Conclusions: This multimodality MWE is meant to address the need for dedicated educational resources to teach trainees the fundamental principles of medical writing. We plan to pilot-test the acceptance and effectiveness of this curriculum in a small sample of nephrology fellows using a pre- and post-test format of knowledge assessment and pre- and post-elective scholarly productivity. If successful, it can be customized for use in other disciplines and specialties.

An Innovative Collaboration between Patients and an Industry-Supported Rare-Disease Registry Len Woodward,[1] Gema Ariceta,[2] Christoph Gasteyger,[3] Sally A. Johnson,[4] Johan Vande Walle,[5] Christoph Licht.[6] *[1]aHUS Alliance; [2]Univ Hospital Vall d'Hebron; [3]Alexion Pharma GmbH; [4]Great North Children's Hospital; [5]Ghent Univ Hospital; [6]The Hospital for Sick Children.*

Background: Partnership between patient (pt) organizations and clinical researchers can promote innovation and support pt-focussed research. Few reports on such activities exist; we describe a collaboration between a group of pt organizations and a pt registry.

Methods: The global atypical Haemolytic Uraemic Syndrome (aHUS) Registry (NCT01522183) is an observational, multicentre registry of pts with aHUS which will assess long-term outcomes. The aHUS Alliance comprises 12 pt organizations worldwide that aim to work with international clinical research networks. The aHUS Registry Scientific Advisory Board (SAB) invited the aHUS Alliance to submit research ideas important to pts with aHUS. Such ideas were subsequently generated independently of the SAB by pts and the aHUS Alliance.

Results: In November 2015, 24 identified research ideas were presented to the SAB. The majority related to three topics: understanding causes of thrombotic microangiopathy, the clinical and psychological/social impact of living with aHUS, and comparing regional disease characteristics. The top five research priorities are shown (Table). The proposals have led to an ongoing analysis of data on pts with kidney transplants enrolled in the registry and a proposal to analyse annual immune cycles is in development that includes three aHUS Alliance members as investigators.

Table. Key research priorities for pts with aHUS

1. What are transplant outcomes without eculizumab and what non-kidney damage is likely from any resulting aHUS onset?
2. What are the barriers to diagnosis, and how can they be overcome?
3. Can a blood test be developed to allow pts in remission to monitor themselves?
4. Is there a "golden period" for diagnosis which predicts more favourable outcomes for pts with aHUS?
5. Do annual immune activity cycles predict a time of year when aHUS onset is more likely?

Conclusions: Research priorities for pts include understanding barriers to rapid diagnosis, avoiding irreversible organ damage and kidney transplantation outcomes. Analyses of the aHUS Registry will include topics proposed by the Alliance as a priority. It is key that the collaboration continues in the long-term. **Acknowledgments:** We thank the patients and the aHUS patient organisations involved.

PUB333

What Can Social Media Tell Us about Patient Experiences of Living with IgA Nephropathy? Jonathan Barratt,[1] Karen Molyneux,[1] Lydia Yijian Chen.[2] *[1]Infection, Immunity & Inflammation, Univ of Leicester, Leicester, United Kingdom; [2]DataTellsLife, DataIntelligence, Co. Ltd, Hong Kong.*

Background: The use of social media around the world has exploded in recent years and is changing the way medicine is practiced and healthcare is delivered. Social media is increasingly used to share experiences of living with chronic disease, the impact of treatments for these diseases and the quality of interactions with health providers. It is often the first port of call for people living with chronic disease who are searching for advice and guidance on managing their condition. IgA nephropathy is a disease that more frequently affects young adults, a population that is immersed in the social media revolution.

Methods: To understand the key issues impacting on the lives of people with IgAN and to identify areas of unmet need, particularly in terms of education about IgAN we undertook a systematic social media text mining and thematic analysis examining both twitter and instagram feeds between 27/07/2015 and 31/05/2016.

Results: Between 27/07/2015 and 27/07/2015 there were 3575 posts including the keyword IgA nephropathy (96.3% twitter, 3.97% instagram). 14% of posts contained public geographic location information and of these 22.5% Europe, 65.56% North America, 9.20% Asia, 1.57% Oceania, 0.78% Africa, 0.39% South America. When analysing posts by content the commonest topics discussed were how to diagnose IgAN, what treatments are available and how to prevent kidney failure. Informal peer support networks were identified and these focused on providing advice and support around several key areas: coping with disease symptoms and side effects of treatments (particularly steroids), diet, feedback on recent blood and urine tests and how to slow progression of IgAN.

Conclusions: Patients with IgAN commonly use social media to share experiences and look for advice on managing their disease. Analysis of social media data provides a rich seam of real life patient experience, highlights common areas of poor knowledge and misconception that can prompt nephrologists to raise these issues during outpatient reviews.

PUB334

Effect of Online Educational Interventions in Hyperkalemia among Nephrologists Edward L. Jackson, Don Blatherwick, Karen Badal. *Medscape Education, LLC.*

Background: Chronic hyperkalemia is a poorly understood condition that has been associated with the use of renin-angiotensin aldosterone system (RAAS) inhibitor therapies in patients that would otherwise benefit from them. A study was conducted to determine whether a curriculum of online educational interventions could address underlying educational needs among nephrologists in the area of evaluation and management of chronic hyperkalemia.

Methods: Educational interventions covered a range of topics related to hyperkalemia and included a text-based introductory primer, a video lecture, and three video discussion-based interventions, which were launched between September 25, 2016 and January 6, 2016. Data were collected between September 25, 2015 and April 5, 2016. Educational impact for each intervention was assessed by comparing each participant's responses to 4 matched, content-related knowledge questions asked both pre- and post-education. Statistical analysis for each question included a paired 2-tailed t-test, McNemar's $\chi 2$ statistic and probability (P values) to determine significance level, with a $P < .05$ as meeting statistical significance.

Results: For nephrologists who participated in at least one of the online interventions and completed all pre- and post-assessment questions, a comparison of responses demonstrated a high level of baseline knowledge of hyperkalemia. Significantly improved learners were observed in several specific topic areas including: Site of drug action of emerging potassium binders (95% versus 80%, n=111); Initiation of potassium binder therapy prior to initiating a RAAS inhibitor (84% versus 66%, n=155); Evidence from clinical trials for maximizing RAAS inhibitor therapy in patients with heart failure (76% versus 43%, n=129); Evidence from clinical trials of novel potassium binders (94% versus 74%, n=124).

Conclusions: As a result of participation in a curriculum of clinically relevant educational interventions in text and video formats designed to address identified gaps, significant improvement in knowledge of hyperkalemia was demonstrated in several areas including knowledge of novel potassium binder therapies, and clinical trials of RAAS inhibitor therapies.

PUB335

Single Tertiary Center Experience with Therapeutic Plasma Exchange Tahir Zaman, Christine K. Raj, Alfred K. Cheung, Josephine Abraham. *Univ of Utah, Univ of Utah, Salt Lake City, UT.*

Background: The field of nephrology has acquired the role of performing therapeutic plasma exchange (TPE) in the U.S. Since November??, 2014 at the University of Utah, the Division of Nephrology has assumed the responsibility of supervision and conduct of TPE . The University of Utah is a tertiary referral center for the Intermountain west, including the states of Utah, Idaho, Montana, Wyoming and Nevada. Herein we report our one-year experience with TPE.

Methods: A retrospective review was performed for TPE procedures provided by our apheresis center from January 2015 to December 2015. We largely followed the guidelines provided by the American Society for Apheresis (ASFA) for indications under 4 categories. Indications at the time of consultation and the numbers of apheresis procedures were recorded.

Results: A total number of 504 TPE procedures were performed, with 64%, 28% and 8% in ASFA Category 1, Category 2 and category 3 indications, respectively. A significant portion of the cases was related to kidney transplants and other renal indications (38%), which was quite similar to that for neurological conditions (42%). Hematology conditions comprised of 10%, while miscellaneous conditions accounted for the remaining 9%. Several indications for TPE are for treatment of renal related pathology. In renal transplantation TPE has been used for pre-transplant desensitization, used in treatment of recurrent FSGS and acute antibody mediated rejection. In general nephrology TPE has been used for treatment of granulomatosis with polyangiitis, thrombotic microangiopathy, cryoglobinemia and for anti-GBM related disease.

Conclusions: Overall the field of nephrology stands to benefit from performing TPE. Though initially there were some start-up struggles including setting up our electronic medical records for ease of usage and teaching both the faculty and nursing how to perform the procedure, ultimately we believe that TPE can be used to enhance the attraction of the field of nephrology.

PUB336

Intensive Lifestyle Program in Chronic Kidney Disease Sahil Bawa,[1] Michael J. Germain,[2] Sam A. Headley.[3] *[1]Nephrology, RTANE, Springfield, MA; [2]Nephrology, Baystate Medical Center, Springfield, MA; [3]Exercise Science, Springfield College, Springfield, MA.*

Background: Cardiorespiratory fitness(CRF) level and Physical Activity(PA) levels are low in Chronic Kidney Disease(CKD) which contribute to increased mortality in these patients(Pt's).There is relatively little research to determine the impact of the lifestyle intervention on the quality of life in CKD Pt's.

Methods: Forty Five,Stage3-4(i.e.GFR 59-15ml/min),CKD Pt's between the ages of 18-75 not currently enrolled in a regular exercise training program(3 days/week for last 6 months) and who do not suffer from severe bowel obstruction,impaction or Pt's without postoperative motility disorders will be enrolled.Pt's will be randomly assigned to intervention or control group,and will be allowed to participate only if their nephrologist gives them the permission to do so following which they will be asked to complete a 3 day diet log and Exercise Benefits/Barrier Scale at the start of the study and also be asked to wear a 7 day activity monitor.An assessment will be done at the start of study which will include evaluation of blood pressure,medications and state of the blood vessels.Other indices of physical function(Functional Movement Screen,hand grip strength,6 minute walk,sit to stand test,short physical performance battery,leg strength and power) will be done.Pt's will be re-evaluated with blood work and physical examination at months1,3 and 6 months.It is expected that all Pt's will be on ACE/ARB,if they are not then also they can participate.Serum Potassium levels will be monitored regularly and if it goes >5.2mEq/L Veltessa(VEL) will be prescribed to the intervention group.

Results: To determine the effect of a 6 month comprehensive,integrated and individualised lifestyle intervention(CIILI) program on SPPB and other indices of physical function,Pt's with ACE/ARB prescribed VEL compared to those not on VEL and CRF levels in patients with stage 3-4 CD.

Conclusions: We hypothesize that a CIILI program will lead to enhanced physical function primarily assessed by SPPB and patients prescribed VEL will better tolerate the ACE/ARB prescription that not on VEL and better CRF levels in the intervention group.

PUB337

Electronic Cigarettes Induce Renal Fibrosis: A Novel MiR-29b-3p Mediated Mechanism Christopher A. Drummond,[1] Laura E. Crotty Alexander,[2,3] Jiang Tian.[1] *[1]Medicine, Univ of Toledo, Toledo, OH; [2]Pulmonary Critical Care Section, Veterans Affairs San Diego Healthcare System, San Diego, CA; [3]Div of Pulmonary, Critical Care and Sleep Medicine, Univ of California San Diego Health Sciences, San Diego, CA.*

Background: Clinical studies indicate that combustible cigarette smoke increases renal and cardiac tissue injury progression and functional decline in the setting of chronic kidney disease (CKD). Novel nicotine delivery devices like electronic (e)-cigarettes are used by over 10% of the population and produce vapor which may also induce renal injury. We undertook these studies to estimate the effects of e-cigarettes and to investigate mechanisms by which renal tissue injury occurs.

Methods: Our current study induced 8 week-old female CD-1 mice to inhale e-cigarette vapor containing 24mg/mL of nicotine suspended in a solution of 50% propylene glycol and 50% vegetable glycerin for 1- and 6-months.

Results: Following e-cigarette exposure, assessment of renal fibrosis and expression of the antifibrotic microRNA miR-29b-3p were evaluated. Mice exposed to e-cigarette vapor suffered a 31% decline in renal tissue expression of miR-29b-3p vs air-exposed controls ($p<0.05$). Additionally, mRNA targets of miR-29b-3p that regulate fibrosis formation or are part of fibrosis were also significantly increased in the kidneys of e-cigarette exposed mice versus air controls, i.e., Collagen 1A1 (increased 98%; $p<0.05$); Collagen 3A1 (129% increase; $p<0.05$); Collagen 4a1 (72% increase; $p<0.05$); Integrin beta 1 (58% increase; $p<0.05$); and Fibrillin 1 (100% increase; $p<0.05$). Lastly, we observed a significant increase in renal fibrosis as assessed by Trichrome staining in these animals.

Conclusions: These data are the first to indicate that e-cigarettes induce renal fibrosis. More importantly, these data provide a novel miR-29b-3p mediated mechanism linking e-cigarette vapor exposure and renal injury.

PUB338

Protection Mechanisms of Ferulaic Acid for Podocyte in Adriamycin-Induce Nephropathy Rats Minggang Wei.[1] [1]*The First Affiliated Hospital of Soochow Univ, Suzhou, China;* [2]*Jiangsu Province Hospital of TCM, Nanjing, China.*

Background: Chronic renal failure (CKD) is one of the importment public health problem. Renal fibrosis is the main reason for the progressing of CKD. Ferulaic acid is one of the main active material which extracted from some chinese herbs such as Radix Angelicae Sinensis et al. The podocyte is the main component of glomerular filtration membrane, and it's damage or apoptosis directly related to renal fibrosis. In this study, we verified that ferulaic acid could delay renal fibrosis through protecting the intact structure of podocyte and regulating the level of cell factors such as TGF-β_1 and Smads et al.

Methods: In this study, we established the adriamycin-induce nephropathy rat modle characterized by podocyte damage and renal fibrosis. We can find that the expression of TGF-β_1, Smad2/3, and extracellular matrix (ECM) such as collagen and fibrotion were significantly increase in renal tissure. Meanwhile, the expression of podocyte remarks protein of nephrin significantly decrease in renal tissure. Using ferulaic acid obviously attenuate the level of collagenI, collagenIV, fibrotion and TGF-β_1. In the vitro, ferulaic acid up-regulate the level of nephrin and podocine for TGF-β_1-induce podocyte. Furthermore, the expression of collagenI, collagenIV, fibrotion, samd2/3 and ILK decrease significantly after add ferulaic acid in the well. If up-regulaing the respond of samd2/3, we can see the cell factors and ECM have the same manifestation as the adriamycin-induce nephropathy rat modle. If inhibiting the respond of samd2/3, we can see the opposite phenomenon.

Results: whether the podocyte is integrity or not has intimate relation with renal fibrosis. Ferulaic acid can relieve the damage of podocyte and the level of ECM both in vivo and in vitro.

Conclusions: Ferulaic acid maybe one of the utility traditional medicine which can delay renal fibrosis.

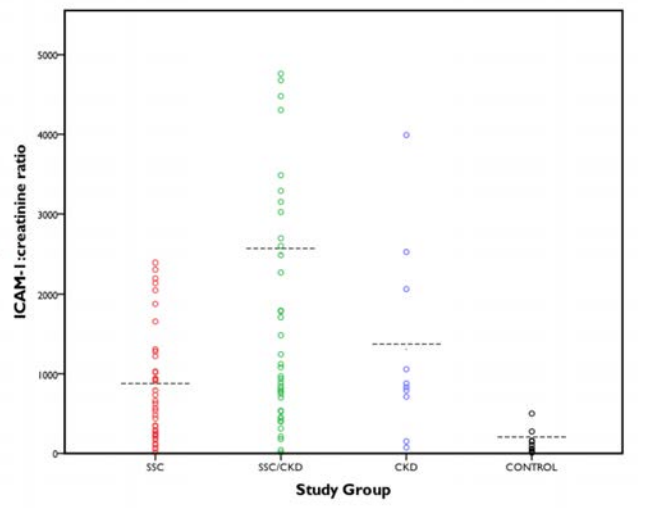
PUB339

Urinary Cell Adhesion Molecules as Markers of Renal Involvement in Systemic Sclerosis Edward Stern,[1] Aine Burns,[2] Robert J. Unwin,[2] Christopher Paul Denton.[1] [1]*Centre for Rheumatology and Connective Tissue Diseases, UCL, London, United Kingdom;* [2]*Centre for Nephrology, UCL, London, United Kingdom.*

Background: Renal involvement in systemic sclerosis (SSc) includes scleroderma renal crisis as well as progressive organ fibrosis. Detection and management of these disease complications is challenging and there is a clinical need for biomarkers that reflect renal involvement. The immunoglobulin superfamily adhesion molecules ICAM-1 and VCAM-1 are upregulated in affected tissues in SSc and other connective tissue diseases. Serum levels of ICAM-1 and VCAM-1 have been elevated in previous studies, but this may reflect the multi-organ burden of disease and organ-specific analysis may be more robust.

Methods: We collected urine and serum from 80 SSc patients, with or without renal disease, and compared them with patients with CKD of other causes (n=10) and healthy controls (n=12). We used bead-based multiplex analysis to measure cell adhesion molecule concentrations. Results were compared among groups by Kruskal-Wallis test.

Results: 40 SSc patients had CKD defined by eGFR. Risk factors for renal involvement (SSc-CKD) included diffuse skin involvement and anti-RNA polymerase III antibodies. Serum concentrations of ICAM-1 or VCAM-1 did not differ significantly between SSc-CKD and the three control groups. Urine VCAM-1 concentrations were increased in SSc patients with renal involvement (mean VCAM-1:creatinine ratio 922, SD 953 versus 654, SD 708 for those without renal involvement) but this did not reach significance. Urine ICAM-1 was significantly upregulated in SSc-CKD (mean ICAM-1:creatinine ratio 1601, SD 1394 versus 806, SD 701 for SSc without renal involvement and 1307, SD 1211 for CKD of other causes, $p<0.001$).



Conclusions: This is the first study to examine urinary cell adhesion molecule concentrations in SSc. Our results confirm the potential utility of urine sICAM-1 as a marker of renal involvement in SSc.

PUB340

Urinary and Serum Trefoil Factor 3 Is Significantly Associated with Renal Tissue Fibrosis in Patients with Tubulointerstitial Nephritis Keiko Tanaka, Hitoshi Sugiyama, Toshio Yamanari, Ayu Akiyama, Akifumi Onishi, Masashi Kitagawa, Tatsuyuki Inoue, Jun Wada. *Dept of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama Univ Graduate School, Okayama, Japan.*

Background: Trefoil factor 3 (TFF3) is a small peptide involved in mucosal protection. TFF3 is widely expressed in multiple tissues including kidney. Previous studies have suggested that serum and urinary TFF3 significantly increase in patients with chronic kidney disease and that urinary TFF3 decreases in rats with acute kidney injury. However, it is unclear whether serum or urinary TFF3 is associated with human renal tissue injury. The aim of this study is to elucidate the relationship between the serum and urinary levels of TFF3 and the degree of renal tubulointerstitial injury.

Methods: The total study population included 112 patients (tubulointerstitial nephritis [TIN], n=34; IgA nephropathy [IgAN], n=57, and patients with minor glomerular abnormalities and thin basement membrane disease as controls, n=21) who underwent renal biopsy. The serum and urinary TFF3 concentrations were determined by a specific ELISA. The degrees of tubulointerstitial cell infiltration and fibrosis in biopsy specimens were semiquantitatively graded and defined by the inflammation score and the fibrosis score, respectively.

Results: The median serum and urinary levels of TFF3, and the mean fibrosis score and inflammation scores of the TIN group were significantly higher than those of the other groups ($p<0.0005$). A statistically significant positive correlation was observed between both the urinary and serum levels of TFF3 and the renal fibrosis score in the TIN group. A similar but non-significant tendency was observed in the IgAN group. There was no correlation between either the serum or urinary level of TFF3 and the renal inflammation score in the control and TIN groups.

Conclusions: The data indicate that the serum and urinary levels of TFF3 are significantly increased and they could reflect renal tissue fibrosis in patients, especially those with tubulointerstitial nephritis. Further studies are required to elucidate the precise distribution of renal TFF3 protein and mRNA, and the mechanism underlying the contribution of TFF3 to renal fibrosis.

PUB341

Icariin Plays a Protective Role in Angiotensin II-Induced Renal Fibrosis Independent of Estrogen Receptor Signaling Pathway Yi Wang, Hongli Zhang, Min Chen, Xiangchen Gu. *Dept of Nephrology, Yueyang Hospital of Traditional Chinese and Western Medicine, affiliated to Shanghai Univ of T.C.M.*

Background: Ang II plays a crucial role in the development and progression of renal fibrosis. Previous studies have demonstrated that estradiol could attenuate AngII induced renal fibrosis. Icariin, an active ingredient extracted from Chinese herb Epimedium, has been proved to have the same effect as estradiol on many animal disease models. In this study, we tried to ascertain the effect of icariin on the Ang II-induced renal fibrosis rodent model.

Methods: Ovariectomized SD rats were randomized into 4 groups, treated with Icariin after implantation of Ang II osmotic mini pumps at the rate of 1000ng/kg/min. The rats were sacrificed after 4 weeks of treatement. The serum estrogen level, pro-fibrotic factors, renal function, renal morphology and ER (estrogen receptor) α and β expression levels

were assessed. NRK-49F cell lines with ER knockdown and empty vector were generated using siRNA. The cell lines were stimulated with Ang II after pretreatment of Icariin. The profibrotic markers were measured as well.

Results: In contrast to AngII model group, rats treated with Icariin exhibited a significant decrease in the mRNA levels of TGF-β1, CTGF, Cola1, ColIV and Fibronectin by qPCR method. Masson Trichrome staining also demonstrated less Collagen depositions in this group. Renal functions of the treatment group were improved as well, compared to that of AngII model group. However, ER α and β expressions remained the same in all groups. In vitro study demonstrated that pretreatment of Icariin significantly decreased the expressions of profibrotic factors induced by AngII in NRK49F cell lines with both ER knockdown and empty vector.

Conclusions: Icariin can attenuate AngII induced renal fibrosis. But it might not be related to the estrogen receptors signaling pathway.

PUB342

Long-Term Lithium Treatment Causes Renal Interstitial Fibrosis in Mice

Mohammad Alsady,[1] Theun de Groot,[1] Leunie Van der Tholen,[1] Toin Van Kuppevelt,[2] Johan Van der Vlag,[3] Peter M.T. Deen.[1] *[1]Dept of Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Dept of Biochemistry, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Dept of Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Lithium is the main treatment of bipolar disorder, but prolonged lithium treatment results in the development of renal interstitial fibrosis in 20% of the patients. Renal fibrosis is a hallmark and common outcome in the development of chronic kidney disease (CKD). To fully understand the development of lithium-induced CKD, the use of animal models is essential. Rats have been instrumental in this and long-term lithium treatment has been shown to induce renal interstitial fibrosis. However, considering the broad knowledge of the renal physiology, the versatility and availability of gene knockout strains, mice are the preferential mammalian model to study lithium-induced CKD, but proper model have never been reported. Therefore, we investigated whether mice could be used as a model to study Li-induced CKD development.

Methods: 10 weeks old male C57Bl/6 mice were fed a normal rodent diet or a diet with 40 mmol/kg food of lithium chloride for 40 weeks. One kidney was used to collect cortex and medulla for RT-qPCR and immunoblot analysis. The other kidney was fixed and stored for immunohistological analysis.

Results: Chromotrop-Anilinblue (CAB) trichrome staining of the kidneys revealed development of interstitial fibrosis in the cortico-medullary region, dilated tubuli, tubular atrophy and decreased glomerular size. Moreover, lithium treatment increased αSMA staining in renal cortex and outer medulla of mice indicating an increase in myofibroblasts in the interstitial compartments. Although EW3D10 staining showed that the endothelium around collecting ducts was pro-inflammatory, no increase was observed for inflammatory markers in RT-qPCR analysis.

Conclusions: We show that 40 weeks lithium treatment results in the development of renal interstitial fibrosis and that mice can be used as a model to study Li-induced CKD development. In line with data in rats, no increase was observed for inflammatory markers.

Funding: Government Support - Non-U.S.

PUB343

Acute Phase Serum Creatinine Correlates with Subsequent Tubulointerstitial Damage and Predicts AKI to CKD Transition in Rats with Ischemia-Reperfusion Injury

Hisako Saito, Tetsuhiro Tanaka, Shinji Tanaka, Mai Sugahara, Kenji Fukui, Masaomi Nangaku. *Div of Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan.*

Background: A strong correlation is reported between AKI episodes and the long term development of CKD. Failed redifferentiation and growth arrest of injured tubules are key processes. Thus, the severity and duration of the initial tubular insult likely predict subsequent development of CKD, which requires experimental proof.

Methods: Male SD rats were subjected to bilateral ischemia-reperfusion injury (IRI, 40 to 50min). Serum creatinine (sCre) and proteinuria were measured at 24, 48 h and day 28. At day 28, the positional relationship of damaged tubules and active fibroblasts was investigated by double immunostaining of γH2AX, vimentin and αSMA. Correlations between acute phase sCre and subsequent sCre, proteinuria and interstitial fibrosis were plotted with each individual IRI rat. As an accelerated model of AKI to CKD transition, rats were subjected to IRI 2 weeks after 75% renal mass reduction, which were followed for 28 days.

Results: sCre reached 1.95±0.207 mg/dL at 24 h, ($P<0.05$ vs sham), which returned to baseline at day 28. Non-significant proteinuria developed at day 28, which had no significant correlation with sCre in the acute phase. Histologically, various degrees of tubular damage and interstitial fibrosis were evident; γH2AX- positive, damaged tubules were observed in a patchy manner, which were surrounded by vimentin- and αSMA- positive active fibroblasts. These fibrotic areas were clearly separated by sharply demarcated normal parenchyma. Percent fibrotic areas positively correlated with acute phase sCre, in both cortex and medulla (cortex: $R^2=0.4033$, $P< 0.01$, medulla: $R^2=0.473$, $P< 0.001$ at 24h). This correlation was retained in kidneys subjected to various severity of ischemia, ranging from 40 to 50 min of cross-clamp, and in kidneys superimposed on renal mass reduction.

Conclusions: These findings emphasize a need to develop more sensitive biochemical markers to detect AKI to CKD transition, and render support to the prevalent view that mitigating initial tubular damage has a key role in preventing subsequent CKD development.

PUB344

Role of Smad3 Linker Region Phosphorylation in Nocantharidin Inhibiting Renal Interstitial Fibrosis

Ying Li, Nannan Yu, Yingjun Liao, Jun Li, Fu-You Liu, Hong Liu, Lin Sun. *Dept of Nephrology, Second Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Our previous study showed that Nocantharidin(NCTD) could inhibit renal interstitial fibrosis and also promote Smad3 linker region phosphorylation. Based on the above results, this study will investigate: 1) effect of Smad3 linker region phosphorylation on renal interstitial fibrosis; 2) role of Smad3 linker region phosphorylation in NCTD inhibiting renal interstitial fibrosis.

Methods: 1.Human proximal tubular cell line (HK-2 cells) separately transfected with Smad3 linker region phosphorylation site mutant viruses (TGF-β1+S3-LM group) or wild type viruses (TGF-β1+S3-WT group) and HK-2 cells without any transfection (TGF-β1 group) were stimulated by 5 ng/ml TGF-β1 for 24h. The expressions of fibronectin (FN) and collagen I (Col-I) mRNA and protein in each group were detected by real-time PCR and western blot. 2. HK-2 cells separately transfected with Smad3 linker region phosphorylation site mutant viruses (NCTD+TGF-β1+S3-LM group) or wild type viruses (NCTD+TGF-β1+S3-WTgroup) were simultaneously treated with 5ng/ml TGF-β1 and 2.5μg/ml NCTD for 24h. The expressions of FN and Col-I mRNA and protein in each group were detected by real-time PCR and western blot.

Results: 1. Compared to blank control group, the expressions of FN and Col-I mRNA and protein were increased in TGF-β1 group. And their expressions were higher in TGF-β1+S3-LM group than in TGF-β1 group and TGF-β1+S3-WT group($P<0.05$). 2. Expressions of FN and Col-I mRNA and protein were decreased in NCTD+TGF-β1+S3-LM group compared to TGF-β1+S3-LM group ($P<0.05$). Similarly, their expressions were also lower in NCTD+TGF-β1+S3-WT group than in TGF-β1+S3-WT group ($P<0.05$). But expressions of FN and Col-1 were higher in NCTD+TGF-β1+S3-LM group compared to NCTD+TGF-β1+S3-WT group($P<0.05$).

Conclusions: 1. Smad3 linker region phosphorylation could block TGF-β1 signaling pathway in HK-2 cells and thus inhibit renal interstitial fibrosis; 2.NCTD's anti-renal interstitial fibrotic effect was not fully dependent on its promotion of Smad3 linker region phosphorylation.

PUB345

A Monoclonal Antibody Neutralizing Transforming Growth Factor Beta Delays the Progressive Decline of Glomerular Filtration Rate in Hyperoxaluria-Related CKD

Stefanie Steiger,[1] Qiuyue Ma,[1] Julia Felicitas Grill,[1] Shrikant R. Mulay,[1] Patrick Finn,[2] Hans J. Anders.[1] *[1]Nephrologisches Zentrum, Klinikum der Univ München, Munich, Germany; [2]Sanofi - Genzyme, Framingham.*

Background: Hyperoxaluria can lead to progressive chronic kidney disease (CKD), e.g. in primary hyperoxaluria, a process that is associated with massive intrarenal crystal deposition, nephron loss and tubulointerstitial fibrosis. There is little evidence that fibrosis is a cause rather than a consequence of nephron loss, hence, we hypothesized that blocking fibrogenesis would not affect CKD progression.

Methods: We used a model of progressive oxalate nephropathy by feeding mice a sodium oxalate-rich, calcium-free diet for 14 days. Mice were randomized to injections with either a neutralizing TGFβ or control IgG antibody until the end of the study.

Results: As expected anti-TGFβ antibody treatment decreased interstitial fibrosis, which was associated with less tubular atrophy and RNA expression levels of kidney injury and fibrosis, and decreased the number of profibrotic macrophages. Most importantly, this antifibrotic effect significantly improved renal excretory function as demonstrated by a significant increase in the glomerular filtration rate from 20μl/min to 100μl/min ($P<0.01$), and reduced serum creatinine (1.7mg/dl to 1.0mg/dl, $P<0.01$) and BUN (78.9mg/dl to 38.2mg/dl, $P<0.05$) levels.

Conclusions: These results support the concept that TGFβ-mediated renal fibrosis contributes to nephron loss. A monoclonal antibody against TGFβ may retard CKD progression in primary hyperoxaluria and potentially other forms of CKD.

PUB346

The Expression of WNT1-Inducible Signaling Pathway Protein-1 Correlates with Renal Fibrosis

Xiang Zhong, Guisen Li, Li Wang. *Renal Div and Inst of Nephrology, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: WNT1-inducible signaling pathway protein-1 (WISP-1) plays a pathological role in pulmonary fibrosis, but the role of WISP-1 in renal fibrosis is unknown. In this study, we explored the expression of WISP-1 in renal fibrosis in patients and in TGF-b-treated tubular epithelial cells (TECs) and in the obstructive nephropathy mouse model.

Methods: The serum and kidney tissues from renal biopsy-proved renal fibrosis patients including IgA nephropathy (IgAN), diabetic nephropathy (DN), primary focal segment glomerular sclerosis (FSGS) was collected to examine the levels of WISP-1 by ELISA and Immunohistochemistry staining, respectively, and the minimal change disease (MCD) and the healthy as controls. The expression of WISP-1 was also examined in TGF-b-induced renal fibrosis in tubular epithelial cells (TECs) and in the fibrotic kidneys of obstructive nephropathy model by Realtime PCR and Western blotting.

Results: Immunohistochemical analysis showed that WISP-1 was highly expressed in tubulointerstitial area in renal fibrosis patients of IgAN, DN and FSGS, but not in the expression of WISP-1 in MCD and the healthy. The WISP-1 expression in serum of renal biopsy-proved renal fibrosis patients by ELISA was significantly increased compared with

the control groups (P<0.05). More importantly, the WISP-1 expression was positively correlated with renal fibrosis (r^2=0.228, P=7.36×10^{-7}) and serum creatinine (Scr) (r^2=0.046, P=0.023), while negatively with estimated glomerular filtration rate (eGFR) (r^2=0.051, P=0.017). In accordance with these results, when the fibrotic indexes including Col I, a-SMA, fibronectin were increased both in TGF-b-induced renal fibrosis in TECs and in UUO mouse model, the expression of WISP-1 was also significantly elevated (P<0.05).

Conclusions: We explored the WISP-1 was highly expressed not only in biopsy-proved renal fibrosis patients, but also in TGF-b-induced renal fibrosis in TECs and in the fibrotic kidneys of obstructive nephropathy model. And the WISP-1 expression level in serum correlated with the fibrosis in renal tissue, and also correlated with the renal function.

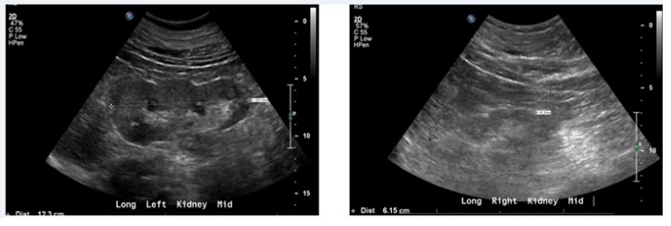
PUB347

A Challenging Case of Poorly Controlled Hypertension in a Patient with a Solitary Kidney

David Levy, Sai Subhodhini Reddy. *Div of Nephrology, Univ of Rochester Medical Center, Rochester, NY.*

Introduction: Patients with a solitary kidney secondary to unilateral renal atrophy often have poorly controlled hypertension (HTN). Elevated renin levels and subsequent activation of the renin angiotensin aldosterone system (RAAS) are expected due to reduced renal perfusion to the atrophic kidney. Since the pathophysiology of HTN in patients with an atrophic kidney is similar to patients with renal artery stenosis, treatment with RAAS blockade seems appropriate.

Case Description: JD is a 36 year old male who was referred to nephrology for evaluation of his poorly controlled HTN and CKD. Prior to his initial visit a renal ultrasound showed an atrophic right kidney (Figure 1). He was treated with losartan and metoprolol. However his HTN remained poorly controlled, and he had worsening azotemia (Table 1). Since he had progressive renal dysfunction and uncontrolled HTN, there were ongoing discussions with the patient of stenting his right renal artery. While he was considering this intervention, amlodipine was added. Subsequently, he had significant improvement in his blood pressures and proteinuria.



Date	Blood Pressure Reading	Medications and Dose	Spot urine TP/Cr (g/day)	Serum Cr (mg/dl)	eGFR (ml/min/1.73m2)	Changes
12/03/2015	197/110	Losartan 50mg daily, Metoprolol XL 50mg daily	3.16	1.84	46	Losartan increased
12/07/2015	197/123	Losartan 75mg daily, Labetalol 400mg BID	Not Checked	1.87	45	Losartan increased
1/21/2016	180/105	Losartan 100mg daily, Labetalol 400mg BID	1.76	2.06	40	Amlodipine started
3/17/2016	142/82	Losartan 100mg daily, Amlodipine 10mg daily, Labetalol 400mg BID	0.89	1.87	45	None

Discussion: Combination therapy with RAAS blockade and amlodipine may reduce the potential need for renal artery stenting in patients with poorly controlled HTN and progressive renal disease in the setting of a solitary kidney.

PUB348

Breast Nodules: An Unusual Metabolic Complication in a Dialysis Patient

Abhilash Koratala, Dara N. Wakefield, Negiin Pourafshar, Rajesh Mohandas. *Univ of Florida.*

Introduction: Calcific uremic arteriolopathy (CUA) or Calciphylaxis affects 1-4% of the population with End Stage Renal Disease (ESRD) and associated with high mortality. About 90% lesions occur on the lower extremities followed by lower abdomen. We report a case of CUA of the breast, which is an uncommon location.

Case Description: A 54 year old Caucasian woman on hemodialysis secondary to diabetic nephropathy for a year was admitted for management of breast lesions. Other past medical history includes hypertension, atrial fibrillation on Warfarin and morbid obesity. She noted a tender nodule under the skin on the lower right breast 3 months ago which progressed to open wound with surrounding redness and intense pain. Also developed similar nodule in the left breast a month ago.

Labs showed creatinine of 5.6mg/dl, phosphate 6.2 mg/dl, Parathyroid hormone (PTH) 340 pg/ml, serum albumin 2.8 g/dl and alkaline phosphatase 186 U/l. Blood cultures negative. Punch biopsy of the lesion showed skin and subcutaneous tissue with mild acute and chronic inflammation, fibrosis and focal necrosis. Focal calcium deposition was seen within a small blood vessel. No malignancy. A diagnosis of CUA was made and she was started on Sodium thiosulfate (STS) with dialysis along with supportive care and Warfarin was discontinued. Lesions showed some improvement during 1 month follow up.

Discussion: Clinicians should consider atypical presentations of CUA and be aware of its risk factors in patients with advanced kidney disease to ensure prompt treatment and avoid unnecessary workup. High Calcium-Phosphate product and PTH, hypoalbuminemia, diabetes, obesity,warfarin use, female sex, protein C or S deficiency are some of the reported risk factors. Also, there are reports of CUA being associated with metastatic malignancy which needs to be ruled out. Early treatment has led to decreases in mortality of this once uniformly fatal disease.

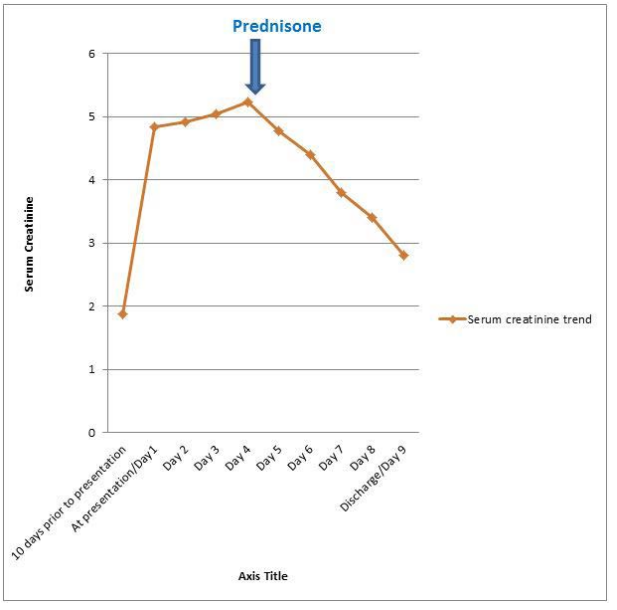
PUB349

Cefepime Induced Encephalopathy and Acute Interstitial Nephritis

Abhilash Koratala, S. Irfan Qadri, Rupam Ruchi. *Univ of Florida.*

Introduction: Cefepime (CP) is an extended-spectrum, 4th generation cephalosporin that has been implicated in encephalopathy especially in patients with renal impairment. Rarely, it can also lead to acute interstitial nephritis (AIN). We report the case of a patient who presented with both these entities.

Case Description: 58 year old Caucasian male with history of Chronic kidney disease stage 3a, Hypertension, Diabetes mellitus was admitted for altered mental status (MS). He was discharged 10 days prior to presentation on IV CP for the treatment of Thoraco-lumbar osteodiscitis, started 2 weeks ago at 2g every 12 hours. CT head was negative. He was completely disoriented and exhibited myoclonic jerks. EEG revealed frequent generalized rhythmic delta activity with triphasic morphology without overt seizure suggestive of possible CP induced encephalopathy. He also had Acute Kidney injury at presentation with serum creatinine (Cr) of 4.84 mg/dL (baseline 1.9). He also had anion gap metabolic acidosis with serum bicarbonate of 16 mmol/L and normal lactate, osmolar gap and toxicology. Urinalysis showed 47 white blood cells per hpf with positive urine eosinophils. No significant proteinuria or evidence of proliferative glomerulonephritis. No skin rash. We suspected CP induced AIN and the drug was discontinued on day 2 of hospital admission. CP level 48 hours after the last dose was 94 mcg/ml (elevated) and Cr stayed high. So, we chose to treat him with oral steroid therapy for AIN (Prednisone approx. 0.8mg/kg/day) and creatinine showed downward trend with improvement in MS.



Discussion: CP is usually considered to be a safe antibiotic and is widely prescribed with few adverse reactions reported. We did the literature search which revealed only

one published case of CP induced AIN (Mac et al. 2015).Clinicians should be aware of its potential nephrotoxic and neurotoxic effects and promptly discontinue the drug with consideration of Steroids if AIN is suspected.

PUB350

Aloe Vera Juice Induced, Biopsy Proven, Acute Tubular Necrosis

Joshua L. Rein, Sri Lekha Tummalapalli, Steven G. Coca, Christina M. Wyatt, Tonia K. Kim. *Div of Nephrology, Dept of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: *Aloe vera* juice is sold over-the-counter as a natural remedy for constipation and arthritis. Numerous compounds contained in the *Aloe vera* plant have been shown to inhibit cyclooxygenase-2 (COX-2). We present a case of *Aloe vera* juice-induced, biopsy proven, acute tubular necrosis (ATN).

Case Description: A 50 year old woman with a past medical history of CKD3, diabetes mellitus, and hypertension presented with increasing dyspnea on exertion, orthopnea, and bilateral leg edema over the past 2 weeks. She denied taking any known nephrotoxins. One month prior, she started drinking *Aloe vera* juice daily for joint pain. Physical exam was remarkable for bibasilar crackles on lung auscultation and 4+ bilateral leg edema. Labs revealed K 5.5 mEq/L, HCO_3 19 mEq/L, BUN 88 mg/dL, Cr 7.14 mg/dL, albumin 2.0 g/dL. Ten months prior to presentation, serum Cr was 1.3 mg/dL. UA showed >1000 protein, 11-25 RBC, 5-10 WBC, FENa 3.7%, and urinary protein excretion was 11.67 g/24hr. Further testing revealed normal C3/C4, A1c 11.3%, negative for HIV, HBV, HCV, anti-GBM ab, normal ANA titer, ASO titer, SPEP and UPEP. Renal US showed normal sized diffusely echogenic kidneys without hydronephrosis or calculi. She remained hypervolemic despite high dose diuretics and hemodialysis was initiated. Renal biopsy revealed ATN with nodular diabetic glomerulosclerosis, moderate arterial sclerosis, and mild parenchymal scarring.

Discussion: *Aloe vera* contains compounds including aloesin, aloeresin A, aloe-emodin, and isorabaichromone, which have demonstrated *in vitro and in vivo* activity against COX-2, NO synthase, and prostaglandin E2 production. Additionally, *Aloe vera* extract can induce ATN in rats. Frequent ingestion of these biologically active substances could therefore induce afferent vasoconstriction in patients who are prostaglandin-dependent to maintain GFR and we hypothesize this prolonged renal hypoperfusion to be the mechanism by which *Aloe vera* can induce ATN. Our case represents a potentially severe side effect of *Aloe vera* juice and nephrologists should be aware of this underrecognized nephrotoxin.

PUB351

An Unusual Case of Atypical Hemolytic Uremic Syndrome

Kelly H. Beers, Kevin Zarrabi, Yezina T. Nigatu, Wilfred Lieberthal. *Stony Brook Univ Hospital.*

Introduction: Hemolytic uremic syndrome (HUS) is characterized by a microangiopathic hemolytic anemia (MHA) and acute kidney injury (AKI). The most common cause of HUS is the classic form associated with a Shiga toxin-producing strain of *E coli*. The combination of MHA and AKI can also be caused by atypical HUS (aHUS), which involves deficiency of complement factors regulating the alternative complement pathway. The incidence of aHUS is far lower than that of than classic HUS.

Case Description: A 19 year old female presented with abdominal pain, bloody diarrhea and oliguria. On admission she was alert and oriented. Vital signs, examination of the heart, lungs and abdomen were normal. Laboratory data: WBC 22 k/uL, Hgb 6.1 g/dL, platelets 290 k/ul, blood urea nitrogen 77 mg/dL, creatinine 7.23 mg/dL, serum LDH 1042 IU/L, haptoglobin undetectable. Coomb's test was negative. Blood smears revealed many schistocytes. A diagnosis of aHUS was made after excluding classic HUS (negative Shiga toxin test) and TTP (ADAMTS13 activity 77%). Blood tests were sent to look for abnormalities in complement factors known to be associated with aHUS. The patient was started on prednisone and plasma exchange. Renal function slowly improved and creatinine eventually fell to 1.5mg/dl. However, the MHA persisted and plasma exchange was continued. The patient then developed nephrotic range proteinuria. A renal biopsy was done which showed features of vascular microangiopathy consistent with aHUS. Complement profiles demonstrated the presence of autoantibodies to complement factor H (CFH) as well as a heterozygous deletion of genes encoding *CFHR1 and CFHR3*. The patient was started on once weekly doses of eculizumab, after which the MHA resolved completely. Plasma exchange and prednisone were discontinued.

Discussion: Atypical HUS can be caused by a genetic defect (caused a *CFH* gene conversion or by a deletion of the genes encoding *CFHR1* and *CFHR3*) or by the presence of autoantibodies to CFH. While most patients have either genomic defect or autoantibodies, this patient has the combination of autoantibodies to CFH as well as a heterozygous deletion of *CFHR1/CFHR3*. The mechanisms responsible, and the clinical implications of this combined abnormality remains to be elucidated.

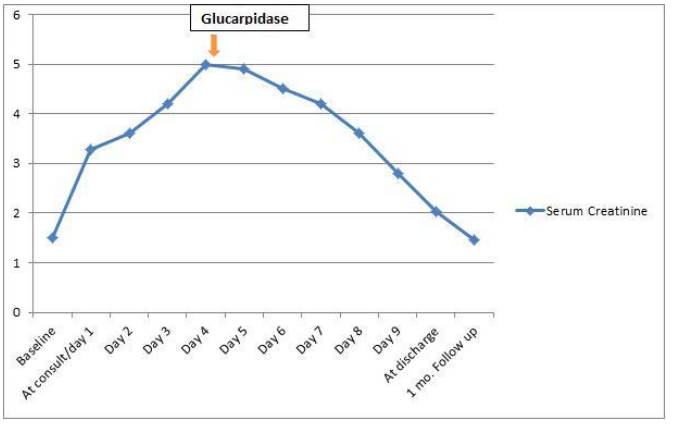
PUB352

Methotrexate Nephrotoxicity Treated with Glucarpidase

Abhilash Koratala, S. Irfan Qadri, Lalitkumar Jaykrishan Mundhra, Rupam Ruchi. *Nephrology, Univ of Florida.*

Introduction: Methotrexate (MTX) is an antimetabolite used in the treatment of malignancies and rheumatologic conditions. High-dose MTX (HDMTX), defined as doses > 500 mg/m,^{2} is implicated in renal toxicity. We report a case of MTX nephrotoxicity successfully treated with Glucarpidase (GP), a recombinant enzyme that inactivates MTX.

Case Description: 67 year old Caucasian male with history of Heart transplant (on Cyclosporine), Hypertension, Chronic Kidney Disease stage 3a likely secondary to calcineurin (CNI) toxicity was admitted for new-onset seizure. He was diagnosed with Post-transplant lymphoproliferative disorder and started on high-dose MTX (8200 mg/day) and rituximab 2 days prior to Nephrology consult for Acute Kidney Injury (AKI). His baseline serum creatinine (Cr) was ~ 1.5 mg/dL. No IV contrast exposure, diarrhea, vomiting, or urinary symptoms. IV sodium bicarbonate & Leucovorin were given with MTX. When we were consulted, Cr was 3.27 mg/dL & urine Ph was 6. The next day, Cr increased to 3.6 & 24-hour MTX level was 26 mcmol/L (markedly elevated). MTX was held and IV hydration was given. Cr continued to rise to 4.2mg/dL (day 3). Decision was made to administer GP on day 4 due to worsening renal function. MTX level on day 5 was 0.69 mcmol/L. His Cr plateaued and trended down to 2 mg/dL at discharge and was 1.47 at 1 month follow up. No renal replacement therapy was needed. Cr trend shown below.



Discussion: HDMTX causes AKI by tubular crystal precipitation, exacerbated by acidic urine & volume depletion. It can also cause transient decline in GFR which may be prolonged in the presence of concomitant nephrotoxins (our patient was on CNI). Even with fluids & urine alkalinization, the risk of HDMTX nephrotoxicity is ~ 2%. Awareness of the utility of GP (FDA-approved) may mitigate the need for dialysis in selected cases of HDMTX renal injury. The drawback of GP is its cost and availability.

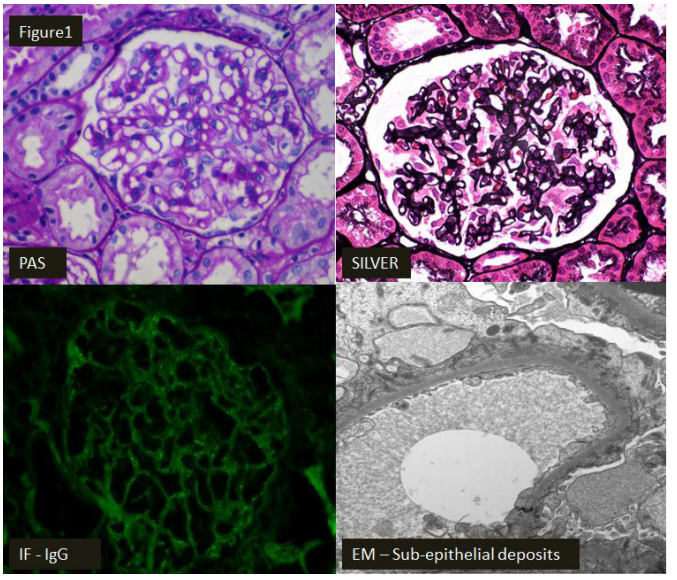
PUB353

Course of Membranous Nephropathy during Multiple Gestations: A Case Report

Abhilash Koratala,[1] Kawther Farouk Alquadan,[1] Dara N. Wakefield,[2] A. Ahsan Ejaz.[1] [1]*Nephrology, Hypertension and Renal Transplantation, Univ of Florida;* [2]*Pathology, Immunology and Laboratory Medicine, Univ of Florida.*

Introduction: Physiological adaptations in Pregnancy (PG) can unmask underlying occult proteinuric renal disease. However, the effect of multiple pregnancies on the course of the disease is unknown. We report the clinical course of a case of idiopathic membranous nephropathy (MN) through multiple pregnancies.

Case Description: 25 year-old Hispanic female was referred for 21gm of proteinuria at 35 weeks gestation during her 3rd pregnancy. She was previously seen at our institution five years ago during her 1st pregnancy when 13gm of proteinuria was recorded at 25 weeks of gestation. At that time, she was treated with oral steroids and delivery was induced at 35 weeks due to intra-uterine growth restriction. Placental biopsy revealed focal, tightly adherent blood clot, consistent with possible abruption. Renal biopsy performed in the postpartum period was consistent with MN.



She was treated with ACEI and at 3-month follow-up she was asymptomatic, without edema and urine protein-creatinine ratio (UPCR) had decreased to 7g/g. She was lost to follow-up for 5 years until this recent admission. In the interim, she apparently had a second successful pregnancy but no data was available. Placental biopsy after the current pregnancy

showed the placenta was critically small for gestational age and had focal intervillous fibrin deposition. At one month post-partum, UPCR was 1.8 g/g, without any treatment. Patient unfortunately was again lost to follow-up.

Discussion: We conclude that spontaneous remission of MN can occur despite physiological changes associated with pregnancy and the natural course of MN probably follows that of non-pregnant individuals. We also provide histological data that these patients may be at increased risk for placento-maternal complications.

PUB354

Not a Malignant or a Granulomatous Process, It's a Lurking Infection: Hypercalcemia with *Pneumocystis jirovecii* Pneumonia

Bhavnish Bucktowarsing,[1] James M. Rajan,[2] Aarthi Rajkumar.[1] *[1]Internal Medicine, Canton Medical Education Foundation/NEOMED, Canton, OH; [2]Nephrology, Kidney and Hypertension, Canton, OH.*

Introduction: 1-25 dihydroxy vitamin D mediated hypercalcemia is observed in granulomatous diseases and many immunocompromised patients are affected. Pneumocystis jirovecii pneumonia (PCP) in HIV patients is rarely implicated as a cause of hypercalcemia through this mechanism.

Case Description: A 74-year-old male presented to us with generalized weakness. He had a calcium level of 13.4 mg/dl, with appropriately suppressed parathyroid hormone (PTH) level (18) and normal PTH-related peptide. Elevation of 1-25 Dihydroxy Vitamin D (155) with a decrease in 25-OH vitamin D (24) was detected. Serum and urine electrophoresis were normal. A bone scan revealed a lesion on the right 7th rib. This was biopsied and found to be negative for malignant cells as well as mycobacterial, fungal, granulomatous and lymphoproliferative disease. His respiratory status declined and he developed acute hypoxic respiratory failure. CT scan thorax revealed bilateral 'ground-glass' opacities and pulmonary nodules. Subsequent bronchoscopy showed organizing pneumonitis with 'cotton-candy' intra-alveolar exudates. Silver stain was positive for PCP. HIV was positive by western blot assay, viral load was 123388 and his CD4 count was 12. No evidence of cytomegalovirus was seen on biopsied specimens. The patient was started on Trimethoprim/sulfamethoxazole and steroids and his Calcium level gradually normalized.

Discussion: Hypercalcemia in HIV patients occurs in the setting of extra renal production of 1-25 dihydroxy vitamin D from granulomatous infection mediated release of cytokines and activation of macrophages. A case report described PCP infection causing hypercalcemia in a renal transplant patient and attributed it to a similar mechanism. Though PCP infection is common in HIV, there have been no reported cases of hypercalcemia in these patients. Exhaustive work up to delineate the cause of elevated calcium led to the discovery of PCP and then HIV in our patient. This case highlights the fact that 1-25 dihydroxy vitamin D mediated hypercalcemia in HIV hosts should raise suspicion for an indolent PCP infection.

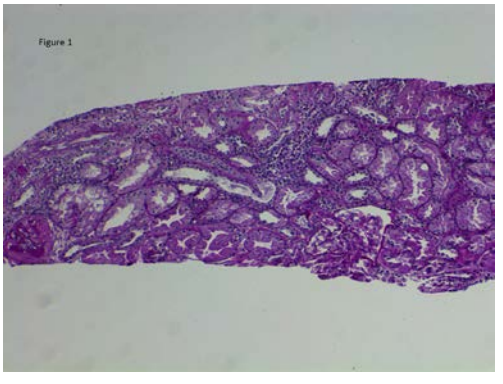
PUB355

Mycophenolate Mofetil for Tubulo-Interstitial Nephritis in Sjogren's Syndrome: A Case Report

Abhilash Koratala, Westley Reeves, Mark S. Segal. *Univ of Florida.*

Introduction: Treatment of renal manifestations of Sjogren's syndrome (SS) is largely based on extrapolations from treatment of other inflammatory conditions and small open-label studies. We report a case of Tubulo-interstitial nephritis (TIN) from SS that remained stable on Mycophenolate mofetil (MMF) for the past 14 years.

Case Description: In 2002, a 25 year old Caucasian woman presented to our clinic for elevated serum creatinine (Scr) for few months and a renal biopsy demonstrating TIN that did not respond to 1 month course of prednisone 60mg/day. In 2000, she was diagnosed of SS. Labs showed Scr of 1.5 mg/dL, non-gap acidosis, potassium 3.4 mmol/L, urine pH 7.5, positive ANA, anti-SSA, anti-SSB and rheumatoid factor. We started MMF 500mg bid along with alkali therapy for RTA. Her Scr remained stable for 2 years & MMF tapered off in early 2004. In late 2004, she was started back on MMF 500mg bid as her Scr increased to 2 mg/dL and her MMF was eventually increased to 1000mg bid. In early 2005, she unilaterally stopped MMF and her Scr increased to 2.7 mg/dL. A repeat renal biopsy showed significant TIN, mesangial expansion without glomerular deposits.



We pulsed her with solumedrol and started back on MMF 1000mg bid. Her Scr stabilized at ~1.8mg/dL. MMF was later tapered to 500mg bid in 2009. She was maintained on MMF of 500mg bid and when we saw her back in 2016, her Scr was 1.9 mg/dL.

Discussion: When our patient was started on MMF in 2002, there was not much experience with it in SS induced TIN and the data favored steroid monotherapy. We chose MMF as a steroid-alternative agent with a better side-effect profile. Though she required prolonged therapy, she did well with stable renal function. Our case supports the use of MMF for SS induced TIN,in line with currently emerging evidence. 14 year follow-up establishes the long term safety of this medication, though results are not necessarily generalizable to all patients.

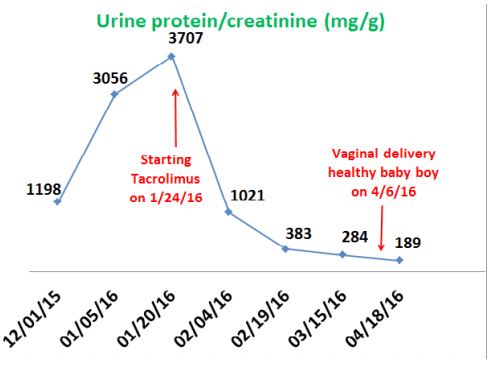
PUB356

The Use of Calcineurin Inhibitors for Lupus Flare in Pregnancy

Le Dung Ha,[1] Yousuf Kyeso,[1] Shubha Shastry.[2] *[1]Internal Medicine - Residency Program, Rochester General Hospital, Rochester, NY; [2]Dept of Nephrology, Rochester General Hospital, Rochester, NY.*

Introduction: When lupus nephritis flares during pregnancy, it becomes challenging to preserve renal function, save the life of the fetus, and avoid teratogenicity. The following case describes a strategy that resolved this dilemma.

Case Description: A 24-year-old woman with biopsy-proven lupus nephritis (class IV) was admitted during her last trimester after deteriorating renal function was discovered on routine blood test. Lupus nephritis was diagnosed in '14 when she presented with skin rash and hematuria. She was treated with Prednisone and Mycophenolate. Renal function improved, but in Mar'15, Mycophenolate was replaced with Azathioprine 200mg BiD because she was not using contraception reliably. In Aug'15, kidney function was stable and Azathioprine was reduced to 150mg BiD with Prednisone 2.5mg daily. Later that month, she became pregnant. For the first 2 trimesters, her creatinine was 0.6mg/dL, but, in early Jan'16, creatinine increased to 1.2mg/dL and she was admitted for 3 days of intravenous steroids. Azathioprine was increased to 200mg BiD and Hydroxychloroquine 400mg daily was added with 60mg Prednisone daily. Her creatinine increased to 1.7mg/dL and urine protein/creatinine ratio increased from 1198 to 3707mg/g. Tacrolimus was chosen for greater immunosuppression with a better safety profile than Mycophenolate or Cyclophosphamide. Within 1 week of starting Tacrolimus, creatinine stabilized at 1.0mg/dL and urine protein/creatinine ratio decreased to 1021mg/g. Her pregnancy went to full-term and a healthy boy was delivered.



Discussion: The heightened risk of lupus nephritis flare during pregnancy is well recognized and Steroids and Azathioprine remain the treatments of choice. In more complicated cases like ours; the use of Tacrolimus can be lifesaving to the mother and the fetus.

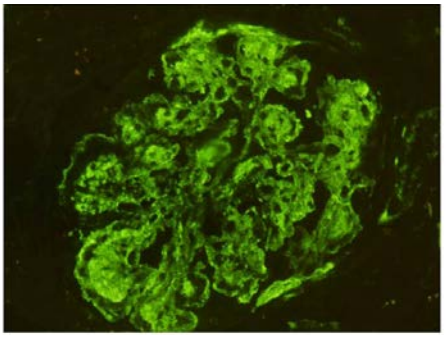
PUB357

C3 Glomerulonephritis [C3GN]Associated with Septic Shock

Hezekiah O. Sobamowo, Elmoutaz T. Mousa. *Nephrology, Texas Tech Univ, Lubbock, TX.*

Introduction: C3GN is characterized by predominant C3 deposits and the absence of immune deposits on immunofluorescence microscopy as well as absence of electron dense deposits on the mesangial and or subendothelial areas. We report a case of C3 glomerulonephritis with associated septic shock.

Case Description: 24y old Hispanic male with past medical history of unknown renal disease. Prior Kidney biopsy in 2009 showed Post infectious glomerulonephritis and possible MPGN type 1. He presented with 3 weeks history of unproductive cough, runny nose, low grade fever, chills, night sweats, SOB/DOE, nausea, vomiting and profuse watery diarrhea with worsening fatigue. He developed severe hypotension requiring pressor support. Urinalysis showed: protein>500, RBC 6, WBC 9,prerenal urinelytes, UPCR 10G, 24Hr urine Protein of 34G with CrCl of 13 and M-Spike on SPEP of unknown significance. Respiratory Viral culture was positive for Influenza Type B. ANA, ANCA, Anti GBM, ASO and HIV serologies were all negative. Low C3 and Normal C4 were noted. Renal Ultrasounds revealed Echogenic small size kidneys. He required hemodialysis twice during the course of the admission. Kidney biopsy revealed obsolescent glomeruli with moderate increase of mesangial matrix and splitting of the glomerular basement membrane. There is moderate tubular loss and atrophy and interstitial fibrosis. Immunofluorescent study revealed 3(+) C3 with diffuse effacement of foot processes.



C5b-9 [MAC] level was elevated while factor H, factor B and C3 nephritic factor were all within normal limits. He was managed with Lisinopril while currently undergoing screening tests to initiate eculizumab.

Discussion: C3 glomerulonephritis, [previously mis diagnosed as Post Infectious GN due to the GBM deposits] is related to dysregulation of alternative pathway of complement. The cause remains relatively unknown.

PUB358

Can Cocaine Cause Lupus Nephritis? Dunia Diaz, Ileana Farrada, Rute C. Paixao. *Cleveland Clinic Florida, Weston, FL.*

Introduction: Cocaine, especially if adulterated with Levamisole, has been associated with several forms of vasculitis. Even though, pauci-immune crescentic glomerulonephritis in association with antineutrophil cytoplasmic antibodies has been the only nephritis described, other forms may soon emerge.

Case Description: A 48 year old Caucasian man with chronic sinusitis was noted to have acute kidney injury (AKI) (creatinine of 2.7mg/dL from baseline of 1.2mg/dL) after having routine lab work. At that time, he was admitted for intravenous hydration. Renal function improved with the intervention, but creatinine did not return to baseline. Work up in the hospital revealed leukopenia WBC 2.9 x 10^9/L, anemia Hb 11.8 g/dL, 2+ protein and 3+ blood on urinalysis, positive ANA of 1:160, positive MPO- and PR3-ANCA, and low C3 88 mg/dL and C4 14 mg/dL levels. Anti-dsDNA and anti-Sm antibodies were negative. On follow up, he only complained of nonspecific arthralgia. Vital signs and physical exam were normal. Urine microscopy showed many RBCs/hpf but no casts. On further questioning, he admitted to chronic cocaine use leading to severe intranasal inflammatory erosion and septal perforation. He then underwent a kidney biopsy, which revealed immune complex mediated membranous glomerulonephritis with focal proliferation. No necrosis, crescents, or thrombi. Immunofluorescence studies showed diffuse membranous and mesangial staining for IgG, IgM, C3, C4, Kappa, and Lambda consistent with lupus nephritis. Further serological work up was negative except for positive anti-chromatin and anticardiolipin IgM antibodies. HIV and hepatitis were negative.

Discussion: In this peculiar case, it is difficult to distinguish with certainty between idiopathic vs drug induced lupus nephritis. Even though cocaine/Levamisole induced lupus nephritis has not been described, there has been case reports that it can lead to cytopenias, low complements, and positive ANA +/- Anti-dsDNA antibody. This patient's presentation of AKI, non-specific arthralgia, cocaine induced septal perforation/severe intranasal inflammatory erosion together with Caucasian ethnicity, no family history of autoimmune disease, and mixed serology makes us wonder if this is more than just idiopathic lupus nephritis.

PUB359

The Saga of Mis-Folded Proteins Ahmed H. Alaini, Saeed Kamran Shaffi. *Nephrology, UNM, Albuquerque, NM.*

Introduction: Amyloid light chain (AL) amyloidosis is a disorder that is characterized by a clone of plasma cells that produce an abnormal protein which deposit on organs. We describe a case of AL amyloidosis with renal involvement, but no bone marrow abnormality.

Case Description: A 74-year-old previously healthy female presented to the hospital with malaise, and swelling of the lower extremities. Physical examination was significant for pallor, normal vitals, a 2/6 ejection systolic murmur and 2+ lower limb edema. Pertinent laboratory data are shown in Figure 1.

Figure 1: Diagnostic data	
Hemoglobin level (gm/dl)	6.7
Creatinine (mg/dl)	2.99
BUN (mg/dl)	31
Serum Albumin (g/dl)	1.2
Serum calcium (mg/dl)	7.7
Urinalysis	Protein +++
Urine protein creatinine ratio (g/g)	15
Urine microscopy	Bland
Serum protein electrophoresis	IgA lambda M-Component of 0.24 mg/dl
Free light chain ratio	1.01 (Kappa 5.61↑, Lambda 5.56↑)

Kidney biopsy showed extensive renal glomerular involvement with amyloidosis. Immunofluorescence and liquid chromatography tandem mass spectrometry showed peptide profile consistent with AL amyloidosis. Bone marrow biopsy was normocellular without plasma cell abnormalities. Fat pad biopsy was negative. Echocardiography was normal. She was started on bortezomib and dexamethasone chemotherapy and is being followed in the nephrology clinic for her progression of kidney disease.

Discussion: Light chain amyloidosis is caused by a small clone of plasma cells which secrete a protein that has a propensity to mis-fold and deposit on organs as beta pleated sheets which stain Congo red on light microscopy. The bone marrow biopsy might be normal because of the paucity of the abnormal cells. This is different from immunoglobulin deposition disease where a large clone of abnormal plasma cells secretes light and/or heavy chains that deposit on renal parenchyma, but do not mis-fold and form beta pleated sheets; thus doesn't stain with congo red. Bone marrow biopsy shows abnormal plasma cells. Plasma cells can also secrete freely filtered light chains that bind to Tam-Horsfall protein and form proteinaceous casts resulting in cast nephropathy. It is imperative to elucidate signs of end organ damage when plasma cell dyscrasias are suspected as the bone marrow biopsy might not reveal plasma cell abnormality.

PUB360

Subscapular Abscess Associated with Buttonhole Cannulation Technique of AV Fistula Abhilash Koratala, S. Irfan Qadri, Volodymyr Chornyy, Kawther Farouk Alquadan, A. Ahsan Ejaz. *Nephrology, Hypertension and Renal Transplantation, Univ of Florida.*

Introduction: Infectious complications of the vascular access are an important cause of morbidity and mortality among HD patients. Type of vascular access and cannulation techniques are risk factors for these complications. Herein, we report an unusual case of subscapular abscess associated with buttonhole cannulation technique (BHCT) of AVF for HD access.

Case Description: 51 y.o. Caucasian male with ESRD secondary to diabetes, on HD using BHCT of RUE AVF for 6 months, presented with a 2 day history of right shoulder pain. Contrast CT demonstrated a complex abscess beneath right scapula without scapular osteomyelitis. Blood cultures were positive for MRSA and appropriate antibiotics were administered. Subsequently, a CT-guided pigtail catheter was inserted to drain the abscess. Culture of the abscess aspirate was also positive for MRSA.TEE was negative for valvular vegetations and US of AVF negative for localized infection. Eventually, symptoms subsided and cultures turned negative. Pre and post-procedure CT images are shown.

In the absence of other etiologies, we suspect that BHCT was the likely source of blood stream infection (BSI) that culminated in subscapular abscess.

Discussion: AVF is the most preferred long term HD access due to lower associated complications. BHCT is gaining popularity due to less pain, aneurysm formation and disfigurement. However, it may pose an additional risk factor for development of infectious complications. In fact, recent evidence suggests a higher rate of local infection and bacteremia associated with BHCT, which is an important concern for immunocompromised dialysis patients. Nephrologists should be aware of these potential risks while recommending BHCT to their patients and have a high index of suspicion for BSI-related complications while evaluating HD patients presenting with unusual symptoms.

PUB361

Acute Kidney Injury with Acute Interstitial Nephritis Nonreversible, Requiring Hemodialysis, Unmasking Primary Amyloidosis Himabindu Valluru, Rahul Valluru, Muner Mohamed, Moro O. Salifu, Mary C. Mallappallil. *Nephrology, SUNY Down State, Brooklyn, NY.*

Introduction: Primary systemic amyloidosis is a monoclonal plasma cell characterized by deposition of extracellular immunoglobulin light chain fibril in various organs. It is a rare disease with broad range of manifestations. Signs and symptoms may not be experienced until the condition is advanced. We report a case of acute interstitial nephritis to an antibiotic which did not resolve despite steroid treatment that unmasked primary amyloid on kidney biopsy.

Case Description: A 64 year-old man with hypertension, presented with confusion, progressive bilateral lower extremity edema and was found to have acute ischemic stroke on CT head. In addition he was also noted to have new onset of systolic heart failure (sCHF). Both CVA and sCHF symptoms were improving but he had a fever with suspected peripheral intravenous line infection for which he was started on prophylactic vancomycin and zosyn. Subsequently, he was noted to have an acute rise in serum BUN and creatinine levels. Acute interstitial nephritis was suspected, antibiotics were discontinued with no improvement in renal function despite being started on prednisone. Hemodialysis was started and a kidney biopsy was obtained which revealed acute interstitial nephritis with interstitial fibrosis/inflammation, tubular atrophy and AL type/lambda light chain restricted amyloidosis. Bone marrow biopsy consistent with lambda restricted plasma cell neoplasm. Echocardiogram revealed cardiac amyloidosis. He progressed to become dialysis dependent while chemotherapy was planned.

Discussion: Upon review of literature, patients with AL amyloidosis presented with symptoms of specific organ involvement at the onset. This is a rare case of a patient who presented with normal renal function and developed acute kidney injury due to acute interstitial nephritis which unmasked an underlying primary systemic amyloidosis with renal and cardiac involvement.

PUB362

Pazopanib Induced Hypertension and Proteinuria: A Case Report

Vikrampal Bhatti, Abhilash Koratala. *Univ of Florida.*

Introduction: Pazopanib (PZ), an oral anti-angiogenic Tyrosine kinase inhibitor targeting vascular endothelial growth factor (VEGF) receptor is one of the first line treatment options for advanced renal cell carcinoma (RCC). Proteinuria (PTN) and uncontrolled hypertension (HTN) from Bevacizumab (a VEGF inhibitor) is well established but there is paucity of such data with the use of PZ. We report a case of PZ induced nephrotic-range PTN and HTN.

Case Description: 68 year old Caucasian male with history of HTN, Coronary artery disease and hypothyroidism presented to our institution with HTN emergency, with a BP of 220/120 and troponinemia from demand ischemia. 5 months prior to presentation, he was diagnosed with metastatic right RCC for which he underwent radical right nephrectomy and started on PZ therapy. His baseline creatinine (Cr) was 1.1 mg/dL, which stabilized at ~1.3 mg/dL after nephrectomy. At presentation, his Cr was 2.3 mg/dL with Urine protein-creatinine (Upc) ratio of ~5.5 g/g. His HTN was well controlled before starting PZ. He was given IV Labetalol without much response and so transitioned to Nitroglycerin drip after which BP improved. His 24-hour urine protein was 4.9 g and serum albumin 3.4 g. His BP improved over the next few days and Cr trended down to 1.7 mg/dL. We diagnosed these as complications of PZ therapy and discontinued the drug. We chose to monitor expectantly without renal biopsy. At 1 month follow up, his serum Cr was 1.6 mg/dL and Upc was ~2.5 g/g.

Discussion: There has been conflicting evidence on whether HTN can be used as a biomarker for efficacy of VEGF inhibitor therapy. However, there is no evidence to say that treatment of HTN in these patients would compromise outcome. Clinicians must monitor all patients treated with VEGF inhibitors for the development of HTN and PTN. Choice of anti-hypertensive depends on patients' co-morbidities. However, it's reasonable to treat with vasodilatory drugs such as ACEIs, Calcium channel blockers & nitrates based on the mechanism of VEGF inhibitors causing decrease in production of Nitric oxide and Prostacyclin in Vascular endothelial cells leading to vasoconstriction. PTN caused by these agents is usually non-nephrotic (unlike our patient) and rarely warrants discontinuation of therapy.

PUB363

Unusual Presentation of an Uncommon Disorder: Type 1 Distal Renal Tubular Acidosis

Joseph H. Zeidan, Gaurav K. Sharma, Luis A. Lopez. *Internal Medicine, Mercy Hospital and Medical Center, Chicago, IL.*

Introduction: Renal Tubular Acidosis (RTA) is an uncommon disorder that rarely occur in adults. Each type of RTA has a different etiology along with a different mode of presentation. As this case will show, following a step-wise approach to acidosis will ultimately lead to a diagnosis.

Case Description: A 33-year old woman presented with abdominal pain and diarrhea for 3 days. On exam, she had tenderness in the RLQ without guarding or rigidity. Labs showed a serum bicarbonate of 14 mmol/L, a normal anion gap of 16, potassium 4.0 mmol/L, urine pH of 6.0. Arterial blood gas was obtained to evaluate the acidosis with a pH 7.32, HCO3 10 and pCO2 19.5. The acidosis worsened to a level of 10 to which the working diagnosis was a RTA. To confirm a urine anion gap was calculated and equaled a positive 32. A continuous bicarbonate infusion was initiated and the level rose to 20. To differentiate the type of RTA a fractional excretion sodium bicarbonate (FeHCO3) was obtained and an undetectable level of bicarb in the urine was found confirming the diagnosis of RTA type 1. The patient was ultimately discharged and followed for further evaluation and treatment of RTA.

Discussion: RTA is defined by a preserved glomerular filtration rate with the inability of the tubules to conduct normal function. The acid-base balance cannot be maintained leading to a metabolic acidosis with a normal anion gap. Type 1 differs from the others by the inability to excrete acid leading to increasing levels of hydrogen ion in the serum. Type 2 is characterized by the kidney's inability to reabsorb bicarbonate. Initial evaluation of a normal anion gap metabolic acidosis involves distinguishing RTA from GI related disorders. History usually provides sufficient information but this case was not clear. Her diarrhea had resolved prior to admission becoming the red-herring of the case. By following step-wise approach toward acidosis confusion was avoided. Using the urine anion gap to differentiate RTA from GI cause, then FeHCO3 to separate type 1 from type 2 led to the diagnosis of type 1 RTA. This case provides insight regarding step-wise approach specifically when history, physical and labs don't formally coincide.

PUB364

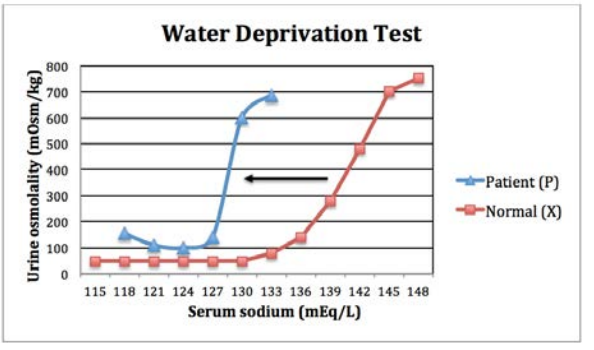
Reset Osmostat after Withdrawal of Chronic Desmopressin

Daniel Christopher Andreoli, William Luke Whittier. *Nephrology, Rush Univ Medical Center, Chicago, IL.*

Introduction: A reset osmostat as a cause of hyponatremia can be found in a variety of clinical settings, including pulmonary and neurological disease, as well as in physiologic circumstances such as pregnancy. We present a case of a 72-y/o Caucasian man with a longstanding history of self-medicating with desmopressin who presented to the hospital with profound hyponatremia. On discontinuation of desmopressin, he was found to have a reset osmostat. We theorize that his reset osmostat may have developed secondary to longstanding use of desmopressin.

Case Description: A 72 y/o male physician presented with symptomatic atrial fibrillation and a serum sodium concentration (SNa^+) of 115 mEq/L. His past medical history was notable for ten years of "polyuria" for which he self-prescribed oral desmopressin, in spite of not having formal urinary measurements or testing. Prior to these practices, his SNa^+ was 140 mEq/L. His oral desmopressin was discontinued on admission and D5W infusion was started to blunt the expected brisk risk in SNa^+. On day 1 of admission, his SNa^+ and urine osmolality (Uosm) were 121 mEq/L and 110 mOsm/kg. By day 2 of admission, his SNa^+ and Uosm were 127 mEq/L and 142 mOsm/kg. A twelve-hour water deprivation test was performed.

Upon water deprivation, his daily urine output decreased from five liters to one, with an increase in his urine osmolality to 685 mOsm/kg while his SNa^+ stayed constant at 130 mEq/L. His SNa^+ remained between 129-132 mEq/L for the rest of the hospitalization and on follow-up (See Figure).



Discussion: A reset osmostat was diagnosed by demonstrating normal urinary dilution at a SNa^+ of 110-127 mEq/L but with urinary concentration at a SNa^+ of 130 mEq/L. We hypothesize that this patient's reset osmostat may have developed secondary to prolonged exposure to exogenous desmopressin.

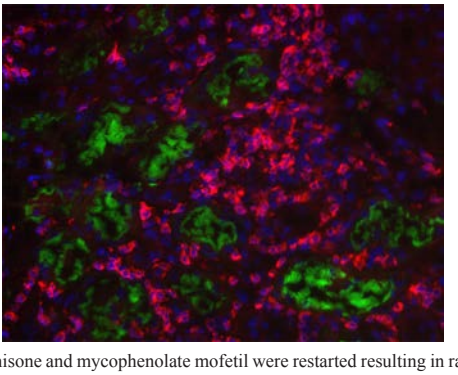
PUB365

Urinary Excretion of a1 Microglobulin Is Not an Accurate Marker of Tubulointerstitial Nephritis

Anneke Bech,[1] Michiel W.P. Bleeker,[3] Meyke Hermsen,[2] Bart Smeets,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center; [2]Pathology, Radboud Univ Medical Center; [3]Nephrology, Bernhoven Hospital.*

Introduction: Tubulointerstitial nephritis (TIN) is a frequent cause of kidney injury. Kidney biopsy is considered the golden standard for diagnosis, however cannot be used for guiding treatment and diagnosing relapse. Serum creatinine is being used but is neither sensitive nor specific. Urinary excretion of alpha1microglobulin (a1m) reflects tubular inflammation and may be a promising tool. Median urinary a1m excretion in 13 patients with suspected TIN indeed was elevated (147 mg/10 mmol creatinine, IQR 98-201). The following case however questions its use in patients with TIN.

A 66 year old lady was evaluated for a rise in serum creatinine. She did not have complaints and did not use any drugs. Her medical history revealed Sjogren's syndrome with two episodes of TIN. The first episode of biopsy proven TIN was in May 2010 for which she was succesfully treated with oral prednisone for 18 months. In October 2012 she developed a relapse with a rise in serum creatinine up to 141 µmol/l. She received oral prednisone and mycophenolate mofetil until June 2015. Since then serum creatinine started to rise from 105 µmol/l to 155 µmol/l. A TIN relapse was considered less likely in view of an a1m excretion of only 47 mg/10 mmol creatinine. A kidney biopsy was performed, which showed an active TIN with multiple infiltrating lymphocytes in proximal tubules. The proximal tubules had normal brush borders and revealed normal staining for megalin (not shown). **Figure legend:** Kidney biopsy with staining for CD3 (lymphocytes) and lectin (brush border) showing active inflammation in the cortex.



Oral prednisone and mycophenolate mofetil were restarted resulting in rapid decrease of serum creatinine.

Discussion: This case shows that a (near) normal urinary excretion of a1m does not rule out active TIN.

PUB366

An Unusual and Fatal Case of Cryptococcal Infection in a Renal Transplant Recipient Yorg Al Azzi, Ibadete Sulejmani, Geoffrey K. Dube. *Medicine, Columbia Univ, New York, NY.*

Introduction: Disseminated cryptococcal infections are a known complication of immunosuppression. However, the presentation can be atypical and can lead in some cases to fatal outcomes. We present here a case of a renal transplant patient who initially presented for evaluation of abdominal pain, was suspected to have military TB but succumbed to splenic rupture in the setting of disseminated cryptococcal infection with lung, liver and renal allograft involvement.

Case Description: 58yo M ESRD 2/2 to type 2 DM,s/p LRRT from his daughter in 11/14(Campath induction, maintained on tacrolimus and mycophenolic acid). Seven months post transplant, he experienced epigastric pain with occasional dry heaves for 1 wk, and noted that this pain was persistent and more intense than his usual reflux. On presentation,CT of the abdomen was unremarkable except for military lesions at the lung base suspicious for TB. His review of systems was positive for night sweats. He worked at a prison and had never had a positive PPD. CT chest and abdomen showed miliary nodules throughout the lungs, two cavitary lesions on the peripheral lung and splenomegaly with nonspecific patchy hyperdense foci likely due to blood products. Sputum cultures were negative for AFB. He was started empirically on anti-TB therapy. One day later, he developed hypotension associated with an acute drop in his hemoglobin from 11 to 8.5. He had a PEA arrest and expired. The next day,his serum cryptococcal antigen was reported to be positive with a titer of >1:1024. His blood and sputum cultures remained negative for AFB. Autopsy showed diffluent spleen with hemorrhagic infarcts and splenic rupture, necrotizing cryptococcal pneumonia with miliary lesions through the parenchyma and pleura, necrotizing cryptococcal hepatitis, cryptococcal myocarditis, and infiltration of the renal allograft with Cryptococcus, consistent with disseminated Cryptococcal infection.

Discussion: To our knowledge, this is the first case of disseminated cryptococcal infection in a renal transplant recipient causing death by splenic rupture. This case highlights the need to be aware of atypical presentations of cryptococcal infection in immunosuppressed patients, especially renal transplant recipients.

PUB367

Is It All in the Head? - An Interesting Presentation of Hyponatremia John Sy, Mitchell R. Lunn. *Div of Nephrology, Dept of Medicine, UCSF, San Francisco, CA.*

Introduction: Inpatient-onset hyponatremia can present an interesting diagnostic and management challenge. We present a case of rapid-onset hyponatremia caused by trimethoprim and review reports of this uncommon occurrence.

Case Description: A 32F was admitted for altered mental status and diagnosed with anti-NMDA receptor encephalitis. A culprit teratoma was excised on hospital day 15. On day 19, she was transferred to our hospital due to limited response to treatment with immunoglobulin and high-dose steroids. On day 23, she was started on a steroid taper, lansoprazole, trimethoprim/sulfamethoxazole, fluconazole, calcium/vitamin D, and tenofovir (to prevent latent hepatitis B reactivation). On day 27, her serum sodium fell to 117 from 133 the day prior, she seized, and nephrology was consulted. Vitals were notable for a BP 113/69, HR 82, temperature 36.8°C, and SpO_2 100% on ambient air. She was obtunded, non-responsive, but euvolemic. Laboratory tests revealed creatinine 0.46, potassium 3.6, bicarbonate 23, glucose 105, magnesium 1.7, urine sodium 159, and urine osmolality 532. TSH was 1.19 and AM cortisol was 17. Aldosterone and renin were 5 and 0.59, respectively. CT head and chest were unremarkable. She was started on hypertonic saline and all medications except steroids were discontinued. On day 28, the patient developed hypotension requiring vasopressor support and continued on hypertonic saline. On day 29, she was weaned off of vasopressors, and serum sodium normalized to 141. She was discharged on day 33 without need for salt supplementation or fluid restriction to a nursing facility.

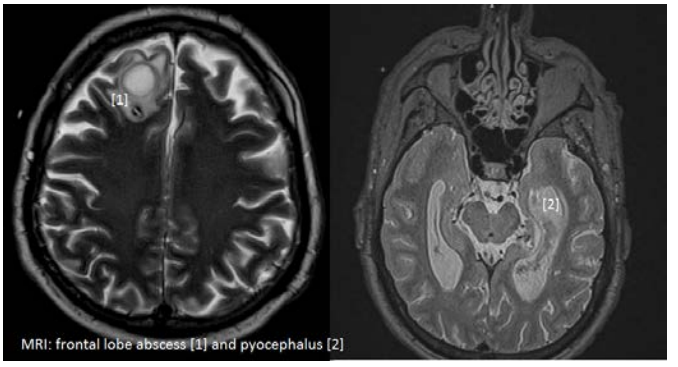
Discussion: Although this presentation was suggestive of SIADH and she was managed accordingly, her hypotension suggested a salt-wasting disorder. Resolution of her hyponatremia after stopping of medications suggested an iatrogenic etiology, and literature review identified trimethoprim as the likely culprit. This case highlights that SIADH remains a diagnosis of exclusion; alternative etiologies should be sought if clinical findings are inconsistent with the presumed diagnosis.

PUB368

Pauci-Immune Glomerulonephritis in the Very Elderly: To Treat or Not to Treat? Volodymyr Chornyy, Abhilash Koratala, S. Irfan Qadri, Rupam Ruchi. *Nephrology, Univ of Florida, Gainesville.*

Introduction: Anti-Neutrophil cytoplasmic antibody (ANCA) positive renal vasculitis constitutes ~ 20% of biopsied acute kidney injury (AKI) cases in the very elderly. Treatment strategies in this population are not well defined. Herein, we report a case of disseminated Nocardial brain abscess as a complication of immunosuppression (IS).

Case Description: An 80 year old Caucasian man with CKD stage 3b due to hypertension & biopsy proven cANCA associated glomerulonephritis (GN), presented with new-onset seizures, altered mental status, AKI & non-nephrotic range proteinuria. Four months prior to presentation, he was diagnosed with ANCA-GN & received 2 monthly doses of IV Cyclophosphamide (~1g/dose). Additional doses were held due to poor tolerance. Prednisone 40mg/day was continued & SCr improved from 3 mg/dl at initial presentation to ~ 2 mg/dL. CT/MRI of the brain revealed multiple intracranial axial lesions suggestive of abscesses with extension of the temporal lobe lesion into the ventricular system causing secondary pyocephalus.



Cultures obtained from brain biopsy were positive for Nocardia. Unfortunately, his mental status and overall condition deteriorated and the patient succumbed to infectious complications.

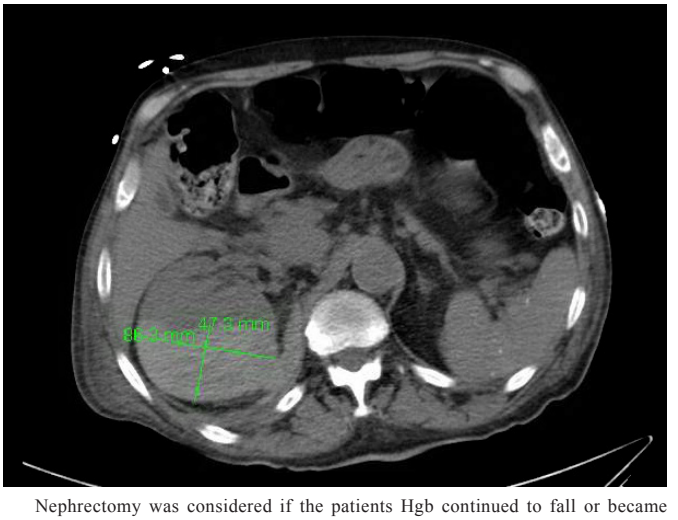
Discussion: Response to therapy in elderly patients with ANCA-GN is variable and there exists a substantial risk of mortality due to the disease state and/or treatment related complications. Current data regarding ANCA vasculitis shows up to 90% of untreated patients will become dialysis dependent or die within the 1st year after diagnosis. Infectious complications are reported in up to 40% of those who are treated with IS resulting in impaired quality of life & an increase in the cost of healthcare. Clinicians should carefully weigh the risks and help guide decision-making regarding the use of IS in this age group.

PUB369

An Unusual and Spontaneous Reason for Anemia and Kidney Failure Joseph H. Zeidan, Gaurav K. Sharma, Lana Akkari. *Internal Medicine, Mercy Hospital and Medical Center, Chicago, IL.*

Introduction: Often anemia and acute kidney injury are common findings in hospitalized patients. Etiology are usually mutually exclusive and then have tailored treatment. During the evaluation of this case an interesting and rare prospective is shown when these two conditions coincide.

Case Description: A 74 year-old man was admitted and treated for pneumonia, but his hospitalization was marred by complications that began with a hemoglobin drop from 13.1 gm/dL to 10.7 by day 2. He denied melanotic stool or other signs of bleeding, two sets of FOBT were negative and the LDH and haptoglobin were normal and Coombs negative. Reticulocyte count showed a proper bone marrow response and physical exam was benign. By Day 5 the Hgb fell to 6.8 gm/dL, so was transfused a unit of packed RBC making it 7.5 but subsequently fell to 6.7. Simultaneously, the creatinine increased from 0.8 mg/dL to 2.1 over the same days despite no offending agent. Suspecting kidney pathology, evaluation with an abdominal CT scan revealed a subcapsular right renal hematoma measuring 8.6cm x 4.7 x 13.4 with mass effect on parenchyma.



Nephrectomy was considered if the patients Hgb continued to fall or became hemodynamically unstable, however neither were the case. The patients hemoglobin eventually stabilized and creatinine would return to baseline.

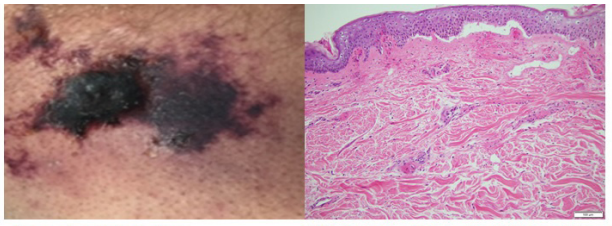
Discussion: Spontaneous renal hematomas are rare and difficult to diagnose. A meta-analysis, by Zhang *et al,* showed that renal hematomas are normally associated with an underlying tumor, vascular disease or infection, but only 6.7% were idiopathic. In this patient, he did not possess any underlying disorder making a diagnosis as this difficult to suspect. Understanding the laboratory findings of this case, the positive and negative, ultimately led to suspicious pathology involving the kidney. The end result was using a modality of 100% sensitivity to diagnoses a spontaneous renal hematoma.

PUB370

The Utility of Skin Biopsy in Dialysis Patients with Necrotic Skin Lesions David Levy, Fatima Khalid, Sai Subhodhini Reddy, Scott E. Liebman. *Medicine - Div of Nephrology, Univ of Rochester Medical Center, Rochester, NY.*

Introduction: Calciphylaxis is a rare but devastating condition that mainly affects patients with end stage renal disease (ESRD). Clinically, diagnosing calciphylaxis can be challenging as it may present similarly to peripheral vascular disease, also common in dialysis patients.

Case Description: A 39 year old male with a history of ESRD due to type 1 diabetes on thrice weekly hemodialysis (Kt/V of 0.7 in the setting of many missed sessions), hypertension and severe peripheral vascular disease complicated by a left lower extremity amputation, presented with necrotizing penile lesions, which ultimately required partial penectomy. Pathology was consistent with ischemia. He was also noted to have a pericardial rub which was managed by daily dialysis to partial effect. Several months later, he presented once again with painful, necrotic thigh lesions. He was noted to have bilateral thigh lesions (see figure) in the setting of inadequate dialysis (Kt/V of 1.1 and many missed sessions), and a recurrent pericardial rub. Due to concern for calciphylaxis a skin biopsy was performed. The biopsy showed pandermal necrosis and intravascular thrombi; findings consistent with calciphylaxis rather than ischemia. His PTH was noted to be 181pg/ml, serum calcium of 7.6mg/dl and phosphate was 7mg/dl which improved to 4.8 after increasing his dose of Sevelamer. He was started on sodium thiosulfate and a pain regimen.



Necrotic thigh lesion

Skin biopsy: Necrosis of the epidermis and upper dermis. A blood vessel also shows a small thrombus

Discussion: Our case demonstrates the potential benefits of obtaining a skin biopsy of dialysis patients presenting with necrotic skin lesions. Since most patients with ESRD have complex medical histories including vascular disease, it can be challenging to clinically differentiate between calciphylaxis and ischemic disease.

PUB371

A Case of Epstein-Barr Virus Associated Post-Transplant Lymphoproliferative Disorder Appearing in Cervix Hafiz Ali Sroya, Rawan T. Al-Odat, Eduardo A. Alas, Antonia Harford, Pooja Singh. *UNM School of Medicine.*

Introduction: PTLD is the most common malignancy complicating solid organ transplantation (excluding non melanomatous skin cancer and in situ cervical cancer). Recent reports suggest that PTLD is increasing in frequency. Manifestations include involvement of the GI tract, lungs, skin, liver, CNS and the allograft itself. PTLD involving the cervix in a renal transplant recipient has not been reported previously, to our knowledge.

Case Description: A 48 YO female with ESRD due to IgA nephropathy underwent DDKT 13 years ago with thymo induction and subsequent maintenance immunosuppression with Tacrolimus & MMF and had excellent graft functions. Two years post-transplant, renal allograft biopsy performed for evaluation of proteinuria, hematuria and worsening renal function revealed recurrence of IgA. Patient was managed conservatively and graft functions returned to baseline. Eleven years post transplantation, during routine healthcare maintenance, she was found to have an abnormal Pap smear leading to colposcopy and cervical conization that showed cervical leiomyomata & residual high-grade CIN. So MMF was stopped and Tacrolimus was switched to Sirolimus (dose 0.5mg daily). Follow-up Pap smear was normal at 6 months; however at one-year was again abnormal with positive high-risk HPV. A cervical cone biopsy showed polymorphic EBV-associated PTLD, rich in B & T cells. She was treated with further reduction in her immunosuppression with Sirolimus dose decreased by 50% to 0.5mg every other day. A repeat biopsy of the cervix after 3 months showed resolution of PTLD.

Discussion: PTLD can involve atypical organs such as the cervix as in our case. Mostly it occurs in the first year post-transplant but in our case PTLD occurred 13 years post-transplant. Although Tacrolimus carries a significantly higher risk of PTLD, in our case, PTLD developed while on Sirolimus. Risk stratifications and optimal treatment strategies specific to kidney transplantation are lacking but immunosuppression reduction is the most accepted treatment and may result in resolution of the disease process as in our case. This case demonstrates the importance of continued cancer surveillance throughout the post renal transplant course.

PUB372

Chloride and Acid-Base Status as a Hint to Diagnose Parathyroid Adenoma Min Zhuo, Jiahua Li. *Internal Medicine, John H Stroger Jr. Hospital of Cook County, Chicago, IL.*

Introduction: PTH level is the first branching point in approaching hypercalcemia. When PTH level is equivocal, a detail medical history could be very helpful. However, medication history could also mislead us to a premature diagnosis. This case we used chloride and acid-base status to correct a misdiagnosis of Milk-Alkali syndrome and found a subtle parathyroid adenoma.

Case Description: A 66-year-old woman presented with a 3-day history of nausea, fatigue, and frequent urination. She denied dysuria, vomiting, abdominal pain, or fevers. She reported taking 6 to 20 tabs of "Tums" (calcium carbonate) daily for the past four months. Her vitals were within normal limit except for heart rate of 110 bpm. The thyroid gland was normal size, and no neck nodules were palpable. Rest of the cardiopulmonary and abdomen exams were unremarkable. Her metabolic panel was remarkable for Na 141 mEq/dl, K 3.2 mEq/dl, Cl 111 mEq/dl, $HCO3^-$ of 19 mmol/dl, anion gap 11, BUN 26 mg/dl and creatinine 1.1 mg/dl, Ca^{2+} of 14.8 mg/dl, Mg^{2+} of 0.7 mg/dl, and Phos 1.2 mg/dl. PTH was 7 pg/ml. Urine pH was 5.5. Urine electrolytes panel was UNa 77 mEq/dl, UCl 85 mEq/dl, UK 17 mEq/dl, yielding a UAG of +9. 24-hr urine calcium was 208 mg. Her calcium normalized to 8.2 mg/dl and bicarbonate normalized to 23 mEq/dl concomitantly with 4-day intravenous hydration. Potassium, phosphorus, and magnesium were replaced. Her OTC multivitamins and calcium carbonate were discontinued, but her repeat BMP remained hypercalcemic in the post-hospital clinic visit. Finally, a sestamibi parathyroid scan revealed a small parathyroid adenoma.

Discussion: PTH was low normal which limited its use for differentiating causes of hypercalcemia. At a glance, patient's history suggested Milk-Alkali syndrome, which was described as excessive calcium and alkali intake and impaired calcium excretion by alkalosis, as the cause of the hypercalcemia. However, patient's hypercalciuria and metabolic acidosis went against Milk-Alkali syndrome. PTH can inhibit Na-H exchange in distal tubule causing increased bicarbonate wasting, hyperchloremia and type 1 RTA. Hyperchloremic metabolic acidosis led to an investigation of PTH-dependent mechanism and the discovery of a subtle parathyroid adenoma.

PUB373

A Case of Wilson's Disease Presenting with Acute Renal Failure Requiring Continuous Veno Venous Hemofiltration Nick D. Youssefi. *Dept of Nephrology, Dartmouth Hitchcock, Lebanon, NH.*

Introduction: Wilson's disease is due to a genetic abnormality inherited in an autosomal recessive manner that disrupts cellular copper transport. Impaired biliary copper excretion leads to accumulation of copper in several organs most commonly the liver, brain, and cornea. Renal failure associated with Wilson's disease has been reported but is very rare.

Case Description: We present a case of a 47 year-old-man who presented to the hospital with chronic progressive abdominal pain for the past 4 months. Patient had a liver biopsy 1 month prior suggestive of Wilson's disease. The patient endorsed 3 weeks of progressive lower extremity swelling. Patient had associated lightheadedness, fatigue, and decreased appetite. Vital signs on admission: BP 100/60mmHg HR 77 T 97.7F 98%RA. Physical exam notable for jaundice, ascites, 2+ edema. No Kayser-Fleischer rings noted. Within 48 hours, the patient developed respiratory failure requiring intubation and hypotension requiring vasopressor support. CXR revealed pulmonary edema. CT abdomen revealed a stable renal cyst, no hydronephrosis. Blood, urine, sputum, ascites fluid cultures were all negative. Serum ceruloplasmin level was 29.9 mg/dL, serum copper 0.96 mcg/mL, 24 hour urine copper excretion 561 mcg/spec. Serum creatinine 3.96mg/dL with baseline 1.24mg/dL. Urine microscopy revealed few granular casts and renal tubular epithelial cells. No renal biopsy was performed. Patient developed oligoanuric renal failure requiring continuous veno-venous hemofiltration (CVVH) support. Patient received plasmapheresis in conjunction with CVVH. No penicillamine given. Patient was transferred to an outside hospital for liver transplant evaluation. On transfer, patient was still intubated, on vasopressors, and oliguric.

Discussion: The association of renal failure and Wilson's disease has been reported in only a few case reports worldwide. Renal involvement in Wilson's disease frequently causes damage to the proximal tubule, acidification defects, and decreases in filtration rate or effective renal blood flow. Our patient developed oligoanuric renal failure requiring CVVH and plasmapheresis.

PUB374

Acidotic Hypercapnia: A Case Series of Acidosis Driven Respiratory Muscle Dysfunction Catherine King, Rahul Mukherjee. *Respiratory Medicine, Birmingham Heartlands Hospital, Birmingham, West Midlands, United Kingdom.*

Introduction: It is commonly assumed that respiratory acidosis follows the development of acute hypercapnia. This case series describes 4 patients with hypercapnia secondary to metabolic acidosis demonstrated through serial arterial blood gases (ABG) treated with Non-invasive Ventilation (NIV).

Case Description: Case 1: A 64 year-old with diabetes on metformin and chronic obstructive pulmonary disease (COPD) with pneumonia and non ST-elevation myocardial infarction. Initial ABG - metabolic acidosis which deteriorated despite standardised treatment, with onset of hypercapnia and NIV requirement. Case 2: A 75 year-old with COPD admitted with breathlessness secondary to congestive cardiac failure required NIV to treat acidotic hypercapnia. Applying the Henderson-Hasselbach equation to his ABG, predicts bicarbonate 29mmol/L not 17.9, confirming metabolic acidosis. Case 3: A 78

year-old with severe COPD and shortness of breath/cough, treated for acute exacerbation COPD. Initial ABG - metabolic acidosis but later developed progressive hypercapnia requiring NIV. Case 4: A 60 year-old obese lady with drowsiness/agitation, treated for sepsis. ABG - mixed respiratory/metabolic acidosis due to combination of obstructive sleep apnoea and non-steroidal anti-inflammatory drug-induced acute on chronic renal failure. NIV was later commenced for worsening hypercapnia.

Case	Initial ABG	Pre-NIV ABG	Post-NIV ABG
1	pH 7.336, PaO2 11.2, PaCO2 5.56, HCO3 20.8, lactate 1.4	pH 7.143, PaCO2 11.8, PaO2 8.76, HCO3 22.8, lactate 2.7	pH 7.462, PaCO2 5.7, PaO2 7.91, HCO3 29.8 lactate 0.9
2	pH 7.06, PaCO2 12.0, PaO2 8.55, HCO3 17.9		pH 7.43, PaCO2 5.10, PaO2 8.11, HCO3 25.4
3	pH 7.30, PaCO2 6.06, PaO2 8.73, HCO3 20.8	pH 7.066, PaCO2 12.3, PaO2 8.52, HCO3 18.2	pH 7.458, PaCO2 6.12, PaO2 7.48, HCO3 31.1
4	pH 7.224, PaCO2 5.93, PaO2 11.5, HCO3 17.2	pH 7.26, PaCO2 8.0, PaO2 10.3, HCO3 23.6	pH 7.464, PaCO2 4.75, PaO2 9.43, HCO3 21.8

Discussion: Acidotic hypercapnia is an under-recognised subtype of respiratory failure; in all 4 cases this acidosis reversed completely with NIV and optimal medical management. Acidosis is a known cause of muscular dysfunction and may contribute to respiratory muscle fatigue. We postulate a similar causation of respiratory failure described previously due to circulatory shock (Type 4 respiratory failure) which resolves when shock is corrected. Further trials are required to decide the best management of acidotic hypercapnia.

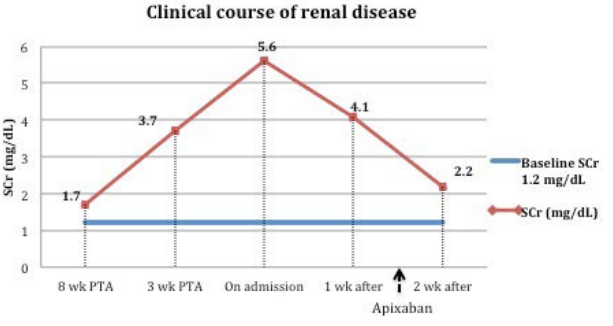
PUB375

Steroid May Be an Effective Treatment for Warfarin Related Nephropathy

Natanong Thamcharoen,[1] Ridhmi P. Rajapakse,[1] Raquel M. Rosen,[1] Vivette D. D'Agati.[2] *[1]Medicine, Bassett Medical Center, Cooperstown, NY; [2]Pathology and Cell Biology, Columbia Univ College of Physicians and Surgeons, New York, NY.*

Introduction: Warfarin-related nephropathy (WRN) manifests as acute kidney injury (AKI) from over-anticoagulation, mostly INR > 3, causing glomerular hemorrhage and tubular obstruction by red blood cell (RBC) casts and oxidative stress damage to tubules. We report a case of a patient with biopsy-proven WRN and therapeutic INR.

Case Description: An 83-year-old man with CKD stage 3A, coronary artery disease, atrial fibrillation, admitted for AKI with creatinine (Cr) of 5.6mg/dL, tea-colored urine. He had several hospitalizations over the past 6 months and was exposed to multiple antibiotics. Last antibiotic use was a month ago. He had gastric bleeding (GIB) 4 months ago from INR of 6 resulting in hypotension and AKI with renal recovery to baseline (1.2 mg/dL). Lab showed rapidly rising Cr over several weeks.



INR was within therapeutic range after the GIB. Urinalysis showed RBC presented since 4 months ago. Urine protein creatinine ratio was 1.8 g/g. Urine sediment showed dysmorphic RBC and RBC casts. Serologic tests and complement levels were all normal. He received steroids for presumed vasculitis related nephropathy. Renal biopsy later showed diffuse acute tubular injury and numerous RBC casts, suggestive of WRN without evidence of glomerulonephritis or allergic interstitial nephritis. Cr improved with steroid therapy which was gradually tapered. Later, warfarin was switched to apixaban.

Discussion: When other causes have been excluded, WRN should be considered as a cause of AKI despite therapeutic INR. The standard treatment includes reversal of coagulopathy and supportive care. Interestingly, prednisone was proven to be effective in our patient, however its role should be further evaluated.

PUB376

Hypernatremia after Bariatric Surgery: A Case of NDI with Unknown Etiology

Jiandong Zhang,[1] Itunu O. Owoyemi,[1] Reginald Ifeanyi Obi,[2] Hsiao Ling Lai.[2] *[1]General Internal Medicine, Vidant Medical Center, Brody School of Medicine, East Carolina Univ, Greenville, NC; [2]Div of Nephrology and Hypertension, Vidant Medical Center, Brody School of Medicine, East Carolina Univ, Greenville, NC.*

Introduction: Hypernatremia is a common electrolyte disorder with incidence of about 0.3-5.5% in hospitalized patient, bearing 30-80% mortality in ICU. Thus, appropriate recognition of underlying etiology is vital to the appropriate treatment of this disorder.

Case Description: Here we report 56 yo CM with Hx of T2DM, morbid obesity, who was referred to nephrology consult for hypernatremia (day 45 of admission). He was initially present for gastric bypass operation, and complicated for EJ tube leakage which require multiple OR visits for drainage manipulation. His lab revealed a serum sodium in the range of 140-150 prior to this episode of 160-165. Serum osmolality as 320-330 mOsm, Uosm 100-200 mOsm on multiple occasions, UA revealed a UNa+ of 20s mmol/L, UCr 18.18 mg/dL. Negative for protein or glycosuria. His free water deficit was calculated as 11L, D5W was initiated to replace free water. Shortly after, patient then developed massive volume of urinary output > 4L per day. DDAVP was administered without improvement in UOP or osmolality, suggesting that nephrogenic diabetes insipidus is likely to attribute to this case. Thereafter, HCTZ and amiloride was started and polyuria-polydipsia was gradually controlled in a period of about 3 weeks course. Pt was educated to have a good management of osmotic load and water intake, and discharged with HCTZ 12.5mg bid.

Discussion: DI is a rare cause of hypernatremia, but inherits with unique interventions. In adult settings, most of DIs are acquired form secondary to medications or electrolyte abnormalities. Here, we ruled out lithium use, hypokalemia or hypercalciuria. Genetic test for possible mutations in patient and his family was discussed. Nephrogenic diabetes insipidus (NDI) is a rare kidney disorder that may be inherited or acquired, caused by impaired ability of kidney collecting duct tubules to concentrate urine. Management for NDI paradoxically involves diuretics beyond correction of modifiable secondary contributing components.

PUB377

A Case of Tenofovir-Induced Acute Kidney Injury (AKI) with Fanconi Syndrome

Michael J. Rogers,[1] Allison Bigeh,[2] Elise J. Barney.[3] *[1]Internal Medicine, Banner Univ Medical Center, Phoenix, AZ; [2]Clinical Medicine, AT Still Univ, Kirksville, MO; [3]Nephrology, Phoenix VA Healthcare System, Phoenix, AZ.*

Introduction: Tenofovir disoproxil fumarate (TDF) is a nucleotide-reverse transcriptase inhibitor used in HAART therapy for HIV. TDF is filtered by the glomerulus and secreted by proximal tubular epithelial cells. Nephrotoxicity, although rare, is well described, specifically causing proximal renal tubular acidosis or rarely Fanconi Syndrome (FS). The suspected mechanism is via inhibition of tubular mitochondrial DNA polymerase. Here we report a case of TDF-induced FS in an HIV+ patient with acute renal failure.

Case Description: A 65 year-old non-diabetic male with history of hypertension and HIV on HAART therapy presented with acute hallucinations, 2 months of oliguria and admitted with AKI. Labs showed BUN 66, creatinine 6.79, total CO2 16, anion gap 15, and normal potassium, phosphorous, and lactate. Urinalysis showed glycosuria and proteinuria; urine protein/creatinine ratio was 829 mg/g. Serologies and workup, including urine microscopy were negative. HgA1c was normal. HIV RNA was 55 copies/mL. Renal ultrasound was unremarkable. TDF was held; however the patient became anuric and required hemodialysis. Two months later, he is non-oliguric but remains dialysis-dependent. Recent urinalysis showed persistent glycosuria and 24-hour urine confirmed proteinuria of 815 mg. Renal biopsy showed acute tubular injury with diffuse early fibrosis. Chart review revealed 7 years of glycosuria, subnephrotic proteinuria with chronic renal dysfunction over the last 2 years (creatinine 1.24-1.39), and recent hypophosphatemia. The consistent factor was TDF therapy for many years.

Discussion: There are limited data regarding TDF-induced FS and its course, although it is thought to be reversible after drug cessation. Chronic kidney disease due to TDF has been debated. As TDF is a cornerstone of HAART, early recognition of FS is crucial. This case highlights the importance of monitoring kidney function closely, as proximal tubule dysfunction may present indolently and could be permanent if diagnosis is delayed.

PUB378

Echocardiographic Evidence of Dialysis-Related Amyloidosis Presenting as New-Onset Ascites and Liver Failure

Carsten R. Hamann,[1] Nicole Syed,[2] Nicole Kristine Shah-Ghassemzadeh,[1] Seyed-Ali Sadjadi.[1] *[1]Dept of Internal Medicine, Loma Linda Univ Medical Center, Loma Linda, CA; [2]Dept of Family Medicine, Univ of California: Riverside, Morreno Valley, CA.*

Introduction: Dialysis-associated amyloidosis(DRA) is a common but infrequently reported complication of long term hemodialysis(HD) and peritoneal dialysis, caused by deposition of beta-2-microglobulin(B2M) amyloid fibrils in articular and visceral tissue. B2M is a ~12,000 dalton glycosylated polypeptide, inefficiently filtered by traditional HD filters, notably low-flux filters. DRA most commonly presents with articular involvement, notably carpal tunnel syndrome and scapulohumeral periarthritis. Visceral involvement of DRA is rarely reported.

Case Description: We present the case of a 33 year old female with end stage renal disease(ESRD) secondary to hemolytic uremic syndrome on HD, hypertension(HTN), pulmonary HTN, and recently diagnosed diastolic heart dysfunction who presented to our university-based medical center with a 1 month history of worsening abdominal distention and pain. Abdominal ultrasound showed hepatic cirrhosis with ascites. Peritoneal fluid analysis was consistent with cardiogenic ascities with a serum-ascites albumin gradient of 1.2. Echocardiogram showed hyperdynamic left ventricular function, an ejection fraction of >70%, right ventricular systolic pressure ~45 mmHg, severe dilation of all four chambers, and a speckled appearance of left ventricular walls suggestive of amyloidoisis. Serum B2M was elevated to 64.8 mg/dl.

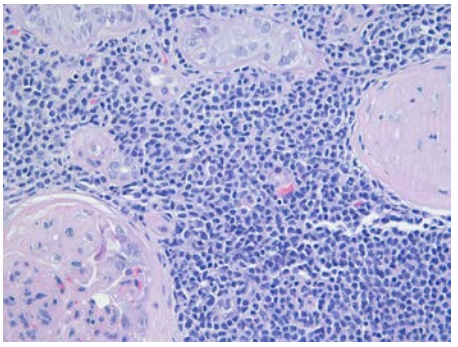
Discussion: We believe this case exemplifies a rare presentation of visceral DRA with cardiac involvement. Clinicians taking care of patients with ESRD who have been on long term hemodialysis or peritoneal dialysis must be cognizant of the myriad ways DRA can present. Visceral DRA, in particular DRA with cardiac involvement, is rare but should be on the differential for any patient with ESRD who presents with signs of infiltrative heart disease, including congestive liver failure, cirrhosis and ascites.

PUB379

Renal Failure due to Direct Infiltration of Chronic Lymphocytic Leukemia Bartlomiej Posnik, Nina Undevia Yedavalli. *Internal Medicine, West Suburban Medical Center, Oak Park, IL.*

Introduction: Chronic lymphocytic leukemia (CLL) is a cancer due to uncontrolled growth and accumulation of mature B lymphocytes. Asymptomatic kidney involvement of is fairly common with up to 90% of patients having interstitial infiltration on autopsy. Less than twenty cases of acute renal failure due to direct CLL infiltration have been reported in the literature.

Case Description: An 86 year-old African American female was diagnosed with stage IV CLL when she presented with extensive lymphadenopathy. Treatment with bendamustine and chlorambucil was discontinued due to poor compliance, creatinine of 1.95 mg/dL, and disease progression. Creatinine was later found to be 4.2 mg/dL with renal ultrasound consistent with medical renal disease. Protein electrophoresis with immunofixation of urine and serum was normal. Creatinine reached a maximum value of 5.7 mg/dL. Renal biopsy demonstrated dense infiltration of small lymphoid cells consistent with low grade B cell lymphoma as well as some focal segmental glomerulosclerosis.



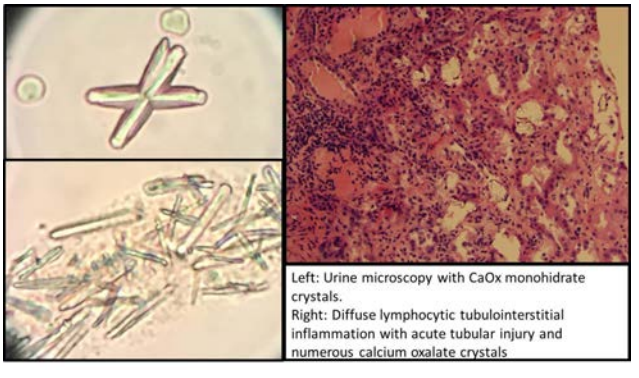
Discussion: Renal insufficiency is not uncommon in CLL patients as it can be seen in 7.5% of patients at the time of initial diagnosis and another 16.2% at some later time. The mechanism of renal failure in patients with direct CLL infiltration is thought to be due to compression of the renal tubules and microvasculature leading to obstruction and ischemia. The most common pattern seen on kidney biopsy is dense interstitial infiltration in the cortex with some degree of glomerular fibrosis/sclerosis. Most important is the absence of immune complexes. There is no agreed upon standard of care for treatment, it should be individualized. Regardless of the treatment modality, there seems to be a high recurrence rate. Recognition of this rare phenomenon is crucial as prompt recognition and intervention may reverse renal damage and recover function.

PUB380

Acute Oxalate Nephropathy- The Answer Is in the Urine Mahrukh Rizvi, Rebeca D. Monk. *Nephrology, Univ of Rochester School of Medicine, Rochester, NY.*

Introduction: Prompt recognition and rapid institution of therapy is crucial to preserve renal function in AKI. An easy but underutilized test is urine microscopy. We highlight the importance of urine microscopy in this case of suspected ethylene glycol (EG) ingestion. Ultimately a renal biopsy confirmed the diagnosis.

Case Description: A 59 y/o male presented with ~ 10 hrs of odd behavior. He was disoriented, afebrile, and hypertensive (225/120) with labs notable for pH 7.2, HCO3 7.8, PCO_2 8.4, anion gap (AG) 26, albumin 4.1, lactate 8.4, BUN 19, Cr 1.9 (0.7 one year ago). A drug screen and toxic alcohols were negative. On transfer to our hospital, ~ 30 hrs after initial symptomatology, an OG was obtained and negative. Urine microscopy revealed sheets of needle shaped calcium oxalate monohydrate crystals. EG ingestion was suspected and he was started on a Na-Bicarb drip to prevent tissue deposition of EG metabolites, however, patient refusal, lack of OG and EG levels continued to lead away from a final diagnosis of EG toxicity and early dialysis. His renal function quickly deteriorated over the next 48 hrs ultimately necessitating dialysis. A renal biopsy was obtained which revealed diffuse lymphocytic tubulointerstitial inflammation, acute tubular injury and numerous calcium oxalate crystals.



Left: Urine microscopy with CaOx monohidrate crystals.
Right: Diffuse lymphocytic tubulointerstitial inflammation with acute tubular injury and numerous calcium oxalate crystals

Discussion: EG is metabolized in the liver with a half life of 2.5-8.4 hrs. A lack of OG, presence of AG and Calcium Oxalate crystals suggest a late presentation when a negative OG and EG level is not unusual. This case highlights the utility of early urine microscopy and the importance of understanding the toxicokinetics of EG and other toxic alcohols to allow prompt diagnosis of ingestion despite significant laboratory gaps and lack of exposure history particularly in high risk patients with severe depression. Our patient ultimately admitted to EG ingestion and currently remains on dialysis.

PUB381

AA Amyloidosis in an IV Drug User – A Cautionary Tale Mahrukh Rizvi, Rebeca D. Monk. *Nephrology, Univ of Rochester Medical Center, Rochester, NY.*

Introduction: Most common reports of renal disease in IV drug users are related to HIV, HBV, and HCV infections. This has led to harm reduction initiatives nationwide aiming to decrease disease transmission via needles. A relatively rare but catastrophic form of renal disease in IV drug users is systemic amyloidosis, first reported in the 70's. Given grave outcomes, it deserves the spot light, especially to encourage early wound care into harm reduction initiatives in this population.

Case Description: A 38 year old Hispanic female with IV heroin and cocaine abuse with chronic lower extremity (LE) ulcers at injection sites presented with pain. Her exam was notable for a BP of 176/105, HR 75, Temp 97.3. Skin exam revealed superficial erosions on bilateral forearms, large wound bed in the left LE and ulceration with tender areas of eschar in the right LE. Admission labs revealed a creatinine of 2.4 mg/dL, albumin of 1.4 g/dL, CRP 70 mg/L, antibodies to Hepatitis C, 18 g of protein in the urine, oval fat bodies in the urine sediment with no red blood cells. A renal biopsy revealed AA amyloidosis with severe tubular atrophy and loss and interstitial fibrosis.

Discussion: In a case series, >50% of patients with AA amyloidosis from IV drug use required dialysis within one month. Median survival is reported to be 25 months, which compares unfavorably with median survival of 52 months for all patients with AA amyloidosis on dialysis. Providing dialysis is challenging in these patients due to difficulty obtaining permanent vascular access, tunneled lines being used for drug injection, poor hygiene, and infectious complications. This case underscores a grave, albeit rare complication of IV drug use resulting from chronic soft tissue infection. Whether street contaminants contribute to development of AA amyloidosis remains unknown. We bring this case to the spotlight to encourage early attention to skin complications in IV drug users. Isolated programs for easily accessible, cost-effective medical and wound care for IV drug users with soft tissue infections have been established. This has resulted in significant reductions in ED visits, hospital admissions, and costs in those areas. Perhaps, similar efforts should be initiated nationally.

PUB382

A Case of Membranoproliferative Glomerulonephritis Secondary to Sjogren's Syndrome Rafael Franjul. *Nephrology Fellowship, Newark Beth Israel Medical Center, Newark, NJ.*

Introduction: This case represents an overview of an atypical acute presentation of a chronic disease that manifested with Nephrotic Syndrome in a 70 years old female needing acute renal replacement therapy and the investigative effort where and autoimmune disease was found and treated in hopes of renal recovery.

Case Description: 70 years old Female from the Philippines presented complaining of dyspnea on exertion and lower extremity edema for 3 weeks prior to presentation. Was started on diuretics to manage symptoms, but there was no improvement and symptoms progressed. An echocardiogram performed revealed pericardial effusion and patient was admitted to the hospital for pericardial window. Developed respiratory distress requiring ventilator support via endotracheal tube. Was started on furosemide drip, but renal function worsened. On admission patient with Scr of 3.17 mg/dL, unknown baseline, no history of kidney disease. Her past medical history was significant for long standing hypertension and patient was deaf and mute since childhood with unknown etiology, family history was noncontributory. Her medications consisted in carvedilol 12.5mg every 12 hours; isosorbide mononitrate 30 mg daily; hydralazine 50 mg every 12 hours; losartan 100 mg daily. No history of tobacco, alcohol or recreational drugs. On Review of systems she admitted to dry eyes for several years as well as joint pain. Her vital signs were stable, and physical exam demonstrated distant heart sounds, diffuse crackles and lower extremity pitting edema of +2 bilateral; no focal neurological deficit and no joint deformities appreciated. Her initial laboratory work up revealed a normocytic anemia; Serum Sodium level 148 mEq/L; Potassium 4.7 mEq/L; CO2 22 mEq/L; Calcium 7.9 mg/dL; Phosphorus 5.8 mg/dL; Albumin 2.5 g/L; BUN 66 mg/dL and creatinine 3.27 mg/dL. Urinalysis was significant for proteinuria +4. Spot urine protein/creatinine ratio of 4.7 g/mg. Further investigation for evaluation of renal failure showed significantly positive SS-A IgG. Kidney biopsy showed a membranoproliferative pattern. A trial of cyclophosphamide was initiated and patient remained on RRT while awaiting progression or recovery of her renal funcion.

PUB383

An Unusual Case of Light Chain (AL) Amyloid Nephropathy Amtul Aala, Basma Omar Merhi. *Nephrology, Alpert Medical School of Brown Univ, Providence, RI.*

Introduction: Light chain (AL) amyloidosis is usually associated with plasma cell dyscrasia but not as common with Lymphoma. Here, we report an unusual case of AL amyloid nephropathy as a renal manifestation of an otherwise quisescent B-cell lymphoproliferative disorder (BCLPD).

Case Description: An 85 year old female with history of breast cancer treated with lumpectomy and radiation therapy, diet controlled diabetes mellitus and hypertension was diagnosed with lambda light chain restricted B-cell lymphoproliferative disorder by bone marrow biopsy (immunophenotypically consistent with Marginal zone lymphoma) five years prior to presentation and managed conservatively. She recently presented with lower extremity edema, dyspnea and 10 lb weight gain and diagnosed with nephrotic range proteinuria with urine protein/ creatinine ratio 5.5 g/g and acute kidney injury with serum creatinine of 1.3mg/dl from baseline 0.6mg/dl. Serologies for hepatitis B & C, HIV, ANA, anti-ds DNA and complement levels (C3 and C4) were negative. SPEP showed high kappa and lambda light chain with normal ratio of 0.9 with negative urine immune-fixation for para-proteins. Age-appropriate cancer screening was negative but no prior colonoscopy reported. CT scan abdomen and pelvis showed stable splenomegaly, and scattered retroperitoneal and right common iliac lymph nodes, the largest measuring 1.1 cm. Kidney biopsy was performed with findings of AL amyloid nephropathy [light chain type (lambda-restricted)], with deposition in the glomeruli and arterioles, mild interstitial fibrosis and tubular atrophy, and moderate arteriosclerosis. As her AL amyloid nephropathy was likely secondary to BCLPD, the plan was to initiate chemotherapy. Due to poor performance status and limited cognitive function, chemotherapy was withheld. Her condition declined and sadly she passed away.

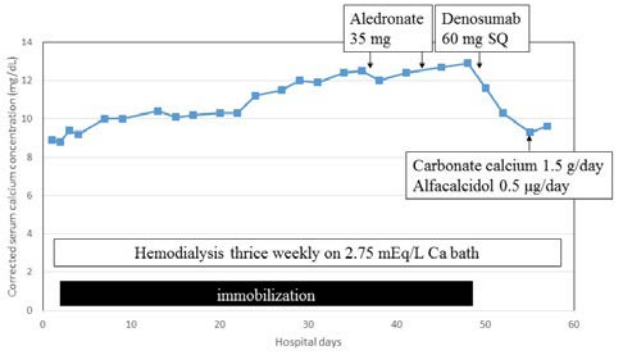
Discussion: AL amyloidosis is a rare manifestation of BCLPD with only limited case reports published. This condition is more common in elderly female patients with multi-systemic involvement upon presentation. Aggressive therapy with high-dose melphalan and stem cell transplantation may improve patient survival. AL amyloidosis should be in the differential diagnosis of proteinuria in patients with BCLPD.

PUB384

Denosumab for Treatment of Immobilization-Related Hypercalcemia in a Patient with End-Stage Renal Disease Atsuko Uehara, Masahiko Yazawa, Yugo Shibagaki. *Div of Nephrology and Hypertension, St. Marianna Univ Hospital.*

Introduction: The effectiveness and safety of denosumab for the treatment of immobilization-related hypercalcemia in end-stage renal disease (ESRD) remain uncertain. Here, we describe a case of immobilization-related hypercalcemia successfully treated with denosumab in a patient undergoing hemodialysis.

Case Description: A 79-year-old man with diabetic nephropathy was diagnosed with gastric cancer and gastric resection was recommended five months prior to admission. However, he developed acute kidney injury due to contrast-induced nephropathy. He admitted and initiated hemodialysis, but he experienced acute myocardial infarction and acute heart failure, for which he became bedridden, and operation was cancelled. Afterwards, his serum calcium gradually elevated from 8.8 to 12.9 mg/dl, and general fatigue developed. Immobilization-related hypercalcemia was diagnosed after excluding other possibilities. Alendronate was given for two weeks, without any improvement. He was then administered 60 mg of denosumab subcutaneously with calcium supplement and alfacalcidol and his serum calcium decreased to 9.3 mg/dl one week later, and was controlled within the 9.0-10.0 mg/dl range.



Discussion: Immobilization-related hypercalcemia in patients undergoing maintenance dialysis is not rare. The report on the effectiveness and safety of denosumab for immobilization-related hypercalcemia in patients with ESRD has been scarce. Our case indicated that denosumab can be a vial for intractable immobilization-related hypercalcemia in patients with ESRD.

PUB385

A Dying Kidney's Last Stand: Removal of Renin-Secreting Atrophic Kidney Improves Blood Pressure Control Robin Shah, Jason Prosek. *Div of Nephrology, The Ohio State Univ Wexner Medical Center, Columbus, OH.*

Introduction: About 20 to 30 percent of cases of hypertension are considered resistant and are often driven by secondary processes. A subset of secondary hypertension features elevated renin levels as its characteristic attribute. A measurable rise in renin could be secondary to decreased arterial blood flow to the kidney. We present a case in which a patient with resistant hypertension is found to have asymmetric renin secretion, prompting nephrectomy which led to improvement in both renin levels and blood pressure control.

Case Description: A 58 year old male with a history of abdominal aortic aneurysm (AAA), hypertension, and chronic kidney disease with a baseline serum creatinine (SCr) of 1.3 mg/dL was referred to the nephrology clinic for resistant hypertension. Five years prior to evaluation, he had an AAA repair with stent which was felt to be obstructing flow to the right renal artery. Despite subsequent angioplasty and stenting, blood flow to the right kidney progressively worsened, confirmed via CT angiogram which revealed severe, diffuse narrowing of the renal artery and an atrophied right kidney. He also continued to have symptoms of headache, flushing, and blood pressure readings of 200/100 mmHg despite 4 antihypertensives including an angiotensin receptor blocker and diuretic. Plasma renin level was 45 ng/mL/hr (normal less than 3.95 ng/mL/hr). Renal vein sampling revealed asymmetric renin release, with right renal vein level at 247 ng/mL/hr and left renal vein level at 65.55 ng/mL/hr (central renin level was 63 ng/mL/hr). The patient was referred for right nephrectomy. Two months after nephrectomy, his blood pressure improved to 130/80 on fewer antihypertensives, and his symptoms improved. Repeat renin level was 1.0 ng/mL/hr. His kidney function has remained stable with a SCr of 1.3 mg/dL.

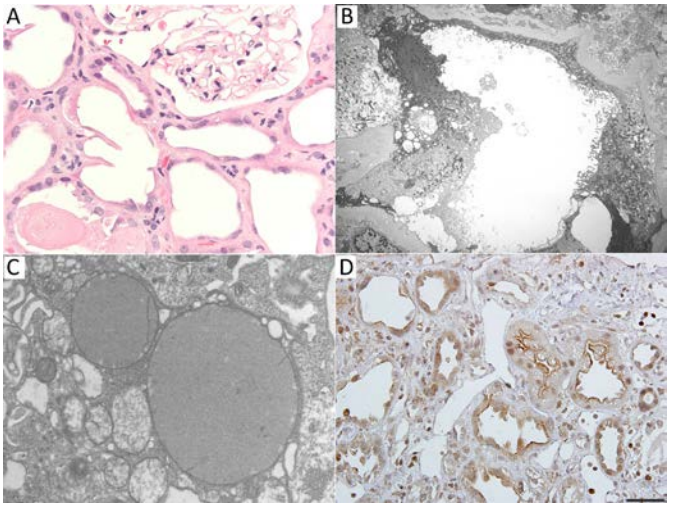
Discussion: This case demonstrates that excessive renin production in an atrophied kidney can cause resistant hypertension. Thus, recognizing this is important as some patients may benefit from nephrectomy that may ultimately improve blood pressure with a measurable decrease in renin secretion and preserve the other kidney's function.

PUB386

Literal ATN: Tenofovir Toxicity, Regeneration and Oxidative Stress Kenneth M. Ralto,[1] Melanie P. Hoenig,[1] Zsuzsanna Zsengeller,[2] Seymour Rosen.[2] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Pathology, Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: In most cases of acute tubular necrosis (ATN) there is limited epithelial injury (Rosen et al, JASN 2008) but in a few situations widespread tubular destruction occurs. Tenofovir disoproxil fumarate (TDF) is a nucleoside reverse transcriptase inhibitor, widely used for prevention and treatment of human immunodeficiency virus infection. TDF is excreted by the kidney via glomerular filtration and active proximal tubular secretion. It has been shown that TDF inhibits mitochondrial DNA polymerase-γ, leading to mitochondrial DNA depletion and cell injury apparently due to the generation of reactive oxygen species (ROS) and reactive nitrogen species (RNS) in rats (Abraham et al, J Biomed Sci 2013).

Case Description: A 54-year-old man with HIV on emtricitabine/rilpivirine/TDF presented with fatigue and nausea. Laboratory studies showed a creatinine of 14.8 mg/dL, bicarbonate of 11 mEq/L, glycosuria and proteinuria. Urine sediment was notable for muddy brown casts. TDF was withheld and a renal biopsy was performed. The biopsy showed regenerative changes with simplified, attenuated epithelium in the proximal tubules on H&E staining (A) and by EM (B). Megamitochondria with markedly diminished cristae, typical of TDF toxicity, were seen (C). Lastly, nitrotyrosine immunostaining highlighted areas of oxidative and nitrosative stress in the proximal tubules (D). The patient required hemodialysis, but subsequently, his renal function improved sufficiently to discontinue hemodialysis and his creatinine decreased over several months.



Discussion: The renal biopsy showed severe proximal tubular damage, megamitochondria and evidence of oxidative/nitrosative stress, features consistent with TDF nephrotoxicity. These findings support the idea that TDF leads to proximal tubular damage through mitochondrial injury and generation of ROS/RNS.

PUB387

MUCIN-1 Kidney Disease in the Family Samuel Mon-Wei Yu,[1] Anthony J. Bleyer,[2] Kisra Anis,[1] Belinda Jim.[1] *[1]Medicine, Jacobi Medical Center, Bronx, NY; [2]Nephrology, Wake Forest School of Medicine, Winston-Salem, NC.*

Introduction: Mucin-1 kidney disease (MKD) is a rare hereditary kidney disease. It is one of several diseases now termed autosomal dominant tubulointerstitial kidney disease (ADTKD), as proposed by a KDIGO consensus report in 2014. Although the pathophysiology of MKD is still under investigation, genetic testing has been developed to detect the most common mutation, a single cytosine insertion into a string of seven cytosines in the variable number of tandem repeat (VNTR) region of the MUC1 gene.

With this diagnostic tool, nephrologists can offer genetic counseling to affected families and closely follow up progression of disease. Here we report a patient with strong family history of chronic kidney disease (CKD) who tested positive for the MUC1 mutation.

Case Description: A 41-year-old Hispanic female with a history of gestational diabetes and hypertension was referred to renal clinic for newly-diagnosed CKD stage 3. Her mother passed away at age of 42 and was on hemodialysis (HD). One brother presented at age 33 with uremic encephalopathy and bilateral atrophic kidneys, which required HD followed by renal transplant. A second brother presented at the age of 32 for evaluation of CKD stage 3 and was found to have tubulointerstitial kidney disease by renal biopsy. A third brother apparently was diagnosed with leukemia the age of 4, developed ESRD due to medications, required HD for 4 years, and died at the age of 19. Our patient had a renal biopsy which revealed chronic tubulointerstitial nephropathy. Given the family history, she was referred for genetic testing and found to have a MUC1 mutation.

Discussion: Unlike ADTKD due to UMOD or REN mutation, MKD does not have associated findings such as hyperuricemia or anemia in childhood. Renal ultrasound usually is normal or shows occasional cysts, and urinalysis is bland without proteinuria. The age of onset of end-stage kidney disease can vary significantly within families, suggesting other genetic variants may affect outcome. To diagnose MKD, it is extremely important for nephrologists to collect a comprehensive family history and refer for genetic testing in order to make a diagnosis and begin counseling.

PUB388

Unconventional Treatment of IgA-Dominant *Staphylococcus* Infection-Associated Glomerulonephritis Abbas Raza,[1] Satyam Arora.[2] *[1]Internal Medicine, St. Luke's Univ Hospital, Bethlehem, PA; [2]Nephrology Associates, St. Luke's Univ Hospital, Bethlehem, PA.*

Introduction: IgA-dominant *Staphylococcus* infection-associated glomerulonephritis is a rare but increasingly diagnosed condition. About 20% of cases are Methicillin-Sensitive *Staphylococcus aureus* (MSSA) associated. Antibiotic treatment is linked with renal recovery in ~60% cases. Duration of antibiotic therapy and use of steroids remain controversial. We report a case of MSSA associated IgA-dominant glomerulonephritis where renal function significantly recovered within 12 months of antibiotics and without steroid therapy.

Case Description: A 67-year-old male with history of diabetes and multiple comorbidities, presented with a right hand cellulitis. He was found to have MSSA sepsis, aortic valve vegetation, L3-L4 discitis, epidural abscess, and osteomyelitis. Patient was started on IV Cefazolin. His recovery was complicated by worsening renal function. Creatinine (Cr) increased from baseline 0.7 mg/dL to 2.8 mg/dL. Workup showed urine protein-to-creatinine ratio (UPC) of 8.2, normal C3 and C4, no monoclonal gammopathy, negative ANA, negative anti-DS DNA, negative ANCA, negative GBM antibody, and high ASO titers. Renal biopsy showed acute glomerulonephritis with mesangial IgA deposition and diabetic glomerulosclerosis. Patient was diagnosed with IgA-dominant *Staphylococcus* infection-associated glomerulonephritis. Along with RAS blockade agents, patient was treated with 12 months of antibiotics. Follow up blood work showed Cr and UPC improved to 1.21 mg/dL and 3.8, respectively.

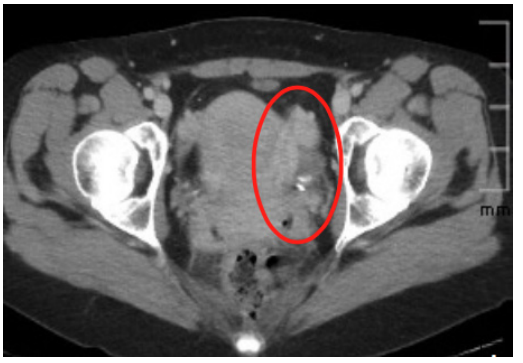
Discussion: Although patients with IgA-dominant *Staphylococcus* infection-associated glomerulonephritis are increasingly recognized, the management has not been well studied. Typically, up to 6 weeks of antibiotics is prescribed. The use of steroids is unclear. Our patient was treated with an unconventionally long duration of antibiotics and without steroids with significant improvement in renal function. Our case illustrates that longer duration of antibiotics may be employed for worsening renal function. Further studies will be needed to focus on the length of an antibiotic course in IgA-dominant *Staphylococcus* infection-associated glomerulonephritis.

PUB389

Three Cases of Uncommon Renal Diseases in Pregnancy Amtul Aala, Basma Omar Merhi. *Nephrology, Alpert Medical School of Brown Univ, Providence, RI.*

Introduction: Renal disorders during pregnancy should be managed by a multidisciplinary team to avoid dangerous clinical consequences to the mother and fetus. Here, we present three uncommon renal disorders in pregnancy: Von-Hippel Lindau disease (VHL), Gitelman syndrome (GS) and Nutcracker syndrome (NS), with successful maternal and fetal outcome in all 3 cases.

Case Description: Case 1: A 30 year-old G4P1 with VHL diagnosed at age 12 presented at 22 weeks gestation. She had a history of successfully resected pheochromocytoma, multiple renal cell carcinomas (RCC) and retinal tumor. After first pregnancy, she stopped annual screening for VHL. Renal ultrasound during this pregnancy revealed bilateral solid masses highly suspicious for RCC confirmed by MRI. She delivered a healthy baby on term. She started the contraceptive vaginal ring and had a follow-up surgical consultation. **Case 2:** 33 year-old G2P1 with GS presented at 10 weeks gestation. She has eight-year history of muscle cramps, palpitations, and intermittent hypokalemia that responded to oral potassium supplement. At 24 weeks gestation, potassium level stayed normal with oral potassium supplement. She was induced by artificial rupture of membranes due to pregnancy-induced hypertension and delivered a healthy baby. **Case 3:** A 31-year-old G2P1 presented at 13 weeks gestation. She denied flank pain; her blood pressure and kidney function were normal. Abdomen and pelvis CT scan showed dilated left gonadal vein consistent with left renal vein compression suggestive of NS. With conservative management, she had an uncomplicated pregnancy and delivered a healthy baby.



Discussion: Experienced specialists, maternal-fetal obstetrics working with nephrologist should care for these patients with intensified surveillance, appropriate treatment plans and mode of delivery to avoid dangerous and preventable clinical consequences, as these renal diseases may affect pregnancy outcome.

PUB390

Carfilzomib-Induced Thrombotic Microangiopathy after Drug Re-Exposure Leading to Acute Renal Failure Emily Lu,[1] Sunil Rangarajan,[2] Steven Salvatore,[1] Sheron Latcha.[3] *[1]Weill Cornell Medicine/New York-Presbyterian Hospital; [2]Univ of Alabama at Birmingham; [3]Memorial Sloan Kettering Cancer Center.*

Introduction: Drug-induced thrombotic microangiopathy (DITMA) has been reported with the 1st generation proteasome inhibitor (PI) bortezomib. There are only a few reported cases of DITMA following treatment with the 2nd generation PI carfilzomib. This is the first report of a case of renal TMA following re-exposure to carfilzomib previously used as maintenance therapy in a patient with Multiple Myeloma (MM).

Case Description: A 56 year old male with MM which was previously treated with bortezomib and carfilzomib underwent autologous stem cell transplant (ASCT) with carfilzomib conditioning. While in serologic partial remission, he received carfilzomib maintenance therapy. One week later, he presented with fever, non-bloody diarrhea, and anuric acute renal failure unresponsive to aggressive volume repletion. Influenza A serology was positive. Vital signs and exam were notable for persistent hypertension and edema. Initial labs showed: Serum creatinine 15mg/dL (0.9 mg/dl one week prior), blood urea nitrogen 115mg/dL, anion gap 17, lactic acid 1.6mmol/L, hemoglobin 8g/dL (baseline 11-12g/dL), platelet 90,000/uL (baseline 300,000/uL); with normal values for C3, C4, ANCAs (MPO, PR3), SPEP/UPEP, hepatitis B and C panels, ADAMTS13, and an atypical HUS panel. Lactate dehydrogenase was >1800 IU/L, haptoglobin 75mg/dL, and the peripheral smear showed 3+ schistocytes. Further workup for infections was negative. Renal ultrasound showed no hydronephrosis. Hemodialysis was started and a renal biopsy was performed. Pathology showed 41 glomeruli, severe acute TMA involving glomeruli and small vessels, global glomerulosclerosis (5 of 41 glomeruli), with no glomerular crescents or immune complex deposits.

Discussion: This is the first case report of biopsy proven TMA from carfilzomib used in a patient who was previously treated with carfilzomib. The patient may have been sensitized to TMA from prior exposure to the drug or from the ASCT.

PUB391

C3 Glomerulopathy with Atypical Hemolytic Uremic Syndrome Misdiagnosed as Primary Membranoproliferative Glomerulonephritis and Malignant Hypertension Robert Schoepe, Keith R. Superdock. *Lankenau Medical Center, Wynnewood, PA.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is caused by dysregulation of the complement system. A genetic defect causes uninhibited activation of the alternative pathway causing thrombotic microangiopathic hemolytic anemia (MAHA) and renal disease. A treatment now exists for aHUS in eculizumab, a monoclonal antibody for C5, a key in complement activation.

Case Description: Ms. S is a 25 year old who presented three years prior with uncontrolled hypertension, severe anemia, renal failure of unknown duration, and nephrotic-range proteinuria. A biopsy revealed membranoproliferative glomerulonephritis (MPGN) in late crescentic stage with severe intrarenal arteriosclerosis. Immunofluorescence showed widespread C3, some C1Q, kappa and lamda chains along the glomerular basement membrane (GBM) and 4+ IgM along the GBM and in the mesangium. It was determined to be "probably type I MPGN", with immunofluorescence not completely typical of a primary MPGN. Work up revealed a low C3 level and a normal C4 level. She was determined to have end stage renal disease (ESRD) and started on hemodialysis. Her course was complicated by persistent anemia and eight admissions for hypertensive emergencies. Review of her records for renal transplantation evaluation revealed low platelet and haptoglobin levels and elevated LDH levels. She again had a low C3 level and a normal C4 level. Her initial biopsy was then re-evaluated revealing dense deposit disease, a C3 glomerulopathy, consistent with aHUS. She was started on eculizumab and has since only had one admission for hypertensive emergency and her hemoglobin, platelet, LDH, and haptoglobin levels have improved.

Discussion: She was misdiagnosed as primary MPGN despite evidence of MAHA attributed to malignant hypertension. No further investigation of her disease process

occurred given the irreversible ESRD. She had systemic manifestations of her disease for years and would have had recurrence in a transplanted allograft. Patients who present with advanced renal disease due to glomerulonephritis and malignant hypertension with MAHA should be evaluated for aHUS as treatment can manage systemic manifestations and prevent recurrence in allografts.

PUB392

Anti-Neutrophil Cytoplasmic Antibody Negative Granulomatosis with Polyangiitis Associated with Crescentic IgA Nephropathy - A Clinical Conundrum Shirin Sharma, Eric J. Bloom, Rasib Raja. *Nephrology, Einstein Medical Center, Philadelphia, PA.*

Introduction: GPA could present as ANCA negative in 40%of the patients. Chen et al reported 32.9% patients who were ANCA negative had fewer extrarenal symptoms than patients who tested positive.Interestingly,there have been several case reports of ANCA vasculitis associated with crescentic IgAN.Since the majority of the patients were ANCA positive,not much is known about the treatment of ANCA negative GPA with Crescentic IgAN.

Case Description: We present the case of a 52 year old gentleman who presented with palpable purpura,epistaxis,polyarthritis,hematuria,proteinuria and chronic sinusitis. A left thigh punch biopsy showed intense perivascular and interstitial infiltrate and leukocytoclasis. He tested negative for hepatitis,ANA,MPO and PR3. He was started on MTX and Prednisone 60 mg daily.CT chest was negative for granulomas.Subsequently,the patient developed right foot drop secondary to mononeuritis multiplex and digital ischemia of bilateral fourth toes,hearing loss and blurry vision. Given the progression of his symptoms he was switched to Rituximab 850 mg every 4 weeks.A kidney biopsy was done given the hematuria and proteinuria which was consistent with IgA nephropathy (MEST score 0).His S.Cr remained normal for 1 year and the U Pr/Cr improved.However the patient stopped MTX on his own.His S.Cr increased to 1.32 and proteinuria worsened. A repeat kidney biopsy showed advanced IgA nepropathy with crescents(M2E1S0T1). Repeat ANCA testing was negative. He was started on pulse steroids and IV Cyclophosphamide and now his S.Cr is 1.37 mg/dL with persistent proteinuria.

Discussion: Due to lack of prospective clinical trials for ANCA negative vasculitis, the treatment is tailored to the patients clinical response and the side effect profile. Rituximab appears to effective for ANCA negative GPA,but steroids and cyclophosphamide have been shown to be more beneficial for Crescentic IgAN.(5yr renal survival 28%).The association between ANCA negative GPA and crescentic IgAN is rare and the interest in an adequate treatment strategy remains high.

PUB393

ANCA Associated Cescentic Glomerulonephritis in a HIV Positive Patient with Disseminated Kaposi Sarcoma Tanu Duggal,[1] Manoj Das,[1] Nilang G. Patel,[2] Pradeep Arora.[2] *[1]Medicine, VCU, Richmond, VA; [2]Medicine, VAMC, Richmond, VA.*

Introduction: A 53 year old male was admitted with serum creatinine of 5.6 mg/dl. He had HIV infection since 1997 **accepting HAART therapy sporadically**, hypertension, drug abuse and hepatitis C Physical examination revealed: T 101 °F, BP 130/80 mmHg, and 1+ lower extremity edema. Laboratory data included: UA with 30 mg/dl protein, 20 RBCs and 30 WBCs; 24 hour urine protein excretion of 6.4 g; HIV PCR viral load of 7400; CD4 count of 300; normal C3 and C4, P-ANCA positive at 1:640. Biopsy of the tongue and a lesion on the shoulder revealed Kaposi tumor. Kidney biopsy showed crescentic glomerulonephritis. Patient was treated with HD + steroid + plasmapheresis without improving kidney function. After re-initiating HARRT therapy, his creatinine improved to his baseline and remained stable for the next 4 years.

Discussion: HSP, PAN, AAV have been reported with HIV. To best of our knowledge this is first case of biopsy proven AAV related to HIV who recovered with HAART therapy.

TMA in the Setting of CMV Reactivation Jordan Gabriela Nestor, Hilda E. Fernandez. *Dept of Medicine, Div of Nephrology, Columbia Univ Medical Center, New York, NY.*

Introduction: Renal disease due to abnormalities in the complement alternative pathway (AP) includes C3 glomerulopathies and atypical HUS. AP disorders result from loss of surface or fluid-phase complement control caused by acquired or genetic defects. TMA diagnosis is often clinically challenging in the setting of multi-organ involvement.

Case Description: 30yo AA F p/w 3/5 strength all extremities. Admitted w/ initial labs notable for Cr 1.0 mg/dL, CPK 22000 iU/L, LDH 2500 IU/L, +SMA Ab, and muscle biopsy c/w necrotizing myopathy. Treated with 7 day steroid pulse w/o improvement. On HD#17, had two witnessed GTCs on HD#17. CT head w/ hypodensities c/f infarcts. MRI with multiple FLAIR hyperintensities. MRA/MRV unremarkable. ICU transfer on HD#19. CBC showed platelet count 49K/mL with repeat count of 6K/mL. Also had low haptoglobin, normal coagulation factors/fibrinogen, elevated bilirubin, transaminitis, and schistocytes on peripheral smear in setting of rising creatinine. SLE/APLS Abs were negative. PLEX initiated HD#19 due to c/f TTP. ADAMTS13 prior to PLEX was 41% (low normal), GI PCR panel negative for STEC. LP bland. Concern for Macrophage Activating Syndrome, started anakinra for elevated ferritin/CRP. BM Bx w/o evidence of malignancy. Developed anuric AKI, initiated CRRT. New CMV viremia HD#23 detected (6K copies/mL), initiated ganciclovir for CMV reactivation. aHUS genetic panel sent to lab. Platelets improved on PLEX. Renal biopsy HD#36 c/w thrombotic microangiopathy . Held Anakinra, received 1st dose of eculizumab on HD#38. HD#60, platelets remain stable, LDH improved, though mental status and renal function have not yet recovered.

Discussion: A genetic susceptibility to de novo TMA in patients with complement gene abnormalities may have played a role in this case, where an initial insult by ischemia–reperfusion enhanced by viral infections, immunosuppressive drugs, or dysregulated complement activation resulted in TMA. Reactivation CMV viremia following pulse steroids may have served as the trigger of TMA.

PUB395

Cardiac Arrest as a Consequence of Tenofovir Induced Hypokalemia Abhilash Koratala, Volodymyr Chornyy, S. Irfan Qadri, Rupam Ruchi. *Nephrology, Hypertension & Renal Transplantation, Univ of Florida.*

Introduction: Tenofovir is a nucleotide reverse transcriptase inhibitor used for the treatment of HIV infection and is a key component of the commonly used anti-retroviral drug, Truvada®. Tenofovir induced proximal tubulopathy and dyselectrolytemia with or without Fanconi syndrome has been documented in the literature. We report a case of severe hypokalemia and renal tubular acidosis (RTA) that lead to cardiac arrest in a HIV patient.

Case Description: 59 year old Caucasian female presented to our institution for weakness, failure to thrive and hypokalemia. She has history of HIV for ~8 years, well controlled on tenofovir containing HAART. 4 months prior to presentation, she suffered a sudden cardiac arrest after a diarrheal episode and required ICU stay at an outside facility where she was told that her serum potassium at admission was 'close to zero'. Cardiac catheterization did not reveal any ischemic etiology. She was discharged with oral potassium supplementation 40mEq twice a day. However, she was feeling sick with weakness, nausea, intermittent vomiting & weight loss and thus came to us. At presentation, her serum potassium was 2.5 mmol/L, magnesium 1.9 mg/dL, phosphate 1.6 mg/dL and bicarbonate 13 mmol/L with anion gap of 14. Her renal function was preserved and had mild proteinuria of ~0.5 g/g. Initial work up was negative for malignancy. We noted that she had glycosuria with normal serum glucose and had a potassium-creatinine ratio of 250 mmol/g and fractional excretion of phosphate 65%. We diagnosed her with Tenofovir induced proximal RTA with Fanconi syndrome.Her HAART was changed to non-tenofovir based regimen and at 1 month follow up, her serum potassium was stable at 3.8 mmol/L on 40mEq/day oral potassium supplementation.

Discussion: Patients on Tenofovir therapy are prone to developing severe hypokalemia in the setting of RTA especially when combined with gastro-intestinal losses and/or poor eating. These patients should be frequently monitored with urinalysis and renal function panel while on therapy. Raising the awareness among clinicians with regard to this potential side effect is vital for early intervention and prevention of life-threatening complications.

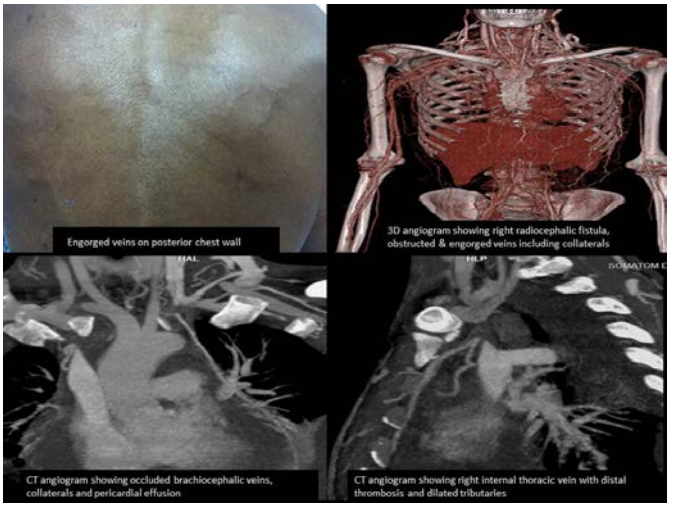
PUB396

Cardiac Tamponade in a Hemodialysis Patient: Delayed Complication of Central Venous Catheter Insertion Boju Sangeetha Lakshmi,[1] Hari Krishna Reddy Mogili,[1] Anil Kumar Cheni Venkata,[1] R. Ram,[1] V. Siva Kumar,[1] Abhilash Koratala.[2] *[1]Sri Venkateswara Inst of Medical Sciences, India; [2]Univ of Florida.*

Introduction: Case reports of pericardial tamponade after a central venous catheter insertion exist in the pediatric literature but generally due to direct mechanical trauma. Tamponade caused by Superior vena cava (SVC) obstruction has been documented in adult oncology patients from tumor compression or infiltration of SVC. We report a case of pericardial effusion (PEF) as a delayed complication of Internal Jugular (IJ) hemodialysis (HD) catheter insertion due to SVC obstruction and impairment of pericardial fluid drainage.

Case Description: A 41 y.o. Asian-Indian male with ESRD secondary to chronic glomerulonephritis, on HD for 7 years presented to our institution with progressive shortness of breath for a month. He has history of secondary failure of multiple AV fistulas in the past. Both IJ veins were cannulated twice each as a temporary access whenever an AVF had failed and catheter retained for ~ 8 weeks. Exam showed facial edema with engorged veins on the neck and chest. Pulsus paradoxus was noted and imaging revealed massive PEF with

tamponade. Pericardiocentesis was done with drainage of ~6L serous fluid and analysis was negative for infection or malignancy. His Kt/V was optimal and we dialyzed him daily for a week but he had recurrent PEF. CT showed thrombosis with total occlusion in left brachiocephalic vein, distal right brachiocephalic vein and proximal SVC with extension into distal part of bilateral internal thoracic veins. Collaterals were noted in abdominal and chest wall as shown in the CT angiogram.



He ultimately required pericardiectomy for management of recurrent PEF.

Discussion: Serious complications of SVC stenosis associated with CVC use is an under-recognized problem and should be considered HD patients with persistent or recurrent unexplained shortness of breath.

PUB397

A Case of Hyponatremia Associated with SGLT-2 inhibitor Empagliflozin

Lauren Paster,[1] Khurram Mehtabdin,[1] Kenar D. Jhaveri,[1] Alyson Myers,[2] Richard L. Barnett.[1] *[1]Div of Kidney Disease and Hypertension, Northwell Health, Great Neck, NY; [2]Div of Endocrinology, Northwell Health, Great Neck, NY.*

Introduction: Sodium-glucose cotransporter-2 (SGLT-2) inhibitors are increasingly used to treat type 2 diabetes mellitus (T2DM). Volume depletion alone or with diuretics has been noted but hyponatremia has not been reported with these agents. We describe the first case of symptomatic hypovolemic hyponatremia in a patient treated with empagliflozin and hydrochlorothiazide (HCTZ).

Case Description: A 69 year old Caucasian female with history of T2DM and hypertension presented with dizziness. She had been initiated on empagliflozin 9 days prior, in addition to 6 month continuous use of HCTZ-lisinopril, diltiazem, atenolol and atorvastatin. At that time she was counseled to augment water intake to reduce risk of urinary tract infections. Labs from one month prior to empagliflozin initiation included Cr 1.3 mg/dL and Na 134 mmol/L. Physical exam was notable for orthostatic changes but negative for edema, confusion or seizure-like activity. Admission bloodwork included Na 112 mmol/L, Cr 1.7 mg/dL and glucose 207 mg/dL. Urine studies included: Na 27, Cl 24, K 20, Cr 58, glucose >1000 (all in mg/dL) and osmolality 261. Cortisol and thyroid studies were normal. Empagliflozin was held, along with HCTZ-lisinopril, diltiazem and atenolol. Sodium increased to 115 within the first 24 hours and further rose to 125 by the following day with the addition of 1.5% saline. After discontinuation of hypertonic saline, Na rose to 133 over the next 48 hours. Serum Cr, which had peaked at 2.22 declined to 1.4 1 week post-discharge. Throughout her hospitalization $U_{Na}>U_{Cl}$, FeCl < 1%, $U_{osm}>250$ and persistent glycosuria were noted, consistent with prolonged empagliflozin +/- HCTZ effect.

Discussion: A literature search revealed no associations between SGLT-2 inhibitors and hyponatremia. Adding empagliflozin to a patient on HCTZ who was advised to increase free water intake promoted her symptomatic hypovolemic hyponatremia. Given the increasing utility of SGLT-2 inhibitors in patients with T2DM and hypertension, caution should be used when combining these agents with thiazide diuretics.

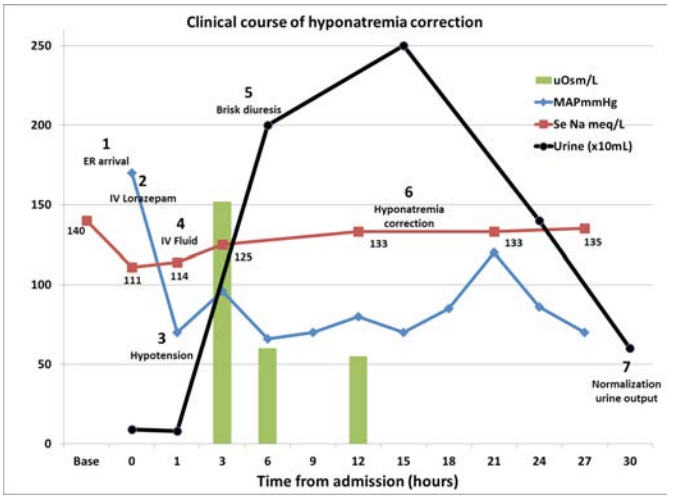
PUB398

Renal Response to Acute Hyponatremia during Alcohol Withdrawal

Vikrampal Bhatti, Volodymyr Chornyy, Kawther Farouk Alquadan, A. Ahsan Ejaz, Abhilash Koratala. *Nephrology, Hypertension and Renal Transplantation, Univ of Florida.*

Introduction: We present this case of hyponatremia to illustrate the renal physiology of sodium and water balance. Clinical presentation and laboratory data are depicted in the form of a graph.

Case Description: A 56 year old female with history of alcohol abuse and binge drinking 1) presented with agitation, tremors, mouth dryness and signs of alcohol withdrawal after abstinence for several days. No nausea, vomiting or pain. On exam, BP was 230/140mmHg with heart rate 120bpm, respiratory rate 22pm, chest clear to auscultation, abdomen non-tender, no organomegaly, no lower extremity edema, non-focal neurologic exam. Routine chemistries including alcohol level and drug screen ordered. 2) Given intra venous Lorazepam and agitation improved. 3) 1hour later, there was a precipitous drop in BP. Serum sodium at admission was 111meq/L. Baseline serum sodium was 140meq/L documented at clinic visit 2 weeks prior to ER visit. 4) 1 liter Normal saline bolus administration, additional Half liter Normal saline. 5) Brisk urine output noted. 6) Serial serum sodium with upward trend. Patient more coherent, intact neurological exam. Urine osmolar changes shown. 7) Urine volume decreased with improved serum sodium. Oral rehydration allowed. Patient discharged to rehabilitation facility after 72 hours with normal neurological, medical and laboratory status.



Discussion: Hyponatremia is a commonly encountered problem and treatment varies with the nature of onset - acute or chronic, severity and symptoms. In the above case of hypovolemic hyponatremia, intravascular volume repletion reduced ADH secretion (decreased UOsm) and the kidneys responded by producing dilute urine (brisk diuresis), excreting free water and subsequent correction of hyponatremia.

PUB399

Dialysis Disequilibrium Syndrome with Mild Azotemia due to Septic Encephalopathy

Sushanta K. Goswami, Joe Ghata, Satish Kumar. *Medicine/Nephrology, Univ of Oklahoma Health Sciences Center and VA Medical Center, Oklahoma City, OK.*

Introduction: Dialysis Disequilibrium Syndrome (DDS) was initially described as a constellation of neurological symptoms of cerebral edema, occurring early during the first dialysis in patients with high BUN. We present a patient who continues to have DDS at low levels of BUN, two years after an episode of severe sepsis.

Case Description: A 24 year old woman presented in septic shock from Group A streptococci, two days after a vaginal delivery. She had DIC with distal gangrene in all four extremities. She also had AKI and has remained dialysis-dependent two years later. Since discharge, she has had persistent memory deficits, and periodic headache and vomiting. These symptoms worsen after 2 hours on dialysis. Pre and post-dialysis CT scans showed cerebral edema on the post-dialysis scan only. MRI of brain showed diffuse cerebral edema with bifrontal predminance. Lab tests done pre and post-dialysis showed changes in osmolality 291 to 289, BUN 17 to 9, CO2 29 to 31 and ADH 2 to 13. There were no signs of volume overload or orthostasis. Symptoms improved with reduction of dialysis time to 2 hrs on a small dialyzer without ultrafiltration, using 145 Na and 35 HCO3 concentration in the dialysate.

Discussion: DDS was first described in 1962, occurring early during first dialysis in patients with high BUN. Animal studies demonstrated that the major mechanism of DDS was the rapid lowering of blood urea by dialysis. Slower diffusion of urea from brain to blood created an osmotic gradient that induced movement of water from the blood to the brain. Classic DDS has now become uncommon, perhaps due to the wide-spread recognition of DDS and the earlier start of dialysis. Recent reports describe DDS occurring without high levels of BUN suggesting that additional mechanisms may be involved. In our patient, a severe episode of systemic sepsis has left her with a propensity for recurrent cerebral edema late in dialysis. We speculate that septic encephalopathy has caused persistent changes in the blood-brain/brain-CSF barriers or in neuronal transporters that make her more susceptible to DDS even with small osmotic shifts at low level azotemia. Disclaimer: None

PUB400

Late-Onset Warfarin-Induced Skin Necrosis Suspected to Be Calciphylaxis in a Patient with End-Stage Renal Disease on Hemodialysis Emily Lu,[1] Joanna Harp,[2] Jeffrey I. Silberzweig.[1] *[1]Nephrology & Hypertension, Weill Cornell Medicine/New York Presbyterian Hospital (WC/NYPH), New York, NY; [2]Dermatology, WC/NYPH.*

Introduction: Warfarin-Induced Skin Necrosis (WISN) is a rare complication almost always occurring <10 days after warfarin initiation; "late-onset WISN" develops beyond this time. It is characterized by cutaneous purpuric, necrotic lesions requiring prompt diagnosis and treatment due to high morbidity/mortality. We present a case of cutaneous purpura and necrosis in end-stage renal disease (ESRD) initially attributed to calciphylaxis.

Case Description: A 58-year-old woman with ESRD on hemodialysis (HD), peripheral vascular disease, and deep vein thromboses on chronic warfarin presented with extensive lower extremity cutaneous purpuric, necrotic lesions. She had calcium 8.9mg/dL, albumin 1.8g/dL, phosphorous 3.4mg/dL (8.5 in the past year); intact parathyroid hormone 99 pg/mL (1000 in the past year). Her INR was 4.0 but labile. Leg X-ray showed marked vascular calcification. Hypercoaguable workup (this admission and one year ago) was unrevealing; Proteins C and S (from warfarin use) and Factor X activity were decreased; but Factor V Leiden, Prothrombin gene mutation, Antithrombin III mutation, Cardiolipin IgG/IgA/IgM antibodies, Homocysteine, complement levels C3 and C4, cryoglobulins, SPEP and HIT antibody were negative/normal. A full APLS workup could not be performed due to warfarin use. Platelet count was normal. Infectious studies were negative. Based on these findings, her skin lesions were initially attributed to calciphylaxis. Two subsequent skin biopsies demonstrated pauci-inflammatory thrombogenic vasculopathy with no vascular calcium deposition (negative Von Kossa stain), suggesting a thrombotic or procoagulant etiology and effectively ruling out calciphylaxis. Given the dramatic presentation of skin lesions, labile INR, and exclusion of other compatible etiologies, we diagnosed late-onset WISN. The skin biopsy findings were pivotal in directing our treatment and led to improvement of skin lesions.

Discussion: This case highlights the diagnostic challenges and importance of skin biopsy in establishing the diagnosis of WISN, particularly in ESRD patients when calciphylaxis is suspected.

PUB401

Idiopathic Tubulointerstitial Nephritis and Uveitis Joana Gameiro, Sofia C.A. Jorge, Joana M. Dias, Jose António Lopes, António Gomes da Costa. *Service of Nephrology and Renal Transplantation, Centro Hospitalar Lisboa Norte, EPE, Lisbon, Portugal.*

Introduction: NIA is an uncommon cause of acute kidney injury, mostly related to infections, drugs or systemic diseases.

Case Description: We report the case of a an eighteen years old caucasian female who presented with vomiting, nausea, fever, weight loss and impaired renal function. She had neither urinary symptoms nor rash, arthralgias or recent infection. She took no regular medication and there was no prior use of antibiotics or non-steroidal agents. Physical examination was normal. Laboratory revealed hemoglobin 9 g/dL, creatininemia 2.9mg/dL and uremia 66mg/dL. Liver function tests and ionogram were normal. Urine examination revealed 24h-proteinuria 400mg and no eosinophiluria. Urine culture was sterile. Renal ultrasound was normal. Immunologic study was negative for antinuclear antibody, anti-neutrophil cytoplasmic antibody against myeloperoxidase and proteinase 3, anticardiolipin antibody, lupic anticoagulant antibody and anti-beta 2-glycoprotein antibody; TASO, rheumatoid factor and IGRA were negative. Serologic study was negative for HIV, HBV, HCV, Adenovirus, Parvovirus, Coxsackie, EBV, CMV, Herpes virus, Salmonella, brucella, borrelia burgdoferi, leptospira interrogans, Togavirus, coxiella burnetii, Legionella, Mycoplasma pneumoniae, Chlamydia pneumoniae and trachomatis. ACE levels and body CT scan were normal. A kidney biopsy was performed and revealed acute interstitial nephritis, with edema and inflammatory cell infiltration with multiple eosinophils. One-week later she was diagnosed with anterior uveitis. The diagnosis of idiopathic tubulointerstitial nephritis and uveitis (TINU syndrome) was then made and she started prednisolone 1mg/kg/day, tapered over 14 weeks, with complete renal function and ocular manifestations recovery.

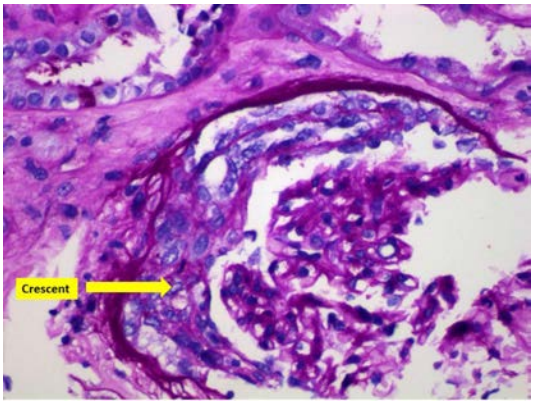
Discussion: TINU diagnosis can be especially difficult in some cases because manifestations may not occur at the same time as illustrated in this case. Still, TINU syndrome should be considered in the differential diagnosis of renal-ocular syndrome. The renal prognosis is excellent and nephritis is often self-limited. Symptoms respond well to corticosteroids, but uveitis often relapses even after a long term follow-up.

PUB402

MPO-C-ANCA-Associated Necrotizing and Crescentic Glomerulonephritis Abhilash Koratala, Dara N. Wakefield, Kawther Farouk Alquadan, A. Ahsan Ejaz. *Univ of Florida.*

Introduction: MPO and PR-3 are the major autoantigens in ANCA-associated vasculitis (AAV). 90% of patients with AAV have either MPO-(P)ANCA or PR-3-(C)ANCA. Generally, antibodies causing cytoplasmic (C) ANCA pattern are directed against PR-3 while those causing perinuclear (P) ANCA are directed against MPO. We present a case of necrotizing and crescentic glomerulonephritis where antibodies against MPO produced a cytoplasmic pattern.

Case Description: 73 y.o. white male, former smoker was admitted with progressive flu-like symptoms and SOB attributed to multifocal pneumonia and pulmonary fibrosis. He was started on antibiotics. Later, he developed ARDS needing mechanical ventilation with FiO2 55-60%. Bronchoscopy showed diffuse alveolar hemorrhage. C-ANCA and MPO positive, but PR-3 negative. Clinical course was complicated by hypotension and SCr worsened from 0.8mg/dL to 2.35mg/dL. However urine output remained at 2-2.7L/day. Renal US revealed 13.5cm right and 12.7cm left kidney. UA: 288 RBC/hpf, 2 WBC/hpf, 1 coarse granular cast and 1 RBC cast. Renal biopsy showed necrotizing and crescentic glomerulonephritis with 50% glomerular involvement with necrosis and/or crescents and arterial and arteriolar nephrosclerosis. IF was nonspecific. Treated with IV methylprednisolone, Cyclophosphamide and Plasma exchange. SCr improved to 1.58mg/dL and he was discharged. He did not require dialysis during hospital stay.



Discussion: False positive MPO-C-ANCA can occur in autoimmune entities whereby antibodies to epitopes on MPO can produce cytoplasmic pattern. Regardless of the staining pattern, it may be the induction of MPO (e.g., propylthiouracil) or anti-MPO antibodies that result in the necrotizing glomerulonephritis as illustrated above. Underlying lung disease, suspected recent flu and other environmental factors are also contributing stimuli for the development of MPO-antibodies. Our case supports the pathogenic role of MPO in AAV.

PUB403

An Obscure Cause of Recurrent Hyperphosphatemia Shameem Ahmad Beigh, David Levy, Sai Subhodhini Reddy. *Nephrology Div, Univ of Rochester Medical Center, Rochester, NY.*

Introduction: Dialysis patients often struggle with multiple dietary constraints imposed on them due to renal failure. Phosphate restriction is commonly stressed due to the known increased risk of mortality of patients with higher serum phosphate levels. The combination of a limited phosphate diet, prescription medication and residual renal function often limit the prevalence of significant hyperphosphatemia among peritoneal dialysis patients. We however, will present a case of a patient with recurrent hyperphosphatemia secondary to drinking water which was refractory to medical therapy.

Case Description: HS is a 51 year old male with ADPKD complicated by ESRD and started on peritoneal dialysis (CCPD, dwell volume of 2L, 4 exchanges with 1.5% glucose solution and manual day exchange with 2.5 L of 2.5% glucose) in November 2014. Since September 2014 he was noted to have high levels of serum phosphate which was initially treated with Sevelamer 2400mg three times daily with meals. In spite of this his serum phosphorous remained high (6.6-7.8 mg/dl) and Sevelamer 800mg with snacks was added. In January 2016 his serum phosphate was noted to be 7.5mg/dl and his Kt/V was 2.33. Velphoro 1000mg with meals was started. In March 2016 he switched from tap water to bottled water and his serum phosphate improved to 4.9 mg/dl. Further investigation was done by the patient and it was determined that phosphorous was being added to the water supply to prevent pipe corrosion.

Date	9/14/15	10/12/15	11/9/15	1/18/16	3/9/16	4/5/16
Serum calcium (mg/dl)	8.8	9.0	8.8	8.6	8.2	8.2
Serum Phosphorus (mg/dl)	6.6	7.8	7.2	7.5	5.8	4.9
PTH (pg/ml)	N/A	N/A	N/A	N/A	N/A	458
Current medications	Sevelamer 2400 mg	Sevelamer 2400 mg	Sevelamer 2400 mg and 800 mg with snacks	Sevelamer 2400 mg and 800 mg with snacks	Velphoro 1000mg	Velphoro 1000mg
Changes	None	Sevelamer 800 mg with snacks added	None	Velphoro 1000 mg satrted, Sevelamer stopped	Changed to bottled water from tap water	None

Discussion: Our case demonstrates the importance of investigating all potential sources (including drinking water) of exogenous phosphate intake.

PUB404

A Case Report Describing Therapy for Acute Urate Nephropathy in Spontaneous Tumor Lysis Syndrome from Chronic Myelomonocytic Leukemia Justin A. Chen,[1] Inderpreet S. Sekhon.[2] *[1]Nephrology, Univ of California, Davis School of Medicine, Sacramento, CA; [2]Nephrology, Veterans Affairs Medical Center, Sacramento, CA.*

Introduction: Tumor lysis syndrome (TLS) with release of intracellular potassium, phosphate and nucleic acids, occurs in certain cancers after chemotherapy, but may occur spontaneously in cancers with a high proliferative rate or large tumor burden. One type of kidney injury from TLS is caused by uric acid crystal precipitation within renal tubules.

Case Description: An 84 year old man with chronic myelomonocytic leukemia was seen in the emergency room for abdominal pain. Serum creatinine (Cr) was 2.56 mg/dL (baseline 1-1.3 mg/dL). A non-contrast CT abdomen/pelvis revealed moderate right hydronephrosis and hydroureter from a 7 mm stone at the ureterovesicular junction and other non-obstructing calculi. He was discharged home with urology follow up, but was admitted to the hospital two weeks later after repeat labs showed a serum creatinine (Cr) of 4.9 mg/dL. On return to the hospital, physical exam revealed normal vital signs and dry mucous membranes. Other findings included hypokalemia (3.1 mmol/L), hyperphosphatemia (5.2 mg/dL), hyperuricemia (22.3 mg/dL), and leukocytosis (100.1 K/mm^3). Urinalysis (UA) detected small blood, pH 5, and uric acid crystals which were confirmed with microscopy. The patient was administered rasburicase, IV fluids (3 amps of sodium bicarbonate per liter of D5 0.45% normal saline at 150 cc/hour), and IV furosemide. Urine output was 3-4 L/day. Repeat UA on hospital day #3 was notable for absence of uric acid crystals and pH 7. Cr was 2.18 mg/dL at discharge on hospital day #6. Repeat CT abdomen/pelvis showed resolution of hydronephrosis and disappearance of uric acid stones.

Discussion: Acute urate nephropathy therapy includes IV fluids and loop diuretics as well as medications aimed at reducing the uric acid burden. Urinary alkalinization is generally not recommended due to concern for calcium phosphate crystal precipitation. Our case illustrates that administration of IV sodium bicarbonate and loop diuretics in select cases may be effective in the treatment of acute urate nephropathy without the untoward consequences of alkali therapy.

PUB405

Unsuspected Protein S Deficiency Caused Vascular Thrombosis and Loss of Pancreas and Kidney Grafts Despite Initial Excellent Function and No Rejection Sushanta K. Goswami,[1,2] Kai Lau.[1,2] *[1]Dept of Nephrology, Univ of Oklahoma, Oklahoma City, OK; [2]Medical Service, VA Medical Center, Oklahoma City, OK.*

Introduction: Thrombophilia poses risks for venous thromboembolism & arterial occlusion causing strokes & MI. It rarely induces thrombosis of allograft without rejection, sepsis, DIC, microangiopathy, proteinuria, protein C or S deficiency. We here report the loss of pancreas & kidney grafts 10 d post-op due to unrecognized protein S deficiency in a 34-year-old non-pregnant type 1 diabetic woman.

Case Description: We reviewed clinical & lab data for hypercoagulable risk factors to define the role of protein S. Both kidney & pancreas functioned well from d 1 to 7. Nadir serum creatinine was 0.9 mg% & glucose normal off insulin. On d 9, she was readmitted for severe pancreas graft pain.

Doppler showed venous occlusion, no arterial diastolic & tiny systolic flow, normal pancreas morphology & iliac vascular flow. Resected pancreas confirmed infarction & no rejection. Doppler showed no flow in renal arcuate, interlobar & interlobular vessels despite good central hilum flow. Renal biopsy showed no rejection. Systemic heparin failed to prevent renal vascular occlusion & relentless failure, forcing graft resection. Parts of her small bowel were resected for ischemia. Detailed thrombophilia workup yielded negative/normal results in: blood & urine cultures, liver function, hepatitis, HIV, CMV, EBV, factors II, V, VII, VIII, XI, AT3, DIC, protein C activity, homocysteine, Leiden genotype, lupus anticoagulant by IgG & IgM vs. cardiolipin & beta 2 glycoprotein-1. Dilute Russell Viper Venom Test was prolonged. It remained so in mixing & confirmation studies. Total protein S level was 78%, but free level (58%) & activity (63%) were low (normal 65-150%), indicating type 3 deficiency.

Discussion: 1.To our knowledge, she is the first reported case of diffuse vascular thrombosis due to protein S deficiency that caused infarction of pancreas & kidney grafts and parts of her bowel. 2. Our experience supports a role for pre-op thrombophilia screening to identify those at increased risks for vascular thrombosis & prophylactic heparin.

PUB406

An Unusal Cause of Relapse of Pseudomonas Peritonitis in a Peritoneal Dialysis Patient Avantika Chenna, Pradeep Reddy Thodima, Eric J. Bloom. *Nephrology, Albert Einstein, Philadelphia.*

Introduction: Per ISPD, peritonitis due to gram negative organisms should be adequately covered by third generation cephalosporin or aminoglycosides and in sometimes floroquinolone. E. Goffin etal in a multicenter study said that oral ciprofloxacin provides satisfactory results in gram-negative infections similar to intraperitoneal ceftazidime or aminoglycosides. We present a case of a 52 yo african american female who is legally blind, with ESRD on PD now diagnosed with relapse of pseudomonas peritonitis. She was taking ciprofloxacin along with her phosphate binder resulting in decreased bioavailability of ciprofloxacin. This is the first case of its kind per our literature review.

Case Description: 52 year old female with h/o ESRD on PD for 4 years and recent pseudomonas peritonitis s/p cathter removal admitted for abdominal pain, nausea and vomiting. Physical exam positive for abdominal tenderness. Vital signs were stable except blood pressure of 190/100 mmHg. Her home medications include sevelamer 2400 mg TID with meals, ciprofloxacin 500 mg qd, lisinopril 20 mg qd, nifedipine 60 mg qd, colicalciferol 50,000 q weekly. During the previous admission 8 days ago, patient was treated with cefepime and PD cathter was removed on the third day of treatment due to persistent, leukocytosis and effluent culture positive for pseudomonas aeruginosa. She was discharged on oral ciprofloxacin to complete antibiotic treatment for duration of 2 weeks after clinical improvement based on sensitivity report.On repeat admission, patient was treated intravenous cefepime and also discharged on intravenous antibiotics because repeat cultures were now resistant to flouroquinolones.

Discussion: Sevelamer is a phosphate-binding cationic polymer that is devoid of calcium which leads to decrease in relative oral bioavailability of ciprofloxacin when administered together.Concomitant administration of these drugs may decrease clinical efficacy of the drug and promote bacterial resistance to ciprofloxacin. It is very important to instruct CKD patients on sevelamer to take ciprofloxacin 2 hrs before or 6 hrs after sevelamer ingestion to avoid decreased bioavailability and to prevent the emergence of bacterial resistance .

PUB407

Case Series Describing Use of Tapentadol for Pain Management in Patients on Chronic Hemodialysis Nicole M. Wegrzyn, Jacqueline Helen Pratt, Mena Milad Raouf, Katie E. Cardone. *Dept of Pharmacy Practice, Albany College of Pharmacy, Albany, NY.*

Introduction: Approximately 50% of patients receiving hemodialysis report musculoskeletal and/or neuropathic pain types. Of those patients, 75% of hemodialysis (HD) patient report that their pain management was inadequate. Limited medication options exist for safe and effective pain management in End Stage Renal Disease (ESRD). Tapentadol is a mu-opioid agonist and also blocks reuptake of norepinephrine, the latter of which is particularly useful for the treatment of neuropathic pain. . Tapentadol is primarily metabolized via Phase 2 glucuronidation to tapentadol-O-glucuronide, which is renally excreted. Neither tapentadol-O-glucuronide nor other metabolites of tapentadol have been found to bind to opioid receptors or any other screened receptor or enzyme. Concerns of tapentadol-O-glucuronide accumulation limit the drug's use in patients on HD. Demonstration of significant HD removal of this major metabolite could justify the use of tapentadol for pain management in patients on dialysis.

Case Description: The main objective of this case series is to describe dialysis clearance of tapentadol and its primary metabolite, tapentadol-O-glucuronide, in patients on high-flux HD who are currently using tapentadol for chronic pain management. This preliminary study will justify the need for a more comprehensive pharmacokinetic study to help elucidate the safety of tapentadol in chronic HD. The study inclusion criteria are as follows: age $\geq$ 18 years, chronic hemodialysis prescription, and active tapentadol therapy. Each subject will provide four 5 mL blood samples for analysis at pre-determined time intervals. Blood samples will be collected and analyzed for concentrations of tapentadol, tapentadol glucuronide, tapentadol-O-sulfate, and N-desmethyltapentadol. Descriptive data analysis will be reported in addition to calculation of tapentadol clearance, metabolite clearance, intradialytic clearance and interdialytic clearance.

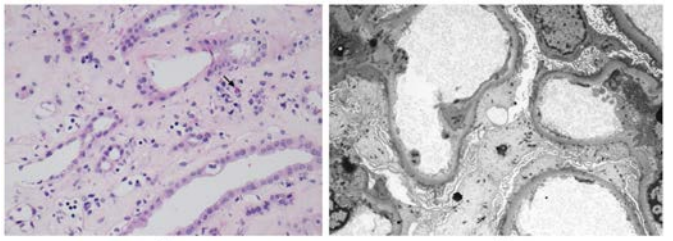
Discussion: This study will provide meaningful data regarding the pharmacokinetic profile of tapentadol and tapentadol metabolites in patients receiving chronic hemodialysis.

PUB408

NSAID Induced AIN and Minimal Change Disease with Complete Resolution George C. Bonifant, Purva D. Sharma, Ira S. Meisels. *Nephrology, Icahn School of Medicine at Mount Sinai and Mount Sinai St. Luke's Hospital, New York, NY.*

Introduction: NSAID use has been linked to Allergic Interstitial Nephritis and Nephrotic Syndrome. We report a case of AIN and Minimal Change Disease (MCD) in a patient with heavy exposure to NSAIDs who was dialysis dependent for a month before full recovery.

Case Description: 77 year old obese female with hypertension came in with cough, tachypnea and edema for 3 days. Reported use of naproxen (500 mg 1-2/day for 6 weeks) for chronic back pain. BP was 146/77, RR 16 and O2 saturation 96% on room air in the ER. Physical exam notable for wheezing with 3+ dependent edema. Labs revealed creatinine 10.47 mg/dL (1.2 ten months prior), CBC 32% Eosinophils, U/A 4+ Protein, MPO, PR3 and anti-GBM negative, Complements normal, polyclonal SPEP, +ve urine eosinophils. Urine Microscopy showed non-dysmorphic RBC's, fine granular casts and no cellular casts. UACR was 7020 mg/g. Initiated on dialysis hospital day 3 for oliguria. Biopsy revealed glomerulosclerosis of 7/17 glomeruli, moderate IFTA, hypersensitivity-type AIN and moderate Arteriosclerosis. EM showed diffuse podocytopathy consistent with MCD. Immunofluorescence was negative. Received Prednisone for 8 days, but chances of recovery were low due to IFTA so steroids were held on discharge. Continued on outpatient dialysis for 3 weeks. Urine output improved in week 4 with repeat creatinine 1.2 mg/dL, so dialysis was held. Last creatinine 1.0 mg/dL with protein-100 on U/A and bland urine sediment.



Renal biopsy during AKI. (a) Hematoxylin and eosin staining showing diffuse edema and focal interstitial inflammation including eosinophils involving the medulla (magnification x200). (b) Electromicroscopy showing diffuse effacement of foot processes with microvillous transformation of podocytes (magnification x1500).

Discussion: Our case shows important features of NSAID induced AIN and nephrotic syndrome. She presented with classic features of drug induced AIN, typically absent in NSAID induced AIN. There was complete recovery of renal function despite interstitial fibrosis. Lastly, complete recovery of kidney function occurred in 3 weeks with withdrawal of the drug without a substantial amount of steroid use.

PUB409

Calcium Kidney Stone Former with Hyponatremia Eman Mohammad Shaban, Jie Tang. *Nephrology, Univ Medicine, Brown Univ, Providecne, RI.*

Introduction: 45-year-old female presented with recurrent calcium phosphate kidney stone. Her past medical history was also significant for anxiety, depression, and hypothyroidism. She was on venlafaxine, alprazolam, buspirone, and synthroid. Her recent TSH was unremarkable. She felt well other than intermittent flank pain, and had been passing small stones once every 3-4 months with stable medullary nephrocalcinosis and stone burden per ultrasound. She underwent another lithotripsy for stone removal recently.

Case Description: Her physical examination was unremarkable. Her BMI was 26. Initial laboratory tests showed normal serum sodium at 137 meq/L, serum potassium at 4.5 meq/L, serum bicarbonate at 23 mg/dl with an anion gap of 10, and normal serum creatinine at 0.8 mg/dl. 24-hour urine showed a low volume at 0.93 liter, pH 7.4, and urine calcium at 100 mg. Her supersaturation of Calcium Oxalate and Brushite were both high (2.3, 3.4 respectively). She was instructed to increase her fluid intake targeting urine output of 2-2.5 liters/day, and restrict salt intake to maintain low urinary calcium excretion. Since then, patient followed the dietary instructions well with increased urine output. But at her 3-month follow-up, she complained of nonspecific weakness. She did not report any flank pain or new stone event. Repeat laboratory test showed acute hyponatremia with serum sodium down to 131 meq/L. The rest of basic metabolic panel were unremarkable, including a baseline serum creatinine and normal serum bicarbonate. Her repeat 24-hour urine showed a total volume of 2.97 liter which was significantly increased from her prior measurement, urine pH was 6.8, and urine calcium remained under control at 138 mg / day. Supersaturation of Calcium Oxalate and Brushite were normalized at 1.15 and 1.19 respectively. She was euvolemic by physical examination, and the rest of laboratory data were consistent with hyponatremia from SIADH.

Discussion: High fluid intake and salt restriction are standard measures for calcium kidney stone prevention. However, the same measures could lead to clinically significant hyponatremia in patients at risk for SIADH, like our patient with long history of mood disorder and taking psychotropic medications.

PUB410

Outbreak of Catheter-Related Bloodstream Infection by Elizabethkingia: Gram Negative Bacteria Poorly Known in Dialysis Center Luis Felipe Cintra, Maria C.C. Andreoli, Nadia Guimaraes- Souza, Thais Nemoto Matsui, Adriano Luiz Ammirati, Ana Karoline Nobrega Cavalcanti, Carlos Tadeu Bichini Guardia, Alessandra Correa Pereira, Marisa Petrucelli Doher, Fabiana Dias Carneiro, Bruna Gomes Barbeiro, Bento C. Santos. *Dialysis Center, Hospital Israelita Albert Einstein.*

Introduction: Multiresistant bacterias are becoming increasingly common in health care centers and today are the global focus due to increasing difficulty on infection´s treatment caused by these micro-organisms.

Case Description: From January to March 2016, were detected 4 cases of catheter-related bloodstream infections (CRBSI) by gram-negative bacteria Elizabethkingia in a dialysis center. This bacteria is associated with severe nosocomial's infections, high antimicrobial resistance, and sensitivity profile not yet well-known. Four patients presented bacteremia during hemodialysis session. Hemocultures collected in the catheter of dialysis (MALD-TOF method) and in peripheral blood culture had growth difference greater than 2 hours. In 3 cases Elisabethkingia miricola and in one case Elisabethkingia meningoseptica. In all cases, the antibiogram was sensitive only to Levolfoxacin and Sulfamethoxazole-trimethoprim, and resistance to all other antibiotics tested. Exchange of the central catheter associated to antibiotic therapy for 14 days in all patients were the treatment choice. The patient with E. menigoseptica and one case with E. miricola were treated with Levofloxacin. The others received sulfamethoxazole-trimethoprim once Levofloxacin minimum inhibitory concentration was higher in this cases. None of patients had complications and three patients were submitted to arteriovenous fistula confection.

Discussion: The early clinical recognition of infection, isolation in hemoculture and treatment based on antibiogram were fundamental to the treatment´s success.

PUB411

An Atypical Presentation of Atypical Hemolytic Uremic Syndrome Marilyn (Linh) M. Phung,[1] Christoph Licht,[2] Jocelyn S. Garland.[1] *[1]Nephrology, Kingston General Hospital, Kingston, ON, Canada; [2]Pediatric Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.*

Introduction: Atypical hemolytic uremic syndrome (AHUS) is a systemic thrombotic microangiopathy (TMA) caused by dysregulation of the complement system that cause significant morbidity and mortality, most notably with renal involvement.

Case Description: A 21 year old previously healthy female presented to the emergency room with a 2 week history of epigastric pain and non-bloody diarrhea. She had been seen twice before with these symptoms but had been sent home after supportive care, with noted preserved renal function. On her third visit, she had developed vomiting, fever, severe bilateral flank pain and anuria. Her creatinine was found to be elevated and continued to worsen despite aggressive fluid resuscitation. Post-renal causes were excluded. Urine microscopy was non-contributory. Hemolytic work up showed worsening anemia and thrombocytopenia, elevated lactate dehydrogenase and bilirubin. Shistocytes were absent on blood smear and direct Coombs was negative. On history, she reported recent exposure to contaminated water from camping. Plasmapharesis was started, and an urgent renal biopsy was performed which later confirmed TMA. ADAMSTS13 activity returned as sufficient and Stool Shiga toxin was negative, suggesting against TTP or STEC-HUS. With complement low, the patient was diagnosed with AHUS. Unfortunately, LDH and creatinine remained high despite plasmapharesis, thus requiring dialysis; she was started on eculizumab after blood counts failed to improve. Her medical condition stabilized and she was discharged home to continue maintenance eculizumab infusions and hemodialysis as an outpatient. Unfortunately, she has not shown renal recovery and is undergoing assessment for transplant.

Discussion: This case highlights the importance of early recognition and treatment of TMA to mitigate the rapid development of end-organ damage. Evidence of a TMA process does not always require the presence of fragments on blood smear, or low haptoglobin levels. Subsequently, it is also important to distinguish between the etiologies of TMA as their management is notably different.

PUB412

Acute Generalized Exanthematous Pustulosis Leading to Acute Kidney Injury through Glomerular Damage Larissa Kruger Gomes, Poorva Bindal, Ryan D. Stephenson. *Internal Medicine Dept, Univ of Connecticut, Farmington, CT.*

Introduction: Acute generalized exantematous pustulosis (AGEP) is a rare drug-mediated reaction leading to sterile pustule formation and systemic inflammation. The most common end-organ involvement in AGEP is acute kidney injury (AKI), happening in one third of cases. Nonetheless, the pattern of renal injury varies. We show a case of AKI mediated by AGEP in the setting of glomerular damage.

Case Description: 51-year-old female with past medical history of chronic obstructive pulmonary disease and morbid obesity presenting with a whole body pustular rash. Two weeks prior to admission the patient had an episode of cellulitis of the left foot for which she was being treated with vancomycin and cefepime. On day nine of treatment she developed a generalized exanthematous pustular rash, which got progressively worse and became associated with altered mental status. Furthermore, on admission she presented with a white blood cell count of 20.000 cells/mcL and a creatinine (Cr) of 2.4 mg/dL, from her baseline of 0.8mg/dL. The urinalysis (UA) showed dysmorphic red blood cells, 0.8 Protein/Cr ratio and a FeNa of 1.1%. Urine was negative for eosinophils or casts. After removing the antibiotics the patient's Cr returned to baseline after one week. No corticosteroids were used. A biopsy of the skin was able to confirm a pattern of involvement compatible with AGEP. No kidney biopsy was obtained.

Discussion: Normally, drug-mediated renal injury involves an acute interstitial nephritis or acute tubular necrosis pattern; nonetheless, in this case, the renal insult pattern was suggestive of a glomerular level damage given UA findings and FeNa. Recent research shows involvement of T-cell mediated response in AGEP that would explain glomerular damage mediated by IV hypersensitivity reaction. Further characterization of renal pattern of injury would be helpful to determine role of immunosuppression or apheresis methods in the management of this ailment. Renal injury by AGEP continues to be a rare form of AKI, however, further studies for characterization of pattern or renal insult are needed to establish beneficial interventions and proper prognostication.

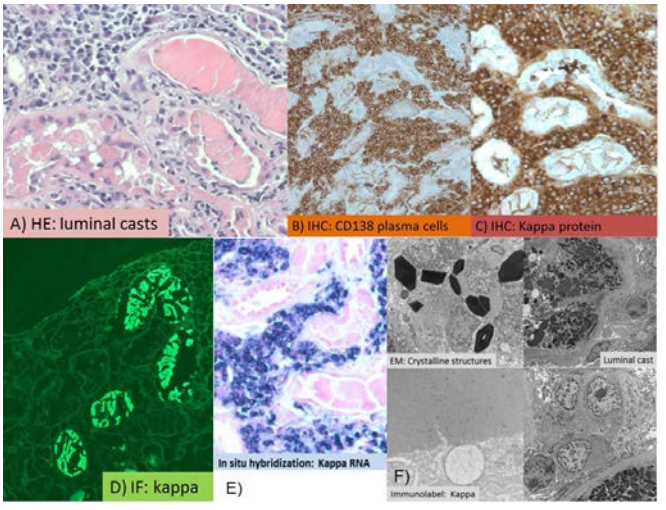
PUB413

Crystalline Light Chain Proximal Tubulopathy with Monoclonal Plasma Cell Infiltrate Abhilash Koratala, William L. Clapp, Dara N. Wakefield, A. Ahsan Ejaz. *Univ of Florida.*

Introduction: We present a rare case of crystalline Light chain proximal tubulopathy (LCPT) in a patient with Multiple myeloma.

Case Description: 69 year-old white male presented to the ER with fatigue and atypical chest pain. MI was ruled out but noted to have elevated SCr of 12.5mg/dL (14 months ago, 0.9mg/dL). On exam, vitals were stable, he was mildly lethargic and no pedal edema. Labs: Na 140meq/L, K 3.8meq/L, Cl 98meq/L, HCO3 19meq/L, BUN 112mg/dL, Ca 9.5mg/dL, Phos 10mg/dL, Hgb 6.2g/dL. UA: pH 6.0, protein 100mg/dL, RBC 1-2/hpf, WBC 2/hpf, no casts. Renal US: R 15.5cm, L 15cm, no hydronephrosis. He did not respond to iv fluids and developed pulmonary congestion and became more lethargic which prompted urgent initiation of hemodialysis. Renal biopsy showed A)Prominent tubulointerstitial injury associated with accumulation of PAS negative luminal casts which have eosinophilic, hard,

and irregular, fracture lines and focally appear broken with a crumbled appearance. Congo red negative. B) Extensive confluent sheet-like infiltrative pattern of kappa-immunoreactive plasma cells (CD138) with C) Intense cytoplasmic positive immunoreactivity for kappa LC. D) Luminal casts show intense staining for kappa LC (4+). E). Kappa RNA. F) Intracytoplasmic electron-dense crystalline cast fragments in tubule cells, plasma cells and the interstitium.



Bone marrow biopsy confirmed Multiple myeloma. Treated with Cyclophosphamide, Bortezomib and dexamethasone. Patient remains dialysis-dependent.

Discussion: Our case of LCPT is characterized by occurrence in an older patient, cytoplasmic inclusion of kappa-restricted monoclonal LC, crystals not detected by LM or IF but by EM and was associated with heavy-burden myeloma. IF-Frozen and IF-Peroxidase have low sensitivity for detection of LCPT, and pronase digestion for formalin-fixed sections maybe required to detect crystalline LCPT. Alternately, immuno-gold staining may be required.

PUB414

An Unusual Case of Nephrotic Syndrome Associated with Increased Bleeding Risk Arjun Sekar,[1] Taranpreet Kaur,[1] Jonathan J. Taliercio,[1] Leal C. Herlitz.[2] *[1]Dept of Nephrology & Hypertension, Cleveland Clinic Foundation, Cleveland, OH; [2]Dept of Pathology, Cleveland Clinic Foundation, Cleveland, OH.*

Introduction: We describe a case of suspected renal amyloidosis with workup revealing increased bleeding risk. We discuss the association of amyloidosis with increased bleeding & methods to prevent bleeding post kidney biopsy.

Case Description: A 75 year old female with IgM Kappa paraproteinemia was evaluated for nephrotic syndrome & CKD stage 3. Workup revealed Factor 10 deficiency, so kidney biopsy was deferred. Bone marrow biopsy suggested lymphoplasmacytic lymphoma and treatment was initiated with bortezomib & rituximab. However, renal function continued to worsen (protein creatinine ratio increased to 28.1 from 22, and creatinine 4.1 mg/dl from 1.8,) with associated fluid overload prompting hospitalization. PLA2R was negative. Abdominal fat pad biopsy was negative for amyloidosis. Serum Monoclonal testing was significant for serum kappa 2150 mg/dl (Normal; 534-1267) & kappa/lambda ratio 33. On admission she got factor 9 infusion (40 units/kg) and factor 10 level increased to 33% from 11%. Prior to kidney biopsy she received 4356 units of prothombin complex concentrate (PCC) & factor 8 inhibitor bypassing activity (FEIBA) & 2673 units post procedure. INR and APTT levels remained stable and she tolerated the procedure without major bleeding. Kidney biopsy revealed kappa light chain amyloidosis with extensive glomerular and tubulointerstitial involvement. Treatment with cyclophosphamide was initiated.

Discussion: Amyloidosis is an established, independent risk factor for bleeding per a prospective study. Proposed mechanisms are increased vessel fragility and impaired vasoconstriction from amyloid deposition in blood vessels. Per a study, 9% of patients with amyloid also had factor 10 deficiency. If kidney biopsy is indicated for suspected amyloidosis, testing for factor deficiency is essential. Ideally it should be avoided and abdominal fat pad biopsy (57-85% sensitivity) should be pursued. However, in our case, kidney biopsy was warranted due to worsening renal function. PCC-FEIBA complex administration can reduce the risk of bleeding in these cases.

PUB415

ANCA Vasculitis with IgA Deposits Tahir Zaman,[1] Divya Raghavan,[1] Josephine Abraham,[1] Monica Patricia Revelo Penafiel,[2] Laith Al-Rabadi.[1] *[1]Nephrology, Univ of Utah, Salt Lake City, UT; [2]Pathology, Univ of Utah, Salt Lake City, UT.*

Introduction: ANCA-associated vasculitis is known to present with rapidly progressive glomerulonephritis with morphologic features of segmental necrosis and crescents with negative immunofluorescence. The coexistence of IgA deposits has been reported in the literature. Presence of immune deposits should not exclude ANCA vasculitis as the main pathologic process.

Case Description: A 59-year-old man presented to the hospital with lower extremity swelling and a 2-month history of tea-colored urine associated with fevers and myalgia. Patient was found to have acute kidney injury with a serum creatinine of 8 mg/dl. Serum creatinine was 1 mg/dl 3 months ago. Urine analysis showed 3+ blood and 2+ protein. Urine microscopy revealed dysmorphic RBCs and RBC casts. His chest radiograph was unremarkable. Serologic workup was pending when the renal biopsy was performed. Light microscopy revealed diffuse necrotizing crescentic glomerulonephritis that raised suspicion for ANCA vasculitis despite the presence of IgA and C3 deposits by immunofluorescence. Serologic workup confirmed our suspicion and revealed a positive ANCA of 1:320 titer (perinuclear pattern) and elevated MPO at 287 AU/ml. Due to the severity of patient's renal failure and impending need for dialysis, he was treated aggressively for microscopic polyangiitis with oral cyclophosphamide, plasmapheresis and steroids. Renal function has improved significantly with Cr down to 2 mg /dl.

Discussion: ANCA vasculitis with IgA deposits is an uncommon entity. The diffuse necrotic and crescentic process in the absence of significant hypercellularity should prompt consideration of ANCA associated vasculitis despite the presence of immune deposits. Renal biopsy and serologic evaluation were critical to finding the unifying diagnosis and initiating the appropriate therapeutic interventions. The relevance of IgA deposits in the setting of ANCA vasculitis is still unclear and warrants further studies.

PUB416

Catastrophic Antiphospholipid Syndrome: A Role for Renal Biopsy in an Unusual Presentation Tahir Zaman,[1] T. S. Bjordahl,[1] Monica Patricia Revelo Penafiel,[2] Monique E. Cho.[1] *[1]Univ of Utah, Univ of Utah, Salt Lake City, UT; [2]Pathology, Univ of Utah, Salt Lake City, UT.*

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is a rare but important cause of thrombotic microangiopathy.

Case Description: A 27 year-old woman with history of lupus, epilepsy, and deep vein thrombosis (DVT) on chronic anticoagulation presented with severe pleuritic chest and back pain and nausea. CT angiogram and transesophageal echocardiogram performed for a peak serum troponin level of 12 ng/ml excluded epicardial coronary thrombosis and aortic dissection. MRI of the heart revealed transmural enhancement of the lateral wall and apex, suggestive of myocardial injury but atypical for infarction. The patient was treated for presumed lupus myopericarditis with methylprednisolone, colchicine, and mycophenolate mofetil without any clinical improvement. Her course was further complicated by worsening thrombocytopenia and new upper extremity DVT. The patient's serum creatinine also increased to 1.3 mg/dL from a baseline value of 1.1 mg/dL with 1.14 g/d of proteinuria and rare urinary dysmorphic red cells. Because of the diagnostic uncertainty, a renal biopsy was performed, revealing thrombotic microangiopathy (TMA) and focal proliferative glomerulonephritis. Serologic tests showed profoundly elevated titers for anti-cardiolipin IgM (108 MPL) and anti-Beta-2 glycoprotein IgM (>150 SMU). Based on multiple sites of thrombosis (extremity, kidney, presumed myocardium), rapid onset, and the presence of antiphospholipid antibodies, CAPS became the unifying diagnosis. The patient was treated accordingly with heparin, pulse steroids, plasmapheresis, and rituximab therapy with marked clinical improvement subsequently.

Discussion: TMA due to CAPS is a rare but important cause of glomerular pathology. Because cardiac MRI cannot differentiate myocarditis from diffuse microvascular ischemia, renal biopsy was key to identifying the correct diagnosis and determining the course of therapy in our case, despite unimpressive renal presentation. A possible therapeutic role for rituximab in lupus patients with CAPS is discussed.

PUB417

Acute Hyponatremic Encephalopathy after Orthopedic Surgery: Should Thiazides Be Withheld Perioperatively? Di Pan,[1] Thalia Salinas,[1] Franco Vallejo,[1] Anip Bansal.[2] *[1]Medicine, Mount Sinai St. Luke's and West; [2]Nephrology, Mount Sinai St. Luke's and West.*

Introduction: Hyponatremia is a common occurrence in patients after orthopedic surgery. In patients who concurrently take thiazide diuretics perioperatively, profound hyponatremia can occur. We present 2 cases of severe symptomatic hyponatremia requiring intensive care after total shoulder arthroplasty (TSA).

Case Description: Patient 1: A 69-year-old female with a history of hypertension and osteoarthritis was found to have dizziness, vomiting, and dysarthria 36 hours after TSA. Laboratory testing revealed a serum sodium of 119 mmol/L that was significantly lower compared to 133 mmol/L at the time of her pre-operative evaluation 2 weeks prior to surgery. The patient did not receive any hypotonic fluids during and after her surgery, but had taken chlorthalidone 12.5mg the night before her operation. Patient 2: A 78-year-old female with a history of hypertension and osteoarthritis was found to have worsening confusion and urinary incontinence 48 hours after TSA. She had a decrease in her serum sodium from 141 mmol/L at the time of admission to 117 mmol/L at time of evaluation. The patient did not receive any hypotonic fluids during and after her surgery but reported increased fluid intake due to high ambient temperatures. She was maintained on her home-dose of hydrochlorothiazide 25mg perioperatively. Both patients received 3% NaCl boluses with prompt resolution of symptoms and improvement in hyponatremia.

Discussion: Hyponatremia is occasionally encountered after orthopedic procedures, and is a common side effect of thiazide diuretics. This can lead to adverse clinical outcomes such as longer hospital stays and significant morbidity, especially in the geriatric population. Post operative pain and nausea causing increased ADH secretion and decreased oral intake impairing free water excretion likely contribute to acute worsening of thiazide associated hyponatremia. As there is limited description of this in the literature, further studies should be done to evaluate the incidence and relative contribution of thiazides to post-operative hyponatremia. Clinicians should consider withholding these medications perioperatively to minimize the risk of this complication.

PUB418

The Efficacy of Eculizumab in Patients with Atypical Hemolytic Uremic Syndrome Daisuke Matsumura,[1] Eiichi Sato,[1] Hongmei Lu,[1] Mayumi Nomura,[1] Mayuko Amaha,[1] Shun Iida,[2] Akiko Fujii,[2] Yuko Ono,[2] Yoshihiko Ueda,[2] Tsukasa Nakamura.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Shinmatsudo Central General Hospital, Matsudo, Chiba Prefecture, Japan; [2]Dept of Pathology, Dokkyo Medical Univ, Koshigaya Hospital, Koshigaya, Saitama Prefecture, Japan.*

Introduction: The effects of eculizumab for treatment of atypical hemolytic uremic syndrome (aHUS) vary by cases. We present three cases of aHUS who recovered from kidney damage, which initially required hemodialysis.

Case Description: Case 1: The patient was a 48 year-old female hospitalized for general fatigue. Blood tests revealed hemolytic anemia, kidney dysfunction,thrombocytopenia and red cell fragments in peripheral blood.She was diagnosed with aHUS. She underwent plasma exchange for one week without improvement in her thrombocytopenia and kidney function. She was thus started on eculizumab. The patient recovered her kidney function, and hemolytic anemia and thrombocytopenia resolved. Kidney biopsy revealed thrombotic microangiopathy (TMA), no evidence of glomerulosclerosis and tubulointerstitial change. Genetic examination showed an abnormality in C3. Case 2: A 67 year-old male was referred to our hospital with a diagnosis of aHUS. Despite receiving plasma exchange treatment, he required hemodialysis. After 2 weeks of hemodialysis, administration of eculizumab was started. The patient recovered kidney function and hemodialysis was stopped. Kidney biopsy revealed TMA, no evidence of glomerulosclerosis and tubulointerstitial change. Case 3: A 43 year-old male was found to have TMA by blood test. He was diagnosed with aHUS. Serum creatinine level was high (18.78 mg/dL) therefore he urgently required hemodialysis. Kidney biopsy revealed TMA, glomerulosclerosis and moderate tubulointerstitial change. Although eculizumab treatment was commenced 4 weeks after starting hemodialysis, his kidney function deteriorated and hemodialysis had to be maintained. Genetic examination showed an abnormality in CFH.

Discussion: We conclude that immediate administration of eculizumab may avoid progression to kidneydysfunction in aHUS. Furthermore, the efficacy of eculizumabmay correlate with the degree of glomerulosclerosis and the extent of tubulointerstitial lesions.

PUB419

Severe Hypercalcemia in a Young Man Who Loves Milk and Takes Vitamin Supplements Paul El Azoury, Alan Segal. *Nephrology, Univ of Vermont, Burlington, VT.*

Introduction: The most common causes of hypercalcemia are primary hyperparathyroidism, paraneoplastic syndromes, and variants of the so-called "milk-alkali" syndrome. Hypercalcemia is common in patients with cancer , mechanisms include : PTHrP ,osteolytic lesions and 1.25 (OH)2D3 production. Milk Alkali syndrome consists of the triad of Hypercalcemia ,metabolic Alkalosis and AKI .

here we report a case of a patient who presented with features and signs of Milk alkali syndrome due to consumption of high amounts of milk and supplements, found to have a Large B cell lymphoma .

Case Description: A 35 year old man with no medical history presented with generalized weakness and was found to have [calcium] 16.1 mg/dL, [tCO2] 40 mM, and Cr 1.7 mg/dL (baseline 0.8 mg/dL). Work-up showed suppression of PTH and no parathyroid hormone-related peptide (PTHrP), but 1,25-dihydroxyvitamin D3 was elevated at 169 pg/mL (nl 18-78). His dietary habits included drinking a gallon of raw whole milk daily and ingestion of multiple vitamin supplements including vitamin A and vitamin D (10,000 IU) daily. These data—along with the triad of hypercalcemia, metabolic alkalosis, and AKI in this young, healthy man—suggested the "milk-alkali" syndrome. However, the severity of the hypercalcemia was atypical, and careful physical examination revealed splenomegaly. Although laboratories rapidly normalized with IV saline, calcitonin, and pamidronate, a CT abdomen showed a large heterogeneous splenic mass and retroperitoneal lymphadenopathy. Biopsy of the splenic mass showed non-Hodgkin lymphoma, diffuse B cell type.

Discussion: The most common cause of lymphoma-associated hypercalcemia is PTHrP secretion by the tumor, but overproduction of 1,25-dihydroxyvitamin D3 also occurs, as in this case. In summary, we report a case of paraneoplastic hypercalcemia with an initial presentation mimicking "milk-alkali" syndrome. Our patient is responding well to chemotherapy.

PUB420

Rare Cause of Hypophosphatemia;Tumor Induced Osteomalacia Manini Vishwanath, Anirban Ganguli, Judith H. Veis. *Medicine/Nephrology, Washington Hospital Center, Washington, DC.*

Introduction: Tumor-induced osteomalacia(TIO) is a rare paraneoplastic syndrome causing severe hypophosphatemia. We present a rare case of metastatic prostate cancer with this condition.

Case Description: 65 year old male with past medical history of untreated Chronic Hepatitis C, HIV on HAART (never on tenofovir) and refractory prostate cancer with vertebral metastasis was admitted with failure to thrive and muscle cramps. Severe hypophosphatemia of 0.3mg/dl was noted(values were low normal 6 months prior, normal 6 years ago). He had hypocalcemia, with normal electrolytes, creatinine and blood gas profiles. Markedly elevated serum alkaline phosphatase, marginally low 25OH Vitamin-D, elevated PTH (290.1 pg/ml) and elevated fractional urinary phosphate excretion of 10% suggesting osteomalacia and renal phosphate wasting. Hypocalcemia resolved with oral calcium carbonate and calcitriol but hypophosphatemia improved only marginally with IV sodium phosphate and oral potassium phosphate. While generalized aminoaciduria was noted, there was no glycosuria suggesting that this could be either from partial Fanconi's syndrome or chronic liver disease as a cause. However markedly elevated FGF-23 levels (5950 RU/ml, normal <180) clinched the diagnosis of oncogenic osteomalacia. Despite maximal phosphate supplementation, moderate hypophosphatemia (1-1.5mg/dl) persisted over the following 2 weeks of observation.

Discussion: Severe and sustained hypophosphatemia of <1mg/dl is uncommon. Causes include renal phosphate wasting from genetic tubular defects causing hypophosphatemic rickets, drugs (cisplatin, ifosphamide, tenofovir), hyperparathyroidism (primary or secondary) or proximal tubular dysfunction (Fanconi's syndrome associated with renal tubular acidosis, aminoaciduria and renal glycosuria) all of which inhibit the specific Sodium-Phosphate cotransporter (NaPi 2a and 2c). Another rare cause is TIO, a paraneoplastic syndrome mostly reported in mesenchymal tumors but rarely in metastatic hormone-refractory prostate cancer with a dismal prognosis. Recently, Fibroblast Growth Factor(FGF-23), a specific phosphaturic hormone inhibiting the expression of NaPi2a and 2c, has been recognized as the primary mediator of this syndrome.

PUB421

Angiotensin Converting Enzyme Inhibitor Causing Seizures Sai Prasad Gadapa,[1] Siwadon Pitukweerakul,[2] Sree V. Pilla.[3] *[1]Internal Medicine, St. Francis Hospital, Evanston, IL; [2]Internal Medicine, St. Francis Hospital, Evanston, IL; [3]Internal Medicine, St. Francis Hospital, Evanston, IL.*

Introduction: This is a case report showing that Lisinopril can cause hyponatremia and when combine with thiazides can cause seizures secondary to hyponatremia.

Case Description: A 54 yo African American male with past medical history of schizophrenia and hypertension was brought to the ED with c/o vomiting since 2 days. H/o vomiting 2-3 episodes a day. Pt became less communicative over 2 days and as per the family member he goes into catatonic state when he becomes sick. He takes aripiprazole, lisinopril. On Examination BP 153/91, PR 94/min, T 98.5 F, RR 16/min, BMI 26.64 kg/m2, spo2 98%, stares blankly without interaction. BUN 12 mg/dL, creatinine 0.69 mg/dL, Na 107 mmol/L, K 4.4 mmol/L, Cl 74 mmol/L, co2 24 mmol/L, Ca 10.2 mg/dL, GFR MDRD Af Amer >60 ml/min/1.73 m, serum osm was 221 mOsm/kg, urine osmolality 734, urine sodium 105, urine creatinine 144, urine chloride 109, urine potassium 43. Patient was started on NS 0.9% 75 cc/hr, sodium improved to 109 mmol/L over 12 hours. Patient was switched to 3% Nacl at the rate of 10 cc/hr. Lisinopril was stopped. Patient was discharged on day 9 with serum sodium of 133 mmol/L and the patient was instructed to stop taking Lisinopril. After 7 months he was admitted with c/o seizures and his seizures were thought to be because of hyponatremia of 119. Review of his home medication showed that he was restarted on Lisinopril and hydrochlorothiazide.

Discussion: Initially patient was thought to have hyponatremia because of dehydration secondary to vomiting but his urine osmolality and urine sodium showed finding consistent with SIADH. Pt was on aripiprazole and Lisinopril. Aripiprazole wouldn't cause hyponatremia. There are few case reports saying that Lisinopril cause hyponatremia. Literature reports that ACE inhibitors are associated with high ADH levels. Other possible mechanism by which ACE inhibitor causing hyponatremia is failure to cross blood brain barrier and inhibit angiotensin converting enzyme therefore causing angiotensin II to stimulate release of Anti-Diuretic hormone.

PUB422

Female Patient with Membranous Nephropathy and Alport Disease: Case Report Mariana Pigozzi Veloso,[1] Precil Diego Miranda de Menezes Neves,[1] Francisco Zanotelli Mattedi,[1] Cristiane B. Dias,[1] Leonardo Abreu Testagrossa,[2] Lectícia Jorge,[1] Luis Yu,[1] Viktoria Woronik.[1] *[1]Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Pathology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Introduction: The association of Hereditary Nephritis due to disorders of collagen IV like Alport Disease (AD) and immunocomplex nephropathies is uncommon.

Case Description: Women, 37 years old was referred to nephrology clinic due to anasarca, foamy urine and ten kg gain during the last two months. She denied any systemic symptoms or any exposure to nephrotoxic drugs. Obstetrical history showed seven pregnancies, eight living childbirths and no abortion. Pre eclampsia was developed in last pregnancy. Since then, she had hypertension and took medications for high blood pressure. Four of her sons had AD, one on dialysis. Two grandmother-sisters and three cousins developed end-stage kidney disease. Her parents were not blood relatives. Laboratory: BUN 10,28 mg/dL, serum creatinine 0.62 mg/dL, Estimated Glomerular Filtration Rate (CKD-EPI): 134ml/min/1,73m^2, albumine 1.3g/dL and 24h protein urine excretion of 5.5g. Urine sediment was unremarkable with 4 leucocytes and 9 red blood cells. Immunological investigation was negative. VDRL (Venereal Disease Research Laboratory test) was positive 1:1 and FTAbs (Fluorescent treponemal antibody-absorption test) was weakly positive (2.73 cut-off 0.216). Kidney Ultrasound: Right kidney 11,4 cm and left kidney 10,8 cm with normal ecogenicity. Kidney Biopsy Light Microscopy: Fourteen glomeruli with normal cellularity, capsule and Bowman space. Basal membrane with occasional spikes. Imunofluoroscence: IgG deposits 3+/3+, Kappa 2+/3+ and lambda 1+/3+ in glomerular capillaries, granular,global and diffuse pattern. Electron Microscopy: Capillary loops with epimembranous subepithelial electrondense deposits with spikes. Basal membrane irregularities characterized by thicked alternating with thinned areas and lamina dense delamination. Histopathologic Diagnosis: Membranous Glomerulonephritis (MGN) grade I and collagen IV genetic disease (AD).

Discussion: We report a double histopathological lesion – glomerular basement membrane lesion of hereditary nephritis and MGN, to our knowledge not described until now.

PUB423

Hypokalemia and Respiratory Alkalosis in Pregnancy Rudrick V. Ledesma,[1] Maureen E. Brogan.[2] *[1]Nephrology, Westchester Medical Center, Valhalla, NY; [2]Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Pregnancy causes physiologic changes in one's body. Cardiovascular, hormonal, renal, and respiratory changes occur. These are normal adaptations to accommodate the fetus and are imperative in an event of complications. We are presenting a case of a pregnant lady with respiratory alkalosis and severe hypokalemia.

Case Description: A 32 yo lady with pmh of hypokalemia exacerbated during pregnancy was seen in renal clinic for hypokalemia. She was 23 weeks with her 2nd pregnancy on her 1st renal visit. Her serum potassium levels were between 2.4 meq/L to 3.8 meq/L. It has been on the higher side after her potassium supplement was increased to 120 meqs per day. Symptoms include nausea and vomiting. Prior to the raising of her supplements, she was complaining of fatigue and leg cramps. No other subjective complaints. Laboratory studies showed glucose 85 meq/L, sodium 134 meq/L, potassium 3.3 meq/L, chloride 103 meq/L, bicarb 21 meq/L, BUN 0.52 mg/dl and creatinine 0.52 mg/dl. Urine pH 7.0 and sg 1.014. Urine lytes: UNa 67, UK 76, UCl 126, Uosm 499 and UCr 44.2 Thyroid function tests were within normal limits. Renin activity was 47 ng/ml/hr and Aldosterone 94 ng/dl. Cortisol level at 12:49 pm was 9.0 mcg/dl. ABG showed pH 7.46, PCO2 30, PO2 105, Bicarbonate 21.3.

Discussion: In pregnancy, there is an increase in total body K but a slight decrease in serum K. Serum renin activity and aldosterone level increase due to decreased systemic vascular resistance. The kaliuretic effect of aldosterone is countered by the potassium retention induced by elevated progesterone. Due to the physiologic changes in the lungs and increased progesterone, respiratory alkalosis is common. In normal pregnancy, serum potassium level is usually normal and serum bicarbonate level can be low. This is a unique case of a pregnant patient with severe hypokalemia and respiratory alkalosis. With her TTKG of 12, her hypokalemia is most likely from renal loss and less likely from intracellular shift caused by alkalosis. In her case, she may have an underlying condition causing hypokalemia that is exacerbated by pregnancy. The plan is to work her up for other causes of hypokalemia after her pregnancy.

PUB424

Unusual Etiology of Rapidly Progressive Glomerulonephritis Samir A. Brahmbhatt,[1] Jaime R. Jimenez Lopez,[1] Robert D. Zenenberg.[2] *[1]Internal Medicine, Morristown Medical Center, Morristown, NJ; [2]Nephrology, Morristown Medical Center, Morristown, NJ.*

Introduction: Between 10 to 40 percent of patients with anti-glomerular basement membrane (GBM) antibody disease are anti-neutrophil cytoplasmic antibody (ANCA) positive, and ANCA is usually directed against myeloperoxidase (MPO) rather than proteinase 3 (PR3). The following is a case of an elderly woman that presented with rapidly progressive glomerulonephritis (RPGN) found to be both PR3-ANCA and anti-GBM antibody positive with a linear pattern of IgG on immunofluorescence.

Case Description: A 60-year-old white woman with controlled hypertension, diabetes and obesity, presented with rash, eye pain, diplopia, and epistaxis that progressed over 6 months. During her hospitalization, she developed acute renal failure with proteinuria, hematuria and red blood cell casts. Her initial serologic workup revealed PR3 ANCA positivity. A subsequent renal biopsy revealed acute, severe and diffuse necrotizing crescentic glomerulonephritis, with linear staining for IgG; and a serum anti-GBM antibody was found to be positive as well. She had been initially treated with Rituximab, steroids and plasma exchange therapy. Because of worsening renal function, and the anti-GBM positivity, Rituximab was stopped, and started on Cyclophosphamide. Fortunately, she never required dialysis, and her creatinine stabilized at 1.4 mg/dL. Both serum PR3-ANCA and anti-GBM were found negative after treatment.

Discussion: To our knowledge, there is only a few reported cases of RPGN due to the coexistence of anti-GBM (proven by kidney biopsy and serology), with a positive PR3-ANCA. In patients with this coexistence, the relationship between the two antibodies is unknown. However, the production of ANCA appears to precede that of anti-GBM antibodies, at least in some patients. Coexistence of anti-GBM with MPO-ANCA is common, but typically associated with a worse prognosis. In this case, the association between anti-GBM disease and PR3-ANCA led to a better outcome.

PUB425

Gordon's Syndrome: A Rare Cause of Hypertension and Hyperkalemia Chinonye Chika Ogbonnaya-Odor. *Internal Medicine, Rutgers NJMS, Newark, NJ.*

Introduction: Gordon syndrome is a rare disorder characterized by hypertension, hyperkalemia, metabolic acidosis in the presence of normal GFR. It has been reported to be caused by genetic mutations that happen sporadically in the population, but can also be inherited in an autosomal pattern.

Case Description: A 23-year-old man with no reported past medical history, presented for evaluation, after referral from his primary provider, for lab abnormalities. The patient reported taking Theraflu for cold symptoms, two days prior to presentation. He denied any complaints except poor vision and headaches both chronic from childhood. He was afebrile, BP 146/78 mmHg, pulse 60 bpm, respiratory rate 16 breaths per minute, and oxygen saturation of 99% on room air. He was blind in the left eye but exam was otherwise benign. Pertinent laboratory studies were:, potassium 7.2 mEq/L, bicarbonate 18 mEq, creatinine 1.0 mg/dl and GFR >60 mL/min. Urinalysis: specific gravity 1.021, pH 5, negative for protein, glucose, ketones, blood, nitrite, and leukocyte esterase, RBC 3, and WBC 1. ECG showed sinus rhythm at 60 BPM with peaked T waves in most leads. He was treated with calcium, insulin and sodium polystyrene, twice within the next twelve hours, each time with improvement in hyperkalemia. His blood pressure was noted to be persistently elevated during hospitalization. Further studies to analyze etiology of hyperkalemia were done. Aldosterone level was slightly elevated but others including, renin level, cortisol stimulation test, TTKG, HIV, ANA, were normal. His blood pressure and hyperkalemia responded with 25 mg of hydrochlorothiazide. Given constellation of findings, patient history and blood pressure response to hydrochlorothiazide, the diagnosis of sporadic Gordon syndrome was made. At one month follow up he had self-discontinued hydrochlorothiazide, and metabolic acidosis and hyperkalemia recurred. Lifelong adherence to medication was stressed.

Discussion: Gordon syndrome is an important and easily treatable cause of hypertension and hyperkalemia that might be a frequently missed diagnosis due to its rarity. Recognition of this entity is important to ensure proper therapy.

PUB426

***Aspergillus niger* Peritonitis** Saad Mohammed Shariff, Eric L. Wallace. *Univ of Alabama, Birmingham, AL.*

Introduction: Fungal Peritonitis is a serious complication of peritoneal dialysis (PD) accounting for 3-10% of PD related peritonitis. Mold peritonitis, such as Aspergillus niger is a rare cause of peritonitis with a high mortality rate.

Case Description: A 70 year-old African American male with end stage kidney disease on PD presented with abdominal pain, chills, generalized weakness, diarrhea, nausea and vomiting for 5 days. Two weeks prior to admission patient noticed cloudy PD fluid and was treated for suspected bacterial peritonitis with Vancomycin and Ceftazidime.

Upon presentation, the patient was in septic shock. PD fluid analysis showed 1,879 WBC's, 82% neutrophils, 13% Macrophages, 3% Mesothelial cells, 2% Eosinophils and cultures were sent. Patient was continued on his original therapy with Vancomycin and Ceftazidime. Despite appropriate empiric antibiotics, repeat PD fluid analysis showed worsening of cell counts at 6994 WBC's with 78% neutrophil. Gram stain was negative. Linezolid and Micafungin were started and PD catheter was removed. Preliminary PD fluid cultures at three days showed mold and on day 7 this was identified as Aspergillus Niger. He was transitioned to Voriconazole. Repeat cultures done after 2 weeks showed no more fungal growth. A home visit by the PD nurse found out that there was mold growing under the PD machine.

Discussion: Aspergillus niger is a rare cause of fungal peritonitis in an immunocompetent patient on PD. Early antifungal therapy with removal of PD catheter is important. Based on our case report it is important for a home visit; especially after multiple episodes of peritonitis to identify and prevent fungal peritonitis; as in this case there was mold growing under the patient's cycler.

PUB427

Sirolimus Induced Pneumonitis Jin Han Lim, Won Kim, Kyung Pyo Kang, Sung Kwang Park, Sik Lee. *Internal Medicine, Chonbuk National Univ Medical School and Research Inst of Clinical Medicine, Jeonju, Korea.*

Introduction: Sirolimus is a potent immunosuppressive drug that has been successfully used with or without cyclosporine as an alternative to calcineurin inhibitors in patients who have undergone kidney transplantation. The major side effects of sirolimus are anemia, thrombocytopenia, and hyperlipidemia. Clinical adverse effects have also been reported with the increasing use of sirolimus. Of these, pulmonary toxicity is a rare but potentially serious complication. Herein, we report a case of sirolimus-induced pneumonitis in a renal transplant recipient 6 month after initiation of sirolimus treatment that was promptly resolved after the discontinuation of the drug.

Case Description: A 34-year-old male visited the emergency room for hemoptysis with dyspnea. He underwent renal transplantation 10 years ago and had switched the immunosuppressive drugs to sirolimus with tacrolimus 6 months ago. His basal serum creatinine level was 1.1 mg/dL. Physical examination revealed coarse crackling breath. Laboratory findings revealed a white blood cell count of 12600/mm^3, hemoglobin level of 13.1 g/dL, and platelet count of 306,000/mm^3. Arterial blood gas analysis showed arterial PO_2 of 55 mmHg. A chest CT scan showed extensive ground-glass opacity and consolidation in both lung fields. However, any definite signs of bacterial or fungal infection were not observed. We considered it as sirolimus-induced pneumonitis and promptly stopped sirolimus use. Treatment was continued with antibiotics and high- flow oxygen therapy. After discontinuation of sirolimus, radiological findings and clinical prognosis of the patient improved.

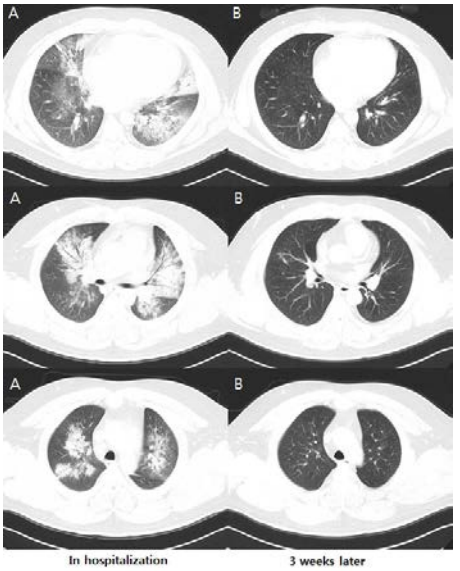


Figure 1. improvement of lung lesion after discontinuation of sirolimus

Discussion: Sirolimus-induced pneumonitis is a potentially fatal side effect. In patients with hemoptysis and being treated with sirolimus, this complication must be considered because early recognition along with drug discontinuation is essential to reverse the adverse effects.

PUB428

Two Cases of Lethal Disseminated *Varicella zoster* Infection with Lupus Nephritis during Remission Induction Therapy Masato Habuka, Michihiro Hosojima, Suguru Yamamoto, Takeshi Nakatsue, Yoko Wada, Junichiro James Kazama, Ichiei Narita. *Div of Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan.*

Introduction: Patients receiving glucocorticoids and immunosuppressants are at high rsik for severe infections, which can be a major cause of death during the disease course. Here we report two rare cases of disseminated varicella zoster virus (VZV) infection with lupus nephritis (LN) during remission induction therapy.

Case Description: Case1. A 46-year-old woman was admitted because of leukocytopenia, proteinuria, hypocomplementemia, and positivity for anti-nuclear antibody. By kidney biopsy, she was diagnosed as LN class III (A/C), and started on remission induction therapy with 45 mg of prednisolone and 3 mg of tacrolimus daily. Because of the kidney dysfunction, the tacrolimus was changed to mycophenolate mofetil (MMF), which led to gradual improvement. However, 52 days after the start of therapy, the patient developed abdominal pain and multiple skin blisters, which were diagnosed as disseminated VZV infection, and laboratory examinations demonstrated liver dysfunction and disseminated intravascular coagulation (DIC). Despite immediate administration of acyclovir and glucocorticoid pulse therapy, she died of hemorrhagic shock 7 days after the onset of abdominal pain. Case 2. A 26-year-old man was admitted because of weight gain, eyelid edema and proteinuria. By kidney biopsy, he was diagnosed as LN class IV (A) +V, and started on remission induction therapy with 60 mg of prednisolone and 500 mg of MMF daily, which was subsequently increased to 3000 mg. However, 76 days after the start of therapy, the patient developed back pain and multiple skin blisters, which were diagnosed as disseminated VZV infection, and laboratory examinations demonstrated liver dysfunction and DIC. Despite immediate administration of acyclovir,plasma exchange and hemodiafiltration, he died of septic shock 18 days after the onset of back pain.

Discussion: Since immunosuppressive agents are now used commonly in patients with autoimmune disorders, clinicians should bear in mind the possibility of disseminated VZV infection when patients suddenly develop abdominal or back pain with liver dysfunction and DIC.

PUB429

Thrombotic Microangiopathy in a Pregnant Kidney Transplant Recipient with De Novo Lupus-Like Nephritis Ryoko Mizuhara, Naoto Hamano, Masahiro Koizumi, Takehiko Wada, Masafumi Fukagawa. *Dept of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

Introduction: Pregnancy and various factors related to kidney transplantation can cause thrombotic microangiopathy (TMA), which can cause graft loss. However, TMA during pregnancy on the background of *de novo* lupus nephritis has not been reported.

Case Description: A 41-year-old Japanese kidney-transplant recipient was admitted to our hospital at a gestational age of 20 weeks due to hypertension, thrombocytopenia, and progressive renal dysfunction. She was initially on peritoneal dialysis for 8 months because of rapidly progressive glomerulonephritis due to anti-glomerular basement membrane syndrome. Four years before the admission, she received a living-donor kidney transplant from her father. Renal biopsy 2 years after transplantation revealed lupus-like nephritis with "full-house" pattern on immunofluorescence. However, her clinical course was stable without additional treatment. She achieved spontaneous pregnancy 4 years after transplantation. At prenatal checkup at 20 weeks of gestation, marked edema and hypertension (160/110 mmHg) along with thrombocytopenia were observed. Her serum creatinine level was elevated from 1.2 mg/dL to 2.1 mg/dL during 4 weeks. Her renal function continued to be deteriorated despite of immediate antihypertensive treatment. Renal pathology diagnosed TMA superimposed on the previous findings. Because of the intrauterine growth arrest, she underwent cesarean section at 25 weeks and delivered a baby weighing 530 grams. Her renal function and the platelet counts returned to the previous level during her uneventful postpartum period. The baby was discharged after the intensive care for 5 months.

Discussion: This case had several underling risks that cause TMA, such as lupus-like nephritis, pregnancy, and tacrolimus. Especially, *de novo* lupus nephritis in allograft is very rare. To determine the precise etiology and make a right decision on treatment strategy, renal biopsy can be a great tool even for pregnant recipients.

PUB430

Antibody-Negative Pauci-Immune Glomerulonephritis. A Case Report Josef Bautista, Nathaniel Nelson, Eric S. Kerns. *Section of Kidney Diseases and Hypertension, Brown Univ - Rhode Island Hospital, Providence, RI.*

Introduction: Pauci-immune crescentic glomerulonephritis is among the most common causes of rapidly progressive glomerulonephritis (RPGN) wherein ANCA antigens play a central role in the development of the disease. Very rarely however, there have been case reports of biopsy-proven pauci-immune glomerulonephritis wherein there is no or very low levels of ANCA antigens.

Case Description: We present a 66-year-old man with chronic obstructive pulmonary disease (COPD) who was brought in to the emergency department for shortness of breath and malaise. Physical exam was remarkable for breathing through pursed lips with diffuse wheezing. Initial blood work demonstrated a serum creatinine of 14.82 (baseline 1.3 measured less than five months prior) and severe metabolic acidosis. Urine studies showed nephrotic-range proteinuria and microscopic hematuria. Renal ultrasound revealed simple multiple cysts, but was otherwise unremarkable. Analysis of the urine sediment revealed numerous non-dysmorphic RBCs, but no cellular or granular casts. Subsequent work-up for his renal failure included negative p:ANCA, c-ANCA of 1:40, normal C3 and C4 levels, and negative MPO, PR3, ANA, dsDNA, HIV, anti-GBM, and hepatitis B and C. A renal biopsy showed numerous glomeruli with fibrocellular crescents but with negative immunofixation. Electron microscopy showed no deposits. He was started on pulse dose steroids and was put on plasmapheresis. He was also given Rituximab using the RAVE protocol and was eventually started on hemodialysis. He remains on hemodialysis up to the present time.

Discussion: ANCA-negative pauci-immune glomerulonephritis is a relatively underappreciated disease. The mechanism for this disease is unclear but neutrophils and possibly other antigens are thought to be involved. This syndrome may be underdiagnosed as ANCA serologies or other serum markers usually influence the decision to perform renal biopsies. This case illustrates the importance of maintaining high clinical suspicion for pauci-immune crescentic glomerulonephritis, particularly in patients with rapid deterioration in renal function, in spite of negative anti MPO or PR3 antigens.

PUB431

A Case of Recurrent Membranous Nephropathy in Transplant Presenting with Deep Vein Thrombosis Divya Raghavan,[1] Dylan V. Miller,[3] Monica Patricia Revelo Penafiel,[2] Josephine Abraham,[1] Faris A. Ahmed.[1] *[1]Dept of Nephrology, Univ of Utah, Salt Lake City, UT; [2]Dept of Pathology, Univ of Utah, Salt Lake City, UT; [3]Dept of Pathology, Intermountain Central Lab, Murray, UT.*

Introduction: Thromboembolism is a known complication of the nephrotic syndrome. We report a case of recurrent membranous nephropathy (MN) in the transplant kidney presenting with extensive deep vein thrombosis (DVT).

Case Description: A 58 year old man presented to clinic with bilateral leg pain (greater on the right). His history was significant for ESRD from MN status post living donor renal transplant a year ago. He was on mycophenolate sodium, prednisone and tacrolimus. Physical exam revealed mild tenderness below the allograft site and swelling of the right lower extremity from thigh to mid-calf. Labs showed a creatinine of 1.69 mg/dl (baseline 1.4-1.5 mg/dl) and urine protein-to-creatinine ratio (UPCR) of 9 g/g. Duplex ultrasound (US) showed DVT involving right common femoral vein and extending into right external iliac vein, along with DVT of left femoral, popliteal and posterior tibial veins. US of the transplant kidney showed a non-occlusive thrombus of the renal vein. He was admitted to the hospital and started on a heparin drip. He underwent catheter-directed thrombolysis of the right common femoral and right external iliac veins and was started on lisinopril for proteinuria and warfarin for anticoagulation. Biopsy was deferred because of anticoagulation. Donor-specific antibody testing was negative. CT chest, abdomen and pelvis to evaluate for secondary causes of MN was unremarkable. He was treated with rituximab 1 g for presumed recurrent MN and the dose was repeated in 2 weeks. His creatinine improved to 1.37 mg/dl and UPCR to 2.2 g/g about 2 months post-discharge.

Development of proteinuria in transplant patients with a history of MN should trigger prompt evaluation. MN can recur in the transplant kidney with a reported incidence between 10-40% in different studies. Patients with recurrence are at risk of graft loss and complications from the nephrotic syndrome. There is some data suggesting the efficacy of rituximab in these cases.

PUB432

Acute Kidney Injury with Use of Inhaled Tobramycin Silvi Shah,[1] Casey T. Weaver,[2] Gaurav Agarwal.[1] *[1]Nephrology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Pathology, Univ of Alabama at Birmingham, Birmingham, AL.*

Introduction: Aminoglycosides nephrotoxicity is a well-known clinical entity. Nebulized aminoglycosides are used to reduce nephrotoxicity. We describe the clinical case of a 57-year-old woman who developed acute kidney injury after using inhaled tobramycin for prevention of pulmonary infections.

Case Description: A 57-year-old white woman with history of end stage renal disease due to unknown etiology and living unrelated kidney transplant seven years ago presented to the clinic for evaluation of acute kidney injury. She received induction immunosuppression with alemtuzumab, and was maintained on tacrolimus and mycophenolate mofetil. She had history of bronchiectasis and recurrent pulmonary infections with multidrug resistant Pseudomonas; and was on preventive therapy with tobramycin inhalation for the last 6 months. Physical examination was unremarkable except for bilateral wheezes on lung auscultation. Her baseline serum creatinine was 1.9 mg/dl. Blood work showed elevated serum creatinine of 2.5 mg/dl corresponding to estimated glomerular filtration rate of 24 ml/min/1.73 m^2. Urine microscopy did not show proteinuria or hematuria. Donor specific antibody and renal transplant ultrasound were unremarkable. Serum BK virus was not detectable. Tacrolimus trough level was therapeutic. Renal biopsy was performed for the evaluation of acute kidney injury. Light microscopy revealed acute tubular injury and acute tubular necrosis superimposed on chronic glomerulosclerosis and mild interstitial fibrosis/tubular atrophy. Electron microscopy showed presence of cytosegresomes and myeloid bodies in proximal tubular epithelial cells consistent with aminoglycoside toxicity. Inhaled tobramycin was discontinued and patient's renal function improved.

Discussion: There is minimal systemic absorption with inhaled aminoglycosides and renal toxicity has not been reported in randomized clinical trials. Acute kidney injury occurred in our patient due to use of inhaled tobramycin. Clinicians should be aware of this rare complication and patients on inhaled aminoglycosides should be monitored closely for worsening renal function.

PUB433

Cryoglobulin Mediated Renal Failure in the Setting of B Cell Lymphma Sudipta Mohanty,[1] Shuchi I. Vyas.[2] *[1]Dept of Medicine, Univ of Californa, Riverside, CA; [2]Nephrology Dept, Kaiser Permanente, Riverside, CA.*

Introduction: Cryoglobulinemia involves the deposition of specific insoluble immune complexes in the microvasculature. While most adults remain asymptomatic, there are a wide variety of potential clinical manifestations - renal failure, MPGN, proteinuria, hematuria, cutaneous lesions, arthralgia, neuropathy, etc. About 80% of cryoglobulinemia is associated with hepatitis C infection, and this concurrence is extensively reported in the literature [1]. However, many other less common etiologies and associations exist.

Case Description: An 84 year old male with history of essential hypertension presented with one year of hematuria and pruritic rash over his chest and lower extremities. He was found to a creatinine of 5.4 (GFR 9) in ER. The patient was admitted for work up and management of acute kidney injury. He developed worsening renal failure so was started on hemodialysis. A broad infectious, autoimmune, and myeloma work up revealed pANCA 1:1280 and qualitative serum cryoglobulin, prompting renal biopsy for suspicion of vasculitic glomerulonephritis. The biopsy revealed immune complex-mediated glomerulonephritis with cryoglobulin deposition and 10% crescents. Given lymphadenopathy noted on CT, a left groin lymph node biopsy was pursued at the same time and revealed atypical lymphoid proliferation nondiagnostic for malignancy. Plasmapheresis was initiated for cryoglobulinemia. The patient was also treated with corticosteroids. The results of the renal biopsy prompted a second left inguinal lymph node biopsy. This biopsy revealed low grade B-cell lymphoma. Oncology was consulted, but chemotherapy was deferred due to the patient's unstable clinical status. Hospital course was complicated by encephalopathy requiring endotracheal intubation for airway security and urobacteremic sepsis requiring broad spectrum antibiotics. The patient eventually stabilized with improvement in mental status, extubation, and resolution of infection. After 1.5 months of hemodialysis and 14 sessions of plasmapheresis, renal function recovered with a creatinine of 1.0 (GFR 69). The patient was discharged to a skilled nursing facility and remains dialysis free.

PUB434

Steadfast Renal Biopsies: Timely Diagnosis and Trigger for Treatment of Hidden AL Amyloidosis Adam Austin, Mauricio Monrroy, Llewellyn A. Foulke, Rafia I. Chaudhry. *Albany Medical College, Albany, NY.*

Introduction: Two cases highlight the crucial role of renal biopsy to establish systemic diseases for initiation of appropriate therapy.

Case Description: Case 1: 65 year-old female referred for microscopic hematuria for 1 year with PMHx of MGUS for 18 years, breast cancer s/p right mastectomy and severe peripheral neuropathy. Laboratory Data: Sr Cr elevation from 1.0 mg/dL to 1.3 mg/dL over 5 months, trace protein and moderate blood on UA with urine spot protein 53 mg/dL and urine Cr 143 mg/dL. No active sediment on urine microscopy was identified. Serum lambda and kappa light chains were not elevated. Serum electrophoresis: M-spike consistent with IgA lambda paraproteinemia. Urine protein electrophoresis was indeterminate, urine immunofixation confirmed Bence Jone protein (lambda type). Urine free light chains were elevated (kappa 139 mg/L, lambda 44 mg/L). This patient carried a diagnosis of "MGUS" without established organ involvement, monitored conservatively for 18 years. Renal Biopsy was diagnostic of Renal AL Amyloidosis, prompting initiation of systemic therapy. Case 2: 49 year-old male presented with 60 pound unintentional weight loss over 6 months, chronic diarrhea and peripheral edema with ascites. Pertinent laboratory Data: Hgb 12.3 g/L, serum Cr 1.3 mg/dL (remarkable considering the patient's high degree of protein and muscle wasting), serum albumin <1.5 gm/dL, calculated LDL 267 mg/dL. UA: +3 protein with urine sediment negative for casts; spot protein 307 g/dL, urine Cr 57.5 g/dL (ratio 5.3). With high degree of clinical suspicion for nephrotic syndrome secondary to systemic disease, renal biopsy was recognized as an important diagnostic component that could hasten treatment while other biochemical studies were pending results. Renal Biopsy confirmed AL Amyloidosis.

In both cases, the diagnosis of AL Amyloidosis associated with Monoclonal Gammopathies was established by renal biopsy prompting initiation of treatment that may have otherwise been delayed.

Discussion: It is crucial to consider renal biopsy early in the diagnostic workup of systemic illnesses, and subtle clues such as microscopic hematuria should prompt a clinical suspicion for renal involvement.

PUB435

Gender Differences in the Associations of Obstructive Sleep Apnea and Cardiovascular Outcomes in Patients with End Stage Renal Disease: A Systematic Review and Meta-Analysis Pulkit Gandhi,[1] Manoj Das,[2] Shweta Sharma.[3] *[1]Internal Medicine, Wright Ctr for Graduate Med Ed, Scranton, PA; [2]Nephrology, Virginia Commonwealth Univ, Scranton, PA; [3]Internal Medicine, Wright Ctr for Graduate Med Ed, Scranton, PA.*

Introduction: Obstructive sleep apnea (OSA) increases risk for cardiovascular events, especially stroke in the general population and in patients with ESRD. However, gender differences in these associations are unclear, as studies that assessed these differences reported conflicting results. We have attempted to systematically review the literature and pool all available evidence that has assessed the gender differences in the associations of OSA and cardiovascular outcomes in ESRD patients.

Case Description: Medline, Embase, Cochrane central library, and electronic databases were searched for relevant studies in all languages and without time restriction.

From a total of 2793 retrieved citations, 7 observational studies, representing 732 men and 550 women with ESRD and a diagnosis of OSA, were included in the review. In the pooled analysis, men were at lower odds for stroke (OR: 0.64, 95% CI: 0.44 – 0.92, P = 0.02, I^2: 78%, 6 included studies), but odds of CAD (OR: 0.86, 95% CI: 0.54 – 1.37, P = 0.51, I^2: 74%, 5 included studies) and cardiovascular mortality (OR: 0.95, 95% CI: 0.71 – 1.27, P = 0.71, I^2: 0%, 5 included studies) was similar in the two groups. When restricted to data from sleep clinic based studies the lower odds of stroke in men persisted (OR: 0.60, 95% CI: 0.37 – 0.98, P = 0.04, I^2: 81%, 6 included studies) but disappeared in population based studies (OR: 0.65, 95% CI: 0.29 – 1.46, P = 0.3, I^2: 84%, 3 included studies). Factors responsible for the high heterogeneity could not be assessed due to lack of availability of gender specific data.

Discussion: Lower odds of stroke among men with OSA may likely be due to selection bias as this was true only in the sleep clinic based studies and not in population based studies. More population based studies with gender specific details of OSA determinants like atrial fibrillation are needed to clearly elucidate this association in ESRD patients.

PUB436

Morton Lite Salt Induced Hyperkalemia Ryan A. Kunjal,[1] Adey Hasan,[2] Abdalagani Ahmed Abakar Baher,[2] Ciel Harris,[1] Andreea Poenariu.[2] *[1]Dept of Internal Medicine, Univ of Florida College of Medicine, Jacksonville, FL; [2]Dept of Nephrology, Univ of Florida College of Medicine, Jacksonville, FL.*

Introduction: We present a case of Morton Lite salt - induced hyperkalemia in a patient with stage 2 chronic kidney disease (CKD). There is increasing use of lower sodium content salt and salt substitutes as healthy alternatives for the control of hypertension. These typically contain high quantities of potassium chloride which can predispose patients with CKD to hyperkalemia.

Case Description: A 61-year-old male with Hypertension, Type 2 Diabetes, CKD and Schizoaffective disorder presented with potassium of 9.2mmol/L found on routine laboratory investigations. His medications included Aspirin, Glimepiride, Metoprolol and Quetiapine. He was asymptomatic on arrival with unremarkable vital signs and physical examination. The EKG demonstrated normal sinus rhythm with diffusely peaked T waves. Repeat serum potassium was consistent with the previous level in the absence of hemolysis. His creatinine was 0.83mg/dL and eGFR was 75ml/min. Serum renin and aldosterone were normal and spot urine potassium was mildly elevated at 154mmol/l. The renal sonogram was essentially normal. Calcium gluconate, insulin and oral sodium polystyrene sulfonate were successful in normalizing his potassium. The peaked T waves on EKG also resolved. Metoprolol was held due to its possible contribution to hyperkalemia. Nevertheless, the underlying cause remained elusive. Later, the patient admitted to daily use of 2 tsp. of Morton Lite Salt for bowel regularity over the past month. This was equivalent to 70mEq of K^+ /day which likely caused such severe hyperkalemia. He made a full recovery.

Discussion: Large potassium intake is a rare cause of severe hyperkalemia especially in the setting of normal or mildly impaired kidney function as in our patient and makes this case unique. However the patients to whom these products are targeted tend to also be those at highest risk for hyperkalemia due to concomitant renal impairment or use of medications such as ACE inhibitors. Greater awareness is needed of the potential dangers of these products and it is imperative that their labeling reflect such risks.

PUB437

ANCA-Positive Pauci-Immune Crescentic Glomerulonephritis and Bronchial Carcinoid: Accomplice or Innocent Bystander? Jason Christopher George,[1] Alicia Meadows,[2] Jamie Alton Green.[1] *[1]Nephrology, Geisinger Medical Center, Danville, PA; [2]Rheumatology, Geisinger Medical Center, Danville, PA.*

Introduction: Paraneoplastic glomerulonephritis (GN) is a well-known but rare phenomenon that can occur with various malignancies. Diagnosis is important to avoid potentially harmful therapy. We present a case of a patient who was concurrently diagnosed with anti-neutrophil cytoplasmic antibody (ANCA), pauci-immune crescentic glomerulonephritis and bronchial carcinoid.

Case Description: A 62-year-old woman with known history of hypertension presented with 7 months of fatigue, shortness of breath and persistent cough. She also had bilateral leg swelling and worsening hypertension. She denied joint pain or rash. Labs showed progressive renal dysfunction (creatinine 3.0 mg/dL from 2.2 mg/dL four months prior), serum albumin 3.5 mg/dL, microscopic hematuria (50+/HPF) and nephrotic-range proteinuria (protein/creatinine ratio 5.53). Serologies showed positive p-ANCA with confirmatory anti-myeloperoxidase antibody. CT scan showed a 2.3 cm lung mass and biopsy confirmed well-differentiated bronchial carcinoid. Renal biopsy showed pauci-immune crescentic glomerulonephritis with mild interstitial fibrosis and tubular atrophy. It was unclear if the GN was idiopathic or related to malignancy. Her primary tumor was resected and she was started on high-dose prednisone and rituximab for treatment of her GN with improvement in proteinuria.

Discussion: Paraneoplastic GN involves renal manifestations of malignancy not directly related to tumor burden. It is most commonly described with membranous nephropathy and minimal change disease. Malignancy-associated ANCA-positive glomerulonephritis has been described with renal cell carcinoma, adenocarcinoma of the lung, and gastric carcinoma. However, association with bronchial neuroendocrine malignancy has not been frequently reported. The pathophysiology is not completely understood but thought to be related to dysregulated T-cell and cytokine response. Treatment with immunosuppression in patients that have undergone complete tumor removal can result in partial or complete renal response. Early recognition and prompt treatment are critical to prevent irreversible renal damage.

PUB438

Dilemma of Choosing between Kidney Alone versus Simultaneous Liver Kidney Transplantation in Autosomal Dominant Polycystic Kidney Disease Patients with Advanced CKD and Significant Hepatic Cyst Burden Reddy Singasani, Hasenia Albanna, Mariella Ortigosa Goggins, K.K. Venkat, Anita K. Patel. *Nephrology, Henry Ford Hospital, Detroit, MI.*

Introduction: In autosomal dominant polycystic kidney disease (ADPKD), while renal cysts commonly cause ESRD requiring kidney transplantation, liver cysts are asymptomatic with preserved hepatic function in most patients.

Case Description: A 56-year-old white male with dialysis-dependent ESRD secondary to ADPKD presented with severe right upper quadrant abdominal pain. Pre-transplant testing revealed normal liver function. He was not qualified for simultaneous liver-kidney transplantation (SLK) as synthetic function of the liver was intact. He then received a kidney transplant following which he continued to feel extremely fatigued with abdominal distention, persistent severe right upper quadrant abdominal pain and marked ascites necessitating frequent paracentesis. Though his liver function tests were normal he received a liver transplant 9 months after kidney transplantation, which resolved his prior disabling symptoms.

Discussion: Organ Procurement and Transplantation Network (OPTN)/ United Network for Organ Sharing (UNOS) Policy 9.3: Score and Status Exceptions, states that "If a candidate's transplant program believes that a candidate's MELD or pediatric end-stage liver disease (PELD) score does not appropriately reflect the candidate's medical urgency, the transplant physician may apply to the Regional Review Board (RRB) for a MELD or PELD score exception." ADPKD may benefit from MELD score exception if they have markedly impaired quality of life and performance limitation (Mayo Modification type D or C).

PLD Classification – Mayo Modification

Types	A	B	C	D
Symptoms	0 - +	++/+++	++/+++	++/+++
Cyst Findings	Focal	Focal	Diffuse	Diffuse
Spared Remnant Volume	≤3	≤2	≤1	<1
PV/HV Occlusion	No	No	No	Yes

In retrospect, our patient may have qualified for simultaneous liver-kidney transplantation in the first place and the morbidity associated with undergoing two separate transplant operations may have been avoided.

PUB439

Catheter-Related Bacteremia and Epidural Abscess Caused by *Citrobacter koseri* in a Hemodialysis Patient Muner Mohamed, Himabindu Valluru, Rahul Valluru, Mary C. Mallappallil, Moro O. Salifu. *SUNY Downstate Medical Center; SUNY Downstate Medical Center; SUNY Downstate Medical Center; SUNY Downstate Medical Center; SUNY Downstate Medical Center.*

Introduction: Low virulent *Citrobacter koseri* is a gram negative bacillus which is a facultative anaerobe from the family of *Enterobacteriaceae* and is part of the flora of human digestive tracts. It may act as an opportunistic pathogen in immunosuppressed patients.*C. koseri* is known to be an uncommon but serious cause of both sporadic and epidemic septicemia and meningitis in neonates and young infants. However, the literature on *C. koseri* as a cause of spinal infection in adults is scant. Epidural abscess due to *C. koseri* is a rare condition. We report a remarkable case of dialysis catheter related *C. koseri* bacteremia complicated by epidural abscess in a patient who has successfully been treated in our hospital.

Case Description: A 77 year old man end stage renal disease on hemodialysis, hypertension, Coronary Artery Disease status post CABG, Heart Failure with Reduced Ejection Fraction and Abdominal Aortic Aneurysm presented to the emergency room with 4 days of constipation and left lower back pain and a white cell count of 22.91 k/ul, He was on hemodialysis (HD) at another facility for the past 23 months via a right internal jugular dual lumen cuffed catheter while his AVF was planned. Systemic blood cultures revealed *Citrobacter koseri* and blood cultures sent from the catheter revealed *Citrobacter koseri*. His cuffed hemodialysis (HD) catheter was removed. Due to his back pain he had an MRI without gadolinium that revealed an epidural abscess at the level of L4-S1.

He was treated with lumbosacral decompressive laminectomy and intravenous ceftriaxone for 2 weeks followed by oral ciprofloxacin for 4 weeks with resolution of the abscess on repeat imaging.

Discussion: We believe this is the first case described in the literature of a dialysis catheter related bacteremia and epidural abscess caused by *C. koseri* in an immunocompetent adult patient. This case emphasizes the need to minimize HD catheter time in patients to prevent complications that can occur even with usually low virulent organisms.

PUB440

Fibrongen A α-Chain Amyloidosis: Case Report Alessandra Correa Pereira,[1] Bento C. Santos,[1] Denise M. Malheiros,[2] Luis Felipe Cintra,[1] Ana Karoline Nobrega Cavalcanti,[1] Marisa Petrucelli Doher,[1] Carlos Tadeu Bichini Guardia,[1] Nadia Guimaraes- Souza,[1] Thais Nemoto Matsui,[1] Virgilio Gonçalves Pereira.[1] *[1]Hospital Israelita Albert Einstein, São Paulo, Brazil; [2]Univ de São Paulo.*

Introduction: Deposition of amyloid fibrils in organs and tissues characterizes one group of diseases known as amyloidosis. Mutations in the fibrinogen Aα-chain gene are the most common cause of hereditary renal amyloidosis in Europe, however it is uncommon in Brazil.Disease clinical course is poorly known, but coronary atherosclerosis appears to be linked. Diagnosis is made by renal biopsy showing amyloid deposit and genetic tests. Treatment options are limited. Hepatorenal transplantation is an alternative in patients with advanced disease.

Case Description: A 55 years old men, from São Paulo, dyslipidemic, presented persistent proteinuria in laboratory tests without clinical manifestation, with regula clinical examination.In 2012, after an increase of proteinuria without renal dysfunction, a renal biopsy was performed showing amyloid deposits. Clinical investigation found no evidence of cell dyscrasias or inflammatory disease that could suggested amyloidosis in other parts. During follow-up hypertension and coronary insufficiency emerged. In 2015, patient evaluated with ankle edema and nephrotic proteinuria (9,26g) with progressive renal impairment (glomerular filtration ratio: 50 mL/min /1.73m2). A second renal biopsy confirmed amyloid deposition. Liquid chromatography spectrometry prompted detected an abnormal sequence of amino acids in the light chain of the fibrinogen Aα (Glu545Val) confirming the diagnosis of hereditary renal amyloidosis. In the follow up patient kept proteinuria and stable renal function until now.

Discussion: Fibrinogen A alpha-chain amyloidosis is mainly a renal disease characterized by variable penetrance, distinct histological appearance, proteinuria, and progressive renal failure. In the presence of glomerular amyloid deposit without systemic amyloidosis should be investigated hereditary renal amyloidosis.

PUB441

A Case of Hypoaldosteronism in Disguise Susanne Francis Mclaughlin, Sreedhar A. Mandayam. *Nephrology, Baylor College of Medicine, Houston, TX.*

Case Description: A 41 year old man with mesothelioma was admitted to the hospital two weeks after his first cycle of Cisplatin for hyponatremia of 112. He was tachycardic, hypertensive, and mildly volume overloaded. There were no neurological deficits. Serum osmolality was 233. Urine osmolality was 697. Urine sodium was 84. TSH was normal. We suspected SIADH due to his lung disease, the Cisplatin, and nausea. He was fluid-restricted and given normal saline with furosemide to promote aquaresis. The following day, sodium was unchanged. We saw that he also had mild hyperkalemia in the preceding few weeks. He had received Fluconazole for a line infection. A diagnosis of adrenal insufficiency was entertained. However, a morning cortisol was 21.2, and he was not hypotensive. Doubting this diagnosis, we then tried two courses of 3% saline with furosemide, and a dose of Tolvaptan 15mg. This only raised his sodium to 113. An ACTH stimulation test was then performed. Cortisol increased from 21 to 22.5 to 23.2 after 30 and 60 minutes respectively. Although the morning cortisol was not low, we speculated that these results showed maximal stimulation of the patient's pituitary gland due to a relative mineralocorticoid

deficiency, and thus he was incapable of producing any more cortisol. We gave a trial of methylprednisolone 500mg. Sodium increased from 113 to 119 by the next morning. A second dose of methylprednisolone 500mg was given and sodium improved further to 127 the next day. Patient was then placed on scheduled fludrocortisone and sodium eventually normalized. We had hoped to more fully evaluate his pituitary-adrenal axis and establish a diagnosis of hypoaldosteronism, but unfortunately the patient succumbed to his illness.

Discussion: We present an interesting case of hyponatremia, initially felt to be SIADH, which did not respond to standard therapy. We then treated with steroids for suspected adrenal insufficiency despite a normal morning cortisol. Perhaps the fluconazole contributed to the hyponatremia, by reducing aldosterone secretion. We advocate for consideration of aldosterone deficiency, in the appropriate clinical scenario regardless of a normal morning cortisol.

PUB442

Anti-Glomerular Basement Membrane Negative Goodpasture Disease with Positive Serum Myeloperoxidase Ernest Daniel Moreno Dytiapco, Shubha Ananthakrishnan. *Dept of Nephrology, UC Davis Medical Center, Sacramento, CA.*

Introduction: In patients who present with rapidly-progressive glomerulonephritis, serologic testing is heavily relied upon in making a diagnosis. Presented here is a case of biopsy-proven anti-GBM disease (Goodpasture Disease) with negative anti-GBM IgG serology, but positive MPO serology.

Case Description: The patient is a 52-year-old woman with a history of Graves disease over 30 years prior, hypothyroidism, and eczema, who presented with 1 month of anorexia and hematuria. She denied hemoptysis, arthralgia, rash, fever, chills, NSAIDs, or herbal agents. Physical exam revealed a well-appearing, thin, white, middle-aged woman with trace peripheral edema. The rest of her exam was normal. Baseline serum creatinine (sCr) was 0.6 mg/dL. 4 weeks prior to presentation, sCr was 1.9 mg/dL, then steadily rose to a peak of 4.6 mg/dL upon presentation. Serum electrolytes and bicarbonate were normal. C3 and C4 were normal, ANA was negative, and MPO was 164 AU/mL (high). Anti-GBM IgG by indirect fluorescent antibody (IFA) and by multiplex bead assay were both negative. She then had a renal biopsy. Light microscopy showed necrosis and cellular to early-fibrocellular crescents involving greater than 50% of sampled glomeruli. Global glomerulosclerosis and segmental scarring/fibrous crescents were noted in 25% of glomeruli. She had mild early tubulointerstitial fibrosis. Immunofluorescence microscopy showed linear staining of glomerular basement membranes (GBM) for IgG, consistent with Goodpasture Disease. She was treated with methylprednisolone 750 mg IV for 3 days, then switched to prednisone and cyclophosphamide. Anti-GBM IgG testing by both IFA and multiplex bead assay were repeated and again, were negative. She received 7 sessions of plasmaphresis. After 3 months of steroids and cyclophosphamide, she was switched to maintenance azathioprine and low-dose prednisone. Her sCr at 3 months had improved to 1.3 mg/dL.

Discussion: This case underscores the importance of renal biopsy for definitive diagnosis of rapidly-progressive glomerulonephritis, as the serologic workup can be misleading. Renal biopsy in this case helped identify the true pathology and helped with therapeutic plan and prognosis.

PUB443

Renal Graft versus Host Disease with Focal Segmental Glomerulosclerosis Dominique Dorsainvil, William S. Asch. *Nephrology, Yale School of Medicine, New Haven, CT.*

Introduction: Graft Versus Host Disease (GVHD) is a feared, yet common complication of stem cell transplant (SCT). kidney involvement remains unusual contrary to the typical liver, skin and gastrointestinal manifestations. Main renal presentations pertain to nephrotic syndrome from either a membranous nephropathy in the majority of cases or minimal change disease. Rare cases related to focal segmental glomerulosclerosis (FSGS) have been described. We present a case of renal GVHD post STC with nephrotic syndrome from FSGS.

Case Description: 56 y/o man with ALL whom underwent chemotherapy prior to a matched unrelated donor allogenic stem cell transplant. He was preconditioned with whole body irradiation and pentostatin, engrafted on day 13 and was maintained on sirolimus and tacrolimus. His course was notable for a biopsy proven skin GVHD, severe sepsis complicated by idiopathic thrombotic purpura requiring pulse steroids, intra venous immunoglobulins and acute kidney injury secondary to acute tubular necrosis from which he recovered fairly rapidly. Sirolimus was stopped for concerns of lung toxicity. He was continued on tacrolimus and prednisone. During the same hospitalization, the former was discontinued for unclear reasons. No recurrent acute kidney injury or other side effects of tacrolimus were documented. Several weeks later, he represented to the hospital with nephrotic syndrome with up to 10g of proteinuria. He underwent a kidney biopsy which showed resolving TMA, enlarged glomeruli with collapsing capillary loops on light microscopy, complete foot process effacement on electron microscopy. Our renal pathologist concluded that these lesions were consistent with FSGS. He was restarted on tacrolimus for those findings along with persistent proteinuria. The proteinuria has since resolved.

Discussion: Case reports have associated cessation of immunosuppression with onset of renal GVHD, which was the case for our patient. What renders this case interesting is the histopathological findings of FSGS. A review by Troxel et al, mentioned that about 6% of published biopsy proven glomerulopathy in renal GVHD has similar findings. We also conclude that in this setting, those lesions respond well to immunosuppressive therapy.

PUB444

A Case of Undifferentiated Connective Tissue Disease with Membranous Glomerulonephritis in a Child Doaa Mohammed Youssef, Mohammed Abdelsalam. *Pediatrics, Zagazig Univ, Zagazig, Egypt.*

Introduction: The diagnosis of undifferentiated connective tissue disease (UDCTD) is used to those with features of autoimmune disease but not fulfilling the criteria of specific disorder**.** Membranous nephropathy (MN) is considered as a primary glomerular disease, also referred as idiopathic (Children have a higher frequency of secondary MN than adults); We described unusual case of coexistence of MN resulting in nephrotic syndrome (NS) with UDCTD in child.

Case Description: A 12 years old male presented to us with NS, proteinuria was 3 gm/day, creatinine normal. C3 was normal. he started steroid full dose for one month with remission. He relapsed after 2 months, there was edema, polymyositis, bilateral symmetrical gluteal and thigh induration with no tenderness, fingers swellings and scales. Dermatological consultation found localized scleroderma (morphea) like lesion, anti- Scl 70 , ANA, anti-double sDNA and pANCAs were negative. Skin biopsy was not done as the parents refused. EMG , nerve conduction velocity for gluteal and muscles of thigh and Doppler on renal arteries were normal. Patient was back on full dose corticosteroid for six weeks without remission. Renal biopsy showed diffuse MN with early secondary segmental sclerosis. We excluded secondary causes ofMN. The patient started cyclophosphamide orally on 2 mg/kg/day, with full dose oral steroids EOD. After 2 weeks of therapy, the patient was completely improved. The gluteal, thigh induration and proteinuria were disappeared. cyclophosphamide completed for 3 months with steroid withdrawal the patient is stable and in complete remission till now.

Discussion: Missing anti RNP excluded MCTD, presence of polymyositis and scleroderma with missing anti Scl 70 excluded the diagnosis of Overlap Syndrome; thus we proposed our case with UDCTD. MN with one of the mixed connective tissue diseases was reported previously in three cases one was 60 years old, one with renal cell carcinoma and one female child with MN for 5 years followed by developing scleroderma. We started cyclophosphamide with steroid as this combination was reported to be safer than using chlorambucil with steroid. Our case is considered one of few cases with this presentation of MN and UDCTD in children.

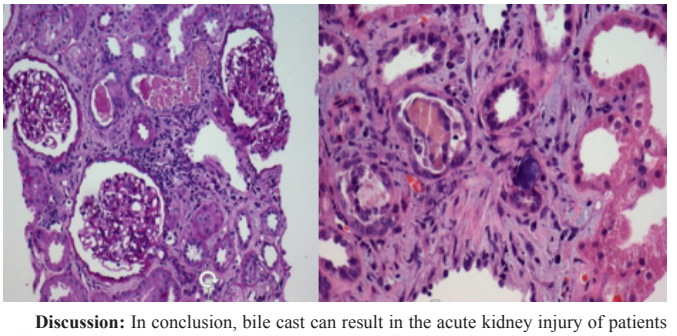
PUB445

Bile Cast Nephropathy Associated with Acute Hepatitis A Jong-Hwan Jung, Seon-Ho Ahn. *Div of Nephrology, Dept of Internal Medicine, Wonkwang Univ College of Medicine, Iksan, Jeonlabukdo, Korea.*

Introduction: Acute kidney injury is well developed in advanced liver diseases, such as liver cirrhosis and acute hepatic failure. This acute renal dysfunction usually results from decrease of renal perfusion caused by hypovolemic condition. Severe jaundice may also contribute to the acute kidney injury caused by bile acid or bilirubin. Now, we present a interesting case, bile cast nephropathy complicated by acute hepatitis A.

Case Description: A 35-year-old male visited our emergent department with symptoms of nausea, abdominal discomfort, and oliguria. These symptoms and signs were developed abruptly recent several days ago, so he took a digestive medicine, however, these symptoms were aggravated more. He had no chronic diseases, such as diabetes, hypertension, and chronic hepatitis. His skin color was changed into yellowish on physical examination. His vital signs were stable on arrival. Serum total bilirubin, direct bilirubin, creatinine were 10.29 mg/dL, 7.95 mg/dL, and 14.30 mg/dL. Immunoglobulin M of hepatitis A was also positive. His uremic signs were aggravated although fluid therapy. His general condition was improved after hemodialysis, however, several clinical signs, such as generalized edema, hypertension, and hyperkalemia were still remained for four weeks. We performed renal biopsy. On the pathology, the renal tubular lumens frequently contain dark pigment casts with foreign body reaction and calcification, and interstitium focally exhibits mononuclear cell infiltration and fibrosis.



Discussion: In conclusion, bile cast can result in the acute kidney injury of patients with severe jaundice and hepatic failure. A direct bilirubin toxicity for renal tubules may contribute to this renal injury. We may carefully suggest that recovery of acute tubular necrosis can be delayed by the presence the tubular bile cast through this case.

PUB446

Intravitreal VEGF Inhibitors Causing Allergic Interstitial Nephritis
Debbie Valsan,[1] Saifullah Kazi,[1] Zia M. Umruddin.[2] *[1]Lankenau Medical Center; [2]Pottstown Memorial Hospital.*

Introduction: This case highlights the effect of intravitreal VEGF inhibitors in causing AIN.

Case Description: A 51 y/o male with a history of DM and HTN presents to his primary care office for nausea and vomiting in December 2010. His creatinine was 1.2 mg/dl in July 2010 and 1.9 mg/dl in October 2010 with repeat creatinine of 11mg/dl with a BUN of 106mg/dl. His medications include metformin, glyburide and Bevacizumab monthly intravitreal injections that he began on February 2010. Physical exam was unremarkable. Urine microscopy showed granular casts and eosinophils were negative. Ultrasound revealed normal sized kidneys with normal echotexture and no hydronephrosis. He was placed on pulse dose steroids given his rapid onset of renal failure with no clear etiology and pending serologic workup. Hemodialysis was initiated for uremic symptoms. Complete serologic panel was negative and complement levels were normal. Biopsy results showed AIN with ATN and early diabetic glomerulosclerosis. Bevacizumab was discontinued. He was placed on dialysis temporarily with oral steroids with improvement of creatinine to baseline. His creatinine was noted to slowly trend up at 1.72mg/dl in October 2015 and then at 2.4mg/dl a month later. Our patient was started on Ranibizumab intra ocular injections since August 2015 by a different ophthalmologist. Given his previous history, recommendations were made to stop the current therapy with Ranibizumab as no other etiology for this acute kidney injury was evident and his creatinine declined to 1.6 mg/dl.

Discussion: Histologic findings in patients who have been on VEGF inhibitors have included TMA, collapsing glomerulopathy, and isolated reports of cryoglobulinemic and immune complex GN. We report the first case of AIN in the setting of intravitreal Bevacizumab used for DME. Discontinuation of the potential causative agent is a mainstay of therapy. Drug-induced AIN is not dose dependent, and recurrence or exacerbation can occur with a second exposure to the same or a related drug. This was seen in our case with initiation of Ranibizumab. Regular monitoring of the renal function in these patients will help identify this problem and avoid significant morbidity associated with these new biologic agents.

PUB447

"Extraperitoneal Dialysis" in Severe Obesity
Sawako Kobayashi, Takamasa Miyauchi, Hiroyuki Yamamoto, Fumika Taki, Masahiko Nagahama, Yasuhiro Komatsu. *Nephrology, St. Luke's International Hospital, Tokyo, Japan.*

Introduction: We report a case where a patient with misplaced Tenckoff catheter in extra-abdominal cavity underwent 5 months of "peritoneal dialysis".

Case Description: A 46 year old male started PD for ESRD secondary to hypertensive nephrosclerosis. He was extremely obese, weighing 158kg with BMI of 51.0kg/m^2. Four exchange of 2.5 L dialysate per day was successfully delivered without any infusion/drainage trouble. He was well despite of relatively low dialysis dose; a weekly Kt/V of 0.99 (peritoneal 0.84, renal 014), a total CCr of 46.0l/week (peritoneal 30.0, renal 15.9), ultrafiltration volume of 1500ml per day. Peritoneal equilibration test showed "low" category. Five months after initiation of PD, he was admitted to our hospital for PD peritonitis. A CT scan, taken with dialysate in the patient's abdomen, revealed a fluid collection approximately the size of 11cm x 19cm x 17cm in the abdominal wall, just between the rectus abdominis and peritoneum membrane. The tip of the catheter was detected outside of peritoneal cavity. Subsequently, he had his catheter surgically removed and switched to HD.

Discussion: Catheter misplacement can be easily detected because it would immediately result in difficulty in infusion and drainage; however, in this case, misplacement was not detected and "peritoneal dialysis" could be continued for a considerable amount of time. This is probably due to the patient's thick abdominal wall, which obscured the symptoms. This case shows that fluid and solute can be transported even when peritoneal dialysate is dwelled outside the abdominal cavity, between abdominal muscle and peritoneum. For obese patients, confirming the catheter position with additional measures such as lateral abdominal radiography is recommended, even without outflow failure at the time of catheter placement.

PUB448

Unusual Diffuse Proliferative Glomerulonephritis with Renal Parenchymal Involvement by CLL
Ana Belen Rivera de Rosales,[1] Duminda Siripala,[1] Agnes B. Fogo,[2] Ivo Lukitsch.[1] *[1]Nephrology, Ochsner Medical Center, New Orleans, LA; [2]Renal Pathology, Vanderbilt Univ.*

Introduction: Female patient with stage I CLL, subarachnoid hemorrhages and massive proteinuria. Biopsy shows an unusual cause.

Case Description: 49yo with stage 1 CLL and increasing WBC to 24K, not requiring therapy. Asymptomatic, without frequent infections. She had stable cervical nodes, mild dependent edema and history of subarachnoid hemorrhages. She again presented with headache, found to have subarachnoid hemorrhage and persistent hematuria and proteinuria of 20 grams that had been increasing over past two months with preserved renal function. Serologic evaluation revealed low C4. Urine sediment showed massive leukocyturia with RBC and WBC casts. Urine culture negative. Renal biopsy was done showing unusual diffuse proliferative glomerulonephritis with endocapillary proliferation and crescents without fibrinoid necrosis. IM was positive for mesangial and arteriolar granular C3 staining only without any deposits by EM. Positive staining for CD20, CD5 and CD23 confirmed renal parenchymal involvement by CLL. Despite initial steroid pulse she continued to have massive proteinuria. Because of the progressing GN and CNS bleed she received chemotherapy with Rituximab 375mg/m2 and cyclophosphamide 750 mg/m2 with high dose dexamethasone monthly times 3. Two weeks after first dose of chemotherapy proteinuria had decreased to 2 grams. On two month follow up her proteinuria reduced to one gram with resolution of leukocyturia.

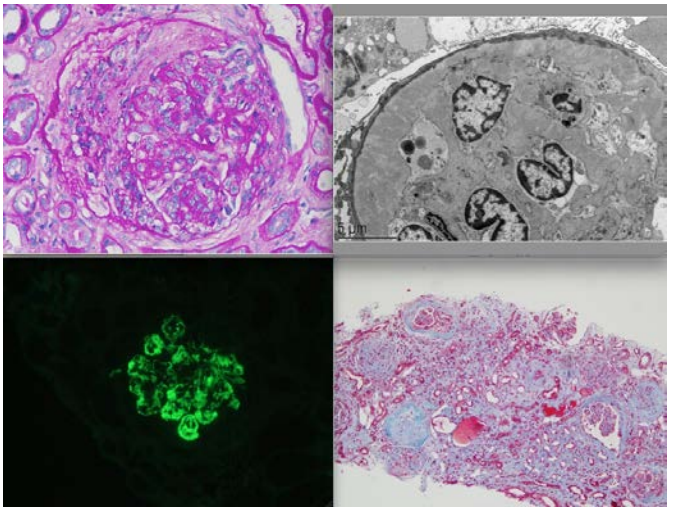
Discussion: Paraneoplastic etiology, not related to immune complex deposition is proposed as the cause for the proliferative glomerulonephritis. A paraneoplastic effect on the CNS vasculature may also be contributing. Treatment with chemotherapy led to resolution of proteinuria and leukocyturia with preserved renal function. To our knowledge has not been previously described.

PUB449

A Mid-Life Renal Crisis of Proteinuria and AKI
Monica Lona Reynolds,[1] Eddie R. Fuller,[1] Volker Nickeleit.[2] *[1]Nephrology, Univ of North Carolina, Chapel Hill, NC; [2]Nephropathology, Univ of North Carolina, Chapel Hill, NC.*

Introduction: Proliferative glomerulonephritis with monoclonal deposits is due to a single clone immunoglobulin that aggregates to form electron dense deposits in the glomeruli. It is common in older Caucasian women and treatment is variable. This 45-year-old previously healthy man presented with AKI, nephrotic proteinuria and active urine sediment.

Case Description: The patient presented to his PCP with fatigue and severe hypertension to 205/125. Labs revealed creatinine of 15.5mg/dl and he was admitted. The patient was well appearing with 1+ pitting edema in lower extremities. ANCA, ANA, HIV and Hepatitis were negative. C3 was 69. His urine protein to creatinine ratio was 13.9g. Urine sediment had dysmorphic RBC's and RBC casts. Biopsy (Figure 1) showed sclerosing MPGN with 30% crescents associated with IgG1 Kappa light chain restricted immune complex deposits. 50-60% of glomeruli were sclerosed. His SPEP/immunofixation revealed monoclonal IgG kappa. K/L free light ratio was 5.60. Myeloma bone survey was without lytic lesions and bone marrow biopsy was normocellular. The patient received three doses of IV methylprednisolone followed by prednisone and seven sessions of therapeutic plasma exchange. After Oncology consult, he received Cyclophosphamide, Bortezomib and Dexamethasone for 4 cycles. Cr is now 6.9mg/dl with persistent proteinuria. His K/L ratio decreased and he is pursuing transplant.



Discussion: In contrast to most patients with a proliferative GN and monoclonal IgG electron dense deposits, this patient presented with features worrisome of an underlying lymphoproliferative disorder/ plasmacytoma. Little data exists regarding treatment for these patients. Prognosis is grim with more than a third of patients with persistent dysfunction. Although he had sclerosis in half of glomeruli, our patient was treated aggressively.

PUB450

An Unexpected Diagnosis when Expecting: Scleroderma in a Patient with Class III Lupus Nephritis Meera Subash,[1] Amber P. Sanchez.[2] *[1]Dept of Medicine, Univ of California, San Diego, San Diego, CA; [2]Dept of Medicine, Div of Nephrology, Univ of California, San Diego, San Diego, CA.*

Introduction: We present an interesting case of a 39 year-old woman who was previously diagnosed with cutaneous lupus with +ANA with low C4, which initially responded to topical treatments. She continued with topical treatments until her third pregnancy. At the beginning of her pregnancy, she was diagnosed with systemic sclerosis when her fetus was unable to be visualized on abdominal ultrasound due to severe skin thickening that rapidly progressed during the pregnancy. She delivered successfully, and continued with steroid-sparing therapy for her cutaneous lupus until her scleroderma symptoms worsened in the setting of lupus nephritis.

Case Description: Her systemic sclerosis became complicated with diffuse skin thickening with calcinosis, chronic skin infections, Raynaud's phenomenon, pulmonary hypertension, and esophageal dysmotility. Her creatinine began to rise from a normal range with the eventual development of non-nephrotic, persistent proteinuria. A biopsy was performed, revealing a low-grade immune complex-mediated glomerulonephritis, most consistent with focal sclerosing lupus nephritis (Class III). She began treatment with rituximab with an increase in serum albumin and decrease in urine protein. Mycophenolate mofteil was slowly uptitrated as a steroid sparing therapy aligning with the Imperial Lupus Trial. Her urine protein levels stabilized and the patient is stable currently.

Discussion: Her case highlights the importance of screening patients who have been previously diagnosed with a single autoimmune disease entity for other autoimmune disorders as these syndromes often cluster and exacerbate renal dysfunction. The initial physical finding of thickened abdominal skin during a first trimester ultrasound that led to her diagnosis of systemic sclerosis is a fascinating component to this case. It can be surmised from the current scleroderma literature that females with scleroderma are encouraged to avoid pregnancy within the first 3 years of diagnosis because disease complications, specifically hypertension and renal function that can complicate pregnancy.

PUB451

Slowly Progressive Light Chain Cast Nephropathy with Proximal Tubulopathy Yuka Kawasaki, Yuhei Kirita, Itaru Nakamura, Yayoi Shiotsu, Tetsuro Kusaba, Keiichi Tamagaki. *Nephrology, Kyoto Prefectural Univ of Medicine, Kyoto, Japan.*

Introduction: Monoclonal gammopathy manifests as various forms of renal diseases. Light chain cast nephropathy (LCCN) is a common cause of acute kidney injury with multiple myeloma. Light chain proximal tubulopathy (LCPT) is an increasingly recognized, yet uncommon renal complication of monoclonal gammopathy. LCPT, particularly with crystals, usually presents as Fanconi syndrome. We report a case of slowly progressive renal insufficiency due to LCCN with LCPT.

Case Description: A 55-year-old man with a medium build presented with a gradual increase in the serum creatinine (Cr) level from 1.2 to 1.6 mg/dL in a year. His estimated GFR-creatinine (eGFRcr) and -cystatin C (eGFRcys) were 35.4 and 59.2 mL/min/1.73 m^2, respectively, with a difference between the values. Laboratory data showed mild proteinuria of 0.21 g/gCr, with no evidence of glycosuria, water-electrolyte imbalance, acidemia, or hypoalbuminemia. Urinary immunofixation showed the presence of free kappa light chains. The levels of serum free kappa and lambda light chains were 1,020 and 13.3 mg/dL, respectively. However, bone marrow-biopsy specimen revealed less than 10% of plasma cells. Renal biopsy showed crystalline variants of LCCN and LCPT. We diagnosed monoclonal gammopathy of renal significance and started chemotherapy along the guidelines for multiple myeloma.

Discussion: This case highlights the fact that LCCN can present an indolent course and LCPT with crystals does not always occur with Fanconi syndrome; thus, a diagnosis of slowly progressive renal insufficiency without any symptoms or abnormalities in laboratory evaluations should be made carefully. This case showed a difference between eGFRcr and eGFRcys, which may be useful for detecting LCPT. Cystatin C is freely filtered by the glomerulus, whereas Cr is not only filtered by the glomerulus but also secreted by the proximal tubule to some extent. Tubular injury induced by LCPT may elevate serum Cr than serum cystatin C, and make a difference between the eGFRcr and eGFRcys.

PUB452

Mycobacterium Genavense in a Kidney Transplant Patient Felix Nadrowitz,[1] Philip Kirschner,[2] Jan Menne.[1] *[1]Dept of Nephrology and Hypertension, Hannover Medical School, Germany; [2]Inst for Medical Microbiology and Hospital Epidemiology, Hannover Medical School, Germany.*

Introduction: Transplant recipients are highly susceptible for atypical infections as a consequence of their immunocompromised state. We report an exceptional case of a disseminated *Mycobacterium genavense* infection in a kidney transplant patient.

Case Description: The 26 years old Caucasian women received a kidney transplant from her father in 2010. In January 2016 she was admitted to our hospital with fever and diarrhea. Her immunosuppressive therapy consisted of tacrolimus, sirolimus and prednisolone. On admission inflammation markers were increased (CRP 23mg/l). Elevated serum creatinine (max. 198 µmol/L) indicated acute kidney injury. Differential blood count revealed pancytopenia and in particular distinct lymphocytopenia with 300/µl. Blood cultures and stool samples were repetitively negative. An Interferon-γ release assay was negative, as well. A kidney biopsy proved polyomavirus nephropathy, which is rare six years after transplantation. Thus, immunosuppression was reduced. Moreover, a colonoscopy and supplemental biopsies showed CMV-Colitis. Treatment with intravenous ganciclovir terminated diarrhea. However, fever persisted and inflammation parameters further increased, despite of additive broad-spectrum antibiotics. A chest CT scan detected bilateral ground glass infiltrates, in particular in the upper left lobe. Bronchoscopy was inconspicuous. 16S rRNA gene sequencing identified *Mycobacterium genavense* in blood cultures and the bronchoalveaolar lavage after six weeks, proving a disseminated infection. Antimycobacterial therapy was started with Clarithromycin, Rifampicin, Moxifloxacin and Ethambutol, adjusted to the impaired kidney function. However, patient's inflammatory parameters and fever episodes did not resolve after 12 weeks of therapy.

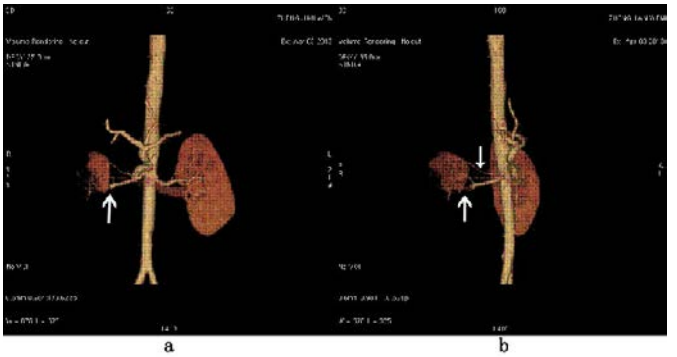
Discussion: This exceptional case illustrates rare infectious complications in a patient six years after kidney transplantion. The identification of *Mycobacterium genavense* is challenging due to the unspecific symptoms and its slow growth.

PUB453

Clinical Manifestations of Nephrotic Syndrome Complicated by Renal Artery Thrombosis: A Case Report Lihua Wang,[1,2] Xi Qiao.[1,2] *[1]Nephrology, Second Hospital of Shanxi Medical Univ, Taiyuan, China; [2]Shanxi Kidney Disease Inst, Taiyuan, China.*

Introduction: Although thrombotic complications in the venous system are common in patients with nephrotic syndrome, arterial thromboses associated with nephrotic syndrome are much less common. The main renal artery thromboses are extremely rarely observed. We report a case of nephrotic syndrome complicated by main renal artery thrombosis.

Case Description: The clinical data of a patient, who suffered from nephrotic syndrome complicated by right main renal artery thrombosis, were analyzed. The patient was a 38-year-old man, who presented with features of main renal artery thrombosis, when the nephrotic syndrome relapses after 1 year complete remission. The clinical manifestations were the appearance of severe lumbago suddenly, fever, percussion pain of ipsilateral kidney area, increase of the total number of white blood cells, white nucleus left, massive proteinuria, and aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH), hydroxybutyrate dehydrogenase (HBDH) was increased obviously, hypertension did not occur. Renal artery thrombosis was diagnosed by echo Doppler and confirmed by computed tomography angiography (CTA).



Intravenous thrombolysis therapy was effective. CTA showed complete lysis of renal thrombus; clinically there was a regression of flank pain.

Discussion: Nephrotic syndrome with main renal artery thrombosis is rare, and the clinical manifestations are acute renal infarction. Renal Doppler and CTA should be carried out in these patients. When the disease is diagnosed at an early stage, an intravenous thrombolysis can be attempted. Timely diagnosis and properly treatment are important for improving the prognosis of patients.

PUB454

C-ANCA+ RPGN following Anti-TNF Use in Autoimmunity Anne S. Yu, Susan E. Quaggin, Jennifer A. Tuazon. *Nephrology, Northwestern Univ, Chicago, IL.*

Introduction: Rapidly progressive glomerulonephritis (RPGN) is characterized by rapid loss of renal function and glomerular crescent formation. In patients with rheumatoid arthritis (RA), there have been 3 case reports of acute renal failure due to pauci-immune necrotizing crescentic GN in the setting of anti-tumor necrosis factor-alpha (anti-TNFα) use. We present a case of a patient with RA who developed RPGN following treatment with etanercept.

Case Description: A 43-year-old woman with history of long standing RA (treated with steroids intermittently for 9 years and etanercept for 5 months), hypothyroidism, and recent pulmonary embolism, presented with headache, nausea, epigastric pain, and malaise. On admission, she was found to have acute renal failure (Cr 5.8 mg/dl from baseline 0.8 six weeks prior) with hematuria (>100 RBCs and RBC casts on urinalysis), sub-nephrotic range proteinuria (1.2 g/g Cr), and anemia (Hb 7.8). On exam, she was not hypertensive, with clear lungs, no leg edema, and no rashes. A renal biopsy was performed which revealed severe pauci-immune necrotizing crescentic GN with significant tubulointerstitial inflammation and minimal scarring. She had a positive C-ANCA (titer 1:1280) and anti-PR3 (158). She received pulse steroids and cyclophosphamide, with downtrend in Cr from peak of 6.5 to 4.6 by day of discharge and never required renal replacement therapy. Renal function continued to improve with Cr down to 1.2 after extended steroid taper and maintenance of cyclophosphamide over 3 months, with plan for a 6 month total treatment course.

Discussion: Treatment of RA with anti-TNFα agents has been associated with development of vasculitis and rarely pauci-immune GN. While anti-TNFα agents may stimulate formation of autoantibodies, mechanisms are unclear. The temporal relation of anti-TNFα use and new-onset renal disease suggests a pathogenic role of TNFα antagonists in development of GN. RPGN should be considered in patients with underlying autoimmunity and exposure to anti-TNFα who develop renal failure, as early diagnosis and initiation of therapy are essential to prevent irreversible loss of renal function.

PUB455

Crescentic IgA Nephropathy in a Patient with Active Pulmonary Tuberculosis Afsaneh Haftbaradaran,[1] Golriz Jafari,[1] Ruchika Bhasin,[1] Phuong-Thu T. Pham,[2] Phuong-Chi T. Pham.[1] *[1]Olive View-UCLA Med Ctr; [2]UCLA.*

Introduction: The presence of crescents in IgA nephropathy (IgAN) may be associated with a 1.5-fold increased risk of kidney failure. Concurrent diffuse mesangial proliferation may lead to a 50% risk of reaching end stage renal disease within 5 years. Given its worse prognosis compared with non-crescentic IgAN, the addition of cyclophosphamide to glucocorticoid has been suggested.

Case Description: 79-year old male with chronic obstructive pulmonary disease and alcoholism presented with anorexia and generalized weakness. Full evaluation revealed active pulmonary tuberculosis (TB). Patient received rifampin, isoniazid, pyridoxine, and ethambutol (RIPE) therapy when he began to develop new onset rapid kidney injury (creatinine [Cr] increase from 0.9 to 6.5 mg/dL within 2 weeks), proteinuria (none to protein/creatinine ratio 2.0 g/g), hematuria, and red blood cell casts. Kidney biopsy revealed active glomerular crescents approximated at 20%, with necrotizing lesions and acute tubular necrosis. Given the concurrent active pulmonary TB, patient was only given minimal glucocorticoids (solumedrol 300 mg IV daily for 3 days followed by a rapid prednisone taper to off within 2 1/2 months). Both kidney injury and proteinuria resolved within 3 months. At 6 month-follow up, patient had a Cr of 1.3 mg/dL and no proteinuria.

Discussion: Active TB has been reported to be associated with IgAN, mesangial proliferative, crescentic, membranous glomerulonephropathies, among others. Of interest, rifampin has also linked to crescentic GN. In the current case, patient received continuing full dose RIPE and a short course of glucocorticoids with complete resolution of proteinuria, hematuria, and marked improvement of Cr within 3 months. Given the acute onset of kidney injury following the diagnosis of active TB and the rapid resolution of kidney injury with RIPE, we suspect that the crescentic IgAN was associated with active pulmonary TB and less likely, rifampin or others. The association is important to recognize because unlike other underlying etiologies of crescentic IgAN where aggressive immunosuppressive may be indicated, it is contraindicated and unnecessary in patients with active pulmonary TB.

PUB456

Hyponatremia in an Unexpected Case of Extrapulmonary Tuberculosis Sayena Sajadi, Reginald Ifeanyi Obi. *Nephrology and Hypertension, East Carolina Univ, Greenville, NC.*

Introduction: Accurate diagnosis of hyponatremia is pivotal to optimum management. Discovery of the cause of hyponatremia is not always straightforward and requires thorough investigation and attention to detail. We describe a case of subacute hypoosmolar hyponatremia in a patient with multiple risk factors for various etiologies of hyponatremia.

Case Description: 51 year old male with history of HIV and subdural hematoma was admitted with concern for septic shock secondary to pneumonia. His exam was pertinent for BP 84/50 mmHg and Pulse 108. He was cachectic, tachycardic, with clear lungs, and irritable. Labs were pertinent for sodium 124 mEq/L, potassium 5.9 mEq/L, serum osmolality 260 mOsm/kg, urine osmolality 681 mOsm/kg, urine sodium 84 mEq/L, and morning cortisol 5.6 ug/dL. His PPD and Quantiferon Gold test were positive. He was started on broad-spectrum antibiotics as well as Haldol for agitation. Pulmonary TB was ruled out. A differential of SIADH and Cerebral Salt Wasting (CSW) was considered. CSW was ruled out after hydration led to further drop in sodium. A suspicion for adrenal insufficiency was entertained because of hyperkalemia in the setting of low normal cortisol. Evaluation with a cosyntropin stimulation test was performed and confirmed primary adrenal insufficiency likely due to infection of the adrenal glands with TB. The patient received appropriate therapy leading to resolution of hyponatremia.

Discussion: In the setting of various potential etiologies for hyponatremia, thorough workup is critical. Based on this patient's history of pneumonia, HIV, antipsychotic medication use, drop in sodium after receiving isotonic fluids, and urine and plasma sodium studies, SIADH may be suspected. However, detailed diagnostics review revealed primary adrenal insufficiency likely secondary to extrapulmonary TB and led to initiation of appropriate therapies. Hyponatremia is the most common electrolyte abnormality in extrapulmonary TB. Infectious adrenalitis secondary to TB can lead to hypocortisolism and relative hypersecretion of antidiuretic hormone, which leads to hyponatremia. Understanding the primary cause and mechanism of hyponatremia in this case led to appropriate therapy and resolution of hyponatremia.

PUB457

A Case of Atypical PostInfectious Glomerulonephritis in an Elderly Male Patient with Liver Cirrhosis Marika Manolopoulou,[1] Mark Lusco,[2] Leslie S. Gewin.[1,3] *[1]Div of Nephrology and Hypertension, Vanderbilt Univ Medical Center; [2]Dept of Pathology, Microbiology and Immunology, Vanderbilt Univ Medical Center; [3]Div of Nephrology and Hypertension, Veterans Affairs Medical Center, Nashville, TN.*

Introduction: Postinfectious Glomerulonephritis (PIGN) is usually a childhood disease that occurs after an upper respiratory tract infection or impetigo and follows a benign course. We present a case of an elderly male patient with liver cirrhosis with clinical evidence of RPGN and pathologic features of PIGN on biopsy.

Case Description: A 60 year old male patient with CKD 3, DM2, HCV cirrhosis (viral load undetectable on Harvoni therapy) presented with shortness of breath, edema, proteinuria (1.4 g), hematuria and serum creatinine 2.3. Hospital course was complicated by oliguria and peak serum creatinine of 5.3. Aside from low complements, he had negative workups both for causes of glomerular disease as well as active infections. Renal biopsy was performed and showed focal proliferative glomerulonephritis, mild diabetic nephropathy with a dominant C3 granular and chunky mesangial and segmental capillary loop staining in a "starry sky" pattern by IF. A late phase or resolving postinfectious etiology was suggested without evidence of subepithelial hump-type deposits. He was treated with a course of steroids, and on hospital day 10 his urine output and subsequently his renal function improved.

Discussion: PIGN follows a more aggressive course in elderly patients with multiple comorbidities. Even though there is no strong evidence that steroids help PIGN, our patient perhaps improved after steroid administration. Given pathologic evidence of PIGN with characteristic staining, this case illustrates the possibility that PIGN and C3 glomerulopathy might be diseases of the same disease spectrum.

PUB458

Bilateral Obstructing Ureter Calculi, the Cause of Stage 3 Acute Kidney Injury Sai Prasad Gadapa,[1] Siwadon Pitukweerakul,[2] Sree V. Pilla.[3] *[1]Internal Medicine, St. Francis Hospital, Evanston, IL; [2]Internal Medicine, St. Francis Hospital, Evanston, IL; [3]Internal Medicine, St. Francis Hospital, Evanston, IL.*

Introduction: Non-contrast CT abdomen and pelvis should be the imaging modality of choice in a patient with rapidly worsening kidney function.

Case Description: A 69-year-old man with altered mental status. His medical history included is alcoholic liver cirrhosis, schizoaffective disorder. His medications included the trazodone. He was admitted for elevated ammonia level and urinary tract infection secondary to E.coli and was getting treatment with antibiotic piperacillin-tazobactum, and lactulose. On hospital day 3 serum creatinine was 3.3 mg/dL, the creatinine the day prior was 1.2 mg/dL. He reported mild diffuse abdominal pain. On physical exam, the patient was afebrile; his HR was 85/min, BP 109/52 mm Hg, RR 20min, and oxygen saturation 94 % on 4 liters nasal cannula. The neurological examination was unremarkable. He did not make urine overnight. On hospital day 4 he made 300 ml of urine. Urine analysis revealed cloudy urine, Specific Gravity 1.002, pH 6, moderate blood, large leukocytes, rbc's 21-50/hpf. Urine sodium revealed 48 mmol/L, FENA 3.6%. The wbc was 21000/ccmm, with 17000 absolute neutrophils. The sodium was 130 mmol/L, K 4.5 mmol/L, cl level 103 mmol/L, HCO3 level 21 mmol/Lr, BUN level 43 mg/dL, creatinine level 5.0 mg/dLr, GFR MDRD 12 ml/min/1.73 m, and blood ammonia level 85 UMOL/L. Renal ultra-sonogram revealed no evidence of hydronephrosis. On hospital day 5 he had myoclonic jerks on neurologic examination. He underwent emergent hemodialysis. On hospital day 6 he had non-contrast CT abdomen and pelvis which revealed bilateral obstructing calculi within the mid distal ureters measuring approximately 8 mm respectively. Patient subsequently underwent bilateral ante-grade pyelogram and bilateral nephrostomy tube placement under ultrasound guidance.

Discussion: Renal ultrasound is the initial imaging of choice in renal failure; but lacks sensitivity to identify the cause of obstruction when obstruction is in the lower part of ureter. This case report give special importance to non-contrast CT abdomen and pelvis in management of rapidly worsening kidney function.

PUB459

A Case of Membranoproliferative Glomerulonephritis in Hyaline Variant Multicentric Castleman's Disease Sindhura Bobba, Davis Massey, Jason M. Kidd. *Depatment of Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ Health system.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) is a pattern of histologic injury characterized by endocapillary proliferation, mesangial hypercellularity, and capillary wall remodeling.MPGN is frequently immune complex mediated or due to complement dysregulation. Less commonly, MPGN can be seen without immunoglobulin or complement deposition. We present an uncommon cause of the MPGN pattern of injury related to Castleman's disease (CD).

Case Description: A 23 year old Caucasian man presented for evaluation of acute renal failure with progressive anasarca and mediastinal mass. At presentation, his serum creatinine was 1.8 mg/dl. Urinalysis was significant for monomorphic hematuria and proteinuria. A spot urine protein to creatinine ratio was 0.9 mg/mg. Hemoglobin was 9.3 g/dl. Contrasted tomography scan of his chest, abdomen and pelvis showed bilateral pleural effusions, anterior mediastinal mass and mediastinal lymphadenopathy.

A serologic work up was unremarkable including negative EBV IgM, CMV, HIV. Biopsy of the mediastinal mass was negative for malignancy. A bone marrow biopsy was unrevealing. Renal biopsy was performed. Light microscopy was significant for a

membranoproliferative pattern of injury. Immunofluorescence was unremarkable. No immune complexes were present on electron microscopy. He underwent axillary lymph node biopsy that showed multicentric Castelman's disease of hyaline vascular variant. He received 4 doses of etoposide and one dose of rituximab. Most recent serum creatinine was 0.72 mg/dl and he has lost 27 kg.

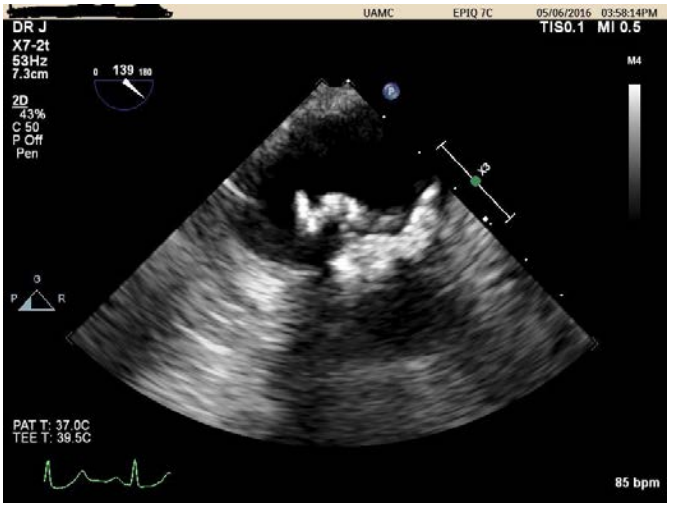
Discussion: A membranoproliferative pattern of injury is present in our patient without any immunune complexes, complement deposition or evidence of TMA. Increased production of IL6 and vascular endothelial growth factor(VEGF) have been implicated in the pathogenesis of CD. In mouse models, increased IL6 has been shown to induce podocyte apoptosis and podocyte specific overexpression of VEGF resulting in collapsing glomerulopathy [1]. It is unclear if either play a role in CD related renal manifestations. More study into the pathogenesis of renal disease in CD is needed. [1]Barlett, annurev-physiol 2016.

PUB460

Calcific Atrial Mass in End-Stage Renal Disease Mohamad Altriki, Prabir Roy-Chaudhury, Bijin Thajudeen. *Nephrology, Banner Univ of Arizona Medical Center, Tucson, AZ.*

Introduction: Metastatic cardiac calcification (MCC) has been widely reported in patients with ESRD promoted by elevated serum calcium-phosphate product, increased PTH,and reduction in body fluid inhibitors of calcification. Dystrophic cardiac calcification(DCC) is often associated with damaged tissue or systemic inflammation and when present, is usually extensive, often encompassing multiple cardiac chambers and valves. We present an unusual case of DCC as well as MCC involving left atrium(LA) in the setting of ESRD.

Case Description: A 55-year-old Caucasian male with h/o HTN, ESRD on HD, failure of previous renal transplant presented with symptoms of fever and chills. He was diagnosed with sepsis due to methicillin-resistant *Staphylococcus aureus* infection. A transesophageal echocardiogram done as part of the workup for MRSA bacteremia showed a large 2.2cm x 1.2cm calcified, highly mobile echo density attached to the Coumadin ridge within LA representing an old, calcified vegetation or a calcified thrombus.



Cardiac MRI confirmed the mobile calcified mass. Laboratory tests showed PTH of 670 pg/ml, corrected calcium of 8.9 mg/dl and phosphorus 6.2 mg/dl.

Discussion: In our patient, the calcification in the LA is a product of DCC promoted by MCC resulting from abnormal bone mineral metabolism disorder. Calcium deposition often involves the mitral valve, left ventricular free wall and septum as well as the LA appendage. It can lead to complicated valvular stenosis, cardiac arrhythmias, cardiac block and abnormal cardiac hemodynamics by effecting systolic and diastolic cardiac function. Over time LA pressure can increase due to decreased compliance of the LA wall and can be transmitted through pulmonary veins resulting in derangements in right heart hemodynamics. Awareness, early detection and treatment of the underlying cause, and resulting complications is the key to the patient outcome.

PUB461

Refractory Hyperkalemia with Calcineurin Inhibitor- Mechanism and Potential Treatment Option Abhisekh Sinha Ray,[1] Anjushree Kumar,[1] Sreeparna Ghosh,[2] Meenakshi Ghosh,[3] Priyeshkumar Patel,[1] Amna Ilahe.[1] *[1]Nephrology and Hypertension, Kansas Univ Medical Center, Kansas City, KS; [2]Internal Medicine, Interfaith Medical Center, Brooklyn, NY; [3]Pulmonary, SIU-SOM, Springfield, IL.*

Introduction: Calcineurin inhibitor (CNI), an important ammunition in immunosuppressive artillery in post-transplant setting, may cause recalcitrant hyperkalemia even with normal renal function. Although CNI can alter renal tubular potassium handling by multiple pathways but hyporeninemic hypoaldosteronism considered to be primary mechanism. Hence, fludrocortisone, a synthetic mineralocorticoid, may be useful in this scenario.

Case Description: A 30year-old female with alcoholic cirrhosis and hepatorenal syndrome received an orthotopic liver transplant (OLT). Post-OLT her renal function returned to normal with good urine output. Discharge medications included mycophenolate sodium, tacrolimus, prednisone and bactrim. For edema and hyperkalemia of 5.6meq/L, furosemide was started. She got readmitted on post-op day 20 with severe hyperkalemia of 7.8meq/L; managed conservatively with insulin-dextrose, sodium-bicarbonate and furosemide. She was discharged on furosemide, potassium (K) restricted diet and as needed Sodium Polystyrene Sulfonate(SPS). She continued to have hyperkalemia with normal serum creatinine and bicarbonate. Tacrolimus trough was maintained within 4-7ng/ml. Hydrochlorothiazide was added and bactrim was discontinued. However, K remained elevated around 6-7meq/L for next 8 weeks despite dual diuretic therapy and low K diet. She had to take SPS frequently and experienced severe abdominal cramping, diarrhea and weight loss. Trans-tubular potassium gradient was low with low plasma renin activity(3.1ng/ml/hour) and aldosterone level(<4ng/dl). CT scan showed bilateral normal adrenal glands. For presumed CNI induced hyperkalemia, fludrocortisone was initiated. Hyperkalemia dramatically improved in few days and remained in 3-4meq/L range over 18 months.

Discussion: Efficacy of Fludrocortisone therapy in CNI induced hyperkalemia is supported by very low level of evidence. However, to avoid the side effects with long term use of SPS or in case of refractory hyperkalemia, Fludrocortisone may be effective.

PUB462

Nivolumab Induced Renal Failure with Collapsing Focal Segmental Glomerulosclerosis (FSGS) - A Case Report Abhisekh Sinha Ray,[1] Sreeparna Ghosh,[2] Meenakshi Ghosh,[3] Sri G. Yarlagadda.[1] *[1]Nephrology and Hypertension, Kansas Univ Medical Center, Kansas City, KS; [2]Internal Medicine, Interfaith Medical Center, Brooklyn, NY; [3]Pulmonary, SIU-SOM, Springfield, IL.*

Introduction: Nivolumab, a monoclonal antibody against PD-1 (Programmed cell death protein 1) receptor, suppresses PD-1 pathway-mediated inhibition of anti-tumor immune response. This agent has been approved for metastatic melanoma, non-small cell lung cancer, advanced renal carcinoma, relapsing Hodgkin's lymphoma. Immune mediated nephritis of varying severity is reported in early literature and most had complete recovery with high dose steroid. However clinical experience is limited. We report a case of severe renal insufficiency with Nivolumab requiring long term renal replacement therapy.

Case Description: 42year-old male with stage IV adenocarcinoma of lung with disease progression despite chemo and radiation therapy received one dose of Nivolumab. Baseline creatinine(Cr) was 1.3mg/dl; urine analysis was negative for proteinuria. His 2nd dose of Nivolumab, scheduled after 2 weeks, was held due to elevated Cr(3.3mg/dl) and he was subsequently admitted. He developed progressive acute kidney injury without any response to conservative management with intravascular volume expansion. He had 30.8g/day proteinuria and was started on high dose intravenous steroid for suspected immune-mediated nephritis. His renal function and urine output worsened and renal biopsy was performed. Pathology showed collapsing focal segmental glomerulosclerosis (FSGS) involving 20 out of 46 glomeruli without any significant immune deposit. He continued to have heavy proteinuria, oliguria with Cr 8.2mg/dl on 12th day of hospitalization. He had to be started on hemodialysis for significant volume overload and severe azotemia. Steroid was slowly tapered off. Nivolumab therapy was never restarted, but even after 8months of the index event, he continued to be dialysis dependent.

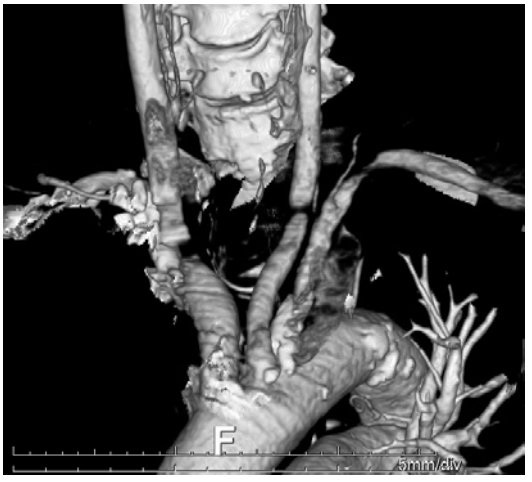
Discussion: Nivolumab is reported to cause steroid-responsive immune-mediated nephritis but our patient, who otherwise had mild non-proteinuric chronic kidney disease, developed end stage renal disease due to non-immune mediated collapsing FSGS after a single dose of Nivolumab.

PUB463

A Case of Subclavian Steal Syndrome Accompanied by Back-Flow of Vertebral Artery Detected after Arteriovenous Fistula Creation Makoto Sagasaki, Yukio Maruyama, Naoki Sugano, Izumi Yamamoto, Nanae Matsuo, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

Introduction: Subclavian steal syndrome (SSS) has a feature of a negative pressure gradient between the vertebral-subclavian artery junctions, resulting in altered vascular hemodynamics. SSS is relatively rare, but diabetes and atherosclerosis are strong risk factors. Especially, SSS becomes a major problem at the time of arteriovenous fistula (AVF) creation because of the diminished cerebral blood flow as a result of increased forearm blood flow.

A 71-year-old man was admitted for the initiation of hemodialysis (HD). He was already diagnosed as end-stage renal disease (ESRD) due to diabetic nephropathy, and got an operation of left forearm AVF creation just a month ago. He had no neurological symptoms including syncope and vertigo. There was no bilateral difference in blood pressure, and he did not complain numbness nor weakness in arm. Because carotid Doppler examination revealed back-flow of left vertebral artery, we considered the presence of SSS. Angiography revealed severe stenosis at the origin of left subclavian artery, and we performed percutaneous transcatheter angioplasty (PTA).



After PTA, stenosis of left subclavian artery disappear, the blood flow of left vertebral artery became normal, and he initiated HD using AVF in safety.

Discussion: In SSS, the proximal subclavian artery is stenosed, blood travels through ipsilateral vertebral artery to basilar artery and descends through contralateral vertebral artery to supply affected upper limb. Because AVF creation of affected forearm, theoretically, exacerbates the damage, we have to keep SSS in mind in the management of ESRD.

PUB464

Posterior Reversible Encephalopathy Syndrome in Chronic Kidney Disease Matthew Abramson,[1] Arun Kottarathara,[2] Yezina T. Nigatu,[2] Nand K. Wadhwa.[2] *[1]Dept of Medicine, Stony Brook Medicine, Stony Brook, NY; [2]Dept of Nephrology, Stony Brook Medicine, Stony Brook, NY.*

Introduction: Posterior Reversible Encephalopathy Syndrome (PRES) is a disorder of vascular dysautoregulation causing cerebral ischemia and edema, with vision loss, headaches, and/or seizures, and is often triggered by extreme fluctuations in blood pressure. We describe two cases of PRES, first in chronic peritoneal dialysis (CPD) and second in undiagnosed chronic kidney disease (CKD) stage 5. Both had vision loss with resolution of symptoms after control of hypertensive emergency.

Case Description: Case 1: A 48 year-old woman with ESRD of unknown etiology, on CPD for five years, who presented with one hour of bilateral vision loss and headaches. She was using frequently 4.25% dextrose PD solution and taking erythropoietin for anemia. BP was 267/120, creatinine 13.0, and hemoglobin 13.6. Head CT and MRI showed foci of edema in the parieto-occipital white matter. After two days of blood pressure control, her vision returned to normal. Repeat CT head 2 months later showed complete resolution. PRES here was likely due to hypertensive emergency in overly treated anemia and change to high solute transport in CPD. Case 2: A 29 year-old man with no medical history, presented with 2 weeks of severely blurred vision and headaches controlled with frequent NSAIDs. BP was 248/143 and serum Cr was 10.8. MRI brain revealed edema and ischemia in both occipital lobes and cerebellar vermis. Ophthalmology noted irreversible retinopathy and possibly permanent loss of vision. Complete recovery of vision occurred in 2 weeks with adequate control of BP.

Discussion: First patient had been receiving CPD for 5 years resulted in loss of ultrafiltration, while the second patient with CKD stage 5 had no medical care in years. Both presented with vision loss and hypertensive emergency, and MRI showed edema of the occipital lobes, confirming PRES. Both patients improved with optimal blood pressure control, as well improvement of ultrafiltration in the second patient. Early recognition of PRES and adequate control of BP in CKD are warranted for possible full recovery.

PUB465

Severe Symptomatic and Prolonged Hypocalcemia Two Weeks after Starting Cinacalcet: A Call for Caution Sahar Koubar, Abd Assalam Qannus. *Nephrology, American Univ of Beirut, Beirut, Lebanon.*

Introduction: Cinacalcet hydrochloride, a calcimimetic allosteric modulator of the calcium-sensing receptor, is now widely prescribed for patients with secondary hyperparathyroidism not responding to activated forms of vitamin D. Mild hypocalcemia is a common complication; however it is rarely severe, abrupt and prolonged.

Case Description: A 55 year old male patient with ESRD presented to the emergency department with headache, nausea, and numbness of his extremities. His laboratory data revealed severe corrected hypocalcaemia of 5.7 mg/dl. He had secondary hyperparathyroidism (serum PTH 1035pg/dl) which was initially treated with activated vitamin D, however the latter was stopped because of significant elevation in serum calcium and phosphorus levels despite concomitant use of non-calcium based phosphate binders. Cinacalcet 30 mg has been started as an alternative two weeks prior to his current presentation. His PTH level was 145 pg/dl. He required a total of 12 g of IV calcium gluconate and 5g of oral calcium carbonate before he became asymptomatic with a serum calcium level above 6mg/dl. He was discharged home on maximum doses of oral calcium and activated vitamin D. His serum calcium level slowly improved over a period of 4 weeks. His PTH level was 230pg/dl by week 6.

	D-60	D-30	D7	D14	D15	D16	D24	D31	D43
PTH	827	1035		145					230
Calcium	10.9	10.3	11.7	5.3	5.6	6.5	6.3	7.3	8.1

Discussion: This dramatic effect of Cinacalcet mimics the effect of parathyroidectomy and consequent hungry bone syndrome, with profound and prolonged decrease in serum calcium levels. The underlying pathogenesis behind this effect is not known, but it could represent an upregulation of the calcium sensing receptor resulting in prolonged over suppression of PTH and hypocalcemia. Conclusion: Cinacalcet can cause acute, severe and symptomatic hypocalcaemia in susceptible patients, yet precipitating factors are not known. It is safer to check calcium level more frequently during the first month after initiating treatment.

PUB466

Spurious High Anion Gap Acidosis Associated with Monoclonal Gammopathy David Selzer, Joanna B. Eldredge, Satyam Patel, Joshua A. Schwimmer, Jordan L. Rosenstock. *Nephrology, Northwell Health - Lenox Hill Hospital, New York, NY.*

Introduction: We present a case in which the measured serum bicarbonate level was persistently 2 mmol/L, which proved to be spurious as blood gas analysis showed the pH and bicarbonate level were in the normal range.

Case Description: An 82-year-old female with chronic heart failure and diabetes mellitus, presented to the emergency department with dyspnea on exertion associated with lower extremity edema. Home medications included metoprolol, metformin, and furosemide. Physical exam and chest x-ray were consistent with an acute exacerbation of her congestive heart failure. Labs showed sodium 140 mmol/L, potassium 3.5mmol/L, chloride 103 mmol/L, bicarbonate 2 mmol/L, BUN 29 mg/dl, creatinine 1.1 mg/dl. Repeat labs confirmed a serum bicarbonate level of 2 mmol/L. Arterial blood gas drawn concomitantly revealed a pH of 7.49 and a PCO_2 33 mmHg, with a calculated bicarbonate of 24 mmol/L. Serum protein electrophoresis demonstrated monoclonal kappa light chains with a concentration of 13.2 mg/dL and both serum and urine immunofixation showed an IgA kappa monoclonal protein.

Discussion: Our case had extreme pseudohypobicarbonatemia on enzymatic assay with an anion gap of 35. However, a gas panel-derived plasma bicarbonate and arterial pH were within normal reference range. A similar case of pseudohypobicarbonatemia had been reported which noted interference in enzymatic assays secondary to paraproteins (IgM and IgG) in the blood with a mean bicarbonate level of 12.4.[i] Our case demonstrates a decrease in bicarbonate to 2 and was likely due to IgA paraprotein. Physicians should therefore consider monoclonal gammopathy when encountered by a significant discrepancy between enzymatic and gas panel derived bicarbonate levels. [i] Goldwasser,P. Pseudohypobicarbonatemia Caused by an Endogenous Assay Interferent: A New Entity *AJKD* 2011, 58 (4) 617-620.

PUB467

Cerebral-Salt-Wasting (CSW) Beyond a Reasonable Doubt Shaker Qaqish,[1] Ashvin Kamath,[1] Golriz Jafari,[1] Phuong-Thu T. Pham,[2] Phuong-Chi T. Pham.[1] *[1]OVMC; [2]UCLA.*

Introduction: CSW is an entity questioned by some experts. CSW-induced hyponatremia cases are often suggested to be misdiagnoses of syndrome of inappropriate secretion of antidiuretic hormone (SIADH).

Case Description: A 26-year old male with no past medical history presented with 1 week of fevers, headaches, and lethargy. Full evaluation with brain CT revealed mild hydrocephalus, lumbar puncture with opening pressure of 55 cm H_2O, CSF consistent with viral vs. tuberculous meningoencephalitis. Patient received empirical ampicillin, acyclovir, and doxycycline. Hospital course was complicated by a rapid fall in serum sodium (SNa) [140 to 122 mEq/L within 41 hours]. This was initially attributed to the infusion of maintenance hypotonic 5% dextrose, 0.45 saline solution in a patient with presumed SIADH. Given evidence of increased intracranial pressure (ICP), plan was to correct hyponatremia by 5% with 600 mL of 3% saline within 6 hours followed by strict free H_2O intake restriction. Despite achieving the initial SNa goal of 125, patient continued to have high urine output (UO) reaching 300-500 mL/h with urine Na+K >200-280 mEq/L leading to a recurrent fall in SNa to 117 within hours of free H_2O restriction alone. Reinitiation of continuous 3% saline infusion was required at 200-400 mL/h to recorrect and maintain SNa to 130-135. Empirical administration of fludrocortisone at 0.2 mg bid did not seem to ameliorate

the condition. At this point, patient was transferred to an outside neurosurgery unit for a ventriculostomy placement. The receiving nephrology team assumed the misdiagnosis of SIADH as CSW and recommended discontinuation of 3% saline infusion. Within 5 hours, SNa dropped from 135 to 124 mEq/L. 3% saline infusion was restarted at high volume. Following a ventriculostomy placement, patient required lower volume of combination 0.9% (200mL/h) and 3% (50-100 mL/h) saline infusion. The etiology of meningoencephalitis is still under investigation. Initial endocrinologic findings: cortisol 25.8 mcg/dL, TSH 0.096 mIU/mL, free T4 0.90 ng/dL, T3 0.54 ng/mL, BNP 89.20 pg/mL.

Discussion: Whatever the contributing mechanisms, severe renal sodium wasting occurred in current patient with meningoencephalitis. Dismissing this condition lead to severe hyponatremia.

PUB468

Severe Acute Tubular Necrosis Associated with Tenofovir Alafenamide

Satyam Patel, Maria V. DeVita, Sandar Win, Michael F. Michelis. *Nephrology, Lenox Hill Hospital, New York, NY.*

Introduction: Tenofovir disoproxil fumarate (TDF) is a prodrug that is metabolized to tenofovir, which is subsequently converted intracellularly via phosphorylation to tenofovir-diphosphate, the active form of the drug responsible for antiviral properties. Elevated levels of tenofovir have been associated with nephrotoxicity. However, tenofovir alafenamide (TAF), a new prodrug of tenofovir, limits plasma exposure of tenofovir to 90% less than TDF, and hence, TAF has been associated with less nephrotoxicity. We describe a case in which TAF was associated with biopsy proven severe acute tubular necrosis (ATN).

Case Description: A 70 year old male with a medical history significant for HIV and chronic kidney disease [baseline creatinine (Cr) 2 mg/dL and Cr clearance > 40 mL/min] presented to the emergency department with complaint of shortness of breath for the past 2 weeks. He was recently switched from a single tablet drug consisting of efavirenz, emtricitabine, and TDF to a combination of elvitegravir, cobicistat, emtricitabine, and TAF 2.5 weeks prior to presentation. Physical exam was remarkable for moderate respiratory distress with use of accessory muscles, diffuse wheezing and rales in bilateral lung fields, and bilateral lower extremity edema. Laboratory values depicted severe anion gap acidosis (pH of 7.07) with serum bicarbonate level of 5 mmol/L, PCO2 of 16, blood urea nitrogen of 125 mg/dL, and Cr 10.5 mg/dL. Urine microscopy showed many red blood cells and white blood cells but no casts. Patient had 2.2 g/24 hrs of proteinuria. Urine output was less than 500 ml/day. Renal ultrasound was unremarkable. Subsequently, patient underwent hemodialysis for volume overload and severe metabolic acidosis. Renal biopsy showed diffuse and severe proximal tubular degenerative changes and mild foot process effacement consistent with acute tubular necrosis.

Discussion: Although TAF is approved for use in patients with mild to moderate kidney disease (Cr clearance of > 30 mL/min), our case depicts a patient who had ATN after being switched to a single tablet antiviral therapy which included TAF. Therefore, clinicians need to be cautious in using this new agent.

PUB469

Streptozocin Induced Acute Tubulo-Interstitial Nephritis

Irfan Ahmed Moinuddin, Sindhura Bobba, Anna K. Vinnikova, Davis Massey, Daniel E. Carl. *Nephrology, VCU Medical Center, Richmond, VA.*

Introduction: Drug induced acute tubulo-interstitial nephritis is an important cause of acute renal failure. Streptozocin has been used as an anti-cancer agent, its nephrotoxicity has been reported as reversible proteinuria, proximal tubular dysfunction; but tubulo-interstitial nephritis has been rarely reported.

Case Description: 65 year old female with adrenal carcinoma, initially on cisplatin based chemotherapy which was changed to streptozocin, presented with acute kidney injury. Her creatinine was <1 mg/dl and urinalysis was benign before streptozocin therapy. She developed fatigue, malaise, nausea/vomiting and decreased appetite within days after starting streptozocin and had a creatinine of 6.2 mg/dl three weeks after streptozocin administration. Urine microscopy showed many muddy brown casts and few non-dysmorphic RBCs. Hemoglobin was 7.5 and platelet count was as low as 11 with normal LDH, haptoglobin and total bilirubin and no schistocytes on peripheral smear. She had peripheral eosinophilia and also had urinary eosinophils. Ultrasound showed normal sized kidneys. She was started on prednisone for presumed interstitial nephritis as biopsy was deferred due to thrombocytopenia. Creatinine improved to 4 mg/dl, and was discharged on a 3 week prednisone taper. She was seen in the outpatient setting and her symptoms recurred after stopping the prednisone. She was re-admitted for worsening renal failure, with creatinine of 10 mg/dl (5 weeks after administration). Renal sonogram and urinalysis were unchanged. Urine eosinophils were negative and peripheral eosinophils were improved. Kidney biopsy was performed which showed severe ATN with interstitial lymphocytic infiltrate and the diagnosis was severe acute tubulo-interstitial nephritis. She was discharged with a creatinine of 9 mg/dl and most recent labs revealed a slight decrease to 8.5 mg/dl (9 weeks after administration). She was given another 4 weeks of prednisone after the biopsy results.

Discussion: Monitoring of renal function after starting streptozocin and early diagnosis of tubulo-interstitial nephritis is important as it is potentially reversible by removing the suspected agent and may respond to short course of steroids.

PUB470

Relapsing Calciphylaxis after Kidney Transplantation

Syed A. Ali, Jayme E. Locke, Song Ching Ong. *Univ of Alabama at Birmingham.*

Introduction: Calciphyaxis is a debilitating condition with calcification and thrombosis of cutaneous arterioles leading to ischemic necrosis. Risk factors include end stage kidney disease (ESRD), female sex, obesity, malignancy, chronic inflammation, hypercoagulable state, elevated calcium and phosphorus product and hyperparathyroidism. Available treatments include sodium thiosulphate, hyperbaric oxygen, parathyroidectomy, surgical resection and good wound care. Kidney transplantation may improve this condition through a reduction in systemic inflammation and restitution of normal calcium-phosphorus metabolism. We describe a kidney transplant patient with relapsing calciphylaxis.

Case Description: A 53-year old woman with ESRD due to lupus nephropathy complicated by antiphospholipid syndrome on hemodialysis for 15 years. The patient had calciphylaxis treated with intravenous sodium thiosulphate and parathyroidectomy 5 years pre-transplant. Lupus was quiescent and patient was on fondaparinux. The patient received a cadaveric kidney transplant with thymoglobulin induction and immunosuppression with tacrolimus, mycophenolate mofetil and prednisone. 4 months post-transplant the patient developed painful purpuric necrotic and indurated lesions on both thighs and forearms. Skin biopsy showed calcification of subcutaneous vessels with necrosis of dermis and epidermis consistent with calciphylaxis. Workup showed normal levels of aluminum, protein C and S and a negative antiphospholipid antibody level. Creatinine 0.9mg/dl. iPTH 38.2 pg/ml, Ca 9.5 mg/dl, Phosphorus 3.5 mg/dl, Alb 3.8 mg/dl. Tacrolimus levels 5-7 ng/dl. Patient received intravenous sodium thiosulphate , hyperbaric oxygen and specialized wound care. A per-cutaneous enteric feeding tube provoked further calciphylaxis lesions with extensive areas of skin and soft tissue necrosis. The patient developed sepsis and expired in spite of preserved kidney function.

Discussion: Kidney transplantation may not prevent recurrence of calciphylaxis. Calcineurin inhibitors decrease osteoprotegerin and increase receptor activator of nuclear factor k-B ligand (RANK-L) leading to increased extraosseous mineralization and vascular calcification and may have contributed to the patient's disease.

PUB471

Mucin-1 Kidney Disease: A Family History

Joana Gameiro, Sofia C.A. Jorge, Jose António Lopes, António Gomes da Costa. *Service of Nephrology and Renal Transplantation, Centro Hospitalar Lisboa Norte, EPE, Lisbon, Portugal.*

Introduction: Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) refers to a group of diseases characterized by autosomal dominant inheritance, bland urinary sediment, absent-to-mild proteinuria, no severe hypertension, normal or small-sized kidneys on ultrasound, pathologic changes of tubular and interstitial fibrosis, and slowly progressive chronic kidney disease (CKD), resulting in the need for dialysis in the fourth through seventh decades of life. It is caused by mutations in the genes encoding uromodulin (UMOD), hepatocyte nuclear factor-1b (HNF1B), renin (REN), and mucin-1 (MUC1).

Case Description: We present the case of a 30 year-old caucasian female who was admitted to our department due to uremic syndrome. She had a chronic kidney disease of unknown etiology, with a previous creatinine of 2.7mg/dL when she was 27 years-old and had had no follow-up since then. She had a chronic hypocalemia and metabolic acidosis, a bland urinary sediment and normal sized kidneys on ultrasound. Imunologic, serologic and disproteinemic study was negative. She had a family history of chronic kidney disease without deafness or visual loss. Her grandmother died after 30 years of chronic kidney disease; her father had a history of gout and received a renal transplant at 37 years old; a cousin with chronic kidney disease in dialysis since he was 57 years old, with multiple kidney cysts, a kidney biopsy with tubulointerstitial nephritis, and negative study of the uromodulin gene; and also an uncle in dialysis since he was 60 years old. Genetic testing of the MUC1 gene was positive. She started peritoneal dialysis one month after being discharged and remains in this technique at a 2 year follow-up.

Discussion: Mucin-1 kidney disease formerly known as medullary cystic kidney disease type 1 is a familial progressive tubulointerstitial nephropathy belonging to the recently defined group of ADTKD. MUC1 gene encodes mucin-1, a protein expressed in many tissues, however no extrarenal manifestations have been described. Onset of end-stage renal disease is very variable between and within families as illustrated in our case.

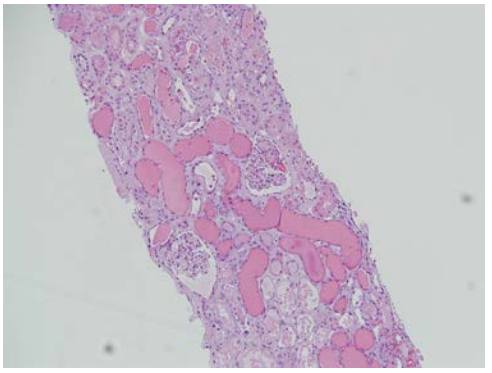
PUB472

Everoliums Associated Acute Tubular Injury with Proteinacious Casts

Zachary Freestone, Fuad S. Shihab, Faris A. Ahmed. *Nephrology, Univ of Utah, Salt Lake City, UT.*

Introduction: Mammalian target of rapamycin (mTOR) inhibitors are associated with marked proteinuria in patients with renal impairment and can lead to a unique form of cast nephropathy. Cast nephropathy with mTOR inhibitors has been associated with simultaneous use of calcineurin inhibitors. Many patients are placed on mTOR inhibitors for immunosuppressive therapy, but caution should be taken in the setting of tubular injury because of the risk associated with proteinuria and increased tubular damage.

Case Description: A 49 year old female with a history of type I DM received a simultaneous pancreas and kidney transplant. She had multiple admission to the hospital due to diarrhea and volume depletion associated with mycophenolate use. She was transitioned to everolimus in additon to tacrolimus due to the significant side effects related to mycophenolate. The patient was later admitted to the hospital with AKI after transition to everolimus and found to have 18 grams of proteinuria. Laboratory studies revealed an everolimus level of 9.2 ng/mL. Renal biopsy was performed and showed marked acute tubular injury and proteinaceous casts.



Everolimus was determined to be the cause of her proteinuria and contributed to her tubular injury. Proteinuria decreased to 3 grams upon cessation of everolimus. The patient had significant renal fibrosis upon recovery as evidenced by repeat renal biopsy 2 months after the insult.

Discussion: Our patient developed cast nephropathy with nephrotic range proteinuria as a result of everolimus use. Proteinuria improved significantly upon cessation of everolimus. Therapy with the use of mTOR inhibitors increases proteinuria and can lead to cast nephropathy. These medications can also delay recovery in the presence of tubular injury. Caution is to be used when using mTOR inhibitors in the setting of acute kidney injury with simultaneous use of calcineurin inhibitors.

PUB473

Anti-Neutrophil Cytoplasmic Antibodies Vasculitis after Influenza Vaccination Okechukwu Ebiem, Bharat Bajantri, Amandeep Singh, Kishore Kumar, Rabih Nasr. *Internal Medicine, Bronx Lebanon Hospital Center, Bronx, NY.*

Introduction: There are rare case reports of temporal association between influenza vaccination and anti-neutrophil cytoplasmic antibodies(ANCA)vasculitis. We describe a case of ANCA vascultis after receiving flu vaccine.

Case Description: A 67 year old man presented to emergency room with complaints of fever and myalgia for 3 weeks. His medical history includes diabetes, hypertension and congestive heart failure. Admission vitals and clinical examination were normal. He denied any systemic symptoms. Initial investigations revealed acute kidney injury with serum creatinine of 4.5, hyperkalemia of 6.1 and elevated ESR and CRP with microscopic hematuria. Autoimmune work up was significant for elevated myeloperoxidase-*anti-neutrophil cytoplasmic antibodies (*MPO-ANCA) titers. Kidney histopathology showed pauciimmune vasculitis with crescentic Glomerulonephritis. He had received flu vaccine 3 weeks prior to onset of symptoms. During hospitalization he was treated with steroids, cyclophosphamide and plasmapheresis that resulted in improvement in renal function.

Discussion: ANCA-vasculitis post influenza vaccination is speculated to be caused by auto-immunity. The mechanisms proposed for the induction of vasculitis by infectious agents include direct microbial invasion into endothelial cells, immune complex mediated vessel wall damage, and the activation of auto-reactive B and/ or T cells through molecular mimicry and superantigens. The latency period between vaccination and autoimmunity has been reported to be around 12 to 21 days and it is a diagnosis of exclusion. Similar vasculitic manifestations have also been reported with other vaccines like BCG and HPV. On review of literature, treatment modalities of influenza vaccine associated ANCA vasculitis includes steroids, cyclophosphamide, rituximab and plasmapheresis with some success. In our case, he received 7 sessions of plasmapheresis, oral cyclophosphamide and steroids with improvement in kidney function. It is important to recognize possible association between flu vaccine and ANCA vasculitis. Nephrologist should be vigilant for the possibility of developing renal vasculitis post flu vaccination.

PUB474

Case Series of Everolimus with Tacrolimus Causing Hemolytic Uremic Syndrome (HUS) within 3 Month Post Kidney Transplantation Sumeet Munjal, Aijaz A. Gundroo, Mareena Susan Zachariah, Shirley Shwu-Shiow Chang. *Div of Nephrology, Univ at Buffalo, NY.*

Introduction: Thrombotic microangiopathy (TMA) is a well recognized complication affecting 3-14% of renal allograft recipients who are on CNI based immunosuppressive regimen. TMA leads to thrombocytopenia, anemia, and acute renal failure. TMA with predominately renal feature is termed as HUS. We are reporting 2 cases of HUS with de novo use of everolimus & tacrolimus in living kidney recipients.

Case Description: Case 1: 31 yo WM S/P kidney transplant for ESRD sec to vesicoureteral reflux, thymoglobulin induction, maintained on prednisone, everolimus & tacrolimus presented with AKI 10 days post transplant with serum Cr 2 (baseline 1.6). He received steroids for presumed rejection. Transplant biopsy showed glomerular TMA with arterial fibrinoid necrosis, C4d 1+, DSA was -ve. PBS showed 1 schistocyte/HPF. Platelets were low, LDH 490, 3+ blood in urine, -ve lupus anticoagulant, ADAMTS13>100, and normal D-dimer and fibrinogen. Acute antibody mediated rejection was ruled out and diagnosis of drug induced TMA was made. CNIs were stopped, switched to Belatacept & MMF, received thymoglobulin and maintained on steroids. Plasmapheresis was initiated until hemolysis resolved. He responded to treatment and has stable allograft function. **Case 2**: 59 yo WM S/P kidney transplant for ESRD sec to DM2, simulect induction, on prednisone, everolimus and tacrolimus presented with AKI serum Cr 3 (baseline Cr 1), had DSA of 4300. Transplant biopsy showed Banff borderline cellular rejection, started on Steroids and IVIG. He presented with AKI Cr 9.2, nose bleed, thrombocytopenia, transaminitis, 2+ blood in urine and was started on dialysis, steroids, thymoglobulin, changed immunosuppression to MMF/tacrolimus. Repeat biopsy showed borderline cellular rejection, TMA, C4d 2. He was started on Plasmapheresis+IVIG. PBS showed no schistocytes, Cr dropped to 1.6 with DSA down to 2800.

Discussion: Our cases illustrate HUS secondary to everolimus/tacrolimus and TMA secondary to acute AMR. Post-transplant TMA should be identified early, differentials include AMR, TTP/HUS, and drugs (CNI/mTOR), with appropriate treatments can reverse AKI resulting in good renal outcome.

PUB475

Acute Renal Infarction as an Unusual Cause of Acute Abdomen and a Rare Complication of Cardiac Angiography Siwadon Pitukweerakul, Sai Prasad Gadapa, Sree V. Pilla, Pye Phyo Aung. *Medicine, Presence Saint Francis Hospital, Evanston, IL.*

Introduction: Renal infarction is a rare complication after coronary angiography. Other causes of renal infarction after coronary angiography are cholesterol emboli, paradoxical emboli via intra-cardiac shunt, extension of aortic dissection into renal arteries. This case demonstrates the case of renal infarction after cardiac angiography and radiographic finding of acute renal infarction.

Case Description: A 43 -year-old man presented with sudden onset of left flank pain and left lower back pain for four hours. Three days ago, he was admitted in the hospital for chest pain, underwent coronary angiography after an abnormal stress test which showed mild coronary artery disease and was subsequently discharged. Left flank pain was severe, stabbing, radiating to lower back. A physical examination was normal except costovertebral angle tenderness on the left side. Laboratory tests were within normal limits with serum creatinine of 0.9 mg/dLContrast computed tomography of abdomen and pelvis was shown in Figure 1 and 2. She was given with long term anticoagulation and pain medication.

Discussion: Acute Renal Infarction(ARI) is a very rare complication of coronary angiography. The most common symptoms of ARI are abdominal and/or flank pain, nausea, and vomiting. The most common cause of ARI is atrial fibrillation. Hypercoagulable disorders, bacterial endocarditis, hematologic disease, are less frequent but important causes of ARI. Contrast computed tomography is considered the gold standard for the diagnosis of ARI. Anticoagulation is the mainstay of the treatment of ARI. However, no definitive treatment strategy for ARI has yet been established due to the rarity of this disease.

PUB476

Non Hodgkin Lymphoma Presenting with Rapidly Progressive Glomeruolonephritis due to Membranoproliferative Glomerulonephritis with Concurrent Thrombotic Microangiopathy: Long Term Remission with Rituximab Suresh Balasubramony,[1] Tarek H. Saleh,[1] Barry M. Wall.[1,2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]VAMC.*

Introduction: Non-Hodgkin's lymphoma has been associated with a number of glomerular diseases.

Case Description: Case report: 73 yr old male with hypertension and diabetes mellitus with normal renal function, presented with an episode of gross hematuria with subsequent microscopic hematuria. Imaging studies of the abdomen and cystoscopy were negative. He subsequently developed anorexia and vomiting and acute renal failure: creatinine 7.2 mg/dl. Urinalysis was 4+ positive for blood and 24 hr urine protein excretion was 0.7 gm. Renal function initially improved with intravenous fluids, creatinine 3.1 mg/dl; however, proteinuria and microscopic hematuria persisted. He subsequently developed worsening anemia, dyspnea, and lower extremity edema. There was no hepatosplenomegaly or lymphadenopathy. Laboratory: hemoglobin 7.5 g/dL and platelets 156 K/uL . Studies for hepatitis B, C, HIV, antinuclear antibody, ASO titer, ANCA panel, ADAMTS13, and urine and blood cultures were normal or negative. C3 was low 75 (90-180 mg/dL) and C4 10 (10-40 mg/dL). Serum and urine electrophoresis did not identify any monoclonal proteins, however, serum free kappa /lambda ratio was elevated, 14.1. Cryoglobulins were trace positive with elevated rheumatoid factor. Kidney biopsy showed membranoproliferative GN with subendothelial immune complex deposition, basement membrane duplication, and concurrent thrombotic microangiopathy. Bone marrow biopsy showed scattered monoclonal lymphoid aggregates consistent with low grade B cell lymphoproliferative disorder. He was treated with 4 weekly doses of rituximab (700 mg). During 6 mos of follow-up, anemia, proteinuria, hematuria, dyspnea, and edema resolved with serum creatinine of 1.6 mg/dL.

Discussion: RPGN due to membranoproliferative glomerulonephritis with concurrent thrombotic microangiopathy is a rare complication of B cell Non Hodgkin lymphoma. Therapy with rituximab resulted in remission of both hematologic and renal manifestations.

PUB477

Acute Alcoholic Pancreatitis Induced aHUS: Role for Eculizumab Gitanjali Singh, Sarika S. Deshmukh, Satyarth Kulshrestha. *Nephrology, Univ of Iowa, Iowa City, IA.*

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is characterized by microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury (AKI). Patients have dysregulated alternative complement pathway, majority have a mutation in complement factors H or I or membrane Cofactor Protein. Acute pancreatitis is reported

to be a trigger for TTP/HUS in literature. We report a rare case of aHUS triggered by acute alcoholic pancreatitis and successful use of Eculizumab in treating AKI/aHUS/ acute lung injury(ALI).

Case Description: A 44 yo Caucasian man, who has past history of hypertension, GERD, alcohol abuse and acute pancreatitis (idiopathic) presented with acute abdominal pain with nausea and dyspnea after binge drinking. On examination:normotensive non-obese man in respiratory distress. HEENT- icterus +; Pulmonary- bilateral diffuse crackles+; Abdomen- tender in periumbilical area with reduced bowel sounds. Laboratory data

	Day 0	Day 3 (Pre-Eculizumab)	Day 7	day 14
Lipase (U/ml)	894	258	37	69
Amylase (U/ml)	1351			
LDH		1453	829	460
T Bili/D bili	2.7/0.8	2.3/0.8	0.7/0.4	0.5
Hemoglobin (g/dL)	17	6.7	7.5	8.2
Platelets (1000/mm3)	211	16	264	494
Creatinine (mg/dL)	0.9	7.8	6.6	2.4
ADAMTS13 activity (%)		34		
Peripheral smear Schistocytes	3+	3+	2+	2+

ADAMTS13: 35%, C3 122, C4 20, Complement factor H 466 mcg/ml, Complement factor I 36 mcg/ml, INR 1. Urinalysis 3+ blood, UPC ratio 1.8. DIC screen negative. Clinical course: Renal function rapidly deteriorated, but stayed non-oliguric. By day 3, he had ALI, for which he was intubated. Eculizumab 900 mg single dose was given on day 4 after administering meningococcal vaccine on day 3. His lipase and amylase continued to trend down and AKI and ALI also started to resolve. He never required dialysis and was extubated 3 days after Eculizumab dose.

Discussion: Acute alcoholic pancreatitis triggered aHUS, a rare complication, reflects the presence of underlying complement dysregulation in our patient. In his case the aHUS continued though pancreatitis was resolving. He tested negative for common mutations and inhibitors. Single dose Eculizumab was effective in this case.

PUB478

Acute Kidney Injury due to Epstein-Barr Virus Faisal Anwar, Hafiz Ali Sroya, Rawan T. Al-Odat, Saeed Kamran Shaffi. *Nephrology, UNM, Albuquerque, NM.*

Introduction: EBV induced acute kidney injury is extremely rare in adults. We present a case of EBV induced acute interstitial nephritis (AIN).

Case Description: A 54 years old male with past medical history of hypertension presented to ED with a 3-week history of fever, distended abdomen, anorexia and skin rash. Physical examination showed epigastric tenderness, hepatomegaly, splenomegaly, and a maculopapular rash on the abdomen and legs. Diagnostic data are shown in Figure 1. During the course of hospitalization, his kidney function deteriorated and hemodialysis (HD) was initiated. Renal biopsy was performed that showed AIN as well as acute tubular necrosis. A diagnosis of EBV induced AIN was made. We started him on a steroid taper with gradual improvement of kidney function and discontinuation of HD.

Figure 1: Laboratory data

Variable	Results
BUN (mg/dL)	27 → Worsened to 161 during hospitalization
Creatinine (mg/dL)	1.58 → Worsened to 10.8 1.64 at the time of discharge
Urine microscopy	Muddy brown casts
HSV I&II and HIV	Non reactive
ANA, ANCA, Cryoglobulins, Hepatitis profile	Negative
EBV IgM	Positive
EBV IgG	Negative

Discussion: Infectious mononucleosis can cause acute interstitial nephritis albeit this is a rare occurrence in immunocompetent patients. Renal disease is self-limited with complete resolution of AKI in most cases. This disease entity should be considered in the patients with appropriate clinical history. Supportive care is the mainstay of treatment. Use of steroids in AIN is not supported by robust randomized trials; however, observational studies show some benefit if used early during the disease course. We used steroid in our patient with gradual improvement in renal function.

PUB479

Anti-Glomerular Basement Membrane Disease: A Case Report of an Uncommon Entity with Atypical Histological Findings Gerren Hobby,[1] Mohammed M. Siddiqui,[1] Shree G. Sharma,[2] Manisha Singh.[1] *[1]Div of Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Renal Pathology, Arkana Laboratories, Little Rock, AR.*

Introduction: Anti-glomerular basement membrane (anti-GBM) disease is an aggressive form of glomerulonephritis associated with a high mortality if not treated promptly. There has been recent increased awareness of atypical forms of anti-GBM disease which display a more indolent clinical course with varied pathological findings. We are reporting such a case.

Case Description: A 57-year-old Caucasian woman was admitted with 5 days of dyspnea and 1 day of hemoptysis. She carried no prior diagnosis of renal disease. Chest x-ray revealed diffuse bilateral opacities. Serum creatinine was 0.9 mg/dl on admission, but increased to 2.7 mg/dl over the course of 1 week. Urine sediment showed dysmorphic RBCs. Serologies were negative for ANA and ANCA. Complement levels were normal. Anti-GBM was positive at 31 units/ml (reference range 0-20 units/ml). Renal biopsy revealed linear IgG, kappa and lambda staining along the glomerular basement membrane but was notable for the absence of a diffuse crescentic picture, which is typically seen in anti-GBM glomerulonephritis. The biopsy also showed nodular glomerulosclerosis which is a very rare finding. After treatment with steroids, cyclophosphamide and plasmapheresis, hemoptysis resolved and serum creatinine improved to 1.8 mg/dl.

Discussion: In contrast to the classical presentation of anti-GBM disease, this patient presented with less severe renal failure in addition to having kidney biopsy findings which lacked an overt crescentic picture. Similar cases have recently been reported which importantly display poor renal survival when treated with conventional therapy despite a mild elevation in serum creatinine. Although this patient improved with standard treatment for anti-GBM disease, the subset of patients with atypical anti-GBM disease require special attention during diagnosis and treatment in order to achieve good outcomes.

PUB480

Complete Normalization of Serum Creatinine from Very High Levels due to Obstructive Uropathy Amar V. Patel, Muner Mohamed, Moro O. Salifu, Mary C. Mallappallil. *Div of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction: Acute renal failure is one of the commonest reasons for inpatient Nephrology consultation. Of these, 5-10% of cases are classified as being obstructive. The time to recovering renal function after the resolution of the obstruction determines the need for emergency dialysis. We report a case of a patient presenting with a serum creatinine of 35.9mg/dL and fully recovering renal function with relief of obstruction and without dialysis.

Case Description: A 66-year-old man with a past medical history of hypertension, presented to the emergency room (ER) with bilateral leg edema, distended abdomen, difficulty urinating and decreased appetite for 3 weeks duration. He was previously seen in the ER when he had a urinary tract infection and was treated with ciprofloxacin and hydrochlorothiazide. Significant finding on physical examination were BP 190/120mmHg, 1+ lower extremity edema, and a distended bladder. Initial laboratory data revealed Na 131mEq/L, K of 7.9mEq/L (non-hemolyzed), HCO3 of 8mEq/L, BUN 148mg/dL, and Cr 35.92mg/dL. Renal consultation requested for urgent dialysis. Foley bladder catheter was placed with approximately 4L of blood tinged urine. Later in the day there was an additional 5L or urine. Over the next 30 hours patient laboratory data improved dramatically.

	Na	K	HCO3	BUN	Cr
Admission	131	7.9	8	148	35.92
30 hours post urinary catheter	147	5.9	18	36	2.39

Patient was ultimately found to have obstructive uropathy secondary to prostatic cancer with a prostate specific antigen noted to be 61. His baseline creatinine 2 months later was 1mg/dL. He never had any hemodialysis.

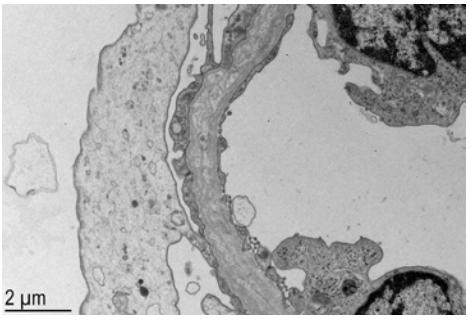
Discussion: Obstructive nephropathy requires advanced clinical decisions due to the multitude of factors potentially requiring a patient to undergo urgent dialysis. Our case exemplifies these points and the patient ultimately did not require hemodialysis with rapid recovery of renal function. The key factor was immediate urinary output after release of obstruction. This is the highest serum creatinine (35.9mg/dL) reported in the literature with complete recovery of renal function (serum creatinine 1mg/dL) after resolution of obstruction.

PUB481

Glomerular Basement Membranes under Stress - When a Big Organ Lands in a Small Body Francois Gougeon,[1] Alexei V. Mikhailov,[1] Keisha L. Gibson,[2] Harsharan Kaur Singh,[1] Volker Nickeleit.[1] *[1]Nephropathology, UNC-Chapel Hill, Chapel Hill, NC; [2]Nephrology, UNC-Chapel Hill, Chapel Hill, NC.*

Introduction: Donor/recipient body weight mismatch in kidney transplantation can be associated with decreased graft survival and increased proteinuria. These findings are reported in patients receiving kidneys too small for their body size. Glomerulomegaly, focal and segmental glomerulosclerosis, and rarely a peculiar form of glomerulopathy with basement membrane (GBM) remodeling have been observed. Glomerular alterations are attributed to non-immunological factors such as hyperfiltration and GBM "shear stress".

Case Description: We present a case of a 9 year old child with dwarfism (below 3rd percentile for age) who received an adult-sized kidney (11 cm in length) at age 5. She developed persistent nephrotic range proteinuria (urine protein to creatinine ratio of 8.1) within a year of transplantation. Serum creatinine levels were stable at 0.2-0.3 mg/dl. Hematuria and donor specific antibodies (DSA) were absent. Two biopsies performed to evaluate the cause of proteinuria (3 and 4 years post-grafting) revealed markedly remodeled GBM with splitting mimicking hereditary nephropathy (changes not seen in a remote native renal biopsy nor in the donor organ at time of transplant). There was no evidence of rejection, no interstitial fibrosis and C4d was not identified along peri-tubular capillaries. Diffuse C4d staining was however noted along the GBM. Graft function and proteinuria remained unchanged until end of follow-up 50 months post grafting.



Discussion: Here we show for the first time that a too large for body size mismatched graft is associated with injury to the GBM and a peculiar form of glomerulopathy. GBM remodeling is associated with GBM-C4d deposits in the absence of rejection and DSAs. Clinically, graft function was stable over 4.2 years with proteinuria as main symptom.

PUB482

Pauci-Immune Vasculitis with Hypocomplementemia: A Rare Presentation

Jennifer K. Bond, Julia Schneider, Benjamin Ling, Maria M. Picken, Kavitha Vellanki. *Nephrology and Hypertension, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Abnormal activation of the alternate complement pathway is increasingly being explored as a key pathogenic event in ANCA asscoiated vasculitis (AAV). While low C3 has been recently reported in AAV with histological signs of thrombotic microangiopathy, both C3 and C4 being low has rarely been described. We report a rare case of AAV where both complements were low on presentation.

Case Description: 60 yr old female presented with acute renal failure after being treated for pneumonia with various antibiotics over 2 months. Extensive infectious work up including pleural fluid analysis was repeatedly negative. She reported increasing fatigue and lower extremity swelling. She had bibasilar crackles, pedal edema and urine showed 2 + protein, large blood and many RBCs. Her labs on presentation are shown

Lab (reference range)	Day 1	Day 20	Day 80
Sodium (136-144mmol/L)	129	138	133
Potassium (3.5-5.1mmol/L)	5.8	4.6	4.4
Creatinine (mg/dL)	6.07	6.44 *on HD	3.85 **off HD
WBC (3.5-10.5 K/UL)	24.5	25.5	11.2
ANCA	POSITIVE	POSITIVE	Negative
ANA	>1:1280	1:640	1:640
Compliment 3 (69-152 mg/dL)	67	88	106
Compliment 4 (16-38 mg/dL)	9	18	25
Proteinase 3AB (<1.0 AI)	113.5	23.9	N/A

Emergent kidney biopsy showed severe cresenteric glomerulonephritis with no evidence of TMA. Additionally, she had leukocytosis as high as 38.5 K/UL and single large lesion on lung imaging suspicious for lung abscess. She was treated with plasmapheresis (3 sessions), pulse dose steroids and IV Cytoxan along with broad-spectrum antibiotics and started on hemodialysis. She responded dramatically with serological markers normalizing within a few weeks of treatment and eventually came off dialysis.

Discussion: While low C3 has been described previously, low C4 along with low C3 has rarely been described in AAV, In a case series of 46 patients with AAV where complement levels were analyzed, only one patient had both low C3 and C4. Here, we report another such a case.

PUB483

Acute Kidney Injury in the Postpartum Period: A Diagnostic Dilemma and Treatment Challenge

Hira Latif,[1] Kavisha B. Patel,[1] Devika Rao,[1] Samuel Mon-Wei Yu,[1] Urvi Ajay Shah,[2] Nikulkumar Chaudhari,[3] Anjali Acharya,[3] Mary King,[4] Marianna Strakhan,[2] Gopichand Pendurti.[2] *[1]Dept of Internal Medicine, Jacobi Medical Center, Bronx, NY; [2]Div of Hematology/Oncology, Jacobi Medical Center, Bronx, NY; [3]Dept of Nephrology, Jacobi Medical Center, Bronx, NY; [4]Dept of Obstetrics-Gynecology, Jacobi Medical Center, Bronx, NY.*

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is a rare disease. Etiology includes infection, drugs, transplant, pregnancy, autoimmune and metabolic disorders. Mutations of complement factor H and I, membrane cofactor protein and CD46 may be seen in some cases.

Case Description: A 23 year old Hispanic female presented 4 days after an elective C-section with nausea and vomiting. Periumbilical tenderness was found on exam. Her hemoglobin dropped from 12 g/dL to 5.7 g/dL and platelets decreased from 359,000 cells/nL to 141,000 cells/nL with a nadir of 58000 cells/nL. Serum creatinine increased from 0.6 mg/dL to 3 mg/dL. LDH and reticulocyte count were high and haptoglobin was low. Hepatic and coagulation profile were normal. Peripheral smear showed schistocytes. Abdominal imaging was unremarkable. Plasmapheresis was started for suspected TTP and she required dialysis for worsening renal function. Plasmapheresis was stopped when ADAMTS13 activity resulted at 75%. Eculizumab was started for probable aHUS. Renal biopsy revealed subacute/chronic thrombotic microangiopathy. Within 2 weeks of treatment, thrombocytopenia resolved and she was off dialysis.

Discussion: In our case, absence of preclampsia or significant transaminitis made HELLP unlikely. The ADAMTS13 level with failure of plasmapheresis made TTP unlikely. Diagnosis of aHUS was substantiated by microangiopathy on biopsy, negative shiga toxin, and improvement in thrombocytopenia and renal function with eculizumab. aHUS accounts for 8–18% of all TMA cases during pregnancy, most occurring postpartum. With complement gene abnormalities the likelihood of recurrence in future pregnancies is higher. aHUS mimics preeclampsia, HELLP and TTP. First episode has a 25% mortality with 50% requiring dialysis. Thus, consideration of early treatment for aHUS is imperative on clinical suspicion alone.

PUB484

Atypical Presentation of Vascular Calcification in a Chronic Haemodialysis Patient

Vishwas Raghunath, Kenneth Yong. *Kidney Care Centre, Prince of Wales Hospital, Sydney, New South Wales, Australia.*

Introduction: Calciphylaxis (calcific uraemic arteriopathy) is a well described entity in patients with end stage kidney disease (ESKD). Though it presents primarily with skin lesions, atypical presentations have been reported. We report a case of calciphylaxis masquerading as giant cell arteritis, causing progressive visual loss in a haemodialysis patient.

Case Description: A 72-year gentleman with ESKD on hospital haemodialysis presented with headache and progressive visual loss in his single right eye. He was on oral anticoagulation for a prosthetic aortic valve and had recently undergone coronary artery bypass surgery, complicated by chronic ulcers at saphenous graft sites. Clinical examination revealed reduced visual acuity. Right eye fundoscopy revealed mild optic disc oedema and cotton wool spots. Investigations revealed an elevated ESR (89ml/hr) and normal calcium phosphate balance. The clinical presentation was suspicious for temporal giant cell arteritis. He received empiric treatment with pulse methyl prednisolone and underwent a temporal artery biopsy which revealed medial arterial calcification with no signs of vasculitis, suggestive of calciphylaxis. His visual loss did not improve and he was given a trial of hyperbaric oxygen therapy to improve retinal blood flow. Further imaging included a CT-angiogram of the brain and neck, which indicated significant calcified bilateral carotid stenosis; an MRI brain showing no acute ischaemia; and a cerebral perfusion scan showing diffuse perfusion abnormality. After a multi-disciplinary meeting, it was determined that his visual loss was irreversible and the benefits of carotid revascularisation were unclear. His dialysis program and medications were optimised to maintain a favourable haemodynamic and biochemical profile, and to retard progressive vascular calcification.

Discussion: This case report illustrates the challenges of managing the atypical presentation of an abstruse condition. There are few cases of calciphylaxis masquerading as giant cell arteritis described in literature. A high degree of suspicion is necessary for early diagnosis of calciphylaxis in a chronic haemodialysis patient on warfarin and assist in appropriate management.

PUB485

Successful PD Catheter Placement in a New ESRD Patient with Combined Antiphospholipid Syndrome and Factor XI Deficiency

Antoney Joseph Ferrey, Roy Fujitani, Minh-Ha Tran, Yongen Chang, Wei Ling Lau. *Univ of California, Irvine, Orange, CA.*

Introduction: Coagulopathies and bleeding disorders impact surgical morbidity and potential dialysis modalities for new ESRD patients. Our patient is a 68 year old female with a history of autoimmune hepatitis, antiphospholipid syndrome (APL), and factor XI deficiency. She is the first reported successful PD catheter placement in a patient with such combined bleeding and clotting disorders.

Case Description: She was diagnosed with APL after a workup for recurrent TIAs and a lacunar CVA, noted to have positive lupus anticoagulant, anticardiolipin, B2-glycoprotein, and antithrombin antibodies. She has a history of recurrent bleeding, for which a detailed evaluation uncovered a factor XI deficiency. Over the last 7 years she has had a gradual decline in eGFR, was referred to Nephrology and found to have nephrotic range proteinuria. A renal biopsy was considered but not done since the risk outweighed potential benefits; in the setting of APL the prolonged PTT could not be corrected despite multiple FFP infusions. When she reached ESRD the decision was made to pursue PD because of multiple risks associated with HD in the setting of her complex hematologic disorders, including bleeding with repetitive needle sticks vs. thrombosis of the AV fistula.

FFP and platelets were administered prior to placement of a temporary HD catheter. Hemodialysis was done before surgery to decrease uremic platelet dysfunction. The following day, additional FFP and platelets were infused followed by successful laparoscopic placement of a peritoneal dialysis catheter. DDAVP was not used due to its (rare) thrombosis side effect, as the patient has history of TIAs/CVA. An additional session of hemodialysis was done before the catheter was removed. Low volume recumbent exchanges were started one week later and her PD prescription has gradually been increased. For two months she has been doing well on PD.

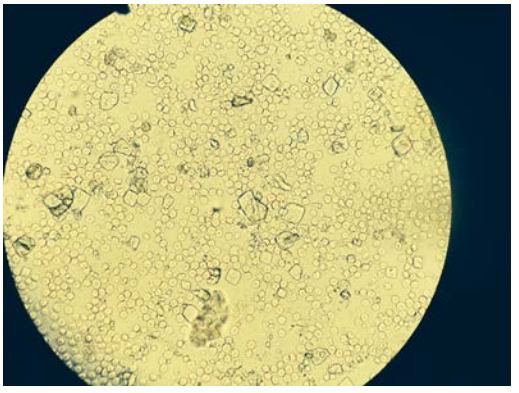
Discussion: To our knowledge, this is the first report of a successful PD catheter placement and initiation of PD in a patient with combined antiphospholipid syndrome and factor XI deficiency. Careful peri-operative planning can avoid adverse thrombotic or bleeding events.

PUB486

Rhabdomyolysis and Acute Uric Acid Nephropathy from Synthetic Bath Salt: (e)Uphoria to Uric Acid Nephropathy Ali Hasssan,[1] Paras Dedhia,[1] Charuhas V. Thakar.[1,2] *[1]Dept of Nephrology and Hypertension, Univ of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VA, Cincinnati, OH.*

Introduction: Bath salts are synthetic cathinone derivatives of plant Catha edulis. "Flakka" is the street name for chemical compound α-Pyrrolidinopentiophenone (α-PVP). It is a stimulant of the monoamine cathinone class.

Case Description: A 37-year-old Caucasian male with no significant past history admitted to medical ICU after found down and unresponsive for unknown duration. He was intubated for airway protection. EMS noted that he was very combative and violent at the time of arrival. Physical examination was remarkable only for sinus tachycardia. Lab data was significant for anion gap metabolic acidosis (AG=15) with venous lactate of 30 mmol/l. Over next 24 hours, lactate decreased to 2.2 mmol/l with IV fluids. Hospital course was complicated by oliguric AKI with rapid worsening of creatinine from 1.1 mg/dl to peak creatinine of 9.9 mg/dl on hospital day7. Urine toxicology screen was negative. Urinalysis showed small blood with 3 RBCs. AKI work up was also significant for rise in creatine phosphokinase from 259 U/L to 11,28,00 U/L over next 24 hours. Uric acid on admission was 16.7 mg/dl and urine sediment showed rhomboid shaped uric acid crystals. His fractional excretion of uric acid was 148 % Due to hyperkalemia and oliguric AKI, he was started on dialysis and required six sessions of dialysis prior to recovery of renal functions. Follow up serum Cr at one month was 0.9 mg/dl. He confirmed injecting "Flakka" prior to hospital admission.



Discussion: Case studies have reported bath salts induced AKI from hemodynamic mediated ATN and rhabdomyolysis. This case highlights possibility of uric acid nephropathy as an additional mechanism.It also underscores importance of examining urinary sediment especially in cases where AKI pathogenesis is not well known.

PUB487

Binge Correction Guilherme Piovezani Ramos,[1] Larissa Kruger Gomes,[2] Kianoush Banaei-Kashani.[3] *[1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Univ of Connecticut, Farmington, CT; [3]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Introduction: Severe hyponatremia (HNa) is associated with high morbidity and mortality, which can be worsened by rapid corrections. Ethanol abuse can lead to HNa through different mechanisms. Identifying the primary process is crucial to correct sodium (Na) appropriately and prevent complications.

Case Description: A 40-year-old male presented with a week history of confusion and frequent falls. He had history of significant alcohol abuse. There were no deficits on neurologic exam. Laboratory evaluation: Na 103mmol/L, creatinine 6.5mg/dL and BUN 89mg/dL – unknown baseline. Urine showed osmolality 230mOsmol/L and Na 50mmol/L. Following admission to the ICU 0.9% NaCl was started with goal of correcting <10mmol/L/24hours. After 12-hours, Na was 115mmol/L and 0.45% NaCl started. Na continued to increase, peaking at 121mmol/L, after 18-hours when all infusions were stopped, and urine output was 12L. On day 3, he developed agitation refractory to alcohol withdrawal protocol. Examination on day 8 showed truncal ataxia, dysarthria and worsening cognition with a MRI-Brain confirming osmotic demyelination syndrome (ODS).

Discussion: Beer Potomania (BP) is an unusual cause of HNa, at high risk of ODS from rapid correction. Beer has minimal electrolytes and carbohydrate load suppresses urea production. As a result, daily solute excretion falls below 250mosmol/L, decreasing the capacity of free water excretion and this, in turn, results in HNa. Re-introduction of solute will lead to brisk diuresis and rapidly correct Na, despite free water replacement. Management of BP should include 1)ICU admission with q2h Na checks; 2)NPO for the first 24 hours with D5W for the caloric intake to promote solute diuresis; 3)intravenous fluids should be limited to symptomatic patients and given on small boluses with goal 2-3meq/L/hrx2-3hours. DDAVP should be utilized to increase free water retention in the case of brisk urination, to avoid rapid Na correction. By reporting an uncommon case of HNa complicated with ODS, we reinforce important aspects of the pathophysiology and Na corrections strategies in BP patients.

PUB488

Key Triggers and Interventions in Renal Cell Carcinoma and Pauci-Immune Crescentic Glomerulonephritis Natalia Plotskaya. *Internal Medicine Residency, Capital Health, Trenton, NJ.*

Introduction: Pauci-immune crescentic glomerulonephritis (PGN) has very high mortality rate and aggressive development. It occurs in association with ANCA positive systemic vasculitis and is recognized to be linked to renal cell carcinoma (RCC).

Case Description: A 59 yo male presented for evaluation of 4 weeks of dizziness, generalized weakness and unsteady gait. He did not have any past medical history and no family history of renal diseases. Physical examination revealed a non-specific unsteady gait. A CT scan discovered a 3.7 cm right renal mass, and after total nephrectomy histology revealed papillary RCC type 2. Non-neoplastic kidney tissue did not have signs of glomerular or tubular disease, nor amyloid deposition. Workup for metastatic disease was negative, however the patient's symptoms did not improve. Three months after nephrectomy, renal function declined and was refractory to intravenous fluids. Another metastatic work up was negative. Laboratory analysis shown proteinuria of 3.79 g/day, creatinine 3.78, BUN 41, ESR 120, CRP 8.7, C -ANCA titer of 1:40. Other serology, including complement levels, anti ds-DNA,ANA,cryoglobulin, anti-CCP antibodies, hepatitis B, C, HIV were all negative. The decision was made to proceed with biopsy of single left kidney as renal function deteriorated. Total of 6 glomeruli were sampled, one was globally sclerotic, 4 of 5 glomeruli were necrotizing with crescenting features. One focus of inflammation was admixed with smooth muscle cells raising the possibility of large vessel vasculitis. High dose steroids and cyclophosphamide was not successful in halting the decline in renal function, and hemodialysis was started.

Discussion: There is increasing evidence that RCC and ANCA associated PGN demonstrate a common underlying immunologic mechanisms of glomerular injury which are regulated by the podocytes Von Hippel Lindau gene. Our patient had severe systemic symptoms that did not improve after nephrectomy, suggesting that another process was active, however review of the surgical specimen confirmed no evidence of PGN at that time. Early ANCA screening could be beneficial in newly diagnosed RCC and further investigation of the role of chemokine specific therapy is warranted.

PUB489

Recurrence of ANCA Negative Pauci-Immune Crescentic Glomerulonephritis Post Kidney Transplantation Pradeep Vaitla,[1] Alton Brad Farris.[2] *[1]Transplant Nephrology, Emory Univ; [2]Renal Pathology, Emory Univ.*

Introduction: Pauci-immune glomerulonephritis is a relatively common cause of rapidly progressive renal failure. Frequency of ANCA negative pauci-immune glomerulonephritis is reported to be 20-30%. Recurrence of pauci immune glomerulonephritis is reported to be about 10-15% post kidney transplantation. However the recurrence of ANCA negative pauci immune glomerulonephritis post kidney transplantation is rarely reported. Very few case reports are available in the published literature.

Case Description: 49 year old caucasian female with no known medical problems presented with acute kidney failure in 2014. She was diagnosed with severe crescentic glomerulonephritis secondary to ANCA negative pauci-immune glomerulonephritis. She was treated with total plasma exchange and Rituximab but progressed to end stage renal failure. She received a living related renal transplantation in July 2015. Immunosuppression protocol: Basiliximab induction followed by maintenance with belatacept, tacrolimus, mycophenolate mofetil and prednisone. Per our institution protocol, tacrolimus was tapered off at 9 months post transplantation. After the taper of tacrolimus, she developed acute kidney injury with non nephrotic range proteinuria and microscopic hematuria. Kidney biopsy revealed severe crescentic glomerulonephritis. Immunofluorescence was negative, electron microscopy revealed no immune complex deposits or basement membrane thickening. Serology was negative for anti nuclear cytoplasmic antibody and anti glomerular basement antibody. She was started on high dose steroids and intravenous cyclophosphamide, response to treatment needs to be followed. Since no detectable circulating antibody was present, total plasma exchange was thought to be not helpful in this scenario.

Discussion: Recurrence of ANCA negative pauci-immune glomerulonephritis is rare. Reported data suggests, ANCA negative pauci-immune glomerulonephritis in native kidneys have poor renal prognosis and patients have less extra renal manifestations. It is important to consider recurrence as a possible etiology as the course of the disease is often rapid.

PUB490

Simultaneous Serious Infection of *Trichosporon asahii* and Multi Drug Resistant *Pseudomonas aeruginosa* in Kidney Transplant Patient Takamasa Miyauchi, Sawako Kobayashi, Hiroyuki Yamamoto, Takuya Fujimaru, Fumika Taki, Masahiko Nagahama, Yasuhiro Komatsu. *Nephrology, St. Luke's International Hospital, Chuo-ku akashi-cho, Tokyo-to, Japan.*

Introduction: *Trichosporon* species are increasingly recognized as a cause of systemic illness in immunocompromised patients. However such infection in kidney transplant patient is rare. We report a life-threating case of simultaneous infection of *Trichosporon asahii* and multi drug resistant pseudomonas aeruginosa (MDRP) in kidney transplant recipient.

Case Description: A 83-year-old Israeli male with ESKD due to ADPKD who received cadaveric kidney transplant six years ago, was admitted for a few days history of fever and right knee pain. His vital signs were a max body temperature of 40°C, heart rate(HR) 90 bpm, blood pressure(BP) 130/73 mmHg, and a pulse oximetry of 98% on room air. On physical exam, his right knee was erythematous and swollen with marked limitation of both active and passive ranges of motion. Blood and synovial fluid were sent for culture, and piperacillin/tazobactam was started empirically. Blood culture grew *trichosporon asahii*,

and synovial fluid grew multi drug resistant pseudomonas aeruginosa (MDRP). Therefore, antibiotics was switched to meropenem and aztreonam, and voriconazole was added. Ocular involvement was not detected. Since he had simultaneous serious infection of *trichosporon asahii* and MDRP, immunosuppressants, cyclosporine and mycophenolate mofetil were discontinued, and left prednisone alone. His medical course was complicated with C.difficile infection, but 6-week course of antibiotics were completed and he was fully recovered.

Discussion: ***Although*** *Trichosporon* infection is increasingly recognized as a cause of systemic illness in immunocompromised patients. Most cases are observed among hematologic malignancies while few cases are reported among transplant recipients. This case was successfully treated with triple antibiotics and discontinuation of immunosuppressants.

PUB491

HIV Associated Immune Complex Disease of the Kidney Rawan T. Al-Odat, Saeed Kamran Shaffi. *Nephrology, Univ of New Mexico, Albuquerque, NM.*

Introduction: HIV associated nephropathy (HIVAN) with histological features of focal segmental glomerulosclerosis (FSGS) has been well described in literature. However, in the era of highly effective anti-retroviral therapy (HAART), HIV immune complex disease of the kidney (HIVICK) is increasingly being recognized.

Case Description: A 43 years old male presented with malaise, fever, chills, night sweats and progressive swelling of the extremities. Physical examination was remarkable for a blood pressure of 170/100 mm/Hg, puffiness of face and trace edema of the upper and lower extremities. Pertinent diagnostic data are shown in Figure 1. Kidney biopsy showed collapsing FSGS as well as immune complex-mediated glomerulonephritis with a focal proliferative pattern of glomerular injury. He was started on HAART and losartan with improvement in kidney function.

Figure 1: Laboratory data

Variable	Results
Na (mmol/L)	134
HCO_3(mmol/L)	15
BUN (mg/dL)	90
Cr (mg/dL)	Admission 7.8 Baseline 1.0
Albumin (g/dL)	2.2
Complement (mg/dL)	Normal C3 and C4
ANA	1:80
Anti Double Stranded DNA	80 (Borderline)
SPEP	Normal
UPEP	Normal
Urine analysis	+3 protein, +2 blood
Urine microscopy	Fatty cast with few dysmorphic RBCs
UPCR (g/g)	7
HIV RNA PCR (copies/ml)	5789
CD4 count	109
Hepatitis panel	Non reactive
Renal U/S	Normal sized kidneys

Discussion: HIV can affect the kidneys in various ways. HIVAN – a condition which was identified in the pre-HAART era – is caused by direct viral infection of the podocytes resulting in collapsing FSGS. In HARRT naive patients, immune complex mediated proliferative pattern of injury is increasingly being recognized with membranous, membranoproliferative and IgA nephropathy phenotypes seen on kidney biopsy. HIVICK lesions are caused by an immune response to HIV antigens and thus require presence of HIV viremia. HIVICK is less likely to progress to end stage renal disease (ESRD) than HIVAN. HAART therapy dramatically improves outcomes of HIV associated renal disease irrespective of histological features.

PUB492

Alport Syndrome with Right-Hand Preaxial Polydactyly in Two Siblings Yuko Fujii,[1,2] Akira Ashida,[1] Hideki Matsumura,[1] Akihiko Shirasu,[1] Satoshi Yamazaki,[1] Hyogo Nakakura,[1] Kandai Nozu,[3] Kazumoto Iijima,[3] Motoshi Hattori,[4] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Osaka, Japan; [2]Internal Medicine, Kanzaki Municipal General Hospital, Hyogo, Japan; [3]Pediatrics, Kobe Univ Graduate School of Medicine, Hyogo, Japan; [4]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Introduction: Alport syndrome is one of the familial hereditary hemorrhagic nephritides leading to end-stage kidney disease. The genes responsible are *COL4A3, COL4A4* and *COL4A5*, which encode the α3, α4, α5 chains of collagen type IV, involved with the glomerular basement membrane. Polydactyly is characterized by supernumerary fingers or toes. Its etiology is not so apparent, but has been explained in terms of heredity, environmental factors, and other influences. Here we present the first report of two siblings with Alport syndrome and polydactyly.

Case Description: The patients were two siblings (a boy and a girl) with Alport syndrome. Their mother had also been diagnosed as having Alport syndrome, and the patients' grandmother and granduncle had requiring dialysis. Both the patients and their mother had hematuria, but had not developed any vision or hearing problems. Genetic analysis of the patients and their mother revealed a missense mutation (c.2822G>A) that can cause a change in the spatial structure of COL4A5. Therefore they were diagnosed as having X-linked Alport syndrome. Furthermore, although absent in other family members, the patients also had congenital preaxial polydactyly of the right hand. The polydactyly was not part of an anomaly syndrome, and no mental retardation was evident.

Discussion: To our knowledge there has been no previous report of patients with polydactyly in Alport syndrome. The present cases of polydactyly cannot be simply explained in terms of Mendel's law on the basis of the phenotypes. Some previous reports have indicated that preaxial polydactyly follows an autosomal dominant model, but this did not seem to be so in the present cases. Therefore, we intend to perform whole-genome sequencing to analyze the gene mutations in these patients. We believe that these two present cases will be useful for clarifying the pathogenesis of polydactyly associated with Alport syndrome.

PUB493

Childlike Spots in an Older Man: A Case of Malignancy-Associated Adult Henoch-Schonlein Purpura with Severe Multi-Organ Involvement Ana Claudia Onuchic,[1,2] Vivek Alaigh,[1,2] Catherine A. Zanoria,[1,2] Tanya L. Belle,[1,2] Sankar Narayan Niranjan,[2] Prashant Grover.[2] *[1]Univ of Connecticut, Farmington, CT; [2]St. Francis Hospital, Hartford, CT.*

Introduction: Henoch-Schönlein purpura (HSP) is a systemic small-vessel vasculitis associated with deposition of IgA immune complexes, typically manifested in childhood. Rare cases are described in adults, often more severe and disseminated, with malignancy as a predisposing factor.

Case Description: A 68 y/o male recently diagnosed with bladder cancer presented with a two-day history of abdominal pain, vomiting and back pain, associated with a persistent dark red rash of lower extremities and torso a few weeks prior. Outpatient skin biopsy had shown leukocytoclastic vasculitis but the rash recurred despite prednisone course. Initial inpatient workup showed acute kidney injury with serum creatinine (S_{Cr}) of 2.3mg/dL and urinalysis with leukocyturia, hematuria, 3+ protein and hyaline and white blood cell casts. Abdominal CT consistent with inflammation in the terminal ileum prompted exploratory laparotomy, revealing terminal ileum erythema/inflammation suggestive of vasculitis. Respiratory and renal deterioration, to S_{Cr} of 8.6mg/dL, required intubation and hemodialysis. Methylprednisolone 20mg IV q12hrs was started for presumed HSP. Skin biopsy was repeated to avoid the risk of renal biopsy, confirming leukocytoclastic vasculitis and IgA deposition by immunofluorescence. Serum IgA was high at 485mg/dL. New onset atrial flutter with episodes of wide complex tachycardia required prophylactic anticoagulation, complicated by intestinal bleed. Abdominal CTA showed contrast extravasation in the ileum, requiring embolization. Pulse-dose methylprednisolone and intravenous immunoglobulin were given; bleeding improved, but not renal function. Despite cardioversion and anti-arrhythmic agents, arrhythmia proved intractable and he expired.

Discussion: We present a case of adult HSP with renal, gastrointestinal, skin and likely cardiac involvement. This is one of few descriptions of HSP associated with bladder cancer in the literature. HSP is a rare but important cause of rapidly progressive glomerulonephritis and should be considered, especially in the setting of malignancy.

PUB494

Cutaneous Marginal Zone B-Cell Lymphoma in a Renal Transplant Recipient Yan Song, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hosptial, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Introduction: A 57-year-old Chinese female was presented with multiple cutaneous nodules and ulcers on the trunk and extremities for 1 month. The lesions first appeared as nodules and subsequently progressed to ulcer. The patient had no fever and fatigue. She had received a kidney from a living donor 11-year prior because of renal failure secondary to hypertension. The patient was maintained on oral prednisone (2.5 mg daily), mycophenolate mofetil (500mg daily), and cyclosporine (100mg daily) to anti-rejection. He had no history of previous opportunistic infections, including Epstein-Barr virus infection. On physical examination, her vital signs were normal. Cutaneous nodules and ulcerations were found on the legs and back.

Laboratory test results revealed a white blood cell count of 4.3* 109/L. Her serum creatinine was 387umol/L. A skin sample obtained from a nodule on the leg showed atypical lymphocytes infiltration. Immunohistochemistry revealed the atypical lymphoid cells were diffuse positive for CD20, CD79a, Bcl-2, and EBER. CD10, Bcl-6 and T cell markers were negative. No evidence of systemic involvement was found for the patient. A diagnosis of cutaneous marginal zone B-cell lymphoma was made. Her anti-rejection drug cyclosporine was changed to everolimus. After four months, the cutaneous nodules disappeared. Post-transplant lymphoproliferative disorders are a group of heterogeneous lymphoid complications, which range from indolent polyclonal proliferations to aggressive lymphomas. Generally, it is considered to be a consequence of intensive immunosuppressive drugs administered following solid organ or hematopoietic transplantation. The overall incidence of post-transplant lymphoproliferative disorders in adult kidney transplantation recipients was 1 - 3% worldwide. Treatment of post-transplant lymphoproliferative disorders includes immunosuppression reduction, chemotherapy, radiotherapy, and surgery.

PUB495

Recurrent Malignant Hypertension in Lupus Nephritis Bogdan Marian Sorohan, Andreea Gamala, Andreea Andronesi, Marina Felicia Paraschiv, Roxana Adriana Jurubita, Bogdan Obrisca, Nicu Caceaune, Gener Ismail. *Nephrology and Internal Medicine, Carol Davila Univ of Medicine and Farmacy, Bucharest, Romania.*

Introduction: Systemic Lupus Erythematous (SLE) is a chronic autoimmune disease that frequently leads to kidney involvement. Hypertension in lupus nephritis (LN) is common, but malignant hypertension (MH) is a rare condition. MH in LN is associated with severe clinical manifestations and intrarenal vascular lesions, chronic inflammation being considered the central pathway.

Case Description: A 19-year-old woman with a history of SLE, class VI LN and MH presented with sudden drop in general status, confusion, diplopia, bradypsychia, bradilalia. Physical exam found cold extremities, cyanosis, high BP (260/100 mmHg) and tachycardia. Neurological exam showed impairment of the cerebelum, left central facial palsy and left sided hemiparesis. Lab work thrombocytopenia(105.000/mm3), hyperuricemia (11.2 mg/dl), hypoalbuminemia (2.8 g/dl) and an eGFR of 66.1 ml/min/1.73m^2. A cerebral CT showed no hemorrhagic lesions, but a diffuse hypodense edematous area in the pons, midbrain and bilateral thalamic nuclei. She was started on antihypertensives, Dexamethasone and Mannitol. After 5 days in ICU for neurological degradation (GSC=8), a brain MRA was performed and showed petechial hemorrhage and signal abnormalities suggestive for swelling lesions in deep thalamic regions, left internal capsule, pons, and midbrain. Nimodipine was added to the regimen. A work-up for JC virus and Listeria monocytogenes was negative.Evolution was favorable with complete remission of neurological symptoms. Repeated brain MRA confirmed regression of swelling and haemorrhagic lesions.

Discussion: This case describes the evolution of a young woman with lupus and recurrent MH, complicated with neurological manifestations.The diagnosis of hypertensive encephalopathy was sustained by improved clinical evolution under anti-edema measures, antihypertensives and by CT/MRI imaging. Differential diagnosis was made with central nervous system vasculitis and infections due to immunosuppressiontheraphy (tuberculosis, HIV, JC virus). MH is an important cause of neurological manifestations in SLE with LN, other than cerebral vasculitis and infections.

PUB496

Orlistat Induced Oxalate Nephropathy Leanne A. Ogden, Laurence R. Solomon, Beena Nair. *Renal Dept, Royal Preston Hospital, Preston, Lancashire, United Kingdom.*

Introduction: Orlistat is used for obesity when dietary and lifestyle changes are unsuccessful. It forms covalent bonds and inactivates gastrointestinal lipases. There are reports of kidney injury due to oxalate nephropathy. We describe 3 cases of Orlistat-induced oxalate nephropathy.

Case Description: 1:A 65-year old man was assessed for CKD. He had been prescribed Orlistat for ten months. Serum creatinine was 423 (106µmol/l a year earlier). Urinalysis showed +1 blood. Urinary oxalate-creatinine ratio was 160µmol/mmol (normal<33). Renal biopsy showed chronic interstitial inflammation with patchy fibrosis and tubular atrophy. Several tubules contained oxalate crystals. Serum creatinine fell to 316µmol/l and oxalate:creatinine ratio to 26µmol/mmol after stopping Orlistat. **2:**A 65-year old woman was prescribed Orlistat intermittently for 7 years. BMI was 36. Urinalysis was benign. Serum creatinine was 284µmol/l (normal 2 years earlier) and UACR<2 mg/mmol. Renal biopsy showed mild tubular atrophy, focal acute tubular necrosis and mild interstitial fibrosis. Many tubules contained oxalate crystals. Serum creatinine fell to 191µmol/l following cessation of Orlistat. **3:**A 74 year old man presented with AKI following a fall and required dialysis. He had pre-existing CKD (creatinine 150µmol/l). Orlistat was first prescribed in 2008 and intermittently until 2015. Renal function was slow to recover so biopsy was performed. This showed diabetic nephropathy and oxalate crystals in tubules. After two months he recovered independent kidney function with a creatinine of 383µmol/l.

Discussion: These cases demonstrate that Orlistat may cause kidney failure, which can be insidious. Two patients had no specific symptom. Urinalysis was benign. Cessation of Orlistat was followed by stabilisation or improvement of kidney function, but recovery was incomplete. Diagnosis required renal biopsy. Patients prescribed Orlistat are often at risk of kidney failure for other reasons such as pre-existing CKD, diabetes, hypertension and obesity. Many nephrologists do not biopsy such patients, the diagnosis is easily missed. Close monitoring of kidney function in patients taking Orlistat is warranted. Availability off-prescription should be reviewed.

PUB497

Successful Treatment with Rituximab for Refractory Steroid-Dependent Nephrotic Syndrome Complicated by Immune Thrombocytopenic Purpura: A Case Report Akihiko Shirasu,[1] Akira Ashida,[2] Hideki Matsumura,[2] Hyogo Nakakura,[2] Satoshi Yamazaki,[2] Yuko Fujii,[2] Motoshi Hattori,[3] Hiroshi Tamai.[2] *[1]Pediatrics, Hirakata City Hospital, Osaka, Japan; [2]Pediatrics, Osaka Medical College, Osaka, Japan; [3]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Introduction: Rituximab is a chimeric anti-CD20 monoclonal antibody that inhibits CD20-mediated B-cell proliferation and differentiation. The use of rituximab for patients with refractory nephrotic syndrome (NS) was approved in Japan in 2014. Rituximab has also administered to patients with immune thrombocytopenic purpura (ITP) if there has no response to first-line therapy. Here, we report a case of refractory steroid-dependent NS complicated by ITP, which was treated successfully with rituximab.

Case Description: The patient was a 14-year-old boy with steroid-dependent NS complicated by severe and frequently relapsing ITP. He had developed NS at the age of 7 years. Histopathological examination by light microscopy showed minor glomerular abnormalities. Although immunofluorescence staining revealed granular IgG deposits along the capillary walls, electron microscopy demonstrated no electron-dense deposits. On the basis of these findings, we diagnosed him as having minimal-change NS, and he responded to a standard glucocorticoid regimen. However, 9 months after onset of NS, he developed ITP, and was treated with glucocorticoid and intravenous immunoglobulin. Although he achieved a temporary response, he was unable to attain permanent remission, and at the age of 9 years suffered a first relapse of NS. As relapses occurred thereafter, we tried additional immunosuppressive agents including cyclosporine and cyclophosphamide, but multiple relapses of both NS and ITP persisted. As he was still steroid-dependent for both NS and ITP at the age of 13 years, we administered rituximab once weekly for 4 weeks. Six months after the rituximab therapy,he has remained in remission of both ITP and NS and the dose of glucocorticoid have been reduced.

Discussion: Although this is a single case report based on short-term observation, we believe that rituximab therapy can be useful option for refractory NS and ITP, especially in adolescent patients who need to avoid the adverse effects of glucocorticoid.

PUB498

Kidney Transplantations with Both Recipients of Kidneys from the Same Deceased Donor with Diabetic Nephropathy Daigo Okada,[1] Masayoshi Okumi,[1] Kohei Unagami,[3] Ken-Ichiro Miura,[2] Hideki Ishida,[1] Motoshi Hattori,[2] Kazunari Tanabe.[1] *[1]Urology, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Introduction: Few reports have been published on the transition of kidney function in kidney transplantation from a donor with diabetic nephropathy. To our knowledge, kidney transplantations with both recipients of kidneys from the same deceased donor with diabetic nephropathy have not been reported yet. We report the cases of two recipients of kidneys from an identical deceased donor who had diabetes. One recipient is a 58-year-old man, and the other is a 15-year-old girl. Both recipients received a kidney transplant from a 60-year-old woman with diabetes. A 0-hour biopsy revealed diabetic nephropathy with nodular sclerosis and polar vasculosis. The former recipient had a serum creatinine (S-Cr) level of 2.1–2.4 mg/dL. The results of the kidney biopsies performed 4 and 14 months after kidney transplantation showed no change as compared with the 0-hour biopsy result. The latter recipient had a S-Cr level of 1.6–1.8 mg/dL and proteinuria at discharge. Her S-Cr level increased gradually to 3.4 mg/dL at 7 months after kidney transplantation. Therefore, we performed an episode biopsy. Histological examination revealed an increment of tubular atrophy and fibrosis of cortical stroma due to diabetic nephropathy. We found no evidence of rejection and recurrence of focal glomerular sclerosis. This report suggests that graft function with diabetic nephropathy might worsen in spite of good glycemic control.

PUB499

Imatinib-Associated Acute Tubular Necrosis Nupur N. Uppal,[1] Valerie Suzanne Barta,[1] Rimda Wanchoo,[1] James M. Pullman,[2] Anna T. Levy,[3] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra Northwell School of Medicine; [2]Pathology, Montefiore Medical Center; [3]Hematology/Oncology, Hofstra Northwell School of Medicine.*

Introduction: Imatinib(Gleevac) is an antineoplastic agent that acts by inhibiting tyrosine kinase enzyme and has been widely used for the treatment of various cancers. Acute kidney injury (AKI) is a rare adverse event of imatinib treatment. We report a case of biopsy proven acute tubular necrosis(ATN) with imatinib treatment.

Case Description: A 76-year-old female with history of hypertension, gastrointestinal stromal tumor (GIST) was initiated on imatinib after surgical resection for adjuvant therapy. A week later, serum creatinine (Scr) increased to 1.6mg/dl(baseline 1.03mg/dl). Patient denied use of any known nephrotoxic agents. There were no clinical or lab findings suggestive for prerenal AKI. Urinalysis revealed 100 milligrams of protein but no hematuria. AKI was thought to be related to imatinib treatment. Hence, dose of imatinib was reduced by 50%. Scr decreased to 1.3mg/dl six days after dose reduction. However, mutational analysis conferred imatinib resistance requiring resumption of previous higher dose of imatinib. Scr increased to 1.7mg/dl a week after increase in imatinib dose. A kidney biopsy was performed that confirmed toxic ATN with vacuolization with minimal interstitial fibrosis and tubular atrophy likely related to imatinib treatment. Patient was continued on imatinib therapy due to lack of availability of alternate chemotherapy with close monitoring of renal function. 3 months out, the Scr stabilized at 1.6mg/dl and the patient is disease free.

Discussion: This case describes fourth reported association of imatinib treatment with AKI. Out of three prior reported cases, two had ATN and one had tubular vacuolization on kidney biopsy. The injury appears to be dose related but only in the initial phase of the treatment. Although risk of nephrotoxicity is small with imatinib treatment, physicians should be aware of this potential adverse effect of this agent and renal function should be closely monitored during imatinib therapy.

PUB500

Recurrent Leg Cramps: An Unsuspected Presentation of Acute Arterial Thrombosis Leading to Amputation in a Child with Nephrotic Syndrome Amirtha Chinnadurai, Olivera Marsenic Couloures. *Pediatric Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Introduction: Although Nephrotic Syndrome(NS) is known to cause hypercoagulability, thromboembolic complication is uncommon, with serious limb-threatening peripheral arterial thrombosis being extremely rare. We report a case of a child with leg cramps, progressing to cold pulseless right leg and amputation of the toes in his first relapse of Nephrotic syndrome.

Case Description: An 8-year-old African American boy with a new diagnosis of Nephrotic syndrome developed a relapse during the steroid wean. Over the next week, he presented twice to the ED with intermittent right leg cramps. Evaluation was unrevealing and he was discharged home after both visits. Subsequently, he developed intense right leg pain and limping. Physical examination revealed a cold, pale right lower leg with absent popliteal and dorsalis pedis pulses. US Doppler of the leg revealed a complete occlusion of the peroneal, anterior and posterior tibial arteries. Emergent surgical thrombectomy was

unsuccessful, thus catheter directed thrombolysis, systemic heparinization and antithrombin III (ATIII) infusion were initiated. Interval thombectomy was then performed together with a fasciotomy for compartment syndrome. The distal perfusion improved, despite this, all 5 digits of the right foot became gangrenous necessitating amputation. Investigation into the etiology of his thrombosis revealed low ATIII levels but normal levels of factors II, VII, IX, X and XIII. Genetic analysis for Prothrombin gene mutation, Plasminogen Activator Inhibitor Type I and Factor V Leiden mutation were negative. Complement levels were normal. Anti-DsDNA, ANCA and antiphospholipid antibodies were negative. Diagnosis of Focal Segmental Glomerulosclerosis (FSGS) was made by renal biopsy. After 7 weeks of hospitalization, the patient was able to ambulate with assistance and was discharged home.

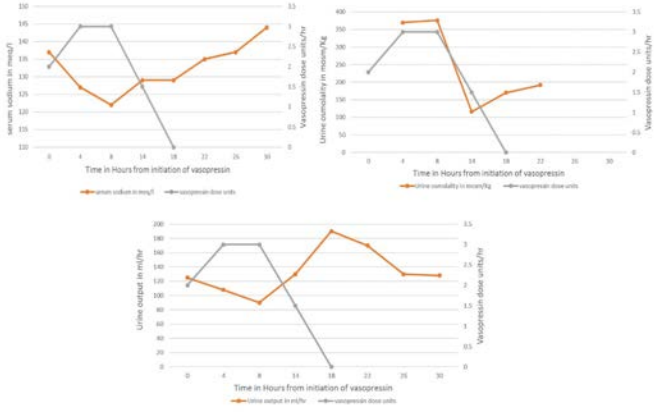
Discussion: Severe arterial thrombosis in our patient occurred during the relapse of NS (FSGS), without evidence of thrombophilia due to other primary or secondary cause. This case demonstrates a need for a high index of suspicion for arterial thromboembolic complications in Childhood Nephrotic syndrome.

PUB501

Pressor-Induced Hyponatremia Pradeep Chaganti, George C. Bonifant, Karim El Hachem, Steven D. Smith, Germaine Z. Chan, Anip Bansal. *Nephrology, Mount sinai St. Luke's and Mount Sinai West Hospital, New York, NY.*

Introduction: Vasopressin has vasoconstrictive effects through smooth muscle V1 receptors and also has antidiuretic activity via renal V2 receptors. Although rare, exogenous vasopressin administration in doses used for management of shock can be responsible for significant hyponatremia.

Case Description: A 39-year-old man with past medical history of Crohn's disease, ankylosing spondylitis, lung fibrosis and schizoaffective disorder was admitted for cavitary pneumonia with sputum positive for tuberculosis. Over the next few days he developed acute respiratory failure with septic shock requiring mechanical ventilation septic and vasopressor support with norepinephrine and vasopressin. His lab data on admission and prior to above decompensation revealed normal serum sodium and creatinine levels. Within hours of starting the vasopressin infusion, he developed significant hyponatremia with a nadir of 120 mEq/L. The patient was also started on IV Bactrim in D5W two days prior to this event for empiric Pneumocystis pneumonia treatment. He had normal cortisol and TSH levels. On switching vasopressin to another pressor, the serum sodium increased rapidly from 122 mEq/L to 135 mEq/L along with a relative increase in urine output and decrease in urine osmolality (see graphs below). Dextrose infusion was started to prevent overly rapid correction.



Discussion: Vasopressin does not usually result in hyponatremia when used in the management of shock. Possible explanations include lack of renal responsiveness secondary to renal hypoperfusion in setting of acute kidney injury, or lack of intake of hypotonic fluids. This rare side effect can happen due to concurrent factors like vasopressin support for shock, endotoxin induced vasopressin release in early septic shock, or relative cortisol deficiency in the setting of hypotonic solution administration.

PUB502

Post-Infectious Atypical Hemolytic Uremic Syndrome in an Adult Presenting without Schistocytes on Peripheral Blood Smear Dianne Victoria Vieja. *Internal Medicine, Section of Nephrology, Philippine General Hospital, Manila, Philippines.*

Introduction: Hemolytic Uremic Syndrome refers to the triad of hemolytic anemia, uremia and acute renal failure. Its hallmark feature is microangiopathic hemolytic anemia. However, there are patients who present with hemolysis and uremia that do not fit the typical criteria of HUS. These patients may be overlooked and hence important disease-modifying therapeutic intervention missed.

Case Description: A 38 year old man with presented with a 2 day history of watery diarrhea. On workup, he was had leucocytosis, hypokalemia, azotemia, hyperbilirubinemia, metabolic acidosis and high LDH. Proteinuria and hematuria were also noted. Stool, urine and blood cultures were negative. Antibiotics and electrolyte correction were started. Over the next days, patient remained oliguric and subsequent exam revealed anemia, thrombocytopenia and worsening azotemia. Further testing showed elevated reticulocyte count, negative Coomb's test but no schistocytes on peripheral blood smear. Renal replacement therapy was done and patient eventually discharged improved.

Discussion: HUS is a Thrombotic Microangiopathies resulting from an infection affecting children and elderly. It is due to Shigella or E.Coli with incidence rate of 90%. However, some cases are due to infections by viruses. Diagnosis rests on evidence of mechanical, non-immune hemolytic anemia (schistocytes), high LDH and renal injury. Clinical presentation may be mild and some may not present typically. Serres and Isenring in 2009 performed a retrospective study which showed that up to 44% of patients with biopsy-proven Thrombotic Microangiopathy HUS had normal platelet counts and no schistocytes. This is due to low level of hemolysis at the time of examination, as seen by the only mild thrombocytopenia in the patient. This case report emphasizes that HUS may be considered in the absence of the usual bacterial growth and also in the absence of schistocytes, both of which are textbook definitions of HUS.

PUB503

A Rare Case of Sweet Syndrome in Azathioprine Treated ANCA Vasculitis Mohamed Elsayed,[1,2] Ahmed Alghali,[1,2] Alaa M. Ali,[1,2] Arunkumar Aruna Udayakumar,[1,2] Muhammad Umair Sharif,[1,2] Austin G. Stack.[1,2,3] *[1]Nephrology Dept, Univ Hospital Limerick; [2]Graduate Entry Medical School, Univ of Limerick; [3]Health Research Inst, Univ of Limerick, Ireland.*

Introduction: ANCA associated vasculitis is frequently encountered in renal practice with immunosuppression being the main stay of management. Azathioprine (AZA) is commonly used and relatively safe for maintaining remission. AZA induced Sweet syndrome is a rare complication that was first reported in 2003.

Case Description: We describe a case of a 53-year-old male with MPO-ANCA vasculitis treated initially with pulse steroid therapy and rituximab achieving clinical remission although his MPO titre remained elevated. Azathioprine was commenced for maintenance therapy. Two weeks later, he presented with an acute onset of a generalized painful rash over the trunk and limbs. This was associated with fever and non-specific constitutional symptoms. Examination revealed conjunctivitis & painful erythematous papules/plaques.

Laboratory results showed 12.8x10^9/l leukocytosis with 87% neutrophilia , CRP of 237 mg/l , ESR of 60mm/hr and stable renal function with benign sediment. Infectious work up was negative. A skin biopsy showed acute neutrophillic dermatosis with no evidence of vasculitis confirming a diagnosis of Sweet syndrome. Work-up for occult malignancy was negative. A diagnosis of azathioprine-induced sweet syndrome was made based on temporality. Almost complete resolution was achieved with AZA discontinuation and a short pulse of oral steroids and colchicine therapy.

Discussion: Immunosuppressive therapy requires good surveillance for side effects and complications. Although rare, it is prudent to consider AZA induced sweet syndrome in patients presenting with fever and rash within weeks of initiating therapy after excluding infections, malignancy and acute vasculitis flare.

PUB504

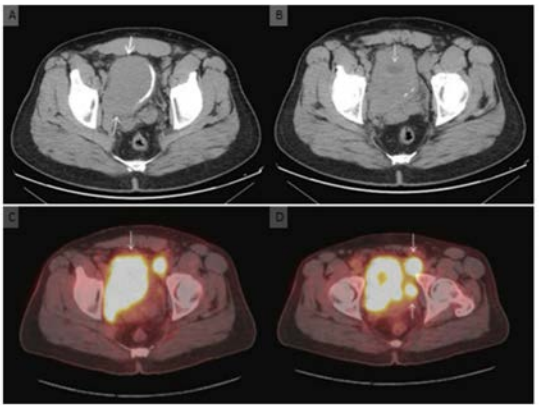
Pheochromocytoma(Paraganglioma) of the Urinary Bladder Causing Secondary Uncontrolled Hypertension Eyerusalem Engida Bayssa,[1,2] Amina Khan.[1,2] *[1]Nephrology, Kansas Univ Medical Center, Kansas City, KS; [2]Nephrology, Kansas City VA, Kansas City, KS.*

Introduction: Secondary hypertension due to a catecholamine secreting paraganglioma is extremely rare.

Case Description: A 56 year-old AAM presented with urinary urgency, frequency, dribbling and lower abdominal discomfort. Blood pressure was 162/110 mmHg on lisinopril 40mg, hydrochlorothiazide 25 mg daily and carvedilol 25 mg twice daily. Abdominal CT showed 9.4 X 6.9 cm right posterior bladder wall mass and enlarged bilateral pelvic lymph nodes. Urinalysis was significant for 11-15 RBCs/hpf. Pathology revealed paraganglioma. Free plasma metanephrine levels were elevated, 14690 pg/ml (normal <= 205). PET scan showed possible extension to the prostate and right lateral pelvic wall and left deep inguinal nodal enlargement. Radical cystoprostatectomy, bilateral lymph node dissection and urinary diversion by ileal conduit was done. Post op BP controlled with Propranolol 20mg every 6 hours, phenoxybenzamine 30mg TID, lisinopril 40mg, amlodipine 5mg

and hydrochlorothiazide 25mg daily. Intraoperative findings showed a bulky tumor that was unrespectable and large grossly positive lymph node. Oncology recommend radiation therapy in 3-4 weeks.

CT showing 9.4 x 6.9 cm right posterior lateral bladder mass(A). Necrotic center of bladder mass(B). PET showing intensely hypermetabolic bladder mass(C). Markedly enlarged left deep inguinal lymph nodes(D).



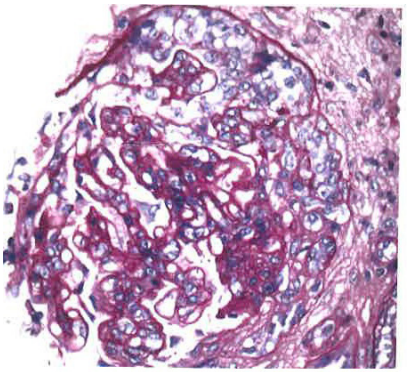
Discussion: Pheochromocytoma is a rare tumor occurs in less than 0.2% of patients with hypertension (1). One-third to one-half of extra adrenal pheochromocytoma associated with an inherited syndromes including MEN II, Neurofibromatosis type I, VHL and Carney-strataskis dyad(2). Plasma free metanephrine still the best biochemical test(3) . MRI and CT scan are useful to localize tumor. Perioperative preparation includes 3-4 weeks of α-adrenoreceptor blocked. Irradiation can be used for metastatic lesions. Chemotherapy plays a role in patients who exhibit symptoms from surgically inaccessible metastases tumors that cannot be controlled by α- and β-blocked.

PUB505

Acute Kidney Injury, Seizures and Thrombocytopenia in a Young Patient with Lupus Nephritis Hector Alvarado Verduzco,[1] Anjali Acharya.[2] *[1]Medicine, Jacobi Medical Center, Bronx, NY; [2]Nephrology, Jacobi Medical Center, Bronx, NY.*

Introduction: Posterior reversible encephalopathy syndrome (PRES) is a complex clinico-radiologic syndrome of varied etiologies, with neurological findings mainly suggestive of the posterior white matter involvement that frequently is reversible. Prompt recognition and treatment of underlying etiology is crucial.

Case Description: A 22 year-old patient with Systemic Lupus Erythematous (SLE) complicated with chronic kidney disease secondary to lupus nephritis class IV, presented with recurrent seizures and uncontrolled hypertension. She had acute kidney injury and thrombocytopenia. Repeat biopsy showed diffuse endocapillary and extracapillary proliferative with crescent (Figure 1) and membranous lupus nephritis (ISN-RPS class IV-G+V), new changes with endothelial swelling secondary to severe hypertension; but no thrombotic microangiopathy. Brain imaging showed left frontal and parietal infarct with improvement of lesions and symptoms after controlling blood pressure (BP), making PRES the diagnosis. She had recurrent episodes of seizures with brain edema on imaging.



Discussion: PRES is thought to be associated with disordered cerebral auto-regulation and endothelial dysfunction. Most cases present with systolic BP over 200 mm Hg or at least a 35% increase from baseline. Our case presents several unusual scenarios as described below. The most common abnormalities on MRI are punctuate or confluent areas of increased signal on T2-weighted images in the posterior fossa but in this patient, the MRI changes were in the frontal and parietal regions. Patient had recurrent seizures, which is unusual in PRES. Diagnosis can pose a challenge, as in our patient, when associated with SLE, as it can be confused with lupus vasculitis. In addition, treatment with cytotoxic agents if required can be an additional problem as these agents can contribute to PRES.

PUB506

Recurrent C3 Glomerulonephritis Treated with Eculizumab: A Case Report Trevor R. Smith, Mazdak A. Khalighi, Monica Patricia Revelo Penafiel, Josephine Abraham, Kalani L. Raphael. *Univ of Utah.*

Introduction: C3 glomerulonephritis (C3GN) is a rare cause of kidney disease that has a high recurrence rate (>50%) in the renal allograft. We present a case of recurrent C3GN in a renal allograft that was treated with and rapidly responded to eculizumab.

Case Description: A 70 year old male with membranoproliferative glomerulonephritis (MPGN) type I diagnosed in 2005 received a deceased donor renal transplant in 2013. Eighteen months later, he developed dysmorphic hematuria, sterile pyuria, and acute creatinine rise from 1.0 to 1.4 mg/dL; urine protein/creatinine was 200 mg/g. His immunosuppressive regimen included prednisone, mycophenolic acid, and tacrolimus. Renal biopsy demonstrated a focal exudative glomerulonephritis, C3-dominant immunofluorescence (IF), and mesangial, subendothelial, and intramembranous deposits by electron microscopy, consistent with C3GN. His original biopsy was re-evaluated, which was also consistent with C3GN. C3, C5 and Factor B levels were normal. However, complement Ba (1.9 mg/L), Bb (3.7 mg/L), and C5b-9 (0.49 mg/L) were elevated. C3 nephritic factor was negative, and no genetic variants were identified. The patient was monitored for 6 months, however, his creatinine increased to 1.7 mg/dL as did proteinuria. Eculizumab was initiated at 900 mg intravenously weekly for 4 weeks followed by 1200 mg every two weeks. After 1 month of therapy, the protein/creatinine ratio decreased from 1500 to 128 mg/g and hematuria and pyuria resolved. The most recent creatinine was 1.2 mg/dL, two months after starting eculizumab.

Discussion: There are few case reports regarding the use of eculizumab in C3GN and even fewer in kidney transplant patients, and the response to this therapy has been variable. This patient had a rapid response to eculizumab with resolution of proteinuria, hematuria, and pyuria and a near normalization of serum creatinine within two months. The sustainability of this response as well as the duration of treatment is uncertain. This case also highlights how the IF-based classification of MPGN, which is based on pathogenetic mechanisms, has impacted the diagnosis, evaluation, and treatment of MPGN.

PUB507

Multifactorial Hypertension - A Challenge to the Clinician Jyotsana Thakkar, Khurram Mehtabdin, Richard L. Barnett, Mala Sachdeva, Jamie S. Hirsch. *Div of Kidney Disease and Hypertension, Northwell Health, NY.*

Introduction: Incidentally discovered adrenal masses are common. About 15% of adrenal adenomas occur bilaterally and present challenges both in diagnosis and management. We describe a case of bilateral adrenal adenomas causing resistant hypertension (HTN).

Case Description: A 50 year old male with uncontrolled HTN for 25 years, chronic kidney disease stage III (baseline creatinine 1.6), and schizoaffective disorder was admitted to the hospital for hypertensive urgency with a blood pressure of 190/130. Patient's anti hypertensive regimen consisted of valsartan, amiloride, metoprolol and doxazosin. He was also taking potassium citrate supplements for hypokalemia and metabolic acidosis, which was attributed to topiramate. Other medications included monthly testosterone injections and over-the-counter caffeine supplements. Workup for secondary HTN was notable for elevated plasma aldosterone level (38.3 ng/dl), suppressed renin (<2.1 pg/dl), and normal metanephrines. Renal artery duplex showed no evidence of significant renal artery stenosis. CT scan and MRI of the abdomen revealed bilateral adrenal adenomas (1.4 x 1.5 cm on the left and 2.4 x 2.5 cm on the right). . Following readmission for AKI and hypertensive urgency (BP >200/110), adrenal venous sampling was undertaken for possible surgical intervention, and demonstrated the presence of an aldosterone producing adenomas with concentrations of 282 ng/dl and 22.9 ng/dl, on the left and right respectively. Surgical resection of the left adrenal mass was offered, but the patient declined and preferred therapy with a mineralocorticoid receptor antagonist. Initiation of spironolactone in conjunction with a thiazide diuretic was modestly helpful in reducing his blood pressure, to a current level of 150/90. He was advised to stop caffeine supplements and testosterone injections.

Discussion: While this patient had multiple reasons for uncontrolled hypertension, we believe that the primary driver was hyperaldosteronism, which may have been initially missed due to the presence of metabolic acidosis. This case emphasizes the importance of evaluating for secondary causes of HTN. Understanding the importance of the multifactorial nature of HTN can aide in the individualized treatment approach.

PUB508

Acute Generalized Exanthematous Pustulosis Associated Acute Interstitial Nephritis Jyotsana Thakkar, Bradley H. Goldberg, Mala Sachdeva. *Div of Kidney Diseases and Hypertension, Northwell Health, NY.*

Introduction: Acute generalized exanthematous pustulosis (AGEP) is characterized by the development of numerous nonfollicular sterile pustules associated with edematous erythema. Systemic organ involvement is uncommon. We present a case of AGEP with acute kidney injury (AKI).

Case Description: A 49 year old Caucasian female with recent bilateral breast reduction surgery ten days prior to admission presented with a diffuse body rash and severe odynophagia. She was started on cephalexin after the surgery. After three days on the antibiotic, she developed high fevers and a diffuse body rash. Due to suspicion of an allergy, antibiotic was discontinued and she was started on oral antihistamine and steroids. Subsequently, the rash worsened, she remained febrile, and developed severe odynophagia, prompting the ED visit on day ten. Initial vitals revealed a blood pressure of 94/65mmHg, and heart rate of 94 bpm. Skin exam showed a diffuse erythematous rash sparing palms and

soles with punctate pustules on her chest, face, and legs. Laboratory examination revealed a WBC 17.5, an absolute eosinophil count of 1000 after steroids were discontinued, BUN of 78mg/dl and creatinine of 6.57 mg/dL. Urinalysis showed trace blood and protein, negative nitrite and leukocyte esterase, 11-25 WBCs, 3-5 RBCs. Urine microscopy showed many WBC clumps. Urine culture was negative. Spot urine protein: creatinine ratio was 0.4. FeNa was 2.0%. Complements, ANA, ANCA, and ASLO titers were negative. Skin biopsy confirmed AGEP. She was treated with intravenous fluids and topical steroid creams. Her serum creatinine normalized to 0.6 mg/dl on day four.

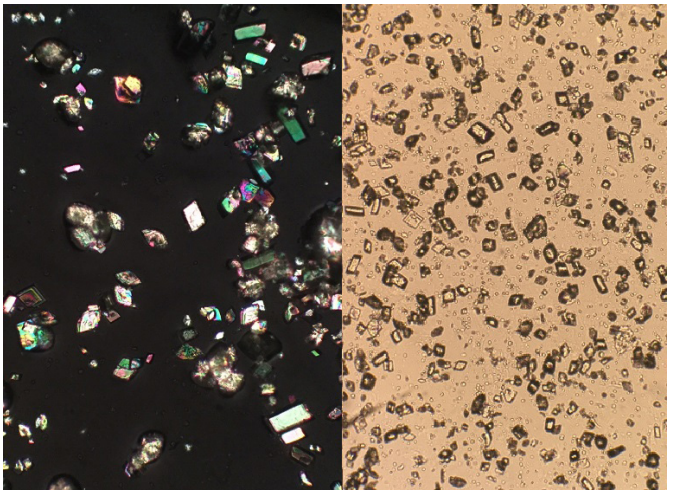
Discussion: AGEP is characterized by T cell mediated inflammatory reaction. Renal involvement is rare. A previously described case of AGEP with AKI was suspected to be of glomerular origin, and other cases have not described the etiology of AKI. We believe the AKI in our patient was primarily an allergic interstitial nephritis, as characterized by rash, fever, peripheral eosinophilia after discontinuation of steroids, sterile pyuria, and its association with a cephalosporin. Clinicians should be aware of this rare dermatological entity and its possible associated renal manifestation.

PUB509

Sulfamethoxazole Crystal-Induced Nephropathy - A Rare Cause of Acute Kidney Injury in an HIV Patient Arani D. Nanavati, Georges Nakhoul. *Nephrology, Cleveland Clinic Foundation.*

Introduction: Drug-induced crystalluria can be a cause of acute kidney injury (AKI). Sulfonamides are known to cause crystallization in the urine. We report a case of AKI due to sulfamethoxazole crystal induced nephropathy in a patient with HIV who was treated with intravenous (IV) Trimethoprim-Sulfamethoxazole (TMP-SMX).

Case Description: 56-year old male with normal baseline serum creatinine(SCr) of 0.7 presented with respiratory failure. He was empirically being treated for community acquired pneumonia. He was diagnosed with HIV with CD4 count of 18. Bronchoalveolar lavage was performed and patient was diagnosed with *Pneumocystis Jirovecii* Pneumonia (PJP). He was started on IV TMP-SMX. Within one day of the treatment initiation, his SCr started to trend up to 1, then to 1.3 and then 2. He also had refractory hyperkalemia with serum potassium of 5.5-6.1 despite medical management. Urine microscopy revealed abundance of polarizing, strongly bi-refringent and polychromatic crystals of various shapes: rhomboid, losangic and hexagonal.



Calculi analysis of urine was performed via Fourier Transform Infrared Spectroscopy and it revealed presence of SMX crystals. Neither cystine nor uric acid were identified. Urine alkalinization was not performed as he had respiratory acidosis with compensatory metabolic alkalosis. Patient received a session of dialysis for refractory hyperkalemia. TMP-SMX was stopped and an alternative antibiotic was started. Patient's renal function recovered and he did not require additional dialysis treatments. Repeat urine microscopy revealed disappearance of the crystals.

Discussion: SMX induced crystal nephropathy is an uncommon cause of AKI. While it is usually considered as a well-known entity, literature describing the appearance SMX crystals is actually scarce. This case provides images of SMX crystals and highlights the importance of urine microscopy in the diagnosis of AKI.

PUB510

It's More Than HIV and HAART in HIV with AKI Deewan Deewan,[1] Matthew J. Diamond,[1] Daniel Kleven.[2] [1]*Dept of Nephrology, Augusta Univ, Augusta, GA;* [2]*Dept of Pathology, Augusta Univ, Augusta, GA.*

Introduction: Immune reconstitution syndrome (IRIS) is a multiorgan inflammatory condition in human immunodeficiency virus (HIV) patients following initiation of antiretroviral (HAART) therapy. Rarely does IRIS cause acute kidney injury (AKI). This case presents a patient who developed AKI thought due to IRIS.

Case Description: A 35-y/o man was hospitalized for uremia (BUN = 146 mg/dL, Cr = 16 mg/dL) and hemodialysis (HD) initiation. He had recently been started on triple therapy for pulmonary MAI (ethambutol, chlarithromycin, and rifabutin), and recently had his HAART modulated to elvitegravir/cobicistat/emtricitabine/tenofovir. He also previosly developed IRIS several months earlier from initiation of HAART. An ultrasound demonstrated normal sized echodense kidneys with with multiple punctate calcific lesions noted in both kidneys and his liver. A kidney biopsy revealed acute tubular necrosis (ATN), mononuclear interstitial infiltrates, and myoglobin cast nephropathy. In addition, one core sample revealed granulomatous material which contained acid-fast bacteria, later identified as MAI. No mitochondrial or glomerular damage was noted. Given the mononuclear infiltrate, sparing of the glomeruli, and disseminated MAI, the AKI was thought to be caused from IRIS. Prednisone was started of IRIS treatment, moxifloxacin replaced ethambutol for MAI treatment, and his HAART was restarted after a brief hiatus. With these changes, the patient recovered renal function, with a new baseline creatinine of 1.73 mg/dL, and no longer required HD.

Discussion: This case demonstrates that IRIS can cause AKI, and is treatable with steroids, as well as continuation of HAART. Although considerably rare, this phenomenon has been reported in the literature over the past 15 years; most are associated with concomitant mycoplasma infection. When appreciated, a mononuclear interstitial infiltrate is demonstrated on the kidney biopsy, with sparing of the glomeruli. Furthermore, this case demonstrates the utilization of kidney biopsy in an HIV patient to accurately define the pathology for proper therapeutic intervention.

PUB511

IgA Vasculitis versus IgA Dominant Post-Infectious Glomerulonephritis? A Case of Severe Oxacillin Resistant *S. aureus* (ORSA) Cellulitis Vivek Ramesh Sanghani, Luanna Yang, Volker Nickeleit, Patrick H. Nachman. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

Introduction: IgA dominant post-infectious proliferative glomerulonephritis has been described in association with ORSA. These cases may be difficult to differentiate from primary IgA nephropathy or IgA vasculitis with superimposed infection. We present a case illustrating this differential diagnosis.

59 yo female with a history of Hepatitis C and venous stasis presented with lower extremity ulcerated wounds and acute kidney injury. A large deep ulcer with heaped borders and purulent base extended from the left knee to the ankle. A smaller ulcer affected the R ankle. A non-blanching erythematous macular and petechial rash involved the thighs, forearms and hands. Wound cultures grew ORSA which was treated with vancomycin. Serum Creatinine (Cr) was 1.92 mg/dl (from <1 a month earlier). Her urine was tea colored, the sediment revealing numerous dysmorphic red blood cells. Urine protein/creatinine ratio = 1.6 g/g. Serum C3, C4, rheumatoid factor, ANA, ANCA and Hepatitis B surface Ag were normal. Hepatitis C viral load was 794775 [IU]/ml with normal AST and ALT. ESR: 44mm/hr and CRP: 2.7mg/dL. A renal biopsy demonstrated moderate mesangial matrix expansion and hypercellularity, focal and segmental endocapillary proliferation and cellular crescents in 15% of glomeruli. There was 3+ IgA and C3 granular deposition within the mesangial space and along peripheral glomerular capillary walls. Intratubular red blood cell casts were noted. No large subepithelial deposits were found by electron microscopy. A skin biopsy from the arm showed granular depositions of IgA and fibrinogen in the papillary dermal vessels, thus confirming a diagnosis of IgA vasculitis. Corticosteroids were initiated because of progressive decline in GFR.

Discussion: This case illustrates an acute nephritic exacerbation of IgA vasculitis, precipitated by the ORSA infection. This is supported by the normal serum complements, the absence of large subepithelial immune complex type deposits, and the skin biopsy findings. Differentiating between this and IgA dominant post infectious glomerulonephritis is crucial to direct therapy.

PUB512

Acute Kidney Injury with Polyclonal Lympho-Plasmacytic Interstitial Infiltrate Secondary to Diffuse Infiltrative Lymphocytosis Syndrome (DILS) in an Untreated HIV Patient Gregory R. Varghese, Navneet Kaur, Sandeep Aggarwal, Suganthi Soundararajan. *Nephrology, Drexel Univ College of Medicine, Philadelphia, PA.*

Introduction: Acute kidney injury (AKI) in HIV is multi-factorial and includes toxic, infectious, and autoimmune etiologies. We present a rare case of Diffuse Infiltrative Lymphocytosis Syndrome (DILS) induced AKI in the setting of HAART noncompliance.

Case Description: A 38 year old AAF with known HIV infection (CD4 count 34 cells/microliter) that had been uncontrolled due to HAART noncompliance. She presented to our facility for fever (102.2 F), loss of appetite, and weight loss. On admission, patient noted to have acute kidney injury (AKI) with creatinine at 2.04 mg/dL (baseline creatinine 0.7-1.0 mg/dL 6 months prior). Urinalysis study showed >100 WBC's, 6-10 RBC's, occasional bacteria, 2+ protein, and 3+ leukocyte esterase. For pertinent labs, CD4:CD8 was 0.35, IgA 676 mg/dL, IgG 3401 mg/dL, IgM 1075 mg/dL, HSV-1 & 2 DNA and IgM antibodies were negative as well as acute viral hepatitis panel. ANA titer was 1:40 with speckled pattern but C3 & C4 were normal. Renal ultrasound was unremarkable. Renal function continued to worsen despite fluid resuscitation with medication adjustments, therefore a renal biopsy was performed. Light microscopy was notable for polyclonal-lymphoplasmacytic interstitial infiltration with diffuse moderate to severe tubulo-interstitial inflammation correlating with a predominance of circulating CD-8 positive T lymphocytes and poly hyper-gammaglobulinemia. Special staining for adenovirus, CMV, HSV were all negative. A diagnosis of DILS with renal involvement was made. Patient was treated with short course of steroids and HAART with improvement of renal function to baseline.

Discussion: DILS is a rare etiology of AKI in HIV-infected patients. The diagnosis should be considered in patients that are treatment naïve or non-compliant to HAART therapy. Early biopsy with multi-disciplinary approach may help improve the outcome of this disease.

PUB513

An Unusual Case of Pulmonary Hemorrhage with Acute Renal Failure due to Systemic Lupus Erythematosus and Polyangitis Mohammed Nazmul, Anustup Datta, Marius C. Florescu. *Nephrology, Univ of Nebraska Medical Center, Omaha, NE.*

Introduction: Pulmonary hemorrhage with proliferative glomerulonephritis is a characteristic manifestation of anti-glomerular basement disease or pauci immune vasculitis but unusual in Systemic Lupus Erythematosus (SLE).

Case Description: A 19 years old woman presented to ER with hemoptysis, dyspnea and decreased urine output for 1 week. Physical examination revealed bibasilar lung crepitation,2+ ankle edema but no rash, organomegaly or lymphadenopathy.Laboratory tests significant for severe renal failure with hyperkalemia.Chest X ray showed bilateral consolidation. She was intubated and anuric. Emergent hemodialysis and plasmapheresis initiated. Labs included positive anti-nuclear, anti-double stranded DNA , anti-nuclear cytoplasmic antibodies with perinuclear pattern of distribution , low C3 and C4;negative lupus anticoagulants, anti-GBM, anti-proteinase 3 and anti-myeloperoxidase antibodies. Blood culture showed Escherichia coli and Enterobacteriaceae. Urine microscopy revealed RBC's and WBC clumps.Renal biopsy showed diffuse proliferative glomerulonephritis with cellular crescents and fibrinoid necrosis, "full house staining" on immunofluorescence consistent with Type IV lupus nephritis. Following plasmapheresis, she received 6 months of oral cyclophosphamide, prednisone and hydroxychloroquine. After 6 weeks hemodialysis her renal function improved and hemodialysis stopped.

Discussion: Pulmonary renal syndrome is a rare life threatening complication of SLE. Presence of p-ANCA may indicate an associated acute vasculitis with biopsy showing fibrinoid necrosis.Antecedent infection could trigger wide spread vasculitis reaction with underlying medical illness of lupus. Clinical presentation was concerning of vasculitis but further work up confirmed active lupus.This case highlights that different disease processes can be responsible for the occurrence of pulmonary renal syndrome. Association between small vessels vasculitis and SLE signifies the fact that small group of patient with SLE may also have an underlying polyangitis where biopsy findings provide valuable guidance for appropriate early intervention which is paramount due to the severity of their illness.

PUB514

Incarcerated Inguinal Hernia as a Presenting Complication of Polycystic Kidney Disease Ahmed Daoud,[1] Mostafa Alfishawy.[2] *[1]Nephrology, UAMS, Little Rock, AR; [2]General Medicine, Queens' Hospital, New York, NY.*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is a multisystemic disorder with renal and extrarenal complications. End stage renal disease is the most feared complication affecting almost 50% of ADPKD patients by 60 years. We are presenting a case of ADPKD that was diagnosed when the patient presented with incarcerated inguinal hernia. The incarcerated hernia is probably a result of increased intra-abdominal pressure due to polycystic kidneys.

Case Description: Herein we present a 56 year old Male with ADPKD who presented to the emergency room with abdominal and groin pain. He was admitted for possible small bowel obstruction and CT scan performed and showed incarcerated inguinal hernia and bilateral huge cystic kidneys, cystic liver and pancreas. Patient was managed conservatively then he was discharged and scheduled for outpatient bilateral inguinal hernia repair with mesh.

Discussion: ADPKD affects approximately one in 1000 people. The most common presentation is a palpable mass, hypertension (after their third decade of life), abdominal pain, and hematuria. Abdominal wall hernias are up to five times more common in ADPKD patients with prevalence estimated to be 45%. The increased prevalence is thought to be due to a combination of increased intraabdominal pressure from enlarged kidneys and weak abdominal musculature due to the connective tissue pathology. Our patient was discovered to have Polycystic Kidneys after presenting with incarcerated hernia. Up to our knowledge, this is the second case of ADPKD presenting with incarcerated hernia. Our point is that incarcerated hernia may be a rare presentation of ADPKD.

PUB515

A Case of Plasmapheresis in Treatment of Myeloma Kidney Shehryar H. Ashraf, Niralee Patel, Ruchir D. Trivedi. *UCONN Health Center, Farmington, CT.*

Introduction: Myeloma kidney, also called light chain cast nephropathy, is caused by monoclonal immunoglobulin infiltration and light chain deposition many times requiring renal replacement therapy. Treatment includes chemotherapy, but the use of plasmapheresis has been used for removal of light chains in acute disease.

Case Description: We present a 69-year-old male patient diagnosed with multiple myeloma with associated acute kidney failure requiring hemodialysis. Due to significantly elevated lambda SFLC and renal disease, plasmapheresis was initiated. He received plasmapheresis for three days, subsequently, began chemotherapy. SFLC levels were obtained daily, prior to any interventions of the day. Lambda SFLC decreased by 19% from two sessions of plasmapheresis prior to starting chemotherapy and a tremendous 60% after 11 days (figure 1).

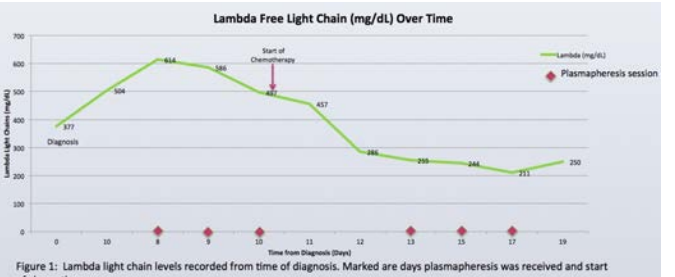


Figure 1: Lambda light chain levels recorded from time of diagnosis. Marked are days plasmapheresis was received and start of chemotherapy.

Discussion: Chemotherapy decreases SFLC production, thus affecting the underlying myeloma kidney disease. However, after initial diagnosis, plasmapheresis can be utilized to physically remove the SFLC and directly decrease the damage to the kidney. Based on a study by Zucchelli et al., there was an observed increased survival with the use of plasmapheresis in addition to chemotherapy. However, Clark et al. reached no statistically significant difference with plasmapheresis with chemotherapy. Hutchinson et al. found that decreasing SFLC by 60% in 21 days resulted with renal recovery. Our patient was treated successfully by reducing SFLC by 60%. We hope for renal recovery in the future, by becoming independent of dialysis.

PUB516

BRAF Inhibitors- Induced Renal Injury and Electrolyte Disturbances Ahmed Daoud, Gerren Hobby, Umbar Ghaffar. *Nephrology, UAMS, Little Rock, AR.*

Introduction: Agents that inhibit the BRAF kinase pathway showed promise in treating malignant melanoma.Two specific agents, vemurafenib and dabrafenib, and the MEK inhibitor, trametinib, have been licensed since 2011 for treatment of patients with unresectable or metastatic melanoma with BRAF mutation. While these drugs have greatly improved the prognosis of this disease, they have been associated with nephrotoxicity & electrolyte disturbances.

Case Description: 74 year old male with recently diagnosed metastatic malignant melanoma, was admitted to our facility with confusion and found to have AKI & hypercalcemia. AKI was initially thought to be due to hypercalcemia but did not improve with volume repletion. Based on urine sediment findings, diagnosis of acute interstitial nephritis was made and patient started on steroids. During admission, patient was continued on BRAF inhibitor therapy with Dabrafenib and trametinib. Renal function continued to deteriorate & patient required hemodialysis for few weeks followed by recovery of renal function. He was readmitted a month later following a syncopal episode with another episode of AKI. At this time his urine showed presence of persistent white blood cells and protein indicating likely chronic interstitial nephritis related to his chemotherapy agents which were stopped. Renal function slowly recovered .He also had persistent hypokalemia with a normal anion gap acidosis that has been described with BRAF inhibitors.

Discussion: BRAF inhibitors vemurafenib and dabrafenib have significantly improved survival in patients with *BRAF* V600–mutant metastatic melanoma, when compared with standard therapy. However, both of these drugs appear to be associated with an increased risk for acute kidney injury. Data from the US Food and Drug Administration Adverse Event Reporting System (FAERS) revealed that from July 2011 through June 2014, 132 cases of acute kidney injury were reported in patients receiving vemurafenib therapy. In addition, 13 cases of renal injury were reported in those receiving dabrafenib. BRAF inhibitors cause tubulointerstitial damage and electrolyte disturbances. Careful monitoring of renal function and electrolytes is strongly recommended for patients on BRAF inhibitors.

PUB517

Successful Outcome Using Belatacept in a Recipient with Systemic Thrombotic Microangiopathy after Receiving a Donor Kidney with Fibrin Thrombi Amit K. Rajput, Beatrice P. Concepcion, Paisit Paueksakon, Derek E. Moore, Manish Anand. *Vanderbilt Univ Medical Center.*

Introduction: Deceased donor kidneys with diffuse fibrin thrombi due to disseminated intravascular coagulation in the donor have a high rate of delayed graft function or primary non-function. Traditionally, this has been in the setting of calcineurin inhibitor (CNI) maintenance immunosuppression. In this case, we describe a patient who received a kidney with known fibrin thrombi resulting in subsequent slow graft function, severe thrombocytopenia, and microangiopathic hemolytic anemia immediately post-transplant. Tacrolimus was switched to belatacept with immediate clinical improvement.

Case Description: A 71 year-old female with end stage renal disease secondary to polycystic kidney disease received a deceased donor kidney transplant from a 22 year-old donor who died of a gunshot wound to the head. The donor's terminal creatinine was 1.9mg/dL and the procurement biopsy showed glomeruli with scattered fibrin thrombi. The recipient had a panel reactive antibody of 98%, was induced with alemtuzumab/methylprednisolone, and started on mycophenolate mofetil on post-operative day (POD) 0 with tacrolimus on POD 1. The post-operative course was complicated by worsening thrombocytopenia (POD 3: Platelets 28,000/mcL) and hemolytic anemia (Hct 19%, LDH 924units/L, Haptoglobin<8mg/dL and shistocytes on peripheral smear). A biopsy was performed, which showed diffuse thrombotic microangiopathy (TMA) and extensive acute tubular injury, but no evidence of acute rejection. Tacrolimus was discontinued and belatacept was initiated. The patient had immediate improvement in both thrombocytopenia and serum creatinine (0.8mg/dL three months post-transplant).

Discussion: Belatacept should be considered as an alternative to CNIs for maintenance immunosuppresion in patients who receive deceased donor kidneys with fibrin thrombi and subsequently have slow/delayed graft function, or in those who develop systemic signs of TMA. CNIs are known to cause drug-induced TMA via endothelial injury and in this setting, may augment ongoing injury in the donor kidney. Avoidance of CNIs may lead to a more rapid resolution of the TMA and improvement in allograft function.

PUB518

Hypokalemic Tetraparesis as the First Manifestation of Autoimmune Disorder: A Case Report Nicola Lepori,[1] Matteo Floris,[1] Andrea Angioi,[1] Riccardo Cao,[1] Maura Conti,[1] Anna Maria Asunis,[2] Alice Atzeni,[1] Valentina Loi,[1] Patrizia Melis,[1] Stefania Aresu,[1] Giulia Dessì,[1] Doloretta Piras,[1] Antonello Pani.[1] *[1]Nephrology, G. Brotzu Hospital, Cagliari, Italy; [2]Pathology, G. Brotzu Hospital, Cagliari, Italy.*

Introduction: We report an unusual case of life-threatening potassium wasting due to selective damage of the distal tubule, hypothesized as being related to circulating ENA-SSA Ab.

Case Description: A 50 y/o woman was admitted to our hospital because of severe hypokalemic tetraparesis (K+: 1.6 mEq/L) with no obvious underlying causes. Further laboratory tests showed normal renal function, hyperchloremic metabolic acidosis, urinary potassium wasting (88 mmol/24h) and alkaline urine, suggesting type 1 renal tubular acidosis (RTA). Supporting therapy with i.v. NaHC03 and KCl led to temporary recovery. Meanwhile, SPEP showed an IgGK monoclonal spike, ANA (1:640), elevated ENA-SSA (689 U/ml), while anti-dsDNA were normal. We recommended a renal biopsy, but the patient refused. Two months later she was admitted to our Division complaining of blood hypertension and ankle swelling. At that time, renal function was normal, K+ 2.7 mEq/L, CRP 0.7 mg/dl. Urinalysis revealed microhematuria and 24h proteinuria of 3.6 g. IgGK monoclonal spike was confirmed by immunofixation. Serology revealed low C3 and C4, ANA (1:320), elevated ENA-SSA (314 U/ml) and rheumatoid factor (258 U/ml); viral serology was negative. A renal biopsy was then performed, revealing MPGN with focal pseudothrombi (with IgG and C3 deposits) and severe tubulointerstitial nephritis (TIN) with preponderant lympho-plasmacytic infiltrate. Finally, mixed cryglobulinemia was confirmed by serology. Sjogren syndrome was suspected, but exocrine glands were unremarkable.

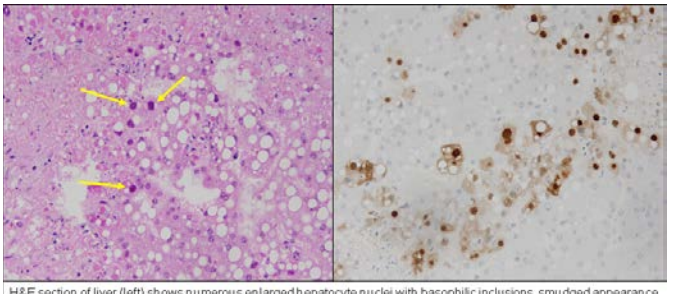
Discussion: Occasionally, type 1 RTA is part of puzzling autoimmune disorders. This case highlights life-threatening hypokalemic tetraparesis as the first manifestation of a systemic autoimmune process, albeit with no evident extra-renal involvement. Hopefully, follow-up and response to treatment will reveal more about it.

PUB519

Fatal Disseminated Adenovirus Infection in Renal Transplant Recipient Darpan Gandhi,[1] Olorunkemi O. Oluwole,[1] Alisa Caudell,[2] Maria N. Salazar,[1] Prince Mohan.[1] *[1]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Dept of Pathology, Medical Univ of South Carolina.*

Introduction: Adenoviruses are increasingly recognized as contributors to morbidity and mortality among solid-organ transplant recipients. Mortality from disseminated adenovirus disease is as high as 75% in immunocompromised host.

Case Description: 61 year old white female with ADPKD received cadaveric renal transplant from 8 year old female who died in motor vehicle accident. She received of basiliximab (induction) with maintenance immunosuppression of tacrolimus, prednisone, and MMF. 49 days post-transplant she presented with cough and diarrhea. She had neutropenia (ANC 0.77 K/CUMM); acute kidney injury, serum creatinine (sCr) of 1.4 mg/dl (baseline sCr 0.9 mg/dl), elevated AST 549 U/L, and ALT 228 U/L. Chest CT showed diffuse bronchiectasis. MMF and tacrolimus were stopped. Colonoscopy showed active colitis with biopsy negative for CMV. Serum adenovirus PCR was 1.3 billion copies, and was also detected in stool and respiratory panel. AST and ALT peaked to 3515 U/L and 555 U/L respectively. She was treated with antibiotics, IVIG and cidofovir. She required hemodialysis, developed respiratory failure and after 7 days, she expired from septic shock despite aggressive resuscitation with vasopressors. Autopsy showed isometric vacuolization of tubular epithelium of transplant kidney without viral inclusions and extensive necrosis of liver.



H&E section of liver (left) shows numerous enlarged hepatocyte nuclei with basophilic inclusions, smudged appearance (arrows), characteristic of adenovirus cytophathic effect. The background liver parenchyma displays patches of necrosis and macrovesicular steatosis. Immunohistochemical stain for adenovirus (right) reveals strong positivity within many hepatocytes confirming diagnosis of adenoviral hepatitis.

Discussion: Adenovirus should be included in differential diagnosis of post kidney transplant hepatitis, hepatic failure and colitis. Infection occurred within first two months of transplant and donor kidney did not show viral inclusion suggesting novel infection or reactivation of latent infection in recipient. Prognosis is poor and therapy remains challenging despite reducing immunosuppression, use of IVIG, and cidofovir.

PUB520

No Smoke but Raging Fire- Urinalysis Is an Imperfect Clue Melissa L. Swee, Lama A. Noureddine. *Div of Nephrology, Univ of Iowa, Iowa City, IA.*

Introduction: The urine dipstick has long been considered a "liquid biopsy of the kidneys," providing valuable diagnostic information. However, the absence of proteinuria or hematuria does not rule out pathology. We present a case illustrating this cautionary principle.

Case Description: A 59 year-old female presented with a two-month history of nightly fevers (up to 101.3*F), decreased appetite and 20-pound weight loss. She denied urinary frequency, hematuria, edema, dyspnea, cough, or rash. Vital signs were notable for fever (100.6*F), tachycardia (109bpm), and hypertension (147/70mmHg); the rest were within normal limits. Cardiopulmonary, dermatologic and musculoskeletal examinations were unremarkable. There was no pedal edema or costovertebral angle tenderness. Comprehensive metabolic panel revealed increased serum creatinine (2.8mg/dL) and blood urea nitrogen (21mg/dL), which, 3 months ago, were 1.1mg/dL and 14mg/dL, respectively. C-reactive protein and erythrocyte sedimentation rate were also elevated (17.3mg/dL and 120mm/hr). Urine dipstick repeated thrice did not reveal any proteinuria, hematuria, leukocyte esterase, or nitrite. ANA, complement levels, and ASO were negative but ANCA titers were elevated at 1:320. MPO was also high (>8 AI) but not PR3. This was confirmed on renal biopsy, which demonstrated pauci-immune, necrotizing glomerulonephritis, with crescents as seen on immunofluorescence staining for fibrin .

Discussion: ANCA-associated vasculitis is a set of systemic vasculitides that frequently leads to pauci-immune crescentic glomerulonephritis. As such, proteinuria and hematuria are the most common renal manifestations of the disease, but this is not strictly required. This case emphasizes that nephrologists should have a high index of clinical suspicion for ANCA-associated vasculitis in patients with deterioration of kidney function even in the absence of proteinuria or hematuria.

PUB521

Case Report: A Case of Anti-Neutrophil Cytoplasmic Antibody Glomerulonephritis, Drug Induced Lupus and Sweet Syndrome Ahmed Daoud,[1] Gerren Hobby,[1] Neriman Gokden,[2] John M. Arthur,[1] Manisha Singh.[1] *[1]Nephrology, UAMS, Little Rock, AR; [2]Pathology, UAMS, Little Rock, AR.*

Introduction: We report a case of ANCA vasculitis with co-existing Sweet syndrome & drug induced lupus. Sweet syndrome is a hypersensitivity reaction that occurs in response to systemic factors, such as hematologic disease, infection, or drug exposure. All three disease processes ANCA GN, drug induced lupus & Sweet syndrome in this patient appear to be secondary to use of Hydralazine.

Case Description: A 73 year old Caucasian man, hypertensive on Hydralazine was referred to Haematology-Oncology for suspected Waldenstrom's Macroglobulinemia (WM). He developed A-fib for which he was admitted. WM was ruled out with bone marrow biopsy. He developed a maculopapular rash after admission on the face, scalp, and upper torso. Dermatology diagnosed the rash to be Sweet syndrome after skin biopsy. Following this he developed acute kidney injury (AKI). Creatinine during hospitalization was initially 2.5 - 2.7mg/dl, but rose to 3.1mg/dl. Urine sediment showed dysmorphic RBCs, and urinalysis had hematuria with nephrotic range proteinuria. Serology showed low complements, with elevated titers of ANA, Anti-chromatin, anti-cardiolipin, anti-histones, leading to diagnosis of drug-induced Lupus. ANCA titers (both MPO & PR3) were also elevated. The patient developed cough with bloody sputum. Kidney biopsy showed Crescentic GN consistent with ANCA vasculitis. He was treated with steroids, plasma exchanges & rituximab, with resolution of hemoptysis and creatinine returned to 2.8 before discharge.

Discussion: Our patient had ANCA vasculitis, drug induced lupus and also Sweet syndrome, as proven by serologies and biopsy. The titers of both ANCA-MPO & ANCA-PR3 were elevated, together with anti-histone titers, as well as lupus panel. All these are known to be associated with hydralazine use. Drug-induced Sweet syndrome has been reported with furosemide, hydralazine, minocycline and Bactrim. There are three reported cases of ANCA vasculitis with sweet syndrome; two of them were on Hydralazine. Up to our knowledge this is the second reported case with the concurrent three hydralazine-induced diagnoses that our patient carries.

PUB522

A Case of Granulomatous Interstitial Nephritis in a Patient with History of Crohn Disease without Evidence of Active Flare or Current Use of Salicylates

Chaitanya Mishra,[1] Maria Joana Angeles Thomas,[3] Lawrence S. Weisberg,[1] Ron Zanger,[1] Dominick Santoriello.[2] *[1]Div of Nephrology, Cooper Univ Hospital, Camden, NJ; [2]Dept of Pathology, Columbia Medical Center, New York, NY; [3]Internal Medicine, Monmouth Medical Center, Long Branch, NJ.*

Introduction: Granulomatous interstitial nephritis (GIN) is a condition associated with Crohn disease and characterized by interstitial inflammation and granuloma formation in the renal parenchyma, most cases of which are reported with an active flare or use of 5-amino salicylate (5-ASA) derivatives. We present a case of GIN in the absence of a clinical flare of Crohn disease or recent 5-ASA exposure, and while taking a TNF-alfa inhibitor, which is used in treatment of granulomatous disorders.

Case Description: A 43 year old lady was admitted with an elevated creatinine. Her history included Crohn disease for 4 years, treated with mesalamine and budesonide for only a few months. Twenty months before admission, she developed jejunal perforation and underwent partial small bowel resection after which she was started on infliximab and achieved complete remission. One month before admission, her plasma creatinine concentration rose from 0.75 mg/dl to 2.30 mg/dl. Her UA revealed WBC casts; the urine protein creatinine ratio was 0.2 g/g. Serological evaluation including ANA, ANCA, Hepatitis Panel, HbA1c was negative or normal. Anti-infliximab antibodies were negative. Serum infliximab concentration was 1.3 mcg/ml (target > 0.5 mcg/ml). Renal biopsy revealed severe GIN. She received no more infliximab. Oral prednisone was started and on follow up 2 weeks later her creatinine had decreased to 1.58 mg/dl.

Discussion: Our patient had not received 5-ASA therapy for over 2 years before evidence of decline in renal function, making 5-ASA an implausible cause of her GIN. Her CD was clinically quiet, thus eliminating the two most common causes of GIN with CD. Her serum infliximab level was in the low end of the target range and may have failed to treat subclinical CD, leading to GIN. Alternatively, TNF-alfa inhibitors are reported to have a paradoxical effect and may have precipitated the granulomatous nephritis in our patient.

PUB523

Lactic Acidosis as the Presenting Sign of a Signet-Ring Cancer

Zhen Cheng,[1] Jing Lin,[2] Qi Qian.[3] *[1]Nephrology, Jinglin Hospital Nanjing Univ & Mayo Clinic, Rochester, MN; [2]Nephrology, Zhongshan Hospital Fudan Univ & Mayo Clinic, Rochester, MN; [3]Nephrology and Hypertension, Mayo Clinic College of Medicine, Rochester, MN.*

Introduction: Lactic acidosis that is not associated with severe sepsis or shock could be due to a variety of causes (type B lactic acidosis). Solid tumors can cause sustained lactic acidosis due to normoxic glycolysis (Warburg effect).

Case Description: A 56 y/o man with ADPKD and cyst-related pain presented to the ED with worsening frank and abdominal pain for a week. He was hemodynamically stable. His abdomen was soft but diffusely tender. His blood HCO3 was 20 mmol/L, Cr 1.9 mg/dL (baseline 1.5) and lactate 3.9 mmol/L (reference range: 0.6-2.3). He was not on medications that may cause lactic acidosis. Abdominal CT scan showed ADKPD and new retroperitoneal lymphadenopathy (not seen 6 months ago). Overnight, the pain subsided; lactate was 2.8. He was discharged with a plan for a repeat CT in 3 months. A week later, he was admitted with severe abdominal pain and shock (BP 70/p). Serum Cr 3.0 mg/dL and lactate 6.5. He was treated for presumed infection, stabilized hemodynamically and HD initiated. The lactate elevation persisted in the next 4 days (ranging 4-8 mmol/L). A contrast-enhanced CT showed metastatic cancer with lesions in bilateral lunch fields in addition to the lymphadenopathy. Percutaneous lymph node biopsy showed poorly differentiated adenocarcinoma with signet-ring presentation, consistent with metastatic cancer of gastric primary. The patient expired 2 weeks after the cancer diagnosis.

Discussion: Cancer contains oxidative and glycolytic cells. Oxidative cancer cells show a lactate preference, saving glucose for glycolytic cells to generate lactic acids. Lactate, in turn, feeds oxidative cells for energy generation. Such a perfect metabolic symbiosis has been observed in cancers of multiple origins. Lactic acidosis through activating HIF-1 and degrading extracellular matrix promotes rapid cancer growth, angiogenesis and metastasis, leading to a high mortality. New lymphadenopathy in the setting of sustained lactic acidosis should be investigated promptly as most of cancers with lactic acidosis tend to rapidly progress and be fatal.

PUB524

Masquerading ANCA-Associated Vasculitis: A Strange Case of Inflammatory Polyneuropathy

Adam Austin, Krishnakumar D. Hongalgi, Llewellyn A. Foulke, Mauricio Monrroy, Rafia I. Chaudhry. *Albany Medical College, Albany, NY.*

Introduction: A rare case of sensory and motor polyneuropathy as the presenting symptom of Microscopic Polyangiitis (MPA).

Case Description: A 69 year-old woman was admitted to the neurology unit with 5-days of progressive right lower extremity (LE) weakness, and 'flu-like symptoms' for several weeks, including fatigue, anorexia and night sweats. PMHx notable only for hypothyroidism. Physical exam demonstrated a right foot drop with sensory deficits below the knee, loss of proprioception along with paresthesias of right upper extremity (UE), and motor deficit of left UE, including left wrist drop. EMG consistent with sensory plus motor axonal neuropathy involving LE>UE, concerning for AIDP vs. mononeuritis multiplex. Laboratory data: Hb 9.7 g/L, WBC 24,000, Platelet 492,000, serum Cr 0.7 mg/dL. UA: +1 Protein, +2 Hb, 3-5 RBC/Hpf. Chest x-ray was unremarkable. CTA and MRI brain revealed a basilar tip aneurysm (11.5 x 9 mm), which did not explain the patient's neurological presentation per neurosurgery. Workup for polyneuropathy included negative lumbar puncture (hence more consistent with mononeuritis multiplex than AIDP), CRP 28.8 mg/dL, ESR 67 mm/HR, EBV Ag and Ab negative, Lyme Ab negative, albumin 1.9 gm/dL, and positive C-ANCA 160 (ref<20), prompting nephrology consultation. Treatment for inflammatory polyneuropathy was initiated with IVIG and steroids. Further pertinent positives included: MPO 489.6 (ref<20), RF 99 IU/mL, ANA Ab 320 (ref <20) with normal complements. Urine (Ur) microscopy negative for active sediment, spot Ur protein 164 mg/dL, spot Ur Cr 105 mg/dL (ratio 1.56), and renal biopsy was performed.

Renal biopsy demonstrated focal segmental necrotizing and pauci immune crescentic glomerulonephritis affecting 10% glomeruli, consistent with ANCA associated vasculitis. Treatment of C-ANCA MPO vasculitis was initiated.

Discussion: Polyneuropathy is a rare primary manifestation of MPA; motor-sensory neuropathies are reported in 7 to 15% of patients with MPO ANCA vasculitis, mostly accompanying RPGN/ renal involvement, but rarely as an initial presentation. Cranial and peroneal nerve involvements are the most frequent neurological manifestations.

PUB525

A Different Kind of Renal Crisis

Albara Said, Darwish Naji, Cybele Ghossein. *Nephrology, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Introduction: Systemic sclerosis (SSc) is an autoimmune disorder characterized by skin thickening with variable systemic organ involvement. Renal involvement often takes the form of scleroderma renal crisis (SRC) and is typically characterized by abrupt onset of severe hypertension and acute kidney injury. Additional findings on presentation include congestive heart failure, encephalopathy and thrombotic microangiopathy (TMA). SRC is sometimes difficult to distinguish from other forms of TMA as the presentations may be similar. We present a patient with an established diagnosis of scleroderma who presented with symptoms consistent with SRC but biopsy revealed TMA not related to SRC.

Case Description: A 47-year-old female with known SSc with positive anti-RNA polymerase III autoantibodies presented to the hospital with shortness of breath and lower extremity edema. She had undergone hematopoietic cell transplantation (HCT) for SSc 15 days prior to admission for which she had received large doses of glucocorticoids. On admission she was found to have an elevated creatinine and a systolic blood pressure 40mmHg above her baseline. ACE inhibitor therapy was initiated for presumed SRC. Kidney function continued to deteriorate. A renal biopsy was performed and showed changes consistent with TMA confined to the glomerular compartment, and none of the classic vascular changes seen in SRC. Her respiratory status worsened necessitating ICU admission where she was found to have H1N1 pulmonary infection. As her infection was treated, her renal function stabilized and her TMA resolved.

Discussion: Due to its significant mortality, SRC should always be empirically treated when patients with SSc present with acute hypertension and AKI. While SRC is typically a clinical diagnosis, renal biopsy can help confirm diagnosis. Our patient's biopsy confirmed the presence of TMA however she had no pathologic features of SSc. Our patient's diagnosis of H1N1 introduces the possibility that her TMA could have been related to H1N1. A literature search revealed two cases of patients with H1N1 associated TMA, however to our knowledge this is the first case in a patient with SSc.

PUB526

Acute Kidney Injury in End Stage Renal Disease Patients on Hemodialysis and Renal Function Recovery

Paul Zamudio, Riffat Jafrin, Kamran Karimi, Heesuck Suh, Nand K. Wadhwa. *Dept of Nephrology and Hypertension, Stony Brook Univ Hospital, Stony Brook, NY.*

Introduction: Chronic kidney disease (CKD) patients are at risk for developing acute kidney injury (AKI) and once labeled as ESRD, emphasis on renal function recovery becomes a lower priority. We report two chronic hemodialysis (HD) patients as AKI-D (dialysis) managed with coordinated care among various health care providers and were successfully taken off HD with return of renal function.

Case Description: Case 1: A 77 year old woman with CKD stage 4 who underwent cardiac and renal artery catheterization for recurrent flash pulmonary edema and hypertension which showed 99% stenosis of the left renal artery with successful stent placement and 80% stenosis of the right renal artery with no stent. Afterward, she became anuric with a serum creatinine 9.63 mg/dL. HD was initiated with left radiocephalic AV fistula. Her intradialytic weight gain and blood pressure control were monitored with improvement in urine output. Her HD frequency decreased twice to once a week. She recovered kidney function (S Cr 2.02 mg/dL) and was taken off HD one year later. She remained off HD for 9 months so far. Case 2: A 70 year old woman with CKD stage 4 and left atrophic kidney who underwent cardiac catheterization due to ST elevation myocardial infarction. She developed AKI with uremic symptoms and creatinine 5.25 mg/dL. She was started on HD with left brachial-axillary Acuseal AV graft. Three months post HD initiation; she was decreased to twice a week HD then once a week six months later. Ten months later, she was taken off HD with current S Cr of 2.14 mg/dL. She has been off HD for 4 months so far.

Discussion: CKD patients who develop AKI needs individualized care, focused on renal function recovery. This type of directed care is important as AKI patients in future can receive HD at ESRD facilities as of Jan 1, 2017. Creation of an arteriovenous access may slow decline in GFR. Both were successfully taken off HD through careful management of their dry weights, blood pressures, medications leading to progressive tapering of their HD schedules.

PUB527

Non-Uremic Calciphylaxis Treated with Intralesional Sodium Thiosulfate

Venkat Ram Rakesh Mundra,[1] Eric L. Wallace,[1] James C. Harms,[1] Christopher D. Adams.[2] *[1]Univ of Alabama, Birmingham, AL; [2]East Alabama Medical Center, AL.*

Introduction: Calciphylaxis is characterized by systemic medial calcification of the arterioles that leads to ischemia and subcutaneous necrosis. It is rarely reported in ESRD patients but even more rarely seen in non-ESRD patients. Treatment strategies are also less defined in non-uremic calciphylaxis with only three cases reporting the use of IV sodium thiosulfate (STS) and no cases reporting treatment with intralesional STS.

Case Description: Case: A 61-year-old female with a history of rheumatoid arthritis, chronic corticosteroids, TNFα inhibitors, Tociluzumab, Abatacept, Tofacitinib, Anakinra and recently started on denosumab developed a left lower extremity lesion that started as papular erythema and progressed to have a necrotic center. Laboratory examination revealed GFR ranging 55 to 77 mL/min and normal serum calcium and phosphorus. Vitamin D was elevated at 111 ng/ml. PTH was elevated at 320 pg/ml. Fibroblast Growth Factor 23 level was only mildly elevated. Anticardiolipin antibody was normal. Other negative work up included, negative PR3 and MPO. Biopsy was consistent with calciphylaxis. The leg wounds continued to worsen until intralesional STS was instituted. Her initial lesion improved significantly, however, further lesions developed on her opposite leg and as such plans to institute IV STS are underway.

Discussion: Intralesional sodium thiosulfate may be a useful strategy for treatment of non-uremic calciphylaxis but based on the appearance of new lesions may not be adequate in all cases if systemic calciphylaxis is present.

PUB528

Aggressive IgA Nephritis Presenting with Microangiopathic Hemolytic Anemia

Andrea L. Oliverio. *Internal Medicine - Nephrology, Univ of Michigan, Ann Arbor, MI.*

Introduction: Microangiopathic anemia (MAHA) is not a classical feature in IgA vasculitis; though, recent case reports have suggested aberrations in the alternative complement cascade may contribute to this phenotype. Here, we describe an aggressive case of IgA vasculitis presenting with acute on chronic nephritis and MAHA without any detectable abnormalities in the alternative complement cascade.

Case Description: A previously healthy 19 year old Caucasian female presented with a six week history of headache, nausea, and abdominal pain. Three weeks after the initial onset of symptoms, she developed arthralgias and decreased urination without hematuria. At presentation, she complained of edema. On exam, she appeared pale with 1+ lower extremity edema but had no rash. Her initial laboratory tests revealed BUN 65 mg/dl, creatinine 14 mg/dL, hemoglobin 7.8 mg/dL, and platelets 70 k/UL. Haptoglobin was undetectable and peripheral smear had rare schistocytes. Serologic testing including ASO, ANA, dsDNA, complements, ANCA, anti-GBM, ADAMTS-13 as well as stool studies were negative. She was started on renal replacement therapy and plasmapheresis. She had a renal biopsy which showed acute on chronic crescentic and necrotizing glomerulonephritis as well as a thrombotic and necrotizing arteriolitis with IgA deposits in the vascular wall in addition to the glomeruli. She had extensive interstitial fibrosis and tubular atrophy. Though her renal function was not thought to be salvageable, the severe vasculitis and MAHA were treated with high dose Solumedrol and Rituximab. Her hemoglobin stabilized, her thrombocytopenia resolved, and haptoglobin remained low but was now detectable. Genetic analysis for complement abnormalities detected no known mutations and complement activation panel was normal, making atypical hemolytic uremic syndrome less likely.

Discussion: This case was confounded by the aggressive IgA vasculitis leading to MAHA. Recent studies have suggested that adding immunosuppressive therapy to intensive supportive care in IgA vasculitis and advanced nephropathy yields no significant outcome benefit. In this unique case, despite the poor renal prognosis, the severe vasculitis prompted use of immunosuppression to curb ongoing MAHA.

PUB529

Isolated Hyperphosphatemia with Suppressed Urinary Phosphate Excretion in a Patient with Undifferentiated Leukemia

Maryam Gondal, Anushree C. Shirali. *Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Introduction: Chemotherapy is mainstay treatment of malignant diseases, providing improved survival for patients, but have adverse effects including electrolyte abnormalities.

Case Description: A 27-year-old female presented with thrombocytopenia and leukopenia which prompted hematology consult. A bone marrow biopsy was performed and revealed acute myeloid leukemia with dysplastic changes. She was admitted for induction therapy with cytarabine and idarubicin. . Her serum phosphate which was 3.9 mg/dL two months earlier had increased to 5.2 despite normal kidney function (Table 1). Post-induction , phosphate level continued to rise to a peak of 7.1 mg/dL, requiring initiation of sevelamer. In addition to labs in Table 1,Serum potassium and alkaline phosphate (AlkP)were normal. She had no evidence of glucosuria or aminoaciduria.One month later, she was re-induced with mitoxantrone, etoposide, and cytarabine. She continued to have isolated hyperphosphatemia. FGF-23 levels were measured at 101 Ru/ml when serum phosphorous was at 6 mg/dL.

	phosphate on admission (mg/dL)	serum creatinine (mg/dL)	FePo4	Ca (mg/dL)	Mg (mg/dL)	PTH (pg/ml)	1.25 Vitamin D (pg/ml)	24 Hr urine calcium (mg/TV)
1st admission	5.2	0.5	<1%	9-9.5	2-2.1	53	16	
2nd admission	5.0	0.5	2.2%	8.9-10.2	1.8-2.1	21	10	75.7

She remains on phosphate binders to maintain normal serum phosphorous levels.

We report a case of hyperphosphatemia in a patient with normal kidney function but markedly suppressed urinary phosphate excretion. Normal AlkP and potassium argue against rapid release of phosphate from cellular or bone stores. There was no history to suggest chronic ingestion of high amounts of phosphate. Serum PTH was normal and 1,25 Vit D was appropriately suppressed.In this case, suppressed urine phosphate excretion with normal kidney function suggests an isolated proximal tubule defect for phosphate excretion. FGF-23 levels were appropriate for the serum phosphate indicating that she has a normal feedback.

Discussion: We suspect the patient may have renal resistance to FGF-23, perhaps mediated by Klotho and associated either with her malignancy or cytarabine.

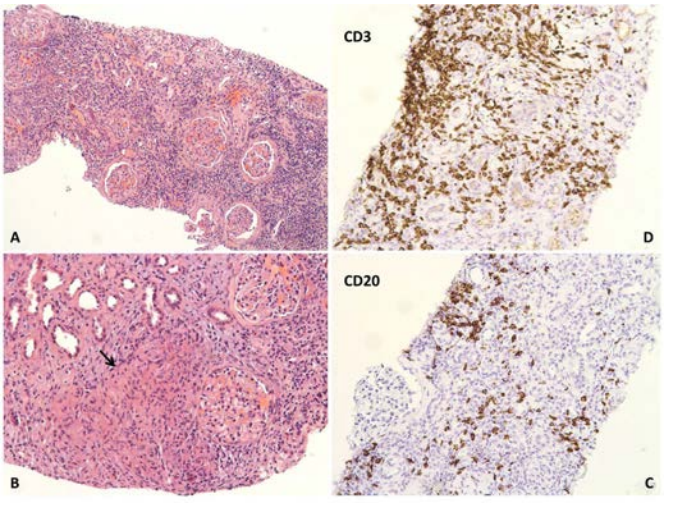
PUB530

Idiopathic Granulomatous Interstitial Nephritis: A Diagnosis Dilemma

Adeleye Annick Edon, Sadiq Ahmed, B. Peter Sawaya. *Nephrology, Bone and Mineral Metabolism, Univ of Kentucky, Lexington, KY.*

Introduction: Granulomatous interstitial nephritis (GIN) is a rare histologic diagnosis found in 0.5% to 0.9% of native renal biopsies. The causes of GIN include medications, sarcoidosis, tubulointerstitial nephritis and uveitis, paraproteinemias and fungal infections. Herein we describe a case of idiopathic GIN and review the workup necessary to exclude secondary causes.

Case Description: A 45 year-old man with a history of positive hepatitis C antibody presents with a serum creatinine (SCr) level of 4.93mg/dl. It was 3.69mg/dl 2 weeks prior, 2.7mg/dl 6 months prior and 0.8mg/dl 2 years earlier. His BP was 138/84; he denied: dysuria, skin rashes, arthralgia, and taking any medications. The urinalysis showed 20mg/dl of protein, 9WBCs, 2RBCs, no cellular casts. Spot urine protein/creatinine ratio was 0.4mg/mg. The following labs were either normal or negative: C3/C4, hepatitis C viral load, Hepatitis B antibodies, anti MPO, anti PR3, ANCA, ANA, ACE level, quantiferon TB gold, cryoglobulins, aspergillus, histoplasma, blastomyces and coccidioides antibodies. A kidney biopsy revealed GIN. Staining for bacteria, mycobacteria, IgG4 was negative. It showed T lymphocytes without monoclonality.



B: Nonnecrotizing granuloma, black arrow. A chest and abdomen CT were unremarkable. Given the progressive rising SCr, that peaked at 6.37, he received 1 gram of solumedrol intravenously for 3 days, followed by 60mg of prednisone. The SCr improved to 4.3mg/dl seven days after treatment. He never required dialysis. Thirty days after initial presentation, the SCr level was 3.7 mg/dl.

Discussion: The workup was negative for secondary causes of GIN. Ruling out infectious etiologies is a priority. Timely initiation of steroid therapy proved beneficial. Further response to the current therapy will determine the need for steroid-sparing agents namely azathioprine or mycophenolate mofetil.

PUB531

Recurrent Thromboembolic Phenomenon: An Unusual Complication in Immunoglobulin A Nephropathy

Wasawat Vutthikraivit,[1] Weera Sukhumthammarat,[1] Prapaipan Putthapiban,[1] Ekamol Tantisattamo.[2] *[1]Mahidol Univ; [2]Oakland Univ William Beaumont School of Medicine.*

Introduction: Thromboembolic phenomenon (TEP) is a rare extrarenal manifestation of immunoglobulin A nephropathy (IgAN). We report a case of man with IgAN complicated by early recurrent unprovoked TEP.

Case Description: A 68-year-old man with IgAN presented with sudden onset of dyspnea 6 months after he was diagnosed with IgAN. He was treated with antibiotics for pneumonia without improvement. Further work-up revealed an acute right popliteal deep venous thrombosis (DVT) and V/Q scan showed high probability for pulmonary embolism. Serum creatinine (SCr) was at baseline of 2.2 mg/dL and urinary total protein to creatinine ratio (UPCR) was 1 g/g of Cr. Serum albumin was 3.1 g/dL. All hypercoagulable work-up were negative. He was treated with heparin and prolonged warfarin given unprovoked TEP. He presented with purpuric rashes with central necrosis on both shins 1 year later. He also had recurrent acute DVT at the same area. Since warfarin-induced skin necrosis was a possibility, warfarin was switched to enoxaparin. He also developed RPGN-type picture with an elevated SCr up to 3.19 mg/dL and UPCR was up to 3.3 g/g of Cr. Renal biopsy was performed and showed IgAN without crescent. He was treated with high dose steroids without improvement of renal function. Nine months later, SCr trended up to 4.16 mg/dL and UPCR was in nephrotic range of 4.4 g/g of Cr (Figure 1). He was referred for pre-kidney transplant evaluation. All routine age-appropriate cancer screening was negative.

Discussion: Our patient presented with an early onset of TEP and slightly hypoalbuminemia; however, he had nephrotic range proteinuria with normal serum albumin at the second episode of DVT. Although IgAN complicated by TEP is not as common as membranous glomerulonephritis, TEP could occur even without a known risk factor such hypoalbuminemia.

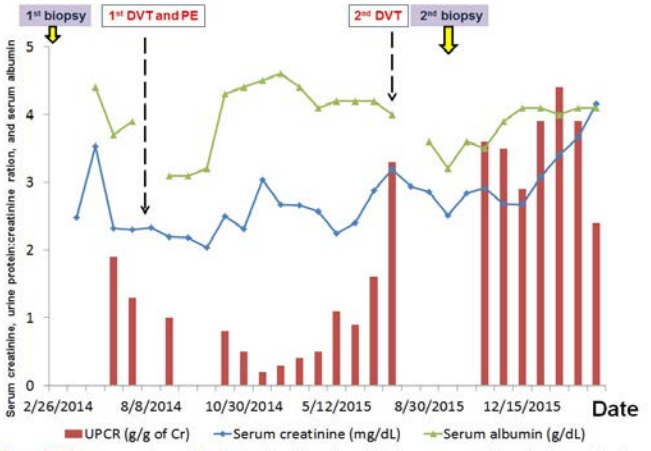


Figure 1: Clinical course demonstrates 2 episodes of thromboembolic phenomenon and the patient's renal function, degree of proteinuria, and serum albumin. *Cr, creatinine; DVT, deep venous thrombosis; PE, pulmonary embolism*

PUB532

Bevacizumab Induced Nephrotic Range Proteinuria Managed with Dual RAAS Blockade Haritha Karuparti, Jason Prosek. *Nephrology, Ohio State Univ, Columbus, OH.*

Introduction: Nephrotic range proteinuria (NRP) caused by vascular endothelial growth factor (VEGF)inhibitors like bevacizumab is a known entity. Patients who develop NRP are at risk for renal and cardiovascular adverse events. While guidelines recommend discontinuing bevacizumab (BZ) in NRP, there is no evidence-based protocol for management of proteinuria. We report a case of a BZ induced NRP managed with dual renin-angiotensin-aldosterone system (RAAS) blockade.

Case Description: 35-year-old Caucasian man underwent resection of glioblastoma followed by chemo-radiation. He began BZ (10mg/kg) every 2 weeks with temozolomide for progression of disease. After 6 cycles, he developed hypertension (HTN) and was started on amlodipine. After 9 cycles 6gm proteinuria developed. BZ was held and he was referred to Nephrology. Amlodipine was replaced by Lisinopril. After 4 weeks, proteinuria decreased to 3 g/day. BZ was resumed at 21 day- cycles. Since BP remained elevated, losartan was added. After 8 weeks of maximal-RAAS blockade, proteinuria declined to 1 g/day. BZ was then resumed at 14 day-cycle. Given dry cough, lisinopril was replaced with eplerenone . After 14 cycles of BZ, proteinuria remains 0.5-1.0 g/day. No adverse effects were noted, with normal renal function and potassium.

Discussion: Renal adverse outcomes from VEGF-inhibitors are NRP and HTN. Etiology of VEGF-inhibitor induced NRP include loss of endothelial fenestration podocyte dysfunction and in rare instances thrombotic microangiopathy. Implications of asymptomatic proteinuria are unknown. However, overt proteinuria is a known risk factor for chronic kidney disease and cardiovascular adverse events. Our case is unique for several reasons. First, it demonstrates the beneficial effects of dual RAAS blockade for NRP. While dual RAAS blockade is not tolerated in patients with vascular disease it may be a viable option in young patients when monitored closely. Second, when BZ was resumed, NRP did not recur while on dual RAAS blockade. This suggests that RAAS inhibitors may provide a direct protective effect on podocytes and endothelial cells. In the appropriate population, dual RAAS blockade is an effective longterm strategy to enable extended use of anti-VEGF targeted therapies.

PUB533

A Case of Azygos Vein Embolism Associated with Transient Antiphospholipid Syndrome in Urinary Tract Infection with *Escherichia coli* Sang Jo Han, Hong Joo Lee. *Dept of Nephrology, Seoul Red Cross Hospital, Seoul, Korea.*

Introduction: The classical antiphospholipid syndrome (APS) is characterized by the presence of antiphospholipid antibodies (aPL)-that is, lupus anticoagulant or anticardiolipin antibodies- which bind target phospholipid molecules and are associated with recurrent fetal loss and thromboembolic phenomena. Many infections may be accompanied by increases in aPL and, in some, these increases may be accompanied by clinical manifestations of APS.

Case Description: A 73-year-old woman with diabetes admitted for treatment of an intertrochanter fracture of the femur and a urinary tract infection (UTI) with *Escherichia coli* developed thrombosis in her right azygos vein, which was thought to be associated with antiphospholipid and IgM anticardiolipin antibodies. After antibiotic therapy, antiphospholipid antibody was undetectable, and a repeat chest computed tomography revealed complete resolution of the azygos vein thrombosis.

Discussion: A wide variety of infections can be associated with thrombotic events in patients with transient antiphospholipid syndrome (APS), and this case serves as a reminder that we should consider the possibility of transient APS in patients who have venous thrombosis in the setting of a UTI.

PUB534

Calciphylaxis in Myeloma Multiple and Chronic Kidney Disease Fernanda Paula Feres Rios Da Costa, Alicia Imada, Luiz Fernando Christiani, Maria Izabel Neves de Holanda. *Nephrology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

Introduction: Calciphylaxis is a rare and serious complication observed mainly in secondary hyperparathyroidism to chronic Kidney Disease(CKD). Others diseases also can complicate with it: HIV, primary hyperparathyroidism and hematologic diseases such as multiple myeloma(MM). It is characterized by cutaneous ischemic necrosis, acute and progressive installation, secondary calcification of blood vessels of small or medium caliber. Diagnosis is done throughhistopathological analysis of the injuries. The pathogenesis is unclear. The treatment is prevention, maintenance of adequate levels of calcium and phosphorus.

Case Description: We report a case of a patient presented CKD and Myeloma multiple(MM) that evolved with Calciphilaxis secondary lesions one year after diagnoses.

G.C.S, 70 y/o,female, diagnosed in june/2015 MM after headache, dizziness, back pain and diarrhea. She denied comorbidities and medications use. The exams showedanemia, renal dysfunction, hyperkalemia, hypercalcemia, lytic lesions in skull and reduced sizes of kidneys. She started hemodialysis and the MM treatment using burtezomib and dexamethasone. During this period, she was admitted several times for infectious episodes and presenting refractory hypercalcemia. She didn't present a good response for the MM. In 02/2016 she was readmitted with pneumonia and evolved ulcerations in the lower limbs. The lesions started as erythematous areas, progressing to ulcerations of necrotic center and intense pain refractory to common analgesia. The venous/arterial doppler excluded thrombosis and skin biopsyshowed calciphylaxis. We started alendronate, low calcium in hemodialysis, phosphate binder(renagel) and dexamethasone as therapy for the underlying disease. Patient died few days after with sepsis and worse in lesions. There are few reports in the literature relating MM and calciphylaxis.

Discussion: This case demonstrated an aggressive calciphylaxis manifestations inone year of Chronic kidney disease. The lack of response of the underlying disease influenced the severity. Calciphylaxisis a rare complication and has high morbidity and mortality, our knowledge is important to prevent its appearance.

PUB535

Leaky Pipes: A Case Report of Pseudo-Azotemia Secondary to Intraperitoneal Extravasation of Urine following a Urological Procedure Payam Pourhassani, Christopher Richard Kern, Sandeep Aggarwal. *Internal Medicine, Drexel Univ College of Medicine, Philadelphia, PA.*

Introduction: Azotemia is a marker of net nitrogen balance that depends on both production and excretion. Consequently, BUN and creatinine may rise in the absence of kidney injury or reduction of GFR if either process is impaired, leading to "pseudo-azotemia." We report a case of a post-operative increase in serum creatinine secondary to a urinoma (pararenal pseudocyst), initially labeled as acute kidney injury.

Case Description: A 50-year-old male with history of prostate cancer underwent robot-assisted laparoscopic prostatectomy with bilateral pelvic lymph node resection. On post-operative day 1, he became oligoanuric and had a sudden rise in serum creatinine which peaked at 8.74 mg/dL. However, he was without uremic signs/symptoms, dyselectrolytemia, or severe acidosis. He subsequently had a retrograde urogram with Cystografin that showed extravasation at the ureterovesical interface. He had an IR drain placed, followed by surgical placement of bilateral ureteral stents with complex foley placement, to ensure that the ureteral orifices were not draining outside of the ureterovesical anastomosis. On the following day his creatinine decreased from 8.74 to 3.31 mg/dL; his discharge creatinine was 2.22 mg/dL.

Discussion: The elevation of serum biomarkers of renal failure (i.e. BUN and creatinine) following bladder rupture is well elucidated and occurs from diffusion of solutes from the extravasated urine through the peritoneal membrane. Patients can develop uremic symptoms requiring hemodialysis if the diagnosis is delayed. Where available, kidney injury biomarkers like NGAL/KIM1 may be helpful in determining true renal tissue injury.

Fortunately, with timely diagnosis and removal of the source of urinary leakage, serum biomarkers often return to normal very quickly as long as there is no concomitant renal injury from another cause.

PUB536

Rare Case of Histiocytic Glomerulopathy with Spontaneous Resolution of Nephrotic Syndrome Tarek Rashid,[1] Kamaldeep Singh,[2] Belinda Jim,[1] Glen S. Markowitz,[3] Kisra Anis.[1] *[1]Dept of Medicine, Jacobi Medical Center, Bronx, NY; [2]Dept of Medicine, North Central Bronx Hospital, Bronx, NY; [3]Dept of Pathology&Cell Biology, Columbia Univ Medical Center, New York, NY.*

Introduction: Histiocytic glomerulopathy (HGP), a recently described glomerular pathology, is characterized by prominent glomerular histiocytic infiltrates. Clinically, it can present with the onset of acute kidney injury (AKI) and nephrotic syndrome and has mainly been reported in association with hemophagocytic syndrome (HPS). **CASE PRESENTATION:** A 33-year-old Female, from Bangladesh, with a past medical history of hypothyroidism, migraines, and occasional NSAID use, presented with a non-specific febrile illness associated with low grade fever, myalgia, arthralgia and dysuria, suspected to be urinary tract infection and treated with NSAIDs and nitrofurantoin.She returned a week later with nausea, vomiting, AKI (creatinine 1.6 mg/dl), and new onset of nephrotic syndrome. Patient was normotensive and physical exam was remarkable for 3+ edema. Urinalysis showed small blood with 0-6 RBC,>300mg/dl protein. Urine protein to creatinine ratio was 14 g/g with a bland urine sediment on microscopy. She had hypoalbuminema, mildly elevated AST/ALT, LDH, triglycerides and ferritin, positive ANA, and depressed C3 and C4 levels. All Other serologies were normal. She had a decreas in her Hgb and platelets during the course of illness. Renal ultrasound was unremarkable. Kidney biopsy showed glomeruli with prominent infiltrating monocytes/histiocytes, endothelial swelling, and foot process effacement, most consistent with histiocytic glomerulopathy. Over the course of 2 weeks, in the absence of immunosuppressive therapy, we witnessed spontaneous resolution of her symptoms and nephrotic syndrome. **DISCUSSION:** HGP is typically associated with (HPS) which can occur in the setting of acute viral infection, autoimmune disease, or malignancy. Our patient did not meet the current diagnostic criteria for HPS on presentation. This is the first reported case of HGP with nephrotic syndrome, occurring without definitive evidence of HPS, with an extremely short self-limiting clinical course.

PUB537

An Interesting Case and Treatment Dilemma Involving a Progressive Immune Complex Mediated Membranoproliferative Glomerulonephritis Abdul Hameed Zaid, Robert D. Zenenberg. *Internal Medicine, Saint Barnabas Medical Center, Livingston, NJ.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) is a pattern of glomerular injury with mesangial and endocapillary proliferation, and glomerular basement membrane thickening. Recently, greater understanding of the pathophysiology has led to subsequent reclassification based on immunoflourescence. Immunoglobulin staining with complement suggests an immune complex mechanism from certain infections, autoimmune diseases or a monoclonal gammopathy. Isolated complement staining suggests disorders of alternate complement pathway. We present an interesting case and treatment dilemma of an immune complex mediated MPGN.

Case Description: A 61 year old Chinese man presented with progressive renal insufficiency and proteinuria. He had chronic Hepatitis B (HBV) leading to end-stage liver disease undergoing an orthotopic liver transplant 4 years earlier, and was on Mycophenolate and Entecavir®. History included a CNS lymphoma and subsequent systemic lymphoma, both treated successfully years earlier. At presentation, creatinine had worsened (1.3 mg/dL to 4 mg/dL over 1 year) with edema and nephrotic range proteinuria. He had undetectable HBV viral loads, negative hepatitis C and ANA as well as negative immunofixation and free light chain assay. CT scan of the abdomen showed no evidence of lymphoma. Further studies showed mildly reduced serum C3, normal C4 and mildly elevated Type III cryoglobulin. Renal biopsy showed immune complex MPGN with cryoglobulin deposits found on closer scrutiny. Corticosteroid therapy led to dramatic improvement in creatinine (to 1.8mg/dL) and proteinuria over several months.

Discussion: This patient presented with a polyclonal immune complex mediated MPGN and had a history of both HBV and lymphoproliferative disease. Steroids should generally be avoided in HBV mediated MPGN, but this patient had persistently undetectable viral loads. The possibility of recurrent lymphoproliferative disease or an infectious process causing the Type III cryoglobulinemia was certainly possible, but was not evident. Considering the progressive nature of the glomerular disease, more aggressive immunosuppression to target the cryoglobulins was warranted.

PUB538

Bile Cast Nephropathy Complicating Primary Sclerosing Cholangitis Sang Jo Han, Hong Joo Lee. *Dept of Nephrology, Seoul Red Cross Hospital, Seoul, Republic of Korea.*

Introduction: Bile cast nephropathy(BCN), a condition of renal dysfunction in the context of cholestatic liver dysfunction is not uncommon. While the exact etiology remains unknown, BCN is presumed to be secondary to multiple concurrent insults to the kidney including direct toxicity from bile acids, obstructive physiology from bile casts, and systemic hypoperfusion from vasodilation. Primary sclerosing cholangitis(PSC) is a chronic cholestatic liver disease of unknown cause and long-standing, progressive course, leading to cirrhosis and requiring orthotropic liver transplant. The association with PSC and BCN has been reported previously in very limited number of cases.

Case Description: A 27-year-old male was admitted with jaundice and dark-colored urine. Laboratory tests showed progressive obstructive jaundice including high bilirubin levels and anuric renal failure requiring prolonged hemodialysis. Computed tomography of the hepatobiliary system revealed normal intrahepatic and extrahepatic duct size with normal common bile duct without any sign of hepatobiliary duct obstruction. Liver biopsy showed primary sclerosing cholangitis. A kidney biopsy, performed a few days after the initiation of dialysis, demonstrated the presence of bile casts along with acute tubular injury. The patient is continuing to be hemodialysis and waiting for liver transplantation.

Discussion: We present here an unusual case of kidney injury secondary to BCN occurring in a context of PSC.

PUB539

Treatment of Recurrent Focal Segmental Glomerulosclerosis (FSGS) in a Post Kidney Transplant Recipient with Adrenocorticotropic Hormone (ACTH) Gel Jose F. Ramirez-Porres,[1] Amr El-Husseini Mohamed,[1] Virgilius Cornea,[2] Nada Alachkar.[3] *[1]Medicine, Univ of Kentucky, Lexington, KY; [2]Pathology, Univ of Kentucky, Lexington, KY; [3]Transplant, johns Hopkins, Baltimore, MD.*

Introduction: ACTH has shown efficacy in idiopathic FSGS and other glomerulopathies. The data on using ACTH to treat recurrent FSGS post renal transplantation is limited. This case report describes our experience using ACTH in treating recurrent FSGS in a live donor kidney transplant.

Case Description: A 38 year old male who underwent live-related kidney transplant secondary to primary FSGS, presented with elevated creatinine, microscopic hematuria and nephrotic range proteinuria approximately two months after transplant. Serum creatinine increased to 1.8 mg/dl from a baseline of 1.3 mg/dl. Spot urine protein creatinine ratio (UP/C) was 2.5 mg/mg.

Graft biopsy revealed findings suggestive of vasculitis and early recurrent FSGS. P-ANCA and C-ANCA serologies were negative. Patient received 3 days high dose pulse intravenous steroids, 3 months of oral cyclophosphamide then switched to Rituximab therapy due to lack of response. Serum creatinine went up to 3.34 mg/dl and UP/C to 6.1 mg/mg. A second graft biopsy revealed only recurrent FSGS. ACTH 40 units subcutaneous twice a week was started and then increased to 80 units subcutaneous twice a week. Four weeks after initiating a repeat serum creatinine was 2.25 mg/dl and UP/C decreased to 4.2 mg/mg. Three months later serum creatinine increased again to 3.5 mg/dl and UP/C increased to 6.2 mg/mg. A third graft biopsy revealed more advanced recurrent FSGS so every other day plasma exchange was started and Achtar gel was continued along with mycophenolate mofetil and prograf. Kidney function continued to decline slowly with progressive rise of serum creatinine to 4.5 mg/dl and UP/C persisted around 6 gm.

Discussion: The response to ACTH treatment in this case with post-transplant recurrent FSGS was not satisfactory. Early initiation of plasma exchange is necessary to remove circulating permeability factors. Further research is necessary to determine if ACTH may be a useful therapy in patients with recurrent FSGS.

PUB540

Diet and the Domino Effect in Oxalate Nephropathy Rungwasee Rattanavich, Laura J. Maursetter, Tripti Singh, Gauri Bhutani. *Nephrology, Univ of Wisconsin, Madison.*

Introduction: Oxalate nephropathy (ON) is an under-recognized entity, important to consider in individuals at risk for fat malabsorption since timely intervention may preserve renal function.

Case Description: 65 year-old male, baseline serum (S.) creatinine (Cr) 1.0 mg/dL, was admitted after incidental discovery of elevated Cr (4.6 mg/dl). He was non-oliguric and denied any acute events/symptoms other than incarceration 1 year back. He had known history of alcoholism, diabetes, hypertension, extrahepatic biliary excision and Roux-en-Y hepaticojejunostomy (2003) for cholangiocarcinoma. His only medication was triamterene-hydrochlorothiazide. Physical exam: BP-154/81mmHg, no edema. Urinalysis: Sp. gravity 1.008, occasional WBCs and renal epithelial cells. A renal biopsy revealed massive calcium oxalate (ox) crystal deposits, interstitial nephritis, and severe chronicity. Daily hemodialysis (HD; Pre-HD Cr 5.37 mg/dl), dietary changes (low ox/fat diet), oral citrate, oxalate binders and pancreatic enzymes were initiated. Diuretics were changed to calcium channel blocker. 24-hr urine revealed severe hyperoxaluria (HO), hypocitraturia and hypocalciuria- 90, <27, 53 mg/day, respectively. Fecal fat level was very high (26.3 g/day) but Pre-HD S. ox only mildly elevated at 11.0 umol/L. HD was halted due to low likelihood of benefit at this ox level. On further review, patient continued to deny diarrhea but prior CT scans disclosed chronic pancreatitis. Dietary history revealed ample peanut butter intake following incarceration. He was discharged on above dietary/pharmacologic measures with a stable Cr of 5.2 mg/dl. Follow up 4 weeks later was notable for improved Cr of 4.34 mg/dL.

Discussion: Our case highlights several known and novel aspects of OH: (a) the domino effect of fat malabsorption, diuretic use and ox/fat rich diet (peanut butter) in OH;(b) Biliary diversion may be a risk factor for OH; (c) severe ON/HO may occur even in setting of only mild S. ox elevation; (d) HD, dietary/pharmacologic measures may result in preservation of renal function although the exact role of these interventions remains poorly defined in literature. Continued incarceration and resultant restricted dietary choices, unfortunately, remain a limiting factor for our patient.

PUB541

Rapidly Progressive Glomerulonephritis: Cause or Consequence of Developing Posterior Reversible Encephalopathy Syndrome

Giovanna Y. Arteaga Muller, Lilia Maria Rizo Topete, Allina Primavera Flores Mendoza, Elisa Maria Guerrero Gonzalez, Jose Guadalupe Martinez Jimenez, Concepcion Sanchez Martinez, Jesus Cruz Valdez. *Nephrology, José Eleuterio González of the Autonomous Univ of Nuevo León, Monterrey, Mexico.*

Introduction: Rapidly progressive glomerulonephritis it is characterized by quick deterioration of renal function. Early diagnosis and immunosupressive therapy plays a key role in kidney survival. More than half of these cases advance into end stage renal disease, this group of diseases are at risk of developing posterior reversible encephalopathy syndrome (PRES). PRES consists of acute neurological symptoms caused by endothelial disfunction, which results in vasogenic cerebral edema mainly in white matter, generated in most cases by severe changes of hypertension, but 15-20% of patients have normal or low blood pressure, so it has been attributed to direct endothelial damage caused by immunosupressant drugs, preeclamsia, and autoimmune disease. Diagnosis is based on clinical symptoms, radiological findings in posterior brain and the pattern of the frontal superior sulcus as well as their reversibility.

Case Description:

Etiology of Rapidly Progressive GMN	Good Pasture syndrome (anti glomerular basement membrane disease)	Pauci-immune GMN (granulomatosis with poliangitis)
Age	22	24
Gender	Female	Female
Neurological symptoms	Headache, encephalopathy, epileptic status	Headache, encephalopathy, epileptic status
Blood pressure at time of evaluation	180/100 mmHg	140/90 mmHg
Systemic involvement of base disease	Lung hemorrhage	Nasal involvement
Treatment for base disease	Metilprednisolone/prednisone/ Cyclophosphamide, Plasmapheresis 10 sessions	Metilprednisolone/prednisone/ Cyclophosphamide Plasmapheresis 4 sessions
Kidney function at time of PRES developement	Patient in chronic hemodialysis 3 months after diagnosis	Patient in chronic hemodialysis 3 months after diagnosis
MRI findings Hyperintense areas in T2		

Discussion: Kidney injury is present in at least 55% of PRES cases. Its association is affected by accompanying presence of hypertension or autoimmune disease, as we can see in case 1 which presented with severe hypertension. Of the established risk factors for PRES both cases present autoimmune disease, kidney injury and the use of immunosupressive therapy. It is important to define if rapidly progressive kidney dysfunction, systemic involvement of base illness, age and gender could be considered independent risk factors for developing PRES. Prospective studies that determine associations, manifestations and prognosis must be continued so that a risk scale can be established which can determine if the sum of these factors increase the risk of developing PRES.

PUB542

Air Embolism: A Rare Complication of Tunneled Dialysis Catheters

Trevor R. Smith, Josephine Abraham. *Nephrology and Hypertension, Univ of Utah, Salt Lake City, UT.*

Introduction: Air embolism is a feared complication of hemodialysis, typically associated with the dialysis procedure itself. Here we report a case of air embolism associated with tunneled dialysis catheter placement.

Case Description: A 60 year old male with ESRD frompolycystic kidney disease (PKD) presented to the hospital with a bleeding left upper extremity AVF and found to have MSSA bacteremia. A temporary dialysis catheter was inserted without complication. The patient was found to have MSSA endocarditis by echocardiogram, with a large vegetation on the mitral valve. The patient underwent ligation of the brachiocephalic fistula due to friable vessel tissue. He subsequently underwent placement of a tunneled dialysis catheter. In the recovery unit, the patient had an acute onset of right sided weakness and slurring of speech. A head CT revealed air in the left frontal and parietal lobes. Echocardiogram with agitated saline contrast demonstrated a late left to right shunt that did not augment with Valsalva maneuver, which is suggestive of an intrapulmonary shunt. The patient was started on high flow oxygen. It was determined that he was a poor candidate for hyperbaric therapy due to his history of COPD and metastatic squamous cell lung cancer. The family then decided to withdraw aggressive medical care and patient died a few hours later.

Discussion: Air emboli can occur at various stages of dialysis catheter use: insertion, manipulation, use or removal. Complications of air emboli depend on the vascular source of the embolization. Typically, use of veno-venous dialysis catheters will result in pulmonary manifestations of air embolization, characterized by dyspnea, tachypnea, wheezing, rales or respiratory failure. In the presented case, the patient exhibited signs of arterial embolization with neurologic compromise. This venous to arterial shunting can be due to a patent foramen ovale, ventricular septal defect, or presence of a pulmonary arteriovenous malformation (AVM). In this patient, he was suspected of having an AVM as a consequence of untreated lung cancer. Although rare, air emboli can cause sudden symptoms of decompensation and the risk of air embolization should be considered when using dialysis catheters.

PUB543

Seronegative Renal Limited Lupus Nephritis

Amit K. Rajput, Paisit Paueksakon, Paul Persad, Roy Zent. *Vanderbilt Univ Medical Center.*

Introduction: Lupus Nephritis (LN) is a common manifestation of systemic lupus erythematosus (SLE) that often presents early in the disease process. However, previous case reports discuss a specific patient population (typically females, childhood to middle aged) that demonstrate LN without meeting American College of Rheumatology (ACR) criteria and have negative serologic markers. Here, we discuss a unique presentation of seronegative LN in an elderly Caucasian male.

Case Description: A 69 year-old male with chronic kidney disease stage 3 from long-standing hypertension was referred to Nephrology for a persistent acute kidney injury (AKI) and new onset hematuria. The patient was admitted three months prior to presentation for altered mental status, attributed to severe sepsis from *S. pneumoniae* pneumonia. The hospital course was complicated by oliguric AKI (Cr 3.0mg/dL from baseline 1.2mg/dL), hypertensive urgency, and hematuria that was attributed to traumatic foley insertion. Despite clinical improvement, the patient had unremitting AKI and hematuria along with newly discovered 7.96g proteinuria. Serologic work up, including ANA, Anti-DNAse B, ASO titers, Anti-Smith, Anti-dsDNA, SPEP/UPEP, ANCA, RF, HIV, Hepatitis Panel, and cryoglobulins were negative. However, the patient was found to be hypocomplementemic (C3: 48mg/dL, C4: <8.0mg/dL), prompting a renal biopsy. Pathology demonstrated classic full house immunofluorescence staining with Focal Proliferative Immune Complex Glomerulonephritis and mild-to-moderate arterionephrosclerosis. The patient was treated with cyclophosphamide IV once monthly for six months along with a prednisone taper. Six months after initiation of treatment, the patient is showing full recovery to baseline (Cr 1.2mg/dL and 0.2g proteinuria).

Discussion: LN is a serious complication of SLE with rapid progression to end-stage renal disease (ESRD) if not diagnosed and treated in a timely manner. Prompt recognition and initiation of treatment are essential for reducing morbidity and mortality. As evident by our patient, relying on ACR classification criteria or serologies alone to diagnose LN can lead to delays in treatment, with an increased risk to ESRD progression.

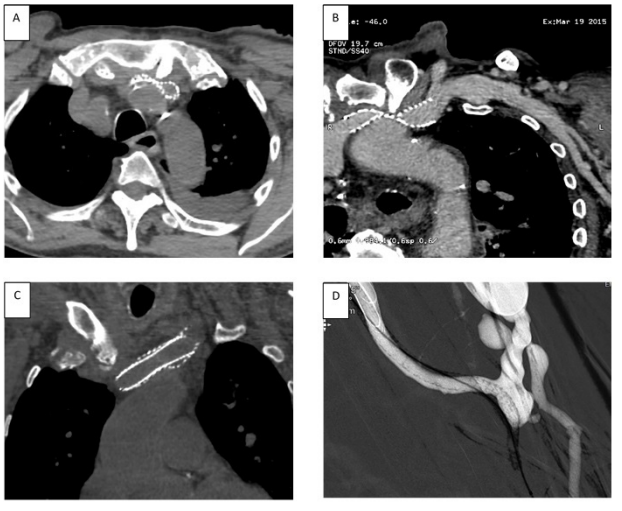
PUB544

A Venous Anonime Stenosis at Costo-Clavicular Junction (CCJ)

Lisa Giovannini,[1] Walter Morale,[2] Gianni Cappelli.[1] [1]*Surgical, Medical and Dental Dept of Morphological Sciences, Section of Nephrology, Univ of Modena and Reggio Emilia, Modena, Italy;* [2]*Dept of Nephrology and Dialysis, Cannizzaro Hospital, Catania, Italy.*

Introduction: Central venous stenosis (CVS) is a frequent complication in hemodialysis (HD) patients. Venous obstruction at the costoclavicular junction (CCJ) requires a different approach beyond PTA and stenting.

Case Description: A 82ys-old man on HD with left radio-cephalic arterovenous fistula (AVF) presented severe edema of AVF arm. Ultrasounds (US) did not show significant venous stenosis. TC showed a severe stenosis of the left brachiocephalic vein so we performed multiple PTA and placing of a 16x60-mm stent. Unfortunately, edema recurred and MS-TC showed an instent-stenosis by left clavicle bony hypertrophy. Vascular surgery performed one third anterior claviculectomy. After surgery for persistent intra-stent stenosis of left brachiocephalic vein we placed 16x40-mm intra-stent Wall Stent Boston stent successfully. After 5 months patient was referred from peripheral dialysis unit for edema and distal ischemic lesions. US showed a decreased flow rate, significant stenosis of cephalic vein, thrombosis of basilic vein and ischemic steal syndrome. We performed endovascular closure of AVF with endoprothesis 6mmViabhan in radial artery.



Discussion: PTA and stenting are the primary option for treating stenosis surrounded by soft tissue. Vein stenosis adjacent to the CCJ poorly respond to PTA/stenting, and, generally, require bony decompression for long-term patency. On our experience, the surgical decompression allowed secondary stent placing intra-stent successfully**.** The long time duration of venous hypertension may cause irreversible arterial microcirculatory stasis and ischemic steal syndrome. Our experience highlights the importance of early diagnosis of CCJ venous stenosis and a multidisciplinary approach for its treatment.

PUB545

IgA Dominant Methicillin-Sensitive *Staphylococcus aureus*-Associated Rapidly Progressive Glomerulonephritis

Amit K. Rajput, Agnes B. Fogo, Paul Persad, Raymond C. Harris. *Vanderbilt Univ Medical Center.*

Introduction: Post-infectious glomerulonephritis (GN) typically refers to poststreptococcal GN, often seen after the infection has resolved. However, an uncommon entity has been demonstrated in the middle aged and elderly patient populations, in which active staphylococcal infections are associated with progressive renal failure. We present a case of rapidly progressive glomerulonephritis (RPGN) from an active Methicillin-sensitive staphylococcus aureus (MSSA) infection.

Case Description: A 72 year-old male with chronic kidney disease stage 3 from long-standing diabetes mellitus type 2 (DM2) was receiving nafcillin IV for a left foot diabetic ulcer with superimposed cellulitis (no osteomyelitis), which was complicated by oliguric acute kidney injury (AKI) with a serum creatinine 5.7mg/dL (from baseline 1.0mg/dL) and new onset hematuria. Investigation revealed MSSA septicemia, with the left foot wound as the infection source. During evaluation, the patient's renal function declined precipitously, warranting an urgent renal biopsy and initiation of renal replacement therapy (RRT). Pathology demonstrated endocapillary proliferation and exudative proliferative glomerulonephritis with IgA and C3 dominant deposits, characteristic of an infection-associated GN, in addition to mild-to-moderate diabetic nephropathy. The patient underwent urgent left below-the-knee amputation for infection source control, but despite intervention, renal function did not recover. The patient was declared end-stage renal disease (ESRD) and passed two months later from a non-renal related illness.

Discussion: As opposed to poststreptococcal GN, staphylococcal-associated GN presents with concurrent infection. Although the mechanism remains unclear, it is postulated that the infection provides an antigen to which an immune complex is formed and deposited in the glomerulus. Staphylococcal infections seem to be associated with IgA dominance on immunofluorescence, compared to IgG dominance in poststreptococcal GN, with skin wounds as the most common infection source. Furthermore, previous analysis suggests a correlation with underlying diabetic nephropathy and worse renal prognosis, as evident with our patient.

PUB546

Severe, Refractory Hypokalemia in a Patient with Systemic Lupus Erythematous Receiving Cyclophosphamide

Ali Iqbal, Mohammed Hadi Tawhari. *Nephrology, McMaster Univ, Hamilton, ON, Canada.*

Case Description: We describe a 42-year-old female patient with a history of systemic lupus erythematous who presented with severe, refractory hypokalemia following cyclophosphamide therapy. She was diagnosed with lupus at age 14 and previously had class III lupus nephritis treated with cyclophosphamide years prior to this admission. She was then maintained on mycophenolate and hydroxycholoquine with a normal eGFR and minimal proteinuria over next few years. She then developed steroid refractory musculoskeletal and cutaneous manifestations, eventually leading to the initiation of cyclophosphamide. Following her fifth infusion of cyclophosphamide, she presented to her community hospital with weakness, nausea and hypokalemia ranging from 1.5 to 2.5 mmol/L. Her relevant home medications included furosemide, metolazone, dexamethasone, and hydroxychloroquine. During her hospitalization, she required transfer to the intensive care unit for an episode of torsades de pointes due to hypokalemia. Her diuretics were held and she was started on parenteral and enteral potassium supplementation. 24 hour urine collection demonstrated urinary potassium of 147 mmol (25-125 mmol), normal urine calcium, magnesium, sodium, and total volume of 6.1 L. Serum bicarbonate was 30 mmol/L (22-29 mmol/L), with elevated supine serum renin and normal aldosterone levels. She was placed on indomethacin, amiloride, spironolactone and ramipril in an attempt to reduce urinary potassium wasting. She remained in hospital with persistent hypokalemia for over six months and was seen in consultation by nephrology, rheumatology, and endocrinology. She was eventually diagnosed with an acquired Bartter like syndrome either secondary to cyclophosphamide or due to an antibody mediated channelopathy. Given the possibility of an antibody-mediated etiology, a trial of IVIG was initiated followed by a trial of plasma exchange consisting of 7 sessions over a two-week period. Her potassium did seem to improve and stabilize following plasma exchange. She eventually was discharged home about a month later on about 100 mEq per day of potassium supplementation, amiloride, ramipril, as well as spironolactone.

PUB547

A Case of Antithyroid Drug-Induced Double ANCA-Positive Vasculitis

Miho Shikata, Fumihiko Furuya, Kenichiro Kitamura. *Third Dept of Internal Medicine, Univ of Yamanashi, Chuo, Yamanashi, Japan.*

Introduction: Antithyroid drugs are shown to induce antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). While both methimazole (MMI) and propylthiouracil (PTU) are potential causes of AAV, the incidence of PTU-induced AAV is 40-fold higher than that of MMI-induced AAV.

Case Description: A 68-year-old woman was admitted to our hospital because of acute kidney injury. She was diagnosed with Graves' disease and had been treated with MMI for 18 years. On admission, she presented proteinuria and microscopic hematuria, and both MPO- and PR3-ANCA were positive. Since MMI-induced AAV was suspected, MMI was discontinued right after the admission. Kidney biopsy revealed pauci-immune crescentic glomerulonephritis. Although intravenous methylprednisolone pulse therapy (1000mg/day for 3 days) followed by oral prednisolone 40mg daily was initiated, her renal failure was exacerbated and hemodialysis was started. Thereafter, urine volume was gradually increased and her renal function was recovered. Following the discontinuation of MMI, serum levels of PR3-ANCA were rapidly normalized and those of MPO-ANCA were decreased before the initiation of steroid therapy.

Discussion: We report a case of MMI-induced double ANCA positive vasculitis with acute kidney injury that was successfully treated with immunosuppressive agent. PTU has been demonstrated to produce multiple antigens including MPO-ANCA and PR3-ANCA. Antithyroid drug-induced AAV usually occurs in patients with Graves' disease who are resistant to drug treatment. Previous reports suggested the possibility that repeated administration of PTU alters the MPO structure surrounding the heme iron and the changes in MPO configuration induces the antigenicity. In our current case, prolonged administration of MMI could alter the MPO structure and induced AAV.

PUB548

A Rare Case of Hodgkin Lymphoma Complicated with Membranous Nephropathy in a Young Male Patient

Naomi Matsuo, Hideki Inoue, Yutaka Kakizoe, Yuichiro Izumi, Takashige Kuwabara, Masataka Adachi, Yushi Nakayama, Masashi Mukoyama. *Nephrology, Kumamoto Univ Hospital, Kumamoto, Japan.*

Introduction: The most common glomerulopathy associated with Hodgkin lymphoma (HL) is minimal change nephrotic syndrome, but other types of glomerulopathy including membranous nephropathy (MN) have rarely been reported. We here report a case of HL complicated with MN, who responded well to the treatment with chemotherapy and radiotherapy.

Case Description: A 16-year-old man was admitted to our hospital due to proteinuria and hematuria. His serum creatinine level was 0.63 mg/dL and urinary protein excretion was 2.18 g/g creatinine. Renal biopsy revealed MN (stage I-II). In the immunofluorescence study, IgG4 was most strongly stained for IgG subclass analysis; there was no evidence of glomerulopathy associated with amyloidosis or paraproteinemia. Only partial remission of proteinuria was obtained despite the treatment with 40 mg/d of oral prednisolone. Four months after starting oral corticosteroid therapy, slightly enlarged lymph nodes were noticed above the collarbone. Lymph node biopsy showed lymphocyte-depleted classical HL (stage II). He was treated with four cycles of ABVD (doxorubicin, bleomycin, vinblastine and dacarbazine) chemotherapy along with radiotherapy, and a complete hematologic response was achieved. Then, the patient showed drastic reduction in proteinuria after an effective treatment of HL.

Discussion: The association between MN and malignancy has well been documented, but HL-associated MN has rarely been reported. Remission in glomerular disease was achieved in accordance with hematologic remission by chemotherapy and radiotherapy, suggesting a causal relationship between the two diseases.

PUB549

Drug Induced Antineutrophil Cytoplasmic Autoantibody Vasculitis Secondary to Propylthiouracil

Elizabeth Upton,[1] Harsharan Kaur Singh,[2] William Franklin Pendergraft.[1] *[1]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [2]Div of Nephropathology, Univ of North Carolina, Chapel Hill, NC.*

Introduction: We describe a case of a 72-year-old male who developed antineutrophil cytoplasmic autoantibody (ANCA) vasculitis after treatment with propylthiouracil (PTU) for hyperthyroidism.

Case Description: A 72-year-old male with a ten-year history of hyperthyroidism treated with PTU presented for evaluation of acute renal failure. On routine labs, he was noted to have renal insufficiency with creatinine 2.5 mg/dL rising to 4.4 mg/dL on recheck from a baseline of 1.1-1.3 mg/dL. Urine microscopy revealed dysmorphic red blood cells and RBC casts. ANA, C3, and C4 complements were normal. MPO-ANCA titer was 118.4 U/mL. Renal biopsy revealed pauci-immune focal crescentic glomerulonephritis with 10% cellular to focal fibrocellular crescent formation, associated diffuse severe tubulointerstitial nephritis, marked peritubular capillaritis, and interstitial hemorrhage, suggesting drug associated ANCA vasculitis in the setting of PTU. Treatment was initiated with pulse dose steroids, 7 treatments of plasma exchange, cyclophosphamide 500 mg/m^2, and rituximab 1000 mg. One month later, he received an additional dose of cyclophosphamide 0.75 mg/m^2 and rituximab 1000 mg. Two months after treatment, creatinine was 1.2 mg/dL and MPO-ANCA titer was 11.3 U/mL.

Discussion: ANCA vasculitis is an autoimmune disorder affecting small vessels caused when autoantibodies to myeloperoxidase or proteinase 3 induce a systemic inflammatory response. Minocycline, hydralazine, levamisole-contaminated cocaine, and PTU are the most common drug culprits. PTU induced ANCA vasculitis typically manifests as a pauci-immune and crescentic necrotizing glomerulonephritis associated with high titer MPO-ANCA positivity. PTU or one of its metabolites may bind to MPO in neutrophils, creating a systemic immunogenic response. Permanent cessation of the offending agent is essential to treatment. Pulse dose steroids, plasma exchange, and immunotherapy are also indicated. Further studies are needed to elucidate the mechanism of autoimmunity in all forms of drug-induced ANCA vasculitis in order to more effectively develop targeted therapies.

PUB550

Recurrent Dense Deposit Disease: A Report of Two Cases with Varying Presentations, Pathologic Findings and Patient Outcomes
Dilini M. Daswatta,[1] Sharon M. Graves,[3] Carla L. Ellis.[2] *[1]Renal Div, Dept of Internal Medicine, Emory Univ, Atlanta, GA; [2]Pathology and Laboratory Medicine, Emory Univ, Atlanta, GA; [3]Emory Univ.*

Introduction: Dense Deposit Disease (DDD), previously classified as a subgroup of primary membranoproliferative glomerulonephritis (MPGN) is currently regarded as a type of C3 glomerulopathy due to developments in the understanding of complement-mediated glomerular disease. We report two cases of recurrent DDD with clinical presentations, pathologic findings and patient outcomes on divergent ends of a spectrum.

Case Description: The cause of end stage renal disease (ESRD) in both patients (male = 1 and female = 2) was MPGN, diagnosed in adolescence. Further similarities include an average of 5 years to renal replacement therapy (RRT), and an average of 3 years to (initial) recurrence. At recurrence, both displayed no evidence of cell/antibody mediated rejection. Both also displayed C3 predominant staining by immunofluorescence with linear and intramembranous dense deposits noted ultrastructurally. Patient 1 was retransplanted 4 years after initial failure secondary to recurrence and developed a second recurrence 8 years later. Proteinuria and serum creatinine at the second recurrence were 3.73 g/day and 1.89 mg/dL respectively. Patient 2 presented with acute pain over the allograft, 12.4 g/day of proteinuria and serum creatinine of 3.33 mg/dL. Recurrent DDD was noted, as well as 6/18 glomeruli (33%) showing crescentic proliferation. Patient 1 is being initiated with Rituximab therapy, however continues to have increasing proteinuria and worsening renal function. Rituximab therapy was attempted on the patient 2, however due to recurrent infections; she was unable to complete therapy and subsequently progressed to require RRT. Serum complement was not measured on either patient.

Discussion: Recurrent DDD can have varying clinical and pathologic presentations. Evaluation of serum complement levels is recommended in patients with a history of, or suspected recurrence of MPGN/C3 glomerulopathy. Our cases also support the accepted theory that regardless of etiology, crescentic glomerulitis is typically associated with an acute presentation and a more rapid progression to ESRD.

PUB551

Rhabdomyolysis and Acute Kidney Injury in Mycoplasma Pneumoniae: A Case Report
Ujwal Gautam, Jason M. Kidd. *Nephrology, Virgina Commonwealth Univ Health System, Richmond, VA.*

Introduction: Mycoplasma pneumoniae is a common cause of atypical pneumonia. Rare complications such as hemolysis, encephalitis, aseptic meningitis, cardiac conduction abnormalities, and rheumatological symptoms have been reported. We report a case of mycoplasma pneumonia leading to rhabdomyolysis and acute kidney injury requiring renal replacement therapy.

Case Description: A 46 year old African American man presented to an emergency room with malaise. Three weeks prior to his presentation, he had dry cough and had been prescribed a course of Bactrim. He had no joint pain. He was found to have a serum creatinine of 8.7 mg/dl. Urinalysis was significant for hematuria, proteinuria and the presence of myoglobin. His serum CPK was greater than 42,670. He became anuric. One day after admission, he was initiated on dialysis for uremic symptoms. He underwent a renal biopsy that showed acute tubular necrosis with granular eosinophilic casts consistent with the diagnosis of rhabdomyolysis. Work up was remarkable for *Mycoplasma pneumoniae* by nucleic acid amplification.

Discussion: Rhabdomyolysis is a common cause of acute kidney injury, but is rarely due to mycoplasma pneumonia. Myalgias are often described in patients with mycoplasma, but rhabdomyolysis is a rare complication and has only been sparingly reported. (Minami 2003) Patients with rhabdomyolysis of unknown cause should be screened for infections such as HIV, legionella and mycoplasma as treatment could potentially decrease muscle breakdown.

PUB552

Patient with an Urgent Need for Initiation of Peritoneal Dialysis
Erika Székelyová,[1] Jiri Vlasak.[2] *[1]Fresenius Medical Care; [2]Fresenius Medical Care.*

Introduction: Patients who require emergent dialysis are not considered suitable for urgent-start peritoneal dialysis in general. Most of them are treated with hemodialysis or continuous renal replacement therapy utilizing a temporary vascular catheter.

Case Description: A 43-year-old man with terminal kidney injury and with obvious signs of uremia, hyperkalemia, volume overload and resistent hypertension refused hemodialysis. The reason for rejection was his father's bad experience with this modality of dialysis in the past. Peritoneal dialysis (PD) catheter was introduced to this patient urgently using a laparoscopically assisted puncture implantation (LAPI) technique. The first three days the patient started with low-volume exchanges and remained in a recumbent position. After this period we have observed regressed uremic symptoms, but uremic catabolities decreased slowly and signs of volume overload and hypertension persisted. Ten days after PD catheter placement the patient went home from the hospital and continued with PD exchanges in our outpatient dialysis center. The procedure was without any complications. Continuously routine education in PD was initiated and 3 weeks after PD catheter placement the patient started with regular chronic PD. Then we initiated adjustement before kidney transplantation. The patient needed cholecystectomy because of cholelithiasis and he refused periprocedural hemodialysis again. One day after laparoscopically cholecystectomy the patient started with peritoneal protocol such as at the beginning. Minor leek was managed conservatively. Fourtheen month after newly discovered end-stage renal disease (ESRD) the patient successfully recieved renal graft. We have fulfilled the wishes of the patient. Since the acute initiation of PD, through abdominal surgery without interruption peritoneal dialysis, we have led him to the desired kidney transplant.

Discussion: Urgent-start peritoneal dialysis appears to be as safe as routine peritoneal dialysis, although there may be an increase in the incidence of peritoneal leaks. We believe, based on our experience, that some patients with urgent need of dialysis may benefit from initiation of renal replacement therapy, using peritoneal dialysis.

Case Report Sustained Low Efficiency Dialysis in a Patient with Severe Acute Kidney Injury Caused by Dengue Shock Syndrome
Reny Duarsa. *Internal Medicine, Kasih Ibu Hospital, Denpasar, Bali, Indonesia.*

Introduction: Dengue infection is a growing problem in Indonesia, where acute kidney injury could be one of the rare and lethal complication of it. The incidence of Dengue Associated Acute Kidney Injury itself was around 13.3%, where two-thirds had mild AKI and one-third had moderate-severe AKI. The incidence of AKI with Dengue Shock Syndrome was around 0.9-3.3%. Mortality was more than 10% for dengue patients with AKI. Renal Replacement Therapy is one option of treatment, but could be very challenging in a low thrombocyte level, shock and severe plasma leakage.

Case Description: A 24-year-old female was referred in a shock condition, decreased of consciousness and restless. Fever was at day 5, no nausea, and had periods with usual volume and schedule. Physicalexamination: restless, dyspnea with BP 93/53, PR 107, RR 40-45X/min and temperature 36°C. She had rhales at both lungs, epigastric pain, ascites,edema was occurred. Urine production was decreased to 150 cc/24 hour. Her BUN was 70 mg/dL and SC was 3.2 mg/dL. Pre admission chest x ray was without pleural effusion which worsened to minimal pleural effusion on the right costo-phrenic angle. She was diagnosed with Dengue Shock Syndrome complicated by massive plasma leakage, hyponatremia (117) and AKI RIFLE Failure. She was treated in ICU, colloid and 2 inotropic agents were administered. Other treatment was levofloxacin iv, cefotaxim, calcium gluconas. She was inserted cvp monitor and temporary double lumen catheter. Thrombocyte concentrate was given before first SLED to raise thrombocyte level from 9 to 26. USG was with normal kidney echogenicities, both sides pleural effusion, ascites, suspected pancreatitis and hepatitis. IgG and IgM dengue were positive. She was treated for 15 days and discharge with urine production of 2.5 liters after 6.05 liters of polyuria phase at day 14. She was discharged with BUN 28 mg/dL, SC 0.86 mg/dl, thrombocyte 159.

Discussion: This case illustrated a severe dengue case with complication of severe kidney failure. Although she had a very low thrombocyte, SLED were done both to ultra-filtrate massive fluid leakage and to dialyze. The balance of anticoagulation is necessary; as long dialysis would decrease thrombocyte level.

Hyponatremia due to Unrelenting Renal Salt Wasting in a Patient with Malignancy
Alwin H. Lopez, Carlos A. Cortes, Hector R. Cordova. *Medicine, Veterans Affairs Caribbean Healthcare System, San Juan, PR.*

Introduction: Cisplatin therapy is well known for its nephrotoxic side effects including renal tubular epithelial cell toxicity. The effects on tubular transport processes can result in urinary magnesium loss and in very rare instances, marked sodium loss leading to the development of a Renal Salt Wasting Syndrome (RSWS).

Case Description: A 72-year-old man with history of head and neck squamous cell carcinoma treated with resection and post-operative radiation, hypothyroidism, and history of tobacco smoking presented with recurrence of his head and neck cancer. Palliative chemotherapy with Cisplatin and Cetuximab was initiated. Physical examination showed a cachectic man with stable vital signs and no orthostatic blood pressure changes. He was alert and oriented, without focal neurologic deficits. A summary of clinical and laboratory data follows:

Days after Chemotherapy	Serum [Na^+] (meq/L)	Urinary [Na^+] (meq/L)	Serum [Mg^{2+}] (mg/dl)	Serum Creatinine (mg/dl)	Free T4 (ng/dl)	Fluid balance(L/day)
0	134		2.08	0.43	0.44	
6	124	118	1.89	0.43	0.47	-1.2
9	120	118	1.85		0.57	+0.15
22	124	137		0.30		+3.0
26	119	134	1.49	0.33	0.99	-2.6

Discussion: The patient developed hyponatremia even after administration of isotonic saline before the first dose of cisplatin, in an attempt to prevent nephrotoxicity. A significant diuresis leading to negative fluid balance ensued on day 6. The patient

persisted with hyponatremia with markedly elevated urinary sodium levels despite volume expansion, thyroid and mineralocorticoid hormone replacements (day 9). The development of signs of volume overload on day 22 prompted the discontinuation of saline infusion but the hyponatremia and the natriuresis worsened (day 26). This clinical presentation is compatible with the RSWS, rarely diagnosed after cisplatin therapy. Our patient seemed to have developed a sodium tubular reabsorptive defect that persisted after a month of a single dose of cisplatin. This syndrome should be included in the differential diagnoses of hyponatremia associated with cisplatin-based chemotherapy.

PUB555

Tacrolimus Induced Thrombotic Microangiopathy: Everolimus Is Not the Answer Reem Daloul, Tarek Alhamad, Rowena B. Delos Santos, Daniel C. Brennan, Thin Thin Maw. *Div of Renal Transplant, Washington Univ School of Medicine, Saint Louis, MO.*

Introduction: Post-transplant calcineurin inhibitor (CNI) induced thrombotic microangiopathy (TMA) is a reported complication associated with poor graft outcomes. Management is based on reduction of CNI or use of alternative agent including mammalian target of rapammune inhibitors (mTORi).

Case Description: Clinical case: A 35-year-old Caucasian female with end stage renal disease presumed secondary to congenital nephrotic syndrome underwent a deceased donor kidney transplant with thymoglobulin induction. Maintenance therapy consisted of tacrolimus, Mycophenolic acid, and prednisone. On post-operative day three she developed acute kidney injury associated with hemolytic anemia and thrombocytopenia in the context of an acute rise in tacrolimus level. Kidney biopsy showed acute tubular injury and one glomerulus with fibrin thrombi. C4d staining was negative and no donor specific antibodies (DSA) were identified. Renal function, hemoglobin, platelets, and lactate dehydrogenase recovered gradually mirroring the decrease in CNI which was changed to everolimus. Two weeks after discharge, patient presented with wound dehiscence, infection, acute renal failure, and recurrence of hemolytic anemia and thrombocytopenia. Repeat graft biopsy showed diffuse TMA, interstitial hemorrhage, and negative C4d staining. DSA remained negative. Everolimus was switched to belatacept along with weekly eculizumab. Patient remained anuric and repeat graft ultrasound was concerning for renal vein thrombosis. Surgical exploration showed a non-viable ischemic graft that was resected without evidence of clotting in renal artery or vein. Genetic testing for complement mutation was negative.

Discussion: CNI induced TMA might reflect an endogenous predisposition to TMA even with a negative testing for genetic mutations. Bearing this in mind, it is advised to avoid mTORi which carries a similar propensity to induce TMA. Belatacept appears to be a reasonable alternative in such situations.

PUB556

Case Report: Collapsing Glomerulopathy Associated with Systemic Lupus Erythematous Sergio A. Trevino Manllo, Daphne Harrington Knicely. *Div of Nephrology, Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Introduction: Collapsing glomerulopathy (CG) is most often associated with HIV. Most cases of CG not associated with HIV are idiopathic. Other secondary causes include infections, autoimmune, malignancies, genetic, drug exposures and post-transplantation. Given a wide variety of disorders, no definable pathogenic trigger factor has been identified.

Case Description: This is a case of CG associated with Systemic Lupus Erythematous (SLE) in a 61 years old African American female who presented with malaise, fever and arthralgias. During the admission, she was found to have an acute kidney injury with a creatinine of 1.9 mg/dL from a baseline of 1 mg/dL. A urine protein-to-creatinine ratio showed 12.07 grams of protein and a follow-up 24-hour urine showed 7,045 mg of proteinuria. During the hospital stay, she was diagnosed with SLE based on a positive ANA, positive ds-DNA, hypocomplementemia, positive direct Coombs, leukopenia, arthritis, and mucosal ulcers. HIV, hepatitis B and C were negative. A kidney biopsy showed collapsing glomerulopathy with extensive podocyte injury associated with scattered immune complex deposits and acute tubular necrosis. She was started on methylprednisolone then transitioned to prednisone 60 mg daily along with hydroxychloroquine 400 mg daily. A prednisone taper was done over 4-months. She had complete remission with a creatinine around 1.2 mg/dL and her a urine protein-to-creatinine ratio is 0.06 grams.

Discussion: CG associated with SLE with or without lupus nephritis is a rare disease. There is an association between collapsing glomerulopathy and SLE specifically in the setting of a lupus flare, massive proteinuria, and renal failure. In the majority of cases, treatment is initiated with high-dose steroids for prolonged periods. Partial and complete responders had fewer collapsing lesions, less global glomerulosclerosis, and less interstitial fibrosis.

PUB557

Reduction of Serum Free Light Chains Not Apheresis Use May Be the Major Determinant of Improved Renal Function in Light Chain Nephropathy Dawson Dean, Richard N. Hellman. *Dept of Medicine, Div of Nephrology, Indiana Univ, Indianapolis, IN.*

Introduction: Acute renal injury (AKI) due to light chain nephropathy (LCN) is common in multiple myeloma (MM) and its presence a major prognostic factor as is recovery from AKI. The role of Apheresis in the management of AKI due to LCN is uncertain with some studies showing no effect and some showing improvement of renal function and less need for renal replacement therapy if free serum light chains (SLC) are reduced by more than 50%.

Case Description: We describe a 78 year old MWF with IgG K MM and cast nephropathy presenting 10/13 as AKI with a presumptive diagnosis of RPGN who was initially treated with solumedrol empirically prior to renal biopsy showing LCN. Subsequent SPEP showed a monoclonal spike. She responded to corticosteroids, with serum creatinine dropping from initial 4.39 mg/dL to 2.85 mg/dL. Due to initial fall of K light chains and drop in Creatinine, Apheresis was held. She was subsequently treated with 7 courses of bortizomab and dexamethasone and is now on q 3 month Zoledronate. At last outpatient visit she was doing well clinically, CBC was normal, serum creatinine fell further to 1.18 mg.dL, serum free K light chains fell from an initial 1082.5 mg/dL to 16.20 mg/dL, and urine protein from 1,310 mg/24hr to 117mg/24hr since initial presentation October 2013 to December 2015.

Discussion: Reduction of serum Free Light Chains, not the method by which it is done such as chemotherapy and/or Apheresis, may be the major determinant of improved renal function in LCN. We propose that Apheresis may not be necessary in the treatment of LCN if SLCs are falling with chemotherapy and renal function is improving. In this case, serum creatinine and serum light chains were used to measure response to initial treatment and defer Apheresis. Additional consideration for Apheresis use may be failure of SLCs to fall with chemotherapy alone, very high SLC levels or inability to promptly initiate chemotherapy.

PUB558

Unusual Presentation of Cocaine-Associated Systemic Vasculitis without Skin Findings Muhammad Farooq, Joe Ghata, Usman Z. Bhutta. *Renal, Univ of Oklahoma HSC/VA Medical Center, Oklahoma City, OK.*

Introduction: ANCA-associated vasculitis (AAV) is a cause of crescentic glomerulonephritis and diffuse alveolar hemorrhage (DAH). Both cocaine and levimasole, an adulterant in cocaine, have been described in cases of cutaneous AAV. We describe a severe instance of cocaine associated microscopic polyangitis (MPA) without skin findings.

Case Description: 61 yo male with Hepatitis C and HTN, who abused cocaine in 12/2015, was admitted in 1/2016 for elevated creatinine, (peak 5 mg/dL; baseline 1 mg/dL in 12/2015) and productive sputum. He received antimicrobials for pneumonia and required 2 dialysis sessions. He left AMA with persistent productive cough in 2/2016, and was readmitted in 3/2016 for worsening renal failure and hemoptysis, with DAH seen on bronchoscopy, requiring intubation/mechanical ventilation. Labs were significant for anemia without schistocytes, no eosinophilia, nephritic range proteinuria, and low C3/C4. ANA, SPEP, UPEP, anti-GBM antibodies and cryoglobulins were negative. P-ANCA and anti-myeloperoxidase (anti-MPO) serologies were elevated in high titers. A kidney biopsy showed necrotizing, crescentic pauci-immune glomerulonephritis consistent with MPA. He received steroids, plasmapharesis, hemodialysis and Rituximab. His DAH responded to treatment, and he was extubated. He unfortunately remains dialysis dependent. He was discharged on a slow prednisone taper. Three months later, his p-ANCA and MPO serologies remain positive.

Discussion: About 70% of illicit cocaine consumed in the United States is contaminated with levamisole, a known immunomodulator. Prolonged cocaine use in humans has been linked to cutaneous vasculitis and production of drug-induced auto-antibodies. In the literature, cocaine-associated ANCA antibodies are mostly high-titer anti-MPO, similar to our patient. Our case highlights not only an association of cocaine and severe ANCA-associated systemic vasculitis but also a diagnostic challenge due to absence of typical skin manifestations. Moreover, this patient's serologies persisted despite cocaine cessation and aggressive treatment, suggesting a potential life-long complication of cocaine-induced vasculitis.

Rapidly Growing Mycobacteria Causing Subcutaneous Abscess in a Case of Renal Allograft: A Case Report Abhishek Goel, Tushar A. Dighe, Atul Sajgure, Atul Mulay, Charan Bhadrappa Bale, Ashwini Sharma, Jayraj Korpe, Nilesh Shinde. *Nephrology, Dr. D Y Patil Medical College, Pune, Maharashtra, India.*

Case Description: A 38-year-old male, milk vendor by occupation was admitted at our hospital, as end stage renal disease of unknown etiology on maintenance hemodialysis from past one year. Patient underwent live donor transplant in January 2016, mother as donor. He was started with corticosteroids, Tacrolimus and Mycophenolate sodium. He had stable renal functions with range of serum creatinine between 0.9 to 1.2 mg/dl and adequate serum tacrolimus levels. Five months post transplant patient presented with local redness without pain, tenderness and without local rise of temperature, three to five centimeters from pubic symphysis. His serum creatinine was 1.2 mg/dl and his tacrolimus level at current presentation was 4.7 ug/l. Ultrasonography and non contrast CT abdomen showed a subcutaneous abscess 3.0x2.0x4.2 cm (25cc) below the suture scar. Evaluation of aspirate showed acid fast bacilli on Ziehl Neelsen stain and culture grew rapidly growing atypical mycobacteria (species identification pending).Patient was initiated on anti tubercular medications- Isoniazid, Pyrazinamide, Ethambutol and Levofloxacin. As per the AFB culture report, linezolid and clarithromycin were added in addition to previously mentioned anti tubercular treatment. Currently patient is doing well, with resolution of local signs and serum creatinine of 1.2 mg/dl.

PUB560

Dapsone Induced Vertigo, a Forgotten Side Effect Valerie Suzanne Barta, Mala Sachdeva. *Nephrology, Northwell Health, Great Neck, NY.*

Introduction: Solid organ transplant patients, particularly liver and kidney, frequently engage with multiple disciplines within a health care system. Their medications include immunosuppressants as well as the prophylactic regimens necessary to keep them free from opportunistic infections. Dapsone is a known alternative to PCP prophylaxis in patients intolerant to Bactrim whether it be secondary to allergy, rise in creatinine, or hyperkalemia. Dapsone is not a first line treatment for PCP prophylaxis, and there seems to be a void of knowledge with respect to a labeled side effect, vertigo.

Case Description: We report a 67 year old male with CKD stage 3, non-alcoholic fatty liver disease status post liver transplant 3 months prior, hospitalized for acute kidney injury and bleeding from lovenox injection sites. He complained of 7 weeks of dizziness described as positional vertigo. Medications included prednisone, tacrolimus and mycophenolate mofetil immunosuppression. Prophylaxis included nystatin, valgangcyclovir, and dapsone. Dapsone replaced Bactrim shortly after transplant secondary to increased creatinine. He was admitted to hospitalist service, and seen by neurology, transplant hepatology, and nephrology during his stay. Work up for vertigo included a negative head CT scan. Vertigo was attributed to orthostatic hypotension secondary to blood loss anemia, however symptoms did not resolve with volume resuscitation. No cause for his vertigo was established and the patient was discharged home. His symptoms persisted, impairing his ability to ambulate. He consulted an outpatient ENT several weeks after discharge who immediately recognized dapsone-induced labyrinthitis. Dapsone was stopped and he was treated with intra-tympanic triamcinolone, leading to complete resolution of symptoms.

Discussion: Transplant medication side effects need to be widely known in the nephrology, gastroenterology, and medicine community, who will inevitably treat these patients. Vertigo is a rare side effect of many antibiotics including dapsone. This case illustrates the importance of improved awareness of dapsone associated vertigo in order to recognize, treat and improve quality of life of affected patients.

PUB561

A Perfect Storm from Ecstasy Associated Multi-Organ Failure Rungwasee Rattanavich, Ali I. Gardezi, Didier A. Mandelbrot. *Nephrology, Univ of Wisconsin, Madison.*

Introduction: Ecstasy or 3,4 methylenedioxymethamphetamine(MDMA) has both stimulant and hallucinogen effects. It is commonly abused, including 39% of college students in the United States, causes euphoria and increased energy. The minor adverse effects of Ecstasy are dry mouth or sweating. Rare but lethal side effects include serotonin syndrome, hyperpyrexia, severe rhabdomyolysis, symptomatic hyponatremia, acute kidney injury and multi-organ failure.

Case Description: 18 y/o man presented after a seizure. He had used Ecstasy 4 hrs prior. Physical exam revealed high grade fever, hypotension, tachypnea and tachycardia, dilated reactive pupils, no response to noxious stimuli. Labs revealed AKI, lactic acidosis, hyperkalemia, hyperphosphatemia, hypocalcemia, hyperuricemia and severe rhabdomyolysis. He was treated with cooling blankets and aggressive IV fluids. He was later started on CRRT. He developed fulminant hepatic failure within 24 hrs of presentation. He had severe hypocalcemia which was treated with aggressive calcium replacement. He underwent orthotopic liver transplantation. He later developed persistent hypercalcemia with evidence of calcium deposition in muscles on imaging studies. It did not respond to IV fluids, furosemide and pamidronate initially and required intermittent hemodialysis. He had full renal recovery by week 12 of hospitalization. He required daily normal saline and furosemide for 4 more weeks before serum calcium normalized.

Discussion: Ecstasy causes release of serotonin, dopamine and norepinephrine into the central nervous system and inhibit serotonin re-uptake which could cause serotonin syndrome. MDMA toxicity, unlike other drugs abuse, is not dose dependent. Direct toxicity on the kidneys is unclear. MDMA associated AKI is reported to be secondary to rhabdomyolysis due to seizures, hyperthermia and serotonin syndrome. There is no specific antidote. The mainstay of treatment is aggressive management of these complications. The persistent hypercalcemia in our case could have been due to sustained release of the calcium deposited in the soft tissues. The likely reason was initial movement of calcium into the injured muscles in rhabdomyolysis resulting in hypocalcemia which was treated with aggressive calcium replacement.

PUB562

A Challenging Diagnosis of Atypical Hemolytic Uremic Syndrome Victoria Chung, Shubha Ananthakrishnan. *Nephrology, UC Davis Medical Center, Sacramento, CA.*

Introduction: Hemolytic uremic syndrome is characterized by microangiopathic hemolytic anemia, thrombocytopenia, and acute renal failure. HUS is further classified into typical or atypical HUS. aHUS is a rare disease of complement dysregulation and carries a poorer prognosis and often requires ongoing renal replacement therapy. It is often difficult to differentiate aHUS from other TMAs. We present a case here with diagnostic challenges.

Case Description: A 68-year-old woman with hyperlipidemia presented with recent complaint of progressive fatigue found to have transfusion dependent hemolytic anemia, thrombocytopenia, and acute kidney injury requiring dialysis. She was initially treated with plasmapharesis prior to transfer to our medical center for further evaluation of and management of TMA. Patient was not taking any medication except for statin. Review of history revealed a vague viral prodrome without diarrhea. Work up for infection and malignancy were negative. ADAMTS13 returned with normal levels, arguing against TTP. Interestingly, patient was found to have new onset hypertension requiring antihypertensive medications, dry eyes, and significant thickened facial skin finding concerning for scleromyxedema. These findings raised concern for scleroderma-type renal crisis that has been associated with cutaneous scleromyxedema. Her extensive workup at our medical center showed evidence of ongoing TMA, normal C3, low C4, weakly positive ANA (1:40), negative anti-DNA, anti-RNP70 Ab, anti-scleroderma, anti-SSA Ab, and RF. Repeated skin biopsies showed evidence of fibrosis and couldn't exclude scleromyxedema. Renal biopsy performed confirmed sub-acute TMA. Complement panel revealed a mutation in exon 6 of CFHR-5 which could explain aHUS. Given her overall diagnostic workup was more consistent with aHUS, the decision was made to proceed with eculizumab, a complement C5 inhibitor. Treatment result is pending at this time.

Discussion: We present a case of aHUS with interesting clinical findings of scleromyxedema, which is a cutaneous process sometimes associated with renal manifestations, similar to scleroderma renal crisis, which made the diagnosis of aHUS challenging. Renal biopsy in such cases can be useful to help identify the disease process.

PUB563

Kidney Transplant after Bench Resection of a Renal Cell Carcinoma in the Donor Organ Jeremy F. Wright, Sara J. Fine, Jahan Montague, Marie A. Sosa. *Dept of Nephrology, Univ of Massachusetts, Worcester, MA.*

Introduction: Ex vivo resection of small renal tumors from live-donor kidneys supports the inclusion of donors with resectable tumors for transplant. Previous reports document the success of this technique with low risk of tumor recurrence in the recipient. The earliest report from Stubenbord in 1982 describes a functioning recipient graft without recurrence at 8 years. The largest case series to date reports transplant of 43 kidneys with tumors up to 3 cm into patients who were elderly, had multiple comorbidities, or were considered high risk for rejection. Among 97 total reported cases of kidney transplantation following resection of small renal cancer, no tumor recurrence has been definitively identified.

Case Description: A 30-year-old woman volunteered to be a living kidney donor to her father with end-stage renal disease. During routine donor evaluation abdominal imaging revealed a small cystic lesion in her right kidney, subsequently characterized by MRI as an 8 mm Bosniak grade IIF lesion in the posterior cortex of the interpolar region. After a review of various management approaches and risks of continuing donation, both patients elected to proceed with the surgery. Right-sided donor nephrectomy was followed by ex vivo excision of a 1cm exophytic tumor with negative margins and successful transplant into the recipient. RCC chromophobe type (chRCC) was identified on pathology. At 1 year follow up, there was no evidence of tumor recurrence in the donor or recipient and both patients have good renal function.

Discussion: This case adds to growing but limited experience with ex vivo tumor resection in a live-donor kidney prior to transplantation. In this case, the tumor was identified as a Bosniak IIF lesion on imaging, which correlates with a 25% risk of malignancy. Although previously published reports have not specified radiologic classification, many of the reported cases were "presumed RCC" and most were shown to be RCC on pathology, suggesting possible Bosniak IIF or higher classification. This case reports chRCC, a rare subtype with reportedly low malignant potential, which has been reported in only one previous living kidney donation.

PUB564

Hypersensitivity Reaction to Magnesium Sulfate Infusion in Gitelman Syndrome Ndidiamaka O. Obadan, Roberto Pisoni, Ruth C. Campbell. *Dept of Medicine, Div of Nephrology, Medical Univ of South Carolina, Charleston, SC.*

Introduction: We report a rare case of a suspected type I hypersensitivity reaction to IV magnesium sulfate used in the treatment of severe hypomagnesaemia in Giltelman syndrome.

Case Description: A 33 year old Caucasian woman with Gitelman Syndrome maintained on oral magnesium sulfate supplementation and daily magnesium sulfate intravenous infusions for repeated episodes of severe hypomagnesaemia was admitted for evaluation of suspected hypersensitivity reaction. She was referred to the ED after reporting an erythematous, pruritic rash that developed after her daily intravenous infusion of magnesium sulfate 5 gm. She had been receiving daily home magnesium sulfate infusions for 5 years. She denied facial/throat swelling or difficulty breathing. She denied illicit substance use or recent medication, lotion, soap or dietary changes. On presentation, BP was 106/66 and she had a pink wheal in the right axilla. Laboratory testing included magnesium=1.2 mg/dL, potassium= 2.9 mmol/L, HCO3=30 mmol/L and creatinine of 0.8 mg/dL. There was concern for latex allergy and she was given magnesium sulfate 1 gm IV in the ED in a latex free preparation under close supervision. An urticarial rash developed during the infusion, which was stopped. There was no hypotension or respiratory compromise. She was transferred to the ICU for observation. She received IV Methyl prednisone and antihistamines with resolution of the rash. A possible reaction to a preservative or salt of the magnesium sulfate solution was suspected. She tolerated IV magnesium chloride for magnesium levels of 1 mg/dL while hospitalized and was eventually discharged on oral magnesium chloride tablets, in addition to amiloride, spironolactone and potassium chloride. At 3 months follow up visit she had not required intravenous magnesium supplementation and the rash did not recur.

Discussion: Anaphylactoid reactions due to magnesium sulfate are rare. This is the sixth case in the literature of clinically diagnosed cutaenous reaction to IV magnesium sulfate. In this case, the patient tolerated IV magnesium chloride, suggesting that the sulfate component was responsible for the reaction.

PUB565

A Case of Acute Interstitial Nephritis Secondary to Novel HCV Treatment Paritaprevir/Ritonavir/Ombitasvirf/Dasabuvir (PrOD)

Krishna Komanduri,[1] Nelson P. Kopyt,[2] Ravindra Bollu.[3] *[1]Medicine, Lehigh Valley Hospital, Allentown, PA; [2]Medicine, Lehigh Valley Hospital, Allentown, PA; [3]Medicine, Lehigh Valley Hospital, Allentown, PA.*

Introduction: A 66 year old AA male with history of CKD Stage IV (presumed secondary to DM and HTN) and HCV, diagnosed at pre-Transplant evaluation, developed Acute Kidney Injury. Admission creatinine [Cr] was 5.57 mg/dL with baseline 3.28 mg/dL He presented with symptoms of generalized weakness, fatigue, and edema. PrOD was started approximately five days before admission. He denied any symptoms of rash, fevers, chills, nausea, vomiting, or diarrhea, and initially was treated for pre-renal azotemia with intravenous fluid hydration (IVF).

Case Description: Point of care urinalysis was bland, with minimal proteinuria and negative for blood, leukocyte esterase or nitrites. His fractional excretion of sodium (FE_{Na}) was 0.53%, suggestive of pre-renal azotemia. Despite 24 hours of hydration with 1.5 liters NSS, there was no improvement in Cr. He was noted to have peripheral eosinophilia as high as 11% prior to the initiation of treatment, however with an elevated urine eosinophil level of 5% and persistent peripheral eosinophilia of 6%, AIN remained high on the differential. Complements (C3 and C4) and cryoglobulin levels were negative. He received two more liters of IVF over the next 24 hours and the Cr gradually returned to baseline over the next four days.

Discussion: AIN is classically seen with drugs such as Proton Pump Inhibitors, antibiotics, and NSAIDs[1]. This is likely one of the first cases of AIN seen with PrOD. Although his urine was bland, the elevated urine and peripheral eosinophils combined with temporal relationship of therapy makes AIN the most likely diagnosis[2]. With renal improvement to baseline after stopping PrOD a biopsy was not performed nor was he treated with steroids. After renal recovery, he was successfully treated with ledipasvir/sofosbuvir without complications.

Symptomatic Hypermagnesemia in Normal Kidney Function with Colonic Cleansing Agent

Yoo Jin Lee, Yang Wook Kim, Bongsoo Park, Sihyung Park. *Internal Medicine, Haeundae Paik Hospital, Busan, Republic of Korea.*

Introduction: Hypermagnesemia is an uncommon clinical situation if the iatrogenic magnesium administration and decreased renal function do not exist. Most of reported cases of hypermagnesemia were related with laxative abuse and impaired renal function. Magnesium containing bowel cleansing agents are widely used before colonoscopy without specific complications. However, we experienced a symptomatic hypermagnesemia with normal renal function after using bowel cleansing agent.

Case Description: A 74-year-old man with normal renal function complained about lethargy and motor weakness after taking bowel cleansing agent containing 14 gram of magnesium before colonoscopy due to hematochezia. His magnesium level was 12 mg/dL and electrocardiogram reveals fisrt-degree atrioventricular block and ventricular premature beat. Fluid stasis in the gut due to colonic obstruction might be the plausible cause of hypermagnesemia. He was treated with bowel enema and intravenous calcium. As magnesium levels declined, his general medical condition improved and his electrocardiogram changes were normalized.

Discussion: The present case suggests that severe hypermagnesemia can occur in the absence of pre-existing renal dysfunction with gastrointestinal diseases. We should be cautious in prescribing drug for colonoscopy if the colonic obstruction is suspected.

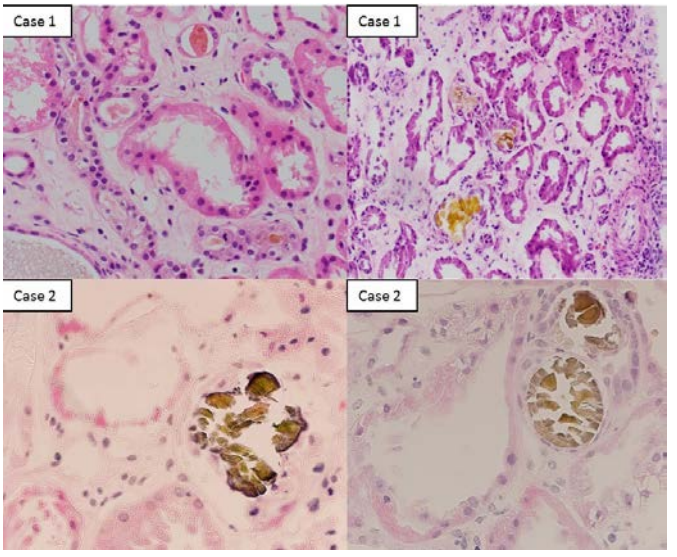
PUB567

Bile Cast Nephropathy: A Potential Cause of Acute Kidney Injury in Hyperbilirubinemia

Mitchell Pitlick, Lisa M. Antes, Prerna Rastogi. *Univ of Iowa, Iowa City, IA.*

Introduction: Acute kidney injury (AKI) in the setting of liver disease is frequently a functional, hemodynamically mediated injury. However, studies have proposed that bile casts can cause tubular injury through obstructive and direct toxic effects, a pathologic entity recently referred to as bile cast nephropathy. We present two cases of patients who developed AKI in the setting of hyperbilirubinemia, both of whom showed bile casts on kidney biopsy.

Case Description: Case 1: 37 y/o male admitted to the hospital with altered mental status and diffuse jaundice. Labs: BUN 38 mg/dL, creatinine 3.8 mg/dL, total bilirubin 27.9 mg/dL, AST 377 U/L, ALT 166 U/L, GGT 1094 U/L. U/A: 2+ bilirubin, urobilinogen, and granular casts. Aggressive treatment for alcoholic hepatitis was started with prednisolone. His creatinine peaked at 11.1 mg/dL on day 9. Kidney biopsy showed orange-brown casts in proximal tubules. He required transient dialysis. His creatinine and bilirubin trended down. He was discharged on day 34. Case 2: 87 y/o male admitted to the hospital with progressive jaundice and pruritus, on Augmentin for an ear infection. Labs: BUN 29 mg/dL, creatinine 0.9 mg/dL, total bilirubin 37.6 mg/dL, direct bilirubin 27.1 mg/dL, AST 36 U/L, ALT 37 U/L, ALP 349 U/L . He was treated supportively for drug-induced liver injury. Creatinine peaked at 3.2 mg/dL on day 14. U/A: 2+ bilirubin, urobilinogen, and granular casts. Kidney biopsy showed yellow-green casts in proximal tubules. His creatinine and bilirubin trended down without aggressive therapy or dialysis. He was discharged on day 18.



Discussion: Bile cast nephropathy is an important pathologic entity that may account for reversible renal dysfunction in some patients with liver disease. As reported in some cases this is associated with severe elevations in bilirubin, as in our cases, and improving renal function with improvement in the cholestasis.

PUB568

Salicylate Toxicity Can Cause Rhabdomyolysis and Sepsis Like Syndrome-A Case Report

Anjushree Kumar, Pooja Budhiraja. *Nephrology, Kansas Univ Medical Center, Kansas City, KS.*

Introduction: Rhabdomyolysis is characterized by myocyte membrane rupture with release of intracellular contents which includes creatine phosphokinase,lactate dehydrog enase,aldolase,myoglobin,purines,potassium and phosphates.We describe a case where patient had rhabdomyolysis and sepsis like syndrome from salicylate.

Case Description: A 41 years old female with unknown past medical history was brought to emergency room because of altered mental status.She was febrile of 102 F,tachycardic of 121,tachypneic at 32 and hypotensive with blood pressure of 70/50.She was intubated for airway protection and started on pressors and antibiotics.Laboratory on presentation**.**

WBC - 25.8 cells/microL	Neutrophils -88%	Hemoglobin-15.4 g/dl	Lactic acid –11 mmol/L	Na–142 mEq/L
K -5.2 mEq/L	Hco3-8 mEq/L	Phosphorus 14.2 mg/dl	Creatine phosphokinase(CPK) -532 U/L on Day 1	Salicylate -78.6 mg/dl on D1
CPK on Day 2(D2)-32,000 maxed to 73,000 U/L	Alcohol Panel-Negative	Drug screen – Negative except Salicylate		

Patient was started on hemodialysis within few hours of admission for salicylate toxicity.After 1 hour of completion of hemodialysis,salicylate level decreased to 13 and then to 8.4 on D2 of hospitalization.Patient developed oliguric acute kidney injury on D2 with elevated CPK.She was started on hemodialysis three times/week and CPK decreased to below 5,000 on D6.Patient was off pressors on D2 and all cultures were negative.Patient was discharged with twice weekly hemodialysis as outpatient.Her kidney function recovered in about 4 weeks with no further need of hemodialysis.

Discussion: The exact mechanisms by which salicylates cause muscle necrosis is unknown.But,it is thought that uncoupling of oxidative phosphorylation by salicylates leads to increase heat production which enhance permeability of muscle enzymes into circulation. Also Salicylates suppress cyclooxygenase pathway and lead to breakdown of arachidonic acid via lipoxygenase pathway,leading to formation of leukotrienes,which has muscle damaging effects.Salicylate toxicity should be considered as cause of rhabdomyolysis and differential diagnosis of septic shock especially in patients who have no obvious source of infection.

PUB569

Polyomavirus Nephropathy in Native Kidneys of an Immunocompetent Patient

Yoo Jin Lee, Yang Wook Kim, Bongsoo Park, Sihyung Park. *Internal Medicine, Haeundae Paik Hospital, Busan, Republic of Korea.*

Introduction: Polyomavirus nephropathy has emerged as an important cause of graft loss in kidney transplant recipients. Polyomavirus rarely affects the native kidneys of an immunocompetent individual.Until now, polyomavirus nephropathy in native kidneys of an immunocompetent individual has not been reported, as far as we know.

Case Description: A 34-year-old man was transferred from a local clinic to be evaluated for the cause of azotemia. He was a hepatitis B carrier and had not been treated for hepatitis B. Serum creatinine was 2.85 mg/dL. His urinalysis revealed red blood cells, 0–2/high-

power field (HPF), and white blood cells, 0–2/HPF. The protein-to-creatinine ratio in spot urine was 69.6 mg/g. Kidney ultrasonography showed increased renal cortical echogenicity and decreased kidney size. Renal biopsy was performed. In the hematoxylin eosin stain and the periodicacid-Schiff stain, tubular epithelial cells frequently showed intranuclear inclusion bodies. The Masson trichrome stain showed interstitial fibrosis. There were localized small electron-dense materials in the mesangium. Epithelial cell foot processes remained relatively patent. The immunofluorescence microscopy showed a strong simian virus 40 large tumor antigen staining mainly in the tubular epithelial cells, confirming the diagnosis of polyomavirus nephropathy.

Discussion: Polyomavirus nephropathy may also be considered a cause of renal dysfunction in the native kidneys of immunocompetent patients.

PUB570

Hypercalcemia due to Calcitriol Secondary to Silicon Injection Butt Augmentation Rahul N. Pawar, Savneek S. Chugh, Venkata Buddharaju. *Nephrology, New York Medical College, Valhalla, NY.*

Introduction: Buttock augmentation and implants are the fastest growing type of cosmetic surgery in 2015, according to American Society of Plastic Surgery with close to 15,000 procedure performed in U.S. only. While the incidence of this is rising, more and more complications are now been uncovered secondary to this type of procedure. One of the rare but lethal complication is severe hypercalcemia mediated by excessive calcitriol (1, 25 Vitamin D) production from the granulomatous inflammation. We are reporting a very rare and interesting case of such entity.

Case Description: A 36 year old lady with history of hypertension, systemic lupus erythematosus, class IV and V lupus nephritis, CKD stage 3, who had multiple hospitalizations due to dehydration and hypercalcemia over the past few months. She has been followed in our renal clinic for few years and currently in remission for lupus nephritis. But over the past few months, she started to develop hypercalcemia with calcium increasing from 8.2mg/dl to 10.5mg/dl. She presented once with lethargy and creatinine of 2.5 when her serum calcium was 14. Work up for the hypercalcemia showed that I, 25 Vitamin D was 90. Of note, she had silicone injection to her buttocks 1.5 years ago. On imaging, her subcutaneous fat of the buttocks and hips demonstrate extensive abnormality including calcifications and nodular soft tissue densities. She was then started on a higher dose prednisone 20 mg to 40 mg per day. Since being on a higher dose of prednisone, her serum calcium levels subsequently improved to 9.4mg/dl and she is been in this for more than 1 year now.

Discussion: While the social media highlights this cosmetic effect, it encourages more and more young females to opt for this procedure. What are not depicted are the underlying dangers to this kind of procedure. We think this is important information for not only the nephrology but entire medical community as more and more of these procedures are desirably performed.

PUB571

Monoclonal Gammopathy of Renal Significance in Light Chain Deposition Disease Gheorghe Ciprian Cazan,[1] Ketki K. Tendulkar.[1] *[1]Nephrology, UNMC, Omaha, NE; [2]Nephrology, UNMC, Omaha, NE.*

Introduction: Light chain deposition disease may have an indolent presentation and a high clinical suspicion is needed for an early diagnosis. We present the case with worsening kidney disease in the setting of a normal UA, SPEP, UPEPand a modestly abnormal K:L ratio.

Case Description: 55-old Caucasian male with HTN and a baseline creatinine of 1.1 mg/dL was referred due to an increase in serum creatinine level to 2.84 mg/dl within 8 months from his last documented baseline creatinine. He was started on lisinopril 10 mg daily 2 weeks earlier and was taking meloxicam 15 mg daily for C6 radiculopathy. UA was negative for proteinuria or hematuria and further investigations revealed normal urinary Pr/Cr ratio, Alb/Cr ratio and renal ultrasound. After discontinuing lisinopril and meloxicam and with better control of his blood pressure, his renal function slightly improved with creatinine nadir of 2.2 mg/dL within 6 weeks. He had a kidney biopsy that was significant for focal global glomerulosclerosis, tubular atrophy and interstitial fibrosis 70%, weak linear staining for Kappa light chain. SPEP and UPEP were normal but Serum free light chains were remarkable for Kappa 530 mg/L, Lambda 19 mg/L (ratio-27.89). Bone marrow biopsy - mild hypocellularity 30%, 5 % plasma cells and 1.69 % cytoplasmic kappa expression. It was considered as a Monoclonal Gammopathy of Renal Significance but no definite criteria for further treatment. He underwent active surveillance with persistent normal UA, SPEP and stable kappa lambda chain ratio for 5 months. When his GFR started to decline. repeat bone marrow biopsy - unchanged, renal biopsy - brighter staining for kappa light chain.

Discussion: Light chain deposition disease can occur in any organbut renal involvement is present in 93-100% of the cases, a high suspicion is needed if a normal UA and no other explanation. There is a strong association between hematologic response to chemotherapy and renal outcome.

PUB572

Delayed Renal Graft Dysfunction following Renal Transplant Pyelonephritis Essa Abuhelaiqa,[1] Jeffrey I. Silberzweig.[1,2] *[1]Nephrology & Hypertension and Medicine, Weill Cornell Medicine, New York, NY; [2]The Rogosin Inst, New York, NY.*

Introduction: Patients presenting with pyelonephritis often present with acute kidney injury due to insteristitial nephritis and/or prerenal azotemia especially in those with renal allografts. We present a case of acute kidney injury, which developed after the patient's pyelonephritis had been treated for four days.

Case Description: A 62 year old male with history of type 1 diabetes mellitus treated by an insulin pump and end stage kidney disease secondary to diabetic nephropathy for which he received a kidney transplant from a deceased donor eight years prior to admission. On admission, he complained of urinary frequency, hesitancy and dysuria accompanied by fever and chills for four days. His admission serum creatinine was 2.6mg/dL, which is at his baseline. Urinalysis was notable for leukocyte esterase and pyuria (> 50 WBC/hpf) and urine culture grew *Klebsiella Pneumoniae*. His blood pressure was controlled throughout his hospitalization. He was treated piperacillin/tazobactam and intravenous fluids, but his creatinine increased to 4.1mg/dL over the subsequent 6 day period, and he developed new tenderness at the renal allograft site. His cyclosporine level was subtherapeutic (59.3ng/mL) so concern arose for transplant rejection and a renal biopsy was performed. Pathology demonstrated global glomerulosclerosis (13 out of 17 glomeruli) with patchy infiltration of neutrophils and mononuclear cells; minimal plasma cells were present. There was only focal tubulitis and tubular injury, staining was negative for C4d, and there was no evidence of glomerulitis or vasculitis. Based on clinical and pathologic data, we diagnosed our patient with acute kidney injury due to interstitial nephritis resulting from pyelonephritis. With continued treatment of his infection, his clinical symptoms improved and he was discharged with improved serum creatinine.

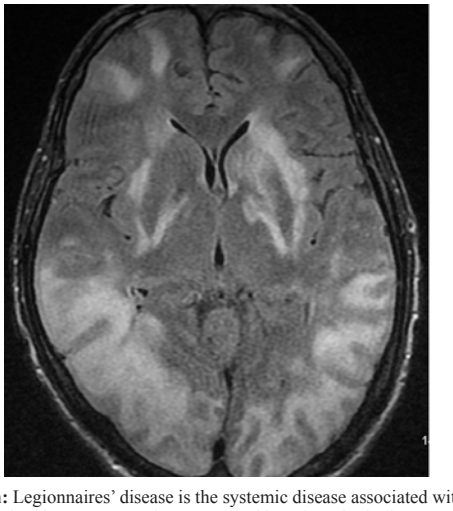
Discussion: Acute interstitial nephritis due to pyelonephritis can cause delayed onset acute kidney injury; biopsy is warranted to differentiate this entity from acute rejection in patients with renal allografts.

PUB573

Therapeutic Plasma Exchange for Acute Disseminating Encephalomyelitis following Legionnaires' Disease Latoya L. Brathwaite,[1] Paras Dedhia,[1] Charuhas V. Thakar.[1,2] *[1]Dept of Nephrology and Hypertension, Univ of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VA, Cincinnati, OH.*

Introduction: Acute disseminating encephalomyelitis (ADEM) is an immune-mediated demyelinating disorder of the brain and usually occurs within 2 to 30 days after an antigenic challenge. Neurological symptoms of Legionnaires' disease range from headache and lethargy to encephalopathy.

Case Description: A 50-year-old male transferred to ICU from other institute with hypoxic respiratory failure secondary to legionella pneumonia. He was diagnosed with legionella pneumonia based on urine antigen and was treated with Azithromycin for 14 days. His hospital course was complicated by oliguric AKI to septic acute tubular necrosis and rhabdomyolysis and required renal replacement therapy. His creatinine increased from 1.1 mg/dl on admission to peak Cr of 4.5 mg/dl. On hospital day 16, noted to be less responsive with significant change in mental status. Exam was significant for increased tone and clonus in all 4 extremities with no response to verbal or tactile stimuli. MRI brain was notable for mixed pattern of diffusion signal involving both cerebral hemispheres and extending into basal ganglia and internal capsules. Also EEG showed an evidence of status epilepticus and was started on Levetiracetam and Fosphenytoin. In view of concern for hemorrhagic variant of ADEM, he was started on therapeutic plasma exchange (TPE) with 5% albumin. He received 5 sessions of TPE and noted to have significant improvement in neurological signs. After TPE, he was alert, awake and following commands and was moving all 4 extremities.



Discussion: Legionnaires' disease is the systemic disease associated with Legionella infection with significant extra pulmonary manifestations including renal failure and neurological abnormalities. This case highlights successful use of TPE in management of hemorrhagic variant of ADEM.

PUB574

Diagnostic Challenges in the Setting of Acute Kidney Injury and Thrombotic Microangiopathy Ian Logan, John Andrew Sayer. *Renal Services, Freeman Hospital, Newcastle upon Tyne, United Kingdom.*

Introduction: Thrombotic Microangiopathy can present in numerous ways, including Acute Renal Failure, and has several causes including Thrombotic Thrombocytopenia Purpura, Malignant Hypertension, Diarrhoeal Haemolytic Uraemic Syndrome and the ultra-rare atypical Haemolytic Uraemic Syndrome (aHUS). An underlying diagnosis of aHUS allows the opportunity to treat with Eculizumab but it can be a difficult diagnosis to make, owing to a lack of tests.

Case Description: We report a 38 year old male presenting with headache, nausea and mild diarrhoea. Past medical history included poorly controlled hypertension for 5 years and obesity. No family history was forthcoming and there were no regular medications. Blood pressure at presentation was 220/110 mmHg. Biochemical tests showed a plasma creatinine of 813 µmol/l, and raised bilirubin / LDH. Haematological tests demonstrated a platelet count of 65, haemoglobin of 11.9, and a blood film with red cell fragments. ECG suggested left ventricular hypertrophy. Percutaneous renal biopsy demonstrated features consistent with a thrombotic microangiopathy, although a lack of vascular intimal thickening that would be expected with hypertensive disease. Case Description: Haemodialysis was started within 48 hours for fluid overload, whilst antihypertensive medications were introduced, resulting in an improvement in platelet count but no renal recovery. The presumed diagnosis was Thrombotic Microangiopathy resulting from Malignant Hypertension. Diarrhoeal Haemolytic Uraemic Syndrome (HUS) was also considered, whereas ADAMTS13 testing excluded Thrombotic Thrombocytopenia Purpura. Genetic testing for aHUS was requested to exclude an underlying complement defect. This revealed a heterozygous deletion encompassing the CFH locus, extending to CHFR1, hereby producing a hybrid regulatory gene. This variant causes complement dysregulation and aHUS, the final diagnosis in this patient.

Discussion: Our case highlights difficulties in the diagnosis and management of Thrombotic Microangiopathy, with the need to consider aHUS. This allows treatment with Eculizumab and the opportunity for genetic screening of family members.

PUB575

Rapid and Progressive Glomerulonephritis Associated with Sweet Syndrome Rahul N. Pawar, Savneek S. Chugh, Rameen Hashemiyoon. *Nephrology, New York Medical College, Valhalla, NY.*

Introduction: Sweet Syndrome Manifesting as Rapidly Proliferative Glomerulonephritis.

Case Description: A 42 year female presented with an erythematous lesion on the leg associated with edema and fevers since her return from Africa, few days ago. This was followed by ulceration and inability to ambulate requiring debridement and empiric antibiotics for necrotizing fasciitis. Her clinical course was complicated by non-oliguric acute kidney injury (AKI) and respiratory failure. Laboratory investigation revealed leukocytosis (24.9), anemia (Hgb 6.7), and AKI (SCr. 0.62 à 1.44). She had ANA positive, in addition to decreased complement levels with negative ds-DNA or anti-smith antibodies. Skin biopsy exhibited acute inflammatory infiltrate involving the epidermis, dermo-epidermal junction, extending to the hair follicles. Direct immunofluorescence presented fibrillary staining with antisera to fibrin-related antigens in the superficial dermis, findings compatible with Sweet Syndrome. Her urinalysis was significant for hematuria with red blood cell casts and proteinuria of around 1gm/day. Patient was hypotensive and unstable for renal biopsy. In addition to antibiotics, patient also received pulse dose of steroids along with intravenous cyclophosphamide infusion and prednisone 60 mg. After two weeks, the patient experienced normalization of her creatinine and resolution of proteinuria.

Discussion: Sweet Syndrome, also referred to as acute febrile neutrophilic dermatosis, is a rare disease process affecting predominantly females aged 30-50 years of age. Sweet syndrome can manifest as kidney disease, specifically mesangiocapillary glomerulonephritis including urinalysis abnormalities (hematuria and proteinuria). Systemic corticosteroids remain the gold standard of treatment. In our patient, constitutional symptoms resolved within 72 hours, followed by clearance of skin lesions in 3-9 days. Corticosteroids were gradually tapered over the course of 2-6 weeks. Clinical and diagnostic acuity along with rapid implementation of treatment remain the mainstay of approaching a patient with Sweet Syndrome for favorable results.

PUB576

Ischemic Monomelic Neuropathy: Rare Complication of Dialysis Access Presenting as a Foot-Drop Like Ravi K. Thimmisetty, Noreen F. Rossi. *Nephrology, Wayne State Univ, Detroit, MI.*

Introduction: Ischemic monomelic neuropathy (IMN) is a rare complication developed after acute arterial occlusion or reduced blood flow to a peripheral nerve. In the review of our literature, we could not find any IMN cases that are reported in lower extremities following vascular access surgery for hemodialysis.

Case Description: A 59-year-old man was admitted for a creation of vascular access at the left femoral site for dialysis. He does have multiple deep venous thrombosis in upper extremities at AV fistula sites. He underwent left superficial femoral artery to vein fistula loop graft without any complications. Post-operatively patient was complaining of pain and weakness at the surgical site. Neurological examination revealed left foot dorsiflexion 1/5, left foot plantar flexion is 3/5. Left hip flexion is 3/5 on laying. Foot invertors are 0/5, foot evertors 0/5. Sensation to light touch, cold, pinprick and temperature are decreased on left from lower 1/3rd of the leg to foot and normal on the right side. Lower extremities pulses are not palpable due to chronic edema. All the imaging (CT scan of abdomen and pelvis, ultrasound of left thigh, MRI of lumbar spine) tests didn't show any acute pathology. Ultrasound of left thigh shows patent AV graft, no hematoma. Pre and post AV Graft Ankle-Brachial Index were 0.93 and 0.67 suggestive of the tibial obstructive disease. Foot drop and weakness after surgery without lumbar radiculopathy pointed to the IMN, which is a diagnosis of exclusion. As patient doesn't have any other sites to create another access, decided wisely to preserve the current graft and managed the complication conservatively by physical therapy and ankle-foot arthrosis.

Discussion: IMN is a difficult clinical diagnosis because of the inconsistency of clinical signs and occurrence in the immediate postoperative period. Owing to the low incidence and under-reporting of these cases, experiences regarding management are insufficient. A more global awareness among the multidisciplinary team is necessary to diagnose early and prompt treatment of IMN to prevent both short and long term disabilities.

PUB577

Rare Case of Lupus Nephritis with Positive Cytoplasmic Anti-Neutrophil Cytoplasmic Antibodies (C-ANCA) Venkata Buddharaju, Savneek S. Chugh, Rahul N. Pawar, Renee E. Garrick. *Nephrology, New York Medical College, Valhalla, NY.*

Introduction: Renal involvement in Systemic lupus erythematosus (SLE) is common with urine abnormalities present in up to 75% patients. Lupus can cause a wide range of renal manifestation including glomerular disease, Tubulointerstitial nephritis, Thrombotic microangiopathy, collapsing glomerulosclerosis and RPGN. ANCA positivity can be seen of lupus patients with predominantly perinuclear pattern (P-ANCA) and atypical pattern. We present to you a rare case Lupus nephritis with C-ANCA positivity.

Case Description: This is a case of a 23 y/o woman with a past medical history of childhood MPGN type 1 (15 years) who was recently diagnosed with lupus nephritis and was sent from her nephrologist's office for induction therapy. She was past treated with prednisone therapy from 15-17 years of age followed by a taper and then subsequently went into remission. However, last month she has been complaining of progressively increased swelling of her lower extremities with normal renal function. Urinalysis showed 3+ protein and 1+ blood with nephrotic range (9 gm) proteinuria in 24 hour collection. Further work up, showed low complements, positive ANA, C-ANCA and negative P-ANCA and ds-DNA. Patient underwent renal biopsy, which on Immunofluorescence staining revealed granular diffuse glomerular capillary wall and focal mesangial staining. There was no extra glomerular staining in the tubular basement membranes or in the blood vessels with any of the immunoreactants. Glomerular capillary wall staining is suggestive of both subendothelial and subepithelial deposits consistent with class IV/V lupus nephritis as seen on histology. She was subsequently started on pulse dose steroids for followed by induction dose of mycophenolate. Since then patient went into complete renal remission with negative C-ANCA titers.

Discussion: SLE is a multisystem disorder with multiple antibody production including ANCA. The prevalence of ANCA is reported to be as high as 31% of patients in lupus patients with predominantly P-ANCA but C- ANCA is rarely associated with Lupus. The pathogenesis of Lupus nephritis associated with C-ANCA and its significance is still unclear and will need further studies.

PUB578

Impact of Hypotonic Fluid on Prevalence of Sodium Disturbances in Children Hospitalized for Treatment of Surgical Conditions Marie Fouad, Poonam Thakore, Zachary Sartor, Janet Meller, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

Background: Pediatric surgical patients are at risk of developing hyponatremia, which can lead to cerebral edema, seizures and death, making fluid management in pediatric surgical patients an important topic. The aim of this study is to evaluate the differences between hyponatremic (HN) and normonatremic (NN) pediatric surgical patients.

Methods: This is a retrospective chart review of pediatric patients hospitalized between January 2012 and December 2012. A subset of 133 surgical patients was obtained for analysis. Only patients with serum sodium level documentation who received hypotonic (HT) fluid were included. Hyponatremia was defined by; mild if Na 130-135 mEq/L, moderate if Na 125-129 mEq/L and severe if <125 mEq/L. Age, sex, length of HT fluid administration and length of hospital stay (LOS) for HN and NN patients was studied. Comparisons were made using a two-tailed unpaired t-test ($p<0.05$).

Results: 16 of 68 patients (23.5%) with an average age of 6.0±0.6 yo had mild hyponatremia. Average sodium level for the HN group was 132±0.4 mEq/L, and the NN group had an average of 138±0.3 mEq/L. No cases of moderate or severe hyponatremia were found, and no cases of hypernatremia occurred. Out of 16 HN patients, 5 were female (3.1%) and 11 were male (68.8%) with no statistical significance ($p=0.5$). The HN group had a lower average age (6±0.6 years) than the NN group (8.7±0.7 years), with no statistical difference in average age ($p=0.09$). The LOS for the HN group was longer (5.3±0.6 days) than the NN group (4.6±0.6 days), with no statistical difference ($p=0.4$). The length of HT fluid administration for the HN group was longer (3.6±0.5 days) than the NN group (2.5±0.2 days), with statistical significance ($p=0.01$).

Conclusions: In our study, mild hyponatremia was prevalent at an overall rate of 23.5% in pediatric surgical patients. The prevalence of hyponatremia was higher in males compared to females. The HN group also had a lower average age than the NN group. Hyponatremia was associated with an increased length of HT fluid administration and longer LOS.

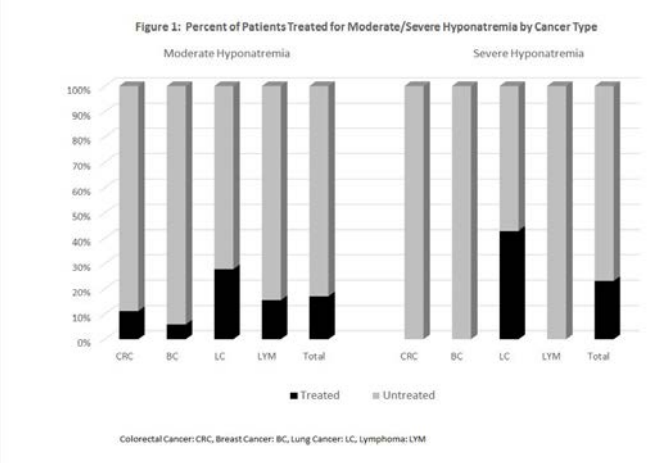
PUB579

Moderate to Severe Hypervolemic or Euvolemic Hyponatremia in Cancer Patients Is Largely Untreated Ilya Glezerman,[1] Jorge Castillo,[2] Holly Krasa,[3] Lois Lamerato,[5] Joseph Chiodo,[3] Kathy Schulman.[4] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Dana-Farber Cancer Inst, Boston, MA; [3]Otsuka PDC, Inc., Princeton, NJ; [4]OR Solutions, Inc., Waltham, MA; [5]Henry Ford Health System, Detroit, MI.*

Background: Hyponatremia (HN) is a negative prognostic indicator in cancer. It's unclear if it's a marker of severe disease or if correction improves quality of life. We characterized treatment/survival in cancer patients with moderate/severe (M/S) HN.

Methods: Tumor registry and medical record data were abstracted from the Henry Ford Health System for 125 adults with incident lymphoma, breast, lung or colorectal cancer having ≥1 episode of moderate (125–130 mEq/L) or severe (<125 mEq/L) hypervolemic or euvolemic HN. Patients were followed until death, clinical trial entry, onset of a new primary cancer or Health Alliance Plan disenrollment.

Results: Most patients (90%) had moderate HN (55% female, mean age 60 yrs, 61% stage 4); 41% were symptomatic. The most common symptoms were fatigue, nausea/vomiting, and headache. Few cases (18%) were treated. Mean (SD) duration of M/S HN was 29 (71.0) days. Thirty-five percent of patients experienced another episode of M/S HN. In the 30 days prior to index, 47% were hospitalized, 46% (14%) received chemotherapy (radiation), 10% were designated a fall risk and 6% experienced a fall. In the 30 days post index, 21% of patients were hospitalized, 44% (28%) received chemotherapy (radiation), 14% received comfort care, 20% were designated a fall risk and 3% experienced a fall. A total of 50 (40%) patients died. Median (95% CI) survival time was 275 (221-432) days; 16% died in the first 30 days.



Conclusions: M/S HN in cancer patients is largely untreated. While some form of end of life or comfort care frequently accompanies M/S HN, the majority of patients in our study lived in excess of three months. The potential exists to improve patient care and outcomes by actively treating HN.

PUB580

Cost Analysis of Treatment of Hyperkalemia with Standard Therapy Compared to the Cation Exchanger Patiromer Maria T. Story,[1] Prakash M. Nadkarni,[1,2] Bradley S. Dixon,[1,3,4] Lama A. Noureddine.[1,3] *[1]Internal Medicine, Univ of Iowa Hospitals and Clinics, Iowa City, IA; [2]Inst for Clinical and Translational Science, Univ of Iowa Hospitals and Clinics, Iowa City, IA; [3]Nephrology, Univ of Iowa Hospitals and Clinics, Iowa City, IA; [4]VAMC, Iowa City, IA.*

Background: Current treatment (tx) of hyperkalemia (HK) is time consuming and costly. Here, we analyzed how the cost for treating HK might change with the use of patiromer.

Methods: We performed a single center, retrospective analysis of current tx costs for HK versus projected costs of tx with patiromer. Adult patients with a serum potassium (K) ≥6.0-6.4 mEq/L (a range used in published studies of patiromer) between 8/1/14-11/30/15 (15 mo) were identified from the electronic medical record. The cost for medications, emergency department (ED) visits, hospitalizations, dialysis, and physician charges were obtained from hospital pharmacy and accounting. All costs for outpatient encounters for HK (K≥6.0-6.4) during the study period were summed and compared to the cost of a prescription for patiromer for the 15 mos (pricing provided by Relypsa, Inc).

Results: 125 outpatients were identified; 53.6% were on an ACE inhibitor or angiotensin receptor blocker. The major etiologies of HK were renin-angiotensin-aldosterone (RAAS) blockade and acute/chronic renal failure. Within 24 hrs of HK, there were 13 ED visits and 18 hospitalizations incurring 109 patient-days (average length of stay 4.9 days). The total cost for tx HK was $183,232; 95% of which was for inpatient services. If all patients on RAAS blockers (53.6%) were tx with patiromer for 15 months, the prescription cost would be $597,975. Hospitalization for RAAS-induced HK might be eliminated ($32,838) but overall costs for tx HK using patiromer would be $748,369.

Conclusions: The current cost for tx acute HK is significantly less than the projected cost of long-term tx with patiromer. However, use of patiromer may allow more patients to be treated with RAAS blockade and possibly reduce costs related to inadequate RAAS blockade. Use of patiromer may also shift more cost of treating HK from insurance to patients, potentially increasing their financial burden.

PUB581

Value of Fractional Uric Acid Excretion in Differential Diagnosis of Hyponatremia Saubhik Sural. *Nephrology, Peerless Hospital & B K Roy Reseach Centre, Kolkata, West Bengal, India.*

Background: Syndrome of inappropriate antidiuretic hormone secretion (SIADH) is an important cause of hyponatremia. The purpose of the study is to compare serum uric acid (UA) and and Fractional Excretion of Uric Acid(FE- UA) between hyponatremic patients with and without SIADH.

Methods: The cases(n= 102) included all patients admitted to our institute with hyponatremia, who met the inclusion and exclusion criteria. The diagnosis of SIADH was confirmed by the existing consensus criteria available. Serum and urinary UA was assayed on an Olympus 480 platform. Fifty three patients were diagnosed to suffer from SIADH. Forty nine hospitalized patients had other types of hyponatremia . The study duration was 3 years and the data obtained was treated statistically using the MedCalc Software for descriptive values and diagnostic performance. Significance was considered at p less than 0.05.

Results: Results showed the mean(SD) serum uric acid(mg/dl) to be significantly lower in SIADH group as compared to other non SIADH Hyponatremia 2.4(0.88) vs 4.6(1.31). FE-UA (%) was significantly higher in SIADH as compared to other non SIADH patients 15.3 (2.97) vs 7.86 (2.6). Receiver Operating Curve (ROC)showed an area under curve (AUC) of 0.88 and 0.98 for Serum UA and FE-UA respectively for SIADH patients. At a cut off less than 3.1 mg/dl for Serum UA in SIADH showed a diagnostic sensitivity of 86 % and specificity of 81 %. Whereas at cut off greater than 13 % for FE-UA the sensitivity was 86% and specificity of 98%.

Conclusions: SIADH patients have significantly lower Serum Uric Acid levels and increased renal excretion (higher FE-UA) as compared with hyponatremic patients with other causes. Combining Fractional Excretion of UA along with Serum UA gives excellent sensitivity as well as specificity in the differential diagnosis of hyponatremia. Particularly in a resource constrained healthcare set ups where very few clinical labs have Osmometers, FE –UA is a very important diagnostic tool in SIADH.

PUB582

Development and Testing of Prediction Models for Fluid Overload Related Hospitalizations in Hemodialysis Patients Yue Jiao,[1] Sheetal Chaudhuri,[1] Terry L. Ketchersid,[1] Dugan Maddux,[1] Brian Scott Ash,[1] John W. Larkin,[1] Len A. Usvyat,[1] Peter Kotanko,[2,3] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Inst, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Hospitalizations due to fluid overload are common in hemodialysis (HD) patients. We aimed to utilize clinical data sources to develop and test predictive models (PMs) that can identify HD patients with a high probability of multiple fluid overload related hospitalizations in the next 12 months.

Methods: We analyzed patient data from the Fresenius Medical Care Data Warehouse from Apr 2013 to Mar 2015. Various PMs were developed for prediction of ≥3 fluid overload related hospital admissions in the next 12 months, and included the generalized linear model, partitioning and regression trees, artificial neural networks, and generalized additive model (GAM). In all, 11,062 of cleaned clinical records on 33 variables was utilized for development of the PMs. Variables included data on patients' history of fluid overload related hospital admissions, demographics, morbidities, laboratories, and other parameters. Of the entire study dataset, 70% was randomly selected for PM development and prediction accuracy of the PMs was tested with the remaining 30%. The area under the receiver operating characteristic curve (AUC), sensitivities and specificities were investigated to determine the PMs' performance. The sensitivities and specificities were derived by taking the maximum of the Youden index to determine the optimal cutoff value.

Results: The GAM had the highest performance, with an AUC of 0.86 (95% CIs 0.83-0.90), sensitivity of 73% (95% CIs 65-81%), and specificity of 83% (95% CIs 82-84%) for the PM utilizing a 30% test dataset.

Conclusions: Testing of the developed PMs demonstrates that predictive analytics utilizing clinical data can assist in identifying patients with a high probability for being admitted to the hospital for fluid overload related complications.

PUB583

Can Urine pH Predict Plasma pH in ICU Patients with Abnormal Plasma Bicarbonate Levels? Navneet Kaur, Jesse M. Goldman. *Internal Medicine, Div of Nephrology, Drexel Univ College of Medicine, Philadelphia, PA.*

Background: Physicians are often called upon to interpret the acid-base status of critically ill patients demonstrating abnormal venous plasma bicarbonate values. It is longstanding dogma that when plasma bicarbonate concentration is either above or below normal, an arterial blood gas is absolutely necessary to obtain a plasma pH and calculate the acid-base condition of an individual patient. Since the kidney is a major sensor and

regulator in maintaining acid-base balance, we wondered whether urine pH might reliably predict arterial pH and thereby (in the right circumstances) correlate with arterial pH, avoiding need for an arterial blood gas specimen.

Methods: We performed retrospective chart review on 181 patients admitted to intensive care units at our institution from September 2013 to September 2014 to identify patients with a urinalysis and an arterial blood gas performed within 24 hours of each other. Of the 181 patients screened, 41 patients met this criteria. We reviewed serum chemistries, urinalyses and blood gases to assess for correlation between urine and plasma pH. We excluded patients with normal serum bicarbonate and patients receiving renal replacement therapy.

Results: Among the 41 patients, only 10 patients (24%) showed successful correlation between urine and serum pH. No correlation was noted in the remaining 31 patients. Within our cohort of 41 patients, 10 had cirrhosis, 5 had urinary infections, 4 with gastrointestinal bleeding, and 7 were ventilator dependent.

Conclusions: On our retrospective chart review of 41 critically ill patients, only 11 patients showed correlation between the urine and blood pH and 31 patients did not demonstrate a useful correlation. Among patients admitted in the intensive care units at our institution, there is a high frequency of sepsis and acute renal failure. In the setting of acute renal failure, there is poor function of renal tubules, not allowing appropriate compensation by the kidney and inability to maintain the acid base status as predicted. Our research supports the need for obtaining a blood pH specimen to interpret the acid-base status in critically ill patients with abnormal plasma bicarbonate values.

PUB584

Not Serum Potassium Level, but Serum Creatinine Level Has More Impact on Clinical Judgement for Emergent Dialysis for Severe Hyperkalemia Takamasa Miyauchi, Masahiko Nagahama, Taisuke Ishii, Sawako Kobayashi, Hiroyuki Yamamoto, Fumika Taki, Yasuhiro Komatsu. *Nephrology, St. Luke's International Hospital, Akashi-cho chuo-ku, Tokyo-to, Japan.*

Background: Hyperkalemia is a relatively common problem in hospitalized patients. However, management of hyperkalemia has been traditionally based on the physician's judgement, or institutional protocols, and treatment practice pattern for hyperkalemia is not well studied. The aim of the present study is to determine overall practice pattern of treatments for severe hyperkalemia, and clarify the most influenced factor for emergent HD in hospitalizes patients.

Methods: We analyzed clinical and biochemical parameters of all hyperkalemic patients admitted to St.Luke's Int Hosp in Tokyo over a 10-year period (2006-2016). Hyperkalemia is defined as serum $K^+ \geq 6.5$mEq/L anytime in hospitalization. Dialysis patients and pediatric patients were excluded.

Results: There were 883 patients who met the criteria for this study. Serum K^+ ranged from 6.5 to 17 mEq/L. The mean serum K^+ was 7.1±0.9 (mean±S.D.) mEq/L. The mean age was 69.1±15.6 yr, the male ratio was 56.3%, the mean serum creatinine level was 2.8±3.1 mg/dl, and the average urine output per day was 820±1034 ml. Insulin plus dextrose was the most commonly used emergent therapy (41.3%), followed by calcium gluconate (29.8%), sodium bicarbonate (22.7%), loop diuretics (12%), albuterol (1.8%), and sodium polystyrene sulfate (1.5%) on the day the hyperkalemia was recorded. 8.9% of patients underwent emergent HD. On univariate analysis, patients treated with emergent HD had significantly higher serum creatinine than patients without emergent HD (8.0±4.9 vs 2.8±3.1 , HD vs. non HD, $p<0.01$). Multivariate logistic regression analysis identified high serum creatinine to be independently associated with emergent HD (odds ratio=1.31, $p<0.01$). Neither higher serum K^+ nor higher urine output was associated with emergent HD.

Conclusions: Emergent treatment for severe hyperkalemia in hospitalized patients was performed successfully. Of interest, emergent HD is prescribed more frequently for the patients with worse kidney function. This implies that not serum K^+ level, but serum creatinine level has more impact on clinical judgement for emergent HD.

PUB585

Evidence-Based Management of Hyperkalemia: A Systematic Review Eirini Palaka,[1] Saoirse A. Leonard,[2] Amy M. Buchanan-Hughes,[2] Anna Bobrowska,[2] Susan Grandy.[3] *[1]AstraZeneca Ltd, Cambridge, United Kingdom; [2]Costello Medical Consulting Ltd, Cambridge, United Kingdom; [3]AstraZeneca, Gaithersburg.*

Background: Hyperkalemia (HK; defined as elevated serum potassium levels of >5.0 mmol/L) is a potentially life-threatening condition that can occur in patients with impaired renal function. To support evidence-based treatment, we conducted a systematic literature review (SLR) to identify studies on the efficacy or safety of interventions for managing HK.

Methods: MEDLINE, MEDLINE In-Process, Embase, CDSR, CENTRAL and DARE were searched from database inception to 27 April 2016 using terms for HK combined with terms for interventional and observational study designs. Abstract books from key congresses and bibliographies of previous SLRs were hand-searched for additional studies. Eligible publications, screened by 2 independent reviewers, reported randomized controlled trials (RCTs), interventional non-RCTs or observational studies investigating the efficacy or safety of pharmacological or non-pharmacological interventions for the treatment or prevention of HK.

Results: Database searches identified 848 unique records of which 151 were selected for full-text review. 126 publications from database searches and 30 additional publications from hand-searches were included for a total of 21 RCTs, 26 interventional non-RCTs and 34 observational studies. Of these, 16 RCTs, 20 interventional non-RCTs and 10 observational studies reported results in patients with renal dysfunction. Key interventions investigated in the RCTs across all patient populations included the newer treatments sodium zirconium cyclosilicate (ZS) and patiromer (3 RCTs each), as well as sodium and calcium polystyrene sulfonate (SPS/CPS; 2 RCTs) and combinations of temporizing agents (eg. insulin, salbutamol; 6 RCTs). RCTs of key interventions on renal dysfunction patients included ZS and patiromer (2 RCTs each), SPS/CPS (2 RCTs) and temporizing agents (5 RCTs).

Conclusions: Despite the mortality risk associated with HK, only a small number of robust published RCTs were identified, especially in high-risk patients with renal dysfunction. This lack of evidence is associated with unclear treatment recommendations for renal patients with HK.

PUB586

Identification of Potential Pediatric Hyponatremia Cases in Three Large United States Patient Databases Siddhesh Kamat, Holly Krasa, Suzanne Watkin, Robert A. Stellhorn, Ann Dandurand, Kimberly D. Sikes. *Otsuka Pharmaceutical Development & Commercialization, Inc.*

Background: Hyponatremia (HN), defined as a plasma sodium concentration less than 135 mmol/L, is one of the most commonly encountered electrolyte disorders; however clinically relevant hyponatremia requiring medical intervention is less common. Clinical trials are ongoing to evaluate pharmaceutical treatments for sodium correction among pediatric patients and large retrospective patient databases may be useful in evaluating the feasibility of conducting such trials. Our objective was to estimate the occurrence of pediatric HN patients using retrospective patient databases.

Methods: Three large US databases (Optum Clinformatics and Truven Marketscan Commercial claims data from 2010-2014, and the Humedica Electronic Health Records database from 2010-2013 covering approximately 12, 43, and 12 million members, respectively) were used to identify potential pediatric HN patients. Patients receiving medical claims with International Classification of Disease – 9th Revision (ICD-9) code of 276.1 (hyponatremia, hypo-osmolality) in primary or secondary diagnosis fields were identified as potential HN cases. Among patients in the Humedica database, serum sodium values of <130 mmol/L in the inpatient or outpatient setting were used in addition to ICD-9 codes to identify potential cases with HN.

Results: Based on occurrence of ICD-9 codes, 22,373 out of approximately 12.3 million members in the Optum database were coded for HN of which 1,004 were <=17 years of age resulting in a rate of 1 in 12,334 members covered in the data. Similarly, analysis of the Truven database resulted in a rate of 1 in 15,374 members. In the Humedica electronic health records data, after applying the criteria of ICD-9 codes for HN and the presence of at least two lab values of <130 mmol/L on separate dates, 1 in 318 patients with HN codes were <=17 years of age.

Conclusions: This retrospective database analysis suggests an infrequent occurrence of potential cases of HN with age <=17 years. From the standpoint of feasibility of clinical trials, results suggest that trial recruitment may be challenging given the low occurrence of potential cases.

PUB587

Utilization of Tolvaptan and Associated Budget Impact among Hospitalized Heart Failure Patients with Hyponatremia Siddhesh Kamat, Robert A. Stellhorn, Shirin Sundar, Holly Krasa. *Otsuka Pharmaceutical Development & Commercialization.*

Background: Hyponatremia (HN), defined as plasma sodium concentration less than 135 mmol/L, is a commonly encountered electrolyte disorders in hospitals. Given the increasing pressures for cost containment, hospitals are likely to consider the budget impact of treatments used in the inpatient setting during formulary policy-making. Fluid restriction and treatments such as tolvaptan (a vasopressin V2-receptor antagonist) are used for correction of clinically significant hypervolemic and euvolemic HN. Our objective was to describe utilization patterns of tolvaptan and evaluate the budget impact among hospitalized heart failure (HF) patients with HN in the real-world inpatient setting.

Methods: A retrospective database analysis was conducted using the Premier Inpatient database representing 700 US hospitals from 1/1/2011 through 12/31/2014 to identify patients with a discharge diagnosis of HF (ICD-9 428.xx) and a secondary diagnosis of HN (ICD-9 276.1x). Utilization patterns of tolvaptan and costs incurred were analyzed using descriptive statistics. Budget impact of tolvaptan use was presented per HF-related inpatient visit with codes for HN.

Results: A total of 23,842 inpatient visits were identified with a discharge diagnosis of HF and codes for HN. Among these visits, 935 or 3.9% visits had evidence of tolvaptan use. Inpatient visits with tolvaptan use had a mean length of stay of 11.5 days (median 9) and 297 (or 31.8 %) of visits included intensive care unit (ICU) services over the duration of the entire hospitalization. Inpatient stays with HF and HN and with evidence of tolvaptan use cost an average of $26,955 (median $14,075) whereas mean costs related to tolvaptan use were $981 (median $480). The budget impact associated with tolvaptan use was $38.4 per HF-related inpatient visit with secondary diagnosis codes for HN (Mean cost of tolvaptan treatment per visit*Number of visits with tolvaptan use/number of HF-related inpatient visits with codes for HN).

Conclusions: Tolvaptan utilization in the inpatient setting is associated with a marginal budget impact in terms of all HF-related hospital visits with codes for HN.

PUB588

Descriptive Analysis of Patients Receiving Tolvaptan in the Inpatient Setting Siddhesh Kamat, Robert A. Stellhorn, Shirin Sundar, Holly Krasa. *Otsuka Pharmaceutical Development & Commercialization.*

Background: Hyponatremia (HN), defined as a plasma sodium concentration less than 135 mmol/L, is one of the most commonly encountered electrolyte disorders in hospitals. Fluid restriction and treatments such as tolvaptan (a vasopressin V2-receptor antagonist) are used for correction of clinically significant hypervolemic and euvolemic HN. Lack of consistent guidelines for the management of HN result in high variability in treatment patterns. Our objective was to conduct a descriptive analysis of patients receiving tolvaptan in the inpatient setting.

Methods: Analysis was conducted using the Premier Inpatient database representing 700 United States hospitals from 1/1/2011 through 12/31/2014. Inpatient visits with use of tolvaptan were described in terms of patient demographic and clinical characteristics, length of inpatient stay, occurrence of HN (ICD-9 276.1x), heart failure (ICD-9 428.x, HF), syndrome of inappropriate antidiuretic hormone secretion (ICD-9 253.6x, SIADH), and other commonly occurring discharge diagnoses.

Results: A total of 11,744 inpatient stays were identified with evidence of tolvaptan use – patients had a mean age of 68 years (median 69 years) and 45.7% male. Among these inpatient visits, 6,647 (56.5%) had ICD-9 codes for HN, 4,063 (34.5%) had codes for HF, and 4,704 (40.0%) had codes for SIADH in any diagnosis field. In terms of discharge diagnosis, the most commonly codes were for SIADH (15.4%), 9.9% for HN and 9.8% of patients had HF. Septicimia (2.5%), pneumonia (2.4%), and rehabilitation procedures- non-specific (2.3%) were other commonly occurring discharge diagnosis in patients prescribed tolvaptan. Average length of stay for patients receiving tolvaptan was 10.6 (median 8) days.

Conclusions: Tolvaptan use was associated with varying diagnosis codes with the majority relating to HN, SIADH, and HF. Discharge diagnosis for those prescribed tolvaptan varied widely potentially reflecting the variability in the use of treatment in the inpatient setting or low rates of coding HN at discharge.

PUB589

Hyponatremia Rarely Associated with Preeclampsia Tokameh Entezari. *Internal Medicine, 1, Reno, NV.*

Background: Introduction:Severe hyponatremia is a rare complication of preeclampsia and only handful cases have been reported in the literature.Early diagnosis and treatment are vitals to reduce maternal and fetal morbidity and mortality.

Case:A 25 years old primiparous woman 27/5 weeks pregnant admitted with new onset of dyspnea on exertion,lower extremity edema and labile hypertension. No prior diagnosis of preelcampsia and no know medical history.

Initial serum sodium was 127 with normal TSH and cortisol level. Total urine protein was up to 6 grams in 24 hours and urine Na was 23. BP was 160/80 and improved with escalating doses of labetalol and nifedipine. Fluid restriction was attempted with limited success initially improving sodium to 130 and later dropped down to 125. At this time, she was 28 weeks and received betamethasone for accelerating fetal lung maturation and baby delivered on hospital day#6. Post partum,her serum sodium started to normalize and BP also improved. Mother and baby were discharged home on day#14 in good health.

DISCUSSION: Pregnancy involves changes in physiology that affect water and sodium homeostasis. The release of hCG during pregnancy may be responsible for a mild resetting of the osmostat downward that is responsible for a fall in the serum sodium concentration of about 5 meq/L. Developement of severe hyponatremia with preeclampsia is rare and only few cases have been reported in the literature. Its exact etiology is not well understood. A non-osmotic stimulation of vasopressin release in the setting of a hypervolemic state with low effective circulating plasma volume is thought to be the main mechanism.

Advanced maternal age and nephrotic range proteinuria have been postulated as risk factors, but their casual role remains unclear. Fluid restriction is a reasonable treatment, and maternal outcomes are favorable. This condition is a rare indication for urgent delivery and often normalizes post-partum.

CONCLUSION: Severe hyponatremia in pregnancy poses diagnostic and therapeutic challenges. Knowledge of these complex physiologic alterations during pregnancy is critical to managing dysnatremias in pregnancy.

PUB590

Clinical Features and Extracorporeal Management of Reported Acetylsalicylic Acid Exposures in the United States Sara Tavernier Burgardt,[1] Meghan A. Jobson,[1,2] Michael Emmett,[3] William Franklin Pendergraft.[1] *[1]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [2]UNC School of Medicine, Chapel Hill, NC; [3]Nephrology, Baylor Univ Medical Center, Dallas, TX.*

Background: Acetylsalicylic acid (ASA, aspirin) is a common analgesic ingredient found in most household medicine cabinets in the US. It has been an important cause of intentional and unintentional poisonings since its discovery. Toxicity can result in severe dyselectrolytemias and cardiac, kidney and central nervous system dysfunction. The objectives of this study were to identify differences in intentional and unintentional poisonings, to identify features unique to cases resulting in death, and to review trends in extracorporeal management of poisonings.

Methods: We used the National Poison Data System to perform a retrospective analysis of reported cases of ASA exposures alone from January 2006 to December 2014. Outcomes were assessed by case intentionality and severity.

Results: There were 85,470 cases of ASA ingestions resulting in 165 deaths. Individuals more likely to experience major effects or death were older and male, and presented with more severe symptoms requiring higher levels of care. Patients who were intubated and mechanically ventilated were more likely to die.

Conclusions: Deaths due to ASA exposure are rare. Of 165 patients who died, only 27% received hemodialysis which continues to be underutilized in management of severe overdoses resulting in major effects or death. Analysis of geographical differences revealed a paucity of dialytic intervention in west south central region of the United States 21% as compared to other regions 27-43% in those with major effects or who died. The decreased utilization of dialysis did not correlate with fewer nephrologists. Standardized management recommendations are made through state or regional poison control centers, thus differences in hemodialysis utilization are unlikely due to differences in management but may be due to underrecognition of severe acetylsalicylic acid poisoning. These data suggest that these regions might benefit from increased public health efforts to limit poisonings and education about prompt management of severe poisoning.

Fabry Disease Screening. Report of a Mexican Hemodialysis Center Raul Emanuel Zamora Hernandez, Leonardo Pazarin, Renato Parra, Javier Soto, Mario A. García, Ángel García Vásquez, Victor Hugo Luquin, Oscar César Martinez Garcia. *Nephrology, Inst Mexican of Security Social, Guadalajara, Jalisco, Mexico.*

Background: Fabry disease (FD) is secondary to a mutation of the gene encoding the enzyme acid α-galactosidase (α-GAL A) located on the chromosome X. This genetic disorder is cause of chronic kidney disease. The purpose of the study was to determine the prevalence of FD patients of a hemodialysis center in Mexico.

Methods: Men and women over 16 years diagnosed with CKD in hemodialysis (HD) were included. FD patients with previously diagnosed discarded. December 2015 to March 2016 after the patients signed consent on information, determination of enzyme activity of α-GAL A was performed using fluorescence in dried blood filter for men; for cases with α-GAL activity was decreased to levels determined GB3 molecular analysis also search for mutations in the gene encoding FD. For women only we made the search for gene mutations. Descriptive statistics were performed with absolute frequencies and inferential; SPSS version 22 was used.

Results: 324 patients were evaluated. A mutation in any woman diagnosed. 98 males had levels of enzyme activity of α-GAL A decreased, all GB3 with normal levels. 3 patients positive for gene sequencing GAL were detected. The median age of patients was positive 36 years with a median time of diagnosis of CKD 5 years. Prior to the diagnosis of FD in this study, recorded the cause of CKD was unknown in 2 patients, 1 secondary to diabetic nephropathy. The average level of α-GAL A and Lyso-Gb3 was 0.93 ± 1.01 mmol/l/h and 1.43 ± 0.19 ng/ml, respectively in patients with FD mutation. There were differences between patients with normal α-GAL A levels when compared with patients who had diminished α-GAL A with and without mutation levels.

Conclusions: This is the first report of the prevalence of FD in HD patients in Mexico. We found a prevalence of 0.9%, being higher than that reported in published studies (0.2-0.3%). Regarding the decline in activity levels of α-GAL A mutation found in patients without this series unrelated to any factor was found. These cutoff levels may not be standardized in our population, so it requires validation of this methodology in Mexican population.

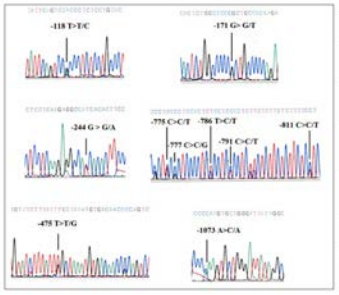
Association between the Regulatory Polymorphisms of Organic Anion Transporter 1 (OAT1) and Chronic Kidney Disease Chiao-Yin Sun. *NTU, NTU, Taipei, Taiwan.*

Background: Organic anion transporter 1 (OAT1, SLC22A6) was a prototype of OATs, and played central roles in the renal secretion of organic anions. Accumulated evidences indicated that OAT1 had critical roles in kidney injury by mediating organic anionic toxins accumulation in kidney. This study aimed to analyze the 5' regulatory region polymorphisms (rSNP) in human OAT1, and possible associations with chronic kidney disease (CKD) clinically.

Methods: A case-control study including normal subjects and CKD patients with age and sex match was designed (n=162 for each group). *In vitro* studies were performed to define the possible mechanisms of rSNP of OAT1 on the OAT1 expression.

Results: Results of direct sequencing (-1 to -1196 region) showed that CKD patients had higher frequency of -475 rSNP (T>T/G) than normal subjects (14/162 *vs.* 2/162).



SNP Location	SNP	Normal control (n=162)	CKD (n=162)
-118	T>T/C	0	1
-171	G>G/T	0	1
-244	G>G/A	1	1
-475	T>T/G	2	14 *
-775	C>C/T	1	2
-777	C>C/G	0	2
-786	T>C/T	1	2
-791	C>C/T	1	2
-811	C>C/T	0	1
-1073	A>C/A	2	0

*: P= 0.0034, Fisher's exact test.

Luciferase activity assay resulted showed that OAT1 promoter with -475 rSNP had higher promoter efficiency than wild type significantly. ChIP and LC/MS/MS analysis results showed that therewere 26 proteins up-regulated and 74 proteins down-regulated by -475 mutant. Hepatoma-derived growth factor (HDGF), a transcription repressor, was noted among these down-regulated protein targets. The Southern-Western blot assay also revealed that -475 mutant had decreased HDGF binding than wild type. HDGF over expression significantly attenuated OAT1 expression in renal tubular cells.

Conclusions: Our study results suggested that OAT1 rSNP might associate with chronic kidney disease clinically. The renal tubular cells with -475 rSNP had increased OAT1 expression, which resulted in increasing organic anion toxin transportation into cells. Cellular accumulation of organic anion toxins caused cytotoxicity, and resulted in chronic kidney injury.

PUB593

Serum LncRNA Expression Profile of Type IV Lupus Nephritis Patients

Qiuling Fan. *Dept of Nephrology, The First Hospital of China Medical Univ.*

Background: To evaluate the specificity of expression patterns of circulating long noncoding RNAs(LncRNAs) in class IV lupus nephritis (LN).

Methods: Total RNAs were purified from plasma of 3 different LN patients, 3 SLE patients, and 3 healthy controls. We screened lncRNAs expression profiles though the Arraystar Human lncRNA Microarray version 3.0.

Results: 8822 lncRNAs, 9886 mRNA were statistically significantly differentially expressed in LN plasma(fold-change>2),compared with the healthy control patients, 6403 lncRNAs , 4581 mRNAs were increased, 8407 lncRNAs , 6403 mRNAs were decreased in LN; 593 lncRNAs, 375 mRNAs were increased, 462lncRNAs, 200 mRNAs were decreased in SLE; compared with SLE, 6462 lncRNAs, 4523 mRNAs in LN were increased, 8969 lncRNAs, 6766 mRNAs were decreased in LN.Among healthy control, SLE and LN , 69 lncRNA, 73mRNAs were increased by degrees, 96 lncRNAs, 56 mRNAs were progressively reduced.

Conclusions: Gene ontology results suggested that the primary biological processes of these genes were involved in regulation of immune responses, cytokine production, cell differentiation, proliferation , apoptosis, cell cycle, cell adhesion, and metabolic process. lncRNA TCONS_00019182 locate in chr11p15.5, have significantly differentially expressed in LN vs N and SLE vs N, may play a role in development of SLE. lncRNA BDNF-AS1,lncRNA RP1-32B1.4 MYB were progressively increased in healthy control, SLE and LN group, and these abnormal expression of lncRNAs may be crucial in LN development and progression.

PUB594

Is It Time to Re-Visit Aluminum Binders in Our Elderly Patients?

Jack Rubin. *Los Alamitos, CA.*

Background: Patients ingest phosphate binders to mitigate metabolic bone and atherosclerotic disease. In the U.S. the most potent and least expensive agents (1) (Daugirdas JT et al, Semin Dial 2011 24(1):41-49) were marginalized due to concerns of aluminum toxicity. All the products substituted were more expensive. Was this a mistake? In patients with limited life expectancy, aggressive phosphorus control may lead to increased costs and pill burden without improvement in survival.

Methods: We identified our hemodialysis patients 65 and older treated at 7 units - 5 DaVita, 1 Fresenius and an independent. Daily phosphate binder pill burden was counted using their April 2016 medication list. Costs of medications were calculated using prices listed in the Medical Letter# 1483. We assumed phosphate binder potency to be as elaborated in ref 1. We estimated survival in "years to live" for each patient by age cohort as described in the USRDS 2013 report (Vol2, table 6.4). The potential decrease in pill burden using an aluminum binder was estimated by dividing the total number of pills standardized to the potency to calcium acetate by 1.5.

Results: There were 47 patients made up of 27 male and 20 female patients. The mean age (yrs) ± standard deviation (SD) was 75.7 ± 8.1, median 74. The mean calcium was 9.2 mg % ± SD 0.8, median 9.3. The mean phosphorus was 5.7 mg % ± (SD) 5.9, median 4.9. The mean albumin was 3.6 g % ± (SD) 0.5, median 3.7. The estimated survival was 3.6 years ± (SD) 0.9, median 3.8. There were 6 patients not using a phosphate binder. There were 18 patients exclusively using Phoslo (Calcium Acetate), 5 using Phoslo plus Renvela (Sevelamer), 15 exclusively Renvela, 1 exclusively using Fosrenol (Lanthanum carbonate), 2 exclusively Auryxa (Ferric citrate) and 1 using 3 agents including Auryxia. The mean pill burden among those taking binders was 7 ± (SD) 4, median 6 and the estimated cost/ day $31 ± (SD) 30, median 17. Aluminum hydroxide substitution was calculated to yield a pill burden of 5 ± (SD) 4, median 5, with the cost under $2 a day.

Conclusions: When treating patients with limited life expectancy wherein development of aluminum toxicity is a non issue, if phosphate control is deemed helpful, using aluminum -binders to decrease pill burden and costs seems reasonable.

PUB595

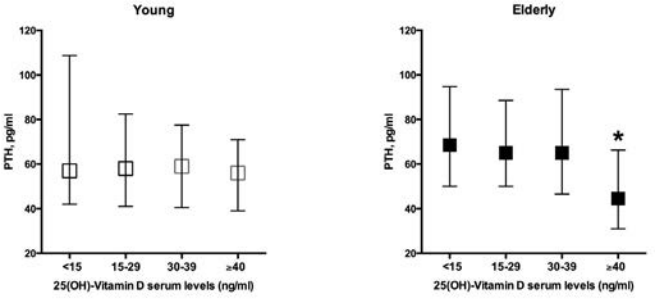
Hyperparathyroidism in Elderly Patients with Chronic Kidney Disease

Rosilene M. Elias,[1] Rosa M.A. Moyses.[1,2] *[1]Nephrology, Univ de Sao Paulo, São Paulo, SP, Brazil; [2]Univ Nove de Julho (UNINOVE), São Paulo, SP, Brazil.*

Background: As the world'spopulation ages, the incidence of chronic kidney disease (CKD) is growing. Since older patients mostly present decreased renal function, there is ongoing debate regarding whether high levels of PTH would be related to age or to renal function. Here, we have tested the hypothesis that secondary hyperparathyroidism is frequent among CKD elderly patients and that this population require higher levels of vitamin D than young patients.

Methods: This is across-sectional analysis of stage 3 CKD patients, in ambulatory patients from a Tertiary Academic Hospital. Elderly patients (age ≥ 65 years, N=518) were compared to a 1:1 sex- and eGFR-matched sample of young patients (age < 65 years), to assess demographic and biochemical differences collected from electronic charts.

Results: Elderly patients presented lower phosphate, and higher levels of serum calcium and parathyroid hormone (PTH). Elderly patients with hyperparathyroidism presented low levels of 25(OH)-Vitamin D.



Hyperparathyroidism (PTH > 65pg/ml) was 1.6 fold more common in elderly patients, which was dependent on age, eGFR, calcium, phosphate, low levels of 25(OH)-Vitamin D and furosemide use.

Conclusions: Elderly patients with CKD are at high risk of hyperparathyroidism, and low levels of vitamin D seem to contribute to this finding. This pattern is independent of renal function, which decreases with age. Further investigation is needed to establish an ideal cut-off value of vitamin D in elderly patients with CKD, and also to test if the supplementation of said vitamin can reduce the incidence of secondary hyperparathyroidism in this population.

PUB596

Longitudinal Association between Kidney Function and Mortality in the Very Old

Paula Ferreira Orlandi,[1] Clineu Mello Almada-Filho,[2] Maysa Seabra Cendoroglo,[2] Ricardo Sesso.[1] *[1]Nephrology Div, Univ Federal de São Paulo, São Paulo, São Paulo, Brazil; [2]Geriatrics and Gerontology Div, Univ Federal de São Paulo, São Paulo, São Paulo, Brazil.*

Background: The association of CKD, older age and mortality among individuals older than 80 years is not well defined. This study evaluates the association between kidney function and mortality in a prospective cohort of community-dwelling very old individuals according to different levels of eGFR and albuminuria.

Methods: A total of 231 independent individuals aged ≥80 yr from São Paulo, Brazil were recruited and followed by an average of 3.1 years. All underwent a hand-grip test, the 'mini-mental' cognitive test and laboratorial assessments, including standardized serum creatinine and urinary albumin to creatinine ratio (ACR). Main outcomes were ESRD and death. Creatinine based CKD-EPI equation was used to estimate eGFR.

Results: Participants were predominantly white (67%), female (70%), with median age of 84 years. At baseline, 45% had eGFR<60ml/min/1.73 m2, 12.9% had eGFR<45ml/ min/1.73m2 and 19.5% had ACR >30mg/g. None developed ESRD. Participants with eGFR<45ml/min/1.73m2 or ACR>30mg/g (n= 61) presented higher rates of death (8.5 deaths per 100 persons-year (p-yr), 95%CI: 5.2 to 13.9) comparing to those with eGFR higher than 45ml/min/1.73m2 and ACR lower than 30mg/g (4.2 deaths/100 p-yr, 95% CI: 2.8 to 6.4) (p=0.033). The eGFR threshold of 60ml/min/1.73m2 combined with ACR lower or greater than 30mg/g was not associated with different mortality rates: 4.6 deaths/100 p-yr

(95%CI: 2.7 to 7.8) in the higher eGFR/no albumin group vs. 5.9 deaths/100 pyr (95% CI: 3.9 to 8.7) (p=0.467). Adjusting for age, sex, dyslipidemia, handgrip and mini-mental test, the hazard ratio of death associated with a eGFR <45 ml/min/1.73m2 or ACR >30 mg/g was 2.16 (95% CI: 1.08 to 4.30, p=0.028).

Conclusions: For independent individuals older than 80 yr, a eGFR lower than 45 ml/min/1.73m2 or the presence of albuminuria (ACR>30 mg/g) yields a higher risk of death adjusting for demographic and functional parameters. In the very old, a lower eGFR threshold combined with albuminuria seems necessary to determine a higher risk of death compared to the younger population.

PUB597

Initiation of Dialysis in the Elderly Patient: A Survey of Nephrology Trainee Perceptions and Practices Emily Lu,[1] Manney Carrington Reid,[2] Ronald D. Adelman,[2] Mark S. Lachs,[2] Brian M. Eiss,[2] Clara Oromendia,[3] Phyllis August,[1] Jeffrey I. Silberzweig,[1] Nathaniel E. Berman.[1] *[1]Nephrology & Hypertension, Weill Cornell Medicine/New York Presbyterian Hospital (WC/NYPH); [2]Geriatrics & Palliative Medicine, WC/NYPH; [3]Biostatistics, Healthcare Policy & Research, WC/NYPH.*

Background: Delaying or not initiating dialysis may not impact mortality in elderly chronic kidney disease (CKD) patients, but Nephrologists have not reached consensus on key factors in making this decision. We assessed Nephrology fellows' perceptions and practices about dialysis initiation in CKD age >75 (ELD) versus general CKD (GEN) patients.

Methods: We surveyed New York City Nephrology fellows via a 30-item questionnaire. Responses were collected anonymously. Data were analyzed using paired T, Cohen's Kappa(K) and Chi-square tests (significant if <0.05).

Results: Respondents (n=40) were mostly female (65%), 1st year trainees (70%). 52% had prior geriatrics/palliative care training. Fellows cited functional status (85%) and patient preference (75%) as key factors in ELD. Many felt after dialysis initiation, functional status would decrease in ELD (63%) but increase in GEN (57%) (K=0.212, p<0.01), while mortality risk would not change in either group (45%) or increase more in GEN (30%) than ELD (15%) (K=0.471, p<0.01). Over half said quality of life in ELD would "sometimes" improve. Fellows would initiate dialysis at lower GFR values in ELD (12.7+/-4.2) versus GEN (14.2+/-5.3) (p=0.02), but their threshold serum creatinine (~7mg/dL) and albumin (~2.5mg/dL) levels were similar in ELD and GEN (p=0.27; p=0.08). 67% felt equally prepared to discuss initiating dialysis in ELD and GEN; only 39% were equally comfortable making the decision. 95% said dialysis initiation in ELD with severe, permanent dementia was likely indicated, but disagreed in ELD with good cognitive function and poor mobility/wheelchair-bound (51% "probably indicated," 26% "probably not indicated," 13% "do not know").

Conclusions: Nephrology fellows are aware that prognosis/outcomes may differ in ELD initiated on dialysis versus GEN, but these distinctions did not translate into shared practice patterns, suggesting need for further study of key criteria/factors affecting this decision.

PUB598

Factors Predicting Mortality in Hemodialysis Patients over 65 Years Old Sofia Correia, Josefina Lascasas, Jorge Malheiro, Isabel Fonseca, Andreia Campos, António Cabrita. *Nephrology, CHP, Porto.*

Background: Patients starting dialysis are increasingly elderly and with high morbidity and mortality. Knowledge of prognostic factors in end-stage renal disease patients has improved dialysis management and should be considered when starting renal replacement therapy(RRT).

Methods: The aim of this retrospective study was to analyze the outcomes of 208 incident dialysis patients over 65 years old. Possible predictors of mortality, included in multivariable Cox analysis were:age, sex, ischemic heart disease (IHD), congestive heart failure(CHF), cancer, chronic pulmonary disease, urgent dialysis, catheter as vascular access (CVC), serum albumin, peripheral vascular disease, smoking, dementia and performance status.

Results: Cohort mean age was 75 years.Survival rate at 6 and 36 months was 88 and 61%, the main cause of death was infection (46 and 55%), followed by cardiovascular(CV) disease (35 and 29%) and cancer. Kaplan-Meier analysis showed that age was significantly associated with mortality at the 36 (p=0.007) but not at 6 (p=0.3) months. Independent predictors of mortality detected by multivariable cox regression model considering all causes, infection or CV are represented below.

6-month mortality (all causes)			
	Hazard ratio	**95% Confidence interval**	**p Value**
CVC	2.67	1.09-6.53	0.031
Albumin<3.5	4.78	1.86-12.28	0.001
36-month (all causes)			
Age>75	2.40	1.36-4.26	0.003
CVC	2.41	1.32-4.40	0.004
IHD	2.07	1.16-3.68	0.013
CHF	2.69	1.46-4.95	0.002
Cancer	2.35	1.12-4.94	0.023
Albumin<3.5	2.41	1.39-4.19	0.002
6-month (infection)			
Age>75	6.7	1.23-36.6	0.028
Albumin<3.5	5.15	1.25-21.29	0.024
36-month (infection)			
Age>75	2.35	1.07-5.18	0.034
CVC	2.43	1.08-5.45	0.032
6-month (CV)			
IHD	6.83	1.08-43.13	0.041
Albumin<3.5	6.81	1.19-39.12	0.032
36-month (CV)			
Age>75	4.10	1.35-12.40	0.013
IHD	4.31	1.36-13.64	0.013

Conclusions: Predictors of mortality varied with time on RRT. Early mortality was associated with hypoalbuminemia and CVC, with age only being predictor of infection related early death. Our data may contribute in the decision making process about RRT indication and timing in the elderly.

PUB599

Anemia Is an Independent Risk for Reduced Physical Function in Elderly Patients with Chronic Kidney Disease Kaori Kohatsu, Masahiko Yazawa, Yasuhiro Taki, Yugo Shibagaki. *Dept of Internal Medicine, Div of Nephrology and Hypertension, St. Marianna Univ Hospital, Kawasaki, Japan.*

Background: Recently the prevalence of sarcopenia defined as reduced muscle strength and function has been increasing and considered as a risk for poor prognosis in elderly patients with chronic kidney disease (CKD). In this study, we investigated the risk factor of physical function in predialysis CKD.

Methods: We conducted a cross-sectional study based on data of 134 outpatients of our hospital who are older than 60 years and estimated glomerular filtration rate (eGFR) is under 60 ml/min/1.73m^2. Besides baseline laboratory data and muscle mass, physical and cognitive function were examined. We used skeletal mass index [SMI:muscle mass (kg) / Height (m^2)] using bioelectrical impedance analysis (BIA)to assess the muscle mass and 4-meter walking speed (4mWS) to assess physical function. We compared the variables in those with 4mWS than 0.8m/sec and in those with slower. Similarly, we compared the variables in those with high SMI(> 7.0kg/m^2 in male, > 5.8 kg/m^2 in female)and in those with lower. Student t or chi-squared test were used for comparison and logistic regression were used to conduct multivariate analysis.

Results: Mean age was 77±7.12 years old, 100 out of 134 patients were male. The average eGFR was 28 ±12 ml/min/1.73m^2, and 57 (42.5%) patients have diabetes mellitus. CKD stage G3 accounted for 44.7 %, G4 41.7 %, G5 12.6 %. Slower 4mWS was associated with older age, lower hemoglobin (Hb; 12.0 vs 10.35 g/dl), higher blood urea nitrogen, higher inorganic phosphorus, lower activated vitamin D, higher urinary albumin and protein. On the other hand, urinary albumin, inorganic phosphorus was correlated with SMI. Multivariate logistic regression analysis identified that Hb was the only independent risk factor for slower 4mWS (RR: 2.905, 95%CI: 1.177-7.170). When stratified by CKD stage, only age was associated with 4mWS in CKD stage G3, but in CKD stage 4-5, Hb was the only significant factor (RR:4.634, 95%CI:1.396-16.437).

Conclusions: Our study suggests that reduced physical function is associated with anemia. In elderly CKD patients. This association is especially strong in advanced CKD.

PUB600

The Clinicopathologic Characteristics of the Very Elderly Chinese Patients with Kidney Disease Dong Liu,[1,2] Xiyan Liao,[1,2] Yanna Dou,[1,2] Zhanzheng Zhao.[1,2] *[1]The Nephrology Center, The First Affiliated Hospital of Zhengzhou Univ; [2]Zhengzhou Univ Inst of Nephrology.*

Background: Data regarding renal disease with pathology in the very elderly(age≥80 years older) Chinese is extremely limited. The aim of this study was to examine clinicopathologic presentations in the very elderly patients who underwent renal biopsy and the complications.

Methods: From May 2012 to March 2016, the patients who underwent renal biopsy from our hospital were screened. The very elderly patients(age≥80 years old) were enrolled in the observed group. Their data were compared with the control group (patients aged 65-70 years old). over the same period. The clinical and pathological classifications of the two groups were analyzed.

Results: 33 patients (24 males, 82.7±1.9 years) were in the observed group and 100 patients (71 males, 67.0±1.5 years) were in the control group. Compared with the control group, the observed group showed lower eGFR (48.8±27.7 vs. 67.4±44.8 (mL/(min*1.73m^2), p<0.05). And there was no significant difference in blood pressure, serum albumin, proteinuria of 24 hours, hemoglobin, creatinine and lipids. Primary glomerulopathy was the most frequent pathologic diagnosis(63.64%),followed by secondary glomerulopathy(21.21%).In the patients of primary glomerulopathy with kidney disease, membranous nephropathy was the most frequent histological type (38.1%) and the ratio is lower than the control group (66.7%, p<0.05); followed by glomerular minimal change(33.33% vs. 16.7%, NS), focal segmental glomerulosclerosis(9.5% vs. 1.5%, NS), IgA nephropathy(9.5% vs. 3.0%, NS). Compared to the control group, the ratio of Secondary glomerulopathy was higher than the control group(21.2% vs. 9.1%, p<0.05), and the ratio of amyloid nephropathy was also higher (57.1% vs. 33.3%, p<0.05). And for the very elderly patients with nephrotic syndrome, minimal change disease was the most common histological type(33.33%),followed by membranous nephropathy(28.57%). And there was no side effects of perinephric hematoma, gross hematuria, arteriovenous fistula or other complications.

Conclusions: The pathology type of the very elderly patients with kidney disease is different with the elderly patients.

Funding: Government Support - Non-U.S.

PUB601

Prevalence, Predictors and Clinical Outcome of Frailty in an Elderly Pre-Dialysis Cohort Hatem Ali, Fatima Abdelaal, Jyoti B. Baharani. *Renal Dept, Heartlands Hospital, Heart of England NHS Trust, United Kingdom.*

Background: The relationship between frailty and CKD in elderly population has been recognised and some studies have demonstrated frailty as a predictor of adverse outcome especially among haemodialysis patients. However studies concentrating on frailty in pre-dialysis patients are limited. The aim of this study was to assess prevalence and predictors of frailty in an elderly pre-dialysis population.

Methods: A cross-observational study was conducted in which 108 patients aged 65 years or above with an eGFR of 25ml or less were included. Data including age, sex, FBC, CRP, ferritin, renal function, calcium, albumin, PTH and co-morbidities were collected at baseline and at 3 months interval for one year. Functional performance was assessed using Karnofsky scale. Frailty was assessed using combination of PRISMA questionnaire and Timed up and Go test (TUGT).Endpoints were death or start of dialysis at 1 year follow up.

Results: A frail group (n=61; male =31, female=30) and a non-frail group (n=47; male=20, female=27) were identified. Frailty was prevalent in 53.6% of selected population. Multiple regression analysis was used to compare different variables to frailty and chi squared test was used to compare the endpoints between the 2 groups. Functional performance was significantly lower in the frail group compared to non-frail (P=0.0001). No significant differences between the 2 groups in terms of age(P=0.8), sex(P=0.6), haemoglobin (P=0.2), white blood cells(P=0.4),CRP(P=0.9), Ferritin(P=0.4), Calcium(P=0.2), Albumin(P=0.3), change in creatinine (P=0.9), PTH(P=0.3) or number of co-morbidities(P=0.8)were seen. 6 patients chose conservative management in the frail group and 2 in non-frail group .Rate of death and start of dialysis were significantly higher in the frail group (death =10, dialysis =21) compared to non-frail group (death =2, dialysis =10) with P= 0.007.

Conclusions: Prevalence of frailty is high amongst elderly pre-dialysis patients. These patients have lower functional performance. Anemia, Calcium homeostasis and inflammatory markers do not predict frailty. Rate of death and start of dialysis is significantly higher in the frail group compared to non-frail group.

PUB602

Intrarenal Renin-Angiotensin System Activity Is Augmented after Initiation of Dialysis Naro Ohashi,[1] Shinsuke Isobe,[1] Sayaka Ishigaki,[1] Takayuki Tsuji,[1] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Shizoka, Japan.*

Background: Circulating renin-angiotensin system (RAS) activation is maintained after renal function has deteriorated. The activation of the intrarenal RAS plays a critical role in the pathophysiology of chronic kidney disease (CKD), independent of the circulating RAS. However, it has not been clarified as to whether the intrarenal RAS is activated after renal function has declined.

Methods: We recruited 19 CKD patients (10 without dialysis and 9 with dialysis) who underwent a heminephrectomy. Circulating RAS was investigated before nephrectomy. The levels of intrarenal RAS components were investigated using radioimmunoassay and immunoblot analysis on samples from the removed kidney. Renal damage was evaluated by the extent of tubulointerstitial fibrosis.

Results: No significant differences in circulating RAS between non-dialysis and dialysis patients were found. However, intrarenal angiotensin II (AngII) and tubulointerstitial fibrosis in dialysis patients were significantly increased compared with non-dialysis patients (AngII (pg/g): non-dialysis; 1.84±0.23 vs. dialysis; 2.26±0.43; p=0.013 and tubulointerstitial fibrosis (%): non-dialysis; 32.1±20.5 vs. dialysis; 96.9±6.2; p<0.01). Prorenin and angiotensin converting enzyme (ACE) levels were dramatically decreased in accordance with renal dysfunction (prorenin: non-dialysis; 1.00±0.71 vs. dialysis; 0.18±0.13; p<0.01 and ACE: non-dialysis; 1.00±0.83 vs. dialysis; 0.013±0.035; p<0.01). AngII type 1 receptor (AT1R) expression was significantly increased in dialysis patients compared with non-dialysis patients (non-dialysis; 1.00±0.29 vs. dialysis; 1.50±0.22; p<0.01). In multiple linear regression analyses, there were significant positive and negative relationships between interstitial fibrosis and angiotensinogen (AGT) (β=0.45, p=0.042) and prorenin levels (β=-0.85, p=<0.01), respectively.

Conclusions: A decrease in prorenin and ACE levels and an increase in AGT, AngII and AT1R levels in the kidney occur in dialysis patients and these changes may be associated with intrarenal RAS activation and renal damage.

Platelet-Activating Factor Induces Transcription of Heparin-Binding Epidermal Growth Factor-Like Growth Factor through κB-binding Activity in MDCK Cells Keisuke Sugimoto,[1] Tomoki Miyazawa,[1] Kohei Miyazaki,[1] Takuji Enya,[1] Hidehiko Yanagida,[2] Mitsuru Okada,[1] Raymond C. Harris,[3] Tsukasa Takemura.[1] *[1]Pediatrics, Kindai Univ Faculty of Medicine, Osakasayama, Osaka, Japan; [2]Pediatrics, Kindai Sakai Hospital, Sakai, Osaka, Japan; [3]Nephrology & Hypertension, Vanderbilt Univ School of Medicine, Nashville, TN.*

Background: Various cytokines and growth factors promote cell proliferation and vascularization in glomerulonephritis. Platelet-activating factor (PAF) is a phospholipid activator/mediator which promotes cell growth as well as secretion of inflammatory cytokines and growth factors, stimulates secretion of heparin-binding epidermal growth factor-like growth factor (HB-EGF), which fosters tissue recovery from renal tubular disorder and some types of glomerulonephritis. Since the nuclear factor involved in HB-EGF production and secretion is unclear, we investigated involvement of PAF stimulation in HB-EGF gene expression and details concerning nuclear factors using MDCK II cells.

Methods: After cells were treated with PAF plus inhibitors and cell extracts were obtained, Northern blotting and electrophoretic mobility shift assays (EMSA) were performed.

Results: PAF enhanced HB-EGF mRNA expression in a dose- and stimulation-duration-dependent manner. PAF-induced NF-kB DNA-binding by NF-kB and HB-EGF mRNA expression were inhibited in the presence of PAF receptor antagonists (L-659989 or WEB 2086). HB-EGF-inducing DNA-binding activity of NF-kB was inhibited by L-659989 and WEB 2086, while mRNA expression and DNA-binding activity of NF-kB were inhibited dose-dependently by PDTC, an NF-kB inhibitor.

Conclusions: PAF is involved in gene control in MDCK cells, activating NF-kB binding, and strongly inducing HB-EGF gene expression.

PUB604

Evaluation of Factors Associated with Central Venous Catheter and Immature Arteriovenous Fistula Use at Initial Dialysis Ken J. Park,[1] Micah L. Thorp,[1] Eric S. Johnson,[2] Ning Smith.[2] *[1]Kaiser Permanente Northwest, Milwaukie, OR; [2]Kaiser Permanente Center for Health Research Northwest, Portland, OR.*

Background: Patients with end stage renal disease (ESRD) have high mortality rate thought related to use of central venous catheters (CVC) for initial dialysis. We sought to examine factors associated with CVC use and presence of immature fistula (AVF) at initial dialysis.

Methods: Retrospective cohort of incident hemodialysis patients from large HMO who started dialysis between 1/1/04 to 1/1/14 (n=918). Variables recorded included age, gender, race, diabetes, peripheral vascular disease, congestive heart failure, grade of proteinuria (divided into <0.2 gm, 0.2-0.5 gm, 0.5-3.5 gm, and >3.5 gm), length of predialysis nephrology care, number of hospitalizations predialysis over 2 year period, early start, history of acute kidney injury, and timing of AVF placement. Primary outcome was presence of CVC at initial dialysis. Secondary outcome was presence of immature AVF at initial dialysis. Multivariable logistic regression model was used to evaluate factors associated with outcome.

Results: At initial dialysis, AVF was used in 36% and CVC was used in 64% of the cohort. Higher odds of CVC use was associated with increased hospitalizations (OR 1.07) while increased length of predialysis care was associated with lower odds of CVC use (OR 0.98). Female gender was associated with higher odds (OR 1.7) of immature AVF at initial dialysis as was shorter time of AVF placement pre dialysis. Grade of proteinuria was associated with both CVC use and presence of immature AVF at initial dialysis. Patients with proteinuria between 0.5-3.5 gm had the lowest odds for starting dialysis with CVC or immature AVF.

Conclusions: Grade of proteinuria was associated with both use of CVC and presence of immature AVF at initial dialysis. Increased predialysis hospitalizations and shorter predialysis nephrology care was associated with increased odds of CVC use but not with presence of immature AVF. Female gender and delayed timing of AVF placement was associated with increased odds of immature AVF use.

PUB605

Haemodialysis Vascular Access: Current Practices amongst Indian Nephrologists Dinesh Bansal,[3] Eric S. Chemla,[2] Vijay K. Kher,[3] Vivekanand Jha,[1] Debasish Banerjee.[2] *[1]PGIMER Chandigarh; [2]St. Georges Hospital London; [3]MEDICITY Delhi.*

Background: Despite the growing number of patients receiving haemodialysis (HD) in India, little is known about vascular access practice. We document use and cost of different vascular accesses as reported by practicing Indian Nephrologists.

Methods: A web-link for a national online survey was emailed to 920 Indian nephrologists in Jan-Feb 2016. A total of 388 (42.1%) completed the survey; 98.5% of whom were responsible for managing dialysis patients, and 98% in hospitals.

Results: At start of RRT, 65% of the patients had HD, 8% PD, 10% kidney transplantation and 20% conservative care. 48% patients were self-paying, 26% had employee reimbursement and 23% had private insurance. According to 59% responders, >75% of patients started dialysis with uncuffed catheter. Less than a quarter patients started dialysis with fistula [82% nephrologists], graft [99% nephrologists] or tunnelled catheters [90% nephrologists]. Among the prevalent haemodialysis patients, over half of the patients were dialysing with fistula [79% nephrologists], rather than uncuffed catheters [15% nephrologists] or grafts [<1% nephrologists]. 16% reported at least one catheter related sepsis in more than ½ of patients. Placement of uncuffed catheters cost <US$150 in 92% facilities, whereas the cost of placing a tunnelled catheter was estimated at >$300 by about 46%. An AVF could be created for <$150 in the practice of 40% nephrologists, and <$300 in 90% centres. 35% of nephrologists reported grafts were not placed at their institute and the cost, where available, was >$500. 46% nephrologists had access to pre-dialysis clinics, <30% to vascular access program, <17% conducted regular audits of vascular access audits. Over 98% responders were willing to participate in projects related to vascular access or dialysis audits.

Conclusions: The survey demonstrates that most patients are self-paid, start HD with uncuffed temporary catheters, with poor access to predialysis care and vascular access team. There are more fistulae in prevalent patients. The survey highlights the suboptimal vascular access care in haemodialysis patients and the need for pre-dialysis clinics, vascular access services and registry audits.

PUB606

Cross-Sectional Study Demonstrating Arteriovenous Fistula Failure Is Not Associated with Age, Comorbidity, Previous Access or Anatomical Location Viyaasan Mahalingasivam, Amrita Ramnarine, Veronica Smith, Pamela Ayling, Abdelgalil Abdelrahman Ali. *Dept of Nephrology, Broomfield Hospital, Chelmsford, United Kingdom.*

Background: Arteriovenous fistula is the preferred form of vascular access for haemodialysis. However, it is associated with failure rates of up to 49% at two years. Several factors are considered to be responsible for this which may influence surgical access planning. The UK Renal Association published a guideline encouraging best-practice access formation.

Methods: We retrospectively audited 107 fistulae formed at our centre between April 2014 and October 2015. Data was collected for variables including age, sex and comorbidity, as well the anatomical location of the fistula and previous access. Data was analyzed to assess whether variables were associated with an increased risk of fistula failure.

Results: Our audit demonstrated a fistula failure rate of 17.7% with 14 out of 71 (19.7%) failed radiocephalic fistulae and 5 out of 35 (14.3%) failed brachiocephalic fistulae. There was no statistically significant correlation between sex, comorbidity, anatomical location, the use of dominant arm or previous access with an increase in fistula failure. Further subgroup analysis was performed after separating radiocephalic and brachiocephalic fistulae. Neither age nor comorbidity were shown to be associated to significantly increase the risk of failure in either of these groups.

Conclusions: Fistula failure rate at our centre is in keeping with rates documented in the literature. We demonstrated that factors such as sex, comorbidity and anatomical location are not associated with increased rate of fistula failure. We would therefore advocate that all patients destined for haemodialysis undergo fistula formation and unless there is contraindication on the basis of ultrasound evaluation, radiocephalic fistula formation should be attempted in the first instance. Prospective studies with longer follow-up are required to confirm these findings.

PUB607

Patency of Translumbar Percutaneous Catheter for Hemodialysis, Experience of Our Center: Instituto Mexicano del Seguro Social, Specialty Hospital "La Raza" Mexico City, Mexico Juan Carlos Garcia Yanez, Guillermo Jimenez. *Nefrologia, Inst Mexicano del Seguro social, Ciudad de Mexico, Mexico.*

Background: In Mexico we do not have reliable statistics which is the first access of patients starting renal replacement therapy. Over 80% of patients in the United States started hemodialysis therapy with a tunneled catheter (CT). (1) The renal replacement therapy based on Hemodialysis requires placement and maintenance of vascular access that allows adequate blood flow. It is ideal using an arteriovenous fistula (AVF) due to the low rate of complications that offers handling. However, many patients start (23-63%) or continue their treatment (23-41%) through tunneled central venous catheters and non-tunneled. Chronic use of these central catheters cause, as an inevitable consequence, vascular stenosis generation exhaustion, intraluminal thrombosis or associated infection. (3-4). In the following complication of superior vena cava stenosis. When the availability of vascular access for hemodialysis fistulas and vascular prostheses, catheters for hemodialysis, jugular, femoral and subclavian is exhausted, it is mandatory to find alternative vascular approach more complex, requiring more technical and advanced technological tools. the experience of our center in placing Translumbar vascular access (AVT) guided by fluoroscopy to a year in which the first catheter is reported.

Methods: A retrospective study on an electronic database of AVT placed in our hospital was performed survival analysis catheters placed one year of the first catheter was used. The procedure to patients with evidence angiography was performed by bilateral central venous obstruction.

Results: The total number of patients undergoing the procedure were 12, of which 8 were men and 4 were women, the average age is 41 years. The median survival of vascular access is 168.5 days. One patient died from causes attributable to the placement of vascular access.

Conclusions: According to these results the placement of percutaneous vascular access for hemodialysis guided by fluoroscopy through Translumbar approach has proven to be a good alternative for patients with depletion of common vascular access before any surgical intervention.

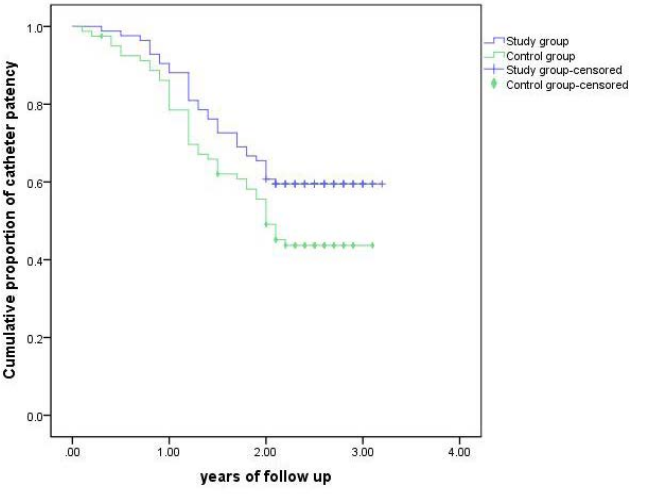
PUB608

A Modified De Novo Insertion Technique for Catheter Replacement in Elderly Hemodialysis Patients: A Single Clinic Retrospective Analysis Li Hua Wang,[1] Fang Wei,[2] Ai Li Jiang.[3] *[1]Dept of Kidney Disease and Blood Purification Centre, Inst of Urology & Key Laboratory of Tianjin, Tianjin, China; [2]Dept of Kidney Disease and Blood Purification Centre, Inst of Urology & Key Laboratory of Tianjin, Tianjin, China; [3]Dept of Kidney Disease and Blood Purification Centre, Inst of Urology & Key Laboratory of Tianjin, Tianjin, China.*

Background: For patients who rely on a Tunneled cuffed catheter, replacement or retrieval is typically necessary. We recently performed a novel de novo insertion technique for catheter replacement in our practice. As the technique has not yet been studied comprehensively, we performed a retrospective study to evaluate the safety and efficacy of de novo placed catheter without delay for catheter replacement in elderly hemodialysis patients.

Methods: A retrospective review of 164 elderly patients was conducted during a period of three years. There were 84 patients in study group, as well as an 80 patient control group, who had catheter replacement by guidewire exchange technique. Clinical follow-up data was collected.

Results: All catheters were placed successfully. The mean survival time per catheter was 641 catheter days (study group) and 485 catheter days (control group).



The primary patency rates of 30 days were 97.7% (study group) and 82.5% (control group), respectively. The episode of catheter infection was similar in both groups (p=0.586), but the case of catheter dysfunction was significantly lower in study group compared to control group (p=0.003).

Conclusions: The de novo placed catheter without delay technique for catheter replacement near the pre-existing venotomy site is safe, and boasts similar infectin rates with lower dysfunction rates compared to tunneled catheter insertion by guidewire exchange technique.

PUB609

Effects of Vascular Access Care on Hospitalization Rates in Hemodialysis Patients Sheetal Chaudhuri,[1] Hao Han,[1] Marta Reviriego-Mendoza,[1] Sophia Rosen,[1] Karen G. Butler,[1] Jane Brzozowski,[1] John W. Larkin,[1] Elsie Koh,[2] Walead Latif,[2] Gregg Miller,[2] Melvin Rosenblatt,[2] Murat Sor,[2] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Vascular Care, Berwyn, PA.*

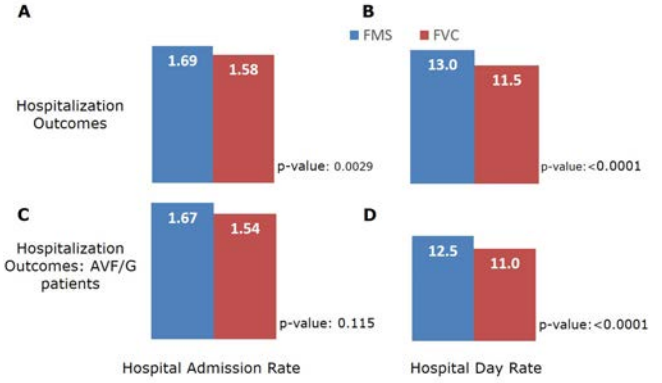
Background: Hemodialysis (HD) patients at Fresenius Medical Care North America (FMCNA) can choose to receive outpatient vascular access (VA) care from Fresenius Vascular Care facilities (FVC). We investigated if hospitalization rates in HD patients receiving VA care from FVC differ from those receiving VA care from other providers that were primarily hospital based or receiving no VA care at all.

Methods: We analyzed data from 4,691 HD patients treated by FVC during entire calendar year 2014. We matched 4,691 control patients exactly by concurrent year of FVC care, state of residence, gender, race, and access type. Also, propensity score matching was performed using the following variables: age, dialysis vintage, albumin, body mass index,

and Kt/v. We repeated the analysis for 4,376 FVC patients with a preexisting arteriovenous fistula/graft (AVF/AVG). Six month hospital admission and day rates per patient year were compared between study groups starting with 1/1/2015.

Results: As compared to controls, we found FVC patients exhibited: 1) 7% and 12% lower rates for hospital admissions and days after ≥1 FVC visit(s) respectively ($p<0.01$ both; Figure 1: A & B); 2) in FVC patients with a preexisting AVF/AVG, there was a nonsignificant reduction of 8% in the admission rate ($p=0.1$; Figure 1: C) 3) hospital days were 12% lower for FVC patients with an AVF/AVG ($p<0.001$; Figure 1: D).

Figure 1



Conclusions: The study results suggest that outpatient VA care at FVC is associated with lower hospitalization rates in HD patients, compared to controls. Further studies are needed to confirm these results.

PUB610

Outpatient Vascular Access Care Is Associated with Improved Access Sustainability in Hemodialysis Patients Marta Reviriego-Mendoza,[1] Sheetal Chaudhuri,[1] Hao Han,[1] Sophia Rosen,[1] Jane Brzozowski,[1] Karen G. Butler,[1] John W. Larkin,[1] Len A. Usvyat,[1] Walead Latif,[2] Elsie Koh,[2] Gregg Miller,[2] Melvin Rosenblatt,[2] Murat Sor,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Vascular Care, Berwyn, PA.*

Background: In hemodialysis (HD) patients, arteriovenous fistula/graft (AVF/AVG) complications are common, life threatening, and can require intermittent catheter exposure. Fresenius Medical Care North America (FMCNA) patients can choose to receive outpatient vascular access (VA) care with Fresenius Vascular Care (FVC). We investigated if FVC VA care is associated with improvements in AVF/AVG sustainability, as compared to matched patients receiving care mainly through hospital VA providers or no care at all.

Methods: Data from 4,691 FVC HD patients during 2014 was analyzed. Control patients (n=4,691) were matched exactly by year of FVC care, state, gender, race, and access type, and nearest neighbor propensity score matching for age, dialysis vintage, albumin, body mass index, and Kt/v. A sub-analysis was performed on 4,376 FVC patients with preexisting AVF/AVG. Duration of AVF/AVG use was calculated by percent of AVFs/AVGs with a stop date in 2015, as well as, via estimating average days from Jan 1, 2015 to the AVF/AVG stop date; an imposed stop date of Jan 14, 2016 was used if none was recorded.

Results: We observed that there were 3% fewer patients requiring AVF/AVG removal/abandonment when enrolled in FVC ($p<0.001$), and on average FVC patients used their AVF/AVG 2.33 days longer than controls ($p<0.001$).

Conclusions: Our analysis suggests that outpatient VA care at FVC is associated with improvements in AVF/AVG sustainability and decrease the need for removal/abandonment, as compared to patients receiving VA care from primarily hospital providers (or no access care). Long term investigations are warranted to confirm the findings.

The Transluminal Interventional Therapy on Heterotopia of Internal Jugular Vein Cuffed Tunneled Catheter Xinxin Jiang,[1] Juan Jin.[2] *[1]Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China; [2]Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: To summarize the transluminal interventional therapy on heterotopia of internal jugular vein cuffed tunneled catheter.

Methods: We retrospectively analyzed the clinical data, transluminal interventional therapy and results of 11 patients who had heterotopia of internal jugular vein cuffed tunneled catheter.

Results: In 11 patients, 9 patients had no central vein stenosis. Two patients whose right internal jugular vein cuffed tunneled catheter in azygos vein were adjusted without smooth guide wire. Seven patients whose left internal jugular vein cuffed tunneled catheter in right brachiocephalic vein were adjusted by help of smooth guide wire. Two patients whose right internal jugular vein cuffed tunneled catheter pulled back to right internal jugular vein had right brachiocephalic vein stenosis. They had right internal jugular vein catheterization before. The cuffed tunneled catheter was placed after pertaneous transluminal angioplasty of right brachiocephalic vein stenosis. There were no severe complications in 11 patients.

Conclusions: The transluminal interventional therapy on heterotopia of internal jugular vein cuffed tunneled catheter was effective and safe.

PUB612

Analysis of the Effects on Two-Locus Puncture Thrombolytic Therapy for Artificial Vascular Thrombosis by Using Urokinase Hua Liu, Hongli Jiang, Kehui Shi, Quan He, Meng Wang, Jinhong Xue. *Blood Purification, The First Affiliated Hospital of Medical College of Xi'an Jiaotong Univ, Xi'an, Shaanxi, China.*

Background: To analyze the effect of two-locus puncture thrombolytic therapy for the treatment of arteriovenous graft (AVG) thrombosis by using urokinase.

Methods: Two positioning near arteriovenous anastomosis were selected as the centripenal puncture points, then the AVG was treated with 5000 U/ml urokinase, which was repeatedly pumped through the scalp needle, meanwhile the low molecular weight heparin could be used as an auxiliary drug. After treatment, the result of the patients with AVG ultrasound, blood routine examination, coagulation indicator, biochemical criterion were compared with that before treatment, and the adverse reactions were observed at the same time.

Results: Observation of AVG thrombosis (n = 30), AVG usage time was 6 months to 5 years, and thrombus formation time was 3 h to 48 h. Among 30 cases of patients with thrombolytic therapy by two-locus puncture, 26 cases obtained successful thrombolysis (86.7%), with average time of thrombolysis (4.74±2.31) h and average urokinase thrombolytic dosage (35.5±5.5 million)U. There was no significant difference in age, dialysis age and AVG usage time between success group and failure group. The success of the treatment was related to the thrombus formation time and the status of venous terminal flow ($P<0.05$). Before and after thrombolytic therapy, there was no significant difference in hemoglobin, platelet, prothrombin time (PT), thrombin time, activated partial thromboplastin time (APTT), fibrous protein, glutamic-pyruvic transaminase, serum albumin and total bilirubin. The slight rise of APTT and PT was considered as the application of low molecular weight heparin.

Conclusions: The two-locus puncture thrombolytic therapy using urokinase discontinuously and repeatedly has a high success rate, which can reduce the temporary catheter and surgical reconstruction as well as their associated complications. It has a high clinical value, as the ideal choice for the thrombolytic treatment of AVG thrombus formation, especially for basic-level hospitals.

PUB613

Financial Impact of Catheter Malfunction in Dialysis Anjali Acharya,[1,2] Samuel Mon-Wei Yu.[2] *[1]Nephrology, Jacobi Medical Center, Bronx, NY; [2]Medicine, Jacobi Medical Center, Bronx, NY.*

Background: Catheter malfunction and infection are major causes of morbidity and mortality in dialysis patients. It also is a financial burden on the health care system and adds to the costs of providing dialysis. Kidney Dialysis Outcomes Quality Initiative (KDOQI) guidelines, defines catheter malfunction as blood flow less than 300mL/min during the first 60 minutes of hemodialysis. Intrinsic thrombus and biofilm formation or fibrin sheath formation are major contributors to catheter malfunction. Mechanical disruption of the fibrin sheath is commonly used to tackle the problem, with variable success. If catheter malfunction cannot be successfully resolved by this method, exchange of catheter is commonly used with attendant cost and potential risk to the patient.

Methods: We describe 2 patients with ESRD on maintenance hemodialysis, in whom catheter dysfunction required catheter exchange (CEX) every 3-4 weeks over a 6 month period. A decision was made for weekly instillation of thrombolysitc (tPA) into each port which resolved the issue.

Results: Since the initiation of tPA use, neither of the two patients has required catheter exchange as opposed to every 3-4 week exchange earlier in their course. In addition to the obvious clinical benefit to the patients, the economic impact of this intervention with weekly instillation of tPA is huge. Considering a conservative estimate of $1,900 per CEX, the cost difference between the two options is tremendous. Please see table 1 below.

Patient	Number of Exchanges	Time period	Number of CEX-Post weekly tPA installation	Additional cost in the time period($)
#1	11	April 2015-Feb 2016	0	20,900
#2	6	Feb 2015 -Jan 2016	0	11,400

In addition, there is the disadvantage of loss of productivity secondary to time lost due to the procedures, which was not assessed in our evaluation.

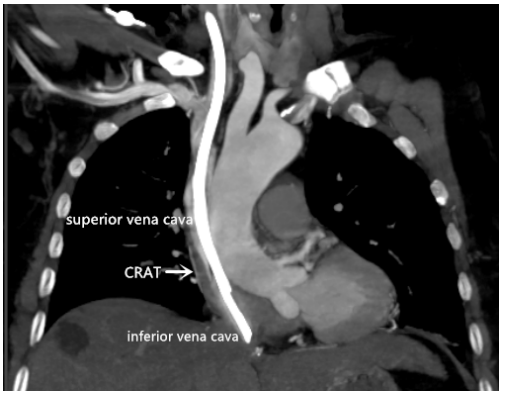
Conclusions: We recommend using weekly tPA protocol in patients with catheter dysfunction before proceeding with catheter exchange, especially in those individuals requiring frequent exchanges. This needs to be explored by further randomized controlled studies and more characterization of the patient population.

PUB614

Management of Right Atrial Thrombi Complicating Use of Tunneled-Cuffed Catheter in Hemodialysis Hongliu Yang,[1] Tianlei Cui,[2] Ping Fu.[3] *[1]Nephrology, West China Hospital, Sichuan Univ, Chengdu, China; [2]Nephrology, West China Hospital, Sichuan Univ, Chengdu, China; [3]Nephrology, West China Hospital, Sichuan Univ, Chengdu, China.*

Background: Catheter-related right atrial thrombosis (CRAT) is a rare as well as underreported but potentially life threating complication of tunneled-cuffed catheter (TCC) in hemodialysis (HD) patients. There is no current guideline for the management of this complication. Thus, we aimed to explore the optimal treatment of HD patients with CRAT and evaluate their outcomes.

Methods: We reviewed hospital records of 20 HD patients dialysed through TCC with diagnosis of CRAT from March 2013 to August 2015 and followed through 31 May 2016. Once CRAT was diagnosed, TCCs were exchanged over a guide-wire in situ with reposition of the catheter tip.



Immediately after insertion and at the end of each HD session, both ports of the catheters were locked with unfractioned heparin solution. Patients younger than 70 were administered with warfarin [target international normalized ratio (INR) 1.5-1.9]. Patients beyond the age of 70 were administered with dual antiplatelet therapy. All the patients maintained regular dialysis without thrombolysis or thrombectomy.

Results: During the follow up, 3 patients died: 2 of gastrointestinal massive hemorrhage and 1 of acute myocardial infarction. 4 patients suffered from pulmonary embolism but none of them died. There was no death directly attributed to CRAT. Resolution of CRAT was observed in 8 patients and size of thrombi decreased in 12 patients.

Conclusions: Regular maintenance HD through replaced catheter with reposition of catheter tip and oral anticoagulation may be a successful management in HD patients suffered from CRAT. Nevertheless, prospective studies are needed to identify risk factors of development and to determine the optimal management of CRAT in HD patients.

Superior Cava Vein Syndrome due to Catheter-Related Thrombosis Treated with Angiojet Rheolytic Thrombectomy Michele Ferrannini,[1] Alessia Centi,[1] Paola Tatangelo,[1] Eleonora Bernabei,[1] Gianluca Smedile,[3] Roberto Cancellieri,[2] Marco Guazzaroni,[2] Roberto Palumbo.[1] *[1]Nephrology and Dialysis Dept, St. Eugenio Hosp., Rome, Italy; [2]Radiology Dept, St. Eugenio Hosp., Rome, Italy; [3]Vascular Surgery Dept, St. Eugenio Hosp., Rome, Italy.*

Background: The rescue of the vascular access is mandatory in hemodialysis. In literature it is know the efficacy of mechanical thrombectomy devices for arteriovenous (AV) fistula thrombosis, but few data about the superior caval or brachiocefalic veins percutaneous declotting. We report 9 cases of superior cava vein syndrome (SCVS) due to central venous catheter-related central vein thrombosis, 8 of which treated with AngioJet™ rheolytic thrombectomy (RT).

Methods: 9 dialyzed patients (3 male) were admitted with SCVS. All of them had long term central venous catheter (lt-CVC), 7 in right and 2 in left Internal Jugular Vein (IGV). Angio-TC scan showed SCV complete obstruction in 1 case and subocclusions in 3 cases, 8 occlusions or subocclusions of brachiocefalic veins. In all cases the lt-CVCs were enveloped into the clot. In one case we desisted to treat because of the complete occlusion of SCV and brachiocefalic veins, the presence of efficient collateral circulations and the dangerous comorbidity of patient. In the others, we performed a double jugular and femoral vein approach: in the first we inserted a guide into lt-CVC just before its removal, in the second we inserted an other guide; this second one was captured by a goose-neck catheter introduced in jugular vein and then dragged out of jugular vein own, to obtaining a unique guide from femoral to jugular vein. From femoral approach, the RT was performed with Angiojet system.

Results: The initial technical success to recanalize cava and brachiocefalic vein was 100%. In all cases adjunctive procedures were performed: balloon angioplasty (8 patients, 12 vessels), and stent placement (3 patients, 6 stents). No pulmonary embolism occurred; in one case a hemotransfusion was performed for haemolysis; bradyarrhythmias and thoracic pain occurred in two cases. The patency at 6 months was 87.5% (7/8 patients).

Conclusions: In our experience AngioJet RT is an useful tool in cases of SCVS due to lt-CVC complications.

PUB616

A Timely Catheter Removal Program Decreases the Time to Hemodialysis Access Appointments and Catheter Exposure Time Michele Inglese,[1] Dugan Maddux,[1] Karen G. Butler,[1] Walead Latif,[2] Yue Jiao,[1] Sheetal Chaudhuri,[1] Hao Han,[1] Jerry Damon Jasperson,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Sandra Bodin,[1] Margaret Milfort,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America; [2]Fresenius Vascular Care.*

Background: In hemodialysis (HD) patients (Pts), the transition from a central venous catheter (CVC) to a permanent dialysis vascular access (VA) reduces the risk of negative outcomes. We implemented a pilot Timely CVC Removal Program (TCRP) and analyzed its impacts on the time to VA appointments, VA surgery, CVC removal, and the total CVC exposure time.

Methods: We deployed the TCRP in 8 Fresenius Medical Care North America clinics, and analyzed VA-related data from HD Pts for the months of August 2015 and May 2016. TCRP includes care coordination between HD clinic staff, vascular access experts (VAEs), interventionalists, and surgeons. Weekly clinic reports were generated and included metrics for all CVC Pts regarding dates of VA appointments, VA surgery, and CVC removal, as well as, total CVC exposure time for each clinic and the Pt population. The "time to" metrics denoted in Figure 1 were utilized to investigate the areas of performance associated with the TCRP.

Results: Overall, we studied data from 144 Pts. After 10 months of the TCRP, we observed notably lower median time from the CVC insertion to the VAE appointment. Despite this, there was an increased time from the VAE appointment to the VA surgeon appointment. The median total CVC exposure time for the clinic and Pt population was found to be lower 10 months after implementation of the TCRP (Figure 1).

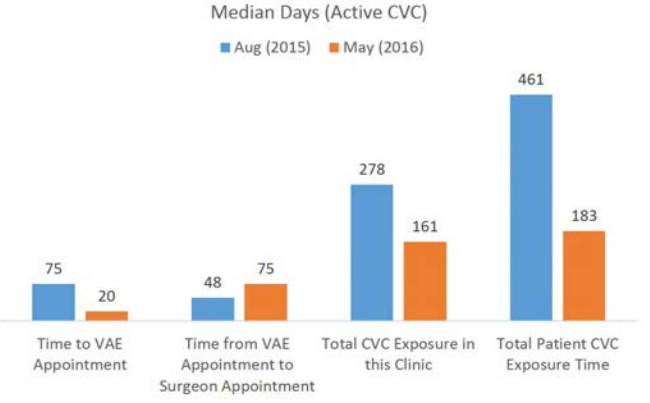

Figure 1

Conclusions: Our findings suggest the TCRP hastens placement of a permanent VA in HD Pts and reduces total CVC exposure. Tracking "time to" metrics was beneficial in identifying areas for improvement, which further enhancements of TCRP might be able to address.

PUB617

Health Economics of Arteriovenous Fistulas (AVFs) among U.S. Hemodialysis Patients Mae Thamer,[1] Timmy C. Lee,[2] Monnie Wasse,[3] Marc H. Glickman,[4] Qian Zhang,[1] Daniel Gottlieb,[5] Scott Toner,[5] Timothy A. Pflederer.[6] *[1]MTPPI; [2]Univ of Alabama; [3][lrm]Northwestern Univ; [4]RenalCare Associates; [5]Proteon Therapeutics Inc; [6]Sentara CarePlex Hospital.*

Background: Despite the importance of vascular access (VA) for adequate hemodialysis, few studies have examined real world costs related to long-term VA management. To address these gaps, we use national claims data to examine per patient VA costs over a 2.5 year period for different clinical outcomes of AVF use, patency and abandonment.

Methods: Observational *intention-to-treat* principle guides this retrospective study using Medicare claims to identify all incident elderly HD patients from 2010-2011 who underwent AVF creation. Using a multidisciplinary expert panel, we identified VA-related diagnostic, imaging, endovascular, surgical, infection, hospitalization and anesthesia codes to calculate total VA costs. The impact on costs of timing of AVF placement was also examined. Total per patient VA costs were calculated for all patients and for subsets based on AVF outcomes prior to use or during the 1st year after AVF creation: 1) no interventions; 2) any intervention to achieve or maintain patency; and 3) AVF abandonment. Patency loss and AVF use were defined using procedure, diagnosis and V (vascular) codes which indicate VA type in use each month. **Results:** Preliminary results suggest total Medicare costs for VA management were substantial and account for a significant portion of reported ESRD expenditures. Results also suggest that AVF patients with no loss of patency in year 1 have significantly lower 2.5 year VA costs compared to patients with loss of primary or secondary patency in year 1 (*final results will be presented at ASN for **Table 1***).

Table 1. VA-related per patient per year (PPPY) costs for incident Medicare HD patients in 2.5 years following AVF creation.

AVF cohorts	*No Intervention*		*Intervention*		*Abandonment*
	Unassisted use	**Primary unassisted patency**	**Assisted Use**	**Loss of primary patency**	**Loss of secondary patency**
	mean, median, 25th and 75th percentile costs				

Conclusions: Improvements in processes of care and technologies to enhance AVF use and patency should result in less morbidity with the potential for significant cost-savings.

PUB618

The Effect of Extended Antibiotic Prophylaxis on Infection in Vascular Access Intervention Therapy Mariko Ichijo,[1] Namiko Kobayashi,[1] Yohei Kono,[1] Ayumu Nomizu,[1] Yoshitatsu Ohara,[1] Yutaro Mori,[1] Shotaro Naito,[2] Takayuki Toda,[1] Noriaki Matsui.[1] *[1]Nephrology, Tsuchiura Kyodo General Hospital, Tuchiura, Ibaraki, Japan; [2]Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Vascular access is the lifeline for hemodialysis patients, and Vascular Access Intervention Therapy (VAIVT) has improved the quality of life of such patients. However, the efficacy of extended antibiotic prophylaxis of bloodstream infection among patients treated with VAIVT remains unknown.

Methods: We performed a retrospective study. To clarify whether antibiotic prophylaxis is effective or not, we reviewed the records of 487 procedures of VAIVT between 2011 and 2015 performed in our hospital. Selection of patient who required VAIVT received prophylaxis was at discretion of the doctor attending the case. We evaluated the association between prophylaxis and incidence of infection by logistic regression analysis.

Results: The 487 procedures of VAIVT (419 stenosis cases, 68 thrombosis cases) involved 260 men (53.5%) and 227 women (46.5%), with a mean (SD) age of 70.2 (11.0) years. 220 patients received prophylaxis, and 267 patients did not. The duration of the VAIVT procedure (34 vs. 31, p = 0.28), the types of VA (arteriovenous fistula 211 vs. 258, p = 0.675), complication of diabetes (81 vs. 109, p = 0.367), between the two groups were not significantly different. In logistic regression analysis, the incidence of infection after VAIVT, defined as hyperthermia (greater than 101 degrees F), was not significantly different between both groups (1 case in prophylaxis group, none in non-prophylaxis groups, odds ratio 1.005 [95% CI 0.996 – 1.014]).

Conclusions: In VAIVT, antibiotic prophylaxis does not influence rates of infection. Future prospective, randomized studies with a larger number of catheters are needed to confirm or refute these results.

PUB619

Gender Differences in Catheter Use over Hemodialysis Vintage: Results from the Monitoring Dialysis Outcomes Initiative (MONDO) Alice Topping,[1] Xiaoling Ye,[1] Jochen G. Raimann,[1] Frank van der Sande,[4] Adrian M. Guinsburg,[2] Bernard Canaud,[2] Xiaoqi Xu,[6] Albert J. Power,[3] Neill D. Duncan,[3] Jeroen Kooman,[4] Len A. Usvyat,[5] Peter Kotanko,[1,8] Maria E. Ferris.[7] *[1]Renal Research Inst, New York, NY; [2]Fresenius Medical Care EMEALA, Bad Homburg, Germany; [3]Imperial College, London, United Kingdom; [4]Maastricht Univ, Netherlands; [5]Fresenius Medical Care North America, Waltham, MA; [6]Fresenius Medical Care Asia Pacific, Hong Kong; [7]Univ of North Carolina Chapel Hill; [8]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Vascular access (VA) is an essential component to successful and efficient hemodialysis (HD). Catheter use is associated with higher mortality rates in HD patients (Xue et al, 2003). Previous research has highlighted differences in VA type by gender (Marcus et al, 2007), but have not compared catheter use over HD vintage across regions (rgs).

Methods: Prevalent patients(pts) in MONDO from 2006-2010 were analyzed for differences in catheter use by gender at HD initiation, and at one yr and three yr vintage. For pts beginning HD with a catheter, time to arteriovenous fistula (AVF) use was compared by gender overall and for each rg using the Wilcoxon-Mann-Whitney (WMW) test.

Results: There were 62,431 pts at baseline, 48,618 at one yr and 9,098 at three yr vintage eligible for analysis. Overall 59.2% of males (M) and 63% of females (F) initiated HD with a catheter ($p<0.0001$). At one yr, 28.3% of M and 34.6% of F ($p<0.0001$) and at three yrs, 21.3% of M and 28.5% of F ($p<0.0001$) had catheters. Statistically significant differences were found in all rgs at baseline and at one yr vintage; Europe and Asia Pacific rgs had the largest gender gaps in catheter use. The median time to AVF use for incident pts with catheter was 104 days for F and 91 days for M. Results from the WMW test show differences in time to AVF use for M compared to F overall ($p<0.0001$), and in all rgs except South America where data were scarce.

Conclusions: We found gender differences in catheter use in all rgs, with F having higher catheter rates. While we observe some variation in size of effect, efforts to reduce catheter rates should take gender inequalities into consideration.

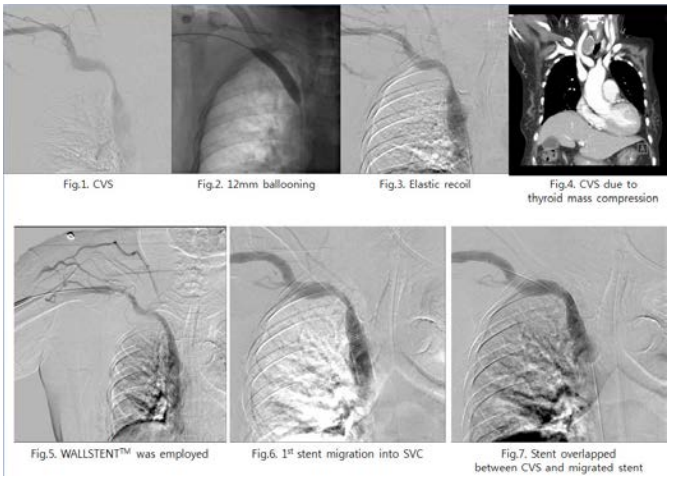
PUB620

Overlapping of Second Stent Placement between Previous Migrated Stent and Elastic Recoil of Rt. Brachiocephalic Vein Stenosis due to Rt. Thyroid Mass: Case Report Jin Ho Lee, Heeryong Lee, Joon Seok Oh, Dongyeol Lee, Yong Ki Park, Yong Hun Sin, Seong Min Kim, Joong Kyung Kim. *Internal Medicine, Bongseng Memorial Hospital, Busan, Dong-Gu, Korea.*

Background: Central vein stenosis(CVS) is commonly associated with arteriovenous fistula for hemodialysis. CVS associated with morbidity, hospitalization and morbidity. Endovascular intervention should be considered to management of CVS, such as balloon angioplasty, stent deployment. Especially, stenting at refractory CVS was choice of treatment. We announced a case that overlapping another stent between previous migrated stent and refractory CVS compressed by thyroid mass.

Methods: 75-year-old woman with advanced DM nephropathy on hemodialysis. Rt. Brachiocephalic AVF op was done at Jan, 2016. Rt. arm swelling and delayed hemostasis was occurred at POD 60days. We decided percutaneous transluminal angioplasty(PTA). Significant Rt. brachiocephalic vein(>80%) stenosis was presented. Despite of 12mm balloon angioplasty(MUSTANG™), stenosis(70~80%) was remained(Fig.1, Fig.2, Fig.3). To find reason of elastic recoil, enhanced chest CT was performed. CT shows Rt. brachiocephalic vein was compressed by thyroid mass(3.4 X 2.7mm), Rt. brachiocephalic artery and 1st rib(Fig.4). Then, stent(WALLSTENT™, 14mm X 4cm) was placed at stenotic lesion because of high radial resistive strength(Fig.5). Immediate technical success was achieved. But, ipsilateral arm edema was recurred 3days after intervention. In central venography, stent was migrated into SVC and Rt. brachiocephalic vein stenosis was remained(Fig.6). Stent(EPIC™, 14mm X 4cm) was overlapped between CVS and migrated stent(Fig.7). Arm swelling was disappeared.

Results:



Conclusions: Stent deployment was one of treatment choice of CVS. But, stent migration often occurred and could be a risk to patient. Our patient was treated by overlapping 2nd stent placement between primary CVS and migrated 1st stent tip.

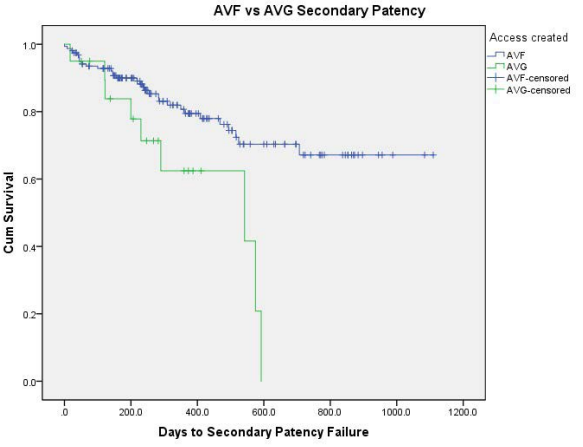
PUB621

Arteriovenous Fistulae Provides Superior Patency and Survival over Arteriovenous Graft Hareeshan Nandakoban, Ananthakrishnapuram N. Aravindan, Govind Surya Narayanan, Stephen T. Spicer, Imelda De Guzman, Jeffrey Wong. *Renal Unit, Liverpool Hospital, Sydney, NSW, Australia.*

Background: Review of permanent hemodialysis (HD) access creation in our institution and their outcomes. Arteriovenous fistulae (AVF) and arteriovenous graft (AVG) primary and secondary patency as well as overall vascular access survival was analysed over the study period.

Methods: A retrospective review of vascular access database over a 3 year period with additional data obtained from the electronic medical record (*e*MR). Student's T-test, Chi-square test, ANOVA and Kaplan-Meier survival analyses were used and significance for $p<0.05$.

Results: From 1st April 2013- 31st March 2016, 177 permanent vascular accesses were created in 159 unique patients: 157 AVFs and 20 AVGs. Patient characteristics: average age 58 yrs; males 67%; diabetes 63%; coronary disease 34%; pre-op tunnelled catheter (TVC) use (52%); and seen in pre-dialysis clinic 58%. Pre-dialysis review was associated with reduced TVC use 8% vs. 45%. 60% of all access worked, 14% failed to work despite intervention with no difference between AVF & AVG, and 26% were not used by study end. Primary patency of AVF was superior to AVG with a median period of 279 vs. 135 days *($p<0.05$)*. Gender, surgeon or access location had no influence. Overall secondary patency at 2 years was 68%. AVFs had superior mean survival to AVGs of 849 vs. 422 days *($p<0.05$)*. The presence of: diabetes, coronary disease, access location or side, or operating surgeon did affect secondary patency rates. Assisted access use within 3 months was 14%, and 41% at 6 months.



Conclusions: AVF were the predominant vascular access created. AVF have a superior primary and secondary patency rate to AVG that is not affected by the patient comorbidities, location of access placement or surgeon. Pre-dialysis clinic has a positive impact in reducing patient TVC exposure. There were low rates of early use of vascular access.

PUB622

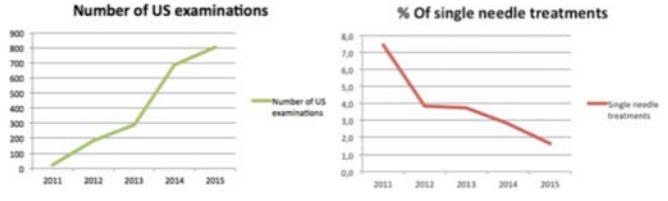
Ultrasound and ColorDoppler in Hemodialysis Patients for the best Management of Vascular Access Federico Nalesso, Sara Samoni, Alessandra Brendolan, Claudio Ronco. *IRRIV - International Renal Research Inst Vicenza, IRRIV - San Bortolo Hospital, Vicenza, Italy.*

Background: Vascular access is a key determinant in adeguate extracorporeal purification in CKD patients. Artero-Venous Fistula and Graft are subject to complications such as ematoma, blood effusions and other injuries during the cannulation procedures. These complications may be avoided by the use of Ultrasound and Color Doppler during the cannulations and the pre-cannulation mapping of the access. In case of complications in the vascular access a single needle is frequently required to obtain the extracorporeal circulation despite of reducing the KT/V and the total ultrafiltration.

Methods: We performed a complete Ultrasound and Color Doppler evaluation in all hemodialysis patients before the first access use. In case of difficult procedures of vascular access cannulation and after the report of abnormalities at the physical examination the ultrasound guide cannulation was performed. In our center we started to use this protocol of US analysis from the second part of 2012. (Figure 1)

Results: During our period of observation the total amount of complications drastically decreased progressively as attested by the total percentage of single needle use compared to the total amount of treatments performed

YEAR	SINGLE NEEDLE TREATMENTS % OF TOTAL HD TREATMENTS	TOTAL US-CD EXAMINATIONS
2011	7,5	20
2012	3,9	186
2013	3,7	290
2014	2,8	686
2015	1,6	802



Conclusions: Ultrasound and Color Doppler is a useful technique that can be performed at bedside reducing the complication related to the cannulations of vascular access. The vascular mapping before the first cannulation allow to determine the best sites to put the needles avoiding injuries and complications that can require the single needle use.

PUB623

Hemodialysis's Catheter Blood Stream Infection: A Great Challenge and Feasible Preventive Strategy in a Public General Hospital Katia V. Carvalho,[1] Augusto C. Haddad,[2] Thais Nemoto Matsui,[1] Fabiana Dias Carneiro,[1] Bento C. Santos,[1] Reginete C. Costa.[2] *[1]Centro de Diálise Einstein, Hospital Israelita Albert Einstein, São Paulo, São Paulo, Brazil; [2]Nefrologia, Hospital Municipa Moysés Deutsch, São Paulo, São Paulo, Brazil; [3]Centro de Diálise Einstein, Hospital Israelita Albert Einstein, São Paulo, São Paulo, Brazil; [4]Centro de Diálise Einstein, Hospital Israelita Albert Einstein, São Paulo, São Paulo, Brazil.*

Background: Blood stream infection catheter related (BSIRC) leads to an increased morbimortality in hemodialysis (HD) patients, associated with sepsis, cardiovascular complications, prolonged hospitalization, high cost, overload in health system and worse survival.The aim was to evaluate a program to prevent BSIRC(PP-BSIRS) in the Intensive Care Unit (ICU) and wards(WD)in a general public hospital at a low income area of São Paulo, where a high rate of ICU nursing staff turnover (45% in 2015) is a constant challenge.

Methods: A cross-sectional study with patients treated with HD between 2014 and 2015 was evaluated. Data from 2014 before and 2015 after PP-BSIRC implementation in January 2015 was analyzed. PP-BSIRC included: Daily patient bath with chlorhexidine 2%, double lumen and best site of catheter insertion, continuing education of nurses, 5 moments of hand hygine protocol, quality and safety audit of curative and interaction with hospital Infection Control Service. BSIRC diagnosis was defined according to CDC 2015 criteria.

Results: In 2014, 1099 HD were performed and 1245 in 2015.The mean age was 58.8 ± 15.4 yo, 62% men, 46% diabetes and 20% with previous diagnosis of CKD V. Patients in both periods did not differ according to gender, age, prevalence of diabetes or vascular access. Of note, in 2015, HD were significantly more incident in ICU patients, therefore with a higher frequency of vascular access manipulation. HD Patients after the PP-ICS had longer time duration of catheter (11.9 ±18.5 *vs* 10.2± 12.5 days**; p <0.001**) and lower frequency of BSIRC (0% vs.14%; **p <0.001**).

Conclusions: Albeit structural difficulties at public hospital in a low income area, target protocols, continuing education and multidisciplinary approach improved catheter survival and decreased incidence of BSIRC.

PUB624

Characteristics of High-Dose Hemodialysis Patients: A Systematic Review Dilip Makhija, Aseel Hatim Bin Sawad, J. Ken Leypoldt, Angelito A. Bernardo. *Baxter Healthcare Corporation, Deerfield, IL.*

Background: Conventional hemodialysis (CHD) (i.e., 4-hour session 3 times/week) is the most common dialysis regimen. High-dose hemodialysis (high-dose HD) (i.e., more frequent and/or longer sessions), has been associated with a 30-45% improved survival rate vs. CHD in large observational studies. Patients on high-dose HD have better blood pressure control, improved quality of life and decreased left ventricular mass. However, the characteristics of patients who may benefit from high-dose HD have not been identified. This systematic review aims to summarize high-dose HD patient characteristics.

Methods: Medline and Embase were used to identify randomized controlled and observational clinical studies evaluating the high-dose HD regimen (i.e., no 2-day gap without dialysis; short-daily: ≥5 sessions of ≥2 hours/week, nocturnal: ≥3.5 sessions of ≥6 hours/week; standard Kt/V ≥3.0). To be included, a study had to have at least 20 patients and published in English language between January 2000 and March 2016. Two independent reviewers selected studies and data extraction was performed.

Results: After screening 91 full text articles (total 3,652 citations), only 13 met the eligibility criteria (2,907 hemodialysis patients - 1,088 on high-dose HD: 509 at home; 579 in-center). High-dose HD patients were generally young (mean age range: 43±2 to 58±18.9 years), mostly men (60%-72%), Caucasian (34%-88%), and mean BMI ranging from 21.5±2.9 to 29.9±14.85 kg/m^2. The most commonly reported causes of ESRD were diabetes (6%-77%), diabetic neuropathy (27%-36%), glomerulonephritis (12%-41%), and polycystic kidney disease (4%-22%). Only 1 study reported a Charlson Comorbidity Index Score (CCI) of 3.2 ± 0.4 for high-dose HD patients. When a short daily regimen was used, patients performed 6-7 sessions/week of 1.5-3 hours/session. For nocturnal dialysis regimen, patients performed 5-6 sessions/week of 6-8 hours/session. The standard Kt/V ranged from 3.24 to 5.86 per week.

Conclusions: Based on the literature, the target patients for a high-dose HD regimen are generally young Caucasian males. In addition, underlying causes for ESRD like polycystic kidney disease are more frequent in high-dose HD patients compared to CHD.

PUB625

Hypertension (HTN) in High School Students (stu): Genetic and Environmental Factors: The Empowerment of Dietary Salt Intake Roberto Bigazzi,[1] Stefano Bianchi,[1] Salvatore Lenti,[3] Roberto Burano,[3] Giada Santini,[1] Francesca Nistri,[1] Chiara Bilanceri,[1] Elisa Poderelli,[1] Silvia Campatelli,[1] Vito M. Campese.[2] *[1]Nephrology, ASLNORDOVEST Toscana, Livorno, Italy; [2]Medici per San Ciro, Grottagie, Italy; [3]Nephrology, USC, Los Angeles.*

Background: Due to the epidemic of obesity, the prevalence of HTN is increasing among children. Identification of pre-HNT at this age is important to implement lifestyle interventions. The aim of this study is to evaluate 3,000 high school stu in 3 regions of Italy (IT); in the north, in the center and in the south to: 1. Determine the prevalence of obesity

and HTN; 2. Perform genetic analyses to determine a link between specific polymorphisms and/or mutations of the Adducin genes and HTN; 3. Explore whether urine Na/K excretion and markers of inflammation and oxidative stress are linked to HTN and CV risk in stu with selected genotypes.

Methods: So far, we have enrolled 753 stu (394 in central and 359 in south IT). Here we present preliminary data referred to the first year of the study focousing on the relationship of dietary Na and K intake with HTN.

Results: The average age was 16.4±1.4 yr;42.7% M and 49.7% F. In central IT, the average BMI was 21.8±0.5; waist circumference 75.5±9.6; 8,2% of stu were overweight and 2.3% obese. Average urinary sodium (UNa) excretion was 83.4±2.5 and potassium (UK) was 36.6±10mEq/g creatinine. In southern IT, the average BMI was 22.5±0.6;19% of stu were overweight and 6 % obese (P<0.01 compared with central IT). The average UNa was 144±5.5 and UK excretion 44±8,3mEq/g creatinine. (P< 0.01 compared with central IT). Among parents of overweight or obese stu, 85.4 % were obese or overweight. Of interest, UNa of stu from hypertensive parents was lower (p<0.02) than those from normotensive patents.

Conclusions: Our data indicate that: 1) overweight and obesity are more common among children from south than central IT; 2) salt intake is higher in south than central IT; 3) UK is low both in central and south IT suggesting that adherence to a Mediterranean diet is currently not applied. 4) The surprising reduced dietary salt intake among children from hypertensive parents may reflect a tendency of families with an hypertensive patients to reduce salt intake.

Renal-Artery Stenosis and Renal Impairment after Renal Denervation

Birgit Doris Bader,[1] Stephan H. Duda,[2] Beata Lux,[2] Christiane M. Erley.[1] *[1]Dept of Medicine 2, St. Joseph Hospital Berlin-Tempelhof, Berlin, Germany; [2]Ihre Radiologen, Center for Diagnostic and Minimally Invasive Therapy, Berlin, Germany.*

Background: Descriptions of renovascular complications after renal denervation (RDN) are rare. We report the case of a 70 yr. old female patient who has developed a significant renal-artery stenosis 3.5 yr. after RDN.

Methods: Our patient had several clinical admissions because of treatment-resistant hypertension between 2009 and 2012. So she was selected for RDN according to the guidelines in September 2012. Blood pressure could not be controlled (RR 160-220/95-115 mmHg) under antihypertensive therapy including beta blocker, AT2 receptor antagonist, calcium channel blocker, moxonidine and loop diuretic. The CT- and conventional angiography showed no stenosis of the renal arteries. The renal function was normal (S-creatinine 0.99 mg/dL). in October 2012 RDN was performed. Blood pressure before intervention was measured to be 220/115, after intervention 130/70 mmHg. In the following time the antihypertensives could be reduced. There were no more clinical admissions due to hypertension.

Results: In January 2016 the patient was admitted to our hospital with a decline of renal function (S-creatinine 2.18 mg/dL) and hypertensive blood pressure levels (RR 170/80 mmHg). Over the last two years a raise in blood pressure was observed and her family doctor has increased the antihypertensives again. We performed a MR-angiograpy of the renal arteries and detected a 90% stenosis of the left renal artery with reduced perfusion of the renal cortex. Due to these findings a percutaneous angioplasty was performed. After sequential dilatations of both lobar arteries there was a rapid development of clot or possibly clot dislodgement that needed arterial thrombolysis with 10 mg of rtPA. Afterwards blood pressure was easier to control but the patients still needs up to seven antihypertensives. The renal function of the patient didn't changed (S-creatinine 2.16 mg/dL).

Conclusions: The complication rate associated with RDN is still considered to be rare. However, we recommend imaging follow-up after RDN, especially in patients showing rising blood pressure levels or worsening of renal function after initially successful RDN.

PUB627

Race, Obesity, and the Renin-Angiotensin System Predict Treatment Response in Pediatric Essential Hypertension

Andrew M. South,[1,2] Lester M. Arguelles,[4] Gal Finer,[3] Craig B. Langman.[3] *[1]Pediatric Nephrology, Wake Forest School of Medicine, Winston Salem, NC; [2]Hypertension and Vascular Research Center, Wake Forest School of Medicine, Winston Salem, NC; [3]Pediatric Kidney Diseases, Feinberg School of Medicine, Northwestern Univ, Chicago, IL; [4]Public Health, Univ of Illinois at Chicago, Chicago, IL.*

Background: Pediatric essential hypertension (peHTN) is increasingly recognized but the effect of patient characteristics on outcomes is not well described. We hypothesized patient parameters such as race, body habitus, first-line medication choice, and the renin-angiotensin system (RAS) influence blood pressure (BP) response in peHTN.

Methods: Retrospective cohort of 102 consecutive patients with peHTN. Primary outcomes were the changes per year in systolic and diastolic BP (SBP, DBP). Secondary outcomes included the change per year in left ventricular mass index (LVMI) and the number of antihypertensive medications. We evaluated whether plasma renin activity (PRA), aldosterone, renin-to-aldosterone ratio (RAR), obesity, race, initial drug choice, and multidrug therapy were associated with the outcomes using linear and logistic regression.

Results: Racially diverse (28% black, 43% Hispanic, 25% white) and predominantly overweight/obese (75%) patients were studied. Median length of follow-up was 14.5 months. Lower baseline aldosterone and obesity were each associated with increased SBP (+1.1 and +21.7 mm Hg/year) and DBP (+8.9 and +17.7 mm Hg/year) during follow up. Lower PRA and obesity were each associated with increased SBP z score (+0.53 and +1.38/year) and increased LVMI (+5.8 and +18.2 $g/m^{2.7}$/year). Higher RAR was associated with increased DBP z score (+0.14/year). Angiotensin-converting enzyme inhibitors (ACEi) and angiotensin-receptor blockers (ARB) lowered the likelihood of polytherapy (OR 0.15, p <0.001), particularly in blacks (OR 0.07, p = 0.04), while obesity increased it (OR 4.91, p = 0.03).

Conclusions: The pre-treatment RAS profile predicted follow-up BP and LVMI. Obese patients were at risk for inadequate treatment response. Treatment with an ACEi or an ARB was associated with monotherapy, especially in black patients.

PUB628

Augmentation Pressure, Augmentation Index and Pulse Wave Velocity in Chronic Kidney Disease Patients

Jafar Al-Said. *Internal Medicine and Nephrology, Bahrain Specialist Hospital, Bahrain.*

Background: CKD patients have an elevated Augmentation Pressure (AUP), Augmentation Index (AUI) and Pulse Wave Velocity (PWV). The association with other Cardiovascular (CV) risk factors among CKD patients is not yet clear. The aim of this study is to test the correlation between AUP, AUI and PWV with major CV risk factors among CKD as compared to non CKD patients.

Methods: This is a retrospective cross sectional study of outpatients visiting the Nephrology clinic with a central pressure checked. Demographic features, CV risk factors as well as AUP, AUI and PWV were obtained from the files. The central BP is measured with a Mobil-O-graph monitor from the Lt. arm. Peripheral and central BP measured from the Lt Brachial artery with an external arm cuff. All measurements were standardized with two readings in a comfortable sitting position over 3 minutes. Forty-seven CKD patients were matched for age, gender and BMI with 47 normal kidney function individuals. Central BP parameters association with CV risk factors were compared between both subgroups.

Results: The total number of patients was 281. Mean age was 49 years (SE 0.9). Males were 59%. Mean BMI was 29 kg/m^2 (SE 0.39). The CKD subgroup were 54. Mean age was 61 years (SE 1.9). Males form 69%. Mean BMI was 31.5kg/m^2 (SE 0.8). Mean eGFR was 26ml/min. AUP, AUI and PWV were significantly associated with CKD in univariate correlations. However, with multivariate regression including demographic and other CV risk factors, AUP was the only central pressure parameter associated with CKD. (RR 0.35), Correlation Coefficient 0.23 (P<0.0001). AUP, AUI and PWV were associated with most of the major CV risk factors among non-CKD patients but not in CKD patients. PWV was the only central BP parameter in CKD subgroup associated significantly with age, DM and Hyperuricemia.

Conclusions: Although AUP, AUI and PWV were significantly associated with CKD, but when considering age, gender, BMI and other major CV risk factors only AUP remained significant. PWV was associated in CKD subgroup with age, DM and Hyperuricemia. The raised central pressure parameters among CKD patients in our cohort was not translated into a significant association with major CV risk factors.

PUB629

Psychological Impact of a Diagnosis of Hypertension in Pediatric Patients

Howard Trachtman, Laura Jane Pehrson, Suzanne M. Vento, Laura Malaga-Dieguez, Nigel Madden. *Pediarics, NYU Langone Medical Center, New York, NY.*

Background: The prevalence of hypertension (HT) in children and adolescents has increased markedly over the last 20 years, primarily as a result of the obesity epidemic. Because high blood pressure (BP) tracks into adulthood and possibly causes increased cardiovascular morbidity, it is considered standard of care to measure BP in pediatric practice. However in 2013, the US Preventive Services Task Force (USPSTF) concluded that there are inadequate data to support routine BP screening in asymptomatic children. The potential adverse consequences of screening for high BP in pediatric patients have not been addressed. The objective of this study was to assess the psychological impact of a diagnosis of HT in children and adolescents.

Methods: Patients, age 10-21 yr old, with a diagnosis of HT and their parents were eligible for inclusion. They were recruited in the Fink Ambulatory Care Center or the Bellevue Nephrology Clinic. A 9-question Hypertension Quality of Life Questionnaire was developed to evaluate emotional, performance, and interpersonal aspects of well-being. The primary outcome measure was the total and three subdomain scores in the child version of the survey, based on a 5-point Likert scale. Child and parent scores were compared for internal consistency in rating the psychosocial burden of a diagnosis of HT.

Results: There were 20 participants, 14M:6F, mean age 16.5±2.1 yr, 11 White, 3 Black, 4 Hispanic and 2 Other. 16 subjects were in middle or high school and 4 attended college. The parents were married in 14, divorced in 2, or single in 4 cases and in 17 families at least 1 parent attended college. 9 participants were receiving antihypertensive drugs. The survey was completed 2.6±2.8 yr after the diagnosis of HT was made. The mean total score was +0.40 units (P=0.75). The mean emotional subscore was -0.95 units (P=0.10) and 15 (75%) had a negative score. There were no significant differences between the participant or parent responses.

Conclusions: Our findings suggest that there may be adverse psychological consequences of being given a diagnosis of high BP, especially in emotional status, in adolescents and young adults. Further work is needed to address this issue.

PUB630

Ankle Brachial Index and Glomerular Filtration Rate as Predictors for Independent Mortality All Causes in Patients with Hypertension Arterial Systemic Franklin Correa Barcellos,[1,2] Annelise Reges,[1] Gabriela Araujo Duarte,[1] Alexia Schuch,[1] Mateus De Mamann Vargas,[1] Jamile Gardin Dos Santos,[1] Luiza Morrone Gastaud,[1] Maristela Bohlke.[1] *[1]Medicine School, Univ Catolic of Pelotas, Brazil; [2]Medicine Faculty, Univ Federal of Pelotas, Pelotas, Brazil.*

Background: High blood pressure, chronic kidney disease(CKD), and peripheral arterial disease (PAD) are predictors of mortality in the general population. It has been suggested that patients with arterial hypertension, glomerular filtration rate (GFR) <60 ml/min/173m2 and PAD diagnosed by the ankle brachial index (ABI) <0.9 also suffer increased mortality rate.

Objective

Identification of predictors of mortality from all causes in a sample of patients with hypertension.

METHODOLOGY

Cohort study that followed nondiabetic patients with hypertension, include variables gender, skin color, age, blood glucose, lipid profile, ABI and GFR calculated from serum creatinine(CKD-Epi-formule) The association between potential predictors and mortality were evaluated using logistic regression.

RESULTS

The sample of 150 subjects had age (mean / SD) of 65.05 (10.88) years, 36.7% male, 67.9% white and 43.0% patients with chronic kidney disease, were accompanied by an average of 2.82 (0.73) years.

There were a total of 13 (10.16%) deaths in the follow-up period. Presence of CKD (OR 5.38; 95% CI 1.07 to 27.08, P = 0.04) or decreased GFR (OR 0.95 95% CI 0.91 to 0.99; p = 0.01) and ITB reduced (OR 0.02 95% CI 0.001 to 0.57, p = 0.02) were independent predictors of death during follow-up. Ten of the 13 deaths occurred in patients with CKD.

CONCLUSIONS: Reduction in GFR, as the lowest ITB has been associated with increased mortality in the general population. This study confirms the prognostic impact of these variables also among non-diabetic elderly patients with hypertension.

PUB631

Single-Pill Irbesartan/Amlodipine Combination Therapy Improves Clinic and Home Blood Pressure Profiles in Hypertensive Patients with Chronic Kidney Disease Kouichi Tamura, Ryu Kobayashi, Hiromichi Wakui, Masato Ohsawa, Kengo Azushima, Kazushi Uneda, Sona Haku, Kotaro Haruhara, Kohji Ohki, Sho Kinguchi. *Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.*

Background: Accumulating evidence indicates that appropriate blood pressure (BP) control is essential to inhibit renal deterioration and to prevent cardiovascular complication in hypertensive patients with chronic kidney disease (CKD).In this study we examined the efficacy and safety of single-pill irbesartan/amlodipine combination therapy for 12 weeks in hypertensive CKD patients, by evaluating self-measured home BP profile.

Methods: Hypertensive patients with CKD who have already been treated with antihypertensive therapy comprised of renin-angiotensin system inhibitors or calcium channel blockers were eligible for this study if they could not achieve the target BP (clinic systolic BP≥ 130 mmHg and/or diastolic BP≥ 80 mmHg). After the run-in period, eligible patients were given a single pill of irbesartan/amlodipine tablet for 12 weeks. Clinic BP and home BP profiles as well as parameters of vascular function were evaluated at baseline and after the protocol therapy. Self-measured home BP values were obtained upper arm cuff oscillometric device with a memory-equipped system (HEM-7080IC, Omron, Kyoto, Japan).

Results: 20 patients were enrolled and assigned to the single-pill irbesartan/amlodipine combination therapy for 12 weeks. Combination therapy for 12 weeks significantly decreased clinic BP and home BP (home morning BP; baseline vs 12 weeks, 150±16/85±10 mmHg vs 133± 12/76±9, *P*<0.01). In addition, the combination therapy significantly decreased within-visit variability of clinic BP and day-by-day variability of home BP after 12 weeks treatment. Concerning parameters of vascular function, the combination therapy significantly improved central systolic BP, AI, baPWV and CAVI.

Conclusions: The results of present study suggest that the single-pill irbesartan/amlodipine combination therapy may exerts beneficial effects on clinic and home BP profiles including BP variability and vascular function, in addition to BP lowering, in hypertensive CKD patients.

PUB632

Variability of Circadian Blood Pressure Differentiates Hypertensive Kidney Damage from Chronic Glomerulopathy Arkadiusz Lubas, Grzegorz Kade, Stanislaw Niemczyk. *Internal Diseases Nephrology and Dialysis, Military Inst of Medicine, Warsaw, Poland.*

Background: Unknown medical history, well-controlled hypertension and clinically latent stable chronic kidney disease (CKD) make it difficult to recognize the initial etiology of kidney damage. The aim of the study was to investigate whether echocardiography or blood pressure profile could help in differentiating between hypertensive nephropathy (HN) and glomerulonephitis (GN) related CKD.

Methods: Sixty nine patients (9 F; 60 M; age 54,3 ±14,1) with stable CKD (CKD-EPI 53,2 ±26,9 ml/min/1,73m^2) and a history of hypertension (44 with HN) were enrolled in the study. Serum Creatinine (Cre), Cystatin C (Cys), echocardiography and ABPM were tested. Renal function was estimated according to Cre and Cys based on CKD-EPI formula.

Results: Groups with HN and GN did not differ in renal function, systolic, diastolic and mean blood pressure (BP), pulse pressure, left and right ventricles dimensions, as well as left ventricular hemodynamic parameters (E/E', ejection fraction, stroke volume). Patients in HN group were older (age 57,5 ±13,2 vs 48,6 ±14,1 years; p=0,01) but had lower day to night drop of mean BP (D/N) (11,2 ±8,5 vs 16,0 ±5,8 %; p=0,01) and preawakening morning surge (PMS) (12,8 ±10,1 vs 18,5 ±7,6 mmHg; p=0,02). Diagnosis of HN correlated with age (r=0,31), PMS (r=-0,30), D/N (r=-0,27) and stroke volume (r=0,25). After adjusting to the age, in logistic regression, only D/N was significantly connected with likelihood of HN (r=-0,084; OR 0,919; 95% CI: 0,847- 0,997; p=0,04). In ROC analysis D/N ≤ 10 % recognized HN with specificity of 88%, and sensitivity of 40 % (p=0.01).

Conclusions: Nondipping pattern of blood pressure promotes recognition of hypertensive nephropathy rather than glomerulonephritis as the etiology of chronic kidney disease.

PUB633

The Effect of Cyclooxygenase-2 Inhibition on Sodium Handling in the Proximal Tubule in Healthy Men and Women Ann A. Zalucky, Shahbal Bill Kangarloo, Sofia B. Ahmed. *Medicine, Univ of Calgary, Calgary, AB, Canada.*

Background: Cyclooxygenase-2 (COX-2) inhibitors are associated with increased cardio- and renovascular risk, with altered renal sodium handling suggested in animal studies as a contributing factor. We examined the effect of COX-2 inhibition on the fractional excretion of lithium, a marker of proximal tubular function in healthy humans.

Methods: Twelve healthy subjects (42% female, 37±10 years) were studied in high-salt balance pre- and post-14d daily ingestion of the COX-2 inhibitor celecoxib 200mg. The set-point of proximal renal tubular sodium excretion was estimated by fractional excretion of lithium (FELi, calculated as $lithium_{urine}$ x $creatinine_{serum}$/ $lithium_{serum}$ x $creatinine_{urine}$), which is not altered by changes in diet. Endogenous serum and urine lithium was measured by graphite furnace atomic absorption spectroscopy. In addition, fractional excretion of sodium (FENa, calculated as $sodium_{urine}$ x $creatinine_{serum}$/ $sodium_{serum}$ x $creatinine_{urine}$) was calculated for comparison.

Results: No significant changes in blood pressure, salt balance, or renal hemodynamics were observed pre- vs post-COX-inhibition. Similarly, COX-2 inhibition was not associated with any significant change in FELi (6.97±2.94 vs 6.48±2.94, p=0.4; pre- vs post-celecoxib). There were no sex differences in FELi at baseline (7.17±2.67 vs 6.83±3.33; p=0.8) or in response to COX-2-inhibition (ΔFELi: 0.01±2.54 vs 0.84±1.97; p=0.6; all values women vs men). FENa did not change in response to COX-2 inhibition (0.72±0.28 vs 0.66±0.47; p=0.7, pre- vs post-celecoxib).

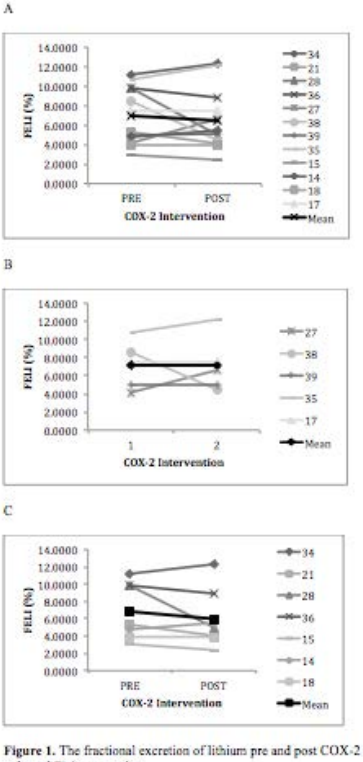

Figure 1. The fractional excretion of lithium pre and post COX-2 inhibition in **A)** all participants **B)** in women only and **B)** in men only.

Conclusions: In healthy humans, short-term COX-2 inhibition is not associated with changes in proximal tubular function. Whether these same findings apply to the CKD population is unknown.

PUB634

Finger Arterial Pressure as Index of Impaired Vessel Wave Reflection and Peripheral Vascular Disease in Hemodialysis Patients Gaetano Alfano, Francesco Fontana, Gianni Cappelli. *Dept of Surgery, Medical and Dentistry, Univ Hospital of Modena, Modena, Italy.*

Background: Nexfin monitor evaluates continuous and non-invasive measurement of arterial blood pressure (BP) through finger-cuff technology; it reconstructs brachial arterial pressure (BAP) analyzing peripherally changes of systolic and diastolic wave reflections. It was validated against the auscultatory method using sphygmomanometer but aim of our study is to evaluate Nexfin in maintenance hemodialysis patients(HD).

Methods: Forty hemodynamically stable HD underwent serial measurement of Nexfix arterial pressure (NAP) and BAP before HD-session. BAP was taken in the upper arm by oscillometric sphygmomanometer.

Results: Patients mean age was 68.9±14.9 years, being 65% > 65 yrs and 29% > 75 yrs; 27% of pts were diabetic. Bland-Altman analysis comparing NAP measurements with BAP revealed: a mean bias±LA of 15.3±34.8 mmHg (29% error) for systolic BP, a mean bias±LA of -0.9±20.34 mmHg (32% error) for diastolic BP and a mean bias of 4.5±21.34 mmHg (26% error) for MAP. Nexfin had poor accuracy in the reconstruction of diastolic and mean BP and extremely inaccurate for systolic BP.

Table 1. Comparison of BAP versus NAP

		Systolic	Diastolic	MAP
No. of patients: 40				
Mean BAP	mmHg	122,3	62,9	82,7
R^2		0,3	0,44	0,44
P value		0,0002	< 0,0001	< 0,0001
Bias	mmHg	15,3	-0,9250	4,575
SD of bias	mmHg	17,8	10,38	10,89
Lower LA	mmHg	-19,6	-21,27	-16,77
Upper LA	mmHg	50,2	19,42	25,92
Percentage error	%	29	33	26

R^2: squared multiple correlation
BAP: brachial arterial pressure; MAP: mean arterial pressure.

Multivariate analysis showed diabetes, neuropathy and increasing systolic BAP as significant predictors of disagreement in systolic BP values between NAP and MAP, F (3.34) = 10.787, p<0.005, R^2 = 0.488. Neuropathy was unrelated to diabetes as correlation analysis showed no significant correlation.

Conclusions: The Nexfin does not meet the criteria of interchangeability with standard oscillometric method in HD. The negative influence of diabetes, neuropathy and increase of systolic BAP limit the feasibility of Nexfin to perform a correct evaluation of BAP in presence of peripheral vasculopathy. On the other hand the unreliability of BAP reconstruction by NAP could be considered as indirect sign of peripheral vascular disease in these patients.

PUB635

Cardiovascular Risk in Healthly Subjects Evaluated with Genetic Test Francisco Javier Lavilla, Pedro Errasti, Maria Jose Molina Higueras, Pelayo Moiron Fdez-Felechosa, Christian Israel Alfaro Sanchez, Paloma L. Martin Moreno, Nuria Garcia-Fernandez. *Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: Evaluate cardiovascular risk (CVR) in healthy subjects.

Methods: Include 94 subjects (médium age 53 years 0.911, male 73.5%) Study CVR genetic test (evaluated cardiovascular age, global cardiovascular risk using validated genetic and clinical score), with carotid echography (intima-media thickness in left –IMTLC- and right -IMTRC- carotid) and ecocardiography (E/A and E/E´ index). We evaluate levels of Glucose, Triglycerides, cholesterol, uric acid, creatinine (mg/dL) and creatinine clearance (ml/min) (MDRD-4 and CKD-EPI).

Results: Mean biological age 53 years (SE 0.911),cardiovascular age 60 years (SE 0.81). Differential age was 6.2 years (SE 0.64) (0-26). Increase in cardiovascular age was >10 years in 21.3%. with more IMTLC (p=0.007), IMTRC (p=0.145) and lower E/E'(p=0.171). CVR measure with genetic test are associated with intima media thickness. CKD-EPI are better associated with genetic test than MDRD. Metabolic parameters (except cholesterol) are associated with genetic test and intima media thickness. Intima media thickness left carotid is better than right to evaluate CVR.

Conclusions: In healthy subjects can evaluated CVR with genetic test, carotid echography and ecocardiography. This CVR is associated with metabolic parameters (especially glucose, triglicerides and uric acid). Intima media thickness measure in left carotid and renal function with CKD-EPI, is better associated with genetic test CVR calculated.

PUB636

Denosumab Induced Severe Symptomatic Hypocalcemia in a Patient with Normal Renal Function Ashwin Reddy Ganta. *Dept of Nephrology, Archbold Memorial Hospital, Thomasville, GA.*

Background: A 69 y/o Caucasian female was referred to our clinic for resistant hypocalcemia with panic attacks over the past 18 months. She complained of severe anxiety symptoms with significant impairment of QOL and was on Buspirone and Aplrazolam with some relief. Her PMH was significant for HTN and Osteoporosis. Her medications included OTC Vitamin D and Calcium Supplements. Her physical examination was significant for Osteoporotic signs and a positive Trousseau sign. Her lab work done a few months ago prior to this presentation was significant for Low Calcium (5.6 mg/dl), Low Ionized Calcium (3.5 mg/dl) with normal albumin and Serum Creatinine (0.7 mg/dl and Cr Clearance 92 ml/min). Her 25(OH) Vit-D level was low (23 ng/ml) with elevated 1,25 (OH)2 Vit-D levels (144 ng/ml) and PTH elevated at 399 pg/ml (Normal 15-65 pg/ml). Her magnesium level was normal. On further questioning, patient admitted that received 4 doses of Prolia (Denosumab) for Osteopenia over the last 2 years. Her hypocalcemia was attributed to Denosumab and her elevated PTH level was most likely compensatory. She has been initiated on high dose Vitamin D analog and elemental Calcium therapy and is doing better. Discussion : Denosumab is a fully human monoclonal antibody that inhibits bone resorption by binding to receptor activator of Nuclear Factor kB Ligand (RANKL). CKD stage IV/V, Male sex and Malignancy have been found to be risk factors for Denosumab induced symptomatic hypocalcemia and mild non symptomatic hypocalcemia has been reported as a side-effect as well. Based on Pubmed review, to our knowledge this is the first case report of Denosumab induced hypocalcemia in a patient with normal renal function and no known malignancy. With Denosumab use increasing due to the side effects with Bisphosphonate use, physicians need to be aware of the potential severe side-effects with Prolia.

PUB637

The Incidence and Prevalence of Hypomagnesemia in the Intensive Care Units Satyam Patel, Maria V. DeVita, David Selzer, Michael F. Michelis. *Nephrology, Lenox Hill Hospital, New York, NY.*

Background: The incidence and prevalence of hypomagnesemia in the critical care setting have both been reported as high as 65%. However, a substantial amount of data is from outside the United States and more than 10 years old. This present study evaluates the incidence and prevalence of hypomagnesemia in the intensive care setting.

Methods: A prospective, observational study was done on consecutive patients admitted to medical and surgical intensive care units at a tertiary hospital. Each patient's chart was reviewed for magnesium (Mg) level and medications in the ICU for up to 7 days. Hypomagnesemia was defined as <1.6 meq/L.

Results: To date, of the 157 patients reviewed, 108 patients had Mg measured on Day 1. In this cohort, the prevalance of hypomagnesemia was 18/108 = 16.7% (95% CI: 10.2-25.1). Among the 90 patients had a normal Mg the 1st day, 6 patients did not have Mg level measured during the remainder of their ICU stay, while 84 patients had Mg measured on at least one occasion from day 2 to day 7. Among these 84 patients, 2 patients developed hypomagnesemia at day 2 and no patient developed hypomagnesemia at day 3 or later. Therefore, the estimated incidence of hypomagnesemia is 2/84 = 2.4% (95% CI: 0.3-8.3). Interestingly, 77 patients had at least one Mg supplementation, for a total of 114 supplements administered; the average Mg level at which supplementation occurred was 1.7 mg/dL, indicating that most patients are supplemented prior to actually reaching a low Mg level. There was not enough evidence to conclude that other selected factors, such as diuretics, PPIs, and antibiotics were associated with hypomagnesemia. The only comorbidity associated with hypomagnesemia was a history of DVT/PE (62.5%) compared to patients without DVT/PE (15.0%) (p=0.005).

Conclusions: These results suggest that the while the prevalence of hypomagnesemia is within the previously reported range, the incidence is significantly lower that previously reported studies. The finding that critical care areas are more readily identifying and treating Mg level even at concentrations deemed to be acceptable shows a change in the standard of care and an awareness of the importance of this electrolyte.

PUB638

Hip Structure Analysis Reflects the Bone Strength Changes after Eldecalcitol Administration Better Than the Bone Mineral Density by DEXA Megumi Sato,[1] Katsuyuki Funato,[2] Junichi Takada.[3] *[1]Jinzo Naika Megumi Clinic, Nephrology, Sapporo, Japan; [2]Jinzo Naika Megumi Clinic, Clinical Laboratory, Sapporo, Japan; [3]Kitago Orthopedics Clinic, Orthopedics, Sapporo, Japan.*

Background: Bone strength has been usually assessed by bone mineral density(BMD) but it is well known that BMD is not directry related to the bone strength.Hip Structure Analysis(HSA) is a new method the bone strength which is calculated by reconstructing 3-dimentional bone structures with BMD by DEXA.We compared the HSA parameters with the BMD after Eldecalcitol administration.

Methods: Eighteen chronic dialysis patients were enrolled to the study;10 males and 8 females, the average of age are 73.7 years old in male, 69.3 years old in female. HSA consists of 4 indices for assessing several bone strength;Cross Sectional Area(CSA),Cross Sectional Moment of Inertia(CSMI), Section Modulus(SM) and Buckling Ratio(BR). These parameters were calculated in following 3 parts of femur; Narrow Neck(NN), Intertrochanteric part(IT) and femoral shaft(FS). BMD were measured both Neck and Total parts of femur.

Results: BMD in male were significantly increased in both Neck and Total at before/12-mo.; Neck, 0.604/0.615, p=0.1406 ; Total, 0.780/0.797, p=0.042. However, BMD in female did not changed; Neck, 0.586/0.592, p=0.515 ; Total, 0.704/0.709, p=0.5452. The HSA parameters were preserved or increased in male but most of them were decreased in female after Eldecalcitol administration.

HSA index	pre.	12 mo.after	p-value
CSA in male			
NN	2.41±0.36	2.43±0.33	*0.0584*
IT	3.90±0.46	3.98±0.50	*0.0411*
CSA in female			
NN	2.11±0.42	1.98±0.61	n.s.
IT	3.36±0.89	3.34±0.80	*0.0460*

Conclusions: In the current study we admitted the increase of BMD after Eldecalcitol; however, the HSA parameters in male were improved but deteriorated in female. It suggests that BMD is not a reliable parameters for monitoring the bone structural changes and strength after some treatment. Bone fracture is one of the serious prognostic factors in dialysis patients and it has been reported that the risk of fractures were closely related to the bone strength rather than BMD. We should assess the bone strength and fracture risk not only by BMD but by HSA.

PUB639

Smoking Is Associated with Decreased Osteocalcin (BGP) Levels in Dialysis Patients (VIKI Study) Maria Fusaro,[1] Maurizio Gallieni,[2] Mario Plebani,[3] Andrea Aghi,[3] Enrico Schileo,[4] Piergiorgio Messa,[5] Carlo M. Alfieri,[5] Nicola Veronese,[3] Marina Foramitti,[6] Laura Cosmai,[6] Stefania Sella,[3] Maria Cristina Mc Mereu,[7] Giovanni Tripepi,[8] Sandro Giannini.[3] *[1]National Council of Research, Pisa, Italy; [2]Univ of Milano, Italy; [3]Univ of Padova, Italy; [4]Istituto Ortopedico Rizzoli, Bologna, Italy; [5]IRCCS Fondazione Ca' Granda, Milano, Italy; [6]Istituti Ospitalieri di Cremona, Italy; [7]Ospedale San Gavino Monreale, Italy; [8]IFC-CNR, Reggio Calabria, Italy.*

Background: BGP is a vitamin K-dependent protein involved in the regulation of bone mineralization and in vascular calcification (VC). In a secondary analysis of the VIKI study, we analyzed the association of osteocalcin and smoking among CKD patients, including the possible consequences on bone metabolism and mineral bone disorders.

Methods: We determined BGP and MGP levels, and verified the presence of any vertebral fractures (VF) and vascular calcification (VC) by spine radiographs. Among patients (36% female), 35% was smoker or former smoker, age 65.4 ± 13.5 years, dialysis duration 61.9±49.4 months, BMI 25.3±4.3 Kg/m^2. Comorbidities among smokers were: 26% diabetes, 82% arterial hypertension, 51% coronary artery disease, 13% cerebrovascular disease, 38% peripheral vascular disease, and 54% of patients had a vertebral fractures.

Results: Smoker patients had significantly lower phosphate levels than non smokers (4.53 ± 1.26, 4.86 ± 1.22 mg/dL, ***p*= 0.013**). Smokers also showed lower albumin (3.73 ± 0.45 vs 3.89 ± 0.40 g/dL, ***p*= 0.001**), and total BGP levels: 152 (92-251), 204.5 (111-362) ng/mL, ***p*= 0.003.** Most of the smoking patients (85%, compared to 77% in the control group, p=0.09) also showed presence of abdominal aortic calcification. We found lower BGP levels in patients with high prevalence of VF levels: 151 (91-276), 213 (107-369) ***p*=0.009** and VC levels: 164 (87-276), 262 (134-436), ***p*<0.001.** Smoking was associated to a reduction of total BGP levels of about 20% in the average values of BGP (Stepwise Table 1, R^2= 0.53).

Variable	Parameter estimate	p-value
Age	-0.01087	< 0.001
BMI	-0.03240	< 0.001
Smoke	-0.22452	< 0.001
R^2= 0.53		

Conclusions: This is the first clinical study in a dialysis population identifying smoke as a factor negatively affecting osteocalcin levels.

PUB640

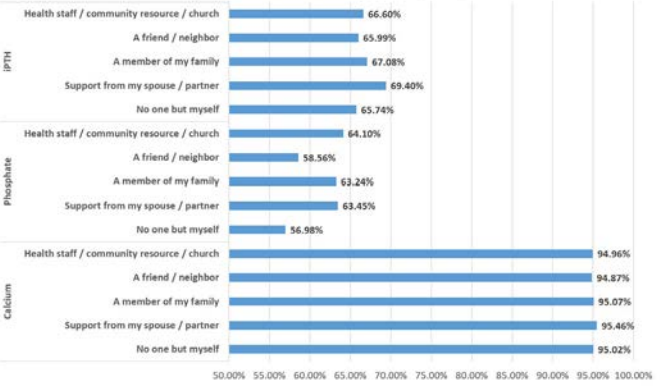
Impact of Social Support on Dialysis Patients Achieving Mineral Bone Disorder Laboratory Goals Felicia N. Speed,[1] Yue Jiao,[1] John W. Larkin,[1] Marta Reviriego-Mendoza,[1] Dugan Maddux,[1] Jessica Demaline,[1] Savannah Roberts,[2] Terry L. Ketchersid,[1] Stephanie Johnstone,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]FreseniusRx, Franklin, TN.*

Background: The type of social support dialysis patients (Pts) receive from family, friends, or caregivers has the potential to affect outcomes, but has not been widely investigated. We studied if the social support type is associated with dialysis Pts achieving mineral bone disorder (MBD) laboratory goals.

Methods: We analyzed data from Jan 2014 to Dec 2015 on 185,131 Pts at Fresenius Medical Care North America who completed the social work assessment questionnaire. We studied responses to the question "when you have a big problem, can you usually rely on?", which has choices for support types including: "no one but myself", "support from my spouse/partner", "a member of my family", "a friend/neighbor", or "health staff/community resource/church". We compared support types to the proportion of Pts meeting mean 6 month laboratory goals for calcium (Ca) [≤10.0mg/dL], phosphate (P04) [=3.0-5.5mg/dL], and intact parathyroid hormone (iPTH) [=150-600pg/mL] prior to completing the questionnaire.

Results: We observed Pts that received social support from a friend/neighbor or nobody had a distinguishably lower proportion of Pts meeting PO4 goals, as compared to other support types. Pts who received support from a spouse/partner had slightly more Pts meeting goals for iPTH versus other support types. Almost all Pts achieved Ca targets with no remarkable differences between types of support (Figure 1).

Figure 1: Percent of MBD Laboratories in Target Range



Conclusions: Our study indicates that social support from a spouse/partner, family member, or health staff/community resource/church may result in better control of PO4 levels, as compared to support from a friend/neighbor or no one. This may be indicative of improved adherence to PO4 binders with improved social support.

PUB641

Tailoring Phosphate Binders to Patients' Needs: Outcomes of a Short Term Pilot Study of a New Web-Based Tele-Medical Device for Smartphones and Tablets (P-MED) Guseppe Rombolà,[1] Luca Neri,[2] Alice Fattori,[2] Elisa Ottonello.[1] *[1]Unit of Nephrology, Ospedale Di Varese, Varese, Italy; [2]Univ of Milan, Milan, Italy.*

Background: Non-adherence to phosphate binders hampers clinical outcomes and increases costs. We assessed the suitability of a new tele-medical device (P-MED) designed to help nurses personalize clinical decisions and improve patient's adherence. We assessed outcomes of P-MED usage in clinical practice over a 2-month follow up.

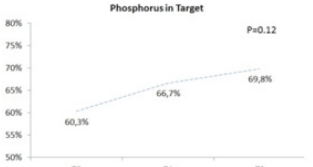
Methods: P-MED allows to record, view and integrate data on phosphorus lab values, medical prescriptions, p-binders dose, dietary habits, and the 8-item Morisky's adherence scale. The dietary interview is administered via a computer assisted system selecting the most informative question based on previous patients responses. Based on p-binders dose equivalence charts and nutritional charts, P-MED calculates and display the binding needs and the "calcium carbonate 1000 mg" equivalent dose (CC1000-ED) taken by the patients in the day preceding each interview. The pilot study took place in a single center in Italy from April to June 2016. Nurses were allowed to take as many interviews as deemed appropriate,

and encouraged to negotiate adjustments to medication dose based on phosphorus dietary intake with patients. Key clinical trajectories have been evaluated with random intercept generalized models.

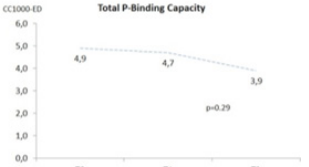
Results: Ten nurses voluntary elected to participate in the study and 63 patients took part to the study. During the 2-month follow up 84 adherence interviews and 380 dietary interviews occurred. Baseline charcteristics and clinical outcomes are reported in figure 1.

Baseline Characteristics	Mean (Std) or n (%)
Age	71.2 ± 5.8 years
Phosphorus	5.2 ± 1.5 mg/dL
Phosphorus in Target	37 (60%)
Estimated Dietary Pi Intake	932 ± 474.8 mg
CC1000-ED	4.9± 2.9
Phosphorus Gap *	9.0 ± 270.3
Morisky's Score=0	18 (29%)

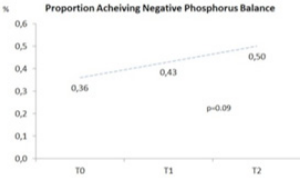
Table 1. Baseline Characteristics. * Phosphorus Gap represents the estimated amount of un-binded ditary intake based on dietary consumption and p-binder dosage



Panel A: Proportion of patients acheiving normal phosphorus levels (3.5<p<5.5 mg/dL)



Panel B: Estimated Total Binding Capacity from Phosphate Binders assumed by patients. 1 equivalent unit represent the binding capacity of 1000 mg of Calcium Carbonate.



Panel C: Proportion of patients who achevied a negative balance between dietary phosphorus intake and phosphorus binding (including phosphorus removal obtained with HD).

Conclusions: The application was well accepted by nurses and patients as showed by the high usage frequency. Despite non statistically significant the improvement in clinical outcomes and the reduction in medication usage is sizeable and merits further investigation in longer term and larger clinical studies.

PUB642

Quality of Mineral Bone Disease Care in Non-Dialysis Chronic Kidney Disease: Results of a Multi-Centre Audit and Survey Questionnaire in the Irish Health System Muhammad Umair Sharif,[1,2] Mohamed Elsayed,[1,2] Ahmed Alghali,[1,2] Mohammed A. Kaballo,[1,2] John P. Ferguson,[4] Xia Li,[2,3] Austin G. Stack.[1,2,3] *[1]Graduate Entry Medical School (GEMS), Univ of Limerick, Limerick, Ireland; [2]Dept of Nephrology, Univ Hospital Limerick, Limerick, Ireland; [3]Health Research Inst (HRI), Univ of Limerick, Limerick, Ireland; [4]Health Research Board (HRB) Clinical Research Facility, National Univ of Ireland, Galway, Ireland.*

Background: Mineral Bone Disease (MBD) is the most prevalent complication of Chronic Kidney Disease (CKD) and contributes to multiple adverse clinical outcomes. We sought to describe the prevalence, disease characteristics and quality of care of CKD-MBD in non-dialysis Irish CKD population. Parallel to this audit we explored the opinions and attitudes of Irish nephrologists, and their adherence to guidelines.

Methods: Data were captured on several aspects of outpatient MBD care in 530 non-dialysis CKD patients from nephrology clinics across 6 Irish health regions. Correspondingly, the survey questionnaire captured the attitudes of nephrologists on use of clinical guidelines and thresholds for intervention. Descriptive statistics and comparisons across groups were made using chi-square, ANOVA and logistic regression.

Results: The overall prevalence of CKD-MBD was 48%. The rate of MBD testing increased from 41% in Stage 3 to 88% in Stage 5. Overall 91% of patients' in Stage 3-5 had optimal phosphate control (Phosphorus <4.6 mg/dL). Among 9% patients with hyperphosphataemia, calcium-based binders were the preferred first-line treatment. The opinion of nephrologists varied widely on the threshold for binder initiation, choice of second line binder as well as the desired target for optimal control. The most frequently used guidelines were from UK Renal Association (41%).

Conclusions: Although control of MBD is generally good in the Irish Health system, residual deficits exist. Low treatment and testing rates didn't correspond to nephrologists' opinions, which varied widely. Variability in clinical practice may in part be due to these differences and may contribute to differential outcomes. Knowledge of these differences will serve as a useful starting point in seeking consensus for the production of national standards.

PUB643

Is There Really an Correlation between Serum Soluble Klotho Levels and Survival in Maintenance Hemodialysis Patients Jie Ma, Xuemei Li, Yang Yu. *Nephrology Dept, Peking Union Medical College Hospital.*

Background: Transmembrane α-Klotho (TM-Klotho) expressed in renal tubules, is a cofactor for FGF23-receptor. Circulating soluble-α-Klotho(**sαKl**) results from TM-Klotho, the extracellular domain of α-Klotho can be cleaved and released into various extracellular fluids, such as blood. Decreased TM-Klotho, prevents actions of FGF23 and lessens circulating sαKl. Thus, levels of sαKl could represent a marker of CKD-MBD, also possibly plays a role in determining the risk of mortality in some populations. The relationship between the level of serum soluble α-Klotho and overall mortality in hemodialysis patients is unclear yet.

Methods: We prospectively followed a cohort of 119 maintenance hemodialysis patients for 30 months in Peking Union Medical College Hospital dialysis center. We assessed the level of the soluble α-Klotho -and FGF23 of these patiens . Cox regression models were used to analyze the relationships between the primary outcomes(death) and the serums soluble α-Klotho and FGF23 levels.

Results: A total of 119 cases were enrolled this study, male 59, female 60, age 19-90years, mean age 59.3years, with duration of dialysis for10-95 months. The mean serum sαKl level and FGF23 level were no significance different between two groups of HD patients.

	Dead HD Patients	Survival HD Patients	*P*
Klotho	285.07±156.56	339.22±201.93	0.397
FGF23	435.05±690.46	1090±848.64	0.234

Also we did not find any correlation between soluble-α-Klotho and FGF23 and all-cause mortality.

Conclusions: We suspect that there may not be an correlation between serum soluble Klotho levels and all-cause mortality in maintenance hemodialysis patients.

PUB644

High-Resolution Magnetic Resonance Imaging to Assess Bone Microarchitecture in Patients with Chronic Kidney Disease Ashish K. Sharma,[1,2] Nigel David Toussaint,[1,2] Grahame J. Elder,[3,4] Stephen G. Holt,[1,2] Patricia L. Robertson,[1,2] Peter Robert Ebeling,[5] Paul A. Baldock,[4] Chamith S. Rajapakse,[6] Rosemary Masterson.[1,2] *[1]Royal Melbourne Hospital, Parkville, VIC, Australia; [2]Univ of Melbourne, Parkville, VIC, Australia; [3]Westmead Hospital, Westmead, NSW, Australia; [4]Garvan Inst of Medical Research, Sydney, NSW, Australia; [5]Monash Health, Clayton, VIC, Australia; [6]Univ of Pennsylvania, Philadelphia, PA.*

Background: Renal osteodystrophy (ROD) affects bone quantity and quality and is associated with increased fracture risk. Screening for ROD is hindered by inadequacy of current diagnostic methods. Bone biopsy is invasive and infrequently performed routinely. High-resolution magnetic resonance imaging (HR-MRI) is a new technique to assess trabecular and cortical microarchitecture. We aimed to validate HR-MRI assessment of bone structure compared to histomorphometry and micro-CT of bone biopsies from kidney transplant recipients.

Methods: Distal tibia HR-MRI scans and iliac crest bone biopsies were performed in 10 transplant recipients at transplantation. Structural parameters of biopsies were analyzed by histomorphometry and 3D micro-CT. Measurements included trabecular bone volume (TV/BV), thickness (TbTh), number (TbN), separation (TbS), mean cortical thickness (CtTh) and porosity (Po.%). Bone mineral density (BMD) was measured by peripheral quantitative computed tomography (pQCT, radius) and dual energy x-ray absorptiometry (DXA, hip). Associations were determined by analysis with Spearman's rank correlation coefficients.

Results: HR-MRI (tibia) and micro-CT (iliac crest biopsy) indices correlated positively for TbN and TbS (r=0.52 and r=0.56 respectively) and TV/BV, with no significant correlation for CtTh at these differing sites. HR-MRI (tibia) CtTh correlated to CtTh and BMD measured by pQCT (radius) (r=0.65 and 0.78 respectively). Micro-CT (iliac biopsy) CtTh correlated to BMD by DXA (hip), and cortical porosity by micro-CT correlated negatively to BMD by DXA (r=-0.65).

Conclusions: Micro-CT histomorphometry correlates to tibial HR-MRI for trabecular indices and to hip DXA for cortical indices. HR-MRI and DXA combined with biochemical turnover markers may provide rapid, accessible information to guide management of ROD.

PUB645

Does Potassium Citrate Have Equivalent Therapeutic Effect in Patients with Diabetes? Kimberly Maciolek, Kristina L. Penniston, Leema M. John, Sara Best. *Dept of Urology, Univ of Wisconsin School of Medicine & Public Health.*

Background: Diabetes (DM) increases the risk of stone formation. Patients with and without DM may have both acidic urine and low citrate but with different etiologies. Potassium citrate therapy (KCit) is used to alkalinize urine and raise citrate, but its efficacy in patients with DM, whose urinary derangements may be more significant, has not been assessed. We compared changes in 24hr urine parameters after KCit in stone formers with and without DM.

Methods: We identified 32 patients (16 with DM) who had 24hr urine results pre- and post-KCit. Changes in urinary risk factors between patients with and without DM were evaluated.

Results: Age and BMI were similar between groups (58 vs 55 y, p=0.39; 35.3 vs 31.5 kg/m2, p=0.25). Median time between starting KCit and the follow-up urine collection was 173 and 300 days (DM vs non-DM, p=0.13). 24hr urinary parameters were similar between groups before KCit. All patients were deemed to be compliant with KCit. Changes in group means for 24hr urine parameters are shown in the table.

Table 1 : Mean change in urinary risk factors after initiating KCit		
	Patients with DM	Patients without DM
Cit (mg/d)	95	126
pH	0.50*	0.40
K (mEq/d)	20*	13
SS Br	0.09	0.66*
SS UA	-0.68*	-0.21
*Statistically significant change (p<0.05) pre- vs post-KCit		

Neither group achieved a statistically significant rise in citrate after initiating KCit. Those with DM experienced a significant rise in pH. A significant proportion of patients without DM achieved therapeutic levels of citrate (>320mg/d) with KCit (81%, p=0.028). Brushite supersaturation (SS) rose significantly only in patients without DM after initiating KCi. Uric acid SS decreased in both groups but was significant only in patients with DM. Other changes in 24hr urine were statistically similar regardless of DM status.

Conclusions: The effect of KCit on 24hr urine risk factors for stone formation is similar in patients with and without DM. Patients with DM may experience a greater improvement in urine pH than patients who do not have DM and may do so without risking a rise in brushite SS.

PUB646

Addressing an Unmet Need in Patients with Secondary Hyperoxaluria Sagar U. Nigwekar,[1] James E. Lingeman,[2] Louis Brenner,[3] Danica Grujic,[3] Annamaria T. Kausz.[3] *[1]Div of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Dept of Urology, Indiana Univ, Indianapolis, IN; [3]Allena Pharmaceuticals, Newton, MA.*

Background: Kidney stones are common, and secondary hyperoxaluria (2^0HOx) is a known risk factor. However, randomized controlled trials (RCT) of 2^0HOx are rare, and little is known about dietary oxalate intake and its correlation to 24h urinary oxalate (UOx) excretion. Here we present characteristics of patients with 2^0HOx enrolled in two Phase 2 double blind, placebo-controlled RCTs of ALLN-177, a novel oral, crystalline enzyme therapy that specifically degrades oxalate in the GI tract, decreasing the amount available for absorption. Our prior trials demonstrated that ALLN-177 reduced 24h UOx in both healthy volunteers and patients with 2^0HOx.

Methods: In Study 649, 42-60 subjects are being randomized to receive 1500, 3000 or 7500 units of ALLN-177 or placebo TID with meals x 7d, then cross over to an alternate arm for 7d. In Study 713, 44 subjects are being randomized to receive 7500 units of ALLN-177 or placebo TID with meals x 28d. Subjects remain on their usual diet, monitored with dietary recalls throughout the study. The primary efficacy assessment is based on mean change in 24h UOx.

Results: To date, 30 and 13 subjects have enrolled in Study 649 and 713, respectively. Across both studies, mean age is 60 years, 74% are male and 26% have 2^0HOx from bariatric surgery or inflammatory bowel disease. Subjects report on average ~6 stones in the past 5 yrs. Nearly 75% of subjects received some guidance to modify dietary intake. Entering the study, mean (SD) dietary intake of oxalate was 351 (435) mg/d, calcium 981 (578) mg/d, and fluids 3.9 (1.3) L/d. Mean (SD) excretion of UOx was 77 (32) mg/d, calcium 248 (178) mg/d and citrate 738 (576) mg/d; urine volume was 2.4 (0.76) L/d.

Conclusions: The characteristics of subjects enrolled in ALLN-177 clinical trials highlight the need for an effective therapy for 2^0HOx. Despite adequate fluid intake and dietary guidance, patients have excess oxalate in their diet, remain hyperoxaluric, and have recurrent kidney stones. Results of these Phase 2 studies will provide further confirmation of the efficacy and tolerability of ALLN-177 for treating 2^0HOx.

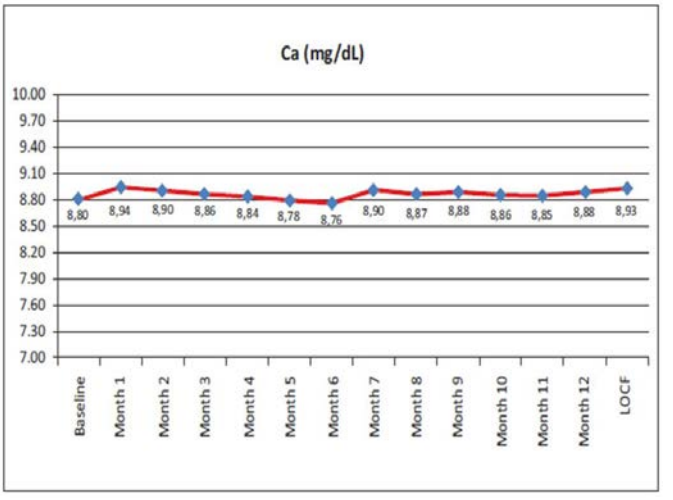
PUB647

Follow-Up of HD Patients Receiving sVDRA for Prevention and Treatment of SHPT: An Observational Study (P12-314) Fevzi F. Ersoy,[1] Hasan Koc,[2] Hasan Hoser,[3] Yalcin Akdag,[4] Cemaliye Kendir.[5] *[1]Akdeniz Univ Medical School, Antalya, Turkey; [2]Hayat Dialysis Center, Istanbul, Turkey; [3]Cinar Dialysis Center, Kutahya, Turkey; [4]Larende Dialysis Center, Karaman, Turkey; [5]Besyuzevler Safak Hospital, Istanbul, Turkey.*

Background: Secondary hyperparathyroidism (SHPT) is caused by decreased calcitriol synthesis, phosphate (P) accumulation and hypocalcemia during chronic kidney disease (CKD). The aim of this study was to evaluate monthly changes of iPTH and other major mineral/bone marker levels in hemodialysis (HD) patients with SHPT receiving paricalcitol.

Methods: 493 (F/M 244/249) adult hemodialysis (HD) patients, who were selected from 22 HD units in Turkey; receiving sVDRA treatment; with iPTH>300 mg/mL; Ca<10.2 mg/dL and P<6 mg/dL were included in this multi-center, national, prospective, observational study. Efficacy, safety and adverse events information on sVDRA treatment were collected by monthly visits along with iPTH, Ca, P and hsCRP values for 12 months. Mortality data was collected 6 months after the end of study.

Results: The mean age and duration of CKD Stage 5 were 58.3±15.8 years and 6.2±5.5 years, respectively. HD duration was ≤1 year in 14.4%, whereas longer than 3 years in 59.2% of subjects. Dialysate Ca concentrations were 125 mmol/L in 77.1% of patients. As of 12th month, no statistically significant changes have been observed in Ca and hsCRP levels (p>0.05) (Figure 1) and iPTH values were decreased from 646±424 pg/mL to 473±387 pg/mL (p<0.001). There were clinically insignificant increases in P and albumine levels at 12th month compared with the baseline (p= 0.017 and p<0.003 respectively).



Conclusions: Our study has shown that, paricalcitol, in addition to successful iPTH control, had favorable effects on serum Ca and P, which are consistent with previous studies. Increased serum albumin levels at Month 12, may be related to nutritional factors.

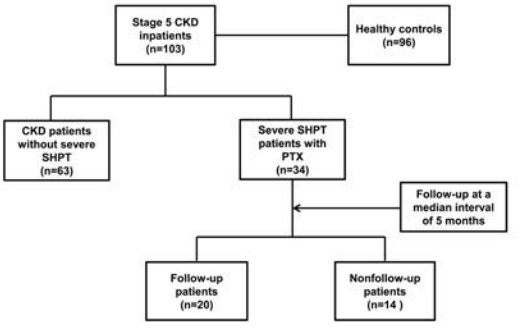
Effects of Parathyroidectomy on Blood Bone Markers and Heart Rate Variability in Stage 5 Chronic Kidney Disease Patients Ningning Wang, Huimin Chen. *Dept of Nephrology, First Affiliated Hospital with Nanjing Medical Univ, Nanjing, China.*

Background: Attenuated heart rate variability(HRV) is associated with cardiovascular autonomic nerve disorders. No study has investigated the correlations between blood bone markers and HRV in chronic kidney disease(CKD), especially in secondary hyperparathyroidism(SHPT) patients.

Methods: We performed cross-sectional and prospective studies.

Figure 1. Study population flow diagram.



Bone parameters included (1)intact parathyroid hormone(iPTH), whole PTH(wPTH), and (7-84)PTH as bone remodeling regulators;(2)bone-specific alkaline phosphatase(BAP), representing bone formation;(3) tartrate-resistant acid phosphatase(TRACP-5b), indicating bone resorption;(4) bone-derived hormone, fibroblast growth factor 23(FGF23) and its cofactor Klotho.

Results: Compared with controls, baseline circulating levels of phosphorus, iPTH, wPTH, (7-84)PTH, BAP, TRACP-5b, and FGF23 were increased, while Klotho and wPTH/iPTH were decreased in CKD patients. Baseline plasma wPTH, (7-84)PTH, TRACP-5b, and FGF23 levels were associated with HRV in CKD. In parathyroidectomy(PTX) group, baseline and postoperative changes of bone markers which predicting the normalization of HRV were shown in table 1.

Dependent Improved HRV variables	Independent bone markers variables
Δmean 24h heart rate	Δ(7-84)PTH
Δmean normal-to-normal R–R intervals	(7-84)PTH
Δstandard deviation of the normal-to-normal R–R intervals	TRACP-5b
Δroot mean square of differences between adjacent normal R–R intervals	ΔiPTH
Δproportion of adjacent R–R intervals differing by >50 ms over 24 h	ΔiPTH
Δvery-low frequency	TRACP-5b
Δlow frequency	TRACP-5b
Δhigh frequency	TRACP-5b

Conclusions: In CKD, (7-84)PTH, TRACP-5b, wPTH, and FGF23 predict imbalances of cardiovascular autonomic nervous system. We offer novel insights into the relationship between bone resorption and cardiovascular disease in CKD.

Does Combination of Cinacalcet with Paricalcitol in Secondary Hyperparathyroidism Treatment Make Sense? Jacek P. Zawierucha,[1] Wojciech Marcinkowski,[4] Jolanta Malyszko,[2] Jacek S. Malyszko,[3] Teresa Dryl-Rydzynska,[1] Tomasz R. Prystacki.[4] *[1]Fresenius Medical Care Polska S.A., Poznan, Poland; [2]Second Dept of Nephrology and Hypertension with Dialysis Unit, Medical Univ of Bialystok, Bialystok, Poland; [3]Depatment of Nephrology with Dialysis Unit, Medical Univ of Bialystok, Bialystok, Poland; [4]Fresenius Nephrocare Polska sp. z o.o., Poznan, Poland.*

Background: Prospective 6 month observation study of the sHPT paricalcitol treatment effectiveness with and without association with cinacalcet in hemodialysis patients.

Methods: The study included 64 hemodialysis patients aged 19-90, average PTH 930pg/mL±440pg/mL (2718;516pg/mL, median 784pg/mL). Paricalcitol included in an initial dose of approximately 48mcg/month (5-180mcg/month depending on the initial iPTH level). 16 patients were additionally administered with cinacalcet (0,6mg/kg/day initially).

Results: Paricalcitol impact on the concentration of iPTH, corrected calcium and alkaline phosphatase activity is shown in table 1.

	PAR(n=48)	PAR+CIN(N=16)	all(n=64)
baseline iPTH(pg/mL)	888	1055	930
week 24 iPTH(pg/mL)	356	516	396
p	<0.05	<0.05	<0.05
baseline corrected Ca(mg/dL)	9.5	7.4	8.9
week 24 corrected Ca(mg/dL)	9.7	10.5	9.9
p	>0.05	<0,05	<0.05
baseline ALP(U/L)	159	295	193
week 24 ALP(U/L)	116	158	127
p	<0.05	>0.05	<0,05

Paricalcitol significant effected significalnly on the corrected calcium concentration. Cinacalcet had also a similar effect on PTH level. In both groups effect on serum calcium and phosphate was observed. In both groups baseline iPTH was similar (888pg/mL (2718;516pg/mL) in paricalcitol group vs 1055pg/mL (2224;523pg/mL) in paricalcitol and cinacalcet group, NS). No significant hypercalcemia during the 6 months treatment with paricalcitol was observed.

Conclusions: Treatment of sHPT with paricalcitol in hemodialysis patients is effective and has a good safety profile. The combination of paricalcitol and cinacalcet does not improve the results of the treatment. The combination of paricalcitol and cinacalcet does not improve the results of the treatment. However, possible combination of two drugs may be considered in case of hypocalcemia, but cost-effectiveness should be taken into account.

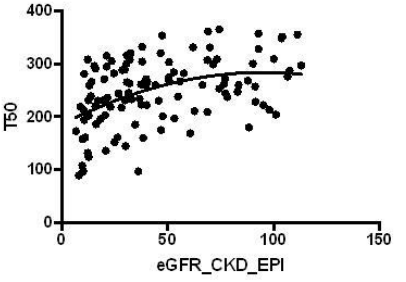
PUB650

Effect of eGFR on a Novel Assay of Calcification Propensity in Chronic Kidney Disease Bernhard O. Bielesz,[1] Thomas Johannes Reiter,[1] Rodrig Marculescu,[2] Andreas Gleiss,[4] Marija Bojic,[1] Daniel Cejka.[3] *[1]Medical Univ of Vienna, Div of Nephrology and Dialysis, Vienna, Austria; [2]Medical Univ of Vienna, Dept of Laboratory Medicine, Vienna, Austria; [3]Elisabethinen Hospital, Div of Nephrology, Transplantation, and Rheumatology, Linz, Austria; [4]Medical Univ of Vienna, Center for Medical Statistics, Informatics, and Intelligent Systems, Vienna, Austria.*

Background: Calcification propensity (CP) of human serum,which can be measured by a novel assay,associates with declining renal function and adverse outcomes such as mortality and cardiovascular events in chronic kidney disease (CKD) 3-4.We assessed which biochemical and bone-mineral metabolism markers modify increasing CP with declining kidney function.

Methods: Propensity of serum for calcification was determined by measuring the half-maximal transition time (T50) from primary to secondary calciprotein particles in serum (Pasch et al.,JASN 2012).Parameters were grouped into six mediator classes (cl1-6). T50,[calcium (Ca),phosphate (Pi),parathyroid hormone (PTH),fibroblast growth factor 23 (FGF23)] cl1;[25OH-Vitamin D;1,25OH-Vitamin D] cl2;[fetuin A (total and free fraction)] cl3;[Osteocalcin (carboxylated and uncarbox.),C-telopeptide,Osteoprotegerin,n-terminal type 1 procollagen] cl4;[sclerostin] cl5;[bicarbonate] cl6;magnesium,albumin were measured in 120 non-dialysis CKD patients.The difference between direct and total (direct and mediated by respective class) effect of eGFR was calculated in linear regression models including 95% bias-corrected and accelerated bootstrap confidence intervals.

Results: Ca,Pi,PTH,and FGF23 significantly alter the effect of eGFR on T50.



Effect eGFR doubling	95%CI	Effect
22.1375	11.7483-32.5266	Total
4.5777	-10.9753-20.1307	Direct
17.5598	3.8403-30.3569	Difference

Conclusions: Mineral-bone metabolism markers modify increased calcification propensity in renal function impairment.

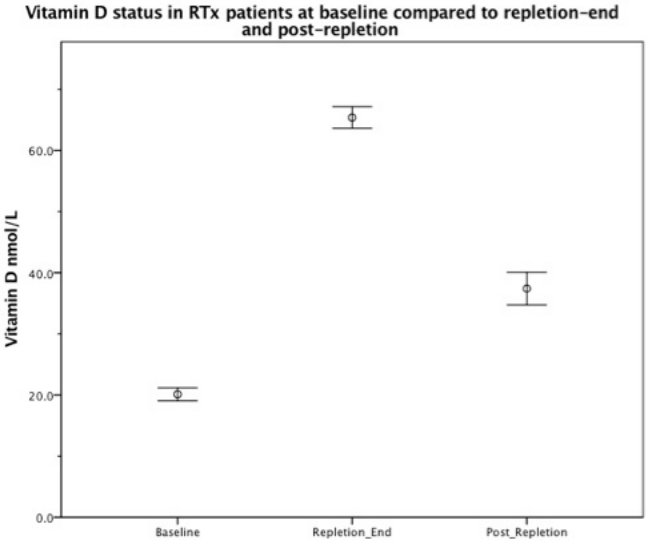
PUB651

Dynamics of Short-Term Native Vitamin D Repletion in Long-Term Renal Transplant Patients Oliver J. Ziff,[1] David Goldsmith.[2] *[1]Inst of Cardiovascular Science, Univ College London, London, United Kingdom; [2]Dept of Nephrology and Transplantation, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom.*

Background: Renal Transplant patients (RTx) are often Vitamin D (VD) depleted by CKD and repletion is warranted for multiple health issues, but how, and for how long, this should be achieved is unknown.

Methods: Bone biochemistry parameters were analysed from 102 repletion courses in 98 RTx patients (>10yr post-engraftment). 6month repletion was either 240,000IU colecalciferol (if 25(OH)D between 20-50), and 360,000IU (if <20nmol/L). 12months post-repletion data were available for 40 patients. All studied patients had stable, functional with PTH > 60ng/L and 25(OH)D <50nmol/L prior to supplementation.

Results: At baseline, 25(OH)D was 20.1±1.0nmol/L (mean±SEM), increasing to 65.4±1.8nmol/L following repletion (median 6months, p<0.0001). Following repletion and no further VD administration, 25(OH)D fell to 37.4±2.7nmol/L (median interval 12 months, p<0.0001).



PTH followed the opposite trend with baseline, repletion-end and post-repletion values being 144.22±12.0ng/L, 109.6±7.5ng/L (p<0.0001), and 122.4±17.0ng/L (p=0.08).

	Baseline (n = 102)	Repletion end (n = 102)	Rate of Change per year	Post repletion (n = 40)	Rate of Change per year
Vitamin D nmol/L	20.1 ± 10.3	65.4 ± 17.2 p<0.0001	+90.6	37.9 ± 16.7 p<0.0001	-27.5
PTH ng/L	144.2 ± 119.2	109.6 ± 72.6 p<0.0001	-69.2	119.5 ± 106.3 p=0.08	+9.9

There was no hypercalcemia (>2.65mmol/L), and renal function remained stable (eGFR change -2.98±10.2 mls/min/yr).

Conclusions: VD repletion can safely and effectively be achieved in chronic stable RTx recipients using a 6months intermediate-dose schedule, while significantly reducing raised PTH. Following repletion, 25(OH)D fell significantly, though at a 3-fold slower rate than seen with the impact of supplementation.

PUB652

Vitamin D: A New Marker for Acute Kidney Injury Progression

Jeanne Kamal,[1] Christine Boumitri,[2] Patricia Nasr,[1] Joseph Saabiye,[1] Lara El Khoury,[1] Firas Safa,[1] Julie Zaidan,[1] Rania El Mais,[1] Suzanne E. El Sayegh,[3] Elie El-Charabaty.[3] *[1]Internal Medicine Dept, Staten Island Univ Hospital, Staten Island, NY; [2]Gatroenterology Dept, Univ of Missouri, Columbis, MO; [3]Nephrology Dept, Staten Island Univ Hospital, Staten Island, NY.*

Background: Acute Kidney Injury (AKI) is a common and serious complication occurring in 5-7% of hospitalized patients. Markers helping in the early recognition of patients at risk are still lacking. Low levels of vitamin D and its metabolites occur in AKI. This raises the interest of studying vitamin D as a predictor of AKI outcome.

Methods: Patients admitted to SIUH with AKI with a normal baseline GFR (>60) were enrolled. All patients had their serum creatinine (SCr) checked within 24 hours of admission (D0) and 3 days after (D3) and Vitamin D levels (25 hydroxyvitamin D; 1,25 hydroxyvitamin D) at D0. Vitamin D was collected at D3 for the patients who remained in AKI and not for those who recovered (50% decrease in SCr or return to baseline).

Results: 56 patients in AKI were enrolled. 37 were men, mean age of 64.6, and BMI of 31.1. 22 (39.3%) were diabetic and 34 (60.7%) were hypertensive. 35 (56.4%) patients recovered from AKI and 21 (43.6%) remained in AKI at D 3. 1,25 DihydroxyVitamin D levels was significantly higher in patients whom kidney function improved (43.63 vs 30.1; p=0.036). There were no significant findings with respect to 25-hydroxyvitamin D (19.51 vs 18.86; p=0.77).

Conclusions: 1,25 DihydroxyVitamin D is the active metabolite of vitamin D. High levels of Calcitriol were associated with clinical improvement of AKI. A possible explanation of the low levels in kidney disease is probably due to the suppressed renal 1α-hydroxylase activity in contrast to 25-hydroxyvitamin D which levels reflect the total body stores of Vitamin D. Higher Calcitriol level is a marker of better outcome in AKI. Could supplementing patients in AKI with Clacitriol be an intervention helping in their recovery?

PUB653

Serum 1, 25-Dihydroxyvitamin D and Clinical Characteristics of End Stage Renal Disease Patients: A Cross-Sectional Study

Jing Luo, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Most patients with end stage renal disease (ESRD) have vitamin D deficiency, including deficiencies in both active (1, 25-dihydroxyvitamin D, 1, 25(OH)2D) and inactive vitamin D (25-hydroxyvitamin D, 25(OH)D). Most of the previous studies examined the inactivated form; however, the serum level of activated form and its role in ESRD patients were largely unknown. In this study we tested the levels of 1, 25(OH)2D in serum and evaluate their relations with clinical characteristics of ESRD patients.

Methods: This cross-sectional study enrolled a cohort of 709 ESRD patients on maintenance hemodialysis for at least 6 month, who came from two different hospitals. The serum concentration of 1, 25(OH)2D was measured by liquid chromatography mass spectrometer. Clinical covariates, including sex, age, dialysis duration were recorded. Serum concentrations of intact PTH (iPTH), calcium, phosphate, fibroblast growth factor 23 (FGF23) and alkaline phosphatase (ALP) were examined. Coronary artery calcification score (CACS), left ventricular ejection fractions (LVEF) and bone density were also measured.

Results: The serum levels of 1, 25(OH)2D were markedly decreased in hemodialysis patients (105.28 ± 65.74 pg/ml) compared with health control (110.70 ± 28.04, P<0.05). According to the quartile of serum 1, 25(OH)2D levels, the hemodialysis patients were divided into three groups. The serum FGF23, LVEF and blood flow rate were significant different among these three groups. However, no statistical differences were found in age, dialysis duration, serum iPTH, ALP and CACS. Nevertheless, no significant difference in serum 1, 25(OH)2D levels was found in patients with or without active vitamin D supplementation (66.24±5.48 pg/ml vs. 65.23±4.85 pg/ml, P>0.05). Moreover, lower serum 1, 25(OH)2D was significantly associated with incidence of osteodynia and skin itching (P<0.05).

Conclusions: ESRD patients have active vitamin D deficiency. It seemed that supplement with active vitamin D could not restore serum active vitamin D level. Lower serum 1, 25(OH)2D levels was associated with the incidences of osteodynia and pruritus.

Does the Treatment for Secondary Hyperparathyroidism in End-Stage Kidney Disease (ESKD) Benefit Phosphorus Metabolism?

Jose Maria Bautista, Fernando Tornero, Serena Gatius, Jose A. Herrero, Marisol Poma Tapia, Amir Shabaka, Virginia López de la Manzanara Pérez, Fabio Procaccini, Mauricio Alejandro Miranda Cam, Ana Sanchez Fructuoso. *Nephrology, Hospital Clinico San Carlos, Madrid, Spain.*

Background: The rationale for increased PTH observed in patients with end-stage kidney disease is probably the increase in urinary phosphorus excretion. For the treatment of secondary hyperparathyroidism (SHP), most of the current clinical practice guidelines recommend lowering PTH levels. However, control of PTH could be accompanied by a decrease in the urinary phosphorus excretion and an increase in its serum concentration. Our goal was to evaluate the influence of PTH reduction on urinary phosphorus excretion in patients with ESKD.

Methods: We analized 64 patients with ESKD, 33 males, mean age 69.3±12.9 years, diagnosed with SHP with PTH-lowering treatment (59 with paricalcitol, 5 with cinacalcet). We evaluated epidemiological factors, renal function, calcium and phosphorus metabolism parameters before and after treatment. Patients with other therapeutic modifications that could have influenced calcium and phosphorus metabolism were not included.

Results: After treatment, we observed a significant decrease in PTH levels (from 385±35.1 pg/ml to 311±36.2 pg/ml; p=0.001), an increase in serum phosphorus levels (from 4.35±0.1 to 4.65±0.1; p=0.003). There was also a significant decrease in phosphorus excretion, measured both as 24-hour phosphaturia (from 582.5±29.2 mg/24 h to 528±28.1 mg/24 h; p=0.024), and as fractional excretion of phosphorus (from 47.9±1.8% to 44.2±2.2%; p=0.029), and parallel to this, an increase in tubular reabsorption of phosphorus (from 52.3±1.9% to 55.3±2.1 %; p=0.029). Regarding renal function, we observed an increase in serum creatinine (from 3.7±0.14 mg/dl to 4.03±0.17 mg/dl; p=0.005), associated to a decrease in the glomerular filtration rate measured by CKD-EPI (from 16.3±0.7 ml/min to 14.6±0.6 ml/min; p=0.002). No significant differences were found in terms of levels of serum calcium and vitamin D.

Conclusions: The treatment for SHP in patients with ESKD can have a detrimental effect on serum phosphorus levels, increasing them by reducing its urinary excretion.

PUB655

Response of Serum 25-Hydroxyvitamin D Levels to Ergocalciferol Administration: Comparison of ESKD Patients and Healthy Volunteers

Ornatcha Sirimongkolchaiyakul, Katherine Wesseling-Perry, Georgina Chow, Barbara Gales, Isidro B. Salusky. *Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Vitamin D deficiency is common in CKD patients and oral ergocalciferol supplementation is often used in this population. However, current studies are inconsistent as to the efficacy of ergocalciferol in ESKD patients as compared to healthy individuals. Thus, we compared changes in serum 25(OH)D between hemodialysis patients and healthy volunteers after the administration of oral ergocalciferol.

Methods: 16 hemodialysis patients (age 53.76 ± 26.1 years) and 7 healthy volunteers (age 44.71 ± 13.77 years) ingested a single dose of 50,000 IU of oral ergocalciferol. Biochemical levels were measured at baseline and 3 days after ergocalciferol ingestion. Changes of the 25(OH)D levels were compared between two groups.

Results: Patient age, sex and race were similar between groups. Baseline 25(OH) D levels were higher and a greater increase in levels was observed with ergocalciferol ingestion in healthy volunteers.

Results

	Healthy controls (N=7)	ESKD (N = 16)	p-value
Sex : female (N)	3 :42.86%	5 :31.25%	
Age (yr)	44.71 ± 13.77	53.76 ± 26.1	0.21
Race (N)			
-white	5 :71.43%	6 :37.50%	
-hispanic	1 :14.29%	4 (25%)	
-asian	1 :14.29%	3 (18.75%)	
-black		3 (18.75%)	
Cause of ESKD (N)

PUB656

The Efficacy of Intra-Operative PTH Assay during Parathyroidectomy for Patients with Renal Hyperparathyroidism

Kevin Wang,[1] David Saxon,[1] Adeleye Annick Edon,[1] Florence Lima,[1] David Sloan,[2] B. Peter Sawaya,[1] Amr El-Husseini Mohamed.[1] *[1]Medicine, Univ of Kentucky, Lexington, KY; [2]Surgery, Univ of Kentucky, Lexington, KY.*

Background: The value of intra-operative parathyroid hormone (ioPTH) during parathyroidectomy (PTX) for renal secondary and tertiary hyperparathyroidism (HPT) remains unclear. The present study aims at evaluating PTX in a single center experience and the ability of ioPTH assay to assist in the proper surgical excision of parathyroid gland (PTG) tissue.

Methods: The ioPTH was determined in 83 consecutive patients (51% males and 49% females) who underwent PTX from 2005 to 2015. Near-total PTX was performed in 74% of patients and total PTX in 26%.Sixty patients were on hemodialysis and 5 on peritoneal dialysis and 18 patients had a functional kidney transplant at the time of PTX. The ioPTH monitoring included 3 samples: pre-intubation (pre-ioPTH), at 10- and 20-minute post PTG excision (10-ioPTH and 20-ioPTH).

Results: Pre-, 10- and 20- ioPTH levels were 1194 pg/ml [403-1892], 123 pg/ml [67-224] and 87 pg/ml [45-149], resp. There was no significant difference in pre-, 10- and 20-ioPTH levels between the 3 PTX procedures (P = 0.60, 0.50 and 0.89, resp.). In patients with a functional kidney transplant, pre-ioPTH levels were lower than those on dialysis, (294 [180-403] vs. 1447 [868-2176] resp., P =0.004). However, the percentages of decrease of PTH at 10 and 20 min normalized with pre-ioPTH were not different in both groups (-83.9% versus -75.7%, P = 0.40 and -10.6% versus -26.5%, P = 0.42, resp.). Thirty-one % of the patients were readmitted to the hospital within 90 days mostly because of hypocalcemia (73.9%). Apart from easily treated hypocalcemia the PTX surgeries were uneventful in most patients (93%), 3 patients had local hematomas, 1 patient had significant local bleeding, 1 had temporary vocal cord palsy and 1 had local wound infection.

Conclusions: PTX is a safe procedure for renal patients with 7.2% surgical morbidities and no surgical related mortalities. As expected, easily correctable hypocalcemia after surgery is common and it accounts for approximately 2/3 of readmissions. Measuring ioPTH is very useful in directing the amount of PTG tissue removed.

The Examination of the Adult Cases with Mild Proteinuria and the Alport-Like GBM Abnormality

Masayo Sato,[1] Kazuho Honda,[2] Kosaku Nitta.[1] *[1]Nephrology, Tokyo Women's Univ, Shinjuku-ku, Tokyo, Japan; [2]Microscopic Anatomy, Showa Univ School of Medicine, Shinagawa-ku,Tokyo, Japan; [3]Dept of Pathology, Tokyo Women's Univ, Shinjuku-ku, Tokyo, Japan.*

Background: Alport syndrome (AS) and Thin basement nephropathy(TBMN) are related to type IV collagen. About 40% of people of TBMD were reported the carrier of autosomal recessive Alport syndrome. Sometimes it is difficult to distinguish AS and TBMN. The genetic screening is useful, but has an ethical problem. To determine whether initial pathology, we examined pathological type and the renal outcomes.

Methods: This retrospective study population of 35 adult patients with biopsy-proven GBM abnormality who were registered at our hospital between 1985 to 2015 wiht a urinary protein<0.5g/gCre, eGFR>60 ml/min/1.73m2. We divided patients with clinical, pathological characters to three groups, which was AS(n=8), TBMN(n=7),atypical group(20 cases). We compared three groups. The primary endpoint was a 25%,50% reduction of eGFR, and secondary endpoint was the increase of urinary protein.

Results: The kidney biopsy for adaptation of the donors was 9 cases(AS:n=2,TBMN:n=3, atypical:n=4), the eGFR of donors was below 60ml/min/1.73 m^2 after the operation. The 50% reduction in the eGFR was observed with the patients of AS(n=2). A urinary protein>1g/gCre was observed at AS (n=5), atypical group(n=2).

Conclusions: AS and TBMN at adult ages are sometimes not clearly divided. We take care these type IV collagen nephropathy.

PUB659

Macular Holes Occur in Alport Syndrome Regardless of Genotype

Martin C. Gregory,[1] Margaret M. Deangelis,[2] Denise Morgan,[2] Paul S. Bernstein.[2] *[1]Div of Nephrology, Univ of Utah Health Sciences Center, Salt Lake City, UT; [2]Moran Eye Center, Univ of Utah Health Sciences Center, Salt Lake City, UT.*

Background: Ocular manifestations occur commonly in patients with Alport syndrome. Most commonly these are diagnostically helpful and do not impair vision, for example retinal flecks and temporal retinal thinning. Less frequently anterior lenticonus can severely affect vision and may require lens extraction and replacement. Macular holes are uncommon, devastating to central vision, appear relatively specific to Alport syndrome, but no molecular genetic information has been published.

Methods: Over decades of studies on Alport syndrome we became aware of 6 patients with macular holes. Mutations in COL4A5 were identified by DGGE, ASOT probe tests, RNAse protection assays, and multiplex genomic PCR-SSCP in 5 families. All were confirmed by direct sequencing.

Results: Molecular characterization showed 5 patients with COL4A5 mutations and one probably autosomal recessive Alport syndrome.

Patient #	Sex	Mutation	Retina	Renal state at diagnosis
5020166	M	COL4A5 L1649R	Macular holes OU	SCr 1.0 mg/dl
2017006	M	COL4A5 Y1597X	Macular holes OU	Transplanted
2224004	M	Likely autosomal recessive	Macular holes OU, retinal flecks	SCr 1.0 mg/dl
2163003	M	COL4A5 G1205S	Macular holes OU, retinal flecks	Hemodialysis
2316001	F	COL4A5 3218+1 g>t	Macular hole OD	Not on dialysis
2158001	M	COL4A5 1981+3 g>t	Macular holes OU	Transplanted

Macular holes developed either early or late in the course of Alport syndrome. Renal phenotypes varied from COL4A5 mutations causing a severe (Y1597X, G1205S, 1981+3 g>t), uncertain (COL4A5 3218+1 g>t), or late onset (COL4A5 L1649R) renal phenotype. One patient comes from a family that appears autosomal recessive by pedigree analysis and by segregation of chromosome 2 haplotypes. Whole exome sequencing of this kindred is currently under way.

Conclusions: Giant macular holes occur occasionally in Alport syndrome, much more commonly than in the general population. They are not confined to a single mode of inheritance nor to COL4A5 mutations that cause a severe renal phenotype.

PUB660

The Novel Arg646Gly SLC4A1 Mutation Is Responsible for Distal Renal Tubular Acidosis

Joaquim T. Calado,[1,2] Sandra Brum,[3] Catarina Sofia Urbano Silveira,[4] Ana Santos,[2] Fernando E.B. Nolasco.[2] *[1]ToxOmics, NOVA Medical School, Lisbon, Portugal; [2]Nephrology, CHLC, Lisbon, Portugal; [3]Nephrology, Hospital de Santo Espírito, Angra, Portugal; [4]GenoMed, IMM, FML, Lisbon, Portugal.*

Background: The Cl^-/HCO_3^- exchanger (AE1), encoded by *SLC4A1*, is differentially expressed in the erythrocyte and kidney. The full transcript (eAE1) has a structural role in the red cell, while the shorter isoform (kAE1) is essential for renal acidification. *SLC4A1* mutations can account for hemolytic anemia or distal renal tubular acidosis (dRTA). Since mutations that give rise to spherocytosis/ovalocytosis are different from those responsible for dRTA, the occurrence of a dual hemolytic and dRTA phenotype is extremely rare. The few cases reported involve mostly a compound heterozygous condition for the Δ400-408 allele, leading to autosomal dominant southeast Asian ovalocytosis (SAO), together with a restricted number of mutations responsible for recessive isolated dRTA.

Methods: We report a 53 years old male of southeast Asian ancestry presenting with severe hypokaliemia (1.7 mmol/L) and a non-anion gap metabolic acidosis, with normal renal function and persistent alkaline urine. Nephrocalcinosis was documented by ultra-sound, recovered calculi were shown to be made of calcium phosphate and a diagnosis of dRTA was established. In spite the lack of anemia, an abdominal ultra-sound revealed cholelithiasis and cavernous transformation of the portal vein. Additional workup characterized a Coombs' negative chronic hemolysis displaying the typical findings of spherocytosis in the blood smear together with hemossiderosis in liver biopsy.

Results: Sanger sequencing of *SLC4A1,* identified 3 heterozygous variations: the c.1199_1225del27 (Δ400-408), the c.166A>G (p.Lys56Glu), known to be in linkage with the former, and the c.1936C>G (p.Arg646Gly) mutation. This latter allele is not found within the 1000 Genomes Project or the Exome Aggregation Consortium and is predicted to be pathogenic by *in silico* analysis.

Conclusions: The current report broadens the spectrum of *SLC4A1* mutations associated with dRTA and suggests this *novel* Arg646Gly mutation, in addition of being a codominant allele for the dual phenotype, may act as a recessive allele for isolated dRTA.

PUB661

Hereditary Transthyretin Amyloidosis and Kidney Injury

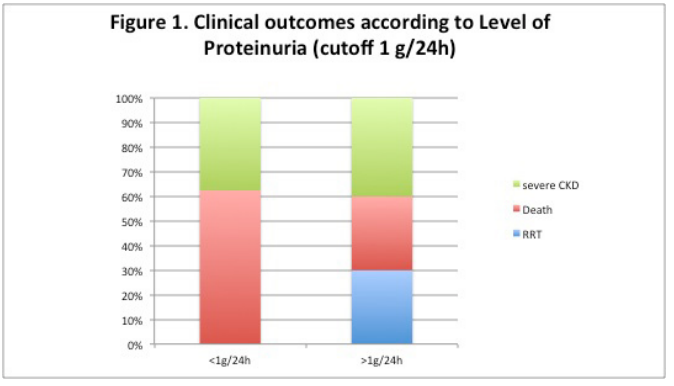
Asuncion Ferrer-Nadal,[1] Cristina Gallego,[2] Manuel Raya,[2] Mercedes Uson,[3] Antoni Figuerola,[3] Carles Montala,[4] Cristina Descals,[4] Tomas Ripoll,[5] Juana Nuñez,[5] Hernan Andreu,[6] Eugenia Cisneros-Barroso,[2] Juan Buades.[2] *[1]Dept of Nephrology, Hospital Son Llàtzer, Palma de Mallorca, Baleares, Spain; [2]D. Internal Medicine, H. S. Llàtzer; [3]D. Neurology, H. S. Llàtzer; [4]Neurophysiology U., H. S. Llàtzer; [5]D. Cardiology, H. S. Llàtzer; [6]D. Gastroenterology, H. S. Llàtzer.*

Background: Transthyretin-associated amyloidosis (ATTR) is a common autosomal-dominant form of amyloidosis frequently associated with the substitution of methionine for valine at position 30. Mallorca represents one of the most important focus of ATTR in the world. Kidney disease has been reported in Portugal as a result of renal deposition. They identified one third of patients with proteinuria and 10% progression to End Stage Renal Disease (ESRD).

Methods: Retrospective and prospective study of renal disease development in ATTR V30M. Renal assessment included clinical and laboratory tests in blood and urine. Chronic kidney Disease (CKD) was considered as a glomerular filtration measured by MDRD formula of 6 variables and Cistatine C.

Results: 155 ATTR V30M carriers were recruited at the Hospital Son LLàtzer among 2002 and 2016. Mean age at the onset was 48,64 years (SD 16,2), median 46,5 (IQR 35,2-62,7). 52% male. 36 cases (23,2%) presented CKD with MDRD < 60 ml/min and 22 (14,2%) with severe CKD (<30 ml/min). Cistatine C formula showed a significant increase

of CKD in this group of patients. 80% of patients developed proteinuria (73% < 500 mg and 27% >1g/24h). Only 4 patients with severe CKD developed nephrotic proteinuria. Liver transplantation was achieved in 53 patients (34,2%). 20 (12,9%) patients died during the study period.



Conclusions: We observed 2 different phenotypes of ESRD, one proteinuric and another not proteinuric, suggesting that the patients develop ESRD by totally different pathophysiologic mechanisms. MRDR formula underestimates CKD in this group of patients.

PUB662

Clinical Utility of Medical Exome Sequenscing/Whole Exome Sequencing in the Diagnosis of Genetic Renal Diseases Tomoko Uehara,[1] Toshiki Takenouchi,[1,2] Midori Awazu,[2] Kenjiro Kosaki.[1] *[1]Center for Medical Genetics, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan; [2]Pediatrics, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Background: Recently, genetic causes have been identified in various renal diseases thanks to the advent of next generation sequencing (NGS). We evaluated the clinical utility of NGS among patients who presumably have genetic renal diseases on clinical grounds.

Methods: The probands and their parents were recruited through the Japanese nation-wide undiagnosed disease program, Initiative on Rare and Undiagnosed Diseases (IRUD). Whole blood was collected from them after informed consent. Comprehensive genetic diagnosis was performed by whole exome sequencing (WES). Variants detected by the sequencer were filtered on quality, frequency, segregation pattern, previous reports, and genetic function and were confirmed by Sanger sequencing.

Results: 27 families with clinical diagnosis of genetic renal diseases were recruited based on positive family history or co-occurrence of extrarenal abnormalities: Ten were diagnosed as having congenital abnormality kidney and urinary tract (CAKUT), 11 presented with ciliopathy phenotype, 2 had VATER association, and others were chronic kidney disease (CKD) with extrarenal phenotypes. We confirmed 12 types of genetic diagnosis in 13 probands: Compound heterozygous mutations in MKKS, UBE3B, CC2D2A, CSPP1, and BBS10, a homozygous mutation in RPGRIP1L, heterozygous mutations in WAS, AGT, RET, PKD1, and JAG1, and a hemizygous mutation in OFD1.

Conclusions: Comprehensive genetic testing allowed genetic mutations in 13 of the 27 families (48.2%). These detection rate was comparable to that reported in the previous reports. Identification of precise genetic cause could contribute to medical management of the patients. An illustrative case was a patient with clinical diagnosis of CKD and thrombocytopenia. He was demonstrated to have WAS mutation through WES. The WES result made renal biopsy unnecessary. In addition, bone marrows transplantation was suggested to be effective. Further analyses are needed for unresolved families.

PUB663

Targeted Next Generation Sequencing of Alport Syndrome in Japan Tomohiko Yamamura,[1] Kandai Nozu,[1] Shogo Minamikawa,[1] Takeshi Ninchoji,[1] Yuko Shima,[2] Koichi Nakanishi,[2] Kazumoto Iijima.[1] *[1]Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Pediatrics, Wakayama Medical Univ, Wakayama, Japan.*

Background: Alport syndrome (AS) is a hereditary disease caused by mutations of *COL4A3/COL4A4/COL4A5* genes. In recent years, comprehensive genetic analyses using next generation sequencer (NGS) are available for diagnosis of many genetic diseases. Comprehensive analyses such as whole genome sequencing or whole exome sequencing are very expensive. In contrast, targeted next generation sequencing using a custom panel is cost-effective and expedient if this method is applied to appropriate patients.

Methods: 40 patients suspected of having AS from their clinical findings and renal pathological findings or family histories were studied. Mutational analyses were performed using the targeted sequencing panel including 44 genes causing AS, other inherited glomerulopathies and X-linked kidney diseases.

Results: 32 patients (80%) were genetically diagnosed with AS by targeted next generation sequencing. 19 patients were diagnosed with X-linked AS (XLAS) caused by mutations of *COL4A5* gene and other 13 patients were autosomal dominant AS caused by mutations of *COL4A3* gene (5 patients) or *COL4A4* gene (8 patients). Of the remaining 8 patients, one patient was diagnosed with XLAS caused by deep intronic mutation using cDNA analysis. One patient was diagnosed with Dent disease caused by mutations of *CLCN5* gene and another patient who showed lamellation of the glomerular basement membrane (GBM) was diagnosed with Pierson syndrome caused by mutations of *LAMB2* gene.

Conclusions: Our results suggest that targeted next generation sequencing is a useful diagnostic tool for patients clinically suspected of having AS. In addition, it was revealed that some other inherited glomeruropathies with GBM changes or X-linked nephropathies can be diagnosed as AS by clinical findings, therefore this method is crucial for the accurate diagnosis of inherited kidney diseases.

PUB664

Development a Method of Estimating Salt Intake by Self-Completed Questionnaire for Japanese Mari Odamaki,[1] Eiko Kawakami,[1] Hiromichi Kumagai,[2] Yoshiko Tsumuraya,[2] Akihiko Kato,[4] Hideo Yasuda,[3] Yoshihide Fujigaki,[3,5] Akira Hishida.[6] *[1]Dept of Health and Nutritional Sciences, Tokoha Univ, Hamamatsu, Japan; [2]Dept of Clinical Nutrition, Univ of Shizuoka, Shizuoka, Japan; [3]First Dept of Medicine, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; [4]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; [5]Dept of Internal Medicine, Teikyo Univ School of Medicine, Tokyo, Japan; [6]Nephrology, Yaizu City Hospital, Yaizu, Japan.*

Background: It is important to know daily salt intake for hypertension treatment. We developed a method of estimating salt intake by self-completed questionnaire for Japanese.

Methods: We recruited 650 (male: female=237:413) people who agreed to participate in this study. We made a list of food which is eaten by Japanese people in their usual diet. We divided the food into seven groups by salt content per serving. We made a self-completed questionnaire to ask how often they consume each group of food per week. From this questionnaire we estimated daily salt intake in each person. In parallel, we calculated salt intake by measuring salt in the urine collected for 24 hours. Using the result of calculated salt intake, we evaluated the accuracy of the estimation method.

Results: A significant positive correlation was found between estimated salt intake by questionnaire and calculated salt intake by 24 hours urine collection ($r=0.03$, $p<0.0001$, $y=0.382x+5.23$). On eleven people, we made the estimation and calculation of salt intake twice, before and after the instruction of salt restriction. The change of the salt intake in each person estimated agreed well with the calculated one. The average decrease in 1.0g of salt intake estimated by the questionnaire corresponded to the decrease in 1.2 g of salt intake calculated by 24 hours urine collection.

Conclusions: The questionnaire we developed is useful for estimating salt intake in Japanese and for evaluating the effects of salt restriction instruction.

PUB665

Nutritional Assessment of Haemodialysis Patients Muhammad Nauman Hashmi, Wael Said Alshazly, Hammad Raza, Fayez F. Alhejaili. *Haemodialysis, King Abdullah International Foundation for Haemodilaysis, Riyadh, Central, Saudi Arabia.*

Background: Malnutrition is a strong predictor of mortality in Haemodilaysis patients. Several Scoring systems have been used previously but either they were on non-renal patients or include costly investigations or more subjective rather than objective.

Methods: This is prospective analysis of maintenance Hemodilaysis patients over period of 12 months in a single centre.This analysis was carried out from June 2015 till May 2016.It includes 5 objective assessments (Body Mass index,No of years on HD, Serum Albumin, Ferritin & Co-morbidities).1 Subjective assessment of Functional capacity was included in this scoring system. These parameters were evaluated every 3 months. Co-morbidities (Diabetes Mellitus, Ischemic Heart disease, Cerebrovascular disease and Hypertension--Every co-morbidity was given 1 score).

Score	0	1	2	3
Body Mass Index	≥20	18-19.99	16-17.99	<16
Functional capacity	Normal	Occasional difficulty	Difficulty with Independent Activity	Bed/Chair bound
No of years on Hemodilaysis	<1	1-3	3-4	>4
Serum Albumin	≥35 gm/l	32-35 gm/l	28-31 gm/l	<28 gm/l
Ferritin	<700 mcg/l	700-800 mcg/l	800-1000 mcg/l	>1000mcg/l
Co-Morbidities(D.M,HTN,CVA,IHD)	1 Co-morbidity	2 Co-morbidities	3 Co-morbidities	4 Co-morbidities

Maximum score is 18. Patients scoring ≥8 were categorised as high risk &<8 as low risk.Total no of patients present throughout assessment 174.

Results: We identified 12,10,11 &11 no of patients scoring ≥8 score in every quarterly assessment during 12 months.There were 6 patients constantly present in high risk group.In High risk group 3 patients died.Low risk group had 1 mortality during this study.

Conclusions: Nutritional Assessment plays key role in management of Hemodialysis patients.With this scoring system we are able to identify patients as high and low risk groups.This tool helps to identify at risk patients so that timely measures are taken to improve patient survival.This scoring system is cost effective and convenient.Our analysis suggests that it is reliable and we will continue to monitor patients with help of this tool to get more data over coming years.

PUB666

Prevalence of Protein Energy Wasting in Predialysis Patients Anita Saxena, Amit Gupta. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, Indonesia.*

Background: Evaluating nutritional status is important for prevention of protein energy wasting (PEW). Objective: Prevalence of PEW in predialysis patients on first visit to a nephrologist.

Methods: Three day dietary intake of 484 CKD stage 3 and 4 patients. ISRNM criteria used for diagnosing PEW.

Results: Serum albumin was 3.77±0.83 (males) and 3.68±0.81 g/dL (females). As appetite, BMI and income decreased dietary protein and energy intake decreased significantly

Average Dietary Intake				
Sex	Energy kcal/kg	Energy deficit	Protein	Protein deficit
male	17.22±8.29	17.78±8.29	0.66±0.28	0.09±28
Female	16.88±7.66	18.12±7.66	0.64±0.30	0.11±0.30
Dietary intake based on Appetite				
	Normal 26.4%	Average 18.6%	Poor 26.4%	Anorexic 20.8%
Protein/M	0.79±0.23	0.58±0.17	0.50 ± 0 .20	0.27±0.17
Protein/F	0.79±0.23	0.56±0.16	0.48 ±0.15	0.29 ±.20
Energy/M	21.57±7.85	25±3.70	12.36±4.26	6.92 ±4.36
Energy/F	21.19 ±5.81	14.67±3.09	12.79±3.92	7.25± 3.95
Dietary Intake Based on BMI				
N%	Normal 52.8%	Uderweight 15.0%	Severly Underwt 32.71%	
Energy kcal/ kg	17.2 ±9.0 Deficit18	17.0±10.0 Deficit 18	15.91±11.1 Deficit 19	
Protein g/kg	0.6 ±0.34	0.5±0.4 (0.1 deficit)	0.5±0.44 (deficit 0.04)	
Based on Income groups				
	High Middle(17.2%)	Low Middle (53.9%)	Poor	
Energy Kcal/ kg	17.0(1037.11±331.99)	15.0(918.47±396.15	14.9 (913.15±392.84	
Protein g/kg/	0.63 (38.92±14.17)	0.57 (35.34±15.30)	0.50 (35.48±16.22)	
Serum Albumin	3.26±0.38	3.57±0.97	3.07±0.92	
BMI	23.98±4.98	23.59±4.41	20.84±3.46	

Appetite correlated with energy, protein, BMI with energy and GFR (p 0.000), income with BMI, protein and energy (p.000). Significant difference in appetite groups in energy, protein, GFR (p0.000) and serum albumin (p 0.025). Significant difference between income groups in BMI (P 0.000), energy (p 0.019), protein (p 0.031), albumin (0.001). Prevalence of PEW based on energy was 91%, protein 57%, BMI 56.6%, and appetite69.2%.

Conclusions: Dietary counseling can help preserve nutritional status. Appetite, BMI and income are markers of PEW in CKD.

PUB667

Which Inflammatory Biomarkers Are Associated with Diabetic Kidney Disease? Flaviu Bob,[1] Romulus Timar,[1] Daniel F. Lighezan,[2] Geta Bujor,[3] Mircea Munteanu,[1] Florica Gadalean,[1] Adelina Mihaescu,[1] Bogdan Timar,[4] Diana Lighezan,[1] Sagren Pillay,[1] Adalbert Schiller.[1] *[1]Internal Medicine 2, Univ of Medicine and Pharmacy, Timisoara, Romania; [2]Internal Medicine 1, Univ of Medicine and Pharmacy, Timisoara, Romania; [3]Biochemistry, Univ of Medicine and Pharmacy, Timisoara, Romania; [4]Medical Informatics, Univ of Medicine and Pharmacy, Timisoara, Romania.*

Background: Inflammation is associated in patients with chronic kidney disease (CKD) with an increased mortality. However, there is still uncertain which of the inflammatory biomarkers are prominently involved in CKD. In the present study we tried to compare the role played by two of these markers (interleukin-6 and C-reactive protein- CRP) in patients with diabetic kidney disease (DKD).

Methods: We performed this study on 52 patients with diabetes mellitus (DM) (13 patients with DM without renal involvement and 39 patients with DKD- with eGFR <60ml/ min or urinary albumin/creatinine ratio > 30mg/g), with a mean age of 64.16 +/- 8.35. In all patients we performed, using standard methods the following: serum creatinine, CRP, serum calcium, phosphorus, iPTH, urinary albumin/creatinine ratio; while IL6 was performed using ELISA method.

Results: In our subjects we tried to see if the studied inflammation markers show any correlation with renal function, and we found out that there was a statistically significant correlation between serum creatinine and IL6 levels (r=0.35, p=0.04), but there was no correlation between serum creatinine and CRP (r=-0.187, p=0.27). When we compared the group of patients with DKD with the control group, we found statistically significant higher levels of IL6 in the patients with DKD (10.74+/- 7.43 pg/ml vs. 5.7 +/-6.3 pg/ml, p=0.02), but no difference regarding CRP. We found also no statistically significant correlation between the two markers of inflammation (CRP and IL-6): r=-0.187, p=0.27. There were also no statistically significant correlations found between IL-6 or CRP with albumin/ creatinine ratio, serum calcium, serum phosphorus or iPTH.

Conclusions: In our study we found that the two inflammation markers studied – CRP and IL-6- showed different patterns of evolution, with an increase of IL-6, and not CRP, in patients with DKD.

PUB668

Is Plasma Electronegative LDL Associated with Obesity in Chronic Kidney Disease Patients? Denise Mafra,[1] Felipe Rizzetto Santos,[2] Gisella Pires Mello,[2] Ana Beatriz Lesqueves Barra,[2] Maurilo Leite.[3] *[1]Federal Univ Fluminense; [2]Federal Hospital of Lagoa; [3]Federal Univ of Rio de Janeiro.*

Background: The progression of atherosclerosis is associated with the synthesis of different forms of modified LDL, including an electronegatively charged LDL subfraction, called LDL(-). In CKD patients the LDL (-) plasma levels are increased, but it is unknown whether obesity may be associated with these high levels. The aim of this study was to evaluate a possible association between obesity and LDL(-) plasma levels in non-dialysis CKD patients.

Methods: A cross-sectional study was conducted in 32 non-dialysis CKD patients (58.5 ± 12.7 years old, 23 men, 17 diabetics, BMI of 27.9 ± 5.7 Kg/m^2, creatinine clearance of 35.5 ± 19.6mL/min). The biochemical parameters were measured using routine methods and the CrCl was calculated according to the simplified MDRD formula.LDL(-) plasma levels were determined by ELISA using an anti-LDL(-) human monoclonal antibody. Body Mass Index (BMI) was defined as weight in kilograms divided by the square of height.

Results: The biochemical parameters are shown in Table 1.

Parameters	Values
Blood urea nitrogen (mg/dL)	90.4 ± 37.1
Creatinine (mg/dL)	2.4 ± 0.8
Glucose (mg/dL)	114.4 ± 42.9
Potassium (mEq/L)	4.9 ± 0.5
Hemoglobin (g/dL)	12.2 ± 1.6
Hematocrit (%)	37.8 ± 5.1
Uric acid (mg/dL)	7.2 ± 1.7
Cholesterol (mg/dL)	197.6 ± 61.9
Triglycerides (mg/dL)	158.0 ± 76.3
LDL (mg/dL)	136.8 ± 65.1
HDL (mg/dL)	32.8 ± 9.2
Albumin (g/dL)	4.3 ± 0.6

According to BMI, 25.8% were eutrophic, 38.7% overweight and 35.5% were obese. The LDL (-) plasma levels were 2.2 (1.2-6.1)U/L and there was a positive correlation with BMI. The linear regression analysis showed that BMI was an independent predictor for LDL (-) levels (β=0.6, p=0.007) after adjustment on age, gender, urea, glucose, cholesterol LDL and total cholesterol levels.

Conclusions: Obesity in non-dialysis CKD patients seems to have association with high levels of LDL (-), a modified, highly atherogenic LDL fraction.

PUB669

Differences in the Nutritional State of Advanced CKD and Hemodialysis (HD) Patients Using Malnutrition Inflammation Score (MIS) Guillermina Barril, Angel Nogueira, Martin Giorgi, Carmen Sanchez-Gonzalez, Jose-Antonio Sanchez-Tomero. *Nephrology, Hospital U. Princesa, Madrid, Spain.*

Background: To evaluate the nutritional state of CKD patients in stages 3-5 without dialysis and those undergoing hemodialysis by comparing malnutrition-inflammation percentages with the MIS . Thus also comparing nutritional parameters such as visceral proteins, hemoglobin, CRP and body composition by bio-impedance (BIVA) in both cases.

Methods: 350 patients were nutritionally evaluated. 180 (51.42%) with CKD and 170 (48,57%) undergoing HD. 61,14% were males. CKD xage was 71.71± 13,25 years vs xHD 68.94±13.76 years (p0.055). The stratified nutritional state diagnosis was established through the MIS and differences between HD and CKD were also found in other nutritional parameters such as Biochemical and body composition by BIA.

Results:

MIS Stages	well nourished	mil-moderate malnutrition	moderate-severe malnutrition	severe malnutrition	extreme malnutrition	Total
CKD	102 (56,6%)	47 (27.22%)	16 (8.88%)	11 (6.11%)	2 (1.11%)	180
Hemodialysis	22 (12,94%)	64 (37.64%)	35 (20.58%)	21 (12.35%)	28 (16.47%)	170
Total	124 (35,42%)	113 (32.28%)	51 (14.57%)	32 (9.14%)	30 (8.57%)	350

The results for MIS in CKD and HD show a lower percentage of well-nourished for HD than CKD in the studied population with under-nutrition being equally higher for HD than CKD for the different MIS strata. Significant differences between CKD vs HD were also found for : weight 72.81±16.20vs 67.70±15.45(p0.003), BCM% 38.52±10.38%

vs 35.46±11.75(p0.010), TBW 54.42±7.52% vs 52.75±7.18%, (p0.034), Muscle Mass% 35.65±9.56 vs 32.06±9.71(p0.001), BCMI6.84±2.17 vs 5.50±2.22 (p0.000), Hb 12.04±1.39 vs 1.32±1.42 p(0,000), albumin4.15±0.72 vs 3.99±0.50 (p0.019), prealbumin 26.46±7.15 vs 24.02±6.76 (p0.003), CRP 0.96±2.22 vs 1.64±2.52(p0.010).

Conclusions: 1. Monitoring the nutritional state in CKD units favoured the maintenance of a good nutritional state in a high percentage of patients. 2. In comparison with HD patients a greater percentage of normo-nourished patients was observed in CKD patients with differences in biochemical parameters , body composition and MIS scale.

Attitudes and Opinions of Canadian Nephrologists Toward Continuous Quality Improvement Options Carina Iskander,[4] Gihad E. Nesrallah,[1] Christian G. Rabbat,[2] Rory F. McQuillan,[3] David C. Mendelssohn.[1] *[1]Nephrology, Humber River Hospital, Toronto, ON, Canada; [2]Medicine, McMaster Univ, Hamilton, ON, Canada; [3]Medicine, Univ of Toronto, Toronto, ON, Canada; [4]Univ of Western Ontario, London, ON, Canada.*

Background: Accountability and public reporting are increasingly prominent in health care. At the present time, quality improvement in Canadian nephrology is based on reporting of facility-wide performance. The objective of the study was to determine the attitudes and opinions of nephrologists towards a potential shift of improvement efforts from facility based to the individual physician level.

Methods: A pilot tested, web-based instrument was used to administer a survey to 330 nephrologists across Canada, through the Canadian Society of Nephrology (CSN).

Results: Out of the initial 320 eligible nephrologists contacted, 137 nephrologists responded (43%). Amongst all respondents, 48% agreed or strongly agreed that "there is significant variation in physician performance in my facility". 79% agreed or strongly agreed that "there are quality metrics that nephrologists should be responsible for". More than 80% agreed or strongly agreed that "there are some appropriate and valid measures that should form a basis for CQI activities". 82% agreed or strongly agreed to "receive a confidential, personalized score card reflecting my individual patient care". Only 30% agreed or strongly agreed that "public reporting of physician performance is likely to improve patient outcomes". Of note, compared to staff nephrologists, medical directors were twice as likely to agree or strongly agree that "shifting from program to physician level measurement and reporting is likely to improve care".

Conclusions: Overall, the majority of nephrologists were not supportive of shifting from program to physician-level measurement and public reporting. Leadership level physicians were more likely to support this shift. As modern medicine evolves towards more accountability and public reporting, the nephrology community must grapple with how to adapt to these trends and apply those methods that are validated and proven to improve patient care and outcomes.

PUB671

Primary Care Providers' (PCPs) Perceptions of Medication Safety in Chronic Kidney Disease (CKD) Clarissa Jonas Diamantidis, John Sperati, Mark A. Perazella, Yang Liu, Khaled Abdel-Kader, Sandeep S. Soman, Kerri L. Cavanaugh, Michelle M. Estrella, Varun Agrawal, Bernard G. Jaar, Michael J. Choi, Raquel C. Greer. *NKF Education Committee, New York, NY.*

Background: Renal clearance and potential nephrotoxicity makes medication safety in CKD a unique challenge, particularly among PCPs managing the complex multi-morbidity of CKD patients.

Methods: We conducted 4 qualitative focus groups of PCPs (n=32) across 4 US metro areas to assess their views of medication management in CKD. Participants were asked: "What aspects of medication safety are the most [and least] challenging for you and why?"; "Please describe resources, tools, or features of your practice that make it easier for you to address medication safety."; "What would you find helpful in addressing medication safety for your patients with CKD?" Focus group content was transcribed, and relevant concepts were identified.

Results: PCPs identified patient-level barriers to medication safety including lack of awareness of nephrotoxins such as NSAIDs and non-disclosure of their over-the-counter use. For example "I think they don't see this [NSAID use] as an issue and I take care of a lot of people who are educated and you would think explaining all this they get it. They don't get it half the time because their kidneys don't bother them." PCPs described inadequate knowledge of recommended dose adjustments in CKD, stating "I always forget like some antibiotics you actually have to adjust and I always forget which ones it is…" Difficulties managing polypharmacy and pain were identified as common challenges: "The guy has severe arthritis taking a lot of pain medicine that affects the kidneys. Then what are your alternatives? That's my problem." PCPs described facilitators of CKD medication safety such as educational materials to increase patient NSAID risk awareness, routine integration of pharmacists in CKD care, and utilization of electronic decision support tools.

Conclusions: Interventions targeting patient awareness of adverse renal effects of medications and enhancement of clinical medication safeguards using pharmacists and decision support tools may improve CKD medication safety in primary care.

Inferior Vena Cava Index: A Bedside Method for Dry Body Weight Assessment in Critically Ill Haemodialysis Patients Mostafa Abd-Elsalam Abd-Elkhalek. *Mansoura Nephrology and Dialysis Unit, Mansoura Medical School, Mansoura, Dakhlia, Egypt.*

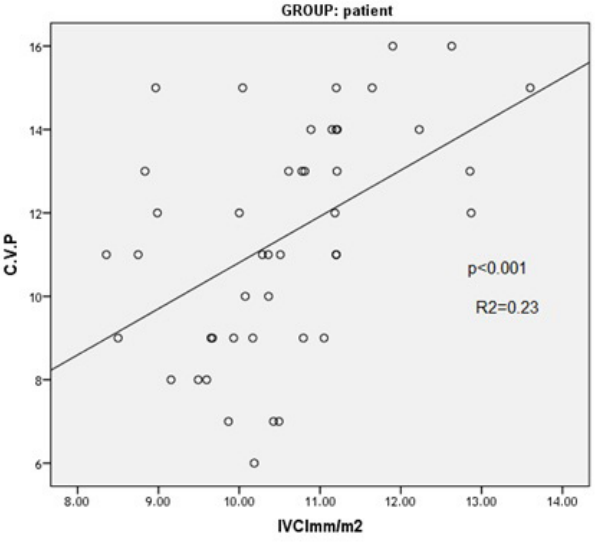
Background: Assessment of dry body weight in emergency conditions is still a matter of mystery. Central venous pressure is accurate but invasive. we try to find a simple non invasive method for assessment of dry weight in critically ill haemodialysis patients.

Methods: This is prospective observational study conducted on 45 haemodialysis patients referred to Mansoura Nephrology and Dialysis Unit from emergency hospital. The candidates for this study were seeking for urgent haemodialysis using temporary central intravascular access. Abdominal ultrasonography for assessment of IVC index was done immediately 30 min after dialysis session with measurement of the CVP through temporary central haemodialysis catheter. Pearson correlation between central venous pressure as an invasive maneuver to assess dry weight in haemodialysis patients, IVC maximum diameter in deep inspiration and IVC index was done.

Results: Pearson correlation between CVP and IVC maximum diameter in deep inspiration and IVC index revealed a statistically significant positive correlation between CVP and IVC maximum diameter (r=.411. P<0.005) and a statistically significant positive correlation between CVP and IVCI (R=.483, P<0.001). Multiple linear regression analysis (table 1) for CVP values as the dependent variable and both the IVC maximum diameter in inspiration and IVC index as independent variables was done using the step wise procedure.

Parameter		C.V.P
IVCI (mm/m2)	r	0.48
	p	<0.001
INSPMax	r	0.41
	p	<0.005

The procedure selected the IVC index as the best independent predictors for CVP value (R2=0.233, p<0.001).



Conclusions: Bedside sonographic measurement of inferior vena cava index which is simple, quick and non invasive method could be used as a reliable and accurate method for assessment of dry weight in critically ill chronic renal failure patients.

PUB673

Concomitant Use of Vancomycin and Contrast Exposure and AKI: Quality Improvement Program Muhammad Muneeb,[1] Farah Dadabhoy,[1] Charuhas V. Thakar.[1] *[1]Div of Nephrology, Univ of Cincinnati Medical Center, Cincinnati, OH; [2]Dept of Nephrology, Cincinnati VA, Cincinnati, OH.*

Background: Supratherapeutic Vancomycin (Vanc) is known to cause tubular toxicity leading to acute kidney injury (AKI). Intensive Vanc dosing and radio-contrast exposure are frequently needed together, for diagnosis and treatment in patients with high morbidity. Thus, a known event that reduces glomerular filtration rate (eGFR) can result in supra-therapeutic Vanc levels, resulting in AKI. In a prior institution wide trainee survey (ASN 2015), 60% providers were uncomfortable with Vanc dosing and depended on pharmacy protocols.

Methods: We describe two case-reports, which led to the development of a Quality Improvement Program (QIP) to reduce kidney adverse events due to exposure to concomitant nephrotoxins.

Results: We noted two cases of AKI to be associated with Vanc dosing protocol and contrast exposure. Patient-1 (33 yo male) and Patient 2 (59 yo male) were admitted for abdominal abscess and diabetic foot ulcer respectively. Figure 1 shows the course of AKI after Vanc and contrast exposure. Both patients were discharged with partial renal recovery (discharge creatinines > 2.0 mg/dl). Current pharmacy protocol utilizes pre-Vanc dosing labs and recent Vanc levels to determine daily dose, and do not consider concomitant nephrotoxin exposure (e.g. contrast), which although reversibly, could temporarily reduce eGFR. This

results in relative overdosing of Vanc for an average daily eGFR. In collaboration with pharmacy service, following recommendations are being adopted when implementing Vanc dosing protocol: 1. Alert to pharmacy of concomitant orders of nephrotoxins; 2. Modify Vanc dose; 3. Use frequent level monitoring.

Conclusions: Cases identified a current gap in drug safety; and multi-disciplinary QI programs in high risk patients could reduce AKI and associated morbidity.

PUB674

Native Kidney Biopsies: Complications and Yield: A Quality Improvement Initiative Mahwash Kamal, Karthikeyan Meganathan, Kotagal Shashi Kant. *Kidney and Hypertension, Univ of Cincinnati, Cincinnati, OH.*

Background: The kidney biopsy is the gold standard in the diagnosis and management of many renal diseases. Sample size is critical for the diagnosis of most renal pathologies. We performed a three year retrospective review to analyse our experience with the complications and diagnostic yield of native kidney biopsies and their impact on patient safety.

Methods: Native kidney biopsies were identified on the basis of pathology coding between January 2013 and December 2015. A biopsy sample was defined as adequate when it had at least 10 glomeruli for light microscopy and sufficient tissue for electron microscopy and immunofluorescence. Complications were defined as minor and major. Minor complications included bleeding requiring monitoring and no intervention. Major complications included, bleeding requiring intervention, nephrectomy and death.

Results: We performed 64 native kidney biopsies in 3 years. 47(73.4%) biopsies were performed by interventional radiologists and 17(26.6%) were performed by nephrologists.6(9.4%) patients had complications; 2 had minor and 4 had major. 33(51.5%) biopsies were adequate and 31(48.5%) were not adequate. There were only 3(4.7%) biopsies in which the pathologist was unable to provide any diagnosis. We found a higher likelihood of inpatient biopsies to be performed by IR. Rising creatinine increases the odds of biopsy to be performed by IR. Rising creatinine also increases odds of complications. Statistically significant difference for complication rates was not found with differences in gender, BMI, clinical setting, operator, age, kidney size, blood pressure and hemoglobin. Statistically significant difference for biopsy adequacy was not found with differences in BMI, operator or kidney size.

Conclusions: Our complication rates were comparable to other centers, however our biopsy sample adequacy was lower. Measures proposed to improve biopsy sample adequacy in our institution include: 1) changing biopsy needle size from 18 gauge to 16 gauge; 2) Visualizing all specimens under direct microscopy for sectioning; 3) identifying operators on the basis of experience and interest and designating them as the preferred operators for native kidney biopsies.

PUB675

Preventing Contrast-Induced Nephropathy in Patients with Renal Disease in a Nephrologic Day Hospital Nuria Rodriguez Mendiola, Maite Rivera, Victor Burguera, Estefania Yerovi, Martha Elizabeth Diaz, Jose L. Teruel, Fernando Liano. *Nephrology, Hospital Ramón y Cajal, Madrid, Spain.*

Background: The best established treatment for the prevention of CIN is intravenous hydration. Traditional regime consist of fluid volume loading before and after intravascular contrast media (CM) administration, which requires the patient to be admitted to hospital. We analyze the efficacy of intravascular hydration with n-acetyl-cysteine (NAC) in only one dose before CM administration, in an ambulatory way.

Methods: From January 2013 to December 2014, 97 patients with preexisting impairment of renal function (GFR<60 ml/min/1, 73 m2) (table 1) received our preventive scheme prior to intravenous radiographic contrast media.

Patients characteristics	
Age (years)	66±13(range 23-89)
Male/female (%)	76/24
Hipertensión (%)	81
Diabetes (%)	36
Peripheral vascular disease (%)	25
Serum creatinine (mg/dl)	3,9±2,9
Charlson index punctuation	5,8±2,7 (range 2-12)
ARB/ACE receivers (%)	58
Chronic kidney disease stages % : 3 4 5	 36 29 35

All the imaging tests were computed tomography (CT) with 100 cc of Iohexol as contrast media (concentration of 350 mg/ml). Imaging tests were programmed in the afternoon. During the morning patients were fluid loaded with 1000 cc isotonic saline solution with intravenous formulation of 2 grams of NAC post CM fluid infusion was not given. This treatment was administrated in the day hospital of Nephrology department, with no need of patient´s admittance. Serum creatinine was measured before and within 10 days of exposure to intravascular CM.

Results: Contrast induced nephropathy was defined as an increase of 25 % in serum creatinine level from baseline (KDIGO definition). With this criteria just 4 patients showed this rise in basal serum creatinine, and three of them recovered later within 1 month.

Conclusions: Intravenous saline solution with NAC precontrast, without infusion postcontrast, is shown to be effective in reducing the risk of CIN in patients with a preexisting renal dysfunction undergoing contrast CT scan. This is administered in ambulatory nephrologic day hospital, what avoids complications associated to hospital admittance and reduces costs.

PUB676

Implementation of an Evidence Based Protocol for Management of Hyperkalemia Jason K. Law,[1] Gaurav Ghosh,[1] Miriam Chung,[1,3] Ezra Gabbay,[1] Jeffrey I. Silberzweig.[1,3] *[1]Medicine, Weill Cornell Medical College, New York, NY; [2]Nephrology, The Rogosin Inst, New York, NY.*

Background: Hyperkalemia (Potassium > 6.0 mmol/L) is a common, potentially life-threatening emergency among hospitalized patients. Most patients at our institution are not routinely evaluated prior to initiation of treatment. Only 85% of patients with a serum potassium value above 6.5 mmol/L had an ECG. Most patients (82.1%) treated with calcium gluconate did not have ECG changes nor did patients treated with insulin and dextrose (68.5%). There is minimal data to guide management of hyperkalemia and common treatments can have serious adverse effects.

Methods: We reviewed the literature to evaluate the safety and efficacy of treatments for hyperkalemia and developed a protocol for management. The protocol incorporates the severity of hyperkalemia, physical examination, ECG findings, renal function as measured by urine output and dialysis status, presence of conditions which could rapidly raise potassium levels and other variables into a stepwise approach. The protocol is currently being piloted among patients admitted to our nephrology service.

Results: Initial results document that since the protocol was implemented, acquisition of ECGs in patients with hyperkalemia improved from 88.4% (61/69) to 100% (11/11). The number of patients unnecessarily receiving calcium gluconate decreased (46.4% (32/69) to 10% (1/10)) as did the utilization of the insulin and dextrose (68.5% (24/35) to 0% (0/9)). There have been no adverse events reported.

Conclusions: Our initial results show that implementing a standardized evidence-based protocol for management of hyperkalemia can improve the treatment of patients by reducing unnecessary treatment and improving monitoring. Our goal is to continue to revise the protocol and eventually distribute it to the rest of the hospital.

PUB677

The Comfort Status after Renal Biopsy Hui-Qun Li,[1] Wenbo Zhao,[1] Geng-Xi Sun,[2] Tan-Qi Lou.[1] *[1]The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Affiliated Hexian Memorial Hospital, Southern Medical Univ, Guangzhou, Guangdong.*

Background: Renal biopsy (RB) is an important auxiliary examination. It is helpful to identify the pathological types, guide treatment and learn prognosis of kidney disease. Because of strictly confined in the bed within 24 hours after RB, patients often have the physiological and psychological discomfort. The purpose of this study was to investigate the comfort status of patients after RB.

Methods: Renal biopsy (RB) is an important auxiliary examination. It is helpful to identify the pathological types, guide treatment and learn prognosis of kidney disease. Because of strictly confined in the bed within 24 hours after RB, patients often have the physiological and psychological discomfort. The purpose of this study was to investigate the comfort status of patients after RB.

Results: The GCQ scale scores increased gradually with the time after RB. The total GCQ score was 68.3±5.42 in the 6 hours and 85.2±6.63 in the 24 hours. The scores of physiological, psychological, social culture and environment dimensions in 24 hours were higher than in 6 hours after puncture. The discomfort which the patients complained mainly included the back pain and dysuria in bed.

Conclusions: Patients after renal biopsy had many uncomfortable aspects, especially in 24 hours. So medical personnel should be as much as possible to help the patients relieve discomfort, promote the patients to recovery and reduce complications.

PUB678

Improving Quality of Care in Acute Kidney Injury and Continuous Renal Replacement Therapy: From Clinical Practice Guidelines to Quality Measures Rhea Bhargava,[1] Saiprasad Narsingam,[1] Himmat Grewal,[3] Reem Mustafa.[2,1] *[1]Dept of Internal Medicine, Univ of Missouri- Kansas City; [2]Dept of Nephrology and Hypertension, Univ of Missouri- Kansas City; [3]Dept of Internal Medicine, Saint Vincent Hospital, Worcester, MA.*

Background: Monitoring quality in health care is of vital significance to avoid preventable medical errors and to improve the quality of health care which is delivered. There is wide variation across the globe in the care of patients with acute kidney injury

(AKI) and who are receiving continuous renal replacement therapy (CRRT). Clinical practice guidelines are available for patients with AKI and for patients who are receiving CRRT. We wish to present potential quality measures and their level of adaptation by health care delivery organizations.

Methods: Databases of Acute Dialysis quality initiative (ADQI) and Kidney Disease Improving Global Outcomes (KDIGO) were reviewed for clinical practice guidelines and potential quality measures prescribed by them for patients with AKI and for those needing CRRT. Then a search was done to determine whether these were endorsed by National quality forum(NQF) and Centers for Medicare and Medicaid services(CMS).

Results: Clinical practice guidelines for the diagnosis and management of AKI and guiding CRRT are available from both ADQI and KDIGO. These include factors affecting CRRT - patient selection, timing for initiation, insertion site of the dialysis catheter, risk of infection, type of anticoagulation, bleeding risk among others and AKI-definition and diagnosis . No clinical practice guidelines were being used as quality measures framed by National quality forum (NQF) or as Centers for Medicare and Medicaid services (CMS) core measures.

Conclusions: Wide scale use of quality measures are needed to monitor and thereby standardize and improve quality of health care delivery to patients with AKI and patients needing CRRT. NQF and CMS core measures do not currently contain measures pertaining to quality for AKI and CRRT populations. Incorporating them could lead to increased adherence to clinical practice guidelines and provide a much needed framework to improve the care for the AKI and CRRT populations in the hospital.

PUB679

Defining the Optimal Method to Monitor Albuminuria over Time in Toddlers Sophie Van den Belt,[1] Valentina Gracchi,[2] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Clinical Pharmacy and Pharmacology, UMCG, Groningen, Netherlands; [2]Pediatric Nephrology, UMCG, Groningen, Netherlands.*

Background: Microalbuminuria can also be found in toddlers. This could have important consequences for understanding pathophysiology and guiding possible treatment. In adults, the guideline for establishing and monitoring microalbuminuria over time recommends to use first morning void (FMV) urine samples collected over three consecutive days. Since such a guideline is absent in toddlers, we tested several urine collection strategies for albuminuria measurement in toddlers.

Methods: A FMV urine sample and random daytime urine sample were collected on three consecutive days at week 0 (period 1), week 4 (period 2) and week 8 (period 3) in toddlers aged 12 - 48 months. Urinary albumin (U_{AC}) and albumin:creatinine ratio (U_{ACR}) were assessed. Intra-individual coefficient of variation (CV), calculated as the standard deviation divided by the geometric mean of U_{AC} or U_{ACR}, was determined using only the first U_{AC} or U_{ACR} measurement of each study period and secondly using all three U_{AC} or U_{ACR} measurements per study period.

Results: A total of 38 toddlers (mean age 28.4 months, SD10.6, 64% male) were included. The geometric mean U_{AC} was 5.0 mg/L in the FMV and 5.2 mg/L in the random daytime sample, U_{ACR} was 13.3mg/g and 18.6mg/g, respectively. The lowest intra-individual CV was observed when U_{AC} was measured in FMV over three consecutive days (table).

Table: Within individual Coefficient of Variation in albuminuria

	Single urine sample per period		Three urine samples per period	
	FMV sample	*Daytime sample*	*FMV sample*	*Daytime sample*
U_{AC}	46.3%	72.7%	33.5%*	38.8%**
U_{ACR}	49.4%	69.8%	40.1%†	52.0%††

* p<0.009 single FMV U_{AC}; †p=0.02 vs single FMV U_{ACR}; **p=0.004 vs daytime single U_{AC}; ††p<0.001 vs daytime single U_{ACR}.

Conclusions: These data suggest that U_{AC} should be measured in FMV urine samples over three consecutive days to assess and monitor (micro)albuminuria in toddlers.

PUB680

L-Carnitine Replacement Improves Proximal Tubular Function in Patients with Fanconi Syndrome Kazuya Matsumura, Nariaki Asada, Midori Awazu. *Dept of Pediatrics, Keio Univ School of Medicine, Japan.*

Background: Fanconi syndrome (FS) is known to cause L-carnitine deficiency due to loss in the urine. On the other hand, L-carnitine deficiency causes FS by the impairment of mitochondrial ß-oxidation. We examined whether L-carnitine replacement improves proximal tubular dysfunction in patients with FS.

Methods: Six patients with FS (2 males and 4 females, age 8 to 22 years; 4 chemotherapy-induced, 1 Lowe syndrome, 1 extremely low birth weight) were studied. The median eGFR was 67 ml/min/1.73 m^2 (range 47-98). We assessed the presence or absence of and the severity of hypophosphatemia, phosphaturia, hypouricemia, uricosuria, glucosuria, ß2 microglobulinuria, enzymuria (assessed as N-acetyl-ß-glucosaminidase-to-creatinine ratio), aminoaciduria, and microalbuminuria.

Results: Total (median 30.3, range 23.1-38.8, normal 45-91 µmol/L) and free carnitine (median 30.3, range 23.1-38.8, normal 45-91 µmol/L) were decreased in all patients. Acylcarnitine was normal in 4 patients (median 8.5, range 4.7-11.9, normal 6-23) and decreased in 2 patients (4.7 and 5.6). The median dose and duration of L-carnitine treatment were 1160 mg/m^2/day (range 330-1980) and 25.5 months (range 18-26), respectively. Total and free carnitine were normalized in all 5 patients in whom serum level was measured after treatment. Acylcarnitine was normal in 4 after replacement, and increased in 1 (40) whose initial level was normal and eGFR was 47. Aminoaciduria, ß2 microglobulinuria, and enzymuria were present in all (6/6), glucosuria and microalbuminuria in 5, phosphaturia and hypophosphatemia in 3, and hypouricemia in 2. No patients had renal tubular acidosis. After replacement, at least one tubular dysfunction improved in all patients. Aminoaciduria, hypophosphatemia, and enzymuria resolved in 3 (50%), 2 (67%), and 1 (17%), respectively. The severity of enzymuria improved in 5 patients.

Conclusions: Free and total carnitine were decreased with low to normal acylcarnitine levels in FS. L-carnitine replacement partially improved tubular dysfunction including aminoaciduria, hypophosphatemia, and enzymuria. These results indicate that L-carnitine deficiency causes secondary proximal tubular impairment in patients with FS.

PUB681

Genotypic and Phenotypic Spectrum of Hereditary Nephrotic Syndrome in a Single Saudi Center Majed Aloufi, Naif Fahad Abdulmajed, Abdulmonem Mohammad Alghamdi, Saeed Ali Alghwery, Saeed Ali Alzahrani. *Pediatric Nephrology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

Background: Hereditary nephrotic syndrome (HNS) is a rare renal genetic disorders that present in children early in life and lead to end stage kidney disease (ESKD). We aim to describe their genotypic spectrum.

Methods: We identified 10 children with HNS presented between 2013 and 2015 in a single centre, where genetic testings and clinical courses reviewed.

Results: Three have PLCE1 mutation, three WT1, two NPHS1, one LAMB2, and one has putatively pathogenic variants at DGKE, KANK1 and PAX2.

Patient	Age (months)/ Sex	Histology	Genotype	Clinical course
HNS1	5/M	FSGS	Homozygous *PLCE1* mutation c.3058C>T (p.Gln1020*)	NS ESKD Septicemia Death
HNS2	5/F	FSGS	Homozygous *PLCE1* mutation c.3058C>T (p.Gln1020*)	NS ESKD Septicemia Death
HNS3	12/F	DMS/FSGS	Homozygous *PLCE1* mutation c.3058C>T (p.Gln1020*)	NS ESKD
HNS4	1/F	Not done	Heterozygous WT1 mutation (c.1385G>A p.Arg462Gln)	AKI ESKD Death
HNS5	7/F	MPGN	Heterozygous mutation in exon 9 of the WT1 gene (c.1357T>C p.Cys453Arg).	AKI ESKD
HNS6	18/M	Collapsing FSGS	Heterozygous variant at position c.299 in exon 1 of the *WT1* gene c.299C>G (p.Ala100Gly).	NS CKD IIIb
HNS7	2/F	Not done	Homozygous deletion of a single nucleotide at position c.139 in exon 2 of *NPSH1*(c.139delG), (p.Ala47Profs*81)	CKD II
HNS8	3/F	Not done	homozygous duplication of one nucleotide at position c.3250 in exon 24 of *NPSH1* (c.3250dupG), (p.Val1084Glyfs*12)	CKD II
HNS9	2/M	Not done	Homozygous mutation in exon27 of LAMB2 gene (c.4276dupG), (p.A1426fs)	NS AKI Septicemia Death
HNS10	18/M	MCD	No mutation detected. Putatively pathogenic variants detected in DGKE, KANK1 & PAX2 genes	NS SDNS FRNS

Conclusions: Correlating genotypic and phenotypic diagnoses will help in identifying the involved genes, so preventive measures such as family counseling can be undertaken. Our result is biased by small sample size, therefore a large national multi-center study is needed, as well as going further toward a national registry of those cases of HNS.

PUB682

GFR-Estimation Using Serum Creatinine Is Not Affected by Corticosteroid Therapy Emil Den Bakker,[1] Joanna Van Wijk,[1] Isabelle Hubeek,[2] Arend Bokenkamp,[1] Berend Koene.[1] *[1]Nefrology, VUMC, Amsterdam, Netherlands; [2]Clinical Chemistry, VUMC, Amsterdam, Netherlands.*

Background: Glucocorticosteroids (GCS) are widely used in patients with kidney disease. While the effect of GCS is well characterized for endogenous GFR markers as urea. cystatin C. β -2 microglobulin and β-trace protein. Little is known about their effect on serum creatinine (sCr) the standard endogenous parameter for GFR estimation.

Aims: To study the effect of GCS on the relationship between sCr and GFR measured by single injection inulin clearance (Cin).

Methods: Retrospective analysis of estimated GFR using the pediatric Schwartz equation (eGFR) and simultaneous Cin. Paired analysis of 22 children with and without GCS (median prednisone dose 35.5 mg/m^2/d). Cross-sectional study in 50 nephritis patients with similar characteristics, 31 of which received long-term GCS (median dose 12 mg/m^2/d, median GFR 93.7 ml/min/173m^2). The difference between eGFR and Cin (ΔGFR) was used to assess the interaction between creatinine and GCS using non-parametric tests and linear regression analysis for paired and cross-sectional data respectively.

Results: There was no significant difference in ΔGFR by paired analysis:

	GCS (-)	GCS (+)	P
	Median [IQR]	*Median [IQR]*	
Cin (ml/min/1.73m²)	103.5 [82.5-130.4]	116.3 [92.0-129.3]	0.123
eGFR	113.6 [91.3-166.9]	105.5 [90.6-163.6]	0.823
ΔGFR	-6.7 [-39.0-6.9]	-8.4 [-31.4-14.0]	0.527

Univariate linear regression analysis with ΔGFR as dependent parameter showed a significant relation with age, while prednisone dose and duration of GCS treatment had no significant effect on ΔGFR.

	B [95% CI]	P
Age	2.393 [0.593 to 1.494]	0.010
Gender	-4.451 [-19.130 to10.228]	0.545
Dose (mg/m²/d)	-0.325 [-0.737 to 0.087]	0.120
Dose (mg/kg/d)	-9.771 [-24.421 to 4.879]	0.186

These findings were confirmed by stepwise multivariate regression analysis in which only age was retained in the final model.

Conclusions: Data in dogs and man indicate that GFR increases in glucocorticoid excess. In the present study this was corrected for by using [ΔGFR as indicator of a potential GCS effect on the performance of serum creatinine as marker of GFR.

Conclusion

In the dosage studied, GCS do not interfere with the use of sCr as an endogenous marker of GFR.

PUB683

Lack of Correlation between Changes in Ejection Fraction and Weight in Patients with Heart Failure Treated with Peritoneal Dialysis

Abhilash Koratala, S. Irfan Qadri, Amir Kazory. *Univ of Florida, Gainesville.*

Background: There is mounting evidence on the beneficial effects of peritoneal dialysis (PD) as an alternate therapeutic modality in patients with chronic heart failure (HF) and fluid overload, in the absence of end stage renal disease (ESRD). Improvement in left ventricular ejection fraction (LVEF) is one of the most frequently reported benefits of PD in this patient population. It is unclear whether the observed amelioration in cardiac function is correlated with correction of hypervolemia and lowered end-diastolic left ventricular pressure or due to less well understood mechanisms.

Methods: Available data from clinical trials of PD in HF performed between January 2000 and March 2016 that included more than 10 patients were selected and reviewed. Those studies evaluating the impact of PD on LVEF and volume status (assessed through changes in weight) in non-ESRD patients were included. Pertinent data were extracted and using Pearson product-moment correlation, the degree of linear dependence and correlation between these two variables was determined.

Results: Nine studies with a total of 426 participants were included. The mean age was 71.5 years, and the mean LVEF and weight before PD were 36% and 70.9 Kg respectively. There was substantial variation in the reporting time point for cardiac function and weight. LVEF changes ranged from -1 to +8.2 % (mean 3.6 ± 2.8) and weight changes ranged from -8.3 to +2 Kg (mean -2.56 ± 3.1). There was no correlation observed between changes in LVEF and weight (r=0.08, 95% CI of Correlation -0.62 to 0.70).

Conclusions: Currently available evidence suggests that changes in cardiac function and weight do not correlate in chronic HF patients who undergo PD. Hence, effective fluid removal and optimization of hemodynamic status via a left-shift on the Frank-Starling curve is unlikely to be the sole mechanism underlying improvement in left ventricular systolic function. Future studies are needed to clarify whether other proposed PD-specific factors, such as reduction in neurohormonal activation or removal of inflammatory mediators may play a role in this setting.

PUB684

Early and Late Patient Outcomes in Urgent Start Peritoneal Dialysis: A Matched Case-Control Study

Emily J. See, Yeoung Jee Cho, Carmel M. Hawley, Lauren R. Jaffrey, David W. Johnson. *Dept of Nephrology, Princess Alexandra Hospital, Australia.*

Background: Significant interest in the practice of urgent start peritoneal dialysis (USPD) is mounting internationally. Although several observational studies have supported the safety, efficacy and feasibility of this approach, little is known about the early complication rates and long-term technique and peritonitis-free survival of USPD compared to conventional start peritoneal dialysis (CSPD).

Methods: This single-centre, matched case-control study evaluated patients commencing peritoneal dialysis (PD) between 2010 and 2015. USPD patients, defined as needing to commence PD within 2 weeks of catheter insertion, were matched 1:3 with CSPD controls. The primary outcomes were early complications, both following catheter insertion and PD start (within 4 weeks). Technique and peritonitis-free survival were secondary outcomes.

Results: 104 patients (26 USPD, 78 CSPD) were included (mean age 50.9±14.1yr, 63% male). USPD patients were more likely to be referred late (73 vs 1%, P<0.01), initiate PD in hospital (58 vs 4%, P<0.01), and be prescribed lower initial exchange volumes (1.0L vs 2.0L, p<0.01). USPD patients experienced more frequent leaks post-catheter insertion and catheter migration post-PD start. There were no significant differences in overall or infectious complications, or technique or peritonitis-free survival between the groups.

	Within 4 weeks of insertion			Within 4 weeks of PD start		
	USPD (n=26)	**CSPD (n=78)**	**P value**	**USPD (n=26)**	**CSPD (n=78)**	**P value**
Overall	8 (31%)	16 (21%)	0.28	8 (31%)	14 (18%)	0.17
Leak	3 (12%)	1 (1%)	0.047	3 (12%)	2 (3%)	0.10
Exit site infection	4 (15%)	10 (13%)	0.92	4 (15%)	5 (6%)	0.38
Catheter blockage	1 (4%)	0 (0%)	0.25	1 (4%)	0 (0%)	0.25
Catheter migration	3 (12%)	3 (4%)	0.16	3 (12%)	1 (1%)	0.047
Peritonitis	0 (0%)	3 (4%)	0.57	0 (0%)	7 (9%)	0.19

Conclusions: Compared with CSPD, USPD has acceptably low early complication rates and similar long-term outcomes. USPD appears to be a safe and effective way to initiate urgent renal replacement therapy and has the significant advantage of vascular catheter avoidance. Serious consideration should be given to its future use.

PUB685

Tenckhoff Catheter Removal Is Not Mandatory in Tuberculosis Peritonitis Patients on Continuous Ambulatory Peritoneal Dialysis

Qijun Wan, Yongcheng He. *Dept of Nephrology, The First Affiliated Hospital of Shenzhen Univ, Shenzhen Second People's Hospital, Shenzhen, Guangdong, China.*

Background: The prevalence and prognosis of tuberculosis peritonitis (TBP) among continuous ambulatory peritoneal dialysis (CAPD) patients are not well known in China. Whether the Tenckhoff catheter must be removed or not in TBP patients still remains controversial. Our aim is to report a single-center experience in the management of TBP on CAPD patients.

Methods: This is a single-center case cohort study. 178 CAPD patients followed up in our center from 1997 to 2015 included. IFN-γ, IFN-γ (PB+P8.10), IFN-γ(P8.10)(ELISpot) in blood and peritoneal effluent fluid were examined in the clinical suspicious TBP patients to confirm the diagnosis, respectively. Anti- tuberculosis combined with CAPD treatment were given to the confirmed TBP patients. Clinical and laboratory data were assessed at the 0 month, 3 th month, 6 th month and 12 th month of the follow-up, respectively.

Results: Only one 39-year old woman with severe thalassemia and without extraperitoneal tuberculosis was diagnosed TBP. The prevalence of TBP in the present study was only 0.56%, which accounted for 0.9 % of all peritonitis episodes. The incidence of TBP was 1/806 months. Fever was normal five days after the initiation of anti-tuberculosis treatment. Other clinical and laboratory data were gradually improved during follow-up. The complications such as intestinal obstruction, peritoneal-wall fistula were not found. The Tenkehoff catheter was in perfect function during the whole follow-up.

Conclusions: The incidence and prevalence of TBP among CAPD patients are rare in this single China center. TBP should be considered in CAPD patients with neutrophilic 'sterile' peritonitis with no response to antibacterial medications. The severe anemia may be the risk factor for TBP in this patient. Tenckhoff catheter removal is not mandatory in TBP patients receiving anti-tuberculous therapy.

PUB686

The Evaluation of Balance and Fall Risk in Patients with Peritoneal Dialysis: Cross-Sectional Controlled Study

Ruya Ozelsancak,[1] Pinar Doruk Analan.[2] *[1]Nephrology, Baskent Univ Faculty of Medicine, Adana Medical and Research Center, Adana, Turkey; [2]Physical Medicine and Rehabilitation, Baskent Univ Faculty of Medicine, Adana Medical and Research Center, Adana, Turkey.*

Background: This study aimed to compare the balance parameter, and fall risk between in patients on peritoneal dialysis (PD) and healthy subjects. It was also aimed to determine whether there is a correlation between biochemical parameters with fall risk and balance assesments in PD patients.

Methods: We evaluated 58 patients on PD treatment (PD Group) and 75 healthy subjects (Control Group) for this cross-sectional controlled study. Balance parameters and risk of fall were masured by using Tetrax® Interactive Balance System. All participants were also evaluated via Berg Balance Scale (BBS) to determine dynamic and functional balance status. These variables were compared between two groups. Duration of PD, Kt/V_{urea} and serum biochemical parameters were recorded in patients on PD. Correlation analysis between these parameters and balance measurements were made in patients on PD.

Results: The mean age of PD and Control Groups were found 54.21±12.16 and 50.38±12.11 years respectively.No statistically significant difference was found between groups in terms of the sociodemographic features. Fall risk of PD Group was significantly higher than control group (p:0.00005) according to Tetrax measurement, but BBS score were similar (p>0.05) between two groups. Age of PD patients was negative correlated with BBS (r:-0.433). Risk of fall was positive correlated with BMI (r:0.339). Blood glucose, BUN of PD patients were positively correlated with balance parameters. There was no statistically significant correlation between duration of PD and Kt/V_{urea} with balance parameters and the risk of fall.

Conclusions: Balance is impaired in patients undertreatment of PD. Fall risk may be evaluated using Tetrax® Interactive Balance System instead of BBS in those patients. BMI and age affect the balance and fall risk. Biochemical parameters are not correlated of balance and risk of fall except BUN and glucose. Duration of PD and Kt/V_{urea} do not affect balance system.

PUB687

Microparticle Formation in Peritoneal Dialysis Rima Abou Arkoub,[1] Shareef Akbari,[2] Suzy Sun,[2] Mercedes N. Munkonda,[2] Swapnil Hiremath,[1,2] Brendan Mccormick,[1,2] Marcel Ruzicka,[1,2] Dylan Burger.[2] *[1]Div of Nephrology, The Ottawa Hospital; [2]Kidney Research Centre, Ottawa Hospital Research Inst.*

Background: Injury to the mesothelial layer of the peritoneal membrane during peritoneal dialysis (PD) is implicated in loss of ultrafiltration capacity but there are no validated biomarkers for mesothelial cell injury. Microparticles (MPs) are 0.1-1.0 µm vesicles shed from the cell surface following injury. Our laboratory and others have previously reported that MPs are sensitive markers of tissue injury in hypertension, hyperlipidemia, and diabetes however there are no studies examining the formation of MPs in the peritoneal cavity during PD.

Methods: We examined MP levels in peritoneal dialysis effluents by electron microscopy, nanoparticle tracking analysis (NTA), flow cytometry, pro-coagulant activity, and Western blot. PD effluents (Dianeal® 4.25%) were collected during a peritoneal equilibration test at 0 hours, 1 hour, 2 hours, and 4 hours dwell.

Results: NTA identified particles in the size range of 30-900 nm, with a mean of ~240 nm. MP levels increased in a progressive, non-linear manner and there was approximately a 4-fold increase in MP levels at 4 hours ($P<0.01$, $n=6$). Electron microscopy confirmed size and morphology of vesicles consistent with characteristics of MPs as well as the presence of mesothelin on the surface. Western blot analysis of the MP fraction also identified the presence of mesothelin after 4 hours suggesting that MPs found in PD effluents arise, at least in part, from mesothelial cells.

Conclusions: Our results show that MPs are formed and accumulate in the peritoneal cavity during PD, possibly as a stress response. Assessing levels of MPs in PD effluents may be useful as a biomarker for peritoneal membrane damage.

PUB688

The Opinion of Nephrologists Regarding Quality Management in Peritoneal Dialysis – The Network-Based Conjoint Analysis Study Hisako Yoshida,[1] Kazuhiko Tsuruya.[2] *[1]Clinical Research Center, Saga Univ Hospital, Saga, Japan; [2]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: In Japan, peritoneal dialysis (PD) is selected as the mode of renal replacement therapy in less than 10% of incident end-stage kidney disease patients, in spite of some medical and social benefits of PD have been revealed. One of the reason might be that quality management by means of PD is considered too difficult for a number of doctors and health care staffs. In the present study, we conducted a questionnaire study to elucidate the opinion of nephrologists regarding PD management using a network clustering-based conjoint analysis method.

Methods: The 34 simulation cases were created to quantify the relative importance of 9 hypothetical patient attributes, including 1) age and living, 2) sex and self-management, 3) blood pressure, volume status and dialysate types, 4) primary disease and cardio-cerebrovascular disease, 5) PD vintage, 6) peritoneal equilibration test, 7) residual renal function and mineral and bone disorders, 8) peritonitis, and 9) anemia. These attributes were extracted using network clustering method which were significantly associated with outcomes defined transfer to hemodialysis or death, in actual 105 PD patients observed from May 2006 to November 2014. The sample size was calculated according to precedent studies (Whitman CB, et al. Clin J Am Soc Nephrol, 2013). In the present study, participants completed 34 tasks with 5 alternatives and 5 levels, producing a sufficient sample size of 15.

Results: Sixteen nephrologists in Kyushu University Hospital were participated in this study. Attribute of "blood pressure, volume status and dialysate types" was the most important factor for nephrologists' evaluation of management in PD patinens, which accounted for 19.1% of decision making, followed by "peritonitis" (13.0%). According to the utility scores of these clinical factors, sustained volume overload and repeated peritonitis had an impact on the opinion of the nephrologists regarding quality management in PD.

Conclusions: For nephrologists, volume overload and peritonitis might be considered important factors to maintain PD.

PUB689

Bedside Peritoneal Dialysis Catheters for the Management of Refractory Ascites: A Multi-Centre Experience Reid Whitlock,[1,2] Paul Komenda,[1,2,3] Navdeep Tangri,[1,2,3] Claudio Rigatto,[1,2,3] Jay P. Hingwala,[3,4] Sean Armstrong.[1,3] *[1]Chronic Disease Innovation Centre, Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [3]Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [4]Nephrology, Health Sciences Centre, Winnipeg, MB, Canada; [5]Nephrology, St. Boniface General Hospital, Winnipeg, MB, Canada.*

Background: Refractory ascites is when fluid recurrently accumulates in the peritoneal cavity, and is a common complication of liver cirrhosis. It can result in symptoms of anorexia, early satiety, nausea and vomiting, shortness of breath, and cause limited mobility. The initial management typically involves sodium restriction and diuretic therapy. When ascites no longer can be controlled by these measures, large volume paracentesis (LVP) is the treatment of choice in many patients. We believe that tunneled, peritoneal dialysis catheters placed at the bedside by trained operators is a safe, effective alternative for the palliation of refractory ascites.

Methods: The Manitoba Renal Program interventional nephrology program has offered the service of placing bedside PD catheters in patients with refractory ascites since 2010. We have collected basic demographic and comorbidity data on these patients in addition to complications of the procedure and outcomes such as peritonitis and survival.

Results: We have placed 29 PD catheters for the sole indication of refractory ascites since 2010. We have experienced no complications with the insertion procedure itself. Our patients had a mean age of 64 years and 52% were male. The reasons for ascites in each patient included cirrhosis (14), malignancy (10), heart failure (4) and other (1). The median survival time from the time of insertion was 56 days. In a total person-time at risk of 302 months, only 1 infection of peritonitis was detected. There were no cases of peritonitis among those whose ascites was caused by cirrhosis.

Conclusions: Bedside PD catheter insertion by trained operators appears to be a safe, effective option for the management of refractory ascites. Prospective, randomized trials are needed to assess survival, quality of life and patient satisfaction metrics for this palliative procedure.

PUB690

Factors of the PD Patient That Affect the Period of the First Incidence Peritonitis Won Min Hwang, Se-Hee Yoon, Sung-Ro Yun. *Dept of Nephrology, Konyang Univ Hopital, Daejeon, Republic of Korea.*

Background: PD peritonitis is the most important cause of failure of peritoneal dialysis and the times of first incidence of peritonitis are not the same on all patients. And there are very few studies on the factors that affect the time of manifestation of the first incidence of peritonitis. So, through this Study we will try to examine the clinical and environmental factors that affect the time of manifestation of the first incidence of peritonitis and the effect of the time of manifestation of the first incidence of peritonitis on convalescing patients.

Methods: Retrospective researches have been executed on the basis of the medical records on the occurrence of peritonitis, clinical factors (cause of ESRD, BMI, serum albumin, hemoglobin, accompanying diseases and microbiologic cause) and environmental factors (gender, age, residence, educational level and whether employed or not) of these subjects. Factors that affect the time of the 1st manifestation of peritonitis were analyzed by conducting multivariate analysis on the aforementioned factors. The subjects were divided into the 'early peritonitis group' and the 'late peritonitis group' on the basis of 6 months as the standard time of manifestation of peritonitis since the commencement of dialysis in order to comparatively analyze the prognosis of the patients.

Results: 478 patients over the age of 18 years who continued to undergo peritoneal dialysis for more than 90 days after having commenced peritoneal dialysis during the period from January 2008 to December 2015 were chosen as the subjects of this study. In this study, two environmental factors, namely, the residence and the level of education, affected the time of manifestation of the first incidence of peritonitis on patients. In addition, the early peritonitis group had a higher incidence of manifestation of peritonitis with longer periods of hospitalization.

Conclusions: Therefore, it is anticipated that delaying the manifestation of the 1st incidence of peritonitis through management and provision of education for the peritoneal dialysis patients would be helpful to the patients not only from the perspective of the prognosis but also save them from long pricy hospitalization.

PUB691

Molecular Hydrogen Dissolved Dialysate Suppress Iron Induced Peritoneal Mesothelial Change in Rat Models Wan-Jun Zhu,[1,2] Ayano Gibo,[1] Shigeru Kabayama,[2] Masaaki Nakayama.[1] *[1]Dept Kidney and Hypertension, Fukusihma Medical Univ, Fukushima, Japan; [2]Medical Device, Nihon Trim, Osaka, Japan.*

Background: Free iron induces oxidative stress by Fenton reaction and causes peritoneal mesothelial injury consequently. Molecular hydrogen (H2) has anti-oxidative and inflammatory effects in biological way. This study is to clarify whether H2 could protect peritoneal mesothelial injury by iron.

Methods: SD male rats (n=10, 8wks old) were divided into two groups: Fe and H2-Fe (HFe) group. Rats were subjected to intraperitoneal injection of peritoneal dialysate (20mL/daily) for ten days; dialysate contained 0.05mM Fe2Cl3 in Fe group, and that with 0.8-1.0 ppm H2 in HFe group, respectively. Parietal peritoneal membrane thickness and shedding length (loss of mesothelium) were analyzed with Masson Trichrome staining pictures. Immunohistochemistry staining was performed for determining proliferative changes (Ki67), apoptosis (m30cyto) and EMT (vimentin). Real time PCR were performed in collected surface cells to analyzed wound healing, inflammation related cytokines.

Results: There were significant differences between the two groups, in peritoneal thickness (HFe vs. Fe: 53.3±5.7 vs. 60.9±3.1mm; $p<0.05$), and in shedding cells analysis (2.4±1.5 vs. 28.9±7.1%; $p<0.05$). In regards to surface immunostaining positive cells, there were significant increases in Ki67 (0.010±0.002 vs.0.004±0.001/mm; $p<0.05$), and decreases in m40cyto (0.018±0.004 vs. 0.013±0.002 /mm; $p<0.05$) in HFe as compared to Fe group, respectively, while no differences were found in vimentin. Real time PCR showed that, expressions in HFe were significantly lower as compared with Fe group, in TNFa (0.6±0.2 vs. 6.3±3.1; $p<0.05$), and IL1b (0.2±0.2 vs. 4.2±1.8; $p<0.05$), while they were higher in TGFb (5.5±2.1 vs. 0.6±0.1), Fibronectin (5.5±2.1 vs. 1.4±0.3) and CTGF (4.4±0.9 vs. 2.5±1.3).

Conclusions: Molecular hydrogen could ameliorate oxidative/inflammatory peritoneal injury induced by iron, through the mechanisms such as, suppression of apoptosis, and enhancing regenerative process of mesothelial cells.

Low Protein Diet in Early Years of PD Initiation Leads to the Preservation of Residual Kidney Function in Peritoneal Dialysis Patients

Mitsutaka Nakahigashi, Takanobu Imada, Ichiro Shiojima. *Second Dept of Internal Medicine, Kansai Medical Univ, Hirakata, Osaka, Japan.*

Background: In peritoneal dialysis patients, dietary protein restriction is recommended 0.9-1.2g/kg/day in Japan. This recommendation is based on the effect of the protein leakage into the dialysis fluid and nutritional status. However, it is not discussed in terms of residual kidney function and few reports examined the protein restriction effects on residual kidney function. This study aimed to evaluate the protein restriction effects on the residual kidney function in peritoneal dialysis patients.

Methods: A total 29 PD patients (15 males, mean age of 53 years old) who visited our hospital between January 2006 and May 2015 were enrolled. We evaluated the relationships between the residual kidney function and clinical parameters in peritoneal dialysis patients over three years after the initiation of peritoneal dialysis.The study protocol was reviewed and approved by the Ethics Committee of Kansai Medical University.

Results: In multivariate models, decreases in residual Kt/V from first PET to second PET were most associated with nPCR at first PET (r2 = 0.319, P = 0.021). Next, to define the effectiveness of protein-restricted diet in PD patients, we conducted a sub-analysis by dividing the patients into two groups: those with nPCR of < 0.8 and >= 0.8 at first PET or second PET. The group of strict dietary restriction of nPCR of < 0.8 slowed the decline of residual renal function compared with that of nPCR of >= 0.8, without worsening indicators of nutrition and arteriosclerosis, for example albumin and skeletal muscle rate.

Conclusions: Our observations indicated that decreases in residual renal function were most associated with nPCR and strict dietary restriction of less than 0.8 nPCR, which is the predialysis level, may postpone reduction of residual renal function without causing malnutrition, during early years of PD initiation.

PUB693

Markers of Rhabdomyolysis in Peritoneal Dialysis

Sofia H. Marques, Rute Carmo, Luís Mendonça, Ana Teresa Nunes, Ana Beco, Ana Oliveira, Manuel Pestana. *Nephrology, Centro Hospitalar São João, Porto, Portugal.*

Background: Rhabdomyolysis results from injury to skeletal muscle and leakage of intracellular contents such as creatine kinase (CK). It may lead to nephrotoxicity, myalgias, muscular weakness and possible electrolyte abnormalities. Little information is available regarding rhabdomyolysis in peritoneal dialysis (PD) patients. We aimed at analyzing its incidence and possible determinants in this population.

Methods: We performed a retrospective analysis of the 115 patients in our PD program in December 2015, reviewing demographic, clinical and laboratory information dating from the last 4 months. All patients had recent results of CK, myoglobin and aldolase.

Results: Mean age was 53.5 years (±14.0), 54.8% of the patients were men and 71.1% were taking statins. Median values for CK, aldolase and myoglobin were 111 (IQR 78-188) U/L; 5.5 (IQR 4.5-7.7) U/L and 254 (IQR 184-409) ng/mL respectively. Only 7.8% of the patients had all markers within the reference range; 31.3% had 2 and 13% had the 3 markers above the normal range. CK correlated well with the 2 other markers (r=0.497 for aldolase and r=0.771 for myoglobin; p=0.00). CK had a positive correlation with the Adragao vascular calcification score (r=0.24; p=0.01), systolic blood pressure (r=0.21; p=0.03), total body water measured by bioimpedance (r=0.34; p=0.00), body mass index (r=0.22; p=0.04) and negative correlation with serum calcium (r= - 0.29; p=0.00). Men had a higher CK than women (median value 144 vs. 88; p=0.00). No significant relationships were found between CK and age, diabetes, use of statins, vitamin D analogs, cinacalcet, phosphate binders, erythropoiesis-stimulating agent, renin-angiotensin system blockers, serum albumin, phosphate, sodium, B-natriuretic peptide, dialysis efficiency by Kt/V or being on continuous ambulatory peritoneal dialysis vs. automatic peritoneal dialysis.

Conclusions: Higher calcification scores were associated with an increased risk for rhabdomyolysis in PD patients, maybe due to tissue hypoxia. Statins were not associated with rhabdomyolysis in our population and seem to be safe, although this is a cross-sectional analysis.

PUB694

Identifying Urine Microbiome in Patients Receiving Peritoneal Dialysis

Esho Georges, Holly J. Kramer, Vinod K. Bansal, Julia Schneider, Michael Zilliox, Kavitha Vellanki. *Dept of Nephrology and Hypertension, Loyola Univ Medical Center, Maywood, IL.*

Background: No data exists on urinary microbiome in peritoneal dialysis (PD) patients. The aim of this pilot study is to identify urinary microbiome and correlate with urinary symptoms in patients receiving PD.

Methods: Patients who were 18 years and older and receiving PD at our institute are included. Patients who received antibiotics within 4 weeks or had an episode of peritonitis 8 weeks prior to enrollment were excluded. 10 cc of random mid-stream urine is collected using routine sterile techniques. 16S rRNA gene sequencing is used to identify bacteria that are not routinely cultivated by clinical microbiology laboratories. Demographic and clinical characteristics are collected from electronic medical records.

Results: Of the 25 PD patients, 5 are excluded (3 patients were on antibiotics and 2 refused).9 of the 20 remaining patients with native urine output are included in the study. Baseline characteristics are shown in table 1.

Table 1: Baseline Characteristics of Study Population in Patients who have urine output (n=9)	
Mean age in years	57.5 years
Sex (M:F)	1:1.25 (5:4)
Race	AA: 33.3 % (3) Hispanic: 44.4 % (4) Others: 22.2 % (2)
Diabetes	44.4 % (4)
History of peritonitis (over the last year)	0 % (0)
History of abdominal surgery	77.7 % (7)
Type of transporter	High Average: 44.4 % (4) Low Average: 44.4 % (4) High: 11.1 % (1) Low: 0 % (0)
Mean dialysis vintage time in years	1.39 years

There is wide variation in the urinary microbiome. Streptococcus is the predominant bacteria in 3 patients (2 female and one male), lactobacillus in one female and prevotella in another male patient. 3 patients have no predominant bacteria. Nocturia (waking up more than once in the middle of the night to urinate) is predominant in male PD patients compared to females (80% vs. 25% respectively). The sample size was too small to make any meaningful correlation between urinary microbiome and urinary symptoms.

Conclusions: Urinary microbiome varies in each patient and further research is needed to delineate its role urinary tract symptoms in PD patients with native urine output.

PUB695

Hypoalbuminemia in Peritoneal Dialysis

Sofia H. Marques, Rute Carmo, Luís Mendonça, Ana Teresa Nunes, Ana Beco, Ana Oliveira, Manuel Pestana. *Nephrology, Centro Hospitalar São João, Porto, Portugal.*

Background: Hypoalbuminemia is associated with mortality in peritoneal dialysis (PD) patients and may result from malnourishment, non-nutrition factors or PD-related factors such as protein loss in the effluent. We aimed to study determinants of serum albumin in a PD population.

Methods: 115 patients in our PD program in December 2015 entered this cross-section analysis. Current therapy, PD modality, clinical data, serum markers dating from the last 4 months were recorded.

Results: Mean age was 53.5 (±14.0) years, 54.8% of the patients were men and only 25.4% had normal serum albumin. The remaining had serum albumin < 4g/dL, in 39.8% of cases < 3.5g/dL. Median protein losses were 18.0 (IQR 12.3-24.5)g/day. Serum albumin had a significant negative correlation with age (r= - 0.19; p=0.047), C-reactive protein (r= - 0.19; p=0.04), B-natriuretic peptide (r= - 0.20; p=0.03) and extracellular/intracellular water ratio by bioimpedance (r= - 0.33; p=0.00). A positive correlation was found with urine output (0.27; p=0.00), hemoglobin (r=0.21; p=0.03), serum calcium (r=0.25; p=0.01), potassium (r=0.20; p=0.03) and sodium (r=0.22; p=0.02). Hypoalbuminemia was significantly more frequent among patients on automatic peritoneal dialysis (APD) vs. continuous ambulatory peritoneal dialysis (3.48±0.54 vs. 3.78±0.48 g/dL; p=0.00) diabetics (3.42±0.54 vs 3.77±0.48 g/dL; p=0.00), those who had a weekly Kt/V under the target of 1.7 (3.42±0.69 vs 3.69±0,45 g/dL; p=0.04) or an Adragao vascular calcification index > 2 (3.34±0.47 vs 3.80±0.50 g/dL; p=0.00). Dialysis vintage, use of icodextrin, protein losses in the effluent, body fat measured by bioimpedance and serum phosphate were not significantly associated with hypoalbuminemia.

Conclusions: We found important correlations between hypoalbuminemia and inflammation, markers of volume overload and factors possibly associated with a higher comorbidity burden and worse condition such as diabetes, vascular calcification index, less efficient dialysis and being on APD.

PUB696

A Comparison of Body Composition between Continuous Ambulatory and Continuous Automatic Peritoneal Dialysis

Carlos Alberto Garza, Gabriela Leal, Bernardo Moguel. *Nephrology, Inst Nacional de Cardiologia Ignacio Chavez, Tlalpan, Mexico City, Mexico.*

Background: Body composition in the literature compares hemodialysis and peritoneal dialysis,an uneven comparison.We analyzed differences in body composition after a transition from Continuous ambulatory(CAPD) to continuous automatic peritoneal dialysis(APD).

Methods: We performed multiple frequency bioelectrical impedance analysis (InBodyS10, InBodyCo) and standard laboratories in patients with CAPD at baseline and 1 month after transition to APD.

Results: Twenty subjects are described, 12 men and 8 women, median age 28 years(22.15-40), height 163cm(157.25-165).Median and IQR along with Wilcoxon rank test for related samples were performed. We found statistical significance in EBW/TBW ratio in favor of APD, and increase in albumin and hemoglobin.

Variable	Units	Baseline	1 month	*p*
Weight	Kilogram	62.95(55.27-71.25)	63.75(53.75-69.10)	0.07
Body Mass Index	Kg/m^2	24.75(20.60-27.52)	24.85(20.45-28.07)	0.07
Systolic Blood pressure	mmHg	148(130-168)	137(126-166)	NS
Diastolic Blood pressure	mmHg	91(77.25-104.25)	89(78.50-107.50)	NS
Total body water (TBW)	Liters (L)	34.70(30.62-39.12)	33.85(31.02-37.30)	NS
Extracellular body water (EBW)	L	13.35(11.82-15.15)	13.05(11.95-14.25)	NS
Intracellular body water (IBW)	L	21.05(18.85-23.90)	21.05(18.87-23.15)	NS
EBW/TBW ratio	Ratio	**0.39(0.38-0.40)**	**0.38(0.38-0.40)**	**0.01**
Lean Muscle Mass	K	44.35(39.30-50.12)	43.50(39.72-47.85)	NS
Body Fat	K	17.35(6.77-23.10)	17.65(8.97-23.42)	0.06
Basal Metabolic Rate	Kcal/day	1388.00 (1274.50-1518.75)	1364.50(1286.00-1462.75)	NS
Hemoglobin	g/dL	**9.35(7.40-10.82)**	**10.30(8.47-11.12)**	**0.05**
Albumin	g/dL	**3.98(3.53-4.25)**	**4.04(3.77-4.27)**	**0.03**
Phosphorus	mg/dL	6.71(5.69-8.16)	6.54(5.63-7.93)	NS
Creatinine	mg/dL	11.33(8.76-15.85)	11.05(8.52-17.42)	NS
BUN	Mg/dL	68.50(54.35-91.75)	63.75(55.71-78.62)	NS

Conclusions: Peritoneal dialysis by CAPD or APD maintain, with exception of the EBW/IBW, a similar body composition.

Telemedicine in the Provision of Remote Peritoneal Dialysis Care: Preliminary Results Vinay Narasimha Krishna,[1] Russell Griffin,[2] Michael Louis Smith,[3] Eric L. Wallace.[1] *[1]Nephrology, Univ of Alabama, Birmingham, AL; [2]Epidemiology, Univ of Alabama, Birmingham, AL; [3]Alabama Dept of Public Health, Montgomery, AL.*

Background: Geography may pose a significant barrier in delivering peritoneal dialysis (PD) care to remote underserved populations leading to low utilization rates and poor outcomes. Telemedicine as a replacement for a face-to-face visit may serve as a solution to overcome geographic barriers in delivering PD care.

Methods: A telemedicine network was established through collaboration with Alabama Department of Public Health. PD patients living in a county different from the University of Alabama (UAB) Home Dialysis Unit were included in the study. A single cohort cross-over design was adopted. Patients started with 6 standard in-person (SOC) visits followed by 2 quarterly SOC visits, followed by 2 telemedicine visits. Kidney Disease Quality of Life (KDQOL-36) and the Illness Intrusiveness Ratings Scale (IIRS) were administered three times in the SOC and telemedicine arm. Telemedicine visits included interactive videoconferencing, physical exam including auscultatory exam using bluetooth enabled stethoscopes, and exit site examination using a handheld high definition camera. Labs were drawn at county health departments and shipped to a central lab. Dialysis flow sheets were faxed at the time of telemedicine visit.

Results: To date 12 telemedicine visits have been completed in 4 different counties/patients. The average physician encounter time was 8 minutes longer for telemedicine versus SOC visits ($p=0.05$). An average of 162 miles and 142 minutes of driving time was saved per telemedicine visit. Preliminary analysis showed the largest improvement was in SF12 physical component of the KDQOL-36 which increased an average of 5 points. IIRS scoring showed an average improvement (decrease) of 7.6 points when comparing telemedicine to SOC visits. All patient concerns were successfully addressed over telemedicine.

Conclusions: Telemedicine visits, although more time consuming for the physician, saves patients substantial driving time and trends towards improvement in quality of life for PD patients who live in a county different from the UAB Home Dialysis Unit.

Cat in the Bag Naseem H. Siddiqi. *Nephrology, Apex Medical Group, Knoxville, TN.*

Background: A.B. is a 33 year old white male, suffering from ESRD secondary to Diabetic Nephropathy and has been on Peritoneal Dialysis. Presented with abdominal pain, nausea, vomiting, elevated temperature and clouded fluid.

Methods: Patient was initially started on IP Vancomycin and Fortaz. His PD fluid showed evidence of Peritonitis with an increased WBC count and the PD culture showed Pasteurella Multocida Infection. After the PD culture results came back, the patient was then switched to Fortaz alone for a period of 14 days. Patient completely recovered from Peritonitis. Pasteurella Multocida Infection comes from cats and dogs. Patient was quizzed about having a cat or dog and confessed that he had acquired a cat therefore his Peritonitis was a result of the cat being handled by him. Therefore he was asked to find another home for the cat.

Results: The patient completely recovered from Pasteurella Multocida Infection.

Conclusions: Pasteurella Multocida Peritonitis is very rare but does occur. We should be screening patients with regard to having pets in the house before starting PD and be vigilant that they do not acquire and handle pets while they are on PD program.

PUB699

Prediction of the Mortality Risk in Peritoneal Dialysis Patients: Machine Learning Approach Using a Prospective Cohort in Korea Kyung Don Yoo,[1] Junhyug Noh,[2] Hajeong Lee,[3] Dong Ki Kim,[3] Chun Soo Lim,[3] Shin-Wook Kang,[4] Chul Woo Yang,[5] Yong-Lim Kim,[6] Gunhee Kim,[2] Jung Pyo Lee,[3] Yon Su Kim.[3] *[1]Dongguk Univ Gyeongju Hospital; [2]College of Engineering, Seoul National Univ; [3]Seoul National Univ College of Medicine; [4]Yonsei Univ; [5]Catholic Univ; [6]Kyungpook National Univ.*

Background: Peritoneal dialysis(PD) has several benefits for ESRD patients compared to hemodialysis in terms of residual renal function, reducing cardiovascular complications, improving quality of life. However, survival benefit was not consistently shown in each subpopulation.

Methods: A total of 1,730 PD patients in the Clinical Research Center for ESRD prospective cohort from Aug 2008 to Dec 2014 were enrolled to this study. Mortality risk model was validated by the individual learning algorithms such as survival decision tree(DT), ridge/lasso/Cox regression, and ensemble learning algorithms such as survival bagging and random forest.

Results: We analyze records of 1,127 prevalent and 603 incident PD patients, among which we use 21 independent attributes to learn our models including. The mean age was 52.7 years, and 57.4% were men. Survival tree algorithm had presented the most accurate prediction model, and it outperforms a conventional method such as Cox regression (Concordance index 0.802 vs. 0.745, respectively). Among various survival DT models, Charlson Comorbidity index(CCI) was selected for the best predictor of mortality. If PD patients with high CCI ($\geq$4) were more than 70 years old, survival hazard ratio (HR) was predicted as 4.61 compared to overall study participants(C-index 0.802). In patient under 70yrs old, if serum uric acid at dialysis initiation is 7.5mg/dl or more, the survival HR is decresed from 0.19 to 1.88. Survival HR is only 0.104, if CCI is 2 or less at the same age. Consequently, low risk patients whose CCI 3 or 4 were depend on serum BUN level and phosphorus level for survival HR (C-index 0.802).

Conclusions: We propose machine learning based models with estimated-death risks for presenting more accurate than conventional models. In our final model, age at dialysis initiation and CCI were interrelated as notable risk factors for mortality in Korean PD patients.

PUB700

Microbiology and Outcomes of Peritoneal Dialysis Peritonitis in a Korean Medical Center Jung-Woo Noh, Eunjung Kim, Dong Ho Shin. *Div of Nephrology, Hallym Univ Medical Center, Seoul, Korea.*

Background: Knowledge on microbiologic profiles and antibiotic resistance patterns are important to guide treatment for peritoneal dialysis (PD) peritonitis. Changes in prevalence of etiologies have been reported. We analyze the incidence of peritonitis, the causative pathogens, antibiotic resistance of commonly isolated pathogens and clinical outcomes.

Methods: We enrolled 321 patients on PD between January 2000 and December 2014. The endpoints analyzed were resolution, catheter loss, death due to peritonitis and shift to hemodialysis.

Results: There were 237 episodes of peritonitis in 138 of 321 patients over a cumulative follow-up period of 1205.5 patient-years. The overall rate was 0.20 episodes/patient-year. Gram+ cocci were identified in 122 (51.5%) episodes, whereas Gram- bacilli were isolated from 67 (28.3%). Methicillin-resistant Coagulase negative staphylococi (CoNS) was the most common isolate. Methicillin susceptibility was observed in 16 of 41 (39%) due to CoNS and 21 of 39 (53.8%) due to S.aureus. The ceftazidime susceptibility rate was 79.1% among Gram- bacilli, 88.5% among E.coli, 88.9% among Klebsiella spp., 33.3% among P. aeruginosa, 74.1% among Acinetobacter spp. The resistance rate was higher among P. aeruginosa than among E.coli (p=0.01). Episodes of Enterococcus spp. (p<0.001) and Pseudomonas spp. (p=0.04) presented lower resolution rates than those caused by CoNS. The death rate was not different among etiological groups (P = 0.6). Antibiotic resistance did not influence outcome. The main empirical antibiotic regimens were i.p. cefazolin plus ceftazidime (210 episodes), and i.p. vancomycin plus ceftazidime (27 episodes). Gram+ coverage with cefazolin was associated with higher resolution rate (91.6% versus 74.1%; p=0.05), lower catheter removal rate (8.4% versus 25.9%; p=0.05).

Conclusions: Although, methicillin susceptibility rate was low in this study, Gram+ coverage with cefazolin did not show negative impact on outcomes. Antibiotic resistance did not influence outcome. These findings suggested empirical antibiotic regimen i.p. cefazolin plus ceftazidime could be acceptable regardless of antibiotic resistance.

PUB701

Predictors of Mortality and Technique Failure in Incident Peritoneal Dialysis Patients in a Larger Center Maria C.C. Andreoli, Marco A. Nadaletto, Cláudia Tótoli, Laurisson A. Costa, Eduardo J.B. Monteiro, Camila Barbosa Silva Barros, Vanessa S. Dutra, Silvia Regina Manfredi, Sergio A. Draibe, Maria Eugenia F. Canziani. *Hospital do Rim - Disciplina de Nefrologia, Univ Federal de São Paulo, Sao Paulo, Brazil.*

Background: Center size has been associated with clinical outcomes in Peritoneal Dialysis (PD), with better results in larger centers. The aim of this study was analyze related factors to the clinical outcomes, death and technique failure, in incident patients in PD in a single larger center, during a period of 13 years.

Methods: All patients admitted in our PD center from January 1, 2003 and December 31, 2015, were evaluated. Technique failure was defined as theswitch from PD to hemodialysis therapy. Kaplan-Meier curves and the log-rank test were used to evaluate mortality and technique failure, and Cox proportional hazards model was used to identify factors associated with outcomes.

Results: A total of 633 patients [58.9 (44.7-68.2) years, 49% male, 33% diabetes] were analyzed.The peritonitis rate in the last 5 years was 1 episode every 34 months. During this period, 213 (34%) patients died: 101 (47%) from cardiovascular events, 64 (30%) from infectious complications not related to therapy and 27 (13%) from infectious complications related to therapy. Technique failure occurred in 204 (32%) patients especially due to peritonitis (51%). One-year and 5-year patient survival were 85% and 42%, respectively, and 1-year and 5-year technique survival were 83% e 51%, respectively. In Cox analysis, age (HR=1.045, CI95% 1.034-1.055; p<0.001) and diabetes (HR=1.636, CI95%1.246-2.149; p<0.001) were associated with mortality, while age was inverse related (HR=0.991, CI95% 0.982-0.999; p=0.037) with technique failure.

Conclusions: Non-modifiable risk factors such as age and diabetes were the important determinants of survival in a larger PD center. The low peritonitis rate observed in this population seem to be not sufficient to avoid transfer to hemodialysis, suggesting that management of this infection should be more effective.

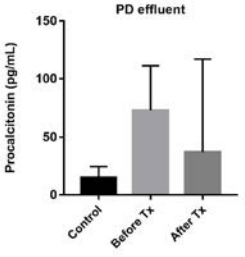
PUB702

Procalcitonin Is Not a Superior Biomarker for Peritoneal Dialysis Peritonitis Jae Seok Kim,[1] Jae Won Yang,[1] Byoung Geun Han,[1] Min Keun Kim,[1] Minseob Eom,[2] Seung-Ok Choi.[1] *[1]Internal Medicine, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea; [2]Pathology, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea.*

Background: Peritonitis is a common complication in peritoneal dialysis (PD). Procalcitonin is a useful biomarker for bacterial infection. We aim to investigate the utility of procalcitonin in PD peritonitis.

Methods: This study included thirty-three PD peritonitis episodes for the periods of total 450 days and peritosol analysis from seven patients without peritonitis. We investigated clinical characteristics and inflammatory markers including serum and PD effluent levels of procalcitonin at the time of initial visit and discharge.

Results: The mean of dialysis vintage in the patients with peritonitis was 1774.4 days, incidence of total peritonitis during their PD periods; 4.3 times, interval from symptom onset to visit; 13.6 hours, duration of intra-peritoneal antibiotic treatment; 8.2 days, and interval from clinical improvement to recurrence; 80.7 days. Initial serum procalcitonin increased to 402.2±278.4 pg/mL (mean±SEM, <50 pg/mL in healthy people). PD effluent procalcitonin increased compared with in control group, but not significantly (72.6±38.6 vs. 14.7±3.8 pg/mL, p=0.503). The serum procalcitonin decreased to 132.5±63.2 pg/mL with clinical improvement but not significantly (p=0.267), and the PD effluent procalcitonin decreased 37.0±16.3 pg/mL, but not significantly (p=0.378) .



Pearson's correlation analysis showed that the serum and PD effluent procalcitonin did not have relationships with existing inflammatory markers such as ESR, CRP. Procalcitonin could not predict recurrence and mortality of peritonitis.

Conclusions: Procalcitonin showed the tendencies corresponding to clinical course of PD peritonitis, but not statistical significances. We believe that procalcitonin is not a superior biomarker in PD peritonitis compared with other existing markers.

PUB703

Remote Blood Pressure Monitoring in Peritoneal Dialysis: A Comparison of Home Blood Pressure Readings with Readings Retrieved via Cycler-Embedded Remote Monitoring Patrick R. Harnett. *Renal Medicine, Southend Hospital, Westcliff On Sea, Essex, United Kingdom.*

Background: Blood pressure control is important for the reduction of cardiovascular risk. We report results of home blood pressure recordings obtained by patients and entered into a remote, PD cycler-embedded, interactive cloud-based platform (Sharesource) with blood pressures collected at home using validated home BP monitors Sharesource enables retrieval of clinical data on blood pressure and dialysis performance remotely and automatically via the wireless 3G network. The data is collated at a server and is presented to the clinical team via an interactive "dashboard".

Methods: Patients at a single centre were changed from conventional automated peritoneal dialysis (APD) to an APD device with embedded remote monitoring features (Claria- Sharesource) in Oct. 2015. Patients were instructed to record daily blood pressures at home using the Omron M10-IT home bp monitor. Readings were then entered by the patient into the Sharesource at the start of each dialysis session. Omron blood pressure monitor data were retrieved and processed by a bespoke data management system.

Results: 4 patients had recorded and entered daily blood pressure via Sharesource for 4 months total of 487 days of readings. The blood pressure data was retrieved for the same period from the Omron/Proton blood pressure collection system and compared to the corresponding month of sharesource blood pressure results.

fig 1	Home BP			Sharesource			
	No. of readings = 488			No. of readings = 541			p value
Mean systolic mmHg	142.55	sd	16.98	137.98	sd	17.93	<0.005
mean diastolic mmHg	82.53	sd	10.36	82.06	sd	9.85	0.232

Conclusions: Mean retrieved home blood pressure was significantly higher. Inaccuracies were also apparent. Protocols and education are required to maintain data quality. Further development of the technique (eg Bluetooth enabled blood pressure monitors) may minimise input error.

PUB704

Peritoneal Dialysis Associated Peritonitis in the Elderly: Clinical Characteristics, Outcomes and Prognostic Factors Chen Yu, Yue Chen. *Nephrology, Tongji Hospital, Shanghai, China.*

Background: To investigate the clinical characteristics, outcomes and prognostic factors of peritoneal dialysis associated peritonitis (PDAP) in the elderly.

Methods: We conducted a retrospective cohort study including all peritonitis episodes cases in peritoneal dialysis (PD) patients at a single center from January 2012 and December 2015. Demographic data, clinical data at admission, causative organisms and drug resistance were collected. The outcomes of patients were recorded at the time of 4 weeks after the completion of antibiotic therapy. Treatment failure included death or removal of PD catheter for peritonitis episodes.

Results: 129 episodes of peritonitis occurred in 87 PD patients including 61 elderly patients and 26 younger patients. The proportion of elderly patients with diabetes was higher (P=0.001). The incidence of primary glomerular diseases (PGD) was lower in the elderly (P<0.001). The levels of serum albumin (Salb), blood urea nitrogen, serum creatinine and uric acid were lower in the elderly (P<0.005). There was minor difference in spectrums of causative organisms from effluents between the elderly and younger. The proportion of Enterococcus species to gram-positive bacteria was lower in the elderly (P=0.029). The occurrences of outcomes were similar in the elderly and younger. More WBC counts in effluent on d5, lower Salb and fungal or polymicrobial infections were associated with treatment failure.

Conclusions: The elderly PDAP patients were more likely to have diabetes as a comorbid disease and had worse nutritional status. The outcomes of the elderly were comparable to those of the younger. The treatment response for PDAP caused by fungi or polymicrobe was challenging in the elderly.

PUB705

How Far We Can Go: Extremes of Body Mass Index in Peritoneal Dialysis Yougandhar Akula,[1] Sohail Abdul Salim,[1] Betzaida Rodriguez,[2] Lajos Zsom,[3] Tibor Fulop,[3] Mehul P. Dixit.[4] *[1]Div of Nephrology, Univ of Mississippi Medical Center, Jackson, MS; [2]Div of Hospital Medicine, Univ of Mississippi Medical Center, Jackson, MS; [3]Dept of Surgery, Div of Transplantation, Univ of Debrecen, Debrecen, Hungary; [4]Div of Pediatric Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: The State of Mississippi leads the nation in the epidemics of obesity and, with the rising tide of chronic kidney disease, inevitably the need for renal replacement therapy (RRT) in many overweight subjects. The feasibility of peritoneal dialysis in extremely obese subjects is not well understood.

Methods: We reviewed our peritoneal dialysis (PD) unit for extremely obese subjects (body mass index [BMI] ≥40 kg/m^2) and evaluated their biochemistry and PD adequacy parameters, in comparison with those with normal weight individuals (BMI 20-25). Results were expressed with means (SD) and percent (%); between-group comparison was performed with independent sample t-test.

Results: : We observed six subjects with BMI > 40 kg/m2: mean weight was 134.7 (SD=12.5) kg, body length 174.8 (11.8) cm with mean BMI 44.3 (SD=4.2) kg/m^2 [range: 40.2-51.6]. Age was 39.3 (7.6) years with PD vintage 15.8 (16.2) months; all African-American and using cycler-assisted peritoneal dialysis. Weekly Kt/V measured 1.8 (0.18), creatinine clearance 90.1 (46.4) liter (L)/1.73 m^2 week with total exchanged volume 12.2 (1.35) L. Residual urine output (RUO) measured 708 (561) mL and residual creatinine clearance 48.5 (44.3) L/week/1.73 m^2. The lean (n=20) subjects had mean weight of 66.5 (9.8) kg and BMI 23.3 (1.4) kg/m^2. While both weight and BMI differed significantly (p<0.0001), weekly global and residual creatinine clearance and RUO did not. Exchanges volumes were larger (p=0.04) and Kt/V smaller (p=0.007) in the obese subjects. None of the serum biochemistry parameters were significantly different between the subcohorts.

Conclusions: Successful PD appears feasible even in massively obese subject and provides RRT access when no arteriovenous fistula available.

PUB706

A Simplified Method to Measure GFR in Swine by the Plasma Clearance of Iohexol Consolacion C. García-Contreras,[1] Marta Vazquez,[1] Sergio Luis Lima,[3] Susana Astiz,[1] Antonio Gonzalez-Bulnes,[1] Esteban Porrini.[2] *[1]Comparative Physiology Group (SGIT-INIA), Madrid, Spain; [2]Univ de La Laguna, La Laguna, Spain.*

Background: There is no definitive method to measure GFR in swine.

Methods: We used two groups (testing and validation), of 8 adult iberian pigs each in which 10 mL of iohexol (6.47 g) was injected intravenously (marginal auricular vein) and blood samples were collected at 15, 30, 45, 60, 90, 120, 180, 240, 300, 360 and 420 minutes (orbital sinus). Iohexol plasma clearance was measured by two-compartment model (CL2-reference method) using all the samples and by one-compartment model (CL1) using the last six.

Results: Plasma clearance calculated by CL1 lead to a ±30% overestimation of CL2. A correction formula [CL= -47.909+(1.176xCL1)-(0.00063968xCL1^2)] was created to recalculate CL1. This approach increased the correlation between CL2 and CL1 (R=0.969). The latter (CL1 and the correction formula) was the simplified method (SM). In the validation group, GFR averaged 229±68.6 µl/min (CL2) and 276.9±85.3 µl/min (CL1). The recalculation of GFR with the formula lead to 224.7±71,5 ml/min, comparable to CL2. Similar results were observed in the testing group.

Testing Group					
Pig ID	Weight (kg)	CL2 (ml/min)	CL1 (ml/min)	SM (ml/min)	Diff (%) SM vs CL2
1	113.5	119.6	150.4	114.6	-4.2
2	172.6	172.6	236.3	194.3	12.5
3	225.8	225.8	301.6	248.7	10.1
4	233,8	233.8	255.4	210.8	-9.9
5	175,8	175.8	216.4	176.7	0.5
6	341,8	341.8	433.1	341.4	-0.1
7	266.1	300.5	345.6	282.1	-6.1
8	311,9	392.0	527.4	394.4	0.6
mean±SD	265.8 ± 65.2	243± 92.8	308.3 ± 128.2	245.3 ± 91.4	
Validation Group					
Pig	Weight (kg)	CL2 (ml/min)	CL1 (ml/min)	SM (ml/min)	Diff (%) SM vs CL2
9	173,7	173.7	213.7	174.2	0,3
10	252,2	246.8	275.9	227.9	-7,7
11	112.1	112.1	128.0	92.2	-17,8
12	289.9	289.9	394.6	316.6	9,2
13	202.8	202.8	253.5	209.1	3,1
14	289.6	289.6	331.2	271.4	-6,3
15	202.8	202.8	257.7	212.7	4,9
16	313.9	313.9	360.9	293.2	-6,6
mean±SD	212.9 ± 39.2	229±68.6	276.9 ± 85.3	224.7 ± 71.5	

Conclusions: We offer a simple method to evaluate GFR in conscious swine which does not need urine collection and allows repeating the measurement in the same animal.

Outcome Measures for Fatigue in Patients on Hemodialysis Angela Ju,[1,2] Jonathan C. Craig,[1,2] Mark L. Unruh,[3] Allison Tong.[1,2] *[1]School of Public Health, The Univ of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [3]Div of Nephrology, Univ of New Mexico, Albuquerque, Mexico.*

Background: Fatigue is a prevalent and debilitating symptom in patients on hemodialysis but is measured infrequently, inconsistently, and using instruments that may not be valid for this population.

Methods: We searched MEDLINE, Embase, PsycINFO, CINAHL to March 2016 for all studies that measured and reported fatigue in patients on hemodialysis. Content, validity, reliability and feasibility were assessed using criteria developed by adapting the COnsensus-based Standards for the selection of health Measurement INstruments (COSMIN) checklist and the National Health Service checklist.

Results: The 117 studies included 36 different instruments; 17 (47%) scales were developed for populations other than hemodialysis, 2 (1%) for chronic kidney disease patients regardless of disease stage, and 17 (47%) specifically for haemodialysis (12 were author-developed for their study). Of these, 26 (72%) were specifically designed to measure fatigue. All scales assessed global fatigue, some of which also included emotional (9 [24%]), cognitive (10 [27%]), and physical fatigue (14 [39%]). Within these domains, the severity of fatigue and life impact were assessed. The most frequently used instrument was the vitality sub-scale of 36-Item Short Form Health Survey (SF-36) (19 [16%] studies) but it has not been validated the hemodialysis population, along with the majority of other instruments used to measure fatigue in this population.

Conclusions: Although several scales have been used to measure fatigue in patients on hemodialysis, there is insufficient evidence of validity to ensure an adequate representation of their experience. A well-validated instrument for fatigue is needed to improve the consistency and accuracy of measurement for a better understanding and management of this important patient-centered outcome.

Comparative Biocompatibility of Polysulfone Hemodialysers Applied in Different Treatment Modalities Stephan Wagner,[1] Ansgar Erlenkoetter,[2] Katharina Brand,[2] Ursula Kreuzberg,[2] Adelheid Gauly.[2] *[1]Praxis für Nieren- und Hochdruckerkrankung, Giessen, Germany; [2]Fresenius Medical Care, Bad Homburg, Germany.*

Background: The biocompatibility profile of two polysulfone hemodialyzers was evaluated based on hemocompatibility markers.

Methods: In a prospective randomized crossover study 24 adult patients on online hemodiafiltration (HDF) were treated one week each with the dialyzers FX100 on hemodialysis (HD), FX CorDiax 100 on HD and HDF (Fresenius Medical Care, Germany). Linear mixed models were used for inferential statistical analysis including fixed effects for treatment, period and a random subject effect. Differences for the estimated means at 10 min. and for the whole treatment (area-under-the-curve, AUC), or relative changes from pre- to post-dialysis were analyzed.

Results: The complement factors C3a and C5a increased early in the treatment, comparable between FX Cordiax and FX in HD, but less with FX Cordiax HDF, likely due to convective elimination. sC5b9 increased in all three phases with the highest level after 60 min., overall (AUC) it was significantly lower with FX Cordiax HDF than in both HD settings. Leukocytes decreased in the first 10 min of the treatment, without significant differences at 10 min. and over the entire treatment in all phases. Thrombocytes decreased slightly in all phases in the first 30 min., with FX Cordiax HDF significantly more than with the two HD settings. TAT increased to a different extent towards treatment end, significantly more with FX Cordiax HDF compared to both HD settings. Elastase increased in the first hour with all dialyser/modality settings, the least with FX Cordiax HDF. Kallikrein as a marker of contact activation showed a slight increase at 10 min, but not significantly different by dialyser/modality at 10 min. or overall. Tryptase decreased significantly more with FX CorDiax HDF than with both dialysers in HD. No difference was observed for IgE and hsCRP. All adverse events occurring during the study were judged as unrelated to dialyser and treatment.

Conclusions: This study confirmed a comparable biocompatibility profile of FX CorDiax and FX. Some differences observed with FXCorDiax HDF are likely due to convective elimination of middle molecules.

Intradialytic Hypotension – Can We Reduce the Incidence? Narayanan Unni Vavullipathy. *Nephrology, Aster Medcity, Kochi, Kerala, India.*

Background: All attempts should be made to avoid Intradialytic hypotension during maintenance haemodialysis **Objectives**:To study the incidence of intradialytic hypotension in patients on maintenance haemodialysis, if the Nephrologist makes an assessment of the patient before each dialysis session and decides on the volume of ultrafitration every time. **Materials & Methods**: Patients with chronic kidney disease stage 5 on maintenance haemodialysis from June 2014 to May 2016 were studied. They were dialysed for 4 hours thrice a week using a Fresenius Polysulfone dialyzer with a surface area equal to 75% of body surface area with Fresenius hemodialysis machine model 4008S. The blood flow was kept at 250 to 300ml per minute , with a dialysate flow of 500ml per minute at 37 degree Celsius. A qualified experienced Nephrologist evaluated the patients before each dialysis session and decided on the volume of ultrafiltration at every session. All patients were asked to have their antihypertensive medications as usual. Pulse rate and blood pressure was monitored every 10 minutes with a Philips multiparameter monitor model Intellivue P5 . Intradialytic hypotension was defined as a fall in systolic blood pressure by 20mmHg or a decrease in mean arterial blood pressure by 10 mmHg , and need for nursing interventions (K/DOQI definition). **Results**: During the study period, 10075 haemodialysis sessions were done in 80 patients (58 males and 22 females). The mean age was 55 years (Range : 24 to 82). Diabetic nephropathy constituted 52% of the cases. Seventy seven patients were hypertensive and the mean BMI was 22.8 (14.1 to 34.6) . Diastolic dysfunction on echocardiogram was seen in 74% of patients. The mean interdialytic weight gain was 1.87 kilograms (0.5 to 3.5Kg.). The incidence of intradialytic hypotension was 1.55%. **Conclusions**: Incidence of hypotension was very low in our patients, compared to published reports. Assessment by the Nephrologist before every dialysis session and determination of the ultrafiltration volume at every session is extremely useful to avoid intradialytic hypotension.

PUB710

Will Flushing of Normal Saline Reduce the Clotting Incidence during Hemodialysis? Jafar Al-Said, Leonor Fontanillia. *Nephrology, Bahrain Specialist Hospital.*

Background: Hemodialysis is the main renal replacement mode for ESRD. Clotting is the major technical problem that could affect the blood flow and the clearance. It carries a significant risk for access loss with all its consequences. Proper Anticoagulation is needed to prevent the clot formation and maintain proper hemodialysis clearance. Adding prefilter saline flush to the regular Anticoagulation might reduce the clotting incidence by diluting the blood and facilitating removal of small clots from the filter.

Methods: Nine patients from our hemodialysis unit were selected. The recruitment was based on stable hemodynamics, no vascular access problems, and those using regular anticoagulant dose. Over two weeks half of their dialysis sessions were performed with hourly flushing of 100ml normal saline in addition to the Heparin boluses. The remaining sessions were performed with only Heparin. Clotting in the filters as well as the arterial

and venous chambers were monitored by the end of each session by two nursing staff. The session was labeled accordingly: **(0)** No clot. **(1)** Clots present in moderate amount. **(2)** Sever clotting required changing of the filter and tubing.

Results: Nine patients had 50 HD sessions over two weeks. Five males and 4 females. Mean Age was 62.5 years (SE 7), Mean BMI 22.3 (SE1.3). The access in 24 sessions were cuffed tunneled catheters, in 16 sessions it was an AVF and 10 sessions were performed via AVG. Aspirin was used on a regular daily dose of 81mg by 5 patients. The mean interdialytic wt. gain was 2.3kg (SE 0.13). The mean Heparin dose used per session was 4313 IU (SE 281). Intradialytic hypotension noticed in 4 sessions during the study period. There were no clots in any of the 25 sessions using saline flush and Heparin. However, among the other 25 sessions, with only Heparin, moderate clotting was identified in one session. The difference was not statistically significant.

Conclusions: Using saline in addition to the regular Heparin anticoagulation during hemodialysis did not make a significant difference in regard to the intradialytic clotting incidence. A Larger study is required to test the effect of saline flushing as a sole method to reduce clotting in dialysis lines.

PUB711

Reusing Dialysis Catheter Caps Jafar Al-Said, Tyrene Joy Sevilla. *Nephrology, Bahrain Specialist Hospital.*

Background: Hemodialysis catheter caps are utilized to secure the venous and arterial ports of the catheter from contamination, prevent blood leak and air embolism. Soaking hemodialysis catheter caps in antiseptic solution to be reused is practiced in our dialysis unit. This procedure was described in KDOQI Vascular Access Guidelines in 2000. It was not included in the 2006 update. Moreover, it is not a CDC recommendation. In the view of possible increased bacterial contamination, the question whether we should use new caps each session or reuse the same caps after sterilization with 10% Betadine was addressed by this study.

Methods: Five patients using cuffed tunneled catheters as their permanent dialysis access were included from our unit. The duration for the catheters use was between 2 - 9 months. The catheter caps were reused after each hemodialysis session from the time the catheters were inserted. The caps were soaked in 10% Betadine during the hemodialysis session. The caps were flushed with 9% saline by the end of the session and then used to cover the arterial and venous ports of the catheter. Personal protective equipment was emphasized and monitored as part of our hemodialysis strict infection control policy. During this study, these caps were sent for culture and replaced with new ones. The caps were transferred to the labs in sterile containers. Each Cap was flushed with 1 ml nutrient broth and incubated at 37°C for 24 hours. The broth was subcultures for another 24 hours in different agar plates. Having a positive bacterial culture within 48 hours would indicate a possible contamination to the catheters and thus to the blood.

Results: Table (1) shows the culture report of the catheter caps as well as the duration of use. All cap cultures were negative with no growth regardless of the duration the catheter caps use.

Patient	Duration of cap reuse in months	Culture result
1	9	Negative
2	8	Negative
3	8	Negqative
4	7	Negative
5	2	Negative

Conclusions: Reuse catheter caps after soaking in Betadine solution does not lead to increased risk of contamination, infection or harm to our dialysis patients. It can be followed with strict aseptic technique and proper infection control procedures.

PUB712

Barriers to Reducing Sodium (Na) Intake among Black ESRD Patients Carla Boutin-Foster,[1] Sania Tahir,[2] Amar V. Patel,[3] Jenna M. George,[3] Subodh J. Saggi.[3] *[1]Div of Internal Medicine, SUNY Downstate Medical Center, Brooklyn, NY; [2]Long Island Univ, Brooklyn, NY; [3]Div of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Black patients are 3 times more likely to have ESRD, which places them at significant risk of adverse cardiac events. Na intake is an important aspect of reducing fluid retention and subsequent cardiac events. The objective was to examine outcomes of a standard program to reduce Na intake among ESRD patients cared for in a dialysis unit located in a medically underserved community.

Methods: Outcomes for patients who had elevated inter-dialytic weights (IDWs) and who received an educational program by a registered dietician were examined. Na intake was calculated using the formula: $V \times ([Na]_{pre} - [Na]_{post}) + (\Delta IDW \times [Na]_{pre})$, where V= total body water. The standard protocol entailed showing patients their actual Na intake, education on low Na alternatives to traditional meals, and keeping a food log. Final Na intake was calculated at 3-months.

Results: Outcomes were reviewed for 13 patients; all were black; 8 were male; age was 49.6 + 11.98; all were hypertensive; and 6 were diabetic. An increase in Na intake was observed at 3 months (3.7 + 1.3g to 4.2 + 1.3g), (P>.05). Patients revealed physical and socioeconomic barriers to reducing Na intake. Physical barriers included difficulty seeing salt labels and measuring salt due to visual impairment. Ambulation and dexterity problems limited the ability to prepare meals, resulting in a high consumption of fast-foods. Patients described a lack of social support by family members for preparing low Na meals. Socioeconomic barriers limited access to buying low Na foods.

Conclusions: Patients face multiple barriers to Na reduction. In medically underserved communities, standard dietary education may need to be enhanced. Future programs may benefit from a greater focus on the social determinants and sociocultural aspects of adherence.

PUB713

Adult Intradialytic Hypotension: A Systematic Review Mohit Gupta,[1] Allen Reeves,[4] Mustafa Ascha,[2] Ramya Vajapey,[3] Rupesh Raina.[1] *[1]Dept of Internal Medicine, Akron General Medical Center, Akron, OH; [2]Clincal and Translational Science Collaborative, Case Western Reserve Univ, Cleveland, OH; [3]School of Medicine, Northeast Ohio Medical Univ, Rootstown, OH; [4]Cleveland Clinic Akron General, Akron, OH.*

Background: Intradialytic Hypotension is a frequent complication of Hemodialysis and occurs in up to 30% of cases. By a systematic review, we will discuss various therapeutic strategies and review their effect on Intradialytic Hypotension.

Methods: PubMed/MEDLINE was searched for the terms "intradialytic" and "hypotension" with parameters for randomized controlled trials. Inclusion criteria were (1) adult population, (2) hemodialysis, (3a) hypotension frequency or (3b) pre-dialysis and post-dialysis blood pressure measurement or (3c) difference between pre-dialysis and post-dialysis blood pressure measurement, and (4) variable dialysate electrolyte concentrations, dialysate temperature, volume management/ultrafiltration strategies, or pharmacological therapy. Exclusion criteria were hemofiltration or hemodiafiltration.

Results: Of 69 results, 47 articles were selected; 11 focused on dialysate temperature, 17 on dialysate electrolyte composition, 11 on volume control, and 4 on pharmacologic therapy. Variable Temperature Approaches: Of the 11 trials, lower dialysate temperatures were linked to a reduced incidence of hypotension. Maggiore et al reported that isothermic dialysis had a lower incidence of hypotension when compared to thermoneutral dialysis. Dialysate composition: 17 studies evaluated the impact of dialysate electrolyte composition. Calcium Dialysate: Gabutti et al found that higher calcium concentrations were associated with a lower incidence of hypotension. Sodium Dialysate: Oliver et al reported use of a sodium-profiled treatment versus constant-sodium was associated with a reduced risk of hypotension. Volume-based: Santoro et al reported that a volume-based approach based on effective blood volume was associated with a lower incidence of hypotension.

Conclusions: We found that the use of dialysis at (a)lower temperatures, (b)higher concentrations of calcium, (c) with sodium profiling and (d) volume-based strategies was linked to a lower incidence of Intradialytic hypotension.

PUB714

Acquired Cystic Kidney Disease in ESRD Patients on Maintainance Hemodialysis at a Tertiary Care Dialysis Center Syed Rizwan A. Bokhari,[1] Maria Rizwan Bokhari,[2] Hafiz I. Ahmad,[1] Syed A. Khalid,[1] Muhammad Zaman Khan Assir.[1] *[1]Nephrology, AIMC/JHL, Pakistan; [2]Radiology, AIMC/JHL, Pakistan.*

Background: Renal cysts are commonly observed in patients on maintenance hemodialysis (HD). Most of these patients are asymptomatic, while some report hematuria and lumbar pain. Its association with renal cell carcinoma is also well known. Frequency of acquired cystic kidney disease (ACKD) is not known in our End stage renal disease (ESRD) population. We studied the prevalence of ACKD and its correlation with patient's characteristics in our dialysis population.

Methods: Seventy-Four ESRD patients on maintenance hemodialysis at Jinnah Hospital Dialysis center were assessed for the study. Three patients with Autosomal dominant polycystic kidney disease (ADPKD) were excluded. None of the other 71 patients had previously known history of renal cysts. These patients underwent ultrasound examination by consultant radiologist for presence of renal cysts.

Results: Median age of patients was 50 years (range 17-82) and 44 (64%) were male. Median duration on hemodialysis was 4 years (1-12 years). Cause of ESRD was Hypertension (63%) Diabetes mellitus (30%) and obstructive uropathy (7%). Twenty-nine (40%) patients had hepatitis C infection. Sixty (85 %) patients were on thrice weekly and 11 (15%) were on twice weekly HD. Fifty five (77%) patients had 1 renal cyst, 26 patients had 2-5 renal cysts and 12 patients had more than 5 renal cysts bilaterally. Thirty-five (49%) Patients getting HD for less than 3 years had median of 3 cysts (range 0-15), while remaining patients on HD for more than three years had median number of 4.5 cysts (range 0-26). Nine (13%) on HD for less than 1 year had multiple renal cysts (1-4). No significant correlation was found between ACKD and duration of dialysis, frequency of dialysis, age, gender, co morbidities, Hepatitis C status. None of these patients had evidence of extra renal cysts, retroperitoneal or intrarenal hemorrhage.

Conclusions: No significant correlation between ACKD and duration of hemodialysis was observed while a high frequency of renal cysts was seen earlier (within 1 year of HD). The reason may be the late initiation of HD at a much lower GFR which is a routine in the developing countries.

PUB715

Hyperphosphatemia and Its Relation with Carotid Intima Media Thickness in ESRD Patients Farah Rizwan,[1] Hafiz I. Ahmad,[1] Syed Rizwan A. Bokhari,[1] Zumar Sardar,[1] Syed A. Khalid,[1] Arif Asif.[2] *[1]Nephrology, Allama Iqbal Medical College/ Jinnah Hospital Lahore, Pakistan; [2]Internal Medicine, Jersey Shore Univ Medical Center.*

Background: Increased phosphate level is commonly observed in chronic kidney disease patients. While its role in vascular calcification is well established, its effect on arterial wall thickness remains largely unknown in end stage renal disease (ESRD) population. We set out to determine the frequency of hyperphosphatemia in ESRD patients on maintenance hemodialysis and to compare the mean carotid intima media thickness (CIMT) in those with and without hyperphosphatemia.

Methods: All56 ESRD hemodialysis patients in the center were enrolled in the study. Serum phosphate level was measured. Hyperphosphatemia was labelled in accordance with KDOQI guidelines. Carotid intima media thickness was measured by ultrasound using linear transducer by a consultant radiologist.

Results: Mean age of the patients was 47.29±14.7 (ranging: 25- 82 years). Thirty-six (63.4%) patients were male. Eleven (19.6%) patients had ischemic heart disease. Nineteen (33.9%) patients had uncontrolled hypertension. Mean carotid intima thickness in patients with and without ischemic heart disease was 1.13±0.5 mm and 0.80±0.24 mm, respectively. Mean serum phosphate level was 5.62±1.95 (range: 1.4- 10.4 mg/dl). Mean carotid intima media thickness was 0.87±0.34mm in our cohort.Twenty-nine (51.8 %) had hyperphosphatemia. Mean carotid intima media thickness in patients with hyperphosphatemia was 0.85±0.34 mm which was similar to those without hyperphosphatemia0.9±0.34 (p value=0.56).

Conclusions: In our dialysis population hyperphosphatemia, common carotid artery intima media thickness was not observed.

PUB716

Regular Treatment with Haemodiafiltration Results in Fewer Hospital Admissions Than Haemodialysis Hemali Kanji. *Nephrology, Univ Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom.*

Background: There is debate whether haemodiafiltration(HDF) is preferable to haemodialysis(HD) in stable patients, and hence a question whether the expense of HDF machines is necessary.

Methods: We compared the admission rate to hospital of 40 patients at a satellite unit who have outpatient haemodialysis(HD) with 40 patients at another satellite unit who have outpatient haemodiafiltration(HDF) over a twelve months.

Results: The HD group were 18 men and 22 women aged 25-74(mean age 63) of whom 24 were diabetic and the HDF group were 16 men and 24 women aged 22-68 (mean age 57) of whom 17 were diabetic. There were 56 admissions in the HD group and 48 in the HDF group. The reason for admission was more often due to difficulties with access in the HDF group And their length of stay was shorter (2-7 days) compared to the HD group (2-40 days).

Conclusions: Having regular HDF is associated with less inpatient stay than HD. Whilst the initial cost of HDF machines may be greater than for machines which provide HD alone, there may be a cost saving in terms of fewer and shorter hospital admissions, and this needs to be considered when planning dialysis units.

PUB717

Low Calcium (Ca) Baths and Relation to Intact Parathyroid Hormone (iPTH) Niralee Patel, Larissa Kruger Gomes, Ibrahim M. El-Ali, Andre A. Kaplan. *UCONN Health Center, Farmington, CT.*

Background: Patients on dialysis have impaired calcium metabolism and can develop vascular and metastatic calcifications. It has been postulated that net positive Ca balance may promote formation of these calcifications. A kinetic analysis of net Ca balance in hemodialysis patients concluded that low Ca baths are required to avoid net Ca accumulation. Furthermore, in patients taking vitamin D analogues and calcium containing phosphate binders, a dialysate bath of 2.0 Ca would be required in order to avoid ongoing positive Ca balance (Gotch et al. KI 78:343, 2010). Given these conclusions, we have employed several low Ca dialysates in the hope of decreasing the net absorption of calcium.

Methods: As a Quality Assurance project we conducted a retrospective, single center study to determine the iPTH response to a lower calcium bath. Three separate study periods were reviewed, each lasting for 3 months. Ten patients who were dialyzed on a 2.25mEq/L bath were switched to 2.0mEq/L, six patients who were dialyzed on a 2.5mEq/L bath were switched to 2.25mEq/L, and 6 patients who were on a 2.5mEq/L bath were changed to 2.0mEq/L.

Results: As seen on Table 1, we found a tendency for increases in iPTH as the bath concentration was decreased but none of these increases were statistically significant in our small samples. Of interest, is that of 6 patients treated with the most substantial drop in Ca bath (2.5 vs. 2.0), 2 developed a decrease in iPTH.

Table 1: Mean Values at the Beginning and at 3 Months After Lowering Calcium Bath

Calcium Bath	2.25mEq/L	2.0mEq/L	2.5mEq/L	2.25mEq/L	2.5mEq/L	2.0mEq/L
Patients (n)	n=10		n=6		n=6	
P_i (mg/dL)	5.38	5.53	5.07	6.23	5.8	6.3
Ca^{2+} (mEq/L)	9.03	9.28	9.03	9.03	9.2	8.8
Ca^{2+} Pi Product	48.5	51.2	45.6	54	52.99	53.33
IPTH (pg/ml)	411	489	322	351	349	512
Calcium Acetate	n=6		n=1		n=4	
Calcium Carbonate	n=2		n=2		n=0	
No Phosphate Binders	n=4		n=3		n=2	
Sevelamer	n=0		n=1		n=0	
Activated IV Vitamin D Hectorol	n=10		n=6		n=6	
iPTH pre vs. post (p value)	0.23= NS		0.74=NS		0.23=NS	

NS = Non-significant

Conclusions: We conclude that low Ca baths are associated with relatively modest and variable changes in iPTH and may prevent calcifications by reducing net Ca balance.

PUB718

Clinical Significance of Serum Ferritin in Malnourished Dialysis Patients Yoo Jin Lee, Yang Wook Kim, Sihyung Park, Bongsoo Park. *Internal Medicine, Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: Malnutrition is an important clinical threat in dialysis patients. Malnutrition is related to high morbidity and mortality rate. Although nutritional status cannot be judged by single method, we planned this study to assess nutritional status in dialysis patients by easy and convenient biochemical parameters.

Methods: Protein, albumin, albumin/globulin ratio, somatomedin-C, ferritin, transferrin saturation, phosphate, hydration status and body mass index were analyzed in hemodialysis, peritoneal dialysis patients. Body composition monitor (BCM) was used to evaluate lean tissue index (LTI). Malnutrition was defined by below 10 percentile of age-sex matched LTI.

Results: A total 34 patients were enrolled. 20 (58%) patients of malnutrition group showed higher ferritin level (450 ng/mL vs 230 ng/mL, r = -0.367). Other parameters were not different significantly. In subgroup analysis, ferritin (655 ng/mL vs 220 ng/mL, r = -0.518) was higher, however, CRP level was not different significantly in malnourished hemodialysis patients (12/19, 63%). In peritoneal dialysis patients, lower Somatomedin-C (214 ng/mL vs 304 ng/mL, r = 0.495) level was revealed in malnourished peritoneal dialysis patients (8/15, 53%).

Conclusions: The prevalence of malnutrition in dialysis patients was higher than we expected. Serum ferritin is a useful and convenient biochemical parameter for assessing nutritional status in dialysis patients.

PUB719

End-Stage Renal Disease Medication Self-Management: What Are the Effects of Everyday Racial Discrimination? Tamara Savage. *College of Social Work, Univ of South Carolina, Columbia, SC.*

Background: Poor medication self-management leads to increased risk for morbidity and mortality in end-stage renal disease (ESRD) patients. African American ESRD patients have poorer rates of medication self-management when compared to Whites. Studies have not investigated the impact of broader social issues such as everyday discrimination on this disparity. It is critically important to understand how everyday discriminatory acts within the healthcare system contribute to this disparity in medication self-management. Thus, a qualitative study was conducted to ascertain how everyday discrimination impacts medication self-management within this population.

Methods: Primary data were gathered from five in-depth interviews with African American ESRD patients (N = 5) in Greensboro, NC. Each interview was 1.5 to 2 hours in duration. Participants were recruited from attendees at the National Kidney Foundation Patient Empowerment Meeting. The interviews were transcribed verbatim. Grounded theory was used to identify themes that emerged from a line-by-line review of the interview transcripts.

Results: Participants explained that everyday discrimination perpetuated within the healthcare system negatively affected their medication self-management. Themes of racial discrimination that emerged which quashed further questions or engendered misunderstandings regarding their medication include: assumptions that patients could not pay for prescriptions not covered by insurance, assumptions that patients were not intelligent enough to understand medication instructions, patients were ignored by medical staff so they had to "pin the nurse down to ask about medication", and information about their medication and lab results being withheld or given to them without further consultation while white patients received in-depth consultation.

Conclusions: These findings provide the basis for development of future research concerning the impact of everyday discrimination on medication adherence in the African American ESRD population. Such research could lead to antiracist praxis, strategies, and targeted interventions that can address the medication adherence health disparity.

PUB720

Predictive Value of Histological Acute Kidney Injury Parameters in Implantation Biopsies for Delayed Graft Function Anke Keijbeck,[1] Tim C. Van Smaalen,[2] Marielle Gelens,[3] Robert Jan Van Suylen,[4] Floortje Steegh,[1] Maarten H.L. Christiaans,[3] Ernest Van Heurn,[2,5] Carine Peutz-Kootstra.[1] *[1]Pathology, MUMC, Maastricht, Netherlands; [2]Surgery, MUMC, Maastricht, Netherlands; [3]Internal Medicine, MUMC, Maastricht, Netherlands; [4]Pathology, Jeroen Bosch Hospital, 's-Hertogenbosch, Netherlands; [5]Surgery, AMC, Amsterdam, Netherlands.*

Background: Ischemia-reperfusion injury (IRI) in kidney transplantation is an important risk factor for later complications such as delayed graft function (DGF) and reduced graft survival. Clinical parameters such as cold ischemia time (CIT) and donor type are indicative for IRI, however, the additional value of post reperfusion histology is not known. The aim of this study was to investigate the predictive value of histological parameters of acute kidney injury for DGF.

Methods: The biopsy results of 192 consecutive donor kidney recipients transplanted between April 2003 and December 2009 at the Maastricht University Medical Centre (MUMC) with representative renal biopsy taken 30-60 minutes after reperfusion and a functional graft one year after transplantation were analysed. Biopsies were scored for 5 parameters for IRI known from animal studies: tubular cell necrosis, oedema, loss of brush border, neutrophils in glomerular capillaries and neutrophils in peritubular capillaries (PTC), which were scored in a dichotomic manner.

Results: Donor types were equally distributed in the cohort: 32.8% living donors, 35.4% donors after brain death (DBD) and 31.7% donors after cardiac death (DCD). The incidence of DGF in the cohort was 35%. Tubular cell necrosis was a risk factor for DGF (OR=2.6 [1.1-6.0]), while oedema was protective (OR=0.39 [0.160-0.954]). Other histological IRI markers didn't affect the risk of DGF in addition to the known clinical factors CIT and DCD donor type. Area under the curve of the ROC curve (0.88 [0.83-0.93]) shows an excellent discriminant power of the model.

Conclusions: This study shows that IRI is already visible in implantation biopsies. Assessment of histological acute kidney injury parameters in the post reperfusion kidney biopsy has added value to predict DGF.

PUB721

The Change of Fcγ Receptor 1α mRNA in the Graft of Acute Rejection Rat Renal Transplantation Model Yiqiao Li. *Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: To study the change of Fcγ receptor 1α mRNA in the graft of the rat renal transplantation model, especially after the acute rejection.

Methods: After at the seventh days and the fourteenth day to collect the samples, 3 rats in each time point. After abdominal aortic blood collection, blood samples is under the 3000rpm centrifugal 10 min to check serum creatinine and renal tissue -80 degree preservation, real-time PCR method was applied to test the change of Fcγ receptor 1α mRNA expression of each group.

Results: In the sham operation group, serum creatinine, maintaining at a normal level, was 27.67mol/L at the 7 days after operation, and 20.33 mol/L at the 14 days after operation, suggestting that renal function was normal. In allograft acute rejection group, the levels of serum creatinine increased gradually, after renal transplantation 7 day was 58 mol/L, 14 day 308 mol/L. The expression level of Fcγ receptor 1α mRNA in renal of sham operation group is relatively stable. In allograft acute rejection group Fcgr-1a mRNA levels were higher than those in the sham operation group, the level of expression of Fcγ receptor 1α mRNA in the kidney was 5.17after operation 7 days, 14 days 4.35, the Fcγ receptor 1α mRNA expression in allograft acute rejection group had significant change (P<0.05). 14 days after operation compared with the the allograft acute rejection group was no significant difference (P>0.05).

Conclusions: Renal Fcγ receptor 1α mRNA expression is up-regulated in the acute rejection, after immune inhibitors to down-regulated, suggesting that Fcγ receptor 1α play a certain role in the acute reaction of renal transplantation, in-depth understanding of its mechanism can provide experimental basis and ideas for clinical prevention.

PUB722

Proteinuria Associated with mTOR Inhibitor Use in Heart Transplant Recipients Negiin Pourafshar, Ashkan Karimi, Seyed Hossein Aalaei Andabili, Amir Kazory. *Univ of Florida, Gainesville, FL.*

Background: The mammalian target of rapamycin inhibitors (mTORi) have been used in patients with orthotopic heart transplant (OHT) to avoid the nephrotoxicity associated with calcineurin inhibitors use as well as prevention of cardiac allograft vasculopthy. Since proteinuria is a known complication of mTORi in renal transplant recipients, we sought to determine whether these agents are associated with increased urinary protein excretion in OHT patients.

Methods: This is a retrospective study of adult patients who received OHT at the University of Florida between January 2000 and December 2015. All patients who received mTORi, whether de novo or following conversion from a calcineurin inhibitor regimen, were included. The patients' clinical and laboratory information were reviewed and relevant data such as renal function and urinary protein excretion were recorded.

Results: There were a total of 411 OHT patients, of which 91 received mTORi (72 sirolimus and 19 everolimus). The mean age of recipients was 47.7 years and 80 % were men. mTORi was started de novo in 35% of the patients. The timing of the measurement of proteinuria was highly variable ranging from 4 weeks to 7 years after starting mTORi (median 15.7 months). mTORi therapy was associated with an increase in the urinary excretion of protein in 31 (34 %) patients. The mean albumin/creatinine and protein/creatinine ratios were as high as 1.11 mg/g and 2.5 g/g respectively, and 17% developed nephrotic-range proteinuria. Interestingly, all these patients had negative or unremarkable proteinuria before initiation of mTORi.

Conclusions: To our knowledge this is the largest study on the impact of mTORi on urinary protein excretion in the setting of OHT. Based on these findings, mTORi use can be associated with development of moderate to severe proteinuria in a significant subset of these patients. Serial assessment of urinary protein excretion should be integrated in the therapeutic protocols that include these agents in OHT. Future studies are needed to determine the risk factors associated with mTORi-related proteinuria and its potential impact on renal and cardiovascular outcomes.

PUB723

Successful Treatment of Severe Antibody Mediated Rejection in Simultaneous Liver Kidney Transplant: A Case Report Aditi Gupta, Abhisekh Sinha Ray, Anjushree Kumar, Sri G. Yarlagadda. *Internal Medicine, Nephrology, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Simultaneous liver-kidney (SLK) transplants are often performed in the presence of donor specific antibodies (DSAs) and/or positive cross match. The presence of DSAs is associated with increased risk of antibody mediated rejection (AMR). We report a case of severe AMR resistant to conventional therapy with steroids, plasmapheresis (PP) and intravenous immunoglobulin (IVIG) respond to Eculizumab, a monoclonal antibody against the terminal complement C5.

Methods: A 64 year-old woman with primary biliary cirrhosis and end stage renal disease received a SLK. She had class I DSA and a positive T cell flow crossmatch. She received induction with anti-thymocyte globulin and solumedrol and was maintained on mycophenolic acid, tacrolimus and prednisone. Since she had DSAs, she received PP and IVIG on post-operative day (POD) 1, 3 and 5, and was discharged on POD 6 with a serum creatinine of 0.9mg/dl. However, on POD 8, she presented with anuria, thrombocytopenia and anemia with laboratory evidence of hemolysis. The renal ultrasound did not show any obstruction or vascular compromise. Intravenous steroids, PP and IVIG were restarted for presumed AMR. She remained anuric after four sessions of PP. She was then treated with eculizumab. Her hemoglobin, platelet count and urine output improved after two doses of eculizumab (POD 12 and POD 19). With improvement in thrombocytopenia, a renal biopsy was performed on POD17 confirming AMR. There was no evidence of thrombotic microangiopathy in the biopsy.

Results: Serum creatinine started to improve and returned to baseline of 0.9mg/dl by POD 25. She received a total of four doses of weekly eculizumab. After 24 months, her renal function continues to remain stable with a serum creatinine of 0.8-0.9mg/dl and without any detectable proteinuria on dipstick.

Conclusions: SLKs are often performed despite presence of pre-transplant DSAs that are associated with early AMR. Treatment with a monoclonal antibody against the terminal complement C5 can prevent early graft loss from severe AMR.

PUB724

Combined Liver and Kidney Transplantation (CLKT) in Children with Autosomal Recessive Polycystic Kidney Disease: Indications, Postoperative Outcomes and Long-Term Results Rainer Büscher, Anja K. Büscher, Peter F. Hoyer. *Pediatric Nephrology, Univ of Duisburg-Essen, Essen, Germany.*

Background: Combined liver and kidney transplantation (CLKT) is a single case decision in children for special indications such as autosomal recessive polycystic kidney disease (ARPKD) or primary hyperoxaluria type 1 (PH1). So far, only limited data on long-term outcomes are available. We report on 8 children and adolescents with ARPKD who underwent CLKT in our hospital between 1999 and 2016.

Methods: Eight children were diagnosed with ARPKD based on clinical and genetic examinations. Children (5 male) were aged 10.0+3.7 years (3.8 to 14 years) at time of transplantation. Average wait time was 1.2±0.5 years (0.6 to 2.1 years); weight was 27.1±11.2 kg (14.0 to 45.4 kg) and length 123.9±23.0 cm (86.0 to 152.0 cm) prior to CLKT. Three patients received dialysis treatment before (1 HD, 2 PD) and preemptive transplantation could be performed in 5 patients.

Results: All 8 ARPKD patients received CKLT. Recurrent episodes of ascending cholangitis (1-2/year) were observed in 3 patients and 2 patients suffered from severe portal hypertension prior to transplantation. Seven patients received a full liver while split liver transplantation (segments 2-3) was performed in one case only. Cumulative time on ICU was 13.8±8.4 days (4 to 41 days). Sufficient renal function was achieved in 5 patients within 48 hours and 3 patients required intermittent HD following CLKT. Surgical complications requiring revision included bleeding in one patient. Cumulative survival of all patients within 5 years was 87.5%. One boy died within 4 weeks of transplantation due to prolonged sepsis, one adolescent died after 10 years. Acute liver rejection after 20 days was observed in one girl only and could be resolved by steroid therapy. So far, four patients could be transferred into adult care and remained on a stable liver and kidney function within an observation period of ten years.

Conclusions: CLKT can be performed in children with good outcomes and long-term survival rates are currently comparable to that of isolated liver or kidney transplantations. However, indications for CLKT must be decided on a case-by-case basis by a multidisciplinary team.

PUB725

Association between Kidney Transplantation and Diabetes Management in Recipients with Kidney Failure due to Diabetic Nephropathy

Samyuktha Balabhadra, Otto G. Schoeck, Vernon M. Chinchilli, Nasrollah Ghahramani. *Internal Medicine, Penn State College of Medicine, Hershey, PA.*

Background: It is important to determine if diabetes self-management improves after renal transplant as this impacts post-operative outcomes.

Methods: Glycemic control was retrospectively measured by hemoglobin-a1c (HbA1C), insulin, hypoglycemic agents, and hospitalizations due to diabetes or transplant complications in 79 transplant patients with renal failure due to diabetic nephropathy. Data was analyzed at initial evaluation, pre-, 1-year post-, and 2 years post-transplant using a linear mixed-effects model and 4 by 4 variance-covariance matrix. Comparison involved two years pre- versus post-transplantation mean. Subgroup analyses accounted for sex, race, education, and age.

Results: There was no statistical significance in pre- versus post-operative HbA1c (slope 0.28; 95% CI -0.14 to 0.71), insulin (OR 0.96; 95% CI 0.70 to 1.31), or antiglycemic agents (OR 0.86; 95% CI 0.62 to 1.19). Hospitalizations were significant (OR 2.26; 95% CI 1.55 to 3.30). There was no statistical significance for HbA1c (slope 0.28; 95% CI -0.14 to 0.72), insulin (OR 0.85; 95% CI 0.59 to 1.21), or antiglycemic agents (OR 0.83; 95% CI 0.57 to 1.20) when adjusted for demographic. Hospitalizations were significant (OR 2.20; 95% CI 1.46 to 3.31).

Conclusions: Hba1c, insulin, and antiglycemic agents were expected to significantly decrease post transplant, but they did not. Diabetes management appears to have remained status quo. Hospitalizations were increased pre- to post-transplant. Lack of optimization of HbA1c, insulin, and antiglycemic agents can be correlated with increased hospitalizations. Transplant management also utilizes immunosuppressive agents that are known to cause hyperglycemia, prompting further inquiry into any confounding due to these agents. No significant difference was found when data was adjusted for demographic, showing that post-transplant diabetes management is not an isolated issue. Further studies are needed to assess post-transplant hospitalization and its correlation with diabetes management – a factor that can reduce the risk of post-operative complications and thus reduce morbidity and mortality in these patients.

PUB726

Kidney Transplantation Outcomes among Patients with Different Causes of ESRD: Nephritic Syndrome versus Nephrotic Syndrome versus Primary Diseases of Non-Autoimmune Origin

Sophia Lionaki,[1] Ilias Makropoulos,[1] Nikolaos Altanis,[1] Konstantinos Panagiotellis,[1] Apostolis Pappas,[1] Aliki Iniotaki,[2] Georgios Zavos,[3] John Boletis.[1] *[1]Nephrology & Transplantation, Laiko Hospital, National & Kapodistrian Univ of Athens, Athens, Greece; [2]Pathology, Laiko Hospital, Athens, Greece; [3]Transplantation Unit, Laiko Hospital, Athens, Greece.*

Background: To compare kidney transplantation (KTx) outcomes of patients with different causes of end stage renal disease (ESRD).

Methods: We retrospectively compared the outcomes of KTx recipients with biopsy proven glomerular primary disease (PD), i.e nephritic and nephrotic syndrome, with those of KTx recipients with a PD of non-autoimmune origin. All patients were transplanted during the period 1/1985-1/2015 and had 1 year of follow up post KTx or more.

Results: 180 KTx recipients with biopsy proven glomerular PD were identified, and a control group of 110 patients with PKD, hypoplastic kidneys or obstructive uropathy, as PD was selected. The two groups were similar with respect to baseline characteristics at KTx, but patients with glomerular PD, had received more grafts from living donors than the controls (p=0.02), most of them (75.35%) had been treated with immunosuppressants prior to KTx (p<0.0001) and had donor specific antibodies (DSA) less frequently.

Parameter (mean±sd), %	KTx with glomerular PD N=180	Control group N=110	p-value
DSA pre-KTx	9	27.6	0.001
De novo DSA	15.6	18.4	0.68
Patients with acute rejection	9.6	8.1	0.68
Survival with functioning graft	77.6	95.3	0.0001
Graft survival	75.7	95.3	<0.0001
Graft survival (living donors)	80	100	0.02
Graft survival KTx after 2000	88.2	96.8	0.02
Ser creatinine at end fup (mg/dl)	1.7±0.9	1.39±0.6	0.007
Follow up time (months)	66±52.3	58±.4	0.14

Conclusions: KTx recipients with a glomerular PD had inferior renal function and worst graft survival, compared to those with a PD of non-autoimmune origin. The difference in graft function and survival remained significant when the analysis was contacted per decade of follow up or was limited to living donor KTx. No differences in KTx outcomes were found between patients with nephritic and nephrotic syndrome as PD.

PUB727

Early Recurrence of Diabetic Nephropathy in Kidney Allografts

Panupong Hansrivijit, Amy K. Mottl, Randal K. Detwiler. *Univ of North Carolina Kidney Center, Chapel Hill, NC.*

Background: Although recurrent diabetic nephropathy (rDN) after kidney transplant (KT) is reported in 70% of cases, most patients are diagnosed after 10 years. Early rDN within 5 years of kidney transplant is extremely uncommon.

Methods: Patients' demographics, clinical data and pathological reports of patients who had KT due to diabetic nephropathy at the University of North Carolina Kidney Center from March 2000 to October 2013 were reviewed. All patients received their allograft from non-diabetic donors. Diagnosis of rDN was made based on pathological classification. The recurrence rate of early DN, defined as pathological lesions present within 5 years post-KT, were reported.

Results: Of 156 patients with native DN, 4 patients (2.5%) had early rDN during median follow-up of 1.78 ± 4.57 years. These patients were described in details. Blood pressure and serum glucose were not well-controlled among these patients. HCV seropositivity was present in one patient. Some patients had rDN without significant proteinuria. In contrast, another patient presented with marked proteinuria. His biopsy revealed co-existing focal segmental glomerulosclerosis (FSGS).

Patient Demographics	Donor Type	Time-to-recurrence	BP (mmHg)	SCr (mg/dL)	UPC	Biopsy Results
55 yo WM	DD	2.5 yr	161/91	1.2	6.3	Moderate mesangial expansion with nodules, FSGS
54 yo WM	ECD	4.5 yr	128/60	1.8	0.2	Mild-to-moderate vaguely nodular mesangial expansion and arteriosclerosis
70 yo WM	DD	2.0 mo	151/69	2.5	1+ (dip-stick)	Segmental scarring, variable mesangial expansion, mild IFTA, mild arteriole hyalinosis
66 yo AAM	DD	1.0 yr	217/99	1.5	4.7	Moderate nodular mesangial expansion, mild IFTA

AA=African-American; BP=blood pressure; DD=deceased donor; ECD=extended criteria donor; IFTA=interstitial fibrosis and tubular atrophy; M=male; SCr=serum creatinine; UPC=urine protein:creatinine ratio; W=white.

Conclusions: To date, it is inconclusive to establish the recurrence rate of early DN after KT. A larger cohort is required to demonstrate the association between clinical characteristics and early recurrent diabetic nephropathy.

PUB728

Effect of Meeting Brain-Dead Donor Management Goals on the Development of Delayed Graft Function in Kidney Transplant Patients

Stéphanie Grondin,[1] Pierre Marsolais,[1] Martin Albert,[1] Anne-Marie Lagacé,[1] Isabelle Houde,[2] Anne Boucher,[1] Dana Baran,[3] Yannick Begin,[4] Melanie Masse,[4] Heloise Cardinal,[1] Josee Bouchard.[1] *[1]Univ of Montreal, Canada; [2]CHUQ, Canada; [3]CUSM, Canada; [4]CHUS, Canada.*

Background: A recent US study suggests that meeting several hemodynamic, respiratory and metabolic goals in organ donors (donor management goals, DMG) could reduce the incidence of delayed graft function (DGF) in kidney transplant recipients (KTR). We determined if DMG goals were met in our kidney donors and how this influenced the incidence of DGF.

Methods: We collected data on consecutive brain-dead donors and corresponding KTR from June 2013 to February 2015. Using guidelines from Transplant-Québec, we evaluated whether DMG were met at donor neurological death (DND), and before organ procurement (OP). We used generalized estimating equations to predict DGF, including DMG parameters and other risk factors for DGF (expanded-criteria donors (ECD), cold ischemia time (CIT), use of Lifeport perfusion, and recipient body mass index).

Results: The 69 consecutive donors had a median age of 50 years (IQR 31.5-62.0), and 36.2% were ECD donors. Mean serum creatinine was 71 (61-91) µmol/L, and Lifeport perfusion was used in 42.2% of cases. The percentages of DMG met increased over time, e.g. central venous pressure (51.2% at DND; 57.9% at OP), urinary output (63.2% at DND; 75.4% at OP) and appropriate use of vasopressors (70.6% at DND; 91.3% at OP). Median CIT was 14.0 hours (8.0-17.8). DGF, defined as dialysis during the first week after transplantation, occurred in 25.0% of 128 KTR. In univariate analysis, no variables significantly predicted DGF, including mean arterial pressure within targets (OR 0.69;95%CI 0.30-1.62). However, the use of Lifeport perfusion was significant in multivariate analysis (OR 0.37; 95%CI 0.15-0.93).

Conclusions: Although DMG were met in the majority of our cases, we were unable to show a significant relationship between this achievement and the occurrence of DGF in KTR. This may be due to small sample size and/or the fact that peri-operative and recipient factors may carry more weight in the context of good donor management.

PUB729

Thrombotic Microangiopathy after Transplant: Which Is the Role for Eculizumab? Ana Avila, Eva Gavela, Mercedes Gonzalez, Marco Montomoli, Asunción Sancho, Julia Kanter, Jose F. Crespo, Luis M. Pallardo. *Nephrology, H. Univ Dr Peset, Valencia, Spain.*

Background: We describe the prevalence and management of thrombotic microangiopathy (TMA) after transplant.

Methods: Retrospective study of the incidence of TMA after kidney transplant from cadaveric donors in our center between Jan-2010 and May-2016. We reviewed the risk factors associated to TMA, management and the evolution after treatment.

Results: 315 kidney transplants were performed. We found 13 TMA cases (4.1%), 8 males. Recipient age was 55 years (r:30-67). Donor age: 42,5 years. Eleven patients presented TMA early after transplant (mean time: 10 days; r:3-33), 2 patients presented late TMA (7 months and 8 years after transplant). Three patients presented TMA in the context of severe intraabdominal bledding, 3 related to AMR, 2 after transplant with a non heart beating donor, 4 to drug induced TMA and one, aHUS relapse. Ten patients presented hematological manifestations and kidney function impairement. A kidney biopsy, performed in 11 patients, showed TMA. ADAMTs13 activity deficiency was ruled-out. The patients were managed controlling TMA risk factors (AMR treatment, drugs withdrawal). Ten required plasma exchange (median 4.5 sessions). In 6/10 patients diagnosed after 2012, after non response to previous measures, eculizumab was started. Mean time to eculizumab treatment was 6 days. A complete hematological response was seen in all of them, but 4 patients loss their grafts. Most of the remaining patients (8/9) improved kidney function (mean Cr 2.45 mg/dl, r:0.9-5.22) at the end of the follow-up (mean follow-up after TMA was 9.3 months (r:1-23). The duration of eculizumab treatment was 133 days (7-240). In 7 patients, a complement system genetic study was performed, showing antiFH antibodies in one case and CFI mutation in another.

Conclusions: TMA is a rare but severe disease that can lead to graft loss or to reduced kidney function. It is associated to several risk factors presented in kidney transplant (AMR, drugs). In patients who do not respond to classic measures (drug withdrawal, plasma exchange) eculizumab can reverse TMA and improve kidney function.

PUB730

Chronic Kidney Disease after Living Kidney Donation: A Single Center Cohort Suthanit Laowalert, Pisut Katavetin, Yingyos Avihingsanon, Kearkiat Praditpornsilpa, Natavudh Townamchai. *Dept of Medicine, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Post kidney donation outcomes in nonwhite living kidney donors (LKDs) are lacking. This is the first study of Thai population to assess the incidence of chronic kidney disease (CKD) after donor nephrectomy and estimated glomerular filtration rate (eGFR) for donation.

Methods: A retrospectively cohort of all 205 LKDs in King Chulalongkorn Memorial Hospital between 1999-2014 were retrieved to ascertain development of CKD stage 3 or higher. The eGFR was determined by the CKD-EPI.

Results: 143 of 205 records were available, mean age at donation was 37.0 years. 18 of 143 (12.6%) had CKD stage 3 after median follow-up duration of 4 years (range 1-17 years). Predonation eGFR was an independent risk factor in developing CKD stage 3. The risk was significantly increased in donor with eGFRs 85-90 mL/min/1.73m^2 and eGFRs<85 mL/min/1.73m^2 compared with eGFRs>90 mL/min/1.73m^2 (HR 10.3, p<0.05, HR 13.7, p<0.001, respectively).

Table 1 Cox proportional hazard analysis of clinical risk factors for development of CKD in 143 LKDs

Variable	Univariate		Multivariate	
	Hazard ratio (CI)	P-value	Hazard ratio (CI)	P-value
Male gender	0.57 (0.23-1.47)	0.235		
Age	1.087 (1.029-1.148)	0.003	1.037 (0.98-1.1)	0.231
Predonation eGFR <85 ml/min/1.73m2 85-90 ml/ min/1.73m2 >90 ml/min/1.73m2 (reference)	17.49 (5.46-56.06) 13.9 (3.44-56.20) -	<0.001 0.046 -	13.65 (4-46.61) 10.32 (2.39-44.45) -	<0.001 0.002 -
BMI	1.08 (0.962-1.218)	0.189		
UPCR	19.68 (0.539-718.70)	0.105		
SBP	1.036 (0.994-1.08)	0.093		
DBP	1.029 (0.97-1.092)	0.344		

Age at donation was associated with the development of CKD stage 3 only in univariate analysis (HR 1.09, P=0.003). There were 17 (11.9%) and 3 (2.1%) donors developed hypertension and diabetes mellitus. One donor (0.7%) experienced ESRD from secondary FSGS.

Conclusions: Incidence of CKD stage 3 and ESRD of kidney donor were 12.6% and 0.7%, respectively. Predonation eGFRs<90 mL/min/1.73m^2 was a strong determinant of development of CKD, which led to the extended thresholds of eGFR for a donor candidate.

PUB731

Donor Specific Antibodies in Living Related Renal Transplant Recipients Anil Bhalla. *Nephrology, Sir Ganga Ram Hospital, New Delhi, India.*

Background: The clinical impact of anti-HLA antibodies is one of the major areas of research in renal allograft transplantation and a lot of advances have taken place in the methodology of detection of these antibodies. Luminex Platform is presently the favoured technology fordetection of HLA antibodies in addition to the CDC crossmatch (XM) which is considered the gold standard. Pre transplant (Tx) Luminex DSA crossmatch has been recently introduced in India for detecting antibodies that are missed by CDC XM.

Methods: The present study includes patients from January 2012 to December 2013 with one year follow up post kidney transplant. Pre-transplant sera from 46 renal transplant recipients with a negative CDC crossmatch were assessed for donor-specific antibodies (DSA) detection on Luminex Platform using Lifecodes DSA kit (Immucor). The serum samples with DSA (HLA-Class I or II or both) of MFI (mean fluorescent intensity) value more than 500 was considered to be positive. The results were then correlated with the clinical outcomes of the renal allograft.

Results: DSAs were found in 19 out of 54 recipients (35.1%). Of the nineteen DSA positive patients, 5 patients (27.27%) developed acute graft rejection. All these 5 patients had positive C4d staining in their biopsies and the MFI value of the DSA on Luminex platform was found to bemore than 1000. The remaining 14 DSA positive patients showed no rejection and had stable graft function. The MFI value of the DSAs in these patients ranged from 500-1000. All the 35 DSA negative patients (64.8%) were also having stable graft function in one year follow up.

Conclusions: There was a higher incidence of AMR in patients with pre-transplant DSA despite a negative CDC crossmatch. The present study clearly establishes that the Luminex DSA crossmatch is helpful for predicting post transplant graft outcome or rejection. The laboratory cut off value of the MFI for positive DSA was increased from 500 to 1000. However, the clinical impact of the pre-Tx DSAs detected by Luminex techniques has to be fully evaluated in terms of graft survival and more r etrospective studies with larger sample size.

PUB732

Median Arcuate Ligament Syndrome at 1 Year Follow-Up in a Living Kidney Donor Sara J. Fine, Jeremy F. Wright, Jahan Montague, Marie A. Sosa. *Nephrology, Univ of Massachusetts, Worcester, MA.*

Background: Median arcuate ligament syndrome (MALS) is a rare disorder of unknown etiology caused by celiac artery compression from the fibers of a low lying median arcuate ligament (1). Symptoms include postprandial abdominal pain and weight loss that resolve with celiac artery decompression, MAL ligation, and celiac ganglionectomy (2). 1.Dunbar JD, Molnar W, Beman FF, Marable SA. Compression of the celiac trunk and abdominal angina. *Am J Roentgenol Radium Ther Nucl Med.* 1965 Nov;95(3):731–744. 2.Jiminez JC, Hariander-Locke M, Dutson EP. Open and laparoscopic treatment of medican arcuate ligament syndrome. J Vasc Surg 2012;56:869.

Methods: A 30-year-old woman undergoing routine evaluation for live kidney donation to her father with end-stage renal disease was found to have a small right kidney lesion. After extensive discussion of possible risks, both patients elected to proceed. The donor underwent right nephrectomy. A 1cm exophytic chromophobe renal cell carcinoma containing negative margins was excised prior to successful recipient transplantation. The donor had no immediate post-op complications, but appeared notably thin at 1 year follow-up. She reported an unintentional 21lbs weight loss with symptoms of severe right flank pain, worse with meals, that prevented her from maintaining a normal diet. Work-up revealed expected range creatinine, no proteinuria, normal LFTs, AFP, CEA-125 and CA19-9. She was seen by oncology, urology, gastroenterology and endocrinology. Contrast imaging of her chest, abdomen and pelvis showed no evidence of solid masses. However, superior indentation of her proximal celiac artery with 80-90% focal stenosis was noted as a new finding, absent on prior studies. A diagnosis of MALS was posited and subsequently confirmed by elevated celiac artery expiratory flow velocities on ultrasound (1). 1. Erden A, Yurdakul M, Cumhur T. Marked increase in flow velocities during deep expiration: A duplex Doppler sign of celiac artery compression syndrome. Cardiovasc Intervent Radiol. 1999;22(4):331.

Conclusions: This case reports the development of MALS diagnosed one year post kidney donation and reinforces the need for close, thorough follow-up after donation.

PUB733

The Effect of Ureteral Stents Post Kidney Transplant on the Incidence of Pyuria, Bacteriuria, and Hospitalization Niralee Patel,[1] Ibrahim M. El-Ali,[1] John F. D'Avella.[2] *[1]UCONN Health Center, Farmington, CT; [2]Hartford Hospital Transplant Center, Hartford, CT.*

Background: In an effort to decrease the incidence of ureteral complications, many programs place ureteral stents in patients post kidney transplant. Patients are routinely screened for asymptomatic bacteriuria up until three months after transplantation. It is unclear what effect the presence of a stent has on the incidence of pyuria, bacteriuria, and hospital admissions. It is thought that urinary tract infections are more common than the general population in post transplant patients; furthermore, they are also associated with higher mortality.

Methods: As a quality project, we looked at the incidence of pyuria (>10 WBC/HPF), bacteriuria (>100,000 colonies of a single bacteria) in transplanted patients during 2014. All patients had ureteral stents for 4 to 6 weeks post transplant. 60 patients were

transplanted, of which 5 were excluded because of age less than 18 years, acute rejection, or anatomical ureteral problems; thus a total of 55 patients were studied. 45% were female and 55% were male.

Results: We found that pyuria and bacteriuria are unreliable predictors of a true symptomatic urinary infection. 87% of our patient sample had pyuria, of which only 33% developed bacteriuria. We additionally found that in patients with bacteriuria, 50% developed symptoms that require treatment. Among the patients that require treatment, only 25% had a ureteral stent in place (Figure 1).

Conclusions: In summary, our study indicates that ureteral stents post renal transplant do not have a higher incidence of true symptomatic infection or hospitalization compared to patients without a stent. Further studies are useful to confirm these findings.

PUB734

Impact of Conversion from Original MMF to Generic MMF in Kidney Transplant Recipients: A Single-Center Experience Hajime Hirano,[1] Haruhito Azuma,[1] Hideki Matsumura,[3] Hideaki Shima,[2] Tatsuhiko Mori,[2] Akira Ashida.[3] *[1]Blood Purification Center, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Dept of Nephrology, Osaka Medical College, Takatsuki, Osaka, Japan; [3]Dept of Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan.*

Background: Recently, more and more generic drugs have been used for immunosuppressive drugs in the field of organ transplantation. Some reports have indicated that blood concentration of most generic drugs is difficult to maintain stability, and it may cause the difference in graft survival of transplanted organs between original drugs and generic drugs. In this article, we report the cases could not maintain blood concentration of generic drugs of mycophenolate mofetil (MMF).

Results: In 4 cases out of 5 cases that we had to change original MMF to generic MMF, there were cases that blood concentration level was not stabilized. There were possibility that the lowered blood concentration level of MMF caused a rejection, in two cases. Mean MMF trough level wase decreased from 3.6±1.9μg/ml to 0.6±0.4μg/m. Due to the early detection, it did not become severe or failure of graft function, however, we cannot deny the possibilities that side effects were increased and rejection rose. In these cases, we discontinued to use the generic drugs thereafter due to unstable plasma concentration of MMF.

Conclusions: Some reports have indicated that failure to maintain plasma concentration of MMF leads to rejection. Therefore, maintenance of effective plasma concentration and prevention of rejection are essential to long-term graft survival in kidney transplant. Conversion to the generic drug,it may cause differences in effects and absorption. If the generic drug should be used, patients should be closely monitored.

PUB735

Allograft Rejection in the HIV Infected Kidney Transplant Recipient Adriana Dejman, Juan E. Kusnir, Juan Camilo Duque Ballesteros, David Roth. *Nephrology, Univ of Miami, Miami, FL.*

Background: Excellent graft survival outcomes have been reported in HIV patients on anti-retroviral therapy with undetectable viral loads and CD4 count >200 at time of transplant. Prior studies also observed higher incidences of acute rejection with limited data on variables that associate with this outcome.

Methods: Retrospective chart review for patients with HIV who had a kidney transplant between 2001-2014. A multivariate logistic regression model adjusted for demographics, co-morbidities, induction immunosuppression (IS), chronic IS with steroids, presence of drug-drug interaction (DDI) between protease inhibitors (PI) and calcineurin inhibitors (CNI), type of transplant, initial graft function (immediate/IGF, slow/SGF or delayed/DGF), calculated panel reactive antibodies (cPRA), histologic type of rejection and donor specific antibodies (DSA) was used.

Results: 58 consecutive patients were included and divided into Group A, no-rejection (N=41, 70.7%) and Group B, biopsy proven rejection (N=17, 29.3%). Mean age was 52.1 ± 9 in A and 53.3 ±8 in B. Six patients (14.2%) in A had hepatitis C. Induction IS included high dose IV steroids (S), antithymocyte globulin (T) and one of two IL2 receptor blockers: basiliximab (B) or daclizumab (D). STB was used in 65.8% of A and 58.8% of B. Chronic IS with steroids was 82.9% in A and 94.1% of B and 39% in A had a DDI between PI and CNI compared with 47% B. In A, 65.8%, 14.6% and 19.5% had IGF, SGF and DGF respectively versus 58.8%, 17.6% and 23.5% in B. In the Cox model, no variables were statistically different between groups. In B, interval (mean) from transplant to rejection was 808 days; 41.2% had T cell rejection, 23.5% had antibody-mediated rejection and 35% was mixed. cPRA was available for 15/17 of B: 86.6% had 0% and 2 were < 80%. At time of rejection 6/17 had DSA: 5/6 pre-existing and 1/6 *de novo*.

Conclusions: We were unable to identify variables associated with the higher incidence of allograft rejection. However, outcomes are excellent and justify continuing to offer kidney transplants to well-managed HIV infected patients. Intense monitoring of these patients is critical because of the significant DDIs and higher incidence of rejection.

PUB736

Living Donor Kidney Transplantation in Atypical Hemolytic Uremic Syndrome: Favorable Outcome without Prophylactic Therapy Jacobien Verhave,[1] Nicole Van De Kar,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Paediatric Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: In atypical hemolytic uremic syndrome (aHUS), kidney transplantation has become feasible with the development of the complement inhibitor eculizumab. Many advocate the use of prophylactic therapy to prevent recurrent disease. Living kidney donation may be associated with lower recurrence rate.

Methods: Since 2011, ten aHUS patients were transplanted with a living donor. There was no prophylactic therapy and the protocol emphasized the reduction of triggers for aHUS recurrence (low dose tacrolimus, blood pressure control, statin therapy).

Results: The table shows patient characteristics. Median follow up was 2.6 years. Thus far, only one patient (no 10) had a recurrence of aHUS and is currently treated with eculizumab. One patient (no 6) had BK nephropathy successfully treated by tapering immunosuppression. One patient (no 8) had type 2a rejection without signs of thrombotic microangiopathy on biopsy. Renal function recovered on methylprednisolone and ATG. One patient (no 9) had presumed rejection and was treated with methylprednisolone. At the end of follow-up mean eGFR was 51ml/min/1.73m2, and proteinuria was negligible.

Conclusions: Kidney transplantation in aHUS is safe without eculizumab prophylaxis by using living donors and a protocol that reduces triggers for aHUS recurrence.

patient	gender	age at Tx	genetic mutation	Previous Tx with aHUS recurrence	Current eGFR	Follow-up (months)

PUB737

Hepatitis C Virus in Kidney Transplant Recipients: A Problem on the Path to Extinction Carmen Gonzalez Corvillo, Alejandro Suarez Benjumea, Gabriel Bernal Blanco, Miguel Angel Gentil Govantes. *Nephrology, Hospital Univ Virgen Rocio, Sevilla, Spain.*

Background: HCV still has significant prevalence in kidney transplant(KT)recipients and is related to poor recipient and graft survival.The new antivirals are leading to a radical change in the problem.

Methods: We study HCV prevalence at time of transplant and in follow-up patients,the way RNA+ cases are handled and the results of direct-acting antivirals(DAA).

Results: From 1978 to 2015,2001 transplants had been performed in our center. Serology was present in 1880cases,being + in 13.4%.1195 were still being monitored by our service,60(5%)were HCV+/RNA+ in 45 cases(3.6%).Of these 45 patients:26 were being treated,6 were about to begin treatment,1 was awaiting a new DAA for low GFR,3 were being evaluated to select the ideal DAA,2 excluded due to high comorbidity,2 denied to be treated and 2 needed to return to hemodialysis.Clinical characteristics:4combined liver-kidney transplants;mean age 50.0±9yo;38% were diabetic;average time on replacement renal therapy:255±130months;average time after KT:145±125months;29% showed advanced fibrosis;genotype prevalence:1b(67%);1a(9.5%);3(14%);4(9.5%);The rate of previously failed treatment was 35%.The data were analyzed on May 31st,2016:21 patients had completed treatment(84%).2 patients had to interrupt DAA(8%),one due to hepatotoxicity and another as a result of a liver transplant.In every case graft maintained function and negativization of viral replication occurred in 100% of cases.The rate of side effects has been low,main side effect:anemia related to Ribavirin.It has frequently been necessary to adjust immunosuppression treatment with higher doses of tacrolimus.Renal function has remained stable(pretreatment serum Cr:1.39mg/dl vs at 1st month:1.39mg/dl).

Conclusions: The prevalence of HCV in KT is about to decrease over time as a result of lower incidence and negative selection.DAA lead us to the virtual eradication of this major negative factor that HCV poses for our patients.Otherwise,the treatment of these patients is complicated because of the use of multiple medications and immunosuppression,which is why it requires close collaboration between nephrologists and hepatologists.

PUB738

Cost-Effectiveness of Machine Perfusion Use in a Brazilian Kidney Transplantation Program Ana Carvalho Matos, Daniel Tavares Malheiro, Silvia Regina Morgado, Eduardo J. Tonato, Milton Borrelli, Mario Nogueira Junior, Marcelino Souza Durao, Lucio Roberto Requiao-Moura, Alvaro Pacheco-Silva. *Renal Transplant Unit, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: The incidence of DGF is one of most important problem in kidney transplant in Brazil: higher than 60%. Static cold storage (CS) is the standard method of preservation performed by governmental allocation. Our center has used perfusion machine (PM) as preservation method since 02/2013, however we have only used PM after long time in CS. Aim: to determine the relative cost-effectiveness between renal machine perfusion (MP) after long CIT in CS and standard CS preservation.

Methods: Probabilistic decision tree was developed to compare MP versus CS and the results and probabilities of our own center were used to construct this model. The model estimated Economic Impact (EI=MPcost–CScost) and Incremental Cost-Effectiveness Ratio (ICER=EI/[Effectiveness MP – Effectiveness CS]). Direct and indirect medical costs were considered and sensitivity analysis was performed with variations of several parameters. IGF and DGF were considered as outcomes.

Results: MP group had TIF 11 hours higher than CS, despite of this the incidence (79.2% vs. 61.1%, p=0.02) and length of DGF (9 vs. 5 days, p<0.001) were reduced significantly, leading to a reduced length of hospital stay (18 vs. 13 days, p<0.001). The mean cost of each transplant was: MP=U$12,588.15 and CS= U$16,660.83.The budget impact was U$ -4,078.28. ICER for each DGF avoided saved was U$ -226.26. The variables that most impacted the costs were length in hospital and length of DGF.

	Prob-ability	Cost (U$)	Probability* Cost (U$)	Cost (U$)	Cost MP-CS (U$)	Effec-tiveness	ICER (U$)
MP IGF	0.39	10,633.02	4,146.88	12,588.15			
MP DGF	0.61	13,838.15	8,441.27				
CS IGF	0.21	11,090.32	2.328.97	16,660.83	4,072.68	18%	-226.26
CS DGF	0.79	18,141.60	14.331,86				

Conclusions: The use of MP after long CS preservation was cost-effective. This is the first economic study performed in Brazil and will enable other transplant centers to decide on incorporating the renal MP as a strategy to prevent DGF and reduce costs.

PUB739

Association of Childbearing Age with Live Birth after Kidney Transplantation: A Retrospective Single-Center Cohort Study Yasushi Ohashi,[1] Yoshihiro Itabashi,[2] Masaki Muramatsu,[2] Yuko Hamasaki,[2] Seiichirou Shishido.[2] *[1]Nephrology, Sakura Medical Center, School of Medicine, Toho Univ, Chiba, Japan; [2]Nephrology, Omori Medical Center, School of Medicine, Toho Univ, Tokyo, Japan.*

Background: Despite the restoration of fertility after kidney transplantation, the live birth rate after kidney transplantation is markedly lower than that in the general population. Our objective is to determine the reasons for this discrepancy.

Methods: With a total of 315 women who underwent kidney transplantation from 1983 to 2015 (a median of age at kidney transplantation [10th–90th percentile] of 32 years [7–55 years]), we experienced 10 abortions and 21 live births from our 23 recipients and 2 abortions and 7 live births in 7 recipients from other transplant center. Age, date of kidney transplantation, underlying disease, modality of dialysis therapy, donor type, type of fertilization, and pregnancy complication were evaluated at childbearing age, which was defined as those aged between 15 and 49 years old.

Results: The 223 recipients who had undergone kidney transplantation at our hospital were between the ages of 15 to 49 years old as of March, 2016. The live birth rate was 8.9 per 1,000 women transplant recipients-childbearing age year. Seven recipients received either treatments of artificial insemination or in vitro fertilization. Average age at pregnancy was 33.2 ± 3.2 years old, and the periods of childbearing age in post-transplantation were longer in recipients with live births than those with no live births (14.1 ± 7.1 vs. 9.9 ± 7.3 years, $P < 0.05$). In 42.9% of them, pregnancy-induced hypertension was observed in the last trimester of pregnancy. The gestational age and the average birthweight were 32.8 ± 5.0 months and 2,184 ± 632 g, respectively. During a median of 14.5-year follow-up period, one graft of them was lost; that incident rate was 2.5 per 1,000 women transplant recipients-year.

Conclusions: Recipients may be concerned about various aspects of having children. The shorter periods of childbearing age in post-transplantation may disrupt pregnancy,even if fertility is restored. Although the frequency of pregnancy complications should not be overlooked, childbirth do not influence long-graft survival.

PUB740

The Risk Factors of Mammalian Target of Rapamycin Inhibitor Associated Post-Transplant Proteinuria Lee-Moay Lim,[1] Hung-Tien Kuo.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [2]Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: The Mammalian Target of Rapamycin Inhibitors (mTORI) has been associated with an increased incidence of proteinuria after kidney transplantation as compared to other immunosuppressive agents, yet the precise mechanism remain unclear. The objective of this study was to investigate the risk factor for proteinuria after mTORI treatment in kidney transplant recipients.

Methods: A total of 123 kidney transplant recipients following up in a medical center in Southern Taiwan from January 1999 till April 2016 were included. We examined the risk factor for mTORI associated proteinuria using multivariate logistic regression analysis. P<0.05 was considered as statistically significant.

Results: The mean transplant days before the initiation of mTORI was 638 days. Patients with higher body mass index (BMI) and hyperlipidemia have higher percentage of proteinuria after mTORI use**.**

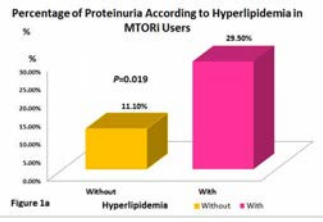

Figure 1a

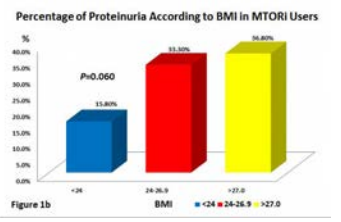

Figure 1b

In univariate analysis, BMI >27 kg/m² (OR=3.111, *P*=0.047) and hyperlipidemia (OR=3.345, *P*=0.024) were associated with proteinuria after mTORI use. After adjusting for confounding factors, hyperlipidemia (adjusted OR=3.740, *P*=0.026) and BMI at 24-26.9 kg/m² (adjusted OR=4.7, *P*=0.021) were significantly associated with risk of proteinuria.

	Adjusted OR (95% CI)	***p* value**
Age at mTORi use	0.957(0.917-0.998)	0.042
Male	1.112(0.415-2.983)	0.833
BMI <24	1	1
24-26.9	4.700(1.265-17.475)	0.021
>27	2.918(0.844-10.088)	0.091
Hyperlipidemia	3.740(1.167-11.983)	0.026

Conclusions: Hyperlipidemia and obesity at the initiation of mTORI treatment were strong predictors for proteinuria. Earlier identification of these risk factors may assist physician to decide the best candidate for mTORI conversion in order to optimize transplantation outcomes.

PUB741

Association of Serum Soluble α-Klotho, Fibroblast Growth Factor 23, and 25 (OH) Vitamin D with Kidney Function in Japanese Kidney Transplant Recipients Makoto Tsujita.[1,2] *[1]Transplant Surgery, Nagoya Daini Red Cross Hospital; [2]Nephrology, Nagoya Univ School of Medicine.*

Background: There are many reasons of deteriorating graft kidney function in kidney transplant recipients. Any marker for predicting kidney function is needed to prevent.

Methods: This was a retrospective cohort study. Forty-seven consecutive patients were enrolled in this study at Nagoya Daini Red Cross Hospital in 2011.Serum intact fibroblast growth factor (FGF) 23, soluble α-Klotho(sαKlotho), 25(OH)Vitamin D[25(OH)D], estimated glomerular filtration (eGFR), and other clinical parameters at 1 year and eGFR at 3 years after kidney transplantation(KTx) were measured to investigate the usefulness of these markers for predicting kidney function. We also evaluated α-Klotho expression in kidney biopsy samples at 1 year after KTx.

Results: The median serum sαKlotho, intact FGF23, 25(OH)D were 516.3 pg/ml, 58.7 pg/ml, and 5.7 ng/ml, respectively. Serum sαKlotho levels were associated with difference between eGFR at 1 year and at 3 years after KTx (ΔeGFR) (*r = 0.37, p= 0.01*). Multivariate regression analysis revealed that serum sαKlotho was the strongest predictor of kidney function. Serum sαKlotho levels were associated with α-Klotho expression in kidney biopsy samples (*r = 039, p= 0.007*) .

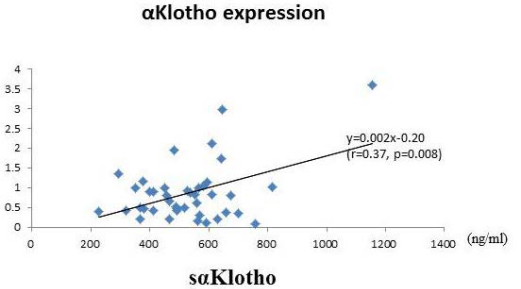

Fig. 1 the relationship between αKlotho in kidney samples and serum sαKlotho levels

Conclusions: Serum sαKlotho may be a good marker for kidney function in Japanese kidney transplant recipients.

PUB742

Collectin Liver 1 and Collectin Kidney 1 of the Lectin Complement Pathway Are Associated with Mortality after Kidney Transplantation
Julia Smedbråten,[1,2] Solbjørg Sagedal,[1] Anders Hartmann,[2,3] Steffen Thiel.[4] *[1]Dept of Nephrology, Oslo Univ Hospital Ullevål, Norway; [2]Faculty of Medicine, Univ of Oslo, Norway; [3]Dept of Transplant Medicine, Oslo Univ Hospital Rikshospitalet, Norway; [4]Dept of Biomedicine, Aarhus Univ, Denmark.*

Background: Kidney recipients have significantly higher mortality compared to the general population. The innate immune system may play an important role during periods with suppression of the adaptive immune system. In the present study, the association of two soluble pattern recognition molecules of the lectin complement pathway, Collectin liver 1 (CL-L1) and Collectin kidney 1 (CL-K1), with long-term graft and recipient survival were investigated.

Methods: The levels of CL-L1 and CL-K1 were measured at the time of transplantation in 382 patients (³17 years) transplanted in 2000-2001. The cohort was subsequently followed until December 31, 2014. Data on patient and graft survival were obtained from the Norwegian Renal Registry.

Results: Both high CL-L1 (≥376 ng/ml) and high CL-K1 (≥304 ng/ml) levels were significantly associated with overall mortality in multivariate COX analyses with HR 1.50, 95 % CI 1.09-2.07, p=0.013 and HR 1.43, 95% CI 1.02-1.99, p=0.038, respectively.

				Multivariable Cox regression analyses			
Variable	HR	95%CI	p	Variable	HR	95%CI	p
High CL-L1	1.50	1.09-2.07	0.013	High CL-K1	1.43	1.02-1.99	0.038
Recipient age, per year	1.07	1.05-1.08	<0.001	Recipient age, per year	1.07	1.05-1.08	<0.001
Diabetic nephropathy	2.17	1.39-3.39	<0.001	Diabetic nephropathy	2.00	1.23-3.15	0.003

Moreover, high CL-K1 levels were significantly associated with cardiovascular mortality. No association between measured biomarkers and death censored graft loss was found. Finally, there was a significant correlation between these two collectins, r=0.83 (95%CI 0.80-0.86).

Conclusions: CL-L1 and CL-K1 were significantly associated with mortality in kidney transplant recipients, when adjusted for other relevant risk factors for mortality. No association with death censored graft loss was found. The levels of those two proteins were significantly correlated.

PUB743

Donor Specific Antibody Kinetics in Patients with Antibody Mediated Rejection Treated with Plasmapheresis and Bortezomib
Lucio Roberto Requiao-Moura,[1] Margareth Afonso Torres,[2] Araci M. Sakashita,[3] Mauricio Fregonesi Rodrigues Silva,[1] Ana Carvalho Matos,[1] Alvaro Pacheco-Silva.[1] *[1]Renal Transplant Unit, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [2]Histocompatibility Laboratory, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [3]Blood Bank, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: The best choice to treat acute antibody mediated rejection (AMR) is not supported by several evidences, and recently the interest in drugs as Bortezomib has improved. Aim: Evaluted the kinetics of donor specific antibody (DSA) in patients with AMR who were treated with Plasmapheresis (PP) or PP and Bortezomib.

Methods: The diagnose of AMR was performed according Banff'07. The treatment consisted of PP added only one dose of Imunoglobulin (0.4g/kg) following the last PP. Bortezomib was used in patients who did not reduce the highest DSA or sum of DSA more than 50% after 6-12 PP. DSA was detected by Luminex and expressed in mfi. The antibodies kinetics were evaluted using three variables: the highest DSA for each patient, all DSA and sum of DSA for each patient.

Results: AMR incidence was 4.2% (N=32), time to diagnose was 14 days and 81.5% patients had diagnose in the first month posttransplant. The changes in biopsies were: ATN-30%, PTC- 58.8%, and C4d was negative in 20%. More than one DSA were indetified in 43.7% of patients. The number of PP was 7.9±6.3 (6[1-24]). Regarding total treatment we observed significant reduction in all variables of kinetics: highest DSA from 6.436 to 1.175 (p<0.001); all DSA (N=56) from 4.872 to 1.087 (P<0.001); sum of DSA from 7.395 to 1.966 (p<0.001). Bortezomib was used in 22% of patients where 57.1% had submitted to desensitization treatment. In these patients PP doesn't change DSA kinetics: all DSA (n=19) from 3,931 to 3,275 and sum of DSA (n=7) from 14,657 to 12,896. After Bortezomib we observed a significant reduction in DSA kinetics to 1,308 P=0.008) and 2,057 (p=0,006), respectivly. One year renal function, graft and patient survival were 1.63±0.80 mg/dl, 81.1% and 100%, respectively.

Conclusions: The AMR treatment using PP was efetive in more than 80% of patients and we observed a good response with Bortezomib in patients who had not a satisfactory response to PP.

PUB744

Renal Sulfate Reabsorption and Long-Term Outcome in Renal Transplant Recipients
Isidor Minovic,[1] Adrian Post,[1] Else van den Berg,[1] Harry Van Goor,[2] Stefanie J.W.H. Oude Elferink,[3] Gerjan Navis,[1] Ido Peter Kema,[4] Stephan J.L. Bakker.[1] *[1]Nephrology, UMCG, Netherlands; [2]Pathology, UMCG, Netherlands; [3]FrieslandCampina Inst, Amersfoort, Netherlands; [4]Lab. Medicine, UMCG, Netherlands.*

Background: Sulfate is the fourth most abundant anion in human plasma, which is freely filtered by the kidneys. Under normal conditions, tubular sulfate reabsorption works at near maximal rate, with up to 90% of the filtered sulfate being reabsorbed in the proximal tubule. When plasma sulfate levels increase, such as during chronic renal failure, the filtered load quickly exceeds the maximal tubular reabsorption and non-reabsorbed sulfate is excreted at high rate in the urine. We aimed to investigate the rate of renal sulfate reabsorption in RTR and potential long-term consequences of variation therein.

Methods: Plasma sulfate was measured in a well-characterized prospective RTR cohort by a validated ion-exchange chromatography assay and RSR was defined as 1-fractional sulfate excretion. Nutritional intake was assessed by validated food frequency questionnaires.

Results: We included 707 RTR (57% male, age 53±13 y, eGFR 52±20 ml/min/1.73m2, and median plasma sulfate 0.42 [IQR 0.35-0.54] mM) and 330 healthy controls (47% male, age 54±11 y, eGFR 91±14 ml/min/1.73m2, and median plasma sulfate 0.27 [IQR 0.24-0.31] mM). Median RSR was 56% [IQR 48-64%] and 65% [IQR 47-76%] for RTR and controls, resp. (P<0.001). In RTR at baseline, RSR was positively associated with BMI, hs-CRP, heart rate, NT-proBNP, and plasma sulfate (all P<0.05). RSR was inversely associated with intake of cysteine, methionine, water, alcohol, and bread (all P<0.01), but not eGFR (P=0.56). After median follow-up of 38 [32-46] months, 81 (12%) RTR died and 45 (6%) developed graft failure. RSR was associated with all-cause mortality (HR 1.67 [95% CI 1.29-2.14]), but not graft failure (HR 1.14 [0.82-1.59]), independent of potential confounders, including age, sex, BMI, and eGFR (HR 1.60 [1.26-2.04]).

Conclusions: RSR is lower in in RTR than controls. RSR in RTR is related to cardiovascular risk factors and dietary intake of sulfate sources. Higher RSR is associated with increased mortality risk in RTR. Renal sulfate handling seems of considerable pathophysiological interest in RTR.

Outcomes of Renal Transplantation in Alport Syndrome Compared with Other Forms of Renal Disease
Yvelynne P. Kelly,[1] Susan Louise Murray,[2] Sam Kant,[3] Mohammed A. Kaballo,[4] Brendan Doyle,[5] Anthony M. Dorman,[5] Patrick O'Kelly,[1] Peter J. Conlon.[1] *[1]Dept of Nephrology, Beaumont Hospital, Dublin 9, Ireland; [2]Dept of Nephrology, Univ Hospital Galway, Galway, Ireland; [3]Dept of Nephrology, Cork Univ Hospital, Cork, Ireland; [4]Dept of Nephrology, Univ Hospital Limerick, Limerick, Ireland; [5]Dept of Pathology, Beaumont Hospital, Dublin 9, Ireland.*

Background: Alport syndrome is an inherited renal disease characterised by haematuria, renal failure and hearing loss. Patients with Alport syndrome who undergo renal transplantation have been shown to have overall survival and graft survival rates similar to or better than those of patients with other renal diseases, though studies have varied in the reporting of this outcome.

Methods: In this national retrospective case series, based in Beaumont Hospital, Ireland, we examine the transplant-related outcomes of all patients with end-stage kidney disease caused by Alport syndrome that were diagnosed there over the past 35 years. These outcomes are compared with those of all other transplant patients with end-stage kidney disease not caused by Alport syndrome, taken from the Irish National Transplant Registry.

Results: 3,918 patients underwent kidney transplantation in Beaumont Hospital between 1982-2014. Of these, 62 patients had end-stage kidney disease due to Alport syndrome. 15-year graft survival was 61% for Alport patients and 42% for non-Alport patients (p = 0.11). Factors that were independently associated with improved graft survival included recipient age, donor age and sex, HLA mismatch, cold ischemia time and the occurrence of acute rejection. 20-year patient survival rate was 70.2% for Alport patients and 44.8% for non-Alport patients (p = 0.01). Factors that were independently associated with improved survival included recipient age and sex, cold ischemia time, donor age and the occurrence of acute rejection. No patients developed *de novo* anti-glomerular basement membrane disease post renal transplantation.

Conclusions: Patients with Alport syndrome have excellent long-term allograft survival, equivalent to that of patients with non-Alport renal disease, and superior overall long-term survival compared to patients with other forms of renal disease.

PUB746

Potential Risk Factors for Resistant BK Viremia in Kidney Transplants
Melissa L. Swee, M. Lee Sanders, Mony Fraer, Sarat C. Kuppachi. *Dept of Nephrology, Univ of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: BK viremia is common post renal transplant, and unchecked BK viremia can lead to allograft dysfunction and loss. The management of BK viremia remains somewhat controversial as no universally agreed upon protocol exists. Immunosuppression (IS) reduction with an option to add leflunomide remains the conservative approach at most centers. Other treatment options for more resistant BK viremia include cidofovir

and IVIG, but these treatments remain controversial and are not usually instituted until the conservative approach fails, increasing risk for allograft injury. We hypothesize that potential risk factors exist which contribute to more resistant BK viremia.

Methods: We performed a retrospective chart review of all patients who underwent renal transplantation at our center between 2003 and 2014. We divided the recipients who developed BK viremia into two groups for analysis: recipients who received only conservative management for BK viremia (IS reduction +/- leflunomide) and recipients who received cidofovir +/- IVIG. Age at transplant, sex, race, body mass index, IS medications (induction and maintenance), type of donor, cytomegalovirus status of donor and recipient, cPRA, HLA mismatch status and cold ischemia time were abstracted. Serum creatinine (sCr) at BK viremia detection and upon resolution were also collected. Parametric statistics were used for data evaluation.

Results: A total of 54 recipients with BK viremia were identified with 42 receiving IS reduction +/- leflunomide and 12 receiving cidofovir +/- IVIG. None of the abstracted parameters were statistically significant between the two groups. The change in sCr between BK detection and resolution within each group also did not statistically differ.

Conclusions: We did not identify any significant risk factors for resistant BK viremia. An interesting finding was that neither management approach contributed to a statistical improvement in sCr. The limitations of our study include a small sample size, single-center experience, and potential for sampling bias. Further studies are needed to better risk stratify patients in order to determine the optimal management strategy for BK viremia.

PUB747

Early Initiation of ACE Inhibitors in the Post Renal Transplant Period: A Study from a State Run Tertiary Care Centre

Umesha Lingaraj. *Nephrology, Inst of Nephrourology, Bangalore, Karnataka, India; Nephrology, Apollo Hospitals, Bangalore, Karnataka, India.*

Background: Angiotensin converting enzyme inhibitors (ACEI) comprise a drug class that inhibit the effects of angiotensin II. ACEI are well documented to be potent antihypertensives with renoprotective effects but are grossly underutilized in renal transplant recipients. However, these drugs have been reported to cause elevated potassium and creatinine levels in some renal transplant patients. There have been no reports of prospective studies of ACEI in renal transplant patients in the early post-transplant period. The purpose of this study is to assess the safety of an ACEI class, when started in early post-transplant setting.

Methods: We reviewed 84 kidney transplant patients during the period of January 2012 to April 2016 at our Institution. 72 patients were initiated on ACEI therapy. patients who initiated therapy after day 5 and before day 365 of post transplant were included.

Results: Recipients were stratified into two groups according to the time of ACEI into early (within 6 months post-transplantation) and late (after 6 months after transplantation) group. For each patient, haemoglobin, serum creatinine and potassium levels were analyzed at the beginning of ACE inhibitors and at the end of the 1st, 6th and 12th month. In the 57(79.1%%) of the 72 patients ACE inhibitors were initiated within six months post-transplantation and in 15 (20.9%) patients ACE inhibitor were initiated, but after six months post-transplantation. There was no statistically significant difference between the two groups related to age or gender and due to the duration of dialysis treatment before the transplantation. Analyzing the Hb, creatinine and potassium serum levels after initiation of therapy with ACEI trough observed period, we did not found any statistically significant difference in all measured parameters between the two groups of patients and also within the same group of patients.

Conclusions: ACEI can be used successfully post-renal transplant with beneficial long term impact on renal function. There is need for further randomized controlled studies for to see the effect of ACEI on Graft function and its survival.

PUB748

Predicting Outcomes in Pediatric Renal Transplant Recipients

Veronica A. Taylor,[1] Cassie L. Kirby,[1] Jens W. Goebel,[2] David K. Hooper.[1] *[1]Cincinnati Children's Hospital Medical Center; [2]Children's Hospital Colorado.*

Background: Pediatric kidney transplant recipients (pKTRs) experience multiple sequelae of their condition, yet an assessment of the cumulative burden and relationship to poor patient outcome is lacking in the literature. Our objective was to develop a composite outcome measure for pKTRs that considers the most common comorbidities and evaluate its ability to predict outcomes 2 years later.

Methods: We retrospectively reviewed all KTRs at our center from 10/2008 through 2/2015. An optimal outcome composite measure was created consisting of 15 criteria in five domains: allograft health (CKD stage <3, urine protein/creatinine ratio < 0.5), histology & immunology (absence of DSAs, no or mild interstitial fibrosis and tubular atrophy, no transplant glomerulopathy, and no history of AMR or ACR), infection (BKV PCR <10,000, CMV PCR ≤0, no history of PTLD or symptomatic EBV), cardiovascular health (triglycerides <500, LDL <130, BP <90th%ile, fasting glucose <126), and growth (BMI <85th%ile, height z-score >-2 SD). We evaluated the ability of these pass/fail criteria to predict poor outcome (patient death, graft failure, and 20% decline in GFR) at years 3 and 5 post-transplant.

Results: A total of 37 patients were evaluated at post-transplant year 3 and 32 patients were evaluated at year 5. Subjects having a low outcome score (lower third quantile) at year 1 and year 3 trended towards poor outcome at years 3 and 5 respectively, although potential prediction was not significant. Of the 15 outcome criteria, presence of proteinuria was the only criteria predictive of poor outcome ($p<0.05$).

Conclusions: The presence of proteinuria is predictive of poor outcome in pKTRs in terms of patient death, decreased allograft function, or failure. The use of a composite score consisting of criteria characterizing allograft health and common comorbid conditions may be predictive of overall outcome, however a larger sample size is needed for validation. Evaluation of risk factors for poor outcomes will allow practitioners to focus clinical outcome improvement efforts.

PUB749

Use of Eculizumab for Atypical Hemolytic Uremic Syndrome in Kidney Transplantation - Single Center Experience in Brazil

Andrea Valeria Andrade, David Machado, Patricia Soares Souza, Flavio De Paula, Elias David-Neto. *Kidney Transplant, Renal Transplantation Service of Clinical Hospital, São Paulo Univ, São Paulo, Brazil.*

Background: Atypical hemolytic uremic syndrome (aHUS) is associated with a 50% rate of mortality/dialysis dependence at 5 years. Kidney transplantation (KTx) is the best treatment for end stage renal disease (ESRD), but in patient with aHUS recurrence rate >80% has historically discouraged transplantation. Eculizumab has caused a shift in the management of these patients. The drug is not available worldwide.

Methods: Case series on aHUS patients using eculizumab either before or after kidney transplantation.

Results: Between June 2012 and August 2014, eight patients received eculizumab, being three on a prophylactic basis before KTx, three after KTx due to aHUS recurrence and two after kidney allograft loss. They were mainly women (7/8); 27±14 years old presenting past history of thrombotic microangiopathy in kidney biopsy, microangiopathic anemia (MA) and extrarenal organ damage. Prior to eculizumab all patients received ACWY anti-meningococcal vaccine and antibiotic prophylactic were maintained lifelong. They were divided in three groups- clinical characteristics and outcomes are presented in (Figure 1).

	Pre-KTx (n=3)	Post-KTx recurrence (n=3)	After kidney allograft loss (n=2)
Age (years)	25.2±7.8	28.1±22	24.5±9.2
Female gender (n)	3	3	1
Time from diagnostic to eculizumab treatment (months)	-514.0± 712.0	0.9 ± 0.4	16.5±35.0
Clinical manifestation pre-eculizumab	ESRD + MA	Nephritic syndrome, proteinuria, AKI + MA	ESRD + MA
ADAMS 13	➢ 70%	➢ 70%	➢ 70%
Reduced C3 level (n)	2	2	2
Gen mutation (n)	Thrombomodulin (1) C3 (1) Factor H (1)	NA	NA
Plasmapheresis (n)	2	2	1
Dialysis post-dx (n)	3	1	2
Live donor (n)	2	1	1
Panel reactive antibody >0% (n)	2	2	0
Imunosupression therapy (n)			
ATG induction	2	2	1
Tacrolimus	3	2	1
mTOR inhibitor	0	0	0
Outcomes Time under eculizumab (months)	19.6 ±9.3	11.5 ±7.2	7.7 ±0.4
Serum creatinine (mg/dl)	1.2 ± 0.1	0.9 ±0.3	Dialysis
eGFR (ml/min)	54.8 ± 17.2	68.6 ± 17.8	Dialysis
Graft loss (n)	0	0	Not applied
Death with Functioning graft (n)	0	2 (pulmonary infection)	0
Anemia recurrence (n)	0	0	0

NA: Not available

Conclusions: Eculizumab, either used for prophilaxis of aHUS recurrence or early after post-Tx recurrence, allowed good renal function and stable hematological profile. The two patients who did not receive eculizumab in an appropriate time-schedule, lost the allografts. Using eculizumab after renal loss avoided microangiopathyc anemia and extrarenal organ damage in this short term follow–up. Death with functioning graft due to pulmonary infection raises awareness of infection risk of eculizumab on top of the current imunosupression regimen.

PUB750

Attitude of Kidney Transplant Recipients about Influenza Vaccination and Preventive Measures: Comparison of 2009 versus 2016

Araminta Guichard-Romero, Roxana Rodríguez Romo, Cristhian R. Arias-Delgadillo, Lluvia A. Marino-Vazquez, Josefina Alberú, Luis E. Morales-Buenrostro. *Nephrology and Transplantation, National Inst of Medical Sciences and Nutrition Salvador Zubirán, Mexico City, Mexico.*

Background: An outbreak of influenza A virus H1N1 was identified in Mexico and USA in Apr/09. The government established intensive campaign of diffusion about preventive measures and vaccination. In early 2016, we had another outbreak of influenza but with little diffusion to the population. Aim: to compare the effect of diffusion campaign on kidney transplant recipients' (KTR) attitude about vaccination and preventive measures during the outbreak in 2009 vs 2016.

Methods: During 2009 outbreak, we applied a standardized survey to evaluate: use of flu vaccine the previous winter, during the outbreak and intention to receive it in next winter, prophylactic measures during contingency. In May/2016 we apply the same survey to KTR and compared them.

Results: We included 131 cases of 2009 and 155 of 2016. In table1 we compare demographic characteristics, vaccination frequency previous and after outbreaks, and use of

preventive measures. Only 4 cases have had influenza since 2009. In cases with symptoms or direct contact with influenza patient, an increase of use of facial mask was observed. 53 patients had symptoms but it didn't change the attitude to vaccination.

Variable	2009 n= 131 (%)	2016 n= 155 (%)
Age (years)	39.8 ± 12.5	39.4 ± 15.1
Female	72 (55.0)	84 (54.2)
Vaccinated last Winter*	26 (19.8)	61 (39.4)
Vaccinated during outbreak	2 (1.5)	9 (5.8)
Vaccine next winter (intention)*	83 (63.4)	118 (81.9)
Contact with sick people	7 (5.3)	11 (7.2)
Facial mask use*	122 (93.1)	80 (51.6)
Hand washing	125 (95.4)	137 (88.4)
Avoid crowded situations*	119 (90.8)	84 (54.2)
Avoid shaking hands / kisses*	102 (77.9)	66 (42.6)
Clean workplace*	95 (72.5)	51 (32.9)
*p<0.01		

Conclusions: Despite an intention to received vaccine next winter increased in 2009 (63.4%), the actual percentage that received vaccine last winter (2015) was substantially reduced (39.4%) despite another outbreak of influenza, most probably due to limited publicity.

PUB751

Urinary Liver Type Fatty Acid Binding Protein and Urinary Albumin Excretion Improve Prediction of Graft Failure after Renal Transplantation

Kirsten Van der Laan,[1] Michelle Pena,[1] Ineke J. Riphagen,[1] Gerjan Navis,[1] Takeshi Sugaya,[2] Dew Doekharan,[3] Jacob van den Born,[1] Stephan J.L. Bakker.[1] *[1]Univ Medical Center Groningen; [2]CMIC Holdings Co.; [3]Bio-Connect Diagnostics.*

Background: Immunosuppression after renal transplantation has improved but long-term risk of graft failure is still high. Early markers are needed as current monitoring is mainly based on serum creatinine and proteinuria. We tested the added value of urinary liver type fatty acid binding protein (L-FABP) and urinary albumin excretion (UAE) as early prognostic markers for risk of graft failure after renal transplantation.

Methods: A longitudinal cohort of 702 stable renal transplant recipients was included median 5.4 [1.9–12.1] years after transplantation. L-FABP and UAE were measured in 24hr urine samples collected at inclusion. Correlations were assessed by Spearman's rho. Cox regression was used to predict risk of graft failure with hazard ratios (HR) expressed per log2 L-FABP and log UAE. L-FABP and UAE were tested on top of traditional risk factors age, sex, serum creatinine, proteinuria, donor status, and history of previous graft failure. Prediction improvement was assessed with Harrell's C and best model fit by AIC.

Results: Participants (57% male, age 53.0±12.7 years) were followed for median 3.1 [2.6–3.8] years. 45 developed graft failure. At inclusion median L-FABP was 2.1ng/mL [0.9–6.8]. Median UAE was 43.3mg/24hr [11.0–203.4]. L-FABP correlated with UAE (r=0.62), eGFR (r=-0.39), proteinuria (r=0.59) and serum creatinine (r=0.52)(all p<0.01), and UAE with eGFR (r=-0.25), proteinuria (r=0.77) and serum creatinine (r=0.35)(all p<0.01). Higher L-FABP (HR=2.80 (95%CI 1.55–5.04)p<0.01) and higher UAE (HR=1.89 (95%CI 1.23–2.90)p<0.01) were independently associated with graft failure. L-FABP and UAE combined improved prediction of graft failure on top of traditional risk factors (increase in Harrell's C from 0.87 (95%CI 0.81–0.93) to 0.90 (95%CI 0.85–0.94)(p<0.01). A best reduced model included sex, serum creatinine, L-FABP and UAE.

Conclusions: L-FABP and UAE improve prediction of graft failure on top of traditional risk factors. These results are promising for use in routine clinical practice but first require confirmation in an external cohort.

PUB752

Creatinine Clearance Measurement in the Immediate Adult Post Kidney Transplant (KTx) Period with Functioning Allograft: Interim Results

Umar Farooq,[1] Nasrollah Ghahramani,[1] Ashokkumar Jain.[2] *[1]Div of Nephrology, Penn State Hershey Medical Center, Hershey, PA; [2]Div of Transplant Surgery, Penn State Hershey Medical Center, Hershey, PA.*

Background: Several formulae are available to estimate renal function based on serum creatinine values. However these do not take into account of progressive decrease in serum creatinine with functioning renal allograft. Primary objective of the study is to compare the urinary creatinine clearance measured by urinary collection every 12 hours with estimated creatinine clearance by currently available formulae.

Methods: Nine (9) consenting post kidney transplant subjects (5 male, 4 female), mean age 51.8 ± 8.1 years, 7 Caucasian, 1 African American and 1 Hispanic, and with primary allograft function were included in the study. Urine was collected to measure creatinine concentration using Foley catheter every 12 hours starting immediately after kidney transplant for first 5 days post KTx. The creatinine clearance was compared with 1) Cockcroft-Gault (CG) formula, 2) eGFR using Modification of Diet in Renal Disease (MDRD) formula, 3) Jellife adult bedside (formulae where creatinine clearance is estimated with single serum creatinine value) and with 4) Brater and 5) Jellife and Jellife.

Results: Mean value of serum creatinine mg/dL before KTx and every 12 hours after the primary allograft function, calculated creatinine clearance by urinary excretion and estimation by various formulae at the same time points are shown in figure 1.

Figure 1: Actual measured Urinary CrCl in comparison to various formulae in post kidney transplant(KTx)period

Post KTx days	-1	1	1.5	2	2.5	3	3.5	4	4.5
Serum Creatinine (mg/dL) (n=9)	6.3 (±1.9)	5.3 (±1.6)	3.8 (±1.3)	2.7 (±1.3)	2.4 (±1.6)	1.8 (±1.2)	1.6 (±0.7)	1.3 (±0.4)	1.3 (±0.3)
Creatinine Clearance(mL/min)		36.9	48.3	55.6	62.5	82.3	78.3	83.9	71.7
Cockcroft-Gault (mL/min/1.73 m2)		20.3	29.2	42.8	53.8	72.8	71.8	74.8	69.3
MDRD (mL/min/1.73 m2)		12.2	18.8	29.5	38.4	54	52.5	55.2	51.6
Jellifie adult bedside		14.2	20.7	30.5	38.4	51.9	50.8	54.1	51.5
Brater (mL/min/70 kg)		3.3	12	17.3	25.2	37.7	46.7	38.9	51.6
Jellifie and Jellifie (ml/min/1.73 M2)		-9	10.5	9.9	5.1	5.8	3.6	7.2	2.7

Conclusions: Our observations suggest that currently used formulae underestimate the renal function in working allograft. The variability is higher in the first few days with rapidly decreasing serum Creatinine. There is a need to develop a new formula to estimate renal function in functioning allografts with rapidly decreasing creatinine.

PUB753

Comparison of Tacrolimus with Everolimus or Mycophenolate Mofetil or Steroid Regimen and Their Association with Tryptophan Metabolism: A Pilot Study

Vinant Bhargava, Kumar Digvijay, Dheeraj Mohania, Devinder S. Rana. *Nephrology & Research, Sir Gangaram Hospital, New Delhi, India.*

Background: Assess graft survival and safety profile at one year. Explore Tryptophan metabolism pathway as a clinical tool to predict graft survival.

Methods: All patients received induction therapy with thymoglobulin(3mg/kg). They recieved Tacrolimus, mycophenolate mofetil, steroid and were randomised into three groups at the end of 3 months. Group 1 (control) patients received Tacrolimus /Mycophenolate/ Steroid. Group 2: Tacrolimus/Mycophenolate Mofetil/Everolimus and group 3: Tacrolimus/ Everolimus/Steroid. Patients were assessed with RFT, Hemogram, Urine R/M, Lipid profile, Blood Sugar levels, Serum Tacrolimus/ Everolimus levels. Adverse events such as anaphylaxis, life threatening infections were noted. Tryptophan metabolite measurement was done using Quantitative real-time RT-PCR.

Results: Graft survival at one year: Control group 1: 7/11 patients had stable graft outcomes, 1 patient had ATN & 3 were lost to follow up. Group 2:4/ 6 patients had stable graft outcomes & 2 had ATN. Group 3: 4/7 patients had stable graft outcome, 1 had ACR+ AMR. **Safety:** No patient had serious adverse events. One patient with Dyslipidemia was reported in each of the Groups 2 & 3. Furunculosis was noted more in group 3. **Tryptophan metabolism enzyme levels:**Control Group**:** No changes were seen in various enzymes levels for the 9 patients available. Group 2 & Group 3**:** Various enzymes showed low expression, but no association was observed with graft survival. Low expression of IDO 1 was observed in 5 patients out of which 4 patients were associated with stable graft outcome & 1 with graft dysfunction. No significant difference was observed in drug levels, Hemoglobin, Creatinine , TLC, Platelets, Triglycerides & Total Cholesterol levels among different groups (*p= NS*).

Conclusions: Larger study is needed to establish the role of Tryptophan metabolizing enzyme as predictive biomarker for graft survival. IDO 1 may possibly show some association. Corticosteroid sparing immunosuppressant regimen(Tac+MMF+EVE) appear to be safe as compared to Steroid containing immunosuppressant regimens (Tac+MMF+Steroid/Tac+EVL+Steroid).

PUB754

Prevalence and Risk Factors for Post-Transplant Anemia in a Reference Center in Mexico

Edgar Solis,[1] Ariadna Escalante,[1] Gaudencio Gabriel Sandoval,[1] Luis Alberto Evangelista-Carrillo,[1] Enrique Rojas-Campos,[2] Benjamin Gomez.[1] *[1]Dept de Nefrologia y Trasplantes, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; [2]Unidad de Investigación Médica en Enfermedades Renales, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: Anemia is a common complication after kidney transplantation (KT) and has a controversial impact on graft or patient survivals. The aim of the study was to describe the prevalence of anemia before and after KT and to find the characteristics of the patients with anemia.

Methods: All the kidney transplants in adult patients (over 16 yrs of age) performed from December 2012-December 2014 in Hospital de Especialidades Centro Médico Nacional de Occidente in Guadalajara were included. We used data collected in our registration program during one year following transplantation. Anemia was defined according the WHO: hemoglobin (Hb) levels <12 g/dl in women and <13 g/dl in men.

Results: 505 recipients were included in the analysis, 361 male and 144 female had an overall mean age at transplantation of 29±10 years. Most patients were from living donor (86%). Evolution is shown.

Parameter	Baseline	3 mo	6 mo	12 mo
Serum Cr (mg/dl)	1.1±0.5	1.2±0.7	1.2±0.8	1.3±1.2
Serum Hb (g/dl)	10.5±2.1	12.8 ± 2.0	13.6±2.2	14.1±2.3
Anemia (yes/no)	(434/71)	(234/271)	(172/333)	(111/394)

Post-transplant anemia at 1 year			
	Yes (n = 111)	No (n = 394)	p
Female recipient (%)	40	25	0.004
Male donor (%)	54	50	0.475
Recipient age (years)	29 ± 10	29 ± 10	0.62
Donor age (years)	39 ± 12	36 ± 11	<0.01
Donor type (%)			0.879
Living Donor	85	88	
Deceased Donor	15	12	
Induction (%)			0.639
Basiliximab	59	57	
Thymoglobulin	41	43	
Maintenance (%)			
Tacrolimus	97	98	0.28
MMF	100	100	--
Time in dialysis (months)	36 (24-71)	28 (18-58)	0.1
Baseline eGFR (ml/min/1.73)	90 ± 29	95 ± 26	0.04
Baseline hemoglobin (g/dl)	10 ± 1.5	11 ± 1.8	0.001
Creatinine (mg/dl)	1.7 ± 1.9	1.15 ± 0.75	0.001
eGFR (ml/min/1.73)	73 ± 33	89 ± 23	0.001
Hemoglobin (g/dl)	11 ± 2.0	15 ± 1.6	0.001
Graft loss (%)	11	1	0.0001
Patient survival (%)	97	99.5	0.008

Variables that predicted anemia at 12 months (mo) were Hb at 6 mo and eGFR at 6 mo *(RR 1.9 (1.6-2.3) p<.0001 and RR 1.02 (1.01-1.03) p<.002)*. Higher baseline Hb level predicted less graft loss *(RR 0.6 (0.3-0.9) p.001)* and higher Hb level at 1 year predicted better patient survival *(RR 0.6 (0.4-0.8) p.001)*.

Conclusions: In contrast with other studies, we had lower incidence of anemia at 1 year. We found relation between graft function and anemia diagnosis. Baseline Hb and at 1 year does impact in graft and patient survival, respectively.

PUB755

Triglyceride Metabolism before and after Meal in Post Kidney Transplant Recipients

Makoto Tsujita,[1,2] Tomoki Kosugi,[2] Shoichi Maruyama.[2] *[1]Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan; [2]Nephrology, Nagoya Univ School of Medicine.*

Background: Many factors cause dyslipidemia after kidney transplantation. Low density lipoprotein cholesterol (LDL-C) has been focused to reduce cardiovascular disease (CVD), but residual risk factors such as triglyceride (TG), remnant-like lipoprotein cholesterol (RLP-C) or small dense LDL-C(sdLDL-C) are also important to reduce CVD.

Methods: TG metabolism could be evaluated by cookie test.(Endcrine Journal 2006,53(2),173-180) We performed the test for sixty three stable kidney transplant recipients at one year after transplantation in 2014. TG, RLP-C, LDL-C/apoB ratio (substitute for small dense LDL-C), Blood sugar (BS) etc. were measured at fasting(f), and at 2 hour (2h) and 4hours (4h) after test.

Results:

Figure 1. Patients' characteristics and the result of this study

Gender(male),n	34
age, years	47.7 ± 13.0
T-CHO, mg/dL	181.0 ± 24.6
HDL, mg/dL	56.2 ± 13.5
non HDL, mg/dL	124.7 ± 21.6
LDL/apoB ratio	1.2 ± 0.2
TG fasting, mg/dL	139.4 ± 62.6
TG 2h, mg/dL	212.2 ± 90.1
TG 4h, mg/dL	206.3 ± 105.2

Tac+MMF+PSL,n	34
CyA+EVL+PSL,n	16
Tac+EVL+PSL,n	2
statin use,n	35
DMN,n	10

CyA: Cyclosporine A, Tac: Tacrolimus, EVL: Everolimus
PSL: Prednisolon, DMN: Diabetic nephropathy, BS: Blood sugar

Figure 1 showed the result of this study. TG2h and TG4h levels were higher than TGf levels (r=0.83 p<0.001, r=0.79 p<0.001, respectively). A negative correlation was seen between TGf and eGFR (r=-0.48 p<0.001).TGf had positive correlation with RLP-C, non HDL-C, LDL-C/apoB ratio(r=0.80 p<0.001, r=0.47 p<0.001, r=0.48 p<0.001 respectively). LDL-C levels were under control because of statin use, but LDL-C/apoB ratio levels in 50% of recipients were below 1.2, meaning the rate of sdLDL-C in LDL-C was high. And LDL-C/apoB ratio was associated with TG4h (r=0.30 p=0.009). TG metabolism in non DM group was similar with that in DM group. In EVL group, TGf levels were higher than that in non EVL group (p=0.04).

Conclusions: This study revealed most recipients had some problems with TG metabolism. Any intervention to improve TG metabolism will be needed.

PUB756

Controlled Cardiac Death Donor (cDCD) for Kidney Transplantation: Factors Associated to Best eGF after 2 Years: Spanish Multicentre SENTRA-GEODAS Group

Jose M. Portoles,[1,2] María Marques Vidas,[1,2] Omar Reynaldo Lafuente Covarrubias,[1] Erika De Sousa Amorim,[1,2] Eva Gavela,[1] Paloma L. Martin Moreno,[1] Domingo Hernandez,[1,2] Francesc J. Moreso,[1] Isabel Beneyto Castello,[1] Julio Pascual.[1,2] *[1]Nephrology, Hospital Puerta de Hierro. SENTRA / GEODAS, Majadahonda, Spain; [2]Public Health Research Net RedinRen16/009/009 RETYC ISCIII.*

Background: Controlled donation after cardiac death (cDCD) programs are running in some countries for years. National transplant organization (ONT) has developed a nationwide program in Spain from Jan2012 and 45 centers had started by Dec2015. Eighteen centers out of them have joined our study group. We present our preliminary analysis for best eGF after 2 years.

Methods: ***Study***: Observational prospective multicentre study. ***Intervention***: Kidney transplantation (KTx) from cDCD at joined units. Local centre surgical procedures and IS protocols. ***Main Variable:*** Best eGF along 1st post –TX year as measured by MDRD-4.

Results: ***Cohort description:*** 430 grafts were obtained from 215 cDCD. 13 kidneys were discharged for several reasons and 28 implanted out of our group. 389 recipients: 56.3 years, 69.1% males, 75,6% first KTx, others 2ndor 3rd. Cold ischemia time (CIT): 12,5h; median warm IT 24min, HLA-mismatch: 4 [0-5]. Immunosuppression: 98,8% induction plus prednisone-MMF-Tacrolimus or mTOR. **Graft Function**: Primary graft failure (PGF): 3%, delayed graft function (DGF): 49,7% Nadir Cr: 1.5 mg/dl [0,6-3,1]. **Best eGFR** was 55,3 (24.6) ml/min. For patient with more than 1 year follow-up, best renal function was 55,3 (SD 24.6) ml/min; serum Cr was 2.1 mg/dl at month, 1.8 mg/dl at 3rd month, 1.9 mg/dl at 6th month, 1,6 mg/dl at 1st year and 1.6mg/dl at 2nd year. In the multivariate analysis for the probability to reach 1st year best eGFR>50 ml/min after the first cDCD-KTx was associated to lower donor age (<54years ,OR 2,2 [1.2-3.9]) a shorter CIT (OR 1,04 per hour) and previous treatment (PD vs HD OR 1.9 [1.0-3.6) but not to HLA-missmatch or DGF.

Conclusions: Modifiable risk factor for best eGFR has been stated. KTx with cDCD present higher DGF than historic reference for brain death donor but similar PGF rate and patient or graft survival rates.

PUB757

Effects of Protein A Immunoadsorption in Patients with Sensitized Penal Reactive Antibody Waiting for Kidney Transplantation

Hua Liu, Hongli Jiang, Kehui Shi, Jinhong Xue, Quan He, Meng Wang. *Blood Purification, The First Affiliated Hospital of Medical College of Xi'an Jiaotong Univ, Xi'an, Shaanxi, China.*

Background: To investigate the effects of protein A immunoadsorption therapy in 4 patients with sensitized penal reactive antibody (PRA) waiting for kidney transplantation.

Methods: 4 patients with sensitized PRA accepted protein A immunoadsorption therapy. Heparin was used for anticoagulation. The PRA, immunoglobulin G (IgG), immunoglobulin M (IgM), immunoglobulin A (IgA), routine blood test, liver function and blood coagulation index were tested before and after each treatment, and adverse reactions were observed, then the PRA was followed up for 3 months after treatment.

Results: There was no obviously adverse reactions occurred in 4 patients. There was significant decline in PRA level after treatment, compared with PRA before treatment (4.375±4.375% vs 25.00±6.847%, $P < 0.05$), and PRA was negative in 3 cases after 2-3 times treatment of protein A immunoadsorption. In the three patients with negative PRA, their antibody isotyping were anti HLA - I type or anti HLA - I + II type, and 1 patient got success renal transplantation after treatment. But there was no change in PRA of another patient, after 2 times consecutive treatment, and we found the PRA genotype of this patient was HLA-DR53, which belonged to HLA - II type. The IgG levels significantly decreased after treatments (7.749±1.097 g/L vs. 2.820±0.447 g/L, $P<0.001$), but there was no obvious change in IgM and IgA levels. Before and after treatment, significant difference was found in the result of activated partial thromboplastin time (APTT) ($P<0.05$), but it was not found in hemoglobin, patelet, fibrinogen, prothrombin time, total bilirubin, albumin and glutamic-pyruvic transaminase. The change of APTT was related to the use of heparin. Follow-up for 3 months after treatment in 3 patients with negative PRA, PRA were rising again on the first month, also include the patient undergoing renal transplantation, but there was no rejection.

Conclusions: Protein A immunoadsorption can reduce serum PRA levels, which can provide opportunity of renal transplantation for patient with sensitized PRA. Its different effect is associated with the types of PRA.

PUB758

The Epstein-Barr Virus DNA Load in the Peripheral Blood of Transplant Recipients Does Not Accurately Reflect the Burden of Infected Cells
Susanne Fink,[1] Ming-Han Tsai,[2] Martin G. Zeier,[1] Patrick Wuchter,[5] Peter Dreger,[5] Uta Behrends,[4] Henri-Jacques Delecluse.[2] *[1]Nierenzentrum Heidelberg, Germany; [2]German Cancer Research Centre (DKFZ) Unit F100, Heidelberg, Germany; [3]Dept of Infectious Diseases, Virology, Univ of Heidelberg, Heidelberg, Germany; [4]Children's Hospital Klinikum Rechts der Isar, Technische Univ München, Munich, Germany; [5]Dept of Medicine V, Univ of Heidelberg, Heidelberg, Germany; [6]Dept of Medicine V, Univ of Heidelberg, Heidelberg, Germany.*

Background: Transplant recipients frequently evince an increased Epstein-Barr virus (EBV) load in the peripheral blood. Predicting post-transplant lymphoproliferative disorders is the rationale behind the quantification of the EBV load in the peripheral blood. However, this assay was shown to have a poor predictive value.

Methods: EBV load was quantified in kidney and stem cell recipients by qPCR. EBV infected cells were determined by in situ hybridisation, lytic antigens by immunostaining. Fluorescence in-situ hybridization (FISH) was used to determine the number of EBV episomes per infected cell. Binding and transformation assays were performed with either plasma or serum.

Results: We quantitated the number of EBV-infected cells in the peripheral blood of 23 transplant recipients and defined the mode of viral infection, latent or lytic. These data indicated that there is no strong correlation between the number of infected cells and the EBV load. This can be explained by a highly variable number of EBV copies per infected cell and by lytic replication in some cells. The plasma of these patients did not contain free infectious viruses. Some of the investigated samples carried a highly variable number of infected cells in active latency. However, a third of the samples expressed neither latent nor lytic proteins.

Conclusions: Patients with an increased EBV load represent a heterogeneous group of patients whose infection cannot be characterized by this method alone. Evaluation of the clinical significance of an increased EBV load, in particular as a predictive marker of PTLD, requires the inclusion of additional investigations, in particular the number of EBER RNA-positive cells.

PUB759

Evaluation of Efficacy and Safety of a Lower Dose of Thymoglobulin as Induction Therapy in Kidney Transplantation
Isabelle Malbouisson, Mayara Ivani de Paula, Marina Cristelli, Erika Y. Tamashiro, Laila Viana, Juliana Mansur, Helio Tedesco Silva, J. Medina-Pestana. *Hospital do Rim - Unifesp, Brazil.*

Background: Thymoglobulin® (rATG), a rabbit antithymocyte globulin is the most common induction therapy used in kidney transplantation. Although its use is essential to reduce acute rejection incidence, it is also associated with many infectious complications, such as cytomegalovirus (CMV) infection. Objective: To evaluate if a 3 mg/Kg single dose of rATG as induction therapy is effective in preventing acute rejection without compromising safety.

Methods: This was a retrospective cohort of 409 patients, whose kidney transplantation was performed from 18-Aug-2014 to 31-May-2015, with a follow-up until 31-May-2016. Before 18-Aug-2014, we used a 6mg/Kg dose of rATG as induction therapy only to sensitized patients (panel reactive antibody-PRA class I or II > 50%) or those with deceased expanded-donor. Since then, we changed the induction protocol to a 3mg/Kg single dose of rATG to all transplanted patients. Outcomes evaluated were acute rejection incidence, renal function, graft and patient survival and CMV infection incidence.

Results: A total of 409 patients receiving the new induction protocol were included. Of these, 58% (n: 238) were under Tacrolimus, Prednisone and Azatioprine as immunossuppression regimen, comprising transplants of living or deceased standard-criteria donors and 42% (n: 171) were under Tacrolimus, Prednisone and Myfortic, comprising transplants of deceased expanded-criteria donors or sensitized patients. Patients had a mean age of 45.8 ± 12.6 years, 82% had deceased donors, 10% had a PRA class I > 50% and 7 % had a PRA class II > 50%. In the Azatioprine group, after one year of follow-up, 8% had biopsy-proven acute rejection and 33% had a CMV infection episode. In the Myfortic group in the same period of follow-up, 6% had biopsy-proven acute rejection and 50% had a CMV infection episode. [table 1] We didn't use a prophylaxis drug for CMV infection. Our strategy was the preemptive treatment for the patients with positive CMV antigenemia.

Conclusions: The 3mg/Kg single dose of rATG as induction therapy was associated with a low incidence of acute rejection after one year of follow-up.

PUB760

On the Significance of Onset of De Novo DSA in Kidney Transplant Recipients after Alemtuzumab Induction
Chelsea C. Estrada, Yezina T. Nigatu, Heesuck Suh, Frank Darras, Mersema Abate, Edward P. Nord. *Nephrology/ Transplantation, Stony Brook Medicine, Stony Brook, NY.*

Background: The presence of de novo DSA (dnDSA) is associated with antibody mediated rejection (ABMR) and reduced graft survival. Despite this, uniform screening and treatment has not been established. One and 5 year incidence of dnDSA post-transplantation varies according to immunosuppression and detection protocols, (~10% and 35% respectively) as does time to appearance, (~2-5 years). Our aim was to evaluate the significance of onset of dnDSA appearance.

Methods: Kidney transplant recipients were screened for dnDSA from 7/1/2014 to 3/31/2016 at 1, 2, 3, 4, 5, 6, 9, 12 and 18 months. Sera were tested with the Luminex assay and levels > 500 mfi considered positive. Induction was with alemtuzumab and maintenance was with tacrolimus and mycophenolate mofetil. DnDSA was treated if mfi was >5,000 or antibody induced injury was seen on biopsy.

Results: In total, 124 consecutive patients were screened for dnDSA appearance. Mean follow-up was 7.2 ± 4.2 months and included 35 patients who completed 1 year. Of these, 42/124 (34%) developed dnDSA. Very early onset (months 1-3) occurred in 32/42 patients, and later onset (month 4+) occurred in 10/42 patients. In the very early group, dnDSA at onset was 14 class I (mean 2,393 mfi), 17 class II (mean 2,093 mfi) and 1 patient with both. In the later onset group, dnDSA at onset was 4 class I (mean 2,090 mfi) and 6 class II (mean 1174 mfi). In all, 9/42 were treated; 7/32 (22%) in the very early group and 2/10 (20%) in the 4+ months group. Of those treated, 4 had evidence of ABMR on biopsy, 3 did not and 2 were not biopsied. The remaining untreated patients (n=33) were serially monitored and of note, 16/33 experienced complete resolution of dnDSA by the end of their first post-transplant year. Interestingly, all patients with dnDSA resolution were from the very early onset group.

Conclusions: Following alemtuzumab induction, dnDSA occurred in 34% of recipients, mostly within the first year post-transplant. Patients with very early dnDSA appearance, both class I and II, were more likely to have resolution of their dnDSA than those who developed dnDSA at 4+ months.

PUB761

The Use of Mammalian Target of Rapamycin Inhibitors (i-mTOR) Could Improve Renal Function in Renal Grafts from Uncontrolled Donation after Cardiac Death Donors (UDCDD)
Maria Molina, Eduardo Gutierrez-Martinez, Enrique Morales, Manuel Praga, Amado Andres. *Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: Ischemia injury in kidneys grafts from UDCDD could produce a poor renal function. Minimized blood levels of CNI associated with i-mTOR therapy could avoid acute rejection and decreased CNI nephrotoxicity.The aim was to describe evolution of renal function before and after CNI minimization associated with conversion from MMF to i-mTOR in a population with renal transplants (RT) from UDCDD.

Methods: All RT from UDCDD received steroids, tymoglobuline, mycophenolate (MMF) and delayed introduction of CNI(tacrolimus). Blood levels of tacrolimus had to be between 8-10 ng/mL at first months after transplantation. We selected for our study patients in whom the immunosuppression was changed after 3 months of transplantation minimization of tacrolimus blood levels to 5 ng/mL and conversion from MMF to i-mTOR. We evaluated renal function before and after these change.

Results: Our center have performed 207 RT from UDCDD. Minimization of tacrolimus blood levels (10 to 5 ng/mL) and conversion from MMF to i-mTOR was performed in 46 (22%) cases at 11 (6,32) months from transplantation. Causes of immunosuppression change were: 20 (44%) CNI nephrotoxicity, 14 (30%) neoplasm, 6 (13%) clinical trials, 3 (7%) viral infections, 1 (2%) BK nephropathy, 1 (2%) posttransplantation diabetes and 1 (2%) gastrointestinal intolerance to MMF. The evolution of renal function is showed in Table 1.

	1 year before	Basal	3 months	1 year after
Serum Creatinine (mg/dL)	1.4±0.4*	1.6±0.4	1.5±0.4*	1.5±0.5
GFR (mL/min)	57±22	501±9	54±20*	52±17
Proteinuria (g/day)	0.2 (0.1-0.4)	0.2 (0.1-0.3)	0.2 (0.2-0.4)*	0.3 (0.2-0.4)*
Aannual GFR		-4 (-10,5)		9 (-3,8)

*p<0.05

Withdrawn of i-mTOR occurred in 8 (17%) patients: 3 edemas, 2 intolerance to i-MTOR, 1 proteinuria, 1 pneumonitis and 1 neurological symptoms.

Conclusions: Minimization of tacrolimus blood levels and conversion from MMF to i-mTOR in kidney transplant from UDCDD is efficient and safe with low rate of i-MTOR withdrawn and improves renal function.

PUB762

Prevalence of HLA-DR15 in Lupus Kidney Transplant Patients
Maria Izabel Neves de Holanda, Fernanda Paula Feres Rios Da Costa, Alicia Imada, Luiz Fernando Christiani. *Nephrology/Kidney Transplant, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

Background: Systemic Lupus erithematosus (SLE) is a severe auto imune disease, characterized by envolvement of multiple organ systems. Lupus Nephritis is one of the mainly complications of the disease and is associated with poor survival and high morbidity, particularly for patients who develop end-stage renal disease (ESRD). the cause of the disease is complex and both environmental and genetic factors are involved. recent studies demonstrated that HLA class II genes are consistently associated with SLE susceptibility, especially some alleles of DR-15.

Methods: The aim of this study is to evaluate the association of HLA-DR15 in a Lupus patients that underwent to a kidney transplant between 1981 and 2016 in Bonsucesso Federal Hospital, Rio de Janeiro, Brazil. This is a retrospective study, and the Lupus group was compared with a control group. The control Group was composed with patients from the subsequent transplants in the same year of the lupus patients transplant. The analyses were performed using Chi square test and spss.

Results: Forty eight patients were included in the lupus group, 41 female patients, 23 were caucasian, 25 african-american.The median age was 31 years old. Thirty one patients in this group was Live donor transplant. The control group was composed by 92 patients, 65 female patients, 43 patients were caucasian, 49 african americans. The median age

was 43 years old. The prevalence of undelying diseases were 51 hypertension patients, 5 diabetes,13 glomeruloesclerosis, 12 Polcistic Kidney disease and 10 others diseases. Forty three underwent to a live donor transplant.The HLA DR-15 was present in 16 patients(33%) in the lupus group compared with 15 patients(16%) in the control group (p=0,021).

Conclusions: The association of HLA DR-15in lupus patients was relevent in this study. Further studies are necessary to evaluate this correlation with lupus nephritis and the progression of this patients after kidney transplant and the graft survival.

PUB763

Graft Survival at 5 Years in Living Donor Renal Transplantation: Does Azathioprin versus MMF Based Immuno Suppression Influence the Outcome? Raju Balasubramaniyam,[1] Sivaram Kannan Swaminathan,[2] Hemalatha Anantha Kumar Naidu.[1] *[1]Nephrology, Kauvery Hospital, Chennai, Tamil Nadu, India; [2]Internal Medicine, Madras Medical College, Chennai, Tamil Nadu, India.*

Background: Retrospective evaluation of renal transplant outcome at 5 years post transplantation, in live transplant program was analysed.

Methods: Live renal transplant recipients from 1998 to 2007 were included .Cadaver transplantation ecipients, who did not follow up and who died prior to reaching 5th year were excluded. Mean age, gender distribution, basic disease, degree of HLA matching, immuno suppression and its influence studied.

Results: 123 patients fulfilled the inclusion criteria -99 men (80.5%) 24 women (19.5%), mean age 38.09 years. Basic disease was Glomerulonephritis in 58(47%), interstitial disease 30 (24.3%), hypertensive nephrosclerosis 20 (16.3%), diabetic nephropathy 12 (9.75%) and 3(2.43%) other diseases. First degree relatives donated in 92 (74.8%) and the rest 31 (25.2%).13 were full house, 69 were haplo identical, 35 mismatches, and 6 were single antigen matched. 86 (70%) received cyclosporine, azathioprin and steroids and 34(30%) received cyclosporine, MMF and steroid based immuno suppression. Among those who took Azathioprin 59/86 patients(68.6%) had normal graft function at 5 years and 25 (31.4%) had varying degrees of azotemia (18 patients had creatinine from 1.5-3 mgm%, 7 had creatinine from 3-5 mgm% and 2 had creatinine > 5 mgm%) . Of the MMF patients 23/37 (62.1%) had normal graft function and 14 (37.9%) had azotemia. (12 had creatinine between 1.5 and 3 mgm% and 2 patients had creatinine > 5 mgm%).Comparison between these 2 groups with respect to normal and with graft dysfunction revealed a 'p' value of 0.53(NS).

Conclusions: 71% of our patients had follow up with us at the end of 5 years and 29% were lost for follow up. Glomerulonephritis and Interstitial nephritis constituted 88 (71.3%) ,the common basic diseases in our transplant program. Mother, sister and spouse were the common donors. 70% of our patients received azathioprin based therapy and 30% received MMF, along with cyclosporine and steroids. Graft function at the end of 5 years did not differ significantly between these two groups.

PUB764

Malnutrition at the Moment of Kidney Transplantation Is Associated to Worst Long-Term Renal Function Carlo M. Alfieri,[1] Maria Teresa Gandolfo,[1] Valentina Binda,[1] Donata Cresseri,[1] Mariarosaria Campise,[1] Anna Regalia,[1] Francesco Cosa,[1] Deborah Mattinzoli,[2] Masami Ikehata,[2] Piergiorgio Messa.[1] *[1]Nephrology, Dialyisis and Renal Transplantation Unit, Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milano, Italy; [2]Renal Research Laboratory, Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milano, Italy.*

Background: The relationship between weight anomalies(WA) and kidney transplantation (KTx) dysfunction is debated. Our study performed in KTx patients aims to: calculate the WA in the 1styear of KTx;Evaluate the relations between body mass index(BMI), clinical and biochemical exams;Explore the influence BMI in renal function (RF) variations.

Methods: Routinely evaluations at 1st(T1) and 12th(T12) mths after KTx were performed in 440(M=250;age 48±11 yrs) KTx pts transplanted between 2004 and 2013. Patients were categorized as: malnourished (MN-BMI≤ 20 kg/m2), normal (N-BMI>20 to ≤25 kg/m2), overweight (OW-BMI>25≤30 kg/m2) and obese (OB->30 kg/m2) and by median BMI(23kg/m2) in upper(BMI-up) or under (BMI-un) median. Serum creatinine(sCr–mg/dL), 24h-proteinuria (Prot-U–g/24h) and eGFR (mL/min) were used as RF indicators. RF variation was calculated by T12-T1 values. Delayed graft function(DGF-12% of patients) was defined by the need of dialysis during the week after KTx.

Results: At T1 and T12, 27% and 7% of patients were MN, and 41%, 28% and 4% at T1 and 50%, 39% and 4% at T12 were N, OW and OB resp. (p<0.0001). During the 1styear of KTx, BMI increased (p<0.0001). BMI-T1 correlated with age, systolic blood pressure(SBP), glucose, acid uric, albumin and Hb. No associations with length of hospital stay and DGF were present. At T12 a decline of sCr,stronger in BMI-up (p=0.02)was observed. Of note, only in MN an increase of sCr was observed(p<0.0001) at T12. Prot-U was lower at T12 (p=0.46), with no relation with BMI. BMI-T1 was associated to sCr reduction(p=0.005). In the 1styear of KTx 12 patients (6 OW) restarted dialysis and 2 (OW) died.

Conclusions: In the 1styear of KTx BMI increased, mostly because of a normalization of malnourished patients. BMI is associated to nutritional parameters and to SBP. No effect of BMI in RF recovery was found, whereas malnutrition seems influence negatively the long term trend of RF.

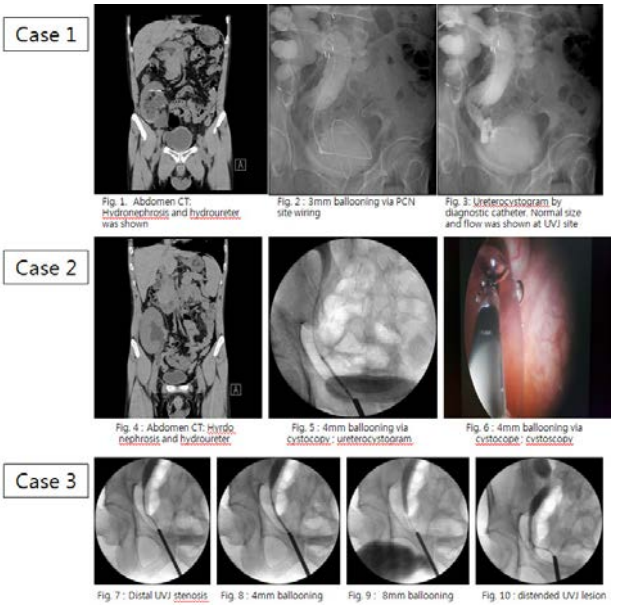
PUB765

Balloon Dilatation at Ureterovesical Junction Stenosis in Kidney Transplantation Patient by Interventional Nephrologist: 3 Cases Jin Ho Lee, Heeryong Lee, Joon Seok Oh, Dongyeol Lee, Seong Min Kim, Yong Ki Park, Yong Hun Sin, Joong Kyung Kim. *Internal Medicine, Bongseng Memorial Hospital, Busan, Dong-Gu, Korea.*

Background: Hydronephrosis is one of the etiology of allograft dysfunction in KTP. Ureter stone, midureter ischemia, surgical technique error, and the other reasons make the hydronephrosis. To eliminate the hydronephrosis due to ureter stenosis, balloon dilatation may be the treatment option. We announced 3 cases of hydronephrosis due to UVJ stenosis causing graft dysfunction was treated balloon dilatation by interventional nephrologist.

Methods: Case 1: 59-year-old man who underwent KTP at Feb, 1989. His serum creatinine was elevated to 3.2mg/dl. Image modalities show hydronephrosis and UVJ stenosis(Fig.1). Then, we underwent percutaneous nephrostomy. We inserted guide wire and ballooning(MUSTANG™, 3.0mm)(Fig.2) was done via PCN site. After that, UVJ stenosis was improved(Fig.3). His serum creatinine was declined to 2.2mg/dl. Case 2: 38-year-old man who underwent KTP with deceased donor at Jan, 2015 was admitted for elevated serum creatinine, from 1.6 to 2.2mg/dl. His CT and abdominal US findings show hydronephrosis and UVJ stenosis(Fig.4). We underwent cystoscopy and ballooning (MUSTANG™, 4.0mm) (Fig.5) was done. After that, diameter was increased at stenotic ureter(Fig.6). His serum creatinine was declined to 1.8mg/dl. Case 3: 28-year-old man who underwent KTP with deceased donor at Sep, 2015. At POD 21, graft kidney CT scan shows hydronephrosis and hydroureter. His serum creatinine level increased slowly. We performed cystoscopy and ballooning at stenotic lesion. Ballooning was done(MUSTANG™, 4.0mm and 8.0mm) (Fig. 7, 8, 9). After that, ureter size was normalized(Fig. 10).

Results:



Conclusions: UVJ stenosis in KTP patient could be treated by balloon dilatation and D-J catheter insertion by interventional nephrologist.

PUB766

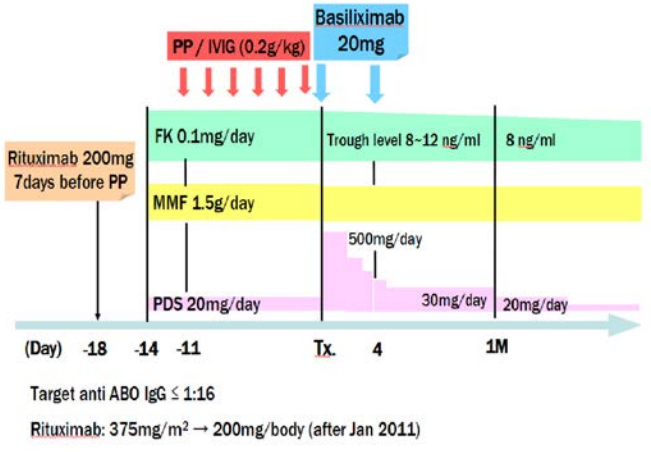
Overcoming of Very High Anti A/B Antibody Titer in ABO Incompatable Kidney Transplantation: Single Center Study Heeryong Lee, Jin Ho Lee, Dongyeol Lee, Joon Seok Oh, Yong Hun Sin, Seong Min Kim, Yong Ki Park, Joong Kyung Kim. *Internal Medicine, Bong Seng Hospital, Busan, Korea.*

Background: ABO incompatable KTP is effective way to reduce the shortage of living donor. In some studies, the presence of high titer of anti A/B Antibody was considered to contraindication for ABOi KTP. With the development of desensitization therapy, 512 or more high titer ABOi KTP could perform.

Methods: Eleven patients with end-stage renal failure underwent ABO-incompatible living kidney transplantation. Baseline anti-A/B antibody titer was 577.16(IgG, range; 512~1024) and 192.72(IgM, range; 8~512), titer was performed by tube method.

Age(year)		55.7±12.2
Sex	Male	4
	Female	7
Causative disease	DM	2
	IgA nephropathy	3
	MGN	1
	MPGN	1
	Unknown	4
Dialysis vitage(month)		17.5 ± 28.6
Initial isoagglutinin titer, IgG(log2)		577.16 ± 207.11(9.18 ± 0.40)
Initial isoagglutinin titer, IgM(log2)		192.72 ± 136.16(6.10 ± 0.98)
ABO incompatibility	A-> O	4
	B-> O	6
	A-> B	1
Donor	Father	1
	Son	1
	Daughter	4
	Brother	1
	Sister	3
	Wife	1
HLA mismatches		2.18 ± 1.72
Plasmapheresis		6.10 ± 0.98

We tried plasmapheresis(PP) and IVIG for removal of the anti A/B antibodies before the kidney transplantation and the number of PP was 6.10 ± 0.98. We used Basiliximab, methylprednisolone for induction immunosuppressant and tacrolimus, mycophenolate mofetil, prednisolone for maintenance IS according to desensitization protocol.



Results: Mean follow-up duration was 41.9 months(range 3~75months). We had one case of biopsy proven acute cellular rejection, and then we loss the graft despite of rescue therapy. There was no antibody mediated rejection episodes and all patients are alive.

Conclusions: Very high Anti A/B antibody titer(≥512, IgG, Isoaggluttinin tube method) in ABOi KTP shows excellent outcomes.

PUB767

The Use of Sirolimus in Patients with Recurrent CMV Infection after Kidney Transplantation: A Retrospective Case Series Analysis Rachel Hung, Ali M. Shendi Mohamed, Ben Caplin, Mark Harber. *Renal, UCL Centre of Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: CMV is the commonest opportunistic infection in kidney transplant recipients (KTRs) and remains a cause of morbidity and mortality. Mammalian target of rapamycin(mTOR) inhibitors have a theoretical antiviral advantage compared to conventional immunosuppression.

Methods: We studied a cohort of 19 consecutive KTRs who were transplanted at the Royal Free Hospital having recurrent(>3) or prolonged(>3 months) CMV viremia before the Sirolimus switch, despite appropriate preemptive anti-viral therapy.CMV titres were analysed for the period from the first positive (>200 copy/ml) test until the commencement of sirolimus and an equal period thereafter. Creatinine levels at discharge,3 months and 1 year were recorded.

Results: 13 males and 6 females with mean age at transplantation of 48 years (20-73) were studied.4 patients had primary CMV infection and 15 patients had CMV reactivation/ reinfection. All patients had standard immunosuppression of basiliximab induction, tacrolimus, MMF and early steroid withdrawal. The first viraemic episode occurred after a mean transplantation period of 28.8±11.8 days.The mean time to starting Sirolimus from transplantation was 125±41 days. Sirolimus was used to replace MMF in all patients. Acute rejection was commoner before starting sirolimus in the context of immunosuppression reduction (4 vs 2 patients after commencement of sirolimus). The mean number of days on anti-viral treatment was reduced after sirolimus conversion (39 ± 31 days vs 74 ± 30 days). 4 patients developed ganciclovir resistance. The area under the curve for Log_{10} CMV viral load was significantly higher before than after the sirolimus switch(p= 0.0034) Mean serum creatinine before conversion to sirolimus was 296.5 (79 – 718), at 3 months after conversion at 159.8 (69-271) and 170.4 (69-287) at 1 year.

Conclusions: Patients with recurrent CMV viraemia who are high immunological risk patients or those with anti-viral resistance risk life-threatening infection or sacrifice of the transplant. In our experience the use of an mTORi is a useful strategy in treating recurrent CMV viraemia without provoking rejection.

PUB768

Validity of Kidney Donor Risk Index for Prediction of Graft Outcome in Deceased Donor Kidney Transplantation; a Singe Center Experience Kyung Sun Park, Jongha Park, Hyun Chul Chung, Jong Soo Lee. *Internal Medicine, Ulsan Univ Hospital, Ulsan, Republic of Korea.*

Background: Donor organ quality is a key determinant of graft outcomes in deceased donor kidney transplantation (DDKT), and several donor quality scoring systems have been proposed.

Methods: To validate the kidney donor risk index (KDRI) for prediction of graft outcome, we screened 134 patients who received DDKTs at Ulsan University Hospital from April 2003 to May 2015. Among them, 91 DDKTs whose KDRIs were available were included this analysis.

Results: Median follow-up was 48 months. Mean age of recipients and donors are 47.3 and 42.5 years, respectively. Mean KDRI was 1.31 ± 0.31 (range from 0.68 to 2.23). During follow up, delayed graft function (DGF) and biopsy-proven acute rejection (BPAR) developed for 6 and 16 patients, respectively. One- and 5-year BPAR-free survival was 88.8% and 79.3%, respectively. BPAR-free survival was tend to be higher for DDKTs from donor with KDRI ≤ 1.0 but not statistically significant (P = 0.073), compared to those with KDRI >1.0. Graft failure occurred to only 2 patients at 5 and 29 months after DDKT, and their KDRIs were 1.28 and 1.98, respectively. In multivariate liniear regression, DGF (standadized beta = -0.273, P = 0.005), BPAR (standardized beta = -0.261, P = 0.012) and KDRI (standardized beta = -0.521, P < 0.001) were significant predictors of last-vistit estimated glomerular filtration rate.

	Coefficient	Standard error	Beta	P
Delayed graft function	-27.549	9.605	-0.273	0.005
Biopsy-proven acute rejection	-17.287	6.671	-0.261	0.012
KDRI	-34.660	6.362	-0.521	< 0.001

Conclusions: KDRI is an easily applicable scoring system and is a good prognostic tool for graft outcomes in DDKTs.

PUB769

Hair Matters: Underrated Side Effect of Immunosuppressive Therapy in Children Antonia Bouts,[1] Maritza A. Middelkamp-Hup.[2] *[1]Pediatric Nephrology, Emma Children's Hospital, Academic Medical Center, Amsterdam, Netherlands; [2]Dermatology, Academic Medical Center, Amsterdam, Netherlands.*

Background: Early steroid withdrawal (ESW) after renal transplantation (rtx) in children improves growth and reduces metabolic risks without increasing the number of acute rejections. Hair loss is reported as a non-frequent side effect of tacrolimus (Tac) and mycophenolate mofetil (MMF). Since we switched to an immunosuppressive regimen of ESW combined with Tac, MMF and basiliximab (ESW protocol) we encountered an increased number of children with hair loss, varying from mild to severe. To assess this observation we compared hair loss in children receiving the ESW protocol with children receiving the previous non-ESW schedule (basiliximab plus steroids; plus MMF or azathioprine; plus cyclosporine which is switched to Tac 6 months after rtx).

Methods: Results are given in median (range). Differences between groups was tested with Fisher exact.

Results: Five of 16 ESW-children (31%) and 3 of 13 non-ESW children (23%; n.s.) developed hair loss, which cannot be put aside as a minor nuisance. As an example, a 12-year old girl received a kidney transplant following the ESW-regimen according to TWIST. One year after rtx she developed near-total hair loss of the scalp, eyebrows and eyelashes. Other causes such as infection, zinc- and iron deficiency and thyroid disorder were excluded. Prednisolone was reintroduced and Tac tapered to a trough level of around 3 ug/L. MMF dosage was maintained at 600 mg/m². Hair growth recovered but remained thin.

	ESW		Non-ESW
patients	16		13
age at rtx (years)	11,5 (1,7-16,4)		10,7 (3,2-16,6)
	ESW maintained ESW	Steroids restarted	
	10	6	
Hairloss (%)	4 (40%)	1 (17%)	3 (23%)
onset after rtx (months)	14,8 (5,3-22,6)	5,3	30 (9-58)

Conclusions: The number of patients in this study is too small to show significant differences, but ESW treatment might give more hair loss than steroid-based therapy. Hair loss after renal transplantation in children is an underrated problem with a significant cosmetic impact, especially for teen-agers. The cause can be multifactorial and needs more exploration.

PUB770

Hemolytic Anemia after Kidney Transplant and Polyclonal Antibodies Alice Lança, Rita Birne, Ivo Laranjinha, Sofia Semedo Coelho, Liliana Maria Goncalves Cunha, Tiago J. Carvalho, Cristina Jorge, Margarida Bruges, Patrícia Matias, Teresa Adragao, Andre L. Weigert, Domingos Machado. *Nephrology, Hospital Santa Cruz, CHLO, Lisbon, Portugal.*

Background: Hemolytic anemia (HA) after renal transplantation (RT) may result from hemolytic-uremic syndrome (HUS), donor-derived antibodies (ab) against recipient's erythrocytes or related to calcineurin inhibitors (CNI). However, an association with polyclonal ab (PAbs) has been poorly described.

Methods: We conducted a single-center cohort study to evaluate the incidence of HA in the first 30 days of RT in patients (pts) who randomly received ATG-Fresenius (ATG-F) or Thymoglobulin-Genzyme (TMG-G) between 01/2009 and 04/2016. HA was defined as decrease of at least 1g/dL hemoglobin (Hb) in 24h and haptogloblin <30mg/dL. Pts with identified causes of HA were excluded.

Results: We enrolled 180 pts; 59% males; mean age 50 ± 11 yrs; Less than 1% was pre-emptive. Six percent obtained a living donor graft and 16% a 2nd RT. Regarding immunossupression, 58.9% received ATG-F (mean cumulative dose (mCD): 17.9/kg) and 41.1% TMG-G (8.4/kg). Out of 180, 11.7% developed HA. Demographic data, RRT modality and vintage, kidney failure etiology, deceased vs. living organ donor, cold ischemic period, anemia, erythropoietin (EPO) use and blood transfusions (BT) before RT were similar in ATG-F and TMG-G group and in HA and non-HA group (NHA). In HA pts, ATG-F was used in 95.2% (p<0,001) in similar doses to NHA pts. HA group had lower Hb at day 1 (9.8 vs 10.6 g/dL; p=0.023), day 3 (8.3 vs 9.3 g/dL; p=0.003), day 7 (8 vs 9.3 g/dL; p <0.001) and day 15 (8.1 vs 9.1 g/dL; p<0.001) after ATG-F/TMG-G use requiring more BT (median 2 vs 0; p=0.006). Higher EPO dose (19238 vs 12952 UI/week; p=0.005) was needed for identical Hb at day 30. No differences were found concerning serum creatinine, maintenance IMS (CNI, mTor inhibitors, anti-proliferative), HLA-mismatches number, donor specific ab and panel reactive ab percentage. HA group had no irregular ab. Overall, 19% of ATG-F pts developed HA compared to TMG-G (0.01%).

Conclusions: In our study, 11.7% pts developed HA in the first month, 95.2% occurring in the ATG-F group. A prospective study on the influence of different PAbs in HA is needed.

PUB771

Monitoring of Serum Fibrinogen in Patients with ESRD Undergoing Plasma Exchange by Single Membrane Separation Technique for ABO Incompatible Kidney Transplantation Joon Seok Oh,[1] Seong Min Kim,[2] Yong Ki Park,[2] Joong Kyung Kim.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Korea; [2]Div of Nephrology, Internal Medicine, Dongnae Bong Seng Hospital, Busan, Korea.*

Background: Some variations in plasma exchange technique for antibody reduction was reported, the confusion about both efficacy and safety were added. We had compared the serum fibrinogen changes of patients who received plasma exchange by single membrane separation technique and centrifuge technique during the last 2 years.

Methods: All subjects were received ABO incompatible living donor kidney transplantation in our hospital. 68 times of plasma exchange were carried out at every other day in 13 patients before transplantation, using the COBE® Spectra™ apheresis system. 50 times of plasma exchange were perfomed at every other day in 10 patients before transplantation, using the Prisamflex ® system with TPE 2000 filter. The levels of serum fibrinogen were measured at pre-exchange, post-exchange one day. In procedure, 1.0 time the calculated plasma volume was replaced with an electrolyte solution containing 5% salt-free human albumin or fresh frozen plasma (FFP).

Results: The serum fibrinogen levels (mg/dL) were markedly reduced immediately following the plasma exchange in cases of 5% albumin solution replacement but increased in cases of FFP replacement. And there were not a significant difference of serum fibrinogen changes between the two methods for plasma exchange.

			Pre-exchange	Post-exchange 1 day
Single membrane separation technique	5% albumin replace	mean	306.10 ± 97.75	1528.57 ± 42.75
		change from the baseline		-147.53
	FFP replace	mean	232.83 ± 66.57	247.93 ± 38.56
		change from the baseline		+15.10
Centrifuge technique	5% albumin replace	mean	274.83 ± 128.82	177.90 ± 49.86
		change from the baseline		-96.93
	FFP replace	mean	233.31 ± 39.03	237.27 ± 39.03
		change frome the baseline		+13.96

Conclusions: According to our experience in plasma exchange, we could say that it is not different the change of coagulation factor during the plasma exchange by single membrane separation technique with the plasmapheresis by centrifugal technique.

PUB772

Experience with IL-1 Blockade in Renal Transplant Patients with Gout Arthritis Vega Goedecke, Marcus Hiss, Hermann G. Haller, Annette D. Wagner. *Dept of Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Hyperuricemia and gout are common comorbid conditions experienced by up to 28% of kidney transplant recipients. Reasons for this include reduced excretory renal function, intake of diuretic medication as well as side-effects of immunosuppressant drugs such as calcineurin-inhibitors. Use of selective IL-1 Inhibitors shows promising results in the treatment of gout. However, data on the use of IL-1 blockade as treatment for gout in renal transplant patients are limited.

Methods: Here we present our experience with interleukin 1 blockade in 3 patients after renal Transplantation with therapy refractory gout arthritis.

Results: Two patients had no gout symptoms since starting IL-1 blocking therapy. One patient suffered from pneumonia. This patient developed hyperuricemia under IL-1 blockade. He was started on rasburicase therapy.

	Patient 1	Patient 2	Patient 3
Age / sex	28 year-old male	59-year old male	64 year-old female
eGFR	25 ml/min	29 ml/min	21 ml/min
Year of transplantation	1996	2009	1991,1992 and 2005
Immunosuppressant regimens	Everolimus, Mycophenolate mofetil, Steroid	Cyclosporin, Mycophenolate mofetil, Steroid	Tacrolimus, Azathioprin, Steroid
Previous gout medication	Allopurinol, Benzbromaron, Febuxostat and Colchicine	Benzbromaron, Febuxostat, Colchicine	Increased Steroid dose, Colchicine
Reason for starting interleukin-1 blockade	Podagra, lumbar facet joint gout arthritis	Raised liver enzymes under current gout therapy, gout arthritis	Gout arthritis, allopurinol and febuxostat due to azathioprine contraindicated
Dose of Interleukin 1 blockade	Canakinumab 150 mg s.c. every 3 months	Canakinumab 150 mg s.c. single dose	Kineret 100 mg s.c. twice weekly
Clinical course	Symptoms resolved	Gout tophi progressed	Symptoms resolved
Systemic inflammation markers	Markedly imroved	Markedly improved	Variable due to Urinary tract infection
Side effects	Medication induced hypertriglyceridemia	Pneumonia, Hyperuricemia	Urinary tract infection

Conclusions: Treatment of gout in renal transplant patients needs to be individualised.

PUB773

Infections in Kidney Transplant Recipients in the Biggest Transplant Hospital of Mexico (Western National Medical Center, IMSS) Alejandra Elizabeth Ramirez, Moises Marcial, Marco A. Torres-González, Jose Ignacio Cerrillos, Benjamin Gomez, Petra Martínez. *Nephrology, Western National Medical Center, IMSS, Gualajara, Jalisco, Mexico.*

Background: Infections are a major cause of morbidity and mortality in kidney transplant recipients. **Aim. To** describe the frequency, risk factors and major clinical syndromes associated to infections in patients renal post-transplant period.

Methods: Retrospective cohort. Medical records of kidney transplant patients who were hospitalized in the department of Nephrology between January to December 2015 and clinical, biochemical and socio-demographical and level of immunosuppression, cultures, kidney function and kind of infections were recorded. All patients over 18 years old, recipients of renal transplant with an infectious processes were included in the statistics analysis.

Results: A total of 1409 kidney transplant patients who were hospitalized in 2015, of these 325 (23%) had infectious, the average age was 31.5±10.8 years old, 63% men, 56% transplant from live donor related, 32 of brain death, in 92% of cases received induction therapy. Acute rejection was present in 11%. Presentation of post-transplant infections median was at 4 (2-11) months. Urinary tract infections were the most frequent 54%, Cytomegalovirus 4%, Pneumonia 3%, 2.5% parvovirus, 2% polyomavirus, invasive fungal infections 2%, 1% lower respiratory tract infections and 0.6% tuberculosis. Added syndromes whose etiology was infectious origin such as febrile syndrome, diarrhea and febrile neutropenia syndrome which accounted for 3%, 4% and 4% respectively.

TABLE 1: ANALYSIS OF PREDICTION OF INFECTIONS $\chi^2 = 285.5$; $P < 0.0001$

VARIABLE	OR	CI 95%	P- value
AGE	0.86	0.78 - 0.96	0.006
INDUCTION	5.20	0.70 - 38.78	< 0.0001
ALBUMIN	7.42	1.64 - 33.55	0.0009
TACROLIMUS	0.013	0.001 - 0.120	0.0001
controlled by gender, type donor, risk infectologic			

Conclusions: Interaction between immunosuppression-infection is the protagonist in renal transplant recipients, related with drugs immunosuppressants, and give us the information to prevent this kind of infections.

PUB774

Monoclonal Gammopathy of Undetermined Significance in Kidney Transplant Patients Gaetano Alfano, Francesco Fontana, Gianni Cappelli. *Dept of Surgery, Medical and Dentistry, Univ Hospital of Modena, Modena, Italy.*

Background: Monoclonal gammopathy of undetermined significance (MGUS) is an asymptomatic pre-malignant plasma cell disorder; its prevalence in the general population in Italy was reported to be 2.9% increasing with ageing. MGUS prevalence after kidney transplant (KT) has been reported in few studies, with conflicting results. We assessed MGUS prevalence in KT recipients at our Center, linked to clinical outcomes.

Methods: We retrospectively reviewed medical charts of patients receiving KT between 1998 and 2015 and assessed MGUS prevalence and its characteristics.

Results: Out of 535 screened patients, MGUS was detected in 61 cases. We further analyzed outcomes of patients with postKT stable MGUS compared with a control KT population matched for sex, age and KT date. In 14 patients MGUS spontaneously disappeared during follow-up, while in 47 remained stable. 42 patients developed MGUS after KT (7.8% of total KTpts). Mean time from KT to MGUS appearance was 5.2 year. At diagnosis 26% of patients were younger than 50 years, representing an extremely uncommon feature for general population; in contrast with previous observations, the occurrence of MGUS was not influenced by age and sex. Plasma concentration of monoclonal protein remained stable during a 8 yrs follow-up; only 1 patient (2%) developed MGUS progressing to multiple myeloma. No differences were found between KT patients with MGUS and matched KT controls for mortality, graft failure, development of "de novo" malignancies, incidence of biopsy-proven rejection and replication of lymphotropic viruses (i.e. HCV and EBV). The MGUS group had a significantly higher prevalence, compared to KT controls, of Monoclonal B-cell Lymphocytosis (MBL) developed after MGUS diagnosis (p=0,03).

Conclusions: In conclusion, we report a high incidence of MGUS after KT, with a younger age at diagnosis compared to general population and with no sex difference. KT patients with MGUS had similar rates of mortality, graft failure, malignant neoplasms, rejection and replication of lymphotropic viruses when compared to a matched KT control group. To the best of our knowledge, this is the first report describing an association between MBL and MGUS in KT patients.

PUB775

Familial Mediterranean Fever Is Associated with Increased Mortality after Kidney Trasnaplantation - A 19-Year Single Center Experience Hefziba Green,[1,2] Shelly Lichtenberg,[1] Ruth Rahamimov,[1,2] Avry Chagnac,[1,2] Benaya Rozen-Zvi.[1,2] *[1]Nephrology and Hypertension, Rabin Medical Center, Israel; [2]Sackler Faculty of Medicine, Tel Aviv Univ, Israel.*

Background: Previous small, short-term studies suggested that kidney transplantation offers a good prognosis for patients with familial Mediterranean fever (FMF) who reaches end stage renal disease (ESRD) secondary to reactive amyloidosis A (AA).

Methods: Between 1995 and 2014 we performed 2160 kidney transplantations in 2086 patients. During this time 20 patients (0.9%) with FMF were transplanted. We compared them to 82 control patients (32 with diabetes mellitus (DM), 50 with nondiabetic kidney disease). Major outcome data included overall patients' and grafts' survival.

Results: Mean overall follow-up was 116.6 ±67.5 months. Patients transplanted because of FMF or nondiabetic kidney disease were younger than patients transplanted due to DM; 43.8±14 and 41.7±13 years versus 52.3±10.6 years respectively (p=0.001). Thirty –seven patients (36%) died during the follow-up period: 11 with FMF (55%), 15 with DM (47%) and 11with other diseases (22%) (p=0.028). Median time of death for patients with FMF was 5.8 years (range 1.3-11); 91% of the deaths (10/11) occurred within 6.7 years after transplantation. FMF was associated with a 2-fold increased risk for death after transplantation; HR 2.2 (95% CI 1.1-4.4, p=0.032); and a 3-fold increased risk for hospitalization because of infection in the first year; HR 3.26 (95% CI 1.36-7.88, p=0.008). Five-year, 10-year and actuarial 15-year overall patients survival rates were 73%, 45% and 39% respectively for patients with FMF; 79%, 53% and 43% respectively for patients with DM; 87%, 75% and 75% for patients with nondiabetic kidney disease (p=0.05). Major causes of death were sepsis and CVD. Absence of hypertension before transplantation and delayed-graft function were significantly associated with increased mortality risk for patients with FMF. Overall graft survival was similar between groups.

Conclusions: In this long-term cohort study we have shown that FMF is associated with increased mortality risk after kidney transplantation compared to patients transplanted for other causes.

PUB776

Neutrophil-Lymphocyte Ratio as a Predictor for Cardiovascular Risk in Patients following Kidney Transplantation Carola-Ellen Ruiner, Louisa Werberich, Miranda Leunga Mbouamba, Roxana Werberich, Rainer Woitas. *Nephrology, Bonn Univ Hospital, Bonn, Germany.*

Background: Neutrophil to lymphocyte ratio (NLR) has been proposed as a predictor for outcome among patients with coronary heart disease (CAD). Patients on chronic renal replacement have a particular high risk for cardiovascular disease (CVD). We determined the prognostic value of NLR for cardiovascular risk and major adverse cardiac events (MACE) in patients following kidney transplantation.

Methods: The study cohort consisted of 422 consecutive patients that were kidney transplanted between March 1996 and May 2015. MACE was defined as myocardial infarction, stroke, intervention requiring CAD or death for cardiovascular reason. Blood samples were drawn prior to the kidney transplantation. C-reaktive protein (CRP) and white blood count (WBC) were measured by routine methods and NLR calculated accordingly. Observation period lasted up to 16 years (median 3 years). Mann-Whitney *U* tests, univariate and multivariate Cox regression analyses were performed. Multivariate Cox regression was adjusted for potential clinical confounders: Age, sex, diabetes mellitus, hypertension, smoking, LDL- and HDL-cholesterol and CAD.

Results: Within the first year after kidney transplantation the incidence of MACE was highest at 0.088%. MACE occurred in 16.1% of patients. Univariate analysis revealed NLR as significant predictor for MACE after renal transplantation (HR 1.16, 95%CI 1.089-1.234, p<0.001). NLR was significantly higher in patients suffering of MACE compared to the other recipients (mean ± SE 4.7 ± 0.45 vs 3.45 ± 0.11, p<0.002). After adjustment for conventional cardiovascular risk factors the multivariable Cox regression revealed NLR as independent cardiovascular risk factor (HR 1.85, 95%CI 1.025-1.149, p<0.05) beside age (HR 1.04, 95%CI 1.009-1.061, p< 0.01), CAD (HR 2.22, 95%CI 1.805-2.733, p<0.001) and smoking (HR 1.67, 95%CI 1.216-2.293, p<0.001). Additionally neither WBC nor CRP were significant predictors of MACE.

Conclusions: NLR is a cheap and easy to perform predictor for cardiovascular disease in kidney transplant recipients independent from conventional CVD risk factors. After kidney transplantation NLR is significantly higher in patients with MACE.

PUB777

Gastrointestinal Pathologies in Patients after Successful Renal Transplantation – One Center Prospective Study Anna M. Dobies,[1] Alicja Kubanek,[1] Marcin Renke,[1] Wojciech Wolyniec,[1] Lukas Palenicek,[1] Ewa Krol,[2] Slawomir Lizakowski,[2] Przemyslaw Rutkowski,[2] Boleslaw Rutkowski,[2] Alicja Debska-Slizien.[2] *[1]Dept of Occupational, Metabolic and Internal Medicine, Medical Univ of Gdansk, Gdansk, Poland; [2]Dept of Nephrology, Transplantology and Internal Medicine, Medical Univ of Gdansk, Gdansk, Poland.*

Background: The aim of this study was to evaluate the prevalence of gastrointestinal pathologies in patients after kidney transplantation .

Methods: Adult patients after kidney transplantation being under care of Outpatient Department of Nephrology in Gdansk after giving their consent were given questionnaire regarding alarm symptoms and referral for testing the presence of fecal occult blood. 186 out of approximately 940 pts being under care completed the questionnaire, 105 performed the stool sample testing. After analyzing the questionnaires and stool results 93 patients were qualified for further investigation.

Results: So far the endoscopic examination was performed in 47 patients (31m/16f) at mean age 59 (range 35-83) years. The examination revealed: gastritis and/or duodenitis in 40 patients, stomach polyps in 6 patients, diverticular colon disease in 18 pts, inflammatory bowel disease in 10, colon polyps in 14 and cancers in 3 patients.

Conclusions: The results indicate that gastrointestinal pathologies are very common in patients after the kidney transplantation. It could be taken into consideration to perform colonoscopy in each patient over 40 years old before the kidney transplantation is performed.

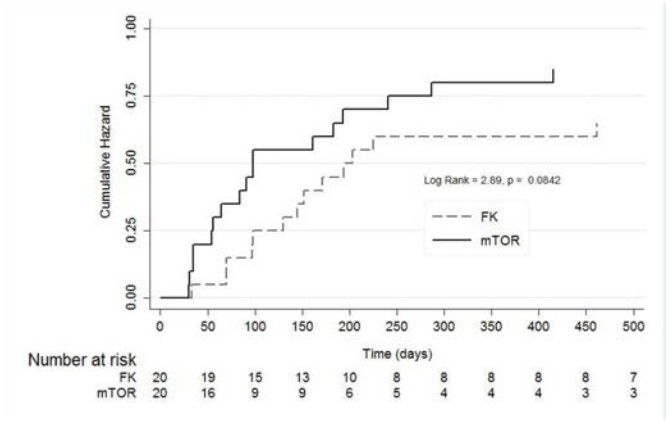
PUB778

mTOR Inhibitors in the Prevention of BK Nephropathy: A Randomized Clinical Pilot Study Sumit Mohan,[1] Mariana C. Chiles,[1] Darshana Dadhania,[3] Samnang Lee,[1] Bekir Tanriover,[2] Russell J. Crew,[1] David J. Cohen.[1] *[1]Columbia Univ; [2]Univ of Texas Southwestern; [3]Weill Cornell.*

Background: BK infection is an early and frequent complication of kidney transplantation that often results in graft loss. BK viremia (BKV) is associated with calcineurin inhibitor (CNI) use while mTOR based immunosuppression (IS) have lower rates of BK viremia. mTOR inhibitors have been associated with low rates of BKV. We compare the impact of CNI based IS reduction compare to mTOR based IS conversion in steroid free transplant recipients.

Methods: The study was a multicenter prospective randomized controlled pilot with 40 patients (Pts) randomized to reduction of CNI and antimetabolite (MPA) IS or conversion to mTOR and reduction of MPA at the time of BKV detection and started on study intervention once BKV PCR >5000 copies/mL. Primary end point was BKV clearance within 12 months of enrollment and groups were compared with an intent to treat analysis.

Results: Pts (56.7±14.0 yrs, 35% female, 23% Black, creatinine 1.41±0.4 mg/dL) were enrolled after BKV was detected 12.3±14.5 months post-transplant. Pts in the FK and mTOR arm were similar with respect to age (61±14.1 v 52.4±12.7,p=0.055), gender (30 v 40%, p=0.51), race (15 v 30%, p=0.45), creatinine (1.49 ±0.46 v 1.34±0.40 mg/dL, p=0.30). The FK and BK groups were similar with respect to complete and partial clearance of viremia (70 and 85%, p=0.58 and 70 and 95%, p=0.092, respectively). Pts exposed to mTOR had a shorter time to complete and partial clearance (134 v 158 and 67 v 109 days, respectively). Pts in the FK arm appeared to be less likely to reach BK clearance (HR=1.87; 95% CI: 0.90– 3.86; p=0.091).



Conclusions: The results from this study indicate that mTOR IS has potential to be an effective treatment option for BKV. Given the observed effect size, a clinical trial with 90 pts is needed to demonstrate a statistically significant benefit.

PUB779

Increase in Epicardial Fat Impairs the Regression of Left Ventricular Hypertrophy in Kidney Transplantation Recipients

Daniel Constantino Yazbek,[1] Aluizio B. Carvalho,[1] Cinara Barros de Sá,[1] Jose Medina-Pestana,[3] Carlos Eduardo Rochitte,[2] Raul Santos,[2] Maria Eugenia F. Canziani.[1] *[1]Federal Univ of Sao Paulo; [2]Heart Inst (InCor). Univ of São Paulo; [3]Hospital Rim.*

Background: Epicardial fat (EF) a component of visceral adipose tissue has been related to increased cardiovascular risk in chronic kidney disease (CKD). Left ventricular hypertrophy (LVH) is associated with high morbidity and mortality in this population and tends to decrease after kidney transplant. The aim of the present study was to investigate the association between changes in EF and left ventricular mass index (LVMI) during the first year after kidney transplant.

Methods: Heart images previously obtained by multislice CT from a randomized, controlled and open-labeled study that tested the effects of statins on coronary calcification in incidents kidney transplant recipients (KTRs), were evaluated. EF (milliliters) was measured by VitreaCore® software, at baseline and after 12 months. LVMI was calculated by transthoracic echocardiography at the same periods.

Results: A total of 87 KTRs, 62% men, aged 41.0 ±10.1 years, average of 24 (11 – 49) months on dialysis were evaluated. LVMI was respectively 128.5±46.1 g/m³ and 102.5 ±33.4 g/m³ at baseline and 12 months. A decrease in LVMI was observed in 39 (79%) patients. EF was 318.1 (269.0 – 356.6) and 325.9 (273.0 – 382.3) ml at baseline and 12 months, respectively. In 58 (66%) patients EF progressed during follow-up (EF progressors). These patients, when compared to those in which EF decreased, had a greater increase in body mass index (2.9 ± 2.1 kg/m² vs. 1.3 ±1.7 kg/m², p<0.001), in serum glucose concentration (6 (-3 – 12) mg/dl vs. -1 (-9 – 7) mg/dl, p=0.046) and a trend to smaller decrease of LVMI (-18 (-37 – -2) g/m³ vs. -42 (-51 – -10) g/m³, p=0.09). . The lipid profile at baseline and after 12 months, as well as the use of statins were similar between the groups. The general linear model analysis showed that the progressor group had a smaller decrease in LVMI during follow up (p for group effect <0.001; p for time-effect =0.09; p for interaction =0.03).

Conclusions: The increase of EF impaired the regression of left ventricular mass in CKD patients after kidney transplant.

PUB780

Percutaneous Ultrasound Guided Renal Transplant Biopsies Outcomes as Performed by Two Specialties

Camilo Cortesi,[1] Franco H. Cabeza Rivera,[2] Phillip Ruiz,[3] Giselle Guerra,[2] Adela D. Mattiazzi.[2] *[1]Internal Medicine, Univ of Miami - Jackson Memorial Hospital, Miami, FL; [2]Transplant Nephrology, Miami Transplant Inst - Univ of Miami, Miami, FL; [3]Surgery and Pathology, Univ of Miami, Miami, FL.*

Background: Percutaneous Ultrasound-guided renal transplant biopsy (US-TB) is the preferred method to assess renal allograft dysfunction. Reported complications rates range between 0.06-13%. We aim to analyze moderate to severe complications related to US-TB when performed either by Interventional Radiology (IR) or Transplant Nephrology (TN) specialists in a teaching hospital.

Methods: We retrospectively reviewed the US-TB performed at our center between Jan 1st 2015 and Dec 31st 2015. Demographic data, blood pressure ≥160/90mmHg, BMI, creatinine, BUN, INR, platelets counts, antiplatelet and/or anticoagulant agents held, biopsy core number, and time of complication were analyzed. Moderate complications were defined as hematoma, hydronephrosis, arteriovenous fistula (AVF), hemoglobin drop >2 g/dl, and need for blood transfusion. Severe complications were defined as development of Page kidney or need for nephrectomy, hematoma/hydronephrosis and/or AVF all associated with kidney dysfunction.

Results: 222 US-TB were performed in 204 patients; 165 (74%) by IR and 57 (26%) by TN. There was no statistical significance among demographic, clinical and laboratory data. 19 (8.5%) complications were reported. 15 (6.7%) in the IR group: 11(73%) moderate and 4 (27%) severe. 4 (1.8%) in the TN group, all moderate (NS). The most common moderate complications were hematoma and need for blood transfusion in both groups. IR group had severe complications with hematoma with kidney dysfunction. Moderate complications were diagnosed on day 1 in 33% IR group and 50% in the TN group. All severe complications were diagnosed within the first 5 days after the procedure.

Conclusions: We found no statistical significance after Percutaneous US-TB performed by the two teaching services at our institution. Further analysis is guaranteed to identify and decrease risk factor for complication.

PUB781

The Efficacy and Safety of Plaquenil in Kidney Transplants Patients with Lupus

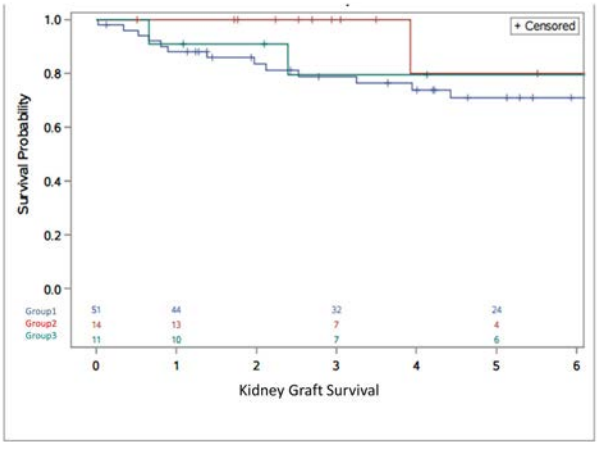
Salwa Rhazouani,[1] Siddiq Anwar,[1] Daniel C. Brennan,[1] Krista L. Lentine,[2] Karthikeyan Venkatachalam,[1] Tarek Alhamad.[1] *[1]Washington Univ; [2]Saint Louis Univ.*

Background: Hydroxychloroquine, also known as Plaquenil (PLQ) is an antimalarial drug with immunomodulatory action. Recent studies have demonstrated a protective effect of PLQ in the management of native renal lupus nephritis. The use of PLQ in kidney transplant recipients has not been examined.

Methods: A retrospective analysis of 76 kidney transplant patients with history of lupus between 1998 and 2014. Patients were categorized into 3 groups according to their PLQ use. Associations between pattern of PLQ use and post-transplant graft failure and patient death over 6 years were examined by Kaplan-Meier analysis and Cox regression.

Results: There were 14 patients who received PLQ as an alternative or adjunctive to standard immunosuppression at the time of discharge (group 2), and the remaining 62 patients were discharged with standard immunosuppression . 11 out of the 62 patients (18%) (group 3) received PLQ at a later time due to lupus nephritis or arthritis. The remaining 51 patients (group 1) never received PLQ after kidney transplantation. Graft survival and Patient Survival at 6 years was similar.

	HR for Graft Survival	HR for Patient Survival
Group 1 (Did not require PLQ)	Reference	Reference
Group 2 (PLQ on Discharge)	0.95, CI 0.27-3.34	1.23, CI 0.25-5.9
Group 3 (PLQ after Discharge)	1.14, CI 0.37-3.49	1.02, CI 0.21-4.9



Acute graft rejection during the study period was similar among the three groups (group 1= 21.5%, group 2= 28.5% and group3=36.3%, p=0.55). Only 4 out of 25 patients discontinued PLQ, mainly for anemia and leukopenia.

Conclusions: Around 20% of kidney transplant recipients with native kidney lupus nephritis require PLQ after transplant discharge for recurrent lupus symptoms or arthritis. In general, the use of PLQ is safe. Larger studies are needed to determine whether PLQ use protects survival of kidney graft.

PUB782

Incidence of Human Parvovirus B19 Infection in Kidney Recipients

Milagros Melissa Flores Fonseca, Pablo Eduardo Nava Diaz, Celina Margarita Rodriguez, Benjamin Gomez. *Nephrology and Organ Transplant Unit, Centro Medico Nacional de Occidente, Guadalajara, Jalisco, Mexico.*

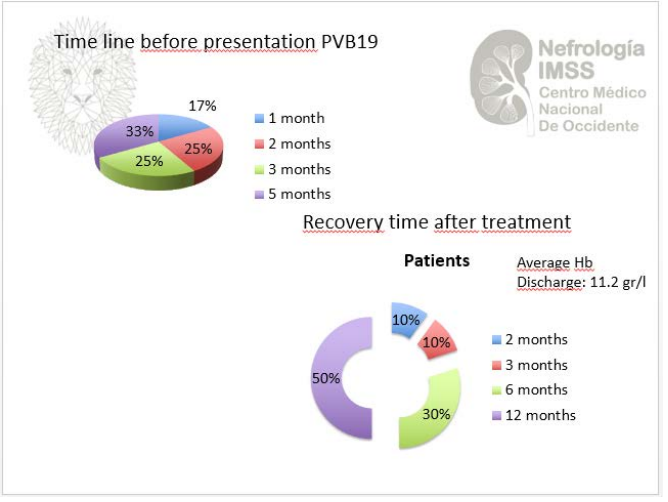
Background: Human parvovirus B19 (PVB19) infection is a rare infectious complication in immunosuppressed patients. The only manifestation is usually evidence of persistent and progressive anemia, occurring during the first year after transplantation, during which immunosuppression reaches its maximum state.

Methods: Retrospective analysis, identifying patients with persistent anemia and confirmed PVB19 in Centro Médico Nacional de Occidente (CMNO) between 2013 -2015.

Results: 12 Patients with confirmed PVB19 were identified, regardless of gender, where the average age was 25.6 years, none recipients of deceased donors, first trimester was the time line of its presentation.

Baseline Characteristics	PVB19: Number/ (%)
Gender -Male -Female	6 (50%) 6 (50%)
Age (years) -0-20 years -21-40 years -41-60 years	 1 (8.33%) 10 (83.3%) 1 (8.33%)
Kidney donor -Living related -Living unrelated	10 (83.3%) 2 (16.67%)
Induction therapy -Basiliximab -Antithymocyte globulin	8 (66.66%) 4 (33.33%)

Finding persistent anemia with hemoglobin (Hb) average 8.14 g/dl, PCR detection of viral DNA 83.3% (10/12) and/or histological evidence in bone marrow 16.67% (2/12).



Recovery evidence during the first six months after treatment 50% with an average Hb 11.2 g/dl. One patient experienced three anemia recurrences, suffering pure red cell aplasia (PRCA) confirmed by bone marrow biopsy.

Conclusions: In this retrospective analysis PVB19 infection agrees with general literature, with an incidence of 2 to 12 %. PCR for PVB19 detection had a rentability 83 %. Initial immunosuppression reduction allows initial diagnostic approach, but does not provide a benefit in the erythrocyte correction. In a patient with high clinical suspicion and PCR viral DNA should not be a criteria for exclusion of it.

PUB783

Histological and Electron Microscopy (EM) Predictors for Progressive Transplant Glomerulopathy Lavanya Kodali, Valerie R. Bloss, Erika R. Bracamonte, Catherine M. Spier, Prabir Roy-Chaudhury. *Univ of Arizona.*

Background: Transplant Glomerulopathy (TG) is an important cause of chronic allograft failure. Despite the magnitude of the clinical problem, there are currently no truly effective *biopsy based* markers of progression in patients with TG. The objective of the current study was to perform a quantitative and descriptive analysis of selected histological and electron microscopy (EM) criteria, in the context of patients with TG.

Methods: Biopsies with a diagnosis of TG and available clinical, histological and EM data were identified. Biopsies were scored for cg and cv using Banff criteria. An EM analysis was used to quantify PTC basement membrane multi lamellation (BML; normal = 0, > 4 layers was scored as 4) and the presence or absence of endothelial swelling (ES). A descriptive analysis of the full dataset for these parameters was performed, followed by a logistic regression analysis (cg 1 vs 2-3; cv 0 vs 1-3; EM changes (present vs not present), to identify predictors for a composite clinical endpoint of ESRD or doubling of serum creatinine at 1 year post biopsy.

Results: Results are shown in Table 1. While there were no statistically significant differences between the ESRD and non ESRD groups, there was a trend towards a higher cg and cv score and the presence of EM changes in patients who progressed to the composite clinical endpoint within a year. There were no differences in the composite end point between patients with lower vs higher cg/cv scores or in those with EM changes (BML and ES).

CRITERIA	TOTAL DATASET	ESRD	NO ESRD
cg Score	2.0+/-0.88	2.0+/-0.89	2.0+/-0.92
cv Score	1.07+/-1.03	1.60+/-1.14	0.75+/-0.88
PTC Multi Lamellation (EM analysis)	2.18+/-1.77	3.0+/-2.0	1.71+/-1.60
Endothelial Swelling present (EM analysis)	27%	33%	25%

Conclusions: These initial data suggest that a more detailed histological and in particular EM analysis of biopsies with TG may be warranted in order to glean the maximum available predictive information from these tissue samples; an important first step towards a more individualized/precision medicine approach to clinical transplantation.

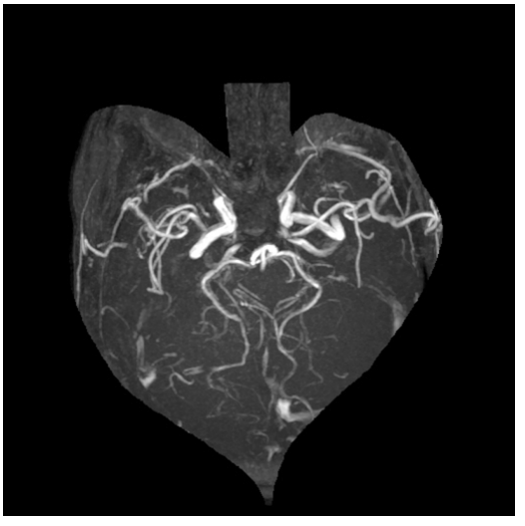
PUB784

Case of Stroke in an Adult Renal Allograft Recipient after Parvovirus B19 Infection Ravindra V. Bhattu,[1] Sonali R. Bhattu.[2] *[1]Nephrology & Renal Transplantation, DHOOT Hospital, Aurangabad, Maharashtra, India; [2]Internal Medicine, MGM's Medical College, Aurangabad, Maharashtra, India.*

Background: Viral infections manifest very differently in renal allograft recipients because of their immunosuppressed status. Parvovirus B19 infection commonly presents as anaemia. Here we present a rare case of stroke secondary to Parvovirus B19 infection in an adult renal allograft recipient.

Methods: A 35-yr old male with stage V CKD underwent pre-emptive renal transplant with his sister as donor. Immunosuppression used was standard Tacrolimus, MMF and steroids, which was started two days prior to transplant. No induction was used in view of low immunological risk. Post transplant course was uneventful with a rapid graft function achievement. Eight weeks post transplant, patient presented with severe anaemia(Hb 4.6gm%). Evaluation revealed confirmed presence of Parvovirus, hence IV Immunoglobulin therapy was started. He developed headache and visual deficit, to start with, and deteriorated within 72 hrs leading to coma and death.

Results: Serum Iron and B12 studies were normal. Bone marrow trephine biopsy revealed severe suppression of erythropoeisis and marrow was remarkable for scattered large erythroid cells (Glycophorin C and CD 117 expressing cells) with prominent large eosinophilic nuclear inclusions suggestive of Parvovirus infection, which was confirmed by Parvovirus B19 DNA demonstration by PCR. MRI brain revealed thrombosis of anterior cerebral arteries bilaterally, along with multiple infarcts in frontal areas, caudate nucleus and thalamus.



Conclusions: Viral infections manifest atypically in renal allograft recipients. Parvovirus B19 commonly presents with severe anaemia. To our knowledge this is the first ever case report of stroke secondary to Parvovirus B19 infection in an adult renal allograft recipient. This has to be kept in mind while evaluating neurological syndromes in post-transplant period.

PUB785

Design of a Real World Program to Transition Kidney Transplant Patients from Pediatric to Adult Care Tamar Y. Springel, Pat Minshall, Beth A. Vogt, Robert J. Cunningham. *Pediatrics, Rainbow Babies and Children's Hospital, Cleveland, OH.*

Background: It is hypothesized that failure of appropriate transition from pediatric to adult care may contribute to the increased risk of graft loss during early adulthood. Few studies have focused on designing a transition program for the non-research, "real world" setting. Most pediatric kidney transplant programs have limited resources to dedicate to a transition program, and may benefit from an easily adaptable program. We set out to design a program to transition kidney transplant patients from pediatric to adult care which will be easily adaptable and require limited resources.

Methods: We performed a thorough literature review of previous studies and guidelines for transitioning patients with chronic disease from pediatric to adult care. We collaborated with adult transplant nephrology physicians and transplant coordinators to ascertain hurdles to patient transition.

Results: We developed a protocol which focuses on helping patients achieve the milestones which are necessary for successful transition. Starting at age 14, readiness for transition is assessed twice yearly through previously published transition questionnaires. Patients complete one survey every 6 months, alternating between two surveys. These questionnaires are used to set patient-centered goals which are reviewed twice yearly

through a transition report card with patients and caregivers. Goals are dependent on patient's individual abilities and the caregiver's future expectations. Patients are reviewed among the pediatric and adult providers on a quarterly basis in preparation for transition in order to align care plans between pediatric and adult care. Following transition, patients are monitored more closely for the first year.

Conclusions: We designed a patient-centered program for transition kidney transplant patients from pediatric to adult care. This program can be easily adapted by most pediatric kidney transplant centers without the need for additional staff. In the future, outcomes, including adherence to appointments, adherence to laboratory testing, graft outcomes, and patient and physician satisfaction may be examined.

PUB786

Rapamycin Induced Minimal Change Disease in a Renal Transplant Recipient: A Case Report

Vasil Peev. *Rush Univ Transplant Program, Rush Univ, Chicago, IL.*

Background: Recurrent or de novo minimal change disease (MCD) in a renal transplant recipient represents a rarity. I report an unusual case of Rapamycin induced MCD in a renal transplant recipient eleven years after transplantation.

Methods: A 42- year old African American male with unknown cause of end stage renal disease (ESRD) received cadaveric renal transplant from donor after cardiac death (DCD). His postoperative course was complicated by slow graft function. He received induction immunosuppression with Campath and Solumedrol followed by maintenance immunosuppression with Prograf (FK) and Prednisone. Renal allograft biopsy preformed two years after transplant for evaluation of elevated serum creatinine revealed mild interstitial fibrosis and borderline cellular rejection. He was treated with high dose steroids. Six years later, due to concern for progressive interstitial fibrosis and persistently elevated serum creatinine he was converted from FK and prednisone to Rapamycin and prednisone. Within nine months of this conversion he developed gradually worsening proteinuria from prior baseline of 0.3g/g, now up to 2.4 g/g with otherwise normal urine sediment. Due to stable renal function and absence of donor specific antibodies (DSA) his renal biopsy was deferred. Eleven years later his proteinuria peaked at 2.5 g/g and he developed mild lower extremity edema prompting repeat renal biopsy. This showed normal glomeruli on light with diffuse foot processes effacement on electron microscopy, consistent with the diagnosis of MCD. Post Transplant Lymphoproliferative Disorder (PTLD) was ruled out based on absence of lymphadenopathy on physical exam and normal thoracic and abdominal computer tomography imaging. Intake of non-steroidal agents was ruled out per history. Conversion of Rapamycin to FK lead to prompt resolution of his near nephrotic range proteinuria.

Conclusions: In conclusion, I report a rare case of Rapamycin induced podocytopathy consistent with MCD.

PUB787

Medium and Long-Term Outcomes following Treatment of Acute Antibody Mediated Rejection Complicating Renal Transplantation- Low Morbidity and Mortality

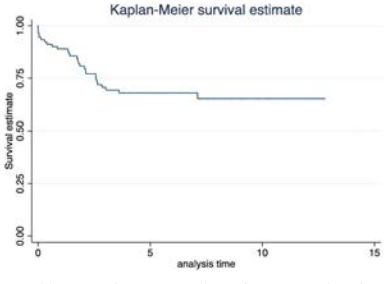
Leny Hidayati,[1] Peter D. Hughes,[2] Michael Lian,[2] Peggy Teh,[2] Marcus B. Tan,[2] Susheel Sharma,[2] Shlomo J. Cohney.[1,2] *[1]Dept of Nephrology, Western Health, Victoria, Australia; [2]Dept of Nephrology, Royal Melbourne Hospital, Victoria, Australia.*

Background: Antibody mediated rejection (AbMR) carries a high risk of graft loss, & significant treatment related morbidity & mortality. Short-term results have improved with intravenous gammaglobulin (IVIG) & plasma exchange (PEx). Little data exists on long-term outcomes, which were examined in this single centre study.

Methods: Outcomes of 87 patients diagnosed with acute AbMR between Jan 2000 & Dec 2011 were reviewed. Standard treatment included PEx, with 1 or 2 doses of intravenous methylprednisolone & no increase in maintenance immunosuppression.

Results: 91 episodes of AbMR occurred in 87 patients, 56 deemed early(<90 days post-transplant) & 35 late (>90 days post-transplant). 68 episodes were treated with PEx and IVIG; in addition, 15 received rituximab & 5 bortezemib. Two had Pex alone, IVIG alone (n=10), rituximab alone (n=1). At median follow-up of 63 months post-AbMR, patient & graft survival at 2 years were 98% & 81% & at 5 years were 93% & 65%.

Figure 1. Graft Survival Curve for All Patients



Graft loss occurred in 28 patients at median of 20.5 months after AbMR began, 12 in early AbMR group and 16 in late AbMR group. Patients with late AbMR had a 2.7-fold increased risk of graft failure (95% CI:1.30, 5.87, p-value = 0.008). There was no difference in outcome in patients receiving rituximab compared to those who did not. Amongst the 6 patients who died, median survival was 4 months after returning to dialysis. No death occurred during or was attributable to treatment of AbMR.

Conclusions: Mortality was low in this cohort of patients with AbMR treated primarily with PEX and without augmented immunosuppression while graft survival was comparable to previously published series using more aggressive therapy.

PUB788

Clinical Outcome of Kidney Re-Transplantation in Comparison with First Kidney Transplantation in Korea: Nationwide Cohort Study

Ji-Yeun Chang,[1,2] Chul Woo Yang,[1,2] Cheol Whee Park,[1] Byung Ha Chung.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea; [2]Transplant Research Center, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: Due to the limitation of the survival of kidney allograft, increasing number of patients needs to take re-transplantation (re-KT) after the first allograft failure. In this study, we investigated the clinical characteristics and clinical outcomes of re-KT recipients in comparison with those of first KT using nationwide registry.

Methods: We retrospectively analyzed 4757 adult kidney transplant recipients(KTR) registered in Korean organ transplantation registry database from 2009 to 2012. These cases were divided into 4 groups; first KT (n=2762) and re-KT (n=162) from living donor (LD), first KT (n=1647) and re-KT (n=186) from deceased donor (DD). We compared the clinical outcomes such as early or late biopsy-proven acute rejection and also allograft or patient survival rate across those groups.

Results: Out of total 4,757 KTRs, 348 (7.5%) cases were re-KT. The proportion of DDKT and sensitized patients was significantly higher in re-KT group compared to first KT group (DDKT; 53.4% vs. 37.4%; P<0.05, sensitized patients; 21.6% vs. 3.7%, P<0.05). Especially in LDKT, the proportion of ABO incompatible KT was higher in re-KT group than first KT group as well (18.5 % vs. 12.5%; P<0.05). The incidence of early biopsy-proven acute rejection (BPAR) was significantly higher in re-KT group than first KT group in DDKT (19.4% vs. 11.3%; P<0.05), but not in LDKT (7.4% vs. 9.0%; P>.05). Incidence of late BPAR was not significantly different between re-KT and first KT groups both in DDKT (0.6% vs. 2.4%; P>.05) and LDKT (1.6% vs. 2.6%; P>.05). In multivariate analysis, re-KT was an independent risk factor for development of early BPAR in DDKT (odd ratio, 1.724; 95% confidence interval, 1.10 to 2.67; P<.05). However, allograft and patient survival rate were not significantly different between re-KT and first KT group in DDKT and LDKT (P>.05, for all).

Conclusions: Our study showed that overall clinical outcomes of re-KT was comparable to those of first KT irrespective of donor type.

Real-World Experience with Astagraf XL™ in the U.S.: A Retrospective, Single-Institution Study to Evaluate Short-Term Clinical Outcomes

Samantha Montag,[1] Christy Houle,[2] Jason J. Schwartz,[2] Lihui Zhao,[1] Edward Lee,[2] Hardik Bhagat,[2] Amna Daud,[1] Asantewaa B. Ture,[1] Bing Ho,[1] Anton I. Skaro,[1] Daniela P. Ladner.[1] *[1]Northwestern Univ Transplant and Outcomes Research Collaborative (NUTORC), Chicago, IL; [2]Astellas Pharma Global Development, Inc., Northbrook, IL.*

Background: Prolonged-release tacrolimus (Astagraf XL™, AXL) is a once daily formulation approved by the FDA in 2013, but data under real-world US practice conditions are lacking. As such, we examined the patient characteristics of kidney transplant (KTx) recipients who received AXL and compared their short-term clinical outcomes [eGFR, acute rejection (AR), and graft loss] with a similar population using twice-daily immediate-release tacrolimus (TAC BID).

Methods: This case-control study was executed using the Northwestern Medicine (NM) Enterprise Data Warehouse, a repository of clinical data capturing electronic health records used at any NM clinical facility. Adult KTx patients with any AXL use through 10/2015 were matched 1:3 to KTx patients using TAC BID. Groups were matched on age, Charlson-comorbidity index (CCI), and propensity score that included gender, ethnicity, insurance status, education, language preference, organ donor type, cold ischemia time, and transplant date.

Results: Overall, 36 AXL patients were matched to 108 TAC BID patients such that there were no significant differences in baseline characteristics between the cohorts. Panel-reactive antibody and time on dialysis were similar between cohorts. AXL patients were mostly male (69.4%), had a mean age of 45.4 years, and a mean CCI of 3.8. Sixty-one percent had received a living donor transplant. After one year, there was no significant difference in eGFR (p=0.629) or graft survival (p=0.997) between the two cohorts. The hazard ratio (HR) for AR at 1 year was not significant (HR=0.317, 95% CI: 0.0395, 2.531), for AXL compared with TAC BID.

Conclusions: Preliminary analyses show that there are no significant differences in relevant short-term clinical outcomes between patients treated with AXL and TAC BID. Long-term outcomes and measures need to be evaluated.

Does Left Ventricular Mass Decrease after Successful Renal Transplantation? An Updated Metaanalysis of Observational Studies Bernhard M.W. Schmidt,[1] Kai Bergmann,[1] Anette Melk.[2] *[1]Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Pediatric Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Left ventricular hypertrophy is the hallmark of uremic cardiomyopathy and has been shown to be of prognostic importance in patients after renal transplantation. Several small studies have examined left ventricular mass index (LVMI) in renal transplant recipients with unequivocal results. We therefore performed a metaanalysis of the available evidence to assess the effect of renal transplantation on (LVMI).

Methods: We identified manuscripts using Medline and Scopus databases. The search terms were ("left ventricular mass" OR "left ventricular hypertrophy") AND (renal OR kidney) AND transplantation. For the final analysis we identified 8 manuscripts comparing LVMI in kidney transplanted patients cross-sectional with healthy controls, 6 manuscripts comparing LVMI in kidney transplanted patients cross-sectional with patients on dialysis, 13 manuscripts examining LVMI longitudinally before and at least 12 months after renal transplantation and 2 studies examining LVMI longitudinally for at least 12 months using a control cohort. Standardized means were computed and a random effect model was used for analysis. A p value 0f .05, two-sided was considered significant. heterogeneity was assessed using I2 test for heterogeneity and Cochran Q test. Publication bias was tested using funnel-plots. "Comprehensive Meta Analysis V2", Biostat, Enlewood, USA" was used for analysis.

Results: Compared to healthy controls LVMI was higher in renal transplant recipients (standardized mean difference=0.584±0.270, p= 0.030; I2= 90; Q=102,5, p<0.001), but compared to patients on dialysis LVMI was lower (standardized mean difference=0.444±0.096, p<0.001; I2= 5.2; Q= 6.3, p=0.387). In the studies with longitudinal observation LVMI was decreased after at least 12 months of follow-up (standardized mean difference=0.431±0.069, p<0.001, I2= 42, Q=20.5, p=0.058).

Conclusions: LVM Decreases after renal transplantation, but remains higher than in normal controls, reflecting a cardiovascular risk that is decreased compared to dialysis patients but remains elevated.

PUB791

Alterations in Glucose Metabolism in the Waiting List for Renal Transplatation Armando Torres, Estefanía Pérez-Carreño, Tatiana Collantes, Maria Jose De la Vega, Ana González Rinne, Domingo Marrero, Esteban Porrini. *Hospital Univ de Canarias, La Laguna, Spain.*

Background: Post-transplant diabetes (PTDM) is a severe complication after renal transplantation. Some risk factors for PTDM are present before transplantation, including obesity and insulin resistance. However, the impact of alterations in glucose metabolism (AGM) i.e. prediabetes and diabetes diagnosed by an oral glucose tolerance test (OGTT) is not completely clear.

Methods: We studied 93 patients on the waiting list, without diabetes (diagnosed by baseline hyperglycemia or the use of medications). All underwent an OGTT and were classified as normal, prediabetes (impaired fasting glucose or glucose tolerance) or occult diabetes (glucose > 200 mg/dL at 120 min). 53 patients were transplanted. OGTT was repeated at 3-m after transplantation. Insulin resistance and secretion indexes were calculated (HOMA-R, McAuley, HOMA-sec and insulinogenic index).

Results: OGTTs were abnormal in 29 (31%) patients in the waiting list (22.5% prediabetes, 8.6% DMo). Age was the best predictor of an abnormal OGTT (OR: 1.07, 95% CI 1.01-1.12, p=0.02), age≥ 55 years was the best cut off point to distinguish a pathological OGTT by (ROC curve and Youden index): <55 yr, 16,1% prediabetes and 4.8% DMo hidden; ≥ 55 yr 35.5% and 16.1% respectively). Age(45±12 vs. 55±9 y), BMI (23±3 vs 29±4) and HBA1C (4.9±0.3 vs 5.2±0.5%) on waiting list were higher in patients who developed PTDM (p<0.01). BMI≥29 and age ≥55 at pre-transplant showed the highest values of the Youden test detect the risk for PTDM at 3 months. 20 of 53 (37%) patients who received a renal transplantation developed PTDM. Of them, 4 (20%) had DMo, 6 (30%) had prediabetes and 10 (50%) had normal OGTT at pre-transplant.

Conclusions: The best strategy to detect patients on waiting list with hidden disorders of glucose metabolism and increased risk for PTDM is to perform and OGTT in subjects ≥ 55 years old and a BMI≥ 29. This may help in the design of preventive strategies to reduce the burden of PTDM.

PUB792

Association of Blood Pressure Levels and Blood Pressure Variability with Left Ventricular Hypertrophy in Pediatric Kidney Transplant Recipients Fatma Lale Sever, Ayse Agbas, Nur Canpolat, Salim Caliskan. *Pediatric Nephrology, Istanbul Univ, Cerrahpasa Medical Faculty, Istanbul, Turkey.*

Background: Recent studies suggest that not only blood pressure (BP) levels but also BP variability (BPV) is important for the development of target organ damage and cardiovascular morbidity. We aimed to evaluate the association of BP levels and BP variability with left ventricular mass index (LVMI) in pediatric kidney transplant recipients.

Methods: 32 patients (20 males, mean age 16.0±3.5 years) with a well-functioning graft (GFR>60 mL/min/1.73 m^2) who had been performed kidney transplantation (Tx) before 18 years of age were evaluated. Demographic data and medications were noted. Ambulatory BP monitoring (ABPM) and echocardiography were carried out. Standard deviation scores (SDS) for 24-h/day/night BP readings were calculated based on normative data. BP dipping and BP loads, BPV parameters [standard deviation (SD) and coefficient of variation (CV) of 24-h/day/night BP readings and average real variability (ARV)]; were recorded from ABPM files. Left ventricular hypertrophy (LVH) was defined as LVMI >95. percentile for age and gender. Hypertension was classified according to American Heart Association criteria.

Results: The median duration of dialysis before Tx was 2.47 (0-16) years and the follow-up period after Tx was 6.5 (0.3-7.5) years. Immunosuppressive protocol included triple therapy (prednisolon, MMF and tacrolimus).16 patients were on antihypertensive therapy (calcium channel blockers and/or renin angiotensin blockers). A total of 18 patients (56%) had ambulatory hypertension and 14 patients (43%) had LVH. Significant correlations were found between ambulatory BP SDS parameters and LVMI whereas BPV parameters were not associated with LVMI. Significant risk factors for LVH are shown in Table 1.

Factors influencing LVMI.

	r	p
Tx Duration	-0.405	0.021
24-h MAP SDS	0.350	0.049
Day SBP SDS	0.518	0.002
Day DBP SDS	0.356	0.045

Conclusions: It is important to note that ambulatory BP levels are strongly associated with LVH in pediatric kidney transplant recipients.

PUB793

Post-Transplantation Graft Function Is Associated with Major Cardiovascular Events in Kidney Transplant Recipients: A Multicenter Cohort Study Jae Yoon Park,[1] Yun Kyu Oh,[2] Chun Soo Lim,[2] Jung Pyo Lee,[2] Yon Su Kim.[3] *[1]Dept of Internal Medicine, Dongguk Univ Ilsan Hospital; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center; [3]Dept of Internal Medicine, Seoul National Univ College of Medicine.*

Background: Reduced kidney function is an independent risk factor for cardiovascular disease in the general population. However, the association between post-transplantation graft function and subsequent cardiovascular disease remains uncertain. Therefore, we investigated the outcomes of transplantation in kidney transplant recipients.

Methods: A total of 2,419 kidney transplant recipients in a multicenter cohort were included to evaluate the effects of post-transplant graft function on major adverse cardiovascular events (MACE: cardiac death, nonfatal myocardial infarction, or coronary revascularization), graft failure, and mortality. Recipients were classified into 3 groups according to their estimated glomerular filtration rate (eGFR): group 1 (eGFR ≥ 60 mL/min/1.73 m^2, n=1,441), group 2 (30 ≤ eGFR < 60 mL/min/1.73 m^2, n=907), and group 3 (eGFR < 30 mL/min/1.73 m^2, n=71). Multivariate Cox hazard model was used to explore the association of eGFR with MACE.

Results: Median age was 42 years and 58.8% were male. Median eGFR was 63.6 mL/min/1.73 m^2. In 2,419 participants, there were 93 cases of MACE, 214 cases of graft failure, and 76 patient deaths over a median of 6.1 years. The cumulative rates of MACE were higher in the group of lower graft function. In multivariate Cox regression, lower graft function was significantly associated with the occurrence of MACE (hazard ratio 1.5, 95% confidence interval 1.0–2.3, *P*[thinsp]=[thinsp]0.04) compared to higher graft function. Additionally, cumulative rates of graft failure and mortality were also significantly higher in recipients with lower graft function.

Conclusions: Post-transplant graft function independently correlates with MACE, graft failure, and mortality, suggesting management of graft function may improve the patient and graft survival and cardiac outcome of kidney transplant recipients.

PUB794

Kidney Transplant Outcomes in Two Adults with Down Syndrome Kammi J. Henriksen,[1] George P. Bayliss.[2] *[1]Pathology, Univ of Chicago, Chicago, IL; [2]Nephrology, Alpert Medical School, Brown Univ, Providence, RI.*

Background: There is little literature about renal transplantation in adults with trisomy 21 (Down syndrome). We present the cases of two adults transplanted at different institutions to describe their post-transplant course and outcomes.

Methods: Electronic medical records (2000-present) were reviewed at two institutions to identify adult patients with Down syndrome who had undergone kidney transplant.

Results: Patient 1 is a 45 year old man with insulin dependent type 2 diabetes initiated on hemodialysis in 2010. He underwent kidney transplant in 2014 from a 52 year-old woman who died of a stroke. Pre-transplant biopsy showed 7% glomerular sclerosis and 1% interstitial fibrosis. He received standard immunosuppression. Post-operative course was marked by delayed graft function (DGF). Initial biopsy showed acute T cell- and antibody-mediated rejection, as well as thrombotic microangiopathy (TMA). Biopsy POD 27 showed acute tubular injury, resolving inflammation, and TMA with acute and chronic features. Final biopsy at 2 months showed TMA with chronic features, despite switching tacrolimus to cyclosporine. Kidney never functioned, and patient 1 remains on dialysis. Patient 2 was a 38 year old man at his time of death in 2014. He had ESRD secondary to type 1 diabetes, and was initiated on hemodialysis in 2000. He underwent kidney transplant in 2006 from a 5 year-old deceased donor who underwent prolonged resuscitation efforts. The postoperative course was notable for DGF, for which the patient received dialysis and thymoglobulin infusion. He was discharged with stable renal function after 2 weeks, and enjoyed excellent renal function for 7.5 years on standard immunosuppression. The patient was admitted from an outside hospital in 2014 with small bowel obstruction and sepsis, and subsequently died.

Conclusions: The cases represent extremes of renal transplantation in an adult. Patient 1 remains inactive on the list, with his mother reluctant to agree to another transplant. Patient 2 enjoyed over seven years of stable renal function prior to his death. Taken together the cases underscore the need to evaluate adults with Down syndrome individually for renal transplantation.

PUB795

Surveillance Biopsy Findings with Different Induction Agents in Kidney Transplant Recipients Hector M. Madariaga,[1] Cinthia Drachenberg,[2] Nadiesda A. Costa,[1] Jonathan Bromberg,[3] Matthew R. Weir,[1] Abdolreza Haririan.[1] *[1]Div of Nephrology, Univ of Maryland Medical Center, Baltimore, MD; [2]Dept of Pathology, Univ of Maryland Medical Center, Baltimore, MD; [3]Dept of Surgery, Univ of Maryland Medical Center, Baltimore, MD.*

Background: Surveillance renal transplant biopsies (SBx) could detect subclinical histological changes that could affect graft outcomes. The impact of the induction agent on SBx findings is not well defined.

Methods: We conducted a retrospective cohort study of 466 patients who underwent SBx from 1/2007 to 12/2012, with stable graft function and no proteinuria, and had received induction with alemtuzumab (ALZ) (60%), anti-thymocyte globulin (rATG) (15%) or basiliximab (BXB) (24%).

Results: 410 patients had SBX at 4.0+-2.1 and 245 at 13.4 +- months post-transplant, 228 had both. Mean creatinine was 1.4 and 1.8 mg/dL, respectively.

First Biopsy Findings

	TCMR					BKV	ABMR			
	Borderline	1A	1B	2A	Total	SV40	Glomerulitis	PTCitis	C4d>10%	DSA
BSX	7	1	1	4	13(13.3%)	3%	9%	8.90%	14%	39.3%
rATG	7	0	0	0	7(10.5%)	4.8%	3%	2.20%	8%	50%
AlZ	9	5	1	1	16(6.5%)	3.3%	4%	2.20%	11%	52%

Second Biopsy Findings

	TCMR					BKV	ABMR			
	Borderline	1A	1B	2A	Total	SV40	Glomerulitis	PTCitis	C4d>10%	DSA
BSX	3	2	1	0	6 (10.7%)	8%	5%	2.90%	9%	39.3%
rATG	3	1	0	1	6 (12.8%)	0	23%	12.0%	13%	58.3%
AlZ	12	4	2	1	19 (11.9%)	3%	13%	5.30%	11%	62.1%

Conclusions: Our study suggests that subclinical histologic changes are not uncommon with modern IS regimens and the prevalence of these findings with ALZ induction was comparable to other induction agents.

PUB796

Incidence of Anti-HLA Antibodies Specific Donor in Kidney Transplant Recipients (KTR) and Its Association with Acute Rejection (AR) on Immunosuppression Schemes with or without Steroids Jorge Andrade-Sierra, Enrique Rojas-Campos, Jose Ignacio Cerrillos, Benjamin Gomez, Luis Alberto Evangelista-Carrillo, Alfonso M. Cueto-Manzano. *Nephrology, IMSS, Guadalajara, Jalisco, Mexico.*

Background: Antigen-specific humoral and cellular immune mechanisms contribute to an increased number and severe episodes of AR, conditioning chronic damage and graft loss. **OBJECTIVE:** To compare the incidence of donor-specific HLA-antibodies (HLA-DSA) and its association with AR in KTR on immunosuppression schemes with and without steroids.

Methods: Prospective Cohort, from March-2013 to March-2014, on participants over 18 years of age, first living donor kidney transplant (LDKT) with maintenance immunosuppression after transplantation without steroids compared to those who remained on steroids. All had negative crossmach (flow cytometry) and anti-HLA antibodies [Lifecodes LifeScreen Deluxe (LMX)] before transplantation.

Results: 77 patients posttransplant were included, 30 without steroids and 47 with steroids. At the end of follow-up the formation of donor-specific HLA-antibodies class I (13% vs 2.1%; p = 0.05) and class II (17% vs 4%; p = 0.06) was higher in the group without steroids and this intervention tended to predict the development of HLA-DSA class II [RR 5.7, CI (0.93 - 34.5). p = 0.06]. A history cellular AR was present in 80% (p = 0.07) in those who formed HLA-DSA class I and 86 % (p = 0.03) among class II and was a predictor for antibody class II formation [RR 7.23, CI (1.2 - 44); p = 0.03] Sixty-two percent of patients with positive HLA-DSA bordering changes for AR corresponded to immunosuppression without steroids.

Conclusions: The HLA-DSA class I and II were present in both groups from the early stages of transplantation, with no significant trend to be higher among those who did not receive steroids. AR predicts production of renal antibody receptors without steroids.

PUB797

Kidney Transplantation in Human Immunodeficiency Virus Positive Recipients - A Single Center Experience Javier Enrique Monserrate, Roberto L. Collazo-Maldonado, Kosunarty Fa. *Nephrology, Methodist Health System Dallas, Dallas, TX.*

Background: HIV-associated nephropathy (HIVAN) is the 3rd cause of ESRD in HIV(+). We report 10 HIV(+) KTx from HIV(-) donors.

Methods: In a 4-year period (2009-2013), data from 10 HIV(+) KTx was reviewed. Transplant criteria were: undetectable HIV RNA levels, CD4+ count ≥ 200/mm^3, stable antiretroviral Rx, and no opportunistic infections. 3 patients had biopsy-proven HIVAN: 1 had IgAN. Of 6 patients presumed to have HIVAN, one had diabetes and one had hepatitis C. Race: Black (9/10), male (7/10), mean age of 49 years. Nine KTx were from a deceased-and 1 from a living related-donor. Immunosuppression: induction with Basiliximab (n=9) or Thymoglobulin (TGB) (n=1) + tacrolimus (FK) + mycophenolic acid + steroids. KTx on Protease Inhibitors (PI) were switched to a non-PI Rx. Demographics, patient (PS) and graft survival (GS), CD4 and HIV RNA counts, renal function, as well as incidence of acute rejection (ACR), opportunistic infections and cancer were evaluated.

Results: KTx were followed for a mean of 45 months (range 19–77). ACR was diagnosed on 4 patients, most of them severe, with a mean time to first ACR of 117 days (range 6-394), and mostly associated with low or undetectable FK levels. Three KTx had opportunistic infections (1 CMV disease, 1 BK viremia and 1 PCP). Two of them had received TGB for previous ACR. One patient developed colon cancer less than 18 months post KTx. Pre-KTx mean CD4 was 574 ± 150 and 321 ± 170, at last follow up. Low CD4+ levels post KTx were attributed to a patient who had received TGB for ACR and another patient receiving chemotherapy for colon cancer. None of the patients showed reactivation of the HIV virus. Among patients with a functioning kidney, the mean serum creatinine was 1.60±0.48 mg/dl with a mean Glofil GFR of 67.2±36.6 cc/min. GS at 1 to 4 years were 90&, 80%, 80% and 80%. PS were, respectively, 100%, 90%, 90% and 90%.

Conclusions: The use of antirejection Rx does not result in the reactivation of the HIV virus. ACR tend to be severe and associated with suboptimal immunosuppression. KTx is a feasible and safe option for renal replacement in HIV(+) patients with equivalent GS and PS to HIV(-) KTx.

PUB798

Low Bioavailability Steroids for Treatment of Diarrhea Associated with Mycophenolate in Renal Transplant Recipents Pooja Budhiraja, Charity Thompson, Amna Ilahe. *Dept of Transplant, Univ of Kansas, Kansas City, MO.*

Background: Mycophenolic acid (MPA) is one of the main immunosuppressant's used in organ transplants. Diarrhea can be seen in 20% of subjects. Mycophenolic acid-acyl glucuronide is a metabolite of MPA, which causes inflammation and cytokine release and plays major role. Corticosteroids due to anti-inflammatory activity are drug of choice for noninfectious inflammatory colitis. Low bioavailability steroids act locally in the intestine and have minimal absorption into systemic circulation.

Methods: We present cases with MPA induced diarrhea who responded to these. They had no history of IBS, IBD, malabsorption and had never experienced diarrhea. Infectious work up and Celiac disease panel were negative. They had colonoscopy which revealed normal appearing terminal ileum and colonic mucosa. Random biopsies taken from the colon revealed acute and chronic inflammation, cryptitis, and focal crypt distortion. Their immunosuppression consisted of Myfortic, Prograf and prednisone. First patient is a 47 year old male with history of kidney transplant in 2014 for PKD. He presented 16 months post-transplant for diarrhea. Patient was having 5-10 episodes of watery diarrhea daily for the 2 months. The patient was started on budesonide 9 mg once a day and had improvement in diarrhea in 2 weeks**.** He continued on 9 mg for a total of 6 weeks and then tapered to 6 mg daily with taper over 12 weeks. He has been on budesonide for 8 weeks and denies diarrhea. Second patient is a 63 year old male with history of kidney transplant in 2014 for MPGN. He complained of chronic diarrhea one year post transplant. His baseline creatinine was 2.5mg/dl and he had low TPMT level. He was started on beclomethasone 2 mg three times a day and reported improvement in symptoms in 2 weeks. It was tapered to 2 mg twice a day at 6 weeks and plan is to taper it over 12 weeks. We will finish the course of oral low bioavailability steroids and observe the patient and repeat colonoscopy in 6 months after they finish treatment.

Conclusions: Oral low bioavailability steroids can improve MPA associated diarrhea and help minimize unnecessary reduction of MPA, help improve compliance and promote long term allograft survival.

PUB799

Crossed Kidney Transplantation from a Multiple-Arteries Living Donor. Arterial Reconstruction and Reimplantation in Gonadal Vein Patch Enrique Broseta, Beatriz Plaza. *Urology, Hospital Univ i Politècnico, Valencia, Spain.*

Background: Multiple arteries exist in almost 30% of these renal grafts,challenging the exvivo repair and implantation.The target of this work is to describe an infrequent arterial reconstruction technique on kidneys with multiple arteries.

Methods: 41 year-old male with chronic renal failure with no-filiated etiology is candidate for renal transplant.Living donor program is accepted.Due to AB0 incompatibility both are included in the crossed living donor program.Multi-centric crossed transplant is initiated,and a compatible left renal graft is received.Remarkably, the graft shows 4 renal arteries(3 short primaries and 1 polar) of 3-4 mm diameter.Due to the complexity

of the vascular surgery, the previous ex vivo repair is performed.During the ex vivo reconstruction,done with continous saline infusion (4ºC)and Celsior solution,the polar artery is linked,due to the endotelial injury during the explant,and the latero-lateral anastomosis of 2 principal superior arteries is done,creating a common ostium.A gonadal vein patch is created and the two joined arteries and the lower artery are anastomosed separately. The implant is made through right para-rectal incision. The arterial anastomosis is made between the right external iliac artery and the gonadal vein patch,acting as a Carrel patch.A terminolateral anastomosis is made from the donor's iliac external vein to the receiver's unic renal vein.Last,a uretheroneocystostomy is done with a Lich-Gregoir technique,including a doubleJcatheter placement.

Results: A good renal parenchyma perfusion was observed as well as positive flow in all arteries with intra-operatory continuous doppler.No intra-operatory complications were observed,and there was no need of hemo-derivates transfusion.The control doppler ultrasounds showed a normal espectral curves and normal resistance index of the renal arteries.The scanner after two months showed permeable renal arteries without signs of tenosis. After two months, the creatinine value is of 1.87mg/dL with a glomerular filtration rate of 43mL/min.

Conclusions: The use of gonadal vein acting as a Carrel patch is a safe surgical alternative in case of donor with multiple-arteries kidney.

PUB800

Oxidative Stress, and Its Association with Vascular Calcification in End Stage Renal Disease Patients Edith Viridiana Alatorre,[1] Enrique Rojas-Campos,[2] Alfonso M. Cueto-Manzano,[2] Benjamin Gomez,[1] Jose Ignacio Cerrillos.[1] *[1]Nfrologia y Trasplantes, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; [2]Unidad de Investigacion Medica en Enfermedades Renales, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: Oxidative stress(OS) is closely associated to uremia, and induce endothelial dysfunction and atherosclerosis. Aim:determine the association between OS and Vascular Calcification(VC) in ESRD patients.

Methods: A cross sectional study performed in 88 patients(HD 50%);VC (Adragao´s score) and OS by means of superoxide dismutase(SOD), catalase and 8 hidroxy-2'-deoxyguanosine(8-OHdG) were evaluated. Other CKD-MBD and metabolic variables were recorded.

Results: Age was 30±11years; males were 52%. Frequency of VC was 48%; of them 56% has ≥3 VC points. Patients with VC had lower 8-OHdG; and higher P, PTH and ALP concentrations compared to non-VC.

Variable	VC	No VC	*P value*
Age (years)	30±11	31±12	0.51
Catalase (U/mg)	16.0±9.0	17.7±9.1	0.54
SOD (UI/ml)	8.2±7.1	8.4±9.4	0.93
8-OHdG (ng/ml)	6.5±5.8	9.2±4.6	***0.03****
25 (OH) Vitamin D (ng/ml)	22±8	23±11	0.55
Paratohormone iPTH (pg/ml)	638 (246-1010)	439 (139-790)	***0.03****
Phosphorus P (mg/dl)	4.1±2.4	2.5±1.4	***<0.0001****
Total cholesterol TC (mg/dl)	163±45	158±32	0.49
Triglycerides TG (mg/dl)	159±100	135±58	0.09
LDL-cholesterol (mg/dl)	89±37	87±29	0.83
Alkaline phosphatase ALP (U/l)	142 (95-314)	97 (77-163)	***0.003****

There was not difference among groups with other variables. Correlations between OS and CKD-MBD markers were: Catalase-Vitamin D (r= -0.39;*p*=0.01), Catalase-ALP(r= -0.35;*p*=0.02); SOD-P(r=0.41;*p*=0.001), SOD-VC(r= 0.25;*p*=0.04); 8-OHdG-P(r= -0.27;*p*=0.03), 8-OHdG-VC(r= -0.41;p=0.0001).

Conclusions: Antioxidant markers were not different between patients with and without VC. DNA damage marker (8-OHdG), was higher in no VC; this finding could represent cellular damage before the VC presence. 25(OH) vitamin D, ALP, and VC were associated with lower antioxidant concentration (catalase). The higher the phosphorus the higgher the SOD(antioxidant).

PUB801

A Time Dependent Analysis of Long-Term Renal Outcome and Mortality among Critical Acute Kidney Injury Patients Receiving Different Dialysis Modality Jian-Jhong Wang,[1] Vincent Wu.[2] *[1]Internal Medicine, Chi Mei Medical Center, Liouying, Tainan, Taiwan; [2]Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Initial dialysis modality could relate to kidney outcome among AKI patients. The aim of this study was to determine the relationship between dialysis modalities and long-term outcome after critical acute kidney injury.

Methods: A retrospective, observational study was conducted to include patients underwent acute dialysis after major operation. All-cause mortality and the renal outcome at the time of hospital discharge, 90 days and 365 days after hospital discharge were assessed. Daily dialysis modalities during critical care units were analyzed using a time-dependent model in regarding to competing risk of mortality.

Results: We identified 1,101 patients (mean age 64.57 years; 66.7% were male). CVVH had the highest mortality rate and was less likely to be dialysis dependence at index time points. However, there was no difference in odds of dialysis withdrawal for patients commencing IHD, SLED versus CVVH, in the time-dependent model analysis taking the competing risk for mortality into account at index times. All cause of mortality and composite outcome also did not different between groups. Daily receipt of CVVH as time dependent modalities, however, had the highest risk of mortality and composite outcomes but was a protective factor for dialysis withdrawal with reference to SLED or IHD (all $p < 0.01$).

Conclusions: We found no significant difference in hazards for long-term dialysis dependence or composite outcomes with initial modalities of dialysis from time dependent approach. However, the subsequently daily receipt of CVVH was a risk for composite outcomes but was a protective factor for dialysis withdrawal.

PUB802

Clinical Significance of Different Carnitine Levels in Improving the Prognosis of Hemodialysis Patients Yumei Zhang,[1] Dapeng Chen,[1] Wenge Li.[1] *[1]Nephrology, China- Japan Friendship Hospital, Beijing, China; [2]Nephrology, China- Japan Friendship Hospital, Beijing, China; [3]Nephrology, China- Japan Friendship Hospital, Beijing, China.*

Background: Carnitine is an amino acid derivative, which produces energy required for muscle and cell metabolism. It has been suggested that disturbed carnitine homeostasis in hemodialysis(HD) patients. The objective of this study was to investigate the clinical significance of different carnitine levels in HD patients.

Methods: HD patients (n=133) were divided into medication group (received carnitine treatment) and non-medication group. According to patients' Fc(free carnitine)level, medication group were further divided into three subgroups: Fc80~199umoL/L group, Fc200~299umoL/L group and Fc≥300umoL/L group. We used non-derivative tandem mass spectrometry to determine carnitine level and observed clinical symptoms, such as weakness, hypotension and muscle cramps during dialysis.

Results: The Fclevel in non-medication group was significantly lower than that in control group, while the Fc, Ac(acyl-carnitine)level in medication group were higher than that in non-medication group (P<0.05). Compared with that in non-medication group, symptoms like weakness, hypotension and muscle cramps during dialysis in medication group is fewer occur (P<0.05). A further intercomparison was made in them and showed the incidence of hypotension and muscle cramps in Fc<80~199umoL/L group was lower than that in Fc≥300umoL/L medication group and non-medication group. The differences were statistical significance.

Conclusions: A general lack of carnitine in patients with hemodialysis. L - carnitine can effectively increase the concentration of Fc. We found that appropriate range of free carnitine can improve complications in dialysis, however, beyond certain range could be counterproductive. The proper range of Fc need to be further studied.

PUB803

Evaluating CTLA-4-Ig and a CXCR4 Antagonist as Potential Treatment Options for Diabetic Kidney Disease (DKD) Bhaskarjyoti Sarmah, Hana Baker, Courtney Wooden, Tao Wei, Paul J. Ryan, Sheng-Bin Peng, Victor Obungu, Matthew D. Breyer, Josef G. Heuer. *Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN.*

Background: Renal inflammation is a hallmark of DKD pathophysiology. CTLA-4 is a co-inhibitory receptor present on activated T and regulatory T cells that blocks co-stimulatory B7-1 and B7-2 ligands on antigen presenting cells, thereby limiting CD28 receptor mediated T-cell activation. Reportedly, soluble CTLA-4-Ig (abatacept) that acts as a B7 ligand trap was shown to reduce proteinuria in FSGS and nephrotic SLE patients.

Methods: We set out to test if targeting B7 molecules with CTLA-4-Ig constitutes a promising therapeutic avenue for treating DKD.

Results: There is increased mRNA expression of B7-1 in glomeruli and B7-2 and CD28 in both glomeruli and tubules of human DKD patients. B7-1 and B7-2 mRNA expression are also increased in kidneys of the *renin-AAV* uninephrectomized *db/db* mouse model. Interestingly, CTLA-4-Ig treatment retards albuminuria progression in this model compared to the vehicle control, but doesn't reduce albuminuria from baseline or further reduce albuminuria when added to Lisinopril. Among other inflammatory pathways prominently upregulated in human DKD kidney is the CXCL12/CXCR4 chemokine signaling pathway. CXCL12/CXCR4 engagement activates several signaling pathways (e.g. MAPK, PI3K/AKT, NF-κB and JAK/STAT) and is known to play a major role in cell survival, angiogenesis, inflammation, and mobilization/homing of bone marrow stem/immune cells. As both B7/CD28 and CXCL12/CXCR4 pathways are concordantly upregulated in human DKD, targeting both pathways simultaneously may result in better efficacy. The CXCR4 antagonist alone or in combination with Lisinopril doesn't impact albuminuria. However, the CTLA-4-Ig + CXCR4 antagonist + Lisinopril combination shows greater reduction of albuminuria compared to Lisinopril alone and reduces BUN and serum creatinine levels consistent with renal function improvement.

Conclusions: We conclude that CTLA-4-Ig has modest preventative effects on albuminuria in a hypertensive model of DKD and requires additional interventions to confer albuminuria reduction.

PUB804

Increasing Serum Chloride Is Associated with Acute Kydney Injury in Critically Ill Patients David Massicotte-Azarniouch,[1] Thomas Mavrakanas,[1] Sheldon Magder,[2] Peter Goldberg,[2] Ahsan Alam.[1] *[1]Nephrology, McGill Univ Health Center, Montreal, QC, Canada; [2]Critical Care, McGill Univ Health Center, Montreal, QC, Canada.*

Background: Physiologic studies have shown hyperchloremia may negatively affect kidney function. However, few studies have looked at the impact of hyperchloremia on adverse outcomes in critically ill patients. We examined the association between serum chloride levels and the development of acute kidney injury (AKI) and mortality in an intensive care unit (ICU) setting.

Methods: We conducted a retrospective, single-center, cohort study of 1866 adults admitted to an ICU between 2006 and 2011. Serum chloride values during the first 48 hours of ICU admission were collected and analysed for baseline levels, peak levels, and change in the first 48 hours. Adjusted logistic regression analysis was used to examine the association between serum chloride and the incidence of AKI (2012 KDIGO criteria) and ICU mortality.

Results: The incidence of AKI was 56.3% and ICU mortality was 12.8%. The mean (SD) baseline chloride was 106 (7.1) mmol/L and average peak chloride 106 (7.1). The mean change in chloride was -2.2 mmol/L, with 12.8% of patients showing an increase within the first 48 hours of admission. An increase in serum chloride was significantly associated with AKI and ICU mortality. In multivariate analysis adjusting for age, APACHE II score, ventilation status and pH value, the association remained significant between the serum chloride increase and severe AKI (OR 1.756, 95% CI 1.140-2.706, p=0.0107) and ICU mortality (OR 2.260, 95% CI 1.384-3.69, p=0.0011). There was no significant association between baseline or peak chloride and AKI or ICU mortality.

Conclusions: An increase in serum chloride in critically ill patients during the first 48 hours of admission is significantly associated with the development of severe AKI and ICU mortality, independent of disease severity (APACHE II score). Serum chloride increase may have a deleterious effect on kidney function. Whether this justifies the use of chloride-restrictive fluid strategies requires further evaluation.

Genetic Ablation or Pharmacologic Inhibition of the Natriuretic Peptide Clearance Receptor NPR-C Delays Chronic Kidney Disease Progression in Mouse Models

Bhaskarjyoti Sarmah,[1] Courtney Wooden,[1] Hana Baker,[1] Derek D. Yang,[1] Marikka Elia,[2] Stephanie M.E. Truhlar,[2] David J. Stokell,[1] Rebecca R. Miles,[1] Rohn Millican,[1] Yiqing Feng,[1] Zhonghua Qi,[1] Josef G. Heuer,[1] Matthew D. Breyer.[1] *[1]BioTechnology Discovery Research, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN; [2]Lilly Biotechnology Center, Lilly Research Laboratories, Eli Lilly and Company, San Diego, CA.*

Background: Natriuretic peptides (NPs, e.g. ANP, BNP, CNP) play a crucial role in cardiorenal homeostasis. NPs signal through NPR-A and NPR-B guanylyl cyclase receptors inducing cGMP signaling cascade, thereby promoting peripheral vasodilation, glomerular filtration, and salt and water excretion, and inhibiting the renin-angiotensin-aldosterone system. The third receptor, NPR-C is primarily involved in NP clearance.

Methods: We hypothesize that NPR-C inhibition will accentuate NP/cGMP signaling locally in the glomerulus, where this clearance receptor is normally expressed alongside the signaling receptors; and could be useful for treating CKD.

Results: In support of this hypothesis albuminuria progression was significantly attenuated in the *NPR-C* loss-of-function mutant mice (*NPR-C*$^{-/-}$) following remnant (3/4th renal ablation) surgery compared to wild-type littermates. No significant change in serum creatinine or BUN but significant decreases in serum renin and urinary cGMP levels are observed in the *NPR-C*$^{-/-}$group. These observations indicate that kidney NP signaling is potentiated in *NPR-C*$^{-/-}$mice which attenuates CKD progression.

To further explore this we generated high affinity NPR-C antagonist mAbs that inhibit ligand binding to the receptor, induce receptor internalization and degradation, and potentiate cGMP signaling in *NPR-A NPR-C* co-expressing cells. Interestingly, one mAb significantly retards albuminuria progression compared to vehicle in the 129*svev* mouse remnant kidney model. This mAb depletes NPR-C protein levels in the kidney confirming target engagement. However, significant changes in urine cGMP levels were not observed.

Conclusions: Overall, the NPR-C blockade was found to retard CKD progression in the hypertensive remnant kidney model.

PUB806

Case Report of Long-Term Recovery from Advanced Chronic Kidney Disease following Alternative Oxidative Therapy and Supplements

Priya Visweswaran Balakrishnan. *Div of Renal Diseases, The Immortality Inst, Houston, TX.*

Background: CKD affects nearly 3-20 million people in the US alone and 20-100 milliom people world-wide. While there are drugs available to slow progression to ESRD, nothing has been shown to absolutely, and consistently, prevent the need for Renal Replacement therapy, when CKD Stage V is attained, or RRT becomes a medical necessity. We hereby report a long-standing diabetic patient with CKD Stage V (who had needed RRT for more than 6 months with an eGFR of 12), who has successfully remained off any modality of RRT, 1 year and 3 months, after receiving thirty of our treatments.

Methods: IV administration of a mixture of oxygen and ozone gases (as described by Drs. Tom Corbett, Howard Robins, Gopal Rabindranath - nephrologist who has described this in human beings, and Sylvia Menendez - who has described this in human beings and animals), was given to the patient through a peripheral IV, at a concentration of 55 mcg/ml, starting with 2.5 ml, and slowly escalating the dose by 5-10 ml each treatment, for a minimum of 3 times a week. Vitamin B12 IM was recommended and administered as well. This is patented.

Results: Patient no longer felt weak, tired, depressed, lethargic; lost around 20 lbs of weight along with copious urination; experienced improvement of peripheral neuropathy and strength and endurance.

Conclusions: We are able to reverse uremia (to a greater or lesser extent), even in long-standing CKD, with a mixture of gaseous substances and other supplements, as needed, delivered carefully, with close observation. This may obviate the need for RRT, in several patients, even in those with long standing CKD, due to diabetes, which is generally considered to be irreversible.

Mortality and Hospitalization in Patients That Fail to Reach Dry Weight

Suzanne E. El Sayegh, Nabil Zeineddine, Raja Asif Masood, Marco Campitelli, Salim Bou Slaiman, Sandy El Bitar. *Internal Medicine, Staten Island Univ Hospital.*

Methods: Patients with end stage renal disease have an elevated risk for hospitalization, cardiovascular complications and increased mortality compared with the general population. The high rate of mortality and the high burden of cardiovascular events in ESRD patients may be related to a set of complications that occur during hemodialysis, such as intradialytic hypotension with consequent tissue hypoxia which is known to occur in relatively large number of dialyzed patients. This study was conducted to investigate the effect of failing to reach dry weight in a hemodialysis patient on mortality, hospitalization and morbidities, and whether a drop in blood pressure during hemodialysis with or without reaching the dry weight will affect a patient outcome. (intradialytic hypotension defined based on the KDOQI as " a decrease in systolic BP by 20 mmhg from predialysis to nadir intradialytic levels plus 2 or more responsive measures (saline administered, rate of dialysis decreased or dialysis stopped).

Results: 49 hemodialysis patients (49% males, 51% females. Mean age 60.7 years) with ESRD charts were reviewed, and data from 1763 hemodialysis session was collected; 37.2% (644) of the hemodialysis sessions ended with the patient reaching his dry weight. In 16.4 % (283) of hemodialysis sessions hypotension occurred. 69.4% (n=34) of the studied patients were hospitalized in a one year follow up period. 20.5% (7/34) were hospitalized for a cardiovascular complication (myocardial infarction, CHF exacerbation,or a newly diagnosed angina), 20.5% (n=7/34) were hospitalized for hemodialysis access site complications.

Conclusions: The high rate of mortality and the high burden of cardiovascular events and access complications seen in ESRD patients may be related to a set of complications that occur during hemodialysis, such as intradialytic hypotension which is known to occur in relatively large number of dialyzed patients. Analysis will be conducted further to investigate the effect of failing to reach dry weight in a hemodialysis patient on mortality, hospitalization and morbidities, and whether a drop in blood pressure during hemodialysis with or without reaching the dry weight will affect a patient outcome.

Relaxin Reverses Contrast-Induced Human Kidney Proximal Tubular Epithelial Cell Apoptosis by Activation of Akt Signaling Pathway In Vitro

Ming Wang, Xiangcheng Xie, Xiao Fei. *Nephrology, Hangzhou First People's Hospital, Affiliated Hangzhou Hospital of Nanjing Medical Univ, Hangzhou, Zhejiang, China*.

Background: Contrast-induced acute kidney injury, CI-AKI, is a common acute renal dysfunction, which is the third most common cause of hospital-acquired acute renal failure. However, the treatment strategies remain limited. The present study was designed to investigate the impact of relaxin on the contrast-induced cell injury in order to find an effective way to treat contrast-induced acute kidney injury(CI-AKI).

Methods: In this experiment, renal tubular epithelial cells (HK-2) were exposed to ioversol (100 mg iodine/mL) for 0.5 hours. The Relaxin (10ng/ml) was added 1.5 hours before Ioversol, as well as the PI3K inhibitor LY294002 (50 uM). Then cells were incubated for 24 hours in normal medium. CCK-8 assay was used to measure cell viability. Apoptotic morphologic alterations were observed using Hoechst 33342 stating method. Apoptosis was detected by Annexin V stain. Western blot analysis was employed to measure the expression of pAKTser473, AKT, Cleaved-Caspase3, Bcl-2, Bax, ACTIN protein.

Results: Ioversol reduced cell viability of HK-2 cells. Western blot results revealed that the expression of phosphorylated Akt (p-Akt) in cells decreased after exposure to ioversol. Ioversol increased both the activities of caspase-3, and the expression of the Bax protein, while the expression of Bcl-2 protein decreased. As a result the Bax/Bcl-2 ratio was therefore increased after the treatment with ioversol. These effects were reversed when co-treated with relaxin. However, when pre-administration of Akt inhibitor LY294002, the effect of relaxin was blocked, indicating that relaxin can attenuate contrast-induced cell apoptosis by activating Akt signaling pathway.

Conclusions: Our study demonstrated that relaxin attenuated the Ioversol induced cell apoptotic injury via activation of PI3K/Akt signaling pathway, suggesting that H2 relaxin might play a protective role in the treatment for CI-AKI.

Liraglutide and Renal Outcomes in Type 2 Diabetes: Results of the LEADER Trial Johannes F. Mann, Kristine Brown Frandsen, Gilbert Daniels, Peter Kristensen, Michael Nauck, Steve Nissen, Stuart Pocock, Neil Poulter, Soren Rasmussen, William Steinberg, Mette Stockner, Bernard Zinman, Florian Baeres, Richard Bergenstal, Steve Marso, John Buse. *Nephrology, Friedrich Alexander Univ, Erlangen, Germany.*

Background: The effects of liraglutide, a long-acting glucagon-like peptide-1 (GLP-1) analog, on renal outcomes in type 2 diabetes are unknown. We conducted a randomized, double-blind, placebo-controlled trial comparing liraglutide vs placebo, both on a background of standard of care, in participants with type 2 diabetes and high cardiovascular risk.

Methods: The Liraglutide Effect and Action in Diabetes: Evaluation of cardiovascular outcome Results (LEADER) trial was initiated in 2010 and completed in 2015. Renal events were key secondary outcomes. The primary renal outcome was a composite of new onset of persistent macroalbuminuria, persistent doubling of serum creatinine, end stage renal disease (ESRD), or death due to renal disease. Risk of renal outcomes was determined using intention-to-treat in time-to-event analyses; competing risk of death was taken into account. Change of eGFR and loss of eGFR by >-30% was also analyzed.

Results: 9340 patients were randomized and median follow-up was 3.84 years. The primary renal outcome occurred in fewer participants treated with liraglutide (268 of 4668) than with placebo (337 of 4672; HR 0.787 [0.670;0.924] p=0.003). The difference was primarily driven by new onset of persistent macroalbuminuria, occurring in fewer participants treated with liraglutide (161 of 4668) than with placebo (215 of 4672; HR 0.74 [0.61;0.91] p=0.004). Doubling of serum creatinine and ESRD tended to be less frequent with liraglutide. eGFR decreased significantly less and albuminuria increased less with liraglutide than placebo. The difference in change of eGFR was driven exclusively by the subgroup with eGFR <60 ml/min at baseline (N=2458). The difference in change of albuminuria was independent of baseline eGFR or albuminuria.

Conclusions: In conclusion, liraglutide in addition to standard of care therapy reduced the progression of diabetic nephropathy.

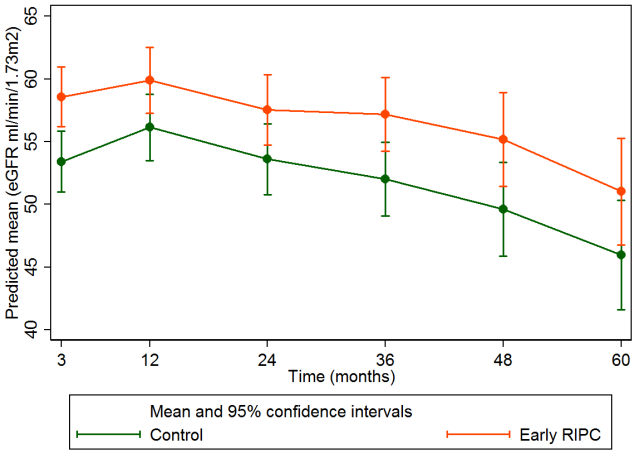
Remote Ischaemic Preconditioning (RIPC) Leads to Sustained Improvement in Allograft Function Following Live Donor (LD) Kidney Transplantation: 5 Year Follow Up in the REnal Protection Against Ischaemia Reperfusion in Transplantation (REPAIR) Study Kristin Veighey,[1] Jennifer Nicholas,[2] Tim Clayton,[2] Raymond Macallister.[3] *[1]Wessex Kidney Centre; [2]London School of Hygiene & Tropical Medicine; [3]Univ College London.*

Background: Ischaemia reperfusion (IR) injury at transplantation contributes to damage that limits allograft longevity. The REPAIR study demonstrated a trend towards improved iohexol GFR (adjusted mean difference 3.08ml/min/1.73m^2; p=0.13), and a significant improvement in eGFR (4.98ml/min/1.73m^2; p=0.011) at 1 year in patients undergoing early RIPC prior to LD kidney transplantation. We analysed eGFR data up to 5 years.

Methods: 406 adult live donor/recipient pairs were randomised by factorial design to: sham RIPC/early RIPC (immediately pre-surgery)/late RIPC (24 hours pre-surgery)/dual RIPC (early+late RIPC). The primary outcome was iohexol GFR at 12 months. eGFR (CKD-EPI) up to 60 months was an important secondary outcome.

Results: eGFR data demonstrated a sustained benefit of early RIPC - adjusted mean differences between control & early RIPC groups were 3.94 (p=0.052), 5.16 (p=0.015), 5.55 (p=0.039) & 5.05 (p=0.104) ml/min/1.73m^2 at 2,3,4 & 5 years (100% completed 3 years, 4 & 5 year follow up ongoing).



There was no strong evidence for an effect of late RIPC on allograft function. There were no clinically significant/prolonged adverse effects. Lower graft loss & mortality was noted in all preconditioned groups.

Conclusions: RIPC, a safe and virtually cost-free intervention, resulted in sustained improvement in eGFR post LD transplantation, reaching 13% by 5 years. This is expected to translate into increased graft longevity, and with longer follow up, RIPC might also reduce mortality & graft loss. Given the resultant clinical, economic & quality of life implications, we recommend that RIPC is adopted into routine care for these patients.

HI-OR03

Rabbit-ATG or Basiliximab Induction for Rapid Steroid Withdrawal after Renal Transplantation: An Open-Label, Multicentre, Randomized Controlled Trial Christian Hugo,[1] Michael Sean Wiesener,[3] Mirian Opgenoorth,[1] Oliver Thomusch.[2] *[1]Univ Hospital Carl Gustav Carus of the Technische Univ Dresden, Dresden, Germany; [2]Univ Hospital Freiburg, Freiburg, Germany; [3]Univ Hospital Erlangen, Erlangen, Germany.*

Background: In this trial we examine the efficacy and safety parameters of rapid steroid withdrawal after induction therapy either with rabbit antithymocyte globulin (rabbit ATG) or basiliximab during the first year after kidney transplantation.

Methods: We randomly assigned 615 renal transplant recipients to receive either basiliximab induction with low dose tacrolimus, mycophenolate mofetil and steroid maintenance therapy (arm A), or rapid corticosteroid withdrawal on day 8 (arm B), or rapid corticosteroid withdrawal on day 8 following rabbit ATG instead of basiliximab (arm C). The primary end point was the incidence rate of biopsy proven acute rejections at 12 months. Glomerular filtration rate (GFR), cardiovascular risk factors and safety parameters were analyzed as secondary endpoints.

Results: Biopsy proven acute rejection rates were not reduced by rabbit ATG (9·9%) compared to both other treatment arms A (11·2%) or B (10·6%) (A versus C: p=0·75; B versus C: p=0·87). As a secondary endpoint, rapid steroid withdrawal reduced posttransplantation diabetes mellitus in arm B to 23·9% and in arm C to 22·7% compared to standard arm A with 39·2% (Odds Ratio: 0·49, 95% CI: 0·30-0·82, p=0·0070). Patient and censored graft survival after 12 months were excellent and equivalent in all arms with 94·7%, 97·4%, 96·9% and 96·1%, 96·8%, 95·8% respectively. Safety parameters did not differ between the study arms.

Conclusions: Rabbit ATG failed to show superiority over basiliximab induction for the prevention of biopsy proven acute rejections after rapid steroid withdrawal within one year after renal transplantation. Nevertheless, rapid steroid withdrawal after induction therapy for patients with a low immunologic risk profile can be achieved without any loss of efficacy and is highly advantageous in regard to posttransplantation diabetes mellitus incidence. (NCT 00724022)

The Sodium Lowering in Dialysate (SoLID) Trial: A Randomised Controlled Trial of Low versus Standard Dialysate Sodium Concentration (DNa) during Hemodialysis (HD) for Regression of Left Ventricular (LV) Mass Mark R. Marshall,[1] Alain C. Vandal,[4] Joanna Leigh Dunlop,[1] Janak Rashme de Zoysa,[5] Imad A. Haloob,[2] Christopher J. Hood,[1] John Irvine,[3] Philip J. Matheson,[6] David Mcgregor,[3] Kannaiyan Samuel Rabindranath,[7] David Semple.[2] *[1]Counties-Manukau DHB, Auckland, New Zealand; [2]Auckland DHB, Auckland, New Zealand; [3]Canterbury DHB, Christchurch, New Zealand; [4]Auckland Univ of Technology, Auckland, New Zealand; [5]Waitemata DHB, Auckland, New Zealand; [6]Nephrology, Capital & Coast DHB, Wellington, New Zealand; [7]Waikato DHB, Hamilton, New Zealand.*

Background: LV hypertrophy contributes to premature cardiovascular (CV) mortality in dialysis patients. Reducing sodium exposure through lower DNa during HD may reduce LV mass.

Methods: Single-blind trial in 99 patients on home/selfcare HD from 11 centers in NZ, randomized to dNA 135mM or 140mM for 12 mo, stratified by center and conventional (≤18 h/wk) vs. extended-hour (>18 h/wk) HD. Main efficacy endpoint: LV mass index (LVMI) at 12 mo by cardiac MRI; Main safety endpoint: LV wall motion score index (WMSI) at 12 mo by cardiac MRI. We performed intention-to-treat analyses, for efficacy using a Gamma GLM with identity link function, for WMSI (dichotomising 1 vs. >1) using binomial with logit link, adjusting for baseline LVMI and WMSI. We adjusted for other covariates after blinded review (protocol BMC Nephrol 14:149/15:120/16:120, ACTRN12611000975998).

Results: Baseline data was similar across groups. Overall mean (SD) age 50.6 (13.5) yr, M/F 67/32, median (IQR) vintage 2.7 (1.3-5.9) yr, diabetes 31%, mean LVMI 94.2 (25.1), WMSI 1.1 (0.3). Conventional HD 90%, extended-hour HD 10%.

LVMI	**Est Treatment Effect (g/m^2)**	**95% CIs**	**P Value**
135mM vs. 140mM (covariate unadj)	-2.03	(-7.61,3.52)	0.47
135mM vs. 140mM (covariate adj)	-2.21	(-7.38,2.95)	0.40
WMSI	**Est Odds Ratio**	**95% CIs**	**P Value**
135mM vs. 140mM (covariate unadj)	1.37	(0.4, 5.03)	0.62
135mM vs. 140mM (covariate adj)	2.15	(0.51,10.86)	0.32

Conclusions: Reducing DNa to 135mM for 12 mo does not reduce LVMI or increase WMSI relative to 140mM. Analyses for other endpoints (e.g. BP, IDWG, IDH) will be presented.

Funding: Government Support - Non-U.S.

AURA-LV: Successful Treatment of Active Lupus Nephritis with Voclosporin William Franklin Pendergraft,[1] James A. Tumlin,[2] Brad H. Rovin,[3] Mary Anne Dooley,[1] David R.W. Jayne,[5] David Wofsy,[6] Frederic A. Houssiau,[7] David Isenberg,[8] Tak mao Chan,[9] Neil Solomons,[10] Robert B. Huizinga.[10] *[1]UNC; [2]UT; [3]OSU; [4]UNC; [5]UCambridge; [6]UCSF; [7]Univ Catholique de Louvain; [8]UCL; [9]HKU; [10]Aurinia.*

Background: In lupus nephritis (LN), complete (CR) or partial remission (PR) is associated with improved renal survival. Voclosporin (VCS) is a novel CNi with improved safety and predictable PK-PD profile.

Methods: The trial primary objective was CR defined as a urine protein/creatinine ratio (UPCR) of ≤0.5 mg/mg using first morning void with an eGFR ≥ 60 mL/min without a decrease of ≥20%. Entry criteria:renal biopsy within 6 months (Class III-V LN, ISN/RPS); UPCR>1.5 (III-IV) or 2.0 mg/mg (V);serologic evidence of active LN; and eGFR >45ml/min. Low (23.7 mg BID) or high dose VCS (39.5 mg BID) was administered with MMF and steroids.

Results: 265 patients were enrolled. Baseline UPCR (mg/mg) was 4.4 (placebo), 5.2 (low dose VCS) and 4.5 (high dose VCS). 24 week CR: **19.3%** (placebo), **32.6%** (low dose) and **27.3%** (high dose) (OR: 2.03, p=0.045 low dose vs. placebo). The results were confirmed by 24 hour urine collections (p=.047). Both the low and high dose VCS were statistically superior to placebo in PR and time to CR and PR. In the VCS groups, eGFR fell by a median of 8-9 ml/min by week 4 and then stabilized. Mean blood pressure between groups was similar. Over 90% of subjects experienced at least one adverse event with the most common being infectious and GI events. More patients experienced serious adverse events in both voclosporin groups (25.8% low, 25.0% high, 15.8% placebo) with the nature of SAEs consistent with those observed in patients with highly active LN. There were 13 deaths (1 placebo, 10 low, 2 high) with 11/13 in Asia. Causes were multi-factorial including sepsis and other lupus-related complications. None were considered related to VCS by investigators.

Conclusions: The AURA study is the first global study to demonstrate the positive effects of VCS in the treatment of active LN. Adverse events were higher in the treated patient group, consistent with increased immunosuppression. There was a higher mortality rate in the low-dose group with heterogenous causation. These favorable data will help plan subsequent studies of voclosporin in LN.

Efficacy and Safety of Sparsentan, a Dual Angiotensin II (Ang II) and Endothelin (ET) Type A Receptor Antagonist, in Patients with Focal Segmental Glomerulosclerosis (FSGS): A Phase 2 Trial (DUET) Howard Trachtman,[1,2] Peter J. Nelson,[3] Radko Komers.[4] *[1]Pediatric Nephrology, NYU School of Medicine, New York, NY; [2]NYU Langone Medical Center, New York, NY; [3]Nephrology, Univ of WA, Seattle, WA; [4]Retrophin, Inc., Cambridge, MA.*

Background: This phase 2, double-blind (DB), controlled trial (NCT01613118) evaluated the efficacy and safety of sparsentan (SPAR) as a treatment for primary FSGS.

Methods: After a 2-week ACEI/ARB washout, 109 patients, aged 8–71 yrs, with biopsy-proven FSGS were randomized to receive SPAR 200, 400, or 800mg/day, or the active control ARB irbesartan (IRB, 300mg/day) for 8 weeks. The primary endpoint was the change in urine protein-to-creatinine ratio (UPC) from baseline. The proportion of patients who achieved UPC ≤1.5g/g with >40% reduction in UPC at Week 8, a modified partial responder analysis, was evaluated as a secondary endpoint.

Results: The analysis included 96 randomized patients who completed 8 weeks of DB treatment with paired urine samples. After pooling all SPAR dose groups per the prespecified analysis plan, SPAR-treated patients demonstrated greater reductions in UPC vs those treated with IRB (45% vs 19%, *P*=.006). A significant reduction in UPC was also observed in pooled 400–800mg groups (47% vs 19%, *P*=.011). The proportion of patients who achieved UPC ≤1.5g/g with >40% reduction was 28% across all SPAR groups and 9% in IRB (*P*=.04). Complete remission (UPC <.3g/g) occurred in 4 SPAR- and 0 IRB-treated patients. In the DB period, the most common treatment emergent adverse event (AE) was hypotension; 2 SPAR patients had serious AEs (anemia, unrelated hospitalization), which did not result in discontinuation of treatment; and 3 patients discontinued due to AEs (AKI and modest LFT elevation in SPAR; hypoalbuminemia in IRB). All patients who completed the DB period were offered to continue on open-label SPAR treatment.

Conclusions: In summary, in patients with FSGS, dual Ang II and ET blockade with SPAR achieved significantly greater antiproteinuric effect compared with blockade of Ang II alone with IRB. In accord with prior studies in essential hypertension, SPAR appears to be safe and well tolerated in patients with FSGS.

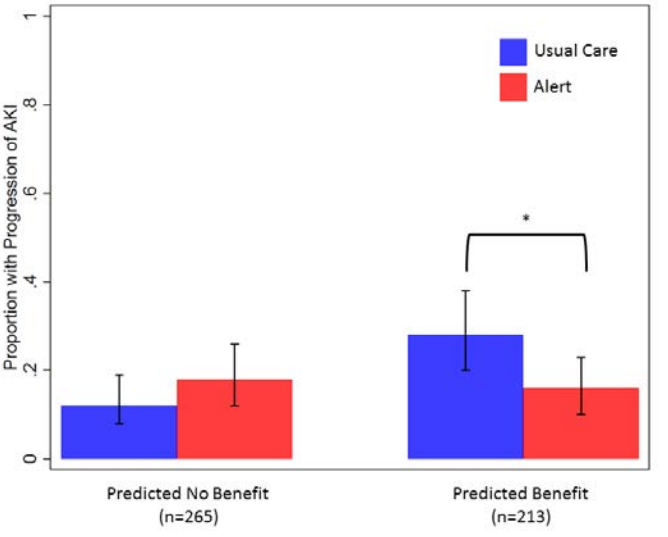
Development and Validation of a Model to Improve Targeting of Electronic Alerts for Hospitalized Patients with Acute Kidney Injury Francis Perry Wilson,[1,2] Aditya Biswas,[1] Chirag R. Parikh,[1,2] Harold I. Feldman,[3] Amit X. Garg,[4] Paul M. Palevsky,[5] Stephen R. Latham.[1] *[1]Program of Applied Translational Research, Yale Univ, New Haven, CT; [2]Clinical Epidemiology Research Center, Veterans Affairs Medical Center, West Haven, CT; [3]Dept of Medicine, Perelman School of Medicine at the Univ of Pennsylvania, Philadelphia, PA; [4]Dept of Medicine, Univ of Western Ontario, Ontario, Canada; [5]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: The proliferation of alerts in the hospital can lead to alert fatigue. Uplift modeling may allow for personalized targeting of alerts to reduce provider burden and increase effectiveness.

Methods: Using data from our prior randomized trial of electronic alerts for acute kidney injury (AKI), we trained a neural-network based uplift model on the first 4/5ths of study participants. We then tested the model in the last 1/5 of study participants to identify a subgroup of individuals who would particularly benefit from alerts, manifested by a reduction in the risk of progression of AKI at 7 days.

Results: A total of 19.7% of patients had progression of AKI in the training set and 17.8% in the test set (p=0.35). Alerting showed no significant benefit on AKI progression in either the training or test set (p=0.12, p=0.60, respectively). The uplift-model identified 213 individuals in the test set predicted to benefit from alerts, and 265 predicted not to benefit. Among those expected to benefit, alerting significantly reduced progression of AKI (OR 0.48, 0.24-0.93, p=0.03). There was no significant alert effect in those not expected to benefit (p=0.19).



Conclusions: An uplift-modeling approach successfully identified a subset of patients for whom AKI alerts were associated with a clinical benefit, and may be a feasible method to personalize alert targeting.

Effect of Oral Curcumin on Markers of Injury and Clinical Acute Kidney Injury from Elective Abdominal Aortic Aneurysm Repair Amit X. Garg. *Western Univ, Canada for Curcumin AAA Investigators.*

Background: Curcumin is a popular herbal supplement from the spice turmeric. It has anti-oxidant, anti-inflammatory and anti-apoptotic properties, and reduces ischemic reperfusion and nephrotoxin injury in animals. We tested whether oral curcumin reduces markers of injury and clinical acute kidney injury (AKI) in patients undergoing elective abdominal aortic aneurysm repair.

Methods: We randomized 606 patients at 10 centres to take oral curcumin or matching placebo for 4 days (2000 mg on 8 occasions) at the time of elective open or endovascular abdominal aortic aneurysm repair. The primary outcomes were 4 makers of injury after the repair. Secondary outcomes included clinical AKI, a composite of adjudicated clinical events, hospital length of stay and safety outcomes (diarrhea, anemia). The methods and analyses were pre-specified (ClinicalTrials.gov NCT01225094).

Results: Oral curcumin was well tolerated with >90% scheduled pills taken. Curcumin (n=304) versus placebo (n=302) had no significant effect on any injury marker, nor any other outcome. Results were consistent in additional analyses.

Randomized Controlled Trial for Renal Denervation in Resistant Hypertensive Patients (SYMPATHY): Relevance of Medication Adherence

Rosa de Jager,[1] Michiel Bots,[2] Peter J. Blankestijn.[1] *[1]Nephrology and Hypertension, UMC Utrecht, Utrecht, Netherlands; [2]Julius Center, UMC Utrecht, Utrecht, Netherlands.*

Background: Randomized controlled trials of catheter-based renal denervation (RDN) as therapy for resistant hypertension produced conflicting results. Medication adherence may be important in (partially) explaining that.

Methods: SYMPATHY is a prospective open label multicenter trial in Dutch patients with resistant hypertension (NCT01850901). Primary outcome was change in daytime systolic ambulatory blood pressure (ABPM) at 6 months. Patients were randomly assigned to RDN or not on top of usual care. Secondary outcome included medication adherence, which was qualitatively assessed by liquid chromatography/tandem mass spectrometry with spectra library search, using blood samples collected on the day of blood pressure (BP) measurements. Patients and physicians were unaware of adherence assessment. SYMPATHY was approved by the Ethics Committee.

Results: SYMPATHY enrolled 139 patients (95 RDN; 44 control) from May 2013 to January 2016. Mean differences between control and RDN in changes in daytime systolic ABPM after 6 months was 2.0 mmHg (95% CI -6.1 to 10.2), in 24h systolic ABPM 1.0 mmHg (-7.1 to 9.1) and in office systolic BP -8.2 mmHg (-17.1 to 0.7). In four out of five patients fewer medications were detected than were prescribed. Baseline mean number of prescribed types of BP lowering drugs was 3.8±1.5 and of detected was 1.7±1.4. The better the adherence, the lower daytime systolic ABPM. A significant increase in number of detected drugs at 6 months (increase of 0.6 pills, (0.1 to 1.0), p=0.03) was found in the control, but not in the RDN group (0.3 pills (-0.2 to 0.8)).

Conclusions: This is the second largest trial in the field of RDN and the first that objectively assessed medication use in both the intervention and the control arm. RDN as therapy for resistant hypertension was not superior to usual care. Medication adherence is poor, when patients were unaware of monitoring. Hypertension which seems "resistant" to treatment is (partially) explained by poor medication adherence. Changes over time in adherence differ between RDN and control group. This complicates the interpretation of the results on BP.

FR-PO1124

Phase 2a Clinical Trial of Mitochondrial Protection (Elamipretide) during Stent Revascularization in Patients with Atherosclerotic Renal Artery Stenosis

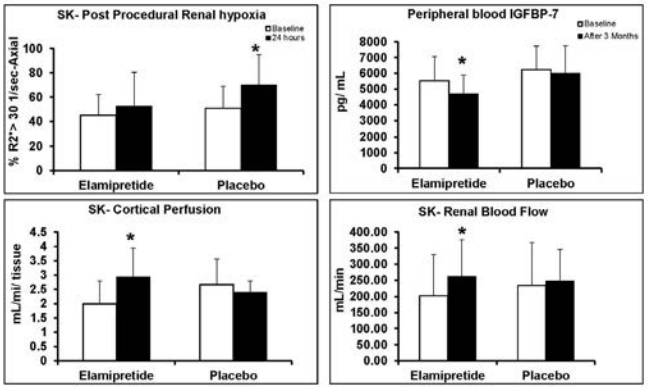
Ahmed Saad, Sandra Herrmann, Lilach O. Lerman, Stephen C. Textor. *Mayo Clinic.*

Background: Atherosclerotic renal artery stenosis (ARAS) reduces renal blood flow (RBF) and GFR and amplifies stenotic kidney (SK) injury.Renal revascularization with percutaneous transluminal renal angioplasty and stenting (PTRA) often fails to recover renal function possibly due to Ischemia reperfusion injury (IRI) developing after PTRA. Elamipretide is a mitochondrial targeted peptide that reduces IRI and improves GFR when infused during PTRA in experimental models. We hypothesized that Elamipretide plus PTRA would improve GFR, oxygenation, RBF and reduce biomarkers of cell cycle arrest (IGFBP-7) in a Phase 2a, randomized, blinded, placebo-controlled pilot study in ARAS patients undergoing PTRA.

Methods: Inpatient studies were performed during 150 mEq Na+ intake and ACE/ARB Rx in patients with severe ARAS scheduled for unilateral or bilateral PTRA. Patients were treated with a 3h IV infusion of Elamipretide (0.05 mg/kg/hour, n=6) or placebo (n=8). We measured plasma levels of IGFBP-7; Tissue oxygenation with BOLD MR before and 24 hours after PTRA. SK cortical perfusion and RBF were measured using contrast-enhanced CT before PTRA and after 3 months.

Results: Age and basal GFR did not differ between the groups. Transient hypoxia developed 24 hours after PTRA only in the placebo group (p< 0.05). IGFBP-7 decreased 3 months after PTRA in the Elamipretide-group only (p<0.05). SK-RBF and cortical perfusion increased 3 months after PTRA (p<0.05 vs. baseline) in the Elamipretide-group. Over 3 months, systolic blood pressure decreased, and eGFR increased in the Elamipretide group only.

	Elamipretide (N=6)		*Placebo (N=8)*	
Age (years)	66.7 ± 6.8		72.5 ± 8.1	
	Baseline	***3 months***	***Baseline***	***3 months***
Creatinine mg/dL	1.58 ± 0.36	1.42 ± 0.34*	1.83 ± 0.52	1.7 ± 0.44
eGFR mL/min	40.7 ± 13.3	46.5 ± 15.1*	35.6 ± 9.5	38.3 ± 10.5
Systolic blood pressure mmHg	154.2 ± 16.3	132.5 ± 16.8 *	154.2 ± 18.5	143.7 ± 26
*P< 0.05 vs baseline. Values are presented as mean ± SD				



Conclusions: Adjunctive Elamipretide during PTRA reduced immediate post-procedure hypoxia and lowered cell-cycle arrest biomarkers. It increased RBF and eGFR at 3 months. These pilot data support a role for targeted mitochondrial protection to improve outcomes of PTRA for human ARAS.

Renal and Vascular Effects of Uric Acid Lowering in Patients with Uncomplicated Type 1 Diabetes Mellitus

Yuliya Lytvyn,[1] Ronnie Lok-Hang Har,[1] Amy Locke,[1] Vesta S. Lai,[1] Derek S. Fong,[1] Andrew Advani,[2] Bruce A. Perkins,[3] David Cherney.[1] *[1]Medicine/Nephrology, Univ of Toronto/ Univ Health Network, Toronto, ON, Canada; [2]Medicine/Endocrinology, Univ of Toronto/St. Michael's Hospital, Toronto, ON, Canada; [3]Medicine/Endocrinology, Univ of Toronto/Mount Sinai Hospital, Toronto, ON, Canada.*

Background: Even within the normal range, higher plasma uric acid (PUA) levels are associated with lower GFR and higher blood pressure (BP) in young adults with type 1 diabetes (T1D). Our aim was to determine the impact of PUA lowering on renal and vascular function in patients with uncomplicated T1D.

Methods: T1D patients (n=49) were studied under eu- and hyperglycemic conditions at baseline and after treatment with the xanthine oxidase inhibitor febuxostat (FBX), for 8 weeks. Healthy controls (HC) were studied under euglycemic conditions (n=24). PUA, GFR (inulin), effective renal plasma flow (ERPF, paraaminohippurate), BP and hemodynamic responses to an infusion of angiotensin II (to assess the intrarenal RAAS) were measured pre- and post-FBX. Arterial stiffness, flow mediated and nitroglycerin mediated dilation (FMD and GMD respectively) were measured pre- and post-FBX. Gomez's equations were used to estimate afferent (R_A) and efferent (R_E) arteriolar resistances and glomerular hydrostatic pressure (P_{GLO}).

Results: FBX decreased PUA in HC (303±71µmol/L to 131±55µmol/L, p<0.0001) and T1D (240±62µmol/L to 124±53µmol/L, p<0.0001). FBX had a modest systolic BP lowering effect in T1D patients (112±10mmHg to 109±9mmHg, p=0.049), but not in HC, which was not accompanied by changes in arterial stiffness, FMD or GMD in either cohort. FBX enhanced the filtration fraction response to hyperglycemia in T1D patients, through larger increases in R_E and P_{GLO}, but without impacting the RAAS.

Conclusions: PUA lowers systolic BP and may modulate the renal R_E responses to hyperglycemia. Ongoing longitudinal outcome trials will determine whether BP and renal hemodynamic effects of PUA lowering modify renal or cardiovascular outcomes in patients with T1D.

Anti-Albuminuric Effects of Topiroxostat in Hyperuremic Patients with Diabetic Nephropathy: A Multicenter, Open-Label, Randomized Trial

Toshihiro Mizukoshi,[1] Sawako Kato,[1] Masahiko Ando,[2] Hiroshi Sobajima,[3] Norimi Ohashi,[3] Tomohiko Naruse,[3] Hideaki Shimizu,[3] Yosuke Saka,[3] Takanobu Nagata,[1] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Center for Advanced Medicine and Clinical Research, Nagoya Univ Hospital, Nagoya, Japan; [3]ETUDE Study Research Group, Japan.*

Background: Proteinuria is an established risk factor for diabetic nephropathy. Recent studies indicate that some xanthine oxidase inhibitors (XOi)s have a renoprotective effect.

Methods: The ETUDE study (Effect of Topiroxostat, a selective XOi, on Urinary albumin in hyperuricemic patients with Diabetic nEphropathy) was a 24-week, multicenter, open-label, randomized (1:1) trial of 80 patients. Hyperuricemic patients with diabetic nephropathy (estimated glomerular filtration rate [eGFR] ≥ 20 mL/min/1.73 m2) and overt proteinuria (0.3 ≤ urine protein to creatinine ratio (UPCR) < 3.5 g/g Cr) were assigned to either high dose (160 mg daily) or low dose (40 mg daily) topiroxostat. The primary endpoint was the change in albuminuria measured by urine albumin-to-creatinine ratio (UACR) after 24 weeks relative to the baseline values.

Results: Baseline characteristics were similar between the groups. In the high dose group after 24 weeks of treatment the UACR significantly decreased by -122 mg/gCr (95% CI: -5.1 to -240.1, P = 0.025), while in the low dose group the decrease in UACR was not significant (-201.4 mg/gCr [95% CI: 14.5 to -417.3, P = 0.066]). In the linear mixed model including baseline albuminuria, eGFR, age, and sex as covariates, the decreases in UACR in patients treated with topiroxostat were still significant from baseline to 12 weeks by 228.7 ± 83.2 mg/gCr (P = 0.0075) in the high dose group and to 24 weeks by 203.9 ± 77.1 mg/gCr (P = 0.001) in the low dose group. There was no significant difference between the groups. Topiroxostat had mild and significant lowering effects on eGFR and systolic and diastolic blood pressure, and it steadily reduced serum uric acid levels. The adverse event profile during this study was not different between the groups.

Conclusions: Topiroxostat 160 mg daily reduced albuminuria in patients with diabetic nephropathy. Trial registeration: UMIN 000015403.

Effects of Blisibimod, a Selective Inhibitor of B-Cell Activating Factor, in Patients with IgA Nephropathy

Jonathan Barratt,[1] Colin Hislop,[2] Jim Pennington,[2] Monica Gangal,[2] Renee Martin,[2] Adrian Liew.[3] *[1]Infection, Immunity & Inflammation, Univ of Leicester, Leicester, United Kingdom; [2]Anthera Pharmaceuticals, California; [3]Dept of Renal Medicine, Tan Tock Seng Hospital, Singapore.*

Background: IgA nephropathy (IgAN) is the commonest glomerulonephritis in the world. Elevated serum B-cell-activating factor (BAFF) correlates with IgAN histological severity. We report interim results of a Phase 2, randomized, double-blind, placebo-controlled trial evaluating the effects of blisibimod, a BAFF inhibitor, in patients with IgAN [BRIGHT-SC Study, NCT02062684].

Methods: Subjects with biopsy-proven IgAN, urine protein:creatinine ratio (UPCR) 1-6g/g,eGFR >30mL/min/1.73m² on renin-angiotensin blockade were randomized to subcutaneous blisibimod (100mg 3x/week for 8 weeks, then 200mg weekly) or placebo.57 subjects met the entry criteria, 47 of whom had been followed for ≥6 months at the time of analysis.

Results: B-cell subsets and immunoglobulin levels decreased significantly in the blisibimod group, demonstrating pharmacological inhibition of BAFF. Proteinuria reduction was seen in the blisibimod group, while a steady increase was seen with placebo, this effect persisted to week 96 (% change from baseline -8.7% vs+59.4%, p=0.017). Separation between treatments in time-average UPCR also increased over time. There was, however, no treatment effect on eGFR. Two subjects progressed to end-stage renal disease, one in each arm. Blisibimod was well-tolerated with no safety concerns reported by the safety monitoring board.

Baseline characteristics	Blisibimob	Placebo	Number
Male(%)	45		57
Asian/White/Black(%)	76/22/2		57
UPCR(g/g)	2.0	2.3	57
eGFR(mL/min/1.73m²)	68.8	68.6	57
Blood Pressure(mmHg)	126/80	122/79	57
Treatment Effects			
UPCR Week 8(g/g)	2.0	2.7	52
UPCR Week 24(g/g)	2.2	2.2	49
UPCR Week 96(g/g)	1.8	3.5	12
B cell count Week 24(% of baseline)	73.2	102.1	41
IgA Week 24(% change)	-7.8	-1.3	47

Conclusions: The data support a hypothesis that blisibimod-mediated BAFF inhibition acts to reduce peripheral B cells and immunoglobulins,and may prevent deterioration of UPCR levels in IgAN. The data support longer-term observation of the cohort.

FR-PO1129

Impact of Vitamin D on Cardiac Structure and Function in Chronic Kidney Disease: A Randomised Controlled Trial

Debasish Banerjee,[1] Nihil Chitalia,[1] Kristel E. Medina-Rodríguez,[1] Laura E. Tooth,[1] Evan Appelbaum,[3] Ravi I. Thadhani,[3] Juan Carlos Kaski,[1] David Goldsmith.[2] *[1]St Georges Univ of London; [2]Guy's Hospital; [3]Harvard Univ.*

Background: CKD is associated with cardiac hypertrophy. We examined impact of oral cholecalciferol supplementation on cardiac structure and function, in a double-blind, placebo-controlled randomised trial.

Methods: After screening 84 stable, non-diabetes, CKD stage 3-4 patients on ACEi/ARB, with vitamin D concentrations <75 nmol/L, 48 patients with left ventricular [LV] mass in the upper tertile of normal range, were randomised to receive either 6 directly-observed doses of 100,000 units of cholecalciferol or matched placebo over 42 weeks. Cardiac MRI and echocardiography were performed at baseline and 52 weeks.

Results: The clinical characteristics were well matched at baseline between vitamin D and placebo groups as follows: age 52±12 vs 52±11 years (p=0.94); eGFR 35±11 vs. 34±11 ml/min/1.73m² (p=0.75); calcium 2.4±0.1 vs 2.4±0.1 mmol/L (p=0.37); phosphate 1.1±0.2 vs 1.0±0.3 mmol/L (p=0.42). The vitamin D concentrations in the vitamin D and placebo groups; at baseline, 24 weeks and 52 weeks, were 43±18 vs. 43±20 nmol/L [p=0.95], 77±14 vs. 49±27 [p<0.001], 78±24 vs. 43±21 nmol/L [p<0.001] respectively. The left ventricular mass by MRI scan at baseline and 52 weeks, in the vitamin D and placebo groups were 104±39 vs. 100±29 gm [p=0.97] and 108±39 vs. 96±27 gm [p=0.28]. At 52 weeks there were no difference in LV volumes, RV volumes and mass, RA area, LA area, Mitral valve E/A ratio, E/e' ratios at septum and lateral wall, pulmonary artery systolic pressure between the vitamin D and placebo groups [see table 1].

Conclusions: Cholecalciferol supplementation over 52 weeks increased vitamin D levels but did not have an impact on cardiac structure of function in stable, non-diabetic, CKD patients with low vitamin D.

Table 1: The outcome variables at 52 weeks

Outcome measures	Placebo	Vitamin D	p value
LV ED Mass (gm)	96±26	108±39	0.28
LV stroke volume (ml)	96±21	95±23	0.86
LV ED Volume (ml)	149±36	154±36	0.67
LV ES Volume (ml)	108±29	118±46	0.25
RV Stroke Volume (ml)	97±24	98±33	0.74
RV ED volume (ml)	161±43	162±39	0.92
RV ES Volume (ml)	66±26	64±15	0.69
RV ejection fraction (%)	59.9±7.0	59.8±8.6	0.97
RA Area (cm²)	20±5	20±4	0.68
LA Area (cm²)	21±3.7	22±3.7	0.63
MV e/a ratio	1.02±0.22	0.96±0.27	0.41
E/e' lateral wall	9.68±4.50	7.6±2.80	0.93
E/e' septum wall	10.8±3.1	9.9±3.2	0.92
PA systolic pressure (mmHg)	22.5±8.0	22.4±5.3	0.96

Efficacy of LDL Apheresis in the Treatment of Drug-Resistant Nephrotic Syndrome

Naoki Takamatsu, Yufu Gocho, Takuto Maeda, Hideki Takizawa. *Nephrology, Teine Keijinkai Hospital, Sapporo, Japan.*

Background: LDL apheresis (LDL-A) is an extracorporeal measure to correct dyslipidemia (DL). In Japan, LDL-A is approved as a treatment of secondary DL associated with refractory nephrotic syndrome (NS) due to focal segmental glomerulosclerosis (FSGS). In addition to correction of DL, LDL-A is thought to enhance responses of immunosuppressants leading to rapid resolution of NS. A frequently encountered dilemma is the management of clinically evident FSGS despite an otherwise established biopsy-proven diagnosis. We investigated the effect of LDL-A on biopsy-proven FSGS (pFSGS) and clinically-diagnosed FSGS (cFSGS).

Methods: 10 cases of LDL-A performed for the first time against drug-resistant NS of FSGS origin (pFSGS=3, cFSGS=7) between 4/2008-8/2016 were enrolled. Clinical parameters before and after LDL-A was compared between pFSGS and cFSGS, and between complete remission (CR) and incomplete remission (ICR) groups. In addition, efficacy of LDL-A and length of hospital stay was evaluated among 3 of the relapsed cases thereafter, where LDL-A was performed for the second time.

Results: All patients received concomitant treatment of immunosuppressants (prednisone=10, cyclosporine=4), and all achieved remission from NS with LDL-A (Up

4.0±2.7 g/day to 0.8±0.8 g/day). Rate of remission did not significantly differ between pFSGS (CR 33%) and cFSGS (CR 42%). There were no clinical parameters that significantly differed between CR and ICR. Of the relapsed cases, length of hospital stay shortened from an average of 59 days to 29 days by early administration of LDL-A.

Patient	Diagnosis	Hospital stay (days)		Up at discharge (g/day)	
		1st time	2nd time	1st time	2nd time
Total		59	29	1.25	1.12
1	pFSGS	53	24	0.13	0.14
2	pFSGS	13	9	3.4	3.1
3	cFSGS	113	54	0.24	0.13

Conclusions: LDL-A was effective in treating drug-resistant NS whether by pFSGS or cFSGS. The high reproducibility of its antiproteinuric effect suggests its potential of shortening hospital stay, especially when initiated early among relapse cases with known efficacy.

Cell-Free DNA to Discriminate Active Rejection in Kidney Allografts Daniel C. Brennan,[1] Roy D. Bloom,[2] Jonathan Bromberg,[3] Emilio D. Poggio.[4] *[1]Washington Univ in St. Louis, St. Louis, MO; [2]Univ of Pennsylvania, Philadelphia, PA; [3]Univ of Maryland, Baltimore, MD; [4]Cleveland Clinic, Cleveland, OH.*

Background: The standard test to differentiate rejection and injury in kidney transplants is the allograft biopsy. Donor-derived cell free DNA (dd-cfDNA) is a noninvasive test of allograft cell injury that may enable more frequent, quantitative, and safer assessment of allograft status.

Methods: We prospectively collected blood specimens from kidney recipients at scheduled post-transplant intervals, as well as concomitantly with clinically indicated or protocol kidney biopsies. Dd-cfDNA levels were measured in blood plasma and correlated with allograft rejection status ascertained by renal biopsy.

Results: Of 384 patients with 1272 blood samples, 219 patients had ≥1 renal biopsy. The dd-cfDNA level discriminated biopsy specimens showing rejection (T cell-mediated (TCMR) and/or antibody-mediated (ABMR)) from those without rejection with a receiver-operating-characteristic (ROC) area under the curve (AUC) of 0.74; 95% CI 0.61- 0.86. The ROC-AUC for discriminating ABMR from no-rejection controls was 0.87 (95% CI 75-97). Median %dd-cfDNA was 2.9 (ABMR), 1.2 (TCMR, Types ≥ IB), 0.2 (TCMR Type IA), and 0.3 in controls (p <0.001, ABMR vs controls; p=0.05, TCMR Type ≥ IB vs controls). In a subset of stable patients, the dd-cfDNA median value was 0.21% (interquartile range 0.12-0.39%), and the 97.5th percentile was 1.20%. The positive and negative predictive values for ABMR at a cutoff of 1.0% dd-cfDNA were 44% and 96%, respectively Mean serum creatinine was 2.5 mg/dl in both the active rejection and control groups (p=0.3), and thus had no discriminatory value for rejection.

Conclusions: The dd-cfDNA level may be used to assess allograft rejection and injury status; a cutoff of ≥1% indicates a risk of active rejection (most likely ABMR or TCMR types ≥IB). Dd-cfDNA levels below threshold reflect absence of moderate or greater active rejection and may be useful to guide immunosuppressive management.

Associations between Functional and Health Status Indices in Elderly Hemodialysis Patients Khin N. Chan, Ralph Rabkin, Yu Chen, Atul A. Nagare, Baruch Vainshelboim, Jenny Kiratli, Jonathan N. Myers. *Research and Development, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.*

Background: Physical function and health status decline as renal failure progresses. While functional and health status measures have been widely studied in cardiovascular and pulmonary disease, little is known regarding these measures in maintenance hemodialysis (MHD), and which is best associated with measured functional capacity.

Methods: Twenty elderly ESRD patients (mean age: 68 ± 7, Male: 15, Female: 5) with on MHD for 3.5 ± 3 years with Kt/V: 2.1 underwent a battery of functional and health status tests, including peak VO2, six-minute walk (6MWT), strength, and one-minute sit-to-stand test to evaluate function, and body composition by Dual-energy X-ray absorptiometry (DXA). Health status was assessed using the SF-36v2 physical (PCS) and Mental (MCS) components.

Results: Mean peak VO2 was 14.52± 4.9 ml/kg/min, representing 61% ± 14.5 of the age-predicted value. Mean values for % percent predicted six-minute walk and one-minute sit-to-stand tests were 66.0 ± 17.68 and 50.7 ± 27.68, respectively. Peak VO2 was significantly related to 6MWT and lower body strength (r = 0.77, p <0.001 and r = 0.71, p <0.001 respectively); whereas peak VO2 was modestly related to upper body strength and 1-minute sit-to-stand test (r=0.54, p=0.02 and r=0.46 p=0.05, respectively). Among health status measures, peak VO2 was modestly associated with PCS (r=0.41, p=0.09) but inversely related to the MCS component (r=-0.35, p=0.16). 6MWT was strongly related to PCS (r=0.59, p=0.01). Measures of physical function were poorly related to body composition determined by DXA, including total and lower body muscle mass (r=0.03, p=0.91) and %percent of total body fat (r= -0.16, p= 0.52).

Conclusions: Functional capacity is impaired in MHD patients, but surrogate measures of function are only modestly related to peak VO2. These findings suggest that although exercise and non-exercise indices of physical function reflect different facets of health status in MHD, it appears that the 6MWT is a valid, easily performed clinical test for monitoring the physical function of MHD patients.

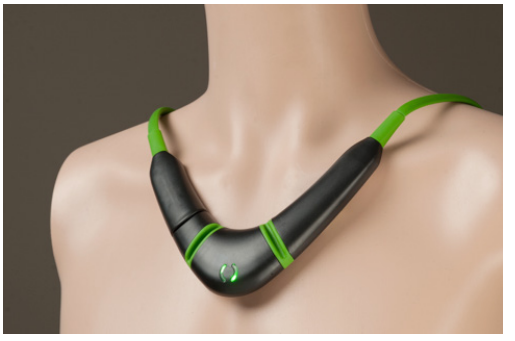
Predicting Adverse Events with Non-Invasive Monitoring Mark S. Segal,[1] Robert W. Nappo,[2] Matthew J. Banet,[3] Susan M. Pede.[3] *[1]Nephrology, Univ of Florida, Gainesville, FL; [2]Operations, UFHealth Dialysis, Gainesville, FL; [3]ToSense.*

Background: To investigate if adverse events can be identified prior to occurrence through non-invasive monitoring. Additional objectives' were estimating true 'dry weight' and evaluation of waveforms to identify hypokalemia.

Methods: Prior to start of a dialysis session, research personnel applied toSense's CoVa™ Monitoring System (the 'Sensor') (figure 1) which made frequent measurements of stroke volume, cardiac output, thoracic fluid index, heart rate, respiration rate, and ECG waveforms and wirelessly communicated the data to a cloud based storage system to patients. Additional data captured and analyzed included patients' weight before and after each dialysis session, blood pressure, fluid removed, adverse events during the dialysis session, and lab values.



Results: 28 males and 22 females participated in the study. 48 adverse events from 22 patients were captured including two patients with hypokalemia. Preliminary results indicate that: i) stroke volume decrease systematically during dialysis and precedes adverse events by 10 – 60 minutes; ii) changes in heart rate and heart rate variability precede adverse events; and iii) blood pressure can be measured without a cuff semi-continuously. One patient experienced a 12.5-kilogram weight loss over 8 dialysis sessions. Thoracic fluid measurements indicated a plateau at a dry weight. Waveform data from the hypokalemic patients is still being analyzed.

Conclusions: This study demonstrates that the Sensor's non-invasive measurements of stroke volume and fluid index may be able to predict adverse events during dialysis. Additionally, the ability to cufflessly measure blood pressure will provide earlier notification of hypotensive events during dialysis. In addition, repeated non-invasive measurements of thoracic impedance may provide insight into true dry weight for dialysis patients.

Predictors of Health Deterioration among Older New Zealanders after Twelve Months of Dialysis Therapy: Provisional Findings Robert J. Walker, Ari Samaranayaka, Bronwen M. McNoe, Mark R. Marshall, John B.W. Schollum, Sarah Derrett. *Univ of Otago, Dunedin, New Zealand.*

Background: The Dialysis Outcomes in those aged ≥65 years old Study (DOS65+) is a prospective longitudinal study examining patient-reported global health outcomes. Baseline characteristics independently predicting Worse health outcomes 12 months later are reported.

Methods: Of all 225 participants in DOS65+, this paper reports 150(88%) who were all dialysing at baseline, and had either completed a 12-month interview or died before the scheduled 12-month interview. The NZ Health and Disability Multi-region Ethics Committee granted ethical approval (MEC/10/084). Trial registration ACTRN 12611000024943. Variables were grouped according to demographic, social, health and functioning, dialysis location ['Home' or 'Clinic' (in-centre dialysis)] and ESKD symptoms. Participants' responses to: "Compared to one year ago, how would you rate your health in general now?" was the outcome of interest; categorised as 'Same or Better' or 'Worse' health. Those who died before their 12-month interview were categorised as Worse health. A modified Poisson regression model estimates relative risks and 95% confidence intervals (95%CI) using robust standard errors.

Results: At 12-month follow-up, 97 (65%) reported Same/Better health compared to one year ago; 53 (35%) reported Worse health. Risk factors for Worse health were: no satisfaction with social relationships at baseline (RR=1.66 95%CI=1.27,2.17); comorbidities (RR=1.19 95%CI=1.09,1.30); EQ-5D anxiety/depression (RR=1.61 95%CI=1.07,2.42) and poor/fair general health (RR=1.60 95%CI=1.37,1.85). Home dialysis had reduced risk of Worse health regardless of modality (HHD RR=0.55 95%CI=0.36,0.83) or (PD RR=0.86 95%CI=0.79, 0.93). Pacific people had reduced risk of Worse health at 12-months compared to European/Other ethnicities (RR=0.63 95%CI=0.52,0.72) and greater ESKD symptoms at baseline were also at reduced risk (RR=0.78 95%CI=0.62, 0.97).

Conclusions: Key findings in this older age group were that those on home dialysis reported better health than those in dialysing in Clinics, social support was important, and Pacific people reported better outcomes than Europeans.

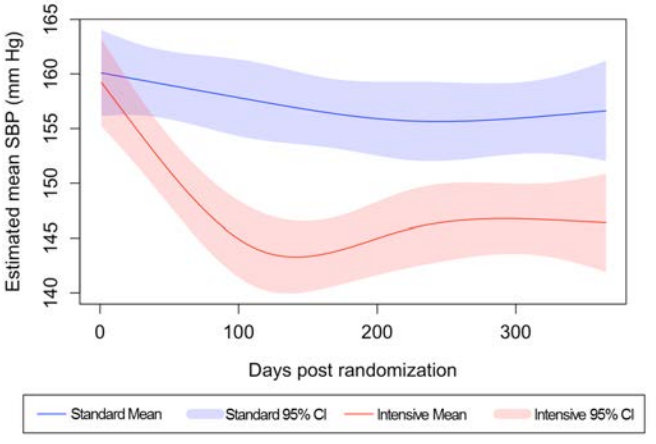
Blood Pressure in Dialysis (BID) Trial Philip Zager,[1,4,5] D. Miskulin,[2,4,5] Jennifer J. Gassman.[3,5] *[1]UNM; [2]Tufts; [3]Cleveland Clinic; [4]DCI; [5]On Behalf of the BID Study Group.*

Background: The KDOQI systolic blood pressure (SBP) guidelines for hemodialysis (HD) are based on expert opinion. Trial data are needed to determine if the benefits of intensive control of SBP in high-risk patients shown in SPRINT extend to HD patients. The BID Pilot assessed feasibility and safety of conducting a full-scale trial of intensive vs. standard control of SBP.

Methods: We randomized 126 patients to a predialysis SBP of 110-140 (n=62) or 155-165 (n=64) mm Hg for 1 year. We estimated mean SBP in each arm from a linear mixed model. We assessed the relationship of SBP to interdialytic weight gain (IDWG). We compared adverse events across arms. Change in left ventricular mass (LVM) was assessed by MRI.

Results:



In days 91 to 365 the mean separation in SBP between arms was 12.9 mm Hg. The number of antihypertensive medications at baseline (2.9 vs. 2.4), 6 (3.3 vs. 2.4) and 12 (3.4 vs. 2.5) months was higher in the intensive vs. standard arm. We used Cox models (referent: standard arm) to assess time to first death (HR 4.29), all cause (HR 1.36) and cardiovascular (HR 1.27) hospitalizations (H), all NS. There were 4 deaths in the intensive (not protocol related) and 1 in the standard arm (possibly protocol related). The numbers of H and vascular access thromboses (T) were higher in the intensive (H 85, T 20) vs. standard arm (H 47, T 7), both P<0.05. However, the number of patients with H and T was similar in the intensive (H 29, T 10) and standard arms (H 25, T 7) (NS). Intradialytic hypotension was more frequent in the intensive vs. standard arm. Overall there were no statistically significant relationships between IDWG and SBP. The median change in LVM was similar in the intensive (-0.8 g) vs. standard arm (1.5g) (NS).

Conclusions: It is feasible to conduct a full-scale trial to determine if intensive control of SBP may improve clinical outcomes. However, the possible safety signal merits inclusion of a vanguard phase.

Blood Volume Monitoring Guided Ultrafiltration Biofeedback on Reduction of Intradialytic Hypotensive Episodes in Hemodialysis: Results of a Randomized Crossover Trial Kelvin C.W. Leung, Pietro Ravani, Robert R. Quinn, Jennifer M. MacRae. *Medicine, Univ of Calgary, Calgary, AB, Canada.*

Background: Intradialytic hypotension (IDH) is associated with significant patient morbidity. One type of biofeedback technology proposed for the prevention of IDH in hemodialysis (HD) is blood volume monitoring (BVM) guided ultrafiltration (UF) biofeedback which automatically adjusts the fluid removal rate based on blood volume parameters. The effect of BVM biofeedback on the reduction of IDH was tested in a randomized trial.

Methods: We performed a 22-week, single blind, randomized crossover trial in maintenance HD patients who had >30% of HD sessions in the preceding 8-weeks complicated by symptomatic IDH in 5 centres in Calgary, Alberta, Canada. Participants underwent a four-week run-in phase for dialysis prescription and dry weight optimization and those meeting inclusion criteria were randomized to best clinical practice HD (control) or best clinical practice plus BVM-guided UF biofeedback (intervention) for 8-weeks. This was followed by a two-week washout phase prior to crossing over for a second 8-week study phase. The primary outcome was the rate of symptomatic IDH. An intent-to-treat analysis was performed.

Results: Thirty-five participants entered the study, 32 met inclusion criteria for randomization, and 26 completed the study. The rate of symptomatic IDH during the biofeedback intervention was 0.0977/hr (95% confidence interval [CI] (0.0556-0.1398/hr) and 0.0741/hr (95% CI 0.0498-0.0984/hr) during the control dialysis (P>0.05). There was no difference in the rate and proportion of sessions effected by asymptomatic IDH or symptoms alone between the two interventions. Results remained consistent when adjusted for randomization order and study week. There was no difference in interdialytic weight gain, proportion of patients achieving target weight, brain natriuretic peptide, cardiac troponins, body water content, ultrafiltration rate, and patient recovery time between the two interventions.

Conclusions: The use of BVM-guided UF biofeedback in IDH prone patients did not reduce the rate of symptomatic IDH events.

Study of the Effect of Dilution Mode of On-Line HDF on the Intra-Dialytic Hemodynamic Stability: EDOIDEA Study Ikuto Masakane,[1] Hideki Kawanishi.[2] *[1]Nephrology, Yabuki Hospital, Yamagata, Japan; [2]Nephrology, Tsuchiya General Hospital, Hiroshima, Japan.*

Background: On-Line hemodiafiltraiton (OL- HDF) is a rapidly developing dialysis modality, however, even in the latest systematic review the advantages of OL-HDF has been still controversial. OL-HDF is generally performed in performed in post-dilution (Post-HDF) in Europe and other many countries but pre-dilution (Pre-HDF) has been the major in Japan. A Randomized control trial evaluating clinical advantages of pre-dilution OL-HDF has been thirsted for to clarify which dilution modality is more effective to solve several issues in chronic dialysis patients. EDOIDEA study was designed and has been performed by Japanese Society for Hemodiafiltration (JSHDF) to answer the question.

Methods: EDOIDEA study is a randomized parallel crossover style for evaluating the influence of dilution method on intra-dialytic hemodynamic stability. The patients with informed consent were randomly divided into the next 2 groups, Group A and Group B. the patients were treated in the conventional therapy, Pre-HDF, Post-HDF, Pre-HDF in Group Aa and in the conventional therapy, Post-HDF, Pre-HDF, Post-HDF in Group B. Primary outcomes were about intra-dialytic hemodynamic stability and secondary outcomes were changes in blood chemistry, dialysis efficacy, albumin loss during dialysis session and patients' subjective symptoms.

Results: Finally 99 patients were divided into 48 patients in Group A and 51 patients in Group B. The average substitution volumes were 54.3 L/session in Pre-HDF and 14.4 L/session in Post-HDF. There were no differences in blood pressure and intra-dialytic hypotension between pre-dilution and post-dilution. Kt/V urea was greater in post-dilution than pre-dilution. The removal rate of beta2 microglobulin was not different between 2 Groups but albumin loss was greater in Post-HDF than Pre-HDF. There were no significant differences in the patients' subjective symptoms.

Conclusions: There were no definitive differences on the hemodynamically stabilities between Pre-HDF and Post-HDF. The risks of albumin loss during dialysis session and hypoalbuminemia were greater in Post-HDF than Pre-HDF.

FR-PO1140

Elevated Tissue Na+ Deposition in Hemodialysis Patients with Insulin Dependent Diabetes Mellitus Detected by 23Na-Magnetic Resonance Imaging Anke Dahlmann,[1] Christoph Kopp,[1] Peter Linz,[2] Matthias Hammon,[2] Daniela Amslinger,[1] Kai-Uwe Eckardt,[1] Friedrich C. Luft,[3] Jens Titze.[4] *[1]Nephrology and Hypertension, Univ Hospital Erlangen-Nürnberg, Erlangen, Germany; [2]Radiology, Univ Hospital Erlangen-Nürnberg, Erlangen, Germany; [3]Max-Delbrück Center for Molecular Medicine and Charité Medical Faculty, Berlin, Germany; [4]Clinical Pharmacology, Vanderbilt Univ, Nashville.*

Background: Long-term elevated blood sugar, as observed in patients with insulin dependent diabetes mellitus (IDDM), results in matrix-compositional changes of skin and muscle tissue. We used ^{23}Na-magnetic resonance imaging (^{23}Na-MRI) to quantify tissue Na^+ storage in skin and muscle of hemodialysis (HD) patients with or without concomitant IDDM. We hypothesized that tissue Na^+ might accumulate to a higher extent in HD+IDDM patients.

Methods: We determined tissue Na^+ content by ^{23}Na-MRI measurements pre- and post HD treatment in 13 HD+IDDM patients and in 46 age-matched control HD patients. Simultaneously, tissue water content was detected by ^{1}H-MRI and blood samples were taken to determine HbA1c values.

Results: ^{23}Na-MRI demonstrated increased Na^+ content in muscle and skin tissue of HD+IDDM patients compared to control HD patients. Simultaneously measured tissue water content detected by ^{1}H-MRI was not significantly different. Ratio of tissue Na^+ to water signal suggested edema-free Na^+ storage. Muscle Na^+ levels correlated with patients' HbA1c values. Na^+ and water mobilization during HD treatment lowered muscle Na^+ and water content to a greater degree in HD+IDDM patients than in HD controls.

Conclusions: ^{23}Na-MRI detected increased Na^+ in muscle and skin tissue of HD+IDDM patients compared to control HD patients. Muscle Na^+ values were directly correlated with HbA1c levels. Our findings provide first evidence that impaired serum glucose metabolism is associated with disturbances in tissue Na^+ and water content in the subpopulation of HD patients co-diagnosed with IDDM.

Intermittent HEMOdialysis Anticoagulation with TINzaparin versus Unfractionated Heparin (HEMO-TIN): A Multicentre Randomized Control Trial Christine M. Ribic,[1] Azim S. Gangji,[1] Louise M. Moist,[2] Michael Walsh,[1] Deborah J. Cook,[1] Mark A. Crowther.[1] *[1]Medicine, McMaster Univ, Hamilton, ON, Canada; [2]Medicine, London Health Sciences Centre, London, ON, Canada.*

Background: The predominant renal elimination of low molecular weight heparins (LMWHs) has raised safety concerns regarding their use as extracorporeal anticoagulants on hemodialysis (HD) due to potential bioaccumulation. Tinzaparin may be less dependent on renal clearance compared to other LMWHs. The safety and efficacy of tinzaparin for HD anticoagulation is unknown.

Methods: We conducted a double-dummy design, crossover RCT to evaluate the safety and efficacy of tinzaparin versus unfractionated heparin (UFH) for anticoagulation in patients maintained on facility-based, thrice weekly HD(NCT01930396). Patients received either UFH and tinzaparin placebo or tinzaparin and UFH placebo for 3 months followed by crossover to the alternate regimen for 3 months. Patients, health care providers and outcome adjudicators were blinded to treatment allocation. Dose titration for clinically apparent clotting of the HD circuit/filter or patient bleeding was protocolized. Primary outcomes were patient and study reported major, clinically important non-major or minor bleeds. Secondary outcomes included: a) anti-Xa and PTT levels pre and post HD; b) dialysis efficacy (Kt/V) and c) sessional HD tubing/membrane clotting using a novel scale which was validated in 205 participating dialysis nurses.

Results: 189 patients from 4 centres were randomized of which 157 crossed over and 125 completed the trial with a total of ~12, 100 HD sessions evaluated. 1238 pre and 1241 post HD anti-Xa values underwent preliminary review by the data safety monitoring board and did not raise concern for bioaccumulation. 26 dose titrations occurred in 18 patients with 13 dose increases (6 UFH; 7 Tinzaprain) for clotting and 13 dose decreases (6 UFH; 7 Tinzaparin) for bleeding events. 139 (88.5 %) patients remained on 2500 units of tinzaparin throughout the trial.

Conclusions: Tinzaparin requires minimal dose titration for bleeding or clotting events in patients requiring HD. Full data with respect to minor and major bleeding, clotting scores, dialysis efficacy and anti-Xa levels will be presented.

Roxadustat for the Treatment of Chronic Kidney Disease-Associated Anemia in Japanese Patients Not on Dialysis Tadao Akizawa,[1] Manabu Iwasaki,[2] Tetsuro Otsuka,[3] Michael Reusch,[4] Toshihiro Misumi.[3] *[1]Showa Univ School of Medicine, Tokyo, Japan; [2]Seikei Univ, Tokyo, Japan; [3]Astellas Pharma Inc., Tokyo, Japan; [4]Astellas Pharma Europe B.V., Leiden, Netherlands.*

Background: Anemia is a complication of CKD. The purpose of this study was to evaluate the efficacy and safety of ASP1517 (roxadustat) in Japanese non-dialysis anemic CKD patients.

Methods: During the 1st 6 weeks of this phase 2, double-blind, 24-week study (NCT01964196), anemic Japanese patients with CKD were randomized to oral placebo (PBO) or roxadustat (50, 70, or 100mg) 3x weekly (TIW). During weeks 6 to 24, dose was adjusted to maintain hemoglobin (Hb) at 10–12 g/dL; patients who met pre-defined criteria were re-randomized to roxadustat TIW or once weekly (QW). The primary end point was rate of rise in Hb (ΔHb, g/dL/week) during the 1st 6 weeks; response rate over the whole study and mean Hb and change in Hb from baseline (BL) at Weeks 18–24 were also evaluated. Safety was assessed by adverse events (AEs). Data are presented as mean (SD).

Results: 107 patients were randomized to PBO (n=27) or roxadustat 50mg (n=27), 70mg (n=26), or 100mg (n=27). Hb (g/dL) at BL was 9.34 (0.66) for PBO, and 9.39 (0.59), 9.39 (0.60), and 9.36 (0.50) for roxadustat 50mg, 70mg, and 100mg, respectively. The primary end point, ΔHb (g/dL/week), was –0.052 (0.142) for PBO and +0.200 (0.160), +0.453 (0.256), and +0.570 (0.240) for roxadustat; differences from PBO for all roxadustat doses were statistically significant (*P*<.0001*)* by the closed testing procedure. Response rate was 14.8% for PBO and 93.8% for pooled roxadustat (n=81). Mean Hb at Weeks 18–24 was 9.42 (0.84) for PBO and 10.48 (0.64), 10.72 (0.56), and 10.88 (0.66) for roxadustat; change from BL in Hb was –0.17 (0.61) for PBO and +1.10 (0.71), +1.33 (0.82), and +1.55 (0.88) for roxadustat. No major adverse cardiac events (ie, myocardial infarction, stroke, death) occurred in roxadustat-treated patients.

Conclusions: These data demonstrate a dose-dependent and significant correction of Hb with roxadustat vs PBO. Roxadustat was well tolerated, which is consistent with previous studies. These results support the phase 3 investigation of roxadustat for the treatment of CKD-associated anemia in patients not on dialysis.
