency. Apoptosis, oxidative stress and reduced angiogenic factors secretion caused by uremic toxins in serum are contributors to CSC dysfunction.

**FR-PO172**

**MicroRNA-22 Is a Master Regulator of Bone Morphogenetic Protein-7/6 Homeostasis in the Kidney** Jianyin Long,[1,2] Shawn S. Badal,[1,2] Yin Wang,[1,2] Farhad R. Danesh.[1,2] *[1]Dept of Medicine/Nephrology, Baylor College of Medicine, Houston, TX; [2]Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston, TX.*

**Background:** Accumulating evidence suggests that microRNAs (miRNAs) contribute to a myriad of kidney diseases. However, the regulatory role of miRNAs on the key molecules implicated in kidney fibrosis remains poorly understood. Bone morphogenetic protein-7 (BMP-7) and its related BMP-6 have recently emerged as key regulators of kidney fibrosis. Using the established unilateral ureteral obstruction (UUO) model of kidney fibrosis, we examined the regulatory role of miRNAs on BMP-7/6 signaling.

**Methods:** We employed several *in silica* analyses to identify conserved, putative, BMP-7/6 targeting miRNAs. Isolation of renal fibroblasts, real-time qPCR of mRNA and miRNA, miRNA *in situ* hybridization, oligonucleotide-directed mutagenesis, and luciferase reporter assays were carried out as previously described.

**Results:** miR-22 was predicted to target BMP-7/6 *in silica* and validated to downregulate BMP-7/6 expression *in vitro*. To further assess the effect of miR-22 *in vivo*, we generated a miR-22 null mouse using a targeted strategy to delete the whole exon containing *pri-miR-22*. We found that knockout of miR-22 significantly attenuated renal fibrosis in the UUO kidney fibrosis model. Interestingly, targeted deletion of miR-22 led to robust elevation of BMP-7/6 protein expression and downstream signaling *in vivo*. We further demonstrated that miR-22 directly binds to 3'-untranslated region (UTR) of BMP-7, BMP-6 and BMPR1B mRNAs *in vitro*. Importantly, transfection of miR-22 mimic into primary renal fibroblasts isolated from miR-22-deficient mice partially restored the pro-fibrogenic genes induced by TGF-β1. Finally, we found that miR-22 by itself is induced by BMP-7/6, and identified two BMP-responsive elements (BREs) in the proximal promoter region of miR-22 gene.

**Conclusions:** Our data suggest that miR-22 serves as a master regulator of BMP signaling cascade and renal fibrosis. Our findings also indicate that miR-22 and BMP-7/6 form a regulatory feedback circuit, where not only miR-22 inhibits BMP-7/6, but miR-22 by itself is induced by BMP-7/6 signaling.

**The Mechanism of Pleiotropic Effect in Endothelial Cells with Pitavastatin Treatment** Tsuyoshi Inoue,[1,2] Yasuharu Kanki,[2] Tatsuhiko Kodama,[2] Youichiro Wada,[2] Masaomi Nangaku,[1] Takashi Maejima.[2] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo; [2]Laboratory for Systems Biology and Medicine, Research Center for Advanced Science and Technology, The Univ of Tokyo.*

**Background:** CKD is an important risk factor for progression of atherosclerosis related cardiovascular disorders. Statins are widely-used cholesterol lowering drugs. Multiple lines of evidence, including randomized clinical trials, suggested that statins also directly protect the kidney and vascular cells. These favorable, so-called "pleiotropic effects" are supposed to occur, in part, through alterations in vascular cell gene expression.

**Methods:** We used various epigenetic methods such as Chromatin Immunoprecipitation assay with deep sequencing (ChIP-seq), Chromatin Interaction Analysis by Paired-End Tag Sequencing (ChIA-PET), Chromosome Conformation Capture (3C)-qPCR assay and 3D-Fluorescence In Situ Hybridization (FISH).

**Results:** Histological analysis using ApoE knockout mouse showed that pitavastatin treatment reduced plaque and macrophage area in spite that the total cholesterol and triglyceride levels were not significantly affected. Repeated microarray analyses of HUVECs treated with pitavastatin identified KLF4 and KLF2 as the most highly induced genes. The up-regulation of these genes was confirmed with mRNA from aortic tissue of ApoE deficient mice. By series of knockdown experiments, MEF2C activated through MEK5/ERK5 pathway was involved in pitavastatin-dependent gene induction. Among MEF2 family, we focused on MEF2C, and identified a novel functional MEF2C binding site at 148 kb upstream of the KLF4 gene by ChIP-seq followed by luciferase assay. By applying whole genome and quantitative chromatin conformation analysis (ChIA-PET and 3C), we observed that the MEF2C-bound enhancer and transcription start site (TSS) of KLF4 took closer spatial proximity by pitavastatin. 3D-FISH imaging confirmed the conformational change in single cell manner.

**Conclusions:** These results showed that drug-responsive chromatin conformation change could be involved in one of the various gene induction mechanisms induced as some part of the pleiotropic effects of the statins in endothelial cells.

**The Mechanism of ANGPTL4 Induction, a Mediator of Nephrotic Syndrome, through Its Chromatin Conformational Change** Tsuyoshi Inoue,[1,2] Imari Mimura,[1] Takahide Kohro,[2] Toshiya Tanaka,[2] Hiroyuki Aburatani,[2] Tatsuhiko Kodama,[2] Youichiro Wada,[2] Masaomi Nangaku.[1] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo; [2]Laboratory for Systems Biology and Medicine, Research Center for Advanced Science and Technology, The Univ of Tokyo.*

**Background:** Angiopoietin-[zwj]like 4 (*ANGPTL4*) has drawn attention as a cause of minimal change nephrotic syndrome recently, but the mechanism of this gene induction has not been elucidated yet.

**Methods:** In addition to Chromatin Immunoprecipitation (ChIP) assay with deep sequencing (ChIP-seq) analysis of hypoxia inducible factor (HIF) 1α, peroxisome proliferator-activated receptor (PPAR) β/δ and RNA polymerase (Pol) II, we used epigenetic methods including ChIP-seq of histone marks, Chromatin Interaction Analysis by Paired-End Tag Sequencing (ChIA-PET) and Chromosome Conformation Capture (3C)-PCR assay to dissect the molecular mechanism of the gene expression.

**Results:** Detailed investigation of HIF1 dependent gene expression led us to realize the importance of crosstalk between PPAR β/δ and HIF1 signaling axes. Migration assay showed that synergistic enhancement with these two stimuli, and *ANGPTL4* was identified as the common target gene by the combination of microarray and ChIP-seq analysis. The reporter assay combined with ChIP-seq identified the functional hypoxia responsive element (HRE) and PPAR responsive element (PPRE) in the promoter and intron regions of *ANGPTL4*. The profile changes of the enhancer histone mark (H3K27ac) under hypoxia, PPARβ/δ ligand, and dual stimulations suggested that the spatial proximity of two response elements was the principal cause of the synergistic transcription induction. ChIA-PET supported the interaction between the two regions, and further, newly developed quantitative 3C-PCR assay showed the quantitative change of the frequency of proximity.

**Conclusions:** These results imply that hypoxic and PPARβ/δ stimulations are important for activation of *ANGPTL4* transcription, and the synergistic activation is achieved by spatial proximity formation in *ANGPTL4* loci.

**FR-PO175**

**Vascular Endothelial Growth Factor-C Production Stimulated by TNF-α through p38/HSP27 Pathway and Its Therapeutic Reduction in Human Proximal Renal Tubular Cells** Hideki Kimura,[1] Daisuke Mikami,[2] Kazuko Kamiyama,[2] Naoki Takahashi,[2] Kenji Kasuno,[2] Haruyoshi Yoshida,[3] Masayuki Iwano.[1] *[1]Dept of Clin Lab, Univ of Fukui Hosp, Fukui, Japan; [2]Div of Nephrol, Sch of Med, Univ of Fukui, Fukui, Japan; [3]Div of Nephrol, Obama Municipal Hosp, Fukui, Japan.*

**Background:** Vascular endothelial growth factor-C (VEGF-C) promotes lymphatic angiogenesis associated with renal inflammation and fibrosis in chronic and active kidney disease (CKD) where glucocorticoids and angiotensin II receptor type 1 blockers (ARB) are widely used as a main remedy. VEGF-C production status and its modification by the two main remedies have remained unclarified in human proximal renal tubular cells (HPTECs) under inflammation.

**Methods:** Confluent HPTECs were treated for 24h with putative VEGF-C inducers in abscense or presence of specific kinase inhibitors (SB203580, H89, PD98059), dexamethsone (DXA;100 nM) or Telmisartan (Telm; 1-10μM), an ARB with peroxisome proliferator-activated receptor (PPAR) activity. VEGF-C expression was assessed by RT-PCR and ELISA. Phosphorylation of signalling molecules and PPAR activity were examined by immunoblotting, and PPRE-luc assay and specific inhibitors, respectively.

**Results:** In HPTECs, TNF-α (1-10 ng/ml), advanced glycation endproducts, and high glucose induced VEGF-C by 2.8-fold, 1.3-fold, and 1.2-fold, respectively, while TGF-β (1-5 ng/ml) and hypoxia (1%O2) had no influence on the production. VEGF-C production by TNF-α was mediated via phosphorylation of p38 MAPK/HSP27 pathway but not ERK or NFkB pathway. HSP27 silencing by siRNA reduced VEGF-C expression. DXA reduced TNF-α-induced VEGF-C production at mRNA and protein levels by about 40% via decreasing p38/HSP27 phosphorylation. Like DXA, Telm also decreased basal and TNF-α-induced VEGF-C production by about 30%. Moreover, Telm served as a specific PPAR-δ activator, and reduced VEGF-C production which was partially explained by PPAR-δ-dependent suppression of p38 phosphorylation.

**Conclusions:** Renal parenchymal inflammation may induce VEGF-C production in proximal renal tubular cells, possibly facilitating the surrounding lymphatic vessel formation. Major remedies for CKD may modulate lymphatic angiogenesis as well as fibrotic status.

**FR-PO176**

**The Effects of Endothelial Microparticles Induced by Indoxyl Sulfate on TGF-β Signaling in Vascular Smooth Muscle Cells** Jung-hwa Ryu, Shina Lee, Dong-Ryeol Ryu, Duk-Hee Kang, Kyu Bok Choi, Seung-Jung Kim. *Dept of Internal Medicine, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea.*

**Background:** Vascular access failure is one of the critical risk factor for the mortality or morbidity in hemodialysis (HD) patients. The venous neointimal hyperplasia (VNH) is the main pathogenesis of access stenosis, and recently it was reported that the proliferation of vascular smooth muscle cells (VSMCs) promoted by activation of TGF-β signaling

took a main portion for VNH. Endothelial microparticles (EMPs) are produced by various inflammatory stimulants associated with endothelial injury and increased in various vascular disease and uremic condition. However, it has not been established about the definite effects of EMPs on VSMCs. This study is aimed to isolate the EMPs induced by indoxyl sulfate(IS), well-known uremic toxin and to investigate whether the EMP directly stimulates the downstream of TGF-β signaling in VSMCs.

**Methods:** Human umbilical vein endothelial cells (HUVECs) were cultured and stimulated by IS of different concentrations. The culture media of HUVECs were collected and spun once and then ultracentrifugated at 100,000 Xg. The pellet was resuspended, incubated with fluorescent endothelial antibodies and analyzed by flow cytometry with comparing calibration beads. The near-confluent human aortic smooth muscle cells (HASMCs) were treated by this collected EMPs. After incubation, HASMCs were solubilized with lysis buffer and the activation of TGF-β signaling analyzed by western blotting for phophated-p38, -ERK1/2, -Akt, and -Smad3.

**Results:** The EMPs were well produced by IS, the quantity of them was similar to the amount generated by positive control, TNF-α(10ng/mL). In western blot analysis, EMPs produced by IS stimulated whole subsignals of p38, ERK1/2, Akt, and Smad3 in HASMCs with similar densities of blots stimulated by TGF-β.

**Conclusions:** The isolation of EMPs is confirmed by flow cytometry and these EMPs stimulated the subsignals of TGF-β in VSMCs. Further investigation is needed to demonstrate how EMPs stimulate the subsignals of TGF-β and affect on proliferation of VSMCs and to evaluate the importance of TGF-β signaling in vascular pathology.

### Microvesicles Released by Vascular Endothelial Cells Increase Hypoxia Inducible Factor Expression in Human Proximal Tubular HK-2 Cells

Javier Lucio,[1] Ana Valdehita,[1] Julia Carracedo,[2] Rafael Ramirez,[1] Ana Belen Fernandez.[1] *[1]Universidad Alcala, Spain; [2]Hospital Reina Sofia Cordoba, Spain.*

**Background:** Co-culture experiments suggest that vascular endothelial cells may influence transcriptional regulation of HK-2 cells and that several hypoxia-inducible factors (HIF)-dependent genes were upregulated (Am J Physiol 2008, 294:C543-C554). Here we aimed to investigate whether endothelial microvesicles (EMVs) increase the expression of HIF and the production of the putative renal protection factor HIF-regulated VEGF-A in HK-2 cells.

**Methods:** HK-2 cells were incubated for 0-48 h with 200.000 EMVs/ml (isolated from TNF-α—treated human umbilical vascular endothelial cells) and expression of HIF-1α and HIF-2α and production of VEGF-A were measured by WB and ELISA, respectively.

**Results:** Expression of HIF-1α and HIF-2α and production of VEGF-A increased over the controls. HIF inhibitor YC-1 partially prevented the increase in VEGF-A. We have recently found that the sequential activation of cyclooxygenases (COX), epidermal growth factor receptor (EGFR), mitogen- and stress.-activated kinase-1 (MSK-1) and retinoic acid receptor-β (RARβ) up-regulates HIF-1α This pathway was also involved in EMVs-induced increase in HIF since it was sensitive to diclofenac, AG1478, H89 and LE135 (which inhibit respectively COX, EGFR, MSK-1 and RARβ). Interestingly, we also found an increased content in EMVs in human urine samples taken from patients with diseases known to induce chronic vascular inflammation, which indicates that tubular cells are exposed to EMVs in vivo.

**Conclusions:** These results suggest that EMVs might influence the in vivo expression of HIF, and thereby that of its target genes, in proximal tubular cells.

### Hyaluronic Acid Induces Lymphangiogenesis in Mouse Unilateral Ureteral Obstruction Model via Stimulation of Macrophage VEGF-C Production

Won Kim, Aesin Lee, Yujin Jung, Dal Kim, Kyung Pyo Kang, Sik Lee. *Internal Medicine, Research Institute of Clinical Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea.*

**Background:** Hyaluronic acid (HA) is one of important component of extracellular matrix proteoglycan. HA level is increased in chronic inflammation and has many biologic and pathologic effects such as inflammation, angiogenensis, wound healing and tissue remodeling. Our group reported that VEGF-C and VEGF-D from macrophages and tubular cells had induced lymphangiogenesis in mouse unilateral ureteral obstruction (UUO) model. However, there is few data about the effect of HA on lymphangiogenesis in renal fibrosis. To elucidate the role of HA in UUO-induced lymphangiogenesis, we investigated the expression of HA in UUO-induced lymphangiogenesis and the effect of HA on VEGF-C production in macrophages.

**Methods:** *In vitro* lymphangiogenic effects of HA in human lymphatic endothelial cells (hLECs) and *>in vivo* effect of HA on VEGF-C expression in UUO-induced lymphangiogenesis were evaluated.

**Results:** In UUO kidney, HA expression was increased in tubulointerstitial area 7 d after UUO. The density of LYVE-1-positive lymphatic endothelial cells was significantly increased in cortical interstitial fibrotic areas. HA expression correlates with lymphangiogenesis in UUO. VEGF-C expression was increased and F4/80-positive cells are costained with VEGF-C in kidney section after 1 w of UUO. About 35% of F4/80-positive macrophages was co-stained by HA and macrophage depletion with clodronate significantly decreased UUO-induced lymphangiogenesis. Our results also showed that low molecular weight HA induced capillary-like tube formation in the hLECs and treatment of HA in bone marrow derive marcrophages increased the expression of VEGF-C in a dose- and time-dependent manner.

**Conclusions:** These results suggest that HA has a lymphangiogenesis effects in UUO-induced renal fibrosis via stimulation of VEGF-C production in macrophages.

### CD148 Tyrosine Phosphatase Promotes Cadherin Cell Adhesion

Keiko Takahashi, Anton Matafonov, Hideyuki Ito, Dana Zemel, Katherine Sumarriva, Rebecca S. Weller, Takamune Takahashi. *Vanderbilt Univ, Nashville, TN.*

**Background:** CD148 is a transmembrane tyrosine phosphatase that is expressed in renal endothelium and tubular cells. CD148 is accumulated at cell-cell contacts. Recent biochemical studies demonstrated that CD148 associates with VE- or E-cadherin/catenin complex, and p120 catenin serves as a substrate. However, the function of CD148 in cadherin adhesion is still unknown. We therefore addressed this issue using a series of stable cells and cell-based assays.

**Methods:** Wild type (wt) and catalytically inactive (c-s) CD148 was stably introduced to A431D (lacking cadherins), A431D/E-cad (expressing E-cadherin), and A431D/E-cadAAA764 (expressing p120-uncoupled E-cadherin) cells. The effects of CD148 on cadherin cell adhesion were assessed by $Ca^{2+}$ switch, cell aggregation, and cell density assays. Phosphorylation of E-cadherin/catenin complex and Rho family GTPase activities were examined using IP/Western blot or Rhotekin/PAK assay.

**Results:** CD148wt, but not CD148c-s, extended cadherin contact zone as early as 30 min after cadherin engagement ($Ca^{2+}$ switch assay) and remarkably strengthened cell-cell adhesion (aggregation assay) in A431D/Ecad cells, although CD148 introduction did not change E-cadherin/catenin levels and complex formation. These effects accompanied p120 and β catenin dephosphorylation and an increase in Rac1, but not RhoA and cdc42, activity. Interestingly, CD148wt increased phosphorylation of p120 Y228 (a Src kinase site) on cell contacts together with an increase in Src activity (well known CD148 activity). The effects of CD148wt to strengthen cell adhesion were abolished by Rac1 inhibition. CD148wt showed no effects in A431D and A431D/EcadAAA764 cells. Notes: β catenin was not dephosphorylated by CD148 in vitro, suggesting β catenin dephosphorylation in intact cells may be a secondary effect; CD148 showed similar effects in endothelial cells.

**Conclusions:** CD148 regulates p120 and β catenin phosphorylation upon cell adhesion via the direct and indirect mechanisms, increases Rac1 activity and extends cadherin contacts, strengthening E- (and VE-) cadherin adhesion. This CD148 effect requires Ecad-p120 interaction.

### Kidney Microvascular Endothelial Cells Exhibit Organ Specific Angiogenic Characteristics in 3D Culture

Takahide Aburatani,[1] Giovanni Ligresti,[1] Ying Zheng,[2] Jeremy Stuart Duffield.[1] *[1]Dept of Medicine, Univ of Washington, Seattle, WA; [2]Dept of Bioengineering, Univ of Washington, Seattle, WA.*

**Background:** The kidney microvasculature is frequently disrupted in Acute Kidney Injury and CKD and shows poor angiogenic responses, leaving a rarefied vasculature and a kidney prone to ischemia, tubular dysfunction and the development of CKD. The reason why the kidney microvascular is so susceptible are poorly understood, and one leading hypothesis has been this response is due to the nature of kidney pericytes. Kidney microvascular endothelial cells (KMVECs), however, have scarcely been studied because of difficulties in culturing them ex vivo.

**Methods:** We isolated, established primary cultures, and characterized KMVECs from 4-6 weeks old mice. The gene expression profile of mKMVEC was analyzed by RT-PCR and their characteristics evaluated by examining their responsiveness to cytokines including VEGF, and pericytes in 2D and 3D in vitro assays.

**Results:** We established methods for culturing mKMVEC isolated by FACS sorting. All cultures were used prior to passage four. In 2D culture they maintain expression of EC proteins. RT-PCR analysis showed that mKMVECs expressed S1P1 other than typical endothelial markers (CD31, VEGFR2, VE-cad, and Ang2). 2D assays such as wound scratch assay and Alamar blue proliferation assay showed that they migrate and proliferate in response to VEGF164 stimulation, but responses were blunted by VEGF120 and VEGF188. mKMVECs were evaluated in 3D angiogenesis assays. Sprouting with tip cell and lumen formation was induced by VEGF and further stimulated by adding macrophages in 3D collagen gel but was extremely poor compared to other EC cell types. By contrast mKMVEC avidly made tubes with tight functions in 3D collagen gel when stimulated by PMA or pericytes.

**Conclusions:** Isolated and cultured mKMVECs express unique genes, as well as typical EC genes. In addition they showed unique endothelial properties in vitro including markedly reduced angiogenic sprouting but a propensity to reassemble capillaries. These properties unique to kidney MVECs may contribute to poor angiogenic responses after kidney injury which predispose to CKD.

**FR-PO181**

**The Effect of Angiotensin (1-7) on Glomerular Angiopoietins-Tie-2 and Its Potential Mechanisms** Chengyan Xu,[1] Wei Ding,[1] Minmin Zhang,[1] Yong Gu.[1,2] *[1]Nephrology, Huahsan Hospital, Fudan Univ, Shanghai, China; [2]Nephrology, The Fifth People's Hospital of Shanghai, Fudan Univ, Shanghai, China.*

**Background:** Angiopoietins-Tie-2 is one of the important angiogenesis system in glomeruli. Though Ang (1-7) has been reported inhibiting endothelial cell tube formation in vitro in human umbilical vein endothelial cells, the research regarding its effect in glomerular angiogensis has not been fully understood. This study aimed to observe the effects of Ang (1-7) on glomerular angiopoietins-Tie-2 system and its potential mechanisms.

**Methods:** The mouse glomerular endothelial cells (MGECs) and podocytes were cultured. Under the condition with/without exogenous Ang II, the cells were treated with Ang (1-7), Losartan, A-779 and PD98059 respectively. Real-time PCR was applied to test the gene expression of Ang-1 in podocytes and Ang-2 in MGECs treated with different doses of Ang (1-7) and AngII. The protein expression of Ang-1, Ang-2, Tie-2, phosphorylate eNOS and ERK1/2 was detected by Western blot. The ability of endothelial cells tube formation was observed by Matrigel method.

**Results:** Losartan and Ang(1-7) co-inhibited the expression of aniopoietins-Tie-2 without exogenous Ang II. While under the condition of exogenous AngII, the downregulating effect of Ang(1-7) on angiopoietin-Tie-2 expression was even more significant ($P < 0.05$). However, the suppressing effect of Ang(1-7) on aniopoietins-Tie-2 could be reversed by Losartan, A-779 and PD98059 ($P < 0.05$). Furthermore, the eNOS pathway could be activated by Ang (1-7) ($P < 0.05$). However, under the condition of exogenous Ang II, the phosphorylate eNOS was downregulated whereas the phosphorylated ERK1/2 was upregulated, which could be reversed by L-NAME ($P < 0.05$).

**Conclusions:** Ang(1-7) inhibited angiogenesis and resisted the effect of AngII of promoting the expression of aniopoietins-Tie-2. With the pretreatment of exogenous AngII, Ang(1-7) inhibited the expression of angiopoietins-Tie-2 more remarkably via downregulating eNOS and activating ERK1/2 pathway, which could be reversed by Losartan.

*Funding:* Government Support - Non-U.S.

**Inhibition of $Ca^{2+}$ Influx through Reverse-Mode $Na^+/Ca^{2+}$-Exchange (NCX) Preserves Endothelial Barrier Function in Response to Thrombin: Implications for CKD** Petros Andrikopoulos, Julius Edward Kieswich, Steven Michael Harwood, Magdi Yaqoob. *Translational Medicine and Therapeutics, William Harvey Research Institute, London, United Kingdom.*

**Background:** CKD patients exhibit high levels of plasma thrombin activity which could have a direct effect on the endothelium through its main receptor protease activated receptor-1 (PAR-1). This may result in loss of barrier function causing pulmonary and peripheral oedema that are hallmarks of CKD and exacerbate the severity of this multifaceted disease. We recently reported that in human endothelial cells (HUVECs), $Ca^{2+}$ influx through reverse-mode NCX is critical for ERK1/2 activation and angiogenesis by VEGF. Here, we investigated whether NCX activity also plays a role in ERK1/2 activation and endothelial barrier dysfunction by thrombin.

**Methods:** ERK1/2 activation was investigated by western blot, $Ca^{2+}$ transients were monitored with Fluo-4NW and permeability was assessed by FITC-dextran flux through an EC monolayer. *In vivo* permeability was determined by the extravasation of Evans blue-albumin (20mg/Kg) in mice stimulated with a PAR-1 agonist peptide (1mg/kg).

**Results:** ERK1/2 activation by thrombin required influx of $Ca^{2+}$ and was suppressed by the specific reverse-mode NCX inhibitors SN-6 and SEA0400 dose- and time-dependently. SN-6 or SEA0400 also attenuated thrombin-induced $Ca^{2+}$-transients. Knocking down NCX1 with siRNA suppressed thrombin-induced ERK1/2 activation. Conversely, loading ECs with $Na^+$ by inhibiting the $Na^+$-$K^+$-ATPase with ouabain, accelerated ERK1/2 activation. Reverse-mode NCX inhibitors also suppressed ERK1/2 activation in response to a peptide agonist of PAR-1. Inhibiting reverse-mode NCX with SN-6 and SEA0400 or knocking down NCX1 significantly preserved endothelial barrier function in response to thrombin. Finally, SEA0400 suppressed Evans Blue-Albumin extravasation to the lung and kidneys of C57bl/6 mice and attenuated oedema formation, in response to PAR-1 activation.

**Conclusions:** $Ca^{2+}$ influx through reverse-mode NCX could be a novel determinant of vascular permeability in response to thrombin and drugs targeting reverse-mode NCX could be beneficial in CKD patients with diminished endothelial barrier function.

**FR-PO183**

**1a, 25-Dihydroxyvitamin $D_3$ Inhibits TNF-α-Induced LOX-1 Expression via Suppression of Rac1 Activation in Human Aortic Smooth Muscle Cells** Wonseok Yang, Su-Kil Park. *Internal Medicine, Asan Medical Center, Seoul, Republic of Korea.*

**Background:** 1α, 25-Dihydroxyvitamin $D_3$($1,25D_3$)is used to treat secondary hyperparathyroidism associated with end-stage renal disease (ESRD). Atherosclerosis is highly prevalent in ESRD patients. Lectin-like oxidized low-density lipoprotein receptor-1(LOX-1) expressed on vascular smooth muscle cells is implicated in atherosclerosis.

**Methods:** We explored the effect of$1,25D_3$ontumor necrosis factor α (TNF-α)-induced LOX-1 expression in cultured human aortic smooth muscle cells.

**Results:** TNF-α increased LOX-1expression, while it was inhibited by preincubation with $1,25D_3$ in a dose-dependent manner. TNF-α-induced LOX-1expression was mediated by Rac1, reactive oxygen species (ROS) and spleen tyrosine kinase (Syk). TNF-α-induced Syk activation was inhibited by both NSC 23766 (Rac1 inhibitor) and N-acetylcysteine (NAC). $1,25D_3$ suppressed TNF-α-induced Rac1 activation, ROS expression and Syk activation. In summary, TNF-α-induced LOX-1 expression occurred through Rac1/ROS/Syk. $1,25D_3$ attenuated TNF-α-induced LOX-1 expression by inhibition of Rac1 activation and thereby subsequent downstream signals.

**Conclusions:** Through inhibition of LOX-1 expression on aortic smooth muscle cells, $1,25D_3$ may have an anti-atherosclerotic effect.

**FR-PO184**

**Activation of mTOR Modulates SREBP-2 to Induce Foam Cell Formation in Vascular Smooth Muscle Cells through Increased Retinoblastoma Protein Phosphorylation** Kun Ling Ma, Jing Liu, Yang Zhang, Wu Yu, Jie Ni, Bi-Cheng Liu. *Institute of Nephrology, Southeast Univ School of Medicine, Nanjing, China.*

**Background:** Our previous studies demonstrated that inflammation contributes to foam cell formation through the disruption of low density lipoprotein receptor (LDLr) pathway. However, this effect is overridden by rapamycin, which is an inhibitor of mammalian target of rapamycin (mTOR). This study investigated the role of mTOR pathway in foam cell formation in vascular smooth muscle cells (VSMCs).

**Methods:** Rat VSMCs were treated with or without lipopolysaccharide(LPS) in the absence or presence of rapamycin or mTOR siRNA. Lipid accumulation in VSMCs was measured by Oil red O staining. The expression and protein phosphorylation of mTOR pathway, LDLr pathway, and retinoblastoma tumour suppressor protein (Rb) were checked by immunofluorescent staining, real-time PCR, and Western blotting.

**Results:** Inflammation increased lipid accumulation in VSMCs, which were correlated with increased expressions of LDLr, sterol regulatory element-binding protein (SREBP) cleavage-activating protein (SCAP), and SREBP-2, as well as with enhanced translocation of SCAP/SREBP-2 complex from endoplasmic reticulum (ER) to Golgi. Furthermore, inflammation increased both the percentage of cells in the S phase of cell cycle and protein expressions of the phosphorylated forms of Rb, mTOR, eukaryotic initiation factor 4E-binding protein 1 (4EBP1), and p70 S6 kinase. After treatment with rapamycin or mTOR siRNA, the activity of mTOR pathway was blocked, and the phosphorylation of Rb was also inhibited. Interestingly, the expression levels of LDLr, SCAP, and SREBP-2 and the translocation of SCAP/SREBP-2 complex from the ER to the Golgi in VSMCs were accordingly decreased even in the presence of inflammatory stress.

**Conclusions:** Inflammation disrupts LDLr feedback regulation through the activation of mTOR pathway. Increased mTOR complex-1activity was found to upregulate SREBP-2-mediated cholesterol uptake through Rb phosphorylation.

**FR-PO185**

**Activation of mTOR Modulates LDL Receptor at Transcriptional and Post-Transcriptional Level to Accelerate Lipid Accumulation in Fatty Livers of Apolipoprotein E Knockout Mice** Kun Ling Ma, Jing Liu, Yang Zhang, Wu Yu, Bi-Cheng Liu. *Institute of Nephrology, Southeast Univ School of Medicine, Nanjing, China.*

**Background:** Our previous studies demonstrated that inflammation exacerbates lipid accumulation in hepatic cells. However, these effects are overridden by rapamycin, which is an inhibitor of mammalian target of rapamycin (mTOR). This study aimed to investigate the role of mTOR pathway in lipid accumulation of fatty livers.

**Methods:** Apolipoprotein E knockout mice were subcutaneously injected with 10% casein to induce chronic inflammation. Serum levels of serum amyloid A, tumour necrosis factor-a, and lipid profiles were measured by enzyme-linked immunosorbent assay and clinical biochemistry assay. Lipid accumulation was evaluated by haematoxylin-eosin and filipin staining.The associated protein expression of mTOR and low-density lipoprotein receptor (LDLr) pathways were checked by immunohistochemical staining, immunofluorescent staining, and Western blotting.

**Results:** Inflammation significantly reduced serum levels of lipid profile compared to the controls. However, inflammation increased lipid accumulation in livers, correlated with increased expressions of LDLr, sterol regulatory element-binding protein (SREBP) cleavage-activating protein (SCAP), and SREBP-2, as well as with enhanced translocation of SCAP/SREBP-2 complex from endoplasmic reticulum (ER) to Golgi. Meanwhile, upregulated LDLr gene transcription recruited proprotein convertase subtilisin kexin 9 (PCSK9) with accordingly increased PCSK9 protein expression. Furthermore, inflammation increased the mTOR phosphorylation. After treatment with rapamycin, mTOR activity was inhibited, accompanied with accordingly decreased expression of LDLr, SCAP, and SREBP-2, decreased translocation of SCAP/SREBP-2 complex from the ER to the Golgi, and increased PCSK9 expression even in the presence of inflammatory stress.

**Conclusions:** The activation of mTOR pathway caused by inflammation disrupted the regulation of LDLr at transcriptional and post-transcriptional level, resulting in lipid accumulation and exacerbated the progression of fatty liver.

**FR-PO186**

**Effect of Cylcosporine Treatment on Akt-FOXO Signaling in $C_2C_{12}$ Muscle Cells** Jill Rahnert,[1] Bin Zheng,[1] Russ Price.[1,2] *[1]Dept of Medicine, Emory Univ, Atlanta, GA; [2]VA Medical Center, Atlanta, GA.*

**Background:** Muscle wasting is a consequence of chronic diseases such as chronic kidney disease (CKD) and type I diabetes (DM). Insulin/IGF-1 deficiency, combined with chronic elevation of glucocorticoids, promotes protein degradation by activating the FOXO

transcription factors. This results in increased expression of key components of multiple proteolytic systems including the ubiquitin-proteasome pathway. Insulin and IGF activate Akt which phosphorylates FOXO, thereby inhibiting its activity; FOXO activity is also repressed by the transcription coactivator, PCG-1α. Calcineurin (Cn), a $Ca^{2+}$-activated phosphatase, induces PGC-1α expression and promotes a slow-twitch fiber phenotype that is inherently less susceptible to atrophy. Although Cn itself does not directly regulate muscle mass, it is down-regulated in multiple models of muscle atrophy including CKD and DM, suggesting that Cn may indirectly affect protein degradation. This is an important point because renal transplant patients routinely take the Cn-inhibitor, cyclosporine A (CsA). Our experiments tested the hypothesis that acute inhibition of Cn with CsA sensitizes muscle to atrophic signals by altering upstream Akt/FOXO signaling.

**Methods:** $C_2C_{12}$ muscle cells were treated with phorbol 12-myristate 13-acetate (PMA) and thapsigargin (Tg) for 1 hour to increase intracellular $Ca^{2+}$ levels and activate Cn, with or without CsA.

**Results:** PMA/Tg increases the nuclear localization of the transcription factor NFATc3, the canonical target of Cn, 2.7-fold and this is prevented by CsA (PMA/Tg x CsA, p=0.013). PMA/Tg or CsA produce minimal changes in the phosphorylation status of Akt and FOXO. ERK mediated FOXO phosphorylation increases 1.6-fold with PMA/Tg and this is sensitive to CsA (PMA/Tg x CsA, p=0.046). However, neither Akt nor ERK signaling is sufficient to see significant changes in FOXO localization.

**Conclusions:** Together, these data do not support a role for Cn-mediated regulation of the Akt-FOXO axis. If down-regulation of Cn increases muscle fiber susceptibility to atrophy, it does so by a different mechanism.

**Vitamin D Receptor (VDR) Expression Determines p53-Induced Tubular Cell Phenotype** Gautam Kishore Valecha, Nirupama Chandel, Partab Rai, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, New York, NY.*

**Background:** P53 displays a bimodal effect on cellular growth-p53 over expressing cells are prone to apoptosis, whereas, p53 mutant cells display proliferation mode. We hypothesize that vitamin D recepetor (VDR) plays a key role in p53-mediated bimodal tubular cell growth.

**Methods:** Human renal proximal tubular cells (HRPTC) were either transfected with siRNA-p53 (siRNA-p53/HRPTC), scrambled siRNA (SCR/HRPTC), or p53 plasmid (p53/HRPTC). Protein blots of C/HRPTCs, siRNA-p53/HRPTC, SCR/HRPTC, and p53/HRPTC were probed for VDR, angiotensinogen (Agt) renin, phospho-p66ShcA, and reprobed for total p66ShcA and actin. To confirm the activation of the renin angiotensin system (RAS), Ang II content of the cellular lysates was measured by ELISA.To determine the modulation of reactive oxygen species (ROS) generation, cells were co-labeled with Red CC1 and mitotracker green in the presence/absence losartan (an Ang II blocker), and a VDR agonist (VDA, EB1089). Cells treated under above mentioned conditions, were also evaluated for occurrence of apoptosis by TUNEL assay/Western blotting for caspase-3 cleavage and for proliferation by labeling for proiiferative cell nuclear antigen (PCNA).

**Results:** p53/HRPTC displayed down regulation of VDR, enhanced expression of renin and Agt and elevated levels of Ang II when compared to C/HRPTC and SCR/HRPTCs; however, EB1089 inhibited these effects of p53. p53/HRPTC showed enhanced expression of phospho-p66ShcA and increased generation of ROS. p53/HRPTC displayed cleavage of caspase-3 and increased number of TUNEL +ve cells. Since both VDA and losartan attenuated enhanced ROS generation as well as apoptosis in p53/HRPTCs, it appears that p53 mediated tubular cell apoptotic phenotype through VDR-induced activation of the RAS. On the other hand, siRNA-p53/HRPTC displayed enhanced VDR expression and down regulation of the RAS and attenuated generation of ROS. siRNA-p53/HRPTC not only showed resistance to apoptosis but also exhibited enhanced number of PCNA +ve cells.

**Conclusions:** These findings indicate that VDR expression determines p53-induced tubular cell phenotype.

## FR-PO188

**Novel Biological Gas $H_2S$ Regulates the Length of Primary Cilia of Kidney Tubular Epithelial Cell** Sang Jun Han,[1] Jee In Kim,[1,2] Kwon Moo Park.[1,2] *[1]Anatomy, Kyungpook National Univ School of Medicine; [2]Cardiovascular Research Institute, Kyungpook National Univ School of Medicine.*

**Background:** Malformation of primary cilia is associated with various kidney diseases such as polycystic kidney disease and ischemia/reperfusion (I/R)-induced acute kidney injury. Others have previously reported that hydrogen sulfide ($H_2S$) attenuated I/R-induced injury in hepatic, myocardial, renal I/R model. Our recent work revealed that length of primary cilia largely depends on oxidative stress and ERK activation. $H_2S$ is known to have antioxidative effect. However, the role of $H_2S$ in cilliogenesis is unknown yet.

**Methods:** To elucidate the role of $H_2S$ in cilia elongation and underlying mechanism, we investigated exogenous $H_2S$ donor NaHS and inhibitors of endogenous $H_2S$ producing enzymes propargylglycine (PAG, an inhibitor of CSE , cystathionine gamma lyase) and hydroxylamine (HA, an inhibitor of CBS , cystathionine beta synthase) in the kidney tubular epithelial cells. To determine the primary cilia length, cells were immunofluorescence stained with acetylated tubulin antibody.

**Results:** NaHS treatment increased expressions of Arl13b and Sec10 which are associated with cilia formation, and elongated primary cilia. Treatment of PAG and HA prevented the elongation of primary cilia. PAG or HA shortened the length of primary cilia. NaHS induced cilia elongation by upregulation of phopho-ERK, Sec10 and Arl13b expressions, whereas PAG and HA suppressed cilia elongation with downregulation of phopho-ERK, Sec10 and Arl13b.

**Conclusions:** Taken together, our results suggest that $H_2S$ accelerate primary cilia elongation by ERK activation, and provide a better understanding of molecular mechanism underlying cilia length regulation in the kidney.

## FR-PO189

**The Mammalian Target of Rapamycin (mTOR) Complex Gets Activated during Tight Junction Biogenesis** Laurence Poma, Jean-olivier Defraigne, Jean-marie H. Krzesinski, Francois Jouret. *GIGA Cardiovascular Sciences, ULg CHU, Liege, Belgium.*

**Background:** The tight junctions (TJ) between renal tubular cells regulate paracellular diffusion and cell differentiation. TJ disruption in acute kidney injury represents one of the earliest events. Still, the signaling network involved in TJ assembly and maintenance remains poorly characterized. The AMP-activated protein kinase (AMPK) has been implicated both *in vitro* and *in vivo* in TJ regulation. Several AMPK kinases have been identified, with Liver kinase B1 (LKB1) and $Ca^{2+}$/calmodulin-dependent protein kinase kinase β (CAMKKβ) being the main ones. In turn, AMPK coordinates various housekeeping mechanisms, including the inhibition of the mammalian target of rapamycin (mTOR) complex. Here, we pharmacologically modulated the AMPK network at the time of a $Ca^{2+}$ switch in order to further characterize TJ biogenesis.

**Methods:** The $Ca^{2+}$ switch, i.e. switching cell culture conditions from low [5 µM] to high [1.8 mM] $Ca^{2+}$ concentrations, is a widely used model to study TJ assembly in Madin-Darby canine kidney (MDCK) cells.

**Results:** A $Ca^{2+}$ switch is not only associated with AMPK phosphorylation (Thr172) and activation, as stated by the phosphorylation (Ser79) of acetyl-CoA carboxylase (ACC), but also with the activation of mTOR, as indicated by an increased phosphorylation (Thr389) of p70 S6 kinase. Incubation of MDCK cells with the AMPK activator, phenformin [5mM], in low or high $Ca^{2+}$ conditions induced AMPK and ACC phosphorylation and mTOR inhibition, as previously reported. Still, phenformin treatment at the time of a $Ca^{2+}$ switch did not prevent p70 phosphorylation. By contrast, exposure to the mTOR inhibitor, rapamycin [20nM], inhibited p70 phosphorylation, even following a $Ca^{2+}$ switch. Similarly, cell loading with the $Ca^{2+}$ chelator, BAPTA-AM [50µM], before a $Ca^{2+}$ switch abolished p70 phosphorylation, with no impact on AMPK activation. Conversely, the inhibition of CAMKK by STO-609 [50µM] at the time of a $Ca^{2+}$ switch abrogated AMPK phosphorylation but did not hamper mTOR activation.

**Conclusions:** A $Ca^{2+}$ switch in MDCK cells, which ultimately leads to TJ assembly, independently involves both the AMPK and mTOR pathways, with a differential role of intracellular $Ca^{2+}$.

**Hgf Stimulates Gsk3-Dependent Lrp5/6 Phosphorylation in Proximal Tubular Cells** Farrukh M. Koraishy,[1] Cynthia J. D'Alessandri,[3] Sherene Mason,[2] Lloyd G. Cantley.[1] *[1]Section of Nephrology, Yale Univ, New Haven, CT; [2]Section of Pediatric Nephrology, Yale Univ, New Haven, CT; [3]Section of Pediatric Nephrology, CT Children's Medical Center, Hartford, CT.*

**Background:** The signaling processes that promote renal repair after acute kidney injury (AKI) remain poorly defined. Two signaling cascades that are activated following AKI are hepatocyte growth factor (Hgf)/Met and Wnt/β-catenin pathways. A critical early event in Wnt signaling is phosphorylation of the co-receptors Lrp5/6, leading to nuclear translocation of β-catenin. We have previously demonstrated that Hgf stimulation of subconfluent TECs leads to increased nuclear β-catenin activity, due to inhibition of Gsk3 via S9 phosphorylation. In the current study we further investigated the cross-talk between these pathways.

**Methods:** Mouse proximal tubule (MPT) cells were stimulated with Hgf or Wnt3a followed by western blotting and immunoprepcitation experiments. For ischemia reperfusion injury (IRI), gGT-Cre;$Met^{fl/fl}$mice (lacking Met receptor in the proximal tubule) or γGT-Cre;$Met^{+/+}$controls were subjected to warm left kidney ischemia with contralateral nephrectomy, followed by reperfusion.

**Results:** In MPTs, Hgf was found to rapidly stimulate Lrp5/6 phosphorylation at 3 separate activation motifs with maximal effect in subconfluent, de-differentiated cells. The phosphorylation was dependent on Gsk3 kinase activity but independent of Wnt. Hgf treatment stimulated the selective association of active Y216/Y279 phosphorylated Gsk3 with Lrp5/6 while S9 phosphorylated inactive Gsk3 was excluded from this association. In vivo, Lrp5/6 phosphorylation was increased within 24 hours after IRI and this was significantly reduced in gGT-Cre;$Met^{fl/fl}$mice as compared to γGT-Cre;$Met^{+/+}$controls.

**Conclusions:** Our results identify a novel mechanism of Hgf mediated transactivation of Wnt signaling that involves the Met-dependent selective association of active Gsk3 with Lrp5/6. The likely relevance of this pathway for epithelial injury responses is supported by the observation that the initial increase in Lrp5/6 phosphorylation after renal IRI in mice is dependent on the Met receptor.

**FR-PO191**

**Tubular Secretion of Indoxyl Sulfate and Residual Renal Function** Sachin Jhawar,[1] Prabhjot Singh,[1] Jiri Zavadil,[1,2] Jerome Lowenstein.[1] *[1]Medicine, NYU Langone Medical Center, New York, NY; [2]Medicine, NYU Langone Medical Center, New York, NY; [3]WHO International Agency for Research on Cancer, NYU Langone Medical Center, New York, NY; [4]Medicine, NYU Langone Medical Center, New York, NY.*

**Background:** Residual Renal Function (RRF), persistent urine production in patients with ESRD, is associated with better patient survival, less severe atherosclerotic vascular disease, and lower plasma concentrations of a putative protein-bound, poorly dialyzable uremic toxin, indoxyl sulfate, IS. This solute is normally secreted via Organic Anion Transporters (OATs) in the proximal renal tubule rather than filtered at the glomerulus.

**Methods:** We devised a reporter system using cultured human renal tubular cells to compare gene expression profiles (using Affymetrix gene chip) in response to incubation with pre- and post-dialysis plasma from subjects with RRF (n=5) and anuric subjects (n=5). Total IS in plasma was measured by HPLC.

**Results:** Patients with RRF had lower pre- (36.3±18.7 μg/ml) and post-dialysis (19.8±12.8 μg/ml) total IS levels than patients without RRF (pre- 51.2±24.8 μg/ml, post-dialysis 27.3±11.9 μg/ml). We examined the hypothesis that plasma from subjects with RRF might display lesser activation of inflammatory pathways than plasma from patients without RRF. Patterns of gene expression in cultured cells revealed a differential response between the two groups. Our tubular cell reporter system detected broad differential biological effects of pre- and post-dialysis plasma from patients with RRF compared to those without RRF, as determined by Gene Set Enrichment Analysis. Plasma from patients without RRF elicited greater activation of the TGF-β pathway and dysregulation of additional pathways that might underlie fibrotic changes or vasculopathy.

**Conclusions:** These findings suggest a role for poorly dialyzable uremic toxins in the pathogenesis of renal scarring and uremic vasculopathy. We suggest that Residual Renal Function may reflect an important component of fluid generated by tubular secretion rather than glomerular filtrate. If true, this paradigm would warrant close attention to the avoidance of medications that compete for transport by OATs.

**FR-PO192**

**The Effect of Farnesyl ThioSalicylic Acid (FTS) on TGFb1 Signaling in Murine Proximal Tubule Epithelial Cells (PTEC)** Subash Somalanka,[1] Claire C. Sharpe,[2] Mysore Keshavmurthy Phanish,[1] Mark Edward Dockrell.[1] *[1]SWTIRR, St. Helier Hospital, London, United Kingdom; [2]Renal Medicine, Kings College, London, United Kingdom.*

**Background:** Targeting Ras-GTPases has been shown to ameliorate renal fibrosis in recent studies. Our group has published that in human PTEC, CTGF expression was upregulated by TGFβ1 in an FTS sensitive manner. Expression of CTGF is regulated by multiple signaling pathways. Hence we probed the downstream effects of TGFβ1 signaling in murine PTEC by using FTS, a Ras inhibitor.

**Methods:** Cells derived from S3 segment of murine proximal tubule of a SV40 transformed brinster transgenic mouse were used for in vitro experiments. Serum starved cells were treated with TGFβ1 [2.5ng/ml] +/- MEK inhibitor PD98059 [20uM] & FTS [5uM] for 5min & 1h for signaling studies & 24h for CTGF protein expression. Cells were pre-treated for 30min in the presence of the chemical inhibitors where appropriate. Cellular lysates were analysed by western blotting. Bio-Plex Multiplex phosphoproteins assay was used to study activation of Akt, ERK1/2, GSK-3α/β, Histone H3, JNK, MEK1 & p38MAPK.

**Results:** TGFβ1 induced 'secreted CTGF' (1.5 fold, $p<0.001$) which was inhibited by PD98059 & FTS ($p<0.001$) at 24h. TGFβ1 induced SMAD activation & phosphorylation of Histone H3 ($p<0.001$) which was inhibited in the presence of FTS [SMAD ($p<0.001$), Histone H3 ($p<0.01$)]. TGFβ1 did not induce PI3-kinase activation ($p=0.08$). The effect of FTS on ERK1/2 activation, p38 MAPK & MEK1 was significant in the presence of TGFβ1 ($p=0.032$, $p= 0.032$ & $p= 0.013$). There was no significant effect of FTS on JNK at 5 mins.

**Conclusions:** Our results show that TGFβ1-driven induction of CTGF is via the Ras/ERK pathway in murine PTECs. Investigation of intracellular signaling produced unexpected & diverse results. Surprisingly FTS inhibited canonical & non-canonical SMAD pathways including pSMAD2 linker region. Inhibition of pSmad2 linker region by FTS may be due to inhibition of GSK3β/Akt at 1h. We also demonstrate for the first time that TGFβ1 rapidly phosphorylates Histone H3 in an FTS sensitive manner. Some of the effects of FTS may not involve Ras and hence more selective Ras inhibition may require other strategies such as antisense oligonucleotides.

**FR-PO193**

**Selective Proximal Tubule Injury Causes Interstitial Fibrosis and Distal Tubule Impairment** Koji Takaori,[1] Jin Nakamura,[1] Tadashi Yamamoto,[2] Motoko Yanagita.[1] *[1]Nephrology, Kyoto Univ, Kyoto, Japan; [2]Structural Pathology, Institute of Nephrology, Niigata Univ, Niigata, Japan.*

**Background:** Recently we clarified that renal fibroblasts including erythropoietin (Epo) producing cells transdifferentiate into myofibroblast and predominantly contribute to fibrosis, with concomitant loss of Epo production in the diseased kidney. It remains unclear, however, what triggers the transdifferentiation of fibroblasts to myofibroblasts and how proximal tubule injury affects other segment of the nephron.

**Methods:** For in vitro analysis, we utilized co-culture of renal fibroblasts and tubular epithelial cells. For in vivo analysis, we utilized *N-myc downstream-regulated gene-1 (Ndrg1)CreERT2* inducible simian diphtheria toxin receptor (DTR) transgenic mice (*Ndrg1CreERT2:iDTR* mice) in which Cre-mediated excision of a STOP cassette is achieved after the administration of tamoxifen, and renders *proximal tubules* sensitive to diphtheria toxin (DT).

**Results:** First, we confirmed that DTR is expressed in almost all proximal tubules and a part of collecting duct in the kidney of *Ndrg1-CreERT2:iDTR* mice after the administration of tamoxifen. A single DT injection to these mice causes proximal tubule injury and interstitial fibrosis accompanied with the proliferation of proximal tubules and fibroblasts. We also confirmed the induction of collagen expression in fibroblasts when co-cultured with damaged tubular epithelial cells. We further demonstrated the induction of distal tubule injury after the administration of DT to *Ndrg1-CreERT2:iDTR* mice.

**Conclusions:** Our data provide the new evidence that selective proximal tubule injury induces the transdifferentiation of fibroblast as well as distal tubule impairment. These results indicate the importance of protecting tubule epithelial cells to suppress kidney disease progression. Further understanding of the crosstalk between proximal tubule and fibroblast as well as the crosstalk between proximal tubule and distal tubule will give us new insight into the mechanism of kidney disease progression.

**FR-PO194**

**Biological Properties of Klotho in the Anti-Fibrotic Process and Establishment of Cell Integrity in Coordination with Cell Signaling Pathway /Translocation of Membrane Transporters** Ken Tsuchiya,[1] Shunji Shiohira,[1] Miki Nishida,[1] Kazuhiro Okano,[2] Hidekazu Sugiura,[3] Kosaku Nitta.[1] *[1]Dept of Medicine IV, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Div of Blood Purification, Tokyo Women's Medical Univ; [3]Dept of Pathology, UT Southwestern Medical Center, Dallas.*

**Background:** Klotho, which exerts anti-aging properties, is known to be acting as an obligate co-receptor of FGF23 to regulate phosphate homeostasis, and also to be involved in Insulin/IGF1 and WNT signaling, suggesting the Klotho should play important roles in establishing specific cell functions and also more primitive cell integrity and identity.

**Methods:** We explored the biological properties of Klotho in cell differentiation and proliferation quantified by using CL-Quant software to analyze time-lapse images in a Nikon Biostation CT combining with a high-throughput cell migration assay, and cell polarity by measuring the expression of Na/K ATPase/PKD-ζ, marker of cell signaling (β-catenine) in 3D culture with collagen mixture. Internal expression of Klotho was modified by siRNA transfection.

**Results:** Recombinant Klotho suppressed the accelerated migration and expression of fibrotic markers of cultured renal fibroblast cells (NRK49F cells) in which internal Klotho expression was negligible, stimulated by TGF-β1. In addition, Quercetin, a Wnt/β-catenine inhibitor, attenuated cell migration and up-regulated E-cadherin expression, induced Klotho expression three fold of mRNA and protein in IMCD cells in which Klotho expression has been confirmed. Klotho siRNA reduced the expression of Klotho, resulting in accelerating cell migration. Moreover, addition of recombinant Klotho up-regulated adhesion molecule and Na/K ATPase/ PKC-ζ translocation to the cell membrane not association with the expression of mRNA level, and Klotho siRNA tended to suppress the effect but was not significant.

**Conclusions:** Taken together, it is likely that Klotho acts anti-fibrotic process in part medicating Wnt/β-catenine pathway and also contribute to establish cell integrity by up-regulation of cell adhesion molecules and one of possible mechanism mediating translocation of membrane transporters.

*Funding:* Government Support - Non-U.S.

**FR-PO195**

**Severe Proximal Tubular Injury after Kidney-Specific Knockdown of Stanniocalcin-1** Luping Huang, Tatiana Belousova, Jenny S. Pan, David Sheikh-Hamad. *Nephrology/Medicine, Baylor College of Medicine, Houston, TX.*

**Background:** Stanniocalcin-1 (STC1) is a paracrine/intracrine protein; it binds to the cell surface, followed by internalization to the mitochondria; it diminishes superoxide generation through induction of uncoupling proteins (UCPs). In vitro, STC1 inhibits macrophages and preserves endothelial barrier function; and transgenic mice which overexpress STC1 globally and display high serum levels of STC1 are protected from anti-GBM GN and ischemia/reperfusion (I/R) kidney injuries. To determine the phenotype following kidney-specific knockdown of STC1, we employed two novel approaches.

**Methods:** We generated STC1 shRNA Tg and scrambled shRNA Tg mice that express STC1 or scrambled shRNA, respectively, upon removal of floxed reporter [phosphoglycerate kinase (PGK)-driven EGFP]; and 2) using ultrasound microbubbles, we delivered to the kidney a plasmid that expresses Cre-recombinase directed by the endothelium specific tyrosine-protein kinase receptor-2 (Tie2) promoter – to achieve kidney endothelium-specific expression of STC1 shRNA or scrambled shRNA.

**Results:** STC1 mRNA is widely expressed in the kidney. Delivery of Tie2-Cre to STC1 shRNA Tg kidneys diminished the expression of STC1 mRNA and protein throughout the kidney 4-fold. We observed no change in STC1 mRNA or protein in similarly-treated scrambled shRNA Tg kidneys. Knockdown of STC1 in STC1 shRNA Tg kidneys was associated with: severe proximal tubular injury (segments that express AQP1) characterized by vacuolization, decreased UCP2 expression, greater generation of superoxide, activation of the unfolded protein response and initiation of autophagy and apoptosis.There was no

change in Cre protein expression in cultured and Tie2-Cre-transfected proximal tubule cells, suggesting that knockdown of STC1 expression in epithelial cells in vivo is likely related to overflow of STC1 shRNA from endothelial cells.

**Conclusions:** These novel observations suggest a critical role for STC1 in tubular epithelial survival. The above approach provides efficient tool to knockdown the expression of any gene in the kidney – avoiding confounding extra-renal effects that may be associated with global gene deletion.

### FR-PO196

**Protein Overload Induces Renal Proximal Tubular Epithelial Cell Apoptosis by Down-Regulating WNT/β-Catenin Signalling** Dickson W.L. Wong, Wai Han Yiu, Hao-Jia Wu, Ruixi Li, Joseph C.K. Leung, Loretta Y.Y. Chan, Kar Neng Lai, Sydney C.W. Tang. *Dept of Medicine, Queen Mary Hospital, The Univ of Hong Kong, Hong Kong.*

**Background:** Numerous studies have demonstrated a tubulotoxic role of excess proteins on renal proximal tubular epithelial cell (PTECs) via various signalling pathways. However, the role of Wnt/β-catenin signalling in PTECs during protein overload remains unknown.

**Methods:** Wnt/β-catenin expressions were measured in control and human serum albumin (HSA)-treated human kidney 2 (HK-2) cells by real-time PCR and Western blotting. Genetic knockdown of β-catenin was achieved using siRNA transfection. Apoptotic phenotypes were evaluated by real-time PCR and TUNEL assay.

**Results:** Upon the 4-day-HSA stimulation, gene expression of β-catenin, frizzled-receptor 1 and Wnt-1 in PTECs declined by 26%±2 ($p<0.05$, t-test), 65%±2 ($p<0.05$) and 57%±6 ($p<0.05$) versus control, respectively. Western blots showed that protein expression of cytosolic and nuclear active β-catenin decreased by 57%±8 ($p<0.05$) and 66%±8 ($p<0.05$) after 4-day HAS treatment, respectively. Simultaneously, Bax/Bcl-2 gene expression ratio increased by 31%±8 ($p<0.05$). Transfection of β-catenin siRNA into HK-2 cells up-regulated Bax/Bcl-2 gene expression ratio by 23%±7 ($p<0.05$) relative to mock transfection. HAS treatment and β-catenin siRNA transfection increased the number of TUNEL-positive cells by 70%±10 ($p<0.05$) and 73%±8 ($p<0.05$), respectively.

**Conclusions:** Protein-overload promotes tubular cell apoptosis via down-regulation of Wnt/β-catenin signalling in PTECs. **Funding:** Research Grants Council of Hong Kong (GRF grant number 7782/12M).

### FR-PO197

**Src Kinase Mediates Renal Interstitial Fibroblast Activation and Renal Fibrogenesis in Obstructive Nephropathy** Shougang Zhuang. *Dept of Medicine, Rhode Island Hospital and Alpert Medical School of Brown Univ, Providence, RI.*

**Background:** Renal Interstitial fibroblast activation and proliferation is central to the development and progression of renal fibrosis after various insults, however, the signaling mechanism regulating this process is incompletely clear.

**Methods:** In this study, we examined the role of Src, a non-receptor tyrosine kinase in renal interstitial fibroblast activation and proliferation in cultured rat renal interstitial fibroblasts and a murine model of obstructive nephropathy induced by unilateral ureteral obstruction.

**Results:** Exposure of cultured renal interstitial fibroblasts (NRK-49F) to PP1, a specific Src inhibitor, resulted in decreased expression of alpha-Smooth muscle actin and fibronectin, two hallmarks of fibroblast activation and type 1 collagen, a key extracellular matrix protein, in a dose-dependent manner. Silencing Src with siRNA also significantly inhibited the expression of these three proteins. Moreover, inhibition of Src kinase activity with either PP1 or siRNA, also blocked cell proliferation, decreased expression of cyclin D1, cyclin B1 and cyclin E and increased expression of p27 and p21. Finally, STAT3, AKT and ERK 1/2 were phosphorylated in cultured NRK-49 cells and presence. of PP1 or knockdown of Src with siRNA inhibited phosphorylation of all of them. In a murine model of obstructive nephropathy, administeration of PP1 attenuated abolished the expression of fibronectin, largely suppressed expression of α-SMA and type I collagen, and reduced the deposition of extracellular matrix proteins.

**Conclusions:** Collectively, our results reveal an important role of Src in mediating activation and proliferation of renal interstitial fibroblasts and renal fibrogenesis, and suggest that Src inhibition might be a potential therapeutic approach for treatment of chronic fibrotic kidney disease.

### FR-PO198

**20-HETE Monoglyceride Induces ERK1/2 Phosphorylation via a Cannabinoid Receptor-Mediated Signaling Pathway** Kimberly Fisher, Jianchun Chen, Jorge H. Capdevila, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

**Background:** We have previously shown that glycerol derivatives of epoxyeicosatrienoic acid activate cannabinoid receptors in the kidney. The present study was designed to investigate whether monoglycerol derivatives of the cyp450 arachidonic acid metabolite, 20-HETE are present endogenously and activate cannabinoid receptors.

**Methods:** For measuring distribution of 20-HETE in mouse plasma, we identified pools by resolution of plasma extracts by TLC on $SiO_2$ plates using mixtures of hexane/ether/acetic acid as solvent. Pools with Rfs corresponding to triglycerides (TG) diglycerides (DG) and monoglycerides (MG) were collected from the plates and submitted to alkaline hydrolysis, and the released 20-HETE quantified by UPLC/MS/MS by collision induced fragmentation, and product ion monitoring. To analyze the effect of 20-HETE and 20-HETE MG on ERK1/2 phosphorylation, Chinese hamster ovary (CHO) cells were transiently transfected with plasmid vector, CB1 (cannabinoid receptor-1), or CB2 (cannabinoid receptor-2), then stimulated with 20-HETE or 20-HETE MG for 10 minutes. Cannabinoid receptor-specific inhibitors were used to determine the role of CB1 and CB2 in the phosphorylation of ERK1/2 resulting from 20-HETE MG stimulation.

**Results:** 20-HETE was prevalent in mouse plasma, and 90% of the 20-HETE was found to be esterified. Immunoblot analysis demonstrated that in CHO cells transfected with either CB1 or CB2 cannabinoid receptors, ERK1/2 phosphorylation increased 3.5-fold ($p<0.05$, $N=5$) after stimulation with 20-HETE MG, but not when treated with non-esterified 20-HETE. ERK1/2 phosphorylation by 20-HETE MG was blocked by the CB1- and CB2-specific inhibitors, AM251 or AM630, respectively.

**Conclusions:** In summary, these studies suggest that 20-HETE in plasma circulates predominantly in an esterified form, and 20-HETE monoglyceride might serve as endocannabinoid. Further studies will be required to elucidate the physiologic and/or pathophysiologic role of this novel compound.

*Funding:* NIDDK Support, Veterans Affairs Support

### FR-PO199

**Phenylbutyric Acid, an ER Chemical Chaperone, Protects against Renal Fibrogenesis In Vivo and In Vitro** Ching-chin Yang,[1] Cheng-tien Wu,[1] Shing-Hwa Liu,[1] Chih-Kang Chiang.[1,2,3] *[1]Institute of Toxicology, National Taiwan Univ, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ, Taipei, Taiwan; [3]Dept of Integrated Diagnostics & Therapeutics, National Taiwan Univ Hospital, Taipei, Taiwan.*

**Background:** Renal tubulointerstitial fibrosis is the common and final pathologic changes of end-stage renal disease (ESRD). Our recent works demonstrated that endoplasmic reticulum (ER) stress contributed to the pathophysiological mechanisms during the development of renal fibrosis. We found that up-regulation of transforming growth factor-β (TGF-β) is associated with the activation of ER stress in the rat unilateral ureteral obstruction (UUO) renal fibrotic model. ER stress-related signals might lead to renal tubular apoptosis and fibrosis. However, the detail mechanisms that ER stress involved in the renal injury and fibrosis have not been completely clarified.

**Methods:** In this study, we applied ER chemical chaperon, sodium 4-phenylbutyrate (4-PBA), in the rat UUO renal fibrosis model and the normal rat kidney epithelial cells (NRK-52E). We explored the modulation of ER-associated signals and profibrotic pathways by 4-PBA.

**Results:** By using this ER-related chemical chaperon to mimics endogenous ER chaperon, we successfully enhanced the effects of unfolded protein response (UPR) in the UUO model. We found that 4-PBA successfully attenuated UUO-induced ER stress, which associated with the suppression of profibrotic factors, including collagen, fibronectin, plasminogen activator inhibitor-1 and connective tissue growth factor. In addition, we also shown that tubulointerstitial injury, renal apoptosis and fibrosis were attenuated by the administration of 4-PBA in the UUO rats. In vitro model, we also demonstrated that 4-PBA attenuated TGF-β-induced ER stress, tubular apoptosis and profibrotic factors activation in the NRK-52E. We successfully demonstrated that the attenuation of ER stress led to lesser renal apoptosis and fibrosis.

**Conclusions:** These results indicate that 4-PBA may have therapeutic potential in renal fibrosis. It is deserve to explore the potential ER stress targets in preventing renal fibrosis.

### FR-PO200

**c-Cbl, a Ubiquitin E3 Ligase That Targets Active β-Catenin–A Novel Layer of Wnt Regulation** Sowmya Shivanna, Vipul C. Chitalia. *Dept of Medicine/ Renal Section, Boston Univ Medical Center, Boston, MA.*

**Background:** Regulation of transcriptionally active nuclear β-catenin during Wnt-on phase is crucial to ensure controlled induction of Wnt target genes. Several ubiquitin E3 ligases are known to regulate cytosolic β-catenin during Wnt-off phase, but little is known about the fate of active nuclear β-catenin in Wnt-on phase.

**Methods:** Following methods were employed: Cell culture, transfection, western blotting, immunoflorescence, cellular fractionation, luciferase assay, ELISA.etc., as per reference literature.

**Results:** We now describe ubiquitination of active β-catenin in Wnt-on phase by a RING finger ubiquitin E3 ligase, Casitas B-lineage lymphoma (c-Cbl) in endothelial cells (EC). c-Cbl binds preferentially to nuclear active β-catenin in Wnt-on phase via armadillo repeat region. Wild-type c-Cbl suppresses and E3 ligase-deficient c-Cbl-70Z increases Wnt signaling. Wnt induces nuclear translocation of c-Cbl where it ubiquitinates nuclear β-catenin. Deletion of c-Cbl UBA domain abrogates its dimerization, binding to β-catenin, Wnt-induced c-Cbl nuclear translocation and ubiquitination of nuclear β-catenin. c-Cbl activity inhibits pro-angiogenic Wnt targets IL-8 and VEGF levels and angiogenesis in β-catenin-dependent manner.

**Conclusions:** This study defines for the first time c-Cbl as an ubiquitin E3 ligase that targets nuclear active β-catenin in Wnt-on phase and uncovers a novel layer of regulation of Wnt signaling.

**Cross Talk between p66ShcA and p70S6K Determines Kidney Cell Injury in HIV-Associated Nephropathy** Partab Rai, Tejinder Singh, Rivka Lederman, Andrei Plagov, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

**Background:** HIV-associated nephropathy (HIVAN) is characterized by both proliferative and apoptotic kidney cell phenotypes. Recently we demonstrated the activation of mTOR pathway leading to proliferative as well as activation of p53 pathway leading on to apoptotic phenotype in HIVAN. Thus, we hypothesize that a cross talk between down stream signaling molecules of mTOR (p70S6K) and p53 (p66ShcA) determines the fate of kidney cells in HIVAN.

**Methods:** Renal tissue lysates of sex and age matched control, Tg26/p66$^{+/+,}$ Tg26/p66$^{+/-}$ mice were evaluated for phospho-p70S6K and downstream signaling. To determine the effect of modulation of p70S6K, control and Tg26 mice were administered either normal saline or rapamycin(5mg/Kg/every other day, intraperitoneally) for 4 weeks. Renal tissue lysates were probed for phospho-p66ShcA and total p66ShcA. For *in vitro* studies, mouse proximal tubular cells (MTC) were transduced with either empty vector (EV/MTC) or NL4-3 (HIV/MTC) and transfected with either siRNAp66, siRNAp70S6K, and scrambled siRNA. Subsequently, protein blots were probed for p66ShcA, p70S6K and actin. To study molecular binding, EV/MTC and HIV/MTC lysates were immunoprecipitated with anti- p66ShcA antibody and probed for p70S6K. To display functional relationship, siRNAp66-HIV/MTC and siRNAp70S6K-HIV/MTC were assayed after co-labeling with H2AX (for DNA damage) and KU80 (DNA repair).

**Results:** TG26/p66$^{+/-}$ mice displayed attenuated renal tissue expression of phospho-p70S6K, whereas, Tg26/Rapa mice displayed attenuated expression of p66ShcA. HIV/MTC displayed enhanced expression of phospho-p66ShcA and phospho-p70S6K. MTC silenced for p66ShcA displayed attenuated expression of phospho-p70S6K, whereas, MTC silenced for p70S6K exhibited attenuated expression of p66ShcA both under control and HIV milieus. EV/MTC and HIV/MTC lysates immunoprecipitated with anti-p66 antibody demonstrated expression of p70S6k. HIV/MTC silenced for either p66 or p70S6K displayed attenuated DNA damage and enhanced DNA repair.

**Conclusions:** Cross talk beween p66 and p70S6K plays a key role in the induction of tubular cell injury in HIVAN.

**Age-Related Nrf2-Keap1 Signaling System Change in the Kidney** Seun Deuk Hwang, Eun Nim Kim, Keun Suk Yang, Myung Hyun Lee, Ji Hyun Yu, Yul Hee Cho, Chul Woo Yang, Cheol Whee Park, Yong-Soo Kim, Bum-Soon Choi. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ, Seoul, Korea.*

**Background:** Aging is a multifactorial process characterized by a progressive decline in physiological function. Therefore, increasing our insight into kidney aging by understanding the anatomic, physiologic, and pathologic changes of aging in the kidney is important to prevent disastrous outcomes in elderly people.

**Methods:** Male 2-, 12-, and 24-month-old C57/BL6 mice were used in this study. We measured histological change, oxidative stress, aging-related protein expression in the kidneys.

**Results:** Twenty-four-month-old mice displayed increased albuminuria. Creatinine clearance decreased with aging, although this was not statistically significant. There were increases in mesangial volume and tubulointerstitial fibrosis in 24-month-old mice. There were also increases in F4/80 expression ps and in apoptosis detected by TUNEL. Urine isoprostane excretion increased with aging and SOD1 and SOD2 were decreased in 24-month-old mice. In our study, expression of Nrf2 in total protein(1 ± 0.2 fold vs. 1.02 ± 0.12 fold, 1.31 ± 0.24 fold)was not decreased in 24-month-old mice. However, Nrf2 expression in nuclear (1 ± 0.44 fold vs. 1.94 ± 0.7 fold, 1.61 ± 0.46 fold; $p < 0.05$ vs. 24M) and in nuclear/total protein ratio (1 ± 0.82 fold vs. 1.83 ± 0.6 fold, 1.08 ± 0.38 fold; $p < 0.05$ vs. 24M) were decreased in 24-month-old mice. Keap1 expression (1 ± 0.16 fold vs. 0.93 ± 0.12 fold, 1.15 ± 0.35 fold) was increased in 24-month-old mice compared with 2-, 12-month-old mice. HO-1 (1 ± 0.08 fold vs. 9.39 ± 0.81 fold, 8.87 ± 0.51 fold) and NQO-1 (1 ± 0.01 fold vs. 0.87 ± 0.19 fold, 0.93 ± 0.24 fold) were decreased in 24-month-old mice compared with 12-month-old mice, although this was not statistically significant.

**Conclusions:** Nrf2 was decreased with aging and may relate to antioxidant pathway. Nrf2 suppression and Keap1 activation with aging could induce oxidative stress, leading to decrease in antioxidant gene expression such as HO-1 and NQO-1. Pharmacologically targeting these signaling molecules may reduce the pathologic changes of aging in the kidney.

**FR-PO203**

**Palladin Is Required for Proper Function of Kidney Cells** Emily H. Chang,[1,3] J. Charles Jennette,[1,2] Ronald J. Falk,[1] Carol A. Otey.[3] *[1]UNC Kidney Center, UNC-Chapel Hill, Chapel Hill, NC; [2]Dept of Pathology and Laboratory Medicine, UNC-Chapel Hill, Chapel Hill, NC; [3]Dept of Cell Biology and Physiology, UNC-Chapel Hill, Chapel Hill, NC.*

**Background:** Palladin is an actin associated protein with multiple isoforms involved in development, wound healing and tumor metastasis. Previous work localizes isoform 4 to multiple kidney cell types. We show differential expression of multiple isoforms in kidney in health and disease and that abrogation affects cell function.

**Methods:** For immunohistochemistry (IHC), mouse kidney was stained with antibodies to palladin. Cells in culture were treated with TGF-β1 or low calcium and lysed for immunoblot or fixed for immunofluorescence (IF) staining. siRNA palladin knockdown cells were used in migration assays, fixed for IF or treated with TGF-β1/low calcium.

**Results:** IHC in normal mice shows palladin in glomeruli, vessels and tubules. Antibodies to different isoforms show cell specific expression: isoform 4 to proximal tubules and glomeruli, isoform 3 to distal tubules, and isoform 6 to nuclei of tubular cells. When injured by ischemia reperfusion, palladin expression in tubular cells increases and moves to the nucleus. In an α-MPO ANCA model, in addition to tubules, cellular crescents are intensely immunopositive. To explore palladin function, we used LLC-PK1 cells where palladin is present at baseline at very low levels in the cytosol by immunoblot and IF. TGF-β1 increases palladin expression primarily on actin stress fibers. Low calcium increases palladin expression further with localization to stress fibers, actin rings and nuclei. Isoform 4 knockdown results in loss of stress fiber localization, although stress fibers still form with TGF-β1. When wounded by scratch, cell migration is impaired. Isoform 6 knockdown leads to lethality.

**Conclusions:** Palladin isoforms are differentially expressed in the kidney in health and disease. Isoform 4 is necessary for proper cell migration, and isoform 6, which localizes to the nucleus, is critical as the knockdown is not viable. Understanding the different functions of the palladin isoforms may identify targets of intervention to protect against kidney injury.

**FR-PO204**

**Targeting the Ubiquitin-Proteasome System in Complement-Mediated Glomerular Injury** Kapil Sareen-Khanna, Simon S. Wing, Andrey V. Cybulsky. *Medicine, McGill Univ, Montreal, Canada.*

**Background:** In experimental membranous nephropathy, complement C5b-9 induces sublethal glomerular epithelial cell (GEC) injury and proteinuria. In parallel, C5b-9 activates pathways to restrict injury. GEC injury is associated with protein misfolding in the endoplasmic reticulum (ER), and blocking the ubiquitin-proteasome system (UPS) exacerbates injury and proteinuria. We tested if enhancement of UPS function may confer protection against complement-mediated GEC injury. Certain deubiquitinating enzymes, including ubiquitin specific protease-14 (USP14), retard protein degradation by the proteasome. Thus, inhibition of USP14 may potentially enhance degradation of misfolded proteins, and attenuate cell injury.

**Methods:** To assemble complement C5b-9, cultured GECs were incubated with antiserum and normal serum. GFP$^u$ (green fluorescent protein fused with the CL1 degron), a misfolded protein, and CD3δ, an ER-associated degradation (ERAD) substrate, were used as reporters of the UPS and ERAD, respectively. The two reporters, as well as human disease-associated nephrin mutants (I171N and S724C), which are misfolded and undergo ERAD, were expressed by transient transfection.

**Results:** In GECs, GFP$^u$ and CD3δ reporters undergo time-dependent proteasomal degradation. The USP14-directed inhibitor, IU1, accelerated degradation of GFP$^u$ and CD3δ. Conversely, overexpression (by transient transfection) of USP14, but not a catalytically-inactive USP14 mutant, reduced degradation of GFP$^u$ and CD3δ. IU1 did not modify global ubiquitination of proteins. In 293T cells, IU1 tended to enhance degradation of the I171N and S724C nephrin mutants, but the change was not significant. Incubation of GECs with complement did not affect expression of CD3δ significantly, but accelerated degradation of GFP$^u$, and this degradation was further accelerated by IU1. However, IU1 did not alter complement-induced cytotoxicity in GECs.

**Conclusions:** USP14 controls proteasomal degradation of some, but not all, misfolded proteins. Thus, targeting USP14 may be useful in alleviating the proteotoxic effects of specific misfolded proteins. USP14 inhibition was not effective in reducing cytotoxicity in the context of global protein misfolding.

**FR-PO205**

**Lack of the Small Ribosomal Protein S6 Phosphorylation Inhibits Compensatory Renal Hypertrophy** Jinxian Xu,[1] Jianchun Chen,[2] Jian-Kang Chen.[1] *[1]Experimental Medicine, Georgia Regents Univ, Augusta, GA; [2]Medicine, Vanderbilt Univ, Nashville, TN.*

**Background:** Nephron loss stimulates increases in cell size, with minimal cell proliferation, in the residual nephrons. This phenomenon is known as compensatory renal hypertrophy (CRH). Previous studies have demonstrated that activation of the mammalian target of rapamycin complex 1 (mTORC1)-S6 kinase 1 (S6K1) pathway is a major mechanism underlying CRH. However, the downstream effector of the mTORC1-S6K1 pathway that mediates CRH remains unknown, because multiple potential downstream phosphorylation targets of S6K1 have been reported.

**Methods:** We backcrossed S6 knock-in mice to the FVB/NJ background for 10 generations and produced congenic mice expressing unphosphorylatable S6 (*S6$^{P-/-}$*). 6-week-old *S6$^{P-/-}$* mice, along with their wild type littermates (*WT*), were subjected to induction of CRH by right uninephrectomy (UNX).

**Results:** *S6$^{P-/-}$* mice and *WT* mice had similar body weight and kidney-to-body weight ratios (K/Bwt). Compared with *WT* mice, UNX-induced CRH in *S6$^{P-/-}$* mice was blocked by 50-60%, assessed by increases in K/Bwt (41.40±4.04 vs. 18.54±3.40%; $P<0.01$, $n=7$-9) and increases in protein-to-DNA ratios (29.33±5.37 vs. 12.57±6.04%; $P<0.05$, $n=5$-9). UNX markedly induced S6 phosphorylation in the remaining kidney of *WT* mice, but no S6 phosphorylation was detected in *S6$^{P-/-}$* mice. However, the phosphorylation of S6K1 and the eukaryotic translation initiation factor(eIF) 4E-binding protein 1 (4E-BP1) was stimulated to equivalent levels in *S6$^{P-/-}$* mice and *WT* mice in response to UNX, indicating that mTORC1 is still activated in both *S6$^{P-/-}$* mice and *WT* mice. There was no change in

BUN levels in *WT* mice and *S6*$^{P-/-}$ mice after UNX. Ki67 staining revealed comparable minimal increases in cell proliferation in the remaining kidney of *WT* mice and *S6*$^{P-/-}$ mice in response to contralateral nephrectomy.

**Conclusions:** This study provides the first unequivocal evidence that phosphorylated S6 is the major downstream effector of the mTORC1-S6K1 activation that mediates 50-60% of the hypertrophy seen in wild type mice. Our data also suggest the existence of additional signaling pathways that mediate 40-50% of compensatory renal hypertrophy.

## FR-PO206

**Role of Retinol Dehydrogenase 9 in Podocyte Injury** Xuezhu Li,[1,2] Yan Dai,[3] Peter Y. Chuang,[1] John C. He.[1] *[1]Div of Nephrology, Mount Sinai School of Medicine; [2]Div of Nephrology, Shanghai East Hospital, China; [3]Div of Nephrology, Shanghai First People's Hospital, China.*

**Background:** Intracellular concentration of retinoic acid (RA) is determined by two sequential oxidation reactions that convert retinol to retinoic acid. Kidney is a major organ for RA metabolism. Our previous work demonstrated that RA synthesis is significantly less in glomeruli of HIV-1 transgenic mice (Tg26) and the expression of retinol dehydrogenase (RDH) 9, which catalyzes the rate-limiting step in RA synthesis, is downregulated. Since it is known that RA has renal protective effects and is able to induce podocyte differentiation, we hypothesize that restoration of RA synthesis could slow the progression of renal disease.

**Methods:** We compared the expression of podocyte differentiation marker in cultured murine podocytes infected with an HIV-1 provirus with or without RDH9 overexpression. Mice with tetracycline (tet)-inducible, podocyte-specific RDH9 overexpression (POD-RDH9$^{Ovx}$) were generated. We examined the effect of podocyte-specific overexpression of RDH9 on glomerular injury in two murine models of podocyte injury: HIV-associated nephropathy (HIVAN) and Adriamycin (ADR) nephropathy. Podocyte differentiation markers and cell proliferation makers were examined by immunostaining. Proteinuria was measured by urinary albumin ELISA. PAS stained sections were used to assess glomerular histololgy.

**Results:** Overexpression of RDH9 in cultured podocytes induced podocyte differentiation. Inducible overexpression of RDH9 in podocyte of Tg26 mice decreased proteinuria, increased podocyte differentiation markers, and reduced glomerular expression of cell proliferation makers. Overexpression of podocyte RDH9 also attenuated ADR-induced proteinuria and glomerulosclerosis.

**Conclusions:** Our data suggests that restoration of RA synthesis mitigates podocyte injury.

## FR-PO207

**Telmisartan Activates Endogenous Peroxisome Proliferator-Activated Receptor-δ and May Have Anti-Fibrotic Effects in Human Mesangial Cells** Daisuke Mikami,[1] Hideki Kimura,[2] Kazuko Kamiyama,[1] Kunio Torii,[2] Seiji Yokoi,[1] Yoshinari Yokoyama,[1] Naoki Takahashi,[1] Kenji Kasuno,[1] Masayuki Iwano.[1] *[1]Div of Nephrol, Sch of Med, Univ of Fukui, Fukui, Japan; [2]Dept of Clin Nephrol, Univ of Fukui Hosp, Japan.*

**Background:** Telmisartan (Telm), an angiotensin II receptor type 1 blocker (ARB), was recently reported to promote lipolysis in mice by acting as a peroxisome proliferator-activated receptor (PPAR)-δ activator, although in clinical studies, it has also been recognized to activate PPAR-γ as a major cause of its pleiotropic actions. Whether Telm activates endogenous PPAR-δ and thereby exerts anti-fibrotic effects in human mesangial cells (HMC) remains to be investigated.

**Methods:** Presence of PPAR-δ in human renal tissues was examined by immunohistochemistry. Confluent HMC were treated for 6-24h with Transforming growth factor-β1 (TGF-β1; 10-50pg/ml) in absence or presence of Telm (10 μM). PPAR activity was determined by PPRE-luciferase assay, spcific antagonists, and PPAR gene silencing.

**Results:** PPAR-δ was detected in mesangial cells of glomeruli with moderately proliferative changes. In HMC, both GW0742, an authentic PPAR-δ agonist, and Telm enhanced PPRE-luciferase activity dose-dependently, and these increases were blunted by GSK0660, a PPAR-δ antagonist, but not GW9662, a PPAR-γ antagonist. Telm also upregulated the expression of PPAR-δ target genes related to fatty acid oxidation; i.e., fatty acid-binding protein and uncoupling protein-2. These effects were inhibited by both PPAR-δ antagonism and PPAR-δ gene silencing. TGF-β1 increased the expression of plasminogen activator inhibitor-1 (PAI-1) and TGF-β1, main profibrotic factors, at least in part via the phosphorylation of extracellular signal-regulated kinases (pERK). Telm suppressed TGF-β1-stimulated PAI-1 expression and pERK, and these effects were weakened by PPAR-δ antagonism, whereas eprosartan, a non-PPAR activating ARB, did not affect TGF-β1-stimulated PAI-1 expression.

**Conclusions:** In HMC, Telm activates endogenous PPAR-δ and may prevent TGF-β1-induced fibrotic changes by reducing ERK phosphorylation in a PPAR-δ-dependent manner, and thus, might be useful for treating hypertensive patients with renal and metabolic disorders.

## FR-PO208

**Role of Calcium-Independent Phospholipase $A_2\gamma$ in Endoplasmic Reticulum Stress** Hanan Elimam, Tomoko Takano, Andrey V. Cybulsky. *Medicine, McGill Univ, Montreal, Canada.*

**Background:** Several glomerular diseases are associated with activation of endoplasmic reticulum (ER) stress and the unfolded protein response (UPR). In the UPR, upregulation of ER chaperones, including Grp94 and Grp78, enhances ER protein folding capacity and may limit cytotoxicity. Recently, we showed that the calcium-independent phospholipase $A_2\gamma$ (iPLA$_2\gamma$) is localized at the ER, that complement C5b-9 activates iPLA$_2\gamma$ and that the iPLA$_2\gamma$ pathway is cytoprotective. The present study addresses whether the cytoprotective effect of iPLA$_2\gamma$ involves the UPR.

**Methods:** iPLA$_2\gamma$ was overexpressed in cultured glomerular epithelial cells (GEC) by transient transfection. To activate the UPR, cells were treated with tunicamycin or thapsigargin. iPLA$_2\gamma$ activity was monitored by prostaglandin $E_2$ (PGE$_2$) production. UPR activation was monitored by immunoblotting for ER chaperones and C/EBP homologous protein (CHOP), and by an activating transcription factor 6 (ATF6) luciferase reporter assay.

**Results:** Tunicamycin and thapsigargin stimulated production of PGE$_2$ in GEC and this effect was amplified by overexpressing iPLA$_2\gamma$. Amplified PGE$_2$ production was blocked by the iPLA$_2\gamma$-specific inhibitor, R-bromoenol lactone (R-BEL). Tunicamycin and iPLA$_2\gamma$ independently stimulated ATF6 reporter activity, and iPLA$_2\gamma$ amplified the effect of tunicamycin. Amplified ATF6 activity was inhibited by R-BEL, but not indomethacin, a cycloxygenase inhibitor. Tunicamycin and thapsigargin increased Grp94 and Grp78. This effect was amplified by overexpression of iPLA$_2\gamma$, and was reduced by R-BEL, but not indomethacin. Tunicamycin stimulated induction of CHOP, but unlike ER chaperones, stimulation of CHOP was not modulated by iPLA$_2\gamma$. Tunicamycin-induced cytotoxicity (lactate dehydrogenase release) was reduced in GEC overexpressing iPLA$_2\gamma$.

**Conclusions:** In GEC, induction of ER stress activated iPLA$_2\gamma$, and overexpression of iPLA$_2\gamma$ amplified the ATF6 pathway of the UPR, resulting in upregulation of ER chaperones and cytoprotection. These effects were dependent on iPLA$_2\gamma$ catalytic activity, but not prostanoids. Thus, iPLA$_2\gamma$ may regulate the UPR via effects on ER membrane lipids. Modulating iPLA$_2\gamma$ activity may provide therapeutic opportunities for glomerular diseases.

## FR-PO209

**Altered Monocyte Expression and Expansion of CD14$^+$CD16$^+$ Subset in IgA Nephropathy Patients** Sharon N. Cox,[1] Grazia Serino,[1] Fabio Sallustio,[1,2] Francesco Pesce,[1,3] Francesco Paolo Schena.[1,2,4] *[1]Emergency and Organ Transplantation Dept, Univ of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy; [3]Genomics of Common Disease, Imperial College, London, United Kingdom; [4]Schena Foundation, Research Center of Kidney Diseases, Valenzano, Bari, Italy.*

**Background:** The basic defect of IgA nephropathy (IgAN) lies within peripheral blood mononuclear cells rather than local kidney abnormalities. Previously we showed an altered gene expression in monocytes compared to B and T cells isolated from IgAN patients (Kidney Int, 2010), thus our aim here was to study this subset more closely at genomewide level.

**Methods:** 33 IgAN patients and 33 healthy blood donors (HBD) were studied. Microarrays were used to evaluate global differences in gene expression between monocytes of IgAN patients and HBD. Bioinformatic analysis was done with GenomeStudio, Genespring. The connectivity between genes was evaluated by IPA. Aberrantly expressed genes/pathways were validated on an independent cohort by RT-PCR, Western blot and flow cytometric analysis.

**Results:** We revealed 710 deregulated probes in IgAN patients' monocytes (FDR-p <0.05). Probes were primarily involved in apoptosis signalling, mitochondrial dysfunction, tnfr2/1 and death receptor signaling canonical pathways. Representative genes belonging to these pathways (*TNF, CD83, TNFRSF1A, NDUFS3*) were validated with RT-PCR. All mitochondrial respiratory chain subunits were found up regulated in IgAN patients, in particular the protein levels of NDUFS3(p=0.003) thus confirming the aberrant mithocondrial homeostasis. The enhanced apoptotic phenotype was confirmed at protein level with a higher percentage of Annexin-V/7-AAD positive staining. In monocytes of IgAN patients the CD14$^+$CD16$^+$ subset was significantly expanded in all IgAN patients, still maintaining the same total monocyte count.

**Conclusions:** Our findings demonstrate an aberrant modulation of the mitochondrial respiratory system in monocytes isolated from IgAN patients. Furthermore, the aberrant expansion of the CD14$^+$CD16$^+$ subset in IgAN patients could explain the enhanced apoptotic function of these cells in IgAN patients.

**Deficiency in Apoptosis Inducing Factor Predisposes to Chronic Kidney Disease Independent of a Decline in Complex I Activity or Assembly**
Melinda T. Coughlan,[1] Gavin Higgins,[1] Sean McGee,[2] David Thorburn,[3] Mike Ryan,[4] Vicki Thallas,[1] Mark E. Cooper,[1] Josephine Forbes.[5] *[1]Baker IDI Heart & Diabetes Institute, Melbourne, Victoria, Australia; [2]Metabolic Research Unit, Deakin Univ, Geelong, Victoria, Australia; [3]Murdoch Children's Research Institute, Melbourne, Victoria, Australia; [4]La Trobe Institute for Molecular Sciences, Melbourne, Victoria, Australia; [5]Glycation & Diabetes, Mater Medical Research Institute, Brisbane, Queensland, Australia.*

**Background:** Deficiency in apoptosis inducing factor (AIF) results in a syndrome likened to disorders of oxidative phosphorylation with a functional loss of complex I activity. Complex I deficiency can also manifest as chronic kidney disease. Here, we have studied Harlequin hemizygous mice (Hq/Y), which are postulated to have defects in both complex I activity and assembly as a result of reduced *Aif* expression.

**Methods:** Eight week old wild type (WT, B6CBACa-A) and Hq/Y mice were rendered diabetic with streptozotocin and followed for 10 weeks. Metabolic caging to obtain 24 hour urine collections was performed at week 10, mice were killed and renal cortical mitochondria were freshly isolated and markers of mitochondrial function were assessed.

**Results:** Hq/Y mice demonstrated progressive renal dysfunction compared with WT mice, which was worsened by diabetes. The renal phenotype was associated with alterations in mitochondrial ATP synthesis and $O_2$ consumption that were exacerbated by diabetes. However, there was no loss of complex I activity or assembly despite a lower AIF protein content. Human primary proximal tubule epithelial cells (PTECs) exposed to high glucose had loss of *AIF* expression and impaired cellular respiration, which was rescued by overexpression of *AIF*. Control and diabetic Hq/Y and WT diabetic mice demonstrated renal cortical mitochondrial swelling and fragmentation and upregulation of proteins involved in mitochondrial fission.

**Conclusions:** These studies demonstrate that AIF deficiency is a risk factor for chronic kidney disease. This risk is not dependent on complex I activity or assembly but relates to specific changes in mitochondrial function in the renal cortex.

*Funding:* Government Support - Non-U.S.

**Human and Mouse EGF Ligand and Receptor Expression in Chronic Kidney Disease**
Shannon Marie Harlan, Derek D. Yang, Jon Wilson, Matthew D. Breyer, Josef G. Heuer. *Biotherapeutic Discovery Research, Eli Lilly and Company, Indianapolis, IN.*

**Background:** The type 1 growth factor receptor (T1GFR) family consists of EGFR, ERBB2, ERBB3, and ERBB4. Accumulating evidence implicates TGFα and other T1GFR ligands in progression of chronic kidney disease (CKD). The purpose of this study was to determine whether renal T1GFR-ligand or receptor levels are altered in human CKD and experimental renal disease.

**Methods:** Kidney tissue, serum and urine samples were obtained from normals or patients with CKD for mRNA expression by Taqman. Serum creatinine and albuminuria was also measured. TGFα protein levels were obtained by ELISA. Microarray analysis by gene chip was done to determine mRNA expression in human podocytes, glomerular endothelial, mesangial and proximal tubule cells which was confirmed by Taqman. Analysis of ligand production from cultured cells was done by specific ELISA assays. The effects of ligands on cultured cells were determined by microarray gene chip analysis as well as cell migration and proliferation assays.

**Results:** mRNA expression of EGF family member ligands including TGFα, Hb-egf and the neuregulins were upregulated in kidneys from CKD patients versus normals. These ligands were also expressed in cultured renal cells. Serum and urine TGFα protein was also significantly elevated in CKD patients and serum TGFα showed a significant positive correlation with serum creatinine. In situ hybridization showed TGFα mRNA was localized to tubules and glomerular podocytes in human and mouse kidneys. Glomerular size, urine TGFα and glomerular EGFR phosphorylation were all significantly elevated in uniNx db/db mice. TGFα induced mesangial cell proliferation and podocyte cell migration *in vitro* and induced the expression of several genes associated with proliferation, inflammation, extracellular matrix and cell migration in podocytes.

**Conclusions:** TGFα levels are elevated in both clinical and experimental CKD and the activity of TGFα on podocytes and mesangial cells is consistent with of a role in disease progression. Other members of this growth factor family are also upregulated in CKD and may also contribute to disease progression.

**Mizoribine Suppresses Pyroptosis and Ameliorates Renal Inflammation in Aldosterone-Salt Treatment Treated Rats**
Toshiki Doi, Ayumu Nakashima, Shigehiro Doi, Takao Masaki. *Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

**Background:** It has been reported that aldosterone-salt treatment induces massive inflammation that contributes to fibrosis in the rat kidney. However, the mechanism underlying renal inflammation remains unclear. Recently, pyroptosis has been recognized as a new type of cell death that is accompanied by activation of inflammatory cytokines. We hypothesized that aldosterone-salt treatment induced pyroptosis and that mizoribine, an effective immunosuppressant, would ameliorate renal inflammation and fibrosis.

**Methods:** Six-week-old male Sprague-Dawley rats underwent left uninephrectomy under anesthesia. Ten days after recovery from surgery, rats were given 1% NaCl to drink. Rats were divided into three groups (n = 7 per group): (1) vehicle infusion, (2) 0.75 μg/hour aldosterone infusion, or (3) aldosterone infusion plus a three mg/kg/day oral dose of mizoribine. All rats were sacrificed six weeks after the start of treatment. Renal tissues were assessed by terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining and Western blot analysis of caspase-1.

**Results:** TUNEL-positive cells and expression of active caspase-1 increased in rats with aldosterone-salt treatment, indicating that pyroptosis was induced by aldosterone-salt treatment in vivo. T lymphocyte and macrophage infiltration were also observed in aldosterone-salt treated rats as well as glomerulosclerosis and interstitial fibrosis. Oral administration of mizoribine suppressed both the number of TUNEL-positive cells and expression of active caspase-1 and it ameliorated renal inflammation and fibrosis.

**Conclusions:** These results suggest that pyroptosis plays an important part in the development of renal injury induced by aldosterone-salt treatment and immunosuppressants could be a rationale therapy.

**FR-PO213**

**Calcineurin Is Involved in Pathological but Not Adaptive Hypertrophy of the Kidney**
Clintoria R. Williams,[1,2] Brandi M. Wynne,[1] Jennifer L. Gooch.[1,2] *[1]Dept of Medicine / Renal Div, Emory Univ, Atlanta, GA; [2]Atlanta Veterans Affairs Medical Center, Decatur, GA.*

**Background:** Calcineurin is well described as a mediator of hypertrophy of the heart and skeletal muscle. Interestingly, calcineurin's involvement appears to be specific for pathological forms of cardiac hypertrophy such as aortic banding and not adaptive forms of hypertrophy such as exercise-induced. Previously, our laboratory showed that calcineurin inhibition blocks whole kidney and glomerular hypertrophy in STZ-induced diabetic rats. More recently, we identified a specific role for the beta isoform of the catalytic subunit of calcineurin (CnAβ) in high glucose-mediated hypertrophy in vitro and in vivo. Activation of CnAβ, in turn, transcriptionally up-regulates Nox4 expression and oxidative stress.

**Methods:** In the current study, we investigated the role of calcineurin in adaptive renal hypertrophy of the remaining kidney following uninephrectomy (UNX). Kidneys were harvested from sham versus UNX WT, CnAα-/-, and CnAβ-/- mice. Total kidney size, renal function, reactive oxygen species (ROS) production, CnAβ activity and Nox4 expression were examined.

**Results:** As expected, UNX induced a significant increase in kidney size in WT mice. Although SHAM kidneys from CnAα-/- mice are smaller, UNX caused an increase in size consistent with adaptive hypertrophy. SHAM CnAβ-/- kidneys were comparable to WT. UNX also induced hypertrophy in CnAβ-/- mice indicating that neither isoform of calcineurin is required for adaptive renal hypertrophy. Consistent with a calcineurin-independent pathway, analyses of the remaining kidneys showed no increase in CnAβ expression or activity. In addition, ROS generation is not increased and there is no change in Nox4 expression.

**Conclusions:** Taken together, these data demonstrate that CnAβ / Nox4 are selectively involved in pathological renal hypertrophy which is associated with progression to renal disease and renal failure. In contrast, adaptive hypertrophy following UNX involves alternative mechanisms that are not associated with chronic disease. Therefore, signaling mechanisms that mediate adaptive hypertrophy could be novel therapeutic renal targets.

**FR-PO214**

**Significant Increase in Podocyte Autophagy in Association with Foot Process Effacement in Patients with Minimal Change Nephrotic Syndrome**
Ayu Ogawa, Hitoshi Sugiyama, Masashi Kitagawa, Toshio Yamanari, Akifumi Onishi, Hiroshi Morinaga, Yoko Kikumoto, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Dept of Medicine III, Okayama Univ Graduate School of Medicine, Okayama, Japan.*

**Background:** Autophagy is a cellular process involved in the bulk degradation of proteins and organelle turnover. Recent studies have demonstrated the significance of autophagy of the tubular epithelium in several renal tubulointerstitial disorders using mouse models. However, the role of autophagy in the regulation of human glomerular diseases remains unclear. This study aimed to elucidate the morphological evidence for autophagy and its association with ultrastructural alterations of podocytes and clinical parameters in patients with minimal change nephrotic syndrome (MCNS).

**Methods:** The total study population included 103 patients with glomerular diseases (MCNS: 30, IgA nephropathy, IgAN: 21, membranous nephropathy, MN: 21, lupus nephritis, LN: 10 and others: 21) who underwent renal biopsies. The study investigated the number of autophagic vacuoles and the degree of foot process effacement (FPE) in podocytes using electron microscopy. The relationships between the expression of autophagic vacuoles, the degree of FPE and the clinical parameters were determined.

**Results:** Autophagic vacuoles were particularly detected in podocytes. Overall, the number of autophagic vacuoles in podocytes was significantly correlated with age ($p = 0.009$, $n = 103$). In the patients with MCNS, the number of autophagic vacuoles in podocytes was significantly correlated with the podocyte FPE score($r = -0.416$, $p = 0.022$), the amount of proteinuria ($r = 0.367$, $p = 0.046$) and the level of serum albumin ($r = -0.428$, $p = 0.018$). The number of autophagic vacuoles in podocytes was significantly increased in the patients with MCNS and MN in comparison to that observed in the patients with IgAN and LN ($p = 0.007$).

**Conclusions:** The data indicate that the autophagy of podocytes is associated with FPE and massive proteinuria in patients with MCNS. The mechanisms underlying the activation of autophagy in association with FPE in podocytes should be further determined in order to elucidate the pathophysiology of MCNS.

### Autophagy Protects Kidney from Chronic Metabolic Stress

Tomonori Kimura,[1] Atsushi Takahashi,[1] Yoshitsugu Takabatake,[1] Tomoko Namba,[1] Takeshi Yamamoto,[1] Jun-Ya Kaimori,[2] Jun Matsuda,[1] Isao Matsui,[1] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Advanced Technology for Transplantation, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

**Background:** Autophagy plays a protective role in several organs including kidney; however, the precise function in pathological metabolic condition is only understood partially. We have demonstrated that autophagy plays a protective role against metabolic stress *in vitro*. This study aimed to determine the systemic role of autophagy against chronic mitochondrial metabolic stress *in vivo*.

**Methods:** Proximal tubule-specific autophagy-deficient mice were treated with cyclosporine A, an inducer of mitochondrial metabolic stress through the blockade of the permeability transition pore of mitochondrial inner membrane, and histological changes and biological profiles were examined. In addition, we exposed kidney for the metabolome analyses.

**Results:** Autophagy-deficiency exaggerates cyclosporine A-induced kidney injury with significant increase in apoptotic cells. This damage is associated with increase in mitochondria ballooning. Metabolome analyses revealed aberrant metabolism of cysteine and its-related pathways, while corroborating our previous findings.

**Conclusions:** These observations not only proved our hypothesis that autophagy protects kidney tubular cells against kidney diseases through quality control of mitochondria, but also added a biological significance in the role of autophagy against metabolism-related diseases.

## FR-PO216

### Cyclosporine A Attenuates Lovastatin-Induced Podocyte Apoptosis

Xue-jia Chen,[1] He-ping Ma.[2] *[1]Dept of Obstetrics and Gynecology, Ruian Maternity and Child Care Hospital, Ruian, Zhejiang Province, China; [2]Dept of Physiology, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** Our recent studies suggest that inhibition of cholesterol synthesis in cortical collecting duct (CCD) cells with a very high concentration of lovastatin causes apoptosis of CCD cells and that cyclosporine A (CsA) attenuates lovastatin-induced apoptosis. We hypothesized that lovastatin and CsA might also have contradictory effects on podocyte viability.

**Methods:** We used confocal microscopy and annexin V-propidium iodide double-staining technique to detect podocyte apoptosis.

**Results:** The data demonstrated that a very high concentration of lovastatin significantly reduced cholesterol levels in the plasma membrane of podocytes and induced apoptosis. The effects of lovastatin on cholesterol levels and apoptosis were attenuated by pretreatment of podocytes with either exogenous cholesterol or CsA. However, acute depletion of cholesterol in the outer leaflet of podocyte membrane with methyl-ß-cyclodextrin failed to induce apoptosis, indicating that cholesterol in the inner leaflet of podocyte membrane plays an important role in regulating podocyte apoptosis. Treatment of podocytes with CsA caused significant accumulation of cholesterol in podocytes. These data suggest that CsA attenuate lovastatin-induced apoptosis via a cholesterol-dependent mechanism.

**Conclusions:** Since statins have been used as a complement of chemotherapy for cancer patients at a relatively high dose, the present study may provide useful information to management of statin-induced podocyte injury in these patients.

### Tumorigenesis and Organprotection–Two Ends of a Continuum?

Roman-Ulrich Mueller,[1,2,3] Puneet Bharill,[1,3] Hakam Gharbi,[1,2] Torsten Kubacki,[1] Marc Johnsen,[1] Tritpi Mishra,[1] Francesca Fabretti,[1] Markus M. Rinschen,[1] Peter Frommolt,[2] Volker Rolf Burst,[1] Bernhard Schermer,[1,2,3] Thomas Benzing.[1,2,3] *[1]Dept 2 of Internal Medicine and CMMC, Univ of Cologne, Cologne, Germany; [2]CECAD, Univ of Cologne, Germany; [3]SyBACol, Univ of Cologne, Germany.*

**Background:** Not only due to its growing incidence acute kidney injury has gained increasing interest during the last decade. On the one hand a growing body of evidence shows its close association with morbidity and mortality. On the other hand no causal treatment exists and preventive measures are limited. However, organ preconditioning has become a potential tool to tackle this problem.

**Methods:** We employ the nematode *Caenorhabditis elegans* as a tool to search for keyplayers in the pathways mediating organoprotection. The major signaling pathways mediating increased stress tolerance upon preconditioning are well conserved in the worm and hypotheses generated using this model can be transferred to a mouse model of renal ischemia-reperfusion injury.

**Results:** In 2009 we had introduced hypoxia signaling as a novel longevity pathway through studies in *vhl-1* knockout worms. More recently, we identified *flcn-1* - the worm orthologue of the gene mutated in Birt-Hogg-Dubé syndrome - to regulate lifespan and stress tolerance in a manner dependent on *hif-1* and TORC1.

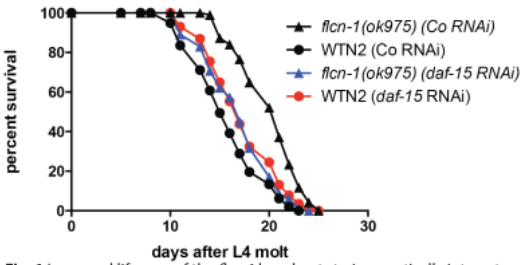

**Fig. 1** Increased lifespan of the *flcn-1* knockout strain genetically interacts with ceTORC1.

**Conclusions:** We have identified FLCN as yet another renal tumor suppressor protein regulating organismal stress resistance. On the one hand increasing knowledge about longevity pathways holds the promise to help finding novel tools to prevent AKI in a broader clinical setting. On the other hand these findings closely link cellular stress resistance, tumorigenesis, aging and organ regeneration and allow for the intriguing hypothesis of a tightly regulated balance between these processes in which reducing tumor suppressive tissue surveillance in a timely limited fashion may be a promising way to prevent AKI.

## FR-PO218

### Everolimus Inhibits Invasion and Migration of Human Renal Cancer Cells by Inhibiting Epithelial-to-Mesenchymal Transition and FAK Pathway In Vitro and In Vivo

Horng-Rong Chang, Jong-Da Lian. *Div of Nephrology, Dept of Medicine, Chung Shan Medical Univ Hospital, Taichung, Taiwan.*

**Background:** Metastasis of kidney cancer, a most important cause of patient death and a multiple and intricate processes, may complicate the clinical management and lead to a poor prognosis for cancer patients and has tremendous physical or economical impact to patients or communities. The epithelial-mesenchymal transition (EMT) is implicated in converting stationary epithelial cancer cells into motile mesenchymal cells during metastasis.

**Methods:** 786-O cells were treated with everolimus at various concentrations for a defined period and then subjected to gelatin zymography, casein zymography and Western blot to investigate the impacts of everolimus on invasive, motility, and migratory potential. An *in vivo* anti-tumor studies were examined using a nude mice xenograft model and a lung metastasis model.

**Results:** In the present study, our results showed that everolimus treatment significantly inhibits invasive, motility, and migratory potential of human renal cell carcinoma 786-O cells. Molecular analyses showed that everolimus increases E-cadherin level and decreases vimentin and RhoA expression by Western blot assay, indicating the anti-EMT effect of everolimus in renal cell carcinoma. We performed western blot to find that everolimus inhibits p-Src and p-focal adhesion kinase (p-FAK) that was localized mainly at cellular membrane as evidenced by confocal analyses in 786-O cells, which might be responsible for morphologically observed shift towards epithelial character. In addition, everolimus was found to be effective in reducing the lung metastases formation via tail vein injection as compared to vehicle treated control animals. Everolimus was also evidenced by its inhibition on the growth of 786-O cells *in vivo* via a cancer cells xenograft nude mice mode.

**Conclusions:** Taken together, our results showing anti-invasive/anti-tumor effects of everolimus and associated mechanisms suggest that everolimus should be tested further in clinically relevant models towards exploiting its potential benefits against metastatic kidney cancer cells.

## FR-PO219

### DIALOGUE* Phase 2 Program for BAY85-3934 a HIF-PH Inhibitor with Daily Oral Treatment in Anemic Patients Suffering from CKD/ESRD

Iain C. Macdougall,[1] Jeffrey S. Berns,[2] Tadao Akizawa,[3] Steven Fishbane,[4] Thomas Bernhardt.[5] *[1]Kings College Hospital, London, United Kingdom; [2]Hospital of the Univ of Pennsylvania, Philadelphia; [3]Showa Univ Hospital, Tokyo, Japan; [4]Winthrop Univ Hospital, Mineola; [5]Bayer Pharma AG, Berlin, Germany.*

**Background:** Anemia, defined as a deficiency of hemoglobin (Hb), is a frequent and serious complication of severe diseases, including chronic kidney disease (CKD) and cancer. The traditional treatment of anemia due to deficient EPO synthesis has included several forms of recombinant human EPO (rhEPO), also known as erythropoiesis-stimulating agents (ESAs). BAY 85-3934, a novel inhibitor of HIF-PH, is developed for the oral treatment of anemia in patients with CKD and end stage renal disease (ESRD). Hypoxia-inducible factor (HIF) is a key transcription factor for the activation of EPO-gene expression. BAY 85-3934, a small molecule inhibitor of HIF-PH, will be evaluated for the induction of endogenous EPO by mimicking hypoxia resulting in an increase of the Hb level.

**Methods:** The BAY 85-3934 Phase 2 program consists of 3 randomized, multicenter parent studies (2 studies in Europe/Asia Pacific and 1 study in US/Japan, each lasting 16 weeks) and 2 safety extension studies (1 study in Europe/Asia Pacific and 1 study in US/Japan). Up to 400 patients suffering from anemia due to CKD or ESRD are planned

to be enrolled in the 3 parent studies to prove the efficacy and safety of BAY85-3934 in comparison to placebo, Darbepoetin alpha and Epoetin alpha/beta. Eligible patients are either treatment naïve with a Hb level below 10 g/dL or on stable ESA dose with a Hb level in the target range per regional ESA label. Different doses of BAY85-3934 will be administered and titrated when indicated. The safety of the treatment is monitored by an independent DMC. An adjudication committee supports the evaluation of reported safety events.

**Conclusions:** In this Phase 2 program BAY 85-3934, a small molecule inhibitor of HIF-PH, will be developed for the induction of endogenous EPO resulting in an increase of the Hb level. * DIALOGUE = Daily Oral Treatment Increasing Endogenous Erythropoietin.

## FR-PO220

**Increased Serum Hepcidin Is a Major Contributor to the Anemia of CKD in an Animal Model** Joshua Zaritsky,[1] Victoria Rivka Gabayan,[2] Grace Jung,[2] Tomas Ganz,[2] Isidro B. Salusky.[1] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Medicine, UCLA, Los Angeles, CA.*

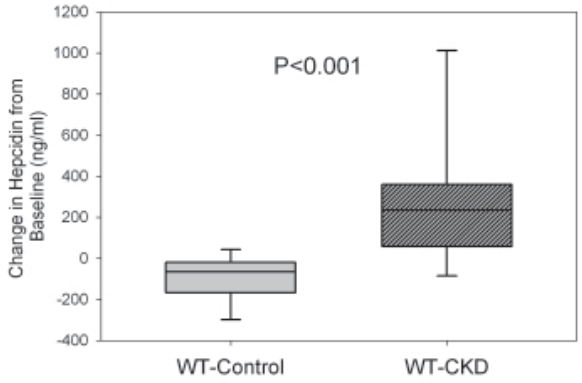
**Background:** Cross-sectional studies have shown that serum concentrations of hepcidin, a key regulator of iron metabolism, are markedly elevated in CKD patients. However it remains unknown if these elevations contribute to iron restriction and the anemia of CKD.

**Methods:** We examined changes in hepcidin levels in a mouse model of CKD, avoiding the confounding effects of ESA and iron therapy. Wild-type mice (WT-CKD) and mice with a targeted disruption of the hepcidin gene (HepKO-CKD) were placed on a 20 ppm iron diet containing 0.2% w/w adenine. Corresponding control groups (WT and HepKO-control) were placed on an identical diet without adenine. Serum hepcidin levels were measured by ELISA at diet initiation and at 2 months along with other key biochemical markers (Table).

**Results:** As expected, renal function (assessed by serum BUN) decreased in animals fed adenine. Significantly, at 2 months, Hgb levels were lower in animals fed adenine with lower MCV values consistent with iron restricted erythropoiesis. ANOVA modeling found a significant interaction between diet and genotype indicating that the HepKO-CKD group had a smaller drop in Hgb than the WT-CKD group ($p<0.04$). Serum hepcidin levels increased only in the WT-CKD group ($p<0.001$) (Figure).

| | | WT Control (n=16) | WT CKD (n=16) | HepKO Control (n=20) | HepKO CKD (n=22) |
|---|---|---|---|---|---|
| Baseline | BUN (mg/dl) | 41.5±6 | 39.8±5 | 46.8±5.2 | 46.5±8.7 |
| | HGB (mg/dl) | 14.6±0.9 | 14.9±1.2 | 12.8±2.4 | 13.1±1.9 |
| | MCV (fl/cell) | 46.7±0.6 | 46.6±0.6 | 45.8±4.3 | 45.5±4.1 |
| | IRON (uM/l) | 105±19 | 114±33 | 120±66 | 127±83 |
| | Hepcidin (ng/ml) | 315±112 | 321±87 | - | - |
| 2 Months | BUN (mg/dl) | 40±5.2 | 115±26* | 44.5±6.5 | 112±20† |
| | HGB (mg/dl) | 14±1.4 | 8.8±2.2* | 15.8±1.7 | 13.5±2.6† |
| | MCV (fl/cell) | 46.2±0.9 | 38.3±2* | 51.6±1.9 | 48.2±1.8† |
| | IRON (uM/l) | 122±51 | 99±20 | 135±76 | 116±29 |
| | Hepcidin (ng/ml) | 220±61 | 623±364* | - | - |

* p<0.01 WT-CKD vs. WT-control; †p<0.01 HepKO-CKD vs HepKO-control



**Conclusions:** We found that hepcidin levels increase as kidney function worsens in this animal model of CKD and that increased hepcidin contributes to the anemia of CKD. Future studies are warranted to examine if a targeted approach to lower serum hepcidin levels could be used to treat the anemia of CKD.

## FR-PO221

**Indole Derivatives Enhance Erythropoietin Production and Have Cytoprotective Effects** Takehiro Suzuki,[1] Hisato Shima,[1] Toshihito Sahara,[1] Yusuke Suzuki,[1] Yuki Oba,[1] Eikan Mishima,[1] Yoichi Takeuchi,[1] Yasutoshi Akiyama,[1] Chitose Suzuki,[1] Ken-ichiro Hayashi,[2] Sadayoshi Ito,[1] Takaaki Abe.[1] *[1]Tohoku Univ Graduate School of Medicine, Japan; [2]Okayama Univ of Science, Japan.*

**Background:** In patients with chronic kidney disease (CKD), the accumulation of uremic toxins promotesrenal damage and anemia. During the analysis of uremic solutes on erythropoietin (Epo) production in Epo-producing Hep3B cells, we identified that some of the indole compounds have a potency of enhancing Epo production. So the aim of this study is to identify the mechanism of stimulating Epo production by indole compounds and to identify the new compounds to prevent the CKD progression and anemia.

**Methods:** Forty one indole derivatives were synthesized and analyzed by Epo production, Epo mRNA production, and the Epo promoter assay as well as ATP production in Hep3B cells. Cytoprotective activity against cytotoxic agents (cisplatin, aristolochic acid) in kidney derived HK2 cells was accessed by cytotoxicity assay kit (WST-8). Intracellular ATP contents were measured by ATP kit (TOYO INK). *In vivo* effect of the compounds were assessed with oral or intraperitoneal administration. Total HIF-1a content was measured by Cell-Based ELISA kit.

**Results:** Indole compound #2, #4, #5 at 10μM enhanced Epo production by 4 fold, Epo mRNA by 60 fold and the Epo promoter activity by 6 fold, while FG4592 at 10μM increased Epo mRNA by 3 fold. Cytotoxic effects of cisplatin (50% reduction) and aristolochic acid (30% reduction) were ameliorated to baseline by#4 at 30μM and #5 at 100μM, respectively. Administration of the compound #2, #4, #5 at 3μM augmented intracellular ATP contents by 7 fold in Hep3B. These compounds have no cytotoxic effect or ROS generation by itself. The kidney Epo mRNA was increased by 3 fold in mice administrated the compound #5 at 50mg/kg intraperitoneally. Total HIF-1a content in Hep3B was increased by compound #21 and #35.

**Conclusions:** These data suggest that the indole derivatives promote Epo production. Stabilization of HIF-1a might be the mechanism of enhancement of Epo. These compounds also have cytoprotective effect as well as increased the intracellular ATP contents without increasing oxidative stress.

*Funding:* Government Support - Non-U.S.

## FR-PO222

**Indole-3-Acetate Inhibits Erythropoietin Receptor Expression and Erythropoietin Signaling In Vitro** Yasutoshi Akiyama,[1,2] Hisato Shima,[2] Yoichi Takeuchi,[2,4] Eikan Mishima,[1,2] Chitose Suzuki,[2] Takehiro Suzuki,[2] Sadayoshi Ito,[2] Takaaki Abe.[2,3,4] *[1]Dept of Community Medical Supports, Tohoku Medical Megabank Organization (ToMMo), Tohoku Univ, Sendai, Miyagi, Japan; [2]Div of Nephrology, Endocrinology and Vascular Medicine, Tohoku Univ Hospital, Sendai, Miyagi, Japan; [3]Div of Medical Science, Tohoku Univ Graduate School of Biomedical Engineering, Sendai, Miyagi, Japan; [4]Dept of Clinical Biology and Hormonal Regulation, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

**Background:** Anemia is one of the major complications of chronic kidney disease (CKD). Although many CKD patients respond to the treatment of erythropoiesis-stimulating agent (ESA), about 10% of patients have poor responsiveness to ESA. It has been known that there are several causes of ESA resistance, such as iron deficiency, inflammation, vitamin B12 deficiency and folate deficiency. However, the pathophysiology of ESA-resistant anemia has not been fully elucidated.

**Methods:** To test the hypothesis that uremic toxin(s) decreases the erythropoietin receptor (EPOR) expression, we examined the effects of uremic solutes on cell viability, EPOR expression and signal transduction through EPOR using erythropoietin-dependent human leukemic cell line, UT-7/Epo cells.

**Results:** First, we compared the cell toxicity of various uremic solutes in UT-7/Epo cells with that in kidney-derived ACHN cells by cell viability assay. Many compounds showed the same cell toxicity between the two cell lines. However, the cell toxicity of indole-3-acetate (IAA), one of the uremic toxins, was about 10-fold stronger in UT-7/Epo cells than in ACHN cells, suggesting that IAA may have the toxicity related to EPO signaling as well as the direct cellular injury. To elucidate the mechanism, we examined the effect of IAA on the expression of EPOR. As a result, the expression of EPOR was dose-dependently decreased by IAA treatment at both mRNA and protein levels. In addition, tyrosine phosphorylation of STAT5 was significantly decreased by IAA treatment, suggesting that IAA inhibited the signal transduction through EPOR.

**Conclusions:** IAA may decrease the expression of EPOR and cause ESA-resistant anemia in CKD patients.

**FR-PO223**

**Chronic Kidney Disease Increases Influx of Bone Marrow Derived Cells into the Heart and Reduces Circulating Endothelial Progenitor Cells** Yvonne Riedl,[1] Katharina Bibl,[1] Karl F. Hilgers,[2] Christoph Daniel,[1] Kerstin U. Amann.[1] *[1]Nephropathology, Univ Erlangen; [2]Nephrology and Hypertension, Univ Erlangen.*

**Background:** Cardiovascular events are common complications in patients with chronic kidney disease (CKD). CKD leads to cardiovascular functional and structural alterations with impaired angiogenesis playing an important pathophysiological role. Here we investigated if impaired cardiac angiogenesis in a CKD model is due to reduced recruitment of endothelial progenitor cells (EPCs) in the heart.

**Methods:** To evaluate the recruitment of EPCs from the bone marrow into hearts of CKD rats we transplanted bone marrow from human placental alkaline phosphatase (hPAP) transgenic F344 rats into wildtype F344. Ten weeks after lethal irradiation and bone marrow transplantation, the chimeric rats were randomly assigned to two groups, i.e. subtotal nephrectomy (SnX) or sham operation (sham). 12 weeks after SnX the experiment was terminated and cardiac pathology and bone marrow derived cell (BMDC) recruitment into the heart and circulating EPCs were analysed.

**Results:** CKD in SnX rats was accompanied by increased proteinuria as well as structural histological changes in the kidney. Blood pressure and left ventricular weight were significantly higher in rats with CKD. In addition, cardiac capillary density was about 20% lower in SnX animals as assessed by staining for CD31 positive cells (p=0.0493). In the blood EPCs were significantly reduced in CKD rats, as assessed by CD45+CXCR4+ cells (1.7±0.2 vs 3.0±0.9, p=0.03). In contrast, recruitment of BMDC into the heart was about 50% higher in the SnX group. However, in our study neither in sham animals nor in SnX rats CD31 positive BMDC could be identified, suggesting that BMDC are not an essential source for cardiac endothelial cells. Immunofluorescence double staining proved that the majority of BDMC could be characterized as CD45+ leucocytes (about 50%) and ED1+ macrophages (about 40%) cells.

**Conclusions:** Chronic kidney disease (CKD) reduced the number of circulating EPCs and simultaneously increased influx of BMDC derived inflammatory cells into the heart. However, BMDC seem not to be an important source for cardiac endothelial cells.

*Funding:* Government Support - Non-U.S.

**FR-PO224**

**Altered Macrophage Polarization Promotes Atherosclerosis in a Mouse Model of Chronic Kidney Disease** Lixia Zeng, Hye Kyong Kweon, Anna V. Mathew, Pradeep Kayampilly, Philip C. Andrews, Subramaniam Pennathur. *Univ of Michigan, Ann Arbor, MI.*

**Background:** Atherosclerotic cardiovascular disease is the leading cause of death in patients with chronic kidney disease (CKD). However, the molecular mechanisms underlying this increased risk remain poorly understood. We investigated the role of macrophages in promoting atherosclerosis in a pathophysiologically relevant mouse model of CKD.

**Methods:** Male LDL receptor deficient ($LDLr^{-/-}$) mice were subjected to sham (Control) or 5/6 nephrectomy (CKD) surgery. Subsequently, the animals were maintained in low (LFD) or high fat diet (HFD) for 24 weeks. LC/MS analysis of macrophage-derived oxidation markers and the phosphoproteomic profiling of bone marrow-derived macrophages from the subgroups were performed. Mouse macrophage cell line RAW 264.7 were used for stable isotope labeling in cell cultures (SILAC). The tryptic peptide digests were subjected to two-step phosphopeptide enrichment and analyzed by on-line nanoLC-MS/MS.

**Results:** The CKD mice had significantly higher plasma creatinine, lower hematocrit, decreased body weight and higher mortality. Quantification of lesion area revealed that both LFD and HFDCKD mice had significantly elevated aortic plaque area fraction, and greater luminal narrowing consistent with accelerated atherosclerosis. Cholesterol content and macrophage infiltration were elevated in the aortic lesions of the CKD animals. LC/MS analysis of macrophage derived myeloperoxidase oxidation markers (nitrotyrosine and dityrosine) showed marked elevation in the aortic lesions and targeted lipidomic analysis revealed inflammatory polarization of macrophages (M1) with increased long-chain fattyacyl COA accumulation. We identified 1,449 unique phosphopeptides from 434 unique phosphoproteins. Gene Ontology annotations showed selective changes in phosphoproteins involved in cellular component biological processes. 53 hyperphosphorylated and 43 hypophosphorylated domains were identified suggesting distinct phosphorylation signatures underlying inflammatory macrophage polarization.

**Conclusions:** These findings strongly implicate that altered macrophage polarization contributes to CKD-accelerated atherosclerosis.

**FR-PO225**

**Nuclear Translocation of β-Catenin Mediates Parathyroid Hormone-Induced Endothelial-to-Mesenchymal Transition in Human Aortic Endothelial Cells** Min Wu, Hong Liu, Bi-cheng Liu. *Institute of Nephrology, Southeast Univ, Nanjing, China.*

**Background:** Secondary hyperparathyroidism is a common complication of chronic kidney disease, which is closely correlated with the development of cardiovascular diseases. Our previous have demonstrated that PTH could induce endothelial-to-mesenchymal transition in human aortic endothelial cells (HAECs). However, the potential molecular mechanism has yet to be clarified. Thus, the present study sought to investigate whether nuclear translocation of β-catenin mediates PTH-induced EndMT in HAECs.

**Methods:** Primary HAECs were treated with PTH ($10^{-10}$ to $10^{-6}$mol/L). DKK1 (500ng/ml) was used to inhibit β-catenin nuclear translocation. The expressions of endothelial marker CD31and mesenchymal markers FSP1 and α-SMA were detected by real-time PCR and western blot. Nuclear and cytoplasmic β-catenin protein levels were examined by western blot and confocal microscopy.

**Results:** PTH treatment significantly down-regulated endothelial marker CD31 expression and up-regulated mesenchymal markers FSP1 and α-SMA expression in concentration- and time-dependent manners ($p<0.05$). Meanwhile, PTH enhanced nuclear β-catenin levels, along with decreased cytoplasmic β-catenin expression in HAECs, suggesting nuclear translocation of β-catenin. Furthermore, DKK1 treatment significantly attenuated the changes of EndMT-related markers induced by PTH ($p<0.05$).

**Conclusions:** These data demonstrated that elevated PTH promoted EndMT in HAECs. And this effect was partially mediated by nuclear translocation of β-catenin.

**FR-PO226**

**FGF-23 but Not Klotho Predicts the Presence of Aortic Valve Calcifications in Moderate Chronic Kidney Disease?** Luca Di Lullo,[1] Antonio Bellasi,[2] Fulvio Floccari,[4] Antonio Gorini,[1] Rossella Faiola,[1] Alberto Santoboni,[1] Domenico Russo.[3] *[1]Dept of Nephrology and Dialysis, L. Parodi - Delfino Hospital, Colleferro, Roma, Italy; [2]Dept of Nephrology and Dialysis, Azienda Ospedaliera S.Anna, Como, Italy; [3]Dept of Nephrology, Federico II Univ, Napoli, Italy; [4]Dept of Nephrology and Dialysis, S. Paolo Hospital - Civitavecchia, Roma, Italy.*

**Background:** Cardiovascular calcification (CVC) is a frequent complication in chronic kidney disease (CKD) patients. Abnormalities in vitamin D receptor (VDR) activation and hyperphosphoremia are all supposed to contribute to CVC. Fibroblast Growth Factor 23 (FGF-23) is a phosphaturic glycoprotein, linked to phosphate and vitamin D metabolism as well as poor outcome in CKD. We investigated association between FGF-23 and cardiac valvular calcification in moderate CKD.

**Methods:** In this cross-sectional study, 100 (60 men; mean age of 51 ± 4.6 years) CKD stage IIIB-IV patients were enrolled and underwent laboratory (25-OH Vitamin D, Klotho, FGF-23, CRP, serum calcium and phosphorus, iPTH, phosphaturia) and echocardiography testing to assess mineral metabolism such as mitral and aortic valve calcification.Parametric and non-parametric tests were used. Finally, Receiving Operating Curve (ROC) was used to test the model performance.

**Results:** Overall mean serum calcium (9,2±0,4 mg/dl), phosphorus (4,3±0,2 mg/dl) 25OH vitamin D (34,8±13,5 ng/ml) and iPTH (59,11±8,6 pg/ml) were within the reference ranges. Serum FGF-23 and Klotho mean values were 10,4±1,7 pg/ml and 887,8±110,3 pg/ml, respectively. Phosphaturia was 1,043±258 g/day. At univariable and multivariable adjusted analyses, aortic but not mitral valve calcification was associated with FGF-23 levels. Notably, Klotho, iPTH, 25OH Vitamin D, serum phosphorous, phosphaturia and CRP were not associated with either valvular calcification.

**Conclusions:** Our data suggests that FGF-23 but not Klotho is strongly and independently associated with aortic valvular calcification. Future studies should test whether therapeutic strategies aimed at lowering FGF23 (diet, phosphate binders, calcimimetics) can affect calcification progression and cardiovascular damage.

**FR-PO227**

**High Density Lipoprotein in Children with Chronic Kidney Disease Is Pro-Atherogenic** Rukshana C. Shroff,[1,2] Thimoteus Speer,[3] Sophie Colin,[4] Danilo Fliser,[3] Stephen Zewinger,[3] Francis O'Neill,[2] Marietta Charakida,[2] Ulf Landmesser,[5] John E. Deanfield.[2] *[1]Renal Unit, Great Ormond Street Hospital, London, United Kingdom; [2]Vascular Physiology Unit, Institute of Child Health, United Kingdom; [3]Dept of Internal Medicine, Saarland Univ Hospital, Germany; [4]Institut Pasteur de Lille, France; [5]Univ Hospital Zurich.*

**Background:** Patients with CKD are at increased risk for premature atherosclerosis. In adults with CKD HDL loses its vascular protective actions and promotes endothelial dysfunction, but the time course of these changes and the potential for reversibility is unknown.

**Methods:** We studied the vascular effects of HDL in 82 children with CKD stages II-V, dialysis and transplant ($HDL^{CKD}$) and compared with 12 matched controls ($HDL^{Healthy}$). Children with inflammatory diseases, diabetes or active infections were excluded. HDL was isolated by density-gradient ultracentrifugation. Endothelial nitric oxide (eNO) and superoxide (eSO) production were analyzed by electron spin resonance spectroscopy in human aortic endothelial cells after incubation with HDL.

**Results:** $HDL^{Healthy}$ stimulated eNO whereas $HDL^{CKD}$ inhibited eNO production ($p<0.0001$). $HDL^{CKD}$ promoted eSO production and reduced endothelial cell migration and cholesterol efflux (p=0.002, p=0.01, p=0.004 respectively). GFR decline was strongly associated with dysfunctional HDL ($r^2= 0.52$). $HDL^{CKD}$ correlated with increased VCAM-1 and IL6 levels suggesting increased vascular and systemic inflammation. Reduced eNO inversely correlated with pulse wave velocity.

Importantly, $HDL^{CKD}$ function was abnormal as early as CKD II with the most profound changes in dialysis and only partial recovery after transplantation. In a longitudinal follow-up of 8 children on dialysis and 3 months after transplantation HDL induced eNO and eSO production significantly improved but did not normalize.

**Conclusions:** In children with CKD and no inflammatory disease, HDL acquires pro-inflammatory and pro-oxidant properties. HDL functional changes showed an independent and graded association with severity of renal failure and clinical measures of arterial stiffness. Transplantation was associated with recovery but not normalisation of HDL properties.

**FR-PO228**

**Circulating Total Uncarboxylated Matrix Gla-Protein as Biomarker for Vascular Calcification in Chronic Kidney Disease** Elke Theuwissen,[1] Elke Magdeleyns,[1] Heather Pham,[2] Cees Vermeer.[1] *[1]Cardiovascular Research Institute, Maastricht Univ, VitaK, Maastricht, Netherlands; [2]Immunodiagnostic Systems, Boldon, United Kingdom.*

**Background:** Matrix Gla-protein (MGP) is an extra-hepatic vitamin K-dependent protein primarily synthesized by vascular smooth muscle cells. MGP is an important inhibitor of vascular calcification and its activity depends on vitamin K-dependent γ-glutamate carboxylation. Vascular calcification is not only common, but progresses aggressively in chronic kidney disease (CKD) patients. Notably, these patients are characterized by subclinical vitamin K deficiency. We have developed an assay detecting the circulating total uncarboxylated MGP (t-ucMGP), measuring both phosphorylated and desphosphorylated ucMGP fractions. We were interested to see whether t-ucMGP may serve as biomarker for vascular calcification in CKD patients.

**Methods:** Circulating t-ucMGP was measured with our lab-developed competitive mono-antibody ELISA. A monoclonal antibody against the uncarboxylated MGP sequence was used and coupled directly to the microtiter plates.

**Results:** CKD patients were characterized by extremely low circulating t-ucMGP values, suggesting high affinity for calcium. Nearly all CKD patients had values well below the healthy adult range.Lower circulating t-ucMGP levels were associatedwith higher calcification scores in these patients.

**Conclusions:** Circulating t-ucMGP levels are significantly lower in CKD patients than in the healthy population, clearly discriminating CKD patients from controls. Low serum levels of t-ucMGP were associated with the burden of vascular calcification in these patients and hence may serve as biomarker for vascular calcification.

**FR-PO229**

**Chest X-Ray May Serve as a Screening Examination for Coronary Artery Calcification in Dialysis Patients** Kyoko Watanabe, Hiraku Yoshida, Yudo Tanno, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Kidney and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Coronary artery calcification (CAC) is highly prevalent among dialysis patients. Moreover, it has been reported that Coronary Artery Calcification Score (CACS) using multi-detector computed tomography (MDCT) is a good predictor of mortality in dialysis patients. However, it is not practical to perform coronary artery examination in every dialysis patient. Therefore, the aim of this study was to clarify which part of the body should be imaged with X-rays for screening of CAC in dialysis patients.

**Methods:** We examined 163 autopsy cases who had all been on dialysis (age 63.5±16.0 years, 102 male:61 female, 46 diabetic:117 non-diabetic, dialysis duration 4.4±5.3 years). Data were analyzed using the logistic model to determine the correlation between CAC and specific vascular calcification sites (aortic valve, carotid artery, thoracic aorta, and abdominal aorta).

**Results:** Logistic analyses revealed that thoracic aorta calcification had the strongest correlation with CAC. The table below shows correlation between CAC and specific vascular calcification sites.

| | Odds Ratio | P Value | 95% CI |
|---|---|---|---|
| Aortic valve calficiation | 1.50 | 0.434 | 0.544-4.136 |
| Carotid artery calficiation | 1.40 | 0.532 | 0.486-4.039 |
| Thoracic aorta calficiation | 5.04 | 0.023 | 1.252-20.26 |
| Abdominal aorta calficiation | 2.01 | 0.362 | 0.447-9.062 |

**Conclusions:** The results suggest that a chest X-ray should be performed in dialysis patients to screen for marked thoracic aorta calcification. It is those patients with marked thoracic aortic calficiation on chest X-ray who should undergo further cardiovascular assessment. Accordingly, Chest X-ray may serve as a screening examination for CAC in dialysis patients.

**FR-PO230**

**Calcified Carotid Plaque in Chronic Kidney Disease: Prevalence and Risk Factors** Angels Betriu,[1,4] Montserrat Martinez-alonso,[2,4] M. Vittoria Arcidiacono,[3,4] Merce Borras,[1,4] Jose M. Valdivielso,[3,4] Elvira Fernandez.[1,3,4] *[1]Nephrology, Univ Hospital Arnau de Vilanova; [2]Biostatistic Unit, IRBLleida; [3]Experimental Nephrology, IRBLleida; [4]NEFRONA Group, Spain.*

**Background:** Atheromatous plaque progression starts with a formation of a lipid core (type1-2) and ends with fibrosis (type3-4), and calcification (type5). The role of plaque calcification on plaque vulnerability is not clear in the general population, and also there are no reports describing which risk factors modulate plaque calcification in chronic kidney disease (CKD). The aim of the study was to define the prevalence of each plaque type in patients with CKD at stage 3(E3), 4-5(E4-5) and 5D(E5D), in comparison with subjects without CKD (C), and the risk factors responsible for plaque calcification.

**Methods:** Athermatous plaque were analyzed in 1406 CKD patients (E3:540; E4-5:460; E5D:406), and in 230 control subjects. Plaques were classified by type 1 to 5 accordingly with carotid B-mode ultrasound images. After a descriptive analysis of plaque types was done, calcified plaques were analyzed by logistic regression to identify the associated risk factors.

**Results:** CKD patients presented a 57.5% of carotid plaques: type1=14.3%; type2=20.1%; type3=51.7%; type4=43.2; and type5=23%. Control subjects presented a 41% of carotid plaque: type1=41%; type2=16.5%; type3=47%; type4=28; and type5=1.7% (p<0.0001). Calcified plaque prevalence was higher as CKD progressed (C=1.7%; E3=19%; E4-5=25%; E5D=26%). Plaque calcification in CKD was associated with dialysis treatment (p=0.05), age>55 years (p=0.01), systolic blood pressure (SBP)>180 mmHg (p=0.04), phosphorus (p=0.03), and C-reactive protein (CRP; p=0.02). Gender, smoking, lipid profile, calcium, PTH did not associate with plaque calcification.

**Conclusions:** In control subjects plaque are more lipidic than those in CKD patients that are more calcified in parallel with the severity of the disease. Within the associated risk factors, SBP, phosphorous and inflammation (CRP) are important modifiable factors for plaque calcification. A prospective study of the NEFRONA study will help to understand the role of calcification on plaque stability/vulnerability to predict cardiovascular events.

**FR-PO231**

**Intima Media Thickness Does Not Parallel Chronic Kidney Disease Progression in Absence of Atheromatosis** Angels Betriu,[1,4] Montserrat Martinez-alonso,[2,4] M. Vittoria Arcidiacono,[3,4] Merce Borras,[1,4] Jose M. Valdivielso,[3,4] Elvira Fernandez.[1,3,4] *[1]Nephrology, Univ Hospital Arnau de Vilanova; [2]Biostatistic Unit, IRBLleida; [3]Experimental Nephrology, IRBLleida; [4]NEFRONA Group, Spain.*

**Background:** Despite the high prevalence of atheromatosis in chronic kidney disease patients (CKD), a small population is free of atheromatosis due to unknown factors. Intima media thickness (IMT) is a subclinical marker of atheromatosis and increases as CKD progresses. The aim of the study was to evaluate if common carotid IMT (cIMT) measurements differed in CKD patients affected or not by atheromatosis.

**Methods:** We selected 2979 subjects with valid cIMT measurements (B-mode ultrasound). Subjects were then divided in two separated groups depending on presenting (WP:999) or not (W/OP:1980) atheromatosis, in carotid or femoral arteries.

**Results:** In CKD patients, W/OP group, compared to WP group, had a lower: average age (48.5 vs 62 years; p<0.0001), percentage of men (50% vs 66.6%; p<0.0001), and percentage of diabetics (15% vs 30%; p<0.0001). There were no differences about CKD stages (3:38%, 4-5:34%, 5D:36%). The same was observed in control subjects (C) not affected by CKD, with a lower: average age for the W/OP group (49.4 vs 59.4 years; p<0.0001),percentage of men (41% vs 65.4%; p<0.0001), and diabetics (5.5% vs 16.3; p=0.0001). Compared with the control group, WP patients presented the highest cIMT at CKD3 (p<0.05) (C:0.76, 3:0.80, 4-5:0.75, 5D:0.75). W/OP patients, presented a lower cIMT than in control subjects, but statistically different only in CKD5D (p<0.05) (C:0.64, 3:0.65, 4-5:0.595, 5D:0.59). When adjusted for traditional cardiovascular risk factors and CKD stages, WP patients had the highest cIMT only in CKD5D, and W/OP patients cIMT was significantly lower than that in C group at all CKD stages (p<0.01).

**Conclusions:** There are a percentage of patients that do not develop atheromatosis and whose cIMT decreases with the severity of CKD, in contrast to what is observed in patients with atheromatosis. A prospective analysis of the NEFRONA study will attempt to investigate the prognostic value of the cIMT on survival from cardiovascular events in CKD patients.

*Funding:* Pharmaceutical Company Support - ABBVIE

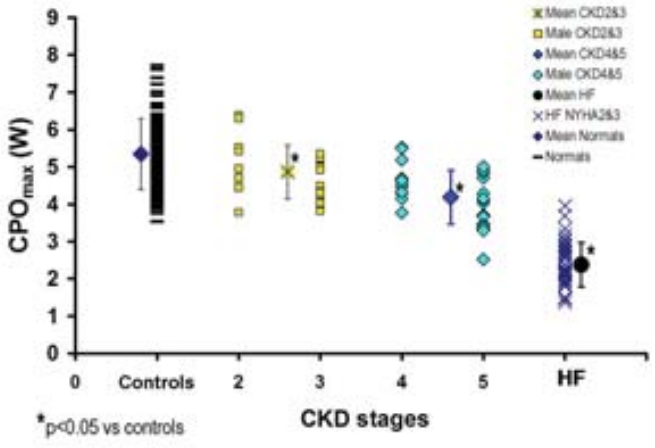
**FR-PO232**

**Evidence of Cardiomyopathy in Asymptomatic Chronic Kidney Disease Patients without Primary Cardiovascular Disease** Shanmugakumar Chinnappa,[1] Andrew F. Mooney,[2] Meguid El Nahas,[1] Lip-Bun Tan.[2] *[1]Sheffield Teaching Hospitals; [2]Leeds Teaching Hospitals, United Kingdom.*

**Background:** Evaluation of asymptomatic cardiac dysfunction in chronic kidney disease (CKD) is highlighted as a research priority by KDIGO to improve our understanding of heart failure (HF) in CKD. The present study is aimed at testing the hypothesis that asymptomatic CKD patients without any known cardiovascular disease or diabetes mellitus have impaired cardiac reserve compared to controls. We measured peak cardiac power output ($CPO_{max}$) to quantify cardiac reserve as $CPO_{max}$ is shown to be a direct indicator of cardiac dysfunction and the best predictor of survival in patients with HF.

**Methods:** We compared the cardiopulmonary exercise performance and non-invasive haemodynamics of 30 male patients with late CKD (stages 4&5) and 20 patients with early CKD (stages 2&3) against 101 healthy male volunteers. Cardiac functional reserve was measured during treadmill exercise testing with standard respiratory gas analyses and a $CO_2$-rebreathing method of non- invasively measuring cardiac output during peak exercise. As positive controls, data from 39 age- and gender-matched HF patients in NYHA class II&III were also obtained. The results are presented as mean±SD.

**Results:** The mean eGFRs of early and late CKD patients were 54.4±18.2 and 16.2±5.8 ml/min respectively. None of the CKD patients had inducible cardiac ischaemia during exercise. Compared to healthy controls, the CKD patients showed a graded reduction in cardiac reserve with 92.4±12.2% (P<0.05) of predicted $CPO_{max}$ in early CKD and 81.4±13.2% (P<0.001) of predicted $CPO_{max}$ in late CKD. In comparison, HF patients had 45.5±10.7% of predicted $CPO_{max}$ (P<0.001).



**Conclusions:** This novel study shows that CKD per se causes impaired cardiac functional reserve, thus confirming the presence of cardiomyopathy, which requires further cardio-renal collaborative research.

## FR-PO233

**High Sensitivity Troponin T in Chronic Kidney Disease** Javier Reque, Borja Quiroga, Soledad Garcia de Vinuesa, Marian Goicoechea, Ursula Verdalles, Juan Manuel Lopez Gomez, Jose Luno. *Nephrology, Hospital Gregorio Marañon, Madrid, Spain.*

**Background:** Chronic kidney disease (CKD) is an independent risk factor for developing coronary heart disease (CHD). The cardiac troponins are structural proteins predictors of (CHD). It has been demonstrated that high sensitivity Troponin T (hs-TnT) has greater predictive value than conventional Troponin T in the development of CHD in the general population. However, its usefulness in patients with CKD is unclear.

**Methods:** We conducted a prospective study including 563 patients: 58% male, 32.5% diabetics, aged 64 ± 17 years, at different stages of CKD. We collected clinical history, routine laboratory parameters and hs-TnT. 20% had CHD history and 9.2% of acute myocardial infarction (AMI). Glomerular filtration rate was 50 ± 29 ml/min/m2 (MDRD-4) and 51 ± 29 mil/min/m2 (CKD-EPI). In 408 patients an echocardiogram was performed simultaneously.

**Results:** The mean hs-TnT was 18.5 ng/ml. Plasma concentrations of as-TnT were directly relate to age (r = 0.643, p <0.001) and inversely with the MDRD 4 (r = -0,674 p <0.001). The hs -TnT is higher in men than in women (20.4 vs 15.9 ng / ml, p <0.01), is significantly higher in patients with history of CHD (p = 0.032) and especially in patients with a history of myocardial infarction ( p <0.01). The mean hs-TnT according to stages of CKD was: Stage1: 3.97 ng / ml; Stagee 5: 45.56 ng/ml, with a statistically significant difference in the variance analysis (p <0.01). When we divided the patients with and without history of CHD, the differences remained significant (p <0.01 and p <0.001 respectively). 19.1% of patients had left ventricular hypertrophy in this group, the values of hs-TnT were higher (40.4 vs 13.8 ng / ml, p <0.001). In a multivariable model, remain as predictors of high hs-TnT values the loss of renal function, history of CHD and LVH.

**Conclusions:** Hs-TnT levels increased as the severity of CKD, even without evidence of acute myocardial damage, so the value of this marker must be adjust according to the degree of renal function. hs-TnT concentrations are higher as in men, patients with history of CHD and those with LVH.

## FR-PO234

**Effect of Adaptive Servo Ventilation Treatment for Chronic Heart Failure in Patients with Chronic Kidney Disease** Akihiro Kuma, Masahito Tamura, Emi Hasegawa, Yoko Fujimoto, Kenichiro Bando, Tetsu Miyamoto, Ryota Serino, Narutoshi Kabashima, Yutaka Otsuji. *The Second of Internal Medicine, School of Medicine, Univ of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

**Background:** Many chronic kidney disease (CKD) patients also have cardiovascular diseases, and it is particularly difficult to treat heart failure (HF) accompanied by CKD. Recent studies have shown that adaptive servo ventilation (ASV) is effective for treating and managing HF. We investigated whether ASV has potential for treating HF in CKD patients.

**Methods:** We registered non-replacement CKD patients (CKD stage II~Ⅴ) with chronic HF in our hospital. We then selected patients whose HF was difficult to control using HF medication alone and who were diagnosed with sleep apnea syndrome by the polysomnography test. These patients underwent ASV therapy while sleeping every night. We then analyzed renal and cardiac function 1 and 6 months after initiating therapy.

**Results:** Patients (n = 23) comprised 16 males and 7 females. Mean age was 66.8 ± 12.2 years. CKD stage was II (33.3%), III (38.1%), IV (23.8%), and Ⅴ (4.8%). Estimated glomerular filtration rate (eGFR) was 46.5 ± 22.4 mL/min per 1.73m$^2$ before ASV therapy (0M), 53.0 ± 21.2 mL/min per 1.73m$^2$ 1month after ASV therapy (1M) (p < 0.01 vs 0M), and 51.4 ± 25.4 mL/min per 1.73m$^2$ 6months after ASV therapy (6M) (p < 0.05 vs 0M). Left ventricular ejection fraction (LVEF) was 31.2 ± 15.1 % (0M), 37.4 ± 12.9 % (1M) (p < 0.005 vs 0M), and 39.0 ± 11.9 % (6M) (p < 0.005 vs 0M). No correlation was observed between eGFR (0M) and improvement in LVEF (0M-6M) (r = 0.2192, p = 0.34). Data are expressed as mean ± standard deviation values.

**Conclusions:** ASV treatment for HF in patients with CKD improved both cardiac and renal functions in the early stage (1M), and functions were maintained for six months. Regardless of renal function, a positive effect of ASV treatment was observed. ASV therapy appeared to be useful for treating HF in CKD patients.

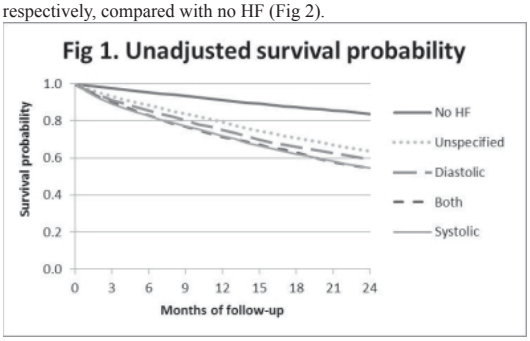
## FR-PO235

**Risk of Death for Systolic and Diastolic Heart Failure in Patients with Chronic Kidney Disease** Shuling Li,[1] Yan Hu,[1] Charles A. Herzog.[1,2] *[1]CDRG/MMRF, U.S. Renal Data System/CVSSC; [2]Univ of MN.*

**Background:** Heart failure (HF) is common in elderly pts and its prevalence increased in pts with chronic kidney disease (CKD). Few studies have examined systolic vs diastolic heart failure and their associated risk of death in elderly CKD pts.

**Methods:** We identified 101,337 CKD pts (age ≥66) prevalent on 12/31/09 and continuously enrolled with Medicare in 2009 using the Medicare 5% sample data. HF was identified from ICD-9 codes 398.91, 428.xx, 402.x1, 404.x1, and 404.x3 in claims during 2009 and included systolic (428.2x), diastolic (428.3x), both systolic and diastolic (428.4x), and unspecified. F/U began on 1/1/2010 and ended at the earlier date of death or 12/31/2011. Unadjusted survival was estimated by Kaplan-Meier method. The risk of death associated with HF types was assessed in a comorbidity-adjusted Cox model.

**Results:** Of all pts, the percent of pts with systolic, diastolic, both, and unspecified HF was 7%, 6%, 2%, and 16%, respectively. Prevalence of HF increased with age; by type, from 6% in 66-69 yrs to 9% in ≥85 yrs for systolic HF, 4% to 8% for diastolic HF, 1% to 2% for both HF, and 10% to 23% for unspecified HF. Prevalence of systolic HF was higher in male than females (9% vs. 6%), but prevalence of diastolic HF was lower in males than females (4% vs. 7%). Two-year survival probability was 54% systolic, 55% both, 59% diastolic, and 64% unspecified HF, and 84% no HF (Fig 1). The adjusted hazards ratio (95% CI) for death was 2.3 (2.2. 2.4) and 1.9 (1.8, 2.0) for systolic and diastolic HF, respectively, compared with no HF (Fig 2).



**Conclusions:** HF of any type in elderly CKD pts is associated with high long-term mortality. Systolic HF has the worst outcome. Future studies targeting this high risk population are warranted.

*Funding:* NIDDK Support

## FR-PO236

**Accumulation of Advanced Glycation End-Products Is Associated with Increased Pulse Pressure in Patients with Progressive Chronic Kidney Disease** Khai Ping Ng, Stephanie J. Stringer, Mark David Jesky, Punit Yadav, Mary Dutton, Charles Ferro, Paul Cockwell. *Renal Medicine, Queen Elizabeth Hospital, Birmingham, Birmingham, West Midlands, United Kingdom.*

**Background:** Accumulation of advanced glycation end-products (AGEs) and chronic kidney disease (CKD) are both strongly and independently associated with cardiovascular mortality. Emerging evidence indicates that both these processes are associated with an increase in arterial stiffness. We investigated whether AGEs accumulation, as measured by skin auto-fluorescence (SAF), is independently associated with pulse pressure (PP), a measure of arterial stiffness, in patients with CKD.

**Methods:** Cross-sectional observation study of the first 500 patients recruited in Renal Impairment in Secondary Care (RIISC) study.

**Results:** The mean age of participants was 64 ± 16 years with 60% of male gender and 71% of white ethnicity. Forty percent were diabetic and 34% had a previous history of cardiovascular disease (CVD). The median estimated glomerular filtration rate (eGFR) was 25 (interquartile range (IQR), 20- 32) ml/min/1.73m$^2$. The mean SAF was 3.0 ± 0.8 AU. In univariate analysis, SAF correlated with age (r=0.521, p<0.001), diabetes (r=0.134, p=0.005), CVD (r=0.171, p<0.001), use of an angiotensin-converting enzyme inhibitor or angiotensin receptor blocker (r= -0.167, p<0.001), PP (r=0.286, p<0.001), natural log-transformed (Ln) eGFR (r= -0.243, p<0.001), Ln albumin:creatinine ratio (r= -0.128, p=0.014), uric acid (r=0.149, p=0.002) and Ln high-sensitivity C-reactive protein (r=0.141, p=0.018). SAF did not correlate with gender or smoking status. In multivariate linear regression model, only age (beta=0.460, p<0.001), PP (beta=0.251, p<0.001) and Ln eGFR (beta=0.112, p=0.034) was independently associated with SAF. The model explained 35% of the variance in SAF.

**Conclusions:** Tissue accumulation of AGEs is independently associated with increased PP in people with CKD. Interventions aimed at preventing the accumulation of AGEs might prevent the development of arterial stiffness in CKD and improve cardiovascular outcomes.

**FR-PO237**

**Skin Perfusion Pressure: An Early Predictor of Peripheral Arterial Disease**

Nia J. Jones,[3] Ian Mathieson,[2] Keith Morris,[2] Aled O. Phillips,[1] Steve Riley.[1] *[1]Institute of Nephrology, Cardiff Univ, Cardiff, United Kingdom; [2]Cardiff Metropolitan Univ; [3]Cardiff and Vale Univ Health Board.*

**Background:** CKD patients treated with haemodialysis have a high prevalence of peripheral arterial disease (PAD), an increased risk of foot ulceration and mortality. Skin perfusion pressure (SPP) assesses the microcirculation and is superior in the diagnosis of PAD compared to Ankle Brachial Pressure Index (ABPI).SPP value ≤70mm/Hg is an independent risk factor for amputation and survival of haemodialysis patients. This prospective study analysed the risk factors for foot ulceration in CKD stage 4 and measured the progression of PAD.

**Methods:** 126 CKD patients (53 with Diabetes) and 46 age matched healthy controls were recruited. PAD was investigated using a Doppler and the Sensilase System (PAD 3000) over a 2 year period.

**Results:** 33 (26%) CKD cohort had a cumulative history of foot ulceration at end point ($p<0.001$). 15 (12%) were referred for vascular intervention and three patients had amputation. Analysis demonstrated a highly significant difference in mean SPP and Tukey's pairwise confirmed the significance was associated with the CKD cohort versus the controls ($p<0.0005$). The right SPP correlated with the left SPP ($p<0.018$) and no differences were observed between SPP values of the CKD and diabetic cohorts. Mann-Whitney U test confirmed the median SPP was significantly lower in participants that developed foot ulceration (SPP 40mm/Hg v 75mm/Hg: $p<0.014$). 20 of the CKD patients at baseline had normal biphasic Doppler waveforms despite a reduced SPP ≤50mm/Hg; 10 of this cohort had developed foot ulceration at end point with 7 of these progressing to monophasic pulse waveform by study end.

**Conclusions:** The micro-circulation is often overlooked during routine foot screening. Risks associated with SPP values ≤ 70 mm/Hg are not confined to the dialysis population. These findings suggest SPP is an important early predictor of lower limb ischemia when compared to the Doppler and may allow early intervention in this patient group to improve outcome.

**FR-PO238**

**Stroke in CKD Patients; Prevalence, Subtypes and Prognosis**

Debasish Banerjee, Hugh Markus. *Div of Clinical Sciences, St. Georges, Univ of London, United Kingdom.*

**Background:** Strokes are common in patients with chronic kidney disease (CKD) and associated with poor outcome. Data on prevalence, stroke subtypes and risk factors in CKD patients within large cohorts of stroke patients are lacking. The study aimed to estimate the prevalence of CKD in stroke patients admitted to an inner-city hyper-acute stroke unit; together with associated risk factors, stroke subtypes and outcome.

**Methods:** Data collected prospectively in 2333 stroke patients were analysed using SPSS 17. Stroke subtypes were reported by clinicians using the "Trial of Org 10172" (TOAST) classification with brain imaging and clinical information. The study was approved as a clinical audit. The GFR was estimated using MDRD equation. CKD was defined as eGFR < 60 ml/min/1.73m$^2$. Short term outcome was estimated with the "Barthel index"; 20 being the best score.

**Results:** In 2333 stroke patients, 639 (27.4%) had CKD. CKD patients were older (79±11 vs. 70±14 years; $p<0.001$), less likely of Afro Caribbean or African descent (11.5% vs. 17.3%; $p<0.0.005$), with less smokers (12% vs. 23%; $p<0.0001$), more diabetes (31% vs. 21%; $p<0.0001$), less hyperlipidaemia (35% vs. 41%; $p<0.01$), lower cholesterol (4.5±1.4 vs 4.8±1.3; $p<0.001$) and lower LDL cholesterol (2.7±1.1 vs. 2.9±1.0; $p<0.001$), compared to non CKD patients.

CKD patients suffered less haemorrhagic strokes (9.2% vs. 14.6%; $p<0.001$) but more cardioembolic ischaemic strokes (36.8% vs. 23.8%; $p<0.0001$) compared to non CKD patients. Adjusted for age, gender, ethnicity, systolic BP and cholesterol; CKD was associated with more cardioembolic strokes (OR=1.31, 95%CI 1.05 to 1.64; p=0.015) and less haemorrhagic strokes (OR=1.51, 95%CI 1.07 to 2.13; p=0.020).

The Barthel Index at 1 week was lower in CKD patients (11.38±7.84 vs. 13.61±7.38; $p<0.001$). In multivariable regression age, diabetes, cholesterol, systolic BP and eGFR were all independently related to lower Barthel Index.

**Conclusions:** Among stroke patients admitted to the hyper-acute stroke unit, CKD was present in 27.4% associated with lower Barthel index at 1 week. The CKD patients were older, more diabetic, with lower cholesterol, similar blood pressure and suffered from less haemorrhagic but higher cardioembolic strokes.

**FR-PO239**

**A Novel Model of Advanced Diabetic Kidney Disease in Mice**

Jean-Francois Thibodeau,[1,2] Dylan Burger,[1] Chet E. Holterman,[1] Kevin D. Burns,[1] Rhian Touyz,[4] Chris R. Kennedy.[1] *[1]Kidney Research Center, Ottawa Hospital Research Institute, Ottawa, Canada; [2]Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, Canada; [3]Institute of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom.*

**Background:** Insight into the pathogenesis of diabetic nephropathy (DN) has been limited by a lack of animal models which recapitulate key features of human DN. While the majority of currently available rodent models exhibit characteristics of early DN (hyperfiltration, mesangial expansion, albuminuria), features of advanced DN (hypertension, GFR decline, tubulointerstitial fibrosis) are absent or require a significant time investment for full phenotype development. A possible explanation for resistance to renal complications of diabetes in rodents is the lack of a concomitant increase in blood pressure. Accordingly, the aim of the present study was to develop a mouse model of advanced DN with hypertension superimposed.

**Methods:** Type 1 diabetic OVE26 mice were crossed with a mouse model of angiotensin-dependent hypertension utilizing mice transgenic for active human renin cDNA under the control of the transthyretin promoter (TtRhRen). TtRhRen mice exhibit angiotensin-dependent hypertension and progressive cardiac hypertrophy beginning at 6 weeks of age.

**Results:** At 20 weeks of age, OVE26 mice exhibited modest albuminuria as compared with wild-type and TtRhRen mice. However, albuminuria was significantly more pronounced in OVE26/TtRhRen mice. Additionally, OVE26/TtRhRen mice displayed renal and glomerular hypertrophy and evidence of tubulointerstitial fibrosis. Interestingly, beginning at 10 weeks TTRhRen/Ove26 mice were severely hypertensive, significantly exceeding that of TTRhRen littermates.

**Conclusions:** In summary, our results suggest that TtRhRen/OVE26 mice are a robust model of type I DN that recapitulates key features of human disease. Such a model may be of significant interest in the analysis of DN pathogenesis and in the assessment of putative therapeutics.

**FR-PO240**

**Hyperglycemia Triggered Inflammosomes Activation in Glomerular Cells via Mitochondrial ROS Contributes to Diabetic Nephropathy**

Madhusudhan Thati, Khurrum Shahzad, Fabian Bock, Hermann-Josef Groene, Berend Heinrich Isermann. *Institute for Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke Univ Magdeburg, Magdeburg, Germany.*

**Background:** Activation of the Nlrp3-Inflammosome has been implicated in many diseases including diabetic nephropathy (dNP). Whether inflammosome activation is causally involved in the pathogenesis of dNP and whether resident or bone marrow derived cells are involved remains to be elucidated.

**Methods:** Here, we analyzed the processing of caspase-1 and IL-1β in two different diabetes models (type 2 diabetic db/db mice and in STZ induced mice). A subset of mice was injected with anakinra, an IL-1β inhibitor. In addition we transplanted bone marrow cells from Nlrp3-/- or caspase1-/- mice into db/db or wt control mice to investigate role of hematopoietic cells. Diabetic mice deficient for the mitochondrial RedOx-enzyme p66$^{shc}$ were analyzed. Supplementary in vitro assays were performed in endothelial cells and podocytes.

**Results:** In renal cortex extracts of diabetic mice an increased expression of Nlrp3 and of mature IL-1β was observed. Nlrp3-/- or caspase1-/- mice as well as anakinra treated mice were protected against dNP. Confocal immunofluorescence analyses revealed that inflammasome activation is enhanced in glomerular cells in mice and humans with dNP. The severity of dNP was unchanged in bone marrow chimeras (Nlrp3-/- or caspase1-/- > db/db, compared with wt > db/db). Inhibition of mitochondrial ROS prevents inflammasome activation in podocytes in vitro. In diabetic p66$^{Shc}$-/- mice ROS-makers and inflammasome activation were reduced and these mice were protected against diabetic nephropathy. In vitro studies revealed activation of Nlrp3 /caspase-1/ pro-IL-1β upon glucose stimulation, while caspase-1 inhibitor/anakinra abolished IL-1β induction. Anakinra had no effect when cells were transduced with mutated Nlrp3 (Q705K) compared with Nlrp3-WT.

**Conclusions:** Taken together, these results strongly support that activation of the inflammasome in residual glomerular cells contributes to dNP. The inflammosomes may be a new therapeutic target in patients with diabetic nephropathy.

**FR-PO241**

**Baseline Characteristics of Diabetic Kidney Disease Patients Enrolled in a Phase 2 Trial of CTP-499**

LuAnn A. Sabounjian,[1] Philip B. Graham,[1] Lijun Wu,[1] Ara Aslanian,[1] Changfu Cheng,[1] David J. Turnquist,[1] James Shipley,[1] George L. Bakris.[2] *[1]Concert Pharmaceuticals, Inc., Lexington, MA; [2]The Univ of Chicago Medicine, Chicago, IL.*

**Background:** CTP-499, a novel, deuterium-containing methylxanthine derivative that selectively inhibits PDE subtypes that modulate cAMP and cGMP hydrolysis, is currently being developed as an additive treatment for delaying the progression of diabetic kidney disease. In preclinical studies, CTP-499 has been shown to suppress inflammatory, oxidative, and fibrotic processes associated with the pathophysiology of diabetic kidney disease. The objective of this double-blind, placebo-controlled, multicenter study (39 centers in the U.S.) is to assess the safety and efficacy of a minimum of 24 weeks of treatment with CTP-499 in patients with macroalbuminuric type 2 diabetic kidney disease who were maintained on a stable ACEi/ARB regimen.

**Methods:** The study randomized 182 patients 1:1 to either CTP-499 (600 mg BID, oral tablet) or placebo. Key entry criteria were: systolic blood pressure ≤ 145 mm Hg, diastolic blood pressure ≤ 90 mm Hg, macroalbuminuria with UACR from 200 for males and 300 for females to a max of 5000 mg/g, and eGFR by MDRD formula between 23 and 89 mL/min/1.73m$^2$. Additionally, patients were not expected to start dialysis in the next year.

**Results:** Based on these parameters, the characteristics of the enrolled population are shown below.

**Characteristics of Enrolled Patients**

| | | |
|---|---|---|
| **Randomized** | Total, N | 182 |
| **Gender** | Males, N (%) | 138 (75.8) |
| | Females, N (%) | 44 (24.2) |
| **Age** | Mean (range) years | 63.5 (29 to 86) |
| **HbA1c** | Mean ± SD (range) | 7.5 ± 1.2 (4.6 to 11.6) |
| **UACR** | Mean (range) mg/g | 1114.6 (173 to 3991) |
| | ≤ 1500 N (%) | 137 (75.3) |
| | > 1500 N (%) | 45 (24.7) |
| **eGFR** | Mean (range) mL/min/1.73m$^2$ | 45.8 (23 to 83) |
| | ≤ 60 N (%) | 148 (81.3) |
| | > 60 N (%) | 34 (18.7) |

The primary endpoint is the change in UACR over a minimum 24 weeks of treatment. Secondary endpoints include changes in eGFR, serum creatinine, inflammatory and fibrotic biomarkers and hematology markers, and assessment of population PK.

**Conclusions:** Phase 2 trial results are expected in the second half of 2013 and will inform the next stage of clinical development.

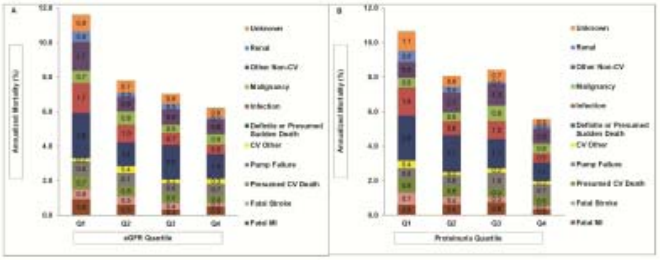
## FR-PO242

**Mode of Death in Diabetic Chronic Kidney Disease: Analysis of the Trial to Reduce Cardiovascular Events with Aranesp (Darbepoetin-Alfa) Therapy (TREAT)** David M. Charytan,[1] Eldrin F. Lewis,[1] Akshay S. Desai,[1] Larry A. Weinrauch,[1] Peter Ivanovich,[4] Robert D. Toto,[2] Jerome A. Rossert,[5] Brian Claggett,[1] Marc A. Pfeffer,[1] Scott D. Solomon.[1] *[1]Brigham & Women's Hospital, Boston, MA; [2]UT Southwestern, Dallas, TX; [3]BHF Cardiovascular Research Centre, Glasgow, United Kingdom; [4]Northwestern Univ, Chicago, IL; [5]Amgen, Thousand Oaks, CA.*

**Background:** How the incidence of specific modes of death changes across the spectrum of chronic kidney disease (CKD) is uncertain.

**Methods:** We analyzed adjudicated endpoints from 4038 subjects with anemia and diabetic CKD enrolled in TREAT, a randomized trial comparing darbepoetin alfa and placebo. Urine protein to creatinine ratio (PCR) at baseline and GFR estimated by the CKD-Epi equation were related to specific modes of death.

**Results:** Median GFR and PCR ranged from 20.6 ml/min/1.73m$^2$ and 4.1 g/g, respectively, in quartile (Q)1 to 47.0 ml/min/1.73m$^2$ and 0.1 g/g in Q4, P<0.01. Annualized mortality (AM) was higher in patients with lower GFR (6.2%, in Q4 to 11.6% in Q1) or higher PCR (5.6% in Q4 to 10.6% in Q1), P<0.01. Both CV and non-CV mortality increased from Q4 to Q1 of GFR or PCR, but there was a trend towards greater increase in non-CV compared with CV death at lower GFR. Sudden death was more frequent with lower GFR (1.4% in Q4, 2.6% in Q1, P=0.02) or higher proteinuria at baseline (1.1% in Q4, 2.6% in Q1, P<0.01). AM from infection was three-fold higher in the lowest GFR (0.6% in Q4 to 1.7% in Q1) and highest PCR quartile (0.5% in Q4 to 1.6% in Q1), P<0.01.



**Conclusions:** In diabetic CKD with anemia both lower GFR and higher PCR at baseline are associated with higher CV and non-CV mortality rates, particularly from infection and sudden death. Efforts to improve outcomes should focus on prevention of infection as well as CV disease.

**PROVALID – A Multinational, Prospective Cohort Study in Patients with Type 2 Diabetes Mellitus** Susanne Eder,[1] Sara S. Roscioni,[2] Hiddo Jan Lambers Heerspink,[2] Dick de Zeeuw,[2] Andrzej Wiecek,[3] Janos Toth,[4] Laszlo Rosivall,[4] Alan G. Jardine,[5] Patrick B. Mark,[5] Gert J. Mayer.[1] *[1]Dep Int Med IV, Med Univ Innsbruck, Innsbruck, Austria; [2]Dep Clin Pharmacol, Univ Med Center Groningen, Groningen, Netherlands; [3]Dep Nephrol, Endocrinol and Metabol Diseases, Med Univ Silesia, Katowice, Poland; [4]Inst Pathophysiol, Nephrol Research and Training Center, Semmelweis Univ, Budapest, Hungary; [5]Nephrol and Transplant Lab, Univ Glasgow, Glasgow, United Kingdom.*

**Background:** One of the most devastating complications of type 2 diabetes is end stage renal disease (ESRD). Interestingly, the incidence of ESRD varies considerably within Europe. PROVALID is a prospective cohort study in 4.000 individuals with type 2 diabetes in five European countries (Austria, Netherlands, Poland, Hungary and U.K.) to determine and compare the cumulative incidence of renal and cardiovascular complications.

**Methods:** Patients aged 18 to 75 years are recruited at primary health care facilities and treated according to local practice. Medical history, incident events and laboratory parameters are entered into a web based data repository. Blood and urine samples for routine laboratory analysis are collected annually; samples for validation of biomarkers at the genome, transcriptome, proteome and metabolome level are collected during the first year of the study and analyzed during follow up. The primary endpoint is the incidence of de novo micro- and macroalbuminuria, doubling of serum creatinine, ESRD or death. Cardiovascular death, non-fatal stroke, myocardial infarction and hospitalization for heart failure will be components of the secondary endpoint.

**Results:** As of May 2013 more than 2600 subjects have been included, recruitment is estimated to be complete by the end of 2013.

**Conclusions:** PROVALID will provide information on the incidence of cardiorenal complications in type 2 diabetes patients in European countries with varying health care systems. Blood and urine samples will be available to allow validation of potential biomarkers to improve monitoring of disease in this high risk population. Funding: European Union (FP7 project no. 241544, SysKid), ABBVIE.

## FR-PO244

**Prevalence of Metabolic Syndrome after Donor Nephrectomy** Pisut Katavetin, Yingyos Avihingsanon, Kearkiat Praditpornsilpa. *Div of Nephrology, Dept of Medicine, King Chulalongkorn Memorial Hospital, Thai Red Cross Society and Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

**Background:** The association between chronic kidney disease and metabolic syndrome has now been widely appreciated. However, the potential mechanisms for this association are still unclear. Studies mostly focused on how metabolic syndrome cause chronic kidney disease. We, therefore, examined the association in the other way around: Could reduction of nephron mass lead to metabolic syndrome?

**Methods:** Data of the donors who visited the 'Donor Clinic' from 2009-2012 were retrospectively review to examine the prevalence of metabolic syndrome after kidney donation. Data of 494 'Donor Clinic' visits (0.1 to 176.9 months after the kidney donation) from 102 kidney donors were included in the present analysis.

**Results:** The prevalence of metabolic syndrome was only 6.1% during the first year after kidney donation. The prevalence of metabolic syndrome in the second and the third year after kidney donation was 10.0 and 20.0% respectively. Prevalences of high blood pressure (≥130/85 mmHg) impaired fasting glucose (≥100 mg/dl) and elevated triglycerides (≥150 mg/dl) were also increasing during the first 3 year after kidney donation.

Prevalence of each component of metabolic syndrome

| Time after kidney donation | High blood pressure (≥ 130/85 mmHg) | Impaired fasting plasma glucose (≥100 mg/dl) | Elevated triglycerides (≥150 mg/dl) | Reduced HDL (< 40 in male or 50 in female) |
|---|---|---|---|---|
| First year | 18.8 | 3.3 | 20.0 | 23.3 |
| Second year | 17.5 | 25.0 | 33.3 | 25.0 |
| Third year | 31.5 | 27.8 | 41.7 | 25.0 |

**Conclusions:** Reduction of nephron mass after kidney donation may increase risk for metabolic syndrome. These findings would explain, at least in part, the association between metabolic syndrome and chronic kidney disease.

## FR-PO245

**Treatment of Chronic Kidney Disease in Rats Early or Late Post 5/6$^{th}$ Nephrectomy with Multiple Doses of Allogeneic, Marrow Stromal Cells Is Effective in Arresting the Progressive Loss of Renal Function** Anna Gooch,[1] Zhuma Hu,[1] Ping Zhang,[1] Christof Westenfelder.[1,2] *[1]Medicine, U. of Utah and VA Medical Centers, Salt Lake City, UT; [2]Physiology, U of Utah, Salt Lake City, UT.*

**Background:** The NIH reported that from 1980-2009 the prevalence of ESRD increased 600%. Chronic kidney disease (CKD) of all etiologies regularly progresses to ESRD, requiring dialysis or transplantation. Our pre-clinical (AJP Renal 2005) and Phase I Clinical studies (Nat Rev Neph 2010) show that allogeneic rat and human Marrow Stromal Cells (MSCs) effectively protect renal function post IRI Acute Kidney Injury (AKI) and prevent secondary development of CKD. Similar early and late renoprotective responses were observed in on-pump cardiac surgery patients at risk for post-op AKI. The current, preclinical study explores whether administration of MSCs also ameliorates or prevents worsening of CKD.

**Methods:** Groups of adult, male Sprague-Dawley (SD) rats (n=7/group) underwent 5/6$^{th}$ nephrectomy and were followed for 12 weeks. Animals were treated with 4 i.v. allogeneic MSC injections (1x10$^6$ cells/kg b.w.) early (during weeks 2 to 3) or late (during weeks 8 to 11) post nephrectomy. Serum Creatinine (SCr), systolic blood pressure (BP) and urinary albumin (U Alb) excretion were assessed weekly and compared to vehicle treated 5/6$^{th}$ nephrectomized control and sham control groups. Renal histology was performed at end of study to assess glomerular sclerosis, interstitial fibrosis and inflammation.

**Results:** At end of study animals treated with MSCs either early or late in the course of CKD showed significantly lower SCr levels and U Alb excretion vs. vehicle control animals, as well as lower scores for interstitial fibrosis and glomerular sclerosis. While BPs were significantly lower in early MSC treated animals vs. vehicle controls, they were not significantly different in late treated animals vs. their vehicle controls.

**Conclusions:** Repeated administration of allogeneic MSCs early or late in the course of CKD appears to arrest the progressive loss of renal function and rise in albuminuria in these preclinical studies, supporting the possibility that these cells may be of use clinically in treating CKD.

**FR-PO246**

**The Enzymatic Activity of the VEGFR2-Receptor for the Biosynthesis of Dinucleoside Polyphosphates** Vera Jankowski,[1] Axel Kretschmer,[2] Mirjam Schuchardt,[1] Markus Van der Giet,[1] Joachim Jankowski.[1] *[1]Med Klinik IV, Charite, Berlin, Germany; [2]Biomarker, Bayer AG, Wupptal, Germany.*

**Background:** The group of dinucleoside polyphosphates encompasses a large number of molecules consisting of two nucleosides which are connected by a phosphate chain of variable length. Dinucleoside polyphosphate are uremic toxins influencing different physiologic and pathophysiologic processes. While the receptors activated by dinucleoside polyphosphates as well as their degradation have been studied in detail, its biosynthesis has not been elucidated so far.

**Methods:** Since endothelial cells released the dinucleoside polyphosphate uridine adenosine tetraphosphate ($Up_4A$), we tested cytosolic proteins of human endothelial cells obtained from dermal vessels elicited for enzymatic activity. When incubated with ADP and UDP these cells showed increasing concentrations of $Up_4A$.

**Results:** The underlying enzyme was isolated by chromatography and the mass-spectrometric analysis revealed that the enzymatic activity was caused by the vascular endothelial growth factor receptor 2 (VEGFR2). Since VEGFR2 but neither VEGFR1 nor VEGFR3 were capable to synthesise dinucleoside polyphosphates, Tyr-1175 is most likely essential for the enzymatic activity of interest. VEGFR2-transfected HEK 293T/17 synthesised dinucleoside polyphosphates in vivo too. The simultaneous biosynthesis of dinucleoside polyphosphates could amplify the response to VEGF, since dinucleoside polyphosphates induce cellular growth via P2Y purinergic receptors. Thus the biosynthesis of dinucleoside polyphosphates by VEGFR2 may enhance the proliferative response to VEGF. Given that VEGFR2 is primarily expressed in endothelial cells, the biosynthesis of dinucleoside polyphosphates is mainly located in the vascular system. Since the vasculature is also the main site of action of dinucleoside polyphosphates, activating vascular purinoceptors, blood vessels appear as an autocrine system with respect to dinucleoside polyphosphates.

**Conclusions:** We conclude that VEGFR2-receptor is capable of synthesizing dinucleoside polyphosphates. These mediators may modulate the effects of VEGFR2 due to their proliferative effects.

**FR-PO247**

**Modulation of NADPH Oxidase Activity by Known Uremic Retention Solutes** Vera Jankowski,[1] Joachim Jankowski,[1] Gerald Cohen.[2] *[1]Med. Klinik IV, Charite, Berlin, Germany; [2]Med. Klinik, Medical Univ of Vienna, Vienna, Austria.*

**Background:** Chronic kidney disease (CKD) and uremia are associated with increased oxidative stress. In addition, a number of diseases like cardiovascular disease are caused by increased concentration of reactive oxygen species (ROS). However, the link between uremic toxicity and enhanced oxidative stress in patients with chronic kidney disease is not well-understood until now.

NADPH oxidase is one of the keyplayer in genesis of oxidative stress by producing superoxide anion and secondarily derived reactive oxygen species (ROS) causing cardiovascular diseases. Based on experiments demonstrating an increased NADPH oxidase activity, when incubated with plasma of CKD patients compared to plasma of healthy volunteers, we investigated the effect of forty eight known and commercial available uremic retention solutes on the enzymatic activity of the NADPH oxidase.

**Methods:** Mononuclear leukocytes isolated from healthy volunteers were isolated, lysed and incubated with NADPH in the presence of plasma from healthy volunteers and CKD patients. Furthermore lysed leukocytes were incubated in presence of uremic retention solute of interest and DPI a specific inhibitor of the NADPH oxidase. The enzymatic activity of NADPH oxidase was quantified by monitoring NADPH degradation.

**Results:** Thirty nine of the tested uremic retention solutes showed a significant effect on the NADPH oxidase activity. All of the thirty nine uremic retention solutes decreased the NADPH oxidase activity. Oxalate has been characterized as the strongest inhibitor of the NADPH oxidase. Furthermore, glyoxal, kynurenic acid, cytidine and homocysteine showed strong inhibition of the NADPH oxidase. None of the investigated uremic retention solutes increased the NADPH oxidase activity.

**Conclusions:** All of the tested uremic retention solutes decreased the NADPH oxidase activity and thus the ROS formation. The results of this study demonstrate that uremic retention solutes may be strong modulators on the genesis of radicals by the NADPH oxidase and thus a cause for cardiovascular complications in CKD patients.

**FR-PO248**

**Endothelial TGF-β Signaling Contributes to Fibrosis Development during Chronic Renal Injury via Microvascular Rarefaction and EndoMT Processes** Sandhya Xavier, Radovan Vasko, Kei Matsumoto, Jun Chen, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

**Background:** Manipulation of TGF-b signaling in a certain cell type provides information on its contribution to the progression of disease as opposed to its untargeted interruption in the whole organ. While several studies focused on the ablation of epithelial TGF-b signaling or fibroblasts on development of fibrosis there is none on its ablation in the endothelium, owing to the unavailability of a KO mouse model due to embryonic lethality. We previously reported a model with partial ablation of TbRII in the endothelium ($TbRII^{endo+/-}$ mice).

**Methods:** Chronic kidney disease was induced in these mice using a folic acid nephrotoxic (FAN) model. We isolated primary endothelial cells from kidneys of $TbRII^{endo+/+}$ and $TbRII^{endo+/-}$ mice using anti-CD31 antibody coated dynabeads and assessed the profiles of Smad signaling and expression levels of TGF-b auxiliary receptor endoglin both short (S) and long (L) isoforms.

**Results:** Chronic injury (6 weeks of FA) showed ameliorated fibrotic response in kidneys of $TbRII^{endo+/-}$ mice as compared to $TbRII^{endo+/+}$ mice. $TbRII^{endo+/-}$ mice exhibited better preserved microvasculature in kidneys and increased angiogenic potential of ex vivo cultured aortic rings following challenge with FA. Endothelial to Mesenchymal transformation was significant in kidneys of $TbRII^{endo+/+}$ mice during FAN but ameliorated in kidneys of $TbRII^{endo+/-}$ mice. Smad signaling was dysregulated. Smad2 phosphorylation was impaired in $TbRII^{+/-}$ EC's, following TGF-b treatment. Interestingly, ALK1 mediated Smad1/5 phosphorylation was reduced at baseline in $TbRII^{+/-}$ EC's, however, following TGF-b treatment phosphorylation of Smad1/5 was not affected. Endoglin S/L mRNA expression ratio was significantly lower in $TbRII^{+/-}$ EC's with and without TGF-b treatment as compared to $TbRII^{+/+}$ EC's. An increased L-endoglin mediated Smad1/5 signaling in $TbRII^{+/-}$ EC's could explain the increased angiogenic potential of these mice observed in vivo.

**Conclusions:** Our data indicate a critical role of endothelial TGF-b signaling in regulating angiogenic and fibrotic response to injury.

**FR-PO249**

**Endothelial Sirtuin 1-Deficiency Leads to Down-Regulation of Matrix Metalloproteinase 14 and Exaggerated Kidney Fibrotic Response to Injury: Relevance to Fibrosis of Vascular Senescence** Jun Chen,[1] Radovan Vasko,[1] Sandhya Xavier,[1] Chi Hua Sarah Lin,[1] Brian B. Ratliff,[1] May M. Rabadi,[1] Julien Maizel,[1] Tanokuchi Rina,[1] Jian Cao,[2] Michael S. Goligorsky.[1] *[1]New York Medical College, Valhalla; [2]State Univ of New York, Stony Brook, NY.*

**Background:** Sirtuin 1 (SIRT1) depletion in vascular endothelial cells mediates endothelial dysfunction and premature senescence. However, the role of endothelial senescent cells and their contribution to organ pathology remain tenuous.

**Methods:** To investigate the contribution of endothelial SIRT1 deficiency *per se* to SIPS and vasculopathy, we used cre-lox strategy to generate mice with truncated SIRT1 gene in Tie-2-expressing endothelial (EC) and endothelial progenitor cells (EPC).

**Results:** Studies of $SIRT1^{endo-/-}$ mice showed impaired endothelium-dependent vasorelaxation and angiogenesis and traces of spontaneous fibrosis already at the early age. In contrast to the mild phenotype of SIRT1endo-/- mice under basal conditions, induction of nephrotoxic stress (acute and chronic folic acid nephropathy, FAN) resulted in a robust acute renal functional deterioration and exaggerated fibrotic response as examined three months later. To disclose the link between endothelial SIRT1 deficiency and exaggerated renal fibrosis, we examined matrix metalloproteases-14 (MMP-14), which was suppressed in $SIRT1^{endo-/-}$ mice. MMP-14 suppression induced by Sirt1 inhibitor was accompanied by impaired angiogenesis of HUVEC and matrilytic activity of mouse aortic rings, as well as retention of cleavage substrates such as tissue transglutaminase and endoglin, both endowed with the pro-fibrotic activity. Restoration of MMP-14 expression via Concanavalin A (ConA) treatment in vitro and in vivo resulted in improved angiogenic and matrilytic functions of the endothelium, prevented renal dysfunction induced by SIRT1 inhibition and attenuated nephrosclerosis. Same antifibrotic effect was observed in $Sirt1^{endo-/-}$ mice with FAN treated with ConA.

**Conclusions:** Data obtained in Endo-SIRT1(-/-) mice demonstrate the pathogenetic link between defective SIRT1 expression, SIPS and fibrosis. The latter is a result of the MMP-14 deficiency that develops as a consequence of SIRT1 deficiency.

**FR-PO250**

**Mechanisms of Proteinuria in a Chronic Kidney Disease (CKD) Model following Ischemic Injury** Silvia B. Campos-bilderback,[1] Monique Desiree Dino,[3] Ruben M. Sandoval,[1] Sarah E. Wean,[1] Bruce A. Molitoris.[1,2] *[1]Medicine/ Nephrology, IU School of Medicine, Indianapolis, IN; [2]Roudebush VAMC, Indianapolis, IN; [3]Univ of Contestado, Mafra, Santa Catarina, Brazil.*

**Background:** The development and or acceleration of CKD progression following acute kidney injury (AKI) is now well recognized, as is the importance of proteinuria as a risk factor for progression of CKD.

**Methods:** Therefore,to further understand the pathophysiology underlying CKD progression and proteinuria we used male Munich Wistar Fromter rats and induced CKD with ischemic injury and a unilateral nephrectomy.

**Results:** Serum creatinine levels increased from 0.3 to 1.5 ± 0.3 ($P<0.01$) and urinary albumin increased from 100 ± 10 to 1150 ± 300mg/24 hr/GFR/100gm ($P<0.01$). There was progression of both proteinuria and loss of GFR in this CKD model. Histologic evaluation revealed tubular atrophy with an interstitial mononuclear infiltrate and edema, peri-glomerular fibrosis, hyaline drop formation and generalized fibrosis. Two-photon microscopy demonstrated albumin glomerular sieving coefficients (GSC) increased from 0.015 ± 0.006 to 0.03 ± 0.010 ($P<0.01$) with intra-glomerular differences also noted within a single glomerulus. In PTs uptake of fluorescently labeled albumin was reduced from 2,911.3 ± 1,815.5 AFU/um2 to 1,763.3± 932.5 AFU/um2 ($p\leq0.05$); the most noticeable difference occurred in the area devoid of albumin uptake among PT's. Untreated rats had only 18.2 ± 7.2% of PT area with no albumin uptake while CKD rats had 42.9 ±21.1% of the PT area devoid of albumin uptake ($p\leq0.05$).

**Conclusions:** These data demonstrate albuminuria in rats with ischemic CKD resulted from a combination of increased $GSC_A$ and reduced albumin uptake by PTC. The model offers a rapid reproducible model of fibrosis and progression to further study glomerular, tubular and interstitial interactions, and to utilize in developing therapeutic agents to minimize CKD and AKI-CKD interactions.

**FR-PO251**

**Abnormal Circadian Rhythm of Blood Pressure Related to Kidney Damage in IgA Nephropathy** Lirong Lin, Yani He. *Nephrology, Daping Hospital, Third Military Medical Univ, Chongqing, China.*

**Background:** Abnormal circadian rhythm of blood pressure is a risk factor of cardiovascular and cerebrovascular lesions in the patients with primary hypertension, also it is closely related with diabetic nephropathy progression and cardiovascular events in hemodialysis patients. The purpose of this study is to investigate the role of abnormal BP rhythm in IgAN.

**Methods:** 341 IgAN patients were recruited in the study. Renal biopsy and 24 hour ambulatory blood pressure monitoring were performed. The pathological scores were evaluated according to the IgAN Oxford criterion. Influencing factors were determined by Spearman and Pearson correlation analysis and logistic regression analysis.

**Results:** (1) Incidence of abnormal BP rhythm is 73.0% (249/341) in IgAN patients, 73.8% (93/126) in IgAN patients with hypertension, 72.6% (156/215) in IgAN patients without hypertension.(2) Cystatin C, urinary P/Cr, uric acid, renal histological score, TIF, hyaline degeneration of small arteries were closely associated with abnormal blood pressure rhythm in IgAN patients with or without hypertension. The decline of nocturnal BP was negatively related with cystatin C, uric acid, renal histological score.(3) EGFR levels was closely associated with abnormal blood pressure rhythm in IgAN patients with hypertension. The decline of nocturnal BP was positively related with eGFR.(4) Urinary P/Cr and night/day ratio of urinary sodium excretion (RN/DUNa)were closely associated with abnormal blood pressure rhythm in IgAN patients without hypertension, and the decline of nocturnal BP was positively related with urinary P/Cr, RN/DUNa.

**Conclusions:** Abnormal blood pressure rhythm is closely related with kidney glomerulus, renal tubulointerstitial and arteriolar lesions in IgAN patients, indicating that abnormal blood pressure rhythm is a potentialrisk factor for IgAN prognosis. Abnormal blood pressure rhythm in IgAN patients is directly related with RN/DUNa and blood uric acid level, implying the ion transport dysfunction caused by renal tubular interstitial lesions in IgAN may be an important cause of abnormal blood pressure rhythm. Abnormal blood pressure rhythm can increase the risk for the progression to ESRD in hypertensive IgAN patients.

*Funding:* Clinical Revenue Support

**FR-PO252**

**Association of Systolic Blood Pressure with Progression to Chronic Dialysis in Patients with Advanced Kidney Disease** Shyamal K. Palit,[1] Anna Jeanette Jovanovich,[1] Alfred K. Cheung,[2,3] James S. Kaufman,[4] Gerard John Smits,[1] Michel Chonchol,[1] Jessica B. Kendrick.[1] *[1]Univ of Colorado Denver, Denver, CO; [2]VASLCHCS, Salt Lake City, UT; [3]Univ of Utah, Salt Lake City, UT; [4]VA New York Harbor Healthcare System, New York, NY.*

**Background:** Hypertension is a risk factor for progression of kidney disease in patients with normal or mildly reduced kidney function. However, the relationship between systolic blood pressure (SBP) and progression to dialysis in patients with advanced kidney disease is unclear.

**Methods:** We performed an analysis on 1,099 patients with advanced kidney disease not yet on dialysis who participated in the Homocysteine in Kidney and End Stage Renal Disease study. Blood pressure was measured in a standardized fashion. SBP levels were examined in clinically defined cutoffs (<120, 120-139, 140-159 and ≥160 mmHg) and as a continuous variable. We used Cox proportional hazard models to examine the association between SBP levels and time to initiation of chronic dialysis.

**Results:** The mean eGFR was 18 ± 7 ml/min. 615 patients (56%) initiated dialysis after a median follow-up of 2.9 years. After adjustment for age, gender and race there was an increased risk of progression to dialysis with a SBP 140-159 and ≥ 160 compared to a level <120 mmHg (HR 1.33, 95% CI 1.02-1.74 and HR 1.47, 95% CI 1.11-1.94, respectively). For every 1 mmHg increase in SBP, there was a 0.7% increased risk of progression to dialysis (HR 1.007, 95% CI 1.004-1.01). After further adjustment for hypertension, diabetes, cardiovascular disease, smoking, BMI, and eGFR every 1 mmHg increase in SBP was still associated with a 0.4% increased risk of progression to dialysis (HR 1.004, 95% CI 1.001-1.008). However, there was no longer an increased risk of progression to dialysis with a SBP 140-159 or ≥ 160 compared to a level <120 mmHg (HR 1.2, 95% CI 0.94-1.62 and HR 1.28 95% CI 0.96-1.70, respectively).

**Conclusions:** Elevated SBP levels were weakly associated with progression to chronic dialysis in patients with advanced kidney disease and there was no increased risk with a SBP >140 or >160 mmHg. Hence, in advanced kidney disease, lowering SBP may not be helpful in slowing progression to dialysis initiation.

*Funding:* NIDDK Support

**FR-PO253**

**Low Serum Levels of High-Density Lipoprotein Cholesterol Are Not Associated with Progression to Dialysis in Patients with Advanced Kidney Disease** Shyamal K. Palit,[1] Anna Jeanette Jovanovich,[1] Alfred K. Cheung,[2,3] James S. Kaufman,[4] Gerard John Smits,[1] Michel Chonchol,[1] Jessica B. Kendrick.[1] *[1]Univ of Colorado Denver, Denver, CO; [2]VASLCHCS, Salt Lake City, UT; [3]Univ of Utah, Salt Lake City, UT; [4]VA New York Harbor Healthcare System, New York, NY.*

**Background:** Patients with chronic kidney disease often have low high-density lipoprotein cholesterol (HDL-C) levels. In the general population and in patients with mild kidney disease, low HDL-C levels are associated with worsening of kidney function. However, the relationship between HDL-C levels and progression to dialysis in patients with advanced kidney disease is unknown.

**Methods:** We performed an analysis on 1,099 patients with advanced kidney disease not yet on dialysis, who participated in the Homocysteine in Kidney and End Stage Renal Disease study. The study population was divided into quartiles based on serum HDL-C levels. We used Cox proportional hazard models to examine the association between HDL-C levels and time to initiation of chronic dialysis.

**Results:** The mean age and eGFR were 69 ± 11 years and 18 ± 7 ml/min/1.73m$^2$, respectively. After a median follow-up time of 2.9 years, 615 patients (56%) initiated chronic dialysis. After adjustment for age, gender and race there was no association between HDL-C levels and kidney disease progression (HR 0.99, 95% CI 0.99 to 1.004). After further adjustment for age, race, gender, diabetes, hypertension, cardiovascular disease, smoking, body mass index, eGFR, systolic blood pressure, low-density lipoprotein cholesterol and triglycerides, HDL-C levels did not predict progression of kidney disease (HR 1.03, 95% CI 0.99 to 1.01, p 0.30). There was no increase in risk of kidney disease progression in patients in the lowest quartile of HDL-C levels compared to the highest quartile (HR 1.2, 95 % CI 0.96 to 1.51, p=0.12).

**Conclusions:** Low HLD-C levels are not associated with progression to chronic dialysis in patients with advanced kidney disease. Further studies are needed to elucidate the role of HDL-C in kidney disease progression.

**Gastric Hormone Ghrelin Improves Exercise Endurance of 5/6 Nephrectomized Mice through PGC1α-Dependent Activation of Muscle Mitochondria** Masanori Tamaki, Kazutoshi Miyashita, Shu Wakino, Masanori Mitsuishi, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.*

**Background:** Chronic kidney disease (CKD) decreases physical performance of the patients, and the physical inactivity constitutes an independent risk for cardiovascular diseases. We have identified a decrease in muscle mitochondria from an early phase of CKD, which lead to a reduction in exercise endurance of 5/6 nephrectomized mice, an animal model of mild CKD. These deteriorative effects on physical performance preceded a loss of muscle mass, which resulted in a decrease in muscle power. To improve the physical performance of the CKD model mice, the effect of a gastric hormone, ghrelin, was examined, whose circulating concentration is reported to increase in CKD patients.

**Methods:** C57bl/6 mice which had undergone 5/6 nephrectomy at 6 to 7 weeks old were examined for physical performance at 16 weeks. Ghrelin (0.1 μg/gBW) or insulin-like growth factor-1 (IGF-1, 0.05 μg/gBW) was administered intra-peritoneally twice a week from 8 weeks old. C2C12 cultured myocytes were treated for 24 hours with ghrelin (1 nmol/l) and were examined for the effects on mitochondrial energy metabolism, with or without siRNA for PGC1α, which promotes mitochondrial biogenesis.

**Results:** 5/6 nephrectomy decreased muscle mitochondria and exercise endurance of the mice. An increase in muscle mitochondria, expression of genes promoting mitochondrial biogenesis, and an improvement of running distance were identified in ghrelin-treated mice. Increases in mitochondrial amount and oxygen consumption were identified in ghrelin-treated C2C12 myocytes, and the effects were suppressed by knocking down of PGC1α gene.

**Conclusions:** The gastric hormone ghrelin improved exercise endurance of 5/6 nephrectomized mice through an increase in muscle mitochondrial amount. The in vitro experiments suggested that ghrelin-induced increases in mitochondria and oxygen utilization were PGC1α-dependent. The results indicate that ghrelin plays novel roles in the improvement of physical performance of CKD patients, who could not perform exercise sufficiently.

**FR-PO255**

**Role of PCSK9 (Proprotein Convertase Subtilisin Kexin Type 9) in the Pathogenesis of Hypercholesterolemia in Nephrotic Syndrome** Kyubok Jin,[1] Bongsoo Park,[1] Yang Wook Kim,[1] Nosratola D. Vaziri.[2] *[1]Dept of Medicine, Inje Univ Haeundae Paik Hospital, Busan, Korea; [2]Dept of Medicine, Div of Nephrology and Hypertension, Univ of California Irvine, Irvine, CA.*

**Background:** Nephrotic syndrome (NS) is associated with impaired LDL clearance and elevated serum total and LDL cholesterol levels. LDL receptor (LDLR) plays a key role in cholesterol metabolism by mediating endocytosis and lysosomal degradation of LDL. In a series of earlier studies we found marked reduction in LDLR despite normal LDLR mRNA expressionin the liver of nephrotic rats, denoting a post-transcriptional or post-translational phenomenon. LDLR is, in part, regulated by PCSK9 which is secreted in the blood by the

liver where it binds, internalizes, and facilitates degradation of LDLR. Thus by preventing recycling of LDLR, upregulation of PCSK9 causes LDLR deficiency.Loss-of-function mutation of PCSK9 is associated with reduced LDL-cholesterol and diminished risk of coronary disease.This has lead to emergence of PCSK9 as a novel target for treatment of hypercholesterolemia. The mechanism(s) by which NS causes LDLR deficiency is not known. This study was undertaken to test the hypothesis that impaired LDL clearance in NS may be due to increased PCSK9.

**Methods:** Study Design: Prospective cohort study. Participants: Fifteen patients with nephrotic range proteinuria and 15 age- and gender-matched healthy individuals. Outcomes: Assessment of plasma PCSK9 and its relationship with serum total and LDL cholesterol and proteinuria. Measurements: Fasting serum PCSK9, lipids, and albumin concentrations and urine protein excretion.

**Results:** Elevation of serum total and LDL cholesterol in the nephrotic group was associated with significant increase in plasma PCSK9 level. Plasma PCSK9 was directly related with total and LDL cholesterol concentrations and urinary protein excretion and inversely related with serum albumin concentration.

**Conclusions:** NS results in elevation of the circulating PCSK9 which can contribute to elevation of LDL by promoting LDLR deficiency.

## FR-PO256

### Is ENPP1 Gene SNP Associated with Lower Pyrophosphate Levels in ESRD

Sean M. Connery, Dianne C. Mitchell, German T. Hernandez, Ramin Tolouian. *Texas Tech Univ HSC at El Paso, TX.*

**Background:** ENPP1 is a trans-membrane glycoprotein, cell surface enzyme, encoded by the *ENPP1* gene. ENPP1 regulates inorganic pyrophosphate (PPi) which is involved in bone mineralization & soft tissue calcification. PPi is an essential inhibitor of calcification and has been reported to be lower in hemodialysis (HD) patients. ENPP1 inhibits soft tissue calcification by generating PPi. The dbSNP rs1044498 single nucleotide polymorphism (SNP) in ENPP1 results in an amino acid change from lysine to glutamine at codon 121 (K121Q) and it has been associated with increased vascular calcification in patients with end-stage renal failure (ESRD). Therefore the purpose of this study was to examine the association between SNP variant dbSNP rs1044498 and the levels of circulating PPi in HD patients.

**Methods:** 75 HD pts studied: mean age of 61 ±12 yr, 87% Hispanic, mean HD vintage of 4 ±3.2 yr (range .12 – 21.3). 25 matched controls were also evaluated: mean age of 51 ±13 yr, 96% Hispanic. Platelet free PPi levels in circulating blood were measured by enzymatic method as previously described by Tolouian. SNPs were measured using Human Omni1-Quad BeadChips (Illumina Inc.; San Diego, CA) from gDNA purified from human PBMCs and analyzed using the Illumina iScan & the Illumina's Genome Studio.

**Results:**

| | | **Genotype** mean ±SD | | |
|---|---|---|---|---|
| **Phenotype** | **A/A** | **A/C** | **C/C** | Group |
| **Ppi** (µm) - **Hemodialysis** n=75 | 1.59 ±0.49 | 1.54 ±0.45 | 1.64 ±0.47 | 1.58 ±0.47 |
| **Ppi** (µm) - **Control** n= 25 | | | | 2.06 ±0.53* |

Eller also reported no significant difference in Ppi in 79 white (Australian) HD subjects: n=60 A/A Ppi = 2.7, n = 19 A/C Ppi = 2.4 µm/L with Minor Allele frequency (MAF) = 0.137. The MAF in our HD group was much higher (0.21) and also higher than the MAF (0.12) of the Hispanic HapMap MEX normal (n=100).

**Conclusions:** In our study of predominantly Hispanic HD patients there was a much higher MAF in rs1044498 SNP, and 5 had the putative ENPP1 risk variant C/C, but there was no significant difference between PPi levels and gene variants. There was a statistically significant difference in PPi levels between the HD group and age- & ethnicity-matched controls.

## FR-PO257

### Akt-Pathway-Selective Insulin Resistance Contributes to Decreased Angiogenic Function of Bone Marrow-Derived Mesenchymal Stem Cells under Uremic Conditions

Hyunjin Noh,[1] Mi Ra Yu,[2] Hyun Joo Kim,[2] Jin Seok Jeon,[1] Soon Hyo Kwon,[1] Dong-Cheol Han.[1] *[1]Dept of Internal Medicine, Div of Nephrology, Soon Chun Hyang Univ, Seoul, Republic of Korea; [2]Hyonam Kidney Laboratory, Seoul, Republic of Korea.*

**Background:** Chronic kidney disease (CKD) is associated with increased risk for cardiovascular disease (CVD). We recently reported a significant functional incompetence in bone marrow (BM)-derived mesenchymal stem cells (MSCs) under uremic conditions, which may contribute to the high risk for CVD in patients with CKD. To study the mechanisms of dysfunctional MSCs induced by uremia, we characterized insulin signaling in MSCs.

**Methods:** BM-derived MSCs were generated from control and subtotal nephrectomized CKD mice. MSCs' multipotency was confirmed by positive differentiation into adipocytes and osteocytes.

**Results:** In mice model of hindlimb ischemia, we confirmed that CKD MSCs show functional incompetence. Blood flow recovery, capillary density, and local production of angiogenic factors in the ischemic limb treated with CKD MSCs were significantly inferior to those promoted by control MSCs. In cultured MSCs, insulin induced HIF-1α, VEGF, and SDF-1α expressions via phospatidylinositol 3-kinase (PI3K)/Akt-dependent pathway. CKD MSCs or control MSCs treated with p-cresol exhibited altered insulin signaling in a selective manner for the activation of IRS-1/PI3K/Akt pathway, whereas the activation of ERK pathway remained active. Insulin-induced tyrosine phosphorylation of IRS-1, p85 association with IRS-1, and IRS-1-associated PI3K activity were significantly reduced by p-cresol. In parallel, p-cresol treatment was associated with basal elevation in inhibitory phosphorylation of IRS-1 at Ser 616 residues. Modifying CKD MSCs by overexpression of HIF-1α restored the impaired blood flow recovery, capillary density, and local production of proangiogenic growth factors induced by CKD MSCs in the hindlimb ischemic model.

**Conclusions:** The present study shows that insulin signaling and actions in MSCs are significantly inhibited in a selective manner for the activation of IRS-1/PI3K/Akt pathway under uremia. We suggest that this might be a biological explanation for the functional incompetence of CKD MSCs.

## FR-PO258

### Carbamylation of Tissue Proteins: A Risk Factor for Complications during Chronic Kidney Disease

Laetitia Gorisse,[1] Christine Pietrement,[2,3] Stephane Jaisson,[1,3] Philippe Gillery.[1,3] *[1]Laboratory of Biochemistry and Molecular Biology, FRE CNRS/URCA n°3481, Faculty of Medicine, Reims, France; [2]Dept of Pediatrics (Nephrology Unit), American Memorial Hospital, Univ Hospital, Reims, France; [3]Laboratory of Pediatric Biology and Research, American Memorial Hospital, Univ Hospital, Reims, France.*

**Background:** Chronic kidney disease (CKD) independently increases the risk of any type of cardiovascular events and generates many other complications. Among other processes, carbamylation of proteins has been recently suggested as a novel risk factor for CKD complications. Carbamylation corresponds to the nonenzymatic binding of isocyanic acid, a urea by-product, to free amino groups of proteins. This reaction leads to the formation of carbamylation-derived products (CDPs). *In vitro* and clinical studies have suggested the potential involvement of CDPs in CKD complications, but their metabolic fate *in vivo* is still unknown, without evidences of CDPs accumulation in tissues.

**Methods:** To address this issue, we have submitted C57Bl/6 mice to sham surgery or 75% nephrectomy. Animals were sacrificed 5, 10 or 20 weeks later. Then we quantified HCit, a CDP resulting from lysine residue carbamylation, in plasma and tissues (aorta, kidney, bone, skin, liver, heart) by LC-MS/MS.

**Results:** We showed that carbamylation was a general biological process since basal plasma and tissue contents of HCit were evidenced in control mice. Carbamylated proteins accumulated to a higher extent in studied tissues after 20 weeks of CKD with a 2-fold increase of HCit content. Carbamylation rate was especially remarkable in type I collagen, a long-lived extracellular matrix protein. Carbamylated collagen accumulated progressively in CKD mice to reach a 5-fold increase after 20 weeks.

**Conclusions:** These results show that CKD increases carbamylation rate of plasma and tissue proteins, and provide new evidences for the involvement of CDPs and especially carbamylated collagen in CKD complications. They reinforce the hypotheses raised by the *in vitro* demonstrations of the deleterious effects of CDPs and by the recently evidenced relationship between plasma CDP concentrations and cardiovascular risk or mortality in CKD patients.

## FR-PO259

### Associations among Chronic Periodontitis, Vitamin D and Cathelicidin in Patients with Chronic Kidney Disease

Marcus Gomes Bastos, Jessica Do Amaral Bastos, Fernando Antonio basile Colugnati, Ana Paula Ferreira, Eduardo Machado Vilela, Patrícia de Castro Daibert, Luiz Carlos Ferreira Andrade. *Medical Clinic, Dentistry, and Institute of Biological Sciences, Federal Univ of Juiz de Fora, Minas Gerais, Brazil.*

**Background:** The occurrence of chronic periodontitis(CP) in patients with chronic kidney disease (CKD) has been associated with adverse outcomes. Vitamin D (25(OH) D), which not uncommonly is reduced in the serum of patients with CKD, directly induces expression of the antimicrobial peptide, cathelicidin (LL-37), which, if low, could explain the severity of CP frequently seen in CKD. The aim of this study was to examine the relationship among CP, 25(OH)D and LL-37 in patients with CKD.

**Methods:** A case-control study was conducted. Case and controls were defined as patients with CKD and CP (CKD+CP; n= 15), CKD without CP (CKD-CP; n= 14), CP but without systemic disease (-SD+CP; n= 14), and participants without both systemic diseases and CP (-SD-CP; n= 15). The demographic, clinical and laboratory data were obtained when the patients were seen at the outpatient clinic. CKD was defined and staged according to the NKF KDOQI™. Serum 25(OH)D was measured by chemioluminescence when evaluating the CP (defined according to the American Academy of Periodontoly). LL-37 and interleukin-6 (IL-6) were measured by ELISA.

**Results:** The data regarding the CP (clinical attachment level or CAL), IL-6, LL-37 and 25(OH)D are presented in the table. Patients with CKD and CP presented a worse CP, were more inflamed, presented lower levels of 25(OH)D and LL-37.

**Conclusions:** CKD patients have a worse CP, probably due to lower levels of LL-37 secondary to inadequate levels of vitamin D.

Table. Clinical and lab results of the 4 study groups.

| | | **GROUPS** | | | **P** |
|---|---|---|---|---|---|
| **VARIABLES** | **-SD-CP** | **-SD+CP** | **CKD-CP** | **CKD+CP** | |
| **CAL, mm** (mean±SD) | 0 | 18±16 | 0 | 28 (±20) | 0.01 |
| **IL-6, pg/mL** median (min-max) | 5 (1-10) | 5.9 (2-11) | 7.6 (2-18) | 14.3 (2-30) | 0.01 |

## FR-PO260

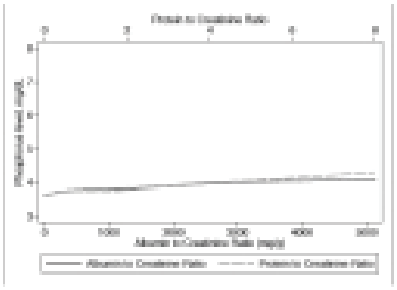
**Albumin-to-Creatinine Ratio versus Protein-to-Creatinine Ratio and Complications of CKD** Herrick Nadine Fisher, Chi-yuan Hsu, Eric Vittinghoff, Feng Lin, Nisha Bansal. *UCSF.*

**Background:** Urine albumin-to-creatinine ratio (ACR) and protein-to-creatinine ratio (PCR) are important markers of kidney damage and are utilized for prognosis in persons with chronic kidney disease (CKD). Despite how commonly these measurements are utilized in clinical practice, relatively few studies have directly compared the performance of these two measures with regard to associations with clinical outcomes. Here we studied the association of ACR and PCR with common complications of CKD.

**Methods:** This was a cross-sectional study of 3,481 participants with CKD in the Chronic Renal Sufficiency Cohort (CRIC). We examined the association between ACR and PCR with measures of common CKD complications: serum hemoglobin, bicarbonate, parathyroid hormone (PTH), phosphorus, potassium and albumin. Restricted cubic spline analyses adjusted for $eGFR_{MDRD}$ were performed to study the continuous association with our predictors with each outcome.

**Results:** Mean eGFR 43 ± 13 ml/min/1.73 $m^2$ and median levels of PCR and ACR were 140 mg and 46 mg/g, respectively. In continuous analyses adjusted for eGFR, higher ACR and PCR were comparable and both associated with lower serum hemoglobin, lower bicarbonate concentration, higher PTH, higher phosphorus, higher potassium and lower albumin (Figure). Across all outcomes, the associations of ACR and PCR were comparable with only small, absolute differences in the outcome measure. Similar associations were seen in patients with and without diabetes mellitus.

**Conclusions:** In persons with CKD, ACR and PCR are relatively comparable in their associations with common complications of CKD. Thus routine measurement of PCR may provide similar information as ACR in managing immediate complications of CKD.



*Funding:* NIDDK Support

## FR-PO261

**Factors Associated with Lower Serum Bicarbonate in Chronic Kidney Disease** Kalani L. Raphael,[1,2] Y. Zhang,[2] Jian Ying,[2] Tom Greene.[2] *[1]Salt Lake City VA Health Care System, UT; [2]Univ of Utah.*

**Background:** Acidosis is common in CKD, yet most with moderate-severe CKD do not have acidosis. The purpose of this study is to identify factors associated with lower serum bicarbonate in CKD.

**Methods:** This is a cross-sectional study using baseline data from the Chronic Renal Insufficiency Cohort (CRIC) Study. A base multivariable linear regression model included eGFR, UACR, age, gender, race, protein intake, diuretic use, and alkali use. Cause of renal disease, waist circumference, CVD, CRP, smoking, blood pressure, use of ACE-i or ARB, anemia, hyperkalemia, income, and education were individually added to the base model.

**Results:** The prevalence of acidosis was 17%. Lower eGFR had the strongest association with lower bicarbonate and higher UACR associated with lower bicarbonate. Older age and diuretic use associated with higher bicarbonate. Other base variables did not associate with variance of serum bicarbonate. Of the additional factors, ACE-I/ARB use, smoking, anemia, hyperkalemia, and larger waist circumference associated with lower bicarbonate.

| Variable | Coefficient (mM) | 95% CI (mM) |
|---|---|---|
| **eGFR (Ref 60 - <90)** | | |
| <15 | -5.7 | -9.1 to -2.4 |
| 15 - <30 | -2.4 | -2.9 to -2.0 |
| 30 - <60 | -0.5 | -0.9 to -0.2 |
| ≥90 | 1.2 | -0.9 to -3.3 |
| **Age (Ref 21 - <45)** | | |
| 45 - <65 | 0.4 | 0.1 to 0.8 |
| ≥65 | 0.5 | 0.1 to 0.9 |
| **UACR (Ref <10)** | | |
| 10 - <30 | -0.3 | -0.6 to 0.0 |
| 30 - <300 | -0.6 | -0.9 to -0.3 |
| 300 - <1000 | -0.7 | -1.1 to -0.3 |
| ≥1000 | -0.6 | -1.0 to -0.2 |
| **Use Diuretic** | 0.9 | 0.6 to 1.1 |
| **Waist circumference** | -0.5 | -0.7 to -0.2 |
| **Smoking** | -0.4 | -0.7 to -0.2 |
| **Use ACE-I or ARB** | -0.4 | -0.7 to -0.2 |
| **Anemia** | -0.4 | -0.7 to -0.2 |
| **Hyperkalemia** | -1.3 | -1.6 to -0.9 |

Other factors considered did not independently associate with a variance of bicarbonate after controlling for factors in the base model.

**Conclusions:** Low eGFR has the strongest relationship with lower bicarbonate in CKD. Albuminuria, use of ACE-i/ARB, younger age, anemia, smoking, hyperkalemia, and larger waist circumference also associate with lower bicarbonate independent of eGFR.

*Funding:* Veterans Affairs Support, Private Foundation Support

## FR-PO262

**Dose-Relativity of Calcium Acetate and Lanthanum Carbonate in the Treatment of Hyperphosphatemia** Rosamund J. Wilson,[1] J. Brian Copley,[2] Michael S. Keith,[2] Peter Preston.[2] *[1]Spica Consultants, Marlborough, United Kingdom; [2]Shire Pharmaceuticals, Wayne, PA.*

**Background:** Hyperphosphatemia can be managed with phosphate (P) binders such as lanthanum carbonate (LC) and calcium acetate (CA). Our aim was to evaluate the dose-relativity between CA and LC monotherapy and assess elemental calcium (Ca) intake.

**Methods:** We completed a *post hoc* analysis from a phase 4 study of patients with end stage renal disease (ESRD) and hyperphosphatemia. The study included a 1-week observation period in which patients remained on their existing P binder, a 12-week LC monotherapy titration phase and a 4-week LC maintenance period. Serum P and daily P binder dose were assessed at baseline for patients treated with CA and at weeks 12 and 16 after switching to LC.

**Results:** At baseline 707 patients received a prior recorded dose of CA monotherapy, 551 of whom were receiving LC at 16 weeks post-baseline. Mean dose, dose relativity, P level and elemental Ca intake overall and by prior CA dose are shown below. The recommended maximum intake of Ca from Ca-based P binders is 1.5g; ~50% of patients exceeded this. The recommended daily intake of 2.0g was exceeded in ~25% of patients based on Ca content of their P binder alone.

| Prior CA dose tab/cap | LC dose g (#tab)[a] | CA dose g (#tab/cap)[b] | Dose relativity g/g[c] | N week 16[d] | Mean P wk 0 mg/dL (*n*) | Mean P wk 16 mg/dL (*n*) | Ca g (SD) |
|---|---|---|---|---|---|---|---|
| ***Overall*** | ***2.8 (3)*** | ***5.6 (9)*** | ***2.0*** | ***551*** | ***6.03 (682)*** | ***6.21 (543)*** | ***1.4 (0.74)*** |
| 1-5 | 2.4 (3) | 2.1 (4) | 0.9 | 103 | 5.51 (122) | 5.73 (102) | **0.5 (1.26)** |
| 6-7 | 2.6 (3) | 4.0 (6) | 1.5 | 162 | 6.08 (193) | 6.15 (157) | **1.0 (0.32)** |
| 8-11 | 2.9 (3) | 6.0 (9) | 2.1 | 144 | 5.84 (193) | 5.97 (143) | **1.5 (0.86)** |
| 12+ | 3.1 (4) | 9.7 (15) | 3.1 | 142 | 6.52 (174) | 6.87 (140) | **2.4 (0.55)** |

[a]Assuming 1000mg LC tablets
[b]Assuming 667mg CA tablets/capsules
[c]CA/LC
[d]One patient had LC dose but no CA dose recorded
Tablet numbers rounded up to whole tablet.

**Conclusions:** The overall CA:LC dose-relativity was 2.0. The lower tablet burden with LC may improve adherence for patients with ESRD. The recommended elemental Ca intake was exceeded by ~50% of patients which may have vascular calcification implications.

## FR-PO263

**Statin Use and Lipid Profiles in a Predialysis Clinic** Mathilde Laferriere, Sarah Bezzaoucha, Vincent Pichette, Jean-Philippe Lafrance, Robert Zoël Bell, Michel Vallee. *Nephrology Dept, Hôpital Maisonneuve-Rosemont, Montreal, Canada.*

**Background:** Dyslipidemia and chronic kidney disease are well-recognized independent risk factors for cardiovascular disease. Large randomized-controlled studies had previously demonstrated that the treatment of dyslipidemia resulted in a substantial reduction in cardiovascular events and mortality. The SHARP trial was the first study to demonstrate that treatment of dyslipidemia resulted in a significant cardiovascular risk reduction in an advanced chronic kidney disease population. The objective of our project was to assess the lipid profile and statin use in our predialysis population, in order to determine the proportion of patients reaching target values.

**Methods:** We have retrospectively collected statin use and the lipid profile in patients at our predialysis clinic between 2010 and 2011. Demographic data as well as other risk factors for cardiovascular disease were also collected.

**Results:** At baseline, lipid profiles were available for 289 predialysis patients. Average age was 68,8 years, 40,8% were women and BMI 31 (SD ± 7). Mean glomerular filtration rate was 19,7 mL/min/1,73$m^2$ (SD ±6,5). Major comorbidities were hypertension (96,4%), diabetes (64,3%) and coronary atherosclerotic disease (49,3%). Mean LDL value was 2,2 mmol/L ±0,9 (85mg/dl ±33), with 76% patients already taking a statin and 5,4% taking ezetimibe. Despite being on atorvastatin, the most frequently prescribed statin, a subgroup analysis demonstrated that 43 % of patients did not achieve ideal target levels of LDL ≤ 2 mmol/L ( 77 mg/dl). Likewise, 27% of patients with LDL > 2 mmol/L were not on statin therapy and had significant cardiovascular risk factors.

**Conclusions:** We observed that most of our patients were already on lipid-lowering therapy. Nevertheless, the average LDL level was above target and we identified a subset of patients that were not taking a statin despite having significant cardiovascular risk factors. Implementation of a standing order for the treatment of dyslipidemia may improve the management of lipid profiles in predialysis patients.

## FR-PO264

**Warfarin Dose Requirements in Patients with Kidney Dysfunction** Sami Sakaan,[1,2] Joanna Hudson,[1,2] Carrie Oliphant,[1,2] Carolyn Cummings,[1,2] Numan Alabdan,[1] Tim Self.[1,2] *[1]The Univ of Tennessee; [2]Methodist Univ Hospital, Memphis, TN.*

**Background:** The effect of chronic kidney disease (CKD) on warfarin response remains largely unstudied despite increased risk of thromboembolism and bleeding in this population. Data suggest that patients with reduced kidney function require lower warfarin doses; however, relatively few patients with end stage renal disease (ESRD) were included in previous studies. The purpose of this study is to evaluate warfarin dosing requirements in patients with stage 3 and higher CKD compared to patients with normal kidney function.

**Methods:** A retrospective review was conducted to evaluate warfarin response in hospitalized patients with "normal" kidney function (glomerular filtration rate > 60 mL/min/1.73 m$^2$) and in patients with CKD stage 3, stage 4/5 or ESRD initiated or maintained on warfarin for ≥4 consecutive days. The average daily dose to maintain a therapeutic INR, time to achieve this INR in patients newly initiated on warfarin, and adverse effects were compared among groups.

**Results:** Of the 225 patients studied, the average daily dose to maintain a therapeutic INR was statistically lower in CKD/ESRD patients compared to patients with normal kidney function (p=0.0014). The median time to reach a therapeutic INR did not differ among groups (p=NS). Significantly more bleeding episodes during hospitalization or within 30 days of discharge were observed in patients with CKD stage 3 or higher compared to patients with normal kidney function (p = 0.0258).

| | GFR≥60 (n=50) | Stage 3 (n=48) | Stage 4/5 (n=27) | ESRD (n=100) |
|---|---|---|---|---|
| Daily Dose (mg) [p vs GFR≥60] | 5.6±1.7 | 4.4±1.6 [p=0.0003] | 4.6±1.9 [p=0.02] | 4.6±1.9 [p=0.004] |
| Days to therapeutic INR* [p vs GFR≥60] | 5.1±1.9 (n=23) | 5.3±1.4 (n=28) [p=0.696] | 3.8±1.3 (n=12) [p=0.059] | 4.7±2.3 (n=41) [p=0.431] |
| # of bleeding episodes | 0 | 3 | 3 | 10 |

*Analyzed for patients newly initiated on warfarin.

**Conclusions:** Our findings suggest that CKD and ESRD patients require 20% lower warfarin doses to maintain a therapeutic INR and warrant more monitoring for bleeding compared to patients with normal kidney function.

## FR-PO265

**Academic Achievement in Pediatric Chronic Kidney Disease** Lyndsay Harshman,[1] Douglas Russo,[1] Sheila Barron,[3] Natalie L. Denburg,[2] Patrick D. Brophy.[1] *[1]Pediatrics, Univ of Iowa Children's Hospital, Iowa City, IA; [2]Neurology, Univ of Iowa Hospitals and Clinics, Iowa City, IA; [3]Education, Univ of Iowa, Iowa City, IA.*

**Background:** Children with chronic kidney disease (CKD) are at risk for neurocognitive impairment. Interest in neurocognition has increased as medical management of CKD improves outcomes. Longitudinal, standardized achievement research is lacking. We examined academic achievement in pediatric CKD using longitudinal achievement measurements benchmarked against state normative data. The medical record was examined for medical comorbidities impacting achievement.

**Methods:** The Iowa Tests of Basic Skills & Iowa Tests of Educational Development are developed by the Iowa Testing Program and widely used achievement tests nationwide, administered annually in grades K-12 across a range of subjects. Achievement data from the Iowa Testing Program and medical data from the University of Iowa Children's Hospital were available for 47 CKD patients and analyzed to examine the association between CKD and achievement.

**Results:** Children with CKD demonstrated underachievement in all domains with significant underachievement compared to state referenced, normative data in Math, Science, and Sources of Information. Low 25OH Vitamin D was associated with underachievement in Reading ($p$ = 0.002), Language ($p$ = 0.024), and Math ($p$ = 0.005).

**Table 1**– Underachievement at mean </=50th percentile.

| Domain | N | Calculated Observations | Mean | SE | 95% CI |
|---|---|---|---|---|---|
| Core Composite | 25 | 86 | 40.6 | 5.7 | 29.5-51.8 |
| Core Total | 34 | 139 | 43.0 | 4.9 | 33.5-52.6 |
| Reading | 43 | 192 | 44.0 | 4.6 | 34.9-53.0 |
| Language | 35 | 150 | 46.9 | 4.8 | 37.5-56.4 |
| Math | 44 | 188 | **39.0*** | 4.6 | 30.0-48.1 |
| Science | 44 | 183 | **37.0*** | 3.8 | 29.6-44.5 |
| Sources of Information | 27 | 96 | **40.7*** | 5.2 | 30.5-50.0 |

**Conclusions:** The current study provides insight into academic achievement in pediatric CKD, indicating that patients demonstrate underachievement in Math and Science, and worsening metabolic disease may predispose patients to and be predictors of underachievement.

## FR-PO266

**Contribution of Whole-Brain Gray Matter Volume to Higher Brain Function in Predialysis Patients with Chronic Kidney Disease without Overt Cognitive Impairment** Kazuhiko Tsuruya,[1] Hisako Yoshida,[1] Takanari Kitazono.[2] *[1]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

**Background:** Previous studies suggest that there are significant relationships between multiple cognitive tests and brain volume in healthy elderly, and age-related loss of gray matter volume (GMV) is involved with age-related cognitive change. However, it remains unclear whether GMV associates with cognitive function in patients with chronic kidney disease (CKD). The purpose of the present study is to examine the association of GMV with cognitive function in predialysis CKD patients without overt cognitive impairment (CI).

**Methods:** One-hundred and two predialysis CKD patients (54 men, 48 women) aged 24–80 (62 ± 11) years without overt dementia and history of cerebrovascular disease were recruited. The subjects underwent brain MRI and three kinds of cognitive tests: Mini-Mental State Examination (MMSE), Revised Hasegawa Dementia Scale (HDS-R), and Japan Stroke Scale-Higher Cortical Function Test (JSS-H). MRI images were analyzed using Statistical Parametric Mapping software (SPM8;Wellcome Department of Imaging Neurosciences, University College London, London, UK). Gray matter (GM), white matter (WM), and cerebrospinal fluid were segmented and each volume was quantified using MRI voxel-based morphometry. GMV was normalized as a percentage of intracranial volume to adjust for variations in head size. Univariate and multivariate linear regression analyses were used to examine the association of %GMV with each score of three cognitive tests.

**Results:** Percentage of GMV was significantly associated with the scores of HDS-R and JSS-H, but not MMSE. The associations between %GMV and the scores of HDS-R and JSS-H remained significant (P = 0.004 and P = 0.038, respectively) even after adjustment of potential confounding factors.

**Conclusions:** The present study demonstrates the association of %GMV with cognitive function, suggesting that brain atrophy might contribute to CI in CKD.

## FR-PO267

**The Sleep Disorder in CKD** Shinji Kitajima, Tadashi Toyama, Norihiko Sakai, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

**Background:** Various sleep disorders, such as insomnia and halfway awakening, deteriorate quality of life in patients with advanced CKD. Although uremic substances would be candidates of the cause, detailed mechanisms remain unclear so far. In this study, we evaluated sleep and awakening related gene expression in CKD patients, and brain tissue and electroencephalographic analysis in a mouse CKD model.

**Methods:** [circ1] Human analysis; Nineteen participants without diabetes were evaluated in this study. The participants were divided into three groups: HT group (8 hypertension patients with eGFR > 60 mL/min/1.73m2), CKD group (7 patients with eGFR < 60 mL/min/1.73m2), and HD group (4 patients on hemodialysis). Age and gender were matched with each group. Blood samples were collected in PaxGene RNA collection tubes at the entry of this study. Sleep and awakening related gene was evaluated by RNA microarray. [circ2] Mouse model; Activity of sleep related neuron in cerebral tissue and electroencephalogram were evaluated in a ischemia-reperfusion model in nephrecomized mice, showing advanced kidney injury.

**Results:** In the human gene expression analysis, several sleep related genes expressions were changed in accordance with renal dysfunction. A waking substance, orexin, and gene expression of its receptors were upregulated in accordance with renal dysfunction (correlation coefficient > –0.4). Similary, in a mouse model with elevated creatinine level, orexin RNA expression was downregulated in an awaking period. These findings were further confirmed by orexin neuron activity in immunostaining. Supporting this gene expression and neuron activity, electroencephalogram analysis revealed that mice with kidney injury tend to awake in sleeping period, and sleep in awaking period, suggesting similar clinical phenotypes to those observed in CKD patients.

**Conclusions:** Gene expression profiling of peripheral blood leukocytes in human CKD patients indicated that orexin would be a candidate factor for sleep disorders accompanied with kidney dysfunction. Cerebral tissue and electroencephalogram analysis of a mouse model support these findings. These results suggested that orexin might play a role in sleep disorder in CKD.

## FR-PO268

**Association between Sex and Incident Chronic Kidney Disease in a Diabetic Cohort** Margaret K. Yu,[1] Bessie A. Young.[1,2] *[1]Univ of Washington; [2]VA Puget Sound Health Care System.*

**Background:** Women with diabetes have a higher prevalence of chronic kidney disease (CKD) risk factors than men, such as hypertension, dyslipidemia, obesity, and poor glycemic control. Despite these increased CKD risk factors, whether diabetic women are at greater risk than men for incident CKD is not clear. Our objective is to evaluate the association between sex and 10-year incident CKD risk in a primary care diabetic population.

**Methods:** The Pathways Study is a prospective, observational cohort of ambulatory, diabetic patients from a large managed care population in Seattle, WA. CKD was defined as an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m$^2$ or microalbuminuria (urine albumin/creatinine ≥25 mg/g for women or ≥17 mg/g for men). Subjects without baseline CKD were followed for 10 years for incident CKD. Stepwise Cox proportional

hazards regression with mortality as a competing risk was used to analyze the associations between sex and incident CKD after adjustment for demographics (age, race/ethnicity, marital status, education, smoking), traditional CKD risk factors (baseline eGFR, hypertension, low-density lipoprotein (LDL), body mass index (BMI), hemoglobin A1c), and behavioral risk factors for CKD (depression and adherence to diet, exercise, glucose monitoring, and self-foot exam). Multiple imputation was used for covariates with missing values.

**Results:** Of the 1,468 total subjects, 766 were women (52.2%). Women were younger, less likely to be married, had lower education levels, and higher LDL, BMI and baseline eGFR compared to men. Taking into account pre-CKD death as a competing risk, women had a 33% greater risk of incident CKD at 10 years (sub-hazard ratio (SHR) 1.33, 95% CI 1.10-1.62). This association persisted after adjustment for demographics (SHR 1.44, 95% CI 1.21-1.72), traditional risk factors (SHR 1.48, 95% CI 1.23-1.77), and behavioral risk factors for CKD (SHR 1.48, 95% CI 1.23-1.77).

**Conclusions:** Compared to men, women with diabetes had an increased 10-year risk of incident CKD which was not attenuated after adjustment for traditional and behavioral risk factors for CKD. Diabetic women may represent a high risk group for the development of CKD.

## FR-PO269

**Incidence of Chronic Kidney Disease in Cancer Survivors Exposed to Cisplatin** Swati Mehta, Sujata Patil, Carlos D. Flombaum, Ilya Glezerman, Sheron Latcha. *Nephrology, Memorial Sloan Kettering Cancer Center, NY.*

**Background:** Cisplatin,an important antineoplastic agent,is notoriously nephrotoxic. Reports in the literature on long term nephrotoxicity of cisplatin are sparse and have focused on pediatric population. We present data on long term (5 to 12 year follow up) renal effects of cisplatin in cohort of 859 adult patients.

**Methods:** Retrospective chart analysis was performed after obtaining approval from the Institutional review board at Memorial Sloan Kettering Cancer Center. We collected data for 859 adult patients treated with cisplatin from 1st Jan 2000 till 20th Sept 2011. Data included age,gender,race,ethnicity,primary malignancy,serum creatinine level prior to cisplatin therapy and subsequent serum creatinine levels. We calculated the estimated glomerular filtration rate (eGFR) using the 3- variable MDRD equation. Inclusion criteria for the study was age at diagnosis of malignancy>18y and patients who survived at least 5 years after their initial dose of cisplatin. Patients who received ifosfamide concomitant or subsequent to cisplatin or in whom baseline creatinine was unavailable were excluded.

**Results:** 859 patients met the inclusion criteria. 63.3% were Male and 84.6% Caucasian. Most patients were between the age of 25 and 65 when exposed to cisplatin. Head & Neck, testicular and gastrointestinal malignancies accounted for 62% cases. Most patients received a cumulative cisplatin dose from 100 to 400 mg/m$^2$ (77%). 742 patients (90%) had eGFR more than 60ml/min per 1.73 m$^2$ at baseline.93% patients maintained an eGFR >60ml/min per 1.73 m$^2$ 5 years post cisplatin exposure and per the data available; none of the patients had eGFR<15ml/min per m$^2$ or developed ESRD.

**Conclusions:** Cisplatin is an important chemotherapeutic agent with well known acute nephrotoxic effects. Long term renal effects of cisplatin in adults has not been studied well. Our study of 859 adults has limitations in being a retrospective chart review. Its strengths are the sheer sample size of 859 adult patients and a first of a kind study to show that while cisplatin is notorious for causing acute renal failure; its long term effects on renal function are not as severe with no patients developing ESRD in our study.

## FR-PO270

**Carotid Plaque Predict Rate of Renal Function Decline in Patients with Chronic Kidney Disease** Jwa-kyung Kim,[1] Sung Jin Moon,[2] Sun Ryoung Choi,[1] Jong-woo Yoon,[1] Jung-woo Noh,[1] Sung Gyun Kim.[1] *[1]Internal Medicine, Hallym Univ Sacred Heart Hospital, Kidney Research Institute, Korea; [2]Internal Medicine, Myongji Hospital, Kwandong Univ College of Medicine, Korea.*

**Background:** Carotid plaque is a surrogate marker of systemic atherosclerosis and closely associated with adverse cardiovascular outcomes. However, prospective data regarding the predictive role of carotid plaque for renal progression are limited in chronic kidney disease (CKD) patients.

**Methods:** As a prospective design, a total of 411 Stage 3 and 4 CKD patients were enrolled, and all patients underwent carotid ultrasonography at the time of CKD diagnosis. A carotid plaque was defined as a focal structure encroaching into the arterial lumen of at least 0.5 mm or 50% of the surrounding carotid intima-media thickness (cIMT) or a thickness >1.5mm as measured from the media-adventitia interface to the intima-lumen interface. Renal function decline was measured by estimated glomerular filtration (eGFR) slope and the renal endpoint was defined as the start of dialysis.

**Results:** Baseline eGFR was 44.5±11.6 mL/min/1.73m$^2$ and eGFR slope was -2.87±3.76 min/1.73m$^2$/yr. A carotid plaque was found in 282 (68.6%) patients, and these patients had significantly faster rates of renal function decline than those without plaque (-3.64±3.84 vs. -1.20±2.85 mL/min/1.73m$^2$/yr, p<0.001). According to multivariate analysis, statistically significant variables determining eGFR slope were diabetes (β=-0.77, p=0.033), increased pulse pressure (β=-0.02, p=0.015), elevated proteinuria (β=-0.50, p<0.001), increased cIMT (β=-4.36, p<0.001) and the presence of a carotid plaque (β=-1.48, p<0.001). During the 2.5-year follow-up, 47 (11.4%) of patients started dialysis. Patients with carotid plaque had a poorer dialysis-free survival rate than those without carotid plaque (hazard ratio 3.3: 95% confidence interval 1.01, 10.77).

**Conclusions:** Carotid plaque was closely associated with rapid decline of renal function and progression to dialysis in stage 3 and 4 CKD patients. Detecting carotid plaque may help identify patients at high-risk for progression of renal dysfunction.

## FR-PO271

**Association of Fluid Overload, Diabetes and Renal Disease Progression in Chronic Kidney Disease** Yi-chun Tsai, Mei-Chuan Kuo, Hung-Chun Chen. *Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

**Background:** Fluid overload is one of major presentation in patients with late stage of chronic kidney disease (CKD). Diabetes is the leading cause of renal failure and progression of diabetic nephropathy has been associated with changes in extracellular fluid volume. The aim of the study was to assess the association of the severity of fluid status, diabetes and kidney disease progression in a late CKD cohort.

**Methods:** This study analyzed the association of the severity of fluid overload measured bybioimpedance spectroscopy method, Body Composition Monitor, with maintenance dialysis and rapid renal progression (estimated GFR slope < -3ml/min/1.73 m$^2$/y) in 472 patients with stage 4-5 CKD.

**Results:** During a median 17.3-month follow-up, there were 71 (15.0%) subjects commencing maintenance dialysis, and 187 (39.6%) subjects presenting rapid renal progression. The adjusted risks of commencing dialysis increased near 3-fold (HR: 2.96, 95% CI: 1.13-7.72, P= 0.03) for non-diabetic patients with fluid overload compared with those without fluid overload. The adjusted risks of maintenance dialysis increased near 4.5-fold (HR: 4.48, 95% CI: 1.69-11.93, P= 0.003) for diabetic patients with fluid overload compared with non-diabetic patients without fluid overload. The adjusted OR for non-diabetic patients with fluid overload compared with those without fluid overload in renal function progression analysis were 4.26 (95% CI: 2.08-8.73, P<0.001). The adjusted risks of renal function progression increased more than 2.8 fold (OR: 2.82, 95% CI: 1.27-6.26, P= 0.01) for diabetic patients with fluid overload compared with non-diabetic patients without fluid overload. However, there was no significant increased risk for renal disease progression between diabetic and non-diabetic patients without fluid overload.

**Conclusions:** Fluid overload is an independent risk factor associated with maintenance dialysis and rapid renal progression. Fluid overload has a higher predictive value for an elevated risk for kidney disease progression than diabetes in late CKD.

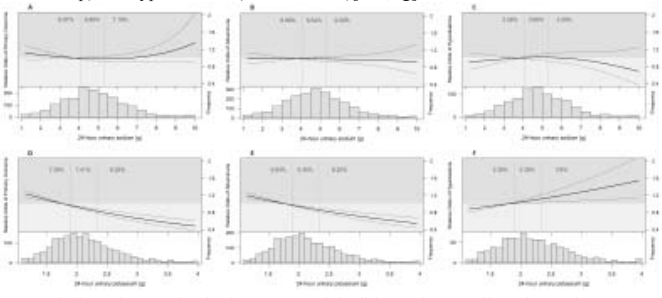
## FR-PO272

**Urinary Potassium but Not Sodium Excretion Predicts Renal Outcomes. Observational Analysis of ONTARGET and TRANSCEND** Andrew Smyth, Daniela Dunkler, Peggy Gao, Koon K. Teo, Salim Yusuf, Martin O'Donnell, Johannes F. Mann, Catherine M. Clase. *McMaster Univ, Hamilton, Canada.*

**Background:** Patients with chronic kidney disease (CKD) are frequently advised to modify sodium (Na) and potassium (K) intake, but supporting evidence is limited.

**Methods:** We studied 28,800 participants at high cardiovascular risk, 90.6% on renin-angiotensin system blockade, followed for a mean of 4.5y in the ONTARGET & TRANSCEND trials. We used the Kawasaki formula to estimate 24hr Na and K from morning fasting urine. The primary outcome was eGFR decline ≥30% or chronic dialysis (CD); secondary outcomes were eGFR decline ≥40% or CD, doubling of creatinine or CD, >5%/yr loss of eGFR, progression of albuminuria and hyperkalemia. We used multinomial logit regression with multivariable fractional polynomials, adjusted for known predictors, to determine the association between Na & K and outcomes, with death as a competing risk. We also analysed Na & K in thirds.

**Results:** At baseline, 9.8% had eGFR<45 and 22.6% eGFR 45-60 mL/min/1.73m$^2$; 3.5% had macro- and 12.5% micro-albuminuria. The primary outcome occurred in 7.0% (n=1,685). There was no significant association between Na excretion and any renal outcomes [A-C, fig] [primary outcome OR 0.97; 95% CI 0.87-1.08 for highest (median 6.1g/d) vs. lowest third (median 3.3g/d)]**.** Higher K excretion was associated with a lower risk of renal outcomes [primary outcome OR 0.71; 95% CI 0.64-0.79 for highest (median 2.7g/d) vs. lowest third (median 1.7g/d)], except doubling of creatinine or CD (no relationship) and hyperkalemia (increased risk)[D-F,fig].



Inclusion of Na and K in the same models did not change effect sizes. There was no interaction with baseline eGFR or albuminuria.

**Conclusions:** K but not Na excretion was associated with clinically important changes in risk of renal outcomes. Our findings do not support low sodium and potassium diets in CKD.

*Funding:* Pharmaceutical Company Support - Boehringer Ingelheim funded the original ONTARGET & TRANSCEND studies but had no role in this work

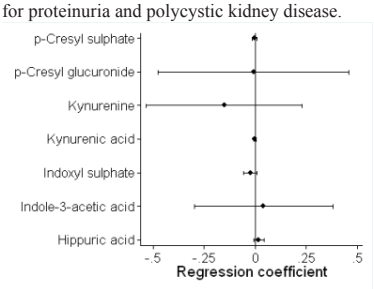
**FR-PO273**

**Uremic Toxins as Risk Factors for Progression in Chronic Kidney Disease**
Jan A.J.G. Van den Brand,[1] Henricus A.M. Mutsaers,[2] Arjan D. Van Zuilen,[3] Peter J. Blankestijn,[3] Rosalinde Masereeuw,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Centre, Nijmegen, Netherlands; [2]Toxicology and Pharmacology, Radboud Univ Medical Centre, Nijmegen, Netherlands; [3]Nephrology, Univ Medical Centre Utrecht, for the MASTERPLAN Study, Netherlands.*

**Background:** The concentration of uremic toxins is increased in patients with kidney failure. We questioned if uremic toxins may influence the rate of eGFR decrease in CKD patients.

**Methods:** Baseline serum samples of patients that participated in the MASTERPLAN trial were used (Van Zuilen *et al. Kidney Int. 2012)*. Cases were rapid progressors, i.e. patients with decline of eGFR > -4.5 ml/min/1.73m$^2$/year. Controls with lower rate of progression were selected and matched for baseline eGFR. Concentrations of uremic toxins (hippuric acid, indole-3-acetic acid, indoxyl sulphate, kynurenic acid, kynurenine, p-cresyl glucuronide, p-cresyl sulphate) were measured using in-tandem mass spectrometry and high pressure liquid chromatography.

**Results:** In total, 27 cases and 65 controls were included. Concentration of all uremic toxins was above control values. Correlations with eGFR ranged between -0.58 to 0.07. Uremic toxins correlated poorly with other known risk factors. Rapid progressors were more likely to be male, younger and have polycystic kidney disease; had higher blood pressure and proteinuria, and lower serum albumin and bicarbonate. None of the uremic toxins was statistically significantly associated to eGFR decline in univariate nor multivariate linear regression analysis. The figure shows regression coefficients and 95% confidence intervals for the association between uremic toxins and the rate of eGFR decline adjusted for proteinuria and polycystic kidney disease.



HA, IAA, IS, KYN, PCG and PCS are in μM, KYNA is in nM.

**Conclusions:** Baseline serum uremic toxin concentrations are not associated with eGFR decline in CKD patients.

*Funding:* Private Foundation Support

**FR-PO274**

**Urinary Trefoil Factor 3 Significantly Predicts the Renal Outcomes in Patients with Chronic Kidney Disease**
Toshio Yamanari,[1] Hitoshi Sugiyama,[1] Hiroshi Morinaga,[1] Masashi Kitagawa,[1] Akifumi Onishi,[1] Ayu Ogawa,[1] Yoko Kikumoto,[1] Shinji Kitamura,[1] Yohei Maeshima,[1] Daisuke Ogawa,[1,2] Kenichi Shikata,[1,3] Yasukazu Ohmoto,[4] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan; [2]Diabetic Nephropathy, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [3]Center for Innovative Clinical Medicine, Okayama Univ Hospital; [4]Otsuka Pharmaceutical Co., Ltd.*

**Background:** TFF3 plays essential roles in mucosal surface maintenance and reconstitution. A decrease in the urinary levels of TFF3 is associated with acute kidney injury in animals. However, whether the urinary levels of TFF3 are associated with renal dysfunction in patients with chronic kidney disease (CKD) is unclear.

**Methods:** We analyzed the urinary TFF (uTFF) levels in spot urine samples from 216 patients with CKD, and assessed the relationships among the uTFF, proteinuria and kidney function. Patients were prospectively followed for three years for doubling of the baseline serum creatinine concentration and the initiation of renal replacement therapy.

**Results:** The excretion of uTFF3 significantly increased with the extent of albuminuria, urinary $\alpha_1$ and $\beta_2$ microglobulin and the decline in the eGFR. A multivariate logistic regression analysis showed that the patients with higher levels of uTFF3 were more likely to have CKD stage ≥ G3b ($P < 0.01$). A longitudinal analysis demonstrated that patients with a higher uTFF3, in combination with macroalbuminuria, had a significantly worse renal prognosis (Log rank, $P < 0.0001$). The levels of urinary TFF3 in the renal end-point group were significantly higher than those in the renal survival group ($P < 0.01$). The AUC of uTFF3 for predicting the progression of CKD (0.879) was significantly higher than that of albuminuria (0.692) ($P < 0.0001$). The levels of uTFF1 and uTFF2 did not correlate with albuminuria.

**Conclusions:** The excretion of uTFF3 is therefore significantly associated with albuminuria and a decline in the renal function. Moreover, the uTFF3 level can be used as a biomarker to predict the renal outcomes in CKD patients.

**FR-PO275**

**Urinary Biomarkers as Risk Factors of End-Stage Renal Disease in the General Population: CKD Biomarkers Consortium**
Meredith C. Foster, Josef Coresh, Joseph V. Bonventre, Chi-yuan Hsu, Paul L. Kimmel, Theodore E. Mifflin, Robert G. Nelson, Vasan S. Ramachandran, Venkata Sabbisetti, Sushrut S. Waikar, Kathleen D. Liu. *CKD Biomarkers Consortium.*

**Background:** We determined the association of 3 urinary markers of tubular injury, liver fatty acid binding protein (L-FABP), kidney injury molecule 1 (KIM-1), and N-acetyl-β-D-glucosaminidase (NAG), with incident end-stage renal disease (ESRD) in the Atherosclerosis Risk in Communities Study, a community-based sample of middle-aged adults.

**Methods:** We performed a nested case-control study with Visit 4 (1996-98) as the baseline. ESRD cases were ascertained through 2008 with 2 controls frequency matched to each case on estimated glomerular filtration rate (eGFR), urinary albumin to creatinine ratio (ACR), diabetes, sex, and race. L-FABP, KIM-1, and NAG were measured and standardized to urinary creatinine. We estimated the incidence odds ratio (OR) for ESRD for an interquartile range increase in each biomarker and for an elevation (highest quartile) in any biomarker using conditional logistic regression.

**Results:** 138 cases were matched to 192 controls with urine available (mean age 64.9 vs. 64.7 years, 43.5% vs. 43.2% women). ESRD occurred a median of 6.0 years after Visit 4. L-FABP and KIM-1 were associated with an increased odds of ESRD, but associations were attenuated with adjustment (**Table**). NAG was not associated with ESRD. In multi-marker analyses, elevated levels for any marker (cases: 59%; controls: 34%) were independently associated with ESRD (**Table**).

**Table:** Adjusted OR and 95% confidence intervals (CI) of ESRD

| Model adjustment* | L-FABP° | KIM-1° | NAG° | Elevation in any biomarker |
|---|---|---|---|---|
| Age | 2.1 (1.2, 3.6)§ | 1.4 (1.0, 1.9)§ | 1.2 (0.8, 1.7) | 2.1 (1.2, 3.8)§ |
| Age, eGFR, ln(ACR) | 1.6 (0.9, 2.9) | 1.3 (0.9, 1.8) | 1.0 (0.7, 1.5) | 1.9 (1.0, 3.4)§ |

*All models account for matching factors. °Log(X+1) transformed with OR for 75$^{th}$ vs. 25$^{th}$ percentile. §P<0.05

**Conclusions:** L-FABP and KIM-1 were associated with risk of ESRD before but not after adjustment for other risk factors. Combinations of markers may have independent risk information.

*Funding:* NIDDK Support, Other NIH Support - The Atherosclerosis Risk in Communities Study is carried out as a collaborative study supported by National Heart, Lung, and Blood Institute contracts (HHSN268201100005C, HHSN268201100006C, HHSN268201100007C, HHSN268201100008C, HHSN268201100009C, HHSN268201100010C, HHSN268201100011C, and HHSN268201100012C).

**FR-PO276**

**Urinary Uromodulin Excretion Predicts Progression of Chronic Kidney Disease Resulting from IgA Nephropathy**
Yuqing Chen,[1] Jingjing Zhou,[2] Xueying Li,[3] Hong Zhang.[4] *[1]Peking Univ First Hospital; [2]Peking Univ First Hospital; [3]Peking Univ First Hospital.*

**Background:** Uromodulin, or Tamm-Horsfall protein, is the most abundant urinary protein in healthy individuals. Recent studies have suggested that uromodulin may play a role in chronic kidney diseases. We examined an IgA nephropathy cohort to determine whether uromodulin plays a role in the progression of IgA nephropathy.

**Methods:** A total of 344 IgA nephropathy patients were involved in this study. Morphological changes were evaluated with the Oxford classification of IgA nephropathy. Enzyme Linked Immunosorbent Assay (ELISA) measured the urinary uromodulin level at renal biopsy day. Follow up was done regularly on 185 patients. Time-average blood pressure, time-average proteinuria, estimated glomerular filtration rate (eGFR) and eGFR decline rate were caculated. Association between the urinary uromodulin level and the eGFR decline rate was analyzed with SPSS 13.0.

**Results:** We found that lower baseline urinary uromodulin level (P=0.03) and higher time average proteinuria (P=0.04) were risk factors for rapid eGFR decline in a follow-up subgroup of the IgA nephropathy cohort. Urinary uromodulin level was correlated with tubulointerstitial lesions (P=0.016). Patients with that had more tubular atrophy/interstitial fibrosis on the surface had lower urinary uromodulin levels (P=0.02).

**Conclusions:** Urinary uromodulin level is associated with interstitial fibrosis/tubular atrophy and contributes to eGFR decline in IgA nephropathy.

**FR-PO277**

**Urine Complement C3 Cleavage Fragments Are Associated with Abnormal Kidney Function and CKD**
Erwin P. Bottinger,[1,2] Avelino Teixeira,[1,2] Girish N. Nadkarni,[1,2] Ilse S. Daehn,[1,2] Joseph V. Bonventre,[2] Kathleen D. Liu,[2] Chi-yuan Hsu,[2] Brad H. Rovin,[2] Robert G. Nelson,[2] Paul L. Kimmel,[2] Harold I. Feldman,[2] Vasan S. Ramachandran.[2] *[1]Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York City, NY; [2]The CKD Biomarker Consortium, NIDDK.*

**Background:** Urine complement C3 fragments have been associated with kidney diseases, yet little is known about urinary C3a (anaphylotactic), C5b-9 (cytotoxic), and iC3b (opsonic) fragments in individuals with abnormal kidney function.

**Methods:** We measured urine complement C3-derived fragments C3a, C5b-9, and iC3b in urine samples obtained from patients as part of routine ambulatory or inpatient clinical care using modified ELISA kits (Quidel® Corp., San Diego, CA).

**Results:** Patient groups included 96 controls, suspected abnormal kidney function without documented CKD (eGFR 60 to 90 ml/min/1.72m$^2$ and/or proteinuria)(N=230), CKDIII or higher with loss of eGFR ≤3 (N=160), or >3ml/min/1.72m2 per year for at least 3 years (N=81). Fractions (%) of samples with detectable urinary C3a, C5b-9, or iC3b were significantly increased in all kidney dysfunction groups compared with controls. In multivariable logistic regression models C3a, C5b-9, or iC3b were significantly associated with kidney dysfunction after adjusting/stratifying by proteinuria (Upro/cr) of >0.5 mg/mg, but not at lower levels.

Table 1. Multivariable logistic regression for suspected abnormal kidney function, CKD III or higher with eGFR loss ≤3, or >3ml/min/1.72m2/yr for at least 3 years, *compared with controls

| | abn. kid. function w/o CKD | | CKDIII or higher; eGFR loss ≤3ml/min/1.72m$^2$/yr | | CKDIII or higher; eGFR loss >3ml/min/1.72m$^2$/yr | |

| Detect. C3a | 2.13(1.17-3.89) | 0.01 | 2.93(1.10-7.81) | 0.03 | 2.56(1.10-5.59) | 0.03 |
| Detect. C5b-9 | 2.58(1.15-5.78) | 0.02 | 3.41(1.08-10.8) | 0.04 | 4.02(1.14-14) | 0.03 |
| Detect. iC3b | 2.00(1.03-3.90) | 0.04 | 3.29(1.14-9.52) | 0.03 | 5.60(1.70-18) | <0.01 |

**Conclusions:** Urine complement fragments C3a, C5b-9, and iC3b were associated with kidney dysfunction. Associations were strongest between C5b-9 or iC3b and CKD with eGFR loss. We are planning validation studies in prospective CKD cohorts accessible in the CKD Biomarker Consortium.

## FR-PO278

**Association of Urinary LFABP, KIM-1, and NAG with Incident End-Stage Renal Disease and Mortality in Type 2 Diabetes** Gudeta D. Fufaa, E. Jennifer Weil, Robert G. Nelson, Joseph V. Bonventre, Venkata Sabbisetti, Sushrut S. Waikar, Theodore E. Mifflin, Xiaoming Zhang, Dawei Xie, Harold I. Feldman, Josef Coresh, Vasan S. Ramachandran, Paul L. Kimmel, Chi-yuan Hsu, Kathleen D. Liu. *CKD Biomarkers Consortium, NIDDK/NIH, Bethesda, MD.*

**Background:** Liver fatty acid binding protein (L-FABP), kidney injury molecule 1 (KIM-1), and N-acetyl-β-D-glucosaminidase (NAG) are urine biomarkers associated with tubular kidney injury. We determined their association with incident end-stage renal disease (ESRD) and all-cause mortality in American Indians with type 2 diabetes.

**Methods:** 258 Pima Indians (69% women, mean age 42 years, mean diabetes duration 11 years, median albumin/Cr ratio [ACR] 38 mg/g, mean glomerular filtration rate [GFR] 149 ml/min) were followed for a median of 11.9 years for ESRD (renal replacement therapy or death due to diabetic nephropathy) and 13.1 years for mortality. Biomarker concentrations were measured at baseline in urine samples stored at -80°C since collection, and associations with ESRD and mortality were evaluated by Cox proportional hazards regression. Hazard ratios (HR) were reported per interquartile range (IQR) of creatinine-normalized KIM-1 and NAG and for detectable vs. undetectable L-FABP; 106 L-FABP samples (41.1%) were below the limit of detection.

**Results:** 63 participants (24.4%) developed ESRD and 79 (30.6%) died. Median concentrations of KIM-1 and NAG were 680.9 pg/mg Cr (IQR 315.5-1377.7 pg/mg Cr) and 9.6 mU/mg Cr (IQR 5.6-14.3 mU/mg Cr), respectively. None of the biomarkers was associated with ESRD after multivariable adjustment; KIM-1 and NAG were associated with mortality. (Table).

| Table: Adjusted HR and 95% confidence intervals for ESRD and all-cause mortality | | |
|---|---|---|
| | **ESRD (n=63/258)** | **All-cause mortality (n=79/258)** |
| KIM-1/Cr | 0.85 (0.64-1.14) | 1.25 (1.05-1.50) |
| NAG/Cr | 1.21 (0.97-1.50) | 1.36 (1.13-1.65) |
| L-FABP | 0.54 (0.28-1.06) | 1.19 (0.68-2.10) |
| Adjusted for age, sex, hypertension, HbA1c, diabetes duration, ln(ACR) and GFR | | |

**Conclusions:** In Pima Indians with type 2 diabetes, urinary concentrations of the tubular injury markers NAG and KIM-1 were associated with all-cause mortality.

*Funding:* NIDDK Support

## FR-PO279

**Urine NGAL and the Risk of Cardiovascular Disease and Death in CKD: Results from the CRIC Study** Kathleen D. Liu, Wei Yang, Alan S. Go, Amanda Hyre Anderson, Harold I. Feldman, Michael J. Fischer, Jiang He, Radhakrishna Reddy Kallem, John W. Kusek, Stephen R. Master, Sylvia E. Rosas, Susan P. Steigerwalt, Kelvin Tao, Matthew R. Weir, Chi-yuan Hsu. *For the CRIC Study.*

**Background:** Patients with chronic kidney disease (CKD), identified using estimated glomerular filtration rate (eGFR) or albuminuria, have increased risk of cardiovascular disease (CVD) and death. The association of tubular injury biomarkers with CVD and death in CKD is not well understood.

**Methods:** We quantified urine neutrophil gelatinase-associated lipocalin (NGAL) (Abbott ARCHITECT) at baseline (2003-2008) among 3386 participants of the Chronic Renal Insufficiency Cohort (CRIC) Study, a large prospective CKD cohort. Time to first adjudicated hospitalization for heart failure, ischemic atherosclerotic event (myocardial infarction, ischemic stroke or peripheral arterial disease) and death were ascertained through March 2011.

**Results:** In Cox models, after adjusting for eGFR, albuminuria, demographics, traditional CVD risk factors and cardiac medications, higher urine NGAL levels were an independent risk factor for ischemic atherosclerotic events (adjusted hazard ratio [HR] highest vs. lowest quintile 1.83; 95% CI 1.20-2.81), but not heart failure events or deaths.

| | | | | Urine NGAL concentration (ng/ml) | | |
|---|---|---|---|---|---|---|
| | | *≤6.9* | *>6.9 -≤12.9* | *>12.9 - ≤22.6* | *>22.6 - ≤49.5* | *>49.5* |
| Heart failure hospitalization | Event rate (per 100 person-year) | 1.50 | 2.40 | 2.58 | 2.65 | 4.18 |
| | Adjusted HR (95%CI) | Ref | 1.45 (1.01-2.08) | 1.09 (0.75-1.59) | 1.01 (0.68-1.49) | 1.05 (0.69-1.59) |
| Ischemic atherosclerotic events | Event rate (per 100 person-year) | 1.42 | 2.03 | 1.94 | 2.19 | 3.46 |
| | Adjusted HR (95%CI) | Ref | 1.54 (1.06-2.23) | 1.26 (0.85-1.87) | 1.52 (1.02-2.27) | 1.83 (1.20-2.81) |
| Death | Event rate (per 100 person-year) | 2.22 | 2.32 | 3.20 | 2.38 | 4.32 |
| | Adjusted HR (95%CI) | Ref | 1.02 (0.74-1.39) | 1.17 (0.86-1.58) | 0.81 (0.58-1.14) | 1.15 (0.81-1.62 ) |

**Conclusions:** Urine NGAL, a biomarker of tubular injury, may measure kidney damage different than that captured by eGFR or albuminuria.

*Funding:* NIDDK Support

## FR-PO280

**Serum Lipoproteins and Progression of Chronic Kidney Disease (CKD)–A Report from the CRIC Study** Mahboob Rahman,[1] Wei Yang,[2] Sanjeev Akkina,[3] Arnold B. Alper,[4] Amanda Hyre Anderson,[2] Lawrence J. Appel,[5] Jiang He,[4] Dominic S. Raj,[6] Jeffrey R. Schelling,[1] Valerie L. Teal.[2] *[1]Case Western Reserve Univ; [2]Univ of Pennsylvania; [3]Univ of Illinois; [4]Tulane Univ; [5]Johns Hopkins Univ; [6]George Washington Univ.*

**Background:** It is unclear whether lipoprotein measurements independently predict kidney disease progression in patients with established CKD.

**Methods:** Adults (n=3939) with CKD were followed in a prospective cohort study for a median of 4.1 years. The predictors for these analyses were baseline total cholesterol, triglycerides, very low-density lipoprotein cholesterol (VLDL-C), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), apolipoprotein A-I (apoA-I), apolipoprotein B (apoB), and lipoprotein (a) [Lp(a)]. The outcomes were a composite of end stage renal disease (ESRD) or 50% decline in estimated glomerular filtration rate (GFR) from baseline, and rate of change of GFR.

**Results:** Mean age of the study population was 58.2 years, and mean GFR was 44.9 ml/min/m$^2$; 48% had diabetes, and 55% were prescribed statin therapy. None of the lipoprotein measurements was independently associated with the risk of the composite renal endpoint, or with rate of change of GFR. However, there were significant (p=0.01) interactions by level of proteinuria. In participants with low levels of proteinuria (<0.2g total protein/day) one standard deviation higher LDL-C was associated with a 26% lower risk of the renal endpoint composite (HR 0.74, p=0.01), and one standard deviation higher total cholesterol was associated with a 23% lower risk of the renal endpoint (HR 0.77, p=0.02). In participants with levels of proteinuria >0.2g/day neither LDL-C nor total cholesterol levels were associated with renal outcomes. Results were consistent when stratified by statin therapy.

**Conclusions:** In this large cohort of patients with CKD, total cholesterol, triglycerides, VLDL-C, LDL-C, HDL-C, apoA-I, apoB, and Lp (a) were not independently associated with progression of kidney disease. However, there was an inverse relationship between LDL-C and total cholesterol levels and kidney disease outcomes in patients with low levels of proteinuria.

*Funding:* NIDDK Support

## FR-PO281

**Serum Fetuin Is Independently Associated with Protection from the Progression of Chronic Kidney Disease** Ben Caplin,[1] Markus Ketteler,[2] Willi Jahnen-dechent,[3] John Cunningham,[1] David C. Wheeler.[1] *[1]UCL Medical School, United Kingdom; [2]Klinikum Coburg, Germany; [3]Achen Univ, Germany.*

**Background:** Decline in kidney function is associated with worsening bone-mineral disorder in CKD patients. The relationship between biomarkers linked to arterial calcification and progression of CKD was investigated in the London Arterial Calcification, Kidney and Bone Outcomes study cohort.

**Methods:** 289 patients with stage 2-5 CKD were recruited. Biomarkers including fibroblast growth factor-23 (FGF23) and fetuin were measured in baseline serum samples. Follow-up data were obtained from hospital records after a median of 40 months and eGFR values over 3 years. A cox-proportional hazards method was used to examine predictors of dialysis (censored at death) and a hierarchical model of eGFR over time (censored at dialysis start) used to examine whether similar factors associated with biochemical decline in kidney function.

**Results:** In the whole cohort, baseline median MDRD eGFR was 39.7ml/min/1.73m$^2$, IQR:26.8-51.1 and median fetuin 0.40g/L, IQR:0.35-0.43. Follow-up data, fetuin, FGF and urinary protein levels were available on 189 subjects (159 with eGFR data). After adjustment for baseline eGFR, proteinuria, age, sex, ethnicity and FGF23, fetuin was associated with a reduced risk of requiring dialysis (HR:0.03 per unit log fetuin; 95%CI:0.00-0.33; Figure).

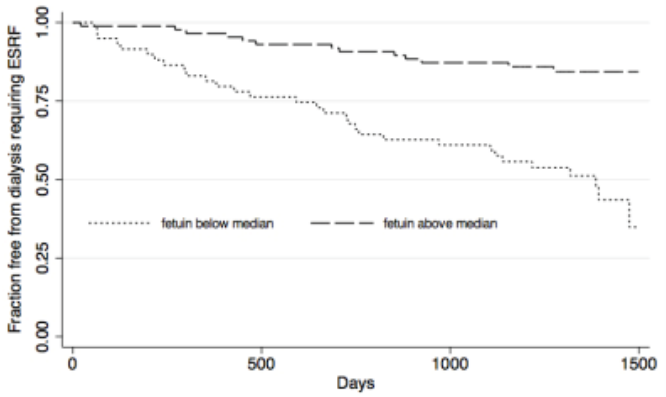

Figure: Kaplan-Meier survival estimates stratified by fetuin at baseline (unadjusted)

In the eGFR model adjusting for the same potential confounders, fetuin was associated with a 6.3mL/min/1.73m$^2$/year slower decline in eGFR per unit log fetuin (95%CI:0.03-12.5). In neither model was the association confounded by a measure of inflammation (hsCRP).

**Conclusions:** Using two independent approaches, need for dialysis and eGFR change, serum fetuin was independently associated with preservation of kidney function. Whether this association is causal and is worth exploring from a therapeutic perspective requires further study.

*Funding:* Private Foundation Support

## FR-PO282

**Associations between Osteoprotegerin, Mortality and Progression of CKD**

Helen Alderson, James Ritchie, Philip A. Kalra. *Salford Royal Hospital.*

**Background:** Elevated levels of osteoprotegerin (OPG) are observed in CKD and have been associated with vascular calcification and mortality. The relationship with cause specific mortality and rate of change in renal function is less well described.

**Methods:** Patients were selected from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS), a prospective observational study of outcome in CKD 3-5. OPG was measured in stored sera from 493 patients. Levels were analyzed in continuous and categorical forms (quartiles of OPG) in relation to all-cause and cardiovascular mortality and progression of CKD.

**Results:** At time of OPG measurement mean eGFR was 31±12ml/min/1.73m$^2$, age 64±14 years. Over a median follow up of 5.4 (3.9-7.2) years 23% of patients reached dialysis, 40% died. Median OPG level was 7.3 (5.7-9.6)pmol/L, with higher levels significantly correlated with increasing age and lower eGFR (r 0.54 and -0.26 respectively, both p<0.001). OPG levels significantly correlated with rate of change in GFR (r -0.11 p=0.009) but did not associate with increased risk for dialysis (HR 1, p=0.5). When divided by quartile of OPG there was a trend towards most rapid eGFR loss in the highest quartile, with a statistically significant difference observed between lowest and highest quartiles (-0.3±3.5 vs. -1.2±3.4 ml/min/1.73m$^2$/year p=0.04) In multivariate Cox regression (adjusted for age, eGFR, blood pressure, diabetes, smoking history and previous macrovascular events) OPG level was associated with all cause mortality, (HR 1.1 [1.04-1.1] p<0.001). The greatest risk was observed in patients in the highest quartile of OPG (HR 2.2 [1.1-4.2] p=0.03). No significant association between OPG and risk for cardiovascular mortality was observed.

**Conclusions:** OPG levels are independently associated with all-cause but not cardiovascular mortality. Patients with the highest OPG levels have a greater annual loss of eGFR but do not have increased risk for dialysis. This is most likely due to the excess mortality observed in this group. With elevated risk clustered in patients in the upper quartile of OPG, our data suggest a threshold value of clinical importance may exist.

## FR-PO283

**The Relationship of Parathyroid Hormone Levels with Cardiovascular Disease Is Stronger When Urine Fractional Excretion of Phosphorus Is Low**

Joachim H. Ix,[1] Cassianne Robinson-Cohen,[2] Michael Shlipak,[3] Andrew N. Hoofnagle,[2] Kenneth J. Mukamal,[4] Ian H. de Boer,[2] Ravi I. Thadhani,[4] S. Ananth Karumanchi,[4] Mary Whooley,[3] Bryan R. Kestenbaum.[2] *[1]UCSD; [2]U. Washington; [3]UCSF; [4]Harvard.*

**Background:** The association of FGF23 with CVD is stronger when accompanied by a low urine fractional excretion of phosphorus (FePi), perhaps due to renal resistance to FGF23 actions. However, whether renal resistance to other hormones identifies risk is unknown.

**Methods:** We tested associations of PTH, FePi, and their interaction with CVD & mortality in patients with normal kidney function (Heart and Soul [H&S]) and moderate CKD (Seattle Kidney Study [SKS]) using Cox regression.

**Results:** In H&S, 205 CVD events & 341 deaths occurred in 8 yrs follow-up. Neither PTH (HR per doubling 1.09; 0.82,1.45) nor FePi (HR 0.89; 0.73,1.09) associated with CVD evemts, but the variables interacted (p interaction=0.01). When grouped by levels above vs. below the medians, the high PTH/low FePi group represented the group at highest risk for CVD. Trends were similar for mortality. In SKS, 75 deaths occurred in 3 yrs. Neither PTH nor FePi were associated with mortality. The p-interaction was 0.09. Again, the high PTH/low FePi groups was at highest risk.

| | HR (95% CI) | P-value | P-interaction |
|---|---|---|---|
| **The Heart and Soul Study (eGFR 71±22ml/min/1.73m$^2$)** | | | |
| **CVD (MI, stroke, CVD death)*** | | | 0.01 |
| Low PTH/Low FePi | 1.00 (ref) | -- | |
| Low PTH/High FePi | 0.73 (0.45,1.17) | 0.19 | |
| High PTH/High FePi | 1.26 (0.83,1.90) | 0.27 | |
| High PTH/Low FePi | 1.61 (1.04,2.46) | 0.03 | |
| **Mortality*** | | | 0.12 |
| Low PTH/Low FePi | 1.00 (ref) | -- | |
| Low PTH/High FePi | 0.85 (0.60,1.20) | 0.36 | |
| High PTH/High FePi | 1.04 (0.76,1.42) | 0.82 | |
| High PTH/Low FePi | 1.31 (0.94,1.82) | 0.11 | |
| **Seattle Kidney Study (eGFR 44±16 ml/min/1.73m$^2$)** | | | |
| **Mortality#** | | | 0.09 |
| Low PTH/Low FePi | 1.00 (ref) | -- | |
| Low PTH/High FePi | 1.87 (0.77,4.55) | 0.17 | |
| High PTH/High FePi | 0.79 (0.36,1.73) | 0.55 | |
| High PTH/Low FePi | 1.94 (0.85,4.45) | 0.12 | |

Adjusted for *age, sex, race, eGFR, ACR, FGF23, diabetes, sbp, bmi, smoking, chol., & CRP. # age, sex, race, eGFR, ACR, & FGF23.

**Conclusions:** High PTH/Low FePi identifies risk for CVD independent eGFR and urine ACR, and may represent kidney tubule resistance to PTH's phosphaturic actions.

*Funding:* Other NIH Support - NHLBI, Private Foundation Support

## FR-PO284

**Unresolved Subclinical Hypothyroidism Is Independently Associated with Progression of Chronic Kidney Disease**

Sangju Lee,[1] Ihnsuk Lee,[2] Yoon-Kyung Chang,[1] Hye Eun Yoon,[1] Chul Woo Yang,[1] Suk Young Kim,[1] Hyeon Seok Hwang.[1] *[1]Div of Nephrology, Depts of Internal Medicine, The Catholic Univ of Korea, Daejeon, Korea; [2]Div of Endocrinology, Depts of Internal Medicine, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** Patients with chronic kidney disease (CKD) often have subclinical hypothyroidism. However, few reports have investigated changes in the status of subclinical hypothyroidism in CKD patients and its clinical significance in CKD progression.

**Methods:** We included 168 patients with nondialysis-dependent CKD stages 2–4. The normalization of subclinical hypothyroidism during follow-up was assessed, and the association between transitions in subclinical hypothyroid status and the rate of decline of the estimated glomerular filtration rate (eGFR) was investigated.

**Results:** At baseline, 127 patients were euthyroid and 41 (24.4%) patients were diagnosed with subclinical hypothyroidism. Of these 41 patients, 21 (51.2%) spontaneously resolved to euthyroid during follow-up. The rate of eGFR decline of patients with resolved subclinical hypothyroidism was similar to that of euthyroid patients. The patients with unresolved subclinical hypothyroidism showed a steeper renal function decline than patients with euthyroidism or resolved subclinical hypothyroidism (all $p < 0.05$). The proportion of CKD patients progressing to end-stage renal disease was significantly greater in those with unresolved subclinical hypothyroidism than in those who were euthyroid ($p = 0.006$). In multivariate linear regression for rate of eGFR decrease, unresolved subclinical hypothyroidism ($\beta = -0.23$, $p = 0.001$), baseline renal function ($\beta = -0.34$, $p = 0.001$) and level of proteinuria ($\beta = -0.44$, $p = 0.001$) were independently associated with the rate of renal function decline.

**Conclusions:** Half of the CKD patients with subclinical hypothyroidism did not resolve to euthyroidism, and this lack of resolution was independently associated with rapid renal function decline.

## FR-PO285

**Comparison of CKD with Modifiable Traditional Cardiovascular Risk Factors in Their Contributions to Mortality in the US**

Kunihiro Matsushita, Yingying Sang, Shoshana Ballew, M. Grams, Josef Coresh. *Dept of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

**Background:** The aim of this study was to compare chronic kidney disease (CKD) with modifiable traditional cardiovascular risk factors regarding their contributions to all-cause and cardiovascular mortality among the participants in the Third National Health and Nutrition Examination Survey (NHANES III).

**Methods:** CKD was defined as eGFR with CKD-EPI creatinine equation <60 ml/min/1.73m$^2$ or urinary albumin-creatinine ratio (ACR) ≥30 mg/g. Modifiable traditional risk factors included hypertension (blood pressure ≥140/90 mmHg or treatment), diabetes (fasting glucose ≥126 mg/dL or treatment), hypercholesterolemia (total cholesterol ≥240 mg/dL), low high-density lipoprotein cholesterol (HDL-C) (<40 mg/dl for men and <50 for women), and current smoking (yes vs. no). Prevalence, hazard ratio for mortality, and % population attributable risk (%PAR) were obtained for each risk factor.

**Results:** Among 15933 participants, the prevalence was highest for low HDL-C followed by smoking, hypertension, hypercholesterolemia, CKD, and diabetes (Table).

During a median follow-up of 8.7 years, there were 2259 deaths (987 due to cardiovascular disease). When all predictors were incorporated into Cox models accounting for sampling probability in addition to age, sex, and race, only CKD, diabetes, and smoking remained significant for both total and cardiovascular mortality (Table). %PAR of mortality outcomes for CKD was 11-14% and higher than that for hypertension, diabetes, or dyslipidemia.

**Conclusions:** In a US national cohort, the contribution of CKD to mortality in the sense of relative risk and %PAR was greater than most of the established cardiovascular risk factors, further underscoring the public health importance of CKD.

Table. Prevalence, adjusted hazard ratio, and % population attributable risk of mortality outcomes for each risk factor of interest

| Risk factors of interest | Prevalence (%) | All-cause mortality | | Cardiovascular mortality | |
|---|---|---|---|---|---|
| | | Adjusted Hazard Ratio | % population attributable risk | Adjusted Hazard Ratio | % population attributable risk |
| CKD | 11.9 | 2.09 (1.87, 2.34) | 11.5 | 2.31 (1.91, 2.81) | 13.5 |
| Hypertension | 22.8 | 1.05 (0.89, 1.23) | 1.0 | 1.32 (0.98, 1.79) | 6.8 |
| Diabetes | 7.7 | 1.46 (1.28, 1.66) | 3.4 | 1.65 (1.39, 1.96) | 4.8 |
| Hypercholesterolemia | 18.5 | 1.01 (0.90, 1.14) | 0.2 | 1.20 (0.99, 1.45) | 3.5 |
| Low HDL-C | 36.6 | 1.11 (0.99, 1.24) | 3.9 | 1.10 (0.90, 1.33) | 3.4 |
| Current smoker | 27.9 | 1.82 (1.58, 2.09) | 18.6 | 1.67 (1.32, 2.12) | 15.8 |

Models included all risk factors above together in addition to age, sex, and race.

*Funding:* Private Foundation Support

## FR-PO286

**Periodontal Disease as a Predictor of Survival in Chronic Kidney Disease: Results from the Third National Health and Nutrition Examination Survey**
Ambarish Athavale,[1] Ana C. Ricardo,[1] Jinsong Chen,[1] Hemanth N. Hampole,[2] Phillip T. Marucha,[1] James P. Lash.[1] *[1]Nephrology, Univ of Illinois at Chicago, Chicago, IL; [2]Internal Medicine, John H Stroger Jr. Hospital of Cook County, Chicago, IL.*

**Background:** Periodontal disease (PD) is more common in patients with chronic kidney disease (CKD). Although PD has also been associated with increased all cause mortality in the general population, its prognostic significance in CKD is not known.

**Methods:** We conducted a study of 10755 participants in NHANES III. CKD was defined as eGFR <60 ml/min/1.73m$^2$ or albumin/creatinine ratio ≥ 30mg/g. Moderate or severe PD (MSPD) was defined as loss of attachment ≥ 6 mm in at least 2 mesial sites and >5 mm pocket depth in at least 1 mesial site (severe PD), or loss of attachment ≥ 4 mm in at least 2 mesial sites or at least 2 mesial sites with 5 mm pocket depth not on same tooth (moderate PD). Vital status was ascertained using the NHANES III Linked Mortality File, which provides follow-up data through December 31, 2006.

**Results:** Mean age was 41.5 years. 75.7% of the study population was non-Hispanic white. MSPD was more common in participants with CKD (9.2%) than in participants with no CKD (4.8%) (P < 0.0001). There were 1773 deaths over a mean follow up period of 14 years. Results of multivariable survival analyses are summarized below (adjusted for age, gender, education, income, smoking, diabetes, hypertension and dental care use).

| MSPD by CKD status | All Cause Mortality Hazard Ratio (HR) (95% confidence interval) | P |
|---|---|---|
| No CKD, No MSPD | Reference | - |
| No CKD, MSPD | 1.42 (1.08-1.85) | 0.01 |
| CKD, No MSPD | 1.63 (1.38-1.92) | < 0.0001 |
| CKD, MSPD | 2.27 (1.77-2.92) | < 0.0001 |

When analyses were restricted to individuals with CKD, MSPD was associated with higher all- cause (HR 1.57, 95% CI 1.16-2.12, p <0.01) and cardiovascular mortality (HR 1.51, 95% CI 1.01-2.26, p<0.05) as compared to CKD and no MSPD.

**Conclusions:** MSPD and CKD are each associated with increased risk for all-cause mortality. In individuals with CKD, MSPD is associated with incremental risk for all cause and cardiovascular mortality. Future work is needed to evaluate mechanisms for this association.

## FR-PO287

**Fibroblast Growth Factor-23 Resistance, in Addition to Fibroblast Growth Factor-23, Is Associated with Clinical Outcome in CKD Patients**
Marc G. Vervloet,[1] Anneke Bech,[2] Annet Bouma-de Krijger,[1] Arjan D. Van Zuilen,[3] Michiel Bots,[4] Peter J. Blankestijn,[3] Jack F. Wetzels.[2] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, UMCN St. Radboud, Nijmegen, Netherlands; [3]Nephrology, UMCU, Utrecht, Netherlands; [4]Julius Center for Health Sciences and Primary Care, UMCU, Utrecht, Netherlands.*

**Background:** FGF23 has emerged as an independent predictor with a high hazard ratio for clinical outcome in CKD patients. Whether FGF23 per se or tubular resistance to the actions of FGF23 is responsible for this increased risk is debated. We aimed to evaluate the effect of fractional excretion of phosphate (FePi) or TmP/GFR on the association of FGF23 with clinical in patients with moderate CKD.

**Methods:** We retrieved baseline data and available urine samples of 166 patients from the Masterplan randomized controlled trial, in two participating centers, which allowed measurement of urine calcium, phosphorus, and creatinine, and calculation of FePi and TmP/GFR. Four categories were compared, based on respective median values of FGF-23 and FePi or TmP/GFR.

**Results:** Median eGFR was 36 ml/min/1.73m$^2$ (IQR 27-44), serum phosphate 1.04 mmol/l (IQR 0.92-1.20), FGF23 140 RU/ml (IQR 81-236) FePi 0.32 (IQR 0.25-0.44) and mean TmP/GFR 0.72 mmol/l (SD 0.21). In survival analyses lnFGF23 confirmed to be a significant, independent predictor for the combined outcome of death, renal survival and cardiovascular events (HR 1.84, p<0.01). HR for the primary outcome gradually increased for the four categories of FGF-23 and TmP/GFR.

| Combined outcome death, renal survival, CV event | | | |
|---|---|---|---|
| | HR | 95% CI | p-value |
| Low FGF23/low TmP/GFR | 1 | ref | ref |
| Low FGF23/high TmP/GFR | 2.32 | 1.03-5.25 | 0.04 |
| High FGF23/low TmP/GFR | 2.81 | 1.32-5.97 | 0.01 |
| High FGF23/high TmP/GFR | 3.78 | 1.71-8.36 | <0.01 |

The results were similar when FePi was used instead of TmP/GFR (data not shown).

**Conclusions:** FGF23 predicts outcome in patients with CKD. FGF-23 resistance as defined by indices of efficacy of phosphate excretion is an additional risk factor. The tubular abnormality that causes FGF-23 resistance may be local klotho deficiency and may be causally related to clinical outcome.

*Funding:* Private Foundation Support, Clinical Revenue Support

## FR-PO288

**Incident Atrial Fibrillation and Risk of Death in Adults with Chronic Kidney Disease**
Nisha Bansal,[1] Dongjie Fan,[2] Chi-yuan Hsu,[1] Juan Daniel Ordonez,[2] Alan S. Go.[2] *[1]UCSF; [2]Kaiser Permanente.*

**Background:** Atrial fibrillation (AF) frequently occurs in patients with chronic kidney disease (CKD). Yet the long-term impact of development of AF on the risk of adverse outcomes among patients with CKD is unknown. In a large, diverse community-based population with CKD, we examined the association between incident AF and risk of all-cause death.

**Methods:** We studied adult members with CKD (glomerular filtration rate [eGFR] <60 ml/min/1.73 m$^2$ by the CKD-EPI equation) enrolled in Kaiser Permanente Northern California who were identified between 2002-2010 and did not have previous AF. Incident AF was identified using primary hospital discharge diagnoses and/or two or more outpatient visits for AF. Death was ascertained from health plan administrative databases, Social Security Administration vital status files, and California state death certificate registry. We used validated algorithms to identify demographics, comorbidity, blood pressure, eGFR, hemoglobin, proteinuria and cardiovascular medication use from health plan databases.

**Results:** Among 81,088 adults with documented CKD, a total of 6,269 (7.7%) patients developed incident AF during a mean follow-up of 4.8 ± 2.7 years. Patients who developed incident AF were more likely to be older, male, white, have other cardiovascular conditions, have higher blood pressure and lower eGFR at cohort entry. There were 2,388 deaths that occurred after development of incident AF (145 per 1000 person-years) compared with 18,865 deaths during periods without AF (51 per 1000 person-years, P<0.001). After adjustment for potential confounders, incident AF was associated with a 63% increase in rate of death.

| | Hazard Ratio (95% CI) |
|---|---|
| Unadjusted | 2.10 (2.01, 2.20) |
| Adjusted for age, gender, race | 1.61 (1.54, 1.68) |
| Adjusted for age, gender, race, socioeconomic characteristics, comorbidity, blood pressure, eGFR, proteinuria, hemoglobin and cardiovascular medication use | 1.63 (1.54, 1.73) |

**Conclusions:** Incident AF is independently associated with increased risk of death in adults with CKD. Further study is needed to identify modifiable risk factors to decrease the burden of AF and subsequent risk of death in this high-risk population.

## FR-PO289

**Chronic Kidney Disease and Long-Term Risk of Cardiovascular Events following CABG for Acute Coronary Syndromes**
Martin Holzmann, Ulrik Sartipy. *Karolinska Institutet, Stockholm, Sweden.*

**Background:** Renal dysfunction is related to cardiovascular events after elective coronary artery bypass grafting (CABG). We aimed to investigate the impact of renal dysfunction on long-term risk of cardiovascular events after CABG for acute coronary syndromes.

**Methods:** From the SWEDEHEART registry we included all 12,956 patients who underwent a first, isolated, non-emergent, CABG for acute coronary syndromes in Sweden between 2000 and 2008. We calculated hazard ratios with 95% confidence intervals (CI) for rehospitalization for heart failure, stroke or myocardial infarction in relation to glomerular filtration rates (eGFR) estimated by the MDRD study equation.

**Results:** During a mean follow-up of 5 years there were 2,844 events. Patients with eGFR 15-45 mL/min/1.73m$^2$ had a 24% increased risk of an adverse event compared with patients with eGFR > 60 mL/min/1.73m$^2$, even after adjustment for confounders including postoperative acute kidney injury. The hazard ratios with 95% CI were 1.08 (0.98-1.19) and 1.24 (1.08-1.43), in patients with eGFR 45-60 and 15-45 mL/min/1.73m$^2$, respectively, after adjustment for age, sex, diabetes, chronic obstructive pulmonary disease, peripheral vascular disease, left ventricular ejection function, atrial fibrillation, prior myocardial infarction, heart failure, stroke or perioperative acute kidney injury.

**Conclusions:** Renal dysfunction is related to rehospitalization for cardiovascular disease in patients undergoing CABG for acute coronary syndromes.

## FR-PO290

**Biomarkers of Inflammation Are Associated with Cardiovascular Disease in Chronic Kidney Disease (CKD)–Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study** Jayanta Gupta,[1] Elizabeth Dominic,[2] Tulsi K. Mehta,[2] Alan S. Go,[3] Marshall M. Joffe,[1] Melanie Glenn,[1] Valerie L. Teal,[1] Dawei Xie,[1] John W. Kusek,[4] Harold I. Feldman,[1] Dominic S. Raj.[2] *[1]U of Pennsylvania; [2]George Washington Univ; [3]U of California, San Francisco; [4]NIDDK.*

**Background:** We hypothesized that inflammatory pathways are important in the development of cardiovascular disease (CVD) in the setting of CKD and that inflammatory cytokines would be associated with CVD even after adjustment for traditional risk factors.

**Methods:** Plasma concentrations of IL-1β, IL-1 receptor antagonist (IL-1RA), IL-6, TNF-α, TGF-β, hs-CRP, fibrinogen and serum albumin were measured at baseline in a sub-group of 2613 CRIC study participants without any history of cardiovascular disease at enrollment. Cox proportional hazards regression was used to examine the association between biomarkers of inflammation and the risk of atherosclerotic vascular disease events (myocardial infarction, stroke, or peripheral arterial disease) (ASVD) and congestive heart failure (CHF) events. Analyses were adjusted for age, sex, race/ethnicity, diabetic status, current smoking status, estimated glomerular filtration rate, proteinuria, systolic blood pressure, body mass index, total cholesterol as well as use of ACEI/ARB and lipid lowering agents.

**Results:** During a 4 year follow-up 130 participants developed ASVD and 139 developed CHF.

| Biomarker | ASVD | | CHF | |
|---|---|---|---|---|
| | Hazard Ratio (95%CI) | p | Hazard Ratio (95%CI) | p |
| IL-6 | 1.23 (1.04, 1.44) | 0.01 | 1.27 (1.09, 1.49) | 0.003* |
| TNF-α | 1.25 (1.04, 1.5) | 0.02 | 1.14 (0.93, 1.4) | 0.21 |
| IL-1RA | 1.17 (0.98, 1.4) | 0.09 | 1.07 (0.89, 1.29) | 0.46 |
| IL-1β | 1.12 (0.93, 1.34) | 0.24 | 1.08 (0.9, 1.29) | 0.40 |
| TGF-β | 1.17 (0.96, 1.42) | 0.11 | 0.96 (0.8, 1.16) | 0.67 |
| Fibrinogen | 1.25 (0.95, 1.64) | 0.12 | 1.45 (1.11, 1.93) | 0.007 |
| hs-CRP | 1.38 (1.14, 1.66) | 0.001* | 1.22 (1.01, 1.48) | 0.04 |
| Albumin | 1.00 (0.83, 1.22) | 0.98 | 0.82 (0.68, 0.98) | 0.03 |
| *significant after Bonferroni correction | | | | |

**Conclusions:** hs-CRP and IL-6 were associated with increased risks of ASVD and CHF respectively in patients with CKD.

*Funding:* NIDDK Support, Other NIH Support - NHLBI

## FR-PO291

**Newer Biomarkers Slightly Improve Prediction of Progression to Renal Replacement Therapy in CKD Patients–Can Predict Study Outcomes** Adeera Levin,[1] Ognjenka Djurdjev,[2] Claudio Rigatto,[3] Francois Madore,[4] Brendan J. Barrett,[5] Norman Muirhead,[6] Myles S. Wolf.[7] *[1]Univ of British Columbia; [2]BC Renal Agency; [3]Univ of Manitoba; [4]Univ de Montréal; [5]Memorial Univ of Newfoundland; [6]Western Univ; [7]Univ of Miami Miller School of Medicine.*

**Background:** Patients with chronic kidney disease (CKD) experience variable progression of kidney disease (KD). Better prediction models are needed. To assess if newer biomarkers (NBM), alone or as a panel, improve risk prediction of renal replacement therapy (RRT), over and above conventional clinical, demographic and laboratory predictors.

**Methods:** Pan-Canadian prospective cohort study of 2544 referred CKD patients, from 25 centres. NBM tests at baseline included asymmetric dimethylarginine (ADMA), high sensitivity C-reactive protein (hsCRP), interleukin 6, pro-brain natriuretic peptide (NTproBNP), troponin I, transforming growth factor β1, cystatin C and fibroblast growth factor (FGF23). Outcome: dialysis or transplantation (RRT) within 3 years. We compared discrimination (C statistic) and classification (net reclassification index (NRI)) of proportional hazards models based on conventional vs. combination of conventional and NBM predictors.

**Results:** Mean age of the cohort is 68yrs; median eGFR was 28ml/min/1.73m2 (20% <20ml/min, 38% 20-29ml/min and 41% 30-45ml/min); 62% were male. 14.4% patients initiated RRT during the 3-year follow-up. Models based on base, base+NBM and 'best' predictors are presented in the following figure:

| Variables | Base Model | Base + NBM | 'Best' Model |
|---|---|---|---|
| Age (per 5 yrs.) | 0.97 (0.93-1.01) | 0.91 (0.87-0.95) | 0.91 (0.87-0.95) |
| Male Sex | 1.88 (1.46-2.40) | 1.77 (1.38-2.27) | 1.68 (1.31-2.15) |
| eGFR (per 1 mL/min/1.73m$^2$) | 0.89 (0.87-0.91) | 0.92 (0.90-0.94) | 0.92 (0.90-0.94) |
| Hemoglobin (per 5 g/L) | 0.94 (0.91-0.98) | 0.97 (0.93-1.01) | |
| Phosphate (per 0.1 mmol/L) | 1.06 (1.02-1.11) | 1.05 (1.01-1.09) | |
| Albumin (per 1 g/L) | 0.96 (0.94-0.98) | 0.97 (0.95-0.99) | 0.97 (0.94-0.99) |
| Bicarbonate (per 1g/L) | 1.06 (1.03-1.10) | 1.06 (1.02-1.09) | 1.05 (1.02-1.09) |
| log ACR (per 1SD) | 2.07 (1.78-2.41) | 1.87 (1.61-2.17) | 1.87 (1.61-2.17) |
| Cystatin C (per 1SD) | | 1.33 (1.15-1.53) | 1.33 (1.15-1.54) |
| log NT-ProBNP (per 1SD) | | 1.36 (1.20-1.55) | 1.36 (1.20-1.55) |
| log TGF-β1 (per 1SD) | | 0.87 (0.78-0.97) | 0.86 (0.77-0.96) |
| log FGF-23 (per 1SD) | | | 1.12 (1.02-1.24) |
| *C* statistic | 85.6 (83.9-87.3) | 86.3 (85.2-87.9) | 86.4 (85.1 - 88.0) |
| NRI Categorical, % | | 6.6 (-1.6 - 10.9) | 2.9 (-6.9 - 10.6) |

**Conclusions:** This is the first analysis of CKD cohort progression that includes NBM as a panel. Although NBMs are independent predictors of RRT progression, addition of the panel of NBMs to models based on conventional clinical, demographic and laboratory predictors results in only modest improvement of RRT risk prediction.

## FR-PO292

**Newer Biomarkers Improve Prediction of Death in CKD Patients – Can Predict Study Outcomes** Adeera Levin,[1] Ognjenka Djurdjev,[2] Claudio Rigatto,[3] Francois Madore,[4] Brendan J. Barrett,[5] Norman Muirhead,[6] Myles S. Wolf.[7] *[1]Univ of British Columbia; [2]BC Renal Agency; [3]Univ of Manitoba; [4]Univ de Montréal; [5]Memorial Univ of Newfoundland; [6]Western Univ; [7]Univ of Miami Miller School of Medicine.*

**Background:** Chronic kidney disease (CKD) patients have variable risk of death. General population risk prediction tools perform poorly in this patient group. Better prediction models are needed. **Objective:** To assess if the inclusion of newer biomarkers (NBM) improves risk prediction of death in the CKD cohort, over and above conventional clinical, demographic and laboratory predictors.

**Methods:** Pan-Canadian prospective cohort study of 2544 referred CKD patients, from 25 centres. NBM tests at baseline included asymmetric dimethylarginine (ADMA), high sensitivity C-reactive protein (hsCRP), interleukin 6, pro-brain natriuretic peptide (NTproBNP), troponin I, transforming growth factor β1, cystatin C and fibroblast growth factor (FGF23). Outcome: all-cause mortality within 3 years. We compared discrimination (*C* statistic) and classification (net reclassification index (NRI)) of proportional hazards models based on conventional vs. combination of conventional and NBM predictors.

**Results:** Mean age of the cohort is 68yrs; median eGFR was 28ml/min/1.73m$^2$; 62% were male. 15.5% patients died during 3-year follow-up. Models based on base, base+NBM and 'best' predictors are presented in the following figure:

| Variables | Base Model | Base + NBM | 'Best' Model |
|---|---|---|---|
| Age (per 5 yrs.) | 1.31 (1.23 - 1.38) | 1.25 (1.18 - 1.33) | 1.30 (1.22 - 1.38) |
| Male Sex | 1.22 (0.97 - 1.53) | 1.29 (1.03 - 1.61) | |
| eGFR (per 1 mL/min/1.73m$^2$) | 0.97 (0.95 - 0.98) | 0.98 (0.96 - 0.99) | 0.98 (0.97 - 0.99) |
| History of CVD | | | |
| Ischemic HD | 1.85 (1.37 - 2.48) | 1.37 (1.01 - 1.86) | 1.46 (1.09 - 1.98) |
| Congestive HF | 2.18 (1.57 - 3.02) | 1.40 (0.99 - 1.97) | 1.48 (1.06 - 2.08) |
| Both IHD & CHF | 2.76 (2.11 - 3.63) | 1.60 (1.20 - 2.15) | 1.67 (1.25 - 2.24) |
| Diabetes | 1.30 (1.05 - 1.62) | 1.27 (1.02 - 1.58) | 1.32 (1.06 - 1.65) |
| Hemoglobin (per 5 g/L) | 0.94 (0.90 - 0.97) | 0.96 (0.92 - 0.99) | |
| Albumin (per 1 g/L) | 0.93 (0.91 - 0.95) | 0.95 (0.92 - 0.97) | 0.95 (0.93 - 0.98) |
| Bicarbonate (per 1g/L) | 1.04 (1.01 - 1.07) | 1.02 (0.99 - 1.06) | |
| log PTH (per 1SD) | 1.19 (1.06 - 1.34) | 1.09 (0.97 - 1.21) | |
| ADMA (per 1SD) | | 1.20 (1.11 - 1.29) | 1.21 (1.12 - 1.31) |
| log NT-ProBNP (per 1SD) | | 1.64 (1.44 - 1.88) | 1.59 (1.39 - 1.81) |
| log hsCRP (per 1SD) | | 1.24 (1.11 - 1.39) | 1.25 (1.12 - 1.40) |
| log FGF-23 (per 1SD) | | 1.23 (1.11 - 1.37) | 1.25 (1.12 - 1.39) |
| *C* statistic | 79.1 (77.7 - 80.8) | 82.4 (81.0 - 84.5) | 82.1 (80.4 - 84.3) |
| NRI, Categorical, % | | 13.8 (8.2 - 26.5) | 13.7 ( 8.8 - 23.1) |

After adjusting for base predictors, NTproBNP yields the highest improvement in mortality prediction (NRI=8.9;95%CI:3.3-17.4), followed by hsCRP (NRI=4.5;95%CI:1.3-9.6) and FGF23 (NRI=3.1;95%CI:0.4-11.4).

**Conclusions:** Inclusion of NBMs in risk prediction models significantly improves precision of death prediction in the cohort of CKD patients but needs to be validated in similar cohorts.

*Funding:* Pharmaceutical Company Support - Ortho Janssen

## FR-PO293

**Cystatin C Independently Predicts Change in Left Ventricular Mass Index (LVMI) in Children with Chronic Kidney Disease (CKD)** Tammy M. Brady, Kelly C. McDermott, Michael F. Schneider, Christopher Cox, Bradley A. Warady, Susan L. Furth, Mark Mitsnefes. *CKiD Study Group.*

**Background:** In the Chronic Kidney Disease in Childhood (CKiD) longitudinal cohort study of children 1-16 yrs with CKD, iohexol GFR (iGFR) is not associated with LVMI. In adults, cystatin C is more associated with cardiovascular (CV) risk factors than GFR. We investigated whether cystatin C had an independent association with LVMI over time among CKiD participants.

**Methods:** The longitudinal association of cystatin C with change in log(LVMI) was assessed using a linear mixed model adjusting for confounders and visit with random subject effects to account for repeated measurements. Log(LVMI) was converted to %change LVMI.

**Results:** 475 children (median age 11.5yrs (Interquartile range (IQR):8.3, 15.2), 39% female, median ieGFR 50.2 mL/min/1.73m$^2$ (IQR:38.3, 65.5)), contributed data at ≥1 of 766 CKiD visits with complete data. Median follow up time was 3.1 yrs (IQR:1.1, 5.0). Over time and after adjustment, each mg/L increase in cystatin C was associated with a 7.9% increase in LVMI. In addition, younger age, lower Hb and height z-scores, greater BMI and SBP z-scores and African American (AA) race were independently associated with a significant percentage increase in LVMI.

| | Percentage Change in LVMI (95% Confidence Interval) | p-value |
|---|---|---|
| Cystatin C, mg/L | 7.9 (4.6, 11.4) | <0.001 |
| Baseline age, yrs | -0.9 (-1.4, -0.4) | <0.001 |
| Race-Age-Sex Specific Hemoglobin (Hb) z-score | -1.6 (-2.8, -0.4) | 0.01 |
| Age-Sex Specific Height z-score | -2.9 (-4.6, -1.1) | 0.002 |
| Age-Sex Specific BMI z-score | 6.8 (5.0, 8.7) | <0.001 |
| log(Calcium*Phosphorus), mg/dL | -4.1 (-12.2, 4.6) | 0.3 |
| Systolic Blood Pressure z-score | 2.7 (0.6, 4.9) | 0.01 |
| Diastolic Blood Pressure z-score | 0.5 (-1.8, 2.9) | 0.7 |
| log(iPTH), pg/mL | -1.2 (-3.2, 1.0) | 0.3 |
| Female | -1.1 (-5.4, 3.3) | 0.6 |
| African American | 9.2 (2.6, 15.6) | 0.005 |

**Conclusions:** Higher cystatin C levels are independently associated with increase in LVMI among children with mild-moderate CKD. His easily obtained serum biomarker has the potential to contribute to CV risk stratification among children with CKD.

*Funding:* NIDDK Support, Other NIH Support - Eunice Kennedy Shriver National Institute of Child Health and Human Development; National Heart, Lung, and Blood Institute

## FR-PO294

**Longitudinal Association of Body Mass Index and Waist Circumference with Left Ventricular Mass in Hypertensive Predialysis Chronic Kidney Disease Patients** Vianda S. Stel,[1] Kyriakos Ioannou,[2] Katharina Brueck,[1] Evangelia Dounousi,[3] Konstantinos D. Pappas,[4] Kostas C. Siamopoulos,[3] Carmine Zoccali,[5] Kitty J. Jager,[1] Dimitrios Tsakiris.[6] *[1]ERA-EDTA Registry, Netherlands; [2]Nicosia General Hospital, Cyprus; [3]Univ of Ioannina, Greece; [4]Univ Hospital of Ioannina, Greece; [5]Ospedali Riuniti, Reggio Cal, Italy; [6]Papageorgiou General Hospital of Thessaloniki, Greece.*

**Background:** Studies with longitudinal data on left ventricular mass (LVM) in chronic kidney disease (CKD) patients are scarce. However, to prevent left ventricular hypertrophy and its major consequences in CKD patients, identification of modifiable risk factors for increased LVM is needed. This is the first study investigating the association of body mass index (BMI) and waist circumference (WC) with LVM in hypertensive predialysis CKD patients.

**Methods:** In 2004 and 2005, 206 incident adult patients from the outpatient CKD clinics of two hospitals in Greece, were included. Inclusion criteria were the presence of CKD and hypertension. BMI (kg/m²), WC (cm) and LVM (g) were assessed annually for three years.

**Results:** Mean age was 68.1 years, mean BMI was 29.1 kg/m², mean WC was 103.7 cm, and median LVM was 245.7 g. In the cross sectional data, BMI (ß=4.7; 95%ci:2.0;7.4) and WC (ß=1.2; 95%ci:0.14;2.3) were significantly associated with LVM after adjustment for age, sex, primary renal disease, smoking and history of cardiovascular disease. These associations were pronounced in CKD stage 1-3, but not in CKD stage 4-5. In the longitudinal analysis, linear mixed models adjusting for confounders showed that an increase in BMI (ß=2.9; 95%ci:0.74;5.1) and WC (ß=1.1; 95%ci:0.28;1.8) were significantly associated with an increase in LVM.

**Conclusions:** In hypertensive predialysis CKD patients, BMI and WC were associated with LVM in CKD stage 1-3, but not in CKD stage 4-5. In these later stages the relationship may affected by uremia and peripheral muscle wasting. Longitudinal analysis showed that an increase of BMI and WC was associated with an increase in LVM. These results suggest that in the early CKD stages, overweight and obese patients should be advised to lose weight to prevent cardiovascular events.

## FR-PO295

**Impaired Kidney Function after Myocardial Infarction Is a Risk Factor for 40 Months All-Cause Mortality** Ellen K. Hoogeveen,[1] Johanna M. Geleijnse,[2] Sabita Soedamah-muthu,[2] Janette De Goede,[2] Daan Kromhout,[2] Erik Giltay.[3] *[1]Nephrology, Jeroen Bosch Hospital, Den Bosch, Noord-Brabant, Netherlands; [2]Human Nutrition, Wageningen Univ, Wageningen, Gelderland, Netherlands; [3]Psychiatry, Leiden Univ Medical Center, Leiden, Zuid Holland, Netherlands.*

**Background:** Post-myocardial infarction patients have an increased risk for all-cause mortality. Chronic kidney disease (CKD) 3-5 (eGFR<60 ml/min/m²) is an important risk factor for mortality. Little is known whether CKD 2 is also a risk factor for mortality.

**Methods:** We explored the relation between kidney function at baseline and all-cause mortality during 40-months follow-up in an observational study of 4650 post-myocardial infarction patients of the Alpha Omega Trial, receiving state-of-the-art cardiovascular treatment. Creatinine-cystatin C-based eGFR was assessed with the CKD-EPI equation 2012.

**Results:** We accrued 14,957 person-years of follow-up. Of all patients 350 (7.5%) deceased. Mean (SD) age was 69y (5.7), 78.5% were men, 21% had diabetes, 60% hypertension, 85% used statins, and 17% were current smokers. At baseline the median (interquartile range) $eGFR_{creat-cyst}$ was 79 (66-91) ml/min/m². Patients were divided into three categories on the basis of their baseline kidney function: CKD 0-1: ≥90 (27%; reference), CKD 2: ≥60 to <90 (55%), and CKD: 3-5 <60 (18%) ml/min/m². Using a Cox proportional hazards model the HRs (95%-CIs) for death by CKD level, after adjustment for the intervention with n-3 fatty acids,age, sex, diabetes, smoking, statin-use, hypertension, and C-reactive protein were: 1 (reference), 1.51 (1.06 to 2.14) and 3.51 (2.41 to 5.12).

**Conclusions:** We conclude that there is a dose response relation between kidney function and all-cause mortality in post-myocardial infarction patients. Independent of classic risk factors, CKD 2 is a 1.5-fold and CKD 3-5 is a 3.5-fold stronger risk factor for death compared with CKD 0-1 in post-myocardial infarction patients.

*Funding:* Other NIH Support - Dutch Kidney Foundation, Dutch Heart Foundation, US National Institutes of Health (NIH) and Unilever R&D

## FR-PO296

**Cardiovascular Events and Mortality in a Prospective Cohort of CKD Patients in Japan: Effects of Underlying Kidney Diseases** Hiroyuki Tanaka, Soichiro Iimori, Shotaro Naito, Tomokazu Okado, Tatemitsu Rai, Shinichi Uchida, Sei Sasaki. *Nephrology, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

**Background:** Individuals with CKD were more likely to die than to reach renal replacement therapy (RRT) in Western countries. We analyzed the risk of cardiovascular (CV) events, CV-related death and initiation of RRT stratified by underlying kidney diseases.

**Methods:** New patients from 16 nephrology centers who were older than 20 years of age and who visited or were referred for the treatment of CKD stage 2-5 were recruited in this study. 1138 patients were registered and classified by underlying kidney diseases: diabetes nephropathy (DN) (n=287), nephrosclerosis (NS) (n=451), glomerulonephritis (GN) (n=216), other nephropathies (ON) (n=173). The association between underlying kidney diseases and cardiovascular events, initiation of dialysis and mortality were analyzed using Cox proportional hazards models.

**Results:** 1. During 12 months follow-up, all groups showed decreased blood pressure (p<0.001) and decreased LDL-cholesterol (p<0.001), and no change in proteinuria. Body mass index and hemoglobin decreased in DN (p<0.05) but did not change in other groups.

2. A total of 44 patients died (including 19 patients of CV-related death), 103 patients reached RRT, and 62 patients were suffered from CV events (ischemic heart disease (n=9), peripheral arterial disease (n=7), stroke (n=10), congestive heart disease (n=36)).

3. The mortality and RRT rates (per 100 patient-years) in the three groups (DN, NS, GN) were as follows: mortality, 9.51, 3.06, 3.28; RRT, 34.1, 5.81, 8.49, respectively, indicating that participants were more likely to reach RRT than to die.

4. Compared to those with GN, patients with DN had significantly higher risks for CV events (HR 3.4; 95%CI 1.3-8.9) and initiation of RRT (HR 5.0; 95%CI 2.5-9.8), but not for all-cause death or CV-related death. NS group did not show significant difference in those events and mortality compared to GN group.

**Conclusions:** This prospective cohort study suggests that new CKD patients in Japan are likely to reach RRT than to die within 12 months observation. Risks of CV events and mortality differ according to underlying kidney diseases.

## FR-PO297

**Differences in Augmentation Index between Different Etiologies of Chronic Kidney Disease** Thilini Nishani Abeygunaratne, Darren Green, James Ritchie, Diana Chiu, Philip A. Kalra. *Salford Vascular Research Group, Univ of Manchester, Manchester, United Kingdom.*

**Background:** Chronic kidney disease (CKD) is associated with increased vascular stiffness. This can be defined by pulse wave velocity and augmentation index (Aix), is independently associated with all cause mortality and cardiovascular mortality. This study aims to consider if Aix varies by cause of CKD.

**Methods:** 360 patients with AIx measured by pulse wave analysis were selected from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS) study, a prospective study of outcome in patients with CKD 3-5. Primary cause of CKD was assigned by notes review. Heart rate adjusted AIx was assessed against primary disease as a binary variable (above/below median) using the Chi-squared test and as a continuous variable using student's t-test.

**Results:** At the time of AIx measurement mean±SD age was 66±12 years, eGFR 30±14 ml/min/1.73 m². 65% of patients were male. 27% had diabetic nephropathy, 13% IgA nephropathy, 14% autosomal dominant polycystic kidney disease (ADPKD) and 46% renovascular/hypertensive renal disease. Median AIx was 24.

For each primary disease a different proportion of patients had a measured AIx above the median - diabetes 36%, IgA 55%, APKD 65% and vascular 53%, p between groups = 0.004.

When individual primary diseases were compared to the other primary disease in combination the most significant differences was observed using diabetic nephropathy as the referent (36% vs. 52% above median AIx p=0.003). This difference persisted when AIx was considered as a continuous variable (21±8 vs. 24±9 p=0.001). Patients with diabetic nephropathy were generally comparable to the remainder of the study population: age 54 vs.57 years p=0.9, systolic blood pressure, 134 ±22mmHg vs. 135±21 mmHg p=0.6; diastolic blood pressure 68±9 mmHg vs. 71±11 mmHg p=0.02, despite having a lower eGFR 26±11 ml/min/1.73 m² vs. 33±16 ml/min/1.73 m², p<0.001.

**Conclusions:** The study suggests primary disease may confound measurements of vascular stiffness in CKD. Also, a major confounder that would need to be considered is the effect of different classes of drugs. Further study is required to validate this finding.

## FR-PO298

**Prognostic Value of Pulse Pressure in Patients with Chronic Kidney Disease: A Report from the Gonryo Study**

Tae Yamamoto,[1] Mariko Miyazaki,[1] Masaaki Nakayama,[2] Hiroshi Sato,[1] Toshinobu Sato,[3] Sadayoshi Ito.[1] *[1]Tohoku Univ, Sendai, Mkyagi, Japan; [2]Fukushima Medical Univ, Fukushima, Japan; [3]Sendai Shakaihoken Hospital, Sendai, Miyagi, Japan.*

**Background:** Cardiovascular disease is high prevalent in chronic kidney disease (CKD) due to decreased kidney function. Studies suggest that pulse pressure (PP) may be a better predictor of outcome, but information about PP on the risk for cardiovascular events (CVE) or renal failure in CKD is limited.

**Methods:** 2,656 CKD patients, the mean age 60 ± 16 years and males 53%, recruited from 11 outpatient nephrology hospitals, and evaluated prospectively the effects of PP on CVE, including ischemic heart disease, congestive heart failure, strokes and death, and on progression of end-stage kidney disease (ESKD).

**Results:** During a median follow-up of 1096 (645 - 1101) days, 124 patients experienced cardiac disease or strokes, 64 died and 225 patients started renal replacement therapy (RRT). PP correlated positively with age ($\rho$= 0.378, p<.0001) and systolic blood pressure (SBP) ($\rho$= 0.735, p<.0001), and negatively with eGFR ($\rho$= -0.203, p<.0001). When patines were divided by PP level of 60 mmHg, patients with high PP were elder, and had higher SBP, higher prevalence of hypertensive renal disease and diabetic nephropathy as the underlying renal disease and a higher eGFR. CVE rate increased linearly in patients with higher PP levels than 60 mmHg. The effect of renal function on CVE modified in patients group with high PP, but did not in patients group with low PP. High PP level modified the CVE risk predicted by renal function at baseline, but did not low PP level. Such modification of high PP level was not observed for the risk of ESKD.

**Conclusions:** We concluded that PP > 60 mmHg increased a risk for CVE in Japanese CKD population, and was a modifier of CVE predicted by decreased renal function.

## FR-PO299

**Stage 4 to 5 Chronic Kidney Disease Is Associated with Coronary Artery Calcification in Patients with Atypical Chest Pain**

Jung-woo Noh, Jong-woo Yoon, Seungyeon Son, Jwa-kyung Kim, Soo Jin Kim, Sung Gyun Kim, Jieun Oh, Youngki Lee. *Dept of Internal Medicine, Hallym Kidney Research Institute, Hallym Univ College of Medicine, Seoul, Republic of Korea.*

**Background:** Coronary artery calcification (CAC) screening can predict the risk of cardiovascular event in individuals with atypical chest pain. It is well known that CACoccursin patients on maintenance dialysis commonly and severely. The increased risk of cardiovascular disease has been also reported even at moderate declines in renal function. But direct relationship between CAC and less severe renal function is still controversial.

**Methods:** To address this question, 2562 participants with atypical chest pain underwent coronary CT from March 2006 to September 2011. CAC score was quantified using the method described by Agatston. Renal function was categorized by estimated GFR (eGFR). Decreased kidney function was definedby an eGFR <60 mL/min/1.73 m2and staging of CKD was done according to GFR (G stage).

**Results:** Fifty-twopercent of subjects had CAC, mean eGFR was 76.44 mL/min/1.73 m2 and 15.3% had eGFR<60 mL/min/1.73 m2. The median CAC scores by CKD stage 3a, 3b, 4 and 5 were 25.6, 55.5, 197 and 119.5, respectively. In unadjusted analysis, eGFR was strongly associated with CAC score (r=-0.203, P <0.001). Logistic regression showed the association between reduced renal function and CAC scores >100, and >400 versus scores <10. Compared with no CKD, stage 4 to 5 CKD was associated with CAC scores >100, (odds ratio(OR), 2.64; 95% confidence interval(CI), 2.03-3.45) and >400 (OR, 2.79; 95% CI, 2.11-3.71) after adjustment for covariates. However, no valuable association was noted between stage 3a to 3b CKD and CAC scores >100 and >400. In diabetic patients, stage 4 to 5 CKD had a more than five-fold increased odds of CAC scores >400.

**Conclusions:** Stage 4 to 5 CKD is associated with increased CAC scores, and this association is more intense in diabetic populations. In future, we need further evaluations in prospective study in patients with CKD.

## FR-PO300

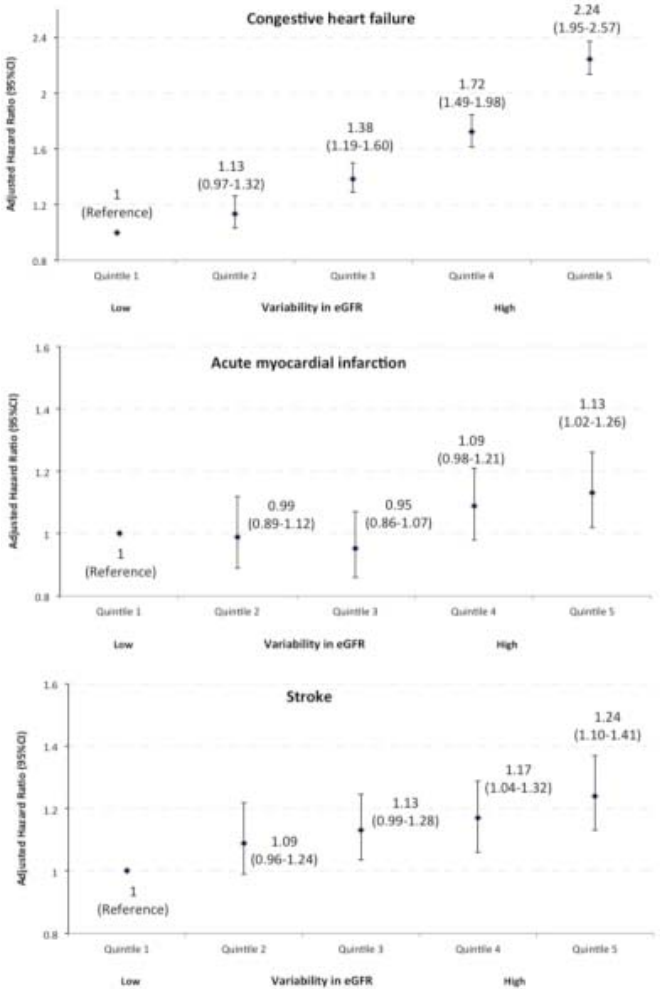
**Association between Variability in eGFR and Risk of Cardiovascular Events**

Tanvir Chowdhury Turin,[1] Min Jun,[1] Marcello Tonelli,[2] Braden J. Manns,[1] Vlado Perkovic,[3] Hiddo Jan Lambers Heerspink,[4] Mark Woodward,[3] Brenda Hemmelgarn.[1] *[1]Univ of Calgary; [2]Univ of Alberta, Canada; [3]Univ of Sydney, Asutralia; [4]Univ of Groningen, the Netherlands.*

**Background:** Relationship between dynamic changes in kidney function, specifically variability in eGFR, and risk of CVD has not been defined. We studied association between eGFR variability and risk of congestive heart failure(CHF), acute myocardial infarction(AMI), and stroke among a community-based population.

**Methods:** We studied 529,954 adults who had atleast 3 outpatient eGFR measurements over 4-year period(the accrual period) in Alberta during 2002-2008. Variability in eGFR was defined using the coefficient-of-variation(CV) from regression of measurements for each participant during the accrual period. Variability was categorized by quintile, with the lowest quintile representing patients with the least variability(referent) and increasing quintiles reflecting greater degrees of variability. Cox models (adjusting for baseline covariates, kidney function, proteinuria, and rate of change in eGFR) were used to estimate the HRs for outcomes during the subsequent follow up period, associated with increasing quintiles of eGFR variability, with follow-up to March 2009.

**Results:** Among the participants(mean age 55y, 42% male) there were 5255(1%) CHF, 4795(0.9%) AMI, and 4014(0.8%) stroke events over a median follow-up of 2.5 y. Increasing eGFR variability was associated with an increased risk of CVD events, including CHF(trend *p*:0.01), AMI(*p*:0.13) and stroke(*p*<0.01). Compared with the lowest quintile, patients in the highest quintile had more than two-fold increased risk of CHF, 13% increased AMI risk, and 24% increased risk of stroke.



**Conclusions:** We observed an independent and graded association between variability in kidney function and the risk of CVD. These results suggest that overall variation in eGFR over time may be an important prognostic marker.

## FR-PO301

**Soluble Urokinase Receptor (suPAR) Predicts Mortality and Cardiovascular Disease in Patients with Mild-to-Moderate Chronic Kidney Disease**

Bjorn Meijers,[1] Ruben Poesen,[1] Markus Storr,[2] Kathleen Claes,[1] Dirk R. Kuypers,[1] Pieter Evenepoel.[1] *[1]Nephrology, Univ Hospitals Leuven, Belgium; [2]Gambro dialysatoren GmbH, Hechingen, Germany.*

**Background:** suPAR is linked to mortality and cardiovascular disease in patients without chronic kidney disease (CKD). Studies evaluating the role of suPAR as FSGS biomarker observed an inverse association between eGFR and suPAR. Whether suPAR accumulates in patients with CKD and whether accumulation of suPAR is associated with mortality in CKD has not been studied to date.

**Methods:** We measured suPAR concentrations in patients with chronic kidney disease (CKD) from the Leuven mild-to-moderate CKD study (Clinical trials protocol NCT00441623) using the human uPAR enzyme-linked immune sorbent assay (R&D systems™). Associations with overall mortality and cardiovascular disease were explored using Kaplan-Meier estimates and multivariate Cox proportional hazards analyses.

**Results:** We determined suPAR concentrations in 486 patients with known non-FSGS CKD patients. eGFR was the strongest determinant of suPAR concentrations (P<0.0001) and suPAR accumulated in patients at low eGFR. suPAR concentrations were associated with overall mortality (P<0.0001) and cardiovascular events (P<0.0001). These associations persisted after correction for age, sex, eGFR and C-reactive protein concentration, but for mortality was lost after correction for serum albumin. suPAR remained associated with cardiovascular disease in multivariate analysis.

**Conclusions:** suPAR accumulates in patients with CKD and is directly and gradually associated with overall mortality and cardiovascular events, independent of kidney function. Given the versatile roles of uPAR as signaling orchestrator, accumulation of suPAR in patients at lower eGFR may be in the causal chain of extrarenal manifestations of CKD.

## FR-PO302

**Atrial Fibrillation Independently Predicts Mortality in Patients with Chronic Kidney Disease after Myocardial Infarction**

Hyeon Seok Hwang,[1] Hye Eun Yoon,[1] Sangju Lee,[1] Yoon-Kyung Chang,[1] Chul Woo Yang,[2] Suk Young Kim.[1] *[1]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Daejeon, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

**Background:** Chronic kidney disease (CKD) is an important predictor for mortality after acute myocardial infarction (AMI), and atrial fibrillation (AF) often coexists with CKD and AMI. However, the impact of AF on mortality and morbidity in patients with CKD is not well understood after AMI.

**Methods:** This study was based on a retrospective cohort, the COREA-AMI registry. A total of 4744 patients with AMI were enrolled, and CKD was defined as estimated glomerular filtration rate <60 mL/min/1.73 m$^2$. Patients were divided into CKD (n = 2181) or non-CKD (n = 2563) groups, and were analyzed to investigate the association of AF with mortality and morbidity risk.

**Results:** Of CKD patients with AMI, 123 (5.6%) had AF and it was significantly more prevalent than those of patients without CKD (2.9%, P< 0.001). The CKD patients with AF were associated with worse in-hospital outcomes than CKD patients without AF; more need of vasopressor and renal replacement therapy and development of resuscitation (all P < 0.05). The all-cause mortality and ischemic stroke during a median follow-up of 3.53 years was significantly higher in CKD patients with AF than in CKD patients without AF (P < 0.001 and P = 0.026, respectively). However, AF had no impact on in-hospital outcomes and all-cause mortality in patients without CKD. The adjusted hazard ratio for all-cause mortality and ischemic stroke including all other risk factors was 1.74 and 2.62 for AF in patients with CKD, respectively.

**Conclusions:** AF was more prevalent in patients with CKD, and only the association of CKD and AF increased hazard for in-hospital events and long-term mortality after AMI.

## FR-PO303

**C-Reactive Protein Mediates the Association between Low Socioeconomic Status and Pulse Pressure in Japanese CKD Cohort (CKD-JAC)**

Naohiko Fujii,[1] Takayuki Hamano,[2] Yoshitaka Isaka,[2] Tsuyoshi Watanabe,[3] Kosaku Nitta,[3] Tadao Akizawa,[3] Seiichi Matsuo,[3] Enyu Imai,[3] Hirofumi Makino.[3] *[1]Dept of Biostatistics and Epidemiology, Univ of Pennsylvania, Philadelphia, PA; [2]Osaka Univ Medical School, Suita, Osaka, Japan; [3]CKD-JAC Steering Committee, Shinjuku, Tokyo, Japan.*

**Background:** High brachial pulse pressure (PP) independently associates with faster decline in renal function and worse outcome. Low socioeconomic status (SES) has been recognized as a key environmental factor of hypertension. While dietary salt intake might explain it partially, the role of CRP, which is also known as a risk factor for hypertension, remained to be elucidated. Here we explored the association between PP, SES, and CRP in CKD patients.

**Methods:** We performed a cross-sectional observational study with the baseline data of the Japanese CKD cohort study (CKD-JAC, N=2,977). SES was assessed by self-administered questionnaire followed by classification into four income groups (Q1-4). Multivariate linear regression analyses adjusting for demographic factors, renal function, commodities, medication, nutritional parameters, and facilities were performed to test the relationships between PP, SES and CRP.

**Results:** 1,854 (62%) patients answered the questionnaire. The prevalence of diabetes and prior cardiovascular disease (CVD) was significantly higher in the lowest income group (Q1). Significant step-wise decrease in eGFR and increases in PP, age, urinary Na/K ratio (uNa/K), and CRP along with the decrease in income were observed. The association between PP and SES was robust after adjustment for age, sex, eGFR, diabetes, prior CVD, Alb, BMI, diuretics, anti-hypertensive drugs, and facilities (Coefficients [95% C.I.] vs Q4, Q1:3.0[1.3, 4.8], Q2:1.6[-0.02, 3.3], Q3:1.3[-0.4, 3.0]). Although addition of uNa/K to the model did not attenuate the coefficients, introduction of CRP dramatically reduced the magnitude of correlation coefficients and even cancelled out the statistical significance of SES (Q1:1.6[-0.3, 3.6], Q2:0.7[-1.2, 2.5], Q3:0.4[-1.6, 2.3]).

**Conclusions:** There was a significant negative correlation between SES and PP in CKD patients, where CRP plays a crucial role.

## FR-PO304

**ABCK, a Target Organ Damage Scoring System, Predicts Mortality Independently of Cardiovascular Risk Factors in a CKD Cohort**

James Ritchie,[1] Philip A. Kalra,[1] Carlo A. Gaillard,[2] Branko Braam.[3] *[1]Salford Royal Hospital; [2]VU Univ Medical Center; [3]Univ of Alberta.*

**Background:** The novel Artery Brain, Cardiac and Kidneys (ABCK) framework is a mortality and cardiovascular staging system based upon the severity of target organ damage (TOD) in an individual. This differs from traditional scoring systems that consider risk factors, not existing/incipient vascular damage. In a low-risk cohort, ABCK added predictive value to the SCORE and Framingham systems. Here we assess the utility of ABCK in predicting mortality in a higher-risk CKD population.

**Methods:** Patients were selected from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS), a prospective study of outcome in CKD 3-5. Patients were scored using ABCK, SCORE and Framingham (all cause mortality). ABCK assigns a stage for TOD from 0-4 for the 4 major target organs. Because of the cohort size 4 degrees of TOD were recognized: very mild (ABCK1-2), mild (ABCK 3), moderate (ABCK 4-6), severe (ABCK 7-9). Risk for death was assessed in a Cox proportional hazards model.

**Results:** Data on 1437 patients were analyzed. Over a median follow-up of 4.1 (1.9-6.4) years, 314 (24%) of patients died. When ABCK was considered in isolation, risk for death increased with increasing score. When considered in the same model as SCORE or Framingham risk classification, ABCK scores remained independently associated with increased risk for death.

| | ABCK alone | Adjusted for SCORE | Adjusted for Framingham |
|---|---|---|---|
| Very mild TOD | 1 | 1 | 1 |
| Mild TOD | 4.4 (1.1-17)* | 2 (0.5-9) | 3 (0.7-11) |
| Moderate TOD | 12 (3-47)** | 5 (1-19)* | 6 (2-25)** |
| Severe TOD | 20 (5-87)** | 7 (2-31)** | 9 (2-40)** |

*Results: hazard ratio (95% CI).* *p<0.05 **p<0.01. When SCORE and Framingham risk scores were weighted for ABCK score, AUC in ROC analysis increased (SCORE 0.66 to 0.71; Framingham 0.63 to 0.70).

**Conclusions:** A systematic, multi-organ TOD staging approach predicted all cause mortality in a high risk CKD cohort independent from risk factor based approaches. The ABCK framework combined with risk factors seems to reflect susceptibility for risk and predict mortality better than risk factor based methods alone.

## FR-PO305

**Relationship of Oxidized to Non-Oxidized PTH in Children with Chronic Renal Failure, Adult Patients on Hemodialysis and Kidney Transplant Recipients**

Berthold Hocher,[1] Christoph Reichetzeder,[1] Torsten Slowinski,[1] Uwe Querfeld,[1] Franz S. Schaefer,[2] Anke Doyon,[2] Martin Tepel,[3] Heinz Juergen Roth,[4] Franz Paul Armbruster.[5] *[1]Center for Cardiovascular Research, Charité, Berlin, Germany; [2]Dept of Pediatric Nephrology, Univ of Heidelberg, Heidelberg, Germany; [3]Odense Univ Hospital, Dept of Nephrology and Institute of Clinical Research, Univ of Southern Denmark, Odense, Denmark; [4]Limbach Laboratory, Heidelberg, Germany; [5]Immundiagnostik AG, Bensheim, Germany.*

**Background:** Oxidized PTH (oxPTH) loses its PTH receptor stimulating properties, whereas non-oxidized PTH (n-oxPTH) is a full agonist of the receptor. This was described in more than 20 studies in the 70ies and 80ies of the last century. However, PTH oxidation was ignored during development of PTH assays for clinical use so far.

**Methods:** We recently developed a new assay to differentiate between oxPTH and n-oxPTH. We established normal values for this assay system. Furthermore, we compared the ratio of oxPTH to n-oxPTH in different populations with chronic renal failure: 620 children with renal failure stage 2-4 of the 4C study, 342 adult patients on dialysis, and 602 kidney transplant recipients.

**Results:** Children had the highest mean as well as maximum n-oxPTH concentrations as compared to adult patients (both patients on dialysis as well as kidney transplant recipients). The relationship between oxPTH and n-oxPTH of individual patients varied substantially in all three populations. The analysis of n-oxPTH in 89 healthy control subjects revealed that n-oxPTH concentrations in patients with renal failure were higher as compared to healthy adult controls (2.25-fold in children with renal failure, 1.53-fold in adult dialysis patients, and 1.56-fold in kidney transplant recipients, respectively).

**Conclusions:** A huge proportion of circulating PTH measured by current state of the art assay systems is oxidized and not biologically active. The relationship between oxPTH and n-oxPTH of individual patients varied substantially. Non-oxidized PTH concentrations are 1.5 - 2.25 fold higher in patients with renal failure as compared to healthy controls.

## FR-PO306

**Improvements in Control of Blood Pressure and A1c among Adults with Chronic Kidney Disease, Diabetes, and Hypertension: U.S. 1999-2010**

Sharon Saydah,[1] Edward Gregg,[1] Meda E. Pavkov,[1] Neil R. Powe,[2] Rajiv Saran,[3] Nilka Rios Burrows,[1] Yi Li,[3] Desmond Williams.[1] *[1]CDC; [2]UCSF; [3]UMich.*

**Background:** Prevention of chronic kidney disease (CKD) progression includes control of blood pressure and glycemia among adults with hypertension and diabetes. Whether control of these conditions has improved among adults with CKD in the past decade is unknown.

**Methods:** NHANES from 1999-2010 was analyzed in 4 year periods to examine trends among adults ≥ 18 years with CKD and treatment for diabetes (DM) (n = 1403), or treatment of hypertension (HYTN) (n = 2817) or treatment for both (n = 985). We report percent of uncontrolled blood pressure (BP) ≥ 140/90mmHg, BP ≥ 130/80mmHg and uncontrolled A1c (A1c ≥ 9.0%). CKD was defined as eGFR < 60 ml/min/1.73 m$^2$ or elevated urinary albumin/creatinine ratio (ACR ≥30 mg/g). Estimates were adjusted for age, sex and race/ethnicity.

**Results:** Trends in uncontrolled BP and high A1c are reported.

| % (95% CI) | 1999-2002 | 2003-2006 | 2007-2010 | Relative % change |
|---|---|---|---|---|
| Treated HTN | Treated HTN | | | |
| BP ≥ 130/80 | 77.8 (73.8, 81.4) | 64.4 (60.6, 67.9) | 59.4 (55.3, 63.4) | -24% |
| BP ≥ 140/90 | 59.2 (55.3, 62.9) | 43.4 (39.7, 47.1) | 39.6 (36.2, 43.1) | -33% |
| Treated DM | | | | |
| A1c ≥ 9.0% | 25.6 (19.7, 32.7) | 12.9 (9.6, 17.1) | 16.8 (13.9, 20.2) | -34% |
| Treated HYTN & DM | Treated HYTN & DM | | | |
| BP ≥ 130/80 | 80.0 (72.7, 85.7) | 63.8 (58.6, 68.8) | 59.9 (54.9, 64.6) | -25% |
| BP ≥ 140/90 | 64.7 (54.9, 73.5) | 42.1 (35.0, 49.5) | 42.2 (36.2, 48.5) | -35% |
| A1c ≥ 9.0% | 24.2 (17.9, 31.9) | 12.6 (9.1, 17.1) | 11.6 (9.3, 14.5) | -49% |

**Conclusions:** While significant declines were observed, 2 out of 5 adults with CKD and treated HYTN have uncontrolled BP and 4 out of 25 adults with CKD and treated DM have high A1c levels. These results indicate that among adults with CKD, there is a need for health care professionals to continue to work to reduce uncontrolled blood pressure and diabetes to prevent progression of CKD.

## FR-PO307

**A New Model for CKD Care: Home Telehealth by an Interprofessional Team** Areef Ishani,[1] Juleen Christopher,[1] Sara Otterness,[1] Deirdre A. Palmer,[1] Mark E. Rosenberg.[2] *[1]Minneapolis VAHCS; [2]Univ of Minnesota.*

**Background:** Chronic kidney disease (CKD) is common and is associated with poor patient outcomes. Multidisciplinary case management with or without telemonitoring has been demonstrated to improve outcomes in non-CKD populations. The purpose of our study was to determine if a multidisciplinary case management with remote video monitoring of patients with CKD (eGFR<60mL/min) reduces a composite outcome (death, hospitalization, ER visits, admission to a skilled nursing facility) compared to usual care.

**Methods:** We recruited 601 veterans from the state of Minnesota with a last eGFR<60mL/min. At baseline all patients completed a home visit including surveys, a brief exam, and collection of blood and urine. 450 patients were randomized to the intervention consisting of a remote monitoring device (touch screen computer, BP cuff, scale, webcam, and glucometer). Patients were also provided with broadband if required. Patients in the intervention group were cared for by a multidisciplinary team of nurses, nurse practitioners, pharmD, dietician, social worker, psychologist, and a nephrologist following CKD guidelines and the chronic disease model of care. The overall goals of care were to optimize chronic conditions and to rapidly identify and resolve acute issues. Patients in the usual care group were informed of their kidney disease and invited to attend CKD education classes. The overall study duration is 12 months, with an anticipated primary event rate of 50% in the usual care group and 35% in the intervention group.

**Results:** Over an 8-month recruitment period 601 patients were enrolled in the study. Baseline characteristics of the overall study group are: age 78 years, male 98.7%, Caucasian 98.7%, eGFR 38mL/min. Patients lived on average 98 miles from the Minneapolis VA hospital, with 147 (24%) patients greater than 200 miles away. 292 (65%) patients had existing broadband, and the study provided broadband to the remaining patients.

**Conclusions:** This is a novel multifaceted intervention aimed to reduce adverse outcomes in CKD patients. The approach is feasible, connectivity can be established, and multidisciplinary care can be delivered using telehealth.

*Funding:* Veterans Affairs Support

## FR-PO308

**Implementation of CKD Care Coordinators Is Associated with Better Outcomes When Starting Dialysis** Dugan Maddux,[1] Daniel Defalco,[1] Kevin Chan,[1] Len A. Usvyat,[1] Monet M. Carnahan,[1] Koshy O. Abraham,[2] Franklin W. Maddux.[1] *[1]FMCNA, Waltham, MA; [2]Columbia Nephrology Assosciates, Columbia, SC.*

**Background:** The Renal Care Coordinator (RCC) Program places CKD case managers and analytical tools in the Nephrology Practice to co-manage late stage CKD patients. We compared outcomes in patients starting dialysis who were previously enrolled in the RCC program to CKD patients who were cared for in the Nephrology practice for 4 months or more (Timely Referral), but were not in the RCC program.

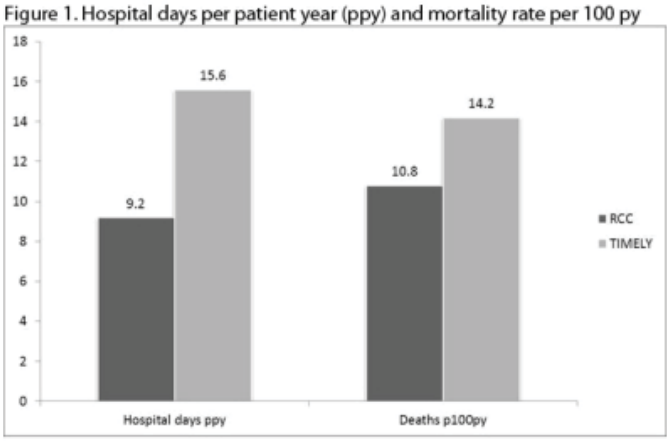
**Methods:** All CKD 5 patients who transitioned to ESRD between 1/2009 and 12/2012 in 10 nephrology practices who adopted the RCC program were included. Within this cohort, we compared outcomes in those patients who were enrolled into the RCC program [RCC] versus those who were considered to have a timely referral for dialysis but with no RCC interaction. For each patient, we noted access type, albumin, neutrophil to lymphocyte ratio [NLR] (as marker of inflammation), hgb, and EPO dose at the first outpatient dialysis treatment. We also computed the rate of hospital days and mortality in the first 120 days of dialysis.

**Results:** 4768 CKD 5 patients were identified for the study where 15% of the population was enrolled in the RCC program. Patients who were in the RCC program had a lower % of patients with catheters, higher albumin, lower NLR, non –significantly different Hgb, and lower EPO dose on the first in-center HD treatment compared to patients with no RCC care. Hospital days were 41% lower and mortality rate was 24% lower in the RCC program compared to patients with Timely Referral alone in the first 120 days.

Table 1. Comparison of parameters at the first in-center HD treatment

| Patient group | Number of patients | Catheters (%) | Albumin (g/dL) | Neutrophil to lymphocyte ratio | Hgb (g/dL) | EPO per HD treatment |
|---|---|---|---|---|---|---|
| RCC | 709 | 34.80% | 3.64 | 5.6 | 10.15 | 3116 |
| TIMELY | 4059 | 50.80% | 3.51 | 5.9 | 10.26 | 6090 |
| p-value | | <0.01 | <0.01 | <0.01 | NS | <0.01 |

Figure 1. Hospital days per patient year (ppy) and mortality rate per 100 py



**Conclusions:** This analysis demonstrates that placement of CKD coordinators in Nephrology Practices is associated with better outcomes, including mortality and hospitalizations, in the first 120 days of dialysis.

## FR-PO309

**Healthcare Resource Utilization and Costs Associated with the Treatment of Autosomal Dominant Polycystic Kidney Disease** Christopher M. Blanchette,[1,2] Serban R. Iorga,[3] Aylin A. Riedel,[3] Jerry G. Seare,[3] Ying Fan,[3] Sandro Rossetti,[1] Ben Gutierrez.[1] *[1]Otsuka America Pharmaceuticals, Inc., Princeton, NJ; [2]Univ of North Carolina, Charlotte, NC; [3]OptumInsight, Eden Prairie, MN.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is a hereditary disease associated with cyst growth and loss of renal function that leads to renal failure. Symptoms of ADPKD can lead to multiple complications, including most commonly hypertension, urinary tract infections, renal cyst infections, hematuria, kidney stones, rupture of intracranial aneurisms, and chronic pain. Real-world data on healthcare costs and resource utilization for ADPKD is lacking; therefore we assessed healthcare cost in a sample of commercially insured (COM) and Medicare Advantage (MAPD) patients.

**Methods:** Patients diagnosed with ADPKD (≥2 claims) with ≥30 days of continuous medical and pharmacy benefits, and no evidence of autosomal recessive polycystic kidney disease were selected from a large health plan claims dataset (1/1/06-8/31/12). Plan and patient paid costs and utilization per patient per month (PPPM) were described in total and by payer type, and estimated using generalized linear models by chronic kidney disease (CKD) stage (defined by ICD-9 or serum creatinine).

**Results:** Of 36,253,096 patients in the database during the observation period 5,051 (0.014%) were identified with ADPKD. After applying exclusion criteria, 4,356 COM and 468 MAPD remained. Patients had an average length of time-in-study of 1,299 days. Post-index complications included hypertension (88%), anemia (47%), urinary tract infections (41%), kidney stones (19%), liver disorders (35%), and kidney transplants (20%).

| | COM, N 4356 | MAPD, N 468 |
|---|---|---|
| **Mean age, years** | 46 | 70 |
| **Dialysis, %** | 41 | 59 |
| **Healthcare cost PPPM, $ (SD)** | | |
| Total | 2,219 (4,536) | 2,540 (3,259) |
| CKD stage 1 | 980 (2,143) | 1,397 (1,856) |
| CKD stage 5 | 5,542 (10,147) | 4,972 (8,915) |
| Dialysis-related (CKD stage 5) | 3,969 (9,022) | 3,547 (8,696) |

**Conclusions:** Total healthcare cost and resource utilization associated with ADPKD was high, which was driven mostly by end-stage renal disease and was similar for COM or MAPD patients.

**Cross-Sectional and Longitudinal Associations with Creatinine Generation Rate (CGR) in the Chronic Renal Insufficiency Cohort (CRIC)** Francis P. Wilson,[1] Wei Yang,[1] Amanda Hyre Anderson,[1] Peter P. Reese,[1] Radhakrishna Reddy Kallem,[1] Sankar D. Navaneethan,[4] Akinlolu O. Ojo,[5] James H. Sondheimer,[6] Raymond R. Townsend,[1] Mary B. Leonard,[3] Harold I. Feldman.[1] *[1]Pereleman School of Medicine at the Univ of Pennsylvania; [2]Tulane Univ; [3]Children's Hospital of Philadelphia; [4]Cleveland Clinic; [5]Univ of Michigan; [6]Wayne State Univ.*

**Background:** Muscle mass may be lower in patients with more severe CKD. We examined factors associated with muscle mass and muscle loss as measured by CGR in a large national chronic kidney disease population.

**Methods:** We used data from 3725 participants in the CRIC study, a national, prospective study of chronic kidney disease and assessed their CGR, a proxy for muscle mass, from 24-hr urine collections yearly for a median of 4 yrs. We examined associations between CGR and factors assessed at study entry using mixed-effects models.

**Results:** Mean (SD) age was 58 (11) years, 55% were male, and 42% reported black race. Mean (SD) baseline CGR was 1333 (591) mg/day, and declined by 13.8 mg/year ($p<0.001$). Compared to participants in the lowest tertile of baseline CGR at study entry, those in the highest tertile were more likely to be black, male, and younger (all $p<0.001$). They also had higher BMI, larger waist circumference, larger fat mass, and lower high-density lipoprotein (all $p<0.001$), but lower rates of diabetes ($p=0.02$) and lower hemoglobin A1C ($p=0.001$). Participants with the highest CGR had lower serum creatinine and cystatin levels ($p<0.001$), greater urine urea appearance ($p<0.001$), but similar urinary protein excretion ($p=0.42$) compared to those in the lowest CGR tertile. Longitudinally, higher cystatin C levels ($p<0.001$), female sex ($p<0.001$), older age ($p<0.001$), more proteinuria ($p<0.001$), non-black race ($p=0.002$), smoking ($p=0.01$), and higher C-reactive protein ($p=0.02$) were independently associated with loss of CGR over time.

**Conclusions:** Greater protein intake is associated with greater muscle mass as measured by CGR in CKD. As well, proteinuria, anemia, and smoking are potentially modifiable factors associated with progressive muscle wasting in CKD.

*Funding:* NIDDK Support

**FR-PO311**

**Association of Creatinine Generation Rate (CGR) with Death and End-Stage Renal Disease (ESRD) in Patients with Chronic Kidney Disease (CKD) in the Chronic Renal Insufficiency Cohort (CRIC)** Francis P. Wilson,[1] Wei Yang,[1] Amanda Hyre Anderson,[1] Peter P. Reese,[1] Radhakrishna Reddy Kallem,[1] Sankar D. Navaneethan,[3] Akinlolu O. Ojo,[4] James H. Sondheimer,[6] Raymond R. Townsend,[1] Harold I. Feldman.[1] *[1]Pereleman School of Medicine at the Univ of Pennsylvania; [2]Tulane Univ; [3]Cleveland Clinic; [4]Univ of Michigan; [5]Univ of Illinois; [6]Wayne State Univ.*

**Background:** Greater severity of CKD may be associated with lower muscle mass, but the association of muscle mass to clinical outcomes in CKD is undefined.

**Methods:** We used data from 3725 participants in the CRIC study, a national prospective study of CKD and assessed their CGR, a proxy for muscle mass, from 24-hr urine collections at study entry. Proportional hazards analysis was used to assess the association between CGR and all-cause mortality or ESRD.

**Results:** Higher CGR was associated with a lower rate of all-cause mortality in unadjusted models with hazard ratio for death 0.68 (0.61 -0.75, $p<0.001$) for each standard deviation increase in CGR. After adjustment for age, sex, race, ethnicity, serum cystatin, urine protein, hemoglobin, diabetes, cardiovascular disease, smoking status, height, weight, waist circumference, and urine urea appearance, CGR remained independently associated with death - aHR 0.86 (0.76 - 0.98, $p=0.02$). CGR was associated with the development of ESRD in unadjusted - HR 0.72 (0.66 - 0.80, $p<0.001$) and fully adjusted models - aHR 0.79 (0.70 - 0.89, $p<0.001$). Accounting for death as a competing risk showed similar results; aHR 0.81 (0.69 – 0.94, $p=0.006$).

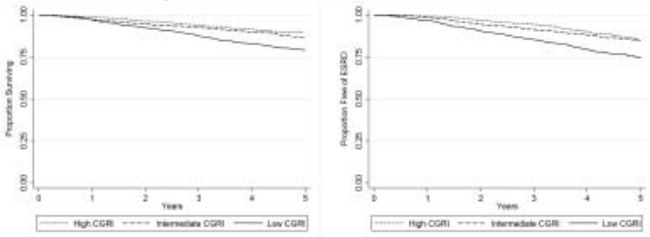

Figure 1. A) Kaplan-Meier curves of all-cause mortality for tertiles of CGR indexed to Height (CGRI). B) Kaplan-Meier curves of ESRD for tertiles of CGRI.

**Conclusions:** Lower CGR, a proxy for low muscle mass, is independently associated with death and ESRD in patients with CKD.

**FR-PO312**

**Low Compliance with Protein Intake Recommendations and Outcomes in Patients with Chronic Kidney Disease** Benedicte Stengel,[1] Wenlun Yuan,[1] Martin Flamant,[2] Pascal Houillier,[2,3] Francois Vrtovsnik.[2,5] *[1]Inserm U1018, Univ Paris Sud, Villejuif; [2]APHP, Paris; [3]Univ Paris Descartes, France; [4]The NephroTest Study Group.*

**Background:** Little is known about real compliance with dietary protein intake recommandations and its outcomes in patients with chronic kidney disease.

**Methods:** We measured glomerular filtration rate (mGFR) and assessed protein intake in g/kg/day based on both 24h-urinary urea nitrogen (UUN) using Maroni's formula and 7-day food record in 1,018 men and 502 women with nondialysis CKD stages 1 to 5. Cox models were used to assess hazard ratios (HR) for end-stage renal disease (ESRD) and death before ESRD over a mean follow-up of 3.5 yrs.

**Results:** Mean age was 60±15 vs 58±15 yrs in men vs women, and mean body mass index, 26.6±4.4 vs 26.2±6.0 kg/m$^2$. Baseline mean UUN-based protein intake did not significantly differ between men and women, 1.35±0.33 g/kg/d *vs* 1.32±0.39 g/kg/d; estimates based on 7- day food record were 0.27±0.44 g/kg/d lower on average in both genders. 24h-UUN significantly decreased from 1.48 to 1.14 g/kg/d with decreasing mGFR from ≥ 60 to < 15 mL/min/1.73 m$^2$ in men and from 1.45 to 1.10 g/kg/d in women. Similar decrease was observed with food record, from 1.50 to 1.15 g/kg/d in men and from 1.54 to 1.29 in women. Fifty-two percent of men and 47% of women had protein intake above the 2012 KDOQI upper limit of 1.30 g/kg/d recommended for CKD patients. Adjusted HR of ESRD associated with 1 g/kg/d UUN increase was 1.54 [0.98-2.43] and for mortality before ESRD, 0.95 [0.52-1.75]. These HR were 3.51 [2.02-6.12] and 1.84 [0.77-4.38] for the association with 7-day record-based protein intake, respectively.

**Conclusions:** Despite lower mean dietary protein intake at lower mGFR levels, compliance with recommandations remains low in patients with chronic kidney disease. High protein intake appeared to be associated with increased risk for ESRD, but not for mortality. It is worth noting that the decrease in 24h-UUN associated with kidney function decline may not be attributed to increased extrarenal urea elimination, since similar results were found for 7-day record-based protein intake.

**FR-PO313**

**Prior Statin Use in the Prevention of Kidney Outcome among Intensive Care Unit Patients** Isabelle Malbouisson,[1] Beata Marie Redublo Quinto,[1] Maria Dalboni,[1] Marcelo Costa Batista.[1,2] *[1]Medicine, Nephrology Div, UNIFESP, Sao Paulo, SP, Brazil; [2]Medicine, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil.*

**Background:** HMG Co-A reductase inhibitors (statins) are effective in primary and secondary prevention of cardiovascular diseases, independently of their lipid lowering action. Recent data suggest that statins have pleiotropic effects which are associated with better outcomes in critical care setting. The aim of this study was to determine wheter pre hospital statin use is associated with a lower risk of dialysis therapy and/or death during Intensive Care Unit (ICU) stay.

**Methods:** Prospective cohort analysis. Patients: 670 patients admitted to the ICU of an academic tertiary-care hospital.

**Results:** Patients included in this study had a mean age of 66 years old, with a mean corporal mass index (CMI) of 26,6 kg/m$^2$ and a mean abdominal circumference of 97 cm. Patients on statin therapy (18,2%) prior to the ICU hospitalization were less likely to need dialysis therapy or die (OR: 0,41, IC: 0,18-0,93, p: 0,03). As secondary outcomes, patients using statins were also less likely to develop sepsis after infection (OR: 0,42, IC: 0,22-0,77, p: 0,006) and had a reduction in hospital length-of-stay (14,7+- 17,5 days vs 22,3 +- 48 days, p: 0,006**).** Groups were adjusted to sex, age, C-reactive protein (CRP), need of mechanical ventilation, use of vasoactive drug and presence of diabetes and/or coronariopathy, in a multivariable analysis.

**Conclusions:** Statin therapy prior to hospital admission was associated with better outcomes during ICU stay, such as lower risk for dialysis need or mortality and lower risk for the development of sepsis.

**FR-PO314**

**Patterns of Serum Tumor Necrosis Factor Receptors 1 and 2 According to the Glomerular Filtration Rate in Korean Population** Su Mi Lee,[1] Ran-hui Cha,[2] Seung Hee Yang,[1] Jung Pyo Lee,[3] Dong Ki Kim,[1] Yon Su Kim.[1] *[1]Seoul National Univ Hospital; [2]National Medical Center; [3]Seoul National Univ Boramae Medical Center.*

**Background:** Tumor necrosis factor alpha(TNFα/TNF) is a central role in the inflammation. TNF signaling is mediated via two distinct receptors, TNFR1 and TNFR2. Elevated plasma concentrations of TNF receptors may contribute to pathogenesis of renal decline. We investigated how circulating TNF receptors varied according to glomerular filtration rate(GFR).

**Methods:** Study subjects were individuals who participated in study of Korean coefficients for GFR estimation by MDRD study equations [CKD(n=201) and healthy volunteers(n=43)]. GFR was measured through systemic inulin clearance. TNF receptors were measured by ELISA. We derived reference values of TNF receptors according to GFR and evaluated diagnostic power. We identified TNF receptors values in patients with early renal decline compare to healthy controls and effect on the progression of renal function. Renal function decline was defined as reduction of GFR more than 5 per year or dialysis requirement.

**Results:** TNFR1 as well as TNFR2 were correlated with measured GFR(r=-0.63andr=-0.67). Median values of TNFR1 and TNFR2 according to GFR were as follows: 594and1579 for GFR≥90, 921and2152 for 90>GFR≥60, 1691and3410 for 60>GFR≥30, 2925and6994 for 30>GFR≥15, 2267and4419 for GFR<15. TNF receptors had similar diagnostic power in patients with GFR less than 60 when compared to SCr through ROC curve. The levels of TNF receptors in CKD1 and 2 patients(n=60) were higher than healthy volunteers. Compared with stable renal function participants, TNF receptors values were elevated in individulas with renal function decline. Multivariate analysis revealed that highest quartile of TNF receptors were associated with renal function impairment compared to the other quartiles.

**Conclusions:** Our study identified that TNF receptors were correlated with measured GFR. TNF receptors showed similar increment pattern and diagnostic power compared with SCr. Even mild renal impairment was associated with higher levels of TNF receptors in comparison to healthy controls. TNF receptors were associated with progression of renal function.

## FR-PO315

**Concentration of Serum Tumor Necrosis Factor Receptors and Progression of Chronic Kidney Disease in Patients with Moderate to Severe Renal Dysfunction** Su Mi Lee,[1] Ran-hui Cha,[2] Hajeong Lee,[1] Sunhwa Lee,[1] Seung Hee Yang,[1] Jung Pyo Lee,[3] Dong Ki Kim,[1] Yon Su Kim.[1] *[1]Seoul National Univ Hospital; [2]National Medical Center; [3]Seoul National Univ Boramae Medical Center.*

**Background:** The prevalence of chronic kidney disease (CKD) has been increased steadily, and it's one of public health problems. However, there is a paucity of biomarkers for the prediction of CKD progression other than high serum creatinin (SCr), reduced glomerular filtration rate (GFR), and proteinuria. Chronic inflammation may contribute to kidney damage and interaction between tumor necrosis factor alpha (TNFα/TNF) and its receptors (TNF receptor 1 and 2) has essential role in the inflammation signaling. We aimed to evaluate the clinical significance of TNF receptors as a biomarker of CKD progression.

**Methods:** We recruited 473 patients with CKD stage 3 (n = 148) and 4 (n = 321). Primary outcome was defined as composite of SCr increase more than 2 times, GFR decrease more than 50 percent, or initiation of renal replacement therapy. We measured serum concentration of TNF receptors by ELISA (DRT100 and DRT200; R&D Systems, Minneapolis, MN).

**Results:** A total of 205 patients reached primary outcomes during 3 years of follow-up. Patients with primary outcomes showed higher baseline level of SCr, glomerular filtration rate (GFR), proteinuria, and TNF receptor 1/ 2 than patients without primary outcomes. When the levels of TNF receptors were categorized as tertiles, there was a significant association between tertiles of TNFR 1 and primary outcome after adjustment for age, gender, GFR, and proteinuria (OR (C.I.) ; 1 (reference), T2: 2.27 (1.137-4.440), T3: 4.719 (2.234-9.971)). In addition, there was a tendency to increased adjusted odds ratio of primary outcome according to increasing TNFR2 tertiles after adjusted with age, gender, GFR, and proteinuria (OR (C.I.) ; 1 (reference), T2: 1.357 (0.718-2.563), T3: 3.096 (1.618-5.926)).

**Conclusions:** This study showed higher serum level of TNF receptors (TNF receptor 1 and 2) are associated with progression of CKD in patients with moderate to severe renal dysfunction (CKD stage 3 to 4).

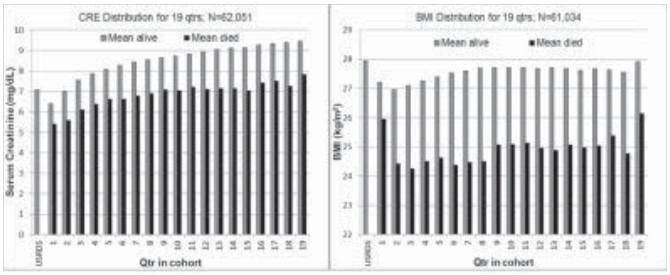
## FR-PO316

**Time Trend of Body Mass Index in Maintenance Dialysis Patients** Elani Streja,[1] Connie Rhee,[1] Lilia R. Lukowsky,[1] Allen R. Nissenson,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Davita Inc., El Segundo, CA; [3]Memphis VA Medical Center, Memphis, TN.*

**Background:** Among dialysis patients, lower body mass index (BMI) has been associated with increased mortality, a phenomenon known as the obesity paradox. This apparent paradox may be explained by protein-energy wasting and loss of muscle mass over time. We hypothesize that there are time trend associations between BMI and serum creatinine levels with dialysis vintage, and that these trends may be associated with patient survival.

**Methods:** Among 62,051 incident (vintage <90 days) dialysis patients over a 5-year period (7/2001-6/2006), repeated BMI and serum creatinine levels were averaged per quarter by patient survival.

**Results:** On average, there was a significant linear increase in the mean serum creatinine level from the first calendar quarter (6.3 mg/dL) over the subsequent seven calendar quarters. Although this trend was similar between patients who survived vs. patients who died within each calendar quarter, those who died had a lower average serum creatinine per quarter compared to those who survived. In contrast, ,whereas survivors did not experience a change in their average BMI over time, after excluding the first quarter there was a trend towards an increased BMI over time. Moreover, those who died had a lower average BMI compared to those who survived.



**Conclusions:** Incident dialysis patients were observed to have a significant increase in serum creatinine level following dialysis initiation irrespective of survival or death status, while BMI increased over time only among patients who survived. Our findings also corroborate prior reports whereby lower creatinine levels and lower BMI is associated with increased mortality. These results offer further insight into the obesity paradox and relationship between BMI, muscle mass and survival in dialysis patients.

*Funding:* NIDDK Support, Private Foundation Support

## FR-PO317

**Circulating Angiotensin Converting Enzyme 2 in Patients with Chronic Kidney Disease without History of Cardiovascular Disease** Lidia Anguiano,[1] Marta Riera,[1] Julio Pascual,[1] Clara Barrios,[1] Angels Betriu,[2] Jose M. Valdivielso,[2] Elvira Fernandez,[2] Maria Jose Soler.[1] *[1]Nephrology, IMIM-Hospital del Mar, Barcelona, Spain; [2]Nephrology, Hospital Arnau de Vilanova, Lleida, Spain.*

**Background:** Circulating ACE2 activity is increased in cardiovascular disease(CVD) and in experimental models of diabetes(DM). It has not been studied in Chronic Kidney Disease(CKD)without history of CVD.

**Methods:** Analysis of 2572 patients without history of CVD from NEFRONA study. Groups:non-dialysis CKD stage 3-5(CKD3-5,n=1458) and dialysis(CKD5D,n=546). 568 patients without CKD were controls. Variables analyzed:gender,age,DM,dyslipidemia,hypertension and ACEi or ARBs.ACE2 activity was measured by fluorimetry.

**Results:** Patients on CKD3-5 had higher levels of ACE2 activity compared to CKD5D(45.2±1.2RFU/μl/h vs 38.5±1.6,p<0.05). Control patients had higher levels of ACE2 activity(52.9±1.5)compared to CKD3-5 and CKD5D(p<0.05). In CKD3-5 ACE2 activity was increased in men compared to women(50.4±1.6 vs 36.6±1.5)and in DM(49.9±2.0 vs 43.3±1.4,p<0.05). In CKD5D,ACE2 activity was increased in men(45.6±2.5 vs 27.7±1.4),in dyslipidemia(42.6±2.8 vs 33.9±1.3,p<0.05) and in ARBs (40.3±1.9 vs 37.6±2.2,p<0.05). Direct correlation between age and ACE2 activity(p<0.05) in CKD3-5 and CKD5D. In CKD3-5 patients HbA1c directly correlated with ACE2 activity(p<0.05). By multiple regression analysis, male, old age and DM were independent predictors of ACE2 activity in CKD3-5. Predictors in CKD5D were male gender, age and ARBs. When all patients included, male gender, older age, ARBs and CKD3-5 were predictors of elevated ACE2.

| ACE2 predictors | β | p-value |
|---|---|---|
| CKD3-5 | | |
| Male | 0.22 | 0.001 |
| Age | 0.06 | 0.03 |
| DM | 0.07 | 0.01 |
| CKD5D | | |
| Male | 0.33 | 0.001 |
| Age | 0.12 | 0.002 |
| ARB | 0.09 | 0.02 |
| All included | | |
| Male | 0.25 | 0.001 |
| Age | 0.08 | 0.001 |
| ARB | 0.05 | 0.03 |
| CKD3-5 | 0.06 | 0.001 |

**Conclusions:** In CKD patients without history of CVD, old age and male gender are predictors for elevated ACE2 activity. Independent additional predictors are DM in CKD3-5 and ARBs in CKD5D. Increased ACE2 activity in CKD might indicate those patients at risk for developing CVD.

## FR-PO318

**Stroll Saves Lives and Delays Renal Replacement Therapy** I-RU Chen, Che-yi Chou, Hsin Hung Lin, I-kuan Wang, Shih-yi Lin, Yao-Lung Liu, Jiung-hsiun Liu, Chih-chia Liang, Yafei Yang, Huey-Liang Kuo, Chiu-Ching Huang. *Dept of Internal Medicine, Kidney Institute and Div of Nephrology, China Medical Univ Hospital, Taichung, Taiwan.*

**Background:** There is increasing evidence of the benefit of increasing physical activity in chronic kidney disease (CKD) patients receiving renal replacement therapy (RRT). Increasing physical activity may improve quality of life and clinical outcomes. There is little evidence for the benefit of increasing physical activity in CKD 3-5 patients. This study reported the effect of frequency, duration and types of exercise in CKD 3-5 patients on clinical outcomes.

**Methods:** We analyzed all CKD 3-5 patients in China Medical University Hospital CKD program from 2003 to 2012. The types, frequency and duration of exercise were recorded on the initiation of CKD program and all patients were followed to the date of mortality, RRT (dialysis or kidney transplant) or Dec 2012. The risk of mortality or RRT was analyzed using Cox regression with adjustments for age and CKD stage (3a,3b,4,5).

**Results:** A total of 4832 CKD 3-5 patients (stage 3a 720, stage 3b 818, stage 4 996 and stage 5 2298) including 2052 female and 2779 male with mean age of 69.1 +/- 13.6 years old were analyzed. 357 (7.4%) patients died and 2596 (53.7%) started RRT in an average 1.7 +/- 1.6 years follow-up. Diabetes and hypertension was not significantly associated with the outcomes while types, frequency, and duration of exercise were taken into consideration. The increasing frequency of exercise was linked to a decrease of overall mortality ($p<0.001$). The increasing duration of exercise was linked to a decrease of RRT risk ($p<0.001$). Stroll, independent of frequency and duration of exercise, was linked to a decreased mortality risk ($p=0.05$) and RRT risk ($p=0.04$).

**Conclusions:** Stroll is a common and easy physical activity in chronic kidney disease patients. Stroll may decrease the risk for mortality and RRT, the benefit of stroll is independent of it's' frequency and duration. More studies are needed to determine if behavior instructions can increase physical activity to improve clinical outcomes in CKD patients.

## FR-PO319

**Predictors of Renal Outcome in Nephrotic Idiopathic Membranous Nephropathy with Declined Renal Function** Xiang-Mei Chen, Yizhi Chen, Li Zhang, Guangyan Cai. *Div of Nephrology, State Key Discipline and State Key Laboratory of Kidney Diseases, Chinese People's Liberation Army (PLA) General Hospital.*

**Background:** The outcome of patients with idiopathic membranous nephropathy (IMN) who presented with nephrotic-range proteinuria and declined renal function was seldom described. The value of pathologic and clinical features in predicting the outcome has long been debated. The aim of this study was to identify factors associated with persistent renal decline and progression to end-stage renal disease (ESRD).

**Methods:** A retrospective study was conducted between 2002 and 2011 in 129 patients with biopsy-proven IMN from a single tertiary referral center in China. The primary outcomes were 20% and 50% decline in renal function and the progression to ESRD.

**Results:** All the 129 patients had nephrotic-range proteinuria (≥3.5 g/day) and declined renal function (chronic kidney disease (CKD) stages 2-4) at baseline. Of the 129 patients, 38 (30%) presented with proteinuria ≥8.0 g/day and 37 (29%) presented with CKD stages 3-4, 13 (10%) presented with focal segmental glomerulosclerosis (FSGS), and 42 (33%) presented with moderate and severe tubulointerstitial injury (T1+T2). During a median follow-up of 34 (range 12-135) months, 51 (40%) and 27 (21%) patients experienced 20% and 50% decline in renal function, respectively. Fourteen (11%) patients progressed to ESRD. Age at baseline (≥ 60 years) and the presence of FSGS and T1+T2 were independent risk factors of both20% and 50% decline in renal function. CKD stages 3-4 at baseline (hazard ratio (HR)=5.76, 95% CI 1.31-25.29, P<0.001) and the presence of FSGS (HR=4.31, 95% CI 1.15-16.08, P=0.030) and T1+T2 (HR=5.44, 95% CI 1.17-25.36, P=0.031)were independent risk factors of the progression to ESRD.

**Conclusions:** Age≥ 60 years and CKD stages 3-4 at baseline and the presence of FSGS and T1+T2 were independent risk factors of the decline in renal function and (or) the progression to ESRD in adult IMN patients with nephrotic-range proteinuria and declined renal function.

## FR-PO320

**The Predictive Factors of Cisplatin-Induced Nephrotoxicity for Urothelial Cancer** Satoru Muto,[1] Syou-ichiro Sugiura,[1] Yasuhiro Noma,[1] Masahiro Inoue,[1] Kousuke Kitamura,[1] Shino Tokiwa,[1] Keisuke Saito,[1] Shuji Isotani,[1] Raizo Yamaguchi,[1] Hisamitsu Ide,[1] Shigeo Horie.[2] *[1]Urology, Teikyo Univ, Tokyo, Japan; [2]Urology, Juntendo Univ, Tokyo, Japan.*

**Background:** Though cisplastin (CDDP) shows excellent anticancer activity, its use has been restricted due to its damaging effect on the kidney. Our team designed a retrospective clinical study on renal damage in anticancer chemotherapy using CDDP.

**Methods:** This study included 63 patients with urothelial cancer who had received chemotherapy with CDDP from March 2000 to February 2012. Renal function were investigated at baseline, the first 10 days after CDDP administration, 3, 6, 12, 24 and 36 months later using the eGFR, MDRD formula, Cockcroft-Gault formula.

**Results:** Mean age was 65.5 ± 8.1 years and median follow-up period was 56 months (range; 3-146 months). In a short period of time after CDDP administration, the univariate analysis revealed the significant differences between the decreased renal function group and the non-decreased group in the renal function before CDDP administration, the volume of infusion on the day of CDDP administration, the volume of extracellular fluid administered on the day of CDDP administration and the urinary volume on the day of CDDP administration. In multivariate analysis, the renal function before CDDP administration and the urinary volume on the day of CDDP administration were significant predictive factor for the prognosis of renal function. Though GFR tended to worsen, significant change was not found . Examination of influential factors on significant reduction in GFR 36 months later revealed that in univariable analysis, the significant predictive factors were GFR during the first 10 days after CDDP administration.

**Conclusions:** Careful long-term follow-up is required after anti-cancer CDDP containing chemotherapy for urothelial cancer. Prevention of kidney function decline immediately after CDDP administration by ensuring sufficient volume of infusion and urine in concurrence with CDDP administration should be considered to prevent a decline in renal function over a prolonged period of time.

## FR-PO321

**Association of Systolic Blood Pressure with Cardiovascular Events in Patients with Advanced Kidney Disease** Shyamal K. Palit,[1] Anna Jeanette Jovanovich,[1] Alfred K. Cheung,[2,3] James S. Kaufman,[4] Gerard John Smits,[1] Michel Chonchol,[1] Jessica B. Kendrick.[1] *[1]Univ of Colorado Denver, Aurora, CO; [2]VASLCHCS, Salt Lake City, UT; [3]Univ of Utah, Salt Lake City, UT; [4]VA New York Harbor Healthcare System, New York, NY.*

**Background:** The optimal systolic blood pressure (SBP) target to reduce cardiovascular events (CVE) in patients with chronic kidney disease is unknown. The purpose of this study was to examine the relationship between SBP and CVE in patients with advanced kidney disease.

**Methods:** We performed an analysis on 1,099 patients with advanced kidney disease not yet on dialysis who participated in the Homocysteine in Kidney and End Stage Renal Disease study. Blood pressure was measured in a standardized fashion. SBP levels were examined in clinically defined cutoffs (<120, 120-139, 140-159 and ≥160 mmHg) and as a continuous variable. We used Cox proportional hazard models to examine the association between SBP levels and CVE defined as a composite of myocardial infarction, stroke and amputation.

**Results:** The mean eGFR was 18 ± 7 ml/min/1.73m$^2$. A total of 215 CVE occurred during a median follow-up of 2.9 years. After adjustment for age, gender and race there was an increased risk of CVE with a SBP ≥ 160 mmHg compared to a level <120 mmHg (HR 1.61, 95% CI 1.01-2.56). There was no increased risk of CVE with a SBP 140-159 or SBP 120-139 mmHg (HR 0.90, 95% CI 1.56-1.45 and HR 1.06, 95% CI 0.66-1.69, respectively). For every 1 mmHg increase in SBP, there was a 0.8% increased risk of CVE (HR 1.008, 95% CI 1.002-1.01). However, after further adjustment for hypertension, diabetes, history of cardiovascular disease, smoking, body mass index, eGFR and treatment arm, SBP ≥ 160 mmHg was no longer associated with an increased risk of CVE compared to a level <120 mmHg (HR 1.42, 95% CI 0.89-2.29). Similar results were obtained when SBP was modeled as a continuous variable (HR 1.005, 95% CI 1.00-1.01, per 1mmHg increase in SBP).

**Conclusions:** After adjustment for known cardiac risk factors, SBP levels were not associated with CVE in patients with advanced kidney disease. Randomized trials are needed to determine the optimal SBP in patients with advanced kidney disease.

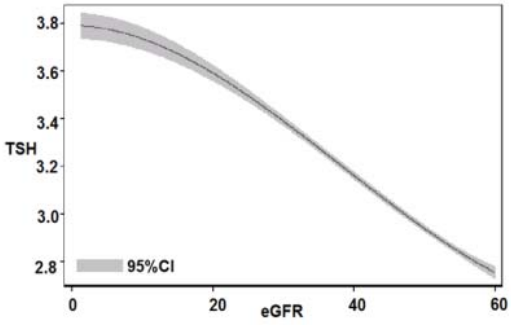
**Hypothyroidism and Impaired Kidney Function among National VA Chronic Kidney Disease Patients** Connie Rhee,[1] Kamyar Kalantar-Zadeh,[1] Elani Streja,[1] Jennie Z. Ma,[2] Jun Ling Lu,[3] Csaba P. Kovesdy.[3,4] *[1]Harold Simmons Center, Orange, CA; [2]Univ of Virginia, Charlottesville, VA; [3]Univ of Tennessee Health Science Center, Memphis, TN; [4]Memphis VA Medical Center, Memphis, TN.*

**Background:** Hypothyroidism is a common condition in the general population with pervasive effects on virtually every organ system. Studies suggest non-dialysis dependent chronic kidney disease (NDD-CKD) patients are disproportionately affected by hypothyroidism, but there is likely underrecognition of disease. We thus sought to examine the association between hypothyroidism and estimated glomerular filtration rate (eGFR) in the national VA NDD-CKD cohort.

**Methods:** We examined data from >400,000 adult patients with ≥1 thyrotropin (TSH) and ≥1 creatinine. The CKD-EPI formula was used to calculate eGFR. Using a random effects model that considered longitudinal TSH levels, we examined the association between TSH and eGFR in case-mix adjusted analyses. In analogous analyses, we examined the association between biochemical hypothyroidism (TSH>5mIU/L) and eGFR.

**Results:** Among 468,739 patients with ≥1 TSH, 8.0% had biochemical hypothyroidism, 21.0% received levothyroxine (LT-4), and 23.3% had biochemical hypothyroidism and/or LT-4 use. Among 463,219 patients with 1,560,797 TSH measurements and complete covariate data, for every 10ml/min/1.73m$^2$ increase in eGFR, there was a 10% decrease in the odds of a 1 mIU/L TSH elevation (OR 0.90 [95% CI] 0.89-0.90). For every 10ml/min/1.73m$^2$ increase in eGFR, there was a 12% decrease in the odds of biochemical hypothyroidism (OR 0.88 [95% CI] 0.87-0.90).



**Conclusions:** Among a nationally representative cohort of VA NDD-CKD patients, hypothyroidism is highly prevalent, and it is inversely associated with eGFR. Further studies are needed to determine the mechanistic link, directionality of association, and prognostic implications of hypothyroidism in CKD.

## FR-PO323

**Short-Term Prognosis of Chronic Kidney Disease with Hyperuricemia Treated by Febuxostat: A Subanalysis from a Prospective Non-Controlled Safety/Tolerability Study**

Yugo Shibagaki,[1] Iwao Ohno,[2] Tatsuo Hosoya,[2] Kenjiro Kimura.[1] *[1]Div of Nephrology and Hypertension, St. Marianna Univ Hospital, Kawasaki, Japan; [2]Div of Nephrology and Hypertension, Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Hyperuricemia (HU) is a very common comorbid condition in patients with chronic kidney disease (CKD) and there is accumulating evidence that treatment of HU may reduce blood pressure (BP) level and progression of CKD.

**Methods:** We conducted a 24-week prospective, open-label, non-controlled study to investigate the safety, tolerability and efficacy of febuxostat in patients with HU and moderate to severe CKD (stage 3b to 5). 71 prevalent adult outpatients (55 males with average age of 66.3 years) at two tertially care hospitals who met the inclusion criteria [serum urate > 8 mg/dl, estimated GFR (eGFR) < 45 ml/min/1.73m$^2$, non-use of urate lowering drug in the previous month] were recruited from November 2011 to April 2012. All the participant received febuxostat. Starting dose of febuxostat was 10 mg qd, increased to 20 mg, 40mg qd in week 4, and week 8, respectively. We analyzed the data of this study to investigate change of BP, eGFR and proteinuria during treatment of HU with febuxostat.

**Results:** Serum urate level (mg/dl) at baseline/24 weeks were 9.9/5/5, 10.6/5.2, and 9.8/4.8, in stage 3b, 4, and 5, respectively. There was no significant change in BP between start and end of the study as a whole, although the diastolic BP was slight but significantly lower at week 8 and 16. eGFR at 24 weeks were not significantly different from that at baseline in CKD stage 4 and 5. However, in CKD 3b, eGFR was significantly higher at 24 weeks compared with that at baseline. There were 15 patients who had data of proteinuria. There was no significant change in level of proteinuria although proteinuria tended to decrease in CKD stage 3b. Multivariate analysis revealed that greater reduction of serum urate predicted increase in eGFR (p=0.0055) and tended to predict reduction of proteinuria (p=0.063).

**Conclusions:** Greater reduction of serum urate level by febuxostat was associated with increase in eGFR, although it did not significantly change the level of BP and proteinuria.

## FR-PO324

**Elevated Level of C-Reactive Protein Identify African Americans with Metabolic Syndrome at High Risk of Developing Albuminuria**

Satyesh K. Sinha,[1] Magda Shaheen,[1] Deyu Pan,[1] Susanne B. Nicholas.[1,2] *[1]Charles R. Drew Univ of Medicine and Science, Los Angeles, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA.*

**Background:** African Americans (AA) have a higher prevalence of the metabolic syndrome (MetS)and chronic kidney disease (CKD) than whites. Inflammation and the MetS have been shown to be associated with renal impairment; however, it is unclear whether higher levels of serum inflammatory biomarkers may account for disparities in the development of albuminuria, as a marker for CKD in AA with MetS.

**Methods:** We analyzed data from the National Health and Nutrition Examination Surveys 1999-2008 of 7,309 adults aged ≥20 years with three or more components of the MetS according to the National Cholesterol Education Program's Adult Treatment Panel III definition. Multivariate analyses were performed to test the relationship of race/ethnicity with *urinary albumin excretion (UAE)* and serum C-reactive protein (CRP), adjusting for age, gender, smoking and components of the MetS.

**Results:** CRP and UAE were significantly higher in AA (0.76±0.77mg/dl and 211.7±990.1µg/mL, respectively), compared to whites (0.54±1.05mg/dl and 48.5±344.0µg/mL, respectively), p<0.01. Adjusted logistic regression indicated that AA had higher odds for CRP ≥0.3mg/dl (adjusted odds ratio [AOR]=1.42, 95% CI 1.15-1.76) and UAE ≥30µg/ml (AOR=2.67, 95% CI=2.11-3.38), compared to whites, p<0.001. Also, adjusted linear regression showed a significant association between UAE and CRP (Adjusted Coefficient; AC=0.15, 95% CI 0.07-0.23) and that the interaction term of CRP and race/ethnicity was statistically significant, p<0.001. The adjusted change in the UAE for one unit change in CRP was higher among AA relative to whites (AC=0.63, 95% CI 0.39-0.87), suggesting a stronger relationship between CRP and UAE in AA.

**Conclusions:** We conclude that elevated CRP may predict the higher risk of albuminuria in AA with the MetS compared to white.

## FR-PO325

**Dialysis at Home–Could It Be a More Frequent Choice?**

Patrik Finne,[1,2] Ilkka Helanterä,[1] Virpi Rauta,[1] Agneta V. Ekstrand,[1] Eero Honkanen,[1] Carola Gronhagen-Riska.[1] *[1]Dept of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; [2]Finnish Registry for Kidney Diseases, Helsinki, Finland.*

**Background:** The proportion of dialysis patients on home dialysis (either peritoneal dialysis (PD) or home hemodialylsis (HD)) varies greatly both between and within countries, which indicates that there is a potential for increasing its use in many places.

**Methods:** All patients who entered dialysis in Finland in 2000 to 2010 and were still on dialysis at day 91 from start (n=4984) were included. Patient data were retrieved from the Finnish Registry for Kidney Diseases. Data on contraindications for home dialysis was collected for a randomized sample of 200 patients on in-centre HD in the healthcare district of Helsinki-Uusimaa (HUS), which has exceptionally high proportion of home dialysis (38%). A multinomial logistic regression equation with stepwise selection of explanatory variables was constructed based on the patients in HUS (n=1128) to estimate probability of home HD, PD and in-centre HD. This model was applied to the patients in the rest of the country in order to estimate whether use of home dialysis could potentially be increased.

**Results:** Out of 30 evaluated variables, 11 were selected to the final model. The most important predictors of home dialysis were young age, high hemoglobin, high albumin and normal body-mass index (for PD). Polycystic kidney disease decreased probability of PD and increased that of home HD. The model identified in-centre HD patients with large probabilities of either home HD or PD and indicated that use of home HD could potentially be increased from 0.2% to 8% and PD from 26 to 28%. Of the in-centre HD patients in HUS, 93% had a reported contraindication of home dialysis in the hospital files. Notably, the model predicted in-center HD for half of patients who in fact had entered PD in the rest of the country.

**Conclusions:** Our model identified a considerable proportion of in-center hemodialysis patients that could be suitable for either peritoneal dialysis or home hemodialysis. Conversely, the model predicted in-center HD for many patients who actually had entered PD, which shows that indications for home dialysis vary between districts in Finland.

## FR-PO326

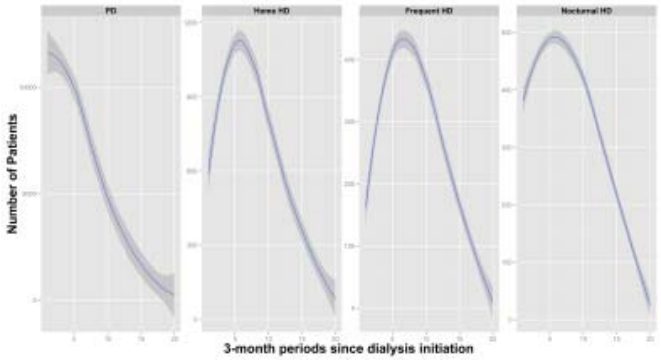
**Time Course of Utilization of Alternative Dialysis Modalities**

Sooraj Kuttykrishnan,[1] Kamyar Kalantar-Zadeh,[2] Jonathan Himmelfarb,[1] Alfred K. Cheung,[5] Onyebuchi A. Arah,[3] Elani Streja,[2] Vanessa A. Ravel,[2] Allen R. Nissenson,[4] Rajnish Mehrotra.[1] *[1]Univ of Washington; [2]Univ of California, Irvine; [3]Univ of California, Los Angeles; [4]DaVita Healthcare Partners; [5]Univ of Utah.*

**Background:** The Institute of Medicine lists studying outcomes with different dialysis therapies among the top 100 priorities for comparative effectiveness research. Understanding the time course of accrual of patients to the various dialysis therapies is needed to adjust for bias inherent in such comparisons.

**Methods:** The time course of utilization of different dialysis therapies was analyzed in three-month increments from the date of first dialysis up to five years, among the 162,671 patients who started maintenance dialysis in 2007-11 in a large dialysis organization.

**Results:** Over 5 years, 23,837 (14.7%) patients were treated with alternative dialysis modalities: PD, 18,279 (11.2%), home hemodialysis (HD), 2653 (1.6%), frequent in-center HD, 1888 (1.2%), and nocturnal in-center HD, 1452 (0.9%). Only 54% of patients ever treated with PD, started treatment with this modality compared to 18%, 7%, and 24% for home HD, frequent HD, and nocturnal HD respectively. The median interval from the time of first dialysis to first ever treatment with home HD, frequent HD, and nocturnal HD was 9, 9 and 12 months respectively (Figure). The median time of treatment with PD, home HD, frequent HD, and nocturnal HD was only 18.3, 12.1, 5.6, and 9.7 months respectively.



**Conclusions:** The actual number of patients treated with alternative dialysis therapies is significantly larger than evident from point-prevalent counts. Most patients treated with alternative modalities do so only after at least some period of treatment with in-center HD and are treated for relatively short periods of time. These are important considerations when studying comparative effectiveness of dialysis therapies.

*Funding:* NIDDK Support

## FR-PO327

**Temporal Trends in Home Dialysis Training**

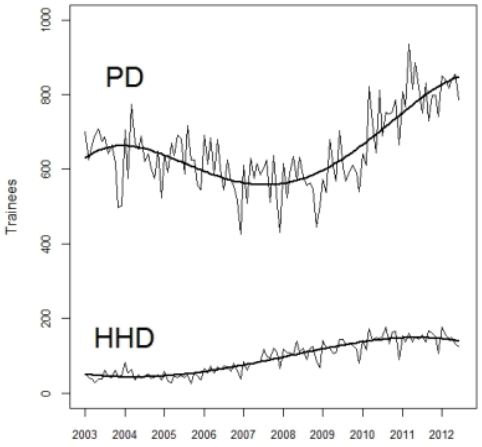
Eric D. Weinhandl,[1] Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Univ of Minnesota, Minneapolis, MN.*

**Background:** To compensate for the cost of home dialysis training, the Medicare End Stage Renal Disease (ESRD) Prospective Payment System (PPS) features a 51% increase in reimbursement for dialysis sessions during the first 120 days after dialysis initiation, as well as an add-on payment of $33.44 per training session after the first 120 days. Critics have argued that these mechanisms fail to properly compensate for the cost of home hemodialysis training. We used Medicare Quarterly Standard Analytical Files (QSAFs) to assess temporal trends in peritoneal dialysis (PD) and home hemodialysis (HHD) training between January 2003 and June 2012.

**Methods:** We searched outpatient facility claims between calendar years 2000 and 2012 for condition code 73 (self-care in training) in tandem with revenue center codes 0821 (HD), 0831 (PD), 0841 (continuous ambulatory PD), or 0851 (continuous cycling PD). For each patient with qualifying claims, we recorded the date and modality of the

first training session. For each month between January 2003 and June 2012, we tallied the number of patients who initiated either PD training or HHD training. To estimate trends, we fit fourth-degree polynomial functions to each time series of trainee counts.

**Results:** Counts of PD trainees reached their minimum in December 2006 (N = 427), and according to trend analysis, began increasing in July 2007, with sustained growth of 4 patients per month beginning in December 2008. In contrast, counts of HHD trainees tended to increase between April 2003 and April 2011, with a maximum in August 2010 (N = 177), but tended to decrease beginning in May 2011.



**Conclusions:** The introduction of the ESRD PPS coincided with sustained month-to-month increases in the number of patients in initial PD training, but was followed shortly thereafter by month-to-month decreases in the number of patients in initial HHD training.

## FR-PO328

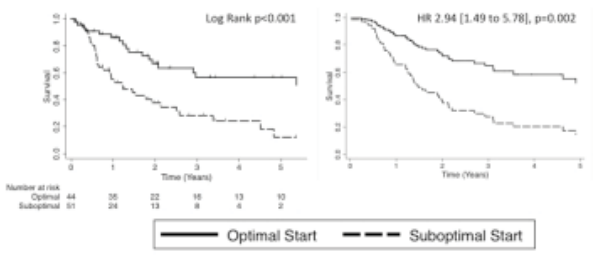
**Suboptimal Initiation of Home Hemodialysis: Determinants and Clinical Outcomes** Annie-Claire Nadeau-Fredette, Karthik K. Tennankore, Joseph Kim, Christopher T. Chan. *Div of Nephrology, Dept of Medicine, Univ of Toronto, Toronto, Canada.*

**Background:** Suboptimal initiation of conventional hemodialysis (CHD) is associated with poor clinical outcomes. In this study, we aimed to ascertain the determinants and adverse events associated with suboptimal starts in home hemodialysis (HHD).

**Methods:** We conducted a retrospective cohort study including consecutive incident HHD patients from January 1996 to December 2011. All patients had HHD as their first renal replacement therapy or returned to HHD after kidney transplantation. A suboptimal start was defined by dialysis initiation either as an inpatient or with a central venous catheter. The primary outcome was time to first hospitalization, technique failure or death. Secondary outcomes included hospitalization rate, hospital days and determinants of suboptimal starts. Suboptimal starts were further categorized as unavoidable as adjudicated by two independent observers with pre-specified criteria.

**Results:** Among 95 incident HHD patients, 44 (46%) and 51 (54%) had optimal and suboptimal starts, respectively. A suboptimal start was associated with a shorter time to the primary outcome (log rank $P$<0.001). In a multivariable Cox proportional hazards model, the hazard ratio for the composite outcome (comparing suboptimal to optimal starts) was 2.94 (95% CI: 1.49, 5.78; $P$ = 0.002).

**Figure 1: Kaplan-Meier and adjusted Cox survival curves for time to composite outcome (hospitalization, technique failure or death).**



Additional variables in the adjusted model: age, gender, Caucasian race, Charlson Comorbidity Index, previous follow-up. HR: Hazard ratio

Transplantation clinic follow-up (OR 3.18 [95% CI: 1.15, 8.79]) and the Charlson comorbidity index (OR 1.47 [95% CI: 1.09, 1.97]) were associated with higher odds of suboptimal starts.

**Conclusions:** Suboptimal initiation of HHD is associated with adverse clinical events including early hospitalization. Given the high proportion of suboptimal starts in patients returning from transplantation, better incorporation of dialysis planning and renal replacement therapy education is warranted.

## FR-PO329

**Bayesian Interpretation of the Estimated Treatment Effects on Mortality in the Daily and Nocturnal Frequent Hemodialysis Trials (FHN)** Tom Greene, John T. Daugirdas, Glenn M. Chertow, Nathan W. Levin, Michael V. Rocco, Gerald J. Beck, Alan S. Kliger. *NIDDK.*

**Background:** The FHN Daily and Nocturnal Trials were considered insufficiently powered to detect effects of frequent dialysis on mortality. However, new analyses of long-term mortality data from these trials (this meeting) suggest mortality may be reduced in patients randomized to daily vs. conventional in-center hemodialysis, but increased in patients randomized to frequent nocturnal vs. conventional home hemodialysis. Because positive results in underpowered studies incur elevated risk of false positive conclusions (Ioannidis, Plos Med, 2005), we performed Bayesian analyses to quantify the uncertainty of these results.

**Methods:** Posterior distributions of the mortality hazard ratios (HRs) were simulated under an "equipoise" prior, with a median prior HR of 1.00, and under a "mildly optimistic prior", with a median prior HR of 0.80 for frequent dialysis.

**Results:** Original and Bayesian Posterior Hazard Ratios assuming equipoise or a median prior HR=0.80. Bottom 3 rows show the original estimated mortality HR or median posterior HR, 95% confidence limits or posterior intervals for frequent HD, and posterior probabilities that HR ≤ 0.8 and that {HR ≤ 1}.

| Daily Trial | | | Nocturnal Trial | | |
|---|---|---|---|---|---|
| Original (56 deaths) | Bayes - equipoise* | Bayes - median prior HR = 0.80* | Original (19 deaths) | Bayes - equipoise* | Bayes - median prior HR = 0.80** |
| 0.54 | 0.65 | 0.63 | 3.82 | 1.71 | 1.34 |
| (0.32, 0.93) | (0.41, 1.02) | (0.41, 0.96) | (1.26, 11.63) | (0.92, 3.20) | (0.77, 2.38) |
| - | 0.82 {0.97} | 0.88 {0.99} | - | 0.01 {0.04} | 0.03 {0.15} |

**Conclusions:** The original estimated treatment effects of frequent HD on mortality were attenuated by Bayesian analysis, illustrating that large estimates of treatment effects in trials with low power may overstate the true effects. Even so, in the Daily Trial posterior probabilities that HR < 0.8 are > 0.80, suggesting that daily dialysis is reasonably likely to substantially reduce mortality. As implemented by the FHN, frequent nocturnal dialysis is unlikely to substantially reduce, and might increase, mortality compared to conventional home dialysis.

*Funding:* NIDDK Support

## FR-PO330

**The Magnitude of Phosphorus Mobilization during Dialysis in the Frequent Hemodialysis Network (FHN) Daily Trial Was Patient-Specific** John T. Daugirdas,[1] Brett Larive,[1] Thomas A. Depner,[1] Andreas Pierratos,[1] Tom Greene,[1] Robert S. Lockridge,[1] Juan Carlos Ayus,[1] Michael V. Rocco,[1] Glenn M. Chertow,[1] J. Ken Leypoldt,[2] Alp Akonur,[2] Brent W. Miller,[1] The FHN Trial Group.[1] *[1]NIH, NIDDK; [2]Baxter Healthcare.*

**Background:** In the FHN Daily Trial we tracked 3 measures of phosphorus mobilization (M) to assess constancy of M status over time.

**Methods:** Monthly values of pre and postdialysis serum phosphorus (P) were used to compute the phosphorus reduction ratio (PRR), PRR/URR (U = urea) and Km, the intercompartment clearance of P from a theoretical very large remote compartment (Agar et al, *CJASN* 2011). Low PRR or PRR/URR and high Km correspond to high M status.

**Results:** Baseline PRR (%), PRR/URR (ratio), and logKm (ml/min) were 57.9 ± 9.8 , 0.79 ± 0.13, and 4.56 ± 0.41. In baseline multivariate models, lower predialysis serum P (preP), male sex, younger age, and greater weight independently associated with higher M. Higher serum PTH associated with higher M (PRR/URR and Km) but here the effect size was small. In high or low M patient subgroups identified at baseline, preP-adjusted M indices were tracked over 12 months. Mean values (3x: n=120; 6x: n=125) are shown in the Table.

| **Baseline M status subgroup** | **Freq** | **PRR** | | **PRR/URR** | | **log Km** | |
|---|---|---|---|---|---|---|---|
| | | Baseline | Mo 10-12* | Baseline | Mo 10-12* | Baseline | Mo 10-12* |
| top 20 | 3x | 45.5 | 52.2 | 0.64 | 0.73 | 5.10 | 4.84 |
| | 6x | 47.5 | 51.0 | 0.67 | 0.81 | 5.06 | 4.87 |
| <top 20; > median | 3x | 54.7 | 57.6 | 0.76 | 0.79 | 4.71 | 4.57 |
| | 6x | 55.9 | 54.2 | 0.78 | 0.83 | 4.68 | 4.84 |
| <median; > bottom 20 | 3x | 60.9 | 58.6 | 0.83 | 0.81 | 4.46 | 4.57 |
| | 6x | 60.5 | 57.3 | 0.82 | 0.91 | 4.45 | 4.62 |
| bottom 20 | 3x | 67.2 | 61.5 | 0.89 | 0.82 | 4.12 | 4.36 |
| | 6x | 63.2 | 58.7 | 0.82 | 0.89 | 4.13 | 4.53 |

*Average values during follow-up months 10-12 for each baseline-defined subgroup.

**Conclusions:** Measures of P mobilization (M) during dialysis were positively associated with lower preP, male sex, younger age, greater weight, and somewhat with higher PTH. PreP-adjusted measures of M were patient-specific over a 12-month period, although some regression to the mean was seen.

*Funding:* NIDDK Support, Private Foundation Support

## FR-PO331

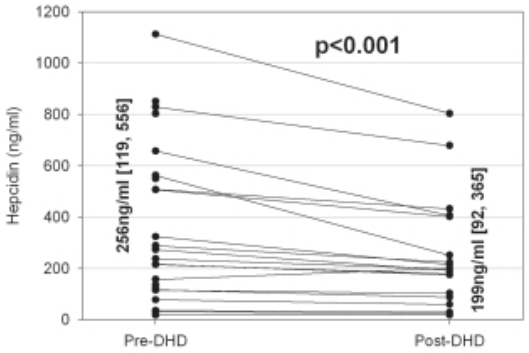
**Short Daily Hemodialysis Is Associated with Lower Serum Hepcidin Levels When Compared to Conventional Hemodialysis**

Joshua Zaritsky,[1] Anjay Rastogi,[1] George E. Fischmann,[1] Jieshi Yan,[2] Barbara Gales,[1] Tomas Ganz,[1] Mark E. Westerman,[3] Isidro B. Salusky.[1] *[1]UCLA, Los Angeles, CA; [2]CKMG, Simi Valley, CA; [3]Intrinsic Life Sciences, La Jolla, CA.*

**Background:** Hepcidin, a key regulator of iron homeostasis, may be the molecular link between inflammation and anemia in ESRD. Short daily hemodialysis (DHD) patients (pts) typically require less recombinant erythropoietin (EPO) than conventional hemodialysis (CHD) pts. Therefore, we compared serum hepcidin levels between the two dialytic modalities.

**Methods:** We compared serum hepcidin levels, indicators of anemia, inflammation and iron status between 24 pts treated with DHD using the NxStage System One® and 54 CHD pts (Table). Serum hepcidin levels were measured by competitive ELISA.

**Results:** DHD pts were younger but there were no differences in the duration of ESRD. In DHD pts, hepcidin levels were lower than in CHD pts, which corresponded to less inflammation (as assessed by high sensitivity C-reactive protein (hs-CRP)). Hepcidin levels post-DHD were lower than pre-DHD (Figure). We previously reported hepcidin was independently predicted by ferritin and hs-CRP in CHD pts by both univariate and multivariate regression analyses (MVA). In DHD pts, hepcidin levels correlated with ferritin ($r=0.7$, $p<0.001$) and hs-CRP ($r=0.4$, $p<0.05$). MVA ($R^2=0.6$) revealed that hepcidin was independently predicted by only ferritin ($p<0.001$). Additionally MVA ($R^2=0.6$) across both groups revealed that hepcidin remained predicted by ferritin ($p<0.001$) and hs-CRP ($p<0.001$).



| Biochemical Variables | DHD mean±SD or median[25,75%] | CHD mean±SD or median[25,75%] | p |
|---|---|---|---|
| Age (yrs) | 47±18 | 61±19 | <0.01 |
| ESRD duration (yrs) | 2.8 [1.1, 7.5] | 2.8 [1.2, 4.3] | NS |
| Hepcidin* (ng/ml)† | 256[119, 556] | 690[200, 905] | <0.001 |
| Hgb (g/dL) | 11.4±1.4 | 11.8±1.3 | NS |
| rhEPO (units/ week) † | 9700 [6000,18000] | 8250 [6600,13200] | NS |
| hs-CRP (mg/L) † | 0.45 [0.3, 1.35] | 3.9 [2.2, 8.5] | <0.001 |
| Ferritin (ng/mL) | 539±461 | 740±409 | NS |
| % Iron Saturation† | 26 [22, 34] | 29 [26, 47] | NS |
| Std weekly KT/V | 2.4 [2.2, 2.7] | 2.4 [2.2, 2.5] | NS |

*Normals= 91±57 ng/ml; †variables were log-transformed for MVA

**Conclusions:** We demonstrated that lower hepcidin values in DHD pts predominantly reflect a lower inflammatory state in this population. Since hepcidin appears to be cleared by DHD, future studies are needed to see if increased dialysis dosages could potentially lower serum hepcidin levels further and in turn decrease EPO requirements.

*Funding:* NIDDK Support, Private Foundation Support

## FR-PO332

**Evaluation of Change in Extracellular Fluid Status Using Calf Bioimpedance in Patients during One Year Frequent Hemodialysis**

Fansan Zhu,[1] George A. Kaysen,[2] Shubho Ranjan Sarkar,[1,3] Fredric O. Finkelstein,[4] Mary Carter,[1] Nathan W. Levin,[1] Nicholas A. Hoenich.[5] *[1]Renal Research Institute, New York, NY; [2]Univ of California, Davis, CA; [3]Nephrology & HIT Ass of Morris County, Morristown, NJ; [4]Yale Univ, New Haven, CT; [5]Newcastle Univ, Newcastle upon Tyne, United Kingdom.*

**Background:** Calf extracellular resistance ($R_E$) reflects both plasma ($R_P$) and interstitial ($R_{Int}$) fluid. The aims of this study were to investigate whether: 1) calf normalized resistivity (CNR) satisfactorily indicates change in fluid status in frequent HD (FHD) patients; 2)The extent to which $R_E$ is affected by $R_P$ at different levels of fluid status.

**Methods:** Patients were switched from 3 to 6 times/week HD. $R_E$ and extracellular fluid (ECV) was measured at baseline (BL) and monthly over one year using the Hydra 4200. Four electrodes and a blood pressure cuff were placed on the calf to separately measure $R_E$ and $R_{Int}$ at zero cuff pressure and at > than systolic blood pressure (SBP) respectively. Change in calf resistance was related to reduction of local plasma volume ($V_P$) (Fig.1). The ratio of $V_P$/ECV is calculated as $1\text{-}R_P/R_{Int}$.

**Results:** In nine available patients' body weight decreased significantly by the first month and then did not differ statistically in following months; SBP decreased continuously and CNR increased significantly from BL to the first month and remained approximately at the same level over one year (Fig 2). $V_p$/ECV did not differ significantly between BL and at any month over the one year period (Table1).

**Conclusions:** Significant improvement in extracellular volume fluid status in patients during one year of FHD was clearly indicated by CNR increase and SBP and ultrafiltration volume reduction. CNR was not affected by plasma volume changes at different levels of fluid load.

Table 1

| | BL | 1 month | 6 month | 12 month |
|---|---|---|---|---|
| $R_E$ (Ω) | 42.6±12 | 61.6±15.6# | 60.5±13 | 62.8±15** |
| $R_{Int}$ (Ω) | 45.9±12 | 65.6±16.3# | 65±13 | 66.8±17** |
| $V_p$/ECV (%) | 7.7±5 | 6.3±3.6 | 6.9±4 | 5.84±3.2 |

**Patient Survival, Treatment Survival and Hospitalization for Intensive Home Hemodialysis Patients Compared to Kidney Transplant Recipients**

Karthik K. Tennankore, Joseph Kim, Christopher T. Chan. *Div of Nephrology, Univ of Toronto/Univ Health Network, Toronto, Canada.*

**Background:** Patients receiving intensive home hemodialysis (IHHD, ≥16 hours/ week) have comparable survival to US deceased donor kidney transplant recipients (KTRs). A comparison between Canadian IHHD patients and KTRs has not been conducted. We hypothesized that IHHD patients would have better outcomes compared to expanded criteria donor (ECD) and standard criteria donor (SCD) recipients.

**Methods:** We analyzed a cohort of IHHD patients and KTRs from 2000-2011. The primary outcomes were time to first hospitalization and time to treatment failure/death for IHHD patients compared to ECD, SCD and living donor (LD) KTRs. Treatment failure was defined as a permanent switch to an alternative form of dialysis for IHHD patients, and graft failure for KTRs.

**Results:** The cohort consisted of 173 IHHD patients, 204 ECD, 643 SCD and 679 LD KTRs. There were 1036 first hospitalizations and 286 treatment failures/deaths (Figure 1). After adjusting for comorbidity, age, gender, race, cause of end-stage renal disease and dialysis vintage, hospitalization risk favoured IHHD in the short term and transplantation in the long term. Time to treatment failure/death was shorter for IHHD patients. **Table 1.Adjusted HRs for time to first hospitalization and time to treatment failure/death.**

| | 0-1 years | >1 year |
|---|---|---|
| **Time to First Hospitalization** | **HR (95% CI)** | **HR (95% CI)** |
| LD | 1 | 1 |
| IHHD | 0.54 (0.39-0.75) | 2.14 (1.52-3.00) |
| SCD | 1.06 (0.87-1.28) | 1.14 (0.86-1.50) |
| ECD | 1.05 (0.81-1.36) | 1.07 (0.71-1.60) |
| **Time to Treatment Failure/Death** | | |
| LD | 1 | 1 |
| IHHD | 2.09 (1.01-4.35) | 2.37 (1.49-3.78) |
| SCD | 1.23 (0.63-2.40) | 0.77 (0.54-1.09) |
| ECD | 1.30 (0.58-2.93) | 0.87 (0.55-1.38) |

**Conclusions:** IHHD is associated with a lower risk of short-term hospitalization compared to transplantation. Outcome-risk in the long term favors transplantation.

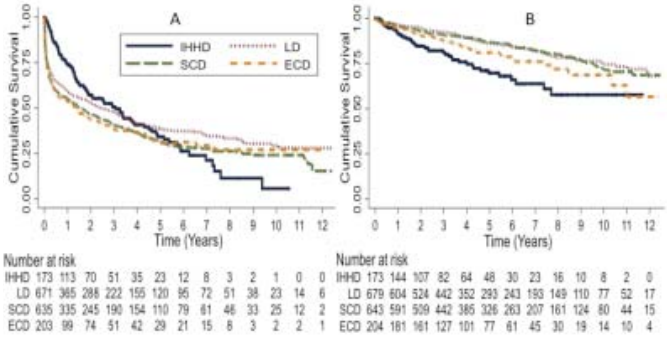

Figure 1. A: Time to first hospitalization (log rank p=0.01) and B: time to treatment failure/death (log rank p<0.001)

## FR-PO334

***Staphylococcus aureus* Bacteraemia: Evaluation of Access Techniques in Home Haemodialysis** Karen E. Brown, James A. Chess, Ashraf I. Mikhail. *Renal Dept, Morriston Hospital, Swansea, Wales, United Kingdom.*

**Background:** Vascular access-related *Staphylococcus aureus* bacteraemia is a major cause of morbidity and mortality amongst haemodialysis patients. Recent studies have reported an increased risk of fatal infective metastatic complications with home haemodialysis patients using buttonhole cannulation.

Methods: Microbiologically reported cases of MRSA/ MSSA bacteraemia were analysed in a retrospective cohort study at a renal tertiary referral centre over a 2 year period (January 2011 - December 2012).

Results: 26 episodes of MRSA/ MSSA bacteraemia were identified from a population of 317 dialysis patients. Risk factors included vascular access type (VasCath vs. AVF), immunosuppression, diabetes and warfarin use. UK Renal Association Guidelines recommend that the annual Staphylococcus aureus bacteraemia rate in the haemodialysis population should be less than 2.5 episodes per 100 HD patients and less than 1.0 for MRSA over 2 years. At our unit 0.53 episodes per 100 HD patients were identified for MSSA (3.19 including acute kidney injury) and 1.06 (2.66) for MRSA. This was in comparison to 12 *episodes of MSSA in home HD patients and 8.11 in self-care. 61% of* Staphylococcus aureus bacteraemias were directly attributable to vascular access complications (infected AVF/ AVG, line sepsis, post- fistula formation). Clinical outcomes of blood culture positive Staphylococcus aureus bacteraemia included death < 30 days, infective endocarditis and microbiologic recurrence.

Conclusions: This study highlights known concerns regarding increased infection rates in patients who self-cannulate using the buttonhole technique. As a result of this study, our centre has commenced the use of topical mupirocin in order to reduce the occurrence of MRSA/MSSA sepsis and therefore promote prolonged patency and AVF survival. The development of mupirocin resistance is being monitored. Further randomised controlled trials would assist in the evaluation of constant vs. different site cannulation in order to establish a superior technique and accurately inform the prevalent haemodialysis population.

## FR-PO335

**At-Home Short Daily Hemodialysis Attenuate Vascular Calcification** Hiromichi Suzuki, Hirokazu Okada, Tsutomu Inoue, Tsuneo Takenaka. *Dept of Nephrology, Saitama Medical Univ, Iruma Gun, Saitama, Japan.*

Background: Vascular calcification (VC) has a significant effect in cardiovascular disease on dialysis patients. However no pharmacological interventions have been demonstrated for prevention and/or attenuation of VC. Recent advances in frequent hemodialysis proves facilitation of hyperphosphatamia. It is proposed that there is a strong relation between VC and hyperphosphatamia. It is therefore likely that frequent hemodialysis reduced VC. Aim To examine whether at-home short dial hemodialysis reduces VC.

Methods: Using Volume Viewer software with a 16-detector CT scan, the total calcification volume of the aorta was calculated with a cut-of of 130 Housefield Unit. Abdominal CT scan was taken before and 2 years after the start of at-home short daily hemodialysis in 37 patients (average age 52 + 7.0 years, male 33). The underlying kidney disease were chronic glomerulonephritis (33), diabetic nephropathy (2) and congenital kidney disease (2).

Results: The base line values of calcification scores of the abdominal aorta were 5.03 + 5.85 (cm3) and at-home short daily hemodialysis reduced to 4.82 + 4.72 at the end of the study. Besides, at-home short daily hemodialysis attenuated several factors contributing to vascular calcification including hyperphosphatemia.

Conclusions: This is the first demonstration that at-home short daily hemodialysis reduces calcification of the abdominal aorta through several factors including serum levels of phosphate.

## FR-PO336

**Removal Water from the Legs Does Not Explain Hypotension in Short Daily Hemodialysis** Alessandra Martins Bales, Luciana Loureiro Nardotto, Rafael Sanches Humel, Ligia Costa Battaini, Bruno C. Silva, Rosa M.A. Moyses, Manuel C. Castro, Rosilene M. Elias. *HCFMUSP.*

**Background:** Previous studies on conventional hemodialysis (CHD) indicate that fluid loss during dialysis occurs from the legs. Whether the fluid loss from the legs is associated with hypotension symptoms in patients on short daily hemodialysis (SDH) is unknown.

**Methods:** Thirty-five conventional and fifteen short daily subjects on hemodialysis had segmental bioimpedance performed using the InBody10 Analyzer, pre and post dialysis. Demographic and biochemical data was also obtained.

**Results:** Baseline characteristics were similar between CHD and SDH. For both groups, from pre to post dialysis, there was a reduction in the extracellular water (ECW) for each of the segments (leg, arm, and trunk), total body water (TBW), and ECW/TBW ($p < 0.05$). The delta of legs ECW was higher on CHD than SDH [-5.4% (-7.3, -2.4) vs. -3.3% (-4.8, -0.7), p=0.009]. Hypotensive symptoms(Hypo+) were observed in 6 patients on SDH(37.5%) and 6 patients on CHD(17.1%). When comparing the subgroups of patients hypo+ and hypo-, the conventional group's leg ECW/TBW was lower in hypo+ (p=0.003) as well as the hemoglobin (p=0.009). However, there was no difference between hypo+ and hypo- in these or any other parameters in SDH.

**Conclusions:** When comparing CHD and SDH, the removal of leg ECW was higher in CHD. Patients on CHD who had hypotension presented low hemoglobin and lower ECW/TBW removal from the legs. This was not observed in SDH. Further studies are needed to better elucidate the hypotension pathogenesis on SDH, other than leg fluid removal.

| | Short Daily | | Conventional | |
|---|---|---|---|---|
| | Hypo+(n = 6) | Hypo-(n = 10) | Hypo+(n = 6) | Hypo-(n = 29) |

## FR-PO337

**Health Related Quality of Life (HRQoL) in Community House Hemodialysis (CHHD) versus Home Hemodialysis (Home HD)** Mark R. Marshall,[1] Sharen K. Supershad.[2] [1]*Renal Medicine, Counties Manukau DHB, Auckland, New Zealand;* [2]*Renal Medicine, Northland DHB, Whangarei, New Zealand.*

**Background:** CHHD is a novel way of increasing uptake of home HD for patients who have inadequate housing and/or other social circumstances. Community houses are unstaffed, and provided through a collaboration with a local patient support group. The houses provide pleasant and home-like settings. Patients share an HD machine with one other and organize their own rosters. Previously, we have shown comparable patient survival between CHHD vs. home HD (Marshall et al, AJKD. 2013;61:598-607). In this abstract, we explore whether HRQoL is also comparable.

**Methods:** All prevalent patients on CHHD or home HD in our service were invited to complete an anonymous KDQoL survey. This was done twice, firstly on 1/1/2007 and then on 1/1/2013. We compared HRQoL between CHHD vs. home HD patients, adjusting for mean vintage and age-and-albumin-adjusted Charlson comorbidity index (CCI, Beddhu et al, Am J Med 2000;108:609-13) as ecological variables.

**Results:** Results are presented as n, or means (SD). Data are pooled across era for analyses. The source population are those who received a survey, the study population those who returned it.

| Parameter (population) | CHHD 2007 | Home HD 2007 | CHHD 2013 | Home HD 2013 |
|---|---|---|---|---|
| n (source) | 15 | 40 | 21 | 54 |
| Male (source) | 9 | 30 | 11 | 33 |
| CCI (source) | 3.5 (1.6) | 4.7 (1.8) | 4.2 (2.5) | 5.2 (2.0) |
| Age, years (source) | 39.6 (12.8) | 50.9 (11.8) | 45.6 (10.9) | 49 (13.3) |
| Vintage, months (source) | 66.4 (35) | 60.2 (41.4) | 79.8 (72.3) | 81.7 (70.7) |
| n (study) | 14 | 31 | 17 | 26 |
| Effects of kidney disease (study) | 55.4 (25) | 63.5 (25.4) | 56.4 (19.2) | 59.5 (22.1) |
| Burden of kidney disease (study) | 40.6 (31.1) | 39.9 (32.8) | 36.4 (22.6) | 49.3 (32.4) |
| SF-12 Physical Composite (study) | 46.2 (9.5) | 38.8 (11.3) | 44.1 (9.4) | 41.3 (10.3) |
| SF-12 Mental Composite (study) | 51.7 (7.0) | 47.5 (10.6) | 45.7 (9.0) | 48.9 (9.3) |

Using Wilcoxon rank-sum testing, HRQoL domains were not significantly different between CHHD vs. home HD, other than SF-12 Physical Composite which was higher for CHHD (P=0.04). Adjusting for vintage and CCI by regression, there were no significant differences in any HRQoL domain between CHHD vs. home HD.

**Conclusions:** Acknowledging small sample, HRQoL is comparable between CHHD and home HD.

**FR-PO338**

**Procedure-Related Serious Adverse Events among Home Hemodialysis Patients–A Quality Assurance Perspective** Ben C. Wong,[1] Deborah Lynn Zimmerman,[2] Frances D. Reintjes,[3] Mark J. Courtney,[1] Scott Klarenbach,[1] Graeme Dowling,[4] Robert P. Pauly.[1] *[1]Div of Nephrology and Transplant Immunology, Univ of Alberta, Edmonton, Canada; [2]Div of Nephrology, Univ of Ottawa, Ottawa, Canada; [3]Northern Alberta Renal Program, Alberta Health Services, Edmonton, Canada; [4]Office of the Chief Medical Examiner, Edmonton, Canada.*

**Background:** There has been resurgent interest in home hemodialysis (HD) in recent years because of the reported benefits and its excellent safety record. However, the potential for adverse events, including potentially catastrophic events, exists when patients are performing HD in their homes without supervision. There is a lack of literature on this important topic.

**Methods:** We present the experience of two adult home HD programs in Canada from 2001 to 2012, including a total of 190 patients and approximately 500 patient-years of treatments. We retrospectively reviewed all life-threatening adverse events occurring in our programs and reexamined our approach to patient training, re-training, and safety monitoring.

**Results:** We report 1 death and 6 potentially fatal adverse events yielding a crude rate of 0.060 events per 1000 dialysis treatments. Six of 7 events involved significant blood loss (including 1 exsanguination); 5 of 7 events involved human error with lapses in protocol adherence. Because such events are rare, evaluation of specific intervention strategies will require much longer follow-up.

**Conclusions:** Life-threatening adverse events in home HD are uncommon, but when one does occur, should prompt review of home HD-related policies and procedures to make this therapy even safer.

**FR-PO339**

**Cost Evaluation of In-Center Nocturnal Hemodialysis** Ben C. Wong, Robert P. Pauly, Mark J. Courtney, Scott Klarenbach. *Div of Nephrology and Transplant Immunology, Univ of Alberta, Edmonton, Canada.*

**Background:** There is interest in providing in-center nocturnal hemodialysis (ICNHD), typically conducted overnight (6-8 hours) thrice weekly. In addition to putative health benefits, this allows a dialysis unit to offer two additional shifts on alternate nights. We conducted a costing study to determine the incremental costs of ICNHD compared with in-center thrice-weekly conventional hemodialysis (CHD) from the health care perspective using data from our program that provides both ICNHD and CHD.

**Methods:** Using micro-costings methods, we identified health care resources that differ between INCHD and CHD, including staffing, dialysis materials, and utilities. The units of resource consumed for each strategy was determined, and the cost of each unit was determined from administrative data (CAN $ 2012) to determine incremental costs of ICNHD and CHD. Alternate scenarios examining nursing grade and ratio, full care (reference case being a 1:3 staft-to-patient ratio) vs. self-care (with attendant training costs), and differences in medication costs were examined.

**Results:** In the reference case, CHD was $54.89 less costly per dialysis treatment compared with ICNHD, with a difference of $8562.84 per HD patient per year, with staffing costs accounting for >80% of the difference. Incremental annual costs for staffing, dialysis materials, and utilities were $7225.92, $1193.4, and $143.52, respectively. Fully independent ICNHD, which utilizes a staff-to-patient ratio of 1:10, results in to an annual saving $15,762.24 for ICNHD patients relative to CHD patients, including patient training costs of $17821 in the first year. If previously described reduction in medication use (erythropoietin-stimulating agents, anti-hypertensives, phosphate binders) occurs, ICNHD is $5126.04 more costly than CHD.

**Conclusions:** Compared to CHD, provision of ICNHD is more expensive, largely driven by increased staffing costs. Alternate staffing models, including fully independent ICNHD, are more attractive. The incremental costs of ICNHD should be balanced with potential improvements in patient outcomes and employment, as well as capital costs associated with creating more CHD capacity if required.

**FR-PO340**

**High Dose Home Hemodialysis and Conventional In-Center Hemodialysis: A Cost Utility Analysis** Frank Xiaoqing Liu,[1] Catrin Treharne,[2] Bruce F. Culleton,[1] Murat Arici,[3] Lydia Lees.[2] *[1]Baxter Healthcare Corporation, Deerfield, IL; [2]Abacus International, Oxfordshire, United Kingdom; [3]Baxter Healthcare Ltd., Compton, United Kingdom.*

**Background:** A cost-effectiveness analysis of home hemodialysis (HD) vs. in-center HD (ICHD) from the National Health Service (NHS) Center for Evidence-based Purchasing showed that Home HD was associated with lower costs and better outcomes than ICHD. The evaluation did not address increased dialysis frequency and/or duration. We performed an analysis to estimate the cost-effectiveness of high dose (higher frequency and/or longer duration) Home HD vs. ICHD.

**Methods:** An Excel-based Markov model was constructed to compare costs and quality adjusted life years (QALYs) associated with high dose Home HD and ICHD using current dialysis reimbursement in England and various hypothetical Home HD reimbursement levels. We modeled the incident adult dialysis population over a 10-year horizon from a payer's perspective. Model inputs included published articles, UK Renal Registry annual reports, NHS Payment-by-Results, and 2010 ERA-EDTA registry report. Future costs and benefits were discounted at an annual rate of 3.5%. One-way and probabilistic sensitivity analyses explored the robustness of the results.

**Results:** Under the current reimbursement (≤458/week, irrespective of the number of HD sessions/week), high dose Home HD is associated with lower total costs (≤8,504 less per patient) and higher QALYs (0.835 higher per patient) vs. ICHD over 10 years. High dose Home HD remained more effective and less costly over ICHD in all sensitivity analyses. High dose Home HD was cost-effective up to a weekly tariff of ≤620. Assuming that the Home HD tariff was equal to 5 times the 2010 reference cost of ≤115/session (i.e., ≤575/week), the incremental cost-effectiveness ratio of high dose Home HD would be ≤12,020/QALY. At this tariff (i.e., ≤575/week), high dose Home HD has an 84-92% probability of being cost-effective at a willingness-to-pay threshold of ≤20,000-≤30,000/QALY.

**Conclusions:** In England, high dose Home HD is cost-effective vs. ICHD, even if the tariff is as high as ≤620/week.

*Funding:* Pharmaceutical Company Support - Baxter Healthcare Corporation

**FR-PO341**

**High Dose In-Center Haemodialysis and Conventional In-Center Haemodialysis: A Head-to-Head Cost-Effectiveness Analysis** Frank Xiaoqing Liu,[1] Catrin Treharne,[2] Lydia Lees,[2] Murat Arici,[3] Bruce F. Culleton.[1] *[1]Baxter Healthcare Corporation, Deerfield, IL; [2]Abacus International, Oxfordshire, United Kingdom; [3]Baxter Healthcare Ltd., Compton, United Kingdom.*

**Background:** High dose haemodialysis (HD) (i.e., short daily HD or frequent nocturnal HD) improves clinical and humanistic outcomes. However, depending upon the location of therapy, it may be associated with higher costs. This study aimed to evaluate the cost-effectiveness of high dose in-centre HD (ICHD) versus conventional ICHD.

**Methods:** An Excel-based Markov model was constructed to estimate the costs and quality adjusted life years (QALYs) associated with conventional and high dose ICHD from the payer's perspective in England. We modeled the incident dialysis patient population over a 10-year time horizon. A scenario where all patients start on conventional ICHD (3 sessions/week) was compared with 3 scenarios where all patients start on high dose ICHD (3.5, 4, or 5 sessions/week). Model inputs were from published articles, annual UK Renal Registry reports, NHS Payment-by-Results, and ERA-EDTA registry report. All future costs and benefits were discounted to their present value at an annual rate of 3.5%. One-way sensitivity and probabilistic sensitivity analyses were conducted to test the robustness of the results.

**Results:** Starting all patients on high dose ICHD is associated with higher costs (an increase of ≤40,542, ≤54,115, ≤81,259 per patient for 3.5, 4, or 5 sessions per week respectively) and higher QALYs (an increase of 0.464 per patient) versus conventional ICHD over 10 years. This gives an incremental cost-effectiveness ratio (ICER) of ≤87,293, ≤116,516, ≤174,961 per QALY for the 3.5, 4, & 5 sessions/week scenarios, indicating that high dose ICHD is not cost-effective vs. conventional ICHD at UK NICE's willingness-to-pay threshold of ≤20,000-≤30,000. Sensitivity analyses showed consistent results.

**Conclusions:** Our analysis indicates that high dose HD, while being more effective than conventional HD, is not cost-effective when performed in-center based on the current UK NICE guideline.

**FR-PO342**

**Effects of Randomization to Frequent In-Center Hemodialysis on Long-Term Mortality: Frequent Hemodialysis Daily Trial** Glenn M. Chertow,[1] Nathan W. Levin,[2] Gerald J. Beck,[3] Paul W. Eggers,[4] Tom Greene,[5] Brett Larive,[3] Michael V. Rocco,[6] Alan S. Kliger,[7] The FHN Trial Group.[4] *[1]Stanford; [2]Renal Research Institute; [3]Cleveland Clinic; [4]NIDDK; [5]U Utah; [6]Wake Forest; [7]Yale.*

**Background:** The FHN Daily Trial randomized 245 subjects to "daily" (6 times per week) versus conventional (3 times per week) in-center hemodialysis (HD) for 1 year. Daily in-center HD resulted in favorable effects on the co-primary composite outcomes of death or change in left ventricular mass and death or change in self-reported physical health, and facilitated control of hypertension and hyperphosphatemia. Here we describe effects on mortality over a mean follow-up of 3.7 years.

**Methods:** We obtained dates of deaths and transplants through July 2011 using linkage to the USRDS and queries to study centers. Long-term mortality was related to the initial randomized treatment assignment using Kaplan-Meier product limit estimates and Cox regression, without censoring transplants as the primary analysis.

**Results:** Most (90/100) surviving non-transplanted subjects randomized to daily HD reverted to 3 or 4 times per week HD within 2 months after the trial period. Numbers of deaths (deaths/patient-year) among subjects randomized to the frequent and conventional groups, respectively, were 5 (0.041) and 10 (0.087) during the 1-year intervention period, 4 (0.034) and 6 (0.057) during the first year after the trial, and 12 (0.050) and 19 (0.089) subsequently. The overall relative hazard of mortality (daily versus conventional) was 0.54, 95% CI (0.32, 0.93), p=0.024; after censoring transplants the relative hazard was slightly attenuated: 0.60, 95% CI (0.34, 1.05), p=0.07.

**Conclusions:** The current results suggest that frequent in-center HD may reduce mortality long-term. Any benefits of frequent in-center HD must be balanced against potential risks including possible adverse effects on the vascular access, and the increased burden and cost of therapy. These results should be interpreted cautiously, as most patients randomized to daily HD reverted to conventional HD after the 1-year intervention, and statistical power was limited by relatively few (56) deaths.

## FR-PO343

**The Impact of Home Haemodialysis on Facility-Based Growth and Total Program Costs in an Australian Dialysis Service** Hasan Falih Alkhayyat, John W. MacD. Agar, Alwie Tjipto. *Renal Unit, Barwon Health, Geelong, Victoria, Australia.*

**Background:** In Australia, as elsewhere, the ever-rising dialysis population is placing increasing strain on an already stretched healthcare system. Yet, Australian home haemodialysis (HHD) has been shown to consume fewer resources, provide better patient outcomes and cost ~AUD $25,000/patient/year less than facility haemodialysis (FHD), HHD patients still comprise only a small fraction of most Australian dialysis units.

We report how the introduction of a home nocturnal haemodialysis (HNHD) program into a single dialysis service has influenced FHD distribution patterns over a 12-year follow-up period.

**Methods:** We have retrospectively reviewed (Jan 2000 - Feb 2013) the HD modality patterns (FHD vs. HNHD) in our renal service. While peritoneal dialysis (PD) is also actively provided, PD numbers have remained stable at 15% of all dialysis throughout the study period and have therefore been excluded from further analysis. In addition, we have the assessed the global program cost savings compared to the notional costs that would have accrued had all patients on HNHD remained on FHD over the study period.

**Results:** Over the 12 years, the total HD population increased (69 to 138) but is predominantly accounted for by an increase in HNHD (3 to 36). There was a relatively smaller proportional rise in FHD (66 to 102). All increase in FHD was confined to the first 3 years (2000 to 2003) while the HNHD program was being established. After 2003, FHD numbers have not altered significantly while HNHD has continued to grow. Furthermore, the HNHD program has notionally saved AUD $6.33 million against the global costs that would have accrued had all HNHD patients been started on and stayed within the FHD program over the full 12 year period. The calculated savings = the mean HNHD program pts/yr (21.1 pts) taken over 12 years @AUD $25,000 less/HNHD pt/year than the equivalent FHD cost.

**Conclusions:** Our HNHD cohort now makes up 26.1% of our total HD population. Most HD program growth has been delivered by HNHD since 2003. HNHD has resulted in significantly lower healthcare costs while synchronously maintaining a high quality of care.

## FR-PO344

**Is Progression of Arteriosclerosis in ESRD Patients Inhibited by Nocturnal Hemodialysis or Renal Transplantation? Baseline Results from the NOCTX Study** Franka E. Van Reekum,[1] Marianne C. Verhaar,[1] Petrus F. Vos,[2] Akin Ozyilmaz,[4] Brigit C. Van Jaarsveld.[3] *[1]Nephrology, Univ Medical Center, Utrecht, Netherlands; [2]Dianet Dialysis Center, Utrecht, Netherlands; [3]Nephrology, VU Medical Center, Amsterdam, Netherlands; [4]Dialysis Center Groningen, Groningen, Netherlands.*

**Background:** Coronary artery calcification (CAC) is associated with cardiovascular morbidity and mortality in patients with ESRD. Improvement of calcium-phosphate homeostasis and uremia by nocturnal HD or kidney transplantation might favorably influence CAC compared to conventional HD and PD. The ultimate goal of this study is to assess whether nocturnal HD and transplantation are associated with less progression of CAC, compared with conventional HD and PD. Here we present our baseline data of CAC.

**Methods:** CAC score (CACS) will be measured with multislice CT of the heart in 4 different groups (4x40 pts): patients treated with conventional HD (3-4x/week, 3-4 hr), PD, incident nocturnal HD (5-7x/week, 6-8 hr) and kidney transplant after dialysis. CAC is expressed as Agatston score and is measured at baseline and repeated after 1, 2 and 3 years of treatment. Apart from clinical characteristics and biochemistry, we will evaluate inflammation markers and serum calcification inhibitors.

**Results:** So far, 93 patients underwent multi slice CT, mean age was 49.1±13.1 yr, 60.2% males. Mean duration of RRT (excluding periods with transplant) was 35.5±28.9 months. Two thirds of our patients had considerable coronary calcifications (31% CACS 0, 36% CACS 1-400, 32% CACS > 400). CACS was significantly associated with age, and not with duration of dialysis treatment, presence of DM, levels of cholesterol, phosphate, albumin or CRP. We included 31 HD, 16 PD, 28 nocturnal HD and 18 kidney transplant patients.

**Conclusions:** There is significant coronary calcification in this Dutch cohort of patients treated with renal replacement therapy. Despite the long duration of dialysis treatment there was no association between duration of dialysis and CACS. We confirm the relation of coronary calcification with age as mentioned in literature. The progression of calcification with the different treatment modalities will be followed up in the NOCTX study.

## FR-PO345

**Effects of Randomization to Frequent Nocturnal Hemodialysis on Long-Term Mortality: Frequent Hemodialysis Network Nocturnal Trial** Michael V. Rocco, John T. Daugirdas, Tom Greene, Robert S. Lockridge, Andreas Pierratos, Brett Larive, Gerald J. Beck, Alan S. Kliger, The FHN Trial Group. *NIH, NIDDK, Bethesda, MD.*

**Background:** The Frequent Hemodialysis Network (FHN) Nocturnal trial randomized 87 subjects to either 6 times per week home nocturnal hemodialysis (NHD) or to 3 times per week home hemodialysis (CHD) for 1 year. We describe long term effects on mortality over an average follow-up of 3.7 years.

**Methods:** Dates of deaths and transplants were obtained through July 2011 using linkage to USRDS and queries of study centers. Long-term mortality was related to initial randomized treatment assignment using log-rank tests and Cox regression, without censoring transplants in the primary analysis.

**Results:** 64% vs 0%, 54% vs 24%, and 45% vs 30% of patients randomized to NHD vs CHD respectively received ≥27 hours of dialysis over ≥4.5 treatments per week during the trial, the first year after the trial, and subsequently. Numbers of deaths (deaths/patient-year) were 2/45.1 (0.047) and 1/42.6 (0.023) in the NHD and CHD groups during the intervention period, 9/37.0 (0.243) and 1/39.3 (0.025) during the first year after the trial, and 3/69.4 (0.043) and 3/85.2 (0.035) subsequently. The overall mortality hazard ratio (HR) for randomization to NHD vs CHD was 3.82, 95% CI (1.26, 11.63), p = 0.011. A similar HR was obtained after censoring transplants; HR 5.84, 95% CI (1.67, 20.40), p = 0.002.

**Conclusions:** These extended follow-up results raise the possibility that CHD may lead to lower mortality than NHD. However, some caution in interpretation is warranted because the mortality rate for patients randomized to the CHD comparison group was surprisingly low (0.03 per patient-year), a substantial portion of patients randomized to conventional home dialysis switched to a frequent hemodialysis regimen after the trial without incurring an observable increase in mortality, and because statistical power was limited by the number of patients randomized (87) and the relatively few (19) deaths.

## FR-PO346

**Intensive Hemodialysis Is Associated with Improved Pregnancy Outcomes: A Canadian and United States Comparison** Michelle A. Hladunewich,[1] Susan H. Hou,[2] Ayodele Odutayo,[1] Tom Cornelis,[3] Andreas Pierratos,[1] Johannes Keunen,[4] Dini Hui,[4] Christopher T. Chan.[1] *[1]Medicine, Nephrology, Univ of Toronto, Toronto, Canada; [2]Medicine, Nephrology, Loyola Univ Medical Center, Maywood, IL; [3]Medicine, Nephrology, Maastricht Univ Medical Center, Maastricht, Netherlands; [4]Obstetrics and Gynecology, Univ of Toronto, Toronto, Canada.*

**Background:** Pregnancy is rare in women with end stage renal disease (ESRD), and when it occurs is often accompanied by significant maternal and fetal morbidity, and even mortality. Preliminary data from the Toronto Nocturnal Dialysis Program suggested that increased clearance of uremic toxins by the provision of intensified hemodialysis improves pregnancy outcomes, but small numbers and absence of a comparator group limited widespread applicability of these findings.

**Methods:** We compared pregnancy outcomes from the *Toronto Pregnancy and Kidney Disease (PreKid) Clinic and Registry* to the *American Registry for Pregnancy in Dialysis Patients (ARPD)*. The primary outcome was the live birth rate.

**Results:** The live birth rate was significantly higher in the Canadian as compared to the American cohort at 85.7 compared to 61.4% (p=0.038). Among established ESRD patients, the duration of pregnancy was longer in the more intensively dialyzed *PreKid* cohort at 36 (32-37) as compared to 27 (24-32) weeks in the *ARPD* patients (p=0.001) along with a trend towards higher birth weights. Further, a dose response between dialysis intensity and pregnancy outcomes emerged with live birth rates of 48% in women receiving < 20 hours of hemodialysis, 73% in women receiving between 21 and 36 hours of hemodialysis, and finally, 85% in women dialyzed in excess of 36 hours a week (p=0.027). Pregnancy complications were few and overall manageable.

**Conclusions:** We conclude pregnancy is safe and feasible in women with ESRD receiving intensive hemodialysis.

## FR-PO347

**Conversion to In-Centre Nocturnal Hemodialysis Was Associated with Regression of Left Ventricular Mass** Ron Wald,[1] Marc B. Goldstein,[1] Ziv Harel,[1] Jeffrey Perl,[1] Niki Dacouris,[1] Darren A. Yuen,[1] Myles S. Wolf,[3] Andrew T. Yan.[4] *[1]Nephrology, St. Michael's Hospital, Toronto, Canada; [2]Nephrology, St. Paul's Hospital, Vancouver, Canada; [3]Nephrology, Univ of Miami, Miami, FL; [4]Cardiology, St. Michael's Hospital, Toronto, Canada.*

**Background:** There are limited prospective data on the cardiovascular effects of in-centre nocturnal hemodialysis (INHD), especially with the use of cardiac magnetic resonance (CMR), the current reference standard for evaluating cardiac effects of intensified dialysis schedules.

**Methods:** We conducted a prospective, 2-centre observational study of 67 prevalent recipients of conventional hemodialysis (CHD, 4 h/session, 3x/week) of whom 37 converted to in-centre nocturnal hemodialysis (INHD, 7-8 h/session, 3 x/week in the outpatient dialysis unit overnight) while 30 remained on CHD. Conversion to INHD was guided by patient preference and/or physician recommendation. CMR performed at study entry and after 1 year were independently analyzed. The outcome was the change in left ventricular mass (LVM). The primary analysis evaluated patients by the dialysis regimen chosen at enrollment; a secondary as-treated analysis reflected the predominant regimen actually used over 1 year.

**Results:** 57 (23 CHD, 34 INHD) patients had CMRs at baseline and end-of-study. As compared to patients who remained on CHD, INHD was associated with a 16.8 (95 % CI, 1.4-32.2) g reduction in LVM after 1 year (p=0.03). In the as-treated analysis, INHD was associated with a decline in LVM of 18.5 g (p=0.02).

| | CHD (n=23) | INHD (n=34) | p-value |
|---|---|---|---|
| Age,y | 51 ± 12 | 57 ± 11 | 0.07 |
| Female (%) | 39 | 44 | 0.71 |
| DM as cause of ESRD (%) | 17 | 47 | 0.02 |
| Median time on dialysis pre-enrollment, months | 51 (23, 102) | 21 (10, 56) | 0.13 |
| Mean baseline systolic BP, mmHg | 138 ± 11 | 146 ± 17 | 0.02 |
| Mean LVM, g | | | |
| Baseline | 118 ± 32 | 139 ± 42 | 0.05 |
| One-year | 126 ± 33 | 131 ± 35 | 0.65 |

**Conclusions:** Compared to continuation of CHD, conversion to INHD was associated with LVM regression at 1 year. The magnitude of LVM regression observed with INHD was comparable to the effects of short-daily and nocturnal hemodialysis in clinical trials.

*Funding:* Government Support - Non-U.S.

## FR-PO348

**Risk of Hospitalization with Home Daily Dialysis Using Slow Dialysate Flow Rates** Rita Suri,[1] Lihua Li,[2] Gihad E. Nesrallah.[3] *[1]Nephrology, CHUM, Univ of Montreal, Montreal, Canada; [2]Kidney Clinical Research Unit, Western Univ, London, Canada; [3]Nephrology, Humber River Regional Hospital, Toronto, Canada.*

**Background:** Daily hemodialysis with slow dialysate flow rates ($DHD_S$) is an emerging home treatment option for end-stage renal disease. Comparative effectiveness studies of home $DHD_S$ and peritoneal dialysis (PD) are needed to help inform patient choice between these therapies.

**Methods:** We identified 2273 consecutive patients prescribed $DHD_S$ (NxStage SystemOne in US DaVita facilitates between Jan 2004 and Dec 2009. All patients received HD ≥5 days/week for ≥4 hours/day for at least 1 month. We matched 1942 of these $DHD_S$ patients by propensity scores to 5103 contemporaneous patients receiving home PD registered in the USRDS. Comorbidities, demographics, hospitalizations, deaths, transplants, and losses to follow-up for both groups were ascertained from the USRDS. Hospitalizations were categorized using the same definitions as in the USRDS 2012 data report. We used an Andersen-Gill model to compare hospitalization rates due to the composite of the pre-specified diagnostic categories of: cardiovascular, infectious, access-related, or bleeding. The single diagnostic categories were specified as secondary outcomes.

**Results:** After matching, between-group standardized differences for all baseline characteristics were <10%. Mean age was 51 years, 32% were male, 73% were white, and 27% had diabetes. Arteriovenous fistulae were present in 64% of $DHD_S$ patients. During 11,949 patient-years, 3952/7045 patients had 11,972 hospitalizations. The composite hospitalization rate was significantly lower for patients receiving $DHD_S$ than those receiving PD ($DHD_S$: 0.69/patient-year, PD: 1.09/patient-year; HR 0.62 (95% CI 0.58-0.66); p< 0.001). The number of days spent in hospital per patient-year was 4.1 with HD and 7.5 with PD (p<0.001). Overall, 61% of $DHD_S$ vs. 37% of PD patients remained admission-free for the pre-specified diagnoses (p=<0.001). Analyses of secondary outcome yielded similar results.

**Conclusions:** Compared to PD, $DHD_S$ was associated with fewer admissions and days spent in hospital. These results may have implications for those considering home-based renal replacement therapy options.

## FR-PO349

**Hemodynamic Profile of Patients with Left Ventricular Assist Device during Hemodialysis** Jessica McAbee, Christopher J. Areephanthu, Bennet J. George, B. Peter Sawaya. *Internal Medicine, Div of Nephrology, Bone and Mineral Metabolism, Univ of Kentucky, Lexington, KY.*

**Background:** Left ventricular assist device (LVAD) has emerged as a common treatment for patients with advanced heart failure. It is not uncommon for these patients to suffer from renal failure requiring renal replacement therapy. However, due to potential hemodynamic instability, hemodialysis (HD) has been performed mainly on an inpatient basis with intensive nursing involvement and high medical cost. The purpose of this study is to retrospectively assess hemodynamic parameters and ability to complete the prescribed HD treatment in a series of patients who underwent numerous HD sessions.

**Methods:** Ten patients with Heart Mate II LVAD received 182 intermittent HD treatments. The following parameters were retrospectively evaluated: vital signs, ultrafiltrate (UF) removed, HD duration, symptoms, adverse events and interventions during each HD session. Hemodynamically significant events were defined as systolic blood pressure (SBP, mmHg) < 80, lowest SBP > 80 with a drop > 20 mmHg from baseline, or inability to register a blood pressure using regular sphygmomanometer due to LVAD-induced reduction in pulse pressure.

**Results:** Pre- and post-HD (mean ± SD): SBP (mmHg) 96 ± 17 and 95 ± 20; heart rate (HR, bpm) 86 ± 17 and 88 ± 20, respectively. The mean lowest SBP during HD was 83 ± 19 mmHg (p < 0.001 vs. pre-SBP). The prescribed and achieved (mean ± SD): UF (liters) 2.6 ± 1.8 and 2.7 ± 1.9 (NS); HD duration (hours) 3.3 ± 0.5 and 3.3 ± 0.6 (NS), respectively. Hemodynamic events, as defined above, occurred in the following frequency: SBP < 80 = 36%; SBP > 80 with a drop > 20 = 9% and inability to register BP = 35%. However, patients during these events were rarely symptomatic. When BP could not be registered, HR assessed by telemetry was 93 ± 19. Albumin was infused in only 16% of all the HD treatments and blood was transfused in less than 4%.

**Conclusions:** Patients with LVAD can often tolerate and complete the prescribed HD treatment. These patients are likely to tolerate outpatient in-center HD.

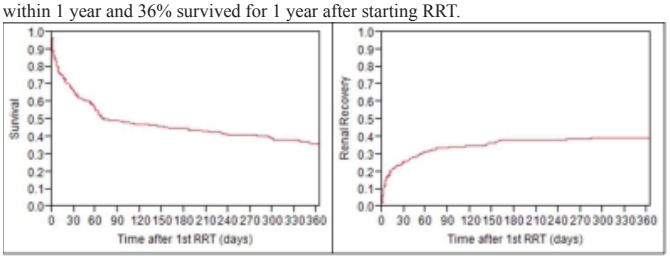
## FR-PO351

**Outcomes and Prognostic Factors for Patients Requiring Dialysis after Cardiac Surgery** Charat Thongprayoon,[2] Ishan Shah,[3] Kianoush Banaei-Kashani,[1] Rahul Kashyap,[4] Soon J. Park,[3] John J. Dillon.[1] *[1]Nephrology, Mayo Clinic; [2]Critical Care Medicine, Mayo Clinic; [3]Cardiac Surgery, Mayo Clinic; [4]Anesthesia, Mayo Clinic.*

**Background:** Acute kidney injury (AKI) requiring renal replacement therapy (RRT) may occur after cardiac surgery and is a risk factor for postoperative mortality. Long-term outcomes, particularly beyond hospital discharge, and their prognostic factors, have not been well studied.

**Methods:** This is a retrospective study of all adult patients requiring RRT for AKI within 30 days after cardiac surgery between Jan. 2007 and Dec. 2011. Patients receiving RRT preoperatively and patients receiving ventricular assist devices or cardiac transplants were excluded. The primary outcomes were all-cause mortality and renal recovery 1 year after starting RRT. We defined renal recovery as remaining alive and free of dialysis for 14 days. Outcomes were presented using Kaplan-Meier plots. Multivariate Cox proportional hazard analysis was used to assess factors associated with outcomes.

**Results:** 202 patients met the inclusion criteria. Of these, 39% recovered renal function within 1 year and 36% survived for 1 year after starting RRT.



Only 4% were both alive and requiring RRT at 1 year. In multivariate analysis, older age, heart failure, lower preoperative creatinine, longer interval between cardiac surgery and RRT start, mechanical ventilation and intra-aortic balloon pump use were independently associated with increased 1-year mortality, whereas vasopressor and extracorporeal membrane oxygenation use were independently associated with renal non-recovery within 1 year.

**Conclusions:** Mortality is high for patients requiring RRT after cardiac surgery, but few survivors require long-term dialysis. An unexpected mortality risk factor was lower preoperative creatinine. This may reflect greater injury among patients with lower preoperative creatinines who require RRT.

## FR-PO352

**Acid-Base (A-B) Changes in Acute Kidney Injury (AKI) Patients with Hypercapnic Respiratory Failure Treated with 24-Hour (h) Sustained Low Efficiency Dialysis (SLED) with Regional Citrate Anticoagulation (RCA)** Jian Li, Lenar T. Yessayan, Jerry Yee, Balazs Szamosfalvi. *Nephrology, Henry Ford Hospital, Detroit, MI.*

**Background:** Previous studies showed that hemodialysis induces transient $Pco_2$ elevation in ESRD patients, returning to baseline post therapy. Metabolic acidosis and alkalosis have been reported with RCA. Studies of A-B changes in patients with respiratory and metabolic acidosis on mechanical ventilation and 24-h SLED-RCA are lacking.

**Methods:** We conducted a retrospective chart review of 268 AKI patients on CRRT between Nov. 2009 and Oct. 2012. 32 had respiratory and metabolic acidosis. 26 had complete ABG data for over 72-h while on 24-h SLED-RCA with Qb 60ml/min, Qd 400 ml/min and Rexeed 15SX filter. Dialysate K was 4 mmol/L, Na was 140-142 mmol/L in all 26 patients, HCO3 was 32 mmol/L in 24 patients, 34 and 36 mmol/L in two. A-B parameters were collected at time(t)= 0, 24, 48 and 72-h (± 4h) on SLED-RCA. Pairwise comparison between any two time points was performed using paired t test. P-value <0.05 was considered statistically significant.

**Results:** Mean age:49.88±17.13 years, 50% male, mean serum creatinine at t=0-h: 4.18±2.16 mg/dL. A-B parameters pre/post SLED-RCA are shown in table.

| ABG | t=0 h | 24 h | 48 h | 72 h | p value |
|---|---|---|---|---|---|
| pH | 7.22±0.10 | 7.26±0.07 | 7.29±0.06 | 7.30±0.06 | 0.001 |
| $Pco_2$(mmHg) | 62.88±12.51 | 57.84±10.57 | 55.99±10.59 | 53.63±9.93 | 0.004 |
| $HCO_3$(mmol/L) | 25.28±6.77 | 25.12±2.83 | 25.59±2.22 | 25.13±3.00 | 0.47 |
| Minute Ventilation(L/Min) | 7.22±3.23 | 8.04±2.53 | 8.01±2.61 | 7.83±2.54 | 0.20 |
| Blood chemistry(mmol/L) | | | | | |
| Na | 139.81±8.28 | 139.58±3.82 | | | |
| K | 4.56±0.9 | 4.48±0.57 | | | |
| CL | 102.54±7.60 | 105.46±4.12 | | | 0.02 |
| $HCO3^-$ | 26.04±6.02 | 25.81±2.61 | | | 0.80 |
| Corrected Anion Gap | 16.96±3.00 | 13.85±3.26 | | | 0.003 |

**Conclusions:** Fixed dialysate bicarbonate delivery with SLED-RCA reduced or did not worsen pCO2; meanwhile it efficiently corrected high anion gap metabolic acidosis while approximating a normal serum bicarbonate concentration.

## FR-PO353

**Factors Associated with Dose of Intermittent Hemodialysis in Acute Kidney Injury** Gunyamol Thamniramol, Pongsathorn Gojaseni, Kolasorn Pakchotanon. *Medicine, Bhumibol Adulyadej Hospital, Bangkok, Thailand.*

**Background:** KDIGO guideline recommends delivering a Kt/V of 3.9 per week when using intermittent RRT in acute kidney injury. In Thailand, however, adequacy of hemodialysis in AKI patients is not routinely monitored. The aim of this study, therefore, was to assess the prescribed and delivered Kt/V and its associated factors in AKI patients underwent intermittent hemodialysis.

**Methods:** A cross-sectional study was performed in Bhumibol Adulyadej hospital, directorate of medical services, Royal Thai Air Force during January 2012 to January 2013. Prescribed Kt/V was calculated from in vitro dialyzer clearance and actual body weight while delivered Kt/V was calculated using natural logarithm formula. Patient clinical data and dialysis prescription were analyzed to determine their association with dialysis adequacy.

**Results:** Fifty-two AKI patients, who collectively underwent 248 dialysis treatments, were studied prospectively. Mean (± SD) age was 69.4 ± 16.9; 50% were male. At dialysis initiation, APACHE II score was 20.6 ± 6.2 and SOFA score 8.2 ± 3.6.Mean session length was 3.54 ± 0.81 h, and 78.9% used a femoral venous catheter. The results showed that the mean prescribed and delivered Kt/V were 1.28 ± 0.51 and 1.20 ± 0.58 respectively. Thirty-nine percent of the prescriptions were for a Kt/V less than 1.2 while 55.6% of treatments delivered a Kt/V less than 1.2. The independent determinants of adequate Kt/V (≥ 1.2) in a multiple logistic regression model were; blood flow rate ≥ 250 ml/min (odds ratio (OR) = 3.87, 95% confidence intervals (CI): 2.04-7.31), dialysis time ≥180 min (OR = 3.01, 95% CI: 1.03-8.81), female gender (OR = 2.80, 95% CI: 1.50-5.21), heparin used (OR = 2.45, 95% CI: 1.13-5.33) and actual body weight < 65 kg (OR = 2.38, 95% CI: 1.18-4.80).

**Conclusions:** More than half of patients with AKI are received an inadequate dose of dialysis. Barriers to adequate dose delivery were patient size, gender and inadequate dialysis prescription, i.e., blood flow rate, dialysis time and anticoagulant.

*Funding:* Government Support - Non-U.S.

## FR-PO354

**Inflammatory Cytokine Reductions with Sustained Low Efficiency Online Hemodiafiltration (Online SLED-f) Using High Cut-Off Dialyzer versus High-Flux Dialyzer in Sepsis-Related Acute Kidney Injury Patients** Khajohn Tiranathanagul, Jeeraluk Tunpornchai, Nattachai Srisawat, Wiwat Chancharoenthana, Asada Leelahavanichkul, Kearkiat Praditpornsilpa, Somchai Eiam-ong. *Div of Nephrology, Dept of Medicine, King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn Univ, Thailand.*

**Background:** Hypercytokinemia plays a central role in the pathogenesis and is related to the high mortality in sepsis-related acute kidney injury (S-AKI). The reductions of these cytokines have been reported to improve clinical outcomes. Sustained low efficiency online hemodiafiltration (online SLED-f) using traditional high-flux (HF) dialyzer could remove some inflammatory cytokines. Interestingly, the potential of enhancing cytokine removal by using newly designed high cut-off (HCO) dialyzer that could theoretically remove larger solutes has never been studied in SLED-f before.

**Methods:** This prospective randomized trial was conducted in 15 S-AKI patients to compare the efficacy of cytokine removal including IL-6, IL-8, IL-10,TNF-α, and VEGF by six-hour SLED-f between using HCO dialyzer (HCO-SLED-f,n=8) and HF dialyzer (HF-SLED-f,n=7). The clinical parameters as well as the adverse effects including albumin loss were observed and compared.

**Results:** HCO-SLED-f provided significantly IL-8 and TNF-α reduction (p=0.012 for both) after treatment whereas HF-SLED-f could only demonstrate significantly TNF-α reduction (p=0.018). However, the degree of all cytokine reductions did not show significant difference between both treatment groups. There were significantly higher total albumin losses in effluent fluid in HCO-SLED-f group than HF-SLED-f group [4.72(range 3.5-5.8) vs. 0 (0-0.11) gram,p=0.010]. However, the percentage of plasma albumin reduction was not different between both groups (p=0.418). There were no significant differences in intra-dialytic blood pressure parameters during both treatments.

**Conclusions:** In S-AKI, HCO-SLED-f could be safely applied and could reduce more types of cytokines when compared with traditional HF-SLED-f despite the degree of reduction did not significant difference. However, the higher degree of albumin loss should be considered when using HCO-SLED-f.

## FR-PO355

**Sustained Low Efficiency Dialysis (SLED) versus Continuous Renal Replacement Therapy (CRRT) for AKI in Critically Ill Patients** Abhijat Kitchlu,[1] Karen E.A. Burns,[2] Jan O. Friedrich,[2] David Klein,[2] Robert M. Richardson,[1] Neill Adhikari,[2] Ron Wald.[1] *[1]Div of Nephrology, U. of Toronto; [2]Div of Critical Care, U. of Toronto, Toronto, Canada.*

**Background:** SLED, which reflects the use of conventional dialysis technology over an extended time, is increasingly used as a renal replacement modality in critically ill patients with AKI and hemodynamic instability. SLED may reduce the hemodynamic perturbations of IHD, while obviating the resource demands of CRRT. Although SLED is being increasingly used in the intensive care unit (ICU), few studies have evaluated its impact on clinical outcomes.

**Methods:** We conducted a cohort study comparing SLED (target 8 h/session, $Q_b$ 200 mL/min) to CRRT in four ICUs at an academic medical centre. The primary outcome was mortality 30 days after RRT initiation, adjusted for demographics, comorbidity, baseline kidney function, and Sequential Organ Failure Assessment (SOFA) score. Secondary outcomes were RRT dependence at 30 days and early clinical deterioration, defined as death or higher SOFA score at 48 hours.

**Results:** We identified 158 patients who initiated treatment with CRRT and 74 with SLED. Mortality at 30 days was 54% and 61% among SLED- and CRRT-treated patients, respectively [adjusted odds ratio (OR) 1.07, 95% CI 0.56–2.03, as compared with CRRT]. RRT dependence at 30 days (adjusted OR 1.36, 95% CI 0.51–3.57) and early clinical deterioration (adjusted OR 0.73, 95% CI 0.40–1.34) were similar between groups.

**Table 1: Baseline data**

| Variable | CRRT | SLED | p value |
|---|---|---|---|
| Patients | 158 | 74 | |
| Age at RRT initiation (mean±SD) | 62.1±5.3 | 60.6±17.3 | 0.50 |
| Male (%) | 59.5 | 67.6 | 0.25 |
| Mechanical ventilation (%) | 95.6 | 86.5 | 0.03 |
| Pre-morbid creatinine (mean±SD) | 130.6±91.7 | 135.3±83.8 | 0.57 |
| SOFA score at RRT initiation (mean±SD) | 16.4±3.08 | 15.4±3.65 | 0.03 |
| Urine output on day of RRT initiation, mL (mean±SD) | 328.8±580.5 | 387.6±607.0 | 0.48 |
| Vasopressors at RRT initiation (%) | 87.3 | 79.7 | 0.17 |

**Conclusions:** Notwithstanding the limitations of this small non-randomized study, our findings support similar clinical outcomes for patients treated with SLED vs CRRT. In hemodynamically unstable patients with AKI, trials to establish the non-inferiority of SLED are needed.

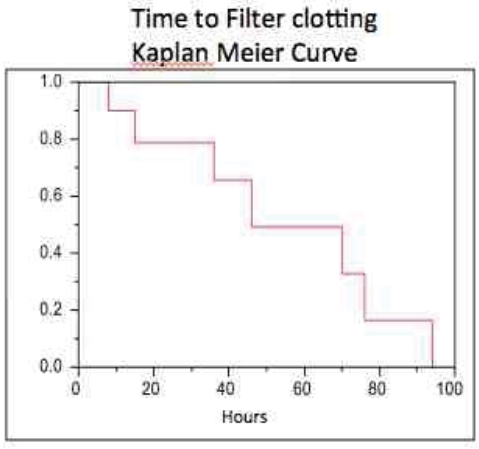
## FR-PO356

**Calcium Replacement Using Post Filter Replacement Fluid during Continuous Renal Replacement Therapy with Citrate Anticoagulation** Nithin Karakala,[1] John M. Arthur,[1] Ashita J. Tolwani.[2] *[1]Medicine, Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Medicine, Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** Continuous Renal Replacement Therapy (CRRT) is the choice of dialysis modality in hemodynamically unstable patients with Acute Kidney Injury (AKI). Anticoagulation is required to prevent filter clotting and is done by using regional citrate anticoagulation or systemic heparin. The recent national calcium shortage has caused major problems in using citrate anticoagulation protocols.

**Methods:** This is a retrospective analysis of data from 4 patients. Gambro Prismaflex machines, with HF 1000 filter sets were used. Commercially available PrismaSol BGK 4/2.5 (potassium 4 meq/L and calcium 2.5 mew/L) was used as replacement fluid. Acid Citrate Dextrose A(ACDA)was used as an anticoagulant. Calcium gluconate (6 grams in 250 ml of 0.9% normal saline) was used if the patients ionized calcium was less than 1 mmol/L.

**Results:** Patients were on CRRT for an average of 6±4.7 days, for a total of 24 days. During this period 4 filters clotted. The calculated Kaplan Meier Curve for time to filter clotting was 46 hours. The average delivered dose of dialysis was 39.66± 9.45 ml/kg/hr. The average systemic ionized calcium was 1.06±0.07 mmol/L. Calcium gluconate drip was needed in for a combined 13 days during this period with an average rate of 6.4±2.35 ml/hr.



**Conclusions:** Use of calcium containing post filter replacement fluid decreased the need for systemic calcium replacement during CRRT treatment. The above described protocol improved the filter patency and the delivered dose in patients who were not suitable for heparin anticoagulation and had filter clotting problem and maintained systemic calcium greater than 1 mmol/L.

## FR-PO357

**A Continuous Veno-Venous Hemofiltration Protocol with Anticoagulant Citrate Dextrose Formula A and a Calcium-Containing Replacement Fluid: An Easy Remedy for the National Calcium Shortage?** Song Ching Ong, Keith M. Wille, Ashita J. Tolwani. *Univ of Alabama at Birmingham.*

**Background:** Regional citrate anticoagulation (RCA) is used as an anticoagulant for continuous renal replacement therapy (CRRT). A systemic calcium ($Ca^{2+}$) infusion is required to replace the $Ca^{2+}$ lost in the effluent. The U.S. shortage of intravenous $Ca^{2+}$ has limited the use of RCA. We describe a continuous veno-venous hemofiltration (CVVH)

protocol with RCA using 2.2% anticoagulant citrate dextrose formula-A (ACDA) and a commercially available dialysate containing $Ca^{2+}$3.0 meq/L, $HCO_3^-$ 35 meq/L and $K^+$ 4 meq/L (NxStage) as post-filter replacement fluid (RF), without need for $Ca^{2+}$infusion.

**Methods:** We prospectively evaluated 5 patients on CRRT who had at least 3 episodes of clotting of the filter within 24 hours. Patients were switched to CVVH using ACD-A infused pre-blood pump with the Prismaflex device and titrated to achieve a post-filter ionized calcium ($iCa^{2+}$) level <0.5 mmol/L. The $Ca^{2+}$–containing dialysate was delivered post-filter as RF at rate 3.0 L/hr and titrated to maintain systemic $iCa^{2+}$ levels between 0.9-1.3mmol/L.

**Results:** Mean age was 57±14 years and mean APACHE II score was 33±3.2. Steady state mean serum chemistries were: $Na^+$: 140.8±2.3meq/L (range 136-145), $K^+$: 4.22±0.44meq/L (range 3.5–5.1) $HCO_3^-$: 30.9±3.7meq/L (range21–36), pH: 7.42 ± 0.07 (range 7.26-7.55), $CO_2$: 47.9 ± 8.3 (range 35–76), total $Ca^{2+}$: 8.08 ± 1.09 mg/dL (range 6.6–10.8). Post-filter $iCa^{2+}$ ranged 0.27-0.36mmol/L, and patient $iCa^{2+}$ ranged 0.81-1.24mmol/L. Mean post-filter RF rate: 3086±164ml/hr (range 3000-3600), mean ACDA rate: 298±21ml/hr (range 250-350). Mean blood flow rate: 200±17 ml/min (range 170–250), mean filtration fraction: 37±0.04% (range 28-48). Mean effluent flow rate: 38.6±6.7ml/kg/hr (range 28.7–55.8). Median filter survival was 24.5 hrs (95% C.I. 16.4-67.3).

**Conclusions:** CVVH using ACDA for RCA and a $Ca^{2+}$-containing RF without a continuous $Ca^{2+}$ infusion was safely and effectively used. Due to the high $HCO_3^-$ content of the RF, patients developed mild alkalemia. Despite high filtration fractions, filter survival was much improved.

## FR-PO358

### Relations of Volume Parameters in Continuous Renal Replacement Therapy

Harin Rhee,[1] Min Ji Shin,[1] Byeong Yun Yang,[1] Il Young Kim,[2] Dong Won Lee,[2] Soo Bong Lee,[2] Ihm Soo Kwak,[1] Eun Young Seong.[1] *[1]Dept of Internal Medicine, Pusan National Univ School of Medicine; [2]Dept of Internal Medicine, Pusan National Univ Yangsan Hospital.*

**Background:** In critically ill patients, acute kidney injury(AKI) is common and these patients often suffer from fluid overload. Once kidney failure occurs, renal replacement is initiated for volume overload, in this setting, successful volume management depends on an accurate assessment of fluid status. We investigated the relationship of volume parameters in AKI patients with continuous renal replacement therapy(CRRT).

**Methods:** Sixty AKI patients with CRRT ≥48 hours were enrolled. Volume status was determined by measuring central venous pressure(CVP), cardiothoracic ratio(CT ratio) in chest x-ray as traditional volume marker and extracellular water(ECW)/total body water(TBW) by bioimpedance analysis, absolute diameter of inferior vena cava(IVCd) and IVC collapsible index (IVCci) by ultrasound. In patients with CRRT ≥72 hours, follow-up volume parametes were measured and the difference between parameters at CRRT start and after 72 hours were calculated.

**Results:** Mean CVP,CT ratio,and ECW/TBW were 9.8±4.6mmHg,0.55±0.08,and 0.412±0.015. Mean IVCd and IVCci were 1.71±0.27cm and 31.8±16.1%. ECW/TBW was positively correlated with IVCd(r=0.604,p=0.001). IVCci was negatively correlated with CVP(r=-0.398,p=0.032). There was no correlation between ECW/TBW,CVP,CT ratio,and IVCci. The difference between parameters of volume status at CRRT start and after 72 hours were 3.7±6.5mmHg, 0.18±0.28, and 0.135±0.200 in CVP, CT ratio, and ECW/TBW. In IVCd and IVCci, the difference were 0.47±0.82cm, and 8.6±17.4%. ΔECW/TBW was positively correlated with ΔCVP(r=0.542,p=0.002), ΔCT ratio(r=0.705,p<0.001), and ΔIVCd(r=0.772,p<0.001). ΔIVCd was positively correlated with ΔCVP(r=0.565,p=0.001), ΔCT ratio(r=0.564,p=0.001), and ΔIVCci(r=0.560,p=0.001). In comparison of volume parametes according to hospital mortality, IVCd(1.82±0.29 vs 1.59±0.20,p=0.015), and IVCci(37.9±11.5 vs 25.2±18.1,p=0.036) was significantly higher in non-survivors.

**Conclusions:** IVCd, IVCci, and ECW/TBW was correlated with traditional volume parametes in CRRT patients.

## FR-PO359

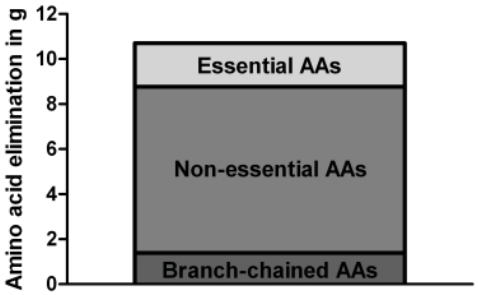
### Removal Characteristics of Glutamine and Other Amino Acids in Critically Ill Patients with Acute Kidney Injury Undergoing Extended Dialysis

Julius Schmidt, Carsten Hafer, Eva Schönenberger, Bernhard M.W. Schmidt, Jan T. Kielstein. *Dept of Internal Medicine, Div of Nephrology, Medical School Hannover, Germany.*

**Background:** Acute kidney injury in critically ill patients is associated with an activation of protein catabolism. Renal replacement therapy (RRT) with modern dialysis membranes may aggravate this problem by eliminating a substantial amount of amino acids (AAs).

**Methods:** Prospective, cross-over study in ten extended dialysis sessions using a polysulfone membrane (either EMiC2 or AV 1000S dialyzer, FMC, Germany). Blood samples for AAs were drawn before, during and after a 10 h treatment. In addition samples for calculation of dialyzer clearance and samples from the total spent dialysate were measured.

**Results:** Despite no significant difference in pre- and post -dialysis plasma AA levels we found an impressive amount of AAs in the collected spent dialysate of 10.48 g/treatment.



Dialyzer clearance is shown below.

| AA | Dialyzer clearance (ml/min) | Eliminated amount (g) |
|---|---|---|
| Lys | 86.61 | 0.74 |
| Met | 74.25 | 0.12 |
| Phe | 67.56 | 0.54 |
| Thr | 86.6 | 0.53 |
| Trp | 67.8 | 0.06 |
| Ala | 88.91 | 0.91 |
| Arg | 94.67 | 0.29 |
| Asp | 82.01 | 0.05 |
| Cys | 93.22 | 0.07 |
| Glu | 80.82 | 0.03 |
| Gln | 87.37 | 3.17 |
| Gly | 94.07 | 0.64 |
| His | 88.66 | 0.26 |
| Pro | 87.42 | 0.99 |
| Ser | 90.84 | 0.29 |
| Tyr | 72.84 | 0.52 |
| Ile | 69.85 | 0.27 |
| Leu | 69.76 | 0.44 |
| Val | 140.0 | 0.67 |
| Total AAs | | 10.48 |

**Conclusions:** Modern means of RRT eliminate AAs to an extent that has not been met by our nutritional support standards. Especially the removal of glutamine, important for immune function and cell regeneration, might have detrimental effects on the recovery of critically ill patients.

### Recombinant Human Soluble Thrombomodulin Administration Improves Septic Shock Requiring Continuous Renal Replacement Therapy: A Retrospective Cohort Study

Naoki Kurashima,[1] Atsushi Ohkubo,[1] Naofumi Yui,[2] Tatemitsu Rai.[2] *[1]Dept of Clinical Engineering, Tokyo Medical and Dental Univ, Japan; [2]Dept of Nephrology, Tokyo Medical and Dental Univ.*

**Background:** Recombinant thrombomodulin (rTM) has emerged as a new treatment option for disseminated intravascular coagulation (DIC). In addition to its anticoagulant properties, rTM is considered to produce direct anti-inflammatory effect. The purpose of this study is to evaluate the efficacy of rTM treatment to critically ill patients with septic shock requiring continuous renal replacement therapy (CRRT).

**Methods:** A retrospective analysis of patients admitted to the intensive care unit of our hospital between June 2009 and April 2013 was performed. Patients diagnosed as septic shock requiring transient CRRT were included. They were either treated with rTM (treatment group) or without rTM (control group) during CRRT. The primary outcome was the decrease in DIC score on day 3 after initiation of CRRT. Secondary outcomes were changes in the severity of patients' conditions on day 3 as assessed by Acute Physiologic and Chronic Health Evaluation II (APACHE II) score and the period of time required for withdrawal from CRRT. Data were expressed as group means ± standard deviations. The Mann-Whitney test was used for comparison and a $p$ value under 0.05 was considered statistically significant.

**Results:** Six and nine patients were assigned to the treatment and control groups, respectively. Baseline characteristics, including DIC and APACHE scores, showed no significant differences between the two groups. A significant decrease in the DIC score was seen in the treatment group compared with that in the control group (1.1 ± 1.1 vs -1.4 ± 2.1, respectively, $p$ = 0.0184). Decrease in APACHE II score also showed significant improvement (treatment group 9.8 ± 2.9 vs control group 4.0 ± 5.8, $p$ = 0.0339). The period until CRRT withdrawal was not significantly different between the two groups (treatment group 4.5 ± 1.8 days vs control group 6.8 ± 3.1 days, $p$= 0.1407).

**Conclusions:** In critically ill patients with septic shock requiring CRRT, treatment with recombinant thrombomodulin may improve patients' severity and coagulation disorders.

## FR-PO361

**Calcium and Phosphate Replacement during Continuous Renal Replacement Therapy with Regional Citrate Anticoagulation Predict Mortality in Critically Ill Patients**

Wee Kim Fong,[1] Markos George Kashiouris,[2] Venu Velagapudi,[2] Abbasali Akhoundi,[2] Kianoush Banaei-Kashani.[2]
*[1]Anesthesiology, Mayo Clinic, Rochester, MN; [2]Pulmonary and Critical Care Div, Mayo Clinic, Rochester, MN.*

**Background:** During the recovery phase, the regenerating cells consume phosphorus for cell cycle and growth. Therefore increase phosphorus requirement during CRRT may be in prognostication of critical illness recovery. On the other hand, increased calcium replacement requirement could indicate cell lysis . We hypothesized that the dosing of calcium and phosphate replacement during CRRT treatment, predicts hospital mortality.

**Methods:** We conducted a retrospective cohort study in eight intensive care units of a tertiary academic center in the United States. We collected demographic and laboratory data and constructed a database of critically ill patients who required CRRT with regional citrate anticoagulation, from December 2007 to January 2009. We performed logistic regression analysis to predict mortality, based on the amount of hourly calcium and phosphate replacement dose. We adjusted for severity of illness with the APACHE III score and comorbidities using the Charlson index score, independent of delivered dose of CRRT.

**Results:** We enrolled 595 patients into the study. The ICU and hospital mortality were 39.7% and 50.9%, respectively. The average APACHE III and Charlson score were 118 (95% CI 112.5 – 117) and 3.0 (95% CI 2.8 – 3.2), respectively. The median calcium and phosphorus replacement dose was 0.94 gr/h of CRRT (IQR 0.79 – 1.05) and 1.25 mMol/h of CRRT (IQR CI 0.8 – 1.8), respectively. In multivariate analysis, each additional incremental unit of the following was significantly associated with differential odds of death: APACHE III OR 1.014 (95% CI 1.007 – 1.02, p<0.01), calcium replacement dose OR 3.0 (95% CI 1.26 – 7.13, p=0.01) and phosphate replacement dose OR 0.67 (95% CI 0.52 – 0.86, p<0.01).

**Conclusions:** Increased calcium replacement and decreased phosphate replacement requirements during CRRT, were associated with increased mortality even after accounting for severity of illness and comorbid conditions.

## FR-PO362

**Perspectives of Continuous Renal Replacement Therapy: A Paired Survey Study of Patients, Physicians, and Nurses**

Andrew Allegretti,[1] Gregory L. Hundemer,[1] Katherine M. Cosgrove,[3] Ednan Bajwa,[3] Ishir Bhan.[2] *[1]Medicine, Massachusetts General Hospital, Boston, MA; [2]Nephrology, Massachusetts General Hosptial, Boston, MA; [3]Critical Care, Massachusetts General Hospital, Boston, MA.*

**Background:** Recent data in suggests considerable discrepancies between patients and providers with respect assessment of hemodialysis prognosis, but such data is lacking for patients undergoing continuous renal replacement therapy (CRRT). We sought compare the prognostic assessment of patients/health care proxies (HCPs) and their providers (physicians and nurses).

**Methods:** A multiple-choice questionnaire was given to a triad of participants around an index case of CRRT. Each triad included (1) a patient (or HCP) on CRRT, (2) his/her resident or attending ICU physician, and (3) his/her ICU nurse administering CRRT. Questionnaires were performed in medical and cardiac ICUs at a single tertiary care center. We assessed knowledge of the probability of patient survival to hospital discharge and the probability of requiring lifelong dialysis if discharged.

**Results:** Twenty two survey triads were completed. All patients/HCPs (n = 22/22) correctly identified the purpose of CRRT. Fifty five percent of patients/HCPs (n = 12/22) incorrectly thought CRRT improved the speed of renal recovery. Probability of survival to hospital discharge (accepted quartile: 25-49%) was correctly identified by 5% of patients/HCPs (n = 1/22), 50% of physicians (n = 11/22), and 45% of nurses (n = 10/22). Both physicians (p = 0.001) and ICU nurses (p = 0.002) were more likely than patients/HCPs to assess survival accurately. Probability of requiring lifelong dialysis if discharged (accepted quartile: 0-24%) was correctly identified by 35% of patients/HCPs (n = 6/17), 23% of physicians (n = 5/22), and 36% of nurses (n = 8/22). Seventy three percent of patients/HCPs (n = 16/22) felt that their doctors "completely" explained the purpose of CRRT.

**Conclusions:** Understanding of CRRT and knowledge of prognosis is poor among patients/HCPs and ICU providers. Patients may overestimate their level of understanding of CRRT. Further intervention is needed to improve this knowledge gap for patients/HCPs, physicians, and ICU nurses.

## FR-PO363

**Hemodialysis Initiation Associates with Highest Stroke Risk in U.S. and European Populations**

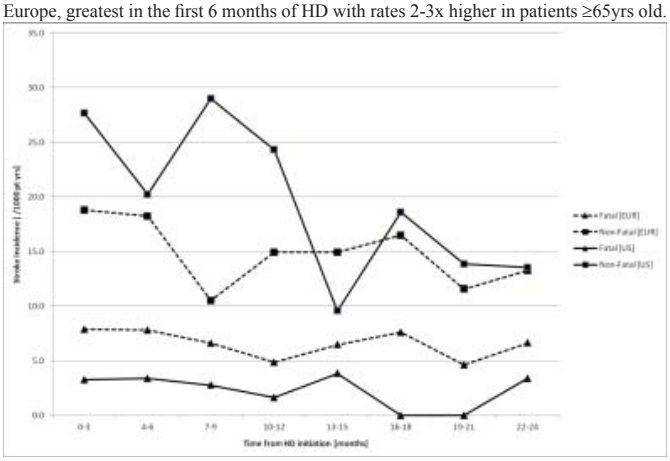
Albert J. Power,[1] Len A. Usvyat,[2] Daniele Marcelli,[3] Neill D. Duncan,[1] Charles D. Pusey,[1] Peter Kotanko,[2] Bernard Canaud,[3] Mondo Consortium.[4] *[1]Imperial College London, London, United Kingdom; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care (FMC), Germany; [4]MONDO Research Consortium.*

**Background:** Stroke is a major cause of death in the US with hemodialysis [HD] patients particularly at risk with rates >8x higher than the general population. Initiation of HD in the elderly appears to confer much greater stroke risk in the US. In the absence of published data we examined if this applied globally especially in younger patients.

**Methods:** The MONDO research initiative consists of HD databases from the US, Europe, Asia & Latin America [Usvyat, Blood Purif 2013]. All incident patients from US Renal Research Institute [RRI] clinics & Fresenius Medical Care [FMC] Europe clinics within 30d of their first ever dialysis [Jan 2010-May 2013] were studied with follow up for a maximum of 2yrs with fatal & non-fatal hospitalized stroke defined by ICD-9 & 10 coding and excluding transient ischemic attack.

**Results:** We studied 1030 strokes in 37793 patients [FMC Europe n=32892; RRI n=4901]. Overall stroke incidence was 22.3 /1000 pt yrs [95%CI 21.0-23.8], higher in patients ≥65yrs old [13.5 vs 30.5 /1000 pt yrs, p<0.001] and similar between Europe & the US [22.1 vs 24.2 /1000 pt yrs, p=0.2].

Stroke incidence was highest within 6 months of HD initiation particularly driven by peak rates of non-fatal stroke [Fig 1]. Incidence of fatal stroke was consistently higher in Europe, greatest in the first 6 months of HD with rates 2-3x higher in patients ≥65yrs old.



**Conclusions:** The first 6 months of HD initiation are a time of maximal stroke risk in all patients, especially in older people who experience greater stroke mortality. Urgent studies are required to reduce the disproportionately high incidence of stroke in HD populations with focus on modulating stroke risk by modifying the HD prescription.

## FR-PO364

**Identical Index Hospitalization and 30-Day Readmission Discharge Diagnosis Codes**

Eduardo K. Lacson, Weiling Wang, Franklin W. Maddux.
*Fresenius Medical Care, North America, Waltham, MA.*

**Background:** Potentially preventable hospital readmissions are most likely those that have the same diagnosis between the index and 30-day readmission events. We preliminarily determined the most common diagnosis codes in hemodialysis (HD) patients.

**Methods:** All adult in-center HD patients, treated 3x/ week as of 1/1/11 in Fresenius Medical Care, North America facilities with at least one hospital discharge in 2011 were followed up to 12/31/11. Hospital readmissions within 30-days of discharge were recorded, along with the index primary discharge and readmission ICD-9 codes (also as classified into diagnosis categories). We sought to determine the most frequent pairs of similar hospital diagnoses.

**Results:** There were 164,258 hospital events in 64,128 patients in 2011. 50,380 (30.7%) 30-day readmissions occurred in 23,575 patients. There were 8,965 (17.8%) readmissions (852 valid ICD-9 codes) with the exact diagnosis as in the index admission. The 10 most common identical ICD-9 code pairs for index and readmission diagnoses are shown in the table.vFluid overload conditions that may present as shortness of breath and CHF rank #1, #2, and #7 on the list, totaling ~11.2% of readmissions. The mean time from discharge to readmission was 10.4±8.3 days (IQR: 3-16; median: 8).The mean (weighted) rate of identical diagnoses was 22.7% for 30-day readmissions. 4,255 of 50,380 (8.4%) readmissions with identical diagnoses occurred within 7 days of discharge.

| Order | ICD-9 Code & Description of Readmission | N of Readmissions | % | N of Same ICD-9 in Prior Hospitalization | % of Same ICD-9 in Prior Hospitalization |
|---|---|---|---|---|---|
| 1 | 786.05 - SHORTNESS OF BREATH | 2484 | 4.93 | 709 | **28.5** |
| 2 | 276.69 - OTHER FLUID OVERLOAD | 1975 | 3.92 | 539 | **27.3** |
| 3 | 786.5 - CHEST PAIN | 1642 | 3.26 | 451 | **27.5** |
| 4 | 780.97 - ALTERED MENTAL STATUS | 1344 | 2.67 | 328 | **24.4** |
| 5 | 780.99 - OTHER GENERAL SYMPTOMS | 634 | 1.26 | 316 | **49.8** |
| 6 | 996.1 - MECHANICALCOMPLICATIONOFIMPLANT,GRAFT | 659 | 1.31 | 255 | **38.7** |
| 7 | 428.0 - CONGESTIVEHEARTFAILURE | 1173 | 2.33 | 248 | **21.1** |
| 8 | 996.73 - OTHER COMPLICATION | 676 | 1.34 | 230 | **34.0** |
| 9 | 787.01 - NAUSEAW/VOMITING | 764 | 1.52 | 202 | **26.4** |
| 10 | 578.9 - HEMORRHAGE OF GASTRO INTESTINAL TRACT | 699 | 1.39 | 201 | **28.8** |

**Conclusions:** Among identically diagnosed readmissions, the most common potentially actionable condition is fluid related. The identical diagnosis rate of 8% of readmissions within 7 days of discharge indicate potential problems with transition to outpatient care and/or that some patients were discharged from the hospital prematurely. Further study is needed in these subgroups of patients to evaluate for actionable items to avoid readmissions.

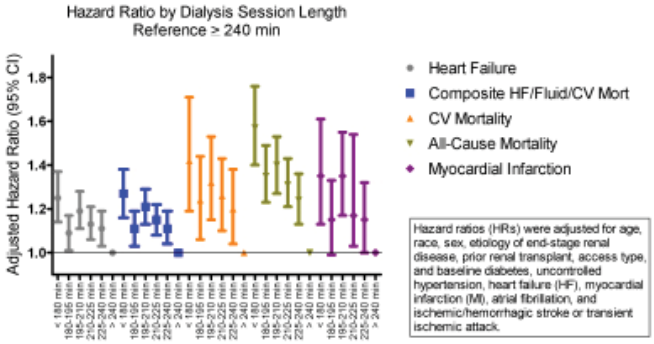
## FR-PO365

**Shorter Hemodialysis Session Length Is Strongly Associated with Higher Rates of Mortality and Hospitalization** Steven M. Brunelli,[1] Emmanuel A. Anum,[1] Karthik Ramakrishnan,[1] Donna E. Jensen,[1] Gilbert Marlowe,[1] Mahesh Krishnan,[1] Allen R. Nissenson.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita Healthcare Partners, Denver, CO.*

**Background:** Prescribing patterns of hemodialysis (HD) vary widely. Prior data demonstrate that shorter HD session length is associated with increased mortality. There is a paucity of data with respect to associations with cause-specific morbid events. The objective of the current study was to determine the relationship between duration of HD and rates of cardiovascular (CV) mortality and events.

**Methods:** The records of in-center HD patients incident to dialysis (1-Jan-07 through 31-Dec-08), treated at DaVita within 30 days of first HD and having Medicare or Medicaid as a primary insurer were studied. Mean session length was calculated over days 91-180. Patients were at-risk for outcomes beginning on day 181 of HD and continuing until death, transfer of care, modality change, or end of study (31-Dec-09). Outcomes were identified through linkage to US Renal Data Systems claims data and included hospitalization for heart failure (HF)/fluid overload, myocardial infarction (MI), all-cause mortality, CV mortality, and a composite hospitalization for HF/fluid overload or CV mortality.

**Results:** Of ~150,000 DaVita patients, 39,497 patients qualified for study. All-cause mortality was greatest for patients receiving mean sessions <180 min (HR 1.57; CI95% 1.40-1.76) and lowest for those receiving mean sessions ≥ 240 min (HR 1, reference).



A similar dose effect was observed with CV mortality, the composite outcome, and hospitalization for HF and MI.

**Conclusions:** These data demonstrate a strong association between shorter dialysis session length and CV events causing hospitalization and death.

*Funding:* Pharmaceutical Company Support - This analysis was supported by Ardelyx, Inc. This publication is supported by DaVita Healthcare Partners, Inc.

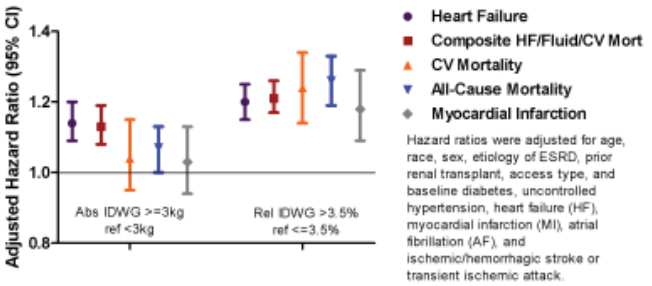
## FR-PO366

**Interdialytic Weight Gain and Cardiovascular Disease Outcomes** Steven M. Brunelli,[1] Claudia S. Cabrera,[2] David P. Rosenbaum,[3] Emmanuel A. Anum,[1] Karthik Ramakrishnan,[1] Donna E. Jensen,[1] Nils-olov Stalhammar,[2] Bergur V. Stefansson.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]AstraZeneca, Molndal, Sweden; [3]Ardelyx, Inc., Fremont, CA.*

**Background:** Patients with end-stage renal disease (ESRD) have a higher risk of cardiovascular (CV) disease-related morbidity and mortality than the general population. One putative risk factor for this is fluid accumulation between hemodialysis (HD) sessions; measured as interdialytic weight gain (IDWG). This analysis examined associative risks between IDWG with incident CV events and deaths.

**Methods:** Study patients were incident to HD (1Jan2007-31Dec2008) and were on in-center HD for at least 181 days. Exposures of interest were absolute and relative IDWG (IDWG as percentage of body weight), each considered as patients' mean value over dialysis days 91-180. Outcomes are listed below and were obtained by linkage to USRDS claims data. Patients were considered at-risk from dialysis day 181 until death, care transfer, voluntary withdrawal, modality change, or study end (31Dec2009).

**Results:** Among the study population (N=39,497) mean age was 62 years; 46% were white, 32% black, 15% Hispanic; 47% had ESRD attributed to diabetes. Absolute IDWG >3kg (26% of patients) was independently associated with greater risk of composite hospitalization and all-cause mortality; Relative IDWG >3.5% (37% of patients) was independently associated with greater risk of HF, composite HF/CV mortality, CV mortality, all-cause mortality, and MI; magnitudes of association were greater than for absolute IDWG.



Considered granularly, there was a strong incremental dose-response association between relative IDWG and all outcomes considered.

**Conclusions:** This analysis found increased risk of CV events for ESRD patients undergoing HD with greater IDWG. Mitigating IDWG may improve health and survival among ESRD patients.

*Funding:* Pharmaceutical Company Support - Ardelyx Inc.

## FR-PO367

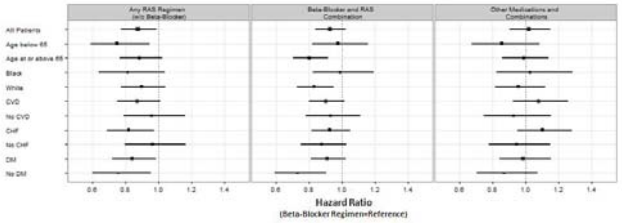
**Antihypertensive Medications and Mortality in Incident Hemodialysis Patients: A Marginal Structural Analysis of a National Cohort** Stephen M. Sozio,[1,2] Tariq Shafi,[1,2] Wendy L. St. Peter,[1,3] Karen J. Bandeen-Roche,[1,2] Patti Ephraim,[1,2] Jason Luly,[1,2] L. Ebony Boulware.[1,2] *[1]DEcIDE Network Patient Outcomes in ESRD Study Investigators; [2]Johns Hopkins Univ; [3]Chronic Disease Research Group.*

**Background:** Despite the burden of hypertension in dialysis patients, the optimal blood pressure medication (BPM) regimen has not been determined.

**Methods:** We performed a retrospective cohort study of all adult patients initiating hemodialysis at Dialysis Clinic, Inc. facilities from 2003-2008 and prescribed a BPM at 6 months. We obtained clinical parameters, BPMs, and outcomes from linked dialysis electronic medical records, USRDS data, and the National Death Index. We classified BPM regimens into 4 mutually exclusive regimens: β-blocker, renin-angiotensin system agent (RAS), β-blocker+RAS containing, or other BPMs. We also allowed discontinuation of BPMs if they were no longer prescribed in follow-up. We quantified each regimen's effect on all-cause and cardiovascular mortality using discrete time proportional hazards regression. Time-varying marginal structural models accounted for confounders and patient-level predictors of BPM prescriptions, including predialysis systolic BP and volume removal on dialysis.

**Results:** Among 11,291 hemodialysis patients, the mean age was 62 yrs, 55% male, 53% White, 56% had CVD and 3200 died in follow-up. Compared to β-blocker regimens, RAS regimens were associated with lower all-cause mortality (HR [95% CI] 0.82 [0.69, 0.97] for RAS regimens, and 0.93 [0.84, 1.02] for β-blocker+RAS regimens), and discontinuing BPMs was associated with higher mortality (HR 1.22 [1.02, 1.46]). Similar results were seen when analyzing cardiovascular mortality.

**Figure: Association of Medication Use on All-Cause Mortality in Incident HD Patients**



**Conclusions:** RAS regimens are associated with lower risk of mortality for patients receiving hemodialysis, and may be preferred in this population. Further studies are warranted to identify additional effects of these agents.

*Funding:* Other U.S. Government Support

## FR-PO368

**Lower Predialysis Blood Pressure Is Associated with Worse Physical Function in HD Patients** Adrian Paul Abreo,[1] Charles A. Herzog,[2] Janice P. Lea,[3] Nancy G. Kutner,[3] Patricia Lynn Painter,[4] Kirsten L. Johansen.[1] *[1]UCSF; [2]Hennepin County Medical Center; [3]Emory; [4]Univ of Utah.*

**Background:** New data suggests tight blood pressure (BP) control may not reduce mortality and may be associated with more side effects. The link between BP and physical function (PF) has not been examined in patients on HD.

**Methods:** We performed a cross-sectional analysis to examine the association between predialysis systolic blood pressure (PBP) and the short physical performance battery (SPPB) among 765 patients in the USRDS ACTIVE/ADIPOSE cohort. The SPPB assesses lower extremity function and includes 3 components: timed repeated chair stands, tests of balance test, and a timed 15-ft walk. PBP was grouped into the following categories: <110, 110-129, 130-159, and ≥160. We used multivariate ordinal logistic regression with PBP as the primary predictor, and SPPB categorized into three ordinal groups (≤6, 7-9, 10-12).

**Results:** Mean age was 55 yr. Participants with PBP 130-159 and ≥160 had lower odds of being in the lowest SPPB category compared to the 110-129 (reference) group (Table), even when BP medication use was added to the model. Each component of the SPPB showed the same pattern of association but results for balance were not statistically significant. **Higher PBP is associated with lower odds of worst PF.**

| CAD | 0.90(0.50-1.62) | 0.73 |
| ESRD vintage (log) | 1.11(0.96-1.28) | 0.15 |

**Conclusions:** PBP at traditionally targeted levels was associated with worse PF among patients on HD, independent of heart failure and BP medications. The risk-benefit tradeoff of aggressive BP control, particularly in low-functioning patients, should be reexamined.

**Characteristics and Outcomes of End-Stage Renal Disease Patients with Cardiac Rhythm Management Device Infections** Oluwaseun Opelami, Ankit Sakhuja, Xiaobo Liu, Jesse D. Schold, Sankar D. Navaneethan. *Cleveland Clinic, Cleveland, OH.*

**Background:** Sudden cardiac death due to arrhythmias remains the leading cause of death in end-stage renal disease (ESRD). This has led to increased use of cardiac rhythm management devices (CRMD) in ESRD patients, contributing to the increased rates of CRMD infection-related hospitalizations. We studied the characteristics and outcomes of ESRD patients admitted with CRMD infections in a large national inpatient database.

**Methods:** We conducted a retrospective analysis of the Nationwide Inpatient Sample (NIS) discharge records (2005-2010). We identified patients with CRMD infections using the ICD-9 codes for device-related infections or other device procedure (change and/or removal) along with bacteremia, endocarditis or systemic infection. Logistic regression and linear regressions were performed to examine inpatient mortality, length of stay and cost in ESRD patients after adjusting for patient demographics, primary payer and hospital characteristics.

**Results:** Of the 88,008 admissions for CRMD infections, 6,751 of them (7.7 %) were ESRD patients. ESRD patients were younger and had higher proportion of African Americans and Hispanics. In the multivariable model, ESRD patients had higher odds (OR = 2.58, 95% CI: 2.2, 3.1) of in-hospital mortality, compared to non-ESRD patients. Among survivors, the mean length of stay for ESRD patients was 18.1 days as compared to 11.9 days among non-ESRD patients (p<0.0001). The mean total charges during the hospitalization for the ESRD group was $158,640 as compared to $102,943 among non-ESRD group (p<0.0001). Among ESRD population, only 26.3% were discharged home (vs. 33.5% in non-ESRD group, p<0.001) and 51.1% were transferred to skilled nursing facility or other rehabilitation center (vs. 34.9% in non-ESRD group, p<0.001).

**Conclusions:** End stage renal disease patients admitted with cardiac rhythm management device-related infections have an increased risk of in-hospital mortality, length of stay and higher costs. Furthermore, ESRD patients most commonly require skilled nursing facilities following discharge, further increasing healthcare costs.

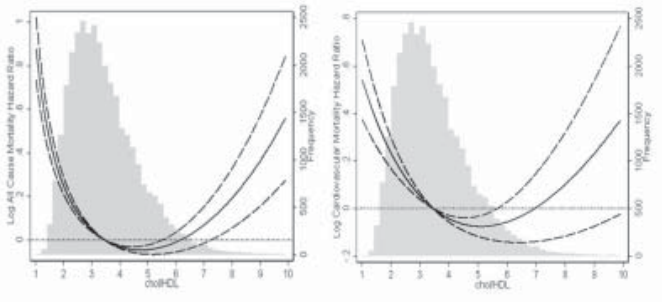
## FR-PO370

**Elevated Serum Total Cholesterol to High Density Lipoprotein (HDL) Ratio Is Paradoxically Associated with Improved Overall and Cardiovascular Mortality in Patient on Hemodialysis** Hamid Moradi,[1,2] Elani Streja,[1,2] Moti L. Kashyap,[2] Nosratola D. Vaziri,[1] Gregg C. Fonarow,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Orange, CA; [2]Univ of California, Irvine; [3]Univ of California, Los Angeles.*

**Background:** In the general population, increasing serum total cholesterol to HDL ratios are associated with increased risk of cardiovascular (CV) mortality. This association is not well established in patients with end stage renal disease. We hypothesize that the association of serum total cholesterol to HDL ratio with all-cause and CV mortality in hemodialysis patients is different from the general population.

**Methods:** We examined the survival impact of serum total cholesterol to HDL ratio in a 3-year (6/2004-6/2007) cohort of 33,109 maintenance hemodialysis patients being treated in clinics of a large dialysis organization using Cox models adjusted for demographics and case-mix variables and cubic splines plots.

**Results:** In this cohort the mean age (mean + SD) was 60+15 years old and included 45% women, 33% African-Americans, and 61% diabetics. In the fully adjusted models, higher serum total cholesterol to HDL ratios were paradoxically associated with better overall and CV survival. This trend remained significant until the cholesterol/HDL ratio increased beyond 6.



**Conclusions:** Increasing serum total cholesterol to HDL ratio are paradoxically associated with improved all-cause and CV mortality in patients on maintenance hemodialysis. These associations are significant despite adjustment for demographics and case-mix variables. The underlying mechanisms responsible for these seemingly paradoxical associations await further investigation.

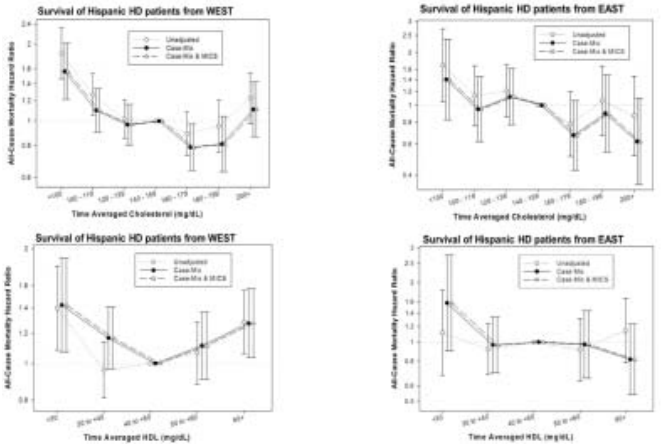
## FR-PO371

**Association of Lipid Profile with Mortality in Dialysis Patients of Hispanic Origin in the East versus West Coast** Hamid Moradi,[1,2] Elani Streja,[1,2] Nosratola D. Vaziri,[1] Moti L. Kashyap,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]Univ of California, Irvine; [2]Harold Simmons Center, Orange, CA; [3]Memphis Veterans Affairs Medical Center.*

**Background:** We have previously shown that in Hispanic patients on maintenance hemodialysis (MHD) paradoxical associations exist between serum lipid levels and mortality. However, significant racial and ethnic differences exist in patients of "Hispanic" background. While the Hispanic population of the West Coast consists mainly of those from Mexico and Central America, on the East Coast there is a large Afro-Caribbean contingency. We hypothesized that major differences exist in association of dyslipidemia and survival in Hispanic MHD patients on the West versus East Coast.

**Methods:** We examined the survival impact of serum lipids in a 2-year (6/2005-6/2007) cohort of 5,185 maintenance hemodialysis patients of Hispanic origin being treated in clinics of a large dialysis organization (in California, Texas, New York, New Jersey and Florida) using Cox models adjusted for case-mix and markers of malnutrition-inflammation complex (MICS) variables.

**Results:** In this cohort there were 4,220 patients from the West and 965 from the East Coast. In the fully adjusted models, significant differences were noted in the association of lipid markers and mortality in Hispanic patients from the West when compared to the East Coast.



**Conclusions:** Significant differences exist in association of serum lipids with mortality in MHD patients of Hispanic background depending on whether they live on the West or East Coast of the United States. These geographical discrepancies most likely reflect ethnic and racial differences which usually go unnoticed. Future studies should take into account these critical variations in a population of patients who will make up a majority of our society in the future.

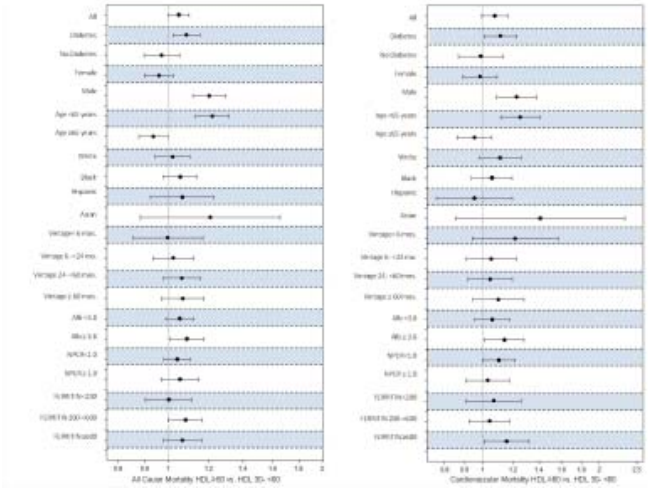
**FR-PO372**

**Subgroup Analysis of Hemodialysis Patients with Elevated Serum High Density Lipoprotein (HDL) Cholesterol Levels Demonstrates Men and Those Younger Than 65 Years of Age Have the Greatest Risk of Overall and Cardiovascular Mortality** Hamid Moradi,[1,2] Elani Streja,[1,2] Moti L. Kashyap,[2] Nosratola D. Vaziri,[2] Gregg C. Fonarow,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Orange, CA; [2]Univ of California, Irvine; [3]Univ of California, Los Angeles.*

**Background:** In the general population, increasing levels of HDL are associated with reduced cardiovascular (CV) mortality. We hypothesize that the association of serum HDL concentration and mortality in hemodialysis patients is different from the general population and that in subgroups of patients on dialysis, elevated serum HDL cholesterol level may be paradoxically associated with increased mortality.

**Methods:** We examined the survival impact of serum HDL level in a 3-year (6/2004-6/2007) cohort of 33,109 maintenance hemodialysis patients being treated in clinics of a large dialysis organization using Cox models adjusted for demographics and case-mix variables. Hazard ratio of overall and cardiovascular mortality for two selected dichotomized levels of serum HDL cholesterol concentrations (left: 30- <60 mg/dl; right: ≥60 mg/dl) were plotted in selected subgroups of the study population.

**Results:** In this cohort, the mean age (mean + SD) was 60+15 years old and included 45% women and 61% diabetics. All-cause and CV mortality HR was 1.05 (1.00-1.10) and 1.08(1.00-1.16) for HDL≥60 mg/dL, respectively (reference: HDL 30-<60 mg/dL). This risk was highest in men, diabetics, those with albumin > 3.8 g/dL and in those under the age of 65.



**Conclusions:** Serum HDL cholesterol levels over 60 mg/dL are associated with increased all-cause and CV mortality in patients on hemodialysis and this risk is most pronounced in men and those younger than 65 years of age. Further studies are needed to determine the mechanisms responsible for these associations.

*Funding:* NIDDK Support

**FR-PO373**

**Intradialytic Cardiac Function and Inflammatory Cytokine Changes during Acetate-Free Online Hemodiafiltration Compared with Standard Online Hemodiafiltration in End-Stage Renal Disease Patients** Kamonwan Tangvoraphonkchai, Khajohn Tiranathanagul, Nattachai Srisawat, Paweena Susantitaphong, Kriang Tungsanga, Somchai Eiam-ong, Kearkiat Praditpornsilpa. *Div of Nephrology, Dept of Medicine, King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn Univ, Thailand.*

**Background:** Acetate in standard dialysis fluid could suppress myocardial function and potentially induce cytokine production, resulting in intradialytic hypotension(IDH) in hemodialysis(HD) patients. Online hemodiafiltration(HDF) provides superior intradialytic hemodynamic stability over HD. The present study was aimed to investigate the potential additive hemodynamic benefits and cytokine changes of the novel acetate-free dialysis fluid in online HDF.

**Methods:** A randomized, double-blind, crossover clinical trial was conducted in 22 stable online HDF patients. The patients were randomly assigned to firstly receive either acetate-free or standard online HDF and then were switched to the other after one week. Clinical parameters, cardiac index(CI), cardiac output(CO), and peripheral vascular resistance(PVR) were hourly assessed as well as the cytokines(IL-2ß, IL-6, IL-8, IL-10, and TNF-α) were measured at pre- and post-dialysis in each study session.

**Results:** The baseline clinical and cardiac parameters were similar between acetate-free and standard online HDF groups. There were comparable changes of arterial pressure($p$=0.86) and the incidences of composite IDH and other adverse events between both groups. The changes of CI, CO, and PVR during dialysis were comparable($p$ = 0.53, 0.20, and 0.64,respectively). The percent reductions of NT-proBNP and troponin-T were not significantly different($p$=0.99 and $p$=0.51). The changes of IL-2ß, IL-6, IL-8, TNF-α, and IL-10 during dialysis were not significant different between both groups.

**Conclusions:** In stable online HDF patients, acetate in the standard dialysis fluid did not adversely affect clinical and cardiac parameters. The hemodynamic stability provided by online HDF might protect the adverse effects of acetate. Therefore, utilization of the costly acetate-free dialysis fluid did not offer additional cardiac benefits for stable online HDF patients.

**FR-PO374**

**Racial Differences in Intra-Dialytic Blood Pressure–Results from the HEMO Study** Finnian R. McCausland, Sushrut S. Waikar. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Racial differences in blood pressure control are evident in both the general and hemodialysis populations, with Blacks generally having higher blood pressure than non-blacks. We examined for differences in intra-dialytic blood pressure parameters according to race in a post-hoc analysis of hemodynamic data from the HEMO Study.

**Methods:** Data from 1825 participants were analyzed, using self-reported race (categorized as Black, Hispanic vs non-Hispanic white) as the exposure of interest. The association of race with nadir intra-dialytic systolic (SBP) and diastolic (DBP) blood pressure was analyzed with generalized linear regression models.

**Results:** The mean age was 57.8 years; 44.7% were diabetic. Blacks accounted for 62.3% and Hispanics for 5.9% of total participants. In unadjusted analyses, compared with non-Hispanic whites, Hispanic and Black participants had 2.9 (95%CI -0.3 to 6.1) and 3.2 (95%CI 1.5 to 4.9) mmHg higher nadir SBP and 2.1 (95%CI -0.1 to 4.4) and 3.1 (95%CI 2.0 to 4.2) mmHg higher nadir DBP. Upon multivariable adjustment for potentially confounding covariates (including pre-dialysis BP), Blacks remained with significantly higher nadir SBP (3.2; 95%CI 1.8 to 4.6 mmHg) and DBP (2.0; 95%CI 1.2 to 2.8 mmHg). Similar patterns were found with post-dialysis systolic and diastolic pressures. There was no evidence for effect modification according to age in all models considered (p-interaction>0.2).

**Conclusions:** We found evidence for racial differences in intra-dialytic blood pressure control, with Blacks appearing to have less marked decline in SBP and DBP during dialysis compared with non-Hispanic whites. Further study is warranted to determine if intra-dialytic blood pressure stability is causally related to lower mortality in Black hemodialysis patients.

**FR-PO375**

**A Predictive Score for Cardiovascular Morbidity and Mortality in Hemodialysis Patients: Retrospective Cohort Study** Stefan D. Anker,[1] Iain A. Gillespie,[2] Kai-Uwe Eckardt,[3] Florian Kronenberg,[4] Sharon Richards,[2] Ronald L. Pisoni,[5] Bruce M. Robinson,[5] Daniele Marcelli,[6] Marc Froissart,[7] Jürgen Floege.[8] *[1]Charite Campus Virchow-Klinikum, Greece; [2]Amgen Ltd, United Kingdom; [3]Univ of Erlangen-Nuremberg, Germany; [4]Innsbruck Medical Univ, Austria; [5]Arbor Research Collaborative for Health; [6]Fresenius Medical Care, Germany; [7]Amgen Europe GmbH, Switzerland; [8]RWTH Univ of Aachen, Germany.*

**Background:** Simple clinical tools to assess HD patients' cardiovascular disease (CVD) risk do not exist, hence clinicians often rely on the Framingham Heart Study score designed to assess ten-year CV risk in the general population. Accordingly, this study aimed to derive and validate a risk score for two-year CV morbidity and mortality (CVMM) in 2007-09 incident European adult HD patients recruited in the second Fresenius Medical Care-based ARO cohort (AROii).

**Methods:** Using a modified Framingham approach, we derived and internally validated a two-year CVMM risk score in patients randomly assigned to either a development (N=4,831) or validation dataset (N=4,796). External validation was conducted in the DOPPS III cohort (N=10,615). Additional discrimination, compared to the Framingham score, was assessed.

**Results:** The two-year CVMM event rate was 22.6 per 100 person-years (95% Confidence Interval 21.9-23.4). Major risk markers included CVD history, increasing age, underlying diabetic nephropathy, high interdialytic weight change, high calcium and low hemoglobin levels. Traditional CV risk factors (gender, blood pressure, cholesterol) were absent. Our new risk score was predictive in AROii (c-index range 0.66-0.67),albeit less so in DOPPS (0.63). In contrast, the Framingham Score was not very predictive of CVMM in AROii (AUC 0.56). Additional discrimination analysis showed that 58% of patients' outcomes were correctly reclassified using our risk model parameters.

**Conclusions:** Our risk score for CVMM in HD patients, which is easy to apply and interpret, represents a major improvement over the Framingham score, the use of which may cloud clinical judgment and should be discouraged in the HD population.

*Funding:* Pharmaceutical Company Support - Amgen (Europe) GmbH

**FR-PO376**

**Associates of Cardiopulmonary Arrest during Hemodialysis** Jennifer E. Flythe,[1] Nien-chen Li,[2] Shu-Fang Lin,[2] Steven M. Brunelli,[1,3] Jeffrey L. Hymes,[2] Eduardo K. Lacson.[2] *[1]Brigham & Womens Hospital, Boston, MA; [2]Fresenius Medical Care, North America, Waltham, MA; [3]DaVita Clinical Research, Minneapolis, MN.*

**Background:** Cardiopulmonary arrest (CPA) during and immediately prior to or after hemodialysis (HD) treatment (i.e. peridialytic period) is a rare event (~7/100,000 treatments) that has a high case fatality rate. This study was designed to elucidate patient and procedural factors associated with peridialytic CPA in the largest cohort reported to-date.

**Methods:** Data from the period prevalent HD population of Fresenius Medical Care, North America over 2010 were analyzed. 924 in-center CPA events (cases) and 75,538 eligible controls were identified. Cases and controls were 1:5 matched on age (+/- 3 years),

sex, race, and diabetes status. A comprehensive multivariate logistic regression model screening for demographic, treatment, and laboratory factors was built to identify factors predictive of peridialytic CPA.

**Results:** All 924 cases were matched to 4614 controls: age (65.7 years), sex (50% male), race (60% white), and diabetes (72%). Missed HD sessions due to hospitalization (prior 30 days), coronary artery disease, heart failure, lower serum albumin and hemoglobin, lower dialysate potassium, higher serum calcium, higher erythropoietin stimulating agent dose, and nPCR (j-shape) were associated with peridialytic CPA. The final model is shown in the table. Dialysate sodium, calcium, and buffer (bicarbonate + acetate) were not significant factors.

| Variables in the Final Model | OR (95% CI) | Variables Removed by the Stepwise Procedure | |
|---|---|---|---|
| Missed HD due to hospitalization (y/ n) | 1.44*** (1.17-1.77) | | |
| Coronary Artery Disease | 1.37** (1.13-1.66) | BMI | Ferritin (ng/ml) x 100 |
| Heart Failure | 1.24* (1.03-1.50) | Vintage (x 100 days) | Bicarbonate (mEq/L) |
| Albumin (g/dL) | 0.63**** (0.51-0.78) | % Interdialytic Weight Gain | eKt/V |
| Hemoglobin (g/dL) | 0.82**** (0.76-0.88) | Treatment shortened >10 minutes (yes vs. no) | EDW |
| Calcium (mg/dL) | 1.18* (1.04-1.33) | Missed treatment without excuse (yes vs. no) | Dialysate Sodium |
| nPCR | 0.54*** (0.38-0.76) | Vascular access: catheter vs. F/G | Dialysate Calcium |
| ESA per Treatment (per 1000u) | 1.01* (1.00-1.02) | Phosphorus (mEq/L) | Dialysate Buffer (Bicarbonate + Acetate) |
| Dialysate Potassium (mEq/L) | 0.77* (0.63-0.94) | Potassium (mEq/L) | |
| nPCR$^2$ | 2.00*** (1.25-3.21) | | |

* p<0.05; ** p<0.01; *** p<0.001; **** p<0.0001

**Conclusions:** Markers of patient-related health status and modifiable procedural factors (dialysate potassium and ESA dose) are significant associates of peridialytic CPA. In addition to maximizing nutritional status, it may be prudent to limit exposure to low dialysate potassium (<2K+ bath) and to use the lowest effective ESA dose. However, further study of peridialytic CPA preventive strategies is needed.

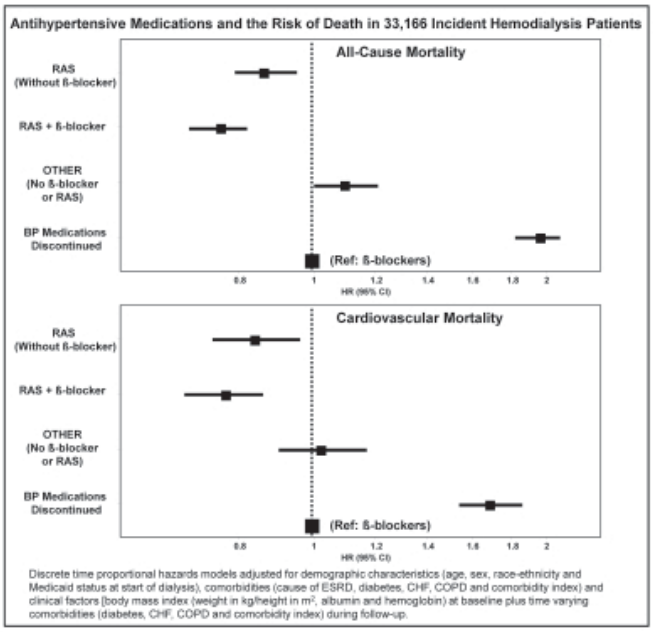
## FR-PO377

**Renin-Angiotensin System (RAS) Blocking Drugs Reduce the Risk of Death in U.S. Incident Hemodialysis (HD) Patients** Tariq Shafi,[1] Wendy L. St. Peter,[2] Stephen M. Sozio,[1] Patti Ephraim,[1] Karen J. Bandeen-roche,[1] L. Ebony Boulware.[1] *[1]Johns Hopkins Univ; [2]Univ of Minnesota.*

**Background:** The optimum blood pressure medication (BPM) regimen for patients on HD remains unclear. We quantified the association of BPM regimens with mortality in HD patients.

**Methods:** Our retrospective study cohort included 33,166 incident in-center US HD patients that initiated HD in 2006-2008 and were on HD at 6 months. We assessed BPM use from Medicare Part D prescription fill data and classified BPM use as 4 mutually exclusive regimens: β-blockers (BB), RAS, BB+RAS or OTHER regimens not including BB or RAS. Patients who discontinued BPM during follow-up constituted the 5th group. We used discrete time proportional hazards models adjusting for demographic and clinical characteristics including time-varying BPM use and comorbidities to assess the association between BPMs and death [all cause and cardiovascular (CV)]. Cause of death was assessed using Form 2746 and National Death Index.

**Results:** Patients' mean age was 65 years, 48% were male and 47% were White. At baseline (day 180), medication regimens were as follows: BB 37%, RAS 19%, BB+RAS 26% and OTHER 18%. There were 9,107 (28%) deaths during follow-up; 4,521 (50%) were due to CV causes. Patients in the BB group were more likely to have CV disease and congestive heart failure. In fully adjusted models, RAS-based regimens were associated with a lower hazard of mortality compared to BB regimens without RAS [HR (95% CI) for RAS group was 0.87 (0.79-0.95) for all-cause mortality and 0.84 (0.74-0.96) for CV mortality and for BB+RAS group was 0.75 (0.69-0.82) for all-cause mortality and 0.77 (0.68-0.86) for CV mortality].



**Conclusions:** RAS-based BPM regimens are associated with a lower risk of all-cause and CV death among HD patients. Our findings suggest that RAS agents may be preferred antihypertensive drugs for patients starting HD.

*Funding:* NIDDK Support, Other U.S. Government Support

## FR-PO378

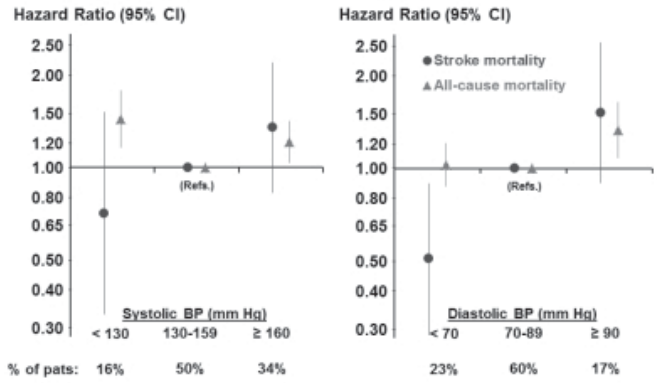
**Association of Pre-Dialysis Blood Pressure with All-Cause Mortality and Stroke in Japanese Hemodialysis Patients: The Japan DOPPS** Masaaki Inaba,[1] Angelo Karaboyas,[2] Takashi Akiba,[3] Tadao Akizawa,[4] Akira Saito,[5] Shunichi Fukuhara,[6] Christian Combe,[7] Bruce M. Robinson.[2] *[1]Osaka City Univ, Japan; [2]Arbor Research, Ann Arbor; [3]Tokyo Women's Medical Univ, Japan; [4]Showa Univ, Japan; [5]Tokai Univ, Japan; [6]Kyoto Univ, Japan; [7]Univ Bordeaux Segalen, France.*

**Background:** The association of low blood pressure (BP) with high mortality is characteristic for hemodialysis (HD) patients. In Japan, HD mortality is lower but there is a burden of high BP. This analysis clarifies the association of BP with mortality and stroke in Japanese HD patients, and examines the association separately for patients with and without antihypertensive medication (BP meds).

**Methods:** We analyzed 9,134 patients from Japan in phases 1-4 (1999-2011) of the Dialysis Outcomes and Practice Patterns Study (DOPPS), a prospective cohort study of in-center HD patients. The association of pre-dialysis systolic (SBP) and diastolic (DBP) BP with all-cause and stroke mortality was assessed using adjusted Cox regression.

**Results:** 34% had SBP ≥160 mm Hg. A U-shaped association between SBP and all-cause mortality was observed (Figure); no evidence of interaction (p=0.97) was found between SBP and use of BP meds. Both SBP and DBP were positively and monotonically associated with stroke mortality: hazard ratio (95% CI) was 1.24 (1.01-1.53) per 20 mmHg higher SBP and 1.23 (1.05-1.44) per 10 mmHg higher DBP. The association between SBP and stroke mortality was slightly stronger (p=0.09) among patients not on BP meds than on BP meds.

**Conclusions:** This analysis documents a positive and monotonic association of BP with stroke-related deaths in Japanese HD patients. High BP remains common, and while our analysis indicates that the prescription of BP meds to hypertensive patients might protect against stroke-related death, additional study is warranted.



Association of Systolic (SBP) and Diastolic (DBP) Blood Pressure with stroke and all-cause mortality; 4 separate Cox models, each stratified by DOPPS phase and adjusted for age, sex, vintage, BMI, 12 comorbidities, albumin, creatinine, phosphorus, hemoglobin, IDWG, Kt/V, and accounted for facility clustering.

*Funding:* Pharmaceutical Company Support - The DOPPS is supported by research grants from Amgen (founding sponsor, since 1996), Kyowa Hakko Kirin (since 1999, in Japan), AbbVie (since 2009), Sanofi Renal (since 2009), Baxter Healthcare (since 2011), and Vifor Fresenius Medical Care Renal Pharma (since 2012), with additional country-specific support provided in Canada by Amgen-Canada, Janssen, BHC Medical, Takeda and Kidney Foundation of Canada, and in Germany by Hexal and WiNe Institute. Support from the DOPPS sponsors is provided without restrictions on publications.

## FR-PO379

**Skin Autofluorescence Predicts Cardiovascular Mortality in Patients on Chronic Hemodialysis** Hiroshi Kimura, Kenichi Tanaka, Makoto Kanno, Kimio Watanabe, Yoshimitsu Hayashi, Koichi Asahi, Hiroyuki Terawaki, Masaaki Nakayama, Tsuyoshi Watanabe. *Nephrology, Hypertension, Diabetology, Endocrinology and Metabolism, Fukushima Medical Univ School of Medicine, Fukushima, Japan.*

**Background:** Tissue accumulation of advanced glycation end products (AGE) is thought to contribute to the progression of cardiovascular disease (CVD). Skin autofluorescence, a non-invasive measure of AGE accumulation using autofluorescence of the skin under ultraviolet light, has been reported to be an independent predictor of mortality and associated with CVD in Caucasian patients on chronic hemodialysis. The aim of this study was to assess the predictive value of skin autofluorescence on all-cause and cardiovascular mortality in non-Caucasian (Japanese) patients on chronic hemodialysis.

**Methods:** Baseline skin autofluorescence was measured with an autofluorescence reader in 128 non-Caucasian (Japanese) patients on chronic hemodialysis. All-cause and cardiovascular mortality was monitored prospectively during a period of 6 years.

**Results:** During the follow-up period, 42 of the 128 patients died; 19 of those patients died of CVD. Skin autofluorescence did not have a significant effect on all-cause mortality. However, age, carotid artery intima-media thickness (IMT), serum albumin, high-sensitivity C-reactive protein (hsCRP), skin autofluorescence and pre-existing CVD were significantly correlated with cardiovascular mortality. Multivariate Cox regression analysis showed skin autofluorescence [adjusted hazard ratio (HR) 3.97; 95% confidence interval (CI) 1.67-9.43], serum albumin [adjusted HR 0.05; 95% CI 0.01-0.32], and hsCRP [adjusted HR 1.55; 95% CI 1.18-2.05] to be independent predictors of cardiovascular mortality.

**Conclusions:** The present study suggests that skin autofluorescence is an independent predictor of cardiovascular mortality in non-Caucasian (Japanese) patients on chronic hemodialysis.

## FR-PO380

**Comparative Risk of Sudden Cardiac Death in Incident Hemodialysis (HD) and Peritoneal Dialysis (PD) Patients** Shuling Li,[1] Charles A. Herzog.[1,2,3] *[1]USRDS/CVSSC, MMRF, Minneapolis, MN; [2]Hennepin County Medical Center; [3]Univ of MN.*

**Background:** HD initiation is a vulnerable period with a markedly heightened risk of death. We previously reported that the hazard of sudden cardiac death (SCD) is markedly increased in incident HD pts in the first 90 days after dialysis initiation. Few published data exist regarding SCD rate in the first 90 days after PD initiation and risk of SCD in HD vs PD pts.

**Methods:** Incident HD and PD pts in 2008-2010 were identified in the USRDS database. Pts were followed from initiation to earliest of death, transplant, modality change, recovery of kidney function, loss-to-follow-up, or 1 yr after initiation. SCD was determined from CMS Form 2746. Cumulative probability of SCD was estimated by Kaplan-Meier method. The association between modality and risk of SCD was examined using piecewise Cox PH model with the cut-offs of F/U intervals ≤ 3 mos., > 3-≤ 6 mos. and > 6-≤ 12 mos. and adjusted for pt baseline characteristics.

**Results:** A total of 314,233 HD and 19,476 PD pts were available for study. More HD than PD pts were aged 65+ yrs (51% vs. 36%) and black (29% vs. 22%), had DM or HTN (74% vs. 68%) as primary cause of ESRD, and comorbid conditions at initiation. The cumulative probability of SCD (HD vs. PD) was 2.5% vs. 0.6% at 3 mos. and 7.0% vs. 2.2% at 1 yr (p<0.001). Overall, HD pts had higher SCD rate than PD pts. But the rate for HD pts decreased steadily with increasing time on dialysis, compared with a roughly stable rate for PD pts (See Table). Although risk of SCD associated with HD attenuated with increasing time on dialysis, it remained a significant 94% higher for HD pts vs PD pts even after 6 mos. of initiation.

| | Rate (SCDs/1000 pt-yrs) | | Adj. HR (95% CI) |
|---|---|---|---|
| F/U intervals | HD | PD | (Ref:PD) |
| ≤ 3 mos. | 102.1 | 23.3 | **3.20 (2.64, 3.88)** |
| > 3 - ≤ 6 mos. | 74.3 | 20.5 | **2.75 (2.21, 3.41)** |
| > 6 - ≤ 12 mos. | 57.6 | 23.3 | **1.94 (1.66, 2.26)** |

**Conclusions:** The hazard of SCD is markedly higher for incident HD pts than PD pts, especially in the first 90 days after initiation. These findings highlight the importance of early prevention of SCD for HD pts at initiation.

*Funding:* NIDDK Support

## FR-PO381

**Risk of Death for Systolic and Diastolic Heart Failure in Dialysis Patients** Shuling Li,[1] Yan Hu,[1] Charles A. Herzog.[1,2] *[1]CVSSC, U.S. Renal Data System; [2]Univ of MN.*

**Background:** Heart Failure (HF) is reportedly the most prevalent cardiac disease in dialysis pts. Few data exist on the comparative outcome of systolic vs diastolic HF in stage 5D CKD.

**Methods:** We identified 191,709 dialysis pts (age ≥20) prevalent on 1/1/09, surviving through 2009, and continuously enrolled in Medicare in 2009 using the USRDS database. HF was identified from ICD-9 codes 398.91, 428.xx, 402.x1, 404.x1, and 404.x3 in 2009 claims and included systolic (428.2x), diastolic (428.3x), both systolic and diastolic (428.4x), and unspecified. F/U began on 1/1/2010 and ended at the earliest of death, transplant, or 12/31/2011. Unadjusted survival was estimated by Kaplan-Meier method. The risk of death associated with HF types was assessed in a Cox PH model adjusting for baseline characteristics.

**Results:** The overall prevalence of systolic, diastolic, both, and unspecified HF was 7%, 6%, 2%, and 22%, respectively. Prevalence of HF increased with age; by type, from 4% in 20-44 yrs to 8% in ≥75 yrs for systolic HF, 3% to 7% for diastolic HF, 1% to 2% for both HF, and 15% to 26% for unspecified HF. Two-year survival probability was 47% systolic, 51% both, 54% diastolic, and 58% unspecified HF, and 74% no HF (Fig 1). The adjusted hazards ratio (95% CI) for death was 1.90 (1.84. 1.95) and 1.58 (1.53, 1.63) for systolic and diastolic HF, respectively, compared with no HF (Fig 2).

**Fig 1. Unadjusted survival probability**

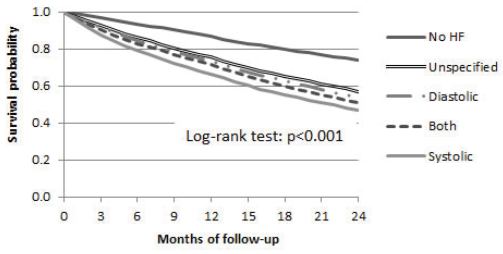


**Fig 2. Adjusted HR for Death by HF Type**

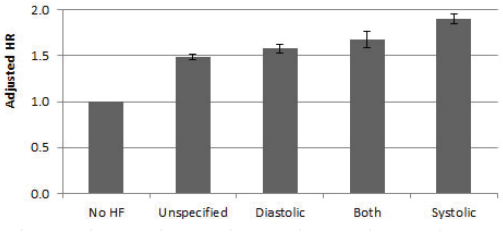

**Conclusions:** Dialysis pts with HF of any type have poor long-term survival. Systolic HF in Stage 5D CKD pts has the worst outcome. Interventions targeting this very high risk population are indicated.

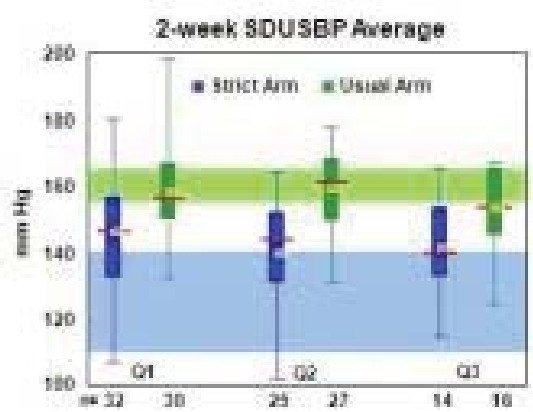
## FR-PO382

**Blood Pressure in Dialysis (BID) Study: A Pilot RCT Assessing Treatment to Two Different BP Targets** Jose L. Vega,[3] D. Miskulin,[1] Jennifer J. Gassman,[2] David W. Ploth,[4] Manisha Jhamb,[5] Christine Stidley,[3] P. Zager.[3] *[1]Tufts Medical Center; [2]Cleveland Clinic Foundation; [3]Dialysis Clinic Inc.; [4]Medical Univ of South Carolina; [5]Univ of Pittsburgh; [6]Univ of New Mexico.*

**Background:** The optimal blood pressure (BP) goal for treatment of hypertensive hemodialysis patients is unknown. More aggressive BP lowering may reduce cardiovascular events, or it may not be tolerated due to intradialytic hypotension. Which BP measure (in-center, home or ambulatory BP readings) should guide management is also unknown. In the ongoing NIH-sponsored Blood Pressure in Dialysis (BID) Study, hypertensive HD patients are randomized to a pre-dialysis in-center BP of 110-140/90 mm Hg vs. 155-165/90 mm Hg.

**Methods:** We assess adherence with prescribed in-center standardized (SDUBPM), home (HBPM) and ambulatory (ABPM) monitoring. SDUBPM was taken each treatment, after 5 minutes rest, 3 readings per sitting, per AHA guidelines. HBPM was to be done twice, 3 readings each sitting, on the day following the mid-week treatment. ABPM was done for 44 hours in one interdialytic period per quarter. We also compared the distribution of BPs across study arms over time.

**Results:** As of 05/01/13, blood pressure data were available for 51 randomized patients. Adherence with requirements for SDUBPM, HBPM and ABPM in the first 3 months (Q1) was 94, 54 and 16%, in Q2 was 84, 47, and 37%, and in Q3 was 79, 50, and 14% respectively. Boxplots of SDUBPM readings across treatment arms is shown in Figure 1. The mean (SD) separation between arms at the end of the 3rd, 6th, and 9th month was 12, 19, and 12mm Hg, respectively.



**Conclusions:** Current data show adherence to staff-measured SDUBPM was substantially better than patient-measured HBPM or ABPM. Only 50% or fewer of patients perform HBPM or ABPM at a given timepoint. Separation in BP between treatment arms was achieved at month 3 and was maintained at month 9.

## FR-PO383

**Blood Pressure in Dialysis (BID) Study: Differences in Blood Pressure Measured inside versus outside the Dialysis Unit** Jose L. Vega,[1] Jennifer J. Gassman,[3] D. Miskulin,[2] David W. Ploth,[4] Manisha Jhamb,[5] Christine Stidley,[1] P. Zager.[1] *[1]Dialysis Clinic Inc.; [2]Tufts Med Ctr.; [3]Cleveland Clinic Foundation; [4]Medical Univ of South Carolina; [5]Univ of Pittsburgh.*

**Background:** Although ambulatory blood pressure monitoring (ABPM) is considered the 'gold standard' for assessing BP since multiple readings are obtained while patients are performing usual activities, they may be difficult to obtain. Pre-dialysis BPs taken in the dialysis unit are used to manage patients, though these may lead to over-treatment as patients are volume expanded. In the Blood Pressure in Dialysis (BID) study we obtain 44-h ABPM, intermittent Home BP and standardized pre-dialysis dialysis unit BP (SDUBPM). We compare differences across measures at baseline.

**Methods:** SDUBPM was measured each treatment after 5 minutes rest prior to dialysis start. Home BPs were measured twice per day the day after the midweek treatment. ABPM was performed during a 44 h interdialytic period. We compared 44 h ABPM (day, night, full 44-hour) with the 2-week averaged SDUBPM (week before and during ABPM) and Home BP (average of week before and after ABPM).

**Results:** 51 patients had all 3 BP measurements within the allotted time frame. Comparisons of Systolic BP across measures are shown in the table.

| | Median (IQR) | > 10 mm Hg lower(%) | > 20 mm Hg lower(%) | > 10 mm Hg higher(%) | > 20 mm Hg higher(%) |
|---|---|---|---|---|---|
| ABPM Day - SDUBPM | -5.2 (-15.6, 7.3) | 43 | 18 | 24 | 14 |
| ABPM Night - SDUBPM | -3.9 (-16.9, 9.3) | 45 | 18 | 22 | 8 |
| ABPM Full - SDUBPM | -6.2 (-17.5, 7.5) | 39 | 2 | 24 | 12 |
| ABPM Day - Home BP | +4.5 (-8.9, 13.2) | 20 | 14 | 37 | 6 |
| ABPM Night - Home BP | +3.3 (-8.9, 14.4) | 24 | 10 | 33 | 12 |
| ABPM Full - Home BP | +4.3 (-8.9, 13.9) | 20 | 6 | 36 | 8 |

**Conclusions:** On average SDUBPM were higher than day and night ABPM. In contrast, Home BP values were lower than either day or night ABPM. However, SDUBPM were not always greater than ABPM and Home BPs were not always lower than ABPM. In a large number of patients the differences between measures were > 10 mm Hg. These results suggest that optimal control of BP in hemodialysis patients requires assessment of BP measured inside and outside the dialysis unit. The feasibility of obtaining ABPM and Home BP measurements longitudinally is being assessed in the ongoing BID Study.

*Funding:* NIDDK Support, Pharmaceutical Company Support - Dialysis Clinic Inc.

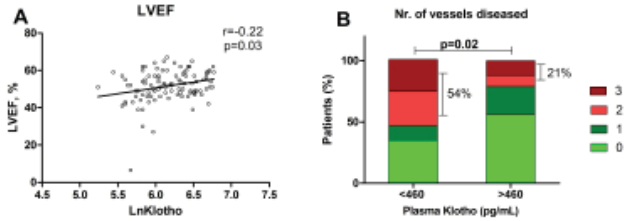
## FR-PO384

**Soluble Klotho Is Associated with Left Ventricular Function and Coronary Artery Stenosis in Dialysis Patients** Maurits S. Buiten,[1] Mihaly K. De Bie,[1] Bastiaan Van Van Dam,[3] Annet Bouma-de Krijger,[4] J.wouter Jukema,[1] Ton J. Rabelink,[2] Joris I. Rotmans.[2] *[1]Cardiology, LUMC, Leiden, Albinusdreef 2, Netherlands; [2]Nephrology, LUMC, Leiden, Albinusdreef 2, Netherlands; [3]Nephrology, MCA, Alkmaar, Netherlands; [4]Nephrology, Spaarne Ziekenhuis, Hoofdorp, Netherlands.*

**Background:** Dialysis patients suffer from a disproportionally high burden of cardiovascular disease which might be due to unique risk factors. Klotho, a protein linked to aging, has been suggested as such a factor. Recently an ELISA has become available to measure soluble Koltho (sKlotho). The purpose of the present study was to determine the relationship between sKlotho, coronary artery stenosis and left ventricular ejection fraction (LVEF) in dialysis patients.

**Methods:** Plasma levels of sKlotho were measured in dialysis patients. LVEF was measured using echocardiography. Coronary artery stenosis was determined by coronary CT scan. Coronary artery occlusion was defined as >50% luminal narrowing. Associations were analysed using linear regression.

**Results:** We included 129 patients (67±7 yrs old, 76% male, 65% HD as dialysis modality). Patients with a low sKlotho (<460pg/mL) had significantly more occluded coronary arteries compared to patients with a high sKlotho.



sKlotho was significantly associated with LVEF, however this association disappeared after adjustment for occluded coronary arteries. Furthermore, patients with high sKlotho used angiotensin receptor blockers (ARBs) and peritoneal dialysis more frequently and had significantly lower PTH.

**Conclusions:** Patients with higher sKlotho levels show significantly less occluded coronary arteries and a better cardiac function than patients with lower sKlotho. Further research is needed to show if low sKlotho levels play a role in the high cardiovascular burden of dialysis patients and if the correlation between ARBs and sKlotho represents a possible therapeutic benefit.

## FR-PO385

**Blood Pressure and Mortality in Patients with End Stage Renal Disease. Results from the CONvective TRAnsport STudy (CONTRAST)** Irina Mostovaya,[1] Michiel Bots,[2] Muriel Grooteman,[3] Marinus A. Van Den Dorpel,[4] Pieter M. Ter Wee,[3] Peter J. Blankestijn.[1] *[1]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Nephrology, VU Medical Center, Amsterdam, Netherlands; [4]Internal Medicine, Maasstad Hospital, Rotterdam, Netherlands.*

**Background:** Contradictory data has been reported on the relation between blood pressure (BP) and clinical events in dialysis patients. The aim of this study is to determine the association between different measures of BP and all-cause mortality in this population during follow-up.

**Methods:** Data from all 714 patients from the CONvective TRAnsport STudy (CONTRAST), were used for this analysis. The primary outcome of CONTRAST was all-cause mortality. At baseline, BP was measured thrice pre-, and thrice post-dialysis. The means of these pre- and post-dialysis measurements were computed, as well as the mean of all six BP measurements. Adjusted Cox proportional hazard models were used to study the relation between systolic BP (SBP), diastolic BP (DBP) and pulse presuure (PP) and mortality.

**Results:** At baseline mean age was 64±14 years, and 445 (62%) of patients were male. The means (of pre- and post- dialysis measurements averaged) of SBP, DBP and PP were 141±19, 73±11, and 68±16 mmHg respectively. After a median follow-up of 2.9 years a total of 269 patients died. The mean of both the pre- and the post-dialysis BP measurements was found to be more predictive for all-cause mortality, than the pre- or post-measurements alone. Patients in the highest tertile (>77mmHg) of DBP had an increased risk of mortality (hazard ratio (HR): 1.44, 95%CI: 1.03 - 2.02), versus patients in the lowest tertile (DBP<66mmHg, HR:1.0; DBP 66 - 77mmHg: HR: 1.31, 95%CI: 0.93 - 1.74). A similar trend, albeit not significant was observed between mortality risk and SBP, and PP.

**Conclusions:** The mean of both the pre- and the post-dialysis BP measurements is a better predictor for mortality, than pre- or post- measurements alone. Baseline DBP is a better predictor of mortality risk than SBP and PP in ESRD patients.

## FR-PO386

**Blood Pressure Changes over Time in Patients with End Stage Renal Disease. Results from the CONvective TRAnsport STudy (CONTRAST)**
Irina Mostovaya,[1] Michiel Bots,[2] Muriel Grooteman,[3] Marinus A. Van Den Dorpel,[4] Pieter M. Ter Wee,[3] Peter J. Blankestijn.[1] *[1]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]2 Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Nephrology, VU Medical Center, Amsterdam, Netherlands; [4]Internal Medicine, Maasstad Hospital, Rotterdam, Netherlands.*

**Background:** Limited data is available on changes over time of blood pressure (BP) in dialysis patients. The aim of this study is to assess changes over time of BP in dialysis patients and evaluate the impact of age, gender, medical history and dialysis-treatment related characteristics on these changes.

**Methods:** Data from all 714 patients from the CONvective TRAnsport STudy (CONTRAST), a randomized trial comparing online hemodiafiltration and low-flux hemodialysis, were used for this analysis. BP measurements [systolic BP (SBP), diastolic BP (DBP), mean arterial pressure (MAP) and pulse pressure (PP)] were performed at baseline and every 3 months up to 6 years, three times pre-, and three times post-dialysis. The means of these pre- and post-dialysis measurements were computed, as well as the mean of all six BP measurements (7025 measurements per variable in total). The rate of change over time of these parameters was estimated using linear mixed effects models.

**Results:** At baseline mean age was 64±14 years, and 445 (62%) of patients were male. SBP, DBP, MAP and PP all declined over time. For every incremental 10 years of age at baseline, the yearly excess decline of SBP was 1.7mmHg (p=0.02), and the excess decline of PP was 1.9 mmHg (p=0.002). Patients with a dialysis vintage of >2 years experienced an excess decline in SBP of 2.0 mmHg (p=0.01) and an excess decline in DBP of 0.4mmHg (p=0.003), when compared to those with a vintage of <2 years. Males experienced an excess decline of SBP of 1.6mmHg (p=0.03) and an excess decline of PP of 1.2mmHg (p=0.02) when compared to females.

**Conclusions:** 1) In dialysis patients all parameters of BP (SBP, DBP, MAP, PP) decline over time. 2) Age, gender and dialysis vintage are important determinants of the rate of decline of BP in this patients group.

## FR-PO387

**Effect of Anticoagulation and/or Antiplatelet Drugs on Cerebrovascular Events in Hemodialysis Patients: Miyazaki Dialysis Cohort Study (MID Study)**
Tatsunori Toida,[1] Yuji Sato,[1] Masao Kikuchi,[1] Hiroyuki Komatsu,[1] Shouichi Fujimoto.[2] *[1]Dept of 1st Internal Medicine, Faculty of Medicine, Univ of Miyazaki; [2]Dept of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki, Japan.*

**Background:** The beneficial effect of antiplatelet (AP) and anticoagulant (AC) drugs on cerebrovascular (CV) events has been shown in the general population, but has not been clarified in hemodialysis (HD) patients. The aim of this study was to examine the association between the onset of CV events and these drugs in Japanese HD patients.

**Methods:** Patients with maintenance HD (n=1,551) were enrolled into the MID Study in December 2009 and were prospectively followed up for 3 years. CV events (cerebral hemorrhage, CH; cerebral infarction, CI) were determined using head CT/MRI in addition to typical neurological symptoms. Kaplan-Meier (KM) and Cox regression (CR) analyses were used to clarify the association between AP and/or AC drugs and CV events.

**Results:** A total of 51 and 74 patients developed CH and CI, respectively, with incidences of 13.1 and 19.2/1000 patient-year. KM analysis showed that CH events were significantly more common in the patients with combination therapy of AP and AC drugs than in other groups. CR analysis revealed that combination therapy (HR 5.06, 95% C.I. 1.71-14.98) was factor contributing to CH, in addition to a past history of CH (HR 4.61, 95% C.I. 2.03-10.48). The incidence of patients with a past history of CI was remarkably higher than in those without this. CR analysis on the patients excluding those with a past history of CI revealed that the presence of atrial fibrillation (AF), diabetes mellitus and age were the predictive factors of CI, while AC and AP therapies were not significant factors. Among the patients with AF, no significant difference was observed in the frequency of CI events between warfarin users and non-users.

**Conclusions:** Combination therapy of AP and AC drugs is a risk factor for developing CH in patients with maintenance HD. HD patients with AF more frequently suffered CI than those without AF; however, preventive effects of AP/AC drugs against developing CI were not evident.

## FR-PO388

**The Subjective Feeling of Thirst and the Presence of Oral Symptoms in People on Hemodialysis and Their Association with Adverse Outcomes: Oral-D Study**
Giovanni F.M. Strippoli,[1,2,3,4] Suetonia Palmer,[5] Marinella Ruospo,[1,2] Patrizia Natale,[1] Valeria Maria Saglimbene,[1,2] Michela Sciancalepore,[1] Letizia Gargano,[1] Fabio Pellegrini,[2] David W. Johnson,[6] Pauline J. Ford,[6] Jonathan C. Craig,[4] Paul Stroumza,[1] Luc Frantzen,[1] Miguel Rodrigues Leal,[1] Marietta Torok,[1] Anna Bednarek,[1] Jan Dulawa,[1] Eduardo Jorge Celia,[1] Ruben Gelfman,[1] Jorgen B.A. Hegbrant,[1] Charlotta Wollheim,[1] Staffan Schön,[1] Michele De benedittis,[3] Massimo Petruzzi.[3] *[1]Diaverum; [2]Mario Negri Sud Consortium; [3]Univ of Bari; [4]Univ of Sydney; [5]Univ of Otago; [6]Univ of Queensland.*

**Background:** The presence of thirst and xerostomia, a subjective complaint of dry mouth, may be increased in people on hemodialysis. The prevalence of thirst and xerostomia and their association with the risk of death and adverse vascular outcomes have not been formally established in large scale cohort studies.

**Methods:** The ORAL-D study is a multinational cohort study of oral diseases in consecutive adults on hemodialysis. We administered xerostomia and thirst inventories based upon validated methodology. We analyzed prevalence data using descriptive analyses and association with death and adverse vascular outcomes is being analyzed with Cox regression.

**Results:** 4324 hemodialysis patients in the participating clinics completed a self-administered questionnaire on oral symptoms. 1274 (30%) patients used candies for dry mouth sensation, 992 (23%) had difficulties swallowing and 2243 (52%) needed to sip to aid swallowing. 1940 (45%) reported waking up during the night to drink, and 2101 (49%) had dry lips. Thirst was a reported problem for 2651 (61%) patients; 3280 (76%) were thirsty during the day and 1995 (46%) during the night. Overall, 1068 (25%) patients reported that thirst influenced their social life. Analyses of association with death and adverse vascular outcomes are in progress.

**Conclusions:** Oral symptoms are highly prevalent in hemodialysis, with marked interference with daily life. Further research will evaluate the impact of these symptoms on clinical outcomes in people in hemodialysis. Analyses of association with death and adverse vascular outcomes are in progress.

## FR-PO389

**The Risk of All Cause and Cardiovascular Mortality in Dentate and Edentulous Patients in Hemodialysis: Oral-D Study**
Giovanni F.M. Strippoli,[1,2,3,4] Suetonia Palmer,[5] Marinella Ruospo,[1,2] Patrizia Natale,[1] Valeria Maria Saglimbene,[1,2] Michela Sciancalepore,[1] Letizia Gargano,[1] Fabio Pellegrini,[2] David W. Johnson,[6] Pauline J. Ford,[6] Jonathan C. Craig,[4] Paul Stroumza,[1] Luc Frantzen,[1] Miguel Rodrigues Leal,[1] Marietta Torok,[1] Anna Bednarek,[1] Jan Dulawa,[1] Eduardo Jorge Celia,[1] Ruben Gelfman,[1] Jorgen B.A. Hegbrant,[1] Charlotta Wollheim,[1] Staffan Schön,[1] Michele De Benedittis,[3] Massimo Petruzzi.[3] *[1]Diaverum; [2]Mario Negri Sud Consortium; [3]Univ of Bari; [4]Univ of Sydney; [5]Univ of Otago; [6]Univ of Queensland.*

**Background:** Dental disease may be a potential determinant of excess death in people on hemodialysis, due to inflammation or as an indicator of general health status. We are exploring whether total teeth loss predicted mortality (total and cause-specific) in patients on hemodialysis.

**Methods: ORAL-D** is an ongoing multinational prospective cohort study of consecutive adults receiving hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Italy, Hungary, Poland, Argentina, Portugal, France and Spain. A dental surgeon evaluated the presence or absence of teeth during a standardized oral examination. We assessed survival at 12 months using centralized mortality data. We conducted analysis using a Cox regression controlling for age, gender, previous cardiovascular events, income status, clinical performance measures, dialysis prescription and performance indicators, and depressive symptoms.

**Results:** 4720 hemodialysis patients in participating clinics received a complete dental evaluation and completed follow up. Median follow up 8 (6.5 to 7.8)months. 868 patients were edentulous (20%) and 344 (10%) died during follow up. Complete loss of teeth had uncertain associations with risks of all-cause (HR 1.06 [95% CI, 0.86-1.31]) and cardiovascular mortality (HR 0.90 [95% CI 0.66-1.22]) when adjusted for potentially confounding variables. Complete 12 month follow-up data will be available by September 2013.

**Conclusions:** Dentate status has uncertain associations with all-cause or cardiovascular mortality in patients on hemodialysis. ORALD will be completed by end of 2013.

## FR-PO390

**Snoring Is a Strong Amplifier of the Risk by Heart Failure for All Cause and Cardiovascular Mortality in Chronic Kidney Disease in Patients on Dialysis (Stage 5D-CKD)**
Claudia Torino,[1] Graziella D'arrigo,[1] Maurizio Postorino,[1] Giovanni Tripepi,[1] Francesca Mallamaci,[1] Carmine Zoccali,[1] Progredire Work Group.[2] *[1]Clin. Epid. and Physiopath. of Renal Dis. and Hypertens., CNR-IBIM, Reggio Calabria, Italy; [2]PROGREDIRE Working Group, Italy.*

**Background:** Self-reported snoring, an indicator of sleep disordered breathing (SDB), may associate with mortality in the general population and in pts with heart failure (HF). SDB and HF are frequent in the stage 5D-CKD population but the hypothesis that snoring

may affect the HF-mortality link in these patients (pts) has never been tested. The issue is important because SDB has been in part attributed to reversible pharyngeal edema secondary to volume expansion in HF pts and may therefore be a modifiable risk factor.

**Methods:** We investigated this problem in a cohort of 827 stage 5D-CKD pts. HF was assessed at baseline on the basis of clinical symptoms and radiological/echocardiographic examinations. At enrolment, participants provided self-reported information about snoring and were followed up for a median time of 28 months.

**Results:** 132 pts had HF at baseline. Overall, 194 pts were classified as heavy snorers, 308 as moderate snorers and 325 as non-snorers. During the follow-up, 233 pts died (CV causes: 54%). Both on univariate (P<0.001) and multiple (P<0.02) Cox analyses, HF significantly predicted the study outcomes whereas snoring did not (P=NS). However, snoring was a strong modifier of the risk of HF for the study outcomes. In Cox models (including Framingham factors, anti-hypertensive treatment, CV comorbidities, dialysis vintage, CRP, P, Hb and albumin), the hazard ratios (HR) associated to HF for the study outcomes were highest in heavy snorers [all-cause death:HR:2.5, P<0.001;CV death:HR:3.1,P<0.001], intermediate in moderate snorers [all-cause death:HR:1.5,P=0.01); CV death:HR:1.6,P=0.009) and not significant in non-snorers [all-cause death:HR:0.9; CV death:HR:0.8].

**Conclusions:** Snoring is an effect modifier of the HF-mortality link in stage 5D-CKD pts. Clinical trials are needed to verify whether intensified surveillance and treatment (UF intensification) of HF snorers on dialysis may translate into better clinical outcomes in these pts.

## FR-PO391

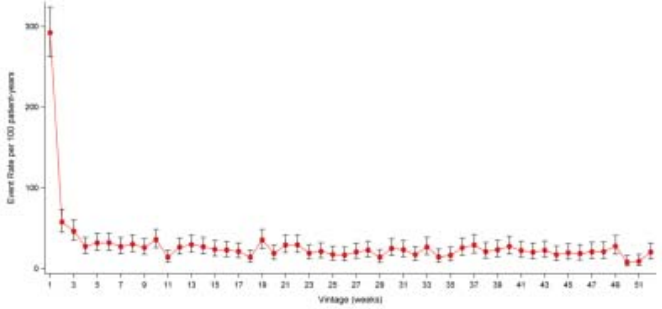
**Early Cardiovascular Events in an Incident European Hemodialysis Cohort**

Kai-Uwe Eckardt,[1] Iain A. Gillespie,[2] Stefan D. Anker,[3] Sharon Richards,[2] Daniele Marcelli,[4] Marc Froissart,[5] Jürgen Floege.[6] *[1]Univ of Erlangen-Nuremberg, Germany; [2]Amgen Ltd, United Kingdom; [3]Charite Campus Virchow-Klinikum, Germany; [4]Fresenius Medical Care (FME), Germany; [5]Amgen Europe GmbH, Switzerland; [6]RWTH Univ of Aachen, Germany.*

**Background:** Hemodialysis (HD) initiation is associated with high all-cause and cardiovascular (CV) deaths rates. However, there is a paucity of data on the occurrence and potential causes of cardiovascular events (CVE) during this crucial period. No studies have examined risk by underlying CV cause.

**Methods:** This study aimed to decipher the early CVE risk in a European Fresenius Medical Care HD patient cohort ('AROii') with a dialysis vintage of <7 days (median 4d) . Monthly rates of the composite fatal/nonfatal CVEs were calculated for the first 2 years on HD. High-risk periods were identified by comparing, with Rate Ratios (RRs), monthly first year rates with the second year rate. Constituent events were also examined.

**Results:** 2411 CVE were reported for 1454/6322 patients (23%). The first year rate (30.4/100 person-years (PY) [95% Confidence Interval (CI) 28.9-31.9]) greatly exceeded the second (19.4/100PY [CI 18.0-20.8]). Whilst incidence was generally highest in the first month and particularly in the first week (figure), the high risk period extended to month 5 (RR 2.17 [CI 1.97-2.38]). High risk periods differed by CVE category (coronary artery: months 1-2; cerebrovascular: month 1; peripheral arterial: month 1; congestive heart failure: months 1-4; sudden cardiac death: month 8). Rate of CVE by weekly dialysis vintage.



**Conclusions:** CVE incidence in early weeks after HD initiation remains very high and is not confined to specific CV disease categories. Extended high risk periods suggest the potential to prevent events in early HD based on risk factor identification, risk stratification and preventive care.

*Funding:* Pharmaceutical Company Support - Amgen (Europe) GmbH

## FR-PO392

**Challenging Physical Activity in Dialysis Patients**

Marine Panaye,[1] Anne Kolko-Labadens,[2] Catherine Deforges-lasseur,[3] Marie Paule Guillodo,[4] Martial Levannier,[5] Daniel Teta,[6] Denis Fouque.[7] *[1]Nephrology, Hopital Edouard Herriot, Lyon, France; [2]Dialysis, AURA Nord, Saint Ouen, France; [3]AURAD Aquitaine, Gradignan, France; [4]AUB Santé, Brest, France; [5]Amgen, Neuilly/Seine, France; [6]Nephrology, CHUV, Lausanne, Switzerland; [7]Nephrology, Centre Hospitalier Lyon Sud, Pierre Benite, France.*

**Background:** Physical inactivity is a risk factor for mortality in dialysis patients and is still poorly documented during maintenance dialysis (MD). The Step by Step initiative aimed at evaluating the weekly physical activity on a large cohort of dialysis patients.

**Methods:** All French nephrologists were invited to participate in this national prospective multicenter observational study. 149 investigators included 1163 adult patients who were on MD since more than 3 months. Physical activity was assessed by the number of daily steps measured by a pedometer (model NO PE317C multifunction pedometer, USA) for 7 consecutive days.

**Results:** Median age was 63 yr (Q1 51-Q3 75), 66% were male. Most patients (95%) were on hemodialysis (median 3yr). 24% were diabetic, 69% had hypertension, and 22% had peripheral arterial disease. 63% were sedentary (<5000 steps/day) with a median of 3688 steps /day. Daily steps were lower on dialysis days (DD) (2912, 1439-5232) compared to non DD (4054, 2136-7108) (p <0.001). Physical activity decreased with age with 57% being sedentary between 50 and 65 yr and above up to 83% after 80 yr. Number of steps increased with dialysis vintage from 3620 steps in patients on dialysis for <5 yr (66% pts) to 4465 for dialysis time>10 yr (18% pts).

**Conclusions:** This survey, largest ever done, highlights the low level of physical activity in MD patients. Patients are mostly sedentary with a number of daily steps less than 5000. Activity is more reduced if they are older and on MD for a shorter time (suggesting that frail patients died earlier). These results confirm the need to enforce rehabilitation programs that promote intra and inter dialytic physical exercise.

## FR-PO393

**Advanced CKD Results in Reduced Cardiovascular Reserve with Loss of Adaptive Cardiac Alterations When Compared to Hypertension**

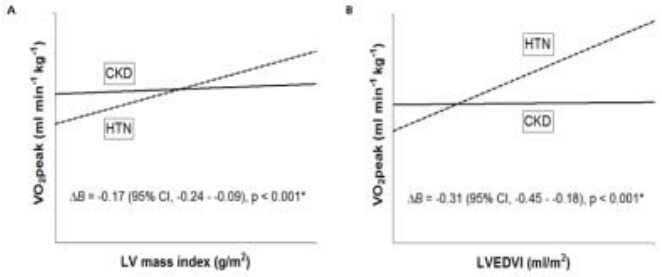
Stephen M.S. Ting,[1,2] Thomas Hamborg,[2] Gordon McGregor,[1] Kenneth Lim,[4] Nicolas Aldridge,[1] David Oxborough,[3] Sudheer Koganti,[1] Rosemary Bland,[2] Robert Higgins,[1] Prithwish Banerjee,[1] Daniel Zehnder.[1,2] *[1]Univ Hospitals Coventry&Warwickshire NHS Trust; [2]Warwick Medical School; [3]Liverpool JohnMoores Univ, United Kingdom; [4]Oregon Health & Science Univ.*

**Background:** Oxygen consumption at peak exercise ($VO_2$peak) is reduced in advanced CKD patients. To-date, no studies have examined whether the reduced functional measure of cardiovascular reserve in CKD is related to an impaired cardiovascular compliance. We also postulate that loss of adaptive cardiac alterations is a contributor to low $VO_2$peak in CKD.

**Methods:** We assessed 136 kidney transplant-waitlisted patients in parallel with 80 healthy hypertensive subjects prospectively between 2010-2012. Cycle-ergometric exercise testing, TD-echocardiography, pulse wave velocity (PWV) were performed.

**Results:** $VO_2$peak was lower in the CKD subjects compared with the hypertensives (19 vs 23 ml $min^{-1}kg^{-1}$,p<0.001). Independent predictors of $VO_2$peak for CKD were PWV(coefficient, *B*=-5.4), LV end-diastolic volume index(LVEDVI;*B*=0.1) & LV filling pressure(E/mean e';*B*=-6.8); in the hypertensives, these were LV mass index(*B*=0.4) & LVEDVI(*B*=0.4).

In demographic-adjusted multiple regression model, significant predictors in the CKD were E/mean e'(*B*=-4.7) & albumin(*B*=0.3); in the hypertensives, it was LVEDVI(*B*=0.3). Interestingly, higher LV mass index & LVEDVI were associated with greater $VO_2$peak in the hypertensives than the CKD subjects.



**Conclusions:** This is the first study to suggest that impaired LV and arterial compliance are mechanistic factors resulting in reduced cardiovascular reserve in advanced CKD. Our data is indicative of dysregulated LV function in CKD patients beyond predominantly ventricular wall changes that occur in otherwise healthy hypertensive patients.

## FR-PO394

**Exercise Anaerobic Threshold Predicts Survival Pre- and Post- Kidney Transplantation**

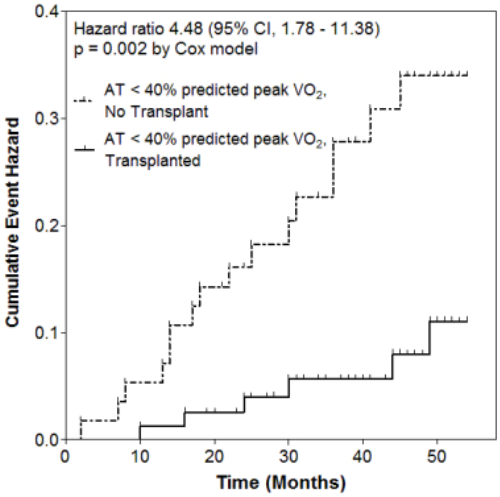
Stephen M.S. Ting,[1,4] Hasan Iqbal,[2] Thomas Hamborg,[5] Nicolas Aldridge,[1] Nithya Krishnan,[1,4] Prithwish Banerjee,[2] Rosemary Bland,[4] Robert Higgins,[1] Daniel Zehnder.[1,4] *[1]Renal Medicine & Transplantation, Univ Hospitals Coventry & Warwickshire NHS Trust; [2]Cardiology, Univ Hospitals Coventry & Warwickshire NHS Trust; [3]Vascular Surgery, Univ Hospitals Coventry & Warwickshire NHS Trust; [4]Metabolic & Vascular Health, Warwick Medical School, United Kingdom; [5]Health Sciences Statistics & Epidemiology, Warwick Medical School, United Kingdom.*

**Background:** Reduced anaerobic threshold (AT) carries a poor prognosis among patients with impaired cardiovascular reserve. This study investigated the prognostic capacity of AT on survival in CKD patients waiting for a kidney transplant and the impact of transplantation on survival in those with reduced cardiovascular reserve.

**Methods:** We performed cardiopulmonary exercise testing in 240 patients who were waitlisted for kidney transplantation between 2008 and 2010. Clinical, exercise and 5-year mortality data were compared.

**Results:** 24 patients who died had a significantly lower AT than the survivors (29.9 vs. 39.7% of predicted peak $VO_2$, p<0.001). Non-survivors were more likely to have CVD (38 vs 13%, p=0.002) and dialysis vintage >1 year (79 vs 49%, p=0.005).

According to Kaplan-Meier estimates, a significantly reduced 5-year cumulative overall survival rate (p<0.001) was observed in patients with AT<40% compared to those with AT≥40% predicted $VO_2$peak. Survival in the cohort with AT<40% was significantly different in kidney transplanted (6 deaths) vs non-transplanted patients (17 deaths) with a hazard ratio of 4.5 (95%CI, 1.8–11.4, p=0.002).



**Conclusions:** This is the first prospective study to demonstrate an association of the functional cardiovascular reserve AT with overall survival in advanced CKD patients. High risk patients with reduced cardiovascular reserve had a better survival after receiving a kidney transplant.

## FR-PO395

### Serum FGF-23 Associated with the Progression of Coronary Artery Calcification in Hemodialysis Patients

Alaattin Yildiz, Abdullah Ozkok. *Internal Medicine, Nephrology, Istanbul, Turkey.*

**Background:** Disordered mineral metabolism is implicated in the pathogenesis of vascular calcification in hemodialysis (HD) patients. Fibroblast growth factor 23 (FGF-23) is the main regulator of phosphate metabolism. In this prospective study, we aimed to investigate the association of serum FGF-23 with progression of coronary artery calcification in HD patients.

**Methods:** Seventy-four HD patients(36 male/38 female,mean age:52±14 years) were included. Serum FGF-23 levels were measured by ELISA. Coronary artery calcification score(CACS) was measured twice with one year interval. Patients were grouped as progressive (PG)(36 patients-48%) and non-progressive (NPG).

**Results:** Age, serum phosphorus, baseline and first year CACS were found to be significantly higher in the PG compared to NPG group. Serum FGF-23 levels were significantly higher in PG (468±132 vs 190±272 pg/mL, p=0.04). Patients were divided into two groups according to baseline CACS (low group, CACS≤30; high group, CACS>30). Serum FGF-23 levels were significantly correlated with the progression of CACS (ΔCACS) in the low baseline CACS group (r=0.510, p=0.006), but this association was not found in high baseline CACS group (r=0.11, p=0.44). In logistic regression analysis for predicting the PG patients; serum FGF-23, phosphorus levels and baseline CACS were retained as significant factors in the model.

**Conclusions:** Serum FGF-23 was found to be related to progression of CACS independent of serum phosphorus levels. FGF-23 may play a major role in the progression of vascular calcification especially at the early stages of calcification process in HD patients.

### Impacts of Dry Weight Determined by Calf Bioimpedance Ratio on Carotid Stiffness and Left Ventricular Hypertrophy in Hemodialysis Patients

Yi-Lun Zhou, Li-jie Ma, Fang Sun, Yang Shen, T.G. Cui. *Dept of Nephrology, Chao-Yang Hospital, Capital Medical Univ, Bei-Jing, China.*

**Background:** Our previous study has shown that modification of bioimpedance technique by the measurement of bioimpedance ratio in the calf (Calf-BR = impedance at 200 kHz / impedance at 5 kHz)) was a simple and practical method in assessing fluid status in hemodialysis patients. Under physiological conditions, the Calf-BR was positively related to the ratio of extracellular volume to total body water. However, the consequences of periodical dry weight (DW) adjustment under the guidance of Calf-BR on target organ damage have not been investigated.

**Methods:** 115 hemodialysis patients were enrolled in this pilot trial. Patients were divided into bioimpedance group and control group according to their dialysis schedule. In bioimpedance group, DW was routinely adjusted under the guidance of Calf-BR every 3 month. In control group, the assessment of DW remained a clinical judgment. Carotid stiffness, left ventricular mass index(LVMI), and Calf-BR were measured at baseline and at the 12th month in both groups. Home blood pressure (BP) was monitored monthly. Dialysis-related adverse events were recorded.

**Results:** No significant differences were observed in parameters between the two groups at baseline. Compared to control group, bioimpedance group had significantly lower values in terms of the annual averages of systolic home BP (147.4±15.3mmHg vs 152.6±16.9mmHg, p=0.019), carotid stiffness index β (10.7±3.3 vs 12.2±3.1, p=0.003), LVMI (155.21±15.64 g/m$^2$ vs 165.17±16.76 g/m$^2$, p<0.001), and the percentage of individuals with Calf-BR over target range (p=0.040) at month 12, with less annual averages of antihypertensive medications used and lower frequency of intradialytic hypotension, muscle cramp, and clotted angioaccess.

**Conclusions:** Probing DW via periodical measurement of Calf-BR may have the potential to improve arterial stiffness and left ventricular hypertrophy. In addition, this intervention may also decrease incidence of intradialytic hypotension, muscle cramp, and arteriovenous fistula complications in hemodialysis patients.

## FR-PO397

### The Progress in Malnutrition and Inflammatory Conditions Affect on Adverse Events and Mortality in the Patients on Maintenance Hemodialysis (MHD)

Takahiro Kuragano, Takeshi Nakanishi. *Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo.*

**Background:** In MHD, protein-energy malnutrition can be critical and is one of the main causes of mortality. Nutritional and inflammatory condition could progress or regress during follow-up period, and may cause the adverse events and premature mortality in MHD. However, few studies reported the influence of changes in nutritional or inflammatory status on adverse events or survival in MHD.

**Methods:** Study design: Prospective, observational multi center study. Observational period: 2 years. Subject and measurement: In 1086 MHD patients, blood levels of Hb, albumin, prealbumin, high sensitive CRP (hCRP), were measured every 3 month. And body mass index (BMI) is also evaluated.

**Results:** In logistic regression analysis, Hb (p=0.008, Exp (β)=0.797) and pre-albumin (p=0.001, Exp (β) =0.968) were selected as the significant predictors of the change in BMI during the follow up period. Moreover, age (p=0.003, Exp (β) =1.039) was selected as a significant predictor of the change in serum albumin. In the time dependent cox hazard model, patients who were under 62 years old, there were no significant changes in BMI and serum albumin levels during 2 years. On the other hand, in the patients over 62 years old, BMI (p=0.0025, from 21.4 ± 0.17 to 21.2 ± 0.17) and serum albumin (p=0.0001, from 3.72 ± 0.015 to 3.66 ± 0.017) levels significantly decreased during the follow-up period. Patients who showed the decline in BMI was associated with elevated risk for cerbro-cardiovascular disease (CCVD) (p=0.012, HR: 2.19) and hospitalization (p=0.002, HR: 1.57). Moreover, patients who showed the decline in serum albumin also associated with higher risk at infection disease (p=0.001, HR: 1.55) and hospitalization (p=0.049, HR: 1.35). On the other hand, patients who showed the increase in hCRP had a higher risk for CCVD (p=0.023, HR: 0.44) and death (p=0.023, HR: 0.32).

**Conclusions:** This study revealed that the downward trend of nutritionnal status was prominent in elderly MHD. Furthermore, the progress in malnutrition and inflammation might be associated with the several adverse events in MHD patients.

## FR-PO398

### Increased Serum Levels of GDF-15 Are Associated with Cardiovascular Death, Subclinic Atherosclerosis in Patients on Maintenance Hemodialysis

Hakki Yilmaz,[1] Huseyin tugrul Celik,[2] Ali Akcay,[1] Ozgul Malcok Gurel,[3] Ayse Mukadder Bilgic,[1] Nuket Bavbek.[1] *[1]Dept of Internal Medicine and Nephrology, Turgut Ozal Univ, School of Medicine, Ankara, Turkey; [2]Dept of Biochemistry, Turgut Ozal Univ, School of Medicine, Ankara, Turkey; [3]Dept of Cardiology, Turgut Ozal Univ, School of Medicine, Ankara, Turkey.*

**Background:** Increased carotid intima media thickness(CIMT) was shown to be independent predictor of cardiovascular(CV) mortality in dialysis and general population. Growth differentiation factor 15(GDF-15), a member of the transforming growth factor superfamily, is produced by cardiomyocytes and atherosclerotic lesions under stress conditions such as inflammation. Increased GDF‐15 levels may be suggested as powerful biomarker for cardiovascular diseases, atherosclerosis and mortality. We assessed associations between serum concentrations of GDF-15, mortality and CIMT for subclinic atherosclerosis in hemodialysis(HD) patients.

**Methods:** Eihgty-seven patients on maintenance hemodialysis and 45 sex and age-matched healthy controls were included in this prospective study. Serum GDF-15 levels were measured by ELISA. CIMT was assessed by Doppler ultrasonography. Association between serum GDF-15 level and mortality was assessed in Cox regression analysis with serum levels categorized into two groups according to median value(328.18 pg/ml). Patients were followed for 2 years and had cause-specific and all-cause mortality determined.

**Results:** The mean serum GDF-15 levels were significantly higher in HD patients than controls (376.57±216.78 vs. 176.32±43.62 p<0.01, respectively). Serum GDF-15 levels were correlated to CIMT ($\rho$=0.607, P<0.01), CRP ($\rho$=0.250, P<0.01) and serum albumin ($\rho$=-0.156, P=0.03). The multivariate analysis revealed that GDF-15 was found to be an independent variable of CIMT in HD patients. In the study, serum GDF-15 level was an independent marker of cv mortality when adjusted for age, CRP, history of diabetes mellitus.

**Conclusions:** The relationship demonstrated between serum GDF-15, mortality, and carotid artery thickening suggests that GDF-15 may be a novel marker of atherosclerosis, inflammation and malnutrition in HD patients.

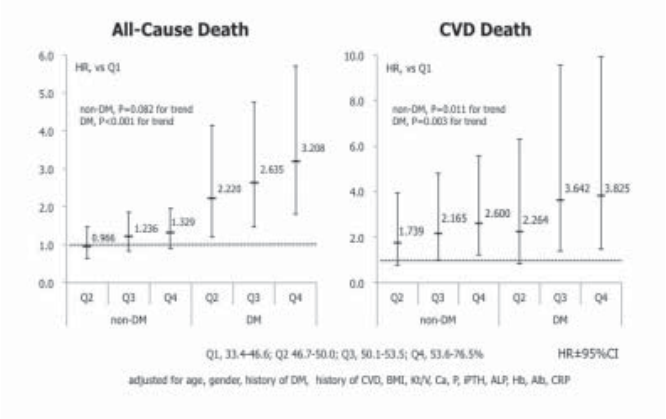
**FR-PO399**

**Cardiothoracic Ratio and All-Cause and Cardiovascular Disease Mortality in Patients on Hemodialysis: Results from the MBD-5D Study**
Hiroaki Ogata,[1] Masahide Mizobuchi,[2] Eriko Kinugasa,[1] Masafumi Fukagawa,[3] Tadao Akizawa,[2] Shunichi Fukuhara.[4] *[1]Dept of Internal Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Japan; [2]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [3]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [4]Dept of Healthcare Epidemiology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan.*

**Background:** The cardiothoracic ratio (CTR) is a non-invasive index of volume status and left ventricular hypertrophy. However, whether or not CTR is associated with cardiovascular disease (CVD) event and mortality in hemodialysis population is unclear.

**Methods:** The MBD-5D is a multicenter, prospective observational study of hemodialysis patients with secondary hyperparathyroidism (SHPT) in Japan. Data from MBD-5D study were analyzed to assess the association between CTR and all-cause, CVD mortality or CVD hospitalization in HD patients (N=3,194, Age 61.9 yrs, female 38.6%, diabetes mellitus (DM) 24.2%, HD vintage 121.7 months).

**Results:** CTR was significantly associated with age, gender, HD vintage, comorbidity, Kt/V, Hb, SCr, P, iPTH levels, and P binders use. All-cause, CVD mortality, and CVD hospitalization increased across quartiles of CTR (Log rank test, P<0.0001, P<0.0001, and P<0.0001, respectively). In time dependent Cox regression analyses, all-cause death increased across quartiles of CTR in DM patients, but in non-DM patients CVD death was significantly higher in patients with the higher quartile of CTR compared to those with the lowest quartiles of CTR in non-DM and DM patients.



Higher CTR across quartiles was associated with greater risk of CVD hospitalization in non-DM patients, but not in DM patients.

**Conclusions:** CTR is associated with all-cause, CVD mortality and hospitalization in HD patients with SHPT.

**Effects of Acute Intradialytic Exercise on Blood Pressure and Circulating Cytokines**
Maurice Dungey,[1,2] Nicolette C. Bishop,[1] Hannah M.l. Young,[2] James O. Burton,[2] Alice C. Smith.[2] *[1]School of Sport, Exercise and Health Sciences, Loughborough Univ, United Kingdom; [2]Leicester Kidney Exercise Team, Univ Hospitals of Leicester, United Kingdom.*

**Background:** Regular exercise can enhance the quality of life of haemodialysis (HD) patients. Intradialytic cycling (IDC) is increasingly offered on HD units but its potential benefits and drawbacks have not been fully investigated. In the general population, exercise causes a transient increase in blood pressure (BP) which falls below resting levels after exercise. Exercise can also stimulate IL-6 production from contracting myocytes, initiating rises in circulating anti-inflammatory cytokines such as IL-1ra. Patients often experience BP fluctuations during HD and are frequently in a state of chronic systemic inflammation which can be exacerbated by HD. This study examined the effects of a bout of IDC on BP and circulating IL-6 and IL-1ra levels.

**Methods:** 10 HD patients (age 59.6 ± 8.3yr) completed two trials in a randomised crossover design. On the control trial patients rested throughout dialysis. On the exercise trial, after 60 min of dialysis, patients cycled for 30 min at a "somewhat hard" intensity (rating of perceived exertion 13) during dialysis. BP was measured before dialysis and with blood samples at pre, post, 1h post-exercise and at the end of dialysis (or equivalent times during control).

**Results:** Systolic BP (SBP) decreased after initiation of dialysis on both trials (P<0.01). ANOVA revealed a time*trial interaction (P=0.003): SBP was significantly higher immediately post-exercise (131 ± 18 vs. 117 ± 22mmHg) and lower 1h post-exercise (109 ± 26 vs. 121 ± 26mmHg) compared with control. Plasma IL-6 increased during dialysis in both trials (P=0.015). Fold-changes in IL-6 and IL-1ra did not differ between trials.

**Conclusions:** IDC does not exacerbate markers of systemic inflammation. SBP increases with exercise and falls substantially in the hour afterwards compared with a resting control trial. As intradialytic BP changes have significant implications for patient outcomes, this novel finding highlights the importance of patient monitoring during and after IDC. The longer term impact of these observations requires further investigation.

**Effects of Sleepiness on Survival in Japanese Hemodialysis Patients: J-DOPPS-Q1**
Kunitoshi Iseki,[1] Kazuhiko Tsuruya,[2] Eiichiro Kanda,[3] Takanobu Nomura,[4] Hideki N. Hirakata.[5] *[1]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara, Okinawa, Japan; [2]Internal Medicine, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences,, Tokyo Kyosai Hospital, Tokyo, Japan; [4]Clinical Research Management Dept Development Div, Kyowa Hakko Kirin Co., Ltd, Tokyo, Japan; [5]Internal Medicine, Fukuoka Red-Cross Hospital, Fukuoka, Japan.*

**Background:** Sleep disorder and poor sleep quality have been claimed as a cause of morbidity and mortality. Survival of Japanese HD patients is better than any other countries, yet the reasons are not clear. Among them, the relationship between the degree of sleepiness and survival has not been studied.

**Methods:** We studied the degree of sleepiness in 1,252 adults (age 20 and over) HD patients using the Japanese version of the Epworth Sleepiness Scale (JESS) questionnaire which was developed to apply for Japanese. Demographic data were presented as mean (standard deviation) for three subgroups: low, intermediate, and high JESS score. Kruskal-wallis test or analyses of covariance were performed to compare the significance of discrete variables and with chi-square test or Fisher's exact test for categorical variables. Cox proportional Hazard regression analysis was performed to estimate the independent effect of several variables on survival.

**Results:** During the study period, there were 85 deaths and 652 hospitalizations. The survival was poor in the high JESS score group. The hazard ratio (95% confidence interval) was 2.268 (1.240-4.148, P=0.008) when the reference was those with low JESS score after adjusting for age, vintage of HD, gender, diabetes, BMI, CVD, HD treatment regimen, laboratory data, and medication. Relative risk of death was significantly higher in high JESS score groups even after multiple adjustments. Patients with elderly, 70 years and over, comorbid conditions such as congestive heart failure, stroke, and diabetes showed significantly higher JESS score, 16 and over.

**Conclusions:** Results showed that the degree of sleepiness is related to survival in Japanese HD patients, in particular elderly patients.

**FR-PO402**

**NT-proBNP Is a More Significant Prognostic Biomarker for Mortality Than Troponin T in Incident Hemodialysis Patients**
Ji Suk Han,[1] Hyung Jung Oh,[1] Hyang Mo Koo,[1] Chan Ho Kim,[1] Tae-Hyun Yoo,[1,2] Shin-Wook Kang.[1,2,3] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul; [3]On behalf of the Clinical Research Center for ESRD Investigators, Korea.*

**Background:** Numerous previous studies have demonstrated that cardiac and inflammatory biomarkers are significant predictors of cardiovascular (CV) and all-cause mortality in ESRD patients. However, these studies were limited by retrospective analyses, inclusion of small numbers of patients, mostly prevalent dialysis patients, and measurement of one or two biomarkers. In this study, we investigated the association between three biomarkers (NT-proBNP, cTnT, and hsCRP) and mortality in incident hemodialysis patients.

**Methods:** A prospective cohort of 864 incident hemodialysis patients from 36 centers of the CRC for ESRD in Korea was followed for up to 30 mo. CV and all-cause mortality were compared between 'high' and 'low' groups according to the median baseline values of biomarkers. Cox proportional hazard analysis was performed to determine the independent prognostic value of each biomarker for CV and all-cause mortality.

**Results:** CV survival rates were significantly lower in the 'high' NT-proBNP and cTnT groups compared to the corresponding 'low' groups. However, there was no significant difference in CV survival rates between the 'high' and 'low' hsCRP groups. All-cause mortality rates were significantly higher in all three 'high' groups. In multivariate Cox models, natural log value (Ln) of NT-proBNP and cTnT but not Ln hsCRP were found to be significant independent predictors of CV (Ln NT-proBNP, HR=2.228, P=0.002; and Ln cTnT, HR=1.274, P=0.015) and all-cause mortality (Ln NT-proBNP, HR=1.392, P=0.012; and Ln cTnT, HR=1.182, P=0.034). Moreover, among the three biomarkers, NT-proBNP had the highest positive predictive values for not only CV mortality (AUC=0.812, P<0.001) but also all-cause mortality (AUC=0.666, P=0.003).

**Conclusions:** Although high levels of NT-proBNP and cTnT, but not hsCRP, were independently associated with CV and all-cause mortality in incident hemodialysis patients, the prognostic value of NT-proBNP for mortality were higher than that of cTnT.

*Funding:* Government Support - Non-U.S.

**FR-PO403**

**Real-Time Monitoring of Cardiovascular Status during Routine Hemodialysis** D. Miskulin,[1] Klemens B. Meyer,[1] John E. Moran.[2,3] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Intelomed, Inc, Pittsburgh, PA; [3]Nephrology, Stanford Univ School of Medicine, Stanford, CA.*

**Background:** Intradialytic hypotension (IDH) is common among patients on maintenance hemodialysis (HD) and may contribute to the high rate of cardiovascular (CV) events and mortality. Studies have shown IDH to be associated with impaired myocardial perfusion and stunning during HD.

**Methods:** 25 patients with a history of frequent hypotensive episodes during routine HD were monitored during 4 HD treatments using the CVInsight device (Intelomed, Inc), which captures and processes the signal from a standard pulse oximeter (Nonin Medical, Inc) to display the rates of change of pulse frequency and pulse amplitude. We assessed the device's prediction of intradialytic events, but did not intervene on the basis of the CVInsight display. Events were defined as either active staff intervention because of perceived hemodynamic instability, such as reduction in ultrafiltration rate or administration of saline, OR a fall in systolic BP below 90 mm Hg.

**Results:** 22 patients (88%) experienced one or more events: 30 episodes of systolic BP < 90 mm Hg, 25 episodes of intervention for symptoms suggesting hypovolemia, including lightheadedness, cramping, and weakness. Events occurred a mean of 93 min. into treatment. A recognized event did not follow 22 false positive alerts; the device yielded 12 false negatives, failing to predict an event, for sensitivity 78.2 % and specificity 51.1 %. CVInsight device alerts occurred a mean of 53 min. into treatment, giving a mean lead time of 40 mins. to allow intervention to prevent CV events.

**Conclusions:** The CVInsight device provides non-invasive real-time monitoring of CV status during HD and predicts the majority of CV events with a lead time which would allow intervention to prevent such events.

*Funding:* Pharmaceutical Company Support - Intelomed, Inc

**FR-PO404**

**Is There an Association between Copeptin and NT-proBNP in Hemodialysis Patients?** Jae Won Yang, Jae Seok Kim, Seung-Ok Choi, Byoung Geun Han. *Nephrology, Yonsei Univ Wonju College of Medicine, Wonju, Gangwon, Republic of Korea.*

**Background:** Copeptin, precursor to vasopressin, is associated with body fluid volume and heart dysfunction. Therefore, this study was intended to investigate the level of copeptin and the relationships with fluid and heart dysfunction markers in patients with hemodialysis.

**Methods:** This study included forty-one patients with hemodialysis. At the time of their visit for hemodialysis treatment, laboratory data including NT-proBNP was collected and excessive body fluid (OH, overhydration, liter) was measured by bioimpedance spectrometry (BIS). In addition, E/Ea ratios were obtained by echocardiography for assessing left ventricular dysfunction (LVDs).

**Results:** The mean concentration of pre-dialysis copeptin was 224.67±241.91 pg/ml. Pre-dialysis copeptin had positive correlation with pre-dialysis OH (r=0.314, P=0.046), but not with NT-proBNP (r=0.163, P=0.308) and E/Ea ratios (r=-0.023, P=0.888). Body fluid markers other than copeptin, such as NT-proBNP and pre-dialysis OH, E/Ea ratio, all showed significant correlation with each other. Based on previous reports, non-LVDs and LVDs in hemodialysis patients were defined by a cut off value of NT-proBNP 5300 [pg/ml] (specificity 0.8, sensitivity 0.93). When comparing the non-LVDs group with the LVDs group (non-LVDs vs. LVDs), the results showed significant differences in pre-dialysis copeptin (141.33±209.20 vs. 259.9±255.7 pg/ml, P=0.014), NT-proBNP (2294.70±1233.53 vs. 22826.85±11739.56 pg/ml, P=0.000), pre-dialysis OH (1.75±1.03 vs. 3.15±1.90 liters, P=0.023), E/Ea ratio (4.33±1.30 vs. 6.60±2.27, P=0.002), KtV (1.32±0.13 vs. 1.47±0.25, P=0.014). In addition, the ROC curve for discriminating LVDs from non-LVDs showed that the AUC of pre-dialysis copeptin was 0.737 (P=0.023), and the cut-off value was 125.48 pg/ml (specificity 0.8, sensitivity 0.7).

**Conclusions:** The level of pre-dialysis copeptins was elevated in patients with hemodialysis. In addition, copeptin was correlated with pre-dialysis volume status. However, copeptin did not show a significant relationships with NT-proBNP, E/Ea ratio. Finally, the patients with LVDs showed higher level of pre-dialysis copeptins than the patients without LVDs.

**FR-PO405**

**Clinical Impacts of Hemocontrol Biofeedback System on Hemodialysis Patients** Jae Won Yang, Jae Seok Kim, Seung-Ok Choi, Byoung Geun Han. *Nephrology, Yonsei Univ Wonju College of Medicine, Wonju, Gangwon, Republic of Korea.*

**Background:** Hemocontrol™ biofeedback system (Gambro) is the new dialysis method for reducing IDH (Intradialytic hypotension). We investigated how this new method affects the dialysis patients in this study.

**Methods:** 7 patients undergoing hemodialysis were enrolled in this study. Study period was 26 weeks, composed of stage A, B1 and B2. 'A' stage was control period, B1 and B2 were identical period for applying hemocontrol system. In each stage, laboratory data and clinical parameters including dialysis and ambulatory blood pressure (BP), pre-post dialysis body weight (BWt), total body water (TBW) measured by bioimpedence spectroscopy (FMC) were checked.

**Results:** After applying hemocontrol system, IDH episodes in B1 period were significantly reduced. Other parameters did not show the significant changes. And hemocontrol-high responsive patients (n=3) as compared with low responsive patients (n=4), showed significant differences in IDH (B1) (1.7 vs 6.5, P=0.032), intervention (B1, B2) (4.7 vs 12.0, P=0.032, 4.7 vs 14.5, P=0.034, respectively), potassium level (A) (4.7 vs 5.8, P=0.032), phosphorus level (A) (4.5 vs 6.1, P=0.032), prothrombin time (B2) (11.1 vs 10.0, P=0.034), pre-dialysis SBP (A) (150 vs 135, P=0.034), pre-dialysis DBP (B2) (67 vs 87, P=0.034), pre-dialysis MAP (B2) (91 vs 106, P=0.032), 48 hours ambulatory DBP (B1, B2) (78 vs 95, P= 0.032, 80 vs 94, P=0.034, respectively), post-dialysis overhydration (OH, liter) by bioimpedance (B2) (1.9 vs -0.5, P=0.032), intradialytic reduced OH (B1, liter) (1.3 vs 2.6, P=0.034), intradialytic reduced Bwt (B1) (1.6 vs 2.6, P=0.032), beta-blocker potency (A, B1, B2) (1.3 vs 0.3, P=0.029, 1.3 vs 0.3, P=0.031, 1.3 vs 0.4, P=0.026, respectively).

**Conclusions:** This study showed that hemocontrol system could be benefit from reducing IDH episodes, but there were no specific changes in other parameters. In addition, hemocontrol-high responsive patients had lower interdialytic BP and less amounts of ultrafiltration. The clinical consideration of these results will be needed in the future.

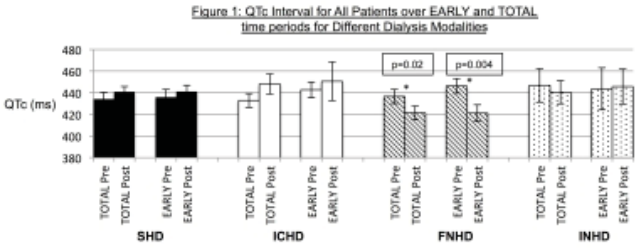
**FR-PO406**

**Frequent Nocturnal Hemodialysis Associates with Improvement of Prolonged QTc Intervals** Benjamin Ka Thomson,[1] Brad Urquhart,[2] Shih-Han S. Huang,[3] Christopher T. Chan,[4] Robert M. Lindsay.[5] *[1]Western Univ; [2]Western Univ; [3]Western Univ.*

**Background:** Sudden cardiac death remains the leading cause of death in hemodialysis (HD) patients. Prolongation of QTc intervals (as measured by the tangent method) increases sudden cardiac death risk in populations without kidney disease.

**Methods:** We performed a retrospective electrocardiograph (ECG) and chart review of HD patients. Our objectives were (1) to establish the effect of one of four different dialysis modalities on interdialytic QTc intervals, (2) to determine the effect of dialysis frequency and time on QTc interval and on the prevalence of borderline or prolonged QTc intervals, and (3) to determine if changes in QTc interval were simultaneous to changes in electrocardiographic left ventricular mass.

**Results:** Frequent nocturnal HD was associated with a decrease in QTc interval for all patients who initiated dialysis with prolonged QTc (468.2 to 438.2 ms, p=0.0134).



This change happened before changes in let ventricular mass were evident. Dialysis duration predicted a decrease in QTc better than dialysis frequency (R2 6.50 vs. 3.00%, p=0.023 vs 0.102). Prevalence of borderline or prolonged QTc increased in patients dialyzed <4hours/session (12/39 to 22/39, p-0.039).

**Conclusions:** Frequent nocturnal HD may be the ideal modality to initiate HD in end-stage kidney disease patients with prolonged QTc.

**The Effects of Study Events and Treatment on Health-Related Quality of Life (HRQoL) in the EVOLVE Trial** Andrew H. Briggs,[1,2] Patrick S. Parfrey,[3] Nasreen Khan,[4] Spring Tseng,[5] Bastian Dehmel,[5] Glenn M. Chertow,[6] Vasily Belozeroff.[5] *[1]Univ of Glasgow, United Kingdom; [2]Oxford Outcomes Inc; [3]Memorial Univ; [4]IMS Health; [5]Amgen Inc; [6]Stanford Univ School of Med.*

**Background:** EVOLVE™ (EValuation Of Cinacalcet HCl Therapy to Lower CardioVascular Events) is a randomized, controlled trial evaluating the effects of cinacalcet in patients with secondary hyperparathyroidism (sHPT) on hemodialysis. The objective of this analysis was to assess the impact of study events and treatment on HRQoL.

**Methods:** HRQoL was measured with the EQ-5D at scheduled visits and after a study event. The pre-planned analysis assessed changes in EQ-5D from baseline to scheduled visits. We also conducted a regression analysis to assess the acute (first three months) and chronic (beyond three months) effects of major sHPT-related health events (see Table) on HRQoL, and , including randomized assignment (cinacalcet vs. placebo) to assess the residual effect of cinacalcet on HRQoL not mediated by events.

**Results:** Data on HRQoL were available for 3547 of 3883 subjects with a total of 1650 events in the placebo and 1502 in the cinacalcet arm. No difference in HRQoL was observed in the direct (naïve) comparison of EQ-5D by treatment arms. The regression analysis (Table) showed significant effects of events. After accounting for events, there was a modest positive effect of cinacalcet on HRQoL.

| Effects of events and treatment on HRQoL | | | | |
|---|---|---|---|---|
| **Parameter** | **Coeff.** | **SE** | | |
| No event | 0.726 | 0.013 | | |
| Treatment | 0.019 | 0.005 | | |
| **Non-fatal events** | **Acute coeff.** | **SE** | **Chronic coeff.** | **SE** |
| Myocardial Infarction | -0.103 | 0.026 | -0.097 | 0.030 |
| Unstable Angina | -0.086 | 0.052 | -0.018 | 0.051 |
| Heart Failure | -0.102 | 0.020 | -0.097 | 0.022 |
| Peripheral Vascular Event | -0.319 | 0.029 | -0.177 | 0.028 |
| Stroke | -0.218 | 0.057 | -0.103 | 0.052 |
| Fracture | -0.310 | 0.024 | -0.118 | 0.020 |
| Parathyroidectomy | -0.049 | 0.020 | 0.013 | 0.017 |

**Conclusions:** A comparison of HRQoL using the EQ-5D score at scheduled visits in EVOLVE showed no difference between randomized groups. A regression analysis showed large decrements in HRQoL after major sHPT-related health events and a modest improvement in HRQoL with cinacalcet.

## FR-PO408

### Coronary Intervention Reduces Mortality among Dialysis Patients with Acute Coronary Syndrome: Taiwan National Cohort Study

Chih-Chiang Chien. *Dept of Nephrology, Chi-Mei Medical Center, Taiwan.*

**Background:** Patients on chronic dialysis have poor outcomes after acute coronary syndrome (ACS). Epidemiological data forAsian patients are scarce.

**Methods:** In the Taiwan National Health Insurance research Database, we examined records of ESRD patients who initiated dialysis between 1999 and 2001. Patients were followed until death, end of dialysis, or December 31, 2008. Predictors of ACS and mortality were calculated using Cox models.

**Results:** A total 19974 incident dialysis patients were examined in this study. ACS was diagnosed in 1785 patients during follow-up (1.78/100 person-years): 832 (46.6%) had acute myocardial infarction (AMI), 681 (38.2%) underwent cardiac catheterization, 398 (22.3%) percutaneous transluminal coronary angioplasty (PTCA), and 50 (2.8%) coronary artery bypass grafting. Male (HR 1.35, 95% CI: 1.23-1.49) and elderly (HR 3.289, 95% CI: 2.71-4.00) patients had a high rate of ACS. Patients with baseline comorbidities (diabetes mellitus, hypertension, congestive heart failure, coronary artery disease,dysrhythmia, other cardiac and chronic obstructive lung diseases) had a higher incidence of ACS than did those without. Overall in-hospital mortality was 9.7%. The cumulative 6-month post-hospitalization survival rate was 79.3%; the 1-year rate was 72.3%. Being elderly (≥ 65 years old), and having DM or AMI were associated with an increased risk for mortality; PTCA was associated with a decreased risk (HR0.77, 95% CI: 0.66-0.91).

**Conclusions:** ESRD dialysis patients had a high incidence of ACS and mortality. Being male, elderly and having baseline comorbidities were independent risk factors for ACS. Coronary intervention is possible benefits for dialysis patients.

## FR-PO409

### The Effect of Cincalcet-Associated Troponin Changes on Cardiovascular Event Rates in Hemodialysis Patients–A Possible Link?

Samra Abouchacra, Ahmed Chaaban, Fares Chedid, Nicole Gebran, Mohammad Budruddin, Mohamed E.O. Ahmed, Hanan Eljack, Muhy Eddin Hashem Hasan. *Tawam Hospital, Al Ain, United Arab Emirates.*

**Background:** Raised troponins in hemodialysis patients are prognostic indicators for cardiovascular (CV) risk and correlate with markers of uncontrolled SHPT. Though evidence suggests that control of the latter may reduce CV risk, however the effect of the calcimimetic agent, cinaclacet, remains uncertain.

**Methods:** This 2 year retrospective study compared trends in troponin and PTH along with CV morbidity and mortality among HD patients with severe SHPT receiving cinacalcet vs matched controls, not on this agent.

**Results:** PTH levels were lower at baseline in controls yet maintained, whereas troponin was similar and did not decrease over time. Conversely, both PTH and troponin levels decreased significantly from baseline in the cinacalcet group vs controls (table 1).

| | Cinacalcet Group (n =63) | Controls ( n =40) |
|---|---|---|
| Baseline PTH (pmol/l) | 95.45±62 | 49.76±44¶ |
| 18 mos PTH | 71.91±48* | 51.37±78¶† |
| baseline Troponin I ( ng/ml) | 0.05±0.11 | 0.04±0.1§ |
| 18 mos Troponin I | 0.02±0.03* | 0.04±0.03§† |
| CV mortality(%) | 3 (5) | 2(5)§ |
| Composite cardiac events(%) | 21(33) | 27(68)¶ |
| CVA events (%) | 1(2) | 8(20))¶ |
| PVD complications (%) | 4(6) | 7(18)§ |

P value vs baseline † NS * p < 0.05
cincalcet vs controls § NS ¶ p < 0.001

Moreover, similar CV mortality was observed in both groups, however cardiac events (composite of acute coronary events, congestive heart failure, arrhythmia ) were lower in cinacalcet group vs controls. Similarly, less cerebrovascular events and PVD complications were seen, but latter did not achieve significance.

**Conclusions:** Our study showed a decrease in troponin levels in cinacalcet -treated patients associated with lower cardiovascular events vs controls. Larger placebo-controlled trials are necessary to further explore the link between cardiac outcomes and changes in biomarker levels associated with cinacalcet use in severe SHPT.

## FR-PO410

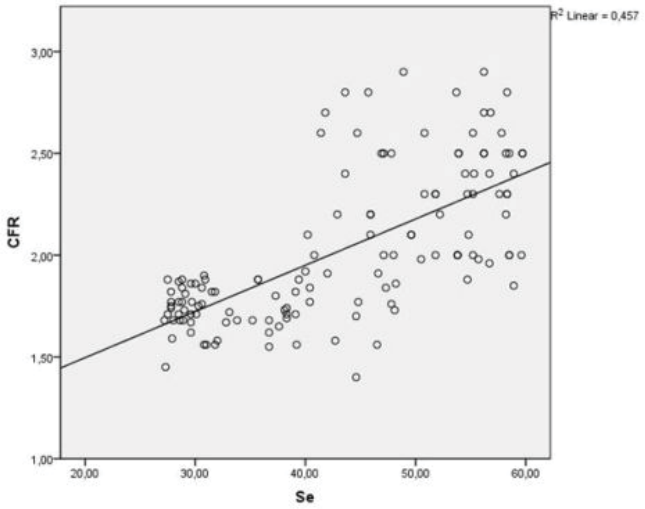
### Serum Selenium Levels Correlate with Coronary Artery Flow Reserve in Hemodialysis Patients

Elif Ari Bakir,[1] Beyza Macunluoglu.[2] *[1]Nephrology, Kartal Research and Training Hospital, Istanbul, Turkey; [2]Nephrology, Uskudar State Hospital, Istanbul, Turkey.*

**Background:** The objective of this study was to assess the correlation between serum selenium levels and coronary artery flow reserve (CFR) as an indicator of endothelial dysfunction (ED) and accelerated atherosclerosis in hemodialysis (HD) patients.

**Methods:** Seventy chronic HD patients and 69 age and sex-matched healthy controls were included in the study. Plasma selenium levels were performed by high-performance liquid chromatography measurements. CFR was assessed by transthoracic Doppler echocardiography.

**Results:** Serum levels of selenium (34,16[lrm]±6,15 vs 52,4[lrm]±5,51, p<0.001) and CFR values (1,73±0,11 vs 2,32±0,28, p<0.001) were lower in HD patients compared to controls. There was a significant positive correlation between CFR and serum levels of selenium (r = 0.676, p<0.001). A linear regression analysis showed that serum levels of selenium were independently and positively correlated with CFR (regression coefficient = 0.457, p<0.05).



**Conclusions:** This study was the first to show a positive and independent correlation between serum selenium levels and CFR as an indicator of ED and accelerated atherosclerosis in HD patients.

## FR-PO411

### Role of Monocyte Membrane Expression of Tumor Necrosis Factor Alpha (TNFα) Receptors in Altered Immune Response of Hemodialysis Patients

Nathalie Neirynck, Griet Lrl Glorieux, Eva Schepers, Annemieke Dhondt, Raymond C. Vanholder. *Nephrology Div, Ghent Univ Hospital, Belgium.*

**Background:** TNFα is elevated in hemodialysis (HD) patients and very likely plays a role in HD-related micro-inflammation. Signal transduction of TNFα depends on the membrane expression of TNFα-receptor 1 (TNFR1) and 2 (TNFR2). We hypothesized that changes in monocyte membrane expression of TNFR1 and TNFR2 could contribute to the altered monocyte function in HD patients. In this study, we compared the expression of membrane (m)TNFR1, mTNFR2 and mTNFα on monocytes in healthy controls and HD patients.

**Methods:** Whole blood samples from healthy controls (C) and predialysis samples of HD patients were labelled in vitro with fluorescent anti-mTNFR1, anti-mTNFR2 and anti-mTNFα at baseline and after stimulation with LPS (1 µg/ml, 30 min) (n = 8) and analyzed by flow cytometry. Monocytes were gated and the mean fluorescence (MFI) was measured.

**Results:** At baseline**,** there was no difference in monocyte mTNFR1, mTNFR2 or mTNFα expression between C and HD. After LPS stimulation, however, the expression of mTNFα and mTNFR2 was lower in HD compared to C, respectively 1265 vs 2266 (p < 0.05) and 840 vs 1324 (p < 0.05). A similar trend was observed for mTNFR1 (HD: 499 vs C: 782, p = 0.092). Comparing the expression after stimulation and baseline, a significant increase in mTNFα in C (2266 vs 753, p < 0.05) and decrease in mTNFR1 in HD (499 vs 681, p < 0.05) was observed. This lower expression of mTNFR1, 2 and mTNFα after stimulation in HD patients may induce a different TNFα signal transduction in HD patients compared to C.

**Conclusions:** There was no difference in baseline expression of mTNFR1, mTNFR2 and mTNFα on monocytes in dialysis patients compared to healthy controls. However, after LPS stimulation, a lower receptor expression in dialysis patients was observed compared to controls. Our findings might play a role in the patho-physiology responsible for the depressed immune response in HD patients upon infection.

## FR-PO412

**Relevance of Fibroblast Growth Factor and Vascular Endothelial Growth Factor in End Stage Renal Disease and Their Relevance to Cardiovascular Events** Vinod K. Bansal, Kristiyana Kaneva, Debra Hoppensteadt, Jawed Fareed. *Pathology and Medicine, Loyola Univ Medical Center, Maywood, IL.*

**Background:** Fibroblast Growth Factors (FGF) represent families of heparin binding growth factors and Vascular Endothelial Growth Factor (VEGF) also known as Vascular Permeability Factor are a potent mediator of angiogenesis and vasculogenesis in various diseases. We hypothesized that both of these growth factors may be upregulated in End Stage Renal Disease (ESRD) and may contribute to the cardiovascular events.

**Methods:** This study included 119 ESRD patients undergoing maintenance hemodialysis after appropriate IRB approval and patient consent. Citrated blood samples were collected prior to and immediately after the dialysis session. The blood samples were centrifuged for 15 minutes at 3000 g at 4°C and platelet poor plasma (PPP) was extracted. Citrated plasma was frozen at -70°C. Samples collected from ESRD patients were analyzed for the circulating levels of FGF-23 by using a sandwich ELISA kit (Millipore, St. Charles, Missouri). The VEGF analysis was carried out using Quantikine sandwich ELISA method (R&D Systems, Minneapolis, Minnesota). Plasma samples collected from normal male and female (n = 80) comprised the normal group.

**Results:** The FGF-23 levels ranged from 0 to 5934 pg/ml (Mean = 1861 pg/ml with S.E.M = 151) in contrast to the normal levels of 18.4 + 6.1 pg/ml. Of the 119 patients, 67 (56.3%) had greater than 1000 pg/ml FGF-23 levels. The VEGF levels ranged broadly from 8.2 to 3673 pg/ml (Mean = 141 pg/ml with S.E.M = 50.1) in contrast to the normal levels of 8.7 + 4.2 pg/ml. Of the 119 patients, 16 (13.4%) had VEGF levels greater than 100 pg/ml of which 4 (3.36%) had levels greater than 1000 pg/ml. No correlation was observed between the VEGF and FGF23 levels.

**Conclusions:** End Stage Renal Disease represents a complex polypathologic disorder where growth factors such as VEGF and FGF-23 play an important role. Both of these growth factors are increased in ESRD and may contribute to the cardiovascular and cerebrovascular events. Newer targets to modulate these growth factors may be useful in the therapeutic management of these patients.

## FR-PO413

**Posterior Reversible Encephalopathy Syndrome in End Stage Kidney Disease: Not Strictly Posterior or Reversible** Mark N. Canney, Dearbhla Kelly, Michael Clarkson. *Dept of Renal Medicine, Cork Univ Hospital, Ireland.*

**Background:** Posterior Reversible Encephalopathy Syndrome (PRES) is an uncommon clinico-radiological condition that can result in severe brain injury. Little is known about PRES in kidney disease despite the presence of recognised risk factors including hypertension and immunosuppression. This study aimed to define the incidence of PRES in an End Stage Kidney Disease (ESKD) population and identify potential aetiological factors.

**Methods:** This was a retrospective observational study. The database of adult incident ESKD patients in South West Ireland was interrogated over the period 2002 to 2012 and cross-referenced with the patient database of the Department of Radiology to identify cases of PRES. Those cases were further assessed by a detailed review of their hospital record.

**Results:** 592 patients developed ESKD between 2002 and 2012. Five individuals (0.84%) developed PRES. The aetiology of their kidney disease included hypertension, bilateral nephrectomy, pyelonephritis, systemic vasculitis and lupus nephritis. Four patients were established on haemodialysis (HD) at the time of onset. One patient commenced HD during the same admission. The dominant feature at presentation was severe hypertension. The average mean arterial blood pressure was 135mmHg (range 123-159). No incident transplant recipient developed PRES (n=150). Two patients were receiving immunosuppression for active nephritis. Seizure was the most common presenting symptom. Neuroimaging showed diffuse white matter lesions not restricted to the posterior territory but including frontal, parietal, occipital and brainstem distributions. Two patients died following cerebral infarction and intracranial haemorrhage respectively. The remaining patients had complete clinical resolution.

**Conclusions:** PRES is an uncommon complication in incident ESKD patients. Marked hypertension appears to be the common aetiological factor. MRI findings were diverse involving both anterior and posterior circulation territories. Three of the five patients had started haemodialysis within weeks of presentation. This group may be particularly vulnerable to devastating hypertension-associated acute microvascular brain injury.

## FR-PO414

**Superhighflux Therapies for Hemodialysis: Ultrafiltrate Proteomic Profile and Protein Identification** Mauro Atti,[1] Aurora Cuoghi,[2] Elisa Bellei,[2] Stefania Bergamini,[2] Emanuela Monari,[2] Giuseppe Palladino,[1] Luca Corazza,[1] Marialuisa Caiazzo,[1] Luisa Sereni,[1] Aldo Tomasi.[2] *[1]Scientific Affairs, Bellco S.r.l., Mirandola, Modena, Italy; [2]Dept of Diagnostic, Clinical and Public Health Medicine, Univ of Modena and Reggio Emilia, Modena, MO, Italy.*

**Background:** End-stage renal disease is often related with the uremic syndrome that leads to an increase in the morbidity and mortality rate. Uremia pathophysiological process is not completely understood but the retention of a high number of toxic solute compounds seems to play an important role. Uremic toxins are heterogeneous group of substances. Hemodiafiltration with on-line endogenous reinfusion (HFR) dialytic method needs an optimal combination of the membrane permeability and cartridge resin bed. In this study, SELDI-TOF and ESI-QTOF Mass Spectrometries were used for protein profiles and identification of pre cartridge ultrafiltrate (UF) obtained from dialysed patients using three different membranes.

**Methods:** 25 dialysed patients were treated with three membranes: polyphenylene High Flux (pHF), polyphenylene Super High-Flux (pSHF) and Synclear 0.2 (Sync 0.2). UF samples, taken at 30, 60, and 240 min during the dialysis, were loaded on ProteinChip and analysed by SELDI-ToF. Differences in protein profiles, in terms of molecular weight and peaks intensities, were detected by statistical analysis. UF samples from Sync 02 treatment were analyzed by ESI-QTOF.

**Results:** Proteomic profiles of UF at 30 min of dialysis, showed higher cluster peaks intensities for the pHF respect to the pSHF and Sync 0.2 membranes. On the contrary, at 60 and 240 min, the cluster peaks intensities decreased for pHF and increased for pSHF and Sync 0.2. Cluster peaks in the range of 30-60 kD and 60-100 kDa, had the lower number of detected peaks and intensities, for the pHF, while the Sync 0.2 showed the higher permeability, especially for the species >60 kDa, during all treatment. Several inflammatory proteins were identified by ESI-QTof.

**Conclusions:** The results of this study demonstrate that, compared to pHF and pSHF, the Sync 0.2 membrane offers the higher permeability and efficiency, showing its potential use for the clearance of high molecular toxins.

## FR-PO415

**A Randomized Control Trial for the Best Dialyzer Choice for Elderly Dialysis Patients** Ikuto Masakane,[1] Jun Minakuchi,[2] Hideki Kawanishi.[3] *[1]Yabuki Hospital, Nephrology, Yamagata, Japan; [2]Kawashima Hospital, Nephrology, Tokushima, Japan; [3]Tsuchiya Hospital, Surgery, Hiroshima, Japan.*

**Background:** Several recent reports warned that high efficient hemodialysis with polysulfone (PS) membrane occasionally led to the deterioration of nutritional status in elder patients. Ethylene vinyl alcohol (EVAL) membrane has high biocompatibility and a broad solute removal property. In the prior studies, EVAL membrane improved the deteriolated nutritional status caused by PS membrane. The E-HOPOED-Study Group was established in 2010 to determine the best dialyzer choice for elder dialysis patients with early dialysis stage.

**Methods:** The E-HOPED-Study is a open-label, dynamically allocated, central registrated, randomized control trial being performed in 325 dialysis facilities in Japan. The patients who accept the enrollment to the study will be randomly divided into the next two groups; the Group A, treated by EVAL membrane; the Group B, treated by several high flux membrane such as PS. The entry criteria of the patients are the age more than 70 years old, the dialysis vintage less than 180 days. The target number of the entry is 800 in each Group. The 5 year-survival, changes in the nutritional status, occurrence of complications and others are the end points.By June 5th 2013, 601 patients have recruited to the study.

**Results:** The mean age of the patients was 78.2 years old (221patients for 80 years of age or older, 380 patients for less than 80 years of age), 389 (65 %) were male, 289 ( 48 %) were diabetes, and 280 patients for serum albumin level 3.5 g/dL or more. Up to now, 23 patients have died (9 patients for Group A and 14 patients for Group B. There are few deferences in clincal parameters between two groups except post-dialysis pulse pressure. At 0-month there were no diffenrecnes in pre-diaysis and post-dialysis pulse pressure between two groups but at 12-month post-dialysis purelse pressure had significantly reduced in Group B.

**Conclusions:** Based on this interim analysis there are no clinically noteworthy differences between EVAL and PS for elder dialysis patients.

*Funding:* Pharmaceutical Company Support - ASAHIKASEI MEDICAL CO., LTD.

## FR-PO416

**Serum Levels of Free Retained Organic Solutes and Outcomes in Hemodialysis Patients** Tariq Shafi,[1] Timothy W. Meyer,[2] Thomas H. Hostetter,[3] Michal L. Melamed,[4] Yang Liu,[1] Tanushree Banerjee,[5] Neil R. Powe.[5] *[1]Johns Hopkins Univ; [2]Stanford Univ; [3]Case Western Reserve Univ; [4]Albert Einstein College of Medicine; [5]Univ of California San Francisco.*

**Background:** Uremia is associated with accumulation of multiple solutes often poorly cleared by dialysis but the association of these solutes with clinical outcomes remains unclear.

**Methods:** We measured free levels of p-cresol, indican, phenylacetylglutamine and hippurate by HPLC in 396 hemodialysis patients of a national prospective cohort study of incident dialysis patients (CHOICE Study). Outcomes evaluated were mortality (all-cause and cardiovascular [CV]) and CV events analyzed using Cox proportional hazards models adjusted for potential confounders.

**Results:** Mean age was 57 years, 60% were White and 55% male. There were 241 deaths (121 CV deaths) and 203 CV events during follow-up. In fully adjusted models, p-cresol was associated with CV events whereas indican, phenylacetylglutamine and hippurate were associated with mortality. Patients with the highest tertile for all solutes had higher risk of outcomes compared with those in the lowest tertile [HR (95%CI), 2.12 (1.18-3.80) for all-cause mortality and 1.81 (1.00-3.29) for CVD mortality].

| | Clinical Outcomes | | | | | |
|---|---|---|---|---|---|---|
| | All-Cause Mortality | | CV Mortality | | CV Events | |
| Solute | HR* | p | HR* | p | HR* | p |
| P-Cresol | 1.08 (0.94-1.24) | 0.29 | 1.13 (0.96-1.32) | 0.15 | 1.25 (1.14-1.37) | <0.001 |
| Indican | 1.13 (0.98-1.30) | 0.09 | 1.15 (0.92-1.44) | 0.22 | 1.05 (0.90-1.23) | 0.50 |
| Phenylacetylglutamine | 1.13 (1.03-1.26) | 0.02 | 1.15 (0.95-1.40) | 0.15 | 1.12 (0.95-1.32) | 0.18 |
| Hippurate | 1.09 (1.01 1.16) | 0.02 | 1.02 (0.93-1.12) | 0.63 | 0.98 (0.88-1.08) | 0.67 |

* Hazard Ratio per SD increase in marker adjusted for age, sex, race, comorbidities, BMI, urine output and serum albumin

**Conclusions:** Certain uremic solutes are associated with adverse outcomes in dialysis patients. Replication of these findings in other studies may allow identification of individuals at highest risk for adverse outcomes and perhaps the choice for optimal dialysis modality.

*Funding:* NIDDK Support

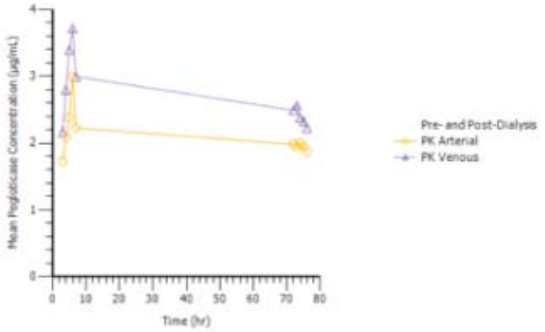
**FR-PO417**

**Pegloticase, a Recombinant Uricase for the Treatment of Advanced Gout, Maintains Therapeutic Concentrations during Dialysis** Anthony J. Bleyer,[1] David E. Wright,[2] Alan Glicklich.[2] *[1]Wake Forest Univ Sch Med, Winston-Salem, NC; [2]Savient Pharmaceuticals, Inc.*

**Background:** Patients (pts) commonly proceed to dialysis with advanced tophaceous gout and information on the use of urate-lowering medications in the dialysis population is scant. Pegloticase is reserved for pts with chronic gout who are refractory to current oral treatments and does not require dose adjustment based on renal function. Here we present results from a pharmacokinetics/pharmacodynamics study of pegloticase in hemodialysis (HD) pts.

**Methods:** A single intravenous dose of pegloticase (8mg) was administered to pts (age 18-75 years; N=12) without gout. The pegloticase infusion was completed over a 2-hour period at 3 hours prior to the Day 1 HD. A second HD was monitored on Day 4. Pts received prophylactic antihistamine and corticosteroid prior to the pegloticase infusion. Blood samples were drawn pre-HD and hourly over 4 hours post-HD during the Day 1 and Day 4 HD sessions.

**Results:** Mean age of this cohort was 44 years, 58% were male, 25% were white, 67% were black, and mean BMI was 28.6 kg/m$^2$. HD vintage was 6.4 years and 2 pts had a prior kidney transplant. Mean arterial and venous pegloticase concentrations across sampling times during the Day 1 and Day 4 HD sessions are shown in the figure.



Baseline mean serum uric acid was 5.98 mg/dL; by 3 hours post-infusion serum uric acid was undetectable and remained so through the final serum sampling at 72 hours. One AE of headache was possibly related to study drug.

**Conclusions:** In this Phase 1 study, pegloticase concentration was not affected by a single HD session and remained stable following a second HD session 3 days later. Serum uric acid levels in this cohort fell to non-detectable levels by 3 hours post-infusion. While additional research is needed, these data support the use of pegloticase in patients with chronic tophaceous gout in HD.

**FR-PO418**

**Low Hip Bone Mineral Density Predicts Mortality in Maintenance Hemodialysis Patients: A Five-Year Follow-Up Study** Sinee Disthabanchong.[1,2] *[1]Div of Nephrology, Saint Louis Univ, Saint Louis, MO; [2]Div of Nephrology, Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Phayathai, Bangkok, Thailand.*

**Background:** Bone loss is common among hemodialysis patients and may contribute to increased mortality. The degree of bone loss is related to the severity of vascular calcification which may explain the increased mortality risk. Studies that investigated the relationship between bone loss and mortality in maintenance hemodialysis patients are limited.

**Methods:** Eighty three maintenance hemodialysis patients underwent the measurements for bone mineral density (BMD) of the hip and lumbar spine by DEXA scan and coronary artery calcification (CAC) by multi-slice CT. The relationship between BMD and mortality were analyzed after adjustments for relevant cardiovascular and CKD risk factors after 5 years of follow-up.

**Results:** The average follow-up duration was 48±15 months. Mortality occurred in 26 patients (31.3%): twelve (46%) were from cardiovascular causes. Eighty percent of the patients had reduced total hip BMD (t-score<=-1) at baseline. Total hip BMD showed negative relationship with CAC scores. In univariate cox regression analyses, age, cardiovascular disease (CVD), dyslipidemia, increased c-reactive protein, increased CAC scores and decreased hip BMD (HR=0.007, 95%CI=0-0.136, *P*=0.001) were associated with mortality. There was no relationship between lumbar BMD and outcome. Low hip BMD remained independently associated with mortality after adjustments for age, gender, DM, CVD, dyslipidemia, serum albumin, c-reactive protein, CAC score, dialysis vintage, serum phosphate and alkaline phosphatase levels (HR<0.001, 95%CI=0-0.055, *P*=0.005). In Kaplan-Meier survival curve, patients with total hip BMD in the lowest tertile displayed the worst survival (*P*=0.045).

**Conclusions:** Low hip BMD is common among maintenance hemodialysis patients and has the ability to predict mortality independent of cardiovascular and CKD risk factors.

*Funding:* Private Foundation Support

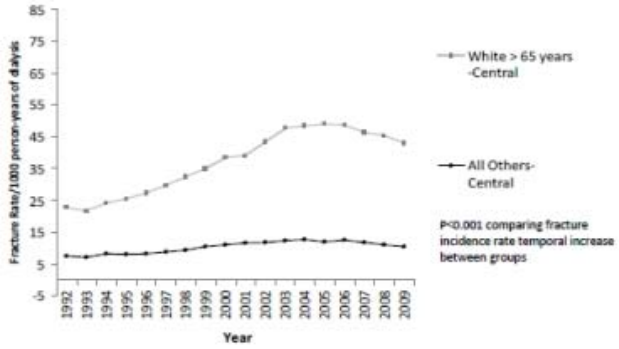
**FR-PO419**

**Increasing Fracture Rates in Elderly Dialysis Patients in the United States** Anna Mathew,[1] John D. Wagner,[1] Lisa M. Rosen,[2] Kenar D. Jhaveri,[1] Steven Fishbane.[1] *[1]Div of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Dept of Biostatistics, Feinstein Institute for Medical Research, Great Neck, NY.*

**Background:** Fractures cause excess morbidity in dialysis patients. New approaches for bone mineral disorders in end stage renal disease have recently evolved. This study aims to determine if rates of fractures in dialysis patients have declined.

**Methods:** Using an overdispersed Poisson regression model, we modeled fracture counts from 935,221 dialysis patients in the United States Renal Data System (USRDS) from 1992 to 2009 for the primary outcome of central fractures (hip and vertebral) requiring hospitalization. The first 90 days of dialysis were excluded. The study population was stratified by the demographic characteristics of age, race and gender.

**Results:** From 1992 to 2004, central fracture rates increased from 12.5 to 25.3 per 1,000 person-years. After 2004 fracture rates stabilized but did not decline. The overall p-value <0.0001 indicated a significant increase in central fracture rates from 1992 to 2009. With stratification by age and race, the sharp rise in central fracture rates was explained almost entirely by patients 65 year or older in age, and occurred primarily in white patients. Taken together, the striking rise in bone fractures occurred almost exclusively in elderly, white patients with 22.7 fractures per 1,000 person-years in 1992 to 48.4 fractures per 1,000 person-years in 2004.



**Conclusions:** Central fracture rates have increased from 1992 to 2004, mostly in white, elderly dialysis patients and despite availability of new treatments. Untreated loss of bone volume and density in ESRD may contribute to these findings, and a "one size fits all" treatment paradigm for bone disease may be harmful to some dialysis patients. Further studies on diagnosis and management of bone disease in elderly dialysis patients are warranted.

**FR-PO420**

**Mineral and Bone Disorder Medication Use Patterns in U.S. Dialysis Patients** Akeem Yusuf,[1,2] Wendy L. St. Peter.[1,2] *[1]USRDS Coordinating Center, MMRF; [2]Univ of Minnesota.*

**Background:** Chronic kidney disease mineral and bone disorder (CKD-MBD) management involves use of multiple therapeutic agents. We describe CKD-MBD medication use trends in US Medicare Part D enrolled dialysis patients.

**Methods:** We created annual cohorts of adult dialysis patients (2007-2010) using Centers for Medicare and Medicaid Services End-Stage Renal Disease database linked with Medicare Part D data. We included patients ≥18 years, alive on December 31 of the previous year, with Medicare Parts A, B and D coverage from January 1 to earliest of death or December 31 of the present year. Medication use was defined as ≥1 claim for an oral medication (or administration record for intravenous (IV) Vitamin D) during follow up, with stratification by low-income subsidy (LIS) status and dialysis organization. Medication groups included prescription phosphate binders, oral and IV vitamin D analogues and cinacalcet. We calculated odds of medication use for LIS vs. non-LIS patients and for patients from various dialysis organizations using logistic regression, adjusted for age, sex, race, vintage and dialysis organization, where appropriate.

**Results:** Phosphate binders (~83% of patients) and IV vitamin D (77.5%-79.3%) were most common CKD-BMD medications used from 2007-2010 followed by calcimimetics (31.0-33.3%), and oral vitamin D analogues (8.5%-9.9%). Sevelamer was the main phosphate binder used (~53%); with decreasing use of calcium acetate and lanthanum over study period. Paricalcitol and calcitriol constituted majority of IV and oral vitamin D use, respectively. The odds of using trade name phosphate binders, IV vitamin D and cinacalcet were significantly higher for LIS vs. non-LIS patients. DaVita patients were more likely to use lanthanum, sevelamer and cinacalcet and less likely to use calcium acetate, while Fresenius patients had highest use of IV Vitamin D.

**Conclusions:** LIS vs. non-LIS and DaVita vs. other provider patients were more likely to be prescribed expensive trade name oral CKD-MBD medications, after adjustment for some factors that affect prescribing. Further research is needed to see if higher use of trade name CKD-MBD agents is associated with better clinical outcomes.

**FR-PO421**

**Costs Associated with Mineral and Bone Disorder Medications in Dialysis Patients** Akeem Yusuf,[1,2] Wendy L. St. Peter.[1,2] *[1]USRDS Coordinating Center, MMRF; [2]Univ of Minnesota.*

**Background:** Dialysis-related chronic kidney disease mineral and bone disorder (CKD-MBD) medications (meds) represent a large portion of Medicare Part D costs in these patients (pts). This has implications for pts, providers and Medicare when these meds are included in the dialysis bundle in 2016. We describe costs associated with these meds in US Medicare Part D-insured dialysis pts.

**Methods:** Using Medicare standard analytic files linked with Medicare Part D data, we created annual cohorts of dialysis pts (2007 through 2010). We included pts >=18 years, alive on Dec 31 of each year, with Medicare Parts A, B and D coverage from Jan to Dec. Per member per month (PMPM) net Part D payment and per user per month (PUPM) out-of-pocket (OOP) meds costs for each Part D-covered CKD-MBD med and med class were computed, with stratification by low-income subsidy (LIS) status and dialysis organization.

**Results:** In 2010, PMPM net Part D costs were $555.22 and $278.65 for all Part D meds and CKD-MBD meds respectively. There was a 22% vs. 36% increase in total Part D vs. CKD-MBD Part D med costs from 2007 to 2010. CKD-MBD meds represented about 50% of overall net Part D costs in 2010 (Phosphate binders(PB) 30%, cinacalcet 19%, oral vit D 2%). Between 2007 and 2010, PMPM Part D costs were highest among DaVita pts for cinacalcet, sevelamer and lanthanum as compared to other dialysis providers. PUPM OOP costs for PB decreased from 2008 to 2009 while OOP costs for sevelamer carbonate had a sustained year-to-year increase. PUPM OOP costs for all CKD-MBD meds were much higher for pts without LIS vs. with LIS.

**Conclusions:** Part D net costs increased faster for CKD-MBD meds compared to all Part D meds in dialysis pts, despite relatively stable use within med classes from 2007-2010. This was mainly due to increases in net Part D PMPM spending for sevelamer and cinacalcet. OOP costs for PB were reduced in 2009, due to availability of generic calcium acetate. However, pts without LIS, on average, had high OOP costs for brand name CKD-MBD meds. In a bundled environment, there will be incentives to shift to generic PB and reduce use of cinacalcet, particularly with no MBD performance measures in place.

**End-Stage Renal Disease due to Multiple Myeloma in the United States, 2000-2010** Scott Reule,[1,2] Donal J. Sexton,[1,2] Craig Solid,[1] Shu-cheng Chen,[1] Allan J. Collins,[1,2] Robert N. Foley.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, Univ of MN, Minneapolis, MN.*

**Background:** As management has advanced rapidly, we combined US census data with data from the USRDS patients to determine whether incidence rates and survival of ESRD from myeloma and light chain deposition disease ('MM') have improved correspondingly.

**Methods:** A total of 13,832 of 1,140,882 (1.2%) patients initiated dialysis due to MM between 2000 and 2010. Using incidence rates for 2000 to calculate expected rates for subsequent years (based on age, sex and race/ethnicity), standardized incidence ratios peaked in 2002 at 1.19, declining subsequently to 0.86 in 2010.

**Results:** Characteristics of MM patients included older age (≥ 65, 63.7% vs. 43.7%), white race (76.3% vs. 65.1%), catheter for hemodialysis (94.9% vs. 82.4%), and < 1 year of prior nephrology care (90.4% Vs. 76.3%). When adjustment was made for demography, MM was associated with a greater likelihood of death (adjusted hazards ratio [AHR] 2.32) and a lower likelihood of listing for (AHR 0.018) and receipt of (AHR 0.2) of a renal transplant. Among patients with myeloma, likelihood of death remained unchanged, transplant listing increased (AHR 1.21 for 2005-2010 Vs. 2000-2004) and transplantation decreased (AHR 0.80). Regional variation in outcomes was apparent, as patients in the South were more likely to die (AHR 1.04 Vs. the Northeast), and less likely to be listed (AHR 0.49) or received a transplant (AHR 0.41).

**Conclusions:** While ESRD due to MM has declined in the United States, outcomes on dialysis remain poor and exhibit substantial geographic variation.

**Cancer Risk in Incident Dialysis Patients in the United States, 2005-2009** Robert N. Foley,[1,2] Craig Solid,[1] Shu-cheng Chen,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, Univ of MN, Minneapolis, MN.*

**Background:** Few recent large-scale epidemiological studies are available to determine whether patients starting dialysis therapy are at greater risk of cancer than the general population.

**Methods:** Hence, we set out to address this information gap among 112,699 patients aged 65 or more with Medicare insurance and no prior history of malignancy that started maintenance dialysis in the United States between 2005 and 2009 and were followed for 1.7 years. We used age, sex and race-specific incidence rates from the US general population (Statistics Epidemiology and End Results (SEER) database, (United States) National Cancer Institute) to calculate expected rates for cancer of any cause, and for the 10 most common types, based on the demographic profile of the dialysis population. Actual cancer rates were calculated from Medicare hospital admissions claims.

**Results:** All cancers studied occurred more frequently than expected ($P < 0.05$) in dialysis patients. For any cancer, actual and expected incidence rates were 14,747 and 682 per 100,000 per year, respectively, an actual-to-expected incidence ratio of 21.6. Incidence ratios for individual cancers were as follows: prostate 5.3, breast 5.1, lung and bronchus 3.0, colon and rectum 3.9, melanoma 2.8, urinary bladder 8.4, non-Hodgkin lymphoma 5.5, kidney 17.3, uterus 3.8, and leukemia 8.2.

**Conclusions:** These data suggest that patients starting dialysis patients have greater risks of the commonest types of cancer.

**FR-PO424**

**Effect of Frequent Nocturnal Hemodialysis (NH) or Renal Transplantation (RT) on Cognition** Bradley S. Dixon,[1] John M. Vanburen,[1] Jacob J. Oleson,[1] Robert S. Lockridge,[2] James R. Rodrigue,[3] Jane S. Paulsen,[1] John B. Stokes.[1] *[1]Univ of Iowa; [2]Univ of Virginia; [3]Harvard Med School.*

**Background:** It is unknown whether frequent hemodialysis or renal transplantation will reverse the cognitive impairments seen in patients with end stage kidney disease on conventional hemodialysis.

**Methods:** We performed a prospective cohort trial analyzing the effect of switching from conventional hemodialysis 3 days per week (HD) to either nocturnal hemodialysis (NH) 6 days per week or renal transplantation (RT) on tests of memory and learning (Rey Auditory-Verbal Learning Test, AVLT and Brief Visuospatial Memory Test, BVMT), executive function (Trails B test) and psychomotor processing speed (Buttons and Digit-Symbol tests). Participants were measured at baseline, 4 and 12 months and tested for significant change at follow-up using a linear mixed model.

**Results:** A total of 77 patients switched to nocturnal hemodialysis (n=18), received a renal transplant (n=28) or remained on conventional hemodialysis (n=31). Baseline characteristics were not significantly different between the groups. 48 patients (62%) returned for their 12-month study visit (67% NH, 46% RT and 74% HD) at a mean (± SD) follow-up of 13.4 (± 2.2) months. Patients who received a renal transplantation showed improvement in AVLT ($p<0.01$) and Digit-Symbol test ($p=0.02$) but not BVMT, Trails B or Buttons. Treatment with nocturnal hemodialysis did not improve any of the cognitive tests and BVMT declined ($p=0.02$). Surprisingly, patients remaining on conventional hemodialysis showed improvement in the Digit-Symbol test ($p<0.01$) and Buttons test ($p=0.05$) and a decline in verbal fluency ($p<0.001$) but no change in AVLT, BVMT or Trails B.

**Conclusions:** After 13 months, renal transplantation improved auditory/verbal memory and processing speed but not executive function. In this small study, no improvement in cognitive testing was seen with initiating nocturnal hemodialysis.

**FR-PO425**

**Cognitive Function and All-Cause Mortality in Hemodialysis Patients** Mark J. Sarnak, Hocine Tighiouart, David A. Drew, Kristina Lou, Saeed Kamran Shaffi, Tammy Scott, Li Fan, Daniel E. Weiner. *Tufts Medical Center, Boston, MA.*

**Background:** Cognitive impairment is highly prevalent in dialysis patients. Although advanced dementia is associated with mortality, it remains unknown whether milder degrees of cognitive impairment, and which components of this impairment, are associated with mortality.

**Methods:** 292 patients enrolled in the Dialysis and Cognition Study underwent a detailed battery of previously validated cognitive tests. Principal factor analysis was used to derive two summary factors representing memory and executive function. Multivariable Cox proportional hazards models were used to evaluate the association of the individual tests, as well the memory or executive component with all- cause mortality.

**Results:** Mean (SD) age was 63 (16) years, 53% were women and 23% African American. 146 patients died during a median follow up of 27.4 months. Higher executive function scores were associated with lower risk of mortality. In contrast, memory was not associated with mortality.

| | Unadjusted | | Model 1* | | Model 2** | |
|---|---|---|---|---|---|---|
| | HR (95% CI) | p-value | HR (95% CI) | p-value | HR (95% CI) | p-value |
| Executive Factor (per 1 SD higher) | 0.62 (0.53, 0.73) | <0.001 | 0.78 (0.65, 0.94), | 0.008 | 0.80 (0.66, 0.97), | 0.02 |
| Memory Factor (per 1 SD higher) | 0.81 (0.68, 0.95) | 0.01 | 0.98 (0.81, 1.18), | 0.8 | 0.98 (0.81, 1.17) | 0.8 |

Executive and memory factors both have mean (SD) of 0 (1)
*Adjusted for age, sex, race, vintage, cause of kidney disease, education, and dialysis access
**Further adjusted for cardiovascular disease, Kt/V, and serum albumin

Consistent with these results, better performance on several individual tests that assess executive function, such as the Block Design and Trail Making Tests, were associated with lower risk of all-cause mortality.

**Conclusions:** Worse executive function is associated with higher risk of mortality in hemodialysis patients. These results need to be verified in additional studies and the mechanism underlying this association evaluated.

## FR-PO426

**End-of-Life Inpatient Cost Trajectories for Patients with Chronic Kidney Disease Compared with Those with Other Chronic Conditions**

Kenn B. Daratha,[1] Ann M. O'Hare.[2] *[1]Washington State Univ; [2]VA Puget Sound Health Care System.*

**Background:** The cost of caring for patients receiving chronic dialysis is extremely high, due mostly to high rates of inpatient utilization. To date, little is known about cost trajectories toward the end of life in patients with kidney disease in relation to those with other chronic conditions.

**Methods:** We conducted a longitudinal study among 7,065 adults who were hospitalized at the time of death in the State of Washington in 2011 (WA-CHARS). We estimated inpatient costs during the last year of life for members of this cohort with the following chronic conditions: heart failure (HF-39% of all terminal cases with select chronic conditions), chronic obstructive pulmonary disorders (COPD-35%), metastatic cancer (METS-21%), kidney failure without renal replacement therapy (CKD-21%) and kidney failure with renal replacement therapy (ESRD-8%).

**Results:** Patients with ESRD were more likely than those with other chronic conditions to have at least one inpatient hospitalization (84%) in the year preceding the terminal hospitalization, as compared with 73% for patients with HF, 71% for CKD, 67% for COPD and 67% for METS. Total costs in the last year of life were also highest for patients with ESRD (Figure 1).

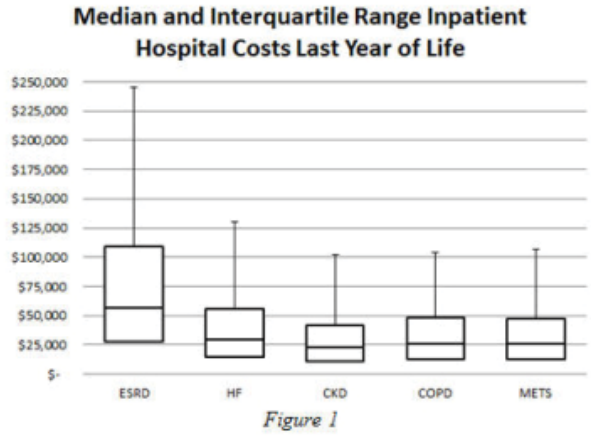

*Figure 1*

For patients with COPD and METS no relationship was found between costs in the last quarter of life and terminal hospitalization costs. A positive relationship was observed between costs in the last quarter of life and the cost of terminal hospitalization for patients with HF (r=0.12, p<0.001), CKD (r=0.15, p<0.001) and ESRD (r=0.17, p=0.002).

**Conclusions:** Among chronically ill patients who died in the hospital, the cost of the terminal hospitalization and overall inpatient costs during the final year of life were markedly higher than for other chronic conditions.

## FR-PO427

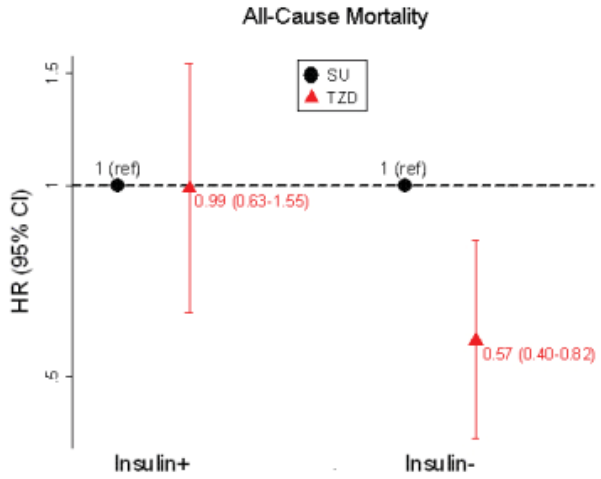
**Thiazolidinedione Use Is Associated with Improved All-Cause Mortality Compared with Sulfonylureas among Non-Insulin Dependent Diabetic Hemodialysis Patients**

Katherine E. Lynch,[1,2] Connie Rhee,[2] Steven M. Brunelli.[2,3] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]DaVita Clinical Research.*

**Background:** Among diabetics on hemodialysis (HD), there are conflicting data as to whether thiazolidinedione (TZD) use improves or worsens survival. Previous studies have compared TZD users to non-users. However, non-user control groups are known to increase risk of bias. The purpose of this study is to evaluate the comparative effectiveness of TZDs versus sulfonylureas (SU) with respect to mortality.

**Methods:** Data were taken from 14,643 prevalent adult HD patients from a large dialysis care organization. Incident TZD users were matched (1: n) to incident SU users on the basis of insulin use and a propensity score based on age, sex, race, dry weight, catheter use, heart failure, and serum albumin. Associations with mortality were estimated using Cox proportional hazard models; analyses were stratified on concurrent insulin use.

**Results:** Among diabetics on insulin, 94 TZD users were matched to 131 SU users; among diabetics not on insulin 136 TZD users were matched to 201 SU users. Cumulative at-risk time was 372 and 594 pt-yrs during which 70 and 128 deaths were observed in the insulin+ and insulin- cohorts, respectively. For the insulin using cohort, the mean age was 63 years, 49% were female, 34% were black, and mean serum albumin was 3.7 g/dL. In comparison, the non-insulin users mean age was 65 years, 49% were female, 36% were black, and mean serum albumin was 3.8 g/dL. Among diabetics not on insulin, TZD use was associated with lower risk of death than SU use; no difference was observed among diabetics on insulin (figure).



**Conclusions:** Among non-insulin dependent diabetics on HD, TZD use versus SU use was associated with 43% lower all-cause mortality. There was no difference in mortality seen for insulin users.

## FR-PO428

**High Prevalence of Elevated Non-A1c Glycemic Indices in Chronic Dialysis Patients without Documented Diabetes**

Neal Mittman,[1] Lin Ma,[2] Mark E. Williams,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[2] Eduardo K. Lacson.[2] *[1]Long Island College Hospital, Brooklyn, NY; [2]Fresenius Medical Care, North America, Waltham, MA; [3]Joslin Diabetes Center, Boston, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

**Background:** Quarterly glycosylated hemoglobin (A1c) has been the standard of care for assessing glycemic control in the general population and in dialysis patients. However, serum fructosamine (SF) and glycated albumin (GA) have both been proposed as alternative markers in dialysis. Based on our previous work (Desiraju et al, 2005), we hypothesized that non-diabetic (NDM) ESRD pts (normal A1c, <=5.6%) may exhibit undetected hyperglycemia when assessed by alternative glycemic indices.

**Methods:** We explored simultaneous measurement of SF and GA in NDM pts by A1c criteria in a national sample of 1192 NDM pt from 26 FMCNA facilities. Residual blood from routine monthly specimens was used for analysis. We report on mean values in these pts for the period January-March 2013.

**Results:** The cohort's mean age was 56 years, 45% female, 43% white, 55% black, and 21% on PD. Fewer than 60% of these non-diabetics had all three glycemic markers within the normal non-diabetic range. More than 50% had elevated SF, 16% had elevated GA, and 15% had increased levels of both. More than 90% of pts with elevated GA had concomitantly elevated SF; however, more than 70% of pts with elevated SF had normal GA.

| All HgbA1c ≤5.6% | GA<=285 | GA>285 | Total |
|---|---|---|---|
| SF<=285 | 577 (57.4%) | 12 (6.4%) | 589 |
| SF>285 | 429 (42.6%) | 174 (93.6%) | 603 |
| Total | 1006 | 186 | 1192 |

**Conclusions:** To our knowledge, there are no published data assessing alternative glycemic markers in non-diabetic dialysis pts and the potential impact on morbidity of elevated values. We and others have reported that elevated levels of SF and/or GA are predictive of morbidity and mortality in diabetic dialysis pts. Therefore, further analyses of these NDM patient subgroups is needed to determine the significance of these elevated glycemic indices.

## FR-PO429

**Biochemical Variables and Survival of Patients with Type 1 Diabetes on Renal Replacement Therapy**

Jaakko Helve,[2] Mikko Haapio,[1] Per-Henrik Groop,[1] Carola Gronhagen-Riska,[2] Patrik Finne.[2] *[1]Dept of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; [2]Finnish Registry for Kidney Diseases, Helsinki, Finland.*

**Background:** End-stage renal disease is one of the most serious complications of type 1 diabetes. Yet, data are limited regarding factors that predict survival of patients with this complication. Our aim was to estimate the effect of biochemical variables on survival of type 1 diabetes patients on renal replacement therapy (RRT).

**Methods:** An incident cohort of all patients with type 1 diabetes entering chronic RRT (n=834) in Finland 2000-2011 was followed up until death or end of follow-up on 31 December 2011. All data came from the Finnish Registry for Kidney Diseases. Creatinine, albumin, urea, ionized calcium, phosphorus, hemoglobin, C-reactive protein, total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, trigycerides, and HbA1c were measured from blood or plasma before the initiation of RRT. Main outcome measure was adjusted relative risk of death according to biochemical variables. Cox proportional hazards models were used for these analyses.

**Results:** When measured before RRT and adjusted for age and sex, low serum creatinine, albumin and hemoglobin, and high C-reactive protein concetration predicted increased mortality. Further adjustment for comorbidities, and initial treatment modality of RRT showed that the most important predictors of death are low creatinine and albumin and high C-reactive protein.

**Conclusions:** Among type 1 diabetes patients entering chronic RRT, biochemical variables independently associating with survival are creatinine, albumin and C-reactive protein. They reflect nutritional status, proteinuria, liver function, and ongoing inflammatory process. Anemia also associates with worse survival. Treatment of these might improve survival.

## FR-PO430

**Propensity-Matched Comparison of New Onset Diabetes Mellitus between Incident Peritoneal Dialysis and Hemodialysis Patients** Chiu-Ching Huang,[1,2] Che-yi Chou.[1,2] *[1]Div of Nephrology, China Medical Univ Hospital, Taichung, Taiwan; [2]Graduate School, China Medical Univ, Taichung, Taiwan.*

**Background:** New-onset diabetes mellitus (NODM) is associated with poor outcome in patients(pts) treated with hemodialysis (HD) or peritoneal dialysis (PD). PD pts were exposed to extra glucose load from daily dianeal dwelling,we ask the question "Are PD pts more prone to develope NODM after dialysis?".We used a propensity score(PS) matching appoach to study this subject. We aim to compare the incidence and outcome of NODM by intention-to-treat analysis in a propensity-score matched HD and PD cohorts.

**Methods:** All HD and PD pts in Taiwan Renal Registry Database(include all pts who survived ≥ 1M after dialysis) were analyzed from 1995 to 2005. Pts were followed until death,renal transplantation or up to December 31, 2008. We attempted to correct for differences between patient charcteristics using a PS-matching method.We matched each PD pt with 4 HD pts with a similar PS. PS accounted for factors recorded in the database, including age, sex, body weight, primary renal disease and co-morbidity . We compared the incidence and survival outcomes of NODM in PD and PS-matched HD pts. Predictors of NODM and mortality were studied using Cox models.

**Results:** We analyzed 2548 non-DM incident PD pts and 10192 PS-matched HD pts with 5.9±3 years follow-up.Mean age of PD pts were 50.2± 14.7y vs. 50.2± 14.4y of matched HD pts.During follow up , 13% of PD patients and 22% of PS-matched HD pts developed NODM. The crude incidence of NODM was 2.2%/y for PD pts, lower than 3.7%/y for HD pts ($p<0.001$). The risk of NODM after starting dialysis is approximately 50% lower (HR 0.48) for pts treated with PD. Male gender, a lower serum albumin and lower hematocrit were independently linked to increased NODM risks. After adjusting for covariates,regardless of dialysis modality,patients who developed NODM had increased overall mortality (HR 3.628, $p<0.001$) than those did not.

**Conclusions:** In a PS-matched Chinese cohort, incident pts receiving HD carry a higher risk of developing NODM than those receiving PD. The pts with NODM are associated with increased overall mortality reardless of dialysis modality chosen.

*Funding:* Government Support - Non-U.S.

## FR-PO431

**Factors Associated with Higher Mortality Rates among Dialysis Facilities in the United States** Janice P. Lea,[1] Muhammad Sarmini,[2] Rachel E. Patzer.[1] *[1]Emory Univ; [2]Univ of Missouri.*

**Background:** Yearly mortality rates average over 20% in the United States (US) End Stage Renal Disease (ESRD) population. It is unclear the extent to which dialysis facility level factors influence the risk-adjusted standardized mortality ratio (SMR) across dialysis facilities in the US.

**Methods:** We analyzed data from the Centers for Medicare and Medicaid Services Dialysis Facility Reports from 2007-2010 to examine dialysis facility-level factors associated with low standardized mortality rates (SMRs) among all dialysis facilities in the United States. Multivariable-adjusted linear regression models were used to identify the facility-level characteristics associated with high SMR.

**Results:** A total of 5,277 dialysis facilities with complete data on SMR from 2007-2010 were examined. Network SMRs ranged from lower than expected (SMR=0.856; SD:0.23 ) in Network 16 (Northwest) and higher than expected (SMR=1.19, SD:0.27) in Network 4 (Pennsylvania and Delaware). In multivariable linear regression models, factors significantly associated with a higher SMR included a higher proportion of African American patients, for profit dialysis facilities, ESRD Network region, and the proportion of patients not informed of transplant options. Clinical factors such as hemoglobin and urea reduction ratio did not influence mortality rates.

**Conclusions:** Dialysis facility demographics such as race, geographic location, for-profit status, and transplant education influence ESRD mortality rates. Clinical factors tested in our study were not associated with mortality. Recent changes in operational aspects of dialysis-i.e., bundling implemented by CMS in 2011 as well as erythropoietin dosing guidelines may change these associations in future analyses.

## FR-PO432

**Epidemic of ESRD Prediabetes: Risk Factors** Mark E. Williams,[1] Neal Mittman,[2] Lin Ma,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[3] Eduardo K. Lacson.[3] *[1]Joslin Diabetes Center, Boston, MA; [2]Long Island College Hospital, Brooklyn, NY; [3]Fresenius Medical Care, North America, Waltham, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

**Background:** In the general population, baseline hemoglobin A1c (HbA1c) levels are an independent predictor of type 2 diabetes, even in the normal range. While the ADA supports hemoglobin A1c of 5.5-6.4% as a screening test for prediabetes, its diagnosis in ESRD patients may be more difficult. We sought to determine risk factors for prediabetes in a dialysis cohort using HbA1c and casual glucose levels as the glycemic markers.

**Methods:** Of 3,447 dialysis patients with laboratory values obtained the first quarter of 2013, 1454 (with mean age 56.6 years; 78% on hemodialysis) were without known diabetes. The distributions of glycemic markers including casual glucose and HgbA1c were determined, using the mean of all available values used in the analysis. Age and BMI subgroup analyses were performed.

**Results:** In those with known diabetes, mean HbA1c was 6.5% (SD=1.4%, CV= .05). In non-DM, mean HbA1c was 5.3% (SD 0.5%,range=3.8-11.5%,CV=.04). Glucose levels without diabetes ranged from 49 to 383mg/dL (mean 106). Initial analyses indicated that 2 percent of nondiabetic HbA1c values were >6.5%, indicating undiagnosed diabetes and that 16% of patients had prediabetes by A1c criteria. Subgroup analyses indicated that the risk of prediabetes almost doubled with body mass index>25(overweight or obese) as well as with increasing age, and in males, but not in Blacks or Hispanics.

**Conclusions:** These data confirm obesity and aging as risk factors for prediabetes in ESRD patients, particularly in males. Results do not suggest an association with race, unlike in the general population. Because HbA1c levels may be reduced in ESRD (previous studies), the prevalence of prediabetes may be even higher. Further studies are needed to determine the sensitivity and specificity of HbA1c in diagnosing prediabetes in ESRD patients.

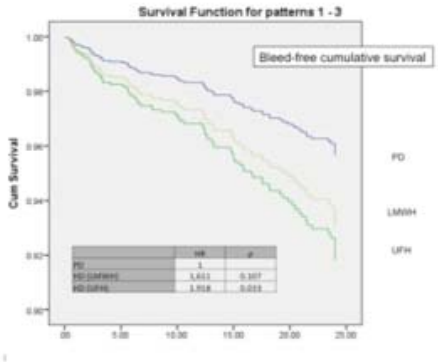
## FR-PO433

**Major Bleeding in Haemodialysis Patients Using Unfractionated or Low Molecular Weight Heparin: A Single Centre Study** Luxme Nadarajah, Stanley Fan, Neil Ashman. *Nephrology Dept, Barts Health NHS Trust, London, United Kingdom.*

**Background:** It is uncertain whether different heparins alter bleeding risk in hemodialysis (HD) patients. We report a comparison of major bleeding in HD patients receiving unfractionated heparin vs tinzaparin (LMWH), using peritoneal dialysis (PD) patients as a control. We also examined any effect of anti-platelet agents or oral anticoagulants on bleeding.

**Methods:** A single centre study conducted before/after a switch from UFH to LMWH as HD anticoagulant. Case notes identified any admission due to bleeding. Bleeding events are described using the ISTH definition of a major bleed (category A), and in more detail, extending to include all bleeds that led to an admission (category B). We report incident event rates and event-free survival calculated using multivariate analysis by Cox-proportional hazard ratio.

**Results:** 889 patients (1200 patient years) on LMWH HD, 522 patients (784 patient years) on UFH HD and 540 patients (1,103 patient years) on PD were studied. The incidence of Category A bleeds was 1.33%, 0.89% and 0.69% bleeds respectively. Incidence of category B bleeds were 3.33 %, 3.96 % and 1.78%. A significant difference in the event free survival of a Group B bleed occurred between HD UFH patients compared to PD patients, (OR 1.918, 95% CI 1.054 - 3.491 *p = 0.03*).



Warfarin usage also significantly increased the risk of bleeding when comparing patients not on any anti-platelet/coagulant (OR 2.755, 95% CI 1.06-7.123, p=*0.037)*.

**Conclusions:** Bleeding risk in our population is similar to that reported elsewhere in the USA and Canada. There is *no* significant difference in major bleeding rates between hemodialysis patients anticoagulated with either UFH or LMWH. There is significantly more bleeding in UFH HD patients compared to PD patients (but not between LMWH HD and PD patients). Warfarin use significantly increases the risk of bleeding episodes.

**FR-PO434**

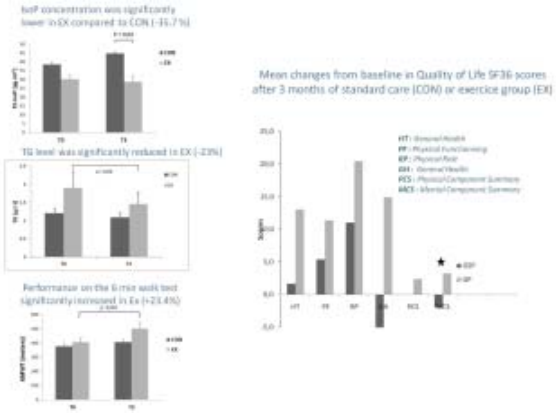
**Oxydant Stress, Quality of Life and Physical Function in Chronic Kidney Disease Patients Are Improved by Intradialytic Aerobic Cycling Program**

Myriam Rouchon Isnard,[1] Céline Coutard,[1] Céline Forte,[5] Cuenin Christine,[4] Nathalie Boisseau.[3] *[1]AURA Auvergne, Chamalières; [2]UFR STAPS, Univ BP, Aubière; [3]Cardiologie, Clinique, Durtol; [4]Biologie, Gen Bio, Clermont-Ferrand.*

**Background:** In Chronic Kidney Disease (CKD), oxidant stress plays a central role in the development of cardiovascular diseases. This study aimed to determine if an intradialytic aerobic cycling training protocol, by improving aerobic fitness, could reduce oxidant stress and others related CKD disorders as lipid profile and quality of life (QOL) of these patients.

**Methods:** Eighteen haemodialysis patients randomly were assigned to either intradialytic exercise training (cycling) group (EX; n = 8) or a control group (CON; n = 10) for 3 months. Aerobic fitness (6 min walk test), pro/antioxidant status (in plasma: 15F2-α-isoprostanes [$F_2$-IsoP], oxidized LDL [ox-LDL], in erythrocytes: SOD, GPX, GSH/GSSG), lipid profile (total cholesterol, HDL, LDL, TG), and QOL (SF36QD) were measured at baseline and 3 months later.

**Results:** Intradialytic training protocol had beneficial effects on pro/antioxidant status, aerobic fitness, lipid profile and QOL. Indeed, at 3 months: i) IsoP concentrations were significantly lower in EX compared to CON (-35.7 %) ii) performance on the 6 min walk testsignificantly increased by 23.4% in EX, but did not change in CON and iii) plasma TG were significantly reduced in EX (-23%) without modification in CON iv) QOL was clinically improved and significantly for the Mental Component Summary +2.2% in EX *vs* -2% in CON.



**Conclusions:** These results show that intradialytic aerobic cycling training protocol exerts beneficial effects in CKD patients by reducing the most sensitive and reliable marker of OS (IsoP) and by improving their lipid profile, physical function, and QOL.

**Association of Daily Physical Activity with Bone Mass in Hemodialysis Patients**

Kei Yoneki,[1] Atsuhiko Matsunaga,[1] Jun Kitagawa,[1] Ryota Matsuzawa,[1,2] Akira Ishii,[1,2] Yoshifumi Abe,[1] Manae Harada,[1] Yasuo Takeuchi,[1] Atsushi Yoshida,[2] Kouju Kamata.[1] *[1]Kitasato Univ, Sagamihara, Japan; [2]Sagami Junkanki Clinic, Sagamihara, Japan.*

**Background:** Low bone mass is a leading cause of fracture. Although daily physical activity is recommended as a preventative measure against bone loss in healthy adults, the effects of physical activity on bone mass in hemodialysis (HD) patients are unclear. This study aimed to determine whether daily physical activity is associated with bone mass in HD patients.

**Methods:** This observational, prospective study consisted of two parts: cross-sectional Study 1 and longitudinal Study 2. At the beginning of the study, 165 HD outpatients (87 men and 78 postmenopausal women; mean age, 68±8 years) who visited our HD center 3 times a week were recruited. Clinical characteristics including age, sex, body mass index, HD duration, and medications (active vitamin D) were recorded from clinical records in both parts of the study. Biochemical parameters including serum phosphorus, corrected calcium, and intact parathyroid hormone levels were also measured. With respect to bone mass, the stiffness index was assessed by quantitative ultrasound of the calcaneus. With respect to physical activity, the number of steps walked per day was measured using an accelerometer. In Study 1, the association between physical activity and bone mass was assessed by multiple regression analysis for each sex. In Study 2, participants were divided into two subgroups according to physical activity based on results from Study 1 (≥5,000 steps per day or not), and two-way analysis of variance (ANOVA) was used to identify the effect of physical activity on bone mass for each sex after a 2-year follow-up.

**Results:** Multiple regression analysis adjusted for clinical characteristics and biochemical parameters in Study 1 indicated that physical activity was significantly associated with bone mass in HD patients of each sex ($P$<0.05, respectively). ANOVA showed that changes in bone mass were significantly different between the two HD patient subgroups for each sex ($P$<0.05, respectively) in Study 2.

**Conclusions:** Decreased daily physical activity is strongly associated with bone loss in HD patients.

**FR-PO436**

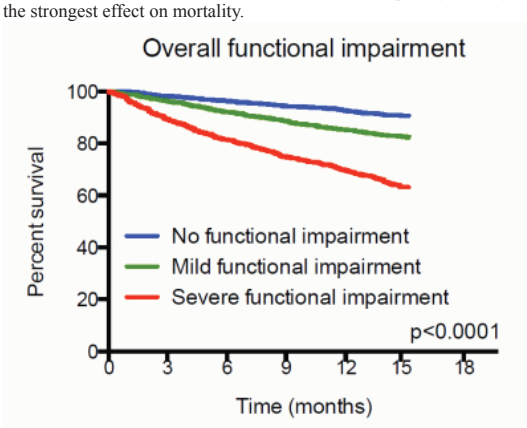
**Functional Impairment and Survival of Dialysis Patients**

Wim P.D. Lemahieu,[1] Maarten Naesens,[2] Johan M.J. De Meester.[3] *[1]Nephrology, Imelda Hospitals, Bonheiden, Belgium; [2]Nephrology, Univ Hospitals Gasthuisberg, Leuven, Belgium; [3]Nephrology, St. Nicolas Hospitals, Sint Niklaas, Belgium; [4]Nephrology, Jessa Hospitals, Hassel, Belgium.*

**Background:** This study aimed to explore functional status of dialysis patients, its possible overlap with classical medical parameters and impact on survival.

**Methods:** 3753 prevalent (95% coverage) Flemish dialysis patients completed a survey on 3 fields: medical (diabetes, wound care, amputations, hospitalization), ambulatory autonomy (ability to walk, recent falls, type of balance, means of transportation to/from dialysis facility) and care dependency (need for assistance with meals, drug management, incontinence and nursing home residency). Patients ≥ 75 years vs those younger were compared by Student's T test. Clustering of individual survey items was assessed by principal components analysis. This was complemented by follow-up on 15 months' mortality and Cox proportional hazards analysis including all survey items, gender and age.

**Results:** Only 15% of all patients was completely impairment-free versus 28% suffering from at least one impairment in each field. For those ≥ 75 years this was respectively 6% and 38% versus 25% and 19% for the younger cohort. Two distinct clusters of patients could be identified: 32% had impairments in all but one ('recent falls') items of ambulatory autonomy and care dependency, and in 11% all (except 'hospitalizations') medical field items clustered. Overall 15 months' mortality was 16 %. The number of impaired items ('no' or 0-1 vs 'mild' or 2-4 vs 'severe' or > 4) composing the major patient cluster had the strongest effect on mortality.



**Conclusions:** Diminished ambulatory autonomy and increased care dependency cluster in an important fraction of Flemish dialysis patients. This clustering does not correlate with classical medical factors but is none the less associated with increased mortality.

**FR-PO437**

**Race and Frailty Differences in a Prevalent Hemodialysis Cohort**

Nancy G. Kutner,[1] Rebecca H. Zhang,[2] William M. McClellan,[3] Quinlyn A. Soltow,[4] Janice P. Lea.[3] *[1]Rehabilitation Medicine, Emory Univ, Atlanta, GA; [2]Biostatistics & Bioinformatics, Emory Univ, Atlanta, GA; [3]Medicine, Nephrology Div, Emory Univ, Atlanta, GA; [4]Medicine, Pulmonology Div, Emory Univ, Atlanta, GA.*

**Background:** Among non-dialysis dependent persons with chronic kidney disease (CKD), blacks are more likely than whites to be identified as frail. No prior research has investigated race and frailty patterns among prevalent end-stage renal disease (ESRD) patients undergoing dialysis, a population in which blacks appear to have better survival and quality of life.

**Methods:** Setting & Participants: 745 prevalent ESRD patients undergoing hemodialysis 2009-2011 in 7 Atlanta dialysis clinics and 7 San Francisco Bay Area dialysis clinics for whom frailty indicators were assessed. Measurements: Study coordinators interviewed participants; measured grip strength, walk speed and body composition; and reviewed charts for clinical and laboratory parameters. Vintage, primary ESRD diagnosis, and receipt of pre-dialysis nephrology care were identified in United States Renal Data System files. Using the Fried frailty index (recent unintentional weight loss, reported exhaustion, low grip strength, slow walk speed, low physical activity), frailty was defined by the presence of 3 or more criteria and pre-frail by the presence of 1 or 2 criteria.

**Results:** In this prevalent hemodialysis cohort (median vintage = 3 years) with mean age = 57, almost 75% were classified as pre-frail or frail. However, the adjusted analysis showed that the risk for being classified as frail was 40% lower among blacks compared with whites ($p < .05$). Peripheral vascular disease and low serum albumin were additional significant predictors of frailty.

**Conclusions:** We observed a lower risk for frail status among black compared with white hemodialysis patients, in contrast with higher frailty risk reported for black compared with white non-dialysis CKD patients. Examination of frailty patterns among black and white CKD patients in the transition to ESRD may offer increased understanding of apparent paradoxes in survival and well-being associated with race among patients with kidney disease.

## FR-PO438

### Frailty: The Strongest Predictor of Quality of Life in Dialysis Patients

Jun Chul Kim,[1] Ki-soo Park.[2] *[1]Div of Nephrology, CHA Gumi Medical Center, CHA Univ, Gumi-si, Gyeongsangbuk-do, Korea; [2]Dept of Preventive Medicine, Gyeongsang National Univ, Jinju, Gyeongsangnam-do, Korea.*

**Background:** Frailty is a growing concern in maintenance dialysis (MD) patients, which is significantly related to the higher incidence of disability, hospitalization and mortality. However, there is no report evaluating the relation of frailty with quality of life (QOL) in this population.

**Methods:** We only included ambulatory MD patients aged ≥20y on hemodialysis (HD) or peritoneal dialysis (PD) ≥6mo, without hospitalization for the last 3mo. Study participants completed the Korean version of Kidney Disease Quality of Life Short Form 36 (KDQOL-36) and other data were obtained by review of medical records. We adopted frailty phenotype composed of the following components; 1)unintentional weight loss >4.5 Kg or 5% of the previous body weight for the last 1y, 2)physical inactivity, 3)physical function (PF) scale <75 and vitality scale <55 as surrogates for weakness/slowness and exhaustion, respectively. Low PF scale was scored as 2 points and other components as 1 point for each. Those with ≥3 points were considered as "frail".

**Results:** 1,658 (1,255 HD, 403 PD) patients evaluated aged 55.9±12.9y (mean±SD) on MD for 5.2±4.5y; 55.7% were male. Compared to the non-frail, frail patients (34.9%) showed significantly (all P-values <0.001) lower scores in Physical Component Score (PCS) (43.7±18.7 vs. 70.4±14.7), Mental Component Score (MCS) (45.9±20.0 vs. 65.8±17.1) and kidney disease (KD) related health concerns such as burden of KD (26.5±24.3 vs. 39.9±26.3), symptom/problems (72.4±16.6 vs. 84.4±12.0) and effect of KD on daily life (63.9±20.6 vs. 77.8±16.5). In multiple regression analysis, frailty was found to be the strongest predictor (all P-values <0.001) for worse conditions of PCS (B=-25.1), MCS (B=-20.1), burden of KD (B=-14.1), symptom/problems (B=-12.7) and effect of KD on daily life (B=-15.3) after adjustment for age, gender, vintage, dialysis modality, co-morbidity, blood hemoglobin, serum albumin and creatinine.

**Conclusions:** Frailty is significantly related to poor outcomes in QOL and KD related health concerns and can be very useful predictor for QOL even in a relatively healthy MD patients.

## FR-PO439

### Predictors of Physical Performance in Patients on Maintenance Haemodialysis: A 12 Month Follow-Up Study

Ying Wang,[1] Cathie Sherrington,[1] Martin P. Gallagher,[1] Alan Cass,[2] Paul Snelling,[1] Meg J. Jardine.[1] *[1]The George Institute for Global Health, NSW, Australia; [2]Menzies School of Health Research.*

**Background:** Poorer physical quality of life is associated with worse outcomes among people with end stage kidney disease (ESKD). While muscle metabolism is known to be impaired, the associations of strength and performance in ESKD remain poorly understood.

**Methods:** We recruited 51 maintenance haemodialysis (HD) patients and 10 healthy volunteers to a longitudinal study. Physical performance (Short Battery Performance Test-SBPT) and strength (ankle dorsiflexion strength-AS) were assessed at baseline and 12 month follow-up. A subgroup of 28 dialysis participants underwent neuropathy assessment (Total Neuropathy Score-TNS). Linear regression was used for normally distributed variables and correlation for skewed variables.

**Results:** Fifty HD patients and 9 controls completed the study. At baseline, HD participants had poorer physical performance than controls (respective median SBPT scores 10 and 12, p=0.002) but similar strength (respective mean AS 13.9 and 14.2, p=0.6). Neuropathy was inversely correlated with physical performance ($r^2$=-0.46, p=0.011) but not strength (p=0.2). At 12 months, strength and physical performance were significantly reduced in the HD group, compared with baseline (mean AS 11.0 versus 13.9, p<0.001; SBPT 9 versus 10, p<0.001, respectively). Neuropathy had deteriorated over 12 months (mean TNS score 7.48 at 12 months versus 6.48 at baseline). Among HD participants, poorer physical performance at baseline was predicted by age (p<0.001), diabetes (p=0.007), strength (p<0.001) and neuropathy (p=0.011) while deterioration over 12 months was predicted by age (p<0.001), diabetes (p=0.008), and strength (p<0.001). Poor strength at baseline was predicted by age (p<0.001) and diabetes (p=0.041) with no strong predictors of deterioration (age, p=0.096; diabetes, p=0.57).

**Conclusions:** Haemodialysis patients have poor physical performance that is not explained by muscle strength alone. Physical performance and strength deteriorated over 12 months in a stable haemodialysis cohort. Better understandings of the underlying mechanisms of the poor physical health in ESKD are needed.

### Physical Activity Energy Expenditure and Quality of Life in Maintenance Hemodialysis Patients with and without Major Comorbidities

Marina Albuquerque Dantas, Jean M. Monteiro, Clarcson Plácido Santos, Gildete Barreto Lopes, Antonio Alberto Lopes. *Federal Univ of Bahia, Salvador, Brazil.*

**Background:** Maintenance hemodialysis (MHD) patients with comorbidities have, in general, lower physical activity (PA) levels and poorer health-related quality of life (HRQOL). We investigated associations between physical activity energy expenditure (PAEE) and HRQOL in patients with > 3 mo. on MHD, separately by groups with and without major comorbidities.

**Methods:** Cross-sectional analysis of data of 640 MHD patients in the Prospective Study of the Prognosis of Chronic Hemodialysis Patients (PROHEMO) developed in 4 clinics in Brazil. The International Physical Activity Questionnaire was used for PA. The following comorbidities were considered in the analysis: diabetes, heart failure, coronary disease, cerebral vascular disease, peripheral vascular disease, pulmonary diseases and cancer; 217 patients were diagnosed and 423 were not diagnosed with any of these comorbidities. Metabolic equivalent of task (MET) was used for determining PAEE and categorized by the median (≤498 and >498 kcal/week). SF-36 was used for scores of 8 primary HRQOL scales and the physical (PCS) and mental component summaries.

**Results:** Among patients without comorbidities, HRQOL scores were higher in those with PAEE>498 kcal/week for all scales, with difference in score (DS) > 4 points for PCS (DS=4.7), vitality (DS=6.8), role emotional (DS=9.6), pain (DS=7.8), role physical (DS=14.9), and physical functioning (DS=13.6). Associations of higher PAEE with better HRQOL were not markedly changed after linear-regression adjustments for age, sex, education, economic class, marital status, and living with family. In patients with comorbidities, the associations followed the same directions and were not substantially different from those without comorbidities (interaction coefficient PAEE*comorbidity>0.2).

**Conclusions:** The results based on PAEE provide further support for potential beneficial effects of physical activity on the health of MHD patients, both for those with and without major comorbidities, but it is not possible to establish causal links or the direction of the association due to the cross-sectional design of the study.

## FR-PO441

### Differences in Health Status and Healthcare Delivery between Men and Women Starting Dialysis Therapy in the United States: 1995-2010

Ahad Abdalla,[1,2] Ailish Hannigan,[2] Liam F. Casserly,[1,2] Austin G. Stack.[1,2] *[1]Medicine and Nephrology, Univ Hospital Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Limerick, Ireland.*

**Background:** Differences in survival between men and women may be related to their health status at the start of dialysis and differences in care delivery prior to dialysis initiation. The aim of this study was to compare health care status and healthcare delivery among men and women in the national US Renal Data System Registry.

**Methods:** We compared baseline health indicators in 1, 220, 000 incident US patients (662, 985 men and 557,015 women) who commenced dialysis from 1995-2010. Comparisons were made across 10 comorbid conditions, and 6 measures of pre-dialysis care delivery (anaemia, nutrition, pre-dialysis care, timing of dialysis initiation, dialysis modality). The timing of dialysis initiation was assessed using the CKD-EPI equation. Multivariable logistic regression was used to compare gender differences for each outcome with the generation of adjusted odds ratios (OR). SAS v9.3 was used for all statistical analysis. Ethical approval was received from the University Hospital Ethics Committee.

**Results:** The likelihood of having a major medical disease was significantly lower for women than men for most conditions listed with the exception of diabetes, heart failure and stroke. However, women were significantly more likely than men to have a low body mass index, hypoalbuminemia at dialysis initiation and were more likely to have dialysis initiated late. These differences persisted when consideration was taken into account for case mix.

Adjusted Odds Ratios (OR) and 95% CI for each Clinical Condition or Health indicator for Women versus Men

| | Age and Race Adjusted OR[1] | Multivariate Adjusted OR[1] |
|---|---|---|
| **Clinical Condition (present vs absent)** | | |
| Coronary Disease | 0.79 (0.78-0.79) | 0.75 (0.74-0.76) |
| Peripheral vascular disease | 0.82 (0.81-0.82) | 0.85 (0.83-0.86) |
| Pulmonary disease | 0.84 (0.83-0.85) | 0.90 (0.88-0.92) |
| Cancer | 0.72 (0.71-0.73) | 0.71 (0.70-0.73) |
| Alcohol use | 0.32 (0.31- 0.33) | 0.38 (0.36- 0.40) |
| Stroke | 1.01 (0.99-1.02) | 1.05 (1.03-1.07) |
| Body mass index < 18kg/m² | 1.17 (1.16-1.19) | 1.19 (1.18-1.21) |
| Heart Failure | 1.08 (1.08-1.09) | 1.27 (1.25-1.28) |
| Diabetes | 1.25 (1.24-1.26) | 1.30 (1.29-1.32) |
| **Health Care Delivery (yes vs no)** | | |
| Haemoglobin < 10g/dl | 0.91 (0.90-0.92) | 0.96 (0.95-0.97) |
| Albumin < 3mg/dl | 1.15 (1.14-1.15) | 1.21 (1.19-1.22) |
| GFR < 5 ml/min/min² | 1.70 (1.69-1.71) | 1.81 (1.79-1.84) |
| Seen by nephrologist | 1.02 (1.00-1.03) | 1.02 (1.00-1.03) |
| Seen by Dietitian | 0.91 (0.90-0.93) | 0.92 (0.90-0.94) |
| Peritoneal dialysis (vs haemodialysis) | 1.11 (1.09-1.12) | 1.09 (1.07-1.11) |

**Conclusions:** Substantial differences in health status and clinical care delivery exist between men and women at the initiation of dialysis. The interplay of these factors require further exploration and may contribute to important survival differences between men and women.

**FR-PO442**

**Fibroblast Growth Factor 23 and the Risk of Infectious Hospitalizations and Deaths in Hemodialysis Patients: Results from the HEMO Study**
Kristen L. Jablonski,[1] Jessica B. Kendrick,[1] Alfred K. Cheung,[2,3] Tom Greene,[3] Michel Chonchol.[1] *[1]Univ of Colorado Denver, Aurora, CO; [2]VASLCHCS, Salt Lake City, UT; [3]Univ of Utah, Salt Lake City, UT.*

**Background:** Fibroblast growth factor 23 (FGF23) acts as a phosphaturic factor. Recently, FGF23 has been suggested to be a regulator of innate immunity, as it has the potential to inhibit the enzyme 25-hydroxyvitamin D-1α-hydroxylase in monocytic cells, with concomitant effects on intracrine responses to 1,25-dihydroxyvitamin D.

**Methods:** The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum intact FGF23 levels were measured in stored serum samples obtained at baseline and annually in 1,340 HEMO participants. Quartiles of FGF23 concentrations were chosen as the primary predictor variable, with the lowest quartile serving as the reference category. Time-dependent Cox proportional-hazards models were used to examine the association between FGF23 levels with a composite of hospitalizations and death attributed to an infectious cause.

**Results:** Participants had a mean age of 57±14 years, 55% were females and 46% were white. During a median follow-up of 3.0 years, 499 (37%) participants had an event attributed to an infectious cause. Median (IQR) serum FGF23 levels was 3118 [726, 12928] pg/mL. Overall, median levels of FGF23 rose during follow-up (p=0.01). After adjustment for potential confounders available in the database, including inflammatory markers and usage of calcitriol, higher serum FGF23 levels were directly associated with higher risks of the infectious composite. Compared to the first (lowest) quartile, the HR (95% CI) for infections were as follows: second quartile, 0.95 (0.72-1.25); third quartile, 1.41 (1.06-1.89) and fourth quartile, 1.58 (1.14-2.21). Similar results were obtained when FGF-23 was examined as a continuous variable (HR; 1.10, 95% CI 1.02-1.13 per doubling of FGF23; p=0.01).

**Conclusions:** In the HEMO study, higher serum FGF23 levels were independently associated with infectious hospitalizations and death in time-dependent Cox regression models.

*Funding:* NIDDK Support

**FR-PO443**

**Associations of Serum 25-Hydroxyvitamin D and 1,25-Dihydroxyviatmin D Levels with Infectious Hospitalization and Infectious Death in the HEMO Study**
Anna Jeanette Jovanovich,[1] Jessica B. Kendrick,[1] Alfred K. Cheung,[2,3] Tom Greene,[3] Michel Chonchol.[1] *[1]Div of Renal Diseases and Hypertension, Univ of Colorado Denver, Aurora, CO; [2]VA Salt Lake City Healthcare System, Salt Lake City, UT; [3]Univ of Utah, Salt Lake City, UT.*

**Background:** Determine whether serum vitamin D levels are related to infectious hospitalization and death in subjects requiring hemodialysis.

**Methods:** The HEMO Study was a randomized multicenter study evaluating the effects of high-dose vs. standard-dose and high-flux vs. low-flux hemodialysis. 25-hydroxyvitamin D (25(OH)D) and 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) levels were measured in stored serum samples obtained at baseline and annually in 1,340 subjects. Serum 25(OH)D and $1,25(OH)_2D$ level quartiles were chosen as the primary predictor variable, the lowest quartile served as the reference category. Time-dependent Cox proportional-hazards models were used to examine the association of vitamin D levels with infectious hospitalization and infectious death.

**Results:** Mean age was 57±14 years, 55% were female, and 46% were white. During a median follow-up of 3.0 years, 499 (37%) subjects were hospitalized for or died of an infectious cause. Median [IQR] serum 25(OH)D and $1,25(OH)_2D$ levels were 19.1 [14.2, 26.6] ng/mL and 6.3 [2.9,14.5] pg/mL, respectively. After adjustment for potential confounders available in the HEMO cohort including inflammatory markers and use of calcitriol, the highest quartile of 25(OH)D was associated with a reduced risk of infectious hospitalization and death (HR 0.72, 95% CI 0.53-0.97; p=0.03) compared to the lowest quartile. When 25(OH)D was evaluated as a continuous variable, higher levels of 25(OH) D were associated with a reduced risk of infectious death and hospitalization (HR 0.84, 95% CI 0.72-0.98 per doubling of 25(OH)D; p=0.02). There was no association between $1,25(OH)_2D$ levels with infectious events (HR; 1.02, 95% CI 0.0.95-1.08 per doubling of $1,25(OH)_2D$; p=0.64).

**Conclusions:** Low serum 25(OH)D level, but not $1,25(OH)_2D$ level, is independently associated with infectious hospitalization and infectious death in subjects requiring hemodialysis.

**FR-PO444**

**Infectious Hospital Admissions among Prevalent Hemodialysis and Peritoneal Dialysis Patients from 1993 to 2011**
Tricia L. Roberts,[1] Robert N. Foley,[1,2] David T. Gilbertson,[1] Craig Solid,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, Univ of Minnesota, Minneapolis, MN.*

**Background:** In the past two decades, infectious hospital admission rates have increased among hemodialysis (HD) patients, while admissions for peritoneal dialysis (PD) peritonitis have fallen close to those for HD vascular access infection. However, infectious admissions traditionally have been defined by principal ICD-9-CM diagnosis codes which could be susceptible to shifts in billing practices. Rates using both principal and secondary diagnosis codes have not yet been assessed.

**Methods:** We included U.S. Medicare period prevalent HD (N=305,901 in 2011) and PD (N=23,558 in 2011) patients from 1993 to 2011. Admission rates were computed for all-cause infection, bacteremia/sepsis, PD peritonitis, and HD vascular access (VA) infection. Two methods defined infectious admissions from inpatient claims using principal diagnosis codes only, method 1 (M1), and principal and secondary diagnosis codes, method 2 (M2). Rates were adjusted for age, gender, race, and primary ESRD diagnosis using model-based adjustment and a Poisson model.

**Results:** For all-cause infection, admission rates were 1.5 to 2.0 times higher with M2 than M1 (in 2011 among HD and PD, respectively, 462 and 551 admissions per 100 patient months with M1; 903 and 935 with M2). All-cause infectious admission rates among PD patients were generally stable across years and higher than HD; however, by 2011, admissions with infection (M2) increased among HD patients to levels similar to PD. Rates were 2 to 4 times higher for M2 than M1 for bacteremia/sepsis (in 2011, 123 and 82 with M1; 282 and 201 with M2) and for PD peritonitis (81 with M1; 354 with M2). With M2, PD peritonitis admissions were 2 to 4 times higher than HD VA infection (88 with M1; 118 with M2).

**Conclusions:** Rates for admissions with infection were strikingly high compared to those for the purpose of infection. Results suggest that attention is needed to address lack of improvement in the last two decades in all-cause infectious admissions among dialysis patients using both methods and high admissions with peritonitis among PD patients.

**FR-PO445**

**Spinal Epidural Abscess in Hemodialysis Patients**
Jennifer Marie White,[1] Chan Jin,[1] Rhonda E. Colombo,[1] Stephanie L. Baer,[1,2] Usman Afzal,[1] Kristina W. Kintziger,[1] Mufaddal F. Kheda,[1] Lu Y. Huber,[1] Puja Chebrolu,[1] N. Stanley Nahman.[1,2] *[1]Georgia Regents Univ, Augusta, GA; [2]Augusta VAMC, Augusta, GA.*

**Background:** Spinal epidural abscess (SEA) may be a serious infectious comorbidity in hemodialysis (HD) patients. SEA may be the result of bacteremia (BAC), but other factors are possible. We have previously shown that BAC occurs in over 20% of incident HD patients, suggesting a significant risk for this condition (Chebrolu, IDSA, 2012). To more fully address the role of BAC and other co-morbidities associated with SEA, we queried the United States Renal Data System (USRDS).

**Methods:** All incident HD cases from the USRDS for calendar years 2005-2008 were queried for a diagnosis of SEA, BAC and several potential clinical covariates using ICD-9 diagnosis codes submitted for Medicare billing. Descriptive statistics and log-binomial regression analysis were performed.

**Results:** For the 4-year period of study, 355,084 patients were available for analysis. The median age was 65 years. SEA was identified in 660 (0.19%) patients. Vascular access type at the initiation of HD included AVF in 47,732 (13.4%), AVG in 14,179 (4.0%) and vascular catheter in 293,173 (82.6%) patients. Of the demographic variables, black race [relative risk (RR) 1.218, 95% confidence interval (CI) 1.025- 1.447] and female sex [RR 1.179, 95% CI 1.009-1.379] carried significant risks for SEA. Infectious comorbidities, including diagnosis of BAC [RR 7.757, 95% CI 6.432-9.355], MRSA infection [RR 2.684, 95% CI 2.192-3.286] and hepatitis C [RR 1.660, 95% CI 1.223-2.253] were associated with the highest risk. Of the non-infectious factors, diabetes mellitus [RR 1.515, 95% CI 1.278-1.797] and vascular catheters [RR 1.347, 95% CI 1.008-1.800] carried an increased risk of SEA.

**Conclusions:** SEA is an uncommon but serious complication of HD. The risk of SEA is highest in patients with infectious co-morbidities, especially BAC, but diabetes and the presence of a vascular catheter are also significant risk factors.

**FR-PO446**

**Nontuberculous Mycobacterial Infections and End Stage Renal Disease in the Outpatient Setting**
Rhonda E. Colombo,[1] Puja Chebrolu,[1] Mufaddal F. Kheda,[1] N. Stanley Nahman,[1,2] Kristina W. Kintziger.[1] *[1]Georgia Regents Univ, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA.*

**Background:** Nontuberculous mycobacteria (NTM) have been implicated as an uncommon cause of peritonitis complicating peritoneal dialysis (PD) and in periodic reports of infection in hemodialysis (HD) patients. We previously characterized NTM infections among hospitalized ESRD patients on HD (Colombo, JIM, 61(2), 2013). However, NTM may have an indolent presentation and be diagnosed in the outpatient setting. We thus conducted a retrospective analysis of the USRDS to describe NTM diagnoses during outpatient visits among the incident ESRD population.

**Methods:** All patients newly diagnosed with ESRD between 2005-2007 were queried for a diagnosis of NTM infection and potential clinical covariates using ICD-9 diagnosis codes. Medicare Part B claims were the source of outpatient data. Classification of NTM disease was via querying separate codes for pulmonary (PULM), disseminated (DISS), cutaneous (CUT), and "other" (OTH) NTM. Univariable and bivariable descriptive analysis was conducted on all variables of interest.

**Results:** During the three year period, 345 individuals had an outpatient visit with an associated NTM diagnosis. Of these, 241 (69.9%) had not been identified in previous hospitalization data. Demographics included: 55.9% male, 59.4% white, and 57.7% ≥ 70 years. HD was the initial treatment modality for 90.7% of individuals. There were 110 (31.9%) PULM, 11 (3.2%) CUT, 61 (17.7%) DISS, and 163 (47.3%) OTH cases. Underlying pulmonary disease was significantly more common in patients with PULM NTM ($p = 0.02$), particularly bronchiectasis ($p < 0.0001$). HIV, documented in 19.4% of cases, was

associated with DISS disease (40.98%, p<0.001). Significant differences (p<0.05) were also seen with age distribution; DISS was more common in patients under age 50. Nearly half (49.6%) of all patients resided in the Southern US at time of diagnosis.

**Conclusions:** Although rare, NTM may infect outpatient ESRD patients. Type and presentation of NTM infection in ESRD varies depending on underlying comorbidities. NTM is most likely to be diagnosed in the Southern United States.

## FR-PO447

**Association of Dietary Sodium Restriction and Thirst in Hemodialysis Patients** Joselyn Reyes, Caroline M. Williams, Jochen G. Raimann, Penny Faith Sheppard, Stephan Thijssen, Nathan W. Levin, Peter Kotanko. *Nephrology Research, Renal Research Institue, New York, NY.*

**Background:** Control of dietary sodium (Na) intake is central to fluid management in hemodialysis (HD) patients. It is generally assumed that lowering dietary Naintake translates into reduction of thirst and interdialytic weight gain (IDWG). Here we test this hypothesis prospectively in a cohort of chronic HD patients.

**Methods:** We report interim results from an ongoing randomized controlled trial (RCT) of salt interventions in chronic HD patients [clinicaltrials.gov#NCT01015313]. Subjects were randomized 1:1 to an intervention group and a control group. The intervention consisted of a comprehensive approach to reduce salt intake, including intensified dietary counseling by a dietitian using Motivational Interviewing, abandonment of intradialytic saline and Na profiling. Dietary Naintake was assessed by a certified dietitian using 72-hours dietary recalls. Associations of monthly self-assessed thirst levels (Thirst Questionnaire; ThQ) and Na-Calorie Intake Ratios (Na/Cal) were assessed by Pearson correlation analysis and in a longitudinal fashion using linear mixed models (LMM).

**Results:** Out of 24 HD patients (age 60±13.7 years, 58% male, 46 % diabetic, 42% Blacks), 11 were randomized to receive low-salt intervention. At baseline ThQ and Na/Cal ratio were not correlated (r=0.2; P=0.4). Analysis employing a LMM in a subgroup of 8 patients who completed the study indicated that the intervention resulted in reduced thirst as quantified by the ThQ (P<0.001). In the same subgroup non-significant decreases of Na intake, Na/Cal ratio, ThQ and IDWG were observed between baseline and the average of the last three months.

| | Na intake(mg/day) | Calories intake (cal/day) | Na+/Cal (mg/cal) | Thirst Q (score) | IDWG(kg) |
|---|---|---|---|---|---|
| Baseline | 2531±1015 | 1576±635 | 1 6±0 2 | 14 2±2 4 | 2 4±1 |
| Average months (9-12) | 2002±1203 | 1323±451 | 1 4±0 5 | 13 3±5 | 2 3±0 7 |
| Delta (95%CI) | -529 ( 9.4 to - 1068) | -253 ( 92 to -598) | -0.2 ( 0.2 to -0.6) | -0.9 ( 3.4 to -5.2) | -0.1 ( 0.2 to -0.4) |

**Conclusions:** The interim analysis of our RCT of salt intervention demonstrates that changes in dietary salt intake associates to reduce thirst.

## FR-PO448

**Alignment of Dialysate (DNa) and Serum Sodium (SNa) in Chronic Hemodialysis (HD) Patients (pts): Results of a Quality Improvement Initiative** Jochen G. Raimann,[1] Linda H. Ficociello,[2] Len A. Usvyat,[1,2] Qingqing Xiao,[1] Yuedong Wang,[3] Claudy Mullon,[2] Jose A. Diaz-Buxo,[2] Paul M. Zabetakis,[1] Peter Kotanko.[1] *[1]Renal Research Institute; [2]Fresenius Medical Care NA; [3]UC Santa Barbara.*

**Background:** Small studies in HD pts indicate favorable effects of DNa to SNa alignment, however, results from larger groups are needed.

**Methods:** At 4 participating HD clinics, pts with SNa<standard DNa (137 mEq/L) received HD with DNa aligned to the average of the last 4 SNa measurements. "Aligned" were matched to "unaligned" pts (from 44 not participating clinics) based on SNa, observation period, age (<, >60 years), HD vintage (<1, 1-3.9, >4 years) and catheter presence. T-Test was employed for group comparisons of changes in weight (wt), systolic blood pressure (SBP), and saline administration. Hospitalization (Hosp) rates per pt year (pt-yr) were compared using linear mixed-effects models.

**Results:** Aligned (n=84) and unaligned (n=84) pts were similar at baseline (68±13 yrs, 50% male, 3.7±3.7 yrs vintage, 62% diabetics and 28% pts with catheters; P >0.05). Treatment effects were significant for pre-HD wt and interH wt gain (IDWG). Although not reaching statistical significance, trends in all parameters suggest alignment to be favorable. Change in all-cause hosp rates from 2.6 to 1.9/pt-yr and 2.4 to 1.6 /pt-yr were observed for aligned and unaligned pts, respectively (p=0.4). Changes in fluid-related hosp rates from 0.3 to 0.3 / pt-yr and 0.4 to 0.1/ pt-yr were observed for aligned and unaligned pts, respectively (p=0.7).

**Table 1:** Treatment effect of sodium alignment on changes in clinical parameters. Mean±SD or mean (95% CI) as appropriate.

| | Aligned patients (N=84) | | | Unaligned patients (N=84) | | | Treatment |
|---|---|---|---|---|---|---|---|
| Parameter | Baseline | Follow up | Change | Baseline | Follow up | Change | Effect |
| IDWG [kg] | 2.4±0.9 | 2.3±0.8 | -0.1 (-0.4 to 0.1) | 2.4±1.0 | 2.5±1.1 | 0.1 (-0.3 to 0.4) | -0.2 (-0.4 to 0) |
| Pre HD SBP [mmHg] | 141.6±21.7 | 138.7±22.8 | -2.9 (-9.7 to 3.9) | 151.8±20.5 | 151.2±19.7 | -0.6 (-6.7 to 5.6) | -2.4 (-5.4 to 0.7) |
| Post HD SBP [mmHg] | 133.9±18.9 | 132.2±19.0 | -1.7 (-7.5 to 4.1) | 142.1±17.6 | 139.9±19.6 | -2.3 (-8 to 3.4) | 0.6 (-2.5 to 3.6) |
| Pre HD wt [kg] | 80.4±21.1 | 78.8±19.8 | -1.6 (-7.8 to 4.6) | 75.8±24.2 | 75.5±24.2 | -0.3 (-7.7 to 7.1) | -1.3 (-2.5 to -0.1) |
| Post HD wt [kg] | 78.1±20.7 | 76.6±19.5 | -1.5 (-7.7 to 4.6) | 73.4±23.7 | 73.1±23.5 | -0.3 (-7.6 to 6.9) | -1.2 (-2.4 to -0.1) |
| Intradialytic saline [mL] | 454±127 | 447±128 | -7.0 (-46 to 32) | 488±162 | 491±163 | 5 (-48 to 54) | -12.0 (-42 to 17) |

**Conclusions:** Consistent with previous reports, results from the largest sodium alignment program to date suggest positive effects on clinical parameters. Well-matched control pts minimize confounding effects. The lack of effect on hosp and small effects on other parameters may be explained by low baseline DNas limiting the interventional change of gradient.

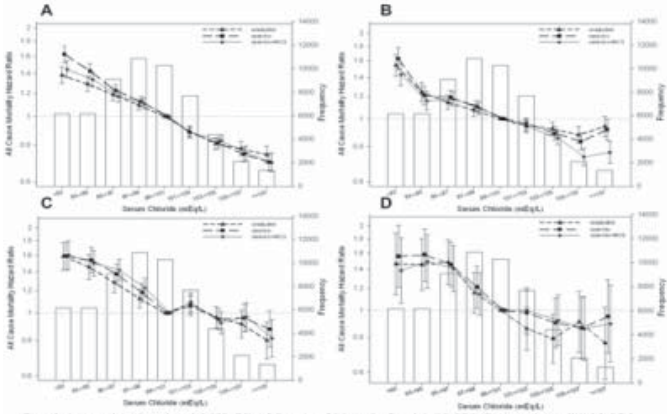
## FR-PO449

**Hypochloremia as a Novel Risk Factor of All-Cause Mortality in Hemodialysis Patients** Vanessa A. Ravel,[1] Connie Rhee,[1] Jongha Park,[1] Elani Streja,[1] Csaba P. Kovesdy,[2,3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Orange, CA; [2]Univ of Tennessee Health Science Center, Memphis, TN; [3]Memphis VA Medical Center, Memphis, TN.*

**Background:** Emerging data suggest that decreased serum chloride (Cl) levels may be associated with increased all-cause and cardiovascular death risk in the general population, but its mortality predictability has not yet been examined in hemodialysis (HD) patients.

**Methods:** Using DaVita clinical data, we identified 104,675 maintenance HD patients who underwent treatment from 2001-2007. Associations between time-averaged Cl level and all-cause mortality were estimated in the overall cohort and within subgroups of race/ethnicity using Cox regression.

**Results:** Patients were on average 61±15 years old and included 45% women and 59% diabetics. In the overall cohort, there was an inverse association between Cl levels and all-cause mortality in unadjusted, case-mix, and case-mix and malnutrition-inflammation complex syndrome adjusted analyses (reference Cl 99-<101mEq/L). In subgroup analyses of race/ethnicity adjusted for case-mix and malnutrition-inflammation complex syndrome covariates, a similar pattern of association was observed among non-Hispanic Caucasians, African-Americans, and Hispanic patients. Among Asians, lower Cl levels were associated with increased mortality, whereas higher Cl levels were not associated with greater risk.



Death hazard ratios (and 95% CI) of 8-year Cl levels for (a) 43,370 Caucasian; (b) 33,854 Black; (c) 16,156 Hispanic; and (d) 3,133 Asian HD patients.

**Conclusions:** Although our findings suggest that hypochloremia is a risk factor for mortality in HD patients, further studies are needed to confirm findings and to determine if Cl level is a direct mediator of increased mortality, or a proxy of an alternative mortality predictor in this population.

## FR-PO450

**Recovery of Renal Function in Patients Treated for End-Stage Renal Disease** Shari T.S. Lewis,[1] Paul L. Kimmel,[1,2] Paul W. Eggers.[2] *[1]Renal Diseases and Hypertension, George Washington Univ, Washington, DC; [2]National Institute of Diabetes Digestive and Kidney Diseases, NIH, Bethesda, MD; [3]National Institute of Diabetes Digestive and Kidney Diseases, NIH, Bethesda, MD.*

**Background:** Recovery of renal function in patients with End-Stage Renal Disease (ESRD) is thought to be uncommon. There are few data showing whether recovery rates have changed recently. Previous work has shown improved renal recovery rates in patients receiving peritoneal dialysis compared to hemodialysis, but this is not a consistent finding. Factors that predict renal recovery as well as patient outcomes after recovery remain unclear.

**Methods:** This observational cohort study included all ESRD patients enrolled in the US Renal Data System (USRDS) and Standard Information Management System (SIMS) who initiated dialysis between January 1st 1996 and December 31st 2010.

**Results:** During the study period, 1,481,248 patients were started on dialysis for ESRD. 53,553 (3.6 %) of them recovered renal function. From 1996 to 2010, there was a four-fold increase in the number of patients who achieved recovery of renal function (1152 to 5907) and a 2.5 fold increase in the proportion who recovered (2.1% to 5.2%). Recovery of renal function was almost twice as likely in White compared to Black patients (4.4% vs 2.3%, p <0.0001). A greater proportion of hemodialysis patients achieved recovery compared to peritoneal dialysis patients (2.2% vs 0.6 %, p<0.0001). 97% of patients who recovered renal function did so by 6 months. Recovery was more likely to occur in patients with baseline GFR ≥ 15 ml/min/1.73m² (6%) and in patients with acute tubular necrosis (28.5%). By 3.5 years after recovery, 50% of patients with recovered renal function had either died or returned to ESRD therapy.

**Conclusions:** We conclude that the rate of renal recovery has increased over time. Trends in early starts, an increase in AKI patients entering the ESRD program and less stringent acceptance criteria for dialysis therapy may contribute to the observed increasing recovery rates. Genetic studies may be warranted to explain the dramatic differences in rates of recovery between White patients and minority groups.

## FR-PO451

### Loss of Residual Renal Function in the First Year on Hemodialysis

Stephan Thijssen,[1] Zachary Z. Brener,[2] Len A. Usvyat,[3] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]Beth Israel Medical Center, New York, NY; [3]Fresenius Medical Care, Waltham, MA.*

**Background:** Residual renal function (RRF) is important for several crucial aspects in kidney disease patients and is a powerful predictor of survival. RRF is generally believed to decline relatively quickly after initiation of hemodialysis (HD). We studied the time course of residual renal urea clearance (Kru) as a surrogate of RRF in the first year on HD.

**Methods:** Data for the first year on HD were extracted for incident patients who started HD between 12/2000 and 09/2009. Missing Kru values were imputed using the "next observation carried backward" method. We analyzed the subset of patients who had a Kru >0 ml/min in the first month on HD and who survived at least 18 months. The time course of Kru over the first 12 months on HD was fit using a 4th order polynomial function. The first derivative of this function was used to assess the instantaneous rate of change in Kru.

**Results:** The analysis cohort comprised 1,654 patients (age 60.4±14.5 years, 61% male, 56% diabetic, 57.3% white, 36.6% black). Average Kru in the first month was 3.3 ml/min (95% CI: 3.06-3.49). The figure shows the time course of Kru over the first 12 months on HD (top panel) and the instantaneous rate of decline in Kru (bottom panel). Kru initially declined at a rate of about 0.36 ml/min/month. This rate of loss progressively decelerated and reached a stable rate of decline of around 0.05 ml/min/month from month 9 onwards.

**Conclusions:** In this U.S. cohort of incident HD patients from Renal Research Institute clinics, Kru declined slower than we had expected. Comparisons with other North American clinics and international data will put these results into perspective and show whether Kru is unusually well-preserved in RRI clinics or whether Kru generally declines more slowly than one might expect.

## FR-PO452

### Angiotensin II Receptor Blockade Does Not Reduce Renal Function Decline in Hemodialysis Patients: A Randomized Controlled Trial

Krista D. Kjaergaard,[1] Christian D. Peters,[1] Bente Jespersen,[1] Kathrine S. Laursen,[2] Jens K. Madsen,[1] Marija K. Novosel,[4] Birgitte Pedersen,[2] I.N. Tietze,[3] Bo M. Bibby,[5] Charlotte Strandhave,[2] J. Dam Jensen.[1] *[1]Dept of Renal Medicine, Aarhus Univ Hospital, Denmark; [2]Dept of Nephrology, Aalborg Univ Hospital, Denmark; [3]Dept of Internal Medicine, Region Hospital Viborg, Denmark; [4]Dept of Internal Medicine, Fredericia Hospital, Denmark; [5]Dept of Public Health - Institute of Biostatistics, Aarhus Univ, Denmark.*

**Background:** Glomerular filtration rate (GFR) declines during chronic dialysis treatment. In peritoneal dialysis, ramipril as well as valsartan reduces GFR decline. Observational studies suggest that similar treatment may preserve renal function in hemodialysis (HD).

**Methods:** A multicenter randomized placebo-controlled double-blinded trial initiated by the investigators with one year follow-up. Primary outcome was the rate of GFR decline. Methods: Inclusion criteria were urine output >300 mL/24h, HD vintage <1 year, and cardiac ejection fraction >30%. Patients were randomized to the ARB irbesartan (300 mg daily), or placebo. Target systolic blood pressure (BP) was 140 mmHg. GFR was estimated as the mean of creatinine and urea renal clearance and measured at baseline, 1 week and 3, 6, 9, 12 months.

**Results:** Of the 82 patients randomized (placebo *n*=41/irbesartan *n*=41), 56 completed one year of treatment. Patients were similar at baseline: males 26/30, (mean±SD) age 62±14/61±16 years, HD vintage 168±95/171±93 days, HD time 10±2/11±3 hours/week, urine volume 1.31±0.71/1.45±0.79 L/24h, GFR 4.8±2.3/5.7±3.3 mL/min/1.73m$^2$. The target BP level was reached in both groups and adverse event rates were comparable. GFR declined by 1.6(1.0;2.0) (mean,95%CI) in the placebo group and 1.7(1.0;2.3) mL/min/1.73m$^2$/year in the irbesartan group, p=0.29. Urine volume decreased with 431(179;684) in the placebo group and 129(-86;144) mL/24h/year in the irbesartan group, p=0.26. In each group, four patients progressed to anuria.

**Conclusions:** In HD patients, the decline in GFR and urine volume over one year was not affected by irbesartan treatment. We found no evidence against that irbesartan could be safely used in HD patients.

## FR-PO453

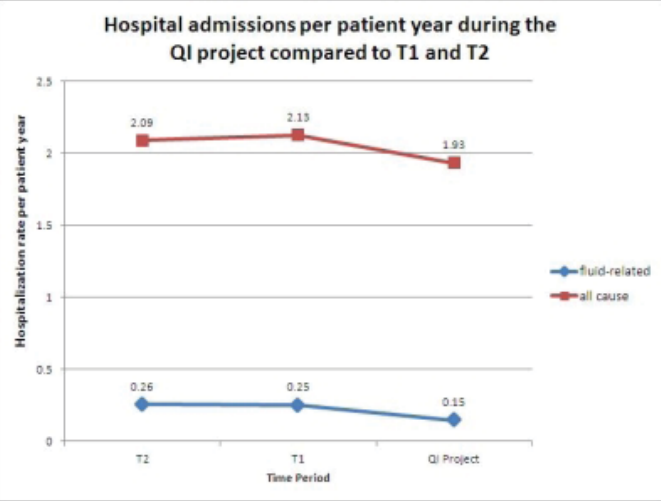
### Hospitalization Rates before and after the Initiation of a Quality Improvement Project on Fluid Management Using Crit-Line Blood Volume Monitors at 8 RRI Clinics

Linda H. Ficociello,[1] Len A. Usvyat,[1,2] Patrice B. Taylor,[2] Claudy Mullon,[1] Paul M. Zabetakis,[2] Jose A. Diaz-Buxo.[1] *[1]Fresenius Medical Care NA (FMCNA), Waltham, MA; [2]Renal Research Institute (RRI), New York, NY.*

**Background:** A quality improvement (QI) project on fluid management using FMCNA's Crit-Line Blood Volume Monitors (CLM) has been ongoing in 8 RRI Clinics. One aim of the QI project is the reduction of hospitalizations, especially fluid-related.

**Methods:** Hospitalization rates were calculated as all-cause or fluid-related hospitalizations across the 8 clinics divided by patient-time accumulated. All patients receiving hemodialysis were included (1000+ patients per time period).These ICD-9 codes were used to define fluid-related: 276.6, 276.69, 398.91, 402.01, 402.11, 402.91, 404.03, 404.11, 404.91, 428, 428.0, 428.21, 428.22, 428.23, 428.3, 428.31, 428.32, 428.33, 428.4, 428.42, 428.43, 514, 518.4, and 786.05. Repeated measures survival analysis was used to compare all-cause and fluid-related hospitalizations during the 7 months of the QI project and two comparison periods: (T2) the same 7 months in the prior calendar year and (T1) 7 months before the QI project.

**Results:** Hospitalization rates were observed to be lower during the QI project (Figure) and, in survival analysis, the difference was statistically significant for fluid-related but not for all-cause. Hazard ratios for fluid-related hospitalizations during QI project was 0.53 (p=0.05) and 0.42 (p=0.009), compared to T1 and T2, respectively. Hazard ratios for all-cause hospitalizations during the QI project was 0.86 (p=0.21) and 0.89 (p=0.30), compared to T1 and T2, respectively.



**Conclusions:** A reduction in fluid-related hospitalizations was observed during a QI project on fluid management using CLM (Hazard Ratios 0.53 and 0.42). Trends toward lower rates were observed for all-cause hospitalizations (Hazard Ratios 0.86 and 0.89).

*Funding:* Pharmaceutical Company Support - Fresenius Medical Care NA

## FR-PO454

**Patient Satisfaction of Different Aspects of Long-Term Haemodialysis Care: A Multinational Cross-Sectional Survey of Patients**

Suetonia Palmer,[1] Giorgia De berardis,[2] Jonathan C. Craig,[3] Allison Tong,[3] Marinella Ruospo,[2,4] Marcello Tonelli,[5] Jorgen B.A. Hegbrant,[4] Charlotta Wollheim,[4] Marco Angelo Murgo,[4] Eduardo Jorge Celia,[4] Ruben Gelfman,[4] Miguel Rodrigues Leal,[4] Marietta Torok,[4] Anna Bednarek,[4] Jan Dulawa,[4] Juan Nin-ferrari,[4] Staffan Schön,[4] Giovanni F.M. Strippoli.[2,3,4,6] *[1]Univ of Otago; [2]Mario Negri Sud Consortium; [3]Univ of Sydney; [4]Diaverum; [5]Univ of Alberta; [6]Univ of Bari.*

**Background:** Patients with end-stage kidney disease experience high rates of mortality, reporting profoundly impaired quality of life. Greater knowledge of how patients experience different facets of long-term dialysis could inform the design of targeted and testable strategies to improve dialysis care and quality of life. The aims of our study were to describe and quantify the satisfaction of long-term patients with their haemodialysis care.

**Methods:** This is a multinational cross-sectional survey using the 23-item CHOICE questionnaire in 2145 long-term outpatient haemodialysis patients in Europe and South America. Patients' ratings of satisfaction with overall care and specific aspects of dialysis care were evaluated.

**Results:** 2145 (78.1%) haemodialysis patients completed the survey. Fewer than half (46.5% [95% confidence interval (CI), 44.5 to 48.6%]) rated their dialysis care as excellent overall. Within countries, global perceptions of care were uninfluenced by most patient characteristics except age and depressive symptoms; older patients were less critical of their care (adjusted odds ratio for excellent rating (AOR) 1.44 [CI 1.01-2.04] for patients 70 years or older compared to those 18-49 years) and those with depressive symptoms were less satisfied (AOR for excellent rating 0.56 [CI 0.44 to 0.71] for patients with a higher depression score).

**Conclusions:** Patients treated with in-centre haemodialysis are least satisfied with the amount and reliability of information they receive during their care, particularly from nephrologists. Meeting patients' expectations of information, prognosis, the likelihood of kidney transplantation and patients' options when choosing dialysis treatment may improve patients' satisfaction with dialysis care.

## FR-PO455

**GFR for Dialysis Initiation and Patient Survival: A Physician-Based Analysis**

Jiannong Liu,[1] Haifeng Guo,[1] David T. Gilbertson,[1] Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, Univ of MN, Minneapolis, MN.*

**Background:** Although a large randomized trial (IDEAL) showed no clear difference between planned early (higher glomerular filtration rate [GFR]) and late (lower GFR) initiation groups in Australia and New Zealand, whether this is the case in the US is unknown. Hence, we linked data from the USRDS and the Medicare 5% database to examine survival associations of receiving care from physicians who typically initiate dialysis at higher GFR levels among stage 4 chronic kidney disease (CKD 4) patients.

**Methods:** Physicians who signed end-stage renal disease (ESRD) Medical Evidence forms for at least 10 patients in 2005-2007 and provided care for these patients in the 6 months before dialysis initiation were included. Patient adjusted mean eGFRs at dialysis initiation were calculated for each physician from a random effect regression model with adjustment for patient demographic and clinical characteristics. Physicians were classified as tending to initiate early (eGFR ≥ 10.9 mL/min/1.73 m$^2$, the mean) or late (eGFR< 10.9) based on the adjusted mean eGFRs. Patients first diagnosed with CKD 4 in 2008 and cared for by one of the classified physicians within 6 months before or after the first diagnosis date, identified in the 5% Medicare data, were included. Follow-up of the CKD 4 patients extended from 6 months after the first diagnosis to death, transplant, or December 31, 2011.

**Results:** 915 physicians and 2241 patients were included, with median follow-up time 33.7 months; early and late groups included 1111 and 1130 patients, respectively, defined based on their physicians. The two patient groups had very similar characteristics. Both unadjusted mortality rates (15.6 per 100 patient-years, early group, vs. 16.1, late group) and the adjusted hazard ratio for death (0.98, early vs. late, *P=0.72*) showed group similarity. For patients who developed ESRD, mean eGFRs were 13.3 and 11.8 mL/min/1.73 m$^2$ for early and late groups, respectively.

**Conclusions:** Patient survival appears to be independent of physician behavior regarding GFR levels for dialysis initiation.

*Funding:* NIDDK Support

## FR-PO456

**Comparison of Survival by Dialysis Modality: Korean Nation-Wide Prospective Cohort**

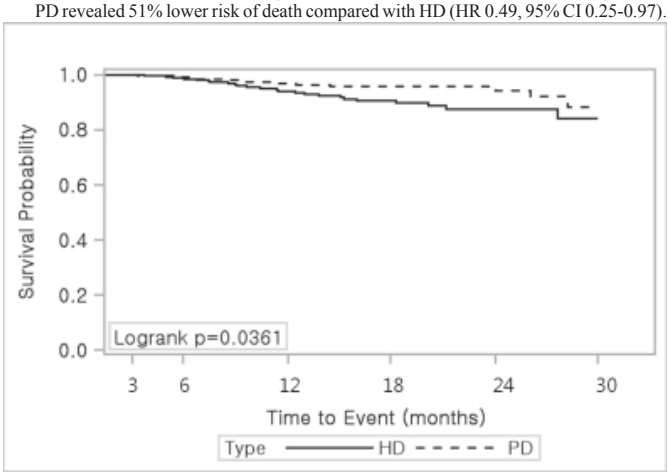
Ji-Young Choi,[1,2] Hye Min Jang,[1,2] Jongha Park,[1,3] Yon Su Kim,[1,4] Shin-Wook Kang,[1,5] Chul Woo Yang,[1,6] Nam Ho Kim,[1,7] Jang-Hee Cho,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Yong-Lim Kim.[1,2] *[1]Clinical Research Center for End Stage Renal Disease (CRC for ESRD) in Korea; [2]Kyungpook National Univ; [3]Univ of Ulsan; [4]Seoul National Univ; [5]Yonsei Univ; [6]The Catholic Univ of Korea; [7]Chonnam National Univ.*

**Background:** The impact of dialysis modality on survival has still some controversies. Given possible differences in patients' characteristics, cause and rate of death among different countries, the issue needs to be further evaluated in various cohorts.

**Methods:** We compared all-cause mortality between hemodialysis (HD) and peritoneal dialysis (PD) using unmatched (n=1,060) and propensity score (PS) matched (n=556) cohorts. Data came from a Korean nation-wide prospective cohort for end-stage renal disease, in which patients starting dialysis therapy from September 1, 2008 to June 30, 2011 were enrolled.

**Results:** Patients (HD vs PD: 69.4% vs 30.6%) were followed up for 16.3±7.9 months. PD patients were significantly younger and had lower body mass index, lower proportion of diabetes, and larger urinary volume compared to HD patients. Infection was the most common cause of death (31.9% in overall, 29.2% in HD, 41.7% in PD). Multivariate Cox regression with unmatched cohort showed PD tended to be associated with 37% lower risk of death compared with HD [hazard ratio (HR) 0.63, 95% confidence interval (CI) 0.36-1.08]. In PS-matched cohort, cumulative survival probabilities from day 90 for PD and HD were 96.9% vs 94.1% at 12 months (p=0.14) and 94.3% vs 87.6% at 24 months (p<0.05).

PD revealed 51% lower risk of death compared with HD (HR 0.49, 95% CI 0.25-0.97).



**Conclusions:** PD therapy shows superior survival to HD in the early period of dialysis even after adjusting differences in patients' characteristics between two modalities.

*Funding:* Government Support - Non-U.S.

## FR-PO457

**Lower Serum Sodium Level Predicts Higher Risk of Infection-Related Hospitalization and Death in Maintenance Hemodialysis Patients**

Shintaro Mandai,[1] Michio Kuwahara,[1] Sei Sasaki.[2] *[1]Dept of Nephrology, Shuuwa General Hospital, Saitama, Japan; [2]Dept of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** Hyponatremia is associated with increased mortality in patients with chronic kidney disease, but the specific factors contributing to mortality are unknown. This study investigated the association of serum sodium level (sNa) with risk of infectious disease in hemodialysis (HD) patients.

**Methods:** This observational cohort study included 332 patients who underwent maintenance HD in our dialysis unit in May 2009. The mean of 3 monthly measurements of glucose-corrected sNa before each dialysis session in May, June, and July 2009 was applied as baseline sNa. The primary endpoint was the first infection-related hospitalization (IRH), and secondary endpoints were infection-related death (IRD) and death of any cause.

Data were analyzed using Cox hazards modeling, adjusted for baseline demographics and characteristics, or laboratory data. Patients were followed up from May 1, 2009 until transfer, kidney transplant, death, or January 31, 2013.

**Results:** Mean sNa was 138.9 mEq/L (tertile 1: <138.0 mEq/L, n=104; tertile 2: 138.0-140.0, n=116; tertile 3: >140.0 mEq/L, n=112). During a median follow-up of 45.0 months, 57 patients experienced IRH (56.4/1,000 patient-years overall; 89.7/1,000 in tertile 1; 57.9/1,000 in tertile 2; 28.0/1,000 in tertile 3), 68 patients died, and 15 of the 68 deaths (22%) were IRDs. Higher sNa was associated with lower risk of IRH (unadjusted hazard ratio (HR) per +1 mEq/L, 0.86; 95% confidence interval (CI), 0.79-0.94; p=0.0005, and adjusted HR, 0.90; 95%CI, 0.81-0.99; p=0.036). Higher sNa was associated with lower risk of IRD (unadjusted HR, 0.80; 95%CI, 0.69-0.93; p=0.003, and adjusted HR, 0.76; 95%CI, 0.61-0.96; p=0.019), but was not associated with all-cause mortality (unadjusted HR, 0.87; 95%CI, 0.81-0.95; p=0.001, and adjusted HR, 0.92; 95%CI, 0.84-1.02; p=0.115).

**Conclusions:** Lower sNa was a predictor of higher risk for infection-related hospitalization and death in maintenance HD patients.

## FR-PO458

**Hypoalbuminemia, Renal Transplantation, and Survival in Prevalent Hemodialysis Patients** James R. Smith, Colin C. Geddes, Neal Padmanabhan. *Dept of Renal Medicine, Glasgow Renal and Transplant Unit, Western Infirmary, Glasgow, United Kingdom.*

**Background:** Hypoalbuminemia is strongly associated with increased mortality among hemodialysis (HD) patients, and guidelines suggest that renal transplantation is contraindicated in those with a predicted survival less than 5 years. The aim of this study was to assess the influence of hypoalbuminemia on mortality and subsequent transplantation in a prevalent HD cohort.

**Methods:** All prevalent patients attending 6 HD units receiving HD for >90 days on 04/06/2007 were included. Laboratory data averaged over 3-months was extracted from a prospectively maintained electronic patient record, as were demographics, hospital admissions, and transplant wait-list status. A Cox regression model was used to analyze the impact of serum albumin (sAlb) as well as phosphate and calcium on 5-year survival.

**Results:** Of 502 prevalent patients, 5-year survival was 63.3% when mean sAlb was >=3.7g/dL, falling to 38.8% if 3-3.69g/dL, and 16.5% if <3g/dL. This remained significant when corrected for age, sex, wait-list status, diabetes, HD access, alfacalcidol use, HD vintage, and weight. Pre-HD serum phosphate and calcium were not associated with survival. 117 patients were transplant wait-listed at census date; 51 had a sAlb <3.7g/dL with a 5-year survival of 70.6% compared with 86.4% for those with a sAlb >=3.7g/dL. However sAlb was not predictive in multivariate analysis. 31 (60.8%) of those wait-listed with a sAlb <3.7g/dL were transplanted, with 90.3% alive at 5 years; while 47 patients (71.2%) wait-listed with a sAlb >=3.7g/dL were transplanted, with 93.6% alive at 5 years. Of the 8 patients wait-listed with sAlb <3g/dL, 4 received a transplant, all surviving to 5 years, while only 1 of the 4 not transplanted survived.

**Conclusions:** In this large, well-defined HD cohort, mild hypoalbuminemia averaged over 3 months predicted reduced survival independent of other factors known to influence survival. However hypoalbuminemia alone may be less important in those deemed otherwise suitable for renal transplant wait-listing.

## FR-PO459

**Education Predicts Non-Compliance with Maintenance Hemodialysis** Kana Noshiro, Kobena A. Dadzie, Nijal R. Sheth, Nikolas B. Harbord, James F. Winchester. *Div of Nephrology & Hypertension, Beth Israel Medical Center, New York.*

**Background:** During a recent disaster in New York, Hurricane Sandy, stranded patients had incomplete knowledge of their hemodialysis(HD) parameters and required triage. We therefore sought to understand the depth of factual knowledge about the patient's individual dialysis prescription. It is known that missed/shortened HD times are associated with increase in hospitalization and mortality. We aimed to identify baseline characteristics which may be predictive of non-compliance with HD therapy.

**Methods:** We conducted a cross sectional study of 100 randomly selected HD patients at a HD center in Manhattan. Patients participated in a 1:1 interview about their socioeconomic status, educational background, and knowledge on hemodialysis and kidney disease. Relevant information from their medical records were retrieved. IRB approval was obtained.

**Results:** Level of education (±high school diploma) appeared to correlate with missed treatments. 27 patients were classified as "skippers" (absent for >3% of scheduled HD); and was associated with less education, less knowledge of potassium rich foods, higher serum phosphorus, more frequent shortening of HD, and more prescribed time on each HD. There were no significant differences in age, sex, number of years on HD, satisfaction, and knowledge of phosphorus rich foods, vascular access, or cause of renal failure. Though not statistically significant, there was a trend towards patients who work being less likely to skip HD.

| Characteristic | Skippers(n=27) | Nonskippers(n=73) | P |
|---|---|---|---|
| Age | 55.6±14.4 | 58.2±14.1 | 0.41 |
| >High school graduate | 21(78%) | 70(96%) | <0.01 |
| Prescribed dialysis time(hours) | 3.9±0.48 | 3.7±0.47 | <0.05 |
| On transplant waiting list | 6(22%) | 40(55%) | <0.05 |
| Know potassium rich foods | 2.26±1.43 | 3.06±2.34 | <0.05 |
| Shortened dialysis(%) | 28.1±32.5 | 8.0±13.2 | <0.01 |
| Potassium(mmol/L) | 4.8±0.73 | 4.9±0.10 | 0.43 |
| Phosphorus(mg/dL) | 5.9±1.5 | 5.3±1.2 | <0.05 |

**Conclusions:** Compliance assessment should include educational level, and efforts should be made to improve understanding and motivation for HD treatment to achieve adequate adherence. It may be necessary to direct specialized educational resources to these patients.

## FR-PO460

**Prevalence of Protective Immunoglobulin G Antibody in Maintenance Hemodialysis Patients in Korea** Jong-woo Yoon, Myung Jin Choi, Youngki Lee, Jwa-kyung Kim, Ja-Ryong Koo, Jung-woo Noh. *Internal Medicine, Hallym Kidney Research Institute, Chuncheon, Gangwon, Korea.*

**Background:** Hepatitis A is one of the most common acute infectious diseases and usually does not cause chronic disease process. But around 1% of it progress to life-threatening fulminent hepatitis. In the past, seroprevalence of anti-HAV was higher, but recently it has been decreasing in Korea. The incidence of acute hepatitis A in 2010 is 10-fold higher than 20 years before. It shows more severe clinical course and composes more than 80% of inpatient hepatitis care. ESRD is associated with increased propensity to infection, more severe clinical outcomes. DOQI guidelines suggest active immunization and having protective antibody for hepatitis A if seronegative is found. But the prevalence of protective immunoglobulin G antibody in maintenance hemodialysis patients is not known.

**Methods:** 171 ESRD maintained more than 3 months dialysis duration were evaluated for seroprevalence of protective immunoglobulin G antibody and its antibody titer for hepatitis A. Individuals with evidence of acute and chronic infection were excluded. Whole blood was centrifused and collected serum was tested by CMIA(Chemiluminescent microparticle immunoassay) to detect antibody titer.

**Results:** 164 from 171 hemodialysis patients have protective level of Immunoglobulin G antibody and prevalence of seropositivity was 95.88%. It was higher with increasing age*(58.74±11.42 vs 30.92±29.32, p=0.01)* and long dialysis duration*(51.08±51.94 vs 30.92±29.32, month, p=0.01)*. Prevalence of seropositive for hepatitis A was not different between patients living in metropolitan Seoul and ruler area Chuncheon. Anti-HAV seroprevalence was about 50% in those aged less than 40 years old and which was significantly lower than that of age over 50. Seroprevalence of anti-HAV of hemodialysis patients was not different from general population.

**Conclusions:** Prevalence of protective immunoglobulin G antibody in maintenance hemodialysis patients in Korea was about 95%. Patients of age under 40 showed about 50% seroprevalence and that was not different from general population. Active immunization against hepatitis A is more strongly recommended for ESRD patients age under 40 years.

## FR-PO461

**N-DEPTH–Nephrology DVT and Pulmonary Embolism Prophylaxis Study in Hospitalized Patients** Jule Pinter, Azim S. Gangji, Catherine M. Clase, Christine M. Ribic. *Medicine, Div of Nephrology, McMaster Univ, Hamilton, Canada.*

**Background:** The prevalence and mortality rate of venous thromboembolism (VTE) among patients on dialysis has been reported to be higher than previously thought. However, the prophylaxis prescription practice, VTE and bleeding risks in hospitalized patients with endstage renal disease (ESRD) have not been studied adequately.

**Methods:** This single centre, retrospective chart review examined the rate of VTE prophylaxis in adult patients treated with chronic dialysis (>3 months) on index admission during Sept 2008 to March 2010. Patients admitted for < 48 hours, suspected VTE, bleed or renal transplant were excluded. VTE prophylaxis was defined as administration of prophylactic doses of heparin within 24 hours of admission. We assessed 27 VTE risk factors per patient based on the 8th edition of ACCP guidelines; VTE events objectively confirmed by imaging and major bleeds were adjudicated.

**Results:** We screened 1183 consecutive admissions of which 238 patients formed the study cohort. 45 (18.9%) patients were ineligible for prophylaxis due to therapeutic anticoagulation (AC), prophylactic anticoagulation, heparin allergy or severe thrombocytopenia on admission. Of the 193 eligible patients, 71(36.8%) received VTE prophylaxis. The number of baseline VTE risk factors (range 1 to 7; p=0.59), anticoagulant or antiplatelet use and typical VTE risk factors such as Immobility (22.3 %), recent surgery (13.5%), a history of malignancy (16.1%) or of VTE (4.7%) did not predict the prescription of VTE prophylaxis.

VTE events (1 pulmonary embolism, 1 deep vein thrombosis) occurred in 2 (1.6%) eligible patients not receiving prophylaxis, no events occurred in those receiving prophylaxis (p=0.53). There was no difference in minor or major bleeds between those that did (n=5) and did not receive prophylaxis (n=12; p=0.51).

**Conclusions:** Approximately 1/3 of eligible hospitalised patients received VTE prophylaxis and prescription practices did not correlate with the quality or summation of VTE risk factors. Further study into individualized risk stratification strategies for hospitalized patients with ESRD are needed to help guide VTE prophylaxis practices.

**The Diagnostic Accuracy of the Tuberculin Skin Test, QuantiFERON-TB Gold, and T-Spot.TB in Determining Latent Tuberculosis Infection in Hemodialysis Patients: A Systematic Review and Meta-Analysis**
Thomas W. Ferguson,[1] Navdeep Tangri,[1] Kerry Macdonald,[3] Brett M. Hiebert,[1] Claudio Rigatto,[2] Manish M. Sood,[2] Salah Mahmud,[1] Souradet Y. Shaw,[1] Blake R. Lerner,[1] Paul Komenda.[2] *[1]Community Health Sciences, Univ of Manitoba, Winnipeg, Canada; [2]Medicine, Univ of Manitoba, Winnipeg, Canada; [3]Library Services, Univ of Manitoba, Winnipeg, Canada.*

**Background:** Detection and treatment of Latent Tuberculosis Infection (LTBI) is a concern in patients with kidney failure (KF) wait-listed for a kidney transplant, since post-transplant reactivation of LTBI is associated with catastrophic outcomes. There are several diagnostic tests available to determine the presence of LTBI: the Tuberculin Skin Test (TST), QuantiFERON-TB Gold (QFT-G), and ELISPOT (T-SPOT.TB). Our objective was to compare the diagnostic performance of these tests for LTBI in the KF population.

**Methods:** We conducted a systematic review of studies from PubMed, Scopus, EMBASE, and Cochrane Database of Systematic Reviews from the date of their establishment until August 2012. Studies reporting test results allowing the calculation of the sensitivity and specificity with respect to clinical risk factors (previous TB contact, history of TB, and/or suggestive chest X-ray) of the TST, TSPOT.TB, and/or QFT-G in the KF population were included. Data was extracted by two investigators with disagreements resolved by consensus.

**Results:** Our search strategy retrieved 1780 citations for screening. Of these, 92 articles were selected for full-text review and 15 met criteria for inclusion. The TST had a pooled sensitivity of 0.22 across 11 studies and a pooled specificity of 0.65 across 10 studies. The QFT-G test had a pooled sensitivity of 0.58 across 8 studies and a pooled specificity of 0.69 across 8 studies. The T-SPOT.TB test had a pooled sensitivity of 0.50 across 3 studies and a pooled specificity of 0.67 across 3 studies.

**Conclusions:** The QFT-G and the T-SPOT.TB tests were more sensitive and specific than the TST for diagnosis of LTBI in the hemodialysis population. This systematic review calls into question the current practice of using the TST to screen for LTBI due to the low sensitivity of this test.

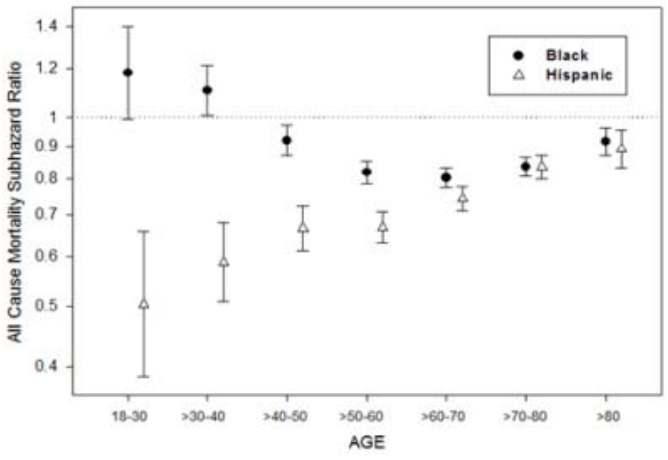
**FR-PO463**

**Age, Race-Ethnicity and Dialysis Patient Mortality Using Competing Risks Regression**
Connie Rhee,[1] Paungpaga Lertdumrongluk,[1] Elani Streja,[1] Jongha Park,[1] Hamid Moradi,[1] Wei Ling Lau,[1] Keith C. Norris,[2] Allen R. Nissenson,[3] Alpesh Amin,[4] Csaba P. Kovesdy,[5,6] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Orange, CA; [2]Drew Univ, Los Angeles, CA; [3]DaVita Inc., El Segundo, CA; [4]UCI, Orange, CA; [5]Memphis Veterans Affairs Medical Center, Memphis, TN; [6]Univ of Tennessee Health Science Center, Memphis, TN.*

**Background:** Recent studies suggest the paradoxical African-American (referred to as black) survival advantage on dialysis is restricted to older ages, but did not separately consider Hispanic ethnicity from white and black racial groups. Prior studies have not examined the impact of age and race-ethnicity on dialysis mortality using competing risks regression, which estimates death risk on dialysis while considering racial-ethnic disparities in kidney transplantation (a competing risk that prevents observing the outcome of interest). We thus re-examined the hypothesis that minorities on dialysis have survival advantages using this method.

**Methods:** We examined associations between race-ethnicity with all-cause mortality among a 2001-2009 cohort of 130,909 adult dialysis patients within 7 age groups using competing risks regression (in which transplant and end of study were considered as competing risk and censoring events, respectively) to account for differential transplant rates in non-Hispanic whites (referred to as whites), blacks, and Hispanics.

**Results:** Compared to whites, blacks had similar, slightly higher, and reduced mortality within age groups of 18-30, >30-40, and >40 years, respectively, in case-mix analyses. Hispanics had decreased mortality compared to whites across all ages.



**Conclusions:** After accounting for racial-ethnic differences in transplantation, we observed that compared to white dialysis patients, Hispanics have greater survival across all ages, while in blacks this survival advantage is limited to patients >40 years old.

**Association between Depression Symptoms and Mortality in Hemodialysis Patients**
Li Fan, Mark J. Sarnak, Hocine Tighiouart, David A. Drew, Kristina Lou, Saeed Kamran Shaffi, Tammy Scott, Daniel E. Weiner. *Tufts Medical Center.*

**Background:** Depression and symptoms of depression are associated with increased risk of mortality in the general population and in people with chronic kidney disease. We evaluated the association between depression symptoms and all-cause mortality in a cohort of hemodialysis (HD) patients.

**Methods:** In 313 maintenance HD patients, depression symptoms were assessed using the Center for Epidemiologic Studies Depression (CES-D) scale, with higher scores indicating a greater burden of depression symptoms. Cox proportional hazards models were used to evaluate the relationship between depression symptoms and mortality in univariate and multivariable analyses.

**Results:** Mean age was 63 ± 16 years, 53% were female and 22% black. Mean CES-D score was 10.6 ± 8.1, and 80 (26%) participants had CES-D scores ≥16, a threshold consistent with depression in prior studies. Participants with CES-D scores ≥16 were more likely to have a history of diabetes, heart failure and smoking and have lower Kt/V and serum albumin. During mean follow-up of 33 ± 25 months, 157 participants died; there were 16.7 and 23.4 deaths per 100-patients years in individuals with CES-D scores <16 and ≥16, respectively. There was a borderline association between CES-D score ≥16 and death in the univariate model [HR 1.40 (0.99 - 1.98)]. After adjusting for age, sex, race, cause of kidney disease, dialysis vintage, vascular access, history of cardiovascular disease, Kt/V and serum albumin, CES-D score ≥16 was associated with an increased risk of all-cause mortality [HR 1.44 (1.00- 2.08)]. In multivariable analyses examining CES-D as a continuous term, for each 1 SD higher CES-D there was a 19% increase in all-cause mortality risk [HR 1.19 (1.00-1.42)].

**Conclusions:** Symptoms of depression are associated with increased risk of mortality in hemodialysis patients. Further studies are needed to confirm these results and evaluate whether effective treatments for depression may impact mortality among HD patients.

**FR-PO465**

**CD4+CD25+Foxp3+ Tregs and TH-17 Cells Balance in Tumor Immunity after Kidney Transplantation**
Jianghua Chen. *Zhejiang Univ.*

**Background:** To find the relationship between tumor incidence of the kidney transplantation and Tregs expression, we analyzed the $CD4^+CD25^+Foxp3^+$ Tregs and IL17 expression in the cancer patients after the kidney transplantation.

**Methods:** Blood samples were obtained from age-matched 19 kidney transplantation patients got tumor, 19 normal kidney transplantation patients and 19 healthy controls. $CD4^+CD25^+Foxp3^+$ Tregs were analyzed by flow cytometry. Serum levels of cytokines IL-17 was measured using enzyme-linked immunosorbent assays.

**Results:** The healthy controls have the highest $CD4^+CD25^+Foxp3^+$ Tregs expression in the peripheral blood, and the normal kidney transplantation patients have the lowest expression, and the cancer group get the middle level of expression. And the healthy controls have the highest IL17 expression in the peripheral blood, and the cancer group have the lowest expression, and the normal kidney transplantation patients get the middle level of expression.

**Conclusions:** Tregs expressions are higher, while IL17 expressions are lower in the patients got tumor after the kidney transplantation, they plays an important role in tumor incidence after the kidney transplantation.

*Funding:* Government Support - Non-U.S.

**FR-PO466**

**An Anti-CD154 Domain Antibody Prolongs Graft Survival and Induces FoxP3+ iTreg in Both the Absence and Presence of CTLA4-Ig**
David F. Pinelli,[1] Anish Suri,[2] Steven Nadler,[2] Mandy L. Ford.[1] *[1]Emory Univ; [2]Bristol Myers Squibb.*

**Background:** Blockade of CD40-CD154 interactions has been shown to be highly effective in inducing long-term survival of allografts in both murine and NHP models. However, the clinical potential has yet to be realized, due to the thromboembolic complications seen during clinical trials of an anti-CD154 monoclonal antibody in humans. Thus, development of novel therapies with improved safety profiles is imperative for the field of transplantation.

**Methods:** We compared the most commonly used clone of anti-CD154 antibody, MR-1, with an anti-CD154 domain antibody with a silent Fc region (dAb). We first measured efficacy of these therapies in a fully allogeneic BALB/c to B6 model of skin transplantation. To further investigate the mechanism of action of these therapies, we used a transgenic model where OT-I CD8 and OT-II CD4 T cells were adoptively transferred to B6 mice that then received skin grafts that ubiquitously express the OVA protein.

**Results:** Mice treated with CTLA4-Ig alone quickly rejected fully allogeneic grafts (MST = 15.5 d), whereas treating with MR-1 or dAb in combination with CTLA4-Ig resulted in significant prolongation of graft survival (MST= 33 and 31 d, respectively). Treatment with either therapy led to a significant reduction in allospecific T cell expansion

in the spleen (No Rx 1.64±0.55%, MR-1 0.50±0.14%, dAb 0.62±0.23%), as well as a reduction in the number of IFN-γ-producing allospecific CD8 T cells (No Rx 31.05±5.68%, MR-1 10.91±4.59%, dAbs 12.66±7.80%). In addition, both treatments led to a significant increase in antigen-specific iTreg conversion (No Rx 3.46±0.86%, MR-1 19.06±2.41%, dAb 14.74±1.55%), and dAb-induced iTreg conversion was even preserved in the presence of CTLA4-Ig (26.35±5.05%), a therapy known to have a negative effect on Treg.

**Conclusions:** Taken together, these data demonstrate that alternative means of blocking CD40-CD154 interactions may provide a safer and equally efficacious way to attenuate alloreactive responses, and suggest the potential for clinical application of this therapy in combination with existing modes of treatment.

## FR-PO467

**Myd88 Plays a Critical Role in Acute and Chronic Rejections of Kidney Allografts** Nadine M. Lerret,[1] Ting Li,[2] Jiaojing Wang,[2] Xueqiong Wang,[2] Zheng Jenny Zhang,[2] Xun-Rong Luo.[1,2] *[1]Medicine, Northwestern Univ, Feinberg School of Medicine; [2]Surgery, Northwestern Univ Feinberg School of Medicine; [3]Microbiology and Immunology, Northwestern Univ Feinberg School of Medicine.*

**Background:** Toll-like receptors in kidney injuries have been best studied in ischemic renal dysfunction and in autoimmune GNs. Their role in kidney transplantation rejection is less well characterized.

**Methods:** In the present study, we used a stringent C57BL/6 (B6) to BALB/c mouse kidney transplant model to study the role of myeloid differentiation protein 88 (MyD88) in kidney allograft survival.

**Results:** We found that Myd88$^{-/-}$ BALB/c recipients significantly protected B6 kidney allografts, with ~50% achieving graft survival >90 days, whereas majority of wild-type (WT) recipients rejected their grafts by day30. In long-term protected Myd88$^{-/-}$ recipients, donor skin grafts were accepted indefinitely but third party skin grafts were rejected, demonstrating donor-specific tolerance. Interestingly, we observed that initial acute rejection (AR) manifested as tubulitis with infiltrating T cells was similar in both Myd88$^{-/-}$ and WT recipients at day7 post transplant, although there was trend towards a decrease in infiltrating Gr1$^{+}$ cells in Myd88$^{-/-}$ recipients and the infiltrates further decreased if Myd88$^{-/-}$ donor B6 kidneys were transplanted. However, by day14, Myd88$^{-/-}$ recipients exhibited a significant decline in both graft infiltrating CD8 T cells as well as Gr-1$^{+}$ cells, accompanied by a decrease in the levels of IL-6, IL-17, IFN-γ, and CCL2. By day90, kidney allografts in Myd88$^{-/-}$ recipients showed minimal cellular infiltration or interstitial fibrosis. T cells from Myd88-/- recipients exhibited diminished proliferation to donor stimulation that could be rescued with exogenous IL-6, providing a mechanism linking the lack of MyD88 signaling to a decrease in cellular infiltration of kidney allografts that resulted in long-term graft acceptance.

**Conclusions:** This study demonstrates that Myd88 signaling plays a critical role in both acute and chronic rejection of kidney allografts, and provides a model for studying druggable targets involving Myd88 signaling in kidney transplantation.

## FR-PO468

**Cell-Based Therapy with S1P3 Deficient Dendritic Cells Induces Prolongation of Heart Allograft Survival and Protection from Kidney Ischemic-Reperfusion Injury** Amandeep Bajwa, Liping Huang, Hong Ye, Peter I. Lobo, Mark D. Okusa. *Dept of Med./CIIR, Univ of Virginia.*

**Background:** The plasticity of dendritic cells (DCs) permits phenotypic modulation *ex-vivo* by gene expression or pharmacological agents and these DCs exert their *in-vivo* therapeutic immunosuppressive effects through direct interactions with T-cells by either deleting or causing anergy. Sphingosine 1-phosphate (S1P), a ligand for 5 receptors (S1P1-5Rs) and S1PR agonists reduced kid ischemia-reperfusion injury (IRI) in mice. S1P3-/- (3KO) mice are protected from kid IRI and allogenic heart Tx 3KO (donors) have prolonged graft function with immature DCs. Since ischemic injury contributes to transplant outcome, we tested therapeutic advantage of using bone marrow derived DCs (BMDCs) from 3KO in kidney IRI and allogenic heart transplants (Tx) in mice.

**Methods:** WT B6DC and 3KO B6DCs from mice were adoptively transferred into Balb/c or B6 (LPS stimulated) mice 2d prior to kidney IRI and 7d prior to heart Tx (B6 heart□Balb/c).

**Results:** Naïve Balb/c mice (no DC) had significant rise in creatinine (Cr; mg/dl) compared to sham operated mice (1.2±0.17 and 0.2±0.004, p≤0.01) and mice pretreated with WT B6DC had Cr that were similar to mice receiving no DCs. However, 3KO B6DCs pretreated Balb/c mice were significantly protected from kidney IRI with Cr of 0.3±0.07, p≤0.01. Additionally, 3KO B6DC pretreated Balb/c mice prolonged allogenic heart allografts (6 vs 12d; sensation of heart beat) with less inflammatory cells compared to no DCs or WTB6 DCs injected mice. 3KO B6DCs pretreated mice had significantly higher Treg compared to naïve Balb/c mice and WT B6DC pretreated mice. 3KO B6DCs induced protection required the recipient to have an intact spleen and B/T cells, as pre-treatment of splenectomized mice or use of Rag1KO rendered 3KO B6DCs ineffective in attenuating IRI.

**Conclusions:** We therefore conclude that adoptive transfer of 3KO B6DCs attenuates kidney IRI and improves graft function through interaction with splenocytes and induction of Tregs (CD4$^{+}$FoxP3$^{+}$). Development of selective S1P3 inhibitors may lead to a new therapeutic strategy to prevent AKI and reduce incident of acute rejection.

## FR-PO469

**Glomerular Endothelial microRNA Expression Profiles in an In-Vitro Model of Acute Humoral Rejection** Stephanie Zell,[1] Philip Zeuschner,[1] Oliver Witzke,[2] Clemens L. Bockmeyer,[1] Jan U. Becker.[1] *[1]Institute of Pathology, Hannover Medical School, Hannover, Lower Saxony, Germany; [2]Univ Duisburg-Essen, Clinic for Nephrology, Essen, Northrhine-Westfalia, Germany.*

**Background:** Acute humoral rejection (AHR) is mediated by alloantibodies against donor endothelial cells with and without complement activation. Histological and serological diagnosis remains challenging. Therefore, identification of a diagnostically useful miRNA signature for complement-mediated and complement-independent AHR is most desirable.

**Methods:** Human renal glomerular endothelial cells (HRGEC) were HLA-typed and treated with binding (HLA-A1) or non-binding (HLA-A2) antibody with and without addition of complement. Expression of 762 microRNAs was analyzed by Taqman Low densitiy arrays in a model for 1. complement-mediated AHR, 2. complement-independent AHR and 3. the additional effects of complement in AHR. Here we defined miRNAs as up- or down-regulated when a p value of < 0.05 in two-sided t-test.

**Results:** In complement-mediated AHR several microRNAs were down-regulated (miR-29b, miR-195, miR-215, miR-641) and miR-770-5p was up-regulated. In complement-independent AHR several miRNAs were up-regulated (miR-125a-5p, miR-374b#, miR-501-3p among others) and down-regulated (miR-520c-3p, miR-1201, miR-1255b). Additional effects of complement in AHR show a signature of up-regulated miRNAs (miR-554, miR-601, miR-604, miR-886-3p, miR-1255b) and down-regulated miRNAs (miR-133a, miR-423-5p, miR-502-3p).

**Conclusions:** With microRNA profiling in an *in-vitro* model we identified a glomerular endothelial-specific microRNA signature of complement-mediated and independent forms of AHR. These miRNA signatures will be validated for the tissue-based diagnosis of complement-mediated and independent forms of AHR. Putative target mRNAs will be identified by *in-vitro* experiments.

## FR-PO470

**Protective Effect of Anti-HMGB1 Antibody against Chronic Cyclosporine Nephrotoxicity in a Mouse Model** Hoon Suk Park, Eun Nim Kim, Min Young Kim, Ji Hee Lim, Jong Hoon Lee, Keun Suk Yang, Ji Hyun Yu, Seun Deuk Hwang, Cheol Whee Park, Chul Woo Yang, Bum-Soon Choi. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** HMGB1 (High mobility group box1) is known to be an important mediator in inflammatory pathway. It is associated with ischemic insults in myocardial and cerebral infarction, so its blockade leads to protection from organ damages. We performed this study to see if the blocking of HMGB1 prevents chronic cyclosporine (CsA) toxicity in a mouse model.

**Methods:** Male ICR mice (25g) were used. Chronic CsA toxicity was caused by its subcutaneous (SC) injection daily for 4 weeks. Each group (n=6) was respectively control group (olive oil 1mL/kg SC injection), CsA toxicity group (CsA 30mg/kg SC injection), anti-HMGB1 group (anti HMGB1 chicken IgY antibody (600mg/mouse) intraperitoneal (IP) injection weekly for blocking HMGB1) and non-specific IgY group (polyclonal non-specific chicken IgY antibody (600mg/mouse) IP injection weekly).

**Results:** Anti- HMGB1 group showed decreased 24 hour albuminuria (23.78 ± 8.06 mcg/day vs. 62.69 ± 28.83 mcg/day, p = 0.03), increased creatinine clearance (0.12 ± 0.03 ml/min vs. 0.07 ± 0.02 ml/min, p = 0.05) and decreased serum creatinine level (0.22 ± 0.02 mg/dl vs. 0.33 ± 0.04 mg/dl, p = 0.01), compared with CsA toxicity group. Tubular interstitial fibrosis area (2.19 ± 1.97 % vs. 14.65 ± 6.54 %, p = 0.008) and TGF-beta immunohistochemical stain (11.47 ± 0.88 fold vs. 16.06 ± 4.81 fold, p = 0.05) were also decreased in anti-HMGB1 group vs. CsA toxicity group. 8 OHDG level in 24 hour urine was decreased, but was not significant (52.94 ± 15.34 mcg/day in anti HMGB1 group vs. 72.45 ± 13.77 mcg/day in CsA group, p = 0.12). RAGE (0.74 ± 0.03 fold vs. 1.27 ± 0.29 fold, p = 0.02) and TLR4 (0.41 ± 0.09 fold vs. 0.89 ± 0.14 fold, p = 0.05), which are known to interact with HMGB1, expressions were decreased in anti-HMGB1 group vs. CsA toxicity group.

**Conclusions:** The administration of anti-HMGB1 brought renal functional improvements and ameliorated fibrosis induced by CsA and it is thought to result from decrease in TLR4 & RAGE expressions.

## FR-PO471

**Analysis of the Impact of Immunosuppressive Drugs on DNA Methylation in Kidney Cells** Jessica Thalmann, Barbara Hertel, Hermann G. Haller, Annette D. Wagner. *Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** Immunosuppressive drugs from different groups, e.g. calcineurin inhibitors, IMPDH inhibitors, or mTOR inhibitors are used to prevent rejection after kidney transplantation. The desired immunosuppressive effects are mediated by distinct molecular mechanisms. Moreover, these drugs produce a variety of nonimmune adverse effects to other tissues, and the molecular mechanisms are widely unknown. Epigenetic side-effects have been described or suggested for other pharmaceuticals, and there is growing evidence that methylation modifications are linked to a number of dysfunctions and diseases. We therefore hypothesize that immunosuppressive drugs alter epigenetic methylation patterns, representing a new molecular mechanism how adverse effects of immunosuppressive drugs are mediated.

**Methods:** In *in vitro* experiments we treated several epithelial kidney cells (Vero cells, the human proximal tubular epithelial cell line HK-2, and the primary human renal proximal tubular epithelial cells RPTEC) with either cyclosporine, tacrolimus, everolimus or mycophenolic acid in various concentrations. For determination of relative DNA methylation levels we established a flow cytometry protocol using anti-5-meC antibody.

**Results:** A significant decrease of DNA methylation was observed after tacrolimus treatment in a dose dependent manner. However, neither cyclosporine, nor mycophenolic acid, nor everolimus induced significant changes in the DNA methylation signal. In order to identify affected genes, and for absolute quantification of the methylation status, a genome-wide screening of DNA methylation was carried out using Infinium HumanMethylation27 BeadChip. Significant methylation changes were found in 323 genes. Network analysis reveals that the top three network functions include hematological system development and function, renal and urological disease, drug metabolism, endocrine system development and function, and inflammatory response, among others.

**Conclusions:** Our data indicate that tacrolimus changes epigenetic patterns, and provide evidence that these changes may contribute to tacrolimus´ adverse effects (nephrotoxicity, hemolytic-uremic syndrome, post-Tx diabetes, BKV infection).

## FR-PO472

**Polyoma Virus Infection Leads to Hypermethylation and Down-Regulation of Matrix Metalloproteinases in Primary Renal Tubulus Epithelial Cells** Jessica Thalmann, Barbara Hertel, Hermann G. Haller, Annette D. Wagner. *Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** BK virus is a ubiquitous polyomavirus that persistently infects the kidney. This otherwise silent infection can reactivate in transplanted and immunosuppressed individuals leading to polyomavirus-associated nephropathy (PVAN) with irreversible renal scarring and fibrosis, even when the infection is cleared. The pathomechanisms are poorly understood. We hypothesize that BK virus infection influences host cell DNA methylation that leads to ongoing alteration of gene expression contributing to the development of PVAN.

Pathological fibrosis results from an imbalance in the normal processes of synthesis and degradation of extracellular matrix components, and kidney scarring is associated with a reduction of matrix metalloproteinases (MMP) activity.

**Methods:** We infected primary human renal proximal tubule epithelial cells (RPTEC) with BK virus and analyzed the CpG island methylation status of matrix metalloproteinases by MassArray. mRNA expression levels were determined by real time PCR.

**Results:** We found that the CpG islands of MMP-1 and MMP-2 show hypermethylation in BKV infected cells as compared to noninfected cells. Moreover, DNA methyltransferase-1 that is known to induce de novo methylation was found to be up-regulated in BKV infection. The mRNA expression of both MMP-1 and MMP-2 was down-regulated.

**Conclusions:** The down-regulation of MMPs might lead to the accumulation of extracellular matrix in the progression of PVAN. These findings might reflect a novel mechanism how BKV infection contributes to the onset and maintenance of renal scarring in PVAN, and provide an explanation for the surpassing effect even in the absence of BKV when the infection is cleared.

*Funding:* Government Support - Non-U.S.

## FR-PO473

**A Novel Mouse Model for Unraveling the Mechanism behind Tacrolimus Mediated Hypertension and Hyperkalemia** Rebecca A. Lazelle, Nick Meermeier, Chao-Ling Yang, David H. Ellison. *Div of Nephrology and Hypertension, Oregon Health and Science Univ, Portland, OR.*

**Background:** Calcineurin inhibitors, such as tacrolimus (FK-506), are used to prevent organ transplant rejection. While effective, tacrolimus causes clinically limiting side effects including hypertension, hyperkalemia, and chronic kidney disease. We have shown that the sodium chloride cotransporter (NCC), located in the distal convoluted tubule (DCT) of the kidney, is necessary for the development of hypertension, but it is unclear whether tacrolimus acts directly in the DCT to cause this pathology. We have developed a unique mouse model, which takes advantage of the fact that tacrolimus requires an endogenous binding partner-FKBP12-to inhibit its target calcineurin. This model allows us to test the role of both components of the immunosuppressive pathway-FKBP12 disruption and calcineurin inhibition-in the DCT *in vivo*.

**Methods:** Using a Doxycycline inducible CRE/LOX system, we excised FKBP12 from renal epithelial cells of adult mice. We characterized these mice using immunofluorescence, Western blots, radiotelemetry and I-stat analysis.

**Results:** Immunofluorescence revealed that FKBP12- considered ubiquitous-is found predominantly in the glomeruli and the DCT of the kidney. Doxycycline treatment reduced FKBP12 by approximately 90%, with deletion occurring only along the nephron. FKBP12 KO mice appeared phenotypically normal. Mean arterial pressure was similar in WT and KO mice (WT 102 ±1 mmHg; KO 101 ±5.7). Total and phosphorylated NCC expression was also comparable (tNCC WT 100 ±11%; KO 90 ±19%, pNCC WT 100 ±10%; KO 102 ±10%), as was serum $Na^+$ (WT 145.3 ±0.42 mmol/L; KO 144.4 ±0.30) and $K^+$ (WT 3.94 ±0.1 mmol/L; KO 3.96 ±0.1).

**Conclusions:** Our data suggests that FKBP12 disruption in the DCT does not drive tacrolimus-mediated hypertension and hyperkalemia. We are now testing whether it protects against tacrolimus-mediated toxicity by preventing calcineurin inhibition in the DCT. The expression pattern of FKBP12, however, may explain the predominance of hyperkalemia in patients treated with tacrolimus compared with calcineurin inhibitors, such as cyclosporine, that have different binding partner requirements.

## FR-PO474

**Antiproteinuric Effects of Green Tea Extract on Tacrolimus-Induced Nephrotoxicity in Mice** Byung Chul Shin, Jong Hun Back. *Dept of Internal Medicine, Chosun Univ Hospital, Gwangju, Republic of Korea.*

**Background:** It has been reported that the proteinuria is a early useful marker in detection of tacrolimus (TAC) nephrotoxicity. Green tea extract (GTE), as an antioxidant , induces apoptosis in renal interstitial fibroblast cells in vitro studies. The aim of this study was to investigatethe anti-proteinuric effects of GTE on TAC-induced acute renal injury in mice.

**Methods:** The mice (n=20) were divided into 4groups (n=5/group); control group wereintraperitoneally (IP) injected 0.9% saline for 7 days,TAC group were IP injected TAC1 mg/kg, iNOS inhibitor group were given inaddition NG-nitro-L-arginine-methyl ester (L-NAME)12 mmol/L by subcutaneous injection. TAC-GTE group were given TAC by IP injection andGTE 100 mg/kg by subcutaneous injection.

**Results:** The 24 hours urine protein levelswere significantly increased in TAC group (36.1± 9.9mg/day) compared to control group (13.3± 5.4mg/day, $P < 0.01$) and significantly decreasedin TAC-GTE group (19.1± 6.9mg/day, $P < 0.01$) compared to TACgroup. The NO production by TAC was significantly suppressed by GTE and iNOS inhibitor ($P < 0.01$). Renal tissue MDA level was significantly increased in TAC group compared to control group andsignificantly decreased in TAC-GTE group compared than that of TAC group ($p<0.01$). The anti-oxidant enzyme activities of superoxide dismutase and catalase were significantly suppressed in TAC group compared with control group and restored in TAC-GTE group compared with CsA group ($p < 0.05$).

**Conclusions:** This study proves that proteinuriaof the TAC induced nephrotoxicity is associated withlipid peroxidation and nitric oxide production. GTE treatment has meaningful anti-proteinuric effects throughantioxidative effect in the kidney from TAC-inducedacute renal injury in mice.

## FR-PO475

**Impact of Blocking Interleukin 6 Receptor with Antibody Producing Nonviral Minicircle DNA in Skin Allograft Rejection** Jian Jin,[1] Kyoung Chan Doh,[1] Long Jin,[1] Shang Guo Piao,[1] Youngkyun Kim,[3] Jihyun Ju,[3] Sun Woo Lim,[1] Byung Ha Chung,[1,2] Chul Woo Yang.[1,2] *[1]CRCID & Transplant Research Center, The Catholic Univ of Korea; [2]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea; [3]Div of Rheumatology, Dept of Internal Medicine, The Catholic Univ of Korea.*

**Background:** Blocking of interleukin-6(IL-6) is effective in decreasing resistance to allogenic tolerance. In this study, we investigated whether anti-IL-6 receptor producing nonviral minicircle(MC)-DNA, is competent to inhibit alloresponse-induced IL-6 in highly immunogenic murine skin allograft model.

**Methods:** We designed MC-DNA producing anti-IL-6R and verified in vitro system. One day before skin allograft modeling, systemic MC-DNA exposed via hydrodynamic delivery(tail vein, single injection). Using GFP tagging MC-DNA, we confirmed its organ distribution. At day 5, we measured the amount of IL-6 and anti-IL-6R in serum. We evaluated survival rate, morphological changes of graft, immune cell infiltration, and population of Th17($CD4^+$/RoRγt) and Treg($CD4^+Foxp3^+$). We compared its alloimmunity and graft survival efficiency with the CsA-treated group.

**Results:** Hydrodynamic delivery of MC-DNA was mainly localized in hepatocytes. Serum IL-6 and IL-6R antibody detected in anti-IL-6RMC-DNA treated mice. At day 8.5, untreated mice completely rejected the graft confirming by daily observation of loss of graft and erosion. However, mice received either anti-IL-6R MC-DNA or CsA presented prolonged acceptance of graft until day 15 or 15.6, respectively. Morphological changes and immune cell infiltration in the graft were also consistent with survival rate. FACS results showed that anti-IL-6RMC-DNA treatment markedly suppressed Th17population compared with the untreated mice. However, there was no effect on Treg population. However, CsA showed the increased Th17and decreased Treg population compared with untreated group.

**Conclusions:** We found that single injection of nonviral MC-DNA targeting IL-6R is effective in both acute allograft acceptance and allogenic tolerance. This suggests that simple and effective gene therapy method using antibody producing minicircle DNA may represent a powerful tool for the transplantation.

## FR-PO476

**X-Linked Inhibitor of Apoptosis Protein Expression Is Not Associated with Increased Apoptosis in an In Vivo Model of Cold Ischemia** Daniel Keys,[1] Swati Jain,[1] Kameswaran Ravichandran,[1] Zhibin He,[1] Danica Ljubanovic,[2] Charles L. Edelstein,[1] Alkesh Jani.[1] *[1]UC Denver, Aurora, CO; [2]Dubrava Hospital, Zagreb, Croatia.*

**Background:** Delayed graft function (DGF) independently predicts reduced 5 yr kidney transplant survival. Cold ischemia (CI) contributes to the development of DGF and results in tubular cell apoptosis and brush border injury (BBI). Our published data demonstrates that mouse kidneys subjected to CI have increased caspase-3, renal tubular cell apoptosis and BBI at 48 hours of CI. XIAP is the most potent inhibitor of apoptosis currently known. The purpose of this study was to evaluate the time course of XIAP, active caspase-3, caspase-3 activity and histologic changes in a mouse model of CI.

**Methods:** C57BL/6 mice were anesthetized and right kidneys were processed at time zero as control following perfusion with cold UW solution. Left kidneys were exposed to CI for 1, 6, 12, and 24 hours. Active caspase-3 and XIAP proteins were evaluated by

immunoblot. Caspase-3 activity was measured using absorbance of cell lysates after incubation with substrate for caspase-3/7. Apoptosis and BBI were quantified by an independent nephropathologist.

**Results:** After CI, BBI occurs first and was significantly increased at 6 hours. Active caspase-3 protein levels and caspase-3 activity levels were significantly increased at 24 hours of CI. Apoptosis was significantly increased at 24 hours of CI. XIAP levels were not significantly different at any time point in this model of CI.

| * = p < 0.05 | Control | 1 hour | 6 hour | 12 hour | 24 hour |
|---|---|---|---|---|---|
| XIAP Densitometry | 0.99 | 1.18 | 1.11 | 1.22 | 1.17 |
| Caspase-3 Densitometry | 0.99 | 0.9 | 1.26 | 1.64 | 2.63 * |
| Caspase-3 Activity | 0.010 | 0.009 | 0.012 | 0.016 | 0.035* |
| Apoptosis / 10 hpf | 0.013 | 3.2 | 8.4 | 3.2 | 13.75* |
| BBI | 13 | 17 | 44* | 58* | 42* |

**Conclusions:** CI injury results in apoptosis in a time dependent manner. Increased apoptosis was associated with an increase in active caspase-3 protein levels and caspase-3 activity but no change in XIAP protein levels in a murine model of CI. Mechanistic studies of caspase-3 activation are planned.

*Funding:* NIDDK Support

## FR-PO477

**Integrated Messenger RNA and microRNA Profiles Suggest an Interferon Alpha Signature in Chronic Antibody-Mediated Rejection (CAMR)**

F. Rascio,[1] Paola Pontrelli,[1] Matteo Accetturo,[1] Margherita Gigante,[2] Giuseppe Castellano,[1] Maddalena Gigante,[2] Anna Zito,[1] Gianluigi Zaza,[3] Annarita Oranger,[1] G. Stallone,[2] E. Ranieri,[2] Loreto Gesualdo,[1] G. Grandaliano.[2] *[1]Dept Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy; [3]Nephrology, Dialysis and Transplantation Unit, Univ of Verona, Verona, Italy.*

**Background:** CAMR is the main cause of chronic graft injury but its pathogenesis is unknown. Aim of the study was to investigate the molecular mechanisms underlying CAMR pathophysiology, integrating microRNAs (miRNAs) and gene expression profiles of peripheral blood mononuclear cells (PBMCs) from CAMR patients and controls.

**Methods:** We enrolled 6 patients with biopsy-proven CAMR and 6 stable transplant recipients with normal graft histology and function (control group). miRNAs and gene expression profiles of PBMCs from both groups were assessed by Agilent technologies. Results were evaluated by statistical analysis and functional pathway analysis and validated by real-time PCR in an independent set of patients.

**Results:** Comparison between CAMR and control patients (FDR<5% and a FC≥2) revealed that18 miRNAs were differentially expressed, all down-regulated in CAMR. The principal component analysis showed the ability of these miRNAs to distinguish the two groups. When matching miRNA data with mRNAdata we identified 4 out of 18 differentially expressed miRNAs, resulted down-regulated in CAMR, as being predicted modulators of 6 mRNAs, resulted up-regulated in our gene expression data. Ingenuity Pathway Analysis (IPA) performed on all 18 miRNAs demonstrated that 9 of them were connected in the interferon-alpha (INF-alpha) network (IPA score=38). IPA assessed on the 6 target mRNAs further confirmed the involvement of INF-alpha pathway (IPA score=14). qPCR performed in an independent set of 6 CAMR and 6 controls of these miRNAs confirmed the microarray data.

**Conclusions:** Our data would suggest a key role of INF-alpha pathway during CAMR and open new perspectives for identification of therapeutic targets.

*Funding:* Government Support - Non-U.S.

## FR-PO478

**Acute Graft-versus-Host Disease in the Kidney after DA-to-Lewis Rat Bone Marrow Transplantation**

Seiichiro Higo,[1,2] Akira Shimizu,[1] Shinya Nagasaka,[1] Yusuke Kajimoto,[1] Go Kanzaki,[1] Akiko Mii,[2] Shuichi Tsuruoka.[2] *[1]Dept of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Dept of Internal Medicine, Nephrology, Nippon Medical School, Tokyo, Japan.*

**Background:** Allogeneic hematopoietic and bone marrow cell transplantation (BMT) causes acute and choronic graft-versus-host-disease (GVHD). Liver, gut, and skin are well known to primary target sites of acute and chronic GVHD. However, kidney is still uncertain to be influenced by GVHD. In the present study, we examined the pathology of kidney in acute GVHD in DA-to-Lweis rat BMT.

**Methods:** Acute GVHD was induced in Lewis rats (RT1l) by transplantation of DA rat (RT1a) bone marrow cells ($6.0x10^7$ cells) without immunosuppression after lethal irradiation (10Gy). We examined the clinical and pathological characteristics of acute GVHD in several organs, including skin, liver, gut, and kindney after BMT.

**Results:** Almost all white blood cells were replaced with DA donor phenotype in peripheral blood. At least 21 days after BMT, severe acute GVHD was developed in all Lewis rats with body weight loss (>20%), skin rush with alopecia, and kyphosis. In laboratory findings, liver and kidney dysfunction was detected: asparate aminotransferase (AST: 382±18.0U/L), alanine aminotransferase (ALT: 75.4±6.70U/L), lactate dehydrogenase (LDH: 1306±645U/L), and blood urea nitrogen (BUN: 33.6±4.50mg/dL). In the circulation, the increase in percentage of CD8+T cells in all peripheral blood cells was detected by flow cytometry. In addition to the development of GVHD in liver, skin, and gut, infiltration of CD3+T cells including most of CD8+ T cells and CD68+ macrophages were noted in the kidney. In kidney, many CD3+T cells, CD8+ T cells, and CD68+ macrophages infiltrated that mediated the interstitial inflammation with peritubular capillaritis, tubulitis, acute glomerulitis and acute endarteritis in small arterioles. No obvious IgG, IgM, and C3 deposition was detected in the kidney.

**Conclusions:** Kidney is one of the target organs of acute GVHD after BMT. The pathology of acute GVHD in the kidney was the quiet similar findings of acute T-cell mediated rejection in kidney transplantation.

## FR-PO479

**Syndecan-1 and Dyslipidemia after Renal Transplantation**

Saritha Adepu,[1] Kirankumar Katta,[1] Arjan J. Kwakernaak,[1] Robin P.F. Dullaart,[2] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Jacob Van den Born.[1] *[1]Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; [2]Endocrinology, Univ Medical Center Groningen, Groningen, Netherlands.*

**Background:** Syndecan-1 is a transmembrane heparan sulfate proteoglycan involved in hepatic uptake of triglyceride-rich lipoproteins. Renal transplantation is often complicated by a currently unexplained dyslipidemia, contributing to an increased cardiovascular risk. We hypothesized that altered syndecan-1 metabolism could be involved in dyslipidemia in renal transplant recipients.

**Methods:** To test this hypothesis, in a rat model of renal transplantation we quantified liver syndecan-1 expression and measured plasma triglycerides. Anti-syndecan-1 monoclonal antibody was injected into mice to localize syndecan-1 in order to assess source of shed plasma syndecan-1. In a cross-sectional human renal transplantation recipient (RTR) cohort of 510 patients plasma syndecan-1 was measured by ELISA.

**Results:** We found syndecan-1 to be localized to the apical cell membranes of hepatocytes. Hepatic syndecan-1 mRNA expression was increased 4-5 fold after renal transplantation ($p<0.01$) and was accompanied by a significant increase in plasma triglyceride values ($p<0.05$). Upon injection of anti-syndecan-1 monoclonal antibody into mice, the antibody mainly localized to the hepatic sinusoids. In a cross-sectional human RTR cohort, multivariate regression analysis showed soluble syndecan-1 independently to be positively associated with triglycerides and inversely associated with HDL cholesterol (both $p<0.0001$).

**Conclusions:** These data suggest liver syndecan-1 to be a major source of soluble plasma syndecan-1, and that via a yet unknown mechanism renal transplantation increases liver syndecan-1 turnover. We speculate shed syndecan-1 as decoy receptor to hamper lipoprotein uptake by the liver resulting in dyslipidemia. Our data opens perspectives towards improvement of lipid profiles by targeted inhibition of syndecan-1 shedding in (renal) transplantation.

## FR-PO480

**Sirolimus (SIR) Induces Increases in Baseline Glomerular Permeability, but Partly Inhibits Puromycin Aminonucleoside (PAN) Induced Hyperpermeability in Rats**

Josefin Axelsson, Anna Rippe, Bengt Rippe. *Dept of Nephrology, Clinical Sciences, Lund, Sweden.*

**Background:** It is well established that the immunosuppressant SIR, an mTOR inhibitor, can produce de novo proteinuria in transplanted patients. On the other hand, SIR has been shown to suppress kidney disease progression in animal models. In the present study we wanted to investigate whether glomerular permeability would be altered by SIR alone and whether SIR can affect PAN induced glomerular hyperpermeability.

**Methods:** In anaesthetized Wistar rats (250-280g) the left urether was cannulated for urine collection, while simultaneously, blood access was achieved. SIR was administered as a single dose i.v. 30 min before the start of the experiments in animals infused with PAN or animals not exposed to PAN. Polydisperse FITC-Ficoll-70/400 (mol.radius 10-80Å) and $^{51}$Cr-EDTA infusion was given during the whole experiment. Measurements of Ficoll in plasma and urine were performed sequentially at start (baseline) and at 5, 15 and 60 min after the start of the experiments. Urine and plasma samples were analyzed by high performance size exclusion chromatography (HPSEC) to assess steady state glomerular sieving coefficients (θ) for $Ficoll_{10\text{-}80Å}$.

**Results:** SIR increased baseline glomerular permeability to $Ficoll_{50\text{-}80Å}$ at 15 min, but not at 5 min or at 60 min. θ for $Ficoll_{70Å}$ thus increased from $2.91 \times 10^{-5} \pm 1.18 \times 10^{-5}$ at baseline to $2.27 \times 10^{-4} \pm 5.02 \times 10^{-5}$ ($p<0.01$) at 15 min after SIR. PAN alone caused a rapid increase in glomerular permeability, peaking at 5 min, and again at ~60 min. SIR blunted the first PAN induced permeability peak and almost completely abrogated the second one.

**Conclusions:** mTOR inhibition with SIR induced rapid, reversible increases in baseline glomerular permeability, but also blunted PAN induced glomerular hyperpermeability in rats, underpinning the complex interactions of SIR with the glomerular filtration barrier.

*Funding:* Government Support - Non-U.S.

## FR-PO481

**MRI Detectable Nanoparticles to Measure the Size and Number of Glomeruli in the Human Kidney**

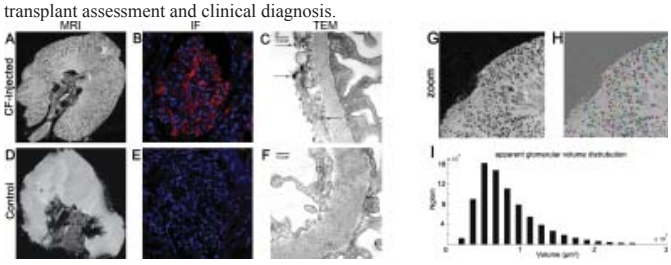
Scott Charles Beeman,[1] Edwin J. Baldelomar,[2] John F. Bertram,[3] Luise A. Cullen-McEwen,[3] Jennifer Richardson Charlton,[4] Teresa Wu,[5] Min Zhang,[5] Kevin Bennett.[2] *[1]Washington Univ in St. Louis; [2]Univ of Hawaii; [3]Monash Univ, Australia; [4]Nephrology, Univ of Virginia Medical Center, Charlottesville, VA; [5]Arizona State Univ.*

**Background:** The number (Nglom) and volume (Vglom) of kidney glomeruli may predict cardiovascular and renal health (Brenner, 1988; Puelles, 2012). There are currently no methods to make these measurements in the clinic. The cationic ferritin (CF) nanoparticle has been proposed as a glomerulus-specific MRI contrast agent (Bennett, 2008; Beeman, 2011, Heilmann, 2012). Here we use intravenous CF to measure Nglom and Vglom in intact human kidneys with MRI.

**Methods:** Four viable human kidneys (not viable for transplant but without known renal disease) were acquired within 24 hours of death though a donor network (IIAM) with IRB and informed consent. Kidneys were perfused with CF, PBS, and formalin. Control kidney received no CF. Kidneys were imaged with 3D MRI (resolution 117 $\mu m^3$). Binding of CF to glomeruli was confirmed by fluorescence (IF) and electron microscopy (TEM). We measured Nglom and Vglom from MRI with custom software.

**Results:** MRI of labeled human kidneys showed dark spots at each glomerulus (Fig. 1A,D). IF (Fig. 1B,E; red is CF) and TEM (Fig. 1C,F; arrows show CF accumulation) confirmed CF-binding to glomeruli. The software identified CF-labeled glomeruli (Fig. 1H), counted glomeruli (772,922, 328,181 and 702,506), and measured glomerular volumes ($8.0x10^6 \pm 4.28x10^6$ $\mu m^3$, $6.9x10^6 \pm 3.9x10^6$ $\mu m^3$ and $6.8x10^6 \pm 2.9x10^6$ $\mu m^3$). Results are consistent with the literature(Nyengaard, 1992). This MRI technique allows for a new metric - the intra-renal glomerular volume distribution; a single-kidney example is shown in Fig. 1I.

**Conclusions:** This work may enable quantitative renal morphology measurements for transplant assessment and clinical diagnosis.



*Funding:* Other NIH Support - Diabetic Complications Consortium

## FR-PO482

**Ultrasound Based Detection of Microbubbles Targeted to T-Lymphocytes for Non-Invasive Imaging of Acute Allograft Rejection in Different Rat Models of Renal Disease** Alexander Grabner,[1] Dominik Kentrup,[1] Mareike Muehlmeister,[2] Helga Pawelski,[1] Eberhard Schlatter,[1] Hermann Pavenstaedt,[1] Klaus Tiemann,[2] Stefan Reuter.[1] *[1]Dept of Internal Medicine D, Univ Hospital Muenster, Muenster, Germany; [2]Dept of Cardiology and Angiology, Univ Hospital Muenster, Muenster, Germany.*

**Background:** We propose anti-CD3-antibody-mediated contrast-enhanced ultrasound targeting human T-lymphocytes for image-based diagnosis and differentiation of acute allograft rejection (AR) established in a rat renal transplantation model.

**Methods:** After tail vein injection of $30x10^6$ human T-lymphocytes, microbubbles conjugated with a human anti-CD3 antibody were i.v. administered to male 10 weeks old uni-nephrectomized, allogeneically transplanted rats (Lewis-Brown Norway (LBN) to Lewis, aTX). Ultrasound was used to investigate the transplanted as well as the native kidney. Syngeneically (sTX) transplanted rats (LBN to LBN), rats with ischemia/reperfusion injury (IRI, 45 min warm ischemia), and rats subjected to acute cyclosporine A toxicity (CSA) (50 mg/kg for 2 days i.p.) served as controls. *In vivo* results were confirmed with immunohistochemical CD3-stainings.

**Results:** Accumulation of human T-lymphocytes was clearly detected by antibody-mediated ultrasonography und was significantly elevated on postoperative day 4 in allografts undergoing AR ($5.41 \pm 1.32$ A.U., $p < 0.05$ vs. all controls, $N = 4$) compared to native control kidneys ($1.09 \pm 0.18$ A.U.). Concordantly no differences were found between native kidneys and sTX ($0.99 \pm 0.30$ A.U.), CSA ($0.12 \pm 0.04$ A.U.) and kidneys with IRI ($0.46 \pm 0.29$ A.U.). A strong correlation between ultrasound signal and results obtained by immunohistochemical analysis was found.

**Conclusions:** Contrast enhanced ultrasound using CD3-antibodies for detection of infiltrating T-lymphocytes is a novel option to highly specific and non-invasively assess AR after rat renal transplantation. This method allows to discriminate between AR, acute tubular necrosis and acute Calcineurin inhibitor toxicity. Since it can easily be transferred into clinics it might potentially be useful to improve the early diagnosis of AR, to investigate its kinetics and to monitor treatment efficiency.

**Non-Invasive Magnetic Resonance Imaging in Rats for Prediction of the Fate of Grafted Kidneys from Cardiac Death Donors** Jun-Ya Kaimori,[1] Satomi Iwai,[2] Masaki Hatanaka,[1] Hidetoshi Tsuda,[1] Yoshitsugu Obi,[1] Naotsugu Ichimaru,[1] Masayoshi Okumi,[1] Hiromi Rakugi,[1] Eiji Kobayashi,[3] Shiro Takahara,[1] Yoshitaka Isaka.[1] *[1]Osaka Univ, Suita, Osaka, Japan; [2]Kitasato Univ, Aomori, Japan; [3]Jichi Medical Univ, Tochigi, Japan.*

**Background:** The worldwide shortage of organs for transplantation (Tx) has highlighted donation after cardiac death (DCD) as new organ sources. But such donor organs have many problems. The main objective of this study was to assess cardiac death (CD) kidney grafts before Tx to determine whether blood oxygen level-dependent (BOLD) and diffusion MRI can predict damage to these grafts after Tx.

**Methods:** We assessed CD kidney tissue by BOLD and diffusion MRI with pathological and gene expression in Rat CD kidney grafts before and after Tx.

**Results:** Although there was significantly more red cell congestion (RCC) in the inner stripe of the outer medulla (IS) in both 1 h after cardiac death (CD1h) and CD2h kidneys destined for grafts before Tx compared with CD0h ($p < 0.05$), CD2h, but not CD1h, kidney grafts had significantly different RCC in the IS 2 days after Tx ($p < 0.05$). Consistent with these pathological findings, tissue plasminogen activator (tPA) gene expression was increased only in the cortex and medulla of CD2h kidney grafts after Tx. BOLD MRI successfully and non-invasively imaged and quantified RCC in the IS in both CD1h and CD2h kidney grafts ($p < 0.05$). Diffusion MRI also non-invasively assessed increased the apparent diffusion coefficient in the IS and decreased it in the outer stripe (OS) of CD2h grafts, in concordance with interstitial edema in the IS and tubule cellular edema in the OS. These two types of edema in the outer medulla could explain the prolonged RCC in the IS only of CD2h kidney grafts, creating part of a vicious cycle inhibiting red cells coming out of capillary vessels in the IS. Perfusion with University of Wisconsin solution before MRI measurements enhanced these differences.

**Conclusions:** BOLD and diffusion MRI, which are readily available non-invasive tools for evaluating CD kidney grafts tissue damage, can predict prolonged organ damage, and therefore the outcome, of transplanted CD kidney grafts.

## FR-PO484

**Oleanolic Acid-Induced Nrf2 Activation Attenuates Renal Oxidative Stress and Tubulointerstitial Fibrosis in Chronic Cyclosporine Nephropathy** Sungjin Chung, Sung Jun Kim, Hye Eun Yoon, Seok Joon Shin, Cheol Whee Park. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** Cyclosporine (CsA)-induced kidney injury is characterized by renal dysfunction with inflammatory cell infiltrations, apoptosis and fibrosis. Nuclear factor erythroid-2-related factor-2 (Nrf2) is known to confer protection against tissue injury by orchestrating antioxidant and detoxification responses to oxidative stress. This study investigated whether upregulation of Nrf2-depedent antioxidative signaling by olenoalic acid (OA) would attenuate renal inflammation and fibrosis in CsA-induced kidney injury.

**Methods:** Male ICR mice fed a low-sodium diet were divided into four treatment groups: control+vehicle, control+OA, CsA+vehicle, and CsA+OA. In the OA-treated groups, 25 mg/kg/day of OA was administrated by intraperitoneal injection for last 1 week of experimental period. Renal inflammation and fibrosis, markers of oxidative stress, and changes in Nrf2 signaling were evaluated at the end of 4 weeks.

**Results:** Following the CsA treatment, kidney function and urine osmolality were decreased, and urine volume and albuminuria were increased. However, these findings were attenuated by OA treatment. Administration of OA decreased tubulointerstitial fibrosis score and $\alpha$-SMA that were increased in CsA-treated mice. Increased apoptotic cell death and a high ratio of Bax to Bcl-2 expression in kidneys of CsA-treated mice were also significantly ameliorated with OA treatment. OA treatment was attributed with the increased levels of nuclear Nrf2 and heme oxygenase (HO)-1. Furthermore, administration of OA improved SOD1 expression and decreased urinary 8-OHdG and isoprostane concentrations. However, there were no changes in the expression of total Nrf2, Kelch-like ECH-associated protein 1 (Keap1), NQO-1 and catalase, indicating that OA enhanced nuclear translocation of Nrf2 and subsequently activated HO-1.

**Conclusions:** Our results suggest that OA has beneficial effects on oxidative stress and fibrosis through activation of Nrf2–HO-1 signaling in the chronic cyclosporine nephropathy.

## FR-PO485

**Renal Oxygenation after Renal Transplantation: Towards Long-Term Telemetry** Diana A. Papazova, Jaap A. Joles, Marianne C. Verhaar, Maarten P. Koeners. *Nephrology & Hypertension, Univ Medical Center Utrecht, Netherlands.*

**Background:** Lower renal $O_2$ is observed after ischemia/reperfusion injury (IRI). Reduced renal graft function and survival are related to IRI. Our aim is to compare the renal $O_2$ in healthy kidneys and kidneys after transplantation (TX). A critical barrier to investigate this is lack of methods to measure kidney tissue $O_2$ continuously. Recently we developed a telemetry-based carbon paste $O_2$ electrode (CPE) which can record renal $O_2$ in rats, unhindered by anaesthesia or restraint. To test this new modality we measured renal $O_2$ before, during and after ischemia.

**Methods:** In a terminal setting renal $O_2$ was measured before, during and after 20 min of ischemia induced by a vascular clamp (n=3). Syngenic renal TX (n=4) was performed using male Lewis rats, controls (n=5) were age-matched. Briefly, donor left kidney was connected to the recipient's left renal vessels and urether with end-to-end anastomoses with a period of 30 min cold ischemia and 30 to 40 min warm ischemia. Two weeks after TX renal function (glomerular filtration rate (GFR): inulin clearance, effective renal plasma flow (eRPF): PAH clearance) were measured. Tubulo-interstitial injury (TI) was scored. Oxygenation of transplanted kidneys was compared to non-transplanted kidneys using CPEs for amperometric detection of $O_2$.

**Results:** During ischemia $O_2$ levels fell to practically zero but stabilized to 1.5 times baseline during reperfusion. Renal $O_2$ ($40.5 \pm 19.2$ uM vs. $110.1 \pm 31.4$ uM) and GFR ($1.02 \pm 0.46$ vs. $1.98 \pm 0.46$ ml/min) were lower in transplanted vs. non-transplanted kidneys (both $p<0.05$), while no significant differences were found in eRPF, filtration fraction and mean arterial pressure. TI was higher in transplanted kidneys vs. controls ($2.0 \pm 0.5$ vs. $0.7 \pm 0.4$, $p<0.05$).

**Conclusions:** CPE could successfully measure renal $O_2$ before, during and after ischemia. As the CPE can be used with telemetry, this method can be applied for continuous long-term monitoring of kidney $O_2$ in, for instance, experimental renal transplantation. The CPE detected a marked decrease in $O_2$ in transplanted vs. non-transplanted kidneys. Whether this is due to delivery or consumption of $O_2$ should be elucidated.

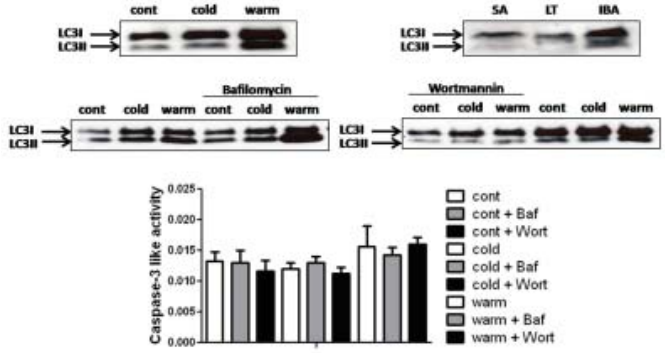
**FR-PO486**

**Increased Autophagic Flux during Extreme Cold Ischemia Followed by Warm Reperfusion** Swati Jain, Daniel Keys, Charles L. Edelstein, Alkesh Jani. *UC Denver, CO.*

**Background:** AKI post transplant DGF is associated with prolonged cold ischemia (CI) of > 30 hours followed by warm reperfusion (WR) and renal tubular cell (RTEC) apoptosis. We have shown that hibernating ground squirrel (GS) kidneys endure CI for **several days** followed by WR during Arousal (IBA) without AKI or RTEC apoptosis. Since Autophagy is a survival strategy employed by cells under stress, we hypothesised that GS kidneys employed Autophagy to survive hibernation. We examined autophagic flux in: 1) i*n vivo* hibernating GS kidneys 2) *in vitro* in GS RTECs.

**Methods:** LC3-II (an autophagosome marker) and cleaved caspase 3 (CC3) were examined: a) *In vivo* after prolonged CI of several days during torpor (LT), followed by WR during IBA; b) *In vitro* in GS RTECs subjected to cold storage (CS) in UW solution followed by rewarming (WR) in normal media to simulate *in vivo* CI/WR. Autophagic flux was examined using Bafilomycin and Wortmannin.

**Results:** *In vivo* IBA kidneys and cells subjected to CS/WR *in vitro* had significantly increased LC3-II expression. Treatment of GS RTEC with Bafilomycin and Wortmannin demonstrated:(a) increased autophagic flux under conditions of CS/WR (b) no increase in CC3 protein or its activity.



**Conclusions:** Hibernators survive WR after several days of CI during IBA that would be lethal to non-hibernators. To determine a mechanisn of tolerance to CI/WR we examined the role of Autophagy, a survival strategy employed by cells. Autopagic flux inhibition with Bafilomycin or Wortmanin did not increase CC3 protein or its activity suggesting that; (a) autophagic flux is employed by hibernators to withstand stress, but (b) is not required for cell survival during WR after CI in hibernators.

**FR-PO487**

**Cold Injury Is Mediated by Loss of Ezrin In Vivo** Peter Hamar,[1] Csaba Imre Szalay,[1] Anita A. Wasik,[2] Laszlo Rosivall,[1] Sanna H. Lehtonen.[2] *[1]Institute of Pathophysiology, Semmelweis Univ, Budapest, Hungary; [2]Dept of Pathology, Haartman Institute, Helsinki, Finland.*

**Background:** Early graft injury is the most important determinant of prognosis after kidney transplantation. Although organ preservation is performed by organ storage at 4°C it has been suggested, that cooling may be associated with substantial organ damage due to cytoskeletal rearrangement including the loss of a crucial cytoskeletal protein: ezrin.

**Methods:** We have investigated renal function in an orthotopic renal transplantation model in inbred male Lewis (L) and Fisher (F) rats. F-to-L allografts (A), F isografts (I) or autografts by performing cold perfusion+ischemia (P) as well as following in-situ ischemia reperfusion (IRI) without cold perfusion, uninephrectomy (U) or sham (S) operations were performed. A, I and P kidneys were cold perfused, whereas IRI, U and S were not. Renal function was measured the day before or 3, 5 and 7 days after surgery (n=8/group/time). In a separate set, histologic investigations and ezrin western blotting was performed, 1, 3 and 5 days after surgery.

**Results:** Before operations GFR was 2.41±0.52 and ClPAH: 11.5±3.5 in F animals. In cold perfused (A, I and P) rats a significantly decreased initial GFR and ClPAH improved later. In I/R initial GFR, and ClPAH decreased less, but remained constant later. Serum crea and urea paralleled these results. Sham and I/R animals did not differ significantly. An intense mononuclear infiltrate and IL-2 mRNA (RtPCR) expression indicated acute rejection only in A, but not in any other group. Light and electronmicroscopic investigations demonstrated mild glomerular and intense tubular damage in transplanted and perfused kidneys. This graft injury caused by cold perfusion was accompanied by a severe reduction of ezrin in cold perfused kidneys.

**Conclusions:** In summary, initial kidney function and histologic tubular damage was not determined by ischemia or acute rejection in this model, but it was severely impaired in cold perfused A, I, and P rats at day 3. In the background loss of the cytoskeletal protein: ezrin was detected. Our study draws attention to cold injury as a possibly deleterious factor in transplantation. Funding: OTKA, K 81972.

**Role of Ubiquitin Proteasome System on Renal Cold Storage: A Possible Link to Mitochondrial Dysfunction?** Nirmala Parajuli, Lee Ann MacMillan-Crow. *Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** Renal transplantation is the treatment of choice for patients suffering from end stage renal disease (ESRD) but, due to the shortage of donor kidneys, many patients die while on the waiting list. Kidneys procured from deceased donors are stored in cold storage (CS) solutions; however extended CS leads to renal damage and poor long-term outcome following transplantation. Our published reports show that CS induces reactive oxidant species generation (ROS), mitochondrial dysfunction, and renal damage. Exciting new studies in the liver and heart suggest that the Ubiquitin Proteasome System (UPS), a proteolytic pathway that removes modified proteins, is activated during CS and appears to contribute to organ damage. Therefore, we hypothesize that CS mediated ROS triggers activation of UPS which leads to mitochondrial dysfunction and renal damage.

**Methods:** Male rodent kidneys were isolated and cold stored for 0-24 hr. Mitochondrial function was assessed via high resolution respirometry and ATP measurements. UPS function was monitored by specific activity assays as well as ubiquitin expression.

**Results:** Our data showed that CS induces altered proteasome activity, loss of total ubiquitin protein expression, and mitochondrial dysfunction (decreased ATP). Interestingly, this CS-mediated ATP depletion is partially restored by a clinically relevant proteasome inhibitor (Bortezomib), suggesting that increased UPS activity contributes to mitochondrial dysfunction. Similar to ubiquitin expression, total protein expression of AMP-activated protein kinase (AMPK), a metabolic regulator that helps to maintain cellular ATP and mitochondrial turnover, is also reduced during renal CS. Interestingly, a cell permeable activator of AMPK (AICAR) partially restored renal ATP and ubiquitin expression, suggesting that loss of AMPK may play a critical role in linking altered mitochondrial and proteasomal function during renal CS.

**Conclusions:** These data suggest, for the first time, that renal CS leads to altered UPS and mitochondrial dysfunction. New studies designed to target the UPS with Bortezomib may have promising therapeutic implications for renal transplantation.

**MitoQ Blunts Mitochondrial Damage during Renal Cold Storage via Improved Mitochondrial Biogenesis** Lee Ann MacMillan-Crow, Nirmala Parajuli, Akira Marine. *Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** A major hurdle in the field of renal transplantation is the severe shortage of suitable donor kidneys despite the increasing number of patients awaiting transplant. Renal transplantation using living-donor organs (not exposed to cold storage) perform better when compared to deceased donor kidneys that were exposed to cold storage prior to transplant. Our published reports showed that cold storage induces mitochondrial and renal damage, and we recently reported in a porcine kidney model that a mitochondrial targeted antioxidant, MitoQ, blunted mitochondrial damage (PLOS One 7:11, 2012). However, it remains unknown what mechanisms are governing the cold-mediated mitochondrial damage or protection with MitoQ.

**Methods:** Male rodent kidneys were isolated and cold stored in University of Wisconsin solution for 0-24 hr +/- MitoQ (100 μM). Mitochondrial function was assessed using fresh renal biopsies via high resolution respirometry and ATP measurements. Mitochondrial biogenesis was monitored using immunohistochemistry and mtDNA integrity assessment.

**Results:** Preliminary data showed that cold storage lead to decreased mtDNA levels, reduced respiratory complex function, and impaired mitochondrial biogenesis. Interestingly, IHC analysis suggested that mitochondrial biogenesis was extensively impaired within proximal tubules, but induced in distal nephron cell types. We also showed that adding MitoQ increased ATP and mtDNA after cold storage (24 hr) alone, and improved renal function following cold storage (4 hr) plus transplantation (24 hr) (serum creatinine: 2.9 versus 1.5 mg/dL + MitoQ).

**Conclusions:** These studies suggest that MitoQ can protect against mitochondrial and renal damage during cold storage and transplantation, possibly by restoring mitochondrial biogenesis.

**NOX4 Activation in Renal Ischemia-Reperfusion (I/R) Injury Is Complement-Dependent** Simona Simone,[1] F. Rascio,[1] Giuseppe Castellano,[1] C. Divella,[1] Paola Pontrelli,[1] P. Ditonno,[1] Loreto Gesualdo,[1] G. Pertosa,[1] G.Grandaliano.[2] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy.*

**Background:** Renal I/R plays a key role in the pathogenesis of delayed graft function after renal transplantation and is characterized by an increased of reactive oxygen species generation. The complement cascade has been suggested to play a pathogenic role in I/R-induced renal damage. Aim of the study was to investigate the activation of NADPH oxidase renal isoform, NOX4, in a pig model of renal I/R injury focusing on complement system.

**Methods:** Renal I/R was induced in 5 pigs by arterial clamping. The NADPH oxidase activity was assessed by chemiluminescence on renal tissue taken before ischemia (T0) and at different time after reperfusion (T15', 30', 60'). NOX4 and 8-oxo-dG, a marker of DNA

oxidation, were evaluated by immunohistochemistry. The α-smooth muscle actin (SMA) expression was assessed by confocal microscopy (in vivo model) and immunoblotting in human proximal tubular epithelial cells (HK2) treated C3a ($5*10^{-7}$M). Chemiluminescence assay was used to evaluate NADPH oxidase activity in HK-2 cells after C3a stimulation.

**Results:** NADPH-oxidase activity was significantly increased during reperfusion in a time-dependent manner with a peak at T60 (T0 1.3±0.4, T60 5.3±2.0 ΔURL/Dt, p=0.03). We observed a significant increase in tubular NOX-4 (T0 5.1±0.8, T60' 18.6±.5, pixels/total area, p=0.03), 8-oxo-dG (T0 3.1±0.8, T60' 28.6±0.5, pixels/total area, p=0.03) and α-SMA expression at the same time point (T0 0.8±0.1, T60' 4.6±0.1, pixels/total area, p=0.02). In vitro, C3a induced both NOX4 and α-SMA protein expression in HK2 cells (p=0.02) and caused a statistically significant increase in NADPH-dependent superoxide generation compared to basal conditions (p=0.01). Interestingly, Nox4 silencing by siRNA abolished both C3a-induced NADPH oxidase activation (p=0.01) and α-SMA expression (p=.02).

**Conclusions:** NOX4 is activated during I/R injury. Complement cascade may play a role in NOX4 activation. Complement and NADPH oxidase may represent a pharmacological targets to prevent oxidative damage during I/R injury.

### Renal Protection through CBS/H2S Pathway in Mammalian Hibernation–A Natural Model of Hypothermic Organ Preservation during Cold Ischemia and Reperfusion

George Johnson Dugbartey,[1] Leo E. Deelman,[1] Robert H. Henning.[1] *[1]Clinical Pharmacology, Univ Medical Center Groningen, Groningen, Netherlands; [2]Clinical Pharmacology, Univ Medical Center Groningen, Groningen, Netherlands.*

**Background:** Hibernation represents the most radical example of hypometabolism among mammalian species and is characterized by repetitive cycles of cooling and rewarming, which resembles several clinically relevant conditions such as deep hypothermia, organ storage for transplantation, major surgery and ischemia-reperfusion. Therefore mechanisms applied by hibernators to undergo hibernation without reperfusion injury or other ill effects may have potential application to human medicine. This study aimed at investigating the role of CBS enzyme and $H_2S$ in the induction of torpor and kidney preservation during hibernation.

**Methods:** Male Syrian golden hamsters (*Mesocricetus auratus*) were housed in cages in a climate controlled chamber at 5°C under dim red light to induce torpor. Movement of all animals was continuously monitored with passive infrared detectors. Osmotic mini-pumps filled with saline or AOAA (100mg/kg/day) were implanted i.p. during torpor following a bolus injection of AOAA (10mg) under 2.5% isoflurane anesthesia. At 4 days following implantation of pumps, hamsters that re-entered torpor were aroused by handling for 4 hours and euthanized under pentobarbital anesthesia . Blood samples were taken and kidney of the hamsters were obtained. Summer euthermic hamsters served as controls.

**Results:** Torpid hamsters were aroused during pump implantation. In contrast to saline infusions, infusion of AOAA prevented hamsters from re-entry into torpor. Infusion of AOAA also induced excess renal damage as indicated by high expression of kidney injury marker as well as changes in renal morphology. In contrast, renal morphology was well preserved during hibernation in the saline and non-hibernating summer control groups.

**Conclusions:** Our data show that CBS/$H_2S$ pathway is essential in entrance into torpor and preservation of kidney morphology and function during hibernation.

### Association of Genetic Polymorphisms of Matrix Metalloproteinases with New-Onset Diabetes after Transplantation in Renal Transplantation

Tae Hee Kim, Sunwoo Kang, Yang Wook Kim, Miseon Kang. *Internal Medicine, Univ of Inje, Busan, Republic of Korea.*

**Background:** New-Onset Diabetes After Transplantation (NODAT) is a serious metabolic complication that may follow renal transplantation. Excess fat deposition requires space, created by adipocyte (hypertrophy and hyperplasia) and extracellular matrix (ECM) remodelling. This process is regulated by several factors, including several adipocyte-derived Matrix metalloproteinases (MMPs) and the adipokine cathepsin, which degrades fibronectin, a key ECM protein. Excess fat, also deposited in visceral organs, generates chronic low-grade inflammation that eventually triggers insulin resistance and the associated diabetes mellitus. Therefore, we examined the association between NODAT and 11 single nucleotide polymorphisms (SNPs) located within the 3 genes of Matrix metalloproteinases (MMPs) which might be related with NODAT.

**Methods:** A total of 309 renal transplants recipients were included without a history of diabetes. We analyzed the association between NODAT development and a panel of 11 SNPs within 3 genes (MMP1, MMP2, MMP3) of MMPs.

**Results:** In terms of allele frequencies, rs243849*C (MMP2) was significantly higher in patients with NODAT. Two SNPs among 11 (18.1%) were significantly associated with NODAT development after adjusting for age, sex, and tacrolimus usage. They include MMP2 (rs1132896) and MMP2 (rs243849).In multiple logistic regression analysis, these 2 SNPs were significantly associated with the development of NODAT in the codominant and recessive or, codominant and dominant models, respectively.

**Conclusions:** The data suggest that excess fat deposition and ECM remodelling might play a role in the pathogenesis of NODAT in renal transplantation recipients. In particular, significant variations of MMP2 might confer susceptibility to NODAT in patients who receive renal transplants.

### Clinical Impact of an Angiotensin I Converting Enzyme Insertion/Deletion and Kinin B2 Receptor +9/-9 Polymorphisms in the Renal Graft Survival

Carlos Eduardo Neves Amorim,[1] Alvaro Pacheco-Silva,[1,3] Niels O.S. Camara,[1,2] Ronaldo Araujo.[1] *[1]Nephrology, UNIFESP, Sao Paulo, Brazil; [2]Medicine, Univ of Sao Paulo, Sao Paulo, Brazil; [3]Hospital Israelita Albert Einstein, HIAE, Sao Paulo, Brazil.*

**Background:** There is a consensus in the scientific literature that supports the importance of the kallikrein kinin and renin angiotensin systems in renal physiology, but few studies have investigated their importance after renal transplantation.

**Methods:** The aim of this study was to investigate the clinical effects of the insertion/deletion polymorphism in the angiotensin I-converting enzyme (ACE) gene and the + 9/-9 polymorphism in the kinin B2 receptor (B2R) gene in kidney-transplanted patients (n = 215 ACE, n = 203 B2R) compared with 443 healthy individuals.

**Results:** Demographic results showed that there is a higher frequency of the D allele (high plasma ACE activity) and + 9 allele (lower B2R expression) in transplant patients compared with control individuals. We also observed a higher frequency of these alleles in patients who had an elevated level of plasma creatinine. At day 7 post-transplantation, we found a higher prevalence of individuals with the DD genotype with elevated plasma creatinine level. Furthermore, individuals with the DD genotype had a higher chronic and acute rejection and graft loss compared with the II patient genotype, which showed no loss of graft. We also found that transplantation performed between a patient DD and a donor II or ID presented a higher chance of acute rejection than the opposite way. In the analyze of the prescription drug, 161 Individuals were medicated with some type of antihypertensive, and 44 were taking ACE inhibitor, 36% of transplanted group, and was observed that ACE inhibitors were renoprotective.

**Conclusions:** Taken them together, our data suggest that the genotyping of these individuals for ACE polymorphism could be clinical relevant.

### Established Renal Trait SNPs and Allograft Function in a Kidney Transplant Population

Paul J. Phelan,[1] Robert P. O'Brien,[2] Gianpiero Cavalleri,[2] Peter J. Conlon.[1] *[1]Nephrology, Beaumont Hospital, Dublin, Ireland; [2]Molecular Medicine, Royal College of Surgeons of Ireland, Dublin, Ireland.*

**Background:** Recent large scale genome-wide association studies (GWAS) in individuals of European ancestry have demonstrated several SNPs associated with estimated glomerular filtration rate (eGFR) and Chronic Kidney Disease (CKD). We recently completed a GWAS in an Irish renal transplant population. Twenty of the previously associated renal-function SNPs were captured by the Illumina Bead Chip we employed for our genotyping. We tested these SNPs for association with eGFR at 5 years post transplant.

**Methods:** Patients were adult, first time, deceased donor, kidney-only transplants, on calcineurin inhibitors between 1993 and 2002. We had data on 263 patients with a functioning graft and eGFR data at 5 years post transplant (median MDRD eGFR 43.5 mls/min/1.73m²). One-third of patients were female and mean age was 47.6 years. Principal components analysis showed our cohort to cluster with other northern European populations.

**Results:** Our results show that while 2 variants approached statistical significance for eGFR in our cohort, none had a p value of <0.05. Our most significant SNP (rs6036478; p=0.05415) was in full LD with rs911119, an intergenic variant on chromosome 20 which associated strongly with eGFR (Cystatin C) in the original study. The second most significant SNP was rs6465825 (p=0.0629; chromosome 7), another intergenic variant which was associated with eGFR (creatinine) in the original study. No other SNPs approached significance. Additionally, if Bonferroni correction is applied to correct for multiple testing, these 2 borderline significant SNPs do not approach significance.

**Conclusions:** It is perhaps not surprising that genetic loci associated with renal function in native kidneys are not validated in a renal transplant cohort. Determinants of renal function in a post-transplant population are likely to be very different from a normal or CKD populations. Non-replication of renal trait SNPs in our transplant cohort may also be due to differences in population structure and our small patient sample which may be underpowered for small effect size SNPs.

### Genetic Predisposition of Donors Affects the Allograft Outcome in Kidney Transplantation; Single Nucleotide Polymorphism of Aquaporin-11

Ji In Park,[1] Jung Pyo Lee,[2] Seung Hee Yang,[3] Yon Su Kim.[1,3] *[1]Dept of Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [3]Kidney Research Institute, Seoul National Univ, Seoul, Republic of Korea.*

**Background:** Aquaporin-11 (AQP11) is a novel aquaporin family member. Disruption of the murine AQP11 gene causes severe proximal tubular injury and renal failure. The rs2276415 (G>A) single nucleotide polymorphism (SNP) in the human AQP11 gene results in Gly102Ser substitution in a functionally important domain. In this study, we evaluated the role of the genetic predispositions of AQP11 rs2276415 (G>A) on renal allograft outcomes.

**Methods:** A total of 206 pairs of donors and recipients were enrolled. Long-term graft survival was traced and clinical parameters that could have influenced graft outcome were collected by reviewing electronic medical record system.

**Results:** Despite similar allele frequencies between donors and recipients, minor allele of AQP11 rs2276415 (GA+AA) from donor, not from recipients, has a harmful effect on the graft survival compared to wild type donor (GG) (P=0.029). This association was significant after adjusting for several risk factors including age, sex, HLA mismatch, donor type, hypertension, and diabetes mellitus (P=0.032).In immunohistochemistry staining, AQP11 was differently expressed according to genetic variations of donor rs2276415 showing higher expressions in the grafts from GG donors.

**Conclusions:** In conclusion, a donor-derived, not recipient derived, genetic AQP11 polymorphism has different effects on graft outcome. Thus, the genetic influence from donors should be carefully considered for the proper management of allografts after kidney transplantation.

## FR-PO496

**Prospective Randomized Study of Tolerability and Efficacy of Combination Therapy on Hypertensive Chronic Kidney Disease (CKD)** Matsuhiko Hayashi,[1] Shunya Uchida,[2] Tetsuya Kawamura,[3] Michio Kuwahara,[4] Masaomi Nangaku,[5] Yasuhiko Iino.[6] *[1]Keio Univ, Sch. Med., Japan; [2]Teikyo Univ, Sch. Med., Japan; [3]The Jikei Univ Sch. Med., Japan; [4]Shuwa General Hospital, Japan; [5]The Univ of Tokyo Sch. Med., Japan; [6]Nippon Med. Sch., Japan.*

**Background:** In the treatment of hypertension in CKD patients, angiotensin receptor blocker (ARB) and calcium channel blockers (CCB) are the two mainstays, although it is not clear which second-line drug is beneficial for CKD patients.

**Methods:** In a randomized, open-label trial, the patients with CKD defined by K/DOQI guideline and hypertension (systolic blood pressure ≥ 130 mmHg and/or diastolic blood pressure ≥ 80mmHg) in spite of usual doses of ARB were randomly assigned to receive losartan 50mg plus either 5mg of amlodipine (CCB group, n=27), 5 mg of enalapril (ACEI group, n=25), or 25 mg hydrochlorothiazide (HCTZ group, n=30). The primary endpoints were changes in blood pressures, ratio of urinary excretion of protein to creatinine (uP/C ratio), and eGFR during 12 months study period. The secondary endpoints were changes in biochemical parameters and side effects.

**Results:** Systolic and diastolic blood pressures were not significantly different between three groups throughout the study period. The percent changes in uP/C ratio was significantly different between HCTZ group (-26.5-±9.8%, means±SE) than that in CCB group(+46.7±33.6%, p<0.05) at 12 months after the assignment to each therapy, while eGFR was significantly lower in HCTZ group than ACEI and CCB groups at 4 months but not at 12 months study period. Serum uric acid levels were significantly higher in HCTZ group than CCB and ACEI groups during the entire period of the study. By logistic analysis, 25% decrease in uP/C ratio was more likely in HCTZ group (odds ratio 5.78, CI 1.14 to 37.8, p<0.05) compared with CCB group.

**Conclusions:** Addition of diuretics to ARB is though to be beneficial combination therapy for the control of hypertension in CKD in terms of urinary excretion of protein compared with addition of CCB or ACEI, while the effects of increased serum uric acid levels in HCTZ group on the progression of CKD should be determined by long-term study in the future.

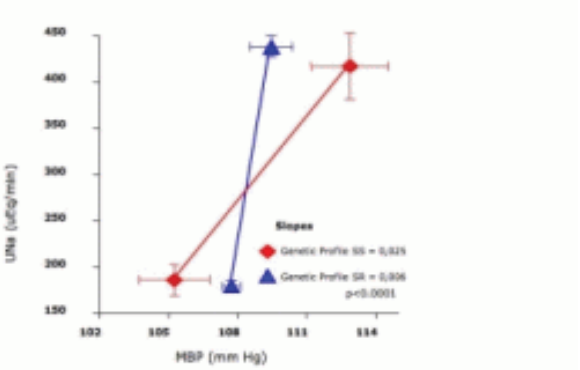
## FR-PO497

**Genetic Profile of Salt Sensitivity in Essential Hypertension** Chiara Lanzani, Marco Simonini, Elena Brioni, Simona Delli Carpini, Lorena Citterio, Laura Zagato Villa, Stefano Tentori, Paolo Manunta. *San Raffaele Scientific Institute, Milan, Italy.*

**Background:** Blood pressure (BP) is controlled primarily by Na and water balance because of the infinite gain property of the kidneys to rapidly eliminate excess fluid and salt. Up to 50% of patients with essential hypertension are salt-sensitive, as manifested by a rise in BP with salt loading.

**Methods:** 626 naive hypertensives underwent an acute Na load to monitor the simultaneous changes in BP and renal Na excretion. Genotyping was performed by Open Array (OA)technique with fluorescent probes arrays and ability to allelic discrimination of 124 SNPs in candidate genes for multiple mid-throughput genotyping. Associations with genetic markers were performed with GLM and chi-squared; logistic regression analysis for salt resistant/sensitive (SR/SS) comparison was used.

**Results:** OA study detected a strong association with variation in BP after acute Na load with 7 genes (ADD1, NCX1, NEDD4L, PRKG1, MYO16, SIK1, UMOD). In combined analyses, we found significant epistatic interactions between these SNPs. A genetic profile is a specific combination of variants in terms of SNPs or SNP interactions. Furthermore, we built a genetic profile able to identify the SS and SR hypertensive: those carrying the SS profile display changes in systolic BP of 10.4±1.25 vs 2.99±0.39 mmHg p<0.0001). SS genetic profile showed OR 6.13, and had a 96% specificity, a 72% PPV. Pressure-natriuresis curve was obtained by plotting urinary Na excretion in Y axis and mean BP in the X axis. The slope of SS pts resulted in a right shift along X axis, while was vertically steep in SR profile (GLM p<0.0001).



**Conclusions:** Our finding suggests a relationship between body Na, genetic pathways regulating the contractile state of muscular vascular cells, renal Na excretion and intracellular activity underline pressure natriuresis and salt sensitive phenotype.

## FR-PO498

**L/N-Type Calcium Channel Blocker Cilnidipine Added to Renin-Angiotensin Inhibition Improves Ambulatory Heart Rate Profile and Suppresses Cardiac Hypertrophy in Hypertension with Chronic Kidney Disease** Kouichi Tamura. *Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.*

**Background:** Pathological alteration of ambulatory blood pressure (BP) and heart rate (HR) profile is proposed to play a critical role in the pathophysiology of renal deterioration and cardiovascular complication in hypertension and chronic kidney disease (CKD). In this study, we examined beneficial effects cilnidipine, a unique L/N-type calcium channel blocker (CCB), in addition to a renin-angiotensin system inhibitor, on ambulatory BP and HR profile as well as cardiorenal function in hypertensive CKD patients.

**Methods:** Forty-five patients were randomly assigned to the cilnidipine replacement group (n=21) or the control CCB group (n=24) after a 2-week run-in period. At baseline and after 24-week active treatment period, 24-h ambulatory BP monitoring and measurements of cardiovascular and biochemical parameters were performed.

**Results:** There was an increase in ambulatory HR in the control group and a decrease in the cilnidipine group, and differences in these changes were significant between the two groups. The ambulatory low-frequency (LF)-to-high-frequency (HF) ratio (LF/HF), an index of cardiac sympathetic nerve activity, was increased in the control group but decreased in the cilnidipine group, and differences in these changes were also significant. In addition, the left ventricular mass index (LVMI) was significantly decreased in the cilnidipine group compared to the control group after the study (LVMI, 135.3±26.4 versus 181.2±88.4, *P*=0.031), with a significant difference in the changes in the LVMI between the cilnidipine and control groups (change in LVMI, -12.4±23.7 versus 26.2±64.4, *P*=0.007). Furthermore, multivariate regression analysis showed that decrease in ambulatory LF/HF was a significant contributing factor to the improvement in LVMI.

**Conclusions:** These results indicate that cilnidipine is beneficial for the suppression of pathological cardiac remodeling through an inhibitory modulation of cardiac sympathetic nerve activity in hypertensive CKD patients.

## FR-PO499

**White-Coat, Masked, and Sustained Hypertension in Chronic Kidney Disease–The CRIC Study** Paul E. Drawz,[1,2] Arnold B. Alper,[2] Amanda Hyre Anderson,[2] Denise C. Babineau,[2] Carolyn S. Brecklin,[2] Jeanne Charleston,[2] Jing Chen,[2] Yonghong Huan,[2] Susan P. Steigerwalt,[2] Jonathan J. Taliercio,[2] Raymond R. Townsend,[2] Matthew R. Weir,[2] Mahboob Rahman.[2] *[1]Univ of Minnesota; [2]CRIC Investigators.*

**Background:** The goal of this prospective study was to evaluate whether elevated proteinuria and low eGFR are associated with increased odds of white-coat (WCH), masked (MH), and sustained hypertension (SH) in a large cohort of participants with CKD.

**Methods:** In the Chronic Renal Insufficiency Cohort (CRIC) study, 24 hour ambulatory blood pressure (ABP) was measured between 2008 and 2012. Clinic blood pressure (BP) was measured in triplicate by study staff. WCH was defined by a clinic BP ≥140/90 mmHg and daytime ABP <135/85 mmHg; MH by a clinic BP <140/90 mmHg and daytime ABP ≥135/85 mmHg; and SH by a clinic BP ≥140/90 mmHg and daytime ABP ≥135/85 mmHg. Urine protein was measured in a 24 hour sample at baseline. Creatinine was measured annually.

**Results:** ABP was obtained in 1439 CRIC participants. The average time from the baseline visit to ABP was 5.1 years. The percent of participants with controlled BP, WCH, MH, and SH was 52.7%, 5.5%, 24.5%, and 17.2%. In a multivariable model, a doubling of urine protein was associated with increased odds of WCH, MH, and SH. In a separate multivariable model, a decrease in eGFR of 10ml/min/1.73m$^2$ was associated with increased odds of MH but not WCH or SH.

| | | Odds Ratio Based on Adjusted Models | |
|---|---|---|---|
| **BP category** | **N (%)** | **Urine protein** | **eGFR** |
| Controlled BP | 759 (52.7) | 1 (ref) | 1(ref) |
| White-coat HTN | 79 (5.5) | 1.14 (0.99 to 1.28) | 1.11 (0.94 to 1.36) |
| Masked HTN | 353 (24.5) | **1.16 (1.08 to 1.24)** | **1.11 (1.02 to 1.22)** |
| Sustained HTN | 248 (17.2) | **1.19 (1.10 to 1.28)** | 1.05 (0.95 to 1.17) |

**Conclusions:** In a large cohort of participants with a wide range of CKD, an increase in urine protein was associated with increased odds of white-coat, masked, and sustained hypertension. Ambulatory BP may be particularly important in patients with CKD in order to better characterize their BP control, especially among those with proteinuria.

## FR-PO500

### Renal Denervation Halts the Decline of Renal Function in Patients with Chronic Kidney Disease and Treatment Resistant Hypertension

Christian Ott,[1] Felix Mahfoud,[2] Axel Schmid,[3] Tilmann Ditting,[1] Roland Veelken,[1] Michael Böhm,[2] Roland E. Schmieder.[1] *[1]Nephrology and Hypertension, Univ Hospital, Erlangen, Germany; [2]Klinik für Innere Medizin III, Universitätsklinikum des Saarlandes, Homburg/Saar, Germany; [3]Dept of Radiology, Univ Hospital, Erlangen, Germany.*

**Background:** Hypertension is a predominant risk factor of renal function decline over time and achieving blood pressure (BP) targets preserves renal function. Renal denervation (RDN) emerged as an interventional antihypertensive therapy in patients with treatment resistant hypertension (TRH) and we asked whether reducing BP by RDN preserves renal function by reducing BP or/and decreasing sympathetic activity.

**Methods:** 12 patients with TRH (office BP ≥140/90 mmHg and diagnosis confirmed by 24-h ABPM ≥130/80 mmHg) and chronic kidney disease (CKD) stage 3 and 4 underwent RDN using the Symplicity catheter (Medtronic Inc., Palo Alto, CA). The study was registered at http://www.clinicaltrials.gov/ (ID: NCT01442883). Renal function was evaluated up to 3 years prior and till 1 year after RDN. Estimated glomerular filtration rate (eGFR) was calculated using MDRD formula and the change in eGFR over time was calculated by regression slope individually for each patient.

**Results:** Patients (66±8 years) were treated with 5.8±1.1 antihypertensive drugs on average, and 73% had type-2 diabetes. One year after RDN, office BP was reduced by 20/6 mmHg (systolic: 156±19 vs. 137±18 mmHg, p=0.029; diastolic: 77±14 vs. 71±12 mmHg, p=0.019) and average 24-h ABPM by 13/6 mmHg (systolic: 157±13 vs. 144±12 mmHg, p=0.028; diastolic: 80±11 vs. 74±8 mmHg, p=0.028). Mean eGFR decline before RDN was -5.6±4.4 ml/min/1.73m$^2$ per year, which fits with postulated decline of renal function based on long-term clinical trials (Bakris et al, Am J Kidney Dis 2000;36:646-61). In contrast, eGFR remained stable after RDN (baseline: 47.0±11 vs. 1 year: 49.2±14 ml/min/1.73m$^2$), with a significance between eGFR change per year before and after RDN (-5.6±4.4 vs. +2.2±8.0 ml/min/1.73m$^2$ per year, p=0.021).

**Conclusions:** Our pilot study data indicate that RDN decreases BP and, most importantly, slows or even halts the decline of renal function in patients with TRH and CKD.

## FR-PO501

### Mindfulness Meditation Lowers Muscle Sympathetic Nerve Activity and Blood Pressure in Chronic Kidney Disease Patients

Jeanie Park,[1,2] Robert H. Lyles,[3] Susan Bauer-Wu.[4] *[1]Renal Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Atlanta VA Medical Center, Decatur, GA; [3]Biostatistics and Bioinformatics, Emory Univ, Atlanta, GA; [4]Nursing, Univ of Virginia, Charlottesville, VA.*

**Background:** Chronic kidney disease (CKD) is characterized by chronic sympathetic nervous system (SNS) overactivity that contributes to hypertension and mortality. Prior studies have shown that mindfulness meditation (MM) lowers blood pressure (BP) and heart rate (HR) in hypertensive individuals. We hypothesized that MM acutely lowers BP and HR in hypertensive patients with chronic kidney disease (CKD), and that these hemodynamic changes are mediated by a reduction in sympathetic nerve activity (SNA).

**Methods:** 13 patients with CKD Stage III and hypertension were studied at two separate study visits to eliminate carryover effects, in a randomized, cross-over design. We measured continuous arterial BP, HR via continuous electrocardiography, respiratory rate (RR), and muscle sympathetic nerve activity (MSNA) using microneurography, at baseline, and during: 1) 14 minutes of guided MM during one study visit, and 2) 14 minutes of BP education (control condition) during the other study visit. Data were analyzed using mixed effects linear modeling.

**Results:** Linear modeling revealed that the rate of change in systolic BP (SBP), diastolic BP (DBP), mean arterial pressure (MAP), and MSNA was significantly greater over time during MM compared to the control condition. At the14-minute time point, there was a significantly greater reduction in SBP (-10.2±2.9 vs. -0.8±1.3 mm Hg, p=0.007), DBP (-6.4±1.3 vs. -1.8±0.8, p=0.005), MAP (-7.7±1.6 vs. -1.4±0.8 mm Hg, p=0.002), during MM versus the control condition, respectively, but no difference in HR. Concomitantly, there was a significantly greater reduction in MSNA during MM compared to the control condition (-10.7±1.6 vs. +1.9±2.8 bursts/min, p=0.02).

**Conclusions:** These data are the first to demonstrate that MM may lower BP in hypertensive patients with CKD, and the reduction in BP may be mediated by an acute reduction in SNS activity. MM may have real physiological effects on autonomic control, and may be a useful complementary therapy in CKD patients.

## FR-PO502

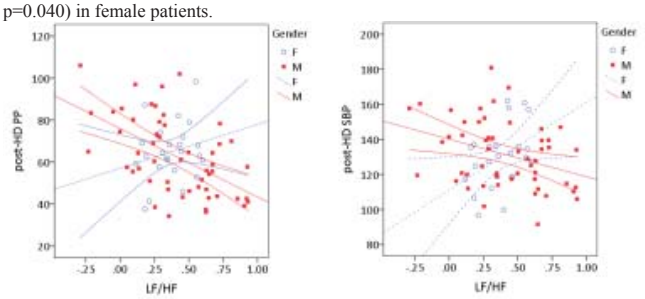
### Sex Dependent Association between Heart Rate Variability and Pulse Pressure in Hemodialyzed Patients

Dimitrios J. Poulikakos,[1,2] Debasish Banerjee,[1,2] Marek Malik.[1] *[1]Cardiovascular Sciences Research Centre, St. George's Univ of London, London, United Kingdom; [2]Renal and Transplantation, St. George's Hospital NHS Trust, London, United Kingdom.*

**Background:** Elevated Pulse Pressure (PP) is associated with increased cardiovascular mortality in hemodialysis (HD) patients. Autonomic imbalance is common in HD patients but its relationship to PP is unknown. We investigated the relationship between cardiac autonomic status assessed by heart rate variability (HRV) spectral analysis and PP in HD patients.

**Methods:** In stable HD patients, continuous electrocardiograms were obtained during HD and repeated 5 times at 2-weeks intervals. The high- (HF) and low-frequency (LF) components and the LF/HF ratio of HRV were calculated every 5 minutes in absolute values and averaged during the first and last hour of each recording. These values and the corresponding pre and post-HD systolic blood pressure (SBP) and diastolic blood pressure (DBP) measurements were averaged in repeated recordings of each patient.

**Results:** We investigated 80 patients aged 60±14 years, 32% females and 37% diabetics. All blood pressure and HRV indices showed intra-subject stability (repeated measures Anova). LF and HF decreased through dialysis but LF/HF did not. LF/HF correlated inversely with pre and post-HD PP (r=-0.369, p=0.007 and r=-0.546, p=0.000 respectively), positively with pre and post-HD DBP (r=0.358, p=0.009 and r=0.306, p=0.028 respectively) and inversely with post-HD SBP in males patients (r=-0.350, p=0.011). In contrast, LF/HF did not correlate with PP or DBP and correlated positively with post-HD SBP (r=0.422, p=0.040) in female patients.



**Conclusions:** Strong association between PP and spectral HRV parameters was found in male but not in female HD patients. The sex differences in autonomic cardiovascular regulation during HD may contribute to the differences in cardiac risk between both sexes.

## FR-PO503

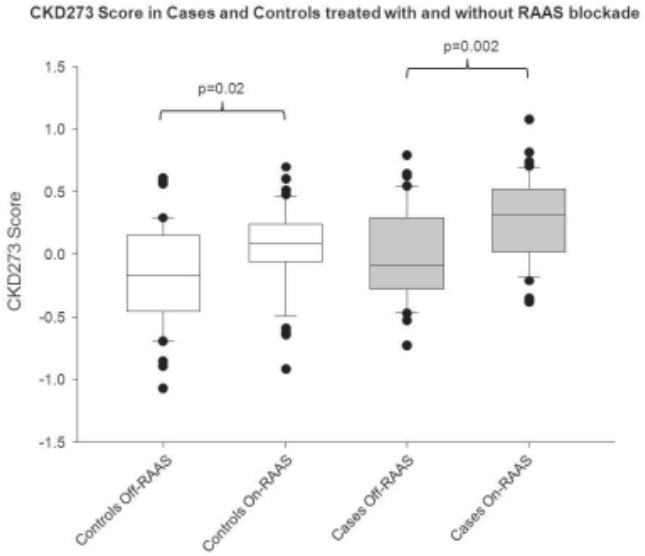
### A Urinary Peptide Score That Predicts Albuminuria Progression Differs in the Presence or Absence of RAAS Blockade

Michelle Pena,[1] Sara S. Roscioni,[1] Petra Zürbig,[2] Harald Mischak,[2] Stephan J.L. Bakker,[1] Ron T. Gansevoort,[1] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Univ Medical Center Groningen; [2]Mosaiques Diagnostics.*

**Background:** Previous studies have shown that a urinary proteomic-based risk score (CKD273) predicts albuminuria progression. We assessed whether CKD273 scores differ in hypertensive subjects treated with or without RAAS blockade.

**Methods:** We performed a case-control study using data from the prospective, general population-based PREVEND Study (The Netherlands). We identified 75 hypertensive cases who progressed in albuminuria stage (from normo- to microalbuminuria or from micro- to macroalbuminuria). We matched these subjects for age, gender, baseline albuminuria stage, and use of RAAS blockade with hypertensive controls who had stable albuminuria during 3.0±0.9 years of follow-up. Mann-Whitney *U* test was used to compare CKD273 scores in subjects treated with or without RAAS blockade.

**Results:** RAAS blockade was used by 52% of cases and controls. CKD273 scores differed significantly between cases and controls (median [interquartile range]: 0.08 [-0.14;0.42] *vs* 0.02 [-0.28;0.22], p=0.03). Baseline characteristics such as blood pressure and albuminuria did not significantly differ between subjects with or without RAAS blockade, except for Hs-TnT, a marker of microvascular damage. CKD273 scores were higher in subjects on RAAS blockade than in subjects off RAAS blockade (cases on-RAAS 0.31 [0.01;0.53] *vs* off-RAAS -0.09 [-0.30;0.28], p=0.002; controls on-RAAS 0.09 [-0.07;0.25] *vs* off-RAAS -0.17 [0.46;0.15], p=0.02).



**Conclusions:** Higher CKD273 scores observed in hypertensive subjects treated with RAAS blockade may reflect more advanced renal/microvascular damage despite similar blood pressure and albuminuria levels. This likely reflects indication bias and suggests that RAAS blockade should be accounted for as a confounder in proteomic studies.

## FR-PO504

**Rapid Test to Identify the Salt Sensitivity** Andrea Pio de Abreu, Giovanio Vieira Da Silva, Isac De Castro, Katia Ortega, Decio Mion Junior. *Nephrology, Univ of Sao Paolo School of Medicine, Sao Paulo, Brazil.*

**Background:** Salt sensitivity, defined as the variation of blood pressure with the intake of different amounts of salt, has both clinical and prognostic implications. Nevertheless, the gold standard test for this diagnosis is hardly used in clinical practice, mainly due to the duration, at least a 2-week period of diet, with compliance difficulties in patients. The objective of study was to evaluate whether the use of fludrocortisone, wich causes sodium retention, is accurate compared to the dietary cycle. Until the moment, there is no practical test with an good accuracy.

**Methods:** A crossover design study was conducted with thirty unmedicated hypertensive patients. The dietary cycle consisted of one week with a low-sodium diet (40 mmol/day) and one week with a high-sodium diet (200 mmol/day). After one month, the fludrocortisone test was performed by administering 0.4 mg/day for 4 days, maintaining the usual food ingestion. BP was measured at the end of each dietary cycle and on the first and fourth day of fludrocortisone intake.

**Results:** The 30 volunteers (60% female), whose mean age was 53.7 ± 7.6 years, had a mean systolic blood pressure (SBP) of 146 ± 12 mmHg and diastolic of 91 ± 10 mmHg. The mean NaU values for the low and high-salt-diet cycles were, respectively, 40 ± 25 mmol/d and 212 ± 44 mmol/d. During the administration of fludrocortisone, there was a significant reduction of renin, aldosterone and potassium levels compared to the basal period. The Area Under Roc Curve (AUCROC) for SBP on the reference test was 0.89 ± 0.04 (p<0.001) and on the fourth day of fludrocortisone was 0.76 ± 0.06 (p<0.001).

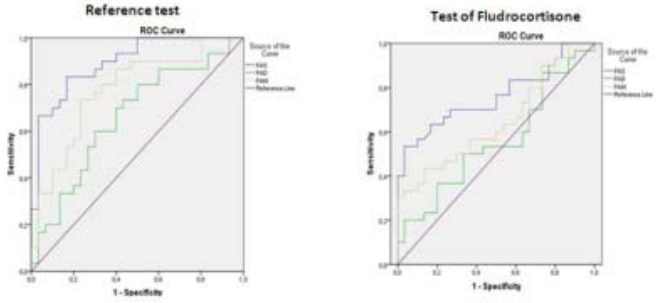


Figure 1 - Area Under Roc Curve (AUCROC) for systolic (PAS), mean (PAM) and diastolic blood pressure (PAD) for the reference and Fludrocortisone tests. AUCROC values for the reference test were 0.89 ± 0.04 (p<0.001), 0.77 ± 0.06 (p<0.001), and 0.66 ± 0.07 (p=0.032), respectively, for systolic (PAS), mean (PAM) and diastolic blood pressure (PAD). The AUCROC values on the fourth day of fludrocortisone were 0.76 ± 0.06 (p<0.001), 0.65 ± 0.07 (p < 0,05), and 0.55 ± 0.07 (p=0.46), respectively, for PAS, PAM and PAD.

**Conclusions:** The Rapid Test To Identify the Salt Sensitivity, which consists in the change in SBP after administration of 0.4 mg / day of fludrocortisone for four days, has good accuracy to identify salt-sensitive hypertensive patients.

*Funding:* Government Support - Non-U.S.

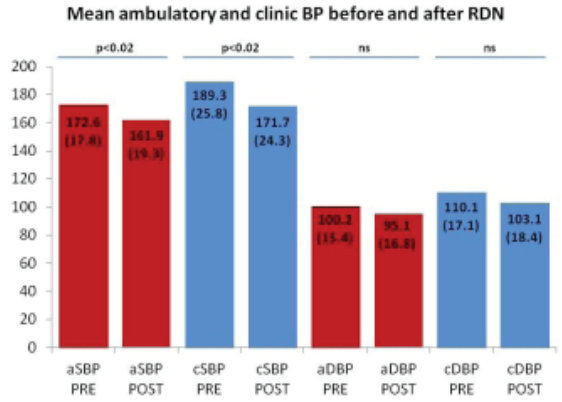
## FR-PO505

**The Impact of Renal Denervation on Ambulatory Blood Pressure in Two Specialist Hypertension Units in the United Kingdom** Alison H.M. Taylor,[1] Patrick B. Mark,[1] Alan G. Jardine,[1] Jonathan S. Freedman,[2] Indranil Dasgupta.[3] *[1]BHF Glasgow Cardiovascular Research Centre, Univ of Glasgow, Glasgow, United Kingdom; [2]Dept of Radiology, Birmingham Heartlands Hospital, Birmingham, United Kingdom; [3]Dept of Nephrology, Birmingham Heartlands Hospital, Birmingham, United Kingdom.*

**Background:** Percutaneous renal artery denervation (RDN) is a novel technique for treatment of resistant hypertension, which has been shown to have major effects on clinic blood pressure (BP). We studied ambulatory BP (ABP), a more accurate representation of BP, in patients undergoing RDN out with a specific clinical trial.

**Methods:** Patients with systolic BP ≥160/90mmHg despite compliance with ≥3 antihypertensive agents and no secondary cause for hypertension were treated with bilateral RDN. All patients underwent ABP monitoring and laboratory tests prior to and 6-months following RDN.

**Results:** 20 consecutive patients (55% female, mean age 50.1 years) were studied. At baseline, the median time since diagnosis of hypertension was 8.5 years (range 1-32 years), 20% of patients had diabetes mellitus and 35% had a history of vascular disease. The median serum creatinine was 0.83mg/dL (range 0.61-3.60). Mean clinic BP was 189/110mmHg (±26/17) and mean ABP 173/100mmHg (±18/15). The mean number of antihypertensive agents prescribed was 5.65 (±1.3). At six months following RDN there was a significant fall in both ambulatory (-9.9mmHg, p<0.02) and clinic (-18.9mmHg, p<0.02) systolic BP. There was a non-significant fall in diastolic BP using both measurements. The mean reduction in number of medications prescribed was 1.6 (±2.1, p=0.003). There was no significant change in renal function at six months.



**Conclusions:** RDN does lead to reduction in ABP in 'real world' patients with resistant hypertension, although the magnitude of effect is less than previously demonstrated.

## FR-PO506

**Comparison of Sleep Apnea Rates and Characteristics in Resistant and Non Resistant Hypertension** John J. Sim, Jiaxiao Shi, Glory Tseng. *Nephrology & Hypertension, Kaiser Permanente Los Angeles Medical Center.*

**Background:** Sleep apnea is associated with hypertension and is a risk factor for resistant hypertension (RH) but the degree to which it is more prevalent in RH is largely unknown. We sought to compare rates and characterize sleep apnea in RH and non RH within a large ethnically diverse hypertension population.

**Methods:** Cross sectional study during 1/1/2006- 12/31/2007 of hypertensive individuals within the Kaiser Permanente Southern California health system. Resistant hypertension defined as uncontrolled blood pressure on 3 meds or requiring >/=4 meds. Sleep apnea identified by ICD-9 coding and CPT coding for dispensation of cpap/bipap. Rates of sleep apnea in RH and non RH determined. Demographic, co morbidity and laboratory information extracted from the electronic medical records. Multivariable logistic regressions performed to calculate odds ratios (OR) for sleep apnea.

**Results:** Among 470,386 individuals with hypertension, sleep apnea was identified in 23,184 (4.9%). RH individuals had a sleep apnea rate of 7.1% (4,007) compared to 4.9% (19,177) in non RH (p<0.001). Among the entire hypertension cohort, adjusted OR for sleep apnea were greater in those with RH, BMI>29, male gender, and diabetes. Whites were more likely to have sleep apnea compared to blacks, Hispanics, and asians.

| **Odds Ratio for Sleep Apnea among a Hypertension Population With adjustment for age, gender, race, BMI, and co morbidities (N=470,386)** | | |
|---|---|---|
| **Variable** | **OR** | **95% CI** |
| Resistant Hypertension | 1.08 | 1.04-1.12 |
| BMI>29 | 3.42 | 3.32-3.53 |
| Male gender | 2.28 | 2.22-2.35 |
| Race Ethnicity (ref white) | | |
| Hispanic | 0.61 | 0.58-0.63 |
| Black | 0.76 | 0.73-0.79 |
| Asian | 0.59 | 0.55-0.63 |
| Diabetes | 1.27 | 1.24-1.31 |
| CHF | 2.02 | 1.94-2.11 |

**Conclusions:** Within a large ethnically diverse hypertension population, we observed a modest increase in rate and risk for sleep apnea in RH compared to non RH. Among the traditional risk factors, BMI>29 had the greatest risk for sleep apnea within our hypertension population.

## FR-PO507

### Disturbed Circadian Rhythm of the Intrarenal Renin-Angiotensin System: Relevant to Nocturnal Hypertension and Renal Damage

Shinsuke Isobe,[1] Naro Ohashi,[1] Hideo Yasuda,[1] Yoshihide Fujigaki.[1,2] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine; [2]Internal Medicine, Teikyo Univ School of Medicine.*

**Background:** The intrarenal renin-angiotensin system (RAS) plays an important role in the development of hypertension and renal damage. Disruption of diurnal blood pressure (BP) variation is an additional risk factor for renal damage. However, little is known regarding whether intrarenal RAS circadian rhythm exists or if it influences the disruption of diurnal BP and renal damage.

**Methods:** We investigated the circadian rhythm of urinary angiotensinogen that reflects intrarenal RAS activity, albuminuria, proteinuria and urinary sodium excretion every hour ($Na^+$/h) in 10 healthy individuals and 33 chronic kidney disease (CKD) patients classified according to circadian BP rhythms.

**Results:** BP values were higher during the day than during the night in healthy individuals and CKD patients. Urinary angiotensinogen levels were not different between the day and night in healthy individuals, but were significantly higher in the daytime in CKD patients (log urinary angiotensinogen/creatinine: daytime, 2.48 ± 0.99; nighttime, 2.31 ± 1.08; p = 0.001). Furthermore, in CKD patients showing a riser pattern of circadian BP, urinary angiotensinogen levels did not decrease during the night compared with those in the day (log urinary angiotensinogen/creatinine: daytime, 2.50 ± 0.65; nighttime, 2.52 ± 0.71; p = 0.092). Circadian fluctuation of albuminuria and proteinuria occurred parallel to that of the urinary angiotensinogen levels. Urinary angiotensinogen levels were significantly and positively correlated with the degree of hypertension and circadian fluctuation of urinary angiotensinogen were correlated with diurnal BP changes.

**Conclusions:** These data suggest that the circadian rhythm of intrarenal RAS activation may lead to renal damage and hypertension, which are associated with diurnal BP variation.

## FR-PO508

### Variables Indicative of Kidney Injury Are Related to the BP-Lowering Effect of Renal Denervation

Eva Vink,[1] Willemien Verloop,[2] Wilko Spiering,[3] Michiel Voskuil,[2] Evert-jan Vonken,[4] Michiel Bots,[5] Peter J. Blankestijn.[1] *[1]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Cardiology, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Vascular Medicine, Univ Medical Center Utrecht, Utrecht, Netherlands; [4]Radiology, Univ Medical Center Utrecht, Utrecht, Netherlands; [5]The Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands.*

**Background:** Renal denervation(RDN) is a promising treatment for resistant hypertension. However, there is a wide range in the BP-lowering effect. Evidence on factors that determine BP-lowering effect after pRDN is limited. Aim of current study was to further explore these factors.

**Methods:** Patients from a prospective cohort of patients treated with RDN with available 6months follow-up data,were included in current analysis. Data collected during routine clinical standardized work-up before RDN were used in present analysis:urine collected during 24-h, blood samples, ambulatory BP monitoring and a captopril challenge test. When considered safe, anti-hypertensive drugs were stopped before these investigations.

**Results:** 54 patients were included in the present analyses. 59% was female, mean age was 61(±11)yrs. At baseline, patients used a median number of 3 antihypertensive drugs, office BP was 202(±25)/109(±14)mmHg and eGFR was 72(±19)mL/min/1.73$m^2$. A higher BP at baseline, a higher level of BP during nighttime(β:-0.53 mmHg/mmHg,P=0.03), a higher albumin-to-creatinine ratio(β:-10.58, P=0.06), higher levels of aldosterone(β:-0.020 mmHg/pmol/L,P=0.09) and catecholamines(norepinephrine(β:-0.07mmHg per nmol/24-h, P=0.03) and VMA(β:-1.04mmHg per µmol/24-h, P=0.05)) in urine as well as a greater decrease in BP after captopril(β:0.731mmHg/mmHg, P=0.53), were related to the BP-lowering effect of RDN. Kidney function was inversely related to the BP-lowering effect of RDN(β:0.597mmHg/mL/min/1.73$m^2$, P=0.003).

**Conclusions:** Present study shows that variables related to kidney injury are related to the BP-lowering effect of RDN. This very well fits within current thinking of the pathophysiology and it may give some insight in the great effect range of RDN.

*Funding:* Government Support - Non-U.S.

## FR-PO509

### BP-Lowering Effect of Renal Denervation in Patients with Multiple Renal Arteries

Eva Vink,[1] Willemien Verloop,[2] Wilko Spiering,[3] Michiel Bots,[4] Evert-jan Vonken,[5] Michiel Voskuil,[2] Peter J. Blankestijn.[1] *[1]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Cardiology, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Vascular Medicine, Univ Medical Center Utrecht, Utrecht, Netherlands; [4]Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands; [5]Radiology, Univ Medical Center Utrecht, Utrecht, Netherlands.*

**Background:** In contrast to previous studies investigating safety and efficacy of renal denervation (RDN), we decided not to exclude patients with multiple renal arteries from treatment with RDN. The aims of present study were: to determine the prevalence of multiple renal arteries in patients referred for RDN, to investigate the relation between presence of multiple renal arteries and blood pressure (BP)-lowering effect of RDN.

**Methods:** Patients referred for treatment with RDN who underwent non-invasive imaging of the renal arteries before treatment, were included in present analysis. Eligible patients underwent RDN. BP and renal function were evaluated 6 months after treatment.

**Results:** 179 patients underwent imaging in the work-up. Thirty-five percent had multiple renal arteries. No differences in baseline characteristics were found between those with and without multiple arteries. Out of 179 patients, 109 underwent RDN, of which 60 patients completed six months follow-up. Office BP significantly changed in these patients from 200(±23) / 108(±14) mmHg to 168(±24) / 96(±14) mmHg (P<0.001). The change in BP was not different in patients with multiple- compared to patients with solitary arteries. Renal function at 6 months did not differ from baseline in both subgroups. A classification of eligibility of the renal arteries for treatment with RDN is proposed.

**Conclusions:** Current analysis suggests that RDN is effective in patients with multiple renal arteries. Based on the results of this present study, and the high prevalence of multiple arteries, it seems reasonable not to exclude patients with multiple renal arteries from RDN.

### The Impact of Sodium, Fructose Restriction and Allopurinol on Blood Pressure amongst Overweight and Prehypertensive Subjects

Magdalena Madero,[1] Francisco E. Rodríguez Castellanos,[1] Silvia Hernández-Lobato,[1] Richard J. Johnson,[2] Maria Villalobos-Martín,[1] Armando Vazquez-Rangel,[1] Jonathan Salazar,[1] L. Gabriela Sanchez-Lozada.[1] *[1]National Heart Institute Mexico; [2]U Colorado.*

**Background:** Fructose causes hypertension partly through rising intracellular and serum uric acid (UA). The objective of this study was to compare the effect of sodium and fructose restriction in addition to allopurinol on blood pressure and metabolic syndrome components.

**Methods:** Randomized trial that included overweight and prehypertensive or hypertensive adults not on antihypertensive meds. The trial consisted of two phases: 1) Wks 1-4 patients were randomized to either isocaloric (with respect to baseline caloric intake) low sodium- low fructose diet (LS-F) or isocaloric low sodium diet (LS) during 4 wks. 2) Wks 4-8) the groups continued with the same diet prescriptions and were further randomized to receive placebo (P) or allopurinol (A, 300 mg/d). Clinic and 24hr ambulatory BP, anthropometric measures, laboratory data, were determined at weeks 0, 4 and 8.

**Results:** 72 patients were included in the trial. Compared to Wk0, at Wk8 clinic SBP and DBP were significantly lower in the LS-F group but not in the LS group. Both diets were associated with a significant day and global ABPM reduction. There were no between group significant differences with diet interventions at Wk4 or 8. Compared to placebo, at Wk8 subjects in the A group had a lower clinic SBP and this was significant within and between group comparisons. The % of dippers was also significantly higher in the A group. In addition weight was significantly reduced in the LS-F and A groups.

Table1

| | LS Diet (n=38) | | LS- F Diet (n=34) | | Placebo (n=36) | | Allopuriol (n=36) | |
|---|---|---|---|---|---|---|---|---|
| | Week | | Week | | Week | | Week | |
| | 0 | 8 | 0 | 8 | 0 | 8 | 0 | 8 |
| Age (years) | 48±7 | | 44±9 | | 47±9 | | 46±8 | |
| Sex (M/F) | 22/16 | | 22/12 | | 22/14 | | 22/14 | |
| Weight (kg) | 86±16 | 87±16 | 90±16 | 89±16[a] | 85±15 | 85±15 | 91±17 | 90±17[a] |
| SBP (mmHg) | 125±11 | 120±16 | 124±13 | 116±10[a] | 125±13 | 122±15 | 124±10 | 115±12[ab] |
| DBP (mmHg) | 86±7 | 82±8[a] | 84±8 | 80±7[a] | 84±7 | 83±7 | 86±7 | 80±8[a] |
| Global SBP - ABPM | 134±10 | 130±10[a] | 132±12 | 129±10[a] | 133±12 | 129±9[a] | 133±10 | 130±10[a] |
| Global DBP - ABPM | 80±8 | 79±9 | 80±7 | 77±7[a] | 80±8 | 77±8 | 80±7 | 79±8 |
| Day SBP - ABPM | 138±10 | 135±10[a] | 136±12 | 132±10[a] | 138±12 | 132±10[a] | 137±9 | 135±10 |
| Day DBP - ABPM | 83±9 | 82±9 | 83±8 | 80±7[a] | 83±9 | 80±9[a] | 83±8 | 82±8 |
| Dippers (%) | 55.2 | 68[b] | 44.8 | 32 | 51.7 | 32 | 48.3 | 68[b] |
| Chol (mg /dl) | 199±43 | 190±56 | 194±32 | 185±31 | 200±39 | 185±51[a] | 192±37 | 190±40 |
| TGL (mg/dl) | 183±99 | 186±93 | 190±114 | 161±64 | 206±124 | 173±70[a] | 167±81 | 177±91 |
| Uric acid (mg/dl) | 6.2±1.6 | 5.2±1.4[a] | 6.1±1.7 | 5.1±1.8[a] | 6±1.7 | 5.9±1.4 | 6.2±1.6 | 4.5±1.4[ab] |

Values shown as mean ± SD. a= p<0.05 week 8 vs. week 0 b= p<0.05 week 8 between group comparisons. SBP: Systolic Blo Pressure, DBP: Diastolic Blood Pressure, ABPM: Ambulatory Blood Pressure Monitor, Chol: Cholesterol, TGL:Tryglicerides

**Conclusions:** Both LS and LS-F diets are efficient to lower BP. Allopurinol significantly reduced clinic SBP and increased the percentage of dippers. Both LS-F and A were associated with weight loss despite the absence of caloric restriction.

## FR-PO511

**Type 2 Diabetic Patients with Treatment-Resistant Hypertension Display Urine Plasmin Excretion That Correlates with Blood Pressure and Activates ENaC *In Vitro*** Kristian B. Buhl,[1] Christina Stolzenburg Oxlund,[2] Ulla G. Friis,[1] Per Svenningsen,[1] Claus Bistrup,[2] Ib A. Jacobsen,[2] Boye Jensen.[1] *[1]Univ of Southern Denmark, Denmark; [2]Univ Hospital of Odense, Denmark.*

**Background:** Aberrant filtration of plasminogen from plasma and subsequent activation to plasmin in the urinary space may proteolytically activate the epithelial sodium channel, ENaC. In conditions with chronic albuminuria this may cause hypertension. It was hypothesized that patients with type 2 diabetes mellitus (T2DM) and treatment-resistant hypertension (RHTN) excrete plasmin(ogen) in urine in proportion to albumin and that plasmin confers to urine the ability to activate ENaC.

**Methods:** A Cross sectional design of 113 patients with T2DM and RHTN (systolic BP > 130mmHg and diastolic BP > 80mmHg despite use of at least three drugs with one diuretic and one renin-angiotensin system inhibitor). 24 hour blood pressure meassurements was obtained and urine was analyzed for albumin, creatinine, plasmin(ogen), protease activity and ability to activate inward current in single collecting duct cells.

**Results:** Mean ambulatory blood pressure was 143 ± 1/77±0.7 mmHg; HbA1c 7.35 %; eGFR 81.4 ml/min/1.73m$^2$ (geometric means). Micro- (39%) and macroalbuminuric (13%) T2DM patients with RHTN displayed significantly elevated levels of urinary plasmin(ogen) normalized to urine creatinine (plg/crea) compared to normo-albuminuric-T2DM-RHTN patients (48%). Urinary plg correlated significantly to urine albumin. Western immunoblotting and gelatine zymografi confirmed active plasmin in urine samples from T2DM-RHTN patients with micro- and macroalbuminuria. Single collecting duct cells showed significantly increased, amiloride-sensitive, inward current when superfused with urine from albuminuric T2DM-RHTN compared to normalbuminuric T2DM-RHTN. Urinary plg/crea correlated significantly to 24 hour ambulatory blood pressure.

**Conclusions:** Aberrant presence of plasmin in pre-urine may inappropriately activate ENaC in patients with type 2 diabetes and microalbuminuria. This may contribute to treatment-resistant hypertension.

## FR-PO512

**Effects of Renal Denervation with a Standard Irrigated Cardiac Ablation Catheter on Blood Pressure and Renal Function in Patients with Chronic Kidney Disease and Resistant Hypertension** Jocemir R. Lugon,[1] Maria A. Carreira,[1] Miguel Luis Graciano,[1] George Luiz Marques Maia,[1] Marcio Galindo Kiuchi,[1,2] Tetsuaki Kiuchi.[1] *[1]Nephrology, Universidade Federal Fluminense, Niterói, RJ, Brazil; [2]Vascular Surgery, Hospital Regional Darcy Vargas, Rio Bonito, RJ, Brazil.*

**Background:** Recently, transcatheter renal sympathetic denervation (RSD) has proved effective in lowering refractory blood pressure (BP). We evaluated the safety and efficacy of this procedure using a standard irrigated cardiac ablation catheter (SICAC) in 24 chronic kidney disease patients (stages 2-4) with refractory hypertension.

**Methods:** Twenty four patients were included and treated with a SICAC. Denervation was performed by single operator following standard technique. Patients included with CKD were on stages 2 (n=16), 3(n=4) and 4(n=4). Data were obtained at baseline and monthly until 180$^{th}$ day of follow up.

**Results:** Data were obtained at baseline and monthly until180th day of follow up. Baseline values of blood pressure

(Mean±SD) were: 186±19 mmHg / 108±13 mmHg in the office, and 151±18 mmHg / 92±11 mmHg by 24 hour ambulatory blood pressure monitoring (ABPM). Office blood pressure values at 180th day after procedure were 135±13 mmHg/88±7 mmHg

(P<0.0001, for both comparisons). Mean ABPM decreased to 132±15 mmHg/ 85±11 mmHg at the 180th day after the procedure (P <0.0001 for systolic and P =0.0015 for diastolic). Estimated glomerular filtration (Mean±SD) increased from baseline (64.4±23.9 ml/min/1.73m2) to the 180th day (85.4±34.9 ml/min/1.73m2, P<0.0001) of follow-up. Median urine albumin:creatinine ratio decreased from baseline (48.5, IQR 35.8-157.2 mg/g) to the 180th day after ablation (ACR = 15.7, IQR 10.3-34.2 mg/g, P=0.0017). No major complications were seen.

**Conclusions:** The procedure using SICAC seemed to be feasible, effective and safe resulting in better control of BP, a short-term increase in eGFR, and reduced albuminuria. Although encouraging, our data are preliminary and need to be validated in the long term.

## FR-PO513

**Microvascular/Hypertensive Disease Is Increased in Patients with Obstructive Sleep Apnea** Sky K. Chew,[1] Deb J. Colville,[1] Ecosse L. Lamoureux,[2] Judith A. Savige.[1] *[1]Dept of Medicine (Royal Melbourne Hospital), The Univ of Melbourne, Melbourne, VIC, Australia; [2]Centre for Eye Research Australia, The Univ of Melbourne, Melbourne, VIC, Australia.*

**Background:** Microvascular/hypertensive abnormalities in the retina reflect systemic small vessel disease. This study used retinal examination to compare the prevalence of of microvascular/hypertensive disease (severity of changes and calibre) in patients with Obstructive sleep apnea (OSA) or Chronic obstructive pulmonary diseas disease (COPD).

**Methods:** Patients were recruited from the Respiratory clinic and wards of a metropolitan teaching hospital. All participants underwent retinal photography using a non-mydriatic camera (KOWA, KOWA Japan). Images were graded for microvascular/hypertensive retinopathy (Wong and Mitchell classification) by an ophthalmologist and a trained observer. Images were sent to the Centre for Eye Research Australia for measurement of the retinal arteriole and venular calibre by a grader using Knudtson's revised version of the Parr-Hubbard formula. Statistical analysis was performed using Stata 11.2 software (Stata Corp).

**Results:** Seventy-nine patients with OSA and 132 with COPD were recruited. Patients with OSA alone were younger (p <0.01), had a higher BMI (p <0.01), and were less likely to be smokers (p <0.01) than those with COPD.

Patients with OSA had more microvascular disease than those with COPD (OR 9.90, 95%CI 2.29 to 42.90, P <0.01). In addition, their arterioles (mean difference 18.00µm, 95%CI 12.88 to 23.08, P <0.01) and venules (mean difference 25.30µm, 95%CI 17.09 to 33.52, P <0.01) were narrower. These changes were not worse with more severe OSA and were not reversed with the use of CPAP. Microvascular/hypertensive retinopathy was still more common and the arteriolar and venular narrowing persisted in patients with OSA after adjusting for age, BMI, hypertension, smoking and dyslipidemia.

**Conclusions:** Patients with OSA have increased small vessel disease compared with patients with COPD, with worse microvascular/hypertensive retinopathy and narrower vessels. This narrowing was not related to OSA severity and was not reversed with CPAP treatment.

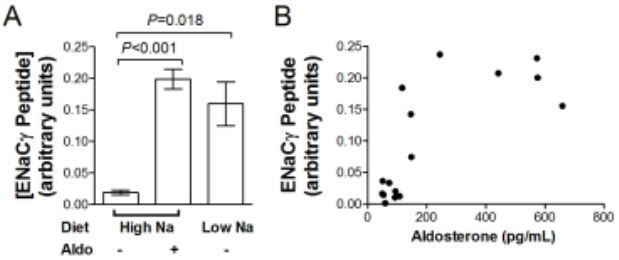
## FR-PO514

**Dietary Sodium Reduction and Aldosterone Acutely Alter the Urine Exosome Proteome in Humans** James M. Luther,[2,3] Ying Qi,[1] Bing Zhang,[1] Kristie Rose,[1] Xiaojing Wang,[1] Kevin Schey.[1] *[1]Biochemistry, Vanderbilt Univ, Nashville, TN; [2]Medicine, Vanderbilt Univ, Nashville, TN; [3]Pharmacology, Vanderbilt Univ, Nashville, TN.*

**Background:** Urinary exosomes are a potential biomarker source for human disease, but their physiologic relevance remains uncertain.

**Methods:** To test the hypothesis that the urinary proteome is regulated by endogenous and exogenous hormones, we analyzed urine exosomes in 14 healthy control subjects in a cross-over study during high (HS, 160mmol/d) and low salt (LS, 20mmol/d) diet to activate the endogenous renin-angiotensin-aldosterone system (RAAS). In a separate cohort during HS diet, we collected urinary exosomes after vehicle and aldosterone infusion (0.7 µg/kg/hr for 10 hrs).

**Results:** LS diet increased renin activity (5.9±3.1 vs 0.8±0.3 ng AngI/mL/hr; P<0.01) and aldosterone (16.4±2.7 vs 7.5±1.1 ng/dL; P<0.001), and aldosterone infusion increased plasma aldosterone (55.9±5.5 vs 7.8±1.5 ng/dL; P<0.001). Urinary exosome peptide analysis by Multidimensional Protein Identification Technology (MudPIT) detected 2,892 unique proteins, 1,342 were significantly altered during LS diet (117 up, 717 down) after correction for multiple testing. In a separate validation cohort, proteins including NCC, ENaC-alpha, and ENaC-gamma were validated using targeted multiple reaction monitoring mass spectrometry (MRM MS). Dietary sodium restriction and acute aldosterone infusion similarly increased urine exosome ENaC-gamma excretion (**Figure A**), which correlated positively with plasma aldosterone (**Figure B**; $R^2$=0.56, P<0.001). Urinary Na/K concentration during LS diet corresponded similarly.



**Conclusions:** The urinary exosome content is dynamically altered by the RAAS and corresponds with anticipated physiologic changes. Furthermore, exosomal ENaC gamma may provide a useful biomarker of sodium channel activation in clinical studies.

## FR-PO515

**Night-Time BP of <120/70 Can Improve the Renal Outcomes in Patients with CKD** Shuichi Watanabe,[1] Hiroyuki Togawa,[1] Daisuke Fuwa,[1] Yukako Isobe,[1] Yoshiaki Ogiyama,[1] Toshiyuki Miura,[1] Tadashi Ichikawa,[1] Shirasawa Yuichi,[1] Michio Fukuda,[1] Genjiro Kimura.[2] *[1]Cardio-Renal Medicine and Hypertension, Nagoya City Univ, Japan; [2]Asahi Rosai Hospital, Japan Labour Health and Welfare Organization.*

**Background:** ABPM has been already widely adopted for the diagnosis and classification of hypertension. In some reports, optimal blood pressure was proposed to prevent hypertensive organ damage especially heart diseases and cerebrovascular diseases. However, the evidence of optimal blood pressure for the renal dysfunction still unclear.

**Methods:** Two hundred and five patients with chronic kidney disease (CKD) (male 106, female 99, age 49±19 year-old, eGFR 57±35 ml/min/1.73m$^2$, mean follow-up 1,207days), who have undergone 24-h ABPM, were studied. The subjects were grouped into 2 according to the presence or absence of the night-time high blood pressure (night time systolic blood pressure>=120 mmHg or <120mmHg). The primary end-point was the composite of a doubling of the base-line serum creatinine concentration, or end-stage renal disease. Analysis was by intention to treat.

**Results:** Fifty out of 80 subjects with night time systolic hypertension subjects reached the primary endpoint, whereas 13 out of 125 subjects without night-time systolic hypertension ($p<0.0001$). Compared with the night-time BP of <120/70 mmHg, the night time BP of ≥120/70 mmHg exhibited higher risk for the primary endpoint (Crude HR 4.68, 95%CI 2.00-11.0, p=0.0004, Adjusted HR 3.68, 95%CI 1.28-10.6, p=0.02), whereas, presence of day time hypertension (≥135/85 mmHg) didn't become the major risk for the renal outcome. Interestingly, ROC analysis also indicated that the optimal night-time blood pressure value to prevent the renal dysfunction was 120/70 mmHg (positive likelihood ratio, 3.27/1.62).

**Conclusions:** The presence of night-time hypertension was a strong predictor of renal dysfunction. Since day time blood pressure was also plays an important role for hypertensive organ damages, further studies are needed to determine the optimal day time blood pressure goal for prevention of the CKD progression.

## FR-PO516

### 8-Week Study on Effects of Chlorthalidone in Hypertensives with Low eGFR

Massimo Cirillo, Fabiana Marcarelli, Alessandra Antonia Mele, Massimo Romano, Cinzia Lombardi, Giancarlo Bilancio. *Dept of Medicine, Univ of Salerno, Baronissi (SA), Italy.*

**Background:** Efficacy of chlorthalidone (CT) and thiazides is considered low in low kidney function (LKF).

**Methods:** A parallel-arm,non-inferiority study was done on CT effects in hypertensives with LKF and hypertensives without LKF (Italian Drug Agency Registry ID#671).Study design included:screening visit,baseline visit, 8-week CT treatment with visits at week 1,2,4,6 and 8.The screening visit selected patients on antihypertensive treatment with uncontrolled hypertension (SBP≥140 or DBP≥90),ages 25-74,complete diagnostic work-up.Eligible patients were prescribed lab evaluations and re-examined after 1-2 week (baseline).Exclusion criteria were treatment with diuretics,CT contraindications,refused consent,SBP≥180 or DBP≥110, severe co-morbidities.At baseline, 25 mg CT was prescribed on the top of ongoing treatments to 60 patients with LKF (eGFR by CKD-Epi equation stably <60 mL/min) and 60 patients without LKF (Control, eGFR stably ≥60 mL/min). Blood pressure was measured at each visit by blinded trained physicians according to WHO guidelines.Lab evaluations were repeated at visit 8. Study power was 80% ($\alpha$=0.01,one sided test,$\sigma$=15,difference in SBP reduction=8).

**Results:** LKF and Control were similar for men% (70.2% and 64.2%),age (mean= 57 and 53),baseline blood pressure (SBP/DBP= 150/90 and 150/91) but differed for eGFR (mean= 39 and 76, range=15-59 and 60-104).Changes over baseline were significant at week 8 in LKF and Control for SBP (mean= -20 and -23; 95%CI= -22/-18 and -26/-19) and DBP (-9 and -10; -11/-7 and -13/-8).Differences between groups were not significant for changes in SBP (-3; -7/+1) and DBP (-1; -4/+2). Baseline eGFR did not predict SBP/DBP changes in either groups (R<0.18,P>0.17). Week 8 changes were significant for eGFR (LKF and Control, mL/min= -2 and -5; -4/-1 and -7/-3), serum potassium (mmol/L= -0.2 and -0.2; -0.3/-0.1 and -0.3/-1), serum uric acid (mg/dL= +0.8 and +0.9; +0.5/+1.1 and +0.7/+1.1). Adverse events incidence was 13.3% in both groups. The commonest events were serum sodium <135 mmol/L and SBP/DBP <110/90.

**Conclusions:** Data do not support the idea of reduced CT efficacy in low kidney function.

*Funding:* Government Support - Non-U.S.

## FR-PO517

### Association of Renin and Aldosterone Concentrations with Race/Ethnicity and Blood Pressure in Community-Living Individuals: The Multi-Ethnic Study of Atherosclerosis

Dena E. Rifkin,[1] Ali Khaki,[1] Nancy Jenny,[2] Robyn L. McClelland,[3] Matthew Jay Budoff,[4] Karol E. Watson,[4] Joachim H. Ix,[1] Matthew Allison.[1] *[1]UCSD; [2]Univ of VT; [3]Univ of Washington, Seattle; [4]UCLA.*

**Background:** Though variations in plasma renin activity (PRA) and aldosterone (aldo) have been examined in Caucasians and African-Americans, little is known about the levels of these hormones and their association with blood pressure in other races/ethnicities.

**Methods:** We measured PRA and aldo in 1021 community-dwelling participants who were not taking antihypertensive medications and then examined the association between race/ethnicity (Caucasian, Chinese, African-American and Hispanic) and both PRA and aldo, as well as the association between PRA and aldosterone with systolic blood pressure (SBP) overall and by race/ethnicity.

**Results:** The average (SD) age was 62(9). Median (IQR) PRA was 0.51 (0.29 to 0.87) ng/ml/hr and aldo was 12.6 (9.1 to 17.1) ng/dl. After age and gender adjustment, compared to Caucasians, African-Americans had 27.5% lower PRA and 17.2% lower aldo, and Hispanics 19.1% higher PRA but similar aldo levels. After multivariate adjustment, compared to Caucasians, only Hispanic race/ethnicity was associated with higher PRA (0.19 ng/ml/hr [95% CI 0.07, 0.31]). African-American race/ethnicity was associated with lower aldo(-1.58 ng/dl [95% CI -2.97 to -0.18]) compared to Caucasians. After similar multivariate adjustment for demographic and clinical characteristics, PRA was associated with lower SBP in Caucasians (-3.2 mmHg [95% CI -5.2, -1.2] per standardized unit PRA), Chinese (-3.5 mmHg [95% CI -6.2, -0.80] per standardized unit) and Hispanics (-2.3 mmHg [95% CI -4.1, -0.6] per standardized unit) but not African-Americans. Aldowas associated with higher SBP only in Hispanics (2.5 mmHg [95% CI 0.4, 4.5] per SD).

**Conclusions:** Compared to community-living Caucasians, African-Americans have lower aldo and Hispanics have higher PRA, whereas levels in Chinese have no significant difference in either measure. Aldo had a significant association with higher SBP in Hispanics compared to other races/ethnicities, a finding that may suggest a different mechanism of hypertension for this race/ethnicity.

## FR-PO518

### Podocyturia Is Not Predictive of the Development of Preeclampsia

Belinda Bun Jim,[1] Swati Mehta,[2] Andi Qipo,[1] Elizabeth Ann Phipps,[1] Kwanghee Kim,[4] Shuchita Sharma.[3] *[1]Nephrology/Medicine, Jacobi Medical Center, Bronx, NY; [2]Medicine, James J. Peters Veterans Affairs Hospital, Bronx, NY; [3]Nephrology/Medicine, Mount Sinai School of Medicine, New York, NY; [4]Medicine, Trinity Health Center, Minot, ND.*

**Background:** Despite the increasing prevalence of preeclampsia (PEC) in the US, the ability to predict its occurrence is still problematic. Recent evidence suggests that podocyturia is highly predictive of PEC at 27 weeks of gestation.

**Methods:** Fresh urine samples of patients who were at high risk of developing PEC (chronic hypertension, diabetes mellitus, CKD, SLE) were collected, as were control patients in their 2nd and 3rd trimesters of gestation. To assess for podocyturia, an aliquot of urine was centrifuged to obtain the cell pellet and fixed for immunofluorescence staining. Podocytes were identified by colocalization of markers podocin and synaptopodin and counted. These counts were expressed as number of podocytes/mL/urine creatinine mg/dL (pod/creat). These subjects were followed until delivery. The unpaired parametric t-test analysis was performed to assess differences in outcome and spearman correlations were calculated to assess trend for continuous variables.

**Results:** There was no statistically significant difference in the pod/creat for high risk patients (n=13) who developed PEC vs. those who did not (n=63) (p=0.34). However, there was a statistically significant difference between control patients (n=13) and high risk patients who did develop PEC (n=13) (p=0.01). There was also a statistically significant difference between control patients (n=13) and high risk patients who did not develop PEC (n=63) (p=0.02). No significant correlation was found between pod/creat and albuminuria (rho=0.14, p=0.63) in those who developed PEC or in those who did not (rho=0.03, p=0.80).

**Conclusions:** Podocyturia does not appear to be predictive of PEC when obtained in the 2nd or 3rd trimester of gestation in high risk obstetric patients. However, there does appear to be a baseline difference between high risk patients and uncomplicated control patients in their podocyturia counts irrespective of whether PEC is the outcome.

### Relationship between Circadian Variation of Blood Pressure and Renal Tissue Damage in Biopsy Proven Glomerulonephritis

Keiji Kono,[1,2] Hideki Fujii,[1] Kentaro Nakai,[1] Shunsuke Goto,[1] Shinichi Nishi.[1] *[1]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Div of Nephrology, Akashi Medical Center, Akashi, Japan.*

**Background:** Hypertension (HT) is a common complication in chronic kidney disease (CKD) patients. It has been reported that CKD patients often have circadian rhythm disorder of blood pressure (BP), which is known to be an independent risk factor for CKD progression. However, the relationship between 24-h ambulatory BP (24-h ABP) pattern and renal tissue damage remains unclear, and thereby we investigate their relationship in biopsy proven glomerulonephritis.

**Methods:** Thirty-seven patients with glomerulonephritis were included in this study. The patients with diabetes mellitus, malignancy, acute kidney injury and vasculitis, were excluded. Clinic BP (CBP) and 24-h ABP measurements were performed in all the study patients. HT was diagnosed from CBP and/or 24-h ABP recordings. Moreover, we calculated nocturnal BP fall (%), after which the patients with HT were divided into three groups (dipper, non-dipper and riser). For assessment of renal tissue damage, we evaluated the percent of sclerotic glomeruli and interstitial fibrosis, and intimal thickening of intra-lobular arteries and arteriolar hyalinosis were classified into four grades (none, mild, moderate and severe) in each biopsy specimen.

**Results:** Twenty-six patients (70%) have had normal blood pressure based on CBP recordings. Of these, nine patients (24%) were diagnosed as HT according to 24-h ABP recordings. When dividing into three nocturnal BP groups in twenty patients who have had HT based on CBP and/or 24-h ABP recordings, the grade of arteriolar hyalinosis was significantly higher in the non-dipper and riser groups compared to the normotensive and dipper groups ($p< 0.05$). Furthermore, the percent of interstitial fibrosis was significantly higher in the riser group compared to the normotensive and dipper groups ($p< 0.05$).

**Conclusions:** Our findings suggest that nocturnal BP elevation develops renal tissue damage potentially through the progression of arteriolosclerosis. Careful ABP control should be performed for protecting against renal tissue damage in CKD patients.

## FR-PO520

### Effects of Oral L-arginine Supplementation and Acute Resistance Exercise on Blood Pressure and Nitric Oxide in Hypertensive Patients

Elisa MS Higa,[1,2] Margaret Mouro,[1,2] Giovana R. Punaro,[1] Marco Túlio Mello,[3] Sérgio Tufik,[3] Marcos A. Nascimento.[2] *[1]Nephrology, UNIFESP; [2]Translational Medicine, UNIFESP; [3]Psychobiology, UNIFESP, Brazil.*

**Background:** High blood pressure (BP) is a world health problem and a risk factor to cardiovascular disease. This study examined the effects of oral L-arginine supplementation and acute resistance exercises on blood pressure and nitric oxide in hypertensive men.

**Methods:** Sixteen hypertensive men (45±7 yrs, 92.46±12.99 kg, body weight and 31.03±3.76 kg/m$^2$, body mass index) volunteered to be in this randomised, double-blind, and repeated-measure study: control placebo (CTL-PLA), control arginine (CTL-ARG), exercise placebo (EXE-PLA) and exercise arginine (EXE-ARG). The supplementation period was (6 g/day of placebo or L-arg for 7 days) separated by a 7-day washout. The

acute resistance exercises (ARE) comprise 8 exercises, with an intensity of 60% of 1 maximum repetition. Each session was performed at the beginning and at the end of the supplementation. The systolic blood pressure (SBP), diastolic blood pressure (DBP), mean blood pressure (MBP), double product (DP) and heart rate (HR) were determined at rest, immediately after ARE and 5, 10, 15, 30, 45 and 60 minutes after ARE; the nitric oxide (NO) was determined at rest, immediately after ARE and 1 hour after ARE.

**Results:** SBP decreased at all periods after ARE in the EXE-PLA and EXE-ARG, but not significantly (P>0.05); DBP decreased at 45' comparing CTL-ARG to EXE-PLA and EXE-ARG (83±2.31 vs 76±2.23 and 75±1.25, P<0.05, respectively), and at 60' comparing CTL-PLA to EXE-PLA and EXE-ARG (85±2.90 vs 79±1.87 and 78±1.09, P<0.05, respectively). DP was increased immediately after ARE, and at 5, 10, 15, 30, 45 and 60' comparing exercises to control groups, with P<0.05 as well as HR, which showed the same result. MBP and NO levels did not show differences (P>0.05).

**Conclusions:** In summary, ARE reduced DBP, and maintained SBP and MBP in lower levels than controls; arginine supplementation groups had lower levels than placebo groups but not significant. HR and DP increased, but into safety levels; NO did not show changes. These results suggest that ARE could be a powerful tool to control the blood pressure in hypertensive men.

### T/L-Type Calcium Channel Blocker Reduces the Composite Ranking of Relative Risk According to New KDIGO Guidelines in Patients with Chronic Kidney Disease

Masanori Abe, Kazuyoshi Okada. *Nephrology, Hypertension and Endocrinology, Nihon Univ School of Medicine, Tokyo, Japan.*

**Background:** Recently, the Kidney Disease: Improving Global Outcomes (KDIGO) group recommended that patients with chronic kidney disease (CKD) be assigned according to stage and composite relative risk on the basis of glomerular filtration rate (GFR) and albuminuria criteria. The aim of this post-hoc analysis was to investigate the effects of add-on therapy with calcium channel blockers (CCBs) on changes in the composite ranking of relative risk according to KDIGO guidelines. Benidipine, an L- and T-type CCB, and amlodipine, an L-type CCB to angiotensin II receptor blocker (ARB), were examined.

**Methods:** Patients with blood pressure (BP) > 130/80 mmHg, an estimated GFR (eGFR) of 30–90 mL/min/1.73 $m^2$, and albuminuria > 30 mg/gCr, despite treatment with the maximum recommended dose of ARB, were randomly assigned to two groups. Each group received one of two treatments: 2 mg benidipine daily, increased to 8 mg daily (n=52), or 2.5 mg amlodipine daily, increased to 10 mg daily (n=52).

**Results:** After 6 months of treatment, a significant and comparable reduction in systolic and diastolic BP was observed in both groups. The eGFR was significantly decreased in the amlodipine group, but there was no significant change in the benidipine group. The decrease in albuminuria in the benidipine group was significantly lower than in the amlodipine group. The composite ranking of relative risk according to the new KDIGO guidelines was significantly improved in the benidipine group; however, no significant change was noted in the amlodipine group. Moreover, significantly fewer cases in the benidipine group than the amlodipine group showed a reduced risk category score.

**Conclusions:** The present post-hoc analysis showed that compared to amlodipine benidipine results in a greater reduction in albuminuria accompanied by an improved composite ranking of relative risk according to the KDIGO CKD severity classification.

## FR-PO522

### Azelnidipine Attenuates the Non-Gaussian Heart Rate Variability in CKD Patients with Preceding Treatment with ARB

Michio Fukuda,[1] Shuichi Watanabe,[1] Daisuke Fuwa,[1] Hiroyuki Togawa,[1] Toshiyuki Miura,[1] Junichiro Hayano.[2] *[1]Cardio-Renal Medicine and Hypertension, Nagoya City Univ, Japan; [2]Medical Education, Nagoya City Univ, Japan.*

**Background:** Sympathetic nervous system can be activated even in the early stage of CKD. However, controversy exists as to whether the frequency-domain HRV (eg, LF/HF) can indicate the sympathetic activity. Recently, we have proposed that the non-Gaussianity index (λ), which exhibited the probability of the large HR deviations from its trend, can be served not only as a marker potentially related to sympathetic cardiac over-drive, but also as a powerful predictor of mortality and morbidity in cardiovascular diseases [Kiyonoetal. 2008; Hayano et al. 2011].

**Methods:** At the interim analysis, 19 men and 3 women (57±14 year-old) were enrolled. When subjects had taken olmesartan for at least two months (10-20 mg/day), subjects underwent a 24-h hECG with a portable ECG recorder under their usual daily activities. After the baseline examinations, the participants received single daily doses of a CCB, azelnidipine (16 mg/day), in the morning to attain the daytime BP goal <130/80 mmHg (or 125/75 mmHg if proteinuria was greater than 1 g/day). During the eight week study period, change in the dosage of olmesartan or additional administration of other antihypertensives were not allowed. After 8-wk add-on treatment with azelnidipine to olmesartan, hECG was recorded again.

**Results:** At baseline, all of the traditional markers (eg, SDNN, VLF, Scaling exponent α1, DC), which represent both reduced parasympathetic and enhanced sympathetic activity, were higher than their cut-off values for cardiac events. However, azelnidipine significantly attenuated the non-Gaussianity index (λ), which was the indicator of sympathetic activity rather than parasympathetic activity.

**Conclusions:** These findings suggested that 1) in patients of post-myocardial infarction, both sympathetic and parasympathetic nervous system can be altered, 2) whereas in patients with CKD, sympathetic nervous activity is the matter of importance, and 3) azelnidipine can suppress the sympathetic overactivity.

## FR-PO523

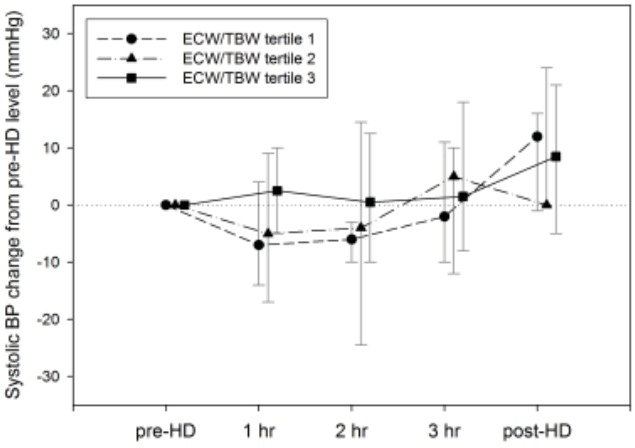
### Blood Pressure Patterns during Hemodialysis According to Volume Status and Ultrafiltration Amount

Jongha Park, Hyun Chul Chung, Jong Soo Lee. *Div of Nephrology, Ulsan Univ Hospital, Univ of Ulsan College of Medicine, Ulsan, Korea.*

**Background:** Blood pressure (BP) pattern during hemodialysis (HD) may be associated with survival. Volume status is a likely major determinant of BP change during HD along with ultrafiltration (UF) amount and/or rate. However, interrelation between body volume and UF amount hampered to evaluate an impact of volume status separately.

**Methods:** A total of 177 incident HD patients (age 56±15 yrs old, female 33.3%, diabetes 54.2%) were analyzed. BP was recorded at pre-HD, 1, 2, 3 hours after, and post-HD during the third HD session (the first 4-hr session). UF amount was calculated as pre-HD body weight *minus* post-HD body weight. Ratio of extracellular water to total body water (ECW/TBW) estimated by bioimpedance analysis (InBody S30, Seoul, Korea) just before HD, was used as an index of volume status. Higher ratio reflects volume overloaded state.

**Results:** Patients were divided based on tertiles of UF amount (≤0.7 kg, 0.7< to 1.9 kg, >1.9 kg) and ECW/TBC (≤0.39, 0.39 to 0.41, >0.41). We plotted change in systolic BP from pre-HD value (median, interquatile range) according to ECW/TBW tertiles in each UF stratum. In patients with UF ≤0.7 kg, systolic BP tended to increase similarly among ECW/TBW tertiles. In the stratum of UF >1.9 kg, systolic BP dropped at 1-hr and 2-hr then rose up in patients with ECW/TBW ≤0.41 (tertile 1 & 2). However, patients with ECW/TBW >0.41 (tertile 3) showed no drop in systolic BP at 1-hr and 2-hr points (Figure).



**Conclusions:** BP pattern during HD differs by volume status as well as UF amount. No dip in BP during HD despite of usual UF amount such as 2 - 3 kg could reflect volume overload.

## FR-PO524

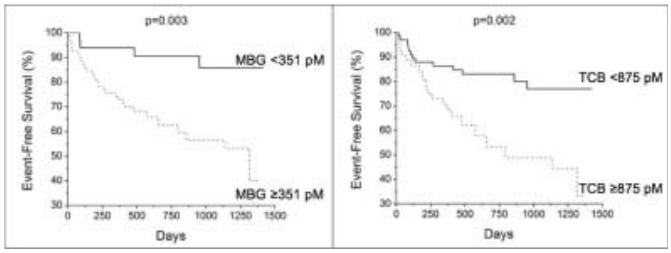
### Elevated Marinobufagenin and Telocinobufagin Levels in Chronic Heart Failure Predict Adverse Long-Term Clinical Outcomes

David Kennedy,[1] Kevin Shrestha,[1] Michael Finucan,[1] Alaa Gabi,[1] Charles M. Medert,[1] Allen Borowski,[1] Olga Fedorova,[2] Alexei Y. Bagrov,[2] W.H. Wilson Tang.[1] *[1]Cellular & Molecular Medicine, Cleveland Clinic, Cleveland, OH; [2]Laboratory of Cardiovascular Science, National Institute on Aging, Baltimore, MD.*

**Background:** Cardiotonic steroids such as marinobufagenin (MBG) and telocinobufagin (TCB) increase in response to volume expansion and induce inflammation, oxidative stress and fibrosis. In chronic heart failure (HF) patients, we hypothesized that elevated MBG and TCB levels are associated with poorer cardiac and renal function as well as increased oxidant stress and adverse long-term clinical outcomes.

**Methods:** In 116 chronic HF patients, we measured MBG and TCB levels and performed comprehensive clinical and echocardiographic assessment. All-cause mortality, cardiac transplantation, and HF hospitalization were tracked for 5 years.

**Results:** In our study cohort (age 56±13 years, LVEF 27±10%, median NTproBNP 1059 pg/mL, eGFR 74±26 mL/min/1.73m2), median MBG levels were 521 [307-734] pM, and median TCB levels were 700 [378-1272] pM. MBG and TCB were directly correlated (Spearman's r=0.55, p<0.0001). Higher MBG and TCB both were associated with higher WBC count (MBG: r=0.53, p=0.010; TCB: r=0.48, p=0.021). Higher MBG was modestly associated with worse baseline renal function (serum creatinine: r= 0.37, p=0.031), worse RV systolic function (RV s': r= -0.33, p=0.018), and worse RV diastolic function (Tricuspid E/e': r=0.39, p=0.008). Higher TCB was modestly associated with higher plasma myeloperoxidase levels (r=0.32, p=0.028). Higher MBG and TCB predicted increased risk of adverse clinical outcomes (MBG≥351 pM: HR 4.36 [1.71-14.73], p=0.001; TCB≥875 pM: HR 2.86 [1.44-5.89], p=0.002).



**Conclusions:** In chronic HF patients, elevated MBG and TCB levels are associated with worse HF disease severity and predict adverse long-term clinical outcomes.

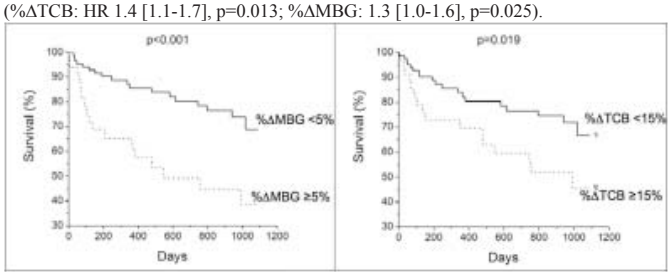
## FR-PO525

**Rising Marinobufagenin and Telocinobufagin Levels during Acute Decompensated Heart Failure Admission Predict Poor Long-Term Clinical Outcomes** David Kennedy,[1] Kevin Shrestha,[1] Allen Borowski,[1] Charles M. Medert,[1] Olga Fedorova,[2] Alexei Y. Bagrov,[2] W.H. Wilson Tang.[1] *[1]Cellular & Molecular Medicine, Cleveland Clinic, Cleveland, OH; [2]Laboratory of Cardiovascular Science, National Institute on Aging, Baltimore, MD.*

**Background:** Cardiotonic steroids such as marinobufagenin (MBG) and telocinobufagin (TCB) increase in response to volume expansion and induce oxidative stress and fibrosis. We hypothesized that elevated levels of MBG and TCB in acute decompensated heart failure (ADHF) patients are associated with poorer cardiac and renal function as well as increased inflammatory and oxidant stress, and adverse long-term events.

**Methods:** In 129 ADHF patients, we measured MBG and TCB levels and performed comprehensive clinical and echocardiographic assessment at baseline and 48-72 hours after admission. All-cause mortality was tracked for 5 years.

**Results:** In our cohort (age 61±14 years, LVEF 31±14%, median NTproBNP 4684 pg/mL, eGFR 72±38 mL/min/1.73m2), median MBG and TCB levels were 630 [438-903] pM and 823 [406-1392] pM, respectively. MBG and TCB were directly correlated (r= 0.51, p<0.0001). Higher baseline MBG and TCB both correlated with higher plasma myeloperoxidase levels (MBG: r=0.27, p=0.014, TCB: r=0.22, p=0.048) and worse RV systolic function (RV s'; MBG: r= -0.26, p=0.039; TCB: r= -0.38, p=0.003) but not LV systolic or diastolic function. In Cox proportional hazard analysis, higher baseline TCB predicted increased risk of death within 5 years (HR 1.4 [1.1-1.8], p=0.018). Rising TCB or MGB levels over the course of admission also predicted increased risk adverse outcomes (%ΔTCB: HR 1.4 [1.1-1.7], p=0.013; %ΔMBG: 1.3 [1.0-1.6], p=0.025).



**Conclusions:** In patients with ADHF, elevated MBG and TCB levels are associated with increased systemic oxidative stress and worse RV systolic function. Rising levels of TCB and MGB after admission predict worse long-term clinical outcomes.

## FR-PO526

**Insufficient Sleep Is Associated with Higher Blood Pressure in Pediatric Nephrology Clinic Patients** Neena R. Gupta,[1] Rakesh Gupta.[2] *[1]Pediatric Nephrology, UMass Memorial Medical Center, Worcester, MA; [2]Pulmonary and Sleep Medicine, Roger Williams Medical Center, Providence, RI.*

**Background:** Hypertension (HTN) is a common concern in pediatric nephrology patients either as primary problem or an associated finding affecting outcomes in other disorders. While several risk factors and mechanisms such as obesity, salt intake, and renal dysfunction get most attention, insufficient sleep is not appreciated as a risk factor for hypertension. Data on sleep disorders and HTN in children are primarily restricted to association with sleep apnea. Some studies have shown sleep deprivation to be associated with higher BP. We have previously shown that weekday sleep time is inversely related to ambulatory BP parameters in children referred for evaluation of HTN (ASN 2012). We hypothesize that low weekday sleep time is likely to be associated with higher BP in all pediatric nephrology patients.

**Methods:** A sleep questionnaire was administered to 34 patients attending pediatric nephrology clinic. It was a sample of convenience. Demographic data, BMI, clinic BP, diagnoses were recorded. Weekday and weekend sleep times were calculated in minutes. Correlation coefficient between weekday sleep time, SBP, DBP, and BMI percentile were calculated.

**Results:** The baseline characteristics for 34 patients were: Age – 13.8±3.5 years, male-60%, BMI percentile 66.3±29.1, Weekday sleep time (WDST) 527.6±75 minutes, weekend sleep time 611±84.9 minutes, SBP 118.2±13.1 mm Hg, DBP 74.7±6.8 mm Hg. Most common diagnoses were Hypertension (61%), VUR (12%), Nephrotic syndrome (12%), Glomerulonephritis (6%), Vasculitis (18%) and others (24%). A significant correlation was found between WDST and SBP (r=-0.29, p=.047), WDST and DBP (r=-0.358, p=0.019). A trend was noticed for correlation between BMI percentile and BP parameters.

**Conclusions:** Low WDST was associated with higher clinic BP in pediatric clinic patients with a wide variety of diagnoses. The link between insufficient sleep and BP as a potential risk factor for HTN as well as therapeutic target needs to be explored further.

## FR-PO527

**Histopathological Diagnoses in Patients Presenting with Hypertension and Kidney Damage** Jennifer R. Joslin, Sarah Wood, Rebecca Suckling, Pauline A. Swift. *Renal Medicine, Epsom and St. Helier Univ Hospitals NHS Trust, London, United Kingdom.*

**Background:** Hypertension is a recognized cause of acute and chronic kidney disease (CKD). It is also a common complication of CKD from any etiology. The underlying histopathological diagnoses have not been well described in patients who present with a clinical diagnosis of hypertensive kidney disease.

**Methods:** We have conducted an observational study of consecutive renal biopsies performed in a 2 year period, in patients with a clinical diagnosis of hypertensive nephropathy (HN). Outcomes were the histological presence of HN or glomerulonephritis (GN), and clinical predictors of HN or GN.

**Results:** 28 out of the 410 native renal biopsies were performed in patients with a clinical diagnosis of HN. Mean age was 48 years, and mean eGFR was 26 mls/min/1.73m$^2$.

| Probable Underlying Diagnosis Based on Histopathological Findings | Cases |
|---|---|
| Hypertensive Nephropathy | 14 |
| Glomerulonephritis | 10 |
| *IgA Nephropathy* | *8* |
| *FSGS* | *2* |
| Diabetic Nephropathy | 1 |
| Inadequate | 1 |
| Chronic damage, no obvious cause | 2 |

21% (6/28) presented with accelerated hypertension. On biopsy 50% (3/6) had confirmed HN and 50% had GN (2/6 IgA nephropathy, 1/6 FSGS). All had at least moderate/severe chronic changes. 43% (12/28) had a documented urinary protein-creatinine ratio (uPCR) >300mg/mmol. This cohort were equally as likely to those with uPCR <300mg/mmol to have a non-hypertensive histological diagnosis. 75% (21/28) had no post-procedure complications. 14% (4/28) patients had minor bleeds, and 4% (1/28) had a major bleed requiring renal arterial embolisation. 2 of the complications (1 major, 1 minor) were in patients with accelerated hypertension.

**Conclusions:** Native renal biopsies performed in patients with a clinical diagnosis of HN showed histological evidence of HN as the primary diagnosis in only 50% of cases. Similar results were seen in the small sub-group who presented with accelerated hypertension, in whom the procedural complication rate was higher. Urinalysis and quantification of proteinuria did not predict histological diagnosis. Kidney biopsy should be considered in individuals who present with hypertension and kidney damage.

## FR-PO528

**Renal Artery Denervation in Patients with Chronic Kidney Disease and Hemodialysis, with Resistant Arterial Hypertension – North Israeli Center Experience** Farid M. Nakhoul,[1,3] Ana Roth,[1] Yonathan Hasin,[2,3] Farber Evgeny,[1] Ganem Diab.[2] *[1]Nephrology, Baruch Padeh Poriya, Lower Galilee, Israel; [2]Cardiology, Baruch Padeh Poriya, Israel; [3]Faculty of Medicine, Bar Ilan Univ, Israel.*

**Background:** A number of cardiovascular disease have been shown to be characterized by a marked increase in sympathetic drive to the heart and peripheral circulation as in essential hypertension, chronic kidney disease (CKD). CKD patients show sympathetic hyperactivity, with aggravation of HTN. In CKD and HD patients is difficult to control HTN, and need multiple drugs. Here we report our first experience on renal sympahthetic nerve ablation for treatment of severe resistant hypertension in CKD patients. Our results demonstrate high efficacy of this procedure for TX of resistant hypertensive in CKD.

**Methods:** 33 patients- aged average between 40-79 yrs old, were treated with RAD,: 66% of them were with diabetes mellitus, 64% with LVH. 24 Patients were with follow up to 3 months (Range 1-12 months) 9 patients with CKD (Two of them were on Hemodialysis and two with RAS). All patients were with systolic BP≥160 mmHg under three drugs. Mean number of antihypertensive drugs per patient were 4.5. Patients with CKD: Pl. Creatinine range was.2-3.6 mg/dl.

**Results:** At Baseline: Mean SBP of the whole group = 179±19 mmHg and Mean DBP= 83±17 mmHg. Three months after RAD: Mean systolic BP = 142±16 mmHg and Mean diastolic BP = 77±11 mmHg. There was significant reduction of the systolic blood pressure an average of 36 mmHg with (P <0.0001 ). Significant reduction in the diastolic BP by an average of 6 mmHg (P= 0.038). Subgroup analysis of patients with CKD: Mean SBP: 183±20 mmHg and Mean DBP: 79±12 mmHg. Three months after RAD: Mean SBP = 147±17 mmHg and Mean DBP = 75±10 mmHg. CKD patients had significant reduction of 36 mmHg in the systolic blood pressure (P- 0.005). There was no significant reduction in the DBP. During follow-up, renal function (eGFR) was unchanged.

**Conclusions:** 1. Bilateral RAD is associated with significant reduction in systolic and DBP in hypertensive patients resistant to multiple drug therapy.

2. CRF patients had significant reduction in systolic BP but no significant reduction in diastolic BP.

*Funding:* Government Support - Non-U.S.

**FR-PO529**

**Telmisartan Improves Blood Pressure Control, Albuminuria and Inflammation in Hypertensive Diabetic Patients Not Adequetely Controlled under ACE-Inhibitor Therapy** Juan F. Navarro-Gonzalez,[1,2] Mercedes Muros,[3] Carmen Mora,[2] Patricia Garcia Garcia,[1] María Adela Getino,[1] Ana Jarque,[1] Nieves Del Castillo Rodriguez,[1] Antonio Rivero,[1] Javier Garcia Perez.[1] *[1]Nephrology Service, Univ Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain; [2]Research Unit, Univ Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain; [3]Clinical Analysis Service, Univ Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain.*

**Background:** Renin-angiotensin system blockade is the mainstay of antihypertensive therapy in diabetic patients. The aim of this study was to evaluate the effect of the switch from angiotensin converting-enzyme inhibitors (ACEi) to angiotensin receptor blockers on blood pressure (BP), urinary albumin excretion (UAE) and inflammatory profile in diabetic patients not adequately controlled despite maximal dosage of ACEi therapy.

**Methods:** Twenty-seven patients with BP >130/80 mmHg and residual albuminuria were switched to Telmisartan (TEL, 80 mg/day). Serum concentrations of high-sensitive C-reactive protein (hsCRP), tumor necrosis factor-α (TNFa) and interleukin-6 (IL-6), as well as mRNA expression levels of TNFa and IL-6 in peripheral blood mononuclear cells (PBMC) were determined.

**Results:** After 4 months, BP decreased from 141±6/89±5 to 133±5/83±5 mmHg ($p<0.0001$), and UAE decreased by 18%. Reduction in UAE correlated with change in systolic BP ($r=0.76$, $p<0.05$). Serum hsCRP, TNFa and IL-6 reduced significantly by 15%, 9% and 16%, respectively ($p<0.001$). Urinary TNFα excretion decreased by 13% ($p<0.01$), whereas mRNA expression levels of TNFα and IL-6 in PBMC also experienced a significant reduction ($p<0.05$). A significant association was found between change in serum hsCRP ($r=0.82$) and TNFα ($r=0.59$), and urinary TNFα ($r=0.66$) with reduction in UAE. Finally, multivariate regression analysis showed that age and change in urinary TNFα were independently associated with reduction in UAE ($r=-0.29$ and $r=0.49$, $p<0.05$, respectively).

**Conclusions:** In conclusion, in hypertensive diabetic patients not adequately controlled under ACEi therapy, change to TEL resulted in a significant reduction in BP and UAE, and an improvement in inflammatory profile.

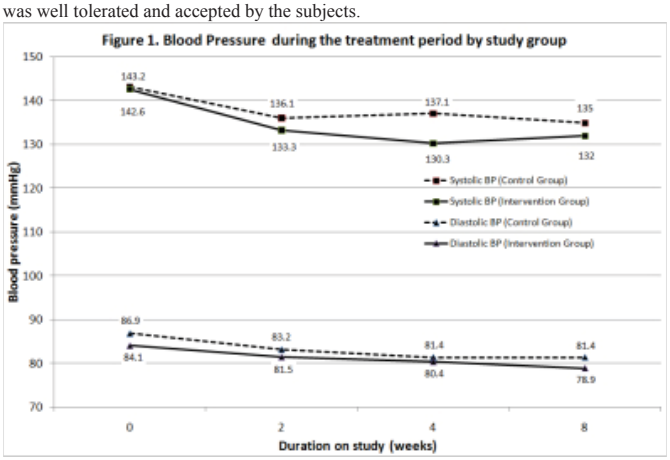
**FR-PO530**

**The Impact of Music Guided Deep Breathing Exercise on Hypertensive Control** Loke Meng Ong, Kum Keong Ng, Fei Ping Kow, Bakar Adlina, Dharminy Thurairatnam, Hadzlinda Z. *Ministy of Health, Penang, Malaysia.*

**Background:** Hypertension (HPT) remains poorly controlled despite drug therapy. Non-pharmacological intervention may enhance control of blood pressure. We conducted a single blinded, multicentre, randomized controlled trial over 8 weeks to evaluate the effects of deep breathing exercise and relaxation music on HPT.

**Methods:** Patients with Grade 1 essential HPT were recruited. They were randomized into control group (CG) or intervention group (IG) in a 1:1 ratio. Both groups listened to relaxation music CD at least 15 minutes once daily. In addition the IG also practised deep breathing exercise guided by the music. Training was conducted by qualified therapists. The primary end point was reduction in Diastolic blood pressure (DBP) at 8 weeks. The managing team was blinded to the treatment arm.

**Results:** 87 patients were recruited. The baseline characteristics were similar between groups. They had a mean age of 61 years, 51% were females and 54% had received more than one anti-HPT agents. The mean baseline BP was 143/86. 93% successfully completed the study. Compliance was good in both groups. There was a significant reduction in Systolic BP (SBP) & DBP from baseline at 8 weeks in both groups. (Fig. 1) Reduction in mean SBP was 10.5mmHg in CG compared to 8.3mmHg ($p< 0.001$) in IG while the mean DBP reduction was 5.2 mmHg ($p< 0.001$) in CG and 5.6 mmHg ($p< 0.001$) in IG. However, SBP & DBP reduction at 8 weeks did not differ significantly between groups. The absolute difference in SBP reduction from baseline in IG & CG was -2.2 (95% CI -7.8, 3.5) & DBP was -0.4 (95% CI -2.9, 3.6). Heart rate did not change significantly. Deep breathing exericse was well tolerated and accepted by the subjects.



**Conclusions:** Relaxation with music was associated with a clinically significant reduction in both SBP & DBP. Deep breathing exercise did not augment the benefit of music in BP control.

**FR-PO531**

**Subclinical Aldosterone Levels Help Distinguish between Future Aldosterone Producing Adenoma and Essential Hypertension** Austin Parker,[1] Kevin C. Abbott,[2] Lisa K. Prince,[2] Stephen W. Olson.[2] *[1]Nephrology Dept, Naval Medical Center Portsmouth, Portsmouth, VA; [2]Nephrology Dept, Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** Aldosterone and aldosterone to plasma renin activity (PRA) ratios are used for the biochemical evaluation of patients with refractory hypertension and incidentally identified adrenal adenomas. However, there is no single threshold of maximum sensitivity and specificity for the diagnosis of aldosterone producing adenoma (APA). Knowledge of subclinical aldosterone trends could improve current diagnostic capabilities.

**Methods:** We performed a DoD Serum Repository (DoDSR) retrospective case-control study to compare aldosterone levels months to years before the histopathologic diagnosis of 28 APA patients versus 82 age-, race-, sex-, and age-of-serum-matched control subjects with essential hypertension. We hypothesized that aldosterone levels would be elevated and rising prior to diagnosis. PRA levels could not be tested on these stored serum samples.

**Results:** A higher percent of APA patients had a serum aldosterone level >10 ng/dL compared to matched essential hypertension disease controls at <3 years (82% vs. 6%; $p<0.001$) and 3-11 years (47% vs. 11%; $p=0.001$) as well as >15 ng/dL at <3 years (59% vs. 0%; $p<0.001$) and 3-11 years (21% vs. 4%; $p=0.03$) prior to diagnosis. A greater percent of APA patients had a serum aldosterone rate of rise of > 0.25ng/dL/year (75% vs. 27%; $p<0.001$), >0.5ng/dL/year (50% vs. 17%; $p=0.001$), and >1ng/dL/year (29% vs. 6%; $p=0.004$).

**Conclusions:** Compared to control subjects with essential hypertension, APA patients more frequently have aldosterone levels > 10 ng/dL that continue to rise over time in the 11 years leading up to diagnosis. Knowledge of the subclinical serum aldosterone trajectory could help to better differentiate between essential hypertension and APA for patients undergoing a secondary hypertension evaluation or with an incidentally discovered adrenal adenoma.

*Funding:* Other U.S. Government Support

**FR-PO532**

**Low Glomerular Density Is a Characteristic Finding in Renal Biopsies of Hypertensive Nephrosclerosis with Massive Proteinuria** Kotaro Haruhara, Nobuo Tsuboi, Go Kanzaki, Kentaro Koike, Akira Fukui, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Hypertensive nephrosclerosis (HNS) is a secondary renal disease that may occur in individuals with hypertension. However, there are likely to be factors other than hypertension that contribute to the development of HNS since only a minority of hypertensive individuals manifest overt proteinuria. In this study, we explored the histological characteristics contributing to the development and progression of proteiuria in hypertensive patients.

**Methods:** Glomerular density (GD; glomerular number per renal cortical area) and mean glomerular volume (GV) in renal biopsies from HNS patients (eGFR>60) with mild (<1g/day) or massive (>1g/day) proteiuria were measured and compared with those in the autopsy kidneys from hypertensive patients without CKD. Renal biopsy specimens from kidney transplant donors (KTD) were also analyzed as healthy controls.

**Results:** The GD of HNS patients with massive or mild proteinuria was significantly lower than that from KTD. The GD of hypertensive patients without CKD was also significantly lower than that from KTD. Of note, the GD of HNS patients with massive proteiuria was significantly lower than those of HNS patients with mild proteiuria and hypertensive patients without CKD. These differences were still significant when global glomerulosclerosis (GGS) were included in the calculation of the GD. Moreover, the GV of both HNS with mild and massive proteinuria are significantly larger than that of KTD.

| | KTD n=34 | HNS; UPE≥1g n=15 | HNS; UPE<1g n=14 | Hypertensive patients without CKD n=35 |
|---|---|---|---|---|

**Conclusions:** These results suggest that a low GD is a renal histological characteristic of HNS with massive proteinuria.

**FR-PO533**

**Lipoprotein(a), an Independent Predictor of ARAS in High-Risk Patients**
Yanqing Mei,[1] Peng Xia,[1] Ling Qiu,[2] Xuejun Zeng,[3] Xuemei Li,[1] Limeng Chen.[1]
*[1]Nephrology Dept, Peking Union Medical College Hospital, Beijing, China; [2]Dept of Laboratory Medicine, PUMCH, Beijing, China; [3]Internal Medicine Dept, PUMCH, Beijing, China.*

**Background:** Lipoprotein(a) [Lp(a)] has been confirmed to be a prospective cardiovascular disease risk factor through large-scale meta-analysis. In this study, we aim to explore that whether Lp(a) is associated with occurrence of atherosclerotic renal artery stenosis (ARAS) among high-risk patients.

**Methods:** We divided consecutive 453 patients who underwent renal angiography into ARAS group (≥ 50%, n=169) and non-ARAS group (n=284). A control group (n=177) was collected among people receiving health checkup. Data collection included the age, sex, lipid profiles, renal function, and liver function. Multivariate logistic regression analysis was applied to explore that whether the clinical and biomedical parameters were associated with ARAS in these high-risk patients.

**Results:** We divided consecutive 453 patients who underwent renal angiography into ARAS group (≥ 50%, n=169) and non-ARAS group (n=284). A control group (n=177) was collected among people receiving health checkup. Data collection included the age, sex, lipid profiles, renal function, and liver function. The levels of Lp(a) were higher in ARAS group in comparison with the control group (median: 172.0 vs 92.0 mg/L, p<0.001). Lp(a) was positively correlated with hsCRP and LDL ($r$ = 0.217 and 0.231, p < 0.001, respectively) among high-risk patients. In comparison with non-ARAS group, the ARAS patients were older (67.1±10.2 vs 65.0±10.4, p=0.002) with higher levels of uric acid (371.0±91.7 vs 333.6±98.3 μmol/L, p=0.001) and lower eGFR (60.0±19.7 vs 68.4±19.7 mL/min/1.73m$^2$, p=0.002). Multivariate logistic regression revealed that Lp(a) (OR = 1.806, 95%CI 1.006, 3.245, p = 0.048) and uric acid (OR = 2.098, 95%CI 1.107, 3.978, p = 0.023) were independent predictors of ARAS among high-risk patients after adjustment of age and eGFR.

**Conclusions:** Lp(a) and uric acid are independently associated with ARAS among high-risk patients. Mei, Y and Xia, P contributed equally to this work.

**FR-PO534**

**Comparison of 24-Hour Blood Pressure Profile between Diabetic and Non-Diabetic Patients with Advanced Chronic Kidney Disease**
Pablo Marcos Braillard Poccard, Cesar Garcia-canton, Pilar Rossique, Ivan Chamorro, Agustin Toledo, Mar Lago, Ernesto Fernandez, Santiago Suria, Eduardo Baamonde, Dolores Checa. *Nephrology, Hospital Insular, Las Palmas, Gran Canaria, Spain.*

**Background:** Blood pressure is a factor in cardiovascular-related morbidity and in the progress of kidney failure in patients with ACKD.

**Methods:** The objective of our study was to offer a descriptive analysis of daily blood pressure profiles of incident ACKD patients through 24-hour ambulatory blood pressure monitoring (ABPM), as well as a comparison between diabetic and non-diabetic patients.

**Results:** The analysis included 547 patients, 64.3 years of age, 57.8% male, 68% diabetic, 44.6% history of cardiovascular disease (CVD). Diabetic patients were older and with worse CVD background. Diabetic patients had higher mean systolic blood pressure (MSBP) and lower mean diastolic blood pressure (MDBP), which resulted in similar mean blood pressure (MBP) in both groups, although with a significantly higher differential pulse pressure (PP) in diabetics.

| | Diabetic | Non diabetic | significance |
|---|---|---|---|
| MSBP | 137.1 | 127.9 | p<0.001 |
| MDBP | 69.7 | 74.9 | p<0.001 |
| MBP | 94.7 | 93.7 | p=0.368 |
| PP | 68.6 | 52.9 | p<0.001 |
| %dipper | 30.1 | 37.4 | P=0.09 |

The fact that diabetic patients had lower diastolic pressure could be accounted for by the use of antihypertensive drugs: 16% of non-diabetic patients used one or no drug, 31% of them used two drugs, 32% used three drugs and 21% used four or more drugs; whereas 3.5% of diabetic patients used one or no drug, 18.5% used two drugs, 41% used three drugs and 37% used four or more drugs. Noticeably, renin-angiotensin axis blockade occurred in 68% of diabetic as compared to 55% of non-diabetic patients (p<0.005).

**Conclusions:** In conclusion, this study revealed that diabetic patients had lower DBP, which could be explained by the use of antihypertensive treatments, and higher SBP, which could be explained by increased vascular stiffness due to older age, worse CVD background or vascular calcification due to diabetes, which result in reduced vascular distensibility and higher pulse pressure.

**FR-PO535**

**Percutaneous Renal Revascularization: A Long Term Follow-Up of 155 Procedures**
Daniel Kushnir, Jerome Marcusohn, Alon Antebi, Tatiana Tanasiychuk, Victor Frajewicki. *Dept of Nephrology and Hypertension, Carmel Medical Center, Haifa, Israel.*

**Background:** Arterial Hypertension and Renal Insufficiency may be improved by percutaneous intervention in patients with Renal Artery Stenosis (RAS) but the clinical benefit of such therapy is still obscure. The aim of the study is to evaluate the long term outcomes after renal artery intervention.

**Methods:** Files of patient who underwent intervention of the renal arteries at the Carmel Medical Center were retrospectively reviewed .

**Results:** Data of 143 patients (79 men and 64 women, mean age, 64±11 years) with RAS who underwent 155 interventions were reviewed. Main indications were Hypertension (70 %) and Renal Insufficiency (26.5 %). The stenosis was bilateral in 26 % and unilateral in 63 %; single kidney in 9 %. When atherosclerosis (90 %) was the cause of obstruction, a stent was placed. In 10 patients with Fibromuscular Dysplasia, an angioplasty was performed without stenting. Average stenosis was 81±15 %, which was ostial in 61 % of cases. Overall angiographic success rate was 92 %. Major complications occurred in 10 % of the procedures. Patients were followed for 96±42 months. Data were analyzed before the procedure, after 36 months and at the end of follow-up. Reduction of systolic (155±25, 145±23 and 134±21 mmHg, P=0.0013) and diastolic (84±12 mmHg, 78±11 and 72±9 mmHg, P=0.004) blood pressure was achieved. Blood pressure improved in 61 %, was unchanged in 18 % and worsened in 21% after 36 months. Serum creatinine of patients on dialysis were censored. Mean serum creatinine was unchanged (1.4±0.7, 1.5±0.8 and 1.5±0.9 mg/dl, NS). After 36 months creatinine improved in 16 %, was unchanged in 70 % and worsened in 14 % of patients. The use of anti- hypertensive drugs was reduced from 3.2±1.3 to 2.4±1.5, P=0.00001. Fifty three patients (37%) died during the observation period, of those 94 % had chronic kidney disease. Seventeen patients (12%) needed chronic renal replacement therapy.

**Conclusions:** Stenting of the renal arteries may be useful for treatment of hypertension in RAS without causing deterioration of renal function. Renal insufficiency patients require careful evaluation before intervention.

**FR-PO536**

**Prevalence of Obstetric Thrombotic Thrombocytopenic Purpura within 8,908 Consecutive Deliveries: A Not to Be Missed Diagnosis**
Yahsou Delmas,[1,2] Sebastien Helou,[1] Pierre Chabanier,[2,3] Anne Ryman,[2,4] Fanny Pelluard,[5] Dominique Carles,[5] Jacques Horovitz,[3] Paul Coppo,[6] Christian Combe.[1,2] *[1]Service de Néphrologie Transplantation Dialyse, CHU de Bordeaux, France; [2]Centre de Compétence des Microangiopathies Thrombotiques, CHU de Bordeaux, France; [3]Pôle Gynécologie-Obstétrique-et Biologie de la Reproduction, CHU de Bordeaux, France; [4]Service d'Hémostase Spécialisée, CHU de Bordeaux, France; [5]Service d'Anatomopathologie, CHU de Bordeaux, France; [6]Département d'Hématologie Clinique and Centre de Référence des Microangiopathies Thrombotiques, Hôpital Saint Antoine, Paris, France.*

**Background: Thrombotic Thrombocytopenic Purpura (TTP)** defined as A Disintegrin And Metalloprotease with ThromboSpondin type 1 domain 13 (ADAMTS13) activity <10% has an unknown prevalence among pregnant women with thrombocytopenia (Tp). Its recognition can lead to efficient prevention of maternal and fetal morbi-mortality.

**Methods:** In a tertiary obstetrical unit, TTP prevalence was assessed retrospectively among women with Tp≤75 G/L. ADAMTS13 functional activity was measured by *full von Willebrand Factor length* technique. ADAMTS13 inhibitor and anti-ADAMTS13 IgG were assessed in these patients.

**Results:** Among 8,908 deliveries over a 2-year period, 80 women had Tp≤75 G/L. Twenty had an identified etiology of Tp ( from TTP) and 11 were lost to follow-up. Among 49 remaining patients, ADAMTS13 activity was in the range of TTP in 4 patients (initially diagnosed HELLP syndrome); Tp spontaneously recovered few days after delivery in all women with TTP. Three primipara patients had sustained ADAMTS13 deficiency without inhibitor. Two of them lost their babies due to prematurity. Prophylactic plasma infusion enabled subsequent successful three pregnancies in two constitutive TTP women with improved placental histopathology.

**Conclusions:** 5% of women with Tp≤75 G/L in a tertiary obstetrical unit had TTP. Platelet normalization after delivery cannot eliminate TTP. Prophylactic plasma therapy during pregnancy in constitutive TTP allows proportional placenta pathology improvement and good mother and child outcome.

**FR-PO537**

**Angiographic Intervention for Renal Artery Stenosis – Predictors of Favourable Renal Response**
Haridian Sosa Barrios,[1] Parthipan Sivakumar,[1] Damien Ashby,[1] Wladyslaw M. Gedroyc,[2] Mohamad S. Hamady,[2] Neill D. Duncan.[1] *[1]Renal and Transplant Services, Hammersmith Hospital, Imperial College, United Kingdom; [2]Interventional Radiology, St. Mary's Hospital, Imperial College, United Kingdom.*

**Background:** Renovascular disease is increasingly recognised as a cause of renal impairment but the role of endovascular intervention in this setting is unclear. The ASTRAL (Angioplasty and Stenting for Renal Artery Lesions) trial established that revascularisation does not improve renal prognosis in the average patient, but many clinicians believe that there is a subgroup of patients who benefit.

**Methods:** In this retrospective single-centre cohort study we included all patients who had renal angioplasty during a 2 year period for whom 12 month follow-up data were available. Patient outcomes were defined according to mean GFR in the year post intervention, compared to baseline: group A improved by 5ml/min, or stabilised after a decline of 5ml/min in the previous year; group B remained the same; group C deteriorated by at least 5ml/min.

**Results:** Ninety-four patients (aged 49-86, 72% male) underwent angioplasty and stent insertion which was technically successful in all cases, and bilateral in 29%. Change in renal function post procedure was symmetrically distributed, with median(IQR) GFR change -2.0(-4.3 to 1.8)ml/min, and with 25.5, 59.6 and 14.9% of patients in groups A, B, and C respectively.

Group A patients tended towards higher GFR during the 12 months prior to intervention (45.0 vs 39.8ml/min, p=0.14), but there were no differences in age or gender between outcome groups. Favourable (group A) outcome was observed more frequently in those with GFR>30ml/min (29 vs 14%, p=0.25), and in those undergoing bilateral intervention (33 vs 22%, p=0.30).

**Conclusions:** Heterogeneity of outcome can be expected after intervention for renal artery stenosis. Patients benefitting from the procedure are not clearly distinguishable from the remainder by simple clinical criteria, but higher GFR and bilateral disease were weakly associated with a favourable response.

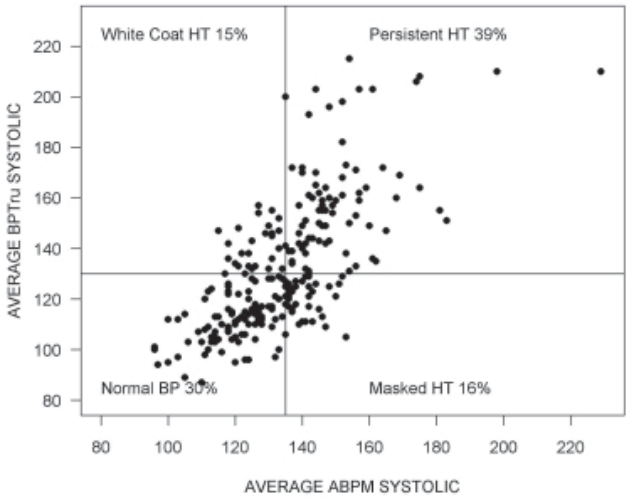
## FR-PO538

**Correlation between Automated Office Blood Pressure and Ambulatory Blood Pressure Monitoring in CKD** George Thomas, Jesse D. Schold, Susana Arrigain, Joseph V. Nally, Sankar D. Navaneethan. *Cleveland Clinic.*

**Background:** Automated office blood pressure monitors (AOBP) have previously been shown to correlate with Ambulatory blood pressure monitors (ABPM) in the general population. We examined the correlation of AOBP with ABPM in CKD patients seen at our institution.

**Methods:** We included 238 CKD patients who had both AOBP and ABPM measured within 2 weeks of each other. Automated office BP was measured using the BPTru device ( VSM MedTech Ltd, Coquitlam, BC, Canada) and is the average of five automated consecutive readings. Ambulatory BP was measured every 20 minutes during the day (6:00 AM to 10:00 PM, "awake" blood pressure) using automated BP monitors on the arm (Spacelabs, Issaquah, Washington, USA). We used Linn's concordance coefficient to assess AOBP and ABPM. We compared characteristics of patients with concordant and discordant data using t-tests and Chi-square tests.

**Results:** We identified 238 patients who fit the above criteria; mean age was 64.2 years, with more females (62%) and more Caucasians (78%). The concordance rates between BPTru and awake ABPM (systolic and diastolic pressure) were 0.65 (95% CI 0.58, 0.71) and 0.64 (95% CI 0.56, 0.71) respectively. Figure 1 shows the scatterplot of BPTru (systolic) and awake ABPM (systolic).



White coat hypertension (WHT) and masked hypertension (MHT) was seen in 15% and 16% of this population, respectively. In our analysis, patients who had WHT and MT were older (67.5 vs. 62.7 years, p=0.03) and were more likely to have associated malignancy (37.8% vs. 21.3%,p=0.008) compared to those who had concordant values. Further, BPTru values among African Americans had higher concordance with ABPM.

**Conclusions:** BPTru correlated moderately well with awake ambulatory systolic BP in patients with CKD. Our data also suggest that BPTru readings from older patients and Caucasians should be interpreted with caution.

## FR-PO539

**Human Kidney Proximal Tubule Epithelial Cells (PTEC) Modulate Autologous Immune Responses in T, B and Dendritic Cells (DC)** Sandeep Sampangi,[1,2,3] Andrew J. Kassianos,[1,2] Xiangju Wang,[1,2] Helen G. Healy,[1,2] Ray Wilkinson.[1,2,3,4] *[1]Conjoint Kidney Laboratory, Pathology Queensland; [2]Dept of Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Australia; [3]Queensland Univ of Technology, Brisbane, Australia; [4]Medical School, Univ of Queensland, Brisbane, Australia.*

**Background:** We have previously demonstrated that PTEC actively participate in the kidney disease process by down modulating autologous human T, B and DC responses within an inflammatory setting (Wilkinson et al NDT 2011, 2013). We now analyse the mechanisms of this suppressive effect further.

**Methods:** B cells, T cells and monocytes were cultured with interferon-activated PTEC, to mimic the inflammatory setting, in the presence of 1) poke weed mitogen (PWM) or toll-like receptor (TLR) agonist R848, 2) phytohaemagglutinin (PHA) or anti-CD3/28 and 3) GM-CSF and IL-4, respectively. The numbers of B cells producing Ab were analyzed using isotype specific ELISPOT. Readouts for T cells and DC included proliferation, antigen expression and cytokine secretion in contact dependent or independent (transwell) cultures.

**Results:** PTEC significantly reduced the number of B cells producing Ab in response to TLR stimulation. PTEC also significantly down modulated T cell proliferation which was restored when cell contact was blocked by a transwell membrane. Similarly, PTEC down modulation of monocyte-derived DC (MoDC) differentiation was partially ablated when the MoDC and PTEC were separated by a transwell membrane, resulting in mature MoDC as defined by loss of monocyte marker CD14 and no or low IL-10 secretion. However, the decreased expression of antigen presentation and co-stimulatory molecules HLA-DR/CD86 and increased expression of the inhibitory signaling molecule PD-L1, seen when MoDC are in contact with PTEC, was not altered upon transwell culture.

**Conclusions:** These results demonstrate for the first time that human autologous PTEC can regulate B cell Ab production and that their modulatory effects on T cells and DC are, at least in part, contact dependent. We are now analyzing the molecular signatures of cell dependent and independent contact to identify putative therapeutic targets.

*Funding:* Government Support - Non-U.S.

## FR-PO540

**The Reactivity of Renal Dendritic Cells for Prostaglandin E2** Shinya Nagasaka, Toru Iwahori, Seiichiro Higo, Go Kanzaki, Kayori Tsuruoka, Yusuke Kajimoto, Akira Shimizu. *The Dept of Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

**Background:** Prostaglandin E2 (PGE2) has been shown to mediate autoimmunity disease to expand Th17 cells via dendritic cells in animal models of multiple sclerosis, rheumatoid arthritis, inflammatory bowel diseases and allergic skin disorders. Recently, the dendritic cell specifically localized in kidney (renal dendritic cells: RDC) was identified. Despite RDCs have been recognized as the earliest producers of pro-inflammatory cytokines in renal ischemia and experimental unilateral ureter ligation, suggesting a sentinel role against kidney injury, their role in reactivity for PGE2 on renal inflammatory disease is still incompletely understood. Here we compared the reactivity between RDCs and splenic DCs (as general DCs) in response to PGE2.

**Methods:** RDCs and splenic DCs were purified by magnetic bead-labeled anti-mouse CD11c antibodies from mouse kidney, and stimulated with 1 μg/ml of LPS in the presence or absence of 100 nM of PGE2. After LPS stimulation, the expressions of PGE2 receptors (EP1, EP2, EP3, and EP4), cyclooxygenase-2 (Cox-2), membrane-associated PGE synthase-1 (mPGES-1), and pro-inflammatory cytokines were measured by real-time PCR.

**Results:** The expression of EP4, one of the PGE2 receptors and IL-12p35 in RDCs were more increased in the presence of PGE2 than in splenic DCs, whereas we obtained no change of IL-12p40 expression. Furthermore, in RDCs, the expressions of Cox-2 and mPGES-1 which associated with PGE2 synthesis were up-regulated in the presence of PGE2 upon LPS stimulation.

**Conclusions:** RDCs apparently had distinct characteristics from splenic DCs. It is suggested that RDC enhances the production of pro-inflammatory cytokine in the presence of PGE2 which is synthetized in renal disease, and therefore regulates inflammatory response in kidney via autocrine loop of PGE2 through the induction of Cox-2 and mPGES-1 expression.

*Funding:* Government Support - Non-U.S.

## FR-PO541

**Cytokines Accentuate Synthesis of Galactose-Deficient IgA1 in IgA Nephropathy by Dysregulating C1GalT1 and ST6GalNAc-II Enzymes** Hitoshi Suzuki,[1,2] Milan Raska,[3] Koshi Yamada,[1,2] Zina Moldoveanu,[1] Bruce A. Julian,[1] Robert J. Wyatt,[4] Yasuhiko Tomino,[2] Ali G. Gharavi,[5] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Juntendo Univ Faculty of Medicine, Tokyo, Japan; [3]Palacky Univ in Olomouc, Olomouc, Czech Republic; [4]Univ of Tennessee Health Science Center, Memphis, TN; [5]Columbia Univ, New York, NY.*

**Background:** IgA nephropathy (IgAN) is characterized by renal immunodeposits containing IgA1 with galactose (Gal)-deficient *O*-glycans (Gd-IgA1). IgA1-producing cell lines from patients with IgAN (IgAN cells), but not those from healthy controls (HC cells), secrete Gd-IgA1 with *O*-glycans with terminal or sialylated *N*-acetylgalactosamine (GalNAc). The aberrant glycans constitute the neoantigen that leads to formation of nephritogenic immune complexes. As clinical disease onset and activity often coincide with mucosal infections and dysregulation of cytokines was described in IgAN, we hypothesized that cytokines may affect IgA1 *O*-glycosylation.

**Methods:** We used IgAN cells and HC cells to assess whether IgA1 *O*-glycosylation is altered by cytokines. To confirm the roles of specific glycosyltransferases in the production of Gd-IgA1, we knocked-down the C1GalT1 and ST6GalNAcII genes by siRNA.

**Results:** Of the eight cytokines tested, only interleukin-6 and, to a lesser degree, interleukin-4 significantly increased production of IgA1 and the degree of galactose deficiency of IgA1; changes in IgA1 *O*-glycosylation were robust for the IgAN cells. Both cytokines reduced galactosylation of the *O*-glycan substrate directly via decreased expression of the galactosyltransferase C1GalT1, and, indirectly, via increased expression of the sialyltransferase ST6GalNAc-II (sialylation prevents subsequent galactosylation by C1GalT1). siRNA knock-down of the corresponding gene and in vitro enzyme reactions confirmed these findings.

**Conclusions:** Interleukin-6 and interleukin-4 accentuated galactose deficiency of IgA1 via coordinated modulation of key glycosyltransferases. These data provide a mechanism to explain increased immune-complex formation and disease exacerbation during mucosal infections in patients with IgAN.

*Funding:* NIDDK Support

**FR-PO542**

**Pathogenic Role of IgA1-Containing Immune Complexes in IgA Nephropathy** Hitoshi Suzuki,[1] Yusuke Suzuki,[1] Kenji Satake,[1] Bruce A. Julian,[2] Jan Novak,[2] Yasuhiko Tomino.[1] *[1]Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Medicine and Microbiology, Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** IgA nephropathy (IgAN) is an autoimmune glomerulonephritis wherein immune complexes (IC) composed of galactose-deficient IgA1 (Gd-IgA1; autoantigen) and anti-glycan IgG autoantibodies deposit in the glomeruli. Serum levels of Gd-IgA1 as well as anti-glycan IgG autoantibodies, responsible for the formation of ICs with Gd-IgA1, are elevated in patients with IgAN. However, the pathogenic roles of Gd-IgA1-containing IC and mechanisms of immune deposits in the mesangium are still obscure.

**Methods:** Polymeric Gd-IgA1 myeloma protein and recombinant anti-glycan IgG were used to form IC (Gd-IgA1-IgG IC) in vitro to inject *i.v.* into nude mice. After various time intervals, mice were sacrificed; blood and urine were collected to determine serum IgA1 and IgG, urinary protein and creatinine and hematuria. Also, to assess the potential capacity of these IC to activate endothelial cells, human renal glomerular endothelial cells (HRGEC) were co-cultured with Gd-IgA1 alone or Gd-IgA1-IgG IC for 72 h. Then, transcript levels of TNF-α, TGF-β, IL-6, ICAM1 and E-selectin in HRGEC were measured by RealTime PCR.

**Results:** Gd-IgA1 and anti-glycan IgG formed IC that deposited with murine C3 in the mesangium and in small amounts in the subendothelial area of the glomerular capillaries, and induced hematuria and proteinuria. In control mice injected with only Gd-IgA1 or Gd-IgA1 with IgG from a healthy control, IgA1 deposited only transiently and did not cause tissue injury. After stimulation with Gd-IgA1-IgG IC in HRGEC, transcript levels of TNF-α, ICAM-1 and E-selectin were upregulated (P<0.01).

**Conclusions:** Our studies confirmed the role of Gd-IgA1-IgG-containing IC in the pathogenesis of IgAN and induction of proteinuria and hematuria. Furthermore, the Gd-IgA1-IgG IC may bind to glomerular endothelial cells and induce release of pathogenic cytokines and chemokines.

**FR-PO543**

**IgA Antibodies to Glomerular Endothelial Cells in Patients with Lupus Nephritis: Correlations with Renal Injury** Kazuo Takahashi, Ayako Kondo, Daisuke Hirano, Shin'ichi Akiyama, Hiroki Hayashi, Shigehisa Koide, Midori Hasegawa, Yoshiyuki Hiki, Shunji Yoshida, Keiji Miura, Yukio Yuzawa. *Fujita Health Univ, Toyoake, Aichi, Japan.*

**Background:** Although anti-endothelial cell antibodies (AECA) against human umbilical vein endothelial cells (HUVEC) have been detected in systemic lupus erythematosus (SLE), their pathological role remains unclear. Because antigens expressed on the endothelial cell (EC) surface are pivotal for autoimmune reactions, methods that detect antibodies only to EC surface molecules are required. Thus, we developed a solubilized cell surface protein capture enzyme-linked immunosorbent assay (CSP-ELISA) that is able to detect antibodies against membrane proteins. We also aimed to elucidate the clinical importance of AECA for tissue-specific EC.

**Methods:** Sera from 52 patients with biopsy-proven lupus nephritis (LN), 25 with SLE without renal involvement (non-LN SLE), 10 disease controls (DC) and 81 healthy controls (HC) were tested for IgG- and IgA-AECA to human glomerular EC (HGEC) by CSP-ELISA.

**Results:** Titers of IgG- and IgA- AECA to HGEC were significantly higher in LN and non-LN SLE patients than in the combined DC and HC ($P < 0.001$) groups. The level of IgG-AECA did not correlate with active lesions, but the level of IgA-AECA to HGEC did correlate with histological evidence of active lesions in LN patients ($P < 0.001$). Immunocytochemical analysis showed AECA recognized membrane proteins on HGEC. The significant correlation of titer of AECA to both HGEC and HUVEC (R = 0.95 for IgG-, 0.93 for IgA-AECA, respectively) indicated AECA in LN patients recognize membrane proteins expressed on HGEC and HUVEC. To identify specific antigens against AECA, biotinylated CSPs were incubated with sera from LN patients with high titers of IgG-AECA, immunoprecipitated with immobilized protein G followed by immobilized avidin, and blotted with NeutrAvidin. A 150-kDa protein band that shifted to a 55-kDa protein band under reducing conditions was detected in patients with LN, but not in HC.

**Conclusions:** IgA-AECA was observed to be associated with pathological activity in LN. These EC membrane components recognized by AECA may be linked with the pathogenesis of LN.

**FR-PO544**

**Enzymatic Sialylation of IgA1 Hinge-Region: Pathogenic Role of Sialic Acid in IgA Nephropathy (IgAN)** Kazuo Takahashi,[1,2] Milan Raska,[1,3] Milada Stuchlova-Horynova,[1,3] Alena Kasperova,[1,3] Stacy D. Hall,[1] Yoshiyuki Hiki,[2] Yukio Yuzawa,[2] Zina Moldoveanu,[1] Bruce A. Julian,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Fujita Health Univ, Toyoake, Japan; [3]Palacky Univ in Olomouc, Olomouc, Czech Republic.*

**Background:** Patients with IgAN have high serum levels of galactose (Gal)-deficient IgA1; some hinge-region (HR) *O*-glycans consist of terminal *N*-acetylgalactosamine (GalNAc) with or without *N*-acetylneuraminic acid (NeuAc, sialic acid). Sialylation of GalNAc blocks subsequent galactosylation. IgA1-producing cells from IgAN patients have increased activity of α2,6 sialyltransferase (ST6GalNAc) that sialylates GalNAc. Thus, premature sialylation of GalNAc may be favor production of Gal-deficient IgA1.

**Methods:** We established protocols for enzymatic α2,6-sialylation or α2,3-sialylation (ST3Gal1; adds NeuAc to galactose) of IgA1 *O*-glycans of an asialo-IgA1 myeloma protein (Ale) that mimics the Gal-deficient IgA1 in IgAN patients. The products were assessed by high-resolution mass spectrometry and ELISA with the GalNAc-specific lectin from *Helix aspersa* (HAA).

**Results:** Changes in SDS-PAGE mobility of the IgA1 heavy chain indicated that both enzymes were active. Enzymatic sialylation of the myeloma protein generated sialylated IgA1 that mimics the circulating nephritogenic IgA1 in IgAN patients, characterized by α2,6-sialylated GalNAc, or the IgA1 typical for healthy controls, characterized by an α2,3-sialylated Gal attached to GalNAc. Lectin ELISA was used to assess binding to the IgA1 before and after the enzymatic reactions. α2,6- or α2,3-sialylation of IgA1 markedly decreased reactivity with the HAA lectin. Neuraminidase treatment (removes sialic acid) completely restored the level of lectin reactivity. Thus, lectin binding to GalNAc decreased after sialylation of a neighboring glycan in the cluster of *O*-glycans of the IgA1 hinge region.

**Conclusions:** Neuraminidase should be used to treat serum IgA1 before a lectin assay to assess the content of hinge-region Gal-deficient GalNAc. Our *in vitro* enzymatic sialylation model will be useful to study the biological roles of NeuAc in the IgA1 HR in the pathogenesis of IgAN.

*Funding:* NIDDK Support, Other NIH Support - NIGMS, Government Support - Non-U.S.

**FR-PO545**

**Proteomic Analysis of Engineered IgA1-IgG Immune Complexes Reveals Association with Activated Complement C3** Nicolas Maillard, Leeann Boerma, Stacy D. Hall, Zhi Qiang Huang, Michal Mrug, Zina Moldoveanu, Bruce A. Julian, Matthew B. Renfrow, Jan Novak. *Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** In IgA nephropathy (IgAN), C3 colocalizes with IgA in mesangial deposits. Deletion of CFHR1,3 genes has been recently described to protect from the occurrence of IgAN, highlighting the contribution of complement alternative pathway (AP). Using an *in vitro* model of polymeric galactose-deficient (Gd) IgA1 with recombinant antiglycan IgG derived from an IgAN patient in immune complexes (ICs) formed in the presence of serum, we identified and characterized by proteomic analyses complement C3 products associated with the complexes.

**Methods:** ICs were formed overnight at 4°C, using purified Gd- polymeric IgA1 (pAle) myeloma protein, recombinant antiglycan IgG (r1123), and IgA- and IgG-depleted serum of a healthy control. High-molecular-mass fractions (HMMFs; >700 kDa) were isolated by size-exclusion chromatography. The fractions that stimulated proliferation of cultured human mesangial cells were pooled, concentrated, and fractionated by SDS-PAGE for proteomic analysis. After silver staining, protein bands were excised, digested by trypsin, and analysed by high-resolution tandem mass spectrometry (LTQ OrbitrapVelos; MS/MS). Identification of proteins was allowed by use of MASCOT and SEQUEST algorithms.

**Results:** Proteomic analysis revealed that C3 α and β chain elements were present in the active ICs and only low amount of β chain was in the corresponding fractions in negative control (serum only). Amino-acid sequence obtained by MS/MS combined with information on the molecular mass of corresponding bands from SDS-PAGE identified iC3b, C3c, and C3dg (confirmed by anti-C3 immunoblotting). The presence of these low-molecular-mass products in HMMFs can only be explained by their binding to ICs. These results thus provide evidence that biologically active IgA1-ICs activate complement C3 and associate with C3 degradation fragments. iC3b, C3c, and C3dg are the products of the action of factor I and H, suggesting a critical role of regulators in the activation of complement AP in IgAN.

**Conclusions:** Soluble engineered IgA1 – IgG ICs can bind C3 elements *in vitro*.

**Prevention of Formation of IgA1-Containing Immune Complexes in IgA1 Nephropathy** Alena Kasperova,[1,2] Hiroyuki Ueda,[1] Milada Stuchlova-Horynova,[1,2] Tyler J. Stewart,[2] Matthew B. Renfrow,[2] Bruce A. Julian,[2] Jan Novak,[2] Jiri F. Mestecky,[2] Milan Raska.[1,2] *[1]Immunology, Faculty of Medicine, Palacky Univ, Olomouc, Czech Republic; [2]Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** IgA nephropathy (IgAN), the most common primary glomerulonephritis in the world, is characterized by mesangial deposits enriched for galactose-deficient IgA1 (Gd-IgA1). These immunodeposits likely originate from circulating immune complexes

consisting of Gd-IgA1 bound by IgG and/or IgA antibodies specific for terminal *N*-acetylgalactosamine (GalNAc) in the *O*-linked glycans in the Gd-IgA1 hinge region. Such circulating immune complexes likely activate mesangial cells upon glomerular deposition, thus inciting renal injury. We tested the hypothesis that a GalNAc-containing competitor will prevent formation of Gd-IgA1-IgG immune complexes.

**Methods:** We tested two potential competitors of immune-complex formation based on non-glycosylated IgA1 heavy chain and its CH1-CH2 fragment. The recombinant proteins were produced in *E. coli*, purified, and glycosylated (GalNAcosylated) *in vitro* using recombinant GalNAc-transferase 2. The reaction products were analyzed by lectin immunoblotting and mass spectrometry. Sera of IgAN patients containing anti-glycan IgG antibodies were supplemented with Gd-IgA1, with or without a competitor, and formation of immune complexes was assessed by ELISA.

**Results:** Supplementation of sera of IgAN patients with Gd-IgA1 induced formation of new immune complexes. GalNAcosylated competitors reduced formation of such complexes by 5-20%. The inhibition was dose-dependent and glycan-specific, because non-GalNAcosylated inhibitors did not affect formation of new immune complexes.

**Conclusions:** GalNAc-containing competitors can interfere with binding of Gd-IgA1 and anti-glycan IgG to form an immune complex *in vitro*. This finding may offer a new approach for disease-specific therapy of IgAN.

## FR-PO547

**Clinical Impact of Tonsillar APRIL on the Severity of IgA Nephropathy** Masahiro Muto,[1] Yusuke Suzuki,[1] Hitoshi Suzuki,[1] Kensuke Joh,[2] Shozo Izui,[3] Bertrand Huard,[3] Yasuhiko Tomino.[1] *[1]Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Sendai Shakaihoken Hospital, Sendai, Japan; [3]Univ of Geneva, Geneva, Switzerland.*

**Background:** A proliferation-inducing ligand (APRIL) is a critical mediator for antibody-producing plasma cell survival. Because immunological disorders in mucosal immunity are recently discussed in the pathogenesis of IgA nephropathy (IgAN), we investigated the clinical impact of mucosal APRIL expression in IgAN.

**Methods:** In addition to clinical background before and after tonsillectomy, the expressions of APRIL and its receptors (TACI; transmembrane activator and calcium modulator cyclophilin ligand interactor, BCMA; B-cell maturation antigen) in tonsils from IgAN patients ($n$=56) and control patients (chronic tonsillitis, $n$=12) were evaluated by real-time PCR, immunohistochemistry (IHC) and flow cytometric analysis (FCM). For IHC and FCM, polyclonal rabbit anti-APRIL antibody specifically recognizing APRIL-producing cells (Stalk-1) was used.

**Results:** Tonsillar transcript levels of APRIL and its receptors were significantly higher in IgAN than those of control ($P$<0.05). IHC revealed that Stalk-1$^+$cells in IgAN were detected not only in the subepithelial area but also germinal centers (GC) much more than those in control. Percentage of Stalk-1$^+$GC (27.4±21.3%) in IgAN patients was significantly higher than that in control (7.2±6.81%, $P$=0.0005) and correlated with amount of proteinuria ($P$=0.0017) and treatment responses, such as decrease of proteinuria ($P$=0.0003). Combined IHC and FCM analysis revealed that CD11c$^+$ dendritic cells and CD19$^+$ B cells are the major cell type of APRIL-producing cells in subepithelial area and GC, respectively in patients with IgAN. Moreover, in case of high percentage of Stalk-1$^+$GC, serum levels of IgA containing immune complexes (IC) were decreased after the tonsillectomy.

**Conclusions:** Up-regulation of tonsillar APRIL impacts on the disease activity in IgAN. This overexpression may involve long-term survival GC B cells responsible for the production of nephritogenic IgA/IgA IC.

## FR-PO548

**microRNA-155 Deficiency in Peripheral Lymphocyte Is Related to IgA Nephropathy** Xiaolei Chen, Wei Qin, Zi Li, Junming Fan. *Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

**Background:** MicroRNA-155 (miR-155) is an important immune regulator involves in lymphocyte homeostasis, which is key pathogenesis of IgA nephropathy (IgAN). miR-155 level in peripheral lymphocytes of IgAN patient was studied in this study.

**Methods:** Forty biopsy-proven IgAN patients and 15 unrelated healthy controls were included. Expression of miRNAs in peripheral lymphocyte was determined using Exiqon microRNA microarray. Realtime RT-PCR of miR-155 was performed. The expression level of Foxp3, a regulator of miR-155, was also measured. Treg and Th17 cell ratio was measured by flowcytometry. Correlation between miR-155, Foxp3 expression level, Treg/Th17 ratio and clinical indexes, such as proteinuria, hematuria, renal function and albumin level was analyzed.

**Results:** Microarrayindicated that in 1035 microRNAs successfully analyzed, 533 are upregulated and 499 are downregulated compared with normal controls. The expression level of miR-155 in IgAN patients was dramatically lower than normal control (fold change: -0.61), which was further confirmed by realtime RT-PCR (IgAN 0.197±0.07 vs Control 0.796±0.13, p<0.01). Significantly correlation between miR-155 and Foxp3 expression level was also noticed (R=0.681, p<0.001). A significant correlation was also observed between Treg/Th17 ratios. Further study showed that proteinuria and hematuria were significantly correlated with miR-155 level (proteinuria: r=-0.594, p<0.001, hematuria: r=-0.590, p<0.001). However, no apparent correlation was observed in serum creatinine, BUN,Cystatin-C and albumin. Moreover, miR-155 expression level is also related to the severity of renal pathology changes.

**Conclusions:** Remarkable lower expression of peripheral lymphocytes miR-155 was observed in IgAN patients, which correlates with proteinuria, hematuria and pathological grade, which suggests that miR-155 might play important roles in the pathogenesis of IgAN and might be a potential biomarker of the disease.

## FR-PO549

**Aberrant *O*-Glycosylation of IgA1 in IgA Nephropathy (IgAN) and the Role of Sialyl-Tn Antigen** Tyler J. Stewart,[1] Hitoshi Suzuki,[2] Milan Raska,[3] Kazuo Takahashi,[4] Koshi Yamada,[2] Milada Stuchlova-Horynova,[3] Bruce A. Julian,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Juntendo Univ, Tokyo, Japan; [3]Palacky Univ, Olomouc, Czech Republic; [4]Fujita Health Univ, Toyoake, Japan.*

**Background:** IgAN is associated with galactose deficiency of circulatory IgA1 hinge-region (HR) *O*-glycans. Previous data revealed enhanced α2,6 sialylation of *O*-linked GalNAc and suggested involvements of ST6GalNAc-II in aberrant IgA1 *O*-glycosylation in IgAN. Using several complementary approaches, we tested whether premature sialylation by ST6GalNAc-II can inhibit the addition of β1,3-linked galactose to IgA1 HR by C1GalT1.

**Methods:** *In vitro* reactions of purified recombinant ST6GalNAc-II and C1GalT1 with IgA1 HR synthetic glycopeptides (previously GalNAcosylated by GalNAc-T2) or desialylated IgA1 were characterized using high-resolution mass spectrometry (MS) or ELISA. Relative MS quantification of different HR glycoforms using total ion counts was performed to determine inhibition of C1GalT1 galactosylation by previous ST6GalNAcII sialylation at the molecular level. Lectin ELISA was used to determine the proportion of terminal (unoccupied) GalNAc.

**Results:** Using lysates from IgA1-secreting B cells from IgAN patients and healthy controls as the source of ST6GalNAc-II or C1GalT1, we performed *in vitro* enzymatic sialylation of desialylated IgA1 followed by galactosylation. Assessment of glycosylation by lectin ELISA revealed that sialylation of IgA1 by ST6GalNAc-II prevented effective galactosylation by C1GalT1. We also plan to confirm these findings by using recombinant enzymes. We have now produced recombinant ST6GalNAc-II and C1GalT1 and demonstrated that both enzymes are active and quantified relative amounts of various HR glycoforms after single glycosyltransferase reactions.

**Conclusions:** Our results suggest that a steric hindrance imposed by the addition of α2,6-linked sialic acid to IgA1 HR inhibited C1GalT1 enzymatic galactosylation of IgA1. Thus, overproduction of sialyl-Tn antigen prior to galactosylation could result in galactose-deficient IgA1 HR, the phenotype associated with IgAN.

## FR-PO550

**In Patients with IgA Nephropathy (IgAN) and Healthy Controls Cells Expressing Mucosal Homing Receptors Secrete Polymeric J-Chain-Containing but Differentially *O*-Glycosylated IgA1** Hiroyuki Ueda,[1] Zina Moldoveanu,[1] Hitoshi Suzuki,[2] Koshi Yamada,[2] Bruce A. Julian,[1] Jiri F. Mestecky,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Juntendo Univ, Tokyo, Japan.*

**Background:** Patients with IgAN have elevated levels of circulatory IgA1 with some *O*-glycans that are galactose-deficient (Gd-IgA1). This IgA1 forms pathogenic immune complexes and is mostly polymeric, indicating a possible mucosal association. However, the origin and nature of the Gd-IgA1-producing cells are not well understood. To address these questions, we developed protocols for separation of cells expressing specific mucosal homing receptors and analyses of IgA1 secreted by these cells.

**Methods:** Using immortalized IgA1-secreting cells derived from the circulation of IgAN patients (IgANP) and healthy controls (HC), we isolated by FACS sorting the cell populations expressing either gut- or upper respiratory tract-homing receptors, α4β7 integrins and L-selectin, respectively. Then, we characterized the molecular forms and *O*-glycosylation of IgA1 secreted by these cells using SDS-PAGE separation under non-reducing conditions followed by Western blotting with anti-heavy chain and anti-J chain antibodies and lectin ELISA, respectively.

**Results:** IgA1 secreted by cells from HC was predominantly monomeric, whereas IgA1 from cells of IgANP was enriched for J chain-containing polymers. IgAN-derived and HC-derived cell populations expressing mucosal homing receptors (α4β7 or L-selectin) secreted predominantly polymeric IgA1. However, only the IgANP cells produced Gd-IgA1, suggesting that galactose deficiency is not an exclusive characteristic of polymeric glycoforms, but may be a disease-specific feature.

**Conclusions:** Separation of circulating IgA1-secreting cells according to specific homing receptors, combined with analyses of molecular forms and *O*-glycosylation of IgA1 at the molecular level, may reveal the origin and nature of the cells producing Gd-IgA1 that plays a key role in the pathogenesis of IgAN.

## FR-PO551

**Production of Aberrantly Glycosylated IgA1 in IgA Nephropathy Is Associated with Abnormal Distribution of ST6GalNAc-II in Golgi Apparatus** Milada Stuchlova-Horynova,[1,4] Zora Smrzova,[2] Miroslav Ovecka,[1] Zina Moldoveanu,[4] Bruce A. Julian,[4] Hitoshi Suzuki,[3] Jiri F. Mestecky,[4] Jan Novak,[4] Milan Raska.[1,4] *[1]Palacky Univ, Olomouc, Czech Republic; [2]Veterinary Research Institute, Brno, Czech Republic; [3]Juntendo Univ, Tokyo, Japan; [4]Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** Patients with IgA nephropathy (IgAN) have IgA1 with galactose (Gal)-deficient *O*-glycans which are recognized by anti-glycan antibodies, resulting in formation of circulating immune complexes (CIC) that deposit in glomeruli. *O*-glycosylation of IgA1 in the Golgi apparatus is initiated by attachment of GalNAc residues to the hinge region by GalNAc-transferases, followed by attachment of Gal to GalNAc residues by galactosyltransferase C1GalT1. Sialic acid (SA) may be attached to Gal by α2,3-sialyltransferase and/or to GalNAc by α2,6-sialyltransferase-II (ST6GalNAc-II). Premature sialylation of IgA1 by the attachment of SA to GalNAc blocks attachment of Gal thus creating Gal-deficient GalNAc. Premature sialylation may be caused by increased concentration of ST6GalNAc-II and/or changes in the enzyme distribution within the Golgi, i.e., moving toward *cis*-Golgi. We generated ST6GalNAc-II-specific monoclonal antibody (mAb) to track this enzyme through the Golgi apparatus.

**Methods:** ST6GalNAc-II-specific mouse mAb was produced by DNA vaccination with plasmid encoding human ST6GalNAc-II. Recombinant ST6GalNAc-II produced in HEK293 FreeStyle cells was used for screening mAbs by ELISA or Western blotting. Our mAb and commercial *cis*- and *trans*-Golgi markers-specific mAbs were used for co-localization of ST6GalNAc-II in IgA1-producing cells by confocal microscopy.

**Results:** Using recombinant ST6GalNAc-II, we isolated ST6GalNAc-II-specific mAb. Confocal microscopy with image analyses revealed that in IgA1-producing cells from IgAN patients ST6GalNAc-II had about 13% more protein localized in *cis*-Golgi compared to cells from healthy controls ($P<0.05$).

**Conclusions:** Partial relocation of ST6GalNAc-II from *trans*- to *cis*-Golgi in IgA1-producing cells may represent a new mechanism contributing to production of Gal-deficient IgA1 in IgAN.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## FR-PO552

**Effect of Urine Protein on Renal Intersitienal Injury of IgA Nephropathy by Interleukin-17 Pathway** Junming Fan,[1,2] Ji Wen,[1] Nan Mao,[1] Zi Li,[1] Man Yang.[2] *[1]Dept of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China; [2]Div of Nephrology, Dept of Internal Chinese Medicine, Luzhou Medical College, Luzhou, Sichuan, China.*

**Background:** IgA nephropathy is a common glomerulonephritis throughout the world. The evidence suggested the imbalance of autoimmune affected the IgA production, transformation and clearance in IgAN. Interleukin-17(IL-17) known as a pro-inflammatory factor could promote the generation cytokines and induce T cell activation and proliferation; function in autoimmune diseases. This study is to investigate the expression of IL-17 in IgAN, and effection of IL-17 on renal interstitial injury.

**Methods:** The plasma and urine samples of 28 IgAN patients and 8 healthy controls were gathered. NRK-52E were cultured in medium and BSA. The concentration of IL-17 was detected by ELISA. Kidney tissue from 8 IgAN patients and 3 patients with renal tumor selecting remote normal tissue as control. The expression of IL-17 in kidney cells was measured by Immunohistochemistry.

**Results:** IL-17 level of urine was increased in IgAN patients compared with normal controls. The urine level of IL-17 was significant positive correlation with level of proteinuria and chronic renal injury. Compared with control group, the expression of IL-17 in renal tissue was increased in IgAN patients. The number of IL-17 positive cells is related with CD68 positive cells. FACS and Immunofluorescence showed the BSA promote renal tubular epithelia cell express IL-17 with dose-dependent and time-dependent manner. ELISA detected the level of IL-17 in supernatant was rised with the concentration of BSA. IL-17 directly promoted macrophage migration in a dose-dependent and time-dependent manner. The supernatant of BSA incubation could promote the macrophage migration.

**Conclusions:** The higher level of urine IL-17 was related with level of urine protein and the infiltration of CD68 positive cells in kidney. Urine protein could induced the secretion of IL-17 in tubular epithelial cells. IL-17 alone or collaborate with cytokine take part in pathogenesis of IgAN.

*Funding:* Government Support - Non-U.S.

## FR-PO553

**The Deposition of Secretory IgA in Patients with IgA Nephropathy Are Associated with Different Clinical, Pathology and Complement Activation Pathway** Junjun Zhang, Yan Liang, Zhangsuo Liu. *Nephrology, First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan Province, China.*

**Background:** Mucosal infection associated with episodic macroscopic haematuria are observed in many patients with IgAN. Secretory IgA (sIgA) is a mainly immunoglobulin involved in mucosal immunity. The aim of this work is to investigate the characteristics and complement activation in IgAN patients with or without renal sIgA deposition.

**Methods:** 186 IgAN patients with different renal pathology were enrolled. Their frozen renal sections were immunofluorescence stained and examined by confocal microscopy to detect the co-deposition of IgA and secretory component (SC),properdinandC4d,MBL and C3d.The association between deposition of sIgA and characteristics of patients, complement activation were analysed.

**Results:** In 186 patients, 59 patients (31.72%) were found sIgA deposition in kidneys. Compared with no sIgA deposition group, the incidence of infection history,gross hematuria history,macroscopic hematuria were higher, the level of serum cystatin C, serum β2 - microglobulin, blood urea nitrogen and serum triglyceride were lower, the percentages of crescents and C3 deposition in glomerulus were higher in sIgA deposition group. Meanwhile, compared with no sIgA deposition group, the co-depositions of properdin and C4d,factor B and C5b-9 were more frequently, the co-localization of MBL and C3d were rarelier in sIgA deposition group.

**Conclusions:** SIgA were deposited in kidneys of part of IgAN patients.which might be associated with different clinical manifestation and renal immunopathogenesis.Compared with IgA, sIgA may activate different renal complement pathway in IgAN.

## FR-PO554

**Overexpression of *N*-Acetylgalactosaminyltransferase-14 Contributes to Galactose-Deficient IgA1 Production: Relevance for IgA Nephropathy** Jana Novakova,[1,2] Tyler J. Stewart,[2] Koshi Yamada,[2,3] Hitoshi Suzuki,[3] Zina Moldoveanu,[2] Bruce A. Julian,[2] Jan Novak,[2] Milan Raska.[1,2] *[1]Palacky Univ in Olomouc, Olomouc, Czech Republic; [2]Univ of Alabama at Birmingham, Birmingham, AL; [3]Juntendo Univ, Tokyo, Japan.*

**Background:** IgA nephropathy (IgAN) is characterized by deposition of IgA1-containing immune complexes in the renal mesangium leading to glomerular injury; IgA1 in these deposits in enriched for galactose-deficient *O*-glycans (Gd-IgA1). IgA1 *O*-glycosylation is initiated by attachment of *N*-acetylgalactosamine (GalNAc) to serine or threonine in the hinge region and is catalyzed by GalNAc-transferases (GalNAc-Ts). Among the known human GalNAc-Ts, only GalNAc-T14 is up-regulated in IgA-producing cells from IgAN patients compared to those from healthy controls; siRNA knock-down has confirmed involvement of GalNAc-T14 in the production of Gd-IgA1. Therefore, we investigated the effect of overexpression of GalNAc-T14 in IgA1-secreting cells on Gd-IgA1 production.

**Methods:** An EBV-immortalized IgA1-secreting cell line was transfected by bicistronic plasmid pT14-EGFP expressing GalNAc-T14 and enhanced-green fluorescent protein (EGFP). EGFP-positive and EGFP-negative cells were sorted by FACS. RT-PCR analysis was used for determination of GalNAc-T14 mRNA levels. ELISA with a GalNAc-specific lectin was used to determine production of Gd-IgA1.

**Results:** Sorting of pT14-EGFP-transfected cells based on EGFP-high positivity yielded a cell population with GalNAc-T14 expression 67-fold higher than in non-transfected cells and 17-fold higher than in transfected EGFP-low positive cells. Lectin ELISA revealed that the GalNAc-T14 overexpression increased production of Gd-IgA1. Furthermore, the lectin ELISA suggested that most GalNAc attached by GalNAc-T14 was not subsequently galactosylated or sialylated.

**Conclusions:** FACS sorting of transfected cells is a suitable method for systems in which the transfection efficiency is low. Our data suggest that overexpression of GalNAc-T14 in IgA1-secreting cells may be associated with production of Gd-IgA1.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## FR-PO555

**Deep-Sequencing Reveals Class-Specific Urinary microRNAs in Human Lupus Nephritis** Beatrice Goilav,[1] Iddo Z. Ben-Dov,[2] Irene Blanco,[5] Olivier Loudig,[4] Dawn Wahezi,[3] Chaim Putterman.[5] *[1]Pediatric Nephrology, Children's Hospital at Montefiore, Bronx, NY; [2]RNA Biology Laboratory, Rockefeller Univ, NY, NY; [3]Pediatric Rheumatology, CHAM, Bronx, NY; [4]Epidemiology, AECOM, Bronx, NY; [5]Rheumatology, Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Lupus nephritis (LN), particularly, class IV LN, is associated with significant morbidity. microRNAs (miRs) are small, non-coding RNAs that regulate translation. Previous studies report changes in miR expression in kidney tissue, urine and PBMCs that correlate with LN disease activity. However, LN class-specific miRs have not been described.

Using deep-sequencing, we aimed to identify class-specific miRs in urine from adult and pediatric patients with biopsy-proven LN.

**Methods:** Cell-free urine from adult (n=25) and pediatric (n=8) female patients with class III, IV (proliferative) and V LN were obtained at time of active disease and during remission. Total RNA was used to prepare small RNA cDNA libraries for sequencing. Multiplexing through sample-specific 3' adapters was applied to limit cost. Sequence reads were mapped to the human genome and small RNA databases. miRs were quantified by relative read abundance. qRT-PCR was used for quantitative validation.

**Results:** We had specimen from adult patients with distinct class III, IV, and V LN and pediatric patients with class III and IV. In a paired-sample analysis we compared miR abundance in adult and pediatric active vs inactive LN, proliferative vs non-proliferative LN, class IV vs class III LN, active class III vs inactive class III LN, active class IV vs inactive class IV LN, and adult active class V vs inactive class V LN. We found significant changes in miR-324, -320, -200c (adult), -375 (pediatric), -200c, -30a, and -671*, respectively. All changes had $p<0.001$, except for miR-30a ($p=0.0011$).

**Conclusions:** We detected significant changes in miR abundance related to specific LN classes. Given that the prognosis of class IV LN is significantly worse than other classes, identifying miRs that are associated with class IV LN is an important step in biomarker discovery of this particular aggressive form of LN.

## FR-PO556

**Tolerance Failure at the Crossroad of Innate and Adaptive Immunity in Murine Lupus Nephritis** Amy G. Clark, Melissa L. Boor, Mary H. Foster. *Medicine and Research Service, Duke Univ Medical Center and DVAMC, Durham, NC.*

**Background:** Failed immune tolerance underlies pathogenesis in lupus nephritis. To identify genetic modulators of disease, we tracked tolerance mechanisms regulating a well-characterized autoantibody (autoIg) transgene (Tg) established on each of four major inbred lupus strains, which collectively model human lupus genetic complexity. We found that Tg B cells in the NZB strain, a contributor of major susceptibility loci for fulminant nephritis, uniquely display aberrant reversible anergy: they produce high levels of autoIg after toll-like receptor 4 (TLR4) stimulation, a phenotype not observed in other strains. Herein we explore the mechanistic and genetic basis of altered tolerance in NZB lupus.

**Methods:** Purified B cells or whole splenocytes from NZB Tg mice (n=4-11/grp) were incubated +/- ligands for TLR4 (LPS), TLR7 (R848), and/or TLR9 (CpG), and 8-10 d supernatants assayed for Tg autoIg by ELISA. NZB Tg mice were bred with B6 or NZW mice to generate Tg (B6xNZB)F1 and Tg (NZBxNZW)F1 (BWF1) lupus mice, respectively.

**Results:** Multiple TLR ligands induce Tg autoIg secretion from NZB Tg B cells: autoantigen binding OD, mean±SD, 1.233±1.30 for LPS, 0.573±0.75 for R848, 0.451±0.30 for CpG, and 3.061±0.32 for LPS+R848+CpG, compared to trace autoIg produced by medium alone or by LPS-stimulated B cells from B6 mice (mean OD < 0.05). In contrast to the innate cell-mediated suppression of anergic cell autoIg secretion previously described for non-lupus strains, NZB non-B cells fail to suppress LPS-stimulated Tg autoIg secretion in whole splenocyte cultures: OD 0.429±0.64 (despite 4.6-fold fewer B cells). LPS also induces autoIg secretion by Tg B cells from (B6xNZB)F1 and >4 month old BWF1 mice: OD 0.361±0.05 and 0.854±0.45, respectively.

**Conclusions:** NZB lupus results in part from defective anergy due to genetic disruption of coordinated TLR and B cell receptor signaling, possibly exacerbated by failure of innate cell suppression. The strain variance pattern suggests high heritability of this NZB tolerance defect. These results point to a genetic basis for lupus that involves inherited failure in autoimmune regulation that intersects innate and adaptive immunity.

## FR-PO557

**Loss of Anergy and Innate Marginal Zone Cell Enrichment in BXSB Lupus Nephritis** Amy G. Clark, Melissa L. Boor, Mary H. Foster. *Medicine and Research Service, Duke Univ Medical Center and DVAMC, Durham, NC.*

**Background:** BXSB mice develop lupus nephritis that is accelerated in males carrying the *yaa* locus. To identify mechanisms by which BXSB genetic susceptibility modifies disease, we established a well-characterized autoantibody (autoIg) transgene (Tg) in BXSB. In contrast to stringent tolerance observed in Tg C57BL/6 (B6) and other strains, BXSB Tg B cells lack hallmarks of anergy (reduced in vivo life span, hypoproliferative responses) and are enriched in innate-like marginal zone (MZ) B cells, a subset resistant to anti-CD20 therapy. Herein we further explore the genetic origins of altered tolerance in BXSB lupus.

**Methods:** BXSB autoIg Tg mice were bred with nonautoimmune B6 mice to generate Tg (B6xBXSB)F1 progeny. B cell subsets and ex vivo proliferation of vital dye-stained purified B cells, +/- Ig receptor crosslinking or TLR4 stimulation, were measured by flow cytometry.

**Results:** B cells from Tg+ (B6xBXSB)F1 mice (n=4) hyperproliferate to TLR4 ligand LPS relative to B cells from nonTg F1 littermates (n=2): % divided cells, mean±SD, 52.0±3.0 vs 36.7±2.5, p<0.05. These results are similar to those using Tg and nonTg cells from the parental BXSB strain as previously reported. Tg+ (B6xBXSB)F1 mice also display a marked increase in frequency of MZ B cells (%CD21hiCD1dhi) vs nonTg F1 littermates: 15.8±3.4 vs 7.5±1.2, p<0.05, although MZ expansion is less than observed in parental Tg+ BXSB mice (31.1±9.8%, n=8, p<0.05). We do not observe sex differences in these phenotypes.

**Conclusions:** Our findings suggest that BXSB lupus mice have heritable defects in B cell tolerogenic signaling that are apparent early in cell development and that divert autoimmune B cell fate from anergy to innate MZ cell enrichment. Defects are detected in F1 progeny and in both sexes, implicating susceptibility genes on BXSB autosomes. Identification of responsible genes or pathways will provide insight into molecular mechanisms regulating autoimmunity that destroys kidneys.

*Funding:* NIDDK Support, Veterans Affairs Support

## FR-PO558

**Innate Immune Cells Produce Interleukin-17A which Drives Autoimmunity and Lupus Nephritis** Shaun A. Summers,[1] Oliver M. Steinmetz,[2] A. Richard Kitching,[1] Stephen R. Holdsworth.[1] *[1]Dept of Nephrology and Medicine, Monash Health and Monash Univ, Melbourne, Victoria, Australia; [2]III. Med Klinik, Univ Hospital, Hamburg, Eppendorg, Germany.*

**Background:** Systemic lupus erythematosus (SLE) and lupus nephritis are significant causes of morbidity and mortality. Clinical studies have demonstrated that serum Interleukin (IL)-17A levels are increased in disease, although direct evidence of pathogenicity is lacking. We sought to define the role of IL-17A in SLE induced by pristane.

**Methods:** We injected pristane (500µl) intraperitoneally into C57BL/6 wild type (WT) mice and assessed IL-17A production after 6 days, using flow cytometry. Subsequently we treated WT and IL-17A-/- mice with pristane and assessed; cellular immunity (8 weeks), humoral autoimmunity and renal injury, both functionally and histologically, after 7 months.

**Results:** After 6 days, IL-17A production was readily detected in pristane treated WT mice, but not in control (WT) mice. The majority of IL-17A producing cells were innate cells (% of IL-17A producing cells: macrophages 41.4±6.3%, neutrophils 24.0±3.3%, natural killer cells 11.5±1.5%, gammadelta T cells 7.7±1.2%) only 13.8±1.8% were CD4+Tcells. After 8 weeks systemic IFNY (WT 591.3±188.6 vs. IL-17A-/- 176.0±15.8ng/ml, P<0.05) and TNF (WT 294.7±11.6 vs. IL-17A-/- 196.6±35.7ng/ml, P<0.05) production were decreased in IL-17A-/- mice. Systemic IL-17A was still readily detected in WT mice. After 7 months humoral autoimmunity was diminished in IL-17A-/- mice, with decreased levels of total IgG and anti-dsDNA, at serial dilutions. Glomerular IgG (WT 1.8±0.1 vs. IL-17A-/- 1.1±0.1 intensity score [0-3], P<0.0001) and complement (WT 2.0±0.1 vs. IL-17A-/- 1.3±0.1 intensity score [0-3], P<0.0001) deposition was decreased in the absence of IL-17A. Compared to WT mice, glomerular injury assessed by albuminuria (WT 271.5±55.8 vs. IL-17A-/- 87.6±15.9µg/24 hours, P<0.05) and histological injury (WT 32.0±2.1 vs. IL-17A-/- 22.9±3.1, % abnormal glomeruli, P<0.05) was diminished in IL-17A-/- mice.

**Conclusions:** These results demonstrate that innate immune cells produce IL-17A, which drives autoimmunity and glomerular injury in experimental SLE.

## FR-PO559

**Mass Spectrometry Based Proteomics Highlights the Replicability of Results between Lupus Nephritis Formalin-Fixed, Paraffin Embedded and Fresh Frozen Tissues** Abhimanyu N. Amarnani, Joe Capri, Ivan Axel Lopez, Ram R. Singh, Julian Whitelegge. *David Geffen School of Medicine, Univ of California, Los Angeles, Los Angeles, CA.*

**Background:** Lupus nephritis (LN) progresses from mild focal inflammation, to diffuse proliferative nephritis, to fibrosis and end-stage renal disease. While current treatments are based on renal pathology, the molecular basis of LN and its progression remains obscure. There is a need to use global, data-driven research techniques for analysis of molecular changes correlated with renal tissue at progressive disease stages. Here, we describe a proteomics workflow applicable to archived, clinical tissue that has been formalin fixed, and paraffin embedded (FFPE). Working towards resolving the accessibility issue of fresh frozen biopsy tissue, our goal was to directly evaluate claims that the FFPE tissue can be "as good as" fresh frozen tissue (FFT) for the purpose of global LN proteomics.

**Methods:** The workflow includes comparing proteomics results from identical transverse kidney tissue cuts from NZM-2328 mice, half FFPE and the other half FFT. Tissue processing included the FASP technique, in-solution dimethyl isotope labeling, stagetip strong cation exchange filtration and the Thermo LTQ Orbitrap XL Mass Spectrometer with Eksigent NanoLC-2d HPLC. In triplicate studies, 2 FFT groups and 1 FFPE were compared.

**Results:** Data analysis using MaxQuant (v1.3.0.5) resulted in identification of 1700+ proteins from both FFT and FFPE groups. More than 91% of proteins were identified between identical FFT groups, and more than 90% of proteins were consistently found between FFPE samples and identical FFT samples. Relative quantitative data among groups also presented good correlation. Our analysis demonstrates that FFPE tissue proteomics can produce results consistent with FFT, allowing further understanding of proteome changes in LN etiopathogenesis.

**Conclusions:** Our methodology is the first to directly compare FFT and FFPE tissue in a manner that is also applicable to clinical samples. With this, we will be able to first evaluate any differences between FFPE and FFT in clinical samples, and then begin utilizing archived, FFPE patient biopsy samples for LN studies.

## FR-PO560

**STAT3 Programs Th17-Specific Regulatory T Cells to Control Glomerulonephritis** Malte A. Kluger,[1] Michael Mülleneisen,[1] Claudia Wegscheid,[3] Hans-Joachim Paust,[1] Hans-willi Mittrücker,[2] Rolf A. Stahl,[1] Ulf Panzer,[1] Oliver M. Steinmetz.[1] *[1]III. Medizinische Klinik, Hamburg Univ, Germany; [2]Immunology, Hamburg Univ, Germany; [3]Experimental Hepatology, Hamburg Univ, Germany.*

**Background:** Th17 cells are central mediators of glomerulonephritis. The mechanisms underlying their counter regulation are largely unknown. Recently, Th17 lineage specific regulatory T cells (Treg17) have been identified which depend on activation of STAT3. To date, not much is known about their role in inflammatory diseases. We therefore studied the function of Treg17 in crescentic glomerulonephritis.

**Methods:** Specific deletion of STAT3 was achieved using Foxp3Cre or CD4CrexSTAT3fl/fl mice. Nephrotoxic nephritis (NTN) was induced and at day 10 renal parameters were assessed. Immune responses were analyzed by FACS/ELISA. In vitro Treg suppression and in vivo Treg trafficking were assessed.

**Results:** Foxp3CrexSTAT3fl/fl mice lacking Treg17 cells did not develop spontaneous disease. However, NTN was significantly aggravated. Renal and systemic immune responses were skewed towards Th17. Analyses of systemic Tregs revealed enhanced activation while numbers, proliferation and suppressive function remained unchanged. Strikingly, however, renal Treg infiltration was significantly reduced. FACS analyzes of renal Tregs from Foxp3CrexSTAT3fl/fl mice revealed complete lack of the trafficking receptor CCR6 which was abundantly expressed on wildtype Tregs. In vivo trafficking was analyzed by competitive co-transfer of CD45.2 knockout and CD45.1 wildtype splenocytes into RAG2$^{-}$ recipients. Renal trafficking of CCR6 negative Tregs from Foxp3CrexSTAT3fl/fl mice was significantly impaired. Finally we confirmed that Th17 cells are the major target of Treg17 cells as aggravation of disease was reversible in the absence of Th17 responses as shown in CD4CrexSTAT3fl/fl mice lacking both Treg17 and Th17 cells.

**Conclusions:** Our data indicate the presence of a new subtype of regulatory T cells in crescentic glomerulonephritis which specifically targets Th17 cells and depends on STAT3-activation. One of their main mechanisms of action is directional migration into areas of Th17 inflammation by using the chemokine receptor CCR6.

**FR-PO561**

**B Cell Derived IL-10 Does Not Vitally Contribute to Experimental Glomerulonephritis** Malte A. Kluger,[1] Annett Ostmann,[2] Michael Mülleneisen,[1] Matthias C. Meyer,[1] Hans-Joachim Paust,[1] Rolf A. Stahl,[1] Ulf Panzer,[1] Gisa Tiegs,[2] Oliver M. Steinmetz.[1] *[1]III. Medizinische Klinik, Hamburg Univ Medical Center, Hamburg, Germany; [2]Institute for Experimental Hepatology, Hamburg Univ Medical Center, Hamburg, Germany.*

**Background:** IL-10 secreting regulatory B cells (B10) have recently been described as negative mediators of inflammation. Their modes of action and their impact on inflammatory renal diseases remain unclear. We therefore studied the function of B10 cell derived IL-10 in a model of crescentic glomerulonephritis particularly in the light of the potential risks associated with B cell depleting therapies.

**Methods:** Analyzes of systemic and renal IL-10 producing B cells during NTN were performed using IL-10 eGFP reporter mice. Specific deletion of IL-10 in B cells was achieved by generating CD19Cre x IL-10fl/fl mice. Nephrotoxic nephritis (NTN) was induced and renal histology and function were assessed at days 4 and 10. Immune responses were analyzed by FACS and ELISA.

**Results:** IL-10 producing B10 cells were present in low numbers in kidneys of healthy mice and their frequency increased during nephritis. Lack of IL-10 production by B10 cells, however, did not influence the clinical course of NTN at early and late time points in terms of renal function and histological damage. Renal leukocyte infiltration and cytokine expression were similar except for an increased infiltration of macrophages in knockout mice. Systemic immune responses, cytokine production, leukocyte composition, proliferation and activation were unaffected in nephritic knockout mice. However, we found impaired antigen specific IgG production in these animals. In line, renal immune complex deposition was slightly reduced. Last but not least, detailed analysis of systemic and renal regulatory T cells did not show any significant differences.

**Conclusions:** In summary, we here show that IL-10 producing B cells infiltrate the kidney during the course of crescentic glomerulonephritis. Nevertheless, specific deletion of B10 cell derived IL-10 did not lead to exacerbation of renal disease. This is good news for B cell directed therapies as a lack of B10 cell derived lL-10 does not seem to deteriorate glomerular injury.

**FR-PO562**

**Complement Blockade via Eculizumab Enhances Nephroprotection in a COL4A3-Knockout Mouse-Model for Alport Syndrome** Oliver Gross,[1] Diana Rubel,[1] Jakob Valk,[1] Fred G. Pluthero,[2] Christoph Licht.[2] *[1]Dept of Nephrology & Rheumatology, Univ Medicine Göttingen, Göttingen, Germany; [2]Div of Nephrology and Cell Biology Program, The Hospital for Sick Children, Toronto, Canada.*

**Background:** COL4A3 -/- mice serve as animal model for progressive renal fibrosis. Testing the hypothesis of complement contributing to the progression of proteinuric kidney disease we investigated the antifibrotic and antiinflammatory nephroprotective effects of eculizumab alone and in combination with ACEI therapy in these mice.

**Methods:** 64 COL4A3 -/- mice were treated in 4 groups: (ECU) with Eculizumab 40 mg/kg,or (PLAC) vehicle 0.1 ml s.c 3x/wk, (ACE) with Ramipril 10 mg/kg/day p.o., and (ECU+ACE) with Eculizumab plus Ramipril. Ramipril and Eculizumab monotherapy started preemptively in week 4. In the ECU+ACEI-group, Ramipril was started in week 4 and ECU was applied in 6 week old animals already showing renal damage (proteinuria >1g/l, mild renal fibrosis) and lasted for 6 weeks. Six animals were sacrificed after 7.5 and 9.5 weeks, respectively, and kidneys were further investigated using histological, immunohistological and Western blot techniques. Survival until end stage renal failure was determined in the remaining animals.

**Results:** ECU+ACEI, but not ECU-monotherapy prolonged overall lifespan by 9% compared to ACEI-monotherapy. In contrast, ECU-monotherapy had a beneficial effect on accumulation of extracellular matrix and renal scarring. Dual therapy with ACEI and ECU showed the best effect in immunehistochemistry.

**Conclusions:** In COL4A3 -/- mice, the complement-inhibitor Eculizumab in combination with ACE-inhibition reduces fibrosis and prolongs survival compared to ACEI monotherapy. Despite the late onset of therapy, this nephroprotective and antifibrotic effect may still be substantial on top of early-on ACEI – an effect possibly applicable also to other chronic progressive kidney disease.

**FR-PO563**

**T-Cell Epitope Spreading in Experimental Autoimmune Glomerulonephritis (EAG) in Rats** Jitendra K. Gautam,[1] Anjana Gevaria,[1] Reetu Mukherji,[2] Kline Bolton.[1] *[1]Dept of Medicine, Div of Nephrology/CIIR, Univ of Virginia Health System, Charlottesville, VA; [2]Temple Univ School of Medicine, Philadelphia, PA.*

**Background:** $\alpha_3$ (IV) NC1 domain causes Goodpasture's Syndrome (GPS) in man and the same disease in rats, EAG. We have shown that an immunodominant pure T cell epitope, p13, that induces EAG, is frequently associated with antibody (Ab) B cell epitope spreading along the $\alpha_3$(IV) NC1 chain (intramolecular Ab spreading), and the $\alpha_4$(IV) NC1, (intermolecular epitope spreading). However, Ab does not occur in many rats, several other peptides can induce EAG, and EAG can be transferred by T cells. We sought to determine if nephritogenic T cell epitope spreading occurred in our model as a potential mechanism to augment disease and could be used as a potential target for therapy.

**Methods:** Rats were immunized with p13. 20 mer overlapping peptides were synthesized to include the full length of $\alpha_3$(IV) NC1. Lymphocyte proliferation assays (LPA) were done weekly and the characteristics of the individual LPA stimulation index (SI) were examined.

**Results:** T cell epitope spreading from p13 occurred to multiple peptides in an ordered chronological pattern. 12 peptides with strong SIs were used to immunize rats to assess their ability to produce EAG. Two regions not previously described induced EAG. Ab was deposited on GBM in all these rats demonstrating Ab cross reactivity and/or epitope spreading associated with the nephritogenic epitope. Non-nephritogenic peptides were not associated with Ab formation to GBM, although many induced Ab to themselves.

**Conclusions:** We have shown in EAG that in addition to B cell epitope spreading, T cell epitope spreading also occurs. However, only a few peptides with positive SI induce EAG, most do not. The nephritogenic new epitopes also are associated with Ab formation. Thus EAG is associated with both T cell and B cell epitope spreading which likely augment the severity of the disease and may be therapeutic targets.

**FR-PO564**

**Mac-1 Deficiency Protects Mouse from Pulmonary Hemorrhage, whereas Exacerbates Glomerulonephritis in Experimental Model of Systemic Lupus Erythematosus** Yiqin Shi, Naotake Tsuboi, Kazuhiro Furuhashi, Shoichi Maruyama, Seiichi Matsuo. *Internal Medicine, Nephrology, Nagoya Univ Graduate School of Medicine.*

**Background:** Mac-1 (CD11b/CD18), a leukocyte adhesion molecule, expressed on neutrophils, eosinophils and macrophages has been shown to mediate several adhesion-dependent processes. Recently, an association of genetic variations in Mac-1 with susceptibility to SLE has been reported in several studies.

**Methods:** To determine the underlying mechanism of how Mac-1 participates in SLE, we introduced pristine (TMPD) to induce pulmonary hemorrhage and experimental lupus nephritis in Mac-$1^{-/-}$ mice on C57BL/6 background. Organ damage was histologically analyzed. Flow cytometric analysis and ELISA were performed for the evaluation of leukocyte infiltration and cytokine concentration in inflamed sites including the peritoneal cavity, lung and kidney.

**Results:** Mac-$1^{-/-}$ mice had reduced prevalence of pulmonary hemorrhage compared to wild-type (WT) mice within 1 month after TMPD injection, but after 4 months demonstrated severe proteinuria that was significantly higher than WT mice. In Mac-$1^{-/-}$ mice, lupus nephritis was evident with glomerular hypercellularity and leukocyte infiltration associated with glomerular IC deposition. The analysis of the peritoneal lavage on day 5 and 10 after pristine treatmentrevealed an increase in eosinophils and immune regulatory (M2) macrophages but lower numbers of neutrophils and classic (M1) macrophages in Mac-$1^{-/-}$ mice compared to WT. Higher expression of IL-4 and IL-13, both key mediators of macrophage polarization toward M2 macrophages, was observed in the peritoneal cavity of Mac-$1^{-/-}$ mice.

**Conclusions:** Mac-1 promotes acute inflammatory immune responses that lead to pulmonary hemorrhage but downregulates chronic immune responses to protect mice from IC-mediated renal injury in a model of experimental lupus nephritis induced by TMPD.

**The Inflammasome-Related Molecules NLRP3 and ASC Suppress Lupus Nephritis of C57BL/6lpr/lpr Mice** Georg Lorenz, Maciej Lech, Onkar Kulkarni, Roman Guenthner, Marian Grosser, Nora Stigrot, Heni Susanti, Hans J. Anders. *Medizinische Klinik und Poliklinik IV, Clinical Biochemistry, Ludwig Maximilians Universität, Munich, Germany.*

**Background:** NLRP3/ASC inflammasome signaling translates infectious and sterile dangers into the secretion of mature IL-1β and IL-18 and subsequently into IL-1R/NF-κB-dependent secretion of multiple pro-inflammatory cytokines. We hypothesized that the NLRP3/ASC inflammasome would contribute in a similar manner to autoimmune tissue inflammation, e.g. to immune complex glomerulonephritis in systemic lupus erythematosus, i.e. lupus nephritis.

**Methods:** To address this question we generated *nlrp3*- or *asc*- or *il1r*- or *il18*- deficient C57BL/6-lpr/lpr mice, the latter being a model of spontaneous SLE-like autoimmunity.

**Results:** Surprisingly, *nlrp3*- and *asc*-, but not *il1r*- or *il18*- deficient C57BL/6-lpr/lpr mice displayed an aggravated autoimmune phenotype with massive lymphoproliferation, severe crescentic immune complex glomerulonephritis, and autoimmune lung disease, which are usually absent in C57BL/6-lpr/lpr mice. Immune phenotyping revealed that both *nlrp3*- and *asc*-deficiency both shifted lymphocyte apoptosis to lymphocyte necrosis, which induced multiple pro-inflammatory elements and suppressed negative regulators of innate immunity such as NLRP1a, NLRP2, NLRP6 and NLRP12. Lymphocyte necrosis and innate immune activation were associated with the expansion and activation of spleen dendritic cells, macrophages, T cells, and B cells.

**Conclusions:** Together, *nlrp3*- or *asc*-deficiency both aggravate autoimmunity and autoimmune tissue injury in lupus-prone C57BL/6-lpr/lpr mice. This reveals an unexpected immunosuppressive role of NLRP3 and ASC in this context, which may be related to a previously unknown role of NLRP3 and ASC in preventing lymphocyte necrosis, which exposes additional lupus autoantigens and drives the autoimmune process. These data identify both Asc and Nlrp3 as previously unknown SLE susceptibility genes in mice.

**CD147 Ameliorates Lupus Nephritis through the Regulation of Helper T Cell 17 Differentiation** Kayaho Maeda, Tomoki Kosugi, Waichi Sato, Hiroshi Kojima, Yuka Sato, Mayuko Maeda, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

**Background:** CD147/Basigin (*Bsg*), a glycosylated transmembrane protein, plays important roles of cell survival, invasion and metastasis. We previously demonstrated deleterious effects of CD147 in renal inflammation caused by ischemia and renal fibrosis. As CD147 identifies activated regulatory T cell (Treg), the attention has become extended to the autoimmune diseases, including rheumatoid arthritis and systemic lupus erythematosus. Interleukin (IL)-17 producing T cell and Treg also serve important roles in the pathogenesis of SLE. However, the molecular mechanism involving CD147 remains unknown. We therefore investigated the role of CD147 in lupus nephritis.

**Methods:** Lupus nephritis was induced in CD147 deficient mice (***Bsg***$^{-/-}$) or wild-type mice (***Bsg***$^{+/+}$) with an intraperitoneal injection of pristane (0.5ml/each mice). They were sacrificed at 6 months after an injection for histological and biochemical analyses. Kidney, spleen and thymus were analyzed.

**Results:** There was no difference between *Bsg*$^{+/+}$ and *Bsg*$^{-/-}$ in serum anti-nuclear/anti-dsDNA antibody during the experimental period, whereas serum C3 decreased in *Bsg*$^{-/-}$. Mesangial and endothelial cells proliferations, macrophages and CD4$^+$ T cells infiltration, wire loop lesion and albuminuria were prominent in *Bsg*$^{-/-}$ mice. Consistent with these data, IgG, C3 and C1q depositions in *Bsg*$^{-/-}$glomeruli were predominantly observed. By flow cytometry analysis, no obvious difference in the number of Treg was found in both genotypes, whereas IL-17A producing CD4$^+$ T cells (Th17) were higher in *Bsg*$^{-/-}$ spleen than *Bsg*$^{+/+}$. Th17-related gene expressions were prominent in *Bsg-/-* kidney. CD4$^+$ T cells from *Bsg*$^{-/-}$ significantly increased IL-17A level more than *Bsg*$^{+/+}$ under Th17-skewing conditions. Interestingly, STAT3 activation, essential for Th17 differentiation, was enhanced by lack of CD147. Treatment with anti-CD147 antibody was downregulated the STAT3 activation and Th17 differentiation.

**Conclusions:** Lack of CD147 promotes Th17 differentiation through the STAT3 activation, eventually leading to the development of lupus nephritis.

**FR-PO567**

**Molecular Characterization of Renal Responses in Lupus Nephritis Using Serial Kidney Biopsies** Samir Parikh,[1] Ana Malvar,[2] Jay C. Vance,[1] Huijuan Song,[1] Bruno Jorge Lococo,[2] Valeria Gabriela Alberton,[2] Brad H. Rovin.[1] *[1]Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Hospital Fernandez, Buenos Aires, Argentina.*

**Background:** The molecular events occurring in the kidney during treatment of LN are unknown, but understanding these could be used to improve therapy. The expression of 511 immune-response genes was examined in serial kidney biopsies done at LN flare and after treatment.

**Methods:** RNA expression was measured in clinical biopsy tissue by Nanostring technology. Differentially expressed transcripts identified by Statistical Analysis of Microarray were compared using ANOVA followed by Tukey's. Controls (n=4) were pre-implantation donor transplant kidney biopsies.

**Results:** Five patients responded well (CR) with normalization of serum creatinine (SCr) and a fall in proteinuria to <0.5g/d, while 3 patients had no response (NR) by the second biopsy. At flare NR patients had more proteinuria (6.7±1 vs 2.7±1 g/d, P=0.03) but SCr was similar. The NIH activity index was higher in NR biopsies (10.3±1.5 vs 6.4±1.7, P=0.016), but the chronicity index and other histologic features, including glomerular and interstitial leukocyte infiltration, were similar. Of the top 50 differentially-expressed transcripts, all but one (CCAAT enhancer binding protein) was higher in LN than control tissue. Twenty-eight of these transcripts were increased only in NR, while 22 increased in CR and NR. Despite a good clinical response, transcript levels in the CR group continued to increase 6 months post-flare (n=2), but after 1-3 years of therapy (n=3) fell significantly compared to 6 month biopsies (P=0.006). Flares leading to CR had higher expression of IL-10 and NO signaling, while NR flares had increased expression of T and B cell signaling pathways. Activation of certain T cell-mediated apoptosis and antigen presentation pathways were unique to NR flares.

**Conclusions:** Despite good clinical responses as early as 6 months after treatment of LN flare, the molecular changes that occur at flare persist. Flares leading to NR have, in general, more intense activation of many pathways in common with CR flares, but also have activation of unique pathways that could be exploited therapeutically.

**FR-PO568**

**CXCR3$^+$ Regulatory T Cells Control $T_H1$ Immune Response in Crescentic Glomerulonephritis** Hans-Joachim Paust,[1] Christian Franz Krebs,[1] Anett Peters,[1] Sabrina Bianca Bennstein,[1] Friedrich Thaiss,[1] Thorsten Wiech,[2] Oliver M. Steinmetz,[1] Jan-Eric Turner,[1] Rolf A. Stahl,[1] Ulf Panzer.[1] *[1]III. Medizinische Klinik, Univeritätsklinikum Hamburg Eppendorf, Hamburg, Germany; [2]Institut für Pathologie, Univeritätsklinikum Hamburg Eppendorf, Hamburg, Germany.*

**Background:** Regulatory T cells (Treg) mediate suppression of excessive immune responses and tissue damage in autoimmune diseases, such as crescentic glomerulonephritis. This depends on the trafficking of Tregs to sites of inflammation. Chemokines and chemokine receptors have been shown to play a pivotal role in the directional trafficking of T cells in general, however their specific function for Treg cell migration is unclear.

**Methods:** In a model of crescentic glomerulonephritis (nephrotoxic nephritis, NTN) we assessed the time-dependent chemokine receptor expression profile of renal Tregs by flow cytometry. Furthermore, we generated conditional CXCR3-deficient mice (CXCR3-flox) and crossbred these mice with FoxP3-Cre mice. Thereby we generated CXCR3-deficiency specifically in Tregs. In addition, we performed FACS analysis from renal biopsies of patients with ANCA-associated glomerulonephritis.

**Results:** Here we show in a mouse model of crescentic glomerulonephritis that Tregs expressing the $T_H1$ chemokine receptor CXCR3accumulate in the kidney during the peak of the $T_H1$ immune response. Treg cell-specific ablation of CXCR3 resulted in reduced renal Treg cell recruitment accompanied with an enhanced $T_H1$ immune response, without affecting $T_H17$ immune response, and an aggravated course of the nephritis. This suggests that CXCR3$^+$ Tregs might control renal $T_H1$ immunity. Finally, we demonstrate the presence of CXCR3$^+$ Treg cells in areas of $T_H1$ immune response in the kidneys of patients with ANCA-associated crescentic glomerulonephritis.

**Conclusions:** These findings indicate that a subset of Tregs express CXCR3 and thereby have trafficking properties of pathogenic CXCR3$^+$ $T_H1$ cells to suppress excessive $T_H1$ responses at tissue-specific sites.

*Funding:* Government Support - Non-U.S.

**FR-PO569**

**A Novel Soluble Epoxide Hydrolase Inhibitor Ameliorates Progression of Cronic Renal Dysfunction in Glomerulonephritis Rats** Yasuhito Nakadera, Yoshiji Asaoka, Mayu Mutsuga, Takashi Serizawa, Mai Yagi, Yoshitaka Yoshizawa, Shinichi Yamaguchi, Eriko Higashi, Yuko Kato, Kazuyuki Tokumaru, Shinnosuke Hayashi, Aiko Nitta, Takumi Aoki, Yutaka Nishimura, Masateru Yamada. *Toray Industries, Inc, Japan.*

**Background:** Epoxyeicosatrienoic acids (EETs) are CYP-derived arachidonic acid metabolism, which are likely to be signaling molecules to help ameliorate a wide variety of pathological conditions. EETs are known to be metabolized by soluble epoxide hydrolase (sEH), whereby the numerous beneficial actions of EETs are eliminated. Inhibition of sEH is expected to effectively provide significant renoprotective effects based on the reports of its vasodilative, anti-proliferative and anti-inflammatory effects. In this study we assessed the hypothesis that a novel sEH inhibitor might ameliorate the progression of chronic renal dysfunction in glomerulonephritis (GN) rats.

**Methods:** GN was induced to rats by injecting anti-glomerular basement membrane antibody. Two weeks after the induction, serum creatinine (sCr) levels in GN rats were significantly elevated. Then, we divided GN rats into three groups and started the administration of vehicle, sEH inhibitior (3 and 10 mg/kg, p.o., once a day) from 2 weeks after GN induction. The levels of sCre, blood urea nitrogen (BUN) and cystatin-C (Cys-C) were measured. In addition, the histopathological changes of glomerular lesion and renal tubules were also evaluated.

**Results:** At 2 weeks after GN induction, the levels of sCr and BUN in GN rats were significantly elevated compared with normal rats, and further increased at 5 weeks. In sEH inhibitor-treated GN rats, the increase in sCr and BUN was significantly prevented. Cys-C levels in GN rats were also increased at 5 weeks. The increase in Cys-C levels was blocked by sEH inhibitor. In histopathological examination, glomerulosclerosis and hyaline cast in renal tubules were markedly observed in GN rats. The severity of these histopathological changes in the kidney was improved by sEH inhibitor.

**Conclusions:** These findings indicate the sEH inhibitor leads to functional and histological improvement in chronic renal dysfunction in GN rats.

**FR-PO570**

**Humanized Models to Study Regulation of Anti-Glomerular Basement Membrane Nephritis** Inge M. Worni-Schudel,[1,2] Melissa L. Boor,[1] Mary H. Foster.[1] *[1]Medicine, Duke Univ Medical Center and DVAMC, Durham, NC; [2]Nephrology, Hypertension, and Clinical Pharmacology, Bern Univ Hospital, Switzerland.*

**Background:** Immune nephritis is a major cause of renal injury, but little is known about genetic origins, environmental triggers, or immune regulatory control in man. A paucity of suitable model systems and an inability to recover human (hu) monoclonal autoantibodies (mAb) have posed barriers to progress.

**Methods:** We assessed the suitability of humanized NOD-scid-gamma (NSG) mice for in vivo study of anti-GBM immune responses. For Hu-HSC mice, CD34+ hu hematopoietic stem cells (HSC) from cord blood were iv injected into NSG recipients (n=2), followed by immunization with α3(IV)NC1 collagen at 14, 17 and 20 weeks. Harvested B cells were EBV transformed using CpG oligos and kinase inhibitors. Stable B cell lines were electrofused with a hu heterohybridoma to generate hu mAb. For the Hu-PBL model, NSG mice were injected with peripheral blood leukocytes (PBL) purified from two subjects with anti-GBM nephritis (n=4) and from two healthy donors (n=14).

**Results:** In Hu-HSC mice 23 weeks after engraftment spleen chimerism was 93.3% (mean % of CD45+ cells); 12.5% and 39% of cells expressed hu CD19+ and hu CD3+, respectively, confirming development of a hu lymphoid system. 47.5% of B cells expressed EBV receptor CD21. One month after transformation, viable cells and antigen-reactive Ig were detected in 49.6% and 35.8% of 240 wells, respectively. A human anti-α3(IV)NC1 mAb was generated for sequence analysis. In the Hu-PBL model spleen chimerism averaged 79% at mean 35 days post engraftment, with 6.5% hu CD19+ and 47% hu CD3+ cells. Serum hu IgG and IgM levels ranged 63-1020 μg/ml, with low levels of auto-Ig detected. Unexpectedly, spleen EBV exposure yielded only rare transformed B cells. Hu-PBL mice established using healthy PBL donors revealed loss of surface CD21 after in vivo transfer: 96% of freshly isolated donor hu CD19+ cells expressed CD21 versus 10% of Hu-PBL spleen hu CD19+ cells at day 21 (n=4).

**Conclusions:** Both Hu-HSC and Hu-PBL models permit development and expansion of human nephritogenic immunity, while posing unique opportunities and challenges for study of human disease.

## FR-PO571

**Independent In Vivo Regulation of a Goodpasture Autoantibody Light Chain** Inge M. Worni-Schudel,[1,2] Amy G. Clark,[1] Melissa L. Boor,[1] Mary H. Foster.[1] *[1]Medicine, Duke Univ Medical Center and DVAMC, Durham, NC; [2]Nephrology, Hypertension, and Clinical Pharmacology, Bern Univ Hospital, Switzerland.*

**Background:** Goodpasture syndrome results from autoimmune attack on α3(IV) collagen in kidneys and lung. To gain insight into origins and structure of pathogenic autoIg, we derived mAb from mice immunized with Goodpasture antigen. Sequence analysis revealed that anti-α3(IV)NC1 mAb from different mice share a heavy chain (HC) CDR3 motif and exclusively use IGKV3-encoded kappa light chains (LC). Biased use of IGKV3 genes was previously reported among anti-collagen IgG in rheumatoid arthritis. Mice bearing transgenes (Tg) encoding anti-α3(IV)NC1 Ig demonstrate B cell tolerance. The current studies assess the role of IGKV3 LCs in determining cell fate and regulation independent of the HC.

**Methods:** Ig Tg mice were generated by insertion of a rearranged IGKV3 LC under control of the kappa enhancer. Five Tg+ founders were bred with C57BL/6 mice deficient in endogenous kappa LCs (k-KO), such that all kappa is derived from the Tg. This strategy permits identification of the Tg LC while eliminating confounding rearrangements and editing at endogenous kappa alleles. Immune cell subsets and serum Ig levels were determined by flow cytometry and ELISA, n=5-8 mice/group.

**Results:** 3 LC-Tg+ k-KO lines display excellent B cell surface expression of LC Tg (range 55-75% of B cells), and varying levels of serum LC Tg. 2 of these lines demonstrate significantly reduced spleen B cell numbers: 9.0±3.0 and 10.4±3.0 million, vs 24.0±11.1 in non-Tg kappa+ littermates, $p<0.05$. Whereas cell counts in the third line (14.9±7.6 million) are not statistically different from non-Tg kappa+ mice, this line manifests marked editing at the lambda locus: 58.3±11.3% of B cells express lambda, compared to 7.4±5.0% in non-Tg kappa+ mice, $p<0.05$. Low levels of serum anti-collagen kappa+ Ig are detected in serum of LC-Tg+ k-KO mice.

**Conclusions:** Mice bearing the IGKV3-encoded LC preferentially expressed by anti-collagen Ig demonstrate evidence of B cell regulation, including deletion and profound receptor editing. This suggests independent roles for this LC in disease and for IGKV3 genes in autoimmunity and tolerance.

## FR-PO572

**High Induction and Low Degradation Abilities on Neutrophil Extracellular Traps of Sera in Patients with MPO-ANCA-Associated Vasculitis** Daigo Nakazawa,[1] Saori Nishio,[1] Masaharu Yoshida,[2] Utano Tomaru,[1] Haruki Shida,[1] Tatsuya Atsumi,[1] Akihiro Ishizu.[3] *[1]Depts of Internal Medicine II, Hokkaido Univ Graduate School of Medicine, Sapporo, Japan; [2]Renal Unit of Internal Medicine, Hachioji Medical Center, Tokyo Medical Univ, Tokyo, Japan; [3]Faculty of Health Sciences, Hokkaido Univ, Sapporo, Japan.*

**Background:** MPO-ANCA-associated vasculitis (MPO-AAV) is a severe and chronic autoimmune disease that closely related to neutrophil extracellular traps (NETs). The disordered regulation of NETs that contain the antigen for ANCA could possibly induce the vicious circle of pathogenesis in MPO-AAV. The aim of this study is to determine the serum abilities on NETs induction and degradation in patients with MPO-AAV.

**Methods:** Patients enrolled in this study included 38 MPO-AAV and 7 SLE patients diagnosed and treated in Hokkaido University Hospital between January 2008 and May 2012. After acquirement of written informed consent, peripheral blood samples were obtained without anticoagulants, and sera were stored at -80 °C until use. NETs induction rate was evaluated by reaction of patient-IgG with healthy neutrophils primed by TNF-α. ANCA affinity was determined by the competitive inhibitory ELISA method. DNase I activity and NETs degradation ability were evaluated by ELISA and the incubation of patient serum with phorbol myristate acetate-induced NETs, respectively.

**Results:** IgGs eluted from sera of MPO-AAV patients induced NETs (NETs induction rate: 16.6±9.7 %). This rate was significantly higher than that of SLE and healthy controls (SLE; 7.2±7.2%, Healthy control; 3.2±1.4%). In addition, the NETs induction rate was correlated with vasculitis activity and ANCA affinity. On the other hand, activity of DNase I, the important regulator of NETs in the serum, was generally low in MPO-AAV patients and many patients showed impaired degradation of NETs. Furthermore, the presence of anti-NETs antibodies, which could interfere with the degradation of NETs by DNase I, was demonstrated in some MPO-AAV sera.

**Conclusions:** These findings demonstrated high induction and low degradation abilities on NETs of sera in MPO-AAV patients.

## FR-PO573

**Hypogalactosylation and Hyposialylation of Serum IgG from Patients with ANCA-Associated Systemic Vasculitis: Relation to Disease Activity** Olivier M. Lardinois,[1] Jacob Hess,[1] Leesa Deterding,[2] Lydia Aybar,[1] Caroline J. Poulton,[1] Candace Henderson,[1] JulieAnne G. McGregor,[1] Donna O. Bunch,[1] Ronald J. Falk.[1] *[1]Medicine, Univ of North Carolina Kidney Center, Chapel Hill, NC; [2]Mass Spectrometry Group, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

**Background:** There is ample evidence that ANCA are primarily and directly involved in the pathogenesis of small-vessel vasculitis. In several inflammatory autoimmune diseases, the subfamily of Fc glycans deficient in terminal sialic acid and galactose (IgG-G0 glycan form) is significantly increased. Studies have shown that this also applies to patients with active ANCA-associated vasculitis (AAV) [1] and that the high incidence of IgG-G0 glycan form in serum of PR3-ANCA patients correlates with disease activity [2]. Here we investigate whether a similar pattern of abnormal IgG glycosylation exists in the serum of MPO-ANCA patients that correlates with disease activity.

**Methods:** Serum or plasma samples were collected from 30 healthy controls, 29 patients with MPO-ANCA, and 21 patients with PR3-ANCA. IgGs from serum or plasma samples were affinity-purified using immobilized protein AG. Isolated IgGs were digested with trypsin, and the released glycopeptides were identified and quantified by liquid chromatography-electrospray tandem mass spectrometry. The disease activity of the MPO- and PR3-ANCA patients was evaluated by Birmingham Vasculitis Activity Score (BVAS).

**Results:** We found that IgG-G0 levels of MPO-ANCA patients are elevated both at the time of active disease and during disease remission and, therefore, do not correlate with disease activity. As expected, IgG-G0 levels of active PR3-ANCA patients significantly dropped during disease remission and regained glycosylation levels indiscernible from those in healthy controls.

**Conclusions:** Our results suggest that significant differences exist between MPO- and PR3-ANCA diseases regarding the association of aberrantly glycosylated IgG levels with disease activity. It is conceivable that these differences may contribute to significant clinical difference in the disease course, severity, or relapse rate observed between the two diseases.

## FR-PO574

**Proteinase 3 and Myeloblastin Are Two Distinct Entities** Elizabeth Alderman McInnis,[1] Anshul K. Badhwar,[1] Akhil Muthigi,[1] Samuel C. Allred,[1] Jia Jin Yang,[1] Olivier Lardinois,[1] J. Charles Jennette,[1,2] Ronald J. Falk,[1] Dominic J. Ciavatta.[1] *[1]UNC Kidney Center, Div of Nephrology and Hypertension, UNC at Chapel Hill; [2]Dept of Pathology and Laboratory Medicine, UNC at Chapel Hill.*

**Background:** Proteinase 3 (PR-3) is a serine protease present in the azurophilic granules of PMNs and one of the major targets of ANCA. There are two annotated transcripts from the PR3 gene: PR3 ($PR3_T$) and myeloblastin ($MBN_T$). Whether the PR3 gene encodes two different protein isoforms, still remains a matter of debate. PMNs isolated from ANCA patients during active disease express elevated levels of myelopoiesis related genes including PR3 and MPO. This marked dysregulation in ANCA patients may extend to the expression of other PR3 transcripts. To test the hypothesis that abnormal expression and/or translation of PR3 transcripts play a role in the pathogenesis of ANCA, the following questions were addressed in this investigation: What is the relative frequency of both $PR3_T$ and $MBN_T$ in our patient population? Is PR3 message translated in mature neutrophils?

**Methods:** Total leukocyte mRNA was isolated from patients with ANCA disease (BVAS range 0-26) and control subjects and screened for PR3 and MBN using transcript specific primers. Total PR3 transcript levels were monitored by qPCR. Potential translation of these transcripts was studied in cell lines and patient neutrophils.

**Results:** Over 30% of unique MPO ANCA patients (n=28) and over 20% of unique PR3 ANCA patients (n=40) were positive for the MBN specific transcript; while, only one healthy subject (n=19) was positive for MBN. Total PR3 expression is elevated in patients positive for MBN. Expression of MBN is not due to an influx of progenitors into the periphery. Samples from patients with "left-shift" were negative for the MBN transcript.

The exclusive transcription of MBN in MCF-7 cell lines indicates that this gene can be translated. Neutrophils isolated from patients with ANCA vasculitis synthesize both PR3 and MPO.

**Conclusions:** MBN and PR3 are not synonymous transcripts, do not encode identical proteins and the transcripts are present in ANCA patients. Also, neutrophils from ANCA patients translate a plethora of proteins, including PR3 and MPO.

*Funding:* NIDDK Support

## FR-PO575

**Gleaning B Cell Phenotype from Rituxin Panel Data: Decreased %$CD5^+$ B Cells in Patients with ANCA Vasculitis Portend a Shorter Time to Relapse after Rituximab** Donna O. Bunch, JulieAnne G. McGregor, Lydia Aybar, Carmen E. Mendoza, Caroline J. Poulton, Elizabeth Studstill, Yichun Hu, Susan L. Hogan, John Schmitz, Ronald J. Falk, Patrick H. Nachman. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

**Background:** To avoid infections and adverse events from therapy in patients with anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV), clinicians require improved markers of disease activity and impending relapse to guide immunosuppression

strategies post-rituximab. $CD5^+$ B cells, a surrogate marker of B regulatory cells, may serve as this needed biomarker but more data is required.

**Methods:** We examined B cell phenotype in 45 patients with AAV after rituximab therapy by flow cytometry. Immunosuppression in addition to rituximab was not an exclusion criterion. Whole blood or PBMCs were stained with antibodies to CD19, CD20, CD45 and CD5. Data from research samples was supplemented with data acquired from clinical Rituxin panels.

**Results:** Patients who had <30% $CD5^+$ B cells at the time of B cell repopulation (≥1% $CD19^+/CD20^+$ lymphocytes, n=5) relapsed sooner (14±5 mos) than patients who repopulated with ≥30% $CD5^+$ B cells (n=40, 25±14 mos; p=0.025) after rituximab. Patients in the two groups were similar with respect to age, gender, PR3 positivity and lung involvement.

**Conclusions:** Our data indicate a low $\%CD5^+$ B cells correlates with a shorter time to relapse following rituximab therapy without taking immunosuppression dose into consideration. Monitoring $\%CD5^+$ B cells serves as an effective biomarker to signal impending flare and can help guide rituximab re-dosing and/or use of other remission maintenance therapy in AAV.

## FR-PO576

**Genetic Regulation of CD177 – A Receptor Presenting Anti-Neutrophil Cytoplasmic Antigen Proteinase 3** Claudia Eulenberg,[1] Sylvia Bähring,[1] Friedrich C. Luft,[1] Ralph Kettritz.[1,2] *[1]Experimental and Clinical Research Center, Charité Medical Faculty and the Max-Delbrück Center for Molecular Medicine; [2]Nephrology and Intensive Care Medicine.*

**Background:** ANCA activate neutrophils leading to crescentic glomerulonephritis. CD177 presents the major ANCA antigen proteinase 3 (PR3) on the neutrophil membrane (mPR3) yielding $CD177^{neg}/mPR3^{low}$ and $CD177^{pos}/mPR3^{high}$ subsets. The percentage of $CD177^{pos}/mPR3^{high}$ neutrophils confers a risk for ANCA vasculitis, is associated with worse clinical course and a stronger response to PR3-ANCA. We studied mechanisms that control CD177 protein expression.

**Methods:** We used human neutrophils, CD34+ stem cells, DNA and cDNA sequencing.

**Results:** We detected CD177 mRNA in $CD177^{pos}/mPR3^{high}$ neutrophils, but neither full-length nor truncated mRNA in $CD177^{neg}/mPR3^{low}$ cells. We separated both cell populations and analyzed their DNA and cDNA. By Southern blot analysis of the CD177 gene we excluded genomic recombination with a neighboring pseudogene and copy number variations to be causes of different CD177 gene expression. Structural DNA aberrations and single nucleotide variations were excluded for both subsets by genome-wide human SNP array 6.0 from Affymetrix® suggesting no differences in the DNA sequences between both subsets. DNA sequences in exon-coding region and in exon-intron transitions of the CD177 gene did also not differ between both subsets. Haplotype analysis in 13 parent-offspring trios identified 12 informative heterozygous SNPs revealing monoallelic CD177 expression in 11/13 trios with no informative SNPs in the remaining 2 trios. We identified the parental-allelic origin in 8/11 trios (2x paternal, 6x maternal). Monoallelic expression was non-synonymous in 9/11 children affecting the primary CD177 protein structure. Haplotype analysis in a neutrophil-differentiated CD34+ stem cell model suggested that one allele was preferentially expressed. The second allel showed minor expression before differentiation that decreased with G-CSF treatment.

**Conclusions:** The findings provide novel insight into CD177 gene regulation and could facilitate studying CD177-related mechanisms in ANCA-associated vasculitis and additional neutrophil-mediated diseases.

*Funding:* Government Support - Non-U.S.

## FR-PO577

**Correlation between the CD4-CD8 Values and Responses to Treatment of Primary Glomerulonephritis** Hilmi Umut Unal,[1] Ali Kilinc,[2] Mahmut Ilker Yilmaz.[3] *[1]Nephrology, Gulhane Military Medical Academy, Ankara, Etlik, Turkey; [2]Internal Medicine, Gulhane Military Medical Academy, Ankara, Etlik, Turkey; [3]Nephrology, Gulhane Military Medical Academy, Ankara, Etlik, Turkey; [4]Immunology, Gulhane Military Medical Academy, Ankara, Etlik, Turkey; [5]Immunology, Gulhane Military Medical Academy, Ankara, Etlik, Turkey.*

**Background:** Focal segmental glomerulosclerosis (FSGS) is a histologic diagnosis. Primary FSGS was previously considered to be largely unresponsive to immunosuppressive therapy; however, glucocorticoids, cyclosporine, and other immunosuppressive agents have been used with considerable therapeutic success. In a study conducted in patients with idiopathic membranous glomerulonephritis, CD4 + / CD8 + ratio was found significantly lower than the control group.In this study a CD4 +, CD8 + level and the CD4 + / CD8 + ratio evaluated the importance of the response to treatment.

**Methods:** In the 6-month follow-up responses to the treatment of patients which as a result of renal bx FSGS (primary) reported CD4+ ,CD8+ values and CD4+/CD8+ ratio evaluated retrospectively. Lymphocyte subgroups were measured by flow cytometry from peripheral blood in 23 patients. In patients between two groups who do not respond and respond to treatment were compared.

**Results:** There was significant difference between the CD 8 values($p<0.05$) in two groups. The CD4+/CD8+ T-cell ratio was significantly decreased in reponse to treatment patients compared with unresponsiveness group.

**Conclusions:** Regulatory T-cells confer negative regulatory effects on the immune response mediated by T-cells, and they can inhibit the proliferation of CD4+ T lymphocytes and the secretion of cytokines (mainly IL-2). In addition, they may also suppress self-reactive T-cells (CD8+). Studies have demonstrated that regulatory T-cells inhibit the activation of helper T-cells normally induced by antigen-presenting cells, which suppresses B lymphocyte activation and reduces the production of autoantibodies by B lymphocytes, thereby resulting in the alleviation of tissue injury mediated by the immune complex.More studies need conducting in order to understand of the importance of the Lymphocyte subgroups in the primary glomerulonephritis.

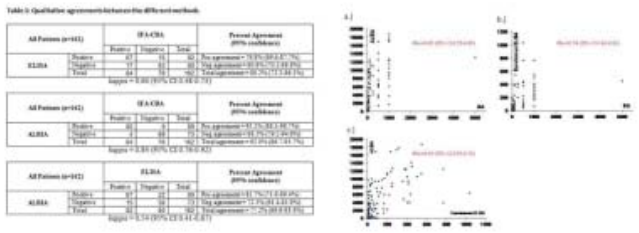
## FR-PO578

**Detection of Anti-Phospholipase $A_2$ Receptor Autoantibodies: A Comparison of Three Different Immunoassays** Astrid Behnert,[1] Mario Schiffer,[1] Laurence H. Beck,[2] Michael Mahler,[3] Marvin J. Fritzler.[4] *[1]Hannover Medical School, Hannover, Germany; [2]Boston Univ School of Medicine, Boston, MA; [3]INOVA Diagnostics, Inc., San Diego, CA; [4]Univ of Calgary, Calgary, Canada.*

**Background:** The detection of $PLA_2R$ antibodies in idiopathic membranous nephropathy (IMN), a common cause of nephrotic syndrome in adults, helps to differentiate between primary and secondary MN, it indicates whether immunosuppressive therapy is required and antibody titers are often used to monitor patients during therapy. We here compare the so far the only commercially available immunoassay, a semi-quantitative cell based assay (CBA-IIF, Euroimmun), to an observer independent, high throughput immunoassay on an addressable laser bead immunoassay (ALBIA) platform and a recently developed ELISA.

**Methods:** Serum samples of 162 patients with IMN were tested on CBA-IIF and ELISA according to the manufacturer's protocol (Euroimmun) and on ALBIA as previously described {Behnert et al., 2013}.

**Results:** Using the cut-off values established by the manufacturer for the ELISA and in our previous study for the ALBIA, good qualitative agreements were found. The overall qualitative agreements were 78.8% for CBA-IIF vs. ELISA, 91.4% for CBA-IIF vs. ALBIA, and 75.5% for ELISA vs. ALBIA. The Spearman rho values were: 0.69 for ALBIA vs. ELISA, 0.74 for ELISA vs. CBA-IIF and 0.85 for ALBIA vs. CBA-IIF.



**Conclusions:** Interestingly, our ALBIA correlated better with the Euroimmun CBA-IIF than the ELISA offered from the same company. This might be explained by the differences in the matrices utilized in these platforms. In ELISA, antigen is absorbed to plastic and reactivity of antibodies is highly dependent on sufficiently exposed epitopes. In ALBIA, the binding of antigen to spherical beads may permit binding of autoantibodies to the cognate, more stearically accessible conformational epitopes.

## FR-PO579

**Serological Profile of Idiopathic Membranous Nephropathy Cohort** Astrid Behnert,[1] Beina Teng,[1] Janina Müller-Deile,[1] Andrej Skoberne,[1] Mario Schiffer,[1] Marvin J. Fritzler.[2] *[1]Hannover Medical School, Hannover, Germany; [2]Univ of Calgary, Calgary, Canada.*

**Background:** Idiopathic membranous nephropathy (IMN), a common cause of nephrotic syndrome, has recently been identified as an autoimmune-mediated disease [Beck et al., 2009]. Autoantibodies (aab) to $PLA_2R$ are fairly specific for IMN and only found to a small percentage in secondary MN [Hofstra et al., 2012]. The clinical outcome of IMN patients is quite diverse (spontaneous remission vs. ESRD vs. proteinuria without progression). We performed serological profiles of 162 IMN patients to compare aab profiles with aab frequencies found in normal healthy individuals (NHI) and to hopefully identify factors that help to predict disease course in IMN.

**Methods:** Serum samples from 162 IMN patients were assayed for a variety of aab by ELISA (DFS70,ACA,$\beta_2$GPI), addressable laser bead immunoassay (ALBIA; Sm,U1RNP,SS-A,Ro52,SS-B,Scl-70,Jo-1,CENP-B,PMScl,PCNA) and to dsDNA by the C. lucilliae IIF assay. $PLA_2R$ aab were detected by a CBA-IIF (Euroimmun) and ALBIA [Behnert et al., 2013].

**Results:** $PLA_2R$ aab were found in ~54% of IMN patients whereas the frequency of other aab was uniformly below 2%. Anti-DFS70 were found in 16% of IMN patients.

| $PLA_2R$ CBA-IIF | $PLA_2R$ ALBIA | ACA ELISA | $\beta_2$ GPI ELISA | DFS70 ELISA | dsDNA Crithidia | Histone ALBIA | Jo-1 ALBIA | Ribosome ALBIA |
|---|---|---|---|---|---|---|---|---|
| 51,85% | 54,94% | 0,00% | 1,23% | 16,05% | 1,85% | 0,62% | 0,00% | 0,00% |

| Sm ALBIA | Sm-RNP ALBIA | Scl-70 ALBIA | PMScl ALBIA | CENP-B ALBIA | PCNA ALBIA | Ro-52 ALBIA | SSA-60 ALBIA | SSB ALBIA |
|---|---|---|---|---|---|---|---|---|
| 0,00% | 0,00% | 1,23% | 0,62% | 0,00% | 0,62% | 1,23% | 0,62% | 0,00% |

Table 1: Frequency of Autoantibodies in IMN Cohort

**Conclusions:** The frequency of anti-$PLA_2R$ aab in our IMN cohort is consistent with what has been previously published [Qin et al., 2011]. The frequency of the other aab, including anti-DFS70/LEDGF, was comparable to what has been reported in NHI and hence do not appear to serve as biomarkers to predict disease outcome or subsets. Anti-DFS70 antibodies are more prevalent in apparently NHI compared to patients with systemic autoimmune rheumatic diseases (SARD) [Mahler et al., 2012] whereas anti-Ro5/

TRIM21 reactivity is often regarded as a marker for SARD. The absence of anti-Ro52/TRIM and the high prevalence of anti-DFS70 confirms that IMN is a rather organ specific autoimmune disease.

### FR-PO580

**Invariant Natural Killer T Cells Are Depleted in Renal Impairment and Recover after Kidney Transplantation** Konrad Peukert,[1] Margret Patecki,[1] Stephan Wagner,[2] Roland Schmitt,[1] Anke Schwarz,[1] Hermann G. Haller,[1] Sibylle Von Vietinghoff.[1] *[1]Internal Medicine, Hannover Medical School, Hannover, Germany; [2]PHV Dialysis Centre, Germany.*

**Background:** Altered immune function in patients with renal failure results in both susceptibility to infection and increased inflammatory response. Invariant natural killer T (*i*NKT) cells are a conserved, immunoregulatory T lymphocyte subset that responds to lipid antigens with near-immediate cytokine production and cytotoxicity. *i*NKT cells are required for antibacterial host response. Whether chronic renal failure and renal replacement therapy alter *i*NKT cell abundance or phenotype has not been investigated.

**Methods:** NKT cells were studied by flow cytometry in peripheral blood of patients with acute renal failure, chronic hemo- and peritoneal dialysis, chronic kidney disease and after renal transplantation.

**Results:** A very marked reduction in NKT lymphocytes was found in acute renal failure before the first hemodialysis session.*i*NKT cells were depleted in peripheral blood of hemodialysis and peritoneal dialysis patients. This phenotype was accentuated after a hemodialysis session. Lesser degrees of *i*NKT cell depletion were observed in patients with chronic kidney disease. The *i*NKT cell phenotype was altered with lower levels of CD56 and CD161 expression. The decrease in *i*NKT cells and CD56 and CD161 expression were reverted within the first year after kidney transplantation.

**Conclusions:** We describe for the first time that *i*NKT lymphocytes are reduced in end-stage renal disease and further depleted by renal replacement therapy. *i*NKT cells are important for early host response including activation of other immune cells and their depletion may contribute to immune dysfunction in renal disease.

### FR-PO581

**A κ-Opioid Receptor Agonist, Identified by a High-Throughput Chemical Screen, Blocks Neutrophil FcγRIIA Mediated Functions** Hiroshi Nishi,[1] Hiroaki Iwata,[2] Ralf J. Ludwig,[2] Detlef Zillikens,[2] Tanya N. Mayadas.[1] *[1]Dept of Pathology, Brigham & Women's Hospital and Harvard Medical School, Boston, MA; [2]Dept of Dermatology, Univ of Lübeck, Lübeck, Germany.*

**Background:** Inflammation mediated by antibody-antigen immune complexes (ICs) contributes to autoimmune diseases. Studies in mice expressing the uniquely human FcγRIIA selectively on neutrophils that lack endogenous murine FcγRs (γ-chain deficient), suggest that human FcγRIIA on neutrophils represent a critical link between IgG and tissue injury in models of glomerulonephritis, arthritis and the reverse passive Arthus (RPA) reaction. Yet, there is little understanding of how this human receptor is regulated.

**Methods:** A high-throughput chemical screen was employed using 8,483 bioactive small molecules and neutrophils from mice expressing the human FcγRIIA. The effect of top-ranked compounds on IC-induced reactive oxygen species generation, phagocytosis, degranulation and adhesion was evaluated *in vitro*. Compound effect on IgG mediated tissue injury in animal models was also assessed.

**Results:** A synthetic κ-opioid receptor (KOR) agonist was identified that potently blocked FcγRIIA-mediated neutrophil cytotoxic functions in a dose dependent manner, while cell viability and responses to the phorbol-myristate-acetate were unaffected. Similar results were obtained with dynorphin A, an endogenous ligand of KOR. The KOR agonist was effective in blocking skin separation in an *ex vivo* model of epidermolysis bullosa acquisita and *in vivo*, inhibited the skin RPA reaction and K/BxN serum transfer arthritis. The effect of the KOR agonist was relatively selective for FcγRs, as it did not prevent thrombohemorrhagic vasculitis, which depends on the complement receptor Mac-1 (CR3). Current studies are evaluating the effect of this compound in glomerulonephritis.

**Conclusions:** A KOR agonist and ligand affects the proinflammatory functions of neutrophils activated with ICs. This raises the possibility that receptor targets of this class of opioids calibrate neutrophil responses to IgG and may be clinically beneficial in human neutrophil FcγRIIA-mediated inflammatory diseases.

### FR-PO582

**Development of an Immunosuppressive Adverse Effects Index: Validity and Reliability Evaluation** Calvin J. Meaney,[1,2] Ziad Arabi,[3] Rocco C. Venuto,[3] Joseph D. Consiglio,[4] Gregory E. Wilding,[4] Kathleen M. Tornatore.[1,2] *[1]Immunosuppressive Pharmacology Research Program, NYS Center of Excellence in Bioinformatics and Life Sciences; [2]Pharmacy Practice, School of Pharmacy and Pharmaceutical Sciences; [3]Medicine, Nephrology, School of Medicine and Biomedical Sciences; [4]Biostatistics, School of Public Health, Univ at Buffalo.*

**Background:** Immunosuppressive regimens (ISR) prescribed in renal transplant recipients (RTR) are complicated by interpatient variability in response and adverse drug effects (AE). Standardized, objective monitoring approaches are not available to evaluate AE of maintenance ISR consisting of calcineurin inhibitors (CNI), either cyclosporine (CYA) or tacrolimus (TAC), with mycophenolic acid (MPA).

**Methods:** An immunosuppressive AE index (index) was developed by transplant nephrologist with multi-disciplinary physician group incorporating objective AE severity in 17 clinical domains using physical exam, patient interview, laboratory and medication evaluations. This index emphasized AE associated with CNI, MPA, and steroids. Stable RTR receiving CYA (n=30) or TAC (n=28) with MPA were assessed with index and AE scores compared. Index evaluation included: face (inspection), content (subject matter expert opinion), and construct (ability to detect known AE) validities. Inter-rater reliability was evaluated with Kappa statistic and intra-class correlation (ICC).

**Results:** Multi-disciplinary index development and application to RTR verifies face validity. Nephrologists (subject matter experts) rated the 17 index domains as 3.1±0.75 of 4 (maximum) for clinical importance providing content validity. This index distinguished 1.75-fold greater gastrointestinal AE in TAC group compared to CYA (p=0.008). This AE difference is established between CNI ISR verifying construct validity. ICC was 0.81 (95% CI: 0.65-0.90) and Kappa statistic 0.68±0.25 for the overall index.

**Conclusions:** This novel immunosuppressive AE index demonstrated validity and reliability in RTR. Incorporation of this AE index into clinical evaluation post-transplantation may enhance therapeutic drug monitoring and quality of life.

### FR-PO583

**Urinary Xist Is a Potent Biomarker in Mouse Model of Membranous Nephropathy** Chia-chao Wu,[1,2] Yuh-feng Lin,[3] Shih-Hua P. Lin.[1] *[1]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Dept and Graduate Institute of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan; [3]DDiv of Nephrology, Dept of Medicine, Shuang Ho Hospital, Graduate Institute of Clinical Medicine, Taipei Medical Univ, New Taipei City, Taiwan.*

**Background:** Membranous nephropathy (MN) is one of the most common forms of nephritic syndrome in adults. The key to a substantial improvement of MN treatment is the identification of reliable biomarkers and pathogenic mechanism.Recently, long noncoding RNAs (lncRNAs) are often expressed in a disease stage-specific manner making these molecules attractive biomarker or therapeutic target. Therefore, this study shows for the first time that identification of MN-related lncRNAs in the pathogenesis of experimental MN model.

**Methods:** The membrane nephritis (MN)-related protein-coding genes, long noncoding RNAs and H3 post-translation modifications during the progression of MN including in serum and urine from experimental murine MN model at different stage were collected and checked. The biological effect and molecular mechanism of MN-related long noncoding RNAs in experimental MN model were also investigated using microarray assay, quantitative RT-PCR, and checking genome-wide binding sites in murine kidney by Chromatin isolation by RNA purification-sequencing (ChIRP-seq).

**Results:** The results indicated that Xist and NEAT1 expression levels are significantly up-regulated in experimental MN kidney. Chromatin immunoprecipitation experiments showed that decreased level of H3K27me3 targeting to NEAT1 and Xist promoter region in MN kidneys. Notably, Xist is upregualted in urine from experimental MN mice using quantification RT-PCR. Moreover, Xist are upregulated in renal biopsies with acute injury using array-based databases.

**Conclusions:** In summary, we provide the first evidence that Xist appears to be a potentially useful biomarker for evaluating kidney damage in experimental MN. These results suggested the potential use of Xist urine assay can aid MN diagnosis.

### FR-PO584

**Increased Serum Soluble Urokinase Plasminogen Activator Receptor in HIV Patients Reduces Nephrin Expression in Human Podocytes** Joanna Mikulak,[1] Massimo Alfano,[2] Manuela Nebuloni,[3] Guido Giusti,[4] Pravin C. Singhal,[5] Domenico Mavilio.[1] *[1]Laboratory of Clinical and Experimental Immunology, Instituto Clinico Humanitas, Mailan, Italy; [2]AIDS Immunopathogenesis Unit, San Raffaele Scientific Institute, Milan, Italy; [3]Dept of Biomedical Clinical Sciences, Univ of Milan, Milan, Italy; [4]Dept of Urology, Humanitas Clinical and Research Center, Milan, Italy; [5]Medicine, Hofstra North Shore LIJ Medical School, New York, NY.*

**Background:** Recently increased level of serum soluble form of urokinase-type plasminogen activator receptor (suPAR) has been postulated as one of the putative causes in adults with primary FSGS. In a mouse model, circulating suPAR has been shown to cause foot process effacement, proteinuria and FSGS through the activation of podocyte β3 integrin. We investigated the possible role of suPAR in HIV-associated kidney damage.

**Methods:** The effect HIV-plasma (containing suPAR, from HIV patients) was studied on human podocyte nephrin expression. To confirm the effect of suPAR, HIV-plasma was pre-treated with anti-suPAR antibody and followed by evaluation of its effects on the expression of nephrin and other markers in podocytes. To confirm its role, the direct effect of recombinant suPAR was also studied.

**Results:** HIV-plasma down regulated only nephrin expression (no change in podocin and synaptopodin) in podocytes. This reduction of nephrin expression was specific for suPAR since it was restored after treatment of HIV conditioned plasmas with the specific anti-suPAR antibody. Similar effect was observed in human podocytes with human recombinant suPAR protein. Nephrin loss was related to nephrin mRNA downregulation and was irreversible. In addition, the effect of suPAR on nephrin reduction was specific for the full length three-domain $D_I D_{II} D_{III}$ protein and not for cleaved $D_I$ or $D_{II} D_{III}$ soluble fragments.

**Conclusions:** Both recombinant and HIV-plasma suPAR were able to downregulate the expression of nephrin in human podocytes. HIV infection may be the potential factor to link increased suPAR concentration and glomerular permeability.

*Funding:* NIDDK Support

## FR-PO585

**Identification of a Human Podocyte Subpopulation Expressing Dc-Specific ICAM-3-Grabbing Nonintegrin Receptor (Dc-Sign)** Joanna Mikulak,[1] Guido Giusti,[2] Stefano Mantero,[3] Manuela Nebuloni,[4] Pravin C. Singhal,[5] Domenico Mavilio.[6] *[1]Laboratory of Clinical and Experimental Immunology, Instituto Clinico Humanitas, Milan, Italy; [2]Dept of Urology, Humanitas Clinical and Research Center, Milan, Italy; [3]UOS/IRGB, CNR, Milan, Italy; [4]Humanita Clinical and Research Center, Milan, Italy; [5]Pathology Uni, Univ of Milan, Milan, Italy; [6]Medicine, Hofstra North Shore LIJ Medical School, New York, NY.*

**Background:** HIV-associated Nephropathy is one of the clinical manifestations of AIDS. Our previous study in human podocytes has demonstrated the contribution of Dc-sign in HIV-1 internalization and establishment of virus reservoir. Since Dc-sign receptor plays a critical role in HIV pathogenesis, we attempted to confirm these findings *in vivo* as well as in prmary podoytes.

**Methods:** Frozen human renal tissues from nephrectomized specimens were immunolabeled for Dc-sign and examined under a confocal microscope; mRNA hybridization probe was also used to localize Dc-sign. In addition, glomeruli were isolated by laser-manipulated micro-dissection and a laser pressure catapulting methods. TaqMan Q-PCR assays were carried out to identify podocyte specific molecular marker transcripts. Primary podocytes cultured from the isolated glomeruli (human renal tissues) were co-labeled for Dc-sign and podocyte specific molecular markers.

**Results:** Twenty percent of glomeruli displayed expression of Dc-sign under confocal microscopic analysis. Both in situ hybridization studies and specific anti-Dc-sign mRNA probe exhibited comparable results. TaqMan Q-PCR assays on captured glomeruli displayed podocyte specific mRNA transcripts not only for nephrin, podocin, synaptopodin, WT-1 but also for Dc-sign. In vitro studies, TaqMan Q-PCR assays on podocytes, confirmed the expression of nephrin, podocin, synaptopodin, WT-1, and DC-sign. Additionally, confocal microscopy revealed that a small percentage of cultured podocytes also express Dc-sign. The cells expressing Dc-sign receptor also co-expressed other podocyte specific markers.

**Conclusions:** These findings indicate that a small sub-population of podocytes able to express Dc-sign receptor.

## FR-PO586

**Angiotensinogen Copies Induce Disparate Effects during the Initiation and Progression of HIV-Associated Nephropathy (HIVAN)** Xiqian Lan,[1] Ankita Sagar,[1] Partab Rai,[1] Guohua Ding,[3] Ashwani Malhotra,[1] Praveen N. Chander,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, New York, NY; [2]Pathology, New York Medical College, Valhalla, NY; [3]Medicine, Wuhan Univ, Wuhan, Hubei, China.*

**Background:** Ang II contributes to the progression of HIVAN through its hemodynamic effects as well as direct cellular effects. We evaluated the effect of different copies of angiotensinogen (Agt) in the initiation and progression of HIVAN in genetically engineered HIVAN mice (Tg26).

**Methods:** Control and Tg26 mice with 2 (Tg26/Agt-2) and 4 (Tg26/Agt-4) copies of Agt were evaluated for severity of renal lesions, arteriosclerosis and hypertension at 8 weeks (Tg26/Agt-2/8wks and Tg26/Agt-4/8wks) and 16 weeks (Tg26/Agt-2/16wks and Tg26/Agt-4/16wks). To score collagen deposition, renal cortical sections were stained with sirus red. RNA was extracted from renal tissues and probed for AT1, AT2, PAI-1, and molecules involved in Tert and epithelial mesenchymal transition (EMT) pathways.

**Results:** Tg26/Agt-4/8wks showed lower blood pressure (110/80 mm Hg) when compared to mice with Tg26/Agt-2/8 wks (140/90 mm Hg). While Tg26/Agt-4/16wks displayed higher blood pressure compared with Tg26/Agt-2/16wks. Tg26/Agt-4/8wks displayed attenuated expression of PAI-1 vs Tg26/Agt-2/8wks; however, Tg26/Agt-4/16wks showed 3-fold greater PAI-1 expression than to Tg26/Agt-2/16wks. Tg26/Agt-2/8wks developed renal lesions which were more advanced than Tg26/Agt-4/8wks. On the other hand, Tg26/Agt-4/16wks displayed more advanced renal lesions when compared to Tg26/Agt-2/16wks. Tg26/Agt-4/8wks displayed attenuated expression of AT1 and AT2 and down regulation of Tert, TGF-β, Snail, and vimentin when compared to Tg26/Agt-2/8wks. However, all these markers were comparable between these groups at 16 wks of age.

**Conclusions:** Tg26/Agt-4 displayed slowed progression of HIVAN at early time periods because of relatively low blood pressure and attenuated expression of AT1, TGB-β, PAI-1, Tert and markers of EMT. However, Tg26/Agt-4 at 16 wks displayed accelerated growth because of high blood pressure and catching up with EMT and profibrotic molecules.

**Pericytes Are Critical Innate Immune Response Sentinels in the Kidney** Shunsaku Nakagawa, Julia Lichtnekert, Gabriela Campanholle, William Arthur Altemeier, Jeremy Stuart Duffield. *Dept of Medicine, Univ of Washington, Seattle, WA.*

**Background:** In recently published studies we showed kidney pericytes markedly activate innate immune pathway in response to kidney injury in vivo, that targeted therapies against pericytes are anti-inflammatory and that Toll-like receptor (TLR)-2/-4 and MyD88 signaling was involved with activation of inflammation and fibrosis after ischemia-reperfusion injury (IRI), but that MyD88 signaling in the myeloid lineage had little impact on macrophage activation or disease progression after IRI (Campanholle et al PLoS ONE 2013). In the following we have dissected innate immune responses to sterile kidney injury in pericytes.

**Methods:** Pericytes were isolated from normal kidney of wild-type, *Tlr2-4-/-* and *Myd88-/-*, *Nlrp3-/-* and *Caspase 1-/-* mice and primary cultures generated. Crude DAMPs were purified and characterized from IRI kidneys 24h after surgery. After stimulation with TLR ligands or DAMPs, pericyte cultures were analyzed for cytokine secretion and functional responses.

**Results:** Stimulation of TLR 1/2, 2/6, 3, 4, 7 and 9 in pericytes resulted in secretion of a broad array of pro-inflammatory cytokines and chemokines including IL-6 and MCP-1. Myd88 deficiency in pericytes attenuated these responses. DAMPs from IRI kidney activated TLR-2/-4, Myd88 signaling inkidney pericytes, but not primary tubular epithelial cells and vascular endothelial cells. Nuclear protein histones were identified as a major component DAMPs. DAMP-mediated pericyte activation resulted in secreted factors including IL-6, MCP-1 but also IL-1b, indicative of activation of inflammasome signaling. These responses were dependent on TLR-2/-4, Myd88 pathway, and the NLRP3 inflammasome. Finally transition of pericytes to myofibroblasts requires active MyD88 signaling.

**Conclusions:** Pericyte activation by DAMPs is a critical step in inflammation, recruitment of leukocytes, myofibroblast transition and progression of sterile kidney injury.

## FR-PO588

**Kidney CD103+ DCs Exacerbate Renal Injury through Activating CD8+ T Cells in Adriamycin Nephropathy** Qi Cao, Guoping Zheng, David C. Harris. *Centre for Transplant and Renal Research, Westmead Millennium Institute, The Univ of Sydney, Sydney, NSW, Australia.*

**Background:** CD103+ DCs, a newly described subset of DCs, display two distinct functions: induction of regulatory T cells and activation of CD8+ T cells by cross presentation of antigen. These have been demonstrated in diseases of lungs, intestine and skin. However, the characteristics and functions of CD103+ DCs in kidney remain unclear.

**Methods:** Adriamycin nephrosis (AN) was induced in BALB/c mice. The distribution, phenotype and *in vitro* function of kidney CD103+ DCs were assessed in normal and AN mice. CD103+ DCs were depleted by neutralizing CD103-saporin (SAP) antibody in AN mice to examine their role *in vivo*.

**Results:** CD103+ DCs were identified in kidney as CD45+/MHC-II+/CD11c+/CD103+/F4/80-/CD11b- cells. CD103+ DCs were distributed predominantly in cortex of normal and AN kidney. The number of CD103+ DCs was significantly increased in kidney of AN mice compared to that of normal mice. Depletion of kidney CD103+ DCs by CD103-SAP antibody improved renal function in AN mice, as evidenced by a decrease in proteinuria & serum creatinine and increase in creatinine clearance. AN mice treated with CD103-SAP antibody also had less glomerulosclerosis, tubular atrophy and interstitial expansion than did AN control mice. The possible mechanisms underlying the pathogenic role of CD103+ DCs were examined. Kidney CD103+ DCs expressed high levels of IL-6in AN mice, but not other inflammatory cytokines including IL-1beta, IL-12, IFN-g, TNF-α and MCP-1. The co-stimulatory molecules CD80, CD86 and B7-H1 were highly expressed in kidney CD103+ DCs in AN mice compared to those of normal mice. Kidney CD103+ DCs displayed higher capability of cross-presenting antigen to CD8+ T cells than did CD103- DCs.

**Conclusions:** CD103+ DCs are present in kidney and induce renal injury in AN mice. The mechanism underlying the pathogenic role of CD103+ DCs in AN mice may relate to their ability to activate CD8 T cells.

## FR-PO589

**Characterization of Innate Lymphoid Cells in the Kidney** Jan-Eric Turner,[1] Rolf A. Stahl,[1] Ulf Panzer.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Div of Molecular Immunology, MRC National Insitute for Medical Research, London, United Kingdom.*

**Background:** Innate lymphoid cells (ILC) are a recently identified cell type that is characterized by production of large amounts of the T helper cell cytokines IL-22, IL-17A, IFN-g, as well as IL-5 and IL-13 during immune responses. As cells of the innate immune system, ILC are activated independently from antigen directly by cytokine signals. So far ILC have mainly been studied in barrier organs, such as the gut, lung and skin.

**Methods:** We used multicolor flow cytometry to identify and characterize this novel cell type in the kidney of naïve and nephritic mice (nephrotoxic nephritis) for the first time.

**Results:** Lineage-negative Thy1.2$^{+}$IL-7R$^{+}$ ILC comprised around 1% of total renal lymphocytes in naïve mice. These renal ILC displayed expression of the surface markers IL-33R, CD25 and Sca-1, and of the transcription factor GATA3, identifying them as IL-13 and IL-5-producing type 2 ILC (ILC2). Furthermore, we could show that repetitive injections

of the ILC2-activating cytokine IL-33 expanded renal ILC2 in naïve and nephritic mice, resulting in a shift to a protective type 2 immune response in the kidney during a mouse model of crescentic glomerulonephritis. In line with this, the course of the disease was ameliorated in IL-33 treated mice.

**Conclusions:** In conclusion, our data provide first evidence for the presence of ILC in the murine kidney and suggest that modulation of the renal ILC response can be a promising therapeutic strategy, warranting further investigation.

## FR-PO590

**Antisense Inhibition of Renal CD40 Attenuates Adriamycin-Induced Nephropathy** Adam E. Mullick, Aaron Donner, Karen He, Huimin Li, Gene Hung, Mark Graham, Rosanne M. Crooke. *Isis Pharmaceuticals, Carlsbad, CA.*

**Background:** Adriamycin nephropathy (AN) is a common experimental model of chronic kidney disease resulting in progressive podocyte depletion and tubulointerstitial inflammation, followed by the development of glomerulosclerosis. Studies have demonstrated that blockage of CD40-CD40L via administration of a CD40L antagonistic antibody was effective at mitigating AN. The promise of such inhibitors has been stymied by thromboembolic events in patients receiving CD40L antagonists, resulting in termination of their clinical development. An alternative approach would be to inhibit CD40 via antisense oligonucleotides (ASOs).

**Methods:** To test this concept, AN was established in BALB/c mice by i.v. administration of 10.5 mg/kg adriamycin. Three days afterward treatments of 25 mg/kg/wk of CD40 ASO or a mismatch control ASO were initiated. After 6 wks, kidneys were harvested and histological and transcriptional assessments of disease severity were evaluated. Additionally, kidney function was evaluated by FITC-inulin clearance following a bolus injection.

**Results:** CD40 ASO treatment resulted in an 80% reduction in renal CD40 target mRNA expression and markers of renal injury, NGAL and KIM-1, were reduced in mice receiving CD40 ASO by 65% and 50%, respectively, relative to control ASO treatment. MCP-1 and CCL5, both downstream inflammatory targets of CD40 activation, were also reduced by >50% in renal tissue from CD40 ASO treated mice. The single dose FITC-inulin test revealed a 50% reduction in residual plasma FITC-inulin after 2hrs post-injection in CD40 ASO treated mice relative to control. Glomerular pathology, as assessed in both H&E- and PAS-stained tissues, was markedly attenuated after CD40 ASO treatment.

**Conclusions:** In summary, inhibition of CD40 in established AN mitigated functional, transcriptional and histologic assessments of disease severity suggesting that antisense inhibition of CD40 could be a therapeutically attractive modality for the treatment of renal inflammation in chronic kidney disease.

## FR-PO591

**Angiotensin II Receptor Blockers in Experimental Chronic Kidney Disease Model** Sun Moon Kim,[1] Hye-Young Kim,[1,2] Han Ro,[3] Ji Yong Jung,[3] Yon Su Kim.[4] *[1]Internal Medicine, Chungbuk National Univ Hospital; [2]Internal Medicine, Chungbuk National Univ, College of Medicine; [3]Internal Medicine, Gachon Univ of Medicine and Science; [4]Internal Medicine, Seoul National Univ, College of Medicine.*

**Background:** Activation of renin-angiotensin system has a detrimental effect on the progression of chronic kidney diseases (CKD). And blockade of RAS demonstrated clinical efficacy. To clarify the specific molecular events of angiotensin II receptor blockers in CKD, we conducted microarray analyses from subtotally nephrectomized (Nx) rats as a model of CKD.

**Methods:** Nx rats were treated early with vehicle or losartan for 8 weeks. Expression of messenger RNA (mRNA) was assessed by 'GeneChip Micorarray' technology.

**Results:** In contrast to the sham group, vehicle-treated Nx rats show increased blood pressure, albuminuria, serum creatinine, and renal lesions. Losartan therapy preserved renal function, abrogated albuminuria, and glomerular histology. Among the 171 transcripts differentially expressed between vehicle-treated Nx group and losartan group, 59 transcripts were overexpressed in vehicle-treated Nx group. These genes are significantly involved in lysosomal pathway. Two genes had the highest overexpression in Nx group: hexosaminidase A and cathepsin B. The expression of the other 109 genes were reduced in vehicle-treated Nx group compared to losartan group, these genes were significantly involved in cysteine and methionine metabolism, glutathione metabolism, selenoamino acid metabolism, and arginine and proline metabolism.

**Conclusions:** These results show that losartan therapy attenuated renal damage in CKD model and that genes implicated in lysosomal pathway, particularly hexosaminidase A and cathepsin B, may play a role.

## FR-PO592

**Effects of FTY720 on the Tubulointerstitial Inflammation in Rats with Albumin-Overload Nephropathy** Min Xu, Dan Liu, Bi-cheng Liu. *Institute of Nephrology, Southeast Univ, Nanjing, China.*

**Background:** Heavy proteinuria induces expression of inflammatory mediators resulting in tubulointerstitial inflammation. The Sphingosine-1-phosphate (S1P) analogue FTY-720 is a newly developed immunomodulatory drug with low cytotoxicity using myriocin as a lead compound, potently sequesters lymphocytes into lymph nodes by functionally antagonizing the activity of S1P receptors. This study was to investigate the effects of FTY720 on urinary protein excretion and inflammatory cells infiltration in albumin-overload rats.

**Methods:** Male Wistar rat was underwent a right-side nephrectomy, and divided into three groups: 1) saline: rats received daily intraperitoneal injections of saline solution (5g▪kg$^{-1}$▪d$^{-1}$), 2) AO (albumin-overload): induced by intraperitoneal injections of BSA 1week after surgery (5g▪kg$^{-1}$▪d$^{-1}$), and 3) AO+FTY720: FTY720 (0.5mg▪kg$^{-1}$▪d$^{-1}$) was administered concomitant to AO. All rats were killed at 9 week after nephrectomy.

**Results:** Compared with controls, urinary protein excretion increased in AO rats from the second week and increased to the highest level at 7 week, FTY720 significantly reduced these effects. In addition, routine blood test showed that FTY720 treatment attenuated inflammatory cells (including lymphocytes and macrophages) in circulation and immunohistochemical analysis showed that the number of inflammatory cells in the tubulointerstitium was decreased by FTY720. Western blot and RT-PCR analysis showed that the increase in gene and protein expression of chemokines MCP-1, TNF-α, IL-6, IL-10, arginase-1 and S1P receptors (S1P1 and S1p3 receptor) in kidney of albumin-overload rats was also decreased by FTY720. Furthermore, the expression of the S1P-synthesizing enzymes-Sphk1 was elevated in albumin-overload rats (according to the immunohistochemical analysis).

**Conclusions:** S1P may have a chemotatic effect via the S1P receptors on inflammatory cells and play a casual role in tubulointerstitial inflammation of albumin-overload nephropathy. FTY720 may function as an antagonist on S1P1 and S1P3 receptors to alleviate tubulointerstitial inflammation and proteinuria excretion.

## FR-PO593

**Cmip Is a Negative Regulator of T Cell Activation** Kelhia Sendeyo, Nahid Tabibzadeh, Djillali Sahali. *INSERM, U 955, Equipe 21, Univ Paris-Est Creteil Val-de-Marne, Créteil, France.*

**Background:** Immunopathology of acquired idiopathic nephrotic syndrome (INS) with relapse remains unclear. Active INS is associated with immune system disorders including hyporesponsiveness of lymphocytes to mitogens, decreased delayed hypersensitivity, defects in immunoglobulin switch and unclassical T helper polarization. We recently reported that cmip is overproduced in T cells of patients with INS relapse. To investigate the functional consequences of cmip induction in INS T cells, we generated transgenic mice selectively overexpressing cmip in mature lymphocytes.

**Methods:** Lck-cmip transgenic (Tg) mice were constructed by a targeting system based on reconstitution of functional X-linked hypoxanthine-guanine-phosphorybosyltransferase (HPRT) locus by homologous recombination. The full-length coding sequence of human cmip was inserted under control of the distal Lck promoter allowing cmip expression only in peripheral T-lymphocytes (TL).

**Results:** Tg mice developed an altered TL phenotype with an increase of naïve T cell subpopulation ($CD4^+$ or $CD8^+CD44^{low}CD62L^{high}$), whereas effector ($CD4^+$or $CD8^+CD44^{high}CD62L^{low}$) and memory T cell subpopulations ($CD4^+$ or $CD8^+CD44^{high}$ $CD62L^{high}$) were decreased, as compared with control littermates (CL).

Following CD3/CD28 (1μg/ml each) activation, Tg T cells displayed lower proliferation and decreased production of IFNg (Th1-like cytokine) and IL4 (Th2-like cytokine) relatively to control littermates, while IL10 production was not altered. This cytokine profile was associated with significant inactivation of ZAP70, LAT and Src kinases. Confocal fluorescence microscopy showed that these proteins colocalize in lipid rafts of activated wild-type, but not in activated Tg T cells. Dynamic videomicroscopy showed that overexpression of cmip in T cells prevents raft clustering and inhibits formation of immunological synapse in the presence of CD3 beads and soluble CD28.

**Conclusions:** Altogether, these results suggest that cmip interferes with T cell activation and may contribute to some T cell disorders including hyporesponsiveness of lymphocytes to mitogens reported in INS relapse three decades ago.

*Funding:* Government Support - Non-U.S.

## FR-PO594

**Down Regulation of Dendritic Interleukin-15 Production and Interleukin-15-Dependent Cytotoxic T-Cell Proliferation by Adenosine** Amos Douvdevani,[1] Hadar Eini,[1] Moshe Zlotnik.[2] *[1]Clinical Biochemistry and Pharmacology, Soroka Medical Center and Ben-Gurion Univ of the Negev, Beer-Sheva, Israel; [2]Nephrology, Soroka Medical Center, Beer-Sheva, Israel.*

**Background:** Dendritic cells (DCs) regulate the immune response through production of various cytokines and signaling molecules, among which is IL-15, an important NK and cytotoxic T-cell (CTL) activator and survival factor. At the site of immune reaction, adenosine is produced from ATP by CD39 and CD73, ecto-enzymes expressed on regulatory T-cells (Treg). The aim of this present study was to examine the effect of adenosine on IL-15 production by DCs and the implication of this effect on CTL proliferation.

**Methods:** Bone marrow derived DCs (BMDCs) were isolated from ICR mice. BMDCs were exposed to various adenosine receptor agonists/antagonist prior to stimulation with LPS and interferon-γ (IFN-γ). Levels of cAMP, IL-15 and IL-15 receptor α chain (IL-15Rα) were measured using QPCR and/or ELISA. To assess the effect on CTL proliferation BMDCs were gamma-radiated and co-cultured with CTLL-2, a cytotoxic T-cell line, in the presence or absence of adenosine.

**Results:** Stimulation of BMDCs with LPS and IFN-γ increased IL-15 and IL-15Rα levels. Treatment of stimulated BMDCs with adenosine significantly reduced IL-15/IL-15Rα mRNA and protein levels. This down-regulatory effect was blocked by the combination of ZM 241385, an $A_{2A}R$ antagonist, and MRS1754, an $A_{2B}R$ antagonist, while addition of only one of them separately yielded a partial inhibitory effect. Treatment of

BMDCs with adenosine receptor agonists increased cAMP levels, and di-butirilic-cAMP, a stable cAMP analog, effectively reduced IL-15Rα levels. Finally, treatment of BMDCs with adenosine, before stimulation and co-culture, significantly reduced PBMC-dependent CTLL-2 proliferation.

**Conclusions:** Our data indicate that adenosine acting through $A_{2A}R$ and $A_{2B}R$ by elevation of cAMP suppresses IL-15 and IL-15Rα levels in activated DCs and restrains CTL proliferation. These finding can set a pharmacological base for CTL dependent pathologies such as graft rejection treatment.

*Funding:* Private Foundation Support

## FR-PO595

**Delayed Treatment with Adenosine 2a Receptor Agonist Protects Kidneys from Long-Term Fibrosis** Isaah Vincent,[1] Diane L. Rosin,[2] Li Li,[1] Liping Huang,[1] Hong Ye,[1] Mark D. Okusa.[1] *[1]Dept of Nephrology, Univ of Virginia, Charlottesville, VA; [2]Dept of Pharmocology, Univ of Virginia, Charlottesville, VA.*

**Background:** Adenosine, released from inflamed tissues, accumulates and signals through its four G-protein-coupled receptor subtypes; activation of the adenosine 2a receptor (A2AR) on immune cells has potent tissue protective/anti-inflammatory effects following kidney ischemia-reperfusion injury (IRI).

**Results:** Using a folic acid (FA) -induced fibrosis model, we tested the hypothesis that A2AR signaling *after* the initial injury blocks kidney fibrosis. We see a large hematopoetic infiltrate into the kidneys after FA injection, with a large infiltrate of CD11b+CDllc-Ly6g- monocytes/macrophages and CD11b+CDllc-Ly6g+. neutrophils (determined by FACS analysis). This infiltrate is diminished by day 5. Tubulointerstitial fibrosis was evident in kidneys at five days after FA injection. Continuous treatment with A2aR agonist, ATL313 (1 ng/kg/min) beginning on day 1 or 3 attenuated fibrosis (trichrome staining or fibronectin immunoreactivity) on day 14. Continuous treatment of mice beginning on day 5, after much of the initial inflammation has subsided, reduced fibrosis by approximately 30% (by stereological analysis of trichrome staining and fibronectin deposition). Continuous treatment with the A2aR antagonist, ZM243185 (5 ng/kg/min), beginning on day 5 alone did not alter fibrosis, indicating endogenous adenosine is not sufficient to block fibrosis.

**Conclusions:** These results suggest that induction of A2aR signaling may reduce fibrosis either by limiting the initial inflammation or alter the repair process. We are currently examining mechanisms by which A2AR signaling diminishes fibrosis in response to FA and we are testing the effect of A2aR activation in 2 other models of fibrosis (postischemic fibrosis and aristolochic acid). These results extend our pharmacological approach to target fibrosis following acute kidney injury.

*Funding:* NIDDK Support

## FR-PO596

**A Pro-Inflammatory Change in Numbers of Monocyte and Dendritic Cell Subtypes Occurs Early in the Course of CKD** Eva Schepers, Griet Lrl Glorieux, Nathalie Neirynck, Annemieke Dhondt, Raymond C. Vanholder. *Internal Medicine, Nephrology, Univ Hospital Ghent, Ghent, Belgium.*

**Background:** Antigen-presenting cells play an important role in chronic inflammation associated with accelerated cardiovascular disease and immune dysfunction. Both monocytes and dendritic cells consist of 3 subpopulations: monocyte subtypes: CD14++CD16-, CD14++CD16+, and CD14+CD16++; and the subtypes of circulating DCs: myeloid DC1 (mDC1), mDC2 and plasmacytoid DC (pDC). The CD14++CD16+ monocytes are described as pro-inflammatory and for DCs the mDCs have antimicrobial activity while pDCs are mediators of antiviral immunity. No study up till now evaluated changes of these cell types in all stages of CKD.

**Methods:** This study for the first time describes the proportional distribution of monocytes and circulating DC populations in 198 patients throughout the consecutive stages of CKD and/or on renal replacement therapy in comparison to healthy controls. Flow cytometric analysis on whole blood was performed. Monocytes were identified based on the pan-monocytic CD86 and the subpopulations were distinguished based on CD14-CD16 expression. For the DCs, an enumeration kit was applied. Both absolute number and percentage of the total leukocyte population were evaluated.

**Results:** Although no difference in total monocytes was observed vs controls, a significant increase of CD14++CD16+ monocytes was found from CKD stage 3 on, which rises further up to a 3-fold rise in HD patients. Only in HD patients a significant decrease in number and percentage of CD14++CD16- cells combined with an increase in CD14+CD16++ monocytes was found. In PD patients no changes were observed. The DCs were decreased, by more than 25% from CKD1 on which was mainly due to a decrease in pDC. The PD group was the only population in which also the number and percentage mDC1 was decreased. An inverse correlation could be found between the CD14++CD16+ and the pDCs throughout the consecutive stages.

**Conclusions:** An increase in CD14++CD16+ monocytes and a decrease in the pDC suggest a pro-inflammatory role for these cells during progression of CKD. This points to the importance of studying these leukocyte subtypes more in depth in different stages of CKD.

## FR-PO597

**Determinants of Sclerostin Concentration in Hemodialysis Patients** Pierre Delanaye, Jean-marie H. Krzesinski, Xavier Warling, Nicole Simone Smelten, Etienne Cavalier. *Nephrologgy-Dialysis, Univ of Liege.*

**Background:** Sclerostin is an inhibitor of bone formation produced by osteocytes. A recent study showed that sclerostin was negatively associated with parathormone (PTH) levels and better predicted high bone turnover. Little is known about the other physiologic determinants.

**Methods:** Among the hemodialysis patients in 3 centers in the area of Liège, Belgium (n=212), we analyzed the results from 165 patients with vascular calcification score (Kauppila method). Sclerostin was available in 164 patients. The following clinical data were considered: age, gender, height, weight, dialysis vintage, hypertension status, diabetes, smoking and previous cardiovascular disease. The following laboratory data were considered: calcium, phosphorus, PTH, 25-OH vitamin D, albumin, troponin T and CRP. Different bone biomarkers were measured: bone-specific alkaline phosphatase(b-ALP), C-terminal telopeptide of collagen type I(CTX), intact amino-terminal propeptide of type I procollagen (PINP), tartrate-resistant acid phosphatase 5b(TRAP-5b) and osteoprotegerin(OPG). Sclerostin was measured with the TECO ELISA (TECO medical, Sissach, CH).

**Results:** The mean age of our population was 71± 14 y (44% of men). Mean sclerostin concentration was 1500±710 pg/mL. In univariate regression analysis, we found a significant positive relationship between sclerostin and age, height, dialysis vintage, albumin, troponin T and OPG . A significant negative relationship was found with PTH, CTX, P1NP and b-ALP. In multivariate analysis, age, height, phosphorus, albumin, troponin T, PTH and b-ALP were still associated with slerostin. Patients in the lower tertile of sclerostin were younger, smaller and had a lower dialysis vintage than those in the third tertile. They had lower levels of albumin, troponin, OPG and higher levels of PTH, CTX, TRAP-5b and b-ALP.

**Conclusions:** We confirm that the concentrations of sclerostin are high in hemodialysis patients. We did not find any association between sclerostin and calcification score. Like others, we found an inverse association between sclerostin and PTH or b-ALP levels. Interaction between sclerostin and albumin or troponin levels would deserve additional studies.

## FR-PO598

**Dephosphorylated-Uncarboxylated Matrix Gla Protein Concentration Is Predictive of Vitamin K Status and Correlated with Vascular Calcification in Hemodialysis Patients** Pierre Delanaye, Jean-marie H. Krzesinski, Xavier Warling, Nicole Simone Smelten, Etienne Cavalier. *Nephrology-Dialysis, Univ of Liege, Belgium.*

**Background:** Matrix Gla protein (MGP) is a potent local inhibitor of vascular calcification. MGP must benefit from a vitamin K-dependent carboxylation. The dosage of the inactive form (uncarboxylated and dephosphorylated: dp-ucMGP) could reflect the status of vitamin K. dp-ucMGP could also be correlated with vascular calcification.

**Methods:** Among the hemodialysis patients in 3 dialysis centers in Liège, Belgium (n=212), we analyzed the results from 165 patients with vascular calcification score (Kauppila method). 5 patients do not have MGP concentrations measured. We compared 23 patients treated with anti-vitamin K and 137 patients without this therapy. The following clinical data were considered: age, gender, BMI, dialysis vintage, hypertension status, diabetes, smoking and previous cardiovascular disease. Following laboratory data were utilized: calcium, phosphorus, PTH, 25-OH vitamin D, bone alkaline phosphatase, albumin, and CRP. dp-ucMGP was quantitated with the automated iSYS system (IDS, Boldon, UK).

**Results:** No difference was observed between patients treated or not with anti-vitamin K regarding the clinical characteristics. We observed significant differences for dp-ucMGP (5549±2230 pM vs. 2217±1134 pM, $p < 0.0001$) and albumin (40 mg / L [38, 41] versus 38 g / L [36, 40] $p = 0.048$). In 137 patients without anti-vitamin K therapy, a slight but significant correlation was found between dp-ucMGP levels and the calcification score ($r=0.17$, $p=0.04$). Considering the tertiles of dp-ucMGP (1647 et 2404 pM), subjects in the high tertile had a significant higher vascular calcification score than those in tertile 1: 9 ± 6 versus 11 ± 6 ($p=0.0414$). Tertile 3 comprised of more men whom had a higher BMI and lower albumin levels.

**Conclusions:** We confirm that the concentration of dp-ucMGP is higher in dialysis patients treated with anti-vitamin K. This confirms the interest of the dp-ucMGP as a marker of vitamin K status. We found an association between the concentration of dp-ucMGP and the level of vascular calcifications.

## FR-PO599

**Sclerostin and DKK-1 Levels across CKD Stages** Geert J. Behets,[1] Liesbeth Viaene,[2] Frank A. Blocki,[3] Patrick C. D'Haese,[1] Pieter Evenepoel.[2] *[1]Univ of Antwerp, Antwerp, Belgium; [2]Catholic Univ Leuven, Leuven, Belgium; [3]DiaSorin Inc, StillWater, MN.*

**Background:** Canonical Wnt pathway inhibitors, Sclerostin and Dickkopf-1 (DKK-1), suppress bone formation. In dialysis patients, serum sclerostin levels correlate positively with bone mineral density and bone volume, and negatively with bone turnover.

**Methods:** In a cross-sectional, observational study we evaluated 169 pre-dialysis (CKD stage 1-5), 98 hemodialysis (HD), 62 peritoneal dialysis (PD) and 78 apparently healthy subjects (HC). Serum sclerostin and DKK-1 were measured by ELISA. Other parameters included 1-84 PTH and FGF-23.

**Results:**

| | HC | CKD 1-2 | CKD 3 | CKD 4-5 | HD + PD |
|---|---|---|---|---|---|
| Age | 54±18 | 45±15 | 64±15 | 67±11 | 68±13 |
| Male (%) | 41 | 32 | 55 | 70 | 60 |
| Sclerostin (pmol/l) | 43.8±13.0° | 28.1±13.7° | 66.1±33.7° | 99.5±45.9° | 116.8±62.3* |
| PTH (pg/ml) | 48.8±29.6° | 25.4±17.7° | 38.5±21.6° | 105.4±88.9° | 231.7±218.4* |
| DKK-1 (pmol/l) | 65.9±21.3° | 41.1±14.0* | 40.7±16.0* | 33.2±13.1* | 37.8±25.8* |
| FGF-23 (pg/ml) | 46±14° | 40±17° | 75±34° | 513±1926° | 5860±5461* |
| Bone Alkaline Phosphatase (U/l) | 19.4±15.7° | 23.0±14.6 | 23.6±10.1 | 31.0±28.8 | 35.3±26.9* |
| *: p<0.001 vs HC; °: P<0.001 vs HD+PD | | | | | |

Interestingly, while the HC group displayed no significant correlation between PTH and sclerostin, the CKD group showed a positive correlation (r=0.272, p<0.001) whilst both dialysis groups showed a negative correlation (r=-0.256, p<0.01 in HD; r=-0.271, p<0.05 in PD). Furthermore, a strong negative correlation with eGFR was found in the CKD group (r=-0.616, p<0.001). DKK-1 levels correlated weakly (r=-0.129, p<0.05) in the whole study population, losing significance when parsed by sub-groups. Sclerostin correlated strongly with FGF-23 in the HC group(r=0.569, p<0.001), weaker in the CKD group (r=0.217, p<0.01), while the HD group showed no correlation.

**Conclusions:** Sclerostin levels increase along with renal failure progression and correlate positively with PTH in CKD and negatively in dialysis patients. The role and mechanism of the increased sclerostin levels in renal failure remains to be clarified.

## FR-PO600

**Effects of a Magnesium (Mg) Based Phosphate (P) Binder on Bone Metabolism in a Rat Model of Chronic Renal Failure (CRF)** Geert J. Behets,[1] Ellen Neven,[1] Kristina Gundlach,[2] Sonja Steppan,[2] Patrick C. D'Haese.[1] *[1]Univ of Antwerp, Antwerp, Belgium; [2]Fresenius Medical Care, Bad Homburg, Germany.*

**Background:** We have previously shown that the Ca-Mg based P-binder Osvaren (CaMg) at doses of 375 and 185 mg/kg/day effectively reduces serum P levels and vascular calcification (VC) in adenine-induced CRF rats . However, due to the severe CRF and resulting hyperparathyroid bone (HPT) disease, this model is not suited to measure dynamic bone parameters. In the current study a less severe CRF model (5/6$^{th}$ Nx) was used to evaluate the possible effect of CaMg on bone.

**Methods:** Six groups of male Wistar rats (N=12 each) underwent a 5/6$^{th}$ Nx. Three groups received a normal P diet (0.8 %; NP) and 3 groups a high P (1.03%; HP) diet. This approach was used to differentiate between possible bone effects resulting from P-deficiency vs. a direct Mg-effect. CaMg (185 and 375 mg/kg/day) was administered orally for 8 weeks.

**Results:** Serum creatinine levels indicated a mild CRF developed 2 weeks after 5/6$^{th}$ Nx (0.48±0.16 vs 1.17±0.33 mg/dl, p<0.05), which remained stable throughout the treatment period (1.51±0.90 mg/dl after 8 weeks). Serum total and ionized Ca levels and serum P levels did not differ between groups. PTH levels were ± 4-5 times higher at week 8 compared to baseline (p<0.05) pointing to a mild HPT. After 8 weeks, only the NP 375 group showed a significant decrease in urinary P excretion (11.1±2.7 vs 52.6±6.7 mg/24h, p<0.05), while it remained stable in the other groups. Bone and serum Mg levels were not different between groups. The NP 375 group showed a (statistically non-significant) increase in osteoid area (OA) versus vehicle (2.80±1.76 vs 0.76±0.030%, p=0.28). In the HP groups, no differences between treatments were found. Osteoblast and osteoclast perimeters as well as mineralization parameters (bone formation rate, mineralization lag time, adjusted apposition rate) showed no differences between groups.

**Conclusions:** In this study, CaMg did not show any direct effect on bone metabolism. The observed slight increase in OA in the NP 375 group is due to a relative P depletion rather than a direct effect of Mg.

## FR-PO601

**PTH, FGF-23, Sclerostin and Bone Mineral Density in End-Stage Renal Disease** Liesbeth Viaene, Kathleen Claes, Pieter Evenepoel. *Nephrology, Univ Hospitals, Leuven, Belgium.*

**Background:** PTH, and the osteocyte derived hormones FGF23 and sclerostin all play an important role in bone biology. Circulating levels of these hormones increase in chronic kidney disease to reach levels that are many folds higher in patients with end-stage renal disease (ESRD) as compared to healthy controls. The relationship between PTH, FGF23, and sclerostin levels and bone mineral density (BMD) in ESRD patients is incompletely understood.

**Methods:** We performed a cross-sectional study in 268 patients (65% M; age 52±13 years) with ESRD referred for renal transplantation. Parameters of mineral metabolism, including serum biointact PTH, FGF23 (Kainos), sclerostin (Tecomedical), calcidiol, and calcitriol were determined prior to engraftment and all patients underwent dual energy X-ray absorptiometry (DEXA) at lumbar spine (LS), total hip (TH) and forearm (1/3R) within 2 weeks after the transplant procedure. DEXA results are expressed as BMD (g/cm$^2$) and T-scores.

**Results:** Serum levels of biointact PTH (130 [67-2377] ng/l), FGF23 (1853 [554-5814] pg/ml), and sclerostin (1.15 [0.79-1.51] ng/ml) were high and as expected in ESRD and did show significant inter-correlations. T-scores less than -2.5 were observed in 19, 8, 29 % at LS, TH and 1/3R respectively. In univariate analysis, biointact PTH (inversely), FGF23 (directly), and sclerostin (directly) correlated with BMD at LS (p<0.05), TH (p<0.05) and 1/3R (p =0.06, FGF23 only). Adjustment for classical BMD determinants (age, gender and vitamin D status) and dialysis vintage only attenuated associations for sclerostin and PTH. Regarding FGF23, significance was lost at TH but reached at 1/3R.

**Conclusions:** High sclerostin and FGF23 levels, as opposed to PTH, associate directly with BMD in ESRD. Whether sclerostin and FGF23 are part of a homeostatic feedback loop aimed at preventing excessive mineralization or whether these hormones merely reflect high osteocyte number remains to be clarified.

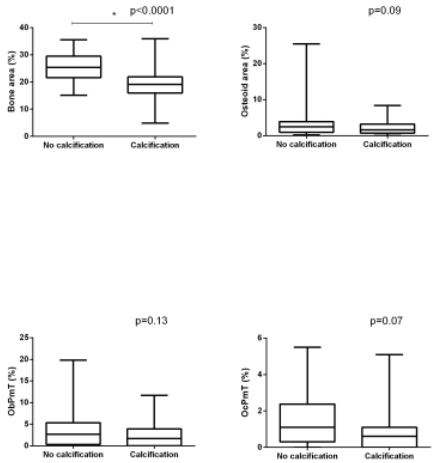
## FR-PO602

**The Bone-Vascular Axis and Inflammation in End-Stage Renal Disease** Liesbeth Viaene,[1] Geert J. Behets,[2] Sam Heye,[3] Kathleen Claes,[1] Diethard Monbaliu,[4] Jacques Pirenne,[4] Patrick C. D'Haese,[2] Pieter Evenepoel.[1] *[1]Nephrology, Univ Hospitals, Belgium; [2]Pathophysiology, Univ of Antwerp, Belgium; [3]Radiology, Univ Hospitals, Belgium; [4]Abdominal Transplantation, KU Leuven, Belgium.*

**Background:** Vascular calcification is a common complication of end stage renal disease (ESRD) and is predictive of subsequent cardiovascular disease and mortality. Mounting evidence linking bone disorders with vascular calcification has contributed to the development of the concept of the bone-vascular axis. Inflammation is involved in the pathogenesis of both disorders. The aim of the present study was to evaluate the relationship between aortic calcification (AC), inflammation, and bone disturbances in patients with ESRD.

**Methods:** Parameters of inflammation and mineral metabolism, AC and bone histomorphometry were assessed in 81 ESRD patients (55±13 year, 68% male) referred for renal transplantation. Static bone histomorphometry parameters such as bone area, and osteoblast- and osteoclast-covered perimeter to total perimeter were determined on transiliac bone biopsies performed during the transplant procedure. AC was quantified on lateral lumbar X-rays using the Kaupilla method.

**Results:** AC, low bone turnover and low bone volume was observed in 60, 37, and 21 % of patients. The association between AC and bone histomorphometric parameters are shown in Figure 1.



Inflammatory markers were found to be independently associated with aortic calcification (hsIL-6) and low bone volume (TNFα). Low bone volume was a significant risk factor for aortic calcification, independent of age, diabetes, and inflammation.

**Conclusions:** Low bone volume, as opposed to turnover, is a significant risk factor for aortic calcification, independent of traditional risk factors. Our data underscore the role of inflammation in the bone-vascular axis in CKD.

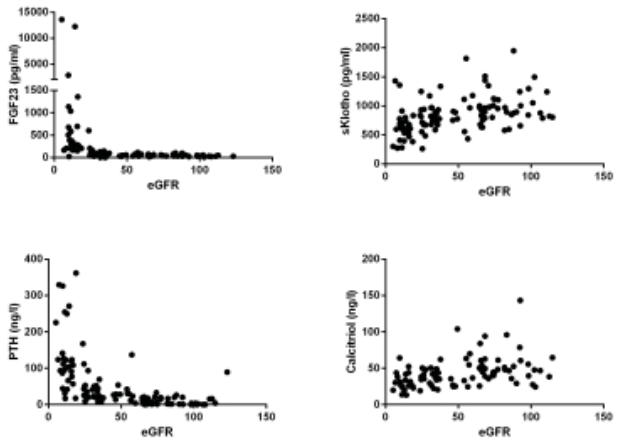
## FR-PO603

**The Protein-Bound Uremic Retention Molecule *p*-Cresyl Sulfate Inversely Associates with Soluble Klotho Levels in Patients with Chronic Kidney Disease** Liesbeth Viaene,[1] Bjorn Meijers,[1] Andreas L. Serra,[2] Pieter Evenepoel.[1] *[1]Nephrology, Univ Hospitals, Leuven, Belgium; [2]Nephrology, Institute of Physiology and Zurich Center for Integrative Human Physiology, Switzerland.*

**Background:** Klotho is a transmembrane protein that is predominantly expressed in the kidney. The extracellular domain is cleaved to generate soluble Klotho in blood, urine and cerebrospinal fluid. Membrane Klotho serves as a coreceptor for FGF23, whereas soluble Klotho functions as a hormonal factor and plays important roles in anti-aging, anti-oxidation, modulation of ion transport, and Wnt signaling. Studies exploring determinants of soluble Klotho levels in CKD patients are scanty. Recent experimental evidence indicates that the protein-bound toxins indoxyl sulfate (IndS) and p-cresyl sulfate (PCS) may suppress Klotho.

**Methods:** In order to identify determinants of soluble Klotho levels in CKD, we performed a cross-sectional observational study. In addition to soluble Klotho (ELISA), mineral metabolism parameters (including, FGF23, calcidiol and calcitriol, C-reactive protein (CRP)) and PCS and IndS were analysed in blood samples of 115 stage 1-5 CKD patients (57 men, 59±15 years, CKD-Epi eGFR 58.2±38.1 ml/min/1.72m²).

**Results:** Mineral metabolism parameters were as expected. Soluble Klotho levels (835 [263-4520] pg/ml) significantly correlated with eGFR and inversely with age, serum CRP, phosphate, FGF23, PTH, PCS and IndS.



Diabetics had significantly lower soluble Klotho levels. In multivariate analysis, PCS remained significantly correlated with soluble Klotho levels, independent of age and eGFR and explaining 13% of its variation.

**Conclusions:** Low eGFR, high age and high p-cresyl sulfate levels are independently associated with low soluble Klotho levels.

## FR-PO604

**Sclerostin: A New Player in the CKD Vascular Disease** Solenne Pelletier,[1] Cyrille B. Confavreux,[2] Julie Haesebaert,[3] Fitsum Guebre-egziabher,[4] Justine Bacchetta,[5] Marie-christine Carlier,[6] Maurice Laville,[1] Roland Chapurlat,[2] Marie-helene Lafage-proust,[7] Gerard M. London,[8] Denis Fouque.[1] *[1]Nephrology, Hopital Lyon Sud, HCL, Pierre-Benite, France; [2]INSERM 1033, Lyon, France; [3]Pôle Information Médicale Evaluation Recherche, HCL, Lyon, France; [4]Nephrology, Hopital Edouard Herriot, HCL, Lyon, France; [5]Centre de Référence des Maladies Rénales Rares, HFME, HCL, Bron, France; [6]Fédération de Biochimie, HCL, Pierre-Benite, France; [7]INSERM U890, IFR 62, Saint-Etienne, France; [8]INSERM U970, Paris, France.*

**Background:** Hemodialysis (HD) patients with adynamic bone are at higher risk of abdominal aortic calcifications (AAC), which are predictive of cardiovascular morbidity. Sclerostin, a factor mainly synthetized by osteocyte, acts on osteoblast as a potent inhibitor of bone formation. Serum sclerostin is increased in HD. We studied relationships between AAC, bone biomarkers and serum sclerostin concentration in HD patients.

**Methods:** Blood was drawn after overnight fast for PTH, calcium, phosphorus, 25OH vit D, bone specific alkaline phosphatase (bSAP). Serum sclerostin was measured by Elisa (Teco®, Switzerland). We used the Framingham risk score to estimate the cardiovascular risk based on age, gender, cholesterol (total and HDL), smoking status and systolic blood pressure. AAC was non-invasively assessed on lateral spine imaging using DXA according to the semi-quantitative Kauppila score.

**Results:** We included 53 HD patients. Median [Q1-Q3] age was 53 [35.2-62.7] and patients were on dialysis for 20 [6-44] months. There were 60% men and 24% diabetic. Framingham risk score was positively associated with the AAC score (p=0.024). Sclerostin was strongly positively associated with AAC score (R=0.48, p<0.001) whereas serum calcium, phosphorus, bSAP and PTH were not. In a multivariate analysis including Framingham risk score, diabetes, hemodialysis duration, BSAP and 25-OH vitamin D, sclerostin remained significantly associated to AAC score with an adjusted OR [95% CI] of 13.68 [2.22-84.37] (p=0.005).

**Conclusions:** Sclerostin may become an interesting cross-talk marker between bone and artery in hemodialysis patients. Whether sclerostin acts directly on arterial calcification process or indirectly through osteoblasts remains to be established.

## FR-PO605

**Association between Serun Sclerostin Levels and Serum Phosphate Levels in Patients on Hemodialysis** Yukari Asamiya,[1] Aiji Yajima,[2] Shigeru Otsubo,[3] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Div of Renal Replacement Therapeutic Science, Akita Univ School of Medicine, Akita, Japan; [3]Dept of Blood Purification, Sangenjaya Hospital, Tokyo, Japan.*

**Background:** Osteocytes have recently been demonstrated to play highly important roles in bone remodeling and phosphate homeostasis. Sclerostin, produced by osteocytes, has been identified as a key protein that inhibits bone formation via the inhibition of the osteoblast Wnt/β-catenin signaling pathway. However, sclerostin's role in renal bone disorders is largely uncertain.

**Methods:** This study examined the association of serum sclerostin levels with clinical and laboratory parameters, including serum levels of phosphate, bone remodeling markers, intact parathyroid hormone (PTH), and estradiol, with the treatment agents for mineral and disorders in hemodialysis (HD) patients. The 102 HD patients (mean age, 66.4 ± 8.9 y) and 30 healthy age-, sex-, and menopausal-status-matched individuals were examined between April and June 2011. The HD patients underwent treatment based on the treatments guideline for patients with CKD-mineral bone disorders.

**Results:** In the HD patients, the mean intact PTH and phosphate levels were 190 ± 185 pg/mL and 5.2 ± 1.4 mg/dL, respectively. The sclerostin levels of the HD patients were extremely high and varied widely compared with those of controls (164.7 ± 77.6 vs. 12.6 ± 4.7 ng/mL, P < 0.0001). A multivariate logistic regression analysis of the HD patient data showed that the serum sclerostin levels were significantly associated with male gender (β = 0.679, P = 0.016, odds ratio [OR] = 3.89), phosphate levels (β = 0.484, P = 0.009, OR = 1.62), duration of HD (β = 0.078, P = 0.047, OR = 1.08), and use of cinacalcet hydrochloride (β = 0.705, P = 0.018, OR = 0.24). Serum sclerostin levels were negatively correlated with serum levels of bone-specific alkaline phosphatase (r = –0.254, P = 0.010) and tartrate-resistant acid phosphatase isoform type 5b (r = –0.229, P = 0.021).

**Conclusions:** Serum phosphate levels may influence serum sclerostin levels in HD patients without severe hyperparathyroidism.

## FR-PO606

**Sequential Skeletal, PTH, FGF23 and Sclerostin Changes in Rats with Renal Failure and Secondary Hyperparathyroidism** Cheryl P. Sanchez,[1,2] Subburaman Mohan.[2,3] *[1]Pediatrics, Loma Linda Univ Children's Hospital, Loma Linda, CA; [2]Musculoskeletal Disease Center, Jerry L Pettis VAHS, Loma Linda, CA; [3]Medicine, Loma Linda Univ, Loma Linda, CA.*

**Background:** Studies have shown decreases in cortical and trabecular bone in chronic kidney disease.

**Methods:** To determine the time course changes in PTH, FGF23, sclerostin and skeletal abnormalities, 39 male rats, underwent 5/6 nephrectomy (Nx=27) or sham Nx (Control, n=12). Nx rats were fed standard rodent diet (Nx-C, N=13), or high phosphorus diet (Nx-Phos, N=14). Femur and lumbar bone mineral density (BMD) were obtained at baseline, 12 and 25 days post-Nx, and micro-CT was obtained 25 days post-Nx.

**Results:** There were no differences in femur length or gain in body length. Serum creatinine increased after Nx. After 12 days post-Nx, iPTH and iFGF23 levels were higher in Nx-Phos, 1232±563 pg/mL and 0.35±0.33 ng/mL, compared to Nx-C, 771±155 pg/mL and 0.12±0.08 ng/mL, and Control, 464±126 pg/mL and 0.10±0.09 ng/mL, p<0.001. Serum sclerostin levels did not change. Lumbar BMD declined in Nx-Phos 12 days post-Nx, 0.10±0.01 g/cm$^2$, compared to Nx-C and Control, 0.11±0.01 g/cm$^2$ and 0.11±0.01 g/cm$^2$, p<0.05. The percent gain in lumbar BMD at 25 days post-Nx was lower in Nx-Phos, 79%, compared to Nx-C and Control, 99% and 112%, p<0.02. Femur BMD did not change between groups. Cortical (femur) BV/TV by micro-CT was lower in Nx-Phos, 0.50±0.03% compared to Nx-C and Control, 0.53±0.02% and 0.54±0.02%, p<0.033. Trabecular (lumbar) BV/TV declined by 20% in Nx-Phos compared to Nx-C and Control, p<0.01, likely due to lower trabecular number and increase in trabecular spacing, p<0.001. There was a 46% decrease in connectivity density and an increase in structural model index in Nx-Phos, 3.9±1.2, compared to Nx-C and Control, 2.0±1.0, p<0.0001, suggesting more rodlike trabecular bone appearance. IPTH and FGF23 negatively correlated with trabecular and cortical BV/TV, R= -0.5, p<0.01. iPTH increased with FGF23, R= 0.8, p<0.001. Compared to micro-CT, BMD did not detect alterations in cortical bone.

**Conclusions:** The findings show that changes in trabecular bone occur early in kidney failure accompanied by an increase in iPTH and FGF23.

## FR-PO607

**The Role of DMP-1, E11 and Sclerostin on High Phosphorus Induced Vascular Calcification and Early Intervention by Sodium Thiosulfate in Remnant Kidney Rats** Yi Yu. *Dept of Blood Purification, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

**Background:** To observe the expression of DMP-1, E11 and Sclerostin involved in vasucular calcification in remnant kidney rats with hyperphosphatemia, and the early effect of sodium thiosulfate (STS) on the progression of vascular calcification.

**Methods:** Sprague Dawley rats (n=35) underwent 5/6 nephrectomy (n=21) or sham operation (n=14). They were fed with diet containing high phosphorus (HP) [phosphate(P)1.2%, calcium (Ca) 1.6%] or normal phosphorus (NP) [P (0.9%), Ca (1.2%)] for 16 weeks, then divided into 5 groups: (1) sham operation rats receiving NP diet (SNP, n=7), (2) sham operation rats receiving HP diet (SHP, n=7), (3) remnant kidney rats receiving NP diet (NNP, n=7), (4) remnant kidney rats receiving HP diet (NHP, n=7), (5) remnant kidney rats receiving HP diet with STS (THP, n=7). Rats in the THP group were intraperitoneally injected with STS 0.4 g/ml/kg three times a week for 16 weeks. Vascular calcification was confirmed by Von kossa staining. DMP1, E11 and Sclerostin mRNA were determined by RT-PCR. E11 expression in aorta were determined by immunohistochemistry or Western blot.

**Results:** After 16 weeks, Scr, $P^{3+}$, iPTH and uric protein were significantly higher in NHP than those in SNP group (P<0.05). With the treatment of STS, THP rats showed a marked decrease in those (P<0.05) compared with NHP group. Significant vascular calcification was found in NHP group while a little in NNP and SHP group occasionally and none in SNP group. The aorta expression of DMP1, E11 and Sclerostin mRNA were higher in NHP than in SNP group (P<0.05); their expression decreased in THP compared with NHP group (P<0.05). The aorta expression of E11 was higher in NHP compared with SNP group (P<0.05); the expression of E11 decreased in THP compared with NHP group (P<0.05).

**Conclusions:** The increase of expression of DMP1, E11 and Sclerostin in aorta shows that vascular calcification involves changes in VSMC transition into osteocyte-like phenotype. Sodium thiosulfate may delay the progression of vascular calcification by down-regulation of DMP1, E11 and Sclerostin.

**FR-PO608**

**Effect of Core-Binding Factor α1 Gene Silenced by siRNA on the Calcification of Vascular Smooth Muscle Cells Induced by High Phosphate**
Yi Yu. *Dept of Blood Purification, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

**Background:** To investigate the effect of Core-binding Factor α1 (Cbfα-1) gene silenced by siRNA on the osteogenic differentiation and calcification of vascular smooth muscle cells (VSMC) induced by high phosphate in vitro.

**Methods:** VSMC were cultured in vitro and passage 3 to 8 were used for the experiment. Four of the Cbfα-1 siRNA were designed and synthesized. VSMC were transfected by using cationic lipid vectors (Lipofectamine 2000). We optimized transfection condition by the FAM fluorescent labeling-siRNA and screened effective siRNA sequence by RT-PCR. VSMC were transfected with effective siRNA sequence. VSMC were divided into four groups: (1) normal phosphategroup (Pi 1.3 mmol/L); (2) high phosphate group (Pi 2.6 mmol/L); (3) siRNA transfection group: high phosphate (2.6 mmol/L) + Cbfα-1-siRNA; (4) negative transfection control group: high phosphate (2.6 mmol/L) + negative control siRNA. Cbfα-1 and osteopontin (OPN) mRNA and protein expression were detected by RT-PCR and Western Blot. Calcium deposition was visualized by Alizarin stain method.

**Results:** The transfection efficiency was about 55% at the condition of Cbfα-1 siRNA with concentration of 100 nmol/L and Lipo 8 μl/well. Cbfα-1 siRNA1952 was chosen as effective sequence with suppression ratio up to 81.8%. 24h and 48h after transfection, the expression of Cbfα-1 mRNA in siRNA transfection group was significantly lower than that in high phosphate group and negative transfection control group($P<0.01$). 48h and 72h after transfection, the expression of Cbfα-1 protein in siRNA transfection group was significantly lower than that in high phosphate group and negative transfection control group($P<0.01$). While Cbfα-1 gene was silenced by siRNA, in siRNA transfection group, the mRNA and protein expression of OPN were significantly declined($P<0.05$), and the calcium deposition in cell layers was reduced.

**Conclusions:** Cbfα-1 siRNA can effectively inhibit the expression of Cbfα-1 mRNA and protein in VSMC, thus suppress transformation of VSMC into osteoblast-like cells and calcification induced by high phosphate. Cbfα-1 may be a potential therapeutic target in vascular calcificationof chronic kidney disease.

**FR-PO609**

**The Combined Therapy with Calcitriol and a Calcimimetic Agent, R568, Ameliorates Phosphorus-Induced Calcification with Altered Expression of SIRT1 and ALP in Human Vascular Smooth Muscle Cells**
Masanori Tokumoto,[1] Shunsuke Yamada,[1] Tomoe Fujino,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono,[2] Hiroaki Ooboshi.[1] *[1]Dept of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Depertmet of Medicine and Clinical Scienece, Kyushu Univ, Fukuoka, Japan.*

**Background:** Vascular calcification is life-threatening pathophysiological abnormality, especially in chronic kidney disease (CKD)-mineral bone disorder (MBD). The main contribution factor for vascular calcification is phosphorus (P), but it is difficult to control P retention completely in CKD. Therefore, we examined direct effects of calcitriol and/or a calcimimetic agent, R568, both of which are effective for treatment of secondary hyperparathyroidism, on P-induced calcification in vascular smooth muscle cells (VSMCs).

**Methods:** Human VSMCs were cultured in medium containing 2.9 mM P and treated with $10^{-10}$~$10^{-6}$M calcitriol and/or $10^{-9}$~$10^{-5}$M R568 in various combinations for two weeks.Precipitated calcium contents and expression of various factors which is involved in calcification were evaluated.

**Results:** Only $10^{-10}$ and$10^{-9}$ M calcitriol and $10^{-8}$M R568 in monotherapy significantly inhibited calcification by 10~20% ($p<0.01$), but the treatment of calcitriol combined with $10^{-8}$M R568 suppressed calcification to about 50% of monotherapy at all concentration. Calcitriol increased the mRNA expression of mammalian sirtuin 1 (SIRT1) which prevents vascular calcification, as well as alkaline phosphatase (ALP) which promote vascular calcification dose-dependently. Both increases became significant at $10^{-6}$ and $10^{-7}$M ($p<0.01$). R568 significantly inhibited ALP mRNA expression at all concentration ($p<0.01$). The combination therapy with calcitriol and $10^{-8}$M R568 decreased ALP mRNA expression with similar increase of the mRNA expression of SIRT1 to calcitriol monotherapy.

**Conclusions:** In conclusion, the combination therapy with calcitriol and a calcimimetic agent, R568, can directly ameliorate P-induced vascular calcification more effectively than monotherapy with calcitriol or R568, by reducing ALP expression and increasing SIRT1 expression, respectively.

**Circulating Soluble Receptor for Advanced Glycation End Product (sRAGE) Levels but Not S100A12 (EN-RAGE) Are Associated with Vascular Calcification in Patients on Hemodialysis**
Ji Yong Jung,[1] Han Ro,[1] Chungsik Lee,[2] Sun Moon Kim,[3] Ae Jin Kim,[1] Hyung Soo Kim,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Gachon Univ of Gil Medical Center, Incheon, Korea; [2]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju; [3]Div of Nephrology, Dept of Internal Medicine, Chungbuk National Univ Hospital, Cheongju.*

**Background:** The receptor for advanced glycation end products (RAGE) has emerged as a central regulator of vascular inflammation and atherosclerosis. Soluble RAGE (sRAGE) and extracellular RAGE-binding protein S100A12 (EN-RAGE) are anti-inflammatory and pro-inflammatory ligands of RAGE, respectively, in the development of vascular complications. We determined the levels of sRAGE and EN-RAGE in hemodialysis (HD) patients and evaluated their relationship with vascular calcification.

**Methods:** We performed a cross-sectional study with 199 hemodialysis patients. Plain X-ray images of the lateral lumbar spine from all subjects were studied to calculate semiquantitative vascular calcification scores (VCSs), as described by Kauppila. Commercially available ELISA kits were used to quantify the serum concentration of sRAGE and EN-RAGE.

**Results:** The patients were 57.1 ± 13.7 years of age; 54.3% were male, 49.2% were diabetic, and 36.2% had a history of cardiovascular disease. Kauppila scores revealed 40 patients (20.1%) with a high VCS (>7). In a univariate analysis, serum sRAGE was negatively associated with high VCS (log sRAGE, $P = 0.035$), whereas EN-RAGE showed a positive tendency (log EN-RAGE, $P = 0.431$). Even after adjustments for confounding risk factors, sRAGE was independently associated with a high VCS (log sRAGE, OR = 0.491, 95% CI: 0.262 – 0.918, $P = 0.026$).

**Conclusions:** This study demonstrated that the circulating sRAGE level was inversely associated with VCS in HD patients independent of the EN-RAGE level and the severity of systemic inflammation. Longitudinal observations and intervention studies are warranted to establish whether this link is causal.

**FR-PO611**

**Inorganic Pyrophosphate and Aortic Valve Calcification**
Swetha Rathan,[1] Ajit Prithviraj Yoganathan,[1,2] W. Charles O'Neill.[3] *[1]School of Chemical and Biomolecular Engineering, Georgia Institute of Technology, Atlanta, GA; [2]The Wallace H. Coulter Dept of Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA; [3]Renal Div, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** Aortic valve (AV) calcification is common in chronic kidney disease but the underlying molecular mechanisms are not well understood. An *ex vivo* model of AV calcification was developed and the role of orthophosphate and inorganic pyrophosphate (PPi), factors well known to influence vascular calcification, was investigated.

**Methods:** Freshly obtained porcine AV leaflets were cultured for up to 8 days in DMEM medium containing varying concentrations of phosphate up to 3.8mM with and without inorganic pyrophosphatase (IP, an enzyme that specifically hydrolyzes PPi).

**Results:** Cell viability and structure were preserved as shown by MTT and Verhoff-Vangieson elastin stains. Calcification, measured as the incorporation of $^{45}Ca$ in the valves and confirmed with alizarin red staining, occurred only in the presence of IP and added phosphate and was prevented by etidronate, a non-hydrolyzable analog of PPi. Calcification was present on both the fibrosa and ventricularis sides of the leaflets. There was no further calcification when alkaline phosphatase, a non-selective phosphatase, was added, indicating that other phosphorylated compounds were not inhibiting calcification. Leaflets released PPi into the medium, which was enhanced by MLS38949, a specific inhibitor of tissue non-specific alkaline phosphatase (TNAP). Leaflets synthesized $^{32}PPi$ from extracellular [$^{32}P$] ATP, which was significantly decreased in the presence of β, γ-methylene-ATP, inhibitor of ectonucleotide pyrophosphorylase phosphodiesterase, (ENPP1).

**Conclusions:** An *ex vivo* model of aortic valve calcification was successfully developed. Extracellular PPi is a key endogenous inhibitor of calcification in this model and its levels appear to be controlled through synthesis by ENPP1 and hydrolysis by TNAP. This suggests that preventive therapy could be based on non-hydrolyzable PPi analogs such as bisphosphonates or on agents that enhance ENPP1 activity or inhibit TNAP action.

**L-lysine Ameliorates Vascular Calcification in Adenine-Induced Uremic Rats**
Akihiro Shimomura,[1] Isao Matsui,[1] Takayuki Hamano,[2] Kazunori Inoue,[1] Yasuo Kusunoki,[1] Chikako Nakano,[1] Yoshitsugu Obi,[1] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Dept of Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Dept of Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

**Background:** Vascular calcification (VC) is one of the major problems in CKD. Although several studies in both animals and humans have tried to reduce the extent of VC, satisfactory therapies have not been established. Therefore, it is important to develop novel strategies. In 2006, Price *et al.* reported that low protein (LP) diet exacerbates VC in

adenine-induced uremic rats. This report suggested that amino-acid-insufficiency correlates with VC. Because L-lysine (L-Lys) is the first-limiting amino acid in most of cereal grains, we investigated the effects of L-Lys on VC.

**Methods:** Male Sprague-Dawley rats at age 13 weeks were divided randomly into four groups; LP diet (group LP), LP+0.75% adenine (group Ade), LP+Ade+2.5% glycine (group Gly), or LP+Ade+2.5% L-Lys•HCl (group Lys). Glycine served as an amino-acid-control, because it is an amino acid that has the simplest structure. We also performed *in vitro* examinations to reveal the underlying mechanisms.

**Results:** At age 18 weeks, groups LP had no VC, whereas groups Ade and Gly had comparable levels of severe VC. L-Lys supplementation almost completely ameliorated VC. Physical parameters and renal functions were not different among groups Ade, Gly, and Lys. Dietary L-Lys strongly suppressed plasma level of iPTH in adenine-induced uremic rats, and thereby protected the femora from osteoporotic changes. Using LC/ESI-MS/MS, we found that dietary L-Lys elevated plasma alanine (Ala), proline (Pro), arginine (Arg), and homoarginine (Homo-Arg). Analyses *in vitro* revealed that L-Pro inhibited apoptosis of cultured human VSMCs, whereas L-Lys, L-Arg, and L-Homo-Arg dose-dependently attenuated spontaneous precipitation of minerals in a solution of supersaturated calcium/phosphate.

**Conclusions:** Dietary L-Lys ameliorated VC in adenine-induced uremic rats. Our findings provide a novel therapeutic approach for VC.

## FR-PO613

**Association of Serum Phosphorus Variability with Coronary Artery Calcification among Hemodialysis Patients** Haiming Li, Mengjing Wang, Li You, Jing Chen. *Nephrology, Fudan Univ, Shanghai, China.*

**Background:** Coronary artery calcification (CAC) is associated with increased mortality in maintenance hemodialysis (MHD) patients, but the pathogenesis of this condition isn't well understood. We evaluated the relationship of CAC score (CACs) and variability of serum phosphorus in MHD patients.

**Methods:** Cross-sectional observational study. **Setting & participants:** 77 adults on MHD at Huashan Hospital (Shanghai). The mean dialysis vintage was 5.9 ± 4.4years. Blood chemistry was recorded every 3 months from January 2008 to July 2010. **Predictor factor:** Phosphorus variation was defined by the standard deviation (SD) and coefficient of variation (CV). **Outcomes:** Three categories of CACs (0~10, 11~400, and > 400). **Measurements:** Phosphorus variation was calculated from patient records, CAC was measured by computed tomography, and CACs were calculated by the Agatston method.

**Results:** The mean patient age was 61.7 ± 11.3 years and 51% of them were men. The mean CACs was 609.6 (± 1062.9), the median CACs was 168.5, and 78% of patients had CACs more than 0. Multivariate analysis indicated that female gender (OR = 0.20, 95% CI = 0.07-0.55), age (OR = 2.31, 95% CI = 1.32-4.04), serum fibroblast growth factor 23 (OR = 2.25, 95% CI = 1.31-3.85), SD-phosphorus calculated from the most recent 6 measurements (OR = 2.12; 95% CI = 1.23-3.63), and CV-phosphorus calculated from the most recent 6 measurements (OR = 1.90, 95% CI = 1.16-3.11) were significantly and independently associated with CACs.

**Table 1.** Multiple logistic regression analysis of factors associated with CAC score tertile in MHD patients.

| Variable | Unadjusted | | Adjusted | | | |
|---|---|---|---|---|---|---|
| | | | Model 1 | | Model 2 | |
| | OR | *P* | $OR_1$ (95% CI) | $P_1$ | $OR_2$ (95% CI) | $P_2$ |
| Female | 0.277 | <0.001 | 0.20 (0.07-0.55) | 0.002 | 0.21 (0.07-0.58) | 0.003 |
| Age (/1-y) | 1.824 | 0.012 | 2.31 (1.32-4.04) | 0.003 | 2.04 (1.18-3.53) | 0.010 |
| Laboratory measurements | | | | | | |
| Alb (/1-g/L) | 0.595 | 0.019 | | | | |
| CRP (/1-mg/L) | 2.40 | 0.04 | | | | |
| PTH (/1-ng/L) | 1.531 | 0.091 | | | | |
| FGF23 (/1-pg/mL) | 1.449 | 0.127 | 2.25 (1.31-3.85) | 0.003 | 2.50 (1.46-4.30) | <0.001 |
| HDL (/1-mmol/L) | 0.574 | 0.026 | | | | |
| Mean and variability measurements | | | | | | |
| Mean-PTH (/1-ng/L) | 1.426 | 0.164 | | | | |
| Mean-Ca (/1-mg/dL) | 1.376 | 0.171 | | | | |
| SD-Pi (/1-mg/dL) | 1.538 | 0.074 | 2.12 (1.23-3.63) | 0.007 | | |
| CV-Pi (/1) | 1.590 | 0.071 | | | 1.90 (1.16-3.11) | 0.011 |

$P_1$ adjusted for female sex, age, FGF23, and SD-phosphate.
$P_2$ adjusted for female sex, age, FGF23, and CV-phosphate.

These associations persisted for phosphorus variation calculated from past 7, 8, 9, 10, and 11 follow-up values. **Limitations:** Patients were from a single center, leading to possible selection bias. Proteins involved in bone metabolism and vascular calcification were not measured.

**Conclusions:** Variability in serum phosphorus is associated with CAC in MHD patients.

*Funding:* Government Support - Non-U.S.

## FR-PO614

**Reversibility of Uremic Vascular Calcification** Koba A. Lomashvili, Courtney A. Washington, W. Charles O'Neill. *Renal Div, Emory Univ, Atlanta, GA.*

**Background:** Research on vascular calcification has focused on formation rather than reversal. Since hydroxyapatite is insoluble under physiologic conditions, reversal requires a biologic process. Whether vascular calcification is reversible and by what mechanism are unknown and have important therapeutic implications.

**Methods:** Mice were fed 0.45 % adenine for 2 months to produce uremia and a 2% phosphorus diet + calcitriol (1000 ng/kg thrice weekly) to induce vascular calcification. After 2 months, calcified abdominal aortas were transplanted orthotopically into normal littermates and harvested after 6 and 12 weeks. The allografts were examined histologically by hematoxylin and eosin (H&E) or tartrate-resistant acid phosphatase (TRAP) staining for osteoclasts, and calcium content (measured after acid extraction by the cresopthalein method) was compared to that in the untransplanted donor aorta.

**Results:** Calcification at transplantation was variable (17 to 2360 nmoles/mg, median: 686; normal: <7) and exclusively medial. Survival after transplantation was greater than 90% and there were no signs of rejection. The reduction in calcification at 6 and 12 weeks after transplantation was 47 +/- 12 % (n=8) and 51 +/- 13 % (n=5) respectively. This reduction was 37 +/- 10% in heavily calcified (>600 nmol/mg) allografts compared with 66 +/- 13% in less calcified allografts. The allografts were histologically similar to untransplanted calcified aorta with calcium deposits readily apparent in heavily calcified allografts and no evidence of cellular infiltration or cell-mediated resorption. TRAP staining was negative. There was no calcification of normal aortas transplanted into normal mice.

**Conclusions:** Approximately half the calcification in uremic aortas is reversible by 12 weeks without histologic evidence of cell-mediated resorption. Almost all of the reversal occurs by 6 weeks and is less in heavily calcified aortas. The results suggest that vascular calcification consists of a readily reversible component that presumably represents non-apatitic calcium and a non-reversible component that likely represents apatitic calcium. The inability to resorb this latter component is likely due to the failure to recruit osteoclasts.

## FR-PO615

**The Role of Nrf2 in Human Aortic Smooth Muscle Cells Calcification and Mechanism Research** Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, China.*

**Background:** To discuss the role and mechanism of Nrf2 in calcification of HASMCs.

**Methods:** HASMCs were cultured in vitro and incubated with beta-glycerophosphate to induce a diffuse mineralization and oxidative stress. Additionally, sulforaphane treatment and short interfering RNA were used to regulate the expression of Nrf2 gene. Calcium deposition was detected by the O-CPC colorimetry method and normalized with regard to protein content. Intracellular ROS levels were measured using DCFH-DA. The expression of Nrf2, HO-1, Runx2, OPN and SM22α were assessed by Western Blot.

**Results:** After 12 days of treatment, calcium deposition was significantly increased in calcification medium group than normal medium group. Within 12 hours of treatment, beta-glycerophosphate increased ROS production, this production being further enhanced after 72h. The beta-glycerophosphate-induced oxidative stress was associated with an early expression of Nrf2 and HO-1 followed by Runx2 and OPN expression at 72h. The sulforaphane treatment and short interfering RNA can up and down regulate the expression of Nrf2 as well as other factors.

**Conclusions:** Beta-glycerophosphate could induce a diffuse mineralization in HASMCs. Nrf2 protect HASMCs from oxidative stress and calcification by participating in resistance to oxidative stress.

## FR-PO616

**A Novel Method to Quantify Relationships between Vascular Calcifications and Bone in Chronic Kidney Disease Patients** Janina M. Patsch,[1] Thomas L. Nickolas.[2] *[1]Radiology, Medical Univ of Vienna, Vienna, Austria; [2]Medicine, Columbia Univ, NY, NY.*

**Background:** In chronic kidney disease (CKD) vascular calcifications (VC) are highly prevalent. They are associated with increased cardiovascular risk and fracture. However, research in osteo-vascular interactions is impeded by the high radiation dose delivered by methods used to quantify VC severity and their skeletal relationships. High-resolution peripheral QCT (HRpQCT, Scanco Medical) measures bone mass and microarchitecture at the distal radius and tibia, detects VCs and delivers low radiation dosage. We determined whether HRpQCT simultaneously quantifies relationships between VCs and bone mass and microarchitecture.

**Methods:** We enrolled patients with CKD stages 2+3 (n=18), 4+5 (n=14), hemodialysis (HD, n=16), and an age, sex, race matched reference group with normal kidney function (n=21). Tibia HRpQCT scans were reviewed for lower leg arterial calcifications (LLAC) with a semi-automated, image-processing algorithm. LLAC mass was expressed in mg hydroxyapatite (mgHA). Relationships between LLAC and eGFR, cortical (Ct) and trabecular (Tb) mass and microarchitecture, PTH, and markers of bone formation (BSAP, osteocalcin, P1NP) and resorption (CTX, TRAP5b) were assessed. Analyses were adjusted for kidney function.

**Results:** Mean±SD age was 65±9 yrs, 57% were male, 45% were Black. Compared to the reference group, LLAC was higher in patients with CKD stages 4+5 by 3.2 mgHA and on HD by 8.8 mgHA (both p<0.05). There were inverse associations between LLAC and

radius total density (r= -0.30, p<0.05) and Tb thickness (r= -0.30, p<0.03), and tibia total (r= -0.30, p<0.05) and Ct density (r= -0.30 p<0.05) and Ct thickness (r= -0.20, p<0.05). LLAC was positively associated with BSAP (r= 0.40, p<0.05).

**Conclusions:** In summary, HRpQCT simultaneously quantifies LLAC and assesses relationships between LLAC and bone mass and microarchitecture. LLAC was more severe in patients with advanced CKD and relationships between VCs and bone mass, microarchitecture and formation suggested pathogenic associations between vascular and bone biology that require further study. We conclude that HRpQCT will facilitate the elucidation of osteo-vascular biology.

## FR-PO617

**The Role of Adipocytes in Calciphylaxis** Nader Kassis Akl, Neal X. Chen, Kalisha O'Neill, Keith March, Dmitry O. Traktuev, Sharon M. Moe. *Indiana Univ, Indianapolis, IN.*

**Background:** Calciphylaxis is a fatal disease in dialysis patients and hyperphosphatemia and obesity are risk factors. The close proximity of the calcified arterioles to adipocytes, and the fact that osteoblasts, adipocytes, and vascular smooth muscle cells (VSMC) have a common mesenchymal origin led us to test the hypothesis that adipocytes can calcify in the presence of elevated phosphate and/or that adipocytes exposed to phosphate can induce VSMC calcification.

**Methods:** 3T3-L1 preadipocytes and human adipose stromal cells (ASC) were induced into mature adipocytes and then treated with media with high phosphorus. Calcification was assessed by biochemical assay after HCl extraction. Total RNA was isolated and real time PCR performed to determine the expression of genes for osteoblast and adipocyte differentiation. Adipocytes were also co-cultured with bovine VSMC using transwell inserts.

**Results:** The results demonstrated that both adipocytes and human ASC calcify in high phosphorus media (3.5 and 2.2 fold greater than cells without phosphate, respectively, both $p < 0.01$). In addition, compared to normal phosphorus, adipocytes treated with high phosphorus had increased expression of RUNX2 at 24 hrs (1.02± 0.40 vs. 0.68±0.07), and decreased expression of PPARPγ (0.97± 0.27 vs. 0.65±0.18, p<0.004) at day 3 and CEBPα (1.56± .57 vs 1.11 ±0.23, p<0.02) at day 7, indicating a switch to more osteoblast like phenotype. Furthermore, VSMC calcification was increased when co-cultured with adipocytes compared to BVSMC alone (2.13 ± 1.90 vs 0.04±.20, p<0.007 ) at day 3. In contrast, there was no difference in adipocyte calcification when co-cultured with or without VSMC.

**Conclusions:** Adipocytes are capable of calcifying in media that contains high phosphorus, in part by up-regulation of osteoblast genes and down-regulation of adipocyte genes. Furthermore, adipocytes exposed to elevated phosphorus can induce calcification of VSMC in a paracrine manner. The results suggest that adipocyte exposure to elevated phosphorus may be an initiating step in calciphylaxis.

## FR-PO618

**High Phosphate Diet Induces Aortic Calcification in a Mouse Adenine CKD Model** Wei Ling Lau,[1] Sogol Pahlevan,[1] Kamyar Kalantar-Zadeh,[1] Cecilia M. Giachelli,[2] Nosratola D. Vaziri.[1] *[1]Nephrology, Univ of California, Irvine, School of Medicine, Orange, CA; [2]Bioengineering, Univ of Washington, Seattle, WA.*

**Background:** Hyperphosphatemia is a non-traditional risk factor for vascular calcification (VC) leading to unfavorable cardiovascular outcomes, the pathophysiologic pathway of which can be examined in rodent models of chronic kidney disease (CKD). Here we characterize biochemical and VC outcomes when calcification-prone DBA/2J mice are subjected to adenine diet to induce uremia, followed by normal vs. high phosphate (NP vs. HP) feeding.

**Methods:** Kidney failure was induced in DBA/2J mice via 0.2% adenine in food x18 days, followed by NP (0.5% phosphate) or HP (1.2% phosphate) diet x3 months. The study groups were: healthy controls on NP diet (CTL), CKD on NP diet (CKD+NP), and CKD on HP diet (CKD+HP) (n=4 per group). A subset of mice was fed adenine diet x21 days to document blood urea nitrogen (BUN) trends.

**Results:** Serum BUN was significantly elevated after 18 days on adenine diet and was 107.8+7.2 mg/dL at day 21 (Figure 1A). Kidney histology showed patchy interstitial nephritis and glomerulosclerosis. At termination of the main study (after 3 months of NP vs. HP diet), serum creatinine remained significantly elevated in CKD groups (0.34+0.04 vs. 0.18+0.03 mg/dL in CTL). The CKD+HP group had increased serum phosphorus, serum FGF23 (Figure 1B) and aortic calcium content (Figure 1C). These parameters were equivalent between the CTL and CKD+NP groups.

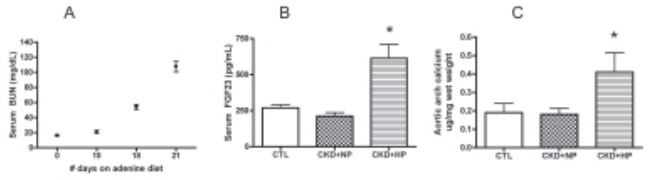

Figure 1. (A) Serum BUN values over time in mice fed a 0.2% adenine diet. (B) Serum FGF23 and © aortic calcium content in CTL, CKD+NP and CKD+HP mice. * *P*<0.05 compared to CTL and CKD+NP groups.

**Conclusions:** High phosphate diet increased serum FGF23 and aortic calcification in mice with adenine-induced CKD. This is a promising model for the study of phosphorus overload and cardiovascular outcomes.

## FR-PO619

**Correlation of Lateral Vertebral Bone Mineral Density with Underlying Bone Histology in Patients with Chronic Kidney Disease** Maria Coco,[1] James M. Pullman.[2] *[1]Medicine, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; [2]Pathology, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Patients with renal disease have extraosseous calcifications that will give falsely elevated measurements of bone mineral density (BMD) on DEXA scans. For this reason, DEXAs, with Anteroposterior (AP) views are not routinely done in these patients. We measure lateral BMD since it may exclude non-bone calcifications and the generated vertebral BMD data more accurately reflects vertebral bone density. We also compare these lateral measurements with underlying bone histology, since it is the gold standard diagnosing bone disease.

**Methods:** BMD was measured in AP (BMD_AP) and lateral (BMD_lat) planes using Hologic QDR-4500 fan beam with C-Arm unit. Lateral and AP measurements were compared. Correlations were obtained between BMD and parameters of bone metabolism and turnover (PTH, Vit D 25OH, Urinary N-telopeptide). correlations were made with bone histology.

**Results:** 45 pts had DEXA scans. There was a significantly lower BMD in the lateral view as compared to the AP view (.718±0.16 vs .942±.16, p= 0.0001). Markers of bone turnover did not correlate with either lateral or AP BMD. There were 13 bone biopsies: Lateral BMD correlated with histology: lower BMD_lat predicted low bone turnover, while higher BMD_lat predicted higher bone turnover. This was not observed with the AP measurements.

**Conclusions:** Pts with renal disease have lower lateral BMD than AP BMD. Underlying bone histology correlates with lateral BMD. Lateral DEXAs may show the true effect of PTH on BMD: higher BMD may represent higher PTH-driven cellular activity with increased bone formation and calcification while lower BMD may represent the absence of bone stimulation with resulting decreased bone formation and decreased calcification. If confirmed with histomorphometry, this minimally invasive tool may be useful in treating renal osteodystrophy.

| | bone turnover | BMD-lateral | BMD-AP |
|---|---|---|---|
| PTH | .193 ns | -.093 ns | .101 ns |
| Vit D 25OH | .386 ns | -.065 ns | .025 ns |
| BSAP | -.437ns | .047ns | .526ns |
| OC | -.394 | -.185ns | .301ns |
| NTx | .333 | -.152 | -.301ns |
| creatinine | -.029 | .115 | -.031ns |
| Bone turnover | | -.661 p<.019 | -.562 |

## FR-PO620

**Pathogenesis, Prevention and Treatment of the Chronic Kidney Disease-Mineral Bone Disorder** Yifu Fang,[1] Charles Ginsberg,[1] Michael E. Seifert,[1,2] Toshifumi Sugatani,[1] Hartmut H. Malluche,[3] Keith A. Hruska.[1] *[1]Pediatrics, Wash. Univ, St. Louis, MO; [2]Pediatrics, S.Ill.Sch. of Medicine, Springfield, IL; [3]Medicine, Univ of Kentucky, Lexington, KY.*

**Background:** The CKD-MBD is recognized as a major contributor to cardiovascular risk during kidney disease, but the cause of the syndrome is unknown, and there is no current therapy. At its inception, the CKD-MBD is characterized by an osteodystrophy, vascular calcification (VC) and stimulation of osteocytic protein levels in the circulation. We tested the hypothesis that the CKD-MBD is caused by increased renal production of circulating Wnt inhibitors.

**Methods:** In the background of atherosclerosis and high-fat feeding with CKD stimulated VC, we staged CKD analogous to the human clinical staging by measuring inulin clearances and BUN.

**Results:** In mice with CKD stage 2, we demonstrated increased production of Dkk-1 in remnant kidneys and increased circulating Dkk-1, sclerostin and c-klotho. There was an osteopenic low turnover osteodystrophy and stimulation of VC. Neutralization of Dkk-1 by a monoclonal antibody (mab) stimulated bone formation rates, prevented the osteodystrophy and CKD stimulated VC. The Dkk-1 mab preserved the expression of membrane α-klotho in the aorta and kidney. In addition, the aortic expression of the osteoblastic transcription factor, RUNX2 was inhibited, and vascular smooth muscle contractile protein expression was increased. Increased plasma c-klotho and FGF23 levels were not affected by the Dkk-1 mab, but FGF23 levels were reduced to normal by a Pi binder. In a treatment (not a prevention) protocol Pi binder therapy had no effect on VC or the osteodystrophy, but when combined with the Dkk-1 mab, the CKD-MBD as characterized in the CKD-2 mice was completely reversed.

**Conclusions:** The CKD-MBD is established in early CKD, characterized by the cardiovascular risk factor, VC, a renal osteodystrophy, and elevated circulating FGF23, c- klotho, and sclerostin. Neutralization of Dkk-1 was sufficient to prevent the VC and the osteodystrophy. The CKD-MBD was treated by the combination of neutralization of the Wnt inhibitor, Dkk-1, and Pi binding.

## FR-PO621

**Abnormal DXA Scans in Hemodialysis Patients Predict Risk of Hip Fractures** Scott A. Rasgon,[1] Richard M. Dell.[2] *[1]Nephrology, Kaiser Permanente, Los Angeles, CA; [2]Orthopedic Surgery, Kaiser Permanente, Downey, CA.*

**Background:** In 2011 and 2012 kidney week we presented data from Kaiser Permanente DEXA scan data base. There was a strong correlation between normal DXA scans in hemodialysis (HD) patients and low hip fracture( FX) risk. Last year we had 1954 HD patients with DXA scans. KDIGO makes the following recommendations for DXA scans in HD patients. " 3.2.2 In patients with CKD stages 3-5D with evidence of CKD-MBD, we suggest that BMD testing not be performed routinely, because BMD does not predict fracture risk as it does in the general population, and BMD does not predict the type of renal osteodystrophy (2B)."This is based on 13 studies with the most subjects in any of the studies was 242. 5 studies showed no correlation with FX rates and 8 showed some correlation with low BMD and increased FX rate. We now have 2387 active HD patients in our data base who have had DXA scans with scores.

**Methods:** We reviewed the HD data base of 4912 HD pateints at Kaiser Permanente SO. CA. of which 2387 had DXA scans with T-scores. The DXA scans were done between 1/1/1998 to 6/1/2013. We wanted to see if there was any correlation between DXA scan results and hip FX in this population.

**Results:** We found the following results 485 patients had a normal DXA wth only 5 hip FX with a 1.03 % FX rate. 1898 patients had an abnormal DXA (T-score <-1) with a FX rate of 5.4%. Pt. with osteoporosis (T-score<-2.5) Had a FX rate of 9.33%.

| | HIP FX | OSTEOPOROSIS T-score<-2.5 | OSTEOPENIA T-score -2.5 TO -1 | NORMAL Tscore>-1 | TOTAL |
|---|---|---|---|---|---|
| HD | N | 661 | 1140 | 485 | 2285 |
| HD | Y | 68 | 29 | 5 | 102 |
| HD TOTAL | | 729 | 1169 | 490 | 2387 |
| HD % HIP FX | | 9.33% | 2.48% | 1.02% | 4.3% |

The realtive risk of FX is 5.01 p=.0004 comparing T-scores of <-1 to >-1. Comparing T-scores of <-2.5 tp >-1 the relative risk of FX is 9.14 p=.0001.

**Conclusions:** Contrary to the KDIGO guidelines our data demonstrate that a normal DXA scan (T-score>-1) predicts a low hip FX risk in HD patients over time. Our data has continued to show that DXA scans can predict HD patient risk for hip FX and should be considered in this population and studied further.

## FR-PO622

**Pathogenesis of Cortical Deficits and Decreased Bone Stiffness after Kidney Transplantation** Kyle K. Nishiyama, Elizabeth Shane, Thomas L. Nickolas. *Medicine, Columbia Univ, NY, NY.*

**Background:** Fractures are more than 4-fold higher after kidney transplantation (KTx) than in the general population. We reported that hyperparathyroidism (HPT) is associated with progressive cortical (Ct) losses in patients with chronic kidney disease. As HPT commonly persists after KTx we hypothesized that Ct deficits would worsen, be directly associated with HPT and elevated bone turnover markers (BTMs) and lead to impaired bone strength.

**Methods:** We scanned the distal radius and tibia by high-resolution peripheral QCT (HRpQCT, Scanco Medical) in 31 patients (22 men, 9 women; age 52±13 years) within 2 weeks of and 1 year after KTx. Ct porosity (CtPo) was quantified. Whole bone stiffness and failure load were estimated using finite element analysis. PTH and markers of bone formation (BSAP, Osteocalcin, P1NP) and resorption (CTX and Trap5b) were measured at 3, 6 and 12 months after KTx and were time-averaged. Mixed linear models were used to determine longitudinal changes.

**Results:** At 1 year, 74% of patients had HPT (PTH>65 pg/mL). At the radius, Ct density decreased by 2.2±1.8%, thickness by 2.2±0.8% and area by 2.5±0.8% (all $p<0.05$); CtPo increased by 78±9% ($p<0.01$) and trabecular area by 0.4±1.8% ($p=0.06$). Stiffness and failure decreased by 3.1±1.3% and by 3.4±1.4% (both $p<0.05$) respectively. At the tibia, Ct density decreased by 1.9±0.6% and thickness by 1.1±0.5% (both $p<0.05$); CtPo increased by 30±5% ($p<0.05$). Changes in stiffness and failure load were not significant. At 1 year, greater CtPo was significantly associated with lower Ct density, thickness and area, and stiffness and failure load (all $p<0.001$). Increases in CtPo were strongly associated with higher levels of PTH and BTMs (PTH r=0.64; BSAP r=0.62; CTX r=0.64, all $p<0.01$). Decreases in stiffness and failure load were strongly associated with higher levels of PTH (r= -0.45, $p<0.05$) and BTMs (Osteocalcin and Stiffness r= -0.70; Osteocalcin and Failure Load r= -0.64, both $p<0.001$).

**Conclusions:** In conclusion, persistent HPT and elevated bone turnover after KTx drive Ct deterioration and decreased bone stiffness. Further studies are needed to determine whether mitigating the adverse effects of HPT on Ct bone protects against fracture.

**Altered Material Properties Are Responsible for Bone Fragility in Rats with Chronic Kidney Disease** Yoshiko Iwasaki,[1] Junichiro J. Kazama,[2] Masafumi Fukagawa.[3] *[1]Health Sciences, Oita Univ of Nursing and Health Scineces, Oita, Japan; [2]Niigata Univ Medical and Dental Hospital, Niigata, Japan; [3]Tokai Univ School of Medicine, Isehara, Japan.*

**Background:** Patients with chronic kidney disease (CKD) have considerably higher risk of fracture. Abnormalities in parathyroid function and/or bone mineral density cannot fully account for their increased bone fragility, while the role of uremia on it remains obscure.

**Methods:** CKD rats with hyperparathyroidism (HP-CKD) were underwent partial nephrectomy (Nx). Those without hyperparathyroidism (Non-HP-CKD) were made by Nx and thyroparathyrioidectomy (TPTx) followed by a continuous exogenous physiological dose of PTH supplementation. Control rats (HP-Cont or Non-HP-Cont) were prepared for each group. Femoral bone elasticity was non-invasively assessed by a direct mechanical assessment method. Bone chemical compositions were analyzed by a raman spectroscopy and a micro X-ray diffraction.

**Results:** Serum creatinine levels were significantly elevated in the CKD groups. Significantly elevated PTH levels and histomorphometrically proven high turnover bone were documented in the HP-CKD group, while PTH remained constant and bone turnover was rather decreased in the Non-HP-CKD group. Compared with each Control group, bone elasticity in femoral bone was significantly reduced in each CKD groups. Decreased BMD level was observed in the HP-CKD group whereas that in the Non-HP-CKD remained unchanged. Raman spectroscopic analyses revealed that carbonate phosphate ratio and crystallinity were altered in both the CKD groups. In addition, mineral matrix ratio and non-physical collagen crosslinks were increased in the Non-HP-CKD group. Apatite c-axis orientation was significantly decreased in both the CKD groups. Multiple regression analysis revealed that apatite orientation and mineral matrix ratio, but not BMD, were independently associated with bone elasticity.

**Conclusions:** Regardless of parathyroid function or bone turnover, altered bone material properties induced by uremia were responsible for bone fragility in CKD animals.

## FR-PO624

**High Frequency of Iron Bone Deposits in a Brazilian Hemodialysis Population with Renal Osteodystrophy** Camila Barbosa L. Oliveira,[1] Alline S. A. Oliveira,[1] Carla Queiroz Neves,[1] Clarissa Jacob Barros Carvalho,[1] Vanda Jorgetti,[2] Jose Edevanilson Gueiros,[1] Ana Paula Gueiros.[1] *[1]Nephrology, UFPE, Recife, Pernambuco, Brazil; [2]Nephrology, USP, Sao Paulo, Brazil.*

**Background:** Little is known about iron bone deposits in dialysis patients. Previous studies have demonstrated the association between iron and the development of low bone turnover. The purpose of this study was to evaluate the presence of iron deposits on bone biopsy of hemodialysis patients.

**Methods:** We performed a retrospective analysis of 158 patients underwent bone biopsy in the period from March 2003 to March 2013. Clinical data were evaluated: age, sex, time on dialysis and occurrence of fractures. Laboratory tests: total calcium, phosphorus, intact parathyroid hormone (iPTH pg/mL), alkaline phosphatase (ALP U/L), iron (µg/dL) and ferritin (ng/mL). Bone biopsy was performed after double tetracycline labeling and specimens were classified as osteitis fibrosa (OF), mixed disease (MD), adynamic bone disease (ABD), osteoporosis (OS) or osteomalacia (OM). To evaluate iron bone deposits, sections were stained with Perl's Prussian blue and for aluminum, solochrome azurine was used. Aluminum intoxication (AI) or iron intoxication (IBD) were defined when more than 20% of the trabecular bone surface were covered by metal. Patients were divided into 2 groups: IBD group (patients with IBD) and NIBD group (patients free of IBD). We performed a comparative analysis between the groups to assess factors associated with IBD.

**Results:** The prevalence of IBD was 32.3%. There were no diferences between the groups regarding clinical parameters. ALP (median 138 vs 297; $p<0.001$) and iPTH (median 645 vs 1514; $p<0.001$) levels were lower in the IBD group. Ferritin levels were higher in IBD group (median 528 vs 313; $p=0.019$). ABD ($p=0.029$) and aluminum intoxication ($p<0.001$) were closely associated with IBD.

**Conclusions:** We found high prevalence of siderosis on the bone of a Brazilian hemodialysis population. IBD was associated with low bone turnover and with aluminum intoxication. More studies are needed to assess the clinical importance of IBD.

## FR-PO625

**Renal Osteodystrophy: 10-Year Experience of a Brazilian Center** Alline S. A. Oliveira,[1] Carla Queiroz Neves,[1] Clarissa Jacob Barros Carvalho,[1] Camila Barbosa L. Oliveira,[1] Vanda Jorgetti,[2] Jose Edevanilson Gueiros,[1] Ana Paula Gueiros.[1] *[1]Nephrology, UFPE, Recife, Pernambuco, Brazil; [2]Nephrology, USP, Sao Paulo, Brazil.*

**Background:** Chronic kidney disease mineral bone disorder (CKD-MBD) is highly prevalente among patients with end stage renal disease. The aim of the presente study was to evaluate the clinical and laboratory profile of patients who underwent bone biopsy.

**Methods:** We performed a retrospective analysis of 158 hemodialysis patients underwent bone biopsy from March 2003 to March 2013. Clinical data were evaluated: age, sex and time on hemodialysis. Laboratory tests consisted of total calcium (Cat, mg/dL), phosphorus (P,mg/dL), intact parathyroid hormone (iPTH,pg/mL) and alkaline phosphatase (ALP,U/L). Bone biopsy was performed after double tetracycline labeling. The specimens were classified histologically as osteitis fibrosa (OF), mixed disease (MD),

adynamic bone disease (ABD) or osteomalacia (OM). Aluminum intoxication (AI) or iron intoxication (IBD) were defined when more than 20% of the trabeluar bone surface were covered by metal. Comparative analysis was performed according to the biopsy diagnosis.

**Results:** The mean age was 49±12.5 years, 58.9% were female. The mean hemodialysis duration was 9.6±4.7 years. OF, MD, ABD and OM were present in 54.4%, 29.7%, 12.6% and 2.5% of patients, respectively. AI and IBD were found in 53.3% and 32% of patients, respectively, and were more associated with the ABD. The table shows the comparative analysis of biochemical parameters according to histological diagnosis.

| | OF | ABD | MD | OM | p= |
|---|---|---|---|---|---|
| CAt | 10.1±1.1 | 9.7±0.9 | 9.9±1.1 | 9±0.6 | 0.16 |
| P | 6.5±1.7 | 5.3±2 | 5.6±1.7 | 3.3±2 | <0.001[a,b,c] |
| ALP | 219 (129;440) | 124 (96;167) | 386 (141;680) | 175 (155;243) | 0.002[a,b,d] |
| iPTH | 1318 (750;2033) | 865 (28;207) | 1533 (827;2101) | 348 (267;657) | <0.001[a,c,d,e,f,] |

.*mean±dp; **median ($P_{25}$;$P_{75}$) [a]OFxABD,[b]OFxMD,[c]OFxOM,[d]ABDxMD,[e]ABDxOM,[f]MDxOM.

**Conclusions:** Our data demonstrate that the high turnover disease are the most prevalent and still is a high prevalence of AI. IBD emerges as a frequent complication and clinical significance undefined. The FA and iPTH were good markers of bone remodeling.

## FR-PO626

**The Skeleton as a Reservoir of Calcium in Dialysis Patients: The Less You Have, the More You Lose** Patricia T. Goldenstein, Rosilene M. Elias, Luciene dos Reis, Fabiana Graciolli, Wagner Dominguez, Gisele Antunes Lins, Hugo Abensur, Manuel Carlos Martins Castro, Vanda Jorgetti, Rosa M.A. Moyses. *Nephrology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brazil.*

**Background:** Calcium (Ca) balance during dialysis session is an important, but unrecognized tool for the management of CKD patients. Current mathematical models estimate dialysis Ca balance employing Ca gradient between serum and dialysate, as well as ultrafiltration (UF). The skeleton, despite being the most important reservoir of Ca, is not included in these models.

**Methods:** The aim of this study was to verify the influence of bone on Ca mass transfer during dialysis in CKD patients with severe hyperparathyroidism (SHPT) who were submitted to bone biopsy. Fourteen patients (11 males), aged 45 ± 12 yrs, on hemodialysis for a median of 75 (48-138) months were dialysed using two different (d[Ca]):1.25 and 1.75mmol/L.

**Results:** When a d[Ca] of 1.25mmol/L was used, all but 2 patients had a negative Ca mass transfer (median -283 mg (-782, +439)), total serum Ca and PTH remained relatively stable (Δ = -0.17 mg/dl and 109 pg/ml, ns). In a d[Ca] of 1.75mmol/L, all but 3 patients had positive Ca balance (median +103 mg (-291, 676)), total serum Ca increased and PTH decreased (Δ = +1.34 mg/dl and -1042 pg/ml; p≤ 0.0001 for both). On a d[Ca] of 1.25mmol/L, stepwise multiple regression analysis adjusted for Ca gradient and UF ($R^2$ = 0.55) showed that Ca balance was dependent on bone volume (p = 0.008) and osteoclast surface (p = 0.0048). On a d[Ca] of 1.75mmol/L, stepwise multiple regression analysis adjusted for Ca gradient and UF ($R^2$ = 0.77) showed that Ca balance was dependent on bone formation rate (p = 0.001) and eroded surface (p < 0.0001).

**Conclusions:** Employing bone biopsy, we could show, for the first time, that Ca balance varies widely during dialysis and the skeleton plays a key role in this acute Ca transfer. Patients with SHPT and lower bone volume lose more Ca when dialyzing with a d[Ca] of 1.25mmol/L. Conversely, in a d[Ca] of 1.75mmol/L, those with a higher bone formation rate and lower bone resorption, gain more Ca. Bone remodelling should be taken into account when choosing d[Ca] in dialysis.

## FR-PO627

**Inter-Method Variability for the Measurement of Bone Alklaine Phosphatase: Implication for the Monitoring of CKD-MBD** Etienne Cavalier,[1] Pierre Delanaye.[2] *[1]Clinical Chemsitry, Univ of Liege, CHU Sart-Tilman, Liege, Belgium; [2]Nephrology, Dialysis Transplantation, Univ of Liege, CHU Sart-Tilman, Liege, Belgium.*

**Background:** KDIGO suggested measuring PTH or bone-specific alkaline phosphatase (b-ALP) to evaluate bone disease. Little information is however available regarding the variability among the b-ALP methods; we aimed to compare the values obtained by 3 different automated b-ALP in a population of hemodialyzed (HD) patients.

**Methods:** Serum from 81 HD, prior a hemodialysis session was obtained and stored at -80°C until analysis. b-ALP was determined with the Beckman Access, DiaSorin Liaison and IDS-iSYS in a single batch on the same day. Intact PINP (iSYS) and 3rd generation PTH (Liaison) were also determined.

**Results:** b-ALP median (95%CI) for Access, iSYS and Liaison were: 16.4(14.9-19.6), 20.9(18.8-25.6) and 14.7(13.4-16.9)µg/L, respectively. Passing-Bablock (PB) regressions were Access=1.16xLiaison-0.02, Access=0.78xiSYS+0.8 and iSYS=1.53xLiaison-1.4. Correlation between iSYS and PTH was weak (0.24) but significant (p<0.05) whereas correlations between Access (0.22) and Liaison (0.18) were not. There was a significant correlation (p<0.0001) between PINP and the 3 methods: 0.61(Access), 0.64(iSYS) and 0.52(Liaison). Recalibration of iSYS and Liaison to the Access according to the PB equations harmonized the results. Bland-Altman plot showed Liaison has a larger variation of the results than others.

**Conclusions:** There is a significant problem in the b-ALP determination today which has clear clinical consequences. The variations among the methods are mainly due to assay drifted and reagents stability. The kit manufacturers should be keen to improve reagents stability, lot-to-lot variation and harmonization of the calibrations. The nephrologists should be aware that, just like PTH, b-ALP results are not transposable from one laboratory to the other. Dialogs between the laboratories and nephrologists remain essential.

## FR-PO628

**Relationship between Bone Parameters on Histomorphometry and microCT** R.C. Pereira,[1] David S. Bischoff,[2] Dean T. Yamaguchi,[2] Barbara Gales,[1] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Medicine, VA Healthcare System, Los Angeles, CA.*

**Background:** Biochemical markers are imperfect markers of bone histology in renal osteodystrophy (ROD); thus, bone histormophometry remains the gold standard for the assessment of bone turnover, mineralization, and volume in CKD. While newer imaging techniques, including QCT and pQCT, have promise in predicting overall bone structure and volume, the ability of CT to assess other histomorphometric parameters remains unknown.

**Methods:** We compared to bone histomorphometry variables to microCT (µCT) analysis of 68 bone biopsy cores from dialysis patients with normal to high bone turnover, adynamic bone and pure osteomalacia and 14 controls.

**Results:** As expected, osteoid accumulation as assessed by bone histomorphometry was higher in patients with osteomalacia than in those with adynamic bone, while bone mineral density as assessed by µCT was lower.

| Parameter | Dialysis: normal to high bone turnover (n=52) | Dialysis:pure osteomalacia (n=7) | Dialysis:adynamic bone (n=9) | Healthy controls (n=14) |
|---|---|---|---|---|
| **Histomorphometry** | | | | |
| Bone volume (BV/TV) (%) | 30.1 ± 1.1 | 29.1 ± 3.5 | 28.0 ± 0.9 | 21.4 ± 1.5 |
| Trabecular thickness (Tb.Th) (um) | 167 ± 5 | 145 ± 15 | 137 ± 13 | 141 ± 14 |
| Trabecular separation (Tb.Sp) (um) | 406 ± 16 | 343 ± 38 | 355 ± 29 | 459 ± 22 |
| Osteoid volume (OV/BV) (%) | 11.9 ± 0.7 | 28.4 ± 3.9 | 1.1 ± 0.4 * | 2.2 ± 0.4 |
| Osteoid surface (OS/BS) (%) | 47.0 ± 1.8 | 67.2 ± 6.5 | 10.0 ± 2.0 * | 16.6 ± 2.7 |
| Osteoid thickness (O.Th) (um) | 19.8 ± 0.6 | 27.8 ± 4.0 | 6.1 ± 0.6 * | 8.3 ± 0.8 |
| Bone formation rate (BFR/BS) (um³/um²/y) | 95.1 ± 1.4 | 11.3 v 9.1 | 21.4 ± 14.1 | 68.7 +- + 7.0 |
| **microCT** | | | | |
| Bone volume (BV/TV) (%) | 32 ± 1 | 29 ± 3 | 29 ± 2 | 20 ± 2 |
| Connectivity Density (#/mm³) | 17.4 ± 1.2 | 36.3 ± 13.4 | 21. 3 ± 2.7 | 16.5 ± 2.2 |
| Trabecular Number (#/mm) | 2.0 ± 0.1 | 2.3 ± 0.2 | 2.1 ± 0.1 | 1.8 ± 0.1 |
| Trabecular Thickness (mm) | 0.16 ± 0.01 | 0.12 ± 0.01 | 0.15 ± 0.01 | 0.14 ± 0.01 |
| Trabecular Separation (mm) | 0.50 ± 0.02 | 0.40 ± 0.05 | 0.46 ± 0.04 | 0.55 ± 0.03 |
| Bone Mineral Density (mg HA/ccm) | 814 ± 7 | 784 v 15 | 821 ± 8 * | 792 ± 9 |

*p≤0.05 between adynamic bone and osteomalacia

In dialysis patients, bone volume measurements by both methods were highly correlated (BV/TV: r=0.70, p<0.001 ; Tb.Th: r=0.77, p<0.001; Tb.Sp: r=0.53, p<0.001 ). Bone formation rate did not correlate with any µCT determinations. Osteoid accumulation correlated with bone mineral density (O.Th: r= - 0.42, p<0.001; OV/BV: r= - 0.32, p<0.01, OS/BS: r=-0.30, p<0.05).

**Conclusions:** Measures of bone volume can be accurately assessed with CT. Skeletal mineralization may also be assessed as bone mineral density is lower in patients with excessive osteoid accumulation and similar amounts of bone volume and higher in patients with adyamic, well-mineralized bone. The potential value of non-invasive assessment of bone by pQCT, CT and bone histomorphometric variables remains to be determined.

## FR-PO629

**Canopy Cells in Renal Osteodystrophy (ROD): Potential Role in Dysregulated Coupling of Bone Formation and Resorption** R.C. Pereira,[1] Thomas Levin Andersen,[3] Peter A. Friedman,[2] Barbara Gales,[1] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Pharmacology and Chemical Biology, Univ of Pittsburg, Pittsburg, PA; [3]Vejle - Lillebaelt Hospital, Univ of Southern Denmark, Vejle, Denmark.*

**Background:** Disruption of canopies--flat cells which are lifted from the bone surface to form an enclosed compartment over the remodeling surface—impairs bone formation (BFR) despite osteolysis in pts with multiple myeloma. Their role in ROD is unknown.

**Methods:** Canopies were assessed in 106 bone biopsies of pediatric pts with CKD stages 2-5 and quantified on a scale of 0 to 4 (0: no surfaces with canopy lift; **0.5**: 1-2 surfaces; **1**: 3-4 surfaces; **2**: 5-6 surfaces; **3**: 7-9 surfaces; **4**: > 10 surfaces). PTHR1 immunoreactivity were assessed (rabbit anti-human PTHR1 (Gramsch Labs, Schwabhausen, Germany)) and quantified on the same scale.

**Results:** PTHR1 immunoreactivity was observed in canopies and in flat cells attached to the bone surface, although not in osteoblasts, osteoclasts, or osteocytes. Circulating PTH values were lower and fewer canopies were seen in CKD than in dialysis pts. Bone PTHR1 immunoreactivity did not differ between groups. PTH levels correlated with canopies (r=0.54, p<0.01) but not with bone PTHR1. Canopies and PTHR1 immunoreactivity correlated with BFR (r=0.31, p<0.01 and r=0.30, p<0.01), osteoid accumulation (OS/BS: r=0.58, p<0.01 and r=0.43, p<0.01) and osteoclast surface (r=0.67, p<0.001 and r=0.32, p<0.01). In multivariable analysis, OS/BS predicted PTHR1 immunoreactivity ($R^2$=0.26) while PTH, OS/BS, and Oc.S/BS were independent predictors of canopies ($R^2$=0.53).

| Parameter | CKD stages 2-4 (n=18) | Dialysis (n=88) |

## FR-PO630

### The Relationship between Micropetrosis and Osteocyte Number in Hemodialysis Patients with Hypoparathyroidism

Aiji Yajima,[1] Masaaki Inaba,[2] Yoshihiro Tominaga,[3] Kosaku Nitta,[4] Shigeru Satoh.[1] *[1]Akita Univ School of Medicine; [2]Osaka City Univ Graduate School of Medicine; [3]Nagoya 2nd Red Cross Hospital; [4]Tokyo Women's Medical Univ.*

**Background:** Bone microcracks are frequently found in patients with low bone turnover probably because of decreased osteocyte number in micropetrotic bone in these patients. We hypothesized that the cause or duration of low turnover may alter these findings.

**Methods:** Fifteen HD patients with low bone turnover with or without total parathyroidectomy (PTX) or cinacalcet hydrochloride were assessed by bone histomorphometry of iliac crest bone biopsy. Group I; taken before and at 1 year (yr) after PTX (n=3) and before and after cinacalcet after 1 yr of treatment (n=4). Group II; HD patients with long-term (over 3 yrs due to unknown causes) low iPTH (< 60 pg/mL; n=8). Micropetrosis volume/bone volume (Mp.V/BV; %), osteocyte number/micropetrosis volume; (N.Ot/Mp.V; N/mm$^2$) and N.Ot/bone volume excluding micropetrosis volume; (N.Ot/(BV-Mp.V); N/mm$^2$) were compared before and after the treatment in Group I. N.Ot/Mp.V was compared with N.Ot/(BV-Mp.V) in Group I (post) and Group II. All bone samples were diagnosed as having low bone turnover.

**Results:** In group I, serum iPTH decreased from 1161 to 86 pg/mL. N.Ot/Mp.V decreased at 1 yr (216.6 ± 103.1(SD) to 145.8 ± 90.0 N/mm$^2$, p=0.016), but N.Ot/(BV-Mp.V) and Mp.V/BV did not change. For group II, iPTH was 15.9 pg/mL at the time of bone biopsies. Mp.V/BV was greater in Group II compared to Group I (63.1 ± 12.4 vs. 29.6 ± 13.6 %, p=0.004). N.Ot/Mp.V was smaller than N.Ot/(BV-Mp.V) in Group I (145.8 ± 90.0 vs. 274.3 ± 66.4 N/mm$^2$, p=0.031) and Group II (94.5 ± 63.5 vs. 172.4 ± 69.4 N/mm$^2$, p=0.007).

**Conclusions:** In patients with long term low turnover not induced by PTX or cinacalcet, there is an increase of micropetrosis with a reduction in overall osteocytes. This implies that the pathophysiology of low turnover induced by cinacalcet or PTX at 1 yr may be very different than that observed in patients without a known cause of low turnover for a long term. The latter may be due to decreased osteocytes survival, perhaps caused by the micropetrosis.

## FR-PO631

### Synergistic Effect of Etidronate Combined with Menatetrenone for Glucocorticoid-Induced Osteoporosis in Patients with Chronic Glomerulonephritis

Yuko Makita, Hitoshi Suzuki, Masao Kihara, Hiromitsu Fukuda, Satoshi Mano, Takashi Kobayashi, Yasuhiko Kanaguchi, Tatsuya Aoki, Teruo Hidaka, Katsuhiko Asanuma, Yasuhiko Tomino. *Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan.*

**Background:** Glucocorticoid therapy is useful for treatment of chronic glomerulonephritis (CGN), however, glucocorticoid may induce secondary osteoporosis. Bone loss initiate just after administration of glucocorticoid, and the degree of osteoporosis depends on the cumulative dose of glucocorticoid. Although bisphosphonate treatment is well known to improve the bone quality and reduce the risk of bone fractures, recent studies have shown that vitamin K2 also maintain stable bone mineral density (BMD). Furthermore, vitamin K2 is essential for bone formation cooperate with osteocalcin. Thus, we examined the clinical efficacy of bisphosphonate alone or bisphosphonate combined with vitamin K2 for preventing glucocorticoid-induced bone loss in CGN patients using serum levels of N-terminal telopeptide of type I collagen (NTx) and uncarboxylated osteocalcin (ucOC) with BMD.

**Methods:** We conducted a 6-month prospective randomized study at Juntendo university hospital. Overall 43 patients (mean age 39.4 ± 17.0) with CGN commencing with prednisolone were recruited from 2011 to 2013. These patients were randomized to Etidronate (17.5 mg/week) alone (Etidronate group, n=19) or Etidronate (17.5 mg/week) with Menatetrenone (45 mg/day) (Combined group, n=24) treatment groups. Serum levels of NTx and ucOC as well as BMD were measured before and after 3 and 6 months of commencing with prednisolone.

**Results:** In the Etidronate group, the percentage changes of serum levels of NTx after 3 and 6 months were -6.1 % and -9.8 %, whereas those were -28.3 % and -27.0 % in the Combined group. The percentage changes of serum levels of ucOC after 3 and 6 months were -8.3 % and -10.6 % in the Etidronate group, -51.3 % and -50.0 % in the Combined group, respectively. There were no significant differences in BMD between these groups during the study.

**Conclusions:** Our data suggested that combination therapy of Etidronate with Menatetrenone may have synergistic effect to prevent glucocorticoid-induced osteoporosis in patients with CGN.

## FR-PO632

### Blood Tests Predictive of Bone Loss in CKD-5D Patients

Hartmut H. Malluche,[1] Daniel Davenport,[2] Marie-Claude M. Faugere.[1] *[1]Div of Nephrology, Univ of Kentucky; [2]Dept of Surgery, Univ of Kentucky.*

**Background:** Low bone mass is frequently seen in patients with chronic kidney disease on dialysis (CKD-5D) and abnormalities in bone volume are an integral part of renal osteodystrophy. Patients with CKD-5D have 4.4 times the risk of hip fracture compared to the general population. This prospective study was conducted to determine whether serum biochemical parameters can help to predict bone loss in CKD-5D patients.

**Methods:** In CKD-5D patients, bone mass was measured by QCT and DXA of the hip and spine at baseline and after 1 year. At time of these bone mass measurements, blood tests were done including: PTH; FGF-23; sclerostin; procollagen type 1 N-terminal propeptide (P1NP); and tartrate-resistant acid phosphatase-5b (TRAP-5b). Demographic and clinical characteristics were recorded.

**Results:** 69 patients completed the study (Table). Bone loss was observed by QCT in the hip in 52% of the patients and in the spine in 36%; by DXA in the hip in 35% and in the spine in 36%. Bone loss in the hip was lower in black patients and in patients exercising regularly (both p<.05). Bone loss was not greater in diabetics and did not correlate with either BMI or dialysis vintage. TRAP-5b, sclerostin and FGF-23 were significantly higher in losers than non-losers (p<0.05). Bone loss by QCT of the hip correlated with baseline P1NP, TRAP-5b and sclerostin (rho=+.245,-.267,-.371 rsp, all p<.05). Bone loss by DXA of the spine correlated with FGF-23 (rho=-.393, p=.001). Sclerostin and TRAP-5b were independent predictors of bone loss by QCT of the hip after adjustment for age, race and exercise (β=-8.4, p=.008 and β=-1.4, p=.011 rsp). Log FGF-23 predicted bone loss by DXA of the spine (β=-.04, p=.003).

| | |
|---|---|
| Gender | 63% M / 37% F |
| Race | 35 Black / 33 White / 1 Other |
| Age, mean y ± SD | 53.6 ± 12.4 |
| BMI, mean kg/m2 ± SD | 32.2 ± 7.3 |
| Dialysis Vintage, median mos. (range) | 39 (3 – 241) |
| Diabetics | 41% |
| Exercises 1-2 times/week | 22% |
| Exercises 3+ times/week | 41% |
| Treated with Vitamin D analogs | 86% |

**Conclusions:** The available blood tests, TRAP-5b, sclerostin, and FGF-23 can be used to assess risk for bone loss in CKD-5D. These findings are relevant for a major clinically challenging problem.

## FR-PO633

### A Retrospective Review of Bone Density Scans in Different Stages of Chronic Kidney Disease

Bhanu Prasad Tikkisetty,[1] Jennifer St.onge.[2] *[1]Nephrology, Regina Qu Apelle Health Region, Regina, Canada; [2]Research and Health Information Service, Regina Qu Apelle Health Region, Regina, Canada.*

**Background:** Our renal program undertook a retrospective chart review of all patients who underwent a baseline dual-energy X-ray absorptiometry (DXA) scan in our multidisciplinary CKD clinic from Jan 2001 to Jan 2010. The purpose of the study was to determine if there was a preferential site of bone loss in CKD patients across different disease stages.

**Methods:** A total of 410 patients were included in the dataset. Measures included glomerular filtration rate (eGFR) in mls/min as per the Modification of Diet in Renal Disease formula, bone density measurements including T-scores and Z-scores for the lumbar spine, both hips, and the one-third distal radius, as well as the number of fractures. We compared these measures across patients in CKD Stages 2 through 5.

**Results:** We found a significant decline in median bone density across Stages 2 through 5 for total hip ($X^2$ (3) = 16.73, $p$=.001) and femoral neck ($X^2$ (3) =12.76, $p$=.005) sites, but not lumbar spine or one-third distal radius. Increasing serum phosphorus was significantly associated with reduced bone mineral density in the total hip (r=.15, $p$<.05, Spearman's rho) and trended towards significance for femoral neck (r=.10, $p$=.056, Spearman's rho). The percentage of patients suffering from a fracture, however, did not significantly change with CKD stage using a between-groups analysis ($X^2$ (3) = 6.42, $p$=.09, Cramer's V = .13, $p$=.09).

**Conclusions:** There is a demonstrable decline in total hip and femoral neck bone density with progression of CKD staging. In contrast, lumbar spine and distal radius bone mineral density were not affected by CKD stage. DXA scans provide information on BMD, they do not comment on trabecular and cortical microarchitecture and the resolution is too

low to distinguish between cortical and trabecular bone. Future research will determine whether decreased bone density as determined by DXA scan is associated with increased fracture risk over time in the same patients. We will also examine the effect of treatment with bisphosphonates on BMD as CKD progresses.

### FR-PO634

**Prescribing Practices and Response to Cinacalcet Treatment in Secondary Hyperparathyroidism – A Single Centre Experience** Nadeeka Kumarihamy Rathnamalala, Graham Warwick. *John Walls Renal Unit, Univ Hospitals of Leicester, Leicester, United Kingdom.*

**Background:** Managing bone disease in advanced chronic kidney disease (CKD) can be challenging. With the introduction of cinacalcet in the United Kingdom, guidelines from National Institute for Health and Care Excellence (NICE) have been issued to guide its use. The aim of this audit was to determine if cinacalcet was used in line with NICE and Kidney Disease Improving Global Outcomes (KDIGO) guidelines.

**Methods:** This was a retrospective observational study of patients under the care of a large tertiary nephrology centre in the UK. Data was extracted from the electronic medical records and included prevalent dialysis ,nephrology and transplant clinic follow ups from 01.08.2012 to 31.10.2012.

**Results:** 65 subjects were identified (M:F 38:27).Mean age was 62 (+/- 17) yrs and 89.2% were Caucasians. Majority (84.6%) were receiving renal replacement therapy(RRT) while 7.7% were transplanted and 7.7% were pre-dialysis CKD. 94.5% on RRT were on unit based haemodialysis for mean of 6.1 yrs. 50.8% had contraindications for parathyroidectomy while 49.2% declined surgery.

76.9 % of patients were already on a phosphate binder and this did not change over one year on cinacalcet. Only 62.5 % of patients were on vitamin D analogues but at the end of one year this had increased to 71.1 % of patients. 82.6 % of patients were started on 30mg cinacalcet and 59% and 62.2% remained on 30 mg at 6 and 12 months respectively.

84.4% of the study population had iPTH levels above the KDIGO targets while only 40.7% and 37.5% still remained over the target at 6 and 12 months respectively.However only 16 (26.2%) of the total study population had dose adjustments during the follow up period.

**Conclusions:** All subjects were started on cinacalcet treatment due to contraindications to parathyroidectomy or preference to have medical treatment. Cinacalcet did not significantly reduce the need for a phosphate binder but there increased requirement for vitamin D analogues. In a significant number iPTH was not reduced to the target but dose escalation was often not performed according to guidelines.

### FR-PO635

**Lanthanum Carbonate or Dietary P Restriction Ameliorates Endothelial Dysfunction in Adenine-Induced Chronic Kidney Disease Rats** Haruka Ueda, Yutaka Taketani, Maerjianghan Abuduli, Hirokazu Ohminami, Hisami Okumura, Hironori Yamamoto, Eiji Takeda. *Dept of Clinical Nutrition, Univ of Tokushima, Tokushima, Japan.*

**Background:** Cardiovascular disease (CVD) is the most important cause of mortality in chronic kidney disease (CKD) patients. Hyperphosphatemia has been identified as an independent risk factor for CVD in CKD patients, as elevation of serum phosphorus (P) levels can be involved in endothelial dysfunction as well as vascular calcification. Dietary P restriction and P binders are useful for correction of hyperphosphatemia, however, it has been unknown whether these treatments have similar beneficial effect on endothelial function or not. Here, we investigated the effect of lanthanum carbonate or dietary P restriction on endothelial dysfunction in adenine-induced chronic kidney disease rats.

**Methods:** Adenine-induced CKD model rats were prepared by feeding 0.5% adenine containing diet for 35 days on male 7-wk-old Sprague-Dawley rats. The adenine-induced CKD rats were divided 5 groups and treated with either control diet (CP; 1%P), low P diet (LP; 0.2%P), 1.5% lanthanum carbonate (La1.5; 1%P, 1.5%LaCO3), 3% lanthanum carbonate (La3; 1%P, 3%LaCO3), or 6% lanthanum carbonate (La6; 1%P, 6%LaCO3) for 14 days. Plasma were collected at sacrificed day and measured P, intact-PTH, FGF23, and creatinine. Aortic rings were also prepared and measured acetylcholine-dependent vasodilation by isometric transducers.

**Results:** Plasma P, intact-PTH, and FGF23 levels were significantly decreased by similar level and plasma calcium levels were increased in LP and La6 groups compared with CP group. Acetylcholine-dependent vasodilation was impaired in adenine-induced CKD rats. This impairment was significantly and similarly improved in LP and La6 groups compared with CP group. However, correction of hyperphosphatemia was not enough in La1.5 and La3 groups so that impaired vasodilation was not significantly ameliorated.

**Conclusions:** In conclusion, both dietary P restriction and lanthanum carbonate can ameliorate endothelial dysfunction observed in adenine-induced CKD rats, but the improvement would be depended on the correction rate of serum P level.

### FR-PO636

**β-Glycerophosphoric Acid Promotes Vascular Smooth Muscle Cells Transdifferentiation and Calcification via miR-125b Downregulation and Ets1 Induction** Ping Wen, Junwei Yang. *2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

**Background:** Vascular calcification is highly prevalent in patients with chronic kidney disease (CKD) and is associated with increased risk of cardiovascular disease and mortality. Accumulated evidences suggested that vascular smooth muscle cells (VSMCs) to osteoblast-like cells transdifferentiation (VOT) plays a crucial role in promoting vascular calcification. MicroRNAs (miRNAs) are a novel class of small RNAs that negatively regulate gene expression via repression of the target mRNAs. In the present work, we sought to determine the role of miRNAs in VSMCs phenotypic transition and calcification induced by b-glycerophosphoric acid (β-GP).

**Methods:** Primary cultured rat aortic VSMCs were treated with β-GP for different time. The protein levels of SM-22α, cbfα-1, osteocalcin, and osteopontin in VSMCs were tested by Western Blotting assay. miR-125b expression was detected by real-time RT PCR. Calcium deposition was determined by Alizarin Red S staining.

**Results:** 1) In VSMCs, after β-GP treatment, the expressions of cbfα1, osteocalcin and osteopontin were significantly increased and SM-22α expression was decreased. ALP activity was induced by β-GP in a time and dose dependent manner. Calcium deposition was detected in VSMCs incubated with calcification media; 2) miR-125b expression was significantly decreased in VSMCs after incubated with β-GP. miR-125b mimic could inhibit β-GP-induced osteogenic markers expression and calcification of VSMCs whereas miR-125b inhibitor promoted the phenotypic transition of VSMCs and calcification; 3) miR-125b targeted Ets1 and regulated its protein expression in VSMCs. Downregulating Ets1 expression by its siRNA inhibited β-GP-induced the VSMCs phenotypic transition and calcification.

**Conclusions:** Our study suggests that β-glycerophosphoric acid, a donor of phosphorus, can stimulate VSMC transdifferentiation and calcification, which is probably through miR-125b downregulation and Ets1 induction.

*Funding:* Government Support - Non-U.S.

### FR-PO637

**Phosphate Overload Induces Local and Systemic Inflammation and Malnutrition in Uremic Rats** Shunsuke Yamada,[1] Masanori Tokumoto,[1] Masatomo Taniguchi,[2] Kazuhiko Tsuruya,[3] Takanari Kitazono.[2] *[1]Div of Nephrology, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

**Background:** Phosphate (Pi) overload plays a pivotal role in the development of cardiovascular disease (CVD) in chronic kidney disease (CKD) patients. Inflammation and malnutrition also contribute to the high prevalence of CVD in patients with CKD. However, the impact of Pi overload on inflammation and malnutrition remains to be elucidated.

**Methods:** The present *in vivo* study determined the effects of Pi overload on inflammation, malnutrition and CVD (cardiac weight and aortic calcium content) in CKD rats fed a diet containing 0.3% adenine, 19% protein and different concentrations of Pi (ranging from 0.3% to 1.2%) for eight weeks. The effects of lanthanum carbonate on Pi-related changes were also investigated. Furthermore, we examined the direct effects of Pi overload on cultured human vascular smooth muscle cells (VSMCs) in an *in vitro* study.

**Results:** Pi loading dose-dependently induced malnutrition (decreased body weight and serum albumin) and CVD (increased cardiac weight and aortic calcium content) without aggravating the kidney function in the CKD rats. The CKD rats exhibited dietary Pi loading-dependent increases in the serum tumor necrosis factor (TNF)-α levels, the mRNA expression of TNF-α in the aorta, heart and kidneys and the levels of an oxidative stress marker (8-hydroxy-2'-deoxyguanosine) in the urine and aorta. Treatment with 6% lanthanum carbonate blunted almost all of the changes induced by Pi loading. A linear regression analysis showed that the serum Pi level was closely correlated with the extent of inflammation, malnutrition and CVD. In the cultured VSMCs, high Pi medium increased the mRNA of TNF-α and Pit-1, and decreased that of Klotho.

**Conclusions:** Dietary Pi overload induces a sequence of events, including inflammation, malnutrition and CVD in CKD rats. Pi-binders have the potential to counteract the changes induced by Pi overload.

### FR-PO638

**Therapeutic Effects of ONO-1301 on Vascular Calcification in a Rat Model of Adenine-Induced Chronic Kidney Disease** Yohei Maeshima,[1] Hiroyuki Watatani,[2] Norikazu Hinamoto,[2] Katsuyuki Tanabe,[2] Kana Masuda,[2] Haruyo Ujike,[2] Hitoshi Sugiyama,[2] Sakai Yoshiki,[3] Hirofumi Makino.[2] *[1]CKD and CVD, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [3]ONO Pharmaceutical Co., Osaka, Japan.*

**Background:** Cardiovascular disease is a leading cause of mortality in patients with CKD, and vascular calcification is a key modifier of disease progression. ONO-1301 (ONO) is a novel prostacyclin analog possessing thromboxane synthase inhibitory activity. We recently reported the renoprotective effects of ONO in experimental models of diabetic

nephropathy and obstructive uropathy. Here, we aimed to investigate the therapeutic efficacies of ONO on progressive CKD and vascular calcification in a rat model of adenine-induced CKD.

**Methods:** Male Sprague-Dawley rats at 13 weeks of age were fed with the diet containing either 0.75% (CKD) or 0% (control) adenine along with 2.5% protein. After 3 weeks, animals were divided into one of two treatment groups with equivalent kidney dysfunction. For the following 5 weeks, animals were fed with standard rat chow, and ONO (6mg/kg/ day) or vehicle buffer was orally administered. Urine, serum, kidneys and thoracic aorta were obtained and subjected to evaluation.

**Results:** Treatment with ONO did not significantly improve adenine-induced renal insufficiency and renal histological alterations. However, vascular calcification (von Kossa staining), the Ca and Pi content of the thoracic aorta and serum osteocalcin levels were significantly decreased by treatment with ONO compared with the control CKDanimals. In addition, treatment with ONO significantly recovered the levels of matrix Gla Protein and Fetuin-A suppressed by adenine-induced CKD, and suppressed the overexpression of RUNX2 in the VSMC of the thoracic aorta (immunohistochemistry).

**Conclusions:** Taken together, these results suggest the protective role of ONO on vascular calcification via regulating the levels of RUNX-2 and locally acting inhibitors of vascular calcification in the experimental CKD model.

*Funding:* Pharmaceutical Company Support - ONO pharmaceuticals

## FR-PO639

**Usefulness of Tubular Reabsorption of Phosphate as a Probable Surrogate Marker for Phosphate Regulation in Chronic Kidney Disease**

Yul Hee Cho,[1] Yu ah Hong,[2] Myung Hyun Lee,[1] Ji Hee Lim,[1] Min Young Kim,[1] Keun Suk Yang,[1] Ji Hyun Yu,[1] Seun Deuk Hwang,[1] Bum-Soon Choi,[1] Chul Woo Yang,[1] Yong-Soo Kim,[1] Cheol Whee Park.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Korea Univ.*

**Background:** Fibroblast growth factor 23 (FGF23) and soluble α-Klotho, which are emerging potential biomarkers of phosphorus and vitamin D metabolism, change progressively beginning in early chronic kidney disease (CKD) to maintain normal phosphorus. However, its use for an early surrogate marker of CKD-mineral and bone disorder (MBD) is limited in clinical practice. The tubular reabsorption of phosphate (TRP) has been commonly used to assess the renal tubular phosphate transport. The aim of this study investigates to find the earliest biomarker for CKD-MBD related to the estimated GFR (eGFR) in CKD patients.

**Methods:** We performed a cross-sectional study in 93 stable patients with predialysis CKD stage 1-5. TRP, eGFR, calcium, phosphate, intact PTH (iPTH), 25-hydroxyvitamin D, serum FGF23 and urine soluble α-Klotho levels were measured.

**Results:** As renal function declined, TRP significantly decreased ($P < 0.001$; $r = 0.763$) and both iPTH and serum FGF23 increased ($P < 0.001$; $r = -0.598$, $P < 0.001$; $r = -0.453$, respectively) for the augmentation of phosphaturia. Decreased eGFR and increased iPTH were found to be independently associated with decreased TRP, but did not associate with urine soluble α-Klotho and serum FGF23 in the multiple linear regression analysis. Increased serum FGF23 was only independently associated with decreased eGFR. The areas under the curve (AUC) for serum FGF23 and TRP are 0.598 and 0.739, respectively ($P < 0.05$).

**Conclusions:** TRP is a simple, useful and cost saving method compared with serum FGF23 and urine soluble α-Klotho for the assessment of the altered mineral metabolism of CKD patients.

## FR-PO640

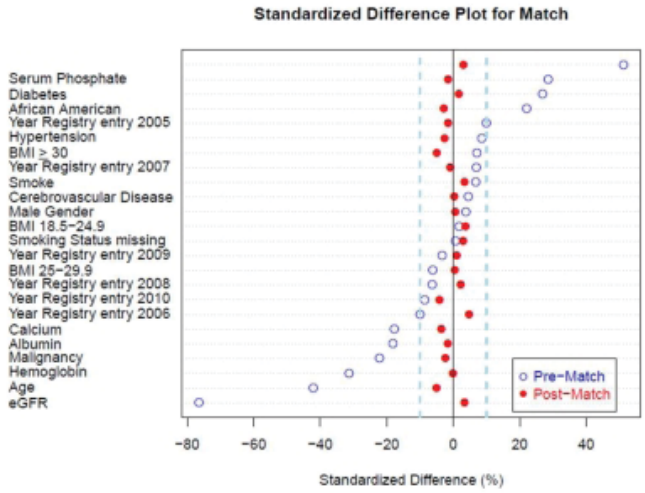
**Phosphate Binder Use and Mortality in Chronic Kidney Disease: A Propensity-Based Analysis**

Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Ankit Sakhuja,[1] Susana Arrigain,[2] John W. Sharp,[2] Joseph V. Nally.[1] *[1]Nephrology; [2]Quantitative Health Sciences, Cleveland Clinic.*

**Background:** Higher serum phosphorus is associated with an increased mortality in chronic kidney disease (CKD). The practice patterns of phosphate binder use and their associations with mortality in non-dialysis dependent CKD were examined.

**Methods:** The factors associated with the use of calcium and non-calcium phosphate binders in those with stage 3 and 4 CKD were studied using logistic regression models. The associations between phosphate binder use and mortality were examined using propensity matching and Cox models.

**Results:** Out of 13,325 patients with serum phosphorus levels measured, 945 patients were on phosphate binders. 939 patients who had phosphate binder during follow up were matched using caliper width of 0.1. After matching, all of the baseline variables had standardized differences <10% between those who were and were not on binders.



238 (25%) of them were prescribed non-calcium based binders and the rest were on calcium based binders. Each 5 kg/m$^2$ higher BMI (OR 1.12, 95% CI 1.01, 1.25), 1 mg/dl higher serum phosphorus (OR 1.35, 95% CI 1.13, 1.61) and 1 mg/dl higher serum calcium (OR 1.35, 95% CI 1.06, 1.72) were associated with higher odds of being prescribed a non-calcium based binder. In the matched cohort, phosphate binder use was not significantly associated with mortality who were treated for at least 6 months. However, those who were treated for one year with a binder had a non-significant lower mortality risk (Hazard ratio: 0.85, 95% CI 0.66, 1.10). There were no differences in the risk for death between calcium and non-calcium based binders.

**Conclusions:** Short-term use of phosphate binder was not associated with lower risk for mortality in stage 3 and 4 CKD. Our results also suggest the need for studying the potential benefits of long-term phosphate binder use in this population.

*Funding:* Pharmaceutical Company Support - Genzyme

## FR-PO641

**Accelerated Progression of Vascular Calcification in Children with CKD Is Associated with Baseline Fetuin-A and Vessel Characteristics**

Rukshana C. Shroff,[1,2,4] Lesley Rees,[1] Melanie Hiorns,[3] John E. Deanfield,[2] Cathy Shanahan.[4] *[1]Renal Unit, Great Ormond Street Hospital for Children, United Kingdom; [2]Vascular Physiology Unit, Institute of Child Health, United Kingdom; [3]Radiology Unit, Great Ormond Street Hospital, United Kingdom; [4]Cardiovascular Div, King's College London, United Kingdom.*

**Background:** Vascular calcification is thought to begin early in CKD and progress rapidly on dialysis. We examined vascular changes as seen on vessel imaging with a quantitative and histological assessment of the vascular Ca load on arterial biopsy samples to study progression of vascular changes through pre-dialysis CKD, dialysis and after transplantation.

**Methods:** 48 children (16 pre-dialysis CKD 4-5 and 32 on dialysis) had vascular imaging (carotid intima-media thickness [cIMT], pulse wave velocity [PWV] and coronary artery calcification [CAC] on CT scan), biomarker analyses and an arterial biopsy (at the time of renal transplantation or PD catheter insertion). The Ca load in the vessel wall was quantitated and detailed histology performed to study hydroxyapatite deposition, vascular smooth muscle cell apoptosis and osteogenic differentiation. 43 children (22 dialysis and 21 transplants) had a second set of imaging after 14.2 ±3.9 months.

**Results:** The baseline vessel Ca load strongly correlated with cIMT in dialysis patients ($p=0.005$) whereas 11 of 16 pre-dialysis patients had normal cIMT. Dialysis patients had a significant annualised increase in cIMT and PWV ($p<0.005$ and $p=0.03$). CAC increased in 5 children with baseline CAC and was found in 3 other.

cIMT progression showed a close correlation with the vessel Ca load ($r=0.67$). Patients with cIMT progression had the highest apoptotic index implying vascular smooth muscle cell loss and greater osteogenic differentiation. The baseline cIMT ($r=0.31$) and Fetuin-A levels ($r=0.41$), but not FGF-23, 25-hydroxyvitamin D or osteopontin associated with cIMT progression. Changes in PWV and CAC did not correlate with vessel Ca load.

**Conclusions:** Calcification is rapidly progressive on dialysis and strongly correlates with baseline vessel wall characteristics and Fetuin-A levels. Fetuin-A may be a useful biomarker to predict rapid progression of vascular calcification in CKD.

## FR-PO642

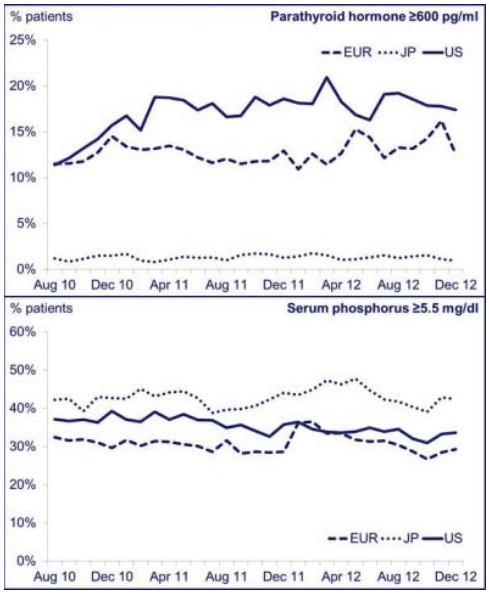
**International Trends in Markers of Mineral and Bone Disorder (MBD) among Hemodialysis Patients** Francesca Tentori,[1,2] Douglas S. Fuller,[1] Bruce M. Robinson,[1,3] Vittorio E. Andreucci,[5] Takashi Akiba,[6] Brian Bieber,[1] Yun Li,[1,3] Raymond C. Vanholder,[4] Ronald L. Pisoni.[1] *[1]Arb Res Collab Hlth, Ann Arbor; [2]Vanderbilt Univ, Nashville; [3]Univ of MI, Ann Arbor; [4]Univ Hosp, Gent; [5]Univ Federico II, Naples; [6]TWMC, Tokyo.*

**Background:** Recent MBD guidelines (KDIGO '09) and changes in reimbursement systems (e.g., Jan '11 US bundled payment) may have led to changes in clinical practice and impacted levels of serum phosphorus (P), calcium (Ca), and PTH. We tested this hypothesis within each region of the international DOPPS cohort.

**Methods:** Survey-weighted linear spline regressions adjusted for seasonality, age, black race (in US), sex, vintage, and catheter use to estimate temporal trends in frequency of PTH measurement; mean serum parathyroid hormone (PTH), P, Ca, and corrected Ca ($Ca_{alb}$); and reported target levels between Aug '10 and Dec '12.

**Results:** The % of patients with a PTH measurement in a 3-mo period declined in the US (96% to 84%) and Europe (EUR; 84% to 75%); but not in Japan (JP; 79% to 75%). There were no trends in the frequency of Ca and P measurement. Mean P fell 0.15 mg/dl (to 5.09 mg/dl) in the US and 0.08 mg/dl (to 4.84 mg/dl) in EUR; no trend was observed in JP (5.33 mg/dl). No clear trend in mean Ca or $Ca_{alb}$ levels were observed for US (mean $Ca_{alb}$ 9.10 mg/dl) and EUR (mean 9.25 mg/dl); $Ca_{alb}$ fell 0.17 mg/dl in JP (9.02 mg/dl in Dec'12). US mean PTH level rose 27% to 432 pg/ml between Aug '10 to Apr '11, stabilizing thereafter. No changes were seen in EUR (mean 333 pg/ml) or JP (mean 149 pg/ml). Reported upper limit of PTH target levels increased in the US but not EUR or JP; no changes in Ca or P upper limits were observed.

**Conclusions:** Trends towards lower P (US and EUR) and higher PTH (US) levels are strong and may reflect practice changes in response to KDIGO guidelines and US bundled payment. The potential impact of these changes on clinical outcomes remains to be determined.



*Funding:* Pharmaceutical Company Support - The DOPPS is supported by research grants from Amgen, Kyowa Hakko Kirin, AbbVie, Sanofi Renal, Baxter Healthcare, and Vifor Fresenius Medical Care Renal Pharma, with additional country-specific support provided in Canada by Amgen-Canada, Janssen, BHC Medical, Takeda and Kidney Foundation of Canada, and in Germany by Hexal and WiNe Institute. ## FR-PO643

**The PARADIGM Trial: Cinacalcet versus Vitamin D as Monotherapies for Treatment of Secondary Hyperparathyroidism in Patients on Dialysis** James B. Wetmore,[1] Konstantin Gurevich,[2] Stuart M. Sprague,[3] Gerald A. Da Roza,[4] John E. Buerkert,[5] Maureen T. Reiner,[6] William G. Goodman,[6] Kerry Cooper.[6] *[1]Hennepin County Medical Center; [2]Fresenius Medical Care Russia; [3]NorthShore U Health System; [4]U British Columbia; [5]Columbia Nephrology Associates; [6]Amgen Inc.*

**Background:** Cinacalcet (Cin) and vitamin D (vitD), often used in combination, have not been compared directly as monotherapy for the treatment of secondary hyperparathyroidism (SHPT) in patients on dialysis.

**Methods:** This study compared the efficacy of Cin to vitD as monotherapies in reducing parathyroid hormone (PTH) levels over 1 yr of treatment. The primary endpoint was mean % PTH reduction between wks 40-52. After SHPT treatment washout, patients (N=312) with PTH > 450 pg/mL were randomized to vitD (n=157) or Cin (n=155).

**Results:** Relatively severe SHPT was present at baseline, with mean (SD) PTH 846 (431) pg/mL in the Cin arm and 816 (428) pg/mL in the vitD arm. PTH reduction was modest and did not differ between study arms (12% Cin vs 7% vit D, P = 0.346). Mean (SD) dose of Cin = 83.1 (5.0) mg/day and vitD = 20.0 (12.4) mcg/wk (paricalcitol equivalents). Secondary efficacy measures also did not differ between arms. Hypercalcemia and hyperphosphatemia were more common in the vitD arm, while hypocalcemia was more common in the Cin arm. *Post hoc* analyses revealed that the use of dialysate calcium < 2.5 mEq/L or non-use of calcium-based binders negatively impacted PTH reduction during Cin monotherapy (reported separately).

**Conclusions:** Patients with relatively severe SHPT demonstrated modest reductions in PTH when using Cin or vitD as monotherapies. Combined treatment, using agents with unique mechanisms of actions and divergent effects on Ca and P levels, may be required among those with more advanced disease.

**Fibroblast Growth Factor 23 Enhances Renal Klotho Abundance** Tsuneo Takenaka, Tsutomu Inoue, Yusuke Watanabe, Takashi Miyazaki, Hiromichi Suzuki. *Saitama Medical Univ, Iruma, Saitama, Japan.*

**Background:** Klotho constitutes the receptor for fibroblast growth factor 23 (FGF23). However, the effects of FGF23 on renal and circulating klotho are not well known.

**Methods:** In vivo experiments were performed to assess the effects of FGF23 (10 μg/kg), parathyroid hormone (PTH, 10 μg/kg), and 1,25-dihydroxy-vitamin D3 (1,25VD, 1 μg/kg) on renal expression and serum concentration of klotho in Wistar rats.

**Results:** Phosphate excretion was increased at 3 hr after FGF23 administration ($p<0.05$). Renal klotho expressions and serum klotho levels were elevated at 3 hr ($p<0.01$) by FGF23. At 24 hr, phosphate excretion was still elevated ($p<0.05$), and serum phosphate, 1,25VD and PTH were reduced ($p<0.05$). However, serum and renal klotho returned to the control level at 24 hr. PTH markedly increased phosphate excretion after 24 hr ($p<0.01$). There were increases in FGF23 at 3 and 24 hr, and 1,25VD at 24 hr after PTH administration ($p<0.05$). Serum klotho concentration and renal klotho expression were elevated by PTH at 3 or 24 hr. After 24 hr exposure to 1,25VD, considerable increases in serum FGF23, calcium and phosphate were seen ($p<0.05$), but PTH was decreased ($p<0.01$). 1,25 VD elevated renal klotho expression and serum klotho ($p<0.05$) at 3 hr, but returned to control levels at 24 hr.

**Conclusions:** Our data constitute new demonstrations that FGF23 rapidly increases renal klotho expression and serum klotho. The present findings are consistent with the notion that PTH increases phosphate excretion at least in part through elevations of FGF23 and klotho . Moreover, our results indicate that 1,25VD increases klotho expression independently of FGF23. Finally, these observations suggest that free klotho may transduce the signal of FGF23 from distal to proximal tubules.

## FR-PO645

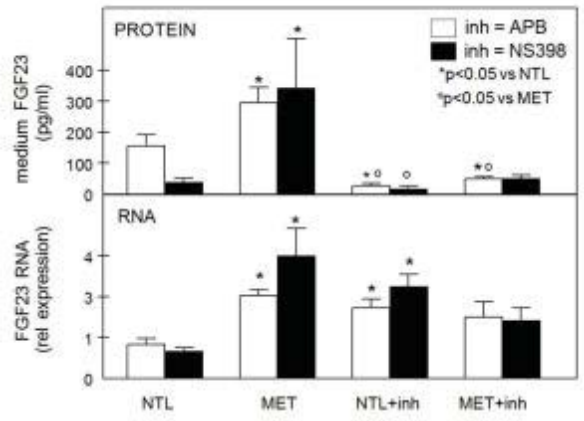
**Metabolic Acidosis Stimulation of Bone Fibroblast Growth Factor 23 Requires Intracellular Calcium Signaling and Prostaglandin Synthesis**

Nancy S. Krieger, Christopher D. Culbertson, Kelly Kyker-Snowman, David A. Bushinsky. *Medicine, Univ of Rochester, Rochester, NY.*

**Background:** Serum fibroblast growth factor 23 (FGF23) increases in chronic kidney disease (CKD) and decreases renal phosphate (Pi) reabsorption and serum $1,25(OH)_2D_3$. Patients with CKD have decreased acid excretion leading to metabolic acidosis (MET). MET is buffered by bone with release of calcium (Ca) and Pi. FGF23 is synthesized in osteoblasts and osteocytes and we have shown that MET stimulates FGF23 in mouse bone and primary osteoblasts. We hypothesize that MET increases FGF23 through intracellular Ca ($Ca_i$) signaling and prostaglandin release.

**Methods:** Neonatal mouse calvariae or primary osteoblasts were incubated in neutral (NTL, pH=7.44, $Pco_2$=38 mmHg, $[HCO_3^-]$=27 mM) or acid (MET, pH=7.18, $Pco_2$=37 mmHg, $[HCO_3^-]$=13 mM) medium ± 2-APB (50 μM), an inhibitor of $Ca_i$ signaling, or ± NS398 (1 μM), an inhibitor of prostaglandin synthesis. Medium FGF23 was measured by ELISA; calvarial or cell RNA was analyzed by realtime PCR with expression normalized to RPL13A.

**Results:** Both 2-APB and NS398 significantly inhibited MET-induced medium FGF23 protein and calvarial FGF23 RNA as well as bone resorption at 48h (not shown).



In primary cells where there is no mineral Pi present, 2-APB significantly inhibited the MET-induced increase in FGF23 RNA expression at 6h (NTL=0.9±0.2, MET=1.6±0.3, NTL+APB=1.1±0.3, MET+APB=1.1±0.2). NS398 also significantly inhibited the MET-induced increase in FGF23 RNA expression in primary osteoblasts at 6h (NTL=1.5±0.4, MET=3.2±0.6, NTL+NS398=1.8±0.3, MET+NS398=0.9±0.2).

**Conclusions:** MET stimulates FGF23 in osteoblasts by a $Ca_i$ / prostaglandin pathway, similar to the initial signaling pathways in MET-induced bone resorption. Therapeutic interventions directed toward correction of MET, especially in CKD, have the potential to lower FGF23 as well as prevent bone resorption.

## FR-PO646

**Comparative Effects of FGF23 Antagonism with Calcimimetic versus FGF23 Neutralizing Antibody in Uremic Rats**

Charles M. Henley III,[1] Victoria Shalhoub,[1] Edward Shatzen,[1] Sabrina Ward,[1] James R. Davis,[1] Sean Morony,[1] William G. Richards.[1] *[1]Metabolic Disorders, Amgen, Inc, Thousand Oaks, CA; [2]Independent, Newbury Park, CA.*

**Background:** Fibroblast growth factor 23 (FGF23), a 32kD protein secreted by bone, is a phosphaturic hormone important in phosphate and vitamin D (VitD) regulation. As renal function declines serum FGF23 increases and is associated with progressive renal failure, left ventricular hypertrophy and increased mortality.

**Methods:** To determine effects of FGF23 antagonism in preclinical uremic (CKD) rats, we compared effects of decreasing serum FGF23 with calcimimetic, R-568, versus FGF23 antibody neutralization in male, S-D rats (5/6Nx or sham-operated) on a high P diet. End points: serum PTH, $Ca^{2+}$, P, bone, survivability, vascular calcification.

**Results:** Calcimimetic R-568 in 5/6Nx rats increased serum P, decreased $Ca^{2+}$, PTH, FGF23, and FGF23 mRNA and protein in bone without significant static or dynamic histomorphometric changes. A separate group of CKD rats treated with 10ng VitD had increased serum FGF-23; concomitant treatment with R-568 decreased FGF-23 and PTH in VitD-treated rats. Suppression of FGF-23 in serum/bone by R-568 is likely through activation of the parathyroid calcium-sensing receptor and resulting decrease in PTH, a regulator of FGF23. FGF23-Ab significantly increased serum P, $Ca^{2+}$, $VitD_3$, lowered PTH and improved high turnover bone disease/mineralization in CKD rats. However, FGF23-Ab promoted aortic calcification and death in CKD rats.

| FGF23 Antagonism in 5/6 Nx rats | |
|---|---|
| **Calcimimetic R-568** | **FGF23 antibody** |
| ↓ $FGF23_{serum}$ | *FGF23 neutralization* |
| ↓ PTH | ↓ PTH |
| ↓ $Ca^{2+}$, ↑ P | ↑ $Ca^{2+}$, ↑ P |
| normalizes bone | ↓ bone turnover |
| ***no vascular calcification, mortality*** | ***↑ vascular calcification, mortality*** |

**Conclusions:** These subtotal Nx rat studies support the notion that calcimimetics control PTH and significantly lower serum FGF-23 without pathological effects observed with mAb neutralization of FGF-23. However, since we do not have a preclinical model adequately reflecting absence of renal function we do not know if direct neutralization of FGF23 would be deleterious in human ESRD-dialysis patients.

## FR-PO647

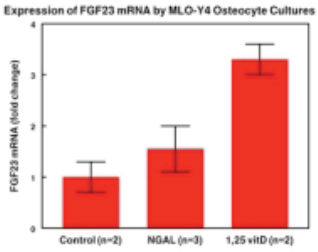
**Neutrophil Gelatinase-Associated Lipocalin (NGAL) Stimulates *In Vitro* Production of Fibroblast Growth Factor-23 (FGF23) in MLO-Y4 Osteocyte Cultures**

Shweta Bansal,[1,2] Khaled Khazim,[1] Basant Bhandari,[1] Sherry L. Werner,[1,2] Hanna E. Abboud,[1,2] Paolo Fanti.[1,2] *[1]Dept of Medicine/ Div of Nephrology, Univ of Texas Health Sciences Center at San Antonio, San Antonio, TX; [2]Renal Section, ALMVA Hospital, San Antonio, TX.*

**Background:** Regulation of FGF23 in chronic kidney disease (CKD) remains only partially defined. Besides established actions of phosphorus and $1,25(OH)_2D$ on FGF23 in CKD, positive correlation has been described described between FGF23 and interleukin-6 and tumor necrosis factor-α (TNFα) in this patient population suggesting a possible stimulatory action of inflammation on FGF23 expression. We recently found strong positive correlation between FGF23 and the acute phase reactant NGAL (r=0.72, p<0.001) in CKD patients. This association was independent of renal function, serum phosphorus and C-reactive protein, suggesting direct functional interaction between NGAL and FGF23. Since osteocytes are the only cell type producing FGF23 and they express the endocytic receptor megalin which binds NGAL with high affinity, we hypothesized that close association between NGAL and FGF23 in CKD patients is explained by direct stimulatory action of NGAL on the osteocytic synthesis and secretion of FGF23.

**Methods:** MLO-Y4 osteocytic cells were conditioned overnight with serum-free medium, incubated with 0.5-5 nM NGAL, 10 nM $1,25(OH)_2D_3$, 10 ng/ml TNFα or vehicle for 24 hours and finally tested for FGF23 mRNA expression by quantitative RT-PCR.

**Results:** FGF23 mRNA expression was increased 1.6 ± 0.5 fold by 2.5 nM NGAL (n=3), 3.2 ± 0.3 fold by $1,25(OH)_2D_3$ (n=2), and was not affected by exposure to TNFα.



**Conclusions:** NGAL directly stimulates FGF23 production in vitro although with lower strength than $1,25(OH)_2D_3$. Since circulating NGAL is very high and $1,25(OH)_2D$ is low in CKD patients, we propose NGAL may contribute to the increased production of FGF23 in CKD.

*Funding:* Veterans Affairs Support

## FR-PO648

**Effect of Standard Low-Protein Diet on Fibroblast Growth Factor 23 Levels in Patients with Early and Advanced Chronic Kidney Disease**

Shunsuke Goto, Kentaro Nakai, Keiji Kono, Hideki Fujii, Shinichi Nishi. *Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.*

**Background:** High serum fibroblast growth factor 23 (FGF23) levels are associated with mortality and cardiovascular diseases in patients with chronic kidney disease (CKD). Although recent studies have demonstrated that dietary phosphorus restriction and/or phosphate binders decreased serum FGF23 levels in patients with CKD, the effects of standard low-protein diet are limited. Our study investigates the effect of standard low-protein diet on serum FGF23 levels in patients with early and advanced CKD. We also evaluate the effects on serum 1,25-dihydroxyvitamin D (1,25D) and intact parathyroid hormone (PTH) levels.

**Methods:** We enrolled 15 patients with CKD stage 1 or 2 as an early CKD group and 20 patients with CKD stage 4 or 5 as an advanced CKD group. Subjects consumed standard low-protein diets for 4 to 6 days after two-day regular diet. Serum FGF23, 1,25D, intact PTH, calcium, and phosphorus levels and 24-hr phosphorus excretion were measured at baseline and the final day of study.

**Results:** Serum FGF23 levels decreased in both groups (early CKD, 52 [36-75] to 39 [23-65], $p < 0.05$; advanced CKD, 185 [126-322] to 138 [97-258], $p < 0.05$). Changes of FGF23 levels were correlated with changes of 24-hr urinary phosphorus excretion in the advanced CKD group (early CKD, $r = -0.25$, $p = 0.37$; advanced CKD, $r = 0.46$, $p < 0.05$).

Serum 1,25 D levels increased in only the early CKD group (early CKD, 36.0 [33.0-39.0] to 47.0 [33.0-78.0], p < 0.05; advanced CKD, 14.5 [13.0-19.0] to 14.5 [9.3-17.0], p = 0.12). Serum intact PTH levels decreased in only the advanced CKD group (early CKD, 23 [19-27] to 25 [21-30], p = 0.89; advanced CKD, 124 [73-194] to 85 [61-168], p < 0.05).

**Conclusions:** Our findings suggested that standard low-protein diet decreases serum FGF23 levels with various benefits on CKD-MBD control from early to advanced CKD stages.

## FR-PO649

**Serum Mineral Parameters Are Associated with Blood Cell Morphology in Non-Diabetic Chronic Hemodialysis Patients**

Basri Budak,[1] Mehmet Kanbay,[2] Ali Akcay,[3] Ali Riza Odabas,[2] Serkan Kubilay Koc.[1] *[1]Fresenius Medical Care Ankara Kecioren Dialysis Clinic, Ankara, Turkey; [2]Dept of Medicine, Div of Nephrology, Medeniyet Univ School of Medicine, Istanbul, Turkey; [3]Dept of Nephrology, Turgut Ozal Univ.*

**Background:** Parathyroid hormone (PTH) is known to induce bone marrow fibrosis in end stage renal disease patients which may influence the morphology of blood cells. We aimed to investigate the possible influence of PTH and serum mineral parameters on blood cell morphology in non-diabetic chronic hemodialysis (HD) patients.

**Methods:** Seventy non-diabetic chronic HD patients (male/female: 41/29) were enrolled in the study. Exclusion criteria were as follows; presence of diabetes mellitus, use of angiotensin-converting enzyme inhibitor or angiotensin receptor blocker, presence of any kind of hematological disorder including iron deficiency anemia. Serum PTH, calcium and phosphorus levels were determined together with hemoglobin, red blood cell count, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red cell distribution width (RDW), white blood cell count, platelet count, mean platelet volume (MPV) and platelet distribution width (PDW).

**Results:** Mean age was 58 ± 14 years and mean dialysis vintage was 98 ± 58 months. Mean serum PTH was 398 ± 339 pg/mL; calcium, 8.53 ± 0.89 mg/dL and phosphorus, 4.43 ± 1.38 mg/dL. Serum PTH was significantly inversely associated with RDW (r= -0.24, p=0.05). Serum PTH was not significantly related to other blood parameters including hemoglobin concentration. Serum calcium levels were correlated with PDW (r= -0.25, p=0.03). Serum phosphorus levels were significantly associated with MCV (r= -0.24, 0.04), WBC (r= 0.30, p=0.01), platelet count (r= 0.38, p= 0.001) and MPV (r= -0.32, p=0.008).

**Conclusions:** Serum PTH was not related to parameters of blood cell morphology except for RDW. Increased serum phosphorus levels were associated with increased total leukocyte and platelet counts which may represent increased inflammation. Also high serum phosphorus levels significantly associated with low red blood cell and platelet volumes.

## FR-PO650

**Low FGF-23 Levels Suggest Malnutrition in Maintenance Hemodialysis Patients**

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Kyoka Ono,[1] Maya Oda,[1] Touru Nakazono,[3] Kohji Usui,[2] Kenichiro Shigemoto.[1] *[1]Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Nephrology, Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Nephrology, Ichiyokai East Clinic, Hiroshima, Japan.*

**Background:** Elevated fibroblast growth factor-23 (FGF-23) level is a risk factor for mortality in incident dialysis patients. High FGF-23 levels can be attributed to hyperphosphatemia. However, poor nutritional status and hypophosphatemia have also been associated with increased mortality in maintenance HD patients (MHD).

**Methods:** Univariate and multivariate analyses into factors that relate to serum intact FGF-23 with SPSS II were performed in 332 MHD. The variables were sex, dialysis period, presence of DM, urine volume, Ccr+Curea/2, Kt/Vurea, β2-MG, cystacin C, BMI, serum albumin, nPNA, geriatric nutritional risk index (GNRI), serum phosphate, serum calcium, iPTH and dosages of activated vitamin D or phosphate binders. Clinical data were also assessed according to quartiles of FGF-23 level.

**Results:** The median age and dialysis period were 69 years and 66 months, respectively, and 83 patients had residual renal function (RRF: UV≥100 ml/day) and 249 patients did not. There were no significant differences in serum phosphate (mg/dl) [4.8 (3.9-5.8) vs. 5.0 (4.1-5.9)] and FGF-23 (pg/ml) [1120 (272-4080) vs. 1570 (357-5860)] levels in patients with and without RRF. In patients with RRF (n=83), serum phosphate levels (P<0.001) and vitamin D dose (P=0.013) were significantly associated with FGF-23 levels. In patients without RRF (n=249), serum phosphate (P<0.001), serum calcium (P<0.001) and iPTH (P=0.012) levels were significantly associated with FGF-23 levels. Patients in the highest FGF-23 group (Q4) were younger, and had longer dialysis period. BMI, nPNA, nPCR, GNRI, nPCR, serum albumin, creatinine, phosphate, dosage of vitamin D, phosphate binders and cinacalcet in Q4 were higher than in other groups and the differences between Q1 and Q4 were significant. Correlation between FGF-23 and serum creatinine levels (r=0.510), or GNRI (r=0.352) was observed (P<0.001).

**Conclusions:** Low FGF-23 levels suggest malnutrition and serum phosphate level but not RRF is the most important factor associated with FGF-23 in MHD.

*Funding:* Private Foundation Support

## FR-PO651

**The Fasting Fractional Excretion of Phosphate Is Correlated with FGF23 Levels, Mortality and Morbidity in CKD Patients Not on Dialysis**

Patricia Quadros Branco,[1] Teresa Adragao,[1] Ricardo Vizinho,[1] Maria Augusta Cabrita Silva Gaspar,[1] Andre L. Weigert,[1] Joao Faro-Viana,[2] Jose Diogo Barata.[1] *[1]Nephrology, Santa Cruz Hospital, Lisboa, Portugal; [2]Clinic Pathology, Santa Cruz Hospital, Lisboa, Portugal.*

**Background:** In CKD patients FGF23 elevation precedes the increase in PTH and phosphate (P). In advanced CKD 24h-phosphaturia is reduced and 24h-fractional excretion of P (FEP) has been inconsistently correlated with FGF23 levels. The aim of this study was to analyze, in pre-dialysis CKD patients, the correlation of the fasting FEP with FGF23 levels, biochemical markers of CKD-MBD and clinical cardiovascular events.

**Methods:** We studied 120 CKD pts (73% male, 27% diabetic, mean age 65 ± 13.7 years, 41%, 45% and 7.5% respectively in CKD stages 3, 4 and 5) during 23.9 ± 7.9 months. FGF23 (C-Terminal, ELISA Immutopics). FEP(%) was calculated with the formula:(UPO4 x PCr):(PPO4 x UCr) x 100. Blood and urine samples were taken simultaneously in a fasting steady state, after discarding overnight urine (Payne RB).

**Results:** P> 4.5 mg/dL, iPTH> normal, FEP> 20% and FGF23> 110 RU/ml, respectively were detected in 14.8%, 43.9%, 89.4% and 89.4% of pts. In a multivariate analysis, adjusted for age, eGFR and PTH, logFGF23 correlated directly with P (p<0.001) and FEP (p=0.008) and inversely with albumin (p=0.01). FEP correlated inversely with eGFR(p<0.001) and P(p=0.001) and directly with logFGF23 (p=0.008). During follow up period, 6 patients died, 26 initiated renal replacement therapy (RRT) and 31 suffered cardiovascular events. Patients with FEP> 40% had a lower survival free of cardiovascular events, death, or RRT initiation (log rank 29.11,p=0.008). In Cox regression CRP, Pulse Pressure and FEP> 40% (OR:5.32,CI:2.1-13.0,p=0.001) were predictors of cardiovascular events, RRT intiation or death (OR: 5.32,CI:2.1-13.0,p=0.001).

**Conclusions:** In summary, in this group of CKD pts, P levels were increased only in 14.8% of pts, while FEP> 20% was detected in 89.4% of pts. FEP, evaluated in fasting conditions, was an independent predictor of FGF23, CV events and RRT. FEP evaluated by this simple method may be a useful tool in the assessment of the altered mineral metabolism of CKD pts.

## FR-PO652

**Study on Correlation between Carotid Intima-Media Thickness with Serum HsCRP, FGF23 and Klotho Protein in MHD Patients**

Ying Sun, Aiqun Chen, Hua Wu. *Nephrology, Beijing Hospital of the Ministry of Health, Beijing, China.*

**Background:** To understand the clinic feature of the maintenance hemodialysis(MHD) patients with carotid artery atherosclerosis, analyze the relationship between carotid intima-media thickness(CIMT) and serum high sensitive c-reactive protein(HsCRP), fibroblast growth factor 23(FGF23), Klotho protein levels.

**Methods:** 88 MHD patients were enrolled in the blood purification center, from January to June 2012. The patients were divided into CIMT thickening group and the CIMT normal group based on their carotid color Doppler ultrasound results. FGF23 and Klotho protein were measured by ELISA. Possible risk factors of CIMT thickening, such as age, duration of dialysis, diabetes, FGF23, Klotho protein, hsCRP, lipids and other biochemical parameters were analyzed and compared between the two groups, while non-conditional logistic regression were used for multivariate analysis to determine the risk factors for CIMT thickening.

**Results:** Among the 88 MHD patients, increased CIMT was found in 53 patients(60.2%), while the remaining 35 patients (39.8%) had normal CIMT. The median of the two sets of CIMT were 1.5mm and 1.0mm respectively. Univariate analysis indicated that the average age of the CIMT thickened group was 66.64±10.61 years, and the average age of the group with normal CIMT was 58.63±11.78 years($t$=3.320, $P$=0.001). Diabetes prevalence of the CIMT thickened group was 37.7%, Diabetes prevalence of the group with normal CIMT was 17.1%($\chi^2$=4.294, $P$=0.038). The median of the two sets of FGF23 were 127.82 ng/L and 86.74 ng/L respectively, the difference was statistically significant($Z$=-3.713, $P$=0.000). The median of the two sets of HsCRP were 5.34mg/L and 2.19mg/L respectively, the difference was statistically significant($Z$=-3.547, $P$=0.000). The median of the two sets of Klotho protein were 42.48 U/L and 41.21 U/L respectively($Z$=-0.085, $P$=0.932). Non-conditional logistic regression analysis showed that age, FGF23 and hsCRP were independent risk factors for CIMT thickening in MHD patients, OR values were 1.061 (1.007,1.118), 1.016 (1.003,1.028), 1.344 (1.115,1.621), respectively.

**Conclusions:** Serum HsCRP, FGF23 and age are independent risk factors for CIMT thickening in MHD patients.

*Funding:* Private Foundation Support

## FR-PO653

**Fibroblast Growth Factor 23 Is Associated with Carotid Artery Plaque in Patients with Chronic Kidney Disease**

Sho Shimamoto,[1] Kazuhiko Tsuruya,[2] Masaru Nakayama.[3] *[1]Dept of Internal Medicine, Kyushu Kosei Nenkin Hospital, Japan; [2]Dept of Medicine and Clinical Science, Kyushu Univ, Japan; [3]Div of Nephrology, Dept of Internal Medicine, National Kyushu Medical Center Hospital, Japan.*

**Background:** Serum phosphate levels have been shown to be associated with the development of atherosclerosis in patients with chronic kidney disease (CKD). Fibroblast growth factor 23 (FGF23) is an important hormone in the regulation of phosphate metabolism. FGF23 has been suggested to play a role in vascular calcification in CKD.

However, it is unclear whether FGF23 is associated with carotid artery plaque (CAP) which is an indicator of atherosclerosis in predialysis patients. The aim of the present study was to clarify the relationship between FGF23 and CAP in patients with CKD not on dialysis.

**Methods:** Two-hundred seventy-seven predialysis CKD patients were enrolled in this cross-sectional study. CAP was assessed by B-mode Doppler ultrasound. Intact FGF23 was measured using a two-site monoclonal antibody ELISA in each patient. The risk factors for CAP were evaluated using a logistic regression model.

**Results:** We found CAP in 66.8% of the patients. The prevalence of CAP increased across CKD stages: 23.3% in CKD stages 1-2, 67.6% in stage 3, 76.2% in stage 4, and 79.8% in stage 5 ($p<0.01$). In a multivariate analysis, age, smoking, diabetes mellitus and log FGF23 (odds ratio [OR], 2.51; 95% confidence interval [CI], 1.26 to 5.36) were each identified as a risk factor for CAP. The study population was divided in quartiles of FGF23 levels. The prevalence of CAP was higher with increasing quartiles of FGF23 levels (first quartile 38.2%; second quartile 70.0%; third quartile 80.0%; fourth quartile 78.3%). Compared with the lowest FGF23 quartile, each subsequent quartile had a progressively higher OR for CAP, adjusted for confounders (OR for second quartile, 4.70 [95% CI, 1.74 to 13.42]; for third quartile, 5.83 [95% CI, 1.89 to 19.30]; and for fourth quartile, 7.72 [95% CI, 2.08 to 31.25], respectively).

**Conclusions:** The prevalence of CAP is increased with the decline in the kidney function. FGF23 was also identified as an independent factor for CAP in patients with CKD not on dialysis.

## FR-PO654

### Increases in FGF23 May Not Be the Initial Trigger of Secondary Hyperparathyroidism in Early CKD

Isabel Martinez,[1] Ramon M. Saracho,[2] Yolanda Almaden Peña,[3] Adriana S. Dusso,[4] Mariano Rodriguez.[3] *[1]Nephrology, Hospital Galdakao, Spain; [2]Nephrology, HUA, Spain; [3]IMIBIC, Cordoba, Spain; [4]IRBLleida, Spain.*

**Background:** Secondary Hyperparathyroidism (SH) starts at early stages of CKD and elevations in FGF23 were shown to precede the changes in serum calcium, phosphate and calcitriol predisposing to increases in PTH. This study examined the contribution of early increases in FGF23 to the onset of SH in CKD stage 1.

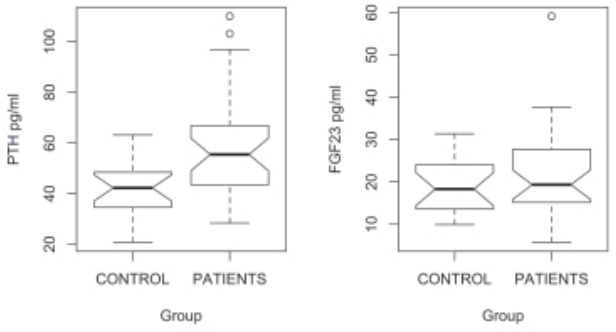
**Methods:** Thirty three patients, CKD1(creatinine clearance >90ml/ml) of different etiology, who were not receiving any vitamin D receptor activator, calcium salts, calcimimetics or bisphosphonates were compared with 17 healthy controls with no kidney disease in their total and ionized calcium, phosphorus, calcitriol, FGF23 and PTH in fasting conditions. Twenty-four hour urine was collected for calcium, phosphorus and creatinine. We estimated GFR with standard CCr corrected for 1.73 m2 of BS, using 24h urine collection. Intact PTH in serum was measured by Immunoassay(Advia Centaur XP, Siemens) and Intact FGF23 by ELISA(Kainos Laboratories Inc).

**Results:** Mean serum PTH in CKD patients was higher than controls (58.1 vs 41.4 pg/ml, p=.0003). However, mean FGF23 levels were similar in both groups, 21.8 vs 19.5 pg/ml, p=.33.

There were no differences in total and ionized calcium, phosphate and calcidiol, or calcitriol levels.

Calciuria, phosphaturia and CCr were similar in both groups, however fractional excretion of phosphate(FEP) was higher in CKD patients, 17% vs 14%, p=.03.

Linear regression analysis showed a mild positive correlation between PTH and FEP(p=.05). Instead, FGF23 and FEP were not associated. Controls were younger than patients, but differences in PTH remained significant after adjustement for age and sex.



**Conclusions:** Elevations in FGF23 is not the earliest event in the onset of SH. The FEP is associated to PTH but it is unrelated to FGF23 in early CKD.

## FR-PO655

### The Modification of the Effect of FGF23 on the Coronary Artery Calcium Score by Fractional Excretion of Phosphate in Patient with Pre-Dialysis CKD

Shin-young Ahn,[1] Seungmi Lee,[2] Kook-Hwan Oh,[2] Curie Ahn,[2] Dong Wan Chae.[1] *[1]Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam-si, Republic of Korea; [2]Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

**Background:** A recent study demonstrated that cardiovascular (CV) mortality was highest in the population having low $FEPO_4$ despite of high FGF23 level. Hence, we investigated the effect of FGF23 on the intermediate variables known to be related to CV mortality such as CACS, pulse wave velocity (PWV) and LVH according to the $FEPO_4$ level in an on-going observational cohort of CKD in Korea.

**Methods:** KNOW-CKD is an on-going, prospective, university hospital based observational cohort study under the sponsorship of Korean Center for Disease Control and Prevention. Cross-sectional analysis was performed in 702 participants. Severe CAC was defined as Ca score of ≥100 Agatston units (AU) and we regarded mean of the brachial-ankle PWV(MPWV) ≥ 1600 cm/s as a significant arterial stiffness.

**Results:** We developed four categories defined by FGF23 and $FEPO_4$ above or below their medians as follows: low FGF23/low $FEPO_4$, high FGF23/low $FEPO_4$, low FGF23/high $FEPO_4$, high FGF23/high $FEPO_4$. The participants with high FGF23/high $FEPO_4$ had more frequently diabetes, hypertension, and advanced CKD compared with the other three groups. They also had lower Hb, albumin, and 1,25 vitamin D and had higher serum P, alkaline phosphatase, and intact PTH. The mean values of CACS and MPWV were significantly higher in this group and the incidence of LVH was also highest in this group. After multivariable regression analysis, neither these groups nor FGF23 level could be an independent risk factor for severe CAC, significant arterial stiffness, or LVH. But, in subgroup analysis, high FGF23 was an independent risk factor for severe CAC in the participants with low $FEPO_4$ (OR=2.309, 95% CI=1.036-5.145, p=0.041).

**Conclusions:** The participants with high FGF23/high $FEPO_4$ demonstrated the most severe features in CAC, PWV and LVH largely due to the more frequent presence of comorbidities such as diabetes, hypertension, and advanced CKD. Only in the participants with low $FEPO_4$, high FGF23 was an independent risk factor for severe CAC.

## FR-PO656

### Fibroblast Growth Factor 23 Predicts Progression of Chronic Kidney Disease in Children

Anthony A. Portale,[1] Alison G. Abraham,[2] Myles S. Wolf,[3] Isidro B. Salusky,[4] Harald Jüppner,[5] Bradley A. Warady,[6] Susan L. Furth.[7] *[1]Univ of CA San Francisco; [2]Johns Hopkins Bloomberg School of Public Health; [3]Univ of Miami Miller School of Medicine; [4]Univ of CA Los Angeles; [5]Harvard Medical School; [6]Univ of Missouri-Kansas City; [7]Univ of Pennsylvania.*

**Background:** Plasma FGF23 concentrations increase early in the course of chronic kidney disease (CKD) in children and predict disease progression in adults. Whether FGF23 associates with risk of CKD progression in children is unknown.

**Methods:** We measured plasma C-terminal FGF23 and determined GFR annually by plasma iohexol clearance or the CKiD estimating equation in 418 children with CKD stages 2-4 enrolled in the Chronic Kidney Disease in Children (CKiD) study. We analyzed the association of baseline plasma FGF23 on time to 50% decline in GFR or start of renal replacement therapy using parametric regression stratified by glomerular or non-glomerular disease, adjusting for age, gender, race, GFR, proteinuria, blood pressure, serum phosphate, and PTH.

**Results:** At baseline, median age was 12 [IQR: 8, 15] years, GFR was 46 [34, 58] ml/min/1.73 $m^2$, and plasma FGF23 was 140 [97, 216] RU/ml - 2.5-fold higher than in healthy children. During a median follow-up of 62 [40, 73] months, 31% of subjects reached the CKD progression endpoint, 35 of 80 (44%) with glomerular and 94 of 338 (28%) with non-glomerular disease. Time to the endpoint was shorter in children with glomerular compared to non-glomerular disease (17 [4, 35] vs. 29 [19, 47] months) ($P<0.001$). Compared to non-progressors, progressors had lower GFR, higher levels of FGF23 and proteinuria, and lower $1,25(OH)_2D$ ($P<0.005$). In univariate analyses, doubling of FGF23 was associated with a significant, 72% [95% CI: 53, 83] shorter time to the CKD endpoint in children with glomerular, and 53% [95% CI: 41, 63] shorter time in those with non-glomerular disease. After adjustment, doubling of FGF23 remained associated with modest reductions in time to the endpoint, 18% [95% CI: -33, 49] shorter time with glomerular, and 12% [95% CI: -6, 27] shorter time with non-glomerular disease, reductions of borderline significance.

**Conclusions:** Increased plasma FGF23 is a novel risk factor for CKD progression in children.

## FR-PO657

### Evaluation of Serum FGF23 Concentration in a Small Subset of Patient-Samples from the EVOLVE Randomized Trial by Two Independent iFGF23 Assays

Marina Stolina, Denise C. Dwyer, Chun-ya Han, Bastian Dehmel, William G. Richards. *Amgen Inc.*

**Background:** Fibroblast growth factor 23 (FGF23, a phosphaturic hormone) is a regulator of calcium-phosphate metabolism. Increased FGF23 in serum from patients on dialysis is associated with increased mortality, treatment-resistant secondary

hyperparathyroidism and left ventricular hypertrophy. Growing interest in plasma/serum FGF23 as a clinical test highlights a need for a comparison of available assays in order to facilitate more meaningful interpretation of data.

**Methods:** In this study we compared the performance of 2 commercially available human intact FGF23 (iFGF23) assays: ELISA from Kainos Laboratories (Tokyo, Japan) and Luminex-based microbead assay (Millipore, Billerica, MA, USA) in a cohort of healthy adults (control, n=8) and baseline samples from patients on dialysis participating in the EVOLVE clinical trial (n=20).

**Results:** Both Millipore microbead iFGF23 and Kainos ELISA iFGF23 demonstrated 75-95% recovery of purified FGF23 standards in an inter-assay setting and acceptable (65-95%) recovery of the range of hrFGF23 concentrations spiked in to control serum. For the healthy adult group, median ($25^{th}$-$75^{th}$ percentile) serum FGF23 was 30 (24-40) pg/ml (Kainos ELISA), and 12 (8-42) pg/ml (Millipore microbead); for the dialysis group corresponding serum FGF23 were 9780 (1955-19850) and 12090 (2195-17420) pg/ml. Kainos ELISA and Millipore microbead iFGF23 assays demonstrated close numerical agreement accessed by inter-assay correlation analysis of individual results ($R^2$=0.9265, p<0.0001). Based on the range of FGF23 in serum from patients with chronic kidney disease, the broad functional concentration range of Millipore microbead assay (14-10,000 pg/ml) allows the use of a single 1:10 dilution for serum with FGF23 > 10,000 pg/ml. Due to the narrow functional dynamic range (10-800 pg/ml) of Kainos ELISA, substantial serial dilutions and repeat testing will likely be required.

**Conclusions:** Overall, the Kainos ELISA and Millipore microbead iFGF23 assays demonstrated desirable interchangeable analytical performance and may support clinical utility.

## FR-PO658

**Fibroblast Growth Factor 23 and All-Cause Mortality in Hemodialysis Patients** David A. Drew, Hocine Tighiouart, Tammy Scott, Kristina Lou, Saeed Kamran Shaffi, Li Fan, Daniel E. Weiner, Mark J. Sarnak. *Tufts Medical Center, Boston, MA.*

**Background:** Fibroblast growth factor 23 (FGF-23) levels are elevated in hemodialysis patients. Few longitudinal studies have evaluated whether high FGF-23 levels independently contribute to mortality in this population.

**Methods:** We measured FGF-23 levels at baseline in 263 maintenance hemodialysis patients who had enrolled in the Cognition and Dialysis longitudinal cohort. The cross-sectional association between baseline patient characteristics and FGF-23 level was assessed using multivariable linear regression. Multivariable Cox regression with adjustment for demographics, cardiovascular risk factors, and measures of mineral metabolism was used to explore the association between FGF-23 levels with all-cause mortality.

**Results:** Mean (SD) age was 63 (17) years, 54% were women and 22% were African American. The median FGF-23 level was 3100 RU/ml ($25^{th}$-$75^{th}$ percentile, 1100 - 8000 RU/ml). Younger age, lower prevalence of diabetes, longer dialysis vintage and higher levels of calcium and phosphorus were independently associated with higher FGF-23 levels (p <0.05 for all). There were 135 deaths over a median follow up time of 2.3 years. Higher FGF-23 was an independent predictor of mortality (adjusted HR [95%CI] = 1.17 per doubling of FGF-23 [1.01, 1.36]).

Association between baseline FGF-23 level and all-cause mortality

| | Unadjusted HR (95% CI) | Model 1 HR (95% CI) | Model 2 HR (95% CI) | Model 3 HR (95% CI) |
|---|---|---|---|---|
| FGF-23* | 1.05 (0.95, 1.16) | 1.22 (1.09, 1.36) | 1.12 (1.01, 1.27) | 1.17 (1.01, 1.36) |

*FGF-23 log transformed, represents the hazard associated with each doubling of FGF-23
Model 1: Adjusted for age, sex and race
Model 2: Adjusted for model 1 variables, vintage, cause of ESRD, access type, history of cardiovascular disease, Kt/V, and albumin
Model 3: Adjusted for model 2 variables, calcium, phosphorus, and 25OH Vitamin D

**Conclusions:** Although attenuated after adjustment for several dialysis related comorbidities, high FGF-23 levels remained an independent risk factor for mortality within prevalent hemodialysis patients. Future studies should explore the mechanisms relating FGF-23 to mortality.

## FR-PO659

**Fibroblast Growth Factor 23 and Cognitive Performance in Hemodialysis Patients** David A. Drew, Hocine Tighiouart, Tammy Scott, Kristina Lou, Li Fan, Saeed Kamran Shaffi, Daniel E. Weiner, Mark J. Sarnak. *Tufts Medical Center, Boston, MA.*

**Background:** Fibroblast growth factor 23 (FGF-23) levels are elevated in hemodialysis (HD) patients and are associated with mortality and left ventricular hypertrophy. Despite FGF receptors being present throughout the brain, there are no prior studies which have assessed whether FGF-23 levels are associated with cognitive performance.

**Methods:** We measured FGF-23 levels in 263 maintenance HD patients who also underwent comprehensive neurocognitive testing. Principal factor analysis was used to derive two factors from cognitive test scores, representing memory and executive function. Multivariable linear regression adjusting for age, sex, education status as well as other relevant covariates was used to explore the relationship between FGF-23 and each cognitive factor.

**Results:** Mean age was 63 years, 46% were women and 22% African American. Median FGF-23 level was 3098 RU/ml ($25^{th}$-$75^{th}$, 1100 - 8000). Higher FGF-23 was independently associated with a lower composite memory score [beta (95%CI) = -0.42 SD (-0.82, -0.02) for highest versus lowest quartile] and a trend towards a lower composite executive function score [beta = -0.28 SD (-0.63, 0.07), for highest versus lowest quartile]. Results were similar using FGF-23 as a log transformed variable.

Table 1. Association between doubling of FGF-23 levels and cognitive function

| | Model 1 | | Model 2 | | Model 3 | |
|---|---|---|---|---|---|---|
| | Beta (95% CI) | p value | Beta (95% CI) | p value | Beta (95% CI) | p value |
| Factor 1 (memory) | **-0.06 (-0.12, -0.01)** | **0.02** | **-0.08 (-0.14, -0.01)** | **0.02** | **-0.08 (-0.16, -0.01)** | **0.05** |
| Factor 2 (executive) | -0.04 (-0.10, 0.01) | 0.15 | -0.02 (-0.08, 0.04) | 0.5 | -0.03 (-0.10, 0.04) | 0.4 |

For each factor, beta represents the change per 1 standard deviation
Model 1 = Adjusted for Age, Sex, and Education Status
Model 2 = Model 1 + Adjustment for Race, Diabetes status, history of CVD, dialysis Vintage, and average pre-HD diastolic blood pressure
Model 3 = Model 2 + Adjustment for calcium, phosphorus, and 25 hydroxy vitamin D

Table 2. Association between Quartiles of FGF-23 and Cognitive Performance*

| FGF-23 level (RU/ml) | Quartile 1 134 to 1139 | Quartile 2 1139 to 3098 | Quartile 3 3098 to 7960 | Quartile 4 7960 to 15568 | |
|---|---|---|---|---|---|
| | | Beta (95% CI) | Beta (95% CI) | Beta (95% CI) | p value for trend |
| Factor 1 (memory) | ref | -0.07 (-0.38, 0.25) | -0.17 (-0.53, 0.19) | **-0.42 (-0.82, -0.02)** | **0.04** |
| Factor 2 (executive) | ref | **-0.29 (-0.57, -0.02)** | **-0.32 (-0.64, -0.01)** | -0.28 (-0.63, 0.07) | 0.13 |

Bold values indicate a p value < 0.05 or confidence intervals that do not include 0
Beta represents the mean difference between Quartile 1 and each subsequent quartile. For Factors 1 and 2, this represents a per standard deviation change.
*Fully adjusted model including age, sex, education level, race, diabetes, history of CVD, dialysis vintage, pre-HD diastolic blood pressure, calcium, phosphorus, and 25 hydroxy vitamin D

**Conclusions:** FGF-23 was independently associated with worse performance on a composite memory score, even after adjustment for potential confounders, including measures of mineral metabolism. High FGF-23 levels in HD patients may contribute to cognitive impairment.

## FR-PO660

**Pretransplant FGF23 Levels Are a Good Marker of Post-Transplant Caicium and Phosphorus Metabolism** Makoto Tsujita, Daijo Inaguma. *Kidney Disease Center, Nagoya Daini Red Cross Hospital, Japan.*

**Background:** Hypercalcemia and hypophosphatemia often occur after kidney transplantation. Recently, preemptive kidney transplantation (PET) has increased in Japan; however, it is not well-known whether PET is beneficial in calcium (Ca) and phosphorus (Pi) metabolism.

**Methods:** Thirty-two consecutive patients were enrolled in this study at Nagoya Daini Red Cross Hospital in 2011. Fifteen patients were in the PET group and 17 patients were in the non PET group. Parameters of Ca and Pi metabolism including full-length fibroblast growth factor 23 (FGF23) and intact parathyroid hormone (iPTH) were measured before transplantation and 1, 3, and 24 weeks after transplantation.

**Results:** FGF23 decreased dramatically in both groups after transplantation; however, FGF23 before transplantation and at 1 and 3 weeks after transplantation was significantly lower in the PET group than in the non PET group ($p < 0.05$). In contrast, although iPTH levels were higher in the PET group than in the non PET group before transplantation, the levels were lower at 24 weeks (p < 0.05). Corrected Ca (cCa) was lower at 24 weeks in the PET group (p < 0.05), whereas Pi was lower in the non PET group at 1 and 3 weeks (p < 0.05), but not significantly different at 24 weeks.

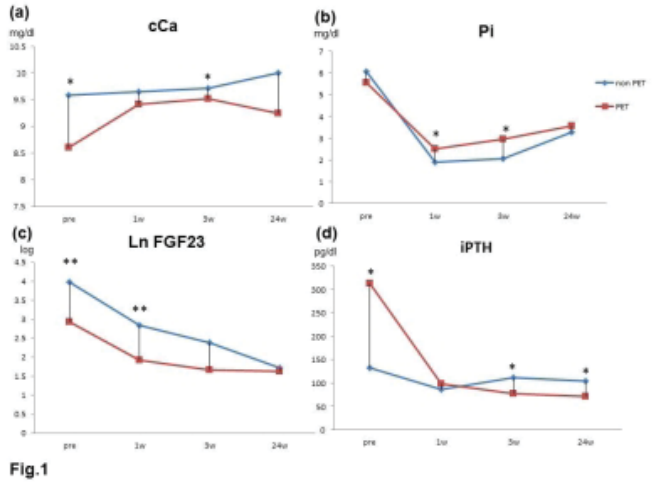

Fig.1

Multivariate linear regression analysis revealed that FGF23 before transplantation was a better predictor of Ca and Pi disorders in early post-transplant recipients.

**Conclusions:** This study suggests that PET has beneficial effects on Ca and Pi metabolism and that pretransplant FGF23 levels are a good marker of post-transplant Ca and Pi metabolism.

## FR-PO661

**Kidney Injury Increases FGF23 Independent of Reduced Glomerular Filtration Rate** Kelsey T. Smith, Tamara Isakova, Julia J. Scialla, Allison Barchi-Chung, Eva Schiavenato, Greg Lacher, Gwen Enfield, Jessica Houston, Patricia R. Wahl Pristau, Jonathan J. Suarez, Jorge Diego, Warren L. Kupin, David Roth, Myles S. Wolf. *Univ of Miami.*

**Background:** The mechanism of FGF23 elevation in CKD remains poorly understood. Decreased GFR is a primary determinant of high FGF23 in advanced CKD, but levels can be elevated in certain CKD patients despite nearly normal GFR.

**Methods:** We tested the hypothesis that kidney injury itself increases FGF23. We measured serum phosphate, calcium, FGF23, PTH, 25D, 1,25D and iohexol GFR in 3 groups: 1) CKD (N=19), 2) stable, long-term kidney transplant recipients (KT; N=8), and 3) kidney transplant donors and individuals with age-related GFR loss but no other evidence of CKD (N=11). We measured the same biochemical profile but used eGFR in healthy volunteers (N=20).

**Results:** Median FGF23 was comparable in kidney donors, individuals with age-related GFR loss and healthy volunteers. In contrast, median FGF23 was significantly higher in CKD group and median PTH was significantly higher in KT group, compared to healthy volunteers. Median FGF23 was significantly higher in CKD than KT patients (117 vs. 78 RU/mL, P=0.03) despite comparable mean iohexol GFR (53 vs. 57 mL/min/1.73 $m^2$; P=0.47). Dietary phosphorus and calcium, serum calcium, PTH, 25D and 1,25D did not significantly vary between CKD and KT groups, suggesting that differences in FGF23 were not driven by these variables. However, serum phosphate was significantly higher in CKD group than KT group (3.6 versus 3.0 mg/dl, P=0.004).

| | CKD N=19 | Transplant N=8 | Donors + Age-related N=11 | Healthy N=20 |
|---|---|---|---|---|
| Age, years | 54 ± 10.4 | 49.5 ± 17.7 | 53.6 ± 15.5 | 49.0 ± 8.9 |
| Women, n | 9 | 4 | 5 | 9 |
| Black, n | 10 | 2 | 1 | 5 |
| Hispanic, n | 5 | 1 | 5 | 12 |
| BMI, kg/$m^2$ | 31.0 ± 7.7 | 29.3 ± 9.2 | 28.0 ± 4.7 | 27.6 ± 3.4 |
| eGFR, ml/min/1.73 $m^2$ | 50.8 ± 11.4 | 62.1 ± 25.2 | 68.4 ± 10.7 | 85.6 ± 13.3 |
| iGFR, ml/min/1.73 $m^2$ | 52.6 ± 14.8 | 57.1 ± 14.0 | 72.4 ± 15.3 | --- |
| Serum Albumin, mg/dl | 4.3 ± 0.3 | 4.3 ± 0.2 | 4.6 ± 0.2 | 4.5 ± 0.2 |
| Serum Calcium, mg/dl | 9.4 ± 0.4 | 9.6 ± 0.5 | 9.5 ± 0.3 | 9.3 ± 0.2 |
| Serum Phosphate, mg/dl | 3.6 ± 0.5 | 3.0 ± 0.2 | 3.3 ± 0.5 | 3.4 ± 0.5 |
| FeCA, % | 0.45 (0.33 – 0.67) | 0.74 (0.36 – 1.28) | 0.77 (0.58 – 1.06) | 0.69 (0.53 – 1.33) |
| FePi, % | 16.3 (12.8 - 21.8) | 16.2 (11.3 – 19.6) | 10.3 (8.8 – 13.7) | 8.8 (5.1 – 11.7) |
| 24-hr Urine Pi, mg/day* | 779 (631 – 965) | 700 (354 – 1302) | 719 (566 – 904) | 800 (578 – 1030) |
| 24-hr Urine Ca, mg/day* | 93 (22 – 132) | 117 (98 – 215) | 133 (97 – 182) | 176 (136 – 366) |
| Total caloric intake, kcal/day† | 1422 (1341 – 1633) | 1473 (1213 – 1921) | 1664 (1494 – 1895) | 1895 (1554 – 2270) |
| Dietary Ca, mg/day† | 500 (388 – 578) | 596 (407 – 740) | 724 (528 – 912) | 639 (331 – 838) |
| Dietary Pi, mg/day† | 977 (842 – 1101) | 893 (731 – 1148) | 1087 (830 – 1142) | 1098 (868 – 1420) |
| FGF23, RU/ml | 117.3 (90.7 – 174.8) | 77.6 (66.9 – 104.3) | 82.0 (69.7 – 118.8) | 69.0 (61.7 – 93.9) |
| PTH, pg/ml | 49.4 (35.2 – 86.4) | 56.4 (48.2 – 74.4) | 32.3 (23.8 – 40.2) | 31.4 (23.1 – 43.4) |
| 1,25D, pg/ml | 52.1 ± 20.7 | 66.0 ± 21.0 | 58.1 ± 13.3 | 59.7 ± 17.4 |
| 25D, pg/ml | 31.1 ± 11.2 | 36.9 ± 17.8 | 38.5 ± 11.3 | 33.6 ± 10.6 |

**Conclusions:** Despite similar iohexol GFR, FGF23 is significantly higher in CKD patients compared to KT recipients. Differences in serum phosphate between the two groups may mediate these relationships. Our findings suggest that in CKD, the presence of kidney disease itself, independent of GFR reduction, could contribute to FGF23 excess.

## FR-PO662

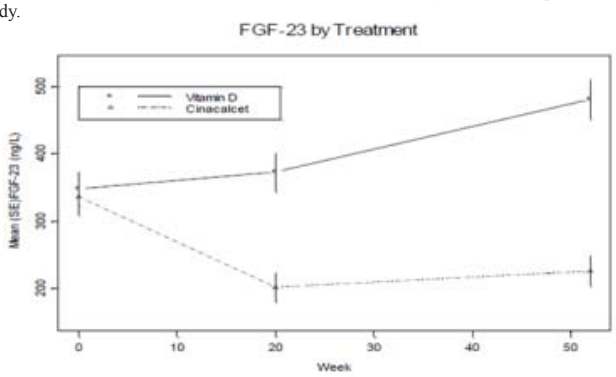
**The PARADIGM Trial: Effects of Cinacalcet and Vitamin D as Monotherapies on FGF-23 Levels during Treatment of Secondary Hyperparathyroidism in Patients on Dialysis** Stuart M. Sprague,[1] James B. Wetmore,[2] Konstantin Gurevich,[3] Gerald A. Da Roza,[4] John E. Buerkert,[5] Maureen T. Reiner,[6] William G. Goodman,[6] Kerry Cooper.[6] *[1]North Shore U Health System; [2]Hennepin County Medical Center; [3]Fresenius Medical Care Russia; [4]U British Columbia; [5]Columbia Nephrology Associates; [6]Amgen Inc.*

**Background:** Elevated levels of fibroblast growth factor-23 (FGF-23) have been associated with increased risk of death in patients on chronic hemodialysis. Previous data suggests that vitamin D (vitD) may stimulate FGF-23, whereas cinacalcet (Cin) may decrease FGF-23 levels, possibly via control of parathyroid hormone (PTH), calcium (Ca), and/or phosphorus (P). Cin and vitD were used as monotherapy in PARADIGM to treat secondary hyperparathyroidism (SHPT), providing a unique opportunity to assess their independent effects on FGF-23. The primary results of PARADIGM (reported separately) demonstrated reductions in PTH that did not differ after 1 year of monotherapy with Cin or vitD.

**Methods:** Herein we report the changes in FGF-23 observed during this trial. FGF-23 was measured by a two-site ELISA (Immunotopics, Inc.,San Clemente, CA).

**Results:** In the vitD arm, there was a median increase in FGF-23 of 47% at wk 52, compared to a median decrease of 40% in the Cin arm. The increase in FGF-23 in the vitD arm and the decrease in the Cin arm occurred despite comparable modest median PTH reductions (-20% vs –29%, respectively). This suggests that the observed changes in FGF-23 were possibly related to changes in P (-12% Cin vs 2% vitD) and/or Ca (-9% Cin vs 2% vitD) or other direct effects of Cin or vitD independent of PTH reduction.

**Conclusions:** Treatment of SHPT with Cin is associated with decreases in FGF-23, while vitD raises levels. The clinical relevance of these divergent effects requires further study.



*Funding:* Pharmaceutical Company Support - Amgen Inc.

## FR-PO663

**High Dose Intravenous Iron and Intact FGF23 in Uremic Rats** Eva Gravesen,[1] Jacob Hofman-Bang,[1] Ewa Lewin,[2,1] Klaus Olgaard.[1] *[1]Nephrological Dept P, Rigshospitalet, Univ of Copenhagen, Copenhagen, Denmark; [2]Nephrological Dept B, Herlev Hospital, Univ of Copenhagen, Copenhagen, Denmark.*

**Background:** Intravenous iron has been proposed to induce elevation of fibroblast growth factor 23 (FGF23), hypophosphatemia and osteomalacia. High FGF23 are associated with increased mortality in the CKD population. CKD patients often develop iron deficiency, anemia and need for i.v iron. As such it is important to study the possible effects of iron on FGF23. In the present study the effect of of two different iron preparations, iron (III) isomaltoside 1000 (Mono) and ferric carboxymaltose (Ferri) are examined on plasma FGF23 levels in uremic rats.

**Methods:** A single high dose of 60 mg/kg b.w of iron (III) isomaltoside 1000 (A), or ferric carboxymaltose (B), or vehicle, was given i.v. and the effects on plasma FGF23, phosphate, $Ca^{2+}$, PTH, transferrin, ferritin and iron was examined. NX rats were kept on a high phosphorus diet (0.9% calcium and 1.2% phosphorus), n=8 in each group. In **study 1** samples for determination of FGF23 were obtained at time 0, 30, 60, 120, 180 min. and after 48 hours, and in **study 2** at baseline and after one week. FGF23 was measured by the intact FGF23 assay from Kainos lab. Japan.

**Results:** The rats had significant uremia and hyperparathyroidism.**Study 1:** In the vehicle group FGF23 levels at baseline were 1354±167 pg/mL and 1551±329 at 30 minutes, and 990±155 at 48 hours. In group (A) FGF23 levels at baseline were 1191±184 and 1219±279 at 30 minutes and 890±257 pg/mL at 48 hours. In group (B) FGF23 levels at baseline were 1568±231 and 2027±267 at 30 minutes, and 1143±202 pg/mL at 48 hours. In **study 2,** FGF23 levels were 2986±780 pg/mL and 2279±475 after one week in the vehicle group, baseline FGF23 was 1711±179 in the iron (III) isomaltoside 1000 group and 1841±243 after one week. In the ferric carboxymaltose group baseline was1506±347 and 1647±327 after one week. No significant differences in FGF23 levels were observed at any time point between the groups.

**Conclusions:** A single high dose of either iron (III) isomaltoside 1000 or ferric carboxymaltose had no effect on intact FGF23 levels for up to one week after an intravenous injection in uremic rats.

*Funding:* Pharmaceutical Company Support - PharmaCosmos A/S, Denmark

## FR-PO664

**Coronary Artery Calcifications and Accelerated Atherosclerosis in Chronic Kidney Disease Patients: A Link between Fibroblast Growth Factor-23 and Diabetes?** Belda Dursun,[1] Ali Riza Aslan,[1] Baki Ya?d?,[2] Simin Rota,[3] Hande Senol.[4] *[1]Nephrology, Pamukkale Univ Medical School, Denizli, Turkey; [2]Radiology, Pamukkale Univ Medical School, Denizli, Turkey; [3]Biochemistry, Pamukkale Univ Medical School, Denizli, Turkey; [4]Biostatistics, Pamukkale Univ Medical School, Denizli, Turkey.*

**Background:** Coronary artery calcifications (CAC) are associated with atherosclerosis and increased cardiovascular mortality. Fibroblast growth factor-23 (FGF-23) is involved in regulation of mineral metabolism. Aim was to investigate the relationship between FGF-23 and coronary calcifications and accelerated atherosclerosis in diabetic and non-diabetic CKD patients.

**Methods:** The study was performed on 40 diabetic stage 3-5 CKD, 40 non-diabetic stage 3-5 CKD patients and 40 controls matched for age and gender. CAC was assessed by multislice computerised tomography and coronary artery calcium score (CACS) was quantified by Agatston score. Carotid intima-media thickness (cIMT) was measured by B-mode high resolution ultrasonography. FGF-23 (C-term) and conventional laboratory parameters were determined.

**Results:** cIMT (mm) levels were higher in diabetic (0.84 ± 0.16) and non-diabetic CKD patients (0.70 ± 0.09) than controls (0.56 ± 0.36), p = 0,001. The mean CAC score (Agatston) was higher in diabetic (443 ±993 ) and non-diabetic CKD patients (98 ± 244) than controls (1.13 ± 0.74 ), p = 0,001. FGF-23 levels (pg/ml) were higher in diabetic CKD patients (237 ± 108) and non-diabetic CKD patients (199 ± 81) than controls (93± 2), p= 0,001. There was a positive correlation between CACS and cIMT levels. Log-FGF -23 levels were found to be positively correlated with cIMT and CACS. FGF-23 levels showed positive correlations with systolic blood pressure, duration of diabetes, phosphorus, Ca × P product and PTH. Multiple regression analysis showed that blood glucose and systolic blood pressure were independent factors associated with CACS; and that log-FGF-23, blood glucose, systolic blood pressure and albumin were independent factors associated with cIMT.

**Conclusions:** Diabetes and FGF-23 is associated with CACS and cIMT in CKD and the affect of FGF-23 seems to be independent of its regulatory function on phosphorus metabolism.

## FR-PO665

**Acute and Six Months Mineral Metabolism Adaptation in Living Kidney Donors: A Prospective Study** Sophie M. De Seigneux, Belen Ponte, Thomas Ernandez, Karine Hadaya, Andrea Trombetti, Pierre-Yves F. Martin. *Nephrology, Univ Hospital of Geneva, Geneva, Switzerland.*

**Background:** Mineral metabolism adaptation to loss of kidney function is debated. Living kidney donors (LKDs) present an abrupt decline in GFR. Following their evolution is important to understand renal adaptation to acute and chronic loss of function and prevent complications in LKDs. In this prospective study, we follow mineral metabolism adaptation of LKDs over six months.

**Methods:** From May 2010 to December 2012, we included and followed in a prospective study 26 adults LKDs. Their mineral parameters and renal function were repeatedly measured at day 0, 1, 2 and 3, and 6 months after donation. α-Klotho expression was also assessed in rats' kidneys after uninephrectomy.

**Results:** After nephrectomy, donors presented transient hypocalcemia and secondary hyperparathyroidism. Both circulating FGF23 and α-Klotho decreased during the first post-operative days and FGF23 decline was positively correlated to hypocalcemia. At 6 months after donation, donors had lower eGFR and $1.25(OH)_2D$ compared to predonation levels, whereas 25(OH)D was unchanged. PTH levels increased at 6 months, resulting in decreased serum phosphate levels and renal tubular reabsorption of phosphate. In comparison to pre-donation, FGF23 levels were unchanged whereas circulating α-Klotho levels were lower than pre-donation. In uninephrectomized rats, tissue Klotho expression levels did not change in the remnant kidney.

**Conclusions:** We show that acutely after nephrectomy, FGF23 is regulated by calcium levels. Six months after kidney donation, donors developed secondary hyperparathyroidism and lower phosphate levels probably related to $1.25(OH)_2D$ deficiency. FGF23 levels did not rise in this specific population, whereas α-Klotho levels were only slightly decreased compared to predonation levels. Mineral metabolism adaptation to loss of kidney function in donors includes decrease in $1.25(OH)_2D$ and increase in PTH and fractional excretion of phosphate resulting in decreased seric phosphate level, independently of FGF23. These results challenge the primary role of FGF23 in phosphaturia and decreased vitamin D hydroxylation in renal mass reduction.

## FR-PO666

**Soluble Klotho Predicts Renal Phosphate Excretion in Moderate to Severe Chronic Kidney Disease** Kraiwiporn Kiattisunthorn, Chanchira Janwijit, Krongkarn Klayklung, Kriengsak Vareesangthip. *Siriraj Medical School, Mahidol Univ, Thailand.*

**Background:** Phosphate retention accelerates FGF23 and PTH secretion to keep phosphate in balance by promoting phosphaturia. Klotho is critical for FGF23-FGFR1 downstream to enhance endocytosis of NaPi2a cotransporters at proximal tubules. Despite high phosphate diet, paricalcitol induced klotho expression suppressed FGF23 but increased phosphaturia in CKD rats. In this study, we assess if soluble klotho directs tubular phosphate excretion in CKD patients.

**Methods:** Plasma, serum and urine were collected from 28 stage 3-5 CKD patients after fasting overnight. Maximal tubular reabsorption normalized by GFR (TmP/GFR) was used to determine renal threshold to filtered phosphate independent of dietary phosphorus, tissue release of phosphorus, and GFR. Serum creatinine was measured by enzymatic creatinine assays for GFR calculation by using CKD-EPI formula. Plasma klotho was measured by using human klotho ELISA kit (CUSABIO Biotech, Newark, DE) [intra- and inter-assay CV 4.9-8.1% and 8.3-13%, respectively]. Plasma c-terminal FGF23 was measured by using human FGF23 (c-term) ELISA kit (Immunotopics, Inc., CA, USA) [intra- and inter-assay CV 1.4-3% and 2.4-5.1%, respectively].

**Results:** Patient characteristics were shown in Table 1.

| Table 1 Patient characteristics | |
|---|---|
| Male [n(%)] | 18 (56%) |
| Age (years)[a] | 64 ± 14 |
| eGFR (ml/min/1.73m$^2$)[a] | 31.6 ±17.2 |
| Calcium (mg/dl)[a] | 9.2 ± 0.4 |
| Phosphate (mg/dl)[a] | 3.5 ± 0.8 |
| PTH (pg/ml)[b] | 86.1 (36.2, 397.2) |
| cFGF 23 (pg/ml)[b] | 130.6 (42.3, 738.5) |
| Klotho (pg/ml)[b] | 607.5 (48.7, 1041.5) |
| TmP/GFR (mg/dl)[a] | 2.5 ± 0.7 |
| [a] mean ± SD, [b] median (min, max) | |

TmP/GFR was negatively correlated with serum phosphate (r -0.45, p=0.048) and plasma klotho (r -0.53, p=0.02), but was not correlated with age, gender, intact PTH, GFR and plasma FGF23. After adjusted for age, GFR, serum phosphate, calcium, iPTH and FGF23, plasma klotho is independently associated with TmP/GFR (r -0.69, p=0.02).

**Conclusions:** Presence of klotho is a determinant for renal phosphate handling. In addition of dietary phosphate restriction, a rationale for klotho induction may be valuable in management of CKD-MBD.

## FR-PO667

**Premature Vascular Aging Is a Major Complication in CKD and Occurs through Dysregulation of Arterial Klotho and Accumulation of Pre-Lamin A** Kenneth Lim,[1,2] Stephen M.S. Ting,[2] Guerman Molostvov,[2] Chih-Ping Chung,[1] Tzongshi Lu,[1] Arnoud Johan Groen,[3] Kathryn S. Lilley,[3] Thomas F. Hiemstra,[3] Daniel Zehnder,[2] Li-Li Hsiao.[1] *[1]Brigham and Women's Hospital; [2]Warwick Medical School, United Kingdom; [3]Univ of Cambridge, United Kingdom.*

**Background:** Accelerated vascular calcification and arteriosclerosis are age-related complications that occur in patients with Chronic Kidney Disease (CKD). We previously showed that Klotho, a 130kDa transmembrane protein is expressed in smooth muscle cells of the arterial wall and its expression is suppressed in arteries from CKD patients. Here, we describe its role as a major regular of arterial aging in CKD.

**Methods:** *In vivo:* Arteries from healthy and CKD patients. *In vitro:* Human aortic smooth muscle (HA-SMC) cells +/- Klotho siRNA. *Immuno and western blot:* Markers of HA-SMC phenotype and vascular aging.

**Results:** Immunohistochemistry analysis showed that arteries from young CKD patients and healthy elderly controls were Klotho deficient compared with arteries from young healthy patients. These arteries exhibited age-related changes, including accumulation of the smooth muscle cell aging marker, pre-lamin A and increased calcification. Molecular analysis confirmed Klotho deficiency and accumulation of pre-lamin A with the functional consequence of increased calcification, using a replicative senescence HA-SMC model. These age-related changes could be induced prematurely by circulating stress factors, including disordered mineral and pro-inflammatory conditions. Mechanistic studies revealed that Klotho knockdown directly resulted in VSMC aging with accumulation of pre-lamin A, phenotypic transformation to an osteogenic phenotype, apoptosis as assessed by caspase 3 activity and increased Poly (ADP-ribose) polymerase activity indicative of DNA damage. Both Klotho knockdown *in vitro* and arteries from CKD patients *in vivo* showed suppressed expression of FACE-1, the pre-lamin A cleavage enzyme.

**Conclusions:** Arterial aging occurs prematurely in young patients with CKD and resembles arteries from healthy elderly patients. Premature arterial aging in CKD occurs through a dysregulated Klotho - FACE-1 – prelamin-A pathway.

## FR-PO668

**Klotho Expression Profile in a Wide Range of Human Tissues** Kenneth Lim,[1,2] Guerman Molostvov,[2] Tzongshi Lu,[1] Arnoud Johan Groen,[3] Kathryn S. Lilley,[3] Thomas F. Hiemstra,[3] Li-Li Hsiao,[1] Daniel Zehnder.[2] *[1]Brigham and Women's Hospital; [2]Warwick Medical School, United Kingdom; [3]Univ of Cambridge, United Kingdom.*

**Background:** Klotho is a 130kDa protein that imparts anti-aging properties and functions as a co-factor for the phosphatonin, FGF-23. Previous studies have shown that it is produced in the kidney, parathyroid gland, vasculature and choroid plexus of the brain. However, no study has explored its expression profile across different tissue types in humans to-date.

**Methods:** Ethics (IRB) approval was first obtained for this study. A wide range of formalin fixed normal human tissues removed during routine therapeutic or diagnostic procedures and part of the clinical tissue bank was analyzed by immunohistochemistry. For each tissue, at least 5 different cases were analyzed. A full length Klotho protein detecting antibody (Abcam, Cat. No. ab69208) was utilized at a concentration of 1:100 to 1:150.

**Results:** As previously described, significant renal Klotho protein expression was observed in the proximal and distal part of the tubular epithelium. On extensive analysis of tissues, differential Klotho expression was found in skin, intestine, endocrine and reproductive organs, and also the central and peripheral nervous system. The epithelial layer of the skin, small bowel, colon, mammary tissue, endometrium, prostate and sertoli cells in testis showed strong Klotho expression. The same observation was made for endocrine cells of the thyroid, islet cells of the pancreas and adrenal medulla. In neuronal tissue, Klotho expression was found primarily in neuronal cells of cerebral cortex, cells of Purkinje in the cerebellum and motor neurons of the spinal cord, but also the myenteric plexus of the intestine. Smooth muscle cell (SMC) Klotho expression was confirmed in arteries of all tissues analyzed, but also observed in SMC of the intestine and myometrium. Hepatocytes did not stain for Klotho protein.

**Conclusions:** This study is the first to report the expression profile of Klotho in human tissues. Expression of Klotho may indicate a diverse function for Klotho in different tissues and cell types and render these cells a target for FGF-23 function.

*Funding:* Private Foundation Support

## FR-PO669

**Serum Soluble Klotho Level Is Associated with Abdominal Aortic Calcification in Patients on Maintenance Hemodialysis** Hong Cai, Yucheng Yan, Renhua Lu, Minfang Zhang, Mingli Zhu, Weiming Zhang, Zhaohui Ni, Jia Qi Qian. *Renal Dept, JiaoTong Univ RenJi Hospital, Shanghai, China.*

**Background:** To determine the relationship between soluble Klotho and abdominal aortic calcification in maintenance hemodialysis(MHD) patients.

**Methods:** 129 cases of MHD patients were collected prospectively. Serum soluble Klotho (sKL) level were detected by ELISA. Abdomen lateral plain were used as a criteria to determine the abdominal aortic calcification. The abdominal aorta calcification score(AAC) was calculated. The level of soluble Klotho were observed in patients with different degree of calcification. Logistic regression analysis was used to determine the risk factor of abdominal aortic calcification in MHD patients. The standard statistics were used along with ROC analysis to evaluate the diagnostic value of soluble Klotho in abdominal aortic calcification.

**Results:** 87 in 129 patients had abdominal aortic calcification. The median AAC was 4.0(0.00, 11.00). The median Klotho concentration was 616.29(378.19, 821.61)pg/ml and the soluble Klotho concentration was negatively correlated with AAC. Risk of moderate to severe abdominal aortic calcification in patients with lowest quartile of the soluble Klotho concentration was significantly higher than those in highest quartile[OR=4.004, 95%CI(1.350-11.826), P=0.012], even by adjustment for demographic data, lifestyle factors and biochemical markers [OR=4.542, 95%CI(1.368-15.081), P=0.013]. Multivariate Logistic regression analysis showed that serum soluble Klotho levels and smoking were independent risk factors for severe calcification of the abdominal aorta. ROC-AUC of serum soluble Klotho for moderate to severe abdominal aortic calcification was 0.746(cutoff:265.39pg/ml, accuracy 88.5% specificity 56.2%, P=0.001).

**Conclusions:** The lower serum soluble Klotho was independently associated with severe abdominal aorta calcification. Serum soluble klotho may have diagnostic value of MHD patients with severe abdominal aorta calcification. But still need to be further confirmed.

*Funding:* Government Support - Non-U.S.

## FR-PO670

**Soluble Klotho (sKl) and Fibroblast Growth Factor 23 (FGF23) Alterations in Pediatric (Ped) Renal Transplant (Tx) Patients (Pts) with Good Function** Rachana Srivastava, Eileen D. Brewer, Poyyapakkam Srivaths. *Ped Renal Section, Baylor College Medicine/Texas Children's Hosp, Houston, TX.*

**Background:** The phosphaturic hormone FGF23 stimulates renal production of Kl, which complexes with FGF receptors & increases binding affinity for circulating FGF23. In adult studies, FGF23 levels are an early marker for CKD (in stage 2) & may be associated with decreased sKl as CKD progresses. Very little is known about sKl & FGF23 in renal Tx or ped pts, except that sKI is higher in children than adults. **Aim:** To determine potential alterations in plasma FGF23 and sKl in ped Tx pts with early CKD & to evaluate for associations with GFR & mineral metabolism parameters.

**Methods:** X-sectional study of 63 ped Tx pts (39M); median age 15y (4-22y); 19C/26His/16B/2other; CKD stages 1-3 (Schwartz eGFR 97±24 ml/min/1.73m2); median time since Tx 1.2y (0.2-11y). Immunosuppression: 51 steroid free (SF). 12 steroid based (SB). Serum Cr, Ca, P, iPTH, 1,25vitD; urine Ca,P,Cr; plasma C-term FGF23 & sKl by ELISA were measured. 14 pts were taking P supp, 13 calciferol, & 4 calcitriol.

**Results:** Our ped Tx pts had higher plasma FGF23 (mean 136 RU/ml, range 29-752 vs normal range 1-48 RU/ml), and lower sKl (median 1429 pg/ml;IQR 906-2356 vs normal 2406;IQR 1710-3352) compared to published values for healthy children. As FGF23 increased, so did sKl (r=0.37, p=0.03). No association was found for sKl & age, eGFR, TRP, or serum Ca, P, iPTH, 1,25vitD. FGF23 & sKl were higher with SB vs SF immunosuppression.

| | Age(y) | eGFR | iPTH pg/ml | 1,25vitD pg/ml | FGF23 RU/ml | s-Klotho pg/ml |
|---|---|---|---|---|---|---|
| SF, n=51 | 14.1±4.8 | 100±24 | 99±78 | 63.4±29.9 | 100±66 | 1648±1267 |
| SB, n=12 | 14.2±3.5 | 85±20 | 85±107 | 60.8±20 | 274±252* | 2812±1932** |

Values as mean±SD;eGFR ml/min/1.73m2;*p= 0.004,**p=0.012

**Conclusions:** In our ped Tx pts with CKD stage 1-3: 1) Plasma FGF23 is higher and sKl is lower than published normals. 2) FGF23 is positively associated with sKl, likely due to intact, though possibly blunted stimulation of Kl production when the Tx kidney has good function. 3) FGF23 and sKl levels are higher with SB than SF immunosuppression, suggesting steroids may be an additional stimulus to increased FGF23 production.

*Funding:* Private Foundation Support

## FR-PO671

**Association with Fetuin-A and Ectopic Calcification in α-Klotho Mutant Mice** Nozomi Yokoyama,[1] Hironori Yamamoto,[2,3] Yutaka Taketani,[1] Masayuki Iwano,[3] Eiji Takeda.[1] *[1]Clinical Nutrition, Health Biosciences, Univ of Tokushima, Tokushima, Japan; [2]Health and Nutrition, Human Life, Jin-ai Univ, Echizen, Japan; [3]Nephrology, General Medicine, Faculty of Medical Sciences, Univ of Fukui, Fukui, Japan.*

**Background:** α-klotho mutant (kl/kl) mice exhibit hyperphosphatemia, hypercalcemia and hypervitaminosis D. These abnormalities are associated with growth retardation and ectopic calcification. Fetuin-A is a hepatic secretory protein acting as a systemic calcification inhibitor. However, it is still unknown about the role of fetuin-A in kl/kl mice.

**Methods:** Wild-type (WT) mice and kl/kl mice at 3- or 6-wk-old were used and given free access to regular chow and water. For histology using paraffin sections of kidney, aorta and heart tissues, calcification sites and fetuin-A expression were detected by von Kossa staining and immunohistochemistry (IHC), respectively. Gene expression analysis were performed using western blots (WB) and Real-time RT-PCR methods.

**Results:** Analysis of serial kidney, aorta and heart sections by IHC and von Kossa staining showed a high regional expression of fetuin-A protein in 6-wk-old kl/kl mice and its localization merged with calcifying sites. We also confirmed its co-localization with the calcified lesions in arota and heart of chronic kidney disease rats. Interestingly, the high regional expression of fetuin-A in kidney was also observed at 3-wk-old kl/kl mice without ectopic calcification. Although WB analysis observed markedly high expression of fetuin-A in kidney of kl/kl mice, its renal mRNA levels were no significant differences between WT and kl/kl mice. In contrast, fetuin-A mRNA levels in liver of kl/kl mice were significantly increased than WT mice from 3-wk-old. Moreover, we found that plasma fetuin-A levels in kl/kl mice were significantly higher than WT mice.

**Conclusions:** These results suggest that the up-regulation of hepatic futuin-A mRNA expression in kl/kl mice contributes to increase plasma fetuin-A levels and co-localize with calcified lesions as a inhibitor of hyperphosphatemia-induced ectopic calcification.

*Funding:* Government Support - Non-U.S.

## FR-PO672

**Transfer of Oral Alfacalcidol to Oral Calcitriol in the Treatment of Secondary Hyperparathyroidism in Chronic Hemodialysis Patients** Sandrine Rauscher, Jean-Philippe Lafrance, Vincent Pichette, Robert Zoël Bell, Martine Leblanc, Sarah Bezzaoucha, Michel Vallee. *Nephrology Dept, Maisonneuve-Rosemont Hospital, Univ of Montreal, Montreal, Canada.*

**Background:** There is no clear evidence in the literature regarding the optimal vitamin D therapy for the treatment of secondary hyperparathyroidism in chronic hemodialysis patients. Recent studies suggest that uremia in terminal renal failure is associated with enzymatic hepatic dysfunction altering vitamin D 25-OH hydroxylation. This may imply that calcitriol could be more effective than alfacalcidol. The goal was to compare the efficacy of calcitriol, the fully hydroxylated active form of vitamin D, to alfacalcidol, which is not hydroxylated at the 25 position, for the treatment of secondary hyperparathyroidism in hemodialysed patients.

**Methods:** We retrospectively reviewed 47 chronic hemodialysis patients to whom alfacalcidol administration was switched to calcitriol for the treatment of secondary hyperparathyroidism. We then compared the different components of mineral metabolism with paired Student's t-tests pre and post conversion.

**Results:** Before the switch, the mean dose of alfacalcidol was 3.50 mcg per week. After being transferred to calcitriol, the mean dose was decreased by 20% to 2.86 mcg ( p<0,0001). We observed a significant decrease in PTH of 11.87 pmol/L (p = 0,02), with a mean PTH of 94.47 and 82.60 pmol/L, pre and post switch respectively. The mean corrected calcium for albumin increased by 0.08 mmol/L (p = 0.0001). No significant hypercalcemia was observed during this study. There was no significant change in phosphorus levels. Also, we observed a mean decrease of PTH of 9.45 pmol/L (p = 0.07) as well as an increase of the mean corrected calcium of 0.05 pmol/L (p = 0.05) in a subgroup of patients (n=22) for whom the medication was administrated during the hemodialysis session, ensuring 100% compliance.

**Conclusions:** According to our study, calcitriol seems more effective than alfacalcidol in lowering serum PTH level in chronic hemodialysis patients. This suggests that calcitriol could be the optimalchoice for the treatment of secondary hyperparathyroidism in chronic hemodialysis patients.

## FR-PO673

**High-Dose Ergocalciferol in Patients with CKD Stage 5 on Dialysis: A Pilot Trial** Elisa Elena Del Valle,[1] Armando Luis Negri,[2] Guillermo Javier Rosa Diez,[1] Marcelo Puddu,[1] Jaime Ryba,[1] Luis Alberto Sintado,[1] Erich Fradinger.[2] *[1]Fresenius Medical Care, Argentina; [2]Instituto de Investigaciones Metabólicas, Argentina.*

**Background:** There is a growing evidence of the usefulness of vitamin D supplementation in dialysis patients who are often vitamin D deficient. There are few data on which vitamin D (D2 or D3) and which dosage scheme is the best to maintain adequate 25 OH D levels safely. **Ojective:** We aimed to determine whether high-dose vitamin D2 supplementation in HD patients is sufficient to obtain optimal vitamin D status (serum 25-hydroxyvitamin D [25(OH)D] concentration ≥30 ng/mL) without inducing hypercalcemia.

**Methods:** Open label-controlled trial.82 subjects with CKD stage 5 on dialysis not taking active vitamin D therapy were supplemented with oral vitamin D2 72.000 IU/wk for 12 wk followed by 24.000 IU wk as maintenance therapy during 36 weeks.

**Results:** By 12 wk, serum 25(OH)D increased: baseline (mean ±SD): 15.2 ± 5.4 to 42.5 ± 13.2 ng/mL; P<0.01 and remained optimal (34.7 ±12.0). iPTH at baseline was 360 ± 143pg/ml and at 48wk values were not significantly different from baseline (362 ± 193 UI; P = 0.16) as well as total alkaline phosphatase (286.7±163.1; p= 0.08). We observed a significant decrease in bone alkaline phosphatase from 54.3 ± 46.0 to 44.3 ± 25.0 (p = 0.022). Uncorrected Serum Ca was 9.03 ± 0.42 at baseline but had asignificant increase at the end of follow-up (9.14 ± 0.62; p = 0.0496); Hypercalcemia presented in the first control visit (week 12) in 2 patients, in 1 patient in the second control (week 30) and in one patient in the third control (week 48). In 222 serum calcium determinations during follow up hypercalcemia was observed in only 1.8% of cases. Serum phosphorus remained without

change (basal 4.9 ± 1.2 and 4.7 ± 1.1during the follow up). In 47 patients we were able to determine 1,25 (OH)2D serum levels: at baseline 3.1 ± 4.84 pg/ml (in 32 patients levels were not detectable); at week 48 it increased to 15.92 ± 8.32 pg/ml (not detectable in 3 patients).

**Conclusions:** This vitamin D2 oral regimen was safe and sufficient to obtain and maintain optimal serum 25(OH)D concentrations and prevent vitamin D insufficiency in CKD patients on dialysis.

## FR-PO674

**1,25-Dihydroxyvitamin $D_3$ Deficiency Induces Podocyte Injury and Proteinuria** Ramon Sonneveld,[1,2] Joost Hoenderop,[2] Marijke P.A. Baltissen,[1] Henry Dijkman,[3] Sandrine Florquin,[3] Angelique Rops,[1] Jack F. Wetzels,[1] Jo H.M. Berden,[1] Johan Van der Vlag,[1] Tom Nijenhuis.[1] *[1]Nephrology, UMC St. Radboud, Nijmegen, Netherlands; [2]Physiology, UMC St. Radboud, Nijmegen, Netherlands; [3]Pathology, UMC St. Radboud, Nijmegen, Netherlands.*

**Background:** The steroid hormone vitamin D plays an important role in renal physiology. Hydroxylation of vitamin D occurs in the kidney by 25-hydroxy-vitamin-$D_3$-1α-hydroxylase (1α-OHase), and 1,25-$D_3$ deficiency is a consequence of renal insufficiency. In animal models and patients with glomerular disease, 1,25-$D_3$ treatment ameliorates proteinuria. In this study, we determined whether 1,25-$D_3$ deficiency induces renal injury.

**Methods:** We assessed renal injury in 1,25-$D_3$-deficient 1α-OHase knockout (KO) mice. *In vitro*, we evaluated the regulation of the podocyte injury marker TRPC6 by six vitamin D analogs.

**Results:** Hypocalcemic 1α-OHase KO mice showed proteinuria and glomerular injury, characterized by partial podocyte foot process effacement and altered expression of nephrin, desmin, podocin, CD2AP and TRPC6, and activation of the calcineurin/NFAT pathway. No significant glomerular immunoglobulin or complement deposition could be shown. Minor glomerular basement membrane changes were accompanied by reduced expression of collagen IV. The 1α-OHase KO mice also showed increased urinary NGAL excretion and interstitial caspase-3 expression. *In vitro*, we found that 1α- and/or 25-hydroxylated vitamin $D_3$ analogs and paricalcitol (1,25-$D_2$) reduced TRPC6 promoter activity and its expression in injured podocytes.1,25-$D_3$ and 1,25-$D_2$ supplementation both reversed glomerular and, in part, tubular damage, and normalized calcium/phosphorus homeostasis. A low dose of 1,25-$D_3$, which did not correct serum calcium, PTH, FGF23 and phosphate, also normalized podocyte injury.

**Conclusions:** 1,25-$D_3$ deficiency is not only a consequence, but also a cause of glomerular and interstitial injury with altered expression of slit-diaphragm-associated proteins. 1,25-$D_3$ and 1,25-$D_2$ supplementation can reverse these changes. Our results are in line with the anti-proteinuric potential of vitamin D analogs in clinical practice. Currently, we are studying the renal phenotype of acquired vitamin D deficiency.

*Funding:* Private Foundation Support

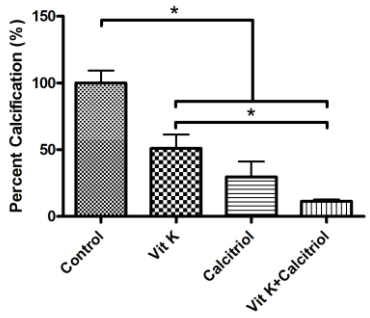
## FR-PO675

**Vitamin K and Calcitriol Attenuate the Development of Vascular Calcification in an *In Vitro* Model of Aortic Calcification** Kristin M. McCabe,[1] Bernard Burgesson,[1] Martin Kaufmann,[1] Dwight F. Newton,[1] Navid Shobeiri,[1] Glenville Jones,[1] Michael A. Adams,[1] Rachel M. Holden.[2] *[1]Biomedical and Molecular Sciences, Queen's Univ, Kingston, Canada; [2]Medicine, Queen's Univ, Kingston, Canada.*

**Background:** Non-traditional risk factors, such as increased phosphate retention, and deficiencies in vitamins D and K metabolism, likely play key roles in the development of vascular calcification (VC) during CKD progression. Matrix Gla protein (MGP) is a vitamin K dependent protein that inhibits vascular calcification and calcitriol is a key transcriptional regulator of MGP. In this study we looked at the effect of calcitriol and K individually and combined in an *in vitro* model of VC.

**Methods:** The thoracic aorta was harvested from male Sprague-Dawley rats at 14 weeks of age, cut into 3mm rings, and incubated in DMEM at 37ºC for 4 days. The media contained 3.8 mM phosphate, as well as calcitriol and vitamin K1. VC was assessed in segments of thoracic aorta using the calcium-O-cresophthalein assay. Calcitriol metabolites were analyzed in the media using LC-MSMS on a Waters BEH-C18 column (1.7 micron, 2.1x50), and a Waters Acquity-Xevo-TQ-S in MRM mode (with a MeOH/$H_2O$ gradient system).

**Results:** Calcitriol ($10^{-10}$, $10^{-8}$, and $10^{-6}$ M) inhibited the development of VC at the two higher concentrations ($p<0.05$). Both calcitriol (□ 70.4%) and vitamin K1 (□ 49.0%) alone ($10^{-6}$ M) partially inhibited VC. Added together, inhibition of VC was nearly complete (□ 88.5%) ($p<0.05$).



1,24,25-$(OH)_3D_3$, the CYP 24A1 generated metabolite of calcitriol, was found in the incubation media.

**Conclusions:** Although calcitriol and vitamin K1 alone partially inhibited VC *in vitro*, the inhibitory effect was greater in combination. Generation of the calcitriol metabolite confirmed the vascular tissue responded via CYP24A1-mediated metabolism. Optimizing the combination vitamins K and D treatment could provide a useful new therapeutic approach.

*Funding:* Government Support - Non-U.S.

## FR-PO676

**Intact PTH and FGF23 Levels of Cinacalcet Pre-Test Predict Refractory Hyperparathyroidism in Hemodialysis Patients** Atsushi Saito,[1] Hitoshi Yokoyama,[1] Hideki Yamaya,[1] Isao Ishikawa.[2] *[1]Nephrology, Kanazawa Medical Univ, Uchinada, Japan; [2]Nephrology, Asanogawa General Hospital, Kanazawa, Japan.*

**Background:** Cinacalcet hydrochloride (cinacalcet) is prescribed for secondary hyperparathyroidism (SHPT) in hemodialysis (HD) patients. However, it had been uncertain to judge the refractory SHPT before therapy. We evaluate the long-term effects of cinacalcet using the early response of intact parathyroid hormone (iPTH) and fibroblast growth factor (FGF) 23.

**Methods:** Fifty-three HD patients with mean iPTH of 720.8 pg/mL and mean corrected calcium (Ca) of 10.0mg/dL were enrolled. Primary end point was defined by iPTH levels of <240pg/mL after 48 weeks therapy. Serum corrected Ca, phosphate (P), iPTH and FGF23 were measured before and 3 hrs after oral intake of a cinacalcet 25mg tablet as pre-test. After that, 46 patients started cinacalcet intake with the daily dose between 25 and 100mg.

**Results:** Forty-two patients completed 48 weeks cinacalcet therapy. The achievement rate of primary end point was 66.7% (i.e. responders, group I). There were significantly difference on the mean levels of iPTH at 0hr (565.5 vs. 1197.5 pg/mL, p=0.001) and 3hrs (293.5vs. 593.6 pg/mL, p=0.001) on pre-test between group I and II (i.e. non-responders). These 2 groups showed quite different response patterns in FGF23 after 3hrs (ΔFGF23) on pre-test (-1493.1 vs. 2401.3 pg/mL, p=0.015). On the base line study, BAP (25.0 vs. 57.3 U/L, p=0.011) and NTx (179.7 vs. 492.6 nmolBCE/L, p=0.007) were also different in these 2 groups. Then, cut off values of cinacalcet treatment resistance were determined at 901.0 pg/mL of 0hr iPTH, 355.5 pg/mL of 3hrs iPTH, and 2500 pg/mL of ΔFGF23 by ROC analysis. A model of three factors including cut off values of ΔFGF23 and iPTH at 3hrs, and NTx >102.3 nmolBCE/L demonstrated overall accuracy of 92.3% (p=0.014) and the odds ratio of 465.6 on refractory SHPT for cinacalcet.

**Conclusions:** FGF23 levels at 3hrs showed a different response for cinacalcet intake in responders or non-responders. Cinacalcet pre-test including iPTH and FGF23 was convenient and reliable to speculate the long-term therapeutic effects of cinacalcet for SHPT.

## FR-PO677

**Vitamin D Status in the Chronic Renal Insufficiency Cohort: Impact of Vitamin D-Binding Protein (DBP) Concentrations and Polymorphisms** Michelle Denburg,[1] Thomas Jemielita,[1] Jayanta Gupta,[1] Martin Hewison,[2] Myles S. Wolf,[3] Mary B. Leonard.[1] *[1]Univ of Pennsylvania; [2]UCLA Orthopaedic Hospital; [3]Univ of Miami.*

**Background:** Serum DBP concentrations influence bioavailability of 25-hydroxyvitamin D (25D). The 3 major DBP polymorphisms differ in affinity for 25D and racial distribution.

**Methods:** Serum 25D, DBP, and PTH were measured in 1280 CRIC participants (pts). Free and bioavailable (bio) 25D were calculated using total 25D, albumin (Alb) and DBP levels, and with mathematical modeling based on DBP polymorphisms (geno-free and geno-bio). Linear regression was used to determine correlates of total, free, and bio 25D.

**Results:** Median DBP was lower in black pts (10.6 vs 24.3 mg/dl, p<0.0001). 92 and 32% of black and non-black pts had ≥1 high-affinity 1F allele, respectively (p<0.001). Winter, obesity, diabetes, hypoalbuminemia, albuminuria, and lower eGFR were independently associated with lower levels of all forms of 25D, while older age, dietary vitamin D, and calciferol therapy were positively associated with all forms. Black race was associated with lower total, free and bio 25D using genotype-specific affinities, but higher free/bio if genotype was not considered.

| **Multivariable Models for Ln(25D)** expressed as % difference in 25D *p<0.05 **p<0.001 | Total | Free | Bio | Geno-Free | Geno-Bio |
|---|---|---|---|---|---|
| Age yr | 0.6** | 0.8** | 0.9** | 0.8** | 0.8** |
| Winter | -17** | -16** | -15** | -18** | -17** |
| Obese | -19** | -18** | -18** | -17** | -17** |
| Diabetes | -14** | -12* | -15** | -14** | -17** |
| DBP mg/dl | 1** | NA | | | |
| Alb <3 g/dl | -50** | NA | | | |
| Urine Alb >300 mg/d | -13** | -18** | -23** | -15** | -22** |
| eGFR <45 | -9* | -10* | -12* | -9* | -11* |
| Diet VitD mcg/d | 4** | 4** | 4** | 4** | 4** |
| On calciferol | 40** | 42** | 42** | 45** | 44** |
| Black | -23** | 24** | 23** | -16** | -17** |

Genotype-based free/bio 25D were better correlated with PTH (r=-0.35/-0.38) than traditional estimates (r=-0.26/-0.29; p<0.002) but not than total 25D (r=-0.37).

**Conclusions:** Marked differences in racial distribution of serum DBP and DBP polymorphisms must be considered when assessing vitamin D status, particularly in the estimation of free/bio 25D.

**A Novel Vitamin D Receptor Modulator, VS-105, Reduces Blood Pressure and Improves Cardiac Function in 5/6 Nephrectomized Uremic Rats**
J. Ruth Wu-Wong, Yung-wu Chen, Jerry Wessale. *Vidasym.*

**Background:** Vitamin D receptor modulators (VDRMs) are commonly used to manage hyperparathyroidism secondary to chronic kidney disease (CKD). A majority of CKD patients die from cardiovascular complications. Clinical observations demonstrate that VDRM therapy may provide cardiovascular and survival benefit for CKD patients. However, current on-market VDRMs exhibit a narrow therapeutic index (TI) of 1-4-fold (hypercalcemic side effects vs. PTH suppressing efficacy). VDRM-induced hypercalcemia remains a serious concern, which leads to the need for frequent drug dose titration and serum calcium monitoring. Significant clinical benefit may be derived from a VDRM with expanded TI and cardiovascular protective effects.

**Methods:** 5/6 nephrectomized (NX) male Sprague Dawley rat with established uremia exhibits elevated PTH, hypertension and abnormal cardiac function. Previously we have shown that after 2-weeks of i.p. or oral dosing in 5/6 NX rats, VS-105 in a non-hypercalcemic dose range suppressed PTH and reduced cardiac fibrosis (TI at ~50-fold). In this study, treatment of 5/6 NX rats by VS-105 (0.5 µg/kg, oral gavage, once daily, for 8 weeks) in the presence or absence of enalapril (30 mg/kg, p.o., via drinking water) suppressed serum PTH effectively without raising serum calcium.

**Results:** VS-105 alone reduced systolic blood pressure (from 174 ± 6 to 145 ± 9 mmHg, $p<0.05$) as effectively as enalapril (from 174 ± 6 to 144 ± 7 mmHg, $p<0.05$). Echocardiographic evaluation showed that VS-105 also improved cardiac function such as E/A ratio, ejection fraction, and fractional shortening. Enalapril or VS-105 alone reduced left ventricular hypertrophy (LVH) significantly and VS-105 plus enalapril did not exhibit further reduction in LVH. The lack of hypercalcemic toxicity of VS-105 is due to its lack of effects on stimulating intestinal calcium transport and inducing the expression of intestinal calcium transporter genes such as Calb3 and TRPV6.

**Conclusions:** These studies demonstrate that VS-105 is a novel VDRM with an overall therapeutic profile that supports clinical development for its expanded use in pre-dialysis and dialysis CKD patients to achieve cardiovascular benefits of VDR activation.

**African-American and South Asian Patients with Chronic Kidney Disease and Vitamin D Deficiency Have a Blunted Response to Therapy with Standard High Dose Ergocalciferol Therapy**
Gavin Dreyer, Magdi Yaqoob. *Nephrology, Barts Health NHS Trust, United Kingdom.*

**Background:** Patients from ethnic minority (EM) groups with CKD have a higher risk of cardiovascular morbidity and mortality and a higher prevalence of vitamin D deficiency. To date, no studies have investigated the response to ergocalciferol of patients from ethnic minorities with CKD and vitamin D deficiency in the UK.

**Methods:** We prospectively analysed 93 patients with non-dialysis dependent CKD who were prescribed high dose ergocalciferol for vitamin D deficiency between 1/8/2008 and 1/8/2010. Baseline 25 hydroxy vitamin D levels were compared to 25 hydroxy vitamin D levels measured at or no more than 30 days beyond the last planned dose of ergocalciferol. Ethnicity was self reported and White ethnicity compared to a combined group containing African-American and South Asian patients. A 25 hydroxy vitamin D level of > 30 ng/ml after therapy was the main outcome measure.

**Results:** White patients (n=33) were older compared to EM patients (n=60), mean age (years) W = 64.4, EM 55.6, p=0.003. Ethnic minority patients had a higher proportion of diabetes as a cause of CKD (W = 18.2%, EM 35.0% p=0.001). There was no difference in stage of CKD at baseline. Baseline 25 hydroxy vitamin D levels were lower in EM compared to W patients (W = 15.8 ng/ml, EM = 11 ng/ml, $p<0.001$). The mean duration of ergocalciferol therapy was 7.1 months, the mean total dose of ergocalciferol prescribed was 360,655 iu and neither differed significantly between groups. In a logistic regression analysis adjusted for age, sex, baseline 25 hydroxy vitamin D level, stage of CKD and cause of kidney disease, EM status was associated with a higher odds of failing to attain the primary outcome (OR 3.75, p=0.044, 95% CI 1.04 – 13.54).

**Conclusions:** EM patients may require intensified therapy with ergocalciferol including higher doses and longer duration of treatment to achieve recommended levels of 25 hydroxy vitamin D. Given this group has a higher burden of diabetes and cardiovascular risk, particular attention is required when prescribing and monitoring ergocalciferol in ethnic minority patients in order to achieve current recommended targets of serum 25 hydroxy vitamin D.

**FR-PO680**

**Effects of 25-OH Vitamin D Levels on Hemoglobin in the Chronic Kidney Disease Population**
Jack Ellis, David Owshalimpur. *Dept of Medicine, Madigan Army Medical Center, Tacoma, WA.*

**Background:** As chronic kidney disease (CKD) progresses, so do the complications of bone mineral disease and anemia, contributing to the morbidity, mortality and overall health care expenditures in this population. 1,25-OH vitamin D has been shown to decrease serum parathyroid hormone (PTH) levels and improve anemia. 25-OH vitamin D has been shown to decrease PTH levels. One prior study found decreased erythropoietin (EPO) use in hemodialysis patients with increased 25-OH vitamin D levels after repletion with ergocalciferol. We examined the association between 25-OH vitamin D levels and anemia in the CKD 3-5 population, expecting that higher 25-OH vitamin D levels would correlate with increased hemoglobin levels.

**Methods:** A retrospective review of adult (18 years or older) patients with CKD 3-5 from January 2005 to January 2011 using the electronic health record in one Pacific Northwest center to determine the association between 25-OH vitamin D levels and hemoglobin. Secondary endpoints include reviewing data for any correlation between multiple variables to include PTH, ferritin, transferrin saturation, hemoglobin, and hematocrit.

**Results:** Three hundred and five CKD 3-5 patients were reviewed and 289 records had 25-OH vitamin D levels. There was not a significant correlation between 25-OH vitamin D level and hemoglobin. There was a statistically significant correlation between PTH and ferritin and a statistically significant inverse correlation between 25-OH vitamin D level and ferritin by Pearson correlation coefficients.

**Conclusions:** Although one prior study did show ergocalciferol use in hemodialysis patients resulted in decreased erythropoietin use, our study did not find a statistically significant correlation between hemoglobin and 25-OH vitamin D in CKD 3-5. Interestingly, an unadjusted analysis found both a direct correlation between ferritin and PTH and an inverse correlation between ferritin and 25-OH vitamin D levels. This is the first time in the literature which an inverse correlation between 25-OH vitamin D and ferritin and a direct correlation between PTH and ferritin has been reported in the CKD population.

**FR-PO681**

**Serum 25-Hydroxy Vitamin D Status Is Predictive of Hospitalization-Free Survival in Predialysis and Dialysis Patients with Chronic Kidney Disease**
Dong Ho Yang,[1] So-young Lee,[1] Seongeun Suh,[1] Hun Jeong.[2] *[1]Internal Medicine, Bundang CHA Medical Center, CHA Univ, Seongnam, Republic of Korea; [2]Internal Medicine, Seoul Bukbu Hospital, Seoul, Republic of Korea.*

**Background:** Vitamin D has pleiotropic effects important for the proper functioning of multiple organ systems. We investigated whether serum 25-hydroxy vitamin D (25(OH) D) levels influence hospitalization-free survival in patients with chronic kidney disease.

**Methods:** In this prospective study, serum levels of 25(OH)D were obtained from 210 patients with chronic kidney disease in the winter of 2009. Data regarding hospitalizations were collected over the subsequent 3 years.

**Results:** Vitamin D deficiency, as defined by a serum 25(OH)D level below 15 ng/ml, was observed in 76.7% of the patients. The mean 25(OH)D serum level was 13.6 ± 7.8 ng/ml in predialysis patients (n=62) and 11.3 ± 6.7 ng/ml in dialysis patients (n=148). During the 3-year follow–up period, 107 patients (28 predialysis and 79 dialysis) were hospitalized because of infectious (27.4%), cardiovascular (23.6%), and cerebrovascular disease (7.5%).The predialysis and dialysis groups were divided into two subgroups based on the mean 25(OH)D serum levels: above and below average.Kaplan-Meier analysis revealed that the risk of hospitalization was significantly lower in both predialysis and dialysis patients with above average serum 25(OH)D levels (log rank test; P = 0.04 and 0.02, respectively). Multivariate Cox proportional hazards models also demonstrated that the risk of hospitalization was significantly lower for patients with above-average serum 25(OH)D levels in both the predialysis (hazard ratio [HR] 0.26, 95% confidence interval [CI] 0.12-0.57) and dialysis groups (HR 0.35, 95% CI 0.20 - 0.62).

**Conclusions:** Serum 25(OH)D status is predictive of hospitalization-free survival in patients with chronic kidney disease. The risk of hospitalization over the next 3 years is significantly reduced in predialysis and dialysis patients with an initial serum 25(OH)D level above 13.6 ng/ml and 11.3 ng/ml, respectively.

**FR-PO682**

**Continously Vitamin D Receptor Activation and Dose Adjustment According to PTH Level Directly Influence Pulse Wave Velocity among Maintenance Hemodialysis Patients**
Siren Sezer,[1] Zeynep Bal,[1] Orhan Guliyev,[1] Ugur Bal,[2] Mehtap Erkmen Uyar,[1] Emre Tutal,[1] Nurhan Özdemir Acar.[1] *[1]Dept of Nephrology, Baskent Univ Medical School, Ankara, Turkey; [2]Dept of Cardiology, Baskent Univ Medical School, Ankara, Turkey.*

**Background:** Vascular calcification (VC) represents an important contributor to the high rate of cardiovascular mortality associated to maintenance hemodialysis (MHD) patients. VC in large arteries of MHD was associated with increased pulse wave velocity (PWV). Recent studies suggest that systemic activation of VDRs may have direct effects on the cardiovascular system to decrease mortality in CKD.The aim of this study is to evaluate the effect of VDR activation on VC among MHD patients.

**Methods:** 156 patients with SHPT on chronic hemodialysis three times a week for at least 3 months were enrolled into the study. Patients were grouped according to type of VDRA: Group P (n:34) patients who recieve paricalcitol; Group C (n:71) patients who recieve calcitriol; Group PC (n:27) patients who recieve paricalcitol plus cinacalcet and Group CC (n:24) who recieve calcitriol plus cinacalcet. PWV were assessed at the beginning and end of the study.

**Results:** Mean PTH, P, Ca and ALP values were significantly higher in group PC and CC compared to group P and C ($p<0.001$). In paricalcitol based treatment groups (Group P and Group PC) percent change in PWV measurement was significantly decreased compared to baseline values ($p<0.001$). When the whole patient group was concerned, mean administerd VDRA dose / PTH ratio and mean administered VDRA dose (mcg/week) were negatively

correlated change of PWV during follow-up period (r:.-312;p<0.001 and r:.-314; p<0.001). According to logistic regression analysis being in calcitriol based treatment group and using lower doses of VDRA for PTH supression were independent risks for the PWV increment.

**Conclusions:** This observational study showed that the importance of vitamin D supplementation with VDRA intensity and maintainability in the management of cardiovascular disease in end-stage renal disease patients. Additionally higher doses of adjusted VDRA for PTH could be protective on vascular calcification.

## FR-PO683

**The PARADIGM Trial: Impact of Dialysate Calcium and Calcium Based Binders** James B. Wetmore,[1] Konstantin Gurevich,[2] Stuart M. Sprague,[3] Gerald A. Da Roza,[4] John E. Buerkert,[5] Maureen T. Reiner,[6] William G. Goodman,[6] Kerry Cooper.[6] *[1]Hennepin County Medical Center; [2]Fresenius Medical Care Russia; [3]North Shore U HealthSystem; [4]U British Columbia; [5]Columbia Nephrology Associates; [6]Amgen Inc.*

**Background:** The PARADIGM trial compared parathyroid hormone (PTH) levels during monotherapy with cinacalcet (Cin) or vitamin D (vitD) in patients on hemodialysis with secondary hyperparathyroidism (SHPT). PTH reduction did not differ between study arms (-12% Cin vs -7% vitD, P = 0.346).

**Methods:** Multivariate analysis revealed a large treatment by region interaction (US vs non-US, p <0.001). Practice patterns differed in regards to use of low (<2.5 mEq/L) dialysate calcium concentrations (DCC) and calcium containing phosphate binders (CB). Low DCC use was limited to US patients, while non US patients were more likely to be on CB. Overall, 33% of all study patients were on low DCC and 43% were on CB. In this post-hoc analysis, PTH reductions were stratified by DCC (≥2.5 vs <2.5 mEq/L) and by CB use.

**Results:** Patients treated with DCC ≥2.5 mEq/L had nominally greater PTH reduction while on Cin compared to vitD (P =0.042). Conversely, with DCC <2.5 mEq/L, there was no difference in PTH reduction. Cin dose did not vary according to DCC, while vitD dose was higher in patients on DCC<2.5 mEq/L; although, this did not result in greater PTH reduction. Cin treated patients also had greater PTH reduction than patients on vitD when on CB, but there was no difference in PTH reduction between arms when not on CB.

**Conclusions:** When used as monotherapy, the efficacy of Cin in reducing PTH levels compared to vitD may depend, in part, on the DCC and the choice of binder type.

| 1. Results Stratified by Dialysate Calcium | Dialysate Calcium ≥2.5 mEq/L | | | Dialysate Calcium <2.5 mEq/L | | |

## FR-PO684

**Whole Exome Resequencing and Homozygosity Mapping Identify Mutation of ARHGAP4 as a Novel Single-Gene Cause of Nephrotic Syndrome** Carolin E. Sadowski,[1] Svjetlana Lovric,[1] Shazia Ashraf,[1] Humphrey Fang,[1] Virginia Vega-Warner,[2] Stefanie Weber,[4] Neveen Soliman,[5] Heon Yung Gee,[1] Friedhelm Hildebrandt.[1,3] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Pediatrics, Univ of Michigan, Ann Arbor, MI; [3]Howard Hughes Medical Institute, Chevy Chase, MD; [4]Dept of Pediatrics, Univ of Essen, Essen, Germany; [5]Dept of Pediatrics, Kasr Al Ainy School of Medicine; Center of Pediatric Nephrology and Transplantation, Cairo Univ; Egyptian Group for Orphan Renal Diseases, Cairo, Egypt.*

**Background:** Idiopathic nephrotic syndrome (NS) represents a heterogeneous group of glomerular disorders occurring mainly in children. 20% percent of the cases show primary steroid resistance with a 30% risk of relapse in a kidney transplant. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain unknown.

**Methods:** We performed whole exome resequencing (WER) combined with homozygosity mapping in 43 sib pairs with steroid resistant nephrotic syndrome (SRNS). To identify additional families we screened our worldwide cohort of ~800 individuals with severe SRNS by an array based multiplex PCR (Fluidigm Access Array™) and next generation resequencing (NGS).

**Results:** By WER in two affected male sibs and their affected maternal grandfather, we detected a hemizygous missense mutation (p.A425V) in the gene *ARHGAP4* (Rho GTPase activating protein 4), which resides on the X chromosome. The mutation segregates in the family and was absent from 10,563 control individuals in the Exome Variant Server (EVS). After screening our worldwide cohort of 800 children with severe SRNS by multiplex PCR and NGS we identified another family with an affected son with a hemizygous missense mutation (p.R115W), which also was absent from the EVS database.

**Conclusions:** We identify mutations of *ARHGAP4* as new cause of NS. The identification of novel genes may shed light on the pathogenesis of NS.

*Funding:* Other NIH Support - DK076683

## FR-PO685

**Identification of GLCCI1 and DDX53 as Novel Genes Mutated in Steroid Resistant Nephrotic Syndrome** Shazia Ashraf,[1] Svjetlana Lovric,[1] Carolin E. Sadowski,[1] Virginia Vega-Warner,[2] Heon Yung Gee,[1] Humphrey Fang,[1] Friedhelm Hildebrandt.[1,3] *[1]Div of Nephrology, Boston Childrens' Hospital, Harvard Medical School, Boston, MA; [2]Dept of Pediatrics, Univ of Michigan, Ann Arbor, MI; [3]Howard Hughes Medical Institute, Chevy Chase, MD.*

**Background:** Steroid-resistant nephrotic syndrome (SRNS) is a malfunction of the kidney glomerular filter that leads to proteinuria, hypoalbuminemia, edema, and renal failure. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain obscure.

**Methods:** To identify a new causative gene for SRNS, we performed array based multiplex PCR (Fluidigm Access Array™) and next generation resequencing (1) of 25 candidate genes to screen worldwide cohort of ~800 individuals with severe SRNS as well as whole exome resequencing (WER) in 30 sib-pairs with SRNS.

**Results:** By multiplex PCR and next-generation resequencing, we detected a homozygous missense mutation (p.F453L) in the *GLCCI1* (glucocorticoid induced transcript 1) gene in a consanguineous family with two affected siblings. The amino acid residue F453 has been continually conserved since *Ciona intestinalis*. *GLCCI1* was regarded as a candidate that may cause SRNS as it has been previously shown that Glcci1 protein is highly expressed in mouse glomeruli and also the knockdown of this gene in zebrafish can result in the morphants with collapsed glomeruli with foot-process effacement (2). Furthermore, by WER of two affected male siblings, we identified a homozygous nonsense mutation (W8X) in the intronless gene *DDX53* on X chromosome. The mutations segregated with the affected status in their families. We are now screening ~800 unrelated SRNS individuals for the coding exon(s) of *GLCCI1* and *DDX53* genes to detect additional mutations in these genes.

**Conclusions:** We identified mutations of *GLCCI1* and *DDX53* genes as new causes of SRNS. The identification of novel genes for SRNS provides new steps toward our understanding of the pathomechanisms of SRNS.

(1) Halbritter J et al, J Med Genet, 2012, 49: 756-767; (2) Nishibori Y et al, J Am Soc Nephrol, 2011, 22: 2037-2046.

## FR-PO686

**Next Generation Sequencing of 37 Genes Associated with Steroid Resistant Nephrotic Syndrome** Agnieszka Bierzynska, Hugh J. McCarthy, Ian N. Day, Gavin Iain Welsh, Moin Saleem. *Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

**Background:** Up to 40% of children presenting with Steroid Resistant Nephrotic Syndrome (SRNS) in early life will have a pathogenic single gene mutation in one of 37 genes currently associated with this disease. Little is known of the effect of polymorphic variants. We followed up our previous findings that the increasing reliability of Next Generation Sequencing (NGS) provides the potential for revolutionising genetic investigation of this and similar patient groups.

**Methods:** We used exome sequencing to screen 100 paediatric SRNS patients for genes known to be associated with hereditary SRNS as well as to look for novel polymorphic variants in other genes, potentially involved in the disease. Patients were collected via a national UK Renal Registry with comprehensive detail of phenotype. Significant variants detected by NGS were confirmed by conventional Sanger sequencing.

**Results:** 9% of the patients had a previously described mutation and another 15% had a variant likely to be disease causing. Analysis revealed known as well as novel disease associated variations in routinely tested genes such as *NPHS1*, *NPHS2* and *WT1* as well as in other, less common, genes such as *SMARCAL1* or *MYO1E*. A phenotypically unexpected mutation was *COL4A5* (homozygous missense) in a patient without hearing loss. Increased burden of R229Q (*NPHS2*), R310Q (*ACTN4*) as well as other rare variants were noted in known SRNS genes in cases versus controls.

**Conclusions:** Our results demonstrate the obvious clinical need for sequencing multiple genes in SRNS where genetic heterogeneity is a defining feature. We identified mutations and potentially pathogenic variants in genes that would not routinely be screened under current testing practice. Our detailed phenotypic information enabled us as well to identify potential modifier variants from this cohort.

## FR-PO687

**Renal Cysts in Thin Basement Membrane Disease, a Marker of Progression?** Angel M. Sevillano, Maria Molina, Enrique Morales, Esther Gonzalez Monte, Natalia I. Polanco fernandez, Manuel Praga. *Nephrology, H.U 12 de Octubre, Madrid, Spain.*

**Background:** Thin basement membrane disease (TBMD) is thought to be an entity with a good renal prognosis. However proteinuria is found in 50% of these patients and in some cases it is accompanied by renal function impairment. Some studies have reported simple renal cysts in proteinuric TBMD.

**Methods:** Retrospective study comparing the characteristics and evolution of three group of patients (n=16 in all of them): 1)Biopsy-proven TBMD and proteinuria >0,5g/24 h (TBMDP), 2) Biopsy-proven TBMD and no proteinuria (TBMDnoP) and 3) Biopsy-proven IgA nephropathy and proteinuria >0,5g/24 h (IgAN).

**Results:** Main results are shown in the table below.

| | TBMDP | TBMDnoP | IgAN |
|---|---|---|---|
| Age | 35,12±17,31 | 19,57±13,34 | 41,90±11,12 |
| Gender | 10♂/6♀ | 6♀/10♂ | 7♀/9♂ |
| Time of follow up | 198 months | 210 months | 206 months |
| Initial Creatinine | 1,06 ±0,35 | 0,80± 0,16 | 1,19 ± 0,38 |
| Initial Proteinuria | 0,74 (0,05-1,58) | 0,00 (0,00-0,02) | 1,08 (0,73-1,57) |
| Final Creatinine | 1,31±0,71 | 0,85±0,15 | 1,71±0,94 |
| Final Proteinuria | 0,42(0,27-1,7) | 0,00(0,00-0,02) | 0,41(0,30-0,72) |
| Cysts | 9(56,25 %) | 0 | 2(12,5%) |

Every patient with proteinuria >0,5g/24h was treated with RAAS blockers with good results. The most striking finding was the presence of simple renal cysts in 9 (56%) TBMDP patients, whereas only one IgAN patient and nobody in the TBMDnoP group presented cysts. The cysts were multiples and bilateral in TBMDP.

**Conclusions:** The presence of bilateral simple renal cysts is common among biopsy-proven TBMD patients who develop proteinuria. This finding could help to orientate the diagnosis in patients with persistent hematuria and proteinuria. The pathogenesis of cyst formation in TBMD with proteinuria is presently unknown.

## FR-PO688

**NPHS2 V260E Is a Frequent Mutation among Unrelated Black South African Children with Steroid Resistant Focal Segmental Glomerulosclerosis** Cheryl Ann Winkler,[1] Rajendra Bhimma,[2] Kareshma Asharam,[2] Sophie Limou,[1] Jeffrey B. Kopp,[3] Victor A. David,[4] George W. Nelson.[5] *[1]Basic Research Laboratory, Center for Cancer Research, Frederick National Laboratory, SAIC-Frederick, Frederick, MD; [2]Nelson Mandela School of Medicine, Univ of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa; [3]NIDDK, NIH, Bethesda, MD; [4]Basic Research Laboratory, NCI, NIH, Frederick, MD; [5]BCGC, Frederick National Laboratory, Frederick, MD.*

**Background:** The incidence and histologic patterns of nephrotic syndrome (NS) vary with geographic location and ethnicity. We sought to determine the roles of *APOL1* and *NPHS2* variants in sporadic steroid resistant (SR) and steroid sensitive (SS) NS in children from Durban, South Africa.

**Methods:** We sequenced *NPHS2* exons and genotyped *APOL1* G1 and G2 in unrelated Indian and Black African children (median age 90 months, range 1-169) with sporadic SRNS (N=60) and SSNS (n=19), and in 116 Indian and Black controls. Kidney biopsies were available for all SRNS cases. FSGS was present in 30/38 (79%) Black and 16/22 (73%) Indian children with SRNS.

**Results:** Steroid resistance was more common in Blacks (97.4%) compared to Indians (55%) with NS ($p=8 \times 10^{-6}$). Heterozygosity in SRNS cases was noted for *NPHS2* A61V, R229Q, and A242V. *NPHS2* V260E was present in the homozygous state in 7 of 23 (30%) Black SR-FSGS (FET=0.0004) and in 1/2 SRNS cases with mesangial proliferative GN, and in no controls. V260E was observed in the heterozygous state in one Black African control (allele freq.=0.8%; 95% CI [0.02-4%]), but not in Indian cases or controls. *APOL1* G1 and G2 frequencies were not significantly different between Black SRNS cases (18.5%) and controls (19.2%) (p>0.05) nor was there significant association between 2 *APOL1* risk alleles and SRNS (p=0.22). No significant associations with *NPHS2* or *APOL1* were found for SSNS in Black or Indian children.

**Conclusions:** *NPHS2* V260E is a significant risk factor for SR-FSGS in unrelated, Black African children; the variant may be polymorphic accounting for the high rate of SR-FSGS among children in this Black African population. Further data will be required to determine population frequency distributions and history of this variant in Africa.

**Genetic and Acquired Abnormalities in the Alternative Complement Pathway in Patients with C3 Glomerulopathy** Dineke Westra,[1] Lambert Van den Heuvel,[1] Jack F. Wetzels,[2] Nicole Van De Kar.[1,3] *[1]Pediatric Nephrology, Radboud Univ Medical Centre, Nijmegen; [2]Nephrology, Radboud Univ Medical Centre, Nijmegen, Netherlands; [3]On behalf of the Dutch Pediatric C3 Glomerulopathy Working Group, Netherlands.*

**Background:** Glomerular pathologies that are characterized by the isolated deposition of C3 are nowadays called C3 glomerulopathies (C3G). These pathologies include DDD and C3 glomerulonephritis, but also immunoglobulin-negative MPGN I and III. It is thought that C3G can be caused by systemic dysregulation of the alternative and terminal complement pathway. Here we report a cohort of 29 C3G patients (all children at time of diagnosis) who have been screened for abnormalities in genes encoding (regulating) proteins of the alternative pathway.

**Methods:** In 29 biopsy proven C3G patients, mutational screening was performed of the alternative pathway genes *CFH*, *CFI*, *MCP*, *CFHR5*, *C3*, and *CFB* by means of PCR on genomic DNA and sequence analysis. For 22 of these patients, serum was available for screening for autoantibodies against CFH.

**Results:** In three patients (3/29; 10.3%) a potentially pathogenic genetic aberration was identified in *CFH*; one of these patients carried a variation in *C3* as well. All sequence variations in *CFH* are located in domains involved in heparin binding (SCR7 and SCR20); two of these have been previously described in aHUS patients. The sequence variation in *C3* is involved in properdin binding and could lead to increased affinity of CFB for C3. In two other patients (2/22; 9.1%), autoantibodies against CFH, associated with dysregulation of the complement system as well, were identified.

**Conclusions:** In 5/29 (17.2%) of the patients with C3G, abnormalities in complement genes were found, either consisting of a genetic aberration in one of the screened genes or the presence of autoantibodies against CFH. These data indicate that dysregulation of the alternative complement pathway is involved in the pathogenesis of C3 glomerulopathy. More research is needed to understand the clinical observed complement activation in C3G.

## FR-PO690

**Atypical Hemolytic Uremic Syndrome and the Application of Whole Exome Sequencing** Dineke Westra, Elena Volokhina, Lambert Van den Heuvel, Nicole Van De Kar. *Pediatric Nephrology, Radboud Univ Medical Centre, Nijmegen, Netherlands.*

**Background:** Atypical hemolytic uremic syndrome (aHUS) is a rare, but severe disease that has a heterogeneous genetic background. Mutations in several genes encoding proteins of the alternative complement pathway have been associated with the disorder. Due to the heterogeneity seen in aHUS, making the genetic diagnosis via regular methods is labor intensive and time consuming. Therefore, whole exome sequencing (WES), in which the coding regions of the entire genome can be studied, might be an option for mutation detection in aHUS.

**Methods:** Exomes of ten patients diagnosed with familial aHUS were captured and enriched using the 50MB Agilent's SureSelect human exome enrichment kit (Agilent, Santa Clara, CA, USA). One of these patients, with an identified *CFI* mutation, was taken along as a positive control.

**Results:** More than 47000 sequence variations were identified per patient. On average, ~230 of these were false substitutions located in an exon or canonical splice site, all absent in the dbSNP database or present in less than 1% of our in-house database. Overall coverage of associated genes was 86%, but SCR19 and 20 in *CFH* were not covered. The *CFI* mutation in one patient was detected. Potential pathogenicity of other identified variations will be further displayed.

**Conclusions:** The hotspot for mutations in aHUS patients (SCR19-20 in *CFH*) was not covered with the used enrichment kit. Therefore, at this moment with this specific method, WES might not be the best option for genetic screening in patients with familial aHUS.

## FR-PO691

**A Disease-Causing Mutation of INF2 Impairs the Integrity of Podocyte Slit Diaphragm in Protamine Induced Kidney Injury** Hua Sun, Victoria Charoonratana, Martin R. Pollak. *Nephrology, Beth-Israel Deaconess Medical Center, Boston, MA.*

**Background:** Rho GTPases mediated actin dynamics determine the morphology of podocyte and the integrity of slit diaphragm. Our previous work established that INF2 interacts with mDia formin protein activated by Rho GTPase and restricts the overactivation of Rho/mDia mediated actin polymerization. By doing so, INF2 regulates the cortical actin architecture responsible for the formation of lamellipodia and the trafficking of slit diaphragm proteins in cultured podocytes. R218Q, an FSGS-causing mutation in INF2, has been shown to disassociate INF2 from mDia and leads to uncontrolled Rho/mDia signaling. Here we show that this INF2-R218Q mutation impairs the morphology and integrity of slit diaphragm in protamine induced podocyte injury in a transgenic mouse model.

**Methods:** An INF2 R218Q point-mutant "knock-in" mouse model was generated. 6-month-old *INF2 wt/wt,* littermate *wt/ ki* and *ki/ki* mice were perfused with protamine sulfate (2 mg/ml in HBSS) X15 min, followed by perfusion with heparin sulfate (800 μg/ml in HBSS) X15 min. The ultra structural features of mouse kidney were examined by transmission electron microscopy. The distribution of slit diaphragm proteins was examined by immunofluorescent stain and immunogold labeling.

**Results:** Neither *wt/ki* nor *ki/ki* mice showed any significant proteinuria or altered glomerular histology up to 12 months of age compared to *wt/wt* animals. In the INF2 R218Q transgenic mouse model, protamine sulfate perfusion of the knock-in mouse (*wt/ki* and *ki/ki*) induced broadened foot process effacement with prominent intracellular actin flattening, accompanied by the mislocation of slit diaphragm proteins. The mutant podocyte (*wt/ki* and *ki/ki*) did not recover normal structure and trafficking of slit diaphragm proteins following additional perfusion with heparin sulfate, as observed in *wt/wt* mouse kidney.

**Conclusions:** Mice carrying INF2 R218Q mutation demonstrate impaired recovery from protamine induced podocyte injury, suggesting the mDia-antagonizing activity of INF2 in the maintenance of normal structure and function of podocyte. This animal model will be useful to address potential mechanisms of INF2-mediated disease *in vivo*.

## FR-PO692

**The Copy Number Variation of FCGR3A Affects Penetrance of Lipoprotein Glomerulopathy** Zhangxue Hu,[1] Maolu Tian,[1] Xiaoxia Liu,[1] Ye Tao,[1] Ping Fu,[1] Yuan Yang.[2] *[1]Dept of Nephrology; [2]Dept of Medical Genetics.*

**Background:** Lipoprotein glomerulopathy(LPG) is a rare hereditary disorder mostly found in east Asia. Our previous work and related literatures have demonstrated that LPG is a dominant inherited disease with incomplete penetrance. However, the mechanism of incomplete penetrance is still unclear. Fcγ receptors play an important role on the pathogenesis of LPG based on evidences from animal studies. The copy number variation (CNV) of Fcgr3 predisposes to glomerulonephritis in rats and humans. We supposed that the CNV affects penetrance of LPG.

**Methods:** LPG patients were diagnosed by renal biopsy, and the APOE mutation was detected by DNA sequencing. Asymptomatic carriers were defined as relatives carrying the identical APOE mutant, with urine protein less than 300 mg/d, eGFR over 60ml/min, and no active urine sediments. Between patients and carriers, the copy numbers of FCGR3A, FCGR3B and FCER1G were detected and analyzed by QRT-PCR ,ABI copycaller Software v2.0 and SPSS.

**Results:** 28 LPG patients and 26 asymptomatic carriers with APOE Kyoto were enrolled. All come from the same county. The average ages and gender distributions between two groups had no statistical difference. In the 54 APOE Kyoto individuals, the frequency of CNV of FCGR3A was 63%, higher than that of general population in China. The frequency of CNV of FCGR3A was higher in asymptomatic carriers than patients (76.9% vs. 50%, p=0.041). The frequency of high FCGR3A copy number(CN=3,4,5)was higher in carriers, compared with patients (73.1% vs. 42.9%, p=0.025). For FCGR3B, no CNV difference was observed between two groups(34.6% vs. 21.4%, p=0.171).

**Conclusions:** APOE Kyoto individuals with low or moderate FCGR3A copy numbers (CN=1,2) may be more susceptible to clinical onset of LPG. The high copy numbers may have renoprotective effect in APOE Kyoto carriers. In our study, the frequency of CNV of FCGR3A are higher than that of other Chinese populations. Because these families all come from the same county, which is fairly isolated, the high frequency of CNV of FCGR3A may prevail in this county.

## FR-PO693

**Exome Sequencing and In Vitro Studies Identify Podocalyxin as a Candidate FSGS Gene** Moumita Barua,[1] Eric Shieh,[2] Johannes S. Schlondorff,[1] Giulio Genovese,[3] Bernard S. Kaplan,[4] Martin R. Pollak.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Harvard Medical School, Harvard Univ, Boston, MA; [3]Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; [4]Dept of Pediatrics, The Children's Hospital of Philadelphia, Philadephia, PA.*

**Background:** The integral membrane protein podocalyxin (PODXL) has been shown to play a critical role for the function of podocytes in rodents, possibly by preserving slit diaphragm patency by its negative charge repulsion. However, whether disruption of PODXL function can lead to human disease has not been previously reported. Exome sequencing in a FSGS family revealed a suspicious *PODXL* variant and we explored its effect on biochemical function.

**Methods:** Exome sequencing was performed in 2 affected cousins of a family with dominant inherited FSGS. Sequencing in 175 probands of a familial FSGS cohort revealed additional rare variants. Biochemical assays comparing expression levels, extracellular domain glycosylation, subcellular localization by immunofluorescence and confocal microscopy, and interaction with a binding partner ezrin between wildtype and rare variant forms of PODXL were performed.

**Results:** A cosegregating private variant, PODXL p.L442R, affecting the transmembrane region was identified in the index family. In comparison to wildtype, this PODXL variant p.L442R facilitates dimerization, although we were unable to establish an effect of this biochemical change on its function. Specifically, the mutation does not alter protein stability, extracellular domain glycosylation, trafficking to the cell surface, global subcellular localization, or interaction with ezrin. Comparison of these parameters between wildtype and other rare PODXL variants identified in the familial FSGS cohort revealed no differences.

**Conclusions:** A variant form of PODXL, p.L442R, is a candidate for causing disease in a FSGS family but its full effect on protein function remains unknown. Our work highlights the challenge faced in the clinical interpretation of exome data for small pedigrees with autosomal dominant diseases.

## FR-PO694

**Natural History and Protein Expression Pattern in Autosomal Recessive Alport Syndrome Based on the Comprehensive Strategy for Genetic Analysis** Hiroshi Kaito,[1] Kandai Nozu,[1] Masafumi Oka,[2] Naoya Morisada,[1] Takeshi Ninchoji,[1] Koichi Nakanishi,[3] Norishige Yoshikawa,[3] Kazumoto Iijima.[1] *[1]Kobe Univ Graduate School of Medicine, Japan; [2]Faculty of Medicine, Saga Univ, Japan; [3]Wakayama Medical Univ, Japan.*

**Background:** Autosomal recessive Alport syndrome (ARAS) is a hereditary disorder caused by mutations in *COL4A3* or *COL4A4*. The most serious problem in the diagnosis of ARAS has been the low mutation detection rate. Moreover, some ARAS cannot be successfully-diagnosed even if detailed pathological examination is completely performed. It is the urgent problem to establish the method of genetic diagnosis and to clarify the natural history of genetically-proven ARAS.

**Methods:** We retrospectively analyzed 29 patients in 23 pedigrees suspected of ARAS with family history and/or kidney biopsy findings. We utilized and proceeded the following 3 steps for mutation detection: (1) genomic DNA analysis; (2) mRNA analysis to detect a splicing abnormality; and (3) semiquantitative PCR analysis to detect a heterozygous large deletion. Rat monoclonal antibodies that recognize type IV collagen α3, α4, and α5 were used for immunohistochemical staining.

**Results:** The mean age was 17.9±8.2 years old. Homozygous or compound heterozygous mutations could be detected in all cases. Four cases in 3 pedigrees had splicing abnormalities and one had a large deletion. Immunohistochemical staining was conducted in 19 patients, and 4 of them (21%) showed completely normal expression of α5 staining. Two with normal expression of α5 showed normal of α3 and α4, on the other hand, two with negative expression of α5 in glomerular basement membrane is also negative of α3 and α4. The median age of end-stage kidney disease was 20 years old.

**Conclusions:** We could successfully detect disease-causing mutations in all cases, and this is the largest-scaled report on patients with genetically-proven ARAS. It is of great help to use our strategy for genetic analyses of ARAS. We could also first elucidate the protein expression pattern of type IV collagen for ARAS, including α3 and α4. Moreover, prognosis for kidney function with ARAS may be severer than that of X-linked.

## FR-PO695

**Urinary Connective Tissue Growth Factor in Boys with Alport Syndrome** Clifford E. Kashtan, Matthew Wroblewski, Kim Y. Nguyen, Theresa F. Cassidy, Gary L. Nelsestuen. *Univ of Minnesota, Minneapolis, MN.*

**Background:** Alport syndrome (AS) is an inherited renal disease that leads to ESRD in all affected males. Studies of murine, canine and human AS showed that tubular injury and interstitial fibrosis are important contributors to renal disease progression in AS. Connective tissue growth factor (CTGF) has been implicated as a mediator of renal fibrosis and a marker of proximal tubular dysfunction in diabetic and non-diabetic kidney disease but has not been assessed in AS. We examined urinary CTGF in boys with early untreated AS.

**Methods:** 64 AM urine samples were collected over 3 years from 35 untreated boys (< 18 yrs) with AS. Creatinine (Cr), albumin (Alb) and total protein (Pr) concentrations were measured in the UMMC Clinical Laboratory. Samples were classified as Normalbuminuric (*NA,* Alb/Cr < 30 mg/g, N=35), Microalbuminuric (*MA,* Alb/Cr > 30, Pr/Cr < 0.2, N=15) or Proteinuric (*Prot,* Pr/Cr > 0.2, N=14). CTGF concentrations were determined by ELISA (Omnikine Human CTGF ELISA Kit, Assay Biotech). CTGF/Cr (ng/mg) was calculated for each sample. The study protocol was approved by the U. of Minnesota IRB.

**Results:** CTGF/Cr was higher in *Prot* samples (mean +/- SD 0.868 +/- .833) than in *NA* (0.365 +/- 0.631) and *MA* (0.499 +/-.616) samples (ANOVA, $p = 0.037$; *Prot* vs *NA*, $p = 0.013$ [*t*-test]). Linear regression showed positive correlations between Alb/Cr and CTGF/Cr ($R = 0.254$, $p = 0.043$) and between Prot/Cr and CTGF/Cr ($R = 0.294$, $p = 0.049$). CTGF/Cr increased in 7/11 serially sampled subjects who advanced from *NA* or *MA* to a higher stage (*MA* or *Prot).*

**Conclusions:** In untreated boys with AS, urinary CTGF excretion is higher in those with microalbuminuria or overt proteinuria than in those who are normalbuminuric. In normal subjects filtered CTGF is reabsorbed in the proximal tubule by megalin-mediated endocytosis. Increased urine CTGF levels in boys with AS may be secondary to altered megalin-mediated endocytosis. It is also possible that increased urine CTGF levels result from increased renal production. Further investigation of CTGF as a marker and potential mediator of renal disease progression and as a possible target of clinical intervention in AS is warranted.

## FR-PO696

**Breakdown of the GBM Ultrastructural Organization in Pierson and Alport Syndromes** Hani Suleiman,[1] Lei Zhang,[1] Adish Dani,[1] Jeffrey H. Miner,[2] Andrey S. Shaw.[1] *[1]Pathology & Immunology, Washington Univ, Saint Louis, MO; [2]Renal Div, Washington Univ, Saint Louis, MO.*

**Background:** The glomerular filtration barrier is composed of three layers: fenestrated endothelium, glomerular basement membrane (GBM), and podocyte foot processes. Numerous mutations, primarily in podocyte genes, cause a dysfunctional filtration barrier leading to proteinuria. Two such mutations, in *LAMB2* and *COL4A3*, affect the GBM and lead to proteinuria and end stage renal failure in Pierson and Alport syndrome, respectively.

**Methods:** We used sub-diffraction resolution stochastic optical reconstruction microscopy (STORM) with a GBM molecular reference frame to identify nanoscale changes in protein localization associated with a defective GBM. Two mouse models were used for this study, *Lamb2* and *Col4a3* null, and they were compared with WT as well as with the *Cd2ap* null.

**Results:** In stark contrast with WT and *Cd2ap* KO mouse kidney, the GBM in both *Lamb2* KO and *Col4a3* KO mice manifested a breakdown of the highly organized molecular architecture. Two agrin layers observed by STORM in the healthy GBM were disrupted in both disease models. In the *Lamβ2* KO, collagen α3α4α5(IV) appeared increased in irregularly thick GBM areas. On the other hand, *Col4a3* KO mice showed changes in laminin-521 positioning as well as in collagen α1α1α2(IV) localization when compared to WT. Using agrin as a reference, collagen α1α1α2(IV) shifted from its normal position near the endothelium to sites across the thickness of the GBM. Using STORM to analyze transgenic mice expressing laminin β1 in the *Lamb2* KO background and collagen a3(IV) in the Col4a3 KO background, we observed restoration of the GBM's molecular architecture to normal, which correlated with reduced proteinuria.

**Conclusions:** STORM can detect nanoscale changes in the molecular architecture of the GBM in disease models that correlated with disease progression. Further analyses of GBM architecture in Pierson, Alport, and other syndromes could reveal novel targets for therapies aimed at restoring the architecture of the GBM and the integrity of the filtration barrier.

## FR-PO697

**Identification of the Pathologic Role of miR-21 in Alport's Kidney Disease** Joseph H. Boulanger,[1] Wenping Song,[1] Jie Zhang,[1] Shweta Pandya,[2] Deidre Mackenna,[2] Lucy A. Phillips,[1] Tai-he Xia,[1] Jike Cui,[1] Lisa M. Potestio,[1] Xiaohong Cao,[1] Rachel Yabkowitz,[1] Steven R. Ledbetter,[1] Susan C. Schiavi,[1] Shiguang Liu.[1] *[1]Genzyme R &D Center, Sanofi, Framingham, MA; [2]Regulus Therapeutics, San Diego, CA.*

**Background:** Alport's syndrome (AS) is a genetic disorder resulting in progressive CKD. Anti-miR21 has been shown to mitigate CKD progression in *Col4a3-/-* mice on 129/SvJ background.The pathologic role of miR-21 in AS and the mechanism of action of anti-miR21 are currently investigated.

**Methods:** F1-hybrid (B6129SF1) *Col4a3-/-* mice generated by crossing female C57Bl6/J *Col4a3+/-* with male 129/SvJ *Col4a3+/-* were characterized by assessing urine albumin, kidney function, pathology, and gene expression at 4, 6, 9, 12 and 15 wks of age. Anti-miR21 efficacy was assessed in the F1 *Col4a3-/-*mice, dosed subcutaneously at 25 mg/kg twice a week starting at 5 wks of age. Urine albumin, renal function and kidney pathology were evaluated.

**Results:** Kidney disease progression of B6129SF1 *Col4a3-/-* mice is significantly slower than that of 129/SvJ *Col4a3-/-* mice. Proteinuria begins at 4 wks, progressive azotemia starts at 9 wks and animals die from renal failure at 17 wks. Progressive glomerular and tubular pathology, interstitial inflammation and fibrosis resembles human AS. Gene expression changes are consistent with the pathology changes. MiR-21 expression is progressively increased in the kidney of *Col4a3-/-* mice. A similar magnitude change in miR-21 expression (~ 2 fold) is observed between tubules and glomeruli at week 9, although the baseline level in tubules is 6 fold higher than that in glomeruli. Anti-miR21 treatment significantly slows the kidney disease progression measured by renal function and pathology in the B6129JF1 *Col4a3-/-* model. Gene expression profiling by RNA seq analysis in the kidney of *Col4a3-/-* mice after anti-miR-21 treatment will be discussed.

**Conclusions:** B6129SF1 *Col4a3-/-* model has a slower disease progression and therefore may be better suited to define therapeutic window. MiR-21 plays an important role in the disease progression of AS. Anti-miR-21 significantly improved both renal function and pathological changes, and therefore may be an important new therapy for AS.

## FR-PO698

**Maculopathy Is a Novel Retinal Manifestation of X-Linked and Autosomal Recessive Alport Syndrome** Judith A. Savige, Deb J. Colville. *Medicine (Royal Melbourne Hospital), The Univ of Melbourne, Melbourne, Victoria, Australia.*

**Background:** Alport syndrome is an inherited form of progressive renal failure associated with hearing loss, corneal dystrophy, lenticonus, and perimacular or peripheral retinopathy. We describe here four women with X-linked or autosomal recessive Alport syndrome and retinal maculopathy.

**Methods:** All four individuals were examined by a renal physician for clinical features and by an ophthalmologist for anterior lenticonus using a hand-held retinoscope, and for retinal changes with direct ophthalmoscopy, slit lamp biomicroscopy with a 78D lens, and by indirect ophthalmoscopy with a 20D lens. They also underwent retinal photography (KOWA non-mydriatic camera, Japan), and optical coherence tomography (OCT), and abnormalities were examined for autofluorescence and with infrared and red-free manipulation.

**Results:** The women included a mother and daughter with p.Q379X in COL4A5 and another woman with presumed X-linked disease and an unknown mutation, as well as one with autosomal recessive disease (due to p.Q131X and p.G874X in COL4A3). All patients were all aged at least 40 years, three had renal impairment or proteinuria, three had a hearing loss, and all four had a peripheral coalescing retinopathy. None had central perimacular flecks. Their macular changes were obvious on fundoscopy and retinal imaging, and confirmed on autofluorescence and infrared manipulation. These changes included depigmentation, and pigmentation at the macula. On OCT, the retinal pigment epithelium was disrupted and thinned. The worst retinal findings were associated with visual loss.

**Conclusions:** The collagen IV a3a4a5 network is found in both the internal limiting membrane and Bruch's membrane in the retina. The perimacular retinopathy results mainly from a damaged internal limiting membrane and the maculopathy described here may be due to thinning of the retinal pigment epithelium of Bruch's membrane. This feature appears to be associated with more damaging mutations and more severe renal disease.

## FR-PO699

**The Genetic Evaluation of Thirteen Israeli Families with Alport Syndrome – Our Experience from the Nephrogenetic Clinic** Idit Maya,[1] Uzi Gafter,[2,5] Miriam Davidovits.[2,4] *[1]The Raphael Recanati Genetic Institute, Rabin Medical Center, Petah Tikva, Israel; [2]The Sackler Faculty of Medicine, Tel Aviv Univ, Tel Aviv, Israel; [3]Nephrology Dept, Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [4]Nephrology Dept, Rabin Medical Center, Petah Tikva, Israel.*

**Background:** Alport syndrome (AS) is a collagen IV-related nephropathy caused by a mutation in *COL4A5* in 85% of cases, resulting in X-linked APS in hemizygous males, or in *COL4A3* or *COL4A4* in autosomal recessive (AR) or autosomal dominant (AD) APS. The most severely affected organs are the kidney, inner ear, and eye. There is progressive renal impairment with a mean age for end stage renal disease of 25 years, and renal replacement is required before the age of 40 in 90% of patients. Knowledge of inheritance has allowed early molecular diagnosis of patient with AS years or even decades before renal failure. After early molecular diagnosis of AS, recent retrospective observational data show that ACE-inhibitor therapy delays renal failure and improves life expectancy in AS with proteinuria.

**Methods:** We have opened a new Nephrogenetic clinic to enable the patients and families to achieve a Molecular Diagnosis evaluated for AS in Israel. In the past year 13 families with clinical diagnosis of AS have begun the molecular workup.

**Results:** Two families were diagnosed with X-linked AS by linkage analysis to *COL4A5* gene. Two families had AR AS, in one due to a homozygous mutation in *COL4A4* and in the other as a result of two mutations in *COL4A3* (compound heterozygous). In one of the family this workup enabled a kidney donation from a family member. In nine of the other families the molecular workup has been partially completed but no definite molecular diagnosis has been reached so far.

**Conclusions:** The molecular diagnosis of AS is a crucial step in the management of patients with a clinical suspicion of AS in order to enable initiation of Pre-implantation Genetic Diagnosis (PGD), molecular diagnosis in family members prior to kidney donation and consideration of early ACE-inhibitor therapy. A Nephrogenetic clinic is a necessary step in order to make the information and molecular diagnosis accessible to patients and families.

## FR-PO700

**Whole Exome Sequencing in Familial Kidney Disease** Daniel P. Gale,[1] Thomas Michael Connor,[1] Nadia Khan,[1] Duriye Deren Oygar,[3] Fujun Fiona Lin,[1] Guy H. Neild,[1] Michael A. Simpson,[4] Patrick H. Maxwell.[2] *[1]Div of Medicine, Univ College London, London, United Kingdom; [2]School of Clinical Medicine, Cambridge Univ, Cambridge, United Kingdom; [3]Nephrology Dept, Nicosia State Hospital, Nicosia, Cyprus; [4]Medical and Molecular Genetics, King's College London, London, United Kingdom.*

**Background:** In many patients the cause of kidney failure is unknown. In some, monogenic disorders are responsible, especially where there is a family history. We used exome sequencing in patients with unexplained familial kidney disease to identify the molecular defect responsible.

**Methods:** Exomes from 48 unrelated patients with a personal and family history of unexplained kidney disease were sequenced using an Illumina Genome Analyzer IIx. Variants were filtered if non-coding, synonymous or present in >0.5% of the 1000 genomes database. This yielded 400-1200 rare, non-synonymous coding or splice site variants per person. Literature and database searches identified likely disease-causing variants. Co-segregation of candidate mutations was ascertained by Sanger sequencing in relatives.

**Results:** Likely causative mutations in genes previously associated with monogenic kidney disease were found in 11 cases. All 11 co-segregated with disease. These variants were found in 9 (33%) of the 27 families with European ancestry but only 2 (9.5%) of the 21 families with non-European ancestry (p=0.05). In 8 further cases plausible candidate variants were identified in genes not previously associated with similar human disease. In the remaining 29 cases no likely causative mutation was identified, presumably owing to one of: causative variants missed or filtered by the exome sequencing strategy used; mutations in novel or unsuspected genes; or non-monogenic disease.

**Conclusions:** Index case exome sequencing is an effective first step in investigating Mendelian kidney disease, identifying the likely causative variant in >20% of cases in this study. In the remainder, coding mutations in known genes were excluded in a single step. The higher diagnostic yield in Europeans may result from either greater representation of European variants in the literature or lower background risk of non-Mendelian kidney disease.

*Funding:* Government Support - Non-U.S.

**FR-PO701**

**Potential Role of Angiotensin II Type I Receptor in TSC Renal Angiomyolipoma Pathogenesis** Brian J. Siroky,[1] Hong Yin,[2] Ryan J. Reichert,[1] Anna R. Hellmann,[1] Marlene Amjad Bunni,[3] Joshua C. Dillon,[3] P. Darwin Bell,[3] John J. Bissler.[1] *[1]Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Pathology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Medicine/Nephrology, Medical Univ of South Carolina, Charleston, SC.*

**Background:** Tuberous Sclerosis Complex (TSC) is a hamartomatous disease that is genetically linked to disruptions of *TSC1* or *TSC2*. Nearly 80% of TSC patients develop renal tumors called angiomyolipomas. These lesions are highly vascularized, and associated with aberrant mammalian target of rapamycin (mTOR) signaling. About 2% of TSC patients have a severe polycystic kidney phenotype, associated with deletions in the adjacent *TSC2* and *PKD1* on chromosome 16p13, which commonly produces hypertension. Clinical observation suggested that tumor development is also decelerated when hypertensive manifestations of TSC are managed with renin-angiotensin system (RAS) blockade.

**Methods:** We reviewed renal imaging from patients with the *TSC2-PKD1* deletion syndrome for presence of renal angiomyolipomas, and noted whether or not they had been treated with angiotensin converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARBs). We evaluated angiotensin II type 1 receptor ($AT_1R$) expression by immunohistochemistry in renal angiomyolipoma tissue from TSC patients. We also measured $AT_1R$ mRNA levels by qPCR in *TSC2*-deficient human renal angiomyolipoma cells (TRI102), and cells in which *TSC2* has been re-expressed (TRI103) with and without mTOR inhibition by RAD001 (20nM, 48hrs).

**Results:** Of 56 patients studied, 4/37 (10.8%) treated with ACE inhibitors or ARBs had angiomyolipomas, while 9/19 untreated patients (47.3%) had these lesions ($P<0.03$ Fisher Exact Test). We observed robust $AT_1R$ expression in TSC-associated angiomyolipoma tissue. In TRI102 cells, $AT_1R$ levels were nearly 10-fold higher than in TRI103 cells, and were markedly reduced by RAD001 treatment.

**Conclusions:** These data suggest that $AT_1R$ may be upregulated in TSC-associated renal angiomyolipoma. In addition, these findings support a possible role of $AT_1R$ signaling in TSC pathogenesis, and suggest the potential of utilizing RAS blockade for tumor management in TSC.

**Long-Term Enzyme Replacement Therapy Is Associated with Reduced Proteinuria and Preserved Proximal Tubular Function in Women with Fabry Disease** Thaneas Prabakaran,[1] Henrik Birn,[1,2] Rikke Nielsen,[1] Erik I. Christensen.[1] *[1]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark; [2]Dept of Nephrology, Aarhus Univ Hospital, Aarhus, Denmark.*

**Background:** Fabry disease is an X-linked lysosomal storage disorder caused by mutations in the GLA gene. Deficiency of α-galactosidase A (α-Gal A) causes intracellular accumulations of globotriaosylceramide (GL-3) and related glycosphingolipids in all organs, including the kidney, often leading to end-stage renal failure. In women with Fabry disease, accumulation of GL-3 in the glomerular podocytes and other renal cells induces progressive, proteinuric nephropathy, but not as severe as in men. Enzyme replacement therapy (ERT) with recombinant α-Gal A reduces cellular GL-3 deposits in podocytes and tubular epithelial cells. We have previously shown that α-Gal A is delivered to these cells by different pathways involving different receptors. This study investigated the long-term changes in albuminuria, eGFR and urinary markers of both glomerular and tubular dysfunction in women with Fabry disease treated with ERT.

**Methods:** A retrospective, single center, cohort study evaluating the long-term association between ERT, albuminuria and eGFR in 13 women with Fabry disease and mild renal involvement. In particular, we analyzed changes in the proteinuric profile including the glomerular marker IgG, the tubular markers $\alpha_1$-microglobulin and retinol-binding protein, and the shared tubular and glomerular markers albumin and transferrin.

**Results:** ERT was associated with a significant reduction in albuminuria and a relatively stable eGFR. The decrease in albuminuria was paralleled by a decrease in both glomerular and tubular urine protein markers.

**Conclusions:** The data indicate that long-term ERT is associated with stable renal function in women with Fabry disease and may advance both glomerular and tubular function.

**Fabry Disease (FD) Is Associated with Progressive Reduction in Glomerular Podocyte Mass in Young Patients** Behzad Najafian,[1] Michael Mauer,[2] Einar Svarstad.[3] *[1]Univ of Washington; [2]Univ of Minnesota; [3]Univ of Bergen.*

**Background:** Chronic kidney disease is a major complication of Fabry nephropathy (FN). There is growing evidence that podocytes (PC) play an important role in progression of FN.We previously showed that PC GL-3 inclusion density [Vv(Inc/PC] and foot process width (FPW) progressively increase with age. We aimed to examine if these findings are associated with a change in glomerular PC mass in young FD patients.

**Methods:** Renal biopsies from 12 (M/F=8/4) FD patients, age 12 [4-19] year, median [range], urine protein/creatinine (UPCR) 40 [0-223] µg/min, glomerular filtration rate (GFR) 106 [90-183] ml/min/1.73 $m^2$ were studied. Volume of glomeruli occupied by podocytes [Vv(PC/glom)], capillaries [Vv(Cap/glom)] and mesangium [Vv(Mes/glom)], Vv(Inc/PC) and FPW were estimated by electron microscopy stereology. The results were correlated with age and renal function.

**Results:** Despite direct relationship between age and Vv(Inc/PC) (r=0.67, p=0.02), Vv(PC/glom) showed inverse relationship with age ( r=-0.65, p=0.02), while, no relationship was found between age and Vv(Cap/glom) or Vv(Mes/glom), confirming a loss in glomerular podocyte mass. 46±5% of glomerular volume was composed of podocytes, 30±5% glomerular capillaries and 14±3% mesangium and about 10% urinary space between the capillaries. UPCR directly correlated with age (r=0.61, p=0.01), FPW (r=0.66, p=0.01) and Vv(Inc/PC), and inversely correlated with Vv(PC/glom). Vv(PC/glom) inversely correlated with FPW (r=-0.59, p=0.046).

**Conclusions:** Although we did not count PC in this study, since GL-3 accumulation leads to podocyte enlargement, our observation of reduced glomerular PC mass is strongly suggestive that FD is associated with progressive PC injury (FPW increase) and loss with age in young patients, both of which correlate with UPCR. These results are confirmatory to our other studies that show urinary podocyte loss increases with age in Fabry patients and correlates with UPCR.

**Endothelial Nitric Oxide Synthase Uncoupling and Microvascular Dysfunction in the Mesentery of Fabry Mice** Liming Shu, Justin J. Kang, James A. Shayman. *Univ of Michigan, Ann Arbor, MI.*

**Background:** A defect in the gene for the lysosomal enzyme α-galactosidase A (*GLA*) results in globotriaosylceramide (Gb3) accumulation in Fabry disease and leads to premature death from cardiac and cerebrovascular events. However, gastrointestinal symptoms are often observed first during childhood and persist throught life in these patients, and are not well understood.

**Methods:** Gla knockout mice on a 129/SvJXC57BL/6 background were used. Second order mesenteric arteries were dissected and mounted in a pressure myograph system. Vessel diameter was monitored in real time. Glycosphingolipid analyses and Western blotting were performed as previously reported.

**Results:** The progressive accumulation of Gb3 in mesenteric arteries (MA) was confirmed byTLC. No endothelium-dependent dilatation was seen in MA of Gla null mice at 8 months, and suppression in acetylcholine-mediated vasodilatation was seen at 2 months. Endothelium-independent dilatation with sodium nitroprusside was normal compared with age-matched WT mice. The microvascular defect in the MA was endothelium-dependent and associated with a suppression of the active homodimer of eNOS. Phosphorylation of eNOS at the Ser1179 activation site was down-regulated while that of the inhibitory site (Thr495) was significantly enhanced in aged Gla null MA. Increased levels of nitrated proteins (3-nitrotyrosine) were seen in parallel with changes in eNOS consistent with eNOS uncoupling in the MAs.

**Conclusions:** The data provide evidence of microvascular endothelial dysfunction marked by early onset endothelial dysfunction and a total loss of acetylcholine-mediated dilatation with age in the MA of Gla deficient mice. The observed Gb3 accumulation and decrease in eNOS bioavailability in the MAs are consistent with the phenotype previously observed in macrovessels such as the carotid and aorta. In addition, the reciprocal dephosphorylation of Ser-1179 and phosphorylation of Thr-495 present in this vascular bed may contribute to the profound dysfunction. These data are consistent with Gb3 mediated eNOS uncoupling. This appears to be the first report of endothelial dysfunction in the mesenteric artery in a murine model of Fabry disease.

**FR-PO705**

**Fabry Disease: Clinical Characterization of the Variant Phenotype R363H Mutation** Eric L. Wallace, Leslie J. Jackson, David G. Warnock. *Div of Nephrology, UAB.*

**Background:** Fabry disease (FD) is a lysosomal storage disease caused by mutations in the α-galactosidase A (AGAL) gene and leads to globotriacylceramide (Gb3) accumulation in lysosomes.Patients with classic FD phenotype,with no AGAL activity, present in childhood with acroparesthesias, hypohidrosis, angiokeratoma, and gastrointestinal symptoms. Ultimately, renal failure, cardiac involvement, and cerebrovascular disease develop. Variant phenotypes with later-onset presentation are recognized and are caused by mutations, such as R118C and N215S, that spare some residual enzyme activity. AGAL mutations which cause no clinical manifestations of FD have also been identified.

**Methods:** We present a family with the variant phenotype R363H mutation and 5 years of clinical follow up characterizing this phenotypic variant of FD.

**Results:** The male, diagnosed at age 16, presented with acroparesthesias. He had no history of hypohidrosis,GI pain,or diarrhea. Angiokeratomas were notably absent. Laboratory studies revealed: creatinine, 0.8 mg/dL (eGFR by CKD-EPI 132 mL/min/1.73$m^2$); 24 hr urine protein, 78mg/24hr; plasma and leukocyte AGAL activity, 2 U/mL (Reference Range (RR) =12.0 +/- 4.2 U/mL) and 5.63 U/mg (RR = 34.6 +/- 14.6 U/mg), respectively, and undetectable urinary lyso-Gb3. Renal biopsy showed minimal multi-laminar inclusions in podocytes but none in the endothelium. Cardiac work up including echocardiogram and EKG showed no cardiac disease. Due to his lack of clinical manifestations, enzyme replacement therapy was not offered. After 5 yrs follow up, despite no therapy, the patient is still free of symptoms including acroparesthesias. His eGFR by CKD-EPI is 96 ml/min/1.73$m^2$, 24 hour urine protein is 162 mg/24 hr while albuminuria was unchanged. The mother had no clinical manifestations of FD, her kidney biopsy showed no endothelial and only scant inclusions in podocytes.

**Conclusions:** The R363H mutation in the AGAL gene represents a mild phenotypic variant of FD. Current guidelines recommend treatment of all 16 yo males with FD. Evidence of AGAL mutation without clinical manifestations of the disease does not suffice to initiate therapy. Better characterization of the clinical course and informative biomarkers are needed to guide treatment decisions in non-classical Fabry variants.

## FR-PO706

**Systems Genetics Identifies PDGFRA as a Candidate Driver Gene for Lupus Nephritis** Celine C. Berthier,[1] Sharon Chung,[2] Elizabeth E. Brown,[3] Carl D. Langefeld,[4] Matthias Kretzler.[1] *[1]Univ of Michigan; [2]Univ of California; [3]Univ of Alabama; [4]Wake Forest School of Medicine.*

**Background:** Lupus nephritis (LN) is a serious manifestation of systemic lupus erythematosus (SLE) and shows familial aggregation and increased morbidity and mortality. Linking transcriptional profiles with gene candidates identified from genome wide association studies (GWAS - SLEGEN) using systems genetics strategies can facilitate identification of molecular mechanisms driving LN.

**Methods:** Affymetrix based expression profiles from 47 microdissected human renal biopsies (ERCB) were used in association with a meta-analysis of 3 LN GWAS studies.

**Results:** The GWAS meta-analysis showed LN associated single nucleotide polymorphisms (SNPs) located near PDGFRA-GSX2 ($P=2.7x10^{-7}$), SLC5A11 ($P=3.0x10^{-7}$), ID4 ($P=4.3x10^{-7}$), HAS2-SNTB1 ($P=6.2x10^{-7}$), COL4A1 ($P=6.4x10^{-6}$). HLA-DR2 and HLA-DR3 (2 well known SLE susceptibility loci) were also associated with LN ($P=0.037$ and $2.2x10^{-5}$, respectively). Linked to disease phenotype, SNPs within as well as outside coding regions can impact the disease trait via associated transcript expression changes (expression quantitative trait locus or eQTL). Thus, renal gene expression profiles from LN biopsies (n=32) compared to living-donor controls (n=15) were studied for the genomic regions identified in the LN GWAS. In both glomerular and tubulointerstitial compartments, PDGFRA (fold-change 2.57 and 2.40, respectively) and COL4A1 (fold-change 2.61 and 1.89, respectively) showed significant mRNA expression changes in LN patients compared to controls. A transcriptional network was built from 961 LN regulated genes to define the functional context of PDGFRA regulation, independent of predefined canonical pathways. This co-citation literature based network highlighted PDGFRA as one of the main nodes interacting with STAT1, FN1, CCND1 .

**Conclusions:** This work is the first large-scale genome-wide investigation of LN and provides evidence of multiple biologically plausible LN susceptibility loci. Consistent with a functional role in LN, DGFRA and associated pathway members showed significant inductions in intra-renal mRNA levels in LN cases compared to controls.

## FR-PO707

**Mutation Analysis in 288 Individuals with Isolated Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) in 20 Known Genes** Daw-yang Hwang,[1,6] Gabriel C. Dworschak,[1,4] Stefan Kohl,[1] Radovan Bogdanovic,[2] Elijah O. Kehinde,[3] Heiko M. Reutter,[4] Velibor Tasic,[5] Friedhelm Hildebrandt.[1,7] *[1]Dept of Nephrology, Boston Children's Hospital, Boston, MA; [2]Medical Faculty, Univ of Belgrade, Belgrade, Serbia; [3]Dept of Surgery, Kuwait Univ, Safat, Kuwait; [4]Institute of Human Genetics, Univ of Bonn, Bonn, Germany; [5]Dept of Pediatric Nephrology, Univ Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; [6]Dept of Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [7]Howard Hughes Medical Institute, Chevy Chase.*

**Background:** Congenital anomalies of the kidney and urinary tract (CAKUT) account for approximately 50% of children with end-stage renal disease, taking a high toll on affected families. Mutations in 20 genes have been identified as causing isolated or oligosyndromic CAKUT (Yosypiv, Int J Nephrol 2012:909083, 2012). Genetic diagnosis has been hampered by genetic heterogeneity and lack of genotype-phenotype correlation. To determine the percentage of cases with CAKUT that can be molecularly solved by known CAKUT genes, we analyzed the coding exons of 20 established causative genes in a cohort of 288 individuals from 244 CAKUT families.

**Methods:** We employed a newly developed method of high-throughput mutation analysis (Halbritter, J Med Genet 49:756, 2012). Coding exons of 20 genes were amplified and barcoded in multiples 48 patients using the Fluidigm 48x48 microfluidic array, followed by next-generation re-sequencing and Sanger sequencing. The most common phenotype of our CAKUT cohort is vesicoureteral reflux, followed by hypodysplasia and duplex ureter.

**Results:** In 37 individuals from 32 families we identified mutations in 10 of the 20 known CAKUT genes, including BMP4 (n=2), EYA1 (n=2), HNF1B (n=2), KAL1 (n=4), PAX2 (n=4), RET (n=8), ROBO2 (n=3), SALL1 (n=3), SIX2 (n=6), SIX5 (n=3). Sixteen of these mutations are novel.

**Conclusions:** This result indicates that 13.1% (32/244) families with isolated CAKUT in our cohort are due to monogenic causes. Our report represented one of the most in-depth diagnostic studies of monogenic causes of isolated CAKUT in children.

*Funding:* NIDDK Support

## FR-PO708

**Identification of Mutations Causing Congenital Anomalies of the Kidney and Urinary Tract through Targeted Sequencing** Nayia Nicolaou, Ies J. Nijman, Edwin Cuppen, Kirsten Y. Renkema, Nine V. Knoers. *Medical Genetics, Univ Medical Center Utrecht, Utrecht, Netherlands.*

**Background:** Congenital anomalies of the kidney and urinary tract (CAKUT) are developmental disorders that involve a spectrum of renal structural malformations. They occur in 1 out of 500 live-births and comprise the major cause of end-stage renal disease in childhood. There are 15 genes reported in the Human Gene Mutation Database with mutations responsible for CAKUT. However, a large proportion of cases remain unexplained. We aim to identify novel rare mutations in candidate genes that play a role in kidney cell differentiation and elucidate their involvement in CAKUT etiology.

**Methods:** We employ a targeted next generation sequencing approach in 500 Dutch CAKUT patients. Enrichment methods allow us to capture and analyze in parallel the protein-coding regions of 208 candidate genes and 36 miRNAs. The genes selected were previously shown to have experimental evidence for their role in human isolated or syndromic CAKUT or were demonstrated to be involved in disrupted nephrogenesis in transgenic animals or cell models. For data analysis we used our in-house mapping and variant calling methodology.

**Results:** Sequencing results from the first 60 patients with severe kidney dysplasia showed that the average read depth is 210X. Approximately 200 variants were called per individual. Further variant prioritization based on variant frequency data from dbSNP and Genome of the Netherlands, evolutionary conservation, and *in-silico* predictions resulted in a list of potentially pathogenic mutations. Variants were validated by Sanger sequencing.

**Conclusions:** This study shows that our targeted sequencing approach and variant prioritization method is efficient in identifying gene mutations in a large cohort of sporadic CAKUT cases. By this approach, previously reported causal mutations in known CAKUT genes were successfully identified. Interestingly, the majority of the novel and promising pathogenic variants identified, were unique for each patient. Hence, CAKUT might be even more heterogeneous in their etiology than expected. Functional studies to test the impact of novel mutations on protein function and kidney development are currently on-going.

## FR-PO709

**Whole Exome Sequencing in 3 Brothers with Posterior Urethral Valves** Alina Hilger,[1] Gabriel C. Dworschak,[2] Daw-yang Hwang,[2] Peter Nuernberg,[3] Stefanie Weber,[4] Goedele Beckers,[5] Michael Ludwig,[6] Friedhelm Hildebrandt,[2,8] Heiko M. Reutter.[1,7] *[1]Institute of Human Genetics, Univ of Bonn, Bonn, Germany; [2]Dept of Medicine, Boston Childrens Hospital, Havard Medical School, Boston, MA; [3]Cologne Center for Genomics, Univ of Colonge, Colonge, Germany; [4]Pediatrics II, Univ Childrens Hospital Essen, Essen, Germany; [5]Dept of Pediatric Urology, VU Univ Medical Center Amsterdam, Amsterdam, Netherlands; [6]Dept of Clinical Chemistry and Clinical Pharmacology, Univ of Bonn, Bonn, Germany; [7]Dept of Neonatology, Childrens Hospital Univ of Bonn, Bonn, Germany; [8]Howard Hughes Medical Institute, Chevy Chase, MD.*

**Background:** Posterior urethral valves (PUVs) are the most common cause of lower urinary tract obstruction leading to severely comprised renal function. The incidence is in 1 in 5,000-8,000 male infants, the etiology remains unknown.

In a family with three affected and one unaffected sons from two different fathers we performed whole exome sequencing (WES) in order to identify the genetic cause of the disease.

**Methods:** X-chromosomal inheritance was excluded by linkage analysis we followed a hypothesis of dominant inheritance, of this male limited phenotype, from the unaffected mother to her 3 affected sons. Out of a total of 78 heterozygous, non-synonymous, rare variants occurring in both of the sequenced brothers 14 variants could be filtered by the criteria of conservation (UCSC Genome Browser), expression (Gudmap, Mouse Genome Database), and data such as diseases that were described previously with the respective gene (OMIM, PubMed). 9 of these variants segregated with the disease in the family. Charactarisation of variants was done by several prediction programs (Polyphen, Mutation Taster, SIFT).

**Results:** After applying the described filter steps 5 variants in the genes COL6A5, GSTA3, MIER3, LRRC27 and PHLPP1 were chosen to be possibly disease causing.

**Conclusions:** The current screening and segregation analysis of parents and affected offspring of a larger cohort of 70 PUV patients from Germany and the US for the presence of these variants should identify the disease causing gene.

*Funding:* Government Support - Non-U.S.

## FR-PO710

**Defective Transport and Epithelial Dedifferentiation: Genesis of Key Events in Nephropathic Cystinosis** Claudia Raggi,[1] Alessandro Luciani,[2] Corinne Antignac,[3] Olivier Devuyst.[2] *[1]UCL, Brussels, Belgium; [2]UZH, Zurich, Switzerland; [3]INSERM, Paris, France.*

**Background:** Nephropathic cystinosis (NC), a lysosomal storage disease caused by mutations in the lysosomal cystine transporter cystinosin (CTNS), is characterized by generalized proximal tubule (PT) dysfunction that progresses, if untreated, to end-stage renal disease. The pathogenesis of defective PT cellular transport in NC remains unclear.

**Methods:** In order to investigate the early events involved into PT dysfunction, we performed biochemical profile on a new line of C57BL/6 *Ctns* KO mice, which accumulate cystin in the kidney and show signs of tubulopathy. Endocytic uptake and dedifferentiation

and proliferation markers were assessed on primary PT cells (mPTC) derived from aforementioned mice.

**Results:** Metabolic studies revealed that *Ctns* KO mice presented with a progressive PT dysfunction with low-molecular-weight proteinuria, glucosuria and phosphaturia, before structural damage and in absence of renal failure. These changes were related to decreased expression of multi-ligand receptor complex megalin/cubilin and to increased dedifferentiation (ZONAB transcriptional factor) and proliferation (PCNA and Cyclin D1) rates. Studies on mPTC confirmed the reduced expression of endocytic receptors, with decreased uptake of specific ligands, resulting from an abnormal transcription program involving a loss of integrity of tight junctions, modified distribution of ZO-1 and release of ZONAB. The mPTC also showed increased markers of proliferation and oxidative stress, as observed in *Ctns* KO kidneys. These changes could be rescued by overexpression of wild-type CTNS.

**Conclusions:** These data reveal that the loss of CTNS function in PT cells triggers an early chain of events leading to dedifferentiation and transport defects, before structural damage. They may provide new targets for interventions which, in turn, could alleviate the burden caused by the urinary loss of vital metabolites in patients with NC.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## FR-PO711

**Increased Urinary Loss of Podocytes and Proximal Tubular Epithelial Cells in Nephropathic Cystinosis** Ekaterina A. Ivanova,[1] Fanny Oliveira Arcolino,[1] Maria Pia Rastaldi,[2] Elena N. Levtchenko.[1] *[1]Univ Hospitals Leuven & Katholieke Universiteit Leuven, Leuven, Belgium; [2]Fondazione IRCCS Policlinico & Fondazione D'Amico, Milano, Italy.*

**Background:** Cystinosis is an autosomal recessive disorder caused by mutations in the CTNS gene that encodes a lysosomal cystine transporter and results in high cystine levels in the lysosomes. Cystinosis is associated with severe renal dysfunction progressing towards end-stage renal failure. We hypothesize that increased urinary loss of podocytes and proximal tubular epithelial cells might underlie renal dysfunction in cystinosis.

**Methods:** We analysed urine samples from healthy donors (n=9) and cystinosis patients (n=14). Urine samples were characterized for the presence of mRNA of podocyte and proximal tubular epithelial cell (PTEC) markers (CD2AP, podocalyxin, CD13 and AQP1) by qRT-PCR (mean expression values calculated as Ct normalized by creatinine). Conditionally immortalized podocyte and PTEC cell lines were generated from freshly voided urine of healthy volunteers and cystinosis patients.

**Results:** We demonstrated in cystinosis a significant increased level of podocyturia and a higher number of PTECs voided into urine. In addition, urine samples from cystinosis patients provided more viable podocytes and PTECs suitable for in vitro culture in comparison to healthy donors. As expected, cystinosis podocyte and PTEC cell lines accumulated cystine. Using viable podocytes and PTEC extracted from urine of both healthy donors and cystinosis patients, we established several conditionally immortalized cell lines and characterized them by the expression of typical markers, including CD2AP, synaptopodin, and nephrin for podocytes and CD13 and AQ1 for PTECs. Cystinosis podocytes demonstrated increased motility in wound-healing assay as compared to the control. Also, the actin cytoskeleton, as shown by phalloidin and alpha-actinin staining, and cellular adhesion sites were altered in cystinosis cells.

**Conclusions:** Our data demonstrate increased urinary loss of podocytes and PTECs in cystinosis. Decreased adhesion to the extracellular matrix might be one of the mechanisms underlying renal damage in this disorder.

*Funding:* Private Foundation Support

## FR-PO712

**Endosomal/Lysosomal Dysfunction in Kidney Proximal Tubular Epithelial Cells Deficient for Lysosomal Cystine Transporter Cystinosin** Ekaterina A. Ivanova,[1] Maria Giovanna De Leo,[2] Maria antonietta De Matteis,[2] Elena N. Levtchenko.[1] *[1]Univ Hospitals & Katholieke Universiteit, Leuven, Belgium; [2]Telethon Institute of Genetics and Medicine (TIGEM), Naples, Italy; [3]Bambino Gesu Children's Hospital, Rome, Italy.*

**Background:** Nephropatic cystinosis is a lysosomal storage disorder caused by a deficiency of cystinosin (CTNS), the lysosomal cystine/H+ co-transporter. The disease is characterized by lysosomal cystine accumulation with renal Fanconi syndrome being an early kidney symptom. Treatment with cysteamine prevents cystine accumulation, but does not restore Fanconi syndrome, suggesting that cystinosin has additional important roles in controlling the reabsorptive function of renal proximal tubular cells (PTC). Here we have explored the role of cystinosin in endocytic membrane trafficking.

**Methods:** We performed a detailed characterization of endosomal compartments and endocytosis in PTC obtained from urine of a healthy volunteer and a cystinosis patient bearing a homozygous 57-kb deletion of the CTNS gene, which results in a complete absence of cystinosin. We also confirmed our observations on HK-2 cells with down-regulated CTNS using specific siRNA.

**Results:** We studied endocytosis and degradation/recycling of various cargo proteins, including a ligand of megalin RAP. Surface binding of megalin ligand GST-RAP was significantly reduced in cystinosis cells. Processing of the ligand upon internalization was slowed-down in cystinosis cells in comparison with the control. Staining for specific markers of cellular compartments revealed dramatically altered early and late endosomal compartments both in PTC cells obtained from cystinosis patients and in HK-2 cells with down-regulated cystinosin. This effect could not be restored by treatment with cysteamine (100 µM, 24h). Moreover, partial co-localization of cystinosin with a motor protein kinesin was observed, indicating a possible involvement of cystinosin in controlling endo-lysosomal motility.

**Conclusions:** We demonstrated altered endocytosis and changes in endocytic compartments in cells deficient for cystinosin.

## FR-PO713

**Assessment of Cystine Stone Growth In Vivo in a Mouse Model of Cystinuria** Amrik Sahota,[1] Jaspreet Parihar,[2] Min Yang,[1] Derek Adler,[1] Wonkuk Kim,[3] Derek Gordon,[1] David S. Goldfarb,[4] Jay A. Tischfield.[1] *[1]Genetics, Rutgers Univ, Piscataway, NJ; [2]Surgery, UMDNJ-RWJMS, New Brunswick, NJ; [3]Math Stat, Univ South Florida, Tampa, FL; [4]Nephrology, NYU Langone Med Ctr, New York, NY.*

**Background:** *Slc3a1* knockout mice are a model for human cystinuria. They have cystine crystalluria from an early age and males from age 3 mo have bladder stones. Newer imaging technologies allow investigation of stone growth and the effects of pharmacologic intervention on this process in live animals. We evaluated the utility of CT for identifying the temporal pattern of cystine stone growth in cystinuria male mice and for assessing the efficacy of cystine dimethyl ester (CDME), a crystal growth inhibitor.

**Methods:** Mice (2-3 mo old) were screened for bladder stones using the Albira CT scanner. Initial bladder volume (indicator of stone volume) was calculated using InviCRO VivoQuant software. Mice with stones were randomly assigned to treatment (200 µl of 10 mg/ml CDME, n=11) or control (200 µl water, n=7), given daily by gavage for 10 wks. Volume measurements were repeated at 1-2 wk intervals. Mice were then sacrificed and stone size and number analyzed using chi-square.

**Results:** 60% of mice had bladder stones. Initial bladder volumes ($mm^3$) in both groups were similar (12-96 for control and 11-86 for CDME). In both cases, there was a linear increase in stone volume that followed the equation y=mx+c. The equation for the control group was y=0.39x+11.0 to y=1.43x+84.3, and for the treatment group it was y=0.99x+18.4 to y=2.67x+73.3. Thus, the two groups could not be distinguished by CT analysis. There was a small but significant difference in the percentage of stone sizes in the two groups (p=0.05). The treatment group had 9.4% more stones and the control group had 19.6% fewer stones in the 1.1-2.0 mm range. The treatment group had 26.1% fewer stones and the control group had 54.6% more stones in the 3.1-4.0 mm range.

**Conclusions:** CT can determine the rate of stone growth in vivo, but longitudinal measurement of stone volume is not suitable for evaluating CDME efficacy since total stone volumes in treated and untreated mice were comparable. Supported in part by Rare Kidney Stone Consortium.

## FR-PO714

**Mutations in HAO1 Encoding Glycolate Oxidase Cause Isolated Glycolic Aciduria** Yaacov Frishberg, Avraham Zeharia, Ruth Belostotsky. *Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel.*

**Background:** Perturbations in glyoxylate metabolism are associated with excessive oxalate synthesis, as oxalate is the product of glyoxylate oxidation. Glycolic aciduria has been regarded as a hallmark of primary hyperoxaluria type I (PH1) manifesting with kidney stones, nephrocalcinosis and kidney failure. Mutations in HAO1, encoding glycolate oxidase, the enzyme catalyzing the oxidation of glycolate to glyoxylate, have been investigated as a possible cause of non-type I/type II PH.

**Methods:** Urinary organic acid profile performed by gas chromatography-mass spectrometry. Direct DNA sequencing was used for mutation screening in the HAO1 gene.

**Results:** Two brothers, born to consanguineous healthy parents of Arab descent, were evaluated for psychomotor delay associated with anisocoria, alacrima and in one, also achalasia (triple A syndrome). 4 sisters are healthy. Urinary organic acid profile performed in the 8-year old proband, showed markedly increased urinary glycolic acid excretion (2,000 mmol/mol creatinine; normal reference for age: 18-92) with normal excretion of oxalate, citrate, glycerate and glycine. Abdominal ultrasound showed normal sized kidneys with normal echotexture. Direct sequencing of the HAO1 gene, encoding glycolate oxidase, revealed acceptor splice site mutation in the invariant AG of intron 6: c. 814-1G>C leading to skipping of exon 6 and to in-frame deletion of 53 amino acids containing the riboflavin-5'-phosphate (FMN) binding domain and adjacent to the substrate binding site. The brother affected by triple A syndrome and 4 healthy sisters, all having normal urinary glycolate excretion did not carry bi-allelic mutations in HAO1. The genetic nature of triple A in this kindred, was recently identified and is unrelated to this metabolic abnormality.

**Conclusions:** Loss-of-function mutations in the HAO1 gene, encoding glycolate oxidase, are responsible for asymptomatic isolated glycolic aciduria without hyperoxaluria.

## FR-PO715

**Muscle Involvement in Dent Disease 2** Yo Han Ahn, Eujin Park, Jiwon M. Lee, Hee Gyung Kang, IL-Soo Ha, Hae Il Cheong. *Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Korea.*

**Background:** Dent disease is an X-linked recessive renal tubulopathy mostly caused by *CLCN5* mutations (type 1). However, some patients have *OCRL1* mutations (type 2), known to be associated with Lowe syndrome. It is somewhat difficult to differentiate these two diseases by clinical features only. Several studies have showed differences in serum muscle enzyme levels between Dent disease 1 and 2.

**Methods:** Patients with Dent disease 1 (Group 1, n=24), Dent disease 2 (Group 2, n=5) and Lowe syndrome (Group 3, n=16) were included. The serum levels of 3 muscle

enzymes were measured; creatine kinase (CK), lactate dehydrogenase (LDH), and aspartate aminotransferase (AST). Serum levels of alanine aminotransferase (ALT) were measured as well as a control. We compared the serum levels of the enzymes in each group to test the validity of the serum levels as a biomarker to predict the genotypes.

**Results:** All of the patients in Group 2 showed no clinical symptoms of muscle involvement except for one patient having muscle hypoplasia of both upper extremities. The serum levels of the enzymes in each group are shown in Table 1. When we compared between Groups 1 and 2, the positive and negative predictive values of the abnormal levels of the enzymes were also shown in Table 1. Serum levels of AST were normal in all of the patients. Table 1. The serum levels of the enzymes in each group and the predictive values (PV) of the levels.

| | Serum levels of the enzymes | | | Comparison between Groups 1 and 2 | | | |
|---|---|---|---|---|---|---|---|
| | Group 1 | Group 2 | Group 3 | PPV | NPV | Sensitivity | Specificity |
| CK (IU/L) | 137.3±45.5 | 262.6±100.9 | 344.0±231.2 | 1.00 | 0.82 | 0.6 | 1.00 |
| LDH (IU/L) | 221.7±37.9 | 365.8±60.5 | 507.9±248.6 | 0.45 | 1.00 | 1.00 | 0.33 |
| AST (IU/L) | 26.5±5.7 | 62.8±22.1 | 77.4±21.8 | 1.00 | 0.96 | 0.8 | 1.00 |

**Conclusions:** Measurement of the serum levels of muscle enzymes in patients with Dent disease can provide useful information to predict genotypes, even though the patients do not have overt clinical signs of muscle involvement. Muscle involvement maybe a cardinal finding in patients with *OCRL1* mutations regardless of the phenotype.

*Funding:* Government Support - Non-U.S.

## FR-PO716

**Urinary 2,8-Dihydroxyadenine Excretion in Patients with APRT Deficiency: Effect of Allopurinol and Febuxostat Therapy**

Hrafnhildur Linnet Runolfsdottir,[1] Vidar O. Edvardsson,[1,2] Margret Thorsteinsdottir,[1,3] Runolfur Palsson.[1,2] *[1]Univ of Iceland; [2]Landspitali - The National Univ Hospital of Iceland; [3]ArcticMass, Reykjavik, Iceland.*

**Background:** Adenine phosphoribosyltransferase (APRT) deficiency results in excessive urinary excretion of poorly soluble 2,8-dihydroxyadenine (DHA), causing nephrolithiasis and chronic kidney disease. Treatment with allopurinol is effective but reliable methods for therapeutic monitoring are lacking. We evaluated urinary DHA excretion in patients with APRT deficiency using ultra-performance liquid chromatography-electrospray tandem mass spectrometry (UPLC-MS/MS).

**Methods:** UPLC-MS/MS was used to measure the concentration of DHA in 24 hr and random urine samples from 28 patients with APRT deficiency, before and after treatment with allopurinol or the alternative agent febuxostat. Urine samples from healthy subjects were used as controls. The pH of the urine specimens was adjusted to 10, using 20 mM $NH_4OH$, to dissolve all precipitates before testing. The urinary excretion of DHA in random urine samples is expressed as DHA-to-creatinine ratio (ng/mmol). Data are expressed as median and range.

**Results:** In 20 healthy controls, the median DHA-to-creatinine ratio was 0.4 (0-2.3) ng/mmol. In untreated patients with APRT deficiency, the median 24 hr urinary excretion of DHA was 1750 (1045-2706) μg/24 hr (n=5) and the median DHA-to-creatinine ratio in random urine samples was 272 (85-374) ng/mmol (n=8). In patients treated with allopurinol, the median 24 hr urinary excretion of DHA was 848 (4.7-2393) μg/24 hr (n=33) and the median DHA-to-creatinine ratio was 126 (2.5-865) ng/mmol in random urine samples (n=12). In patients treated with febuxostat, the median 24 hr urinary excretion of DHA was 293 (43-319) μg/24 hr (n=3) and the median DHA-to-creatinine ratio in random urine samples was 74 (5-246) ng/mmol (n=4).

**Conclusions:** Marked reduction in urinary excretion of DHA was observed after pharmacotherapy was initiated. Febuxostat may be a more effective agent than allopurinol. These preliminary data suggest that the UPLC-MS/MS assay greatly enhances monitoring of pharmacotherapy in patients with APRT deficiency.

## FR-PO717

**Kidney Function and Chronic Kidney Disease in Patients with APRT Deficiency**

Hrafnhildur Linnet Runolfsdottir,[1] Runolfur Palsson,[1,2] Vidar O. Edvardsson.[1,2] *[1]Univ of Iceland; [2]Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland.*

**Background:** Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive disorder characterized by nephrolithiasis and/or chronic kidney disease (CKD). The aim of this study was to examine kidney function and the development of CKD in patients with APRT deficiency.

**Methods:** All 46 patients listed in the APRT Deficiency Registry of the Rare Kidney Stone Consortium were included in the study. Estimates of glomerular filtration rate (eGFR) were calculated from serum creatinine, using the MDRD equation in adults and the modified Schwartz equation in children. CKD was defined as eGFR <60 ml/min/1.73 $m^2$ and the slope of eGFR per year was calculated. Data are presented as median and range.

**Results:** Of the 46 patients, 21 were males (45.6%). The median age at diagnosis was 33.9 (0.6-62.8) years and treatment with allopurinol was initiated at the age of 44.4 (7.3-62.8) years. The slope of eGFR per year was –0.17 and –8.65 ml in treated and untreated patients, respectively. At last follow-up, 9 of 32 (28%) Icelandic patients had developed CKD, of whom 3 (9.4%) had progressed to ESRD. These 3 patients received limited or no treatment prior to the onset of ESRD, which occurred at age 44.0 (36.7-53.7) years. Nine of 11 (82%) US patients had CKD, of whom 5 (44.5%) had developed ESRD at age 37.7 (21.2-62.1) years. All 5 US patients with ESRD were first diagnosed with APRT deficiency and placed on allopurinol after initiation of dialysis (n=2) or a failed kidney transplant (n=3). Two Austrian patients and one from the UK with CKD received limited or no treatment. Twenty-five patients, aged 31.9 (2.4-74.9) years, with eGFR ≥60 ml/min/1.73 $m^2$ received treatment with either allopurinol or febuxostat for 17.6 (0.1-34.8) years.

**Conclusions:** The greater decline in renal function in untreated patients compared to those who received allopurinol and/or febuxostat underscores the importance of timely diagnosis and treatment. The high proportion of US patients developing ESRD prior to the correct diagnosis is of concern and suggests lack of awareness of APRT deficiency among physicians.

## FR-PO718

**Estimated Prevalence of APRT Deficiency Based on Population Frequencies of Mutated Alleles**

Runolfur Palsson,[1] Vidar O. Edvardsson,[1] Wei Wang,[2,3] Zhi Wei,[2,3] Hakon Hakonarson.[3] *[1]Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland; [2]New Jersey Institute of Technology, Newark, NJ; [3]The Children's Hospital of Philadelphia, Philadelphia, PA.*

**Background:** Adenine phosphoribosyltransferase (APRT) deficiency is a rare autosomal recessive disorder of purine metabolism, characterized by nephrolithiasis and/or chronic kidney disease (CKD). Despite an estimated heterozygote carrier rate of 0.4–1.2%, only a handful of cases have been identified in many countries, including the US. The aim of this study was to estimate the prevalence of APRT deficiency based on frequencies of mutated APRT alleles in genomic databases.

**Methods:** We searched for 47 reported *APRT* mutations in two large databases of genome sequences available in the public domain, the 1000 Genome Project (n=1092) and the NHLBI GO Exome Sequencing Project (n=6503). Minor allele frequencies (MAF) <0.01% were determined and the heterozygote carrier frequency defined as the sum of pathogenic alleles. The prevalence rate of homozygous genotypes was calculated using the Hardy-Weinberg principle.

**Results:** In the two databases combined, 5 mutations were detected with MAF <0.01% that were predicted to have pathogenic effects on the protein function. The rare pathogenic *APRT* alleles are shown in the Table.

| No. | Position | MAF (%) | Homozygous frequency (%) | Base change | Amino acid change | Location | Mutation |
|---|---|---|---|---|---|---|---|
| 1 | 88876549 | 0.0077 | 0.00005929 | 1759T → C | L110P | Exon 4 | Missense |
| 2 | 88876953 | 0.0077 | 0.00005929 | 1355C → T | R67X | Exon 3 | Nonsense |
| 3 | 88876886 | 0.0005 | 0.00000025 | 1422G → A | R89Q | Exon 3 | Missense |
| 4 | 88876532 | 0.0005 | 0.00000025 | 1776G → A | A116T | Exon 4 | Missense |
| 5 | 88876902 | 0.0005 | 0.00000025 | 1406G → A | V84M | Exon 3 | Missense |

Considering only rare pathogenic variants yielded a homozygous frequency of 0.00005929–0.00011858%, suggesting an overall disease prevalence in the range of 1/8,000 to 1/17,000.

**Conclusions:** These data indicate a prevalence of APRT deficiency in the range of 1 in 8,000 to 1 in 17,000. Thus, APRT deficiency appears to be a seriously underrecognized cause of kidney stones and CKD.

## FR-PO719

**Estimated Incidence of Primary Hyperoxaluria Using Population Allele Frequencies of Disease Variants**

Katharina Hopp,[1] Andrea G. Cogal,[1] Hakon Hakonarson,[2] Dawn S. Milliner,[1] Peter C. Harris.[1] *[1]Mayo Clinic; [2]Children's Hospital of Philadelphia.*

**Background:** Primary Hyperoxaluria (PH) is a rare recessive condition characterized by oxalate buildup plus ESRD and caused by mutations to *AGXT* (PH1), *GRHPR* (PH2), and *HOGA1* (PH3). Clinical prevalence is estimated at 1 to 3 per million but the true disease frequency is unknown.

**Methods:** We have used allele frequencies reported in the NHLBI Exome Sequencing and the 1000 Genome Project to better estimate the incidence rate (IR) and carrier frequency (CF) of PH. This is based on published pathogenic PH alleles and data obtained within Mayo's RKSC PH Registry. Additionally, we scored the likely pathogenicity of non-synonymous variants with a minor allele frequency (MAF) <0.01% using *in silico* tools. Variants scoring as highly likely pathogenic were considered as PH mutant alleles.

**Results:** Based on published pathogenic variants an overall PH CF of ~1:84 with an IR of ~1:28,079 was determined. Including predicted mutations the CF/IR increase to ~1:70 and ~1:19,361, respectively. Interestingly, PH is predicted to be ~69% less prevalent in African American (AA) than in European American (EA) (EA: CF ~1:72, IR ~1:20,206; AA: CF ~1:129, IR ~1:66,200), due to two common EA alleles, *AGXT* p.G170R (MAF 0.1%, CF 1:429) and *HOGA1* c.700+5G>T (MAF 0.3%, CF 1:165). The *AGXT* p.R289H variant is the most prevalent AA allele and accounts for ~41% of AA mutant alleles (MAF 0.2%, CF 1:289; EA CF 1:1,956). When separated by type, PH1 and PH3 have comparable CF's (~1:174 vs ~1:204) and IR's (~1:119,714 vs ~1:165,029), while PH2 is ~94% less prevalent (CF ~1:807, IR ~1:2,602,898). Including scored likely pathogenic variants for PH2 may provide a better estimate of CF (~1:462) and IR (~1:851,037), since its rarity limits the number of mutations seen in the clinic. Interestingly, within the RKSC PH Registry, PH1 is 8 times more prevalent than PH3, highlighting a great underdiagnosis of PH3, presumably due to its milder phenotype.

**Conclusions:** PH is more common than previously estimated, suggesting that the disease is underdiagnosed/non-penetrant, especially in the case of PH3.

*Funding:* NIDDK Support, Other NIH Support - NACTS

**FR-PO720**

**Phenotype-Genotype Correlations in Primary Hyperoxaluria**
Andrea G. Cogal, Katharina Hopp, Eric J. Bergstralh, Barbara M. Seide, Julie B. Olson, Alicia Meek, Dawn S. Milliner, Peter C. Harris. *Mayo Clinic, Rochester, MN.*

**Background:** Primary Hyperoxaluria (PH) is a recessive disease characterized by the accumulation of renal oxalate and often resulting in ESRD. Three PH loci have been identified: *AGXT* (PH1), *GRHPR* (PH2), and *HOGA1* (PH3), however, limited data is available on the extent that genetic factors dictate phenotype.

**Methods:** The Rare Kidney Stone Consortium PH Registry has 367 patients with a clinical diagnosis compatible with PH. Of these, 299 were screened for mutations in the known genes. Disease variables were evaluated to derive phenotype-genotype correlations at the genic and allelic level.

**Results:** Of the analyzed patients, 74.4% were PH1, 9.8% PH2, 9.3% PH3, and 6.5% no mutation detected (NMD) but with a characteristic PH phenotype. PH1 patients had more severe disease with a higher proportion of ESRD at diagnosis (31.1%, compared to 8.3%, 0% and 4.2% for the other PH types, respectively; P<0.0001). Also, the median 24h urine oxalate was highest in the PH1 group (2.0 mmol/1.73m$^2$,compared to 1.5, 1.3 and 1.3, respectively; P=0.0001), and median 24h urine Ca was lowest in that group (54mg/1.73m$^2$), compared to 70, 109 and 161 in the other groups (P<0.0001). Interestingly, no PH3 proband carried two truncating changes, whereas 11.3% of PH1 and 60% of PH2 probands did; suggesting lethality associated with complete loss of *HOGA1*. Differences in age at diagnosis between PH1 mutation types was highly significant (P=0.0001); cases with two likely mistargeting variants had the mildest disease (median 32.4y) compared to 6.9y with two truncating mutations, 6.5y with one truncating and one mistargeting and 10.2y with two non-mistargeting, in-frame. Urine oxalate and Ca levels were lowest and highest, respectively, in the two mistargeting mutation group. No strong allelic effects were seen in the smaller PH2 and PH3 groups.

**Conclusions:** As larger PH populations are collected, the significance of genic effects for diagnostics and prognostic becomes clearer. The combinations of mutations in PH1 are also a key indicator of the disease course and can potentially help target therapies, highlighting the value of molecular diagnostics in this disease.

*Funding:* NIDDK Support, Other NIH Support - National Center For Advancing Translational Sciences (NCATS)

**FR-PO721**

**Sustained Pyridoxine (VB6) Response in Primary Hyperoxaluria Type 1 (PH1) Recipients of Kidney Alone Transplantation (KTx)**
Elizabeth C. Lorenz, John C. Lieske, Eric J. Bergstralh, Dawn S. Milliner. *Mayo Clinic, Rochester, MN.*

**Background:** PH1 patients homozygous for the G170R mutation develop normal or near normal urine oxalate (Uox) with VB6. The purpose of this study was to examine the efficacy of long-term VB6 in G170R homozygous patients after KTx.

**Methods:** G170R homozygous patients enrolled in the Rare Kidney Stone Consortium PH Registry who underwent KTx were included. Patients were maintained on VB6 post-KTx. Uox was monitored.

**Results:** 5 G170R homozygous patients underwent KTx between 9/99-11/11. Median age was 39 yrs (range 22-67), 80% were female and 80% received LD KTx. One patient was on VB6 prior to ESRD. Median follow-up was 8.2 yrs (range 1.6-13.4). Median VB6 dose was 7.7 mg/kg/d (range 5.4-9.4). At end of follow-up, 4 grafts were functioning and 1 graft (patient 5) failed due to rejection.

| Patient | Follow-up (yr) | Mean Uox post-tx (mmol/d) | Mean Pox post-tx (mcmol/L) | Last Uox (mmol/d) | Last eGFR (ml/min/1.73m$^2$) | Allograft biopsies |
|---|---|---|---|---|---|---|
| 1 | 11.8 | 0.5±0.2 (n=14) | 2.2±1.3 (n=14) | 0.4 | 45 | Protocol bx 60.7 mos: no CaOx |
| 2 | 1.6 | 1.2±0.6 (n=7) | 13.4±6.4 (n=16) | 0.7 | 31 | Protocol bx 0 mos: no CaOx<br>Protocol bx 1.0 mos: rare CaOx<br>Protocol bx 6.1 mos: rare CaOx<br>Protocol bx 18.8 mos: no CaOx |
| 3 | 8.2 | 0.5±0.1 (n=21) | 2.2±1.0 (n=19) | 0.4 | 69 | Protocol bxs (5 between 0-61.0 mos): no CaOx |
| 4 | 13.4 | 0.4±0.2 (n=12) | 4.0±3.2 (n=10) | 0.3 | 27 | For-cause bx 37.0 mos: no CaOx |
| 5 | 2.2 | n/a | n/a | n/a | n/a | For-cause bx 26.5 mos: rejection, moderate CaOx |

Uox remained normal or near normal in the majority of patients throughout follow-up. The Uox of 1 patient who received standard 3 times per wk hemodialysis without VB6 for 1 yr prior to KTx did not normalize until 9 months post-KTx. However, her allograft biopsy 1.6 yrs post-KTx demonstrated no CaOx and only mild fibrosis.

**Conclusions:** Patients homozygous for the G170R mutation demonstrate sustained response to VB6 following KTx. The majority of allograft biopsies showed no evidence of recurrent oxalosis and long-term graft outcomes were excellent. Thus KTx with VB6 should be considered in PH1 patients homozygous for the G170R mutation.

*Funding:* NIDDK Support, Other NIH Support - National Center For Advancing Translational Sciences (NCATS)

**FR-PO722**

**Acute Intermittent Porphyria: An Underdiagnosed Cause of Chronic Tubulo-Interstitial Nephritis**
Alexandre Karras,[1] Nicolas Pallet,[2] Eric Thervet,[1] Hervé Puy.[3] *[1]Nephrology, Hôpital Européen Georges Pompidou, Paris, France; [2]Biochemistry, Hôpital Européen Georges Pompidou, Paris, France; [3]Centre Francais des Porphyries, Hopital L Mourrier, Colombes, France.*

**Background:** Acute Intermittent Porphyria (AIP) is a rare inherited disorder of heme biosynthesis. This autosomic dominant disease is frequent (1/1600 in Western Europe) but most cases are asymptomatic or undiagnosed. Chronic kidney disease (CKD) is frequent among patients with AIP, but there is no large epidemiological study to determine the prevalence of kidney dysfunction in this population.

**Methods:** In collaboration with the French National Reference Center for Porphyria, a large coss-sectionnal study was conducted among 415 AIP patients with proven hydroxymethylbilane synthase deficiency and available laboratory data, including a serum creatinine measurement. Renal Insufficiency (RI) was determined as an estimated GFR<60 ml/min/1.73m2 (according to MDRD).

**Results:** RI prevalence in the entire AIP study population was 26.5%. Distribution of RI patients in different CKD stages was : CKD 3a in 53%, CKD 3b in 38%, CKD 4 or 5 in 9%. RI was more frequent in female (35%) than in male (9%) patients (OR 5.44), in symptomatic (48%) than in asymptomatic (9%) patients (OR 9.33). Prevalence of kidney disease increases with age : among female AIP patients, prevalence of MDRD<45 is 0% before the age of 40 yrs, 14% between 40 and 60 yrs , 28% after the age of 60. These risk factors are cumulative, yielding a 65% prevalence of RI among the 52 female symptomatic AIP patients aged >60. Patients with RI have a mean proteinuria of 0.39±0.32 g/24h, and are hypertensive in 93% of cases. Renal biopsy, when performed, shows mainly tubulo-interstitial lesions. For the 12 patients that reached ESRD, the mean age at dialysis initiation was 58±11. Six patients underwent kidney transplantation, without recurrence of tubulointerstitial nephritis on the renal allograft.

**Conclusions:** Renal involvement is frequent in AIP, especially among female patients. As AIP symptoms are unconstant and non specific, a screening for a deficiency of heme metabolism should be performed in all patients with unexplained chronic tubulo-interstitial nephropathy.

**FR-PO723**

**Functional Modeling of Compound Heterozygous KCNJ1 (ROMK1) Mutations Identified in a Kindred with Bartter's Syndrome**
Shalabh Srivastava,[1] Ann Marie Hynes,[1] Dimin Li,[2] Paul A. Welling,[2] John Andrew Sayer.[1] *[1]Institute of Genetic Medicine, Newcastle Univ, Newcastle-Upon-Tyne, United Kingdom; [2]Dept of Physiology, Univ of Maryland Medical School.*

**Background:** We report clinical, genetic and biophysical data relating to Pakistani kindred with Bartter's Syndrome.

**Methods:** A multiplex family was identified with biochemical and clinical features suggestive of Bartter's syndrome. The eldest sibling presented with developmental delay and rickets at 3 years of age with biochemical evidence of hypercalciuria and hypokalemia. The second sibling had a similar presentation. She went on to develop gestational diabetes and advanced renal impairment by 18 years of age. The third child was born after premature delivery with a history of polyhydramnios and was initially diagnosed with hypocalcemia. Following treatment she developed hypercalciuria and a hypokalemic metabolic alkalosis. There was evidence of secondary hyperreninemia and hyperaldosteronism in all 3 siblings consistent with Bartter's syndrome. Known Bartter's syndrome genes were screened.

**Results:** We detected a compound heterozygous missense changes in KCNJ1 gene, encoding the potassium channel ROMK1. The S219R/L220F mutation segregated from father and mother, respectively. In silico modeling of the missense amino acids suggested deleterious changes. Studies in Xenopus oocytes revealed that both S219R and L220F had a deleterious effect on KCNJ1 mediated potassium currents. Co-injection to mimic the compound heterozygosity produced a synergistic decrease in channel function.

**Conclusions:** In a multiplex family with Bartter's syndrome, we identified a compound heterozygous mutation in KCNJ1. Functional studies confirmed the pathogenicity of these mutations.

**FR-PO724**

**A Novel Homozygous FAH R237Q Missense Associated with Chronic Form of Tyrosinaemia Type 1**
Jie Ding, Fang Wang, Yong Yao, Yanqin Zhang. *Dept of Pediatrics, Peking Univ First Hospital, Beijing, China.*

**Background:** Autosomal-recessive tyrosinaemia type I, characterized by liver and renal tubular damage and neurological crises, is caused by a defect in the enzyme fumarylacetoacetate hydrolase (FAH). The aim of this study was to characterize FAH gene mutation in a Chinese boy with chronic form of tyrosinaemia type 1 and his family.

**Methods:** An 8-year-old boy of unrelated healthy Chinese parents developed X-type legs at the age of 4. There was no history of neonatal jaundice and he had never been transfused. At age 8, physical examination showed this patient had hepatomegaly, 4 cm below the costal margin in the right midclavicular line. Moreover, the skeletal deformities were noted, such as ribs valgus, X-type legs, and thickening of the wrists. The results of the laboratory tests performed were as follows: aspartate aminotransferase was normal, alkaline phosphatase 1671 U/L (<750 U/L), and AFP 566.1 ng/ml (0–20 ng/ml). In plasma, there was normal level of tyrosine and phenylalanine, but decreased phosphorus (0.38 mmol/L; 1.45–2.1 mmol/L). Urinary succinylacetone, 4-hydroxyphenylpyruvate

and 4-hydroxyphenyllactate were elevated. Aminoaciduria, phosphaturia and distal renal tubular acidosis were also detected. Abdominal MRI examination revealed diffuse hepatic parenchymal nodular changes and enlarged bilateral kidneys. Morphology and size were normal in the spleen. In addition, skeletal X-ray showed bone changes of rickets. All exons of FAH with adjacent intron–exon junctions were analyzed using direct sequencing.

**Results:** DNA analysis in our patient and his younger brother (clinically asymptomatic at the age of 5 months) revealed a homozygous G-to-A transition at nucleotide 710 in exon 9 of the FAH gene that leads to a R237Q substitution in the resulting protein. The carrier status of both the parents was revealed by sequencing the respective PCR product. The mutation R237Q was not detected in 100 Chinese control chromosomes.

**Conclusions:** Our report extends the phenotypic and genotypic spectrum of tyrosinaemia type I.

## FR-PO725

**The Efficient Use of Oxygen in the Kidney Is Impaired in Claudin-2 Deficient Mice** William J. Welch,[1] Lei Pei,[2] Glenn Solis,[1] Lynn Magenheimer,[2] Alan S.L. Yu.[2] *[1]Medicine, Georgetown Univ, Washington, DC; [2]The Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** The proximal tubule (PT) is responsible for 65-70% of reabsorption of the glomerular filtrate, much of it driven by active transcellular transport processes requiring ATP and oxygen. However, a portion of PT transport is facilitated by passive paracellular movement of ions and fluid through tight junctions. Claudin-2, an integral membrane protein expressed in tight junctions of the PT functions as a paracellular cation channel and mediates Na+ movement from the lumen to the peritubular space.

**Methods:** We hypothesized that claudin-2 enhances the efficiency of renal oxygen consumption by promoting paracellular uptake of Na+. We calculated the ratio between whole kidney Na+ reabsorption ($T_{Na}$ = GFR X PNa) and oxygen consumption (QO2 = RBF X A-VO2) in anesthetized wild type (n=8) and claudin-2 KO mice (n=9).

**Results:** GFR (WT: 845±45 vs KO: 915±48 µl/min/g kw, ns), RBF (WT: 6.9±0.6 KO: 6.7±0.7 ml/min/g, ns) and MAP (WT: 102±5 vs KO: 106±6 mmHg, ns) were not different between strains. $T_{Na}$ was similar between strains (WT: 133±15 vs KO: 142±34 µmol/min/g, ns), whereas $Q_{O2}$ was higher in KO mice (WT: 17.5±1.5 vs KO: 29.6±2.1 µmol/min/g, $p<0.01$), resulting in lower $T_{Na}/Q_{O2}$ in claudin-2 deficient mice (WT: 7.26±0.66 vs KO: 4.96±0.77 µmol/µmol, $p<0.01$). Renal $O_2$ extraction was also higher in KO mice (WT: 2.5±0.4 vs KO: 4.0±3 µmol/min, $p<0.01$).

**Conclusions:** These data show that the efficient use of oxygen to reabsorb $Na^+$ in the kidney is reduced in mice deficient of claudin-2. Further these data suggest that paracellular movement of $Na^+$ is an important pathway for PT reabsorption of $Na^+$.

**Aldosterone Upregulates Claudin-4 Expression and Decreases Paracellular $Na^+$ Permeability in the Renal Cortical Collecting Duct** Madhumitha Rajagopal, Alan S.L. Yu. *Internal Medicine, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Aldosterone upregulates $Na^+$ reabsorption in the renal cortical collecting duct by increasing transcellular $Na^+$ transport. Whether it also regulates paracellular transport pathways is largely unexplored. Paracellular permeability is known to be mediated by tight junction membrane proteins called claudins. We used the murine cortical collecting duct cell line (mpkCCDc14), to study the effect of aldosterone on paracellular $Na^+$ permeability and the role of claudins.

**Methods:** We treated mpkCCDc14 cells with aldosterone or vehicle. In the presence of apical amiloride, which blocks transcellular $Na^+$ permeability, the transepithelial resistance (TER) reflects paracellular ion permeability. We measured TER with an electronic volt/ohm meter and mounted cell sheets on an Ussing chamber to calculate paracellular $Na^+$ and $Cl^-$ permeabilities. We used immunoblotting to measure changes in claudin expression.

**Results:** Aldosterone treated cells had 51.5 ± 4.3% higher TER than vehicle treated cells (9147 ±383 Ω.cm$^2$ compared to 6564 ± 295 Ω.cm$^2$). These cells also showed a 45.5 ± 2.8 % lower paracellular $Na^+$ permeability ($P_{Na}$), than vehicle treated cells ($p < 0.005$). Of the claudins known to be expressed in the collecting duct, aldosterone caused a 3.5 fold increase in protein expression of claudin-4 (which behaves as a $Na^+$barrier and $Cl^-$ pore) but did not change expression of claudin-3, -7 -8 or -10. The aldosterone-mediated increase in TER was almost completely reversed by treatment with the steroid receptor antagonist, RU486. Treatment with SGK1 inhibitor, GSK650394 significantly decreased TER in both aldosterone- and vehicle-treated cells suggesting a role for SGK1 in modulating the decrease in $P_{Na}$.

**Conclusions:** In summary, our data suggests that aldosterone might signal via SGK1 to upregulate claudin-4 expression and thereby decrease paracellular $Na^+$ permeability in the collecting duct. A decrease in paracellular $Na^+$ permeability would reduce back-flux of actively reabsorbed $Na^+$, significantly enhancing net $Na^+$ reabsorption.

**AUP1 Promotes Polyubiquitination and ER-Associated Degradation of NKCC2** Elie Seaayfan, Sylvie Demaretz, Nadia Defontaine, Kamel Laghmani. *INSERM UMRS 872; CNRS ERL 7226; Univs Paris V, Paris VI, Paris, France.*

**Background:** Mutations in the apical Na-K-2Cl co-transporter, NKCC2, cause type I Bartter syndrome (BS1), a life-threatening kidney disease. Yet the mechanisms underlying the regulation of NKCC2 trafficking in renal cells are scarcely known. We have previously shown that export from the ER constitutes the limiting step in the maturation and cell surface expression of NKCC2. Indeed, the majority of newly synthesized NKCC2 proteins is trapped in the ER and destined for ER associated degradation (ERAD). The aim of the present study was to identify the protein partners specifically involved in ERAD of NKCC2.

**Methods:** Protein-protein interactions were investigated by the yeast two-hybrid system (Y2H) and co-immunoprecipitation assay (Co-IP). The expression of NKCC2 protein was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging.

**Results:** Using the Y2H, we identified ancient ubiquitous protein 1(AUP1), as a specific binding partner of NKCC2. AUP1 is a member of a protein family that contains the coupling of ubiquitin conjugation to ER degradation domain (CUE)**.** Co-IP assay showed that endogenously expressed AUP1 interacts mainly with NKCC2 immature forms. Accordingly, immunocytochemistry analysis showed co-localization of the proteins mainly in the ER. Co-expression with dominant negative AUP1 decreased the cotransporter polyubiquitination and increased the amount of total NKCC2 protein. Cycloheximide chase assay demonstrated that the marked increase in the cotransporter protein levels was essentially due to decreased protein degradation of NKCC2 immature forms. Consistent with this, knockdown of endogenous AUP1 by small interfering RNA decreased the polyubiqitination of NKCC2 and increased therefore its expression. Finally, inactivation of the CUE domain of AUP1 prevented its action on NKCC2.

**Conclusions:** In summary, our results demonstrate the presence of an AUP1 mediated ERAD pathway in renal cells promoting polyubiqitination and degradation of immature NKCC2 proteins. The identification and selective modulation of ERAD components specific for NKCC2 and its disease causing mutants might provide novel therapeutic strategies for the treatment of BS1.

## FR-PO728

**Regulation of NKCC2 Activity by Inhibitory SPAK Isoforms: KS-SPAK Is a More Potent Inhibitor Than SPAK2** James A. McCormick. *Medicine (Nephrology and Hypertension), Oregon Health & Science Univ, Portland, OR.*

**Background:** The WNK-SPAK/OSR1 pathway plays an important role in the regulation of ion homeostasis, and the maintenance of extracellular fluid volume and blood pressure. SPAK and OSR1 phosphorylate and activate the cation chloride cotransporters NKCC1, NKCC2 and NCC. Two putative inhibitory SPAK isoforms have been identified, Kidney-Specific SPAK (KS-SPAK) which lacks the majority of the full-length SPAK kinase domain, and SPAK2, which only lacks the initial portion of the kinase domain. Both isoforms are highly expressed in kidney, but their functional relevance is unclear.

**Methods:** We tested the ability of KS-SPAK and SPAK2 to inhibit the activity of NKCC1 and NKCC2 in *Xenopus* oocytes. $^{86}$Rubidium uptake experiments were performed under hypotonic low chloride (160 mOSM), isotonic (210 mOSM), or hypertonic (340 mOSM) conditions.

**Results:** While KS-SPAK strongly inhibited activity of NKCC2 at all tonicities (by 60-72%), SPAK2 only inhibited its activity, mildly, under hypotonic low chloride conditions (18%). Since it was reported that SPAK2 strongly inhibits NKCC1 activity, we compared the effects of KS-SPAK and SPAK2 on NKCC1 and NKCC2 activity under hypotonic low chloride conditions, which maximally activate full length SPAK/OSR1. KS-SPAK inhibited uptake by both cotransporters to a similar degree (84% and 88% respectively). In contrast, SPAK2 exerted a significantly greater effect on NKCC1 (77% inhibition) than on NKCC2 (23% inhibition). Truncation of SPAK2 revealed that deletion of the catalytic loop resulted in an inhibitory effect on NKCC2 similar to that of KS-SPAK (61% and 65% inhibition respectively). For KS-SPAK, mutagenesis studies showed that a WNK phosphorylation site in KS-SPAK (S133) is not required for its ability to inhibit NKCC2 activity, but residues involved in its interactions with cation cotransporters (D238 and L252) are required for its inhibitory effect. Finally, coimmunoprecipitation experiments showed that both KS-SPAK and SPAK2 associated with NKCC2.

**Conclusions:** These data reveal that while both KS-SPAK and SPAK2 interact with NKCC2, SPAK2 is a relatively weak inhibitor of NKCC2 activity. This difference may be physiologically important.

## FR-PO729

**Salt Loading Alters Renal Expression of Tamm-Horsfall Protein, $Na^+$, $K^+$, $2Cl^-$ Cotransporter and Cyclooxygenase-2** James M. Bates, Satish Kumar. *Dept of Medicine/Nephrology Section, Univ of Oklahoma HSC and VA Medical Center, Oklahoma City, OK.*

**Background:** The American diet contains more salt than recommended. The thick ascending limb of the loop of Henle (TAL) plays a critical role in renal sodium handling. It has constitutive expression of $Na^+$, $K^+$, $2Cl^-$ cotransporter (NKCC2) and Tamm-Horsfall Protein (THP), and inducible expression of cyclooxygenase-2 (COX-2). We investigated the effect of high salt on NKCC2, phosphorylated NKCC2 (pNKCC2) and COX-2 in THP-deficient (THP $^{-/-}$) and wild-type (THP $^{+/+}$ ) mice.

**Methods:** Six THP $^{-/-}$ and THP $^{+/+}$ mice were fed high salt diet (HS,8% NaCl) for 8 months with 6 THP $^{-/-}$ and THP $^{+/+}$ mice on normal salt diet (NS, 0.4%) as controls. Kidney homogenates were processed to obtain membrane and microsomal fractions. Western Blot analysis was performed for NKCC2, pNKCC2 , COX-2 and THP. The data were statistically compared by Student's t-test and two-way analysis of variance.

**Results:** In the THP$^{+/+}$ mice, membrane-bound THP increased on HS (NS THP$^{+/+}$ 0.233 ± 0.07 vs HS THP$^{+/+}$ 0.45 ± 0.1, P = 0.021). Membrane-bound NKCC2 was elevated in THP$^{-/-}$ mice on NS and HS (NS THP$^{+/+}$ 0.07 ± 0.06 vs THP$^{-/-}$ 0.18 ± 0.03, P = 0.005, HS THP$^{+/+}$ 0.03 ± 0.005 vs THP$^{-/-}$ 0.063 ± 0.013, P = 0.015 ) , and decreased by HS in both THP $^{-/-}$ and THP $^{+/+}$ mice (genotype factor significance, F = 15.45, P = 0.0008; salt factor significance, F = 17.62, P = 0.0004, no interaction). Membrane-bound pNKCC2 was similar between THP $^{-/-}$ and THP $^{+/+}$ mice on NS and lower in THP$^{-/-}$ mice on HS (NS THP$^{+/+}$ 0.78 ± 0.15 vs THP$^{-/-}$ 0.70 ± 0.13, P = 0.3, HS THP$^{+/+}$ 1.68 ± 0.31 vs THP$^{-/-}$ 0.84 ± 0.27, P = 0.03). It was increased by HS in THP$^{+/+}$ mice (NS 0.78 ± 0.15 vs HS 1.68 ± 0.31, P = 0.013). Microsomal COX-2 was reduced in THP$^{-/-}$ mice on NS and similar between THP $^{-/-}$ and THP $^{+/+}$ mice on HS (NS THP$^{+/+}$ 0.4 ± 0.10 vs THP$^{-/-}$ 0.2 ± 0.03, P = 0.015, HS THP$^{+/+}$ 0.4 ± 0.1 vs THP$^{-/-}$ 0.34 ± 0.04, P = 0.3). It was increased by HS in THP$^{-/-}$ mice (NS 0.2 ± 0.03 vs HS 0.34 ± 0.04, P = 0.03).

**Conclusions:** Renal expression of THP is increased with chronic salt loading suggesting a role for it in sodium handling. More studies are needed to define the interactions among THP, NKCC2 and COX-2 in TAL.

## FR-PO730

### The Sodium Chloride Cotransporter and Epithelial Sodium Channel Associate in a Complex in the Distal Convoluted Tubule

Robert S. Hoover, Hui-fang Bao, Brandi M. Wynne, Rickta Mallick, Douglas C. Eaton, Abinash C. Mistry. *Emory Univ School of Medicine, Atlanta, GA.*

**Background:** The sodium chloride co-transporter (NCC) and the epithelial sodium channel (ENaC) are two key sodium transporting proteins in the distal tubule of the mammalian kidney. Hyperactivity of either protein results in hypertension and hypoactivity results in hypotension. These two proteins are co-expressed in the second part of the distal convoluted tubule (DCT2), and are regulated by many of the same proteins. However, associations between the two have not been investigated. Therfore we investigated whether these proteins associate.

**Methods:** We utilized confocal microscopy, immunoprecipitation, and immunoblotting to asess the interaction between NCC and the subunits of ENaC.

**Results:** Utilizing a recently defined model of the mammalian DCT (mDCT15 cells) that natively expressess DCT2 proteins, including NCC and the alpha, gamma and beta subunits of ENaC, we demonstrated this association. We immmunoprecipitated NCC utilizing our immunopurified polyclonal anti-NCC antibody. Immunoblotting the immunoprecipitated sample for alpha ENaC revealed clear presence of alpha ENaC. Lysate for mDCT15 cells also demonstrated expression of alpha ENaC. Immunoprecipitation with resin only and no antibody had no ENaC. The Na-K ATPase pump and GAPDH were present in the lysate, but not the IP sample. Immunoprecipitating with anti-alpha ENaC antibody and immunoblotting with anti-NCC antibody demonstrated presence of NCC, confirming the association. Immunoprecipitating a mouse kidney cortex sample with anti-NCC antibody pulled down alpha and gamma ENaC, confirming the association in vivo. Confocal microcospy demonstrated colocalization of NCC and gamma ENaC in DCT2 cells in mouse.

**Conclusions:** NCC and ENaC co-immunoprecipitate, both in a cell culture model and in mammalian kidney cortex. This data demonstrates that these proteins associate, likely in a sodium transporting complex. This novel association between ENaC and NCC that could alter our understanding of salt transport in the distal tubule.

## FR-PO731

### Augmented Calcium-Binding Protein 39 (Cab39) Expression in Renal Tubule Contributes to Salt-Sensitive Hypertension through Activating N(K)CC

Sung-Sen Yang,[1,2] Yu-wei Fang,[2] Min-hua Tseng,[2] Chih-jen Cheng,[1] Shih-Hua P. Lin.[1,2] *[1]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, Taipei, Taiwan; [2]Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, Taiwan.*

**Background:** Enhanced SPAK and OSR1 kinases phosphorylation in vivo by WNK4 may lead to salt-sensitive hypertension through activating their substrates Na-(K)-(2)Cl cotransporter [N(K)CC]. Recently, it was shown that a ubiquitously expressed Cab39 protein could stimulate N(K)CC through activating SPAK/OSR1 but independent of WNK1/4 in *in vitro* study. The purpose of this *in vio* study is to uncover the physiological role of Cab39 on the regulation of SPAK/OSR1 and N(K)CC, especially in the renal tubules.

**Methods:** We generated and analyzed the kidney tubule-specific cadherin gene promoter driven flag-tagged mouse Cab39 transgenic (Tg) mice fed with normal rodent chaw. At age of 10-12 wks, phenotype including blood pressure as well as serum electrolytes was measured with or without 0.9%NaCl in tap water ad libitum.

**Results:** We obtained 8 strains of Cab39 Tg mice. However, offspring could not be got from the Cab39 Tg mice with the abundance of flag-tagged mCab39 over 50% of endogenous wild-type (WT) Cab39. Thus we chose a strain with the mildly overexpressed abundance of the flag-Cab39 (25% ±6%) in this study. With tap water, the Cab39 Tg mice were phenotypically normal but a slightly increased p-SPAK/OSR1, p-NKCC2 and p-NCC in the kidneys was found. When these mice drunk 0.9%NaCl water for 5 days, a significantly elevated blood pressure (155 ±8% in Cab39 Tg vs 135 ±7% mmHg in WT n=6, p<0.05) and slightly hyperkalemia (4.6 ±0.5 in Cab39 Tg vs 4.1 ±0.6% mEq/l in WT n=6, p=0.16) were observed in the Cab39 Tg mice. Although the amount of WT and flag-Cab39 was not affected in the kidneys of both WT and Cab39 Tg mice, the expression of p-SPAK/OSR1, p-NKCC2 and p-NCC was suppressed in WT mice but not affected in Cab39 Tg mice.

**Conclusions:** Augmented Cab39 expression in renal tubule may lead to salt-sensitive hypertension through activating SPAK/OSR1-N(K)CC signaling. Whether WNK1/4 is independent in the activating SPAK/OSR1- N(K)CC complex by the Cab39 in vivo merits further evaluation.

## FR-PO732

### Co-Localization and Fluorescence Resonance Energy Transfer Demonstrate Interaction between the Sodium Chloride Cotransporter and the Epithelial Sodium Channel

Brandi M. Wynne,[1] Alexa L. Mattheyses,[2] Abinash C. Mistry,[1] Rickta Mallick,[1] Robert S. Hoover.[1] *[1]Medicine, Renal Div, Emory Univ, Atlanta, GA; [2]Dept of Cell Biology, Emory Univ, Atlanta, GA.*

**Background:** Regulation of systemic blood pressure occurs predominately via renal maintenance of sodium and water balance. The sodium chloride cotransporter (NCC) and the epithelial sodium channel (ENaC), are both primary mechanisms for sodium reabsorption and have been found to be expressed apically in the late distal convoluted tubule (DCT2). Hyperactivity of sodium reabsorption by either protein can produce increases in blood pressure. Classically, these transporters have been thought to work independently of each other. However, regulatory systems such as aldosterone and angiotensin II for both NCC and ENaC contain appreciable overlap. Preliminary data from this laboratory suggests an interaction as shown by co-immunoprecipitation. Thus, we hypothesized that NCC and ENaC may be co-localized intracellularly, as well as interacting with each other.

**Methods:** To test this hypothesis, COS-7 cells were co-transfected with vectors containing either: GFP-tagged NCC and/or mCherry-tagged subunits of ENaC α or β. Co-localization experiments were performed along with fluorescence resonance energy transfer (FRET) acceptor photobleaching (Nikon 1AR, Emory Integrated Cellular Imaging Core).

**Results:** Transfection of COS-7 cells with GFP-tagged NCC and one subunit of mCherry-tagged ENaC (α or β) revealed significant intracellular co-localization of NCC with each ENaC subunit. Furthermore, using FRET acceptor photobleaching technology in the dual transfected (NCC+ENaC α or β), NCC+mCherry vector only or ENaC α only transfected cells, we observed a significant increase ($p<0.05$, ANOVA) in EGFP fluorescence following mCherry photobleaching. Cells co-transfected with NCC and ENaC α or β exhibited more than a 23% increase in EGFP fluorescence, as compared to NCC+mCherry vector only expressing (9.1% ± 1.9) cells.

**Conclusions:** These novel data suggest an intimate association and possible interaction between NCC and the α and β subunits of ENaC, which may influence our understanding of salt transport in the distal nephron.

## FR-PO733

### Hydrochlorothiazide Lowers Blood Pressure Predominantly in Volume Depleted States via Extra Renal Mechanisms That Are Independent of Na-Cl Co-Transporter (NCC)

Saeed Alshahrani,[1] Kamyar A. Zahedi,[2] Sharon L. Barone,[2] Jie Xu,[2] Manoocher Soleimani.[2] *[1]Dept of Pharmacology, Univ of Cincinnati, Cincinnati, OH; [2]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH.*

**Background:** Hydrochlorothiazide (HCTZ) is an inhibitor of NCC in the distal nephron, and the most commonly used diuretic for treatment of mild hypertension. With regard to the antihypertensive effect of thiazides some investigators suggest that the primary mechanism is extra-renal and via direct vasodilatation, whereas others emphasize that the initial diuresis and salt depletion is necessary, indicating that vasodilatation is secondary to ECF contraction. We propose that HCTZ reduces blood pressure largely via extra-renal effects that are exaggerated in volume-depleted states, and that these effects are independent of NCC inhibition.

**Methods:** Age and sex matched wild type (WT), Pendrin KO, NCC KO and NCC/Pendrin double knock out (dKO) mice, which are severely volume depleted, were treated with HCTZ (40mg/kg/day) for 4 days. Balanced studies were performed and urine samples were analyzed for salt and fluid excretion. In parallel studies the blood pressure (BP) was determined by computerized tail cuff method.

**Results:** 24hr salt and urine production did not change significantly in WT mice treated with HCTZ. In NCC/pendrin-dKO mice, HCTZ caused multiple systemic derangements, including a significant reduction in urine output and salt excretion. The reduction in urine output of dKO mice as a result of HCTZ treatment was accompanied by a significant drop in their BP. WT mice did not display any significant effect on their BP in response to HCTZ treatment. HCTZ did not have a significant effect on BP of pendrin- or NCC-KO mice, both of which have normal vascular volume, but it increased the urine output in pendrin-KO mice, indicating the important role of pendrin in compensatory salt absorption in response to NCC inhibition/ablation.

**Conclusions:** 1. HCTZ reduces BP independent of the kidney function and NCC inhibition. 2. The antihypertensive effect of HCTZ is exaggerated in volume-depleted states. 3. Current studies will test the hypothesis that thiazides activate the vasodilatory signaling pathway(s) in volume-depleted states.

## FR-PO734

**Regulation of NCC by Angiotensin II in Response to Low K Diet** Jie Liu,[1] Richard A. Coleman,[1] P. Richard Grimm,[1] Eric J. Delpire,[2] Paul A. Welling,[1] James B. Wade.[1] *[1]Dept of Physiology, Univ of Maryland School of Medicine, Baltimore, MD; [2]Dept of Anesthesiology, Vanderbilt Univ School of Medicine, Nashville, TN.*

**Background:** Low K diet stimulates the renal NaCl cotransporter (NCC) by an unknown mechanism. Since the STE20/SPS-1-related proline-alanine-rich protein kinase (SPAK) can function to stimulate NCC by phosphorylation of specific N-terminal sites, we investigated if the acute response of NCC to low K diet is mediated by SPAK and is associated with changes in angiotensin II.

**Methods:** Using phospho-specific antibodies in Western blot and immunolocalization studies of wild type (WT) and SPAK$^{-/-}$ mice fed a low K or control diet for 4 days, we examined the effect of K diet on expression and phosphorylation of NCC and SPAK. Levels of angiotensin II and aldosterone were measured by enzyme immunoassay.

**Results:** In WT, we found that Low K diet more than doubled total NCC expression and phosphorylation of NCC at the T58 site. This was associated with an increase in total SPAK expression in cortical homogenates and an increase in phosphorylation of SPAK at the S383 activation site. By contrast, Low K diet had no effect on NCC or pNCC in SPAK knock-out mice. The increased NCC abundance and phosphorylation with low dietary potassium occurred concomitantly with an increase in angiotensin II but not aldosterone.

**Conclusions:** These findings indicate that SPAK is a critical mediator of increased pNCC in dietary K restriction. The findings support the idea that low K increases angiotensin II to increase SPAK-dependent phosphorylation of NCC. Such a response would limit Na/K exchange in CNT/CCD segments to limit urinary K loss with Low K diet.

*Funding:* NIDDK Support

## FR-PO735

**Ovarian Steroids Recover the NaCl Cotransporter Activation/ Phosphorylation in Gonadectomized Female Rats** Lorena Leonor Rojas,[1] Luis Antonio Reyes Castro,[2] Juliette Hadchouel,[3] Elena Zambrano,[2] Gerardo Gamba.[1] *[1]Molecular Physiology Unit, INNSZ-IIB, UNAM, Mexico City; [2]Reproductive Biology Dept, INNSZ, Mexico City; [3]INSERM, Paris, France.*

**Background:** The thiazide-sensitive NaCl cotransporter NCC is subjected to sexual dimorphic regulation in rats. One study showed that response to thiazide diuretics was higher in female than in male rats (JASN, 1994) and another revealed, in the distal convoluted tubule, that NCC expression of ovariectomized rats is increased by estradiol (JCI, 1998). Little is known, however, about the mechanisms and the role of other female hormones.

**Methods:** We analyzed in rats the NCC activity by urinary response to bendroflumethiazide (BFTZ), as well as the total and phospho-T58 NCC, total and phospho-S383-SPAK expression, using specific antibodies, in proteins from kidneys of control and gonadectomized male and female rats, four weeks after sham or gonadectomy. Wild type and prolactin receptor knockout (PRLR$^{-/-}$) female and male mice were also studied. Serum radioimmunoanalysis confirmed the absence of sex hormones in gonadectomized animals. To assess if ovarian hormones or prolactin restore the activity/phosphorylation of NCC, ovariectomized rats were treated with 30 µg/kg of 17-β-estradiol or 50 mg/kg of progesterone i.p for three weeks, or one adenohypophisis was transplanted into the renal capsule to produce hyperprolactinemia.

**Results:** The urinary response to BFTZ was higher in female than in male rats. No difference was observed in total NCC expression, but phospho-T58-NCC was significantly higher in female than in male rats. This was associated with increased expression and p-S383 SPAK in female rats. The differences were eliminated by ovariectomy. No effect of orquiectomy on NCC and SPAK expression/phosphorylation was observed. NCC phosphorylation in ovariectomized rats was recovered by 17-β-estradiol and progesterone administration. Hyperprolactinemia did not recover NCC phosphorylation. In addition, the higher NCC phosphorylation in female rats persisted in PRLR$^{-/-}$ animals.

**Conclusions:** We conclude that sexual dimorphic increase of NCC phosphorylation in female rats is dependent on ovarian steroidal hormones, with little to no participation of prolactin.

## FR-PO736

**Clinical Significance of Urinary Thiazide-Sensitive Na-Cl Cotransporter (NCC) Measurement by Newly Developed Enzyme-Linked Immunosorbent Assays** Kiyoshi Isobe, Takayasu Mori, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** Na-Cl cotransporter (NCC) in the distal tubules in kidney is known to be excreted in urine. However, its clinical significance has not been established because of the lack of quantitative data of urinary NCC.

**Methods:** We developed highly sensitive enzyme-linked immunosorbent assays (ELISAs) for urinary total NCC (tNCC) and its active form, phosphorylated NCC (pNCC).

**Results:** We first measured the excretion of tNCC and pNCC in urinary exosomes in pseudohypoaldosteronism type II (PHAII) patients since PHAII is caused by NCC activation. Highly increased excretion of tNCC and pNCC was observed in PHAII patients, indicating that both assays could detect the increases of urinary NCC excretion caused by NCC activation in the kidney. Then, we measured tNCC and pNCC in the urine of outpatients with chronic kidney disease (CKD). Urinary pNCC was positively correlated with the estimated glomerular filtration rate (eGFR) and became undetectable when eGFR was less than 16.8 ml/min/1.73 m$^2$, which is consistent with the clinical observation that thiazide has less effect in patients with such low eGFR. pNCC excretion was also found to be negatively correlated with the fractional excretion of sodium. These data in CKD patients further validate that the ELISA systems for urinary NCC are valuable tools for estimating NCC activity in vivo. Moreover, an link between serum phosphorus and urinary NCC was observed.

**Conclusions:** Thus, the measurements of NCC, especially pNCC, in human urinary exosomes would provide novel information about the status and the regulation of NCC in the human kidney.

*Funding:* Government Support - Non-U.S.

## FR-PO737

**Unscrambling the Molecular Mechanism of Calcineurin Inhibitors-Induced Hypertension after Kidney Transplantation** Pedro San-Cristobal,[1] Marleen L.A. Kortenoeven,[2] Robert A. Fenton,[2] Joost Hoenderop,[1] René J. Bindels.[1] *[1]Physiology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Biomedicine, Aarhus Univ, Aarhus, Denmark.*

**Background:** To survive, end stage renal disease patients must immediately undergo either: *a*) dialysis treatments or *b*) kidney transplantation. Transplantation is currently the best method of treatment. Calcineurin inhibitors (CNI) are the foundation of immunosuppressive management after transplantation. CNI diminish the graft rejection rate, but have serious side-effects leading to a phenotype similar to Pseudohypoaldosteronism II. Overactivity of the thiazide-sensitive NaCl cotransporter (NCC) is the postulated mechanism of action. Indeed, patients with CNI-induced hypertension exhibit features that fit with an augmented activity of NCC.

**Methods:** We developed a unique procedure to isolate a highly enriched preparation of fluorescently labelled distal convoluted tubules (DCT) from transgenic mice employing an advanced tubular sorter. Using primary cultures of these isolated segments, a reproducible methodology to measure NCC-mediated $^{22}Na^+$ reabsorption in DCT cells was established.

**Results:** Our data showed that incubation with 5 µM CNI (Cyclosporine A or Tacrolimus) significantly stimulates the thiazide-dependent $^{22}Na^+$ transport across the primary DCT cultures. The recorded response to CsA was higher compared to control groups treated with hypotonicity, or angiotensin II (NCC stimulatory maneuvers). In line with our hypothesis, 100 µM hydrochlorothiazide added to the media prevented the NCC enhanced response. Furthermore, time courses from 1.5 to 24 hr showed similar enhanced $^{22}Na^+$ transport. Finally, in mouse kidney lysates CsA phosphorylated NCC in a dose and time response.

**Conclusions:** This study supports the hypothesis that CNI-induced hypertension is caused by a rise in NCC activity involving a phosphorylation of the amino-terminal domain at Threonine 58. In parallel, produce a molecular hallmark of the mechanism involved in CNI-induced hypertension. This could be the first step towards designation and implementation of future clinical trials to develop new guidelines for transplanted patients.

*Funding:* Government Support - Non-U.S.

## FR-PO738

**KLHL3 Modulates Kidney-Enriched WNK Kinase Isoforms to Modulate NCC** Chong Zhang,[1] Nick Meermeier,[1] Andrew Terker,[1] Maria Chavez-Canales,[3] Gerardo Gamba,[3] Juliette Hadchouel,[2] David H. Ellison,[1] Chao-Ling Yang.[1] *[1]Nephrology & Hypertension, Oregon Health & Science Univ, Portland, OR; [2]Paris Cardiovascular Research Center, INSERM-U970, Paris, Namibia; [3]Molecular Physiology Unit, Universidad Nacional Autónoma de México,, Mexico City, Mexico.*

**Background:** Mutations of two components of the cullin-RING ligase complex, Cul3 and KLHL3, cause familial hyperkalemic hypertension (FHHt). It has been reported that WNK1 and WNK4 bind to KLHL3, fostering ubiquitylation and degradationvia the proteasome. It has been postulated that the FHHt-causing KLHL3 or Cul3 mutations impairtheir ability to ubiquitylate WNKs, leading to accumulation of WNK1 and WNK4, activating NCC.

**Methods:** We used transient transfection in HEK293 cells followed by western blotting. We also used overexpression in Xenopus oocytes, with measurement of 22Na uptake.

**Results:** Surprisingly, KLHL3 did not affect endogenous WNK1 and WNK3 in HEK293 cells, although it degraded WNK4 strongly. Alternative splicing generatesdifferent isoforms of WNK kinases in a tissue-specific manner, so we compared effects of WNK1, KS-WNK1, and a WNK1 D11, an isoform highly expressed in the kidney. We also tested forms of WNK3expressed preferentially in brain(B-WNK3) and kidney (K-WNK3). Like WNK4, K-WNK3 and WNK1 D11 were degraded more than 70% at the protein level, whereas L-WNK1 was unchanged. We have reported WNK kinase form signaling complex via protein interaction and phosphorylation to regulate NCC activity. In the mammalian or Xenopusoocyte expression system, WNK4 inhibits NCC, whereas WNK1 and WNK3 activate it. Since WNK isoforms, regulated by KLHL3, are all expressed in the DCT, mutations in KLHL3 must affect not only WNK4, but also WNK1 D11 and K-WNK3. In agreement with this hypothesis, co-expression of wild type KLHL3 reduced Na uptake in oocytes expressing NCC. In contrast, FHHt-mutant KLHL3 stimulated Na uptake to more than 150%, suggesting that the mutations are not simply loss of function.

**Conclusions:** KLHL3 exerts differential effects on renal and extrarenal WNK isoforms; FHHt-mutant KLHL3 mutations may exert dominant effects on NCC activity.

## FR-PO739

**Acidic Motif in WNKs Are Crucial Components for the Binding with KLHL3** Akihito Ohta,[1] Shinichi Uchida,[1] Sei Sasaki,[1] Dario Alessi.[2] *[1]Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]MRC Protein Phosphorylation Unit, College of Life Sciences, Univ of Dundee, Dundee, United Kingdom.*

**Background:** Pseudohypoaldosteronism typeII (PHAII) is an autosomal-dominant disorder characterized by hyperkalemia, metabolic acidosis, and hypertension. WNK1 and WNK4 gene mutations were reported to cause PHAII. Lifton and another group identified KLHL3 and CUL3 mutations in PHAII, suggesting these two proteins may also form CRL E3 complex that regulates blood pressure. After these reports, we started to search for KLHL3-interacting partner and analyze how these KLHL3-CUL3 complex are related to the pathogenesis causing PHAII.

**Results:** We generated Wild-type KLHL3 and mutant KLHL3 expressing 293 cell lines and immunoprecipitated KLHL3 interacts with CUL3 and WNKs. Some KLHL3 mutations causing PHAII lost the binding with WNKs but WT- KLHL3 could bind with WNKs in 293 cell. To further analyze which parts of WNK1 interact with KLHL3, WNK1 fragments were co-transfected in WT-KLHL3 293 cell lines and found WNK1(479-667) fragment containing coiled-coil domain could bind WT-KLHL3. WNK1 fragments mutated in E633K ,D635A and Q636E which are same sites reported in PHAII WNK4 patients, also transfected in KLHL3 cell and immunoprecipitated mutated WNK1 fragments could lose binding ability of WT-KLHL3, indicating these mutated sites in not only WNK4 but WNK1 also are important for the KLHL3 interaction. To narrow the site which part interacts between WNK1 and KLHL3, small WNK1 fragments in WNK1(479-667) were transfected and found that acidic motif in WNK1 should be crucial for the bind with WT-KLHL3. With the evidence that this motif are conserved in another WNKs(WNK1-4), WT-KLHL3 or PHAII mutant (N529K) KLHL3 were transfected in WNK2, WNK3 293 cell lines and found WNK2 or WNK3 could bind WT-KLHL3 but not mutant KLHL3 (N529K).

**Conclusions:** These results indicate that acidic motif in WNKs are crucial components for the binding with KLHL3 and speculating that abolishing the ability to interact between WNKs and KLHL3 in PHAII, modulating the ubiquitilation WNK isoforms cause that the accumulation of WNKs which leads to abnormal sodium absorption in kidney causing hypertension.

## FR-PO740

**Low Salt Intake Decreased Transcription and Protein Level of KLHL3 in Mouse Kidney** Koichiro Susa, Eisei Sohara, Moko Zeniya, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** WNK-OSR1/SPAK-NaCl cotransporter (NCC) signal cascade is important for regulating salt balance and blood pressure in the body. It is well known that low salt diet activates and high salt diet inhibits this cascade, leading to regulation of sodium reabsorption through NCC. Recently, we found that Cullin3-KLHL3 E3 ligase complex interacted with acidic motif of WNK kinase family and induced WNK4 ubiquitination, leading to reduction of the WNK4 protein level. However, physiological regulation of KLHL3 by dietary salt intake is still unclear. In this study, we sought to determine whether dietary salt intake regulates the transcription the protein level of KLHL3.

**Methods:** Male C57BL/6J mice fed high-salt, normal or low-salt diet were sacrificed, and their kidneys were dissected. The protein expression levels of KLHL3, WNK1, WNK4 were determined by immunoblots. mRNA levels of KLHL3 were determined by real-time PCR.

**Results:** Both mRNA and protein level of KLHL3 were decreased in the kidney of mice fed low-salt diet, compared to those fed normal diet. Concomitantly, WNK1 and WNK4 protein levels were increased in the kidney of mice fed low salt diet, indicating that decreased expression of KLHL3 resulted in increased protein expression of WNK1 and WNK4 under low-salt diet, leading to activation of WNK-OSR1/SPAK-NCC phosphorylation cascade. On the contrary, protein levels of KLHL3 were increased in the kidney of mice fed high salt diet, although mRNA was not increased. WNK1 and WNK4 protein levels were not decreased in the kidney of mice fed high salt diet neither.

**Conclusions:** We demonstrated that low-salt intake decreases the transcription and the protein level of KLHL3 in mouse kidney. This could be one of the physiological mechanisms how low salt diet activates WNK-OSR1/SPAK-NCC phosphorylation cascade.

## FR-PO741

**Modest Increase in Plasma [$K^+$] Reduces Na-Cl Cotransporter (NCC) and STE20/SPS1-Related Proline Alanine-Rich Kinase (SPAK) Phosphorylation and Drives Kaliuresis and Natriuresis** Alicia A. McDonough,[1] Srinivas Rengarajan,[1] Donna Lee,[1] Youngtaek Oh,[2] Jang Youn.[2] *[1]Cell and Neurobiology, Keck School of Medicine of USC, Los Angeles, CA; [2]Physiology, Keck School of Medicine of USC, Los Angeles, CA.*

**Background:** Dietary potassium ($K^+$) loading results in rapid kaliuresis, natriuresis and diuresis. We aimed to test the hypothesis that the diet provoked increase in plasma [$K^+$] *per se* drives the acute kaliuresis in Sprague Dawley rats.

**Methods:** In the first protocol, after overnight fast, rats were fed a 2% $K^+$ meal for 3 hr and compared to control rats fed a 0% $K^+$ meal. In the second protocol, plasma [$K^+$] was raised by tail vein infusion over a period of 3 hr to 5.5 ± 0.12 mEq in overnight-fasted conscious rats to mimic the change measured after meal feeding; controls were also fasted and received a matched amount of saline.

**Results:** The 2% $K^+$ meal increased plasma [$K^+$] from 4.01±0.12 to 5.18±0.16 mEq, with no change in plasma [$Na^+$] or kallikrein; The 2% $K^+$ meal also decreased abundance of phosphorylated NCC (NCCp) and cortical SPAK (SPAKp) to 40% and 60% of control, respectively; abundance of cortical Na/H exchanger 3 (NHE3), Na-K-2Cl cotransporter (NKCC), NKCCp, epithelial $Na^+$ channel (ENaC) subunits and renal outer medulla $K^+$ channel (ROMK) were unchanged. Raising plasma [$K^+$] by tail vein infusion also provoked significant kaliuresis and natriuresis compared to controls, decreased NCCp and SPAKp to 40% and 60% of control, respectively, and did not alter NHE3, NKCC, NKCCp, NCC or SPAK.

**Conclusions:** In summary, a modest increase in plasma [$K^+$], equivalent to that observed in response to a single $K^+$ rich meal, triggers renal kaliuretic and natriuretic responses likely driven by decreased abundance of SPAKp and NCCp. These changes can drive tubular $Na^+$ reabsorption from the distal convoluted tubule to the collecting duct where $Na^+$ reabsorption drives $K^+$ secretion. We conclude that a modest increase in plasma [$K^+$] can drive acute homeostatic kaliuresis via depressing NCCp and activity.

## FR-PO742

**A Dithiothreitol-Sensitive Kidney Protease Cleaves SPAK to Regulate NaCl Co-Transporters** Nicolas Markadieu,[1] Paul A. Welling,[2] Eric J. Delpire.[1] *[1]Anesthesiology, Vanderbilt Univ, Nashville, TN; [2]Physiology, Univ of Maryland, Baltimore, MD.*

**Background:** Distal $Na^+$ transport in the mammalian kidney is mediated in part by Na-K-2Cl and Na-Cl cotransporters. The cotransporters are regulated by a variety of dietary conditions and hormones that converge to their phosphorylation and activation. SPAK and OSR1 are Ste20-like serine/threonine kinases which bind, phosphorylate, and activate NKCC2 and NCC. The molecular size of SPAK is slightly larger than the size of OSR1, due to the presence of an N-terminal proline-alanine rich domain. In kidney medulla, SPAK also exists as smaller C-terminal fragments, which identities are not fully understood.

**Methods:** Recombinant SPAK proteins were purified from bacteria and incubated with cell extracts under different conditions. Proteolytic cleavage was monitored by Western blot analysis.

**Results:** We show that protein lysates prepared from mouse kidney possess protease activity that leads to the cleavage of SPAK into several fragments. The size of these fragments is consistent with the size of the fragments observed in mouse kidney. The activity is not present in protein lysates prepared from brain, liver, and spleen. The activity is also found in rabbit and human kidney lysates. We also show that the activity is time and concentration-dependent, and occurs at temperatures ranging from 4°C to 45°C. The protease activity is resistant to a variety of protease inhibitors such as aprotinin, leupeptin, pepstatin, PMSF and EDTA. The activity is also insensitive to doxycycline and $CuSO_4$, suggesting that it is likely not due to the activity of a metalloprotease. Finally, we show that the activity is prevented by the reducing agent dithiothreitrol (DTT) and this effect can be reversed by treatment with N-ethylmaleimide or 5,5'-dithiobis-(2-nitrobenzoid acid) (DNTB). As cleavage is observed using a cystein-less SPAK protein, the DTT effect indicates the presence of key sulfhydryl groups within the protease.

**Conclusions:** Our data indicate that the SPAK fragments observed in kidney could be the product of kidney-specific protease(s). Efforts are taken to identify the sites of cleavage and the identity of the protease(s) involved.

## FR-PO743

**Aldosterone Modulates NCC via Altering Its Interaction with 14-3-3 Gamma** Xiuyan Feng,[1,4] Yiqian Zhang,[3] Matthew Lee,[1,4] Guangping Chen,[2] Dingying Gu,[3] Hui Cai.[1,2,4] *[1]Renal Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Dept of Physiology, Emory Univ School of Medicine, Atlanta, GA; [3]Dept of Nephrology, The 2nd Affiliated Hospital, Wenzhou Medical Univ, Wenzhou, Zhejiang, China; [4]Renal Section, Atlanta VA Medical Center, Decatur, GA.*

**Background:** 14-3-3 gamma belongs to a family of multifunction regulatory proteins that mainly bind to phosphorylated Ser/Thr residues in the target proteins. Aldosterone was shown to increase NCC abundance via SGK1 and Nedd4-2 pathway. Interaction of Nedd4-2 with 14-3-3 was shown to involve the regulation of epithelial sodium channel (ENaC). Previous data have shown that 14-3-3 disrupted Nedd4-2-mediated ubiquitination of ENaC, leading to increase in ENaC activity.

**Methods:** Cell cultures, transfection, immunoprecipitation and western blot analysis were used in the study.

**Results:** To determine whether 14-3-3 is involved in aldosterone-mediated regulation of NCC, we have tested the effect of 14-3-3 gamma on NCC protein expression. We found that 14-3-3 gamma down-regulated total NCC and membrane NCC protein expressionsin a dose-dependent manner in HEK293 cells transiently transfected with GFP-NCC and 14-3-3 gamma plasmids. Aldosterone treatment (10 μM, for 3 hours) increased both total and membrane NCC protein expression in HEK293 cells transfected by GFP-NCC and 14-3-3 gamma, while decreasinginteraction of NCC with 14-3-3 gamma. We also found that aldosterone increased both total and membrane NCC expression via decreasing NCC ubiquitination.

**Conclusions:** These data suggest that aldosterone increases NCC expression through deceasing binding of 14-3-3 gamma to NCC, and therefore decreasing NCC ubiquitination.

## FR-PO744

**RNA Profiling Reveals Compensatory Up-Regulation of Intercalated Cell Transcriptome in SPAK-Null Mice Having a Gitleman-Like Phenotype** P. Richard Grimm,[1] Eric J. Delpire,[2] James B. Wade,[1] Paul A. Welling.[1] [1]*Physiology, Univ of Maryland School of Medicine, Baltimore, MD;* [2]*Anesthesiology, Vanderbilt School of Medicine, Nashville, TN.*

**Background:** An adaptive increase in salt reabsorption preserves salt balance when the thiazide-sensitive sodium-chloride cotransporter (NCC) is lost in Gitleman Syndrome or NCC phosphorylation is lost in Ste20/SPS-1 related proline-alaine-rich protein kinase (SPAK) null mice. To explore the mechanism of adaptive salt reabsorption, global-transcriptome analysis of the renal cortex from WT and SPAK-null animals was performed.

**Methods:** RNA was extracted from the cortex of SPAK-null and WT littermate mice, microarray analysis was performed using Affymetrix GeneChip (Mouse Gene 1.0 ST) containing probes of all mouse genes and analyzed on an Affymetrix GeneChip 3000 system. Quality control analysis, Robust Multi-array Averaging, and Linear Model for Microarray based differential expression analysis were subsequently performed. The altered expression of highlighted genes was verified by RT-PCR.

**Results:** Statistical analysis indicated that 176 genes were down-regulated and 263 genes were up-regulated significantly in the SPAK-null cohort compared to WT. Intercalated cell (ICs) markers, transporters and enzymes were especially prevalent, including pendrin, the sodium-dependent chloride bicarbonate exchanger, anion-exchanger 4, carbonic anhydrase 4 and 15, and the B1-, C2-, G3-, and d2-subunits of the V-type $H^+$-ATPase. Significantly, these transport components represent a system recently proposed to facilitate thiazide-sensitive sodium-chloride reabsorption in the β-ICs. These changes were paralleled by an increase in transcript abundance of the β- and γ-subunits of ENaC. Specific distal nephron fate factors and signaling elements were also significantly up-regulated, highlighting potential molecular pathway(s) that underlie the adaptive process.

**Conclusions:** Transcriptome-profiling reveals intercalated cell sodium-chloride transport is up-regulated to preserve sodium balance in the absence of NCC phosphorylation.

## FR-PO745

**Chemical Library Screening for WNK Signaling Inhibitors by Using Fluorescent Correlation Spectroscopy** Takayasu Mori, Eriko Kikuchi, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medical and Dental Sciences, Bunkyo-ku, Tokyo, Japan.*

**Background:** We have shown that WNK-oxidative stress-responsive 1 (OSR1)/STE20/SPS1-related proline-alanine-rich protein kinase (SPAK)-Slc12a transporters cascade regulates blood pressure by controlling vascular tone as well as renal NaCl excretion. Therefore, agents that inhibit this signal cascade could be a new class of antihypertensive drugs. Since the binding of WNK to OSR1/SPAK kinases was postulated to be important for signal transduction, we sought to discover inhibitors of WNK-SPAK binding by screening chemical compounds that disrupt the binding. For this purpose, we established a system capable of high-throughput screening to detect the binding of two molecules.

**Methods:** Fluorescence correlation spectroscopy (FCS) was used to detect the binding. Fluorescent TAMRA-labeled small peptides of WNK4 were mixed with the GST-SPAK with different concentrations in the wells of 384-well microtiter plates.

**Results:** We succeeded in detecting the binding of SPAK to WNK in FCS assay, and we used this newly developed system to screen compounds. As a result of screening 17,000 compounds, we discovered two novel compounds that reproducibly disrupted the binding of WNK to SPAK. To improve the drug activity and toxicity, we performed derivative expansion of the hit compound. One of the 30 derivatives showed more potent inhibitory activity than the hit compound ($IC_{50}$ : 8.1 μM). Furthermore, the derivative showed a dose-dependent inhibitory effect on the phosphorylations of NCC and NKCC1 in the mouse kidney and on NKCC1 phospshorylation in the mouse aorta. These results indicate that the derivative functions in vivo, and the vasodilatory effect was also expected.

**Conclusions:** The compounds obtained in this study could be promising seeds of new types of antihypertensive drugs, and the method that we developed could be applied to any screening to identify compounds that disrupt the binding of two molecules.

## FR-PO746

**Sp1 Trans-Activates and Is Required for Maximal Aldosterone Induction of the αENaC Gene in Collecting Duct Cells** Zhiyuan Yu, Qun Kong, Bruce C. Kone. *The Univ of Texas Medical School at Houston, Houston, TX.*

**Background:** The epithelial Na channel (ENaC) in distal nephron constitutes the rate-limiting step for renal Na reabsorption. Aldosterone increases αENaC transcription in the collecting duct. Af9 binds to +78/+92 of the αENaC promoter and recruits Dot1a to repress basal and aldosterone-sensitive αENaC transcription in mIMCD3 cells. Despite this epigenetic repression, basal αENaC transcription is still evident and physiologically necessary, indicating basal operation of positive regulators.

**Methods:** mIMCD3 cells were treated with vehicle or 1 μM aldosterone, with or without 1 μM spironolactone, in charcoal-stripped medium. Gel shift, antibody competition, ChIP/qPCR and re-ChIP assays were used to measure interactions of Sp1, Dot1a, and Af9 with the αENaC promoter. Af9 and Sp1 binding site mutant promoter-reporter genes were stably transfected in mIMCD3 cells and used for promoter activity and ChIP/qPCR assays. Sp1 levels were manipulated by overexpression and siRNA knockdown.

**Results:** Gel shift and antibody competition assays with a +208/+240 αENaC probe revealed DNA-Sp1-containing complexes. Mutation of +222/+229 abrogated Sp1 binding in vitro and in stably expressed promoter-reporter constructs. Compared to the wild type promoter, a +222/+229 mutant αENaC promoter-luciferase construct lower activity and impaired Sp1 trans-activation. Conversely, Sp1 knockdown inhibited endogenous αENaC mRNA and the activity of the wild type αENaC promoter but not the mutated construct. Aldosterone triggered Sp1 recruitment to the αENaC promoter, which was required for maximal promoter activity and was blocked by spironolactone. ChIP/re-ChIP assays and functional tests of +78/+92 and +222/+229 αENaC promoter mutants indicated that while Sp1, Dot1a, and Af9 co-occupy the αENaC promoter, the Sp1 effects are functionally independent from Dot1a and Af9.

**Conclusions:** Sp1 binding to +222/+229 of the αENaC promoter independently offsets Dot1a-Af9-mediated epigenetic repression to foster basal αENaC transcription in mIMCD3 cells. Moreover, aldosterone-mediated, and mineralocorticoid receptor-dependent enrichment of Sp1 at this element is required for maximal aldosterone induction of the gene.

## FR-PO747

**Biphasic Regulation of the Epithelial Sodium Channel by Inflammation and the IKK/NF-κ Pathway** Hui Li, Eric D. Morrell, Robert S. Edinger, Nuria M. Pastor-Soler, Kenneth R. Hallows. *Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** The kidney collecting duct epithelial sodium channel (ENaC) is critical for hormonal regulation of volume and blood pressure but also responds to pathologic conditions like sepsis-induced inflammation. We have previously shown that the inflammatory mediator IκB kinase-β (IKKβ) stimulates ENaC by phosphorylating the ubiquitin ligase Nedd4-2. Others have observed that the downstream mediator NF-κB inhibits ENaC. To define the time course and mechanisms of ENaC regulation by this pathway, we treated polarized epithelial cells with lipopolysaccharide (LPS) or TNFα, activators of this pathway, or IKK inhibitor and measured ENaC whole-cell and surface expression levels and currents.

**Methods:** Mouse polarized kidney cortical collecting duct ($mpkCCD_{c14}$) and primary airway epithelial cells were cultured on Transwells and then treated with 100 ng/ml LPS or TNFα prior to measurements. Amiloride-sensitive short-circuit currents were measured in Ussing chambers or with an epithelial volt-ohmmeter. Immunoblots, cell surface biotinylation assays and co-immunoprecipitations were performed to measure changes in ENaC whole-cell and apical surface expression and binding to Nedd4-2. Confocal microscopy was performed on immunofluorescently labeled ex vivo kidney slices to examine changes in ENaC subcellular localization in response to IKK modulation.

**Results:** ENaC activity increased at 1 h but decreased by 18 h in response to activation of the IKK/NF-κB pathway by TNFα treatment in primary airway epithelial cells. This decrease correlated with decreased α-ENaC and mineralocorticoid expression. Overnight treatment of $mpkCCD_{c14}$ cells with either TNFα or LPS similarly decreased ENaC currents and also β- and γ-ENaC apical surface expression. TNFα acutely decreased the binding of Nedd4-2 to β-ENaC, an effect that was reversed by treatment with IKK inhibitor. Finally, acute TNFα treatment of kidney slices induced apical translocation of β-ENaC, which was blocked in the presence of IKK inhibitor.

**Conclusions:** Biphasic ENaC regulation by the IKK/NF-κB pathway may help integrate the response of ENaC and epithelial salt transport to hormonal and inflammatory stimuli.

*Funding:* NIDDK Support

## FR-PO748

**ENaC Inhibition Stimulates Conductive H and Cl Secretion in the Mouse Cortical Collecting Duct** Masayoshi Nanami,[1] Hui-fang Bao,[1] Alan Mark Weinstein,[2] Takeshi Nakanishi,[3] Douglas C. Eaton,[1] Susan M. Wall.[1] [1]*Medicine and Physiology, Emory Univ School of Medicine, Atlanta, GA;* [2]*Medicine, Weill Medical College of Cornell Univ, New York, NY;* [3]*Medicine, Hyogo College of Medicine, Nishinomiya, Japan.*

**Background:** Inhibiting the epithelial $Na^+$ channel (ENaC) reduces $Cl^-$ absorption in the cortical collecting duct (CCD). Since ENaC does not transport $Cl^-$, the purpose of this study was to explore how ENaC modulates $Cl^-$ absorption in mouse CCDs perfused in vitro.

**Methods:** Wild type or collecting duct-specific ENaC null mice consumed a NaCl-replete diet or diet with aldosterone administered by minipump. CCDs were perfused in vitro in the presence and absence of an ENaC inhibitor (benzamil, 3 mM) in the luminal fluid.

**Results:** Application of an ENaC inhibitor (benzamil, 3 mM) to the luminal fluid unmasked conductive $H^+$ and $Cl^-$ secretion. Benzamil-sensitive $HCO_3^-$ and $Cl^-$ flux were reduced or abolished with the application of the non-selective $Cl^-$ channel blocker, DIDS, or the $H^+$-blocker, bafilomycin to the perfusate. Similarly, ENaC gene ablation unmasked DIDS-sensitive Cl- secretion. Single channel recordings of intercalated cell apical membrane in split open CCDs demonstrated a stilbene-sensitive $Cl^-$ channel with properties that resembles ClC-5.

**Conclusions:** 1) In CCDs from aldosterone-treated mice, most $Cl^-$ absorption is benzamil-sensitive, 2) Benzamil application stimulates stilbene- and bafilomycin-sensitive conductive secretion of $Cl^-$ and $H^+$, and 3) an intercalated cell apical membrane $Cl^-$ channel may mediate benzamil-sensitive $Cl^-$ secretion.

**FR-PO749**

**An Exon Deletion Activates the Epithelial Sodium Channel** Jingxin Chen, Thomas R. Kleyman, Shaohu Sheng. *Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** Epithelial $Na^+$ channels (ENaC) have essential roles in the regulation of extracellular fluid volume and blood pressure. The three ENaC subunits typically present in functional channel complexes in epithelia are encoded by their corresponding multi-exon genes that have a similar architecture. Common isoforms of all three human ENaC subunits (α, β and γ) are translated from mature mRNAs that are similarly spliced with inclusion of 13 exons. While the channel pore is formed by amino acid residues encoded by exons 2 and 13, ten exons (3 through 12) encode the large extracellular region.

**Methods:** We examined whether exons 3 through 12 were required for functional ENaC expression by generating a series of exon deletions. Human ENaCs with in-frame deletions of individual exon sequences in α subunit cDNAs were expressed in *Xenopus* oocytes and their functional properties were examined by two-electrode voltage clamp.

**Results:** Deletion of any of these exon-encoding sequences eliminated channel activity, with the exception of exon 11 that encodes the knuckle domain. Cells expressing channels with an α subunit exon 11 deletion showed 4-fold greater amiloride-sensitive currents than oocytes expressing wild type (WT) channels. The increased channel activity primarily reflected an increased channel open probability (5-fold greater than WT), as both levels of surface expression and single channel current were similar to WT. Surprisingly, deletion of exon 11 from either the β or γ subunit diminished channel activity, reflecting a reduced level of surface expression.

**Conclusions:** Our results suggest that the α subunit knuckle domain regulates channel gating.

**FR-PO750**

**Specific Inactivation of the Epithelial Sodium Channel (ENaC) in Connecting Tubule: Effect on Sodium and Potassium Homeostasis** Søren Brandt Poulsen,[1] Jeppe Praetorius,[1] Lance Miller,[2] Raoul D. Nelson,[2] Edith Hummler,[3] Birgitte M. Christensen.[1] *[1]Aarhus Univ; [2]Univ of Utah School of Medicine; [3]Univ of Lausanne.*

**Background:** In the kidney, ENaC is crucial for $Na^+$ reabsorption, but it is also involved in the excretion of $K^+$. ENaC is expressed in the late distal convoluted tubule, connecting tubule (CNT), and collecting duct (CD), where it is tightly regulated by the steroid hormone aldosterone. Inactivation of the αENaC subunit in the CD does not disturb $Na^+/K^+$ balance in mice (Rubera et al, JCI 2003). However, αENaC deletion in both the CNT and CD causes symptoms of pseudohypoaldosteronism type 1 as evidenced by disturbance in $Na^+$ and $K^+$ balance on standard and challenging diets (Christensen et al, JASN, 2010).

**Methods:** To further investigate the significance of αENaC in the CNT, mice with Cre-recombinase expressed under the control of the V-ATPase B1-subunit promoter (these mice also express Cre in a portion of the CNT cells, Miller et al, KI, 2009) were crossed with floxed *Scnn1a* mice (Hummler et al, Genesis, 2002). Thus, KO mice with a deletion of αENaC in part of the CNT were generated.

**Results:** Results revealed that at baseline level (standard diet), KO mice showed no difference in urinary $Na^+$ and $K^+$ excretion, urine output, water intake, blood $K^+$, osmolality or aldosterone compared to controls. On low $Na^+$ diet (7 days), however, KO mice showed increased urinary $Na^+$ excretion (on day 5 and 6) but no difference in blood $K^+$ (sampled on day 7). When challenged with high $K^+$ diet (2 days), KO mice decreased their food intake, lost weight, and excreted less $K^+$ through the urine (on day 1 and 2; $P < 0.05$). Moreover, they showed a lower water intake and urine output (on day 1; $P < 0.05$).

**Conclusions:** All baseline levels were unchanged in KO mice deficient for αENaC in part of the CNT, but on challenging diets the KO mice appeared with a phenotype. The phenotype was however less severe compared to mice with αENaC deleted in both the CNT and the CD. This may suggest that expression of αENaC both in the CNT and the CD are important for $Na^+$ and $K^+$ balance.

**Effects of Long-Term Aldosterone Administration on mRNA Expression Levels in the Renal Distal Nephron Examined by FACS and RNA Sequencing** Søren Brandt Poulsen, Jeppe Praetorius, Robert A. Fenton, Birgitte M. Christensen. *Aarhus Univ.*

**Background:** Renal sodium reabsorption and potassium excretion in the distal convoluted tubule 2 (DCT2) and connecting tubule (CNT) are tightly regulated by aldosterone. Previously, microarrays have been used to investigate the regulatory role of aldosterone. However, the emergence of next generation sequencing (RNA sequencing) offers improved sensitivity by employing sequence-based approaches directly determining the mRNA sequence, thus making it possible to generate a more complete catalog of aldosterone regulated genes. In this study, we used FACS sorting and RNA sequencing to identify genes in the DCT2 and CNT not previously known to be regulated by aldosterone.

**Methods:** We used a mouse model expressing EGFP driven by the TRPV5 gene promoter, i.e., the mice expressed EGFP in DCT2 and CNT cells. The mice were administrated saline (n = 7) or 100 μg aldosterone/kg body weight (n = 7) for six days. Following, a population of EGFP positive cells (DCT2 and CNT) was generated using FACS sorting (purity ~90%). The cell population was sequenced using an Illumina High seq 2000 (yield: ~40 mio paired end 100 bp reads.). Finally, data was analyzed using the tophat pipeline (Trapnell et al, Nature Protocols, 2012).

**Results:** Western blotting of cells isolated from whole kidney of aldosterone-administrated mice and corresponding control mice confirmed that NCC and αENaC, which are proteins classically regulated by aldosterone, were increased in abundance ($p < 0.05$). RNA sequencing showed a similar trend for mRNA levels in the DCT2/CNT cell population (NCC: $p = 0.058$; αENaC: $p = 0.147$). Furthermore, RNA sequencing showed an increase in Sgk1 ($p = 0.002$) and a decrease in Nedd4-2 ($p = 0.011$), proteins known to be involved in ENaC regulation. Based on regular *p*-values (significance level set to 0.05) and changes in abundance of ≥ 50%, the RNA sequencing identified 354 genes differentially regulated by aldosterone.

**Conclusions:** Using RNA sequencing, we have identified a high number of genes that are regulated by aldosterone. The data may contribute to a better understanding of the complex regulatory role of aldosterone.

**FR-PO752**

**The Role of Epithelial Sodium Channel ENaC and the Apical $Cl^-/HCO_3^-$ Exchanger Pendrin in Compensatory Salt Absorption in the Distal Nephron in NCC (Na-Cl Cotransporter) KO Mice** Mina Patel- Chamberlin,[1] Kamyar A. Zahedi,[1,2] Sharon L. Barone,[1,2] Manoocher Soleimani.[1,2] *[1]Dept of Internal Medicine, Univ of Cincinnati; [2]Research Services, Veterans Administration.*

**Background:** Lack of NCC function does not cause significant salt wasting under basal conditions. NCC KO mice have increased expression of ENaC and pendrin, suggesting enhanced compensatory salt absorption in the distal nephron. Pendrin/NCC double knockout (KO) mice develop profound salt wasting compared to wild type (WT), NCC KO or Pendrin KO mice, demonstrating the important role of pendrin in compensatory salt absorption in NCC KO mice. We hypothesize that the inhibition of ENaC or down regulation of pendrin can cause significant salt wasting in NCC KO mice.

**Methods:** WT and NCC KO mice were treated with daily injection of amiloride, an ENaC inhibitor, or acetazolamide (ACTZ), a carbonic anhydrase inhibitor (CAI), for 6 days. Animals were subjected to balanced studies. At the end of studies, kidneys were harvested and examined for proteins and mRNAs of interest. Blood samples were collected for electrolytes and acid base analysis.

**Results:** There was an ~80% increase in urine output (UO) in NCC KO compared to WT mice after amiloride treatment (0.74ml vs. 1.29ml, $p<0.02$). Salt excretion increased and urine osmolality decreased more significantly in NCC KO vs. WT mice after amiloride treatment ($p<0.02$). Daily treatment with ACTZ resulted in ~85% reduction of pendrin expression in both WT and NCC KO mice at 6 days of treatment. However, the diuretic response was more exaggerated in NCC KO mice (1.1 ml/day before to 2.3 after ACTZ) ($p<0.01$) vs. WT mice (1.05 ml/day before to 1.30 after ACTZ).

**Conclusions:** 1. ENaC plays an important role in salt reabsorption in NCC KO mice. 2. NCC plays an important role in salt reabsorption in the setting of carbonic anhydrase inhibition, which is associated with increased delivery of salt from the proximal tubule and the down regulation of pendrin. We propose that the combined inhibition or inactivation of NCC and ENaC or NCC and carbonic anhydrase can provide a strong diuretic regimen, particularly in salt retaining conditions (e.g. congestive heart failure and nephrotic syndrome).

**Albumin-Induced Oxidative Stress Prevents Aldosterone-Induced Expression of ENaC in Collecting Ducts of Nephrotic Rats** Khalil Mohammad Udwan, Gaëlle Brideau, Alain Doucet. *Centre de Recherche des Cordeliers, Paris, France.*

**Background:** Puromycin aminonucleoside (PAN) nephrotic rats show high plasma aldosterone and retain sodium via stimulation of ENaC and Na,K-ATPase in the late aldosterone-sensitive distal nephron. PAN nephrotic rats with clamped aldosteronemia (adrenalectomy plus supplementation with constant infusion of aldosterone and dexamethasone) do retain sodium although ENaC is not induced. We evaluated the role of albumin in the regulation of ENaC expression.

**Methods:** Experiments were performed either in cortical collecting ducts (CCD) from control and PAN nephrotic rats or in mCCD cells (mCCDs). Production of reactive oxygen species (ROS) was evaluated through the nuclear labeling with dihydro-ethidium (DHE), and gene expression was quantified by RT-PCR.

**Results:** In mCCDs, apical addition of albumin induces its endocytosis and the production of ROS. Albumin-induced accumulation of ROS was prevented by dynasore, an inhibitor of endocytosis, by apocynin, an inhibitor of NADPH oxidase, and by N acetyl cysteine (NAC), a ROS scavenger. Addition of $H_2O_2$ (0.5-1 mM) altered the basal level of ENaC subunits mRNAs and abolished aldosterone-induced increase in aENaC mRNAs. This suggests that the balance between the plasma level of aldosterone and the cellular oxidative stress controls the expression of ENaC. In CCDs, we observed intracellular albumin and accumulation of ROS in PAN nephrotic rats but not in controls. We also observed high levels of several subunits of NADPH oxidase 2, the main isoforms expressed in CCDs.

**Conclusions:** Luminal endocytosis of albumin in collecting ducts of nephrotic rats triggers oxidative stress, via activation of NADPH oxidase, which counter balances aldosterone-induced expression of aENaC.

## FR-PO754

**Apical Shear-Stress Regulates Sodium Transport in Principal Cells of the Collecting Duct** Thomas Ernandez,[1,2] Alexandra Chassot,[2] Pierre-Yves F. Martin,[1] Eric Feraille.[1,2] *[1]Service of Nephrology, Univ Hospital of Geneva, Geneva, Switzerland; [2]Dept of Physiology and Cellular Metabolism, Univ of Geneva, Geneva, Switzerland.*

**Background:** Sodium (Na) transport in renal tubules is tightly controlled and plays a central role in homeostasis of the body extracellular fluid volume. In addition to the classical neuro-endocrine regulatory inputs (incl. RAA system), other local factors such as apical shear-stress produced by tubular luminal urinary flow might participate to Na homeostasis.

**Methods:** We designed an in vitro experimental setting to explore the effect of apical flow on a cellular model of collecting duct (CD) using the well-described mouse CD cell line mCCDcl1 grown on polycarbonate filters. Directional flow was generated using an orbital shaker delivering a shear stress of 2 dyne/cm2 mimicking physiological luminal flow.

**Results:** We observed a delayed and sustained 40% decrease of the amiloride-sensitive Na current in cells subjected to flow. This was correlated with a significant decrease of ENaC subunits and SGK1 mRNA expression. The flow-mediated Na transport reduction was not prevented by PKD1 or KIF3A silencing, excluding a role of the primary cilium as a mechanosensor in this mechanism. On the other hand, whole-genome transcriptional analysis of wild-type mCCDcl1 cells subjected to flow suggested a role for PKA signaling and PKA substrates phosphorylation including CREB was increased by flow. This was further confirmed by PKA inhibition that partially prevented the flow-mediated decrease of Na transport in vitro as well as the downregulation of ENaC subunits mRNA expression.

**Conclusions:** These results are in line with physiological adaptation reported after unilateral nephrectomy in rodents in which a larger tubular fluid delivery is observed together with an increased CD fractional excretion of Na. We propose that such shear-stress mediated adaptive mechanism is involved in the homeostasis of extracellular fluid volume after nephron reduction.

## FR-PO755

**Primary Cilia Influence the Roles of TRPM3 and TRPV4 in Renal Epithelial Cell Adaptation to Acute Hyperosmolal Stress** Brian J. Siroky,[1] Bradley P. Dixon,[1] Raven Gail Comer,[1] Nancy Kleene,[2] John J. Bissler.[1] *[1]Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Cancer and Cell Biology, Univ of Cincinnati, Cincinnati, OH.*

**Background:** Ability of renal epithelial cells to adapt to changes in extracellular osmolality is critical to cell volume regulation. Primary cilia sense environmental conditions including osmolality, but whether cilia participate in osmotic response in renal epithelial cells is not known. Transient receptor potential (TRP) channels TRPV4 and TRPM3 are osmoresponsive. TRPV4 localizes to cilia in certain cell types, while cellular localization of TRPM3 is not known. We investigated the role of cilia in the adaptive response of renal epithelial cells to acute osmotic stress, and whether TRPV4 and TRPM3 are involved.

**Methods:** TRPV4 and TRPM3 expression was determined in ciliated (176-5) and nonciliated (176-5Δ) murine renal epithelial cells by RT-PCR, and TRPV4 localization was observed by immunocytochemistry. Cells were challenged with 16 hours of osmotic stress at 400 or 500mOsm/kg with NaCl, or maintained under control conditions. This stress was applied in the presence or absence of a TRPV4 agonist, 100nM GSK1016790A, or a TRPM3 agonist, 100μM pregnenolone. Expression of betaine-GABA transporter (*Bgt1*) and aldose reductase (*Akr1b*), osmotic response genes, was measured by qPCR. Aldose reductase expression was confirmed by immunoblotting.

**Results:** Ciliated and non-ciliated cells expressed TRPV4 and TRPM3. TRPV4 was observed in apical and basolateral membranes of both cell types, but was absent from cilia of 176-5 cells. Hyperosmolal stress induced *Bgt1* and *Akr1b* expression several fold in both cell lines. However, this induction was attenuated in non-ciliated cells compared to ciliated cells. Presence of TRPV4 agonist abrogated *Bgt1* and *Akr1b* induction in non-ciliated cells only. Presence of TRPM3 agonist attenuated *Bgt1* and *Akr1b* induction primarily in ciliated cells.

**Conclusions:** These findings suggest that cilia mediate osmotic response in renal epithelial cells, and that TRPM3 is involved in this mechanism. Furthermore, in the absence of cilia, TRPV4 appears to modulate the attenuated osmotic response.

## FR-PO756

**Cholesterol Is a Biomechanical Regulator of Flow-Mediated Prostaglandin E2 (PGE2) Secretion in the Renal Collecting Duct (CD)** Yu Liu,[2] Daniel Armando Flores,[1,2] Rajeev Rohatgi.[1,2] *[1]Medicine, James J. Peters VAMC, Bronx, NY; [2]Medicine, Icahn School of Medicine, New York, NY.*

**Background:** Essential hypertension (HTN) affects millions of adults worldwide, the etiology of which remains obscure. Deficiency in renal prostaglandin E2 (PGE2) synthesis, which augments renal sodium (Na) avidity, is suspected to contribute to essential HTN. Moreover, dyslipidemia and, in particular, hypercholesterolemia is also associated with the development of HTN. Evidence from endothelial cells suggest that cholesterol-rich lipid rafts (LRs) act as flow sensors. Tubular flow rate in collecting ducts (CDs) mediates PGE2 release, and led us to hypothesize that cholesterol, and its incorporation into LRs, regulates mechanostimulated signaling pathways; specifically, suppressing flow-induced PGE2 release that, in turn, enhances Na absorption in the distal nephron.

**Methods:** PGE2 secretion is measured in flow-exposed CD cells and microdissected CDs before and after manipulating plasma membrane cholesterol.

**Results:** Cholesterol extraction of inner medullary CD3 (IMCD3) cells stimulates basal-(cholesterol replete vs. deplete cells; 3.8±0.9 vs. 31.5±1.5 pg/mL PGE2 per μg protein; $p<0.05$) and flow-(cholesterol replete vs. deplete cells; 24.7±2.3 vs. 83.4±16.8 pg/mL PGE2 per μg protein; $p<0.05$) mediated PGE2 release while cholesterol integration suppresses flow-(6.9±0.7 pg/mL PGE2 per μg protein; $p<0.05$) mediated PGE2 synthesis. Cholesterol extraction raised intracellular $Ca^{2+}$ ($[Ca^{2+}]i$) and chelation of $[Ca^{2+}]i$ suppressed cholesterol-dependent PGE2 release, implying that cholesterol extraction raises $[Ca^{2+}]i$ to release PGE2. To validate our *in vitro* experiments *in vivo*, mice were fed a control or high cholesterol diet, injected with isotonic saline to generate high urine flows, and CDs microdissected in media. The PGE2 secreted into the media by CDs from control mice was 221±50 vs. 113±34 pg/mL/mm tubule (n=3, $p<0.05$) from cholesterol fed mice.

**Conclusions:** Plasma membrane cholesterol regulates flow-stimulated PGE2 release in CDs, *in vitro* and *in vivo*, which presumably affects Na transport. We speculate that hypercholesterolemia leads to Na retention and HTN, by suppressing CD PGE2 release.

## FR-PO757

**Long-Term Amiloride Therapy Partially Normalises Chronic Lithium-Induced Nephrogenic Diabetes Insipidus (NDI) in a Rat Model** Priyakshi Kalita,[1] Andrew Bahn,[1] Jennifer J. Bedford,[2] John P. Leader,[2] Robert J. Walker.[2] *[1]Physiology, Univ of Otago, Dunedin, New Zealand; [2]Medicine, Univ of Otago, Dunedin, New Zealand.*

**Background:** Lithium therapy is associated with the development of impaired water handling through to NDI in about 60% of patients prescribed lithium. Lithium down-regulates the expression and synthesis of aquaporin 2 (AQP2), reducing collecting duct water reabsorption. We have previously shown that amiloride, blocking ENaC mediated lithium uptake in the principal cells, partially attenuates NDI after 3 weeks of therapy (1). However, the long-term (5 months) effect of amiloride in this model has not been studied. **Aim:** To investigate the long-term effects of amiloride on chronic lithium induced nephrogenic diabetes insipidus in an established rat model.

**Methods:** Male wistar rats were divided into control, lithium alone and lithium plus amiloride groups (n=6 per group). Lithium was provided in rat chow (60 $mmol \cdot kg^{-1}$ food) for 6 months and amiloride was introduced in drinking water (0.2 $mmol \cdot l^{-1}$) following the establishment of NDI after one-month of lithium treatment and continued for 5 months. Following metabolic studies the rats were euthanised andkidneys processed for histology, immunohistochemistry and western blotting.

**Results:** Amiloride partially restored the urinary concentration from 199±14 $mosm \cdot kg^{-1}$ (lithium alone) to 612±72 $mosm \cdot kg^{-1}$ (lithium + amiloride) vs controls 2258±182 $mosm \cdot kg^{-1}$. This effect was accompanied by a decreased urine output (lithium alone 174±31 $\mu l \cdot min^{-1} \cdot kg^{-1}$ vs amiloride/lithium 54±8 $\mu l \cdot min^{-1} \cdot kg^{-1}$ vs control 11±4 $\mu l \cdot min^{-1} \cdot kg^{-1}$).AQP2 water channel expression examined by western blotting and immunohistochemistry showed a significant decrease (40.37± 2%; $p < 0.01$) in the lithium alone treated rats and it was restored (88.72 ±16 %; $p < 0.01$) with amiloride administration.

**Conclusions:** This study demonstrates a persistent partial recovery from NDI with amiloride over 6 months in long-term lithium treated rats. This has potential clinical significance for the management of patients with lithium-induced NDI.

## FR-PO758

**Pharmacological Blockade of $P2Y_{12}$ Receptor Reverses Lithium-Induced Downregulation of NKCC2, NCC and α-ENaC Protein Abundances in Mice** Yue Zhang,[1] Noel G. Carlson,[1] Bellamkonda K. Kishore,[1] Carolyn M. Ecelbarger.[2] *[1]Univ of Utah & VA Medical Center, Salt Lake City, UT; [2]Georgetown Unv, Washington, DC.*

**Background:** $P2Y_{12}$, is an ADP-activated G protein-coupled receptor (R) that inhibits adenylyl cyclase activity, potentially reducing cellular cAMP levels. We found that $P2Y_{12}$-R protein is expressed in the rodent kidney, and its irreversible blockade by clopidogrel (CLPD; Plavix®), significantly increased urinary concentration and vasopressin (AVP) and AQP2 protein abundance in the kidney, and ameliorated lithium (Li)-induced diabetes insipidus (DI) in rodents. Since Li also affects renal sodium transport, here we examined the effect of CLPD on Li-induced alterations in renal sodium transporters/channels in mice.

**Methods:** Groups of mice (B6D2 strain; n = 5-7/group) were fed Li-added diet (40 mmol/kg chow) with or without addition of CLPD (80 mg/kg bw/day) to drinking water. Other groups were fed regular diet with/without CLPD. After 14 days, major renal sodium transporter, channel, and exchanger expressions were measured by immunoblotting in cortex (Cx) and medullary (Md) fractions. Urinary AVP and PGE2 levels were quantified.

**Results:** The most striking finding was upregulation of the abundance of the thick ascending limb (TAL) Na-K-2Cl cotransporter (NKCC2) by CLPD treatment alone (30 and 137%, respectively in Md and Cx). In the presence of Li, CLPD restored the moderate down-regulation of NKCC2 (19 and 52%, respectively in Cx and Md) to control levels. In addition, in Li-treated mice, CLPD restored the abundance of the thiazide-sensitive cotransporter (NCC) and α-subunit of the epithelial sodium channel (ENaC) in Md. Li-induced increases in urinary AVP and PGE2 were either augmented ($P < 0.001$) or reversed ($P < 0.01$), respectively, by CLPD.

**Conclusions:** CLPD was able to reverse Li-induced down-regulation of major apical proteins involved in sodium reabsorption in the TAL through collecting duct (CD). This effect was not solely the result of increased AVP levels, but appears to be due to re-sensitization of the TAL and CD to AVP action, aided by the reversal of Li-induced increased PGE2 levels. Thus, $P2Y_{12}$-R antagonism may be a promising approach for the treatment of Li-induced DI.

## FR-PO759

**Physiological Roles of Moesin, a Crosslinker between Membrane Proteins and Actin Cytoskeleton in the Electrolytes and Water Reabsorption**
Ryo Hatano, Kotoku Kawaguchi, Shinji Asano. *Dept of Molecular Physiology, Ritsumeikan Univ, College of Pharmaceutical Sciences, Kusatsu, Shiga, Japan.*

**Background:** Moesin is a member of ERM (ezrin-radixin-moesin) family protein, which is known to function as a crosslinker between membrane proteins and actin cytoskeleton. Moesin is expressed in several tissues including kidney, liver, lung, and intestine. In the kidney, moesin is mainly expressed in the endothelial cells, and epithelial cells as proximal tubule cells, although the physiological importance in the kidney still remains unclear. Recently, Carmosino *et al*. reported that moesin but not radixin interacts with the intracellular C-terminal region of $Na^+$-$K^+$-$2Cl^-$ cotransporter (NKCC2) (*Biol Cell*. 104(11): 658-676, 2012). They reported that moesin regulated the exocytosis of NKCC2 in cultured cells, although it is not clear whether moesin regulates the apical surface expression of NKCC2 directly or indirectly. However, it is reported that moesin deficient mice did not exhibit apparent phenotypes in vivo (Doi Y *et al*. *J Biol Chem*. 274(4): 2315-2321, 1999).

**Methods:** In the present study, we investigated the physiological roles of moesin in the functional regulation of NKCC2 using moesin deficient mice.

**Results:** In wild type (WT) mice kidney, relatively low level of moesin was expressed in the thick ascending limb of Henle (TALH) compared to endothelial cells and brush border membrane of proximal tubules, and it co-localized with NKCC2 at apical membrane of TALH. In moesin deficient mice, the apical localization of NKCC2 was disturbed in the TALH. Furthermore, the metabolic cage studies revealed that moesin deficient mice exhibited the urinary losses of electrolytes as $Na^+$, $K^+$, and $Cl^-$ whereas daily urine volume were not different between WT and moesin deficient mice.

**Conclusions:** These results suggest that moesin plays important role in the regulation of electrolytes/water homeostasis in the kidney. Further experiments are required to reveal the detailed mechanism how moesin regulates the apical membrane localization of NKCC2.

## FR-PO760

**Relation between BK-α/β4-Mediated K Secretion and ENaC-Mediated Na Reabsorption**
Donghai Wen, Ryan J. Cornelius, Dianelys Rivero, Steven C. Sansom. *Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.*

**Background:** The BK-α/β4 channel is located in the intercalated cells (IC) of the distal nephron and mediates K secretion when mice are on a high K, alkaline diet. The present studies were conducted to determine whether BK-α/β4-mediated K secretion was dependent on ENaC-mediated Na reabsorption from principal cells.

**Methods:** Wild type (WT) and BK-β4 knockout mice (β4KO) were adapted to a low Na, high K, alkaline diet (LNaHK) for 7-10 days to maximize Na reabsorption-driven K secretion in the aldosterone-sensitive distal nephron. At the end of diet treatment, we gave a 12 hr bolus of vehicle, hydrochlorothiazide (HTZ; 50 mg/kg) or amiloride (5 mg/kg; ENaC inhibitor). Plasma and urine [Na], [K], [amiloride] and osmolality were measured using a flame photometer, HPLC, and osmometer, respectively. Luminal [K] and [Na] in the terminal cortical collecting duct (CCD) were calculated via the formulas: U[K] • POsm / UOsm, and U[Na] • POsm / UOsm.

**Results:** The calculated concentration of amiloride in the lumen of the terminal CCD, determined by HPLC and the plasma and urine osmolalities, was at least 20 μM, which would maximally block ENaC-mediated Na reabsorption. We found that HTZ, which enhanced Na excretion in WT on a control diet, did not affect Na handling in mice on LNaHK. However, amiloride significantly enhanced Na excretion, reduced plasma [Na], and evoked volume depletion in WT and β4KO on LNaHK. The amil-sensitive K secretion to Na reabsorption ratio (-Ks/Nar), calculated from the luminal [K] and [Na] in vehicle and amil-treated mice, was 1.5 in WT and 0.49 in β4KO, which was close to a value of 0.54 found in WT on a control diet.

**Conclusions:** We conclude that the high -Ks/Nar in WT, compared with β4KO, on LNaHK demonstrates a mechanism for BK-α/β4-mediated K secretion in intercalated cells that is driven by ENaC-mediated Na reabsorption in principle cells, by a mechanism likely involving recycling of Na from plasma to lumen.

*Funding:* NIDDK Support

## FR-PO761

**WNK1 Ativates BK Channel Activity through MAPK ERK1/2 Signaling Pathway**
Yingli Liu,[1] Xiang Song,[2] Weihui Niu,[3] Yanling Shi,[1,4] Hui-fang Bao,[2] He-ping Ma,[2] Douglas C. Eaton,[2] Jieqiu Zhuang,[3] Hui Cai.[1,2,4] *[1]Renal Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Dept of Physiology, Emory Univ School of Medicine, Atlanta, GA; [3]Dept of Nephrology, The 2nd Affiliated Hospital, Wenzhou Medical Univ, Wenzhou, Zhejiang, China; [4]Renal Section, Atlanta VA Medical Center, Decatur, GA.*

**Background:** WNK (with no lysine) kinase is one of the serine/threonine kinase family. We have previously shown that WNK4 inhibits BK channel activity through enhancing its degradation via a lysosomal pathway. WNK4 was also found to inhibit BK channel activity which is kinase-dependent and via activating MAPK ERK1/2 and p-38 signaling pathways. However, little is known on the role of WNK1 in the regulation of BK activity.

**Methods:** To determine the role of WNK1 in regulation of BK channel activity, we have investigated the effect of WNK1 on BK channel activity using cell attached single channel recording technique, cell cultures, transfection, siRNA knock-down and western blot analysis.

**Results:** We have found that the knock-down of WNK1 expression in HEK 293 cells stably expressing alpha subunit of BK (HEK BKα cells) channel significantly inhibited both BKα activity (NPo, 0.024 ± 0.036, n=18, compared to the control group, 0.1316 ± 0.0573, n=36, p =0.006) and open probability (Po, 0.0094 ± 0.0098, compared to the control group, 0.0512 ± 0.0573, p<0.001). Western blot analysis showed that knock-down WNK1 significantly inhibited BKα total expression in HEK BKα cells in a dose-dependent manner (1.0 ± 0, 0.848 ± 0.213, 0.422 ± 0.297, n=3, p < 0.05). Over-expression of WNK1 was also shown to increase BKα protein expression in a dose-dependent manner (1.0 ± 0, 1.723 ± 0.136, 2.729 ± 0.385, n=3, p < 0.05) in HEK 293 cells transiently transfected with myc-BKα and HA-WNK1. We also found that WNK1 decreased ERK1/2 phosphorylation in a dose-dependent manner.

**Conclusions:** These data suggest that WNK1 enhanced BKα activity and total protein through inhibiting MAPK ERK1/2 signaling pathway.

## FR-PO762

**Dietary K Changes Modulate BKα Protein Abundance through MAPK Signaling Pathway**
Yanling Shi,[1,5] Yanhui Wang,[3] Matthew Lee,[1,5] Xiuyan Feng,[1,5] Yingli Liu,[1] Dingying Gu,[4] Hui Cai.[1,2,5] *[1]Renal Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Dept of Physiology, Emory Univ School of Medicine, Atlanta, GA; [3]Dept of Nephrology, The First Affiliated Hospital, Wenzhou Medical Univ, Wenzhou, Zhejiang, China; [4]Dept of Nephrology, The Second Affiliated Hospital, Wenzhou Medical Univ, Wenzhou, Zhejiang, China; [5]Renal Section, Atlanta VA Medical Center, Decatur, GA.*

**Background:** Dietary K loading has been shown to increase urinary K excretion. High K diet has been shown to suppress renin-angiotensin system, whereas low K diet stimulates rennin-angiotensin system. High K diet increased BKα activity in rabbit cortical collecting duct (CCD) cells. Inhibiting ERK1/2 and p-38 was found to increase BKα channel activity in rat CCD cells. However, exact mechanism on how dietary K changes modulate BK channel activity remains not entirely clear.

**Methods:** Mice metabolic cage study, cell cultures, transfection, western blot analysis were used for the studies.

**Results:** To investigate the mechanism on how the dietary K changes affect BKα abundance, we have fed mice with low K (K deficient diet), normal K (1.0 %) and high K (10 %) diets for 10 days. After 10 days of dietary K challenges, mice fed with high K diet exhibited a high urinary K excretion, whereas mice fed with low K diet exhibited a low urinary K excretion. We have found that high K diets increased BKα protein abundance (200.03 ± 96.41, n=9, vs normal K group 100.00 ± 28.25, n=8, p=0.01), whereas low K diets decreased BKα abundance (54.39 ± 35.62, n=6, vs normal K group 100.00 ± 12.24, n=6, p=0.01). High K diet decreased p-38 phosphorylation, whereas low K diet increased p-38 phosphorylation. We also found that angiotensin II (Ang II) treatments decreased BKα protein expression in a dose-dependent manner in HEK293 cells transiently transfected with myc-BK plasmids.

**Conclusions:** These data suggest that dietary K changes modulate BKα protein abundance possibly via altering Ang II-mediated p-38 MAPK signaling pathway.

## FR-PO763

**The BK Channel Localizes to Lipid Rafts in the Apical Membrane of the Cortical Collecting Duct**
Rolando Carrisoza-Gaytan,[1] Carlos Schreck,[1] Marcelo D. Carattino,[2] Thomas R. Kleyman,[2] Lisa M. Satlin.[1] *[1]Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Medicine, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

**Background:** The $Ca^{2+}$- and stretch-activated BK channel, present in principal (PC) and intercalated (IC) cells but more abundant in IC, mediates flow-induced K secretion (FIKS) and the enhanced K secretion observed in response to dietary K loading in the cortical collecting duct (CCD). BK channel activity is regulated by membrane cholesterol (Pharmacol Ther 135: 133-150, 2012). Studies by others have shown in non-renal cells that (i) BK channels localize to sphingolipid-cholesterol-rich lipid rafts (LRs) and (ii) channel activity is regulated by the composition and/or integrity of LRs. We hypothesized that BK channels in the CCD localize to LRs which provides a structural foundation for signaling complexes that regulate channel activity.

**Methods:** Single CCDs from NZW rabbits were microperfused in vitro for immunofluorescence labeling of endogenous BKα (the pore forming subunit of the BK channel) and caveolin 1 (Cav-1), a protein marker of LRs, and visualized by confocal microscopy. Monolayers of MDCK C7 and C11 cells (PC and IC models, respectively) were transfected with c-myc-tagged BKα and assayed for colabeling of c-myc and Cav-1. LRs were isolated from MDCK cells by sucrose density fractionation and analyzed by Western blotting (WB) for c-myc and Cav-1; CoIP was also performed using total membrane for c-myc-BK and Cav-1.

**Results:** Endogenous apical BKα colocalizes with Cav-1 in the native CCD. MDCK C11 cells express more recombinant BKα than C7 cells, but in both cell lines, the channel colocalizes with Cav-1. Immunodetectable recombinant BKα and Cav-1 were identified in the same sucrose fraction, corresponding to the migration pattern of LRs. Immunoprecipitation using anti-myc followed by WB demonstrated that Cav-1 and BKα are physically associated.

**Conclusions:** BKα in the CCD localizes to lipid rafts, which we speculate serve as a platform for flow-induced signal transduction leading to FIKS.

## FR-PO764

**Regulatory Adaptation of ROMK Channel in Thick Ascending Limb**
Yuliya Sharkovska, Alexandra Böhlick Böhlick, Kerim Mutig, Sebastian C. Bachmann. *Institute of Vegetative Anatomy, Charite Universitätsmedizin Berlin, Berlin, Germany.*

**Background:** The renal outer medullary potassium channel (ROMK) plays a critical role in the regulation of potassium recycling across the *apical membrane* in thick ascending limb (TAL) of Henle's loop, providing K availability for the action of the luminal Na-K-2Cl cotransporter (NKCC2).

*ROMK localization along rat TAL* has previously revealed a cellular heterogeneity. *Some cells* demonstrated *strong ROMK signal in the apical plasma membrane, whereas* others exhibited little or no immunoreactivity. This study aimed to characterize the expression and regulation of ROMK in the TAL after short- or long-term stimulation of transport by vasopressin (AVP).

**Methods:** Vasopressin-deficient Brattleboro rats were treated with the vasopressin V2 receptor-selective agonist desmopressin (dDAVP) *using* osmotic minipumps for 7-hour (short-term) or 72-hour periods (long-term study). Biosynthesis and cellular distribution of ROMK were studied in the kidneys.

**Results:** Double immunofluorescencelabeling in Brattleboro ratsshowed an intermittent ROMK-immunoreactivity pattern in the apical membrane of TAL, whereas the expression of NKCC2 was continuous. ROMK-deficient portions comprised TAL cells with low or absent signal. Treatment with dDAVP induced the expression of ROMK abundance in parallel with pNKCC2 expression (+130% in cortex and +73% in medulla for long-term study). Numerical evaluation of ROMK and NKCC2 double staining in TAL cells revealed that the ROMK-positive cells were differentially increased in number upon short- and long-term dDAVP treatments. In long-term treated rats, ROMK-positive cells were increased by 21% in cortical and by 35% in medullary TAL. Measuring the inner, ROMK-positive perimeter of TAL profiles, there were increases by 21% and 14%, respectively. Western blot revealed no significant difference of ROMK abundance in the cortex and an 1.7-fold-increase in the outer medulla ($p<.05$ for all values).

**Conclusions:** Our results show that activation of TAL transport by AVP involves the recruitment of ROMK-positive cells in medullary and cortical TAL. The change is considered as an adaptive, regulatory response of the loop of Henle.

## FR-PO765

**Renal Potassium Conservation Is Impaired in a Kidney-Specific Kir4.1 Knock Out Mouse**
Daniel A. Gray, Emily Lambert, Wilson Nino, Jonathan Tran, Anita de Oliveira Silva. *Nephrology, Univ of Rochester.*

**Background:** Mutations in the Kir4.1 potassium channel underlie the SeSAME/EAST syndrome, a neuro-renal condition characterized by hypokalemic, hypomagnesemic metabolic alkalosis. The generalized Kir4.1 knock out mouse lives only to 2-3 wks of age. To better understand the pathophysiology of this syndrome, we therefore developed a kidney-specific Kir4.1 knock out mouse (ksKO).

**Methods:** The ksKO was generated by first crossing a mouse expressing the cadherin 16 promoter, which drives Cre recombinase expression in the distal nephron (P. Igarashi), with a generalized Kir4.1 heterozygote. Offspring that were $Kir4.1^{(+/-)}Cre^{+}$ were then crossed with a floxed Kir4.1 mouse, $Kir4.1^{(f/f)}$ (K. McCarthy). Offspring included the ksKO ($Kir4.1^{(f/-)}Cre^{+}$) and associated controls. Blood, obtained by cardiac puncture, and urine, from bladder aspiration, were analyzed in a reference lab. Significance (*) was taken at $p<0.05$.

**Results:** ksKO mice grew normally to adulthood. Kir4.1 protein expression (by immunofluorescence) in the distal nephron was markedly reduced but not abolished. Under basal conditions, the mice showed metabolic alkalosis but not hypokalemia or hypomagnesemia. They had a severe urinary concentration defect associated with hypernatremia, grossly enlarged kidneys and dilated collecting ducts. On low K, low Mg diet x 1 wk, ksKO mice showed marked hypokalemia (K 1.5 vs 3.0 mEq/L) associated with an inappropriately elevated TTKG (11.0 vs. 1.7).

| | Na, mEq/L | K, mEq/L | HCO3, mEq/L | Mg, mEq/L | U Na, U K, mEq/L | U osm, mOsm/Kg | TTKG |
|---|---|---|---|---|---|---|---|
| **KO** (n=4) | *153±4 | *1.5±0.1 | *25±5 | *2.7±0.2 | 25±4, 27±4 | *523±91 | *11.0±0.8 |
| **WT**(n=10) | 141±1 | 3.0±0.1 | 21±1 | 1.9±0.1 | 136±23, 23±5 | 1466±163 | 1.7±0.5 |

Metabolic alkalosis, hypernatremia and a urinary concentrating defect were again seen. Serum Mg level was paradoxically increased, suggesting that Kir4.1 function in the DCT was intact or that compensation elsewhere (ie in TAL) had occurred.

**Conclusions:** Our results suggest that Kir4.1, which underlies basolateral K recycling in the distal nephron, is required for adaptation to low K diet.

## FR-PO766

**RNA-Seq Identification of Transcriptome of Native DCT1 Cells**
Jae Wook Lee, Chung-Lin Chou, Fahad Saeed, Mark A. Knepper. *NIH.*

**Background:** Complete transcriptomes have been identified for the inner medullary collecting duct, medullary thick ascending limb, and proximal tubule cells because they can be biochemically isolated from kidney in large enough numbers for DNA microarray analysis. However, only limited data from SAGE experiments exist for the DCT1 segment.

**Methods:** Here, we use deep-sequencing technology (RNA-seq) to identify the transcriptome of native rat DCT cells manually microdissected from collagenase-treated rat kidneys. The microdissection used a high resolution optical system capable of discriminating cell types. The DCT1 segment was carefully identified and cells from adjacent segments were trimmed away. Several DCT1 segments were pooled yielding 300-500 cells per sample. Deep sequencing was done on an Illumina HiSeq 2000 sequencer after RT-PCR amplification. Expression levels were calculated in 'reads per kilobase exons per million mapped reads' (RPKM).

**Results:** After mapping to the rat reference genome (rn4), transcripts corresponding to a total of 5171 distinct genes were identified in 6 DCT1 samples. Comparison to RNA-seq data in all 11 other tubule segments revealed that 58 transcripts were unique to the DCT1. These include 3 protein kinases (*Nek6*, *Stk17b*, and *Fgr*), 7 receptors (*Gfra1*, *Gpr37*, *Gpr39*, *Gpr137*, *P2ry1*, *Ptger4,* and *Olr1104*), 3 solute transporters (*Slc12a3*, *Slc29a2* [nucleoside transporter], and *Slc39a2* [zinc ion transporter]) and 1 transcription factor (*Zfp189*). Of more than 100 protein kinases expressed, the 10 most abundant were *Wnk1*, *Cdkl1*, *Stk16*, *Fastk*, *Map2k2*, *Pink1*, *Pdk2*, *Wnk4*, *Sgk1*, and *Stk39* (SPAK). Of G protein-coupled receptors expressed, the 10 most abundant were receptors for somatostatin (*Ssr2* and *Ssr3*), parathyroid hormone (*Pth1r*), glucagon (*Gcgr*), calcium ion (*Casr*), PGE2 (*Ptger3*), zinc ion (*Gpr39*), vasopressin (*Avpr2*), and unknown ligands (*Gpr56* and *Gprc5c*).

**Conclusions:** These data provide a new resource for the study of the DCT1 segment and its associated transporter function. Further studies are needed to address whether any of the newly identified DCT1 genes play roles in regulation of transepithelial NaCl transport.

## FR-PO767

**Use of Serum Total Protein (TP) to Correct for Colloid-Related Bias of Serum Sodium (Na) Measured by the Indirect Ion-Selective Electrode (ISE) Method**
Pratima Ghimire,[1] Isabelle Ayoub,[1] Robert H. Barth,[2] Philip Goldwasser.[2] *[1]SUNY Downstate; [2]VA NY Harbor Healthcare System, Brooklyn, NY.*

**Background:** When the serum colloid level is lower than normal, the measurement of Na by the usual indirect ISE method (iNa) tends to be artifactually high—compared with direct ISE (dNa) used in gas panels—while above normal serum colloid results in the opposite. Studies disagree on whether a linear equation using TP (as a proxy for serum colloid) can be used to predict iNa - dNa (ΔNa). Jones & Twomey ('07) found ΔNa fell by 1.2 mM per g/dL increase in TP, while Dimeski ('05) found the TP effect to be nonlinear.

**Methods:** To test this, we (i) paired chemistry and gas panels obtained < 20 minutes apart (median=5 min.) in a retrospective cohort of all patients (pts) admitted to our critical care units during a 1 year period, (ii) calculated ΔNa and the inter-panel glucose difference (ΔGlu), and (iii) examined the influence of TP on ΔNa, adjusting for ΔGlu and dNa. Limiting each pt to one pairing and excluding hemolyzed or turbid samples left 228 iNa/dNa pairs.

**Results:** Significant differences [mean ± se] were found between the panels (ΔNa: 1.8± 0.1 mM, $p<10^{-30}$; ΔGlu: -5.9±1.9 mg/dL, $p<.002$) indicating bias. TP ranged from 2.1-10.1 g/dL. ΔNa correlated significantly with TP ($r= -0.28$ $p<10^{-4}$), weakly with ΔGlu ($r= -0.11$ $p<.09$), and not at all with iNa + dNa ($r=0.05$). The trend of ΔNa means versus TP, grouped into categories, is shown.

| TP CATEGORY | N | TP, g/dL | ΔNa, mM | Range | T-test |
|---|---|---|---|---|---|
| A (< 4 g/dL) | 8 | 3.4±0.2 | 2.9±0.6 | 0 to 6 | |
| B (4-5.9 g/dL) | 64 | 5.2±0.1 | 2.3±0.2 | -4 to 8 | |
| C (6-7.9 g/dL) | 137 | 6.9±0.1 | 1.8±0.2 | -3 to 8 | |
| D (>7.9 g/dL) | 19 | 8.4±0.1 | 0.0±0.6 | -5 to 7 | p<001 vs. A, B, & C |

Trend analysis indicated only a significant linear component ($P<.001$); deviation from linearity was not quite significant ($p<0.07$). By regression, for each g/dL increase in TP, ΔNa fell by 0.49±0.11 mM ($p<10^{-5}$) [or 0.34±0.12 mM ($P<.004$) in the subset with TP<8] adjusted for ΔGlu(slope = -1.0 mM per 100 mg/dL; $p< .04$) and dNa.

**Conclusions:** In summary, the discordance between iNa and dNa varies inversely with the level of TP, and can be corrected using a linear equation based on TP.

## FR-PO768

**Renal Effects of Caveolin-1 Deletion**
Yan Willière, Tatiana Nikitina, Andreas Patzak, Mauricio Michalak Sendeski, Sebastian C. Bachmann, Kerim Mutig. *Charité-Universitätsmedizin Berlin, Berlin, Germany.*

**Background:** Caveolin-1 (Cav1) is essential for caveolae biogenesis. These cholesterol-rich subdomains of lipid rafts microdomains are involved in signal-transduction, vesicular trafficking, and functional modulation of plasma membrane proteins. Little is known about the role of the caveolae in the kidney. In this study we tested the hypothesis that caveolae interfere with renal NaCl- and water reabsorption.

**Methods:** To evaluate the role of caveolae in the kidney, Cav1-deficient (Cav1-/-) mice were analyzed for their physiologic kidney performance, kidney morphology, biochemical profile of renal transporters, and renal vascular contractility.

**Results:** In wildtype (WT) mouse kidneys, Cav1 was strongly expressed in the endothelium and moderately expressed in the epithelial cells of the late distal convoluted tubule (DCT2) and collecting ducts. No Cav1 expression and no caveolae were detected in Cav1-/- mice. Physiologic evaluation of WT and Cav1-/- mice showed significantly increased urinary excretion of water (+124%) and electrolytes upon Cav1 disruption (+94% for $Na^{+}$). Immunoblotting evaluation of distal epithelial salt transporters and water channels revealed decreased levels of phosphorylated Na-Cl cotransporter in DCT2 (-40%) and of $Na^{+}/K^{+}$-ATPase (-33%) in the collecting duct upon Cav1 disruption. Functional analysis of renal interlobar arteries showed significantly decreased contractile response of Cav1-deficient vessels to phenylephrine. Concomitant inhibition of NO production by L-NAME has suppressed the differences between WT and Cav1-/- indicating that Cav1 disruption goes along with an increased activity of NO synthases. Indeed, abundance of the endothelial NO synthase (eNOS) was significantly increased in Cav1-/- kidneys compared to WT controls (+212%).

**Conclusions:** Our data suggest that Cav1 promotes renal reabsorption of water and electrolytes by inhibiting eNOS and facilitating the function of the distal epithelial transporters.

**FR-PO769**

**Total Body Adiposity Is Associated with Inflammation and Vitamin D in Chronic Kidney Disease** Maria Ines Barreto-Silva,[1] Márcia R.S.G. Torres,[1] Carla C.S. Lemos,[2] Simone Vargas Da Silva,[3] Rachel Bregman.[2] *[1]Nutrition, State Univ of Rio de Janeiro; [2]Nephrology, State Univ of Rio de Janeiro; [3]Pharmacology, State Univ of Rio de Janeiro, Brazil.*

**Background:** High body adiposity, inflammation and vitamin D 25(OH)D deficiency may contribute to poor outcome in chronic kidney disease (CKD) patients.

The aim was to describe vitamin D profile and its association with inflammation and body adiposity in CKD patients.

**Methods:** CKD patients under multidisciplinary treatment were evaluated. Total body adiposity was evaluated by X-ray absorptiometry- (DXA-total-BF; %); central body fat evaluated by DXA trunk fat (%) and by anthropometry (waist circumference, waist-to-hip-ratio; waist-to-height-ratio). Body mass index (BMI; kg/m2) was estimated. Serum levels analysis for: leptin, high molecular weight adiponectin (HMWAdipo), C-reactive protein, interleukin-6, tumor necrosis factor alpha (TNFα), interferon-gamma and 25(OH)D.

**Results:** One hundred patients (56% men) under treatment for at least 1 year were studied. Results as mean±SD: age=66±12 years, estimated glomerular filtration rate (eGFR)=29±13 ml/min (CKD-EPI), BMI=25±4. Overweight/obesity prevalence:52% (29±3) vs 48% normal (22±2). DXA-total-BF was positively associated with leptin (r=0.6) and negatively with HMWAdipo (r= -0.33) (p<0.0001; adjusted for confounders: age, gender, eGFR). TNFα was the only inflammatory parameter associated with DXA-total-BF (r=0.24; p<0.01; adjusted for confounders). Vitamin D profile was: 40% insufficiency (25±3), 25% deficiency (15±4), 35% normal (37±7 ng/mL) (ANOVA: p<0.001), i.e. 65% patients with low vitamin D levels. The 25(OH)D was inversely associated with DXA-total-BF (r= -0.25; p=0.02), but showed no association with central body fat parameters. TNFα was independently associated with 25(OH)D by multiple regression analysis (R2 adjusted=0.14; multiple correlation coefficient=0.42; p<0.0001; Stepwise MODEL, variables: dependent 25(OH)D; independent: DXA-total-BF, leptin,HMWAdipo, TNF-αlpha).

**Conclusions:** TNFα was the best inflammation marker in overweight CKD patients. High body adiposity may contribute with inflammation and vitamin D deficiency and should be a target in the nutritional treatment of this population.

**FR-PO770**

**Renal Inflammation and Injury Induced by Cisplatin Are Regulated by Magnesium Status** Malvika H. Solanki, Prodyot K. Chatterjee, Madhu Gupta, Xiangying Xue, Christine N. Metz. *Center for Immunology and Inflammation, The Feinstein Institute for Medical Research, Manhasset, NY.*

**Background:** Cisplatin-induced acute kidney injury (AKI) occurs in 1/3 of patients taking cisplatin. The risk of cisplatin-AKI increases with age and is higher among females. Cisplatin impairs renal handling of magnesium (Mg) and Mg deficiency is common among US adults. Because Mg deficiency is associated with enhanced inflammation, we examined the effects of Mg deficiency and supplementation on inflammation during cisplatin-AKI.

**Methods:** Older female C57BL/6 mice (10/group, 10mo old) were fed either normal (100%Mg) or Mg-deficient (10%Mg) diets. After 2wks, saline or cisplatin (12mg/kg, ip) was injected. An additional group of Mg-deficient mice was supplemented with $MgCl_2$ in water and $MgSO_4$ s.c prior to cisplatin. Mice were euthanized 48hrs post-cisplatin. Blood urea nitrogen (BUN) levels and renal inflammatory markers (mRNA and protein) were measured. Renal neutrophil infiltration was measured by Leder staining and myeloperoxidase (MPO) levels. Renal STAT3 and ERK1/2 expression/activation were analyzed by Western blotting.

**Results:** Mg deficiency elevated BUN levels and increased markers of inflammation (*Cxcl2, Ccl2, Cxcl10* and *Tnfa*-mRNA and CXCL2, CCL2, IL-6, IL-1β and CXCL10-protein) following cisplatin compared to 100%Mg-cisplatin controls (P<0.05). Renal neutrophil infiltration and MPO levels were higher in cisplatin treated Mg-deficient mice when compared to controls (P<0.01). Mg-deficient mice treated with cisplatin exhibited enhanced renal STAT3 protein expression/phosphorylation, as well as ERK1/2 phosphorylation compared to controls (P<0.05). Mg replacement reversed cisplatin-induced renal damage and inflammation and cisplatin-mediated STAT3 and ERK1/2 phosphorylation (P<0.01).

**Conclusions:** Mg deficiency significantly exacerbates cisplatin-associated renal inflammation and AKI; Mg replacement reverses this effect. Mechanistic studies reveal the renoprotective role of Mg in controlling STAT3 and ERK1/2 activation, two pathways involved in cisplatin-mediated inflammation. These findings support investigating the effects of Mg status before and during cisplatin therapy on renal outcomes in patients.

**Effect of Brazilian Nut Supplementation on Nrf2 and NF-kB Expression in Hemodialysis Patients** Ludmila Fmf Cardozo,[1] Liliana M. Pedruzzi,[1] Milena Barcza Stockler-pinto,[1] Julio Beltrame Daleprane,[2] Juliana M.S. Siqueira,[3] Olavo M. Cabral,[3] Maurilo Leite,[4] Denise Mafra.[1] *[1]Post Graduation Program in Cardiovascular Sciences, Federal Fluminense Univ (UFF), Niterói, Rio de Janeiro (RJ), Brazil; [2]Institute of Nutrition, State Univ of Rio de Janeiro (UERJ), RJ, Brazil; [3]Nefrológica Clinic, Niterói, RJ, Brazil; [4]Div of Nephrology, Federal Univ of Rio de Janeiro (UFRJ), RJ, Brazil.*

**Background:** Previous studies in our laboratory showed that the supplementation of 1 unit of Brazilian nut (Bertholletia excelsa, family *Lecythidaceae, t*he richest known food source of selenium-Se) a day during 3 months, is effective to improve Se status, reduce oxidative stress and inflammation markers, and increase the antioxidant levels in hemodialysis (HD) patients. However, we did not evaluate whether this nutritional compound can modulate the expression of nuclear E2-related factor 2 (Nrf2), a protein that regulates the expression of detoxifying enzymes by recognizing the human Antioxidant Response Element. This study evaluated the effect of nut supplementation on the mRNA expression of Nfr2 and NF-kB in HD patients.

**Methods:** Fourteen HD patients (50% men; 55.1±13.8yrs; BMI 24.2±3.2 kg/m$^2$; time on dialysis 80±42.7 months) from Nefrológica Clinic in Niterói, RJ, Brazil were studied. They received 1 nut (5g, courtesy: Agriculture Arauanã) a day for 3 months. Blood samples were obtained after 12h fasting and the peripheral blood mononuclear cells were isolated before and after supplementation. Quantitative Real-Time PCR analysis was performed using *7500 Real-Time PCR* System (*Applied Biosystems)* to evaluate the levels of mRNA expression encoding Nrf2 and NF-kB.

**Results:** After nut supplementation, the NF-kB expression decreased from 1.92±0.64 to 0.71±0.36 (p=0.001) and the Nrf2 expression increased from 0.60±0.39 to 1.45±0.27 (p=0.001).

**Conclusions:** These data suggest that the consumption of only one Brazilian nut per day during 3 months can activate Nrf2 and diminish inflammation by reducing NF-kB expression in HD patients. This study is the first to report and confirm the molecular beneficial effects of nuts on reducing inflammation and oxidative stress on HD patients.

**Nrf2/Nf-kB Equilibrium Is Altered in Hemodialysis Patients** Ludmila Fmf Cardozo,[1] Liliana M. Pedruzzi,[1] Milena Barcza Stockler-pinto,[1] Julio Beltrame Daleprane,[2] Juliana M.S. Siqueira,[3] Olavo M. Cabral,[3] Maurilo Leite,[4] Denise Mafra.[1] *[1]Post Graduation Program in Cardiovascular Sciences, Federal Fluminense Univ (UFF), Niterói, Rio de Janeiro (RJ), Brazil; [2]Institute of Nutrition, State Univ of Rio de Janeiro (UERJ), RJ, Brazil; [3]Nefrológica Clinic, Niterói, RJ, Brazil; [4]Div of Nephrology, Federal Univ of Rio de Janeiro (UFRJ), RJ, Brazil.*

**Background:** Reactive oxygen species (ROS) activate NF-kB that regulates the transcription of several genes, including pro-inflammatory cytokines. Oxidative stress and inflammation are frequent findings in patients with Chronic Kidney Disease (CKD), and considered mediators of cardiovascular disease. Several studies address the strategies to halt this process, including the activation of the transcription nuclear E2-related factor 2 (Nrf2), which regulates the expression of detoxifying enzymes. The aim of this study was to evaluate the expression of Nfr2 and NF-kB in CKD patients on hemodialysis.

**Methods:** Twenty hemodialysis patients (65% men, BMI 23.6±3.0 kg/m$^2$, time of dialysis 78±46.4 months, DM 21,4%, 54.9±15.2yrs) from Nefrológica Clinic in Niterói, RJ, Brazil, were compared to 11 healthy individuals (45.5% men, BMI 23.8±1.9 kg/m$^2$, 50.9±8.0 yrs). Blood samples were drawn after 12h fasting, and the peripheral blood mononuclear cells were isolated. Quantitative Real-Time PCR analysis was performed using *7500 Real-Time PCR* System (*Applied Biosystems)* to evaluate the levels of mRNA expression encoding Nrf2 and NF-kB.

**Results:** The HD patients had lower expression of Nrf2 (0.58±0.35) when compared to healthy individuals (1.13±0.64, p=0.005). By contrast, the NF-kB expression were 2 fold in HD patients (2.18±0.8), when compared to healthy individuals (1.04±0.22, p=0.0001). The HD patients presented NF-kB expression inversely correlated with Nrf2 levels (r=-0.54, p<0.01) and this correlation was positive for the healthy individuals (r= 0.85, p=0.001).

**Conclusions:** The results show that HD patients present an increased NF-kB and reduced Nrf2 expression, which is the opposite of healthy individuals. NF-kB may participate in the negative regulation of Nrf2 expression in these patients.

**The Effect of Coenzyme $Q_{10}$ Dose-Escalation on Oxidative Stress in Hemodialysis Patients** Frederic Tremaine Billings,[1] Catherine K. Yeung,[2] Danny D. Shen,[2] T. Alp Ikizler,[1] Jonathan Himmelfarb.[2] *[1]Vanderbilt Univ, Nashville, TN; [2]Univ of Washington, Seattle, WA.*

**Background:** Coenzyme $Q_{10}$ ($CoQ_{10}$) supplementation improves mitochondrial coupling of respiration to oxidative phosphorylation and decreases reactive oxygen species generation in endothelial cells. Oxidative stress is increased in patients with end stage renal disease and may partially account for the increased risk of cardiovascular disease in this population.

**Methods:** We performed a $CoQ_{10}$ dose escalation study (2 weeks each of 300, 600, 1200, and 1800 mg/day) in 20 chronic hemodialysis patients to test the hypothesis that $CoQ_{10}$ therapy reduces oxidative stress. $F_2$-isoprostanes, isofurans and high-density lipoprotein (HDL) apolipoprotein A1 (apoA-1) oxidation were measured to assess oxidative stress and $CoQ_{10}$ to determine dose, concentration, and response relationships.

**Results:** Plasma $CoQ_{10}$ levels increased in a linear fashion from 704 ± 286 ng/mL at baseline to 4033 ± 1637 following 1800 mg/day, and plasma isofuran concentrations, a marker of oxidative stress reported to be associated with mitochondrial dysfunction, decreased from 141 ± 67.5 pg/mL at baseline to 72.2 ± 37.5 following 1800 mg/day (P=0.003 vs. baseline and P<0.001 for the effect of dose escalation, Figure, Panel A). In addition, reduced plasma isofuran concentrations correlated with increased plasma concentrations of $CoQ_{10}$ (P=0.02, Figure, Panel B). Plasma $F_2$-isoprostane concentrations and HDL apoA-1 oxidation did not change during the study.

**Conclusions:** Short-term daily $CoQ_{10}$ supplementation significantly decreased plasma isofuran concentrations in a dose-dependent manner but did not affect HDL oxidation. This might indicate improved mitochondrial function and decreased oxidative stress in hemodialysis patients treated with CoQ10.

## FR-PO774

**Targeting of Rho Kinase Protects Mice from Progressive Nephropathy by Improving Podocytes Lipophagy during Diet-Induced Hyperlipidemia**

Wenjian Wang,[1] Xinling Liang,[1] Farhad R. Danesh.[2] *[1]Div of Nephrology, Guangdong General Hospital, Guangzhou, Guangdong, China; [2]Div of Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** The trapping of lipid-laden podocytes in the glomerulus is a critical but reversible step in glomerulosclerosis. Recently, an alternative pathway of lipid metabolism through the lysosomal degradative pathway of autophagy is described and now termed lipophagy. However, whether and how this pathway is involved in the progression of lipid-induced nephropathy remains unclear.

**Methods:** In this study, we demonstrate the first evidence that Rho kinase (ROCK) pathway plays a critical role in lipophagy in podocytes treated with oxidative low density lipoprotein in vitro. Overexpression of ROCK increase of lipid retention in oxidative low density lipoprotein treated podocytes, which consequently activates, and results in a marked increases of reactive oxygen species production. Interestingly, this process is reversed by ROCK inhibition evidenced by increased lipophagy which associated to low phosphorylated Akt and actin-related protein 2 levels. Furthermore, pharmacological inhibition of ROCK in high fat diet mice exhibits a significantly ameliorated albuminuria and mesangial matrix accumulation compared to control. The renoprotective effect of fasudil, a ROCK inhibitor, on high fat diet mice is attributed to the decreased lipid retention and improved lipophagy in kidney.

**Results:** Our data suggests a previously unknown contribution of ROCK to lipid-induced nephropathy. Constitutive inhibition of ROCK may be a major protective strategy to ameliorate lipid-overload in podocyte and lipid-related loss of renal function.

**Conclusions:** Constitutive inhibition of ROCK may be a major protective strategy to ameliorate lipid-overload in podocyte and lipid-related loss of renal function.

## FR-PO775

**Docosahexaenoic Acid Counteracts Palmitate-Induced Proteolytic Signaling in Myotubes**

Myra Woodworth-Hobbs,[1,2] Matthew B. Hudson,[1] Jill Rahnert,[1] Bin Zheng,[1] Harold A. Franch,[1] Russ Price.[1,3] *[1]Dept of Medicine/Nephrology, Emory Univ, Atlanta, GA; [2]Nutrition and Health Sciences, GDBBS, Emory Univ, Atlanta, GA; [3]Atlanta VAMC, Decatur, GA.*

**Background:** Dyslipidemia is a comorbidity of illnesses such as diabetes and chronic kidney disease that contributes to insulin resistance and dysfunctional protein metabolism in skeletal muscle, resulting in debilitating muscle atrophy. The saturated fatty acid palmitate (PA) induces muscle insulin resistance and dysregulated protein metabolism in cultured myotubes, whereas the omega-3 fatty acid docosahexaenoic acid (DHA) has beneficial metabolic effects. The purpose of this study was to evaluate the effects of PA and DHA on atrophy-related signaling in skeletal muscle. We hypothesized that DHA prevents PA-induced myotube atrophy by counteracting its effects on protein degradation.

**Methods:** C2C12 myotubes were treated with 500uM PA and/or 100uM DHA for up to 28h. The rate of protein degradation was measured by monitoring the release of radiolabeled phenylalanine into the culture media, and the expression of mRNAs and proteins involved in atrophic signaling pathways were measured by quantitative real time PCR and western analysis, respectively.

**Results:** PA increased the rate of protein degradation by 31% (P<0.05 vs. all other groups), while co-treatment with DHA completely prevented the response. Akt is a key modulator of protein balance that inhibits the FoxO3 transcription factors which regulate "atrogene" expression. PA reduced the activation state of Akt (phospho:total Akt) by 24%-40% at timepoints ranging from 2h-24h (P<0.05 vs. control) and increased the nuclear protein levels of FoxO3 by 40%. PA also increased the mRNA levels of three FoxO3 atrogene targets, the E3 ubiquitin ligases MuRF-1 and atrogin-1/MAFbx and the autophagy mediator Bnip3. DHA attenuated the effects of PA on Akt, FoxO3, and all three atrogenes.

**Conclusions:** These data indicate that PA induces myotube atrophy by inducing the ubiquitin-proteasome and autophagic proteolytic systems and that DHA counters the catabolic effects of PA by improving Akt signaling.

## FR-PO776

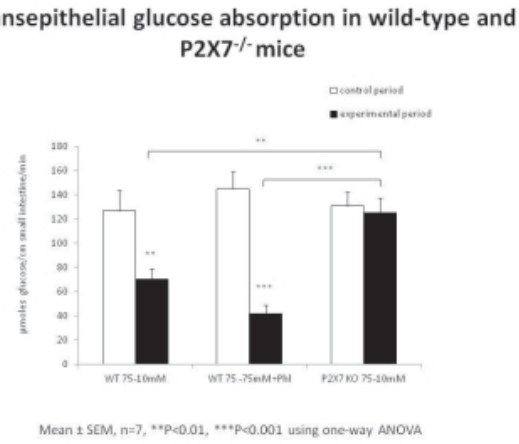
**P2X7 as a Potential Target for Improved Glycemic Control in Diabetes**

Joanne Marks,[1] Ballal Seddique,[1] Gregory Fong,[1] Frederick W.K. Tam,[2] Edward S. Debnam,[1] Robert J. Unwin.[1] *[1]Centre for Nephrology, Univ College London, London, United Kingdom; [2]Dept of Medicine, Imperial College London, London, United Kingdom.*

**Background:** Dynamic regulation of GLUT2 at the enterocyte brush border membrane (BBM) provides a high capacity route for post-prandial dietary glucose absorption; however, GLUT2 is permanently expressed at the BBM in diabetes and probably contributes to hyperglycemia and development of diabetic complications, including nephropathy. Our study investigated the putative role of the P2X7 receptor in regulating intestinal GLUT2 expression *in vivo*.

**Methods:** Wild-type (WT) and $P2X7^{-/-}$ mice were anaesthetized and 10cm segments of proximal small intestine were cannulated *in vivo*. These were perfused with Krebs buffer containing 75mM glucose, oxygenated with 95%$O_2$:5%$CO_2$ to create segmental flow at a rate of 1ml/min. The intestine was removed and placed in an organ chamber at 37°C and allowed to equilibrate for 30 mins. Serosal fluid was collected after an additional 30 mins (control period) and 30 mins after the solution was switched to one containing 10mM glucose or 1mM Phloretin (Phl), a competitive inhibitor of GLUT2 (experimental period). Serosal glucose concentration was measured using a glucose oxidase assay.

**Results:** In WT animals, glucose absorption was decreased by switching the perfusate to 10mM glucose, indicating rapid loss of GLUT2 expression after removing the high glucose stimulus. The reduction in transport induced by phloretin confirmed the contribution of GLUT2-mediated transport at 75mM glucose. In contrast, in $P2X7^{-/-}$ mice glucose absorption was unaffected by reducing glucose concentration.



**Conclusions:** These data suggest a role for P2X7 receptor in controlling GLUT2 expression at the enterocyte BBM and provide evidence that this pathway may be a novel target to improve glycemic control in diabetic patients.

## FR-PO777

**Iron Metabolism in Kidney and Erythropoietin Synthesis: A Case of Hepcidin**

Karim Zoubida,[1] Boualem Moulouel,[1] Dounia Houamel,[1] Laurent Gouya.[1] *[1]Paris Diderot Univ, INSERM U773, Paris, France; [2]Paris Diderot Univ, INSERM U773, Paris; [3]Paris Diderot Univ, INSERM U773, Paris.*

**Background:** Erythropoietin (EPO) is produced exclusively in renal interstitial fibroblasts. Of interest, it has been shown that the production of EPO is regulated by iron but the mechanism of this regulation remains unclear. We have recently shown that hepcidin, the iron regulatory hormone, regulates renal handling of iron and that hepcidin knockout mice (hepc-/-) exhibited a marked iron deposition within the thick ascending limb of Henle. In this study we investigated whether EPO synthesis is monitored by the intrarenal hepcidin-dependant regulation of iron. Indeed, EPO-producing fibroblasts that are immersed in a faintly vascularized environment and their iron content may be modulated by the degree of iron reabsorption in the tubular cells.

**Methods:** Iron deposits in renal fibroblasts were analysed by electron microscopy (EM). After iron restricted diet (ID) renal and serum EPO were quantified by RT-qPCR and ELISA.

**Results:** -in hepc$^{-/-}$ mice, EM analysis showed significant iron deposits in renal interstitial fibroblasts.

-EPO mRNA was reduced in hepc$^{-/-}$ mice as compared to WT. ID induced the expression of EPO in WT but not in hepc$^{-/-}$ mice. Similar data were obtained after phlebotomy suggesting that iron deposits in interstitial fibroblasts may impair renal EPO production.

-Hepcidin mRNA level in liver was decreased in ID mice versus controls. However in kidney, hepcidin expression was slightly increased, which may probably potentiate iron depletion of interstitial fibroblasts and therefore EPO production.

-Treatment of REPC cells (obtained from J. Fandrey, Essen) with the iron chelator DFO increased EPO-mRNA level whereas iron excess (Fe-NTA) decreased EPO-mRNA. However, when cells were incubated with hepcidin, EPO synthesis remained unchanged suggesting no direct effect of the hormone on renal fibroblasts.

**Conclusions:** Our data indicate that hepcidin, by controlling renal tubular iron transport, may exert a feedback control on EPO production. Thus a crosstalk between tubular cells and interstitial fibroblasts may be required for an appropriate EPO production in normal and pathological situations.

*Funding:* Government Support - Non-U.S.

## FR-PO778

**Oxidative Balance Score (OBS) Is Associated with Chronic Kidney Disease (CKD)** Titilayo O. Ilori,[1] Young Sun Ro,[3] Orlando M. Gutierrez,[4] Soyeon Joyce Kong,[2] William M. McClellan.[1,2] *[1]Dept of Medicine, Emory Univ; [2]School of Public Health, Emory Univ; [3]School of Public Health, Seoul National Univ, Seoul, Korea; [4]Dept of Medicine, Univ of Alabama.*

**Background:** The OBS measures the overall oxidative balance status of an individual. The aim of this study was to investigate the relationship between OBS , albuminuria, eGFR <60 ml/min/1.73m$^2$ (CKD),and End Stage Renal Disease (ESRD) in the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study.

**Methods:** Data was collected from 2003-2007 by phone questionnaire and in-home examination. OBS was calculated by combination of 13 *a-priori* pro- and anti-oxidant factors; polyunsaturated fatty acid, iron, selenium, vitamin C & E, α-& β -carotene, lutein lycopene, aspirin, NSAID, and alcohol use. Quartiles of OBS were the exposure, with the lowest quartile (high pro-oxidants) as the reference.The p for trend was calculated by MH chi square test for prevalence (albuminuria and CKD), poisson regression for incidence rate (ESRD), logistic regression for odds ratio OR (albuminuria and CKD), and cox-proportional hazard regression for HR (ESRD).

**Results:** 19,462 participants were analyzed, 2,519 had albuminuria and 1,957 had CKD. During a median follow-up of 3.5 years, 90 participants developed ESRD. Decreased prevalence of albuminuria and CKD were noted at higher quartiles of OBS. ESRD rates were higher at lower OBS quartiles (pro-oxidant) (p for trend <0.01), and the trend persisted, but was not statistically significant, after controlling for other covariates.

| | CKD | | ESRD | |
|---|---|---|---|---|
| | | Model 1 | | Model 1 |
| OBS | % | OR (95% CI) | IR** | HR(95%CI) |
| Q1 | 10 | 1 | 154.2 | 1 |
| Q2 | 10.2 | 0.93(0.8-1.08) | 169.8 | 1.27(0.7-2.29) |
| Q3 | 10.4 | 0.90(0.77-1.04) | 140 | 1.08(0.59-2.01) |
| Q4 | 9.6 | 0.77(0.66-0.91) | 105.5 | 0.81(0.41-1.63) |
| p for trend | 0.56 | <0.01 | <0.01 | 0.47 |

Model 1: completely adjusted model **IR = incident rate per 100,000 person-years.

**Conclusions:** These findings suggest that higher OBS is associated with decreased prevalence of kidney disease. The reason for this is unknown and warrants further study.

## FR-PO779

**In Utero Exposure to Maternal Obesity Can Affect Gene Expression within the Kidneys of Rat Offspring** Sarah J. Glastras,[1] Ibrahim Al-odat,[2] Hui Chen,[2] Carol A. Pollock,[1] Sonia Saad.[1] *[1]Kolling Insitute, Univ of Sydney, NSW, Australia; [2]Univ of Technology, Sydney, NSW, Australia.*

**Background:** Maternal obesity can 'program' the offspring to be prone to obesity, hyperglycaemia, dyslipidaemia, diabetes, hypertension and chronic kidney disease. We aimed to study the effect of maternal obesity on renal gene expression in the offspring in rats.

**Methods:** Female breeders were fed either normal or high-fat diet and the kidneys from the offspring were collected at postnatal Day 1 and Day 20 (weaning). The kidneys were weighed and snap frozen for further analysis. The anthropometric measures, plasma triglycerides and glucose/insulin levels were measured. mRNA expression of profibrotic factors (TGFß, CTGF, PAI-1), pro-inflammatory cytokines (TNF, IL-6 and MCP-1), and lipid metabolic markers (FXR, PPAR, SREBP) were measured by real time PCR.

**Results:** Offspring from obese rats displayed increased body weight, fat and kidney mass, blood triglyceride levels, and glucose intolerance compared with those from the lean rats. mRNA expression of TGFß, PAI-1 and MCP1 was significantly increased by maternal obesity at postnatal Day 1. The upregulated TGFß was sustained at Day 20. FXR expression was reduced by maternal obesity at both postnatal Day 1 and Day 20.

**Conclusions:** Maternal obesity is associated with the downregulation of renal FXR and upregulation of TGFß and MCP1 expression at Day 1 in the offspring. This effect was sustained until weaning. Given the known role of inflammatory cytokines in CKD, this suggests that maternal obesity confers an increased risk of kidney disorders in the offspring.

## FR-PO780

**Sex Differences in Dietary-Fructose-Induced Renal Hypertrophy and Electrolyte Abnormalities in Mice** Nikhil Sharma, Lijun Li, Shehar-bano Awan, Allison Yunghans, Carolyn M. Ecelbarger. *Dept of Medicine, Georgetown Univ, Washington, DC.*

**Background:** Consumption of fructose has been implicated in the development of renal disease and impaired kidney function, but the mechanisms are not fully understood. Because females may be more sensitive to certain electrolyte disturbances such as hyponatremia, we tested the impact of chronic fructose feeding on electrolyte homeostatic mechanisms in the kidney.

**Methods:** Young (2-month) male (M) and female (F) mice (129/Sv background) were *offered ad libitum* access to either a corn-starch based control (C) or a high fructose (HFr, 60% dry weight) diet as pelleted chow and plain drinking water for 15 weeks (n = 6/sex/diet). Diets contained similar amounts of sodium (Na+), potassium (K+), and chloride (Cl-). Urine (24-hr) was collected for measurement of urine electrolytes. Kidneys and blood (cardiac puncture) were collected under anesthesia at euthanasia.

**Results:** HFr diet did not largely affect final body weight (bw) or weight gain, both which were higher in M; however, average kidney weight was increased by HFr in both sexes (g/30 g bw): 0.18 ± 0.01 (MC), 0.18 ± 0.01 (FC), 0.21 ± 0.01 (MHFr), 0.20 ± 0.003 (FHFr), $p < 0.005$ for diet, (2-way ANOVA, diet X sex). HFr diet also significantly increased 24-hour urine volume ($p = 0.011$) with a greater effect in F (increased 66% in M and 258% in F). Plasma Na+ and Cl- concentrations were reduced by HFr but only in F mice. Na+ (mmol/L): 151 ± 1 (MC), 151 ± 1 (FC), 153 ± 1 (MHFr), 142± 2 (FHFr); Cl- (mmol/L): 111 ± 1 (MC), 113 ± 1 (FC), 114 ± 1 (MHFr), 106± 2 (FHFr), $p = 0.008$, and 0.045 for a significant interaction between diet and sex for Na+ and Cl-, respectively. In contrast, plasma K+ was elevated by HFr in F (mmol/L): 3.7 ± 0.1 (MC), 3.2 ± 0.1 (FC), 3.9 ± 0.1 (MHFr), 4.0 ± 0.01 (FHFr), $p < 0.001$ for interaction. Plasma aldosterone, urine osmolality, and a glucose tolerance were not affected by HFr diet.

**Conclusions:** Our results demonstrate renal hypertrophy and altered plasma electrolytes in response to HFr, with F mice being more sensitive. More studies are warranted to fully elucidate the impact of specific carbohydrates including HFr on renal function, and cellular mechanisms involved.

*Funding:* Other NIH Support - NHLBI

## FR-PO781

**Effects of Kefir on Cytokines and Nitric Oxide Production, by Peritoneal Macrophages of Streptozotocin-Induced Diabetic Rats** Fabiane R. Maciel,[1] Giovana Punaro,[1] Adelson M. Rodrigues,[1] Marcelo Macedo Rogero,[2] Cristina Bogsan,[3] Marice Oliveira,[3] Thamires Fernandes,[1] Guilherme Nogueira,[1] Margaret Mouro,[1] Elisa MS Higa.[1] *[1]Medicine, UNIFESP, Sao Paulo; [2]Nutrition, School of Public Health, USP, Sao Paulo; [3]Biochemical Technology - Pharmaceuticals, USP, Sao Paulo.*

**Background:** The excessive production of reactive oxygen species in diabetes mellitus is due to hyperglycemia, and the oxidative stress decreases immune response. Careful control of gycemic status is known to minimize the diabetic complications. Kefir (K) is a fermented dairy product, which presents immunological properties.

**Methods:** Male adult Wistar rats received injection of streptozotocin (45mg/kg, I.V.). DM was defined as glycemia ≥200mg/dL. The animals were allocated in 4 groups (n=4 each): control (CTL); CTLK; DM; DMK. They received K, or its vehicle at 1.8 mL/day by gavage, started in the 5$^{th}$ day of DM, during 9 weeks. Before and after the treatment, the animals were maintained in metabolic cages for 24 hour urine collection. Retro-ocular blood was collected to determine the glycemia. The animals were sacrificed and macrophages were obtained from the peritoneal cavity, for cytokines and NO determination. The results are presented as mean±SEM, analyzed by One way ANOVA with Newman-Keuls post-test.

**Results:** DMK when compared to DM presented decreased levels of glycemia (mg/dL) (421±46 vs 567±12) accompanied by decrease in water ingestion (mL/24h) (94±14 vs 124±12), chow intake (g/24h) (31±2 vs 37±2) and diuresis (mL/24h) (71±9 vs 91±9); increased levels of IL-10 (µg/mL) (925±69 vs 555±92), TNF-α (µg/mL) (178±19 vs 109±20), IL-1β (µg/mL) (101±14 vs 70±5) as well as the NO (µM) (102±9 vs 66±5), $p<0.05$.

**Conclusions:** Probiotic supplementation resulted in attenuation of the classic symptoms of diabetes, with decrease in glycemia and increased levels of IL-10, TNF-α, IL-1β and NO. These results suggest that K could be an adjuvant therapy in DM, resulting in a better control of the metabolic parameters, with potential to modulate the immune response, improving the immunocompetence of diabetic patients.

*Funding:* Government Support - Non-U.S.

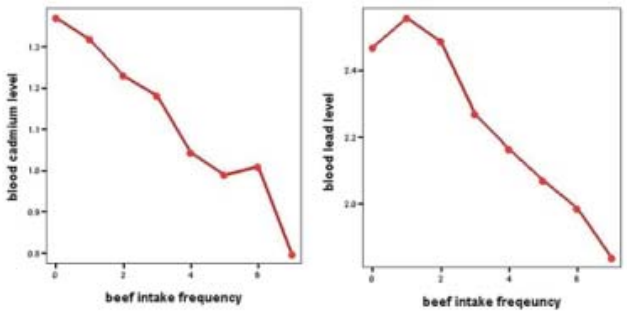
## FR-PO782

**The Levels of Blood Mercury, Cadmium and Lead Are Associated with Age, Dietary Intakes and GFR in Korean Population: KNHANES 2011** Ji Hye Ahn, Won Suk An, Ki Hyun Kim, Seong Eun Kim. *Internal Medicine, Dong-A Univ Hospital.*

**Background:** Heavy metals are widely distributed in the environment and oral exposure is a main route in the general population. There are few studies about the association between heavy metal concentration, dietary intakes and glomerular filatraton rate (GFR). The aim of this study is to investigate whether heavy metals (mercury, cadmium, lead) are associated with GFR and dietary intakes.

**Methods:** We examined the association between heavy metal concentration, dietary intakes and estimated GFR using data from the Korean national Health and Nutritional Examination Survey 2011. For the present study, the analysis was restricted to 1,753 adult participants who were aged >18 years and provided serum heavy metals levels, eGFR and diet survey.

**Results:** The mercury, cadmium and lead were negatively correlated with eGFR and positively correlated with age (p<0.001). The mercury was positively correlated with the mackerel and shellfish intake (p<0.001). The cadmium and lead were positively correlated with shellfish intake and negatively correlated with pork and beaf intake.



The mercury was independently associated with age (β=0.208;p<0.001), shellfish (β=0.138;p<0.001), mackerel intake (β=0.132;p<0.001). The cadmium was independently associated with age (β=0.327;p<0.001), shellfish intake (β=0.126;p<0.001), pork (β=-0.064;p=0.018) and beaf intake (β=-0.076;p=0.004). The lead was independently associated with age (β=0.338;p<0.001), eGFR (β=-0.048;p=0.005), shellfish (β=0.054;p=0.022), pork (β=-0.081;p=0.003) and beaf intake (β=-0.101;p<0.001).

**Conclusions:** Age, GFR and dietary intake were associated with level of heavy metals. Shellfish intake may increase heavy metal levels, beaf and pork intake may decrease cadmium and lead levels. Therefore, attention to heavy metals is necessary in elderly chronic kidney disease patients needing protein restriction.

## FR-PO783

**Altered Renal Lipid Metabolism Results in Lipotoxicity and Progression of Human Diabetic Nephropathy and Obesity Related Glomerulopathy** Michal Herman-Edelstein,[1] Moshe Levi,[2] Pnina Scherzer,[3] Ana Tobar,[1] Amalia Getsztain Bakshi,[1] Uzi Gafter.[1] *[1]Nephrology, Felsenstein Medical Research Center and Rabin Medical Center, Petah Tikva, Israel; [2]Div of Renal Diseases, Univ of Colorado, Denver; [3]Nephrology, Hadassah, Jerusalem, Israel.*

**Background:** Animal models link ectopic lipid accumulation to renal dysfunction, but whether this process occurs in the human kidney is uncertain.To this end we investigated whether there is altered renal triglyceride and cholesterol metabolism resulting renal lipid accumulation and lipotoxicity in human *diabetic nephropathy* (DN) and *obesity related glomerulopathy* (ORG).

**Methods:** Lipid staining and the expression of lipid metabolism genes were studied in kidney biopsies of patients with diagnosed DN (n=40) or ORG (n=10) comparing those with normal kidneys (n=15). We further characterized the effect of free fatty acid and ox-LDL on lipid metabolism in human podocyte cell line.

**Results:** We observed heavy lipid deposition and increased intracellular lipid droplets both in glomerular and tubular cells. Lipid deposition was associated with dysregulation of lipid metabolism genes. Fatty acid β-oxidation pathways including PPAR-α, CPT1, ACO and L-FABP were down-regulated. Down-regulation of lipid catabolism enzyme lipoprotein lipase was associated with increased expression of angiopoietin-like protein 4 (ANGPTL4). Cholesterol uptake receptors including LDL receptor , oxidized LDL receptors (OLR-1, CD36), and acetylated-LDL receptor (SR-A1) expression were all significantly increased, while there was down-regulation of genes effecting cholesterol efflux including ATP-binding cassette transporters (ABCA1, ABGC1) and ApoE. There was a highly significant correlation between eGFR, fibrosis, inflammation and lipid metabolism genes supporting the role of abnormal lipid metatabolism in the pathogenesis of DN and ORG.

**Conclusions:** These data imply that studying lipid metabolism may serve as a target for specific therapies aimed at slowing the progression of glomerulosclerosis.

*Funding:* Private Foundation Support

## FR-PO784

**Protein Intake and Kidney Function in the Population: Differences in Cross-Sectional and Longitudinal Data** Massimo Cirillo,[1] Cinzia Lombardi,[1] Daniela Chiricone,[1] Natale Gaspare De Santo,[2] Alberto Zanchetti,[3] Giancarlo Bilancio.[1] *[1]Dept of Medicine, Univ of Salerno; [2]Second Univ of Naples; [3]Istituto Auxologico Italiano.*

**Background:** Protein intake is considered a determinant of glomerular filtration rate (GFR). Urinary urea (U-urea) is an objective marker of protein intake. This population-based study investigated cross-sectionally and longitudinally the association of U-urea as index of protein intake with GFR indexed by serum creatinine (S-cr) and estimated GFR (eGFR).

**Methods:** Data were collected about overnight U-urea, S-cr, eGFR, and other variables in 1,522 men and women aged 45-64 year who participated in the Gubbio Study (baseline). Age, S-Cr, and eGFR were re-assessed after 12-year follow-up in 1,144 of the 1,425 surviving participants.

**Results:** Mean±SD of U-urea was 17.0±7.1 mmol/h corresponding to an estimated daily protein intake of 71.5±29.8 g/d. U-urea associated inversely with S-cr and directly with eGFR in cross-sectional quartile analyses (P<0.001). In multi-variable cross-sectional regression, 7 mmol/h higher U-urea (approximately one SD of U-urea corresponding to 30 g/d higher protein intake) related to 0.026 mg/dL lower S-cr (95%CI= 0.020/0.032) and 2.56 mL/min higher eGFR (2.01/3.12). At follow-up, change over baseline was an increase for S-cr (+0.054±0.100 mg/dL) and a decrease for eGFR (-11.8±9.1 mL/min x 1.73 $m^2$). Baseline U-urea associated directly with S-cr change and inversely with eGFR change in quartile analyses (P <0.001). In multi-variable regression, 7 mmol/h higher baseline U-urea related to 0.011 mg/dL more positive S-cr change (95%CI=0.006/0.016) and -0.07 mL/min more negative eGFR change per year (95%CI=-0.111/-0.038).

**Conclusions:** In middle-aged adults, higher protein intake is associated cross-sectionally with higher GFR but longitudinally with faster GFR decline over-time.

*Funding:* Government Support - Non-U.S.

## FR-PO785

**Kidney Function, Adipokines, and Quality of Life after Weight Loss Surgery in Obese Patients with Stages 3-4 Chronic Kidney Disease: A Randomized Controlled Pilot Study** Helen L. MacLaughlin,[1,2] Wendy L. Hall,[2] Ameet G. Patel,[1] Rochelle Maree Blacklock,[1] Iain C. Macdougall.[1] *[1]King's College Hospital, London, United Kingdom; [2]King's College London, United Kingdom.*

**Background:** Obesity is an independent risk factor for chronic kidney disease (CKD). Weight loss is associated with improvements in eGFR, yet few studies have examined changes in measured GFR (mGFR) in obese patients with CKD. This pilot study aimed to determine the effect of weight loss on iohexol clearance GFR in obese patients with stages 3-4 CKD.

**Methods:** 16 obese patients with stages 3-4 CKD were randomized to either laparoscopic sleeve gastrectomy (SG) weight loss surgery or best medical care (BMC), including dietary & physical activity modifications. Body weight, fat mass, adipokines, insulin resistance (HOMA-IR) & quality of life (QOL) scores were measured. Differences between groups were examined at 12 months with ANOVA corrected for baseline values or by Hodges-Lehmann median difference.

**Results:** 11 patients (9F, 2M; median age 52y, median BMI 39.5 kg/$m^2$) completed the 12-month study; 5 in the SG group & 6 in the BMC group. Significantly greater weight loss was achieved in SG at 12 months vs BMC (mean diff -29kg; 95% CI -36, -22). There was no association between eGFR and mGFR, eGFR significantly under-predicted mGFR, & there was hyperfiltration at baseline in both groups. Hyperfiltration was reversed in SG, but not in BMC, at 12 months. In SG, adiponectin increased (med diff 6.1 mg/L; 95% CI 1.0, 19.8) & HOMA-IR decreased (-8; 95% CI -29, -1) at 12 months vs BMC, & both were associated with decreased fat mass. SF-36 QOL physical domain score significantly improved in SG compared to BMC at 12 months (mean diff 20; 95% CI 4, 35). Hospital Anxiety & Depression Scale scores decreased significantly in SG compared to BMC at 12 months (Anxiety mean diff -4; 95% CI -7,-1; Depression mean diff -5; 95% CI -8,-2). There were 3 minor adverse events (2 SG; 1 BMC) & no mortality during the study.

**Conclusions:** eGFR significantly underestimated mGFR in obese patients with CKD. Weight loss surgery may reduce hyperfiltration & insulin resistance, & improve adiponectin & QOL in obese patients with eGFR determined stages 3-4 CKD.

*Funding:* Government Support - Non-U.S.

## FR-PO786

**Changes in Abdominal Fat and Thigh Muscle Masses over 1 Year after Initiation of Maintenance Hemodialysis Therapy** Akihiko Kato,[1] Yukitoshi Sakao,[1] Naoko Tsuji,[2] Shinsuke Isobe,[2] Masafumi Ono,[2] Tomoyuki Fujikura,[2] Takayuki Tsuji,[2] Naro Ohashi,[2] Hideo Yasuda.[2] *[1]Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; [2]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

**Background:** Initiation of hemodialysis (HD) therapy is reported to increase whole body fat mass by dual X-ray absorptiometry. However, it remains to be determined whether abdominal adiposity and skeletal muscle mass may change over time after HD initiation.

**Methods:** We enrolled 75 patients who had started HD therapy within 18 months (time on HD: 6±4 [1-18] months, age: 66±15 [29-91] years old, male/female=53/22, diabetes n=31), and measured abdominal subcutaneous fat mass area (ASFA), abdominal visceral fat mass area (AVFA), thigh muscle mass area (TMA), and thigh fat mass area (TFA) form cross-sectional CT images using the software (Fat index view, The Aquilion™ TSX-101A, TOSHIBA. Japan). We then followed all of the patients for the next 12±1 [5-15] months, and repeatedly assessed nutritional parameters.

**Results:** During the follow-up period, there was a significant increase in serum albumin (3.3±0.4 vs. 3.5±0.4 g/dL, p<0.01) and prealbumin (27±7 vs. 29±8 mg/dL, p<0.05). Body mass index (BMI) was identical, but ASFA was increased from 107.4±53.2 to 117.0±63.2 $cm^2$ (p<0.05). There was a significant decrease in TMA both in the right (84.5±25.2 vs. 80.8±26.6 cm2, p<0.01) and in the left legs (82.1±23.9 vs. 78.2±26.1 cm2, p<0.01). In patients who had gained body weight (+3.8±4.3%, n=38), a significant increase was found in ASFA (110.4±55.3 vs. 134.2±65.9 $cm^2$, p<0.01) and AVFA (99.7±51.3 vs. 116.0±56.3 $cm^2$, p<0.01), while TMA and TFA did not change. In patients who had lost their weight (-3.9±4.2%, n=37), a significant decrease was found in TMA and TFA in the both legs, but ASFA and AVFA did not alter.

**Conclusions:** These findings suggest that initiation of maintenance HD therapy increased abdominal adiposity while decreased thigh muscle volume over 1 year, indicating the accelerated sarcopenic obesity in incident HD patients.

### FR-PO787

**The Beneficial Effects of Body Weight Reduction in Overweight Patients with Proteinuric Immunoglobulin A Nephropathy: A Randomized Controlled Trial** Piyawan Kittiskulnam, Talerngsak Kanjanabuch, Wiwat Chancharoenthana, Kearkiat Praditpornsilpa, Somchai Eiam-ong, Kriang Tungsanga. *Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

**Background:** The study was conducted to examine the effects of body weight (BW) reduction on proteinuria in overweight and biopsy-proven IgA nephropathy (IgAN) patients (body mass index, BMI>23 kg/m$^2$) with persistent proteinuria ≥1 g/day.

**Methods:** 26 overweight IgAN patients were randomized into 2 groups: 1) control-usual dietary intake (n=13) and 2) low-calorie, a 500-Kcal/d subtraction from basal energy expenditure, and normal protein diet (n=13). Patients were treated with the maximal doses of ACEI/ARB and other anti-hypertensive agents to control BP at the level of less than 130/85 mmHg. At baseline and 6-month treatment, anthropometric measurement, dietary food record, urine protein nitrogen appearance (PNA), plasma adipokines (leptin, adiponectin & resistin) and interleukin (IL)-6 as well as laboratory parameters were assessed. (NCT01773382)

**Results:** There were no significant differences in baseline characteristics and demographics, including BP, BMI, renal function, 24-hour urine protein, normalized PNA (nPNA), and plasma cytokines. After 6 months, nPNA and dietary protein intake were not different, indicating comparable protein intake. Total daily calorie intake were significantly lower in the low-calorie diet group (1,307±171 *vs.* 1,772±315 Kcal/d, $p$<0.01). There were significant reductions in BW (3.9±2.6 kgs, $p$<0.001) and 24-hour urine protein (0.6±0.4 g/d, $p$<0.001) in the low-calorie diet group. BP and renal function parameters were not different. In the low-calorie diet group, patients with BW reduction of more than 5% had significantly lower plasma levels of leptin (46.5±27.6 *vs.* 1.9±37.8%, $p$=0.02) but higher adiponectin than the control group (18.6±14.7 *vs.* 3.1±21.2%, $p$=0.03).

**Conclusions:** 6-month BW reduction is independently associated with significantly decreased proteinuria in overweight IgAN patients. This effect may be partly mediated by changes in adipokine levels. Further studies are required to examine the long term effect of BW reduction in IgAN.

*Funding:* Government Support - Non-U.S.

### FR-PO788

**Increased Daily Caloric Intake Is Associated with Increased Exercise Capacity in Obese Diabetic Patients with Chronic Kidney Disease** Cheryl Cooper, Eileen Collins, Jolene Butler, Susan O'Connell, Christine Jelinek, Conor McBurney, Anne Garabedian, Holly J. Kramer, David J. Leehey. *Medicine and Research, Hines VA Hospital, Hines, IL.*

**Background:** Patients with diabetes, obesity, and chronic kidney disease (CKD) are generally physically inactive which may be an important contributor to their high mortality rate. Whether higher daily caloric intake has a beneficial or detrimental effect on ability to exercise in this population is unknown.

**Methods:** We examined baseline data from a VA funded randomized controlled trial (NCT01036490) to assess physical fitness in this population. Inclusion criteria are type 2 diabetes, obesity (body mass index > 30 kg/m$^2$), chronic kidney disease (stage 2-4) and persistent proteinuria (> 200 mg/day for at least 3 months). Data from the baseline symptom-limited treadmill test were analyzed. We calculated daily caloric intake at baseline using a 24-hour diet recall. Average daily intake in kilocalories (kcal) was calculated using Food Processor software (Version 9.5.0, ESHA Research, Salem Oregon).

**Results:** Baseline data on 30 subjects were evaluated. Mean values (± SD) were as follows: age 66 ± 8.1 yrs, body mass index 36.5 ± 4.9 kg/m$^2$, percent body fat 41.3 ± 6.6%, glycated hemoglobin 8.1 ± 1.8%, serum creatinine 2.3 ± 1.0 mg/dL, creatinine clearance 46.5 ± 35.7 mL/min, urinary albumin excretion rate 1013 ± 1073 mg/24h. Average treadmill time was 6.8 ± 3.8 minutes and peak oxygen consumption ($VO_2$ peak) was 13.1 ± 3.6 mL/kg/min (peak METS 3.7 ± 1.0; range 2.0-5.8). Average daily caloric intake was 2102 ± 591 kcals (range 1076-3266). Daily caloric intake was highly correlated with $VO_2$ peak and METS (r = 0.49, p < 0.01) and creatinine clearance (r = 0.52, p < 0.01). Interestingly there was no correlation between caloric intake and body mass index (r = - 0.06) or percent body fat (r = - 0.19).

**Conclusions:** These data indicate that obese diabetic subjects with CKD have markedly impaired baseline physical fitness (peak METS less than half of what would be expected in a healthy population). However, despite obesity, increased caloric intake was associated with a beneficial rather than a detrimental effect on treadmill exercise capacity.

*Funding:* Veterans Affairs Support

### FR-PO789

**Body Cell Mass, Measured by Electrical Body Impedance, Is Adequate to Estimate Muscle Mass in Renal Patients** Carlo Donadio. *Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.*

**Background:** Malnutrition is particularly evident in ESRD patients treated by dialysis (MHD). Malnutrition can be found also in pre-ESRD patients. Since the nutritional status is a major determinant of long-term outcome of renal patients, there is a need for simple and accurate methods to evaluate nutritional status.

The measurement of the electrical impedance of the body (BIA) is a simple, rapid, and inexpensive method to analyze body composition and body fluid compartments. Among other parameters, BIA allows to estimate Body Cell Mass (BCM), which is the metabolically active component of fat-free mass and is mainly related to muscle mass.

Aim of this study was to validated the measurement of BCM obtained with single and multifrequency BIA as an indicator of the amount of muscle mass in pre-ESRD and in MHD patients.

**Methods:** Sixty-two adult renal patients (29 F, 33 M) aged 19-79 years, affected by different kidney disease. Their serum creatinine (Creat) ranged between 0.55 and 2.27 mg/dL and GFR (99mTc-DTPA) between 32 and 127 mL/min/1.73 m$^2$. Other 19 anuric MHD patients (7 F, 12 M) aged 28-82 years, dialysis vintage 0.6-15y, mean 7.3 years were evaluated. The values of BCM were obtained using a single frequency and a multifrequency tetrapolar impedance plethysmograph. In CKD patients 24 hour urinary creatinine excretion (24h Ucr) was calculated. In MHD patients 24h Creat Generation was calculated by the increase in serum Creat in the inter-dialytic period.

**Results:** A very high linear correlation was found between the values of BCM and 24h Ucr (r=0.807). The correlation between BCM and Creat generation was even higher (r=0.894). Similar results were obtained by single and multifrequency BIA. Since Creat is produced by muscle cells 24h UCr in CKD and Creat Gen in MHD patients equal creatinine production, and both are useful tools to assess the amount of muscle mass.

These data indicate that the value of BCM obtained with BIA is strictly related to the amount of muscle mass, estimated from 24h Ucr in CKD patients and by creatinine generation in MHD patients.

**Conclusions:** In conclusion, the measurement of body cell mass seems an adequate tool to evaluate muscle mass and nutritional status of renal patients.

### FR-PO790

**Low Grade Albuminuria and Its Relationship with Metabolic Syndrome and eGFR in a Mexican Population: Results of the Salmex Study** Olynka Vega, Maria de Los Angeles Mendoza-De la Garza, Rodolfo Rincon-Pedrero, Yolanda Victoria Baeza-arias, Angeles Espinosa-cuevas, Jorge Ignacio Fonseca-Correa, Bertha Herrero-bervera, Ricardo Correa-Rotter. *Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute, Mexico, Distrito Federal, Mexico.*

**Background:** Low-grade microalbuminuria (LowACR, <30 mg/day) has previously been identified as a cardiovascular risk factor. Metabolic syndrome (MS) has also been shown to be related with microalbuminuria. We assessed the relationship among LowACR, renal function, and the present components of the MS from the Salmex Cohort Study.

**Methods:** From a cohort of 1009 subjects, we included 983 adults (62.3% women). Participants with albuminuria greater than 300 mg/g (n=26) were excluded. MS components were defined using the AHA definitions.

**Results:** A high prevalence of MS (30.3%) was observed. Table 1 shows the studied variables according to the number of components of the MS. LowACR correlated with BMI (r 0.23, p <0.0001), MS components (r0.22 p <0.0001), CKD-EPI (r0.16, p0.03), age (r0.12, p<0.001), and systolic blood pressure (SBP, r0.09, p0.005). In a stepwise multiple regression model, with LowACR as the dependent variable, the final model identified, age, CKD-EPI, and MS components as the independent variables explaining the variance of the LowACR (model R=0.36).

**Conclusions:** LowACR was associated with MS and its components.

### FR-PO791

**Calibration of the Brief Food Frequency Questionnaire among Patients on Dialysis** Cynthia Delgado,[1] Patricia Ann Ward,[2] Glenn M. Chertow,[3,7] Lindsey Storer,[1] Lorien S. Dalrymple,[4] Torin Block,[5] George A. Kaysen,[4,7] John Kornak,[6,7] Barbara A. Grimes,[6,7] Nancy G. Kutner,[2] Kirsten L. Johansen.[1,7] *[1]Univ of California, San Francisco; San Francisco Dept of Veterans Affairs; [2]Emory Univ; [3]Stanford Univ School of Medicine; [4]Univ of California, Davis; [5]NutritionQuest Berkley; [6]Univ of California, San Francisco; [7]USRDS Nutrition Special Studies Center.*

**Background:** Accurately estimating dietary intake is particularly challenging in patients with chronic diseases. The aim of this study was to develop a calibrated equation based on dietary intake restricted by food items from the Block Brief 2000 food frequency questionnaire (BFFQ) using 3-day food diary records among patients on dialysis.

**Methods:** 3-day food diary data from 146 incident dialysis patients were reviewed and entered into a web-based dietary interview system. Information was re-entered omitting any foods in the diaries that were not included in the BFFQ to generate a "BFFQ-restricted" set of intakes. Major dietary components were modeled separately using linear regression. Independent variables were BFFQ-restricted food diary estimates as the average of the 3 days of diaries, restricted to items included in the BFFQ, with the unrestricted 3-day food diary averages as dependent variables.

**Results:** The BFFQ-restricted diary energy estimate of 1325 ± 545 kcal was 87% of the energy intake in the full food diary (1510.3 ± 510.4, p<0.0001). BFFQ-restricted diary carbohydrate intake was 83% of the full food diary (156.7 ± 78.7 g vs. 190.4 ± 72.7, p<0.0001). The BFFQ-restricted fat intake was 90% of full diary-reported fat intake (50.1 ± 24.1 g vs. 56.4 ± 21.6 g, p<0.0001). Daily protein intake assessments were not statistically different. Associations among BFFQ-restricted diary and unrestricted intake were linear. Final equations did not include adjustments for age, sex, or race because the patterns of associations were not significantly different.

**Conclusions:** Energy and macronutrient estimates by BFFQ are lower than estimates from 3-day food diaries, but simple calibration equations can be used to approximate total intake from BFFQ responses.

## FR-PO792

**Validating a Computer Generated Food Frequency Questionnaire in Children with Hypertension** Rossana Baracco, Nancy Fassinger, Mauricio Romero Olvera, Murty Adabala, Amrish Jain, Gaurav Kapur. *Pediatrics, Children's Hospital of Michigan/Wayne State Univ, Detroit, MI.*

**Background:** Lifestyle modifications, including a low sodium diet, are the cornerstone in the management of hypertension (HTN). VioFFQ is a computer generated food frequency questionnaire that collects detailed nutritional intake data and processes it immediately into a user friendly report that helps the healthcare team assess dietary habits and provide counseling. The aim of this study was to validate VioFFQ in children with HTN using 24 hour urine excretion of urea.

**Methods:** Prospective study of children ages 10 to 19 who were referred for evaluation and management of HTN. Twenty four hour urine was collected for estimating excretion of sodium and urea. The VioFFQ was administered on the morning after the urine collection was done. Pearson correlation was done for intake assessed by the questionnaire and 24 hour urinary measurement of sodium and urea.

**Results:** Of 50 patients enrolled, 36 completed the study and were included. Of these, 51.4% were African American, 58.3% were male and 58.3% were obese. The medians of age, weight and BMI were 15 (11 – 18), 75.2 kg (42.6 – 131.4) and 27.9 (16.1 – 47.1) respectively. Protein and sodium intake measured by VioFFQ correlated with urine excretion of urea and sodium (r=0.5, p<0.05; r=0.05, p<0.05 respectively). The median sodium intake measured by VioFFQ was 3795 grams (2077 – 12765). Obese and African American patients had higher sodium intake.

| | Obese median (range) | Non Obese median (range) | African-American median (range) | Non-African-American median (range) |
|---|---|---|---|---|
| Sodium intake (mg) | 4199 (2295 - 12765) | 3608 (2077 - 8123) | 4324 (2077 - 12765) | 3618 (2442 - 10676) |
| Sodium intake per 1000 calories (mg) | 1792 (1452 - 3159)* | 1494 (1103 - 2126)* | 1603 (666 - 2776) | 1497 (585 - 2640) |
| *p<0.01 | | | | |

**Conclusions:** VioFFQ is a reliable tool to estimate dietary patterns of sodium and protein intake in children. Obese children have higher intake of sodium as assessed by the survey. As the VioFFQ is picture based, meaningful and easy dietary recommendations can be made regarding dietary changes in children with HTN.

## FR-PO793

**Increasing Dietary Fiber Reduces Plasma Levels of Colon-Derived Uremic Solutes in Hemodialysis Patients** Tammy L. Sirich,[1] Natalie Plummer,[1] Thomas H. Hostetter,[2] Timothy W. Meyer.[1] *[1]Medicine, Stanford Univ, Palo Alto, CA; [2]Medicine, Case Western Reserve Univ, Cleveland, OH.*

**Background:** Numerous uremic solutes are derived from the breakdown of amino acids by colon bacteria. Two such solutes, indoxyl sulfate (IS) and p-cresol sulfate (PCS), have been associated with adverse outcomes in renal failure. This randomized study tested whether increasing fiber intake would lower the plasma levels of IS and PCS in hemodialysis patients.

**Methods:** Forty patients on maintenance hemodialysis received either daily supplements of fiber (n=20) or a control starch (n=20) for 6 weeks. Fiber was administered as 18 g/day of resistant starch from high amylose maize. The pre-dialysis plasma levels of IS and PCS were assessed at week 0 and week 6 by liquid chromatography and tandem mass spectrometry. The free, unbound solute concentrations were measured as these are the levels to which body tissues are exposed.

**Results:** Results showed (mean±sd; [a],p<0.025 Week 0 vs Week 6; [b], p<0.025 Fiber vs Control):

| | | Fiber | Control |
|---|---|---|---|
| IS (mg/dl) | Week 0 | 0.36 ± 0.23 | 0.28 ± 0.16 |
| | Week 6 | 0.25 ± 0.17 [a] | 0.28 ± 0.15 |
| | % change | - 27 ± 39 [b] | 8 ± 39 |
| PCS (mg/dl) | Week 0 | 0.27 ± 0.15 | 0.22 ± 0.13 |
| | Week 6 | 0.21 ± 0.14 [a] | 0.23 ± 0.14 |
| | % change | -24 ± 44 | 7 ± 46 |

Increasing fiber intake reduced the plasma levels of IS while the control starch had no effect. Comparison of the % change in plasma levels of IS confirmed a statistically significant effect of increasing fiber intake. Increasing fiber intake also reduced the plasma levels of PCS but the difference between the fiber and control groups did not achieve statistical significance. There were no differences in gastrointestinal or other side effects between the two groups.

**Conclusions:** Results are in accord with the hypothesis that by providing colon microbes with carbohydrate that escapes digestion in the small intestine, increasing fiber intake reduces microbial production of uremic solutes from amino acids. Increasing fiber intake thus provides a potential means to reduce levels of colon-derived solutes without intensifying the dialysis prescription.

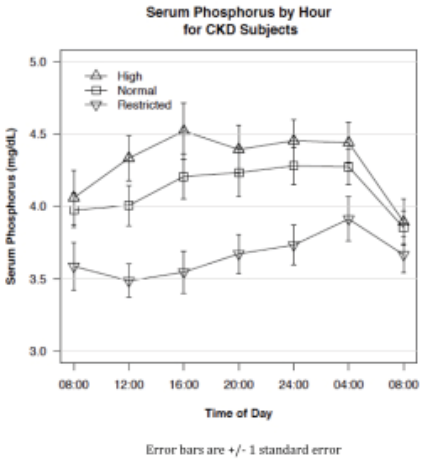
## FR-PO794

**Effects of Dietary Phosphorus on Circadian Rhythm of Serum Phosphorus in Chronic Kidney Disease** Cheryl A. Anderson,[1] Dena E. Rifkin,[1] Joachim H. Ix,[1] Gerard John Smits,[2] Geoffrey A. Block.[2] *[1]Univ of California San Diego; [2]Denver Nephrologists PC.*

**Background:** Effects of dietary phosphorus (P) on circadian rhythm of serum P have been described in healthy individuals, but not in individuals with moderate chronic kidney disease (CKD). We describe the effects of three diets with varying P on circadian rhythm of serum P.

**Methods:** We conducted a crossover trial in 11 individuals with eGFR 30 – 45 mL/min/1.73m$^2$. Participants received 3 different P diets sequentially ("restricted": 750 mg/day + Lanthanum Carbonate 1000 mg (TID), "normal": 1500 mg/day, and "high": 3000 mg/day). Participants ate only foods provided for 7 days, and were then admitted to an in-patient facility for 24-hours of observation followed by a 10-day washout. Serum P was collected every 4 hours starting at 8am during in-patient observation. Mixed effects regression models were used for analyses.

**Results:** Participants were 91% white, 64% female; with baseline mean(SD) age of 67(14) years, serum P of 3.6(0.5), and eGFR of 36.5 (8.4) mL/min/1.73m$^2$. There was a significant time*diet interaction on serum P (P< 0.05). On normal and high P diets, serum P increased from morning through the afternoon, whereas no diurnal difference was seen on the restricted P diet (Figure). Serum P was lowest and had the least difference by diet at 8am. The largest difference in serum P by diet was observed at 4-8pm.



**Conclusions:** Change in serum P was observed in CKD patients consuming normal and high P diets. There was also evidence of a circadian pattern with the nadir at 8am. Future intervention studies targeting intestinal P absorption may benefit from evaluation of afternoon/evening measurements rather than morning serum P.

## FR-PO795

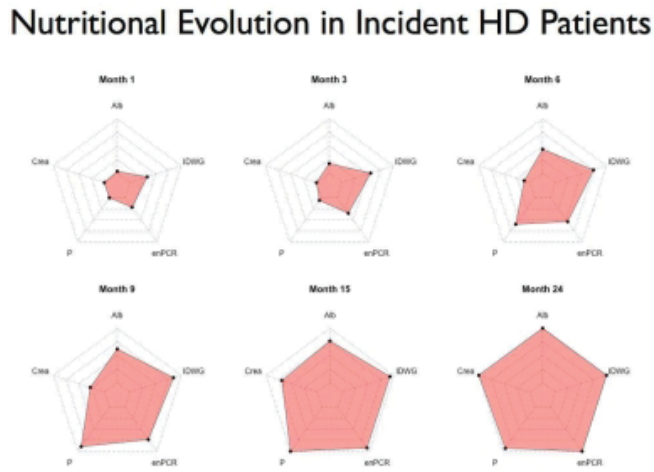
**Trajectories of Nutritional Parameters and Formulation of a Composite Nutritional Score in Hemodialysis Patients** Michelle M.Y. Wong,[1] Stephan Thijssen,[1] Len A. Usvyat,[2] Peter Kotanko,[1] Franklin W. Maddux.[2] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA.*

**Background:** Nutritional status is assessed using a combination of multiple parameters in hemodialysis (HD) patients. However, most existing nutritional scores are derived from cross-sectional data and do not consider trajectories of nutritional parameters. Therefore, a cohort study was performed 1) to assess temporal patterns of nutritional parameters using radar plots and 2) to generate a composite nutritional score.

**Methods:** The patient cohort was derived from the Fresenius Medical Care North America database, and included incident patients who started HD between 2007 and 2011. Serum albumin (Alb), creatinine (Crea), phosphate (P), equilibrated normalized protein catabolic rate (enPCR) and interdialytic weight gain (IDWG) were graphed on radar plots at months 1,3,6,9,15,24 after initiating HD. A composite nutritional score was formulated by converting these five component variables to z scores and generating an additive composite, which was then converted to percentiles. The nutritional score was tracked over two years.

**Results:** The full dataset comprised 47,238 patients, but not every patient had data available for every parameter each month. Early after HD initiation, albumin, creatinine, phosphate, enPCR and IDWG values indicated poorer nutritional status. Over the first 2

years of HD, each of these nutritional parameters improved, as illustrated on radar plots. The composite nutritional score also improved from the 26th percentile at the start of HD to the 57th percentile at 2 years.



**Conclusions:** Serial radar plots are useful tools to assess overall nutritional status by incorporating multiple nutritional parameters and their trajectories over time. In future analyses, trajectories of the composite nutritional score can be applied to predict outcomes in HD patients.

## FR-PO796

**Does a Low Salt Diet Affect Protein Intake in Chronic Kidney Disease Patients?** Eiichiro Kanda,[1] Toshitaka Muneyuki,[2] Kaori Sakamoto,[3] Tomoya Hirayama,[4] Kei Nakajima,[5] Yoshihiro Matsumoto,[6] Sanae Watanabe,[3] Yoshihiko Kanno.[7] *[1]Dept of Nephrology, Tokyo Kyosai Hospital; [2]Saitama Citizens Medical Center; [3]Kagawa Nutrition Univ; [4]Kitasaito Hospital; [5]Josai Univ; [6]Shizuoka City Hospital; [7]Tokyo Medical Univ.*

**Background:** Among chronic kidney disease (CKD) patients with severe diet restriction, their compliance to diet restrictions declines. We have reported that protein intake can be estimated on the basis of creatinine-correlated urinary urea nitrogen (UNC) level of spot urine. In this study, we investigated the relationship between salt intake and UNC as an alternative index of protein intake.

**Methods:** 132 CKD patients (80 males), who were administered a low salt diet, were enrolled in this prospective cohort study in Japan. Their UCN and urinary sodium (UNa) levels were measured three times at separate outpatient clinics. Salt intake was estimated using the salt intake formula of The Japanese Society of Hypertension Guidelines 2009. The relationship between salt intake and UNC was evaluated on the basis of Pearson's correlation coefficient (r) with the initial measurement, and generalized estimating equation (GEE) and generalized linear mixed model (GLMM) with repeated measurements. GEE and GLMM were adjusted for age, gender, estimated glomerular filtration rate, proteinuria level, and diuretic use.

**Results:** The mean age (SD) was 64.6(13.0) years; eGFR 64.1(25.9) ml/min/1.73m$^2$; UPro/Cr 4.5(11.1) mg/gCr; UNC 6.97(2.51) g/gCr; estimated dietary protein intake 48.5(8.6) g/day; and salt intake 10.02(3.0) g/day. Salt intake correlated with UNC at the initial measurement (r=0.341, p=0.0005). After adjustment for baseline patient characteristics, a positive longitudinal relationship was indicated by GEE between the salt intake and UNC (beta=0.345, p=0.0001). The GLMM showed that the increase in salt intake can predict the increase in UNC (beta=0.346, p=0.0001).

**Conclusions:** This study showed that UNC is associated with salt intake in CKD patients administered a low salt diet. Because UNC is positively associated with protein intake, it is suggested that a protein intake restriction may be achieved with only salt restriction.

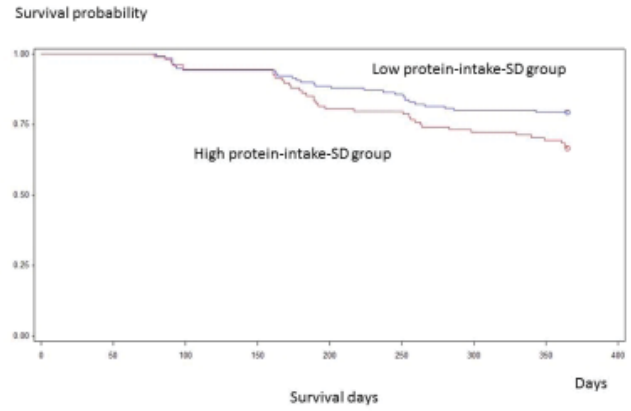
## FR-PO797

**Fluctuating Protein Intake Is an Independent Risk Factor for the Progression of Chronic Kidney Disease** Eiichiro Kanda,[1] Masumi Ai,[2] Renjiro Kuriyama,[3] Masayuki Yoshida,[2] Tatsuo Shiigai.[4] *[1]Tokyo Kyosai Hospital; [2]Tokyo Medical and Dental Univ; [3]Kokubunji Minamiguchi Clinic; [4]Shiigai Clinic.*

**Background:** A low-protein diet prevents the progression of chronic kidney disease (CKD). However, the consistent adherence to a low-protein diet is difficult. We investigated the longitudinal effects of changes in protein intake on the CKD progression in elderly CKD patients.

**Methods:** CKD patients (n=249, 190 males) administered a low-protein (0.6 to 0.8 g/kg/day) were enrolled in this retrospective cohort study in Japan. Their protein intake was measured every three months. The longitudinal change in protein intake was evaluated by the standard deviation (SD) of their protein intake (protein-intake SD). The endpoint was 25% decline in estimated glomerular filtration rate (eGFR) or starting dialysis. The outcome was evaluated using a time-dependent Cox proportional hazard model adjusted for demographics.

**Results:** The mean age (SD) was 70.6 (7.0) years; eGFR 22.2 (14.1) ml/min/1.73m$^2$; protein intake 0.85 (0.22) g/day; protein-intake SD 0.12 (0.07) (median, 0.10; Q1, 0.07; Q3, 0.15). The primary endpoint was observed in 65 patients (26.1%). The patients with high protein-intake SD (>0.10) had a high risk of the renal death: hazard ratio (HR), 1.712 (95%CI 1.050, 2.792); adjusted HR, 2.144 (1.046, 4.391).



An increase in protein-intake SD by 0.1 increased the risk of renal death; adjusted HR, 2.386 (1.293, 4.405). A generalized estimating equation model showed a longitudinal relationship between protein intake and serum albumin level [beta=0.0011 (0.0001), p=0.0043].

**Conclusions:** This study showed that protein-intake SD is associated with CKD progression. Because protein intake is associated serum albumin level, a stable protein intake and nutritional monitoring are necessary to prevent CKD progression and malnutrition.

## FR-PO798

**Efficacy of Eicosapentaenoic Acid (EPA) on Chronic Kidney Disease (CKD) due to Benign Nephrosclerosis** Yoshihiko Inoue, Tadahide Maezumi, Daisuke Komukai, Kiyoko Inui, Ashio Yoshimura. *Div of Nephrology, Showa Univ Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

**Background:** We studied the efficacy of EPA to prevent the progression of both renal impairment and atherosclerosis in CKD stage 3-4 patients due to benign nephrosclerosis (BNS).

**Methods:** 31 CKD stage 3-4 patients due to BNS with dyslipidemia were followed for 1 year after the start of EPA treatment. The dosage of 1800 mg/day was newly started. T-cho, LDL-cho, Triglycerides (TG), EPA, arachidonic acid (AA), Dihomo-gamma-linolenic acid (DGLA), docosa hexaenoic acid (DHA), right and left (RL) brachial-ankle pulse wave velocity (baPWV), RL maximum carotid intima-media thickness (max IMT), RL maximum carotid plaque thickness and RL ankle-brachial index (ABI) were studied at before treatment (baseline) and at the end of the study. eGFR and the amount of proteinuria were studied at 1year before the start of treatment, baseline and at the end of the study.

**Results:** EPA treatment elicited statistically significant increase in EPA (1-year of EPA: 242.2±100.7 vs. baseline: 73.0±39.3 μg/ml, P<0.01), EPA/AA ratio and decrease in TG. RL baPWV and RL max IMT were significantly improved (1-year of right baPWV: 1564.3±333.4 vs. baseline: 1686.1±369.2, 1-year of left: 1597.1±332.0 vs. baseline: 1723.4±378.8 cm/s, 1 year of right max IMT: 0.85±0.26 vs. baseline 0.96 ± 0.35, 1-year of left: 0.80±0.24 vs. baseline 0.92±0.31, P<0.05). eGFR and amount of proteinuria also showed significant improvement at the end of the study (1-year of eGFR: 46.9±13.0 vs. baseline: 43.8±11.1 ml/min/1.73m$^2$, P<0.05). Both EPA and DHA levels were significantly low in eGFR exacerbation patients group (n=7) compared with eGFR improvement patients group (n=24) at both baseline and the end of the study. The highest EPA level patients at baseline (EPA: 127.2±16.3 μg/ml, n=8) showed significant improvement changes in both eGFR and baPWV compared with the lowest EPA level patients (EPA: 30.1±8.1 μg/ml, n=8). There was no difference on both plaque thickness and ABI between baseline and the end of the study.

**Conclusions:** EPA may prevent both the development of renal dysfunction and the atherosclerotic change in CKD stage 3-4 patients due to BNS.

## FR-PO799

**Selenium Supplementation and Antioxidant Outcome Markers in Hemodialysis Patients** Elizabeth J. Sussman,[1] Carol S. Johnston,[2] Kenneth R. Boren,[3] Bhupinder Singh.[3] *[1]Family and Consumer Sciences, California State Univ, Northridge, Northridge, CA; [2]School of Nutrition and Health Promotion, Arizona State Univ, Phoenix, AZ; [3]Southwest Kidney Institute/DaVita, Inc., Tempe, AZ.*

**Background:** Hemodialysis (HD) patients elicit an oxidant-antioxidant imbalance in addition to a selenium deficiency, possibly contributing to cardiovascular disease mortality. The objective of this study was to evaluate the effect of selenium supplementation on antioxidant status in HD patients.

**Methods:** In this intervention trial, 27 maintenance (≥90days) HD patients (61.1±17.5y, 14M, 13F) receiving treatment in the greater Phoenix, AZ area were randomized to receive either a tablet of selenium (200µg/day [purported] of selenium as selenomethionine), or placebo daily for three months. Antioxidant status outcome measures included total antioxidant capacity, vitamin C, and RBC and plasma glutathione peroxidase (GSH-Px). Repeated measures ANOVA analyzed changes over time and between groups at months 0 and 2 and months 0 and 3.

**Results:** Independent analysis showed the pill provided 266µg of selenium/day. 21 patients completed 2 months of the study and 17 patients completed the study in its entirety. Data were analyzed for months 0, 1 and 2. No significant differences were noted for antioxidant status outcome measures with the exception of plasma GSH-Px. Patients receiving the selenium pill had a significant increase in plasma GSH-Px compared to the placebo group (6.0±11 and -4.0±7.6, respectively, p=0.023 for change between month 0 and month 2). In addition, vitamin C concentrations were well below normal ranges at all time points for both groups throughout the study (group averages ranged from 0.24 to 0.38 mg/dL and there were no differences between groups at any time point).

**Conclusions:** These data indicate that selenium supplementation increased plasma GSH-Px concentration in HD patients. Moreover, the low vitamin C status of HD patients warrants further research, specifically in conjunction with selenium supplementation to improve antioxidant status.

## FR-PO800

### Association of Height with Death Risk in End-Stage Kidney Disease

Austin G. Stack,[1,2] Lookman Olalekan Abdul,[1] Ailish Hannigan,[2] Bhamidipati V.R. Murthy,[3] Liam F. Casserly.[1,2] *[1]Nephrology and Internal Medicine, Univ Hospital Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland; [3]Dept of Transplantation, Baylor College of Medicine.*

**Background:** Studies in the general population have identified an inverse association between height and the risk of death with tall individuals having lower mortality over shorter individuals. The aim of this study was to explore the associations of height with mortality among patients with end stage kidney disease.

**Methods:** We identified 989, 994 incident US dialysis patients who began dialysis treatment between 1995 and 2008 and followed until December 2010. Individual height measurements were recorded prior to the onset of first dialysis therapy. The association of height with 2-year mortality was explored in quintile groups of Q1 < 157.5 cm, Q2 157.5 to <165, Q3 165 to <170.2, Q4 170.2 to <177.8 cm and Q5 > 177.8 cm with Q1 as the referent, stratified by race, and with adjustment for age, sex, weight, clinical conditions, laboratory variables and lifestyle indicators These relationships were expressed as adjusted Hazard Ratios (HR). All analyses were conducted using SAS v 9.3 (Cary NY).

**Results:** The average age of the population was 62.8 years, 65 % were white, 30% Black, 3.6 % Asian and 1.1% Native American/Alaskan Native. Race-specific heights for White, Black, Asian and Native Americans were 174, 175, 167 and 174 cm respectively for men and were 160, 163 , 155, and 160cm respectively for women. Increasing height was associated with significantly higher mortality although this relationship did not extend to all race groups. **P<0.001

**Adjusted Hazard Ratios for Death by Height among US Dialysis Patients**

| | | Adjusted HR for Height in Quintiles (cm) | | | | |
|---|---|---|---|---|---|---|
| | | Q1 | Q2 | Q3 | Q4 | Q5 |
| Race | Patients | 122-158 | 158-165 | 165-170 | 170-178 | >178 |
| Native American | n=11, 089 | 0.97 | 1.00 | 1.02 | 1.03 | 1.05 ** |
| Asian | n=41,564 | 0.99 | 1.00 | 1.00 | 1.02 | 1.02 |
| Black | n=296, 365 | 0.99 | 1.00 | 1.01 | 1.00 | 1.02 |
| White | n=640, 976 | 0.96 ** | 1.00 | 1.02 | 1.01** | 1.02 ** |

| | | Adjusted HR for Height (cm) | | |
|---|---|---|---|---|
| Race | Patients | Per increasing quintile | | P-trend |
| Native American | n=11, 089 | 1.07 | (1.01-1.12) | < 0.01 |
| Asian | n=41,564 | 1.01 | (0.98-1.05) | NS |
| Black | n=296, 365 | 1.01 | (0.99-1.02) | NS |
| White | n=640, 976 | 1.04 | (1.03-1.04) | <0.0001 |

**Conclusions:** Unlike the general population, tallness is associated with higher mortality in patents who reach end stage kidney disease. This reverse epidemiological phenomenon requires further study to uncover putative mechanisms.

## FR-PO801

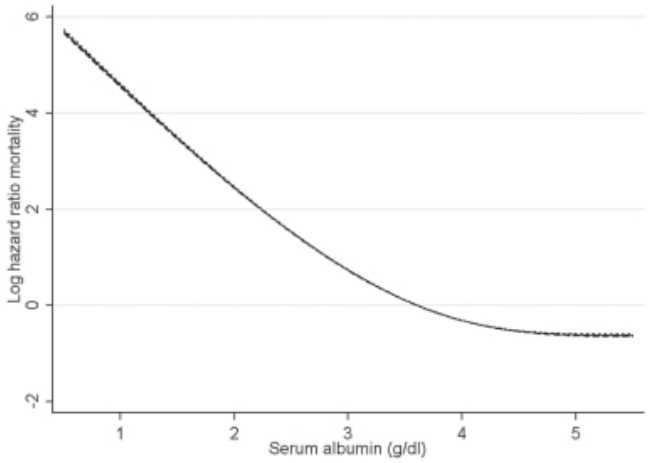
### Changes in Serum Albumin Associated with Decreased Kidney Function, and Its Effects on Mortality in a Nationally Representative Cohort of U.S. Veterans with Non-Dialysis Dependent CKD

Csaba P. Kovesdy,[1,2] Jun Ling Lu,[2] Miklos Zsolt Molnar,[3] Jennie Z. Ma,[4] Joel D. Kopple,[5] Kamyar Kalantar-Zadeh.[6] *[1]Memphis VA Medical Center; [2]Univ of Tennessee Health Science Center; [3]Univ of Toronto; [4]Univ of Virginia; [5]Harbor-UCLA Medical Center; [6]Univ of California-Irvine.*

**Background:** Serum albumin (ALB) level is a marker of protein-energy wasting and is associated with increased mortality. It is unclear if worsening CKD is associated with progressive decrease in ALB, and if intra-individual changes in ALB affect its association with mortality in patients with non-dialysis dependent (NDD) CKD.

**Methods:** We examined longitudinally ALB and its association with all-cause mortality in a cohort of 484,157 US veterans with NDD-CKD stages 1-5 and at least 2 ALB measurements, using mixed effects regression models, time-dependent Cox models and joint modeling, adjusted for demographic characteristics, comorbidities and medication use.

**Results:** Patients had 3,285,026 ALB measurements (median (IQR): 5/patient (3-9)) over 5.9 years median follow-up. The adjusted odds ratio (95%CI) of ALB<3.6 g/dl associated with a 10 ml/min/1.73m$^2$ lower eGFR was 1.09 (1.08-1.10, p<0.001), and individuals experienced an ALB decline at 0.047 g/dl/year (95%CI: 0.046-0.048, p<0.001). 159,761patients died (mortality rate: 61.4/1000 patient-years (95%CI: 61.1-61.7)). The adjusted mortality hazard ratio (95%CI) associated with each 1 g/dl lower ALB was 3.24 (3.21-3.27, p<0.001, Figure 1).



**Conclusions:** Thus, hypoalbuminemia worsens over time in patients with NDD-CKD, and progressively lower ALB is associated with increased mortality. The effect of therapeutic interventions to prevent or treat hypoalbuminemia will need to be examined in clinical trials.

## FR-PO802

### Acute Kidney Injury in Shoshin Beriberi – A Case Series

Shashidhar Baikunje,[1] Rama S. Prakasha,[2] Glaxon Alex.[2] *[1]Dept of Nephrology, K. S. Hegde Medical Academy, Mangalore, India; [2]Dept of Medicine, K. S. Hegde Medical Academy, Mangalore, India.*

**Background:** Shoshin Beriberi is a rare and unusual metabolic cause of acute kidney injury and literature in this regard is sparse worldwide. Patients often present with evidence of right heart failure, severe shock and metabolic acidosis in addition to renal failure.

**Methods:** Retrospective analysis of eight cases with above manifestations.

**Results:** The mean age was 34.8 years and five out of eight were males. Three patients were alcoholics. The most common presenting features were edema, breathlessness and oliguria. Mean creatinine on admission was 2.54 mg/dl and mean MDRD eGFR was 36.6 ml/min/1.73 m$^2$. Mean haemoglobin was 11.9 g/dl, total count 13,412/cu.mm, mild proteinuria was present in seven, RBCs in urine in two and granular casts in four. Abnormal liver enzymes were noted in six of the eight patients, CPK and CK-MB were elevated in four. Echocardiographic evidence of right heart dilatation and pulmonary hypertension were seen in all the cases. Severe metabolic acidosis was noted with mean pH of 7.06 and mean arterial bicarbonate of 5.74mmol/l. Three patients required renal replacement therapy, two needed ventilatory support and four were treated with inotropes. Six patients were treated with broad spectrum antibiotics but the cultures were negative in all except one. IV thiamine was used in seven patients with excellent clinical response and one patient who did not receive thiamine died. There was improvement in acidosis, blood pressure and renal function within 48-72 hours and all the seven of them had normalization of creatinine levels.

**Conclusions:** Presentation with multiorgan involvement, severe metabolic acidosis, evidence of right heart dilatation with pulmonary hypertension on echocardiogram and dramatic response to IV thiamine were the basis of the diagnosis since the diagnostic tests for thiamine deficiency are rarely used in acute setting. Renal dysfunction has excellent prognosis and the recovery is complete if the condition is suspected and treated promptly.

**FR-PO803**

**Investigation of Carnitine Deficiency in Children Receiving Continuous Renal Replacement Therapy** Kristen Sgambat, Kirtida Mistry, Shamir Tuchman, Asha Moudgil. *Nephrology, Children's National, Washington, DC.*

**Background:** Carnitine deficiency is common in patients receiving chronic hemodialysis (HD) due to inadequate intake, decreased production, and removal during dialysis. The effect of continuous renal replacement therapy (CRRT) on carnitine homeostasis has not been previously studied. We hypothesized that children receiving CRRT may be at risk for carnitine deficiency due to continuous removal, absent intake, and comorbidities related to underlying critical illness.

**Methods:** Medical records of all patients recieving CRRT at Children's National between 2011 and 2013 were reviewed for total carnitine (TC)and free carnitine (FC) levels. Patients on carnitine supplementation were excluded. Prevalence and progression of carnitine deficiency at baseline, 0.5, 1, 2, and 3 weeks duration on CRRT was assessed. Mean TC and FC levels of children on CRRT were compared to those of a prospective comparison group of children on chronic HD for > 3 months by Student's t test.

**Results:** The study group included 27 CRRT patients with mean age 9.9±7.4 years. At initiation of CRRT,14.3% of children were TC deficient. Prevalence of deficiency increased with duration of CRRT to 54.5%, 72.7%, 75%, and 100% at 0.5,1,2,and 3 week time points, respectively. The prevalence of FC deficiency similarly increased wtih duration of CRRT from 42.9% at baseline to 70%, 72%, 75%, and 100% at 0.5,1,2,and 3 weeks. Mean carnitine levels after 1 week on CRRT were significantly lower compared with baseline levels (TC decreased from 41.7 to 20.9 and FC from 27.1 to 14.1 µmol/L), p<0.01. Mean carnitine levels of children on CRRT for 0.5 week was lower compared with levels of 9 children on chronic HD for mean duration of 9.3±6 months (TC 27.1±17.5 vs 49±5.1 and FC 17.5±13.0 vs 29±3.6 µmol/L), p<0.03.

**Conclusions:** Carnitine levels significantly decrease with longer time on CRRT, and the majority of children on CRRT for 1 week are carnitine deficient. Deficiency is more severe after only 0.5 week on CRRT in comparison to children on chronic dialysis for a mean of 9.3 months. Consequences of carnitine deficiency and possible benefits of supplementation in the critically ill pediatric CRRT population should be investigated.

**FR-PO804**

**The Effect of Serum Zinc on Salt Taste Acuity, Preference and Dietary Sodium Intake in Hemodialysis Patients** Hyun woo Kim,[1] So Mi Kim,[1] Eun Kyoung Lee,[2] Ji Eun Lee.[2] *[1]Div of Nephrology, Jeju National Univ Hospital, Jeju, Korea; [2]Div of Nephrology, Dankook Univ Hospital, Cheonan, Korea.*

**Background:** High sodium intake has been known for the major cause of fluid overload in hemodialysis patients, leading to increased cardiovascular mortality. High sodium intake is related to low salt taste acuity and high salt preference and zinc status is known to influence taste acuity. We tried to analyze the effect of serum zinc status on salt taste acuity, preference and dietary sodium intake in hemodialysis patients.

**Methods:** This cross-sectional study enrolled 77 patients, who underwent hemodialysis in the Jeju national university hospital or Dankook university hospital. The patients were divided into two groups based on the level of serum zinc : 26 patients showed normal range and 51 patients showed zinc deficiency. 1-day dietary recall was used to estimate the dietary sodium intake and Salt taste acuity and preference were determined by sensory test using variable concentration of NaCl solution.

**Results:** Baseline characteristic, mean age, sex, cause of ESRD, HTN medication, BP were not different between the two groups. The NaCl solution concentration of both salt taste acuity and preference showed higher tendency in the Zn deficient group than that in the Non- Zn deficient group ( mean NaCl % of taste acuity : 0.13±0.05 vs 0.16±0.57 p=0.04, mean NaCl % of salt taste preference : 0.48 ±0.13 vs 0.54±014, *p*=0.07). Although the sodium intake showed high tendency in zinc deficient group, there was no significant difference ( 2134 ± 937 vs 2546 ± 297 mg/day, *p*=0.056). But the correlation between the sodium intake and the serum zinc showed the significant negative linear relationship ( r=-0. 313 , *p* <0.05 ). Interdialytic weight gain was significantly higher in the zinc deficient group than that in non-zinc deficient group (2.68± 1.02 *vs.* 3.18 ± 1.02 kg, *p*=0.04).

**Conclusions:** We conclude that zinc deficiency may lead to high sodium intake in hemodialysis paitents, affecting on the salt taste acuity and preference.

**FR-PO805**

**Inadequate Dietary Intake Correlates with Thiol Markers of Oxidative Stress in Maintenance Hemodialysis Patients (HD)** Paolo Fanti,[1] Daniela Giustarini,[2] Ranieri Rossi,[2] Franco Folli,[1] Khaled Khazim,[3] Padam Hirachan,[1] Sue Cunningham,[1] Georgiana Gross,[1] Shweta Bansal.[1] *[1]Div of Nephrology, UT Health Science Center San Antonio, San Antonio, TX; [2]Univ of Siena, Italy; [3]Western Galilee Hosp., Israel.*

**Background:** Anorexia and poor nutrition are the most important immediate causes of protein-energy wasting (PEW) in uremia. Oxidative stress (OS) is believed to participate in the pathogenesis of uremic PEW, but it is unclear if direct association exists between poor nutrition and OS in this disease state.

**Methods:** To test the hypothesis that poor nutrition and OS are linked in uremia, we analyzed the 3-day diet record and the plasma thiols redox of 76 clinically stable HD and 24 age-matched healthy controls (C). 3-day diet record was analyzed with The Food Processor software (ESHA, Salem OR). Analysis of thiol redox included plasma total cysteine (CYS), cystine (CYSS) and protein thiolation index (PTI) a new marker of OS *[Giustarini D, et al. Free Radic Biol Med 53:907, 2012]*.

**Results:** As expected, HD showed very low intake of Calories (18 ± 7 kcal/kg/day) and Protein (0.8 ± 0.4 g/kg/day) and they displayed profound abnormalities of circulating thiols as compared to C, including high PTI (0.77 ± 0.21 vs. 0.46 ± 0.09; *p<0.001*), CYS (448 ± 101 vs. 316 ± 48 µM; *p<0.001*) and CYSS (101 ± 29 vs. 66.9 ± 11.6 µM; *p<0.001*). In multiple linear regression of appropriately transformed variables, HD showed negative association of PTI with Protein/kg/day (β=-0.360; *p=0.007*) and positive with age (β=0.274; *p=0.038*) while controlling for HD clinic, sex, ethnicity, cause of ESRD, body mass index and intake of Calories, Carbohydrates and Fat. Moreover, CYS was negatively associated with Calories/kg/day (β=-0.480; *p<0.001*), and CYSS was negatively associated with Calories/kg/day (β=-0.292; *p=0.021*) and positively with age (β=0.306; *p=0.015*) while controlling for the same co-variables as above.

**Conclusions:** Markers of thiol redox correlate negatively with Protein and Calorie intake in HD, raising the possibility that poor nutrition may contribute to OS in HD. Prospective studies are needed to determine whether cause-and-effect relation exist between low dietary intake and OS in CKD.

**FR-PO806**

**The Effect of Oral Vitamin D Supplementation in Non-Dialytic CKD Patients** Sun Moon Kim,[1] Soon Kil Kwon,[1] Hye-Young Kim,[1] Han Ro,[2] Ji Yong Jung.[2] *[1]Internal Medicine, Chungbuk National Univ, College of Medicine; [2]Internal Medicine, Gachon Univ of Medicine and Science.*

**Background:** The anti-inflammatory, antifibrotic, and antiproteinuric properties of vitamin D have been defined in studies using active vitamin D analogs. Here, we study the effects of nutritional vitamin D supplementation on bone mineral metabolism and progression of renal disease in chronic kidney disease (CKD) patients.

**Methods:** We conducted the study in adult, vitamin D deficient [25(OH) D < 30 ng/mL], non-dialytic CKD patients. The patients were classified into oral vitamin D supplementation (cholecalciferol 1,000 IU/day) or not for 6 months. The serum level of 25(OH) D, parathyroid hormone (PTH), calcium, phosphate, alkaline phosphatase, creatinine, and urinary protein excretion were measured serially.

**Results:** Ninety seven patients were enrolled. The baseline characteristics were not different between vitamin D group vs. control group. Vit D supplementation achieved the improvement in serum 25(OH) D level (vitamin D vs. control, 28.01 ± 12.82 ng/mL vs. 13.50 ± 7.29 at 3 month, p <0.001; 29.49 ± 16.19 vs. 14.17 ± 8.17 at 6 month, p < 0.001). This difference was persistent in the subgroup analysis of baseline GFR <30 mL/min/1.73m$^2$ vs. GFR 30-60 or 25(OH) D <15 ng/mL vs. 25(OH) D 15-30. PTH level was decreased in the vitamin D group compared to control group (vitamin D vs. control; 40.2 (26.8 – 72.0) pg/mL vs. 54.2 (38.2 – 101.1) at 3 month, p = 0.013; 38.8 (19.2 – 65.3) vs. 58.1 (39.5 – 137.0) at 6 month, p = 0.014). Vitamin D supplementation increased corrected calcium level compared to control at 3 month, whereas the difference was not significant at 6 month. The level of phosphate, estimated GFR, and random urine protein-to-creatinine ratio were not different. During the study period, four patients in vitamin D group and five in control group started renal replacement therapy. The most common adverse effect was gastrointestinal irritation. There was no case of symptomatic hypercalcemia.

**Conclusions:** Oral vitamin D supplementation was effective in replenishing vitamin D store in CKD patients. However, we could not find any beneficial effect on renal disease progression.

**FR-PO807**

**The On-Line Hemodiafiltration Improves the Nutritional Status in Hemodialysis Prevalent Patients: A 1-Year, Prospective, Controlled Study** Pablo Molina,[1] Belen Vizcaino,[1] Angela Maria Serrato,[1] Daniel A. Molina,[1] Sandra Beltrán,[1] Avila Ana,[1] Julia Kanter,[1] Mariola D. Molina,[2] Jose L. Gorriz,[1] Luis M. Pallardo.[1] *[1]Dept of Nephrology, Hospital Universitari Dr Peset, Valencia, Spain; [2]Dept of Statistics and Operational Research, Universidad de Alicante, Spain.*

**Background:** Compared to conventional haemodialysis, on-line hemodiafiltration (OL-HDF) removes more efficiently uremic toxins, which could attenuate the hypercatabolism and increase the protein anabolism of hemodialysis patients. The present study evaluated the 1-year effect of OL-HDF on nutritional status in prevalent haemodialysis patients.

**Methods:** This single-center, controlled, intervention study enrolled all high-flux hemodialysis (HF-HD) subjects attending our Unit from 2012 to 2013 (n=33; mean age: 60.2±17.5 years; women: 42%; median time on dialysis:37(8-133) months). Patients were randomized to receive posdilution OL-HDF (n=17) or to remain on HF-HD (n=16). Changes in multifrequency bioimpedance parameters (primary outcomes) and other biochemical and anthropometric parameters (secondary outcomes) were used to assess the effect of OL-HDF in nutritional status. A repeated-measures analysis between baseline to 12-month follow-up was conducted.

**Results:** OL-HF treatment group showed no changes in body composition.

| Effect parameter | OL-HF | HF-HD | *p* |
|---|---|---|---|
| LTM (kg), mean | 0.3 | -7.5 | 0,001 |
| | -2.8 to 3.8 | -11.1 to -3.8 | |
| 95% CI | | | |
| Fat (kg), mean | 0.3 | 7.3 | 0,005 |
| | -1.9 to 2.4 | 2.8 to 11.8 | |
| 95% CI | | | |
| TBW (L), mean | -0.8 | -3.5 | 0,014 |
| | -2.2 to 0.7 | -5.6 to -1.5 | |
| 95% CI | | | |
| ICW (L), mean | -0.1 | -2.3 | 0,005 |
| | -1.0 to 0.8 | -3.8 to -0.9 | |
| 95% CI | | | |
| ECW (L), mean | -0.6 | -1.2 | 0,249 |
| | -1.5 to 0.2 | -2.0 to -0.4 | |
| 95% CI | | | |

A significant decrease in lean-tissue mass and intracellular water was observed only in the HF-HD in absence of changes in protein intake, with an increase in fat mass. Creatinine levels decreased only in HF-HD group (9,96±3.0 mg/dl vs. 9.5±3.5; p<0.001). Transferrin levels were reduced in both groups. No other changes were observed.

**Conclusions:** 1-year after its implementation, OL-HDF preserved protein nutritional status better than HF-HD. These results support the hypothesis that the convective dialysis treatment could ameliorate the hypercatabolic state of dialysis patients.

## FR-PO808

**The Effect of Lanthanum Carbonate on Metabolic Acidosis in Stage IV-V Chronic Kidney Disease Patients** William Beaubien-souligny, Jean-Philippe Lafrance, Denis Ouimet, Vincent Pichette, Robert Zoël Bell, Michel Vallee. *Dept of Medicine, Div of Nephrology, Maisonneuve-Rosemont Hospital, Montreal, Canada.*

**Background:** Hyperphosphatemia and metabolic acidosis are two frequently encountered problems in advanced CKD patients that are associated with significant mortality and morbidity. Lanthanum carbonate is a potent phosphate binder frequently used for control of hyperphosphatemia. Some studies have showed an increase in bicarbonate concentration in renal replacement patients but this effect have never been demonstrated in predialysis patients.

**Methods:** Retrospective data was collected from 2009 to 2012 on 62 consecutive CKD IV-V patients (46 hemodialysis, 3 peritoneal dialysis patients and 13 pre-dialysis patients) who start using lanthanum carbonate in a single center. Laboratory assays for phosphorus, calcium, parathormone (PTH) and serum bicarbonates were analyzed. The primary outcome identified was the serum bicarbonate change after introduction of lanthanum carbonate.

**Results:** Compare to baseline, introduction of lanthanum carbonate led to a mean increase in serum bicarbonate concentration of 2.33 mmol/L (p = 0.03) at one month. No significant increase was found after the initial month. The initial increase at one month tended to be greater in the pre-dialysis patients (3.33 mmol/L p = 0.13) compared with the renal replacement groups. A decrease in the phosphorus level of 1.11 mg/dL (0.36 mmol/L, p = 0.001) was found after the introduction of lanthanum carbonate, and was maintained over time. There was no significant change in calcium and PTH concentration compared with baseline.

**Conclusions:** Lanthanum carbonate introduction temporarily increased serum bicarbonate concentration in CKD IV-V patients. Further studies are needed to explore the role of lanthanum carbonate on the control of metabolic acidosis in predialysis patients.

*Funding:* Government Support - Non-U.S.

## FR-PO809

**Kidney Failure Is Associated with an Imbalance between Pro- and Anti-Oxidant Agents: Relationship with Uremic Solutes** Bertrand Gondouin,[1] Noemie Jourde,[1] Philippe Brunet,[1] Stephane Burtey,[1] Guieu Regis,[2] Bertrand Dussol.[1] *[1]Centre de Nephrologie et Transplantation Renale, Hôpital Conception, Assistance Publique des Hopitaux de Marseille, Marseille, France; [2]Service de Biochimie et Biologie Moleculaire, Hôpital la Timone, Assistance Publique des Hopitaux de Marseille, Marseille, France.*

**Background:** Patients with chronic kidney disease (CKD) are at high risk for cardiovascular events.This is related to non-classical risk factors, including oxydative stress. We evaluated a wide range of parameters involved in oxidative stress in CKD population and their relationship to different uremic solutes.

**Methods:** We performed an observational study on 50 hemodialysis (CKD HD) and 50 patients with CKD stage 3 to 5 not on dialysis (CKD NOD) and 38 healthy subjects (control). We performed dosages of (i) anti-oxidant agents: super oxide dismutase (SOD), vitamin C, A, E, zinc (Zn), copper (Cu) and selenium (Se), (ii) pro-oxidant agents: malondialdehyde (MDA), ischemia modified albumin (IMA), (iii) enzymes: xanthine oxidase (XO), red blood cells glutathione reductase (RBC-GR). and (iiii) 5 uremic solutes: indoxyl sulfate (IS), indole acetic acid (IAA), para cresyl sulfate (PCS), homocysteine (HCYS), Beta 2 microglobulin (B2M).

**Results:** Se and Zn were decreased (p<0.001 respectively) in CKD HD and CKD NOD compared to controls. Vitamin C was dramatically decreased in CKD HD and CKD NOD compared to control (both p <0.001). SOD activity was decreased in CKD HD compared to control (p<0.01). RBC-GR was increased in CKD HD and CKD NOD when compared to control (both p<0.001).

IMA levels were increased in CKD NOD and CKD HD compared to controls (both p<0.001). MDA and XO activity levels were increased in CKD HD compared to controls (p>0.001).

MDA was inversely correlated with eGFR in CKD NOD (r=-0.288; p <0.05). In CKD HD, IAA was positively correlated with IMA (r= 0.487; p=0.01), para cresyl sulphate (PCS) was inversely correlated with RBC-GR (r= -0.33; p <0.05), B2M was positively correlated with MDA (r= 0.51; p=0.001).

**Conclusions:** These results showed an imbalance in favour of an oxidative stress in CKD patients and a clear relationship between markers of oxidative stress and different uremic solutes.

## FR-PO810

**Treatment of IgA Nephropathy Using a Chinese Herbal Medicine Prescription (Long Hua-1)** Lin Wang,[1] Bing Xu,[2] Yueyi Deng,[1] Zhi Qiang Huang,[3] Yiping Chen.[1] *[1]Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, China; [2]Yue Yang Hospital, Shanghai Univ of Traditional Chinese Medicine, China; [3]Univ of Alabama at Birmingham.*

**Background:** Long Hua-1 (LH-1) is a Chinese herbal medicine prescription used to treat IgA nephropathy (IgAN) in Long Hua Hospital for decades. To evaluate its efficacy, we compared treatment responses to LH-1 with those to LH-1 plus steroids, cytotoxic agents and/or ARB (LH-1+).

**Methods:** Fifty-eight biopsy-proven IgAN patients with normal renal function and blood pressure were included in this retrospective study. Average age was 32±10 and 34±11 years respectively. Urinary protein (UP) ranged from 0.5 to 2 g/24 h in both groups, with or without microscopic hematuria. Thirty patients were treated with LH-1 only, 160 g bid, and 28 patients with LH-1+. Median follow-up time was around 13 mo. In each group, patients were divided into two sub-groups according to biopsy results: group 1: major changes were mesangial cell proliferation; group 2: mesangial cell proliferation with focal segmental sclerosis.

**Results:** There were no differences in blood pressure and renal function changes among the groups with different treatments. In group 1 treated with LH-1, UP dropped from 1.04±0.34 to 0.35±0.21 g/24 h after the treatment; in group 1 treated with LH-1+, UP dropped from 1.08±0.48 to 0.48±0.27 g/24 h. In group 2 treated with LH-1, UP dropped from 1.08±0.44 to 0.55±0.43 g/24 h after the treatment; in group 2 treated with LH-1+, UP dropped from 1.13±0.39 to 0.33±0.22 g/24 h. There was no statistically significant difference between UPs in group 2 after LH-1 vs. LH-1+. Among patients treated with LH-1+, 6 patients developed upper-respiratory infection followed by exacerbated proteinuria. Five other patients developed fungal and/or skin infections. Another patient showed liver function changes with increased GPT. No side effects were reported for patients treated with LH-1 only.

**Conclusions:** LH-1 improved proteinuria in IgAN with similar efficacy as LH-1+. Significant side effects were found in LH-1+ group but not in LH-1. These data justify future randomized clinical trials to assess the clinical impact of LH-1 in IgAN treatment.

## FR-PO811

**Brachial–Ankle Pulse Wave Velocity Predicts Decline in Renal Function and Cardiovascular Events in Early Stages of Chronic Kidney Disease** Hye Eun Yoon, Sung Jun Kim, Hyeon Seok Hwang, Seok Joon Shin. *Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

**Background:** In this study, we investigated the predictive capacity of the brachial–ankle aortic pulse wave velocity (baPWV), a marker of arterial stiffness, for the decline in renal function and for cardiovascular events in the early stages of chronic kidney disease (CKD).

**Methods:** Two hundred forty-one patients who underwent a comprehensive check-up were included and were divided into two groups according to their estimated glomerular filtration rates (eGFR): patients with CKD stages 2 and 3 (30 £ eGFR < 90 ml/min/1.73m$^2$, the eGFR < 90 group; n=117) and those with eGFR ≥ 90 ml/min/1.73 m$^2$ (eGFR ≥ 90 group; n=124). The change in renal function, the eGFR change, was determined by the slope of eGFR against time. We analysed whether baPWV was associated with eGFR change or predicted cardiovascular events.

**Results:** baPWV was independently associated with eGFR change in a multivariate analysis of the total patients (b=–0.011, p=0.011) and remained significantly associated with eGFR change in a subgroup analysis of the eGFR < 90 group (b=–0.008, p=0.028). baPWV was independently associated with cardiovascular events (odds ratio=1.002, p=0.048) in the eGFR < 90 group, but not in the eGFR ≥ 90 group. The receiver operative characteristic curve analysis showed that 1,568 cm/sec was the cut-off value of baPWV for predicting CV events in the eGFR < 90 group (area under curve=0.691, p=0.03).

**Conclusions:** In patients with early stages of CKD, baPWV was independently associated with the decline in renal function and short-term cardiovascular events.

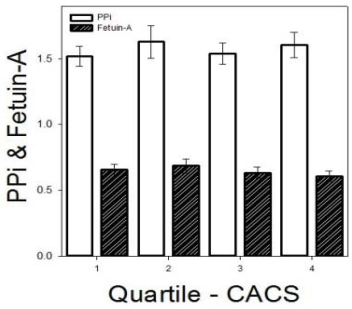
**FR-PO812**

**Inhibitors of Vascular Calcification and Coronary Artery Calcification in ESRD** Ramin Tolouian, Sean M. Connery, German T. Hernandez. *Texas Tech Univ HSC at El Paso, TX.*

**Background:** Vascular calcification (VC) is an important predictor of cardiovascular mortality in ESRD. Disturbances in mineral metabolism, especially Ca and $PO_4$, have been linked to enhanced calcification of blood vessels but the Ca & PO4 levels do not adequately explain this pathology. □ levels of inhibitors of the calcification process, such as Fetuin-A and inorganic pyrophosphate (PPi), are thought to VC. Therefore, we evaluated the association between Fetuin-A and PPi, and coronary calcification scores in maintenance HD.

**Methods:** 106 maintenance HD patients were studied (mean ±SD) : Age (yr.) 58 ±11.2, HD vintage (yr.) 4.0 ±3.2, Ca*P (mg/dl) 43 ±11.6, Male 63%, Hispanic 89%, diabetic 72%. Platelet free plasma Ppi was measured by radiometric, enzymatic method. Serum Fetuin-A was measured with the Ultrasensitive ELISA kit (Alpco 43-FETHUU-E01) on a Beckman DTX 800 microplate reader. Coronary arterial calcification score (CACS) was measured by sub-second gated helical computed tomography with an Imatron C-150 XL ultra fast CT scanner using a standard CACS protocol: slice thickness 3mm, Density Threshold (HU) 130, Pixel threshold 3, Algorithm Discrete, read by a single, experienced cardiologist.

**Results:**



There was no statistically significant difference between PPi and Fetuin-A when comparing low-risk CACS (<300) and high risk CACS (≥300), Ppi (mM) 1.56 ±0.49 vs 1.57 ±0.46, Fetuin-A (g/L) 0.67 ±0.24 vs 0.65 ±0.25. Furthermore, there was no significant difference in PPi and Fetuin-A levels between CACS quartiles (p=ns Kruskal-Wallis test). Mean CASC for each quartile were 0.80, 66, 391, and 2,957 respectively. Error bars indicate error of the mean.

**Conclusions:** There does not appear to be an unadjusted inverse relationship between inhibitors of vascular calcification and CACS our study of HD patients. The possibility of confounding by age, HD vintage, and diabetes needs to be further evaluated.

*Funding:* Private Foundation Support

**FR-PO813**

**Dietary Habits Are Associated with Proteinuria Independent of Major Cardiovascular Risk** Makoto Kanno,[1] Koichi Asahi,[1,2] Kenichi Tanaka,[1] Yoshimitsu Hayashi,[1] Masaaki Nakayama,[1] Kunitoshi Iseki,[2] Toshiki Moriyama,[2] Kunihiro Yamagata,[2] Kazuhiko Tsuruya,[2] Hideaki Yoshida,[2] Shouichi Fujimoto,[2] Tsuyoshi Watanabe.[1,2] *[1]Dept of Nephrology, Hypertension, Diabetology, Endocrinology and Metabolism, Fukushima Medical Univ School of Medicine, Fukushima, Japan; [2]Steering Committee for "Research on the Positioning of Chronic Kidney Disease (CKD) in the Specific Health Check and Guidance System of Japan", Fukushima, Japan.*

**Background:** Irregular dietary habits are associated with a number of risk factors for cardiovascular disease (CVD), including obesity, insulin resistance, and dyslipidemia. However, few studies have examined the relationship between these habits and proteinuria or chronic kidney disease (CKD).

**Methods:** This cross-sectional cohort study examined 181,524 subjects (73,753 men; 107,771 women; mean age, 63.8 years; age range, 40-74 years) who participated in an annual nationwide health checkup system in 2008. We compared prevalence of proteinuria (≥1+ on dipstick test) among participants according to the number of irregular dietary habits (skipping breakfast (SB), dinner within 2 h before bedtime (DbB), snacking after dinner (SaD) and eating quickly (EQ)) obtained by questionnaire response. Multivariate logistic regression models were used to adjust for possible confounding factors.

**Results:** Overall prevalence of proteinuria was 5.9%, and increased significantly from 5.2% to 8.6% with increases in the number of irregular dietary habits. The odds ratio (95% confidence interval) for proteinuria was 1.24 (1.17-1.32) with SB, 1.14 (1.08-1.20) with DbB, 1.08 (1.02-1.15) with SaD and 0.97 (0.93-1.01) with EQ, after adjusting for sex, age, body mass index, metabolic syndrome, hypertension, diabetes, dyslipidemia, estimated glomerular filtration rate, history of stroke, cardiac disease and kidney disease, smoking and exercise habit.

**Conclusions:** Some irregular dietary habits are associated with proteinuria independent of major CVD risk factors. Future research should investigate whether aggressive intervention regarding daily dietary habits can prevent the development of CKD.

**FR-PO814**

**Outcomes Associated with Oral Protein Supplementation during Maintenance Hemodialysis: A Quality Improvement Prospective Interventional Study** Buthayna Dinary, Keyvan Ravakhah, Fazel Dinary. *Internal Medicine/Nephrology, St. Vincent Medical Center, Cleveland, OH.*

**Background:** Low serum albumin levels in dialysis patients are associated with increased morbidity & mortality. Dietary protein intake is a cheap and equally effective way of achieving an increase in serum albumin and improve quality of life (QOL).

**Methods:** A multicenter, prospective, Interventional study included patients from three HD units affiliated with academic and tertiary-care hospitals in Cleveland OH. Patients were adult patients aged > 18 YO and have been treated by HD for at least 6 months. An inclusion criterion was: serum albumin concentration < 3.8 mg/dl in HD patients. Exclusion criteria were documented malignancies and any acute infectious diseases within the last 2 months. From a cohort of 106 patients who were enrolled, 87 were eligible for the analysis. LiquaCel, which provides 16 gm protein and 2.5 gm L-Arginine per 1 oz. serving, was given to patients with albumin level < 3.8. Blood samples for serum albumin were drawn on the day of midweek HD session. On the same day, the Quality of life Health Survey (QOLHS) Score was evaluated. Patients were evaluated for Serum albumin concentration which was measured monthly for 6 months as primary outcome and they were assessed for QOLHS score obtained before supplementation and at the end of project.

**Results:** A total of 87 patients were included in the analysis. The mean Baseline QOLHS score was 16.2 and the mean Baseline Albumin was 3.37, when the pre and post protein supplementation data were analyzed using paired *t*-tests, significant differences were present; the mean increase in serum albumin concentration of 0.9 mg/dL observed ($P < .05$).The QOLHS score correlated significantly with the serum albumin level at all measurements (baseline: r = -0.37, P = .0001; and 6 months: r = -0.46, P < .0001).

**Conclusions:** Following oral protein supplementation, paired comparisons (i.e., paired pre to post supplementation for individual patients) showed that there was significant improvement in the malnutrition parameter (represented by hypoalbuminemia). This correlated with a significant improvement in the responses to the overall QOL. (P value < 0.5).

**FR-PO815**

**Effects of Intravenous Ascorbic Acid on Vascular Function and Oxidative Stress in Chronic Kidney Disease** Keith Gillis,[1] Kathryn K. Stevens,[1] Markus P. Schneider,[3] Scott Morris,[1] Christian Delles,[1] Alan G. Jardine,[1] Patrick B. Mark.[1] *[1]Univ of Glasgow, Glasgow, United Kingdom; [2]Glasgow Renal and Transplant Unit, Glasgow, United Kingdom; [3]Univ of Erlangen-Nuremberg, Erlangen.*

**Background:** Endothelial dysfunction and arterial stiffness may explain premature cardiovascular disease seen in chronic kidney disease (CKD). Antioxidant therapy may improve endothelial dysfunction and reduce cardiovascular risk. We studied the effect of intravenous ascorbic acid (VitC) on oxidative stress and arterial stiffness in hypertensive patients with normal renal function (HTN) and with CKD.

**Methods:** This was a single-blind crossover study. Patients received both VitC and normal saline (NaCl). At baseline and following each intervention, vascular function, (pulse wave analysis, augmentation index (Aix) and pulse wave velocity) was measured and bloods were drawn for markers of oxidative stress. Rate of reactive oxygen species (ROS) production was measured by electron paramagnetic resonance and total antioxidant capacity (TAC) by colorimetric assay.

**Results:** 12 CKD and 12 HTN patients were recruited with a mean age of 56 (SD 12) and a mean blood pressure (BP) 142/88mmHg (SD 15/13). There were no significant differences between the groups in gender, age or BP. The CKD group had an eGFR of 28.3 ml/min (SD 10.5) compared with 98.2 ml/min (SD 10.9) in the HTN group ($p<0.05$). VitC led to a significant reduction in AIx in both goups: from 26% (SD 8%) after NaCl to 16% (SD 11%) after VitC ($p<0.05$) in CKD patients and 24% (SD 12%) to 19% (SD 11%) ($p<0.05$) in HTN. There was no significant difference between the groups. Rate of ROS production was transiently increased in both CKD (43% $p<0.05$) and HTN (37% $p<0.05$) at 10 minutes, before falling to a baseline level at 60 minutes. TAC was initially increased in both CKD (57%, $p<0.05$) and HTN (50%, $p<0.05$) before falling to baseline at 60 minutes.

**Conclusions:** Ascorbic acid ameliorates arterial stiffness and paradoxically increases ROS production in both CKD in HTN. Whilst the pro oxidant effect of ascorbic acid is acknowledged, this is the first in vivo evidence of increased ROS production and further research is required to elucidate the mechanisms of this.

**Fruits and Vegetables or Oral $NaHCO_3$ Prevent Progression of Kidney Injury in Stage 1 CKD due to Hypertensive Nephropathy** Nimrit Goraya,[1,2] Chanhee Jo,[4] Jan Simoni,[3] Donald E. Wesson.[1,2] *[1]Internal Medicine, College of Medicine, Texas A and M, Temple, TX; [2]Internal Medicine, Scott and White Healthcare, Temple, TX; [3]Surgery, Texas Tech Univ Health Sciences Center, Lubbock, TX; [4]Biostatistics, Scott and White Healthcare, Temple, TX.*

**Background:** Dietary alkali reduces kidney injury and slows GFR decline in patients with reduced GFR due to hypertensive nephropathy (HN). Reduced GFR further increases cardiovascular risk of HN and kidney injury typically precedes GFR reduction. Consequently, preventing further kidney injury appears to benefit hypertensives with

presently normal GFR. We explored if dietary alkali as base-producing fruits and vegetables (F+V) or oral $NaHCO_3$ ($HCO_3$) prevents kidney injury progression in hypertensives with normal MDRD-estimated GFR (eGFR).

**Methods:** Macroalbuminuric HN subjects with eGFR>90 ml/min (n=71) had systolic blood pressure (SBP) reduced to <150 mm Hg with regimens including ACE inhibition, then randomized to receive F+V, (n=23) in amounts to reduce dietary potential renal acid load 50%, oral $NaHCO_3$ ($HCO_3$, n=23) 0.4 meq/Kg/day, or no added alkali (Time Control, n=25). Urine excretion of albumin (Ualb), N-acetyl-D-glucosaminidase (UNAG), an index of tubule-interstitial kidney injury, and urine angiotensinogen (UATG), an index of kidney levels of angiotensin II, a possible mediator of progressive nephropathy, were measured at time zero and at one year.

**Results:** Ualb (347±82 to 387±73 mg/g cr, p<0.01) and UNAG (2.5±0.5 to 2.7±0.4 U/g cr, p<0.01) increased at one year in Time Control but were not different at one year for F+V (Ualb: 350±75 to 344±53 mg/g cr, p=0.46; UNAG: 2.5 ±0.4 to 2.4±0.4 U/g cr, p=0.23) or $HCO_3$ (Ualb: 341± 83 to 327±73 mg/g cr, p=0.10; UNAG: 2.5±0.3 to 2.5±0.3 U/g cr, p=0.33). UATG increased in Time Control (21.3±3.1 to 22.7±3.0 ug/g cr, p<0.01) but decreased in F+V (21.2±3.4 to 20.1±2.9 ug/g cr, p<0.01) and $HCO_3$ (21.4±3.6 to 20.7±3.0 ug/g cr, p<0.01).

**Conclusions:** Kidney injury progressed in macroalbuminuric HN despite SBP reduction and ACE inhibition. By contrast, dietary alkali as added F+V or oral $NaHCO_3$ prevented progression of kidney injury, possibly through reduced kidney angiotensin II activity.

## FR-PO817

### Epoetin Beta Pegol (C.E.R.A.) Augmented Dietary Iron Absorption by Decrease in Serum Hepcidin Levels and Increase in Expression of Duodenal Iron Transporters

Yusuke Sasaki, Mitsue Kurasawa, Keigo Yorozu, Yasushi Shimonaka. *Chugai Pharmaceutical Co., Ltd., Japan.*

**Background:** Epoetin beta pegol (C.E.R.A.) is a novel long-acting erythropoiesis stimulating agent. We previously reported C.E.R.A. promotes mobilization of iron storage from reticuloendothelial cells through intensive suppression of serum hepcidin levels. The aim of this study is to evaluate the contribution of dietary iron utilization for erythropoiesis after C.E.R.A. treatment in mice.

**Methods:** Hematological and iron parameters including serum hepcidin levels were analyzed in C57BL/6N (B6) mice intravenously treated with 10 μg/kg of C.E.R.A. or vehicle. The expression of duodenal iron transporters, ferroportin (FPN) which is internalized by hepcidin binding and divalent metal transporter (DMT) -1, were assessed by immunohistochemical staining. B6 mice intravenously treated with 10 μg/kg of C.E.R.A. or vehicle were fed iron deficiency diet to inhibit dietary iron absorption or control diet, and transitions of hematological parameters were analyzed.

**Results:** C.E.R.A.-treated mice showed significantly higher hemoglobin (Hb) levels than vehicle-treated mice for 14 days after treatment, while serum hepcidin levels were continuously suppressed and serum iron levels were markedly decreased on the fifth day in C.E.R.A.-treated mice. FPN expression on the basolateral membrane of intestinal enterocytes and DMT-1 expression on luminal surface of them were increased after C.E.R.A. treatment. The inhibition of dietary iron absorption resulted in impaired Hb elevation and decrease in mean corpuscular volume (MCV) after C.E.R.A. injection.

**Conclusions:** C.E.R.A. augmented dietary iron absorption by the suppression of serum hepcidin levels and thereby increasing duodenal expression of FPN and DMT-1, and absorbed iron was beneficially utilized for erythropoiesis. C.E.R.A. has a strong power to promote iron utilization for erythropoiesis through enhancement of dietary iron absorption as well as mobilization of iron storage from reticuloendothelial cells.

## FR-PO818

### Calcitriol Regulates Monocyte Hepcidin and Ferritin: A Role for Vitamin D in Iron Homeostasis

Anjali B. Nayak,[1] Justine Bacchetta,[1] Joshua Zaritsky,[1] Isidro B. Salusky,[1] Martin Hewison.[2] *[1]Dept of Pediatric Nephrology, Univ of California Los Angeles, Los Angeles, CA; [2]Dept of Orthopaedic Surgery, Univ of California Los Angeles, Los Angeles, CA.*

**Background:** Calcitriol (1,25OHD), is an important component of chronic kidney disease(CKD)therapy, and its diverse effects on immune function may have additional benefits for CKD patients. We have shown that hepatocytes and monocytes treated with calcitriol show decreased expression of hepcidin, a key iron-regulatory protein that targets ferroportin, the only known exporter of intracellular iron. To investigate further the iron-regulatory function of calcitriol, we carried out studies using human monocytes exposed to varying levels of iron.

**Methods:** THP-1 human monocytic cells were cultured in regular medium with or without added ferric nitrate ($FeNO_3$) at (5-45 μM) and 1,25OHD for 24 hrs. Cells were then lysed to generate RNA and the expression of various target genes analyzed using qRT-PCR.

**Results:** THP-1 cultured with 5, 15 or 45 μM $FeNO_3$ in the absence of calcitriol showed increased mRNA for hepcidin (4.35-, 2.81- and 4.26-fold respectively) relative to cells in regular medium. Conversely, mRNA for ferritin was decreased with increasing $FeNO_3$ (0.27-, 0.07-, 0.17-fold respectively. In the absence of $FeNO_3$, THP-1 treated with 1,25OHD(1,10 and 100 nM) showed decreased expression of hepcidin (0.25-, 0.14-, and 0.21-fold), and ferritin (0.17-, 0.15-, and 0.11-fold). This effect was also observed in THP-1 cultured with 10nM calcitriol in the presence of low dose(5μM) $FeNO_3$. 10 nM calcitriol in 5 μM $FeNO_3$ decreased expression of hepcidin (0.26-fold) and ferritin (0.25-fold) relative to vehicle. However, 10 nM calcitriol had no effect on expression of mRNA for hepcidin or ferritin at higher(15 or 45 μM) $FeNO_3$ concentrations.

**Conclusions:** These data indicate that active vitamin D, calcitriol, is a potent suppressor of hepcidin and also suppresses ferritin, a surrogate marker for intracellular iron concentrations. These effects are lost under conditions of enhanced hepcidin expression following exposure to high dose exogenous iron, suggesting a selective role for vitamin D in regulating intracellular iron concentrations.

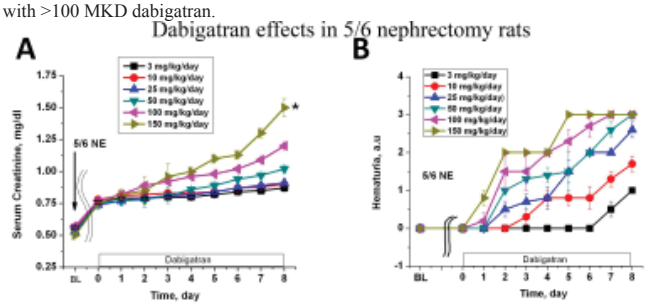
### Direct Thrombin Inhibitor Dabigatran Induces Glomerular Hemorrhage with Acute Kidney Injury Similar to Warfarin Related Nephropathy

Kyle M. Ware, Zahida Qamri, Anjali A. Satoskar, Omar Sameer Hassanain, Lee A. Hebert, Brad H. Rovin, Tibor Nadasdy, Sergey V. Brodsky. *The Ohio State Univ, Columbus, OH.*

**Background:** Excessive anticoagulation with warfarin can result in acute kidney injury (AKI) by causing glomerular hemorrhage and renal tubular obstruction by red blood cell (RBC) casts in some patients, especially in those with chronic kidney disease (CKD). This condition was described early as warfarin related nephropathy (WRN). An animal model of WRN is developed. Recent evidence suggests that WRN-like syndromes are not confined to anticoagulation with warfarin, but may be seen with novel anticoagulants, such as dabigatran. The aim of this study was to investigate dabigatran effects on kidney function in an animal model of CKD.

**Methods:** Sham-operated (control) and 5/6 nephrectomy rats (5/6NE) were treated with different doses of dabigatran for 1 week. Changes in serum creatinine (Scr), hematuria and renal pathology were studied.

**Results:** Dabigatran resulted in 2-fold increase in aPTT in rats at 50 mg/kg/day (MKD). Dabigatran in a dose-depended manner increased Scr and hematuria in both control and 5/6NE (Figure 1, A). Increase in Scr were noted in both groups when >100 MKD dabigatran were used. Hematuria increase and numerous RBC tubular casts in the kidney were seen in 5/6NE treated with >25 MKD dabigatran (Figure 1, B) and in control with >100 MKD dabigatran.



**Conclusions:** Our data indicate that WRN represents part of a broader syndrome, which is anticoagulant related nephropathy. Dabigatran resulted in AKI not only in CKD, but in control rats as well, which was not the case in WRN. Our findings suggest that not only CKD patients, but other patients as well are at high risk of developing AKI if the therapeutic range of anticoagulation with dabigatran is exceeded. Close monitoring of kidney function in patients on dabigatran therapy is warranted.

## FR-PO820

### Intravital Multiphoton Microscopy Can Visualize Oxidative Damage and Tubulointerstitial Fibrosis after Kidney Ischemia-Reperfusion Injury

David M. Small,[1] Washington Yamandu Sanchez,[2] Glenda C. Gobe,[1] Sandrine F. Roy.[3] *[1]Centre for Kidney Disease Research; [2]Therapeatics Research Centre, Sch Medicine, Univ Queensland; [3]Diamantina Institute, Brisbane, Australia.*

**Background:** Acute kidney ischemia-reperfusion (IR) injury is common, serious, and may progress to chronic kidney disease (CKD). Mediators of oxidative stress exacerbate acute injury but their role in CKD is unclear. The aim of this project was to use in vivo multiphoton microscopy (MPM) to visualize IR-induced tubulointerstitial damage in real time, and correlate these with histology.

**Methods:** Bilateral IR (20min) was performed in male 4-6 week old C57BL6 mice followed by reperfusion. Groups compared with MPM were: control kidneys; 10min ischemia; immediately at reperfusion after 20min ischemia; and 21 days post-IR. A Lavision Biotec MPM, was used to excite NAD(P)H fluorescence (740nm) and collagen (900nm) in kidney microstructure. Z-stack images were acquired from three separate areas of cortex in each kidney and the average weighted lifetime ($\tau_m$) of NAD(P)H was determined. H&E staining was performed on fixed kidney post-MPM. Oxidative stress markers were determined by Western blots and immunohistochemistry.

**Results:** NAD(P)H and collagen fluorescence in control kidneys clearly showed structure of proximal and distal tubules, and sparse interstitial space with little collagen. With ischemia and immediately after reperfusion, tubules were swollen and NAD(P)H fluorescence increased, indicating oxidative stress. At 21 days post-IR, there was focal tubular atrophy, interstitial space expansion, intense endogenous fluorescence in remaining normal-looking tubules, and the $\tau_m$ of NAD(P)H increased significantly. Intense cytoplasmic autofluorescent "hot spots" in atrophic tubules were seen, and histology indicated these may be evidence of apoptosis. Histology confirmed other in vivo changes identified with MPM. Markers of mitochondrial destabilisation, apoptosis and autophagy were increased.

**Conclusions:** Oxidative stress mediates acute injury and CKD after renal IR. MPM is a powerful tool to visualize the cellular, subcellular, and metabolic profile of the kidney *in vivo*.

*Funding:* Government Support - Non-U.S.

## FR-PO821

**Targeting Connexin 43 Protects against Chronic Kidney Disease in Experimental Nephropathy in Mice** Christos E. Chadjichristos, Ahmed Abed, Carlo M. Alfieri, Christos Chatziantoniou. *UMR S702, INSERM, Paris, France.*

**Background:** Excessive recruitment of leukocytes and progression of renal fibrosis are hallmarks of chronic kidney disease (CKD). We have recently reported that the expression of connexin 43 (Cx43) was upregulated within kidney in experimental nephropathy. The aim of our study is to investigate the role of Cx43 in the progression of CKD.

**Methods:** We interbred RenTg mice, a genetic model of hypertension-induced CKD, with Cx43+/- mice. RenTgCx43+/- and littermates were sacrificed at 5 months (n=10 mice/group). Moreover, 11 month-old RenTg mice received during 1 month a Cx43 antisense (AS) or scrambled sequence (SCR) via minipump infusion (n=8 per group). After sacrifice kidneys were assessed for morphometry, inflammation and interstitial fibrosis.

**Results:** Renal cortex of RenTgCx43+/- mice presented lesser upregulation of VCAM-1 (2.1 fold) mRNAs ($p<0.05$), leading to reduced monocyte infiltration compared to RenTgCx43+/+ mice (quantification of F4-80 immunostainings showed 4.3±1% and 1.8±0.2% of cortex surface respectively, $p<0.05$). In addition, Sirius Red colorations shown limited renal fibrosis in RenTgCx43+/- mice (0.8% versus 1.3% of cortex surface for RenTgCx43+/+, $p<0.05$). Furthermore, functional and histological parameters such as albuminuria ($p<0.05$) and glomerulosclerosis ($p<0.05$) were both reduced by half in RenTgCx43+/- mice. Interestingly, administration of a Cx43AS produced remarkable regression of the F4-80 signal (4.5±0.5% of cortex surface for SCR versus 1.9±0.4% for Cx43AS, $p<0.01$) and fibrosis (8±1% and 4±0.5% of cortex surface for SCR and Cx43AS respectively, $p<0.001$) in one year-old RenTg mice and consequently improved renal function (125±12mg/mmol versus 45±5mg/mmol of microalbuminuria for SCR and Cx43AS respectively, $p<0.001$). Moreover Cx43 was highly increased in renal biopsies of patients suffering from neproangiosclerosis.

**Conclusions:** Our results show for the first time the importance of Cx in renal diseases and may open towards new therapeutic strategies targeting Cx43 to protect against the progression of CKD.

## FR-PO822

**miR-205 Expression Correlates with Severity of Renal Involvement in a Mouse Model of Congenital Obstructive Nephropathy** Susan E. Ingraham, Michael Wilhide, Ashley R. Carpenter, Kirk M. McHugh. *The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

**Background:** Congenital obstructive nephropathy (CON) is the leading cause of CKD in children. CON is a complex disease process involving pathological changes in kidney development and function resulting from obstructed urine flow beginning *in utero*. The megabladder (*mgb-/-)* mouse is an animal model of CON that develops kidney disease secondary to a bladder-specific defect in smooth muscle development.

**Methods:** Expression levels of specific microRNAs were compared by microarray analysis on the Agilent platform and by qPCR of kidney samples from wild type and *mgb-/-* mice. *In situ* hybridization and immunohistochemistry demonstrated the sublocalization of mir-205 and tubular markers within the nephron.

**Results:** There is increased expression of miR-205 across a panel of *mgb-/-* kidneys compared to wild-type controls (2.94-fold, $P=0.01$). Furthermore, upon stratification of the *mgb-/-* population by severity of kidney involvement, relative miR-205 expression levels rise with increasing severity of hydroureteronephrosis (Mild: 1.35-fold, $P=0.02$; Moderate: 2.30-fold, $P<0.001$; Severe: 5.32-fold, $P<0.001$; all values are relative to wild-type control). Thus, miR-205 expression correlates with the severity of CON in this animal model. *In situ* hybridization studies show miR-205 localizes to the renal urothelium in wild-type and *mgb-/-* kidneys, and to dilated collecting ducts in *mgb-/-* kidneys. In collecting ducts, miR-205 expression shows an inverse relationship with the presence of aquaporin-2 (Aqp2), suggesting a possible role for miR-205 in the physiological response to obstruction via Aqp2 expression or trafficking.

**Conclusions:** MiR-205 in the kidney increases proportionally to the degree of hydronephrosis in the *megabladder* mouse kidney. An inverse pattern of collecting duct expression relative to Aqp2 indicates a possible role for miR-205 in regulation of water transport. Future studies will explore the target molecules and pathways affected by miR-205 in the pathogenesis and physiology of CON, as well as the potential of miR-205 as a noninvasive biomarker of renal maldevelopment or injury in congenital urological obstruction.

## FR-PO823

**Renal Epithelial Toxicity Is an Important Mechanism of Shigatoxin 2-Mediated Kidney Failure. Clinical and Experimental Evidence** Stefan Porubsky,[1] Giuseppina Federico,[1] Stefan Büttner,[4] Nicholas Obermueller,[4] Oliver Jung,[4] Ingeborg A. Hauser,[4] Helmut Geiger,[4] Hermann-Josef Groene,[1] Christoph Betz.[4] *[1]Cellular and Molecular Pathology, German Cancer Research Center (DKFZ), Heidelberg, Germany; [2]Institute for Hygiene, Univ of Muenster, Muenster, Germany; [3]Medical Research Center, Univ of Heidelberg, Mannheim, Germany; [4]Dept of Nephrology, Univ Hospital Frankfurt/Main, Frankfurt/Main, Germany.*

**Background:** The pathogenesis and optimal therapy of Shigatoxin (Stx) mediated kidney failure remain controversial.

**Methods:** Long-term outcome was investigated in patients with Stx-associated hemolytic uremic syndrome at the University Hospital in Frankfurt/Main, Germany. Patients (n=11) had kidney biopsies and were treated with supportive therapy (without complement inhibiting antibodies). To corroborate clinical and histological data *in vivo*, murine models with global and tissue specific (renal tubular cells, endothelial cells and platelets) deficiencies for the Stx-receptor Gb3 were analyzed.

**Results:** Despite a severe affection [LDH 1944U/l (753-2792), platelets 33/nl (19-124) and hemoglobin 6.2g/dl (5.2–7.8); median (range)], all patients were discharged after 33 days (19-43) with no neurological symptoms and no dialysis requirement [creatinine 1.39mg/dl (0.84-2.86)]. After a 12-month follow-up, the creatinine decreased to 0.90mg/dl (0.82-1.52). Analysis of kidney biopsies revealed a dominant acute tubular damage but not thrombotic microangiopathy as the leading cause of the renal failure. To identify the tubular compartment as the determinant of the acute renal damage, mouse models were implemented. In wild-type mice, which -like humans- express Gb3 in renal tubular epithelium, Stx-mediated tubular damage led to lethal electrolyte disturbance. Tubule-specific depletion of Gb3 protected mice from acute renal failure, but favored development of cerebral purpura.

**Conclusions:** Acute tubular damage is a clinically important and currently underestimated mechanism of Stx-mediated acute kidney failure. An excellent renal outcome can be achieved by supportive therapy only.

*Funding:* Government Support - Non-U.S.

## FR-PO824

**RAGE Deletion Enhances Lymphoproliferative Syndrome and Lupus Nephritis in B6-MRL-Lpr-J fas$^{-/-}$ Mice** Antoine Goury,[1] Karim Belmokhtar,[1] Vincent Vuiblet,[1] Aida Meghraoui,[3] Jerome Devy,[1] Thierry Tabary,[2] Jacques Cohen,[2] Annmarie Schmidt,[4] Philippe Rieu,[1] Fatouma Toure.[1] *[1]Nephrology, CHU Reims Hopital Maison Blanche - CNRS FRE3481, Reims, France; [2]Immunology, CHU Reims Hopital Maison Blanche, Reims, France; [3]Immunology, EA 4683 IMAB - Reims, Reims, France; [4]Diabetes Research Program, NYU Medical Center.*

**Background:** The Receptor for Advanced Glycation End products is a multiligand receptor able to interact not only, with AGEs, but also with S100 proteins, Amyloid fibrils and nuclear proteins such as HMGB1. Following engagement RAGE induces a pro-inflammatory signal involved in a number of disease characterized by vascular pathology. Systemic Lupus Erythematosus is associated with increased expression of HMGB1 and RAGE. The exact role of RAGE in this disease is unknown.

**Methods:** To analyze the potential role of RAGE in SLE we generated mice invalidated for RAGE in the lupus prone genetic background B6-MRL-Fas-lpr/J. We compared these mice to littermates B6-MRL-lpr-J-Fas$^{-/-}$ and WT mice.

**Results:** Mice invalidated for RAGE and carrying the Fas mutation (n=18) had a greater lymphoproliferative syndrome and increased size of the spleen compared to B6-MRL-lpr-J-Fas$^{-/-}$ mice (n=21). RAGE deletion in the B6-MRL-lpr-J-Fas$^{-/-}$ background was associated with more severe lupus nephritis (III and IV) and more frequent cutaneous lesions (75%) compared to the B6-MRL-lpr-J-Fas$^{-/-}$(25%) or WT(0%). INFγ levels were higher in the serum of the 2 groups of lupus prone mice compared to WT. In peripheral blood and in the spleen we found a significantly higher proportion of abnormal CD3+CD45R+ lymphocytes and activated T cells in B6-MRL-lpr-J-Fas$^{-/-}$ compared to WT. These subpopulations were further increased in B6-MRL-lpr-J-Fas$^{-/-}$RAGE$^{-/-}$ mice. Lastly we found an increased expression of TLR9 in the B6-MRL-lpr-J-Fas$^{-/-}$RAGE$^{-/-}$ splenocytes.

**Conclusions:** Our results suggest a critical role for RAGE in regulation of lymphoproliferation in the B6-MRL-lpr-J-Fas$^{-/-}$ backgroung. Deletion of RAGE in this genetic strain exacerbates lymphoproliferation, lupus nephritis and cutaneous lesions. Mechanisms involved could be related to a dysregulation of apoptosis and a greater involvement of TLRs.

## FR-PO825

**An Antifibrotic Role of Hypoxia-Inducible Factor 3 in Renal Tubular Cells** Tetsuhiro Tanaka, Kumi Shoji, Junna Yamaguchi, Masaomi Nangaku. *Div of Nephrology and Endocrinology, Univ of Tokyo School of Medicine, Tokyo, Japan.*

**Background:** Chronic hypoxia in the tubulointerstitium is a final common pathway in CKD. Accumulating evidence suggests both pathogenic and protective roles of a family of hypoxia-iducible transcription factors (HIF), mainly HIF-1 and HIF-2. However, the function of a third member, HIF-3, remains elusive. In this study, we characterized the expression of HIF-3α in the ischemic kidney and investigated its functional role in tubular epithelial cells.

**Methods:** The expression of HIF-3α protein was characterized in models of renal fibrosis by immunohistochemistry. In vitro, the effect of HIF-3 on the induction of HIF-1 target genes was examined by luciferase reporter assays and real-time PCR. Hypoxia-responsive enhancers were identified in the lysyl oxidase (LOX) promoter by luciferase reporter assays and site-directed mutagenesis. Migration of tubular epithelial cells in hypoxia was evaluated by scratch assays, using human proximal tubular cells (HK-2) transduced with HIF-3α or MOCK, or in Caki-1 renal cancer cells transfected with HIF-3α siRNA or its control. The effect of HIF-3α on E-cadherin and fibronectin expression was examined by promoter assays and immunoblotting, respectively.

**Results:** In immunohistochemistry of renal fibrosis models, HIF-3α protein was observed in the nuclei of ischemic tubules located in the outer medulla. In vitro, overexpression of HIF-3α suppressed the hypoxic induction of LOX most consistently and strongly among other HIF-1 target genes. Promoter analysis of the human LOX gene revealed multiple hypoxia-responsive enhancers, against each of which HIF-3 had

an inhibitory effect. Functionally, overexpression of HIF-3α in human proximal tubular cells (HK-2) suppressed cell migration under hypoxia, which was phenocopied by pharmacological inhibition of LOX and was offset by LOX overexpression. Furthermore, HIF-3 decreased the expression of fibronectin and counteracted the loss of E-cadherin in hypoxic renal carcinoma cells (RCC).

**Conclusions:** Results of these studies identify HIF-3α as a novel antifibrotic gene which potentially plays a role in ischemic renal diseases.

### FR-PO826

**$P2Y_2$ Receptor Deficiency Aggravates Progression in a Model of Chronic Renal Failure** Sebastian Alexander Potthoff, Johannes Stegbauer, Lars C. Rump, Oliver Vonend. *Dept of Nephrology, Medical Faculty, Univ Düsseldorf, Düsseldorf, Germany.*

**Background:** In chronic kidney disease, sympathetic overactivity, endothelial dysfunction and increase in shear stress contribute to a higher extracellular abundance of ATP. $P2Y_2$ receptors play an important role in renal tubule function, inflammation and proliferation. Knockout mice ($P2Y_2$-R KO) were used in order to investigate the impact of $P2Y_2$ receptors in a model of chronic kidney failure.

**Methods:** Wildtype (WT) and $P2Y_2$-R KO mice underwent subtotal nephrectomy (SNX) with a follow up of 56±2 days. Sham surgery mice served as controls. Survival, kidney function, kidney size, blood pressure (BP), glomerulosclereosis index were assessed. To examine the effect of extracellular ATP on cultured glomerular epithelium cells, a [3H]-thyimidine based proliferation assay was performed.

**Results:** During the observation period, survival was inferior in $P2Y_2$-R KO SNX mice. After 56 days, SNX caused an increase in serum creatinine and serum urea with a significant decrease in creatinine clearance. The decline in creatinine clearance was significantly more pronounced in $P2Y_2$-R KO than in WT mice (day 56, $P2Y_2$-R KO vs. WT: 53.9±7.7vs.84.3±8.7µl/min, $p<0.05$). BP increased after SNX to a higher extent in $P2Y_2$-R KO mice compared to WT mice (day 56, $P2Y_2$-R KO vs. WT: 177±2vs.156±7mmHg). After SNX, $P2Y_2$-R KO showed a 2.5-fold higher urinary albumin-creatinine ratio compared to WT (day 56, $p<0.05$). 56 days after SNX, in contrast to $P2Y_2$-R KO mice, WT remnant kidneys showed significant hypertrophy (increase of kidney weight compared to day 0: $P2Y_2$-R vs. WT: 113±6vs.150±6%). Markers for tissue damage (TGF-β1, PAI-1) and proinflammatory target genes (MCP1) were significantly upregulated in $P2Y_2$-R KO compared to WT SNX mice.In cultured glomerular epithelial cells, ATP induced a significant, dose dependent increase in DNA synthesis up to 180.1±20.5%.

**Conclusions:** $P2Y_2$-R KO has a detrimental impact on outcome after SNX compared to WT mice. Higher BP, increased UACR and absence of compensatory hypertrophy are the likely cause for the observed findings. The $P2Y_2$ receptor is crucial for blood pressure regulation and tissue adaptation after induction of chronic kidney disease.

### FR-PO827

**Dickkopf Related Protein-1 Attenuates Connective Tissue Growth Factor Induced Fibrogenic Responses in Pericytes by Binding to LRP-6** Shuyu Ren, Cécile Olivia Fligny, Jeremy Stuart Duffield. *Univ of Washington.*

**Background:** Pericytes are mesenchymal cells thatattached to peritubular capillaries. Recent genetic fate-mapping studies have identified pericytes and closely related fibroblasts as the major progenitors of scar-forming myofibroblasts. Understanding mechanisms by which pericytes become myofibroblasts is critical in development of therapeutics to treat kidney disease. We have recently reported a central role for WNT signaling pathways in this process. CTGF has been shown to be an important regulator of fibrogenic responses. Here we investigate the role of CTGF in pericyte functions and its capacity to signal via the WNT pathway.

**Methods:** Col1a1-GFP, TCF/LEF:H2B-GFP, LRP6flox/LRP5flox mice were used to generate primary cell cultures. Synthesis and purification of recombinant DKK-1.

**Results:** CTGF induces myofibroblast gene activation, migration, morphological changes and stress fiber formation in pericytes and these effects are abolished by rDKK-1, LRP6 gene silencing, blockade of WNT blockade. CTGF rapidly phosphorylates the WNT co-receptor, LRP6. Although CTGF activates WNT/bcatenin signaling in kidney pericyte cultures and this is inhibited by recombinant rDKK-1, the functional changes in response to CTGF are predominantly independent of b-catenin translocation. CTGF rapidly induces JNK and MAP kinase activity, that are critical in CTGF responses in pericytes. rDKK-1 blocks these responses.

**Conclusions:** rDKK-1 is a candidate therapeutic protein that potently inhibits fibrogenesis by mechanisms including blockade of CTGF induced fibrotic responses.

### FR-PO828

**Deletion of Extrarenal NADPH-Cytochrome P450 Reductase Causes Vacuolization in Renal Proximal Tubular Epithelial Cells** Senyan Liu,[1,2] Changlin Mei,[1] Jun Gu.[2] *[1]Div of Nephrology, Shanghai Changzheng Hospital, China; [2]Wadsworth Center.*

**Background:** Vacuolization is a nonspecific histologic change for cells. It can be observed in many conditions. The NADPH-cytochrome P450 reductase (CPR) is needed for activity of microsomal cytochrome P450 (P450) monooxygenases. Cpr -low mouse model was generated to study the function of P450s . In previous study we found the vacuolization in renal proximal tubular epithelial cells (PTECs) of 6-month-old male Cpr -low mice.

**Methods:** Oil red O staining and transmission electron microscopy (TEM) were performed to figure out the origin of vacuoles. Serum creatinine levels were determined. Then kidney sections from proximal tubule-Cpr-null mice (PTCN), extra-proximal tubule-Cpr-low mice (XPT-CL), liver-Cpr-null mice (LCN) and extrahepatic-Cpr-low (XH-CL) mice were examined. Immunofluorescence double stainging was done to study the relation between CPR expression and vacuoles in proximal tubules.

**Results:** Our results showed these vacuoles were Oil red O and PAS negative. TEM examination showed these vacuoles were lysosome origin. The mice with proximal vacuolization had normal serum creatinine levels. Beside *Cpr*-low mice, the vacuolization was seen in kidney of XPT-CL mice and XH-CL mice, not in KCN mice and LCN mice. Double staining showed vacuoles had no relation to CPR expression in proximal tubules.

**Conclusions:** These results suggested that vacuolization in proximal tubular tubules of *Cpr*-low mice was caused by deletion of extra-proximal tubular or extra-hepatic *>Cpr* gene. The significance of this vacuolization need further study.

*Funding:* Government Support - Non-U.S.

### FR-PO829

**Feedback Loops between the Kidney and Peripheral Organs Link Proteinuria and Hypertriglyceridemia in Nephrotic Syndrome** Camille E. Mace,[1] Lionel C. Clement,[1] C. Avila-Casado,[2] Sumant S. Chugh.[1] *[1]Medicine / Nephrology, Univ of Alabama at Birmingham; [2]Pathology, UHN-Totonto General Hospital.*

**Background:** Circulating levels of Angiopoietin-like-4, a PPAR target gene, are increased in patients with nephrotic syndrome when proteinuria reaches nephrotic levels. Unlike podocyte secreted hyposialylated Angptl4, circulating Angptl4 is fully sialylated and does not induce proteinuria.

**Methods:** We conducted Angptl4 mRNA expression studies in animal models of nephrotic syndrome, and noted Angptl4 upregulation in heart, skeletal muscle, liver and adipose tissue.

**Results:** Circulating Angptl4 had 2 major effects (a) Inhibiting lipoprotein lipase (LPL), reducing hydrolysis of triglycerides to free fatty acids (FFA), reducing FFA uptake into heart, skeletal muscle and adipose tissue, and causing hypertriglyceridemia. Wefound significantly elevated plasma FFA/albumin ratio in nephrotic patients and in animal models of MCD and FSGS. Loss of urinary albumin with low fatty acid levels in nephrotic syndrome and progressive hypoalbuminemia were the principal determinants of increased plasma FFA/albumin ratio. (b) Circulating Angptl4 binds to the glomerular endothelium and reduces proteinuria. Using recombinant Angptl4, transgenic rats and beta 5 integrin - / - mice, we showed that reduction in proteinuria was mediated by binding to alphav beta5 integrin. Injection of four human Angptl4 mutants with reduced LPL interaction reduced proteinuria without inducing hypertriglyceridemia in Buffalo Mna rats (FSGS) and Zucker Diabetic Fatty rats.

**Conclusions:** In summary, there are two feedback loops in nephrotic syndrome mediated by FFA and Angptl4. First, proteinuria results in selective loss of albumin with low FFA levels, raising plasma FFA/albumin ratio, increasing FFA entry in peripheral organs, which activates PPARs, increases Angptl4 expression and secretion, that inhibits hydrolysis of triglycerides, thereby reducing FFA uptake, but inducing hypertriglyceridemia. Second, the increased circulating Angptl4 reduces proteinuria by binding to glomerular endothelial alphav beta5 integrin, which, reduces urinary loss of low FFA bound albumin, and decreases the plasma FFA/albumin ratio.

### FR-PO830

**The Effect of GSK-3β in the Glomerular Injury of db/db Mutant Diabetic-Nephropathy Mice** Zhangsuo Liu.[1,2] *[1]Nephrology, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China; [2]Key-Disciplines Laboratory Clinical-Medicine Henan, Zhengzhou, Henan, China.*

**Background:** To observe the effect of BIO and diabetic nephropathy on EMT, GSK-3β expression and glomerular injury in the kidney of db/db mice, and to explore the possible mechanism of proteinuria and glomerular injury in DM, by determining whether EMT is caused by high glucose.

**Methods:** Male db/+m mice were served as normal control. The age-matched db/db mice were randomly divided into BIO treated group and untreated group. Each group were sacrificed 8 mice every 3 weeks. On the day before sacrifice, mice were individually housed in metabolic cages for urine collection over 24 hours. Sections of renal tissues were used to observe structural changes with electron and light microscope. Expression of nephrin, α-SMA, GSK-3β, β-catenin, VDR, etc. were quantified by Western blot, RT-PCR or immunofluorescence.And the activities of GSK-3β were assayed by TRAPEZE enzyme detection kit.

**Results:** 1. Diabetic db/db mice had heavy albuminuria and remained hyperglycemic. BIO administration attenuated albuminuria, but had no significant effect to blood glucose. 2. Compared with NC group,the expressions of epithelial phenotype markers and VDR were downregulated time-dependently. And the expressions of β-catenin, snail and mesenchymal phenotype markers did the opposite. 3. The expression and activity of GSK-3β in cortex of db/db mice were time-dependently upregulated, compared with db/+m mice. 4. BIO administration to db/db mice suppressed the trends mentioned in result 2 and 3, and alleviated the pathologic changes caused by diabetic nephropathy.

**Conclusions:** 1. DM could lead renal cortex of db/db mice undergo EMT, BIO could partly inhibit it. 2. In high glucose conditions, GSK-3β could probably regulate EMT through VDR and other factors, besides Wnt/β-catenin signaling. 3. In diabetic kidney, BIO could protect renal function through reducing the urine albumin excretion, but not regulating the blood sugar.

## FR-PO831

**Extracellular Sulfatases Regulate PDGF Signaling and Promote Nephropathy in Diabetes** Yasutoshi Takashima,[1] Hiroshi Yashiro,[1] Kumi Ohashi,[1] Hanako Yamashita,[1] Satoshi Hara,[1] Namiko Kobayashi,[1] Toshiharu Ueno,[1] Masayuki Masu,[2] Kazuko Keino-masu,[2] Michio Nagata.[1] *[1]Renal Pathology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Molecular Neurobiology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan.*

**Background:** Growth factors have important roles to regulate glomerular homeostasis. Extracelluar sulfatase (Sulf) 1 and 2 are known to regulate growth factors by controlling growth factor binding with intrinsic 6-O sulfation in HSPGs. Last ASN, we demonstrated that Sulf1 and Sulf2 double knockout (DKO) mice showed mesangiolysis, mesangial hyperplasia accompanied by up-regulation of PDGF-B, PDGF-D and its receptor. In addition significant increase of GBM out pockets suggesting PDGF-mediated GBM synthesis by podocytes. Because mesangial lesions are hallmark of diabetic nephropathy and it was partly promoted by PDGF signaling, the present study examined the role of sulfatases in the development of glomerulopathy in diabetes.

**Methods:** STZ-induced diabetes in Sulf DKO and Wild type(WT) was examined (100 mg/Kg BW, n=6 each). Glomerulopathy was estimated by morphometrical counting of mesangial lesion as previously shown. mRNA expressions for PDGF-B, PDGF-D and its receptor and mesangial phenotype change's marker (a-SMA) were done by real time PCR. Protein expression and location of growth factors, those receptor and protein phosphorylated by PDGF signaling were estimated by western blotting, and immunohistochemistry.

**Results:** STZ-treated Sulf DKO mice with showed significantly milder mesangial changes compared to those of STZ treated WT mice at 12 weeks. STZ-treated WT mice revealed significant increase in PDGF-B, PDGF-D, PDGFR-β and a-SMA mRNA, whereas Sulf DKO mice showed no increase in those parameters at 8 weeks after STZ injection. Immunohistochemistry showed that increase of PDGF-B expression in podocyte and endothelial cells and PDGFR-β expression in mesangial cell in STZ-treated WT and the expression was suppresed in Sulf DKO mice.

**Conclusions:** Sulfs may modulate PDGF signaling in glomeruli and promote mesangial lesions under diabetic mellitus.

## FR-PO832

**Pharmacological Stabilization of Hypoxia Inducible Factors Ameliorates Adenine-Induced Tubulointerstitial Nephritis** Gunnar Schley,[1] Bernd Klanke,[1] Kerstin U. Amann,[2] Kai-Uwe Eckardt,[1] Carsten Willam.[1] *[1]Nephrology and Hypertension, Univ Hospital Erlangen, Erlangen, Germany; [2]Nephropathology, Univ Hospital Erlangen, Erlangen, Germany.*

**Background:** Chronic inflammation, vascular rarefaction and extensive fibrosis of the tubulointerstitium are common hallmarks of progressive chronic kidney diseases (CKD). All three processes impair the oxygen supply to the renal tissue and can thus lead to a vicious circle. The Hypoxia Inducible Factors (HIF) are transcription factors which have a key position in regulating gene transcription under hypoxia and ischemia in order to adapt cells and organs to low oxygen tensions. In experimental models of acute kidney injury, genetic or pharmacological stabilization of HIF led to better preserved kidney structure and function. We therefore aimed to investigate the effects of HIF stabilization in an experimental CKD model.

**Methods:** Male C57BL/6 mice were fed with an adenine-supplemented diet for 3 weeks to induce chronic tubulointerstitial nephritis. Mice were treated with either two HIF stabilizers (pyridine-2,4-dicarboxylate, PDCA; 2-(1-Chloro-4-hydroxyisoquinoline-3-carboxamido) acetic acid, ICA) or vehicle for 3 weeks starting concomitantly with the adenine-containing diet.

**Results:** In control animals creatinine levels rose from 0.09±0.01 mg/dl to 0.39±0.11 after 3 weeks and kidneys showed extensive tubulointerstitial fibrosis. Pharmacological HIF stabilization reduced serum creatinine by 21% (PDCA) and 36% (ICA) as well as proteinuria. Interstitial fibrosis (assessed by Sirius Red, fibronectin and collagen IV immunohistochemistry, tissue collagen content, and real-time PCR for fibrosis-related genes) and peritubular capillary rarefaction (MECA-32 immunohistochemistry, real-time PCRs for endothelial markers) were not significantly improved by both substances. But both HIF stabilizers markedly reduced the infiltration with F4/80 positive macrophages suggesting a reduced inflammatory reaction due to HIF stabilizer treatment.

**Conclusions:** HIF stabilizers ameliorated kidney function in a model of chronic tubulointerstial nephritis induced by an adenine-containing diet by reducing inflammatory cell infiltration.

## FR-PO833

**Preconditional Activation of Hypoxia-Induced Factors Improves the Impaired Angiogenic Response to Ischemia in Chronic Kidney Disease in Rats** Karl F. Hilgers, Isabel Schellinger, Nada Cordasic, Bernd Klanke, Johannes Jacobi, Rafael Heiss, Christoph Daniel, Andrea Hartner, Kai-Uwe Eckardt, Carsten Willam, Kerstin U. Amann. *Univ of Erlangen-Nuremberg.*

**Background:** Improving capillary supply in response to ischemia is an important mechanism for adaptation to macrovascular disease. This mechanism is impaired in chronic kidney disease (CKD). We tested the hypothesis that preconditional activation of hypoxia-inducible factors (HIF) improves the impaired capillary angiogenesis in response to ischemia.

**Methods:** CKD was induced in male rats by 5/6 nephrectomy; control rats were sham operated. Eight weeks later, ischemia of the right limb was induced by ligation and resection of the femoral artery. Preconditional activation of HIF target genes was performed by adding 0.1% CO to the rats' breathing air for 6 h, beginning 24 h before the onset of ischemia. Rats were sacrificed 24 h or two weeks after the onset of ischemia to analyze gene expression or capillary density, respectively. Capillary area was assessed after immunostaining for CD31 of the gastrocnemius muscle.

**Results:** In control rats, capillary area increased in the ischemic hindlimb by 44±3 % after 2 weeks, compared to the non-ischemic limb ($p< 0.001$, N=10). In contrast, there was no significant increase in the ischemic over the opposite limb in CKD rats (N=10). Pretreatment with CO did not affect the capillary density in non-ischemic limbs of CKD and control rats, nor in ischemic limbs of control rats. However, CO significantly augmented the increase of capillary area after ischemia in CKD rats (80±22% over the opposite limb, $p<0.004$, N=6). RT-PCR analysis showed a 2.4fold increase of VEGF after 24 h in non-CKD rats which was blunted in CKD animals (1.7fold, $p<0.05$). CO treatment increased VEGF expression 4.2fold in the non-ischemic and 7.2fold in the ischemic limb in CKD rats ($p<0.001$). The expression of other known HIF target genes, including VEGFR1, IGFBP-3, PAI-1 and HIG-2, was also induced by CO.

**Conclusions:** Our data provide proof of principle that HIF activation can correct the impaired angiogenic response to ischemia in rats with chronic kidney disease.

## FR-PO834

**Podocyte-Specific VEGF Overexpression Stimulates Glomerular Angiogenesis but Is Insufficient Alone to Prevent Progression of Existing Sclerosis** Shaojun Liu,[1,3] Anne P. Wilson,[1] Ji Ma,[2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Pathology, Microbiology and Immunology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Pediatric Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; [3]Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

**Background:** Glomerulosclerosis is characterized by increased matrix, obliteration of capillary lumens and loss of podocytes. VEGF is a secreted by podocytes and induces endothelial tip cell formation and new vessel branches. VEGF is decreased in sclerotic glomeruli. In this study, we investigated whether up-regulation of human VEGF in podocytes after development of glomerulosclerosis could induce angiogenesis and interrupt progression of sclerosis.

**Methods:** Subtotal nephrectomy (5/6Nx) was performed in 129/sv TetO-podocin-Cre /human VEGF loxp (RV, n=9) and TetO-podocin-Cre mice (R, n=11). At 8 weeks after 5/6 Nx, renal biopsy was done and sclerosis assessed (0-4 scale). VEGF was induced by doxycycline in drinking water. Mice were sacrificed four weeks later. Change in blood pressure, proteinuria, and glomerular morphology from biopsy to autopsy were assessed. DLL4, a marker of endothelial tip cells, was detected by immunostaining. VEGF was quantitated in isolated glomeruli.

**Results:** Human VEGF expression in RV glomeruli was significantly induced after doxycycline (44.9 ± 14.6 pg/mg),and mouse VEGF was also increased. Thus total glomerular VEGF in RV mice was 3.2 folds higher than R mice (276.0 ± 88.1 vs. 85.9 ± 83.6pg/mg , $P<0.05$). RV mice had significantly reduced blood pressure,but there were no effects on proteinuria and glomerulosclerosis. Glomerular volume was not affected by VEGF induction. However, there were more DLL4 positive endothelial cells (double staining of DLL4 and CD31) in glomeruli of RV induced mice than R control (RV 0.73±0.15 vs. R 0.27±0.28/glom, $P<0.05$).

**Conclusions:** Our data indicate that overexpression of VEGF in podocytes stimulates angiogenesis, but is not sufficient alone to prevent glomerulosclerosis progression. Thus, we speculate that coordinated interventions to augment angiogenesis and decrease matrix are necessary to optimize effects on progressive glomerulosclerosis.

*Funding:* NIDDK Support

## FR-PO835

**Klotho Reduces Kidney Injury and Fibrosis by Targeting Renin-Angiotensin System** Li Li Zhou,[1] Dong Zhou,[1] Roderick J. Tan,[2] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** Activation of the renin-angiotensin system (RAS) plays a pivotal role in the pathogenesis of kidney disorders in both animal models and human subjects. We recently demonstrated that Klotho, an anti-aging hormone and an endogenous antagonist of Wnt/β-catenin signaling, is lost in renal tubular epithelia in multiple CKD models. As Wnt/β-catenin controls the expression of multiple RAS genes, we hypothesized that Klotho may protect kidneys by targeted inhibition of RAS activation in diseased kidneys.

**Methods:** To test this, a remnant kidney model after 5/6 nephrectomy was utilized in adult CD-1 male mice. Groups of mice were intravenously administered the expression vector encoding the secreted form of Klotho (pV5-sKlotho) through hydrodynamic-based gene delivery. At 5 weeks after 5/6 nephrectomy, mice were killed and kidneys collected for renal pathology and various analyses.

**Results:** We found that kidney injury was evident, characterized by elevated albuminuria and serum creatinine, and excessive deposition of interstitial matrix proteins. These lesions were accompanied by loss of kidney Klotho, and upregulated expression of RAS components including angiotensinogen (AGT), renin, angiotensin-converting enzyme (ACE) and angiotensin II receptor type 1 (AT1). *In vivo* expression of exogenous Klotho inhibited renal β-catenin activation, abolished the induction of multiple RAS components including AGT, ACE, renin and AT1, and ameliorated morphological lesions and fibrosis. In cultured human proximal tubular epithelial cells (HKC-8), ectopic expression of Wnt1 or Wnt4 induced the expression of all major components of RAS, and co-transfection of Klotho expression vector dose-dependently blocked Wnt-triggered RAS activation.

**Conclusions:** Taken together, these results suggest that Klotho exerts its renal protection by targeted inhibition of RAS, a key pathogenic pathway in the evolution and progression of kidney and cardiovascular diseases.

## FR-PO836

**Exploring the Mechanistic Pathways in Developing Renal Injury Using the Rat UUO Model and Next Generation Sequencing (NGS)** Steven M. Weldon, Thomas B. Freeman, William Loging, Peng Sun, Glenn Gibson, Xiaojun Ren, Hu Sheng Qian, Glenn A. Reinhart. *CardioMetabolic Diseases and Scientific Knowledge Discovery, Boehringer Ingelheim Pharm Inc, Ridgefield, CT.*

**Background:** Unilateral ureteral obstruction (UUO) is a well established model used to mimic the pathophysiology involved in tubulointerstitial fibrosis (TIF). Key pathological features of UUO include oxidative stress, inflammation, apoptosis, vascular/tubular loss and TIF. NGS can generate large, reproducible data sets in a timely manner and is now relatively low cost.

**Methods:** We used UUO+NGS to further explore the transcriptional regulation of molecular pathways and biological processes (BP) associated with developing TIF in rats. Rats received sham or UUO±enalapril (ENA;30 mpk) for up to 10d post-UUO. mRNA from cortical tissue was subjected to NGS and computational analysis to explore BP and differentially regulated genes across key pathological pathways in UUO. TIF was assessed by sirius red morphometry (SRM) for cortical collagen.

**Results:** UUO induced robust fibrosis in controls (+65% vs sham) that was inhibited 73% by ENA. We found 417 specific genes associated with the key mechanistic features of UUO pathology; 27 genes were present in 3 or more key features. Gene Ontology (GO) pathway analysis identified >2300 specific BPs that were significantly enriched and temporally regulated over 10d post-UUO. Extracellular matrix signaling and Ub-dependent proliferation are examples of BPs regulated in early (D1-4); oxidative stress and macrophage cytokine production are examples of BPs regulated in late (D5-10), phases of renal damage in UUO. ENA showed most significant effects on inflammation and cell proliferative BPs.

**Conclusions:** These are the first data using NGS to describe quantitative transcriptional regulation of the pathology associated temporal renal injury in rats following UUO. We show that temporal changes in the transcriptome of key pathological pathways in UUO correlate with TIF and are differentially regulated by time and treatment with ENA. These data extend our previous findings using NGS in UUO as a powerful approach to identify new target pathways and potential biomarkers of fibrotic renal disease.

## FR-PO837

**Renoprotective Effect of Metformin in Mice with Unilateral Ureteral Obstruction** Rita de Cassia Cavaglieri, Denis Feliers, Hanna E. Abboud. *Dept of Medicine, Univ of Texas Health Science Center, San Antonio, TX.*

**Background:** Metformin, an indirect activator of adenosine monophosphate-activated kinase (AMPK) is widely used in patients with type 2 diabetes. Metformin has been shown to have renoprotective effects in early diabetic nephropathy. We studied the effect of metformin on inflammation and fibrosis in obstructive nephropathy.

**Methods:** Adult C57Bl/6 mice were subjected to unilateral ureteral obstruction (UUO) or sham operated and subdivided into 3 groups: **S (n=6),** sham-operated mice, **UUO (n=6),** mice subjected to unilateral ureter obstruction model; and **UUO+Met (n=6),** UUO mice receiving metformin by gavage (200mg/kg/day). Animals were followed for 7 days and injury of the obstructed kidney was studied. Markers for inflammation (F4/80-positive macrophages; VCAM-1; TNF-alpha); tubular injury (E-cadherin), myofibroblasts (alpha-SMA); and fibrosis (Fibronectin, Collagen and TGF-beta) were analyzed. AMPK activity was measured by in vitro kinase assay. Reactive oxygen species production was measured and correlated with expression of NADPH oxidases.

**Results:** Metformin significantly reduced inflammation (macrophage infiltration, TNF-alpha and VCAM-1 expression), tubular injury, interstitial fibroblast activation and tubulointerstitial fibrosis (collagen and fibronectin expression and deposition) in obstructed kidneys. AMPK activity was unchanged in obstructed kidneys and increased by metformin, suggesting that metformin acts through activation of AMPK. Superoxide anion production and Nox4 and Nox2 expression were significantly increased in obstructed kidneys and were inhibited by metformin.

**Conclusions:** Our data show for the first time that metformin reduces inflammation and tubulointerstitial fibrosis in obstructed kidneys. This effect appears to be mediated by AMPK and could involve inhibition of oxidative stress. Our study suggests that metformin could be use to accelerate renal healing in patients with obstructive nephropathy.

## FR-PO838

**The Macula Densa Controls Glomerular Cell Remodeling** James L. Burford,[1] Karie G. Villanueva,[1] Anne Riquier-brison,[1] Sanjeev Kumar,[2] Jing Liu,[2] Andrew P. McMahon,[2] Janos Peti-Peterdi.[1] *[1]Physiology and Biophysics, Univ of Southern California, Los Angeles, CA; [2]Stem Cell Biology and Regenerative Medicine, Univ of Southern California, Los Angeles, CA.*

**Background:** Macula densa (MD) cells are strategically positioned at the vascular entrance of the glomerulus and control renal hemodynamics and renin. Here we addressed if MD cells play non-traditional roles in glomerular cell plasticity/remodeling.

**Methods:** Serial multiphoton microscopy of the intact kidney *in vivo* was performed in *NG2-DsRed* mice to track chondroitin sulfate proteoglycan (NG2, an established progenitor cell marker) expressing pericytes over several days. In established conditions of strong MD stimulation (low salt diet/ACE inhibition) and unilateral ureteral ligation (UUO). MD cells were FACS sorted from freshly digested kidneys of mice with MD-specific expression of GFP and their RNA isolated.

**Results:** In established conditions of strong MD stimulation (low salt diet/ACE inhibition) and unilateral ureteral ligation (UUO), increased renal interstitial density and migration of NG2+ cells to the MD area and then into the glomerular parietal layer and mesangium were observed. NG2, Ki67, and renin immunofluorescence found a significantly increased number of NG2+ proliferating cells in the MD area with partial co-localization with renin in response to low salt diet/ACEI for one week. The increased density of NG2+ cells was 70% inhibited by the administration of the selective COX-2 inhibitor SC58236. GUDMAP-based microarrays confirmed high expression of known MD-specific genes and identified new MD-enriched genes including Car15, Emb, Klk1b22, Wnt10a, Bmp3, Thsd4, Angptl7, Slit2 that play roles in cell growth, development, guidance, and extracellular matrix interactions.

**Conclusions:** Our results suggest that NG2+ pericytes maybe an important progenitor cell population in the kidney. Also, via MD-derived paracrine factors MD cells play new important roles in the maintenance and remodeling of the glomerulus and the renal interstitium in health and disease.

*Funding:* NIDDK Support

## FR-PO839

**Renin Angiotensin System Activates mTOR Pathway in HIV-Associated Nephropathy (HIVAN)** Partab Rai, Rivka Lederman, Tejinder Singh, Viki Kumar, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, New York, NY.*

**Background:** Both renin angiotensin system (RAS) and mTOR pathways have been reported to play a critical role in the development and progression of HIVAN. However the role of the RAS pathway in the activation of mTOR pathway has not been investigated so far. We hypothesize that the RAS activates mTOR pathway in HIVAN.

**Methods:** Renal cortical sections and tissues of age and sex matched control and HIV transgenic mice (Vpr) were evaluated for the expression of renin, angiotensinogen (Agt), phospho-mTOR and phospho-p70S6K. To determine the role of renin, control and Vpr mice were administered either normal saline or aliskiren (50 mg/kg/day by miniosmotic pump, an inhibitor or renin) for 4 weeks followed by renal tissue probing for the expression of phospho-mTOR, phospho-p70S6K, and actin. To determine the effect of HIV on kidney cell renin expression, mouse proximal tubular cells (MTC) were transduced with either empty vector (EV/MTC) or NL4-3(HIV/MTC) and evaluated for renin expression. To determine the effect of renin and Ang II, MTCs were treated with variable concentrations of renin or Ang II for 24 h followed by Western blot analysis for the expression of phospho-p70S6K and actin. To determine the role of pro-renin receptor (PRR), control and siRNA-PRR transfected MTCs were treated with renin and then evaluated for phospho-p70S6K.

**Results:** Renal tissues of Vpr mice displayed enhanced expression of renin, phospho-mTOR and phospho-p70S6K. Vpr mice receiving aliskiren displayed attenuated expression of phospho-mTOR and phospho-pS706K when compared to saline receiving Vpr mice. HIV/MTC displayed enhanced expression of renin, phsopho-mTOR and phospho-p70S6K. However, this effect of HIV was inhibited by aliskiren. Both renin and Ang II enhanced tubular cell expression of phospho-p70S6K in a dose dependent manner. Since MTC silenced for PRR displayed attenuated expression of phospho-p70S6K in response to renin, it appears that the RAS contributes to the activation of mTOR pathway both by renin as well as by Ang II.

**Conclusions:** HIV enhances activation of mTOR pathway in HIVAN via generation of both renin and Ang II.

*Funding:* NIDDK Support

**FR-PO840**

**Sclerotic Glomerular Phenotype in HIV-Associated Nephropathy Is Dependent on the Activation of the Renin Angiotensin System** Andrei Plagov, Partab Rai, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical Center, New York, NY.*

**Background:** HIV-associated nephropathy (HIVAN) is a common complication of HIV-1 infection in patients with African ancestry in general and with APOL1 gene risk variants in particular. Although collapsing glomerulopathy is considered a hallmark of HIVAN, significant numbers of glomeruli in patients with HIVAN also display other variants of FSGS. We propose that collapsed glomeruli as well as glomeruli with other variants of FSGS are manifestations of HIVAN and their prevalence depends on associated host factors. We explored whether renin-angiotensin system (RAS) contributes to sclerotic, collapsing or both types of lesions in HIVAN. We hypothesized that activation of the RAS will contribute predominantly to sclerotic lesions rather than to collapsing ones.

**Methods:** To evaluate the role of the RAS we have used a genetically engineered mouse model of HIVAN (Tg26) with two and four copies of angiotensinogen (Agt) gene (Tg26/Agt2 and Tg26/Agt4). Severity of renal lesions was scored in 8 weeks old control and Tg26 mice with 2 and 4 copies. To confirm the role of the RAS on the development of glomerular phenotype, Tg26 mice in groups of 4, were administered either normal saline, aliskiren (50 mg/Kg, a renin inhibitor), aliskiren + captopril (20 mg/Kg, an angiotensin converting enzyme inhibitor), aliskiren + telmisartan (300 microgram/kg, an Ang II receptor blocker) for 4 weeks followed by scoring of severity of renal lesions.

**Results:** In Tg26/Agt2, 1 out of 6 glomeruli exhibited sclerosed phenotype, whereas 1 out of 25 glomeruli displayed collapsed phenotype; on the other hand, in Tg26/Agt4, 1 out of 3 glomeruli exhibited sclerotic phenotype and only 1 out of 7 glomeruli showed collapsed phenotype. In all experimental groups there was significant reduction of percentage of sclerosed glomeruli and only minimal reduction in collapsed glomeruli comparing to normal saline receiving Tg26/Agt2.

**Conclusions:** These findings suggest that manifestation of sclerosed phenotype in HIVAN is predominantly dependent on the activation of the RAS.

**HIV Induces Podocyte Vitamin D Receptor Downregulation through Epigenetic Factors** Nirupama Chandel, Tejinder Singh, Noopur Goel, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

**Background:** Recent reports indicate that HIV induces podocyte injury through down regulation of vitamin D receptor (VDR) and associated activation of renin angiotensin system (Am J Physiol, 2013). However, the involved mechanism of HIV-induced down regulation of VDR is not clear. We hypothesized that HIV down regulated VDR through hypermethylation of cytosine phospho gunaosine (cpg) islands.

**Methods:** Renal tissues of age and sex matched control Tg26 (n=4) were assayed for VDR expression and DNA methyltransferases (Dnmt) 1, 2, and 3 and reprobed for actin. Conditionally immortalized human podocytes (CIHP) were transduced with either empty vector (EV/CIHP) or NL4-3 construct (HIV/CIHP). Protein blots of EV/CIHP and HIV/CHP were probed for Dnmt1, 2, and 3. Additionally, cpg methylation status of EV/CIHP and HIV/CIHP was evaluated by Epitecht mRNA assay and bisulphite pyrosequencing. To determine the potential of VDR agonists on normalization of VDR in HIV/CIHPs; EV/CIHPs and HIV/CIHPs were incubated in medium containing EB1089 (1nM, a VDR agonist) for 24h (n=3) followed by protein blots preparation and subsequent their probing for VDR and actin expression . To confirm the role of hypermethylation in VDR expression, effect of 5-azacytiidine (AZAC), a demethylating agent was evaluated on VDR expression in HIV/CIHP in the presence/absence of a VDR agonist.

**Results:** Renal tissues of Tg26 mice displayed attenuatd expression of VDR but enhanced expression of Dnmt. HIV/CIDHPs displayed down regulation of VDR and enhanced expression of Dnmt3b. Epitecht assay displayed more than 70% VDR cpg methylation in HIV/CIHPs. Bysulphite pyrosequencing studies in HIV/CIHPs confirmed enhanced methylation of cpg islands when compared to EV/CIHPs. Both AZAC alone and EB1089 alone increased VDR expression in HIV/CIHPs but only sub-optimally. However, AZAC exhibited an additive effect on EB1089 in enhancing VDR expression by HIV/CIHPs.

**Conclusions:** HIV induced podocyte VDR expression through hypermethylation of VDR. Optimal expressoin of VDR could be achieved only by combining VDR agonist with a demethylating agent.

**Nicorandil Protects Podocyte from Puromycin Aminonucleoside-Induced Injury in the Rats** Yoshifuru Tamura,[1] Takeshi Shiraishi,[1] Takahiko Nakagawa,[2] Shunya Uchida.[1] *[1]Dept of Internal Medicine, Teikyo Univ School of Medicine, Tokyo, Japan; [2]TMK Project, Medical Innovation Center, Kyoto Univ, Kyoto, Japan.*

**Background:** Nicorandil causes vasodilatation by opening ATP-dependent potassium channels and donating nitric oxide. Recently, we reported the protective effect of nicorandil in the rat remnant kidney model, in which such beneficial effect was associated with protection of podocytes (Tamura, et al Am J Physiol 2012). In order to further confirm such podocyte protection, we here examined the effect of nicorandil in another model with podocyte injury, the puromycin aminonucleoside (PAN) induced nephrosis model.

**Methods:** PAN nephrosis was induced by a single intraperitoneal injection of PAN (10 mg/100 g body weight). Rats were divided into three groups: Normal control rats, PAN model group, PAN rats treated with nicorandil 30 mg/kg/day. 9 days later, the rats were sacrificed.

**Results:** Proteinuria was significantly ameliorated by nicorandil compared with that with no treatment at 9 days. Interestingly, puromycin significantly lowered number of WT-1-positive cells and reduced podocin immunoreactivity while both were prevented by nicorandil in PAN rats. In addition, electron microscopy documented thatthe number of filtration slits in podocyte was reduced in PAN rats whereas such reduction was significantly rescued by nicorandil treatment.

| | Serum creatinine | Proteinuria | Podocyte | Podocyte | Podocyte |
|---|---|---|---|---|---|
| | mg/dl | mg/day | podocin positive area /glomeruli | WT-1 positive cell number/glomeruli | The number of filtration slits/10 μm of GBM |
| Control (n = 4) | 0.22 ± 0.02*** | 15.3 ± 4.6*** | 50.3 ± 3.4* | 14.0 ± 1.2*** | 21.2 ± 1.3*** |
| PAN (n = 4) | 0.31 ± 0.02 | 267.7 ± 54.8 | 20.8 ± 6.1 | 7.2 ± 0.3 | 1.8 ± 0.2 |
| PAN + Nicorandil (n = 4) | 0.37 ± 0.06 | 165.8 ± 10.9** | 40.1 ± 2.7* | 10.5 ± 0.3* | 10.7 ± 1.1** |
| ***P<0.001. **P<0.01. *P<0.05 vs. PAN. | | | | | |

**Conclusions:** These results suggest that, nicorandil, a K channel opener, reduces proteinuria and ameliorates podocyte injury seen in PAN nephrosis rats. Nicorandil may serve as a novel strategy for kidney of diseases involving podocyte injury.

**A Single Low Dose of Lithium Protects against Proteinuria by Improving Podocyte Focal Adhesion and Actin Cytoskeleton Integrity** Weiwei Xu,[1] Yan Ge,[1] Zhi-hong Liu,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ, Providence, RI; [2]Research Institute of Nephrology, Nanjing, China.*

**Background:** Evidence suggests that glycogen synthase kinase (GSK) 3β plays a detrimental role in acute and chronic renal diseases. This study examined the effect of lithium, a selective inhibitor of GSK3β, on podocytopathy.

**Methods:** Adriamycin induced podocytopathy was employed in mice and in conditionally immortalized mouse podocytes and podocyte dysfunction evaluated.

**Results:** In cultured podocytes, adriamycin elicited immediate cellular shrinkage and actin cytoskeleton disorganization as evidenced by increased cortical F-actin and diminished stress fibers and lamellipodia. Focal adhesion turnover was also promoted and podocyte motility amplified, concomitant with an increase in the number of focal adhesions and a reduction in their size. These changes were largely obliterated by lithium. Mechanistically, adriamycin reduced cofilin phosphorylation, congruent with an amplified actin-serving activity of cofilin that accounts for the loss of long bundled F-actin. Lithium counteracted adriamycin-induced cofilin hypophosphorylation by suppressing the activity of a cofilin phosphotase Slingshot (SSH)2. In addition, adriamycin-induced hyperphosphorylation of paxillin, a focal adhesion-associated adaptor protein, was abrogated by lithium. Inhibitory phosphorylation of GSK3β seems to be essential and sufficient for lithium's effects because ectopic expression of an uninhibitable mutant of GSK3β abrogated, whereas overexpression of a kinase dead GSK3β mimicked lithium's activities in podocytes. Of note, both paxillin and SSH2 interacted with GSK3β in podocytes and served as putative substrates for GSK3β. In adriamycin injured mice, a single low dose of lithium attenuated proteinuria by more than 70%, associated with an early prevention of foot process effacement. Consistently, lithium therapy inhibited GSK3β activity in injured glomeruli and blunted cofilin and paxillin activities in podocytes.

**Conclusions:** Inhibition of GSK3β by lithium protected against podocyte injury and proteinuria by reinstating podocyte actin cytoskeleton stability *via* SSH2/cofilin pathway and regulating focal adhesion-associated paxillin.

**FR-PO844**

**Deficient Autophagy Results in Mitochondrial Dysfunction and the Development of Focal and Segmental Glomerulosclerosis of the Kidney** Takahisa Kawakami,[1,2] Shuyu Ren,[2] Kelly L. Hudkins,[2] Ivan G. Gomez,[2] Allie M. Roach,[2] Charles E. Alpers,[2] Jeremy Stuart Duffield.[2] *[1]Univ of Tokyo; [2]Univ of Washington, Seattle.*

**Background:** Focal and Segmental Glomerulosclerosis (FSGS) is a heterogeneous fibrosing disease whose etiology remains poorly understood, and for many, lacks an effective therapy. It is also recognized as a component of other kidney diseases. Autophagy is the process by which cells degrade damaged organelles, cell membranes and proteins. The failure of autophagy may be one reason for the accumulation of cell damage and disturbance to cell homeostasis. Our Lab has recently implicated mitochondrial dysfunction, abnormal b-oxidation of triglycerides, and the aberrant production of reactive oxygen species (ROS) in the pathogenesis of tubulointerstitial kidney disease. Because of the central role of autophagy in cell homeostasis processes related to metabolism, mitochondrial and endoplasmic reticulum turnover, we explored autophagy deficiency in the kidney epithelium.

**Methods:** We mutated critical autophagy genes *ATG5* or *ATG7* during nephrogenesis, using Cre recombinase expressed in the progenitors of kidney epithelium, under regulation of the transcription factor SIX2.

**Results:** Mice with *ATG5* or *ATG7* mutations develop effacement of podocyte foot processes and albuminuria with minimal histological changes by 2 months of age. By 4 months they exhibit profound glomerular and tubular changes, which bear remarkable similarity to human FSGS, developing severe albuminuria, advanced renal failure and death by six months. Ultra-structurally, in addition to the characteristic features of FSGS, podocytes and tubular cells show vacuolization, smaller damaged mitochondria, and

changes to the endoplasmic reticulum. At these early time points, ATG5 and ATG7 deficient tubules and podocytes show evidence of ER and mitochondrial distress, reduced ATP, and increased ROS levels.

**Conclusions:** Mitochondrial dysfunction and ER stress are the result of impaired autophagy organelle turnover in podocytes and kidney tubular epithelium. The impairment in autophagy is sufficient to cause all the manifestations of FSGS.

### FR-PO845

**Calcineurin Is Mainly Localized at the Slit Diaphragm Area, and Its Altered Expression Precedes Proteinuria in Rat Nephrotic Syndrome Models** Ayako Wakamatsu,[1] Asami Takasaki,[1] Yuichi Takahashi,[1] Yoshiyasu Fukusumi,[1] Masayuki Tomita,[1] Ichiei Narita,[2] Hiroshi Kawachi.[1] *[1]Cell Biology, Inst Nephrol, Niigata Univ Medicine, Niigata, Japan; [2]Medicine II, Niigata Univ Medicine, Niigata, Japan.*

**Background:** Calcineurin (CaN) is the target molecule of cyclosporine A, which is used for the treatment of proteinuric kidney diseases. Recently, it was reported that cyclosporine A blocked CaN-mediated dephosphorylation of synaptopodin, and stabilized the actin cytoskeleton of the podocyte. However, pharmacological mechanism of cyclosporine A, and the function of CaN in podocyte are not fully understood yet.

**Methods:** The glomerular expressions of CaN-A and cyclophilin A (CyA), a binding protein of cyclosporine A were analyzed in normal rat glomeruli, and in glomeruli of puromycin aminonucleoside nephropathy (PAN) and adriamycin nephropathy (ADR). The expression of these molecules were analyzed by dual labeling IF with podocyte markers. mRNA expression of two isoforms of CaN-A -α and -β and CyA, was analyzed with RT-PCR.

**Results:** Clear 58kDa band was detected in glomerular lysate with anti-CaN-A antibody recognizing both isoforms of CaN-A (MILLIPORE). Clear immno-staining of CaN-A along capillary loop was observed in normal rat glomeruli. CaN-A was co-stained with nephrin, and was slightly apart from synaptopodin. CyA was also observed as a similar pattern as CaN-A. The staining of CaN-A shifted to discontinuous granular pattern, and its intensity decreased on day 5 of PAN, when proteinuria was not observed yet. The decrease in the staining became more remarkable on day 10. Such an alteration was also observed in CyA staining. The decrease of CaN-A staining was observed also in ADR. mRNA expression of CaN-A α was decreased already at 1h of PAN (14% to normal) and the decrease was also observed on day 28 of ADR (5%), whereas the decrease of CaN-A β was not detected at any time points of these models.

**Conclusions:** CaN-A and CyA were mainly localized at the SD area. Their altered expression was detected before the onset of proteinuria, suggesting that these molecules play a role in maintaining the integrity of the SD, and that their altered expression is involved in the development of proteinuria.

### FR-PO846

**The Reduction and Morphological Alterations of Podocyte Slits Cause Acute Kidney Injury in Minimal Change Nephrotic Syndrome** Satoshi Kinugasa, Kensuke Asaba, Masaomi Nangaku, Akihiro Tojo. *Dept of Nephrology and Endocrinology, Univ of Tokyo, Tokyo, Japan.*

**Background:** Some cases of minimal change nephrotic syndrome (MCNS) present with acute kidney injury (AKI). The decrease in the number of podocyte slits due to foot process effacement, and tight junction-like alterations may contribute to the reduction of eGFR in these patients. We verified this hypothesis in human MCNS patients.

**Methods:** All biopsy-proven MCNS patients in our institute in the past 20 years who had electron microscopy images available for analysis were included in the study (n=38). We compared clinical indices at the time of renal biopsy, and several ultrastructural morphological parameters between AKI (n=13) and non-AKI patients (n=25). We also made similar evaluations in puromycin aminonucleoside (PAN) nephrotic rats.

**Results:** The rate of AKI in MCNS was 34% (13/38). The AKI group showed a signihicant reduction in podocyte slit number density (383 ± 26/mm vs 549 ± 47/mm, $p < 0.05$), and the width of the slits were significantly narrowed (20.5±2.3 nm vs 35.8±6.0 nm, $p < 0.05$). Multiple logistic regression analysis showed a significant association between the onset of AKI and slit number density. Spearman's rank correlation analysis revealed that both slit density (rS=-0.489) and slit width (rS=-0.528) was strongly correlated with AKIN stage. Also, the ratio of foot process effacement along the glomerular capillaries was significantly correlated with the amount of proteinuria (R=0.475). Between PAN nephrotic rats treated with the usual dose of PAN (n=3), and those which were administered a two-fold dose (n=3), the latter had a greater effacement ratio (69.6 ± 4.9 % vs 90.4 ± 2.0 %, $p < 0.01$) and increased proteinuria (27.1 ± 3.4 % vs 79.1 ± 1.2 %, $p < 0.01$), and presented with AKI, which was in accordance with the human biopsy study. Immunogold staining showed increased expression of the tight junction protein claudin 5 in PAN rats compared to controls.

**Conclusions:** AKI is a common complication of MCNS. In MCNS with concurrent AKI, a reduction in podocyte slit number and narrowing of slits was observed. The degree of foot process effacement correlated with urinary protein.

### FR-PO847

**Mitochondrial Dysfunction in Podocyte Induces Proteinuria via Decrease of Alpha Actinin-4 and Synaptopodin** Dae Eun Choi,[1] Jin Young Jeong,[1] Sarah Chung,[1] Yoon-Kyung Chang,[2] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National Univ Hospital, Daejeon, Republic of Korea; [2]Internal Medicine, Daejeon Saint Mary Hospital, Daejeon, Republic of Korea.*

**Background:** Our previous report showed that Crif1 deletion induce severe mitochondrial destruction in mice podocyte. There results induce massive albuminuria and effacement of foot process in mice. Actin cytoskeleton architecture and dynamics in podocyte are important constituents of the glomerular filtration barrier. There have been few studies about relation of mitochondria and actin cytoskeleton in podocytes of glomerulus. We evaluated the changes of actin cytoskeletal proteins and artchitecture in mitochondrial injured podocyte.

**Methods:** We used immortalized mouse podocyte cell line. . Crif1 silencing(si) RNA treatment was used for inducing mitochondrial injury. We divided 3 groups; control podocytes, scrumble(sc) RNA treated podocytes, Crif1 siRNA treated podocytes. We checked the expression of mitochondrial respiratory complex I~V, WT-1, and Crif1 for mitochondrial dysfunction in immortalized podocyte. We evaluated the expression of alpha actinin 4, synaptopodin, nephrin, ZO-1, and colfillin using western blot. Using confocal microscopy, we examined actin cytoskeleton architecture and mitochondria of podocyte. For evaluation of cell migration, we performed scratch assay.

**Results:** Crif1 siRNA treatment reduced the expressions of mitochondrial respiratory complex IV and $O_2$ consumption in cultured podocytes. Alpha actinin-4 and synaptopodin were decreased in Crif1 siRNA treated podocyte compared to control and Crif1 scRNA treated podocytes. There were no differences in nephrin and ZO-1. Crif1 siRNA treated podocyte showed an enhanced formation of dot-like alpha actinin-4 and an increase of fragment mitochondria in confocal microscopy compared to scRNA treated podocyte. Podocyte migration was increased in Crif1 siRNA treated podocyte.

**Conclusions:** With the above results, it is speculated that mitochondrial dysfunction induced by crif1 inhibition reduces alpha actinin-4 and synaptopodin in podocyte.

*Funding:* Government Support - Non-U.S.

### FR-PO848

**ApoL1 Protein in Non-Diseased Human Podocytes: Endogenous Synthesis versus Uptake?** Lijun Ma,[1] James A. Snipes,[1] Mariana Murea,[1] Peter A. Antinozzi,[1] Gregory S. Shelness,[1] Moin Saleem,[2] Simon C. Satchell,[2] Bernhard Banas,[3] Peter W. Mathieson,[2] Matthias Kretzler,[4] Snezana Petrovic,[1] Michael D. Ross,[5] Martin R. Pollak,[5] Lawrence Rudel,[1] John S. Parks,[1] Barry I. Freedman.[1] *[1]Wake Forest School of Medicine; [2]Univ of Bristol, United Kingdom; [3]Univ of Regensburg, GA; [4]Univ of Michigan at Ann Arbor; [5]Harvard Medical School.*

**Background:** Based on heat-induced epitope retrieval on paraffin-embedded kidney sections, ApoL1 protein is found localized to human proximal tubule cells (PTCs) and podocytes; however, it is unknown the extent to which this reflects local synthesis versus uptake.

**Methods:** Immunofluorescence microscopy (IF) was performed on non-diseased nephrectomy cryo-sections from subjects with normal kidney function and in various cell lines using an antibody specific for native human ApoL1. RNA *in situ* hybridization (ISH), Western blot (WB), and RT-PCR studies were also performed.

**Results:** IF revealed that ApoL1 co-localized with synaptopodin and Wilm's tumor repressor in podocytes and was present in renal tubule cell cytoplasm, albeit with lower signal intensity than podocytes. ISH detected *APOL1* mRNA in both glomeruli and tubules, consistent with endogenous synthesis in these cell types. Based on RT-PCR, *APOL1* mRNA was absent in mesangial cell lines and HEK293 cells; however, comparable expression was observed in all other cell types analyzed, including: immortalized human podocytes, glomerular endothelial cells (GEC) and PTC; primary GECs and podocytes; and HepG2 cells. Based on IF and WB, ApoL1 protein was also detected in these cell lines but not in mesangial or HEK293 cells. Based on IF, ApoL1 signal intensity was lower in both the immortalized and primary podocytes, as compared to the kidney cryo-sections. To explore the basis for this apparent discrepancy, we observed that ApoL1 protein (reference sequence) was readily taken up by human podocyte and PTC lines *in vitro*, but not by mesangial or GEC lines.

**Conclusions:** We speculate that the higher *in vivo* levels of ApoL1 observed in human podocytes on cryo-section may reflect endogenous protein synthesis as well as uptake of additional ApoL1 from the circulation or glomerular filtrate.

*Funding:* NIDDK Support

### FR-PO849

**Rituximab Ameliorates Proteinuria in Rat Adriamycin Nephropathy Independently with Its Action to B Lymphocyte** Yuichi Takahashi, Hisashi Kamada, Asami Takasaki, Ayako Wakamatsu, Yoshiyasu Fukusumi, Masayuki Tomita, Hiroshi Kawachi. *Dept of Cell Biology, Insutitute of Nephrology, Niigata, Japan.*

**Background:** Rituximab, a monoclonal antibody against CD20 on B lymphocytes, is reported to reduce proteinuria in some kidney diseases. It is postulated that Rituximab has cross-reactivity to sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b), and plays a protective role for podocyte by preserving the SMPDL3b function. However, the direct action of Rituximab in podocyte is not proved yet, and the pharmacological mechanism of rituximab and the function of SMPDL3b in podocyte are still uncertain.

**Methods:** Because it is reported that rituximab has no reactivity to rat CD20, we analyzed the effect of rituximab on proteinuria in rat experimental model. Adriamycin (ADR) nephropathy was induced in rats by the single injection of 6 mg/kg BW of ADR, and the rats were intravenously injected with rituximab (10 mg/kg BW/week) from day 0. The kinetics of proteinuria were analyzed, and the kidney materials were removed on day 28 after disease induction. To elucidate the pharmacological mechanism of rituximab, the expression of nephrin and podocin, the functional molecules of the slit diaphragm, and SMPDL3b were analyzed.

**Results:** The rituximab treatment clearly reduced the amount of proteinuria in ADR nephropathy (day 18, 25.62 mg/day vs. 84.56, $p<0.005$: day 28, 52.99 vs. 138.06 $p<0.05$). The rituximab treatment rescued the decrease in the staining of nephrin and podocin on day 28. The binding of the injected rituximab to glomeruli was confirmed in rat kidney sample removed 1 h after the rituximab injection. The injected rituximab is observed at the discontinuous linear pattern along the capillary loop of glomeruli, and the staining pattern is very similar to that of SMPDL3b detected by the specific antibody against SMPDL3b. SMPDL3b staining clearly decreased at very early phase of ADR nephropathy.

**Conclusions:** The findings suggested that the decreased expression of SMPDL3b was involved in the initiation event of ADR nephropathy. It is conceivable that the injected rituximab bound SMPDL3b in podocyte and ameliorated proteinuria independently with its action to B lymphocyte.

*Funding:* Government Support - Non-U.S.

## FR-PO850

**Repopulation of Denuded GBM by Visceralized Parietal Epithelial Cells (vPECs) Is a Transient Mechanism to Limit Proteinuria**

Samy Hakroush,[1] Angelika Cebulla,[1] Thomas Schaldecker,[1] Peter H. Mundel,[1] Astrid Weins.[2] *[1]Div of Nephrology, Massachusetts General Hospital, Charlestown, MA; [2]Dept of Pathology, Brigham and Women's Hospital, Boston, MA.*

**Background:** Damage to podocytes is a central pathomechanism of proteinuric kidney disease. However, it is not fully understood how podocyte injury evolves to irreversible glomerulopathies such as Focal Segmental Glomerulosclerosis or Collapsing Glomerulopathy. In particular, the role of PECs remains controversial. Here, we provide novel insights into the role of PECs in the development of these lesions following podocyte injury.

**Methods:** Mice on a mixed *C57Bl6/Balb/c* background were analyzed at baseline and at several timepoints after *i.v.* injection of various concentrations of adriamycin (ADR) or vehicle, using clinical parameters, light and electron microscopy as well as immunohistochemistry.

**Results:** We found that ADR induces podocyte lysis through DNA damage. In contrast to other models, autophagy, ER stress and necroptosis are not involved in the pathogenesis of ADR nephropathy. Following podocyte loss, PECs are activated in two pathways: In the majority of glomeruli, PECs undergo striking vacuolization to attach to denuded glomerular basement membrane (GBM), which is followed by detachment of PECs from the parietal basement membrane (PBM). This results in repopulation of denuded GBM by PECs, ultimately leading to glomerulosclerosis. Less frequently, PECs do not undergo vacuolization, but cover the denuded GBM via formation of proliferative pseudocrescents. Of note, all "visceralized" PECs (vPECs) covering the GBM do not express VEGF, but instead show high expression of HIF1. The clinical relevance of our findings was underscored by detection of vPECs in biopsies of human glomerulopathies.

**Conclusions:** In conclusion, we propose that repopulation of the glomerular tuft by vPECs represents a compensatory response following podocyte loss in sclerotic and proliferative glomerular lesions, which is triggered by denuded GBM and is aimed at diminishing urinary protein loss. However, as vPECs do not express VEGF, they fail to induce revascularization of the hyalinized tuft, which results in hypoxic cell death.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## FR-PO851

**Rac1 in Podocytes Protects Glomeruli against the Formation of Sclerosis**

Rin Asao,[1] Katsuhiko Asanuma,[1,2] Fumiko Kodama,[1] Miyuki Takagi,[1] Yoshiko Hosoe,[1] Eriko Tanaka,[3] Takuto Seki,[1,2] Kanae Nonaka,[1,2] Yu Sasaki,[1] Teruo Hidaka,[1] Lawrence B. Holzman,[4] Yasuhiko Tomino.[1] *[1]Div of Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Medical Innovation Research, TMK Project, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Dept of Pediatrics, Tokyo Medical and Dental Univ, Tokyo, Japan; [4]Dept of Internal Medicine, Renal-Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia.*

**Background:** Rac1, one of the Rho family of GTPases, is ubiquitously expressed and plays a crucial role in various events like cell motility. In this study, we investigated the role of Rac1 in podocytes under pathological conditions.

**Methods:** Mice with podocyte-specific Rac1 conditional knockout (Rac1 cKO) were generated using Cre-lox technology and injected adriamycin, which causes nephrosis and glomerulosclerosis. Rac1-constitutively active (CA) podocytes and Rac1- dominant negative (DN) podocytes were generated for in vitro study. To evaluate the morphological variation and cell motility, immunofluorescence and cell migrating assay were performed.

**Results:** Under physiological conditions, Rac1 cKO mice didn't develop proteinuria and showed no deterioration. Histologic alteration of kidneys from Rac1 cKO after injection of ADR demonstrated a higher ratio of sclerotic glomeruli than in control at day 28 (19.12±3.85 % versus 0.56±0.23 %; $p<0.001$). However, there was no difference between Rac1 cKO and control in the number of podocytes and in the levels of urinary protein at day 28. By electron microscopy, areas of denuded GBM in Rac1 cKO were observed more frequently than in control. In in vitro study, the formation of actin stress fiber and lamellipodia were suppressed more in Rac1 DN than in WT and Rac1 CA. In wound healing assay, Rac1 CA significantly promoted directional podocyte migration compared with WT and Rac1 DN after 6 and 12 hours. Moreover, Rac1 DN is significantly less motile than WT and Rac1 CA in transwell cell migration assay.

**Conclusions:** Rac1 regulates actin organization and controls cell motility in podocytes. Loss of Rac1 in podocytes might play an important role in the formation of glomerulosclerosis.

## FR-PO852

**Urine Podocyte and TGF-β1 mRNAs as Progression Markers in Crescentic Glomerulonephritis**

Akihiro Fukuda,[1] Yuji Sato,[1] Takashi Iwakiri,[1] Masao Kikuchi,[1] Kazuo Kitamura,[1] Roger C. Wiggins,[2] Shouichi Fujimoto.[1] *[1]First Dept of Internal Medicine, Univ of Miyazaki, Miyazaki, Japan; [2]Nephrology Div, Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

**Background:** Glomerulosclerosis (GS) and interstitial fibrosis (IF) are the major pathlogic processes causing progression to end stage kidney disease (ESKD). Podocyte depletion causes GS leading to IF, and we have demonstrated that persistent podocyte loss is a major factor driving the progression process (podocyte depletion hypothesis: Wiggins R. KI 2007). We have also demonstrated that urine podocyte mRNA could be a useful for diagnostic and monitoring for progression process in two models of controlled podocyte depletion (Sato Y et al. JASN 2009, Fukuda A et al. KI 2012).

**Methods:** To determine whether tha same principles apply to crescentic glomerular injury we used the crescentic anti-GBM glomerulonephritis rat model and in parallel experiments we examined urine samples of patients with crescentic glomerulonephritis. Podocyte loss was measured by WT1 positive nuclear counting, the GLEPP1 positive podocyte tuft area, and by urine podocyte mRNAs excresion. GS and IF were evaluated by AZAN staining, and also measured urine TGF-β1 mRNA.

**Results:** In the model system, sequential kidney biopsies at 1, 2, and 4 weeks revealed that glomerular podocytes continued to decrease over time until global podocyte depletion (ESKD) by estimations using these three different methods. Urine podocyte and TGF-β1 mRNAs were excreted persistently at high levels throughout the time course of progression in experimental but not in control rats. In addition, methylprednisolone (MP) therapy slowed podocyte depletion and progression process, and also decreased urine TGF-β1 mRNA excretion. Furthermore, in patients with crescentic glomerulonephritis, urine podocyte and TGF-β1 mRNA excretion were significantly increased compared with healthy control.

**Conclusions:** These results emphasize the podocyte depletion hypothesis, and show that urine podocyte and TGFβ1 mRNAs could serve to identify and monitor the progression process in crescentic glomerulonephritis.

## FR-PO853

**A Protective Role of Indoleamine 2, 3-Dioxygenase (IDO)-General Control Non-Repressed-2 (GCN2) Kinase Axis in Glomerulonephritis**

Kapil Chaudhary,[1] Lei Huang,[1] Maggie McMenamin,[2] Michael P. Madaio,[2] Tracy L. McGaha.[1] *[1]Cancer Immunology, Inflammation and Tolerance Program, Georgia Regents Univ, Augusta, GA; [2]Dept of Medicine, Georgia Regents Univ, Augusta, GA.*

**Background:** Indoleamine 2, 3-dioxygenase **(IDO)**, a tryptophan (Trp) catabolizing enzyme rapidly induced in dendritic cells and macrophages by interferons (type I and II), depletes Trp at the site of inflammation. **G**eneral **C**ontrol **N**on-repressed **(GCN2)** kinase senses amino acid depletion (uncharged t-RNAs) and activates cellular stress response by affecting global as well as specific m-RNA translation. Including in kidney much is unknown about the functional role of IDO during inflammation in stromal cells.

**Methods:** Nephrotoxic serum nephritis (NTN) was induced in IDO-KO, GCN2-KO and WT (C57B6) mice by passive administration (i.p.) of low and high dose sheep nephrotoxic serum (NTS). Multiple i.v. injections of CpG free DNA coated nano-particles (DNPs) were used to induce IDO expression in-vivo. Enzymatic activity of IDO (kynurenines production) was measured by HPLC. Autophagy response in differentiated podocytes was measured by staining for LC3B.

**Results:** Compared to WT, IDO-KO and GCN2-KO mice developed more severe kidney damage by 3rd week of NTN as evident by significantly higher BUN, proteinuria levels and histopathological scores. IDO1 expression was induced at mRNA and protein levels in podocytes by day 10 of NTN. Interferons (IFN-γ and IFN-β1) induced IDO activity in podocytes in-vitro. Systemic administration of DNPs induced IDO activity in kidneys and significantly reduced BUN and proteinuria levels, and NGAL expression by day 21 of NTN, while IDO-KO mice did not show any protection. Expression of CHOP, a marker of GCN2 kinase activation was significantly higher in kidney cortex of NTN mice and differentiated podocytes cultured in tryptophan-depleted conditions. Tryptophan depletion suppresses IL-1β and CCL-2 production upon LPS treatment and induces autophagy in podocytes in-vitro.

**Conclusions:** IDO induces cellular stress response and autophagy in podocytes, and limits progression of immune mediated kidney injury.

## FR-PO854

**Role of miRNA let-7b in the Deregulation Process of IgA1 Glycosylation in IgA Nephropathy** Grazia Serino,[1,2] Fabio Sallustio,[1,2] Claudia Curci,[2] Sharon N. Cox,[1] Francesco Pesce,[3] Giuseppe De Palma,[2] Francesco Paolo Schena.[1,2,4] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy; [3]Dept of Genomics of Common Disease, Imperial College, London, United Kingdom; [4]Schena Foundation, Research Center for Kidney Diseases, Valenzano, Bari, Italy.*

**Background:** IgA Nephropathy (IgAN) is characterized by aberrant O-glycosylation in the hinge region of IgA1. The initiation step in O-glycan formation is attachment of N-acetylgalactosamine (GalNAc) to the IgA1 hinge region, catalyzed by GalNAc-transferase 2 (GALNT2). In our previous work (JASN 23: 814-24,2012) we found that let-7b is one of the miRNAs, significantly upregulated in IgAN patients.

**Methods:** To investigate the molecular mechanisms in which let-7b is involved, we performed a bioinformatic analysis to predict the target genes which were biologically validated by transient transfection experiments *ex vivo* using peripheral blood mononuclear cells (PBMCs) of 3 IgAN patients and 4 HBD. Then, we measured by Real-time PCR the content of let-7b in PBMCs of 60 Caucasian IgAN patients and 60 healthy blood donors (HBD).

**Results:** We identified let-7b gene targets using the overlapping results of at least two different algorithms (miRBase 19.0, TargetScan 5.2, PicTar and RNA22 1.0). Bioinformatic analysis revealed that GALNT2, the enzyme initiating O-Glycosylation of IgA1, was the potential target of let-7b. Then, we demonstrated that let-7b decreased GALNT2 levels in PBMCs of IgAN patients ($p=0.01$) whereas the loss of let-7b function in PBMCs of HBD led to an increase of GALNT2 mRNA and protein levels ($p= 0.02$). Let-7b was found significantly upregulated in PBMCs of 60 IgAN patients ($p< 0.0001$) and positively correlated with high serum levels of the galactose-deficient (Gal-deficient) IgA1 ($r=0.3$, $p=0.007$) supporting that abnormal increase of serum Gal-deficient IgA1 is consequent to higher let-7b content in PBMCs of IgAN patients.

**Conclusions:** We speculate that the deregulation of let-7b causes GALNT2 reduction that could lead to aberrant O-glycosylation of IgA1 in IgAN patients. Our results give novel additional information on the abnormal O-glycosylation process of IgA1 in IgAN patients.

## FR-PO855

**Recombinant Pentraxin-2 Therapy Attenuates the Progression of Alport Nephropathy in Col4a3 Deficient Mice** Naoki Nakagawa,[1] Allie M. Roach,[1] Bryce Gordon Johnson,[1] Ivan G. Gomez,[1] Mark L. Lupher,[2] Jeremy Stuart Duffield.[1] *[1]Renal Div, Kidney Research Institute, Univ of Washington, Seattle, WA; [2]Promedior Inc, Boston, MA.*

**Background:** Alport syndrome in humans is an inherited form of kidney disease caused by a mutation in the gene coding the capillary basement membrane collagen IV. The disorder is characterized by progressive glomerulonephritis, leading to glomerulosclerosis, tubulointerstitial disease and organ failure. Col4a3$^{-/-}$ mice also spontaneously develop severe kidney disease highly similar to human disease. Pentraxin-2 is a naturally produced circulating plasma protein involved in innate immunity. Recent studies have shown that pentraxin-2 inhibits interstitial kidney disease with fibrosis by acting as a macrophage differentiation factor, promoting anti-inflammatory/reparative Mreg macrophages in response to tissue injury. We hypothesized that treating Col4a3$^{-/-}$ mice with recombinant Pentraxin-2 would prevent progression of disease.

**Methods:** Col4a3$^{-/-}$ mice were given pentraxin-2 (10 mg/kg, d29-31 then q2w, IP) or vehicle from wk4 to wk9. Urine, plasma and kidneys were harvested at the end of wk9. All samples were analyzed to determine changes in kidney function and fibrosis.

**Results:** Pentraxin-2 treatment significantly attenuated the loss of kidney function and development of albuminuria. Glomerulosclerosis and interstitial fibrosis were also attenuated. Proximal tubules and Podocyte number were preserved. Furthermore, Pentraxin-2 reduced infiltrating macrophage and myofibroblast appearance. Pentraxin-2 stimulates Mreg macrophages in tissue injury and phenotypic characterization of macrophage subsets in this model will be presented.

**Conclusions:** Recombinant Pentraxin-2 prevents progressive loss of kidney function in the Col4a3$^{-/-}$ mouse, attenuates both glomerular and tubulointerstitial disease. Pentraxin-2 is a potential new therapy for human Alport Nephropathy and other chronic kidney diseases.

## FR-PO856

**Epigallocatechin-3-Gallate (EGCG) Inhibits Amyloid Formation in Amyloiodgenic Light Chain Perfused Kidney** Jiamin Teng,[1] Elba Turbat-herrera,[1] Takahito Moriyama,[2] Guillermo A. Herrera.[1] *[1]Pathology, LSU Health, Shreveport, LA; [2]Medicine, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** In our previous studies, we have shown amyloid formation after treatment with glomerulopathic amyloidogenic light chains (AL-GLC) purified from the urine of patients with renal biopsy-proven AL-amyloidosis. C-fos plays an important role in the generation of signals resulting in amyloidogenesis. Other studies have shown that EGCG, found in green tea and red wine, is able to ameliorate amyloid-beta protein –associated amyloidosis in Alzheimer's disease.

**Methods:** Human mesangial cells (HMC) were grown until confluent, made quiescent for 2 days, and then incubated with AL-LC and EGCG for 4 hours. Western blots and immunofluorescence stains were used to assess the effect on c-fos. Rat kidneys were isolated and mounted on an ex-vivo kidney perfusion platform. AL-LC and EGCG were perfused through the renal artery for 24 hours, then the kidneys were fixed and examined using light, immunofluorescence, and electronic microscopy (transmission and scanning). Proper controls were used to compare with experimental data.

**Results:** After incubation with AL-LC, amyloidogenic light chains were noted in mesangial areas and c-fos translocated from HMC cytoplasm into nuclei. In EGCG treated group, cytoplasmic to nuclear translocation of c-fos was inhibited and amyloid formation was significantly decreased.

**Conclusions:** EGCG down-regulates translocation of c-fos into MC nuclei when MCs are incubated with AL-LCs. In MCs co-incubated with EGCG, nuclear c-fos translocation is significantly decreased and amyloid formation is decreased. The inhibitory effect of EGCG on amyloid fibril formation occurs concomitantly with inhibition of translocation of c-fos from cytoplasm to nuclei. EGCG has an important effect in regulating amyloid formation in MCs.

## FR-PO857

**TLR4-Deficient Mice Are Protected from Chronic Kidney Disease Progression and Spleen Apoptosis in a Remnant Kidney Model** Ana C. Souza, Takayuki Tsuji, Alejandro Alvarez-Prats, Xuzhen Hu, Yuning George Huang, Robert A. Star, Peter S.T. Yuen. *NIDDK, NIH, Bethesda.*

**Background:** TLR4, the LPS receptor, recognizes HMGB1, a danger associated molecular pattern (DAMP) protein. HMGB1 is increased in patients with CKD, and after 5/6 nephrectomy (5/6Nx) in mice. We showed that CKD worsens sepsis-AKI by releasing HMGB1, and that apoptotic splenocytes are a major source of HMGB1 (KI 2011). Now we test if the HMGB1-TLR4 pathway participates in the progression of CKD.

**Methods:** C3H/HeOuJ (TLR4+) vs. C3H/HeJ (TLR4-) mice were subjected to 5/6Nx then a continuous infusion of low dose (0.0625 µg/Kg/min) Angiotensin II (AngII) by osmotic minipump for 4 weeks (N=10/group). Mice subjected to 5/6Nx without AngII infusion did not progress to CKD and were used as controls (N=8/group). BUN was measured by colorimetry, creatinine by HPLC, albumin and serum HMGB1 by ELISA. ACR was analyzed weekly. Histological analyses of kidney sections were performed. Spleen apoptosis was measured by anti-caspase-3 immunohistochemistry. Statistical analysis was performed by ANOVA.

**Results:**

| | Control TLR4+ (5/6Nx) | Control TLR4- (5/6Nx) | 5/6Nx + AngII TLR4+ | 5/6Nx + AngII TLR4- | p value (ANOVA) |
|---|---|---|---|---|---|
| BUN (mg/dl) | 73±2 | 83±11 | 223±41 | 70±5 | <0.0001 |
| SCr (mg/dl) | 0.2±0.0 | 0.2±0.0 | 0.6±0.1 | 0.2±0.0 | <0.0001 |
| ACR at 4 wks (µg/mg) | 114±26 | 113±25 | 4730±1120 | 73±9 | <0.0001 |
| Glomerulosclerosis Score | 1.3±0.1 | 1.4±0.3 | 3.1±0.3 | 1.6±0.1 | <0.0001 |
| Interstitial Fibrosis Score | 1.3±0.0 | 1.5±0.2 | 2.3±0.2 | 1.3±0.0 | <0.001 |
| Serum HMGB1 (ng/ml) | 7±1 | 7±0.4 | 64±23 | 19±5 | <0.01 |
| Spleen apoptosis (+cells/HPF) | 4±0.3 | 4±0.2 | 18±2 | 2±0.2 | <0.0001 |

**Conclusions:** TLR4 plays an essential role in CKD progression in mice. Serum creatinine and HMGB1, albuminuria, and spleen apoptosis are increased in TLR4+ but not TLR4- mice after 5/6 Nx+AngII. Both 5/6Nx and AngII are necessary, but not sufficient, for TLR4-dependent increases in spleen apoptosis, serum HMGB1, and CKD progression.

*Funding:* NIDDK Support

## FR-PO858

**CD36 Receptor Blockade Protects against Chronic Kidney Disease Progression in a Remnant Kidney Model** Ana C. Souza,[1] Alexander V. Bocharov,[2] Alejandro Alvarez-Prats,[1] Yuning George Huang,[1] Xuzhen Hu,[1] Erik H. Koritzinsky,[1] Thomas Eggerman,[1] Robert A. Star,[1] Peter S.T. Yuen.[1] *[1]NIDDK, NIH; [2]CC, NIH, Bethesda.*

**Background:** Scavenger receptor CD36 is a widely expressed cell surface receptor important in lipid metabolism, inflammation and atherosclerosis. We have demonstrated that CD36KO mice are protected from CKD progression after 5/6 nephrectomy (5/6Nx) + Angiotensin II (AngII) infusion (ASN 2012). Now we test the effect of a synthetic peptide, L37pA, a potent receptor antagonist for CD36, on CKD progression.

**Methods:** CD36KO and WT (C57BL6 background) mice were subjected to 5/6Nx plus AngII infusion (0.75 µg/Kg/min) for 4 wks by osmotic minipump (N=12/group). WT 5/6Nx mice without AngII infusion did not develop progressive CKD and served as controls (N=12). Another group of WT mice subjected to 5/6Nx+AngII received L37pA peptide (5mg/Kg/day) by osmotic mini-pump (N=9). All mice were followed for 4 wks. Albuminuria was measured weekly by ELISA; creatinine by HPLC. A blood chemistry panel was performed by an auto-analyzer (N=6/group). Masson's and PAS staining of kidney sections were performed. Statistical analysis was done by ANOVA.

**Results:** At 4 wks Scr was increased in WT mice subjected to 5/6Nx+AngII, while KO and WT+L37pA had values similar to control (control 0.28±0.02, WT 0.59±0.13, KO 0.33±0.03, WT+L37pA 0.20±0.04 mg/dl, $p=0.01$). This protection in kidney function was accompanied by reduced levels of albuminuria (ACR at 4 wks control 74.2±22.6, WT 3510±805, KO 1830±570, WT+L37pA 2220±542 µg/mg, $p<0.0001$), glomerulosclerosis (control 1.4±0.1, WT 3.2±0.2, KO 2.3±0.1, WT+L37pA 2.1±0.2, $p<0.0001$), and interstitial fibrosis scores (control 1.3±0.1, WT 3.0±0.2, KO 2.2±0.2, WT+L37pA 2.0±0.1, $p<0.0001$). Serum calcium, phosphorus and magnesium were elevated in the WT group ($p<0.05$), and not in KO and L37pA groups. Serum AST, ALT, uric acid, albumin, amylase and CK were similar in all groups.

**Conclusions:** CD36KO protection is not due to a developmental abnormality, since adult WT mice treated with L37pA are also protected from CKD progression. At this dose and route of administration, L37pA did not cause any detectable side effects.

### FR-PO859

**The Role of the Intestinal Microbiota in the Development of Diabetes in BTBR and BTBR ob/ob Mice** Kelly D. Smith, Tomasz Wietecha, Kelly L. Hudkins, Xiaodan Zhao, Charles E. Alpers. *Pathology, Univ of Washington, Seattle, WA.*

**Background:** Obesity and diabetes are associated with an altered gut microbiota that further aggravates metabolic syndrome, and may promote inflammation and contribute to diabetic complications. The BTBR$^{ob/ob}$ mouse is leptin-deficient, resulting in progressive obesity and type II diabetes. A novel aspect of this mouse model of type II diabetes is that these mice also develop clinical and morphologic features that closely mimic diabetic nephropathy in humans (J Am Soc Nephrol. 2010;21(9):1533-42). In this study we analyzed the role of the microbiome in modulating the BTBR and BTBR$^{ob/ob}$ mouse models of diabetes.

**Methods:** Starting at age 4 weeks, BTBR and BTBR$^{ob/ob}$ mice were fed normal mouse chow, and either water or water with an antibiotic cocktail (Ampicillin, Vancomycin, Metronidazole and Neomycin). Mice were analyzed for weight, blood glucose, glucose tolerance, urine protein, and histopathology. Fecal bacteria were analyzed by culture and 16S rDNA sequencing.

**Results:** Antibiotic treatment suppressed intestinal microbiota in BTBR mice, which was associated with a significant improvement in fasting glucose levels and glucose tolerance. In contrast, antibiotic treatment altered but did not suppress microbiota in BTBR$^{ob/ob}$ mice, resulted in an overgrowth of fungal organisms within the gut, and led to decreased survival (50% at 16 weeks).

**Conclusions:** Antibiotic mediated suppression of the intestinal microbiota improved diabetic parameters in non-obese type II diabetic BTBR mice. Antibiotics altered but failed to suppress microbiota in obese type II diabetic BTBRob/ob mice, and failed to suppress the development of diabetes.

### FR-PO860

**Timing Is Critical in Determining Intervention Effectiveness. Moderate Calorie Restriction Enhances Angiotensin II Blockade Effectiveness in Preventing Progression** Ryuzoh Nishizono, Su Qing Wang, Mahboob A. Chowdhury, Yan Yang, Larysa T. Wickman, Roger C. Wiggins. *Div of Nephrology, Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

**Background:** Obesity is and independent risk factor for progression, and increasing obesity may account for increasing prevalence of FSGS reported worldwide. We previously demonstrated that 40% calorie restriction (CR) prevented FSGS, proteinuria, podocyte loss, glomerulosclerosis and progression to ESKD in the AA-4EBP1 rat model system (Fukuda et al, JASN, 2013).

**Methods:** Transgenic AA-4EBP1 Fischer 344 rat podocytes express a dominant negative AA-4E-BP1 transgene driven by the human podocin promoter. Homozygous 4EBP1 transgenic rats were uni-nephrectomized (NX) at 100g body weight ("time 0"). Interventions (20% calorie restriction or angiotensin converting enzyme inhibition by enalapril [A2B at 0.1mg/ml in drinking water] or the combination of these two treatments were started either immediately after nephrectomy ("early start") or three weeks later when the urine protein:creatinine ratio had reached 10 ("later start"). Outcomes measurements assessed were proteinuria, urine podocyte mRNAs, glomerulosclerosis, podocyte number per glomerulus, and serum creatinine.

**Results:** Homozygous NX 4EBP1 rats reached ESKD by 12 weeks.(% glomerulosclerosis was 85.1±5.5 at week 11). Both 20%CR and A2B started immediately after NX prevented progression. However neither treatment alone prevented progression when started later after injury had become established (3 weeks after NX). % glomerulosclerosis in 20%CR was 62.3±5.4 and 52.5±8.5 in A2B at week 12. In contrast the combination of moderate CR and A2B did prevent progression when started after injury had been established(% glomerulosclerosis was 26.2±7.0 at week 12).

**Conclusions:** Timing of intervention is critical in determining its effectiveness. The combination of moderate calorie restriction together with A2B was significantly more effective at preventing progression of established injury than was either treatment alone. The impact of moderate calorie reduction is an under-recognized variable in clinical trials for prevention of progression of glomerular diseases.

### FR-PO861

**Dipeptidyl Peptidase 4 Deficiency Reduces Renal Injury in the Remnant Kidney Model in the Rat** Christoph Daniel,[1] Stephan Von Hoersten,[2] Kerstin U. Amann.[1] *[1]Nephropathology, Univ Erlangen; [2]Experimental Biomedicine, Univ Erlangen.*

**Background:** Dipeptidyl peptidase 4 (DPP4) is an exopeptidase inactivating incretins that promote insulin secretion and were therefore used in the treatment of type II diabetes. Beside its ability to cleave incretins, several chemokines like RANTES and CCL2 were also regulated by DPP4. In lung as well as in renal ischemia/reperfusion injury (IRI) and in acute heart rejection, treatment with DPP-4 inhibitors were protective, but the effect of DPP4 inhibition in chronic kidney disease is unknown.

**Methods:** Wildtype Dark Agouti (DA) rats (n=21) and congenic rats who did not express DPP4 (DPP4-/-) (n=20) were divided in SHAM-operated controls (n=7+8) and animals who underwent 5/6-nephrectomy (SnX; n=14+12). Kidney function was monitored every 4 weeks. Twelve weeks after model induction we measured intraarterial blood pressure and renal inflammation, fibrosis and morphologic changes.

**Results:** In both SnX groups proteinuria and serum urea raised up starting on week 4 and remained on high levels during the whole experiment showing lower levels in DPP4-/- rats. Twelve weeks after SnX mean arterial blood pressure was increased in DA rats (135±4 vs. 172±19 mmHg), but was significantly lower in DPP4-/- rats (151±23 mmHg). Kidney morphology from DPP4-/- rats was significantly preserved after SnX as shown by lower glomerular sclerosis (GSI score: 1.1±0.5 vs. 1.7±0.7) and tubulointerstitial injury (TSI score: 1.0±0.5 vs. 1.6 ±0.5). In addition, renal fibrosis was markedly lower in DPP4-/- SNx rats (sirius red score: 1.0±0.6 vs. 2.0±0.4). Of note, renal macrophages (ED1 positive cells/mm2: 30.1±8.1 vs. 65.5±17.4) and T-cell infiltrates (CD3 positive cells/mm2: 22.4±7 vs. 46.3±12.6) were also significantly decreased in DPP4-/- SnX. Interestingly, the number of renal CD163 positive M2 macrophages was also lower in DPP4-/- Snx rats but the difference did not reach significance level.

**Conclusions:** DPP4 deficiency ameliorates renal injury in rats with 5/6-nephrectomy as shown by preserved renal function, lower inflammation and fibrosis. Thus, DPP-4 inhibitors might be a therapeutic option also in the treatment of progressive chronic kidney disease.

*Funding:* Government Support - Non-U.S.

### FR-PO862

**Erlotinib Attenuates the Progression of Chronic Renal Failure in 5/6 Nephrectomized Rats** Yasutaka Yamamoto, Masayuki Iyoda, Yukihiro Wada, Kei Matsumoto, Yuki Shindo-Hirai, Yoshihiro Kuno, Taihei Suzuki, Tomohiro Saitou, Ken Iseri, Takanori Shibata. *Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan.*

**Background:** The effects of blocking the epidermal growth factor receptor (EGFR) in chronic renal failure are unknown. In the current study, we investigated the renoprotective effect of erlotinib, a tyrosine kinase inhibitor that can block EGFR activity, in the progression of established renal failure.

**Methods:** Adult male Sprague Dawley rats were subjected to 5/6 nephrectomy (n=34) or laparotomy (sham-operated, n=9). Rats with 5/6 nephrectomy were then administered either erlotinib (20 mg/kg, n=18) or vehicle (n=16) via daily oral gavage from 2 weeks after surgery, and for a period of 8 weeks. Blood pressure (BP), proteinuria (U-P), serum creatinine (Cr) and body weight (BW) were measured periodically. Renal morphological investigations were performed at sacrifice.

**Results:** Systolic BP (8 weeks: 164.30 ± 8.20 vs. 161.50 ± 7.64 mmHg, NS) and BW (8 weeks: 404.42 ± 14.40 vs. 402.93 ± 6.94 g, NS) were comparable between the two treatment groups throughout the study. The serum Cr levels in the erlotinib-treated rats were significantly lower than that of the vehicle-treated rats at each time point (8 weeks: 1.07 ± 0.17 vs. 0.75 ± 0.05 mg/dL, $p < 0.05$; 0.28 ± 0.01 mg/dL in sham-operated rats). When compared to vehicle treatment, erlotinib-treated rats demonstrated reduced U-P at 2 weeks after treatment (62.58 ± 9.70 vs. 35.64 ± 2.34 mg/day, $p < 0.01$). This reduction was maintained over the course of the study (8 weeks: 154.08 ± 28.66 vs. 101.09 ± 14.13 mg/day, $p < 0.05$; 36.08 ± 1.75 mg/day in sham-operated rats). Erlotinib treatment reduced glomerular tuft area (11574.07 ± 368.11 vs. 10409.65 ± 252.03 mm$^2$, $p < 0.01$), and the scores of glomerulosclerosis (semiquantitative score (SEMQ-S) (0-4): 2.18 ± 0.20 vs. 1.63 ± 0.09, $p < 0.01$) and tubulointerstitial damage (SEMQ-S (0-5): 3.28 ± 0.29 vs. 2.71 ± 0.16, $p < 0.05$).

**Conclusions:** Erlotinib treatment significantly attenuates renal injury following subtotal renal ablation in rats. Our results suggest that erlotinib may prove useful in limiting the progression of chronic renal disease to end-stage renal failure.

### FR-PO863

**Implantation of a Femoral Catheter in 5/6-Nephrectomized Rats Induces Heart Fibrosis: Intravenous or Oral Treatment with PBI-4050 Reduces Both Kidney and Heart Fibrosis** Lyne Gagnon, Lilianne Geerts, François Sarra-Bournet, Kathy Hince, Mikaël Tremblay, Liette Gervais, Alexandra Felton, Martin Leduc, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, Canada.*

**Background:** PBI-4050 is a first-in-class novel orally active compound which displays anti-inflammatory/antifibrotic activities via a novel mechanism of action. The aims of this study were to determine the effect of a "permanent" vascular catheter on heart fibrosis, and to investigate the potential protective effect of PBI-4050 on kidney and heart in 5/6-nephrectomized (NX) catheterized rats.

**Methods:** Sprague-Dawley rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7, the right kidney was removed and a catheter was implanted via the femoral vein. On day 21, rats were randomized based on glomerular filtration rate (GFR) results. NX animals were divided in five groups (n=10). Two groups were not catheterized and received vehicle or PBI-4050 (oral, 200 mg/kg). Three groups were catheterized, of which one group received vehicle, another group was treated with daily oral administration of PBI-4050 (200 mg/kg) and the other group was treated three times a week with intravenous administration of PBI-4050 (10 mg/kg).

**Results:** Non-catheterized NX rats were found to have few heart lesions (low grade). However, implantation of a catheter induced a significant increase (four fold) in heart lesions (fibrosis, necrosis and inflammation). Treatment with PBI-4050 significantly reduced

($p<0.05$) total heart lesions. Furthermore, there was a marked increase in hydroxyproline level (collagen) observed in catheterized-NX rat hearts which was significantly reduced by both IV and PO treatments with PBI-4050.This reduction in hydroxyproline level correlated with the histological heart sections (Masson's trichrome stain). Moreover, GFR was increased and inflammation of the kidney (as measured by urinary MCP-1 level) was decreased in PBI-4050-treated catheterized-NX rats.

**Conclusions:** Taken together, our results suggest that implantation of a catheter may induce heart fibrosis, and PBI-4050 offers the potential as a novel therapy for the treatment of kidney and heart fibrosis.

## FR-PO864

**Galacto-Oligosaccharides Modified Gut Microbiota and Attenuated Renal Injury** Satoshi Unuma,[1] Takamoto Ohse,[1] Airi Jo,[1] Akira Shigehisa,[2] Koji Kawakami,[2] Takahiro Matsuki,[2] Osamu Chonan,[2] Masaomi Nangaku.[1] *[1]Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Yakult Central Institute, Kunitachi, Japan.*

**Background:** Tubulointerstitial injury is a final common pathway to end stage renal disease. We have previously reported that uremic toxins cause tubulointerstitial injury through oxidative stress and endoplasmic reticulum (ER) stress. Galacto-oligosaccharides (GOS) are utilized by beneficial microbes. Since the precursor of indoxyl sulfate, indole, is synthesized by gut microbiota, we focused on the effects of GOS on indoxyl sulfate synthesis by gut microbiota and renal function in kidney disease.

**Methods:** Two weeks after induction of the 5□6 nephrectomized (Nx) model, the rats were divided into two groups, control diet group (ConNx) and GOS-fed group (GOSNx). After two weeks administration of GOS, we measured serum indoxyl sulfate and examined the gut microbiota with pyrosequencing method, the cecal contents, and the renal injury.

**Results:** A comprehensive analysis of gut microbiota revealed a significant increase in Bifidobacteriaceae and decrease in Ruminococcaceae by GOS. While no significant changes were detected in blood pressure, body weight and food consumption of the rats, cecal indole and serum indoxyl sulfate were significantly reduced in GOSNx. Renal injury was improved and infiltrating macrophages were significantly decreased in GOSNx. We next examined ER stress as a pathway of renal injury caused by indoxyl sulfate. Immunohistochemistry and quantitative PCR revealed that GRP78, CHOP, and ORP150 were significantly increased in ConNx and significantly decreased in GOSNx compared with ConNx. TUNEL positive cells were also significantly increased in ConNx and significantly decreased in GOSNx compared with ConNx.

**Conclusions:** GOS administration to 5/6 nephrectomized rats modified gut microbiota, reduced serum indoxyl sulfate, and attenuated renal injury. ER stress was reduced by GOS administration and amelioration of ER stress was implicated in a mechanism of kidney protection. GOS can be a novel therapeutic agent against kidney injury.

## FR-PO865

**Integrin β6 in Macula Densa Cells Modulates Potential Tubuloglomerular Feedback** Beom Jin Lim, Haichun Yang, Agnes B. Fogo. *Pathology, Microbiology and Immunology, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** The heterodimeric integrin αvβ6 is expressed in tubular epithelial cells and the juxtaglomerular apparatuses (JGA) in the kidney.It binds and activates latent transforming growth factor-β (TGF-β), and thus has profibrotic effect. We previously observed that$\beta6^{-/-}$ mice showed increased glomerulosclerosis vs.wild type (WT) mice with disproportionally milder interstitial fibrosis after 5/6 nephrectomy (Nx). The development of glomerulosclerosis was TGF-β-independent, but was related to increased renin activity in JGA. These results suggested that$\beta6^{-/-}$ mice may have dysregulated tubuloglomerular feedback. We therefore evaluated the effect of integrin β6 knock down in isolated mouse macula densa cells (MMDD1).

**Methods:** 5/6 Nx kidneys of $\beta6^{-/-}$ *vs.* WT mice were analyzed for nNOS and COX-2. Integrin β6-specific gene knock down was performed by shRNA transduction in MMDD1 cells,and assessed by real time RT-PCR and immunofluorescence microscopy. Cells were then treated with isoosmolar normal salt or low salt solution for 8 hours. nNOS and COX-2 were measured by western blot.

**Results:** Kidneys from $\beta6^{-/-}$ mice showed decreased nNOS expression and similar COX-2 expression vs WT mice, but immunohistochemistry showed decreased nNOS and increased COX-2 intensity in $\beta6^{-/-}$ mice.β6 mRNA assessed by real time RT-PCR in shRNA-transfected MMDD1 cells was decreased to 41.5% of WT cells. Control scrambled shRNA had no effect. Integrin β6 knock down cells showed higher baseline expression *vs.* WT cells of both COX-2 (COX-2/α-tubulin 0.15±0.02 *vs.* 0.01±0.00, $p<0.05$) and nNOS (nNOS/α-tubulin 0.10±0.01 *vs.* 0.02±0.01, $p<0.05$). After stimulating with low salt, COX-2 expression was similarly increased in β6 knock down and WT cells (0.83±0.01 *vs.* 0.78±0.01, pNS), but nNOS expression was increased only in β6 knock down cells (0.20±0.02 *vs.* 0.06±0.01, $p<0.05$).

**Conclusions:** We conclude that the absence of integrin β6 in macula densa dells results in altered expression of tubuloglomerular feedback-related molecules. The findings support our hypothesis that the absence of integrin β6 may affect progression of glomerulosclerosis by dysregulated tubuloglomerular feedback mechanisms.

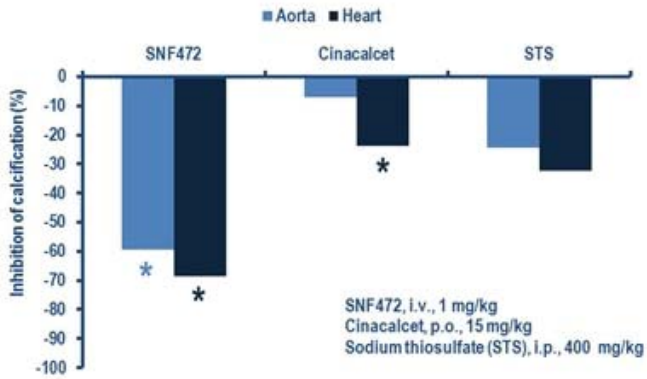
**SNF472 Inhibits Vitamin D Induced Cardiovascular Calcification in Rats** Markus Ketteler,[1] Miquel D. Ferrer,[2] Fernando Tur,[3] Bernat Isern,[2] Carolina Salcedo,[2] Joan S. Perelló,[2,3] Pieter H. Joubert.[2] *[1]Div of Nephrology, Klinikum Coburg GmbH, Coburg, Germany; [2]Research and Development Dept, Laboratoris Sanifit SL., Palma de Mallorca, Spain; [3]Laboratory of Renal Lithiasis Research, Institute of Health Sciences Research (IUNICS), Univ of the Balearic Islands, Palma de Mallorca, Spain.*

**Background:** Cardiovascular calcification has been shown to be an independent predictor of cardiovascular events in CKD patients. This study investigated the effects of SNF472, an intravenous formulation of myo-inositol hexaphosphate, on vitamin D induced vascular calcification, and compare its effects with cinacalcet and sodium thiosulfate (STS).

**Methods:** The study was done in 40 male Sprague Dawley rats divided into 3 groups of 10-16 animals. Group 1 received daily intravenous vehicle or 1 mg/kg SNF472. Group 2 received vehicle or 15 mg/kg of cinacalcet p.o. Group 3 received vehicle or 400 mg/kg of sodium thiosulfate i.p. Calcification was induced by 5 daily oral administrations of 75000 IU/kg of vitamin D starting on day 3 of treatment. Five sham treated animals served as control. Serum samples for the determination of calcium and phosphorus concentrations were collected on days 8 and 14. Rats were sacrificed on day 14 and aortas and hearts removed for calcium analyses.

**Results:** The administration of vitamin D induced a marked increase in aortic and heart calcium levels. Calcium and phosphorus from control serums increased significantly compared to the sham group, and were not affected by any of the treatments. The intravenous administration of SN472 at 1 mg/kg resulted in reductions by 60% in aortic and 68% in heart tissues. Animals treated with Cinacalcet and STS showed small reductions. The only significant reduction occurred with cinacalcet in the heart (24% reduction).



**Conclusions:** SNF472 might be an alternative therapeutic principle for cardiovascular calcification treatment.

**Vitamin D Inhibition of the Proteases ADAM17 and Cathepsin L Contributes to Attenuate High Phosphate-Induced Renal and Cardiovasular Damage** Petya Valcheva,[1,2] Yolanda Almaden Peña,[2] Mariano Rodriguez,[2] Adriana S. Dusso.[1] *[1]Experimental Nephrology, IRBLleida, Lleida; [2]Research Unit, Hospital Reina Sofia, Cordoba, Spain.*

**Background:** High serum phosphate (HP) is a recognized inducer of accelerated renal and cardiovascular (CV) aging through mechanisms unrelated to its potency to worsen the severity of secondary hyperparathyroidism or the osteoblast-like phenotype in vascular smooth muscle cells (VSMC). Based upon the critical impact of ADAM17 and cathepsin L (CTSL) in renal and CV damage through excessive inflammation and DNA damage, this study examined the contribution of these mechanisms, and of ADAM17 cleavage of klotho, to the potent adverse effects of HP on renal and cardiovascular function.

**Methods:** Western blots and immunohistochemical analysis of ADAM17, CTSL, and klotho was performed in VSMC, rat kidneys and renal human arteries.

**Results:** In VSMC, an 8 hour exposure to HP (3.3 mM) suffices to enhance ADAM17 expression at the cell membrane, and nuclear CTSL content. Levels of both proteases increased further in VSMC from the vitamin D receptor (VDR) null mice. Importantly, in slices of normal rat kidneys, exposure to HP results not only in similar increases in ADAM17 and nuclear CTSL, but also in a reduction in klotho content, essential to maintain the phosphaturic response to FGF23. All of these rapid adverse effects of HP in a normal kidney are markedly attenuated by co-incubation with HP and the combination of 25-hydroxyvitamin D ($10^{-10}$ M) + paricalcitol ($10^{-8}$ M). In addition, also in slices of normal human renal arteries, the nutritional+active vitamin D combination effectively counteracts the rapid HP induction of ADAM17 and nuclear CTSL with a potency for the former as that of the ADAM17 inhibitor TAPI-2 (10 and 20 μM).

**Conclusions:** Thus, maintenance of normal serum levels of nutritional and active vitamin D in kidney disease patients could prevent/attenuate HP-induced progression of either renal or cardiovascular aging through the inhibition of ADAM17 and CTSL activation and klotho loss.

## FR-PO868

**Coagulation Protease-Activated Protein C Selectively Trans Activates XBP1 via p85α and p85β to Restore Endoplasmic Reticulum Homeostasis in Diabetic Nephropathy** Madhusudhan Thati, Hongjie Wang, Hermann-Josef Groene, Jochen Reiser, Berend Heinrich Isermann. *Institute for Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke-Univ Magdeburg, Magdeburg, Germany.*

**Background:** A growing body of recent work suggests that endoplasmic reticulum (ER) stress response is causally linked to diabetes complications. However the specific physiological stimuli and molecular mechanism through which hyperglycemia modulates ER stress are not known.

**Methods:** In an attempt to determine the role of hyperglycemia in regulating ER-stress we have employed mouse models of both type-1(streptozotocin) and type-2 (db/db) diabetic nephropathy (DN).

**Results:** In DN hyperglycemia selectively impairs nuclear translocation of the highly conserved transcription factor spliced X-box binding protein-1 (sXBP1). This result in severe ER-stress associated with increased nuclear levels of the active form of activating transcription factor-6 (ATF6) and ATF6 mediated transcriptional activation of CHOP. In addition inducible expression of ATF6 specifically in podocytes aggravates ER-stress and DN. We next show that treatment with activated protein C, a coagulation protease with well-established nephroprotective properties, selectively trans activates sXBP1 via PI3K regulatory subunits p85α and p85β and restores ER-homeostasis in DN. In a mice model with impaired thrombomodulin (TM) -dependent PC activation ($TM^{Pro/Pro}$) ER-stress and DN is aggravated. Conversely in a mouse model with constitutively higher plasma levels of aPC ($APC^{high}$) ER-stress is inhibited, highlighting the physiological role of aPC in regulating ER-stress and DN. While deletion of CHOP or inhibition of ER-stress with tauroursodeoxycholic acid protected against DN in $TM^{Pro/Pro}$ and wild type mice, Conditional deletion of XBP1 ($XBP1^{flox/flox}$ x $Pod^{Cre}$) abolished the protective effect in $APC^{high}$ mice. In podocytes and endothelial cells sXBP1 is selectively, but independently of IRE1, activated by aPC in trans via p85α and p85β, which is required to inhibit hyperglycemia induced ER-stress.

**Conclusions:** These studies revise our understanding of regulation of ER-stress in DN and might have major implications for treatment of DN in humans.

## FR-PO869

**Glycogen Synthase Kinase 3 and the Podocyte: A Tale of Two Isoforms** Jenny Hurcombe,[1] Abigail Charlotte Lay,[1] Gavin Iain Welsh,[1] C. Avila-Casado,[3] Peter W. Mathieson,[1] Satish Patel,[4] James R. Woodgett,[5] Susan E. Quaggin,[2] Richard Coward.[1] *[1]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom; [2]Cardiovascular Research Institute, Div of Nephrology, North Western Univ, Chicago; [3]Univ Health Network, Toronto General Hospital, Toronto, Canada; [4]Lunenfeld Institute Univ of Toronto; [5]Lunenfeld Univ of Toronto.*

**Background:** Glycogen synthase kinase 3 (GSK3) is a multi-functional serine/threonine kinase existing as two distinct but related isoforms (α and β) with an established role in the modulation of insulin signaling. There is evidence that the GSK3 isoforms have different functions: GSK3β null mice die during late embryogenesisis due to hepatocyte apoptosis whereas total GSK3 α knockout mice are viable and interestingly, exhibit enhanced insulin sensitivity. A number of cell-specific GSK3 knockout mouse models have been described and indicate that the functions of the GSK3 isoforms are cell-type dependent.

**Methods:** In order to investigate the role of the GSK3 isoforms in podocyte development, we have used Cre/ LoxP technology to generate mice with podocyte-specific ablation of GSK3 α and/or GSK3β.

**Results:** Using an *in vitro* and *in vivo* approach we have shown that in the glomerulus, GSK3 is preferentially expressed in the podocyte and that both of its isoforms are phosphorylated and thus deactivated in response to insulin. Mice lacking either GSK3α or GSK3β specifically in the podocyte are viable with normal life span (up to 2 years), no evidence of proteinuria and normal renal histology indicating a degree of redundancy between the isoforms in the podocyte. In contrast, mice null for both GSK3 isoforms (13 of 107 mice studied), although born at normal Mendelian frequency, die predictably at 12-14 days at which time they are proteinuric, with grossly abnormal vacuolated glomeruli on histological analysis.

**Conclusions:** This work reveals a fundamental role of GSK3 in the podocyte and its importance in glomerular development and survival.

## FR-PO870

**APOL1 Encodes a Novel miRNA That Induces PKR, and miRNA Levels Are Increased in Plasma Exosomes from G1 Homozygous Individuals** Koji Okamoto,[1] Cheryl Ann Winkler,[2] Jeffrey B. Kopp.[1] *[1]Kidney Section, NIDDK, NIH, Bethesda, MD; [2]Molecular Genetics Epidemiology Section, NCI, NIH, Frederick, MD.*

**Background:** Coding variants in *APOL1* (S342G and I384M termed G1) and NYK388K (termed G2), compared to ancestral G0) are strongly associated with FSGS among African Americans. We hypothesized that ApoL1 variants might harbor an miRNA that would alter mRNA expression.

**Methods:** We used MFOLD software to analyze APOL1 mRNA structure. We amplified miRNA from cultured human podocytes using stem loop primers and 5' RACE, from either total cell RNA or AGO2 protein immununoprecipated RNA. We transfected into HEK293 cells cDNA vectors encoding recombinant FLAG-tagged APOL1 or 400 bp of APOL1 RNA including the predicted miRNA sequence.

**Results:** RNA folding prediction revealed a stem loop construct located in the APOL1 mRNA region that contains the G1 S342G polymorphism. Using 5-RACE, we identified a 21-nucleotide miRNA, which is also RNA precipitated with AGO2. S342G is located on the antisense strand of a mature miRNA. In exosomes isolated from human plasma samples, more miRNA was detected in G1 homozygotes (n=6) compared with G0 homozygotes (n=5, p = 0.025). The novel miRNA formed dimers and long dsRNA, suggesting that it may trigger phosphorylation (activation) of interferon-induced, double-stranded RNA-activated protein kinase (PKR). Both transfection of APOL1 cDNA and APOL1 miRNA induced PKR phosphorylation; these effects were seen with G1 but not G0. Human podocyte-like urine-derived epithelial cells (G1/G2 genotype, compared to G0/G0 genotype) manifested PKR activation, and downstream effects including increased type 1 interferon production, phosphorylation of eIF2a and inhibition of protein translation, all of which were reduced following APOL1 knock down.

**Conclusions:** We report that APOL1 mRNA generates a miRNA whose expression is higher in G1 genotype cells. APOL1 G1 cells exhibit an activated PKR-related host defense pathway compared to G0 cells. Up-regulation of APOL1 derived miRNA provides a new pathogenic mechanism for APOL1 nephroapthy associated with the G1 variant and suggests that possible therapeutic targets include APOL1 miRNA and PKR.

## FR-PO871

***ARHGDIA*: A Novel Gene Implicated in Nephrotic Syndrome** David Auguste,[1] Richard Robins,[1] Jasmine El andalousi,[2] Lamine Aoudjit,[1] Cindy Baldwin,[1] Indra R. Gupta,[2] Tomoko Takano.[1] *[1]Medicine, McGill Univ, Montreal, Canada; [2]Nephrology, Montreal Children's Hospital, Montreal, Canada.*

**Background:** RhoGDIα (GDIα, encoded by *ARHGDIA*) is a negative regulator of Rho-GTPases that play a critical role in cytoskeleton and cell motility. We previously reported that a single amino acid deletion, D185Del, is a loss-of-function mutation of GDIα and causes congenital nephrotic syndrome. We hypothesize that the loss of the inhibitory action of GDIα leads to hyper-activation of Rac1 in podocytes and nephrotic syndrome.

**Methods:** GDIα was knocked down (KD) by an shRNA in mouse podocytes. KD cells were rescued with wild-type or D185Del GDIα resistant to the shRNA. Rac1 activity was quantified by pull-down assay and immunocytochemistry for active Rac1 (aRac1). Cell motility was studied by wound healing. GDIα and aRac1 in the mouse kidney were detected by immunofluorescence staining. The constitutively active Rac1 (CA-Rac1) was induced in podocytes *in vivo* by treating double transgenic mice (carrying a tetracycline-inducible CA-Rac1 and a reverse tetracycline transactivator driven by the podocin promoter) with doxycycline.

**Results:** The KD cells showed a significantly higher Rac1 activity and aRac1 was localized at the plasma membrane more prominently, as compared with controls. The motility of KD cells was significantly reduced, as compared with controls and this reduction was rescued by wild-type but not by the mutant GDIα. GDIα protein was detected in glomerular precursor structures such as the S-shaped body and was strongly expressed in podocytes within the mature glomerulus. In contrast, aRac1 protein was most prominent in comma and S-shaped structures, and was not detected in podocytes after the late capillary stage. When CA-Rac1 was induced in podocytes in adult mice, 3/7 double transgenic mice demonstrated heavy proteinuria after 3-5 days of doxycycline treatment, while none of the control mice, 0/17, developed proteinuria.

**Conclusions:** D185Del mutation of GDIα induced Rac1 hyper-activation and nephrotic syndrome. In the normal mature glomerulus, Rac1 is inactive in podocytes. Aberrant Rac1 activation in podocytes, possibly combined with dysregulation of other Rho-GTPases, may lead to podocyte dysfunction.

## FR-PO872

**Ezrin Is Downregulated in Diabetic Kidney Glomeruli and Regulates Cortical Actin Dynamics and Glucose Transport in Cultured Podocytes** Anita A. Wasik,[1] Susanna Koskelainen,[1] Mervi E. Hyvonen,[1,2] Luca Musante,[1] Eero Lehtonen,[1] Kerttu Koskenniemi,[3] Jukka Pekka Tienari,[4] Antti Vaheri,[1] Pekka Varmanen,[5] Tuula A. Nyman,[6] Peter Hamar,[7] Harry B. Holthofer,[1] Sanna H. Lehtonen.[1] *[1]Haartman Institute, Univ Helsinki, Finland; [2]Children's Hospital, Univ Helsinki, Finland; [3]Dept Veterinary Biosciences, Univ Helsinki, Finland; [4]Dept Pathology, HUSLAB and Helsinki Univ Hospital, Helsinki and Hyvinkää, Finland; [5]Dept Food and Environmental Sciences, Univ Helsinki, Finland; [6]Institute of Biotechnology, Univ Helsinki, Finland; [7]Institute of Pathophysiology, Semmelweis Univ, Budapest, Hungary.*

**Background:** Diabetic nephropathy (DN) is a major cause of end-stage renal disease but the pathophysiological mechanisms associated with its development are poorly characterized.

**Methods:** To characterize the early pathophysiological mechanisms leading to podocyte injury in DN we performed quantitative proteomic profiling of glomeruli isolated from rats with streptozotocin-induced diabetes and controls using fluorescence-based two-dimensional difference gel electrophoresis coupled with mass spectrometry.

**Results:** We identified 29 differentially expressed spots, including ezrin and its interaction partner NHERF2 that were downregulated in the streptozotocin group. Ezrin and NHERF2 link plasma membrane proteins to the actin cytoskeleton. Quantitative Western blot and immunofluorescence analyses confirmed downregulation of ezrin and NHERF2 in the glomeruli of streptozotocin-treated rats. Knockdown of ezrin by siRNA in cultured podocytes induced cortical actin remodeling and glucose uptake at basal conditions, but reduced insulin-stimulated actin remodeling and glucose uptake as compared to

control siRNA-transfected cells. The ezrin-dependent actin remodeling involved an actin depolymerizing protein cofilin that is essential for actin filament turnover. Furthermore, immunohistochemical analysis revealed reduced expression of ezrin in the podocytes of human patients with diabetes.

**Conclusions:** Our findings suggest that ezrin may play a role in the development of the renal complication in diabetes by regulating actin cytoskeleton organization and glucose transport in podocytes.

## FR-PO873

**Nck1 but Not Nck2 Regulates Podocyte Actin Dynamics through Activation of RhoA** Lisa Maria Buvall,[1] Priyanka Rashmi,[1] Astrid Weins,[2] Anna Greka,[1] Peter H. Mundel.[1] *[1]Nephrology, Harvard Medical School and Massachusetts General Hospital, Boston, MA; [2]Pathology, Harvard Medical School and Brigham and Women's Hospital, Boston, MA.*

**Background:** Podocyte dysfunction, represented by foot process effacement, disruption of the slit diaphragm and proteinuria, is often the initial insult leading to progressive kidney disease. Nck1/2 are widely expressed adapter proteins that recruit proline rich proteins via their SH3 domains. Ncks are essential for the development and maintenance of the glomerular filtration barrier and stabilize the podocyte actin cytoskeleton by phosphorylating the slit diaphragm protein nephrin.

**Methods:** To study Nck actin-regulatory pathways in cultured podocytes we use cell biological and biochemistry assays in combination with lentiviral gene silencing and over expression approaches.

**Results:** Here we identify Nck1 but not Nck2 as regulators of RhoA signaling in podocytes. We show that Nck1, but not Nck2, is a substrate of the ubiquitin ligase c-Cbl, which mediates ubiquitination and proteasomal degradation of Nck1. We uncover lysine 178 in Nck1 as the ubiquitin acceptor site, which is conserved from Xenopus to human. We have previously reported that synaptopodin, a proline rich actin binding protein, promotes stress fiber formation by blocking the Smurf1 mediated ubiquitination of RhoA. Now we find that synaptopodin competes with c-Cbl for binding to Nck1, thereby blocking the ubiquitination of Nck1 by c-Cbl. Gene silencing of c-Cbl in synaptopodin depleted podocytes restores Nck1 abundance, confirming c-Cbl as the specific ubiquitin ligase responsible for ubiquitination of Nck1. Expression of c-Cbl resistant Nck1(K178R), but not Nck2, restores stress fibres in synaptopodin depleted podocytes through activation of RhoA signaling.

**Conclusions:** These findings highlight the functional difference between Nck1 and Nck2 and reveal proteasomal regulation as a key to distinct and non-redundant Nck effects on RhoA signaling.

*Funding:* NIDDK Support

## FR-PO874

**Synaptic Vesicle Protein 2B Is Essential for Maintaining the Integrity of the Podocyte Slit Diaphragm; SV2B KO Mice Are Vulnerable to the Podocyte Injury** Yoshiyasu Fukusumi, Asami Takasaki, Ayako Wakamatsu, Yuichi Takahashi, Naoko Miyauchi, Masayuki Tomita, Hiroshi Kawachi. *Dept of Cell Biology, Institute of Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

**Background:** We have previously reported synaptic vesicle protein 2B (SV2B) was expressed in podocyte, and the cultured podocyte of which SV2B was knock-downed with siRNA failed to arrange the proper localization of CD2AP, which is one of the component of slit diaphragm (SD) (JASN, 2006). SV2B is expressed on vesicle surface and plays a role in vesicle trafficking. However, synaptic vesicle like trafficking system in podocyte and the role of SV2B are not well understood.

**Methods:** To elucidate the function of SV2B in vivo, we generated SV2B knockout (KO) mice. The expression of CD2AP and other critical molecules of the SD (nephrin, NEPH1, podocin and ZO-1) in SV2B KO mice, and their sensitivity to podocyte injury were analyzed.

**Results:** In SV2B KO mice without any treatment, a slight increase in the amount of proteinuria (KO 1.39 mg/24 h vs. wild type (WT) 0.64, $p<0.02$), and the alteration in the staining pattern of CD2AP, nephrin and NEPH1 were detected. The KO mice overloaded with BSA (15 mg/kg/day) showed higher amount of proteinuria than WT mice with same treatment (KO 19.88 mg/24h vs. WT 2.39). The staining of CD2AP, nephrin, NEPH1, podocin and ZO-1 was clearly decreased in KO mice overloaded with BSA (nephrin: score KO 2.64 vs. WT 3.26, $p<0.005$, podocin: 2.98 vs. 3.40, $p<0.01$). No WT mice died after uninephrectomy, whereas about 50% of SV2B KO mice died after the treatment. Next, to identify the molecules related with SV2B in podocyte, the expression of other synaptic vesicle associated proteins were analyzed in SV2B KO mice. mRNA expression of neurexin, a molecule expressed on the presynaptic membrane, was decreased, whereas the expression of vesicular glutamate transporter, a molecule expressed on synaptic vesicle membrane, was increased.

**Conclusions:** These results indicated that SV2B is involved in maintaining the integrity of the SD molecules, and that the mice with defect of SV2B were vulnerable to injury in podocyte.

*Funding:* Government Support - Non-U.S.

## FR-PO875

**CD2AP Phosphorylation on Tyrosines Y10 and Y273 Has a Physiological Relevance for Slit Diaphragm Stability** Irini Schaefer, Beina Teng, Kirstin Worthmann, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hannover, Hannover, Germany.*

**Background:** CD2AP is an adaptor protein that can transmit intracellular signals involved in survival and cytoskeletal regulation of the cell. We have shown that CD2AP tyrosine phosphorylation determines binding to nephrin. Until now it is unknown if phosphorylation of CD2AP has a physiological relevance for slit diaphraghm stability. The aim of these studies was to analyze the involvement of CD2AP phosphorylation for slit diaphragm stability in vivo.

**Methods:** Evolutionary highly conserved tyrosine residues were identified in every SH3 domain of CD2AP on positions Y4/8/10, Y119 and Y273/280. By site directed mutagenesis we established for every tyrosine a single mutant or for close-by tyrosines double or triple mutants. We furthermore generated mRNA from WT- and mutated CD2AP DNA. By cross-species rescue experiments in CD2AP-knockdown zebrafish we analyzed the physiological relevance of every single tyrosine for slit diaphragm stability. Analyzation was performed by morphology, mortality rate and filtration of GFP-labeled fatty acid-binding protein.

**Results:** Knockdown of CD2AP by morpholino injection in zebrafish leads to edema and foot process effacement. Most of the larval fishes died after 5 days. Cross-species rescue experiments by injection of CD2AP mRNA after morpholino injection showed a rescue of the CD2AP-knockdown phenotype. To analyze the importance of the tyrosines we injected mRNA of the single tyrosine mutants. The absence of tyrosines Y10 or Y273 showed no rescue of the CD2AP-knockdown phenotype. These zebrafish larvals developed big edema, showed a high mortality rate and GFP-labelled fatty acid-binding protein was filtrated through the damaged glomerular filtration barrier. Larvals with rescued phenotypes remain healthy with intact filtration barrier.

**Conclusions:** These results suggest that CD2AP phosphorylation on tyrosines Y10 and Y273 have a physiological importance for stability of the slit diaphragm in vivo.

*Funding:* Government Support - Non-U.S.

## FR-PO876

**Role of Podocytes in Endocytosis and Glomerular Filter Integrity** Madhusudan M. Venkatareddy, Rakesh Verma, Puneet Garg. *Div of Nephrology, Univ of Michigan, Ann Arbor, MI.*

**Background:** Vesicular trafficking and autophagy is a vital part of cell development and growth and to maintain a balance between synthesis, degradation and recycling of cellular components. We generated a Podocyte specific deletion of vps34, a phosphoinositol kinase that plays a critical role in both vesicular trafficking as well as autophagy. Careful characterization of the vesicles showed differences from what was reported in recently published podocyte specific deletion of vps34. Furthermore, using this model we examined the role of podocyte in preventing filter clogging as endocytosed protein processing is altered in the absence of vps34.

**Methods:** Kidneys for IHC and Immunogold EM (IEM) were harvested from wild type and podocyte specific vps34 deleted mice (*vps34KO*). Cell culture studies used stable podocyte cell line generated from the $vps34^{fl/fl}$ mouse infected with adenovirus carrying *cre* ($Pod^{vps34-}$).

**Results:** As previously reported, *vps34KO* mice are normal at birth, develop massive proteinuria and accumulation of vesicles by 3 weeks of age. IHC and IEM studies from kidney section and $Pod^{vps34-}$Cells reveal two distinct populations of vesicles, early and late endosomes that are Rab5 and Lamp1 positive and syntaxin 6 positive vesicles that are in flux with the trans-golgi network (TGN). Autophagic vesicles were not seen. Immunogold EM shows Nephrin in vesicles suggesting either endocytosis of Nephrin or aberrant trafficking of newly synthesized Nephrin from the TGN. To study the role of podocytes in enodcytosis of filtered proteins we perfused mice with FITC-human albumin (FITC-*h*alb) as wells as stained for endogenous IgG and albumin in wild type and *vps34KO* mice. There was no leak of mouse IgG, albumin or infused FITC-*h*alb in normal wild type mouse using IF and IEM studies. There was accumulation of mouse IgG and albumin in Podocyte vesicles of non-proteinuric 2 weeks old *vps34KO* mice.

**Conclusions:** Perturbing the endocytic machinery suggests the improper targeting of slit diaphragm proteins is in part due to failure of trafficking of vesicles to and from the golgi network. This model also provides evidence for the role of podocytes in maintaing a healthy filter and prevent clogging.

## FR-PO877

**AMPK Activation by AICAR Is Protective against Podocyte Damage and Glomerulosclerosis** Stephen O'Brien, John N. Vassiliadis, Mandy M. Smith, Hong Ling, Steven R. Ledbetter, Cynthia M. Arbeeny, Stefan Wawersik. *Tissue Protection and Repair Unit, Genzyme/Sanofi R&D Center, Framingham, MA.*

**Background:** Podocyte injury is a key step in the onset and progression of glomerulosclerosis. Cellular functions that counteract cell stress, such as autophagy and mitochondrial biogenesis, are critical for podocyte damage resistance. AMP-activated Protein Kinase (AMPK) regulates multiple stress-protective responses, and we therefore hypothesized that AMPK activation can protect podocytes from injury.

**Results:** To functionally test the role of AMPK in podocyte health, puromycin aminonucleoside (PAN) was used to cause oxidative stress in cultured immortalized podocytes.PAN treatment reduced $AMPK^{Thr172}$ phosphorylation in podocytes, indicating decreased AMPK activation. Furthermore, PAN induced apoptotic markers, mitochondrial

membrane depolarization, and expression of the ER stress marker CHOP. Co-treatment with 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR), an AMP analog capable of activating AMPK, increased phospho-AMPK$^{Thr172}$ and blocked mitochondrial damage, CHOP induction, and apoptosis. To test whether in vivo AMPK activation can reduce glomerular injury, we examined the effects of AICAR treatment in adriamycin-induced nephropathy (AN), a mouse model of glomerulosclerosis.Vehicle-treated AN mice were heavily albuminuric, and kidney histology revealed extensive glomerular and tubular injury. Immunostaining with the proliferation marker Ki67 revealed an increase in dividing cells in the glomerular, tubular, and interstitial compartments. In contrast, AN mice treated with 500/mg/kg/day AICAR showed a marked reduction in albuminuria ($p<0.05$ vs. AN + Veh.). Scoring of glomerular pathology ($p<0.001$ vs AN + Veh.) and of the number of Ki67+ cells/glomerulus ($p<0.001$ vs. AN + Veh.) also indicate reduced glomerular injury in AICAR-treated AN mice.

**Conclusions:** Taken together, these data suggest that AICAR treatment prevents glomerular damage by reducing podocyte injury, and that the mechanism of this protection is through AMPK activation.

## FR-PO878

**Expression of Cleavage Resistant CD2AP in a Model of Inflammatory Glomerular Disease** Mehmet M. Altintas,[1] Changli Wei,[1] Jing Li,[1] Phillip Ruiz,[2] Jochen Reiser.[1] *[1]Medicine, Rush Univ, Chicago, IL; [2]Surgery, Univ of Miami, Miami, FL.*

**Background:** We recently showed that a cytosolic variant of the cysteine protease cathepsin L (CatL) was a common downstream effector in many glomerular diseases. The GTPase dynamin, synaptopodin and CD2AP were shown to be the key targets of this enzyme. These findings emphasized the need for the integrity of these target proteins and thus podocyte foot process (FP) structure and function.

**Methods:** We utilized the serum nephritis (SN) mouse model in which injection of an antibody that reacts with the glomerular basement membrane (GBM) causes glomerular disease. We deleted CatL cleavage site from CD2AP aminoacid sequence by site directed mutagenesis. We analyzed proteinuria, podocyte apoptosis, crescent formation, glomerular sclerosis and glomerular hypercellularity.

**Results:** SN is associated with cytosolic CatL induction in podocytes that leads to proteolysis of CD2AP N-terminus but a stable C-terminal fragment (p32) and the release of dendrin to podocyte nucleus, a response that was largely absent in CatL KO mice.

Both, wild type (WT) and CatL KO mice developed strong and comparable levels of proteinuria in response to anti-GBM antibody. Interestingly, the expression of the CatL cleavage targets synaptopodin and dynamin remained the same in WT mice suggesting that development of proteinuria is independent of CatL during SN. In contrast, kidney histology after SN revealed that only WT animals developed features of disease progression.

To further analyze the effects of stable CD2AP on progressive kidney disease, we expressed WT CD2AP and CD2AP that is cleavage resistant against CatL. Mice received WT CD2AP showed a significant reduction of N-terminal CD2AP but not the mice expressed cleavage resistant CD2AP after SN. The expression of cleavage resistant CD2AP directly impacted on the severity of disease progression.

**Conclusions:** The stabilization of CD2AP by removing CatL or protecting CD2AP alters the course of a glomerular disease shifting progression into a more benign phenotype. This finding will allow us to develop additional strategies for renal protection that are in addition to anti-proteinuric modalities focusing on podocyte survival.

**Akt Recruits Dab2 to Albumin Endocytosis** Elif Erkan, Hui Li, Kenneth R. Hallows. *Univ of Pittsburgh.*

**Background:** Proximal tubule epithelial cells encompass a highly sophisticated endocytic machinery to retrieve albumin in the glomerular filtrate. Megalin-cubilin complex and the endocytic adaptor disabled-2 (Dab2) play a pivotal role in albumin endocytosis. We demonstrated that protein kinase B (Akt) mediates albumin endocytosis in the proximal tubule through an interaction with Dab2. Our goal was to examine the nature of Akt-Dab2 interaction. We proposed that Akt phosphorylate Dab2.

**Methods:** We utilized GST-pulldown and yeast two hybrid experiments to examine the interaction sites between Akt and Dab2. Phosphorylation of Dab2 and the phosphorylation sites by Akt were examined by in-vitro phosphorylation experiments and site-directed mutagenesis. Physiological relevance of this phosphorylation event was investigated by albumin uptake studies. The effect of Akt on membrane expression of megalin-cubilin was validated in-vivo in Akt1 and Akt2 knock-out mice.

**Results:** Pleckstrin homology and catalytic domain of Akt had an interaction with Dab2-proline-rich domain (PRD) and the initial eleven amino acids of Dab2-PRD were sufficient to establish this interaction. Experiments to delineate the Akt isoform that was involved in Akt-Dab2 interaction revealed that Akt1 and Akt2 were both involved in albumin endocytosis. Furthermore Akt phosphorylated Dab2 at 448-449 serine residues. Mutation of Dab2- 448-9 serine to alanine inhibited albumin endocytosis revealing the physiological relevance of this novel phosphorylation event. To confirm the effect of Dab2 phosphorylation by Akt on expression of megalin and cubilin, we examined the Akt1 and Akt2 knock-out (KO) mice. Akt1 and Akt2 KO resulted in a significant decrease in expression of renal megalin and cubilin.

**Conclusions:** We concluded that Akt is an important mediator of albumin endocytosis in the proximal tubule and phosphorylation of Dab2 by Akt is essential in recruitment of Dab2 to the endocytic pathway and trafficking of megalin- cubilin. We propose that understanding the link between cell signaling events and albumin endocytosis may decipher the mechanism of tubulointerstitial injury that is inflicted by proteinuria. Further research is warranted to investigate other potential Akt targets in the endocytic machinery.

**Cyclic AMP Signaling Prevented against Podocyte Apoptosis via Activation of Protein Kinase A and Mitochondrial Fusion** Zhaohui Ni,[1] Xiaoying Li,[1] Hua Tao,[1] Yucheng Yan,[1] Peter Y. Chuang,[2] John C. He,[2] Leyi Gu.[1] *[1]Renal Div, Renji Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China; [2]Div of Nephrology, Mount Sinai School of Medicine, New York, NY.*

**Background:** Our previous in vitro studies suggest that cyclic AMP (cAMP) signaling protects against doxorubicin (ADR) and puromycin aminonucleoside (PAN) induced apoptosis in podocytes. Since cAMP is an important second messenger and plays a key role in cell survival and differentiation via protein kinase A (PKA) or exchange protein directly activated by cAMP (Epac) pathways, we sought to determine the mechanism in cAMP-mediated protection of podocytes.

**Methods:** Doxorubicin was used to induce nephrosis in mice. Conditional immortalized mouse podocytes were used in vitro studies.

**Results:** In the doxorubicin nephrosis model, we found that forskolin—a selective activator of adenylate cyclase—attenuated albuminuria and improved the expression of WT-1. We failed to find 8-pCPT-2-O-Me-cAMP, a selective cAMP/Epac activator, improved PAN-induced apoptosis of cultured podocytes. When podocytes were treated with pCPT-cAMP (a selective cAMP/PKA activator), PKA activation were increased in a time-dependent manner and prevented against PAN-induced podocytes loss and caspase 3 activation, as well as mitochondrial membrane potential reduction.We found that PAN and ADR resulted in a decrease in Mfn1 expression and mitochondrial fission in podocytes. Both PAN and ADR had no effect on Drp1 phosphorylation and Fis and Opa expression. pCPT-cAMP restored the Mfn1 expression in puromycin or ADR-treated podocytes and induced Drp1 phosphorylation, as well as mitochondrial fusion. Treatment podocytes with arachidonic acid resulted in mitochondrial fission, podocytes loss and cleaved caspase 3 expression. Arachidonic acid abolished pCPT-cAMP protective effects on PAN-treated podocytes. Mdivi, a mitochondrial division inhibitor, prevented PAN-induced cleaved caspase 3 expression in podocytes.

**Conclusions:** We concluded that activation of cAMP alleviated doxorubicin mice podocyte injury. PKA signaling resulted in mitochondrial fusion in podocytes, at least partially mediated the effects of cAMP.

**Twisted Gastrulation, a BMP Antagonist, Exacerbates Podocyte Injury** Motoko Yanagita,[1] Sachiko Yamada,[1] Jin Nakamura,[1] Misako Asada,[1] Masayuki Takase,[1] Taiji Matsusaka,[2] Taku Iguchi,[1] Ryo Yamada,[1] Hiroshi Kawachi,[3] Eri Muso,[4] Aris N. Economides.[5] *[1]Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan; [2]Internal Medicine, Tokai Univ School of Medicine, Kanagawa, Japan; [3]Cell Biology, Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [4]Nephrology and Dialysis, Kitano Hospital, Osaka, Japan; [5]Regeneron Pharmaceuticals, Inc., NY.*

**Background:** Podocyte injury is the first step in the progression of glomerulosclerosis. Previous studies have demonstrated the beneficial effect of bone morphogenetic protein 7 (Bmp7) in podocyte injury and the existence of native Bmp signaling in podocytes. Because the local activity of Bmp7 is controlled by cell-type specific Bmp antagonists that inhibit the binding of Bmp7 to its receptors, we screened for Bmp antagonist expressed by podocytes, and analyzed the function.

**Methods:** We utilized conditionally immortalized murine podocytes, and *Twsg1-lacZ* reporter mice.

**Results:** The product of Twisted gastrulation (Twsg1), a Bmp antagonist, was the most abundant Bmp antagonist in murine cultured podocytes. The administration of Bmp induced podocyte differentiation through Smad signaling, whereas the simultaneous administration of Twsg1 antagonized the effect. Twsg1 was expressed in the glomerular parietal cells (PECs) and distal nephron of the healthy kidney, and additionally in damaged glomerular cells in a murine model of podocyte injury. Twsg1 null mice exhibited milder hypoalbuminemia and hyperlipidemia, and milder histological changes while maintaining the expression of podocyte markers during podocyte injury model.

**Conclusions:** Twsg1 plays a critical role in the modulation of protective action of Bmp7 on podocytes, and inhibition of Twsg1 is a promising means of development of novel treatment for podocyte injury.

**Nephrin Activation Induces Endosomal Signaling Necessary for Coordinated Focal Adhesion and Lamellipodial Dynamics** Qingfeng Fan, Lawrence B. Holzman. *Renal Div, Univ of Pennsylvania, Phila., PA.*

**Background:** Nephrin ligation induces Nephrin tyrosine phosphorylation-dependent endocytosis. Nephrin endocytosis might be a mechanism by which podocyte junctions are disassembled and by which Nephrin protein and signaling is degraded in disease

states. Alternatively, receptor-mediated endocytic trafficking can have signal-propagating functions, wherein "signaling endosome" complexes signal to distinct subcellular compartments. We hypothesized that Nephrin signals from a signaling endosome.

**Methods:** We evaluated the dynamics of Nephrin endosomal trafficking, focal adhesion (FA) turnover, and lamellipodial activity in cultured podocytes following chimeric CD16-nephrin cytoplasmic domain (CD16NCD) ligation focusing on the necessity of Nephrin-induced endosomal signaling in these integrated processes.

**Results:** Ligation of CD16NCD results in synchronized cellular events that culminate in lamellipodial induction peaking at 20 min. By 1 min, CD16NCD forms fine clusters on the cell surface, becomes tyrosine phosphorylated and is associated with Fyn, FAK, Cas, and caveolin. Soon thereafter, CD16NCD is dephosphorylated and undergoes endocytosis, disappearing from the cell surface and co-localizing with EEA1. By 5 min, FA proteins (e.g., FAK, Cas, paxillin, vinculin) disassemble and are transiently found associated with CD16NCD positive early endosomes between 5-10 min. By 20 min, FA proteins reassemble into linear FA when lamellipodial activity is first observed. At 40 min, CD16NCD endocytosis results in only limited CD16NCD degradation by endosomal trafficking via the late endosomal pathway. All aspects of this process require initiation by nephrin tyr phosphorylation, since Y-F mutation of all 10 CD16NCD tyr residues blocks endocytosis, FA turnover, and lamellipodial activity. Results using a mouse protamine sulfate model suggest a similar process in vivo.

**Conclusions:** Mechanisms governing lamellipodial activity in culture may be similar to those employed in vivo during foot process effacement. We suggest that podocyte injury-induced Nephrin tyr phosphorylation initiates Nephrin endosomal signaling that in turn is necessary for FA turnover, actin remodeling and foot process spreading.

### GSK3β Controls Podocyte Process Elongation via Tau and CRMP2 Mediated Regulation of Microtubule Dynamics: Role in Compensatory Adaptation to Podocyte Loss

Weiwei Xu,[1] Yan Ge,[1] Zhi-hong Liu,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ, Providence, RI; [2]Research Institute of Nephrology, Nanjing, China.*

**Background:** Upon podocyte loss, remnant intact podocytes exhibit a limited adaptive capacity to extend podocyte processes and cover the denuded glomerular base membrane. Microtubules, a major cytoskeletal component of podocyte primary processes, are necessary for process outgrowth, branching and elongation. This study explored the role of glycogen synthase kinase (GSK)3β regulated microtubule dynamics in podocyte injury.

**Methods:** Adriamycin induced podocytopathy was employed *in vivo* and *in vitro* in conditionally immortalized mouse podocytes and microtubule dynamics examined.
