Primary Nephrotic Syndrome Independently Increases the Risk of Developing End-Stage Renal Disease in Adults Alan S. Go,[1] Dongjie Fan,[1] Thida Tan,[1] Janet M. Wojcicki,[2] David Law,[1] Leonid V. Yankulin,[1] Sijie Zheng,[1] Kenneth K. Chen,[1] Glenn Matthew Chertow,[3] Juan Daniel Ordonez.[1] *[1]Kaiser Permanente Northern California; [2]Univ of California, San Francisco; [3]Stanford Univ.*

Background: Few studies have systematically evaluated the independent association of primary nephrotic syndrome (NS) with the risk of end-stage renal disease (ESRD) within representative populations. We identified a cohort of adults with primary NS and a matched cohort without NS in a large integrated healthcare system and examined characteristics associated with development of ESRD.

Methods: Within Kaiser Permanente Northern California, we identified adults aged >=18 years between 1996-2012 who had nephrotic range proteinuria (UACR>3500 mcg/mg, PCR>3.5 mg/mg, 24-hr protein>3500 mg or dipstick>300 mg/dL) or diagnosed NS (ICD-9 581.x) in electronic records and lab databases. Of these, nephrologists reviewed health records for clinical presentation, labs and biopsy results to confirm primary NS. Compared with a matched cohort of patients without NS during the study period matched on age (+/- 1 month), active membership and having known kidney function, we examined the independent association between NS and the risk of developing ESRD after adjustment for potential confounders (gender, race, comorbidities, baseline estimated glomerular filtration rate, baseline hemoglobin level) using multivariable extended Cox regression models.

Results: We identified 907 adults with confirmed primary NS and 89,593 matched adults without NS. The annual incidence of ESRD was 4.65 per 100 person-years in NS patients vs. 0.03 per 100 person-years in matched non-NS patients (P<0.001). After adjustment for potential confounders, NS was independently associated with a substantially higher rate of ESRD (adjusted hazard ratio 14.6, 95% CI: 9.6-22.3).

Conclusions: Among a large, diverse community-based population, primary nephrotic syndrome was a strong, independent risk factor of developing ESRD.

SA-PO649

Tacrolimus in the Treatment of Pediatric Steroid Resistant Nephrotic Syndrome (SRNS) Ankana Daga, Avi Traum. *Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA.*

Background: Data on tacrolimus use in the treatment of pediatric SRNS is limited and biopsy findings are variable. Given the focal nature of glomerulosclerosis, whether Minimal Change Disease (MCD) in SRNS patients is a different disease or an effect of biopsy sampling continues to generate controversy. Thus, the aims of this study were to characterize the response rate to tacrolimus in pediatric SRNS, and to further describe the response rate based on biopsy findings.

Methods: This was a single-center, retrospective study of children with SRNS treated with tacrolimus. SRNS was defined as no improvement in proteinuria after 8 weeks of full dose steroids. Complete Response (CR) was defined as a urine protein-to-creatinine ratio (UPC) ≤ 0.2 and Partial Response (PR) as ≥ 50% reduction in proteinuria. Biopsy findings were recorded as MCD vs. Focal Segmental Glomerulosclerosis (FSGS).

Results: In 47 patients who met inclusion criteria, 57% were male, 45% were Caucasian, with the average age at diagnosis of 7.2 ± 5.6 years. Thirty-six (77%) patients responded to therapy after 6 months of tacrolimus (32% CR, 45% PR). Twenty-eight (60%) patients responded to therapy after 12 months of tacrolimus (28% CR, 32.6% PR). Acute kidney injury was the most common side effect, occurring in 17 (36%) patients. FSGS was detected on biopsy in 27 patients while 16 patients had MCD. The average number of glomeruli per biopsy sample was 16.7 ± 9.8. Of the 27 patients with FSGS, 67% responded to therapy (15% CR, 52% PR) at 6 months. Interestingly, of the 16 patients with MCD, 88% responded (50% CR, 38% PR) at 6 months. The response rate at 12 months of treatment with tacrolimus was 67% in the FSGS group versus 56% in the MCD group. The MCD group at 12 months included 2 lost to follow up and 2 with <12 months of therapy, while among FSGS patients, 3 had therapy discontinued, which included 2 who developed ESRD, and 1 who was diagnosed with cancer.

Conclusions: Tacrolimus is an effective therapy in children with SRNS irrespective of histologic findings. Biopsy revealing MCD in SRNS patients should not preclude use of tacrolimus. Multi-center studies are needed in the future to validate these findings.

SA-PO650

Rituximab Treatment for Frequently Relapsing Nephrotic Syndrome or Steroid-Dependent Nephrotic Syndrome Mika Sonoda, Eiji Ishimura, Shuko Ueda, Shinya Nakatani, Mitsuru Ichii, Yoshiteru Ohno, Akihiro Tsuda, Katsuhito Mori, Masaaki Inaba. *Osaka City Univ Graduate School of Medicine, Osaka, Japan.*

Background: Frequently relapsing nephrotic syndrome (FRNS) and steroid-dependent nephrotic syndrome (SDNS) requires long-term corticosteroid therapy and/or immunesupressive agents, which cause significant adverse effects. Recently, rituximab, a chimeric monoclonal antibody against the CD20 antigen, has been expected for the treatment of FRNS /SDNS in children in some countries. However, there are few reports on the treatment for adult patients with childhood-onset FRNS and/or SDNS.

Methods: Six patients (24.6 +/- 5.9 year-old, 2 males and 4 females) of FRNS/SDNS were treated by rituximab. All patients had nephrotic syndrome of childhood-onset, which relapsed more than fifteen times. They had been orally taking prednisolone and/or cyclosporine. After premedication, such as acetoamiophen and chlorphenamine, to prevent infusion reaction, 500 mg rituximab was intravenously administered. Effect of rituximab on inhibition of relapse and changes in B cell counts in blood were examined up to ten months.

Results: All patients could receive intravenous 500mg rituximab, without any infusion reaction and adverse events. In the follow-up period, oral predonisolone and/or cyclosporine could be reduced gradually without relapse of nephrotic syndrome. B cells in blood significantly decreased. Changes in B cell counts in all patients were as followings; before administration, CD 19 cells were 8.5 +/- 4.1%, and CD 20 cells 10.1 +/- 3.6%; after 6 months: 2.8 +/- 3.3% (CD19) and 2.8 +/- 3.5% (CD20). In one patient, rituximab was re-administered because increase of B cells were seen.

Conclusions: Intravenous rituximab treatment is effective against relapse of nephrotic syndrome in adult patients with childhood-onset FRNS /SDNS. It is safely administered with appropriate anti-allergic pretreatment. It causes significant decrease in B cell counts in blood. It can reduce the dose of corticosteroid in adult patients with childhood-onset FRNS/SDNS. Long-term observation is currently undergone.

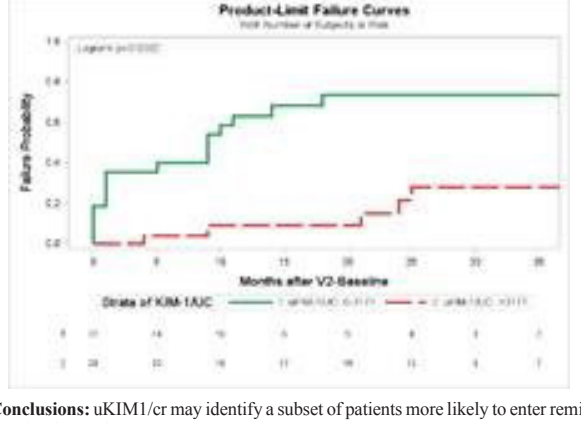
SA-PO651

Urine KIM-1/Creatinine as a Marker of Glomerular Disease Severity and Treatment Response in the Nephrotic Syndrome Study Network Qiaoyuan Wu,[1] Jonathan P. Troost,[2] Tiane Dai,[1] Boxian Wei,[2] Peter X.K. Song,[2] Debbie S. Gipson,[2] Cynthia C. Nast,[1] Matthias Kretzler,[2] Sharon G. Adler.[1] *[1]Div of Nephrology & Hypertension, Los Angeles Biomedical Research Inst, Torrance, CA; [2]Div of Nephrology, U Michigan, Ann Arbor, MI.*

Background: We tested whether at baseline (BL) the proximal tubule injury marker urine KIM-1/creatinine (uKIM1/cr) correlated with BL disease severity and/or improved a remission prediction model.

Methods: uKIM1/cr was measured on BL protease-protected spot urine from non-immunosuppressed patients (Minimal change (MC), n= 7; Focal segmental glomerulosclerosis (FSGS), n= 24; Membranous nephropathy (MN), n= 12; and other glomerulopathies (OG), n= 12). Urine protein/creatinine (UPCR) was measured at BL, and Q4-6 mos. Correlations with BL uKIM1/cr and UPCR, morphometrically measured histopathologic features, and renal outcomes were assessed. Associations between uKIM1/cr and time to first complete remission were tested using a Kaplan-Meier analysis and Cox proportional hazards models adjusting for baseline proteinuria, diagnosis, and subsequent treatment. Subgroup variation by diagnosis in the effect of uKIM1/cr on reaching remission was tested using interaction terms.

Results: Median follow-up was 24 mos; 16 of 55 patients were subsequently treated (steroids, n=9; calcineurin inhibitors, n=4; mycophenolate mofetil, n=3). BL uKIM1/cr correlated with UPCR (r=0.45; p<0.001), but not with eGFR. uKIM1/cr was lower in MC than FSGS, MN, and OG (p=0.006) and correlated with foot process effacement but not with global or segmental sclerosis, interstitial fibrosis, tubular atrophy, or acute tubular injury. After adjusting for BL proteinuria, pathologic diagnosis, and treatment, uKIM1/cr was a significant predictor of time to complete proteinuria remission.



Conclusions: uKIM1/cr may identify a subset of patients more likely to enter remission from nephrotic syndrome.

SA-PO652

Effect of Tacrolimus on Endothelial-Derived Microparticles in Pediatric Patients with Nephrotic Syndrome Howard Trachtman,[1] Laura Jane Pehrson,[1] Suzanne M. Vento,[1] Laura Malaga-Dieguez,[1] Brandon Renner,[2] Jennifer Laskowski,[2] Joshua M. Thurman.[2] *[1]Pediatrics, NYU Langone Medical Center, New York, NY; [2]Medicine, Univ of Colorado School of Medicine, Aurora, CO.*

Background: Tacrolimus (TAC) causes direct injury to endothelial cells that in kidney transplant recipients is characterized by increased circulating levels of endothelial-derived microparticles (EDMP). The objective of this study was to determine the effect of TAC on EDMP in pediatric patients receiving the drug to treat nephrotic syndrome (NS), a cohort without longstanding kidney disease and fewer comorbid conditions.

Methods: Children with NS due to minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS) treated with TAC were recruited in the Fink Ambulatory Care Center or Bellevue Nephrology Clinic. The following material was obtained from the medical record: age, gender, TAC dose, BP, eGFR, proteinuria, and trough TAC level. A plasma sample was obtained every 6 months for measurement of EDMP by flow cytometry using antibodies to CD31, CD44 and complement C3. Results were compared to those from a cohort of 30 healthy control subjects.

Results: 13 patients (9M: 4F), 11.7±4.9 yr old, were enrolled in the study. The underlying disease was MCD in 6 and FSGS in 7 cases. The initial eGFR was 142±100 and 112±50 ml/min/1.73 m^2 at 6 months. The TAC dose was 0.1±0.5 mg/kg/day and the trough drug level was 3.7±1.3 ng/ml. The number of EDMP in the patients with NS was 1,605±170/ml at entry and 1,381±97/ml after 6 months of follow-up (P = NS) and both values were compared with healthy controls (1,178±69/ml; P < 0.05). C3 deposition on the EDMP was similar in children with NS compared to healthy controls (86±11 vs. 80±41 RFU; P = NS) and did not increase after 6 months of TAC treatment (95±12 RFU).

Conclusions: Administration of TAC to pediatric NS patients is associated with an increased number of EDMP that is steady over 6 months. The number of EDMP in patients with NS was significantly higher than in healthy controls, suggesting that NS itself is associated with increased EDMP generation. EDMP may be a useful biomarker to monitor vascular injury in patients with NS treated with TAC.

SA-PO653

Assessing Patients' Interest and Barriers to Clinical Research Participation in Nephrotic Syndrome Laura H. Mariani,[1,2] Chelsey Fix,[3] Kathleen Broderick,[3] Julie Abramson,[3] Abigail L. Swan,[3] Lauren Lee,[3] Elizabeth L. Cope.[1] *[1]Arbor Research Collaborative for Health; [2]U. Michigan; [3]NephCure Kidney International.*

Background: Recruitment for clinical research studies in primary Nephrotic Syndrome (NS) is hindered by the rarity of the disease, diverse care settings and geographic spread of affected patients. Better understanding of the level of interest and barriers to participation from a diverse group of patients with NS is critical to successful recruitment and study design.

Methods: The NephCure Kidney Network (NKN) is a web-based patient opt-in registry for primary NS. Participants provide data including kidney disease history, demographics and research participation preferences. Logistic regression models were fit to identify predictors of willingness to participate.

Results: As of May, 2016, 587 participants from 32 countries have been recruited. Mean(SD) age is 26(12) yrs, 50% female, 22% non-Caucasian and 10% Hispanic. 38% have FSGS, 23% MCD, 2% IgAN, 2% MN and 2% MPGN. 62% are currently on immunosuppression. 45% had achieved remission, 17% had been on dialysis and 13% had a transplant prior to enrollment. Only 15% reported having participated in a clinical trial, yet 56% reported being interested in a study testing "an experimental therapy that may or may not help him or her." Increasing age was associated with higher odds of being interested (OR 1.3 per 10 years, p 0.001), but there was no association with sex, race, ethnicity, prior medication exposure or remission status. Figure 1 describes interest by study requirements and participation barriers.

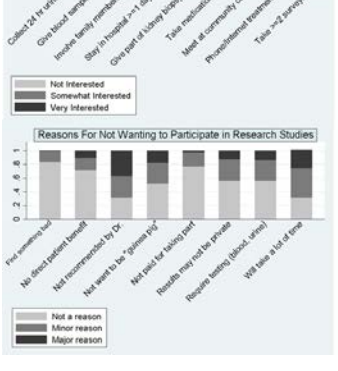

Figure 1: Patient reported interest and barriers to research participation in Nephrotic Syndrome

Conclusions: While the majority of NKN participants indicate a high interest in many types of clinical research, few reported previously participating. Designing studies around topics of high value to the patient, engagement from their primary nephrologist, ensuring appropriate data privacy and limiting time burden may help to increase participation.

Serum 1,25-Dihydroxyvitamin D Better Reflects Renal Parameters Rather Than 25-Hydoxyvitamin in Patients with Biopsy-Proven Glomerular Disease Yu Ah Hong, Hyeon Seok Hwang, Yoon-Kyung Chang, Suk Young Kim, Cheol Whee Park, Sungjin Chung. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Impaired vitamin D metabolism may contribute to the development and progression of chronic kidney disease (CKD). The purpose of the study was to determine associations of circulating vitamin D metabolites with the degree of proteinuria and impaired estimated glomerular filtration rate (eGFR) in patients with biopsy-proven glomerular disease.

Methods: Blood samples for 25-hydroxyvitamin D (25D) and 1,25-dihydroxyvitamin D (1,25D) levels were collected from 173 patients who admitted for renal biopsy. All clinical and laboratory data were obtained at the time of the renal biopsy, and therapeutic medication after renal biopsy was collected.

Results: As serum 1,25D levels declined, renal function was significantly decreased ($p<0.001$). However, serum 25D levels were not different according to the change of eGFR ($p=0.786$). Serum albumin was significantly increased and total cholesterol and 24hr urine protein were significantly decreased in patients with the higher levels of 25D and 1,25D than in those with the lower values. The prevalence of nephrotic range proteinuria and moderate to severe renal dysfunction (eGFR ≤ 60ml/min/1.73m^2) progressively increased with declining 1,25D, but not 25D. Multiple linear regression analysis showed that 25D was significantly correlated with serum albumin and total cholesterol ($\beta=0.224$, $p=0.006$; $\beta=-0.263$, $p=0.001$) and 1,25D was significantly correlated with eGFR, serum albumin and serum phosphorus ($\beta=0.202$, $p=0.005$; $\beta=0.304$, $p<0.001$; $\beta=-0.161$, $p=0.024$). In adjusted multivariable linear regression, eGFR and 24hr proteinuria were independently correlated only with 1,25D ($\beta=0.154$, $p=0.018$; $\beta=-0.171$, $p=0.012$), but not 25D. The lower level of 1,25D was associated with the frequent use of immunosuppressive agents after renal biopsy ($p<0.001$).

Conclusions: According to these results, it is noteworthy that circulating 1,25D may be superior to 25D as an indicative marker of disease severity in patients with biopsy-proven glomerular disease.

SA-PO655

Rituximab Therapy for Idiopathic Nephrotic Syndrome Montserrat M. Diaz Encarnacion,[1] Iara Karlla Dasilva,[2] Luis F. Quintana,[4] Manuel Praga,[5] Juliana Bordignon Draibe,[6] Jose Ballarin.[7] *[1]Fundacio Puigvert; [2]Fundacio Puigvert; [3]Hospital Puerta de Hierro; [4]Hospital Clínic; [5]Hospital Univ 12 de Octubre; [6]Hospital Univ de Bellvitge; [7]Fundacio Puigvert.*

Background: Steroids continue to be the main treatment at idiopathic nephrotic syndrome (INS). Approximately 40%–50% of patients are steroid-dependent (SD) and require repeat courses of prednisone and/or the addition of other immunosuppressive (IS) medications. Rituximab (RTX) is effective for the treatment of SD or frequently relapsing (FR) in pediatric patients, but this efficacy in adult patients is not established. **The aim** our study was to evaluate the effects of RTX in adult with a diagnosis of difficult-to-treat INS, and to compare the outcomes with control patients treated with steroids in combination with other IS, excluding RTX.

Methods: We reviewed 50 patients with SD and FR INS, 28 patients received RTX between 2008-2015, and 22 control group patients in 6 Spanish hospitals. The minimal follow up is 8 month post-RTX. Data are expressed as means ± standard deviation. Comparisons before and after RTX treatment (baseline vs last follow up) were assessed by the paired Student's parametric *t*-test (significant=$p<0.05$).

Results: 23 patients (82%) responded to RTX with complete remission, 20 patients (71%) had no relapses after RTX and 13 without IS. 8 patients (29%) experienced at least one relapse of NS after RTX. We observed a highly significant reduction in the total number of relapses ($p<0.001$) and a decline in proteinuria (p 0,03) after RTX. The mean follow-up of 31±26 m (8–86) after RTX. We observed a significant reduction in frequency of relapses/ year in the RTX group compared with control group. There were differences in the final dose of steroid and tacrolimus needed to obtening sustained remission between both groups.

Conclusions: RTX treatment is safe and well tolerated and effectively reduced the incidence of recurrences and need for maintenance IS in adult patients with difficult-to-treat INS, but a few data is available about the long-term in adult.

Funding: Government Support - Non-U.S.

SA-PO656

Rituximaab in the Treatment of Children with Steroid Dependent/ Resistant Nephrotic Syndrome Sooraj Yesudas Santhakumari. *Cochin Kidney Centre, Kochi, Kerala, India.*

Background: About 10 -20 percent of children with nephrotic syndrome are steroid resistant/dependent. Though a variety of treatment modalities including cyclophosphamide, Calcineurin inhibitors (CNIs), mycophenolate, azathioprine etc are available for these children, still a small percentage remains refractory to these medicines. Rituximab is a

chimeric antibody directed against the CD 20 receptors of B cells. There are studies which have shown that it is useful in Steroid dependent Nephrotic Syndrome (SDNS)/Steroid Resistant Nephrotic Syndrome (SRNS).

Methods: 15 children who satisfied the criteria for SDNS/SRNS were involved in the study. All had undergone treatment with Cyclophosphamide, CNIs and mycophenolate but were not able to achieve sustained remission and also was unable to withdraw steroids. Renal biopsy was done whenever possible. All the children were given 2 doses of Rituximab 375 mg/sq.m 2 weeks apart. They were then followed up for a period of minimum 8 months. Steroids and other immunosuppressents were withdrawn whenever possible.

Results: There were 15 children - 9 males and 6 females. The average age was 8.4 +/- 2.4 years. The average duration of nephrotic syndrome was 30.46 +/- 8.61 months. All had received treatment with steroids and other immunosuppressives. 6 patients had undergone renal biopsy out of which 5 were minimal change disease and one was FSGS. All of them received 2 doses of Rituximab 375 mg/sq.m 2 weeks apart. The average followup was 12.46 +/- 2.92 months. The minimum followup was 8 months and maximum followup was 18 months. 14 patients responded to the treatment (93%) and we were able to stop immunosuppression. One child continues to be on steroid and CNIS. All children tolerated the drug well. There were no major adverse events except one episode of Herpes Zoster in a child which responded to treatment.

Conclusions: We conclude that Rituximab is a safe and effective treatment option in children with Resistant Nephrotic Syndrome. However more studies and more followup is required.

SA-PO657

Short-Acting Natural ACTH Induces Rapid Remission of Steroid-Dependent Nephrotic Syndrome Followed by Delayed-Onset Resistance: Implications of Newly Formed Neutralizing Antibodies Pei Wang,[1,2] Minglei Lu,[1] Xianhui Liang,[1] Yan Ge,[1] Zhangsuo Liu,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ; [2]The First Affiliated Hospital of Zhengzhou Univ, China.*

Background: There is increasing evidence supporting the use of adrenocorticotropic hormone (ACTH) as an alternative treatment for refractory proteinuric glomerulopathies. The efficacy of short-acting ACTH, however, remains unknown and was tested here.

Methods: A 21-year-old man with a 5-year history of steroid-dependent nephrotic syndrome due to minimal changes disease developed Cushing's syndrome and was recently afflicted with severe cellulitis. He was weaned off all immunosuppressants, including corticosteroids, and this resulted in a relapse of generalized anasarca, associated with massive proteinuria and hypoalbuminemia. ACTH monotherapy was subsequently initiated.

Results: The initial regimen consisted of subcutaneous injections of 25 IU of short-acting animal-derived natural corticotropin given daily at 09:00 AM with reference to the Columbia ACTH gel therapy regimen. Short-acting ACTH treatment induced a rapid response, marked by massive diuresis, substantial reduction in body weight and partial remission of proteinuria. Ten days later, the patient developed mild skin rash and subcutaneous nodules at injection sites. A relapse followed despite doubling the dose of corticotropin, consistent with delayed-onset resistance to treatment. Immunoblot-based antibody assay revealed *de novo* formation of antibodies in the patient's serum that were reactive to natural ACTH. In cultured melanoma cells known to intensely express melanocortin receptors, addition of the patient's serum strikingly mitigated dendritogenesis and cell signaling triggered by natural ACTH like the extracellular signal-regulated kinase (ERK) and glycogen synthase kinase (GSK)3β pathways, denoting neutralizing properties of the newly formed antibodies.

Conclusions: Short-acting ACTH was likely effective in inducing remission of steroid-dependent nephrotic syndrome. The delayed resistance might be attributable to the formation of anti-ACTH neutralizing antibodies. The experimental protocols established here may aid in determining the cause of resistance to ACTH treatment in future studies.

SA-PO658

Novel Paradigm for Categorizing Subtypes of Focal Segmental Glomerulosclerosis: A Pilot Study Thomas Kitzler,[1] Nadezda Kachurina,[2] Martin M. Bitzan,[3] Elena Torban,[2] Paul R. Goodyer.[3] *[1]Medical Genetics, McGill Univ Health Centre, Montreal, QC, Canada; [2]Dept of Medicine, McGill Univ and McGill Univ Health Centre, Montreal, QC, Canada; [3]Dept of Paediatric Nephrology, McGill Univ Health Centre, Montreal, QC, Canada.*

Background: Focal segmental glomerulosclerosis (FSGS) is found in the majority of children with steroid resistant nephrotic syndrome (SRNS), many of whom progress to end-stage renal disease despite second-line treatment with immunosuppressive agents. About half of these children harbour mutations in genes relevant for podocyte structure and integrity, whereas of the other half, some appear to have a circulating, yet to be identified, cytotoxic "FSGS factor" that directly causes damage to the podocyte ultrastructure. Children with genetic podocyte defects tend to fare well on treatment with renal transplant, while children with a circulating factor are at high risk of recurrence of FSGS on renal allograft, but may benefit from novel targeted therapeutic approaches instead. Here we present a novel approach on how to distinguish these subgroups.

Methods: This is an analysis of 16 patients with clinically confirmed SRNS. We employed a combined approach of Next Generation Sequencing of 37 known FSGS genes and a functional assay, which indirectly tests for the presence of a podocyte-toxic factor in patients' sera by use of cultured human podocytes. Toxicity of sera is evidenced by disassembly of podocyte focal adhesion complexes (Kachurina et al., Am J Physiol Renal Physiol, 2015).

Results: Preliminary analysis of patients' sera demonstrated absence of podocyte-toxicity in patients with identifiable genetic podocyte defects, whereas indirect evidence for a circulating factor (i.e., podocyte-toxicity) could only be detected in patients without identifiable genetic defects.

Conclusions: Based on these preliminary observations, we propose that SRNS comprises three subgroups: 1) patients with genetic causes of SRNS who fare well after renal transplantation; 2) patients without genetic causes with high risk of recurrence in the allograft, as evidenced by serum podocyte-toxicity; and 3) patients without genetic causes and low recurrence risk, i.e., absence of podocyte-toxicity.

SA-PO659

A Prospective, Open Label Study of the Safety and Treatment Efficacy of ACTHar Gel for Fibrillary Glomeruloneprits James A. Tumlin,[1] Brad H. Rovin,[4] William G. Paxton,[2] Isabelle Ayoub,[4] Salem Almaani,[4] Dawn J. Caster,[5] Alice Sue Appel,[3] Gerald B. Appel.[3] *[1]Renal Div, Univ of Tennessee College Medicine, Chattanooga, TN; [2]Georgia Nephrology Associates, Atlanta, GA; [3]Renal Div, Columbia Univ, New York, NY; [4]Renal Div, Ohio State Univ, Columbus, OH; [5]Renal Div, Univ of Louisville, Louisville, KY.*

Background: Fibrillary glomerulonephritis (FGN) is a rare glomerular disease characterized by randomly deposited Congo-red negative fibrils within the mesangium and glomerular basement membranes. The therapeutic options for FGN are poor, with more than 50% of patients progressing to ESRD within 5 years. ACTHar gel has shown benefit in the treatment of multiple forms of proteinuria glomerular diseases. To determine its therapeutic efficacy in FGN, we retrospectively reviewed 14 patients treated with ACTHar gel.

Methods: A total of 14 patients with biopsy proven FGN were reviewed. Mean age was 59+4 yrs with 93% Caucasian and 57% female. The FGN subtypes included 3-MGN, 8-Mesangial, 2-MPGN, and 1 Crescentic. Seven (50%) received prior immunosuppression; Pred-4, CNI-5, Rituximab-2. All patients but one received 6 mths ACTHar; dose range (80-240 units 2-3 inj/wk)(mean dose 174+9 units) (range 2-24 mths). Complete responses were defined as UP/Cr ratio < 0.30; partial responses were defined as a > 50% reduction in pre-ACTH UP/Cr ratios.

Results: A complete response was achieved in 1 patient (7%), partial remissions in 6 (43%) and no response in 7 (50%). Responsive patients did not differ in FGN subtypes or prior treatment. Patient responses are shown in Table-1. (Proteinuria-UP/Cr gm/gm) *(p=0.009).

Table-1	Number	Age	Prior Tx	Peak UP/ Cr ratio	Pre-ACTH UP/Cr ratio	Post-ACTH UP/Cr ratio
Responders	7	57.1±6	4/7 (57%)	7.53+1.0	5.43+0.67	1.34+0.31*
Non-Responders	7	61.0±3	3/7 (43%)	6.44+1.0	4.93+1.2	5.81+0.87

Conclusions: FGN is a rare and refractory form of glomerular disease with a high rate of progression to ESRD. We have shown that a prolonged course of ACTHar gel (8+months) leads to a complete or partial remission in 50% of patients. ACTHar gel may be an alternative therapy for FGN.

SA-PO660

Hypothyroidism Secondary to Severe Nephrotic Syndrome Anna Matyjek,[1] Aleksandra Rymarz,[1] Slawomir Literacki,[1] Dorota Brodowska-Kania,[1] Tomasz Rozmyslowicz,[2] Stanislaw Niemczyk.[1] *[1]Military Inst of Medicine, Warsaw, Poland; [2]Univ of Pennsylvania, Philadelphia.*

Background: The issue of clinically significant hypothyroidism secondary to urine loss of free hormones, TBG and albumin is currently widely discuss in paediatric population with nephrotic syndrome. In adults, however, the data are limited. The aim of the study was to estimate the thyroid function in severe nephrotic syndrome in adults, defined as serum albumin level *(SA)* ≤ 2.5 g/dl.

Methods: The 25 adult patients (mean age 45±18 years, 68% men) with severe nephrotic syndrome and eGFR >30 ml/min/1.73m^2 were included into the prospective pilot study. The thyroid hormone profile was assessed using electrochemiluminescence immunoassay *(ECLIA)*. The Spearman correlation coefficient was used to statistical analysis *(Statistica 12, StatSoft)*.

Results: The mean values of measured parameters were: SA 1.8±0.4 g/dl, TP 4.2±0.6 g/dl, daily proteinuria 11.5±6.0 g, daily albuminuria 8.9±6.7 g, urine albumin-to-creatinine ratio *(ACR)* 4.77±1.9 g/mgSCr, TSH 4.1±2.2 µIU/ml, fT4 12.7±3.2 pmol/l, fT3 3.4±0.8 pmol/l, antithrombin activity 75±20%. The study revealed the impaired thyroid hormone profile in 76% subjects, in 81% with SA <2.0 g/dl and in 67% with SA 2.0-2.5 g/dl. The main abnormality was overt hypothyroidism (28%) and euthyroid sick syndrome (*ESS*, characterized by decreased level of serum fT3 or fT4, or both, accompanied by normal TSH range) (28%), followed by subclinical hypothyroidism (20%). TSH level inversely correlated with SA (r=-0.415, p=0.007) and antithrombin activity (r=-0.58, p=0.009). The significant negative correlations were observed between free hormones and daily proteinuria (for fT3 r=-0.255, p=0.043; for fT4 r=-0.528, p=0.029) and ACR (for fT3 r=-0.495, p=0.028; for fT4 r=-0.559, p=0.016). The ACR >4.0 g/mgSCr was associated with 77% risk of thyroid free hormone deficiency.

Conclusions: Severe nephrotic syndrome causes significant disturbances in the thyroid function. In most of the patients hypothyroidism or ESS was observed. The thyroid function monitoring in patients with severe nephrotic syndrome seems to be necessary to avoid possible clinical consequences.

Collapsing Glomerulopathy in Kidney Allografts: Donor Ethnicity and Clinical Course Ndidiamaka O. Obadan, Evelyn Bruner, Girish K. Mour, Juan Carlos Q. Velez. *Nephrology, Medical Univ of South Carolina, Charleston, SC.*

Background: Collapsing glomerulopathy (CG) is a variant of focal segmental glomerulosclerosis (FSGS). In native kidneys, almost all affected individuals are African American (AA), 75% of whom carry 2 *APOL1* risk alleles. However, in kidney allografts, CG can also affect non-AAs. The largest published series of allograft CG involved 10 patients and did not report donor race. We hypothesized that a larger series that includes donor race data could provide insights about the pathogenesis and clinical course of this entity.

Methods: Kidney allograft biopsies performed at our institution from 2001-2016 were reviewed for cases of CG. Clinical data were extracted from medical charts. Outcomes were assessed by donor race.

Results: Among 116 cases of allograft FSGS, we identified 22 as CG (19%). Donor race was AA in 13 (59%) and white (W) in 9 (41%) cases. No difference was found in recipient's mean age (56 vs. 47 yrs), gender (23% vs. 33% female), race (23% vs. 55% AA), time from transplant to CG (35 vs. 19 months) or cold ischemia time (13 vs. 16 hrs) for AA-CG and W-CG, respectively. Among AA-CG cases, native nephropathy were diabetic (DN) (6), hypertensive (5) and FSGS (2), suggesting possible recurrence in 2 cases. On the other hand, all W-CG cases were possibly *de novo* (native nephropathy: DN in 4, IgA in 2, lupus, ADPKD and aHUS in 1). DNA for CMV and BKV was found in 2 AA-CG cases, whereas CMV, parvo, coxsackie and EBV viremia were found in 4 W-CG cases. No difference was found in mean serum creatinine (4.2 vs. 2.6 mg/dL) or urine protein-to-creatinine (7.6 vs. 4.8 g/g) at the time of diagnosis, although there was a trend for a greater incidence of nephrotic syndrome in AA-CG (83% vs. 55%, p=0.17). More importantly, graft loss occurred in 12 (95%) AA-CG vs. in 4 (44%) W-CG cases (p=0.02).

Conclusions: CG is a form of FSGS with increased relative incidence in kidney allografts that presents frequently as *de novo* disease. Viremia is detectable in about 25% of cases. CG affecting kidneys from AA donors appear to have a more ominous outcome; Whether *APOL1* risk alleles account for the difference remains to be determined.

SA-PO662

Apoptosis Inhibitor of Macrophage (AIM) Expression in the Kidney Was Associated with Increased Proteinuria and Decline in Renal Function Yasunori Iwata, Megumi Oshima, Kengo Furuichi, Norihiko Sakai, Miho Shimizu, Akinori Hara, Tadashi Toyama, Yasuyuki Shinozaki, Yasutaka Kamikawa, Shinji Kitajima, Akihiro Sagara, Takashi Wada. *Nephrology, Kanazawa Univ.*

Background: Apoptosis inhibitor of macrophage (AIM) expressed on macrophages prolongsinflammation by protecting macrophages from apoptosis. Most circulating AIM co-exists with immunoglobulin M (IgM). AIM's pathophysiological role in relation to IgM remains unclear. Here we evaluated the glomerularexpression/deposition of AIM and IgM in the kidney using immunohistochemistry and its associations with clinical manifestations in 43 patients with biopsy-confirmed kidney diseases.

Methods: Kidney biopsy tissue from all patients was immunostained for AIM and IgM. Staining patterns and percent stained areas within the glomeruli were determined. Cells expressingAIM were identified by co-staining with macrophage and endothelial cell surface markers. Correlations between stainingresults and clinical parameters were evaluated using univariate and multivariate analyses.

Results: AIM was deposited in various areas, such as mesangial and capillary area. A part of AIM expressionwas localized to CD68-positive macrophages in the glomerulus. Amount of glomerular expression was positivelycorrelated with urinary protein in patients with severe proteinuria andkidney dysfunction. Urinaryprotein was higher in patients exhibiting overlapping glomerular expression of AIM and IgM. Annual eGFR decline ratenegatively correlated withAIM-positive area. AIM-positive area and initial serum creatinine were independently associated with decreased kidney function.

Conclusions: AIM expression in the kidney was associated with urinary protein and decline in renal function.Co-expression with IgM appeared to exacerbate AIM's deleterious effects on renal function. Combined glomerular AIMand IgM expression is a candidate prognostic index for kidney disease.

SA-PO663

Natural History of Lithium Nephropathy: Cross-Sectional Analysis of a Cohort of Li-Treated Bipolar Disorder Patients Martin Flamant,[1,3] Emmanuelle Vidal-Petiot,[1,3] Fideline Serrano,[1,3] Pedro Fernandez,[1,3] Frank Bellivier,[2,3] Francois Vrtovsnik.[1,3] *[1]Bichat Hospital, APHP, Paris, France; [2]Center for Bipolar Disorder, APHP, Paris, France; [3]Paris Diderot Univ, Paris Diderot Univ, Paris, France.*

Background: Lithium (Li) therapy may lead to secondary renal disease including diabetes insipidus, hypercalcemia and chronic microcystic nephropathy but the natural history of these disorders in this setting is still unclear.

Methods: measured GFR (clearance of ^{51}Cr-EDTA), maximal urinary osmolality following 12h of water restriction and injection of 0.4 µg ddAVP (UOsm-max, in mosm/kg), osmotic load (OsmL, mosm/d), ionized calcium, PTH before and after iv calcium load were measured in 87 consecutive patients (pts) referred by the Center for Bipolar Disorder and treated with Li for 0-1y (G1, n=17), 1-5y (G2, n=21), 5-15y (G3, n=24), >15y (G4, n=25). Kidney microcysts were counted by MRI imaging in 37 pts.

Results: In the whole cohort (36% men), mean(SD) age and GFR, were 50.2 (15.3) years and 73.7 (22.6) mL/min/1.73m². GFR was independently correlated (multiple regression) with both duration of Li exposure (-0.98ml/min/1.73m²/y, p<0.0001) and age (-0.55ml/min/1.73m²/y, p<0.001). Polyuria (>3L/day) was found in 25% of pts and associated with a higher OsmL (p<0.05) and decreased UOsm-max (p<0.001) in pts from G1 to G4. Hypercalcemia (HCa) was present in 23 pts and associated with high PTH in 9, all in G4. PTH decrease following iv Ca load was blunted with longer therapy (p<0.05). Prevalence of microcysts increased from G1 to G4 (p<0.002) but lacked in 25% of G4 pts.

	GFR (ml/mn/>1.73m²)	diuresis > 3L/d (%)	UOsmax if P (if w/o P)	OsmL if P (if w/o P)	HCa (%)	ΔPTH>50% after iv Ca	>2 microcysts (%)
G1	94.7	20	776 (738)	999 (560)	12	86	8
G2	79.6	24	616 (717)	803 (580)	6	76	20
G3	73.7	28	519 (627)	726 (610)	40	55	56
G4	54.4	29	296 (530)	699 (663)	44	42	75

Conclusions: Li-induced diabetes insipidus occurs early during the course of Li therapy. Microcysts are frequent but not systematic in long-term treated pts. In this cohort, GFR decrease is highly correlated with length of exposure to Li and reaches -1.5 ml/min/1.73m/y, with 1/3 attributable to aging and 2/3 to Li.

SA-PO664

Interstitial Nephritis Associated with Programmed Cell Death-1 Inhibitors Samer Mohandes, Vahagn A. Zakaryan, Jason Prosek. *Ohio State Univ Wexner Medical Center, Columbus, OH.*

Background: Programmed Cell Death-1 (PD-1) inhibitors are immune checkpoint inhibitors used to treat malignancies= by blocking inhibition to T-cell activation. Current PD-1 inhibitors include nivolumab and pembrolizumab. Acute interstitial nephritis (AIN) has been described with ipilimumab but not well described with PD-1 inhibitors. Here we report 6 cases of suspected AIN due to use of PD-1 inhibitors.

Methods: Six patients who underwent treatment with PD-1 inhibitors in whom AIN was clinically observed are presented. PD-1 inhibitors were used for RCC, melanoma and urothelial carcinoma. AKI attributed to AIN was observed within 3 days to 5 months. AIN was proven by biopsy in 2 cases. Clinical features are summarized in Table 1. One patient developed hypercalcemia with elevated 1,25-OH vitamin D level suggesting granulomatous AIN. All of the patients who received prednisone achieved remission. 5 patients were rechallenged, 3 remained on low dose prednisone. Recurrent AIN was not observed after rechallenge.

Results:

Case	1	2	3	4	5	6
Age	59	63	66	44	56	53
Malignancy	Melanoma	Urothelial Ca	RCC	RCC	RCC	Melanoma
Anti-PD1	Pem	Niv	Niv	Niv/Ax	Ipi/Niv	Ipi/Niv
Time to AKI	5 weeks	3 days	5 months	6 weeks	4 weeks	10 days
Enlarged Kidneys	Yes	Yes	N/A	No	N/A	Yes
Aseptic Leukocyturia	Yes	N/A	Yes	Yes	No	Yes
Eosinophilia	none	13%	none	19%	none	none
Response to Steroids	Yes	N/A	Yes	Yes	Yes	Partial
Anti-PD1 resumed?	Yes	N/A	Yes	Yes	Yes	N/A

Clinical features and course of the 6 cases. Pem - pembrolizumab, Niv - nivolumab, Ax - axitinib, Ipi - ipilimumab, RCC - renal cell carcinoma.

Conclusions: The above demonstrates an association of PD-1 inhibitors with AIN. A kidney biopsy is the gold standard for diagnosis of AIN however this option is limited for patients with RCC, many whom are left with a solitary kidney after nephrectomy. Thus clinicians will need to feel comfortable making this diagnosis on clinical grounds to initiate therapy. Rechallenging patients with anti-PD1 therapy after resolution of AIN appears to be a safe option with close monitoring.

SA-PO665

Renal Involvement in Primary Sjögren's Syndrome Duvuru Geetha, Andreas Goules, Alan N. Baer. *Johns Hopkins Univ.*

Background: Renal disease is rare in Primary Sjögren's syndrome (PSS) and manifests as interstitial nephritis and glomerulonephritis. This single center study aims to describe the clinico-pathologic features and treatment outcome of renal disease in PSS.

Methods: PSS patients with renal disease were identified from PSS database retrospectively and clinical features, renal biopsy findings, treatment details and renal outcome were recorded.

Results: Twenty patients with a diagnosis of PSS and renal disease were included. Of the 20 patients, 14 had interstitial nephritis (IN), 3 had glomerulonephritis (GN) and 3 had both entities and were classified as having GN. IN occurred before the onset of glandular manifestations in 3 and after their onset in 11 patients (median SS duration 4.5 yrs, range: 0-9). In the IN group, 3 patients presented with chronic kidney disease (CKD), 4 with renal tubular acidosis (RTA), 2 with symptomatic hypokalemia, 4 with renal

colic and 1 with hematuria/proteinuria. Eight of 14 patients with IN received systemic immunosuppression (prednisone, mycophenolate mofetil, azathioprine, rituximab and anti-TNF agents) during the renal disease course but in 7 patients no beneficial effect was observed on renal function, hypokalemia and RTA. Six of 14 patients with IN developed CKD (median duration of renal disease 6 yrs, range: 1.5-17) while 5 of them preserved normal renal function during follow up (median follow up duration: 14 yrs, range: 5-20).GN occurred later during PSS course (median SS duration 8 yrs, range: 0-14.5) and 2 patients presented with CKD, 3 with proteinuria/hematuria and 1 with nephrotic proteinuria. In the GN group, renal biopsy findings revealed membranoproliferative (MPGN) (n=3), focal segmental glomerulosclerosis (n=1) and fibrillary glomerulopathy (n=1). All 3 MPGN patients had cryoglobulinemia and in 1 patient cryoglobulinemic MPGN was clinically diagnosed. All GN patients were treated with immunosuppressive therapy with stabilization or improvement of renal function in the 4 MPGN patients only.

Conclusions: IN occurs early in disease course in PSS and does not improve with systemic immunosuppression. On the contrary, GN appears as a late complication of PSS and a favorable treatment response is seen in those with MPGN pathology.

SA-PO666

Study on the Mechanism of Renal Tubular Proteinuria in Children with OCRL Gene Mutations

Chikushi Suruda,[1] Shoji Tsuji,[1] Jiro Kino,[1] Sohsaku Yamanouchi,[1] Takahisa Kimata,[1] Hiroyuki Kurosawa,[2] Akihiko Saito,[3] Kazunari Kaneko.[1] *[1]Pediatrics, Kansai Medical Univ, Osaka, Japan; [2]Reagent Research and Development Dept, Denka Seiken Co., Ltd, Japan; [3]Applied Molecular Medicine, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: The oculocerebrorenal syndrome of Lowe (*OCRL*) gene is located on Xq25-26 and encodes a phosphatidyl inositol 4,5 bisphosphate ($PI(4,5)P_2$) phosphatase (OCRL-1). Mutations in this gene cause Lowe syndrome (LS) or type 2 Dent disease (T2D) in which low molecular weight (LMW) proteinuria is a cardinal finding. It is considered that megalin plays an important role in the development of renal tubular proteinuria. Megalin is expressed on the luminal side of proximal tubular cells (PTCs) and is involved in the reabsorption and metabolism of LMW proteins, such as α_1-microglobulin (AMG), β_2-microglobulin (BMG) and retinol-binding protein. Recently, it was revealed that two fractions of megalin are excreted into the urine: full-length megalin (C-megalin) and megalin ectodomain (A-megalin). This study was conducted to explore the mechanisms of LMW proteinuria in patients with *OCRL* mutations by determining the urinary megalin fractions.

Methods: Using spot urine samples obtained from five male patients with *OCRL* mutations (median age: 9 years), A- and C-megalin were measured with enzyme-linked immunosorbent assays and corrected for excreted creatinine. The data were compared with those of 50 control subjects.

Results: All patients demonstrated normal levels of urinary C-megalin. However, patients with *OCRL* mutations showed abnormally low levels of urinary A-megalin, except a 5-year-old boy, who was the youngest subject of the present study.

Conclusions: Considering the decreased excretion of urinary A-megalin in 4 out of 5 patients with *OCRL* mutations,LMW proteinuria may be caused by impairment of megalin recycling within the PTCs while a homologous enzyme, such as INPP5B, may compensate for the defective OCRL-1 function to some extent during early childhood.

SA-PO667

Persistent B Cell Depletion and Recurrent Neutropenia: A Rare Complication of Rituximab

Frank B. Cortazar,[1,2] Katherine M. Cosgrove,[1,2] Karen A. Laliberte,[2] John Niles.[1,2] *[1]Div of Nephrology, MGH, Boston, MA; [2]MGH Vasculitis and Glomerulonephritis Center, Boston, MA.*

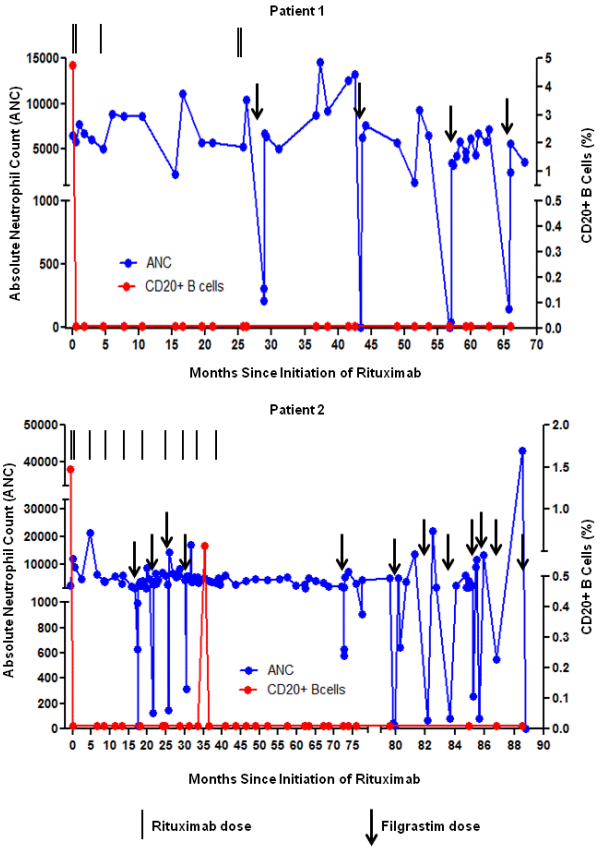
Background: B cell depletion with rituximab (RTX) is an important therapeutic strategy in the treatment of glomerular diseases. We describe a syndrome of persistent of B cell depletion and recurrent neutropenia (NTP) in 2 patients with ANCA vasculitis who received RTX for maintenance of remission.

Methods: We performed a retrospective analysis of clinical data in patients who had persistent B cell depletion for at least 2 years after their last RTX dose in conjunction with recurrent episodes of NTP.

Results: Two of 519 (0.3%) patients in our cohort receiving RTX for ANCA vasculitis or other glomerular diseases developed a syndrome of persistent B cell depletion and recurrent NTP.

Characteristic	Pt 1	Pt 2
Age at first RTX	27	60
Sex	F	F
ANCA serotype	MPO	MPO
Induction therapy	CYC, Pred	CYC, Pred
Prior maintenance therapy	Aza, Pred	Aza, Pred
Total RTX (gm)	5	10
Episodes of NTP	4	12

Patient 1 received 5, 1gm doses of RTX (horizontal lines) and continues to have B cell depletion 40.0 months after her last RTX dose. She developed 4 episodes of NTP, the last occurring 39.6 months after her last RTX dose. Each episode of NTP was treated successfully with filgrastim (arrows). Patient 2 received 10, 1 gm doses of RTX and had B cell depletion on her last check 51.4 months after her last RTX infusion. She developed 12 episodes of NTP, all treated with filgrastim. The last episode of NTP, occurring 51.6 months after her last RTX infusion, was complicated by a fatal infection.



Conclusions: RTX rarely leads to a syndrome of persistent B cell depletion and neutropenia that can be fatal. Clinicians treating glomerular diseases with RTX should be aware of this complication.

Study of Risk Factors for Valproate-Induced Fanconi Syndrome

Sohsaku Yamanouchi, Takahisa Kimata, Chikushi Suruda, Jiro Kino, Shoji Tsuji, Kazunari Kaneko. *Pediatrics, Kansai Medical Univ, Hirakata, Osaka, Japan.*

Background: In recent years, there has been an increase in reports of proximal renal tubular impairment caused by valproate (VPA), VPA-induced Fanconi syndrome (FS). The etiology is presumed to be a malfunction in the mitochondria in the cells of the proximal renal tubules stemming from a carnitine deficiency caused by VPA though there remain many points to be addressed. Delayed diagnosis of VPA-induced FS may cause pathological bone fracture. In order to achieve early diagnosis, this study was conducted to elucidate the risk factors for development of VPA-induced FS.

Methods: The subjects were 91 cases (median age 16 years, interquartile range 11-26 years, 55 males) for whom detailed data could be obtained among 312 cases taking VPA to control seizures at our institution. Cases with a urinary BMG of at least 230 μg/L were classified in the FS group (15 cases), cases with less than 230 μg/L were in the non-FS group (76 cases), and the patient backgrounds and laboratory findings were compared between them.

Results: There was no difference in age, duration of administration and blood levels of VPA, or number of drugs used together between the two groups. However, the FS group had a significantly higher proportion of male children compared to the non-FS group (73% vs. 36%), and more bedridden cases (47% vs. 17%, p=0.029) and cases of total enteral nutrition (40% vs. 5%, p<0.001). Also, among the clinical test values, we found depressed serum uric acid levels (FS vs. non-FS median value: 3.1 vs. 5.3 mg/dl, p<0.001), serum phosphorus levels (3.4 vs. 4.1 mg/dl, p=0.26), and decreased serum free carnitine concentrations (27.7. vs. 44.2, p<0.01), and an elevated urinary BMG (287.0 vs. 102.0 μg/L, p<0.001).

Conclusions: Patients with being bedridden, having total enteral nutrition, a depressed serum uric acid level,and a decreased serum free carnitine concentration have higher risk for VPA-induced FS. In such cases, a carnitine preparation should be administered when using VPA, and it is necessary to switch from VPA to another anti-convulsant in cases with elevated urinary BMG suggesting renal tube impairment.

SA-PO669

Anti-Brush Border Antibody Disease in Humans: Clinicopathological Features and a Putative Common Autoantigen Christopher Patrick Larsen,[1] Paige A. Coles,[3] A. Bernard Collins,[2] Michael Merchant,[4] Jon B. Klein,[4] Ivy A. Rosales,[2] Robert B. Colvin,[2] Laurence H. Beck.[3] *[1]Arkana Laboratories, Little Rock, AR; [2]Massachusetts General Hospital, Boston, MA; [3]Boston Univ Medical Center, Boston, MA; [4]Univ of Louisville, Louisville, KY.*

Background: Primary tubulointerstitial disease caused by antibodies to proximal tubule brush border antigens (ABBA) with tubular basement membrane (TBM) immune complex deposition was described in experimental animals in the 1960s. Human cases with similar pathologic findings were reported in the early 1970s and the finding of serum anti-brush border antibodies (ABBA) was reported in 1981. More recently, a case report described a patient with recurrence of this disease in a transplant. Despite this long history, little is known about the disease.

Methods: Sera from patients with idiopathic TBM deposits on biopsy were screened by indirect IF (IIF) for the presence of ABBA in two renal biopsy laboratories. Sera from cases positive for ABBA were then tested by western blot (WB) and immunoprecipitation (IP) using human tubulointerstitial extract.

Results: We identified 8 ABBA+ cases by IIF. The patients (7M:1F) were 68-78 years old and had a mean serum Cr of 5.3 mg/dl at diagnosis. All renal biopsies showed acute tubular injury (ATI) and 3/8 also had interstitial inflammation. Granular IgG deposits were along the TBM, Bowman's capsule, and segmentally in the GBM in all cases. IgG4 was the predominant or co-dominant IgG subclass in 6/8. Despite treatment, none of the 6 patients with follow-up (mean 4.8 mo) had evidence of remission. Remarkably, WB revealed a common high molecular weight Ag detected by all 8 patients. IP and mass spectrometric analyses, as well as confocal co-localization studies using patient serum on normal kidney, have been performed to identify and characterize candidate Ags.

Conclusions: We present the largest case series to date of renal disease due to ABBA. This disease primarily affects elderly males and presents with acute renal failure. Pathologic findings include ATI with granular basement membrane IgG staining, often with minimal inflammation. WB and IP analysis suggests a common autoantigen.

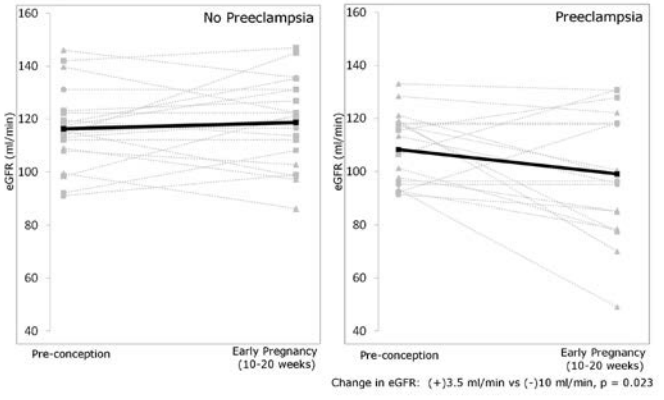
SA-PO670

Impaired Glomerular Hyperfiltration in Early Pregnancy and Adverse Pregnancy Outcomes Jessica Sheehan Tangren, Camille Elise Powe, Ravi I. Thadhani. *Massachusetts General Hospital, Boston, MA.*

Background: Glomerular hyperfiltration, an early marker of renal disease, is a normal phenomenon that begins early in pregnancy. The role of gestational hyperfiltration (GH) in maintaining a healthy pregnancy is unknown. We determined if impairments in gestational hyperfiltration in early pregnancy predict the development of adverse outcomes in women with early stage CKD.

Methods: We studied women with CKD stage I who delivered infants between 1998 and 2007 at the Massachusetts General Hospital. eGFR (CKD-EPI) was calculated at baseline (pre-conception) and in early pregnancy (<20 weeks gestation). Outcomes in women whose eGFR declined during early pregnancy (impaired GH, iGH, n=21) were compared to women whose eGFR increased during early pregnancy (preserved GH, pGH, n=22). We defined a composite adverse outcome of delivery by cesarean section, preeclampsia, small for gestational age offspring and progression to CKD III within 5 years of delivery.

Results: Baseline serum creatinine, age, blood pressure and BMI were similar between the groups. Women with iGH had higher rates of preeclampsia (62% vs 32%, p=0.048). In women with iGH, 90% met the composite adverse outcome versus 59% with pGH (p=0.02). In women who developed preeclampsia, the eGFR decreased on average in early pregnancy while in women who did not develop preeclampsia, the eGFR increased (Figure 1).



Conclusions: In women with CKD I, impaired hyperfiltration in early pregnancy is associated with poor maternal outcomes, including preeclampsia.

SA-PO671

Kidney Biopsy Has Significant Clinical Utility in Advanced Chronic Kidney Disease Amit J. Joshi, Ambarish Athavale, Radhika Jaiswal, Albert M. Osei, Peter D. Hart. *Dept of Nephrology, John H. Stroger Hospital of Cook County, Chicago, IL.*

Background: Kidney biopsy is not commonly performed in advanced CKD (ACKD) with eGFR of ≤ 30 ml/min due to perceived non-diagnostic utility and higher complication rate. Therefore, we assessed the clinical utility and safety of native kidney biopsy in patients with ACKD with negative ANA and ANCA serology.

Methods: Retrospective review of our biopsy database from Jan 2010-Dec 2015 identified 97 cases. Mean age was 46.5 (±12.7) years and women accounted for 42% of the study cohort. African Americans constituted 51%, Hispanics 31%, Caucasians 8%, and other races 10%. Mean S. Creatinine was 4.3 (±2.0) mg/dL with eGFR of 18.5(±7.1) ml/min. Mean proteinuria was 5.2 (±5.5) g/g of Cr and 62% cases had hematuria on urinalysis. Diabetes, paraproteinemia, HIV and hepatitis C antibody were present in 28.6%, 6.1 %, 19.4%, and 9.2% of cases respectively.

Results: Biopsy ascertained renal diagnosis in a majority (84.5%) of which the most common were IgAN, FSGS and Diabetic nephropathy. 10% had unsuspected diagnosis namely Fibrillary GN, Necrotizing GN, Amyloidosis and Sarcoidosis. 15.5% had advanced glomerulosclerosis and 48.5% had severe (>50%) tubulointerstitial disease. Based on biopsy findings, disease specific therapy was initiated in 37.1% and non-diabetic renal disease was identified in 46% of cases with diabetes.

Table 1: Biopsy diagnoses (number, %)

Advanced glomerulosclerosis: 15 (15.5%)	IgAN: 14 (14.4%)	FSGS: 13 (13.4%)
Diabetic nephropathy: 13 (13.4%)	Membranous nephropathy: 6 (6.1%)	Tubulointerstial nephritis: 6 (6.2%)
HIV associated nephropathy: 4 (4.1%)	Hypertensive nephrosclerosis: 4 (4.1%)	Membranoproliferative GN: 4 (4.1%)
Amyloidosis: 3 (3.1%)	Minimal change disease: 3 (3.1%)	Thrombotic microangiopathy: 3 (3.1%)
Necrotizing GN: 3 (3.1%)	Fibrillary glomerulonephritis (GN): 2 (2.1%)	Mesangioproliferative GN: 2 (2.1%)
Sarcoidosis: 2 (2.1%)		

Complications: Major (PRBC transfusion ±intervention): 1%, Minor (hematoma not requiring any intervention): 8 %.

Conclusions: Kidney biopsy remains an important diagnostic tool even in patients with advanced CKD. It guides clinical management and can be done safely.

SA-PO672

Renal Biopsy - Specimen Adequacy and Safety: A Performance Improvement (PI) Project Abhisekh Sinha Ray,[1] Sri G. Yarlagadda,[1] Neville Irani.[2] *[1]Nephrology and Hypertension, Kansas Univ Medical Center, Kansas City, KS; [2]Radiology, KUMC, Kansas City, KS.*

Background: Renal biopsy in this era is shared by nephrologists and interventional radiologists (IR). Available literature suggests wide variability in bleeding risk (0.5-7%) and specimen adequacy. Increasing needle size has been attempted to improve adequacy of biopsy sample, however, bleeding risk increases. There is also concern for significant inter-operator variability. We therefore undertook a PI project to assess sample adequacy, bleeding risk, analyze risk factors and effect of change in needle size.

Methods: We collected data from 454 patients who had renal biopsy from 2014 to April 2016. All patients were observed for 24hrs to monitor for complication. Bleeding complication was defined as radiologic demonstration of hematoma, need for transfusion or embolization by IR. Biopsy sample was considered adequate if it had at least 10 glomeruli. In May 2014, we downsized biopsy needle to 18gauze and in March 2015, we restricted operator pool to find any effect of these interventions on outcome measures.

Results: We found thrombocytopenia (<100,000/cmm, Odds ratio [OR] 5.28), hemoglobin <8.5g/dl (OR 5.24), advanced renal failure (eGFR <30ml/kg/min, OR 3.99) and INR >1.5 (OR 3.2) are associated with increased bleeding; however, hypertension and type of kidney biopsy (native or transplant) didn't significantly alter the risk. Decreasing needle size didn't affect sample adequacy or bleeding risk. There is no significant variability observed between trainee physicians and experienced operators. Limited number of biopsies performed in our institution might have culminated into significant monthly variation in outcome without any identifiable factor and also restricted ability to detect whether specific etiologies leading to renal dysfunction contribute to any increase in post-procedural bleeding risk.

Conclusions: In our tertiary care center with medium volume of renal biopsies done, sample adequacy was not impacted by decreasing needle size. We didn't find any significant inter-operator variability. Patients with anemia, thrombocytopenia, advanced renal failure or coagulopathy are at significantly increased risk for procedural bleed.

SA-PO673

Successful Use of Renal Denervation (RDN) in Patients with Loin Pain Hematuria Syndrome- The Prairie LPHS Study Bhanu Prasad, Jennifer St. Onge, Shelley Giebel. *Nephrology, Regina Qu Appelle Health Region, Regina, SK, Canada.*

Background: Loin pain hematuria syndrome (LPHS) is a painful and incapacitating condition that typically afflicts young women. Attempts to relieve pain by dorsal rhizotomy, renal capsulectomy, and thoracolumbar sympathectomy have been unsuccessful. Surgical transection of the renal nerves by auto transplantation of the kidney leads to recurrence of pain after variable periods. Bilateral nephrectomy has been associated with complete pain relief but at the burden of ongoing need of renal replacement therapy.

Methods: Four patients with LPHS from southern Saskatchewan, with LPHS and intractable pain unresponsive to conservative measures underwent endovascular ablation of the renal nerves between July and November 2015 using the Vessix™ renal denervation system. The number and frequency of pain medications, and responses to the EQ-5D, McGill Pain Questionnaire, Geriatric Depression Score, Short Form Health Survey (SF-36), and Oswestry Disability Index were measured at baseline and at 3 and 6 months post-procedure to evaluate changes in pain, disability, quality of life and mood. Renal denervation (RDN) was performed after seeking Health Canada approval for this indication.

Results: There were significant improvements in pain (McGill Pain Questionnaire), disability (Oswestry disability index), and quality of life (EQ-5D and SF-36) from baseline to 6-months post-procedure. Two out of four patients were off all pain medications; the remaining two had a 75% reduction in the dose of pain medications.

Conclusions: We present four successful cases of RDN, a novel treatment of intractable pain in patients with LPHS. Reduction in pain was accompanied by considerable improvement in functionality and quality of life. All the patients in our study post-RDN, reported less absenteeism, remarkably fewer trips to ER and hospitalizations, relief of caregiver burden, and considerable reduction in number, dose and frequency of pain medications.These results suggest that percutaneous catheter based renal nerve ablation with radiofrequency energy is a safe and rapid treatment option that should be considered in all patients with LPHS.

SA-PO674

Impact of Percutaneous Endovascular Ablation of the Renal Nerves (RDN) on Central Blood Pressures in Patients with Chronic Kidney Disease (CKD): Prairie RDN Study Bhanu Prasad,[1] Jennifer St.Onge.[2] *[1]Nephrology, Regina Qu Appelle Health Region, Regina, SK, Canada; [2]Research and Performance Support, Regina Qu Apelle Health Region, Regina, SK, Canada.*

Background: Central aortic blood pressures (CBP) in comparison to brachial blood pressures more accurately reflect loading of the left ventricular myocardium, coronary arteries, and cerebral vasculature and thereby, better relate to cardiovascular target organ damage and to cardiovascular events.We investigated the impact of minimally invasive catheter based renal denervation (RDN) on central blood pressures and vascular stiffness in patients with stage 3 and 4 CKD with resistant hypertension.

Methods: Twenty-six patients with resistant hypertension from our multidisciplinary chronic kidney disease (CKD) clinic underwent either unilateral or bilateral RDN from February 2013 to August 2014. CBP, 24-hour ambulatory blood pressures, average of 6 office BP readings on BP Tru, along with carotid-femoral pulse wave velocities were measured at 3,6,12 and18 months. Radial arterial pressure waveforms were obtained by applanation tonometry using a solid transducer; central arterial waveforms and pressures were calculated by the use of the SphygmoCor device.

Results: Baseline (mean ± standard deviation) central systolic/diastolic blood pressures (mm Hg) were 131±22.57/ 77.09±16.36 and at 18 months were 120.16±14.67/ 70.58±14.35 respectively. In contrast the 24-hr ambulatory blood pressures (mm Hg) at baseline and 18 month were 142.8±16.27/65.63± 11.59 and 145.34± 13.99/66.53±13.36. Central pulse pressures (mm Hg) at baseline and 18-month post-RDN were 55.59±25.17 and 49.54±20.07 respectively. Similarly, the augmentation pressures at baseline and 18 month were: 14.09±11.35 and 11.32±11.52 mm Hg respectively. Augmentation index (%) was 22.86±11.98 at baseline and 18.45±12.63 at 18 months. Pulse wave velocity was 15.95 (14.15) at baseline and 15.03 (4.93) at 18 months.

Conclusions: We conclude that RDN is associated with modest improvement in aortic pulse pressure, augmentation pressure, and augmentation index relative to the brachial ambulatory blood pressures in patients with stage III and IV CKD. There was no negative impact on renal status post procedure.

Tyrosine Kinase Inhibitor-Induced Hypertension in Patients Diagnosed with Renal Cell Carcinoma Is Associated with Decreased Urinary Excretion of Nitrogen Oxide Metabolites Kirsten Madsen,[1,2] Anne Robdrup Tinning,[1] Niels Viggo Jensen,[3] Lars Bastholt,[3] Boye Jensen.[1] *[1]Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; [2]Dept of Pathology, Odense Univ Hospital, Odense, Denmark; [3]Dept of Oncology, Odense Univ Hospital, Odense, Denmark.*

Background: Tyrosine kinase inhibitors (TKIs) are important in the pharmacological treatment of several malignant diseases. A common side effect is hypertension due to a yet unknown mechanism. Most TKIs target the receptors of VEGF, a vascular growth factor known to stimulate NO production. We hypothesize that TKIs increase blood pressure by impaired renal NO bioavailability.

Methods: 22 patients (11 males and 11 females) diagnosed with renal cell carcinoma (RCC) undergoing treatment with the TKI pazopanib were included in the study. Home blood pressure measurements were recorded and blood and urine samples collected at baseline and at two follow-up visits (FU) 4 and 8 weeks after initiation of treatment.

Results: At baseline, mean systolic and diastolic blood pressure was 137±3/76±2 mmHg. After 4 weeks of treatment, both systolic and diastolic blood pressure was significantly increased compared to baseline (150±4/89±2 mmHg, P<0.05) whereas after 8 weeks, systolic but not diastolic blood pressure had returned to baseline values (137±4/81±2 mmHg). Five patients initiated or intensified ongoing antihypertensive treatment before 1st FU and additionally 4 patients before 2nd FU. No changes in eGFR were observed during treatment. Urinary protein/creatinine ratio increased significantly after 4 weeks compared to baseline. A transient decrease in plasma NO metabolites (NOx) was seen at 1st FU, whereas plasma cGMP was significantly reduced at both FU visits. Moreover, a significant reduction in both urinary NOx and cGMP excretion normalized to creatinine was seen at both 1st and 2nd FU.

Conclusions: Pazopanib treatment in RCC patients leads to hypertension associated with decreased urinary excretion of NO metabolites suggesting an important role of reduced renal NO bioavailability in TKI-induced hypertension.

Can We Prevent Recurrent Pre-Term Preeclampsia? Line Malha, Franco B. Mueller, Phyllis August. *Div of Nephrology and Hypertension, Weill Cornell Medicine, New York, NY.*

Background: Preterm preeclampsia (PTPE) (< 34 weeks of gestation) is a life-threatening complication of pregnancy with a high recurrence rate (20-60%). Low dose aspirin (ASA) may prevent recurrence, and some trials suggest that low molecular weight heparin (LMWH) and ASA together is more effective but results are inconclusive. We report the recurrence rate of PE in women with prior PTPE and the impact of therapy on fetal birth weight (BW) and gestational age at delivery (GA).

Methods: We prospectively followed 41 women with PTPE in a prior pregnancy throughout 53 subsequent pregnancies. Women were screened for genetic and acquired thrombophilias and treated with either ASA or LMWH and ASA as determined by treating physicians. Maternal and fetal outcomes in subsequent pregnancies were ascertained including preeclampsia (PE), GA, and BW.

Results: The mean (±SD) age of the women was 36±5 years at the time of their subsequent pregnancy, and BMI was 25.6±5.4kg/m^2. 66% were white, 5% black and 15% Hispanic. Genetic thrombophilias were detected in 91% and acquired thrombophilias in 36%. Thirteen women (25%) were not treated with ASA or LMWH, 12 (23%) received ASA alone, and 27 (52%) received LMWH±ASA. PE recurred in 6 pregnancies (11%) and PTPE in 5 (9%). In subsequent pregnancies BW was higher (1473±743 grams prior pregnancy vs. 2880±778 grams in the subsequent pregnancies, p<0.001), and GA at delivery was later (29±4 weeks vs. 36±4 weeks, p<0.001). PE recurrence was numerically higher in the untreated group compared to those treated with ASA alone, or LMWH ±ASA (3/13 vs., 1/12 or 2/27). BW and GA increased similarly in subsequent pregnancies in all groups although women treated with LMWH±ASA had a greater increase in GA (8.8 vs 4.4 weeks, p=0.021).

Conclusions: The risk of recurrent PE or PTPE in women with prior PTPE was lower than reported in prior studies. BW and GA at delivery were significantly better in subsequent pregnancies. We found a trend towards a decreased incidence of PE and greater prolongation of pregnancy in those treated with LMWH±ASA compared to no treatment or ASA alone. We propose an appropriately designed clinical trial to determine the benefits/ risks of LMWH in women at risk for PTPE.

SA-PO677

Renin-Angiotensin-Aldosterone Profiles Predictive of Superimposed Preeclampsia Line Malha,[1] Cristina P. Sison,[2] Phyllis August.[1] *[1]Div of Nephrology and Hypertension, Weill Cornell Medicine, New York, NY; [2]Biostatistics Unit, Feinstein Inst for Medical Research, Northwell Health, Manhasset, NY.*

Background: Women with preexisting, or chronic hypertension (CHT) in pregnancy are at heightened risk for significant morbidity and death, primarily due to further elevations in blood pressure (BP) and development of superimposed preeclampsia (SPE). The pathophysiology for the elevations in BP remains unresolved.

Methods: We performed a prospective, longitudinal trial of 108 women with CHT and investigated the hypothesis that renin-angiotensin aldosterone profiles (RAAS) are associated with BP and SPE. We measured plasma renin activity (PRA), 24h urine Na, K and aldosterone (UA) at 12, 20, 28, and 36 weeks gestation and post-partum to investigate the association between these potentially pathophysiologic parameters and elevations in BP and SPE.

Results: Mean Arterial Pressure (MAP) was inversely related to PRA (r=-0.23, p<0.0001) and UA (r=-0.11, p=0.047). PRA and UA were significantly and positively associated with each other (r=0.5327, p<0.0001). Whereas PRA, and UA increased similarly in the first and second trimesters of pregnancy in women who did or did not develop SPE, the levels of both PRA (P=0.005) and UA (P=0.039) were significantly lower at 28 weeks in those who developed SPE compared to those who did not develop SPE. Interestingly, PRA was significantly lower in black women compared to other racial groups (p = 0.026 at 36 weeks and <0.003 at all other time points including postpartum) and UA was also significantly lower in black women at 36 weeks (p<0.03). After adjusting for MAP, urine

Na, urine K and serum K, both UA (0.0001) and race (P=0.0018) were significant predictors of PRA, while gestational age (P<.0001), PRA (P=0.0001), urine K (P<.0001) and urine Na(P=0.0005) were predictors of UA.

Conclusions: We conclude that renin-angiotensin- aldosterone profiles, ascertained in the third trimester of pregnancy, foretell the development of SPE in pregnant women with CHT. The RAAS profiles characterized in our investigation, in addition to serving as prognostic biomarkers, advance sodium retention as the primary mechanism for the elevation in BP in women with SPE.

SA-PO678

Pathway Analysis and Targeted Proteomics of Human Urinary Exosomal Proteins during Aldosterone Administration James M. Luther,[1] Kristie Rose,[2] Bing Zhang,[2] Kevin Schey.[2] *[1]Medicine, Vanderbilt Medical Center; [2]Vanderbilt Univ.*

Background: Exosomes are microvesicular bodies which are secreted from all cell types. Urinary exosomes contain >3,000 identifiable proteins which may provide insight into human disease, but their physiologic regulation remains undefined.

Methods: To test the hypothesis that the urinary proteome is dynamically regulated by exogenous hormones, we analyzed urine exosomes from 10 healthy subjects in a cross-over study after vehicle and aldosterone infusion (0.7 µg/kg/hr for 10 hrs) while on a standardized diet (160mmol Na/d for 5 days). Urinary exosomes were isolated by a two-step centrifugation method after reduction of the Tamm-Horsfall protein (uromodulin) with DTT. After isolation by ultracentrifugation, proteins underwent trypsin digestion and were subjected to MudPIT analysis. Statistical analysis was performed using a quasi-likelihood analysis with Benjamini & Hochberg correction for multiple comparisons. Validation was performed by targeted multiple-reaction-monitoring analysis for selected peptides quantified with stable-isotope peptide standards.

Results: Aldosterone infusion increased plasma aldosterone (55.9±5.5 vs 7.8±1.5 ng/dL; P<0.001) without acutely altering blood pressure or serum potassium. At a False Discovery Rate <0.05, 101 proteins were identified as up-regulated in the ALDO group, while 189 proteins were down-regulated. Gene ontology enrichment analysis of significantly altered proteins revealed that aldosterone altered small GTPase-mediated signal transduction, GTP binding, protein binding, and GTPase activity. In particular, aldosterone treatment altered pathways involving regulation of the actin cytoskeleton, which could be implicated in sodium channel trafficking. In separate validation samples, changes in RAC3 and TAO3 were verified using multiple-reaction monitoring mass spectrometry targeting with isotopic standards.

Conclusions: These data demonstrate that aldosterone dynamically alters the urinary exosome content in humans, including those involved in actin-cytoskeleton regulation. Furthermore, exosomal protein assays may provide a useful physiologic biomarkers in future clinical studies.

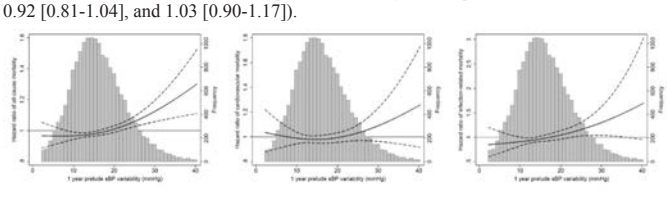
Higher Pre-ESRD Visit-to-Visit Variability in Systolic Blood Pressure Is Associated with Increased Post-ESRD Mortality in Advanced CKD Patients Transitioning to Dialysis Keiichi Sumida,[1,2] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Elani Streja,[3] Kunihiro Yamagata,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of Tsukuba, Ibaraki, Japan; [3]Univ of California, Irvine, CA; [4]VA Medical Center, Memphis, TN.*

Background: Higher systolic blood pressure visit-to-visit variability (SBV) is associated with higher mortality. However, little is known about the association of pre-ESRD SBV with outcomes after dialysis initiation.

Methods: We identified 17,994 US veterans with advanced CKD transitioning to dialysis between 10/2007-9/2011 who had at least 3 outpatient BP measurements to calculate SBV using the intraindividual standard deviation (SD) of all SBP values during the last 1 year before dialysis initiation. Associations of SD quartiles (<11.6, 11.6-15.6, 15.7-20.3, ≥20.4 mmHg) with post-ESRD all-cause and cause-specific mortality were examined using Cox (for all-cause) and competing risk (for cause-specific mortality) regressions and cubic splines with adjustment for potential confounders.

Results: Greater SBV was linearly associated with higher all-cause and infection-related mortality, and showed a U-shaped association with CV mortality (Figure). The multivariable adjusted hazard/subhazard ratios [95% CI] for the highest (vs. lowest) quartile of SBV were 1.11 [1.04-1.19] and 1.39 [1.08-1.79] for all-cause and infection related mortality, respectively. The middle quartiles of SBV were associated with the lowest CV mortality (subhazard ratios [95% CI] for SBV quartiles 2 through 4 (vs. quartile 1); 0.98 [0.87-1.11], 0.92 [0.81-1.04], and 1.03 [0.90-1.17]).



Conclusions: High pre-ESRD SBV is associated with increased post-ESRD mortality. The lowest SBV is associated with higher CV mortality, the mechanisms of which (e.g. autonomic dysfunction) need further elucidation.

Patterns of Blood Pressure Response during Intensive BP Lowering in the Secondary Prevention of Small Subcortical Strokes (SPS3) Trial Elaine Ku,[1] Rebecca Scherzer,[1] Michelle Odden,[2] Michael Shlipak,[1] Carole White,[3] Oscar Benavente,[3] Pablo E. Pergola,[4] Carmen A. Peralta.[1] *[1]UCSF; [2]Oregon State Univ; [3]SPS3 Coordinating Center; [4]Univ of Texas.*

Background: Whether there are identifiable,discrete patterns of concomitant responses of systolic (SBP) and diastolic (DBP) blood pressure during intensive BP lowering, and the associations of these patterns with risk of mortality, major vascular events (MVEs), and stroke are not well known.

Methods: We used an unsupervised, group-based cluster procedure (machine learning) to identify distinct patterns of BP change among 1,331 participants in the Secondary Prevention of Small Subcortical Strokes (SPS3) Trial previously randomized to intensive anti-hypertensive therapy (target SBP <130 mm Hg) after lacunar stroke.

Results: Among persons undergoing active, aggressive BP lowering, the cluster procedure partitioned subjects into three groups, according to BP response during the active intensification period: 1) mildly elevated baseline mean SBP and minimal visit-to-visit BP variability (mild reducers); 2) moderately elevated baseline mean SBP and moderate visit-to-visit BP variability (modest reducers); and 3) very elevated baseline mean SBP with very large visit-to-visit BP variability during intensification (large reducers). Compared to mild reducers, modest reducers had a higher adjusted risk of death, MVE, and stroke.

Outcome	Cluster	Event Rate per 1000 PY	Demographic-adjusted[a] HR (95% CI)	Multivariable-adjusted[b] HR (95% CI)
Mortality	1	11.2 (7.8, 16.0)	ref	ref
	2	20.0 (14.7, 27.1)	1.71 (1.07, 2.75), p=0.026	1.64 (1.01, 2.67), p=0.046
	3	27.3 (17.2, 43.3)	2.30 (1.25, 4.21), p=0.0071	2.30 (1.20, 4.42), p=0.012
MVE*	1	18.0 (13.3, 24.3)	ref	ref
	2	41.1 (32.6, 51.9)	2.28 (1.55, 3.34), p<.0001	2.13 (1.44, 3.15), p=0.0002
	3	28.0 (17.1, 45.7)	1.51 (0.82, 2.77), p=0.18	1.67 (0.89, 3.11), p=0.11
Stroke**	1	12.3 (8.5, 17.7)	ref	ref
	2	34.3 (26.6, 44.2)	2.76 (1.77, 4.31), p<.0001	2.63 (1.67, 4.13), p<.0001
	3	18.9 (10.5, 34.2)	1.45 (0.69, 3.05), p=0.32	1.62 (0.76, 3.46), p=0.21

[a]Model 1 = age, sex, race, and education level.
[b]Model 2 adjusts for model 1 plus cardiovascular risk factors (smoking, baseline cholesterol, baseline diabetes, baseline cardiovascular disease (congestive heart failure or coronary heart disease), body mass index).
[a,b] For MVE and stroke, Fine-Gray competing-risk analysis accounts for competing risk of death
* MVE = stroke, myocardial infarction, or vascular death
** Stroke = Ischemic or hemorrhagic stroke (primary study outcome)

Large reducers had the highest risk of death. Risk of MVE and stroke was also higher for large reducers compared with mild reducers, but this finding did not reach statistical significance.

Conclusions: Among persons with prior lacunar stroke, baseline SBP and large SBP and DBP variability during anti-hypertensive treatment intensification can identify discrete groups of persons at higher risk of adverse outcomes.

SA-PO681

Threshold Value of Blood Pressure before 20 Weeks' Gestation for the Prediction of Preeclampsia Development in Healthy Pregnant Women: A Cohort Study in Korea Sung Woo Lee,[1] Eunjeong Kang.[2] *[1]Internal Medicine, Eulji General Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Preeclampsia is a dangerous pregnancy-related complication. Blood pressure (BP) during early pregnancy could be a good marker for preeclampsia development. However, the threshold values have not been evaluated. Therefore, we performed the current cohort study.

Methods: Among 11,059 pregnant women who delivered a baby in a tertiary care hospital between 2003 and 2015, 3925 who had BP and dipstick proteinuria data, and did not have comorbidities were included. BP before 20 weeks' gestation was used as the main factor to determine preeclampsia development. For visual evaluation of non-linear associations, a restrictive cubic spline curve was used. For threshold evaluation, the area under the receiver operator curve was used with the Youden index.

Results: For the 3925 women, mean age was 32.6 years; 65.7% of women were nulliparous and 12.1% had a multifetal gestation. Mean systolic BP and diastolic BP before 20 weeks' gestation were 113.2 mm Hg and 63.9 mm Hg, respectively. The calculated threshold values were 118.3 mm Hg for systolic BP (sensitivity 0.50 and specificity 0.70) and 66.9 mm Hg for diastolic BP (sensitivity 0.53 and specificity 0.69). In a multivariate logistic regression analysis, systolic BP ≥118.3 mm Hg or diastolic BP ≥66.9 mm Hg was independently associated with preeclampsia development (adjusted odds ratio, 2.151; 95% confidence interval, 1.400 – 3.306; $P < 0.001$).

Conclusions: The threshold values of systolic BP and diastolic BP for preeclampsia development were 118.3 mm Hg and 66.9 mm Hg, respectively. Clinicians need to care for women more intensively if their BP is above these levels. Future prospective studies are needed to confirm our study results.

SA-PO682

Profiles of Systolic Blood Pressure Patterns in Patients Who Died in the First Year of Hemodialysis

Marta Reviriego-Mendoza,[1] Peiran Yu,[1] Dugan Maddux,[1] Danqing Xu,[1] Jochen G. Raimann,[2] Xiaoling Ye,[2] Hanjie Zhang,[2] John W. Larkin,[1] Jeroen Kooman,[3] Frank van der Sande,[3] Len A. Usvyat,[1] Peter Kotanko,[2,4] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, MA; [2]Renal Research Inst, NY; [3]Maastricht Univ Medical Center, Netherlands; [4]Icahn School of Medicine at Mount Sinai, NY.*

Background: Previous studies indicate that lower predialysis systolic blood pressure (SBP) is a risk factor for short term mortality in HD patients (pts) (Maddux D, et al., ASN 2014 & 2015). We aimed to understand the profiles of SBP in pts who died during the incident year of HD.

Methods: Data from 192,379 Fresenius Medical Care North America pts during 2008 to 2014 was analyzed. Pts were grouped according to mean SBPs at 0-15, 30-45, and 90-105 days after HD initiation. SBP groups included low (LSBP; <110mmHg), normal (NSBP; 110 to <140mmHg), high (HSBP; 140 to ≤180mmHg), and very high (VHSBP; >180mmHg) in each of the periods. The respective percent (%) mortality in each SBP group for periods of 0-29, 30-89, and 90-364 days from the start of HD was computed. The % mortality relative to NSBP was calculated to compare the relative difference in % mortality between SBP groups.

Results: SBP profiles of pts who died during the incident year of HD are shown in Figure 1. We observed two major findings: i) The 2nd and 3rd months after initiating HD were the timeframe where the % mortality is highest for all SBP groups, particularly for the LSBP group (Figure 1A). ii) When compared to NSBP, the relative difference in % mortality appears to be 2.8 to 4 times higher in patients with LSBP, and lowest in pts with HSBP and VHSBP (Figure 1B).

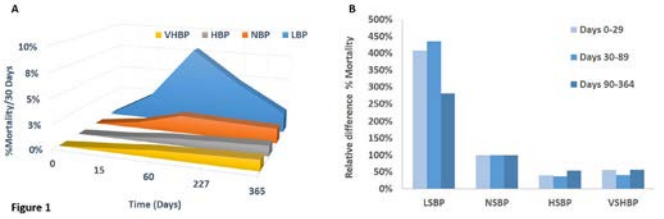

Figure 1

Conclusions: Our findings indicate that relative mortality rates are highest in pts with LSBP in the first year on HD, particularly during the first 90 days of HD. Pts with SBP 140 to ≤180mmHg appear to have lower relative mortality compared to other SBP groups.

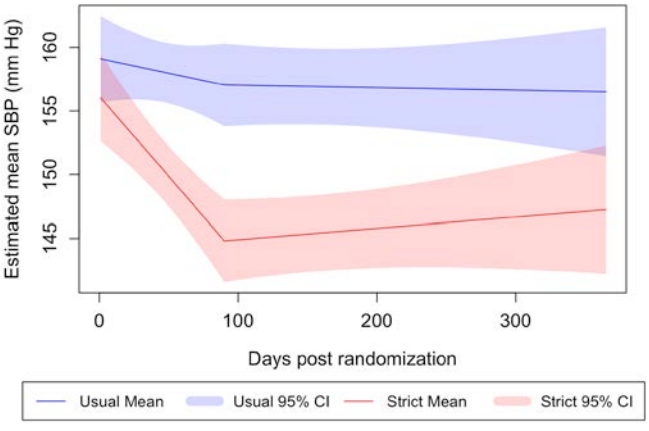
Results of the BID Pilot Study

D. Miskulin,[1,8] R. Schrader,[8] Jennifer J. Gassman,[2] Manisha Jhamb,[3] David W. Ploth,[4] Mahboob Rahman,[5] Lavinia A. Negrea,[5] Raymond Y. Kwong,[6] Philip Zager.[7,8] *[1]Tufts; [2]Cleveland Clinic; [3]UPMC; [4]MUSC; [5]CWRU; [6]BWH; [7]UNM; [8]DCI.*

Background: Optimal predialysis systolic blood pressure (SBP) for hemodialysis (HD) patients is unknown. The current KDOQI guideline is SBP <140 mm Hg. However, SPRINT results suggest that lower SBP may be beneficial. The BID Pilot assessed feasibility and safety of conducting a full-scale RCT of usual vs. strict SBP control.

Methods: We randomized 126 HD patients to a predialysis SBP of 110-140 (n=62) or 155-165 (n=64) mm Hg for 1 year. Primary outcomes were feasibility and safety. We estimated mean SBP in each arm throughout the study from a linear mixed model. We assessed the relationship of SBP to interdialytic weight gain (IDWG), expressed as percent estimated dry weight. We compared the frequency of serious adverse events (SAEs) across arms. The secondary outcome was change in left ventricular mass (LVM) by MRI.

Results: Over the last 9 months mean separation in SBP between arms was 12.9 mm Hg. Only 31.8% and 43.8% of patients in the strict and usual arms, respectively, sustained the target SBP.



There was a trend in each arm for IDWG to be higher in those with SBP above vs. in the respective targets. Overall and in each arm there were no statistically significant relationships between IDWG and SBP. The number of hospitalizations (H) and vascular access thromboses (T) was higher in the strict (H 85, T 20) vs. usual arm (H 47, T 7), both P<0.05. However, the number of patients with H and T was similar in the strict (H 29, T 10) and usual arms (H 25, T 7) (NS). In an intent-to-treat analysis the median change in LVM was similar in the strict (-0.8 g) vs. usual arm (1.5g) (NS). In an as-treated analysis, the median change in LVM was greater in the strict (-11.1 g) vs. usual (-1.2g) arm (p=0.03).

Conclusions: It is feasible and safe to conduct a full-scale RCT to explore the hypothesis that intensive control of SBP in hypertensive HD patients may improve clinical outcomes.

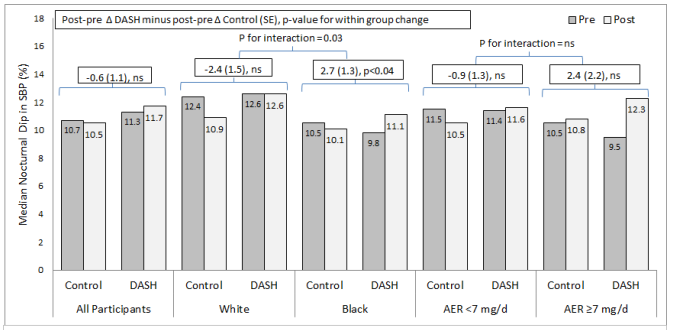
Effect of the DASH Diet on Nocturnal Dipping and Nighttime Blood Pressure: Moderating Role of Race and Albumin Excretion Rate

Crystal C. Tyson,[1] Huiman Barnhart,[2] Shelly K. Sapp,[2] Pao-Hwa Lin,[1,3] Laura P. Svetkey.[1,3] *[1]Medicine, Duke Univ, Durham, NC; [2]Duke Clinical Research Inst, Durham, NC; [3]Stedman Nutrition & Metabolism Center, Duke Univ, Durham, NC.*

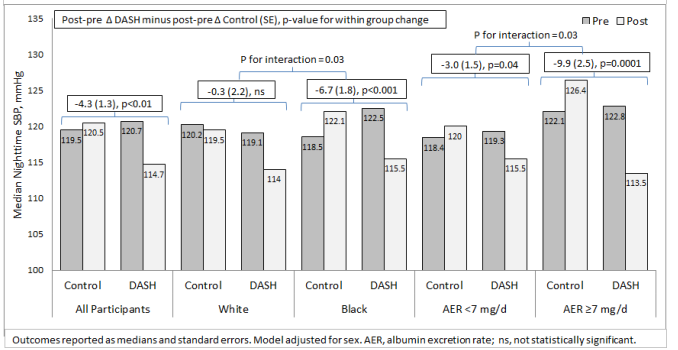
Background: Blunted nocturnal dip in blood pressure (BP) and elevated nighttime BP are independently associated with increased cardiovascular mortality. The effect of the DASH diet on nocturnal dip in BP is not known, nor is whether response differs by race or presence of low-grade albuminuria, which may be a marker for subclinical kidney disease.

Methods: DASH multicenter, randomized controlled feeding trial data were used to examine whether the DASH diet, compared to a control diet, enhances nocturnal dip in SBP and lowers nighttime SBP. A total of 202 pre-hypertensive and hypertensive adults randomized to 8 weeks of the DASH diet or control diet had pre- and post-intervention ambulatory BP data and pre-intervention 24-hour urine samples. Nocturnal change in SBP was defined as daytime mean SBP minus nighttime mean SBP expressed as a percentage of daytime mean SBP. We report a negative nocturnal change value as "dip". Median regression was used to compare pre-post changes in nocturnal dip in SBP and nighttime SBP between treatment arms. We also tested for interaction effects between diet, race (black versus white), and albumin excretion rate ([AER] ≥7 mg/day versus <7 mg/day) on changes in SBP.

Results: Mean age was 45±10 years, 51% were men, 59% were black, and 26% had AER ≥7 mg/day.



Outcomes reported as medians and standard errors. Model adjusted for baseline hypertension (yes/no). AER, albumin excretion rate; ns, not statistically significant.



Outcomes reported as medians and standard errors. Model adjusted for sex. AER, albumin excretion rate; ns, not statistically significant.

Conclusions: DASH enhanced nocturnal dip in SBP and reduced nighttime SBP in blacks but not whites and caused larger reductions in nighttime SBP in subjects with AER ≥7 mg/day than <7 mg/day. Our study suggests the DASH diet may improve nocturnal dipping and nighttime BP in blacks and adults with low-grade albuminuria.

SA-PO685

Antihypertensive Effects of Sparsentan, a Dual Angiotensin II and Endothelin Type A Receptor Antagonist Radko Komers,[1] Alvin Shih,[1] Rene Belder.[2] *[1]Retrophin, Inc., Cambridge, MA; [2]Sanofi, Bridgewater, NJ.*

Background: Two randomized, controlled, double-blind, Phase 2 studies evaluated the efficacy and safety of sparsentan as a treatment for Stage I and II hypertension.

Methods: Study 1 (NCT00522925) randomized 113 patients (1:1:1) to receive sparsentan 200 or 500 mg/day or placebo (PBO) for 4 weeks and compared mean change from baseline in 24-hour ambulatory systolic (SBP) and diastolic blood pressures (DBP). Study 2 (NCT00635232) randomized 261 patients (1:1:1:1:1) to receive sparsentan 200, 400, or 800 mg/day, irbesartan (IR) 300 mg/day, or PBO for 12 weeks to evaluate the change in sitting SBP and DBP. Both studies assessed the rates of treatment-emergent adverse events (TEAEs).

Results: In study 1, sparsentan-treated patients had greater reductions in SBP and DBP compared with PBO-treated patients (SBP: 200 mg, -12.2 mmHg; 500 mg, -14.8 mmHg PBO, -0.4 mmHg; $P<.001$). TEAEs were similar for all groups (200 mg, 21%; 500 mg, 26%; PBO, 25%). Edema was noted in 3% of PBO and 0% and 5% of sparsentan 200- and 500-mg treated patients. In study 2, sparsentan 200- and 400-mg doses resulted in greater reductions in BP than PBO ($P<.001$), and was similar to IR-treated patients. SBP and DBP reductions in patients on sparsentan 800-mg doses were greater than in patients on IR (SBP: -23.4 vs -10.7 mmHg; $P=.009$). The proportion of responders (BP <140/90 mmHg) on 400- and 800-mg doses (52% and 62%), but not the 200-mg dose (36%), were greater than in patients on IR (32%) and PBO (9%). TEAE rates were dose-dependent with sparsentan, but the TEAE rates at the 2 lower doses did not differ from PBO or IR. Edema occurred in 3%, 7%, and 11% of patients who received sparsentan 200, 400, and 800 mg, respectively, compared with 3% in IR-treated and 2% in PBO-treated patients, and resulted in 2 study withdrawals in the SP 800-mg group.

Conclusions: In the setting of Stage 1 and 2 hypertension, sparsentan reduced BP compared with PBO, and provided better BP control at 400- to 800-mg doses compared with IR. Both sparsentan 200 and 400 mg had a favorable safety profile, while sparsentan 800 mg showed an increased number of TEAEs including edema and early study withdrawals.

Funding: Pharmaceutical Company Support - Ligand Pharmaceuticals, Inc., funded this study and participated in the study design, study research, data collection, analysis, and interpretation of data. Retrophin, Inc., acquired sparsentan from Ligand and participated in the writing, reviewing, and approving this abstract for presentation

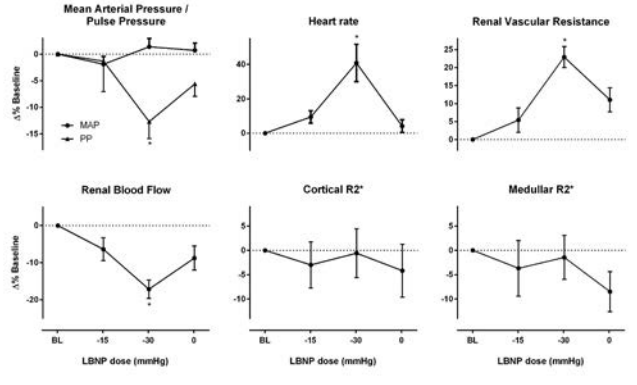
SA-PO686

Renal Blood Flow and Oxygenation during Systemic Sympathetic Activation by Lower Body Negative Pressure René van der Bel,[1] Jasper Verbree,[2] Oliver J. Gurney-Champion,[3] Erik Stroes,[1] Aart J. Nederveen,[3] C.T.P. (Paul) Krediet.[1] *[1]Internal Medicine, Academic Medical Center at the Univ of Amsterdam, Netherlands; [2]Physiology, Academic Medical Center at the Univ of Amsterdam, Netherlands; [3]Radiology, Academic Medical Center at the Univ of Amsterdam, Netherlands.*

Background: In kidney disease, renal hypoxia and systemic sympathetic activation are thought to augment each other, but direct observations in humans are lacking. To explore the relation between renal oxygenation and systemic sympathetic activity we studied the effects of Lower Body Negative Pressure (LBNP) on renal blood flow (RBF) and RO in healthy humans. LBNP induces systemic sympathetic activation, sodium retention and decreases GFR and renal plasma flow.

Methods: After a 15 min baseline, 8 healthy volunteers (age 19-31 years) were subjected to LBNP at -15 and -30 mmHg for 15 minutes per dose. RO and RBF were assessed by BOLD and phase contrast MRI, respectively. Off-line, R2* values were calculated for cortex and medulla, via mono-exponential fitting to multi-echo 2-dimensional fast field-echo data. RBF was calculated in the proximal renal artery after manual vessel segmentation.

Results: Mean arterial blood pressure (proxy of renal perfusion pressure) did not change, pulse pressure (proxy of stroke volume) decreased from 50±10 to 43±7 mmHg. Heart rate and renal vascular resistance increased dose dependently (by 28±15% and 23±8%, p<0.05, respectively), while RBF decreased from 9.6±1.9 to 7.9±1.6 ml/s(p=0.02). There was no change in cortical or medullary R2*.



Conclusions: These data do not support the widely held view that systemic sympathetic hyperactivity causes renal hypoxi a per se. Either renal oxygen demand and supply are equally suppressed during sympathetic activation or the changes in RO are below the detection threshold of BOLD MRI.

Non-Lateralizing Aldosterone-Producing Adenoma Benefited by Unilateral Adrenalectomy George Thomas. *Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: Current guidelines recommend adrenal vein sampling (AVS) in patients with primary aldosteronism (PA) to differentiate bilateral from unilateral disease when the patient desires surgical cure and there are no contraindications. There are no reports of non-lateralizing aldosterone producing adenomas (APA) that benefit from unilateral adrenalectomy. The objective of this study is to describe clinical outcomes of patients with APA who undergo unilateral adrenalectomy despite non-lateralization by AVS.

Methods: This is a single center, prospective, observational study. We included patients with PA who underwent dedicated adrenal CT scan followed by AVS. Sequential bilateral AVS was done with continuous ACTH (50 micrograms/hour) infusion. A selectivity index (adrenal vein cortisol/ peripheral vein cortisol) of 4:1 and cortisol-corrected aldosterone lateralization index of 5:1 were the criteria set for lateralization. We report the outcomes of 6 patients who underwent adrenalectomy despite non-lateralization. The primary outcome was decrease in PA to ≤ 10 ng/dl and serum potassium (K) increase to ≥ 3.8 mEq/L without treatment. The secondary outcome was blood pressure (BP) ≤ 140/90 mm Hg without treatment or the use of less anti-hypertensive medication.

Results: Of 50 patients with solitary APA who underwent AVS, 8 had lateralization index of less than 5:1 (range: 0.43 to 3.03). Six with solitary adenomas ranging between 1.9 to 3.0 cm chose surgery despite non-lateralization. Post-operatively, PA decreased from an average of 62 ng/dl (range: 37 to 145) to 5.5 ng/dl (range: 2.3 to 9.1). Serum K increased to ≥ 3.8 meq/l without treatment in all patients. BP significantly decreased from a mean of 137/86 mm Hg to 119/76 mm Hg. Anti-hypertensive medication use decreased from a mean of 4.5 to 0.8.

Conclusions: The management of a solitary APA should not rely solely on findings of AVS but should include patient preference and the clinical setting (drug intolerance, resistant hypertension, hypokalemia leading to adverse cardiovascular events, or progressive renal disease). We show that patients with biochemical evidence of PA and clear-cut solitary APA on imaging benefit from unilateral adrenalectomy irrespective of findings of AVS.

SA-PO688

Racial Differences in Nocturnal Dipping Status in Diabetic Kidney Disease (DKD): Results from the STOP-DKD Study Leah L. Zullig,[1] Clarissa Jonas Diamantidis,[1] Manjushri V. Bhapkar,[2] Huiman Barnhart,[3] Megan M. Oakes,[1] Hayden Bosworth,[1] Uptal D. Patel.[1] *[1]Dept of Medicine, Duke Univ, Durham, NC; [2]Duke Clinical Research Inst, Duke Univ, Durham, NC; [3]Biostatistics & Bioinformatics, Duke Univ, Durham, NC.*

Background: Abnormal nocturnal blood pressure (BP) dipping is associated with higher cardiovascular risk, progressive kidney disease and death, potentially contributing to racial differences in outcomes. We sought to determine the association of race with dipping status among STOP-DKD study participants with type 2 diabetes and kidney disease (DKD).

Methods: STOP-DKD is a randomized, controlled trial evaluating the impact of a multifactorial clinical pharmacist-administered telehealth intervention on progression of DKD compared to an education control in patients with DKD recruited from Duke Primary Care clinics in 2015. Eligible patients had: annual averaged glomerular filtration rates (eGFR) > 45 mL/min/1.73m^2; evidence of nephropathy and/or retinopathy; and uncontrolled hypertension (HTN; > 140/90 mmHg). 24-hour ambulatory blood pressure monitoring (ABPM) values were collected at baseline, and analyzed by wake and sleep-periods. Nocturnal non-dipping was defined as a fall in sleep-period BP of ≥0% to <10% compared to waking BP.

Results: Of 281 participants, 117 (42%) completed 24-hour ABPM, about half of whom were black (n=56, 48%). Participants were predominantly male (n=64, 55%), married (n=73, 63%), and had completed high school (n=106, 91%). Average daytime and nocturnal DBPs were higher in blacks than whites (76.8 vs.73.4, p=0.02; and 71.7 vs. 66.8, p=0.004, respectively) while the average SBPs did not differ significantly. Black participants were less likely to have a ≥10% SBP dip than whites (15.1% vs. 31.5% respectively; p=0.067). Males and black patients were less likely to have a ≥10% dip in diastolic BP (31.3% vs. 57.4% for male vs. female, p=0.007; 30.2% vs. 53.7% for blacks vs. whites, p=0.019).

Conclusions: Non-dipping status is more common among black patients with DKD than their white counterparts. Interventions targeting BP in black patients may minimize such differences, and in turn, improve outcomes in this high-risk group.

SA-PO689

Lateralization Index of Adrenal Vein Sampling Is a Predictor of Blood Pressure Improvement after Adrenalectomy for Primary Aldosteronism

Miho Tagawa,[1] Muriel Ghosn,[2] Scott O. Trerotola,[2] Heather Wachtel,[2] Debbie L. Cohen,[2] Raymond R. Townsend.[2] *[1]Nara Medical Univ; [2]Univ of Pennsylvania.*

Background: Adrenal Vein sampling (AVS) is recommended in primary aldosteronism (PA) to determine if lateralization occurs. Lateralization index (LI) > 4 is considered a positive result. It is unclear however what LI value predicts BP response.

Methods: This is a retrospective observational study on patients who underwent AVS and adrenalectomy for PA at Penn from 1997 to 2015. Improvement of BP was defined as reduction in systolic BP (SBP)>10mmHg with same number of antihypertensives, or SBP within 10mmHg with reduction in number of antihypertensives. Data were analyzed using multivariable logistic regression analyses.

Results: There were 169 patients who underwent AVS and adrenalectomy. Mean age was 53 (46-60) years, 64 % were male, 34% were African American, 55 % were Caucasian. LI of AVS was 11.9 (8.1-22.2) and 8.0 (5.1-18.5) for patients with or without BP improvement at 0-6 months, respectively (p=0.16). After adjustment for known predictors of BP improvement after adrenalectomy, LI >9 was independently associated with BP improvement at 0-6 months.

	OR for improvement in BP	95 % (CI)
Age	1.0 7	0.94-1.22
Male sex	4.48	0.40-49.9
Duration of hypertension (years)	0.79	0.65-0.96
Body mass index	0.80	0.66-0.98
estimated glomerular filtration rate	0.95	0.89-1.00
Family history of hypertension	3.56	0.45-28.3
Plasma aldosterone concentration/plasma renin activity	1.00	1.00-1.01
Systolic blood pressure	1.14	1.03-1.27
Diastolic blood pressure	0.91	0.81-1.01
African American	1.65	0.17-16.4
LI > 9	17.2	1.30-229.5

At 12-24 months, LI>9 was associated with modest tendency for BP improvement [OR (95% CI) was 5.7 (0.3-96.6)].

Conclusions: LI >9 was independently associated with improvement in BP at 0-6 months after adrenalectomy. LI > 9 may be a useful predictor for short-term improvement in BP after adrenalectomy for PA.

SA-PO690

Split Renal Function in Patients with Unilateral Atherosclerotic Renal Artery Stenosis - Effect of Renal Angioplasty

Aso Saeed, Elzbieta Nowakowska-Fortuna, Gert Jensen, Hans V. Herlitz, Gregor S. Guron. *Sahlgrenska Univ Hospital/ Sahlgrenska Academy, Dept of Molecular and Clinical Medicine, Inst of Medicine/Nephrology, Gothenburg, Sweden.*

Background: The objective of the study i to evaluate the effect of percutaneous transluminal renal angioplasty (PTRA) on split renal function (SRF) in patients with unilateral atherosclerotic renal artery stenosis (ARAS).

Methods: Retrospective analysis of all consecutively examined patients at our Centre with significant ARAS undergoing PTRA during 2002-2007. A significant ARAS was defined as a lesion with a trans-stenotic mean arterial pressure gradient (MAPG) of at least 10 mmHg or a diameter stenosis ≥ 60%.Ambulatory (24 h) SBP (ASBP) and DBP (ADBP) and calculated SRF using ^{99m}Tc-DTPA renal scintigraphy were evaluated before (baseline) and 4 weeks after PTRA.

Results: ASBP and ADBP were significantly lower 4 weeks after PTRA compared to baseline levels (Table 1). Although total estimated glomerular filtration rate (eGFR, 4-variable MDRD) had not changed by PTRA, analysis of SRF showed significantly increased eGFR in stenotic kidneys and comparable decreases in eGFR in non-stenotic kidneys 4 weeks after PTRA (Table 1).

Table 1. Effect of PTRA on ambulatory blood pressure, kidney function and split renal function.

	Baseline (n=52)	4 weeks after PTRA (n=52)	P-value
ASBP, mm Hg	145±14	138±16	0.005
ADBP, mm Hg	80±9	77±11	0.005
S-Creatinine, µmol/l	116±39	117±41	0.81
eGFR (MDRD) ml/min/1.73m2	57±21	58±21	0.77
% stenotic renal function	38±19	41±19	<0.0001
% non-stenotic renal function	62±19	59±19	<0.0001
eGFR stenotic kidney, ml/min/1.73m2	22±14	26±17	0.004
eGFR non-stenotic kidney, ml/min/1.73m2	37±16	34±15	0.026

Conclusions: In patients with unilateral ARAS, PTRA significantly improved eGFR in stenotic kidneys and decreased filtration in contralateral, non-stenotic kidneys. These potentially beneficial effects may not be apparent when total kidney function remains stable. The clinical significance of these findings needs to be evaluated further.

SA-PO691

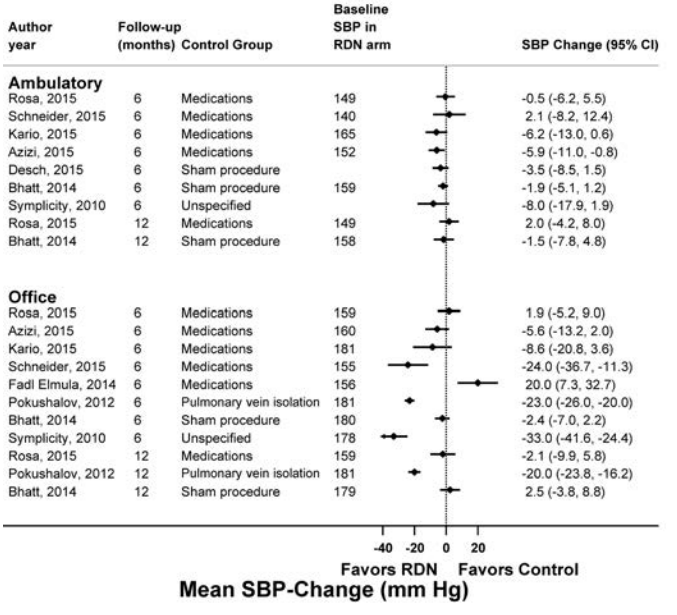
Renal Denervation for Resistant Hypertension: A Systematic Review

Tariq Shafi, Matt Chacko, Zackary Berger, Lisa M. Wilson, Jessica L. Gayleard, Eric B. Bass, Stephen M. Sozio. *Johns Hopkins Univ.*

Background: Renal denervation (RDN) may reduce blood pressure (BP) in patients with resistant hypertension, but data on its effectiveness are conflicting.

Methods: ***Studies:*** We reviewed studies published through March 2016 if they reported a randomized controlled trial (RCT), a comparative cohort with ≥10 patients in each arm, or a non-comparative cohort with ≥25 patients. ***BP:*** We abstracted systolic BP (SBP) measured by 24-hour ambulatory BP monitoring (ABPM) or in office. ***Changes in SBP:*** Defined as follows: 1. Within-group change: the absolute change in SBP during follow-up within either the RDN or control/sham group. 2. Between-group change: within-group change in RDN group minus within-group change in control/sham group. ***Primary metric for effectiveness of RDN:*** Between-group SBP change measured by ABPM.

Results: We retrieved 1,233 unique citations. 83 studies met inclusion criteria; 9 (11%) were RCTs, 8 (10%) were comparative cohorts, and 66 (80%) were non-comparative cohorts. The between-group ABPM SBP change with RDN was small in RCTs (range: -8 mm Hg to +2 mm Hg). The within-group change in office SBP with RDN was higher in RCTs and comparative cohorts (-42 mm Hg to -8 mm Hg) as well as in non-comparative cohorts (range -58 mm Hg to +12 mm Hg), suggesting potential observer bias. Data were scant on clinical endpoints, such as hospitalization or death. Adverse effects were uncommon but potentially serious, and included hematomas, pseudoaneurysms, and renal artery interventions.



Conclusions: Renal denervation may lower systolic BP in patients with treatment-resistant hypertension, but the results are highly variable. Further research is needed to clarify its role in improving clinical outcomes. *Primary Funding Source:* Agency for Healthcare Research and Quality.

Systolic Blood Pressure Patterns during the Incident Year of Hemodialysis

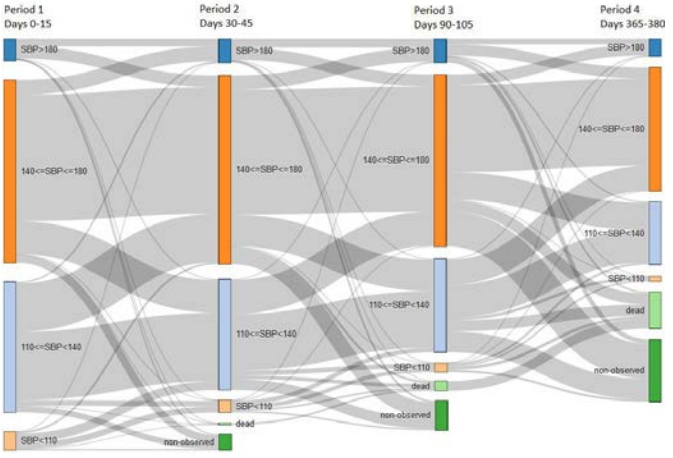
Peiran Yu,[1] Dugan Maddux,[1] Danqing Xu,[1] Jochen G. Raimann,[2] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Jeroen Kooman,[3] Frank van der Sande,[3] Len A. Usvyat,[1] Peter Kotanko,[2,4] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America; [2]Renal Research Inst; [3]Maastricht Univ Medical Center, Netherlands; [4]Icahn School of Medicine at Mount Sinai.*

Background: KDOQI guidelines recommend managing systolic blood pressure (SBP) in hemodialysis (HD) patients to achieve a pre-HD SBP <140/90mmHg and post-HD SBP <130/80mmHg. Despite this, previous studies suggest that lower pre-HD SBPs are associated with increased risks for mortality (Robinson BM, et al. Kidney Int. 2012 Sep;82(5):570-80). We aimed to understand SBP patterns in those who survived or died during the first year of HD.

Methods: Data from 192,379 incident HD patients during 2008 to 2014 was analyzed. Patients were grouped by SBP level at 0-15, 30-45, 90-105, and 365-380 days after the initiation of HD. SBP groups included low (LSBP; <110mmHg), normal (NSBP; 110 to

<140mmHg), high (HSBP; 140 to ≤180mmHg), and very high (VHSBP; >180mmHg). Changes in SBP groups were tracked in those who survived or died utilizing a Sankey diagram (river plot).

Results: We observed three key findings that are shown in Figure 1: i) there appeared to be the greatest number of patients in the HSBP group during the incident year, as compared to other SBP groups. ii) Compared to patients in the NSBP group, mortality rates appeared higher for patients in the LSBP group, and lowest for the HSBP and VHSBP groups. iii) The proportion of patients with fluctuations in SBP groups between time points appeared more noticeable in the LSBP and VHSBP groups, followed by patients in the NSBP group.



Conclusions: While the majority of patients in the first year on HD have high pre-HD SBP (140 to ≤180mmHg), our findings indicate considerable SBP fluctuations. The mortality appeared to be highest in patients with SBP <110 mmHg.

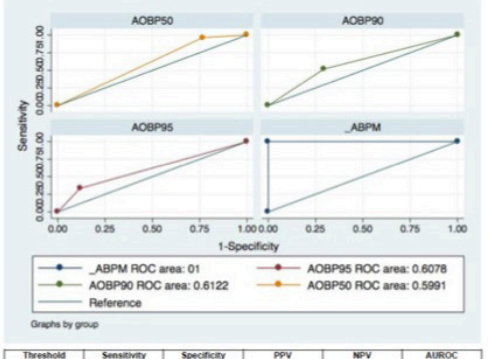
SA-PO693

Accuracy of Half Hour Automated Office Blood Pressure in the Diagnosis and Monitoring of Hypertension in Pediatrics Sally Anne Kellett, Samuel R. Crafter. *Nephrology Dept, Women's and Children's Hospital, Adelaide, SA, Australia.*

Background: This study was designed to determine the accuracy of half hour automated office blood pressure ($AOBP_{30}$) compared to 24 hour ambulatory blood pressure (BP) monitoring (ABPM), the gold standard test. Currently, the majority of patients referred to the Adelaide Women's & Children's Hospital for diagnosis or monitoring of hypertension (HTN), undergo $AOBP_{30}$ before ABPM. In adults, AOBP correlates with ABPM, but the relationship in pediatrics is unknown.

Methods: A single centre retrospective cohort study of 46 patients who received both BP tests between 2012-2014. Both tests classified patients as hypertensive or not based on the mean systolic and/or diastolic BP during the day and/or night, relative to the 95th centile. ABPM was conducted in accordance with AHA Guidelines using Meditech ABPM-04. For $AOBP_{30}$, BP was recorded at 3 minute intervals using the Welch Allyn Vital Signs Monitor 6000 series, and compared to Fourth Report normative data. The data was also re-analysed post-hoc using lower BP thresholds for $AOBP_{30}$ (90th and 50th centiles). Accuracy was assessed by sensitivity, specificity, positive and negative predictive values (PPV/NPV) and area under the receiver operating curve (AUROC).

Results: The sensitivity, specificity PPV, NPV and AUROC [95% confidence interval] were 32%, 89%, 82%, 46% and 0.6078 [0.49-0.721] respectively. 42% of false negatives on $AOBP_{30}$ were nocturnal HTN on ABPM.



Threshold	Sensitivity	Specificity	PPV	NPV	AUROC
95th centile	32%	89%	82%	46%	0.608
90th centile	50%	72%	74%	48%	0.612
50th centile	96%	22%	64%	80%	0.599

Conclusions: $AOBP_{30}$ in its current format shows poor accuracy compared with ABPM across a range of patient subgroups and diagnostic thresholds. Based on this study we recommend not using $AOBP_{30}$ as a screening test for the diagnosis and monitoring of hypertension outside of a study setting. Future studies could consider altering the format of the AOBP by increasing the frequency of measurements and/or including algorithms to deal with outlying data.

SA-PO694

Renal Artery and Parenchymal Changes after Renal Denervation Margreet F. Sanders,[1] Pieter Jan Van Doormaal,[2] Peter J. Blankestijn.[1] *[1]Dept of Nephrology & Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Dept of Radiology, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Renal denervation (RDN) is a treatment for difficult to control hypertension, with the intent to disrupt sympathetic renal nerves and lower blood pressure. Relatively little is known about the incidence of renal injuries after RDN. The aim of this study was to investigate the incidence of renal artery and parenchymal changes after RDN with contrast enhanced magnetic resonance angiography (MRA).

Methods: The present study is an initiative of the European Network COordinating research on Renal Denervation (ENCOReD), a collaboration of hypertension expert centers performing RDN. Patients treated with endovascular radiofrequency RDN and with available MRA both before and after RDN were included. Pre and post scans were evaluated in random order by two independent, blinded radiologists. Primary outcome was the change in renal artery and parenchyma after RDN.

Results: Ninety-six patients were included. Indication for RDN was treatment resistant hypertension in all patients. After a median time of 366 days (IQR 185) post RDN, MRA showed a new stenosis (25-49% lumen reduction) in two patients. Furthermore, there was progression of pre-existing lumen reduction (from <25% to 50-74%) in one patient. In one of the three patients, we concluded from procedural angiography that ablations were applied near the location of the observed stenosis. The incidence of vascular changes 12 months after RDN was 3.1% (95% confidence interval -0.4; 6.7%). No other renal vascular or parenchymal changes were observed.

Conclusions: Twelve months after RDN, the incidence of new or progression of pre-existing vascular abnormalities is 3.1%, when assessed by MRA. Ablations were applied near the observed stenosis in only one patient. No renal parenchymal changes were found.

SA-PO695

Serum Irisin Levels and Urotensin II Levels Are Independent Determinant Factors of Blood Pressure in Patients with Preeclampsia Li Jie Zhang, Ai Hua Zhang. *Dept of Nephrology, Peking Univ Third Hospital, Beijing, China.*

Background: Irisin is a newly identified myokine secreted from skeletal muscle that can promote energy expenditure and alleviate insulin resitant. The aims of this study were to observe irisin level and urotensin II (UII) in serum and placenta in normal pregnant and preeclamptic women, investigate the relationship between serum irisin and UII, and their association with blood pressure.

Methods: A total of 71 pregnant subjects were recruited, including 32 healthy and 39 preeclamptic pregnant women. Serum irisin were measured by using enzyme-linked immunosorbent assay, and serum UII concentrations were measured by radioimmunoassay analysis. Expressions of fibronectin type III domain-containing protein 5 (FNDC5) (irisin precursor) and UII in placenta specimens were performed using immunohistochemistry (IHC) and western blot.

Results: There was no difference of serum irisin levels between preeclamptic patients with normal controls (157.78±21.96ng/ml vs. 159.88±16.94ng/ml, P>0.05). While serum UII was significantly higher in preeclamptic women than normal pregnancy (35.59±21.27pg/ml vs. 24.64±14.20pg/ml, P=0.041). FNDC5 and UII expressions were both upregulated in placental tissue of preeclamptic pregnancy by IHC and western blot analysis. In patients with preeclampsia, serum irisin was negatively associated with systolic and diastolic blood pressure (r=-0.340, P=0.005; r=-0.304, P=0.012), while serum UII was positively associated with systolic blood pressure (r=0.286, P=0.033). There was no relationship between serum UII and irisin level in normal pregnancy and preeclampsia patients.Serum irisin and UII, urinary protein level, BMI and serum creatinine are independent determinants of blood pressure in preeclampsia by multiple regression analysis.

Conclusions: Serum irisin and UII are independent determinants of blood pressure in preeclampsia.

SA-PO696

Comparison of Efficacy of Atenolol versus Lisinopril in Hypertensive Patients on Hemodialysis: A Randomized Control Trial Zara Nisar. *Nephrology, Khyber Teaching Hospital, Peshawar, KPK, Pakistan.*

Background: The Aim of this study is to establish the efficacy of these drugs in terms of cardiovascular events in Hypertensive patients on hemodialysis, and maintenance of Blood Pressure.

Methods: 50 patients were randomized to open-label Atenolol group and 50 patients were randomized to open-label Lisinopril group, each administered 2 times per week after dialysis. Blood pressure was monitored and recorded and was controlled to less than 140/90 mmHg with medications and sodium restriction. The primary outcome was to look for serious cardiovascular events within 12 months.

Results: Serious Cardiovascular events occurred in 20 patients who had 26 episodes in the Atenolol group as compared with the lisinopril group in which 35 patients nearly had 61 episodes. The serious cardiovascular events Myocardial Infarction, heart failure, ventricular arrhythmias and stroke were found in 12 patients in atenolol group with 16

episodes where as 21 patients in Lisinopril group with 26 episodes . Patients on Atenolol were found to recover better in hospital setup as compared to those on lisinopril in these cardiovascular events. The ambulatory 24-h BP was found to be similar in both groups. However, the monthly measured BP was found to be higher in Lisinopril group.

Conclusions: Atenolol has better coverage for BP maintenance and preventing Cardiovascular events in hemodialysis patients as compared to Lisinopril in our setup. Note: This study is done in Khyber teaching hopsital, Peshawar, Pakistan and here 2 times dialysis regime is followed.

SA-PO697

A Novel Method of Determining Adiposity and Its Relationship with Blood Pressure in the Modification of Diet in Renal Disease Study

Preeya Tushar Shah, Zeid Khitan, Prasanna Santhanam, Joseph I. Shapiro. *Medicine, Marshall Univ, Huntington, WV.*

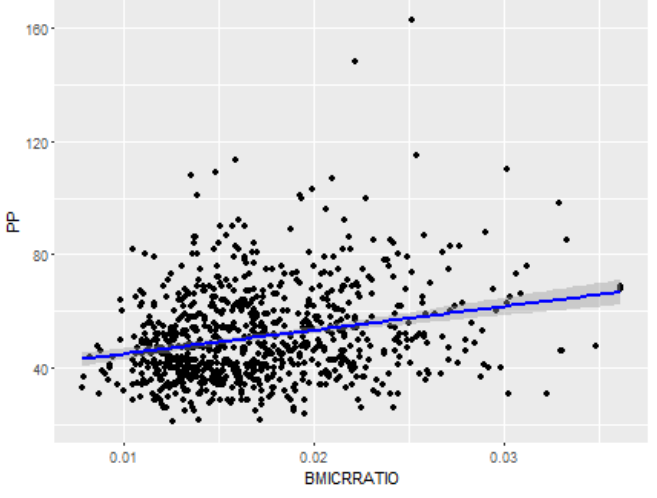
Background: Obesity is a known risk factor for hypertension and other diseases. The Body Mass Index (BMI, kg/m^2) is the most commonly used method of assessing obesity, yet this approach does not directly measure the quantity of fat. Because urinary creatinine excretion (UCrV) is believed to be a marker of skeletal muscle mass, we hypothesized that a ratio of the BMI to UCrV (BMI/UCrV) might provide a better index of adiposity. Specifically, we developed this ratio to attempt to emphasize non-muscular body size by normalizing for UCrV. We next chose to examine whether this ratio might correlate more strongly with systolic (SBP), diastolic (DBP) and pulse pressure (PP) within participants of the Modification of Diet in Renal Disease (MDRD) Study.

Methods: A retrospective analysis of the MDRD data identified 840 unique patients, ages 19-71. Data was extracted and imported into R Studio Correlational analysis between recorded components of blood pressure (Systolic, Diastolic, and Pulse Pressure) and the BMI/UCrV ratio was executed.

Results: We found that although systolic (SBP) and diastolic blood pressure (DBP) was predicted similarly by the BMI/UCrV ratio and BMI, the BMI/UCrV ratio predicted pulse pressure (PP) better than either BMI or UCrV alone.

	SBP	DBP	PP
BMI	0.0205**	0.0029	0.0139**
UCrV	0.0083	0.0334**	0.0242**
BMI/UCrV	0.0181**	0.0229**	0.0580**

Data shown as adjusted R2. * p<0.05, ** p<0.01.



Conclusions: We found that a novel indicator of adiposity, the BMI/UCrV ratio, correlated better with pulse pressure than either BMI or UCrV alone. If validated, this may be a useful clinical parameter to track and address.

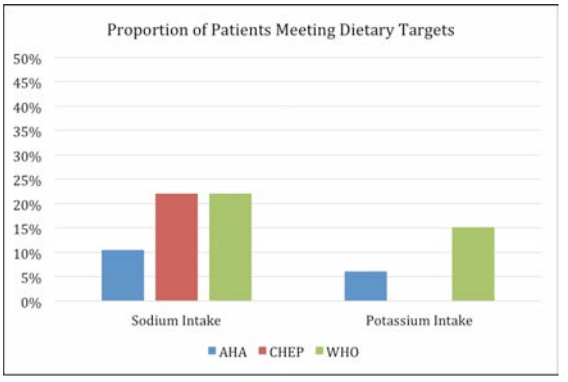
Dietary Sodium and Potassium Intake in a Referred Population with Difficult to Control Hypertension

Simon D.G. Parlow,[1] Swapnil Hiremath,[1,2] Marcel Ruzicka.[1,2] *[1]Medicine, Univ of Ottawa, Ottawa, ON, Canada; [2]Nephrology, Univ of Ottawa, Ottawa, ON, Canada.*

Background: High sodium intake and low potassium intake in the diet are important risk factors for the development and persistence of hypertension. NHANES and Health Canada data report higher than recommended consumption of sodium in the general population, but little data exists examining sodium intake in referred patients with difficult to control hypertension (DCHT). In this chart review, we report the dietary sodium and potassium intake in such a population.

Methods: This retrospective observational study included patients over 18 years of age referred to The Ottawa Hospital Renal Hypertension Clinic for management of DCHT. Patients were included if they had a documented 24 hour urinary electrolyte measurement, which was used to estimate daily sodium and potassium intake. We used current guidelines from American Heart Association (AHA, <65 mmol/day Na, >120 mmol/day K), Canadian Hypertension Education Program (CHEP, <87 mmol/day Na), and World Health Organization (WHO, <87 mmol/day Na; >90mmol/day K) for dietary goals.

Results: Of the 556 patients screened for inclusion, 95 (17.1%) had a 24 hour urinary sodium documented, with a mean intake of 142 mmol/day. 10 patients (10.5%) met the AHA target and 21 patients (22.1%) met the CHEP and WHO target for sodium intake. 33 patients had a 24 hour urinary potassium documented, with a mean of 60.7 mmol/day. 2 patients (6.1%) met the AHA target while 5 patients (15.2%) met the WHO target for potassium intake.



Conclusions: Even in a referred population of patients with DCHT, the dietary sodium intake is at an acceptable threshold for only a minority of patients, with the dietary potassium intake being acceptable for an even smaller proportion. While this may represent a selection bias, where poor intake results in higher blood pressure, it does represent a promising opportunity for intervention.

SA-PO699

Hypotension and Vasopressor Use during Elective Surgery in Patients Advised to Continue Angiotensin Converting Enzyme Inhibitor or Angiotensin Receptor Blocker Medications on the Day of Surgery

Katherine Mikovna Scovner,[1] Nicole M. Benson,[2] Alexander F. Friend,[3] Emily Stebbins.[3] *[1]Internal Medicine, Brown Univ, Providence, RI; [2]McLean Hospital Psychiatry, Massachusetts General Hospital, Boston, MA; [3]Anesthesiology, Univ of Vermont Medical Center, Burlington, VT.*

Background: Continued use of angiotensin converting enzyme inhibitors (ACE-I) and angiotensin receptor blockers (ARB) on the day of surgery is associated with intraoperative hypotension requiring vasopressor therapy. Here we assess the efficacy of the recommendation to hold ACE-I/ARB medications in preventing intraoperative hypotension. We hypothesized that the recommendation to continue as well as the patient's report of having taken an ACE-I/ARB medication on the day of surgery would be associated with increased intraoperative hypotension and vasopressor use.

Methods: We retrospectively studied 629 patients aged 50-75 on ACE-I/ARB therapy undergoing elective surgery with general anesthesia. Independent variables were (a) whether the patient was *advised* to hold or continue their ACE-I/ARB medication and (b) whether the patient *reported* having taken an ACE-I/ARB medication on the day of surgery. We also assessed invasiveness of surgery. Outcomes included (a) intraoperative vasopressor use and (b) lowest systolic blood pressure (SBP) during surgery.

Results: The advice to hold ACE-I/ARB was associated with intraoperative severe hypotension (SBP <65) (OR: 0.0977; CI: 0.043 – 0.221). A patient's report of taking an ACE-I/ARB was associated with vasopressor use (OR:1.663; CI: 1.183 – 2.340) and moderate hypotension (SBP <85) (OR: 1.5; CI: 1.069 to 2.105). Both vasopressor use and intraoperative hypotension were associated with surgery invasiveness (P<0.001).

Conclusions: Severe hypotension is associated with the recommendation to hold ACE-I/ARB therapy; however, a patient's report of having held the treatment was not. As hypotension correlated to surgery invasiveness, we postulate that the recommendation to hold the medications was most commonly made to patients planned for invasive surgery and thus at higher risk for hypotension; this recommendation, however, was unable to prevent it.

SA-PO700

Neurocognitive Function in Children with Primary Hypertension

Marc Lande,[1] Donald Lee Batisky,[2] Juan C. Kupferman,[3] Joshua A. Samuels,[4] Stephen R. Hooper,[5] Bonita E. Falkner,[6] Shari R. Waldstein,[7] Peter G. Szilagyi,[8] Hongyue Wang,[1] Jennifer Staskiewicz,[1] Heather Adams.[1] *[1]Univ of Rochester; [2]Emory Univ; [3]Maimonides Medical Center; [4]Univ of Texas at Houston; [5]Univ of North Carolina; [6]Thomas Jefferson Univ; [7]Univ of Maryland, Baltimore County; [8]Univ of Califonia at Los Angeles.*

Background: While young hypertensive adults have lower neurocognitive test (NT) performance compared with normotensive controls, data on neurocognition in pediatric primary hypertension (HTN) are limited. Our objective was to compare NT performance of children with primary HTN to that of normotensive controls. We also explored potential interactions of HTN with disordered sleep, a highly comorbid condition.

Methods: 75 children (10–18 y) with newly diagnosed, untreated HTN and 75 frequency matched normotensive controls had baseline NT for a prospective multicenter study of cognition in primary HTN. Subjects completed tests of general intelligence, attention, memory, executive function, and processing speed. In addition to medical and demographic variables, parents completed the Pediatric Sleep Questionnaire (PSQ).

Results: By design, the HTN and control groups did not differ significantly in sex, maternal education, or obesity. They were also found to be similar in age, income, race, ethnicity, anxiety, depression, cholesterol, glucose, insulin, and C-reactive protein.

HTN subjects had higher PSQ scores (p=0.04). In multivariate analyses, HTN was independently associated with worse performance on the Rey Auditory Verbal Learning Test (p=0.012), CogState Groton Maze Learning Test delayed recall (p=0.002), Grooved Pegboard (p=0.045), and Wechsler Abbreviated Scales of Intelligence Vocabulary (p=0.016). Results also indicated a significant interaction between PSQ score and HTN (p=0.04), such that HTN heightened the association between increased disordered sleep and worse executive function in the HTN group.

Conclusions: Youth with primary HTN demonstrated significantly lower NT performance compared with normotensive controls, particularly on measures of memory, attention, and executive functions. Further study is needed to determine if these performance differences will reverse with antihypertensive therapy.

Extracellular Water Is an Independent Determinant of Uncontrolled and Resistant Hypertension in CKD: The Nephrotest Cohort Study

Emmanuelle Vidal-Petiot,[1,2] Marie Metzger,[3] Jean-Jacques Boffa,[4] Jean-Philippe Haymann,[4] Eric Thervet,[5] Pascal Houillier,[5] Benedicte Stengel,[3] Francois Vrtovsnik,[1,2] Martin Flamant.[1,2] *[1]Pysiology and Nephrology, Bichat Hospital, APHP, Paris, France; [2]Paris Diderot Univ, Sorbonne Paris Cité, Paris, France; [3]Inserm U1018, Villejuif, Paris, France; [4]Physiology and Nephrology, Tenon Hospital, APHP, Paris, France; [5]Physiology and Nephrology, HEGP, APHP, Paris, France.*

Background: Hypertension is highly prevalent during chronic kidney disease (CKD) and in turn worsens CKD prognosis. We aimed to describe the determinants of uncontrolled and resistant hypertension, including extracellular water (ECW) during CKD.

Methods: We analysed baseline data from the Nephrotest cohort study. Patients with CKD stage 1 to 5 underwent thorough renal exploration including measurements of GFR (clearance of ^{51}CrEDTA) and of extracellular water (ECW, volume of distribution of the tracer). Hypertension was defined as blood pressure (BP, average of three office measurements) above 140/90 mmHg or the use of antihypertensive drugs. Resistant hypertension was defined as uncontrolled BP (>140/90) despite 3 drugs including a diuretic or the use of 4 or more drugs, regardless of BP level.

Results: In 2015 patients (mean age 59±15 years, 67% male, mean GFR 42±15 mL/min/1.73m²), prevalence of hypertension was 88.4%. In hypertensive patients, the mean number of treatments was 2.7±1.4, and prevalences of uncontrolled and resistant hypertension were 44.1 and 32.4%, respectively. In multivariable analysis, older age, higher albuminuria, diabetic nephropathy and the absence of aldosterone blockers were independently associated with uncontrolled BP. Older age, lower GFR, higher albuminuria, and BMI, African origin, diabetes and diabetic and glomerular nephropathies were associated with resistant hypertension. In addition, ECW was independently associated with both uncontrolled BP [OR for 1L increase, 1.06, 95% confidence interval (CI) 1.02-1.11] and resistant hypertension [OR 1.08, 95% CI 1.03-1.14].

Conclusions: A lower GFR is associated with hypertension severity but not with BP control. ECW is an independent determinant of both resistant and uncontrolled hypertension during CKD, which advocates for the large use of diuretics in this population.

SA-PO702

Plasma Peptidomics Based Multivariable Model for Identification of Mediators Involved in Hypertension

Joachim Jankowski, Vera Jankowski. *Inst for Molecular Cardiovascular Research, Univ Hospital RWTH Aachen, Aachen, Germany.*

Background: Hypertension is a major risk factor for cardiovascular disease and is also a risk factor for other end-organ diseases. Despite of advancements in lowering blood pressure, the best approach to lower it, remains controversial due to the lack of information on its development. We therefore, performed plasma proteomics to identify the markers discriminating hypertensive from normotensives.

Methods: Plasma samples from hypertensive and normotensive subjects were used for the study. We performed LC-MS/MS analyses of the plasma samples. Hypertension specific plasma peptides were identified and a model was developed using least absolute shrinkage and selection operator logistic regression. The underlying peptides were identified and to get an insight in to the mechanisms, pathway analysis was performed.

Results: By comparison of plasma samples, 27 biomarkers were identified discriminating hypertensives from normotensives. 70% of the features selected were found to occur less likely in hypertensive patients. A cross-validated predictor model was developed with the overall R square of 0.434 and the area under the ROC curve was 0.891 with 95% confidence interval 0.8482 to 0.9349, P<0.0001. The mean value of the cross-validated predictor score of normotensive and hypertensive patients was found to be -2.007 ± 0.3568 and 3.383 ± 0.2643, respectively. Phosphtidylinositol 3 kinase regulatory, humanin, anoctamin 10, NIK related protein kinase, Mannose-6- phospho isomerase, tryptophan, erythrocyte membrane glycopeptide, transcription factor Dp-2, pleckstrin homology domain-containing family O member 1, cardiac phospholamban, osteocalcin or sarcolipin, ras-related protein Rab-13, protein prune homolog, nexilin and palladin were the identified peptides. The pathway analysis revealed that these proteins had mostly cardiac related functions.

Conclusions: Plasma proteomics model was able to predict the hypertensive-normotensive status based on 27 molecular features. After validation in other cohorts for reproducibility, the identified markers may be useful to clarify the causes of hypertension and to predict the development of hypertension and hence of cardiovascular events.

SA-PO703

The Long Term Prognosis of IgA Nephropathy with Malignant Nephrosclerosis Patients

Jiaxin Lang, Xiaoxiao Shi, Peng Xia, Yubing Wen, Xuemei Li, Xuewang Li, Limeng Chen. *Nephrology Dept, Peking Union Medical College Hospital, Beijing, China.*

Background: This study is aimed to investigate the correlation between clinicopathological characteristics and long term prognosis of IgA nephropathy with malignant nephrosclerosis patients (IgAN-MHN) and essential malignant nephrosclerosis (EMHN).

Methods: This is a retrospective cohort study of 34 IgA-MHN patients and 82 EMHN patients confirmed by renal biopsy in Peking Union Medical College Hospital (PUMCH). IHC staining of CD34 and CD68 were used to evaluate the area of peritubular capillaries (PTC) and macrophage infiltration respectively. The primary end point were defined as renal replacement therapy, kidney transplant as well as death. Kaplan-Meier analysis and Cox regression was used to detect factors related to prognosis.

Results: Among 1765 cases of IgA nephropathy from 2003 to 2012, there were 550 patients (31.2%) with hypertension and 34 patients (1.9%) with MHT. Compared with EMHN patients, the IgAN-MHN patiens were younger (31.6±8.6 vs 35.7±8.5, *P*=0.042), and less rate of males (71% vs 92% male, *P*=0.008) with lower blood pressure (211.4±28.8/142±20.5 vs 224.2±25.8/149.8±23.6, *P=0.038 or 0.15*). IgAN-MHN patients showed higher urinary proteins (3.69±3.55 vs 2.00±1.33, P= 0.006) and lower serum albumin (39.45±4.24, 34.66±5.24, P<0.001) and serum creatinine (Scr) levels than EMHN patients(410.80±237.07 vs 311.86±177.30, P=0.042).The PTC proportion was decreased in both IgAN-MHN and EMHN patients compared with the glomerular minor lesion group, which correlated well with eGFR. After 5ys follow up,no significant difference of kidney survival rate was observed between IgAN-MHT and EMHT groups (59% vs 63%, p>0.05). Except PTC injury and CD68 staining, the eGFR at biopsy and the poor controlled blood pressure were risk factors of the ESRD.

Conclusions: PTC injury correlated well with eGFR of MHN patients. No significant difference of long term kidney survival was observed between IgAN-MHN and EMHN patients.

SA-PO704

Assessing the Validity of the OMRON HEM-907XL Oscillometric Blood Pressure Measurement Device in Non-Hemodialysis Chronic Kidney Disease Patients

Tiffany Wong, Jordana B. Cohen, Raymond R. Townsend. *Renal, Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

Background: An integral component of chronic kidney disease (CKD) care is the management of hypertension, requiring accurate blood pressure measurement. Automated blood pressure devices that use oscillometry to determine blood pressure (BP) are commonly employed in BP measurement, but operate on the assumption that oscillometric signals are similar between patients with and without co-morbidities like CKD. The OMRON HEM-907XL is a commercial device that measures BP oscillometrically and was the device used in SPRINT, in which 28% of participants had chronic kidney disease. This device has been validated in the general population, but not in patients with non-dialytic CKD. The objective of this study was to validate the accuracy of the OMRON HEM-907XL in non-dialytic CKD patients.

Methods: Patients were recruited from SPRINT and CRIC trial follow-up visits as well as the nephrology clinic at the University of Pennsylvania. 87 patients met inclusion criteria, defined as estimated glomerular filtration rate <60 mL/min/1.73m² or the presence of albuminuria. The measurement protocol was developed according to the Association for the Advancement of Medical Instrumentation guidelines for validation of blood pressure devices, with one observer recording measurements from the OMRON device and two clinicians obtaining simultaneous aneroid values.

Results: There was a 5 mmHg (+/- 7.5) difference in mean systolic blood pressure between the OMRON and aneroid values, and a 0.3 mmHg (+/-5.3) difference in mean diastolic blood pressure, which met criteria for validation based on the Association for the Advancement of Medical Instrumentation guidelines.

Conclusions: In conclusion, the OMRON HEM-907XL oscillometric blood pressure device provides consistent readings in comparison to aneroid measurements, and appears valid for use in patients with chronic kidney disease.

Effects of Blood Pressure Control in Uncomplicated Grade 1 Hypertension

Xianhui Qin,[1] Youbao Li,[1] Binyan Wang,[1] Yong Huo,[2] Genfu Tang,[3] Mingli He,[4] Delu Yin,[4] Xiping Xu,[1] Xin Xu,[1] Fan Fan Hou.[1] *[1]Nanfang Hospital, Southern Medical Univ; National Clinical Research Center for Kidney Disease; [2]Peking Univ First Hospital; [3]Anhui Medical Univ; [4]First People's Hospital, Lianyungang.*

Background: Effects of blood pressure(BP) control(<140/90mmHg) in patients with grade 1 hypertension are unclear. We aimed to examine the effect of BP control in prevention of cardiovascular events and deaths in patients with grade 1 hypertension in the China Stroke Primary Prevention Trial(CSPPT).

Methods: A total of 3187 patients, with a median antihypertensive treatment duration of 4.6 years, were divided into subgroups according to (1)the percentage of on-treatment visits in which BP was controlled(<140/90mmHg); or (2) the time-averaged mean SBP/DBP levels achieved throughout the treatment period or up to the occurrence of an event.

Results: Compared with those with BP control <25% of the on-treatment visits(3.7%), the incidence of first stroke decreased progressively as the percentage of BP control increased(25-<50%, 1.8%; HR,0.47;95%CI:0.21-1.07; 50-<75%, 1.3%; 0.34;0.16-0.73; ≥75%, 1.3%;0.36;0.16-0.83; P for trend=0.019).

Proportion of visits with BP control	Outcome, No(%)	HR(95%CI)	Adjusted HR(95%CI)
First stroke			
<25%	11(3.7)	ref	ref
25-<50%	13(1.8)	0.46(0.20-1.02)	0.47(0.21-1.07)
50-<75%	16(1.3)	0.32(0.15-0.69)	0.34(0.16-0.73)
≥75%	12(1.3)	0.33(0.15-0.76)	0.34(0.16-0.73)
P for trend		0.010	0.019

Consistently, compared with patients with time-averaged SBP≥140 or DBP≥90mmHg, the risk of first stroke was reduced in patients with SBP<140mmHg(1.1% vs 2.9%; 0.40;0.22-0.70) or DBP<90mmHg(1.5% vs 2.7%; 0.42;0.18-1.02). Similar results were observed for the composite cardiovascular events and all-cause death. The beneficial results were consistent across the age(<60 vs ≥60years), sex, baseline SBP(<150 vs ≥150mmHg) and hypertension subtypes(isolated systolic hypertension or systolic-diastolic hypertension). Furthermore, only 1.5% of the patients discontinued the treatments due to adverse events.

Conclusions: The control of BP(<140/90mmHg) had significant beneficial effects on stroke and all-cause death in patients with grade 1 hypertension.

Nocturnal Blood Pressure Variability Is Associated with Renal Arteriolar Hyalinosis Suffering from IgA Nephropathy

Shinsuke Isobe,[1] Naro Ohashi,[1] Sayaka Ishigaki,[1] Takayuki Tsuji,[1] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Abnormal blood pressure (BP) variability (BPV) occurring on beat-to-beat, within 24-hour and day-to-day is related to target organ damage. However, the association between abnormal BPV and renal structural damages has not been clearly investigated.

Methods: We investigated the 24-hour, daytime and nighttime BP standard deviations (SDs) which reflect very short-term BPV, nighttime to daytime (N/D) ratio of SBP and 7-day BPV in 27 IgA nephropathy patients (age 41.7 ± 15.2 years, 9 men and 18 women, estimated glomerular filtration rate (eGFR) 69.2 ± 17.2 ml/min/1.73m^2, urinary protein excretion (UP) 0.64 ± 0.46 g/gCr). Renal biopsy tissues were scored as follows: the levels of arteriolar hyalinosis; the proportion of arterioles affected (0: absent, 1: 1-25%, 2: 26-50%, 3: 51-100%), the levels of arteriosclerosis in arcuate and interlobular arteries (0: normal, 1: intima thickness and less than media thickness, 2: intima thickness and more than media thickness), and percentages of global sclerosis (GS) and tubulointerstitial fibrosis.

Results: The levels of arteriolar hyalinosis were positively correlated with age, body mass index (BMI), 24-hour SBP, SBP, DBP and SD of SBP in nighttime, N/D ratio of SBP and SBP in 7-day and were negatively correlated with eGFR. The levels of arteriosclerosis were positively correlated with age, UP, N/D ratio of SBP and SD of SBP in nighttime and negatively correlated with eGFR. Percentages of GS and tubulointerstitial fibrosis were not correlated with BP parameters. Multiple liner regression analysis revealed that the levels of not arteriosclerosis but arteriolar hyalinosis were associated with SD of SBP in nighttime, when age, sex, BMI, eGFR and SBP in nighttime were adjusted (b= 0.441, p= 0.008). No significant correlations were found between the levels of arteriolar hyalinosis and N/D ratio of SBP or SD of SBP in 7-day after multiple liner regression analysis.

Conclusions: In IgA nephropathy patients, short term BPV in nighttime was associated with arteriolar hyalinosis.

SA-PO707

Complement in Renal Disease-Potential Effect during Pathogenesis of Hypertension?

Christoph Daniel,[1] Kerstin Benz,[2] Maike Julia Buettner,[1] Kerstin U. Amann,[1] Laura Alina Röscher,[1] Lisa Schmidtgen.[1] *[1]Nephropathology, FAU Erlangen-Nürnberg, Erlangen, Germany; [2]Pediatric Nephrology, FAU Erlangen-Nürnberg, Erlangen, Germany.*

Background: Complement deposition is frequently observed in kidney biopsies of patients with hypertensive renal disease, but an association of hypertension and complement deposition or involvement of complement in the pathogenesis of hypertensive nephropathy has not been investigated.

Methods: In this retrospective study archival human renal biopsies from 230 patients with known hypertension and 80 control patients with non-hypertensive renal diseases were investigated using immunohistochemistry and semi-quantitative scores and the results were correlated with renal function. To address whether complement was only passively deposited on or also actively expressed by renal cells, complement deposition as well as C1 and C3 mRNA expression was analyzed in a rat model of hypertension i.e. the 5/6-nephrectomy rat (n=12) and controls (n=10).

Results: Glomerular C1q and C3c complement deposition was significantly higher in hypertensive patients and rats than in non-hypertensive controls. Mean arterial blood pressure in 5/6-nephrectomy rats correlated well with the amount of C1q (r=0.790; p<0.0001) and C3c deposition (r=0,697; p<0.0003) and also with left ventricular weight (C1q: r=0.819; C3c: r=0.621; both p<0.002). C3 were not only deposited but also actively produced by renal cells of hypertensive rats as assessed by quantitative mRNA analysis. Of note, in hypertensive patients renal function as measured by creatinine clearance correlated significantly negative with the intensity of C1q staining (r=-0.322; p=0.001), but not with that of C3c.

Conclusions: Hypertensive nephropathy, but not other non-hypertensive renal diseases, was significantly associated with in-situ expression and deposition of complement. Since complement activation is known to have multiple disease promoting effects further investigations are needed to identify whether it is involved in the pathogenesis or progression of hypertensive nephropathy.

SA-PO708

Preeclampsia and Severe Proteinuria during Pregnancy and Postpartum Follow-Up: Results from a High Risk Center in Brazil

Jose Paulo Siqueira Guida,[1] Marcos Vinicius Sousa,[2] Marilda Mazzali,[2] Maria Laura Costa.[1] *[1]Dept of Gynecology and Obstetrics, State Univ of Campinas, Campinas, Sao Paulo, Brazil; [2]Dept of Nephrology, State Univ of Campinas, Campinas, Sao Paulo, Brazil.*

Background: Preeclampsia (PE) is a disease of pregnancy and puerperium and a leading cause of morbidity and mortality worldwide. Women with PE must be followed after delivery to evaluate long term complications as cardiovascular and renal diseases. The kidney injury may remain after delivery and the long term consequences of massive proteinuria are still unclear.

Methods: Retrospective cohort of pregnant women with proteinuria≥2g/24h followed at UNICAMP from January 2009 to December 2013. Exclusion criteria: previous nephropathy, delivery in other center or absence of PE diagnosis. Data on demographic characteristics, laboratory findings, maternal and fetal/neonatal outcomes were recorded and analyzed with Epi-Info 7.

Results: 254 women screened and 196 met the criteria for review. Of those, 32 had normal proteinuria (during pregnancy <0.3g/24h) prior to the onset of PE and were further studied. The mean age was 31±6.1 years, majority white (72%) and more than a half were multiparous. The mean proteinuria first evaluated during pregnancy (gestational age 25 weeks±7.7) was 0.16g/24h (±0.07) and after onset of PE, which happened around 33 weeks (±4.1), it rose to 3.7g/24h(±2) and 81% had severe PE. Gestational age at delivery was 33(±4.1) and 75% delivered by cesarean. Less than half showed up for a postpartum visit and only 12 women had quantification of proteinuria after delivery and among those, 4 had normal proteinuria (<0.15g/24h), while 8 remained proteinuric (1,3±1.7g/24h). None had further then 3 months follow-up.

Conclusions: PE is a severe disease with impact in outcomes during pregnancy and childbirth but also with possible long term consequences. Women who develop massive proteinuria during pregnancy may remain proteinuric, and a few may develop chronic disease and must be diagnosed and referred. An accurate long term follow-up of those women is mandatory. Future studies must address follow-up of those women after puerperium, onset of other hypertension-related diseases and impact in future pregnancies.

Funding: Government Support - Non-U.S.

SA-PO709

Changes of Blood Pressure Patterns and Target Organ Damage in Patients with Chronic Kidney Disease: Results of the APrODiTe-2 Study

Ran-Hui Cha,[1] Hajeong Lee,[2] Jung Pyo Lee,[3] Eunjeong Kang,[2] Yon Su Kim,[2] Sung Gyun Kim.[4] *[1]Internal Medicine, National Medical Center; [2]Internal Medicine, Seoul National Univ College of Medicine; [3]Internal Medicine, Seoul National Univ Boramae Medical Center; [4]Internal Medicine, Hallym Univ Sacred heart Hospital.*

Background: Blood pressure (BP) control is the most established practice for preventing the progression of chronic kidney disease (CKD). We examined the BP control and nocturnal dipping pattern changes in hypertensive patients with CKD and their effects on target organ damages.

Methods: We recruited 378 hypertensive CKD patients from 4 centers in Korea. The patients underwent clinic and ambulatory BP monitoring at the time of enrollment and 1 year later. High clinic and ambulatory BP were defined as > 140/90 mmHg and > 135/85 mmHg (daytime)/ > 120/70 mmHg (nighttime), respectively.

Results: The BP control states at the 2 time points were as follows: true controlled (16.5, 17.5%), white-coat (2.9, 0.4%), masked (50.0, 53.3%), and sustained uncontrolled (30.6, 28.8%) hypertension. The dipping states at 2 time points were as follows: extreme-dipping (11.4, 10.8%), dipping (22.2, 20.5%), non-dipping (31.3, 34.7%), and reverse-dipping (35.0, 34.0%). Better changes (to true controlled and white-coat) of BP control status were associated with initially lower levels of serum uric acid, urea nitrogen, and proteinuria and higher estimated GFR (eGFR). When we divided the patients according to the median eGFR and proteinuria changes, more stable changes in eGFR and proteinuria were associated with better initial and follow-up BP control statuses. Moreover, better BP control and dipping (to dipper) changes were also associated with more stable eGFR and proteinuria changes. Good initial and follow-up BP control statuses were associated with less LVH. And masked and sustained uncontrolled hypertension was associated with more cardio-cerebrovascular events in the univariate analysis.

Conclusions: A large majority of Korean hypertensive CKD patients had uncontrolled BP and abnormal dipping patterns. Furthermore, better BP control and dipping status changes were associated with better renal function and proteinuria as well as less cardio-cerebrovascular damages.

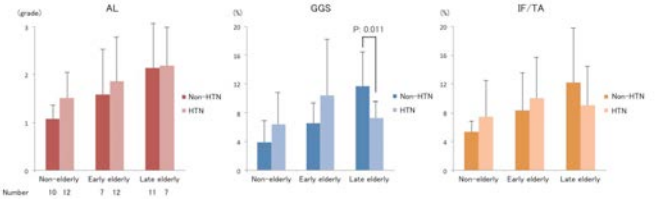
SA-PO710

Aging vs. Hypertension: An Autopsy Study of Sclerotic Renal Histopathologic Lesions in Non-CKD Adults Yusuke Okabayashi, Nobuo Tsuboi, Go Kanzaki, Takaya Sasaki, Kotaro Haruhara, Kentaro Koike, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Both renal ischemic arteriosclerosis and arterial hyperperfusion co-exist in elderly hypertensive patients. Thus, the two conflicting purposes of renal tissue perfusion maintenance and reduction of pressure overload have to be achieved for renal protection in such patients. In this study, we aimed to clarify the impacts of aging and/or hypertension in the development of sclerotic renal lesions in non-CKD adults.

Methods: Fifty-nine Japanese non-CKD autopsies, with or without hypertension, were analyzed to compare the clinicopathologic features among age groups. Arteriosclerotic lesions (AL), interstitial fibrosis/tubular atrophy (IF/TA), global glomerulosclerosis (GGS), and the mean glomerular volume (GV) were evaluated in both juxtamedullary and superficial cortexes (about 50 glomeruli for each).

Results: The studied kidneys had an average age of 66 years and an average eGFR of 98 ml/min/1.73 m^2; 47% had hypertension. In the non-elderly group (<65 years) and early elderly group (65–74 years), the degree of IF/TA and GGS in hypertensives were higher than those of normotensives. In the late elderly group (>75 years), the degree of GGS was significantly lower in hypertensives than those in normotensives.



Multivariate analysis revealed that age but not hypertension was identified as an independent factor that associated with AL, GGS, and IF/TA. In contrast, hypertension was a factor independently associated with GV.

Conclusions: In non-CKD adults, it is likely that normal aging plays a major role in the development of sclerotic renal histopathologic lesions. In contrast, hypertension may be protective against these lesions in the very elderly.

SA-PO711

Comparison of Salt Taste Thresholds and Salt Usage Behaviors between Adults in Myanmar and Korea Jae Wan Jeon, Soon Bae Kim, Hyosang Kim. *Internal Medicine, Nephrology, Asan Medical Center, Seoul, Republic of Korea.*

Background: Excessive oral salt intake can induce hypertension. According to previous studies, the prevalence of hypertension is higher in Myanmar than in Korea. We postulated that Myanmar adults had higher salt taste thresholds and eat much saltier food. This study aimed to compare salt taste thresholds and salt usage behavior scores between adults in Myanmar and Korea.

Methods: This cross-sectional study enrolled patients who visited volunteer medical service clinics at Ansung in Korea and Hlegu and Bago in Myanmar in August 2014. We measured the vital signs, heights, and weights of each patient and evaluated detection thresholds, recognition thresholds, and salt preferences. All patients underwent urinalysis and spot urine Na tests. Additionally, they each completed a salt usage behavior questionnaire.

Results: A total of 131 patients were enrolled, including 64 Myanmarese patients and 67 Korean patients. Blood pressure was significantly higher in the Myanmarese than in the Koreans. Detection and recognition thresholds, salt preferences, and spot urine sodium and salt usage behavior scores were also higher in the Myanmarese than in the Korean subjects. We calculated correlation coefficients between systolic blood pressure and parameters that were related to salt intake. The detection and recognition thresholds were significantly correlated with systolic blood pressure.

Conclusions: All parameters related to salt intake, including detection and recognition thresholds, salt preference, salt usage behavior scores and spot urine sodium concentrations, are significantly higher in Myanmarese than in Korean individuals.

SA-PO712

Nationwide Multicenter Kidney Biopsy Study of Japanese Patients with Type 2 Diabetes Kengo Furuichi,[1] Yukio Yuzawa,[2] Yoshifumi Ubara,[3] Miho Shimizu,[1] Tadashi Toyama,[1] Yasunori Iwata,[1] Norihiko Sakai,[1] Takashi Wada.[1] *[1]Div of Nephrology, Kanazawa Univ, Kanazawaa, Japan; [2]Dept of Nephrology, Fujita Health Univ Hospital, Toyoake, Japan; [3]Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: The pathological manifestations of diabetic nephropathy in Type 2 diabetes are diverse. However, pathological study with large scale and long observation is very limited. In this nationwide multicenter, retrospective study, we demonstrated the impacts of pathological findings as predictors for kidney events in Japanese patients with Type 2 diabetes in detail.

Methods: Kidney biopsy was performed for and clinical data were collected of 600 patients with Type 2 diabetes from 13 centers across Japan. In this study, thirteen pathological findings were clearly defined and scored.

Results: The mean observation period was 72.4 months. Three hundred and four composite kidney events (dialysis, doubling of Cr or halving of eGFR), 31 kidney deaths, 76 cardiovascular events, and 73 deaths occurred during the observation period. One hundred three cases, 149, and 348 were in Green and Yellow, Orange, and Red categories of CKD heat map, respectively. Even in cases of Green and Yellow categories, diffuse lesion, polar vasculosis and subendotherial space widening were commonly detected (positive cases; diffuse lesion 81.6%, polar vasculosis 42.6%, subendotherial space widening 35.1%). Cox proportional hazards analysis revealed that presence of nodular lesion, exudative lesion, and mesangiolysis in cases of Green and Yellow categories in CKD heat map were significantly high impacts on composite kidney events after adjustment for clinical risk factors (HR, 95% CI; nodular lesion: 21.1 , 5.3 to 84.6, exudative lesion: 5.1, 1.3 to 20.3, mesangiolysis: 7.6, 2.0 to 28.8).

Following points were limitation of this study; only evaluated by light microscopy, retrospective study, limited to cases with kidney biopsies, no evaluation of the therapeutic interventions.

Conclusions: In summary, this nationwide kidney biopsy study of 600 cases with Type 2 diabetes revealed that pathological findings (presence of nodular lesion, exudative lesion, and mesangiolysis) were strong predictors of kidney events in low-risk CKD heat map patients.

Nodular Lesions in Diabetic Nephropathy: Collagen Staining and Renal Prognosis Koki Mise,[1,2] Toshiharu Ueno,[1] Junichi Hoshino,[1] Masayuki Yamanouchi,[1] Noriko Hayami,[1] Jun Wada,[2] Hirofumi Makino,[2] Kenmei Takaichi,[1] Yoshifumi Ubara.[1] *[1]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [2]Dept of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Nodular lesions are one of the most characteristic pathological changes of advanced diabetic nephropathy (DN). Previous studies have demonstrated that the pattern of both routine and collagen staining of nodular lesions changes during their development. However, the association between such changes of staining and the renal prognosis remains unclear.

Methods: Among 252 patients with biopsy-proven DN, 67 met the selection criteria and were enrolled to investigate this relationship. In all patients, staining of nodular lesions with periodic acid Schiff (PAS), periodic acid methenamine silver (PAM), Masson trichrome, and collagens I, III, IV, V, and VI was performed. The endpoint was commencement of dialysis due to end-stage renal disease. The Cox proportional hazard model was used to calculate the hazard ratio (HR) and 95% confidence interval (CI) for the death-censored endpoint.

Results: At least one mesangiolytic nodular lesion (MNL) that showed faint staining for PAS and PAM was found in 61% of the patients. Type IV collagen was decreased in these lesions, whereas type VI collagen was markedly increased, consistent with previous reports. In patients with at least one MNL, the HR for the endpoint was significantly higher than in patients without MNL after adjusting for known promoters of renal progression (HR: 2.94, [95% CI: 1.24-7.07]).

Conclusions: MNL may reflect characteristic changes of collagen and could be a useful prognostic indicator that should be assessed in patients with nodular lesions. Further investigation of the mechanism underlying this change could contribute to finding new therapeutic targets for DN.

Paratubular Basement Membrane Insudative Lesions Predict Renal Prognosis in Patients with Type 2 Diabetes and Biopsy-Proven Diabetic Nephropathy Koki Mise,[1,2] Yutaka Yamaguchi,[3] Junichi Hoshino,[1] Akinari Sekine,[1] Toshiharu Ueno,[1] Noriko Hayami,[1] Masayuki Yamanouchi,[1] Hitoshi Sugiyama,[2] Hirofumi Makino,[2] Jun Wada,[2] Kenmei Takaichi,[1] Yoshifumi Ubara.[1] *[1]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [2]Dept of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [3]Yamaguchi's Pathology Laboratory, Matsuo, Japan.*

Background: Glomerular insudative lesions are a pathological hallmark of diabetic nephropathy (DN). However, paratubular basement membrane insudative lesions (PTBMIL) have not attracted much attention, and the association between such lesions and the renal prognosis remains unclear.

Methods: Among 142 patients with biopsy-proven DN and type 2 diabetes encountered from 1998 to 2011, 136 patients were enrolled in this study. Patients were classified into 3 groups (Group 1: mild, Group 2: moderate, Group 3: severe) according to the extent of cortical and medullary PTBMIL. The endpoint was a decline of the estimated glomerular filtration rate (eGFR) by ≥ 40% from baseline or commencement of dialysis for end-stage renal disease. The Cox proportional hazard model was employed to calculate hazard ratios (HRs) and 95% confidence interval (CIs) for the death-censored endpoint.

Results: During a median follow-up period of 1.8 years (IQR: 0.9-3.5 years), the endpoint occurred in 104 patients. Baseline mean eGFR was 43.9 ± 22.8 ml/min/1.73 m^2, and 125 patients (92%) had overt proteinuria. After adjusting for known indicators of DN progression, the HR for the endpoint was 2.32 (95% CI: 1.20-4.51) in PTBMIL Group 2 and 3.12 (1.48-6.58) in PTBMIL Group 3 versus PTBMIL Group 1. Furthermore, adding the PTBMIL Group to a multivariate model including known promoters of DN progression improved prediction of the endpoint (c-index increased by 0.02 [95% CI: 0.00-0.04]).

Conclusions: PTBMIL may be useful for predicting the renal prognosis of patients with biopsy-proven DN, but further investigation of these lesions in various stages of DN is needed.

Interstitial Fibrosis and Tubular Atrophy Are Dominantly Associated with Progressive Renal Decline in Patients with Type 2 Diabetes and Biopsy Proven Diabetic Nephropathy Masayuki Yamanouchi,[1] Toshiharu Ueno,[1] Junichi Hoshino,[1] Koki Mise,[2] Yoshifumi Ubara,[1] Kenmei Takaichi.[1] *[1]Okinaka Memorial Inst for Medical Research, Tokyo, Japan; [2]Okayama Univ Graduate School of Medicine.*

Background: Which histological lesions (glomerular, tubulointerstitial, and/or arterial lesions) of diabetic nephropathy are dominantly associated with progressive renal decline is unknown.

Methods: 223 individuals with Type 2 diabetes and biopsy proven diabetic nephropathy were identified between 1985 and 2011 in the Toranomon Hospital (Tokyo, Japan). Histological classification was performed by two pathologists based on the Tervaert's Pathologic Classification of Diabetic Nephropathy. The rate of eGFR loss in these patients was determined by serial measurements of eGFRcre using linear regression model. The primary outcome was to become a decliner who has an eGFR rate loss >= 3.3 mL/min/year. Clinical data as well as laboratory data such as HbA1c, eGFR, and urinary protein were collected at the date of renal biopsy.

Results: The median follow up, after excluding the first one-year observation period, was 4.3 years. The majority of individuals have a linear eGFR trajectory and 124 decliners were identified among them. With IFTA (interstitial fibrosis/tubular atrophy) score 1 as reference, Odds Ratios of IFTA score 2 and 3 were; 8.0 (95%CI, 3.4-18.9) and 5.4 (95%CI, 2.5-12.0) in unadjusted model; 6.2 (95%CI, 2.5-15.6) and 5.2 (95%CI, 2.2-12.5) in the model adjusted for clinical variables (age, sex, duration of diabetes, and BMI); and 4.7 (95%CI, 1.3-17.0) and 9.6 (95%CI, 1.7-53.9) in the model adjusted for clinical variables plus baseline HbA1c, eGFR, and urinary protein levels with other histologic lesions. Though other histologic lesions including glomerular lesions reveal significant in unadjusted analysis, none of them remain significant in adjusted analysis.

Conclusions: Although glomerular lesion is important for diagnosis of diabetic nephropathy, our finding suggests that interstitial fibrosis/tubular atrophy may be more strongly associated with progressive renal decline than other histological lesions.

SA-PO716

Polar Vasculosis Is Early Morphological Change in Diabetes Noriko Uesugi,[1] Kengo Furuichi,[2] Michio Nagata,[1] Takashi Wada.[2] *[1]Renal Vascular Pathology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: Aggregation of neovascular arterioles with hyalinosis around glomerular poles (porlar vasulosis (PV)) is hallmark of advanced diabetic nephropathy(DN) and is usually associated with prominent afferent arteriolar (AA) hyalinosis, but can be seen in very early stage of DN. PV might occur in diabetes (DM) with no DN and no prominent AA hyalinosis. To clarify this, we analyzed paraffin embedded human surgical kidney specimen of non-tumor parts of renal carcinoma.

Methods: We analyzed PAS, PAM, MT, EVG, HE staining sections from 22 Japanese cases including 12 DM with no urinary abnormalities (65y.o, S-Cre 1.0 mg/dl) and 10 control without hypertension or renal disease(64y.o, S-Cre 0.8 mg/dl) and investigated frequency of PV, % hyalinosis of AA and % of glomerular global sclerosis(GS). Origin of PV was determined by serial sections double stained by endothelial marker, CD34, and vascular medial marker SMA, followed by PAS staining.

Results: No definite glomerular abnormalities was observed in all except two DM cases. The two showed mildly expanded mesangial area with a few small nodules. Average 548(380-750) and 551(390-824) glomeruli were analyzed in control and DM,respectively. Percentage of GS and hyalinosis of AA showed no difference in control (10±8, 25±20,respectively) and in DM (11±7, 30±25, respectively). PV was found in all DM cases (1-52/specimen), but not in control. PV was observed in glomeruli with no or mild AA hyalinosis and was frequently seen in cases with glomerular change and severe arteriosclerosis. Serial immunostained sections confirm the PV was originated from efferent arteriole.

Conclusions: PV is representative early damage of glomerular microcirculation in DM before overt diabetic nephropathy clinically.

SA-PO717

Diffuse and Intense Glomerular C4d Staining Reflects Endothelial Injury in Diabetic Nephropathy Shigeo Hara,[1] Shinichi Nishi.[2] *[1]Dept of Diagnostic Pathology, Kobe Univ, Kobe, Hyogo, Japan; [2]Dept of Nephrology, Kobe Univ, Kobe, Hyogo, Japan.*

Background: Endothelial injury plays a critical role in the disease progression in diabetic nephropathy (DN). Recent study has reported C4d as a common denominator in thrombotic microangiopathy (JASN 2015). The aim of the present study was to examine the utility of C4d as an indicator of endothelial damage in DN.

Methods: The study consists of 12 cases of histologically-proven diabetic nephropathy without concurrent glomerulonephritis and tubulointerstitial nephritis. According to the glomerular C4d staining on frozen section, the cohort was divided into two groups with intense (Group I; n = 9) or weak (Group W; n = 3) C4d staining. Clinical and pathological characteristics were examined between both groups.

Results: Group I was clinically characterized by more severe level of proteinuria compared to Group W (6.85 g/gCr vs. 0.32 g/gCr, $p < 0.01$), whereas serum creatinine levels, eGFR and HbA1c levels at the time of biopsy were not significant. Pathologically, all but one case in Group I showed nodular lesion corresponding to class III, whereas two cases and one case in Group W were assigned class IIa or IIb, respectively. Exudative lesions including capsular drop and subepithelial widening of renal tubules were noted in the four cases in group I. In Group W, however, only capsular drop was found in one case. The degree of interstitial fibrosis, tubular atrophy, arteriosclerosis and arteriolar hyalinosis were comparable between both groups. C4d staining in Group I was almost confined to the glomeruli without diffuse positivity in peritubular capillaries. In addition to linear IgG staining, IgM were positive in 5 cases of Group I, but none of Group W. In Group I, electron microscopy revealed marked subendothelial widening which was not observed in Group W.

Conclusions: C4d staining can be a reliable ancillary test to designate glomerular endothelial damage in DN.

Differential Diagnostic Models of Diabetic Nephropathy and Non-Diabetic Renal Diseases Meijun Si, Zengchun Ye, Wenbo Zhao, Xun Liu. *Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Non-diabetic renal diseases(NDRD) could be detected among patients with type 2 diabetes mellitus(T2DM) and chronic kidney disease(CKD).The treatment and prognosis of NDRD is different from diabetic nephropathy(DN), which makes the differential diagnosis of great importance. We aim to build up diagnostic models for differentiating NDRD from DN.

Methods: Patients with T2DM and CKD who had performed renal biopsies between 2004 and 2013 were enrolled.Renal pathology was regarded as the gold standard for the diagnosis of DN and NDRD. A logistic regression model was built by multiple regression analysis while artificial neural network (ANN) models were constructed by MATLAB 2011A software.

Results: Among the103 patients enrolled,49 had DN while 54 had NDRD. 36 multicenter subjects with T2DM and CKD were applied as the external validation. Through univariate and multivariate regression analysis, four significant factors : diabetic retinopathy(DR), diabetes duration, hemoglobin(Hb) and urinary protein(Upro) were included in logistic regression model: $P(DN) = \exp(3.682* DR+0.227Diabetes\ duration-0.043*Hb +0.207*Upro+0.350)/[1+ \exp(3.682* DR+0.227\ Diabetes\ duration\ -0.043*Hb +0.207*Upro+0.350)]$.We built up an artificial neural network based on the same four parameters.103 subjects were randomly divided into the training set (N=69) and the internal validation set (N=34). In the external validation, the optimized genetic algorithm GA-MLP-6-7-1 harvested preferably predictive effect(consistency 91.7%,sensitivity 91.0% and specificity 61.6%),which is significantly greater than the regression model (consistency 75.0%,sensitivity 55.0% and specificity 100.0%).The kappa test indicated that the reliability of the ANN GA-MLP-6-7-1 was greater than the logistic regression model($P<0.05$).

Conclusions: Both logistic regression model and artificial neural network could help with the clinical differentiation between DN and NDRD. ANN GA-MLP-6-7-1 based on DR, diabetes duration, Hb and Upro could differentiate NDRD from DN more efficiently than the regression model.

Evaluation of Renal Pathological Classification in Patients with Diabetic Nephropathy Meijun Si, Zengchun Ye, Wenbo Zhao, Xun Liu, Hui Peng, Tan-Qi Lou. *Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: In 2010,a pathological classification of diabetic nephropathy(DN) mainly based on mesangial expansion and Kimmelstiel–Wilson nodules was proposed by Professor Tervaert. We classified the biopsy specimen of patients with type 2 diabetic nephropathy according to Tervaert's classification to assess the relationship between pathological classification and prognosis.

Methods: We retrospectively analyzed the pathological features of patients diagnosed with DN between January 2004 and December 2013. Tervaert's classification was applied to the specimens. All patients enrolled were censored by telephone calls or out-patient clinic by the deadline on 31 December 2014. The end point was defined as doubling of serum creatinine or introduction of dialysis.We further conducted the survival analysis to evaluate the impact of pathological classification on the prognosis of DN.

Results: 49 Patients enrolled were divided into four categories of IIa(N=5), IIb(N=8), III(N=21) and IV(N=15) according to Tervaert's classification.The eGFR in III was significantly lower than II,while the serum albumin in II was significantly higher than III(all $P<0.05$). The proportion of glomerular and segmental sclerosis and the score of interstitial fibrosis and tubular atrophy(IFTA) was higher in III than II($P<0.05$). The longest diabetes duration, highest level of SBP, urinary protein and serum creatinine were detected in IV. The mesangial expansion is more severe in IV than II and III($P<0.05$). There was significant difference of prognosis among the four groups($P<0.05$). The cumulative survival rate for five years in IIa, IIb, III and IV was 100%, 85.7% ,32.5% and 26.7% respectively. II has a better prognosis than IV($P<0.05$).

Conclusions: Our results indicated that clinical and pathological findings and renal outcomes in four DN groups classified by Tervaert's classification were different. IV might suggest the terminal stage of DN while IIa presented with the mildest clinical leisions and better prognosis compared with IV, which was important for early diagnosis and treatment of DN. Terveart's pathological classification could help predict the prognosis of DN.

SA-PO720

Clinical Features and Prognosis of Patients with Type 2 Diabetes Melitus and Chronic Kidney Disease Meijun Si, Wenbo Zhao, Zengchun Ye. *Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: The renal pathology type in patients with type 2 diabetes mellitus and chronic kidney disease (CKD) could be diabetic nephropathy (DN), non-diabetic renal diseases (NDRD) and DN with NDRD. We aim to investigate the clinical characteristics and prognosis of type 2 diabetic patients with different types of renal pathology.

Methods: We conducted a retrospective investigation of type 2 diabetic patients with CKD who had performed renal biopsies between 2004 and 2013. According to the pathological diagnosis, patients were categorized into three groups: DN group, NDRD group and DN with NDRD group(MIX group). All patients were censored by telephone calls or out-patient clinic by the deadline on 31 December 2014. The end point was defined as doubling of serum creatinine or introduction of dialysis.

Results: Among 110 patients enrolled, 49(44.5%) patients had DN alone, 54(49.1%) patients had NDRD while 7(6.4%) patients had concurrent DN and NDRD. Compared with NDRD, DN patients had a longer diabetes duration and a higher diabetic retinopathy(DR) rate(all P<0.05).The prevalence of having both nephrotic range proteinuria and kidney function decrease (eGFR<60ml/min) was higher in DN than NDRD(P<0.05). The mean follow up time was 41 months. 25 patients reached the endpoint with 18 in DN,5 in NDRD and 2 in MIX group. The prognosis of NDRD is better than DN(P=0.013) and MIX group(P=0.037), while the 5 year renal survival rate of NDRD, DN and MIX group was 87% , 63% and 33% respectively. Among the clinical indicators, Multiple linear regression model indicated the independent risk factors for endpoint event were urinary protein(OR1.277,95%CI 1.102-1.479), hemoglobin(OR0.963,95% CI 0.940 -0.987) and serum creatinine(OR1.005,95%CI1.001 -1.009).

Conclusions: Our results indicated that type 2 diabetic patients with CKD had different pathologic features and clinical manifestations. The short duration of diabetes and the absence of DR were factors associated with NDRD. The poorest prognosis was observed in patients with concurrent DN and NDRD.

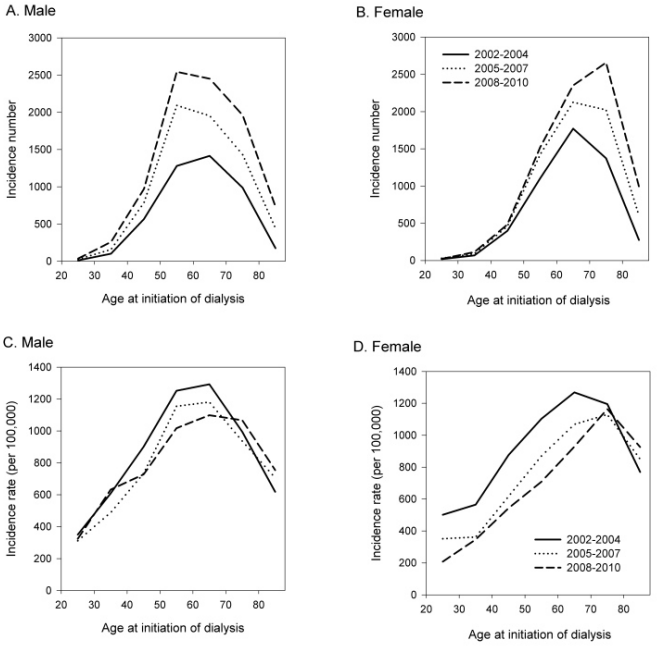
SA-PO721

Time Trends and Gender Differences in Incidence of Diabetes-Related Dialysis – A 2002-2010 Population-Based Study in Taiwan Jinn-Yang Chen,[1] Pei-Hung Chuang.[2] *[1]Div of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan; [2]Foundation for Poison Control, Taipei, Taiwan.*

Background: The prevalence of type 2 diabetes increases worldwide. Understanding burden of diabetes-related dialysis is important in order to allocate health resources, and to encourage measures to counteract trends for increasing prevalence.

Methods: Data were retrieved from 2001-2010 Taiwan National Health Insurance claim records. The gender and age-specific incidence rate of long-term dialysis was calculated for type 2 diabetes patients in the periods of 2002-2004, 2005-2007 and 2008-2010, seperately. Poisson regression was performed to evaluate the effects of age, gender and period with a log (person-year) off-set term and a deviance scale parameter adjustment. All statistical analyses were conducted using the SAS statistical software, Version 9.2.

Results: There were 20,397 male and 19,933 female diabetes-related dialysis occurring between 2002 and 2010. The incidence number of diabetes-related dialysis increased from 2002 to 2010 in every age group. During 2008-2010, the numbers of male patient peak at the age-range of 50-59 years and those of female patients peak at the range-range of 70-79 years. There was a decreasing trend of incidence rate from 2002 to 2010 in female patients younger than 70 years old. In contrast, there was an increasing trend of incidence rate in female patients older than 80 years old from 2002 to 2008.



Initially, Poisson regression model showed that the relative risk (RR) of diabetes-related dialysis in 2002-2004 was higher than that in the other two periods. However, this period effect disappeared after adding interaction terms gender&age and period&age into the model.

Conclusions: For adult female patients younger than 70 years, there was a decreasing trend of diabetes-related dialysis incidence rate from 2002 to 2010 in Taiwan.

Funding: Government Support - Non-U.S.

SA-PO722

Association between Renal Function and Diabetic Foot Ulcer in Type 2 Diabetic Patients Haitham Ezzat, Abd el Basset El Shaarawy, Amr Mohab. *Nephrology Dept, Ain Shams Univ, Cairo, Egypt.*

Background: Diabetic nephropathy and diabetic foot syndrome (DFS) are two major complications of diabetes. The aim of this study was to evaluate renal function in patients with diabetic foot ulcers and to identify a potential association between them.

Methods: In this cross sectional study 75 adult patients with type 2 DM were enrolled. They were divided into 2 groups , group 1 included 50 patients with diabetic foot ulcer (DFU) (25 male & 25 female) and group 2 included 25 patients without DFU (12 male & 13 female).The stages of DFU were recorded according to Wagner and Armstrong grading. Demographic data was collected from all subjects. Laboratory parameters included s.creatinine, serum urea, HbA1C, lipid profiles, urinalysis, urinary microalbumin and albumin/creatinine ratio (ACR). The eGFR was estimated using the Modification of Diet in Renal Disease equation (MDRD).

Results: Compared with type 2 patients without DFU, those with DFU were significantly older ($P < 0.001$), exhibited a higher HbA1c (8.42%±1.02 vs 7.58%±0.57, P<0.001) , had a longer duration of diabetes (18.0±10.74 years vs 4.327±2.497 years , $P < 0.001$),higher mean systolic blood pressure (135.40±19.91 vs 126.00±15.81 mmgH; P=0.043) , higher serum creatinine levels (2.46 mg/dl ±1.005 vs 1.68 mg/dl ±0.516, $P < 0.001$), and had a lower eGFR (41.196 ml/min ±25.542 vs 61.856 ml/min ±24.641, $P = 0.001$). There was increase in the prevalence of foot ulcers by increasing the degree of renal impairment (14% with CKD stage 2, 30% with CKD stage 3 and 56% with CKD stage 4). Also there was increase in the prevalence of foot ulcers with increasing degree of albuminuria (12% with normo-albuminuria ,26% with microalbuminuria and 62% with macro-albuminuria). In group 1, there was significant correlation between the Wagner stages of DFU and eGFR ($P < 0.001$) as well as Armstrong stages of DFU and eGFR ($P < 0.001$).

Conclusions: There was a strong association between the degree of renal function impairment and DFU. Thus diabetic patients with CKD should regularly screened for the presence of DFS with early preventive strategies.

SA-PO723

Detection of Early Renal Function Decline in Type 1 Diabetes: Comparison of eGFR Slopes Based on Serum Creatinine versus Cystatin C Adam Smiles, Melissa Major, John J. Tsay, Jan Skupien, Monika A. Niewczas, James Warram, Andrzej S. Krolewski. *Joslin Diabetes Center, Boston, MA.*

Background: The second Joslin Kidney Study is an observational study of the natural history of Early Renal Function Decline (ERFD) in type-1 diabetes.

Methods: A cohort of patients with normo- or micro-albuminuria (ALB) was recruited from among patients of the Joslin Diabetes Center. Serial measurements of creatinine (Cre) and cystatin C (Cys) were collected over 3.5 to 11 years. CKD-EPI equations were used to calculate eGFRcre and eGFRcys. Slopes of decline of eGFRcre and eGFRcys were estimated using generalized linear models.

Results: ERFD was defined as an eGFR loss greater than 3 mL/min/1.73 m^2 per year. The table shows the proportion of patients with ERFDcre or ERFDcys according to their respective estimates of baseline eGFR.

	Normo-ALB n=451		Micro-ALB n=304	
Baseline eGFR	Creatinine ERFD	Cystatin C ERFD	Creatinine ERFD	Cystatin C ERFD
120+	21% (20/95)	12% (17/145)	27% (16/59)	22% (19/86)
90-119	10% (31/300)	13% (35/272)	23% (43/184)	35% (58/167)
60-89	9% (5/56)	23% (8/34)	21% (13/61)	39% (20/51)
TOTAL	12% (56/451)	13% (60/451)	24% (72/304)	32% (97/304)

While detection of ERFD by eGFRcre and eGFRcys was similar in Normo-ALB (12% for Cre and 13% for Cys), it was higher for eGFRcys in Micro-ALB (24% and 32%, p=0.02). Interestingly, the proportion of patients with ERFDcys was independent of baseline eGFRcys in both Normo-ALB and Micro-ALB (p=0.2 and 0.06). eGFRcys slope was also better correlated with covariates than the eGFRcre slope. The most striking were ACR (–0.25 Cys vs. –0.15 Cre, p=0.04) and serum TNFR1 (–0.20 vs –0.15, p=0.3).

Conclusions: In conclusion, cystatin C may be a more sensitive tool to identify ERFD, especially in a population with micro-ALB. Further investigation is required into any trends in rates of ERFD across baseline eGFR groups.

SA-PO724

Real World Analyses of Urinary Albumin and eGFR Decline in 329,841 Diabetic Patients Michael Cressman,[2] Jennifer L. Ennis,[1] Dajie Luo,[4] Barry Goldstein,[2] George L. Bakris.[3] *[1]Litholink/LabCorp, Chicago, IL; [2]Covance, Princeton, NJ; [3]Medicine, Univ of Chicago, Chicago, IL; [4]LabCorp, Durham, NC.*

Background: Renal outcome trials in diabetic kidney disease (DKD) have generally used severely increased albuminuria as an eligibility criterion to enrich kidney disease progression risk. However, this approach can hinder recruitment, particularly when reduced estimated glomerular filtration rate (eGFR) is also required.

Methods: In order to estimate prevalence and renal prognostic significance of lesser degrees of albuminuria, we analyzed renal laboratory data obtained at LabCorp testing facilities in a cohort of 18-75 year old diabetic patients who had urinary albumin to creatinine ratio (ACR) and at least 3 eGFR results over a period of at least 1 year (n=329,841) between November 2011 and August 2015. Individual eGFR linear regression coefficients were calculated to assess annual rates of eGFR decline across the entire population and in subsets classified according to initial eGFR (>90, 60-89, 30-59 or 15-29 mL/min/1.73m^2) and ACR category (<30, 30-99, 100-299, 300-2999 or > 3000 mg/g).

Results: Mean (SD) age, initial eGFR and duration of follow-up were 59 (10) years, 81 (21) mL/min/1.73m^2, and 2.6 (0.7) years, respectively. Mean (SD) number of eGFR results was 8 (4). ACR was >30, >100, >300, or >3000 mg/g in 29%, 14%, 7% and 1%, respectively, across the entire population with a shift toward higher levels among patients with lower initial eGFR. Although the overall mean rate of eGFR decline was low (2.17 mL/min/year), 21% had reductions > 5 mL/min/yr. Among patients with initial eGFR 30-59 mL/min/1.73m^2 who were followed for at least 2 years (n=40,454), the proportion of patients with eGFR decline > 40% (initial vs last eGFR) was 7.3% in patients with ACR < 30 mg/g but increased progressively with higher ACR levels (ACR 30-99 mg/g: 12.3%, ACR 100-299 mg/g: 18.8%, ACR 300-2999 mg/g: 44.4%, ACR > 3000 mg/g: 81.1%).

Conclusions: These findings support inclusion of patients with lower ACR levels in large DKD outcome trials and the utility of a current, large clinical laboratory database to optimize renal entry criteria and derive sample size estimates for these studies.

Prevalence of Proteinuria and Albuminuria in Obese Patients Undergoing Bariatric Surgery Max R. Pommier, Satyam Patel, David Selzer, Jordan L. Rosenstock. *Nephrology, Lenox Hill Hospital, NYC, NY.*

Background: Obesity is recognized as a risk factor for kidney disease and both proteinuria and albuminuria have been associated with obesity. The actual prevalence of albuminuria and proteinuria in obese patients in the US has not been clearly described. Furthermore, obesity is associated with risk factors of kidney disease such as diabetes and hypertension and the prevalence excluding these risk factors is uncertain. In this study, we sought to determine the prevalence of albuminuria and proteinuria with and without diabetes and hypertension.

Methods: Consecutive patients undergoing bariatric surgery were recruited. Urine samples were collected from each patient prior to surgery and sent for urine albumin/creatinine and urine protein/creatinine. Albuminuria was defined as an albumin to creatinine ratio of more than 30 mg and proteinuria as a protein to creatinine ratio of greater than 300 mg.

Results: The study included 219 patients. The mean age was 42 years and mean BMI was 44. Diabetes (DM) was present in 25%. Hypertension (HTN) was present in 47%. The prevalence of proteinuria and albuminuria was 7.5% (95% CI: 4.3-11.9%) and 19.7% (95% CI: 14.2-26.2%) respectively. Among those without DM but who had HTN, 3.2% (95% CI: 0.4-11.2) had proteinuria and 17% (95% CI 8.4-30.9) had albuminuria. Of patients with neither DM nor HTN, 3% (95% CI: 0-6%) and 11% (95% CI: 5-17%) had proteinuria and albuminuria respectively. Diabetics had more proteinuria and albuminuria than the non-diabetic groups. The non-diabetic groups did not differ significantly from each other in terms of prevalence of proteinuria and albuminuria. The BMI for diabetics did not differ from non-diabetics. On multivariate analysis, only the presence of DM was associated with proteinuria and albuminuria.

Conclusions: In conclusion, we found a relatively high prevalence of microalbuminuria and proteinuria in an urban, obese population. When diabetics were excluded, there was a much lower prevalence. Patients who had neither DM nor HTN had less microalbuminuria than those with hypertension, but still had much more than seen in the general US population, likely reflecting an adverse effect of obesity itself on renal physiology.

SA-PO726

Effects of Bariatric Surgery on Albuminuria and Estimated Glomerular Filtration Rate in Obese, Diabetic Patients Pei Loo Tok,[1] Chieh-Suai Tan,[1] Meifen Zhang,[2] Kwang Wei Tham.[2] *[1]Renal Medicine, Singapore General Hospital, Singapore, Singapore; [2]Endocrinology, Singapore General Hospital, Singapore, Singapore.*

Background: Bariatric surgery is an established treatment for patients who have obesity with BMI more than 35kg/m2 and type two diabetes mellitus (T2DM) not achieving recommended targets with medical therapy. However, renal outcomes after bariatric surgery are not well studied. The aim of our study is to determine the impact of bariatric surgery on urine albumin creatinine ratio (UACR), serum creatinine and estimated glomerular filtration rate (eGFR) in our multi-ethnic population in Singapore.

Methods: This is a single centre retrospective study of obese T2DM patients who underwent bariatric surgery from 2008 to 2013. Comparison was made between serum creatinine and UACR before surgery and at the last follow up visit. Estimated glomerular filtration rate was calculated by substitution of adjusted body weight (ABW) into the Cockcroft gault equation. Secondary outcomes of weight, glycemic control and blood pressure (BP) were also recorded.

Results: A total of 83 patients (Age 45+/- 9 years; 55% females) with BMI 42 +/- 9 kg/m2 and HbA1c 8.5+/-1.6% underwent bariatric surgery (78.3% laparoscopic gastric bypass and 21.7% laparoscopic sleeve gastrectomy). UACR results done preoperatively and on follow up was done for 82% of the patients (68/83). Of the patients who were microalbuminuric, 69% (20/29) regressed to normoalbuminuria (p<0.01). Of the patients who were macroalbuminuric, 50% (6/12) patients regressed to microalbuminuria but none to normoalbuminuria. The mean creatinine at baseline and at last follow up was 87+/- 48 umol/L and 79+/- 49 umol/L. The eGFR at baseline and at last follow up was 128 +/- 55 ml/min and 137 +/- 61 ml/min (p<0.001). At last follow up, the BMI was 32 +/- 8 kg/m2 and the HbA1c was 6.1 +/- 0.9 %.

Conclusions: There is significant improvement of UACR in obese T2DM patients after bariatric surgery in addition to benefits of weight loss and improved glycemic control.

SA-PO727

Glomerular Hyperfiltration and Increased Efferent Arteriolar Resistance Are Present in Subjects with Impaired Fasting Glucose and/or Impaired Glucose Tolerance Akihiro Tsuda, Eiji Ishimura, Hideki Uedono, Mitsuru Ichii, Shinya Nakatani, Masaaki Inaba. *Dept of Nephrology, Dept of Metabolism, Endocrinology and Molecular Medicine, Osaka City Univ Graduate School of Medicine, Osaka, Japan.*

Background: Glomerular hyperfiltraton is known to be present in subjects with impaired fasting glycaemia (IFG)(Melsom T, et al. Diabetes Care, 2011). However, little is known about the precise intrarenal hemodynamic abnormalities in subjects with with IFG and/or impaired glucose tolerance (IGT). The aim of the present study is to evaluate intrarenal hemodynamics in subjects with normal glucose tolerance (NGT) and in those with IFG and/or IGT.

Methods: 36 subjects (57.1 ± 12.1 years, 17 males and 19 females), who were planned to provide a kidney for transplantation, were enrolled. 75g oral glucose tolerance test (75g-OGTT), measured GFR (inulin clearance;C_{in}) and renal plasma flow (para-aminohippurate clearance) were performed in all subjects. Intrarenal hemodynamic parameters (R_e; efferent arteriolar resistance, R_a; afferent arteriolar resistance, P_{glo}; intraglomerular hydrostatic pressure) were calculated by Gomez's formulae.

Results: Of 36 subjects, 25 showed NGT, and 11 showed IFG and/or IGT by 75g-OGTT. eGFR of IFG and/or IGT was not significantly different from that of NGT. C_{in} (100.0±28.4 vs.78.7±17.1, p=0.065), FF (0.26±0.08 vs. 0.22±0.04 %;p=0.09), R_e (3574.7±1573.0vs.2423.7±536.3, p=0.0078) and P_{glo} (59.6±9.0vs.54.6±5.5, p=0.025) of IFG and/or IGT subjects were higher than those of NGT subjects. R_e (r=0.642, p<0.0001) and FF (r=0387,p=0.0197) were significantly, positively associated with fasting plasma glucose (FPG). In multiple regression analyses after adjustments of age, gender, and body mass index, FPG (R_e : β=0.59, p<0.0001, FF: β=0.300, p=0.077), 2-hr average glucose levels in 75g-OGTT (R_e : β=0.45, p=0.019, FF: β=0.430, p=0.015) and HbA1c (R_e : β=0.35, p=0.065, FF: β=0.440, p=0.009) were significantly associated with R_e and FF.

Conclusions: eGFR cannot be used in evaluation of glomerular hyperfiltration in IFG and/or IGT subjects. Hemodynamic abnormalities, possibly caused by increased R_e, associated with poor glycemic control are present even in IFG and/or IGT subjects.

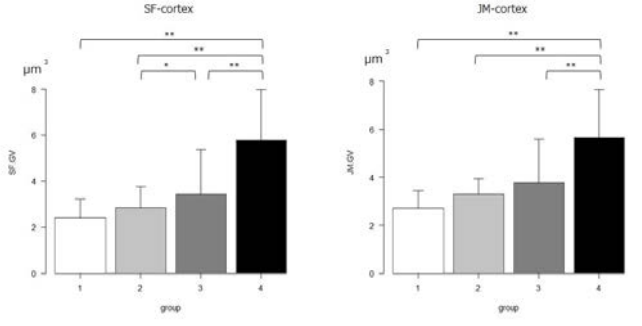
SA-PO728

Diabetes and Hypertension Synergistically Exacerbates Glomerular Hypertrophy Takaya Sasaki, Kentaro Koike, Kotaro Haruhara, Nobuo Tsuboi, Go Kanzaki, Yusuke Okabayashi, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Nephrology and Hypertension, The Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan.*

Background: Glomerular hypertrophy is an early histopathological finding in diabetic nephropathy that precedes the development of diabetes-specific glomerular lesions. Although hypertension is a major clinical feature associated with a poor renal outcome in diabetes, no previous study has analyzed diabetic glomerular hypertrophy in relation to hypertension in humans.

Methods: Autopsied kidneys without renal dysfunction (eGFR >60 ml/min/1.73 m^2) were analyzed to estimate the glomerular volume (GV) in different parts of the renal cortex. The mean GV was calculated from a formula involving the glomerular surface area (approximately 50 glomeruli measured per cortex).

Results: We analyzed a series of 80Japanese autopsy specimens. The average values were age of 70 years and estimated glomerular filtration rate (eGFR) of 98 ml/min/1.73m^2. The autopsied specimens were obtained from normotensive non-diabetes patients (n=31), hypertensive non-diabetes patients (n=28), normotensive diabetes patients (n=13), and hypertensive diabetes patients (n=8). The mean GV in the diabetic hypertensive patients was markedly higher than in the other groups in both superficial (SF) and juxtamedullary (JM) cortices (figure).



*:p<0.05, **:p<0.001
Group 1: non-diabetic normotensive group, Group 2: non-diabetic hypertensive group
Group 3: diabetic normotensive group, Group 4: diabetic hypertensive group

The factors independently associated with the mean GV were a low glomerular density, diabetes and hypertension in the SF cortex, and diabetes and hypertension in the JM cortex. In contrast, neither age nor renal function nor degree of glomerulosclerosis were found to be related to the mean GV in either cortex in multivariate analyses.

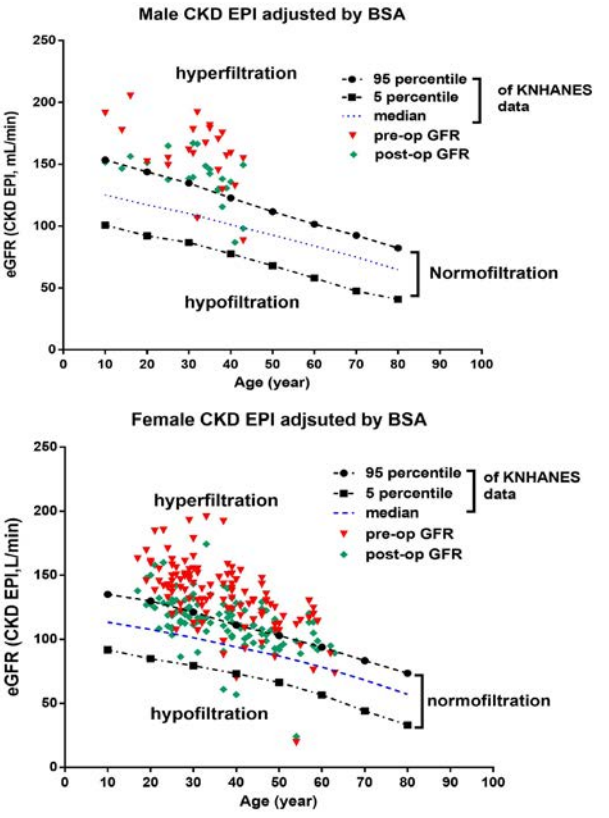
Conclusions: These results suggest that diabetes and hypertension may synergistically exacerbate glomerular hypertrophy across all layers of the human renal cortex.

SA-PO729

Predictors of Resolution of Glomerular Hyperfiltration in Obese Patients following Bariatric Surgery Sinae Lee,[1] Suyeon Park,[2] Hye Ran Kang,[1] Jin Seok Jeon,[1] Hyunjin Noh,[1] Dong-Cheol Han,[1] Soon Hyo Kwon.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Soonchunhyang Univ Seoul Hospital, Seoul, Korea; [2]Dept of Biostatistics, Soonchunhyang Univ Seoul Hospital, Seoul, Korea.*

Background: Obesity is associated with increased glomerular filtration rates (GFR). Bariatric surgery is efficient to improve glomerular hyperfiltration. The aim of this study was to elucidate the predictors of resolution in glomerular hyperfiltration.

Methods: We prospectively enrolled obese patients who underwent bariatric surgery and had follow up more than one-year.Glomerular hyperfiltration was defined as estimated GFR (eGFR) above 95 percentile of GFR values in age, sex-matched cohorts extraced from the Korea National Health and Nutrition Examination Survey (KNHANES) Database. GFR was estimated using a body surface area (BSA)-adjusted Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) creatinine equation (mL/min) at the time of surgery and annually during follow-up period.



Results: Among total 136 of eligible patients, ninety-nine patients with glomerular hyperfiltration (age range, 14-58; 16 men; 83 women) were analyzed. Median follow-up period was 2 years (range, 1 to 4 years). 44 Diabetic (32%) and 45 hypertensive (33%) patients were included. Bariatric surgery decreased eGFR (150.0±18.5 vs. 126.5±16.7 mL/min; p<.0001). Among them, eGFR of 49 (50%) patients returned to the normofiltration range (5-95 percentile of eGFR in KNHANES). Multivariate analysis identified pre-operation BMI (p=0.001, OR=0.80; 95% CI= 0.70-0.92) and age (p=0.01, OR=1.12; 95% CI=1.02-1.21) as independent factors of resolution of glomerular hyperfiltration at surgery.

Conclusions: The predictive factors for resolution of increased GFR following bariatric surgery include BMI and age at surgery time.

SA-PO730

Urinary Angiotensinogen (AOG) Is Increased in Type I Diabetes with Microalbuminuria Minghao Ye, Jan A. Wysocki, Ahmed Mohamed Khattab, Hasan Issa, Matthew Adam Gutterman, Mark E. Molitch, Daniel Batlle. *Nephrology/Endocrinology, Feinberg School of Medicine, Chicago, IL.*

Background: An increase in urinary AOG, a key component of the RAS, has been reported in CKD patients including some with type 1 and 2 diabetes. These patients usually had macroalbuminuria and were receiving RAS blockers which may alter AOG. At the stage of macroalbuminuria AOG, like albumin, can be filtered as alterations in glomerular permeability have developed since both proteins have a similar molecular weight. We evaluated urinary AOG in biosamples from patients with mild elevations in albumin excretion rate (AER) from a cohort where hypertension was an exclusion criteria and RAS blockers were not used.

Methods: Biosamples were obtained from NIDDK repositories from participants in the Diabetes Control and Complications Trial (DCCT). AOG in patients with microalbuminuria was compared to a group of normoalbuminuric participants matched for the following: GFR, SBP, DBP, HbA1C, age, gender, diabetes duration and allocation to intensive or conventional insulin therapy. (Table)

Results: Urine AOG was increased in biosamples from the group with microalbuminuria as compared to those with normoalbuminuria and similar GFR, HbA1C blood pressure and disease duration (Table). There was no significant correlation between AOG and UAE (R=0.2) within the low range of UAE examined. This suggests that the source of increased AOG is not only filtered AOG from the circulation but also AOG formed intrarenally.

Variable	AER (mg/24hr)	eGFR (ml/ min/1.73m^2)	SBP (mmHg)	HbA1c (%)	Diabetes Duration (months)	Insulin (standard/ intensive)	Urine AOG/ Creatinine (ng/mg)
Controls (n=44)	8 (2-18)	123 (98-150)	112 (96-150)	8.2 (5.4-11.7)	82 (22-172)	24/20	4.0 (0.22-48)
Micro (n=39)	41 (30-88)	126 (97-147)	118 (92-140)	8.3 (6.0-11.7)	99 (26-180)	18/21	9.7 (1.38-393)
p value	0.0001	NS	NS	NS	NS	NS	0.004

With exception of insulin treatment, all other values represent median (range).

Conclusions: Urinary AOG is increased in persons with type 1 diabetes who have microalbuminuria in the absence of hypertension or RAS blocker therapy for albuminuria. Urinary AOG is a potential early biomarker of diabetic kidney disease and possibly overactivity of the kidney RAS.

Urinary Prorenin Is Increased in Patients with Type 1 Diabetes and Nephropathy Jan A. Wysocki,[1] Johannes Rein,[1] Maryam Afkarian,[2] Daniel Batlle.[1] *[1]Northwestern Univ, Chicago, IL; [2]Univ of Washington.*

Background: Prorenin is increased in patients with T1D and T2D with complications, whereas plasma renin activity is not. Recent studies have shown that the soluble prorenin receptor can activate non-enzymatically prorenin, and therefore activate RAS. There is no information on urinary prorenin from patients with diabetes, and the levels are very low in subjects without diabetes. Proteolytic and non-proteolytic activation of prorenin may be important in kidney RAS overactivity in DN. We evaluated urinary prorenin as well as active renin in biosamples from subjects with T1D who have developed DKD and controls who had not, despite longstanding diabetes (>25 years).

Methods: Biosamples and clinical data from people with T1D were obtained from the Kidney Research Institute DKD Repository of the University of Washington. DKD was defined as either a urine ACR ≥300 mg/g or an eGFR <60 mL/min per 1.73 m^2 and ACR ≥30 mg/g. People with longstanding diabetes but no evidence of DKD had≥30 years of T1D, estimated eGFR>90 mL/min per 1.73 m^2, and ACR <300 mg/g. Samples for active renin were first concentrated before applying to ELISA. Urinary prorenin was measured using ELISA detecting prorenin only.

Results: Prorenin was detectable in 81% (30/37) of samples from the cases but only in 51% of the urines (22/43) from the controls with diabetes who did not have diabetic kidney disease. Median urine Prorenin/Cr (IQR) was significantly higher in DKD biosamples 99 (33,303) pg/mg than in biosamples from those without DKD 39 (21, 84) pg/mg, p<0.005. Median urine active renin/Cr was also increased in subjects with DKD 2.9 pg/mg (1.8,7.5) as compared to those without it 1.4 pg/mg (0.9, 3.6), p<0.05. There was a significant positive correlation between urinary prorenin and active renin protein (0.676, p<0.001).

Conclusions: Urinary prorenin could be a source of increased urinary active renin in persons with type 1 diabetes. Both prorenin and active renin are increased in patients with DKD as compared to those who have escaped this complication after longstanding diabetes. Prospective studies are needed to examine the potential predictive value of urinary prorenin and active renin for the development of DKD.

Urinary Excretion of Podocyte mRNA Is an Early Diagnostic Biomarker in Diabetic Nephropathy Akihiro Fukuda, Akihiro Minakawa, Yuji Sato, Kazuo Kitamura, Shouichi Fujimoto. *First Dept of Internal Medicine, Univ of Miyazaki, Miyazaki, Japan.*

Background: Albuminuria is used for early diagnostic assessment of diabetic nephropathy but does not always reflect disease activity. Recent studies suggest that podocyte injury has already begun at the early stage of diabetic nephropathy. Podocyte cell lineage-specific mRNA can be recovered from urine pellets. The study examined whether urinary excretion of podocyte mRNA can be used as an early diagnostic biomarker in diabetic nephropathy.

Methods: We examined both animal models of diabetic nephropathy and human urine samples. The leptin-deficient Zucker diabetic Fatty (ZDF-fatty) rat model of type 2 diabetes was compared with heterozygous ZDF rats as a control. From January 2015 to June 2015, spot urine samples from out-patients at various stages of diabetes (normoalbulinuria group: n=99, microalbuminuria group: n=38, macroalbuminuria group: n=37) and healthy controls (n=41) without diabetes or hypertension, were taken. We examined urinary excretion of podocyte mRNA and urine albumin/creatinine ratio, and measured glomerular volume, and podocyte number and density in the rat model.

Results: ZDF-fatty rats became diabetic with increased blood glucose and glycosuria by 10 weeks. Albuminuria significantly increased by 10 weeks, however, urinary excretion of podocyte mRNA increased by 8weeks in ZDF-fatty rats. At 6 weeks, podocyte numbers had not decreased, while glomerular volume significantly increased and podocyte density significantly decreased compared to controls, suggesting that podocyte stress had begun at the early stage of diabetes. Similar results were observed in human participants. Urinary excretion of podocyte mRNA increased dependent on albuminuria level in diabetes patients *vs.* controls (normoalbuminuria: 4.3-fold; microalbuminuria: 4.2-fold; macroalbuminuria: 16.7-fold). Urinary excretion of podocyte mRNA in the normoalbuminuria group at the interquartile range of the control level of albuminuria significantly increased *vs.* controls (6.7-fold).

Conclusions: Urinary excretion of podocyte mRNA begins to increase much faster than albuminuria in both animal models and humans, and could be an early diagnostic biomarker in diabetic nephropathy.

Impaired Leukocyte Glucose 6-Phosphate Dehydrogenase (G6PD) Response to Hyperglycemia Is Associated with Rapidly Progressive Kidney Disease in Individuals with Diabetes Matthew R. Lynch,[1,2] Robert C. Stanton.[1,2] *[1]Div of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Kidney and Hypertension Section, Joslin Diabetes Center, Boston, MA.*

Background: Mechanisms of diabetic kidney disease (DKD) progression are unclear. An appropriate response to oxidative stress is an increase in G6PD activity, the source of the essential antioxidant NADPH. Impaired G6PD activity occurs in animal models of DKD and in leukocytes from animals and persons with diabetes, suggesting that leukocyte G6PD activity correlates with kidney GP6D activity. We hypothesized that leukocyte G6PD activity response would be impaired in patients with progressive DKD.

Methods: 45 patients with DKD were recruited; those with at least a 3.3 ml/min/year loss in eGFR since establishing care were deemed to be rapid progressors. Rapid progressors with an uninterrupted decline in eGFR were judged linear rapid progressors (LRP), while the rapid progressors with at least one period of at least one year of stable eGFR were called non-linear rapid progressors (NLRP). Non-rapid progressors (NRP) included all remaining patients. The change in leukocyte G6PD activity to high glucose stress was measured. Leukocytes were isolated from whole blood and incubated in normal (5.5 mM glucose) or high glucose (25 mM) conditions for one hour at 37°C. Serum glucose, hemoglobin A1C, creatinine, hemoglobin, albuminuria and medications were abstracted from medical records.

Results: Compared to baseline, leukocyte G6PD activity changes to high glucose stress were decreased in LRP (-19.52±13.85%), unchanged in NLRP (1.9±10.3%), and increased in NRP (18.2±6.47%; p=0.035 versus LRP). There was no difference between the groups' baseline leukocyte or erythrocyte G6PD activity. Albuminuria was higher in LRP than in the other groups (LRP: 3815±1310 mg/g, NLRP: 724.9±569.9 mg/g, and NRP: 454.5±165.8 mg/g; p=0.01 and p<0.001, respectively).

Conclusions: Leukocyte G6PD activity response to high glucose stress was significantly impaired in patients with linear rapidly progressive DKD. Leukocyte G6PD response may act as a surrogate for renal G6PD activity, suggesting that G6PD may be both a biomarker and potential therapeutic target in human DKD.

SA-PO735

Proteomic Analysis Suggests Role of TGF-β Regulatory Proteins in Development of Diabetic Kidney Disease Elwaleed Elnagar,[1] Christian Herzog,[1] Maria Lopes-Virella,[2] Kelly J. Hunt,[2] Michael G. Janech,[2] Ricky Edmondson,[1] John M. Arthur.[1] *[1]Univ of Arkansas for Medical Sciences; [2]Medical Univ of South Carolina.*

Background: Diabetic nephropathy is the leading cause of ESRD in the US but a relatively small percentage of patients with type 2 diabetes have reduced renal function after 15 years. Albuminuria is used to predict decline in renal function but it is neither sensitive nor specific. The goal of this study is to identify novel predictive biomarkers and pathways involved in development of diabetic kidney disease.

Methods: Urine from 10 subjects enrolled in the VA Diabetes Trial who had normal serum creatinine (SCr) and normoalbuminuria at enrollment, but doubled their SCr during follow up, were matched to 10 that had no increase in SCr. Urine proteins were digested with trypsin and analyzed by liquid chromatography/tandem mass spectrometry. Identified proteins were quantified using spectral counting and differences between progressors and nonprogressors were identified using a t-test with Benjamini-Hochberg correction for multiple comparisons.

Results: We identified 888 proteins with a decoy false discovery rate of 0.08%. After removing proteins primarily expressed in bladder or skin, 20 had p values ≤0.05. Vasorin had the smallest p value (0.001) and was lower in progressors. Vasorin binds TGF-B preventing its stimulation of the receptor. Among the 20 proteins with p≤0.05, 7 (vasorin, plasma serine protease inhibitor, gamma-glutamylcyclotransferase, oxidized low-density lipoprotein receptor 1, angiotensinogen, kallikrein-1 and L-selectin) were involved in TGF-B signaling and the directional changes in five are consistent with increased TGF-B signaling. Observed changes in other mediators with slightly higher p values also would result in an increase in TGF-B (MMP-9, latent TGF binding protein 2, activin receptor).

Conclusions: A high percentage of differentially abundant urine proteins in patients that will develop diabetic kidney disease are involved in regulation of TGF-B signaling and most of the differentially abundant proteins in the pathway should lead to an increase in TGF-B. This is an intrarenal pro-fibrotic signal that can potentially be used to predict patients that will develop CKD.

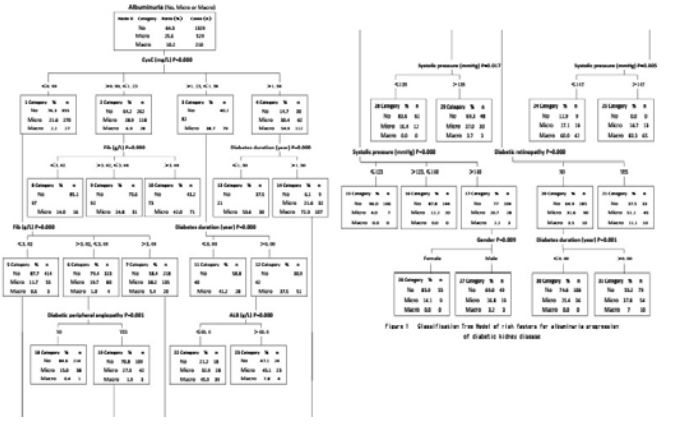
Classification Tree Model Analysis on Related Factors of the Incidence and Degree of Albuminuria of Diabetic Kidney Disease Wenbo Zhao,[1] Meijun Si,[1] Hui-Qun Li,[1] Zhouqing Gan,[2] Weiming Han,[2] Tan-Qi Lou.[1] *[1]Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Zhongshan School of Medicine, Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: To analyze the impact factors for the degree of albuminuria of diabetic kidney disease by the classification tree model.

Methods: A total of 2068 hospitalized patients with type 2 diabetes were enrolled. According to glomerular filtration rates and urine albumin quantification,the patients were divided into type 2 diabetes group (1329 cases) , early diabetic renal damage group (529 cases) and macroalbuminuria group(210 cases) . The clinical data of the patients were recorded to analyze the main influential factors for the microalbuminuria of type 2 diabetic patients using the Exhaustive CHAID classification tree algorithm.

Results: Eight important explanatory variables were screened out by the classification tree model from the 30 candidate variables related to microalbuminuria and macroalbuminuria., including Cys C levels, fibrinogen,SBP , retinopathy, sex, diabetes peripheral vascular disease, diabetic duration, serum albumin . CysC was the main factor of DKD,CysC > 1.58 mg/L and diabetes duration of 1.50 years or less appear microalbuminuria is a 53.6% chance;CysC > 1.58 mg/L, diabetes duration > 1.50 years and SBP > 147 mmHg have 83.3% chance of macroalbuminuria.



Conclusions: Classification tree model can effectively analyze the different levels of albuminuria related influencing factors, and identify people at high risk characteristics, is conducive to early prevention and treatment.

SA-PO737

Fibrinogen May Be an Independent Predictor of Diabetic Kidney Disease Wenbo Zhao,[1] Hui-Qun Li,[1] Zengchun Ye,[1] Ming Li,[1] Meijun Si,[1] Zhouqing Gan,[2] Weiming Han,[2] Tan-Qi Lou.[1] *[1]Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Zhongshan School of Medicine, Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Analysis of the correlation of fibrinogen and different stages albuminuria in diabetic kidney disease.

Methods: As a Cross-sectional study,we collected hospital clinical data of 1152 cases for type 2 diabetes, without albuminuria group (785 cases), microalbuminuria group (285 cases) and macroalbuminuria group (112 cases),analying albuminuria progress related influence factors for multiple factors regression.

Results: The levels of fibrinogen was in the three groups respectively for(3.46±1.33) g/L, (4.16±1.32)g/L, and(4.85±1.28)g/L(P=0.000). In the without albuminuria group and microalbuminuria group, the multi-factor Logistic regression analysis showed fibrinogen (Fib) (β= 0.463, P = 0.000, OR = 1.589), and retinopathy, CysC, systolic blood pressure into the model. In microalbuminuria group and macroalbuminuria group, the multi-factor Logistic regression analysis showed fibrinogen (Fib) (β=0.463,P=0.000, OR=1.589), and retinopathy, CysC, Waist-to-hip ratio into the model.

Conclusions: Fibrinogen associated with different stages albuminuria , that could be independent predictors of diabetic kidney disease.

SA-PO738

Non-Alcoholic Fatty Liver Disease Is Not Related to the Incidence and Degree of Albuminuria of Diabetic Kidney Disease Wenbo Zhao, Zengchun Ye, Ming Li, Meijun Si, Hui-Qun Li, Tan-Qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzou, Guangdong, China.*

Background: To analyze the association between non-alcoholic fatty liver disease (NAFLD) and the Incidence and degree of albuminuria of diabetic kidney disease in patients with type 2 diabetes.

Methods: the incidence of diabetic nephropathy was assessed in 2068 type 2 diabetic patients. The NAFLD was diagnosed based on liver ultrasound. The difference in diabetic nephropathy incidence between patients with and without NAFLD was tested by $\chi 2$. Multinomial logistic regression analysis was used to assess the factors associated with degree of albuminuria of diabetic kidney disease.

Results: The incidences of NAFLD and diabetic nephropathy in participants were approximately 44% (910/2068) and 35.7% (739/2068) respectively, microalbuminuria and macroalbuminuria in participants were approximately 25.6% (529/2068) and 10.1% (210/2068) respectively, and there were difference in the prevalence of degrees of albuminuria of diabetic kidney disease between patients with and without NAFLD (p= 0.000). The incidences of NAFLD was highest in Patients without albuminuria (64.3%, 628/1329), in Patients with microalbuminuria (25.6%, 225/529), in Patients with macroalbuminuria (10.2%, 57/210). In multinomial logistic regression analysis, Fasting blood-glucose, BMI, Waist–hip ratio, fibrinogen, peripheral neuropathy, diabetic retinopathy, CysC, history of hypertension were significantly associated with Patients with microalbuminuria, whereas age of onset, high blood pressure, fibrinogen, diabetic retinopathy, CysC, triglyceride (TG), high-density lipoprotein, low density lipoprotein were significantly associated with were significantly associated with Patients with macroalbuminuria. NAFLD were not associated with the degree of albuminuria of diabetic kidney disease.

Conclusions: The present results suggest that NAFLD is not related to the the Incidence and degree of albuminuria of diabetic kidney disease .

SA-PO739

Glomerular IgM Deposition Predicts Renal Outcome in Patients with Type 2 Diabetes Xi Tang, Li Li, Yu Han Li, Fang Liu. *Nephrolgoy, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: Immunofluorescent staining reveals IgG, IgM, C3 deposits in renal tissue of some patients with type 2 diabetes. However, the clinical implication of such immune complex deposition is unclear.

Methods: A retrospective study was carried out in the west china hospital, Sichuan university, China. Among the 347 patients with diabetes who underwent renal biopsy from 2001 to 2015, 190 cases had pure diabetic nephropathy. According to the classification of Tervaert et al, 108 patients (glomerular class I to III) with at least 12-month follow-up were enrolled in this study. Clinical and pathological data were collected. Immunofluorescent staining was classified into three categories according to the intensity (0=none, 1=weekly positive, and 2=positive).Renal survival was estimated by the Kaplan-Meier method. The Cox proportional hazards model was employed to identify the risk parameters associated with renal survival.

Results: The number of cases with positive glomerualr IgG, IgM and C3 staining were 29, 40, and 28, respectively. Over a median follow-up of 32 months, 38 cases developed into ESRD, 19 cases died. The Median time of renal survival 60(47.40,72.60)months. The renal survival rates at5 years after biopsy were 41.7%. By multivariate Cox proportional analysis, smoking [HR, 2.775(1.281, 6.010), *P*=0.010], eGFR [HR, 0.981(0.962, 0.999),*P*=0.045], and positive glomerular IgM deposit [1.997(1.095,4.269),*P*=0.039] were independent predictors of ESRD. According to the intensity of IgM deposits, patients were divided into three groups. Compared with those with none renal IgM deposits, patients with positive staining of glomerular IgM had significant lower baseline eGFR (45.78±18.08 *v.s.* 66.69±30ml/min/1.732m2). Age, gender, duration, hypertension, BMI, diabetic retinopathy , diabetic peripheral neuropathy, 24 hour proteinuria, serum IgG, IgM, C3 and albumin, glomerular class were similar among the groups.

Conclusions: Glomerular IgM deposits as well as smoking and eGFR at the baseline of renal biopsy were the independent risk factors of ESRD in the patients with type 2 diabetic nephropathy.

SA-PO740

Impact of Anti-Erythropoietin Receptor Antibodies in Diabetic Patients with Chronic Kidney Disease Akinori Hara, Akihiko Koshino, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: To examine the clinical significance of autoantibodies to the erythropoietin receptor (EPOR) in diabetic patients with chronic kidney disease (CKD).

Methods: One hundred and twelve type 2 diabetic patients with CKD who have been followed up until 2014 (mean age, 62.9±12.5 years) were enrolled in this study. Anti-EPOR antibodies in sera from these patients were measured using enzyme-linked immunosorbent assay.

Results: Anti-EPOR antibodies were detected in 26 (23%) of the 112 diabetic patients enrolled. Patients with anti-EPOR antibodies were older and had lower estimated GFR (eGFR) than those without. In addition, in patients with anti-EPOR antibodies, hemoglobin concentration was lower than those without. During follow-up period, end-stage renal failure (ESRF) requiring dialysis therapy was more frequently observed in patients with anti-EPOR antibodies than in those without, and presence of the antibodies were significant risk factors for progression of ESRF. In 52 patients who had undergone renal biopsy, positivity for anti-EPOR antibodies was associated with the extent of interstitial inflammation.

Conclusions: These results suggest that anti-EPOR antibodies might be involved in the progression of CKD through interstitial inflammation, and the presence of the antibodies may be a predictor for renal dysfunction in type 2 diabetic patients.

Novel Tubular Biomarkers Predict Renal Progression in Type 2 Diabetes Mellitus: A Prospective Cohort Study Kasemsan Aramsaowapak, Bancha Satirapoj, Theerasak Tangwonglert, Naowanit Nata, Amnart Chaiprasert, Prajej Ruangkanchanasetr, Ouppatham Supasyndh. *Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand.*

Background: Estimated glomerular filtration rate (GFR) and albuminuria are routine for assessing renal progression. Tubulointerstitial injury is both a key feature of diabetic nephropathy and an important predictor of renal dysfunction. Novel tubular biomarkers that relate to renal injury in diabetic nephropathy could improve risk stratification and prediction.

Methods: A prospective cohort study, a total of 303 type 2 diabetes patients were followed up. The baseline values of urine Cystatin-C to creatinine ratio (UCCR), urine angiotensinogen to creatinine ratio (UANG), urine NGAL to creatinine ratio (UNGAL) and urine KIM-1 to creatinine ratio (UKIM-1) were measured. The primary outcome was a decline in estimated GFR of ≥25% per year from baseline.

Results: The median follow-up period was 12.5 months, and the primary outcome was noted in 13.5%. Urine tubular biomarkers of UCCR, UANG, UNGAL and UKIM-1 were significantly higher according to the degree of albuminuria and all of them had significant higher in patients with the rapid decline in estimated GFR of ≥25% per year from baseline. All biomarkers predicted primary outcome with ROC for UCCR = 0.72; 95% CI 0.64-0.79, UANG = 0.71; 95% CI 0.63-0.79, UNGAL = 0.64; 95% CI 0.56-0.72. In multivariate COX regression analysis, the number of patients with rapid renal progression was higher in those in the upper quartiles of all biomarkers than in those in the lower quartiles.

Conclusions: The study supported that type 2 diabetic patients with high levels of urine tubular biomarkers (Cystatin-C, angiotensinogen, KIM-1 and NGAL) had more rapid decline in renal function. These tubular biomarkers may be independent predictors of the progression of type 2 diabetic nephropathy.

SA-PO742

p66Shc: A Novel Biomarker of Tubular Oxidative Injury in Patients with Diabetic Nephropathy Xiaoxuan Xu,[1,3] Xuejing Zhu,[1] Yachun Han,[1] Chun Hu,[1] Chang Wang,[1] Shuguang Yuan,[1] Yuan Yang,[1] Li Xiao,[1] Fu-You Liu,[1] Yashpal S. Kanwar,[2] Lin Sun.[1] *[1]Second Xiangya Hospital, China; [2]Depts of Pathology & Medicine, Northwestern Univ, Chicago; [3]Health Management Center, Xiangya Hospital.*

Background: Increased p66Shc expression has been associated with diabetic nephropathy (DN). However, whether p66Shc can serve as a potential biomarker for tubular oxidative injury in DN is unknown.

Methods: We measured the expression of p66Shc in peripheral blood monocytes (PBMs) and renal biopsy tissues from DN patients and then analysed the relationship between p66Shc expression and the clinical characteristics of patients with DN. Patients were divided into 4 groups (class IIa, class IIb, class III and the control group). qPCR, Western blotting and immunohistochemistry were performed.

Results: The results showed that both p66Shc and p-p66Shc expression significantly increased in PBMs and kidney tissues of DN patients. Moreover, Spearman's correlation and multiple regression analyses were carried out. A positive relationship between the p66Shc expression and oxidative stress was found. p66Shc and oxidative stress were significant predictors of the degree of tubular damage. In addition, p66Shc expression was positively correlated with the concentrations of β-NAG, UACR and 8-OHdG, low-density lipoprotein and blood glucose levels, and duration of diabetes in patients with DN from class IIa to class III.

Conclusions: These data indicated that increased expression of p66Shc may serve as a therapeutic target and a novel biomarker of DN.

Funding: Government Support - Non-U.S.

SA-PO743

APX-501 Protein as a Novel Biomarker for Diabetic Nephropathy in Type 2 Diabetes Jin Joo Cha,[1] Young Sun Kang,[1] Gyu Sik Choi,[1] Hye Sook Min,[2] Ji Eun Lee,[2] Hyunwook Kim,[3] Jungyeon Ghee,[1] Ji Ae Yoo,[1] Kitae Kim,[4] Sang Youb Han,[5] Kum Hyun Han,[5] Sewon Oh,[5] Dae R. Cha.[1] *[1]Korea Univ; [2]Wonkwang Univ; [3]Yonsei Univ; [4]Dong-A Univ; [5]Inje Univ, Republic of Korea.*

Background: Excess production of reactive oxygen species in many tissues leads to tissue injuries through inflammation and fibrosis. Recently, we identified that APX-501 protein was synthesized from endothelial cells and is involved in oxidative stress in the kidney. Therefore, we investigated the role of APX-501 as a new biomarker for diabetic nephropathy in type 2 diabetic patients.

Methods: Preliminary animal and in vitro expriments were performed to identify the expression of APX-501 protein in renal tissues and cells in diabetic condition. For human study, 171 type 2 diabetic patients and 65 healthy control subjects participated in the study. The study subjects were divided into 1) nondiabetic healthy controls with normoalbuminuria (n=65), 2) normoalbuminuric diabetic group (n=66), 3) microalbuminuric diabetic group (n=52) and 4) overt proteinuria group (n=53). Plasma levels of APX-501 were measured by ELISA.

Results: In type 2 diabetic db/db mice, plasma level and renal expressions of APX-501 were increased according to age compared with those in nondiabetic db/m mice. In cultured murine podocytes and mesangial cells, high glucose condition markedly increased APX-501 synthesis and secretion. In type 2 diabetic patients, plasma APX-501 concentrations were significantly higher compared to healthy controls. Plasma APX-501 levels were the highest in patients with overt proteinuria. APX-501 levels were inversely correlated with body mass index (BMI) and positively correlated with systolic blood pressure, postprandial glucose levels, HOMA-IR, plasma retinol binding protein 4 (RBP-4) and urinary albumin(UAE) excretion. UAE, RBP-4 and BMI were independent determinants of plasma APX-501 concentration. APX-501 levels were not correlated with estimated glomerular filtration rate and we could not detect urinary excretion of APX-501 even in the overt proteinuria group.

Conclusions: These findings suggest that APX-501 synthesis may be activated in early stage of diabetic environment, may be a new biomarker for diabetic nephropathy in type 2 diabetic patients.

SA-PO744

Longitudinal Associations of Urinary Sodium and Potassium Excretion with eGFR and Albuminuria in Type 1 Diabetes Jessica B. Kendrick,[1] Leila R. Zelnick,[2] Michael Steffes,[3] Michel Chonchol,[1] Ian H. De Boer.[2] *[1]Univ of Colorado; [2]Univ of Washington; [3]Univ of Minnesota.*

Background: Patients with type 1 diabetes are at high risk of renal complications. Whether dietary sodium or potassium intake affects the development of kidney disease remains unclear.

Methods: We performed a cohort study of 1391 participants with type 1 diabetes in the Diabetes Control and Complications Trial and its observational follow-up, the Epidemiology of Diabetes Interventions and Complications Study. We measured urinary sodium and potassium excretion in 4-hour timed urine samples collected between 1989-1996. Up to 3 measurements were made per participant and averaged. Over the subsequent 14 years, we ascertained the development of incident reduced eGFR (sustained eGFR <60 ml/min/1.73m^2), ≥30% decline in eGFR and incident albuminuria (sustained albumin excretion rate (AER) ≥30 mg/d). Cox proportional hazards models were used to examine associations of tertiles of urinary sodium and potassium excretion with each outcome, excluding participants who had developed the outcome of interest prior to follow-up.

Results: Baseline mean (SD) age and eGFR were 38 (7) years and 109 (15) ml/min/1.73m^2. After adjustment for demographics, BMI, smoking, SBP, DBP, baseline eGFR and AER, duration of diabetes, HbA1c and use of ACEi/ARBs, lower urinary excretion of sodium and potassium tended to be associated with lower and higher estimated risks of renal outcomes, respectively, but none of these associations was statistically significant (Table).

	Sustained eGFR <60 ml/min/1.73m^2 N=63 HR (95% CI)	≥ 30% decline in eGFR N=70 HR (95% CI)	Sustained AER ≥ 30 mg/d N=319 HR (95% CI)
Urinary Sodium Exretion (mg/d)			
<4122	0.63 (0.33-1.20)	0.79 (0.49-1.28)	0.97 (0.74-1.29)
4122-5843	0.79 (0.41-1.49)	0.62 (0.37-1.04)	0.94 (0.70-1.26)
≥5844	1.0 (REF)	1.0 (REF)	1.0 (REF)
Urinary Potassium Excretion (mg/d)			
<3180	1.22 (0.62-2.41)	1.19 (0.72-1.98)	1.21 (0.90-1.61)
3180-5281	1.25 (0.62-2.41)	0.93 (0.56-1.55)	1.08 (0.81-1.45)
≥5282	1.0 (REF)	1.0 (REF)	1.0 (REF)

Conclusions: Urinary sodium and potassium excretion were not significantly associated with incident kidney disease in type 1 diabetes.

Funding: NIDDK Support

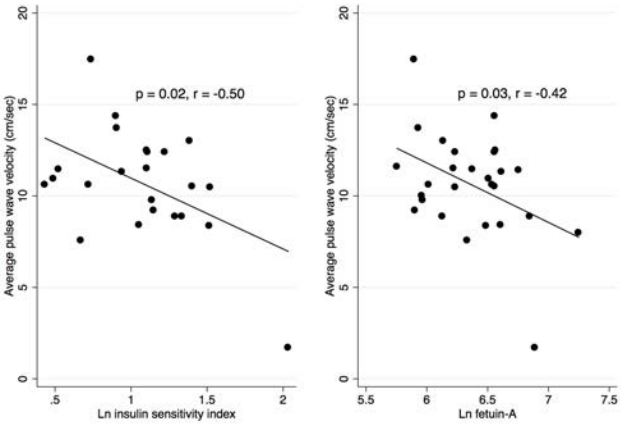
SA-PO745

Fetuin-A and Insulin Resistance Measured by Hyperinsulinemic Euglycemic Clamp Are Independent Determinants of Aortic Stiffness in Patients with CKD Stages 3 and 4 Sudipa Sarkar,[1] Serpil Muge Deger,[1] Leon Hsueh,[3] Ian H. De Boer,[4] Brijesh Patel,[1,2] Edward D. Siew,[1,2] Talat Alp Ikizler,[1,2] Adriana Hung.[1,2] *[1]Vanderbilt Univ, TN; [2]Nashville VA; [3]Univ of Illinois; [4]KRI, Seattle.*

Background: Both increased arterial stiffness and insulin resistance (IR) are highly prevalent and closely associated with cardiovascular disease in chronic kidney disease (CKD). Fetuin-A is a hepatic protein that inhibits arterial calcification and insulin action. In this study, we evaluated whether IR and fetuin-A are important determinants of arterial stiffness.

Methods: In this cross-sectional study, we enrolled 33 individuals with nondiabetic CKD stages 3 and 4 from the Nashville VA Hospital and Vanderbilt. Insulin sensitivity was measured by hyperinsulinemic euglycemic clamp (HEGC). Arterial stiffness was assessed by aortic pulse wave velocity (aPWV). Fetuin-A was measured by ELISA. Pearson correlation was used for univariate analysis and linear regression was used for both univariate and multivariate analyses.

Results: The mean age was 65±11 years, 74% were male, and 27% were African Americans. The mean BMI was 31±5 kg/m^2. Both fetuin-A and insulin sensitivity index (ISI) were negatively correlated with aPWV (r=-0.42, p=0.03 and r=- 0.50 p=0.02, respectively). In the multivariate analysis, ISI (β=-3.54 cm/sec per ln ISI, p=0.02), fetuin-A (β=-3.69 cm/sec per ln fetuin-A, p=0.05), and age (β=0.14 cm/sec per year, p<0.01) were significantly associated with aPWV, but truncal fat (β=-0.01 cm/sec per kg, p=0.34) and creatinine (β=1.57 cm/sec per ln creatinine, p=0.57) were not.



Conclusions: Lower fetuin-A and decreased insulin sensitivity are associated with increased aPWV and may contribute to increased CV risk in patients with CKD. Larger studies are needed to further evaluate the beneficial effect of higher levels of fetuin A in arterial stiffness in CV outcomes in CKD.

NGAL and C-Cystatin Association with Albumin-Creatinine Relation in Type 1 Diabetes Patients Marcelo Rodrigues Bacci, Priscila Fernandes Alfieri, Francisco Winter Dos Santos Figueiredo, Fernando Luiz Affonso Fonseca. *General Practice, ABC Medical School, Santo Andre, São Paulo, Brazil.*

Background: Type 1 diabetes(T1DM)renal disease is well known because of its histological findings and stablished timeline since the beginning.Early injury kidney biomarkers are well studied in acute status however in chronic conditions as diabetes their relationship with albuminuria is not known.The aim of the study was analyse early kidney injury biomarkers between patients with T1DM and type 2 diabetes(T2DM)with the same pattern of glycemic control.

Methods: It is a cross-sectional study.Patients with the diagnosis of diabetes(type 1 and type 2)were recruited in order to compare the following kidney injury biomarkers:NGAL,C cystatin,creatinine,HbA1C,urinary beta trace protein and urinary albumin/creatinine relation(ACR).Exclusion criteria included patients with end stage renal disease in dialysis, cancer and hospitalized for any reason in the previous 30 days of blood collection.The modified diet of renal disease equation was used in adults to estimate glomerular filtration rate and the modified Schwartz equation to estimate eGFR in children.

Results: A total of 77 patients were included.Of them,56 with T2DM and 21 with T1DM.T1DM had 56.7% of females and a mean age of 23.9 years.T2DM were composed by 69.6% of females and a mean age of 63.5 years. The mean eTFG was 89.76 ml/min/1.73m2 for T1DM patients and 76.8 ml/min/1.73m2 for T2DM.Adjusting the analysis for the same HbA1C level for both groups they did differ with the following parameters:ACR, NGAL and C cystatin.T1DM had a median value of 4.69 for c cystatin and T2DM 4.07 with a $p< 0.001$.Also,ACR was different between them with a $p< 0.001$.The mean value for T1DM was 40.86 mg/g and for T2DM 157.98 mg/g.NGAL mean value was 1.19 in T2DM and 0.19 in T1DM with a $p<0.001$.Groups did not have a statistically significant difference for urinary beta trace protein.

Conclusions: For a same glycemic level, patients with T1DM and T2DM had different patterns of biomarkers of renal dysfunction eve3n with a normal eGFR.NGAL was associated with worse ACR and eGFR in T2DM. C Cystatin was associated inversely with ACR in T1DM. Despite same glycemic control, T2DM had worse ACR than T1DM.

Examination of Glycemic Control Index in Diabetic Dialysis Patients under On-Line Hemodiafiltration Yukie Kitajima,[1] Toru Hyodo.[2] *[1]Tokyo Healthcare Univ, Setagaya, Tokyo, Japan; [2]Eijin Clinic and Kurata Hospital Dialysis Center, Hiratsuka, Kanagawa, Japan.*

Background: Glycohemoglobin (HbA1c) of diabetic dialysis patients has been reported to underestimate diurnal blood sugar fluctuations as it is affected by red cell survival, erythropoietin, etc. Therefore, it is recommended in Japan that glycoalbumin (GA) should be used for glycemic control index of diabetic dialysis patients. However, recently in Japan, on-line hemodiafiltration (o-HDF) with high albumin (Alb) leakage has been widely used in dialysis treatment methods due to the reimbursement in the national insurance system since 2012. As GA is affected by albumin metabolism, evaluation of GA values needs to be reexamined for diabetic dialysis patients under HDF. In this study, we examined GA values for different dialysis treatment methods.

Methods: The subjects were 156 diabetic dialysis patients (99 males and 57 females) with an average age of 69.2 ± 12.7 years. Those with Hb of less than 8.0 g/dL, hepatic dysfunction, and transfusion history, were excluded. [Methods] The subjects were divided according to treatment types: a hemodialysis (HD) group (23 patients) and an o-HDF group (133patients). We examined the correlation of GA and HbA1c in comparison with known correlation, and the amount of Alb removed in the HDF group.

Results: A significant positive correlation was observed between GA and HbA1c in the HD group ($R2 = 0.809$ and $p < 0.0001$). Inaba et al. reported a similar result ($r = 0.777$ and $p < 0.001$: J Am Soc Nephrol, 2007). However, the correlation in the o-HDF group was lower than in the HD group ($R2 = 0.316$ and $p < 0.0001$). In the o-HDF group, average of GA, HbAlc and Hb is 20.4 ± 4.7%, 6.0 ± 0.9% and 10.6 ± 1.0g/dl. The mean amount of Alb removed in the effluent in the o-HDF group (24 diabetic dialysis patients) was 2.5 ± 2.17 g per a session. [Discussions] It is possible that GA value is underestimated in the o-HDF group due to the effect of Alb leakage. If Hb value is stable by the therapy, HbA1c may be the golden standard of the diabetic estimation even also in dialysis patients.

Conclusions: For glycemic control index of diabetic dialysis patients, GA and HbA1c need to be used along with the dialysis treatment method.

SA-PO748

Don't Hang Your Hat on Retinopathy in Diabetic Kidney Disease Ambarish Athavale, Amit J. Joshi, Radhika Jaiswal, Albert M. Osei, Peter D. Hart. *Nephrology, Stroger Hosp of Cook County, Chicago, IL.*

Background: In ethnic minorities with type II Diabetes (DM) and "atypical" kidney disease, the frequency of non-diabetic glomerular disease is unknown and whether retinopathy correlates with Diabetic nephropathy (DN) is undetermined. Aim: 1.To describe prevalence of non-diabetic glomerular disease in patients with DM. 2.Correlate retinopathy with Diabetic nephropathy in patients with DM with atypical features.

Methods: Retrospective review of the medical records of 94 patients with DM who had kidney biopsy at our hospital between 01/2010 and 12/2015.

Results:

Age	54.5 ±9.5 yrs	
Gender (M: F)	45:49	
African American Hispanic White Asian/Pacific islander Other	49 36 4 4 1	
Diabetes duration	10 ±7.08 yrs	
Creatinine	2.5±2.1 mg/dl	
A1C	7.06±1.7	
Proteinuria	5.09±4.07 g/day	
Hematuria	49	
Atypical features that prompted kidney biopsy		
Unexplained rise in creatinine	25 (26.5%)	
Nephrotic syndrome, no retinopathy	24 (25.53%)	
Hematuria	9 (9.57%)	
Positive ANA	14 (14.89%)	
Low complements	4 (4.25%)	
Hepatitis C	7(7.44%)	
+ ANCA	4(4.25%)	
Monoclonal band	6(6.38%)	
	Retinopathy	No Retinopathy
DM Nephropathy	19	12
Non Diabetic glomerular disease	14	36
	33	48 (P<0.0001)

60% had non-diabetic glomerular disease and the most common were IgAN (14%) and FSGS (13%), 31% had Diabetic nephropathy and 9% had Diabetic nephropathy and another primary glomerular disease (most commonly arteriolar nephrosclerosis). Retinopathy information was available in 81/94 patients. 33/81 had retinopathy and 48/81 had no retinopathy. Presence of retinopathy did not accurately predict Diabetic nephropathy. Of 33 patients with retinopathy, 14/33 (42.42%) had a non-diabetic glomerular disease while 12/48 (25%) patients with no retinopathy also had Diabetic nephropathy.

Conclusions: Non-diabetic kidney disease is very common in Diabetic ethnic minorities with atypical features. Retinopathy did not reliably predict Diabetic nephropathy. Thus, atypical features, with or without retinopathy warrants kidney biopsy.

SA-PO749

Incidence of Peripheral Arterial Disease in Hemodialysis Patients in 2 Separate Dialysis Units David H. King,[1] Philip Davis,[2] Viyaasan Mahalingasivam,[1] Amrita Ramnarine,[1] Sumith C. Abeygunasekara,[1] Abdelgalil Abdelrahman Ali,[1] Iain C. Macdougall.[2] *[1]Renal Unit, Broomfield Hospital, Chelmsford, Essex, United Kingdom; [2]Renal Dept, Kings College Hospital, London, United Kingdom.*

Background: The true incidence of Peripheral Arterial Disease (PAD) in Chronic Kidney Disease (CKD) is unknown. Conventional Ankle/Brachial (ABI) screening is inaccurate in the presence of severe medial artery wall calcification as seen in CKD and diabetic patients. We have used a new instrument *BlueDop*^{TM},capable of achieving accurate PAD triaging in the presence of calcification.

Methods: *BlueDop™* Vascular Expert Technology was employed in the PAD screening role. This system does not require external compression of the calf arteries as used in conventional ABI systems. Dialysis patients were screened in two units A (City) and B (Urban), some 50 miles apart. Patients underwent a 4 minute test involving application of non-invasive Doppler Ultrasound to each leg with automatic PAD recognition by *BlueDop™*.

Results:

Number Pts/ Limbs	% Female Gender	% Caucasian Ethnicity	Mean Age yrs	% diabetic	% PAD	%diabetic +PAD	% non-diabetic +PAD
A 53/103	64	62	65	24	63	33	10
B 45/90	18	91	70	20	31	39	11

Conclusions: Incidence of PAD in the diabetic group in this study was 3.3 to 3.5 times that in the non-diabetic group. This was remarkably consistent between the 2 dialysis units despite large differences between them in gender mix, ethnicity and PAD incidence. Interestingly, although much has been published on the incidence of PAD in hospitalized diabetic patients, the data are subject to selection bias since, by definition, these patients have been referred as a result of ischemic symptoms. The strength of this study is that the findings are 'incidental' and not related to the reason for hospital attendance. Further work should be aimed at ascertaining whether early detection of PAD in this high-risk population may allow earlier intervention and treatment of this devastating condition.

Cross-Sectional Study of Chronic Kidney Disease Prevalence in Association with Monoinfected Patients Hepatitis C Virus in ANRS CO-22 Hepather Cohort

Eric Thervet,[1,2] Vincent Bonnemains,[2] Laurent Alric,[2,4] Jean-Jacques Boffa,[2,5] Philippe Mathurin,[6] Benedicte Stengel,[2] Fabrice Carrat,[2] Stanislas Pol,[1,3] Carole Cagnot,[7] Linda Wittkop.[2,8] *[1]Nephrology, HEGP, Paris05, France; [2]UMR970,U1223,UMR1136,UMR152,U1219, INSERM, France; [3]Hepatology, Cochin, Paris 05, France; [4]InternalMed-Dig, CHUToulouse3, France; [5]Nephrology, Tenon, Paris6, France; [6]Hepatology, CHULille, France; [7]ANRS, France; [8]ISPED, France.*

Background: Patients with chronic HCV infection have an increased risk of CKD. HCV is also more common in CKD patients than in the general population. The purpose of this study was to estimate the prevalence of ≥ stage3CKD in HCV patients and to look for correlation with the liver disease severity.

Methods: We analyzed the eGFR using CKDEPI formula in patients with a positive virus C serology in a multicenter observational prospective national cohort Hepather CO-22 (n = 20802). Exclusion criteria was kidney transplant recipients.

Results: The analysis included 8571 patients (pts). The characteristics were: 56% men;57 ± 20 years;30% hypertensive;HCV since 17 ± 13 years;detectable HCV RNA in 96%;genotype 1, 2, 3, 4 and 5/6/7 in 66%, 6%, 13%, 13% and 2%, respectively;40% of cirrhotic patients (96% Child A and MELD average 8 ± 3);and 59% previously treated with anti-viral (interferon and ribavirin in 67%). The prevalence of an eGFR≤60 ml/min was 6.3%. In univariate analysis, risk factors were sex, age, BMI, duration of infection, HCV treatment, diabetes, hypertension, high cholesterol, level of education, a history of heart disease, liver transplantation, the genotype but not the stage of fibrosis, cirrhosis and Child score. In multivariate analysis, predictors of CKD were:

Covariate	OR (CI 95%)	p
Age (10 yrs)	1,7 (1,6-1,9)	<0.01
HBP	4,4 (3,4-5,6)	<0.01
Diabetes	1,8 (1,0-2,4)	<0.03
Cardiopathy	1,6 (1,0-2,4)	<0.03
Hypercholesterolemia	1,4 (1,0-1,9)	<0.04

Conclusions: In our cohort, the CKD prevalence was 7.3% and was associated with age, hypertension, diabetes, hypercholesterolemia, and history of cardiac disease but not the severity of the liver disease. Longitudinal analysis will analyze the effect of anti-viral combinations on long-term renal function based on the usual nephropathy risk factors.

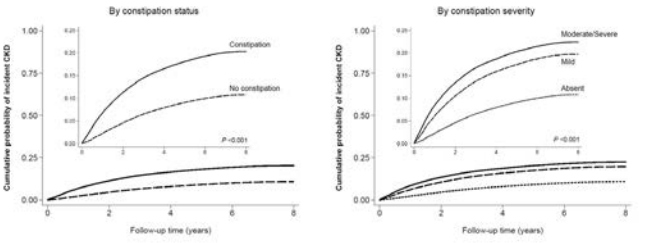
Constipation and Incident Chronic Kidney Disease

Keiichi Sumida,[1,2,3] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Elani Streja,[4] Kunihiro Matsushita,[2] Kunihiro Yamagata,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1,5] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Johns Hopkins School of Public Health, Baltimore, MD; [3]Univ of Tsukuba, Ibaraki, Japan; [4]Univ of California, Irvine, CA; [5]VA Medical Center, Memphis, TN.*

Background: Constipation is one of the most prevalent conditions in primary care settings, and it increases the risk of cardiovascular disease, potentially through inflammation by altered gut microbiota. Little is known about its association with incident CKD.

Methods: In a nationwide cohort of 3,504,732 U.S. veterans with eGFR ≥60 mL/min/1.73 m^2 between 2004 and 2006 and follow-up through 2013, we examined the association of constipation status and its severity (absent, mild, or moderate/severe), defined using ICD9 codes and laxative use, with incident CKD and ESRD, and change in eGFR in Cox (for time-to-event analyses) and multinomial logistic (for eGFR slope) regressions, with adjustment for sociodemographics, comorbidities and medications.

Results: The mean (SD) age was 60.0 (14.1) years; 93% were male; and 25% were diabetic. Patients with (vs. without) constipation had a higher multivariable adjusted risk of CKD (HR, 1.25; 95% CI, 1.24-1.27) and ESRD (HR, 1.17; 95% CI, 1.08-1.26), and experienced faster eGFR decline (multinomial ORs [95% CI] for eGFR slope <-10, -10 to <-5, and -5 to <-1, vs. -1 to <0 mL/min/1.73 m^2/year, 1.12 [1.10-1.15], 1.07 [1.05-1.09], and 1.03 [1.02-1.05], respectively). More severe constipation was associated with incremental risk for all renal outcomes.



Conclusions: Constipation status and its severity are independently associated with higher risk of incident CKD and ESRD, and with progressive eGFR decline. Further studies are needed to elucidate the underlying mechanisms and to determine whether the amelioration of constipation can prevent adverse renal outcomes.

External Validation of the Framingham Risk Score for Incident Chronic Kidney Disease at 10 Years in a Thai General Population

Chagriya Kitiyakara,[1] Krittika Saranburut,[2] Prin Vathesatogkit,[1] Nisakron Thongmung,[2] Piyamitr Sritara.[1] *[1]Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand; [2]Research Center, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.*

Background: A risk score for incident CKD has been developed for the general population using the Framingham Heart Study (FHS) Offspring cohort. This score has been validated in Caucasians, African-Americans, but has not in an Asian population. Thailand has among the highest rise in ESRD in the world. The ability to identify patients at high risk of CKD may be essential to reduce ESRD rates. We aim to assess the performance of the FHS CKD risk predictors for incident CKD at 10 years follow-up in a Thai general population cohort.

Methods: Employees of EGAT (The Electric Generating Authority of Thailand) were studied prospectively in 2002 and followed up in 2012 (n=2568). Incident CKD refers to subjects without CKD at baseline who develop CKD (GFR <60) at follow up. CKD was defined alternatively by MDRD or CKD-EPI. The performance of the FHS simplified risk score (developed using MDRD) and the FHS 5 variable algorithms (separate algorithms for MDRD or CKD-EPI) for predicting incident CKD were assessed. Differences between predicted and observed rate were compared using Hosmer-Lemeshow test. Discrimination was quantified by c statistic. Recalibration was performed to correct for differences in CKD and risk factors prevalence.

Results: After excluding CKD at baseline, 10.4% of subjects developed incident CKD by MDRD, and 10.0% developed incident CKD by CKD-EPI. For the original simplified risk score, the agreement between predicted and observed rates were not high (MDRD: $\chi2$ =30, P<0.001; CKD-EPI: $\chi2$ =256, p<0.001), and the discrimination were modest (AUC:MDRD, 0.69;CKD-EPI, 0.63). The observed versus predicted probability of CKD using the recalibrated FHS algorithm were fair: (MDRD $\chi2$ =19, p=0.015; CKD-EPI $\chi2$ = 20, p=0.01) with CKD-EPI having better discrimination (AUC: MDRD, 0.67; CKD-EPI, 0.75).

Conclusions: The CKD-EPI FHS algorithm performs well in estimating a Thai individual's 10-year probability of developing chronic kidney disease using clinical factors readily accessible in primary care.

SA-PO753

Association of Urine Sulfate with Death and Kidney Outcomes in Hypertensive Chronic Kidney Disease

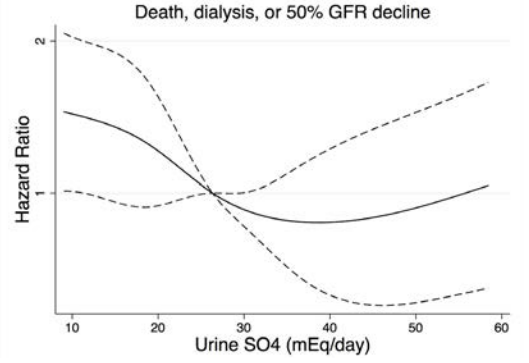
Kalani L. Raphael,[1] Jennifer L. Murray,[2] David J. Carroll,[1] Srini Beddhu.[1] *[1]Univ of Utah; [2]Colorado College.*

Background: The type of dietary protein, plant or animal, might be an important determinant of outcomes in chronic kidney disease (CKD) patients. We examined the association between urine sulfate excretion, an indicator of animal protein intake, with CKD progression and death in the African American Study of Kidney Disease and Hypertension (AASK).

Methods: Baseline urine [sulfate] (mEq/L) was measured by the barium precipitation method (n=1057). Daily sulfate excretion was calculated from 24-hour urine volumes. Participants were divided into tertiles of urine sulfate excretion (mEq/day). Cox and spline regression models related baseline urine sulfate excretion to the AASK primary composite outcome (death, dialysis or GFR reduction by 50%). Models were adjusted for demographics, randomized group, protein intake, urine potassium excretion, body mass index, measured GFR (mGFR), proteinuria, and serum bicarbonate at baseline. The lowest tertile was the reference group in the Cox model. The median sulfate excretion value was the reference in the spline model.

Results: Baseline characteristics were: age 54 years, 61% male, mGFR 47 ml/min per 1.73m^2, median proteinuria 81 mg/gm, and median urine sulfate excretion rate 26.3 (95%

CI 9.02-58.4) mEq/day. After adjustment, the hazard ratios of the composite outcome were 0.73 (95% CI, 0.56-0.96) in the middle tertile and 0.57 (95% CI, 0.39-0.85) in the highest tertile compared to the lowest tertile of sulfate excretion. Results were similar after adding blood pressure, heart disease, and smoking status in the model. Adjusted spline regression model showed higher risk of the composite outcome with lower urine sulfate excretion.



Conclusions: Lower urine sulfate excretion was associated with a higher risk of death and CKD progression in African Americans with hypertensive CKD independent of mGFR, proteinuria, protein intake, and other factors.

High Prevalence of Chronic Kidney Disease and Hypertension in the First 3 Years after Pediatric Cardiac Surgery Michael Zappitelli,[1] Chirag R. Parikh,[2] Steven G. Coca,[3] James S. Kaufman,[4] Paul L. Kimmel,[5] Marva M. Moxey-Mims,[5] Vernon M. Chinchilli,[6] Alan S. Go,[7] Prasad Devarajan.[8] *[1]Montreal Children's Hosp, McGill U, Montreal; [2]Yale U, New Haven; [3]Icahn School of Med Mount Sinai, New York; [4]VA New York Harbor Healthcare System, New York; [5]National Inst of Diabetes, Digestive and Kidney Disease, NIH, Bethesda; [6]Penn State Coll of Med, Hershey; [7]Kaiser Permanente Northern California, Oakland; [8]Cincinnati Children's Hosp, Cincinnati.*

Background: Late chronic kidney disease (CKD) and hypertension (HTN) outcomes after pediatric cardiac surgery (CS) are unclear. We determined CKD and HTN prevalence in the 3 years post-pediatric CS.

Methods: The **AS**sessment, **S**erial **E**valuation and **S**ubsequent **S**equelae in **AKI** study includes a prospective cohort of children having CS at Montreal and Cincinnati Hospitals. Children were recruited pre-CS, followed post-operatively (postop) and at 3, 12, 24 and 36 m post-discharge. AKI definition: ≥50% or ≥0.3 mg/dL serum creatinine (SCr) rise from baseline or dialysis. Follow-up included blood pressure (BP), SCr and Cystatin C-glomerular filtration rate (eGFR), urine albumin to creatinine ratio (ACR). HTN definition: systolic (Sys) or diastolic (Dia) BP ≥95th percentile for height, gender, age. CKD definition: eGFR< or ACR> normal for age. HTN and CKD prevalence was calculated in the whole cohort and in AKI *vs*.non-AKI groups.

Results: 124 children (52% boys, 46% AKI) were enrolled (11% loss/death over 3 years). In the whole cohort, CKD prevalence at 3, 12, 24, 36 m was 22, 32, 33, 34%, respectively. Similarly-defined CKD prevalence in the US general child population ranges from <2-12%. Follow-up HTN prevalence was 31, 28, 16, 22%, respectively, compared to general child population HTN prevalence of 1-4% (US/Canada population data). CKD or HTN prevalence did not significantly differ between AKI groups at any visit (p>0.05).

Conclusions: Within 3 years of pediatric CS, about one-third and one-fifth patients have CKD and HTN, respectively. This warrants close follow-up of children after CS, for renal and cardiovascular risk reduction.

SA-PO755

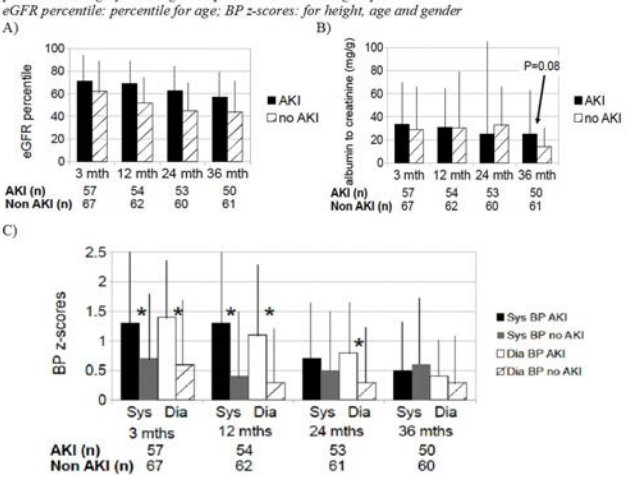
Renal Function and Blood Pressure Recovery 3 Years after Pediatric Cardiac Surgery-Associated Acute Kidney Injury: A Two-Center Study Michael Zappitelli,[1] Chirag R. Parikh,[2] Steven G. Coca,[3] James S. Kaufman,[4] Paul L. Kimmel,[5] Marva M. Moxey-Mims,[5] Vernon M. Chinchilli,[6] Alan S. Go,[7] Prasad Devarajan.[8] *[1]Montreal Child Hosp, McGill U, Montreal; [2]Yale U, New Haven; [3]Icahn School of Med Mount Sinai, New York; [4]VA New York Harbor Healthcare System, New York; [5]NIDDK, NIH, Bethesda; [6]Penn State Coll Med, Hershey; [7]Kaiser Permanente Northern California, Oakland; [8]Cincinnati Child Hosp, Cincinnati.*

Background: Long-term acute kidney injury (AKI) outcomes of pediatric cardiac surgery (CS) are unknown.

Methods: **AS**sessment, **S**erial **E**valuation and **S**ubsequent **S**equelae in **AKI** Study includes children having CS at Montreal and Cincinnati Hospitals, recruited pre-CS, followed postop and 3, 12, 24, 36m post-discharge. AKI definition: ≥50% or ≥0.3 mg/dL serum creatinine (SCr) rise from baseline or dialysis. Follow-up included SCr+Cystatin C-eGFR (age-adjusted percentile), urine albumin to creatinine ratio (ACR), systolic (SBP) and diastolic (DBP) blood pressure (age-gender-height z-scores). AKI *vs* non-AKI follow-up eGFR percentile, ACR and BP z-score were compared.

Results: Of 124 enrolled children undergoing CS, 11% died or were lost to follow-up in 3 years. 57(46%) had AKI. AKI patients were younger (median 7 *vs* 47m), had higher preop eGFR (mean 138 *vs* 110 ml/min/1.73m^2) and longer hospital stay (12 *vs* 10d)(p<0.05). eGFR percentile was higher in AKI patients at each follow-up (Fig). At 3, 12, 24m, AKI *vs.* non-AKI ACR were similar (Fig). At 36m ACR was within normal in both groups (Fig). AKI BP z-scores were significantly higher at 3 and 12m. AKI DBP was higher at 24m (Fig). By 36 m, BP z-scores were similar in both groups (Fig). In both groups, there was a reduction in eGFR, ACR and BP over time (Fig).

Figure. AKI *vs.* non-AKI eGFR percentile (A), ACR (B) and BP z-score(C) at 3, 12, 24 and 36 months post cardiac surgery discharge. * = p<0.05 between AKI groups.
eGFR percentile: percentile for age; BP z-scores: for height, age and gender



Conclusions: Although CS children experiencing AKI had elevated BP up to 24m post-CS, we observed no significant impact of AKI on eGFR or ACR at 36 m. AKI effects on BP resolved by 36m suggesting resilience to AKI in this population.

Funding: NIDDK Support

SA-PO756

Charles Comorbidity Index and the Progression of Renal Disease Filipa B. Mendes,[1] Joao Santos,[2] Luisa H. Pereira,[1] Ana Paula Silva,[1,2] Ana Marreiros,[3] Pedro Neves.[1,2] *[1]Nephrology Dept, Algarve Hospital Centre; [2]Dept of Biomedical Science, Algarve Univ; [3]Algarve Univ.*

Background: With the worldwide ageing of population, associated with the consequent comorbidities, chronic kidney disease (CKD) prevalence is progressively increasing. These conditions multiply the dependence on health care units and increase costs. Because comorbidities could be expected to worse the kidney function, the Charlson Comorbidity index (CCI) may have a role in the prediction of renal survival. In this study we evaluated the degree of comorbidities in a pre-dialysis population and investigated the relationships between the CCI and the renal progression disease.

Methods: A retrospective observational study included 693 patients, with an eGFR< 30 ml/min/1.73m^2, followed in a pre-dialysis clinic during a four years period (2008-2012). The population was divided into four groups according to the CCI: G1 (n=172)- CCI ≤ 5.2; G2 (n=162)- CCI 5.4-6.4; G3 (n=177)- CCI 6.5-7.4 and G4 (n=182)- CCI ≥ 7.5. Descriptive statistics, the ANOVA and the chi-square tests were used for comparison between groups. *Bonferroni* test was used as a post-hoc test. Multivariate and univariate logistic regressions for relationship between CCI and the other variables.

Results: The mean age of patients was 70.09 years, 54% (371) male gender and the mean eGFR (MDRD) was 20.17 ± 9.16 ml/min. When compared with the other groups, G1 showed lower age (p<0.001) and higher hemoglobin (p<0.001), eGFR (p=0.025), calcium (p=0.033) and albumin (p<0.001). In a multivariate logistic regression model adjusted to gender, phosphorus, eGFR, albumin and blood pressure, we found that CCI (OR= 1.297, 95% CI, 1.103–1.525 p=0.002), female gender (OR= 2.046, 95% CI, 1.272-3.292, p=0.003), phosphorus (OR=2.212; 95% CI, 1.576-3.105 p<0.001) and eGFR (OR=0.868 95% CI, 0.823-0.915 p<0.001) were independent risk factors for renal disease progression and renal replacement therapy. By the univariate logistic regression, G4 was a predictive factor for the progression of renal disease, when compared with G1 (OR: 1.622; 95% CI: 1.002–2.623 p=0.049).

Conclusions: In our study CCI was a strong predictor of renal disease progression in patients with chronic kidney disease stages IV-V.

SA-PO757

Oral Medicinal Charcoal Adsorbent Ameliorates Uremic Serum-Induced Intestinal Epithelial Barrier Disruption Shanshan Liang, Hongli Jiang. *Dialysis Dept of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong Univ.*

Background: Chronic kidney disease (CKD) causes intestinal barrier dysfunction which by allowing influx of endotoxin and other noxious products. Oral activated charcoal has been shown to markedly reduce plasma concentration of uremic toxins like indoxyl sulfate and p-cresol sulfate which are produced by the gut microbial flora.This study determined whether CKD-associated disruption of intestinal tight junction is mediated by activated charcoal adsorptive removal retained uremic toxins/ metabolites.

Methods: The human intestinal epithelial cells Caco2 were seeded on the Transwell plates and utilized when transepithelial electrical resistance (TEER) exceeded 500Ω*cm2 to ensure full polarization and TJ formation. The cells were then incubated for 24 h in media containing 10% serum from healthy individuals, 10% serum from regular hemodialysis patients(HD) or patients taking medicinal charcoal tablets(MCT) 2.7g/day, 3 times/day for 3 months also receive hemodialysis (HD-MCT). The serum of HD and HD-MCT were both collected after hemodialysis. TER was then measured and cells were processed for MTT assay and Western blot analyses.

Results: Compared with the controls, incubation in media containing serum from regular hemodialysis patients for 24h and 48h both resulted in a marked drop in TEER pointing to increased epithelial permeability. This was also accompanied by significant reductions in claudin-1, occluding, and ZO-1 protein abundance. The severity of TJ damage and dysfunction was significantly less in cells exposed to the HD as well as HD-MCT patients in comparison to HD serum. Cell viability and proliferation ability decreased significantly after treatment with HD serum compared with the HD-MCT and control group. These results point to the presence of as-yet unidentified product(s) in the uremic serum capable of depleting epithelial TJ and administration of medicinal charcoal tablets resulted in partial restoration of the epithelial TJ proteins.

Conclusions: Uremic milieu can impair the intestinal epithelial TJ and its barrier function, and administration of oral medicinal charcoal tablets attenuated uremia-induced disruption of intestinal epithelial TJ.

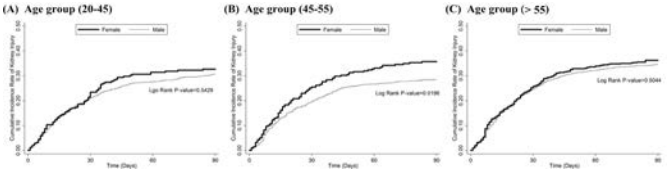
The Nephrotoxicity of Cisplatin May Have Gender Difference Chia-Chun Wu, Hsien-Yi Wang, Wei-Chih Kan. *Dept of Medicine, Div of Nephrology, Chi Mei Medical Center, Tainan, Taiwan.*

Background: Gender difference is reported in various diseases, in general, women seems have less common and less severe acute kidney injury and chronic kidney disease compare to men. However, female animals have more susceptibility of cisplatin induced nephrotoxicity(CIN) were reported.Herein, we want to know if the CIN has gender difference in human based on nation-wide population database.

Methods: The National Health Insurance Research Database in Taiwan was used to identify patients received cisplatin treatment for cancer therapy. Patients have any history of acute or chronic kidney disease before using cisplatin, have multiple cancer or sex organ cancer and younger than 20 years old were excluded. Outcome is defined as diagnosis of either acute or chronic kidney disease within 3 months after first cisplatin administration. Age, non-steroid anti-inflammatory disease, treatment with aminoglycoside or exposure of contrast media were regarded as confounding factors and adjusted. Subgroups according to age of childbearing, perimenopause and post menopause in women were further analysed.

Results: A total of 3973 male and 1154 female patients with cisplatin treatment were analysed. The mean age was 56.15±12.85 and 56.31±12.40 in male and female separately without significant difference. Overall, 37.4% of patients who treated cisplatin had CIN without significant difference between men and women. Age older than 55 years old, history of diabetes mellitus, higher Charlson comorbidity score and treated with aminoglycoside after cisplatin were risk factors of CIN. In different age groups, women in perirenopause stage have a 1.28 times higher risk of CIN compare with men in the same age.



Conclusions: Women in perimenopause stage have a greater risk of CIN compared with men. Estrogen level is higher in the stage of perimenopause, which might imply the the role of oestrogen in gender difference of CIN.

SA-PO759

The Renal Response to an Acute Protein Load Strongly Predicts Outcome in Chronic Kidney Disease Amelia Rita Bernasconi,[1] Ricardo M. Heguilen.[2] *[1]Medicine, Hospital Juan A Fernandez Univ de Buenos Aires, Buenos Aires, Argentina; [2]Nephrology, Hospital Juan A Fernandez Univ de Buenos Aires, Buenos Aires, Argentina.*

Background: Chronic kidney disease (CKD) characterizes by its progressive nature. In clinical studies, outcome measures include –among others-doubling serum creatinine (DSC), and/or the need for renal replacement therapy (RRT) but a single and reliable predictor has not been identified yet. The aim of this study was to evaluate the role of renal reserve (RR) as an early predictor of outcome in patients with CKD.

Methods: Consecutive adults with recent diagnosis of CKD whose RR was evaluated through an acute oral protein challenge were included in this study. They were grouped according to its RR index (RRI) in RR1 (RRI >1.3) or RR0 (RRI <1.3). The main outcome measure was DSC

Continuous variables are expressed as mean (sd) and categorical variables as frequency. Unpaired t-test, chi2 or Fischer's exact test were used as appropriate. Cox proportional hazard regression was used to estimate the hazard ratio (HR) for DSC, comparing RR0 with RR1, adjusting for age, sex, diabetes, hypertension, tobacco use, the presence of hyperuricemia or lipid abnormalities, baseline creatinine, urinary albumin etc. The Kaplan-Meier survival estimate along with the log-rank test to compare survival to DSC was calculated. p values < 0.05 were considered significant.

Results: 78 stages 1-3 CKD individuals (39 male) aging 21 to 72 years were assessed. Both groups were similar with regard to age, gender distribution, as well as baseline characteristics. There was a tendency for a higher baseline Scr in individuals from the RR0 group. The median survival to DSC was 51mo and 72mo in RR0 and RR1 respectively (p 0.03). After adjusting for potential covariates and confounders, the HR in RR0 was 2.75 (95%CI 1.02 – 7.43).

Conclusions: The inclusion of RR studies may help to generate an accurate model to predict outcome in CKD.

SA-PO760

Kidney Disease Progression and Associated Factors in HIV+ Patients Pedro Pereira Campos,[1] Iola Pinto,[3] Ana Luisa Papoila,[2] Karina Soto.[1,2] *[1]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal; [2]Bioestatistics, FCM, Univ Nova de Lisboa, Lisbon, Portugal; [3]Matematicas, ISEL, Lisbon, Portugal.*

Background: Chronic kidney disease is more prevalent in HIV+ patients than in the general population. Large studies have shown that the improved management of these patients has decreased HIV-related causes of CKD. We aimed to determine the evolution of kidney function in HIV infected patients, searching for early kidney dysfunction and its risk factors. Additionally, we studied the influence of serum Cystatin C on the eGFR of this cohort.

Methods: A longitudinal analysis was performed in 1761 consecutive HIV+ outpatients. Clinical data and laboratory analysis were registered prospectively at admission and biannually during 3y of follow-up. The primary endpoint was decreased kidney disease (eGFR ≤90 ml/min estimated by using the CKD-EPI based on serum creatinine (SCr-eGFR) and serum cystatin C (SCysC-eGFR). Univariable and multivariable mixed regression models were used.

Results: Among 1761 patients (mean age 45 CI38.0-53.0); 54.5% were male; 44% African ancestry 92.2% HIV type1; 24.4% Hypertension; 7.0% Diabetic. Mean CD4 count 477 (CI 326-649)cels/μL; viral load 68.2% <20 copies/mL. In univariable regression, the variables associated with significantly eGFR increase were: age (<0.001); DM (0.001); HT (<0.001); HVC (0.121); CVD (0.007); abacavir (0.039); atazanavir (0.200); and ritonavir (0.010). Multivariable results in table 1.

eGFR	OR	SE	z	P>z	95%CI	
AGE	1.116	0.015	8.00	0.000	1.08	1.14
Hipertension	2.098	0.512	3.03	0.002	1.30	3.38
HVC	2.282	0.782	2.41	0.016	1.16	4.46
ARV Ritonavir	1.783	0.397	2.60	0.009	1.15	2.75

CD4, viral load were not significant, whereas age, hypertension, virus C hepatitis, and only ritonavir among antiretroviral therapy were significantly associated with decreased eGFR. For each 0.1 mg/L of Cystatin C the eFGR decrease 3.10 mL/min.

Conclusions: Decreased kidney function in HIV patients remains frequent and is associated with traditional factors as age and hypertension, of those related to HIV only was associated with VCH and among antiretroviral therapy only ritonavir was determinant for kidney disease progression.

SA-PO761

Predicting Progression to Dialysis in Patients with Advanced Chronic Kidney Disease Wael F. Hussein, Rossana Rocco. *Dept of Nephrology, Tallaght Hospital, Trinity Health Kidney Centre, Dublin, Ireland.*

Background: Identifying patients at high risk for progression to dialysis initiation helps triaging care. The Kidney Failure Risk Equation (KFRE) developed using data from Canadian patients, and validated in multiple trial cohorts, gives a risk estimate for progression to dialysis. We aimed to validate the KFRE in patients with advanced chronic kidney disease in a clinical non-trial cohort.

Methods: Retrospective observational study on nephrology clinic patients in a large teaching hospital between Jan 2010 and Dec 2013. Patients with a stable eGFR between 15 and 20 ml/min/1.73 m^2 were included. Two year risk of progression was calculated using the eight variable (age; gender; eGFR; serum albumin, calcium, phosphate, and bicarbonate; and urinary albumin:creatinine ratio) KFRE. Kidney failure was defined as commencement of dialysis within 2 years from the inclusion date. Patients who received a pre-emptive kidney transplant, were lost to follow up or died before development of kidney failure were excluded. Performance of the KFRE was evaluated by comparing the predicted and the observed risk, Brier's score, and the area under the receiver operating characteristic curve (ROC-AUC).

Results: Of 3,901 nephrology patients, 199 satisfied the inclusion criteria. Of those, 1(0.5%), 8(4.0%) and 29 (14.6%) were excluded because of pre-emptive transplantation, loss to follow up and death respectively. Of 161 patients included in the final analysis, the median age was 70 years (IQR: 57 – 78), 78 (48%) were female, and 64 (32%) had diabetes. During the observation period, 33 patients (20%) required dialysis. Calibration of observed versus predicted risk of kidney failure across quartiles of predicted risk is shown in Table 1. Brier score was 0.13. The ROC-AUC was 0.761 (95% CI: 0.660 – 0.863).

Quartile of predicted risk	n	Mean predicted risk	Mean observed risk	n predicted	n observed
2.1 - 5.6%	42	3.9%	7.1%	2	3
- 11.1%	39	8.1%	10.3%	3	4
- 23.7%	40	18.0%	18.0%	7	7
- 79.6%	40	40.9%	47.5%	16	19

Conclusions: Among patients with advanced CKD, KFRE can identify high risk patients, and may be used to triage these patients to prepare for renal replacement therapy.

SA-PO762

Association between GSTM1 Copy Number and Incident End-Stage Renal Disease in the Atherosclerosis Risk in Communities (ARIC) Study Adrienne Tin,[1] Morgan Grams,[1] Robert B. Scharpf,[1] Michelle M. Estrella,[1] Megan Grove,[2] Dan Arking,[1] Eric Boerwinkle,[2] Josef Coresh.[1] *[1]Johns Hopkins Univ; [2]The Univ of Texas Health Science Center at Houston.*

Background: Glutathione S- transferase mu 1 (*GSTM1)* catalyzes the conjugation of glutathione with a range of electrophiles. Having 0 copies of *GSTM1* (*GSTM1-0*) has been associated with chronic kidney disease (CKD) progression in African American patients in the AASK trial. Whether *GSTM1-0* is associated with ESRD in the general population independent of hypertension and diabetes is unknown.

Methods: In the African American cohort of the ARIC study, we estimated *GSTM1* copy number using whole exome sequencing reads and ascertained ESRD events using linkage to the US Renal Data System (USRDS). We evaluated the association between *GSTM1* copy number and ESRD using Cox regression controlling for age, sex, baseline eGFR, prevalent diabetes and hypertension. We estimated the association between *GSTM1* copy number and ESRD in participants with and without 2 *APOL1* renal risk alleles.

Results: Of the 1924 African Americans in this study, 52% had hypertension and 16% had diabetes. The mean baseline eGFR was 112 mL/min/1.73 m^2. The median follow-up time was 23 years. *GSTM1-0* was significantly associated with 1.72-fold higher risk of ESRD compared with those with 2 copies of *GSTM1* (table, p-trend=0.04). When stratified by *APOL1* risk, *GSTM1-0* vs. 2 copies was associated with 2.43-fold higher risk of ESRD in those with 2 *APOL1* risk alleles and 1.6-fold high risk in those with 0/1 copy of the *APOL1* risk allele (p for interaction 0.70).

Conclusions: *GSTM1* was significantly associated with ESRD independent of traditional risk factors. These results are consistent with those reported from the AASK trial and extend the association between *GSTM1* and CKD to a population-based cohort. Our results suggest *GSTM1* is a potential treatment target for the prevention of CKD progression.

	Overall	*APOL1* 2 risk alleles	*APOL1* 0/1 risk allele
n (event)	1924 (125)	263 (20)	1661 (105)
	HR (95% CI)	**HR (95% CI)**	**HR (95% CI)**
GSTM1 0 copy	1.72 (1.03, 2.86)	2.43 (0.56, 10.6)	1.60 (0.93, 2.76)
GSTM1 1 copy	1.45 (0.92, 2.29)	2.19 (0.61, 7.86)	1.34 (0.82, 2.19)
GSTM1 2 copies	1.00	1.00	1.00

SA-PO763

Phosphate Balance and Outcome in Advanced CKD Antonio Bellasi,[1] Lucia Di Micco,[2] Domenico Russo,[3] Luca Di Lullo,[4] Andrea Galassi,[5] Mario Cozzolino,[6] Biagio Raffaele Di Iorio.[2] *[1]ASST-Lariana; [2]PO Landolfi; [3]Federico II Univ, Napoli; [4]Ospedale Parodi Delfino; [5]ASST Monza - Desio; [6]Univ of Milan.*

Background: Perturbation of phosphate homeostasis portends unfavorable outcome in CKD. Although some lines of evidence suggest an association with mortality, serum levels of phosphate poorly reflect phosphate balance. A considerable effort is devoted to definine new markers of phosphate homeostasis. We investigated the association of fraction excretion of phosphate (FeP) with relevant outcome in advanced CKD.

Methods: Retrospective, longitudinal study of 407 CKD subjects (age 66 years, 43% female, mean creatinine clearance 32 ml/min) receiving Nephrology care in Italy. Demographic and clinical characteristics were obtained at the time of referral. Routine laboratory and 24-urine collection were used. Risk of CKD progression to ESRD, all-cause mortality as well as the composite of the 2 were regarded as outcome of interest. ANOVA, logistic regression and survival analysis were used to compare patients' characteristics across quartiles of FeP, detect predictors of FeP and the association of FeP with the outcome of interest.

Results: Higher FeP was associated with older age, higher azotemia and PTH levels as well as lower creatinine clearance, serum phosphate and 24-h urine potassium excretion (all p-values<0.01). After adjustment for confounders, abnormal FeP (>20%) was inversely associated with creatinine clearance (B-0.03, p=0.006), diastolic blood pressure (B-0.04, p=0.01) and serum phosphate (B-0.43, p=0.008). Independent of multiple adjustments, a graded and independent association between quartiles of FeP and ESRD but not all-cause mortality was detected.

Risk/quartile of FeP	Low	Mid-Low	Mid-High	High
ESRD	ref	3.28(0.87-12.3)	7.33(2.13-25.1)	12.3(3.64-41.7)
Mortality	ref	1.44(0.83-2.48)	1.68(0.98-2.88)	1.33(0.72-2.45)
Composite	ref	2.01(1.22-3.31)	2.29(1.41-3.70)	2.39(1.44-3.99)

Conclusions: FeP is associated with ESRD but not all-cause mortality risk in a large cohort of advanced CKD patients. Future efforts are required to validate FeP as a marker of phosphate balance and if CKD progression explains the risk burden of phosphate imbalances in this high-risk population.

Funding: Government Support - Non-U.S.

SA-PO764

Acute Kidney Injury, Proteinuria, Glycemic Control, and Kidney Disease Progression in Diabetes Mellitus Mollie Y. Sands, Anthony C. Leonard, Charuhas V. Thakar. *Univ of Cincinnati, Cincinnati, OH.*

Background: Acute kidney injury (AKI), proteinuria (PU), and glycemic control (A1c), are each known to influence the risk of chronic kidney disease (CKD) in diabetics. The relationship between these risk factors and CKD progression is not well studied.

Methods: In a de-identified Veterans Affairs cohort of 3,679 type 2 diabetics (T2D) with baseline glomerular filtration rate (eGFR) > 30ml/min (followed between 1999 and 2008, inpatient and outpatient), we examined relationships between PU, AKI (during hospitalizations), and mean A1c > 7 (averaged for study period) as major predictors. CKD progression outcomes were: annualized mean glomerular filtration rate (eGFR) decline; rapid decline (eGFR decline > 5 ml/min/year); and reaching Stage IV CKD. Logistic regression and Cox models (adjusted for demographics, co-morbidities and baseline eGFR) generated risk estimates expressed as odds and hazard ratios (OR, HR) with 95% confidence intervals (CI). The sample was 97.7% male (mean age of 61.7 yr), with mean baseline eGFR of 79.7 ml/min.

Results: Linear rates of eGFR decline across 3 risk groups [High (N = 421) mean A1c > 7, PU, and AKI; Medium (N=2,134) 1-2 of these risk factors present; Low (N=1,124) 0 present] showed a mean annual rate of decline of 4.33, 2.88 and 2.29 ml/min respectively (ANOVA p = 0.005; adjusted ANOVA p = 0.002). Overall, 14% (N=503) reached Stage IV CKD; compared to low-risk, the high-risk group was more likely to do so (adjusted OR, 7.2, 95% CI 5.1 – 10.1). For the rapid decliner outcome (N=903) logistic regression models showed significant positive interactions between PU and mean A1c >7 (p = .005), and between PU and AKI (p = .007). The crude mortality rate was higher in rapid decliners (27.2% vs others 20.1%; p< .0001); as well as in those reaching Stage IV CKD (36.2% vs 19.8% in others; p < .0001).

Conclusions: Diabetics with AKI, PU, and mean A1c > 7 experience faster rates of linear eGFR decline, and are 7-fold more likely to reach Stage IV CKD than those without these risk factors. The effect of two risk factors at once (AKI and PU, or PU and mean A1c > 7) imparts more than respective additive effects on the rapid decliner outcome.

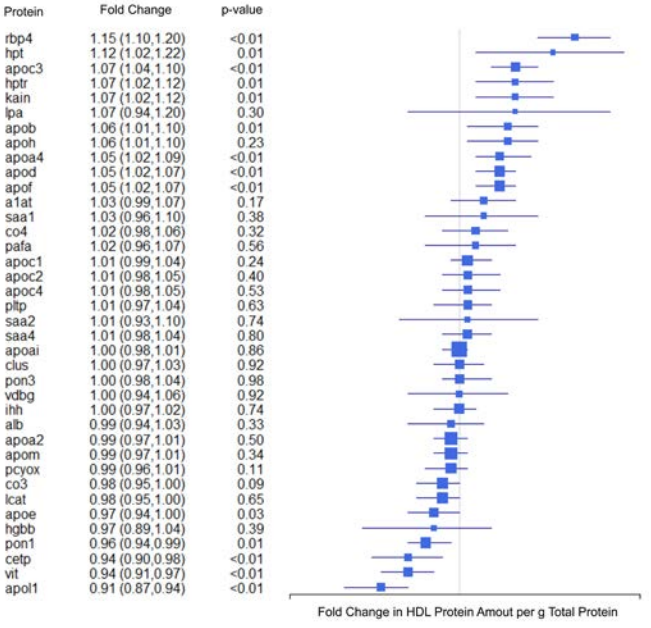
Protein Composition of High Density Lipoprotein Varies with Progression of Chronic Kidney Disease Andrew N. Hoofnagle, Cassianne Robinson-Cohen, Ian H. De Boer, Bryan R. Kestenbaum. *Univ of Washington, Seattle, WA.*

Background: High density lipoprotein (HDL) particles contain a heterogeneous composition of proteins of humoral and cellular origin and serve important anti-atherosclerotic functions. HDL particles from chronic dialysis patients are enriched in several proteins involved in inflammation, vitamin binding, and lipoprotein metabolism. We used novel mass spectrometric methods to characterize the protein composition of HDL particles across the spectrum of kidney function.

Methods: We analyzed plasma samples of 507 participants from the Seattle Kidney Study, a clinic-based prospective study of chronic kidney disease (CKD). We used sequential density gradient ultracentrifugation to isolate the HDL fraction. HDL proteins were quantified using trypsin digestion and liquid chromatography-tandem mass spectrometry. We used linear regression to estimate associations of each 15 ml/min/1.73m^2 lower estimated glomerular filtration rate (GFR) with the log transformed concentration of each HDL protein after adjustment for age, race, sex, diabetes, body mass index, smoking, and statin use.

Results: Mean participant age was 58 ±14 years, 24% were African American, 33% were female, and 50% had diabetes. The mean estimated GFR was 45 ±26 ml/min/1.73m^2 and the mean plasma HDL cholesterol concentration was 42 ±17 mg/dL. Lower estimated GFR was associated with significant differences in the concentration (per g total HDL protein) of multiple proteins within HDL. After full adjustment and accounting for multiple comparisons, lower estimated GFR was significantly associated with higher HDL concentrations of retinol binding protein 4, apoC-III, apoF, and lower HDL concentrations of vitronectin and apoL1.



Conclusions: In CKD patients not requiring dialysis, decreased kidney function is associated with significant differences in the amounts of several proteins within HDL.

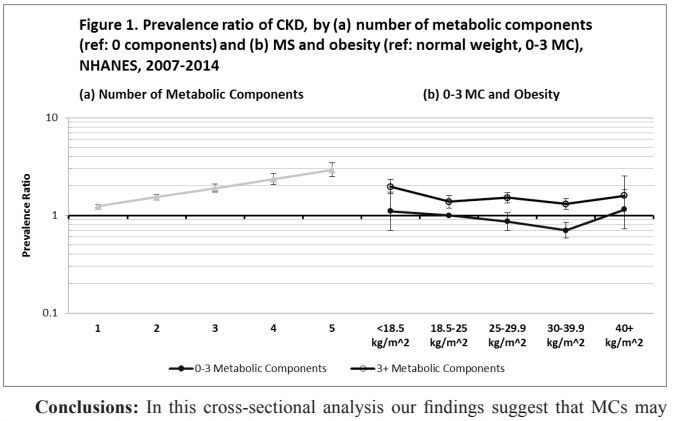
Metabolic Components and Chronic Kidney Disease (CKD) Prevalence in the United States Patrick J. Albertus,[1] Jennifer L. Bragg-Gresham,[1] Hal Morgenstern,[1] Chi-Yuan Hsu,[2] Neil R. Powe,[2] Rajiv Saran.[1] *[1]KECC, Univ of Michigan; [2]Univ of California San Francisco.*

Background: Obesity is thought to affect CKD risk. We examined the association between the metabolic components (MC) related to obesity and CKD in a national sample.

Methods: The analysis included participants ≥20 years old in the National Health and Nutrition Examination Survey 2007-14. CKD was defined as eGFR<60 ml/min/1.73^2 or urine albumin-to-creatinine ratio≥30 mg/g. We measured 5 binary MCs: fasting glucose≥100 mg/dL or diabetes (HbA1c≥7%, self-reported diagnosis, or medication); high density lipoprotein<40 mg/dL for men or <50 mg/dL for women; triglycerides≥150 mg/dL; systolic blood pressure>130 mmHg or diastolic blood pressure>85 mmHg, or hypertension medication; and waist circumference>40" for men or >35" for women. Modified Poisson regression was used to estimate the association (prevalence ratio [PR] and 95% CI) between MCs and CKD prevalence, adjusting for age, sex, race/ethnicity, family income, education, serum albumin, and (with/without) body mass index (BMI).

Results: Among 9,673 subjects, the proportion with ≥3 MCs was 37.8%. Compared with subjects with <3 MCs, in those with ≥3 MCs the adjusted PR of CKD was 1.6 (1.5, 1.8) without BMI adjustment and 1.6 (1.4, 1.7) with BMI adjustment. A higher number of MCs was associated with higher prevalence of CKD (Fig 1.a). Additionally, adjustment for the number of MCs resulted in little association between BMI and CKD prevalence (Fig 1.b).



Conclusions: In this cross-sectional analysis our findings suggest that MCs may incrementally increase the risk of CKD and that there may be little or no effect of BMI on CKD beyond these MCs.

ErbB4 Deletion Induced Metabolic Syndrome in Mice on a High Energy Diet Fenghua Zeng, Lance A. Kloepfer, Raymond C. Harris. *Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Patients with obesity and diabetes have a higher risk to develop chronic kidney diseases. Although reports have indicated a possible relationship between decreased ErbB4 expression and diabetic nephropathy, its role in the development of diabetes has not been previously examined.

Methods: Heart rescued ErbB4 deletion (ErbB4^{del}ht$^+$) and wild-type (WT) mice were fed a high energy diet (HED) that contains 11% fat. Body weight, blood glucose, and lipid profile were measured. Insulin sensitivity were studied using IPGTT and IPITT.

Results: ErbB4^{del}ht$^+$ and WT mice were fed the HED after weaning when they had similar body weight. At 20-week of age compared to WT mice, ErbB4^{del}ht$^+$ mice developed metabolic syndrome manifested by increased body weight and fat weight; hyperglycemia; abnormal IPGTT, IPITT, and increased HOMA-IR index; and dyslipidemia shown by elevated levels of free fatty acid, cholesterol, triglycerides, and LDLcholesterol. Even though serum leptin levels were significantly increased in ErbB4^{del}ht$^+$ mice, there were no differences in food intake from controls. Serum adiponectin tended to be reduced in ErbB4^{del}ht$^+$ mice. Pathologically, ErbB4^{del}ht$^+$ mice developed severe liver steatosis, and larger adipocytes with large lipid droplets. Severe inflammation was predominantly detected in epididymal white adipose tissue (eWAT) demonstrated by increased F4/80 immunoreactivity and widely spread crown-like structures, with increased mRNA levels of iNOS, an M1 macrophage marker, with no significant changes of Arg1 expression, a marker for M2 macrophage. The mRNA levels of proinflammatory cytokines, TNF-α, MCP1/CCL2, and CXCL1, were significantly increased in the eWAT of ErbB4^{del}ht$^+$ mice. There was no significant changes in the mRNA levels of IL-10 and IL-4, the antiinflammatory cytokines.

Conclusions: Our findings suggested ErbB4 is involved in energy homeostasis possibly through regulating insulin sensitivity and inflammation in adipose tissues, and may constitute a novel therapeutic target for the treatment of obesity and diabetes.

Obesity Predicts Steeper Measured Glomerular Filtration Rate Decline in a Non-Diabetic General Population Vidar T.N. Stefansson,[1] Jørgen Schei,[1,2] Trond G. Jenssen,[1,3] Toralf Melsom,[1,2] Bjorn Odvar Eriksen.[1,2] *[1]Metabolic and Renal Research Group, UiT The Arctic Univ of Norway, Tromsø, Norway; [2]Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; [3]Dept of Organ Transplantation, Oslo Univ Hospital, Oslo, Norway.*

Background: Obesity is associated with an increased risk of end-stage renal disease. Hypertension and diabetes are established mediators of the effect of obesity on kidney function. Whether obesity also contributes directly to the wide variation in age-related decline in the glomerular filtration rate (GFR) seen in healthy persons, is unknown. Previous studies of obesity and GFR decline have shown mixed results, depending on whether creatinine or cystatin C was used to estimate GFR. These estimates are confounded by non-GFR-related factors, and are inaccurate in the normal and high ranges of GFR. We aimed to explore the relationship between obesity and the measured GFR (mGFR) decline rate.

Methods: GFR was measured using iohexol clearance in 1594 non-diabetic middle-aged subjects without cardiovascular or renal disease from the general population. The study was repeated after a median observation time of 5.6 years in 1324 (83%) subjects in the Renal Iohexol Clearance Survey Follow-Up (RENIS-FU) study. Obesity was measured using the body mass index (BMI), waist circumference, the waist-hip ratio, and estimated body fat percentage (BFP). The mGFR decline rate was analyzed using multivariable adjusted linear mixed models, and non-linear relationships were explored using fractional polynomial transformations.

Results: The mean (SD) mGFR decline rate was -0.95 (2.23) ml/min/year. The obesity variables were not linearly associated with a change in the mGFR decline rate in multivariable adjusted linear mixed models. However, statistically significant non-linear relationships were found between the mGFR decline rate and both BMI and estimated BFP in separate models ($p<0.05$). For BMI, the mGFR decline rates were -0.93, -0.94, -1.13, -1.60 and -2.44 mL/min/year at 25, 30, 35, 40 and 45 kg/m^2, respectively. A similar pattern was observed in relation to BFP.

Conclusions: Severe obesity contributes to a steeper age-related mGFR decline in the non-diabetic general population.

SA-PO769

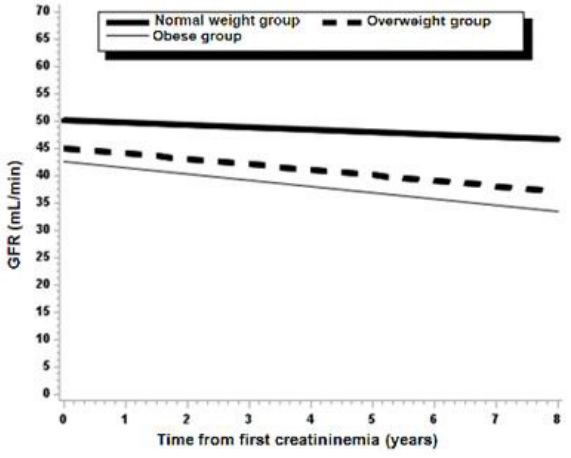
Overweight Is Associated with Chronic Kidney Disease Progression Louis De Laforcade,[1] Christelle Maurice,[3] Maurice Laville.[1,2,3] *[1]Dpt of Nephrology, Hospices Civils de Lyon, Pierre Bénite, France; [2]INSERM Unit 1060 CarMeN, Univ Lyon I Claude Bernard, Oullins, France; [3]TIRCEL Renal Care Network, Lyon, France.*

Background: Obesity and overweight are frequent in patients suffering from chronic kidney disease (CKD). Previous studies are discordant about the link between CKD progression and body mass index (BMI). We examined the database of our renal care network to study CKD course according to BMI.

Methods: We analyzed patients followed in the renal care network. All patients with two serum creatinine (Scr) values at an interval of 6 months or more were included. Patients with glomerular filtration rate (eGFR, MDRD equation) below 15 mL/min were excluded.

Standard demographic data, SCr, eGFR, and main comorbidities were recorded. Patients were divided into three groups: normal weight (NW : BMI < 25kg/m²), overweight (OW : BMI 25 - 30 kg/m²) and obesity (OB : BMI > 30 kg/m²). The slope of eGFR decrease was compared between the 3 groups using a mixed-model approach.

Results: 1203 patients were included, with a maximal follow-up of 8 years. Men accounted for 53% of the study population, median age was 67 years, 11% of the patients were diabetic. According to BMI, 44% were in the NW group, 36% in the OW group and 20% in the OB group. eGFR ranged between 60 and 30 mL/min in 58 % patients, between 30 and 15 mL/min in 20%. The slope of eGFR decrease was significantly lower in NW (- 0.43mL/min per year) than in OW (-1mL/min per year) or OB group (- 1.15 mL/min per year ; p = 0.002 between three groups). This difference persisted after adjustement on sex, age, systolic blood pressure and weight changes in our mixed-model approach.



Conclusions: Obesity and overweight are associated with a faster decrease of renal function in CKD patients. This relationship had been previously studied Asiatic or North American patients, but our study is the first to show this association in Continental Europe.

SA-PO770

Psoriasis as a Systemic Disease: Kidney Involvement Lisa Giovannini,[1] Andrea Conti,[2] Gianni Cappelli.[1] *[1]Dept of Surgery, Medical and Dentistry, Univ Hospital of Modena, Modena, Italy; [2]Dept of Specialist Surgery, Unit of Dematology, Univ Hospital of Modena, Modena, Italy.*

Background: Studies to date examining kidney disease in patients with psoriasis have primarily small sample sizes and have yielded conflicting results. However, renal involvement in course of psoriasis could not be an infrequent event.

Methods: We determined prevalence of CKD by estimating GFR (CKD-EPI GFR) and albuminuria in moderate-severe psoriatic patients, according to KDIGO guidelines. Urinary albumin was detected by turbidimetric immunoassay. Student's t and Chi squared tests were used to compare continuous or categorical data. Forward multiple linear regression analysis assessed possible influences on microalbuminuria. ROC analysis tested the variable "duration disease" to microalbuminuria occurrence.

Results: 219 patients gave informed consent and entered the study. Prevalence of AUCR>30mg/gr was 17,35%. Indeed, 17,35%, 5,02%, 3,66% of our population showed a moderately increased, a high, and a very high risk of CKD respectively. Cumulative Cyclosporine dose explained significantly AUCR according to multiple regression analysis (p<0,0001). In the adjusted cohort of CKD risk-factors free pts, prevalence of microalbuminuria was 12.79%. Presence of arthritis (p<0,0001), disease duration (p<0.0001) and actual PASI score (p<0,001) demonstrated a positive correlation with microalbuminuria. Patients with psoriatic arthritis had 14 times more probability to show a microalbuminuria than psoriatic patients without arthritis (p=0.0001; OR 14,25; 95%CI: 2,815 to 72,12). A long time psoriasis higher than 21 years added 106.5 time risk to present microalbuminuria (p<0,0001; OR 106.5; 95%CI 5.902 to 1921) with comparable age, BMI and eGFR. At the same time, long time psoriasis (>21years) arthritic patients have OR 1,88 to present microalbuminuria.

Conclusions: Duration of disease and psoriatic arthritis have a strong independent association with microalbuminuria. Patients with psoriatic arthritis, especially with a disease duration longer than 21 years, should be routinely screened for microalbuminuria for a more comprehensive management.

SA-PO771

Estrogen Receptor b Hinders Renal Fibrosis in Obstructive Nephropathy by Selectively Inhibiting Snail 1-Induced Renal Tubular Epithelial Cells Epithelial to Mesenchymal Transition Rong Cao, Yongcheng He. *Dept of Nephrology, The First Affiliated Hospital of Shenzhen Univ, Shenzhen, Guangdong, China.*

Background: Renal fibrosis is the final common pathway of virtually all kinds of progressive CKD(Chronic Kidney Disease) leading to ESRD(End-Stage Renal Disease). Estrogen Receptor β (ERβ) is a nuclear transcription factor, and increasing evidence suggests that ERβ can delay the progress of a variety of tissue fibrosis, but the role of ERβ in renal fibrosis is still unknown. The purpose of this study is to investigate the effect of ERβ in renal fibrosis and its underlying mechanism.

Methods: 40 biopsy-proven CKD patients were collected .The model of unilateral ureteral obstruction (UUO) was used in vivo, and mouse primary renal tubular epithelial cells(PTECs)were treated with TGFβ1 in vitro.

Results: 1)The expression of ERβ and snail 1were significantly down-regulated in fibrotic renal tissues among the 40 biopsy-proven CKD patients. Besides, both ERβ mRNA and protein were decreased in UUO mice,compared with the sham group. 2)ERβ was widely expressed in mouse kidney, highest in the cortex, followed by the outer medulla and inner medulla.Moreover, ERβ was also expressed in mouse primary renal tubular epithelial cells . 3)UUO mice exhibited marked interstitial inflammation and fibrosis in renal tissue stained with hematoxylin and eosin and Masson's trichrome. However, treatment with DPN, a specific agonist of ERβ, 5 days after UUO operation, significantly reduced inflammatory cell infiltration and interstitial fibrosis score. What's more, UUO-induced renal fibrosis was aggravated in ERβ knockout mice, compared with the WT mice. 4)DPN can significantly decrease collagen production in PTECs and reduce TGFβ1-induced PTECs EMT. Consistent with this, treated with ERβ-siRNA, collagen production and cell migration were increased in PTECs. 5) Over expression of snail 1 by plasmid can increase collagen production in PTECs and reduce TGFβ1-induced PTECs EMT.

Conclusions: ERβ hinders renal fibrosis in obstructive nephropathy by selectively inhibiting snail 1-induced renal tubular epithelial cells Epithelial to Mesenchymal Transition.

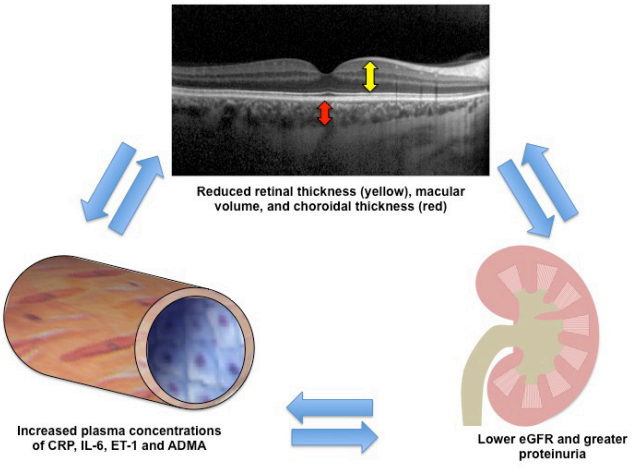
Chorioretinal Thinning in Chronic Kidney Disease Links to Inflammation and Endothelial Dysfunction Neeraj Dhaun. *Centre for Cardiovascular Sciences, Univ of Edinburgh.*

Background: Chronic kidney disease (CKD) is strongly associated with cardiovascular disease (CVD) and there is an established association between vasculopathy affecting the kidney and eye. Optical coherence tomography (OCT) is a novel, rapid method for high-definition imaging of the retina and choroid. Its use in patients at high CVD risk remains unexplored.

Methods: We used the new SPECTRALIS OCT machine to examine retinal and retinal nerve fibre layer (RNFL) thickness, macular volume and choroidal thickness in a prospective cross-sectional study in 150 subjects – 50 patients with hypertension, 50 with CKD and 50 matched healthy controls. The same, masked ophthalmologist carried out each study. Plasma IL-6, TNFα, ADMA, and ET-1, as measures of inflammation and endothelial function, were also assessed.

Results: Retinal thickness, macular volume and choroidal thickness were all reduced in CKD patients compared to hypertension and health (p<0.001 for CKD *vs.* both hypertension and health for each). RNFL thickness did not differ between groups. Interestingly, a thinner choroid was associated with a lower eGFR (p<0.0001) and, in CKD, with greater proteinuria as well as increased plasma concentrations of CRP, IL-6, ADMA and ET-1 (all p<0.05). Finally, choroidal thickness associated inversely with renal histological inflammation and arterial stiffness. In a model of hypertension, choroidal thinning was seen only in the presence of renal injury.

Conclusions: The decreases in chorioretinal thicknesses in CKD are associated with lower eGFR and higher proteinuria but not blood pressure. Larger studies, in more diverse groups of CKD patients, are now warranted to clarify whether these eye changes reflect kidney pathology and the natural history of CKD. Similarly, the associations with measures of arterial stiffness, inflammation and endothelial dysfunction should be examined further.



SA-PO773

Nuclear Phosphatase, SCP4 Interacts with the FOXOs Transcriptional Factors Contributing to Muscle Wasting in Chronic Kidney Disease

Xinyan Liu,[1] Yanlin Wang,[2] William E. Mitch,[2] Zhaoyong Hu.[2] *[1]Nephrology Div, The 2nd Hospital of Shanxi Medical Univ, Tianyuan, Shanxi, China; [2]Nephrology Div, Balyor College of Medicine, Houston, TX.*

Background: Chronic kidney disease (CKD) and related inflammatory cytokines stimulate protein-energy wasting (PEW), a complication which manifests sustainably loss of muscle mass. The mechanisms leading to muscle wasting are complex but primarily resulting from accelerated protein degradation and activation of autophagic/lysosomal and proteasomal pathways. However, the regulation of these proteolysis pathways during muscle wasting remains unclear. We examined how a novel nuclear phosphatase, SCP4 (Small C-terminal Phosphatase 4) influences muscle protein metabolism by regulating FoxO transcription factors.

Methods: We measured protein synthesis and degradation in C2C12 cells with knockdown or forced-expression of SCP4 and examined the signaling pathway by which SCP4 regulates muscle protein metabolism. In muscles of CKD mice, we tested if knockdown of SCP4 ameliorates the loss of muscle protein.

Results: In muscle cell cultures, overexpression of SCP4 stimulates muscle proteolysis; conversely, knockdown SCP4 prevent cytokines and serum starvation induced muscle protein loss. SCP4 overexpression causes FOXO1/3a accumulation in nuclei and this response is accompanied by induction of atrogin-1/MuRF-1 and activation of autophagic pathway. Treatment of myotubes with proinflammatory cytokines stimulates SCP4 expression and NF-κB mediates this response. In muscle of CKD mice, SCP4 is up-regulated. Similar results are also observed in muscles of patients with CKD. Mice with SCP4 knockout or knocking down SCP4 by electroporation of SCP4 shRNA in muscle decrease FoxO1/3a nuclear accumulation and transcription activities despite of CKD. These led to suppression of protein degradation and maintain muscle mass.

Conclusions: SCP4 expression stimulates muscles proteolysis in CKD. Targeting SCP4 may prevent muscle wasting in CKD and perhaps other catabolic conditions.

Magnetic Resonance Imaging Sensitive to Hypoxia and Fibrosis in a Multi-Center Study of Chronic Kidney Disease

Pottumarthi V. Prasad, Wei Li, Eugene Dunkle, Ying Zhou, Stuart M. Sprague, Combine Investigators. *NorthShore Univ HealthSystem, Evanston, IL.*

Background: Renal hypoxia and interstitial fibrosis are key contributors to CKD progression according to chronic hypoxia theory [PMID: 9551436]. Phosphate and FGF23 excess have been linked to accelerated CKD progression. COMBINE (CKD Optimal Management with Binders and Nicotinamide) is a multicenter trial to test whether nicotinamide and lanthanum carbonate will safely lower serum phosphate and FGF23 levels in an attempt to prevent cardiovascular and progressive renal disease compared to placebo. In this study, we evaluated both renal cortical oxygenation and diffusion coefficients using blood oxygenation level dependent (BOLD) and diffusion MRI at baseline in subjects participating in COMBINE and compared them to measures in a cohort of healthy subjects with no known renal disease.

Methods: To-date data was available for a total of 98 subjects with CKD (age=65.8±11.9 years; eGFR=33.0±7.1 ml/min/1.73m^2) and 29 healthy controls (age=41.3±18.9 years; eGFR=99.3±17.4 ml/min/1.73m^2). BOLD and Diffusion MRI data was acquired on a 3.0 T scanner. BOLD MRI measurements were repeated following administration of 20 mg *i.v*. of furosemide. Large cortical and whole kidney regions of interest (ROI) were used for analysis [PMID: 26193455]. Lower oxygenation should result in higher R2* values and presence of fibrosis should result in lower apparent diffusion coefficient (ADC).

Results: Both cortical R2* (20.6±3.4 *vs*. 18.0±1.62 s^{-1}; p<0.0001) and ADC (1460.0±165.5 *vs*. 1715.5±92.0 mm^2/s; p<0.0001) were significantly different in CKD compared to controls. Further the response to furosemide was significantly reduced in CKD (1.0±0.9 *vs*. 2.3±1.1 s^{-1}; p<0.0001). All the three MRI measures showed significant correlation with eGFR (ρ(R2*)=-0.34 (p=0.0003); ρ(ADC)= 0.41 (p<0.0001); ρ(Kid_Delta_R2*=0.48 (p<0.0001)). Even though age was found to be a confounder, in an age matched subset, all three parameters were significantly different between the two groups.

Conclusions: The lower cortical oxygenation and decrease in cortical diffusion coefficients in CKD are consistent with increased hypoxia and presence of fibrosis and support the chronic hypoxia hypothesis.

SA-PO775

Urinary Human L-Type Fatty Acid Binding Protein on Chronic Phase Reflects the Degree of Chronic Tubular Loss after Ischemia-Reperfusion Renal Injury

Daisuke Ichikawa,[1] Atsuko Ikemori,[1,2] Takeshi Sugaya,[1] Mikako Hisamichi,[1] Kenjiro Kimura,[3] Yugo Shibagaki.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine; [2]Anatomy, St. Marianna Univ School of Medicine; [3]Tokyo Takanawa Hospital.*

Background: AKI is an important risk factor for onset of CKD and notable detector of chronic tubular loss after AKI is needed for monitoring the CKD after AKI. The aim of this study is to elucidate that urinary human L-type fatty acid binding protein (hL-FABP) on chronic phase is associated with the degree of tubular loss on chronic phase after AKI.

Methods: Male hL-FABP chromosomal transgenic (Tg) mice were subjected to ischemic reperfusion (I/R) model. The Tg mice were divided into three groups: short duration ischemia group (short-I/R) received procedure of renal ischemia induced by left renal artery clamping for 10 min; long duration ischemia group (long-I/R) received ischemia for 20 min; and the sham operated group. Contralateral nephrectomy was performed at the same time of tissue reperfusions. Kidneys were obtained 20 days after last I/R.

Results: Although serum creatinine levels at 1 and 20 days after I/R in the short-I/R mice were similar to those in the control mice, these levels in the long-I/R mice were significantly higher than in the short-I/R and control mice. Urinary hL-FABP levels at 1 day after I/R were significantly higher in the long-I/R mice than in the short-I/R and control mice, and in the short-I/R than in the control mice. Urinary L-FABP levels at 20 days after I/R in the long-I/R mice were significantly higher than those in the control mice, and tended to be higher than those in the short-I/R mice. The degree of MCP-1 protein expression, macrophage infiltration, tubular damage and renal fibrosis at 20 days after I/R were significantly more severe in the long-I/R than in the short-I/R and the control mice, and in the short-I/R than in the control mice. Urinary L-FABP levels at 20 days after I/R were significantly correlated with the degree of renal damage.

Conclusions: Urinary L-FABP on chronic phase reflects the degree of chronic tubular loss after I/R and, therefore, may be useful for monitoring the CKD after AKI in clinical practice.

SA-PO776

Relationships of Dietary Phosphate Intake and Serum Phosphate with Clinical Outcomes in Chronic Kidney Disease Stages 3-5: Findings from the KoreaN Cohort Study for Outcome in Patients with Chronic Kidney Disease (KNOW-CKD) Study

Yong Un Kang,[1] Ha Yeon Kim,[1] Chang Seong Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Kook-Hwan Oh,[2] Soo Wan Kim,[1] Curie Ahn.[2] *[1]Chonnam National Univ Medical School; [2]Seoul National Univ Hospital.*

Background: We investigated the relationships of dietary phosphate intake and serum phosphate with clinical outcomes in chronic kidney disease (CKD) stages 3-5.

Methods: We collected the data of 849 CKD stage 3-5 non-dialysis patients from a prospective cohort study (KNOW-CKD). A renal event is defined by a >50% decrease inestimated glomerular filtration rate (eGFR) from the baseline values, doubling of serum creatinine, or end stage renal disease. CV event is defined myocardial infarction (fatal and nonfatal), coronary revascularization, stroke and new onset or aggravation of congestive heart failure. We used multivariate logistic regression models to assess associations of baseline 24-h urine phosphate excretion and serum phosphate with clinical outcomes (renal and CV event).

Results: Among the 849 participants in this study, the mean age ± SD was 56.5 ± 11.2 years (range 20–75), 61.7% were male. 24-h urine phosphate excretion was not correlated with serum phosphate concentrations after eGFR adjusted (r=-0.073, P=0.034). Models were adjusted for age, sex, primary renal disease (glomerulonephritis, diabetes, hypertension, polycystic kidney disease and others), eGFR, 24-h urine protein and nitrogen excretion, body mass index, smoking, use of phosphate binder and coronary artery disease. There was no association of 24-h urinary phosphate excretion with renal event, CV event and total event. Whereas, higher serum phosphate concentrations were not associated with renal (oddi ratio [OR] 1.839, 95% confidence interval [CI] 0.839-4.028, P=0.128) and CV event (OR 1.491, 95% CI 0.566-3.925, P=0.419). But, strongly associated with total event (OR 1.957, 95% CI 1.008-3.800, P=0.047).

Conclusions: There was no evidence that dietary phosphate intake assessed by 24-h phosphate excretion is associated with clinical outcomes. On the other hand, higher serum phosphate was associated with clinical outcomes in CKD stages 3-5.

Patient Awareness of Target Blood Pressure and Hypertension Control in Chronic Kidney Disease

Natalia Alencar de Pinho,[1] Celine Lange,[1,2] Luc Frimat,[3] Denis Fouque,[4] Maurice Laville,[4] Christian Jacquelinet,[1,2] Bruce M. Robinson,[5] Christian Combe,[6] Ziad Massy,[1,7] Benedicte Stengel.[1] *[1]CESP Inserm U1018, Villejuif; [2]Agence Biomedecine; [3]CHU Nancy; [4]CHU Lyon; [5]Arbor Research Collaborative for Health, Ann Arbor; [6]CHU Bordeaux; [7]CHU A.Paré –APHP, France.*

Background: Patient awareness of treatment goals may help improving risk factor control in CKD. We assessed awareness of target blood pressure (BP) among CKD patients and its associations with BP control.

Methods: We used baseline data from the CKD-REIN/CKDOPPS study, a prospective cohort study of patients enrolled with CKD stage 3 and 4 in a nationally representative sample of 40 nephrology clinics in France. We compared patients who reported target systolic BP (SBP) values <140 (or <130) mm Hg to those who did not. We performed separate analyses with achieved BP <140/90 or <130/80 mm Hg as dependent variable.

Results: Of 2850 patients, 86% had a diagnosis of hypertension registered in medical records. Median age was 69 [IQR 62-77] years, 66% were men, 41% had stage 4 CKD, 91% were aware of their hypertensive condition. Among 37% who reported "to have been told about target BP", 94% reported target SBP <140 (including 67% reporting target SBP value <130), 5% reported target SBP value ≥140, and 1% did not remember their target. Fewer patients (75%) reported a diastolic BP target value. Overall, 40% of the patients had office BP <140/90, and 17%, office BP <130/80. Awareness of target SBP was associated with younger age, higher education level, CKD awareness, and self-BP monitoring. After adjusting for potential confounders, patients reporting target SBP values <140 did not have

better BP control, whatever the threshold. Those who reported target SBP <130 were more likely to have BP <140/90 (OR 1.34 95% CI 1.09-1.65, p 0.006), but not <130/80 (OR 1.16 95% CI 0.90-1.51, p 0.26).

Conclusions: Both awareness of BP target and achievement of BP <140/90 mm Hg are low among CKD patients. Given the importance of hypertension control in preventing CKD progression and cardiovascular complications, setting lower SBP targets (<130) may be a strategy to achieve minimally acceptable BP control (<140/90).

Geographic Variation in Rapid Kidney Function Decline

Benjamin Charles Bowe,[1] Yan Xie,[1] Hong Xian,[1,2] Ziyad Al-Aly.[1,3,4] *[1]Clinical Epidemiology Center, Research and Education Service, VA St. Louis Health Care System, St. Louis, MO; [2]Dept of Biostatistics, St. Louis Univ, St. Louis, MO; [3]Dept of Medicine, Washington Univ School of Medicine, St. Louis, MO; [4]Div of Nephrology, VA St. Louis Health Care System, St. Louis, MO.*

Background: Geographic variation in the prevalence of CKD and incidence of ESRD has been previously reported. However, the geographic epidemiology of rapid eGFR decline has not been examined. We aimed to characterize the spatial epidemiology of rapid eGFR decline using a national longitudinal cohort of United States Veterans.

Methods: We built a cohort of 2,107,570 US veterans and investigated the prevalence of rapid eGFR decline (defined as eGFR slope <-5 ml/min/1.73 m^2/year) and potential ecologic risk factors using mixed effect logistic regression models. To examine possibility of clustering, cluster analysis was performed.

Results: : Prevalence of rapid eGFR slope adjusted for age, race, gender, diabetes, and hypertension varied by county from 4.10-6.72% in the lowest prevalence quintile to 8.41-22.04% in the highest prevalence quintile (p for heterogeneity <0.001). Examination of adjusted prevalence by diabetes and hypertension status showed that while these conditions were major drivers of rapid eGFR decline, substantial geographical variation was present in those with and without diabetes and those with and without hypertension. Compared to rural areas, living in metropolitan neighborhoods was associated with increased odds of rapid eGFR decline (OR: 1.09; CI: 1.03-1.14). Residents of counties with higher proportion of people living in poverty, and higher percentage of African Americans exhibited highest odds of rapid eGFR decline (OR: 1.05; CI: 1.01-1.10; and OR: 1.20; CI: 1.16-1.27; respectively). Spatial analyses suggest the presence of cluster of counties with high prevalence of rapid eGFR decline.

Conclusions: In conclusion, our findings show substantial geographic variation in rapid eGFR decline among United States veterans; the variation persists in analyses stratified by presence of diabetes and hypertension; results also suggest ecologic factors associated with rapid eGFR decline.

Optimizing Timing of Pre-Emptive AV Access Creation: Results from the CRIC Study

Chi-Yuan Hsu, Wei Yang, Lawrence J. Appel, Nisha Bansal, Jing Chen, Josef Coresh, Paul E. Drawz, Harold I. Feldman, Jiang He, Edward J. Horwitz, James P. Lash, Qiang Pan, Andrew S. Levey, Mahboob Rahman, James H. Sondheimer, Matthew R. Weir, Navdeep Tangri. *CRIC & Collaborators.*

Background: Scant data exist to guide clinicians regarding optimal timing of pre-emptive AV access surgery (surgery) in preparation for chronic dialysis. We hypothesized that using a trigger based on predicted likelihood of developing ESRD would be a superior strategy compared with using a static GFR threshold (and superior to current clinical practice).

Methods: We studied Chronic Renal Insufficiency Cohort (CRIC) enrollees with eGFR <30 ml/min/1.73m^2 after 8/2010 (N=608). We compared 3 potential strategies: i) current practice, captured by patient self-report of surgery; ii) hypothetically triggering surgery when eGFR <20 ml/min/1.73m^2; iii) hypothetically triggering surgery when Kidney Failure Risk Equation (KFRE)(Tangri JAMA 2011) estimated likelihood of developing ESRD within 1-yr >20% (thresholds chosen *a priori*). We calculated sensitivity as the probability of appropriately undergoing/correctly triggering surgery among those who actually developed ESRD within a year. Specificity is the probability of correctly not undergoing/not triggering surgery among those who did not develop ESRD within a year.

Results: Mean age of the study population was 66 years, 49% were female, 40% non-Hispanic whites and 41% non-Hispanic blacks. 118 cases of chronic hemodialysis were observed. A strategy guided by likelihood of developing ESRD within the next year had the best disease odds ratio (DOR) at 27.9 (Table 1).

Current practice (patient self-report of AV access surgery)	Specificity (95% CI)	0.987 (0.980, 0.992)
	Sensitivity (95% CI)	0.118 (0.072, 0.187)
	DOR (95% CI)	10.4 (5.0, 21.5)
Scenario if AV access surgery triggered by eGFR <20 ml/min/1.73m^2	Specificity	0.831 (0.806, 0.853)
	Sensitivity	0.787 (0.659, 0.876)
	DOR	18.1 (9.2, 35.4)
Scenario if AV access surgery triggered by likelihood of ESRD within 1-yr >20%	Specificity	0.932 (0.913, 0.947)
	Sensitivity	0.672 (0.548, 0.776)
	DOR	27.9 (15.5, 50.3)

Conclusions: Using predicted likelihood of ESRD to guide pre-emptive AV access surgery may be a promising strategy.

The Expression of VDR in Renal Tissue of Lupus Nephritis and Its Association with Renal Injury Activity

Jian Sun,[1] Shuang Zhang,[1] Youzhou Tang,[1] Ming Gui,[1] Wei Zhang,[1] Hao Zhang.[1] *[1]Dept of Nephrology, The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China; [2]Dept of Medicine, Div of Biological Sciences, Univ of Chicago, Chicago.*

Background: The incidence of systemic lupus erythematosus is closely related to the polymorphism of vitamin D receptor (VDR). To further explore the role of VDR in lupus nephritis (LN), we observed the expression of VDR in renal tissue of LN and evaluated the renal pathological index.

Methods: 20 renal biopsy specimens were collected from 35 patients with LN according to ISN/RPS2003 lupus nephritis type standards pathological type and carrying out the activity index (AI), chronic index (CI). 5 tissue specimens over 2cm far from kidney tumor of renal cancer patients were used as normal control. The expression of VDR were detected by immunohistochemistry in renal tissue of two groups. The relationship between VDR expression and histological injure index, proteinuria and SLICC renal activity scores were analyzed.

Results: 1, Compared with the control group, the expression of VDR in the lupus nephritis were lower(P <0.05). 2,The expression of VDR were negatively correlated with AI (r=-0.548, P =0.012), and no correlation were observed between VDR level and CI (P >0.05). 3,The expression of VDR in renal tissue is negatively correlated with SLICC renal activity scores. (r=-0.470, P =0.037) .

Conclusions: Down-regulation of VDR in renal tissue of lupus nephritis were associated with renal activity injury severity.

SA-PO781

Renal Outcomes in Patients with Colorectal Cancer and Repeated Intravenous Contrast Exposure

Jennifer Heinen, Meier Hsu, Roman A. Shingarev. *Medicine, Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Renal function in cancer patients is affected by exposure to various nephrotoxins. Its preservation is important for effective cancer treatment and surveillance. Contrast-induced nephropathy is a well-recognized acute complication in this population, but the long-term effects of repeated contrast exposure are unknown. We analyzed the association of the number of contrasted computed tomographies (cCT) and other clinical factors with the reduction of eGFR in colorectal cancer (CRC) survivors after CRC resection.

Methods: We retrospectively queried a prospective surgical CRC database to identify 592 patients with stage I or II CRC who underwent resection in 2007-2012 and were alive for at least 3 years. CKD-EPI equation was used to calculate eGFR, and >20% decline in eGFR relative to baseline was defined as significant and used as the primary outcome. The association of clinical factors with the primary outcome at 1 and 3 years was analyzed using logistic regression.

Results: At 1 year, 313 patients had creatinine (Cr) available for eGFR calculation. Significant eGFR decline was observed in 51 (16%) of these patients. In multivariable analysis, cardiovascular disease (CVD) was independently associated with significant eGFR decline [OR=2.4, 95%CI (1.18-4.89), p=0.02]. At 3 years, 208 patients with measured Cr were available with 34 (16%) demonstrating significant eGFR decline that was associated with comorbid hypertension, CVD and operation time. Exposure to ≥4 cCTs was marginally associated with significant eGFR decline.

Figure 1. Univariate analysis of eGFR decline

	eGFR decline by 1 year		eGFR decline by 3 years	
Characteristic	OR (CI)	p-value	OR (CI)	p-value
CVD (Yes vs. No)	**2.87 (1.44-5.71)**	**0.003**	**2.49 (1.03-6.02)**	**0.04**
Diabetes (Yes vs. No)	**2.04 (1.08-3.86)**	**0.03**	1.66 (0.74-3.69)	0.22
HTN (Yes vs. No)	1.34 (0.71-2.52)	0.37	**2.42 (1.00-5.86)**	**0.05**
Nephrotoxic chemotherapy (Yes vs. No)	**0.45 (0.22-0.94)**	**0.03**	1.15 (0.53-2.49)	0.72
OR time (per10 min increase)	1.03 (1.00-1.06)	0.06	**1.04 (1.00-1.07)**	**0.03**
Number of cCTs by 3 years (≥4 vs. <4)	*NA*		2.09 (0.94-4.63)	0.07

Conclusions: Cumulative contrast exposure was marginally associated with a >20% eGFR decline at 3 years after surgical resection in patients with early stage CRC. This trend calls for further studies to elucidate the long-term effects of contrast exposure in cancer patients. CVD was found to be a consistent risk factor of post-operative eGFR decline.

SA-PO782

The Tissue Expressions of Tubular Injury Marker, NGAL and KIM-1, Are Associated with Renal Function Decline in Diabetic Nephropathy

Subin Hwang, Eun Jeong Lee, Jae Shin Choi, Hee Jin Kwon, Hye Ryoun Jang, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Jung Eun Lee. *Div of Nephrology, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

Background: The tubular injury may be involved in the pathogenesis and progression of renal dysfunction in addition to glomerular damage in diabetic nephropathy (DN). This study was conducted to examine whether tubular expressions of neutrophil gelatinase-associated lipocalin (NGAL) and kidney injury molecule-1 (KIM-1) predict the subsequent decline of renal function in human DN.

Methods: We identified 122 patients with diabetes who underwent renal biopsy from 2000 to 2014 and confirmed to have DN. After exclusion of patients with coexisting other renal disease, estimated glomerular filtration rate (eGFR) < 30 ml/min/1.73m^2, 35 subjects were included in the analyses. Annual decline of eGFR (GFR slope) was calculated by linear regression analysis. We assessed tissue tubular expressions of NGAL and KIM-1 by immunohistochemistry.

Results: Overall, GFR slopes were linear. The median baseline urinary protein to creatinine ratio (PCR) was 6.76 (2.18 - 7.61) mg/mgCr, the median baseline eGFR was 50.4 (42.6 - 66.4) ml/min per 1.73m^2, and median GFR slope was -15.6 (-32.9 - -4.4) ml/min per 1.73m^2 per year. In linear regression analyses, tubular expressions of NGAL were correlated with GFR slope and interstitial fibrosis and tubular atrophy score (P = 0.012, P = 0.088, respectively). Those of KIM-1 were correlated with GFR slope and PCR (P = 0.002, P = 0.003, respectively). In multivariate analyses, tubular expressions of NGAL remained as an independent predictor of GFR slope (P = 0.011). However, the association between KIM-1 expressions and GFR slope was dependent on PCR.

Conclusions: Tissue expressions of tubular injury marker, NGAL were closely associated with GFR decline, independently of PCR. These findings suggest that tubular injury might play an independent role in the pathogenesis of DN.

Age at Onset, Complement Abnormality and Renal Survival in Patients with aHUS Enrolled in a Global Registry

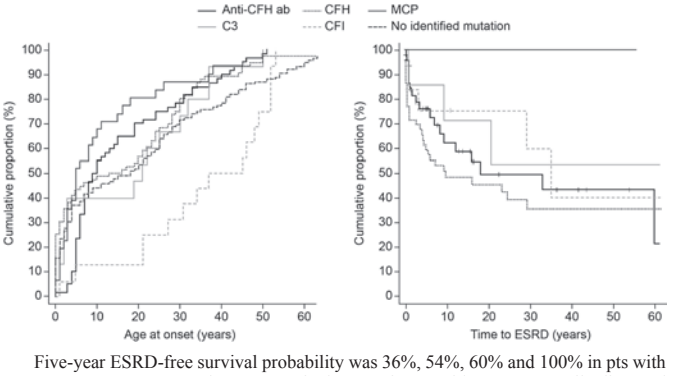
Franz S. Schaefer,[1] Fadi Fakhouri,[2] Varant Kupelian,[3] Christoph Licht.[4] *[1]Heidelberg Univ Hospital; [2]CHU de Nantes; [3]Alexion Pharmaceuticals Inc; [4]The Hospital for Sick Children.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, genetic, life-threatening disease of chronic, uncontrolled complement activation that leads to thrombotic microangiopathy with severe organ damage. Here we characterize renal survival in patients (pts) with aHUS enrolled in the global aHUS Registry.

Methods: All pts diagnosed with aHUS are eligible for enrolment. Exclusion criteria: Shiga toxin *Escherichia coli*-positive HUS or ADAMTS13 activity <5%. Data are collected at enrolment and every 6 months thereafter. Data are reported prior to treatment with eculizumab.

Results: As of November 2015, 851 pts were enrolled (387 childhood, 464 adult onset). Prior dialysis was recorded for 56% of pts, while 19% had received a kidney transplant. Five year end-stage renal disease (ESRD)-free survival probability was 73% and 57% for pediatric and adult pts respectively. Cox proportional hazard regression analysis shows age of onset associated with ESRD risk (p<0.001). Gender, race, family history of aHUS, and time from onset to diagnosis, were not associated with ESRD risk. Pts with CFI mutations had their first aHUS manifestation later than pts with other complement abnormalities.

Figure: Age of onset and ESRD survival probability by individual complement abnormality



Five-year ESRD-free survival probability was 36%, 54%, 60% and 100% in pts with CFH, C3, CFI, MCP mutations, respectively, 49% in pts with CFH autoantibodies, and 67% in pts with no identified complement abnormality.

Conclusions: Our data suggest pts with aHUS who have disease onset in adulthood or a CFH mutation are at highest risk of ESRD. These pts may especially benefit from rapid initiation of eculizumab, which has been shown to be effective in the treatment of aHUS.

Acknowledgments: The authors wish to thank the patients, registry investigators, and the other members of the aHUS Registry Scientific Advisory Board.

Associations of Blood Pressure with End Stage Renal Disease in Chronic Kidney Disease

Matthew F. Blum,[1] Jesse D. Schold,[1] Stacey Jolly,[1] Susana Arrigain,[1] Joseph V. Nally,[1] Sankar D. Navaneethan.[2] *[1]Cleveland Clinic; [2]Baylor College of Medicine.*

Background: Hypertension is a risk factor for kidney disease progression, but the optimal blood pressure for CKD patients is undetermined. We studied the associations of systolic and diastolic blood pressure with ESRD among non-dialysis dependent CKD patients.

Methods: We included 31,280 patients with eGFR <60 ml/min/1.73m^2 (twice 90 days apart) and on at least one antihypertensive agent. ESRD details were ascertained from the US Renal Data System. We fitted competing risk regression models for ESRD to evaluate various SBP (<110, 110-119, 120-129, 130-139, 140-149, and ≥150 mmHg) and DBP (<50, 50-59, 60-69, 70-79 80-89 mmHg) targets. The competing event was all-cause mortality. The model was adjusted for age, gender, race, insurance group, diabetes, hyperlipidemia, BMI, albumin, hemoglobin, malignancy, coronary artery disease, congestive heart failure, cerebrovascular disease, peripheral vascular disease, ACE/ARB, beta blocker, smoking, and CKD stage.

Results: During a median follow-up of 2.2 years, 915 patients developed ESRD. In multivariate models, SBP <110 and 110-119 mmHg were associated with lower risk of ESRD, while SBP ≥150 mmHg was associated with greater risk of ESRD. DBP was ≥90 mmHg was associated with higher risk of ESRD.

Baseline SBP vs. ESRD		
	Unadjusted ESRD SHR (95%CI)	Adjusted ESRD SHR (95%CI)
<110	0.87 (0.66, 1.15)	0.54 (0.40, 0.72)
110-119	0.80 (0.61, 1.03)	0.65 (0.50, 0.85)
120-129	0.87 (0.69, 1.08)	0.97 (0.77, 1.2)
130-139	Ref	Ref
140-149	1.22 (0.98, 1.52)	1.10 (0.87, 1.4)
≥150	2.27 (1.87, 2.74)	1.7 (1.4, 2.1)
Baseline DBP vs. ESRD		
	Unadjusted ESRD SHR (95% CI)	Adjusted ESRD SHR (95%CI)
<50	1.37 (0.77, 2.44)	0.70 (0.36, 1.35)
50-59	1.00 (0.77, 1.31)	0.77 (0.59, 1.02)
60-69	0.87 (0.73, 1.04)	0.86 (0.72, 1.04)
70-79	Ref	Ref
80-89	1.11 (0.93, 1.33)	1.07 (0.89, 1.29)
≥90	2.77 (2.28, 3.38)	1.50 (1.20, 1.86)

Conclusions: In a non-dialysis dependent CKD population, SBP <120 mmHg was associated with a lower risk of ESRD. SBP ≥150 mmHg and DBP ≥90 mmHg were associated with a higher risk of progression to ESRD.

Funding: Pharmaceutical Company Support - Development of CCF CKD registry is supported by an unrestricted grant to the Department of Nephrology and Hypertension, Cleveland Clinic from Amgen

The Effect of Calcitriol and Cholecalciferol Supplementation on Proteinuria in CKD Stage 3-4

Jessica B. Kendrick,[1,2] Emily Decker,[1] Zhiying You,[1] Michel Chonchol.[1] *[1]Univ of Colorado Denver; [2]Denver Health & Hospital.*

Background: Vitamin D deficiency is associated with an increased risk of proteinuria and kidney disease progression in patients with chronic kidney disease (CKD). The effect of vitamin D supplementation on proteinuria has not been well studied. We examined the effect of calcitriol vs. cholecalciferol supplementation on proteinuria in a randomized double-blind, direct head-to-head comparison.

Methods: In a randomized trial to evaluate the effect of calcitriol vs. cholecalciferol on vascular endothelial function, 128 patients with CKD stage 3-4 (estimated GFR 15-44 ml/min/1.73m^2) with vitamin D deficiency, defined as serum 25-hydroxyvitamin D level < 30 ng/mL, and proteinuria < 3.5 g/day, were randomly assigned to receive either cholecalciferol (4000 IU daily x 4 weeks then 2000 IU daily x 20 weeks) or calcitriol (0.25 mcg daily x 4 weeks then 0.5 mcg daily x 20 weeks). Urinary albumin to creatinine ratio (ACR) was measured at baseline and end of study. We examined the change in ACR from baseline to end of study in the calcitriol group vs. cholecalciferol group.

Results: 115 patients completed the study. The mean (SD) age and eGFR was 58.1 ± 12.5 years and 33.2 ± 10.0 ml/min/1.73m^2, respectively. The use of angiotensin converting enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARB) was similar between the two groups (69.6% in the calcitriol group vs. 68.5% in the cholecalciferol group). The baseline median (IQR) ACR was 222.0 (39.7-846.8) mg/g in the calcitriol group and 158.8 (29.2-585.6) mg/g in the cholecalciferol group. Over the 6 month time period, the ACR decreased from baseline in the calcitriol group by 14.6%, p=0.02 and increased in the cholecalciferol group by 5.8%, p=0.35. The change in ACR during the follow-up period between the two groups was significant (-3.96, 95% CI -7.25 to -0.62, p=0.02). The between group difference in ACR remained after adjustment for age, gender, race, systolic blood pressure and use of ACEi/ARB. Incidence of hypercalcemia and adverse events was similar between the two groups.

Conclusions: Treatment with calcitriol but not cholecalciferol results in a significant decrease in albuminuria in patients with CKD stage 3-4.

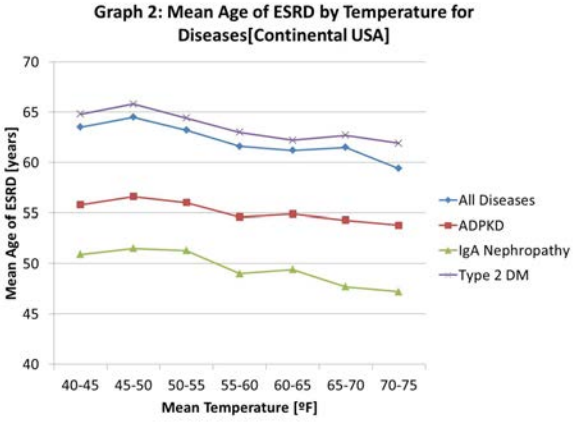
SA-PO786

Increasing Climate Temperature Is Associated with Earlier Age of Onset of End Stage Renal Disease Michael E. Bleyer, Ebunoluwa Esther Taylor, Gregory B. Russell, Anthony J. Bleyer. *Section of Nephrology, Wake Forest Baptist Health, Winston-Salem, NC.*

Background: Global temperature is increasing, and there has been a rising concern that high climate temperatures may be associated with chronic kidney disease such as Meso-American Nephropathy. To explore the relationship between climate temperature and age of ESRD, we evaluated data from the United States Renal Data System (USRDS). US data is particularly useful because of a relatively standard approach to when dialysis is started and because of a broad range in climate temperature in the US.

Methods: We obtained data for all patients with new onset ESRD between ages 30 and 90 in the continental United States. We were particularly interested in where individuals were likely to have spent most of their life rather than where they lived when dialysis was initiated. We therefore obtained from the USRDS the state where each patient obtained his social security number. In the US, social security numbers are usually obtained before or at the age of 18 years. We obtained median annual temperature data from the US National Oceanographic and Atmospheric Association. A multivariate linear regression model was developed with age of ESRD as the outcome variable, and gender, race, median income, and median annual state temperature as independent variables.

Results: 2.3 million individuals were included in the analysis. There was an inverse linear relationship between age of onset of ESRD and climate temperature.



This relationship was found with autosomal dominant polycystic kidney disease, IgA nephropathy, and type II diabetes. The relationship remained significant after adjusting for race, gender, and median income.

Conclusions: Higher climate temperatures are associated with a younger age of onset of ESRD. This could significantly contribute to ESRD incidence in developing countries, and could be affected by climate change.

Estimation of Nephron Number of Japanese CKD Patients Toshiyuki Imasawa,[1] Takehiko Kawaguchi,[1] Kensei Yahata,[2] Takashi Nakazato.[3] *[1]Kidney Center, National Hospital Organization Chiba-East Hospital, Chiba-city, Chiba, Japan; [2]Dept of Nephrology, National Hospital Organization Kyoto Medical Center, Kyoto-City, Kyoto, Japan; [3]Dept of Medical Information Management, National Hospital Organization Chiba Medical Center, Chiba-city, Chiba, Japan.*

Background: Previous studies showed that nephron number is a good predictor of CKD progression. However, all these results were based on animal studies or on autopsied human kidneys (retrospective studies). Because nephrologists cannot count nephron number of CKD patients, this knowledge is unavailable at a real clinical place. Recently, we established an estimation formula for nephron number in CKD patients who were received kidney biopsies (BMC Nephrol 2012, 13:11).

Methods: Patients were from PRONEP (Predicting the Outcome of Chronic Kidney Disease by the Estimated Nephron Number) study (protocol: BMC Nephrol 2012). In this analysis, 573 Japanese patients were included. By the estimation formula, we calculated nephron numbers of Japanese CKD patients. In addition, nephron numbers of IgA nephropathy, diabetic nephropathy, and FSGS (focal segmental glomerulosclerosis) due to hemodynamic factor were individually calculated. Because sclerosed glomeruli might be absorbed, we also calculated nephron numbers of cases whose eGFR were over 45ml/min/1.73m^2.

Results: All results are in Table.

	Japanese CKD patients	IgAN	DMN	FSGS (hemodynamic)
n	573 (386)	216 (170)	45 (24)	15 (7)
eGFR	64.4 +/- 38.9 (85.7 +/- 34.9)	74.1 +/- 37.8 (88.9 +/- 33.0)	45.8 +/- 21.4 (66.3 +/- 11.4)	55.2 +/- 29.2 (79.0 +/- 25.8)
nephron number /kidney	667,460 +/- 310,730 (712,366 +/- 287,733)	680,702 +/- 302,604 (723,997 +/- 294,190)	821,262 +/- 280,784 (818,819 +/- 237,968)	557,340 +/- 322,246 (472,928 +/- 113,628)

In parentheses, data of cases over eGFR 45ml/min/1.73m^2. Values are shown as mean+/-SD.

Conclusions: Nephron numbers of Japanese are expected to be lower than Caucasian. Interestingly, nephron numbers of FSGS due to hemodynamic factor (mostly perihilar variant) were significantly lower than those of other CKD patients. Now, we are prospectively following these patients and will analyze whether these estimated nephron numbers can predict CKD progression.

SA-PO788

The Association of Sleep Duration and Quality with Chronic Kidney Disease Progression Ana C. Ricardo, Kristen Knutson, Jinsong Chen, Lawrence J. Appel, Lydia Bazzano, Manjula Kurella Tamura, Mahboob Rahman, Susan P. Steigerwalt, John Thornton, Matthew R. Weir, Eve Van Cauter, James P. Lash. *On Behalf of the Chronic Renal Insufficiency Cohort (CRIC) Study Group.*

Background: Although there is increasing evidence that sleep disorders are common in individuals with chronic kidney disease (CKD), its association with CKD progression is not known. We examined the association of sleep duration and quality with CKD progression and all-cause death.

Methods: We conducted a prospective longitudinal study of 432 adults (mean age 60 years, 48% women, and mean estimated glomerular filtration rate [eGFR] 38 ml/min/1.73m^2) enrolled at two participating sites of the CRIC Study. Participants wore a wrist actigraph for 5-7 days to measure sleep duration and quality. Subjective sleep quality, apnea risk and daytime sleepiness were self-reported using validated questionnaires. We used Cox proportional hazards models to evaluate the association of sleep measures with incident end stage renal disease (ESRD) and all-cause death, and linear mixed-effects models to assess differences in eGFR slope.

Results: Participants slept an average of 7.4 hours/night, and the mean sleep fragmentation was 21%. Over median follow-up of 5 years, we observed 70 ESRD events and 48 deaths. In analyses adjusted for sociodemographic factors, body mass index, blood pressure, diabetes, cardiovascular disease and baseline kidney function, longer sleep duration was associated with 19% lower risk of ESRD (HR 0.81, 95% CI 0.67-0.99 per hour increase in sleep duration), and higher sleep fragmentation was associated with 4% increased ESRD risk (HR 1.04, 95% CI 1.01-1.07 per 1% increase in fragmentation). In adjusted mixed effects regression models, higher sleep fragmentation was associated with significant eGFR decline (-0.17 ml/min/1.73m^2/year, p = .016). Self-reported daytime sleepiness was associated with 10% increased risk for all-cause death in the fully adjusted model (HR 1.10, 95% CI 1.02-1.18, per 1 unit increase). We found no significant association between sleep start time, self-reported sleep quality or apnea risk with outcomes.

Conclusions: These findings suggest that short and poor quality sleep are unappreciated risk factors for CKD progression.

Funding: NIDDK Support

The Association of Histopathological Lesions with Renal Function Decline and Mortality in Biopsy-Confirmed Kidney Disease Anand Srivastava,[1] Arnaud Djou Kaze,[1] Isaac Ely Stillman,[3] Helmut G. Rennke,[2] Sushrut S. Waikar.[1] *[1]Renal Div, Brigham & Women's Hospital, Boston, MA; [2]Pathology Dept, Brigham & Women's Hospital, Boston, MA; [3]Pathology Dept, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Kidney biopsy is the gold standard for diagnosing many kidney diseases, and may also provide prognostic information. No study to our knowledge has tested whether histopathologic lesions independently predict outcomes across a variety of kidney diseases.

Methods: We enrolled 654 patients undergoing kidney biopsy at three tertiary care hospitals in Boston, MA into a prospective observational cohort study. We fit multivariable-adjusted Cox proportional hazards models to test the association of histopathological lesions involving the mesangium, vessels, and tubulointerstitium with the composite endpoint of renal function decline (doubling of serum creatinine or need for renal replacement therapy) or mortality.

Results: The most common diagnoses were lupus nephritis (13.6%), IgA nephropathy (11%), and diabetic nephropathy (10.4%). 38.3% had other primary glomerular diseases and 37.1% had non-glomerular diseases. 127 patients reached the primary endpoint over a median follow-up time of 21.9 [IQR 10.9–42.8] months. Table shows the associations of histopathological findings with the composite endpoint, adjusted for age, race, sex, log(proteinuria), and estimated glomerular filtration rate (eGFR).

	Adjusted HR [95% CI]
Mesangial Expansion*	
Mild	2.36 [1.33-4.17]
Moderate	2.60 [1.41-4.80]
Severe	2.38 [1.23-4.58]
Glomerulosclerosis*	
11-25%	1.05 [0.59-1.86]
26-50%	1.47 [0.87-2.46]
>50%	2.02 [1.18-3.44]
Interstitial Fibrosis/ Tubular Atrophy*	
11-25%	1.88 [0.97-3.65]
26-50%	2.12 [1.08-4.19]
>50%	3.39 [1.77-6.46]
Arterial Sclerosis+	
Moderate	0.96 [0.58-1.59]
Severe	1.28 [0.79-2.07]
Arteriolar Sclerosis+	
Moderate	1.53 [0.93-2.50]
Severe	1.86 [1.13-3.06]
*Reference is None/0-10% of cortical volume +Reference is None/Mild	

Conclusions: Across a diverse group of kidney diseases, histopathological lesions on kidney biopsy provide independent prognostic information even after adjusting for known risk factors including proteinuria and eGFR.

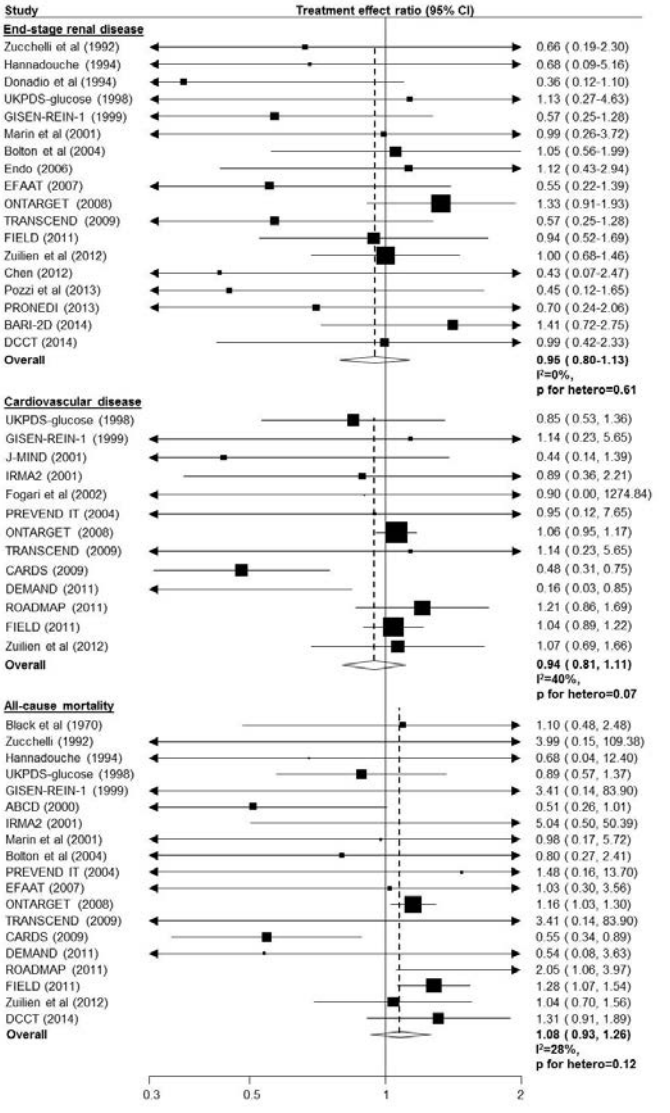
Assessing the Association between Change in Albuminuria and Clinical Outcomes: A Systematic Review and Meta-Analysis Tyrone Harrison, Helen Tam-Tham, Brenda Hemmelgarn, Min Jun. *Univ of Calgary, Calgary, AB, Canada.*

Background: Albuminuria is a significant predictor of kidney disease progression, cardiovascular morbidity, and mortality among patients with diabetes and/or established chronic kidney disease. However, there is limited information on the prognostic value of albuminuria change on clinically important outcomes. We aimed to assess the association between albuminuria progression and adverse clinical outcomes (all-cause death, cardiovascular disease [CVD], and end-stage renal disease [ESRD]) in adults based on a systematic review of the literature.

Methods: CENTRAL, EMBASE, and MEDLINE were systematically searched for randomized controlled trials (1946-January 2015) that reported change in albuminuria and at least 1 of the 3 clinically important outcomes. Two reviewers abstracted trial characteristics and and outcome data independently. To determine the association between change in albuminuria and clinical outcomes, we determined the treatment effect ratio (TER), defined as the ratio of the treatment effects on clinical outcomes and the effects on the change in albuminuria.

Results: We identified 27 trials (50300 patients) that met the inclusion criteria. 18 reported data on ESRD, 13 on CVD, and 19 on all-cause death. Treatment effects on albuminuria and ESRD were consistent with minimal heterogeneity (TER 0.95 [0.80-1.13), while relatively similar levels of consistency were observed for the outcomes of CVD and all-cause death, however, with evidence of greater heterogeneity (I^2=40% and 28%, respectively).



Conclusions: This review identifies a potentially important correlation whereby progression of albuminuria may be a valid surrogate for ESRD. However, greater heterogeneity was observed for the outcomes of CVD and death. Assessment of the surrogacy of albuminuria in large prospective trials is needed.

SA-PO791

U-Shaped Relationship between Serum Uric Acid Levels and Intrarenal Hemodynamic Parameters in Healthy Subjects Hideki Uedono, Akihiro Tsuda, Eiji Ishimura, Mitsuru Ichii, Shinya Nakatani, Masaaki Inaba. *Dept of Nephrology, Dept of Metabolism, Endocrinology and Molecular Medicine, Osaka City Univ Graduate School of Medicine, Osaka, Abeno-ku, Asahi-machi, Japan.*

Background: Hyperuricemia has been reported to affect renal hemodynamics (Uedono H, et al. Kidney Blood Press Res 2015). However, it is recently reported that low levels, as well as high levels, of serum uric acid are associated with the loss of kidney function (Kanda E, et al. PLOS One 2015). In the present study, we evaluated the relationship between serum uric acid levels and intrarenal hemodynamic parameters in healthy subjects, utilizing plasma clearance of para-aminohippurate (C_{PAH}) and inulin (C_{in}).

Methods: Renal and glomerular hemodynamics were evaluated by simultaneous measurements of C_{PAH} and C_{in} in 40 healthy subjects (17 males and 23 females, 55.3±12.4 years). Intrarenal hemodynamic parameters, including efferent arteriolar resistance (R_e), afferent arteriolar resistance (R_a), and intraglomerular hydrostatic pressure (P_{glo}), were calculated by Gomez's formulae. Serum uric acid levels were compared with these intrarnal hemodynamic parameters.

Results: In a quadratic regression analysis, serum uric acid levels had a significant, inverse U-shaped relationship with C_{in} and with C_{PAH} (p=0.0068, R^2=0.237 and p=0.0335 R^2=0.160, respectively), and U-shaped relationship with R_a (p=0.0005, R^2=0.340). In a multiple regression analysis, in which normal uric acid levels (between 3.0 to 6.4 mg/dL) and abnormal uric acid levels (less than 3.0 or more than 6.4) were entered as dummy variables

of 0 and 1, respectively, abnormal uric acid levels were demonstrated to be significantly and independently associated with R_a (β= 0.315, p = 0.0254) after adjustment of age, gender, body mass index, and systolic blood pressure. (R^2=0.550, p<0.0001).

Conclusions: These findings suggest, for the first time in human, that both mild hyperuricemia (> 6.4 mg/dL) and mild hypouricemia (< 3.0 mg/dL) are significantly associated with increased R_a in healthy subjects with C_{in} > 60 ml/min. The increase in R_a in subjects with hyperuricemia as well as hypouricemia, even in mildly abnormal levels, may be related to renal hemodynamic abnormalities in human.

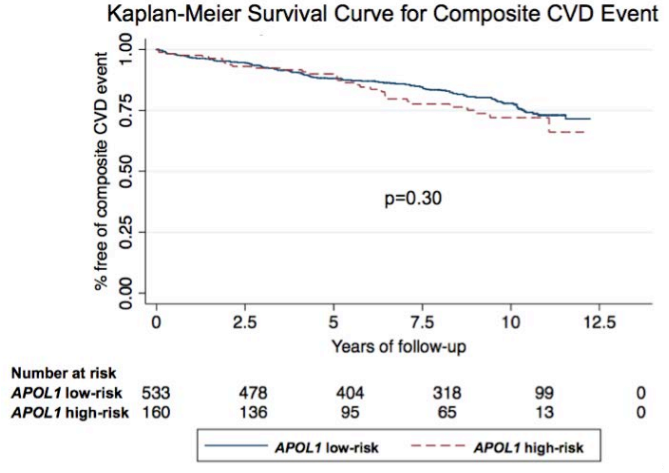
APOL1 Variants and Cardiovascular Disease: Results from the African American Study of Kidney Disease and Hypertension (AASK)

Teresa K. Chen, Lawrence J. Appel, Adrienne Tin, Michael J. Choi, Michelle M. Estrella. *Johns Hopkins Univ.*

Background: Studies on the association between *APOL1* risk variants and cardiovascular disease (CVD) have been conflicting thus far. We aimed to determine whether *APOL1* high-risk variants are associated with increased risk for adverse CVD outcomes in the context of established hypertension-attributed chronic kidney disease (CKD).

Methods: Using data from the trial and cohort phases of AASK (mean follow-up 7.7 years), we constructed Cox proportional hazards models to estimate the relative hazard of experiencing a composite CVD outcome (cardiac revascularization procedure, nonfatal myocardial infarction, heart failure exacerbation, stroke, or cardiovascular death) among African Americans with the *APOL1* high-risk (2 alleles) vs. low-risk (0-1 allele) genotypes. We adjusted for age, gender, ancestry, smoking, body mass index, total cholesterol, randomized treatment groups, and baseline and longitudinal estimated glomerular filtration rate (eGFR), systolic blood pressure, and proteinuria. Censoring occurred at ESRD, death, lost to follow-up, or administrative censoring.

Results: Among the 1094 AASK trial participants, 693 had *APOL1* genotyping available (23% high-risk genotype) and were included in our study. At baseline, the *APOL1* high-risk group had a lower mean eGFR (44.7 vs. 50.1 ml/min/1.73 m^2) and more proteinuria (median 0.19 vs. 0.06) compared to the low risk group. In both unadjusted (HR: 1.23; 95% CI: 0.83 to 1.81; p=0.31) and fully adjusted (HR: 1.14; 95% CI: 0.76 to 1.72; p=0.53) models, individuals with the *APOL1* high-risk genotype had similar risk for the composite CVD outcome as those with the low-risk genotype. Use of additive or dominant genetic models yielded similar findings.



Conclusions: Among African Americans with hypertension-attributed CKD, *APOL1* high-risk variants are not associated with an increased risk for cardiovascular disease.

High Erythropoiesis-Stimulating Agent Dose Is Associated with Increased Healthcare Resource Utilization and Risk of Adverse Events in Non-Dialysis-Dependent Chronic Kidney Disease Patients

David T. Gilbertson,[1] Suying Li,[1] Yi Peng,[1] Haifeng Guo,[1] Shaum Kabadi,[2] Sean Zhao,[2] Trudy Pendergraft,[2] Louise Janice Sargent Heuer,[2] Wendy L. St. Peter.[1] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]AstraZeneca, Wilmington, DE.*

Background: High-dose ESA (HDE), a measure of ESA resistance, is associated with increased comorbidities, adverse events, and healthcare resource utilization (HRU) in hemodialysis patients. Little is known about this association in non-dialysis-dependent chronic kidney disease (NDD-CKD) patients.

Methods: We investigated this association in stage 3-5 NDD-CKD patients with anemia using 2011-2013 Medicare data. A baseline period was used to define CKD, anemia, and comorbidities from diagnosis codes, and ESA use from drug codes. A 1-year follow-up period was used to define HRU and adverse events. HDE as a measure of ESA resistance was defined by an average monthly ESA dose >90th percentile of monthly doses. Analyses were adjusted for patient characteristics, IV iron use, RBC transfusion, and CKD stage.

Results: A total of 12,901 stage 3-5 NDD-CKD patients with anemia receiving ESAs were included. HDE cut-points were ≥75,630 units for erythropoietin and ≥351 mcg for darbepoetin. HDE use was associated with a significantly increased burden of cardiovascular and thromboembolic events. Furthermore, the risk of death was 60% higher among HDE patients (HR 1.60, [1.43-1.79]), and the risk of major adverse cardiac event (MACE) was 46% higher (1.46, [1.31-1.62]) (Table). Medicare payments were 52% higher for HDE patients (1.52, [1.41-1.63]).

Outcome	Hazard Ratio (95% CI)
All-cause death	1.60 (1.43-1.79)
Major adverse cardiac event	1.46 (1.31-1.62)
Hypertensive emergency	0.95 (0.37-2.45)
Deep vein thrombosis	1.42 (1.18-1.72)
Pulmonary embolism	1.64 (1.22-2.20)
Hospitalization	1.36 (1.26-1.47)
Emergency department visit	1.14 (1.04-1.26)
Hospice	1.55 (1.34-1.80)
Outpatient visits	1.34 (1.33-1.36)
Medicare payment	1.52 (1.41-1.63)

Conclusions: Anemia requiring HDE use in stage 3-5 NDD-CKD patients is associated with increased death, MACE, cardiovascular events, thromboembolic events and HRU. Further research is needed to confirm these associations in other cohorts that include more precise data on hemoglobin measurement and ESA dose.

Unexpected Medical Consequences of Revised ESA Label in Non-Dialysis-Dependent Chronic Kidney Disease Patients with Anemia

Suying Li,[1] Haifeng Guo,[1] Shaum Kabadi,[2] Sean Zhao,[2] Trudy Pendergraft,[2] Louise Janice Sargent Heuer,[2] Yi Peng,[1] Wendy L. St. Peter,[1] David T. Gilbertson.[1] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]AstraZeneca, Wilmington, DE.*

Background: In 2011, the US Food and Drug Administration (FDA) revised labeling for erythropoiesis-stimulating agent (ESA) treatment in non-dialysis-dependent chronic kidney disease (NDD-CKD) patients, and a Hb target of 10-12 g/dL was replaced by guidance to initiate therapy when Hb fell to <10 g/dL. This study aimed to examine changes in anemia treatment, comorbidities, and outcomes after the ESA label change.

Methods: Stage 3-5 NDD-CKD patients with anemia were selected from a 20% Medicare random sample. Two study cohorts were created: the "2008 cohort," consisting of patients identified from the 2007-2009 claims, and the "2012 cohort," based on the 2011-2013 claims. Use of ESAs, intravenous (IV) iron, red blood cell (RBC) transfusions and cardiovascular (CV) comorbidities were defined in a 1-year baseline period, and outcomes (major adverse cardiac events [MACE] including all-cause death, hypertensive emergency [HE], deep vein thrombosis [DVT], and pulmonary embolism [PE]) were defined in a 1-year follow-up period for each study cohort. Results were unadjusted.

Results: ESA use in NDD-CKD patients with anemia declined in 2012 relative to 2008, while use of IV iron and transfusions remained stable (Table). Although the prevalence of baseline comorbidities was similar between the two cohorts, rates of HE, DVT, and PE increased in the 2012 cohort by 100%, 31%, and 45%, respectively. In addition, all-cause death and MACE incidence did not decline.

	2008 cohort	2012 cohort
n	71,744	109,251
Anemia treatment, %		
ESA	29.4	12.7
IV iron	6.3	6.7
RBC transfusion	21.3	22.2
Baseline comorbidities, %		
Atherosclerotic heart disease	51.7	52.7
Congestive heart failure	43.0	43.0
Cerebrovascular accident/transient ischemic attack	21.9	24.1
Peripheral vascular disease	34.2	36.8
Other cardiac-related comorbidities	33.6	36.6
CV Outcomes, rate per 100 patient-yrs (unadjusted)		
All-cause death	15.4	15.2
MACE (including all-cause death)	23.2	22.4
HE	0.3	0.6
DVT	18.7	24.5
PE	7.6	11.0

Conclusions: After the 2011 ESA label change, a reduction in all-cause death and MACE was not observed, while HE, DVT and PE rates increased. Adjusted risk of these unexpected medical outcomes warrants further investigation.

SA-PO796

Hyperkalemia and Prescription of Antihypertensive Medications: Early Findings from the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) Francesca Tentori,[1,2] Charlotte Tu,[1] Lindsay Zepel,[1] Brian Bieber,[1] Michelle M.Y. Wong,[1] Friedrich K. Port,[1] Christian Combe,[3,4] Benedicte Stengel,[5] Danilo Fliser,[6] Ricardo Sesso,[7] Ichiei Narita,[8] Bruce M. Robinson.[1] *[1]Arbor Research; [2]Vanderbilt U.; [3]CHU de Bordeaux; [4]U. Bordeaux; [5]Inserm U1018; [6]Saarland U. Med. Ctr.; [7]UNIFESP; [8]Niigata U. Grad School of Med. and Dental Sci.; [9]CKDOPPS and CKD REIN Investigators.*

Background: Current guidelines identify renin angiotensin system inhibitors (RASi) as a key element in the treatment of patients with chronic kidney disease (CKD). However, these drugs may be limited in the presence of hyperkalemia. We postulated that prescription of antihypertensive medications in CKD patients varies according to serum potassium (SK) levels, and that these practices vary across countries.

Methods: We leveraged early data from the CKDopps (2013-2016), a prospective cohort study of patients (pts) with eGFR <60 ml/min/1.73m2 from national samples of nephrology clinics in Brazil (BR), France (FR), Germany (GER) and the US to provide descriptive analyses of prescription of anti-hypertensives and K-binding resins by country and SK.

Results: Among 5,104 pts, mean age by country was 66 to 73 yrs; 35-48% were female; 41-58% had diabetes; 46%-67% had eGFR < 30. RASi use was less common in the US and BR than GER and FR; no large differences were seen between diabetics and non-diabetics. RASi use in the US was less common at SK>5 than SK≤5. Prescription of K-binding resins in pts with SK>5 was common in FR and GER, but almost absent in BR and US (Table 1).

Table 1. Selected anti-hypertensive medications and potassium-binding resins prescription, by country and potassium level

	Brazil[a]		France[b]		Germany[c]		US[a]	
Serum Potassium (mEq/L)	**≤ 5**	**> 5**	**≤ 5**	**> 5**	**≤ 5**	**> 5**	**≤ 5**	**> 5**
% of patients*	72%	28%	84%	16%	79%	21%	82%	18%
RASi prescription								
Non-Diabetics	37%	63%	69%	80%	72%	86%	51%	51%
Diabetics	49%	56%	78%	89%	71%	76%	59%	45%
Diuretic†	61%	68%	--	--	72%	68%	60%	52%
K-binding resins‡	0%	0%	10%	25%	5%	16%	1%	4%

* among patients with non-missing serum potassium value: 242, 2913, 1276 and 673 in Brazil, France, Germany and US, respectively
† loop or other diuretics
‡ Na-based (e.g. Kayexalate) or Ca-based (e.g. Calcium Resonium)
a. data from the first interval in which both labs and meds data were available
b. data from the values at enrollment
c. data from the most recent interval

Conclusions: Among pts with advanced CKD, prescription patterns vary across countries. Pharmacological treatment of hyperkalemia, especially in FR and GER, may allow for more liberal prescription of RASi. There is a substantial opportunity for improvement in management of diabetic pts, especially in the US where only half were prescribed a RASi and use of K-binding resins was exceedingly rare.

Asymmetric Dimethyl Arginine Modifies the Relationship between High Soluble Urokinase-Type Plasminogen Activator Receptor (suPAR) and the Risk of Death and Cardiovascular (CV) Events in Stage 2-5 CKD Patients Carmine Zoccali, Patrizia Pizzini, Graziella D'arrigo, Daniela Leonardis, Claudia Torino, Maurizio Postorino, Giovanni Tripepi, Francesca Mallamaci. *CNR-IFC, Nephrol Dial Transplant, Reggio Calabria, Reggio Calabria, Italy.*

Background: suPAR is an innate immunity/inflammation biomarker strongly related with plaque instability and atherosclerotic events in patients with cardiovascular disease and in chronic kidney disease (CKD). Asymmetric dimethylarginine (ADMA), an endogenous inhibitor of nitric oxide (NO), is substantially raised in CKD patients and predicts mortality and cardiovascular events (CV) in CKD. Inflammation powerfully activates NO synthesis and there may be a biological interplay between suPAR and ADMA in CKD.

Methods: We measured serum suPAR levels (R&D ELISA) and ADMA (ELISA (DLD Diagnostika GMBH, Hamburg, Germany) in 753 stage G2-5 CKD patients with a 31+10 months follow-up.

Results: suPAR was strongly and independently related with ADMA (r=0.22, P<0.001) as well as with major biomarkers of inflammation (IL-6 r=0.27, P<0.001; Procalcitonin r=0.21 P<0.001; CRP r=0.137, all P<0.001). During follow-up 130 patients developed the combined end point death-CV events and in an adjusted model suPAR predicted this end-point (P<0.001). In further analyses a strong competitive interaction emerged between ADMA and suPAR and a 0.1 uMol/L increase in ADMA signalled a 33% risk excess for the end-point in patients in the first suPAR tertile (HR 1.33; 95% CI: 1.08-1.64, p=0.006) while no risk excess by ADMA was registered in the second and third suPAR tertiles.

Conclusions: suPAR robustly associates with ADMA and biomarkers of innate immunity in CKD and shares a pathogenic pathway whereby ADMA competitively interacts with suPAR for the risk of death and cardiovascular events. ADMA and suPAR should be jointly considered in mechanistic and in clinical studies.

APOL1 Risk Variants and Subclinical Cardiovascular Disease (CVD) in HIV+ and HIV- Men Tessa Kimberly Novick,[1] Ruibin Wang,[1] Sudhir Penugonda,[2] Michael Shlipak,[3] Carl Grunfeld,[3] Adrienne Tin,[1] Jeremy J. Martinson,[4] Matthew Jay Budoff,[5] Rulan S. Parekh,[6] Wendy S. Post,[1] Michelle M. Estrella.[1] *[1]Johns Hopkins; [2]UCSF; [3]Northwestern Univ; [4]Univ of Pittsburgh; [5]UCLA; [6]Univ of Toronto.*

Background: HIV is associated with increased CVD risk and augments adverse effects of *APOL1* risk variants. We assessed whether the *APOL1* variants are associated with subclinical CVD in HIV+ and HIV- blacks in the Multicenter AIDS Cohort Study (MACS).

Methods: We conducted a cross-sectional analysis of men who were genotyped for the *APOL1* G1 and G2 variants and took part in the CVD substudy which enrolled men aged 40-70, weighed <136kg and had no prior coronary revascularization. We used Poisson regression to compare associations of high-risk (2 variants) vs. low-risk (0/1 variant) genotypes with prevalence of coronary artery calcium (CAC), coronary artery plaque and if present, type of coronary artery plaque (non-calcified, mixed and calcified) on CT imaging.

Results: Mean age and eGFR were 52 and 93 ml/min/1.73m^2, respectively, and were similar by *APOL1* genotype. Of 214 HIV+ and 95 HIV- men, 15% had 2 risk variants, 39% had CAC and 69% had coronary artery plaque present. Overall, high- vs. low-risk genotypes were associated with lower prevalence of CAC, but there was little difference in the presence of coronary artery plaque or its subtypes (Table). Stratified analyses showed a stronger association of *APOL1* variants with less CAC and greater non-calcified plaque presence in HIV+ than in HIV- men, though the interactions did not reach statistical significance.

Table. Associations of *APOL1* high- vs. low- risk genotypes with prevalence of subclinical CVD in HIV+ and HIV- black men

	Prevalence ratio (95% CI)	P-value
Overall*		
CAC	0.53 (0.30-0.92)	0.02
Any coronary plaque	1.09 (0.87-1.37)	0.46
Non-calcified plaque	1.14 (0.88-1.48)	0.33
Mixed plaque	1.21 (0.64-2.31)	0.56
Calcified plaque	1.03 (0.54-1.94)	0.94
HIV+ black men**		
CAC	0.37 (0.15-0.92)	0.03
Any coronary plaque	1.12 (0.84-1.48)	0.44
Non-calcified plaque	1.32 (0.98-1.78)	0.07
Mixed plaque	0.71 (0.26-1.97)	0.51
Calcified plaque	0.67 (0.26-1.72)	0.40
HIV- black men**		
CAC	0.81 (0.42-1.56)	0.53
Any coronary plaque	1.04 (0.71-1.52)	0.85
Non-calcified plaque	0.82 (0.50-1.35)	0.44
Mixed plaque	2.29 (0.85-6.15)	0.10
Calcified plaque	1.81 (0.65-5.03)	0.26

*Adjusted for age, CT scanning center, cohort status, ancestry, HIV serostatus, CVD risk factors, eGFR and proteinuria.
**Adjusted as above except for HIV serostatus. P-interactions for HIV x *APOL1* >0.05 for all models.

Conclusions: *APOL1* risk variants are associated with lower CAC burden in blacks. This association is particularly robust and may be driven by presence of non-calcified plaque in HIV+ men. Studies are needed to delineate underlying mechanisms and further evaluate if associations of *APOL1* variants with subclinical CVD indicators differ by HIV serostatus.

SA-PO799

Serum Magnesium and Mortality Risk in Patients with and without CKD in the Dallas Heart Study Silvia Ferrè, Xilong Li, Beverley Adams-Huet, Naim M. Maalouf, Robert D. Toto, Orson W. Moe, Javier A. Neyra. *UT Southwestern, Dallas, TX.*

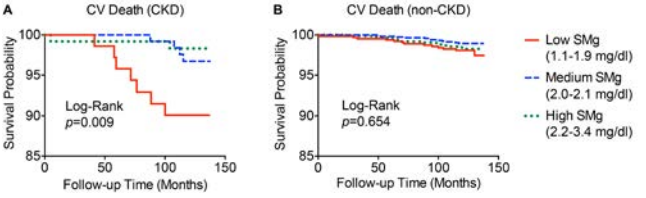
Background: Low serum magnesium (SMg) has been linked to increased mortality in hemodialysis patients and cardiovascular disease (CVD) in the general population. We examined whether similar associations exist in patients with prevalent CKD in the multiethnic population-based Dallas Heart Study (DHS) cohort.

Methods: The whole cohort, CKD and non-CKD subgroups were analyzed. The independent variable was SMg as a continuous variable and divided into tertiles. Study outcomes were all-cause and CV death evaluated using multivariable Cox regression hazards models adjusted for demographics; comorbidity; anthropometric and biochemical parameters including albumin, phosphorus, and PTH; use of diuretics; and their interactions. Median follow-up=12.3 yrs.

Results: Among 3550 participants, 404 (11.4%) had prevalent CKD. Mean SMg (mg/dl) was 2.07 (SD=0.18) in the whole cohort, 2.08 (0.19) in the CKD and 2.07 (0.18) in the non-CKD subgroups. All-cause and CV death occurred in 135 (4.4%) and 52 (1.7%) participants, respectively. SMg was independently associated with all-cause death in the whole cohort (adjusted HR, 1.9; 95% CI, 1.3–2.6; for low vs high tertile). Every 0.2 mg/dl increase in SMg reduced the adjusted hazard for all-cause death by 80%. These

observations were observed in both CKD and non-CKD subgroups. In contrast, SMg was only associated with CV death in the CKD subgroup (adjusted HR, 8.4; 95% CI, 1.6–43.6; for low vs high tertile).

Figure 1. Kaplan-Meier curves for CV death in (A) CKD and (B) non-CKD participants stratified by SMg tertiles.



Conclusions: Low SMg was independently associated with all-cause death in both CKD and non-CKD participants, and with CV death only in CKD participants. The pathophysiologic mechanisms of the effect of Mg on CVD and whether Mg supplementation may impact the CVD burden in CKD patients warrants further investigation.

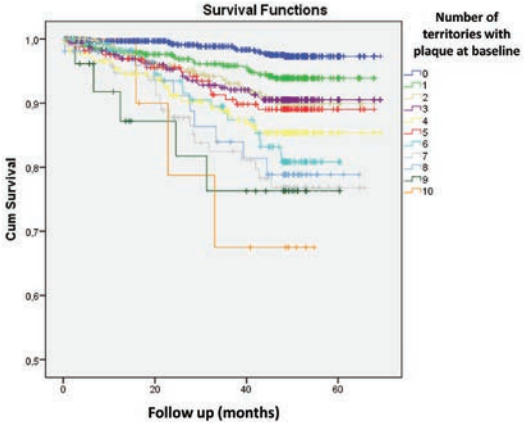
Subclinical Atheromatosis Detection by Arterial Ultrasound Predicts the Time Free from Cardiovascular Events in Chronic Kidney Disease. Results of the NEFRONA Study Jose M. Valdivielso, Montserrat Martinez-Alonso, Angels Betriu, David Arroyo, Maria Abajo, Elvira Fernandez. *IRBlleida, Lleida, Spain.*

Background: Cardiovascular disease remains the leading cause of morbidity and mortality in patients with chronic kidney disease (CKD).

Methods: The NEFRONA study enrolled 2445 CKD patients without previous cardiovascular disease and 559 subjects with normal renal function. The aim of the study was to assess the value of ultrasound detection of subclinical atheromatosis in the prediction of cardiovascular risk. This study shows the competing risk regression analysis of cardiovascular events (CVE) at the end of the study.

Results:



There have been 216 CVE (48 fatal and 168 nonfatal), 110 non-cardiovascular deaths and 588 renal transplants (both considered competing events). The number of missing patients is 99. The cumulative incidence of CVE is of 7.19% (69.4% men and 30.6% women) with a median of follow-up of 48.09 months. Kaplan Meier curves of survival free from CVE show that it decreases gradually and progressively with increases in the number of territories with plaque. The competing event regression analysis of the whole population shows that the factors significantly predicting CVE incidence are age in non-diabetic subjects, the number of territories with plaque, being a CKD patient in any stage, diabetes and low 25OH vitamin D in CKD stage 3. The stratified analysis showed that factors affecting survival in CKD stages 3-4 were age in non-diabetics, the number of territories with plaque, the levels of 25OH vitamin D, potassium levels over 5 and cholesterol over 240. In dialysis the number of territories, the dialysis vintage, the levels of phosphate, sex and diabetes significantly affected survival.

Conclusions: The severity of arterial atheromatosis estimated by ultrasound predicts the time free from CVE in CKD. Arterial ultrasound is a useful tool to predict cardiovascular risk in CKD patients.

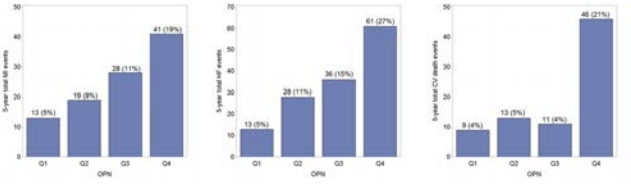
SA-PO801

Osteopontin and Cardiovascular Outcomes in Patients with Stable Coronary Disease Meyeon Park, Debbie Huang, Rakesh Mishra, Michael Shlipak, Mary Whooley. *UCSF.*

Background: Osteopontin (OPN) is an adhesion molecule upregulated by cardiac myofibroblasts and synthesized by endothelial cells in atherosclerotic plaques. OPN promotes hypoxia-induced proliferation of kidney mesangial cells and is stimulated by angiotensin II. We investigated the association between OPN and cardiovascular outcomes in patients with stable ischemic heart disease and variable levels of kidney function assessed by eGFR and ACR.

Methods: OPN was measured in 985 patients with stable coronary disease enrolled in the Heart and Soul Study between 9/2000-12/2002. Poisson regression models were used to examine the relationship between baseline OPN and myocardial infarction (MI), heart failure hospitalization (HF), and all-cause death. Five-year mortality rates were stratified by quartile of OPN.

Results: Spearman correlations between OPN and eGFR and ACR were -0.40 and 0.23. In unadjusted models, risks of MI and HF were significantly higher for participants in Q4 OPN compared to the lower 3 quartiles [incident rate ratio (IRR) 2.48 (95% CI 1.71, 3.60) and 2.96 (2.17, 4.03)] (Fig. 1). Adjusting for demographics and clinical risk factors, participants in Q4 OPN had a higher risk of HF [IRR 1.56 (1.08, 2.25)], while risk of MI was not different between OPN quartiles after adjustment [IRR 1.39 (0.90, 2.16)]. The association between OPN and HF was no longer significant after adjusting for eGFR and ACR [IRR 1.35 (0.90, 2.03)]. Risk of death was highly significant in unadjusted models [IRR 3.59 (2.61, 4.94)] and remained so even after adjustment for eGFR and ACR [IRR 1.83 (1.23, 2.71)].



Conclusions: Higher levels of OPN were associated with risk of HF after adjusting for demographic/clinical factors, but eGFR and ACR attenuated these associations. Higher levels of OPN were nevertheless associated with risk of death independent of eGFR and ACR. OPN may mediate CV risk via angiotensin II-dependent pathways in both kidneys and heart.

Plasma Dephosphorylated Uncarboxylated Matrix Gla Protein Associate with Vascular Calcification and Vascular Stiffness in Chronic Kidney Disease Paweena Susantitaphong, Sipanan Thamratnopkoon, Pisut Katavetin, Nattachai Srisawat, Khajohn Tiranathanagul, Kearkiat Praditpornsilpa, Somchai Eiam-Ong. *Div of Nephrology, Dept of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Vascular calcification causes cardiovascular morbidity and mortality in chronic kidney disease (CKD) patients. Matrix Gla protein (MGP) is a potent inhibitor of vascular calcification and needs vitamin K–dependent phosphorylation and carboxylation for its activity. Therefore, the plasma level of "inactive" dephosphorylated uncarboxylated MGP (dp-ucMGP) which would reflect vitamin K status might associate with vascular calcification. This study was conducted to investigate the association between plasma dp-ucMGP and vascular calcification as well as vascular stiffness in CKD patients.

Methods: Eighty-three CKD stage 3-5 patients were enrolled in this study. Vascular calcification was determined using abdominal aorta calcification (AAC) score from lateral lumbar film, vascular stiffness was assessed by cardio-ankle vascular index (CAVI), and plasma dp-ucMGP levels were measured using ELISA method, Maastricht,The Netherlands.

Results: The mean age was 62.9±13.9 years. The plasma dp-ucMGP levels in CKD stage 3, and CKD stage 4&5 were 604.0 (457.5-925.0) and 1,056 (523.3-1,663.5 pmol/L, respectively (normal <500 pmol/L). The prevalence of vascular calcification (AAC score≥1) was 63.4% and that of vascular stiffness (CAVI≥9) was 46.3%. Multivariate logistic regression analysis to predict vascular calcification showed that age and plasma dp-ucMGP were significantly associated with vascular calcification (OR 1.23;95%CI 1.09-1.37);p<0.001 and OR 1.003 95%CI 1.001-1.005;p=0.002,respectively). In contrast, there was no association between plasma dp-ucMGP and vascular stiffness.

Conclusions: Plasma dp-ucMGPlevels increase progressively with more advance stage of CKD. Plasma dp-ucMGP associated with vascular calcification could be the marker for vascular calcification in CKD patients. Since vitamin K supplement is the readily available treatment to reduce of dp-ucMGP, the effect of vitamin K supplement on vascular calcification in CKD patients should be further explored with the long-term randomized clinical trial.

SA-PO803

Need for Insulin Is Associated with Increased Risk of All-Cause Mortality (ACM) in Various CKD Stages in Type 2 Diabetes Mellitus (T2DM) Rabia Nadeem Kiani,[1] R. E. Boucher,[1] Guo Wei,[1] Debra Lynn Simmons,[1] T. S. Bjordahl,[1] Linda F. Fried,[2] Tom Greene,[1] Srini Beddhu.[1] *[1]Univ of Utah, SLC, UT; [2]VA, Pittsburgh, PA.*

Background: In more advanced CKD, insulin use might reflect insulin resistance and/or contraindication to oral hypoglycemic agents. Therefore, we examined the relationship between the need of insulin and ACM at various stages of CKD in a national cohort of 1,561,876 veterans with serum creatinine and serum HDL-cholesterol measured within 3 months of each other from Jan 1, 2000 to Dec 31, 2008.

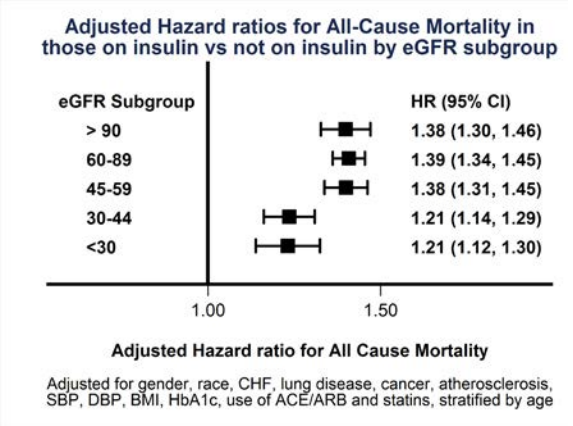
Methods: There were 188,544 veterans with T2DM (defined by ICD9 codes). Data on filled medications were obtained from outpatient pharmacy database. Laboratory data were

obtained from routine clinical labs. Mortality data were from vitals files. Within each eGFR subgroup, the risk for ACM in those on insulin vs. those not on insulin were examined in separate Cox regression models.

Results: Mean age was 65± 11 yrs. 97.4 % were males and 18.4% were black. 20.4% were using insulin. The mean eGFR was 73 ± 23 ml/min/1.73 m^2.

eGFR group	N		ACM / 100 person years (# deaths/total follow-up years)		HR (95% CI)*
	Not on insulin	On insulin	Not on insulin	On insulin	
>90	36,085	9,635	1.1 (4708/420,923)	1.6 (1736/106,479)	1.41 (1.34, 1.49)
60-89	75,227	15,333	1.7 (14,408/846,149)	2.4 (3805/161,675)	1.38 (1.33, 1.42)
45-59	24,761	6,844	2.7 (6802/255,966)	3.6 (2340/65,659)	1.32 (1.26, 1.38)
30-44	11,001	4,374	4.2 (4156/99,969)	4.8 (1809/37,331)	1.13 (1.08, 1.19)
<30	4,006	2,528	7.0 (2053/29,312)	7.2 (1302/18,186)	1.03 (0.97, 1.10)

*Unadjusted HR for comparison of those on insulin vs. not on insulin within each GFR group



Conclusions: Need for insulin in more advanced CKD is associated with elevated mortality risk in adjusted models. Interventions that decrease the need for insulin might decrease mortality in advanced CKD.

SA-PO804

Brain Deep and Subcortical White Matter Hyperintensity in Predialysis CKD Patients Hideaki Shima,[1] Tatsuhiko Mori,[1] Hajime Hirano,[1] Mika Sonoda,[2] Mikio Okamura,[3] Tetsuo Shoji,[2] Eiji Ishimura,[2] Masaaki Inaba.[2] *[1]Nephrology, Osaka Medical College, Takatsuki, Japan; [2]Internal Medicine 2, Osaka City Univ, Osaka, Japan; [3]Nephrology, Kayashima-Ikuno Hospital, Kadoma, Japan.*

Background: CKD patients have higher risk for stroke than the general population. Magnetic resonance imaging (MRI) of brain is highly sensitive for detecting ischemic lesions such as deep and subcortical white matter hyperintensity (DSWMH). DSWMH reported to be a risk factor for future stroke and dementia in non-CKD population. In this study, we investigated the prevalence of DSWMH and its relation to clinical severity in predialysis CKD patients without prior stroke.

Methods: The participants of this cross-sectional study included 505 CKD patients and 100 Non-CKD subjects who underwent brain MRI without enhancement to evaluate DSWMH between January 2008 and December 2011.

Results: DSWMH was more prevalent in the CKD (58.4%) than in the Non-CKD (27.0%) groups. In Non-CKD group, those with DSWMH had higher age (66.0±12.0 vs. 56.2±11.6 years), higher systolic blood pressure (125.0±14.3 vs. 116.5±11.2mmHg), and higher proportion of smokers (53.9% vs. 21.0%).In addition to these factors, lower eGFR(27.9 ± 22.2vs.55.4 ± 34.5 ml/min/1.73m²), higher proteinuria (3.09 ± 3.47 g/gCre vs. 2.45 ± 3.18 g/gCre), anemia (Hb11.4 ± 2.4 vs. 12.4 ± 2.4 g/dl) and diabetes (44.7% vs. 29.0%) were associated with the presence of DSWMH in the CKD group. Multivariate logistic regression analysis revealed that eGFR (p<0.01) but not proteinuria (p=0.79) was a significant factor associated with the presence of DSWMH independent of age, sex, diabetes and blood pressure. Moreover, the severity of DSWMH evaluated by the Fazekas scale was significantly and positively correlated with CKD stages.

Conclusions: DSWMH was more prevalent and severer in more advanced stages of CKD. A lower eGFR, rather than proteinuria, was the factor associated with the presence of DSWMH independent of age, sex, diabetes mellitus, and blood pressure. DSWMH may explain the higher risk of stroke in this population.

SA-PO805

Determinants of Long-Term Outcomes in Patients with Atherosclerotic Renovascular Disease and High-Risk Clinical Features Diana Vassallo, James Ritchie, Constantina Chrysochou, Darren Green, Philip A. Kalra. *Dept of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom.*

Background: Although most patients with atherosclerotic renovascular disease (ARVD) remain stable on multitargeted vascular protective therapy, a small but important proportion of patients present with a 'high-risk' clinical phenotype and do not respond to conservative management. In this study we aimed to identify determinants of long-term outcomes in such a selected high-risk subgroup.

Methods: Patients with a radiological diagnosis of ARVD were recruited into our single-center study between 1986 and 2014. Patients with >70% unilateral or bilateral ARVD together with one or more of these presentations were designated 'high-risk': flash pulmonary edema (FPE), severe hypertension, rapidly deteriorating renal function. Patients who did not meet these criteria were designated 'low-risk'. Univariate Cox regression analysis was used to explore the association between individual variables and the following end-points: death, end-stage kidney disease (ESKD), cardiovascular event (CVE) and the first of any of these events.

Results: Out of a total of 843 patients who met inclusion criteria, 131 (15.5%) were designated high-risk.

	Low-risk patients n=712	High-Risk patients n=131	p-value
Median age (years)	71.9	73.3	0.4
Diabetic (%)	27.5	36.6	0.04
Macrovascular disease (%)	68.8	79.4	0.02
Congestive heart failure (%)	17.6	33.3	<0.001
Renin-angiotensin blockade (%)	47.2	59.5	0.01
Statin (%)	52.1	67.9	0.001
Median baseline eGFR	32.6	32.7	0.6
Revascularized (%)	12.8	42.0	<0.001

In the high-risk group, multivariate analysis showed that renin-angiotensin blockade was associated with reduced risk of death (HR 0.42 [95% CI 0.23-0.77], p=0.004), CVE (HR 0.65 [95% CI 0.42-0.99] p=0.046) and any event (HR 0.64 [95% CI 0.41-0.94] p=0.024). Revascularization conferred protection against ESKD (HR 0.58 [95% CI 0.36-0.92] p=0.02) and CVE (HR 0.63 [95% CI 0.41-0.97] p=0.037).

Conclusions: Both intensive vascular protective therapy and revascularization may optimize clinical outcomes in patients with ARVD and 'high-risk' clinical features.

SA-PO806

The Effect of Revascularization in Patients with Atherosclerotic Renovascular Disease and High-Risk Clinical Features - A Single-Center Observational Study Diana Vassallo, James Ritchie, Constantina Chrysochou, Darren Green, Philip A. Kalra. *Dept of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom.*

Background: There is evidence that certain patients with atherosclerotic renovascular disease (ARVD) may benefit from revascularization. In this study we explored the effect of revascularization on long-term clinical outcomes in patients with specific clinical presentations who would meet current criteria for revascularization.

Methods: Patients with a radiological diagnosis of ARVD were recruited into our single-center study between 1986 and 2014. Patients with >70% unilateral or bilateral ARVD together with one or more of the following presentations were designated 'high-risk': flash pulmonary edema (FPE), severe hypertension, rapidly deteriorating renal function. Outcomes in these patients, those specifically with bilateral ARVD and those with <1g proteinuria at baseline were compared to 'control' patients who had the same degree of RAS but did not exhibit these high-risk features. Multivariate Cox regression was used to investigate the effect of revascularization on death, progression to end-stage kidney disease (ESKD), cardiovascular event (CVE) and the first of any of these events in this selected population.

Results: Of 872 patients recruited, 131 (15%) had a 'high-risk' presentation while 144 (16.5%) were designated 'controls'. Revascularization was associated with reduced risk of death in patients presenting with FPE (HR 0.38 [95% CI 0.15-0.96], p=0.04) and reduced risk of ESKD in patients with rapidly deteriorating renal function (HR 0.44 [95% CI 0.24-0.82], p=0.009). In patients with bilateral ARVD, revascularization reduced the risk of both death (HR 0.45 [95% CI 0.20-0.99], p=0.047) and ESKD (HR 0.49 [95% CI 0.27–0.89] p=0.019). High-risk patients with <1g proteinuria at baseline had reduced risk of ESKD (HR 0.56 [95% CI 0.34-0.94] p=0.029), CVE (HR 0.54 [95% CI 0.33-0.89] p=0.016) and any event (HR 0.61 [95% CI 0.38-0.98] p=0.042) following revascularization.

Conclusions: Our results indicate that revascularization may be of benefit in patients with FPE, rapidly deteriorating renal function, severe bilateral renal artery disease and those with <1g/day proteinuria.

SA-PO807

Kidney Dysfunction and Left Ventricular Hypertrophy in Population-Based Autopsy Samples: The Hisayama Study Kensuke Izumaru,[1] Jun Hata,[2] Yutaka Nakashima,[1] Toshiaki Nakano,[3] Kazuhiko Tsuruya,[3] Yoshinao Oda,[4] Takanari Kitazono,[3] Yutaka Kiyohara,[5] Toshiharu Ninomiya.[2] *[1]Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [2]Dept of Epidemiology and Public Health, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [4]Dept of Anatomic Pathology, Pathological Sciences, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [5]Hisayama Research Inst For Lifestyle Diseases, Fukuoka, Japan.*

Background: Growing evidence has suggested that subjects with kidney dysfunction develop left ventricular hypertrophy (LVH) with the progression of renal disease. However, there are limited studies addressing pathologically the association between kidney dysfunction and LVH.

Methods: In 334 population-based autopsy samples, we investigated the thickness of left ventricular wall according to estimated glomerular filtration rate (eGFR) levels. In 95 sample selected randomly from these samples, the sizes of cardiac cell and the percentages of fibrosis in left ventricular wall were also estimated.

Results: The thickness of left ventricular wall increased significantly with eGFR levels of ≥60, 45-59, 30-44, and <30ml/min/1.73m^2, being 9.1, 9.5, 9.8, and 10.3 (mm), respectively (p for trend <0.05). Lower eGFR levels were associated significantly with greater mean values of cardiac cell size in left ventricular wall after adjusting for confounding factors: 15.3, 16.1, 16.4, and 17.4 (μm) in eGFR levels of ≥60, 45-59, 30-44, and <30ml/min/1.73m^2,(p for trend <0.001). Likewise, subjects with lower eGFR had significantly higher multivariable-adjusted mean values of percentage of fibrosis in left ventricular wall, being 3.22, 4.33, 3.83, and 6.14 (%) in eGFR levels of ≥60, 45-59, 30-44, and <30ml/min/1.73m^2 (p for trend <0.001).

Conclusions: Our findings suggest that renal dysfunction is associated with the cardiac hypertrophy and fibrosis of left ventricle via cardiac cell enlargement and cardiac fibrosis.

SA-PO808

Utility of High-Sensitivity Troponin I in Patients with Impaired Renal Function Eve Victoria Miller-Hodges. *Centre for Cardiovascular Science, Univ of Edinburgh, Edinburgh, United Kingdom.*

Background: Cardiovascular disease remains the leading cause of death in Chronic Kidney Disease. The optimal diagnosis and exclusion of acute myocardial infarction is limited in these patients by the uncertain role of cardiac biomarkers such as Troponin. We investigated whether low serum High-Sensitivity Troponin I (hsTnI) continued to identify those at low risk of cardiac events in the presence impaired renal function (eGFR<60).

Methods: Patients with impaired renal function (eGFR<60) were identified from two prospective cohorts of patients presenting to emergency departments with suspected acute coronary syndrome (Shah AS, *Lancet* 2015 & Shah AS, *BMJ* 2015; n=5050). Serum hsTnI was measured at presentation. The negative predictive values for a range of hsTnI concentrations were established for a composite outcome of myocardial infarction or cardiovascular death at 30 days and at 1 year, compared to the normal population (eGFR >60).

Results: 1160/5050 [23%] patients had an eGFR<60. 302 [26%] had a diagnosis of myocardial infarction at presentation compared to 478 [12.3%] of those with an eGFR>60 (p<0.01). These patients were at significantly higher risk of subsequent myocardial infarction or cardiac death at 30 days (104 [9%] *vs.* 55 [1.4%]) and at 1 year (302 [26%] *vs.* 478 [12.3%]). Serum hsTnI concentration at admission was higher in patients with impaired renal function (median 15.5ng/L [IQR 6-53] *vs.* 4.00ng/L [IQR 2-10]) but the majority of patients were below the 99th centile threshold (702 [61%]). As in health, a low hsTnI threshold at presentation (<5ng/L) continued to identify those patients with impaired renal function at very low risk of myocardial infarction or death within 30 days (negative predictive value 99.4% [98.4-99.9]).

Conclusions: In this large representative cohort of patients presenting with suspected acute coronary syndrome, patients with impaired renal function were at the highest risk of myocardial infarction and cardiac death. A low serum hsTnI concentration identified those at very low risk of myocardial infarction and cardiac death.

SA-PO809

Evaluation of Clinical Outcomes among Nonvalvular Atrial Fibrillation Patients Treated with Warfarin or Rivaroxaban Stratified by Renal Function Matthew R. Weir,[1] Lloyd P. Haskell,[2] Jeffrey S. Berger,[3] Veronica Ashton,[2] François Laliberte,[4] Concetta Crivera,[2] Kip Brown,[4] Patrick Lefebvre,[4] Jeff R. Schein.[2] *[1]Univ of Maryland School of Medicine, Baltimore, MD; [2]Janssen Scientific Affairs, LLC, Raritan, NJ; [3]New York Univ School of Medicine, NY, NY; [4]Groupe d'Analyse, Ltée, Montréal, QC, Canada.*

Background: Renal impairment is linked to increased risk of thromboembolic and bleeding events in NVAF patients.This study compares these events for patients treated with warfarin or rivaroxaban stratified by renal function.

Methods: Patients with first dispensing of warfarin or rivaroxaban after 11/2011 from IMS PharMetrics Plus data (05/2011-6/2015) were included. Ischemic stroke, major bleeding, VTE, and MI outcomes, stratified by estimated creatinine clearance (eCrCl from Cockcroft-Gault formula), were analyzed with hazard ratios. Confounding adjustments were made with inverse probability of treatment weights.

Results: Analyses included 874 rivaroxaban and 1,069 warfarin users. Baseline characteristics for weighted cohorts were similar. Outcomes are reported in table.

Renal Function	Outcomes	Unweighted Incidence Rate (per 100 person-year)		Adjusted HRs (95% CI)	P-Values
		Rivaroxaban	Warfarin		
Overall	Ischemic stroke	0.9	2.6	0.69 [0.23-2.04]	0.5020
rivaroxaban=874	Major bleeding	4.4	6.4	1.18 [0.72-1.94]	0.5166
warfarin=1,069	Composite	7.0	15.0	0.69 [0.46-1.05]	0.0850
eCrCl < 80 mL/min	Ischemic stroke	2.0	4.1	1.21 [0.23-6.48]	0.8201
rivaroxaban=201	Major bleeding	10.2	8.7	1.51 [0.77-2.95]	0.2323
warfarin=406	Composite	9.9	16.6	1.17 [0.53-2.61]	0.6954
eCrCl ≥ 80 mL/min	Ischemic stroke	0.5	1.6	0.56 [0.14-2.18]	0.4040
rivaroxaban=673	Major bleeding	2.8	4.8	0.92 [0.47-1.81]	0.8164
warfarin=663	Composite	6.2	14.0	0.58 [0.36-0.93]	0.0230
Composite = VTE, MI, or stroke					

Conclusions: Rivaroxaban-treated patients with eCrCl ≥ 80 mL/min had significantly lower risk for the composite measure. Ischemic stroke and major bleeding rates were not statistically different between rivaroxaban and warfarin, in patients with or without renal impairment. Further research is warranted to corroborate these findings.

Early Mortality and Late Outcomes for Coronary Revascularisation in Chronic Kidney Disease - A Systematic Review and Meta-Analysis Robin Ramphul, Debasish Banerjee. *Renal and Transplantation Unit, St. George's Univ Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: Despite the high prevalence of coronary artery disease in patients with chronic kidney disease (CKD), the optimal method of coronary revascularisation remains unclear. We conducted a systematic review and meta-analysis of the available literature comparing early mortality and long-term outcomes of percutaneous coronary intervention (PCI) and coronary artery bypass graft (CABG) in patients with CKD.

Methods: We reviewed contemporary studies, conducted after the year 2000 as PCI therapy have improved, comparing PCI to CABG in CKD patients, using Review Manager 5.1 for statistical analysis and PRISMA guidelines for reporting. Clinical end-points compared were early (in-hospital or 30-day) and late (> than 1 year) mortality; repeat revascularisation, occurrence of major adverse cardiovascular events (MACE) and myocardial infarction (MI) after revascularisation.

Results: 4 studies investigated early mortality. The pooled analysis showed similar early deaths for PCI and CABG (4% v 6%, p=0.44, Figure 1a). In 6 studies reporting late mortality, CABG was associated with less deaths compared to PCI (26% v 30%, p<0.001, Figure 1b). Repeat revascularisation was reported in 3 studies with CABG less likely to lead to further revascularisation compared to PCI (2% v 14%, p=0.01, Figure 1c). The occurrence of MACE was reported in 3 studies. CABG was associated with significantly less events compared to PCI (18% v 28%, p=0.01, Figure 1d) and although MI alone occurred less often with CABG than PCI this was not statistically significant (4% v 10%, p=0.41). There existed a selection bias with PCI preferred to CABG in single vessel disease and CABG for multivessel or left main disease.

Conclusions: The results favour CABG for late mortality, repeat revascularisation and MACE whilst PCI is marginally beneficial for early mortality.

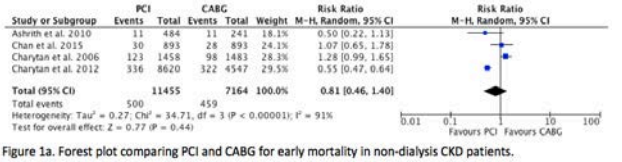

Figure 1a. Forest plot comparing PCI and CABG for early mortality in non-dialysis CKD patients.

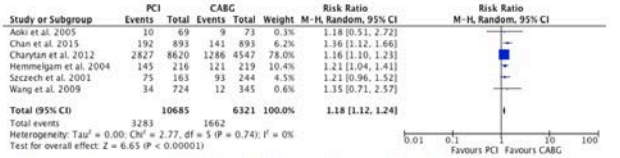

Figure 1b. Forest plot comparing PCI and CABG for late mortality in non-dialysis CKD.

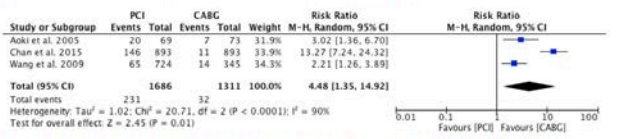

Figure 1c. Forest plot comparing PCI to CABG for need for repeat revascularisation in non-dialysis CKD.

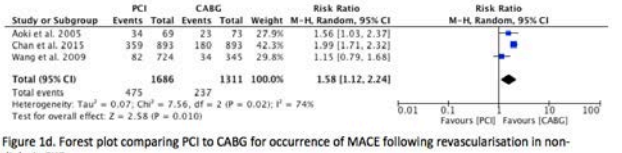

Figure 1d. Forest plot comparing PCI to CABG for occurrence of MACE following revascularisation in non-dialysis CKD.

SA-PO811

Role of TCF7L2 Gene and PPARG2 Gene Polymorphism on Renal and Cardiovascular Complications in Patients with Type 2 Diabetes: A Cohort Study Pamila Tasanavipas, Bancha Satirapoj, Amnart Chaiprasert, Naowanit Nata, Theerasak Tangwonglert, Prajej Ruangkanchanasetr, Ouppatham Supasyndh. *Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand.*

Background: The emerging renal and cardiovascular complications of type 2 diabetes genetics involves differently assembled gene variants including transcription factor-7-like-2 (TCF7L2) and peroxisome proliferated activated receptor gamma 2 (PPARG 2) polymorphism. However, the relevance of these genes for complications prediction has not been extensively tested.

Methods: We analyzed the SNPs rs7903146 in TCF7L2 and PPARG2 gene polymorphism for their contribution to incidence of CKD and CVD complications in the prospective cohort study. All type 2 diabetes patients were followed the estimated glomerular filtration rate (eGFR) and CV outcomes. Cox proportional hazards regression models were used to estimate the genotype effect on the incidence of CKD and CV complications.

Results: A total of 422 patients with mean age of 62±11.8 years and eGFR of 72.8±31.8 mL/min/1.73 m^2 were included. SNPs rs7903146 in TCF7L2 gene were classified into 3 groups: C/C 385patients (91.2%), C/T 32patients (7.6%) and T/T 5 patients (1.2%) and PPARG2 gene were classified into 2 groups: Pro12Pro 404 patients (95.7%) and Pro12Ala 18 patients (4.3%). The prevalence of CKD, CV disease and death at the end of the 5-year follow-up was 16.8%, 29% and 7.9%, respectively. The Pro12Ala variant of PPARG2 gene was significantly was associated with increased CKD risk at the end of the study (adjusted HR 3.45 [95% CI 1.01–11.77, p = 0.046), it did show significant association with increase stroke risk, but not CV diseases and mortality. Whereas, no genotype effect of rs7903146 in TCF7L2 gene was apparent on renal and CV complications in type 2 diabetes over time except that it increased coronary artery disease risk.

Conclusions: The findings of our study are that Pro12Ala variant in PPARG2 gene is associated with risk of developing CKD in Asian type 2 diabetes in the prospective cohort. Further investigations are warranted to understand the pathway-based functional implications of the important loci in PPARG2 gene.

SA-PO812

Cardiac Stress Testing in U.S. Patients with Chronic Kidney Disease: Is the Epoch of Nihilism and Renalism Ancient History? Charles A. Herzog,[1,2] Tanya Natwick,[1] Shuling Li,[1] David M. Charytan.[3] *[1]MMRF, Chronic Disease Research Group, Mpls, MN; [2]HCMC, Univ of MN; [3]Brigham & Women's Hospital, Boston, MA.*

Background: A "nihilistic approach" to coronary artery disease (CAD) in pts with chronic kidney disease (CKD) has previously been reported. We have revisited this "truism" in the context of cardiac stress testing in the modern era (2008-12).

Methods: The 20% Medicare sample was searched by single cohort yrs (2008-12) to identify pts age 65+ with no CKD (n = 4,232,080 in 2012) and Stages 1-5D CKD (n= 332,058 in 2012). Incidence rates of non-invasive CAD testing (Stress: Echo, Nuclear, MRI, and ECG and CT: angiography or Calcium score) were estimated within each cohort by yr.

Results: Demographics of pts receiving tests (2012): **non-CKD**: 35% age 75-84, 6% age 85+, 88% white, 7% black, 48% male; **CKD**: 44% age 75-84, 10% age 85+, 80% white, 13% black, 54% male, 7% CKD stages 1 & 2, 67% 3,4,5ND, 8% ESRD and 17% unknown stage. The rate of stress testing (per 100 pt-yrs) was 11.5 for non-CKD and 16.8 for CKD pts in 2008, declining to 9.4 and 13.4 respectively in 2012 (see figure). Stress nuclear testing was dominant: 80.3% (non-CKD) and 88.2% (CKD) of all stress tests in 2008 and 77.7% (non-CKD) and 87.1% (CKD) in 2012 vs stress echo: 11.6% (non-CKD) and 7.4% (CKD) in 2008 and 12.6% (non-CKD) and 7.4% (CKD) in 2012. There was a trend towards higher rates (per 100 pt yr) of stress testing with worse kidney function: No CKD (9.4), Stage 1-2 (13.0), Stage 3-5ND (14.0), ESRD (18.4) in 2012.

Conclusions: There has been a progressive decline in rates of stress testing in both non-CKD and CKD pts from 2008 to 2012. Stress nuclear imaging accounts for more than three-fourths of all stress tests. CKD pts have consistently higher rates of stress testing compared to non-CKD pts in 2008-12. Commonly held perceptions of under-utilization of stress testing for CAD in CKD pts are false in the current era.

SA-PO813

Efficacy of Statin Therapy in Early-Stage Chronic Kidney Disease Han Ro,[1] Sun Moon Kim,[2] Yun Jung Oh,[3] Ae Jin Kim,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung,[1] Ji Yong Jung.[1] *[1]Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; [2]Dept of Internal Medicine, Chungbuk National Univ Hospital, Cheongju, Republic of Korea; [3]Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: Chronic kidney disease (CKD) is a major risk factor for the development of cardiovascular disease (CVD), and statin treatment can reduce the risk of CVD. However, whether statin treatment affects renal progression and outcomes in CKD patients remains unclear.

Methods: We retrospectively reviewed CKD patients who visited to Gachon University Gil Medical Center with renal problems from 2003 to 2013. From a total 14497 CKD patients, 858 statin users were paired with 1:1 with non-users for analysis using propensity score matching. The outcomes of this study were creatinine doubling, renal death, all-cause mortality, and interactive factors for composite outcomes.

Results: Statins were prescribed to 13.5% of the study subjects. Statin treatment-associated hazard ratios (HRs) [95% confidence intervals (CIs)] for the doubling of serum creatinine levels were significant only in patients with an estimated glomerular filtration rate (eGFR) ≥30 mL/min/1.73 m^2, and were 0.744 (0.635–0.873) in the unmatched cohort and 0.767 (0.596–0.986) in the matched cohort. In analyses of secondary outcomes, the HRs (95% CIs) for all-cause mortality were 0.655 (0.502–0.855) in the unmatched cohort and 0.537 (0.297–0.973) in the matched cohort. The HRs (95% CIs) for composite outcomes among patients with and without eGFR ≥30 mL/min/1.73 m^2 were 0.764 (0.613–0.952) and 1.232 (0.894–1.697), respectively (P for interaction, 0.017).

Conclusions: Statin treatment in the early stages of CKD may be related to renal progression and the all-cause mortality rate.

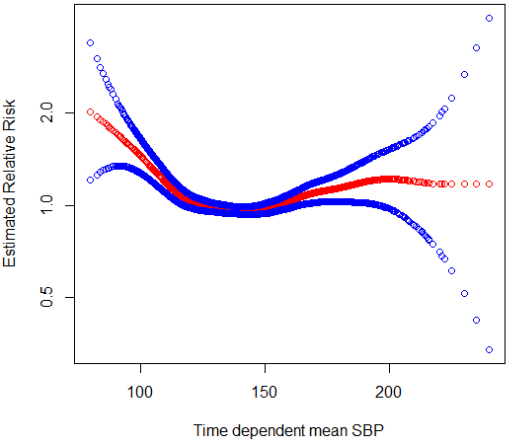
SA-PO814

Low Systolic Blood Pressure during the Follow-Up Period Is Associated with Increased Risk of Cardiovascular Disease in Patients with Type 2 Diabetes and Renal Impairment with and without Heart Failure - The Swedish National Diabetes Register (NDR) Hanri Afghahi,[1] Maria K. Svensson.[2] *[1]Nephrology, Skaraborg Hospital, Skövde, Sweden; [2]Medical Sciences, Uppsala Univ, Uppsala, Sweden.*

Background: Current guidelines recommend a SBP target of <140 mmHg in patients with diabetes and renal impairment (RI) and <130 mmHg when albuminuria is presence . The aim of this study was to further evaluate the relationship between SBP and risk of cardiovascular events (CVEs) in patients with type 2 diabetes (T2D) and (RI), with or without a history of chronic heart failure (CHF) using time-updated mean SBP.

Methods: 27 732 patients with T2D and RI (eGFR< eGFR 60ml/min/1.73m^2 according to MDRD) were followed for mean 4.7 years. The relationships between SBP and CVEs were examined by time-dependent Cox models, to estimate hazard ratios (HR), adjusting for cardiovascular risk factors and medications.

Results: The patients were mean age of 75±9 years, their diabetes duration was 10±8 years, 43% were male, mean SBP at baseline was 138±18 mmHg and 15% had a history of CHF. Patients were classified into 4 groups by time-updated mean SBP (<130, 130-140, 141-160 and >160 mmHg). A time updated mean SBP between 130 and 140 mmHg was used as a reference group. All patients with a time updated mean SBP <130 mmHg had a higher risk of CVEs (HR 1.23, 95% CI 1.19-1.34). In patients without a history of CHF a time-updated mean SBP <130 mmHg was also associated to a higher risk of CVEs (HR 1.23 95% CI 1.14-1.32).



Conclusions: In patients with type 2 diabetes and renal impairment a systolic blood pressure <130 mmHg over the time was associated with a higher risk of cardiovascular events. This association was also found in patients without a history of CHF.

SA-PO815

Trimethylamine-N-oxyde (TMAO) Accumulates in Patients with Chronic Kidney Disease (CKD): Correlation with the Measured Glomerular Filtration Rate (mGFR) Caroline C. Pelletier,[1,2] Mikael Croyal,[3] Michel Krempf,[3] Laurent Juillard,[1,2] Christophe O. Soulage.[2] *[1]Nephrology, Hospices Civils de Lyon, France; [2]Univ Lyon, INSA-Lyon, INSERM U1060, CarMeN Lab, France; [3]INRA, UMR 1280, CRNH, Mass Spectrometry Area, Nantes, France.*

Background: TMAO is associated with poor cardiovascular outcomes in the general population. Significant higher TMAO levels has been ever been reported in patients with CKD. However, these observations were only based on estimated GFR. We wanted to further confirm plasma TMAO accumulation and its relationship with kidney function in a cohort of CKD patients characterized by measured GFR.

Methods: Control and CKD patients were recruited in the E.Herriot university hospital, in Lyon (France) to perform a measurement of GFR by an inuline clearance and plasmatic TMAO determination by LC-MS/MS.

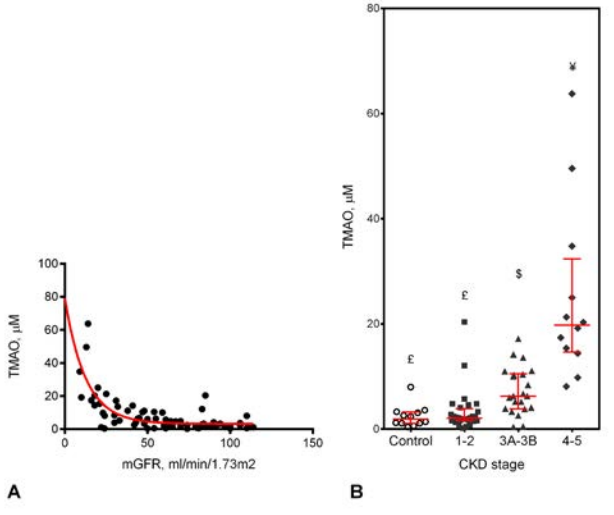
Results: TMAO was measured in 75 patients and was stronlgy associated with the level of mGFR.

Characteristics of healthy volunteers and CKD patients.

	Healthy volunteers	CKD patients			P-value
		Stage 1-2	Stage 3	Stage 4-5	
Effective	12	27	22	14	
Age, y	41.2±10.5	47.3±14.8	63.8±15.5	51.5±21.0	***
Creatinin, µM	64.3±14.7	83.1±17.6	122.5±40.6	275.3±114.6	****
UAlb/UCreat, mg/mmol	1.2±1.0	12.0±28.1	59.5±195.7	52.7±67.1	****
mGFR, ml/min/1.73m^2	102±8.2	76.1±10.6	43.4±8.9	18.4±5.3	****
TMAO, µg/L	2.4±2.1	3.3±4.1	7.3±4.5	21.5±17.7	****

Means were compared with ANOVA test with a significant p<0.05.

We observed a significant differences between the stages 4-5 and the stage 3 as well as between the stage 3 and all the other patients with better renal function.



Conclusions: Plasma TMAO is increased in patient with CKD and negatively associated with the stages of CKD, defined by mGFR. We confirmed that TMAO accumulates in CKD as a result of the decreased GFR suggesting that TMAO could be considered as a novel uremic toxin.

SA-PO816

The Predictive Value of Serum Triglyceride to High-Density Lipoprotein Cholesterol Ratio According to Renal Function in Patients with Acute Myocardial Infarction (From the Korea Acute Myocardial Infarction Registry) Jin Sug Kim, Yu Ho Lee, Da Rae Kim, Chun-Gyoo Ihm, Tae Won Lee, Kyung-Hwan Jeong. *Kyung Hee Univ Hospital.*

Background: Serum triglyceride to high-density lipoprotein cholesterol (TG/HDL-C) ratio has been reported as an independent predictor for cardiovascular events in general population. However, the prognostic value of this ratio is unclear in patients with renal dysfunction. We examined the association of TG/HDL-C ratio and major adverse cardiovascular events (MACEs) according to renal function in patients with acute myocardial infarction (AMI).

Methods: This study was based on the Korea Acute Myocardial Infarction Registry database. Among 13,897 patients who diagnosed AMI from November 2005 to July 2008, 7,016 patients were enrolled. Patients were stratified into three groups by estimated glomerular filtration (eGFR) and TG/HDL-C ratio was categorized into tertiles based on the distribution of TG/HDL-C ratio. We investigated the 12-month MACEs, including cardiac death, MI, and repeated percutaneous coronary intervention or coronary artery bypass grafting.

Results: During follow up period, 593 patients (8.5%) had MACEs. There was a significant association between the TG/HDL-C ratio and MACEs (p<0.001). The Cox regression analysis shows that high tertile of TG/HDL-C ratio was an independent factor for 12-month MACEs (HR 1.64, 95% CI 1.26-2.14, p<0.001). Then we performed subgroup analyses according to renal function. In patients with normal renal function (eGFR≥90 ml/min/1.73 m^2) and mild renal dysfunction (eGFR 60≤to<90 ml/min/1.73 m^2), higher TG/HDL-C ratio was significantly associated with increasing risk of MACEs (hazard ratio [HR] 1.65, 95% confidence interval [CI] 1.04-2.49, p=0.018; HR 1.60, 95% CI 1.16-2.19, p=0.004, respectively). However, in patients with moderate renal dysfunction (eGFR<60 ml/min/1.73 m^2), higher TG/HDL-C ratio lost predictive value(HR 1.25, 95% CI 0.84-1.86, p=0.274).

Conclusions: Among patients with AMI, the TG/HDL-C ratio is a useful independent predictor of 12-month MACEs. However, this ratio lost predictive power in subgroup with moderate renal dysfunction. Further studies are needed to investigate underlying mechanism.

SA-PO817

A Predictive Model for Development of Peripheral Artery Disease among Patients with Chronic Kidney Disease Jing Chen, Wei Yang, Jason Roy, Xiaoming Zhang, Damodar R. Kumbala, Pranav S. Garimella, Mahboob Rahman, Raymond R. Townsend, Bernard G. Jaar, Edward J. Horwitz, Madhumita J. Mohanty, Esteban A. Cedillo-Couvert, Stephen M. Sozio, Harold I. Feldman, Emile Mohler, L. Lee Hamm, Jiang He. *Tulane Univ.*

Background: Patients with chronic kidney disease (CKD) have an increased risk of peripheral artery disease (PAD). A predictive model may help evaluate risk before significant changes in ankle-brachial index (ABI) to provide early detection, prevention, and treatment.

Methods: A total of 3,146 adult CKD patients in the Chronic Renal Insufficiency Cohort Study without PAD at the baseline visit were included in this analysis. Incident PAD was defined as a new onset ABI of <0.9 or clinical PAD confirmed by an endpoint assessment committee. Models were developed using Cox proportional hazards regression methods and evaluated using C statistics. The LASSO approach was used to select predictors, where the best fitting model is the one that minimizes the deviance in cross-validation.

Results: 635 individuals developed PAD over 6 years of follow-up. The hazard ratios for selected risk factors in the predictive models are presented in the table.

Variables	Model 1 HR (95% CI)	Model 2 HR (95% CI)
Log ABI	0.60 (0.54, 0.66)	0.61 (0.55, 0.68)
Log age	1.27 (1.16, 1.39)	1.21 (1.09, 1.34)
Female	1.37 (1.17, 1.61)	1.28 (1.08, 1.52)
Black	1.53 (1.31, 1.79)	1.19 (1.01, 1.42)
Current smoker		2.01 (1.63, 2.48)
Diabetes		1.28 (1.02, 1.59)
Log pulse pressure		1.16 (1.05, 1.28)
Log alkaline phosphatase		1.10 (1.01, 1.20)
Log C-reactive protein		1.12 (1.03, 1.22)
Log fibrinogen		1.08 (0.97, 1.19)
Log hemoglobin		0.99 (0.90, 1.09)
Log Hemoblobin A1c		1.11 (1.01, 1.23)
Log eGFR		0.90 (0.82, 0.99)
C-Statistics	0.67 (0.69, 0.74)	0.72 (0.65-0.70)

The final model 2 was significantly (P<0.001) more accurate than the model 1.

Conclusions: A model using readily available clinical and laboratory tests can improve the risk prediction over ABI for development of PAD in CKD patients. Further studies should validate this predictive model.

Efficacy and Safety of Warfarin Therapy in Chronic Kidney Disease Patients with Atrial Fibrillation Priscilla P. How,[1,4] Timothy Koh,[1] Xin Yi Wong,[2] Doreen Tan,[2] Ying-Ying Seow,[3] Hersharan Sran.[4] *[1]Dept of Pharmacy, National Univ of Singapore; [2]Dept of Pharmacy, Khoo Teck Puat Hospital; [3]Dept of Renal Medicine, Khoo Teck Puat Hospital; [4]Dept of Medicine (Nephrology), National Univ Hospital.*

Background: While anticoagulation of atrial fibrillation (AF) patients without chronic kidney disease (CKD) to reduce stroke risk is well-established, it is less straightforward in patients with both conditions due to their increased bleeding and stroke risk. This study aimed to determine warfarin's efficacy and safety in local AF patients with varying degrees of renal impairment.

Methods: Patients who filled warfarin prescriptions at two acute care hospitals in Singapore between June 2010 and May 2012 were included if they were ≥ 21 years old, received warfarin for AF for ≥ 3 months prior to study entry (target INR 2-3), and for 2 continuous years or until discontinuation due to an event or death. The patients were classified by CKD stages into 4 groups. Risk of major adverse cardiovascular events (MACE) and major bleeding were estimated using time-dependent Cox regression analyses.

Results: Of the 250 patients recruited, 81 (32.4%) had stage 3 CKD, 32 (12.8%) had stage 4-5 CKD and 16 (6.4%) had end-stage renal disease (ESRD) and were receiving dialysis. Compared to patients with no CKD (eGFR>60 ml/min/1.73m^2, reference group), risk of MACE was similar among stage 3 CKD (hazard ratio [HR] 0.55; 95%CI 0.09–3.26), stage 4-5 CKD (HR 1.81; 95%CI 0.26–12.51) and ESRD patients (HR 3.66; 95%CI 0.33–40.34). Risk of major bleeding was similar among those with stage 3 (HR 0.60; 95%CI 0.21–1.68) and stage 4-5 CKD (HR 3.31; 95%CI 0.70–15.79), while a trend of increased bleeding risk was observed among ESRD patients (HR 9.21; 95%CI 1.00–84.71). Proportion of patients with labile INR was also highest among ESRD patients (68.8% vs. 47.1-53.1%, P=0.407).

Conclusions: Similar risk of MACE and major bleeding was observed among our local AF patients with varying degrees of renal impairment receiving warfarin. However, ESRD patients may be at increased risk of major bleeding.

SA-PO819

Impact of Updated Recommendations for Aspirin Use for the Primary Prevention of Cardiovascular Disease Fanny Lepeytre, Myriam Khalili, Stephan Troyanov, Josee Bouchard, Francois Madore. *Nephrology, Hôpital du Sacré-Coeur de Montréal, Montréal, QC, Canada.*

Background: Newly updated guidelines of the U.S. Preventive Services Task Force (USPTF) recommend initiating low-dose aspirin use for the primary prevention of cardiovascular disease (CVD) in adults aged 50-59 yrs who have a ≥ 10% 10-yr CVD risk. In adults aged 60-69 yrs or at increased risk of bleeding, the decision to initiate aspirin use should be individualized. The impact of these new recommendations remains largely unknown especially for patients with CKD.

Methods: We studied 20,004 randomly selected individuals from the general population aged 40-69 yrs to estimate the number and the characteristics of individuals with and without aspirin therapy. We evaluated CVD history and risk factors, Framingham score, medication use and kidney function.

Results: Among participants aged 50- 59 yrs with no history of CVD and a ≥10% 10-yr CVD risk, 15.5% (n=462) were currently taking aspirin or another platelet aggregation inhibitor. For individuals aged 60-69 yrs, this proportion was higher (28.3%). Factors independently associated with current aspirin use in patients with no history of CVD and increased risk are shown below.

Characteristics	OR	95% CI	P-Value
Age	1.06	1.05, 1.08	<0.001
Male gender	1.37	1.16, 1.61	<0.001
Obesity (BMI, kg/m^2)	1.20	1.03, 1.40	0.02
Regular medical visits *	1.92	1.28, 2.88	0.01
Diabetes *	1.60	1.07, 2.41	0.02
Diabetes treatment	2.84	1.87, 4.33	<0.001
Dyslipidemia *	1.29	1.08, 1.54	0.01
Statin use	3.30	2.74, 3.98	<0.001
Anti-hypertensive treatment	3.36	2.88, 3.91	<0.001
CKD EPI < 60ml/min	0.71	0.54, 0.95	0.02

No association was found with hypertension*, income, education, ethnicity, tobacco use. *: self reported.

Conclusions: Current aspirin use for primary CVD prevention is low (15.5%) and is associated with CVD risk factors and corresponding treatments. Patients with chronic kidney disease are less likely to receive aspirin. Implementation of updated USPTF guidelines will require significant practice changes.

SA-PO820

Quantitative Evaluation of Antihypertensive Adherence in Chronic Kidney Disease Lee Lee Zhu, Thuy Hoang, Linda Awdishu. *Skaggs School of Pharmacy and Pharmaceutical Sciences, Univ of California, San Diego, La Jolla, CA.*

Background: Adherence to ACEI and ARB therapy is important to reduce blood pressure (BP) and proteinuria in patients with chronic kidney disease (CKD). No studies to date has reported measurements of antihypertensive concentrations in biological fluids to assess medication adherence.

Methods: This is a prospective medication reconciliation and adherence study of 492 patients at University of California, San Diego Health System. Adult patients taking ACEI or ARB who were able to provide urine or saliva sample were included in the study. Medication reconciliation and adherence by patient interview was conducted by a pharmacist or student pharmacist. Urine and saliva were analyzed for ACEI and ARB concentrations using liquid chromatography-mass spectrometry. Patients with CKD (eGFR<60 ml/min/1.73m2) were compared to those without CKD for ACEI or ARB and/or metabolite concentrations in the urine or saliva as well as office and home BP measurements. Fisher's exact test was used to compare count data and student's t-test was used to compare continuous data.

Results: A total of 135 patients were included with 62 and 73 in the CKD and non-CKD groups, respectively. Self-reported adherence was high in both groups with 97-100% of patients reporting missing or being late on 0-5 doses/month. CKD patients reported better accuracy in self reporting (somewhat accurate 94% vs 88%, p=0.003). In CKD, urine and saliva detection of parent drug was: lisinopril 90%, losartan 92%, olmesartan 100%, ramipril 0%, valsartan 91% and metabolites: benazeprilat 75%, enalaprilat 100%, losartan carboxylic acid 100%, ramiprilat 100%. There was no difference in the detection of drugs or metabolites in CKD vs non-CKD patients. Office BP readings were lower in the CKD group (SBP 123 vs 130 mmHg, p=0.015). There was no difference in home BP readings or serum potassium concentration.

Conclusions: Adherence to ACEI and ARB therapy was similar between CKD and non-CKD patients. CKD patients had lower blood pressures without evidence of elevated serum potassium concentrations. Detection of ACEI or ARB drug concentrations in the urine provides a quantitative measure of adherence to support self-reporting.

Effects of CKD on Survival Who Were Screened for Sleep Apnea Syndrome Kunitoshi Iseki.[1] [1]*Clinical Research Support Center, Tomishiro Central Hospital, Tomigusuku, Okinawa, Japan;* [2]*Internal Medicine, Nakamura Clinic, Urasoe, Okinawa, Japan.*

Background: Sleep Apnea Syndrome (SAS) is common in CKD patients, but the prognosis is not precisely examined based on the overnight polysomnography (PSG).

Methods: We enrolled all subjects (n=10,856) who were evaluated by PSG during September 1990 to December 2010 at the Nakamura Clinic, Okinawa, Japan (the ONSLEEP registry). Among them, serum creatinine (SCr) at the time of PSG examination was available in 3,676 patients (70.7% men; mean age 48.9 years). Survival was confirmed by medical charts, letters, and telephone calls. Follow ups were from the date of PSG to the last visit of 2014 or the dates of response to mail or telephone call. Outcomes were starting dialysis (ESRD) or death, whichever came first. We excluded those age <20 years old and those were already on dialysis. CKD was defined as eGFR<60 ml/min/1.73m^2 which was estimated using Japanese formula. SAS was diagnosed when the apnea-hypopnea index (AHI) ≥5. Cox analysis was done to examine the risk of SAS, CKD, and the combination on survival.

Results: Prevalence of CKD increased with AHI; 14.8% in AHI<5 (N=704), 18.9% in AHI 5 to <15 (N=773), 22.7% in AHI 15 to <30 (N=706), and 20.3% in AHI≥30 (N=1,493). The total follow-up period was 16,358 patient-years and the mean observation period was 4.5 years. The number of death and ESRD was 89 and 19. The outcome rate per 1,000 patient-years was 6.6 (combined), 5.4 (mortality) and 1.2 (ESRD), respectively. The event rate was as 0.5% in SAS (-)/CKD (-), 2.4% in SAS (+)/CKD (-), 4.8% in SAS (-)/CKD (+), and 7.1% in SAS (+)/CKD (+). The hazard ratio (95% confidence interval) was 1.82 (0.67 to 7.45) in SAS (+) & CKD (-), 5.74 (1.41 to 28.04) in SAS (-) & CKD (+), 3.78 (1.37 to 15.61) in SAS (+) & CKD (+) when the group of SAS (-) & CKD (-) was taken as a reference. Limitations are the limited number of SCr measurements and lack of details of SAS treatment such as continuous positive air pressure (CPAP) and medications.

Conclusions: The present study supports the notion to evaluate CKD among SAS patients.

SA-PO822

Circulating ACE2 as a Biomarker of Cardiovascular Outcomes Lidia Anguiano,[1] Marta Riera,[1] Julio Pascual,[1] Sergi Clotet-Freixas,[1] Angels Betriu,[2] Jose M. Valdivielso,[2] Clara Barrios,[1] Elvira Fernandez,[2] Maria Jose Soler.[1] [1]*Nephrology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona, Spain;* [2]*Nephrology, Hospital Arnau de Vilanova, Lleida, Spain.*

Background: ACE2 activity from human EDTA-plasma samples directly correlated with the classical CV risk factors namely older age, diabetes and male gender and with atherosclerosis progression at 2 years of follow-up. In a CKD population without previous history of CV disease. **Aim**: To study circulating ACE2 activity as a biomarker of CV outcomes in CKD stages 3-5(CKD3-5) patients at 4 years of follow-up.

Methods: Prospective study of 1237 CKD3-5 patients. Circulating ACE2 activity was analyzed. Variables assessed: non-fatal and fatal CV event, non-CV mortality, all-cause mortality (CV and non-CV), and the composite all-cause mortality + non-fatal CV event. For the overall survival analysis, stratified baseline circulating ACE2 activity (low-level ACE2: <24.9 RFU/μL/h and high-level ACE2: ≥24.9 RFU/μL/h) was used.

Results: Non-fatal and fatal CV events was higher in the high-level ACE2 group (9.4%) as compared to the low-level group (5.1%, p=0.008). Estimated mortality was also assessed in patients with the composite all-cause mortality and non-fatal CV event and in patients with all-cause mortality. In both cases, estimated mortality was higher in the high-level ACE2 group (14.1% and 8.5%, respectively) as compared to the low-level ACE2 group (8.7% and 4.8%, respectively; p=0.008 and p=0.024, respectively). Multivariate logistic regression was adjusted for 10 variables (see Table).

Conclusions: In CKD3-5 patients without history of CV, circulating ACE2 may help to detect patients at risk for CV event and non-CV mortality at 4 years of follow-up.

		Adjusted analysis	
		HR (95% CI)	p-value
Non-fatal and fatal CV event	Age, <65 vs ≥65 years	1.51 (1.03-2.23)	0.036
	Diabetes, yes vs no	2.30 (1.57-3.38)	<0.001
	Baseline circulating ACE2 activity, <24.9 vs ≥24.9 RFU/µL/h	1.62 (1.01-2.60)	0.046
Non-CV mortality	Age, <65 versus ≥65 years	4.46 (2.41-8.24)	<0.001
	Creatinine, mg/dL	1.34 (1.10-1.64)	0.003
	Baseline circulating ACE2 activity, RFU/µL/h	1.01 (1.00-1.01)	0.002
All-cause mortality and non-fatal CV event	Age, <65 versus ≥65 years	2.30 (1.66-3.20)	<0.001
	Current smoker, yes vs no	1.53 (1.10-2.12)	0.012
	Diabetes, yes vs no	1.91 (1.40-2.61)	<0.001

Prognostic Value of Reverse Dipper Blood Pressure Pattern in Patients with Non-Dialysis Chronic Kidney Disease: A Prospective Cohort Study

Zengchun Ye, Cheng Wang, Ming Li, Meijun Si, Wenbo Zhao, Tan-Qi Lou. *Div of Nephrology, Dept of Medicine, The Third Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, China.*

Background: Reverse dipper blood pressure(BP) pattern has been studied among the general and hypertensive population. However, the prognosis of reverse dipper BP pattern in chronic kidney disease (CKD) patients remains unknown.

Methods: We monitored BP throughout the day and followed health outcomes in 588 CKD patients admitted to our hospital. Time to all-cause mortality, to cardiovascular mortality, to renal and to cardiovascular events was recorded. Multivariate-adjusted Cox regressions were carried out to detect the prognostic value of reverse BP pattern for total mortality, cardiovascular mortality, renal events and cardiovascular events.

Results: The prevalence of dippers, non-dippers and reverse dippers was 34.69%, 43.54% and 18.03% respectively. Patients with reverse dippers had higher incidence of total mortality, cardiovascular mortality, renal and cardiovascular events than patients with dippers (P<0.05), and also had higher incidence of total mortality, cardiovascular mortality and events than patients with non-dippers (P<0.05). Multivariate-adjusted Cox regression analyses showed that reverse dippers (*versus* dippers) was associated with a higher risk of total mortality (HR=5.085, P=0.002), cardiovascular mortality (HR=4.437, P=0.013), renal events (HR=3.291, P<0.001) and cardiovascular events (HR=4.259, P=0.006) even adjusted by 24h systolic BP (SBP).

Conclusions: In conclusion, we have provided the first evidence that reverse dipper BP pattern, independent of 24-hour SBP levels, had prognostic value in Chinese patients with non-dialysis chronic kidney disease. Further prospective randomized clinical trials are needed to clarify whether correcting blood pressure pattern by administration of antihypertensive drugs at night has a beneficial effect in improving the prognosis and attenuating the progression of cardiovascular and renal disease in CKD patients.

Testosterone Replacement Therapy (TRT) to Normalize Serum Total Testosterone (T) Levels Is Associated with Delayed Progression of CKD and Lower All-Cause Mortality

Archana Goel,[1] Mukut Sharma,[1,2] Peter Sigurd Wiegmann,[2] Olurinde Oni,[1] Rajat S. Barua,[1] Ram Sharma,[1] Rishi Sharma,[1] Virginia J. Savin,[1] Thomas Wiegmann.[2] *[1]Nephrology, Kansas City VA Medical Center, Kansas City, MO; [2]Research, Midwest Biomedical Research Foundation (MBRF), KCVA Medical Center, Kansas City, MO.*

Background: The effect of TRT on the progression of CKD is not known. We used data from a large cohort to retrospectively determine whether TRT has adverse effects on patients with CKD.

Methods: The Veterans Administration Informatics and Computing Infrastructure (VINCI) data were extracted using SAS Enterprise Guide 7.1 and analyzed using SPSS. Serum creatinine (mg/dl) as a measure of renal function was compared between groups of Veterans with low total testosterone (T). (Gp1) who normalized with TRT (N=38729, creatinine 1.06 ±0.001, FU 6.1 years) and (Gp2) untreated subjects who maintained low T levels (Gp2, N=9755, creatinine 1.11 ± 0.004, FU 5.1 years). Change was defined by time to various plasma creatinine concentration thresholds and all-cause mortality.

Results: Table 1A shows that increase in serum creatinine levels from <1.5 to ≥1.5, <3 to ≥3 and <6 to ≥6 was significantly (P<0.001) delayed in Gp1. Table 1B shows that all-cause mortality in individuals <50 years and those ≥50 years was significantly lowered in Gp1 (P<0.001).

TABLE 1A			
	N	**Final Creatinine**	**Days to event±SEM (P, Normalized *vs.* untreated)**
Creatinine from <1.5 to ≥1.5		mg/dL±SEM	
Normalized	8042	1.72±0.01	899±10 (P<0.001)
Untreated	1815	1.70±0.01	757±19
Creatinine from <3 to ≥3			
Normalized	1146	3.92±0.04	1315±32 (P<0.001)
Untreated	335	3.76±0.08	1053±54
Creatinine from <6 to ≥6 (ESRD)			
Normalized	280	7.19±0.09	1317±64 (P<0.001)
Untreated	66	7.40±0.22	1059±107

TABLE 1B			
Death, all-cause			
Age (yr)		**N**	**Median survival days ±SEM (P, Normalized *vs.* untreated)**
<50	Normalized	102	1596±96 (P<0.001)
	Untreated	30	1369±210
≥50	Normalized	1407	1681±27 (P<0.001)
	Untreated	786	1343±35

Conclusions: Normalization of T levels does not hasten decline in renal function and may lower all-cause mortality.

Thyroid Hormone Replacement May Decrease the Risk of Cardiovascular Events in Diabetic Nephropathy Patients with Subclinical Hypothyroidism

Changhwan Seo, Hyoungnae Kim, Min-Uk Cha, Seonghun Kim, Dae-Suk Han. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Recent studies have revealed that subclinical hypothyroidism is associated with several adverse cardiovascular outcomes in diabetic nephropathy. Although thyroid hormone replacement therapy (THRT) could restore these conditions in general population, the effectiveness of THRT in diabetic nephropathy combined with subclinical hypothyroidism is not investigated.

Methods: From 2000 to 2014, we identified 257 patients who diagnosed with diabetic nephropathy combined with subclinical hypothyroidism. Subclinical hypothyroidism was defined as normal free thyroxine (fT4) with elevated thyroid stimulating hormone (TSH). THRT was defined as the replacement of thyroid hormone at least 60 days. The primary outcomes are defined as all-cause mortality and incident major cardiovascular events.

Results: The mean age was 65.6±12.5 years. Among 257 diabetic nephropathy combined with subclinical hypothyroidism patients, 83 (32.3%) were classified as the THRT group. THRT group showed significantly high TSH level (7.10±1.53 vs 6.16±1.21, P < 0.001). During a mean follow-up duration of 38.0±29.2 months, all-cause mortality and incident major cardiovascular events were observed in 21 and 98 patients, respectively. In multiple Cox analysis, THRT did not reduce all-cause mortality (hazard ratio [HR], 1.833; 95% confidence interval [CI], 0.440-7.642, P = 0.406), while was independently associated with the lower risk of incident major cardiovascular events (HR, 0.558; 95% CI, 0.332-0.939, P = 0.028) even after adjustment for age, sex, TSH, HbA1c and estimated glomerular filtration rate.

Conclusions: These findings suggest that THRT in patients with diabetic nephropathy combined subclinical hypothyroidism might be considered the therapeutic options.

SA-PO826

The Subclinical Fluid Overload Is Significantly Associated with Coronary Artery Calcification in Patients with Chronic Kidney Disease

Changhwan Seo,[1] Seohyun Park,[1] Hae-Ryong Yun,[1] Boyoung Nam,[2] Ji Min Park,[2] Tae-Hyun Yoo.[1,2] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Republic of Korea; [2]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Republic of Korea.*

Background: The aim of this study is to identify the relationship between fluid status and underlying renal function, and to elucidate the association between fluid overload and coronary artery calcification in patients with chronic kidney disease (CKD).

Methods: The data was retrieved from the prospective observational cohort for Cardiovascular and Metabolic Disease Etiology Research Center-High Risk (CMERC-HI, NCT02003781). Fluid status was measured by bioimpedance analysis and extracellular water was adjusted by total body water (ECW/TBW). The subjects were excluded from the study if they had severe overhydration (ECW/TBW≥0.40). Finally, 1,148 CKD patients were eligible in present analysis.

Results: The mean age of the study subjects was 60.0±10.9 years, and 656 (57.1%) patients were male. The fluid overload valued by ECW/TBW was gradually intensified according to CKD stages. The participating individuals were divided into four groups according to the quartiles of ECW/TBW. Age, prevalence of diabetes, peripheral and central pulse pressure, and coronary calcium score (CCS) increased in accordance with increasing quartiles of ECW/TBW. In multiple linear regression analysis, age, diabetes, serum albumin, C-reactive protein, and eGFR were independently associated with ECW/TBW. In addition, ECW/TBW was found to be independently associated with CCS after adjustment for multiple confounding factors (per 0.001 increase in ECW/TBW; odds ratio=1.06, 95% confidence interval=1.02-1.10, P=0.003) in multiple logistic regression analysis. Subgroup analysis in patients with CKD stage 1-3a also demonstrated the significant association between ECW/TBW and CCS.

Conclusions: Extracellular volume status is significantly associated with coronary artery calcification in patients with CKD throughout all stages.

SA-PO827

High-Normal Albuminuria Is Associated with Subclinical Atherosclerosis in a Nondiabetic Population without Chronic Kidney Disease Toshinori Ueno, Ayumu Nakashima, Shigehiro Doi, Aki Sanada, Takao Masaki. *Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Low-grade albuminuria is considered to be a predictor of cardiovascular mortality, while little is known about the relationship between high-normal albuminuria and subclinical atherosclerosis in the general population without diabetes mellitus.

Methods: In this cross-sectional study, 2137 non-diabetic, Japanese middle-aged men (mean age, 53 years), who attended general health checkups between April 2012 and March 2015, underwent blood sampling, urinalysis, and carotid ultrasonography. Presence of chronic kidney disease (CKD) was diagnosed by the clinical criteria, estimated glomerular filtration rate <60 ml/min per 1.73m^2 or urine albumin to creatinine ratio (UACR) ≥30 mg/g. Carotid intima-media thickness (IMT) and the number of focal atheromatous plaques were used as indicators of subclinical atherosclerosis. To assess independent predictors of IMT and carotid plaque formation in the non-CKD subpopulation, multivariate stepwise analysis was used.

Results: Among 2137 participants, 324 (15.2%) had CKD. Both IMT (0.68±0.13 vs. 0.64±0.13 mm, p<0.01) and the presence of plaques (71.0 vs. 59.0%, p<0.01) were significantly higher in the CKD than in the non-CKD subjects. In subjects without CKD (n=1813), mean UACR was 5.1 (range 0.0–29.8) mg/g, and a significant positive trend across UACR quartiles was observed for IMT and the number of carotid plaques. Age, body mass index, and hypertension were independentlyassociated with thickened IMT, whereas UACR did not show a significant correlation. In contrast to IMT, UACR was independently associated with the number of carotid plaques.

Conclusions: Our results indicate that high-normal albuminuria is associated with carotid plaque formation in a nondiabetic population without CKD.

SA-PO828

Endogenous Ouabain as a Biomarker of Heart Failure and a Predictor of Mortality after Cardiac Surgery in CKD Patients Marco Simonini, Simona Pozzoli, Nunzia Casamassima, Chiara Lanzani, Lorena Citterio, Simona Delli Carpini, Elisabetta Messaggio, Stefano Tentori, Elena Bignami, Paolo Manunta. *San Raffaele Scientific Inst, Milan, Italy.*

Background: Cardiovascular diseases remain the main cause of mortality and morbidity worldwide and, in particular, in patients with Chronic Kidney Disease (CKD). The identification of subjects with increased risk of developing new cardiovascular events remains a priority in order to guide treatments and determine individual prognosis. Biomarkers are useful tools that are able to help physicians in decision-making. Our aim is to investigate Endogenous Ouabain (EO), an adrenal stress hormone with hemodynamic effects, as a valuable biomarker of heart failure in patients with impaired renal function.

Methods: From a population of more than 800 patients undergoing elective cardiac surgery, we selected those patients with impaired renal (eGFR < 90 ml/min/m^2) function at baseline. In this subset of patients (550) have investigated the relationships between EO with well known and codified markers of heart failure. We also explored the predictive power of this biomarker for 30-days morality after cardiac surgery.

Results: EO was found to be correlated negatively with left ventricular EF (p=0.011), positively with Cardiac End Diastolic Diameter (p=0.05) and positively with plasmatic NT-proBNP level (p=0.001). Moreover, a different plasmatic EO level (both preoperative and postoperative) was found according to NYHA class (p=0.005). Finally, a higher EO level in the immediate post-operative time was indicative of a more severe cardiological condition and it was associated with increased perioperative mortality risk (p=0.041 for 30-days morality). All data were corrected for sex, age, BMI, basal eGFR, and EuroSCORE. All correlation remains significant if we consider the whole population (802 subject) for the analysis.

Conclusions: Our data suggest that in CKD population preoperative and post-operative plasmatic EO level identifies patients with a more severe cardio-vascular presentation at baseline. These patients have a higher risk of morbidity and mortality after cardiac surgery.

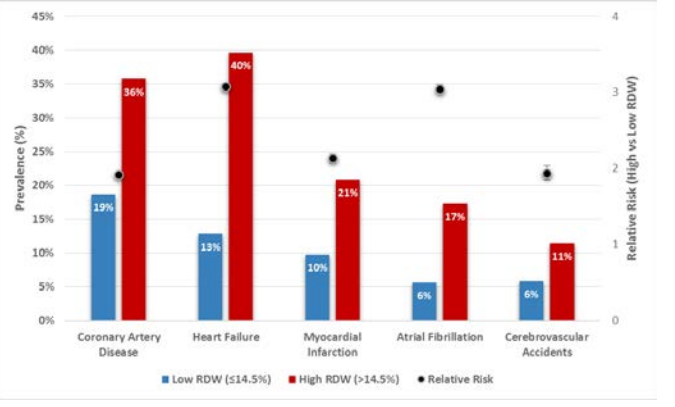
SA-PO829

Red Cell Distribution Width as a Biomarker of Cardiovascular Disease in Patients with Chronic Kidney Disease Nissreen Elfadawy, Chang H. Kim, Sadeer Al-Kindi. *Internal Medicine, Case Medical Center - Univ Hospitals - Case Western Reserve Univ, Cleveland, OH.*

Background: Cardiovascular risk stratification in patients with CKD is required to direct prevention and intervention strategies. Anisocytosis, as measured by Red Cell Distribution Width (RDW) has been linked to adverse cardiovascular outcomes in patients with heart failure. It is unknown whether higher RDW is associated with increased prevalence of cardiovascular disease (CVD) in CKD population. The aim of the study is to evaluate the association between high RDW and prevalence of CVD in patients with CKD.

Methods: Using Explorys database, we identified patients with CKD (age 18-65 years) and have active records between 1999 and 2016. Patients were stratified into normal RDW (≤14.5%) and high RDW (>14.5%). We studied the frequency of CVD, namely: coronary artery disease (CAD), heart failure (HF), myocardial infarction (MI), atrial fibrillation (Afib), and cerebrovascular accident (CVA), based on the ICD diagnoses, in the 2 groups. Statistical comparison between the normal and high group was performed with chi-square test, and risk ratio (RR) of the CV adverse events was calculated.

Results: A total of 231,390 CKD patients (stages I- V) were included. The proportion of the CKD patients with CVD was significantly higher in the RDW high group compared to the RDW normal group. The RR was greater in the HF (3.1 [3.0-3.1]) and A fib (3 [2.9-3.1]). When patients were stratified by CKD stage, the RR was highest in the early CKD stages and decreased with advancing stage.



Conclusions: In this large cohort of CKD patients, elevated RDW was associated with significantly increased CVD prevalence specially in early CKD stages I-II. RDW could identify patients for CVD prevention trials in this high risk population.

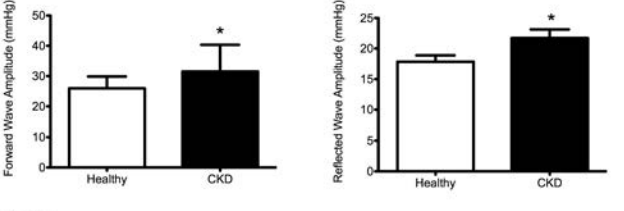
SA-PO830

Arterial Wave Reflection and Cardiorespiratory Fitness in Mild to Moderate CKD Danielle L. Kirkman,[1] Bryce J. Muth,[1] Raymond R. Townsend,[2] David G. Edwards.[1] *[1]Univ of Delaware; [2]Univ of Pennsylvania.*

Background: Cardiorespiratory fitness levels are reduced in Chronic Kidney Disease (CKD) patients and are associated with a poor quality of life, increased cardiovascular disease (CVD) risk and premature death. Disease related structural and functional cardiac and vascular changes provide central limitations to exercise tolerance. Increased arterial wave reflection amplitude may contribute to increased left ventricular pulsatile load and thus hamper oxygen delivery during activity. The relationship between arterial wave reflection and cardiorespiratory fitness in CKD is unknown.

Methods: Cardiopulmonary exercise testing (CPX) and assessment of central aortic pressure with wave separation analysis were carried out in 27 stage 3-5 CKD patients (Mean±SD, age 60±13yrs; eGFR 44±13ml/min/1.73^2) and 20 healthy controls (57±5yrs). VO_{2peak} was measured by expired respiratory gas analysis during graded CPX. Aortic pressure waves were synthesized from radial artery waveforms acquired by applanation tonometry and use of a generalized transfer function. Augmentation Index (AI) was calculated and the central pressure waveform was separated into forward and reflected waves using a physiologic flow waveform.

Results: VO_{2peak} was reduced in CKD patients (27±7 *vs.* 18±5ml/kg/min, p<0.01). Central aortic systolic pressure was increased in CKD patients (134±21 *vs.* 119±14mmHg, p=0.01). AI was similar between groups (29±11 *vs.* 27±14%, p=0.5), however both forward and reflected wave amplitudes were higher in CKD.



* p < 0.05

In CKD patients, moderate to strong inverse relationships were shown between VO_{2peak} and both forward (r=-0.68, p<0.01) and reflected (r=-0.55, p<0.01) wave amplitudes.

Conclusions: Forward and reflected wave amplitudes are increased in CKD, which may contribute to the high CVD risk in these patients. Increased arterial wave amplitudes may pose a central limitation to exercise tolerance in CKD.

SA-PO831

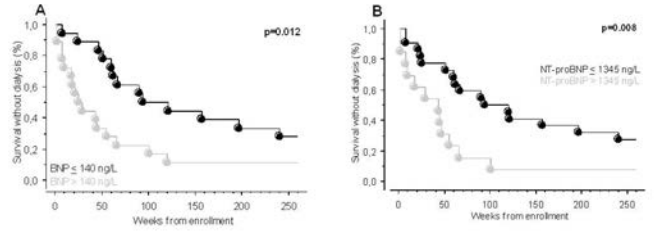
Clinical Value of Natriuretic Peptides in Predicting Short- and Long-Term Dialysis in Stage 4 and 5 Chronic Kidney Disease Patients

Dominique Guerrot, Sofia Anna Sundqvist, Frank Le Roy, Michel R. Godin. *Nephrology, Rouen Univ Hospital, Rouen, France.*

Background: Anticipating the time to renal replacement therapy (RRT) in chronic kidney disease (CKD) patients is an important but challenging issue. Natriuretic peptides are biomarkers of ventricular dysfunction related to poor outcome in CKD. We comparatively investigated the value of B-type natriuretic peptide (BNP) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) as prognostic markers for the risk of RRT in stage 4 and 5 CKD patients within a 5-year follow-up period.

Methods: Baseline plasma BNP (Triage, Biosite) and NT-proBNP (Elecsys, Roche) were measured at inclusion. Forty-three patients were followed-up during 5 years. Kaplan-Meier analysis, with log-rank testing and hazard ratios (HR), were calculated to evaluate survival without RRT.

Results: During the first 12-month follow-up period, 16 patients started RRT. NT-proBNP concentration was higher in patients who reached endpoint (3221 ng/L vs 777 ng/L, p=0.02). NT-proBNP concentration > 1345 ng/L proved significant predictive value on survival analysis for cardiovascular events (p=0.04) and dialysis within 60 months follow-up (p=0.008 ; Figure). BNP concentration > 140 ng/L was an independent predictor of RRT after 12 months follow-up (p<0.005), and of significant predictive value for initiation of dialysis within 60 months follow-up.



Conclusions: Our results indicate a prognostic value for BNP and NT-proBNP in predicting RRT in stage 4 and 5 CKD patients, regarding both short- and long-term periods. NT-proBNP also proved a value in predicting cardiovascular events. Natriuretic peptides could be useful predictive biomarkers for therapeutic guidance in CKD.

SA-PO832

Sodium/Urea Nitrogen in Second Urine Is the Best Tool in Predicting 24-Hour Urinary Sodium

Sang Youb Han,[1] Hyeong Cheon Park,[2] Sang-Woong Han.[3] *[1]Internal Medicine, Inje Univ Ilsan-Paik Hosp.; [2]Yonsei Univ; [3]Hanyang Univ.*

Background: Determining daily salt intake is important in predicting public health. Sodium intake has been calculated based on using spot urine to estimate sodium intake instead of 24-hour urine due to inadequate collection. However, it is still unclear what is best to estimate daily sodium intake. We measured sodium and other electrolytes for each samples collected as every episode of urination during 24 hours, and examined any correlation to represent 24-hour urinary sodium.

Methods: Fifteen male adults(age: 33.7±6.43) were participated. They had only 3 meals per day which includes total of 2.0g of sodium and no restriction to water intake. The 24-hour urine was collected starting from second urine of the first day to first urine of the second day. The 24-hour sodium intake was estimated using Tanaka's equation. Urine sodium, potassium, chloride, urea nitrogen, creatinine, and specific gravity were measured from the spot urine. We used ratio of Na to other parameters to analyze any correlation to total 24-hour urinary sodium. Each urine samples were compared in three sets; first morning urine of the second day, second urine of the first day, and every 88 collected urine samples of 15 enrolled participants.

Results: The 24-hour urinary sodium (24UNa) was 143.9±42.1mg. The 24UNa was significantly correlated with Na/urea nitrogen(r=0.56), Na/Osm (r=0.51), age (r=0.548), Na/Cr (r=0.392) and estimated sodium using Tanaka's equation (Tanaka's Na, r=0.463). Most significant correlation was seen in second urine of the first day: 24UNa was correlated with Na/urea nitrogen (r=0.710), Na/Osm (r=0.680), Na/Cr (r=0.589), age (r=0.544), Na/Cr (r=0.589), and Tanaka's Na (r= 0.666). However, first morning urine of the second day showed unexpected poor correlation: Na/urea nitrogen (r=0.322), Na/Osm (r=0.308), age (r=0.544), Na/Cr (r=0.202) and Tanaka's Na (r=0.375).

Conclusions: In conclusion, second urine sample is more suitable than first morning urine to estimate 24UNa. The Na/urea nitrogen had significant correlation with 24UNa in second urine in all participants. Further studies are necessary to validate valuable index and optimal time for urine sample in predicting 24-hour urinary sodium.

SA-PO833

Association of Serum Aldosterone Levels with Clinical Outcomes in the Elderly

Amanda K. Leonberg-Yoo,[1] Ronit Katz,[2] Linda F. Fried,[3] Stephen Kritchevsky,[4] Michael Shlipak,[6] Joachim H. Ix,[5] Mark J. Sarnak.[1] *[1]Div of Nephrology, Tufts Medical Center; [2]Div of Nephrology, Univ of Washington; [3]Renal-Electrolyte Div, Univ of Pittsburgh; [4]Stitch Center on Aging, Wake Forest School of Medicine; [5]Div of Nephrology, Univ of California, San Diego; [6]Div of Nephrology, Univ of California, San Francisco.*

Background: Elevated serum aldosterone levels have been associated with adverse outcomes in persons with hyperaldosteronism and cardiac disease. We investigated the relationship between serum aldosterone and clinically important outcomes in a healthy elderly cohort.

Methods: Serum aldosterone was measured at baseline in the Health ABC Study, a cohort of well-functioning adults aged 70-79 years. Using a case-cohort study design, cases were selected for kidney disease progression (30% reduction in eGFR), incident heart failure (HF), incident cardiovascular disease (CVD), and all-cause mortality. Weighted Cox proportional hazards models, sequentially adjusted for cardiovascular and kidney factors, were used to examine the associations of serum aldosterone with each clinical outcome.

Results: Mean (SD) age was 73.6 (2.8) years; 49% were women, and 61% were white. Median (25th, 75th) serum aldosterone was 5.12 (3.15, 8.85) ng/dL. There was no association between serum aldosterone with kidney disease progression, incident HF, or all-cause mortality. After adjustment for cardiovascular and kidney factors, medication use and urine sodium, there were significant lower atherosclerotic CVD events with high serum aldosterone levels.

	Event Rate*	Unadjusted†	Adjusted Model 1†	Adjusted Model 2†
Progression of Kidney Disease	2.85	1.00 (0.91, 1.09)	1.00 (0.92, 1.10)	1.01 (0.92, 1.10)
Incident HF	1.92	1.08 (0.97, 1.22)	1.04 (0.93,1.16)	1.03 (0.92, 1.17)
Incident CVD	2.63	0.92 (0.79, 1.07)	0.0.86 (0.73, 1.01)	0.85 (0.72, 0.99)
All-Cause Mortality	4.73	0.98 (0.92, 1.05)	1.01 (0.92, 1.06)	0.99 (0.91, 1.07)

Legend:
*Event rates per 100 person-years
†Model outcomes are reported as HR (95% confidence intervals). Hazard ratios are reported per doubling serum aldosterone
Adjusted Model 1 = Adjusted for age + race + gender + BMI + prevalent diabetes mellitus + prevalent HTN + systolic BP + LDL + smoking + eGFR + ACR
Adjusted Model 2 = Model 1+ RAS blockade + any diuretic + urine sodium excretion

Conclusions: There was no relationship between high serum aldosterone and kidney disease progression, incident HF, or all-cause mortality. Higher aldosterone levels were associated with lower CVD risk after adjustment for urine sodium excretion and medications. Additional studies are needed to confirm these relationships in healthy, younger people.

SA-PO834

Association of Urine Sodium with Clinical Outcomes in the Elderly

Amanda K. Leonberg-Yoo,[1] Ronit Katz,[2] Linda F. Fried,[3] Stephen Kritchevsky,[4] Michael Shlipak,[5] Joachim H. Ix,[6] Mark J. Sarnak.[1] *[1]Div of Nephrology, Tufts Medical Center; [2]Div of Nephrology, Univ of Washington; [3]Renal-Electrolyte Div, Univ of Pittsburgh; [4]Stitcht Center on Aging, Wake Forest School of Medicine; [5]Div of Nephrology, UCSF; [6]Div of Nephrology, UCSD.*

Background: Recent studies in persons at high cardiovascular risk suggest a U-shaped relationship between sodium intake and cardiovascular outcomes. We assessed the relationship of urine sodium, as a proxy for sodium intake, to clinical outcomes in healthy older adults. Because aldosterone levels may increase with low sodium intake, we evaluated whether aldosterone is an important confounding variable.

Methods: Baseline spot urine sodium and serum aldosterone were measured in the Health ABC Study, a cohort of well-functioning adults aged 70-79 years. 24-hr urine sodium excretion was estimated by the Kawasaki formula. Using weighted cox proportional hazards models in a case cohort study design, we evaluated the association of urine sodium with kidney disease progression (30% decrease in eGFR), incident heart failure, incident atherosclerotic cardiovascular disease (CVD), and all-cause mortality. Sequential adjustments for cardiovascular and kidney factors as well as aldosterone were performed.

Results: Mean (SD) 24-hr urine sodium excretion was 4174 (1546) mg. Lower levels of urine sodium were associated with CVD but not kidney disease progression, heart failure, or all-cause mortality. Aldosterone did not attenuate the relationship of low urine sodium with CVD. There was no interaction between aldosterone and urine sodium for CVD (p-interaction=0.6).

Growth Arrest-Specific Gene 6 May Be a Biomarker of Non-Complicated Atherosclerotic Plaque Burden Rachel M. Holden,[1] Laura E. Couture,[1] Michael A. Adams.[2] *[1]Medicine, Queen's Univ, Kingston, ON, Canada; [2]Biomedical and Molecular Sciences, Queen's Univ, Kingston, ON, Canada.*

Background: Growth arrest-specific gene 6 (Gas6) belongs to the family of vitamin K-dependent proteins. Gas6 is not detected in normal vessels but is expressed by vascular smooth muscle cells at all stages of human atherosclerosis and is markedly higher in non-complicated plaques than in complicated (i.e. vulnerable) plaques. Gas6 may act as a protective factor, in part, by reducing the pro-inflammatory phenotype of VSMCs. The objective of this study was to determine the association of Gas6 with measures of atherosclerosis quantified by carotid ultrasound.

Methods: In 204 patients referred for coronary angiography, blood was collected and maximum plaque height and carotid intima media thickness (CIMT) was assessed in the internal carotid arteries (ICA) and carotid bulbs by ultrasound. Gas6 and FGF-23 were measured in plasma via ELISA (Immunotopics Inc). Multi-variable models evaluated independent predictors of maximum plaque height, CIMT and the difference between maximal plaque height and CIMT (PH-CIMT).

Results: In bivariate analysis, Gas6 was significantly higher in females (p=0.019), diabetics (p=0.010) and those with BMI > 30 kg/m^2 (p=0.004). There was a significant correlation between gas6 and FGF-23 (r=0.262, p<0.001). There was no association between gas6 and CIMT. In multivariate models adjusted for age, sex, and diabetes, a higher level of gas6 was associated with lower plaque height and lower PH-CIMT. This significant relationship remained robust after adjustment for smoking, hypertension, hyperlipidemia, phosphate and FGF-23.

Conclusions: Although Gas6 levels were higher in diabetics and obese subjects, there was a significant and inverse association between Gas6 and plaque height. Gas6 is anti-inflammatory and its expression is markedly higher from non-complicated plaques. Therefore, gas6 could be a biomarker reflecting the presence of less vulnerable plaques in humans. Whether vitamin K is a significant mediator of this process is not known.

Social Support and Health Outcomes in Hispanics with Chronic Kidney Disease Anna C. Porter,[1] Jesse Yenchih Hsu,[2] Eunice Carmona,[1] Clarissa Jonas Diamantidis,[3] Michael J. Fischer,[1] Edward J. Horwitz,[6] Marie Krousel-Wood,[4] John W. Kusek,[5] Claudia M. Lora,[1] Eva Lustigova,[4] Bhavik P. Patel,[1] Ana C. Ricardo,[1] Anne M. Slaven,[4] Xue Wang,[2] James P. Lash.[1] *[1]Univ of IL; [2]Univ of PA; [3]Duke; [4]Tulane; [5]NIDDK; [6]MetroHealth OH.*

Background: Low social support is a predictor for negative health outcomes in the general population and in patients with chronic disease. However, less is known about social support in patients with chronic kidney disease (CKD), particularly in Hispanics. We evaluated the association of social support with CKD progression, cardiovascular (CV) events, and all-cause mortality in Hispanic adults with CKD.

Methods: We conducted a prospective observational study of 322 Hispanic adults with CKD enrolled in the Hispanic Chronic Insufficiency Cohort Study. Social support was measured at baseline with the Medical Outcomes Study Social Support instrument. Depression was measured with the Beck Depression Inventory. Outcomes included CKD progression (50% loss of eGFR or incident ESRD), CV events (heart failure, stroke, myocardial infarction, peripheral arterial disease), and death. Low social support was defined as a score > 1 standard deviation below the cohort mean.

Results: The mean age was 57 years, 62% were men, 17% had low social support, and the mean eGFR was 38 ml/min/1.73 m^2. Compared with individuals in the highest quartile of social support score, individuals in the lowest quartile had a demographic-adjusted OR for depressive symptoms of 3.11(1.59-6.07). Over a median follow-up of 5 years, the event rate per 100 person-year was 8.6 for ESRD, 4.6 for CV events, and 3.7 for death. Cox regression analyses adjusted for sociodemographics, diabetes, eGFR, and proteinuria are shown in the Table.

	ESRD	CV Events	Death
Adjusted HR (95% CI)			
Social support score > 1 SD below mean	0.63(0.34-1.18)	0.53(0.24-1.21)	0.61(0.27-1.42)

Conclusions: Despite the strong association between low social support and depressive symptoms, low social support was not associated with ESRD, CV events, or mortality in this cohort. Further work is needed to understand the role of social support in this population.

SA-PO837

Sensory and Motor Nerve Deficits in Patients with Pre-Existing Chronic Kidney Disease in the Health, Aging and Body Composition (Health ABC) Study Ranjani N. Moorthi,[1] Simit Doshi,[1] Linda F. Fried,[2,7] Ann Schwartz,[3] Mark J. Sarnak,[4] Suzanne Satterfield,[5] Anne B. Newman,[6] Michael Shlipak,[3,7] Sharon M. Moe,[1,7] Elsa S. Strotmeyer.[6] *[1]Indiana Univ, Indpls; [2]VA Pittsburgh; [3]UCSF, San Francisco; [4]Tufts Medical Center, Boston; [5]Univ of Tenessee; [6]Univ of Pittsburgh; [7]Veterans Administration.*

Background: Neuropathy is prevalent in the elderly and associated with loss of functional independence. We hypothesize that pre-existing CKD in the elderly predisposes to worsening sensory and motor nerve deficits over time.

Methods: The Health ABC Study is a longitudinal cohort of community-dwelling white and black Medicare beneficiaries with initial enrollment in 1997-98 (year 1). Subjects underwent sensory and motor nerve testing at years 4 and 11. We examined the relationship between CKD (eGFR < 60 ml/min in 1999/2000 or year 3) with new nerve deficits that were detected at year 11 but were not present at year 4. Sensory deficit was defined as insensitivity to light (1.4g) or standard (10g) touch and motor deficit was defined as compound peroneal motor action potential < 1mV or nerve conduction velocity (NCV) < 40 m/s. Multivariable regression was used to compare odds of developing a new sensory and/or motor deficit at year 11, excluding those with existing deficits, in pre-existing CKD.

Results: Mean (SD) age of participants at year 11 was 82(3) years, 45.2% were men, 34.6% were black and 13.8% had CKD based on eGFR at year 3. After excluding existing nerve deficits, participants with CKD at year 3 had worsening monofilament insensitivity at year 11 (p<0.01) and developed more NCV decreases (p<0.05). Presence of CKD was associated with a 1.9 higher odds (1.1-3.7) of having one or more new nerve deficits (sensory and/or motor) at year 11, adjusted for age, race, gender and diabetes.

Nerve Function (at year 11 compared to year 4)	eGFR>60 year 3	eGFR<60 year 3	p value
SENSORY			
New or worsening deficit (from light to standard touch) in monofilament insensitivity	49.8% (456)	62.0% (106)	0.004
MOTOR:			
CMAP< 1mV New Deficit	15.4% (110)	18.8% (22)	0.35
NCV<40 m/s New Deficit	22.2% (138)	32.7% (32)	0.02

Conclusions: CKD is associated with future development of sensory and motor nerve deficits.

Funding: NIDDK Support

SA-PO838

A Prospective Study of Peripheral Neuropathy in Chronic Kidney Disease and Electrophysiological-Pathological Correlation Pinaki Mukhopadhyay. *Nephrology, NRS Medical College, India.*

Background: The present study aims to study the spectrum and severity of peripheral neuropathy in CKD patients and correlate electrophysiological findings with estimated GFR and to establish electrophysiological and pathological correlation in assessment of the progression of peripheral neuropathy with progression of CKD.

Methods: A prospective cross-sectional observation study where 60 consecutive patients with CKD (eGFR<60 mi/min) were enrolled excluding patients with neuropathy due to any other causes except diabetes.Detail history and clinical examination including neurology symptom score (NSS) score and electrophysiological examinations were done. Sural nerve biopsy was done and correlated with severity and progression of CKD using suitable statistical tool.

Results: Out of 60 CKD patients,29 were diabetic CKD.About 81.66% of subject had distal symmetric polyneuropathy and NS Score was 1.75(+-)1.36.In 25% mononeuropathy, 3.33% (CTS) Cranial Neuropathy and 11.6% autonomic involvement were found. Among 49 neuropathy positive patients, 48.97%had sensory motor polyneuropathy while 51.02% had pure sensory polyneuropathy.Neuropathic group were more symptomatic and had higher s. creatinine level(p- 0.012) compared to non-neuropathy group. Hyperkalemia was seen more in neuropathic group with mean serum.K+ level of 5.39 compared to non-neuropathy group (mean s.K+ 4.93) (p-0.17). Diabetes patients were at higher risk of neuropathy with odds ratio of 6.89 compared to non-diabetic in CKD subjects. Paresthesia and/or dysesthesia were the most common symptoms in 40(66.66%),while most common abnormality in examination was abnormal vibration sensitivity in 37(61.66%) subjects. Nerve conduction study revealed sural sensory action potential (81.66% abnormal) was the most common abnormal parameter, while tibial motor action potential and peroneal distal latency were second most common findings. Sural nerve biopsy revealed mostly axonopathy in advanced CKD and in few cases demyelination which closely correlated with EP study.

Conclusions: 1.Peripheral neuropathy is common and linearly correlated with severity of CKD. 2. Axonopathy is common in advanced CKD and there is a clear relationship between electrophysiological – pathological study.

SA-PO839

Factors Predicting Renal Events among Chronic Kidney Disease Patients Including Post-Kidney Transplantation Cases

Satoshi Tanaka,[1] Ryo Yamada,[1] Ken Matsuo,[1] Yoko Matsuo,[1] Masaaki Murakami,[1] Akihiro Sonoda,[2] Kiyoshi Mori,[1,3] Noriko Mori.[1] *[1]Dept of Nephrology, Shizuoka General Hospital, Shizuoka, Japan; [2]Dept of Laboratory Medicine, Shizuoka General Hospital, Shizuoka, Japan; [3]School of Pharmaceutical Sciences, Univ of Shizuoka, Shizuoka, Japan.*

Background: Increase in urinary biomarkers of tubular injury is associated with poor renal outcome among patients with chronic kidney disease (CKD) but relative significance of each biomarker remains elusive. Much less is known about utility of those biomarkers in post-kidney transplantation (KT) cases. We carried out single-center, prospective, observational study among 250 out-patient CKD subjects including KT cases.

Methods: Urine albumin, alpha1-microglobulin (a1MG), liver-type fatty acid binding protein (L-FABP) and N-acetyl glucosaminidase were measured in 250 CKD subjects. Cox proportional hazards models were used to examine association of creatinine (Cr)-normalized urinary biomarker levels with renal events defined by serum Cr doubling, end-stage renal disease (ESRD) or death. Decline rate of renal function was also studied by comparing serum Cr changes after 2 years.

Results: Ages of participants were 59.0±16.1 (mean± SD) years, 61% were men, 11% had diabetes mellitus and 20% were KT cases. Median follow-up period was 4.5 years. Among patients who did not develop renal events within 2 years, relative serum Cr values after 2 years were 129±73% (diabetic nephropathy, n=14), 111±29% (nephrosclerosis, 36), 96±21% (chronic glomerulonephropathy, 37), 87±10% (lupus nephritis, 15) and 104±28% (KT, 48), reflecting response to treatment. After post hoc analysis using stepwise method, independent variables predicting renal events were male gender [hazard ratio (HR) 2.2, P<0.05), eGFR (HR per SD increase 0.285, P<0.001), urinary albumin (1.51, P<0.001) and a1MG/Cr (1.33, P<0.05). Urinary L-FABP/Cr was not independently associated with renal events, likely because it was highly proportional to urinary a1MG/Cr (r=0.89).

Conclusions: In addition to classical risk factors for ESRD, urinary a1MG was independently associated with increased risk of renal events in individuals with CKD including KT cases.

SA-PO840

Understanding Pharmaceutical Care Needs of Living Kidney Donors Through Linked Transplant Registry and Pharmacy Claims Data

Krista L. Lentine,[1] Sally K. Gustafson,[2] Mark Schnitzler,[1] Gregory P. Hess,[3] Dorry L. Segev,[4] Amit X. Garg,[5] Bertram L. Kasiske.[2] *[1]Saint Louis Univ; [2]Chronic Disease Research Group; [3]Symphony Health; [4]Johns Hopkins; [5]Western Univ.*

Background: Limited data are available on pharmaceutical care needs of living kidney donors (LKD).

Methods: We integrated 1) national US Scientific Registry of Transplant Recipients data for LKD (1987-2012) with 2) pharmacy fill records from a nationwide pharmacy claims clearinghouse to examine utilization patterns of diabetes treatments, antihypertensive medications, and antidepressants as measures of these conditions before and after donation.

Results: The linked data captured 32,065 LKD actively filling in the first year before, and 36,597 actively filling in the first year after donation **(Table).** A very small but surprising fraction of LKD were treated with insulin or an oral hypoglycemic agent in the 3 years prior to donation. In year 10 yrs after donation, 0.4% received insulin and 2.3% received an oral glucose-lowering agent. Angiotensin converting enzyme inhibitors comprised the most common class of antihypertensive agent used in the years after donation, with use in 11.3% by year 10. Among the sample, 8.6% received a diuretic by year 10. The most common antidepressant prescriptions filled before and after donation were selective serotonin reuptake inhibitors (SSRI). 9.3% of LKD filled an SSRI prescription in the year before donation, and 8.7% in the year after donation.

Prescription fills among living kidney donors, before and after donation.

Type of Prescription	Percentage of Donors with Prescription Fills in Given Years Before and After Donation								
	Year Before Donation			Year After Donation					
	Year -3 (N=23,749)	Year -2 (N=27,730)	Year -1 (N=32,065)	Year 1 (N=36,597)	Year 2 (N=32,726)	Year 4 (N=29,961)	Year 6 (N=26,765)	Year 8 (N=22,354)	Year 10 (N=16,834)
Diabetes Treatment									
Diabetic supplies	0.28%	0.26%	0.24%	0.26%	0.36%	0.58%	0.89%	1.25%	1.51%
Insulin	0.10%	0.08%	0.06%	0.07%	0.09%	0.12%	0.19%	0.31%	0.37%
Oral hypoglycemic agents	0.30%	0.37%	0.35%	0.23%	0.35%	0.66%	1.12%	1.82%	2.29%
Antihypertensive Medications									
Diuretics	2.47%	2.56%	2.62%	2.26%	2.82%	3.93%	5.45%	6.84%	8.64%
Calcium channel blockers	0.62%	0.65%	0.74%	1.16%	1.37%	1.90%	2.66%	3.31%	3.57%
Beta-blockers	1.58%	1.72%	1.87%	2.05%	2.52%	3.38%	4.35%	5.56%	6.69%
ACE inhibitor	1.72%	1.71%	1.91%	2.38%	3.22%	5.08%	6.86%	9.18%	11.33%
Other antihypertensives	0.23%	0.29%	0.28%	0.29%	0.31%	0.48%	0.67%	0.82%	0.97%
Antidepressant Medications									
Tricyclic antidepressants	1.58%	1.72%	1.46%	1.63%	1.89%	1.92%	2.12%	2.17%	2.26%
SSRIs	9.66%	9.86%	9.29%	8.68%	9.70%	9.38%	9.65%	9.37%	8.96%
SNRIs	2.21%	2.30%	2.18%	2.02%	2.38%	2.44%	2.66%	2.80%	2.92%
MAOs	0.00%	0.01%	0.01%	0.00%	0.00%	0.01%	0.01%	0.03%	0.01%
New generation antidepressants	3.41%	3.54%	3.66%	3.21%	3.74%	3.82%	3.93%)	4.15%	4.22%

Denominators = Number of donors having *any* medication prescription filled in that given year.

Abbreviations: ACE, angiotensin converting enzyme inhibitor; SSRI, selective serotonin reuptake inhibitor; SNRI, serotonin-norepinephrine reuptake inhibitor; MAO, monoamine oxidase inhibitor.

Conclusions: Use of antihypertensive and diabetes medications increase over time after live kidney donation, while antidepressant use appears stable. These data demonstrate the rich potential for linked transplant registry data and pharmacy claims data to examine the incidence and prevalence of medically-treated conditions before and after donation. Future work should compare pharmaceutical care needs of living donors to that of controls with similar baseline good health.

SA-PO841

Diagnostic Utility of Stored sFlt-1 for Future Renal Deterioration

Hideo Tsushima, Masaru Matsui, Miho Tagawa, Ken-Ichi Samejima, Yasuhiro Akai, Yoshihiko Saito. *First Dept of Internal Medicine, Nara Medical Univ, Kashihara, Japan.*

Background: Soluble fms-like tyrosine kinase-1 (sFlt-1), produced by alternative splicing of Flt-1 pre-mRNA is an endogenous antagonist as VEGF and placental growth factor signaling. We have already demonstrated that in the baseline condition, the majority of sFlt-1 is stored in the endothelial cell surface, with an extremely small amount in the circulation, and that stored sFlt-1 is significantly decreased in patients with advanced CKD, as verified by heparin-stimulation; however the relationship between stored sFlt-1 and renal deterioration clinically remains unknown.

Methods: We recruited 104 participants undergoing heparin-loading test, defined as blood collection before and 5 minutes after intravenous heparin injection at a dose of 0.4 IU/kg.

Results: Estimated stored sFlt-1 levels were calculated by subtracting pre-heparin from post-heparin levels of sFlt-1. Heparin injection significantly increased median (interquartile range) sFlt-1 levels from 93 (68-117) pg/mL to 273 (213-383) pg/mL, showing stored sFlt-1 levels of 189 (108-276) pg/mL. Pre-heparin sFlt-1 levels were inversely correlated with eGFR (r=–0.372), but the relationship of post-heparin and stored sFlt-1 levels with eGFR was reversed, resulting in a highly direct correlation (r=0.420 and r=0.597, respectively). Decreased post-heparin and stored sFlt-1 levels but not pre-heparin sFlt-1 levels were significantly associated with the severity of proteinuria (p<0.001, ,p<0.001, respectively). During study period, 42 renal events including all-cause mortality, end-staging renal disease or doubling of baseline creatinine levels were occurred. A univariate hazard ratio [95% confidence interval] of above versus below median levels of pre-heparin, post-heparin and stored sFlt-1 for adverse events was 2.52 [1.32-5.15], 0.66 [0.34-1.25], 0.38 [0.17-0.77], respectively. The c-statistics of pre-heparin, post-heparin and stored sFlt-1 levels was 0.758, 0.678 and 0.798, respectively, suggesting that stored sFlt-1 had more predictive accuracy in renal deterioration than other sFlt-1.

Conclusions: Decreased stored sFlt-1 is significantly associated with renal events.

SA-PO842

CKD Pregnant Patients in Jalisco, Mexico: Maternal and Perinatal Outcomes

Karina Renoirte, Maria de la Luz Alcantar Vallin, Guillermo Garcia-Garcia. *Nephrology, Hospital Civil Guadalajara, Guadalajara, Jalisco, Mexico.*

Background: Medical indications to start RRT during pregnancy have been established by international studies, but risk factors for RRT initiation have not been determined yet. Hospital Civil de Guadalajara (HCG) is a tertiary care facility responsible for managing pregnant patients with CKD without social security in the Western region of the country. Our objective was to determine risk factors for RRT among pregnant CKD patients at HCG.

Methods: Prospective, descriptive maternal-fetal outcome analysis among pregnant CKD patients at HCG from June 2013 to September 2015. CKD was defined as kidney damage for ≥3 months (KDIGO guidelines) before pregnancy. Data was recorded at first visit and 3 months after delivery. Clinical complications and perinatal outcomes were evaluated: need for RRT, preeclampsia, anemia (WHO, Hb<11g/dL), preterm delivery (newborn <37 weeks) and need for Neonatal Intensive Care (NIC). Dialysis was initiated when blood urea nitrogen (BUN) was ≥45 mg/dL or if the classic criteria for RRT were met.

Results: 27 pregnant women with known CKD were included and followed from June 2013 to September 2015. Ten patients (37%) required RRT (HD). 2 patients in the CKD-HD group (both with CKD stage 3 at first visit) showed recovery of renal function and were free of hemodialysis in the follow up period (3 months after delivery).

Gestational Age (Capurro)	37±2.15	31.22 ± 3.76	0.005
Premature baby, (%)	7 (44)	5 (63)	0.667
Weight at birth, mg	2460 ±693.65	1837 ±684.17	0.049
Need for NIC, (%)	4 (25)	4 (40)	0.2036
Died after birth, (%)	0	0	NA

Conclusions: CKD stage and anemia at first visit were risk factors for RRT during pregnancy. Urgent pregnancy cessation due to eclampsia, preeclampsia and polyhydramnios was more frequent in the HD group. As expected, babies from the HD group had lower gestational age and lower weight at birth when compared to babies of CKD mothers that did not require HD. Renal recovery after delivery remains low, but perinatal and maternal outcomes are improving.

SA-PO843

Pregnancy in Mexican, Low-Income, Chronic Kidney Disease Patients

Maria de la Luz Alcantar Vallin, Angela Maria Soto Cruz, Karina Renoirte, Guillermo Garcia-Garcia. *Nephrology, Hospital Civil Guadalajara, Guadalajara, Jalisco, Mexico.*

Background: CKD is a global public health problem and it is linked to adverse outcomes in pregnancy. The prevalence of CKD in childbearing age may reach 3%. However, few settings offer an integrated nephrological and obstetric follow up in this population. We report outcomes in CKD low-income, pregnant women, followed at our Pregnancy & CKD Clinic.

Methods: This is a prospective observational study at the Hospital Civil de Guadalajara. From July 2013 to September 2015, 27 pregnant patients with eGFR < 60 ml/min/1.73 m2 and/or markers of kidney damage ≥ 3 months previous to conception were included. The group was compared to a historic cohort of pregnant women without CKD. Chi-square and t-test were used when appropriate. Multivariate logistic regression analysis was used to estimate odds ratios and 95% CI. Significance was assessed at p <0.05.

Results: 89% of pregnancies had a live birth. Pre-eclampsia (OR 13.53, 95% CI 2.69-68.15, p < 0.001), pre-term delivery (OR 8.27, 95% CI 2.56-26.74, p < 0.001), low-birth weight (OR 8.27, 95% CI 2.56-26.74, p < 0.001), and admission to NICU (OR 9.47, 95% CI 1.79-50.16, p < 0.001) where more frequently seen in the CKD group.

Live birth (%)	48 (100)	24 (89)	0.13
Birth weight (g)	3022 ± 455	2253 ± 739	< 0.001
Birth weight < 2,500 g (%)	6 (12.24)	13 (54.16)	< 0.001
Pre-term delivery (%)	7 (14.28)	13 (48.14)	< 0.001
Admission to NICU (%)	2 (4)	7 (29)	0.006

Conclusions: Low-income, CKD pregnant women, have a higher rate of adverse materno-fetal outcomes. Our study supports an integrated, multidisciplinary, approach and follow-up for pregnant patients with all stages of CKD. Multi-center studies are needed to establish standard protocols for the appropriate management of this condition.

SA-PO844

Renal and Obstetric Outcomes of Pregnant Women with CKD 3-5

Philip Webster,[1] Matt Hall,[2] Louise Webster,[1] Sue Carr,[2] Nigel J. Brunskill,[2] Liz Lightstone.[1] *[1]Imperial College Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom.*

Background: Chronic Kidney Disease (CKD) affects up to 6% of women of childbearing age & women with more advanced CKD are now rarely advised to avoid pregnancy. There are variable data on the effect of pregnancy on CKD & this observational study is the largest to our knowledge to look at both renal & obstetric outcomes in women with CKD 3-5.

Methods: Women with an MDRD eGFR below 60ml/min/1.73m^2, either prior to pregnancy or by 12 weeks of gestation, from 2 tertiary centres were included. Women already on dialysis or with early fetal loss were excluded. Outcomes analysed included a 25% increase in serum creatinine (SCr), requirement for renal replacement therapy (RRT) & gestation at delivery.

Results: 88 women (2003-2012) were identified & followed up for a median 1408 days. 12 had a renal transplant, 3 of whom had pancreas transplants. Median age: 32.2yrs (IQR 29.3, 35.8). Median baseline SCr: 128µmol/l (IQR 113, 149). A 25% increase in SCr was seen in 21% (18/88) & this was in the 3rd trimester in 15 of the 18. Baseline eGFR did not predict those with a 25% rise in SCr during pregnancy. During follow up, 16% (14/88) went on to require RRT (1 during pregnancy) & this was more likely in those with a baseline eGFR <30 ml/min/1.73m^2 (46% *vs* 12%, p=0.013). Preterm delivery (<37 weeks) was common (58% (51/87)) & median gestation was lower in women with CKD 3b (35 weeks; IQR 32, 37; n=36; p=0.011) or CKD 4/5 (34 weeks; IQR 33, 37; n=11; p=0.013) than those with CKD 3a (37 weeks; IQR 35, 39; n=41). Obstetric outcomes available on 47/88 women showed 100% live births. Mode of delivery (13 (28%) emergency caesarean section, 18 (38%) elective caesarean section, 16 (34%) vaginal delivery) was not affected by baseline renal function.

Conclusions: Women with CKD 3-5 are at risk of adverse renal and obstetric outcomes, with renal decline most commonly occurring in the 3rd trimester. The worse the renal function at conception the greater the risk of requiring RRT and preterm delivery.

SA-PO845

Secular Trends in the Incidence of End–Stage Renal Disease and Its Risk Factors in IgA Nephropathy

Shigeru Tanaka,[1] Toshiharu Ninomiya,[2] Ritsuko Katafuchi,[3] Kosuke Masutani,[2] Akihiro Tsuchimoto,[2] Masanori Tokumoto,[1] Hideki N. Hirakata,[4] Hiroaki Ooboshi,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono.[2] *[1]Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Kidney Unit, National Fukuoka–Higashi Medical Center, Fukooka, Japan; [4]Fukuoka Renal Clinic, Fukuoka, Japan.*

Background: There are limited data on the secular trends in the incidence of end–stage renal disease (ESRD) and frequencies of its risk factors and treatment modalities in patients with IgA nephropathy (IgAN).

Methods: This study divided 1259 patients with IgAN into three groups according to the timing of renal biopsy: 1979–1989 (n=232), 1990–1999 (n=574) and 2000–2010 (n=453). The mean follow–up periods of these three cohorts were 37.4, 43.4 and 48.4 months, respectively.

Results: A total of 63 (5.0%) developed ESRD. The age–adjusted incidence of ESRD decreased significantly over time, from 12.5 per 1000 person–years (95% confidence interval [CI)], 2.5–24.6) in 1979–1989, to 6.5 per 1000 person–years (95% CI, 1.7–25.2) in 1990–1999; to 4.2 per 1000 person–years (95% CI, 1.8–17.5) in 2000–2010. The proportions of patients with preserved renal function and acute inflammatory histologic changes (i.e. endocapillary hypercellularity, extracapillary proliferation, and acute crescentic lesion) at the timing of biopsy increased over time, as did the rates of prescriptions of renin–angiotensin system inhibitors and corticosteroids (all P for trend<0.001). The impacts of acute inflammatory histologic lesions on renal prognosis were drastically reduced with the times.

Conclusions: These findings suggest that early diagnosis in the acute inflammatory phase and subsequent aggressive treatment may have contributed to the significant downward trends over three decades in the incidence of ESRD in Japanese patients with IgAN.

SA-PO846

Hospitalization Burden of Chronic Renal Insufficiency Cohort (CRIC) Study Participants Amanda Hyre Anderson,[1] Jason Roy,[1] Eugene Lin,[2] Michael J. Fischer,[2] L. Lee Hamm,[2] James P. Lash,[2] Eva Lustigova,[2] Emile Mohler,[1] Akinlolu O. Ojo,[2] Mahboob Rahman,[2] Julia J. Scialla,[2] Susan P. Steigerwalt,[2] Harold I. Feldman.[1] *[1]Univ of Pennsylvania; [2]The CRIC Study.*

Background: Patients with chronic kidney disease (CKD) experience a substantial burden of morbidity requiring hospitalization. However, hospitalizations prior to development of end-stage renal disease (ESRD) are not well characterized.

Methods: Participants of the multi-center prospective observational CRIC Study (N=3,939; mean estimated glomerular filtration rate (eGFR): 45 mL/min/1.73m²; age range: 21-75 years; 48.4% with diabetes). Over a median of 6.9 years, hospitalizations were ascertained by patient reports, confirmed by queries of local hospitals, and categorized by ICD-9 codes. Hospitalization rates (unadjusted and adjusted for age, gender, race/ethnicity, clinical center, education, eGFR, and proteinuria in Poisson regression models) were compared across sub-groups.

Results: Through mid-2013, 14,794 hospital stays were confirmed pre-ESRD with a mean duration of 2.8 days. Prior to ESRD, the mean time spent in the hospital per participant per year was 2.6 days, with 50% and 10% of participants spending 0.5 days and nearly one week hospitalized annually, respectively. Unadjusted hospitalization rates (95% CI) were 61.5 (60.5-62.5), 49.3 (48.2-50.5), and 77.3 (75.6-79.0) per 100 person-years among those overall, without and with diabetes, respectively. Unadjusted rates were highest among older participants, non-Hispanic blacks, and those with lower levels of education, higher levels of proteinuria, higher SBP, history of CVD, and lower eGFR. Multivariable-adjusted rates were significantly higher with lower baseline eGFR, higher proteinuria, diabetes, and higher systolic blood pressure. The top three primary ICD-9 codes included those for congestive heart failure, chest pain, and acute kidney injury.

Conclusions: The burden of pre-ESRD hospitalizations among individuals with CKD is substantial and varies by sociodemographic and clinical factors.

SA-PO847

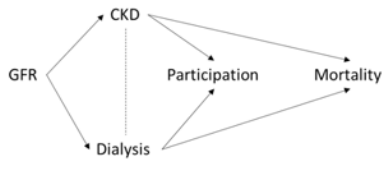
Chronic Kidney Disease and All-Cause Mortality: The Influence of Selection Bias in a National Health Survey Seth P. Kuranz. *Decision Resources Group, Burlington, MA.*

Background: The National Health and Nutrition Examination Survey (NHANES) collects biologic measures to assess CKD among participants who travel to mobile examination centers. NHANES likely under-ascertains severe cases of CKD due to issues of patient mobility. We assess the influence of potential selection bias due to under-ascertainment of severe cases on the association between CKD and all-cause mortality.

Methods: NHANES data (cycles 2005-06, 2007-08, and 2009-10) linked to NCHS mortality files were assessed the association between CKD (GFR < 60 ml/min, calculated using both the CKD-EPI and MDRD equations, or self-reported dialysis) and all-cause mortality among US adults aged 20+, using Cox Proportional Hazards models. Findings from the literature, and a directed acyclic graph were used to identify parameters necessary to conduct a quantitative bias analysis addressing the relationship between CKD, all-cause mortality, dialysis, and participation in the NHANES laboratory examination.

Results: Crude and age-adjusted models found CKD was associated with all-cause mortality (HR=7.51 (7.50-7.53)). Accounting for selection bias, due to conditioning on participation (Figure 1), attenuated the association between CKD and all-cause mortality (HR=4.11 (3.39-4.91)). Attenuation was smaller in the age-adjusted analyses. Only small differences were observed between the MDRD and CKD-EPI GFR equations.

Figure 1. Directed Acyclic Graph



Conclusions: Restriction is a commonly employed strategy to control for confounding in epidemiologic research. Unintentional restriction arising from differential participation may induce relationships between unmeasured/uncontrolled variables and both the exposure and outcome. Although NHANES is a well conducted nationally representative survey, this particular form of selection bias should be considered in studies that use NHANES data to assess associations between CKD and other health outcomes.

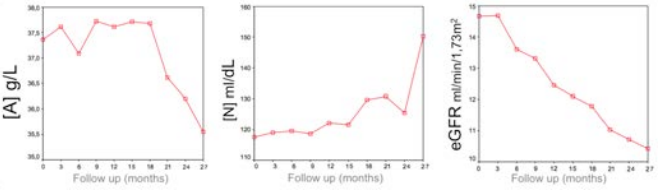
Prolonged Conservative Therapy in End Stage Renal Disease: A Therapeutic Option? The Verona Experience Vincenzo De Biase, Alfredo Petrosino, Alessandra Dalla Gassa, Giuseppina Pessolano, Isabella Squarzoni, Chiara Branco, Antonio Lupo. *Renal Unit, Univ Hospital of Verona, Verona, VR, Italy.*

Background: The prolonged conservative therapy (CT) of End Stage Renal Disease (ESRD) ameliorates uremic symptoms and postpones the initiation of renal replacement therapies (RRTs). There is no evidence of survival advantage from early initiation of dialysis, thus CT could be considered as a common path for ESRD patients, both in "palliative care" as well as in those intended to RRTs.

Methods: We observed 144 ESRD patients in CT in our low-clearance clinic, followed up in the period 01/2013–05/2016 and enrolled as they reached a eGFR (CKD-EPI)<15±4 ml/min/1,73m². The observation ended at the initiation of RRTs (haemo [HD] or peritoneal [PD] dialysis or kidney transplant [T]) or in case of death. RRTs where started when indicated, in according to KDIGO 2012 guidelines. The duration of follow up [FU] was the main end point. We further evaluated serum albumin [A] and azotaemia [N], as indexes of dietary adequacy, and eGFR variations.

Results: The mean FU at the end point was 20.2 months (CI 16.50-23.86), with no differences between those who initiated RRTs and those who did not. 37 patients (60.7%) started HD, 4 (6.6%) PD, 3 (4.9%) received a T. 12 patients (19.7%) died without RRTs. 88 patients continued the FU. Mean eGFR at the endpoint was 10.43 ml/min/1,73m2. [A] did not change within 21 months (p<0.027, quadratic regression) and [N] showed a similar but opposite trend (p<0,066, quadratic regression); eGFR slightly declined (p<0.0001).



In a general linear model, [A] and eGFR only were positively related to FU.

Conclusions: CT in ESRD patients seems to confer a stable nutritional status, as assessed by [A] and [N], within 21 months of treatment. Moreover, it allows postponing the beginning of RRTs of nearly 2 years, proving RRTs to be avoidable in many cases.

SA-PO849

Factors Affecting Secondary Care Referral of Older People with Advanced Chronic Kidney Disease and Their Outcomes: An Observational Cohort Study Anirudh Rao,[1,2] Stephanie J. MacNeill,[1,2] Yoav Ben-Shlomo,[2] Fergus J. Caskey.[1,2] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Univ of Bristol, Bristol, United Kingdom.*

Background: Aim of this study was to identify patient characteristics and outcomes associated with advanced chronic kidney disease (CKD) being managed solely in primary care rather than co-managed in primary and secondary care as current evidence is limited.

Methods: The Health Improvement Network (THIN) primary care database was used to identify patients aged ≥65 years with new advanced CKD(eGFR ≤20mls/min/1.73m²) managed solely by a general practitioner(GP)(Primary care cohort) or co-managed with a nephrologist(Secondary care cohort). Multivariable regression models were used to explore cohort differences in baseline demographics, clinical & laboratory markers, and survival in the 12 months following the index eGFR. Cohort differences in GP consultations and proportion having ≥4 hospitalisations was assessed using Mann Whitney and Chi-square tests respectively.

Results: There were 632 and 2,464 patients in the Primary and Secondary care cohorts, respectively. In a multivariable logistic model, older patients (65-69yrs (ref); 70-74yrs: OR 0.5, 95% CI 0.2-1.8; 75-79yrs: 2.2, 0.8-6.0; 80-85yrs: 3.3, 1.3-8.7; >85 yrs 10.6, 4.1-27.1), women(OR 2.2, 95% CI 1.6-3.1), those living in rural areas(OR 2.1,95% CI 1.5-3.1), cardiovascular disease(OR 1.7, 95% CI 1.2-2.4) and cancer(OR 1.6, 95% CI 1.1-2.4) were more likely in the Primary care cohort. Patients in this cohort had fewer GP consultations(median (IQR) 7(3-13) vs 9(5-15), p<0.001) and a lower proportion required ≥4 hospitalisations(3.6% vs 9.8%, p<0.001) in the first year when compared to those in secondary care. Mortality remained higher in primary care cohort despite adjustment for sociodemographic, clinical measures and Charlson Index(HR 1.6, 95% CI 1.1-2.2, p=0.008).

Conclusions: People with advanced CKD are more likely to be managed solely in primary care if they are older, female and have a co-existing diagnosis of cardiovascular disease or cancer. They have a higher mortality rate, but are less likely to consult their GP or be admitted to hospital. Further study is required to understand the reasons for and appropriateness of these referral decisions.

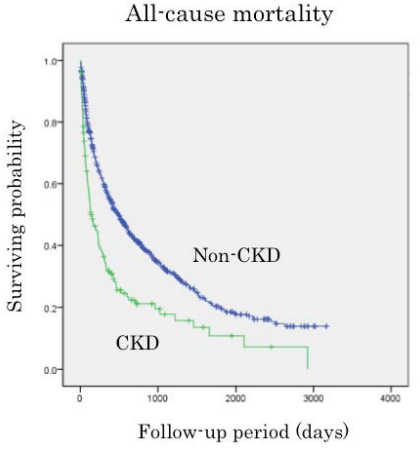
SA-PO850

Chronic Kidney Disease Is Associated with Mortality in Stage IV Cancer Patients Taisuke Ishii,[1,2] Takuya Fujimaru,[1] Gautam A. Deshpande,[3] Eriko Nakano,[2] Yasuhiro Komatsu.[1] *[1]Nephrology, St. Lules International Hospital, Chuo-ku, Tokyo, Japan; [2]Medical Oncology, St. Lules International Hospital, Chuo-ku, Japan; [3]Center for Clinical Epidemiology, St. Lules International Univ, Chuo-ku, Tokyo, Japan.*

Background: The prevalence of chronic kidney disease (CKD) is increasing among cancer patients. However, the impact of CKD on the prognosis of patients with advanced cancer is unknown. The aim of this study is to examine the association between CKD and mortality in stage IV cancer patients.

Methods: In this single-center, retrospective cohort study, we collected data from all patients with newly diagnosed stage IV solid cancer from April 2009 to December 2014, with follow-up through December 2015. CKD was defined as eGFR ≤ 60 ml/min/1.73m^2 at the time of diagnosis. The primary endpoint was all-cause mortality. The secondary endpoint was cancer-specific mortality. Log-rank test and Cox proportional hazard analysis were used for analysis.

Results: Of 962 patients (age 69±10, 51.8% of males) meeting inclusion criteria, 150 patients (16%) had CKD. During follow-up (median 293 days, IQR 79-751 days), 639 patients (66.4%) died. On Kaplan-Meier survival analysis, patients with CKD showed significantly poorer survival compared to those without CKD (log-rank test, $p < 0.001$). After adjusting for age, gender, BMI, type of cancer, anticancer therapy, baseline serum sodium, glucose, WBC, hemoglobin, CRP, and ECOG Performance Status, CKD remained significantly associated with all-cause mortality (HR 1.63, 95% CI 1.26-2.10). For cancer-specific mortality, CKD was also correlated with poorer survival (log-rank test, $p < 0.001$) and was identified as an independent risk factor in multivariate analysis (HR 1.67, 95%CI 1.26-2.22).



Conclusions: This study is the first to report CKD as an independent predictor of mortality in patients with advanced cancer.

SA-PO851

Canadian Child Multi-Centre ABLE Study: Long-Term Renal Outcomes 3 Months Post-Cisplatin Kelly McMahon,[1] Tom D. Blydt-Hansen,[2] Maury N. Pinsk,[3] Cherry Mammen,[2] Shahrad Rod Rassekh,[2] Ross T. Tsuyuki,[4] Prasad Devarajan,[5] Michael Zappitelli.[1] *[1]McGill U, Montreal; [2]U British Columbia, Vancouver; [3]U Manitoba, Winnipeg; [4]U Alberta, Edmonton, Canada; [5]Cincinnati Children's Hosp, Cincinnati.*

Background: Acute kidney injury (AKI) during cisplatin therapy is common in children. Cisplatin may cause late kidney disease (chronic kidney disease [CKD] or hypertension [HTN]). The late cisplatin renal outcome phenotype remains unclear. ABLE is a pan-Canadian study on biomarkers of late child cancer treatment effects, including nephrotoxicity. Aim: Describe CKD and HTN 3 months post-child cisplatin therapy.

Methods: Ongoing 12-site prospective study of cisplatin-treated children. Exclusion: GFR<30 ml/min/1.73m^2. Protocol: 2 acute visits (AV) at an early (1st or 2nd - AVE) and later (≥3rd - AVL) cisplatin infusion; 3 follow-ups (FU): 3, 12, 36 months post-cisplatin with urine/blood, blood pressure(BP) collection. AKI: serum creatinine rise≥50% from baseline at AVE or AVL. FU outcomes: CKD: eGFR<90ml/min/1.73m^2 [by 1) serum creatinine, 2) cystatin C] ***or*** albumin-to-creatinine ratio (ACR)>30 mg/g; HTN: BP≥95th percentile for age, gender, height. We calculated % with low eGFR, albuminuria or HTN at 3 months. We compared AKI *vs.* non-AKI groups (chi-square or non-parametric tests).

Results: Of 56/110 with 3-month data (median[IQR] age 6[3-12] years; 53% male), HTN (7%) and albuminuria (39%) were very common (Table, "All"). Albuminuria was more common in AKI patients (though not significant); eGFR was higher in AKI (not significant, Table). 3-month HTN was more common in AKI patients ($p<0.05$) due to higher diastolic BP (Table).

Conclusions: ABLE will be the largest renal follow-up of cisplatin-treated children. 3-month post-cisplatin CKD and HTN prevalence is high overall. HTN is more common in patients with cisplatin-AKI. Patients with AKI may have relative hyperfiltration 3 months post-cisplatin.

Table: Long-term renal abnormalities 3 months after cisplatin treatment end in all patients, AKI patients and non-AKI patients.

Outcome	All	AKI	Non-AKI	P-value
Albuminuria	23/59 (39%)	10/20 (50%)	13/39 (33%)	0.21
Systolic BP percentile (median [IQR])	39th [26th-50th] N=41	41st [34th-50th] N=16	39th [15th-50th] N=25	0.30
Diastolic BP percentile (median [IQR])	50th [40th-73rd] N=41	61st [47th-80th] N=16	46th [39th-67th] N=25	**0.03**
Hypertension (HTN)	3/42 (7%)	3/16 (19%)	0/26 (0%)	**0.049**
SCr-eGFR (median [IQR] mL/min/1.73 m^2)	136 [115-158] N=49	144 [115-172] N=20	135 [115-152] N=29	0.38
SCr-eGFR<90 mL/min/1.73m^2	5/49 (10%)	2/20 (10%)	3/29 (10%)	1.00
CysC-eGFR (median [IQR] mL/min/1.73 m^2)	124 [105-145] N=62	131 [110-144] N=20	122 [104-148] N=42	0.34
CysC-eGFR<90 mL/min/1.73m^2	5/62 (8%)	2/20 (10%)	3/42 (7%)	0.52
CKD (low SCr-eGFR *or* albuminuria)	27/61 (44%)	11/21 (52%)	16/40 (40%)	0.36
Low SCr-eGFR *or* albuminuria *or* HTN	28/62 (45%)	12/21 (57%)	16/41 (39%)	0.18

Abbreviations: AKI: Acute kidney injury, IQR: Interquartile range, BP: Blood pressure, HTN: Hypertension, eGFR: Estimated glomerular filtration rate, SCr: Serum creatinine, CysC: Cystatin C.
SCr-eGFR: estimated by updated Chronic Kidney Disease in Children (CKiD) formula;
CysC-eGFR: estimated by Zappitelli CysC equation;
Blood pressure: measured by an automated device; mean of 2 lowest out of 3 readings is used.
Albuminuria: using random untimed urine sample at time of follow-up visit.
Additional information: 3/59 (5%) had severe albuminuria (ACR>300 mg/g)

Funding: Government Support - Non-U.S.

SA-PO852

Risk of Metformin-Associated Lactic Acidosis in Chronic Kidney Disease Benjamin Lazarus,[1] Aozhou Wu,[1] Yingying Sang,[1] Josef Coresh,[1] Alex R. Chang,[2] Morgan Grams.[1] *[1]JHU, Baltimore, MD; [2]Geisinger Health System, Danville, PA.*

Background: Metformin is a first-line treatment for diabetes mellitus, but is frequently avoided in those with CKD due to the risk of metformin-associated lactic acidosis (MALA). The FDA recently expanded the metformin label to allow for use at eGFR 30-60 ml/min/1.73m^2, but limited data exists regarding the risk of MALA in this range of kidney function.

Methods: Using Poisson regression and a new-user, active comparator design, we evaluated the risk of acidosis events, defined by an ICD-9 code of 276.2, in 12,437 new metformin users compared to 6,541 new sulfonylurea users in the Geisinger Health System from 2004-2014, by categories of baseline eGFR.

Results: Overall, there were 366 acidosis events over a mean 2.6 years of follow-up. Metformin and sulfonylurea users were similar in age, sex, race, baseline serum bicarbonate concentration, HbA1c, smoking status and BMI. Cardiovascular disease and hypertension were more prevalent in sulfonylurea users, whereas concomitant use of insulin, statin, renin-angiotensin system inhibitors, diuretics and NSAIDs were more frequent in metformin users. The demographic-adjusted incidence of acidosis for metformin users was 5, 6, 8, 17 and 84 events per 1,000 person years for baseline eGFR >90, 60-89, 45-59, 30-44 and <30 ml/min/1.73m^2, respectively. The corresponding incidence for sulfonylurea users was 7, 7, 15, 10 and 45 events per 1,000 person years. Overall, there was no significant difference in acidosis risk between metformin and sulfonylurea users, but there was a trend toward increased risk at eGFR <30 ml/min/1.73m^2.

Table 1. Risk of lactic acidosis for metformin users versus sulfonylurea users.

eGFR (ml/min/1.73m^2)	Incidence rate ratio*	95% CI
>90	0.75	0.49-1.15
60-89	0.87	0.59-1.28
45-59	0.55	0.30-1.00
30-44	1.16	0.45-2.98
<30	2.24	0.51-9.88

*Adjusted for age, sex, race, serum bicarbonate, HbA1c, smoking status, BMI, cardiovascular disease, hypertension and concomitant medication use.

Conclusions: Patients with eGFR >30 ml/min/1.73m^2 who use metformin do not appear to be at greater risk of acidosis than those who use sulfonylureas, supporting the FDA label expansion.

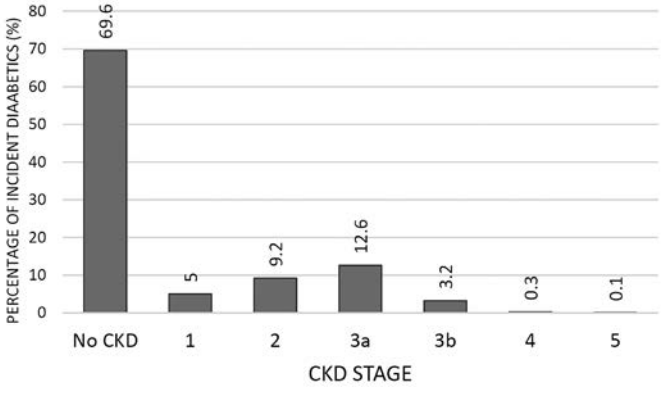
SA-PO853

Evidence of Chronic Kidney Disease in Veterans with Diabetes prior to Treatment Justin Gatwood,[1,3] Marie Chisholm-Burns,[1] Robert L. Davis,[2] Fridtjof Thomas,[2] Praveen Kumar Potukuchi,[2,3] Adriana Hung,[4] Csaba P. Kovesdy.[2,3] *[1]College of Pharmacy, Univ of Tennessee Health Science Center, Memphis, TN; [2]College of Medicine, Univ of Tennessee Health Science Center, Memphis, TN; [3]Nephrology, Memphis VA Medical Center, Memphis, TN; [4]Nephrology, Vanderbilt Univ School of Medicine, Nashville, TN.*

Background: Diabetes mellitus (DM) is a growing public health threat, and its impact on chronic kidney disease (CKD) remains of paramount importance. This study evaluated the extent of CKD in a national cohort of US veterans prior to initiating oral antidiabetic (OAD) therapy for incidence cases of DM.

Methods: The VA Corporate Data Warehouse was used to identify the first diagnosis for uncomplicated DM and the presence of disease was confirmed by an accompanying prescription for an OAD agent during 2002-2014. CKD was measured using estimated glomerular filtration rates (eGFR) and urine albumin-to-creatinine ratios as recorded nearest to the initial DM diagnosis and up to the date of the first OAD prescription fill.

Results: A total of 41,658 patients were analyzed, and most were White (77.7%) and male (96%). At DM diagnosis, mean (SD) age and hemoglobin A1C were 61.4 (10.18) and 7.4% (1.37), respectively, and 69.9% exhibited normal kidney function (UACR <30 and eGFR ≥60). However, 30.1% had CKD and 16.2% exhibited at least moderately reduced eGFR (CKD Stages 3a-5, Figure). The odds of any CKD stage (vs. no CKD) increased with age and hemoglobin A1C (p <0.0001 for both). Self-identified Asian (OR = 1.45, CI: 1.12-1.88) or African American race (OR = 1.12, CI: 1.05-1.20) was associated with a higher risk of CKD compared to White race.



Conclusions: CKD is common in veterans with incident DM, especially among older patients and certain minorities. Efforts to diagnose CKD should be made in conjunction with attempts to lower blood sugar early in the treatment process.

SA-PO854

Evaluation of Non-Prescribed Opioid and Illicit Drug Use in Chronic Kidney Disease Patients Thuy Hoang, Linda Awdishu, Lee Lee Zhu. *Pharmacy, Univ of California, San Diego Skaggs School of Pharmacy & Pharmaceutical Sciences, La Jolla, CA.*

Background: Over 58% of CKD patients experience pain and 49% of patients report their intensity of pain to be moderate to severe. Neuropathic and musculoskeletal pain are among the most common types of pain experienced by this population. The objective of this study was to determine the prevalence of non-prescribed pain medication or illicit drug use in patients with and without CKD using urinary and saliva samples.

Methods: This was a sub-study from a larger prospective medication reconciliation and adherence study of 493 patients at UCSD Health System and ambulatory care clinics. Medication reconciliation was conducted by a pharmacist or student pharmacist for each patient. Urine and saliva specimens were collected at the time of medication reconciliation and analyzed using triple quad liquid chromatography with tandem mass spectrometry (LC-MS/MS) for the presence of opioids and illicit drugs. Patients with a GFR <60mL/min/1.73m^2 (by MDRD equation) were defined as CKD. We hypothesized that patients with CKD were more likely to use non-prescribed pain medications and illicit drugs than patients without CKD. A Fishers's exact test was used to compare the occurrence of non-prescribed pain medications and illicit drug use detected in biological samples between CKD and non-CKD groups.

Results: A total of 251 patients were included in this study, 145 in non-CKD group and 106 in the CKD group. The detection of a prescribed pain medications were similar between CKD and non-CKD patients (p=0.60) indicating similar rates of adherence. Illicit drug use in CKD and non-CKD patients were overall low. No difference was found between the two groups (6.2% vs 2.9%, p=0.37) regarding illicit drug use. Patients without CKD were more likely to use non-prescribed pain medications, mostly consisting of opioids, than CKD patients (40% vs 10.6%, p= 0.0001).

Conclusions: Urine and saliva testing provides an objective measurement of medication reconciliation and adherence. Despite current knowledge that CKD patients are under-treated for pain, we found that CKD patients are less likely to use non-prescribed pain medications compared to non-CKD patients.

Renoprotective Effect of Dipyridamole in Pre-Dialysis Advanced Chronic Kidney Disease -A Nationwide Database Analysis Ko-Lin Kuo,[1] Szu-Chun Hung,[1] Jia-Sin Liu,[2] Chih-Cheng Hsu,[2] Der-Cherng Tarng.[3] *[1]Taipei Tzu Chi Hospital, Taiwan; [2]National Health Research Insts, Taiwan; [3]Taipei Veterans General Hospital, Taiwan.*

Background: Dipyridamole decreases proteinuria and improves renal function progression in patients with glomerular disease through its inhibition of platelet activation and enhanced nitric oxide expression. Whether the effects of dipyridamole on renal outcome or survival is unclear in CKD stage 5 patients who have not yet received dialysis (CKD 5 ND).

Methods: A prospective cohort study was conducted based on the Taiwan National Health Insurance Research Database. From January 1, 2000 to June 30, 2009, we enrolled 28497 CKD 5 ND patients with serum creatinine levels >6 mg/dL and hematocrit levels <28% and who were treated with erythropoiesis-stimulating agents (ESAs) but not yet received renal replacement therapy. All patients were further divided into two groups with or without dipyridamole within 90 days after starting ESA therapy (index date). Patient follow-up took place until long-term dialysis, death before initiation of dialysis or December 31, 2009.

Results: With a mean follow-up of 12 months, 20,152 patients (70.7 %) required long-term dialysis and 5,697 (20.0%) died before progression to end-stage renal disease requiring dialysis. After propensity score-matching, use of dipyridamole was associated with a lower risk for long-term dialysis (HR, 0.96; 95% CI, 0.93-0.99) and pre-dialysis death (HR, 0.89; 95% CI, 0.84-0.95) as compared with nonusers.

Conclusions: Dipyridamole exhibited a protective effect in reducing the risk for long-term dialysis and pre-dialysis death in CKD 5 ND patients. Randomized studies are needed to validate this association.

SA-PO856

Effect of Rituximab on Malignancy Risk in Patients with ANCA-Associated Vasculitis Emma Van Daalen,[1] Raffaella Rizzo,[2,3] Andreas Kronbichler,[3,4] Ron Wolterbeek,[5] Jan A. Bruijn,[1] David R.W. Jayne,[3] Ingeborg M. Bajema,[1] Chinar Rahmattulla.[1,3] *[1]Pathology, Leiden Univ Medical Center; [2]Nephrology, Dialysis and Hypertension Unit, St. Orsola-Malpighi Univ Hospital; [3]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge Univ Hospitals; [4]Internal Medicine IV (Nephrology and Hypertension), Medical Univ of Innsbruck; [5]Medical Statistics and Bioinformatics, Leiden Univ Medical Center.*

Background: Patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) who are treated with cyclophosphamide have an increased malignancy risk compared to the general population. We investigated whether treatment with rituximab instead of cyclophosphamide has decreased the malignancy risk in patients with AAV.

Methods: The study included patients with AAV treated at a tertiary vasculitis referral centre between 2000 and 2014. The malignancy incidence in these patients was compared to the incidence in the general population by calculating standardized incidence ratios (SIRs). Malignancy incidence was compared between rituximab- and cyclophosphamide-treated patients.

Results: Of the 323 included patients, 33 developed a total of 45 malignancies during a mean follow-up of 5.6 years. This represented a 1.89-fold increased (95% confidence interval [CI], 1.38 to 2.53) malignancy risk compared to the general population. Cyclophosphamide-treated patients had an increased malignancy risk compared to the general population (SIR, 3.10; 95% CI, 2.06 to 4.48). In contrast, rituximab-treated patients had a malignancy risk similar to the general population (SIR, 0.67; 95% CI, 0.08 to 2.43). The malignancy risk in patients treated with cyclophosphamide was 4.61-fold higher (95% CI, 1.16 to 39.98) than the risk in patients treated with rituximab.

Conclusions: The malignancy risk in patients with AAV was lower in patients treated with rituximab than in patients treated with cyclophosphamide. Notably, rituximab treatment was not associated with an increased malignancy risk compared to the general population. Rituximab may therefore be a preferable alternative therapy to cyclophosphamide.

SA-PO857

Malignancy in Membranous Nephropathy: Evaluation of Incidence Basil Alnasrallah. *Nephrology, Auckland City Hospital, Auckland, New Zealand.*

Background: Membranous Nephropathy (MN) is known to be associated with malignancy. However, the exact risk remains unclear. In addition, the number of inflammatory cells in the glomeruli has been reported to be associated with malignancy in MN and has been suggested to direct screening; this has not been further validated.

Methods: We looked for the association of malignancy and MN in a cohort of 201 MN patients in Auckland region; we systemically reviewed the clinical records and linked them to the New Zealand Cancer Registry. We calculated the expected risk of a matched population by gender and age taking into account the annual change of risk. We also examined the pathology of renal biopsies of 17 MN patients with malignancies and compared the number of inflammatory cells per glomerulus with matched controls.

Results: 40 malignancies were identified. 28 after the MN diagnosis, the standardized incidence ratio (SIR) was 2.1 (95%CI, 1.3 - 2.85) which was similar between patients ≥60 years and <60 years. The SIR was higher in the first 5 years at 2.3 (95%CI, 1.29 - 3.4) but diminished and lost significance after that. The median number of inflammatory cells per glomerulus didn't differ between MN patients with and without malignancies at 1.86 (IQR, 1.17-2.7) and 2.07 (IQR, 1.17-3.65), respectively (*p*-value 0.56).

Conclusions: The relative risk of malignancy in MN patients was similar across different age groups at 2.1; this risk was most prominent in the first 5 years. The number of inflammatory cells per glomerulus did not differentiate between MN patients with and without malignancies.

SA-PO858

Risk of Renal Progression Is Higher in Upper Tract Urothelial Carcinoma Than in Renal Cell Carcinoma after Unilateral Nephrectomy - A Population-Based Study Huei-Lan Lee,[1] Ming-Yen Lin,[1] Wei-Ming Li,[2,4] Sheng-Wen Niu,[1] Chun-Nung Huang,[2,4] Wen-Jeng Wu,[2,4] Li-Tzong Chen,[3] Shang-Jyh Hwang.[1,4] *[1]Nephrology, Kaohsiung Medical Univ Hospital; [2]Urology, Kaohsiung Medical Univ Hospital; [3]National Inst of Cancer Research; [4]Faculty of Medicine, Kaohsiung Medical Univ.*

Background: Impairment of renal function in patients at diagnosis as upper tract urothelial carcinoma (UTUC) seemed more frequent than in renal cell carcinoma (RCC), which influenced renal outcome and also resulted in a worse clinical outcome. Limited information is available to compare the risk of progression of preexisted renal impairment to end-stage renal disease (ESRD) in patients of UTUC and RCC, respectively. The aim of study was to compare risk of renal progression in patients with UTUC and RCC after receiving unilateral nephrectomy.

Methods: We conducted a population-based cohort study through Taiwan National Health Insurance Research Dataset. Incident UTUC and RCC patient who underwent nephrectomy from 2002 to 2007 was identified from Taiwan Cancer Registry Dataset and linked to claim data.Primary endpoint was defined aspostoperative dialysis 3 months after surgery. Differences of characteristics between UTUC and RCC patients were described as mean ± standard deviation or percentage and tested by independent t test and chi-square test. Competing risk approach was used for estimating cause-specific hazard ratio (CSHR) and 95% confidence interval (CI).

Results: Totally, 1571 UTUC and 1910 RCC patients were included and traced until dialysis or end of the 3-years follow-up. Similar prevalence of CKD stages in UTUC (48.7%) and RCC (45.8%) patients was represented at the baseline. UTUC patients were significantly older, more female, and had more diabetes and stroke than RCC patients. After adjusting factors of age, sex, tumor grade, and co-morbidities, patient with UTUC was significantly associated with excessive risk of postoperative dialysis (CSHR: 2.09, 95%CI: 1.61-2.69, p<0.01) than that of patient with RCC.

Conclusions: UTUC is associated with increased risk of dialysis than RCC. Base on this finding, the strategy of renal function screen after nephrectomy should depend on the type of urinary tract cancer.

Prevalence and Outcomes of Chronic Lung Disease in Patients with Chronic Kidney Disease: A Systematic Review and Meta-Analysis Chung-Jiah Justin Chen, Sreedhar A. Mandayam, Wolfgang C. Winkelmayer, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Chronic lung diseases and CKD are both major public health issues. The burden and impact of chronic lung diseases in the CKD population has not been systematically studied. Hence, we conducted a systematic review and meta-analysis to study the prevalence of chronic lung disease and its impact on all-cause mortality in those with CKD.

Methods: We searched MEDLINE (1966-May 2016) using appropriate MESH terms to identify relevant observational studies reporting obstructive or restrictive lung disease prevalence in CKD patients and mortality outcomes in CKD patients with lung disease. Prevalence rates of chronic lung disease (obstructive and restrictive lung disease separately) and all-cause mortality risk estimates were extracted from individual studies and pooled using a random effects model.

Results: Seven studies were included (n = 839,736). Overall, prevalence of COPD was 18.4% (6 studies, 95% CI: 11.7%, 27.6%) in CKD population. Prevalence was significantly higher among studies that used spirometry to diagnose COPD (3 studies, prevalence rate:34%, 95% CI: 14.6%, 60.9%) than the prevalence among studies that used chart review (ICD-9 codes, medication use etc.) for diagnosing COPD (3 studies, prevalence rate:9%, 95% CI: 5%, 13%). There was an increased risk for all-cause mortality in CKD patients with COPD (vs. without COPD) (Hazard ratio: 1.26, 95% CI: 1.09, 1.41). One study reported prevalence rate of 10% for restrictive lung disease in CKD population. Further, restrictive lung disease was inversely associated with albuminuria and eGFR.

Conclusions: Obstructive and restrictive lung diseases are highly prevalent and are significantly associated with higher all-cause mortality in CKD. Prevalence rates of COPD in CKD patients who underwent spirometry are significantly higher than those of CKD patients with COPD identified by medical records, suggesting that chronic lung diseases are probably underdiagnosed in CKD patients. Even though restrictive lung disease appears to be common in CKD population, formal studies are lacking. Further studies are required to characterize pathogenic mechanisms between lung disease and CKD.

SA-PO860

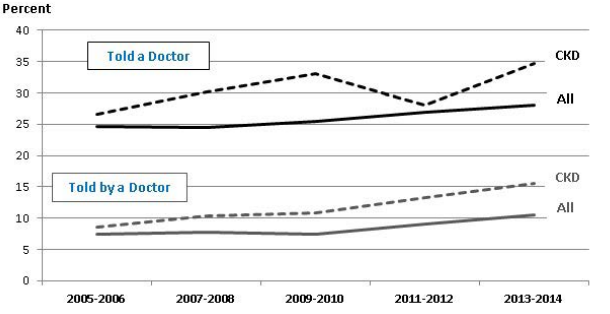
Trends in Self-Reported Communication of Sleep Problems between U.S. Adults with CKD and Their Doctors Jennifer L. Bragg-Gresham,[1] Monica Shieu,[1] Hal Morgenstern,[1] Neil R. Powe,[2] Delphine S. Tuot,[2] Sharon Saydah,[3] Deborah Rolka,[3] Rajiv Saran.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]UCSF, San Francisco, CA; [3]CDC, Atlanta, GA.*

Background: Given sleep's importance for health, we explored trends in the prevalence of self-reported communication of sleep problems between US adults with CKD and their doctors.

Methods: A sample of 25,255 adults aged 20+ from the 2005-2014 National Health and Nutrition Examination Survey was used to estimate the prevalence of (1) having ever told a doctor about having trouble sleeping, and (2) having ever been told by a doctor s/he had a sleep disorder. Prevalence was estimated for each 2-year survey interval. CKD was defined as eGFR <60 ml/min/1.73 m² or UACR >30 mg/g. Logistic regression was used to assess unadjusted and age-sex-BMI-adjusted trends over time among adults with CKD and all adults.

Results: From 2005 to 2014, the crude and adjusted prevalence of each sleep outcome increased in both adults with CKD and all adults (all *p* for trend <0.02). The crude prevalence of both outcomes was greater in adults with CKD than in all adults throughout the 10-year period. Adults with CKD had a greater absolute increase than all adults in the percentage told by a doctor they had a sleep disorder (8.0% vs. 3.0%). In both groups, age and BMI were positively associated with poor sleep outcomes, women were more likely to tell a doctor of their sleep problems, and men were more likely to be told they had a sleep disorder (all p<0.0001).

Crude Prevalence (%) of each sleep outcome in US adults with CKD and all adults, by 2-year interval



Conclusions: The frequency of sleep problems communicated between adults with CKD and their doctors increased in the US in the past decade and were consistently greater in adults with CKD than all adults.

The Rise of Kidney and Related Chronic Diseases in Remote Living Aboriginal People in the Context of the Epidemiologic and Health Transitions Wendy E. Hoy,[1,2] Susan A. Mott,[1] Cheryl E. Swanson,[1] Suresh Kant Sharma,[1,2] Jennifer J. Nicol.[1] *[1]CKD.CRE, The Univ of Queensland, Herston, Brisbane, QLD, Australia; [2]Menzies School of Health Research, Darwin, Northern Territory, Australia.*

Background: The increase in chronic diseases in Aboriginal communities is poorly understood. We describe the emergence of chronic disease and CKD in one remote community since 1960 in the context of epidemiologic and health transition.

Methods: We analysed deaths and renal replacement records (RRT) records (deaths=1,166, RRT=91) for the Tiwi Aboriginal community in the Northern Territory from 1960 to 2010, inspected birthweights since 1956 and used population estimates in 1957 and census data since 1986.

Results: In the early 1960s, >50% of Tiwi deaths were in infants or children: >45% of newborn were low birthweight (LBW, <2.5 kg), and infant mortality rate was about 130/1000 live births, higher in LBW subjects, Deaths in infants and children fell by >95% by the late 1980s, with a greater absolute and relative reduction for LBW persons. Now nearly all babies survive to adult life, with nearly all deaths occurring in adults, and increasingly in adults >45 years old. Most adult natural deaths are from pulmonary, cardiovascular, renal and liver disease, with a >2-fold increase in LBW persons-- evidence of the "Barker hypothesis". As treatment postpones pulmonary and CV deaths, and people are ageing, renal deaths are increasing. However, age at renal failure has risen by 20 years since the 1970s. The Tiwi population has tripled since 1957, and the age-structure is maturing from a third world to an intermediate pattern. A pressing current concern is deaths from misadventure (often suicide) of young adults.

Conclusions: Emergence of chronic disease is a consequence of triumphs in public health and healthcare delivery in the last 5 decades. Such phenomena are most certainly echoed in the developing world, although it is unlikely that many other populations have experienced these events in such a compressed way. As birthweights continue to increase and chronic disease management improves further, longevity will continue to increase.

SA-PO862

Negative Psychosocial Factors and Chronic Kidney Disease (CKD) Outcomes among African Americans Clarissa Jonas Diamantidis,[1] Nrupen Anjan Bhavsar,[1] Mario Sims,[2] Julia J. Scialla,[1] Clementina A. Davenport,[1] Rasheeda K. Hall,[1] Crystal C. Tyson,[1] Wei Wang,[2] Adolfo Correa,[2] L. Ebony Boulware.[1] *[1]Duke Univ School of Medicine; [2]Univ of Mississippi Medical Center.*

Background: Established CKD risk factors do not fully account for the renal outcomes of African Americans. We studied the association between negative psychosocial factors and CKD prevalence, incidence and progression in the Jackson Heart Study (JHS).

Methods: We used factor analysis to identify common domains of 12 baseline psychosocial factors (perceived daily, lifetime, and burden of discrimination; anger in, anger out, hostility, pessimism, stress, John Henryism, spirituality, perceived social status, social support). We quantified the association of identified factor domains with baseline CKD prevalence (estimated glomerular filtration rate [eGFR] <60 mL/min/1.72m^2 or urine albumin-to-creatinine ratio of ≥ 30 mg/g) and CKD progression (annualized rate of eGFR decline), or incident CKD (new eGFR <60 mL/min/1.72m^2 at follow-up and 25% eGFR decline from baseline, or new onset albuminuria) in multivariable models adjusted for sociodemographics and comorbidity. Those missing key CKD or psychosocial variables were excluded.

Results: Of 3390 (64%) participants with baseline CKD status available, 656 (19%) had CKD. Those with CKD (vs. no CKD) had lower perceived daily, lifetime and burden of discrimination; lower hostility, stress, and perceived social status; less John Henryism; higher pessimism, all $p < 0.05$. Factor analysis identified 3 psychosocial domainsfor CKD prevalence: 1) stressors (perceived discrimination, stress), 2) moods (anger, hostility), and 3) coping strategies (John Henryism, spirituality, social status, social support). After adjustment, those with greater stressors were less likely to have prevalent CKD (OR 0.76 [0.65-0.89]). Psychosocial domains were not associated with CKD incidence or progression.

Conclusions: Negative psychosocial attitudes were less common among those with CKD and not associated with CKD incidence or progression. Our study, limited to a single US area, may not be generalizable. Further study should explore the role personal expression of negative attitudes plays in engagement in care among African Americans.

Funding: NIDDK Support, Other NIH Support - NHLBI

SA-PO863

Level of C-Reactive Protein Is Associated with the Progression of Diabetic Nephropathy in African Americans in the Jackson Heart Study Cohort Satyesh K. Sinha,[1] Keith C. Norris,[2] Susanne B. Nicholas.[2] *[1]Internal Medicine, Charles R Drew Univ of Science and Technology, Los Angeles, CA; [2]David Geffen School of Medicine, Univ of California Los Angeles, Los Angeles, CA.*

Background: The reasons for the disparities in the prevalence and incidence of diabetic nephropathy (DN) and end stage renal disease (ESRD) in African Americans (AA) remain unclear but may involve complex inflammatory mechanisms that contribute significantly to the development and progression of DN. We recently reported a strong association between C-reactive protein (CRP) and urinary albumin excretion (UAE). The level of CRP and UAE both were significantly higher in AA compared to whites, suggesting that inflammatory processes of DN may be influenced by ethnicity. However, the association of CRP with progression of DN in the longitudinal follow-up data has not been examined. In this study, we tested the hypothesis that circulating inflammatory markers, such as CRP, are associated with the progression of DN in AA.

Methods: We analyzed longitudinal follow-up data from Exam 1 (2000-2004), Exam 2 (2005-2008) and Exam 3 (2009-2012) at the JHS to determine the role of inflammation in the development of DN in AA using the inflammatory marker, high sensitive CRP (hs-CRP), and kidney function (measured by UAE). We analyzed data using Cox regression to estimate the hazard ratio (HR) for DN according to tertile of hsCRP, controlling for demographics. Data are presented as HR, and 95% confidence interval (CI); $p<0.05$ was statistically significant.

Results: In the fully adjusted model, the elevated hsCRP (>4.24 mg/L) was associated with DN (HR= 2.34, 95% CI 1.1-5.01, $p<0.05$) compared to the reference group (hsCRP <1.46 mg/L). The mean survival time was significantly reduced with hsCRP >4.24mg/L compared to low hsCRP (<1.46mg/L), $p<0.001$.

Conclusions: We conclude that elevated hsCRP is associated with progression of DN and mortality in AA.

SA-PO864

Rapid Changes in Estimated GFR Associates with All-Cause Mortality: A Prospective Cohort Study from Chinese Community-Based Populations Yang Luo. *Dept of Nephrology, Beijing Shijitan Hospital, Capital Medical Univ, Beijing, China.*

Background: Reduced kidney function is an independent risk factor for all-cause mortality and cardiovascular events, but data from longitudinal studies about the association of decline of estimated GFR (eGFR) with clinical outcomes are limited.

Methods: We investigated whether 4 year annual changes in eGFR associated with the risk of all-cause mortality and cardiovascular events in the next 2 consecutive years in a Chinese community-based population, 36404 qualified participants of the Kailuan study were included in this analysis.

Results: After adjustment for baseline covariates including age, gender and eGFR in Cox proportional hazards models, the participants with the rapid decline in eGFR (annual decline greater than 4ml/min.1.73m^2) were at significantly greater risk for all-cause mortality (hazard ratio 1.56[95% confidence interval 1.22 to 1.99]), but not at cardiovascular events (0.96 [95% confidence interval 0.78 to 1.18]) compared with the non-rapid change participants (annual decline less than 4ml/min.1.73m^2). We also observed that the first quartile of decline of eGFR (annual decline from 0.81to 21.19ml/min.1.73m^2) associated with all-cause mortality but not with cardiovascular events in Cox proportional hazards models with the same adjustment baseline covariates when we made the second quartile of decline of eGFR as reference; the third and fourth quartile of the decline of eGFR didn't showed association with all-cause mortality and cardiovascular events, perhaps as a result of clinical instability.

Conclusions: In conclusion, a rapid decline in eGFR associates with a higher risk for all-cause mortality but not cardiovascular disease. Increases in eGFR among participants don't associate with similar clinical outcomes.

SA-PO865

HBV and HCV Prevalence and Incidence among ESRD Patients in France Corinne Isnard-Bagnis,[1] Cécile Couchoud,[4] Luc Haudebourg,[2] Gilbert Deray,[1] Patrice Cacoub,[5] Sophie Tezenas du Montcel.[2,3] *[1]Nephrology, Hopital Pitié Salpetriere APHP, Paris, Ile de France, France; [2]Biostatistics, Hopital Pitié Salpetriere APHP, Paris, Ile de France, France; [3]UMR_S1136 and INSERM UMR_S 1136 Inst Pierre Louis d'Epidémiologie et de Santé Publique, Sorbonne UPMC Univ Paris 06, Paris, Ile de France, France; [4]REIN Registry, Agence de la Biomédecine, Saint Denis La Plaine Cedex 93212, Ile de France, France; [5]Internal Medicine-Immunotherapy Dept i2B and UMR_s959, Hôpital Pitié Salpetriere APHP and Sorbonnes Univ, Paris, Ile de France, France.*

Background: Risk for HBV and HCV is increased in ESRD patients. New HCV treatments have prompted us to generate updated epidemiological data.

Methods: In a multi center cohort study, using the REIN National French prospective registry (ESRD), we extracted data for patients who initiated dialysis/had been put down on the kidney transplant waiting list (Jan, 2005 to Dec, 2013). We extracted records related to: "inclusion in REIN", "annual dialysis follow-up", "dialysis after graft failure", "registration on the kidney transplant waiting list " and "kidney transplant". A positive HBsAg and a positive HCV RNA defined HBV and HCV infections.

Results: 72,948 patients started dialysis or were preemptively transplanted, 45,591 men (62.5%), (mean age 66.9±16.1 yrs).13,609 (18.7%) patients received a kidney graft, (mean age 50.9±15.5 yrs). At inclusion, 615 patients were HBV and 1,026 HCV infected. The prevalence of HBV and HCV infections were 0.84% (95% PI: 0.78 – 0.91) and 1.41% (95% PI: 1.32 – 1.49). Prevalence of HBV and HCV infection by age group increased progressively until a maximum rate of 1.80% (95% PI: 1.46 – 2.20) and 3.14% (95% PI: 2.68 – 3.65) in the 4th decade, then regularly decreased. During follow up, we identified new HBV or HCV infections in 117 and 81 patients, respectively. Overall incidence for HBV and HCV infections between 2005 and 2013 were 0.076% (95% PI: 0.062 – 0.090) and 0.053% (95% PI: 0.041 – 0.065) respectively. During the 1st year of dialysis, the incidence of HBV infection was 0.35% (95% PI: 0.28 – 0.43) and that of HCV 0.22% (95% PI: 0.16 – 0.29).

Conclusions: Our data highlights the need for HCV therapy for over 1000 patients and persistence of nosocomial cases.

SA-PO866

Heterogeneity of Chronic Kidney Disease with Age in a Major Metropolitan Renal Service Usman Mahmood,[1] Wendy E. Hoy,[2] Helen G. Healy,[1,2] Andrew John Mallett,[1,2] Adrian Lawrence Kark,[1,2] Anne Cameron (Salisbury),[1,2] Zaimin Wang,[2] Rajitha Asanga Abeysekera.[1] *[1]Royal Brisbane & Women's Hospital, Australia; [2]Univ of Queensland, Australia.*

Background: Aim of the study is to describe the characteristics of disease and outcomes with increasing age in people with CKD.

Methods: 1,265 patients enrolled into the CKD.QLD registry at Royal Brisbane and Women's Hospital were grouped according to age into <25, 25-34, 35-44, 45-54, 55-64, 65-74, 75-84, 85+ years at consent and followed till start of renal replacement therapy (RRT), death, discharge or November 2015. Characteristics were described as mean (SD), proportions as percentage (%) and outcomes defined as mortality, start of RRT, hospitalization and progression of kidney disease.

Results: 651 of the cohort were male and 614 were female, mean ages of 66.7 and 65.6 years respectively. Reno-vascular disease (including hypertension) (RVD) was the leading primary diagnosis in both genders, followed by diabetic nephropathy. Proportions with RVD progressively increased from undetectable in the <25 year to 69.4% in the 85+. A single diagnosis was recorded in 76% of <25 years, compared to 58% in > 85 years, with remainder having two or more etiologies listed. In the youngest and older age group, proportions with CKD stage 3A to 5 were 27.6% and 98% respectively. Up to 8 comorbidities were documented per patient, with means of 0.5 in <25 and 2.9 in 85+ age groups. All comorbidities were more common in males than females (mean 2.8 (1.7) vs. 2.2 (1.5)). Mortality rates increased from 1.6 to 17.4 per 100 person years, whilst RRT rates decreased from 1.7 to 0.4 per 100 person years in the 35-44 to 85+ age groups. Rates of hospitalization, length of stay and cost progressively increased from the youngest to eldest groups. The proportion of patients who lost more than 5 mls/min of eGFR during follow up increased from 10.5% in the youngest age group to 29.2% in the eldest.

Conclusions: The characteristics of CKD patients differ by age. Older people more likely have vascular and metabolic disease, have less conversion to dialysis, higher deaths rates and are more likely to access acute hospital services. There is opportunity to personalize CKD care delivery taking this heterogeneity into account.

SA-PO867

The Association of Monocyte Count and eGFR with All-Cause Mortality

Farrukh M. Koraishy,[1,3] Benjamin Charles Bowe,[2] Yan Xie,[2] Hong Xian,[2,4] Ziyad Al-Aly.[1,2,5] *[1]Div of Nephrology, Veterans Affairs St. Louis Health Care System, St. Louis, MO; [2]Clinical Epidemiology Center, Veterans Affairs St. Louis Health Care System, St. Louis, MO; [3]Div of Nephrology, St. Louis Univ, St. Louis, MO; [4]Dept of Biostatistics, St. Louis Univ, St. Louis, MO; [5]Dept of Medicine, Washington Univ, St. Louis, MO.*

Background: Chronic kidney disease (CKD) is associated with a high all-cause mortality risk. Elevated monocyte count has been associated with increased risk of death in the general population, however, data in CKD is limited. Whether monocyte count modifies the association of estimated glomerular filtration rate (eGFR) and mortality is not known.

Methods: We built a national cohort of 1,706,589 U.S. veterans and followed them over a median of 9.16 years to examine the association of monocyte count with eGFR categories:15-30 ml/min/m^2, 30-45 ml/min/m^2, 45-60 ml/min/m^2, 60-90 ml/min/m^2, 90-105 ml/min/m^2 (reference) and >105 ml/min/m^2, and with all-cause mortality risk. Monocyte count was divided into quartiles: 0.00-0.40 k/cmm (reference) 0.40-0.56 k/cmm, 0.56-0.70 k/cmm and >0.70 k/cmm. Interaction analyses were undertaken to test whether monocyte count modifies the risk of mortality associated with eGFR.

Results: A high monocyte count (>0.56 k/cmm) was associated with increased risk of death overall and across each eGFR category. A high monocyte count was associated with high (>90 ml/min/m^2) and low (<45 ml/min/m^2) eGFR; eGFR levels that were associated with higher mortality risk. The maximum joint mortality risk was noted in the lowest eGFR and highest monocyte category (HR = 2.68, CI = 2.59-2.79). The mortality risk associated with high monocyte count and low eGFR exhibited a significant negative interaction on both additive and multiplicative scales.

Conclusions: To our knowledge this is the first study to investigate the interactions between monocyte count, eGFR and their association with death. Increased monocyte count and both low and very high eGFR were associated with higher all-cause mortality risk. Monocyte count modified the risk of death associated with eGFR at low eGFR levels and is a valuable parameter in determining the prognosis of patients with CKD.

SA-PO868

Infection as a Major Cause of Death in Japanese Elderly Chronic Kidney Disease: The Gonryo Study

Tae Yamamoto,[1] Gen Yamada,[1] Mariko Miyazaki,[1] Masaaki Nakayama,[2] Toshinobu Sato,[3] Hiroshi Sato,[1] Sadayoshi Ito.[1] *[1]Tohoku Univ, Sendai, Japan; [2]Fukushima Medical Univ School of Medicine, Fukushima, Japan; [3]Japan Community Health care Organization Sendai Hospital, Sendai, Japan.*

Background: Chronic kidney disease (CKD) *is increasing in* Japan, based on the *rapidly* growing ageing-population. Infection is a major complication by ageing, and the second cause of death in Japan under the dialysis population. However the cause specific death except cardiovascular disease (CVD)is limited, and the clinical feature who died by infection inCKD before dialysis is not fully known.

Methods: We prospectively followed up 2,694 outpatients, who satisfied estimated glomerular filtration rate <60 ml/min and/or presenting proteinuria, under the care of nephrologists. Patients were stratified by age at 65 years to 1,495 of non-elderly and 1,199 of elderly. And elderly divided into 65-74, 75-85 and over 85 years old. Deaths, censored for RRT, were recorded for a follow-up time of 5 years. Cause of death was classified as CVD, infection, malignancy or other reported using International Classification of Diseases codes.

Results: Among 2,694 patients, the median age 62 (qurtile 51– 72) years, males 53% and a median eGFR 53.7 (qurtile 33.4 – 74.0) ml/min, and 118 died and 308 patients started RRT during a median follow-up of 4.5 (qurtile 1.9 – 5.0) years. Among 118 deaths, the most common cause was CVD (28.0%) followed by infection (19.5%) and malignancy (17.8%). While the CVD and malignancy observed in all generation, infection-related death was observed only in elderly, and in over 75 years infection-related mortality (22.9%) was as frequent as CVD (24.3%). In elderly population, the survival risk before developing ESKD associated significantly with high age, low body mass index (BMI), and history of cardiovascular disease. In those,increased the risk of infection-related mortality was associated with the lower BMI.

Conclusions: Infection is the second leading the cause of death in our CKD population, especially is that in elderlies.

SA-PO869

The Interplay between *Clostridium difficile* Infection (CDI) and Renal Disease: Epidemiology, Treatment Management and Outcomes

Anjay Rastogi,[1] Ravina Kullar,[2] Setareh Alipourfetrati,[1] Farid Arman,[1] Helen S. Hanna,[1] Saif Faiek,[1] Laura Puzniak.[2] *[1]Div of Nephrology, Dept of Medicine, Univ of California, Los Angeles, Los Angeles, CA; [2]Center of Observational and Real World Evidence, Merck & Co, Inc, Kenilworth, NJ.*

Background: Despite increased risk of CDI among patients (pts) with renal impairment, there is limited data evaluating treatment and outcomes in these pts. We evaluate the impact of CDI along the continuum of renal impairment.

Methods: Retrospective, observational study of consecutive cases of CDI, verified by positive PCR at UCLA (12/2013-12/2014). Pts were stratified into two groups: renally impaired (acute kidney injury, chronic kidney disease, end stage renal disease) (renal) and no renal impairment (non). Charts were reviewed for demographics, comorbidities, CDI therapy and clinical outcomes.

Results: Overall, 222 pts had CDI, 90% were considered first CDI episode. 89 (40%) pts were renal (24.7% on dialysis) and 133 (60%) pts were non. Baseline demographics displayed in mean (standard deviation) or n (%); age: 67 years (16) vs. 60 years (20); admitted from community: 60 (67.4) vs. 99 (74.4); private insurance: 16 (18) vs. 48 (36); medicare: 50 (56.2); 64 (48.1). Most common comorbidities included chronic pulmonary disease (36 vs. 27.1%), acute coronary syndrome (37.1 vs. 25.6%), and diabetes mellitus (39.3 vs. 23.3%). CDI-related shock was most common in renal (15.7 vs. 3.8%). Most pts were initially treated with metronidazole (metro) (75.2 renal and 76.8% non). Renal were more likely to receive both metro then vancomycin than non (38.2 vs. 24.8%). Hospitalists were the most common prescribers of CDI therapy. Length of hospital and ICU stay was longer in renal; 24 (33) vs. 22 days (24), and 9 (24) vs. 3 days (8), respectively. Readmission and CDI recurrence were more frequent in renal: 36.9% vs. 27% and 20.2% vs. 16.7%, respectively.

Conclusions: 40% of pts with CDI were renal and almost half of these received various CDI treatments, with most pts initially treated with metro. Recurrence and readmission rates were frequent in these pts. Renal pts are at high risk for CDI and poor outcomes and require aggressive treatment management.

SA-PO870

Increased Serum Alkaline Phosphatase Predicts Rapid Decrease of Glomerular Filtration Rate in Patients with Normal Renal Function/Early Chronic Kidney Disease

Sunhwa Lee,[1] Eunjeong Kang,[1] Jung Nam An,[2] Mi-Yeon Yu,[1] Hyung Ah Jo,[1] Dong Ki Kim,[1] Yun Kyu Oh,[2] Yon Su Kim,[1] Chun Soo Lim,[2] Jung Pyo Lee.[2] *[1]Internal Medicine, Nephrology, Seoul National Univ Hospital, Republic of Korea; [2]Internal Medicine, Nephrology, Seoul National Univ Boramae Medical Center, Republic of Korea.*

Background: High alkaline phosphatase has been associated with increased mortality and coronary calcification in many subgroups, but the impact of alkaline phosphatase on decline in glomerular filtration rate (GFR) is unknown.

Methods: We retrospectively included patients with normal renal function or early chronic kidney disease who underwent cardiac CT angiography (CCTA) from March 2008 to June 2013 in a single medical center. We gathered available medical records of patients as follows; demographics, baseline laboratory findings at the time of CCTA scan, serum creatinine data of 0, 3, 6, 12, and 24 month (±3 weeks). The latest serum creatinine level, any mortality events and major cardiovascular events were retrieved till February 2016.

Results: Of 2,132 patients, there were 110 (5.2%) patients who showed decreases in GFR above 30% within a median 3.1 years. In multivariate Cox regression analysis, high alkaline phosphatase (>120 IU/L) was a definite predictor for GFR decrease even after adjusting following variables; age, gender, comorbidities, CRP, liver enzyme, coronary calcium score (CCS) and GFR at the time of CT scan (HR 2.20, 95% CI 1.08-4.51, *P*=0.031). For subgroup analysis, subjects with lower arterial calcification (CCS<100), non-diabetes, male, high-GFR (≥60ml/min/1.73m^2), and lesser age (age<70 years) revealed significant increased risk of GFR decline by high alkaline phosphatase level, while the opponents did not. On the other hand, high alkaline phosphatase (>120 IU/L) had little influence on major cardiovascular events (OR 1.106, 95% CI 0.516-2.373, *P*=0.795), and CCS was not related to elevation of serum alkaline phosphatase (*P*=0.367).

Conclusions: We found that elevated serum alkaline phosphatase in normal renal function/early chronic kidney disease can predict more decrease in GFR, which mechanism may not related to arterial calcification.

SA-PO871

Associations of Liver Histopathology with Inflammatory Markers in Non-Uremic and Uremic Hepatitis C Positive Patients

Sukran Kose,[1] Bengu Tatar,[1] Sabri Atalay,[1] Erhan Tatar.[2] *[1]Infectious Diseases and Clinical Microbiology, Tepecik Education and Research Hospital, Izmir, Turkey; [2]Dept of Nephrology, Izmir Education and Research Hospital, Izmir, Turkey.*

Background: The aim of this study is to investigate the association between hepatic activity index (HAI) and fibrosis score (FS) with inflammation in non-uremic hepatitis C positive patients.

Methods: Fifty chronic hepatitis C (CHC) positive patients, 15 with end-stage renal disease (ESRD), having a liver biopsy were included in this study. 25 patients with similar age and gender were also enrolled as control group. Liver biopsies were scored according

to modified ISAAC scoring system: mild and severe according to fibrosis observed in the biopsy. Serum YKL-40, neutrophil/lymphocyte ratio (NLR), trombocyte/lymphocte ratio (PLR), CRP and Immunglobulin (Ig)G, A, and M levels were used to determine inflammation. AST to Platelet Ratio Index (APRI) score was also evaluated.

Results: Patients with CHC had increased inflammation compared to the controls (NLR, 2.52±1.26,1.91±0.92;P<0.05), (IgG,1491±491mg/dL,1143±229mg/dL;P<0.001), (YKL-40, 134±170 ng/mL,18±9.1 ng/mL; P<0.001). ESRD patients had lower HCV RNA levels IU/mL (p=0.201), HAI (p=0.01) and FS (p=0.007) compared to non-uremics. Patients with ESRD and high FS were older (40±7.7, 53±10 years old; p=0.01) and had higher APRI score (0.28±0.21,0.53±0.21, p=0.06). In adjusted models, APRI score (t value:3.98, p=0.002) was an independent predictor for FS. In non-uremic cHepC patients with higher FS, AST (p=0.005), ALT (p=0.01), Ig G (p<0.001), YKL 40 levels (p=0.02) and APRI score (p=0.002) were significantly higher. In adjusted analysis, YKL 40 levels (t value: 3.48; p=0.001) and APRI score (t value:4.57, p<0.001) were found as independent predictors of FS.

Conclusions: In non-uremic CHC patients, serum Ig G and YKL 40 levels may be valuable markers of HAI. In ESRD patients, there is not sufficient data for prediction of HAI and FS. In these patients, APRI score may provide better information.

SA-PO872

Neutrophil Gelatinase-Associated Lipocalin (NGAL) and Cystatin C as Predictors of Undiagnosed Kidney Injury in Diabetic African American Men Elimelda Moige Ongeri,[1] Olugbemiga E. Jegede,[2] Susan Sumner,[3] Lakmini S. Premadasa,[1] Scott H. Harrison,[1] Robert H. Newman.[1] *[1]Biology, North Carolina A&T State Univ, Greensboro, NC; [2]Community Health & Wellness Clinic, Cone Health, Greensboro, NC; [3]Eastern Regional Comprehensive Metabolomics Resource Core, RTI International, Research Triangle Park, NC.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease (ESRD). Ethnic minorities disproportionately bear the burden of complications of diabetes, yet minorities, especially African American men, are underrepresented in research studies that serve to develop biomarkers for diagnosis and therapeutics. Traditional tests for DN lack sensitivity and are often inaccurate. As a result, DN is underdiagnosed in patients in the early stages of the disease, making it difficult to implement interventions to slow progression to ESRD. Assays for recently developed protein-based biomarkers such as NGAL, Cystatin C, and kidney injury molecule-1 (KIM-1) are more sensitive and thus suitable for early diagnosis of kidney injury. However these assays are not widely available in clinical settings.

Methods: Enzyme-linked immunosorbent assays (ELISA) were used to determine the levels of creatinine, NGAL, Cystatin C, and KIM-1 in 67 African American men from three groups: 1) diabetics without diagnosed DN, 2) diabetics with diagnosed DN, and 3) non-diabetic controls.

Results: The levels of serum NGAL and Cystatin C were significantly higher ($p \leq 0.0001$) in patients with diagnosed DN compared to non-diabetic controls. However, there was no significant difference in the levels of urine KIM-1. Importantly, a substantial proportion (17%) of the diabetic patients without diagnosed DN exhibited both NGAL and Cystatin C levels that were ³ 2 SD above the mean levels found in non-diabetic controls.

Conclusions: A combination of NGAL and Cystatin C could be used to predict early stage DN in African American men. The data will serve as a basis for the development of educational material to engage African American men in community participatory research to prevent and/or manage diabetes and slow progression to DN and to encourage collection of biological samples for biomarker development.

SA-PO873

The Effect of Annual Income on the Progression of CKD in Japan Naohiko Fujii,[1] Takayuki Hamano,[2] Tadao Akizawa,[3] Seiichi Matsuo,[4] Hirofumi Makino,[5] Enyu Imai,[6] Tsuyoshi Watanabe,[7] Kosaku Nitta,[8] Shoichi Maruyama,[4] Masafumi Fukagawa,[9] Akira Hishida.[10] *[1]Hyogo Prefectural Nishinomiya Hospital, Japan; [2]Osaka Univ, Japan; [3]Showa Univ, Japan; [4]Nagoya Univ, Japan; [5]Okayama Univ, Japan; [6]Nakayamadera Imai Clinic, Japan; [7]Fukushima Medical Univ, Japan; [8]Tokyo Women's Medical Univ, Japan; [9]Tokai Univ, Japan; [10]Yaizu City Hospital, Japan.*

Background: The effect of socioeconomic status on the disparity in medical treatment and healthcare should not be overlooked as an interventional target. However, such evidences are limited in CKD. We assessed the association between income levels and eGFR trajectory over time, by using the dataset from the Japanese CKD prospective cohort study (CKD-JAC, N=2977, mean eGFR 28.7 ± 12.2 mL/min/1.73m^2).

Methods: We enrolled 1849 (62%) participants that responded to the questionnaire on annual household income at baseline, which were stratified into quartiles. We evaluated eGFR change by using a joint model analysis, incorporating both random-effects and survival models to take into account fewer observations due to worse outcomes. We first adjusted for demographics and renal function at baseline (Model 2), and then for other possible confounders, such as systolic BP, administration of ACEI/ARB, and CRP (Model 3).

Results: The income quartiles were defined as Low (Q1, N=456), Middle (Q2, N=506), High (Q3, N=434), and Q4 (Highest, N=453) for the subjects with annual household income of <$30,000, $30,000-49,999, $50,000-79,999, and ≥$80,000, respectively. The subjects with lower income were likely to be significantly older, female, diabetic, and hypertensive. They also had a lower renal function, a higher prevalence of CVD, and a higher prevalence of inflammation. When we adjusted for demographic factors and renal function at baseline, the overall time-interaction term of income quartiles became significant (overall P=0.029), where we observed the fastest eGFR decline in income Q3 (-0.43 [0.86, 0.01], P=0.055); however, the further adjustment for other covariates diminished the significance of time-interaction by income quartiles (Model 3).

Conclusions: The annual household income level was not associated with eGFR decline among CKD patients in Japan.

Application of Group-Based Trajectory Modeling (GBTM) in Renal Research Zhiying You, Jessica B. Kendrick, Michel Chonchol. *Medicine, Univ of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: In epidemiological studies of chronic kidney disease (CKD) and autosomal dominant polycystic kidney disease (ADPKD), kidney function and total kidney volume and other variables are repeatedly or longitudinally measured. The group-based trajectory modeling (GBTM) is a powerful approach that summarizes such data collected across the study period and divides the subjects into groups based on their trajectories or pattern of change over time. The identification of clinical variables associated with trajectories may help identify new risk factor and novel therapeutic targets. In the published renal literature there is a lack of use of GBTM. Here we report two examples of GBT application.

Methods: We used GBTM to identify five trajectory groups of plasma fibroblast growth factor 23 (FGF23) levels among patients with end stage renal disease (ESRD) in the first example, using data from the Hemodialysis (HEMO) study. In the second example, we identify four trajectory groups of serum calcium levels among patients with CKD of stage IIIB and IV and with vitamin D insufficiency or deficiency, using data from a randomized controlled trial titled "Vitamin D and arterial function in patients with chronic kidney disease" that was funded by NIH/NIDDK (5K23DK087859). All analyses were performed by using SAS procedure TRAJ under SAS version 9.4 (SAS Institute, Cary NC).

Results: Five trajectory group of FGF23 were considered reasonable based on consideration of (1) the criterion of the Bayesian information and Akaite information, (2) sample size, and (3) the patterns of the identified trajectory groups and their percent. The five groups were stable lower and higher level, going up from low and stable low level, and going down from high level. Similarly, four trajectory groups of blood calcium were considered appropriate and they were stable low, moderate and high level, and going up from high level.

Conclusions: The SAS TRAJ procedure is user friendly and is easy to use. Exploratory analysis is necessary because GBTM was developed to empirically examine what trajectory groups present in a target population.

SA-PO875

Slope of Renal Decline as an End-Point for Intervention Trials to Prevent End-Stage Renal Disease Jan Skupien,[1,2] James Warram,[1] Adam Smiles,[1] Robert C. Stanton,[1] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]Jagiellonian Univ Medical College, Krakow, Poland.*

Background: Clinical trials of interventions to prevent ESRD enroll high-risk patients with impaired renal function. Recently validated surrogate end-points include a 40% or a 30% decline from baseline eGFR within 1-3 years, predicting ESRD occurrence several years later. However, no end-points have been proposed for early intervention studies, enrolling patients whose ESRD develops after 10 years of follow-up. We examined data from patients in whom ESRD developed and whose eGFR had been followed since it was normal. Our aim was to investigate the relationship between validated end-points and the slope of eGFR decline.

Methods: We analyzed data from 264 Joslin Clinic patients (49% women) participating in natural history studies of diabetic nephropathy who developed ESRD 2-25 years after their enrolment with normal eGFR. Median duration of follow-up and rate of renal decline were 7 years and 9 ml/min/year, respectively. At entry, median age was 32 years, diabetes duration 18 years, glycated hemoglobin 9.7% and baseline eGFR 84 ml/min.

Results: The frequencies of alternative end-points according to year of follow-up were:

Time (years)	ESRD	Doubling serum creatinine	40% loss	30% loss
1	0%	0%	6%	10%
2	2%	11%	24%	40%
3	10%	26%	47%	62%

For 90% of patients with ESRD within 3 years, the slope of renal decline was 21 ml/min/year or more. For 90% of those with a doubling of serum creatinine, a 40% loss or a 30% eGFR loss within 3 years, the slope of decline was ≥14, ≥10 and ≥8 ml/min/year, respectively. Among the 38% who were not detected by any surrogate endpoint, in > 95% the time to ESRD was 8-18 years, and the rate of renal decline ≥4 ml/min/year.

Conclusions: Currently approved surrogate end-points develop during a clinical trial only in high-risk patients with rapid renal decline or significantly impaired renal function. It limits external validity of such trials. Early intervention trials should enroll patients whose renal decline is 4-8 ml/min/year. We urge diligent efforts to validate slope of renal decline as a surrogate end-point for intervention trials to postpone or prevent ESRD.

Vitamin D Associates with Higher Physical Activity and Comorbidities in Chronic Kidney Disease: Result from the KoreaN Cohort Study for Outcomes in Patients with Chronic Kidney Disease (KNOW-CKD)

Eunjeong Kang,[1] Hyo Jin Kim,[2] Hyunjin Ryu,[1] Miyeun Han,[1] Hyun Suk Kim,[1] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Internal Medicine, Dongguk Univ Gyeongju Hospital, Gyeongju, Korea.*

Background: Although vitamin D (Vit D) is known to be related the physical activities and comorbidities, there was a lack of evidence of their relationship in chronic kidney disease (CKD) patients.

Methods: Data were collected from the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD, NCT01630486 at http://www.clinicaltrials.gov). Baseline serum 25-OH Vit D concentration was measured using chemiluminescence immunoassays in the central laboratory. Vit D insufficiency was defined by 25-OH vit D below 20ng/mL. We categorized patients into 3 groups (low, moderate, high physical activity level) according to their physical activity, quantified by the International Physical Activity Questionnaire. We used age-adjusted Charlson comorbidity index (CCI) for assessment of comorbidities, and divided into 2 groups based on ≥ 4 points of CCI or below. The associations were assessed by multivariate linear regression analyses with log-transformed 25-OH Vit D because of skewed distribution of 25-OH Vit D.

Results: A total number of patients with measurement of 25-OH Vit D was 1,133, among whom 925 patients reported physical activity. Median 25-OH vit D was 16.5 ng/mL in overall patients, 17.2 ng/mL in male, and 15.0 ng/mL in female. The proportion of 25-OH vit D insufficiency was 33.6%. Physical activity (P = 0.026) and age-adjusted CCI (P = 0.037) was independently associated with log 25-OH Vit D after adjustment for age, sex, diabetes, CKD stages, albumin, and season, respectively.

Conclusions: The results of this study suggest that 25-OH Vit D concentration is independently associated with self-reported physical activity and age-adjusted CCI in CKD patients.

Clinical Characteristics of Age Distribution in 496 Severe Secondary Hyperparathyroidism Patients Undergoing Parathyroidectomy

Ningning Wang, Yao Jiang. *Dept of Nephrology, First Affiliated Hospital with Nanjing Medical Univ, Nanjing, China.*

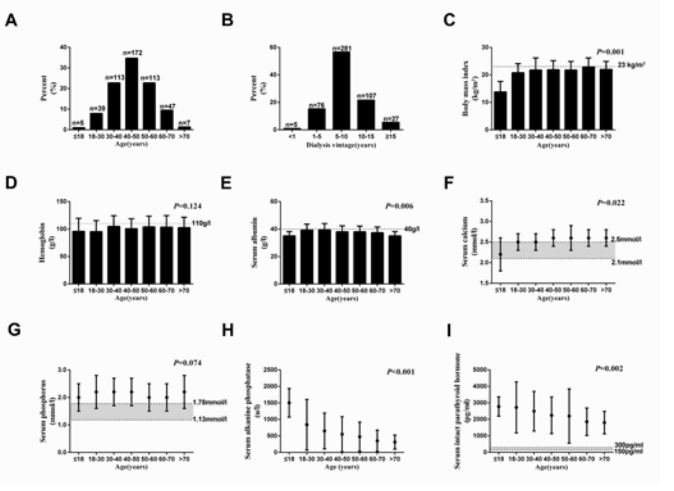
Background: Severe secondary hyperparathyroidism(SHPT) patients are characterized by systematic clinical manifestations and parathyroidectomy(PTX) is recommended for treatment, the relationships between age and clinical characteristics of severe SHPT are unknown.

Methods: Clinical baseline data were analyzed according to the stratification of age in retrospective study of 496 PTX patients from single centre.

Results: Clinical characteristics of patients were shown in table 1.

	Total (n=496)
Age(years)	46.0±11.4
Male/Female(n)	274/222
Body mass index(BMI, kg/m²)	21.8±3.6
Causes of ESRD(n,%)	
Chronic glomerulonephritis(CGN)	457(92.1%)
Diabetic nephropathy	6(1.2%)
Others	33(6.7%)
Dialysis mode(n,%)	
Hemodialysis	461(92.9%)
Peritoneal dialysis	35(7.1%)
Dialysis vintage(years)	7.7±3.6
Laboratory values	
Hemoglobin(g/l)	102.3±19.4
Hematocrit(%)	31.9±6.0
Glucose(mmol/l)	4.3±1.3
Creatinine(μmol/l)	877.3± 276.2
Urea(mmol/l)	22.4±8.3
Total cholesterol (mmol/L)	4.2±1.0
Triglyceride(mmol/l)	1.6±1.1
Albumin(Alb,g/l)	38.3±4.4
Calcium(Ca,mg/dl)	10.2±0.9
Phosphorus(P,mg/dl)	6.7±1.6
Alkaline phosphatase(ALP,u/l)	360.6(176.8-805.9)
Intact parathyroid hormone(iPTH,pg/ml)	2134.1(1512.4±2964.2)
Weight of resected parathyroids(g)	4.2±2.6

BMI, hemoglobin, and serum Alb levels in each group were <23 kg/m², <110g/L, and <40 g/L, respectively. Serum Ca, ALP, and iPTH levels were different among groups, while serum P wasn't. Serum iPTH and ALP were lower in elderly patients.



Higher serum iPTH were related with lower BMI and serum Alb in study population.

Conclusions: Young and middle aged groups are the major component of severe SHPT patients. Their majority etiology is CGN and serum iPTH level is a risk factor for malnutrition.

Funding: Government Support - Non-U.S.

A Real-World Cost-Effective Analysis of Sevelamer versus Calcium-Based Binders for the Treatment of Hyperphosphatemia in Korean Dialysis Patients

Taehoon Yim, Inryang Hwang, Min Jung Kim, Wonseok Do, Kyu Yeun Kim, Youngae Yang, Sukyung Lee, Hee-Yeon Jung, Ji-Young Choi, Jang-Hee Cho, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim. *Dept of Internal Medicine, Kyungpook National Univ Hospital, Daegu, Republic of Korea.*

Background: Sevelamer, a non-calcium based phosphate binder, has been shown to attenuate the progression of vascular calcificationand improve survival in dialysis patients compared with calcium-based binders (CBBs). We conducted a cost-effectiveness analysis (CEA) comparing sevelamer with calcium acetate in dialysis patients using real-world data from the Health Insurance Review Agency (HIRA) database in Korea.

Methods: Data from 4674 patients enrolled in Korean multicenter prospective cohort study between Sep. 2008 and Dec. 2012 were linked to the HIRA database. After propensity score matching, the final dataset used in the CEA comprised 501 sevelamer-treated and 501 calcium acetate-treated patients. A Markov model was used to estimate costs, life years (LY), quality-adjusted life years (QALYs), and cost effectiveness. Forty-month treatment-specific survival was analyzed.

Results: Patients receiving sevelamer had lower mortality compared with patients receiving calcium acetate (HR, 0.64; 95% CI, 0.45–0.91; p=0.012). In the base case analysis, treatment with sevelamer was associated with a gain of 1.758 in LYs and 1.108 QALYs per patient compared with calcium acetate. The incremental cost effectiveness over a lifetime horizonwas acceptable at KRW (South Korean Won,₩) 6,966,350 per LY gained and ₩ 11,057,699per QALY gained for sevelamer compared with calcium acetate. One-way sensitivity analyses demonstrated that sevelamer was cost effective compared with calcium acetate across a wide range of alternative assumptions. Probabilistic sensitivity analysis showed that sevelamer was cost effective in 100% of the model iterations, using a willingness-to-pay threshold of ₩ 31,355,740 per QALY gained.

Conclusions: Sevelamer was associated with better survival and acceptable cost effectiveness in dialysis patients compared with calcium acetate. Treatment of hyperphosphatemia with sevelamer could serve as a cost-effective alternative treatment option to CBBs in dialysis patients in Korea.

Shotgun Lipidomics Reveals Alteration of Acyl Chain Carbon Number and Unsaturation with Advancing Chronic Kidney Disease

Farsad Afshinnia, Thekkelnaycke Rajendiran, Tanu Soni, Subramaniam Pennathur. *Univ of Michigan.*

Background: Alteration in carbon number and double bonds in complex lipids are linked with poor outcome. Impact of chronic kidney disease (CKD) on such alterations has not been studied. We systematically determined abundance of lipids across different stages of CKD using mass spectrometry based shotgun lipidomics.

Methods: In a cross sectional observation, 214 CKD patients from stage 1 to 5 with available baseline clinical characteristics were selected from the Clinical Phenotyping Resource and Biobank Core (CPROBE). Lipids from plasma was extracted with modified Bligh-Dyer method carrying the extraction in a 2:2:2 volume ratio of water/methanol/dichloromethane, spiked internal standards, reconstituted in Buffer B (10% ACN and 90% IPA in 10mM ammonium acetate) and injected in ABSciex 5600 quadrupole time

of flight mass spectrometer. MS/MS spectra were obtained in electrospray positive and negative modes with Analyst TF software and processed with MultiQuant 1.1.0.26. Data were normalized, log2 transformed and z-score standardized. Mixed linear models were applied to test independent alteration of lipid abundance by acyl chain carbon number of double bond across various stages of CKD.

Results: The selected patients included 36 (16.8%), 99 (56.3%), 61 (28.5%), and 18 (8.4%) participants from stage 1 to stage 5, respectively. Using shotgun lipidomics we identified 330 compounds from 17 lipids. In stage 2, there was a significant linear increase in abundance of free fatty acids by number of double bonds and carbon numbers in acyl chains ($p=0.006$), a trend which was reversed in CKD stage 5, independent of any covariates ($p=0.002$). On the other hand there was a significant linear decrease in abundance of triacylglycerols, phosphotidylcholines, phosphtidylethanolamines (PE), LysoPE, cardiolipins, and cholesteryl esters by number of double bonds and carbon numbers is stage 2 ($P\leq0.02$), a trend which was revered in stage 5 ($p\leq0.035$), independent of other covariates.

Conclusions: We conclude that CKD stage is associated with dynamic alteration of acyl chain carbon number and double bonds which may have mechanistic implications on outcomes which should be studied in future investigation.

Diffusion Tensor Imaging Demonstrated White Matter Structural Abnormalities in Hemodialysis Patients

David A. Drew,[1] Bang-Bon Koo,[2] Rafeeque Bhadelia,[3] Hocine Tighiouart,[1] Sarah M. Duncan,[1] Maria de Los Angeles Mendoza-De la Garza,[1] Tammy Scott,[1] Daniel E. Weiner,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center; [2]Boston Medical Center; [3]BIDMC.*

Background: Patients treated with dialysis have high rates of clinical stroke and structural brain disease. There are limited data regarding the presence of more subtle damage to white matter integrity.

Methods: In the Boston Dialysis Study, we compared brain magnetic resonance imaging (MRI) using a diffusion tensor imaging (DTI) protocol in hemodialysis (HD) patients to community dwelling persons without known kidney disease who underwent the same MRI protocol. Using a tract based spatial statistics (TBSS) software package, significant differences in Fractional Anisotropy (FA) and Mean Diffusivity (MD) between patients and controls were placed on a three dimensional skeleton highlighting white matter fiber tracts. Statistical comparison of each overlaid voxel was age controlled, using a permutation based corrected p value of <0.05.

Results: Thirty HD patients and twenty six controls had adequate imaging for analysis. Mean age was similar (52 vs 49 years for HD vs control). The HD group had fewer women (38% vs 23%), more African Americans (38% vs 23%), and a higher rate of diabetes (29% vs 8%). Hemodialysis patients had significantly lower FA across multiple white matter fiber tracts, with fronto-temporal lobes, genu of the corpus callosum and fornix more significantly affected than posterior parts of the brain.

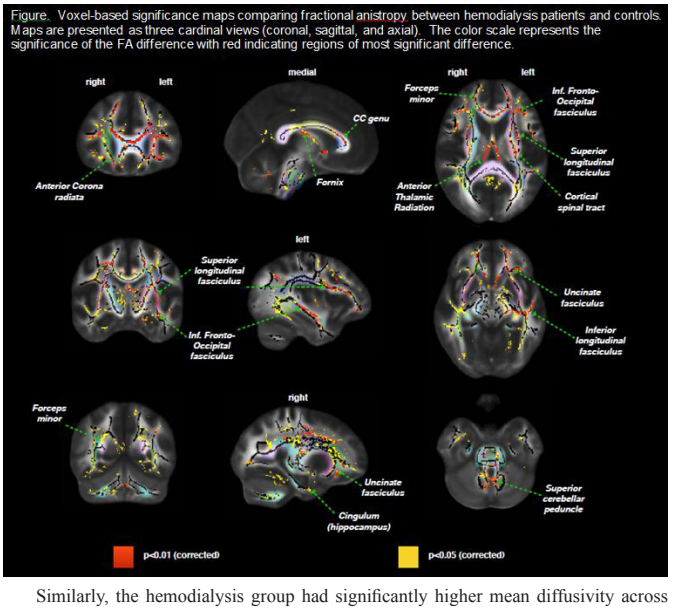

Figure. Voxel-based significance maps comparing fractional anistropy between hemodialysis patients and controls. Maps are presented as three cardinal views (coronal, sagittal, and axial). The color scale represents the significance of the FA difference with red indicating regions of most significant difference.

Similarly, the hemodialysis group had significantly higher mean diffusivity across multiple anterior brain regions.

Conclusions: Hemodialysis patients show loss of white matter integrity on DTI, more anterior than posterior, compared to those without known kidney disease. The pattern of injury may imply accelerating aging as it is most similar to that seen in elderly adults.

SA-PO881

Renal SCAN-ECHO and Renal e-Consults Improve Care and Value for Rural and Highly Rural Veterans Who Live Distant to Veterans Affairs Renal Specialty Care

Raimund H. Pichler,[1] Nancy M. Harris,[1] Maureen Germani,[1] Elizabeth A. Mattox,[1] Lauren Beste,[1] Michael F. Chang,[2] Bessie A. Young.[1] *[1]Dept of Veterans Affairs, Puget Sound Healthcare System, Seattle, WA; [2]Dept of Veterans Affairs, Portland Healthcare System, Portland, OR.*

Background: Renal Specialty Care Access Network-Extension for Community Health Outcomes (SCAN-ECHO) is a provider-to-provider telemedicine program linking primary care providers (PCPs) with specialists. In 2010 the VA launched a form of consultations (i.e. non-visit consults or NVC) involving reviews of the electronic medical records by specialists. We evaluated differences in SCAN-ECHO, NVC, and traditional in-clinic consults (ICC) in a geographic area of the Pacific Northwest.

Methods: We reviewed patient demographics and characteristics of patients served through either renal SCAN-ECHO consults (n=105), NVCs (n=350) or ICCs (n=380). Patient rurality and driving distance to specialty clinic were established.

Results: Veterans served by SCAN-ECHO lived the furthest away and were more likely to be highly rural, followed by NVC, and ICC Veterans (see Table). The total number of round trip driving miles saved by SCAN-ECHO was 98,280, which represented $40,786 saved in travel reimbursement compared to 127,824 miles saved NVCs ($53,045).

VISN 20 Renal Consults FY15	SCAN-ECHO (n = 105)	Non-Visit (n = 350)	In Clinic (n = 380)
Average distance of patient to VA nephrologist	468 miles	182 miles	54 miles
% of patients living more than 300 miles from a VA nephrologist	43%	12.5%	1%
Total number of round trip miles saved ($ saved (0.415/mile))	98,280 ($40,786.20)	127,824 ($53,045.96)	N/A
% Rural/Highly Rural Veterans	68%/3%	40%/3%	32%/0%
% Female Veterans	11%	6%	4%
% Black Veterans	3%	11%	22%

Conclusions: VISN 20 Renal SCAN-ECHO and renal NVCs serve a more rural patient population that live further away from VA specialty care compared to ICCs. VA VA Telemedicine efforts improve specialty care access for rural veterans and save money. Future research should be directed towards assessing the impact of telemedicine initiatives on patient outcomes.

Telenephrology May Improve Rural Primary Care Provider (PCP) Satisfaction and Nephrology Care within Veterans Affairs

Raimund H. Pichler,[1] Nancy M. Harris,[1] Maureen Germani,[1] Elizabeth A. Mattox,[1] Lauren Beste,[1] Michael F. Chang,[2] Bessie A. Young.[1] *[1]Dept of Veterans Affairs, Puget Sound Healthcare System, Seattle, WA; [2]Dept of Veterans Affairs, Portland Healthcare System, Portland, OR.*

Background: PCPs practicing in rural areas have more difficulty accessing specialty care for their patients and have been shown to report professional isolation, lack of access to professional development. As part of the Veterans Affairs (VA) Specialty Care Access Network-Extension for Community Health Outcomes (SCAN-ECHO) we launched a provider-to-provider Nephrology telemedicine consultation service to provide mentoring for PCPs who treat predominantly rural Veterans with renal disease.

Methods: We conducted an e-mail survey of VA-based PCPs (n=55) in the rural Pacific Northwest who attended a longitudinal Nephrology telemedicine program. We used a validated survey to assess provider measures.

Results: Most PCPs reported that the program increased their knowledge and competencies (92.8%), improved the quality of care for their patients (85.4%), improved coordination of care between PCPs and Nephrologists (72.7%), was useful in treating patients not discussed in the program (83.7%), felt that their participation was rewarding (94.5%) and felt more integrated into their local clinical team (54.5%). The majority of PCPs felt that Renal SCAN-ECHO increased their overall job satisfaction (67.3%) and they felt more connected to a community of practice (83.7%). 92% stated that they would recommend the program to a colleague. 60% of PCPs felt that SCAN-ECHO improved access to nephrology care for their patients. Participation in SCAN-ECHO led to an improvement in job satisfaction in 90% of rural PCPs vs 70% of urban PCPs. 80% of rural PCPs felt that SCAN-ECHO improved the quality of care for their patients (as compared to 58% urban PCPs).

Conclusions: A renal provider-to-provider Nephrology telemedicine service can be a rewarding experience that improves provider self reported knowledge, job satisfaction and quality of nephrology care in more rural areas. Future research is needed to study the effect of such an intervention on patient outcomes.

SA-PO883

Telenephrology: An Effective Strategy for Improving Access and Opportunity of Nephrologist Evaluation of Primary Care Chronic Kidney Disease Patients Carlos Zuniga,[1,2,3,4] Maria Cecilia Riquelme,[1] Hans K. Müller,[2,3] Camila Andrea Astorga Parra,[1] Francisco J. Albornoz.[2,5] *[1]Health Service, Concepcion; [2]Health Service, Talcahuano; [3]Med School, Univ de Concepcion; [4]Medical School, Univ Catolica Sma Concepcion; [5]Medical School, Univ Andres Bello.*

Background: Chronic Kidney Disease (CKD) is a significant public health problem in Chile, leading to a great demand of unsatisfied renal consultations, which is worsened by a workforce shortage of nephrologists. This study assessed the impact of telenephrology (TN) to improve access and opportunity of care by renal specialist in a public health care network.

Methods: A retrospective cohort of TN asynchrony consults between 55 primary care providers (PCP) and 3 nephrologists in two cities of southern Chile, between Oct 2012 and May 2016 were analyzed. The main analyzed variables were: 1. Average response time versus historical response for in person consult; 2. Average invested time per consult/nephrologist; 3. Identification of patients in need of advanced care 4. User satisfaction questionnaire among PCP.

Results: 2256 consultations were included, (59 % females), mean age 69 years (15-96), CKD stage III (57%), IV (24%), V (4.5%). Average historical response time for traditional in person consult diminished from 195 days to 1 day for electronic consult; Invested time per consult/nephrologist diminished from 20 minutes for in person to 10 minutes for electronic consult. Following consultation, 1268 patients (56,2%) were sent back by the nephrologist to primary care with treatment advice and 988 patients (43,8%) were sent to renal outpatient evaluation for CKD predialysis stage and complex nephropathy. Additionally, at six month of TN implementation we reach No waiting list of referred renal patients. PCP rated 85% approval of the electronic model, highlighting the decreasing waiting time for consult, health network integration and continuous education.

Conclusions: The tele-consult model is an efficient method for improving access to nephrologist assessment, prompt treatment, selection of patients for specialized and complex care and optimizes the available time of nephrologist in an integrated network with PCP.

Funding: Government Support - Non-U.S.

SA-PO884

Implementation and Evaluation of Electronic Consultation in Nephrology Mallika L. Mendu, Gearoid M. McMahon, Sushrut S. Waikar. *Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: The care of kidney disease patients is fragmented and poorly coordinated between referring primary care providers (PCPs) and nephrologists. Nephrology is a specialty that could embrace an electronic consultation (e-consult) model to improve the process of referral by facilitating communication and determining the need and urgency of a referral.

Methods: We conducted a pilot study to examine the impact of an e-consult system for patients with kidney-related conditions over the course of 15 months. Nephrologists (n = 2) reviewed questions submitted by PCPs (n = 49), and provided recommendations within an EHR-based platform. We sought to determine what types of kidney-related conditions were best suited for e-consults, as well as PCP and nephrologist satisfaction.

Results: 74 total nephrology e-consults were completed during the study period. The median time required for completion was 10 minutes for both provider groups. The most common kidney conditions leading to an e-consult were stage 3 CKD (16.2%), medication-related questions (13.5%), abnormal imaging findings (10.8%), electrolytes (9.5%), and proteinuria (8.1%). Satisfaction with the e-consult model was high among both nephrologists and PCPs (see Figure 1).

Figure 1. Nephrology and PCP satisfaction with e-consult tool

Survey Question	Nephrologists' Responses (N, %)	PCPs' Responses (N, %)
Did you feel that was an appropriate e-consult?		
Yes	60 (84.5%)	NA
No, in-person referral preferred	9 (12.7%)	NA
No, neither e-consult or in-person referral was warranted	2 (2.8%)	NA
Did the e-consult answer the clinical question you posed?		
Yes	NA	47 (95.9%)
No	NA	2 (4.1%)
If e-consult did not exist do you believe PCP would have sought informal or formal nephrology care?		
Yes	59 (83.1%)	NA
No	12 (16.9%)	NA
If e-consult did not exist would you have referred your patient to see a nephrologist?		
Yes	NA	27 (55.1%)
No	NA	22 (44.9%)
If e-consult did not exist would you have sought any informal nephrology advice via email or telephone?		
Yes	NA	29 (59.2%)
No	NA	20 (40.8%)
Do you feel confident that the patient can be managed without an in-person referral?		
Yes	46 (64.8%)	34 (69.4%)
No	5 (7.0%)	4 (8.2%)
In-person referral was recommended	20 (28.2%)	11 (22.4%)
How many minutes did you spend utilizing the e-consult for the patient?		
Median	10 (IQR 10, 15)	10 (IQR 5, 10)
Did you feel the e-consult was efficient?		
Yes	70 (98.6%)	47 (95.9%)
No	1 (1.4%)	2 (4.1%)

Conclusions: In this pilot of an e-consult for patients with kidney conditions, we found that utilizing e-consults was efficient, well received by both nephrologists and PCPs, and could improve the appropriateness of in-person nephrology referral.

SA-PO885

iConnect Care - A Web Based Chronic Kidney Disease Virtual Consultation Program Vishwas Raghunath,[1,2] Ivor Jonathan Katz.[1,2] *[1]Renal Medicine, St. George Hospital and Community Services, Sydney, New South Wales, Australia; [2]Univ of New South Wales, Sydney, New South Wales, Australia.*

Background: Specialists are overwhelmed with chronic kidney disease (CKD) patients, who can be managed in primary care (PC). Opportunistic screening of high risk (HR) CKD patients and follow-up in PC is the most sustainable form of CKD care. The iConnect Care CKD program provided a 'virtual consultation' (VC) instead of face to face (F2F) consultation.

Methods: A total of 70 patients were recruited from GP sites and Hospital clinics and followed for one year. The HR patients (eGFR< 30ml/min/1.73m^2 +/- albuminuria >30mg/mmol/L) were randomised to either VC or F2F. Patients were monitored every 6 months by a Clinical Nurse Specialist (CNS). The specialist team providing VCs comprised a Nephrologist, Endocrinologist, Cardiologist and a Palliative care Physician.

Results: Sixty one (87%) patients were virtually tracked or consulted with 14 (23%) of these being HR. At 12 months there was no difference in progress or outcomes in VC versus F2F groups nor a difference in low risk (LR) patients followed by CNS or GP. All were successfully followed. Software integration was challenging affecting enrolment. GPs reported high level of satisfaction and patients found the system attractive. VC consults occurred within a week and a second specialist opinion within another two.

Conclusions: The program allowed safe, quick and efficient consultation from multiple specialists. VC has a role to play in future patient care and ongoing evaluation is necessary.

SA-PO886

Source and Content of Chronic Kidney Disease Videos on YouTube®: Stream with Caution Elizabeth Ortiz, Claudia M. Lora. *Univ of Illinois at Chicago.*

Background: Many individuals with chronic diseases use the internet to obtain health information. Recently, concerns have been raised about the content of this information on YouTube; the second most globally used internet site. YouTube videos related to pre-dialysis chronic kidney disease (CKD) have not been evaluated.

Methods: We identified 362 videos using the following search terms: "chronic kidney disease," "chronic kidney failure," "chronic renal failure," "chronic renal insufficiency," "kidney disease" and "kidney failure." We excluded videos that were not in English, did not relate to CKD in humans or were duplicates. We examined the source, target audience, the number of views and comments, and the content.

Results: We excluded 211 videos. Of the remaining 151, 20% were uploaded by universities and professional societies, 50% by commercial organizations, 7% by individuals without clear credentials, and 23% by individuals with CKD. Target audiences were patients (66%), students (5%), health care personnel (2%), or were unspecified (27%). The mean number of views was 96,323, and the mean number of comments was 20. Table 1 summarizes the content of the videos. A total of 36 (24%) videos contained misleading or incorrect information, and 73 (48%) videos marketed a non-evidenced based treatment for CKD. Specifically, 12 (8%) advertised an herbal supplement for CKD.

Conclusions: Most YouTube videos on CKD are uploaded by commercial organizations and target a patient audience. A large number of videos included misleading information or advertised treatments that could be harmful in CKD. Patients should be cautioned about using YouTube as a source of health information. Future studies need to examine YouTube as an intervention aimed at improving knowledge of CKD.

Table 1. Content of YouTube Videos Related to CKD, n=151

Topic	n(%) of videos
Kidney Functions	41 (27)
Diagnosis	25 (17)
Symptoms	29 (19)
Treatment	75 (50)
Dietary Modification	53 (35)
Complications	90 (60)

Funding: NIDDK Support

SA-PO887

Tracking Health Behavior Using Google Analytics: A New Clinical Investigative Tool Stephanie W. Ong,[1] Kelly Min,[1] Akib Uddin,[2] Sarbjit Vanita Jassal,[1] Emily Seto,[2] Alexander G. Logan.[1] *[1]Nephrology, Univ Health Network, Toronto, ON, Canada; [2]Centre of Global eHealth Innovation, Univ Health Network, Toronto, ON, Canada.*

Background: We have developed and tested an integrated smartphone app system for advanced CKD, which allows patients to track blood pressure (BP), medications, symptoms and lab tests and have access to CKD care resources and provider contact information. Results suggest improved outcomes; however its effect on health behaviors remains unknown. Google Analytics (GA) can track interactions with electronic devices, and thus evaluate health behaviors. In this study we evaluated the app's features using GA.

Methods: GA was used to determine the frequency of visits to each feature and the pattern of use over a 6-month period. At exit, participants were interviewed about usability and feasibility of the app, and the results were correlated with GA usage.

Results: Patients (n=45) used the app consistently throughout the study. There were 33,085 unique views with the total time spent per person averaging 8.1 hours. BP was the most utilized feature, followed surprisingly by laboratory results as most participants had tests done at baseline and once or occasionally twice during the study, and then by medications. The use of the symptom feature was infrequent, even though patients were asked to complete the symptom checklist at a minimum month and more often if symptomatic. The CKD resources and contact features were rarely used. Pattern analysis revealed multiple unexplained spikes in use of the BP feature. In exit interviews (n=38) patients stated that BP and labs were most useful features due to their interactive nature and supportive feedback, while many questioned the value of tracking symptoms as it lead to few changes in treatment.

Conclusions: GA is a valuable and inexpensive tool that may help clinicians track, and better understand, changes in health behaviors over time. Apart from tracking feature use, GA provides insights into which features patients are most likely to use and which do not provide enough value and may require redesign. It also raises questions about clinical correlates to changes in the pattern of use.

Funding: Government Support - Non-U.S.

SA-PO888

Racial Disparities in Cardiopulmonary Resuscitation Knowledge in Chronic Kidney Disease Patients due to Low Health Literacy

Nwamaka Denise Eneanya,[1] Kabir O. Olaniran,[1] Ravi I. Thadhani,[1] Michael Paasche-Orlow.[2] *[1]Massachusetts General Hospital; [2]Boston Medical Center.*

Background: Patients (pts) with chronic kidney disease (CKD) experience poor survival after receiving cardiopulmonary resuscitation (CPR). Minority CKD pts also receive CPR more often than other racial groups. Low health literacy (HL) affects one's ability to understand health information to make appropriate health decisions and disproportionately affects minorities. As low HL affects up to 32% of CKD pts, we investigated whether HL mediates racial disparities in CPR knowledge.

Methods: Cross-sectional study of CKD pts in nephrology clinics affiliated with two academic centers in Boston, MA. Inclusion: age ≥ 45 years, English-speaking, Black or White race and, Stage 4 or 5 CKD (defined by eGFR < 30 ml/min/1.73m^2). Exclusion: listed for kidney transplantation or history of dementia. An 8-item multiple choice CPR knowledge survey was administered. HL was assessed via the Rapid Estimate of Adult Literacy in Medicine (REALM).

Results: 149 pts completed the study.

	Total (N=149)	Black (N=62)	White (N=87)	P - value
Mean age,years (± SD)	68 (± 11)	66 (± 11)	70 (± 10)	0.02
Low HL	34	63	14	<0.01
CPR knowledge items (% pts with correct responses)				
Cardiac arrest	46	39	52	0.12
CPR purpose	84	77	89	0.07
Physical trauma	43	34	49	0.06
Respiratory failure	**48**	**31**	**60**	**<0.01**
Mechanical ventilation	81	77	83	0.42
Speaking while intubated	**44**	**31**	**54**	**<0.01**
Post-CPR survival	6	8	5	0.38
Daily activities post-CPR survival	60	60	60	0.99
Mean summary percentage score (± SD)	**51 (± 20)**	**45 (± 19)**	**56 (±20)**	**<0.01**

Blacks and Whites differed on HL and CPR knowledge in unadjusted and multivariate analyses adjusted for age, education, income, and comorbidities. The addition of HL to this model revealed mediation with HL - and not race - that was related to CPR knowledge.

Conclusions: Overall CPR knowledge is low among CKD pts. CPR knowledge is lower for Blacks than for Whites, but this difference is mediated by HL. Future CPR educational interventions should target HL barriers to improve decision-making and decrease racial disparities for CKD pts.

SA-PO889

The Portal Patient in Kidney Disease: One Center's Experience on Who Uses Health Portals and How

Julie A. Wright Nunes,[1] Eve Kerr,[1,2] Akinlolu O. Ojo,[1] Angela Fagerlin.[3] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Veterans Affairs Healthcare System and Ann Arbor Center for Clinical Management Research, Ann Arbor, MI; [3]Population Health Sciences, Univ of Utah and Salt Lake City VA, Salt Lake City, UT.*

Background: Patient health portals are increasingly promoted to facilitate chronic disease management. It remains unclear which patients routinely access portals and what information they seek as most relevant to chronic kidney disease (CKD) care.

Methods: Adults with CKD Stages 1-5 were enrolled to take a cross-sectional survey from April 2015-May 2016. We asked patients if they used the Internet to learn about kidney disease, whether they used the patient health portal, and if so, which features they utilized. To examine for associations between demographics and item responses we used logistic regression.

Results: 202 patients enrolled with a mean (SD) age 59 (16) years. 48% were men, 78% Caucasian, 17% African American (AA), 73% CKD Stage 3-5, 51% had an annual income > $50K, and 95% had ≥ H.S. education. 128 (63%) used the Internet to learn about CKD. 127 (63%) utilized the portal to: 89% - check lab results, 76% - view/request appointments, 74% - send messages to providers, 74% - view personal health history, and 59% - review/request prescription changes. Patients with income >$50K were more likely (OR 2.50 p<0.01) to use the portal compared to those of lower income. After adjustment for age, sex, race, income, education, and CKD stage, this association was diminished and older patients were found less likely to use the portal (OR 0.97 p=0.02). Older patients (OR 0.97 p<0.01) were less likely, and patients with annual income > $50K (OR 3.27 p<0.01) and more advanced CKD (OR 2.42 p=0.02) more likely, to use the Internet to learn about CKD. In adjusted analysis, these associations remained significant [older (OR 0.94 p<0.01), annual income > $50K (OR 6.90 p<0.01) and more advanced CKD (OR 3.54 p=0.02)].

Conclusions: Portals offer benefits to communication and care, but older patients and those of lower income may be less likely to reap these benefits. Future work must ensure health portals are useful and accessible to all patients with CKD.

Funding: NIDDK Support

SA-PO890

Disparities in Patient Reported Barriers to Optimal Self-Management for Chronic Kidney Disease

Julie A. Wright Nunes,[1] Eve Kerr,[1,2] Akinlolu O. Ojo,[1] Angela Fagerlin.[3] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Veterans Affairs Healthcare System and Ann Arbor Center for Clinical Management Research, Ann Arbor, MI; [3]Population Health Sciences, Univ of Utah and Salt Lake City VA, Salt Lake City, UT.*

Background: Patient self-care is critical to chronic kidney disease (CKD) management. The study goal was to determine barriers that impact patients' ability to practice healthy behaviors.

Methods: 202 adults with CKD Stages 1-5 completed a cross-sectional survey between April 2015-May 2016. Patients rated how often barriers got in the way of keeping their kidneys healthy; scale from 0=never to 3=almost all the time. Topics included: lack of psychosocial support, poor communication with providers, lack of resources/motivation for healthy behaviors, and low knowledge. We used linear regression to examine associations between demographics and ratings.

Results: Mean (SD) age was 59 (16) years, 48% were male, 78% Caucasian, 17% African American (AA), 73% had CKD Stage 3-5, 51% had an annual income > $50K, and 95% ≥ H.S. education. Ratings ranged from mean (SD) 0.28 (0.63) [poor communication with doctor(s)] to 1.10 (0.96) [not having motivation to exercise]. 31% rated not having motivation to exercise and 29%, not being healthy enough to exercise, as most frequent barriers. In univariate analysis, annual income < $25K was significantly associated with 9 out of 10 barriers and many remained significant after adjusting for age, sex, race, income, CKD stage, and education: lack of social support (β=0.40 p=0.04), insurance situation (β=0.37 p=0.04), poor access to fresh foods (β=0.25 p=0.01), low income (β=0.91 p<0.01), low motivation to exercise (β=0.53 p<0.01). Although most felt poor communication with doctors was not a barrier, AA race (β=0.31 p<0.01) and income < $25K (β=0.21 p=0.04) were associated with perceiving this as a barrier more often, and were significant after adjustment [AA race (β=0.45 p<0.01), income < $25K (β=0.36 p=0.02)].

Conclusions: Barriers to healthy behaviors are reported more often in those most vulnerable to CKD progression. Future efforts must focus on more support and improved communication for minority and low income patients.

Funding: NIDDK Support

SA-PO891

Quantitative Analysis: What Patients Want from Kidney Disease Education

Julie A. Wright Nunes,[1] Eve Kerr,[1,2] Akinlolu O. Ojo,[1] Angela Fagerlin.[3] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Veterans Affairs Healthcare System and Ann Arbor Center for Clinical Management Research, Ann Arbor, MI; [3]Population Health Sciences, Univ of Utah and Salt Lake City VA, Salt Lake City, UT.*

Background: Chronic kidney disease (CKD) patients often lack understanding of their disease, treatment options, and the potential for disease progression. The study purpose was to understand patients' wants and needs for CKD education.

Methods: 202 adults with CKD Stages 1-5 completed a cross-sectional survey between April 2015-May 2016. Questions focused on: Barriers to using current education materials (10 sub-topics with yes/no response), desired educational content (21 sub-topics rated 0=less important to 4=more important), preferred timing to use materials, and design of materials (4 sub-topics rated 0=not a helpful to 4=extremely helpful).

Results: Mean (SD) age was 59 (16) years. 48% were male, 78% Caucasian, 17% African American, 73% had CKD Stage 3-5, 51% had an annual income > $50K, and 95% had ≥ H.S. education. The most common barriers to using current education materials included too little information provided (36%) and content perceived as too general (33%). Topics rated most important to include in future materials were medications that can hurt kidneys [mean (SD) rating 3.7 (0.7)], foods to avoid with advanced CKD [3.6 (0.7)], treatment options for kidney failure [3.6 (0.7)] and explanations about how CKD progresses [3.6 (0.8)]. Descriptions of other patients' experiences with CKD was ranked

lowest [2.5 (1.3)]. 28% wanted to review education materials prior to doctor visits and 46% wanted to use them in combination (before, during and after visits). Suggestions from providers was rated highest to include in material design [mean (SD) rating 3.3 (0.8)], followed by tips for communicating with doctors [3.2 (1.1)], use of charts/graphs/tables [2.2 (1.3)] and descriptions of others' experiences [2.2 (1.3)]. 53% were willing to review materials for ≤ 30 minutes.

Conclusions: This study suggests current education materials are deficient in patient individualization and details. Improved education materials should strive not to be too burdensome on patients' time.

Funding: NIDDK Support

SA-PO892

Illness Experience of Undocumented and Emergently Dialyzed Hispanics

Lilia Cervantes,[1,2] Claudia Camacho,[1] Maria Francisca Zabalaga Palma,[1] Stacy M. Fischer.[2] *[1]Denver Health; [2]Univ of Colorado.*

Background: Undocumented US patients with end-stage renal disease (ESRD) do not have access to routine dialysis in Colorado. At Denver Health, undocumented patients with ESRD are admitted to the hospital for two consecutive days of emergency-only dialysis when they present critically ill. The purpose of our study was to describe their illness experience.

Methods: We conducted a qualitative, descriptive study, using semi-structured interviews with undocumented Hispanic adults with ESRD. The interview guide utilized open-ended questions to elicit the symptom burden and personal impact of emergency-only dialysis. Interviews were audio-recorded, transcribed verbatim, and analyzed by three members using an inductive approach.

Results: We interviewed 20 undocumented Hispanics with ESRD between August 2015 and March 2016. Participants speak primarily Spanish, live below the poverty line, and have resided in the US for over three years. Four themes were described: escalating symptoms, imminence of death, burden of being undocumented, and family. Patients go an average of 6-7 days between dialysis sessions and thus describe the escalating symptoms during the last 3 days of the week leading up to their emergency department visit. Patients risk being turned away and not receiving dialysis when they present before they are critically ill so they must wait for the sensation of 'drowning.' Patients also describe the sense that death is imminent because they suffer several near death experiences with many describing previous cardiopulmonary resuscitation for arrhythmias. Expressing fears that they will not survive, many say their 'last goodbye' to their family prior to each hospital admission. Patients describe a great burden in being undocumented because they do not receive pre-dialysis care and have a willing family kidney donor yet no transplant benefits. Their lack of access to care also impacts their family such that they describe protecting their family by hiding their escalating symptoms to prevent further distress.

Conclusions: Patients describe significant personal and family distress as a result of lack of access to care.

Funding: Private Foundation Support

SA-PO893

High Moral Distress in Health Care Providers Providing Care to Undocumented Immigrants Needing Dialysis

Areeba Jawed, Sharon M. Moe, Melissa D. Anderson, Alexia Torke. *Div of Nephrology, Dept of Medicine, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: No national standards exist for chronic dialysis in undocumented immigrants posing a unique ethical dilemma for providers.

Methods: Cross Sectional Internet Survey in April 2016 of Nephrology, ICU, ER, IM, Palliative Care nurses and physicians at a safety-net hospital. Survey was developed in collaboration with center for Ethics; it employed the Moral Distress thermometer to score moral distress on a scale of 1 to 10, with 10 representing higher distress. Predictors:Specialty, Age, Years in practice, patient encounters, and Education in Bioethics.

Results: 299 out of 765 participants completed the survey. 47% were nurses; the remaining were physicians from multiple specialties. 48% had >20 patient encounters with undocumented immigrants needing dialysis in the last year. Score distribution was skewed: 48% reported intense to severe moral distress and 33% none to mild. This pattern was observed across each specialty; median score for the entire cohort was 6 (95%- 2,9). Younger providers (<40 years old) and trainees reported a significantly higher score. No differences were found between nurses and physicians, specialties, gender, no. of patient encounters and education in bioethics. More than 70% of respondents attributed their distress to suffering of patients due to inadequate dialysis and tension between what is considered ethical and what the law allows or forbids; 78% quoted the patients' quality of life to be worse than the average citizen with ESRD. Among Nephrologists, caring for these patients led to moral distress levels similar to that of dealing with a violent dialysis patient. Venting, team approach to patient care and withdrawing from situation were predominant coping mechanisms.

Conclusions: Provision of inadequate dialysis causes significant moral distress in providers from all specialties involved in the care of undocumented immigrants; younger providers and trainees being particularly at risk for burnout and detachment. Legal and fiscal policies need to be balanced with the strong ethical and moral commitments providers have for ensuring quality standard of care to all patients.

SA-PO894

Gender Disparities in Cardiovascular Outcomes and Mortality in Persons with Chronic Kidney Disease

Ana C. Ricardo, Wei Yang, Lawrence J. Appel, Esteban A. Cedillo-Couvert, Jing Chen, Rajat Deo, Marie Krousel-Wood, Anne Frydrych, Mahboob Rahman, Sylvia E. Rosas, Daohang Sha, Jackson T. Wright, Martha L. Daviglus, James P. Lash. *On Behalf of the Chronic Renal Insufficiency Cohort (CRIC) Study Group.*

Background: Data from general populations indicate that cardiovascular events are less common in women than men, but studies of individuals with chronic kidney disease (CKD) are limited and less conclusive. We evaluated gender-related disparities in cardiovascular events and all-cause mortality in adults with CKD.

Methods: This was a prospective, longitudinal study of 1778 women and 2161 men enrolled in the CRIC Study (mean age 58 years, 42% non-Hispanic white, 42% non-Hispanic black, 13% Hispanic, and mean estimated glomerular filtration rate [eGFR] 45 ml/min/1.73m^2 at entry). Using Cox-proportional hazards models, we investigated the association of gender (women vs. men) with adjudicated atherosclerotic events (myocardial infarction, stroke or peripheral arterial disease), incident heart failure and all-cause mortality.

Results: Over a median follow-up of about seven years, we observed 585 atherosclerotic, 638 heart failure, and 853 death events. The table below summarizes multivariable analyses results.

Outcome	HR (95% CI)* Women vs. Men	P value interaction Gender*Age	P value interaction Gender*Diabetes
Atherosclerotic events	0.64 (0.52-0.79)	0.13	0.77
Heart failure		0.23	0.04
Diabetes	0.86 (0.69-1.09)		
No Diabetes	0.58 (0.40-0.82)		
All-cause mortality	0.59 (0.48-0.72)	0.19	0.92

*Adjusted for clinical site, age, race/ethnicity, education, marital status, nephrology care, health insurance, systolic blood pressure, diabetes, history of cardiovascular disease, smoking status, physical activity, body mass index, LDL cholesterol, ACEi/ARB, aspirin and statin use, baseline eGFR, proteinuria, serum FGF23, calcium and phosphorus.

Conclusions: In this large and diverse CKD cohort, women had lower risk of atherosclerotic events and death than men. Among participants without diabetes, women were less likely to experience a heart failure event.

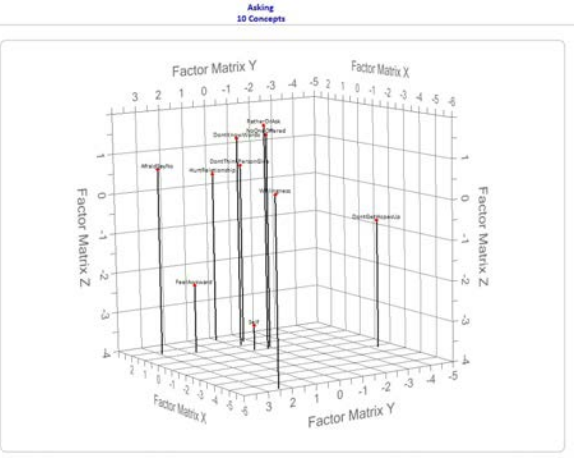
A Mapping Study of Dialysis Patients' Perceptions of Kidney Transplantation

Heather Marie Traino,[1] Sarah Bauerle Bass,[1] Laurie A. Maurer,[1] Avrum Gillespie,[2] Dorian R. Schatell.[3] *[1]Social & Behavioral Sciences, Temple Univ, Philadelphia, PA; [2]Nephrology, Temple Univ Hospitals, Philadelphia, PA; [3]Medical Education Inst, Inc, Madison, WI.*

Background: Kidney transplantation remains the preferred treatment modality for patients with end stage renal disease, but continues to be underutilized. While previous studies have identified barriers to transplantation, to date no research has explored the relationships between patients' unique perceptions of transplant-related barriers and facilitators.

Methods: We employed perceptual mapping techniques (multidimensional scaling and vector modeling) to understand and visualize patient-level barriers and facilitators to living and deceased donor kidney transplantation. These methods generate 3-dimensional maps of transplant-related concepts, which can be used to inform message strategies aimed at increasing patients' interest in transplantation and pursuit of living donors.

Results: Preliminary findings of data collected via an online survey suggest that patients (n=30) consider themselves well informed, and understand the pros, cons and long-term effects of transplantation. However, patients were most concerned by the anticipated pain associated with the transplant surgery and the potential for being placed back on dialysis. With regard to living donation, perceptual maps revealed fears of troubling and feeling indebted to the donor as well as fears of becoming hopeful and having potential donors decline to donate.



Conclusions: Although data collection is ongoing, interim findings indicate that certain concepts may be instrumental to moving patients along the path to kidney transplantation. Specifically, messages highlighting the severity of kidney disease and countering the emotional aspects of making requests for living donation with instruction on how to effectively pursue this treatment option are needed.

SA-PO896

Patient Preferences for End-Stage Renal Disease Management Eric Finkelstein,[1] Semra Ozdemir,[1] Chetna Malhotra,[1] Lina Choong,[2] Gan Sheryl Shien Wen,[2] Lydia Lim Wei Wei,[2] Andy Sim Gim Hong,[2] Tazeen H. Jafar.[1] *[1]Duke-NUS Medical School, Singapore; [2]Singapore General Hospital, Singapore.*

Background: For very elderly (age 75+) end-stage renal disease (ESRD) patients with multiple comorbidity, there is little expected survival and quality of life (QoL) benefits for dialysis compared to conservative management (CM). Dialysis is also costlier compared to CM. Despite this, dialysis is the most common management option for very elderly ESRD patients including those with co-morbidities in Singapore. To better understand the high dialysis uptake rate, we aimed to investigate the patient level factors influencing decision to choose dialysis or CM.

Methods: We administered a discrete choice experiment survey to 250 Stage 3b-5 chronic kidney disease (CKD) pre-dialysis patients aged >65 years visiting outpatient clinics of the Renal Medicine Department of the largest hospital in Singapore. Prior to the DCE, patients were asked to provide their best estimate of survival for a hypothetical patient with similar health problems as themselves, and their expected QoL and cost if they undergo dialysis and CM. They were then asked a series of hypothetical choice tasks that varied by expected survival, QoL, out-of-pocket cost, and treatment type and asked to choose the one that most appealed to them should they be faced with this decision.

Results: Patients were on average aged 74 (SD=6) years, mostly males (65%) and with average CKD-Epi eGFR of 23.7 (SD=10.5) ml/min/1.73m^2. Over 60% of patients could not provide an estimate of expected survival under any treatment option. Over 40% could not provide an estimate of the expected costs of dialysis or CM, although 66% expected dialysis to be costlier. 60% reported that CM offers better QoL. Expected survival, QoL, cost and treatment type were significant predictors of patient treatment choices. On average, CM was preferred over a form of dialysis for the management of ESRD.

Conclusions: Findings suggest that most elderly patients with advanced CKD were unaware of key factors that should be considered in the decision making process for dialysis or CM. However, despite this knowledge gap, a majority had a clear preference for CM. Future efforts should be made to inform patients on these factors.

SA-PO897

Identifying Factors That Influence Physicians' Recommendations for Dialysis and Conservative Management Eric Finkelstein,[1] Semra Ozdemir,[1] Chetna Malhotra,[1] Tazeen H. Jafar,[1] Lina Choong.[2] *[1]Duke-NUS Medical School Singapore, Singapore; [2]Singapore General Hospital, Singapore.*

Background: For elderly end-stage renal disease (ESRD) patients with multiple comorbidities, dialysis may offer little survival benefits compared to conservative management (CM). Dialysis patients also incur greater costs and greater rates of hospitalization, and lower life satisfaction. Yet, many elderly ESRD patients receive dialysis when it is available. This might be partly due to physician recommendations on treatment choice. Yet the factors that influence these recommendations remain largely unknown.

Methods: We surveyed physicians who attended the 9th Asian Forum of Chronic Kidney Disease Initiative conference to understand factors that influence physicians' recommendations for managing ESRD. We used vignettes that vary by age and comorbidity status, and asked physicians to predict survival of hypothetical patients undergoing dialysis or CM. We then asked them to choose whether they would recommend dialysis or CM for a hypothetical patient with that profile. We also compared the physician's recommendations for patients to what they would recommend for themselves if they were diagnosed with ESRD.

Results: On average, physicians believe that dialysis extends life relative to CM. Yet, many believe that CM confers *greater* survival. Estimates range from 17.3% (for a vignette depicting a 65 year old with diabetes and CHF) to 50% for vignettes depicting patients with advanced cancer. Results further reveal high discordance in treatment recommendations. For a 65 year old with diabetes, 62% recommended dialysis. For those with advanced cancer, 25% recommended dialysis. Those who were more optimistic about the ability of dialysis to extend life were far more likely to recommend it to their (hypothetical) patients. Physicians were far *more* likely to recommend dialysis for themselves than for their patients.

Conclusions: This study suggests that physicians would benefit from a greater understanding of the survival benefits of dialysis and CM for elderly patients with different comorbidity profiles. This information could then be used to better inform patients to ensure that they receive treatment most consistent with their preferences for care.

SA-PO898

Barriers and Facilitators to Chronic Kidney Disease Patient Education as Perceived by Primary Care Physicians: A Qualitative Study Varun Agrawal, Sandeep S. Soman, Clarissa Jonas Diamantidis, Michelle M. Estrella, Kerri L. Cavanaugh, John Sperati, Khaled Abdel-Kader, Bernard G. Jaar, Michael J. Choi, Mark A. Perazella, Yang Liu, Raquel C. Greer. *NKF Education Committee, NY.*

Background: Education of patients with chronic kidney disease (CKD) in nephrology practice is associated with improved dialysis readiness. Little is known as to how primary care physicians (PCPs) view their role in education of CKD patients.

Methods: We conducted 4 focus group interviews of PCPs in 4 US cities to determine challenges and possible solutions to providing CKD education in primary care. A questionnaire was administered to assess comfort with education of patients with CKD. A trained moderator conducted group discussions using standardized open-ended questions. Two independent abstractors coded the transcribed recorded interviews and identified major themes.

Results: 32 PCPs were interviewed and most (85%) were in private practice. While many PCPs felt comfortable educating patients about CKD (84%), only about half had resources to assist with education on CKD (56%) or hypertension (50%). Even fewer had patient education tools for CKD complications such as anemia (25%), bone disorders (25%), or hyperkalemia (28%). PCPs identified numerous barriers to CKD education at various levels of healthcare, including the patient level (low public awareness of CKD, lack of CKD-specific symptoms and patient's fear of dialysis) and the provider and healthcare system levels (complexity of CKD educational concepts, lesser emphasis on CKD as compared to other medical conditions at the clinic visit, lack of ancillary support to provide CKD education and limited time). Strategies suggested by the PCPs to facilitate CKD patient education included raising public awareness of CKD, better tools to facilitate patient involvement in CKD care, and nephrology referrals.

Conclusions: While many PCPs felt comfortable educating patients about CKD, they identified numerous barriers to CKD education. Education programs in primary care that enhance patient awareness and knowledge of CKD in the non-dialysis stage, possibly with effective educational tools and nephrologist collaboration, may improve patient's self-management and outcomes.

Abstract Withdrawn

SA-PO900

Primary Care Providers' Perceptions of Barriers to Management of Chronic Kidney Disease: A Qualitative Study John Sperati, Sandeep S. Soman, Michelle M. Estrella, Yang Liu, Clarissa Jonas Diamantidis, Mark A. Perazella, Khaled Abdel-Kader, Kerri L. Cavanaugh, Varun Agrawal, Bernard G. Jaar, Michael J. Choi, Raquel C. Greer. *NKF Education Committee, NY, NY.*

Background: Primary care providers (PCPs) care for the majority of patients with chronic kidney disease (CKD), yet there are missed opportunities for optimal care. This study aims to further identify the causes.

Methods: We conducted 4 PCP focus groups (n=32) (Baltimore, MD, St. Louis, MO, Raleigh, NC, & San Francisco, CA) to identify barriers to PCP management of CKD. A questionnaire was administered to obtain PCPs' demographics, practice characteristics, and comfort with management of patients with CKD. Standardized, open-ended questions developed by the authors were used to identify PCPs' perceived barriers to management of CKD, as well as tools to facilitate improved CKD care. Groups were audiotaped and transcribed verbatim. Two investigators independently coded concepts addressed during the discussions, which were categorized into major themes.

Results: 45% (n=14) of PCPs surveyed reported not following CKD guidelines. Most PCPs (n=27, 84%) felt comfortable managing patients with CKD, but many were uncomfortable managing specific complications of CKD such as anemia (n=14, 44%), bone disorders (n=16, 50%), and acidosis (n=22, 69%). PCPs cited a lack of tools to manage specific complications of CKD (19-69%) and a lack of educational resources for patients (44-78%). Other significant barriers identified spanned patient (*e.g.*, low awareness of CKD and poor adherence to treatment recommendations), provider (*e.g.*, staying current with CKD guidelines), and system levels (*e.g.*, limited time and reimbursement for complex patients). PCPs desired electronic prompts, lab decision support, medical homes, concise guidelines, PCP education, improved compensation, patient access to self-monitoring tools, and better insurance coverage as tools to facilitate CKD management.

Conclusions: PCPs experience substantial barriers in providing care to patients with CKD. Interventions to address these barriers and increase implementation of facilitative tools may improve PCPs effectiveness and capacity to care for CKD patients.

Advantages of Nutrition Counseling in CKD Patients by a Professional Dietician on the Physical or Psychological State Atsushi Ueda,[1] Aki Hirayama,[2] Kunihiro Yamagata.[3] *[1]Hitachi General Hospital, Japan; [2]Tsukuba Univ of Technology, Japan; [3]Univ of Tsukuba, Japan.*

Background: In Japan, most of chronic kidney disease (CKD) patients go to a clinic. However, it is frequently observed that the patients going to a clinic don't have access to good nutrition counseling. This lack of opportunity is usually due to the absence of a national registered dietician the clinic. To solve this problem, we dispatched a national registered dietician to a clinic and subjected CKD patients to nutrition counseling. This study evaluates the advantages of this nutrition counseling method.

Methods: The studies group consisted of 46 (male31, female15) patients with CKD stage2~4, age 54-87 (average 70). Nutrition counseling was performed twice within 3 months, and each session lasted 30 minutes. A dispatched a national registered dietician used an iPad including original nutrition counseling software and a textbook. During the session, we first identified the main issues such as obesity, salt restriction, protein restriction or potassium restriction, according to the patients' health. We then accordingly issued specific nutrition instructions. Finally, we examined the patient's status, several laboratory data and the behavior modification stage (BMS) by using the transtheoretical model. The previous factors were examined before the first session of counseling and also two months after the second session of counseling. Furthermore, we linked the different BMS to the patient's status and various laboratory data.

Results: Obesity counseling (34%, 16/46), salt restriction (23%, 10/46), protein restriction (11%) or potassium restriction (5%) counseling were issued. In general after counseling, the BMS improved remarkably. Body mass index (BMI) and HbA1c decreased significantly in the group with improved BMS. BMI also decreased significantly in the group with diabetic nephropathy.

Conclusions: This counseling method using an iPad and a textbook by professional dieticians is effective in improving the stage of behavior change, BMI and HbA1c in CKD patients. Therefore, our study demonstrates that the delivering on-demand of nutritional counseling may be useful for preventing the physical or psychological deterioration in CKD patients.

SA-PO902

Utilization of Medical Nutrition Therapy in Patients with Non-Dialysis Chronic Kidney Disease Jennifer K. Bond, Ruth Kafenztok, Kavitha Vellanki, David J. Leehey, Vinod K. Bansal, Anuradha Wadhwa, Julia Schneider, Benjamin Ling, Holly J. Kramer. *Nephrology and Hypertension, Loyola Univ Medical Center, Maywood, IL.*

Background: Medical nutrition therapy (MNT) has been associated with slower progression of chronic kidney disease (CKD). As of January, 1 2011 the Patient Protection and Affordable Care Act allows Medicare to fully cover recommended preventive services that were only previously covered through cost-sharing, including MNT. Medicare beneficiaries with diabetes and non-dialysis CKD stage 3-5 may receive MNT with no out of pocket costs. Many private insurers also cover MNT services with no out of pocket patient costs. The objective of this study was to examine the utilization of MNT services by a cohort of patients with non-dialysis CKD receiving care at Loyola clinics from 2009-2015 and determine if MNT utilization increased after implementation of the Affordable Care Act.

Methods: Data were obtained from Loyola University Medical Center's EMR. The patient population was limited to adults with non-dialysis CKD (ICD-9 codes 585.3-585.4) receiving continued care in Loyola nephrology clinics. Utilization of MNT for each year was identified by billing codes: 97802-97804, G0270, G0271, G0447, G0473, S9449, S9452, S9470, G0108 paired with a charge (58139510) or procedure code (5110403) for MNT. Co-morbid conditions identified by ICD-9 codes. Generalized estimating equation models were used to assess temporal differences in MNT utilization (years 2009-2010 vs. 2011-2015) adjusting for the demographics.

Results: A total of 334 adults with CKD, mean age of 69.3 years, were identified. Overall, 56.0% male , 26.7% black, 6.9% Hispanic, 65.3% white. Obesity, diabetes and coronary artery disease were present in 46.7%, 56.6% and 37.4%, respectively. Medicare and private insurance was primary insurance for 63.2% and 31.1%, respectively. During the 6 year follow-up, 80.2% had no MNT, 8.7% had 1 MNT visit and 11.1% had 2 or more MNT visits. No significant difference in MNT utilization was noted by time period (p=0.3).

Conclusions: In conclusion, MNT utilization is low at our institution. Future studies should examine potential barriers for MNT utilization in patients with non-dialysis dependent CKD.

SA-PO903

Diabetes and Kidney Disease Specific Health Literacy in Urban and Reservation Based Native Americans Vallabh O. Shah,[1] Stephens Lancer,[2] Chistopher Aston,[2] Donica M. Ghahate,[1] Jeanette Bobelu.[1] *[1]Univ of New Mexico; [2]Univ of Oklahoma.*

Background: Health literacy (HL) is a measure of a patients' ability to read, comprehend, and act on medical information to make appropriate health decisions. Poor HL is disproportionately burdensome on vulnerable populations, such as Native Americans. Little is known about the extent to which HL affects clinical health outcomes including diabetes and kidney disease in reservation based vs non-reservation based Native Americans (NA).

Methods: We conducted a HL survey using validated instrument in Zuni reservation based (n=200) and Oklahoma (n=200) non-reservation based Urban NAs.

Results: HL regarding diabetes and kidney disease was significantly higher in NM (reservation) compared to OK (non-reservation) NAs. However it did not differ between diabetics and non-diabetics. HL varied significantly with age, education and work status both within state and within diabetic status, but not with gender, or with propensity to speak a tribal language. HL was significantly higher in younger participants, those with higher levels of education, and those employed rather than unemployed. Those with complications due to diabetes, such as kidney disease, neuropathy or eye disease, tended to have lower HL than those that did not have complications, suggesting lower HL may lead to poorer preventive care. On the other hand, those with one or more family members with complications due to diabetes tended to have higher HL than those that did not have such family members, suggesting affected family members were a motivation for improving HL.

Conclusions: Reservation based NAs had significantly higher health literacy regarding diabetes and kidney disease than non-reservation based NAs, however, this did not translate into improved (lower) prevalence of diabetes or its associated complications. Higher health literacy appeared to be a consequence rather than a preventative of diabetes or its associated complications.

SA-PO904

Veterans Affairs (VA) eKidneyClinic: Addressing Chronic Kidney Disease Health Literacy Gap Devasmita Choudhury,[1] R. Brooks Robey,[2] Rose Mary M. Pries,[3] Dorian R. Schatell,[4] Susan T. Crowley.[5] *[1]Medicine, Salem Veterans Affairs Medical Center, Salem, VA; [2]Medicine, White River Junction Veterans Affairs Medical Center, White River Junction, VT; [3]Veterans Health Education & Information Program, Veterans Health Administration, Durham, NC; [4]MEI INC, Madison, WI; [5]Medicine, Veterans Affairs Connecticut Health Care System, West Haven, CT.*

Background: Chronic kidney Disease (CKD) health literacy can be critical in preventing CKD progression. CKD literacy gap is high amongst CKD patients despite clinic education. Well designed, interactive education improves education/outcomes. To address CKD literacy gap, VA developed a comprehensive, freely available VA eKidneyClinic (http://ckd.vacloud.us) web-tutorial detailing at 5th grade reading level (using Flesch-Kincaid formula), basic disease process, nutritional, laboratory, social, pharmacy, and treatment aspects of all CKD stages in written & graphical format, with video narrative vignettes. Pre-/ post-tutorial questions engage, test, reinforce understanding through action planning. Additional Internet links allow further knowledge acquisition.

Methods: To gain understanding of eKidney tutorial usefulness, basic metrics were obtained using Google analytics resources.

Results: Users: 40% US, 60% worldwide (all continents). No users- middle east, developing African nations; Male 54%, female 46%. 89% <55 years age. Web access:18% VA network; 82% other (i.e. broadband). > 500 active users /30 day: 82% new, 18% repeat. Of repeat users, 11.4% visit site >1/ 30 days. Of multi- session users: 34% new, 66% return.

Conclusions: VA eKidneyClinic provides novel, patient-centered, readily accessible Internet resource to address gaps in CKD education. eKidney use is worldwide by veterans & non-veterans in countries with internet availability. Young & middle age populations are common users. Nearly 20% are repeat users of eKidney. Early data suggests usefulness of eKidney in addressing the CKD literacy gap. Web-education familiarity for those >55 years may be a limiting factor. Further research is important to correlate and validate utility of eKidneyClinic in addressing CKD literacy.

Funding: VA Support

SA-PO905

Physical Activity and Kidney Function in U.S. Hispanics/Latinos: Findings from the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) Bhavik P. Patel, Ana C. Ricardo, Nora Franceschini, Marc D. Gellman, David X. Marquez, Neil Schneiderman, Daniela Sotres-Alvarez, Gregory A. Talavera, Elizabeth Vasquez, Denise C. Vidot, Martha L. Daviglus, James P. Lash. *HCHS/SOL Investigators.*

Background: Hispanics/Latinos are disproportionally affected by chronic kidney disease (CKD). We evaluated the association of physical activity with kidney function in a representative sample of US Hispanic/Latino adults.

Methods: HCHS/SOL is population-based cohort of 16,415 Hispanics/Latinos aged 18-74 yr at baseline (2008-2011) enrolled using a probabilistic sample from 4 US cities. Analyses include individuals with at least 3 days (≥10 hours/day) of accelerometer-measured physical activity, and kidney function measures (n=11622). Using 2008 Physical Activity (PA) Guidelines for Americans we classified PA as high (moderate PA ≥300 min/wk and/or vigorous PA ≥150 min/wk), medium (moderate PA 150-<300 min/wk and/or vigorous PA 75-<150 min/wk), and low/inactive (not meeting above criteria). Kidney function was measured via estimated glomerular filtration rate (eGFR) using the CKD-EPI creatinine-cystatin C equation, and urine albumin-to-creatinine ratio (UACR). Complex survey linear regression analyses were conducted adjusting for sociodemographic and clinical variables.

Results: Mean eGFR for Hispanics/Latinos in the high, medium and low/inactive categories were 111, 109 and 103 ml/min/1.73m^2 respectively. The corresponding UACR medians were 5.8, 6.1 and 7.1 mg/g. Compared with high PA, Hispanics/Latinos in the low/inactive category were significantly ($p<0.05$) more likely to be older (mean age, 45 years vs 37 years), female (60% vs 33%), foreign born (83% vs 69%), and Spanish-speaker (81% vs 65%). They were also more likely to have diabetes (20% vs 9%), and hypertension (28% vs 15%). After adjustments, low/inactive and medium PA were associated with significantly ($p<0.05$) lower eGFR (β -2.5 and -1.5 ml/min/1.73m^2, respectively) compared with high PA. There was no significant association between PA and UACR.

Conclusions: US Hispanic/Latino adults not meeting PA recommendations had lower kidney function compared to individuals with high PA. Longitudinal studies are needed to further evaluate the association of PA and incident CKD.

SA-PO906

Differences in the National Prevalence of Chronic Kidney Disease (CKD) in Urban versus Rural Veterans within the U.S. Department of Veterans Affairs (VA)

Bessie A. Young,[1,2,3] Joleen A. Borgerding,[2] Maureen Germani,[2] Raimund H. Pichler.[1,3] *[1]Hospital and Specialty Medicine, VA Puget Sound Health Care System, Seattle, WA; [2]Center of Innovation, VA Puget Sound Health Care System, Seattle, WA; [3]Kidney Research Inst and Div of Nephrology, UW, Seattle, WA.*

Background: Little is known regarding rural versus urban differences in prevalence of CKD among Veterans. Our objective was to determine the prevalence of CKD from a national sample of rural and highly rural (R/HR) compared to urban Veterans, and to further evaluate treatable risk factors for CKD progression and adverse outcomes prior to program implementation.

Methods: We created a 10% stratified sample from over the 5.3 million enrolled Veterans with at least one primary care outpatient (PC) visit from fiscal year (FY) 2011-2015 with proportional allocation by facility from VA's Corporate Data Warehouse (CDW). Rurality status was based on the CDW geospatial information using the patient's primary address. We determined prevalence of CKD stage using estimated glomerular filtration rate (eGFR) by three different methods: 1) CKD-EPI, 2) Modification of Diet in Renal Disease (MDRD), and 3) VA clinical result (MDRD). Standard stages of CKD were defined; additional comorbid conditions were determined using standard ICD-9 codes.

Results: From FY2011-FY2015, R/HR Veterans comprised 35-38% of all Veterans who received PC within VA. Almost 95% of R/HR Veterans were male and older as compared to urban Veterans. R/HR Veterans had greater prevalence of comorbid conditions vs. urban Veterans, including diabetes (22% vs. 20%), hypertension (48% vs. 43%), congestive heart failure (3.9% vs. 3.7%) respectively. The mean creatinine was similar among R/HR vs. urban Veterans (1.1 (SD=0.49) vs 1.1 (0.61) mg/dl). The estimates of CKD stage showed R/HR Veterans had Stage 1 CKD (32.9 vs 37.1%), Stage 2 (48.6 vs 45.2%), Stage 3 (16.8 vs 15.7%), Stage 4 (1.3 vs1.4%), and Stage 5 (0.4 vs0.6%) CKD, respectively.

Conclusions: Compared to urban Veterans, R/HR Veterans had a greater prevalence of latter stage CKD (3-5). Data are needed to determine how risk factor treatment compares in urban and rural settings prior to Nephrology program implementation.

The Spectrum of Chronic Kidney Disease in Public Renal Services of Queensland, Australia: Data from the CKD.QLD Registry

Wendy E. Hoy,[1,2] Helen G. Healy,[1,2] Zaimin Wang,[1,2] Jianzhen Zhang,[1,2] Rajitha Asanga Abeysekera,[1,2] Ken-Soon Tan,[3] Anne Cameron (Salisbury).[1,2] *[1]CKD.CRE, CKD.QLD, Univ of Queensland, Brisbane, QLD, Australia; [2]Kidney Health Service (RBWH), Metro North Hospital and Health Service, Brisbane, QLD, Australia; [3]Logan Renal Service, Brisbane, QLD, Australia.*

Background: We describe the spectrum of CKD from 13 renal services in a state of 4.6 million people, and an area of 1.85 million km^2, covering urban, regional and remote regions. Service areas have emphases on farming, mining, and tourism (F, M and T), a retirement area (R), two city-hospital referral services (C1, C2), and a large, multiethnic disadvantaged urban population (L).

Methods: Data were extracted from the CKD.QLD registry, which embraces all public renal services in Queensland. Patient enrolment began in May, 2011.

Results: 6,534 patients have been enrolled, and followed for 17,147 years. Median age was lowest (63yr) in F, M and T and highest (74yr) in R. Males ranged from 58% in F and M to only 35% in R. Proportions in the lowest three SES deciles were 45% for L, 20% for C1 and zero for R. In all sites >80% of patients were overweight/obese/very obese. Among nonIndigenous patients, proportions with diabetic nephropathy ranged from 9% in T to 37% in L, while renovascular diagnosis ranged from 8% at M to 25% at R, and GN ranged from 9% at C2 to 20% at T. About 30% of subjects generally lacked micro or macro-albuminuria. The number of comorbidities was age-related. Indigenous people constituted 3.5%: they were more often female, about 15 years younger, more often had diabetic nephropathy (32% and 51% at two sites), and had higher death rates. In all sites, only 25% of persons progressed (eGFR loss of >5ml/min/yr) over one and two years. Proportions who progressed were higher with diabetic nephropathy and renovascular disease, and least in those with GN. Incidence of RRT with stage 5 CKD was 37/100 person years, while deaths without RRT rose by stage, peaking at 21/100 person.

Conclusions: There is marked variation among patients with CKD in the public health sector in Queensland. This should influence regional health care policies and resource consumption. Surveillance might ultimately allow calculation of regional prevalence and incidence rates.

Socioeconomic Status Shows Stronger Association for Risk of ESRD Than Incidence of CKD in the ARIC Study

Priya Vart,[1] Morgan Grams,[1] Mark Woodward,[1,2] Shoshana Ballew,[1] Josef Coresh,[1] Kunihiro Matsushita.[1] *[1]Johns Hopkins Univ; [2]Univ of Oxford, United Kingdom.*

Background: Low socioeconomic status (SES) is strongly associated with ESRD but associations with CKD are less certain and comparing the two will provide insight into whether disparities are wider in early or late in CKD.

Methods: 13,515 participants with eGFR ≥60 at baseline (1987-1989) in the ARIC Study with household income and educational attainment data were examined for their association with subsequent CKD incidence (eGFR<60 and ≥25% decline in eGFR or CKD hospitalization or ESRD) and ESRD (dialysis, transplantation or death due to kidney disease). We performed seemingly unrelated regression to compare the association of SES measures with CKD and ESRD.

Results: During a median follow-up of ~23.2 years, 3,300 participants developed CKD and 385 participants developed ESRD. In a demographically adjusted model, with high household income as reference, low household income was associated with increased incidence of CKD (HR=1.27, CI: 1.14–1.42) and ESRD (HR=2.31, CI: 1.74–3.07) (Table). After additional adjustment for major CKD risk factors, the association across three levels of SES did not reach statistical significance for CKD but did for ESRD ($p<0.001$; stronger association with ESRD vs. CKD). Similar results were obtained for educational attainment, although its association was attenuated for both CKD and ESRD when adjusted for risk factors. No significant interaction was observed between SES measures and race for CKD or ESRD.

Conclusions: Low SES was associated with increased risk of CKD and ESRD, with stronger association for ESRD. Our results suggest that interventions to reduce disparities are at least as important late in CKD as early.

Table: Hazard ratios for CKD and ESRD events by SES categories

	Overall			
	High	Medium	Low	p-trend
Household income (N)	**8,544**	**2,997**	**1,974**	
CKD, % (n)	22.9 (1,958)	25.6 (773)	28.8 (569)	
Model 1 (HR, 95% CI)	Ref.	1.06 (0.97 – 1.16)	**1.27 (1.14 – 1.42)**	<0.001
Model 2 (HR, 95% CI)	Ref.	1.00 (0.91 – 1.09)	1.04 (0.93 – 1.17)	0.56
ESRD, % (n)	1.8 (153)	3.6 (107)	6.3 (125)	
Model 1 (HR, 95% CI)	Ref.	**1.51 (1.16 – 1.96)**	**2.31 (1.74 – 3.07)***	<0.001
Model 2 (HR, 95% CI)	Ref.	1.29 (0.99 – 1.69)	**1.52 (1.14 – 2.04)***	0.01
Educational attainment (N)	4,921	5,584	3,010	
CKD, % (n)	22.7 (1,117)	23.2 (1,295)	29.5 (888)	
Model 1 (HR, 95% CI)	Ref.	1.05 (0.97 – 1.14)	**1.25 (1.14 – 1.37)**	<0.001
Model 2 (HR, 95% CI)	Ref.	0.98 (0.90 – 1.06)	1.04 (0.94 – 1.15)	0.52
ESRD, % (n)	2.0 (100)	2.2 (120)	5.5 (165)	
Model 1 (HR, 95% CI)	Ref.	1.10 (0.84 – 1.44)	**1.82 (1.40 – 2.36)***	<0.001
Model 2 (HR, 95% CI)	Ref.	0.90 (0.69 – 1.18)	1.16 (0.88 – 1.52)*	0.24

Income (in 2016 US$): high (>$50,000), medium ($25,000-$50,000), low <$25,000); Education: high (>High School, HS), medium (HS), low (<HS)

*p<0.05 for ESRD stronger than CKD. Model 1: Adjusted for age, gender and race-center; Model 2: Model 1 + smoking status, alcohol intake, physical activity, body mass index, high blood pressure, diabetes, total cholesterol and high density lipoprotein

Interactions were not significant for race-income (p=0.45 for CKD and 0.11 for ESRD),or race-education (p=0.68 for CKD and 0.12 for ESRD)

SA-PO909

The Association between Socioeconomic Status and Risk Factors for Cardiovascular Mortality in Chronic Kidney Disease: Result from the KoreaN Cohort Study for Outcomes in Patients with Chronic Kidney Disease (KNOW-CKD)

Eunjeong Kang,[1] Hyo Jin Kim,[2] Hyunjin Ryu,[1] Miyeun Han,[1] Curie Ahn,[1] Hyun Suk Kim,[1] Kook-Hwan Oh.[1] *[1]Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Internal Medicine, Dongguk Univ Gyeongju Hospital, Gyeongju, Korea.*

Background: Although cardiovascular (CV) disease is a major cause of death in chronic kidney disease (CKD) patients, a relationship between socioeconomic status (SES) and risk factors of CV mortality in CKD are less well known.

Methods: Data were collected from the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD, NCT01630486 at http://www.clinicaltrials.gov). SES was characterized on the basis of monthly income and education attainment, which were divided into 3 categories, respectively. Left ventricular hypertrophy (LVH) was defined as left ventricular mass index (LVMi) >115g/m^2 for male, or >95g/m^2 forfemale. Anemia was defined as hemoglobin <13mg/dL for male, or <12mg/dL for female. Mean brachial-to-ankle pulse wave velocity (baPWV) and coronary calcium score (CCS) were divided into higher or lower groups based on their median values. We conducted logistic regression to evaluate the association between SES - categorized into the tertiles of education level or monthly income - and cardiac surrogate markers or anemia. Age, sex, diabetes, CKD stage, body mass index, blood pressure were included as covariates.

Results: Total 1,661 patients were enrolled. The lowest education level was independently associated with LVH (adjusted odds ratio [OR] 1.75, 95% confidence interval [CI] 1.26-2.42, *P*=0.001), higher baPWV (adjusted OR 1.54, 95% CI 1.09-2.17, *P*=0.014) and anemia (adjusted OR 1.559, 95% CI 1.11-2.20, *P*=0.011). The lowest monthly income was independently associated with LVH (adjusted OR 1.48, 95% CI 1.03-2.12, *P*=0.034), but not with anemia or higher baPWV. Neither education attainment nor income level showed a significant relationship with CCS.

Conclusions: In the CKD population, lower SES defined by education attainment exhibited a significant association with LVH, arterial stiffness, and anemia, while monthly income was associated with only LVH. Further efforts are warranted to improve the outcomes for CKD patients in the lower SES.

SA-PO910

Association of Comorbidity with Late Nephrology Referral - A Population-Based Study Ming-Yen Lin, Yiwen Chiu, TengHui Huang, Huei-Lan Lee, Shang-Jyh Hwang. *Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Kaohsiung, NA, Taiwan.*

Background: Timely referral to nephrology can ensure adequate care, reduce mortality and medical expenses in patient with chronic kidney disease. However, factors associated with timely nephrology referral are not systematically explored. We hypotheses patient's comorbidity can contribute to timing of nephrology referral.

Methods: One retrospective population-base cohort study was conducted to include patient newly underwent long-term dialysis from 2000 to 2008 year through Taiwan National Health Insurance Research Databases. The early referral (ER) and late referral group (LR) were defined as patients who were referred to a nephrologist more than or less than half year prior to dialysis initiation, respectively. The suggested 29 comorbidities by previous study for claim data within three years before dialysis were applied for these patients.

Results: A total of 24,846 (38.1%) patients and 40,442 (61.9%) patients were ER and LR group. A proportion of ≥3 comorbidities was higher in ER group than in LR group (57.3% vs 50.8%, p<0.001). In multiple logistic regression adjusting age, sex, insurance amount, urbanization, and various comorbidities demonstrated that patients with alcohol misuse (odds ratio 1.23, 95% confidence interval 1.06-1.43), asthma (1.12, 1.03-1.21), cancer with metastatic (1.26, 1.03-1.54), chronic heart failure (1.19, 1.14-1.23), dementia (1.30, 1.15-1.47), and stroke or transient ischemic attack (1.07, 1.02-1.13) were more likely to have late nephrology referral than those without. However, patients with pain (0.82, 0.73-0.91), chronic viral hepatitis B (0.63, 0.52-0.76), depression (0.78, 0.72-0.86), hypertension (0.53, 0.50-0.55), hypothyroidism (0.71, 0.62-0.81), irritable bowel syndrome (0.80, 0.72-0.88), peptic ulcer disease (0.89, 0.85-0.93), psoriasis (0.77, 0.62-0.95), severe constipation (0.84, 0.80-0.88) were negative associated with late nephrology referral.

Conclusions: Various comorbidity in patient with chronic kidney disease determines the timing of nephrology referral. However, the complex relationship between comorbidity and adequate pre-dialysis care needs further study.

SA-PO911

Healthcare Cost Rises Exponentially by Stage of Chronic Kidney Disease Ladan Golestaneh,[1] Paula J. Alvarez,[2] Nancy Reaven,[3] Susan Funk,[3] Karen J. Mcgaughey,[4] Cristine A. Sproles,[2] Wade Benton,[2] Macaulay A. Onuigbo.[5] *[1]Albert Einstein College of Medicine; [2]Relypsa, Inc; [3]Strategic Health Resources; [4]California Polytechnic State Univ; [5]Mayo Clinic, Rochester.*

Background: Prevalence of chronic kidney disease (CKD) is rising, but the economic impact of CKD progression on US health plans is not well known.

Methods: A large electronic medical record (EMR) database (Humedica) was queried to identify patients (pts) with renin-angiotensin-aldosterone system inhibitor prescription (Rx) history. Pts with 90+ days of ≥1 CKD stage (by GFR or diagnosis), plus CKD-free controls, were studied. Since the EMR database did not contain claims data, mean claims costs to US Commercial (Comm) and Medicare (Medi) plans for specific services and Rxs were obtained (OptumInsight) and applied to services and Rxs in EMR data of pts <65 and ≥65 years of age, respectively. Dialysis in ESRD, rarely reported in EMRs, was excluded. Annualized all-cause cost was computed per pt in each CKD stage, and ESRD, and summed. Payer-specific means were compared between CKD stages (Chi-square).

Results: 93,912 pts <65 years (41,737 with CKD/ESRD; 52,175 controls) and 81,829 pts ≥65 years (77,243 with CKD/ESRD; 4586 controls) were evaluated. Mean annualized all-cause cost per pt in 2016 USD rose exponentially from $7500 (no CKD) to $27,200 at Stage 3a and $77,000 by Stages 4-5 (Comm) and from $8100 (no CKD) to $20,500 at Stage 3a and $46,100 by Stages 4-5 (Medi); all p<0.0001 (figure). Mean cost per pt in ESRD pts, excluding dialysis was $122,000 for Comm and $87,300 for Medi plans (p<0.0001 vs Stages 4-5). In each stage, inpatient care was the largest contributor to total costs and its relative contribution increased as CKD progressed.

Conclusions: All-cause health plan costs rise exponentially at each stage of CKD progression for both Medi and Comm health plans in the US. ESRD patients cost more even without the burden of dialysis procedure expenses.

SA-PO912

Costs of Chronic Kidney Disease during Transitions between Stages of CKD among U.S. Veterans David W. Hutton,[1] Debabrata Ray,[1] Hal Morgenstern,[1] Anca Tilea,[1] Joel Segel,[1] Diane Steffick,[1] Aaron Pearson,[1] Michael J. Fischer,[2] Denise M. Hynes,[2] Chuan-Fen Liu,[2] Edward D. Siew,[2] Daniel F. Balkovetz,[2] Susan T. Crowley,[2] Rajiv Saran.[1] *[1]Univ of Michigan; [2]VA Healthcare System.*

Background: While CKD becomes more expensive with advancing stage, how costs change as individuals transition across stages is unknown. We sought to estimate cost of care for Veterans transitioning the CKD continuum to inform prioritization of VA CKD prevention efforts.

Methods: We analyzed existing data in the VA Renal Information System (VA REINS), an internal national data system that informs the VA about CKD in its population.An operational definition of a VA user (≥1contact with VA in 3yrs) was used. All users were categorized as CKD stages 3a-5 based on their outpatient eGFR and followed 2010-2011 to determine how the cost of care changed with CKD stage shift. Total annual inpatient, outpatient, and pharmacy costs were aggregated from VA internal cost accounting, external fee-based service, and linked Medicare payments to calculate VA spending on CKD as well as mean annual costs by CKD stage.

Results: In 2011, combined (VA + Medicare) aggregate cost for VA users with ≥1 eGFR<60 (n= 845,610) was over $18 billion. Average annual per patient (PP) costs increased by CKD stage: stage3a $17,742; stage3b $23,084; stage4 $33,564; stage5 $85,177. Among users whose CKD stage changed 2010 to 2011, worsening CKD conferred an increased cost; for those with improving CKD status a downward cost. For patients who died in 2011, the change in cost depended on their 2010 stage.

Figure1: Change in annual PP cost among VA users with CKD (2010-2011)

		CKD stage in 2011					
		3a	3b	4	5	ESRD	Dead
CKD stage in 2010	3a	**$1,650**	$5,170	$18,290	$32,220	$26,670	$7,360
	3b	-$570	**$2,450**	$8,070	$27,960	$23,900	$3,520
	4	-$8,200	-$1,550	**$2,970**	$12,010	$22,990	-$2,120
	5	-$16,790	-$17,070	-$7,150	**$1,620**	$5,070	-$31,190

Negative numbers = decreased cost, Positive numbers = increased cost

Conclusions: Total cost of caring for US veterans with CKD is high, and change in costs with shift in CKD stage has implications for gauging cost effectiveness of VA CKD prevention strategies.

SA-PO913

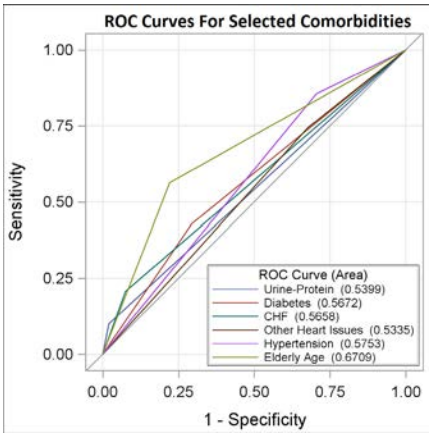
Billing Codes Are Not Reliable in the Detection, Staging, and Progression of Chronic Kidney Disease Kabir Jalal,[1] Edwin J. Anand,[2] Rocco C. Venuto,[2] Pradeep Arora.[3] *[1]Biostatistics, Univ at Buffalo, Amherst, NY; [2]Nephrology, Erie County Medical Center, Buffalo, NY; [3]Nephrology, Veterans Affairs, Buffalo, NY.*

Background: Billing codes are not only used for reimbursement, but are also used by administrators and investigators for population health management and therefore need to be reliable. The accuracy of administrative coding was studied, using Chronic Kidney Disease (CKD) as the condition of interest. Clinical progression was compared to progression assessed by coding changes.

Methods: Data from a large third party payer, with an average annual enrollment of 1.3 million, from 2007- 14. Patients with eGFR readings less than 60 for 2 months or having proteinuria were identified as CKD cases. ROC analysis examined the sensitivity/specificity of billing codes in capturing CKD. Analysis was stratified based on demographic and comorbid factors. The correlation of CKD severity data from billing codes with eGFR was analyzed. Longitudinal mixed model analysis identified rapid progressors (eGFR loss greater than 4 per year), and changes in coding were examined for disease progression.

Results: 38,857 CKD cases were identified. 46% were male and 54% were females. CKD stages 3, 4 and 5 were found in respectively 50, 28, and 9%. Billing codes identified

10,567 patients, giving a sensitivity of 27.19%.The specificity was 97%. With regards to severity, the accuracy of the codes for CKD stage 3 was 69.58%; stage 4, 46.14%; and stage 5, 46.77%. Changes in coding alone identified only 11.95% of rapid progressors.



Conclusions: 1. Inaccuracies in billing codes preclude use of this data for identifying patients with a disease of interest. 2. Administrative codes have poor sensitivity in the identification of patients with CKD, but are highly specific 3. Billing codes inaccurately identify rapid progressors 4. Physician education on accurate coding is crucial in the EHR era.

SA-PO914

Trends in the Timing of a Second GFR after a First GFR Lower than 60 in a Primary Care Setting Claudine T. Jurkovitz, Richard Caplan, Sarahfaye Heckler, James Thomas Laughery, Edward Ewen. *Christiana Care Health System, Newark, DE.*

Background: The KDOQI guidelines recommend 2 measurements of glomerular filtration rate (GFR) <60 mL/min/1.73m^2 at 3 months intervals or more to establish the diagnosis of chronic kidney disease (CKD). We examined the timeline of measuring a second GFR in an outpatient primary care setting.

Methods: We used the CKD-Epi equation to assess GFR from the serum creatinine records of patients seen in a large network of primary care offices from 2007 to 2015. Our study population was defined as patients 18 or older with at least one GFR<60. We excluded patients whose first GFR was <15. Followup began at the time of the first GFR<60. We calculated the time interval between the first GFR<60 and the second GFR and stratified the patients according to their first GFR into 3 categories (GFR 15-<30; 30-<45; 45-<60). We used Analysis of Variance test for linear contrast to assess the trend of the time interval according to GFR categories and the Cochran-Mantel-Haenszel for linear association for the trend in the proportion of patients who had a second GFR within 3 months, between 3-12 months, and more than 12 months after the first GFR.

Results: A total of 13,320 patients had at least one GFR<60, 1,880 patients who did not have any followup serum creatinine and 353 with GFR<15 were excluded. Of 11,087 patients, 62% were female, 81% white, 18% black, 6% had a first GFR 15-<30, 20% had a first GFR 30-<45 and 74% a first GFR 45-<60. Mean age was 69. Overall, 39% had a second GFR within 3 months, 44% between 3 and 12 months, and 17% after 12 months. Among patients with first GFR 15-<30, 30-<45, 45-<60 respectively, the median time intervals between GFR measurements were 82, 105, and 140 days (p <0.0001); 52%, 46% and 36% had a second measurement within 3 months, 37%, 40% and 46% had a measurement between 3 and 12 months, and 11%, 14% and 18% had a measurement after 12 months (p<0.0001).

Conclusions: In a primary care setting, the timing of the second GFR depends primarily on the level of the first GFR. It is likely that at low levels of GFR, physicians are concerned about ruling out acute kidney injury and choose to re-measure serum creatinine closer to the first measurement.

SA-PO915

Using Primary Care Database to Understand the Generalizability of the European QUALity (EQUAL) Study in the UK Anirudh Rao,[1,2] Stephanie J. MacNeill,[1,2] Yoav Ben-Shlomo,[2] Fergus J. Caskey.[1,2] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Univ of Bristol, Bristol, United Kingdom; [3]On Behalf of EQUAL Investigators.*

Background: The EQUAL Study is an ERA-EDTA funded cohort study looking at the timing of dialysis start in elderly patients with advanced CKD. Most observational studies are likely to recruit a selected sub-sample of eligible participants which could affect the generalizability. The aims of the study were 1.Quantify selection biases by identifying factors that were associated with participation/non-participation in EQUAL 2.Describe differences in outcomes between patients participating & not participating in EQUAL.

Methods: EQUAL data(UK) from first 250 patients was compared to patients identified from The Health Improvement Network(THIN) database, under a nephrologist meeting EQUAL inclusion criteria(2,464). Descriptive statistics and regression models were used to examine differences in baseline demographics, clinical & laboratory markers, hospitalization and mortality between the two cohorts.

Results: In a multivariable logistic model, older patients(every 5-year age band,OR 0.7, 95%CI 0.6-0.8), women(OR 0.6, 95%CI 0.5-0.9); those with cardiovascular disease(OR 0.6, 95%CI 0.4-0.9), vascular disease(OR 0.5, 95%CI 0.3-0.9) & rheumatological disease(OR 0.3, 95%CI 0.2-0.7) were less likely to be in EQUAL cohort. Greater proportion of patients started renal replacement therapy in EQUAL in the first year after reaching eGFR ≤20 mls/min when compared to THIN cohort(8% vs 2%,p<0.001). Patients in THIN had worse outcomes compared to EQUAL cohort; 7% vs 1.6%(p=0.001) required ≥4 hospitalisations in the first year and relative mortality was increased(HR 1.7, 95%CI 1.1-2.6,p=0.02),this was moderately attenuated after adjustment for various confounders(HR 1.5, 95%CI 0.92.3,p=0.10).

Conclusions: This study provides empirical evidence regarding factors associated with participation in an cohort study of elderly people with advanced CKD: older and sicker patients were less likely to be recruited and this was supported by follow up data on health outcomes. This selection pattern is likely in most observational studies of chronic diseases and needs consideration when generalizing the results to a wider population.

SA-PO916

In Their Own Words: Symptoms and Impacts on the Lives of Patients with Anemia Associated with Chronic Kidney Disease Vanja Sikirica,[1] Susan Mathias,[2] Steven I. Blum,[1] Kirsten L. Johansen.[3] *[1]GlaxoSmithKline, Afghanistan; [2]Roivant Sciences; [3]Nossuli Research.*

Background: We conducted qualitative interviews with patients with anemia associated with Chronic Kidney Disease (aCKD) to identify and explore the most relevant symptoms and impacts from the patient's perspective.

Methods: One-on-one interviews were conducted with aCKD patients recruited from dialysis centers in the US. Patients were ≥18 years of age, with a confirmed diagnosis of CKD, and hemoglobin (Hgb) level <12.0 g/dL. Patients receiving dialysis (≥3 times/week) also: 1) received an erythropoietin stimulating agent (ESA) for ≥12 weeks; or 2) initiated dialysis within the past 4 weeks. Non-dialysis aCKD patients had to either: 1) have been receiving an ESA for ≥12 weeks; or 2) not within the prior 12 weeks. Protocol was IRB approved; all patients provided consent.

Results: Twenty-eight aCKD patients (mean age 60±17.2) were interviewed. Most were female (75%), and receiving treatment with an ESA (82%) or IV Iron (54%). Most were CKD Stage 5 or receiving dialysis (68%). Mean Hgb was 9.6 g/dL (SD=0.9, range: 7.2-11.5 g/dL). Patients with aCKD reported (spontaneously or probed) a range of symptoms and related impacts, which were mostly similar across the different sub-groups (dialysis or ESA status or Hgb level). Frequently mentioned concerns included: difficulty remembering things (n=12 out of the 12 patients that were asked; 100%); feeling weak/lacking strength (n=10/10 patients with Hgb <10g/dL; 100%); feeling tired/exhausted/fatigued (n=27/28; 96%); interference with daily activities (n=19/20; 95%); shortness of breath (n=16/17; 94%); GI symptoms (n=11/15; 73%); difficulty sleeping (n=10/16; 63%); emotional (n=10/16; 63%) and social impacts (n=9/21; 43%); and difficulty concentrating (n=9/24; 38%). Non-dialysis patients were more likely to have difficulty remembering things (n=5/9; 56% vs n=7/15; 47%) or difficulty sleeping (n=5/7; 71% vs n=5/9; 56%).

Conclusions: Regardless of treatment with dialysis and ESAs, aCKD patients experienced a wide range of symptoms and impacts. Some differences were noted between patients based on dialysis status and Hgb level. This study captures the burden and unmet needs associated with aCKD.

SA-PO917

Development of a Patient Reported Outcome Symptoms Measure for Use with Patients with Anemia Associated with Chronic Kidney Disease Susan Mathias,[1] Steven I. Blum,[2] Vanja Sikirica,[2] Kirsten L. Johansen.[3] *[1]Health Outcomes Solutions, Winter Park, FL; [2]GlaxoSmithKline, Collegeville, PA; [3]Univ of California, San Francisco, CA.*

Background: To develop a new disease-specific patient-reported outcome (PRO) measure to capture relevant symptoms and impacts of anemia associated with Chronic Kidney Disease (aCKD).

Methods: Development included an iterative approach following best practices for PRO development. An initial literature review was conducted to identify the existence of relevant PRO measures and concepts to explore during qualitative research with patients with aCKD (≥18 years old; hemoglobin <12 g/dL). Concept elicitation (CE) interviews were conducted using an Interview Guide developed specifically for this study to identify symptoms and impacts associated with aCKD reported with high frequency. Based on analyses of these transcripts, draft measures were developed, further evaluated and refined based on clinical input and cognitive debriefing (CD) interviews with patients. The study received IRB approval; all patients provided informed consent.

Results: Eight dialysis [5 hemodialysis (HD); 3 peritoneal dialysis (PD)] and 6 non-dialysis (ND) patients (71% female; mean age 65±18) completed the initial CE interviews. Interview transcripts were coded and analyzed which led to the development of draft questions to assess the most relevant symptoms and impacts. Draft questions were subsequently revised in an iterative fashion, based on CD interviews with an additional 22 aCKD patients (9 HD, 3 PD and 10 ND; 68% female; mean age 61±17), and clinician input. The final questionnaire, the Chronic Kidney Disease and Anemia Questionnaire (CKD-AQ), containing 23 items, assesses severity and frequency of the most relevant

symptoms and impacts identified by aCKD patients, including: tiredness, energy levels, weakness, shortness of breath, chest pain, and impacts on cognition and daily activities. The CKD-AQ has been translated into 72 languages for use in future studies.

Conclusions: The CKD-AQ is a new PRO measure which captures frequency and severity of the most relevant symptoms and impacts associated with CKD-related anemia. Future studies will evaluate its psychometric properties.

Funding: Pharmaceutical Company Support - This study was funded by GlaxoSmithKline

SA-PO918

Adherence to Anemia Management Guidelines among Kidney Transplant Candidates Meteb M. AlBugami,[1,2] Fahad Eid Alotaibe,[1,2] Khalid Bel'eed-Akkari.[1] *[1]Multi-Organ Transplant Center, King Fahad Specialist Hospital, Dammam, Saudi Arabia; [2]Dept of Internal Medicine, College of Medicine, Univ of Dammam, Dammam, Saudi Arabia.*

Background: Anemia is one of the major comorbidities of chronic kidney disease (CKD). It is linked to cardiovascular disease (CVD), and low quality of life. Achieving target levels of hemoglobin requires replenishing iron stores and supplemental erythropoiesis stimulating agents. Overshooting could happen and is associated with unwanted complications. This study aimed to measure the extent to which kidney transplant (KT) candidates complied with the National Saudi Anemia Guidelines.

Methods: All potential KT recipients evaluated at the Kidney and Pancreas Transplant Department at King Fahad Specialist Hospital-Dammam, between January 2009 and December 2012 were reviewed. Data were collected from electronic database. Blood samples were obtained during patients' initial visit to the pre-transplant evaluation clinic. For patients on hemodialysis, pre-dialysis samples were obtained.

Results: A total of 678 candidates were evaluated, with a mean age of 43±13.7 years, and 396 (58%) of the subjects were males. Data were missing in 81 (12%) of the cases. Mean hemoglobin level was 11.7±1.8 gm/dL, and 20% achieved the guideline target. Median ferritin level was 260 ng/mL (IQR 111 – 519), and 26% had level more than 500 ng/mL. Mean transferrin saturation 30±19%, and 30% had level less than 20%. 347 (58%) subjects had hemoglobin 11.5 gm/dL and above.

Conclusions: Substantial proportion of KT candidates referred for pre-transplant evaluation failed to meet the national Saudi guideline targets of anaemia management. moreover, overshooting target hemoglobin is common. This should prompt us to place greater and more rigorous emphasis on adherence measures to the guidelines in order to improve the cardiovascular risk and quality of life.

SA-PO919

Geographic Variation in Access among Adults with Kidney Disease: Evidence from Medical Expenditure Panel Survey, 2002-2011 Mukoso N. Ozieh,[1] Kinfe Gebreegziabher Bishu,[2] Rebekah J. Walker,[2] Jennifer A. Campbell,[2] Leonard Egede.[2] *[1]Nephrology, MUSC, Charleston, SC; [2]Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.*

Background: To understand geographic variation in access to care over time in patients with kidney disease.

Methods: We analyzed 4,404 (weighted sample of 4,251,129) adults with kidney disease from the Medical Expenditure Panel Survey over 10 years. Three dependent variables were created to investigate variation in access: usual source of care (USC), overall medical access to care, which took into account usual source of care, ability to get care, and delay in care, and prescription access, which took into account ability to get prescriptions and delay in getting prescriptions. Multiple logistic regression was used with geographic region as the main independent variable, adjusting for relevant covariates.

Results: Compared to the Northeast region, adults living in the Midwest (OR=0.56; 95% CI 0.35–0.89), South (OR=0.48; 95% CI 0.32–0.72) and West (OR=0.53; 95% CI 0.34–0.84) had significantly lower odds of reporting a USC. For the combined access measure, compared to Northeast, adults in Midwest (OR=0.60; 95% CI 0.40–0.88), South (OR=0.62; 95% CI 0.44–0.88) and West (OR=0.50; 95% CI 0.34–0.72) had significantly lower odds of medical access to care. Region was not significantly associated with the odds of having prescription access, though a significant increase in prescription access was observed over time.

Conclusions: Geographic variation in access to care among adults with kidney disease exists independent of income, education, insurance and comorbid conditions, with those in the South least likely to have a USC and those in the West least likely to have overall access to care.

SA-PO920

Factors Shaping the CKD Awareness among the University Nephrology Patients Emma Rebecca Segal,[1] Colin A. Hinkamp,[1] Xuerong Wen,[1] Ashutosh M. Shukla.[1,2] *[1]Medicine, Univ of Florida; [2]NF/SG VHS, Gainesville, FL.*

Background: CKD awareness is known to be poor among patients with CKD. Factors influencing this are not well understood and are a major hindrance to interventional approaches.

Methods: We conducted a cross sectional study in a university nephrology practice, aimed to assess the effects of patient related factors on their CKD awareness. After consent, subjects were administered a survey packet that included assessment of demographics, health literacy (REALM-SF), KD-QoL, and Charlston Comorbidity Index. A novel 45-item survey adjusted for a grade 5 literacy was developed after initial checks for reproducibility, to assess CKD knowledge.

Results: Preliminary findings of an ongoing study with the first 108 enrollees is presented. Participants were 67% Caucasians, 44% women, 60±17 years, had eGFR of 36±20 ml/min/1.73m^2, and renal care for 5.3±5.9 years. Majority lived in a two-person household (48%) with household income (57.7%) below the median for general population. Subjects displayed poor matrices of CKD awareness (19.6 ± 9.2, Range: 0-36). Univariate analyses showed CKD awareness had significant zero phase correlations with age (ρ=-0.33, P=0.0004), eGFR (ρ=-0.19, P=0.04), duration of renal care (ρ=0.21, P=0.03), physical composite of QoL (ρ=0.28, P=0.006), health literacy (ρ=0.18, P=0.06), and household income (ρ=0.35, p=0.0002). The multivariate model after Mallow's Cp selection showed: Awareness is positively influenced by household income, physical QoL and comorbidities but is negatively influenced by age and severity of renal dysfunction.

	Significant Risk Factors	Estimates ± SE	p
CKD Awareness (transformed)	KDQoL-Physical	6.4 ± 2.7	0.02
	eGFR (transformed)	-39 ± 17	0.03
	Charlston Comorbidity Index	36 ± 14	0.01
	REALM score	40 ± 26	0.13
	Household Income	235 ± 58	0.0001
	R^2	0.43	

Conclusions: The results will provide a preliminary validation for our CKD questionnaire, showing significant correlations between CKD awareness and known parameters of health awareness. Ongoing prospective evaluations will be needed to determine if this correlates with hard outcomes including dialysis modality choice, and future importance of educational interventions.

SA-PO921

A Quality Improvement Project to Increase Transplant Referrals in Chronic Kidney Disease Patients in Nephrology Fellows' Continuity Clinic Lori- Ann M. Fisher, Haldane Porteous, Daphne Harrington Knicely. *Nephrology, Johns Hopkins Univ, Baltimore, MD.*

Background: Kidney transplantation remains the optimal treatment for patients with advanced chronic kidney disease (CKD) and end-stage renal disease (ESRD). Pre-emptive and/or early renal transplantation is associated with optimal outcomes in terms of patient and graft survival. In the Kidney Disease Improving Global Outcomes (KDIGO) guidelines for the management of CKD, living donor pre-emptive renal transplant in adults should be considered when the GFR < 20 mL/min/1.73m^2 and there is progressive and irreversible CKD over the preceding 6-12 months. The Kidney Disease Outcomes Quality Initiative (KDOQI) guidelines recommend that patients with an eGFR < 30 mL/min/1.73m^2 be prepared for dialysis and transplantation. The aim of this quality improvement project was therefore to increase the number of transplant referrals in patients with an eGFR < 20mL/min/1.73 m2 to more than 80% in the nephrology fellows' continuity clinic.

Methods: Charts of patients with CKD stages G3a to G5 in the nephrology fellows' continuity clinic at Johns Hopkins Bayview Medical Center from May 2015 to August 2015 were audited by peer review. The data was obtained from review of the clinic notes. A transplant documentation template or "smart phrase" was made available in the electronic medical record (EMR) for use in all patients with CKD stage G4 or greater. It was implemented into use in November 2015. Reminders were sent to the nephrology fellows every month for continued use of the transplant smart phrase. Charts were audited from November 2015 to January 2016.

Results: A total of 208 charts were reviewed pre-intervention, and 118 charts were reviewed post-intervention. Of the pre-intervention charts, 43 were seen with an eGFR < 20 mL/min/1.73m^2 versus 23 in the post-intervention charts. The total number of transplant referrals increased from 21% to 48% after the intervention.

Conclusions: Simple documentation reminders or smart phrases in the EMR may improve overall compliance with transplant referral and improve coordination in care as exemplified in this quality improvement project. This model could be applied to other CKD quality measures.

SA-PO922

Acceptability of a Multi-Level Intervention to Improve Health Outcomes among Safety-Net Patients with Chronic Kidney Disease Adrienne Strait, Alexandra Velasquez, Karen Leong, Neil R. Powe, Adriana Najmabadi, Delphine S. Tuot. *Univ of California, San Francisco, San Francisco, CA.*

Background: The Kidney Awareness Registry and Education (KARE) trial tested the impact of a multi-level intervention to improve blood pressure control among low-income patients with CKD. KARE consisted of a primary care CKD Registry with point-of-care provider notifications and quarterly feedback on care provision and a patient CKD self-management support (CKD-SMS) program that included low literacy educational materials, automated telephone administered self-management (ATSM) modules, and live telephone health coaching. We explored acceptability of KARE interventions among providers and patients.

Methods: At trial conclusion, we surveyed participating primary care providers (PCPs) and conducted focus groups (n=4) among non-PCP staff to assess acceptability of the registry. We conducted 8 focus groups with English and Spanish-speaking patients to evaluate their experience with the CKD-SMS program. Focus group transcripts were analyzed using grounded theory analysis.

Results: Nearly 60% of PCPs completed the survey (n=61/105). Most (93.8%) PCPs believed the point-of-care notifications benefited clinic workflow and agreed that quarterly feedback enhanced their ability to identify (88.9%) and manage (72.2%) CKD. Staff focus groups confirmed that point-of-care notifications were helpful to order overdue diagnostic studies (i.e. microalbuminuria) and noted that better communication among health team members would enhance the registry's uptake. Patient focus groups suggested the ATSM system was impersonal, though easy to use; that frequent (i.e., weekly) automated calls were preferred to reinforce self-management behaviors; that content should include more dietary advice; and that the convenience of telephone (vs. in-person) health coaching was a program strength. There were diverse opinions about adding mobile text messages to the program but no desire to include Skype functionality.

Conclusions: A registry is acceptable to healthcare provider teams and has the potential to enhance identification and management of CKD in safety-net primary care clinics. A telephone based CKD-SMS program is appreciated by low-income patients.

Funding: NIDDK Support

SA-PO923

Assessing Literacy Skills Related to NSAID Medication Labeling in Primary Care Amy Barton Pai,[1] Nelson Polanco,[2] Mara Garfinkel,[2] Verina Mansour.[2] *[1]Univ of Michigan College of Pharmacy, Ann Arbor, MI; [2]Albany College of Pharmacy and Health Sciences, Albany, NY.*

Background: In primary care, NSAID prescriptions account for up to 20% of prescriptions. Both prescription (Rx) and OTC NSAIDs have medication guides and/or labeling that vaguely describe kidney risks of these products. The purpose of this study was to evaluate the performance of a medication label health literacy tool focused on NSAIDs (MedLit-NSAID).

Methods: The study recruited patients from a large primary care practice in upstate NY. The MedLit NSAID questions assess locating, calculating integrating literacy. Two MedLit-NSAID questions query participants regarding kidney risks using the FDA medication guide (for Rx) and the OTC label to answer the questions. The Newest Vital Sign (NVS) health literacy assessment tool was also administered for comparison. Participants scores were analyzed in the following strata: male/female, age <65 year, age > 65 years, eGFR > or < 60 mL/min/1.73m^2. Data on age, ethnicity, education, number and management of medications was collected.

Results: The study enrolled 145 patients (mean (SD)) age 56 (15) with the majority being white and self-reporting they manage their own medications. Analysis of total MedLit-NSAID scores in the gender, age and eGFR strata showed that male participants and those with eGFR < 60 had significantly lower scores ($p<0.05$ for all comparisons). There was no difference in total MedLit-NSAID scores between participants aged < or > 65 years. A higher proportion of participants with eGFR < 60 vs. eGFR > 60 had some or completed high school (47% vs. 24%, respectively). Participants with eGFR < 60 scored similarly on the Rx question related to NSAIDs, however 61% incorrectly answered the OTC question compared to only 11% with eGFR > 60 ($p<0.01$). The total NVS score was positively correlated with total MedLit-NSAID score (r=0.52).

Conclusions: There is variability in literacy related to NSAID medication labeling in the primary care setting. Literacy among those with eGFR < 60 regarding NSAIDs appears to be poor compared to people with intact kidney function. Labeling for NSAIDs should be re-evaluated and better educational initiatives should be developed.

Funding: Other U.S. Government Support

SA-PO924

Factors Affecting Medication Management among Patients with Chronic Kidney Disease Katie E. Cardone,[1] Sabrina Daoui,[2] Rachid Daoui,[2] Kirsten M. Donato,[1] Wendy M. Parker.[1] *[1]Albany College of Pharmacy and Health Sciences, Albany, NY; [2]Div of Nephrology, Saratoga Hospital, Saratoga Springs, NY.*

Background: Patients with chronic kidney disease (CKD) have complex medication regimens and are at high risk for medication-related problems including non-adherence. Effective medication management strategies are required to optimize outpatient treatment of CKD and/or its underlying conditions. Few data exist regarding medication management in patients with CKD. The primary objective of this study was to identify factors affecting medication management skills and strategies in CKD.

Methods: Patients of an outpatient nephrology office were surveyed during regularly-scheduled appointments. Patients completed a series of validated survey tools, including the Short Test of Functional Health Literacy in Adults (S-TOFHLA), the Medication Adherence Rating Scale (MARS), and the Self-Efficacy for Appropriate Medication Use Scale (SEAMS). Additional questions about medication management strategies and demographic factors were also included. Correlations between demographic, health literacy and performance on medication management scales were performed using SAS.

Results: Twenty-nine patients participated. Most participants had "adequate" health literacy (S-TOFHLA). N=26 (90%) participants were adherent based on MARS and most were highly confident in their abilities to manage medications (SEAMS). Despite indicating they were organized and managing their care appropriately, nearly half (48%) indicated they forget to take their medications at times and only half (56%) indicated they ask a pharmacist questions on their medications. Aging and female gender were positively associated with use of a pill box.

Conclusions: Lessons learned from this highly literate patient population highlight opportunities to improve medication management and adherence. Medication management strategies should be explored in more diverse cohorts of patients with CKD.

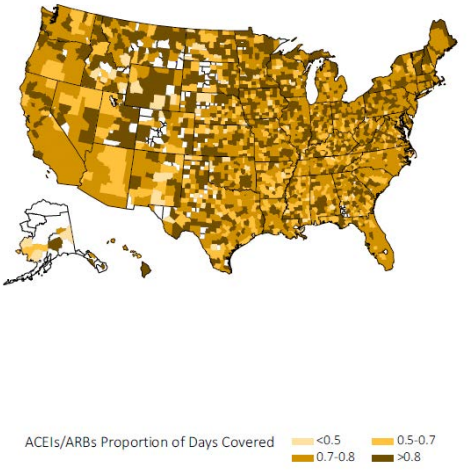
SA-PO925

Environmental and Individual Predictors of Medication Adherence among Elderly Patients with Hypertension and Chronic Kidney Disease (CKD): A Geospatial Approach Yun Han,[1] Steven Erickson,[1] R. Hirth,[1] Rajiv Saran,[1] Rajesh Balkrishnan.[2] *[1]U of Michigan; [2]U of Virginia.*

Background: Few studies have assessed geographical variation in medication adherence across different regions. This study aimed to explore local variations in medication adherence and examine environmental and individual influences on adherence to ACEIs and ARBs among elderly hypertensive CKD patients in the United States.

Methods: This retrospective cohort study utilized a linked dataset from Medicare 5% sample claim data (2006-2013), American Community Survey 5-Year Data (2005-2009) and the Primary Care Service Area (PCSA) data (2007). We included hypertensive CKD patients who were aged 67 and above, continuously enrolled in Medicare Part D and had at least one ACEIs/ARBs pharmacy claim. Patients' 1-year adherence to ACEIs/ARBs was measured using Proportion of Days Covered (PDC), and then aggregated at county level. The geographically weighted regression and the linear mixed-effects models were applied to investigate the relationship between environmental, individual factors and medication adherence.

Results: Significant spatial autocorrelation was observed in ACEIs/ARBs adherence, as the West North Central and New England region had higher adherence rate than the East South Central and West South Central regions. Residing in Medically Underserved Areas (MUAs) and a higher deprivation score were related with lower average PDC. Patients, who were female, white, enrolled in Part D Low-income-Subsidy program, having diabetes and atrial fibrillation were associated with better adherence.



Conclusions: Medication adherence is geographically differentiated across the United States. Residing in MUAs, county deprivation score, and having Part D LIS are potentially modifiable factors that could improve medication adherence. Such factors may be helpful in the design of interventions focused on improving patient outcomes.

Receipt of Nephrology Care and Clinical Outcomes among Veterans with Advanced Chronic Kidney Disease Enrica Fung,[1] Tara I. Chang,[1] Glenn Matthew Chertow,[1] I-Chun Thomas,[1] Steven M. Asch,[1,2] Manjula Kurella Tamura.[1,2] *[1]Stanford Univ; [2]Palo Alto VA.*

Background: Clinical practice guidelines recommend referral to nephrology once estimated glomerular filtration rate falls (eGFR) below 30 ml/min/1.73m^2; however evidence for benefits of nephrology care remains conflicting.

Methods: We assembled a national cohort of veterans with advanced CKD, defined by anoutpatient eGFR ≤25 ml/min/1.73m^2 between January 1, 2010 to December 31, 2010 and a prior eGFR <60 ml/min/1.73m^2, using administrative and laboratory data from the Department of Veterans Health Affairs and the United States Renal Data System. We used landmark analysis to determine the associations among the receipt of outpatient nephrology care over a 12-month period, survival and progression to ESRD, defined as receipt of dialysis or kidney transplantation.

Results: Of 11,489 patients included in the cohort, 37.2% received nephrology care. Older age, prior hospitalization, more than 4 outpatient visits to non-nephrology providers, heart failure, dementia, cancer, depression, post-traumatic stress disorder, and rapidly declining kidney function were independently associated with the absence of nephrology care. Over a mean follow up of 1.8 years, 17.0% of patients died and 10.1% progressed to ESRD. In models adjusting for demographics, comorbidities, and trajectory of kidney function, nephrology care was associated with a lower risk for death (HR 0.85, 95% CI 0.78-0.95) but a higher risk for ESRD (HR 1.21, 95% CI 1.05-1.40). Patients who received nephrology care were more likely to have serum phosphate within recommended ranges, but less likely to have blood pressure within recommended ranges.

Conclusions: Among patients with advanced CKD, nephrology care was associated with lower mortality but did not dampen the risk for progression to ESRD.

International Variations in the Frequency of the Types of Patient-Physician Contact for CKD Patients: Early Findings from CKDopps

Elodie Speyer,[1] Benedicte Stengel,[2] Koichi Asahi,[3] Brian Bieber,[1] Antonio Alberto Lopes,[4] Ronald L. Pisoni,[1] Nidhi Sukul,[5] Francesca Tentori.[1,6] *[1]Arbor Research, Ann Arbor, MI; [2]UMRS 1018, Paris Sud Univ, Villejuif, France; [3]Fukushima Medical Univ, Fukushima, Japan; [4]Faculdade de Medicina da Bahia, Univ Federal da Bahia, Salvador, Brazil; [5]Dept of Nephrology, Univ of Michigan, Ann Arbor, MI; [6]Vanderbilt Univ, Nashville, TN.*

Background: Regular patient-physician contact by multiple caregivers is recommended in CKD to manage complications and improve outcomes.

Methods: CKDopps is an ongoing prospective cohort study of patients with stage 3-5 CKD from national samples of nephrology clinics. The frequency of visits to different health care providers during the year prior the enrollment was self-reported by patients and described by country [Brazil (BR), France (FR), the United States (US)], CKD stage, and patient's characteristics.

Results: As of May 2016, 3496 patients (mean age=67.1 (SD 12.9); 61% male; 41% diabetics) completed a questionnaire (67% of enrolled patients). 31% of patients in BR reported that they had not seen a general practitioner in the year prior the enrollment (vs. 2-8%), while not seeing a cardiologist was more common in the US (49% vs. 32-37%). Although the proportion of patients having not seen a dietician or social worker decreased with CKD progression, it still remained high in CKD Stage 5 (59-75%, and 77-94%, respectively). Among diabetics, 32-46% according to the country, reported having not seen a diabetes doctor, and 43% in BR had not seen an ophthalmologist (vs 13-17%)**.** Practices were similar among men and women and across age groups.

Table1: Patients reporting to have not seen the following health care professionals during the past year, by country, CKD stage and diabetes status

	Brazil				France				United States			
	Stage 3-5	Stage 3	Stage 4	Stage 5	Stage 3-5	Stage 3	Stage 4	Stage 5	Stage 3-5	Stage 3	Stage 4	Stage 5
N patients	405	139	190	76	2596	1416	1073	107	495	195	247	53
Health professional												
Internist/General Practitioner	31%	43%	23%	25%	2%	2%	3%	3%	8%	10%	6%	9%
Heart doctor	37%	37%	34%	45%	32%	33%	32%	26%	49%	51%	52%	31%
Dietician	59%	60%	62%	51%	75%	77%	74%	66%	73%	81%	70%	60%
Social Worker	77%	81%	75%	75%	94%	95%	92%	91%	90%	95%	89%	80%
Among diabetics (n=1,409)												
Diabetes doctor	42%	48%	39%	50%	32%	28%	37%	44%	46%	51%	50%	40%
Foot doctor	91%	93%	91%	94%	80%	78%	81%	91%	53%	97%	51%	46%
Eye doctor (Ophthalmologist)	43%	47%	39%	47%	13%	10%	16%	19%	17%	20%	15%	17%
Dietician	61%	56%	66%	57%	68%	69%	67%	56%	71%	78%	66%	63%

Conclusions: These early findings based on patient self-report suggest an underuse of specialist care for advanced CKD patients internationally. Additional work is needed to gain further understanding of specialist use, integration of care, and association with outcomes, which may eventually inform optimal practice.

Geography, Life Expectancy, and Age of Mortality in Dialysis Patients

Peiran Yu, Yue Jiao, Marta Reviriego-Mendoza, John W. Larkin, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America.*

Background: Dialysis patients (pts) have an estimated life expectancy ranging from 30 to >50% lower than the general population depending on age (USRDS 2015 Annual Data Report). We aimed to compare the age of mortality in dialysis pts in differing geographies versus the life expectancy in the general population.

Methods: We analyzed data from the Fresenius Medical Care Knowledge Center on all pts with records of a death date, birthday and home zip code. Pts were assigned to a commuting zone according to their zip code, and the largest 50 commuting zones were selected based on regions with the largest number of female and male pts. Average age of death, geographical location, and the life expectancies of the general population within those locations were calculated. Income levels were adjusted to represent the dialysis population using an estimated income assignment in weighted quartiles: 40% quartile 1 (lowest income), 30% quartile 2, 25% quartile 3, and 5% quartile 4 (highest income).

Results: We studied data from 193,630 pts who died (92,309 female & 101,321 male). We observed that the age of death in dialysis pts to life expectancy in the general population was distinguishable between females and males overall and in the differing geographic commuting zones (individual points). Dialysis pts had a life expectancy about 12-20 years shorter than those in the general population in differing geographies (Figure 1). The age of death was positively correlated to life expectancies in the general population for females (correlation coefficient (r) =0.560) and males (r =0.667).

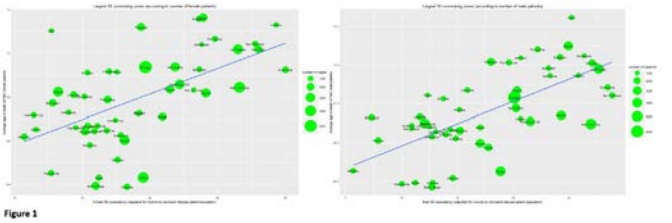

Figure 1

Conclusions: Our findings illustrate that age of mortality in dialysis pts is lower than the life expectancies in the general population, and vary considerably for differing geographies in a gender specific manner. These observations may be important to consider how to improve longevity of dialysis pt population.

Family History of Kidney Disease and Diabetic Nephropathy among Remote Canadian Indigenous Peoples - Results from the FINISHED Screen/Triage/Treat Project

Stephanee Ophey,[1] Paul Komenda,[1] Thomas W. Ferguson,[1] Navdeep Tangri,[1] Caroline D. Chartrand,[2] Lorraine L. Mcleod,[2] Audrey Gordon,[1] Allison Dart,[1] Claudio Rigatto,[1] Barry Ad Lavallee.[1,2] *[1]Max Rady College of Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Diabetes Integration Project, Winnipeg, MB, Canada.*

Background: Indigenous Canadians have a high prevalence of Chronic Kidney Disease (CKD). We aimed to determine the relationship between family history of kidney disease and current kidney disease status among remote Canadian Indigenous. We accomplished this using a subset of data from The First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) project, a CKD screening initiative in remote First Nations communities in Manitoba, Canada between 2012 and 2015.

Methods: An interdisciplinary team screened for CKD using both urine-albumin-to-creatinine ratio (ACR) and eGFR in 630 adults from 4 remote First Nations communities. Our primary outcome of interest was the association between reported family history of kidney disease and current diabetic nephropathy (defined as hemoglobin A1C $\geq$ 6.5% and urine ACR $\geq$ 3mg/mmol or eGFR < 60 ml/min/1.73m^2) or non-diabetic nephropathy (defined as elevated urine ACR or low eGFR without elevated hemoglobin A1C).

Results: 402 of the 587 respondents provided information on family history of kidney disease (first degree relatives and grandparents). Of those with a reported family history of kidney disease (n = 156), 31.4% were found to have diabetic nephropathy, in comparison to 21.1% in those with no family history (p = 0.02). No statistically significant relationship was observed between family history and presence of non-diabetic nephropathy (13.5 vs. 14.2%; p=0.83).

Conclusions: Remote dwelling Indigenous Canadians have a high prevalence of CKD. Family history is a risk factor for diabetic CKD, but not for non-diabetic CKD. The high incidence of non-diabetic CKD requires further study to establish etiology and improve outcomes.

SA-PO930

Mortality in Patients with Chronic Kidney Disease in New South Wales – A Cohort Study 2000-2010

Sradha S. Kotwal,[1] Martin P. Gallagher,[1] Alan Cass,[2] Angela C. Webster.[3,4] *[1]The George Inst for Global Health, Univ of Sydney, Sydney, NSW, Australia; [2]Menzies School of Health Research, Darwin, NT, Australia; [3]Sydney School of Public Health, The Univ of Sydney, Sydney, NSW, Australia; [4]Centre for Transplant and Renal Research, Westmead Hospital, NSW, Australia.*

Background: Patients with CKD have a higher mortality, but there is limited local data onhow this effect differs with the use of renal replacement therapy (RRT – dialysis or transplant) and geographical remoteness. This study compares chronic kidney disease (CKD) progression and survival for hospitalised patients in NSW.

Methods: The NSW Admitted Patient Data Collection identified all patients with an ICD-10 AM code for CKD on any admission between 1/7/2000 and 31/07/2010. Patients were linked to the death registry and ANZDATA. We defined RRT using the ANZDATA Registry and rural status using residential postcode and by ARIA scores. Competitive risk regression was conducted comparing rural versus urban populations.

Results: 165,901 people with CKD were admitted to hospital in NSW (982,887 patient years) and had a median follow up of 6.3 years. Only 16% (n=26,412) of patients lived rurally. During the study follow up period, 6285 (4.2%) people received RRT and 85163 (51.3%) died. Of those that received RRT, 1027 (3.9%) were rural and 5868 (4.2%; p=0.02) were urban. Of those that received RRT, 2979 (43.1%) died by the end of the study compared to 82,190 (51.7%) of those that did not receive RRT (p<0.001). Competitive risk regression showed minimal difference in the risk of receiving RRT between rural and urban residents (HR 0.93 95%CI 0.87-1.00; p=0.04).

Conclusions: The presence ofICD-10 codes for CKD in administrative data is associated with very high mortality, greater than that seen in dialysis patients. The frequency of CKD codes and the subsequent mortality far outstrips the burden of requirement for RRT.Further exploration of stages of CKD, differences in baseline characteristics will enhance understanding further.

SA-PO931

Engaging Kidney Disease Patients and Family Members as Co-Investigators in Patient Centered Outcomes Research Teri Browne,[1] Gary Green,[2] Katina Lang-Lindsey,[3] Patti Ephraim,[4] Patty Danielson,[5] Suzanne Ruff,[6] Holly St. Clair,[5] Lana Schmidt,[5] Amy Swoboda,[6] Peter Woods,[5] Tara Smith Strigo,[7] L. Ebony Boulware.[7] *[1]College of Social Work, Univ of South Carolina, Columbia, SC; [2]American Association of Kidney Patients, Tampa, FL; [3]Univ of Mississippi, Jackson, MS; [4]Johns Hopkins Univ, Baltimore, MD; [5]Patient with Kidney Disease; [6]Family Member; [7]School of Medicine, Duke Univ.*

Background: While often patients and family members are engaged peripherally in patient centered outcomes research (PCOR), our novel model includes them as fully engaged co-Investigators in a currently funded Patient-Centered Outcomes Research Institute (PCORI) kidney disease clinical trial.

Methods: Patients and family members partnered with researchers to develop an intervention, establish outcomes and write a PCORI proposal. We transcribed our meeting discussions, identified common themes, and refined our ideas prior to funding.

Results: Patients and family members were leading participants in all pre-award discussions and contributed to more than 5 major study design revisions. The study intervention evolved from a simple education program into a comprehensive health system intervention including provider tools and educational, behavioral, and psychosocial support for patients to improve kidney care. Patients and family members identified their most important research outcomes as: control, empowerment, acceptance, grief, anxiety, depression and CKD knowledge. Patients and family members are active and full co-Investigators on this project. They meet at least monthly with all investigators, provide feedback on all components of the study protocol, revise all recruitment and communications materials, and ensure all aspects of the intervention respond to patient and family members' needs.

Conclusions: Patients and family members can be fully engaged in research projects, thereby substantially improving the relevance and quality of PCOR studies. Our example could serve as a model to improve kidney disease PCOR studies and outcomes.

SA-PO932

Can-SOLVE CKD: A Pan-Canadian Patient-Oriented Research Network Adeera Levin,[1] Braden J. Manns,[3] Mila Tang,[2] Helen Chiu,[2] Heather A. Harris.[2] *[1]Dept of Medicine, UBC; [2]PHCRI, BC; [3]Dept of Medicine & Community Health Sciences, U of Calgary, AB.*

Background: The optimal conduct of patient-oriented research (POR), a priority for many research funding agencies, is uncertain. The Canadian nephrology community has been working for 4 years to develop an integrated POR network—Canadians Seeking Solutions and Innovations to Overcome (Can-SOLVE) CKD. The network's vision: By 2020, every Canadian with, or at high risk for CKD will receive the best recommended care, experience optimal outcomes and have the opportunity to participate in studies with novel therapies, regardless of age, sex, gender, location or ethnicity.

Methods: Using James Lind Alliance methodology and workgroups including patients and policy-makers, we identified the top research questions for early and advanced CKD. Key research questions identified by patients were formulated into a comprehensive research program. Partnerships with patients, researchers and policy-makers were leveraged to co-build a pan-Canadian patient-oriented research network.

Results: A research program with 3 themes and 19 projects spanning basic science, clinical and population health research was formed. National core infrastructure resources were developed.

A Patient Council and Indigenous Peoples' Engagement and Research Council are at the core of the network. Universities, provincial renal programs, and >100 researchers from multiple disciplines (e.g nursing, pharmacy, epidemiology etc.) from across Canada are involved. Peer-reviewed federal funding aimed at POR has been secured for this network, as part of the strategy to improve health of patients with chronic diseases.

Conclusions: Can-SOLVE CKD is a novel POR network, aimed at overcoming challenges that thwart the translation of discoveries into clinical research, and uptake of evidence into practice. Lessons learned can be shared with researchers from other countries seeking to partner with patients in research.

Funding: Government Support - Non-U.S.

Multi-Disciplinary Care Is Cost-Effective in Chronic Kidney Disease Eugene Lin,[1] Glenn Matthew Chertow,[1] Jeremy D. Goldhaber-Fiebert.[2] *[1]Internal Medicine - Nephrology, Stanford Univ; [2]Centers for Health Policy and Primary Care and Outcomes Research, Stanford Univ.*

Background: End-stage renal disease (ESRD) accounts for 5.6% of total Medicare expenditures, though patients on dialysis make up 1.6% of its beneficiaries. Multi-disciplinary care (MDC) has been proposed as a way to mitigate the morbidity and costs associated with the transition from chronic kidney disease (CKD) to ESRD.

Methods: To evaluate the cost-effectiveness of MDC relative to usual care, we developed a Markov model of progressing from CKD to ESRD. Unlike previous models, ours captures patient heterogeneity. We assumed that CKD progression depended on age, gender, CKD stage, and level of albuminuria. We calibrated progression probabilities to published data on risks of death and of developing ESRD. The cost-effectiveness analysis adopted the Medicare payer perspective. Using data from a recent systematic review, the model assumes that MDC decreased mortality rates by 15% and progression rates to ESRD by 55%. We modeled a typical MDC program which involved four nurse practitioner (NP) visits per year. We obtained ESRD mortality rates and costs from the United States Renal Data System (USRDS). Sensitivity analyses focused on potentially lower efficiency and higher costs of MDC and on clinical characteristics of the target CKD population.

Results: Compared to usual care, MDC costs $24,613 per QALY gained. MDC remained below $35,000 per QALY gained over a wide range of severities of CKD (from stage 3 to 5), ages (25 to 75 years), and albuminuria (100 mg/g to 1000 mg/g). Cost-effectiveness estimates were robust to changes in the efficiency of MDC. An MDC program that decreased mortality and progression rates by only 2% cost $84,916 per QALY gained. Likewise, an expensive MDC program of 12 NP visits a year cost $44,285 per QALY gained.

Conclusions: Even if deployed inefficiently, MDC programs would likely be cost-effective in CKD patients in the United States.

The Cost-Effectiveness of Community Health Workers: A Chronic Kidney Disease Markov Model David N. van der Goes,[1] John P. Ney,[2] Rajan Bishwakarma,[1] Kristina Nicole Piorkowski,[1] Mark L. Unruh.[3] *[1]Dept of Economics, Univ of New Mexico, Albuquerque, NM; [2]Dept of Neurology, Boston Univ, Boston, MA; [3]Dept of Internal Medicine, Univ of New Mexico, Albuquerque, NM.*

Background: Given the rise in rate of CKD and the increase in number of Americans over 60, there is a clear need to improve outcomes for patients with CKD earlier in the disease; early intervention may be the answer. We explore the use of community health workers (CHW) as an add-on intervention for patients with Stage 3 CKD and Stage 4 CKD to reduce costs and enhance quality of life by slowing the rate of progression and increasing the interval between diagnosis of CKD and ESRD. CHWs and care coordinators have been shown to be effective in educating patients about both their health state and the health care system.

Methods: We constructed a six health state cost-utility Markov model: 1) CKD 3a, 2) CKD 3b, 3) CKD4, 4) ESRD, 5) Transplant, and 6) Death to compare the current standard of care to care with CHWs. We use payer (Medicare) perspective and lifetime time horizon. We estimate transition probabilities and costs from publicly available data. Our CHW program is theoretical and its impacts are based on the current literature. We ran a baseline model and evaluate uncertainty through probabilistic sensitivity analysis.

Results: The model shows that CHWs reduce costs and improve quality of life. CHWs reduce lifetime costs by about 1 percent and increase quality adjusted life years (QALY) by about 1% compared to current standard of care. The model is most sensitive to, in order, the cost of dialysis, the cost of Stage 4 CKD, and CHW program costs.

Conclusions: Adding CHWs to standard care would reduce costs and improve quality of life for patients with CKD. CHWs should be considered as part of the CKD care team.

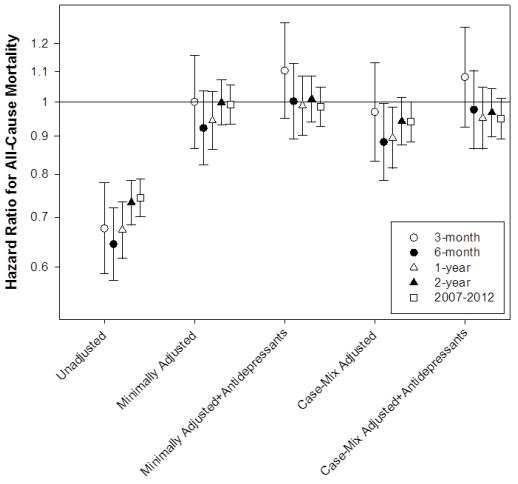
Posttraumatic Stress Disorder and Mortality in Veterans with Advanced CKD: A Transition of Care in CKD Study Elani Streja,[1] Melissa Soohoo,[1] Joline L.T. Chen,[3] Daniel L. Gillen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.; [3]VA Long Beach.*

Background: End stage renal disease (ESRD) patients starting dialysis treatment often experience worse mental health and quality of life. It is not known whether posttraumatic stress disorder (PTSD) has any impact on outcomes in these patients. A previous study in veterans showed that late-life PSTD was associated with increased cardiovascular (CV) disease, yet the association of PTSD and outcomes remains unknown in veterans who transition to ESRD.

Methods: We investigated a cohort of 34,681 US veterans who initiated dialysis between 10/2007-9/2011 and utilized the VA healthcare system. We used Cox proportional

hazard models to examine the association of pre-ESRD (prelude) PTSD (identified by ICD9 codes) with all-cause mortality occurring in the first 3 months, 6 months, 1 year, 2 years post transition to dialysis and over a 6 year period (2007-2012). We minimally adjusted for demographic covariates and additionally adjusted for comorbidities and prior prescription of antidepressants.

Results: Patients were 70±12 years old, among whom 25% were African-Americans, 6% Hispanic and 52% were ever prescribed antidepressants; 2,592 (7.5%) of the cohort was diagnosed with PTSD prior to dialysis initiation. PTSD was associated with lower crude post-ESRD mortality. However, after adjustment for demographics, this association was nullified, and further adjustment for antidepressants did not modify the association.



Conclusions: Pre-ESRD PTSD does not exhibit a clear associative pattern with early dialysis mortality in veterans transitioning to ESRD after adjustment for demographics, comorbidities and antidepressant use. Whether this is a result of better and more focused treatment and management of PTSD in veterans remains to be seen.

Depression and Factors Affecting It in Patients of Chronic Kidney Disease at a Tertiary Care Public Teaching Hospital: Evidence from a Cross Sectional Study Sanjay D'Cruz,[1] Pramil Tiwari,[2] Rajiv Ahlawat.[2] *[1]General Medicine, Government Medical College and Hospital, Chandigarh, India; [2]Pharmacy Practice, NIPER, SAS Nagar, Punjab, India.*

Background: Chronic kidney disease (CKD) is progressive disease and known to cause premature mortality. CKD patients are at increasing risk of depressive disorder because of considerable psychological stress due to physical and social changes brought on by disease. The presence of depression in patients of CKD can lead to poor outcomes. The present study was conducted to assess the prevalence of depression and the factors influencing it in patients of chronic kidney disease.

Methods: This cross-sectional study was carried out in 408 patients diagnosed with CKD over a one year from Sept 2014 to Sept 2015 at our tertiary care hospital. CKD was defined according to KDIGO guideline. Nine-item Patient Health Questionnaire (PHQ-9) from PRIME-MD was used to assess the presence of depression. Depression was classified further on the basis of score as minor, moderate and major. Unpaired Student's t-Tests and multiple logistic regression test were used for analysis.

Results: Of all the patients, 41.1% had no depression on the basis of PHQ. Mild depression was found to affect 29% of the patients followed by moderate depression (14%), moderately severe depression (11%) and severe depression in 5%. None of the patients were receiving any antidepressant. The likelihood of depression was significantly higher with age >60 (OR 1.10, 1.12-1.53; P<0.05). Depression was found to be associated with duration of CKD >2 yrs (OR 1.92, 0.80-1.43; P<0.001) lack of reimbursement (OR 0.55, 0.45-1.12; P<0.05), Anemia Hb ≤10 (OR 1.87 (0.86-1.25; P<0.05)), GFR ≤30 (OR1.55, 0.99-1.86; P<0.001, and Hb1Ac ≥7 (OR 1.73, 0.82-2.42; P<0.05). The risk of depression was not significant for gender, duration of diabetes, area of residence, education status, dialysis status and BMI of the patients.

Conclusions: Fifty nine percent of all patients were found to be affected by depression. Age, duration of kidney disease, lack of medical bill reimbursement, hemoglobin, GFR and Hb1Ac levels were found to be significant risk factors for depression.

SA-PO937

Prevalence and Correlates of Sexual Dysfunction in Women on Hemodialysis: A Multinational Cross-Sectional Study Valeria M. Saglimbene,[1,2] Suetonia Palmer,[3] Giovanni F.M. Strippoli.[1,2,4] *[1]Diaverum Medical Scientific Office; [2]Univ of Sydney; [3]Univ of Otago Christchurch; [4]Univ of Bari, on behalf of the CDS Investigators.*

Background: Sexual dysfunction may affect 80% of women with chronic kidney disease, however the specific domains of sexual function most affected and the clinical correlates of sexual dysfunction remain poorly described. We assessed the prevalence and correlates of the domains of sexual dysfunction among women with ESKD treated with hemodialysis.

Methods: We conducted a prospective multinational, cross-sectional study involving 1309 women treated with hemodialysis. Individual domains of sexual dysfunction were assessed using the self-reported Female Sexual Function Index (FSFI).Women provided responses anonymously with lower scores in each domain representing greater sexual dysfunction. The individual domain scores were then totaled and multiplied by a predetermined factor to weigh each domain equally. Correlates of each domain were identified using stepwise multivariable linear regression. Sensitivity analyses considered women who reported being sexually active.

Results: Of 1309 enrolled women, 659 (50.3%) provided complete responses to FSFI survey questions and 35% reported being sexually active. Overall, most respondents reported either no sexual activity or high sexual dysfunction in all measured domains (orgasm 75.1%; arousal 64.0%; lubrication 63.3%; pain 60.7%; satisfaction 60.1%; sexual desire 58.0%). Respondents who were waitlisted for a kidney transplant reported scores consistent with less sexual dysfunction, while older respondents reported scores consistent with greater dysfunction. The presence of depression was associated with worse lubrication and pain scores [mean difference for depressed versus non-depressed women (95% CI) -0.42 (-0.73 to -0.11), -0.53 (-0.89 to -0.16), respectively] while women who had experienced a previous cardiovascular event reported higher pain scores [-0.77 (-1.40- to -0.13)].

Conclusions: Women with ESKD report marked sexual dysfunction across a range of domains, which appear to be associated with medical comorbidity.

SA-PO938

The Association of Albuminuria and Kidney Dysfunction with the Risk of the Major Dementia Subtypes in a Japanese Community-Based Population: The Hisayama Study Keita Takae,[1] Jun Hata,[1] Tomoyuki Ohara,[1] Masaharu Nagata,[2] Kazuhiko Tsuruya,[1] Takanari Kitazono,[1] Yutaka Kiyohara,[3] Toshiharu Ninomiya.[1] *[1]Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Shin-eikai Hospital, Kitakyushu, Fukuoka, Japan; [3]Hisayama Research Inst for Lifestyle Diseases, Fukuoka, Japan.*

Background: Several prospective studies have reported that albuminuria and kidney dysfunction are both risk factors for cognitive impairment and dementia. However, few studies have assessed this issue considering dementia subtypes in Asian populations.

Methods: A total of 1,651 community-dwelling Japanese subjects aged ≥60 years without dementia were followed for 10 years. The hazard ratios (HRs) for the development of all-cause dementia and its subtypes, namely, Alzheimer's disease (AD), and vascular dementia (VaD), were estimated according to the levels of urine albumin-creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR) using a Cox proportional hazards model.

Results: During the follow-up, 358 subjects developed all-cause dementia (238 ADs and 93 VaDs). Compared with those with UACR of ≤6.9 mg/g, multivariable-adjusted HRs (95% confidence intervals [CI]) for the development of all-cause dementia were 1.12 (0.78-1.61), 1.64 (1.17-2.30), and 1.55 (1.10-2.17) in subjects with UACR of 7.0-12.7, 12.8-29.9, and ≥30.0 mg/g, respectively, after adjustment for age, sex, educational level, history of stroke, systolic blood pressure, anti-hypertensive treatment, diabetes, total cholesterol, body mass index, eGFR, smoking habits, alcohol intake, and regular exercise.Likewise, higher albuminuria levels were associated with greater adjusted risks of AD(HR [95% CI]: 1.22 [0.79-1.89], 1.74 [1.15-2.63], and 1.57 [1.03-2.40], respectively) and VaD (HR [95% CI]: 1.03 [0.46-2.29], 1.94 [0.96-3.95], and 2.19 [1.10-4.38], respectively). However, kidney dysfunction (eGFR ≤60 mL/min/1.73m^2) was not associated with the development of AD or VaD after adjustment for confounding factors.

Conclusions: Albuminuria is a significant risk factor for the development of both AD and VaD, but kidney dysfunction was not in a Japanese community-based population.

SA-PO939

Renal Metabolic Factors and MRI Findings in CKD: The BRain IN Kidney Disease Study Anne M. Murray,[1] Yelena Slinin,[2] Cynthia S. Davey,[3] Prashanthi Vemuri.[3] *[1]Hennepin County Medical Center, Minneapolis, MN; [2]Mayo Clinic, Rochester, MN; [3]Univ of Minnesota, Minneapolis, MN.*

Background: The extent that renal metabolic factors beyond eGFR contribute to the recognized increased risk of MRI pathology in CKD patients has not been adequately measured. We previously identified elevated phosphorus, anemia, and low cholesterol as factors associated with cognitive impairment in our BRain IN Kidney disease (BRINK) study cohort.

Methods: We included non- dialysis BRINK CKD participants with eGFR <60 mL/min/1.73 m^2. We assessed the cross- sectional relation between baseline hemoglobin, serum phosphorus, and cholesterol and baseline brain MRI outcomes using linear regression models adjusted for age, gender, race, education, eGFR, stroke and diabetes.All MRI scans were acquired on a 1.5 T Phillips Ingenia scanner. We used structural MRI (MPRAGE), to measure gray matter regional cortical thickness, FLAIR to measure cerebrovascular disease, T2* GRE imaging for microhemorrhage, and diffusion tensor imaging (DTI) for microstructural changes.

Results: 166 CKD BRINK patients with baseline MRI were included in analyses: mean age = 70, mean eGFR = 32.4 (± 10.4), 8.4% Black race, mean education 14.2 years, 48% with diabetes, 15% previous stroke, mean phosphorous 3.6 (± 0.7) mg/dL, mean hemoglobin 12.9 (±1.8) g/dL,and mean cholesterol 176(± 44) mg/dL. Lower hemoglobin (-1 mg/dL) was associated with a) lower occipital thickness (-0.04 [0.02], P = 0.025), parietal thickness (-0.08 [0.04], P = 0.027), and mean whole brain cortical thickness (-0.014 [0.01], P = 0.045) and with (b) higher DTI medial diffusivity in the gray matter temporal lobe (5.5 [2.3], P=0.021) and white matter occipital lobe (3.5 [1.7],P= 0.043). Higher phosphorus (1 mg/dL) was associated with increased subcortical infarcts (0.21 [0.09], P=0.025).

Conclusions: We identified anemia and elevated phosphorus as potential mechanisms of MRI pathology in CKD, but 3 year follow up MRIs are needed to confirm these results and their association with cognitive impairment.

SA-PO940

Association between Brain Magnetic Resonance Imaging Pathology and Cognitive Performance in Patients Receiving Maintenance Hemodialysis David A. Drew,[1] Rafeeque Bhadelia,[2] Hocine Tighiouart,[1] Tammy Scott,[1] Sarah M. Duncan,[1] Daniel E. Weiner,[1] Mark J. Sarnak.[1] *[1]Tufts; [2]BIDMC.*

Background: Although hemodialysis (HD) patients have high rates of clinical stroke and cognitive impairment, there are limited data on the association between subclinical structural brain pathology and cognitive function.

Methods: In the Boston Dialysis Study, we obtained brain magnetic resonance imaging (MRI) in 45 HD patients without clinical history of stroke. We assessed the severity of white matter disease and cerebral atrophy (sulcal and ventricular prominence) using a semi-quantitative scale (0 to 9) and determined hippocampal size (0 to 3) as well as prevalence of small and large vessel infarcts. A comprehensive battery of cognitive tests was administered, with individual test results reduced into two summary scores, representing memory and executive function. Summary scores have a mean of zero and standard deviation of one. Using multiple linear regression, we determined the association between each MRI finding and summary scores, adjusting for demographics, education, vascular access type, and history of cardiovascular disease.

Results: Mean age (SD) was 55 (17) years, with 50% women, 43% African American, 49% with at least some college education, and median dialysis vintage (25^{th} – 75^{th}) of 20 months (7 – 39). Both greater ventricular and hippocampal atrophy were associated with worse memory in unadjusted analyses but were non-significant in fully adjusted analyses. More severe white matter disease, cerebral atrophy and presence of subclinical infarcts were all associated with worse executive function. After adjustment, sulcal prominence remained significant, while ventricular prominence showed a trend.

MRI findings	Memory Function Summary Score				Executive Function Summary Score			
	Unadjusted		Adjusted*		Unadjusted		Adjusted*	
	SD difference (95% CI)	p	SD difference (95% CI)	p	SD difference (95% CI)	p	SD difference (95% CI)	p
White Matter Grade	-0.07 (-0.23, 0.10)	0.4	0.07 (-0.11, 0.25)	0.5	**-0.14 (-0.27, -0.01)**	**0.04**	-0.03 (-0.18, 0.13)	0.7
Sulcal Grade	-0.08 (-0.24, 0.08)	0.3	0.18 (-0.03, 0.39)	0.09	**-0.23 (-0.35, -0.12)**	**<0.001**	**-0.23 (-0.40, -0.06)**	**0.01**
Ventricular Grade	**-0.14 (-0.28, -0.01)**	**0.04**	-0.04 (-0.21, 0.14)	0.7	**-0.17 (-0.28, -0.06)**	**0.002**	-0.14 (-0.28, 0.01)	0.06
Hippocampal Grade	**-0.53 (-0.92, -0.13)**	**0.01**	-0.19 (-0.66, 0.27)	0.4	-0.29 (-0.64, 0.07)	0.1	-0.21 (-0.60, 0.19)	0.3
SVI or LVI	0.11 (-0.48, 0.70)	0.7	0.48 (-0.13, 1.08)	0.1	**-0.51 (-0.98, -0.04)**	**0.04**	0.02 (-0.52, 0.57)	0.9

SD = standard deviation, SVI = small vessel infarct, LVI = large vessel infarct
Bold = statistically significant findings
White Matter, Sulcal and Ventricular Grades scored from 0-9, with 9 indicating worse pathology. Hippocampal grade scored from 0-3, with higher scores indicating greater atrophy. Effect size is per 1 point increase in scale for all predictors, except for SVI or LVI which is binary
*Adjusted for age, sex, race, education, vascular access, and history of cardiovascular disease

Conclusions: Structural brain pathology in patients treated with hemodialysis is associated with worse cognitive function. Demographics, including age and cardiovascular disease may in part explain these associations.

Funding: NIDDK Support, Private Foundation Support

SA-PO941

Chronic Kidney Disease in Patients with Alzheimer Disease Wieslawa Janczak, Jolanta Malyszko. *2nd Dept Nephrology, Medical Univ, Bialystok, Poland.*

Background: Elderly people suffer from physiological or pathological ageing. The prevalence of both dementia and CKD increases in age above 65 years. It is important to assess CKD prevalence in elderly patients with dementia.

Methods: We analyzed retrospectively a group of n=188 elderly (aged 80.6 years) people with Alzheimer disease hospitalized in Geriatric Department, Medical University for whom renal function had been evaluated using three following formulas: CKD-EPI, Cockcroft-Gault (CG) and MDRD. All of the patients has normal serum creatinine according to the hospital central laboratory (IDMS validated Jaffe method). Neurocognitive functions had been tested with use of Mini-Mental State Examination (MMSE). For all of selected patients MMSE score was less than 24.

Results: For analyzed group with Alzheimer disease obtained mean value of eGFR/creatinine was different depending on evaluation method.

eGFR ml/min/1.73m^2	eGFR > 90	eGFR 60-89	eGFR 30-59	eGFR 15-29	eGFR <15
CG	1.06%	17.55%	70.74%	10.64%	0.00%
MDRD	6.38%	50.00%	42.02%	1.60%	0.00%
CKD-EPI	0.53%	44.68%	53.19%	1.60%	0.00%

Mean serum creatinine in the studied group was 1.01 mg/dl. CKD was defined when level of eGFR was less than 60ml/min/1.73m^2 and it was diagnosed in 81.38% of the group according to CG, in 43.62% according to MDRD and in 54.79% according to CKD-EPI. Despite normal serum creatinine CKD was found in more than half of the studied population. Mean BMI was 25 kg/m^2. MMSE score did not correlate with eGFR/creatinine.

Conclusions: CKD frequently occurs among group of elderly people with Alzheimer disease. However it is determined for different percentage of the group depending on estimation method (CKD-EPI, C-G, MDRD). This may lead to uncertainty of diagnosis for some patients. As patient with Alzheimer disease hardly cooperates, it is important to emphasis the presence of impaired kidney function on patient's and caregiver's education on renal function and its consequences. The difference between CG- and other two formulas may be due to nutrition status and body mass. Assesment of kidney function is of utmost importance for drug dosing, as they are subjected for polypharmacy.

Funding: Government Support - Non-U.S.

SA-PO942

Depressive Symptoms and Cognitive Impairment in Adults with Chronic Kidney Disease Michael J. Fischer,[1] Dawei Xie,[2] Melissa Lamar,[1] Qiang Pan,[2] Lydia Bazzano,[4] Alan S. Go,[5] Edward J. Horwitz,[6] Manjula Kurella Tamura,[3] Eva Lustigova,[4] Akinlolu O. Ojo,[7] Ana C. Ricardo,[1] Stephen L. Seliger,[8] Jonathan J. Taliercio,[9] Kristine Yaffe,[3] James P. Lash.[1] *[1]U. Illinois; [2]U. Penn; [3]UCSF; [4]Tulane; [5]Kaiser Permanente; [6]MetroHealth; [7]U. Michigan; [8]U. Maryland; [9]Cleveland Clinic.*

Background: Depression and cognitive impairment are common in adults with chronic kidney disease (CKD), and are associated with worse health outcomes. While the relationship between depression and cognitive impairment has been studied in end-stage renal disease, it has not been examined in earlier stages of CKD.

Methods: We conducted cross-sectional and longitudinal analyses of depressive symptoms (DS) and cognitive function among adult participants with CKD in the prospective multicenter Chronic Renal Insufficiency Cohort (CRIC) Study. Elevated DS were defined by a Beck Depression Inventory (BDI) score >= 11. Global cognitive function was assessed by the Modified Mini-Mental State Exam (3MS) where scores range 1-100. At baseline, linear regression was used to examine the relationship between elevated DS and 3MS scores. During follow up, mixed linear models were used to evaluate the relationship between baseline elevated DS and change in 3MS scores over time. All analyses were adjusted for center, sociodemographic, comorbidity, laboratory, kidney function, and proteinuria covariates.

Results: Among 3863 adults with CKD, 27% had elevated DS at baseline. Mean (SD) 3MS score was 89.4 (0.3) and 93.2 (0.3) in those with and without elevated DS at baseline, respectively (p < .0001). In fully adjusted analyses, mean 3MS score was significantly lower among those with elevated DS [beta coefficient = -0.81 (-1.34 to -0.29)] at baseline. During a median follow up of 5.9 years, the overall mean annual change in 3MS score was -0.03. In fully adjusted analyses, the relationship between baseline elevated DS and change in 3MS score over time was not significant (p=0.92).

Conclusions: In a large diverse adult cohort with CKD, elevated depressive symptoms are independently associated with worse cognitive function at baseline but not with changes in cognitive function over time. Whether treatment of depression leads to improvement in cognitive function warrants further study.

SA-PO943

Depression and Suicidal Ideation Is Associated with Renal Function in Predialysis Chronic Kidney Disease Patients Hae-Ryong Yun, Jong Hyun Jhee, Min-Uk Cha, Hyoungnae Kim, Seung Hyeok Han. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Depression including suicidal ideation is prevalent mental health problems in patients with end-stage renal disease (ESRD). Uremia related factors have been suggested as causes of this increased prevalence in ESRD patients. Although uremic toxicity is known to be increased even in early chronic kidney disease (CKD) patients, the relationship between depression and renal function is not well elucidated. Therefore, the association between renal function and depressive symptoms including suicidal ideation was investigated in predialysis patients with CKD.

Methods: Subjects whoparticipated in the Korea National Health and Nutritional Examination Survey (KNHANES) from 2010 to 2014 were evaluated. Subjects younger than 18 years or older than 75 years and CKD stage 5 patients were excluded. Depression was screened using the Korean version questionnaire. Suicidal ideation was assessed by a positive answer to the question 'In the last 12 months, have you ever thought about committing suicide?'.

Results: A total of 21,250 subjects were evaluated.Suicidal ideation was found in 2518 (11.8%) patients, and 5235 (24.6%) patients had depressive symptoms. Suicidal ideation was reported in 101 (11.5%), 86 (12.9%), 63 (18.4%), and 6 (33.3%) of each CKD stage 1, 2, 3 and 4 respectively (P for trend <0.001). Depressive symptoms were reported in 193 (21.9%), 170 (25.4%), 111 (32.5%), and 8 (44.4%) of each CKD stage 1, 2, 3 and 4 respectively (P for trend 0.002). When the relationship between renal function and mental health problems was evaluated, lower eGFR showed a significant relationship with having suicidal ideation (OR 0.95, 95% CI 0.97-0.99, P=0.02) even after adjustments with confounding factors.

Conclusions: Depressive symptoms and suicidal ideation were significantly more common in advanced CKD stage patients. Evaluation and management strategies for mental health issues should be considered in predialysis CKD patients.

SA-PO944

Qualitative Study of Coping Strategies Used by Patients with Advanced Kidney Disease Lalita Subramanian,[1] Martha Quinn,[2] Junhui Zhao,[1] Jarcy Zee,[1] Laurie Lachance,[2] Francesca Tentori.[1,3] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]The Center for Managing Chronic Disease, Univ of Michigan, Ann Arbor, MI; [3]Vanderbilt Univ Medical Center.*

Background: Chronic kidney disease (CKD) and its treatment impact patients' physical and mental health, as well as identity, lifestyle and relationships. Strategies used by patients to cope with these are not well elucidated. Using data from the Empowering Patients on Choices for Renal Replacement Therapy (EPOCH-RRT) Study, coping strategies were explored.

Methods: CKD patients with eGFR <25 mL/min/1.73 m^2 were interviewed in 2013, using a protocol developed in collaboration with patients, caregivers and healthcare

professionals. Data from 65 CKD not on dialysis (CKD-ND), 76 hemodialysis (HD), 38 peritoneal dialysis (PD) patients on how they cope with their kidney problems were analyzed to identify thematic categories, and then classified based on the Hierarchical Factor Structure of the Coping Strategies Inventory (CSI, Tobin et al., Cog. Ther. Res. 1989).

Results: 17 of the 38 themes that emerged were common to HD, PD and CKD-ND patients, while some were specific to each group. "Take care of myself and follow doctor's orders" and "rely on family and friends for support and encouragement" were among the top three themes for all three groups.

Table 1: Top themes classified using primary, secondary and tertiary CSI subscales

Top Themes	CSI Subscales	Sample Quotes
Take care of myself and follow doctor's orders	1° Problem solving 2° Problem focused 3° Engagement	"I just make sure I stay on my diet and try not to cheat very much! (*laughs*) And, uh, and, and keep up with my blood work and stuff." (CKD-ND patient)
Accept it	1° Cognitive restructuring 2° Problem focused 3° Engagement	"Uh, just, uh, I have no choice! I have to accept it, for what it is. If I was railing against it, that's not gonna get me anywhere! (*laughs*) So, I just, I accept it and, uh, try to live a productive life." (PD patient)
Rely on family or friends for support and encouragement	1° Social support 2° Emotion focused 3° Engagement	"I have an amazing support system of family and friends that, that I would not be able to, to deal with everything that's, as well as I do without them. They, they keep me sane." (HD patient)
Positive attitude	1° Cognitive restructuring 2° Problem focused 3° Engagement	"I just keep attempting to re-direct. If I do go into a negative space, I just keep attempting to re-direct, stay positive, think about what I do have, do what I can do, not focus on what I can't do" (HD patient)

Conclusions: CKD patients use a variety of coping strategies to deal with their disease. Some strategies were more commonly reported according to the stage of disease and treatment type. Overall, engagement strategies were more diverse and more frequently cited than disengagement strategies. Awareness of effective coping strategies used by others could improve coping and result in better health outcomes for CKD patients.

Physical Activity Level Impacts Life Quality in Patients with CKD

Mai Ots-Rosenberg,[1] Jana Uhlinova,[2] Ülle Pechter.[1] *[1]Internal Medicine, Univ of Tartu, Tartu, Estonia; [2]Internal Medicine, Tartu Univ Hospital, Tartu, Estonia.*

Background: The aim was to investigate the relationship between the main lifestyle-related factor, physical activity (PA) and health-related quality of life (HRQoL) in a samples of patients (pts) with chronic kidney disease (CKD), with chronic conditions (CC) and controls with respect to the age, gender or body mass index (BMI) differences in groups.

Methods: A cross-sectional study was conducted on 1006 pts (322 male and 684 female pts, age range 18.9–89.1 years) recruited at primary health care centers and the university hospital. The patient's age, self-reported smoking status and BMI were used as independent variables to predict PA level (MET-mins/week, assessed by International Physical Activity Questionnaire, IPAQ), the physical component scores (PCS) and mental component scores (MCS) of HRQoL (assessed by SF-36).

Results: Mean SF-36 score among pts with low PA was 113.5 (95% CI: 105.3…121.8), median PA 122.2 (95% CI: 117.9…126.5) and high PA 123.2 (95% CI: 119.0…127.4; p = 0.1144. After adjustment for age, gender, disease status, smoking, or BMI no statistical differeneces were found (p = 0.0737). However, among CKD pts similar analysis revealed a statistically significant result: mean score 110.9 (95% CI: 102.6…119.2; p = 0.0000). PA impact to SF-36 score was statistically different between studied pts groups (p=0.014). Low, median and high PA unadjusted mean score was in CKD pts accordingly 70.7, 115.6, 120.9, in CC pts 104.0, 124.1, 131.6. After the adjustment p = 0.0064. Mean TOTAL_MET in CKD pts 3773.8 (95% CI: 2678.8…4868.8). Pts with low PA formed 17.1% (95% CI: 10.5…25.7%), mean PA 44.8% (95% CI: 35.0…54.8%) and high PA 38.1% (95% CI: 28.8…48.1%). Interestingly, there was no statistically significant differences in distribution of PA levels between CKD and CC pts (p = 0.1642); CKD pts and controls (p = 0.5494) or CKD pts with eGFR >45 and < 45 ml/min.

Conclusions: PA level impacts life quality in patients with CKD. The distribution of PA level is similar among CKD pts irrespectively the kidney function.

SA-PO946

Membranous Nephropathy (MN): Baseline Health Related Quality of Life (HRQOL) in Patients with Severe Nephrotic Syndrome (SNS) in the Membranous Nephropathy Trial of Rituximab (MENTOR) RCT

Heather Beanlands,[1] Daniel C. Cattran,[2] Fernando C. Fervenza.[3] *[1]Ryerson Univ, Canada; [2]Toronto General Hospital, Canada; [3]Mayo Clinic; [4]MENTOR Trial Group.*

Background: HRQOL is an important patient reported outcome compromised in people with kidney failure. MN with SNS has potential physical and emotional consequences for patients but its impact on HRQOL has not been studied.

Methods: Baseline HRQOL data were collected from 130 patients (77% male; age 52 + 12.5 years) with MN and SNS (Uprotein 10.4 gm +4.7; CrCl 89.6 +32.6 ml/min/BSA; Salbumin 2.6 +0.5g/dL) participating in MENTOR. HRQOL was measured with the KDQOL-SF™1.3 (modified by removing dialysis questions and adding symptoms unique to MN).

Results: Scores for Effects of Kidney Disease (m=72 .7+ 21.8) and Symptom burden (m=76.5 + 15.5) showed only moderate impact with swelling of the feet/ankles and feeling washed out being the most burdensome symptoms. Whereas Burden of Kidney disease (m=52.7 + 28.5) and Overall Health (62.8 + 18.4) scores were more severely effected and only marginally better than reported for dialysis patients. On generic items, Role Limitations-Physical (55.1 + 45,4) and Energy/fatigue (47.9 +24.8) were considerably worse than healthy controls and only slightly better than dialysis patients. Physical Health Composites (PCS) (42.5 +11.1) were better than dialysis populations but worse than healthy controls, while Mental Health Composites (MCS) (48.8+9.7) were only marginally different than people on dialysis (better) and healthy controls (worse). Regression models were calculated to predict PCS and MCS by selected demographic and clinical variables. Male sex (p=0.002) and higher CrCl (p=0.02) were significant predictors of better PCS scores. None of the variables significantly predicted MCS.

Conclusions: MN impacts HRQOL, particularly physical functioning, burden of kidney disease and overall health. Women and those with worsening kidney function are at particular risk for poor physical functioning. Given the association between HRQOL and clinical outcomes (e.g.morbidity and mortality), it is essential for clinicians to assess the impact of MN on HRQOL and to develop strategies to help patients minimize the burden of their disease.

SA-PO947

Quality of Life Progression during Dialysis Initiation

Harley Meirovich,[1] Daniel Hercz,[2] Gavril Hercz.[1] *[1]Nephrology, Humber River Hospital, Toronto, Canada; [2]Statistics Core, UCLA Dept of Medicine, Los Angeles, CA.*

Background: Dialysis initiation is associated with emotional distress and poorer quality of life (QOL). Reduced internal (resilience) and external (emotional support) resources may predict which patients are at greater risk of QOL decline.

Methods: This prospective enrolment study assessed QOL parameters (see below) in relation to Connor-Davidson Resilience Scale and Emotional Support scores at 3 time periods: 183 ± 154 (mean ± SD) days prior to dialysis initiation, and 19 ± 14, and 104 ± 13 days after dialysis initiation. The repeated QOL measurements were analyzed using a longitudinal mixed effects model with either resiliency or emotional support, at enrolment, included as independent predictors, adjusting for temporal and patient level factors.

Results: In the 49 patients who successfully completed the three QOL assessments, the resiliency and emotional support scores were 84.7 ± 9.2 (score range 0-100), and 44.7 ± 21.0 (score range 0-60), respectively. All QOL parameters tended to drop significantly with the initiation of dialysis, and then rising towards baseline at the last assessment. Resiliency and emotional support had a strong positive association with nearly all the QOL parameters included in this study before, during, and after dialysis initiation.

Quality of Life (QOL) Parameters	Estimate (p-value) Resiliency*	Estimate (p-value) Emotional Support*
KDQOL-36:		
Physical Component	0.33 (0.004)	NS
Mental Component	0.32 (<0.001)	0.11 (0.016)
Kidney Disease Burden	1.07 (<0.001)	0.39 (0.005)
Symptoms/Problems	0.25 (0.026)	0.13 (0.004)
Effects of Daily Life	0.29 (0.003)	0.12 (0.005)
PROMIS:		
Global Physical Health	0.13 (<0.001)	0.04 (0.016)
Global Mental Health	0.18 (<0.001)	0.06 (0.001)
Applied Cognitive Abilities	0.87 (<0.001)	0.25 (0.040)

**Estimated effect of a 1-point change in Resiliency/Emotional Support on QOL parameters.*

Conclusions: During sequential measurements, QOL declines during dialysis initiation and returns to baseline in most patients. Lower levels of internal (resiliency) and external (emotional support) resources are associated with lower QOL scores, suggesting a possible modifiable relationship during this vulnerable period.

SA-PO948

Survey Questionnaire on Improved Quality of Life (QoL) in Chronic Kidney Disease (CKD) Patients with One or More Co-Morbid Conditions Using Renadyl™, a Pro and Prebiotic Dietary Supplement

Natarajan Ranganathan,[1] Usha N. Vyas,[1] Pari Ranganathan,[1] Henry I. D'Silva,[1] Bohdan Pechenyak,[2] Alan D. Weinberg.[3] *[1]Kibow Biotech Inc, Newtown Square, PA; [2]Temple Univ School of Medicine, Philadelphia, PA; [3]Mount Sinai School of Medicine, New York, NY.*

Background: Probiotics and Prebiotics are widely used for digestive and immune health. Recent scientific advances, in the field of "Gut Microbiome" and its modulation using Pro/Prebiotics beyond gut health is growing in various diseases including gut-brain connection and gut-kidney connection. Renadyl™; a Pro/Prebiotic dietary supplement has demonstrated its potential to reduce serum uremic toxins in a pharma like validation with *in vitro* and clinical studies in animals and humans. This case study aimed to collect information on QoL and health status through modulation of gut microbiome in CKD patients using Renadyl™.

Methods: 834 patients using Renadyl™ were sent survey questionnaires. Results were analyzed using SAS V9.2 and MS Excel.

Results: 168 responses were received (20% response rate, 42% female, 47% male, aged 12-98 years). 85% were over 51 years of age, 58% in stage III/IV of kidney disease with 77% having at least one comorbid condition, and 48% were retired. 61% experienced improvement since taking Renadyl™. Statistical analysis indicated a significant difference ($p<0.0001$) in distributions of QoL responses before and after taking the product. Multivariate analysis indicated that duration of administration ($p<0.0001$), employment ($p<0.012$), comorbidity ($p<0.012$), and GFR ($p<0.0015$) were significant factors influencing the reported QoL. Even disabled respondents reported significant improvement.

Conclusions: This patient/consumer survey showed the ability of Renadyl™to provide benefit to patients in all stages of CKD and dialysis and with a variety of comorbid conditions. It appears to have a stabilizing effect on the overall health status and QoL, maintaining or improving kidney health in particular. Further, adequately powered studies that could establish a clearer correlation between this supplement and its impact on GFR are warranted.

SA-PO949

Differences in Patient and Renal Provider Assessment of Physical Symptoms, Quality of Life, General Health, and Depressive Symptoms in Chronic Kidney Disease Fredric O. Finkelstein,[1] Juan Calderon,[1] Alan S. Kliger,[1] Bridget A. Forbes,[2] Monica Cimini.[2] *[1]Nephrology, Yale School of Medicine, New Haven, CT; [2]Metabolism Associates, New Haven, CT.*

Background: Wide discrepancies in symptom burden perception between dialysis patients and their renal providers have been previously well documented. This can result in significant undertreatment of dialysis patients' symptoms. Providers' ability to recognize physical symptoms (PS) and perceptions on general health (GH) and quality of life (QoL) in patients with chronic kidney disease (CKD) has not been studied yet. The aim of this study is to examine the degree of patient-provider concordance in terms of their perceptions of PS, GH, and QoL in patients with CKD.

Methods: A standardized questionnaire was administered synchronously to each patient and the treating renal provider at the time of their routine clinic appointment. The survey was comprised of eighteen questions addressing PS, overall GH and QoL. We used a Likert scale to grade severity of symptoms. We compared the net sum of all rated physical symptoms, PHQ2 score, GH and QOL between patients and providers and analyzed discrepancies based on CKD stages.

Results: A total of eighty patients and providers completed the survey. Providers underscored severity of PS in 27% of cases and overscored them in 18% of cases. Net sum of PS severity across the entire sample was 1150 points for providers versus 1301 points for patients. Agreement in severity of physical symptoms occurred in 55% of cases. Underrecognition of PS was highest at stage 5. The percentage of concordance when assessing perception of GH was 34%, with highest percentage of concordance in advanced stages of CKD. For QoL analysis, providers underestimated their patients QoL in 36% of cases and both had concordant scores in only 44% of cases.

Conclusions: Underrecognition of the severity of PS and underestimation of perception of quality of life in CKD patients by renal providers, particularly in more advanced CKD, is problematic. In contrast, both providers and patients' perception of general health have increased concordance, particularly at more advanced CKD stages.

SA-PO950

Is Caregiver Burden Associated with Chronic Kidney Disease (CKD) Patients' Quality of Life? Tara Liaghat, Khaled Iskandarani, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: The kidney disease quality of life 36 (KDQOL36) is an instrument developed to measure several components related to the quality of life of patients with CKD, while the burden interview survey (BIS) is an instrument developed to measure caregiver burden. The aim of this study was to investigate whether caregiver burden indicated by BIS total score is associated with patients' quality of life components as measured by the KDQOL36.

Methods: Stage 4 and 5 CKD patients were paired/ matched to a caregiver. The patients completed the KDQOL36 instrument, while their respective caregivers completed the BIS. A multivariable linear regression model of caregiver BIS total score predicted by patients' scores on each of the 5 subcomponents was fit while adjusting for age, sex, and Hispanic ethnicity of caregiver.

Results: The sample consisted of 62 patient-caregiver pairs. Lower scores indicating worse performance on the KDQOL36 subscales with the exception of physical composite were statistically significantly associated with higher scores on the BIS, indicating increased care giver burden.

KDQOL36 Subcomponent	Estimate	Standard Error	P-value
KD Symptoms Lists	-0.2683*	0.1181	**0.0272**
KD Effects	-0.2400*	0.08727	**0.008**
KD Burden	-0.1524*	0.04991	**0.0036**
KD Physical component	-0.1569*	0.1481	0.2947
KD Mental component	-0.4903*	0.1476	**0.0017**

*All estimates were adjusted for age, sex, race, and ethnicity. Bolded p-values are statistically significant at $\alpha<0.05$.

Conclusions: Caregiver burden is associated with CKD patients' quality of life, whereby improvements in the patients' quality of life reduce caregiver burden.

SA-PO951

Peer Mentoring for Patients with Chronic Kidney Disease and Their Caregivers: A Qualitative Study Tara Liaghat, Eugene Lengerich, Nasrollah Ghahramani, Jennifer Kraschnewski. *Penn State College of Medicine.*

Background: Peer mentorship may enhance patient engagement for those with advanced chronic kidney disease (CKD) (stages 4 and 5); yet, the approaches and qualities (i.e., online vs in-person) that make a good mentor are unclear. This study sought to determine these qualities by conducting focus groups with mentees from the mentorship program in a randomized peer-education study.

Methods: Seven focus group meetings were conducted with mentees (n=20). Mentees were patients with advanced CKD and their caregivers who were matched with trained patient and caregiver peer mentors for in-person or online mentorships. Meetings were audio-recorded, transcribed, and thematically analyzed by three facilitators who concurred with the significant results.

Results: Three important themes emerged, which were: (1) in-person meetings facilitated meaningful partnerships, more than phone or online communication: "But she knows how I'm feeling when I'm saying it versus when I'm typing it."; (2) good mentors were relatable and good listeners: "They have to be a caring person about other people. Be able to relate. I guess they can relate because they are in the same predicament or already was in that predicament… a good listener too."; and (3) mentorship program provided support: "It changed a whole lot. Him giving me support and also outside my family…so that's been a big positive change for me. A lot of support for the last year and a half since I started."

Conclusions: A mentorship program for patients with advanced CKD may provide them with substantial support, particularly when mentorship is conducted in-person and the mentor is a relatable, empathetic listener. **Funding Disclosure:** Dr. Nasrollah Ghahramani is funded by CDR-1310-07055 from the Patient- Centered Outcomes Research Institute (PCORI).

SA-PO952

Assessment of Quality of Life in Children with Chronic Kidney Disease Based on First 5 Years Data of the Pediatric CKD Cohort Min Hyun Cho,[1] Hee Sun Baek,[1] IL-Soo Ha,[2] Hee Gyung Kang,[2] Hae Il Cheong,[2] Hyun-Jin Choi,[2] Young Seo Park,[3] Joo Hoon Lee,[3] Heeyeon Cho,[4] Jae Il Shin,[5] Kyoung Hee Han,[6] Seong Heon Kim.[7] *[1]Pediatrics, Kyungpook National Univ Children's Hospital; [2]Seoul National Univ Children's Hospital; [3]Asan Medical Center Children's Hospital; [4]Samsung Medical Center; [5]Severance Children's Hospital; [6]Jeju Univ Hospital; [7]Pusan National Univ Children's Hospital.*

Background: Quality of life (QOL) is an essential subject in children with chronic kidney disease (CKD) and their family. In Korea, a 10-year longitudinal study on the patient and renal survival by specific causes of CKD (KNOW-CKD study) has been pursued from 2011 and pediatric cohort is one of subgroups in the groups of KNOW-CKD study.

Methods: We performed a cross-sectional investigation of QOL in children with CKD (Pediatric cohort) using the PedsQL 4.0 Generic Core Scale Module. During 5 years, total 381 pediatric patients with CKD aged 2-18 year old were enrolled from five Korean university hospitals.

Results: The male to female ratio was 259:122 and mean age was 10.1 years old. According to CKD staging, patients were distributed as follows; stage I 72, stage II 75, stage III 124, stage IV 67, stage V 43. Patients with higher CKD stage had significantly lower QOL score in all domains of the parent-proxy reports, but not child-self reports. According to gender, boys had a tendency to present better QOL than girls in the child-self reports, especially in emotional functioning, psychosocial health summary score and total score, but, in the parent-proxy reports, there was no significant difference between these two groups. Age discrepancy was not a significant factor to decide QOL in children with CKD. In addition, there was significant difference between parent-proxy reports and child-self reports and QOL scores in the child-self reports was significantly higher than in the parent-proxy reports.

Conclusions: Residual renal function and gender in children with CKD can be important factors to decide QOL, but there was a significant difference of these results between parent-proxy and child-self reports. Therefore, we need systemic, individualized supporting tools to improve QOL of children with CKD and their families.

SA-PO953

The Association of Depression, Perceived Health Status, and Quality of Life between Individuals with and without Chronic Kidney Disease: An Analysis of the National Health and Nutrition Examination Survey 2011-2012 Hoang Anh Nguyen, Cheryl A. Anderson, Cynthia Miracle, Dena E. Rifkin. *UCSD, San Diego, CA.*

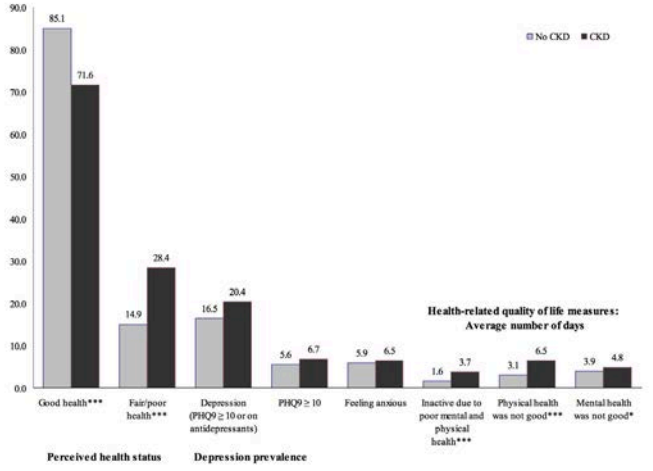
Background: Depression is the most common mental health disorder among those with ESRD, with prevalence of 15-40%. However, the association between CKD and depression is more variable in the literature. We examined associations of CKD with depression, perceived health status, and quality of life in the National Health and Nutrition Examination Survey (NHANES) 2011-12.

Methods: This study included 5,364 adults. Depression was defined by a Patient Health Questionnaire score ≥ 10, or reported antidepressant use. Overall health status was self-rated. Reduced quality of life was defined by the average number of days having poor mental and physical health, or feeling anxious. We calculated odds ratios for the associations

between CKD and depression and self-perceived health status, and used linear regression to examine the associations between CKD and the average number of days of poor health and self-reported anxiety.

Results: The prevalence of CKD was 15.5% and of depression was 16.9%. Figure 1 shows unadjusted results. Those with CKD were not more likely to be depressed vs those without CKD after multivariate adjustment. Although they were 1.8 times more likely to have fair/poor health status after adjusting for demographic characteristics, this was non-significant after adjusting for both demographic and clinical confounders. Those with CKD reported 2 more days of poor physical health and being inactive due to poor health in the past month (p-values < 0.01), after multivariate adjustment. No differences were found for self-reported anxiety.

Figure 1: Perceived health status, depression prevalence, and quality of life among U.S. adult population with chronic kidney disease in NHANES 2011-2012.



Student t-tests were used in the analysis.
***p-value < 0.001, **p-value < 0.01, *p-value < 0.05

Conclusions: Our findings suggest that NHANES participants with CKD have more days of poor health, but are not more likely to be depressed or anxious. This may reflect differences between clinical CKD populations and community-based samples.

Funding: Other NIH Support - T32 Grant

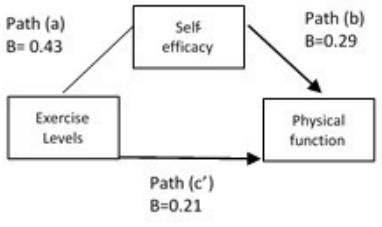
SA-PO954

Exercise and Physical Function in Patients with CKD: The Mediating Role of Self-Efficacy Amy L. Clarke,[1] Joseph Chilcot,[2] Alice C. Smith.[1] *[1]Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; [2]Inst of Psychiatry, Psychology & Neuroscience, King's College London, United Kingdom.*

Background: Chronic kidney disease (CKD) is characterized by low physical functioning (PF), associated with increased mortality. Exercise (EX) may help to retain independence but CKD patients are sedentary. Self-efficacy (SE) is both a determinant and an outcome of EX and may explain the relationship between EX and PF. This study explored if the direct effect of EX levels on PF was, in part, mediated by an indirect effect of SE.

Methods: A survey of non-dialysis CKD patients was conducted between 2012 and 2015. This included 3 validated questionnaires: Duke Activity Status Index to estimate PF, Leisure Time Exercise Question to explore EX levels, and EX Self-Efficacy Questionnaire to explore confidence to EX. Mplus path models were used to estimate the total and indirect effects (with bootstrapped confidence intervals), using maximum likelihood estimation. Standardised model estimates are reported.

Results: 966 patients (age 61SD±18, 57%male, eGFR 39SD±24) were evaluated. EX levels were an independent predictor of PF(B= 0.21, p<.01) and SE(B=0.43, p<.01) after adjustment for age, eGFR and co-morbidity. SE significantly predicted PF after adjusting for above factors and controlling for EX levels(B=0.29, p<.01). There was a significant indirect effect between EX and PF, through SE(Beta = 0.12, 95% CI 0.10, 0.14, p<.05) which accounted for ~37% of the total effect. Overall 54% of the variance in PF was explained.



Conclusions: EX levels are positively associated with PF. Patients who engage in greater levels of EX are more efficacious which may positively impact PF. SE is a modifiable construct important for EX behavioural interventions. Interventions should target processes to enhance SE such as mastery experiences, vicarious learning, social persuasion and physiological/emotional responses.

SA-PO955

Collecting Patient Reported Outcomes in Chronic Kidney Disease: The UK Renal Registry Experience Fergus J. Caskey,[1,2] Retha D. Steenkamp,[1] Rachel May Gair,[1] Sabine Van der Veer,[3] Richard J. Fluck,[4] Claire Louise Corps.[5] *[1]UK Renal Registry, United Kingdom; [2]Univ of Bristol, United Kingdom; [3]Univ of Manchester, United Kingdom; [4]Royal Derby Hospital, United Kingdom; [5]Univ of Leeds, United Kingdom.*

Background: Renal registries are starting to collect patient reported outcomes. This study explores the feasibility of collecting such data in people with CKD in secondary care in England and presents initial results.

Methods: Ten of the 52 adult renal units in England participated. The survey consisted of i) 5 questions on overall health (EQ-5D-5L), ii) 17 questions on symptoms (iPOS-S renal) and iii) 13 questions on the patient's ability to manage their health (PAM). A paper copy of the survey was given to outpatients with pre-dialysis CKD or a transplant and those on maintenance haemodialysis/peritoneal dialysis. Completed surveys were returned to the Registry and scanned into the database. The EQ-5D-5L and iPOS-S renal questions use scales from '0' representing no problems/concerns to '4' representing the highest level of severity/concern. These were recoded to absent/mild (0,1) and moderate/severe/overwhelming (2, 3, 4). PAM was classified from 1 (least) to 4 (most) activated.

Results: In round 1, 334 patients returned surveys from 6 units. The majority (83%) were on haemodialysis. Most completed the survey on their own (49%); the remainder were helped by friends (24%) or clinical staff (27%). They did so at the renal unit (69%), at home (24%) or in clinic (7%). In all patient groups, at least moderate impairments in mobility, self-care, usual activities, pain/ discomfort, anxiety/ depression were reported in 52%, 30%, 54%, 42%, 31%, respectively. The presence of at least moderate symptoms ranged greatly from 12% for vomiting and 15% for diarrhoea to 45% for difficulty sleeping, 54% for poor mobility and 60% for weakness/lack of energy. Amongst respondents, 30% and 10% had activation levels 3 and 4, respectively.

Conclusions: The routine national collection of patient reported outcomes poses practical and logistic challenges. The high burden of symptoms and low activation levels of the majority of patients highlights the importance of capturing these alongside traditional markers of quality of care.

Funding: Government Support - Non-U.S.

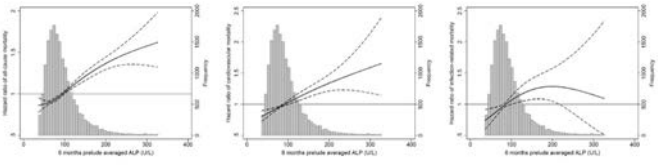
SA-PO956

Prognostic Significance of Pre-ESRD Serum Alkaline Phosphatase for Post-ESRD Mortality in Late-Stage CKD Patients Transitioning to Dialysis Keiichi Sumida,[1,2] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Yoshitsugu Obi,[3] Connie Rhee,[3] Elani Streja,[3] Kunihiro Yamagata,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of Tsukuba, Ibaraki, Japan; [3]Univ of California, Irvine, CA; [4]VA Medical Center, Memphis, TN.*

Background: Higher serum alkaline phosphatase (ALP) has been associated with increased mortality in both non-dialysis dependent CKD and ESRD patients. However, little is known about the impact of ALP levels in advanced CKD on outcomes after dialysis initiation.

Methods: We examined the association of the averaged ALP levels over the last 6 months preceding transition to dialysis, with all-cause and cause-specific mortality during the two-year period following dialysis initiation in 17,985 US veterans transitioning to dialysis between 10/2007-9/2011. ALP levels were categorized into quartiles (<66, 66-85, 86-111, ≥112 U/L). Associations were examined using Cox (for all-cause) and competing risk (for cause-specific mortality) regressions and cubic splines with adjustment for demographics, comorbidities, medications, pre-ESRD 6-month averaged serum albumin and eGFR levels, and access type at dialysis initiation.

Results: Higher ALP levels were associated with increased risk of all-cause, CV, and infectious mortality (Figure). The adjusted hazard/subhazard ratios [95% CI] for ALP quartiles 2 through 4 (vs. quartile 1) were 1.10 [1.04-1.17], 1.12 [1.05-1.19], and 1.42 [1.33-1.51] for all-cause; 1.07 [0.95-1.21], 1.12 [0.99-1.26], and 1.30 [1.15-1.47] for CV; and 1.20 [0.93-1.55], 1.24 [0.96-1.59], and 1.39 [1.09-1.78] for infectious mortality, respectively.



Conclusions: Higher pre-ESRD ALP is associated with increased post-ESRD mortality risk. Further studies are needed to determine if interventions that lower pre-ESRD ALP levels reduce mortality in incident dialysis patients.

Funding: NIDDK Support, VA Support

SA-PO957

Low Serum Levels of Alkaline Phosphatase Are Associated with Greater Total Kidney Volume in Patients with Early Autosomal Dominant Polycystic Kidney Disease

Berenice Y. Gitomer,[1] Myles S. Wolf,[2] Isidro B. Salusky,[3] Zhiying You,[1] Michel Chonchol.[1] *[1]Univ of Colorado; [2]Northwestern Univ Feinberg School of Medicine; [3]David Geffen School of Medicine at UCLA.*

Background: We have previously identified a low bone turnover state in patients with early autosomal dominant polycystic kidney disease (ADPKD) characterized by decreased bone formation, resorption and low serum levels of alkaline phosphatase (AP). While increased levels of serum AP have been associated with progression in chronic kidney disease (CKD), we sought to determine whether serum AP levels are related to the risk of total kidney volume (TKV) progression in ADPKD.

Methods: Serum AP levels were measured in 524 ADPKD patients with stage 1 and 2 CKD. The data were collected from the HALT- PKD study A, a randomized, placebo-controlled trial to determine whether the combination of an angiotensin converting enzyme inhibitor (ACEI) and angiotensin II-receptor blocker was superior to the ACEI alone, and whether intense blood pressure lowering was superior to standard blood pressure in delaying height-corrected TKV (HtTKV) measured at baseline, 24, 48, and 60 months. AP was modeled as a categorical variable derived from the median value (<56 vs. > or =56 IU/L). We used Generalized Estimating Equation models to examine the association between serum AP levels with repeat measures of HtTKV categorized as below and above 800 ml/m.

Results: At baseline, participants had a mean age and CKD-EPI eGFR, of 37 ± 8 years and 91.4 ± 17.4 ml/min/1.73m^2, respectively. The median (IQR) for AP and HtTKV were 56 (45-69) IU/L and 589 (405-860) ml/m, respectively. After adjustment for age, gender, race, randomization group, body mass index, systolic blood pressure, eGFR, urine albumin excretion, serum calcium, phosphate and parathyroid hormone level a lower AP (< 56 IU/L) serum level was independently and significantly associated with increased odds of a higher HtTKV (OR:149; 95% CI: 1.02-2.18; p=0.04).

Conclusions: Low serum AP, is independently associated with a higher HtTKV in patients with early ADPKD. These findings suggest that altered bone biology in patients with ADPKD may be related to renal disease progression.

Association between Serum Alkaline Phosphatase and Mortality in Maintenance Haemodialysis Patients

Bala Waziri,[1] Saraladevi Naicker.[1] *[1]Internal Medicine, Univ of the Witwatersrand, Johannesburg, Gauteng, South Africa; [2]Internal Medicine, Univ of the Witwatersrand, Johannesburg, Gauteng, South Africa.*

Background: Studies mainly from the developed countries have revealed higher levels of intact parathyroid hormone (iPTH), calcium, phosphate and alkaline phosphatase as independent predictors of mortality in haemodialysis patients. Data on the existence of this link in African haemodialysis patients are sparse. Therefore, the aim of this study was to assess the impact of serum total alkaline phosphatase (TAP) on mortality in maintenance haemodialysis (MHD) patients.

Methods: This study enrolled a total of 223 patients on MHD from two dialysis centers in Johannesburg between January 2009 and March 2016. Patients were categorized into low TAP group (<112 U/L) versus high TAP group (≥112 U/L) based on median TAP of 112 U/L. By multivariate Cox regression analysis the impact of serum TAP on primary outcome (Death) was assessed.

Results: The MHD patients (147 men, 76 women) had a mean age of 54.5±15.6 years with a median dialysis vintage of 24 months (IQR, 12-48) and a mean kt/V (single pool) of 1.4±0.3. During a period of 7 years there were 52 (23.3%) deaths. After adjusting for cofounders such age, makers of bone disorder (calcium, iPTH, phosphate)and co morbidity (DM); patients in the high TAP group had significant higher risk of death compared to patients in the low TAP group (hazard ratio,2.6;95% CI 1.23-5.45, p=0.01). Similarly, corrected calcium <2.75mmol/L was associated with a lower risk of death compared to patients with calcium ≥ 2.75 mmol/L(HR=0.18, 95%CI 0.04-0.95 ; p=0.04). TAP correlated significantly with iPTH (r=0.3; P<0.001).

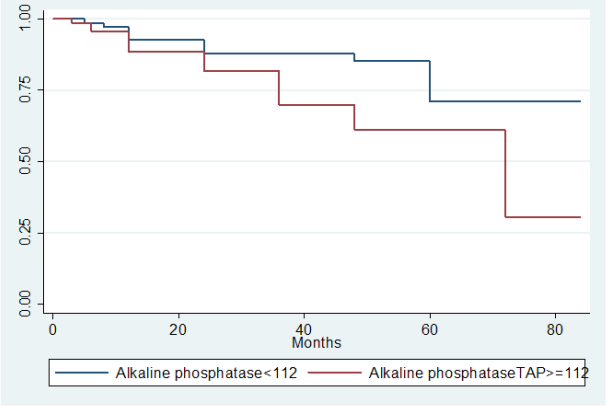

Figure1. Kaplan – Meier survival curves comparing patients with total alkaline phosphatase (<112U/L) to those with total alkaline phosphatase (≥112 U/L).

Conclusions: High levels of serum alkaline phosphate are associated with an increased risk of death in MHD patients. This relatively inexpensive test may be utilized as a surrogate marker for monitoring treatment in End Stage Renal Disease.

SA-PO959

Serum Bone-Specific Alkaline Phosphatases/Total Alkaline Phosphatases Ratio as a Risk Factor for Mortality in Hemodialysis Patients

Zuanhong Jiang, Zijin Chen, Zhiyu Wang, Xiaobo Ma, Haijin Yu, Xiaonong Chen. *Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

Background: The aim of our study was to determine the association between b-ALP,t-ALP, b-ALP/t-ALPand theall-cause mortality in hemodialysis patients.

Methods: The study included226 maintenance hemodialysis patients. Levels of serum b-ALP were measured by ELISA. Survival rates were analyzed using Kaplan–Meier survival curves. A Cox regression model was used to access the possible influence of variables on all-cause mortality.

Results: Study patients had an median age of 58 (48-68) yr-old, with dialysis vintage of 41 (21-72.3) mo, 11.1% with diabetes,and 63.7% male. The respective concentrations of b-ALPandt-ALPwere 19.71(14.85-26.72)U/L and 63.0(50.0-80.5)U/L.The b-ALP/t-ALP ratio ranged from 0.09 to 0.64(median 0.336).B-ALP / t-ALP ratio were significantly lower inhemodialysis patientsversus health controls(P=0.035),whereas there were no differences in serumb-ALPand t-ALPlevel.Significant correlations were found between serum b-ALP and t-ALP,b-ALP / t-ALP ratio,iPTHand P.Patients were followed-up prospectively from the first day of the laboratory measurement for a maximum of 36 monthsor until death. A total of 50 patients died.Kaplan–Meier survival analysis showed higher mortality in the first tertile of b-ALP / t-ALP than in the third tertile (P = 0.042). Cox regression hazard analysis identified lowerb-ALP / t-ALP as a significant predictor [HR 2.39 (95%CI:1.16–4.90)] for all-cause mortality, After adjustment for various factors,this effect is moderate[HR 1.90(95%CI:0.759–4.751)].

Figure1. The association between serum b-ALP ,t-ALP, b-ALP / t-ALP, PTH and P

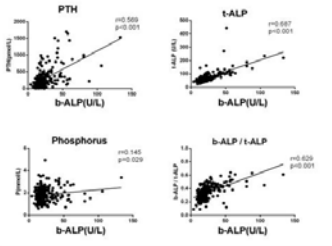

Figure2. The Kaplan-Meier analysis of all-causemortality

Model 1 :unadjusted.
Model 2 :adjusted by sex ,age ,dialysisduration, DM
Model3 :adjusted by sex ,age ,dialysisduration, DM, Hb, ALB, PTH, CA, P

Conclusions: In patients undergoing hemodialysis, lower b-ALP/t-ALP ratiois associated with higher mortality.

SA-PO960

Severity of Secondary Hyperparathyroidism Is Associated with Higher Baseline Bone Markers and Greater Reductions in Calcium in Etelcalcetide-Treated Subjects

Pieter Evenepoel,[1] Jan Iles,[2] Yan Sun,[2] Pablo A. Urena.[3] *[1]Univ Hospitals Leuven; [2]Amgen Inc.; [3]U Rene Descarte.*

Background: Etelcalcetide (ETL), a novel IV calcimimetic, has been shown to reduce parathyroid hormone (PTH) and corrected calcium (cCa) in adults on hemodialysis (HD) with secondary hyperparathyroidism (SHPT). Bone-specific alkaline phosphate (BSAP) and collagen type 1 cross-linked C-telopeptide (CTx) have also been studied in this population.

Methods: Adult subjects (N=1023) on HD with baseline PTH>400pg/mL were randomized to 26 wks ETL or placebo. ETL was initiated at 5mg IV per dialysis session and titrated every 4 wks (max 15 mg) to achieve PTH<300pg/mL. Results are shown for the ETL arm only (total and by baseline PTH strata) for proportion of subjects with cCa<8.3 mg/dL or <7.5mg/dL and % change in mean PTH and cCa during the efficacy assessment phase (EAP) at wks 20 to 27 compared to baseline values. BSAP and CTx are shown for wks 12 and 27 compared to baseline values.

Results: Table 1 shows baseline laboratory values by baseline PTH strata. The highest PTH stratum demonstrated greater reduction in cCa and included the highest proportion of subjects with <7.5mg/dL despite comparable PTH reduction across strata. Reductions in CTx were observed at wks 12 and 27, which were similar across PTH strata. Conversely, BSAP increased at wk 12 similarly across strata, but decreased at wk 27, which was most pronounced in the highest baseline PTH stratum. Mean ETL dose during EAP increased with SHPT severity.(Table 2)

Conclusions: Following initiation of ETL, early decreases in CTx were observed whereas BSAP actually increased, potentially driving net bone calcium influx. With

increased SHPT severity, there were higher baseline biomarkers of bone metabolism (BSAP and CTx), a greater percentage reduction in cCa, and a higher proportion of subjects with low calcium.

Table 1. Baseline Laboratory Values by baseline PTH

	Entire Cohort (N = 509)	Stratum A PTH < 600 pg/mL (n =172)	Stratum B PTH 600 - 1000 pg/mL (n = 225)	Stratum C PTH > 1000pg/mL (n = 112)
PTH pg/mL	846.9 (492.6)	509.8 (71.0)	780.6 (120.6)	1497.6 (679.1)

Effects of Etelcalcetide by Severity of Secondary Hyperparathyroidism

John Cunningham,[1] Geoffrey A. Block,[2] Kerry Cooper,[3] Sharon M. Moe,[4] Yan Sun,[3] David A. Bushinsky.[5] *[1]UCL Medical School; [2]Denver Nephrology; [3]Amgen Inc.; [4]Indiana U Dept of Med; [5]U of Rochester School of Med.*

Background: Etelcalcetide (ETL), a novel IV calcimimetic, has been shown to reduce levels of parathyroid hormone (PTH), corrected calcium (cCa), phosphate (P) and fibroblast growth factor (FGF-23) in adults on hemodialysis (HD) with secondary hyperparathyroidism (SHPT).

Methods: Adult subjects on HD with SHPT (PTH>400pg/mL) were randomized to 26 wks ETL or placebo. ETL was started at 5mg IV per HD session and titrated every 4 weeks (max 15 mg) to achieve PTH≤300pg/mL. The efficacy of ETL was evaluated post hoc by baseline disease severity. Results shown are for the ETL arm only for % change in mean PTH, cCa, or P during the efficacy assessment phase (EAP, wks 20-27) and FGF-23 at wk 27 compared with baseline and % of subjects achieving PTH≤300pg/mL, P<5.5 mg/dL, and combination of PTH≤300 and P<5.5 during EAP.

Results: Subjects with higher baseline PTH levels had higher baseline levels of cCa, P, and FGF-23.(Table 1) %PTH reduction did not differ across strata. However, % reductions in cCa, P, and FGF-23 were greatest in the higher PTH strata. Achievement of PTH, P and PTH+P targets was highest in subjects in the lowest PTH stratum. Subjects in the lowest PTH stratum had the lowest dose of ETL during EAP. (Table 2)

Conclusions: ETLwas effective in reducing PTH levels regardless of baseline SHPT severity though achievement of targets was greatest and mean dose was the least in those with lesser disease severity. Subjects with the most severe SHPT at baseline had both the highest levels of cCa, P and FGF-23 at baseline and the greatest reductions during treatment with ETL.

Table 1. Baseline Laboratory Values by baseline PTH

	Entire Cohort (N = 509)	Stratum A PTH < 600 pg/mL (n =172)	Stratum B PTH 600 – 1000 pg/mL (n = 225)	Stratum C PTH > 1000 pg/mL (n = 112)

WELCOME - Web-Based Evaluation of the Clinical Benefit of Cinacalcet (MIM) in End-Stage Renal Disease (ESRD) in Central and Eastern Europe (CEE)

Jaroslav Rosenberger,[1] Piotr Mierzicki,[2] Alexander Selyutin,[3] Frantisek Svara,[4] Margit Hemetsberger.[5] *[1]FMC Kosice and Inst of Health Psychology, Medical Faculty Univ PJ Safarik, Kosice, Slovakia (Slovak Republic); [2]Wojewodzki Szpital Specialistyczny, Chelm, Poland; [3]Regional Clinical Hospital Orenburg, Moscow, Russian Federation; [4]Strahov General Univ Hospital, Prague, Czech Republic; [5]Hemetsberger Medical Services, Vienna, Austria.*

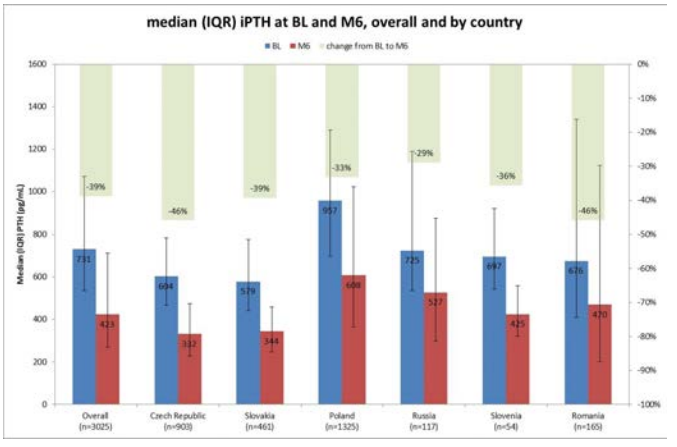
Background: This multicenter, observational study was conducted from 01/07 to 10/15. Aims: describe changes in CKD-MBD parameters after MIM start overall and before (BGR) *vs* after (AGR) KDIGO guideline release; describe characteristics of patients (pts) initiating MIM.

Methods: Eligibility: ESRD pts, MIM use according to SmPC. Data collected at baseline (BL=first MIM dose) and up to 6 months (M6). Endpoints: achieving PTH ≤300 pg/mL [primary]; KDOQI target for calcium (Ca) or phosphorus (P); vitamin D (Vit D) and P binder (PB) use; MIM dose; adverse drug reactions (ADR).

Results: 3025 pts were eligible; 2680 (89%) completed study; 345 discontinued (death 28%; transplantation 26%; adverse events 15%; loss to follow-up 11%; other 20%); 2582 (85%) completed ≥144 days of MIM.

	N=3025	
	BL, n (%)	**M6, n (%)**
PTH ≤300 pg/mL	58 (2)	884 (29)
PTH 150-300 pg/mL	50 (2)	664 (22)
Ca 8.4-9.5 mg/dL	1504 (50)	1584 (52)
P 3.5-5.5 mg/dL	938 (31)	1234 (41)
PB use	2528 (84)	1721 (57)
Vit D use	1736 (57)	1199 (40)

Median (IQR) MIM dose: 30 (30-42) mg/day. PTH varied between countries.



BGR *vs* AGR comparison was inappropriate: not all countries enrolled pts in both periods. 114 pts (4%) reported ADR (incl. gastrointestinal disorders, n=72; hypocalcemia, n=26); 1 pt had 2 serious ADR (cholecystitis, cholelithiasis). All-cause mortality: 3%.

Conclusions: MIM substantially reduced PTH and improved target achievement for PTH, Ca, and P; PTH values varied across countries.

Funding: Pharmaceutical Company Support - Amgen GmbH, Headoffice for CEE, Vienna, Austria

SA-PO963

Parathyroidectomy Achieves KDIGO Targets for Mineral and Bone Metabolism on Hemodialysis Patients?

Adriana Belo Lopes Prazeres, Teg Marcos Veiga, Amadeu de Assis Marinho Neto, Ana Paula Gueiros, Jose Edevanilson Gueiros. *Nephrology, UFPE, Recife, Pernambuco, Brazil.*

Background: Secondary hyperparathyroidism (SHP) is a common complication of chronic kidney disease. The Kidney Disease Improving Global Outcomes (KDIGO) guidelines provides target ranges for serum calcium, phosphorus and parathyroid hormone levels. Parathyroidectomy (PTX) is indicated for patients with refractory SHP despite clinical treatment. The aim of this study was to evaluate how PTX impacts KDIGO targets for CKD-MBD.

Methods: A retrospective review of patients on dialysis that underwent PTX was performed. Total calcium (Cat), phosphorus (P) and intact parathyroid hormone (iPTH) levels were analyzed immediately before PTX and after 6 and 12 months and compared with KDIGO targets. The PTX was indicated if the patient had untreatable SHP with medications or major complications of SHP (bone fracture, brown tumor, calciphylaxis).

Results: Between january 2004 and april 2015, 79 patients underwent PTX, 64.6% women with a mean age of 45.8 years and mean time on dialysis of 9.7 years. Total PTX with autotransplantation was the most common surgical technique. Laboratory tests are shown in Table 1.

	Baseline	6 months	12 months	p
Cat (mg/dL) *	10.55 ± 1.16[a,b]	8.96 ± 1.78[a]	8.76 ± 1.27[b]	<0.001
P (mg/dL) *	6.3 ± 1.81[a,b]	4.21 ± 1.82[a]	4.55 ± 1.38[b]	<0.001
iPTH (pg/mL) #	2046[a,b]	72,5[a]	81.2[b]	0.006
*values in mean±sd;# median; (a) baseline vs 6 months; (b) baseline vs 12 months.				

The percentage of patients that, after 6 months, had laboratory values of P, Cat and iPTH in agreement with KDIGO targets were 50.9%, 37.3% and 9.1%, respectively. After 12 months the percentage were 61.7%, 50% and 22.6%, respectively. When analyzed the three parameters together, no patient had laboratory values in target range defined by KDIGO at 6 months and, after 12 months, only 6.7% of patients. After 1 year, 64.5% of patients had iPTH < 150 pg/mL.

Conclusions: PTX is useful in the control of calcium and phosphorus, however keeps the level of iPTH off target level. Additionally, PTX determines high prevalence of hypoparathyroidism.

SA-PO964

Long-Term Mortality and Bone Safety in Patients with End-Stage Renal Disease Receiving Lanthanum Carbonate

Ravi I. Thadhani,[1] Alastair J. Hutchison,[2] Gillian Hall,[3] A. Whelton,[4] Heinrich Achenbach,[5] Jingyang Wu.[6] *[1]Massachusetts General Hospital, Boston; [2]Manchester Royal Infirmary, Manchester, United Kingdom; [3]Gillian Hall Epidemiology Ltd, London, United Kingdom; [4]Johns Hopkins Univ, Baltimore; [5]Shire, Zug, Switzerland; [6]Shire, Lexington.*

Background: This was a phase 4, long-term, observational, safety study of patients with ESRD treated with lanthanum carbonate (LaC) in the USA (NCT00567723).

Methods: The exposed group, comprising patients (≥18 years) who had received ≥12 consecutive weeks of LaC treatment, included patients from clinical trials of LaC and patients prescribed LaC as part of normal clinical practice. A matched comparator group, comprising patients treated with any other phosphate binder, was identified from the USRDS (1:4 matching). Both groups were on dialysis and were observed for up to 5 years using the USRDS. Primary endpoints were time to all-cause mortality and bone fracture rates requiring hospitalization. Secondary endpoints were time to gastrointestinal disease; liver disease; malignancy; and major infectious episodes requiring hospitalization.

Results: Of the 2136 exposed patients enrolled, 2027 were included in the analysis. Using 2014 USRDS data, a Kaplan–Meier analysis showed that median 5-year survival (95% CI) was 51.6 (49.1, 54.2) and 48.9 (47.3, 50.5) months for patients in the exposed (n=2027) and comparator groups (n=8103), respectively. Bone fracture rates were 5.9% and 6.7%, respectively. A Cox proportional hazards model was fitted to adjust for patient baseline characteristics. LaC was not associated with an increased risk of any of the safety endpoints; however, in one of the secondary endpoints, LaC had a significant 17% reduced risk of time to major infectious episodes (P<0.001).

Primary endpoints	Hazard ratio (95% CI)
All-cause mortality	0.96 (0.90, 1.03) P=0.262
First bone fracture	0.91 (0.74, 1.11) P=0.351
Secondary endpoints	
Gastrointestinal disease	0.90 (0.79, 1.02) P=0.090
Liver disease	0.85 (0.68, 1.07) P=0.163
Malignancy	1.20 (0.72, 2.01) P=0.488
Major infectious episodes	0.83 (0.77, 0.90) P<0.001

Conclusions: These data support the long-term safety of LaC in patients with ESRD.

SA-PO965

Effect of Kidney Donation on Bone and Mineral Metabolism: The KARMA Prospective Controlled Observational Study

Thomas F. Hiemstra,[1] Shreya Kulkarni,[1] Ragada El- Damanawi,[1] Carmel M. McEniery,[1] Laurie A. Tomlinson,[2] Ian Wilkinson.[1] *[1]Univ of Cambridge; [2]London School of Hygiene and Tropical Medicine.*

Background: Chronic Kidney Disease (CKD) is an independent risk factor for cardiovascular disease. Unilateral nephrectomy for live transplant donation represents an ideal model to study the effects of an acute decrement in GFR in the absence of renal pathology. Recent evidence suggests detectable differences in cardiac morphology early after kidney donation. We sought to determine the effect of kidney donation on bone and mineral metabolism.

Methods: We enrolled pre-donation living transplant kidney donors and healthy controls in this single-centre prospective cohort study. Biochemical parameters were determined before and after donation and after 12 months, and at baseline and 12 months in the control group.

Results: Between 2012-2015, we enrolled 34 donors (male=20, 59%) and 34 controls (male=16, 47%). The mean donor age was 53±10 years, vs controls 50±14 years (p=0.33). Most patients were Caucasian (94% and 97% respectively). Baseline eGFR was similar between groups (donor 83±15 mL/min, control 88±21 mL/min, p=0.21). In the control group, biochemical parameters did not change significantly over time. In contrast, kidney donation reduced eGFR significantly to 56±10 mL/min after 6 weeks (p<0.0001), and remained lower than baseline after 12 months 63±13 (p<0.0001). Alkaline phosphatase increased from 99±21 IU/L to 106±22 IU/L after 6 weeks (p=0.01), but after 12 months had reduced to significantly below baseline (83±22 IU/L, p=0.0003). PTH increased from 4.7 pg/mL (3.4-5.8) at baseline to 5.8 pg/mL (4.6-8.6, p=0.0007) after 12 months. Soluble α-klotho decreased markedly from 931 pg/mL (663-1145) at baseline to 721 pg/mL (562-957, p=0.0004) after 12 months. 1,25-Dihydroxyvitamin D concentrations decreased from 50±12 pg/mL at baseline to 42±13 pg/mL (p=0.0046) after 12 months.

Conclusions: Kidney donation results in a decrement in eGFR with incomplete recovery. This reduction in renal function results in persistently abnormal markers of bone mineral metabolism. Together with a lower ALP after 12 months, this suggests reduced bone turnover and may contribute to cardiovascular sequelae of reduced kidney function.

SA-PO966

Efficacy of Microwave Ablation for Severe Secondary Hyperparathyroidism in Subjects Undergoing Hemodialysis

Zongli Diao, Wenhu Liu, Guo Weikang. *Dept of Nephrology, Beijing Friendship Hospital, Capital Medical Univ, Beijing, China.*

Background: Severe secondary hyperparathyroidism is a serious problem in patients undergoing hemodialysis. The efficacy of microwave ablation, a minimally invasive treatment, for severe secondary hyperparathyroidism is as yet unclear. In this study, we studied its efficacy for patients with severe secondary hyperparathyroidism.

Methods: This was a prospective, single-arm, clinical trial. We enrolled patients with severe secondary hyperparathyroidism attending our hemodialysis center who met the inclusion and exclusion criteria. We then assessed primary outcome measures: serum concentrations of intact parathyroid hormone (iPTH).

Results: Twenty-six patients were enrolled in this study, 10 of whom (38.46%) were responsive to microwave ablation and 16 (61.54%) of whom were not. In response group patients, serum iPTH concentrations declined to within the target range (124–558 pg/mL) immediately after microwave ablation, the changes compared with baseline values being statistically significant (1272.02±440.34 vs. 176.09±75.84 pg/mL, P<0.001). During follow-up, the iPTH concentrations of seven of these patients remained within the target range; however, the remaining three patients experienced recurrences at the 15, 19, and 21-month follow-up. Sixteen patients with No Response stopped follow-up at 3 months (when they were identified as having No Response). Compared with baseline values (1691.42±354.48 pg/mL), iPTH concentrations declined significantly immediately after microwave ablation (1022.02±427.05 pg/mL), and at the 1-week (1161.82±437.21 pg/mL) and 1-month (1210.61±505.34 pg/mL) follow-ups, P values being <0.001, 0.005 and 0.013, respectively. However, iPTH concentrations did not decline to the target range. Furthermore, they started to increase from immediately after microwave ablation, increasing by the 3-month follow-up to concentrations that did not differ significantly from those at baseline. The main complication was recoverable hypocalcemia (10 cases, 38.46%).

Conclusions: Microwave ablation is relatively ineffective in patients with severe secondary hyperparathyroidism and should not be the initial therapy in such cases.

SA-PO967

Microwave Ablation for Mild-to-Moderate Secondary Hyperparathyroidism Patients on Hemodialysis

Zongli Diao, Wenhu Liu, Guo Weikang. *Dept of Nephrology, Beijing Friendship Hospital, Capital Medical Univ.*

Background: Secondary hyperparathyroidism (SHPT) is a common complication in hemodialysis patients. The main treatment for mild-to-moderate SHPT is calcitriol, but as the control rate is low. Microwave ablation (MWA) has been used for severe SHPT, and shows its unique advantages, such as little trauma. As MWA may be useful for mild-to-moderate SHPT, this study examined efficacy of the procedure.

Methods: In this prospective, randomized, controlled study, we compared efficacy of MWA plus calcitriol and calcitriol in patients with mild-to-moderate SHPT. All SHPT patients with iPTH 300–800 pg/mL at our hemodialysis center were eligible. Serum iPTH was recorded at month 0, 1, and 2 and then at 2-month intervals until month 12. Primary end points were: (1) overall rate to achieve iPTH target; (2) iPTH change after MWA; and (3) rate at which participants developed severe SHPT. The secondary end point was weekly calcitriol dosage.

Results: Twenty-eight patients were enrolled in this study. There was no statistical difference in rate to achieve iPTH target between MWA and calcitriol groups (23.33% *vs.* 20.73%; P=0.72). Rate of iPTH <150 pg/mL (lower limit of target range) in the MWA group was higher than the calcitriol group (23.33% *vs.* 8.54%; P=0.01). iPTH after MWA was significantly lower than the calcitriol group. iPTH of the MWA group was higher than the calcitriol group at baseline (610.24±210.69 *vs.* 521.68±164.9 pg/mL; P=0.227), but lower during follow-up. Maximum difference between MWA and calcitriol groups was 275.11 pg/mL at month 8 (554.66±289.78 *vs.* 279.55±172.78 pg/mL; P=0.02). Minimum difference was 58.06 pg/mL at month 2 (572.58±387.72 *vs.* 514.52±453.13 pg/mL; P=0.66), which was considered clinically significant. Only one case (7.14%) developed severe SHPT in the MWA group and six (42.86%) in the calcitriol group (P=0.038). Weekly calcitriol dosage of the MWA group was lower than the calcitriol group (1.56±1.49 *vs.* 4.72±4.72 μg; P=0.03).

Conclusions: MWA decreases iPTH levels significantly for mild-to-moderate SHPT and prevents development into severe SHPT. It is worthwhile attempting to treat mild-to-moderate SHPT with MWA.

SA-PO968

Calciphylaxis New Aspects of an Old Entity Enrique Morales, María Fernández Vidal, Eduardo Hernández-Martinez, Eduardo Gutierrez-Martinez, Manuel Praga. *Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: Calcific uraemic arteriolopathy (CUA), also called calciphylaxis, is a rare but disastrous and life-threatening disease mostly affecting patients with chronic kidney disease treated with dialysis. There is little information about the incidence of this entity in patients with a functioning kidney transplant (KT) and patients with normal kidney function (NKF). The aim of this study was to analyze risk factors (RF) and treatment of CUA in different types of patients.

Methods: Retrospective study that includes patients diagnosed with CUA from December 1999 to December 2015. Clinical features, laboratory evaluation, treatment and outcome were investigated.

Results: Twenty-eight patients (53.6% women) were included. The mean age was 67.2 ± 11.8 (38-88) years. The prevalence of diabetes mellitus and obesity (BMI>30 kg/m2) was 46.4 and 42% respectively. At the time of diagnosis, 53.6% were on hemodialysis (HD), 25% were KT patients and 21.4% had NKF. Skin biopsy confirmation was reported for 78.6% and the remaining were diagnosed clinically. 82.1% of cases showed peripheral CUA. The vitamin K antagonists (VKA) (68.7%) and steroids (100%) were considered a significant RF in patients with KT. The multimodal treatment (66.7% bisphosphonates, 58.3% intravenous sodium thiosulfate and 42.9% cinacalcet) was used in patients. The resolution of CUA was present in 62.5% patients. The mean follow-up time was 26.3 ± 45.2 (1-192) months. The 1-year patient survival in patients with CUA was 23, 56, 100% in the KT, HD and NKF patients respectively (log rank 6.8, p .032). Eleven patients died (39.3%) during the CUA, 6 cases (40%) of HD and 5 cases (71.4%) in patients with KT. The presence of renal insufficiency (p .03), Charlson's index (CI)> 7 (p .06), central CUA lesion (p .04) and hypoalbuminemia (p .02) were the significant RF of mortality in patients with CUA.

Conclusions: Although the incidence of CUA remains low in our population, the mortality is extremely high, mainly in the KT. The VKA should be considered as new and significant RF in the majority of groups. The identification of RF before CUA development and standard therapy should be the main objectives to conduct randomized clinical trials.

The Role of Calciprotein Particles in the Mineralisation Paradox in Chronic Kidney Disease Michael Ming Xin Cai,[1,2] Edward R. Smith,[1] Sven-Jean Tan,[1,2] Nigel David Toussaint,[1,2] Timothy D. Hewitson,[1,2] Stephen G. Holt.[1,2] *[1]Royal Melbourne Hospital, Australia; [2]Univ of Melbourne, Australia.*

Background: Vascular calcification in chronic kidney disease (CKD) is often accompanied by a paradoxical reduction in bone mineralisation. In CKD, a fraction of serum calcium (Ca) and phosphate (Pi) circulates as colloidal nanocrystals stabilised by a protein shell, termed calciprotein particles (CPPs). CPPs are associated with arterial stiffness, coronary calcification and mortality. This study tested the differential effect of CPP on vascular smooth muscle cell (VSMC) and osteoblast mineralisation.

Methods: Saos-2 (an osteosarcoma cell line) and MOVAS-1 (murine VSMC) were treated for 7 days with either control media (CM), osteogenic media (OM, +3mM Pi), CM supplemented with secondary CPP (CPP) or OM supplemented with CPP (OM+CPP). Mineralisation was detected with alizarin red and von Kossa staining, and quantified as Ca corrected for protein. Cell viability was determined by the ratio of live/total cell count. Alkaline phosphatase (ALP) activity was assayed using p-nitrophenyl phosphate based method.

Results: OM treatment increased Saos-2 mineralization, but not MOVAS-1. OM+CPP treatment yielded a dose-dependent *decrease* in Saos-2 mineralisation. In contrast, treatment of MOVAS-1 with OM+CPP resulted in a *synergistic increase* in mineralisation compared to OM and CPP respectively. OM+CPP but not OM or CPP reduced MOVAS-1 viability(P<0.01). ALP activity was similar between treatment groups in both cell lines. Compared to freshly prepared OM+CPP, media pre-incubation for 24 h at 37^{o}C reduced monolayer mineralisation in both cell lines despite an increase in CPP bound calcium.

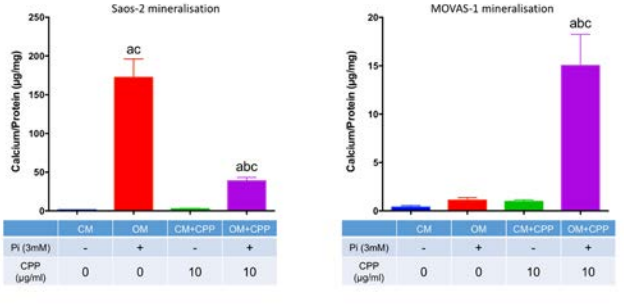

Figure 1: Differential effects of Pi and CPP on Saos-2 and MOVAS-1 cell monolayer mineralisation over 7 days.
Legend: a, P<0.01 vs CM; b, P<0.01 vs OM; c, P<0.01 vs CM+CPP.

Conclusions: In high Pi, CPP reduce mineralisation of an osteoblast-like cell but increase mineralisation of a VSMC cell line. Our findings suggest circulating CPP in CKD serum may be a novel mediator of the calcification paradox in CKD.

Cortical Unlike Trabecular Bone Is Not Associated to Coronary Artery Calcification Progression in Chronic Kidney Disease Patients Larissa Rodrigues,[1] Amandha Bittencourt,[1] Aluizio B. Carvalho,[1] Raul Santos,[2] Carlos Eduardo Rochitte,[2] Maria Eugenia F. Canziani.[1] *[1]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil; [2]Heart Inst Univ of Sao Paulo Medical School Hospital, Sao Paulo, Brazil.*

Background: Vascular calcification progression has been associated with loss of trabecular bone in chronic kidney disease (CKD) patients. There are few data evaluating the relation between cortical bone and vascular calcification in this population. The aim of this study was to analyze cortical bone density (BD) from vertebral tomographic images and its association with coronary artery calcification (CAC) progression in non-dialyzed CKD patients.

Methods: Over time changes of cortical and trabecular bone were analyzed by using vertebral tomographic images at the level of the aortic root from a previous prospective study. Automatic delineation of cortical bone layer was performed by *Image J* software, and trabecular bone was determined by selecting a region of interest placed at mid-vertebral body including only trabecular bone using Vitrea2 workstation software. Cortical and trabecular BD were expressed in Hounsfield Units (HU). Coronary artery calcium score was expressed as Agatston Units (AU). The presence of CAC was considered when calcium score was equal or higher than 10 AU.

Results: 70 asymptomatic patients (57.8 ± 10.2 years, 63% males, 20% diabetics, estimated glomerular filtration rate (eGFR) = 37.3 (24.8 – 51.3) ml/min/1.73m^2) were followed for 24 months. Cortical bone density was 400.0 ± 89.9 and 404 ± 94.8 HU (p= 0.41), at baseline and at 24 months, respectively. During follow-up, 29 (41.4%) patients reduced their cortical BD. Changes in cortical BD were not associated to age, gender, diabetes and baseline or changes of eGFR and mineral bone parameters. There was no association between cortical and trabecular BD changes (r=0.19; p=0.12). CAC was observed in 33 (46%) patients at baseline, and 30 (91%) of them showed CAC progression. Cortical bone changes were not associated with CAC progression (r=0.18; p=0.34).

Conclusions: Despite a substantial number of patients showed cortical bone loss there was no association between changes in cortical BD and coronary calcification progression.

SA-PO971

Trabecular Bone Score and Incident Fragility Fracture Risk in Adults with Reduced Kidney Function Kyla Lynn Naylor,[1] Jerilynn C. Prior,[2] Amit X. Garg,[1,3] Claudie Berger,[4] Lisa Langsetmo,[5] Jonathan D. Adachi,[6] David Goltzman,[4] Christopher S. Kovacs,[7] William Leslie.[8] *[1]Inst for Clinical Evaluative Sciences; [2]Univ of British Columbia; [3]Univ of Western Ontario; [4]McGill Univ; [5]Univ of Minnesota; [6]McMaster Univ; [7]Memorial Univ; [8]Univ of Manitoba.*

Background: Trabecular bone score (TBS) is a gray-level textural measure obtained from dual energy X-ray absorptiometry (DXA) lumbar spine images which provides information independent of areal bone mineral density (BMD). The association between TBS and incident fractures in adults with reduced kidney function, and whether this association differs from adults with normal kidney function, is unknown.

Methods: We included 1426 participants aged ≥40 years (mean age 67 years) in the community-based Canadian Multicentre Osteoporosis Study. We stratified participants at cohort entry by estimated glomerular filtration rate (eGFR <60 [n=199, 72.4% stage 3a, 25.1% stage 3b, and 2.5% stage 4] versus ≥60 ml/min/1.73 m^2 [n=1227]). TBS was obtained from lumbar spine (L1-L4) DXA images, with a lower TBS representing worse bone health. Over an average of 4.7 years follow-up we documented incident fragility (low-trauma) fracture events (excluding craniofacial, foot, and hands). We used a modified Kaplan-Meier estimator to determine the 5-year probability of fracture. Cox proportional hazard regression per standard deviation decrease in TBS expressed the gradient of fracture risk.

Results: Individuals with an eGFR <60 mL/min/1.73 m^2 who had a TBS value below the median (<1.277) had a significantly higher 5-year fracture probability than those above the median (18.1% versus 6.2%; *P*=0.01). The association between TBS and fracture was independent of BMD and other clinical risk factors in adults with reduced and normal kidney function (adjusted hazard ratio [aHR] per standard deviation decrease in TBS: eGFR <60 ml/min/1.73 m^2,aHR 1.62, 95% confidence interval [CI] 1.04-2.51; ≥60 ml/min/1.73 m^2, aHR 1.44, 95% CI 1.13-1.83).

Conclusions: Lower lumbar spine TBS is independently associated with a higher fracture risk in adults with reduced kidney function.

SA-PO972

Association of Bone Mineral Density with Fractures across the Spectrum of Chronic Kidney Disease - The Prairie DXA Study Bhanu Prasad,[1] Jennifer St.Onge.[2] *[1]Nephrology, Regina Qu Appelle Health Region, Regina, SK, Canada; [2]Research and Performance Support, Regina Qu Apelle Health Region, Regina, SK, Canada.*

Background: Bone mineral density (BMD) by dual energy x-ray absorptiometry (DXA) scans predict fractures rather robustly in otherwise healthy men and women, but its role in CKD patients has been less defined. DXA quantifies areal bone mineral content, which measures bone density but it does not pick up derangements of bone quality or architecture which are inevitable in CKD.Impaired architecture may present as low BMD on DXA scans.Therefore, DXA may not be the most robust instrument to accurately predict the risk of fracture. We wanted to examine the relationship of BMD with fracture risk across the spectrum of CKD.

Methods: We conducted a retrospective review of 410 consecutive patients who underwent DXA scan at the point of entry into our multidisciplinary chronic kidney disease (CKD) program. BMD data, T score and Z scores were collected at four sites: the lumbar spine, total hip, mean of left and right femoral neck, and the proximal radial region (radius 33%). We collected data on demographic, lab markers of mineral metabolism and fractures.

Results: 35.9% stage III CKD, 28.4 % stage IV CKD, and 32.4% stage V CKD patients experienced a clinical fracture during the study period. On multivariate analysis, a decline of 1.0 SD in total Hip BMD T-score was associated with a statistically significant increase in the risk of fracture (OR= 1.36, 95% CI: 1.02, 1.72, p=.04) while controlling for parathyroid hormone, alkaline phosphatase, calcium and phosphorus and GFR of <30. Compared to a GFR of ≥30 mls/ minute, the OR of identifying a fracture was 1.54 in comparison to OR of 1.14 in patients with GFR <29 mls/minute.

Conclusions: This is the largest Canadian cohort of CKD patients with DXA scans to our knowledge.We were able to show that T-scores predict fractures across stage III, but had a modest ability in stage IV. As fractures lead to significant morbidity and mortality, we believe there is a role for DXA scans which, are inexpensive, non-invasive, safe, and readily available have a role in clinical practice for identifying patients at risk for fractures in different stages of CKD.

SA-PO973

Association of Dialysate Calcium Concentration, Vitamin D Use, and Hip Fracture in Hemodialysis Patients Miho Tagawa,[1] Takayuki Hamano,[2] Shinichi Sueta,[3] Seiji Hashimoto,[2] Satoshi Ogata.[2] *[1]Nara Medical Univ; [2]Patient Registration Committee of Japan Renal Data Registry; [3]Kyoto Univ.*

Background: The effects of dialysate calcium concentration (D[Ca]) on bone and mineral markers have been studied, however, the association between D[Ca] and fracture has not been studied. In Japan, most dialysis facilities use central supply system for dialysate.

Methods: This was a longitudinal study based on the Japan Renal Data Registry from 2008 to 2010. Hemodialysis patients without prior hip fracture were enrolled. Predictor variable was D[Ca] (≥3.0 vs 2.5 mEq/L). Use of active vitamin D (VitD) in each D[Ca] category was also considered. Outcome variable was incidence of hip fracture during 2 years. Statistical analyses were performed using multivariate logistic regression model, adjusted for potential confounders.

Results: Among 301,649 patients on the database, data for 47,352 patients were available after excluding missing data. There were 979 events of hip fracture during 2 years. Adjusted OR for D[Ca]≥3.0mEq/L was 0.89 (0.78-1.02), 0.93 (0.77-1.12), 0.89 (0.69-1.14), and 0.75 (0.52-1.08) for total cohort, patients with intact parathyroid hormone (PTH) <150, 150-300, and >300 pg/mL, respectively. Among patients with PTH 150-300 pg/mL, VitD use was associated with significant reduction in hip fracture for both D[Ca] categories and D[Ca] of 2.5 mEq/L with VitD use was associated with lower incidence of hip fracture compared to D[Ca]≥3.0 mEq/L without VitD. Among patients with PTH>300 pg/mL, the use of D[Ca] of 2.5 mEq/L without VitD was associated with significant increase in hip fracture.

	PTH<150 pg/ml	PTH 150-300 pg/ml	PTH > 300 pg/ml
D[Ca]≥3.0, Vit D (-)	1 (reference)	1 (reference)	1 (reference)
D[Ca]>3.0, Vit D (+)	0.85 (0.68-1.07)	0.68 (0.49-0.95)	1.39 (0.74-2.63)
D[Ca]2.5, Vit D (-)	1.20 (0.92-1.57)	1.37 (0.91-2.06)	2.37 (1.11-5.08)
D[Ca]2.5, Vit D (+)	0.83 (0.65-1.07)	0.69 (0.49-0.98)	1.57 (0.83-2.96)

Conclusions: The effects of D[Ca] of 2.5 mEq/L on incident hip fracture is dependent on PTH levels and concomitant VitD use. The results suggest that vitamin D should be prescribed not to increase the risk of fracture when using D[Ca] of 2.5 mEq/L.

SA-PO974

The Prevalence and Risk Factors of Low Bone Mineral Density in Chinese Chronic Kidney Disease Patients Ying Qian, An Jin Chang, Xiaonong Chen. *Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

Background: Bone and mineral disorder is one of the most common clinical complications in CKD patients. Since Chinese research in this field is only at the beginning, we need more data to analysis the prevalence and risk factors of low bone mineral density in Chinese CKD patients.

Methods: We selected CKD inpatients from 2009 to 2015.Patients were excluded if they used glucocorticoid and calcitriol. GFR was estimated using MDRD formula for Chinese. All patients were classified into 5 CKD stages according to K/DOQI guideline and were measured BMD at lumbar spine, femoral neck and total hip by dual energy X-ray absorptiometry (DXA). Osteoporosis was defined by BMD according to the reference values suitable for Chinese population. Clinical characteristics of all patients were also collected. The correlation between BMD and detection indexes was analysed and the independent risk factors for low BMD in CKD patients were also explored.

Results: A total of 429 patients were enrolled in the study.Mean age of the patients (221 males and 208 females) was 53.89±16.14 years. Totally 43.59% of all patients were diagnosed as low BMD (including osteopenia 23.31% and osteoporosis 20.28%). The number of patients in CKD1-5 was 127, 72, 75, 39 and 116, respectively. And the prevalence of low BMD in CKD1-5 were 33.1%,41.7%,40%,38.5%,60.3%. Simple linear regression analysis showed that BMD at femoral neck and total hip (g/cm^2) were positively associated with BMI, eGFR, CO2-CP, Ca and 25(OH)D_3, but negatively associated with age, Scr, AKP, iPTH and P. The BMD of lumbar spine (L1-L4) were only positively associated with BMI, and negatively associated with age, AKP. Multiple linear regression analysis showed that femoral neck BMD or total hip BMD was independently associated with Scr after adjusting potential confounding factors. Multiple logistic regression analysis revealed that serum creatinine was the independent risk factor for low BMD in CKD.

Conclusions: The prevalence of low BMD was high in Chinese CKD patients. And the femoral neck BMD and total hip BMD decreased with the decline of renal function.

SA-PO975

Improvement of Reduced Bone Mineral Density after Total Parathyroidectomy in the End-Stage Renal Disease Patients with Severe Secondary Hyperparathyroidism Li Fang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: The ESRD patients with secondary hyperparathyroidism (SHPT) usually display reduced bone mass which might lead to a substantial increase in osteoporosis and fracture. Despite the development of new therapeutic agents, a majority of patients still require parathyroidectomy (PTX). However, the effect of total PTX on bone mass changes in SHPT is not well understood yet. The aim of this study was to evaluate whether BMD changes after total PTX and identify which factor contributes most to bone changes.

Methods: 34 patients undergoing total PTX because of severe secondary hyperparathyroidism were included. Preoperative and postoperative bone mineral density (BMD) values measured by dual energy X-ray absorptiometry (DEXA) and some other clinical parameters were collected.

Results: Before PTX, we found that the prevalence of osteopenia and osteoporosis at different lumbar vertebra sites vary greatly. Osteoporosis at L1 was revealed in11.8%, while at L4 was 32.5%. Osteopenia at L1 was in 32.5%, while at L4 was in 32.3%. For the hip, DEXA showed osteopenia in 55.9% and osteoporosis in 23.5% at femoral neck, and 61.7% and 5.9% at trochanter. After PTX, lumbar spine BMD significantly increased from 0.92±0.157 g/cm2 to 1.04±0.171 g/cm2 and femoral neck BMD increased from 0.69±0.127 g/cm2 to 0.79±0.131 g/cm2. Accordingly, the prevalence of osteoporosis and osteopenia were decreased (Osteoporosis: L1 5.9%, L4 5.9%, femoral neck 0%, trochanter 0%; Osteopenia: L1 26.5%, L4 32.3%, femoral neck 55.9%, trochanter 61.8 %). At the most affected site L4, 91.2% had significant improvement (>5%), 2.9% moderate improvement (0.1-5%) and 5.9% declining bone mineral density. Patients who significantly improved usually had lesser preoperative BMD values (P =0 .001), greater preoperative levels of parathyroid hormone (P = .002), and higher parathyroid gland weight (P = 0.008).

Conclusions: Bone mineral density signicantly improves after surgery, which support total PTX in ESRD patients with severe secondary hyperparathyroidism. The hip and lumbar spine had similar response to PTX, especially in the load-bearing trabecular bone.

SA-PO976

The Characteristics of Bone Mineral Density Changes in the End-Stage Renal Disease Patients with Severe Secondary Hyperparathyroidism Through Separate Analyses Li Fang, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Bone mineral density (BMD) measurement using dual-energy X-ray absorptiometry (DEXA) was still controversial in screening for and monitoring of renal osteodystrophy in end-stage renal disease (ESRD) patients. However, considering the significance of secondary hyperparathyroidism (SHPT) in the pathogenesis of renal osteodystrophy, the purpose of this study was to evaluate the characteristics of BMD changes in the ESRD patients with severe secondary hyperparathyroidism.

Methods: 126 patients who were hospitalized for severe secondary hyperparathyroidism were included in this cross-sectional study. BMD values and some other clinical parameters were collected.

Results: We found that BMD values decreased significantly from L1 to L4 in the lumbar spine and the prevalence of osteoporosis seemed to be much higher in the lumbar spine but lower in the hip, which indicating that the bone loss seemed predominant in the load-bearing trabecular bone. Correlation analysis revealed that parathyroid hormone (PTH) was negatively correlated with the BMD Z-scores of the lumbar spine and hip. To further investigate the impact of PTH on BMD changes, we stratified the patients according to their i-PTH levels (500-1000, 1000-2000, and >2000pg/ml, respectively). We found that along with the increase of parathyroid hormone, the loss of bone mineral content was prior to the loss of bone area for the lumbar spine, especially in the load-bearing bones. However, for the hip, the changes of bone mineral content were not significantly, while the bone area at intertrochanter was even significantly increased in the group with PTH above 2000 pg/ml.

Conclusions: Bone densitometry reveals pronounced decrease in bone mineral density in severe secondary hyperparathyroidism and the significance of PTH induced bone abnormalities would actually be diverse depending on the sites. BMD measurement by DEXA might be of major clinical relevance in the evaluation of bone loss in ESRD patients with severe secondary hyperparathyroidism.

Funding: Government Support - Non-U.S.

Free Testosterone Is Positively Associated with Bone Mineral Density in Kidney Transplant Candidates Hanne Skou Joergensen,[1] Simon Winther,[2] Lars Rejnmark,[3] My Svensson,[4] Per R. Ivarsen.[1] *[1]Nephrology, Aarhus Univ Hospital, Aarhus, Denmark; [2]Cardiology, Aarhus Univ Hospital, Aarhus, Denmark; [3]Endocrinology, Aarhus Univ Hospital, Aarhus, Denmark; [4]Nephrology, Akerhus Univ Hospital, Oslo, Norway.*

Background: Hypogonadism is common in CKD. Both testosterone (T) and estradiol (E) decrease bone resorption and are positively associated with bone mineral density (BMD) in healthy elderly, but little is known of the effects of sex hormones on bone health in CKD. We investigated associations between free T, free E and BMD in male kidney transplant candidates.

Methods: Volumetric BMD (vBMD) of lumbar spine and total hip were measured by quantitative computed tomography. Total T, total E, sexual hormone binding protein (SHBG), intact parathyroid hormone (iPTH) and albumin were analyzed from fasting morning blood samples. Free T and free E were calculated based on constants for protein binding to SHBG and albumin.

Results: Analyses included 107 patients. Free T correlated to age (r= -0.20, p=0.04), weight (r= -0.25, p=0.01), Ln Free E (r=0.42, p<0.001) and dialysis treatment (r=0.47, p<0.001). Ln Free E correlated to Free T, type 1 diabetes (r=0.22, p=0.03) and ln-iPTH (r=0.20, p=0.04). Figure 1 shows the association between sex hormones and vBMD. In the multiple linear regression model, both hormones were significant predictors at lumbar spine and Free T was significant at total hip (Table 1).

	Lumbar spine (Adj. R^2=0.23)		Total hip (Adj. R^2=0.21)	
	β	*p*	*β*	*p*
Age	-0.975	0.004	-0.304	0.46
Weight	-0.188	0.47	-0.003	0.99
Dialysis	-19.69	0.009	-27.52	0.003
Type 1 diabetes	-5.70	0.52	-35.29	0.001
Type 2 diabetes	13.90	0.17	29.21	0.02
Ln iPTH, pmol/L	-9.59	0.01	-13.14	0.007
Free T, pmol/L	0.094	0.049	0.137	0.02
Ln Free E, pmol/L	17.24	0.04	10.75	0.30

Conclusions: Sex hormones may play an important part in bone health in men with late stage CKD.

Large Variations between Four Methods for Sclerostin Determination in Patients Undergoing GFR Measurement and in Hemodialyzed Patients before and after a Single Dialysis Session Etienne Cavalier,[1] Pierre Delanaye.[2] *[1]Clinical Chemistry, Univ of Liege; [2]Nephrology, Univ of Liege.*

Background: Sclerostin (SCL) is a promising biomarker for bone research. It has also been associated, in some studies, with mortality in hemodialyzed (HD) patients. However, literature is conflicting on that point and some authors have pointed out that assays used for SCL might explain these discrepancies. Also, the impact of renal function on SCL levels remains poorly studied.

Methods: We have measured SCL concentration in 150 healthy and CKD patients who had undergone GFR determination with the iohexol method. We have also measured SCL before and after a single dialysis session in 44 patients. Each sample has been measured with 4 different ELISA: Biomedica (B), MSD (M), R&D (R) and Teco (T).

Results: Median [IQR] SCL concentration in the non-HD patients were very different according to the method: B : 1017 [546], M : 36 [21], R : 160 [101] and T : 629 [325] pg/mL. We did not observe any systematic differences between the methods. In univariate analysis, we observed a significant and inverse relation between GFR and SCL when measured by B, R and T but not with M. The different assays also showed a wide variation in HD patients. With B and R methods, HD patients presented median values higher than those whose GFR was >45 mL/min, but were similar with those presenting GFR <45 mL/min. With T method, the median observed in HD patients was higher than in non-HD patients, whatever the GFR. On the contrary, median SCL was lower in HD than in non-HD patients with the M method. After a dialysis session, a significant decrease was observed in HDF, but not in HD mode and was always more important if SCL was measured with T, B and R methods, compared to the M one.

Conclusions: SsCL determination in CKD patients is challenging and any conclusion is method-depending. Previously described relations between GFR and SCL levels may be an analytical artifact with inactive SCL fragments that would accumulate when GFR decreases and would be recognized by T, B and R, but not M method. In conclusion, method for SCL determination clearly impacts findings previously observed in CKD and HD patients.

SA-PO979

Sclerostin – A Debutant on the Autosomal Dominant Polycystic Kidney Disease Scene? Magdalena Jankowska,[1,2] Abdul Rashid Tony Qureshi,[1] Bengt Lindholm,[1] Peter Stenvinkel,[1] Pieter Evenepoel.[3] *[1]Div of Renal Medicine and Baxter Novum, Karolinska Univ Hospital at Huddinge M99, Karolinska Inst, Stockholm, Sweden; [2]Dept of Nephrology, Transplantology and Internal Medicine, Medical Univ of Gdansk, Gdansk, Poland; [3]Dept of Immunology and Microbiology, Laboratory of Nephrology, Katholieke Univ Leuven, Leuven, Belgium.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disease originating from a mutation in genes encoding polycystin 1 and 2. Recent evidence suggests that these polycystins mediate mechanosensation not only in the primary cilium of kidney cells but also in bone cells. The Wnt/β-catenin signaling pathway plays a central role in mechanotransduction in osteocytes. Mechanical unloading causes the upregulation of the Wnt inhibitor sclerostin. We tested the hypothesis that ADPKD associates with higher circulating sclerostin levels.

Methods: Circulating levels of sclerostin and other laboratory parameters of mineral and bone disease, including intact parathyroid hormone (PTH), calcium, phosphate, magnesium, 25(OH)D-vitamin, 1.25(OH)D-vitamin and bone specific alkaline phosphatase (bALP) were assessed in 503 patients with end stage renal disease recruited from ongoing longitudinal cohort studies in Stockholm, Sweden (**cohort 1**; n=100, 19% ADPKD) and Leuven, Belgium (**cohort 2**; n=403, 19% ADPKD).

Results: Patients with ADPKD had higher sclerostin levels and lower bALP levels as compared to patients with other primary renal disease. In multivariate analysis, ADPKD associated with circulating sclerostin levels, independent of the established determinants including age, gender, body mass index, diabetes, phosphate, PTH, and 1,25(OH)D-vitamin.

Conclusions: Circulating sclerostin levels are increased in ADPKD, possibly reflecting impaired mechanosensation. The clinical relevance of this finding, e.g. with regard to vascular and bone health, remains to be investigated. Our finding draws attention to etiology of kidney disease as an important, yet neglected, confounder or the association between renal failure and mineral and bone disease.

SA-PO980

Bone Marrow Adipocyte after GH Supplementation in Pediatric ESKD Patients Ornatcha Sirimongkolchaiyakul, Renata C. Pereira, Katherine Wesseling-Perry, Isidro B. Salusky. *Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Mesenchymal stem cells are precursors for both osteoblasts and adipocytes. Marrow adipogenesis is associated with osteoporosis in adults with normal kidney function. GH increases osteoblast proliferation and differentiation and is commonly used to promote growth in children with CKD. The effects of GH on bone marrow adipogenesis; however are unknown.

Methods: 24 pediatric peritoneal dialysis patients age 10.3 + 4.6 (SD) years with high (n=14) or low/normal (n=10) bone turnover were randomly assigned to treatment with GH or not. Patients with high bone turnover group also received intraperitoneal Calcitriol. Bone biopsy was performed at baseline and after 8 months of therapy.

Results: Marrow adipocytes/tissue area did not change with therapy in patients with either high turnover or low/normal bone turnover, irrespective of treatment with GH versus standard therapy.

Table 1 Biochemical and marrow adipocyte

	High Bone Turnover			Low/normal Bone Turnover		
	Baseline	Calcitriol + GH (N = 6)	Calcitriol + no GH (N = 8)	Baseline	GH (N = 6)	Nothing (N = 4)
S-Ca (mg/dl)	9.66 ± 0.89	8.98 ± 0.48	6.55 ± 1.49	10.10 ± 0.72	9.7 ± 0.26	9.45 ± 0.41
S-PTH (pg/ml)	602 ± 373	1045 ± 154	291 ± 169	127 ± 75	500 ± 130	381 ± 343
N. adipocyte	1748 ± 898.87	1498.17 ± 1079.13	1717.75 ± 777.55	1866.70 ± 788.79	1624.5 ± 1115.19	2101.75 ± 562.06
N. adipocyte/T. Ar (/mm2)	145.98 ± 62.85	122.09 ± 78.15	144.89 ± 50.82	178.84 ± 63.48	147.56 ± 87.39	183.81 ± 55.72

Table 2 Changes of marrow adipocyte in patients received GH or noting

	GH (N = 12)	no GH (N=12)	p-value
N. adipocyte/T.Ar (/mm2)	25.93 ± 57.14	39.77 ± 37.30	0.48

Table 3 Changes of marrow adipocyte in high and low/normal bone turnover

N. adipocyte/T. Ar (/mm2)	High Bone turnover (N = 14)	Low/normal bone turnover (N = 10)	p-value
GH	41.46 ± 66.68	10.39 ± 40.01	0.39
no GH	12.09 ± 61.89	-26.35 ± 16.56	0.29

Conclusions: Marrow adipocity did not change in response to GH therapy in this sample of pediatric ESKD patients.

SA-PO981

Canonical Wnt Signaling May Contribute to Altered Pre-Osteoblast Maturation Characteristics in CKD Renata C. Pereira,[1] Richard Bowen,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Orthopedic Surgery, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Dentistry, UCLA, Los Angeles, CA.*

Background: Bone disease in chronic kidney disease (CKD) has been traditionally defined by changes in bone turnover stemming from altered circulating parathyroid hormone (PTH) concentrations. However, we have shown that primary pre-osteoblasts from CKD patients have increased proliferation and decreased mineralization rates *ex vivo*, suggesting that CKD induces intrinsic changes to osteoblast biology that are independent of circulating PTH concentrations.

Methods: To understand potential mechanisms mediating these changes, primary pre-osteoblasts from 6 adolescent dialysis patients (3 with high and 3 with low bone turnover) and 3 healthy adolescent controls were plated at 10,000 cell/cm^2 and cultured in the presence of growth media (10% fetal bovine serum and 100 μg/ml ascorbic acid) until achieving confluence. Maturation/mineralization was promoted by the addition of 10mM β-glycero-phosphate and cells were grown for 7 days after which time RNA was harvested from cultures for RNA Seq analysis (Genewiz). Parallel cultures were grown for 14 days after which time total protein was isolated.

Results: RNA Seq analysis revealed marked differences in expression of genes of the *Wnt* signaling pathway; thus, beta-catenin expression was evaluated in protein extracts. Beta catenin protein was increased in CKD as compared to healthy control cells.

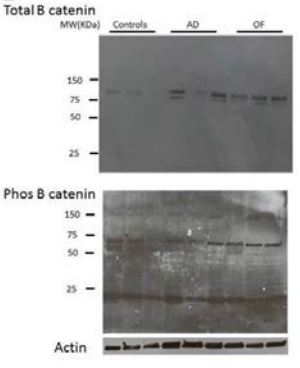
B



Conclusions: Increased proliferation and decreased mineralization rates in pre-osteoblasts from CKD patients suggests that increased canonical *Wnt* signaling may contribute to this phenotype.

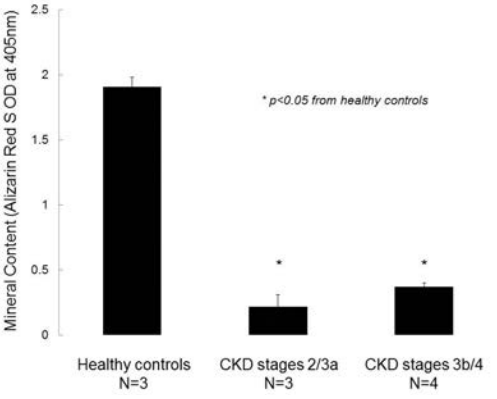
SA-PO982

Pre-Osteoblast Maturation Failure Is a Feature of Early Chronic Kidney Disease Renata C. Pereira,[1] Kathleen Noche,[1] Richard Bowen,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Orthopedic Surgery, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Primary pre-osteoblasts from ESKD patients have decreased mineralization rates *ex vivo* (Pereira RC, KI 2015) suggesting that CKD induces intrinsic changes to osteoblast biology resulting in maturation failure.

Methods: To evaluate whether this phenotype is a feature of early CKD, pre-osteoblasts from 7 adolescent patients with CKD stages 2-4 with normal serum calcium, phosphorus, and PTH levels and from 3 healthy adolescent controls were plated at 10,000 cell/cm^2 and cultured in 10% fetal bovine serum and 100 μg/ml ascorbic acid until achieving confluence. Cells were stimulated to mineralize with 10 mM β-glycero-phosphate for 21 days then washed with PBS, fixed with 10% formalin, and stained with 2% Alizarin Red S. Mineral content was measured by acetic acid-extracted Alizarin Red S dye OD at 405 nm. Subsequently, the potential of CKD and healthy control pre-osteoblasts to transition to an adipocyte-like phenotype was examined by culturing confluent cells in the presence of insulin (1μM), dexamethasone (10^{-6}M), and isobutylmethylxanthine (0.5mM) for two weeks. Cells were then stained with Oil Red O; fat was extracted using 100% isopropanol for 30 minutes and absorbance measured at 490 nm.

Results: Cells from pre-dialysis CKD patients with all stages of pre-dialysis CKD mineralized more slowly (figure 1) and transitioned to an adipocyte-like phenotype more readily than healthy controls (Oil red O OD: 0.28+0.06 v. 0.18+0.03, respectively; p<0.05 between CKD and healthy controls).



Conclusions: Decreased mineralization rates and an increased propensity for pre-osteoblasts to transition to an adipocyte-like phenotype may represent bone cell maturation failure in early CKD.

Bone Biopsy Results in Chronic Kidney Disease Orfeas Liangos,[1] Silvia Kirchhoff,[2] Joachim Buchholz,[1] Markus Ketteler.[1] *[1]Nephrology, Klinikum Coburg, Coburg, Germany; [2]Faculty of Medicine, Univ of Wuerzburg, Wuerzburg, Germany.*

Background: Although bone histology remains the gold standard in the differential diagnosis of renal osteodystrophy, biomarkers are more commonly used for diagnosis and to guide therapy. However, their predictive value may be questionable. Notwithstanding these facts, data comparing bone biopsy results and biomarkers of bone metabolism remain sparse.

Methods: Here we present a retrospective analysis of bone biopsy results from a single center comprising N=109 patients, categorized according to renal function and compared with intact parathyroid hormone (iPTH), alkaline phosphatase and other biomarkers. We tested associations of these markers with renal osteodystrophy (ROD) class IIIb according to Delling's classification. Results are shown in mean (SD) or percent, as appropriate. Comparisons are made using the Mann-Whitney test due to skewed distribution of values.

Results: Mean (SD) age was 69 (13) years, 55% were women, 25% diabetic, 76% hypertensive, 34% had vertebral fracture. Mean alkaline phosphatase (AP) and bone-specific AP were 112 (83) and 21 (14) U/l, respectively, and iPTH 16 (19) pmol/l. 12% of patients had normal renal function, 37% were in CKD stage 3-5 not on dialysis and 50% were in CKD stage 5D (ESRD). iPTH values were significantly higher in ESRD with high-turnover mixed uremic osteodystrophy (ROD IIIb), 29 (18) pmol/l, if compared to patients without, 9 (9) pmol/l (p<0.001). No significant associations were found for AP or bone-specific AP serum levels. In CKD patients not on dialysis, the finding of ROD IIIb was associated with elevated iPTH, 37 (50) versus 9 (10) pmol/l (p=0.008), bone-specific AP, 55 (44) versus 17 (7) U/l (p=0.04), and decreased blood pH, 7.36 (0.05) versus 7,44 (0.06) (p=0.04). As expected, no phenotypes of RA were found in patients with normal renal function.

Conclusions: While in ESRD patients, presence of high-turnover renal osteodystrophy on iliac crest biopsy was associated with elevated iPTH and serum urea level but not with bone-specific or total AP; the same diagnosis in patients with CKD not on dialysis was also associated with iPTH but, in addition, with elevated bone specific AP and decreased blood pH.

SA-PO984

Osteitis Fibrosa versus Mixed Disease: What Are the Differences? Teg Marcos Veiga,[1] Adriana Belo Lopes Prazeres,[1] Amadeu de Assis Marinho Neto,[1] Jose Edevanilson Gueiros,[1] Ana Paula Gueiros,[1] Vanda Jorgetti.[2] *[1]Nephrology, UFPE, Recife, Pernambuco, Brazil; [2]Nephrology, USP, Sao Paulo, Brazil.*

Background: Bone mineralization is fundamental for the formation of healthy bone and various factors contribute to this process. In high bone turnover, it is the mineralization deficiency present in mixed disease (MD) that distinguishes it from osteitis fibrosa (OF). The aim of this study was to identify clinical and laboratory parameters capable of clinically distinguishing between these two conditions.

Methods: Retrospective analysis of 166 patients on dialysis with a histological diagnosis of high bone turnover. The clinical data examined were age, sex, underlying disease, time on dialysis, fractures, vascular calcification on radiography and the presence of osteoporosis in the bone biopsy. Laboratory tests consisted of total calcium (Cat), phosphorus (P), intact parathyroid hormone (iPTH) and alkaline phosphatase (AP).

Results: The mean age and time on dialysis were equivalent between OF and MD of 47.5 vs 50.1 years and 9.4 vs 9.9 years, respectively. Female were more prevalent in both groups (61% vs 62.3%). No difference in the occurrence of fractures and the presence of vascular calcification. Laboratory tests are shown in table 1.

	OF	MD	p
Cat (mg/dL)*	9.99 ± 1.08	9.74 ± 1.13	0.13
P (mg/dL)*	6.34 ± 1.65	5.5 ± 1.7	0.002
AP (U/L)#	214	355	0.023
iPTH (pg/mL)#	1240	1352	0,92
*values in mean±sd; # median			

Osteoporosis was present in 29.5% of the patients with OF and 47.5% with MD (P= 0.02). Aluminum toxicity (AT) was more prevalent in OF group (51.4% vs 34.4%; P= 0.03).

Conclusions: In the absence of BB and the presence of hyperparathyroidism, higher levels of AP in combination with lower levels of P suggest diagnosis of MD and may be of assistance in clinical management of CKD-MBD. Even in patients with high bone turnover, AT is still very prevalent. The deficiency in bone mineralization contributes to the occurrence of osteoporosis.

SA-PO985

The Profile of Renal Osteodystrophy at a Single Brazilian Center: 12-Year Register Amadeu de Assis Marinho Neto,[1] Ana Paula Gueiros,[1] Jose Edevanilson Gueiros,[1] Vanda Jorgetti,[2] Adriana Belo Lopes Prazeres,[1] Teg Marcos Veiga.[1] *[1]Nephrology, UFPE, Recife, Brazil; [2]Nephrology, USP, São Paulo, Brazil.*

Background: Clinical and laboratory parameters are not always sufficient for diagnosis of CKD-MBD and bone biopsy (BB) is thus the gold standard. The aim of this study was to evaluate the clinical and laboratory profile of patients who underwent BB.

Methods: A retrospective analysis of 200 patients undergoing BB between August 2003 and December 2015. The clinical data examined were age, sex, underlying disease and time on dialysis. Laboratory tests consisted of total calcium (Cat), phosphorus (P), intact parathyroid hormone (iPTH) and alkaline phosphatase (AP). BB specimens were classified histologically as osteitis fibrosa (OF), mixed disease (MD), adynamic bone disease (ABD) or osteomalacia (OM). Aluminum intoxication (IAL) was defined when more than 20% of the trabeluar bone surface were covered by metal. Comparative analysis was performed according to the histological diagnosis.

Results: The mean age of patients was 48.8 years and 58.7% were women. The mean time on dialysis was 9.4 years. Only 7% of the population was diabetic. OF was the most prevalent histologic type (52.2%), followed by MD, present in 30.3% of patients. ABD and OM were found in 13.9% and 3.0%, respectively. Table 1 shows the comparative analysis of the histological types.

	0F	MD	ABD	OM	p
Cat (mg/dL)*	9.9±1.1	9.7± 1	9.6± 1	9.1 ± 0.7	0.052
P (mg/dL)*	6.34±1.6[a,c]	5.5±1.7[a]	5.6±1.8[f]	2.3±1.4[c,f]	< 0.001
AP (U/L)#	214[a,b]	355[a,d,e]	108[b,d]	154[e]	<0.001
iPTH (pg/mL)#	1240[b,c]	1352[d,e]	107[b,d]	313[c,e]	<0.001
*values in mean±sd; # median; (a) OF vs MD; (b) OF vs ABD; (c) OF vs OM; (d) MD vs ABD; (e) MD vs OM; (f) ABD vs OM.					

IAL was present in 47.8% of patients, who had lower iPTH (p<0.001) and AP (p<0.001) compared to patients without IAL. Osteoporosis was found in 37.3% of the BB.

Conclusions: The data show a high prevalence of high bone turnover diseases and indicate that IAL is still an undesirable reality in this setting. AP and iPTH are good markers of bone remodeling. Osteoporosis is highly prevalent in patients on dialysis, even in the case of a young population.

SA-PO986

Relationship between Osteoclast Released Clastokines and Parathyroid Hormone in Hemodialysis Patients Cai-Mei Zheng,[1,2,3] Chien-Lin Lu,[1] Jing-Quan Zheng,[1,2,4] Wenya Ma,[5] Wen-Chih Liu,[1,5] Yung-Ho Hsu,[1,2,3] Jia-Fwu Shyu,[1,6] Yuh-Feng Lin,[1,2,3] Kuo-Cheng Lu.[1,5] *[1]Graduate Inst of Clinical Medicine, College of Medicine, Taipei Medical Univ, Taipei, Taiwan; [2]Dept of Internal Medicine, School of Medicine, College of Medicine, Taipei Medical Univ, Taipei, Taiwan; [3]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, New Taipei, Taiwan; [4]Div of Critical Care Medicine, Dept of Emergency Medicine-Critical Care Medicine (EM-CCM), Shuang Ho Hospital, Taipei Medical Univ, Taipei, Taiwan; [5]Div of Nephrology, Dept of Internal Medicine, Cardinal Tien Hospital, School of Medicine, Fu-Jen Catholic Univ, New Taipei, Taiwan; [6]Dept of Biology and Anatomy, National Defense Medical Center, Taipei, Taiwan.*

Background: Patients on long-term dialysis may develop bone loss due to imbalance in bone formation and bone resorption. We believed that changes in osteoclast released clastokines occur according to different levels of parathyroid hormone in dialysis patients and responsible for bone changes in these patients.

Methods: A total of 223 patients under maintenance dialysis for more than 3 months were enrolled. Patients were grouped according to PTH levels (PTH<150, PTH 150-300, PTH ≥ 300). Serum FGF 23, procollagen type 1 amino-terminal propeptide (P1NP), TRAP 5b, Wnt 10b, Wnt 16, osteoprotegerin (OPG), RANK-L, beta-catenin, DKK-1, sclerostin (SOST) and total alkaline phosphatase (ALP) were measured and compared the changes according to PTH levels among three groups.

Results: Among 128 patients with PTH level ≥300 pg/mL, higher Wnt10b (p< 0.0001), P1NP (p=0.006) and higher OPG (p=0.003) than those of lower PTH groups (PTH< 150 pg/mL and PTH=150-300 pg/mL) were noted. Serum FGF 23 was higher (p=0.005) and DKK1 was lower (p=0.02) among higher PTH group (PTH ≥300 pg/mL) than lower PTH group (PTH< 150 pg/mL). No significant changes in Wnt 16 (p=0.08), RANK-L (p=0.19), beta-catenin (p=0.11),SOST (p=0.91) and TRAP 5b (p=0.15) with PTH levels were noted.

Conclusions: Our results suggest that osteoclast released clastokine Wnt 10b is increased in relation with higher PTH levels, which might be explanation for the compensatory role of clastokine mediated bone formation among dialysis patients.

SA-PO987

Comparison of Calcimimetic R568 and Calcitriol in Mineral Homeostasis in Hyp Mice: An Animal Model of X-Linked Hypophosphatemia Maren Leifheit-Nestler,[1] Julia Kucka,[1] Geert J. Behets,[2] Patrick C. D'Haese,[2] Dieter Haffner.[1] *[1]Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [2]Laboratory of Pathophysiology, Univ of Antwerp, Belgium.*

Background: We studied the calcimimetic R568 and calcitriol in *Hyp* mice, an animal model of X-linked hypophosphatemia, which is characterized by elevated levels of FGF23, renal phosphate wasting, 1,25-dihydroxyvitamin D (1,25D) deficiency, and rickets. Current medical treatment with oral phosphate and 1,25D is inefficient, associated with side effects, and secondary hyperparathyroidism (sHPT). We hypothesized that mineral homeostasis is differentially affected by R568 and 1,25D in *Hyp* mice with respect to the PTH-vitamin D-FGF23-Klotho axis and skeletal function.

Methods: Male *Hyp* mice aged 28 days received R568 (3 and 10 ng/kg BW/d), 1,25D (150 ng/kg BW/d) or vehicle for 4 weeks. Vehicle-treated wildtype mice served as controls. Blood C-term/intact FGF23, and PTH were measured. Kidneys were analyzed for Cyp24, Cyp27, and Klotho by qPCR and immunoblotting. Bones were investigated by mCT, histomorphometry, and qPCR.

Results: R568 and 1,25D prevent sHPT, yet only 1,25D raises serum phosphate levels in *Hyp* mice. Diminished tubular phosphate reabsorption was unaffected by either treatment. 1,25D increases calciuria and further enhances FGF23 synthesis in bone and circulating FGF23 levels. By contrast, R568 lowers bone *FGF23* expression and serum C-term FGF23 concentration. Renal 1,25D production is further suppressed by 1,25D treatment and improved by R568. *Hyp mice* showed reduced renal Klotho levels, which were normalized by 1,25D and unaffected by R568 treatment. 1,25D but not R568 improved femur length and weight gain, and restored mineralized growth plate and mineralized bone area. R568 significantly improved trabecular but not cortical bone parameters. By contrast, 1,25D improved cortical but not trabecular bone parameters.

Conclusions: R568 reduces PTH and skeletal/circulating FGF23, improves renal vitamin D synthesis, but only partially corrects skeletal abnormalities in *Hyp* mice. 1,25D improves body growth, and defective mineralization despite further enhancement of skeletal FGF23 synthesis.

SA-PO988

Renin-Angiotensin System Inhibition Ameliorates Bone Fragility Through Blocking Both Osteocytic and Osteoblastic Actions in Uremic Rats Takuya Wakamatsu,[1] Yoshiko Iwasaki,[2] Suguru Yamamoto,[1] Akemi Ito,[3] Yoshimitsu Takahashi,[1] Fumitake Gejyo,[1] Junichiro James Kazama,[4] Masafumi Fukagawa,[5] Ichiei Narita.[1] *[1]Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, NIigata, Japan; [2]Dept of Health Sciences, Oita Univ of Nursing and Health Sciences, Oita, Japan; [3]Ito Bone Histomorphometry Inst, Niigata, Japan; [4]Dept of Nephrology and Hypertension, Fukushima Medical Univ, Fukushima, Japan; [5]Div of Nephrology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Chronic kidney disease (CKD) patients are at an extremely high risk of bone fracture regardless of parathyroid function. Osteocyte apoptosis is elevated in uremic conditions, leading to the deterioration of elastic mechanical properties in weight-bearing bones. The pharmacological use of renin-angiotensin system (RAS) inhibitors is associated with approximately 30% reduction of fracture risk in hemodialysis patients. However, the mechanism remains unknown.

Methods: Sprague-Dawley rats undergone subtotal nephrectomy were administered olmesartan (Nx-O, n=7) or hydralazine (Nx-H, n=6) for 6 weeks. The direct effects of RAS on osteoblasts were observed using MC3T3-E1 cells and primary osteocytes obtained from the mouse femur.

Results: Comparable levels of kidney damage and blood pressure were observed in the Nx-O and Nx-H rats. Compared to Nx-H,Nx-O showed less osteoclast activity (erosion depth; 8.47±1.01 μm vs Nx-H 12.39±2.37 μm, *p<0.01)*, increased mineralization (MAR; 2.43±0.17 μm/day vs Nx-H 0.76±0.88 μm/day, *p<0.01*), raised bone elasticity (storage modulus; $3.01\times10^9\pm1.00\times10^9$ Pa vs Nx-H $1.19\times10^9\pm0.79\times10^9$ Pa, *p=0.046*), and reduced osteocyte apoptosis (empty lacunae; 36.6±12.2N/mm^2 vs Nx-H 67.9±13.6 N/mm^2, *p<0.01*). Angiotensin II (AII) significantly increased the expression of RANKL in MC3T3-E1 cells. AII also increased ROS production and DNA fragmentation in cultured primary osteocytes. These changes were inhibited by olmesartan.

Conclusions: AII modulates bone metabolism through both direct action on osteoblasts and pathways via the promotion of osteocytic apoptosis leading to deteriorated bone mechanical properties, which were improved by AII receptor-1 blockade.

SA-PO989

The Rapid Down-Regulation of Klotho in an Obstructed Kidney Is Not Accompanied by a Compensatory Up-Regulation in the Contralateral Kidney

Anders Nordholm,[1] Maria Lerche Mace,[1,2] Eva Gravesen,[2] Jacob Hofman-Bang,[2] Klaus Olgaard,[2] Ewa Lewin.[1] *[1]Dept of Nephrology, Herlev Hospital, Univ of Copenhagen, Denmark; [2]Dept of Nephrology, Rigshospitalet, Univ of Copenhagen, Denmark.*

Background: The anti-ageing hormone, Klotho, is a renoprotective protein alleviating acute kidney injury and promoting kidney regeneration. The kidney is a major source of Klotho. In the present study the time course of Klotho changes in experimental unilateral ureter obstruction (UUO) and in the contralateral kidney (CK) was followed.

Methods: UUO rats (n=37) were studied at 0, 1, 2, 3, 4, and 10 days (D) and the results of the obstructed kidney were compared to those of CK and to kidneys from unilateral nephrectomized (UNX) control rats (n=35) as well as normal kidneys. Kidney Klotho, the renoprotective BMP7 and LGR5 together with markers of fibrosis, TGF-β and Periostin, gene expressions were examined.

Results: Unilateral ureter obstruction resulted in significantly decreased Klotho expression already at day 1, which decreased further progressively to day 10. Baseline: 1.91±0.30; D1: 0.91±0.18 ($p<0.01$), D10: 0.21±0.02 ($p<0.01$). LGR5 was reduced from 0.80±0.30 at baseline to 0.19±0.03 at D1 ($p<0.01$) in the obstructed kidney, suggesting stem cell depletion. The decrease in Klotho expression in UUO kidney was associated with a decreased expression of BMP7 (Baseline: 0.87±0.11, D1: 0.57±0.07, D10: 0.63±0.08, $p<0.01$) and an increased expression of TGF-β (Baseline: 0.51±0.07, D1: 0.69±0.11, D10: 1.51±0.17, $p<0.01$) and induction of Periostin (0.09±0.10 to D1: 0.67±0.40, $p<0.05$). The expressions of BMP7, TGF-β, Periostin and LGR5 were similar in contralateral, UNX and normal kidneys. The contralateral kidney had similar expression of Klotho (D1: 2.20±0.27 and D10: 1.80±0.15) compared to normal and UNX kidneys (D1: 1.91±0.28 and D10: 2.05±0.83).

Conclusions: In an unilateral ureter obstruction model a very rapid and significant decrease in the expression of Klotho took place already at day 1 in the obstructed kidney. The unilateral ureter obstruction was associated with upregulation of pro-fibrotic genes and down-regulation of anti-fibrotic BMP7. The contralateral kidney did not respond with a compensatory increase in Klotho.

SA-PO990

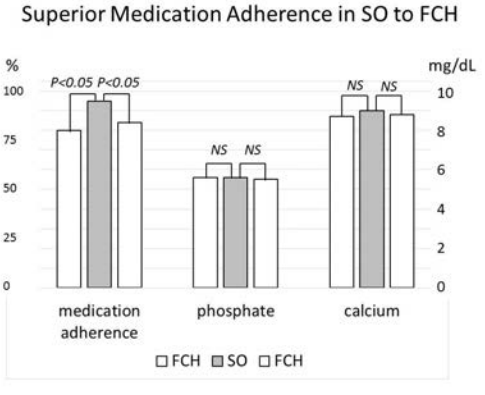
Comparison of the Two Types of Iron-Based Phosphate Binders, Sucroferric Oxyhydroxide and Ferric Citrate, on Lowering Serum Phosphate Effects in Patients on Hemodialysis

Kazuyo Teshima,[1] Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Takashi Harada,[1] Kenji Sawase,[1] Hiroshi Ichinose,[1] Osamu Sasaki,[1] Kenta Tsukuda,[1] Rei Moriyama,[1] Chigusa Fukagawa,[1] Yoko Obata,[2] Tomoya Nishino.[2] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Univ Hospital, Nagasaki, Japan.*

Background: Sucroferric oxyhydroxide(SO), a new type of iron-containing phosphate binder, is reported to exerts stronger phosphate lowering effect compared with ferric citrate hydrate (FCH) in equivalent dose resulting in lower pill burden.

Methods: To compare the effects of SO and FCH on medication adherence as well as serum phosphate-lowering effects in patients on hemodialysis (HD) in a crossover study. Thirty-two subjects were already treated with 1500 mg to 2250 mg of FCH daily. Subjects were switched to 750 mg to 1000 mg of SO daily for 4-6 weeks, then previous treatment with FCH. Measurement of plasma bone mineral parameters including phosphate and calculation of the medication adherence (total actual number of tablets taken during a period / number of tablet expected to be taken during a period x 100) were achieved at the end time point of each arm.

Results:



As shown in figure 1, there was no significant difference in serum phosphorous concentration in SO or FCH (FCH: 5.6 ± 1.3 – SO: 5.6 ± 1.4 – FCH: 5.5 ± 1.1 mg/dL). A significant increase was observed in medication adherence in SO compared to FCH (FCH: 79 ± 10 - SO: 95 ± 14 - FCH: 84 ± 14%). No significant difference was observed in other bone mineral parameters.

Conclusions: Thus, SO can potentially exert similar phosphate-lowering effects to FCH with better medication adherence and lower pill burden in patients on maintenance HD.

Bone Biopsy Findings and Biochemical Markers before and after Two Years of Renal Transplantation

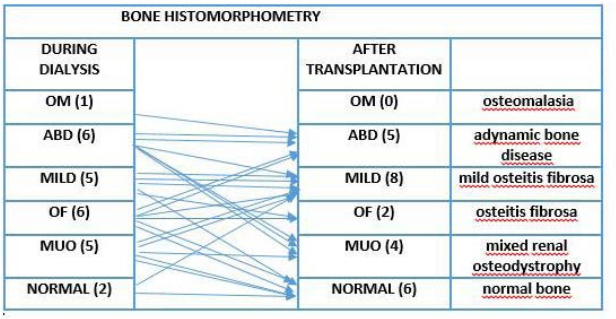
Satu Keronen,[1] Leena Martola,[1] Patrik Finne,[1] Inari S. Burton,[2] Tobias E. Larsson,[3] Heikki Kroger,[4] Eero Honkanen.[1] *[1]Abdominal Centre, Nephrology, Helsinki Univ Central Hospital and Helsinki Univ, Helsinki, Finland; [2]Univ of Eastern Finland, Terveystalo Jyväskylä, Jyväskylä, Finland; [3]Astellas Pharma, Sweden; [4]Kuopio Univ Hospital, Kuopio, Finland.*

Background: There are only few studies on bone biopsies before and after renal transplantation (RTX). The aim of this study was to investigate the changes in histomorphometric pattern of bone disease after RTX.

Methods: Bone biopsy was taken from the iliac crest and analyzed using the turnover -mineralization -volume classification on 25 consecutive dialysis patients (80% men, 48 % on PD) at baseline and 25 (24- 26) months after RTX. The median time on dialysis prior to RTX was 24 (15-42) months. Median GFR was 64 (41-70) ml/min per1.73 m^2 (MDRD). Immunosuppressive therapy comprised CNI, MMF, and prednisone. Serum markers of bone turnover were obtained.

Results: The changes in bone histomorphometry before and after RTX are shown in Figure 1. Bone biopsy findings were divided into three subgroups based on bone turnover. Biochemical findings after RTX are shown in Table 1. At baseline, 44% of dialysis patients had OF or MUO, 28% mild OF or normal turnover and 28% of patients had OM or ABD. After two years of RTX 24%, 56% and 20% of patients had OF/MUO, mild OF/normal or OM/ABD, respectively. Following RTX osteocalcin and bone alkaline phosphatase (BAP) were significantly higher in OF+ MUO group.

Fig.1 The changes in bone histomorphometry before and after renal transplantation



Variables	All n = 25 (median + IQR)	OM + ABD n=5	Mild OF + normal n=14	OF + MUO n=6	P
GFR ml/min per 1.73m²	64 (41-70)	48	68	35	0.19
osteocalcin ug/l	41 (35-74)	37	39	86	<0.05
BAP ug/l	15 (11-27)	14	14	36	<0.05

Conclusions: After two years of renal transplantation bone turnover normalized in almost 80% of the patients. Lower GFR might explain higher osteocalcin and BAP seen in OF + MUO group.

Kidney Transplantation Alters the Association between Serum Sclerostin and Bone Sclerostin Expression

Mathias Haarhaus,[1] Henrik Boltenstål,[1] Abdul Rashid Tony Qureshi,[1] Geert J. Behets,[2] Bengt Lindholm,[1] Peter Stenvinkel,[1] Patrick C. D'Haese.[2] *[1]Div of Renal Medicine and Baxter Novum, Karolinska Univ Hospital at Huddinge, Karolinska Inst, Stockholm, Sweden; [2]Laboratory of Pathophysiology, Dept of Biomedical Sciences, Univ of Antwerp, Antwerp, Belgium.*

Background: The osteocyte derived protein sclerostin inhibits bone turnover. Serum sclerostin rises early in chronic kidney disease (CKD) but to what extent this reflects osteocyte sclerostin production is not clear. We investigated associations between serum sclerostin, bone sclerostin expression and different types of renal osteodystrophy.

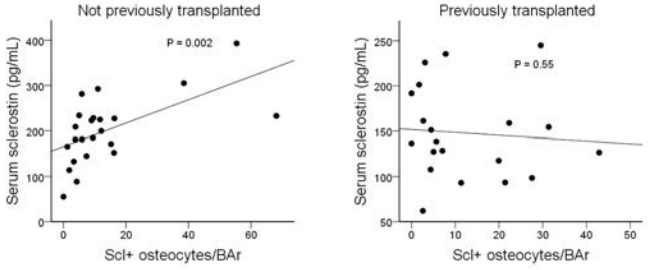
Methods: Immunohistochemical staining of sclerostin was performed in bone biopsies from 43 CKD patients (pts), including 15 pts undergoing dialysis and 20 pts who had received a kidney transplant. Bone sclerostin expression was correlated to bone histomorphometric parameters and serum sclerostin levels.

Results: Pts with low bone formation rate (BFR < 97µm²/mm²/day) had higher serum and bone sclerostin expression than pts with normal or high BFR.

	Low BFR (N=13)	Normal + high BFR (N=28)	P
	median (range)	median (range)	
Serum sclerostin (pg/mL)	224.7 (126.5-393.0)	141.7 (55.3-392.9)	0.004
Scl+ /BAr (number/mm²)	12.1 (1.3-68.1)	5.0 (0-38.6)	0.008

Whereas a strong association between serum and bone sclerostin expression was observed in non-transplanted pts (figure 1) no such association was observed in transplanted

pts, independent of kidney graft function. Females had higher bone sclerostin expressions than males (P=0.046), despite similar serum sclerostin levels and bone histomorphometric parameters.



Conclusions: Serum sclerostin and bone expression of sclerostin are inversely associated with bone turnover in CKD. In non-transplanted CKD pts, serum sclerostin reflects bone sclerostin expression. Bone sclerostin expression is affected by gender in CKD.

Kidney Transplantation Increases Bone Esclerostin Expression

Maria Julia C.L.N. Araujo, Igor Marques, Fabiana Graciolli, Wagner Dominguez, Luciene dos Reis, Ivone Braga de Oliveira, Rosilene M. Elias, Vanda Jorgetti, Elias David-Neto, Rosa M.A. Moyses. *Nephrology Div, Univ of Sao Paulo, Brazil.*

Background: Most of the metabolic disorders improve after kidney transplantation (Tx), although bone metabolism can remain compromised, which is evidenced by high rates of bone loss, fractures and vascular calcification. Osteocytic bone protein expression is dysregulated in CKD, and this seems to contribute negatively to bone health in these patients. It has been described that FGF-23 and sclerostin (Scl) expression is increased in children after solid organ transplantation. Nonetheless, little is known about bone-related proteins expression in adult recipients, which were analyzed prospectively in this study.

Methods: Transiliac bone biopsies were obtained from 30 adult patients one week before and one year after Tx. Bone fragments were used for histomorphometric analysis, as well as for bone proteins, measured by immunohistochemistry and MILLIPLEX® MAP.

Results: Patients were relatively young (41 ± 11 yrs), with a pre Tx dialysis vintage of 30 (15-55) months. After a successful Tx, there was an increase in serum calcium and a decrease in PTH and alkaline phosphatase. No changes were seen in bone DKK1, whereas a decrease was observed in bone osteoprotegerin (OPG) and FGF-23. Although serum Scl decreased after KTx [1.2 (0.6-1.9) vs. 0.5 (0.4-0.6) ng/ml; p = 0.001)], an increase of this protein in bone was observed with both methods.

	Pre-Tx	1 year after Tx	p
MILLIPLEX® (mg/g protein)			
DKK1	2.94 (2.23-3.68)	2.87 (2.05-4.28)	0.954
OPG	0.62 (0.43-0.76)	0.38 (0.29-0.63)	0.037
Scl	531 (371-941)	760 (482-1,395)	0.059
FGF-23	5.97 (4.19-12.49)	4.73 (3.74-6.89)	0.005
Immunohistochemistry (%+/total osteocytes)			
Scl	5.6 (2.0-13.8)	24.5 (6.7-44.5)	0.008
FGF-23	7.7 (1.5-25)	11.4 (3.8-40.7)	0.215

Conclusions: Kidney function recovery after Tx is accompanied by significant changes in most bone proteins expression. Contradictory to the decrease in levels of serum Scl, its bone expression, actually, has increased. This finding may explain the persistence of Tx-related bone disease.

SA-PO994

Cinacalcet Hydrochloride Increases Sharpey Fiber Area in Patients with Secondary Hyperparathyroidism

Aiji Yajima,[1,2] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Biomedical Engineering, Indiana Univ, Indianapolis, IN; [2]Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Bone formation without prior bone resorption, namely, minimodeling is increased in patients with hypoparathyroidism (Ubara Y. Kidney Int 2005) or those who received parathyroidectomy (Yajima A. Kidney Int 2008). Skeletal muscle interaction is quite important in thinking about bone formation through the osteocyte (Bonewald LF. J Bone Miner Res 2013). Sharpey fiber connects periosteal surface with muscle layer and it is very important for the transmission of mechanical loading. And little is known about sharpey fiber in the field of bone disease. We investigated sharpey fiber as one of the causes of reduced fracture rate in patients treated with ciacalcet hydrochloride (Moe SM. J Am Soc Nephrol 2015).

Methods: Hemodialysis patients suffering from secondary hyperparathyroidism (n=14, Age; 61.8±7.3 yrs, Dialysis duration; 8.7±5.2 yrs) were treated with cinacalcet hydrochloride (HCL) and concomitant administration of low doses of oral or intravebous vitamin D for one year. The dose of cinacalcet HCL was ranged from 25 to 100 mg/day. Serum intact parathyroid hormone (i-PTH) and sharpey fiber area (Sharpey fiber surface/periosteal surface; %) was measured before and after the treatment with cinacalcet HCL in these patients.

Results: Serum i-PTH level was decreased from 857.3±213.0 to 184.6±50.4 pg/mL. Sharpey fiber area was increased from 42.5±15.7 to 75.3±16.5 % (p<0.001, Wilcoxon signed rank test) after the treatment with cinacalcet HCL in patients with secondary hyperparathyroidism.

Conclusions: Cinacalcet hydrochloride is a potential candidate to increase sharpey fiber, which increases minimodeling volume through the osteocyte (Tatsumi S. Cell Metab 2007). It is possible that one of the causes of reduced fracture rate in patients receiving cinacalcet hydlochloride is an increased sharpey fiber area in dialysis patients.

SA-PO995

Sclerostin Is a Good Predictor of Marrow Adipocyte in Dialysis Patients

Aiji Yajima,[1,2] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Biomedical Engineering, Indiana Univ, Indianapolis, IN; [2]Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Some papers regarding the relationship betweem sclerostin (Scl) and bone turnover and osteocytic perilacunar/canalicular remodeling was published (Poole KE. FASEB 2005, Kogawa M. J Bone Miner Res 2013, Nakashima T. Nat Med 2011, and etc.). However, only one basic paper regarding the relationship between Scl and marrrow adipocyte has been published (Ukita M. Sclerostin enhances adipocyte differentiation in 3T3-L1 cells. J Cell Biochem 2016). And parathyroidectomy increased marrow adipocyte differentiation in dialysis patients (Yajima A. presented). We analyzed the relationship between serum Scl or i-PTH and marrow adipocyte parameters in hemodialysis patients.

Methods: We measured serum Scl (ELISA, Biomedica Medizinprodukte, Vienna, Austria) and intact parathyroid hormone (iPTH) (Electrochemiluminescence immunoassay, Elecsis PTH, Roche Diagnostics GmbH, Mannheim, Germany) levels in 23 hemodialysis patients (Age; 60.5±6.0 yrs, dialysis duration; 10.7±7.3 yrs). At the same time, iliac bone biopsy specimens were obtained from the patients to measure (1) adipocyte volume/marrow volume (Ad.V/Ma.V (%)), (2) Number of adipocyte/Ma.V (N.Ad/Ma.V (N/mm^2) and (3) mean adipocyte volume (Ad.V/N.Ad (μm^2)). The relationship between serum parameters and adipocyte parameters were analyzed by linear regression analysis.

Results: I, 1, Serum Scl was 70.6±44.3 ng/mL, ranging from 25.0 to 172.2 and i-PTH was 589.3±479.2 pg/mL, ranging from 5 to 1430. Ad.V/Ma.V was 37.8±18.5 %, N.Ad/Ma.V was 212.6±57.8 N/mm^2 , and Ad.V/N.Ad was 1815.6±644.3 μm^2. II, 1, Serum Scl was positively associated with Ad.V/Ma.V (r=0.752, p<0.001) and Ad.V/N.Ad (r=0.582 (p<0.005)). But Scl was not associated with N.Ad/Ma.V. 2, Serum i-PTH was negatively associated with Ad.V/Ma.V (r=0.526, p<0.01) and Ad.V/N.Ad (r=0.511 (p<0.01)). But i-PTH was not associated with N.Ad/Ma.V.

Conclusions: In dialysis patients, marrow adipocyte parameters were strongly associated with serum Scl as compared with i-PTH levels. It is highly possible that sclerostin regulates the metabolism of marrow adipocyte. Sclerostin is important because adipocyte suppresses osteoblast function.

Increase of Bone Marrow Adiposity Is Associated with Decrease of Bone Formation and Volume in Pre-Dialysis Chronic Kidney Disease Patients

Joao Victor Salgado, Maria Dalboni, Aluizio B. Carvalho, Maria Eugenia F. Canziani. *Discipline of Nephrology, Federal Univ of São Paulo, São Paulo, São Paulo, Brazil.*

Background: Metabolic disorders and accumulation of uremic toxins might contribute to bone fat deposition and skeletal fragility in CKD patients. We aimed to investigate the relationship between bone marrow adiposity and bone Turnover, Mineralization and Volume (TMV system) in CKD patients not yet in dialysis.

Methods: Twenty-two transiliac bone biopsy specimens obtained in a cross-sectional study previously performed in 2-5 stages CKD patients (52±11 yrs, 59% male, 32% diabetes, 33±17 ml/min/1.73m^2) were evaluated by quantitative histomorphometry to assess bone and marrow adipocyte parameters. For TMV system, bone formation rate (BFR/BS) was considered as Turnover, mineralization lag time (MLT) as Mineralization and trabecular bone volume (BV/TV) as Volume. Adipocyte number (Ad.N) and adipocyte volume / total volume (Ad.V.TV) was used as adipocyte parameters. Serum bone and biochemical markers were measured.

Results: Ad.N and Ad.V.TV did not differ significantly with regards to age, gender, diabetes mellitus and CKD stages. Ad.N correlated negatively with LDL-cholesterol (r= -0.48, p=0.02) and BV/TV (r= -0.58, p=0.005). Ad.V.TV correlated negatively with BV/TV (r= -0.61, p=0.002) and BFR/BS (r= -0.46, p=0.03). Adipocyte parameters, Ad.N and Ad.V.TV, did not correlate with MLT.

Conclusions: Increase of bone marrow adiposity seems to be associated with decrease of bone formation and volume but not with mineralization in pre-dialysis CKD patients.

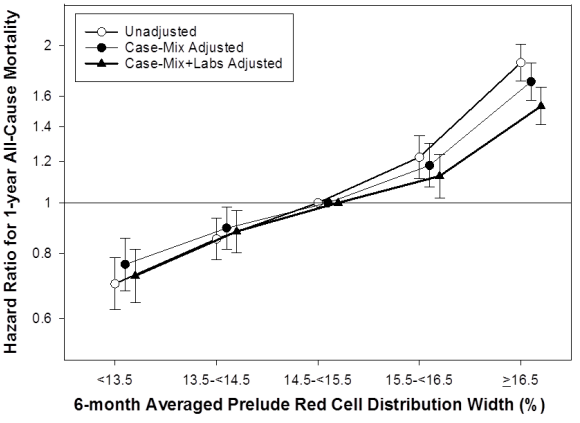
SA-PO997

Association of Pre-ESRD Red Cell Distribution Width and Early Dialysis Mortality: A Transition of Care in CKD Study Melissa Soohoo,[1] Miklos Zsolt Molnar,[2] Elani Streja,[1] Connie Rhee,[1] Daniel L. Gillen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: Recent studies have shown that red blood cell distribution width (RDW), a marker of red blood cell size and variability and likely an iron store marker, is a predictor of mortality in the hemodialysis population. However, the association of RDW in the prelude period prior to transitioning to end-stage renal disease (ESRD) and post-ESRD mortality is unknown.

Methods: We examined a cohort of 18,924 US Veterans transitioning to ESRD between 2007-2011 with RDW measured in the 6 months prior to dialysis initiation (prelude period). We analyzed the association of RDW with all-cause and cardiovascular mortality in a cohort using Cox proportional hazards and Fine & Gray competing risk regression models, respectively. Each analysis was adjusted for case-mix (demographics and comorbidities) and laboratory measurements. RDW was divided into 5 categories <13.5, 13.5-<14.5, 14.5-<15.5, 15.5-<16.5, and ≥16.5 %.

Results: The mean age (mean±SD) of the cohort was 68±11years old and included 2% females, 71% diabetics and 25% African Americans. Across all levels of adjustment, higher 6-month prelude RDW was linearly and incrementally associated with higher all-cause mortality compared to the reference group (14.5-<15.5%). This association was consistent for 3-, 6-, 12 and 24-month all-cause mortality. In addition, 6-month prelude RDW was also linearly associated with post-ESRD cardiovascular mortality, although the magnitude was somewhat attenuated.



Conclusions: In very advanced CKD patients, higher RDW is associated with higher all-cause and cardiovascular mortality in patients transitioning to ESRD independent of comorbidities and laboratory measures. Future studies are needed to confirm these findings as well as to further understand the mechanism underlying these RDW associations.

SA-PO998

Correlates of Red Blood Cell Life Span in Chronic Hemodialysis Patients Jie Ma,[1,3] Yanna Dou,[1] Hanjie Zhang,[1] Stephan Thijssen,[1] Schantel Williams,[1] Viktoriya Kuntsevich,[2] Nathan W. Levin,[2] Peter Kotanko.[1,2] *[1]Research Dept, Renal Research Inst, New York, NY; [2]Mount Sinai Beth Israel, New York, NY; [3]Nephrology, Peking Union Medical College Hospital.*

Background: The pathogenesis of anemia in hemodialysis (HD) patients is multifactorial, with decreased red blood cell life span (RBC-LS) being a significant contributor. The impact of reduced RBC-LS is recognized but not well researched. The objective of this study was to investigate the relationship between RBC-LS and EPO dose and inflammatory markers in HD patients.

Methods: The RBC-LS (calculated from measured alveolar carbon monoxide concentrations), inflammatory markers IL-6, IL-18, IL-10 (measured by LuminexÔ) and hsCRP were assessed at baseline and during follow up.Monthly hemoglobin (Hgb) levels, weekly EPO dose and clinical parameters were obtained from electronic health records. The association between RBC-LS, weekly EPO dose and inflammatory biomarkers was evaluated by using linear mixed effects models.

Results: Forty-five HD patients were enrolled with an average age of 58.5±13.9 years, 71% male, 46.7% diabetics, and a mean HD vintage 47 ± 46 months. In 22 patients up to 5 repeated RBC-LS measurements were available. RBC-LS was 74± 23 days (range 30 to 125). RBC-LS was inversely correlated with the EPO requirement.

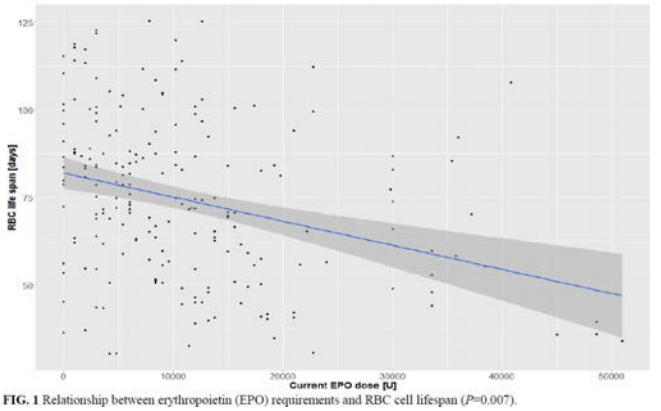

FIG. 1 Relationship between erythropoietin (EPO) requirements and RBC cell lifespan (P=0.007).

While RBC-LS was positively correlated with uric acid (P=0.018), no correlation was found with any of the inflammatory biomarkers, Kt/V, β_2-microglobulin, ferritin, RBC and reticulocyte counts, PTH, and HbA_1C.

Conclusions: In chronic HD patients RBC-LS is markedly reduced and inversely correlated with EPO dose. The positive correlation with uric acid raises the possibility that its anti-oxidant effects may protect RBCs. The lack of an association between levels of inflammatory biomarkers and RBC-LS suggests a limited role of inflammation as a determinant of premature RBC death.

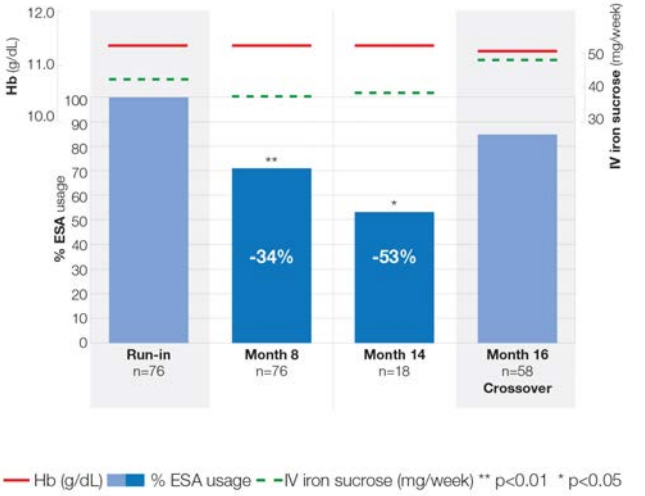
SA-PO999

Improving Anemia Therapy in Hemodialysis Patients Iain C. Macdougall,[1] Antonio Sousa,[2] Thomas Ryzlewicz,[3] Franz-Ferdinand Becker,[4] Amelia Fairburn-Beech,[4] William Kilgallon.[4] *[1]Renal Unit, King's College Hospital, London, United Kingdom; [2]Fundação Renal Portuguesa, Portuguesa, Portugal; [3]Via Medis Nierenzentren, Riesa, Germany; [4]Oxyless Ltd, London, United Kingdom.*

Background: Hemodialysis (HD) patients have a shortened red cell survival, partly due to hemolysis associated with uremia, and partly due to the HD process itself. Blood-air contact within the extra-corporeal circuit contributes to the latter problem. A novel bloodline (Oxyless) which reduces the blood-air contact by 99.1% has been shown to reduce Erythropoiesis-Stimulating Agent (ESA) dose requirements in HD patients. We now report data over a longer treatment period (14 months).

Methods: 142 patients (>18 years, HD > 3 months via an A-V fistula), in two cohorts, were selected for treatment with Oxyless bloodlines, in an open label, prospective, audit following a 3 month run-in period. After 8 months, cohort 1 (109 patients) reverted to the control bloodlines (Nikkiso/Gambro) in the crossover phase for a further 8 months. Cohort 2 (33 patients) remained on the Oxyless bloodlines for 14 months without crossover.

Results: Mean ESA dose fell by 34% (p<0.01) by Month 8, further reducing to 53% (p<0.05) by Month 14. Hemoglobin (Hb) levels were stable throughout at 11.5g/dL. IV iron dose fell by 12% (Month 8) and 25% (p<0.05) by Month 14 each compared to baseline.



By Month 16 (Cohort 1), ESA doses increased to 82% of their baseline levels. Hb levels were 11.3g/dL. Iron dose returned to 120% of pre-treatment levels. Patients of a shorter dialysis vintage (<4 years, n=45) showed a greater reduction in ESA usage at Month 8 (-47%, p<0.01) compared with patients of a longer vintage (4-17 years, n=31, -16%), irrespective of their diabetic status.

Conclusions: These results provide further evidence that this bloodline can optimise anemia management, increasing confidence in the data validity, and suggesting clinical and economic benefits from the use of this technology.

Modeling Outcomes by Dopps-Identified Modifiable Dialysis Practices in the Monitor-CKD5 Study Christian Combe,[1] Johannes F. Mann,[2] Gerard M. London,[3] David Goldsmith,[4] Philippe Zaoui,[5] Frank Dellanna,[6] Michael Gorray,[7] Nadja Hoebel,[7] Karen Macdonald,[8] Ivo Abraham.[8,9] *[1]Centre Hospitalier de Bordeaux, Univ of Bordeaux, Bordeaux, France; [2]Friedrich Alexander Univ Erlangen-Nürnberg, Erlangen, Germany; [3]Centre Hospitalier FH Manhés, Fleury-Mérogis, France; [4]Guy's and St. Thomas' NHS Foundation Hospital, London, United Kingdom; [5]Univ de Grenoble-Aples, Grenoble, France; [6]Dialysezentrum, Düsseldorf, Germany; [7]Sandoz/Hexal AG, Holzkirchen, Germany; [8]Matrix45, Tuscon, AZ; [9]Univ of Arizona, Tuscon, AZ.*

Background: Six modifiable hemodialysis (HD) practices were found to be predictive of mortality in the DOPPS (Port et al. *Blood Purif* 2004). We assess associations between the 6 modifiable practices and 4 outcomes in MONITOR-CKD5, a prospective 2-year real-world study of 2023 HD patients with renal anemia in 10 European countries.

Methods: Exploratory analysis between 6 modifiable HD practices (adequate dialysis dose, partial correction of serum albumin, phosphate control, reduced interdialytic weight gain, use of fistula, anemia correction) at baseline and 4 outcomes: chronic hypo-response to erythropoiesis stimulating agents (ESAs), thrombo-embolic event (TEE), hospitalization, and mortality. Each outcome was modeled with each HD practice using multi-level logistic regression corrected for center effect.

Results: Table 1 presents modeling results. Rates of modifiable HD practices and outcomes are also listed.

Table 1.

Modifiable Practices		Chronic hypo-response to ESA^ (8.0%)		TEE (14.4%)		Hospitalization (17.1%)		Mortality (14.2%)	
	% Yes	OR	95%CI	OR	95%CI	OR	95%CI	OR	95%CI
Kt/V ≥ 1.2*	82.9%			0.593	0.358–0.983				
Serum albumin ≥ 3.5 g/dL*	82.5%			0.508	0.294–0.877			0.527	0.285–0.976
Phosphate ≤ 5.5 mg/dL*	61.5%			0.699	0.489–0.999				
Interdialytic weight gain ≤5.7%*	92.2%	0.265	0.156–0.451						
Fistula*	83.4%					0.438	0.272–0.705	0.458	0.279–0.754
Baseline Hb (1 g/dL)	11.1±1.1*	0.608	0.516–0.717			0.778	0.652–0.928		

^ ≥4 consecutive months of ESA Resistance Index >15 (IU/kg/wk)/(g/dL)
* yes vs. no
* Mean±SD
Only results with p< 0.05 shown

Conclusions: Two or more modifiable HD practices were related to each of the 4 outcomes in this real-world study. The desired state of each practice had an odds-lowering association with all outcomes. Given their strong association with significant clinical outcomes, these 6 modifiable HD practices should be monitored in each center.

Funding: Pharmaceutical Company Support - SANDOZ

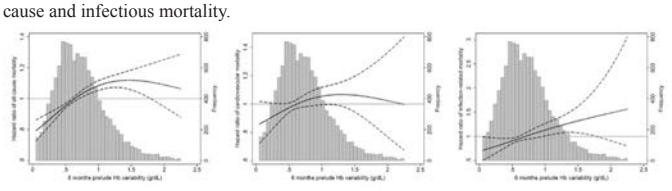
SA-PO1001

Association of Pre-ESRD Hemoglobin Variability with Post-ESRD Mortality in Advanced CKD Patients Transitioning to Dialysis Charles Dyer Diskin,[1] Keiichi Sumida,[1,2] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Connie Rhee,[3] Elani Streja,[3] Kunihiro Yamagata,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of Tsukuba, Ibaraki, Japan; [3]Univ of California, Irvine, CA; [4]VA Medical Center, Memphis, TN.*

Background: Hemoglobin variability (Hb-var) has been associated with increased mortality both in non-dialysis dependent (NDD)-CKD and ESRD patients, however, the impact of Hb-var in late-stage NDD-CKD on outcomes after dialysis initiation remains unknown.

Methods: We analyzed a cohort of 12,016 US veterans with advanced CKD transitioning to dialysis between 10/2007-9/2011 who had at least 3 Hb measurements in the last 6 months before dialysis initiation. Hb-var was defined by residual standard deviation of all Hb values in the 6 months before dialysis initiation using within-subject linear regression models. Associations of Hb-var quartiles (<0.46, 0.46-0.69, 0.70-0.96, ≥0.97 g/dL) with all-cause and cause-specific mortality after dialysis initiation were examined using Cox (for all-cause) and competing risk (for cause-specific mortality) regressions and cubic splines with adjustment for demographics, comorbidities, medications, CV medication adherence, pre-ESRD 6-month averaged eGFR levels, and Hb-var parameters (Hb intercept and slope).

Results: Higher Hb-var was associated with increased risk of all-cause and infectious mortality, but not for CV mortality (Figure). The adjusted hazard ratios [95% CI] for the highest (vs. lowest) quartile of Hb-var were 1.20 [1.11-1.29] and 1.49 [1.11-2.00] for all-cause and infectious mortality.



Conclusions: Pre-ESRD Hb-var is associated with higher post-ESRD mortality, and especially with infectious mortality. Further research is needed to clarify the underlying mechanisms and true causal nature of the observed association.

Transfusion Practice for Incident Dialysis Patients in Canada: A Prospective Observational Study Aminu K. Bello,[1] Christine M. Ribic,[2] Serge Cournoyer,[3] Mercedeh Kiaii,[4] Martine Leblanc,[5] Melanie Poulin-Costello,[6] David N. Churchill,[2] Norman Muirhead.[7] *[1]Univ of Alberta, Edmonton, AB; [2]McMaster Univ, Hamilton, ON; [3]Univ de Sherbrooke, Sherbrooke, QC; [4]Univ of British Columbia, Vancouver, BC; [5]Univ de Montréal, Montréal, QC; [6]Amgen Canada Inc.; [7]Univ of Western Ontario, London, ON.*

Background: KDIGO guidelines in 2012 recommended conservative ESA use. Study objectives were to identify blood transfusion (BT) rates in incident dialysis patients in Canada after 2012, factors associated with BT and the clinical context.

Methods: Data were obtained by monthly chart review. Transfusion data were recorded as units transfused and as transfusion episodes (≥ 2 units within 24 hrs.)

Results: 314 patients were enrolled; 80% completed 12 months follow-up. 65% were male and 75% were Caucasian with mean age of 64 yrs. 75% received pre-dialysis care for > 12 months. Overall, 30% received at least 1 unit during follow-up. During the first 90 days, 168 units were transfused over 76 patient-years (PY) (221 units/100 PY). From day 91-365, there were 215 units transfused over 208 PY (104 units/100 PY). Expressed as transfusion episodes, the rates per 100 PY were 148 for the first 90 days and 63 for days 91-365. Univariate Cox regression for time to first transfusion showed an association with older age, no pre-dialysis care, BT prior to starting HD, use of a temporary dialysis catheter and starting dialysis as an inpatient ($p < 0.05$). The most common reason for transfusion was a low hemoglobin value (92%) with concurrent clinical reasons being gastrointestinal bleeding (10%) and peri-surgical blood loss (9%). The mean Hb values before the first 3 transfusion episodes were 78.6, 75.3 & 75.9 g/L and 88-91% had Hb < 90 g/L. Univariate Cox regression for time to first hospitalization showed an association with in-patient start of dialysis and receiving a BT before hospitalization ($p < 0.05$).

Conclusions: The transfusion rate was higher in the first 90 days. The time to first transfusion was associated with age and factors associated with pre-dialysis care. The most common indication was a low haemoglobin value rather than clinical factors.

SA-PO1003

Effect of Altitude on Dosage Requirement of C.E.R.A. (Continuous Erythropoietin Receptor Activator) to Correct Hemoglobin (Hb) Levels in Chronic Kidney Disease (CKD) Patients (pts) Maria Guadalupe Suarez,[1] Alfredo Chew-Wong,[2] Raymundo Alfredo Aviles,[3] Luis E. Morales-Buenrostro,[4] Francisco Eduardo Quintana,[5] Sandro Avila Pardo,[6] Manuel Avendano Garcia,[7] Octavio Cabrera-Anaya.[8] *[1]Hosp Angeles Lindavista, Mexico City, Mexico; [2]Clinica San Cosme, Aguascalientes, Mexico; [3]Hosp San Javier Marina, Pto Vallarta, Mexico; [4]Nefros Investigacion S.C., Mexico City, Mexico; [5]Hosp Star Médica, Morelia, Mexico; [6]Hosp Reg Alta Esp, Veracruz, Mexico; [7]Centro de Hemodiálisis del Norte, Mexicali, Mexico; [8]Roche Servicios de México SA de CV, Mexico City, Mexico.*

Background: Severe anemia in CKD pts is associated with increased risk of adverse clinical events and mortality. Iron and erythropoiesis-stimulating agents (ESAs) are the standard of care for dialysis pts. Hemodialysis (HD) pts living at higher altitudes have higher Hb levels and lower ESA requirements.The long half-life, low binding affinity and low systemic clearance of C.E.R.A. allow once-monthly dosing. The primary objective of the multicenter Phase IV ALTITUDE trial (NCT01519947) was to determine the C.E.R.A. dose needed to achieve an Hb of 11–12g/dL in ESA-naïve CKD pts living either <50m above sea level (masl) or ≥1800masl.

Methods: C.E.R.A. was administered according to label to 86 pts (29 <50masl; 57 ≥1800masl) with stage III–V CKD (34 pre-dialysis; 52 HD).

Results: Mean age was 56 yrs, 44% were male, and etiology of CKD was diabetes in 57 pts and hypertension in 28. All had an adequate iron profile. At baseline, in the <50 and ≥1800 masl groups, mean Hb values were 9.4 and 9.0g/dL and mean C.E.R.A. doses were 71 and 52.2µg, respectively. 66 pts completed the study (4 lost to follow-up, 4 withdrew for protocol violation, 3 for adverse events and 9 for other reasons). 64 pts achieved target Hb, with mean C.E.R.A. doses of 160.5 and 70.0µg in the <50 and ≥1800 masl groups, respectively. The significant difference between groups was largely driven by the HD population. Safety was consistent with the known profile for C.E.R.A.

		C.E.R.A. dose required (µg)			
	Patients	Mean	SD	Median	Range
<50masl	22	160.5*	107.7	150	50-442
≥1800masl	42	70.0*	33.9	59	30-175

*p<0.05.

Conclusions: Lower C.E.R.A. doses are required to correct Hb in CKD pts living at altitude than at sea level.

SA-PO1004

Efficacy of Continuous Erythropoietin Receptor Activator (CERA) on End-Stage Renal Disease Patients with Renal Anemia before and after Peritoneal Dialysis (PD) Initiation Daisuke Fujimoto, Masataka Adachi, Yushi Nakayama, Hideki Inoue, Yutaka Kakizoe, Takashige Kuwabara, Yuichiro Izumi, Teruhiko Mizumoto, Masashi Mukoyama. *Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: There have been few reports on the management of renal anemia using CERA throughout the period from pre- to post-PD initiation. We investigated the usefulness of CERA in PD patients to examine its efficacy and dosage before and after PD initiation.

Methods: 16 patients (6 males; mean age, 59.9 years) who started PD between 2011 and 2015 were investigated. Hemoglobin (Hb) levels, iron parameters (transferrin saturation and ferritin), CERA dosage, and erythropoietin resistance index (ERI) (CERA amount μg/body weight kg/Hb (g/dL)/4) for 24 weeks were examined retrospectively before and after PD initiation.

Results: The mean Hb levels were 10.4 g/dL at 24 weeks prior to PD initiation, 10.2 g/dL at PD initiation and 11.7 g/dL at 4 weeks after that, showing a significant increase after PD initiation. The proportion of patients whose Hb levels were 11g/dL or higher increased from 40.0% to 81.2% after PD initiation. The mean CERA dosage was 73.3 μg/month(M) at 24 weeks prior to PD initiation, 87.5 μg/M at initiation, and 71.9 μg/M at 4 weeks after that. Thus, CERA dosage tended to increase just before PD initiation and then decreased after that. In non-diabetic patients, CERA dosage to maintain Hb levels decreased after PD initiation by approximately 25% compared to that prior to PD initiation. In contrast, it did not change after PD initiation in diabetic patients. ERI was 0.027 at 8 weeks prior to PD initiation, 0.036 at initiation, and 0.026 at 8 weeks after that, indicating that it tended to increase just before initiation and decreased significantly after that. With regard to iron metabolism, no significant changes in TSAT or ferritin levels were observed, suggesting relatively stable iron metabolism with CERA treatment during PD initiation.

Conclusions: Treatment with CERA prior to PD initiation resulted in fair anemia management for both diabetic and non-diabetic patients. Our data also suggest that CERA dosage might be reduced in non-diabetic patients after initiation of PD.

SA-PO1005

Dosing Penalty after Switching from ESA Originator to Biosimilar: Matched Cohort Study in Stable Hemodialysis Patients Roberto Minutolo,[1] Piergiorgio Bolasco,[2] Domenico Santoro,[3] Maurizio Mb Borzumati,[4] Alberto Santoboni,[5] Stefano Sposini,[6] Carlo Mura,[7] Oliviero Filiberti,[8] Fulvio Fiorini,[9] Gianni Carraro,[10] Luca De Nicola,[1] Domenico Russo.[11] *[1]Nephrology Div, Hospitals of II Univ of Naples; [2]ASL Cagliari; [3]Univ of Messina; [4]Verbania; [5]Colleferro; [6]Massa; [7]Montevarchi; [8]Vercelli; [9]Rovigo; [10]Padova; [11]Univ Federico II, Italy.*

Background: In hemodialysis (HD), switch from ESA originator to biosimilar associates with dosing penalty (DP) of about 10% according to industry-driven studies. However, DP in daily clinical practice is ill-defined.

Methods: From 12 non-profit centers, we selected consecutive ESA treated HD patients (2011-14) receiving stable i.v. ESA dose and not transfused in the previous 3 months. Patients switched from originators to biosimilars (BIO, n=153) were matched with those persisting with ESA originator (CON, n=153) to evaluate DP (difference of ESA dose between BIO and CON).

Results: Age (70±13y), males (63%), diabetes (30%), history of CVD (40%), BW (68±15 kg) and vascular access (87% AV fistula) did not differ in the two groups. Biosimilars were HX575 (Binocrit, 79%) or SB309 (Retacrit, 21%).

	Basal	Wk 4	Wk 8	Wk 12	Wk 16	Wk 20	Wk 24
CON							
Hb (g/dL)	11.2 ±0.8	11.3 ±1.0	11.3 ±0.9	11.3 ±0.8	11.2 ±0.8	11.2 ±0.8	11.3 ±0.8
ESA (IU/w)	7,729 ±5,160	7,379 ±5,379	7,557 ±5,188	7,291 ±5010	7,101 ±5,089	7,192 ±5,004	7,118 ±4788
BIO							
Hb (g/dL)	11.2 ±0.9	11.1 ±1.0*	11.1 ±1.0*	11.1 ±1.0	11.0 ±0.9	11.1 ±1.0	11.2 ±0.9
ESA (IU/w)#	7,740 ±5,388	8,515 ±5,793	8,815 ±5,728*	9,369 ±6,334*	9,647 ±6,392*	9,716 ±6,484*	9,807 ±6,663*

Mean±SD. #P<0.001 for trend; * P<0.05 vs CON. At week-24, DP was 2,690 IU/wk, 95%CI 1,384-3,995, equal to 35% (95%CI 21-49). In CON and BIO, TSAT (25±11 and 28±13%, respectively) and ferritin (398±244 and 382±282 ng/mL, respectively) were similar at each visit and unchanged versus baseline. The same held true for iron therapy, Kt/V, CRP, albumin and PTH.

Conclusions: In controlled conditions, switch from ESA originator to biosimilar requires doses higher than expected to maintain constant Hb. Besides economic issue, these data call for long-term studies to assess whether the lower efficacy of biosimilars poses a safety threat.

SA-PO1006

A U.S. Phase III Trial to Compare HX575 (Proposed Biosimilar Epoetin Alfa) with Epogen®/ Procrit® in Renal Anemia Patients Matthew R. Weir,[1] Rajiv Agarwal,[2] Jeffrey C. Fink,[1] Nelson P. Kopyt,[3] Susanne Schmitt,[4] Gregor Schaffar,[4] Jim Mckay,[5] Radmila Kanceva,[4] Pablo E. Pergola.[6] *[1]Univ of Maryland School of Medicine, Baltimore, MD; [2]Indiana Univ School of Medicine, Indianapolis, IN; [3]Lehigh Valley Hospital, Allentown, PA; [4]Sandoz/Hexal AG, Holzkirchen, Germany; [5]Sandoz Inc, Princeton, NJ; [6]Univ of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: This study aimed to show biosimilarity of HX575 (Sandoz/Hexal AG) with the licensed reference product Epogen®/Procrit® (Amgen/Janssen), following subcutaneous (sc) administration.

Methods: Randomized, double-blind, parallel-group, multicenter (n=49) study consisting of a 4-wk screening period followed by a 52-wk treatment period. Patients (pts; n=435) on dialysis and treated with a stable dose of Epogen®/Procrit® sc at least once per wk were included and randomized to treatment with HX575 (n=217) or Epogen®/Procrit® (n=218). Primary endpoint was mean absolute change in hemoglobin (Hb) level between the screening (wk -4 to -1) and evaluation periods (wk 21 to 28). The incidence of Ab formation against epoetin was a secondary endpoint.

Results: Patient demographics were comparable between the 2 groups. Mean Hb level at baseline and evaluation period was comparable for HX575 and Epogen®/Procrit® treated pts. Mean (SD) change in Hb level from baseline to evaluation period was -0.11 (1.001) g/dL for HX575 and 0.01 (0.953) g/dL for Epogen®/Procrit® treated pts. ANCOVA analysis found the estimated difference in Hb level was -0.0926 g/dL with a 90% CI (-0.2264, 0.0413) entirely within the pre-specified equivalence limits (-0.5 g/dL, 0.5 g/dL). 9 pts tested positive (transiently) for anti-epoetin antibodies by radioimmunoprecipitation assay (2 pts were already positive at baseline); no patient tested positive for neutralizing Abs. Exposure-related incidence rates of anti-epoetin Abs were similar between the 2 groups (HX575, 0.036; Epogen®/Procrit®, 0.011).

Conclusions: SC administration of HX575 in pts with renal anemia was therapeutically equivalent to Epogen®/Procrit® in terms of maintaining stable Hb levels and immunogenic potential.

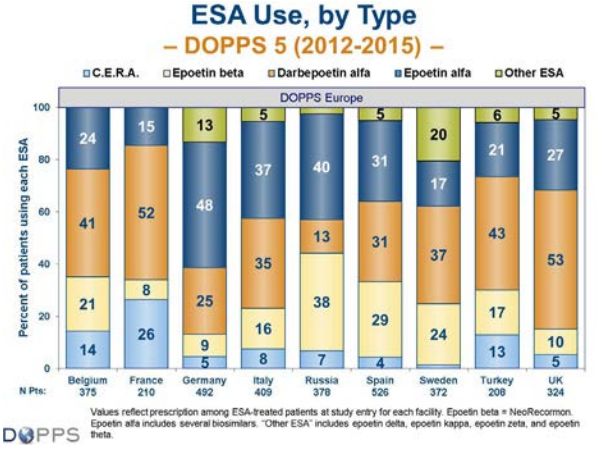
SA-PO1007

Prevalence and Dosing Patterns of ESAs Used in 9 European Countries: DOPPS Douglas S. Fuller,[1] Bruce M. Robinson,[1] Boris Bikbov,[2] Francesco Locatelli,[3] Ronald L. Pisoni.[1] *[1]Arb Res Collab Hlth, Ann Arbor, MI; [2]Moscow St. Univ of Med and Dent, Moscow, Russian Federation; [3]A. Manzoni Hosp, Lecco, Italy.*

Background: C.E.R.A. (methoxy polyethylene glycol-epoetin beta), darbepoetin alfa (DA), and epoetin beta (EB) are erythropoiesis-stimulating agent (ESA) alternatives to epoetin alfa (EA) commonly used in Europe. C.E.R.A. is now available in the US; availability of EA biosimilars is anticipated in coming years.

Methods: We provide prevalence and dosing patterns for C.E.R.A., DA, EB, and EA using weighted analyses of data from 9 European countries (Belgium, France, Germany, Italy, Russia, Spain, Sweden, Turkey, UK; 167 facilities (fac); 4230 pts) in the Dialysis Outcomes and Practice Patterns Study (DOPPS) phase 5 (2012-2015).

Results: Overall prevalence was 8% C.E.R.A., 35% DA, 19% EB, and 31% EA. The % of facs using C.E.R.A. ranged from 20% (UK) to 58% (Fra); for DA: 30% (Rus) to 87% (Tur); for EB: 15% (UK) to 53% (Ita/Tur); for EA: 17% (Fra) to 86% (Ger). In facs using C.E.R.A., median % ESA-treated pts using C.E.R.A. was 13% [IQR=6-38%, mean=28%]; for DA: 43% [IQR=17-85%, mean=49%]; for EB: 33% [IQR=15-90%, mean=47%]; for EA: 48% [IQR=26-89%, mean=54%]. Common C.E.R.A. dosing frequencies were 1x/mo (81%) and 2x/mo (12%); for DA: 1x/wk (66%) and 2x/mo (22%); for EB/EA: 3x/wk (39%), 2x/wk (27%), and 1x/wk (30%). Median dose for C.E.R.A. was 109 mcg/mo [IQR=69-162, mean=157]; for DA: 121 mcg/mo [IQR=64-211, mean=171]; for EB: 5.6 ku/wk (IV, 57%) and 5.1 ku/wk (SC); for EA: 5.8 ku/wk (IV, 81%) and 4.2 ku/wk (SC). Achieved mean hemoglobin (Hb) levels were similar (11.1-11.2 g/dl) among pts prescribed C.E.R.A., DA, EB, or EA.



Conclusions: Combinations of C.E.R.A., DA, EB, and EA are used in European facs to maintain Hb at recommended levels. As C.E.R.A. and EA biosimilars become available in the US, this real-world practice data can provide useful insight for US clinicians interested in the use of these medications.

SA-PO1008

Serum Concentration of Non-Transferrin Bound Iron in HD Patients Is Higher Than Normal Control and Is Increased after Intravenous Iron Administration

Noriko Saito,[1] Shigeru Miyazaki,[2] Kazuhide Saito,[2] Tetsuo Morioka,[1] Hisaki Shimada,[1] Kozo Ikarashi,[1] Yutaka Tsubata,[1] Kazuhiro Yoshita,[1] Yutaka Kohgo.[3] *[1]Shinraku-en Hospital, Niigata, Japan; [2]Niigata Univ, Niigata; [3]International Univ of Health and Welfare Hospital, Nasushiobara, Japan.*

Background: Non-transferrin bound iron (NTBI), which appears in the serum under iron overload, is associated with organ damage through free radical production.intravenous iron administration (IVIA) is a common treatment for renal anemia in hemodialysis(HD) patients.

Methods: NTBI, Hepcidin25, soluble Tf receptor(sTfR), 8-oxo-2'-dehydroguanosine, high sensitive CRP, serum iron, TSAT and ferritin were evaluated in 44 HD patients who were not recieved iron administration nor erythropoietin stimulating agents (ESA) for at least 2months and as a control 30 healthy volunteers. NTBI was measured by recently described assay system(Clin Chim Acta 437(2014) 129). 23 HD patients without any iron load within 2 weeks were administered saccharated ferric oxide (Fe 40mg) intravenously after HD session. 19(83%) patients had received ESA. We evaluated the NTBI and above markers before and at 0.5, 1, 2, 4, 6, 20, 44 hours after IVIA.

Results: The NTBI levels in HD patients was higher than that in control (3.3(3.0~3.9) vs 2.7(2.5~3.0) μg/ml p<0.001). In HD patients NTBI correlated with Tf and the predictor of NTBI was Tf by stepwise analysis(β=0.328, p=0.030, R^2=0.107). TSAT before IVIA was 20(14~27)%, and increased to 81(65~100%) at 0.5hours after IVIA and then decreased to the level before IVIA at 44hours. NTBI before IVIA was 1.5(1.1～2.25)μg/dL, increased to 2.2(1.8～2.7)μg/dL at 4 hours (p=0.021) and decreased to 1.8(1.2～2.25)μg/dL at 44 hours. Maximum increase rate of NTBI((NTBI at peak - NTBI before IVIA) x 100 / NTBI before IVIA) was 80(50~146)%. By stepwise analysis, sTfR before IVIA was a negative predictor for NTBI (β=-0.494, p=0.016, R^2=0.244). (Medians (interquartile range) or numbers(%)).

Conclusions: NTBI in HD patient was higher than healthy control, correlates to Tf and significantly increase at 4 hours after IVIA. The predictor of NTBI maximum increase rate was sTfR of before IVIA. NTBI could be a novel marker to assess iron metabolism in HD patients.

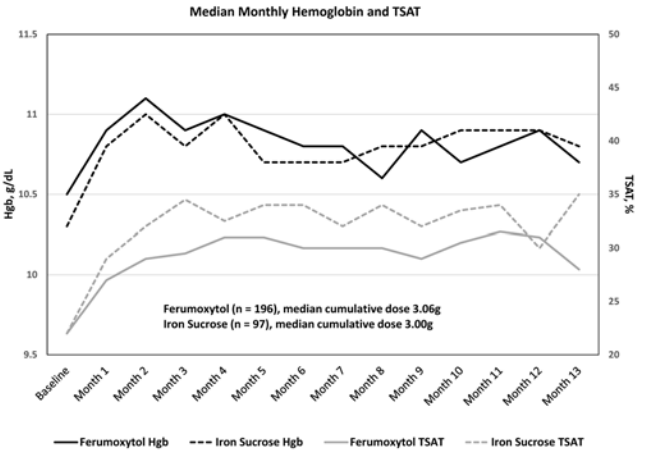
The FACT-Study: A Randomized Controlled Trial of Repeated Doses of Ferumoxytol or Iron Sucrose in Patients on Hemodialysis

William Strauss, Naomi V. Dahl, Kristine Bernard, Zhu Li. *AMAG Pharmaceuticals, Inc., Waltham, MA.*

Background: Data from prospective randomized controlled trials comparing different IV iron formulations over a period of >1 year are lacking. The purpose of this study was to gain a better understanding of the long-term safety, efficacy, and frequency of use of IV iron in the episodic treatment of iron deficiency anemia (IDA) in CKD-HD patients.

Methods: This open-label multicenter, prospective study (NCT01227616) conducted at 35 sites in 3 countries, randomized patients with Hgb<11.5 and TSAT<30% 2:1 to ferumoxytol (FER) (2 X 510 mg, 2-8 days apart) or iron sucrose (IS) (10 X 100 mg at consecutive HD sessions), administered by infusion or injection. Patients with persistent or recurrent IDA (Hgb<11.5 g/dL and TSAT <30%) at any monthly observation visit over the following 12 months were treated again with an additional course of their randomized treatment. Safety was continuously monitored.

Results: Demographics were balanced between the two treatment groups (196 FER; 97 IS). Mean age was 58.8 (SD 13.96), 58.4% were male, 50.5% were White, and 30% were Black or African American. Over the 13-month study period, adverse events (AEs) were reported in 158 (80.6%) of FER and 81 (83.5%) of IS patients. These were considered treatment related by the investigators in 9 (4.6%) of FER and 4 (4.1%) of IS patients. Serious AEs were reported in 93 (47.7%) of FER patients and 49 (50.5%) of IS patients, none of which were considered treatment related by the investigators. For both treatment arms, the median month-by-month change in ESA dose remained zero throughout the study.



Conclusions: Ferumoxytol and iron sucrose demonstrated comparable efficacy and AE profiles during episodic treatment over a 13-month period in CKD patients undergoing HD.

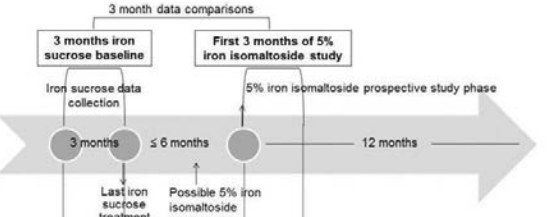
An Observational Study of Iron Isomaltoside 5% in Haemodialysis: A Novel Intravenous Iron for Dialysis

Ashraf I. Mikhail,[1] Staffan Schön,[2] Jorgen B.A. Hegbrant,[2] Christopher Brown,[1] Inger Nilsson,[2] Gert Jensen,[3] Jason Moore,[4] Lennart D. Lundberg.[5] *[1]ABMU HB, United Kingdom; [2]Diaverum Sweden AB; [3]Sahlgrenska Univ Hospital, Sweden; [4]Royal Devon & Exeter Hospitals, United Kingdom; [5]Norrland Univ Hospital, Sweden.*

Background: Iron isomaltoside 5% (Diafer®) is a recently approved IV iron for dialysis patients. The controlled-release matrix minimises labile (free) iron. Minimising labile iron may be important to reduce iron toxicity which may carry long term risks. The tight iron binding also allows for fast push injection. This study aims to determine the effectiveness and safety of iron isomaltoside in clinical practice in a haemodialysis (HD) cohort.

Methods: This interim analysis includes data from 95 patients for the first 3 months of an ongoing 12 month study of 209 HD patients in Sweden and the UK. Patients entering the study had to have 3 month data for iron sucrose within month -9 to 0 from the start of the prospective phase. Data for iron sucrose are compared to cross-over data for iron isomaltoside. The primary endpoint is comparison of Hb levels.

Results:



Iron sucrose	Iron isomaltoside	Clinical data over 3 months
111	**114**	**Mean Hb (g/L)**
54	**40**	**Patients with all Hb values in range 100-120 g/L (%)**
21	17	Patients with at least one Hb <100 g/L but no Hb >120 g/L (%)
25	41	Patients with at least one Hb >120 g/L but no Hb <100 g/L (%)
420	**434**	**Mean ferritin (microgram/L)**
53	45	Patients with mean ferritin in range 200-500 micrograms/L (%)
29	39	Patients with mean ferritin > 500 micrograms/L (%)
26	**26**	**Mean TSAT (%)**
40	36	Patients with mean TSAT in range 20-30% (%)
33	32	Patients with mean TSAT < 20% (%)
		Drug data over 3 months
6	6	Mean number of iron doses/patient
544	**648**	**Mean cumulative iron dose/patient (mg)**
181	216	Mean cumulative iron dose/patient/month (mg)
93	90	Patients on ESA (%)
8151	7707	Mean cumulative ESA dose/patient/week (IU)
not collected	2	Patients with ADRs (%)
not collected	0	Patients with serious ADRs (%)
28	1	Patients with metallic taste (%)

Iron isomaltoside maintains Hb levels and adequate iron status in patients converted from iron sucrose. Higher Hb values with iron isomaltoside are the result of higher (16%) elemental iron doses; with a consequential reduction in ESA requirement of 6%. Iron isomaltoside is well tolerated. One patient experienced headache and one patient metallic taste (1%). In comparison, 28% experienced metallic taste with iron sucrose. Logistical benefits were enabled by fast push injection requiring less than 3 minutes for preparation and intradialytic administration of iron isomaltoside.

Conclusions: Iron isomaltoside 5% safely and effectively maintains Hb levels for CKD patients on HD. By optimising the iron dose, ESA use can be reduced. This novel formulation that reduces labile iron may have potential benefit to patient outcomes but this requires determination.

Comparison of Hb Levels and Dose of Iron Associated with Adverse Events between Younger and Elderly Hemodialysis Patients Takahiro Kuragano, Takeshi Nakanishi. *Dept of Internal Medicine Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Japan.*

Background: We recently demonstrated that high dose of ESA and iron were associated with higher risk of death and/or adverse events in maintenance hemodialysis patients(MHD) in TRAP study (Kidney Int. 2014). Elderly MHD are increased and the optimal renal anemia treatment for them should be examined. We performed a secondary analysis of the patients enrolled in the TRAP study.

Methods: In 1095 MHD, we compared the relation of anemia, nutritional and inflammatory markers to adverse events between younger (<65 yo) and elderly (≥65 yo) during 3 years. The composite events (CEs) were defined as cerebro-cardio vascular disease, infection, hospitalization, and death. A time dependent cox hazard model was applied to the evaluation of the association between these clinical factors and CEs.

Results: Compared with younger MHD, serum albumin level and body mass index were significantly lower (P<0.05) and high sensitive CRP was higher (p<0.05) in elderly MHD. In elderly MHD, Hb levels was significantly lower (p =0.02), and ferritin (p=0.01) and the index of ESA hypo-responsiveness 'ESA/Hb' (p=0.01) were higher than those of younger MHD. In the elderly MHD, the risk of CEs was significantly smaller in only the patients Hb levels with 10-11g/dL (HR:0.67, P=0.035), but not in those >11g/dL. In younger MHD, compared to the patients with Hb <10g/dL, the risk of CEs was significantly decreased in higher Hb levels (10-11g/dL (HR:0.47, p=0.02), 11-12g/dL (HR:0.31, p=0.01), and >12g/dL (HR:0.12, p=0.04)). Both of younger and elderly MHD, higher ESA/Hb levels (≥400) was significantly associated with higher risk for CEs (HR:2.24, p=0.01, HR:1.90, p=0.01). Dose of intravenous iron was significantly associated with higher risk of CEs in both younger (HR:1.2, p=0.02) and elderly (HR:1.2, p=0.02) MHD.

Conclusions: The elderly MHD might have the higher ESA hypo-responsiveness and iron storage which could be related to chronic inflammation and malnutrition. In elderly MHD, targeting higher Hb level similar to younger might not be necessary for the prevention of adverse events. Further studies for examining the adequate anemia management for elderly MHD are needed.

SA-PO1012

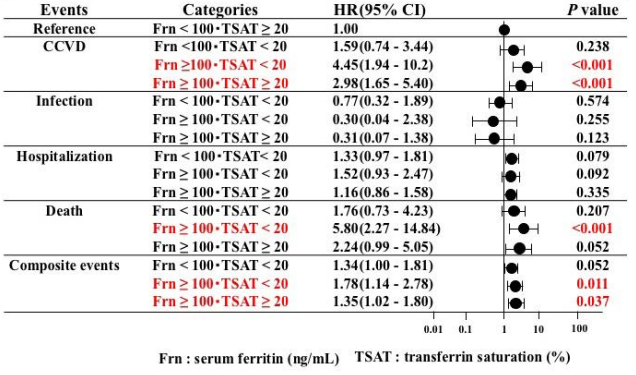
The Relationship between Iron Dysutilization for Erythropoiesis and Adverse Events or Survivals in Patients Undergoing Hemodialysis Takahiro Kuragano, Takeshi Nakanishi. *Dept of Internal Medicine Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Japan.*

Background: Patient with high serum ferritin and low transferrin saturation(TSAT) levels could be considered as dysutilization of iron for erythropoiesis in which iron administration might increase TSAT and Hb levels. Long-term safety of iron administration to these patients has not been well studied.

Methods: Study design was the observational multicenter study for period of 3 years. We defined dysutilization of iron for erythropoiesis as the patients with lower TSAT(<20%) and higher ferritin(≥100ng/mL) levels. In 805 patients with maintenance hemodialysis (MHD), the association between dysutilization of iron for erythropoiesis and adverse event was investigated with the time dependent cox hazard model.

Results: Compared with low TSAT(≤ 20%) level, patient with normal TSAT(20-30%) was significantly lower risk for cerebrovascular and cardiovascular disease(CCVD) (HR:0.25, P=0.04), and patients with higher TSAT(≥30%) were lower risk for death(HR:0.12, P=0.01). Male, younger patients, without diabetes, low high sensitive(h) CRP, and low β2microglbulin were selected as significant predictors of high TSAT. Compared with low ferritin(<100ng/mL) and high TSAT(≥20%), patients with high ferritin(≥100ng/mL) and low TSAT, and with high ferritin and high TSAT had a significantly higher risk of CCVD. Patients with high ferritin and low TSAT had a significantly higher risk of death than low ferritin and high TSAT.

Fig. 1 Relationship between TSAT and ferritin levels and adverse events



Conclusions: Although patients with low TSAT levels had a significantly higher risk of CCVD or death, higher TSAT level was not associated with iron administration or iron storages. Patients who were suspected as dysutilization of iron for erythropoiesis had a higher risk of CCVD and death. The administration of iron should be cautious to the patients with dysutilization of iron for erythropoiesis.

SA-PO1013

Dysregulated Iron Metabolism in Bone Marrow of a Mouse Model of Chronic Kidney Disease Tomoko Kimura, Kiyoko Yamamoto, Yuki Morikami, Takanori Nagai, Masayoshi Nanami, Yasuyuki Nagasawa, Yukiko Hasuike, Takahiro Kuragano, Takeshi Nakanishi. *Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Japan.*

Background: Causes of anemia in CKD are thought to be primarily caused by inadequate EPO synthesis,shortened erythrocyte life span,and failure in bone marrow(BM) due to chronic inflammation. But the major mechanism has not been well clarified. In the present study,we examined the differentiation pattern of erythroid in the BM using flow cytometry(FACS),renal EPO production and hepatic hepcidin expression using mouse model of adenine-induced renal failure(RF).

Methods: RF was induced by the administration of 0.15 to 0.3% adenine-containing chow for 8weeks to male C57BL/6J mice. Liver,kidney,BM,and blood were obtained from control(C) and RF mice. Then Hb,serum iron and ferritin levels were measured. Serum hepcidin levels were quantified using LC-MS/MS methods. Hepatic hepcidin(Hamp),renal EPO and BM Fam132b(erythroferrone)mRNA from C and RF were semi-quantified using RT-PCR. To evaluate the maturation of erythron,BM erythroid precursors were analyzed using CD71(Transferrin receptor) and Ter119 markers by FACS.

Results: We confirmed that Hb levels were significantly lower(8.8±0.3vs13.4±0.1g/dL) and serum ferritin levels were higher(2.6±0.6vs1.1±0.1μg/mL) in RF than C. Renal EPOmRNA expression in RF was increased compared to C(2.5:1). FACS analysis showed the percentages of Pro EB(CD71+/Ter119-) and Baso EB(CD71+/Ter119+) in the BM were decreased in RF compared to C. Hepatic Hamp mRNA expression was increased(2.4:1) and serum hepcidin levels were also higher(397.6±79.4vs99.6±6.9ng/dL) in RF compared to C. Serum iron(105.4±5.1 vs121.4±3.8μg/dL) and TSAT(37.2±1.1%vs43.0±1.2%) were lower in RF than C. Further,BM Fam132b mRNA expression was significantly decreased(0.6:1) in RF compared to C.

Conclusions: Erythroblast maturation was affected in the steps of late differentiation,those are the decrease in CD71+cells. In RF,erythroferrone might be decreased,which could cause the increase in hepcidin although renal EPO expression was increased.Finally we presumed that the increase in hepcidin expression could be associated with the dysregulated erythroblast differentiation in RF model.

SA-PO1014

Disturbance of Iron Utilization in Erythropoiesis of Presensitized High-Risk Kidney Transplant Recipients Treated by Non-Antigen-Specific Immunoadsorption Sebastian Markus Schaefer, Martin G. Zeier, Matthias Schaier. *Div of Nephrology, Heidelberg Univ Hospital, Heidelberg, Germany.*

Background: Non-antigen-specific immunoadsorption (IA) is an established method for desensitization of presensitized high-risk kidney transplant recipients. Despite of concomitant intravenous iron and erythropoietin substitution, patients under IA treatment regularly show significant decrease in haemoglobin levels. We hypothesised that IA influences systemic iron homeostasis and subsequently affects the erythropoiesis. Hepcidin is the key regulator of systemic iron homeostasis that coordinates iron uptake, storage and release to the blood stream. High erythroid iron demand inhibits hepcidin secretion from hepatocytes, thus increasing the intestinal iron uptake and iron levels in blood.

Methods: In a pilot study in eight presensitized high-risk transplant recipients, differnt parameters of iron homeostasis were measured.

Results: Haemoglobin levels decreased over the course of IA treatment (Δhaemoglobin ±SD: after 6 treatments 0.55 ±0.90, after 10 treatments 1.16 ±1.29). In pre-post-treatment comparison, hepcidin levels in blood were reduced following an IA treatment cycle, suggesting direct elimination through adsorption. Hepcidin levels increased until next treatment cycle, however did not reach baseline levels. Despite hepcidin depletion as well as iron and erythropoietin substitution, the percentage of hypochromic erythrocytes constantly increased during the entire IA treatment. Conversely, transferrin and ferritin levels as indicators of iron deposits remained unchanged during the course of IA. Furthermore, continuously declining levels of soluble transferrin receptor indicated sufficient erythroid iron deposit.

Conclusions: Collectively, our data indicate clinically relevant disturbed iron utilization in erythropoiesis of IA treated patients leading to hypochromic anaemia despite of sufficient iron and erythropoietin substitution.

SA-PO1015

Discriminative Effect of Oral and Intravenous Iron Administration on the Fibroblast Growth Factor-23 and Inflammatory Cytokines in Patients on Maintenance Hemodialysis with Iron Deficiency Anemia Yukiko Hasuike,[1] Wataru Fukao,[1] Soshi Yorifuji,[1] Yuki Morikami,[1] Tomo Yamakawa,[2] Kazuhiro Toyoda,[2] Takeshi Nakanishi.[1] *[1]Div Kidney and Dialysis, Dept Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Dept Kidney and Dialysis, Meiwa Hospital, Nishinomiya, Hyogo, Japan.*

Background: FGF-23, a bone-derived hormone, plays an important role in the pathogenesis of several complications in patients with chronic kidney disease. The effect of iron supplementation, oral vs intravenous (IV), on fibroblast growth factor-23 (FGF-23) and inflammatory cytokines were examined in maintenance hemodialysis (MHD) patients with iron deficiency anemia (IDA).

Methods: MHD patients with absolutely iron deficiency (n=61, serum ferritin <50 ng/ml) treated with erythropoiesis stimulating agents (ESA) were enrolled. Oral iron (ferric citrate hydrate 50 mg daily, Oral group, n=29,) or IV iron (saccharated ferric oxide 40 mg weekly, IV group, n=32) were administrated for 10 weeks. Iron supplementation was halted when serum ferritin level was >100 ng/ml. Factors related to anemia, iron metabolism, inflammation, oxidative stress (pentosidine), and FGF-23 (ELISA, Kinos) were measured at the start and after 3 months of iron supplementation.

Results: Mean age of 68.6±11.1 years, mean dialysis vintage 7.3±6.7 years, and serum ferritin levels of 11.3±7.2 ng/ml. In both the 2 groups, Hb, MCV, serum ferritin, TST, hepcidin, IL-6 (Oral: 5.71 to 8.20 pg/ml, IV: 5.17 to 5.45 pg/ml, median), and TNF-α (Oral: 34.8 to 42.0 pg/ml, IV: 36.4 to 47.9 pg/ml, median) were significantly increased and ESA resistance index was decreased by the iron supplementation. Soluble transferrin receptor of only the Oral group was decreased (p=0.0058), and FGF-23 of only the IV group was increased compared with at the start (1800 [614-4300] pg/ml to 2850 [659-6850] pg/ml, p=0.0004). There was no change of high-sensitivity CRP and pentosidine levels of the 2 groups.

Conclusions: Iron supplementation might stimulate the production of inflammatory cytokines. Iron administered intravenously could induce the elevation of serum FGF-23 level.

SA-PO1016

Association between Fibroblast Growth Factor 23 and Iron Metabolism in Hemodialysis Patients Hirokazu Honda,[1] Tetsuo Michihata,[2] Kanji Shishido,[3] Takanori Shibata.[4] *[1]Div of Nephrology, Dept of Medicine, Showa Univ Koto Toyosu Hospital, Tokyo, Japan; [2]Ebara Clinic, Tokyo, Japan; [3]Dept of Dialysis, Kawasaki Clinic, Kawasaki, Japan; [4]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan.*

Background: Recent study demonstrated the association among inflammation, iron metabolism and fibroblast growth factor (FGF) 23 (KI. 2016;89:135). The present clinical study aimed to assess associations between anemia, iron metabolism and FGF23 in hemodialysis (HD) patients.

Methods: This prospective observational study examined a cohort of prevalent HD patients (n=282). Blood samples were obtained before dialysis session at baseline to measure levels of hemoglobin (Hb), transferrin saturation (TSAT), ferritin, albumin-adjusted calcium (Ca), phosphate (P), intact (i)-PTH, 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, FGF23, and high sensitive (hs)-CRP. After the baseline measurement, study patients were followed-up for 6 months. Levels of Hb, TSAT and ferritin, and hs-CRP were measured every 1 month, 2 months and 3 months, respectively. Doses of ESAs, epoetin or darbepoetin-alfa, and intravenous iron supplementation during 6 months were recorded.

Results: FGF23 were positively correlated with Ca, P, i-PTH and inversely correlated with TSAT and ferritin. Whereas levels of Hb and hs-CRP and doses of ESAs during 6 months did not differ among FGF23 tertiles, levels of ferritin and TSAT in higher FGF23 tertile were continuously lower than those in middle to lower FGF23 tertiles. Higher FGF23 tertile was independently associated with repeated measurements of TSAT and ferritin by a univariate repeated measures analysis, however, the association of ferritin with higher FGF23 tertile, but not of TSAT, was only confirmed by multivariate repeated measures analysis. Doses of intravenous iron supplementation were significantly increased in higher FGF23 tertile in multivariate models.

Conclusions: High FGF23 levels may be associated with prolongation of low levels of ferritin, resulting in increased doses of iron supplementation to manage anemia in HD patients.

SA-PO1017

Association between Intact Parathyroid Hormone and Soluble Klotho Levels on Iron Metabolism in Anemic Hemodialysis Patients Miguel Uriol Rivera,[1] Gonzalo Gómez Marqués,[1] Manuel Luque-Ramírez.[2] *[1]Dept of Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; [2]Dept of Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.*

Background: High intact parathyroid hormone (iPTH) levels and soluble a-klotho (s-klotho) deficiency are two conditions associated to renal anemia. We evaluate in hemodialysis patients: i) the influence of iPTH on s-klotho levels; ii) the potential association of s-klotho levels with ferrokinetics and ESA needs.

Methods: This is a *post-hoc* analysis from the MIR-EPO study (EudraCT: 2009-015511-40). Patients were divided in 3 groups according to baseline iPTH: group A (n:5; <150 pg/ml), group B (n:8; 150-300 pg/ml), and group C (n:15; >300 pg/ml). ESA and iron supplements were administered to maintain hemoglobin levels between 10.5 and 12.0 g/dl and transferrin saturation(TSAT) ≥20%. s-klotho were measured after 3 months of ESA titration at 2 time points (month 3 and 6). We assessed s-klotho changes throughout the study and the differences among its mean changes as a function of iPTH subgroups.

Results: In the Group A, s-klotho did not change throughout the study [+0.01pg/ml$_{log}$; P=0.81], whereas decreased in groups B and C [-0.12pg/ml$_{log}$ (P=0.01), and -0.06pg/ml$_{log}$ (P<0.01), respectively]. Percentage mean change of s-klotho between groups A and B was significantly (28%, P=0.01). No significant differences among other groups were found. As a whole, a positive correlation between changes in s-klotho and serum iron, TSAT, and transferrin plasma levels were observed. A log-lineal regression model determined that increased s-klotho levels in group A were associated with a decrease in iron supplementation and ESA needs (X^2:5.0, P=0.02, and X^2:3.9, P=0.04, respectively).

Conclusions: In haemodyalisis patients, lower iPTH levels have a beneficial impact on iron metabolism.This effect may be mediated by s-klotho levels.

SA-PO1018

Differences between 25-OH Vitamin D, 1,25-$(OH)_2$ Vitamin D and Paricalcitol on the Erythropoietic Response of Anemic Hemodialysis Patients Miguel Uriol Rivera,[1] Sheila Cabello Pelegrin,[1] Angel Garcia-Alvarez,[2] Manuel Luque-Ramírez.[3] *[1]Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; [2]Pharmacy, Inca Hospital, Palma de Mallorca, Islas Baleares, Spain; [3]Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.*

Background: Vitamin D(VD) deficiency is associated to renal anemia. However, it is not well-known if there are differences between 25(OH)-VD or 1,25-$(OH)_2$ VD, and the potential interaction of paricalcitol(PRC) use, on the erythropoietic response. We evaluate the association of 25VD, 1,25VD levels and paricalcitol use on the iron metabolism and hematologic parameters in hemodialysis patients.

Methods: This is a *post-hoc* analysis from the MIR-EPO study(EudraCT: 2009-015511-40). Erythropoietic stimulating agents(ESA) and iron supplements were administered to maintain haemoglobin(Hb) between 10.5 and 12.0 g/dl and transferrin saturation ≥20%. Calcifediol(n:17) was given to achieve 25VD ≥30ng/ml. PRC was used for secondary hyperparathyroidism(n:23). The relationships between the changes(Δ:month6 – month0) in 25VD or 1,25VD with iron supplements, ESA doses, hematologic and iron metabolism parameters were assessed by correlation analysis.

Results: Thirty-one patients were analysed. Direct correlation between Δ25 and Δ1,25VD levels were found (r:0.50, P<0.01) and inverse between Δferritin with Δ25VD and Δ1,25VD was found. Δ1,25VD showed an inverse correlation with ΔHb levels. Those patients who achieved 25VD levels ≥ 30ng/ml needed higher ESA doses (49%, P=0.01). In those patients on PRC, ferritin and ESA doses decreased significantly at the end of the study with respect to baseline.

Conclusions: PRC therapy is associated with decreasing iron stores and ESA doses. 25VD and 1,25VD are also associated to iron stores. However, current recommended 25VD levels seems not to be beneficial for erythropoietic response.

Funding: Private Foundation Support

SA-PO1019

A Negative Impact of Calcium on Hematopoiesis in Hemodialysis Patients Takahito Ito. *Kataguilli Medical Center, Shibata, Niigata, Japan.*

Background: In hemodialysis patients, efficient hematopoiesis is crucial. We retrospectively studied an effect of calcium on hemoglobin level.

Methods: As of June 1, 2015, we had 106 Japanese patients on maintenance hemodialysis. Thereafter, doses of oral calcium carbonate, cinacalcet, and intravenous maxacalcitol were adjusted to maintain serum albumin-corrected calcium concentration (C-Ca) within the target range. In parallel, doses of intravenous erythropoiesis stimulating agents (ESA) and saccharated ferric oxide were adjusted to optimize hemoglobin level (Hb). Six months after, 98 patients were analyzed (63.5 ± 10.9 y, 59 males, 21 diabetics, dialysis vintage 13.0 y [Q1-Q3, 5.0-23.25]). Eight patients were excluded from the analysis because of insufficient blood analysis or patient loss.

Results: Decrease of calcium carbonate and/or increase of cinacalcet lowered C-Ca (P=0.0010 and =0.0007), respectively. Adjustment of maxacalcitol did not significantly change C-Ca. Intact PTH increased from 204.3 ± 127.7 to 251.3 ± 143.2 (P=0.0042). Hb and transferrin saturation changed from 10.78 ± 1.34 g/dL and 32.0 ± 13.1% to 11.1 ± 1.31 and 28.2 ± 13.0, respectively (P=0.0319 and 0.0128). In univariate analysis, Hb at baseline, C-reactive protein (CRP) at baseline, increment of serum albumin concentration during 6 months (ΔAlb), and increment of C-Ca (ΔC-Ca, -0.02 ± 0.87 mg/dL) were associated with ΔHb (0.37 ± 1.84 g/dL). Multivariate analysis with ΔHb as the dependent variable revealed that lowering C-Ca, but not CRP or ΔAlb, linked with the increase of Hb (table1). Similar results were obtained in the patients (N=54) who had received stable or reduced doses of ESA and ferric oxide during the 6 months (table1).

Conclusions: Our results imply that calcium level may be responsible for hematopoiesis or red blood cell survival, regardless of ESA or ferric oxide.

Model	R^2	Independent Variable	Standard β	95% Confidential Interval
All Patients (N=98)	0.509	Hb at Baseline	-0.668	-1.128 — -0.730
		ΔC-Ca	-0.274	-0.881 — -0.277
Subset (N=54)	0.533	Hb at Baseline	-0.621	-1.171 — -0.616
		ΔC-Ca	-0.338	-1.138 — -0.312
Subset: In these 54 patients, doses of ESA and ferric oxide remained unchanged or decreased during the study period.

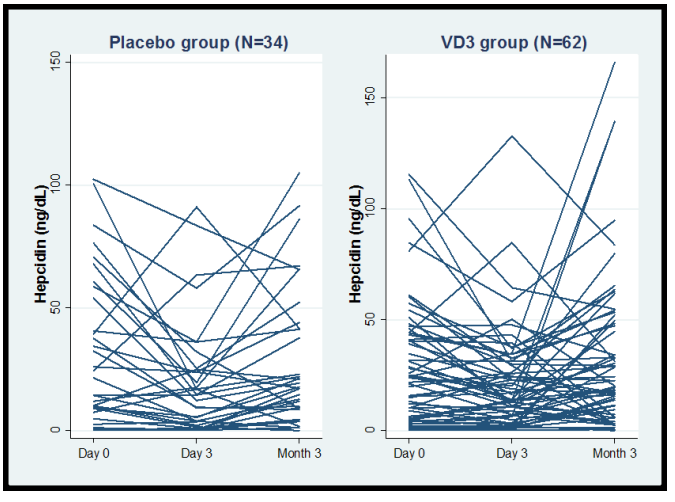
Cholecalciferol Supplementation and Serum Hepcidin-25 Concentrations in Hemodialysis Patients - A Randomized Controlled Trial

Yoshitsugu Obi,[1,2] Takayuki Hamano,[1] Yusuke Sakaguchi,[1] Akihiro Shimomura,[1,2] Yoshitaka Isaka.[1] *[1]Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Univ of California Irvine, Orange, CA.*

Background: A previous study demonstrated that nutritional vitamin D supplementation decreased serum hepcidin levels in healthy subjects. However, it still remains unknown whether it is also true with maintenance hemodialysis (MHD) patients.

Methods: This is a double-blind RCT of cholecalciferol (VD_3) supplementation in MHD patients. Patients were randomly assigned to either thrice-weekly (TW) 3,000 IU VD_3, once-monthly (OM) VD_3 (equivalent to 9,000 IU/week), TW placebo, or OM placebo. The primary outcomes were log-transformed serum hepcidin levels at Day 3 and Month 3. Based on the intention-to-treat principle, we compared VD_3 vs. placebo by using *a priori* defined generalized linear model ignoring the administration intervals. We also examined the differences between TW vs. OM VD_3.

Results: Out of 96 participants, 3 dropped out between Day 3 and Month 3. Median (IQR) serum 25(OH)D levels at baseline and Month 3 were 13 (10–15) and 13 (11–17) ng/mL in the placebo group and 10 (8–13) and 24 (20–29) ng/mL in the VD_3 group, respectively. Likewise, median (IQR) hepcidin levels at baseline, Day 3, and Month 3 were 18 (8–54), 13 (2–25), and 18 (9–42) ng/mL in the placebo group, and 23 (5–43), 15 (6–31), and 22 (9–50) ng/mL in the VD_3 group, respectively (Figure). After baseline adjustment, VD_3 was associated with 1.7 (95%CI, 1.2–2.4) times higher hepcidin levels at Day 3, which lost significance at Month 3 [1.1 (95%CI, 0.7–1.9)]. There were no significant differences in serum levels of TNF-α, IL-6, hemoglobin, or ferrodynamics. Any indices did not show differences between TW and OM VD_3.



Conclusions: Contrary to the previous study in healthy subjects, cholecalciferol supplementation increased serum hepcidin-25 levels in the short term among MHD patients.

SA-PO1021

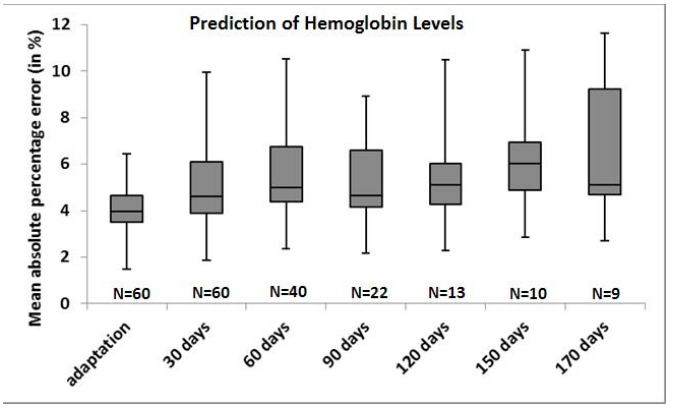
Prediction of Hemoglobin Levels in Individual Hemodialysis Patients by Means of a Mathematical Model of Erythropoiesis

Doris H. Fuertinger, Stephan Thijssen, Peter Kotanko. *Renal Research Inst, NY.*

Background: Prediction of hemoglobin levels in individual hemodialysis (HD) patients treated with erythropoietin (EPO) is highly desirable but challenging. The non-linear dose responsive curve differs between patients and is influenced by multiple factors, such as iron status and inflammation. We adapt a complex mathematical model of erythropoiesis to individual HD patients and predict their hemoglobin (Hgb) response to EPO therapy for up to 24 weeks.

Methods: A mathematical model of erythropoiesis (Fuertinger et al, J Math Biol 2013) is adjusted to individual HD patients treated with EPO. Crit-Line® monitors provided Hgb measurements. Hgb data measured during a 150 days baseline period together with the model are used to estimate a patient's individual erythrocyte lifespan, bone marrow response to EPO, endogenous EPO production, and EPO half-life. Model predictions are compared to measured Hgb data. Boxplots are used to present the mean absolute percentage error (MAPE). Depending on the availability of follow-up data we predict individual Hgb levels for up to 170 days.

Results: We studied 60 chronic HD patients with an age of 59.4 ± 14.7 years, 29 males, 30 Blacks, 37 with diabetes, and a body mass index of 27.9 ± 6.7 kg/m^2. Figure 1 shows the quality of the model adaptations (left boxplot) and Hgb predictions made by the individualized model. Median MAPE is ~4.2% and remains stable for up to 170 days, while MAPE interquartile range increases from ~1.2% in the first 150 days to ~4.5% at 170 days.



Conclusions: The individualized erythropoiesis model predicts individual Hgb levels for up to 21 weeks with clinically satisfactory accuracy and precision. These findings indicate that the mathematical model is able to capture patient-level hemoglobin dynamics, a necessary requirement for its intended use as an individualized anemia management tool.

SA-PO1022

Optimal Hemoglobin Level in Patients with Chronic Kidney Diseases on Hemodialysis in High Altitude Cities

Cesar O. Toral. *Nephrology, Univ of Azuay / Unidad Renal del Austro, Cuenca, Ecuador.*

Background: In patients with anemia due to chronic renal disease, it is recommended in order to avoid complications, to maintain hemoglobin levels between 10-12 g/dl, according to studies conducted at sea level; however, the optimal value allowed in patients residing in high altitude cities is still unknown.

Methods: A descriptive study was conducted in the Renal Unit of the Austro (UNIREAS) Cuenca, Ecuador, (altitud: 2,560mts) during the period January 2010 to December 2011, obtaining data from physical medical records of each patient.

Results: A total of 3,423 measurements of hemoglobin in patients with chronic renal disease stage 5D was obtained, of which 57% were women and 43% men. The complications were divided int different ranges of hemoglobin, from 10 to 12 gr/dl (31.2%), from 12.1 to 13g/dl (45.5%), from 13.1 to 14g/dl (30.3%), from 14.1 to 15 g/dl (21.2%) and over 15g/dl (3%). Additionally, the distribution of complications according to the chronic pathologies assessed was evaluated. Arterial Hypertension (43.7%), Arterial Hypertension plus Diabetes Mellitus type 2 (34.3%), Diabetes Mellitus type 2 (6.25%), Diabetes Mellitus type 1 (1.5%) and others (14%).

Conclusions: The complications increase as the value of hemoglobin increases. However, from the total of measurements greater than 12 g/dl only 1.84% showed compiications. In addition, the complications rate found int he groups with a range of 10 to 12 g/dl hemoglobin was 1.49% compared with a rate of 1.62% found in the group with a wader range of 10 to 13 g/dl.

SA-PO1023

Achievement of Renal Anemia KDIGO Targets by Two Different Strategies - A European Hemodialysis Multicenter Analysis

Maciej B. Drozdz,[1] Stefan H. Jacobson,[2,3] Werner Kleophas,[4] Mahesh Krishnan,[5] Abdulkareem Alsuwaida,[6] Fatima Ferreira Silva,[7] Andre L. Weigert.[7] *[1]DaVita, Poland; [2]Karolinska Inst, Stockholm, Sweden; [3]DaVita, Europe; [4]DaVita, Germany; [5]DaVita Inc; [6]DaVita, Saudi Arabia; [7]DaVita, Portugal.*

Background: Hemoglobin target levels can be achieved through more frequent i.v. iron use with less ESA or vice versa. ESA therapy to correct anemia may result in adverse clinical outcomes and i.v. iron may exacerbate oxidative stress, potentiate atherogenesis and increase the propensity to infections. By tradition, anemia treatment strategies differ significantly between Portugal and Poland.

Methods: We included 1,247 patients on hemodialysis from Portugal (n=730) and Poland (n= 517) in an analysis of the achievement of KDIGO renal anemia targets and focused on treatment strategies.

Results: In Poland, the use and doses of i.v. iron were 35% higher than in Portugal ($p<0.001$) while the use and doses of ESA were 17% higher in Portugal (5034 vs 3133 IU [adjusted]/week, $p<0.001$). Hb 10-12 g/dl was achieved in 70% of pts in Poland and in 66% of pts in Portugal (NS, Chi-2). In Poland vs Portugal, 74% and 78% of pts had ESA ($p=0.056$), 87% vs 83% had ferritin>200 ug/l ($p=0.08$), 36% vs 16% had ferritin>800 ug/l ($p<0.001$), 89% vs 76% had TSAT ≥20% ($p<0.001$), and 15% vs 8% had TSAT≥50% ($p<0.001$). Comorbidity index <7 (Poland 52%, Portugal 39%) vs 7-12 (45% and 58%) vs >12 (3% and 4%) were significantly different between countries ($p<0.001$).

	Age	Vint	BMI	Kt/V	TT ..	Hb	TSAT	Ferri	Alb	Ca	P	iPTH	CVC	AVF
Poland	67	53 m	27	1.6	737	11	35	757	41	8.7	4.7	565	19%	76%
Portugal	69	66 m	25	2.0	724	11	29	498	40	8.9	4.1	561	15%	77%
p	**	***	***	***	***	NS	***	***	NS	***	***	NS	***	NS

t-test **=0.01, ***=0.001

Conclusions: The KDIGO hemodialysis anemia target was achieved in the two countries through different treatment strategies in terms of ESA use and doses of i.v. iron. These differences may have clinical implications: future evaluations will show how these differences in treatment strategies correlate with the future risks of complications, hospitalization and mortality.

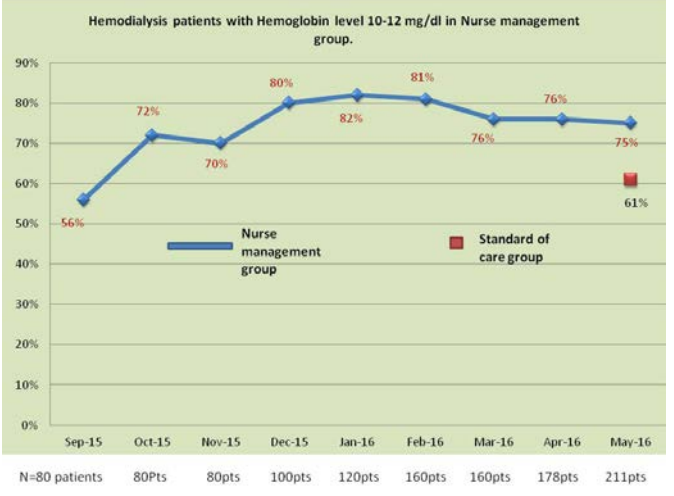
Nurse Based Anemia Management in Hemodialysis: An Observational Prospective Study Abdullah Hamad, Fatma Ahmed Ramadan, Nadiya Noor Khan, Hany Ezzat Ismail, Tarek Abdellatif Ghonemy, Sahar Aly, Fadwa S. Al-Ali. *Nephrology, Hamad General Hospital, Doha, Qatar.*

Background: The concept of anemia nurse manager (ANM) was explored because of her availability in the dialysis unit which provides a chance to address management swiftly and timely. We did a prospective observational study to compare our new ANM model to our standard of care (SOC) in regard to achieving hemoglobin (Hg) in target (10-12 g/dL) and avoid extreme Hg (below 9 or above 13).

Methods: ANM team consisted of two part-time nurses under supervision of an expert nephrologist who provided extensive training for them for 2 months. We randomly selected and gradually included all patients located in 1st floor (our center is the largest in Qatar and has 380 patients in 2 floors). They were followed for 8 months (September 2015 to May 2016). We followed Hg, iron sat and ferritin per our protocol. Nurses reviewed the results one day after blood draw with the nephrologist and prescriptions for erythropoietin stimulating agents (ESA) and iron were written simultaneously (physician prescription is mandatory per health authority in Qatar). Patients who did not have any Hg values during this period were excluded.

Results: We started with 66 patients and gradually reached 211 patients by May 2016. Percentage of patients with Hg within target range steadily improved.



There was a statistically significant difference in the number of patients in target range in the new model (1st floor) versus SOC (2nd floor, n=147) (75% versus 60.5%) (pValue 0.005 fisher exact test). Number of patients with extreme Hg has improved from 10.7% in Sep. 2015 to 6.4% in May 2016 (censored for ESA naïve patients) compared to 12% in SOC group (p 0.08). The two groups did not differ in iron parameters.

Conclusions: Our ANM model designed to fit local requirements in Qatar significantly improved percentage of Hg in target and decreased extreme Hg levels compared to SOC.

Trajectories of Hemoglobin Levels before and after Initiation of Dialysis Dugan Maddux,[1] Frank van der Sande,[2] Jeroen Kooman,[2] Jennifer A. Vosburgh,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Peter Kotanko,[3,4] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Maastricht Univ Medical Center, Maastricht, Netherlands; [3]Renal Research Inst, New York, NY.*

Background: Anemia affects about 82% of stage 5 chronic kidney disease (CKD) patients (Pts) (Shaheen FA, et al. Saudi J Kidney Dis Transpl 2011). As reported by the USRDS these Pts exhibit a drop in mean hemoglobin levels (Hgb) from about 13g/dL to <11g/dL in the 5 years prior to end stage renal disease (ESRD). We studied Hgb trajectories in Pts who transitioned from CKD to ESRD by survival status in the first year of dialysis.

Methods: We analyzed data from the Fresenius Medical Care CKD Data Registry on 14,095 Pts with Hgb results in the 12 months pre-dialysis who transitioned to ESRD between 2008 and 2016. Changes in mean monthly Hgb were analyzed by survival status in the 12 months after starting dialysis.

Results: Two main observations are notable: i) Hgb gradually declined in the year prior to dialysis initiation, more precipitously in the final 2 months (Figure 1A); compared to those who survived the first year of dialysis, the Hgb decline is more pronounced in those who die (Figure 1B). ii) Hgb rapidly rose after dialysis initiation; by month 2 after dialysis start, mean Hgb was similar to levels 12 months prior to dialysis start. (Figure 1A). In Pts who died in the first year of dialysis, the Hgb increase was lower than, and never reached Hgb levels of survivors.

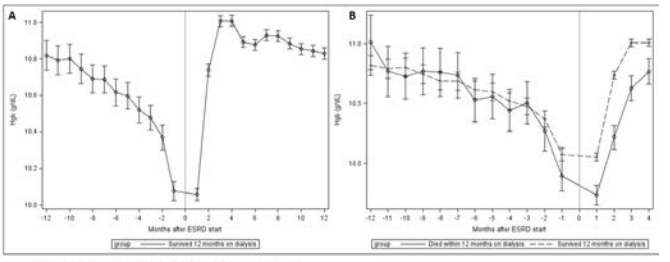

Figure 1. Error bars represent the 95% confidence intervals.

Conclusions: We found Hgb declines during the 12 months before transition from CKD to ERSD. Hgb rebounds during the incident dialysis period exceeding levels 12-months before dialysis initiation. The drop in Hgb is most pronounced in Pts who die within the first year of dialysis. Our study is limited since ESA doses prior to dialysis are not available in this dataset.

SA-PO1026

Effect of Ultrapure Dialysate on Erythropoietin Response in Hemodialysis Patients Chai L. Low, Calantha K. Yon, Meili Chang. *Pharmacy, VA San Diego Healthcare System, San Diego, CA.*

Background: Chronic inflammation often leads to resistance to treatment with erythropoietin (EPO) in hemodialysis patients. Cytokines such as IL-6 and TNF- α are known to inhibit response to EPO. The presence of endotoxins in dialysate can induce proinflammatory cytokines. Currently, endotoxin level not exceeding 0.50 unit/ml in dialysate is recommended by AAMI. Preliminary studies have shown that ultrapure dialysate (endotoxin <0.03 unit/ml) may be associated with less resistance to EPO and decreased EPO requirement in hemodialysis patients. The aim of this study was to evaluate the effect of ultrapure dialysate on EPO response in hemodialysis patients at VASDHS.

Methods: This prospective study was conducted from Aug 1, 2015 to Mar 31, 2016. Nephros® Dual-Stage ultrafilters were installed in Oct 2015. Inclusion criteria:hemodialysis patients at least 18 years old who were clinically stable and receiving standard ESRD care at VASDHS for at least 3 months prior to enrollment. Exclusion criteria:(1)acute or chronic infection;(2)chronic inflammatory disease states;(3)bleeding disorders, or(4)newly diagnosed malignancies. Erythropoietin Resistance Index (ERI), defined as EPO dose/kg/Hemoglobin, was used to compare intra and inter individual changes in EPO response. Outcome measures were changes in CRP levels, EPO dose, and ERI. Repeated measures ANOVA and Wilcoxon signed rank test were used for statistical analysis.

Results: 39 patients included in data analysis. There were 38 males and 1 female, mean age 65.6±9.01, and average duration on hemodialysis 5.4±3.8 years.

N=39	Baseline	With Ultrafilters	P
CRP (mg/L)	1.57 ± 2.56	1.68 ± 2.05	0.67
Weekly Epo dose (unit)	7778	7789	0.84
ERI	10.17 ± 8.48	10.54 ± 10.28	0.55
Endotoxin (unit/ml)	<0.01	<0.01	NA
Hemoglobin (g/dl)	10.30 ± 0.71	10.47 ± 0.11	0.42
Ferritin (ng/ml)	588.41 ± 242.19	593.18 ± 180.49	0.90
TSAT (%)	24.46 ± 8.93	25.31± 9.52	0.69

Conclusions: There were no statistically significant differences in all outcome measures after the installation of ultrafilters. At baseline endotoxin of 0.01 unit/ml, lowering endotoxin levels further does not affect EPO responsiveness in our hemodialysis patients.

SA-PO1027

Impact of Dialysis Adherence on Anemia Management Vibha S. Nayak, Kausar Hamiduzzaman, Adam E. Gaweda, Michael E. Brier. *Nephrology and Hypertension, Univ of Louisville, Louisville, KY.*

Background: The impact of patient dialysis adherence on anemia management has not been evaluated recently. We tested the hypothesis that nonadherence to dialysis treatment results in a significant decrease in hemoglobin achieved.

Methods: Data were retrospectively collected from the University of Louisville dialysis facility for the years 2004 to 2015. Patient adherence was noted in the EMR. Data were cleaned to remove duplicate records and treatments were marked as complete if

erythropoietin and/or iron was administered. 516 patients data were used for the analysis with a minimum of 90 schedule treatments during the calendar year. The following information was calculated: percentage of completed treatments, total ESA and iron administered, and the yearly mean run time, ultrafiltration, hemoglobin, T sat, and ferritin achieved. ESA and iron doses were adjusted by dry weight and reported as weekly dose. Statistical analysis was by decision tree classification technique.

Results: Results of the decision tree analysis are shown in the following table.

	Population Mean Hemoglobin 11.4 ± 1.3						
Nodes	1	2	3	4	5	6	7
ESA U/ week/kg	0	0 to 1.5	1.5 to 3.3	3.3 to 11.3	11.3 to 15.3	15.3 to 35.1	>35.1
Hb g/dl	13.1	11.5	10.9	11.0	11.2	11.4	11.0
Ferritin ng/ ml (nodes 8-18)	<523, >523			<737, 737-1149, >1149	<977, >977	<1148, >1148	<849, >849
Hb g/dl	13.6, 12.5			11.4, 10.9, 10.6	11.4, 10.8	11.6, 10.7	11.2, 10.7
% Adhearance (nodes 19-26)				(<737) 95% | (737-1149) 96% | (>1149) 95%		(<1148) 92%	
Hb g/dl				11.2, 11.6 | 10.6, 11.2 | 10.3, 10.9		11.3, 11.8	

The analysis resulted in 26 decision points (nodes), with 7 nodes related to ESA dose shown as the dose range included and mean Hb for that node. In nodes 1,4,5,6, and 7 ferritin significantly added 11 further nodes and is shown as a single break point or range with the corresponding mean Hb for that node. In nodes 4 and 6 adherence significantly added 8 additional nodes. All p values were < 0.012.

Conclusions: Adherence less than 92 to 95% resulted in significantly decreased Hb ranging from 0.4 to 0.6 mg/dl. Higher ferritin resulted in lower Hb ranging from 0.5 to 1.1 mg/dl.

Reducing Blood Volume Waste from Dialysis Central Venous Catheters (CVCs) Emily Xue,[1] Bette J. Gilmartin,[2] Virginia L. Hood.[1,2] *[1]Univ of Vermont College of Medicine, Burlington, VT; [2]Univ of Vermont Medical Center, Burlington, VT.*

Background: Anemia is a major complication of end stage renal disease. As treatment is costly and associated with risks, it is important to reduce unnecessary blood loss in this population, including during hemodialysis (HD). Under the current protocol for HD in patients with CVCs, the first 10mL of blood is discarded to "clear the line" before sampling blood for labs or connecting the patient to the HD machine, leading to a yearly blood loss of approximately 1.5L per patient. We propose a protocol to reduce the blood discarded without affecting standard laboratory measurements by comparing values in samples drawn after less blood is discarded with those using the current protocol.

Methods: Eight patients with CVCs undergoing HD gave informed consent to have two samples of blood taken from CVCs for monthly tests. The first sample (S1), experimental, was drawn after 3mL of blood per CVC lumen was discarded; the second (S2), control, was drawn after 5-7mL per lumen was discarded. Results of hemoglobin, Na, K, Cl, BUN, Ca, Phos, albumin, and CO2 from S1 and S2 samples were analyzed using paired t-tests and Bland Altman plots constructed.

Results: For each of the values measured, there was no significant difference between the experimental and control values. P-values ranged from 0.12 to 0.50. Predetermined power to detect a 1-4% difference was 95%. There was no systematic bias suggesting lower values in S1 compared with S2 that would indicate dilution in the first sample.

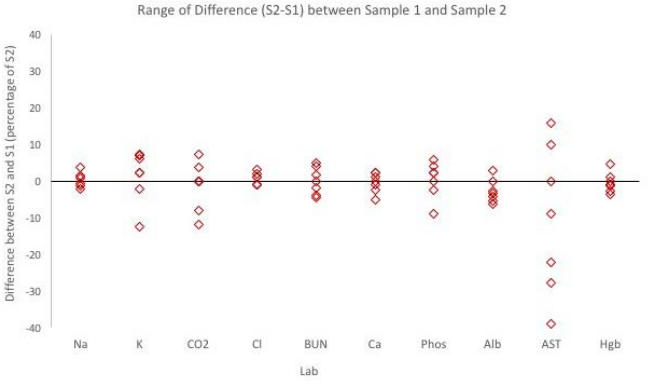

Figure 1. Plot of calculated differences between sample 2 and sample 1 for each parameter. Differences are normalized as percentage of sample 2 ([S2-S1]/S2).

Conclusions: Discarding 6 versus 10mL blood from CVCs did not change values of standard pre-dialysis blood values in any way that would affect clinical care. The proposed protocol of discarding less blood when accessing CVC lines could save at least 600mL blood/HD patient/year and may be generalizable to non-dialysis patients with CVCs.

SA-PO1029

Hemodialysis Patient Plasma Trace Metals Associate with Dialysis Incidence versus Prevalence, Gender, and Response to Erythropoiesis Stimulating Agents Michael Merchant,[1] Michael E. Brier,[1] Jessica Gooding,[2] Susan Sumner,[2] Susan Mcritchie,[2] James M. Harrington,[2] Jason P. Burgess,[2] Brad H. Rovin,[3] Jon B. Klein,[1,4] Jonathan Himmelfarb.[5] *[1]Univ of Louisville; [2]NIH Eastern Regional Comprehensive Metabolomics Resource Core at RTI International; [3]Ohio State Univ; [4]Robley Rex VAMC; [5]Univ of Washington, Seattle.*

Background: Uremic toxins can form blood metal binding protein-adducts, that are associated with mortality and response to erythropoiesis stimulating agents (ESAs). Knowledge of trace metal levels associating with hemodialysis (HD) patient response to ESA dosing might improve anemia management. We tested the hypothesis that plasma trace metal concentrations correlate with markers of anemia and response to ESA treatment.

Methods: EDTA-Plasma from 110 HD patients (77 prevalent, 33 incident) participating in the NIDDK funded study (R01-01DK091584) were analyzed by ICP-MS for the plasma concentration of As, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Sn, V, and Zn. Associations were determined between trace metals and gender, race, HD status, monthly hemoglobin (Hgb) values, total ESA dose for the month the sample was collected, erythropoietin response index (ERI), transferrin percent saturation, ferritin, iron, hepcidin and c-reactive protein (CRP).

Results: Cd(p-value<0.001)*, Sn*, Ni(p-value<0.05)**, and Mo** concentrations were significantly higher in prevalent patients, as was detection of V*. Conversely, Mn* concentrations were lower in prevalent patients. Spearman correlations of trace metals in prevalent plasma samples revealed: Cd concentrations were inversely correlated with Hgb levels, and positively correlated with EPO and ERI. Sn was positively correlated with EPO. Zn was negatively correlated with ERI. Cd** concentrations were significantly higher in females compared to males. Cu* and Se** were positively and Mo** was negatively correlated to CRP by multivariable regression. V** was negatively correlated with hepcidin.

Conclusions: Plasma trace metal concentrations associate with dialysis vintage, gender, correlate with ESA response, and may be useful in guiding HD patient specific approaches to anemia management. We hypothesize specific trace metals may play a causal role in ESA resistance.

Levocarnitine Injections Decrease the Need for Erythropoiesis Stimulating Agents in Hemodialysis Patients with Renal Anemia Seishiro Baba, Tomoyasu Otsuki, Kazuyoshi Okada, Masanori Abe. *Nephrology, Hypertension and Endocrinology, Nihon Univ School of Medicine, Tokyo, Japan.*

Background: Patients with chronic kidney disease often develop anemia, which can be treated with erythropoiesis stimulating agents (ESAs). However, there are concerns about the negative side effects of ESA treatment, including an increased risk of an adverse cardiovascular event and death. Therefore, it is desirable to minimize ESA use. Carnitine is thought to be associated with the maintenance of red blood cells, including their numbers, substrate storage capacity, membrane lipid turnover, and protein construction. In hemodialysis patients, carnitine imbalance or deficiency can result from insufficient intake, a decrease in carnitine biosynthesis, or removal of carnitine from the body during dialysis. In the study, we gave levocarnitine injection to the hemodialysis patients to evaluate its efficiency for anemia in renal disease.

Methods: We randomly assigned maintenance dialysis patients at our hospital to receive levocarnitine injections (n = 30) or no injection (n = 30), and monitored the patients during 12 months of treatment. The treatment group was injected with levocarnitine doses of 1000 mg three times each week after hemodialysis. All patients received recombinant human erythropoietin as an erythropoiesis stimulating agent (ESA). Response to ESA therapy was determined by calculating the erythropoiesis resistance index (ERI; ESA dose/kg/g/dL/week).

Results: (1) The target levels of hemoglobin and hematocrit were maintained during the period of the study in both levocarnitine group and control group. (2) The quantity of ESAs required to maintain these levels decreased gradually in levocarnitine group, and was significantly lower during study initiation than at months 6 and 12 and was also significantly lower than the levels required in the control group at these time points. (3) ESIs showed a significant decrease at months 6 and 12 in levocarnitine group, with a significant difference between the two groups at months 6 and 12.

Conclusions: The results suggest that levocarnitine can reduce the quantity of ESAs used in renal anemia patients on hemodialysis and improve the response to therapy with ESAs.

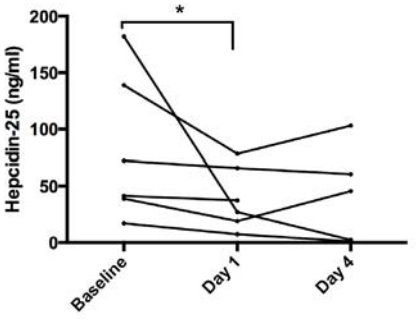
SA-PO1031

Glucocorticoids Inhibit HAMP mRNA in HEPG2 Cells and in CKD Patients with Vasculitis Adam Rumjon, Iain C. Macdougall. *Dept of Renal Medicine, King's College Hospital, London, United Kingdom.*

Background: Hepcidin is the master regulator of iron homeostasis encoded for by the *HAMP* gene, and CKD patients have increased circulating levels of the hormone. Knowledge on factors controlling its production is expanding, and previous studies showed that hepcidin is suppressed by oestrogen and testosterone. There are no data on the effect of glucocorticoids on hepcidin, and the aim of this study was to investigate the effect of steroids on *HAMP* gene expression in vitro, as well as on hepcidin levels in CKD patients with acute vasculitis.

Methods: HepG2 cells were exposed to increasing doses of dexamethasone from 1.25 to 80 ng/mL, for a period of 18 hours. HepG2 cells were pre-treated with dexamethasone (10ng/mL) or vehicle for 4 hours before the addition of 12.5 ng/ml of interleukin-6 or vehicle, for 2 hours. Total cellular RNA was extracted and reversed transcribed; quantitative rt-PCR was then performed and amplification was performed using Taqman *HAMP* and GAPDH (housekeeping) primers. Serum hepcidin-25 levels were measured using mass spectrometry in 6 patients admitted with suspected ANCA-positive vasculitis before and after the administration of 500mg IV methylprednisolone.

Results: The dexamethasone-HAMP dose-response curve showed suppression of HAMP at concentrations ≥20 ng/mL. IL-6 stimulated HepG2 cells not pre-treated with dexamethasone showed an 11-fold rise in HAMP compared to only a 7.5-fold increase in cells pre-treated with dexamethasone. Hepcidin-25 levels in all 6 patients were lower 24 hours post-administration of methylprednisolone.



Conclusions: These data suggest that the glucocorticoid dexamethasone suppresses *HAMP* expression *in vitro*, and this may be IL-6-mediated. Administration of methylprednisolone reduced levels of circulating serum hepcidin within 24 hours. The consistency of both the in vitro and human in vivo data increases confidence in the validity of this effect.

SA-PO1032

A Single Center Retrospective Review of Incident Catheter Rates in an Academic Outpatient Dialysis Unit Eric Loman, Thurein Kyaw, Brendan T. Bowman. *Nephrolgy, Univ of Virginia, Charlottesville, VA.*

Background: K/DOQI guidelines recommend an Arteriovenous Fistula (AVF) rate of 68% in prevalent End Stage Renal Disease (ESRD) patients and at least 50% in incident ESRD patients. We reviewed data of all incident ESRD patients initiating hemodialysis (HD) in a University based outpatient unit to identify factors associated with catheter starts.

Methods: We conducted a chart review of all 78 incident HD patients (Nov 2012–Aug 2015). Data included: demographics, ESRD cause, pre-dialysis nephrology care, documented episodes of AKI, eGFR drop preceding ESRD, and time to access placement referral.

Results: 65 patients (83.3%) initiated HD with a catheter versus 13 patients (16.7%) with AVF or AVG. There were no major differences in demographics or cause of ESRD between the two groups. The main factor associated with a catheter start was AKI, occurring in 62% of patients. The catheter group had a profound loss of GFR in the 12 months preceding ESRD: nearly 80% of the group experienced a GFR loss of 50% or more compared to the gradual decline in the AVF/AVG group. 73.3% of the catheter group had a CKD diagnosis at HD start, with only 61.5% seen by a Nephrologist previously. In the AVF/AVG group, all patients were followed for at least 3 years by a Nephrologist prior to HD. 83% of patients starting with an AVF/AVG were seen by a surgeon 6 months or longer before initiating HD vs 40% in the catheter group. Less than half of catheter patients changed to an AVF or AVG.

Conclusions: Previous studies have shown high incident catheter rates associated with late diagnosis of CKD, lack of pre-dialysis nephrology care, and AKI. Our study confirms this. In addition, our study demonstrates the importance of rapid loss of GFR from prior stable moderate CKD on incident catheter rates. This suggests focusing access placement in outpatients with gradual GFR loss will not prevent high incident catheter rates. Further emphasis should be also placed on inpatients with rapid GFR loss/AKI leading to ESRD; ideally during the index hospitalization.

SA-PO1033

The Associations between Vascular Access Care and Mortality Rates in Hemodialysis Patients Hao Han,[1] Marta Reviriego-Mendoza,[1] Sheetal Chaudhuri,[1] Karen G. Butler,[1] Sophia Rosen,[1] Jane Brzozowski,[1] John W. Larkin,[1] Walead Latif,[2] Elsie Koh,[2] Len A. Usvyat,[1] Gregg Miller,[2] Melvin Rosenblatt,[2] Murat Sor,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Vascular Care, Berwyn, PA.*

Background: Fresenius Vascular Care (FVC) offers outpatient vascular access (VA) care for Fresenius Medical Care North America (FMCNA) hemodialysis (HD) patients. We studied the associations in mortality rates for FVC outpatient VA care versus other VA providers that are mostly in a hospital setting or no VA care received at all.

Methods: We analyzed data from 4,691 HD patients who visited FVC at any time during calendar year 2014. Control patients were selected by 1:1 matching exactly for concurrent year of FVC care, state of residence, gender, race, and access type, as well as, nearest neighbor matching on the logit of the propensity score for age, dialysis vintage, albumin, body mass index, and Kt/v. Further analysis was performed for 4,376 FVC patients with a preexisting arteriovenous fistula or graft (AVF/AVG). Six month mortality rates per 100 patient years were compared between study groups after 1/1/2015.

Results: Data from a total of 9,382 HD patients was analyzed for this study. Compared to matched control patients, mortality rates in FVC patients were decreased by 33%($p<0.001$; Figure 1A). Similarly, in patients enrolled in FVC with a preexisting AVF/AVG showed a 28% reduction in mortality when compared to controls ($p<0.001$; Figure 1B).

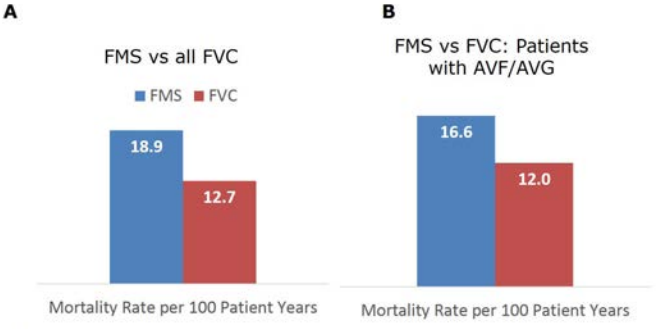


Figure 1

Conclusions: The results of this analysis suggest that outpatient VA care may have the potential to reduce mortality rates in HD patients when compared to patients receiving VA care in other settings or no care at all. Ongoing studies are warranted to determine the long term mortality outcomes associated with FVC VA care.

SA-PO1034

Analysis of 5,000 Cases of Vascular Access Interventional Therapy for Vascular Access Failure at a Single Facility – How Well Were the AVG Maintained? Teruhiko Maeba, Shigeru Owada. *Internal Medicine, Asao Kidney Clinic, Kawasaki, Kanagawa, Japan.*

Background: Sustaining a functional vascular access (VA) is one of the most important factors in the maintenance of an HD modality. The application of vascular access interventional therapy (VAIVT) for VA trouble is increasing recently but the effectiveness of VAIVT has not been entirely satisfactory because of the relatively high rate of re-stenosis.

Methods: We have experienced 5,028 cases (in 947 patients) of VA trouble treated with VAIVT over the last twelve years in which primary assisted and secondary assisted rates were analyzed.

Results: 1. We have used a noncompliant type of balloon catheter for 98.6% of cases and primary assisted patency rates were 99.2%. 2. Secondary assisted patency rates were 72.3% at two years, 64.3% at 4 years, 72.0% at 6 years, 51.0% at 8years and 47.7% at 11years in all patients. 3.In diabetic patients, assisted patency rate was 47.4% at 11years and it was 47.6% in non-diabetic patients ($p=0.82$, Log rank). There were no significant differences found between the arteriovenous fistulas (AVF) and the arteriovenous grafts (AVG) ; 49.8% and 37.0% at 11 years, respectively. 4. Failure of secondary assisted patency was observed in 517 patients. In these, a new AVF was made on the same side in 38.0% of the patients, a contralateral side AVF was made in 6.0% and an AVG in34.0%, superficialized reposition of brachial artery in 4.0% and death occurred in 18.0%.

Conclusions: The results for the initial clinical success rate and secondary assisted patency rates were excellent. It was possible to reduce the economic burden for patients by using a noncompliant type of balloon catheter. Long-term maintenance of AVG was possible by the use of VAIVT.

SA-PO1035

Outcomes of Multi-Disciplinary Interventional Nephrology Service in Singapore General Hospital Chee Yong Ng, Swee Ping Teh, Ru Yu Tan, Chieh-Suai Tan. *Renal Medicine, Singapore General Hospital, Singapore.*

Background: Singapore General Hospital (SGH) has established an interventional nephrology suite (INS) for management of vascular access issues. This is a multidisciplinary set-up comprising of interventional nephrologists (IN), interventional radiologists (IR) and vascular surgeons (VS).

Methods: This study reports the outcome of thrombolysis / thrombectomy of haemodialysis access performed in INS from 1st March 2015 to 29th February 2016.

Results: A total of 198 patients with thrombosed access had interventions done in INS during this period. Of these, 104(52.5%) were arteriovenous fistula (AVF). Mean age of study subject was 63.5±11.9, predominantly Chinese (62.6%), and of male gender (51%). Majority of patient in this study develop End Stage Renal Disease(ESRD) from diabetes mellitus (58.6%). Procedures performed by IN, IR and VS were 38.9%, 51.6% and 9.5% respectively. 96.5% of patient had reestablishment of flow in the vascular access radiologically, while 94.9% had successful haemodialysis post procedure. There was no significant difference in baseline characteristics among patients who underwent procedure done by the 3 groups of proceduralist. Radiological success rate of procedures done by IN, IR and VS were 98.7%, 94.1% and 100% (p=0.176) and clinical success rate was 98.7%, 92.2%, 94.7% (p=0.141) respectively. Complications occurred in 4.5% of patients but there's no significant difference in complications rate among the 3 groups of proceduralist. 3 months patency recorded for intervention done by IN were 40.3%, IR 33.5% and VS 26.3% respectively (p=0.433).

Conclusions: There was no statistically significant difference in the radiological and clinical success rate of interventional nephrologists, interventional radiologists and vascular surgeons. The centre's 3 month primary patency after percutaneous thrombectomy and clinical success rate of intervention for AVGs are in keeping with NKF KDOQI guideline standards of 40% and 85% respectively.

SA-PO1036

Vascular Access (VA) Triage and Clinical Events in Haemodialysis (HD) Sandro Mazzaferro,[1] Maria Luisa Muci,[2] Lida Tartaglione,[1] Luciano Carbone,[2] Silverio Rotondi.[2] *[1]Scienze Cardiovascolari, Respiratorie, Nefrologiche, Anestesiologiche e Geriatriche, Sapienza Univ, Rome, Italy; [2]Nephrology and Dialysis Unit, ICOT Hospital, Latina, Italy.*

Background: VA type (AVF vs CVC) affects morbidity and mortality in HD, but its performance is not routinely evaluated. We developed a system of VA triage representative of its monthly performance. We report here on the relationship between this VA triage and clinical events.

Methods: Nurses report each session data (weights, BP, HR, Blood flows, VA pressures, symptoms, clots and KT/V) on a data sheet. Pathologic values generate a score that, with empiric thresholds, flags the VA green, yellow or red. We retrieved clinical events (admissions and deaths) of those patients whose VA had been triaged for >3 months between 1/1/2014 and 12/31/2015. For each patient we considered the average triage of the available follow-up, separately for different VA types.

Results: 111 patients (62 AVF and 49 CVC), followed for 18±7 months, experienced 12 deaths and 170 hospital admissions which lasted 16±26 days. Prevalence of events was greater in CVC as compared to AVF patients (75% vs 51%,p<.02). Based on average triage, patients were separated into groups that resulted different for prevalence of events (36, 68 and 100% in the green, yellow and red groups respectively; p<0.001), but not for age, dialysis duration or diabetes. This difference was confirmed in the subgroup with AVF (30, 62 and 100% respectively, p<0.01) but not in patients with CVC.

Triage		Green	Yellow	Red	p<
Case,n°		50	57	4

	CVC only, n°(%)	19 (70%)	16 (80%)	2 (100%)	n.s.
Events= admission/deaths. Data are mean±SD;(^) ANOVA;(*)X^2					

Conclusions: We confirm the role of VA type as a risk factor for events and suggest that a triage system evaluating the performance of each type of VA could represent, in particular for AVF, a useful sensor of increased clinical risk.

Twelve-Month Patency Rate after a First PTA for Failed Arteriovenous Fistula: Comparison between Low- and High-Pressure Balloon Dilation (YOROI Study) Koki Wakamoto, Kensuke Sasaki, Toshinori Ueno, Ayumu Nakashima, Shigehiro Doi, Takao Masaki. *Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Low-pressure balloon dilation for failed hemodialysis fistulas has recently exhibited a better patency rate in comparison with conventional strategy in achieving complete balloon expansion, even in patients with residual stenosis. In this study, we investigate the 12-month patency rates for low- and high-pressure dilation in patients who underwent their first percutaneous transluminal angioplasty (PTA) for failed arteriovenous fistula.

Methods: This study was a multicenter, prospective, randomized, two-comparison, non-inferiority trial. The YOROI balloon (Kaneka Medics, Osaka, Japan), with a diameter of 4 mm, was used for dilation of stenotic lesions. Balloons were inflated to a pressure of 8 atm (low-pressure group), or to a pressure of up to 30 atm to achieve complete expansion (high-pressure group). The 12-month patency rate after balloon angioplasty was analyzed by Kaplan–Meier analysis and a log-rank test. We also investigated the incidence of complications.

Results: A total of 71 patients who received their first PTA were enrolled. One patient in the low-pressure group dropped out due to peripheral ischemia after PTA, and one patient in the high-pressure group died during the observation period. 12-month patency rates did not show a significant difference between the low- and high-pressure groups. In addition, the patency rate of the group with incomplete expansion was not significantly lower than that of the group with full balloon expansion.

Conclusions: Full expansion of the balloon using high pressure was highly probable. However, with no significant difference noted in the 12-month patency rate, our results suggest that complete balloon expansion does not affect patency rates.

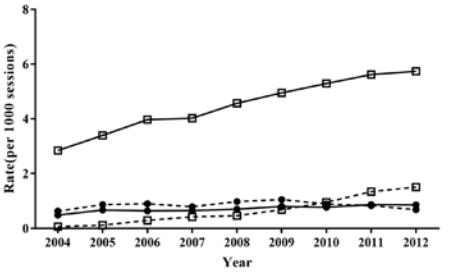
SA-PO1038

Hemodialysis Center of Frequent Percutaneous Transluminal Angioplasty Use Is Not Associated with Fewer Vascular Access Recreation-A Nationwide Population Study at Taiwan Yiwen Chiu, Feng-Xuan Jian, Ming-Yen Lin, Shang-Jyh Hwang. *Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Kaohsiung, NA, Taiwan.*

Background: The percutaneous transluminal angioplasty (PTA) frequency increased dramatically but its effect on vascular access (VA) recreation was not so clear.

Methods: Prevalent patients under maintenance hemodialysis (HD) at Taiwan from 2004 to 2012 were included. The demographics, baseline clinical characteristics, number of PTA and VA recreation for each patient were collected. The mean/media/portion/frequency which appropriate for all the variables above was assigned annually to each center as its characteristics. Generalized estimating equation was used to test the association between center's PTA frequency and VA recreation rate.

Results: Total 81,225 patients were included (mean age 61.8(±13.9) y/o, male 50 %, DM 49 %, mean HD vintage 5.2(±3.9) y) as well as 820 HD centers. PTA frequency increased by 3 times from 1.10 at 2004 to 3.57 at 2012 (per 1000 HD sessions) and VA recreation rate were kept around 0.80 (per 1000 HD sessions). Compared with the HD centers of infrequent use of PTA (annual lowest quartile, range: 0-2.19 per 1000 HD sessions), the ones of frequent use (annual highest quartile, range: 2.12-29.41 per 1000 HD sessions) didn't have lower VA recreation.



PTA (●) and VA recreation (□) rate at centers of frequent (—, highest quartile of PTA rate) and infrequent (---, lowest quartile of PTA rate) PTA use.

The independent predictors for HD center of lower VA recreation rate were those with more female, at earlier time cohort, fewer myocardial infarction history history, shorter HD vintage, and lower mortality (all p<0.05), but not frequent PTA use (p=0.37).

Conclusions: Frequent use of PTA seems not improve VA patency at center level for no significant association identified with lower VA recreation. The indication of PTA in daily practice should be re-evaluated with regard to its efficiency in term of lowering VA recreation.

SA-PO1039

Diagnostic Accuracy of Computed Tomography Angiography and Magnetic Resonance Angiography in the Detection of Hemodialysis Arteriovenous Fistula Dysfunction: A Meta Analysis

Weiying Li, Yuliang Zhao, Ping Fu. *Div of Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: We sought to evaluate the diagnostic accuracy of computed tomography angiography (CTA) and magnetic resonance angiography (MRA) compared with invasive digital subtraction angiography (DSA) or surgery for the detection of ateriovenous fistula dysfunction in hemodialysis patients.

Methods: PUBMED, MEDLINE, Cochrane library, and EMBASE searches were performed until May 31th, 2016 for potential related articles. Inclusion criteria were 1) at least one of the following diagnostic methods: CTA or MRA were included as a diagnostic test for hemodialysis AVF; (2) >50% diameter stenosis or occlusion selected as the cut-off criteria; (3) DSA or surgery as the standard of reference; (4) absolute numbers of true positive, false positive, true negative, and false negative results could be derived. Standard meta-analyses were applied.

Results: Seven studies reported the diagnostic accuracy for detection of AVF malfunction by CTA. They indicated a pooled sensitivity of 95% (90% to 97%), specificity of 96% (93% to 97%), positive likelihood ratio of 17.01 (11.40 to 25.36) and negative likelihood ratio of 0.09 (0.04 to 0.19) with a sDOR of 207.32 (97.85 to 473.12) and AUC of 0.9810. Seven studies reported the diagnostic accuracy for detection of AVF dysfunction by MRA. The pooled sensitivity, specificity, positive likelihood ratio, negative likelihood ratio, sDOR and AUC of were 97% (93% to 99%), 98% (96% to 99%), 27.21 (14.68 to 50.43), 0.05 (0.03 to 0.09), 788.21 (350.38 to 1773.15) and 0.9865 respectively.

Dynamic Access Pressure Surveillance Predicts Venous Needle Dislodgment

Stanley Frinak,[1] Jerry Yee,[1] Anatole Besarab,[2] Gerard Zasuwa.[1] *[1]Nephrology, Henry Ford Hospital, Detroit, MI; [2]Nephrology, Stanford Univ, Palo Alto, CA.*

Background: Venous needle dislodgment (VND) incidents may be as high as 200/day with 2 serious adverse outcomes/day. Venous pressure (VP) measured during dialysis is variable > 130 mmHg. Recent data showed 56% of fistulas (AVF) and 6% of grafts had intraccess pressures (AP) ≤ 30 mmHg; 39% of AVF had AP ≤ 20 mmHg. Therefore, the current alarm threshold (T) for VND must be lower T"VP – (20 to 30 mmHg) yet not produce excessive false alarms. Low AP could place patients at greater risk for VND. We evaluated a Dynamic access pressure surveillance (DAPS) algorithm which continuously monitors AP for used as a more sensitive detection device for VND.

Methods: A Fresenius 2008 K dialysis machine (DM) was tested. A DAPS alarm for VND was implemented using LabVIEW software from National Instruments . VP data was obtained using an A to D converter connected to the analog output of the VP module, TX data was read every 2 sec from the DM serial port. A sham dialysis circuit with an artificial access site, QB = 800 ml/min and AP variable 40 to 0 mmHg was used for testing. DAPS alarm threshold was AP < 5 mmHg and the DM asymmetric VP limit was 25 mmHg. Circuit was filled with blood, QB=400 and the height of a 1L blood reservoir was adjusted to set the AP to 40mmHg. Reservoir height was decreased to set AP = 0 mmHg and alarms recorded. Procedure was repeated for QB=400 and 300. AP values of 30, 20, 15 and 10 were also tested for all QB values.

Results: Figure shows the results of the study. The DM alarm was only activated when the AP was decreased from 40 to 0 mmHg. In contrast, DAPS alarm was consistently positive even down to AP of 10 mm Hg. Tests repeated at QB=500 showed variable results for the DM alarm. In total 75% of studies produced no DM alarm.

Conclusions: The DAPS alarm implemented in a DM could be used for a more sensitive alarm system to detect VND.

An Increase in Mean Platelet Volume/Platelet Count Ratio Is Associated with Vascular Access Failure in Hemodialysis Patients Dong Ho Shin, Eunjung Kim, Jung-Woo Noh, Ja-Ryong Koo. *Hallym Univ College of Medicine.*

Background: After stenosis of arteriovenous vascular access in hemodialysis patients, platelets play a crucial role in subsequent thrombus formation, leading to access failure. In a previous study, the mean platelet volume (MPV)/platelet count ratio, but not MPV alone, was shown to be an independent predictor of 4-year mortality after myocardial infarction. However, little is known about the potential influence of MPV/platelet count ratio on vascular access patency in hemodialysis patients.

Methods: A total of 143 patients undergoing routine hemodialysis were recruited between January 2013 and February 2016. Vascular access failure (VAF) was defined as thrombosis caused by stenosis after having undergone thrombectomy, or as greater than 50% stenosis on angiography requiring either surgical revision or percutaneous transluminal angioplasty. Platelet indices, including MPV/platelet count ratio and their changes were compared in patients with and without VAF by using linear mixed model analysis. Additionally, Cox proportional hazards model analysis ascertained that the change of MPV/platelet count ratio between baseline and 3 months [Δ(MPV/platelet count ratio)$_{3mo\text{-}baseline}$] had prognostic value for VAF.

Results: Of the 143 patients, 38 (26.6%) were diagnosed with VAF. During a median follow-up of 26.9 months, Δ(MPV/platelet count ratio)$_{3mo\text{-}baseline}$ significantly increased in patients with VAF compared to that in patients without VAF [6.7 (3.1–18.9) vs. 3.9 (-0.2–9.9), $P = 0.02$]. Moreover, a liner mixed model revealed that there was a significant difference in the increased MPV/platelet count ratio over the first 3 months in patients with VAF compared to those without VAF ($P = 0.003$). In multivariate analysis, Δ(MPV/platelet ratio count)$_{3mo\text{-}baseline}$ was an independent predictor of VAF (hazard ratio, 1.04; 95% confidence interval, 1.00–1.08; $P = 0.03$).

Conclusions: An increase in MPV/platelet count ratio was an independent risk factor for VAF. Therefore, continuous monitoring of the MPV/platelet count ratio may be useful to stratify the risk of VAF in patients undergoing routine hemodialysis.

SA-PO1042

The Effect of Vascular Access Type on the Variation of Intra-Access Flow Volume during Hemodialysis Younhee Lee, Hoon Suk Park. *The Catholic Univ of Korea, Seoul, Korea.*

Background: The current surveillance protocol for vascular access (VA) recommends intraaccess flow volume (Qac) should be measured within the first one and a half hours during hemodialysis (HD) to avoid errors. Several previous studies access resistance, which may cause Qac variation, was different among VA types. Therefore, we investigated Qac variation according to VA types.

Methods: Qac was measured at 30, 120, and 240 minutes in each HD session in 144 VA for comparison. 58 VA were lower arm arteriovenous fistula (AVF), 14 were lower arm arteriovenous graft (AVG), 27 were upper arm AVF and 45 were upper arm AVG. The other Qac (%) were expressed as the percentages of Qac at 30mins (100%). The variation of Qac over time was analyzed using repeated measures ANOVA.

Results: Repeated measures ANOVA revealed that the time factor significantly affected access flow ($p < 0.001$), which decreased over time. With regard to group effect, there was significant difference among Qac (%) by VA types ($p < 0.001$). Qac (%) of lower arm AVG at 240 minutes was 75.8 ± 11.3 whereas Qac (%) of upper arm AVF at 240 minutes was 99.5 ± 7.8. There also existed a significant interaction between the effects of time and VA type ($p < 0.001$) suggesting that VA type affected Qac variation during HD. Post hoc analysis revealed Qac variation during HD was significantly different in lower arm AVG.

Conclusions: Our study suggested that Qac of lower arm AVG should be measured according to the current surveillance protocol, but Qac of the other VA types, especially upper arm AVF one, can be measured at anytime during HD.

Intimal Hyperplasia Does Not Explain Focal Stenosis in Two-Stage Arteriovenous Fistulas Marwan Tabbara,[1] Laisel Martinez,[1] Juan Camilo Duque Ballesteros,[2] Angela Paez,[1] Guillermo Selman,[1] Loay H. Salman,[3] Roberto I. Vazquez-Padron.[1] *[1]DeWitt Daughtry Family Dept of Surgery, Leonard M. Miller School of Medicine, Univ of Miami, Miami, FL; [2]Dept of Medicine, Miller School of Medicine, Univ of Miami, Miami, FL; [3]Section of Interventional Nephrology, Miller School of Medicine, Univ of Miami, Miami, FL.*

Background: Intimal hyperplasia has been historically recognized as the cause of venous stenosis. Recently, we have revealed that IH is not associated with two-stage arteriovenous fistula (AVF) maturation failure. The purpose of this study is to compare the degree of IH in stenotic and nearby non-stenotic segments collected from the same AVF.

Methods: Focal areas of stenosis were detected in the operating room in seven patients (n=7) during the second stage basilic vein transposition procedure. The entire vein was inspected prior to the transposition and the areas of stenosis were visually located with the aid of manual palpation and hemodynamic changes in the vein peripheral and central to the narrowing. Close up photography was used for documentation before tissue collection (7 tissue pairs). Intimal area, thickness and intimal to media ratio were assessed in hematoxylin and eosin stained cross-sections, followed by pairwise statistical comparisons.

Results: The intimal area in stenotic and non-stenotic segments ranged from 1.25 to 5.57 mm^2 and 0.16 to 5.30 mm^2, respectively. There was no significant difference between these two groups (p=0.8). The intimal thickness (p=0.6) and intima/media area ratio were also similar between both segments (p=0.8).

Conclusions: Although a higher number of patients are needed to confirm these findings, our results concur with our previous study and suggest that IH does not explain focal venous stenosis in two-stage brachiobasilic fistulas.

Overexpression of Cathepsins in Arteriovenous Fistula Stenosis in Maintenance Hemodialysis Patients Shang Guo Piao,[1] Jian Jin,[2] Can Li.[1] *[1]Nephrology, YanBian Univ Hospital, YanJi, JiLin, China; [2]Nephrology, The Catholic Univ of Korea, Seoul, Korea.*

Background: Increasingevidence has demonstrated that cathepsins (Cats), a family of lysosomal cysteine proteases, play a critical role in various cardiovascular diseases. However, their role and expression in arteriovenous fistula (AVF) dysfunction are undetermined. The present study was undertaken to examine the expression of Cats and extracellular matrix (ECM) components in maintenance hemodialysis patients with AVF stenosis.

Methods: A total of 38 maintenance hemodialysis patients in YanBian University Hospital were enrolled. Of these, 18 subjects with AVF occlusion or severe stenosis served as AVF stenosis group, and 20 subjects with end-stage renal disease served as control group. Tissue samples were obtained from vein segments undergoing surgical AVF repair or creation. Basic parameters, histopathology, oxidative stress (MnSOD), and expression of Cats (K and S) and ECM components (PIA-1, TIMP-1, and βig-h3) were examined by immunohistochemistry and immunoblotting. In addition, the pearson-single-correlation coefficient analysis were used to compare Cats expressions withβig-h3 and MnSOD expression.

Results: Compared with the control group, serum CatK and CatS levels were increased in the AVF stenosis group. These increases in serum Cats levels were accompanied by upregulation of CatK and CatS protein expressions in the intima and medial layers of vein segments by approximately of 3-folds and 2.5-folds. In parallel, expression of TIMP, PAI-1 and βig-h3 was significantly increased in the AVF stenosis group compared with the AVF control group. Immunoblotting of oxidative stress biomarker revealed that MnSOD protein expression was enhanced in the AVF stenosis group. The upregulation of Cats expression was positively correlated with βig-h3 and MnSOD ($r=0.69$, $r=0.57$; $r=0.61$; $P<0.01$).

Conclusions: Our observations indicate that an increase in Cats expression, along with ECM components upregulation, is closely associated with AVF stenosis in maintenance hemodialysis patients.

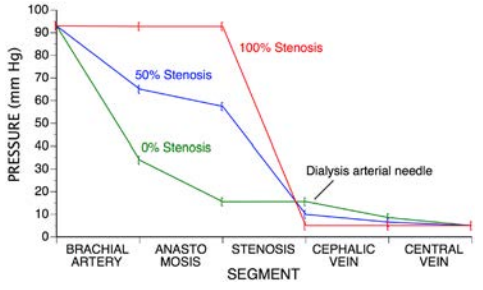
Stenosis at Arteriovenous Anastomosis of Fistula: A Challenge for Dialysis Pressure Surveillance William D. Paulson,[1] Kim Hirschman,[2] Sulav Bastola,[3] John Jason White,[1] Steven A. Jones.[4] *[1]Medicine, Augusta Univ, Augusta, GA; [2]Vasc-Alert LLC, Lafayette, IN; [3]Charu Polyclinic and Diagnostic Center, Kathmandu, Nepal; [4]Biomedical Engineering, Louisiana Tech Univ, Ruston, LA.*

Background: Dialysis pressure surveillance is widely recommended for detection of stenosis in vascular accesses. However, the native fistula (AVF) is problematic in that dialysis needles are downstream to the arteriovenous (AV) anastomosis, where stenosis often develops. We used a mathematical model of the brachiocephalic AVF and clinical dialysis arterial pressures to determine the limitations in detecting AV anastomosis stenosis.

Methods: The model used engineering equations to determine influence of stenosis at the AV anastomosis on dialysis arterial pressure. The model included cephalic V. anastomosed end to side to brachial A., radial & ulnar A., palmar arch, and vein that drains the hand and connects to cephalic V. Mean arterial pressure = 93 mmHg, central venous pressure = 5 mmHg. Luminal diameter of inflow artery was less than outflow vein (0.6 vs. 0.8 cm). We used data from 49 patients with trouble-free AVFs in the Vasc-Alert on-line surveillance program to determine variability of arterial needle pressures with blood pump running.

Results: Model predicts AVF pressures at stenosis = 0%, 50%, 100% are 15.7, 10.0, 5.0 mmHg, respectively. Thus, stenosis causes only small pressure changes. The SD for differences in pressure between 2 measurements with similar blood pump speed = 14.1 mmHg, so that change in pressure must be >28.3 mmHg to be significant at P <0.05.



Conclusions: Stenosis at the AV anastomosis causes a decrease in pressure that may be too small to detect when the dialysis pump is running. Static pressure measurements or on-line surveillance programs that apply trend analysis and adjust for the effect of blood pump speed on pressure may compensate for this problem.

Treatment of Arteriovenous Fistula Complications Using Far Infrared Therapy: Cambridge Experience Regin Lagaac,[1] Nicholas Pritchard.[2] *[1]Renal Medicine, Cambridge Univ Hospitals NHS FT, Cambridge, United Kingdom; [2]Renal Medicine, Cambridge Univ Hospitals NHS FT, Cambridge, United Kingdom.*

Background: It is vital that Arterio Venous Fistulas (AVF) will continue to function efficiently. Complications of AVF includes pain of the AVF site, bruises and infiltration, underdeveloped AVF with weak thrill and bruit due to small calibre of veins, calcified arteries with reduced blood flow leading to thrombosis. There are limited treatment options for patients presenting with these problems. Increasing evidence shows that far infrared radiation has beneficial effects on tissue healing and endothelial function, this has led to its use in the treatment of skin necrosis and wound healing. The application of Far Infrared therapy to AVFs in HD patients has been studied as a way to improve fistula blood flow, thereby reducing complications of fistula thrombosis and improving dialysis clearance and adequacy.

Methods: A protocol has been developed by the Cambridge renal team to decide which patient will undergo the FIR treatment: It should be used for patients with the following characteristics: just undergone AVF surgery, with a maturing AVF, with steal syndrome, with low access blood flow, showing early signs of stenosis, and AVF bruises due to infiltration from previous cannulation. FIR therapy is a 40 minutes applications during each haemodialysis session for 4 to 6 weeks. Discontinuation of the treatment based on clinical discretion.

Results: 22 patients received FIR therapy. In summary, 6 patients had an improvement of pain score on needling of AVF, 14 patients AVF needle-site haematomas resolved quicker and 2 AVFs matured with demonstrably better blood flow rates on doppler.

	Number of patients
Improvement of AVF pain score	6
Haematomas resolved quicker	14
Better blood flow rates	2

Conclusions: We have found FIR therapy to be of use in the maturation of AVFs, particularly in patients with challenging access, as well as in the treatment of problems such as haematoma formation and those experiencing AVF pain during HD. It is a safe and effective treatment modality that has been shown to reduce complications and improve the efficiency of AVFs through its direct anti-inflammatory properties.

SA-PO1047

Statin Treatment Improves Vascular Access Outcome among Diabetic Hemodialysis Patients Manabu Kanda, Satoru Sanada, Yasunori Miyasaka, Atsuhiro Kanno, Kozo Sato, Mitsuhiro Sato, Yoshio Taguma, Toshinobu Sato. *Dept of Nephrology, Japan Community Health Care Organization Sendai Hospital, Sendai, Miyagi, Japan.*

Background: An effective therapeutic approach to reduce the risk of hemodialysis vascular access dysfunction is still unclear despite previous studies. Prior research has shown conflicting results of statin treatment probably because the pathogenesis of vascular access dysfunction is multifactorial and some confounding factors such as underlying causes of end-stage kidney diseases or type of vascular access could influence the results. In this study, we focused on diabetic hemodialysis patients and evaluated the impact of statin treatment on vascular access patency.

Methods: A retrospective cohort study of 243 consecutive patients who newly started hemodialysis due to diabetic nephropathy between January 2011 and December 2013 at Japan Community Health Care Organization Sendai Hospital was performed and the patients were followed for two years. The primary outcome was vascular access dysfunction. Effect of statin treatment was examined using Kaplan Meier analysis and Cox proportional hazard, after adjusting for covariates.

Results: The mean follow-up period was 426.7 days, and 131 (53.9%) patients developed vascular access dysfunction. Vascular access survival was significantly longer among statin users (547.9±29.9 versus 430.6±21.2 days, log-rank: P =0.008). The two-year patency rate was 58.7% among statin users and 38.6% in non-users. In multivariable analysis, statin treatment is significantly associated with better vascular access outcomes, in which the hazard ratio was 0.73 (95%CI, 0.54 to 0.97; P=0.03) in the unadjusted model and 0.63 (95%CI, 0.46 to 0.87; P =0.004) after adjustment for covariates.

Conclusions: The present study provided better vascular access outcomes among statin users in diabetic hemodialysis patients, which was only performed with diabetic hemodialysis patients. Native radiocephalic arteriovenous fistula was mainly used as a vascular access. This could account for the difference between our results and those of previous studies.

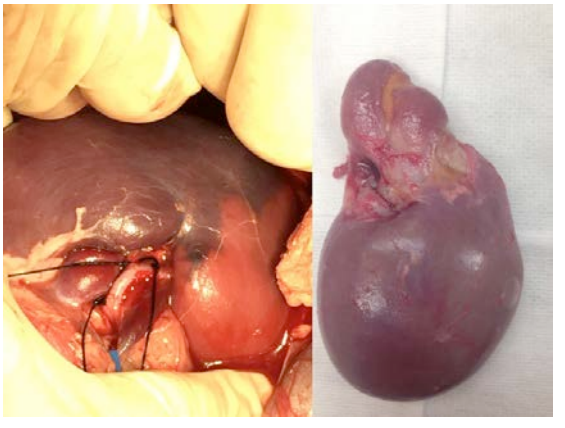
SA-PO1048

Creation of a Pig Model of Chronic Renal Insufficiency Diego Celdran-Bonafonte,[1] Begoña Campos,[2] Aous Jarrouj,[1] Sanjay Misra,[3] Matthew Kurian,[2] Sukit Raksasuk,[1] Prabir Roy-Chaudhury.[1] *[1]Univ of Arizona; [2]Univ of Cincinnati; [3]Mayo Clinic.*

Background: Uremia is an important contributor to the huge increase in the incidence of cardiovascular morbidity and mortality in CKD and ESRD patients; as a result of inflammation, oxidative stress and endothelial dysfunction. Despite this, we do not at the present time, have a reliable large animal model that replicates the uremic milieu. The objective of the current study was to develop a pig model of uremia with a GFR between 15-30 ml/min.

Methods: 4 Yorkshire pigs were used in this study. Renal insufficiency was induced through a total nephrectomy of the right kidney followed by selective ligation of the vascular supply of the contralateral kidney under direct vision. 2 animals were left with 15% remnant renal mass (caudal pole of the left kidney was left perfused), while the other two animals were left with 7% remnant renal mass (ventral aspect of the mid hilum was left perfused). Blood samples were collected sequentially over a 42 day period for BUN and creatinine. Samples were stored for future measurement of inflammatory markers and also for genomic, proteomic and metabolic analyses.

Results: Animals with 15% of remnant renal mass (left panel in Figure 1) had an initial increase in the creatinine to 4-5mg/dL followed by a stabilization at 1-2mg/dL by 2 weeks. In contrast, animals with only 7% of remnant renal mass had an initial increase in creatinine to greater than 8mg/dL followed by a stabilization between 3-4 mg/dL by 2 weeks. A macroscopic post mortem evaluation of the animal with the caudal pole left unligated demonstrated significant hypertrophy of this region with ischemic necrosis of the upper pole (right panel in Figure 1).



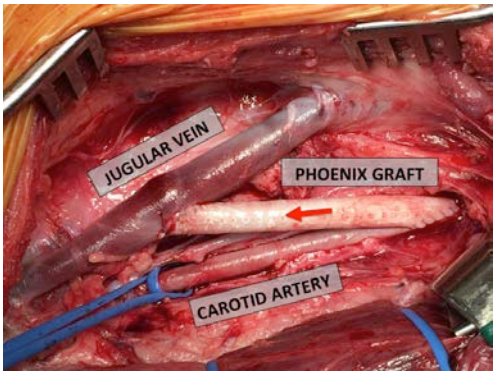
Conclusions: Our data describe the development of a reproducible large animal model of uremia (7% remnant renal mass) that could be used for mechanistic and therapeutic investigation.

SA-PO1049

Cellular Integration and Early Cannulation Potential in a Bioengineered Arteriovenous Vascular Access (Phoenix) Diego Celdran-Bonafonte,[1] Chelsea Elizabeth Stowell,[3] Begoña Campos,[2] Aous Jarrouj,[1] Sukit Raksasuk,[1] Peter L. Jernigan,[2] Yadong Wang,[3] Prabir Roy-Chaudhury.[1] *[1]Univ of Arizona; [2]Univ of Cincinnati; [3]Mayo Clinic.*

Background: Hemodialysis vascular access dysfunction continues to be the Achilles heel of hemodialysis. The objective of our study was to develop a bioengineered scaffold (the Phoenix), which when placed *in-situ* would allow for both early cannulation *and* rapid cellular integration.

Methods: Porous vascular graft cores were electrospun from a blend of polyglycerol sebacate (PGS) prepolymer and polyvinyl alcohol (PVA). Cores were reinforced with polycaprolactone (PCL) and a non-porous synthetic sealant layer. Phoenix grafts of varying sizes were surgically placed between the carotid artery and jugular vein in four Yorkshire Cross pigs.



Results: Reinforcement significantly improved structural tensile strength and suture retention load. Ultrasound examination documented flow and patency until sacrifice at 2 weeks. Movat staining revealed an active cellular repopulation of the scaffold (progressing radially outward from the lumen upto 2/3 of the wall thickness) with muscle cells and ECM deposition. Endothelial (CD31 positive), and possible intimal and medial layers were identified. No such repopulation was evident in a contralateral PTFE graft. Successful cannulation of the Phoenix was performed *in-vivo,* and *ex-vivo* attempts at cannulation revealed rapid closure of the needle site.

Conclusions: Our results indicate that the Phoenix appears to combine the autogenous benefits (note active host cell repopulation of the scaffold) of an AVF, with the early cannulation benefits (downstream reduction of catheter complications) of an AVG. Patency studies are currently in progress but these initial data suggest that the Phoenix could significantly reduce the morbidity and mortality currently associated with dialysis vascular access dysfunction.

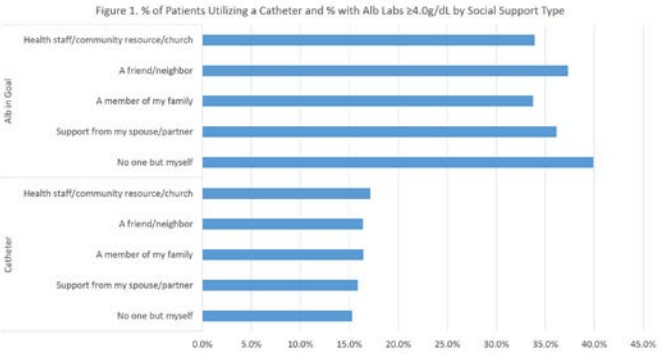
SA-PO1050

Impact of Social Support Types on Nutritional Status and Catheter Utilization in Hemodialysis Patients John W. Larkin, Yue Jiao, Marta Reviriego-Mendoza, Dugan Maddux, Joy R. Lutz-Mizar, Stephanie Johnstone, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America.*

Background: The associations between outcomes and the type of social support dialysis patients (Pts) receive from family, friends, or caregivers have not been widely studied. We aimed to investigate whether social support types in hemodialysis (HD) Pts are associated with nutritional status. Also, we studied catheter utilization, since it was hypothesized that stronger family support may help patients have a permanent access placed.

Methods: We analyzed data from Jan 2014 to Dec 2015 on 168,688 Pts at Fresenius Medical Care North America who completed a social work questionnaire. We captured responses to the question "when you have a big problem, can you usually rely on?", which has choices for support types of: "no one but myself", "support from my spouse/partner", "a member of my family", "a friend/neighbor", or "health staff/community resource/church". We compared support types to the proportion (%) of Pts achieving mean albumin (Alb)≥4.0g/dL and the % of Pts with a catheter during the 6 month period prior to completing the questionnaire.

Results: We observed that Pts who received social support from no-one or a friend/neighbor were found to have a higher % of Pts with an Alb ≥4.0g/dL, as compared to others. Those who received support from no-one had the lowest % of Pts with a catheter (Figure 1).



Conclusions: The findings indicate the social support type that Pts receive may have a small impact on their nutritional status and use of catheters. Although we found that support from no-one was associated with the most Pts meeting Alb≥4.0g/dL and least Pts utilizing catheters, these observations could potentially be representing a healthier or younger sub-population. Further analyses are needed controlling for differences in demographic and clinical parameters.

Epidemiology of Dialysis Catheter-Associated Bloodstream Infections in an Emergent Dialysis Cohort Hal Zhang,[3] Maulin Shah,[1] Nicolas Cortes-Penfield,[2] Jingbo Niu,[1] Eric Wu,[3] Roya Zamani,[3] Daniel Chen,[3] Sreedhar A. Mandayam.[1] *[1]Nephrology, Baylor College of Medicine, Houston, TX; [2]Infectious Disease, Baylor College of Medicine, Houston, TX; [3]Internal Medicine, Baylor College of Medicine, Houston, TX.*

Background: Dialysis catheter-related bloodstream infections (CRBSIs) cause significant morbidity and mortality in end-stage renal disease (ESRD) patients. Harris Health in Houston provides dialysis to hundreds of undocumented immigrants on an emergent basis and is often unable to support fistulas, leaving these patients chronically dependent on tunneled dialysis catheters. The epidemiology of CRBSI in this population has not been described until now.

Methods: We performed a retrospective chart review of all ESRD patients who receive hemodialysis solely on an emergent basis through Harris Health System in Houston, Texas between 1/1/2012 and 12/31/2015. We recorded patient demographics, comorbidities, and all CRBSIs that occurred during the study period. We defined CRBSI as a positive blood or catheter tip culture and treated as catheter-related infection by the treatment team. We assessed the association between potential risk factors and the number of CRBSIs using negative binomial regression. The magnitude of the association for risk factors significantly related to CRBSIs in the crude model were assessed in a multivariate model adjusting for each other.

Results: Of the total 342 ESRD patients, 78 patients had 120 CRBSIs. The infection rate was about 1/1000 catheter days. 23 patients had multiple CRBSIs and there were 17 recurrent infections (recurrence rate 16.5%). The risk of CRBSIs was 1.7 (95% CI: 0.7, 3.9), 2.8 (95% CI: 1.2, 6.4), 1.8 (95% CI: 0.7, 4.7) and 0.5 (95% CI: 0.2, 1.7) among patients with age 40-49, 50-59, 60-69 and 70 years older compared with patients younger than 40 years. Patients with hemodialysis frequency≥6 sessions per month had 2.3 (95% CI: 1.0, 5.6) times higher risk of CRBSI than those with frequency≤3.

Conclusions: In our cohort of emergent HD patients, CRBSI was less frequent than the CDC national average and is more frequent in the 50-59 age group and in patients receiving more frequent dialysis.

SA-PO1052

Hemodialysis Infection Prevention Using Polysporin Ointment with Shower Technique in Satellite Centres (HIPPO-SAT): A Pilot Randomized Control Trial Sarah Daisy Kosa,[1,2] Amiram Gafni,[2] Gabrielle Ene,[1] Andrew A. House,[3] Julieann L. Lawrence,[3] Louise M. Moist,[3] Paul Y. Tam,[5] Lehana Thabane,[2] George G. Wu,[6] Charmaine E. Lok.[1,2] *[1]Toronto General Hospital; [2]McMaster Univ; [3]London Health Sciences Centre; [4]Mackenzie Health Hospital; [5]The Scarborough Hospital, Scarborough, ON, Canada; [6]Credit Valley Hospital.*

Background: We developed the Toronto Hemodialysis Catheter Shower Technique protocol (STP) to permit HD patients with catheters to shower without increase infection risk. The study objective was to determine the feasibility of conducting a definitive parallel randomized controlled trial (RCT) called HIPPO-SAT that will evaluate the impact of STP on catheter-related bacteremia (CRB) in adult satellite HD patients.

Methods: Adult HD patients using catheters were recruited from 3 in-centre and 8 satellite HD units, randomized to receive STP or standard care, and followed for 6 months (Registration:NCT02002169). The primary outcome of study feasibility was based on 5 outcome measures, each with its own statistical threshold for success (threshold), of which 4 must be achieved for HIPPO-SAT to be deemed feasible. Secondary exploratory outcomes included CRB rates and patient-reported satisfaction with their vascular access care.

Results: 68 patients were randomized (33 in STP group) and 4/5 feasibility measures of feasibility were achieved: 1) accurate CRB rate documented (threshold: kappa level

>0.80), 2) 97.8% (279/285) of satellite patients with catheters screened (threshold: >95%), 3) 88% (23/26) in the STP arm successfully educated by 6 months (threshold: >80%), and 4) 0% (0/29) patients in the control arm using STP (threshold: <5%). However, only 44.2% (72/163) of eligible patient consented to participate (threshold: >80%). The rate of CRB was similarly excellent in STP and control groups (0.68 vs. 0.88/1000 CVC-days), and patients showed high levels of satisfaction in both groups.

Conclusions: This HIPPO SAT pilot study demonstrated feasibility of the larger HIPPO SAT study, especially due to the high levels of education success with the STP arm, and low levels of STP use in the control arm.

Prevention of Hemodialysis Catheter-Associated Bloodstream Infection: A Single Center Experience Yo Komatsuzaki, Izumi Yamamoto, Mayuko Kawabe, Ai Katsuma, Yasuyuki Nakada, Taketo Uchiyama, Yukio Maruyama, Yudo Tanno, Ichiro Ohkido, Nobuo Tsuboi, Keitaro Yokoyama, Takashi Yokoo, Nanae Matsuo. *Dept of Internal Medicine, Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Central-line-associated bloodstream infection (CLABSI) is a dangerous health care-associated infection that increases hospital costs and length of stay. Several reports have shown that using a multidisciplinary team and "prevention bundles(PB)" approach, which includes staff education, hand hygiene, the use of maximum sterile barrier precautions, the use of chlorhexidine gluconate (CHG), and catheter checklists, has markedly reduced the infection rate. However, there are limited data on CLABSI in dialysis access. This study investigated the efficacy of PB in patients using dialysis access in our dialysis center.

Methods: We retrospectively evaluated the incidence of CLABSI before (October 2012 to March 2013) and after (April 2013 to April 2015) the intervention PB were adopted for patients with dialysis access using the formulae of the Dialysis-related Infections Surveillance Research Consortium (DRISRC) in Japan: [infection cases/dialysis session×1000]. The PB included hand hygiene, maximum sterile barrier precautions, the use of 1% CHG, avoiding the femoral vein, and checklists for dialysis access. The checklist for dialysis access included the date and place of insertion, type of catheter (short- or long-term), reason for insertion and withdrawal, and appearance of the insertion site. We then checked the compliance status and obtained feedback from staff members.

Results: Overall, four patients developed CLABSI in the 6 months before adopting the PB versus only two cases per year after the intervention. The incidence of CLABSI in dialysis access before intervention was 6.97 (4/575×1000), which was comparable with the value of 6.96 from DRISRC in Japan. After the intervention, the incidence decreased to 3.19 (2/626×1000), 2.52 (2/793×1000), and 3.3 (2/606×1000) in 2013, 2014, and 2015, respectively.

Conclusions: PB effectively reduced CLABSI in dialysis access. Checking the compliance with technique and methods, and feedback from staff are important for maintaining the PB system.

SA-PO1054

A Novel Device for Reducing Catheter-Related Bloodstream Infections: A Multi-Center, Controlled, Randomized Clinical Trial of the ClearGuard HD Antimicrobial Barrier Cap Jeffrey L. Hymes,[1] Ann Mooney,[2] Carly R. Van Zandt,[2] Laurie Lynch,[3] Robert Ziebol,[3] Douglas Killion.[3] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Frenova Renal Research, Waltham, MA; [3]Pursuit Vascular, Inc., Maple Grove, MN.*

Background: Bloodstream infections (BSIs) have been a significant problem for hemodialysis catheter patients for decades, leading to poorer outcomes such as death and hospitalization, and increased cost to the healthcare system. This clinical trial studied use of antimicrobial central venous catheter (CVC) caps intended to prevent BSI.

Methods: 12-month, prospective, cluster-randomized, multi-center, pragmatic, open label clinical trial conducted at 40 Fresenius Medical Care North America dialysis facilities. We matched facilities by positive blood culture (PBC) rate and number of CVC patients. Patients were randomized in a 1:1 ratio to use ClearGuard HD Antimicrobial Barrier Caps® or standard CVC caps. 2,470 patients participated in the study, accruing approximately 350,000 CVC-days. The primary endpoint was PBC rate as an indicator of BSI rate. PBCs, hospital admissions for BSI, hospitalization-days for BSI, IV antibiotic starts, and CVC-days were measured.

Results: The treatment and control groups were well matched. Use of ClearGuard HD CVC caps was associated with a 55% reduction in PBC rate compared to standard CVC caps during the 12-month study (0.27 vs. 0.60/1,000 CVC-days, P<0.001). Sustained use of ClearGuard HD CVC caps (last 6 months of study) demonstrated a 69% reduction in PBC rate (0.22 vs. 0.70/1,000 CVC-days, P<0.001), a 43% reduction in hospital admissions for BSI (0.27 vs. 0.48/1,000 CVC-days, P=0.03), and a 51% reduction in hospitalization-days for BSI (2.41 vs. 4.93/1,000 CVC-days, P<0.001). No device-related adverse events were reported.

Conclusions: Use of ClearGuard HD Antimicrobial Barrier Caps significantly reduced BSIs, hospital admissions for BSI, and hospitalization-days for BSI.

SA-PO1055

A New Dialysis Catheter Dressing (Cath Dry) Significantly Reduces Catheter Infections Omaran Abdeen,[1] Alexander J. Martos.[2] *[1]Kidney Consultants Medical Group, Inc., Kidney Consultants Medical Group, Inc., Mission Hills, CA; [2]Dept of Public Health, Columbia Univ Mailman School of Public Health, New York, NY.*

Background: Dialysis catheter infections are a significant cause of morbidity/mortality and adversely impacts quality of life. We evaluated the use of a novel, water resistant, and breathable dialysis catheter dressing, Cath Dry.[figure1]

Methods: Participants were recruited from a dialysis center in Mission Hills, CA. The dressing was applied to enrolled participants (n=45) via sterile technique by dialysis nurses. Participants were instructed to not remove the dressing and advised to shower without restriction. All participants completed a quality of life survey before and after the study. Data on infections were collected during the study period.

Results: Participants were enrolled for 3 months, for a collective study period of 139 catheter-months. The expected infection rate for our population was approximately 3 episodes (based on National Healthcare Safety Network (NHSN) 2014 data of 2.16 infections per 100 catheter-months). During the study, we observed ***no*** catheter related infections. We compared our rate of zero infections to the 2014 NHSN infection rate using a one-sided exact test based on the binomial distribution. Our infection rate was significantly less than the NHSN rate (p = 0.0449). Quality of life survey results showed 78% of patients felt their catheter was not clean/protected prior to the study whereas 100% of patients felt their catheters were clean/protected during the study. Similarly, 68% of participants felt their inability to shower adversely affected their quality of life. At the end of the study 100% of participants felt that Cath Dry improved their dialysis experience.

Conclusions: Cath Dry, a water resistant and breathable dialysis catheter dressing significantly reduced infections in our participants when compared to 2014 NHSN infection rates. Use of Cath Dry contributed positively to the quality of life, dialysis experience and hygiene of our participants.

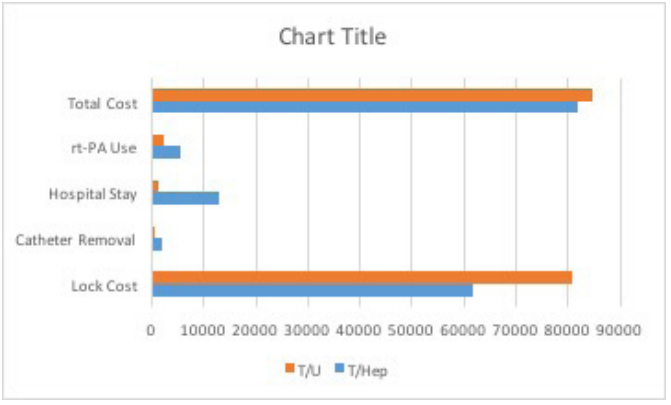
Randomized Controlled Trial of Taurolidine Citrate versus Taurolidine Urokinase Lock to Prevent Tunneled Catheter Thrombosis in Hemodialysis Patients: Cost Analysis and Effectiveness Study Abdullah Hamad, Rania Abdelaziz Ibrahim, Ashraf A.F. Ibrahim, Fadwa S. Al-Ali. *Nephrology, Hamad General Hospital, Doha, Qatar.*

Background: Catheter malfunction is a frequent complication and responsible for most of catheter removals. In a recent trial, we found benefit of using Taurolidine citrate with Urokinase (T/U) versus Taurolidine Citrate with Heparin (T/Hep) in decreasing catheter thrombosis and infection. We are presenting a cost effectiveness analysis of the trial.

Methods: In a prospective randomized controlled trial in Qatar. HD patients received T/Hep or T/U catheter locks and followed for 6 months. We analyzed incremental cost. Cost was calculated based on actual purchasing price for our hospital for T/Hep, T/U and rt-PA. Hospitalization and procedure costs estimated from hospital billing department.

Results: There were 93 patients in T/Hep and 84 in the T/U. Total 7 catheters were removed in T/Hep versus 1 only in T/U. Rt-PA use was lower in T/U than T/Hep. Cost for T/U lock was significantly higher than T/Hep (80800 US$ versus 61700 US$ pValue < 0.05). Cost difference was eliminated when adding additional costs of hospitalizations, catheter removal procedure and rt-PA (total cost was 82000 US$ in T/Hep versus 84720 US$ in T/U, p Value 0.9 NS). Detailed cost analysis shown in Table 1/Figure 1.

	Taurolock/Hep (#unit)	Cost (US dollars)	Taurolock/U (#unit)	Cost (US dollars)
catheter lock	4491	61700	4386	80800
catheter removal	7	2000	1	300
hospital length of stay	47 days	13000	5 days	1370
rt-PA use	118 times	5300	50 times	2250
Total	N/A	82000	N/A	84720



Conclusions: In a comparison trial where we found clinical benefit for T/U with less need for rt-PA and catheter removal compared to T/Hep, cost analysis confirmed cost effectiveness in T/U (although it is higher cost) after adding the saving of less hospitalization, less rt-PA use and catheter removal cost.

Funding: Government Support - Non-U.S.

SA-PO1057

Use of Taurolidine Citrate with Urokinase Lock for Dialysis Catheter Malfunction: A Prospective Pilot Study Mohamed Yahya Mohamed, Abdullah Hamad, Hicham Bouanane, Hoda Tolba, Ramshad Netoth Kuniyil, Mohammed Ezzat Mohammed, Aisha Abdulla, Fadwa S. Al-Ali. *Nephrology, Hamad General Hospital, Doha, Qatar.*

Background: Thrombolytics are used to treat hemodialysis (HD) catheter malfunction. Blood flow rate (BFR) during dialysis is a surrogate outcome and an established marker of catheter malfunction. We are presenting a prospective pilot study to introduce Taurolidine-urokinase-U25.000 (T/U) catheter lock in regard to improving catheter malfunction.

Methods: All HD patients in the 2 largest outpatient facilities in Qatar (460 patients) were evaluated. Patients were included if they have permanent dialysis catheter with poor BFR (mean of less than 250 ml/min for 6 weeks prior to inclusion in study) (phase 0). We have 2 phases. Phase 0 was observation for 6 weeks with our current practice followed by phase 1 where patients were started on T/U catheter lock every session for 6 weeks. BFR in HD sessions and need for recombinant tissue plasminogen activator (rt-PA) treatment for acute nonfunctioning catheters were monitored in both phases.

Results: 25 HD patients included in the study (14 Males and 11 females). Baseline catheter locks (phase 0) were heparin 5000 unit/mL (11 patients), heparin 5000 unit/mL with rt-PA lock on weekend session (10 patients) and 4 patients on Taurolodine with Heparine 500 units. Mean BFR was significantly higher in phase (1) with T/U (252+/-36 ml/min) compared to phase (0) lock solutions (198+/-23) (pValue 0.0001 95% CI of this difference: From -65 to -40). Rt-PA treatment needed for acute catheter malfunction was significantly less in T/U (phase1) versus other locks (phase 0) (0.7 +/- 1.4 versus 3.2+/-3.1 pValue 0.0007, 95% CI 1.12 to 3.92). Sixteen patients (64%) achieved BFR > 250 ml/min after applying T/U while 3 patients only (12%) showed no improvement in BFR. One patient expired due to congestive heart failure complications 3 weeks into the study. No adverse events reported during study period. Cost analysis comparison was 12700 (T/U) versus 6900 US dollars (baseline locks).

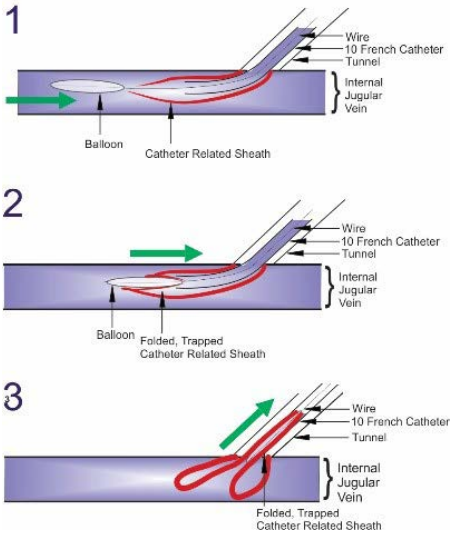
Conclusions: In a pilot study to introduce T/U catheter lock, we found significant improvement in BFR, decrease in need for rt-PA and most patients achieved BFR above 250 ml/min but with 84% increase in cost.

SA-PO1058

A Novel Technique for Catheter-Related Sheath Removal Grant Meltzer,[1,2] Adam S. Przebinda,[1,2] Zahid Bashir Ahmad.[1,2] *[1]Dept of Nephrology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Dept of Nephrology, Veterans Affairs Hospital, Oklahoma City, OK.*

Background: Catheter-related sheaths (CRS) are sock-like structures composed of inflammatory cells and connective tissues which form on the outside of indwelling central venous catheters (CVC), as a thrombogenic response. CRS, also known as fibrin sheaths or sleeves can inhibit tunneled dialysis catheter function through obstruction of the side ports or catheter tip.

Methods:



Step 1: Angiogram estimates terminal position of CRS. Balloon is deployed beyond this point and partially retracted

Step 2: CRS is folded and trapped against the 10 French catheter

Step 3: Balloon and sheath are withdrawn.

Results: Current techniques to salvage affected catheters include thrombolytic agents and/or stripping procedures. However, standard care at most centers is catheter exchange with balloon disruption of the CRS. Disruption of the CRS, though generally well tolerated, raises concern for potential complications, notably pulmonary embolism of CRS fragments.

Conclusions: We report a new technique which retrieves the CRS, thereby eliminating the risk for pulmonary embolism.

Outcomes after Stent Graft Placement for Cephalic Arch Stenosis – Effect of Access Flows and Cephalic Arch Angle Florian E. Toegel,[1] Patrick McGlynn,[1] Prakrati C. Acharya,[2] Adina Simona Voiculescu,[1] Dirk M. Hentschel.[1] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Medicine, Mount Auburn Hospital, Cambridge.*

Background: Cephalic arch stenosis (CAS) is a common complication of brachial-cephalic autogenous accesses and limits access survival. Treatment with angioplasty (PTA) is complicated by high recurrence rates. Covered stent placement is widely practiced but outcomes data are limited. We report the long-term outcome after CAS stent graft placement in relation to access flows and cephalic arch angle.

Methods: Retrospective chart review of patients undergoing PTA and stent graft placement between 2008-2013.

Results: 50 patients underwent placement of stent grafts for CAS after failure of PTA due to recoil and clinical symptoms < 90 days, or rupture during any PTA. Time from fistula creation to first procedure in the cephalic arch averaged 564 days. Progression from first angioplasty for CAS to stent graft placement averaged 342 days (range 23-1369) and follow up after stent graft placement was on average 2.7 years (1001 days). An average number of 1.5 stents was placed per cephalic arch. The acuteness of the cephalic arch angle was neither associated with time to first intervention nor with recurrence of stenosis after initial angioplasty, but a more acute angle was associated with a higher number of procedures after stent placement. Time between interventions before stent graft progressively declined from 131 days to 85 days and decline was faster with higher access flows. After stent placement time between procedures significantly increased to 379 days, 187 days and 307 days (1st, 2nd and 3rd procedure) and procedure frequency significantly declined to an average of 0.97 procedures per year. Higher flow accesses had a longer intervention-free interval after stent placement (440 days flow >1400 ml/min, 247 days flow 800-1400ml/min, 174 days flow < 800 ml/min).

Conclusions: Stent graft placement extents the procedure free interval, extending access life. Higher flow accesses benefited proportionally more from stent graft placement compared to lower flow accesses. The acuteness of the cephalic arch angle is associated with a higher number of procedures after stent graft placement.

SA-PO1060

Blood Flow Velocity Predicts Cephalic Arch Stenosis in Patients with Brachiocephalic Fistula Access Mary S. Hammes, Sydeaka Watson, Alkesh A. Amin, Brian Funaki. *Univ of Chicago.*

Background: The lower arm radiocephalic fistula (RCF) is the first access recommended for patients with ESRD on hemodialysis; however, there is a high failure rate compared to other arteriovenous fistula (AVF) configurations. An upper arm brachiocephalic fistula (BCF) is the next recommended access to be placed, but these most commonly fail owing to cephalic arch stenosis (CAS). Patients with BCF are 37 times more likely to develop

CAS than those with RCF. Our hypothesis is that the high incidence of CAS in patients with BCF is due to an unphysiologic high flow state that worsens over time after AVF placement. The aim of the current study was to examine the relationship between time to CAS (from surgical creation) and blood flow velocity (BFV) measured over time. A secondary aim was to examine the relationship between demographic variables that may predict CAS.

Methods: Thirty-seven patients with a primary BCF were included in the analysis. A venogram of the cephalic arch and venous Doppler was done at time of BCF maturation, and annually up to the time of CAS or 36 months. BFV was measured 10 cm proximal to the cephalic arch over several heart cycles and the average calculated. A joint model for longitudinal and survival data was used to determine variables associated with BFV trends or time to CAS. A bivariate analysis was performed to determine the association between variables and BFV trends or time to CAS.

Results: Using a joint longitudinal and survival model, BFV was predictive of CAS when adjusted for BMI, coronary artery disease (CAD), diabetes, and gender ($p < 0.001$). Using a longitudinal model fit for each variable (gender, age, ethnicity, BMI, CAD or diabetes), CAD was the only significant predictor of high BFV ($p = 0.008$).

Conclusions: There is a relationship between BVF and the development of CAS over time.As an AVF ages, increased flow within the artery and vein induces dilatation resulting in gradual reduction in resistance. The high flow circuit in BCF leads to altered hemodynamics causing pathological accelerated access growth including aneurisms, cardiac overload and as we have shown in this analysis, CAS. Efforts to decrease high flow in an AVF are needed to prevent these adverse complications.

SA-PO1061

Impact of Banding Procedure and Factors Associated with Cephalic Arch Stenosis in Brachiocephalic Fistulae Yaeni Kim, Ji Hyun Yu, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Cephalic arch stenosis (CAS) is the most common stenosis in brachiocephalic fistula (BCF). Recurrent stenosis and unacceptable primary patency rate after percutaneous transluminal angioplasty (PTA) often occur in CAS. We aimed to evaluate the patency rate of CAS in dysfunctional BCF and to identify factors that may affect their patency rate and the impact of banding procedure.

Methods: Out of 374 angiography in 178 patients with dysfunctional BCF from 2010 to 2015 in our center, 234 angiography in 86 patients revealed CAS. PTA was the first choice of management. Cutting balloon angioplasty was performed when resistant to high pressure PTA. Endovascular banding (MILLER) was done in cases of recurrent CAS (>3 times) with high access flow (>1.5 L/min). Kaplan–Meier method was employed to evaluate patency rates.

Results: Primary, primary assisted, and secondary patency rates of CAS were 60.9%, 96.3%, and 94.1% at 3 months and were 52.1%, 95%, and 91.3% at 6 month and were 33.4%, 86.9%, and 88% at 1 year, respectively. Number of PTAs less than or equal to 1.65 per access-year showed favorable primary and secondary patencies when compared to those with more than 1.65 PTAs per year. Maximal diameter of distal cephalic vein to cephalic arch (CV_CA) ratios showed a significant difference between dysfunctional BCF with CAS and without CAS. ROC curve drawn to predict the value of CV_CA ratio in the development of CAS revealed that ratio of 1.61 had 86% sensitivity and 100% specificity in predicting the development of CAS. Proximal 1/3 lesion in CAS was associated with poorer primary patency rate than those with distal lesion. MILLER procedures were performed in 15 patients. The number of PTA prior to MILLER was 4.26 per access-year, whereas it reduced to 1.16 following the procedures.

Conclusions: Size discrepancy between CV_CA during fistula maturation might be a risk factor for developing CAS. MILLER procedure could improve the outcome of recurrent CAS. We need further studies to determine the indications for the banding in dysfunctional BCF with CAS.

SA-PO1062

Survival and Central Vein Stenosis in Catheter-Only Dialysis Patients Sarah Hildebrand, Neill D. Duncan, Damien Ashby. *Imperial Renal and Transplant Centre, London, United Kingdom.*

Background: Compared to other forms of access, arteriovenous fistulae are associated with improved survival in haemodialysis patients, and are widely believed to be superior. In a recent meta-analysis, compared to fistula access, catheters were found to carry an increased risk for mortality with hazard ratio 1.5, though the substantial potential for bias was noted. Centre level data avoids some of this bias, so the outcome in centres with unusual practice patterns can be informative.

Methods: This retrospective study examined survival after 90 days, in a cohort of patients who never had non-catheter access. A subgroup were assessed for the presence of central venous stenosis.

Results: Between March 2006 and November 2014, 1514 patients (mean age 61.4, range 16–91, 60.2% male) started dialysis via tunneled catheter, reached at least 90 days, and remained on this type of access throughout the observation period. Over a follow-up period covering 4758 patient-years, there were 608 deaths (40.2%) and unadjusted median survival was 60.3 months. One year (after 90 days) survival was 89.0%, with survival constant over at least the first three years, at 87.8%. Over the same period, average survival in UK prevalent dialysis patients was 89.0% (standardized to age 60). Adjusting for national fistula prevalence, this suggests that compared to dialysis by fistula, dialysis by catheter access carries a modestly increased risk for mortality with hazard ratio 1.2. From a randomly selected subgroup of 110 patients, central venous stenosis was present in 12 (10.9%). Compared to those unaffected, patients with central vein stenosis did not have a significantly longer haemodialysis vintage (64.8 vs 55.3 months), but did have a significantly greater number of previous catheter insertions (3.4 vs 2.0, p=0.02).

Conclusions: The disadvantage of catheter dialysis appears to be diminished in catheter-only patients. This could be because catheter outcomes are improved in centres where they are more frequently used, or because the advantages of fistula access are over-estimated, as a result of selection bias. The risk of central venous stenosis more closely associates with number of procedures, than the duration of line use.

Superior Vena Cava Stenosis in Hemodialysis Patients with a Tunneled Cuffed Catheter: Prevalence and Risk Factors Benjamin Seront,[1] Michel Y. Jadoul,[1] Ralph Crott,[2] Laura Labriola.[1] *[1]Nephrology, Cliniques Univ Saint-Luc, Université Catholique de Louvain, Brussels, Belgium; [2]Public Health, Cliniques Univ Saint-Luc, Belgium.*

Background: Central vein stenosis (i.e. subclavian/internal jugular/superior vena cava) is a major cause of vascular access (VA) failure and morbidity in hemodialysis (HD) patients. However the actual prevalence and risk factors of superior vena cava stenosis (SVCS) are unknown.

Methods: In this monocentric retrospective observational study, all in-center HD patients with a tunnelled cuffed catheter (TCC) between Jan 1st 2008 and Dec 31st 2012 were included (n=117, 65.9 + 15 y, 43.5% diabetics). SVCS was defined as >50% reduction of vein diameter on phlebography or injected CT (and/or need of angioplasty). Imaging was triggered by clinical SVCS syndrome or VA dysfunction. We recorded demographics and medical history (including port, pace-maker, defibrillator), as well as medications potentially influencing catheter permeability, and obtained a detailed VA history, i.e. *n* of previous arteriovenous fistulas (AVF), and last or "culprit" (in use at time of stenosis detection) TCC details (location, brand, diameter and length).

Results: Among the 117 patients [214 TCC carried for 697 (range 44-4,246) days, total 80,911 catheter-days, median HD vintage 1,202 (60-6,126 days)], 11 had a SVCS (9.4%, 0.136/1,000 catheter days). Only 2 presented with clinically obvious SVCS, with complete occlusion in one. *N* of TCC per patient was 1.8 (range 1-7): 2.64 + 1.8 in SVCS group *vs* 1.75 + 0.94 in negative group (*p* 0.13). On multivariate analysis (Poisson), diabetes [IRR 4.63 (1.2-17.8) *p* 0.03] and total duration of TCC carriage [IRR 1.47 (1.2-1.7) per year; *p* 0.0001] (but not HD vintage, *n* of previous AVF, *n* of TCC, site or length of TCC) were associated with SVCS. Limitations: As not all patients underwent imaging, the prevalence of SVCS may be higher than detected.

Conclusions: Superior vena cava stenosis is all except a rare condition, mostly asymptomatic, strongly associated with diabetes, and promoted by long-term TCC carriage. Thus, as the prevalence of TCC is growing worldwide, the morbidity associated with SVCS may be expected to grow in the future.

SA-PO1064

A Novel Method to Visualize the Position of Hemodialysis Central Venous Catheter: Dynamic Sonographic Visualization of Microbubbles Rogerio Passos, Zilma Regia de Sousa Barreto, Roseanne Ferreira de Freitas Euzebio, Paulo Benigno Pena Batista. *General Intensive Care Unit I, São Rafael Hospital, Salvador, Brazil.*

Background: The insertion of hemodialysis catheter is an integral part of the management of critically ill patients requiring continuous renal replacement therapy (CRRT). Doppler ultrasound imaging guidance for the insertion compared with anatomic landmarks has benefits regarding clinical outcomes and its use is strongly recommended. Traditionally, a postprocedural chest radiography (CXR) is performed for catheter confirmation; however obtaining one can take up to several hours, delaying catheters use in patients requiring emergent dialysis initiation. The primary goal of this study was to determine if sonography microbubble protocol after central venous access was accurate to identify catheters tip correct position compared to CXR and mean time of each procedure.

Methods: This study included a convenience sample of critically ill patients requiring CRRT with supradiaphragmatic hemodialysis catheters and a CXR for confirmation. Ultrasound was used for confirmation by visualizing microbubble artifact in the right atrium after injection of saline through the distal port. Blinded chart review was performed to assess CXR timing and catheter position. Sensitivity, specificity, negative predictive value, positive predictive value and time difference between the procedures relative to the standard reference, the CXR, were analyzed.

Results: 97 patients were enrolled. The microbubble test was 87,5% sensitive (95% CI= 0.42-1.00) and 97,6% specific (95% CI= 0.92-1.00) in confirming catheter placement, with 75% PPV, 98,8% NPV. Concordance between the tests was 97%, with an expected agreement of 59%. The mean time required to perform microbubble protocol was 10.55±3.89 minutes vs 133.51±44.75 minutes for CXR. The interrater reliability was strong: k=0.78 (95% CI= 0.54-1.02) for all images ($p<0.001$).

Conclusions: The rapid appearance of prominent turbulence in the right atrium on chest ultrasound after CVC saline flush serves as a precise bedside screening test of optimal hemodialysis catheter position and was significantly faster than CXR in our population of critically ill patients requiring CRRT.

SA-PO1065

Effect of Argatroban for the Prevention of Hemodialysis Tunneled-Cuffed Catheters Thrombosis Hua Liu, Hongli Jiang, Kehui Shi, Quan He. *Blood Purification, The First Affiliated Hospital of Medical College of Xi'an Jiaotong Univ, Xi'an, Shaanxi, China.*

Background: Thrombosis-related malfunction of tunneled-cuffed central venous catheters (TCCs) for hemodialysis (HD) currently leads to a high rate of untimely catheter removal. To examine argatroban in the prevention of thrombosis of TCCs, and investigate further the efficacy and safety of argatroban in preventing thrombosis.

Methods: To compare the effect of preventing thrombosis between using urokinase group (UK group) and argatroban group (AT group), the 42 patients of TCCs were collected since Jan. 2013 to Jan. 2014, including 23 patients using UK, 19 patients using AT, and drugs were taken monthly, a total of 12 months. The adverse events and interventions of pre-dialysis, blood flow, transmembrane pressure and venous pressure of dialysis were observed in two groups. The changes of C-reactiveprotein (CRP) were observed in two groups after treatments.

Results: The intervention rates of the two groups after treatments were 4.8% vs. 10.3% (AT vs. UK, $P < 0.05$). In the two groups, the blood flow were all increased after treatments, and transmembrane pressure and venous pressure were all reduced ($P < 0.05$). Before and after each preventive therapy, there was significant difference in activated partial thromboplastin time (APTT) in the two groups (UK vs. AT, P<0.05). In AT group, the CRP gradually reduced during 12 months of treatment ($P < 0.05$).

Conclusions: Argatroban or urokinase could prevent the thrombosis of TCCs, by dripping at regular periods, and the blood flow of dialysis was increased. Argatroban group had higher safety, less thrombosis incidence and inflammatory reaction than urokinase group, which may predict that the long-time argatroban application could reduce inflammatory in maintenance hemodialysis patients .

SA-PO1066

Tunneled Hemodialysis Catheter (TDC) Survival with Use of Tissue Plasminogen Activator (tPA) Instillation Seyed-Ali Sadjadi, Sreesh G. Iyengar, Navin Jaipaul. *Nephrology, Loma Linda VA Medical Center, Loma Linda, CA.*

Background: In the United States up to 80% of patients start dialysis by way of TDCs despite attempts to reduce this. Besides carrying a higher risk of infection, TDC's may cause formation of blood clots, impairing blood flow and thus adequate dialysis, causing increased morbidity and mortality. Prior studies have shown that tPA is effective in maintaining patency of TDCs, especially short term and in the setting of catheter dysfunction. In our study we attempt to establish evidence for long-term patency with use of thrombolytics.

Methods: This is a retrospective cohort study with 169 study subjects. The Nephrology dialysis unit database was searched to identify all hemodialysis patients with TDC's placed. The electronic medical record was reviewed to see if subjects had or had not received tPA. The data was analyzed to compare "early" (30 days), "late" (90 days) and "very late" (180 days) TDC survival with and without tPA. Secondarily we also determined average number of tPA doses used.

Results: With regards to "early" catheter survival at 30 days, there was no significant difference in survival between catheters that did and did not receive tPA (p value 0.591). There was no significant difference in "late" catheter survival at 90 days either (p value 0.497). With regards to "very late" catheter survival at 180 days, the difference was not significant (p value 0.252). The number of tPA doses averaged 4.9 doses with a wide standard deviation of 8.8. With regard to catheter survival, catheters treated with tPA survived 80 days versus 77 days in those catheters not treated with tPA (p value 0.124). With regards to TDC location, left versus right sided, there was no significant difference in survival (p value 0.392).

Conclusions: If one considers the "gold standard" for a TDC as one that remains functional without the need for tPA until removal. In our study, the overall catheter survival in days was improved with the use of tPA by 3 days, neither statistically or clinically significant. TDCs treated with tPA survived the same length of time as the "gold standard" catheters, thus leading to our conclusion that use of tPA in TDC's is non inferior to the "gold standard."

SA-PO1067

Expanded Indications of Occluded Arteriovenoius Graft Puncturing with Ultrasound Guide Akashi Togawa. *Dept of Nephrology, Shizuoka Saiseikai General Hospital, Shizuoka, Japan.*

Background: We have tried placing a regular needle catheter through the occluded arteriovenoius graft (AVG) to the brachial artery as a temporary vascular access ("occluded AVG puncturing"). We previously reported that the occluded AVG puncturing is useful as a back-up hemodialysis vascular access (Togawa 2012 J Vasc. Accsess). After the first report, we tried to expand the indication of occluded AVG puncturing with ultrasound-guided puncturing technique.

Methods: Occluded AVG puncturing was performed approximately 15-30 mm from the site of anastomosis between the artery and graft. The body of the catheter passes through the coagulated blood in the graft and the tip of the catheter is placed in the artery. We used 50mm needle for occluded AVG puncturing. The subcutaneous veins or deep veins were used for the return circuit of hemodialysis. In some patients, ultrasound guided puncturing was performed for catheter insertion of veins.

Results: From June 2011 to May 2016, we performed 143 punctures of 12 patients. Puncture was performed in patients with difficulty of immediate intervention or re-surgery. In the patients undergoing the longest period, we performed 75 occluded AVG puncturing for 6 months. Even if there was a bend in the anastomotic site in some degree, it was possible to place the tip of the catheter in the artery under ultrasound guide. Sufficient blood flow was able to obtain in all patients. None of the patients experienced complications such as hematoma formation, injury of the artery, arterial occlusion or puncture-related infection. With the occluded AVG puncture, the patients were able to avoid hospitalization with catheter insertion and urgent VA repair. In addition, with the occluded AVG puncturing, some patients were able to continue hemodialysis as an outpatient for long-time.

Conclusions: Occluded AVG puncturing with ultrasound guide might be safe for long-term use. Occluded AVG puncturing might be considered in patients who have difficulty in AVG re-creation because of low cardiac function or vulnerability of the skin.

Shall We Abandon Frequently Thrombosed Accesses? Janet Yanqing Mei,[1] Zubin Irani,[2] Jie Cui.[3] *[1]Harvard School of Public Health; [2]Interventional Radiology Div, Massachusetts General Hospital; [3]Renal Div, Massachusetts General Hospital.*

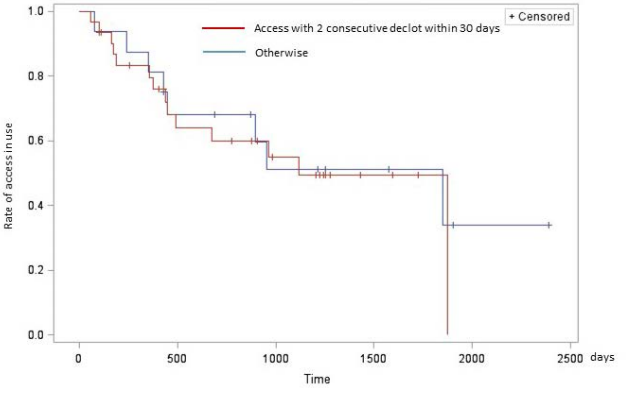
Background: Whether and when a frequent thrombosed access should be abandoned is unclear. In this study, we had a 5 year follow up of those accesses, which defined as having 2 thrombectomies within 30 days.

Methods: This is a retrospective cohort study. Patients received thrombectomy/declotting procedures in 2012 in interventional radiology division at Massachusetts General Hospital were included. Information regarding all arteriovenous accesses those patients have had until April, 2016 were collected. Kaplan-Meier estimator was used to evaluate the rate of access-in-use.

Results:

	Patients(n=43)
Age at 1st access	58.8±15.0
Men	60.5%
No. of access per patient	2±1
Access type	
Fistula	30
Graft	68
Hypertention	81.4%
Diabetes	60.5%
CHF	53.5%

Sixty-eight accesses had at least one clotting event and 48 (70.6%) had subsequent events. Thirty-three accesses had at least three events; three cases showed decreasing intervals between each event. There were 31 accesses with two declots within 30 days; 5 had new accesses within approximately 3 months (range: 21 to 98 days); 65.2% had a following declot within 30 days. Frequently thrombosed group had similar rate of access-in-use across time compared to access group that did not need frequent declot.



Conclusions: In this study, the intervals between clotting events generally do not hold a decreasing pattern. For frequently clotted accesses, they have a moderate risk of a following declot within 30 days. Their longevity is similar to that of their counterparts. We conclude that frequent-thrombosed accesses should not be abandoned quickly.

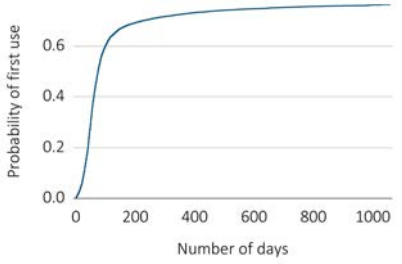
SA-PO1069

Successful Arteriovenous Graft Placements in Hemodialysis Patients: Results from the USRDS Kenneth J. Woodside,[1] Sai Hurrish Dharmarajan,[1] Brett W. Plattner,[1] Douglas E. Schaubel,[1] Purna Mukhopadhyay,[2] Kaitlyn Ratkowiak,[2] Ronald L. Pisoni,[2] Rajiv Saran.[1] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

Background: While an arteriovenous fistula (AVF) is the vascular access of choice for hemodialysis (HD), some patients cannot support an AVF, and an arteriovenous graft (AVG) is placed. We previously described AVF maturation in prevalent HD patients. Herein, we describe predictors of successful AVG placement.

Methods: We assessed the relationship between patient characteristics and time to first AVG use by Cox regression in HD patients with AVG placements in 2013 or 2014 using ESRD Medicare claims data and CROWNWeb in the USRDS, with follow-up through 12/31/15.

Results: There were 24,222 AVGs placed in 22,634 prevalent HD patients. Of these AVG, 18,229 (75.3%) were successfully utilized (Figure). Of successful AVG, 52.8% were used by 2 months and 85.2% by 4 months (median 57 days [IQR 39-87 days]). Patients 22-44 years were less likely (HR 0.94 [95%CI 0.89, 0.99]), and those ≥75 years were more likely (HR 1.11 [95%CI 1.07, 1.16]), to successfully use the new AVG, compared to the 45-64 year reference group. Successful AVG use was more likely in black vs white HD patients (HR 1.05 [95%CI 1.02, 1.09]). There were no significant differences by sex or comorbidities. HD vintage interval ≥2 years were associated with successful AVG use. Those with AVG at HD initiation were more likely (HR 1.33 [95%CI 1.22, 1.44]), and those with AVF at HD initiation were less likely (HR 0.95 [95%CI 0.89, 1.01]), to have subsequent successful AVG, compared to patients who initiated HD by catheter only. There was wide variation in successful AVG placement by ESRD Network.



Conclusions: We have characterized AVG maturation in a national US sample and identified important associations with multiple patient and regional factors. National time to AVG first use was longer than expected and requires further study .

An Innovative Vascular Access for Chronic Hemodialysis: Subcutaneous Polytetrafluoroethylene (PTFE) from Internal Iliac Artery to Left Renal Vein

Nelia Antunes,[1] Marcio Gomes Filippo,[2] Alessandra Collares Motta,[2] Eduardo Rocha.[1] *[1]Nephrology Div, Federal Univ Rio de Janeiro, Rio de Janeiro, RJ, Brazil; [2]Vascular Surgery Div, Federal Univ Rio de Janeiro, Rio de Janeiro, RJ, Brazil.*

Background: The longer hemodialysis (HD) patients survive, the longer vascular access becomes a problem. This may reach life-threatening proportions and eventually lead to the need of innovative solutions.

Methods: We report a case of a 44-yr. old woman with unknown etiology stage 5 CKD on HD for 14 years, during which she had thrombosed fistulas on both upper and lower extremities and also failed peritoneal dialysis (PD) and a kidney transplantation (KT). A second KT was discarded by the transplant team. HD became temporarily possible due to extreme vascular accesses: two arterio-arterial PTFE grafts (bilateral axillary-axillary artery bypass) and a translumbar inferior vena cava tunneled catheter, successful for only a short period. Considering the exhaustion of options, we placed a double-lumen catheter (DLC) into right femoral artery as an emergency access, until a whole-body CT angiography revealed occlusion of all main venous trunks - jugular, subclavian, and iliacs) and infrarenal vena cava – with the exception of the left renal vein and suprarenal vena cava. We then decided to construct an unconventional long term vascular access for HD, using an abdominal 6 mm subcutaneous tunneling PTFE linking the internal iliac artery (end-to-side) to the left renal vein (after nephrectomy).

Results: As venogram demonstrated a patent anastomosis, this innovative access was used 11 days from the surgery (July 3rd, 2014) and remains patent 23 months thereafter. So far, no infectious or thrombotic complications were detected.

Conclusions: Placement of a PTFE arteriovenous graft from internal iliac artery to left renal vein is a viable option for HD patients excluded from PD or KT with exhaustion of vascular access.

SA-PO1071

Role of CTGF in Peritoneal Fibrosis in Mice

Naohiro Toda,[1] Masato Kasahara,[2] Kiyoshi Mori,[3] Masashi Mukoyama,[4] Motoko Yanagita,[1] Hideki Yokoi.[1] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Inst for Advancement of Clinical and Translational Science, Nara Medical Univ, Nara, Japan; [3]School of Pharmaceutical Sciences, Univ of Shizuoka, Shizuoka, Japan; [4]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Connective tissue growth factor (CTGF/CCN2) regulates signaling of other growth factors and promotes fibrosis. CTGF is shown to be an aggravating factor in thickening peritoneum and peritoneal function. Inhibition of CTGF using knockout mouse has not been examined in peritoneal fibrosis because of its perinatal death.

Methods: To study the role of CTGF in peritoneal fibrosis of adult mice, we generated CTGF floxed mice, and these mice were crossed with RosaCreER^{T2} mice. We administered tamoxifen (TAM) to 3, 6-week old mice to delete CTGF gene throughout the body in Rosa-CTGF cKO mice. We evoked peritoneal fibrosis by intraperitoneal injection of chlorhexidine-gluconate (CG) in wild-type and Rosa-CTGF cKO miceand examined peritoneal injury by Masson's trichrome staining, immunohistochemistry, mRNA expression of peritoneum and peritoneal equilibration test.

Results: After induction of peritoneal fibrosis in wild-type mice, mice showed increased CTGF expression and severe thickening of peritoneum.In contrast, CG-treated Rosa-CTGF cKO mice exhibited reduced thickening of peritoneum by 30%on day 28. Peritoneal CTGF mRNA expression was decreased by 80% in Rosa-CTGF cKO mice in peritoneal fibrosis. Peritoneal equilibration test also revealed that increase of peritoneal permeability in CG-treated wild-type mice was normalized in CG-treated Rosa-CTGF cKO mice. Immunohistochemical study revealed that CG-treated Rosa-CTGF cKO mice showed number of αSMA- and CD31-positive cells in peritoneum. Analyses of peritoneal mRNA showed that CG-treated Rosa-CTGF cKO mice exhibited reduced expression of αSMA, CD31 and VEGF.

Conclusions: These results indicate that the deficiency of CTGF can reduce peritoneal thickening and maintain peritonealfunction by reducing angiogenesis and fibrosis in peritoneal fibrosis model, suggesting that CTGF plays an important role in the progression of peritoneal fibrosis.

SA-PO1072

Blocked Heat Shock Factor 1 as Novel Pathomechanism Caused by Relevant Stressors in Peritoneal Dialysis Fluid

Rebecca Herzog,[1,2,3] Klaus Kratochwill,[1,3] Christoph Aufricht.[3] *[1]Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Medical Univ of Vienna, Austria; [2]Zytoprotec GmbH, Vienna, Austria; [3]Pediatric Nephrology, Medical Univ of Vienna, Austria.*

Background: PD-fluids (PDF) cause injury of mesothelial cells but also induce cytoprotective mechanisms. Recent studies, however, suggest that PDF blocks the heat shock response, one of the evolutionary most important stress responses. The resultant increased vulnerability of the mesothelial cells could lead to progressing fibrosis of the peritoneal membrane. The aim was to identify the molecular mechanisms leading to the PDF-induced inadequate stress response.

Methods: The induction of the stress response in mesothelial cells was analyzed using combined *in-vitro* and *in-vivo* models of PDF exposure and heat stress as the gold standard. In addition single cytotoxic components of PDF, like glucose degradations products (GDP) and acidosis as well as the impact of cytoprotective additives were investigated. The status of heat shock factor 1 (HSF1) activation, Hsp72 expression, the stress-proteome and viability of the mesothelial cells were analyzed.

Results: Compared to heat, PDF leads to increased lethality but decreased Hsp72 expression. A concurrent blockage of the nuclear shift, phosphorylation and DNA-binding of HSF1 with reduced activity of the promotor was found. The inadequate HSF1 activation could be unblocked by a neutral pH, filter-sterilized PDF (without GDPs) or addition of alanyl-glutamine. The HSF1 blocking caused by the acidosis was associated with activation of GSK-3β, while the GDPs directly interfered with HSF1 promotor activity.

Conclusions: The PDF-mediated inadequate induction of the cellular stress response represents a new pathomechanism in PD. Our results demonstrate that the cytotoxic factors such as acidosis and GDPs of PDF lead to a HSF1 block via different molecular mechanisms and post-translational modifications resulting in decreased stress response and increased vulnerability of mesothelial cells exposed to PDF which could be restored by addition of alanyl-glutamine.

SA-PO1073

The Role of WNT Signalling in Peritoneal Membrane Injury

Manreet K. Padwal, Limin Liu, Peter Margetts. *Medicine, McMaster Univ, Hamilton, ON, Canada.*

Background: Patients on peritoneal dialysis are at risk of developing peritoneal fibrosis and angiogenesis which can lead to a decline in peritoneal membrane function. Transforming growth factor beta (TGFB) is the primary cytokine involved in inducing epithelial to mesenchymal transition (EMT) and fibrosis. The WNT/b-catenin (canonical) signalling pathway has been shown to interact with the TGFB pathway to promote fibrogenesis. In contrast, non-canonical WNT signalling may have protective effects. Therefore, we investigated the role of WNT signalling in peritoneal membrane injury.

Methods: Using adenovirus mediated gene transfer of TGFB, we induced fibrosis and EMT in the mouse peritoneum. Using an adenovirus, we concurrently overexpressed the WNT inhibitor DKK1, or the non-canonical WNT5a, and evaluated EMT, fibrosis, and angiogenesis.

Results: The addition of AdDKK1 to AdTGFB mediated injury resulted in attenuation of angiogenesis in the mouse peritoneum. This also resulted in a decrease in EMT and an increase in the expression of the epithelial marker E-cadherin. This demonstrates that the WNT/b-catenin pathway is involved in peritoneal membrane angiogenesis. The treatment of mouse peritoneum with AdTGFB and AdWNT5a also resulted in a decrease in angiogenesis and reduction in vascular growth factor expression. Furthermore, addition of WNT5a inhibited glycogen synthase kinase 3 phosphorylation suggesting WNT5a may antagonize the canonical WNT pathway.

Conclusions: The WNT/b-catenin pathway is involved in epithelial cell transition and angiogenesis. WNT5a may be protective against peritoneal membrane injury by antagonizing β-catenin dependent WNT signalling.

The Effect of Protein Transduction Domain Recombinant Bone Morphogenetic Protein-7 on Epithelial-Mesenchymal Transition in Peritoneal Mesothelial Cells Ji Min Park,[2,3] Seonghun Kim,[1] Youn Kyung Kee,[2] Hyoungnae Kim,[2] Min-Uk Cha,[2] Tae-Hyun Yoo.[1,2] *[1]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [3]Dept of Internal Medicine, Severance Biomedical Science Inst, Brain, Korea.*

Background: We investigated the effect of Protein transduction domain (PTD)-mediated bone morphogenetic protein-7 (tissue-regeneration polypeptide 2, TRP2) on TGF-β1-induced epithelial-mesenchymal transition (EMT) in cultured human peritoneal mesothelial cells (HPMCs). In addition, we investigated how to deliver the drugs to peritoneum in vivo models.

Methods: In vitro, HPMCs were cultured in normal glucose + TGF-β1 with or without TRP2. In vivo, saline (control group, n=3), 4.25% PD solution (PD group, n=3), or 4.25% PD solution + TRP2 (PD + TRP2 group, n=5) were infused for 4 weeks in 11 Sprague-Dawley rats, then sacrificed after 4 weeks. E-cadherin, ZO-1, α-SMA, snail, vimentin, type I collagen, and fibronectin were estimated. PF was assessed by Masson's trichrome (MT) staining.

Results: In vitro, protein expression of E-cadherin and ZO-1 (epithelial marker) were significantly decreased, while α-SMA, snail, vimentin (mesenchymal marker), type I collagen and fibronectin were significantly increased in TGF-β1-stimulated HPMCs compared to control group, and these changes were significantly improved by TRP2 treatment. In vivo, peritoneal EMT and PF were significantly increased in PD rats compared to control rats. The thickness of mesothelial layer and the intensity of MT staining in the peritoneum of PD rats were also significantly higher compared to control rats. These changes of the peritoneum in PD rats were significantly ameliorated by the administration of TRP2.

Conclusions: This study suggests that TRP2 directly inhibits the process of TGF-β1-induced PF via peritoneal EMT in HPMCs. In addition, TRP2 mitigates PF in PD rats. The effect of PTD-mediated recombinant protein delivery system may be a potential therapeutic strategy for prevention of PF in PD patients.

SA-PO1075

MicroRNA-200c Inhibits TGF-β1-Induced Epithelial-to-Mesenchymal Transition and Fibrogenesis in Peritoneal Mesothelial Cells Susan Yung, Jessica Y.S. Chu, Mel Chau, Mandy K.M. Kam, Daniel Tak Mao Chan. *Dept of Medicine, The Univ of Hong Kong, Hong Kong.*

Background: Progressive peritoneal fibrosis is a common complication that limits the effectiveness of long-term peritoneal dialysis (PD). Epithelial-to-mesenchymal transition (EMT) of mesothelial cells is a salient feature in peritoneal fibrosis but how this is triggered remains obscure. This study investigated the role of microRNA-200c (miRNA-200c) in EMT and fibrogenesis in a murine PD model and cultured peritoneal mesothelial cell.

Methods: Male C57BL/6N mice were administered PBS or glucose-based PD fluid twice daily by intra-peritoneal injection for up to 30 days. Parietal peritoneum was obtained and miRNA-200c expression examined using locked nucleic acid in-situ hybridization. Cultured human peritoneal mesothelial cells were stimulated with exogenous TGF-β1 and the expression of miRNA-200c and EMT markers was investigated. The effect of miRNA-200c overexpression on fibrogenesis was investigated in separate experiments.

Results: PD fluid, but not PBS, reduced peritoneal miRNA-200c expression in C57BL/6N mice. This effect was observed after 3 days and was sustained for 1 month, and was associated with mesothelial cell denudation and increased submesothelial collagen deposition. TGF-β1 decreased miRNA-200c and E-cadherin expression in mesothelial cells in a dose-dependent manner, and this was accompanied by increased SNAIL, fibronectin and collagen I synthesis. Over-expression of miRNA-200c suppressed the pro-fibrotic effect of TGF-β1 in mesothelial cells.

Conclusions: Our data demonstrate that miRNA-200c regulates EMT and fibrogenesis in mesothelial cells, and reduced peritoneal miRNA-200c expression is associated with peritoneal fibrosis in PD.

Funding: Government Support - Non-U.S.

SA-PO1076

High Glucose and Mannitol Concentrations Differentially Influence the Adhesive and Proliferative Properties of Mesothelial Cells Vassilios Liakopoulos,[1] Vasiliki Peppa,[2] Michail Daniilidis,[1] Konstantinos I. Gourgoulianis,[2] Chrissi Hatzoglou,[2] Sotirios G. Zarogiannis.[2] *[1]Dialysis Unit, 1st Dept of Medicine, Medical School, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; [2]Dept of Physiology, Medical School, Univ of Thessaly, Larissa, Greece.*

Background: Peritoneal mesothelial cells in the case of peritoneal dialysis are exposed to hyperosmotic conditions that result in chronic inflammation and consequently fibrosis of the peritoneal membrane. Hyperosmotic stress is an established fibrotic inducer as seen in several *in vitro* studies. However, the *in vitro* models used until now focused on acute hyperosmotic effects on mesothelial cells. The aim of our study was to investigate the chronic in vitro hyperosmotic stress, on cell adhesion and proliferation of mesothelial cells.

Methods: Mesothelial cells (MeT-5A) were constantly exposed to high glucose (100mM) or high mannitol (100mM) concentrations and adhesion and proliferation assays were performed on the first and second passage after the first application of hyperosmotic stress.

Results: Chronic exposure to mannitol increased the adhesion rate of MeT-5A cells, while the opposite effect was observed when cells were chronically exposed to glucose (1st passage: $OD_{isosmotic}$=0.13±0.03, $OD_{Mannitol}$=0.18±0.02, p<0.05; $OD_{Glucose}$=0.08±0.01, p=ns, 2nd passage: $OD_{isosmotic}$=0.19±0.01, $OD_{Mannitol}$=0.27±0.01,p<0.001; $OD_{Glucose}$=0.06±0.01, p<0.01). The proliferation rate was significantly reduced only in the presence of glucose-rich solution (p<0.001) and was not affected by chronic exposure to mannitol-rich solution.

Conclusions: The results of our study indicate that chronic exposure to osmotic stress affects mesothelial cell adhesion and proliferation depending on the osmotic agent used. High concentration of mannitol caused a significantly milder effect than high concentration of glucose. Our results implicate that the model that we employed for the mimicking of chronic stress may prove beneficial for studying peritoneal membrane changes with possible clinical relevance.

SA-PO1077

The Role and Mechanism of β-Catenin Signaling Pathway of High Glucose Induced Peritoneal Fibrosis in C57BL/6 Mice Hao Deng,[1] Jia Shen,[1] Xiuxiu Li,[1] Yan Jiang,[1] Jingyi Zhou,[1] Jianghua Chen.[1] *[1]Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China; [2]Dept of Nephrology, The People's Hospital of Zhejiang Province, Hangzhou, Zhejiang, China.*

Background: Long-term exposure to bio-incompatible high glucose peritoneal dialysate leads to peritoneal fibrosis and thus decrease dialysis efficiency. This study explored the possible role of β-catenin in high glucose dialysate induced peritoneal fibrosis.

Methods: C57BL/6 mice received daily intraperitoneal injection with 10% body weight of saline, 4.25% glucose peritoneal dialysis fluid (PDF), or PDF combined with 5 mg/kg ICG-001 for 30 days. Mouse peritoneal epithelial cells (mPEC) were cultured in 4.25% glucose or combined with 10 μM ICG-001 for 48 h.

Results: The greater thickness of parietal peritoneum, lower expression of E-cadherin, and higher expressions of Vimentin, β-catenin and Snail were demonstrated in the PDF treated mice, and Vimentin, GSK-3β, Snail expression as well as β-catenin activation were increased in HG treated mPEC, which were all modulated by treatment with ICG-001 combination treatment.

Conclusions: The activation of β-catenin signaling participated in the process of high glucose induced peritoneal fibrosis, and the epithelial-to-mesenchymal transition (EMT) of PECs is one of underlying mechanisms of this pathological change.

Tight Junction Protein Expressions from Peritoneal Dialysis Effluent: The Role of Claudin-15 Gheun-Ho Kim, Jong Wook Choi, Sua Kim, Eun Young Choi. *Internal Medicine, Hanyang Univ College of Medicine, Seoul, Republic of Korea.*

Background: We hypothesized that tight junction (TJ) proteins may have roles in paracellular transport of solute and water in peritoneal dialysis (PD) patients. Previous studies on TJ proteins in PD patients were only from cultured human peritoneal mesothelial cells. Here, we explored expression of TJ proteins directly from PD effluent and investigated their relationship with functional parameters in performing PD.

Methods: PD effluents were collected for the previous 24 hours from 20 patients when they visited outpatient clinic for the scheduled peritoneal equilibration test (PET) using a 4.25% glucose solution over 4 hours. Different molecular sizes (3 kDa, 30 kDa, and 100 kDa) of Amicon Ultra-15 Centrifugal Filter Units were used to concentrate proteins in PD effluents before immunoblot analyses for occludin, ZO-1, claudin-1, and claudin-15 were carried out. We also collected clinical data including patient demographic characteristics, fundamental laboratory findings, residual renal function, peritoneal clearance, and results of PET.

Results: Immunoblotting from PD effluents revealed discrete bands of occludin (~65 kDa), ZO-1 (~215 kD), claudin-1 (~22 kDa), and claudin-15 (~22kDa) in all 20 patients. Peritoneal KT/V urea, peritoneal creatinine clearance, and ultrafiltration volume did not significantly correlate with the individual TJ protein expression. According to the transport characteristics in PET, patients were grouped into those with low (L, n=3), low-average (LA, n=11), and high-average (HA, n=6). The claudin-15 expression was significantly decreased in HA (68 + 26%, P<0.05) compared with L (102 + 44%) and LA (117 + 34%) whereas the expression of occludin, ZO-1, and claudin-1 were not significantly different between groups. Notably, claudin-15 expression significantly correlated with the decrease in dialysate sodium concentration at 1 h during PET (r=0.47, P<0.05).

Conclusions: In this pilot study, we could detect significant levels of TJ proteins from the PD effluent and suggest the possibility of new peritoneal functional biomarkers. In particular, the roles of peritoneal claudin-15 in PD patients need to be investigated by further studies.

The Effect of Periostin on the Progression of Peritoneal Fibrosis Jae Yoon Park,[1] Jin Ho Hwang,[2] Seung Hee Yang,[3] Kook-Hwan Oh,[4] Yon Su Kim,[4] Jung Pyo Lee.[5] *[1]Dept of Internal Medicine, Dongguk Univ Ilsan Hospital; [2]Dept of Internal Medicine, Chung-Ang Univ Hospital; [3]Kidney Research Inst, Seoul National Univ Hospital; [4]Dept of Internal Medicine, Seoul National Univ College of Medicine; [5]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center.*

Background: Peritoneal fibrosis limits long-term peritoneal dialysis(PD). Periostin,a matricellular protein,was initially identified in osteoblasts as an adhesion molecule during bone formation. Recently,the role periostin has been reported in diverse processes and pathologies in tissue remodeling through the promotion of adhesion,cell survival,cellular dedifferentiation and fibrogenesis. However,its role in peritoneal fibrosis is not known well.

Methods: We investigated expression of periostin in overnight PD effluents using the enzyme linked immunosorbent assays from 127 PD patients and *in vivo* in C57BL/6 mice with peritoneal fibrosis model that was induced by intraperitoneal injection of 0.1% chlorhexidine solution.

Results: Mean periostin protein concentration was 6,543pg/mL in first overnight effluents(1 month after start of PD) and 7,404pg/mL in 1 year effluents of the patients. Peritoneal transport type and equilibration ratios between dialysate and plasma for creatinine were significantly related with the periostin level of the 1 year effluents of the patients. Periostin expression was strongly induced in peritoneal fibrosis model. Periostin was expressed predominantly in submesothelium and in lesser abundance in upper margin of abdominal muscle layer of mice with peritoneal fibrosis. Periostin messenger RNA was increased in peritoneal fibrosis model compared to the control. Messenger RNA expression of monocyte chemotactic protein-1,α-smooth muscle actin,fibronectin and collagen 1 was also increased in peritoneal fibrosis model.

Conclusions: Periostin expression becomes higher in the peritoneal cavity of PD patients and its level can differentiate the peritoneal permeability after 1 year from the start of PD. In addition, periostin expression is related in peritoneal fibrosis in C57BL/6 mice. Thus, our study implicate periostin signaling in the mediation of peritoneal fibrosis as a consequence of PD.

SA-PO1080

Periostin-Binding DNA Aptamer Ameliorates Peritoneal Dialysis-Induced Peritoneal Fibrosis Boyoung Nam,[1] Youn Kyung Kee,[2] Hae-Ryong Yun,[1] Changhwan Seo,[1] Tae-Hyun Yoo.[1,2] *[1]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Peritoneal fibrosis (PF) is a major complication, leading to ultrafiltration failure in patients on peritoneal dialysis (PD). In PD-related PF, the protein expressions of various extracellular matrix including periostin are increased via the transforming growth factor-β1 (TGF-β1) pathway. This study was undertaken to evaluate the impact of periostin inhibition by novel aptamer-based inhibitor on TGF-β1-induced epithelial-mesenchymal transition (EMT) in human peritoneal mesothelial cells (HPMCs) and in an animal model.

Methods: In vitro, HPMCs were exposed to TGF-β1 (2ng/ml) to induce EMT and fibrosis with or without periostin siRNA (100nM) or periostin-binding DNA aptamer (200nM). In vivo, PD catheters were inserted into 48 C57BL/6 mice, and saline (C group, N=24) or 4.25% PD solution (PD group, N=24) was infused for 4 weeks. Twelve mice from each group were treated with periostin-binding DNA aptamer (500μg/kg/d) (PA). mRNA and protein expressions of periostin, fibronectin, α-smooth muscle actin (α-SMA), snail, and E-cadherin in HPMCs and mouse peritoneum were evaluated by real-time PCR and western blot analysis. PF was also assessed by Masson's trichrome (MT) staining.

Results: In vitro, TGF-β1 treatment up-regulated periostin, fibronectin, α-SMA, and snail expressions, while E-cadherin expression was decreased by TGF-β1 in cultured HPMCs ($P<0.01$). Not only periostin siRNA but also periostin-binding DNA aptamer attenuated TGF-β1-induced periostin, fibronectin, α-SMA, and snail expressions and restored E-cadherin expression in HPMCs ($P<0.05$). In vivo, the expressions of periostin, fibronectin, α-SMA, and snail were increased, whereas E-cadherin expression was decreased in the peritoneum of PD mice ($P<0.05$). The thickness of the submesothelial layer and the intensity of MT staining in the peritoneum were higher in PD mice compared to C mice ($P<0.05$).

Conclusions: These findings suggest that PA can be a potential therapeutic strategy for PF in PD patients.

SA-PO1081

Protein Kinase C-β Deficiency Increases Glucose-Mediated Peritoneal Damage in a Mouse Model of Peritoneal Dialysis via Up-Regulation of Protein Kinase C-α Michael S. Balzer,[1] Wang Le,[2] Song Rong,[1] Sibylle Von Vietinghoff,[1] Barbara Hertel,[1] Hermann G. Haller,[1] Nelli Shushakova.[1] *[1]Dept of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Dept of Nephrology, Tongji Medical College, Wuhan, China.*

Background: Peritoneal membrane (PM) damage during peritoneal dialysis (PD) is mediated largely by high glucose-induced pro-inflammatory and neoangiogenetic processes, finally resulting in PM fibrosis and ultrafiltration (UF) failure. We have previously shown that classical protein kinase C (PKC)-alpha exerts glucose-mediated pro-inflammatory properties in a PD mouse model. In other organ systems, PKC-beta similarly exerts glucotoxic effects. In this study we evaluate the role of PKC-beta in glucose-mediated PM damage.

Methods: SV129 WT and PKC-beta$^{-/-}$ mice on SV129 background were subjected to a PM damage model comprising catheter-delivered once-daily treatment with high glucose (4.25%) PD fluid (PDF) for 5 weeks. We performed UF capacity testing, PM histology and immunofluorescence. Peritoneal cellular and cytokine response was analyzed by FACS and ELISA. We further analyzed LPS and PDF-induced inflammatory responses in WT, PKC-alpha$^{-/-}$ and PKC-beta$^{-/-}$ immortalized mouse peritoneal mesothelial cells (MPMC) in vitro.

Results: When compared to WT mice, in PKC-beta$^{-/-}$ mice PDF treatment resulted in disproportionate PM fibrosis and UF failure, marked PM leukocyte recruitment with a high proportion of infiltrating neutrophils and highly significant up-regulation of pro-inflammatory cytokines (MCP1, CXCL2, TNF-alpha, IL-6), TGF-β, and VEGF. In vitro LPS and PDF-stimulated immortalized PKC-beta$^{-/-}$ MPMC demonstrated an increased inflammatory response compared to WT cells, which could be abrogated by additional pharmacological PKC-alpha blockade. This was corroborated by significant mesothelial in vivo and in vitro up-regulation of PKC-alpha in PKC-beta deficiency.

Conclusions: At the PM, PKC-beta exerts anti-inflammatory properties in a glucose-mediated, catheter-based in vivo PD mouse model via regulation of PKC-alpha expression in mesothelium and is essential for adequate inhibition of pro-inflammatory cytokine production and cell influx into the peritoneal cavity in response to PDF treatment.

Inhibition of the H3K9 Methyltransferase G9a Ameliorates Methylglyoxal-Induced Peritoneal Fibrosis Kazuya Maeda, Shigehiro Doi, Toshinori Ueno, Takao Masaki. *Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: According to reports, H3K9 histone methyltransferase G9a activity is induced by transforming growth factor-β1 (TGF-β1) and plays an important role in the progression of cancer and fibrosis. In peritoneal dialysis (PD) patients, long-term exposure to PD fluid causes peritoneal fibrosis through induction of TGF-β1. In this study, we investigated whether inhibition of G9a-mediated H3K9 methylation attenuates peritoneal fibrosis in a mouse model of peritoneal fibrosis and human peritoneal mesothelial cells (HPMCs).

Methods: Peritoneal fibrosis was induced by peritoneal injection of methylglyoxal (MGO) in male C57/B6 mice for 3 weeks. BIX01294 was administered by subcutaneous injection at the same time. In an *in vitro* study, HPMCs were pre-incubated with 2 μmol/l BIX01294 1 hour before stimulation with 5 ng/ml of TGF-β1. In peritoneal dialysis patients, HPMCs were isolated from human peritoneal dialysis effluent.

Results: G9a was upregulated in the peritoneum of MGO-injected mice, TGF-β1-stimulated HPMCs and human PD effluent. Subcutaneous injection of BIX01294, a G9a inhibitor, significantly suppressed submesothelial zone thickness and cell density in MGO-injected mice. Immunohistochemical staining revealed that BIX01294 treatment not only decreases mono-methylation of H3K9 (H3K9me1), but also decreases the number of mesenchymal cells, the accumulation of collagen and the infiltration of monocytes. In addition to pathological change, BIX01294 also inhibited expression of TGF-β1 in peritoneal fluid and improved peritoneal function. Furthermore, BIX01294 treatment inhibited TGF-β1-induced epithelial-mesenchymal transition by suppressing H3K9me1 in HPMCs.

Conclusions: These results suggest that BIX01294 is a candidate drug for reducing peritoneal fibrosis through the suppression of G9a-mediated H3K9 methylation.

Angiotensin Blockade Limits Peritoneal Inflammation Caused by Short-Term Peritoneal Dialysate and Catheter Effects in Rats Tiane Dai,[1] Pei Zhang,[1] Qiaoyuan Wu,[1] Sharon G. Adler,[1] Cynthia C. Nast.[2] *[1]Nephrology, Los Angeles Biomedical Research Inst at Harbor-UCLA Medical Center, Torrance, CA; [2]Pathology, Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Angiotensin blockade is advocated for peritoneal dialysis (PD) patients to preserve residual renal function (RRF). We tested whether losartan, an angiotensin II blocker (ARB) attenuates peritoneal inflammation.

Methods: PD was performed using 4.25% Dianeal (n=6) or 4.25% Dianeal + Losartan (n=6) BID x 10 days in a non-uremic rat model as described (Dai et al, KI 86:1197, 2014). PD fluid was collected for MCP-1, IP10 (aka CXCL10 and mob-1), and VEGF cytokine measurements, and parietal peritoneum was harvested for morphometric analysis of peritoneal membrane thickness. Cytokine measures were log-transformed for normalization and analyzed by 2-tailed t-test. Morphometric data were analyzed similarly without log-transformation.

Results: Morphometric measurements of mean peritoneal membrane width, reflecting peritoneal edema, inflammation, early fibrosis and reactive mesothelium, was higher in rats receiving Dianeal alone (107.5 + 32.5 (SD)) vs Dianeal+Losartan (66.2 + 19.7)($p=0.02$). In PD fluid, there were higher levels of IP10 ($P<0.01$) and VEGF ($P<0.05$), but not MCP-1, in rats with Dianeal+Losartan vs Dianeal alone. Weak correlations were observed between morphometrically measured peritoneal thickness and IP10 ($r = -0.42$) and between peritoneal width and VEGF ($r = -0.38$). In this experimental model, at least in the short-term, losartan limited edema, inflammation, fibrosis, and mesothelial hypercellularity in the peritoneum caused by combined catheter and dialysate exposure.

Conclusions: Apart from their known beneficial impact on RRF, ARBs may also preserve peritoneal integrity by limiting peritoneal injury.

Tamoxifen Attenuates High Glucose-Induced Peritoneal Fibrosis by Reducing β-Catenin Activation In Vivo and In Vitro Pengpeng Yan,[1] Jia Shen,[1] Xuelin He,[1] Hongfeng Huang,[1] Xiang Zhao,[2] Jianghua Chen.[1] *[1]Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China; [2]Dept of Nephrology, The People's Hospital of Zhejiang Province, Hangzhou, Zhejiang, China.*

Background: Peritoneal fibrosis is a severe complication of long-term peritoneal dialysis, which has been successfully attenuated by Tamoxifen in clinic treatment; however, the definite mechanism remains obscure.

Methods: C57BL/6 mice received daily intraperitoneal injection of saline, 4.25% high glucose PDF or PDF combined with Tamoxifen for 30 days, and mouse peritoneal epithelial cells (mPECs) were cultured in 4.25% glucose or combined with Tamoxifen for 48h.

Results: Tamoxifen alleviated thickening of peritoneum, and reversed the expression of E-cadherin, Vimentin and β-catenin induced by PDF in mice model. Furthemore, Tamoxifen diminished epithelial-to-mesenchymal transition, as well as the phosphorylation of GSK3β, nuclear β-catenin and Snail in mPECs after high glucose exposure.

Conclusions: Tamoxifen significantly attenuates EMT progression of peritoneal epithelial in fibrosis pathology partly via suppressing β-catenin signal activation.

Biocompatibility of a New Bicarbonate Containing PD Solution, Reguneal - Measured as In Vitro Proliferation of Fibroblasts Bart Dioos,[1] Goedele Paternot,[1] Rose-Marie Jenvert,[4] Annick Duponchelle,[1] Mark R. Marshall,[2] Souzana S. Deenitchina,[3] Anders Per Wieslander.[4] *[1]Europe R&D, Baxter International Inc, Braine-l'Alleud, Belgium; [2]Therapeutic Area, Baxter Healthcare (Asia) Pte Ltd, Singapore, Singapore; [3]Medical Affairs, Baxter Japan Ltd, Tokyo, Japan; [4]Europe R&D, Baxter International Inc, Lund, Sweden.*

Background: Long term exposure to conventional peritoneal dialysis fluids (PDFs) often leads to peritoneal membrane remodeling and failure. Such fluids typically have suboptimal pH and supraphysiologic concentrations of lactate, and high concentrations of glucose degradation products (GDPs) mainly formed during heat sterilization. Many GDPs are highly reactive carbonyl compounds that are cytotoxic and promoters of advanced glycation end products. To improve biocompatibility, a new bicarbonate-based PDF for Japan has been developed (Reguneal™, Baxter), manufactured in a two-compartment bag and optimized on pH and GDPs. This study investigates biocompatibility of Reguneal™ using a well-established in-vitro fibroblast proliferation assay with neutral red uptake.

Methods: PDFs were diluted 1+1 with tissue cultures media plus 10% serum before 72 h exposure for cytotoxicity testing. Reguneal™ and other enhanced-biocompatibility two-compartment PDFs available in Japan were compared to a lab-made sterile filtered control.

Results: Data are presented as % inhibition of proliferation (mean±SD), from 2 assays / bag in 2 bags of each PDF. The results demonstrate that the Reguneal™ is comparable to the sterile filtered control (i.e. causing no harm for the cells, thus without any cytotoxic effects) and significantly different from other PDFs (P<0.05).

2L PDF Products (% dextrose)	% Inhibition of Proliferation
Baxter Reguneal (2.5%)	4±3
JMS Perisate NL (2.5%)	11±4
Terumo Midpelliq L (2.75%)	19±7
Fresenius Staysafe Balance (2.5%)	17±4
Baxter Dianeal-N (2.5%)	14±3

Conclusions: Recently, others have shown that Reguneal™ improves markers of peritoneal membrane failure in effluent dialysate, compared to conventional PDFs (Taro Hoshino 2016). Using in-vitro biological analysis, we now show that Reguneal™ is a highly biocompatible PDF. Such fluids might help to reduce PDF-induced peritoneal membrane remodeling and failure.

Effects of a Bicarbonate/Lactate-Buffered Neutral Peritoneal Dialysis Fluid on Angiogenesis-Related Proteins in Patients Undergoing Peritoneal Dialysis Hiromichi Ueno, Tetsu Miyamoto, Yumi Furuno, Kenichiro Bando, Junichi Nakamata, Yoko Fujimoto, Yutaka Otsuji, Masahito Tamura. *2nd Dept of Internal Medicine, UOEH, Kitakyushu, Japan.*

Background: Continuous exposure to peritoneal dialysis fluid (PDF) drives pathological responses including peritoneal angiogenesis, resulting in a high peritoneal solute transport rate. Experimental evidence supports the view that high lactate content in PDF is a non-physiological factor that results in the development of peritoneal membrane failure. This study used the antibody array method to evaluate the effects of a newly available bicarbonate/lactate-buffered neutral PDF on the profile of angiogenesis-related proteins in drained dialysate of patients undergoing peritoneal dialysis (PD).

Methods: This was an 8-week crossover trial of 10 PD patients. Five patients each completed 4 weeks of PD using bicarbonate/lactate-buffered neutral PDF (Reguneal-LCa®) or lactate-buffered neutralPDF (Dianeal N PD-4®) and crossed over to the other treatment arm with no change of glucose concentration in the PDF. The concentrations of 19 angiogenesis-related proteins in the dialysate after each treatment were semi-quantitatively determined using the RayBio® C-Series Human Angiogenesis Antibody Array, and were compared between the two treatments.

Results: In the 19 angiogenesis-related proteins investigated, the expression of CXCL1/2/3, which belongs to the CXC chemokine family, significantly decreased after use of the bicarbonate/lactate-buffered PDF compared to the lactate-buffered PDF (P=0.04). The bicarbonate/lactate-buffered PDF tended to lower PDGF-BB and VEGF-D levels in dialysate (P=0.08 and 0.05 respectively). Patients with shorter dialysis period tended to have lower levels of angiogenesis-related protein levels when using the bicarbonate/lactate-buffered PDF. Antibody array-derived values were validated by the enzyme-linked immunosorbent assay.

Conclusions: The bicarbonate/lactate-buffered neutral PDF may modulate the profile of angiogenesis-related proteins, including CXC chemokines, in the effluent of PD patients, suggesting that bicarbonate/lactate-buffered PDF is more biocompatible than lactate-buffered PDF.

SA-PO1087

Neutral Peritoneal Dialysis Solutions Prevent Morphological Changes in the Peritoneal Membrane Mitsuhiro Tawada,[1] Yasuhiko Ito,[1] Chieko Hamada,[2] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Fumiko Sakata,[1] Shoichi Maruyama.[1] *[1]Dept of Nephrology and Renal Replacement Therapy, Nagoya Univ, Nagoya, Aichi, Japan; [2]Dept of Nephrology, Juntendo Univ, Tokyo, Japan.*

Background: The morphological changes induced by bioincompatible peritoneal dialysis solutions are well known. However, the morphological damage induced by long-term peritoneal dialysis neutral solutions has not been reported in detail. The aim of this study was to investigate the effects of pH neutral solutions on the peritoneal membrane.

Methods: This study used pathological and immunopathological techniques to assess peritoneal membrane biopsy samples from peritoneal dialysis patients treated with acidic solutions or neutral solutions.

Results: The morphological changes were compared between the acidic solution group (n=52) and neutral solution group (n=45). According to the analyses, the ratio of lumen diameter to vessel diameter (L/V ratio) was significantly smaller (p<0.01), peritoneal membrane was thicker (p<0.01) and accumulation of advanced glycation end-products (AGEs) was higher (p<0.01) in the acidic solution group than in the neutral solution group. In addition, the L/V ratio in the acidic solution group significantly decreased over time (p<0.01), although no such change was seen in the neutral solution group. There was no significant difference in the number of CD31 positive vessels between the two groups. Furthermore, we compared biopsy samples from subjects in the acidic solution group (n=33) with samples from subjects in the neutral solution group (n=22) who were treated for 4 to 10 years. In this cohort, PD duration was matched between the two groups. Further, while the L/V ratio (p<0.01) and AGEs (p<0.01) were significantly different, there was no significant difference in peritoneal thickness and number of CD31 positive vessels between the two groups.

Conclusions: These findings suggest that neutral peritoneal dialysis solutions prevent morphological changes after long term PD treatment, particularly in terms of vasculopathy.

SA-PO1088

Histopathological Characteristics of Visceral Peritoneal Injury in Patients Treated with Neutral pH Peritoneal Dialysis Solution Maiko Furuya, Yudo Tanno, Yu Honda, Nanae Matsuo, Yukio Maruyama, Ichiro Ohkido, Masato Ikeda, Keitaro Yokoyama, Takashi Yokoo. *Dep of Nephrology and Hypertension, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Encapsulating peritoneal sclerosis (EPS) develops when intestinal peristalsis is inhibited by inflammatory adhesions of encapsulating membrane to visceral peritoneum. Since it is difficult to obtain samples of visceral peritoneum, it could be histopathologically evaluated only at the timing of enterolysis with severe EPS.For that reason, little has been known about characteristics of visceral peritoneal injury in early stage or newly formed membrane-like structure (neomembrane) resulting in encapsulation. We previously reported laparoscopic approach for evaluation of EPS (KI 2012). In this study, we would report macroscopic findings of visceral peritoneum in patients treated with neutral pH solution alone for 4 years or more by laparoscopy, and histopathological investigation of the neomembrane.

Methods: 23 patients underwent laparoscopy at the time of PD catheter removal. Duration of PD in these patients was 66±17 months. Clinically, none of these patients had developed EPS by the time of the investigation. Macroscopic findings of visceral peritoneum were categorized according to color changes, presence of neovasucularizations, neomembranes, and adhesions. Subsequently, neomembranes were pathologically studied.

Results: As compared with laparoscopic findings in patients treated with acidic solution, the degrees of color changes, presence of neovascularizations, and adhesions were all mild. Neomembranes identified in 5 patients were all soft and elastic. None of them had severe adhesions to the visceral peritoneum, and intestinal peristalsis under the neomembrane was maintained. In pathological findings, the neomembrane showed no mesothelial cells, presented with discontinuous and undeveloped elastic fibers different from the existing biomembranes, and had no inflammatory cellular infiltration or fibrin deposition.

Conclusions: Unlike encapsulating membrane in EPS, neomembrane observed in patients receiving neutral pH PD solution had no inflammatory adhesions to the visceral peritoneum, suggesting its lower effect on intestinal peristalsis.

SA-PO1089

Ferric Pyrophosphate Citrate (Triferic) Delivery via Peritoneal Dialysate for Iron Supplementation in Rats Ajay Gupta, John E. Dillberger, Raymond D. Pratt. *Rockwell Medical Inc., Wixom, MI.*

Background: Iron deficiency is commonly present in peritoneal dialysis (PD) patients. Intraperitoneal (IP) route is convenient and merits investigation for iron delivery. In previous animal studies IP iron dextran was found ineffective in delivering iron in CKD-PD patients (Moniem et al, 2007), while causing iron deposition, inflammation, and fibrosis in peritoneal membrane. Soluble $FeCl_3$ by IP administration also failed to increase serum iron levels in an animal study (Suzuki et al, 1994). Administration of ferric pyrophosphate citrate (FPC, Triferic®) via hemodialysate is safe and effective in maintainin iron balance and hemoglobin in CKD-HD patients (Fishbane et al, 2015). We have examined toxicity (T) and toxicokinetics (TK) of intraperitoneal FPC in iron-replete rats.

Methods: Rats with chronic implanted catheters were administered intraperitoneally 10 mL/kg of either vehicle (Dianeal 1.5%) or FPC (50, 150, or 450 µg iron/kg with 1.5%Dianeal) over ~1 minute, 3 times/week for 4 weeks (T animals, n=30 each group). Using similar procedure, another group of animals were administered vehicle (n=6) or FPC (n=18/dose group) according to the same schedule for determination of serum iron parameters (TK animals). Animals were euthanized at the end of the dosing period or after a 3-week recovery period.

Results: FPC did not cause any significant histologic changes in peritoneal membrane and abdominal organs including liver. There was a dose dependent increse in total serum iron and transferrin saturation (TSAT) with each dose of Triferic.

FPC induced increase in serum iron lvels and peak TSAT achieved in TK animals

Dose (µg FPC iron/kg body weight)	Increase in serum iron above baseline (µg/dL)	Peak TSAT
50	91	55%
150	124	64.5%
450	278	88%

There was no histologic evidence of systemic iron accumulation.

Conclusions: IP infusion of Triferic is effective in increasing circulating serum iron levels and TSAT in iron-replete rats with no significant local toxicity. Delivery of Triferic via perioneal dialysis merits further investigation in CKD-PD patients.

Matrine Prevents Escherichia Coli Biofilm Formation Through Blockade of Outer Membrane Protein A Expression Yun-Hua Ma, Yunhua Liao, Xi Peng. *Renal Div, Dept of Medicine, First Affiliated Hospital of Guangxi Medical Univ, Nanning, Guangxi Zhuang Autonomous Region, China.*

Background: Escherichia coli (E.coli) is the common pathogenic bacteria causing peritoneal dialysis (PD)-associated peritonitis. In our previous studies we found that sophora flavescens had the interventional effect of E.coli biofilm (BF) formation. However, the precise mechanism is largely unknown. The present study is to investigate the relationship between matrine and OmpA expression.

Methods: We established a model of matrine interfere with E.coli biofilms in vitro. We observe the effect of effective of E.coli BF formation using the crystal violet staining. Detecting the expression of OmpA mRNA in different stages of BF formation by real-time fluorescence quantitative PCR.

Results: The minimum inhibitory concentration (MIC)for E.coli of Matrine and levofloxacin were 4096µg/ml and 0.015625 µg/ml, respectively. In presence of 1/2MIC matrine at 1,3 and 7days, the E.coli viable counts was significantly increased from111.3±12.9 ×104 CFU/ml 155.4±18.6×104 CFU/ml, 163.9±8.0 ×104 CFU/ml to 71.0 ±5.7 ×104 CFU/ml in the buffer control , to 89.0±11.1 ×104 CFU/ml, 69.1±5.7 ×104 CFU/ml in 1/2MIC matrine group(P<0.001), respectively. There was no significant difference between 1/2MIC levofloxacin group and 1/2MIC matrine group (P>0.05). Consistently, the biofilm formation capacity of each strain was estimated using the crystal violet staining. Compare with the buffer control, the OD_{570} values was significantly decreased from 0.956±0.118, 1040±0.335, 1.119±0.245 to 0.694±0.184, 0.689±0.098, 0.504±0.133(P<0.001) in different stages of BF formation, respectively.The aforementioned effect was significantly attenuated in OmpA mRNA expression(P<0.001).

Conclusions: Matrine prevents E.coli biofilm formation through blockade of OmpA mRNA expression in vitro.

Pig Trial of Automated Wearable Artificial Kidneys Based on Peritoneal Dialysis Martin Roberts, Christian G. Bluchel, Jezreel S. Zaragosa. *Nephrology, VA Sepulveda, UCLA Geffin, AWAK Technologies, Los Angeles, Burbank, CA; Biomedical Engineering Research Centre, Temasek Polytechnic, Singapore, Singapore; AWAK Technologies LTD, Singapore, Singapore.*

Background: We have developed an automated wearable artificial kidney (AWAK PD) using Tidal PD. To test the safety and efficacy of the AWAK PD we needed a pig PD model. There are no reports in the literature of pigs maintained on PD other than our recently published abstracts on CAPD and APD. Our objective was to maintaining pigs on the AWAK PD for 1 week.

Methods: The pigs were received in 2 groups. Group 1 consisted of 2 pigs, average weight 20.5 kg and group 2 of 4 pigs, average weight of 40 kg. The pigs were 5/6 nephectomized by removing 2/3 of the left kidney and the whole right kidney. A Tenckhoff catheter and central venous line was installed. CAPD with 2.5% Dianeal was performed during which the fill volume was increased from 0.5 to 1 L. Afterwards the pigs were maintained on APD. PD was conducted through a tether system linking the tether-end plate in the jacket worn by the pig and a swivel arrangement. The system provided the pig with unrestrained movement within the cage while protecting the integrity of the catheter line and the exit-site. Blood and dialysate samples were assayed for urea, creatinine and phosphorus and the volume of the drained dialysates measured.

Results: Both pigs in group 1 developed hernias which were partially restrained with bandages. In addition, 1 pig was excluded because of puncture of the peritoneal catheter. One pig in group 2 was excluded because of peritonitis during APD. Ninety 7hr dialyses were averaged to give clearances and standard deviations of urea,12.3 ±1.6, creatinine 5.8 ±1.1, and phosphorus 10 ±2.8. Average weekly Kt/V/SD of urea was 5.2 ±2. Daily ultrafiltration in group 1 was negative due to the hernia and in group 2 was 1275 ±349. All the pigs continued to have urine output.

Conclusions: Four pigs were successfully maintained for 1 week on the AWAK PD. The AWAK PD was safe and effective. Kt/V was adequate to maintain a 5/6 nephrectomized pig. Ultrafiltration was negative in the first group because of hernia leakage. The second group had adequate UF.

SA-PO1092

The Dialysate Losses of Vitamin D-Binding Protein Do Not Predict Their Impaired Physiological Function Thalita Moura Santos Braga, Erica Adelina Guimarães, Rodrigo Souza Adao, Wagner Dominguez, Fabiana Graciolli, Hugo Abensur, Rosilene M. Elias, Rosa M.A. Moyses. *Nephrology, Faculty of Medicine, Univ of São Paulo, São Paulo, Brazil.*

Background: Vitamin D-binding protein (VDBP) transports and prolongs the serum half-life of 25-hydroxyvitamin D (25OHD). Patients on peritoneal dialysis (PD) lose VDBP to the dialysate, which aggravates as the therapy extends. However, whether VDBP loss in patients on PD has any clinical importance and compromises its biological role is not known.

Methods: Dialysate and serum VDBP levels were measured in 13 adults on automatic peritoneal dialysis (APD). Concentrations of serum free (FDBP), bioavailable (Bio-DBP), and VDBP-bound 25(OH)D (VDBP-D) were calculated, as well as the amount of total dialysate lost in 24-hour. The patients were submitted to peritoneal equilibrium test and nutritional status evaluation by subject global assessment (SGA) and bioimpedance analysis. 25OHD, alkaline phosphatase (AP), lipid profile, 24-hour total protein and albumin lost were also assessed.

Results: Patients aged 43±15 years (69.2% women), on APD for 23 months. Nine patients (69.2%) were classified as well nourished/mild nutritional risk (WN/MNR) and 61.5% had high/high average transport (H/HA) characteristics. Serum FDBP correlated with AP (r=-0.621, p=0,024) and LDL (r=0.616, p=0.025). Bio-DBP correlated with 25OHD (r=-0.600, p=0.039); VDBP-D correlated with total (r=-0.567, p=0.043) and LDL cholesterol (r=-0.737, p=0.004). The dialysate VDBP concentration correlated with HDL (r=0.634, p=0.049) and SGA (r=0.758, p=0.029). The 24-hour loss of VDBP correlated with the 24-hour loss of albumin (r=0.806, p=0.005), muscle mass (r=0.857, p=0.007) and bone mass (r=0.738, p=0.037). The serum Bio-DBP was higher among WN/MNR patients than in those with mild/moderate malnourished (5.6±2.9 *vs.* 2.0±0.0 mcg, p=0.030). VDBP did not differ between H/HA and low/low average transporters.

Conclusions: The loss of VDBP through the dialysate occurs in parallel with albumin loss and depends on nutritional status and muscle reserves, but not peritoneal permeability. High total and LDL cholesterol may result in reduced biological function of VDBP in patients on APD.

SA-PO1093

The Effect of Low-Calcium Peritoneal Dialysis Solution in Transperitoneal Calcium Balance in Peritoneal Dialysis Patients Sandra Beltrán, Belen Vizcaino, Pablo Molina, Mercedes Gonzalez, Luis M. Pallardo. *H. Univ Dr. Peset; H. Univ Dr. Peset; H. Univ Dr. Peset.*

Background: Despite that guidelines recommend the use of low-calcium peritoneal dialysis solution, its use is not very extended in the current practice.

The objective of the study was to analyse the effect of low-calcium peritoneal dialysis solution on the mineral metabolism and the transperitoneal balance of calcium on a cohort of patients that started Peritoneal Dialysis (PD).

Methods: Prospective observational study of 44 patients starting PD between May 2013 to September 2015. We compared data after one year of treatment with low-calcium peritoneal dialysis solution. The transperitoneal calcium balance was calculated on the 24 hours peritoneal effluent collection according to the formula for peritoneal mass transfer as: (Concentration of Calcium x Drained volume)-(Concentration of Calcium x Infused volume).

Results: Mean follow up period was 14±8 months. Serum calcium remained stable (9.3±0.6 to 9.2±0.5 mg/dL, p=<0.39), no episodes of hipocalcemia were reported. PTH-i increased not significantly (254±148 to 282±162 pg/mL, p=0.28), serum phosphorous slightly increased (4.5±1.2 to 4.9±1.61 mg/dL, p=0.04). Residual Renal Function decreased significantly after one year of follow up (7.8±3.5 to 6.09±4.0 ml/min /1.73 mm^2, p=0.005). Nine patients with (PTH-i< 150 pg/mL), significantly increased their level of PTH-i (94.2±38.7 to 221±145 pg/mL, p=0.020). Nineteen patients had hipercalcemia (Serum Ca >9.5 mg/dL) at the start of PD, and except one, all of them normalized their calcium levels

after treatment. (9.8±0.26 to 9.5±0.23 mg/dL, p=0.001). The transperitoneal calcium balance was negative (-37 mg/dl/day. IC 95% -54 to -237). We did not find significant differences on the transperitoneal balance of calcium depending on the peritoneal membrane transport.

Conclusions: The use of low calcium peritoneal dialysis solution is safe, and is associated to a slight negative calcium balance with a good control of PTH-i levels. Moreover, patients with low PTH-i levels could improve with this strategy. Our results support guidelines recommendations of using low-calcium peritoneal dialysis solution in our PD patients.

SA-PO1094

Restored Stress Responses and Immune Competence in Clinical Peritoneal Dialysis Effluents Explored by a High Performance Multi-Omics Approach

Klaus Kratochwill,[1,2] Rebecca Herzog,[1,2] Seth L. Alper,[3] Andreas Vychytil,[4] Christoph Aufricht.[4] *[1]Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Medical Univ of Vienna, Austria; [2]Zytoprotec GmbH, Austria; [3]Beth Israel Deaconess Med Ctr, Harvard Medical School, Boston, MA; [4]Medical Univ of Vienna, Austria.*

Background: Although PD effluent (PDE) represents a rich source of protein biomarkers for monitoring disease and therapy, the presence of high-abundance plasma proteins in PDE has limited proteomics analysis of its constituents. Here we report a search for PDE biomarkers following patient treatment with a novel PD fluid, using highly sensitive proteomics analysis of enriched low-abundance proteins, combined with metabolome and transcriptome analyses.

Methods: In 2 randomized cross-over trials, PD patients (n=26) received either standard PD fluid or PD-protec™ (same fluid with 8 mM alanyl-glutamine). PDE supernatants were directly used for metabolomics or were depleted of high-abundance plasma proteins, and resulting enriched low-abundance proteins were subjected to TMT-labeling and filter-aided sample preparation liquid chromatography coupled to mass spectrometry (FASP-LC-MS). Cellular fractions were analyzed by microarrays and RNA sequencing.

Results: Using this workflow, PDE proteome coverage was increased 18-fold as compared to combined existing literature. The proteins identified in PDE include representatives of biological processes and pathways previously undetected in PDE proteomes. Proteins linked to membrane remodeling and fibrosis were overrepresented in standard PDE compared to plasma, whereas underrepresented proteins indicate decreased immune competence. PDE from patients treated with PD-protec™ exhibited restoration of proteomic and transcriptomic indicators of important immune processes.

Conclusions: Our data suggests feasibility of a novel proteomics technique to investigate cell-derived biomarkers for PD pathomechanisms. Treatment with PD-protec™ was associated with restoration of immunorelevant biomarkers. These results indicate that PDE biomarkers may serve as surrogates for evaluation of novel interventions in PD, providing novel tools for monitoring PD therapy.

Low Dentin Matrix Protein 1 Is Associated with Incident Cardiovascular Events in Peritoneal Dialysis Patients

Min-Uk Cha, Chang-Yun Yoon, Hyoungnae Kim, Youn Kyung Kee, Tae-Hyun Yoo. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Recent reports demonstrated that dentin matrix protein 1 (DMP1) acts as an inhibitor of vascular calcification (VC). We investigated the prognostic value of DMP1 on cardiovascular outcomes in prevalent peritoneal dialysis (PD) patients.

Methods: We recruited 223 prevalent PD patients and measured DMP1 levels. Lateral lumbar spine radiographs were used for measurement of VC. Major cardiovascular events were compared between the two groups. In vitro, osteocytes were cultured in media containing indoxyl sulfate (IS), then the expressions of DMP1 were examined.

Results: The mean age was 52.1±11.8 years, and 116 (52.0%) patients were male. The median value of log DMP1 was 0.91 (0.32–2.81 ng/ml). The multiple logistic regression analysis indicated that DMP1 levels were independently associated with the presence of VC after adjustment for multiple confounding factors (P=0.005). In IS-stimulated osteocytes, transcript and protein expression levels of DMP1 were significantly decreased compared to control osteocytes. During a mean follow-up duration of 34.6 months, incident cardiovascular events were observed in 41 (18.4%) patients. A Kaplan-Meier plot showed that the low DMP1 group had a significantly higher rate of incident cardiovascular events compared with the high DMP1 group (log-rank test, P=0.026). In addition, multiple Cox proportional hazard analysis showed that low DMP1 was significantly associated with incident cardiovascular events (P=0.029) after adjustment for multiple confounding factors.

Conclusions: DMP1 might be considered the novel factor that contributing the pathophysiology of cardiovascular disease in dialysis patients.

SA-PO1096

The Effects of Peritoneal Effluent Mitochondrial DNA on Intraperitoneal Inflammation and Peritoneal Solute Transport Rate in Peritoneal Dialysis

Xishao Xie, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Local chronic intraperitoneal inflammatory status commonly affects peritoneal dialysis (PD) patients. Mitochondrial DNA (mtDNA) released into extracellular subsequent to cell injury and death can promote inflammation in patients and animal models. However, the effects of peritoneal effluent mtDNA on intraperitoneal inflammation and peritoneal solute transport rate (PSTR) in PD patients remain unclear. We aimed to examine the peritoneal effluent mtDNA and elucidate their relationship with intraperitoneal inflammation and PSTR.

Methods: We select the incident patients who began PD therapy at the First Affiliated Hospital of Zhejiang University between January 1, 2009, and December 30, 2010. Peritoneal dialysis effluent was collected at the time of peritoneal equilibration test. The peritoneal effluent mtDNA was detected by quantitative real-time PCR assay, the concentrations of dialysate IL-6, IL-17A, TNF-α and IFN-γ were quantitated by ELISA assay. The results were compared with PSTR, patient survival and technique survival.

Results: One hundred and eighty-nine patients were included in the study. The average age was 47.1 ± 13.5 years, 55.6% of the patients were males. The median follow-up period was 41.9 months. The average PSTR was 0.66 ± 0.12, the median mtDNA level was 4325 copies/ul. The median concentrations of IL-6, IL-17A, TNF-α and IFN-γ were 25.9, 10.8, 25.8 and 17.9 pg/ml, respectively. We found that peritoneal effluent mtDNA was significantly correlated with PSTR (r =0.461, P < 0.001), IL-6 (r = 0.568, P < 0.001), TNF-α (r = 0.454, P < 0.001) and IFN-γ (r = 0.203, P = 0.005). After adjustment for multiple covariates, peritoneal effluent mtDNA was independently correlated with IL-6 and PSTR. Peritoneal effluent mtDNA was not associated with patient and technique survival.

Conclusions: We found that theperitoneal effluent mtDNA level correlated with the degree of intraperitoneal inflammatory status in PD patients. Peritoneal effluent mtDNA was an independent determinant of PSTR but did not affect patient and technique survival.

SA-PO1097

Irisin Levels and Adequate Dialysis in Nondiabetic Peritoneal Dialysis Patients

Hui Peng, Zhijun Tan, Zengchun Ye, Cheng Wang, Xun Liu, Tan-Qi Lou. *Div of Nephrology, Dept of Medicine, 3rd Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guangdong, China.*

Background: Irisin is a recently discovered hormone thought to be involved in energy regulation. However, only a single study has focused on irisin levels in peritoneal dialysis patients, but that study did not control for multiple factors. Therefore, it remains unclear whether irisin is affected by dialysis adequacy or whether irisin is associated with protein-energy wasting and insulin resistance in chronic kidney disease.

Methods: Atotal of 59 nondiabetic peritoneal dialysis (PD) patients and 52 healthy controls were enrolled in this cross-sectional study. Case histories and blood, urine, and dialysate samples were analyzed. Serum irisin levels were measured by ELISA and compared between the two groups.

Results: Serum irisin levels were lower in nondiabetic PD patients (median (interquartile range): 17.02 (11.27-20.09) ng/ml) compared with age- and sex-matched healthy controls (22.17 (17.00-26.57) ng/ml). Multivariate regression analysis revealed that fasting glucose levels were inversely correlated with serum irisin levels in PD patients. No association of serum irisin levels with homeostatic model assessment of insulin resistance was observed, nor was there an association between the Geriatric nutritional risk index and serum irisin levels. Conversely, peritoneal Kt/Vurea (β=4.933; 95% CI, 0.536-9.331; P =0.029) and peritoneal C_{Cr} (β= 0.259; 95% CI, 0.053-0.465; P=0.015) were positively associated with serum irisin levels among PD patients.

Conclusions: Serum irisin levels in non-diabetic PD patients were lower than those in healthy controls, and peritoneal Kt/V and creatinine clearance were positively correlated with serum irisin levels. Thus, adequate dialysis may improve irisin secretion.

Peritoneal Dialysis Removes More Serum Sclerostin Than Hemodialysis in Uremic Patients

Lin Yang,[2] Lihua Luo,[1] Yaohui Chen,[2] Chunyan Lang,[2] Zhenhua Liu,[2] Yun Li.[2] *[1]Nanchang Univ, School of Medicine, Nanchang, Jiangxi, China; [2]Dept of Nephrology, Jiangxi Provincial People's Hospital, Nanchang, Jiangxi, China.*

Background: It's not known whether PD could remove serum sclerostin in uremic patients or not. This study observed the removal of sclerostin by PD and compared the difference of the removal of it between PD and HD.

Methods: Subjects in four groups were from Jiangxi Provincial People's Hospital. Control: 56 healthy volunteers; CKD5: 24 cases in stage 5 CKD but not on dialysis; HD: 42 cases on HD; PD: 100 cases on PD (only 81 serum samples). Sclerostin was determined with ELISA kit.

Results: (1) Compared with control, serum sclerostin in CKD5 and HD groups was increased, with it was higher in CKD5 than in HD, the differences among all groups were statistically significant (P < 0.05); on the other hand, sclerostin in serum and PD fluid in PD group was close to that in control.

Table1-1. Sclerostin in each group (Mean±SD)					
	Control	CKD5	HD	PD(serum)	PD(Fluid)
Sclerostin(pg/ml)	6.59±2.30	10.79±3.25	8.76±3.50	6.25±4.96	5.13±1.42
Table1-2. Sclerostin in PD group patients stratified by age					
	Number	Mean	SD	P	
1(≤45yrs, serum)	41	5.89	5.577		
2(>45yrs, serum)	40	6.06	3.271	0.868	
1(PD fluid, PD fluid)	48	5.10	1.470		
2(PD fluid, PD fluid)	52	5.16	1.326	0.836	
Table1-3. Sclerostin in PD group patients stratified by PD time					
1(≤12mos, serum)	58	5.27	3.810		
2(>12mos, serum)	23	7.74	5.778	0.068	
1(≤12mos, PD fluid)	72	5.1	1.344		
2(>12mos, PD fluid)	28	5.2	1.527	0.76	

(2) Patients in PD group were stratified according to age (45yrs or older) or PD time (on PD for 12 months or longer). For resulting groups, the differences in serum or PD fluid sclerostin were all not statistically significant (P>0.05) (Table1-2, 1-3).

Conclusions: Serum sclerostin was increased in CKD5 patients than in normal individuals. HD and PD both could remove serum sclerostin while PD removed more. Patient's age and time in PD had no effects on the removal of it in PD group. The findings could provide insights for CKD-MBD pathogenesis in CKD patients and the basis for choosing dialysis modes.

Relationship between Glucose Spike and Cardiovascular Risk Factors in Diabetic Patients with Peritoneal Dialysis: A Cross-Sectional Study

Kenji Harada,[1] Shigeru Tanaka,[2] Hidetoshi Kanai.[1] *[1]Div of Nephrology, Kokura Memorial Hospital, Kitakyusyu, Fukuoka, Japan; [2]Div of internal medicine, Fukuoka Dental College, Fukuoka, Japan.*

Background: Several reports have reported that glucose spike (GS), postprandial increase in blood glucose, may be a risk factor for mortality and CVD incidence in patients with diabetes. We investigated relationship between glucose spike and cardiovascular risk factors in diabetic PD patients.

Methods: We measured diurnal variation in blood glucose for 7 days using continuous glucose monitoring (CGM, *ipro2: Medtronic, Northridge, CA, USA*). GS was defined as mean amplitude of glycemic excursion (MAGE), which calculated as an average value of times exceed over 1SD of average blood glucose. We evaluated relationships between MAGE and cardiovascular risk factors, including HbA1c, GA, blood pressure (BP), peritoneal function, echocardiographic findings, pulse wave velocity (PWV).

Results: Overall, 22 diabetic PD patients were included (mean age; 65.7 year old, male/female; 16/6, average PD vintage; 31 months). Median value of MAGE was 60±22.85. We deviated participants into two groups; Low MAGE (<60) group and high MAGE (≥60) group. Low MAGE group was older, longer PD vintage and lower PWV levels. There was no difference in HbA1c, ejection fraction, BP, peritoneal function, past history of CVD, and smoking between two groups. In the multiple regression analysis, higher level of MAGE was an independent predictor for worsening PWV (P=0.0045).

Conclusions: Higher MAGE was strongly correlated with high level of PWV. Even after adjusting by cardiovascular risk factors, higher level of MAGE was an independent predictor for PWV. These results suggest that GS might be involved in atherosclerosis progression in diabetic PD patients.

SA-PO1100

Adequacy of a Single Daily Icodextrin Exchange as Initial Therapy for Incident End-Stage Renal Disease Patients with Residual Kidney Function: Predictions from the Three-Pore Model

Baris U. Agar, J. Ken Leypoldt, James A. Sloand. *Baxter Healthcare, Deerfield, IL.*

Background: Incremental dialysis is the treatment of ESRD patients with gradually increasing dialysis doses in response to declines in their residual kidney function. Incremental PD may impose fewer restrictions on patients' lifestyle, help attenuate lifetime peritoneal and systemic exposure to glucose and its degradation products, and minimize connections that could compromise the sterile fluid path. In this study, we utilized a three-pore kinetic model to assess fluid and solute removal for single daily icodextrin regimens for patients with varying glomerular filtration rates (GFR).

Methods: Single icodextrin exchanges of 8 to 16 hours using 2 and 2.5 L bag volumes were simulated for different patient transport types (i.e. high to low) to predict daily peritoneal ultrafiltration (UF), daily peritoneal sodium removal, and weekly total (peritoneal + residual kidney) Kt/V (Kt/V_{Total}) for patients with GFRs ranging from 0 to 15 mL/min/1.73m^2. Adequacy of treatments was assessed based on weekly $Kt/V_{Total} \geq 1.7$.

Results: Daily peritoneal UF varied from 359 to 607 mL and daily peritoneal Na removal varied from 52 to 87 mEq depending on length of icodextrin exchange and bag volume. Both were effectively independent of patient transport type. GFR needed to achieve adequate dialysis varied between 5 and 10 mL/min/1.73m^2 depending on patients' total body water (TBW) and bag volume.

Single Daily Icodextrin	GFR needed to achieve weekly $Kt/V_{Total} \geq 1.7$			
	TBW: 30L (55 kg)	TBW: 40L (73 kg)	TBW: 50L (91 kg)	TBW: 60L (109 kg)
2L	6	8	9	10
2.5L	5	7	9	10

Conclusions: A single daily icodextrin exchange can be tailored to provide adequate UF and Na removal in incident ESRD patients with sufficient RKF. UF and Na removal are relatively independent of patient transport, but achieving an adequate Kt/V_{Total} is highly dependent upon TBW/BSA. Smaller patients (i.e. 55 kg) may achieve adequate dialysis (weekly $Kt/V_{Total} \geq 1.7$) with GFR as low as 6 mL/min/1.73m^2. A solitary icodextrin exchange may therefore be reasonable initial therapy for some incident ESRD patients. Potential lifestyle and clinical benefits need to be evaluated.

The Role of Inflammation in the Effect of BMI on Patient Survival in Peritoneal Dialysis Patients: Results from the GLOBAL Cohort Study

Mark Lambie, Emma H. Elphick, Simon J. Davies. *Inst for Applied Clinical Research, Keele Univ, Stoke on Trent, United Kingdom.*

Background: A higher body mass index (BMI) is known to predict better survival in haemodialysis, with a recent report demonstrating that this is primarily in patients with high levels of systemic inflammatory markers. Studies of patients on peritoneal dialysis (PD) have not shown a consistent relationship between BMI and survival but the reasons for this are unclear. We hypothesised that the reason for the lack of association in previous studies was due to lower levels of systemic inflammation in PD patients.

Methods: We used incident (measures within 3 months of starting) and prevalent PD patients from the Global Fluid Study, a cohort study of 10 centres from Korea, Canada and the UK. Plasma samples were assayed for IL-6 and a contemporaneous BMI was measured. The primary analysis was Cox regression stratified by centre testing the effect of BMI in a univariable model on patients with plasma IL-6 above median, with sensitivity analyses including using plasma IL-6 levels above the 75th centile, testing plasma IL-6 and BMI for an interaction, using patients with albumin levels <35g/l and <30g/l and testing for an effect of dialysate glucose load and restricting the analysis to 1 year follow up.

Results: Of the 559 incident and 376 prevalent patients, 241 and 186 respectively died during follow up. The median and 75th centile for plasma IL-6 levels were 1.49 and 2.83 in incident patients and 1.26 and 2.46 in prevalent patients respectively. There was no benefit of BMI in the inflamed group in either incident (HR 1.03, 95% CI 0.99-1.07) or prevalent (HR 0.98, 95% CI 0.95-1.02) patients. This pattern was replicated in patients with plasma IL-6 levels >75th centile and there was no interaction between IL-6 and BMI in either incident or prevalent patients. There was no benefit in patients with albumin levels <35g/l or <30g/l, nor any interaction or effect of dialysate glucose load.

Conclusions: The protective effect of BMI for inflamed haemodialysis patients is absent in inflamed peritoneal dialysis patients. This might be due to the extra caloric loading in PD but it is not affected by the amount of dialysate glucose prescribed.

SA-PO1102

Association between Diuretic Use and Residual Kidney Function in Peritoneal Dialysis Patients: International Comparison from the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS)

Simon J. Davies,[1,5] Junhui Zhao,[2] Brian Bieber,[2] Bruce M. Robinson,[2] Angela Yee Moon Wang,[3,5] Jeffrey Perl.[4,5] *[1]Keele Univ, Stoke-on-Trent, United Kingdom; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Univ of Hong Kong, Hong Kong, China; [4]Univ of Toronto, Toronto, ON, Canada; [5]On Behalf of the PDOPPS Dialysis Prescription and Fluid Management Workgroup, Ann Arbor, MI.*

Background: Preservation of residual kidney function (RKF), as determined by urine volume or mean urea and creatinine clearances (GFR_r), is strongly associated with better survival on dialysis. Modest sized trials have demonstrated that diuretics can maintain urine volume and that renin angiotensin system inhibitors (RASi) might preserve RKF in PD patients.

Methods: The PDOPPS is a prospective cohort study of PD treatment and outcomes in Australia, Canada, Japan, New Zealand, Thailand, the United Kingdom and the United States (US). Based on an initial cross-section of 1,655 patients in Australia, Canada, Japan and US, linear models were used to estimate the associations of diuretic, ACEi/ARB use with 24-hour urine volume and GFR_r.

Results: Among patients with RKF,diuretic use was highest in Japan (74%) and lowest (39%) in Australia. ACEi and/or ARB use was highest in Japan. In adjusted models, greater urine volume and higher GFR_r were associated with shorter PD vintage and diuretic use, but not with ACEi or ARB use.

Table 1a) Patient characteristics by country

	Australia	Canada	Japan	US
Number of patients	198	402	522	533
24-hour urine volume measurement in 8 months	70%	76%	58%	94%
Prior HD	27%	27%	26%	38%
Anuric	6%	12%	5%	20%
24-hour urine volume (L), median [IQR]	0.98 [0.48,1.49]	0.75 [0.32,1.29]	0.73 [0.30,1.21]	0.55 [0.10,1.15]
Weight (Kg) , mean (std)	79.6(18.8)	76.7(19.3)	59.5(12.4)	81.2(21.8)
GFR, (mL/min/1.73m^2) , median [IQR]	4.0 [1.5,6.4]	4.0 [1.6,6.2]	0.7 [0.3,3.5]	2.9 [0.5,6.6]
Diuretic use for patients with urine output	39%	60%	74%	51%
ACEi	27%	29%	7%	20%
ARB	22%	27%	62%	24%
PD vintage (years), mean (std)	1.9(1.8)	2.4(2.7)	3.1(3.0)	2.1(2.0)

Table 1b) Effect estimates with 95% CI for PD vintage, Diuretic, ACEi, and ARB in two models*

	Model Outcomes	
	log(24-hour Urine Volume+1)/Weight*100	log(GFR,+1)
PD vintage	-0.06(-0.07,-0.04)	-0.12(-0.15,-0.09)
Diuretic	0.14(0.06,0.21)	0.16(0.02,0.29)
ACEi	0.04(-0.06,0.13)	0.10(-0.07,0.26)
ARB	-0.03(-0.11,0.05)	-0.02(-0.17,0.13)

*Models adjusted for PD vintage, patient age, black race, gender, and diabetes, accounting for facility clustering.

Conclusions: Diuretic use is strongly associated with urine volume in this early cross-sectional analysis. As the study accrues follow-up time, PDOPPS will provide important longitudinal data on practice variation and outcomes to evaluate the role that diuretics may play in preserving residual kidney function among PD patients.

SA-PO1103

Substantial Decrease in Renal Function and Quality of Life in Peritoneal Dialysis Patients with Diabetes Mellitus after Discontinuation of Vasopressin-2-Receptor Antagonist, Tolvaptan Takeyuki Hiramatsu, Yuko Asano, Masatsuna Mabuchi, Akiko Ozeki, Hideaki Ishikawa, Shinji Furuta. *Dept of Nephrology, Konan Kosei Hospital, Konan, Aichi, Japan.*

Background: Last year we reported that tolvaptan preserved residual renal function in peritoneal dialysis (PD) patients. Here, we followed the patients after tolvaptan discontinuation.

Methods: Twenty four incident PD patients with congestive heart failure were followed for 24 months. Patients were divided into two groups, group A (n=15) and group B (n=9). In group A, patients received 15 mg/day of tolvaptan from the initiation of PD, and in group B, tolvaptan was administered when urine volume lowered below 500 ml/day. We evaluated the medical costs, urine volumes, urine Kt/V, quality of life (QOL) assessed with Short – Form Health Survey (SF-36), and comorbidities which occurred during 12 months after tolvaptan discontinuation.

Results: In group A, urine volume, urine Kt/V, and QOL scores were substantially decreased after tolvaptan discontinuation(* : p<0.05 vs at baseline).

		before 6 months	at baseline	after 6 months	after 12 months
Residual renal function	urinary volume (mL/day)	1080.0 ± 465.7	984.0± 490.0	650.0 ± 484.2	552.0 ± 414.1*
	urine Kt/V	0.862 ± 0.362	0.831 ± 0.452	0.455 ± 0.359*	0.306 ± 0.256*
SF - 36	summary of physical components	38.6 ± 13.8	37.8 ± 13.4	28.3 ± 13.2*	25.1 ± 10.6*
	summary of mental components	51.2 ± 9.0	49.6 ± 9.4	48.4 ± 11.3	40.6 ± 9.2

Hospitalization was seen in total 9 patients (6 for heart failure, 1 for myocardial infarction, 2 for severe infection), 2 patients died, and 2 patients were switched to hemodialysis (HD). Eleven patients continued on PD. In group B, all patients showed that urine volume was not increased by tolvaptan use, however decreased to 0 mL within 6 months after tolvaptan discontinuation. Moreover 3 patients died, 6 were switched to HD in group B. The medical costs were also increased in group B.

Conclusions: After discontinuation of tolvaptan, renal function and QOL were substantially decreased in PD patients. Residual renal function was thought to be important for the survival and QOL in PD patients.

SA-PO1104

Association of Plasma Brain Natriuretic Peptide Concentration with Loss of Residual Renal Function in Peritoneal Dialysis Patients Yasuhiro Kawai,[1] Shigeru Tanaka,[2] Masatoshi Hara,[1] Hiroaki Tsujikawa,[1] Hisako Yoshida,[3] Kazuhiko Tsuruya,[1,4] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka City, Fukuoka Prefecture, Japan; [2]Div of Internal Medicine, Fukuoka Dental College, Fukuoka City, Fukuoka Prefecture, Japan; [3]Dept of Clinical Research Center, Saga Univ, Saga City, Saga Prefecture, Japan; [4]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka City, Fukuoka Prefecture, Japan.*

Background: Plasma brain natriuretic peptide (BNP) concentration is widely accepted as a marker of fluid status in patients with chronic kidney disease (CKD) including dialysis. We have reported that BNP is independently associated with kidney function decline in predialysis CKD patients (Yoshitomi R, et al. J Hypertens, 2016). However, the relationship between BNP and residual renal function (RRF) in peritoneal dialysis (PD) patients remains unclear. The aim of this study was to elucidate the relationship between BNP and loss of RRF in PD patients.

Methods: We followed retrospectively 104 PD patients who started PD in our hospital between June 2006 and May 2016. Five patients were excluded because of missing data. We divided the remaining 99 subjects into two groups with high and low BNP by a median of plasma BNP concentration (95.7 pg/mL). We estimated the association between BNP and loss of RRF (daily urine volume <100 mL) using a Kaplan-Meier method and Cox proportional hazards model.

Results: During a median range follow-up period of 24 (12-36) months, 31 patients had lost RRF. The event-free RRF survival in the high BNP group was significantly lower than in the low BNP group by the Kaplan-Meier method (p = 0.004). After adjusting for potential confounders such as age, sex, diabetic nephropathy, systolic blood pressure, urinary protein/creatinine ratio, and renal Kt/V, high plasma BNP concentration was independently associated with loss of RRF (hazard ratio for high BNP group vs. low BNP group, 3.34; 95% confidence interval, 1.29 to 9.17; p = 0.012).

Conclusions: Plasma BNP concentration at PD initiation could be an independent predictor of loss of RRF in PD patients.

SA-PO1105

Association of Serum Total Bilirubin with Loss of Residual Renal Function in Peritoneal Dialysis Patients Hiroaki Tsujikawa,[1] Shigeru Tanaka,[2] Masatoshi Hara,[1] Yasuhiro Kawai,[1] Yuta Matsukuma,[1] Hisako Yoshida,[3,4] Kazuhiko Tsuruya,[1,4] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [3]Dept of Clinical Research Center, Saga Univ, Saga, Japan; [4]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan.*

Background: Bilirubin has been recognized as a novel endogenous antioxidant. Low serum bilirubin has been reported to be associated with the progression of kidney disease in patients with chronic kidney disease. However, it is unclear whether a relationship exists between low serum bilirubin and loss of residual renal function (RRF) in peritoneal dialysis (PD) patients. The aim of this study was to investigate the relationship between serum total bilirubin concentration and loss of RRF within 3 years after starting PD.

Methods: We followed retrospectively 104 PD patients who started peritoneal dialysis in our hospital between June 2006 and May 2016. Ten patients who had chronic liver disease or cirrhosis were excluded and the remaining 94 patients were included in the present study. Patients were divided into three groups based on tertile of serum total bilirubin concentration: Tertile 1 (T1) <0.3; T2 = 0.3; T3 ≥0.4. We estimated the relationship between serum bilirubin and loss of RRF (defined as daily urine volume <100 mL) within 3 years after starting PD using a Cox proportional hazards model.

Results: During the 3-year observation period, 22 patients had lost RRF. The incidence rate of loss of RRF increased linearly with the decrease in serum total bilirubin levels (*P* for trend <0.05). After adjusting for confounding factors, low serum total bilirubin level was an independent predictor of loss of RRF (hazard ratio [HR] for every 0.1 mg/dL decrease, 1.50; 95% confidence interval [CI], 1.01 to 2.51; HR (95%CI) for T2 and T1 [vs. T3] 2.03 (0.65-7.88) and 3.70 (1.00-15.9), respectively.

Conclusions: This result suggests that lower serum total bilirubin level is associated with loss of RRF in PD patients.

SA-PO1106

Statin Treatment Strongly Prevents Residual Renal Function in Peritoneal Dialysis Patients Using Contrast Medium Administration Saeko Miura, Fumiko Kuwahara, Kenji Harada, Hidetoshi Kanai. *Dept of Nephrology, Kokura Memorial Hospital, Kitakyushu City, Japan.*

Background: Recently, prospective studies have demonstrated that statins have a protective effect in preventing contrast-induced nephropathy (CIN), but there has been no study that statins have prevent residual renal function (RRF) in peritoneal dialysis (PD) patients. Here, we investigated whether or not statins prevent RRF and decrease the rate of transferred to hemodialysis (HD) in PD patients undergoing iodinated contrast medium administration (ICMA).

Methods: This study was based on a single center retrospective registry that consisted of 116 patients initiated PD between January 2010 and December 2012. We allocated 85 patients who underwent ICMA. The patients were divided into two groups according to

use of statin at the time of ICMA, as follows: statin-treated group (Group A, n=41), and statin-naive group (Group B, n=44). RRF was determined based on the mean 24-hour urine volume and estimated glomerular filtration rate (eGFR). These measures of RRF were determined on the day before ICMA (baseline), and 48 hours, 2 weeks, and 4 weeks after ICMA. The primary endpoint was defined as the rate of decline in RRF. Secondary endpoints were defined as the rate of transfer to HD. The 3-year event rates were estimated by Kaplan Meier analysis with P values from log-rank tests.

Results: Group A had higher BMIs, and higher baseline eGFR than Group B. There were significant differences between Group A and Group B with respect to the decline in urine volume 2 weeks after ICMA (192±205 vs. 335±329 mL : P=0.018). Between the two groups, there were no significant differences in the rate of declined eGFR. After 3 years, the rate of transferred to HD of Group A was significantly lower than that of Group B (P <0.001, log-rank test). In multivariate Cox proportional hazard model, we demonstrated that statin treated group was a significant lower risk for the transferred to HD (HR 0.280, 95% CI 0.114-0.686, P=0.005) after ICMA.

Conclusions: Pre-procedure statin treatment is associated with preservation of the RRF and transfer to HD among PD patients undergoing ICMA.

SA-PO1107

Comparison of Advanced Image-Guided Percutaneous (AIP) versus Advanced Laparoscopic Surgical (ALS) Technique for the Placement of Peritoneal Dialysis (PD) Catheters

Neelam M. Bhalla, Todd Drasin, Sijie Zheng, Jeanne A. Darbinian, Paul Dybbro. *Kaiser Permanente, Northern CA.*

Background: PD offers more advantages to patients with ESRD.Timely placement of a functional PD catheter with minimal complications is crucial to ensure patient acceptance and long term PD success. AIP and ALS techniques both represent best practice catheter placement options as taught by the PD University. We conducted a retrospective cohort study to compare access time to procedure, complications, and overall catheter survival between placement techniques.

Methods: Patient charts for a subpopulation of KPNC members who had either an ALS or AIP PD catheter placed between 1/1/2011 and 12/31/2013 were reviewed by two nephrologists and two Interventional Radiologists. Wilcoxon two-sample tests were employed to compare access times. Occurrence of complications was compared using chi-square tests. Modified least squares regression was used to compare adjusted one-year catheter survival.

Results: We identified 191 PD catheters placed via AIP and 238 via ALS technique. Adjusted one year PD catheter survival was 80% by AIP vs. 91% by ALS. Major complications were rare in either group (<1%). Minor complications occurred in 45.6% of AIP and 38.7% of ALS cases. Median access time to procedure was 12 and 33 days for AIP and ALS patients, respectively.

	AIP (n=191)	ALS (n=238)	p-value
Adjusted One year catheter survival (Proportion (95% CI)	0.80 (0.74-0.87)	0.91 (0.87-0.96)	0.009
Access time, days, (Median IQR)	12.0 (6.0, 19.0)	33.0 (13.0, 57.0)	<0.0001
Major Complications (n, %)			0.49
None	190 (99.5)	237 (99.6)	
Any	1 (0.5)	1 (0.4)	
Minor Complications (n, %)			0.17
None	104 (54.4)	146 (61.3)	
Any	87 (45.6)	92 (38.7)	

Conclusions: Both AIP and ALS techniques have excellent one year survival with very low major complication rates. Though a slightly lower one year catheter survival rate was demonstrated among AIP cases, these patients had a much shorter access time. The techniques complement each other; therefore either may be used based upon local resources and expertise to increase the adoption of PD.

Fluoroscopic and Ultrasound Guided Placement versus Laparoscopic Placement of Peritoneal Dialysis Catheters: A Single Center Experience

Ammar Almehmi,[1] Bradford Jackson,[2] Ahmed Kamel Abdel Aal.[3] *[1]Nephrology and Radiology, UAB; [2]Preventive Medicine, UAB; [3]Radiology, UAB.*

Background: A variety of peritoneal dialysis catheter (PDC) placement techniques are available including laparoscopic placement by surgeons, and percutaneous placement by interventional radiologists. The aim of this study was to compare the one-year outcomes of both techniques.

Methods: We retrospectively reviewed the medical records of 240 patients who had their first PDC placed between January 2005 and December 2015. We compared the outcomes of the catheters placed using fluoroscopic and ultrasound guidance (IR group, n=50), with the catheters placed using laparoscopic technique (LAP group, n=190). The primary endpoint was complication-free catheter survival at 365 days. Secondary endpoints were complication-free catheter survival at 90 days, overall catheter survival at 365 days, median days-to-first complication and median days-to-catheter removal. Between-group differences were assessed using Chi square, Mann-Whitney U tests and Kaplan Meier methods.

Results: The study included 240 patients, 134 females (56%), median age was 54.7 years (IQR=41.3-64.3), and median BMI was 28.3 (IQR=24.1-34.5). There was no significant difference in the baseline characteristics of both groups. In the IR group, the complication-free catheter survival at 90 and 365 days were 64% and 48%, compared to 70.5% (p=0.37) and 53.4% (p=0.49) respectively, in the LAP group. Catheter malfunction was significantly higher in the LAP group (30%) compared to the IR group (16%, p=0.05). Catheter leak was significantly higher in the IR group (10%) compared to the LAP group (3.2%, p=0.05). There was no statistically significant difference in the overall catheter survival at 365 days between the two groups.

Conclusions: The fluoroscopic and ultrasound guided placement of PDC offers a clinically effective alternative to laparoscopic placement with similar survival rates. The rate of catheter malfunction was higher in the LAP group, while the rate of catheter leak was higher in the IR group.

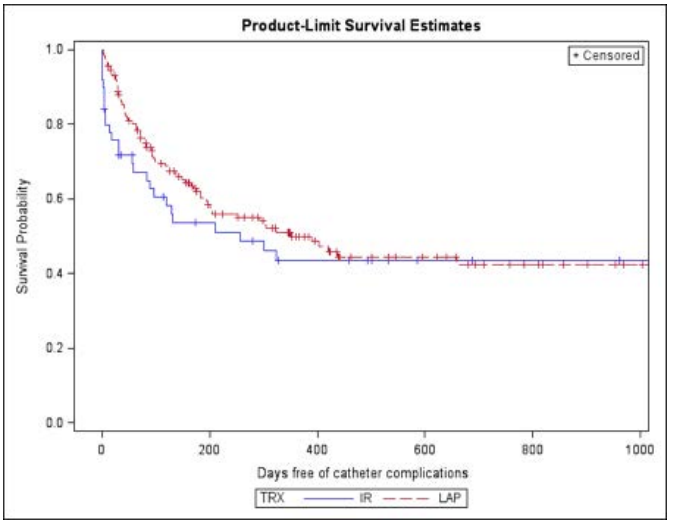

Figure 1: Complication-free catheter survival for the two groups

Table1: Demographic characteristics of patients in each group.

Laparoscopic versus Radiologic Peritoneal Catheter Outcomes in Urgent and Elective Dialysis Starts

Ammar Almehmi,[1] Bradford Jackson,[2] Ahmed Kamel Abdel Aal.[3] *[1]Nephrology and Radiology, UAB; [2]Preventive Medicine, UAB; [3]Radiology, UAB.*

Background: Urgent unplanned dialysis starts are commonly seen in clinical practice, responsible for about one third of the incident dialysis cases. Both radiologic (IR) and laparoscopic (LAP) placement of peritoneal catheters (PDC) have been utilized in both urgent and elective dialysis starts. The aim of our study is to compare PDC outcomes between urgent dialysis start and elective dialysis start in both LAP and IR groups.

Methods: We retrospectively reviewed the medical records of 240 patients who underwent de novo PDC placement. The study cohort was divided based on dialysis start and placement technique as shown in Table 1. Medians and interquartile ranges (IQR) were calculated for continuous variables, and frequencies and percentages for categorical variables. Between group differences were compared using Fisher's Exact test and Kruskal-one way analysis of variance. Complication free survival and overall catheter survival curves were estimated using the Kaplan Meier approach, and Log-Rank tests were used to assess homogeneity across strata.

Results: In the urgent start cohort, the complication-free catheter survival at 90 and 365 days were 61% and 39%, respectively, in the IR group, as compared to 73% (p=0.69) and 73% (p=0.07), respectively, in the LAP group. Further, in the elective start cohort, the

complication-free catheter survival at 90 and 365 days were 66% and 53%, respectively, in the IR group, as compared to 70% (p=0.59) and 52% (p=0.92), respectively, in the LAP group. Overall survival at 365 days among urgent start cases was 33% in both IR and LAP groups (p=0.99). Similarly, in the elective start cohort, the overall survival at 365 days was 64% and 49% (p=0.15) in the IR and LAP groups, respectively.

Conclusions: Peritoneal catheters placed radiologically or laparoscopically had comparable outcomes in urgent and elective dialysis starts.

Study Cohort (n= 240)			
Laparoscopic (LAP) group (n= 190)		Radiologic (IR) group (n=50)	
Urgent dialysis start	Elective dialysis start	Urgent dialysis start	Elective dialysis start
n= 11	n= 179	n= 18	n = 32

SA-PO1110

Modified Simple Peritoneal Wall Anchor Technique in Peritoneal Dialysis Hideaki Oka,[1] Shunsuke Yamada,[2] Taro Kamimura,[1] Yutaro Hirashima,[1] Tomoya Shukuri,[1] Seishi Aihara,[1] Atsumi Harada,[1] Kazuhiko Tsuruya.[2,3] *[1]Div of Kidney Center, Matsuyama Red Cross Hospital, Matsuyama, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Outflow obstruction, a common complication in patients with peritoneal dialysis (PD), usually results in unnecessary catheter removal or replacement. This studydescribes a modified, simple method of anchoring a PD catheter on the anterior peritoneal wall without using a laparoscopic system (peritoneal wall anchor technique, PWAT).

Methods: We performed a retrospective cohort study of consecutive PD catheter insertions, and compared the catheter survival rate between the traditional method and the modified, simple PWAT. The traditional method was used in 54 cases and the modified, simple PWAT was used in 17 cases. The primary endpoint was the occurrence of surgical catheter repair because of outflow obstruction by day 365. The secondary endpoint was the occurrence of catheter migration with obstruction requiring any interventions, including the alpha-replacement method by day 365. Catheter survival was analyzed by Kaplan-Meier survival curves.

Results: Migration-free catheter survival was significantly (P=0.02) higher in the PWAT group (100%, 17/17) than in the traditional group (72.2%, 39/54). Catheter survival without surgical repair or cessation of PD was also significantly (P=0.04) higher in the PWAT group (100%, 17/17) than in the traditional group (77.8%, 42/54). Similarly, migration-free and surgery-free catheter survival rates in cases with a straight-type catheter in the PWAT group were significantly higher than those in cases with a straight-type catheter in the traditional group.

Conclusions: Our results suggest that the modified, simple PWAT provides a better catheter survival rate than the traditional method by preventing catheter migration with obstruction in PD.

SA-PO1111

A Modified Seldinger's Percutaneous Peritoneal Dialysis Catheter Implantation Method; Viable Option for Patients Requiring Unplanned Urgent-Start Peritoneal Dialysis Il Young Kim, Jong Man Park, Harin Rhee, Sang Heon Song, Eun Young Seong, Dong Won Lee, Soo Bong Lee, Ihm Soo Kwak. *Dept of Internal Medicine, Pusan National Univ School of Medicine, Yangsan, Republic of Korea.*

Background: Urgent-start peritoneal dialysis (UPD) is applied to patients who need PD in less than 2 weeks, but are able to wait for more than 48 hours before starting the PD. A modified Seldinger's percutaneous PD catheter implantation method with no break-in time performed by nephrologists has been used for more than 10 years in our institution. To evaluate the usefulness and safety of this method in patients undergoing UPD, we reviewed the clinical outcomes of the two (percutaneous and surgical) PD catheter implantation methods in our university hospital.

Methods: This study included 172 patients who underwent UPD. Based on the PD catheter implantation method, the patients were divided into a percutaneous group (n = 104) and a surgical group (n = 68). PD catheters for percutaneous group were placed using a modified Seldinger's percutaneous implantation method with tapered dilators.

Results: The percutaneous group showed higher BUN, higher serum creatinine, lower hemoglobin, and lower serum albumin levels compared with the surgical group. The percutaneous group showed significantly shorter break-in time after catheter implantation (0.6±2.5 vs. 6.4±3.9 days, p<0.05). There were no significant differences in 90-day infectious complications (peritonitis, exit site infection, and tunnel infection), and also 90-day mechanical complications (pericatheter leakage, catheter migration, diminished outflow, hemorrhage, bowel perforation, hernia and catheter reinsertion) between the two groups. One-year catheter survival was 96.2% in percutaneous group, and 97.1% in surgical group with no significant difference.

Conclusions: The percutaneous group showed more advanced kidney dysfunction, but was able to start PD successfully with shorter break-in time. Moreover, no significant differences of 90-day infectious/mechanical complications and 1-year catheter survival rates were seen between both groups. A modified Seldinger's percutaneous catheter implantation method by nephrologists can be a safe and effective option for unplanned UPD.

SA-PO1112

Tailoring the Peritoneal Catheter Access: One Size Does Not Fit All Mercedes Gonzalez, Sandra Beltrán, Antonio Vazqueez, Belen Vizcaino, Pablo Molina, Luis M. Pallardo. *Nephrology, H. Univ Dr. Peset; Nephrology, H. Univ Dr. Peset; General and Digestive Surgery, H. Univ Dr. Peset; Nephrology, H. Univ Dr. Peset; Nephrology, H. Univ Dr. Peset; Nephrology, H. Univ Dr. Peset.*

Background: Tenckhoff catheter remains the first choice in the treatment of peritoneal dialysis (PD). The selection of the catheter length is not usually done increasing the risk of catheter dysfunction. The objective of the study was to analyse the correlation between patient's height and intraperitoneal length (IP-L), measured from the peritoneal entry (at the level of the deep cuff) to the Pouch of Douglas during catheter insertion procedure.

Methods: A protected rigid guide was introduced in the peritoneal cavity during catheter insertion and when the Pouch of Douglas was reached, the protected guide was removed and length measured with a sterile ruler. If IP-L was less than 19 cm, a 16.3 cm of IP-L self-locating PD-catheter was placed (short catheter), and if it was higher than 19 cm, a 21.5 cm of IP-L self-locating PD-catheter (long-catheter) was used. Test of correlation were made with patient's height and with navel-pubic symphysis length. Mechanical complications were recorded.

Results: 64 catheters were placed. The mean follow-up was 14.6±7.6 months. The patient's height was positively correlated with IP-L, R^2=0.136, p=0.03. Mean patients' height with long-catheter was 171.63±7.45 cm vs 166.18±8.45 cm for patients with short-catheters (p=0.009). Patients' height was divided in three groups: > 170 cm, between 171 to 168 cm and < 168 cm. A significantly higher percentage of differences between IP-L and height were observed in the 171 to 168 cm group (35%, 91% and 38%, respectively, p=0.008). There was no significant correlation of IP-L measured with this procedure with navel-pubic symphysis length (R^2=0.69,p=0.08). During all the follow-up period, only five patients (3%) had an omental wrapping that required surgical repair.

Conclusions: Measuring IP-L during the catheter insertion procedure is an easy way of improving the election of the best catheter length. Patients of height from 168 to 171cm could benefit from this new measurement.

SA-PO1113

Mortality and Hospitalizations in Intensive Dialysis: A Systematic Review and Meta-Analysis Anna Mathew,[1] Jody-Ann McLeggon,[1] Nirav R. Mehta,[1] Sam Leung,[1] Valerie Suzanne Barta,[1] Thomas Mcginn,[1] Gihad E. Nesrallah.[2] *[1]Hofstra Northwell School of Medicine, Northwell Health, NY; [2]Dept of Nephrology, Humber River Hospital, Canada.*

Background: Most ESRD patients are treated with 3 times/week hemodialysis (HD), but some receive intensive HD as short or nocturnal regimens. Existing data on mortality and hospitalization in intensive compared to conventional HD is conflicting. The objective of this study was to review the available evidence on intensive compared to conventional HD to evaluate outcomes of mortality and hospitalization.

Methods: We searched Cochrane Central Register, MEDLINE, EMBASE and Web of Science until March 15, 2016. We included observational studies and RCTs comparing intensive HD (>4 HD/week or >5.5 hrs/HD) with conventional HD (≤4 HD/week and ≤5.5 hrs/HD) that reported mortality and/or hospitalization. We evaluated risk of bias using standard tools. We conducted meta-analyses using random effects models. When reported, we analyzed home vs. in-center, and nocturnal vs. short daily HD separately to reduce heterogeneity.

Results: Twenty-three studies (2 RCTs and 21 observational) with 48,018 reported patients (38,300 on conventional HD and 9,718 on intensive HD) were included in the systematic review. Due to incomplete data reporting, 8 studies were included in the meta-analysis. Compared with conventional HD, home nocturnal [HR 0.45; 95% CI 0.32, 0.63; I^2=31%], home short daily [HR 0.86; 95% CI 0.78, 0.96; I^2=0%] and in-center nocturnal [HR 0.73; 95% CI 0.60, 0.90; I^2=57%] HD had significantly lower mortality. Compared to conventional HD, hospitalization rate/year [mean difference -0.25; 95% CI -0.41, -0.08; I^2=7%] and hospitalization days [mean difference -1.97; 95% CI -2.32, -1.61;I^2=2%] were significantly lower in nocturnal HD. Selection bias, lack of data, and limited number of RCTs precluded some data pooling and comparisons between important subgroups.

Conclusions: Intensive HD may be associated with reduced mortality and hospitalization compared to conventional HD. Confounding by indication and the lack of multiple randomized controlled trials limits the preferential use of intensive HD. Focus is needed on identifying specific patient groups who benefit from intensive HD.

SA-PO1114

Meta-Analysis of Cardiovascular and Quality of Life Outcomes in Randomized Clinical Trials of Intensive Hemodialysis Eric D. Weinhandl,[1,2] Fredric O. Finkelstein,[3] Allan J. Collins.[2] *[1]NxStage Medical, Inc., Lawrence, MA; [2]Univ of Minnesota, Minneapolis, MN; [3]Yale Univ, New Haven, CT.*

Background: There have been 3 parallel-group randomized clinical trials of intensive versus conventional hemodialysis: a trial of frequent nocturnal hemodialysis in Canada (*JAMA*, 298:1291-1299), the Frequent Hemodialysis Network (FHN) Daily Trial (*N Engl J Med*, 363:2287-2300), and the FHN Nocturnal Trial (*Kidney Int*, 80:1080-1091). We conducted a meta-analysis of individual treatment effects on cardiovascular and quality of life outcomes that were reported in all of these trials.

Methods: We abstracted end-of-study treatment effects in the aforementioned trials for each of the following outcomes: left ventricular mass, pre-dialysis systolic blood pressure

(SBP) and diastolic blood pressure (DBP), serum phosphorus, and physical component summary (PCS) and mental component summary (MCS) scores from 36-Item Short Form Survey (SF-36). Each summary treatment effect was estimated by a random effects model.

Results: Sample sizes of the trials were 51, 245, and 87. The duration of the Canadian trial was 6 months, whereas the duration of each FHN trial was 12 months. Summary treatment effects for intensive versus conventional hemodialysis are shown in the table. Summary treatment effects on left ventricular mass, pre-dialysis SBP and DBP, serum phosphorus, and SF-36 PCS and MCS were statistically significant ($P < 0.01$) and all favored intensive hemodialysis. Individual treatment effects on serum phosphorus were heterogeneous ($P = 0.02$), due to a smaller effect size in the FHN Daily Trial.

	Summary Treatment Effect	95% Confidence Interval	P-value
Left ventricular mass (g)	-13.4	(-19.5, -7.3)	<0.001
Pre-dialysis SBP (mmHg)	-9.6	(-12.8, -6.3)	<0.001
Pre-dialysis DBP (mmHg)	-4.9	(-6.8, -3.0)	<0.001
Serum phosphorus (mg/dL)	-1.0	(-1.6, -0.3)	0.005
SF-36 PCS	2.4	(0.7, 4.1)	0.007
SF-36 MCS	3.4	(1.4, 5.4)	0.001

Conclusions: In meta-analysis of 3 randomized clinical trials that collectively included 383 patients, intensive versus conventional hemodialysis had significant, beneficial effects on left ventricular hypertrophy, blood pressure, phosphorus balance, and health-related quality of life.

SA-PO1115

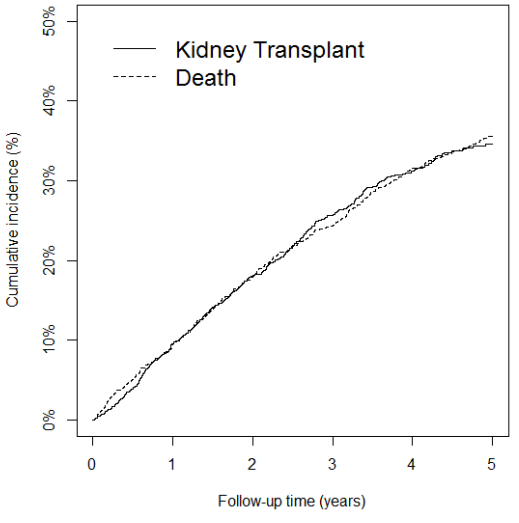
Cumulative Incidence of Kidney Transplant and Death in Incident ESRD Patients on Intensive Home Hemodialysis

Eric D. Weinhandl,[1,2] Allan J. Collins.[2] *[1]NxStage Medical, Inc., Lawrence, MA; [2]Univ of Minnesota, Minneapolis, MN.*

Background: Intensive home hemodialysis (HHD) has been primarily prescribed as a reactive therapy for patients who have accumulated years on dialysis. Clinical outcomes in incident ESRD patients on intensive HHD have not been described. We analyzed incidence of kidney transplant and death in incident ESRD patients on intensive HHD with the NxStage System One cycler (NxStage Medical, Inc., Lawrence, Massachusetts).

Methods: HHD patients were ascertained from NxStage records. We identified patients who initiated HHD between January 1, 2006, and December 31, 2012, and within 3 months after the date of ESRD onset. Comparator cohorts of incident ESRD patients on conventional hemodialysis (CHD) or peritoneal dialysis (PD) were ascertained from United States Renal Data System (USRDS) records. We followed patients from dialytic modality initiation to the earliest of transplant, death, or December 31, 2013, but for a maximum of 5 years. For HHD, we estimated cumulative incidence of transplant and death. For each modality, we estimated transplant and death rates, standardized by age, race, and sex with HHD.

Results: The HHD cohort comprised 1898 patients. Mean age was 56.6 years, 70.4% were male, and 81.6% were white. At 5 years, cumulative incidence of transplant and death were 34.5% and 35.6%, respectively.



With HHD, 5-year rates of transplant and death were 11.6 and 11.6 events per 100 patient-years (PY), respectively. In incident ESRD patients on CHD, standardized rates of transplant and death were 3.7 and 17.7 events per 100 PY, respectively; on PD, corresponding rates were 8.4 and 13.1 events per 100 PY.

Conclusions: Prescription of intensive HHD in incident ESRD patients is associated with equal 5-year probabilities of transplant and death. More studies are needed to assess benefits and risks of intensive hemodialysis as a first prescription, relative to both CHD and PD.

SA-PO1116

Hemodialysis Adequacy and Biochemical Outcomes in the FREEDOM Study of Daily Home Hemodialysis

Eric D. Weinhandl,[1,2] Allan J. Collins,[2] Michael A. Copland.[3] *[1]NxStage Medical, Inc., Lawrence, MA; [2]Univ of Minnesota, Minneapolis, MN; [3]Univ of British Columbia, Vancouver, BC.*

Background: Questions regarding hemodialysis adequacy and biochemical control with low dialysate volume persist. We analyzed dialysis dose and biochemical parameters in Following Rehabilitation, Economics and Everyday-Dialysis Outcomes Measurements (FREEDOM), a prospective cohort study of daily home hemodialysis on the NxStage System One cycler (NxStage Medical, Inc., Lawrence, Massachusetts).

Methods: We identified FREEDOM participants who completed 12 months of follow-up on daily home hemodialysis. Urea clearance and ultrafiltration volume were was assessed once per month; standardized Kt/V was estimated according to Leypoldt *et al* (*Hemo Int*, 8:193-197). Biochemical parameters were ascertained from monthly and quarterly blood tests. Adjusted mean differences between month 12 and baseline were estimated by mixed models.

Results: The cohort comprised 247 patients. Mean age was 51.4 years, 65% were male, and 63% were white. Mean standardized Kt/V was 2.28 at baseline and between 2.29 and 2.38 during the follow-up months. Mean biochemical parameters at baseline and month 12 and adjusted mean differences between month 12 and baseline are shown in the table.

	Baseline	Month 12	Adjusted Mean Difference	P-value
Blood urea nitrogen (mg/dL)	59.6	58.4	-1.7	0.27
Creatinine (mg/dL)	9.5	9.1	-0.3	0.24
Bicarbonate (mmol/L)	23.1	23.9	0.9	0.008
Potassium (mmol/L)	4.8	4.5	-0.3	<0.001
Sodium (mmol/L)	137.9	136.6	-1.2	<0.001
Albumin (g/dL)	3.9	4.0	0.1	0.001
Hemoglobin (g/dL)	11.8	11.1	-0.7	<0.001
Ferritin (ng/mL)	573.7	599.9	-57.0	0.16
Transferrin saturation (%)	31.4	28.4	-2.5	0.12
Alkaline phosphatase (IU/L)	107.3	108.3	0.0	>0.99
Calcium (mg/dL)	8.9	9.0	0.1	0.14
Parathyroid hormone (pg/mL)	434.4	512.3	54.8	0.23
Phosphorus (mg/dL)	5.6	5.3	-0.3	0.03

Conclusions: Daily home hemodialysis with low volume dialysate delivered an adequate dialysis dose in patients that completed FREEDOM. Treatment for 12 months was associated with statistically significant increases in bicarbonate and albumin and significant decreases in potassium, sodium, hemoglobin, and phosphorus.

SA-PO1117

Incidence of Therapy Cessation among Home Hemodialysis Patients in the United States

Eric D. Weinhandl,[1,2] Allan J. Collins.[2] *[1]NxStage Medical, Inc., Lawrence, MA; [2]Univ of Minnesota, Minneapolis, MN.*

Background: Therapy cessation is a headwind to home hemodialysis (HHD) program growth and maintenance. Assumptions about the magnitude of incidence of cessation are diverse. We assessed incidence of cessation in a national population of HHD patients.

Methods: We identified patients who initiated HHD training on the NxStage System One cycler (NxStage Medical, Inc., Lawrence, Massachusetts) between January 1, 2010, and December 31, 2014, according to NxStage records. We followed patients from training initiation to the earlier of therapy cessation or March 31, 2016. We estimated cumulative incidence (CI) of cessation due to technique failure (TF), death, transplant, and composites thereof. We also estimated interval rates of cause-specific cessation.

Results: The cohort comprised 15,108 patients. Mean (standard deviation) duration of successful HHD training was 32 (23) days. CI of therapy cessation is shown in the table. After training, 60-month CI was 38.6% for technique failure 32.4% for death and transplant.

	Cumulative Incidence (%)					Relative Rate (=1.00 during First Year at Home)	
	Technique Failure	Death	Transplant	Death + Transplant	Total	Technique Failure	Death + Transplant
Training	15.5	0.7	0.3	1.0	16.6	5.18	0.63
0-1 mo	17.5	1.2	0.5	1.7	19.2	0.98	0.60
1-2 mo	19.6	1.9	0.6	2.5	22.1	1.07	0.81
2-3 mo	21.9	2.5	1.0	3.5	25.4	1.21	0.91
3-6 mo	27.4	4.3	2.1	6.4	33.8	1.06	1.04
6-9 mo	31.8	5.7	3.6	9.2	41.0	0.95	1.13
9-12 mo	35.3	7.0	4.7	11.8	47.1	0.86	1.14
12-24 mo	44.2	11.5	8.9	20.4	64.6	0.69	1.22
24-36 mo	49.3	14.6	11.5	26.1	75.4	0.58	1.21
36-48 mo	52.1	17.0	13.6	30.6	82.7	0.46	1.36
48-60 mo	54.1	18.5	14.9	33.4	87.6	0.47	1.16

Relative to rates of cause-specific cessation during the first year at home, TF was more likely during training and the first 6 months at home. Death and transplant were more likely after the first 6 months at home.

Conclusions: Most patients who initiate HHD training transition to home. In the long run, roughly half of therapy cessation at home is due to TF. Studies are needed to assess whether TF during training can be reduced and to identify predictors of TF at home.

SA-PO1118

Association between Daily Hemodialysis, Access to Renal Transplantation and Patients' Survival in France Adelaide Pladys,[1] Sahar Bayat,[1] Cécile Couchoud,[2] Cecile M. Vigneau.[3] *[1]METIS, Ecole des Hautes Etudes en Sante Publique, Rennes, France; [2]Registre REIN, Agence de la Biomedecine, La Plaine Saint Denis, France; [3]Service de Nephrologie, CHU Pontchaillou, Rennes, France.*

Background: Daily Hemodialysis (DHD) has been developed to enhance patients' quality of life and blood purification. But its association with survival remains controversial and the association between DHD and the access to renal transplantation has never been evaluated.

Methods: All incident patients ≥18 years starting DHD between 2003 and 2012 for a period ≥30 days in France were extracted from REIN (Renal Epidemiology and Information Network). Using a propensity score, we matched each patient on DHD to three patients on hemodialysis (HD) 3x/week. Survival was studied using the Cox model and access to renal transplantation using the Fine and Gray model.

Results: Were included 575 patients on DHD and 1696 on HD 3x/week. Survival: At the endpoint (31/12/2013), 48% patients on DHD and 32.5% patients on HD 3x/week were dead. After adjustment, DHD was associated with an increased risk of death (HR=1.58 95%CI: 1.4-1.8). The risk of death 2 years after dialysis initiation was 20% in DHD patients and 10% in HD 3x/week ones. Placement on the renal transplant waiting list:Patients older than 80 years were excluded (n=232). By the end of 2013, 176/516 (34.1%) patients on DHD and 598/1523 (39.3%) on HD 3x/week were waitlisted. In the adjusted model, DHD was not significantly associated with the probability of being waitlisted. Access to renal transplantation after waitlisting: Patients on DHD had a reduced access to renal transplantation (SHR=0.72 95%CI: 0.56-0.91). The probability of transplantation 2 years after placement on the waiting list was 51.5% in DHD patients and 60.3% in HD 3x/week ones.

Conclusions: In France, DHD is associated with a lower chance of renal transplantation after being waitlisted and with a higher risk of death. DHD is addressed to various profiles: young patients who access to renal transplantation and old ones in bad clinical conditions. DHD indications in France might be different from other countries. However, the development of new low-flux machines might modify the nephrologists' indications for DHD.

SA-PO1119

Cognitive Impairment in Patients with ESRD and Impact on Dialysis Modality Choice Anuradha Jayanti,[1] Philip Foden,[3] Alison J. Wearden,[2] Sandip Mitra.[1] *[1]Nephrology, Central Manchester Foundation Trust, Manchester, United Kingdom; [2]School of Psychological Sciences, Univ of Manchester, Manchester, United Kingdom; [3]Biostatistics, Univ of Manchesterl, Manchester, United Kingdom.*

Background: Kidney disease is associated with significant cognitive dysfunction.We investigate the association between objective and subjective cognitive function in predialysis patients and investigate if either, can predict dialysis modality choice.

Methods: Two hundred and twenty predialysis patients' data were used to ascertain the demographics, clinical, laboratory and neuropsychometric variables. The latter includes trail making tests A and B- executive function; 3MS- global cognitive function and metacognition questionnaire for subjective assessment of one's cognitive ability. The outcome variable was hospital and self-care modality choice.

Results: Within the study cohort, 90 patients chose fully-assisted haemodialysis and 114 patients chose self-care dialysis. The median 3MS, TMT-A and B scores were greater for assisted vs self-care group. Metamemory was not significantly different between groups but metaconcentration score was significantly worse in the 'assisted-dialysis' group. Univariate analysis showed that variables significantly ($p<0.05$) associated with self-care modality choice include lower TMT A and B scores and higher metaconcentration scores amongst others. Hierarchical regression showed highly significant association between perceived concentration and self-care modality choice ($p<0.01$). Adjusted and unadjusted analyses showed a significant association between perceived concentration and TMT-B scores ($p<0.01$). With every 1.6-minute increase in TMT-B there was a one-unit reduction in metaconcentration score and this was associated with 20% lower odds of choosing self-care over fully-assisted dialysis modality.

Conclusions: Patient's own perception of their cognitive ability is a significant predictor of self-care dialysis modality choice. Subjective report of 'metaconcentration' is strongly associated with poorer outcome on trails making test B, a test of executive brain function.

SA-PO1120

Home Hemodialysis in a Large U.S. Dialysis Organization Suzanne Laplante, Angelito A. Bernardo, J. Ken Leypoldt, Gregory C. Cherkowski, Amin Torabkhani, Dilip Makhija. *Baxter Healthcare Corporation, Deerfield, IL.*

Background: The number of home hemodialysis (home HD) patients is growing in the USA. However, little is known of their disease and dialysis characteristics. This study was undertaken to describe the home HD patient population of a large dialysis organization (LDO) in the USA.

Methods: Stable (same modality for last 60 days of first 90 days on dialysis) incident home HD patients were identified from 2012-2015 US LDO anonymized records. Patient demographics and disease characteristics were compared to in-center population (ICHD) using Student t-tests or Chi-Square tests. Home HD treatment characteristics were summarized with descriptive statistics.

Results: 447/673 (66.4%) stable incident home HD patients were men (ICHD: 56.2% of 94,645; $p<0.0001$). Patients were on average 58.2±14.2 years old at dialysis initiation (ICHD: 63.2±14.8; $p<0.0001$) with a body mass index of 31.6±8.6 (ICHD: 29.5±10.3 kg/m^2; $p<0.0001$). 74.3% were Caucasians (ICHD: 44.6%; $p<0.0001$). 26.2% had a Charlson comorbidity index of ≤3 (ICHD: 16.8%; $p<0.0001$). The primary cause of ESRD was: diabetes (34.3%; ICHD: 43.1%), hypertension (23.3%; ICHD: 29.0%), glomerulonephritis (9.1%; ICHD: 4.6%), cystic disease (8.2%; ICHD: 1.4%) ($p<0.0001$). Baseline serum albumin was 3.7±0.5 (ICHD: 3.4±0.5 g/dL; $p<0.0001$). Most patients (n=512/549; 93.3%) performed at least 3 sessions per week and 498 (90.7%) regularly (i.e., ≥ 70% of the time) avoided a 2-day gap. Treatment duration was available for ≥10% of dialysis sessions in 362 patients (65.9%); most patients (n=544; 99.1%) dialyzed for ≥2 hours. Four (4) patients used a nocturnal regimen. Weekly standard Kt/V was ≥ 2.1 in 412/524 patients (78.6%).

Conclusions: Patients on home HD are generally overweight Caucasian males with less comorbidity compared with ICHD patients. In addition, glomerulonephritis and cystic disease are more frequent primary causes of ESRD in home HD patients. Most patients avoid a 2-day gap without dialysis, but 21.4% do not reach the minimal weekly standard Kt/V of 2.1. Better recording of the dialysis parameters, for example through remote connectivity, could ensure optimal treatment monitoring and clinical outcomes.

Funding: Pharmaceutical Company Support - Baxter Healthcare Corporation

SA-PO1121

Usage of High-Dose Hemodialysis at Home in a Large U.S. Dialysis Organization Suzanne Laplante, Angelito A. Bernardo, J. Ken Leypoldt, Gregory C. Cherkowski, Amin Torabkhani, Dilip Makhija. *Baxter Healthcare Corporation, Deerfield, IL.*

Background: To date, technological advances in hemodialysis (HD) have not resulted in significant survival improvement. The 2-day weekly gap in the conventional hemodialysis (CHD) 3 days-a-week regimen (weekly standard Kt/V=2.1) has been associated with increased mortality. Several large observational studies have shown an association between a high-dose regimen (i.e., more frequent and longer HD with weekly standard Kt/V ≥3.0) and 30-45% superior survival. Home is the best place to perform high-dose HD. There is a growing population of home HD patients in the USA, but the number of patients using a high-dose HD regimen is unknown. This study aimed at identifying the proportion of patients on high-dose home HD.

Methods: Stable (same modality for last 60 days of first 90 days on dialysis) incident home HD patients were identified from 2012-2015 anonymized records of a large US dialysis organization (LDO). Patients were categorized as using a CHD regimen or high-dose HD regimen (no 2-day gaps without dialysis; if short-daily: ≥5 sessions of ≥2 hours per week, if nocturnal: ≥3.5 sessions of ≥6 hours per week; standard Kt/V ≥3.0). Patient demographics as well as disease and treatment characteristics were to be compared using Student t-tests and Chi-square tests.

Results: 673 stable incident home HD patients were identified with information on the dialysis regimen available for 549. Most home HD patients (n=498; 90.7%) avoided the 2-day gap ≥70% of the time. Only 34 patients (6.5%) reported a standard weekly Kt/V ≥3.0 in ≥70% of the time and only 2 patients (0.4%) had a regimen corresponding to high dose. Hence, no statistical comparison between the high dose HD and CHD cohort was performed.

Conclusions: Despite the wealth of evidence supporting high-dose HD, only 0.4% of home HD patients of a large US LDO have been using this regimen. While patients regularly avoid the 2-day gap; the session durations and/or dialyzer clearance are likely insufficient to reach a high-dose regimen. This may be due to lack of awareness on the benefits of high dose or unfavorable dialysis provider economics in the US single bundle payment environment.

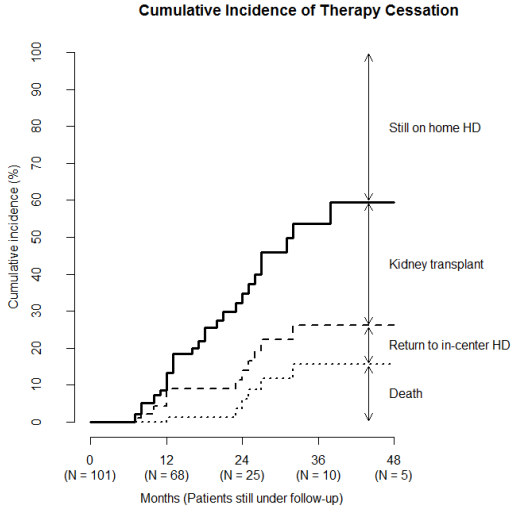
SA-PO1122

Rapid Training, High Long-Term Retention, and Good Clinical Outcomes in a European Cohort of Home Hemodialysis Patients Using the NxStage System One Maria Fernanda Slon,[1] Natalie L. Borman,[2] Maxence Ficheux,[3] Hafedh Fessi,[4] Giacomo Colussi,[5] Roberto Corciulo,[6] Maria A. Bajo.[7] *[1]Hospital de Navarra, Spain; [2]Queen Alexandra Hospital, United Kingdom; [3]CHR Clémenceau, France; [4]Hôpital Tenon, France; [5]Niguarda Hospital, Italy; [6]Policlinic Univ, Italy; [7]Hospital Univ La Paz, Spain.*

Background: Home hemodialysis (HHD) facilitates more flexible and frequent treatment, which may improve clinical outcome and quality of life. We assessed training intensity, therapy cessation, and clinical outcomes in a European cohort of HHD patients using the NxStage System One.

Methods: We collected baseline and follow-up data about 127 home hemodialysis patients on the NxStage System One at 7 centers in France, Italy, Spain, and the United Kingdom. We followed patients from HHD initiation until the earliest of death, return to in-center HD, kidney transplant, or October 31, 2015. We analyzed the subset of patients with complete baseline data and >6 months on HHD.

Results: The study cohort comprised 101 patients. Mean age was 49.7 years, 66% were male, and mean lifetime dialysis duration was 3.2 years. Most patients (95%) were prescribed 5 or 6 sessions per week and mean treatment duration was 15.1 hours per week. Mean training duration was 3.8 weeks and 7% required >6 weeks; mean number of training sessions was 16.7 and 9% required >30 sessions. Cumulative incidence of therapy cessation is shown in the figure. After 2 years, 6% had died, 7% had returned to in-center HD, and 21% had received a transplant. After 4 years, 79% of those still on dialysis remained on HHD. During all 162.6 follow-up years, rates of death and transplant were 3.7 and 10.5 events per 100 patient-years, respectively.



Conclusions: Home hemodialysis with the NxStage System One in 4 European countries was associated with rapid training, high long-term therapy retention, and good clinical outcomes, including high incidence of transplant and low risk of death.

SA-PO1123

Tablet-Based Training for In-Center Self-Care Dialysis – A Pilot Study

Luis Alvarez,[1] May L. Yau,[2] Shivani Shah,[2] Glenn Matthew Chertow.[3] *[1]Div of Nephrology, Dept of Medicine and Nephrology, Palo Alto Medical Foundation, Palo Alto, CA; [2]Outset Medical, Inc., San Jose, CA; [3]Div of Nephrology, Dept of Medicine and Nephrology, Stanford Univ School of Medicine, Stanford, CA.*

Background: Educating dialysis patients about their therapy options, kidney function and health maintenance is a goal for everyone caring for this complex patient population. It is thought that educated patients may make better choices and will be more adherent with their therapy. However, training today is labor intensive and time consuming for staff and has been noted as a burden and barrier to patients in selecting a self-care modality.

Methods: A new tablet-based patient training app has been developed as part of the Tablo™ Hemodialysis System. It is designed as a self-guided educational tool to reduce training time for the patient and minimize clinic staff time burden in providing training. Patients (n=16) from 4 dialysis units agreed to complete the app which has 10 modules with comprehension quizzes. Each quiz must be successfully completed prior to moving on to the next module. The time spent completing each module was recorded into the app's proprietary algorithm and analyzed. Patients also completed a survey on their experience.

Results: Of the 16 surveys collected, 94% (n=15) agreed that the app was easy to understand and 75% (n=12) believed that the app provided information that would increase their interest in becoming more involved in their dialysis therapy. The format and content was considered easy to follow (88%) and 81% reported that they were surprised at how much they learned. The average time spent on the app to complete the training was 3 hours and 19 minutes.

Conclusions: A new tablet-based app developed for the Tablo™ Hemodialysis System provides approachable patient education that may increase patient interest in self-care and reduce the amount of training time required to reach competency needed for self-care whether at home or in-center.

SA-PO1124

More Intensive Dialysis in the FHN Daily Trial Provided Limited Reduction in Uremic Solute Levels

Tammy L. Sirich,[1] Kara Fong,[1] Natalie Plummer,[1] Glenn Matthew Chertow,[1] Timothy W. Meyer,[1] The FHN Trial Group.[2] *[1]VA Palo Alto HCS and Stanford Univ, Palo Alto, CA; [2]NIDDK, NIH.*

Background: The Frequent Hemodialysis Network (FHN) Daily Trial compared conventional 3 times weekly hemodialysis to more frequent treatment with a longer weekly treatment time. Evaluation at 1 year showed modest or no effects on physical or cognitive performance.

Methods: This study compared concentrations of uremic solutes in pre-treatment samples at 1 year from 53 FHN subjects who received hemodialysis 3 times weekly for 10.9 ± 1.3 hours/week and 30 subjects who received hemodialysis 6 times weekly for 14.6 ± 1.7 hours/week. Relative concentrations of solutes identified as uremic in previous studies were assessed by metabolomic analysis and concentrations of selected solutes were further quantified by liquid chromatography/tandem mass spectrometry with isotopic dilution.

Results: Metabolomic analysis showed that the FHN's combined increase in frequency and weekly time reduced the levels of 107 uremic solutes by an average of only 15%. Quantitative analysis confirmed limited reduction in the concentrations of selected protein-bound uremic solutes:

	3x weekly	6x weekly	% Difference (mean; 95% CI)
p-cresol sulfate (mg/dl)	3.2 ± 1.4	3.3 ± 1.6	4 (-18, 26)
indoxyl sulfate (mg/dl)	2.9 ± 1.1	2.5 ± 1.0	-13 (-30, 4)
hippurate (mg/dl)	5.7 ± 4.0	4.8 ± 3.3	-17 (-45, 12)

Kinetic modeling suggested that our ability to lower solute concentrations by increasing hemodialysis frequency and weekly time may be limited by the presence of non-dialytic solute clearances and/or changes in solute production.

Conclusions: The failure to achieve larger reductions in uremic solute levels may account in part for the limited improvement in physical and cognitive performance observed with increasing frequency and weekly treatment time in FHN Daily Trial subjects.

SA-PO1125

Does the Extracorporeal Blood Flow Affect Solute Removal on Short Daily Hemodialysis with Low Dialysate Flow Rate?

Maxence Ficheux,[1] Maxime Leclerc,[1] Patrick Henri,[1] Elie Zagdoun,[2] Erick Cardineau,[3] Clémence Béchade,[1] Thierry Lobbedez.[1] *[1]Nephrology Transplantation Dialysis Dept, Univ Hospital, Caen, France; [2]Nephrology Dialysis Dept, General Hospital, Saint-Lo, France; [3]Nephrology Dialysis Dept, General Hospital, Alençon, France.*

Background: Short daily home hemodialysis (SDHD) with low dialysate flow rate (Qd) confers advantages, especially improved quality of life. The blood pump flow rate (Qb) is an important part of the dialysis prescription, but its effect on solute clearance during a short treatment with low Qd has not been described. We conducted a prospective study to assess the impact of changes in Qb on dialysis dose and solute removal.

Methods: We studied 17 patients starting SDHD. Each patient was observed for 3 consecutive HD sessions, across which only Qb was altered (300, 400 and 450 mL/min). For all sessions, Qd was 180 mL/min and session duration was 2 hours. Urea, Beta-2-microglobulin (β2m), and phosphorus were measured in the blood before and after each dialysis session.

Results: Mean (standard deviation) age and dialysis vintage were 42.9 (13.7) and 5.4 (7.8) years, respectively; 53% were male; 62.5% had residual renal function;and 94,1% had an arterio-veinous fistula . Mean (standard deviation) single pool Kt/V (spKt/V), B2m reduction ratio (B2mRR), and phosphorus reduction ratio (PRR) are displayed in the table 1.

Qb(ml/min)	spKt/V	β2m RR	PRR
300	0.54(0.1)	0.40(0.07)	0.46(0.10)
400	0.58(0.08)	0.45(0.06)	0.48(0.08)
450	0.61(0.09)	0.48(0.06)	0.49(0.07)

In bivariate analysis with accounting for repeated observations, increasing Qb resulted in a significant increase in spKt/V (0.048 [95% confidence interval, 0.03-0.06] increase in spKt/V per 100 mL/min increment in Qb [$p < 0.05$]) and a significant increase in β2mRR (5-point [95% confidence interval, 3-7] increase in β2mRR per 100 mL/min increment in Qb [$p < 0.05$]). Increasing Qb had no significant effect on PRR.

Conclusions: Increasing Qb on SDHD improves the removal of urea and beta-2-microglobulin, but with potentially limited clinical impact. Patients with a vascular access that does not permit use of a high blood pump flow rate can still benefit from this dialytic modality.

SA-PO1126

Weekly Standard Kt/V and Clinical Outcomes in Home and In-Center Hemodialysis Matthew B. Rivara,[1] Vanessa A. Ravel,[2] Elani Streja,[2] Yoshitsugu Obi,[2] Scott V. Adams,[1] Alfred K. Cheung,[3] Kamyar Kalantar-Zadeh,[2] Rajnish Mehrotra.[1] *[1]Kidney Research Inst, Seattle, WA; [2]UC Irvine, Irvine, CA; [3]Univ of Utah, Salt Lake City, UT.*

Background: Patients undergoing hemodialysis (HD) with a frequency other than thrice-weekly are not included in clinical performance metrics for dialysis adequacy. Weekly standard Kt/V (stdKt/V) is comparable across treatment frequencies and location (in-center or home), but there is a paucity of data on its association with clinical outcomes.

Methods: We examined data from incident dialysis patients treated with in-center (N = 109,273) or home HD (N = 2,373). We used multivariable linear regression to examine the association of baseline stdKt/V with blood pressure and metabolic control (serum potassium, calcium, bicarbonate, and phosphorus) stratified by dialysis modality. We used Cox regression to examine the association of stdKt/V with mortality, first hospitalization, and for home HD, transfer to in-center HD.

Results: There were no clinically significant associations between baseline stdKt/V and markers of metabolic control, irrespective of dialysis modality. Patients with stdKt/V >2.3 had lower adjusted blood pressures compared to patients with stdKt/V <2.1, and this difference was greater for home HD relative to in-center HD. There was no association between stdKt/V and adjusted risk for mortality, hospitalization, or transfer to in-center HD among patients undergoing home HD (Table). Among patients undergoing in-center HD, stdKt/V ≥ 2.3 was associated with a 4% lower risk (95% CI: 2% to 7% lower) for death compared to stdKt/V 2.1 to < 2.3.

Conclusions: Differences in in achieved stdKt/V are associated with few clinically meaningful differences in blood pressure or metabolic complications. Additionally, current targets for stdKt/V have limited utility in identifying individuals at increased risk for adverse clinical outcomes among those undergoing home HD.

Table:

	StdKt/V	Mortality		Hospitalization		Transfer to In-Center HD	
		HR	95% CI	HR	95% CI	HR	95% CI
In-Center HD	<2.1	1.14	1.11, 1.18	1.13	1.10, 1.15	-	-
	2.1 to <2.3	Ref	Ref	Ref	Ref	-	-
	≥ 2.3	0.96	0.93, 0.98	0.99	0.98, 1.01	-	-
Home HD	<2.1	1.17	0.79, 1.74	1.11	0.95, 1.30	1.20	0.91, 1.60
	2.1-<2.3	Ref	Ref	Ref	Ref	Ref	Ref
	≥2.3	1.17	0.77, 1.79	1.03	0.87, 1.23	1.16	0.84, 1.58

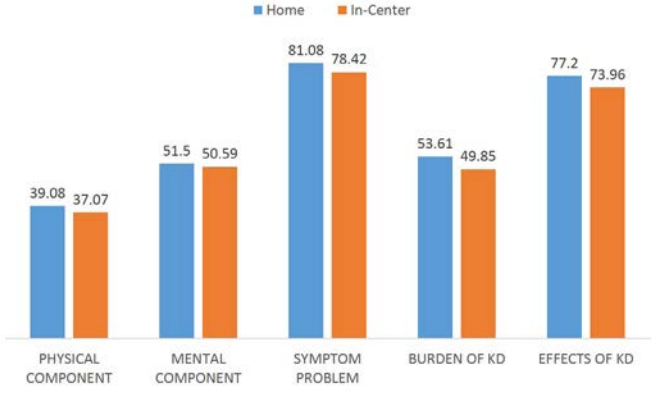
SA-PO1127

Profiles of Quality of Life in Home and In-Center Dialysis Patients in a Large National Population Nwamaka Denise Eneanya,[1] Sophia Rosen,[2] Marta Reviriego-Mendoza,[2] Dugan Maddux,[2] Stephanie Johnstone,[2] John W. Larkin,[2] Len A. Usvyat,[2] Franklin W. Maddux.[2] *[1]Div of Nephrology, Massachusetts General Hospital; [2]Fresenius Medical Care North America.*

Background: Although profiles of quality of life (QOL) are well-characterized for the in-center hemodialysis (HD) population, there is limited data investigating QOL in home dialysis patients (Pts). We aimed to determine the profiles of, and differences in, Kidney Disease QOL (KDQOL) survey scores in dialysis Pts treated at home versus in-center within a large national population.

Methods: We analyzed data from 3,434 home peritoneal and HD dialysis Pts who completed the KDQOL survey during 120 to 365 days after the first date of dialysis (FDD) between Jan 2013 to Dec 2015. The Pt's modality was determined using the active record of modality 120 days from FDD. Clinically similar in-center Pts during the same time frame were identified using 1:1 nearest neighbor matching on logit of propensity score for: age at FDD, race, and sex, as well as, body mass index and albumin during the first 120 days of dialysis. KDQOL scores were compared between groups.

Results: We observed home dialysis Pts had on average 2.0 and 0.91 points higher physical and mental component scores respectively than in-center dialysis Pts (both p<0.001; Figure 1). Home Pts also exhibited on average 2.7, 3.8 and 3.2 points lower dialysis-related symptoms & problems, burden of kidney disease (KD), and effects of KD on daily life scores respectively (all p<0.001; Figure 1).



Conclusions: Pts treated by home dialysis modalities appear to have slightly better QOL outcomes, compared to their in-center HD counterparts. Albeit significant, differences in KDQOL scores between groups are small and further studies are needed to determine clinical relevance. This study was limited to a partial population of home Pts secondary to poor documentation of clinical parameters used for matching.

SA-PO1128

Home Hemodialysis Using NXTStage System One Improves Blood Pressure Control and Reduces Risk of Intra Dialytic Hypotension Nicholas Sangala, Katey Atkins, Venkat Gangaram, Natalie L. Borman. *Wessex Kidney Centre, Queen Alexandra Hospital, Portsmouth, Hampshire, United Kingdom.*

Background: Chronic hypervolaemia and hypertension are significant contributors to cardiac mortality in patients with end stage renal disease on maintenance haemodialysis. Dry weight reduction can achieve better blood pressure control but is associated with an increased risk of intra dialytic hypotension (IDH), which is itself an independent risk factor for cardiac death. Home dialysis is associated with better blood pressure control but its impact on IDH is unknown.

Methods: We reviewed the records of 33 patients receiving home haemodialysis using NXTstage System One between June 2014 and March 2016. For each patient observations from 21 consecutive haemodialysis sessions including pre and post dialysis blood pressure & weight, dialysis length and ultrafiltration volume were recorded along with patient co-morbidities, antihypertensive medication, and episodes of IDH. We collected the same data from in-centre haemodialysis patients matched for age and co-morbidities who had received 21 consecutive sessions of haemodialysis at their usual centre to use as a comparator.

Results: Home haemodialysis patients had a lower systolic blood pressure (131mmHg vs 139mmHg p=0.052) and a lower drop in their systolic blood pressure (0.84% vs 7.2% p=0.0013) than in-centre patients. Ultrafiltratiion volume (1.16L vs 1.85L p=0.0001) and rate (4.46ml/kg/hr vs 6.33mls/kg/hr p=0.0001) were also lower. In-centre patents were more likely to experience IDH than those dialysing at home (RR=2.48 p=0.019). IDH complicated more in-centre sessions than home haemodialysis sessions (RR=6.47 p<0.0001). Antihypertensive use was similar in both groups.

	Home HD	In Centre HD (Matched)	*p* value
Total Patients	33	91	
Age	54.4	56.8	NS
Symptomatic Patients	6	41	0.019
Episodes of IDH	6	107	<0.0001
Pre Dialysis Systolic (mmHg)	131	139	0.052
Ultrafiltration Rate (ml/kg/hr)	4.46	6.33	0.0013
Ultrafiltration Volume (L)	1.16	1.85	0.0001

Conclusions: Home haemodialysis is associated with better blood pressure control and less IDH than in-centre haemodialysis.

SA-PO1129

Improved Long-Term Clinical Parameters in Nocturnal Hemodialysis Thijs Thomas Jansz,[1] Akin Ozyilmaz,[2] Tiny Hoekstra,[1] Brigit C. van Jaarsveld.[1] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Dialysis Centers Groningen, Groningen, Netherlands.*

Background: Nocturnal hemodialysis (NHD), characterized by 8hr dialysis sessions at least thrice weekly, has been shown to improve clinical parameters in HD patients. However, it is not yet known to what extent these improvements last in the long run. We aimed to study long-term clinical parameters in NHD.

Methods: A longitudinal historical cohort was created by collecting data from medical records of 159 in-center and home-treated NHD patients from two centers in the Netherlands, from switch from conventional HD to NHD (any time after April 2004) until discontinuation of NHD. We followed patients until February 1, 2016. Data were collected on phosphate and hypertension control, nutritional status and anemia control at 0, 3, 6, 12, 18, 24 months of NHD treatment, and yearly thereafter. We compared data between baseline and 12 months, and also used generalized linear mixed models for a 6 year longitudinal analysis, adjusting for patient demographics and clinical parameters.

Results: At baseline, mean age was 52.0 ±1.2 years, 32.1% of patients were female, and median duration of end-stage renal disease was 41 (IQR 12-101.5) months. Patients underwent NHD 8 hrs 3-5 times weekly. Median follow-up duration was 18.4 (IQR 7.5-35.4, range 0.4-129.6) months. Phosphate levels and number of phosphate binding pills were lower at 12 months (p<0.01), decreasing predominantly in the first 3 months and remaining stable afterwards. Diastolic blood pressure decreased -1.2 ±0.4 mmHg annually (p<0,01), and number of types of antihypertensive agents was lower at 12 months (p<0.01), again with a major decrease in the first 6 months. CRP decreased -0.08 ±0.04 mg/l annually (p=0,03), while albumin increased 0.22 ±0.07 g/l annually (p<0,01). Post-dialysis weight remained stable over the years. Erythropoiesis-stimulating agent (ESA) resistance index decreased significantly over time (p<0.01), with a 43% reduction in median weekly ESA dose (p<0.01) and a stable hemoglobin.

Conclusions: After switching to NHD, patients develop a considerably lower need for phosphate binding pills, antihypertensive agents and ESA, while clinical parameters remain stable or improve during a 6-year follow-up.

SA-PO1130

Pregnancy Outcomes in Women on Intensive Hemodialysis Compared to Renal Transplant Recipients Arrti A. Bhasin, Anny V. Gonzalez, Nusrat Zaffar, Sarah Mullin, Dini Hui, Rohan D'Souza, Christopher T. Chan, Michelle A. Hladunewich. *Medicine, Obstetrics and Gynecology, Univ of Toronto, Toronto, ON, Canada.*

Background: Data from the US and Italy suggest that patients with a functional renal graft typically have more successful pregnancy outcomes than those with end-stage renal disease (ESRD) on dialysis. As a result, pregnancy counselling often encourages women to wait until after transplantation to conceive. However, reported pregnancy outcomes to date have included women on conventional hemodialysis (HD), while comparisons to women on intensive HD regimens (>36 hours of HD per week) have yet to be made. As such, we sought to compare pregnancy outcomes in renal transplant recipients to women with ESRD on intensive HD.

Methods: In this retrospective cohort study that spanned 2000-2016, pregnancy outcomes of 19 women with ESRD on intensive HD were compared to 45 pregnancies amongst women conceiving post renal transplantation. The primary outcome was the live birth rate, with secondary outcomes including gestational age, birth weight and pregnancy-associated complications.

Results: The two cohorts were comparable with respect to age and cause of ESRD with the average age being 32 in both cohorts. There was no significant difference in the live birth rate at 89 vs 86% in the HD patients and the transplant recipients, respectively (p= 0.71). Similarly, there was no significant difference in gestational age (33.9±7 vs 31.5±11 weeks). However, babies born to women on intensive HD were significantly smaller (2264±727 g) compared to those born to transplant recipients (2935±477 g; p=0.001). With respect to pregnancy complications, significantly more transplant recipients were delivered by caesarean section than dialysis patients (47 vs 17%, p=0.03), and fewer pregnancies were without complications (26 vs 53%, p=0.04) with the most frequent complications in transplant recipients being hypertension, preeclampsia and cholestasis while the intensively dialyzed HD population most frequently developed cervical incompetence.

Conclusions: Pregnancy outcomes in intensively dialyzed HD patients are similar to renal transplant recipients. As such, pregnancy on intensive HD can be considered a viable reproductive option.

SA-PO1131

Association between Bioimpedance, Overhydration and Inflammation Biomarkers in a Spanish Home Dialysis Unit Loreto Fernandez,[1] Maria Fernanda Slon,[1] Carmen Sayon-Orea,[2] Jesus Arteaga.[1] *[1]Nephrology, Complejo Hospitalario de Navarra (CHN), Spain; [2]Preventive Medicine, CHN, Pamplona, Spain.*

Background: Peritoneal dialysis (PD) and in-center hemodialysis patients are at increased risk of overhydration thus leading to cardiovascular events and mortality. Bioimpedance is a useful tool to assess body composition. However, there is scarce data of this tool in frequent home hemodialysis (HHD). The aim of this work is to compare hydration status in two Home-dialysis groups (PD versus HHD) measured by means of bioimpedance and BNP (Brain Natriuretic Peptide). Interestingly, we analysed their correlation and also with some inflammation markers (PCR, Il-6).

Methods: This is a cross- sectional study of 53 Spanish home- dialysis patients: 37 on PD and 16 on HHD. Demographics, dialysis adequacy and cardiovascular risk (presence of heart disease and/or LVH measured by echocardiogram) data were collected from their medical records. Hydration status biomarker (Brain Natriuretic Peptide, BNP), inflammation (CRP, IL-6) and nutritional (albumin, cholesterol) parameters were collected from blood tests. Also a bioimpedance was conducted. We took as overhydration (OH) parameter the OH%ECW (extracellular water), and for nutrition: LTI (lean tissue index), FTI (fatty tissue index).

Results: We found no differences among DP and HHD groups in terms of demographics and cardiovascular characteristics. The OH%ECW was >10% only in 30% of patients with no differences among groups. Moderate and positive association was observed between OH (% ECW) and BNP levels(r = 0.4; p = 0.002); however among groups only held significance in PD (r = 0.4 and p 0,01). Cholesterol was positively associated with FTI (r = 0.29 and p = 0.03), while albumin did with LTI (r 0.28, P = 0.03). IL-6 and CRP were positively associated (r 0.42, p = 0.002) and this association was stronger among the HHD group (r 0.75, p = 0, 0019). No relationship between inflammatory markers and hydration status, LVH or time on dialysis was observed.

Conclusions: BNP levels may be a good marker of overhydration in home dialysis patients, especially in those on PD. HHD patients have better control of dry weight, nevertheless they could be more inflamed than PD patients.

SA-PO1132

The Relationship of Hydration Status to Macro and Microcirculation in Conventional and High Dose Hemodialysis Nicos Mitsides,[1] Tom Cornelis,[2] Nanda Diederen,[3] Natascha Broers,[3] Jeroen Kooman,[3] Sandip Mitra.[1] *[1]Manchester Academic Health Science Centre, United Kingdom; [2]Jessa Hospital, Hasselt, Belgium; [3]Univ Hospital Maastricht, Netherlands.*

Background: Fluid management presents one of the greatest challenges in hemodialysis(HD). Overhydration(OH) has been linked to adverse cardiovascular outcomes but the link between circulation and fluid compartments remains poorly defined.

Methods: We report the baseline findings of a 2yr multicentre, longitudinal study investigating compartmental fluid distribution with macro- and micro-circulation parameters in conventional (CHD) and high dose HD (HDHD). We assessed Fluid compartments with Multifrequency bioimpedance, macrocirculation with pulse-wave velocity(PWV) and mean arterial pressure (MAP) measurements and microcirculation with sublingual dark-field capillaroscopy.

Results: 72 participants, were equally split between CHD and HDHD (>12hrs/wk). Visit MAP correlated with OH index (p=0.02), Total Body Water (TBW)(p=0.01), Extracellular Water (ECW)(p=0.01) and Intracellular Water (ICW)(p=0.02) in a linear regression model adjusting for age, cardiovascular disease(CVD), diabetes(DM), BMI and dialysis modality. 24hr MAP was also linked to TBW (p=0.02), ECW (0.03) and ICW (p=0.03). Although PWV correlated with MAP (p=0.01), it was not associated with fluid indices. Microvascular luminal diameter (dynamic % Cell filling) was correlated with ECW ($p<0.05$) but the positive relationship of injury to the Perfused Boundary Region of endothelial glycocalyx to ECW/ICW ratio (p=0.04) was explained by loss of ICW (p=0.01). MAP was not associated with microcirculation parameters but high PWV did and correlated well with dynamic Red Cell width (p=0.02).

Conclusions: MAP shows strong association with all fluid indices but PWV is predominantly linked to microcirculatory parameters across all haemodialysis modalities.

SA-PO1133

Dalteparin for Circuit Anticoagulation in Patients Undergoing Daily Hemodialysis Karen Qi,[1] Norman Muirhead,[1,2] Seadna Ledger,[1] Nicole Seymour,[1] Jarrin D. Penny,[1] Shih-Han S. Huang.[1,2] *[1]London Health Sciences Centre, London, ON, Canada; [2]Dept of Medicine, Nephrology, Western Univ, London, ON, Canada.*

Background: Dalteparin, a low molecular weight heparin, has been shown to be effective and safe for hemodialysis (HD) circuit anticoagulation and has advantages over unfractionated heparin (UFN). However, there is limited evidence for its use in frequent HD. We had conducted an observational study in our in-centre short-hour daily HD program to assess the effectiveness, the dosage and the bleeding risk of dalteparin in this specific population.

Methods: We recruited 7 patients who were part of the in-centre short-hour daily HD program at the London Health Sciences Centre. All patients were switched from UFN to dalteparin at a starting dose of 2500 units(u) every 48 h. The dosage was titrated based on the circuit clotting score and the bleeding risk. All patients were followed from May 2015 to May 2016. We used descriptive analysis to report the mean (+/- standard deviation) UFN and dalteparin doses, number of bleeding episodes and mean clotting scores.

Results: Of the 7 patients (57% male, age 52 ± 6 y, dialysis vintage 11 ± 6 y, receiving median 12 hours over 6 HD treatments/week), the mean UFH dose during HD treatments was 1142± 351 u/h and the clotting score was <2 over 99% of the treatments. Within the first 4 weeks of switching, the mean dalteparin dose was 1687 ± 602 u/ treatment and 9% of the treatments had clotting score > 2. One patient required dose increase. All anti-Xa levels were <0.4. After 1 year, one patient passed away due to sepsis, one discontinued due to new diagnosis of diabetic retinopathy and another was dialyzing well without anticoagulation. Three patients remained on starting dose. During the 1 year period, no patient experienced significant bleeding events requiring hospitalization or interventions. No fistula clamping/compression times were increased.

Conclusions: This small but important pilot study has demonstrated the effectiveness and safety of dalteparin in short-hour HD. This should be further assessed in a larger and perhaps home HD population, which is being conducted at this point.

SA-PO1134

Comprehensive Dialysis Transportation: The Way to Sustain a Long-Term In-Center Short Daily Hemodialysis Program Felipe Pascoal, Adolfo Simon, Kelia Xavier, Vilber Bello, Juliane Lauar, Istenio Pascoal. *Centro Brasiliense de Nefrologia, Brasília, DF, Brazil.*

Background: There is a rising demand for dialysis treatment among senior population. Dialysis physical toll prevents many patients arriving at the dialysis clinic via traditional transit from safely returning home the same way. While in-center short daily hemodialysis has been consistently associated with better outcomes, the availability of convenient transportation may be its most important limiting factor. Therefore, we examined the impact of a comprehensive transportation program on in-center daily hemodialysis compliance, vintage and survival.

Methods: We assessed the prevalence of absences from hemodialysis sessions (no shows), the length of time on dialysis and the actuarial survival rate of 145 privately insured patients (93M/52F; mean age 56.1±19.3 yrs, range 8-95) receiving in-center short daily hemodialysis treatments (6-7 times/week; lasting 118±18.7 min, range 90-180; ultrapure dialysate and single-use highflux dialyzer). Round-trip free of charge shared passenger-transportation has been provided by a dedicated fleet of 10 midsize vans and 10 full time trained drivers, running about 1200 km throughout the day to timely attend 5 dialysis shifts, from 7am to 9pm, 7 days a week.

Results: From June 2006 to May 2016, 74% (108/145) of our short daily hemodialysis patients were transported to and from the clinic by an exclusive transportation service and the remaining 26% (37 patients) used their private transportation (self-driven or brought by a family member or caregiver). No patients relied on public transport. Over the 10-year study period, average missed treatment rate was 1.4% or 4.4 days per patient-year. There was no patient dropout, allowing a dialysis vintage of 42.1±33.6 mo (3-120). In parallel,

the 5-year cumulative patient survival rates were 97%, 92%, 84%, 71% and 63% at 12, 24, 36, 48 and 60 mo, respectively. Institutional transport costs have been offset by combining low missed treatment rate with high patient retention rate.

Conclusions: Providing reliable transportation options for all patients helped us overcome compliance challenges on the way to establishing and sustaining an active in-center short daily hemodialysis program.

SA-PO1135

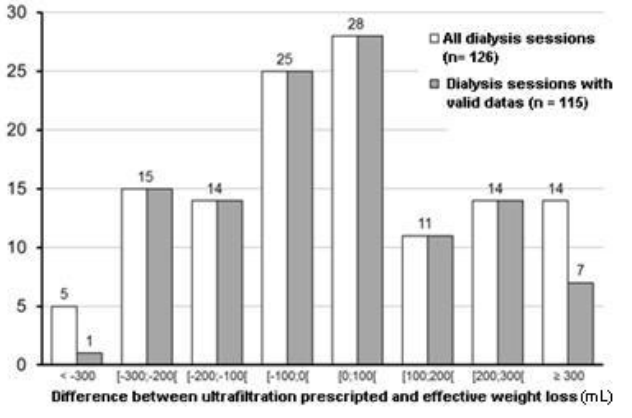
Short Daily Hemodialysis Is Feasible and Safe with Physidia S3 Monitor

Louis De Laforcade,[1] Roula Galland,[3] Walid Arkouche,[4] Maxence Ficheux,[5] Patrick Henri,[5] Francois Babinet,[7] Maurice Laville.[1,2] *[1]Dpt of Nephrology, Hospices Civils de Lyon, Pierre Bénite, France; [2]Unit 1060 CarMeN, Univ Lyon I Claude Bernard, Oullins, France; [3]Calydial, Vénissieux, France; [4]AURAL, Lyon, France; [5]Nephrology Hemodialysis, CHU Caen, Caen, France; [6]Nephrology Hemodialysis, CH Cherbourg, Cherbourg, France; [7]ECHO Association, Le Mans, France.*

Background: Short daily hemodialysis (SDH) improves hemodynamic tolerance, life quality and cardiac outcomes. Physidia S3 is a low flow dialysis machine designed for SDH.

Methods: We designed a multicentric, prospective, observational study. Main inclusion criterias were: patients treated with hemodialysis since 3 months or more, clinically stable, who were 18 years old or more, stable vascular access (No catheters). Inclued patients underwent SDH (5 or 6 times a week) on Physidia S3machine with bicarbonate buffer, during 2 weeks. Primary outcome was the ability to deliver a conform dialysis session (session duration with a ±15% tolerance and weight loss with a tolerance of ±300g in accordance with medical prescriptions).

Results: 11 patients (6 men) were inclued. Median age was 53 years, median dry weight was 60 kg, median BMI was 24.4 kg/m2. 126 sessions were analysed, dialysis duration was respected in 96% of them, and weight loss in 85%. 82% of the dialysis respected both duration and weight loss criteria. After excluding human errors in weighting or result reporting, 90% of the dialysis sessions were conform.



SDH on Physidia S3 provided an adequate quality of dialysis: median eKt/V was 0.54 per session and median stKt/V 2.45 per week. Median blood urea was reduced by 44% during a dialysis session, median plasma potassium was reduced from 4.8 mmol/l to 3.8 mmol/l, median phosphatemia was reduced from 1.70 mmol/l to 0.84 mmol/l.

Conclusions: SDH with Physidia S3 provides a good conformity with medical prescriptions, and a good adequation of dialysis.

SA-PO1136

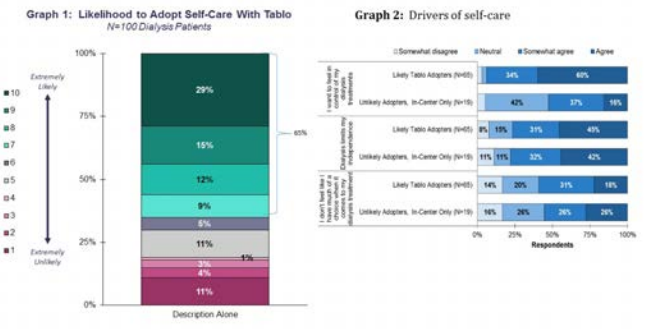
An Analysis of Patient Interest in In-Center Self-Care Hemodialysis with a Novel Hemodialysis System

Sarah S. Prichard,[1] Luis Alvarez,[2] Glenn Matthew Chertow.[3] *[1]Independent Consultant, North Palm Beach, FL; [2]Div of Nephrology, Dept of Medicine and Nephrology, Palo Alto Medical Foundation, Palo Alto, CA; [3]Div of Nephrology, Dept of Medicine and Nephrology, Stanford Univ School of Medicine, Stanford, CA.*

Background: Approximately 90% of dialysis patients are on in-center hemodialysis (ICHD), 9% on peritoneal dialysis (PD) and the remainder on HHD. Studies indicate a significant percent of patients are interested in in-center self-care hemodialysis (ICSCHD). Potential advantages for patients who select ICSCHD, include greater independence, flexibility, and control over their care. Barriers to adoption have been attributed to complexity of technology, training burden and the inability to be independent. We report on factors associated with patient selection of ICSCHD with the Tablo™ Hemodialysis System, designed to make ICSCHD easier and more accessible.

Methods: Patients (n=100) from a panel of dialysis patients across the US who had agreed to participate in survey research. Distribution of age range, sex, and race/ethnicity were pre-specified to ensure adequate representation of the overall US dialysis population. Participating patients reviewed the steps that they would perform independently during ICSCHD along with an image of the Tablo™ System. They completed a questionnaire on the likelihood of choosing ICSCHD using Tablo™, their attraction to the modality and reasons behind their selection.

Results: The patient population had an average age of 51 years (range 18 to 70) and included 56 women and 35 non-whites. Half the patients were on dialysis for 2 years or more. Graph 1 shows 65% of would likely adopt ICSCHD with Tablo™ while Graph 2 shows drivers behind their selection.



Conclusions: A high percentage of patients across broad demographic lines indicate interest in performing ICSCHD with the Tablo™ Hemodialysis System.

Funding: Pharmaceutical Company Support - Outset Medical, Inc.

SA-PO1137

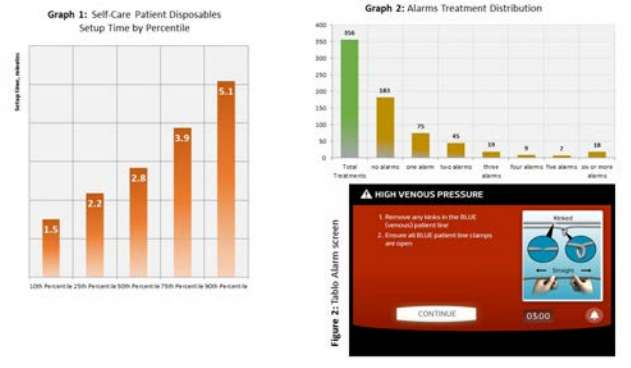
Initial Experience of In-Center Self-Care Patients with the Tablo™ Hemodialysis System

Sarah S. Prichard,[1] Luis Alvarez,[2] May L. Yau,[3] Dean Hu,[3] Paul Chen,[3] Michael A. Aragon,[5] Glenn Matthew Chertow.[4] *[1]Independent Consultant, North Palm Beach, FL; [2]Div of Nephrology, Dept of Medicine and Nephrology, Palo Alto Medical Foundation, Palo Alto, CA; [3]Outset Medical, Inc, San Jose, CA; [4]Div of Nephrology, Dept of Medicine and Nephrology, Stanford School of Medicine, Stanford, CA; [5]North Texas Kidney Consultants, Grapevine, TX.*

Background: Patients on hemodialysis (~70%) are interested in performing in-center self-care hemodialysis (ICSCHD) because it provides flexibility and control relative to in-center hemodialysis (ICHD). Yet, only ~8% of patients are on self-care in the US. Lack of adoption has been attributed to complexity of technology, and fear of self-cannulation. ICSCHD combines the clinical benefits of self-care with the security of a clinic setting. We assess the capability of patients performing ICSCHD with the Tablo™ Hemodialysis System.

Methods: We evaluated a subset of patients (n=20) who transferred to ICSCHD using the Tablo™ System. Using internal log file data that can be transmitted wirelessly after treatment, we measured the time required to set up, and the number and type of alarms that occurred. After each set-up step is completed or an alarm occurs a flag is logged in the data. The timing between flags was measured to determine set-up and alarm resolution times.

Results: System data files for 356 treatments were analyzed. Patients did not have dexterity or visual deficiencies, age ranged from 28-69 and there were 11 females. In 90% of treatments patients were able to set-up Tablo™ in 5 minutes.



There were 472 alarms, or 1.32 alarms per treatment, with a weighted average of 22.4 seconds to resolve an alarm, using the Tablo™ touchscreen. In 183 (51%) treatments there were no alarms.

Conclusions: Patients performing ICSCHD can quickly set-up and successfully manage their treatments using the Tablo™ Hemodialysis System.

SA-PO1138

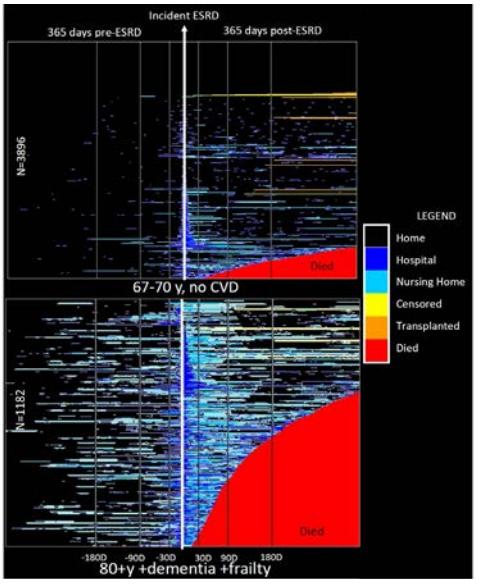
Institutionalization before and after the Transition from CKD to ESRD on Dialysis

Maria E. Montez-Rath,[1] Yuanchao Zheng,[1] Manjula Kurella Tamura,[1] Vanessa Grubbs,[2] Wolfgang C. Winkelmayer,[3] Tara I. Chang.[1] *[1]Stanford; [2]UCSF; [3]Baylor.*

Background: The transition from CKD to ESRD can be particularly unstable. We sought to examine the frequency of days spent institutionalized (hospital or nursing home) during the 1-year prior to and after dialysis initiation in older patients.

Methods: We used the USRDS to identify patients aged ≥67y at the time of incident ESRD with Medicare A+B. We created "heat maps" by color-coding each day in the 365 days pre- and post-ESRD; each patient is represented by a single horizontal row with dark/light blue indicating institutionalized days. We used zero-inflated negative binomial models that accounted for number of days alive to quantify the mean number of institutionalized days in the 1st year post-ESRD, adjusting for baseline characteristics.

Results: The top heat map (Figure) depicts 67-70 year-olds without cardiovascular disease (CVD). The larger amount of black vs. blue reflects the larger proportion of time spent at home vs. in an institution. The bottom heat map depicts 80+ year-olds with dementia+frailty, and shows a relatively large proportion of institutionalization and death.



The adjusted average number of institutionalized days differs widely depending on the subgroup (Table).

Table: Adjusted average number of institutionalized days in the first 365 days post-ESRD

	Age Category (y)			
	67-70	**71-74**	**75-79**	**80+**
Overall	49	55	63	75
CVD+	53	59	67	79
CVD-	33	37	42	54
Dementia+	75	85	88	103
Dementia-	47	53	61	72
Frail+	86	93	96	105
Frail-	41	47	54	66
Dementia+Frail+	108	113	113	120
Dementia-Frail-	42	46	52	59

Conclusions: Older patients who initiate dialysis spend a substantial proportion of time institutionalized, particularly octogenarians and patients with dementia, frailty and CVD. Continued efforts to improve shared decision-making about dialysis initiation in high-risk subgroups are needed.

Funding: NIDDK Support

Generalisability of SPRINT to Community Dwelling Individuals over the Age of 75: Informing Estimation of Baseline Adverse Event Risk

Donal J. Sexton,[1,2,3] Mark Canney,[1,2] Mark Alan Little,[2] Conall M. O'Seaghdha,[3] Rose Anne M. Kenny.[1] *[1]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin, Dublin, Ireland; [2]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [3]Dept of Renal Medicine, Beaumont Hospital, Dublin, Ireland.*

Background: With the publication of the ≥ 75 yrs subgroup analysis of the SPRINT trial, the generalizability of this study merits evaluation. SPRINT found reduced cardiovascular events and all-cause mortality in those randomized to a systolic BP target of < 120 mmHg.

Methods: Data from the 1st (2009-2011) and 3rd wave (2015) of The Irish Longitudinal Study on Ageing, a prospective cohort study of community dwelling older adults in Ireland (N=5390). We applied the inclusion/exclusion criteria for SPRINT.

Results: Mean follow up was 3.42 yrs. For those ≥ 75 yrs meeting final inclusion criteria we compared characteristics and outcomes of those with CKD: 37.8%(45,566 in the population) to those without CKD: 62.2%(74,933). Frailty (by Fried Index) was more common at baseline in CKD: 12.6% Robust (15,121), 19.4% Pre-frail (23,200) and 5.9% Frail (7,100) compared to 23.8% (28,703) Robust, 35.2% Pre-frail (42,450) and 3.2% Frail without CKD (3,805) P = 0.02. Those reporting difficulties climbing one flight of stairs was more common in CKD (28.8% No, 9% yes) than without CKD (53.4% no and 8.8% yes), P=0.04. A history of having previously fractured a hip, was more common in CKD (33.1% No, 4.8% Yes) than without CKD (59% No and 3.2% Yes) P=0.03. Reporting a fear of falling was also more common at baseline in CKD (29.8% No, 8% Yes) than without CKD (56.7% No and 5.5% Yes), P=0.003. Outcome rates over follow up in this study per 100 person years (95%CI) were: Syncope 1.4(0.5-3.6) in CKD and 1.2(0.5,2.7) without CKD, Injurious falls 14.8(8.6,25.5) in CKD vs 11(6.3, 19.4) without CKD, fractures (hip/wrist/spine) due to falls 0.7(0.2,2.7) in CKD vs 0.6 (0.2, 1.8) without CKD.

Conclusions: Community dwelling individuals ≥ 75 yrs meeting eligibility for SPRINT are a heterogeneous group. Given the observation of higher baseline frailty in those with CKD than without in this study, the balance of risk:benefit when implementing the results of SPRINT may be influenced by the presence of CKD.

SA-PO1140

A Delphi Study on Frailty in Adults with End Stage Renal Disease

Sarah Rasmussen, Dorry L. Segev, Mara McAdams-DeMarco. *JHU.*

Background: End stage renal disease (ESRD) patients are at higher risk of frailty, a loss of physiologic reserve that is associated with poorer outcomes. However, some components of the frailty phenotype may not accurately characterize frailty in ESRD patients.

Methods: In a two-round Delphi study we distributed 2 anonymous surveys to nephrologists, geriatricians and transplant surgeons at JHU (round 1 n=41; round 2 n=36). Consensus and moderate consensus were defined as >80% and 60-80% agreement, respectively. Fisher's exact test was used to examine differences by specialty.

Results: The response rate for both rounds was 87%. 98% of clinicians said ESRD patients are more likely to be frail than healthy adults. There was consensus that 4 of the 5 Fried frailty components should not be removed from the definition of frailty in ESRD patients, but only moderate consensus that weight loss should not be removed (71%). Nephrologists were less likely to want to remove weight loss (p=.03). 10 new ESRD-specific components were identified (9 included in round 2). There was moderate consensus that history of falls and physical decline should be added. Nephrologists were more likely to want to add history of falls (p=.01); gerontologists were less likely to want to add cognition (p=.03).

1st round: components identified	2nd round: % wanting to add component	% wanting to add component by specialty			
		Nephrology	Gerontology	Transplant Surgery	P-value
History of falls	64	83	38	100	**.01**
Physical decline	64	67	50	100	.46
Cognition	39	50	19	100	**.03**
Nutrition, diet	36	44	25	50	.38
Albumin	17	28	6	0	.24
Health care utilization	11	11	12	0	1.0
Metabolic bone disease	6	11	0	0	.54
Excess fluid	3	6	0	0	1.0
Ultrafiltration	3	6	0	0	1.0

There was consensus that prehabilitation could make transplant patients less frail (97%) and that patients will be interested in prehabilitation (97%). There was moderate consensus that using foot peddlers during dialysis would make patients less frail (80%) and that patients would be interested in foot peddlers (69%).

Conclusions: There is consensus that frailty is common in ESRD patients and that interventions could improve frailty in this population. However, some clinicians suggest a need for an ESRD-specific measure of frailty.

Kidney Function and Objective Markers of Frailty in Community-Dwelling Older Adults

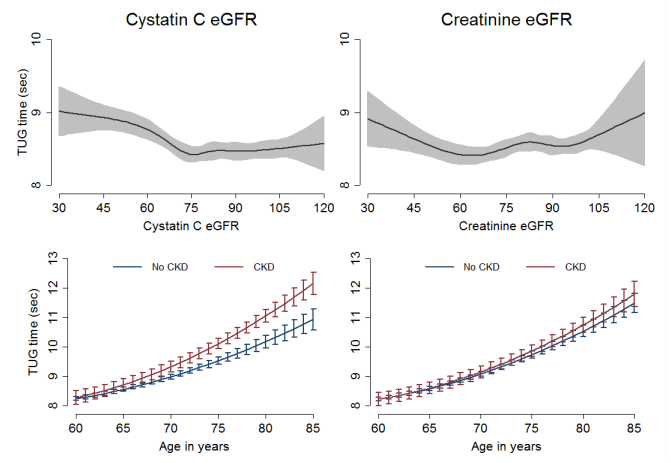
Mark Canney,[1,2] Donal J. Sexton,[1,2] Matthew D.l. O'Connell,[1] Neil O'Leary,[1] Rose Anne M. Kenny,[1] Mark Alan Little,[2] Conall M. O'Seaghdha.[3] *[1]The Irish Longitudinal Study on Ageing, Trinity College Dublin; [2]Trinity Health Kidney Centre, Trinity College Dublin; [3]Nephrology Dept, Beaumont Hospital, Dublin.*

Background: Frailty is a means of risk-stratification in advanced chronic kidney disease (CKD). We sought to determine the association between objective physical performance tests and kidney function across the spectrum of estimated glomerular filtration rate (eGFR) in older adults.

Methods: Cross-sectional analysis of 4562 participants from The Irish Longitudinal Study on Ageing, a representative national cohort of community-dwelling adults aged

≥50yrs. We categorized eGFR (mL/min/1.73m²) from cystatin C ($eGFR_{cys}$) and creatinine ($eGFR_{cr}$) as follows: ≥90(ref);75-89;60-74;45-59;<45. We used multivariable linear regression to examine the association between eGFR groups and gait speed, timed-up-and-go (TUG) and grip strength. Restricted cubic splines of continuous eGFR were modeled to further examine the relationship with TUG. We examined effect modification by CKD (eGFR<60) in the relationship between age and TUG.

Results: Mean(sd) age was 61.8(8.3)yrs, 54% were female and mean(sd) $eGFR_{cys}$ was 81(17.7)mL/min/1.73m². Participants with $eGFR_{cys}$<45 had slower gait speed (-3.6cm/s [95%CI, -6.9, -0.3]), longer TUG (0.4s [0.1, 0.7]) and weaker grip (-1.3kg [-2.4, -0.1]) vs the reference group. Associations between $eGFR_{cr}$ groups and outcomes were not significant. An $eGFR_{cys}$<75 represented a turning point for slower TUG; the relationship between $eGFR_{cr}$ and TUG was U-shaped. CKD defined by $eGFR_{cys}$, but not $eGFR_{cr}$, modified the relationship between age and TUG.



Conclusions: We observed a relationship between $eGFR_{cys}$ and objective frailty markers in older community-dwelling adults, evident at early eGFR declines. CKD defined by $eGFR_{cys}$, but not $eGFR_{cr}$, modified the relationship between age and physical performance.

SA-PO1142

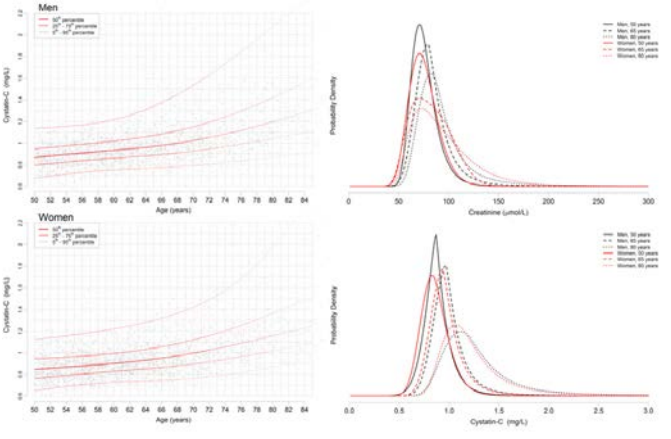
Distribution of Cystatin C and Creatinine with Advancing Age

Mark Canney,[1,2] Donal J. Sexton,[1,2] Neil O'Leary,[1] Rose Anne M. Kenny,[1] Mark Alan Little,[2] Conall M. O'Seaghdha.[3] *[1]The Irish Longitudinal Study on Ageing, Trinity College Dublin; [2]Trinity Health Kidney Centre, Trinity College Dublin; [3]Nephrology Dept, Beaumont Hospital, Dublin.*

Background: Little is known about filtration marker distribution as we age. We modelled creatinine and cystatin C distributions across the age spectrum in the general population of older adults.

Methods: Cross-sectional analysis of 5387 participants from The Irish Longitudinal Study on Ageing, a representative national cohort of community-dwelling adults aged ≥50 years. Creatinine and cystatin C were measured simultaneously using standardised assays. Using generalized additive models we flexibly modelled the distribution of each biomarker from four parameters of the Box-Cox Power Exponential distribution: location, dispersion, skewness and kurtosis. The best fitting model for each parameter was sought using 3 to 5 cubic splines with age, sex and an age-sex interaction term as covariates. All models incorporated an inverse probability weight for study participation.

Results: Mean(sd) age was 63.9(9.2) years and 53% were female. We observed a strong non-linear relationship between cystatin C and age, with an upstroke at age 65 beyond which cystatin C levels rose sharply. The shape of the cystatin C distribution differed by age in both genders. As well as having higher median values, older individuals demonstrated greater variability in cystatin C compared to younger participants. The trajectory of creatinine with age was comparatively flat. Creatinine distribution also varied with age but to a lesser extent.



Conclusions: The relationship between cystatin C and age is complex and non-linear. Older adults demonstrate progressively greater variability in filtration marker distribution with advancing age, particularly for cystatin C. Such variability may contribute to the uncertainty of estimation of kidney function in the ageing population.

SA-PO1143

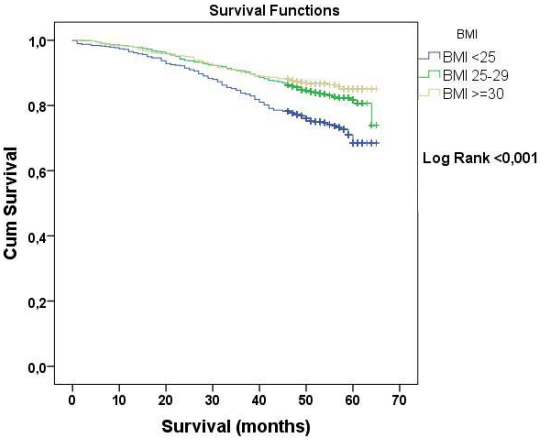
Low Body Mass Index as Risk Factor for Mortality in Older Adults

Natalie Ebert,[1] Olga Jakob,[2] Peter Martus,[3] Elke Schaeffner.[1] *[1]Inst of Public Health, Charité, Berlin, Germany; [2]Inst for Clinical Epidemiology and Biostatistics, Charité, Germany; [3]Inst for Med. Biometry, Eberhard Karls Univ Tübingen, Germany.*

Background: High body mass index (BMI) is a known risk factor for cardiovascular events and mortality in middle aged adults. Its relationship in older age is less clear.

Methods: We used baseline and follow-up data from the Berlin Initiative Study (BIS), a population-based cohort that examines kidney function over time in subjects who are 70 years and older. Kaplan Meier analysis and Cox proportional hazard models were applied to assess the predictive value of BMI (3 categories: ≥30, 25-29, <25) with regard to overall mortality. Analyses were done for BMI only and adjusted for age, gender and additional known risk factors. Median follow-up were 54 months.

Results: 2068 BIS participants with a mean age of 80 years were followed. 52.6 % were female, 26.1 % had diabetes, 14 % had suffered from myocardial infarction (MI), 8.7 % from stroke, 78.8 % had antihypertensive medication, 53 % had a GFR_{BIS2} <60 ml/min/1.73m². Mean albumin was 39.9 g/L. After 4.5 years 385 had died. Survival was worst for subjects with a BMI <25 compared to subjects with a BMI >30 (log rank <0.001).



After multivariable adjustment for age, gender, albumin, diabetes, smoking, MI, stroke, hypertension, and decreased kidney function (GFR <60 ml/min/1.73m²) the relationship was less strong but still statistically significant.

	univariate			multivariate		
	p-value	HR	95% CI	p-value	HR	95% CI
BMI ≥30 (reference)	<0.001			0.003		
BMI 25-29	0.14	1.23	0.93-1.62	0.79	0.96	0.73-1.28
BMI <25	<0.001	2.03	1.54-2.67	0.02	1.43	1.06-1.92

Hazard ratios were attenuated by albumin, stroke, smoking and hypertension (not shown). Decreased GFR did not influence the results.

Conclusions: Lower BMI was associated with higher mortality in older adults.

Prevalence of Frailty in Chronic Dialysis Patients in Japan

Hidemi Takeuchi,[1] Haruhito A. Uchida,[1] Yuki Kakio,[1] Yuka Okuyama,[1] Ryoko Umebayashi,[1] Michihiro Okuyama,[2] Taro Sugimoto,[1] Hitoshi Sugiyama,[1] Jun Wada.[1] *[1]Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama Univ, Okayama, Japan; [2]Cardiovascular Surgery, Okayama Univ, Okayama, Japan.*

Background: Recently, frailty has raised as the problematic expression of the elderly population, especially dialysis patients. Since potential causative factors of frailty present in the patients with CKD and ESRD, they are prone to develop frailty. The prevalence of frailty has reported 14 % of CKD patients and 42 % of dialysis patients in Western studies. However, that in dialysis patients in Japan remains unknown. The aim of this study was to examine the prevalence and the predictors of frailty in Japanese hemodialysis patients.

Methods: This study was a multicenter, cross-sectional and observational investigation, which was conducted at 6 institutions including 5 general hospitals and 1 clinic. The subjects were all chronic hemodialysis patients who regularly visited the institutions and were recruited from October 2015 to January 2016. To evaluate frailty status, we used the modified Fried's frailty phenotype definition modified for Japanese as the self-report questionnaire.

Results: Of 542 patients visiting each institution, 388 patients were enrolled in this study. Participants were 67 ± 12 years old, with more male gender (62.4 %). In total, 21.4 % of participants were categorized as frailty, 52.6 % as pre-frailty and 26.0 % as normal.

The prevalence of frailty increased steadily with age, was more prevalent in female and polypharmacy. Next, we performed multivariate logistic regression analysis for the predictors of frailty. The factors independently associated with frailty were determined as follows: female (OR = 3.864, 95 % C.I. 1.595-9.361), 75 years and over (OR = 5.375, 95 % C.I. 1.932-14.953), the number of medications (OR = 1.335, 95 % C.I. 1.156-1.541), DM (OR = 2.885, 95 % C.I. 1.181-7.048) and MNA-SF score ≤ 11 (OR = 8.550, 95 % C.I. 3.300-22.149).

Conclusions: The prevalence of frailty in Japanese dialysis patients was relatively lower than that of previous studies in Western countries. The patients of 75 years old and over, female, DM, polypharmacy and MNA-SF were closely associated with frailty.

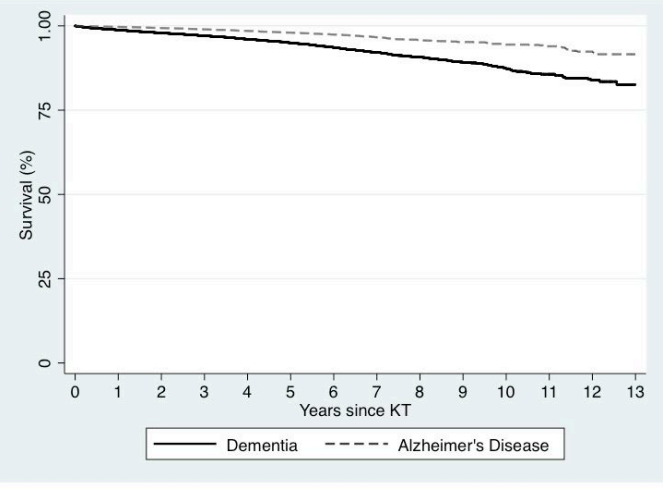
SA-PO1145

Dementia and Alzheimer's Disease among Older Kidney Transplant Recipients Mara McAdams-DeMarco, Sunjae Bae, Dorry L. Segev. *Johns Hopkins.*

Background: End stage renal disease and cognitive impairment share a common pathogenesis and dialysis increases the risk of cognitive impairment. KT is a growing treatment option for older adults yet, older recipients may develop dementia and Alzheimer's disease (AD) as the result of both their long standing kidney disease and the lifelong dependence on immunosuppressants, which are known to be neurotoxic.

Methods: We studied 43,606 older (aged >=55) KT recipients who were Medicare Primary (between 1/1/99-12/31/11) using SRTR data linked to Medicare claims. We estimated the cumulative incidence of dementia and AD (based on claims) using the Kaplan-Meier method. We developed a prediction model based on recipient, transplant, and donor factors known prior to KT for the post-KT incidence of dementia and AD (separately) using an AIC-based selection method for the Cox proportional hazards model.

Results: We estimated the post-KT cumulative incidence of dementia and AD to be 5.0% and 2.0% at 5 years and 12.7% and 5.6% at 10 years, respectively.



The prediction dementia model included recipient (age, race, education, BMI, history of diabetes, and time on dialysis), transplant (year of KT, previous KT, ABO incompatible, and peak PRA), and donor factors (race, hypertension, diabetes, and HCV) (C-statistic=0.66). The AD prediction model included recipient (age, education, BMI, history of diabetes, and time on dialysis), transplant (year of KT and previous KT), and donor factors (race and HCV) (C-statistic=0.70). The strongest predictors for both dementia and AD were recipient age (5y increase in age: dementia HR=1.49, 95%CI:1.43-1.56; AD HR=1.68, 95%CI:1.57-1.80) and history of diabetes (dementia HR=1.81, 95%CI: 1.43-1.56; AD HR=1.48, 95%CI:1.25-1.75).

Conclusions: Older KT recipients are at risk of dementia and AD. Recipient, donor, and transplant factors obtained prior to KT can be used to predict which older recipients are at risk of post-KT dementia and AD.

SA-PO1146

Comparison of Geriatric and Medical Multi-Morbidity on Physical Function in Older Adults with Chronic Kidney Disease Christine Liu,[1,2] Eamon F. Fleming,[2] Jamie Giffuni,[3] Kieran Reid,[2] Sushrut S. Waikar,[4] Stephen L. Seliger,[3] Daniel E. Weiner.[2] *[1]Boston Univ, Boston, MA; [2]Tufts Univ, Boston, MA; [3]Univ of Maryland, Baltimore, MD; [4]Harvard Medical School, Boston, MA.*

Background: Geriatric conditions are combinations of signs and symptoms not linked to a disease, such as fatigue. Medical conditions relate to specific diseases. Geriatric multi-morbidity (2+ geriatric conditions) and medical multi-morbidity are common in older CKD patients and may impact physical function. We compared the impact of geriatric and medical multi-morbidity on physical function in older CKD patients.

Methods: The Aerobics, Weights, and Renal Disease Study is an ongoing randomized trial of exercise in adults 55+ years with CKD stage 3b-4. Data are from baseline. Persons were defined with 1) fatigue if ≥"good bit of time" to feeling worn out on Short Form-36 (SF-36); 2) chronic pain if ≥"moderate" pain on SF-36; 3) cognitive impairment if Montreal Cognitive Assessment <26; 4) poor appetite as reported on Memorial Symptom Assessment Scale (MSAS); and 5) dizziness as reported on MSAS. Hypertension, diabetes, CAD, cancer, and COPD were defined by self-report or record review. Physical function was assessed with the Short Physical Performance Battery (SPPB) and the SF-36 physical function domains. Linear regression was used, adjusting for age, sex, study site, BMI, and eGFR.

Results: Of 93 persons (27% female, mean age 68.2±8.3 years, mean eGFR 33.0±9.2 ml/min/1.73m^2), 46 (50%) had geriatric multi-morbidity and 70 (75%) had medical multi-morbidity. Geriatric multi-morbidity was associated with lower SPPB and SF-36 scores, but not medical multi-morbidity (Table).

Conclusions: In older adults with CKD, geriatric multi-morbidity likely has a stronger association with physical function than medical multi-morbidity.

Table: Least square means of associations of geriatric and medical multi-morbidity with physical function (N=93)

Outcomes	Multi-morbidity	Yes	No	Adjusted p value
SPPB	Geriatric	8.7	9.8	**0.05**
	Medical	9.1	9.3	0.72
SF-36 Physical function	Geriatric	53.8	75.3	**0.0001**
	Medical	61.0	68.1	0.19
SF-36 Role limitations-physical function	Geriatric	26.9	79.1	**<0.0001**
	Medical	49.3	56.6	0.37

Symptom Burden in Geriatric Hospitalized End Stage Renal Disease Patients: Quantifying Symptoms to Increase Nephrologist Awareness and Use of Palliative Care Consultation Areeba Jawed,[1] Sharon M. Moe,[1] Ranjani N. Moorthi,[1] Alexia Torke,[2] Michael T. Eadon.[1] *[1]Div of Nephrology, Dept of Medicine, Indiana Univ School of Medicine, Indianapolis, IN; [2]Internal Medicine, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: End Stage Renal Disease (ESRD) patients have significant symptom burden. Reduced provider awareness of symptoms contributes to underutilization of symptom management resources. We hypothesized that improved nephrologist awareness of symptoms leads to symptom improvement.

Methods: In this prospective, multicenter intervention study, 51 geriatric ESRD inpatients underwent symptom assessment using the modified Edmonton Symptom Assessment System (ESAS) at admission and 1 week post-discharge. Enrollees were sequentially randomized into 2 groups. The nephrologist of each individual was provided baseline symptom assessment in group 1, but was unaware in group 2. Severity ratings were compared between in-hospital and post discharge scores and between groups.

Results: 50 patients completed the study; 1 died. Baseline characteristics were compared. For 70% of the total cohort physicians reported not being surprised if their patient died within a year. There was no difference in baseline scores between groups. Total ESAS scores improved more in group 1 (13.3) than group 2 (9.5) (p=0.04). Among individual symptoms, there was greater improvement in pain control (p=0.01), and itching (p=0.05) in Group 1 as compared to Group 2. There were three palliative care consults.

Conclusions: Our findings reinforce the high symptom burden prevalent in geriatric ESRD patients. The improvement in total scores, and individual symptoms of pain and itching in group 1 indicates better symptom control when physician awareness is increased and simple pharmacological interventions are available. Residual symptoms post hospitalization and low utilization of palliative care resources is suggestive of a missed opportunity by nephrologists to address the high symptom burden at the inpatient encounter which is selective for sicker patients and/or inadequacy of dialysis to control these symptoms.

Funding: Private Foundation Support

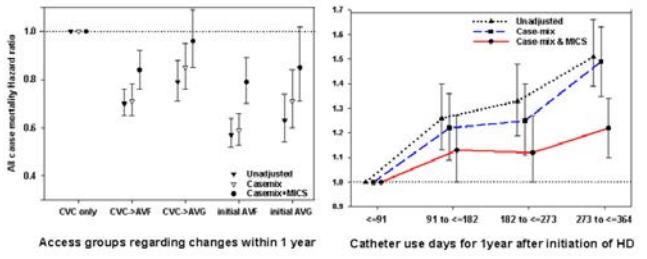
SA-PO1148

Use of Arteriovenous Fistula within 1 Year of Hemodialysis Initiation Was Associated with Better Survival in Comparison with Catheter Use among Patients Older Than 80 Gang Jee Ko,[1] Connie Rhee,[1] Tae Ik Chang,[1] Yoshitsugu Obi,[1] Melissa Soohoo,[1] Tae Woo Kim,[1] Rieko Eriguchi,[1] Hamid Moradi,[1] Vanessa A. Ravel,[1] Csaba P. Kovesdy,[2] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: While arteriovenous fistulas (AVFs) are recommended as the preferred vascular access type in most hemodialysis (HD) patients, this remains widely debated in very old HD patients given their lower rates of AVF maturation and limited life expectancy.

Methods: We examined the conversion of access types within 1 year after HD initiation, and evaluated the association of dialysis access with mortality using Cox regression with adjustment for case-mix (demographics, comorbidities) and markers of malnutrition and inflammation (MICS) in 8,326 incident HD patients age 80 years, who survived the first year of HD from a large dialysis organization during 2007-2011.

Results: During the first year of HD, 27% of elderly patients exclusively used a central venous catheter (CVC). Ever use of AVF (CVC-to-AVF or initial AVF) within the first year of HD was associated with better survival compared to the CVC-only use. In fully adjusted models, no significant differences were noted between ever-use of AV graft in the first year of HD, compared to CVC-only. Longer use (total number of days in the first year of HD) of CVC following HD initiation was associated with incrementally worse survival (right panel).



Conclusions: It is suggested to consider converting access type to AVF from CVC and decreasing the periods time using CVC even in very old HD patients. Initiation of dialysis with a CVC catheter could be an acceptable option in elderly patients, as long as it is converted to an AVF as soon as possible.

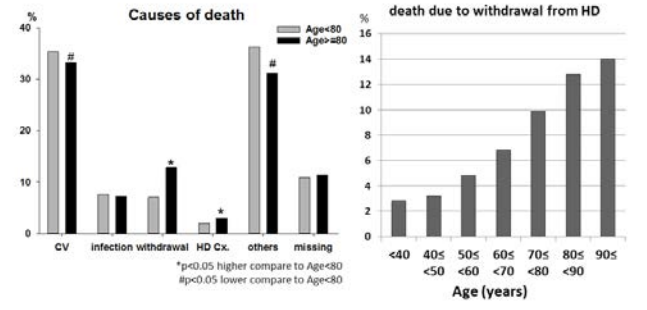
SA-PO1149

Death due to Dialysis Withdrawal among Elderly Incident Hemodialysis Patients Gang Jee Ko,[1] Tae Ik Chang,[1] Connie Rhee,[1] Tae Woo Kim,[1] Yoshitsugu Obi,[1] Rieko Eriguchi,[1] Melissa Soohoo,[1] Daniel L. Gillen,[1] Vanessa A. Ravel,[1] Csaba P. Kovesdy,[2] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: The population of elderly patients is rapidly growing among ESRD patients initiating dialysis. However, it is not clear whether death due to withdrawal from dialysis differs across age and which pattern it has, in particular among octogenarian and nonagenarian patients.

Methods: We compared causes of death, including withdrawal from dialysis, within the first year of dialysis among incident hemodialysis (HD) patients aged ≥80 years (N=17,296) vs. those <80 years of age (N=115,866) from a large national dialysis organization over a 5 year period (2007-2011). Comparisons were modeled using reported frequencies and logistic regression.

Results: Compared to patients <80 years of age, octogenarian and nonagenarian were more likely to be female (45.8 *vs.* 43.0%) and non-Hispanic White (67.7 *vs.* 43.7%), and were less likely to have diabetes (45.6 *vs.* 57.0%). Loss to follow-up during the 1st year of HD was more frequent in octogenarian and nonagenarian, and a greater proportion of these events was due to dialysis withdrawal as compared with younger patients (7.2 *vs.* 2.9%) besides death. Among octogenarian and nonagenarian, death due to dialysis withdrawal was the second most common cause of death (left panel), and we observed higher rates of dialysis withdrawal among death with increasingly older age (right panel). Octogenarian and nonagenarian showed a higher likelihood of death due to dialysis withdrawal compared to younger patients even after adjustment for demographics and comorbidities: adjusted OR 1.61 (95% CI: 1.47-1.77).



Conclusions: Withdrawal from dialysis is a major cause of loss to follow-up and death among elderly incident HD patients. Further studies are needed to determine the reasons underlying the differential causes of death across age groups.

Funding: NIDDK Support

SA-PO1150

Survival and Outcomes in Advanced Age with Renal Insufficiency (SOAAR) Hui Xue,[1] Shayna L. Henry,[2] Qiaoling Chen,[2] Mi Chang,[1] Nichole Mihara,[1] Mark P. Rutkowski.[1] *[1]Nephrology, Kaiser Permanente Southern California, CA; [2]Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA.*

Background: While the elderly are the fastest growing segment of individuals with End Stage Renal Disease (ESRD), there is limited evidence for an overall survival or quality adjusted life advantages of Renal Replacement Therapy (RRT) compared to conservative approaches in this group. This study aims to illuminate the outcomes and survival of elderly patients with advanced renal failure with respect to RRT choice, and to identify factors associated with disease progression and worse outcomes.

Methods: From 2003 to 2008, 2,062 adults, mean age 81.1±4.7yrs (range 75-99), 49.5% female, who initiated RRT or maintained eGFR ≤ 20 for at least 3 consecutive months were followed for 5 years with censoring at December 31, 2013. Subjects who did not initiate RRT were observed until death or censor date. Risk of transition to ESRD vs death was stratified into 5 year age groups. Healthcare utilization was also assessed based on RRT use.

Results: The risk of progression to ESRD is higher than death upto age 90, p<0.001. Median survival was 33 (95% CI 30, 36) and 20 (17, 22) months for RRT and non-RRT groups, respectively (p<0.001). Quality-adjusted survival was 21 (19, 23) and 14 (12, 15) months for RRT and no RRT groups, respectively (p<0.001). Peritoneal dialysis offered greatest survival benefit compared to hemodialysis or no RRT (p<0.001). Initial results suggest that age is a better predictor of death than baseline eGFR, with age and survival inversely related, and those patients initiating RRT at the oldest ages (90+ years) experiencing the most limited survival (logrank p<.001). However, RRT was associated with greater healthcare utilization, including more hospitalizations and ER visits, greater SNF use, and lower hospice referral (p<0.001).

Conclusions: RRT appears to afford older adults with ESRD a survival advantage over conservative, non-RRT approaches, but decrements in quality of life may still limit its utility among the elderly. The potential for these findings to provide decision support for initiating or forgoing RRT in elderly patients will be discussed.

SA-PO1151

Impact of Race and Socioeconomic Factors on Mortality among Nursing Home Patients on Maintenance Dialysis Robert Nee,[1] Lawrence Agodoa,[2] Kevin C. Abbott.[2] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Insts of Health, Bethesda, MD.*

Background: The impact of race and socioeconomic factors on survival rates of nursing home (NH) patients with treated end-stage renal disease is unknown. We evaluated race/ethnicity, health insurance and ZIP code-level median household income (MHI) as predictors of mortality of NH patients on dialysis.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 56,194 nursing home patients initiated on maintenance dialysis from January 1, 2007 through December 31, 2013, followed until 31 May 2014. Covariates include demographic and clinical characteristics and other co-morbid conditions from the Medical Evidence Form 2728. ZIP code-level MHI data was obtained from the 2010 United States Census. We conducted adjusted Cox regression analyses with all-cause mortality as the outcome variable.

Results: Within this NH cohort, 50.5% were female, 26.7% were African-Americans (AA), 8.9% were Hispanic, and the mean age was 71.1 ± 12.1 years. Adjusted Cox analysis showed significantly lower risk of death among AA vs non-AA NH patients (adjusted hazard ratio [AHR] 0.89; 95% confidence interval [CI] 0.87-0.91) and Hispanic vs non-Hispanic NH patients (AHR 0.87; 95% CI 0.84-0.91). Employer group health insurance (AHR 0.94; 95% CI 0.91-0.97) and dual-eligibility for both Medicare and Medicaid (AHR 0.75; 95% CI 0.73-0.77) were significantly associated with lower risk of death. However, Medicare (AHR 1.12, 95% CI 1.09-1.15) and Medicaid (AHR 1.13; 95% CI 1.10-1.16) alone were significantly associated with higher risk of death. Compared to those in higher area-level MHI quintile levels, NH patients in the lowest quintile were significantly associated with higher risk of death (AHR 1.10; 95% CI 1.07-1.13).

Conclusions: AA and Hispanic NH patients on dialysis had an apparent survival advantage. The type of health insurance coverage and area-level income were also independent predictors for survival.

SA-PO1152

Association of Dietary Sodium Intake with Change in Cognitive Function and Brain Magnetic Resonance Imaging Indices Kristen L. Nowak,[1] Linda F. Fried,[2,3] Anna Jeanette Jovanovich,[1,4] Joachim H. Ix,[5] Anne B. Newman,[2] Zhiying You,[1] Suzanne Satterfield,[6] Michel Chonchol.[1] *[1]Univ of Colorado Anschutz Medical Campus; [2]Univ of Pittsburgh; [3]VA Pittsburgh Healthcare System; [4]Denver VA Medical Center; [5]Univ of California San Diego; [6]Univ of Tennessee Health Science Center.*

Background: Dietary sodium may influence cognitive function via its influence on cerebrovascular function and cerebral blood flow. We hypothesized that high dietary sodium intake is associated with a decline in cognitive function over time. We further hypothesized that sodium intake is associated with micro- and macro-structural brain magnetic resonance imaging (MRI) indices.

Methods: 1,216 participants in the Health ABC study with measurement of dietary sodium intake and change in the modified mini mental state exam (3MS) were included. Multivariable logistic regression was used to examine the association between baseline dietary sodium intake (food frequency questionnaire) and odds of a clinically significant decline in 3MS score after 7 years (>5 points or to <80 points). In a sub-group who participated in the Healthy Brain substudy (n=257), multiple linear regression models were used to assess the association of sodium intake with micro- and macro-structural brain MRI indices.

Results: Participants were 74±3 years with a mean dietary sodium intake of 2,645±1098 mg/day. During follow-up, 340 (28%) had a clinically significant decline in 3MS score (i.e. cognitive impairment). Dietary sodium intake was not associated with increased odds of cognitive impairment in either the unadjusted model (OR: 1.15, 95% CI: 0.93-1.41 per doubling of sodium intake) or model adjusted for demographics, education, co-morbid conditions, smoking, alcohol, body-mass index, blood pressure, estimated glomerular filtration rate, total kcals, and potassium intake, (OR: 1.36, 95% CI: 0.90-2.07 per doubling of sodium). Similarly, sodium intake was not associated with micro- or macro-structural brain MRI indices in unadjusted and adjusted models.

Conclusions: In the Health ABC study, higher sodium intake was not associated with a decline in cognitive function over time or with micro- and macro-structural brain MRI indices.

Chronic Hyponatremia and Association with Bone Frailty Associated Falls and Fractures Simran K. Bhandari,[1] Annette Adams,[1] Bonnie H. Li,[1] Shirin Sundar,[2] Holly Krasa,[2] Siddhesh Kamat,[2] John J. Sim.[1] *[1]Dept of Nephrology and Hypertension, Kaiser Permanente Southern California; [2]Otsuka Pharmaceuticals.*

Background: Chronic hyponatremia is known to cause cognitive impairment and contribute to osteoporosis, both of which may lead to greater risk of serious falls/fractures (FX) among the elderly. We sought to evaluate whether chronic hyponatremia was associated with increased risk for FX based on serial sodium (Na) measurements among a large diverse population.

Methods: A cohort study was performed within Kaiser Permanente Southern California between 1/1/98 – 12/31/14 among individuals ≥ 55 years with ≥ 2 Na measurements and with dual x-ray absorptiometry (DXA) result. Time weighted (TW) and arithmetic mean Na values were used to define chronic hyponatremia as Na <135 mEq/L. FX were determined from combinations of ICD-9 diagnosis codes, procedure codes, and E codes. Multivariable logistic regression models were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for FX.

Results: 385,778 subjects were identified for the study (68% women and mean age 63). Osteoporosis (DXA T-score < -2.5) was found in 43.7%. Chronic hyponatremia was identified in 12% (n = 46,444) and 2.8 % were found to have TW mean Na of < 135 mEq/L. A total of 49,840 (13%) subjects had a FX. Hyponatremia was present in 24.1% with FX compared to 10.3% without a FX. Individuals who had FX were more likely female and had greater rates of osteoporosis and cardiovascular disease. Compared to Na ≥ 135, chronic hyponatremia was associated with an increased risk of FX (OR 1.41 (1.38, 1.45)). A 5mEq/L increase in TW mean Na was associated with a decreased risk of FX (OR 0.89 (0.84, 0.93)).

Figure 1. Unadjusted and adjusted estimates of the association between hyponatremia and falls/fractures.

Model	Na<135mg/L OR (95% CI)	TW Na, 5 unit increase OR (95% CI)
Unadjusted	2.32 (2.28, 2.36)	0.83 (0.78, 0.88)
Adjust for demographics[1]	1.89 (1.86, 1.93)	0.88 (0.84, 0.94)
Adjust further for comorbidities[2]	1.87 (1.84, 1.91)	0.88 (0.84, 0.94)
Adjust further for labs[3]	1.57 (1.54, 1.61)	0.85 (0.81, 0.90)
Adjust further for pharmacologic exposures[4]	1.41 (1.38, 1.45)	0.89 (0.84, 0.93)

[1]Age, sex, race/ethnicity
[2]Diabetes, cardiovascular disease, peripheral vascular disease, hypertension, hypothyroidism, and prior fracture
[3]Potassium, carbon dioxide, chloride, BUN, creatinine, calcium, hemoglobin, TSH, alkaline phosphatase, HgbA1C, albumin
[4]Bisphosphonates, other osteoporosis druges, anti-hypertensives, anti-arrythmics, anti-coagulants, anti-seizure medications, endocrine and hormonal therapies, corticosteroids, thiazide diuretics, benzodiazepines, anti-depressants, proton-pump inhibitors

Conclusions: Among a large population with DXA measurements, we found chronic hyponatremia was associated with higher risk for having FX. There was a dose dependent protective association with higher TW mean Na values and FX.

Medicare Advantage Plan Star Rating and Voluntary Disenrollment of Incident Dialysis Patients Qijuan Li,[1] Amal Trivedi,[1] Omar Galarraga,[1] Daniel E. Weiner,[2] Vincent Mor.[1] *[1]Health Services, Policy and Practice, Brown Univ; [2]Tufts Medical Center.*

Background: There has been limited focus on Medicare Advantage (MA) plan quality ratings and beneficiaries' decisions to disenroll, particularly among high-cost populations with intensive health care needs. Accordingly, we assessed the association between publicly reported MA plan quality ratings and voluntary disenrollment by incident dialysis patients.

Methods: Data on 50,391 incident dialysis patients were assembled from four national administrative databases spanning 2007 and 2013. We used conditional logit regression, controlling for patient and plan characteristics, to examine the association between MA plan star ratings at the time of initiating dialysis and disenrollment rates from MA plans to Traditional Medicare in the following year.

Results: Disenrollment rates for incident dialysis patients ranged from 8.8% among plans rated with 2.5 or fewer stars to 22.7% among plans rated with 4 or more stars. Compared to MA plans with star ratings of 4 or above, adjusted disenrollment rates were 3.9 (95% CI 2.4 to 5.5), 5.0 (95% CI 3.5 to 6.5), and 12.1 percentage points (95% CI 10.0 to 14.3) higher among MA plans with star ratings of 3.5, 3 and 2.5 or less, respectively. The disenrollment rate from MA plans to Traditional Medicare among incident dialysis patients was significantly higher than among all MA beneficiaries (14.9% vs 12.0%; p<0.01). Among MA plans with 2.5 or fewer stars, the adjusted disenrollment rate of incident dialysis patients was about 5.8 percentage points (95% CI 1.4 to 10.1) higher than that of all MA beneficiaries.

Conclusions: MA plans with worse star ratings had higher rates of disenrollment by incident dialysis patients in the following year. The association between star ratings and disenrollment was stronger among incident dialysis patients than among all MA beneficiaries, especially in low-quality plans. These findings suggest that the rate of voluntary disenrollment among high-cost, high need patients may be an important measure of MA plan quality. Low plan quality may lead to increased expenditures in Traditional Medicare by shifting this high-cost population from MA plans to Traditional Medicare.

Serum 25-Hydroxyvitamin D Status, Body Composition, and Muscle Strength in Ambulatory Patients on Hemodialysis Dong Ho Yang,[1] So-Young Lee.[1] *[1]Internal Medicine, CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [2]Internal Medicine, Seoul Bukbu Geriatic Hospital, Seoul, Republic of Korea.*

Background: Sarcopenia and muscle weakness are prevalent in patients with end stage renal disease, and vitamin D has various actions in skeletal muscle. We investigated the relationship between serum 25-hydroxyvitamin D [25(OH)D] status and skeletal muscle mass and muscle strength in ambulatory hemodialysis patients.

Methods: The current study involved 122 ambulatory hemodialysis patients. We evaluated serum 25(OH)D, body composition including skeletal muscle mass as measured by bioimpedance, muscle strength as measured by dynamometer (handgrip strength), and 4-meter walking speed in these participants. Alow muscle mass was defined by the SMM index (SMI: SMM [kg] / height [m2] > 7.0kg for men, > 5.7kg for women). Sarcopenia was defined if the patients having a low hand grip or walking speed (thresholds defined on the basis of the lowest sex-specific quintiles among general population) were identified as having a low muscle mass.

Results: The participants' average age was 60.6±1.2 years old, 54.1% were male, 57.4% had diabetes mellitus, and their mean duration of dialysis was 44.7±49.6 months. The mean 25(OH)D serum level was 16.2±0.9 ng/ml. Sarcopenia was identified in 16.4% of the participants. An analysis using the Pearson's correlation coefficient revealed a positive correlation between serum 25(OH)D levels and skeletal muscle mass (Pearson = 0.455, p < 0.001). Patients having a higher serum 25(OH)D level had a better hand grip strength (Pearson = 0.351, p< 0.001). Binary logistic regression analysis showed that ambulatory hemodialysis patients with above-median serum 25(OH)D levels had significantly more skeletal muscle mass (odd ratio [OR] 1.34; 95% Confidence interval [CI]: 1.20-1.51, p <0.001) and better hand grip strength (OR 1.06; 95% CI: 1.02-1.10, p=0.03).

Conclusions: In this study, serum 25(OH)D level was significantly associated with handgrip strength as well as skeletal muscle mass among ambulatory hemodialysis patients.

SA-PO1156

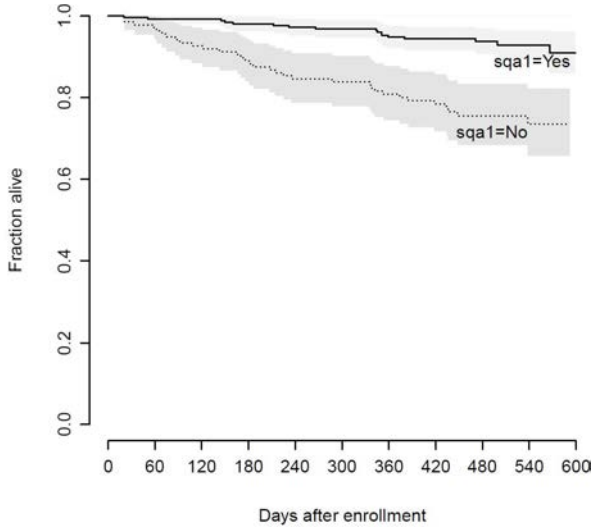
The Utility and Reliability of a Provider-Based Subjective Health Measure in Older Adults with CKD Stage 4-5 Andrei Javier,[1] Rocio Figueroa,[2] Huzaifah Salat,[1] Cesar Y. Cardona,[3] Jennifer Morse,[1] Thomas G. Stewart,[1] Manisha Jhamb,[4] Edward D. Siew,[1] Talat Alp Ikizler,[1] Khaled Abdel-Kader.[1] *[1]Vanderbilt Univ; [2]Univ of New Mexico; [3]Meharry Medical College; [4]Univ of Pittsburgh.*

Background: Nephrologists report prognostic uncertainty as a key barrier to advance care planning. We hypothesized the surprise question (SQ) would demonstrate acceptable test-retest and inter-rater reliability (until now uncharacterized) and be an effective predictor of mortality in older adults with CKD 4-5.

Methods: We enrolled 388 patients at a nephrology clinic from June 2014 to January 2015. Eligibility criteria were age > 60 years and CKD stage 4-5. Exclusion criteria were ESRD or kidney transplant prior to enrollment or eGFR > 60 within 12 months. Baseline characteristics were obtained from the health record. We collected SQ responses from attendings and fellows in a blinded fashion immediately after each visit.

Results:

	Total N=388 (%)	SQ 'Y' N=251 (65%)	SQ 'N' N=137 (35)	P
Age, median (IQR)	71 (65-77)	69 (65-74)	74 (68-80)	<.001
Female	195 (50)	127 (51)	68 (50)	0.9
Race				0.7
White	321 (83)	209 (84)	112 (82)	
Black	58 (15)	36 (14)	22 (16)	
DM with microvascular dsz	196 (51)	117 (47)	79 (58)	0.04
HTN	381 (98)	247 (98)	134 (98)	0.9
CAD	151 (39)	86 (34)	65 (47)	0.01
CHF (reduced EF)	34 (9)	10 (4)	24 (18)	<.001
Arrhythmia	97 (25)	49 (20)	48 (35)	<.001
Cerebrovascular dsz	88 (23)	49 (20)	39 (28)	0.04
PVD	78 (20)	48 (19)	30 (22)	0.5
eGFR	23 (16-28)	24 (18-29)	20 (15-25)	<.001



The SQ demonstrated good inter-rater (Kappa 0.60, 95% CI 0.48-0.68) and test-retest reliability (Kappa=0.64, 95% CI 0.55-0.74), and associated with mortality (P<0.001).

Conclusions: The SQ can be a helpful tool to identify CKD 4-5 patients at higher risk for short term mortality, but will likely require use in conjunction with other patient characteristics.

The Pattern of Renal Histopathology in Elderly Korean with Renal Diseases: A 12-Year Review of a Single-Centre Renal Biopsy Database Yong Un Kang, Ha Yeon Kim, Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Chonnam National Univ Medical School.*

Background: Studies on biopsy-proven renal disease in the elderly are extremely limited in Korea. This study aimed to investigate the spectrum of renal histopathology and their clinical manifestations in elderly patients undergoing renal biopsy.

Methods: All native renal biopsies (n=99) performed in patients aged ≥65 years from January 2004 to December 2015 were retrospectively analyzed.The results were compared with a control group of 1,045 patients aged <65 years receiving renal biopsy during the same period.

Results: The number of the elderly was 99 patients with an age of 69.78±4.11 (range 65–81) years at the time of biopsy (men, 55 patients; women, 44 patients). The most common indication for renal biopsy was nephrotic syndrome (NS) (44.5%), followed by acute kidney injury (AKI) and NS (16.2%) and AKI (14.1%). Idiopathic membranous nephropathy (iMN, 16.2%) was the most frequent diagnosis, followed by minimal change disease (14.1%), diabetic nephropathy (DN, 12.1%), focal sclerosing glomerulonephritis (6.1%), IgA nephropathy (IgAN, 6.1%), lupus nephritis (LN, 6.1%) and vasculitis (5.1%) and amyloidosis (4%). In patients with NS and AKI, iMN (25.0%) and vasculitis (20.0%) was the leading cause. Comparison with the control group showed iMN (P=0.004), DN (P=0.005), vasculitis (P<0.001) and amyloidosis (P<0.001) to be more frequent and IgAN (P<0.001) and LN (P=0.014) less frequent in the elderly.

Conclusions: These datas indicate that their clinical manifestations and histopathology differ between elderly and non-elderly Korean with renal diseases. Our data are an important contribution to the epidemiology of renal disease in elderly Korean.

10 Years Follow-Up of Renal Function in Elderly with Chronic Kidney Disease Manuel M. Heras,[1] Maria Teresa Guerrero,[2] Maria Jose Fernandez Reyes,[1] Angelica Muñoz,[2] Alvaro Molina,[1] Maria Astrid Rodriguez Gomez,[1] Ramiro Callejas,[1] Leonardo Calle,[1] Carmen Rita Martin Varas.[1] *[1]Nephrology, General Hospital Segovia, Segovia, Spain; [2]Geriatrics, General Hospital Segovia, Segovia, Spain.*

Background: Chronic Kidney Disease (CKD) is a global public health problem. Prevalence of low estimated glomerular filtration (eGFR) increases with age. We followed-up for 10 years the renal function (RF) of elderly with CKD.

Methods: 80 clinically stable patients, with a median age of 83 years; women: 68,8%; diabetics: 35%; alleatory recruited in the Departments of Geriatric and Nephrology, within January-April 2006, were followed-up for 10 years. We separated them in two groups based in their serum creatinine (sCr) baseline: Group 1: 38 patients with sCr≤1,1 mg/dl (range:0,7–1,1); and Group 2: 42 patients with sCr>1,1 mg/dl (range: 1,2–3,0). We measured creatinine, urea in serum; and estimated GFR baseline and 10 years, using abreviated MDRD. Statistical comparisons using repeated measures, SPSS 15.0 program.

Results: After 10 years of follow-up, 61 patients died (Group 1=23, Group 2=38, P=0,003) and 19 patients (including 2 males) with a mean age of 86,47±6 years (range: 79-97) remained in the study. Overall data regarding changes in RF (baseline/10 years) in surviving patients were as follows: sCr (mg/dl): 1,02±0,20/ 1,14±0,91 (not significant [ns]); urea (mg/dl): 43,08±12,0/ 66,16±57,0 (ns); MDRD (ml/min/1.73m2): 60,21±12,0/ 63,33±20,0 (ns). No significant differences in changes in RF by groups. Deterioration of sCr (mg/dl) was higher in those with/without proteinuria baseline: 1,25±0,35/ 2,80±2,68 vs 0,99±0,18/ 0,93±0,32, P=0,002. Three patients (Group 2) progressed to end-stage renal disease (ESRD), only one is alive at 10 years.

Conclusions: Elderly patients with worse baseline RF, the risk ESRD is attenuated when an excess of mortality is taken into account. Only proteinuria determinated worse follow-up of RF. Therefore allow us an optimist message for elderly with low eGFR without proteinuria.

SA-PO1159

One Year Mortality after Dialysis Initiation in a Portuguese Elderly Cohort:Development of a Predictive Mortality Risk Score Andreia Campos, Josefina Lascasas, Jorge Malheiro, Sofia Correia, Sofia Santos, António Cabrita. *CHP, Nephrology Dept.*

Background: In the last years, Portuguese elderly(≥65 years old,y)population has grown significantly. Because early mortality after dialysis(D)initiation is common, we aimed to analyze 1y mortality in elderly starting D and to establish a predictive risk scoring model(SM).

Methods: We selected a cohort of 208 patients(P) who initiated D between 2012-2015. A scoring system was constructed in which points(Ps) were assigned to each risk factor by using the b-coefficients(B) from the final Cox regression. A risk score was made by adding points for each risk factor(RF). We compared SM with others previously described.

Results: The overall 1y mortality was 20,2%. In a univariate analysis of demographics, clinical and social variables, the significant predictors of mortality were: nephrology follow up<1y(Fup), age>75y, ischemic nephropathy, congestive heart failure(CHF), hemiplegia, past malignancy history(M), chronic lung disease, lower albumin level(A), need of urgent D and beginning by catheter. These variables were included in a multivariate analysis: independent predictors of mortality were identified and points were assigned to each RF for the SM.

RF	B	HR IC95%	*P*	Ps
Fup<1y	0.8	2.2(1,0-4,6)	0.038	1
>75y	0.8	2.3(1,1-4,6)	0.028	1
M	0.9	2.6(1,1-6,3)	0.035	1
CHF	0.8	2.1(1,0-4,4)	0.046	1
A(mg/dl)			0.025	
<3	2.0	7.7(1,6-35,7)		2
3-3,5	2.1	8.0(1,7-38,1)		2
3,5-4	1.4	4.0(0,8-19,4)		1

Mortality rates ranged from 0% to 61.5% according to SM.

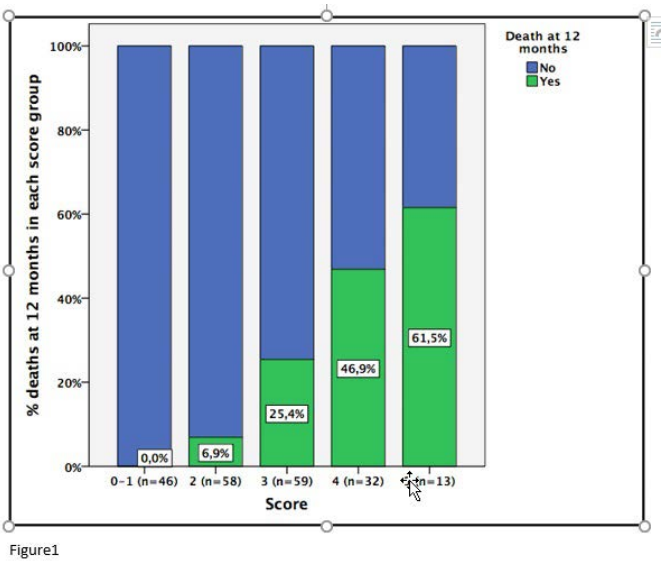

Figure1

AUC in SM, Couchoud and Cohen scores are 0.82, 0.77 and 0.85 respectively. There is no difference between them(p>0,05).

Conclusions: This simple prediction tool based on readily available clinical and laboratory data can assist in predicting short-term prognosis among elderly patients starting D. It may be useful in counseling patients and guiding clinical decision making.

SA-PO1160

Detecting the Minimum Recommendation of Physical Activity Level in Hemodialysis Patients: A 7-Year Retrospective Cohort Study

Ryota Matsuzawa,[1] Takahiro Shimoda,[2] Noritaka Mamorita,[2] Kei Yoneki,[2] Manae Harada,[2] Takaaki Watanabe,[2] Mika Matsumoto,[2] Atsushi Yoshida,[3] Yasuo Takeuchi,[2] Atsuhiko Matsunaga.[2] *[1]Kitasato Univ Hospital, Sagamihara, Japan; [2]Kitasato Univ, Sagamihara, Japan; [3]Sagami Circulatory Organ Clinic, Sagamihara, Japan.*

Background: Sedentary lifestyle is a well-known indicator of poor prognosis in hemodialysis patients. However, because the minimum recommendations for physical activity level are unknown in these patients, we retrospectively investigated the association between physical activity level and mortality risk.

Methods: A total of 282 outpatients (age, 64.8 ± 10.6 years; hemodialysis duration, 7.0 ± 7.8 years) who required hemodialysis 3 times a week were followed up for up to 7 years. Physical activity levels and patient characteristics, including age, sex, body mass index, hemodialysis duration, comorbid conditions, and nutritional status, were obtained at baseline. Physical activity was objectively evaluated using an accelerometer as the number of steps taken on a non-dialysis day based on the data of 4 consecutive non-dialysis days. A Cox proportional hazard regression model with smoothed plot for hazard ratios of all-cause mortality according to physical activity levels was used to detect the minimum recommendation.

Results: Fifty-six patients died during follow-up. In a Cox proportional hazard regression model adjusted for patient characteristics, the hazard ratio in the group with lower physical activity level was 2.18 (95% confidence interval = 1.16 - 4.09) compared with that in the group with higher level. Based on the smoothed plot for hazard ratios, we detected 2500 steps per non-dialysis day as a cut-off point of physical activity for poor prognosis (Fig. 1).

Conclusions: Lower physical activity level is associated with higher mortality risk. We recommend that hemodialysis patients take at least 2500 steps per non-dialysis day to avoid the worst possible outcome.

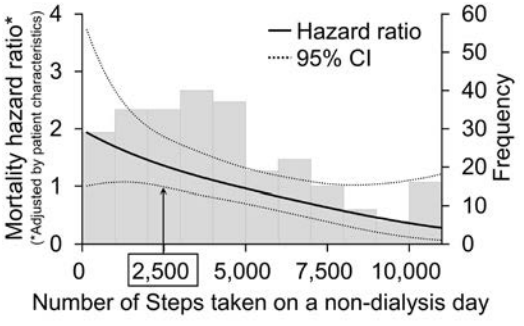

Fig 1. Smoothed plot for hazard ratios of the all-cause mortality according to physical activity.

SA-PO1161

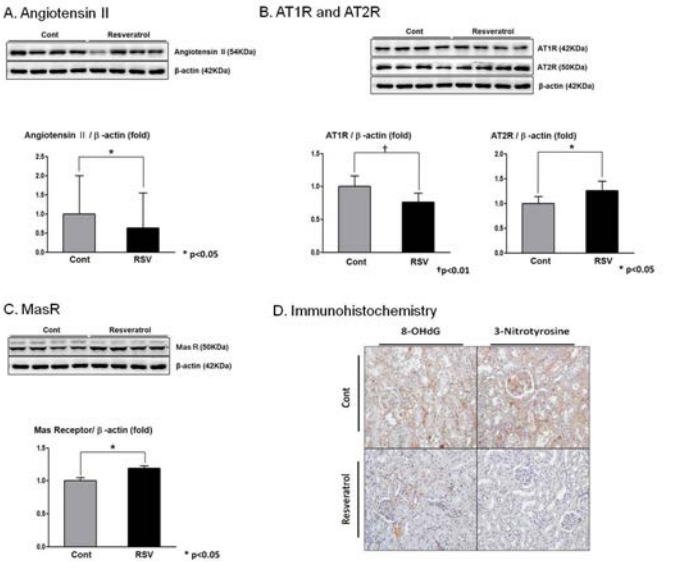
Effects of Resveratrol on Renin-Angiotensin System in the Aging Kidney

In-Ae Jang, Eun Nim Kim, Tae Hyun Ban, Hye Eun Yoon, Cheol Whee Park, Bumsoon Choi. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: The renin-angiotensin system, especially angiotensin II (ANGII) / angiotensin II type 1 receptors (AT1R) axis plays an important role in aging process of kidney through progressively increased oxidative stress. In the present study, we aimed to evaluate the effect of resveratrol, a naturally found polyphenol with antioxidant activities, in modulation of renin-angiotensin system in aging kidney of mice and to identify the putative underlying signaling pathways.

Methods: 18-month-old male C57BL/6 mice were divided into two groups and received either normal mice chow or underwent resveratrol treatment for 6 months. Intrarenal expression of renin-angiotensin system molecules, as well as pro- and antioxidant enzymes were measured, and mice kidney was isolated for histological analysis.

Results: Resveratrol-treated group showed significant improvement in renal function; serum creatinine decreased (0.25±0.05 mg/dL vs. 0.67±0.34 mg/dL; p <0.03 vs. control group), creatinine clearance increased (0.28±0.07 ml/min vs. 0.10±0.04 ml/min; p <0.001) and albuminuria decreased (29.47±14.32 μg/24hr vs. 67.69±22.79 μg/24hr; p <0.03) compared with control group. There were decreases in mesangial volume and tubulointerstitial fibrosis in resveratrol-treated mice. The expressions of ANGII, ACE and AT1R significantly decreased in resveratrol group, whereas those of ACE2, AT2R and MasR increased. Resveratrol increased the expression of phosphorylated eNOS and SOD2 significantly while the expressions of Nox4, fibronectin and collagen IV decreased. Immunohistochemistry revealed that 8-OHdG-positive area and 3-nitrotyrosin-positive area decreased in resveratrol group.



Conclusions: Resveratrol exerts renoprotective effects on aging kidney, associated with reduction of oxidative stress and inflammation through AT2R and MasR activation.

PUB001

Effects of High Dietary Sodium on Renal Tissue Sodium Content, Renal Heparan Sulfate Proteoglycans and Tubulo-Interstitial Remodeling Ryanne S. Hijmans, Pragyi Shrestha, Saleh Yazdani, Gerjan Navis, Jacob van den Born. *Nephrology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: High sodium intake is associated with hypertension and renal damage. Studies suggest that sodium-induced blood pressure-independent pathways can also cause renal damage. Heparan sulfate proteoglycans act as co-receptors for growth factors and chemokines and orchestrate tubulo-interstitial (TI) remodeling. Our aim is to investigate blood pressure-(in)dependent effects of high sodium intake on TI remodeling associated with structure and function of renal proteoglycans.

Methods: Wistar rats (N=5/group) received a normal chow diet for 4 weeks (C) or 8% NaCl chow diet (High Salt: HS) for 2 or 4 weeks. Blood pressure (BP) was monitored, and plasma, urine and tissue collected. Cortex homogenates were dissolved in nitric acid and sodium was measured by flame spectroscopy (expressed per dryweight or nitrogen content). Stainings were done for podoplanin+ lymphvessels, α-SMA+ myofibroblasts, collagen III, CD3+ T-cells, ED1+ macrophages (Mφ), heparan sulfate domains JM403, 10E4 and functional domains for MCP-1 and L-selectin binding. Statistical differences and correlations were tested by Kruskall Wallis and Spearman Rank correlation.

Results: HS rats showed a BP increase of ~10-15 mmHg at week 1 ($p<0.05$), which returned to C values later on. At week 4 cortical sodium increased ~0,1 mmol/mg in HS rats vs. week 2 ($p<0.05$), accompanied by partial loss of JM403 and 10E4, and increased MCP-1 and L-selectin binding to heparan sulfate. HS rats showed renal lymphangiogenesis, inflammation and profibrotic changes (all $p<0.05$ vs C). Cortical sodium correlated with L-selectin binding (r=0,668, p=0,007) and T-cells influx (r=0.554, p=0.03). Reduced (peri-) glomerular 10E4 and JM403 correlated with increase of myofibroblasts (r=-0.579, p=0.02) and Mφ (r=-0.644, p=0.01). Reduced JM403 correlated with increased lymphangiogenesis (r=-0.549, p=0.03) and L-selectin binding (r=-0.595, p=0.02).

Conclusions: These data suggest that increased cortical sodium by HS diet changes heparan sulfate structure and contributes to pro-fibrotic and pro-inflammatory tissue responses. Whether this is BP-independent is not clear yet.

PUB003

Protective Effects of Epigallocatechin Gallate and Dipeptidyl Peptidase IV Inhibitor Gemigliptin on Tacrolimus-Induced Nephrotoxicity in Mice Hyun Lee Kim,[2] Hyun Ho Ryu,[1] Byung Chul Shin.[2] *[1]Emergency Medicine, Chonnam National Univ Hospital, Gwangju, Republic of Korea; [2]Internal Medicine, Chosun Univ, Gwangju, Republic of Korea.*

Background: It has been reported that the proteinuria is an early predictive marker in detection of tacrolimus (TAC) nephrotoxicity. The aim of this study was to investigatethe renoprotective effects of eipgallocatechin gallate (EGCG) and dipeptidyl peptidase IV (DPP IV) inhibitor gemigliptin on TAC-induced acute nephrotoxicity in mice.

Methods: The mice (n=20) were divided into 5 groups (n=5/group); control group wereintraperitoneally (IP) injected 0.9% saline, TAC group were IP injected TAC2 mg/kg, DPP IV inhibitor group were given inaddition gemigliptin 20 mg/kg (G20) by oral gavage. TAC-EGCG group were given TAC by IP injection and EGCG 100 mg/kg by subcutaneous injection. TAC-EGCG-G20 group were given with same dosages.

Results: The 24 hours urine protein amounts were significantly increased in TAC group (46.1 ± 10.9mg/day) compared to control group (11.3 ± 4.4mg/day) and significantly decreasedin TAC-EGCG-G20 group (13.1 ± 5.9mg/day, $P<0.01$) compared to TAC group. The nitric oxide production by TAC was significantly suppressed by EGCG and gemiglipin management. Renal tissue malondialdehyde level was significantly increased in TAC group compared to control group andsignificantly decreased in TAC-EGCG-G20 group compared than that of TAC group. The renal function and antioxidant enzyme activities were significantly suppressed in TAC group compared with control group and restored in EGCG and gemiglipin treatment group.

Conclusions: EGCG and gemigliptin treatment has beneficial antiproteinuric and renoprotective effects onTAC-inducedacute renal injury in mice.

PUB004

The Role of Calpain and Caspase System in Fractalkine Regulation in Lipopolysaccharide-Treated Endothelial Cells Hye Min Choi, Young Eun Kwon, Dong-Jin Oh. *Dept of Internal Medicine, Myongji Hospital, Seonam Univ College of Medicine, Goyang, Korea.*

Background: Chemokines and adhesion molecules expressed by vascular endothelial cells are essential for endothelial cell-leukocyte interactions. Fractalkine (CX3CL1) is a chemokine with a unique CX3C motif, and is produced by endothelial cells stimulated with tumor necrosis factor (TNF)-α, interleukin (IL)-1, lipopolysaccharide (LPS) and interferon (IFN)-γ. There have been several reports that the caspase/calpain proteases are activated in endotoxemia that leads to acute inflammatory process, and we aimed to determine the role of caspases/calpain in regulating fractalkine levels in LPS-treated endothelial cells.

Methods: Human umbilical vein endothelial cells (HUVECs) were exposed to LPS. The changes of CX3CL1 expression were compared in control, LPS-(0.1 μg/ml), IL-1α-(50 μM), IL-1β-(50 μM), LPS+IL-1α-, LPS+IL-1β-, and LPS+IL-1α+IL-1β-treated HUVECs. The changes of CX3CL1 expression was compared with 50 μM inhibitor of caspase-1, caspase-3, caspase-9, and calpain, and a pancaspase inhibitor in LPS-treated HUVECs.

Results: It was observed that 1) there was a dose-dependent increase in CX3CL1 expression in LPS-treated HUVECs. 2) the expression of CX3CL1 was highest in IL-1β-treated HUVECs compared to control, LPS-, IL-1α-, LPS+IL-1α-, LPS+IL-1β-, LPS+IL-1α+IL-1β-treated cells. In addition, 3) the expression of CX3CL1 was highly inhibited with calpain inhibitors, and significantly decreased with the individual inhibitors of caspase-1, caspase-3, and caspase-9. On the contrary, CX3CL1 expression was significantly augmented with a pancaspase inhibitor.

Conclusions: It is concluded that the caspase and calpain system are important modulators of CX3CL1 levels in LPS-treated endothelial cells.

PUB005

Protective Effects of Celastrol in a Mouse Model of Acute Tubular Injury Zhechi He, Jia Shen, Jingyi Zhou, Yan Jiang, Rending Wang, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital of Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Celastrol, extracted from a Chinese traditional herb Tripterygium wilfordii, as a potent immunosuppressive and anti-inflammatory agent, while the effects on acute tubular injury(ATI) is little known.

Methods: Kidney ischemic-reperfusion (KIR) model was induced in C57BL/6 mice by clamping the right renal artery for 45 minutes, and saline orcelastrol (5mg/kg) was given by intraperitoneal injection daily after reperfusion.Oxygen-glucose deprivation (OGD) mimicks ischemia injury on HK2 cells, and celastrol (10 ng/ml) was administrated the cells with re-oxygenation. Tissue sections was revealed by hematoxylin-eosin and Masson's stainings. The inflammation cytokines (IL-6,IL-10,TNF,IFN-γ) in serum and kidney tissues were measured by a cytometric bead array.An intracellular signaling array was used to screen the activation of signaling nodes *in vivo* and *in vitro* models. The expressions of p-Akt, total Akt,p-p53, and total p53was measured further to confirm the array assay.

Results: The tubular injury, and the levels of inflammation cytokines were significantly decreased by celastrol administration. The activation levels of Akt and p53 were reduced by celastrol *in vivo* and *in vitro*.

Conclusions: Celastrol is a potential drug candidate to alleviate the ATI, and the protective effect partly through the reduction of Akt and p53 activation and inflammation.

PUB006

Reproduction of Aristolochic Acid-Induced Nephropathy by Prescribed Herbal Medicine in Experimental Mouse Model Long Jin, Jian Jin, Chul Woo Yang. *Convergent Research Consortium for Immunologic Disease, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: The Chinese medicine (CM) in the slimming preparations contained aristolochic acid (AA), and AA extracted from CM is now considered to induce the nephropathy, such as interstitial fibrosis and tubular atrophy. To demonstrate the exact effect of this renal disease, we studied mouse treated with AA and CM on the renal injury.

Methods: C57BL/6 mice were divided into control, vehicle, AA and herbal medicine groups, and each group comprised five mice. The Same dose of AA and herbal medicine (5 mg/kg) was given to mice intraperitoneally for five days. The AA dose was chosen based on the previous study that 5 mg/kg of AA produces characteristic AA nephropathy in mice. We observed survival rate for each group, and measured body weights and serum creatinine. As a marker of oxidative stress, we measured serum 8-hydroxy-2'-deoxyguanosine (8-OHDG) levels.

Results: After five days, the survival rate was significantly decreased in the mice treated with AA and herbal medicine compared with the control and vehicle groups. There was marked body weight in both of AA and herbal medicine groups compared to the control and vehicle groups. Serum creatinine levels were significantly increased in both of AA and herbal medicine groups compared with control and vehicle groups ($P<0.05$, respectively) and there was no significant difference between AA and herbal medicine groups. Serum 8-OHDG levels were significantly increased in the AA and herbal medicine groups compared with control or vehicle groups ($P<0.05$, respectively) and there was no significant difference between AA and herbal medicine groups.

Conclusions: Intake of medications containing AA will induce renal injury and there is a strong relation between renal disease and the consumption of Chinese medicine, which is containing AA.

Sulodexide Protects Contrast-Induced Nephropathy in Sprague-Dawley Rats Feng Wang, Jianyong Yin, Zeyuan Lu, Nian-Song Wang. *Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Sulodexide is a powerful atithrombin agent, nevertheless, its effect on contrast-Induced Nephropathy (CIN) remains unknown. In current study, we evaluated the therapeutic effects of sulodexide on CIN and investigate underlying mechanisms.

Methods: CIN model was induced by intravenous injection of indomethacin, followed by Ioversol and L-NAME in Sprague-Dawley rats. Sulodexide or an equivalent volume of vehicle was intravenously delivered 30 min before induction of CIN. The animals were sacrificed at 24h after CIN and tissues were harvested to evaluate renal injury, kidney

oxidative stress and apoptosis levels. Plasma Antithrombin (ATIII) activities were also measured. For in vitro studies, HK2 cells were exposed to Ioversol or H2O2, respectively and the cyto-protective effects of sulodexide were also determined.

Results: Compared to untreated CIN group, improved renal function, reduced tubular injury, decreased levels of oxidative stress and apoptosis and were observed in CIN rats receiving sulodexide injection. In addition, our results also showed that ATIII activity was significantly higher in sulodexide-administered group than that in vehicle-injection CIN rats. Our in vitro experiments demonstrated that sulodexide pretreatment protected HK2 cells against the cytotoxicity of Ioversol via inhibiting caspase-3 activity, and preincubation with sulodexide could also attenuate H2O2-induced increases in ROS, apoptosis and caspase-3 levels.

Conclusions: Sulodexide could protect against CIN through activating ATIII, and inhibiting oxidative stress and apoptosis.

PUB008

Sulodexide Protect against Renal Ischemia-Reperfusion Injury by Activation of Antithrombin III Feng Wang, Jianyong Yin, Zeyuan Lu, Nian-Song Wang. *Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Sulodexide is a potent atithrombin agent, however, its effect on renal ischemia-reperfusion injury (IRI) is unknown. In present study, we assessed the therapeutic effects of sulodexide for renal IRI and tried to investigate the potential mechanism.

Methods: One dose of sulodexide were injected intravenously in rats immediately after unilateral kidney ischemia for 45 min. The animals were sacrificed at 3h and 24h respectively. Renal function and tubular injury were assessed. TUNEL staining and caspase-3 expression were utilized to assess cell apoptosis. SOD concentration and Antithrombin III (ATIII) activity were also assayed. For in vitro study, hypoxia injury model for HK2 cells were carried out. Apoptosis and ROS level were evaluated after sulodexide pretreatment.

Results: Sulodexide pretreatment improved renal dysfunction and alleviated tubular pathological injury at 24h after reperfusion. Meanwhile, the levels of oxidative stress and cell apoptosis were also remarkably reduced by sulodexide administration. In addition, our results also showed that ATIII was activated at 3h after reperfusion, which preceded alleviation of renal injury. It was also observed that sulodexide pretreatment could reduce apoptosis and ROS level in HK2 cells under hypoxia injury.

Conclusions: Injection intravenously of sulodexide could protect against renal IRI. The therapeutic effects might be attributed to its activation for AT-III.

PUB009

MicroRNA-375 Is Induced via p53 and NF-κB to Repress Hnf-1β in Cisplatin Nephrotoxicity Jielu Hao,[1,2] Qiang Lou,[1,3] Qingqing Wei,[1,2] Shuqin Mei,[1,2] Lin Li,[1,2] Changlin Mei,[1,2] Zheng Dong.[1,2] *[1]Nephrology, Shanghai Changzheng Hospital, Shanghai, China; [2]Cellular Biology and Anatomy, Augusta Univ, Augusta, GA; [3]Henan Univ, Kaifeng, Henan, China.*

Background: Nephrotoxicity is a major limiting factor for cisplatin-mediated chemotherapy in cancer patients. The pathogenesis of cisplatin-induced nephrotoxicity remains largely unclear and effective kidney protective approaches are currently lacking.

Methods: We tested the PT-Dicer$^{-/-}$ mouse model where Dicer (a key enzyme for microRNA production) was specifically ablated from kidney proximal tubule cells resulting in the depletion of the majority of microRNAs. To identify the specific microRNAs involved in cisplatin nephrotoxicity, we profiled microRNA expression changes by microarray analysis.

Results: We show that cisplatin nephrotoxicity was not affected by overall depletion of microRNAs from kidney proximal tubular cells in conditional Dicer-knockout mice. MiR-375 was identified by microarray and further verified in cisplatin-treated renal tubular cells. Inhibition of miR-375 led to a significant decrease of tubular cell apoptosis during cisplatin treatment, suggesting that miR-375 is injurious or pro-apoptotic.Blockade of p53 or NF-κB led to the attenuation of miR-375 induction during cisplatin treatment, supporting the involvement of p53 and NF-κB in miR-375. At the downstream of miR-375, hepatocyte nuclear factor 1 homeobox B (Hnf-1β) was identified as a key target of this microRNA. Notably, Hnf-1β was shown to cytoprotective in renal tubular cells.

Conclusions: Together, these results suggest that upon cisplatin exposure, p53 and NF-κB may work collaboratively to induce miR-375, which represses the cytoprotective gene Hnf-1β, resulting in renal tubular cell apoptosis.

PUB010

Correlation between Atherosclerosis and Markers of Kidney Injury in Brazilian Afrodescendants Natalino Salgado Filho, Dyego José Araujo Brito, Joyce S. Lages, Gyl Barros-Silva, Bernardete Jorge Leal Salgado, Elton Jonh Freitas Santos, Alcione Santos. *Federal Univ of Maranhão.*

Background: Atherosclerotic lesions are highly prevalent among afrodescendants leading to increased morbidity and mortality from cardiovascular events. Thus, the aim of this study was to investigate the association between atherosclerosis and markers of kidney injury in hypertensive afrodescendants from quilombo remnants communities in northern of Maranhão State/Brazil.

Methods: Cross-sectional study that assessed hypertensive afrodescendants from PREVRENAL cohort underwent two different imaging methods for diagnosis of atherosclerosis disease: 1- Carotid doppler ultrasonography (doppler US) to assess the intima-media thickness (cIMT) and/or 2- Coronary computed tomography for determination calcium score (CCS). The markers of kidney injury evaluated were 1- estimated glomerular filtration rate (eGFR) and; 2- albuminuria. Information about clinical, laboratory and imaging data were collected in PREVRENAL study database. To evaluate factors associated with the occurrence of coronary and carotid atherosclerosis was adjusted Poisson model with robust variance.

Results: Two hundred-six patients (mean age 61.32±12.44 years and 61.65% women) underwent carotid doppler US and 155 patients (mean age 61.42±12.42 years and 62.58% women) underwent coronary CT were included in the study. cIMT presented high in 59.22% individuals evaluated and 41.94% of patients had CCS> 0. In the multivariate regression model, age> 60 years (PR 1.23, p-value = 0.001), ACR> 30mg/g (PR 1.18, p-value = 0.040) and eGFR/CKD-EPI using cystatin C (PR 1.25, p-value = 0.045) were independently associated with carotid atherosclerosis. The model for coronary calcification were associated with CCS: male gender (PR 1.53, p-value = 0.010), age ≥ 60 years (PR 1.78, p-value = 0.001), use of ASA (PR 1.67, p-value = 0.018) and smoking (PR 1.51, p-value = 0.011).

Conclusions: The occurrence of atherosclerotic lesions was high in this group. Markers of kidney injury were associated only with carotid lesions, whereas traditional factors for atherosclerotic disease were associated with coronary lesions.

PUB011

Ischemic Postconditioning Inhibits Ischemia-Induced AKI-to-CKD Progression via Akt/GSK3β Pathway Jia Shen,[1,2,3] Hao Deng,[1,2,3] Yan Jiang,[1,2,3] Hongfeng Huang,[1,2,3] Jianghua Chen.[1,2,3] *[1]Kidney Disease Center, The First Affiliated Hospital Zhejiang Univ, Hangzhou, Zhejiang, China; [2]Kidney Disease Immunology Laboratory, The Third Grade Laboratory, State Administration of Traditional Chinese Medicine of the People's Republic of China, China; [3]Key Laboratory of Zhejiang Province, China.*

Background: Ischemia-reperfusion (IR) injury, a relevant factor of acute kidney injury (AKI), will induce renal fibrosis, and then chronic kidney disease(CKD). Postconditioning can minimize the effect of IRI, while its function and related mechanism in the transition of AKI to CKD remains unknown. It has been reported previously that type II epithelial-to-mesenchymal transition (EMT) in tubular epithelial cells plays a vital role in the pathogenesis of renal fibrosis. This study aims to investigate the underlying molecular mechanism.

Methods: We established a single renal IR model in C57BL/6 mice. All mice with IR injury were divided into 2 groups, which are with (IR group) or without (PC group) additional ischemic interruption reperfusion before permanent perfusion. Renal function, fibrosis and EMT-related makers were detected and measured. A protein array was used to evaluate the expression and activation levels of signal node proteins in kidneys.

Results: PC group was associated with reduced BUN of 54.0 ± 5.7 mg/dl and Cr of 0.420 ± 0.033 mg/dl ($p<0.05$) as well as amelioration in acute tubular necrosis from 2 weeks to 8 weeks compared with I/R group. Immunohistochemistry and western blotting at both 4 weeks and 8 weeks indicated lower expressions of Snail and EMT-related protein makers (α-SMA, fibronectin and S1004A) in PC group. The protein chip showed down regulation of phosphorylation levels of Akt (Ser473), Akt (Thr308), and GSK3β (Ser9), and verified by *in vivo* Immunohistochemistry and western blotting.

Conclusions: Postconditioning suppressed the EMT of tubular epithelial cells caused by IRI, and it related with a down regulation of Akt/GSK3β signal pathway, and this could be a therapeutic procedure to kidney IR injury and reduce the pathological progress of AKI to CKD.

PUB012

A New, Human In Vitro Model for Renal Ischemia Reperfusion Injury Marc J. Weidenbusch, Johannes Bauernschmitt, Hans J. Anders. *Nephrologisches Zentrum, Klinikum der Univ München, München, Bavaria, Germany.*

Background: During transplantation long-lasting damage is done to the graft by ischemia reperfusion injury (IRI), which to a large extent are not well characterized until today. Therefore, good models are needed to further investigate diagnostic and therapeutic options for IRI. Mouse models allow complex investigations, but results often cannot be transferred to humans. There is intriguing new evidence for an important involvement of the Krebs cycle and the accumulation of intracellular succinate in the formation of IRI**.** Therefore, our goal was to establish a new IRI model incorporating new pathophysiological insights in a human cell culture system.

Methods: HK-2 cells were treated with different substances to mimic IRI. Therefore, besides from hydrogen peroxide (H2O2) we used the inhibitors of the respiratory chain Antimycin A and Oligomycin as well as the citric cycle metabolites succinate and malonate. Subsequently, the cell toxicity was assessed by the established LDH release assay and the results were additionally validated using the AO/PI assay. All experiments were repeated at least twice and results were examined for statistical significance using two-sided student's t-tests.

Results: All substances were able to induce cell death. Because IRI in vivo leads to massive cell death within a short period of time, we concentrated especially on those substances that were able to induce significant cell death in less than two hours. While H2O2 doesn't cause any significant cell death at that time point, the combination of Antimycin A and succinate showed to be very effective (more than 60% cell death) and started to kill cells already after 30 minutes of incubation. Importantly, Antimycin A and succinate

elicited cell death also in a dose-dependent manner. Cell death in our model involves reverse electron flow through the respiratory chain, since the effect could be completely suppressed by complex II inhibition using malonate.

Conclusions: Significant cell death in human tubular epithelial cells can be induced by IRI typical reversal of electron flow in the respiratory chain. Therefore the combination of Antimycin A and succinate appears to be an appropriate model for renal IRI.

The Role of Glycosphingolipids in Cisplatin-Induced Acute Kidney Injury

Tess Dupre,[1] Mark A. Doll,[1] Parag P. Shah,[2] Cierra Sharp,[1] Deanna L. Siow,[1] Judit Megyesi,[3] James A. Shayman,[4] Levi J. Beverly,[2] Leah J. Siskind.[1] *[1]Pharmacology/Toxicology, Univ of Louisville; [2]Medicine, Univ of Louisville; [3]Internal Medicine, Univ of Arkansas for Medical Sciences; [4]Medicine, Univ of Michigan.*

Background: Acute kidney injury (AKI), resulting from chemotherapeutic agents such as cisplatin, remains an obstacle in the treatment of cancer. Cisplatin-induced AKI involves apoptotic and necrotic cell death, pathways regulated by sphingolipids such as ceramide. Data indicate that C57BL6 mice treated with cisplatin had elevated ceramide synthase and acid sphingomyelinase activities as well as increased ceramide levels in the renal cortex 72 h following cisplatin treatment. We hypothesized that inhibition of ceramide synthesis would protect mice from cisplatin-induced AKI. Pre-treatment of mice with inhibitors of acid sphingomyelinase and *de novo* ceramide synthesis (amitriptyline and myriocin, respectively) protected from cisplatin-induced AKI. Data indicate that ceramides are also metabolized into glucosylceramides (GluCers) in the renal cortex following cisplatin treatment. GluCers play a role in kidney aging, diabetic nephropathy, and lupus nephritis. Thus, we determined whether ceramide and/ or its metabolism to GluCers plays a causative role in cisplatin-induced AKI.

Methods: To determine which lipid species is contributing to kidney injury, we treated mice with a potent and highly specific inhibitor of glucosylceramide synthase, the enzyme responsible for catalyzing the glycosylation of ceramide to form GluCers.

Results: Inhibition of glucosylceramide synthase exacerbated cisplatin-induced AKI according to markers of kidney injury, inflammation, cell stress, apoptosis, and mitochondrial homeostasis.

Conclusions: Taken together, data suggest that ceramides play a role in kidney injury in response to cisplatin, whereas the metabolism of ceramides to GluCers is renoprotective.

PUB014

Repeated, Low-Dose Administration of Cisplatin Leads to Long-Term, Irreversible Fibrosis

Cierra Sharp,[1] Mark A. Doll,[1] Deanna L. Siow,[1] Tess Dupre,[1] Levi J. Beverly,[1,2,3] Leah J. Siskind.[1,3] *[1]Pharmacology/Toxicology, Univ of Louisville, Louisville, KY; [2]Dept of Medicine, Univ of Louisville, Louisville, KY; [3]James Graham Brown Cancer Center, Louisville, KY.*

Background: Cisplatin is a potent chemotherapeutic used in the treatment of many solid tumor cancers. The dose-limiting toxicity of cisplatin is nephrotoxicity, which can lead to acute kidney injury (AKI). Thirty percent of patients treated with a cisplatin will develop AKI. The long-term effects of AKI are an increased mortality rate and an increased likelihood of developing chronic kidney disease (CKD). CKD in itself is a progressive, irreversible disease characterized by a permanent loss of kidney function that often culminates in fibrosis. Currently, there are no therapeutic interventions to stop the progression of AKI to CKD. One potential reason for this is that there are no animal models that can be used to study the transition from AKI to CKD. In the standard model of AKI, mice receive a high dose of cisplatin (15-30 mg/kg) that leads to moribund status 72 hours after injection, and thus long-term studies are not feasible. We have previously developed a repeated, low-dose cisplatin regimen that allows for long-term studies of kidney function. With this model we found that repeated, low dosing of cisplatin induces fibrosis after 24 days.

Methods: To determine whether the fibrosis induced by this model is irreversible and progressive, we treated 8 wk old FVB mice with our repeated dosing regimen and followed treatment with a 6 month age out.

Results: We found that fibrosis was still present after this 6 month period as evidenced by increased Pai-1 mRNA expression levels, positive staining for α-SMA indicative of myofibroblasts, and elevated levels of overall collagen deposition. Furthermore, BUN remained elevated compared to baseline levels even though injury as measured by NGAL was no longer detectable.

Conclusions: These data indicate that fibrosis is a permanent pathological outcome following repeated injury from low-dose cisplatin, suggesting that targeting mediators of the fibrotic pathway might be beneficial for the development of therapeutic agents to prevent cisplatin-induced AKI to CKD progression.

Src Inhibition Protects against Ischemic Acute Kidney Injury in Mice

Chongxiang Xiong, Xiaoxu Zhou, Monica V. Masucci, Shougang Zhuang. *Dept of Medicine, Rhode Island Hospital, Brown Univ, Providence, RI.*

Background: Activation of Src has been associated with the development of renal fibrosis and diabetic nephropathy. However, its role in acute kidney injury (AKI) is still poorly understood.

Methods: In this study, we examined the effects of Src inhibition in a murine model of ischemia-reperfusion (I/R)-induced AKI using PP1, a highly selective inhibitor of Src family kinases.

Results: At 48 h after I/R, mice developed renal dysfunction and renal tubular damage, which was accompanied by elevated expression and phosphorylation of Src. Administration of PP1 immediately after the onset of reperfusion protected against renal dysfunction and attenuated kidney damage. The protective actions of PP1 were associated with inhibition of renal tubule injury and cell death and suppression of l expression of multiple proteins involved in the assembly of cell-cell adhesion and tight junction such as E-cadherin, ZO-1, claudin-1/4. Similarly, PP1 treatment inhibited expression of these proteins in vitro cultured renal tubular cells following oxidant injury. Moreover, I/R injury led to an increase in phosphorylation (activation) of STAT3 and NF-kappa B in the kidney; treatment with PP1 diminished this response.

Conclusions: Collectively, these results indicate that Src inhibition is effective against renal tubule injury through maintaining epithelial cellular attachment and integrityand suppressing proinflammatory responses after I/R injury. Thus targeting Src may be a promising therapeutic strategy for treatment of AKI.

PUB016

Contribution of DNases to Kidney Cell Death after Acute Injury In Vitro or In Vivo

Dae Song Jang,[1] Todd Fite,[1] Dolapo Taiwo Odeniyi,[1] Alena Savenka,[1] Alexei G. Basnakian.[1,2] *[1]Dept of Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Our previous studies showed that genetic inactivation of two kidney apoptotic endonucleases, DNase I and EndoG, was partially protective against tubular epithelial cell death induced by cisplatin. Recent discovery of endonuclease inhibitors provides a unique opportunity to determine the contribution of individual endonuclease to kidney cell death.

Methods: This study was aimed to determine if the two new endonuclease inhibitors recently identified by us, IG-17 for DNase I and PNR-3-82 for EndoG, could ameliorate cisplatin toxicity to kidney tubular epithelial cells *in vitro* and *in vivo*.

Results: *In vitro* experiments using NRK-52E cells showed that the compounds are able to suppress endonuclease activity inside the cells, provide partial protection against cisplatin toxicity measured using LDH release assay and TUNEL. *In vivo* experiments were done in mice, which received cisplatin (20 mg/kg, IP) after SC injections of the inhibitors (5 mg/kg). Kidney failure was measured by serum creatinine and BUN. Structural kidney damage was assessed by acute tubular necrosis. The results from both *in vitro* and *in vivo* experiments showed that TUNEL was inhibited the most, followed by structural protection, and followed by kidney function (*in vivo*).

Conclusions: This observation suggests that enzymatic DNA fragmentation only partially is responsible for mechanism leading to cell death or spreading of cell death (necrosis). The other part of endonuclease activity, may, in fact, act in an opposite direction by protecting against kidney cell death.

Intra-Arterial Continuous Infusion Is Less Harmful Than Bolus Infusion of Contrast Dye in CI-AKI Rodent Model showing Hyperacute Rise in Serum NGAL and L-FABP

Tsung-Chun Lee,[1,2] Chih-Kang Chiang.[1,3] *[1]Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [2]Dept of Physiology, National Taiwan Univ, College of Medicine, Taipei, Taiwan; [3]Graduate Inst of Toxicology, National Taiwan Univ, College of Medicine, Taiwan, Taiwan.*

Background: Contrast induced acute kidney injury (CI-AKI) is the second common cause of in-hospital AKI, leads to higher morbidities and mortalities. Despite in vitro studies revealed dose proportional toxicity of contrast media, there is yet no data on whether the method of contrast medium administration will alter the risk of CI-AKI. In this preliminary study, we aimed to prove that continuous intra-arterial infusion of contrast media would cause less CI-AKI than bolus infusion, even under the same amount.

Methods: Female SD rats were sedated with urethane and catheterized at left carotid artery. Urografin, high osmolarity contrast media, was given intra-arterially via the carotid artery catheter for the same total amount (20ml/kg, LD50 dose). Bolus group received four boluses within 20 minutes, and continuous group received continuous infusion for 20 minutes. Serum and urine samples were taken at baseline and at 5 hours after completion of infusion. After 5 hours, rats were sacrificed, and we further examined survival rates, and measured kidney tissue, serum and urine creatinine and AKI biomarkers (NGAL, KIM-1, L-FABP, Cystatin C) by ELISA.

Results: Bolus group had higher mortality (3/10 rats vs. 1/12 rats), and higher CI-AKI rate (9/10 rats vs. 8/12 rats) than continuous group at 5 hours. There is a trend of higher serum creatinine in bolus group (0.69 +/- 0.32 mg/dL) than in continuous group (0.46 +/- 0.23 mg/dL). Notably, there is an early rise of serum NGAL and L-FABP in bolus group (serum NGAL 5hr/baseline ratio: 25.75 vs. 3.62, p=0.017, serum L-FABP 5hr/baseline ratio: 55.52 vs. 3.09, p=0.012). Histological examinations demonstrated tubular vacuolization in both bolus and continuous groups, implying cellular stress to contrast toxicity.

Conclusions: Our preliminary data suggested a novel method to ameliorate CI-AKI by continuous infusion to kidneys, in association with a less hyperacute rise in serum AKI biomarkers of NGAL and L-FABP.

PUB018

Human Peripheral Blood Mononuclear Cells Incubated by Quality and Quantity-Control Culture System Dramatically Improve Ischemia/Reperfusion Acute Kidney Injury in Mice Takayasu Ohtake,[1] Maki Sumida,[2] Daisuke Katagiri,[2] Ryo Matsuura,[2] Eisei Noiri,[2] Shuzo Kobayashi.[1] *[1]Nephrology, Immunology, and Vascular Medicine, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan; [2]Nephrology and Endocrinology, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.*

Background: There is currently no established treatment that promotes kidney repair after acute kidney injury (AKI). We examined the capacity of human peripheral blood mononuclear cells (MNCs), which was incubated using quality and quantity control (QQc) culture system (Masuda H. et al: Stem cells Translational Research 2012), on ischemia/reperfusion (IR) AKI in mice.

Methods: IR was induced in male NOD/SCID mice. Human peripheral blood MNCs were incubated for 1 week in QQc culture media. A hundred μL saline containing 10^6 human post-QQc MNCs was infused via tail vein at 24 hours after IR induction (post-QQc group). 10^6 human pre-QQc MNCs group (direct MNCs injection without QQc culture: pre-QQc group) and vehicle group were used as control. Blood urea nitrogen (BUN), serum creatinine (sCr), tubular damage scores, peritubular capillary (PTC) loss, and interstitial fibrosis were evaluated.

Results: QQc-culture significantly increased the number of CD34+ cells and endothelial progenitor cell (EPC) colonies compared with pre-QQc human MNCs. Human post-QQc MNCs administered 24 hours after IR AKI dramatically improved kidney function at 48 hours after cell infusion compared with vehicle control group (vehicle control vs. post-QQc: BUN; 99.5±39.4 vs. 36.1±4.3 mg/dl, $p<0.05$, Cr; 0.89±0.19 vs. 0.25±0.06 mg/dl, $p<0.05$, N=13 in each group, mean±SE). Tubular damages significantly improved in post-QQc group compared with vehicle control group. PTC loss at 48 hours after cell injection was also significantly improved in post-QQc group (vehicle: post-QQc: 50.2±1.5 vs. 27.2±2.0 %, $p<0.01$). Furthermore, interstitial fibrosis area (%) 2 weeks after AKI was also significantly improved in post-QQc group (vehicle vs. post-QQc: 45.2±1.8 vs. 21.9±1.4 %, $p<0.01$). These beneficial effects were not found in pre-QQc MNCs group.

Conclusions: Human post-QQc MNCs dramatically improved kidney function, tubular and microvasculature damage, and interstitial fibrosis in mice IR AKI.

Mild Intracellular Acidification by Dexamethasone Attenuates Mitochondrial Dysfunction in a Human Inflammatory Proximal Tubule Epithelial Cell Model Jitske Jansen,[1] Tom Schirris,[2,3] Milos Mihajlovic,[1] Lambertus P.W.J. Van den Heuvel,[4] Frans G. Russel,[2,3] Rosalinde Masereeuw.[1] *[1]Pharmacology, Utrecht Inst for Pharmaceutical Sciences, Utrecht, Netherlands; [2]Pharmacology & Toxicology, Radboudumc, Nijmegen, Gelderland, Netherlands; [3]Center for Systems Biology and Bioenergetics, Radboud Center for Mitochondrial Medicine, Radboudumc, Nijmegen, Gelderland, Netherlands; [4]Pediatrics, Radboudumc, Nijmegen, Gelderland, Netherlands.*

Background: Mitochondria are assumed to be important targets to improve renal function during acute kidney injury (AKI) and glucocorticoids may exert beneficial effects on these organelles. Here, we investigated the effect of dexamethasone in an experimental inflammatory renal cell model to unravel its mitochondrial target.

Methods: Matured conditionally immortalized proximal tubule epithelial cells (ciPTEC) were treated with the endotoxin lipopolysaccharide (LPS; 10 μg/ml) for 24 hours, with or without co-treatment of dexamethasone (10 μM) for 4 hours, 37°C, 5% (v/v) CO_2. A panel of mitochondrial parameters and intracellular pH was investigated in the presence or absence of dexamethasone.

Results: LPS treatment of cells led to increased generation of reactive oxygen species (ROS) (122 ± 6 % of control; $p< 0.001$), which was attenuated by dexamethasone. In addition, the membrane potential was reduced in LPS challenged cells (85 ± 4 % of control; $p< 0.05$), which was counteracted by dexamethasone (124 ± 5 %; $p< 0.001$). The mitochondrial oxygen consumption was decreased in LPS treated cells (17.6 ± 7.5 *vs.* 55.5 ± 4.7 pmol×s^{-1}×10^6 cells in control; $p< 0.001$) and again this was improved towards control levels upon dexamethasone co-treatment (43.1 ± 7.5 pmol×s^{-1}×10^6 cells). Finally, we demonstrated that dexamethasone acidified the intracellular milieu (87 ± 2 % of control; $p< 0.05$) and reversed the LPS-induced alkalization.

Conclusions: Dexamethasone restored mitochondrial function under inflammatory conditions by decreasing cellular pH. This supports the hypothesis that mitochondria are key modulators in renal inflammation and interesting targets for the treatment of septic-AKI.

PUB020

Contrast Medium Induced Autophagy and Apoptosis in Kidney Proximal Tubular Cells Jasmine Fuller, Zheng Dong. *Cellular Biology and Anatomy, Augusta Univ, Augusta, GA.*

Background: Contrast medium-induced acute kidney injury (CM-AKI) is one of the leading causes of acute kidney failure during hospitalization. It has been defined as the occurrence of acute renal impairment within 2-7 days after administration of iodinated contrast medium in medical imaging. The mechanism of CM-AKI is not completely understood and there is no effective treatment for this disease. Autophagy is a cellular process of "self-eating," wherein various cytoplasmic constituents are broken down and recycled through the lysosomal degradation pathway. Autophagy has been shown to play a protective role in acute kidney injury models such as cisplatin treatment and ischemia-reperfusion.

Methods: To study the role of autophagy in CM-AKI, we administered 150 mgI/mL of contrast medium to renal proximal tubule cells (RPTC) for 24 hours.

Results: Contrast medium induced apoptosis at 24 hours as shown by cell morphology and the cleavage of caspase-3 into active forms. Contrast medium also induced autophagy at 6 hours as shown by increased LC3II protein signal. During contrast medium treatment, inhibition of autophagy by chloroquine (CQ) enhanced apoptosis in RPTC, while activation of autophagy by rapamycin (Rap) diminished apoptosis, further supporting a protective role of autophagy.

Conclusions: These results reveal autophagy induction and its protective role during contrast medium treatment of kidney tubular cells.

PUB021

Nephropreventing Effect of Hypoxia-Inducible Factor 1α in a Rat Model of Ischemic Acute Kidney Injury Nanmei Liu. *Dept of Nephrology, Jiming Hospital of Shanghai, China.*

Background: Characterized with acute renal dysfunctions, acute kidney injury (AKI) is often found in 5% hospitalized patients and 50% in patient with sepsis. Until now, no safe and effective therapy has been found to treat or prevent AKI specifically. Hypoxia condition was shown to influence renal injuries and function.

Methods: As HIF-1 α is the main regulator of cell response to hypoxia, in this study we investigated the potential protective effect of HIF-1 α in a rat AKI model. We found that HIF-1 α injection increased survival of rat with AKI, and the function of kidney was also protected in terms of Cr and BUN. A HE and PAS staining assay was used to assess the structural damages of kidney in different groups.

Results: Our data showed that ischemic injury induced damages to kidney tubules and nephrocytes, and in HIF1-α treated group, AKI caused less damage obviously. HIF1-α also inhibited AKI induced cell apoptosis, and retained cell proliferation in kidney tissues. We also found the downstream factors EPOR, VEGF, PHD3 was also regulated by HIF1-α in response to AKI damage. Finally, it was observed that HIF1-α also increased the percentage of adult resident progenitor cells (ARPC), which was found very low in AKI rats. The survival of ARPC isolated from AKI rat was also increased by HIF1-α.

Conclusions: HIF1-α plays a protective role in ischemic AKI model, which was related with the protection of ARPC, indicating a novel potential therapy for AKI.

PUB022

Effect of Adipose-Derived Stem Cells Incubated with Astragaloside IV on the Model of Acute Renal Injury in Mice Nanmei Liu. *Jiming Hospital of Shanghai.*

Background: To evaluate the effect of biological behaviour on human adipose-derived mesenchymal stem cells (hADSCs) incubated with Astragaloside IV(Ast). hADSCs were labeled with PKH26, and then incubated with Ast. The effect and mechanism of Ast-hADSC transfected on the model of acute renal injury (ARI) were investigated.

Methods: We used P3-P5 cells labeled with PKH26, and observed cell morphology under light microscope and fluorescence microscope. Cellular proliferation was determined by Cell-Counting Kit-8 (CCK8). The experimental model was established 24hrs later, hADSC or Ast-hADSC suspension containing 1105 were injected into tail vein. The AKI mice were injected with 100μl normal saline as the controls. After all the mice were sacrificed, the renals were dyed by H&E and TUNEL. The protein level of Caspase-3, Bcl-2, and Bax in renal tubules was detected by Western blot. The level of TNF, IL-6, RANTES in renal tissue homogenate was detected by ELISA. The hADSC and Ast- hADSC desposition in kidney was observed by fluorescence histochemistry.

Results: Absorbanee values of cultured cells were significantly increased at different time points but absorbanee values was the most obvious change at 72hrs. Renal tubular structure were impaired in AKI group after cisplatin administration, the HE staining tubular necrosis count were lower in hADSC and Ast-hADSC group than those in model group. The levels of TNF-,IL-6,RANTES in AKI group's renal tissue homogenate were increased significantly, while hADSC and Ast-hADSC group intervention changed these cytokines levels to the opposite direction. Contrasted with those in the model group, the level of Caspase-3, Bax in hADSC and Ast-hADSC group decreased notably, while the level of Bcl-2 increased siginificantly. A small quantity of red fluorescent protein from hADSC and Ast-hADSC was presented in renal tissue, but transformatation to the renal tubular epithelial cells was not observed.

Conclusions: Implantation of hADSC and Ast-hADSC could provide advanced benefits in protection against renal tubular injury by improving microcirculation, regulation apoptosis protein expression and proliferation in vitro and hADSC incubated with Ast can better improve the effect of the repair of damaged kidney tissue.

PUB023

The Role of Toll-Like Receptors in Myeloma Light Chain Toxicity on Renal Proximal Tubule Cells M-Altaf Khan,[1] Vecihi Batuman.[1,2] *[1]Medicine, Nephrology & Hypertension, Tulane Univ, School of Medicine; [2]VA, SLVHCS, New Orleans, LA.*

Background: The role of innate immunity mediated by Toll-like receptors (TLRs) in multiple myeloma (MM) nephropathy and their potential use as therapeutic target have not been investigated previously. We evaluated the effect of (S,R)-3-phenyl-4,5-dihydro-

5-isoxasole acetic acid (GIT27), an active immuno-modulatory agent which suppresses TLR2/6- and TLR4-mediated signaling, on kappa light chains (K-LC) toxicity on renal proximal tubule epithelial cells (RPTECs).

Methods: Urinary monoclonal free K-LC were isolated from a MM patient. Confluent human RPTECs were treated with or without GIT27 (25 μM - 300 μM) 1 hr prior exposure to 25 μM of K-LC for 24 hr.

Results: K-LC significantly injured RPTECs, arrested cell growth and induced significant release of inflammatory cytokines (IL-6, TNF-α, and MCP-1). GIT27 significantly inhibited secretion of TNF-α in a dose-dependent manner with an effective optimum dose of 150 μM (Untreated = 15.6 ± 1.4 vs K-LC = 143.7 ± 19.4 vs GIT27 + K-LC = 20.6 ± 1.2 SE, pg/ml). The mRNA expression of kidney injury biomarkers (KIB) NGAL was significantly increased by 424 fold and KIM-1 by 3.2 fold in RPTECs exposed to K-LC compared to untreated RPTECs. After exposure to K-LC, the mRNA expression of kidney injury-prominent TLRs (TLR2, TLR3, TLR4, TLR6 and TLR9) was significantly upregulated in RPTECs. TLR6 showed the highest increase (5.7 fold) followed by TLR2 (3.5 fold). In this study, TLRs followed both MyD88- and TRIF-dependent pathways as mRNA expression of both adaptor proteins was significantly upregulated. TLRs activation resulted in increased expression of pro-inflammatory cytokines (IL-6, 35.7 fold; TNF- α, 21.5 fold and IL-18, 0.21 fold), chemokines (MCP-1, 23.3 fold), pro-fibrotic (TGF-β1, 1.5 fold). The pro-apoptotic genes (P53, 0.17 fold and Bcl2, 1.3 fold) were also significantly upregulated by K-LC in RPTECs.

Conclusions: K-LC is highly nephrotoxic and NGAL could be a diagnostic KIB for MM. Innate immunity mediated by TLR2, TLR4 and TLR6 play a major pathogenic role in LC toxicity on kidney and could prove to be promising drug targets. The TLRs suppressor GIT27 may be a potential therapeutic to ameliorate K-LC-induced kidney injury in MM.

PUB024

Improving Long-Term Outcome of AKI by eEPC Pharmacological Preconditioning

Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Clinic of Nephrology and Rheumatology, Univ Hospital of Göttingen, Göttingen, Niedersachsen, Germany.*

Background: Exogenously administered early Endothelial Progenitor Cells (eEPCs) significantly protect mice from acute kidney injury (AKI). AKI may increase long-term mobidity since it has been identified as risk factor for chronic kidney disease. Aim of this study was to analyze long-term alterations of kidney function in mice after systemic eEPC treatment with versus without pharmacological cell preconditioning. Our additional interest focused on the analysis of different markers of renal excretory dysfunction / damage.

Methods: 8-12 weeks old male C57/Bl6N mice were subjected to bilateral renal pedicle clamping for 45 minutes. Donor-derived syngeneic eEPCs (0.5×1.000.000) were i.v. injected at the end of ischemia. Cells were either administered natively or after preincubation with established eEPC agonists (Angiopoietin-1 - Ang-2 and Bone Morphogenetic Protein-5 - BMP-5). Analyses were performed 6 weeks later. The following parameters were evaluated and compared: serum creatinine, serum cystatin C, and serum and urinary KIM-1.

Results: Ischemia induced a significant and persistent increase in serum creatinine at week 6. Administration of native eEPCs did not protect from renal excretory dysfunction if evaluated by creatinine levels. Ang-2 failed to further stimulate renoprotective competence of the cells while BMP-5 preconditioning significantly improved serum creatinine. Cystatin C was more sensitive than creatinine since serum levels were lower even after the injection of native cells. There were no differences in serum or urinary KIM-1 concentrations between any of the respective groups.

Conclusions: (I) BMP-5 potentiates AKI-protective competence of eEPCs in the long-term. (II) cystatin C is more sensitive for detecting alterations in renal excretory function than serum creatinine, even after several weeks. (III) In mice, KIM-1 is not useful for diagnosing kidney damage late after ischemia.

PUB025

Characters of Exosome Secretion under Three In Vitro Models of AKI

Wei Zhang,[1,2] Hao Zhang,[1] Zheng Dong.[2] *[1]Dept of Nephrology, The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China; [2]Cellular Biology and Anatomy, Augusta Univ, Augusta, GA.*

Background: Exosomes are cell-produced vesicles of 50-100nm in diameter that contains proteins, RNAs, and DNAs. Recent work has implicated exosomes as important ways of intercellular communication. The production, regulation and function of exosomes in kidneys and kidney cells remain largely unclear. In this study, we characterized exosome production during stress or injury of renal tubular cells.

Methods: Mouse proximal tubular BUMPT cells and were treated with or without Hypoxia (in chamber with 1% oxygen for 8h, 16h, 24h) or Cisplatin (40 nM for 8h, 16h, 24h) or ATP-depletion (10 mM Azide for 1.5h or 3h ATP-depletion, then recovery in fresh media without FBS for 6h,12h, 24h). The media were collected for exosome isolation by a commercial kit (Invitrogen, Total Exosome Isolation) or by standard ultracentrifugation. Transmission electron microscopy was used to verify the morphology of the isolated exosome. Nanoparticle Tracking Analyzer (NTA,Zeta View) was used to measure the concentration and size of the samples. Immunoblot analysis of exosome markers CD63 and TSG101 was conducted to confirm the quality and quantity of exosome.

Results: Both Invitrogen kit and ultracentrifugation were able to isolate exosomes from cell culture media. The average size of exosome secreted by BUMPT cells in all 3 injury models was 113.18±14.3 nm by the NTA measurement which was comparable to that from normal control cells(111.42±12.6nm, $P < 0.05$). Hypoxia significantly increased exosome production in a time dependent manner ($P < 0.05$); 1.5h ATP-depletion with azide followed by recovery could slightly inhibit exosome release ($P > 0.05$), while 3h ATP-depletion with azide significantly increased exosome production during 12h recovery($P < 0.05$). Cisplatin might also induce exosome production, but thei increase was not statistically significant ($P > 0.05$).

Conclusions: Renal tubular cells may produce more exosomes in response to hypoxia and ATP-depletion with recovery, but cell injury or stress does not have significant effect on the size of exosome released by the cells.

PUB026

Acutely Injured Kidneys Release Proteins into the Serum That Cause Oxidative Stress and Are Partially Inhibited by Catalase, N-Acetyl Cysteine, or Rotenone

Jon D. Ahlstrom,[1] Huihui Shi,[1] Christof Westenfelder.[1,2] *[1]Dept of Medicine, Div of Nephrology, Univ of Utah and Salt Lake City VA Medical Center, Salt Lake City, UT; [2]Dept of Physiology, Univ of Utah, Salt Lake City, UT.*

Background: The uremic state that is induced by Acute Kidney Injury (AKI) adversely affects multiple organ systems by mechanisms that are still poorly characterized. To study the consequences of the AKI environment on therapeutically employed Mesenchymal Stem Cells (MSC) and renal tubular cells, we developed a novel in vitro assay of exposing MSCs or cultured rat proximal tubular cells (NRK) to serum from animals that had AKI, Nephrectomy (NPHX), or SHAM surgeries.

Methods: Serum was obtained from rats 24 hrs post ischemia/reperfusion-AKI (50 min bilateral pedicle clamp, AKI serum, SCr ~4.9 mg/dL), and control serum was obtained following SHAM surgery (SHAM serum), or bilateral nephrectomy (NPHX serum, SCr ~4.8 mg/dL). Serum samples were evaluated for ROS activity with the Amplex Red H_2O_2 assay.

Results: Culturing normal rat kidney cells (NRK, proximal tubular) or rat MSCs in 10% AKI serum (compared to SHAM or NPHX serum) for 48 hrs resulted in increased oxidative stress, including increased anti-oxidant gene expression, increased GSH levels, and increased cellular ROS activity. Compared to SHAM or NPHX serum, serum from rats with AKI had increased Amplex Red activity, which identifies the injured kidney as the source of potentially multiple pro-oxidant factors. The ROS generating properties of AKI serum were completely eliminated with heat inactivation (65°C for 35 min), which is suggestive of a protein mediator. Catalase, N-Acetyl Cysteine (NAC), or rotenone partially reduced—but did not eliminate-- the ROS activity of AKI serum in a dose-dependent manner.

Conclusions: These results suggest that the injured kidney releases heat-sensitive factors into the blood stream (likely proteins) that generate ROS and may adversely affect both renal tissue and distant organs. The AKI serum ROS activity is only partially reduced by catalase, NAC, or rotenone treatment. The exact nature of the pro-oxidant principle that is released by the injured kidney remains to be determined.

PUB027

Neferine Modulates Cisplatin- Induced Acute Kidney Injury via Activating Autophagy

Wenbin Tang, Hui Li, Linlin Qiu, Yuchen He, Qiaoling Zhou, Ping Xiao. *Dept of Nephrology, Kidney Inst, Changsha, Hunan, China.*

Background: Extensive studies have shown that apoptosis and autophagy are involved in the pathogenesis of cisplatin-induced AKI. Neferine is not only a strong inducer of autophage, but also has antiapoptosis properties. The objective of this study is to determine the effect of Neferine in cisplatin-induced AKI.

Methods: In vivo,Neferine with different concentration was used to pretreat the cisplatin induced acute kidney injury (AKI) in BALB/c mice. The pathological changes were observed by HE staining. The apoptosis was detected by TUNEL assay and cleaved-caspase3 expression level. The autophage was determined by LC3 expression detection and transmission electron microscope observation. In vitro, changes of apoptosis and autophage were further clarified in NRK-52E cells treated with cisplatin and different concentrations of Neferine. Autophage inhibitor Chloroquine and AMPK inhibitor Compound C were used to indentify the possible mechanism modulating the protective role of Neferine in cisplatin-induced AKI.

Results: Both in vivo and in vitro, Cisplatin induced extensive renal tubular damage, increased cleaved-caspase3 expression obviously but increased the expression of LC3 slightly. Neferine pretreatment ameliorated the cisplatin-induced pathological changes and apoptosis, increased the expression of LC3 significantly and decreased cleaved-caspase3 expression obviously. The transmission electron microscope confirmed the observations. Further study found that Neferine pretreatment couldn't ameliorate the apoptosis induced by Cisplatin in NRK-52E cells while autophage was inbibited by Chloroquine. Stimulation of NRK-52E cells with cisplatin resulted in a significant decrease of the expressions of p-AMPK and increased the expression of p-mTOR in the NRK-52E cells compared with the control. More interesting, while AMPK/mTOR pathway was inbibited by Compound C, Neferine pretreatment couldn't attenuate the damage induced by Cisplatin in NRK-52E cells.

Conclusions: Neferine plays a protective effect on cisplatin induced AKI possibly through promoting autophagy by AMPK/mTOR signaling pathway. Neferine may serve as a potential treatment strategy to suppress cisplatin-induced AKI.

PUB028

Inhibition of Histone H3 K27 Demethylase Aggravates Rhabdomyolysis Induced Acute Kidney Injury Na Liu, Shougang Zhuang. *Dept of Nephrology, Shanghai East Hospital, Shanghai, China.*

Background: Accumulating data reveal epigenetic change regulates chronic kidney diseases and acute kidney damage. However, role and exact mechanisms of protein methylation mediated acute kidney injury (AKI) are still obscure.

Methods: In this study, we establish a glycerol-induced murine rhabdomyolysis model. Following glycerol (GL) injection intramuscular, the mice developed severe acute tubular injury as indicated by worsening renal dysfunction, increased NGAL and KIM1 expression and enhanced tubular cell apoptosis. GSK J4, a special JMJD3 inhibitor, treatment significantly enhanced serum creatinine and BUN as well as severe renal pathologic damage in GL injured kidneys.GSK J4 also increased expression of NGAL and KIM-1compared with GL treated alone group. To detect cell apoptosis change with or without GSK J4 in GL injured kidney, we further proceed TUNEL staining and cleaved caspase-3 immunoflurescence. JMJD3 inhibition prodominantly upregulated TUNEL and cleaved caspase-3 positive cells in GL treated kidney.

Results: To discuss the underlying mechanisms of GSK J4 on AKI process, we investigate GSK J4 role on histone methylation as well as tubular epithelial cell dedifferation and proliferation which play pivotal role in AKI regeneration. After Rhabdomyolysis-induced AKI, the kidney displayed a remarkable regenerative capacity by evidence of increased expression of Pax-2 and vimentin,and upregulation of PCNA. GSK J4 administration predominantly downregualated expression of Pax-2 and vimentin as well as PCNA. Further mechanism studies revealed that the injured kidney after AKI underwent hypermethylation indicated by increased level of di-methyl-histone H3 K27 and tri-methyl-histone H3 K27. JMJD3 inhibition further upregulated methyl-histone H3 K27 after acute kidney injury.

Conclusions: In summary, we have demonstrated that inhibition of Histone H3 K27 demethylation aggravates Rhabdomyolysis induced acute kidney injury. This effect was associated with upregulation of methyl-histone H3 K27 as well as downregualtion of tublular epithelial cell dedifferation and proliferation. As such, methylation inhibition may hold a therapeutic potential for treatment of Rhabdomyolysis induced acute kidney injury.

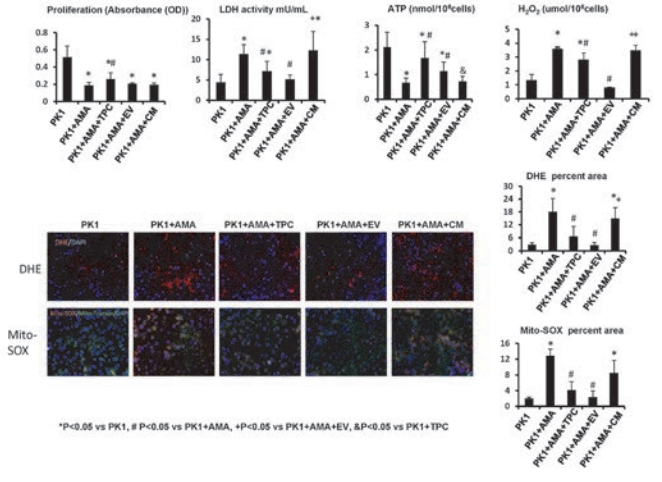
PUB029

Renal Tubular Progenitor Cells Protect Tubular Epithelial Cells by Shuttling Extracellular Vesicles Xiang-Yang Zhu, Xiangyu Zou, Soon Hyo Kwon, Alfonso Eirin, Amir Lerman, Lilach O. Lerman. *Divs of Nephrology & Hypertension and Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: In situ tubule-committed progenitor cells (TPC) contribute to the turnover and repair of the kidney tubule, but their mode of communication is unknown. Extracellular vesicles (EVs) are important mediators of intercellular communication, but the role of TPC-derived EVs in kidney tubular protection is unclear. We hypothesized that TPC may ameliorate kidney tubular cell injury through their EV progeny.

Methods: TPCs (CD133+/CD24+) were isolated from normal pig kidneys, and EVs from the culture medium. Antimycin A (AMA, 1μmol/L) was used to induce mitochondrial and cellular injury in porcine tubular epithelial cells (PK1), which were then co-cultured for 3d with TPCs (transwell), TPCs-derived EVs, or EV-depleted conditioned medium (CM) alone. MTT and LDH activity assays were used to evaluate PK1 proliferation and injury. PK1 energy production was measured by ATP levels, cellular oxidative stress by hydrogen peroxide assay and Dihydroethidium (DHE), and mitochondrial oxidative stress with Mito-SOX staining.

Results: AMA impaired PK1 proliferation, increased LDH release, decreased ATP production, and increased cellular and mitochondrial oxidative stress. Co-culture with TPC without cell contact improved all these injury indices. TPC-derived EVs showed similar beneficial effects, except for cellular proliferation. Contrarily, these protective effects were abolished using EV-depleted CM.



Conclusions: TPCs alleviated AMA-induced tubular cell injury by releasing EVs that restored energy production and decreased oxidative stress. These findings underscore the endogenous repair capacity of renal tubular cells, and the role of EVs as vectors of the protective effects and intercellular communications of TPCs.

Autophagy Protects against Contrast Induced Tubular Epithelial Injury Moo Yong Park, Seung Duk Hwang, Byung Chul Yu. *Dept of Internal Medicine, Soonchunhyang Univ Bucheon Hospital, Bucheon, Republic of Korea.*

Background: Radiocontrast-induced nephropathy (RCN) is common cause of acute kidney injury in hospital. However, preventing and treating strategies against developing RCN were very limited. The role of autophagy in the pathogenesis of RCN remains undetermined, therefore we investigated its role in RCN.

Methods: We examined the expression of autophagic and apoptotic proteins during progression of contrast (idoxanol) induced injury to renal tubular epithelial cells (RTEC). For determine protective role of autophagy against contrast injury, we inhibit autophagy with small interference RNA (siRNA) for ULK1, and measured the changes of cell viability and induction of apoptotic and autophagy protein for 48hr.

Results: Following contrast exposure to RTEC, cell viability was reduced for 3hr, but it was increased at 24hr and 48hr. Apoptosis was detected as early as 1hr after contrast exposure as indicated by induction of caspase 3 and 8 and they were increased for 48hr. Otherwise autophagy, indicated by LC3 and autophagy-related gene protein 7 (ATG7), was detected at 3hr after contrast exposure, and induction of LC3 and ATG7 were further increased up to 48hr. After inhibiting autophagy by ULK1 siRNA, survived RTEC was not increased at 24 and 48hr after contrast exposure.

Conclusions: Autophagy plays cytoprotective role in contrast induced RTEC injury and it may occur independently of apoptosis.

PUB031

Activation of 5-Hydroxytrptamine Receptor 1F Mediates Mitochondrial Biogenesis through AKT/eNOS and ERK/FOXO3a Pathways in the Kidney Whitney Sharee Gibbs, Craig Cano Beeson, Rick G. Schnellmann. *Dept of Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: We recently made the novel observation that LY344864 (LY), a selective 5-HT_{1F} receptor agonist, induces renal mitochondrial biogenesis (MB) and accelerates recovery of renal function following I/R-induced acute kidney injury in mice. The mechanism of 5-HT_{1F} receptor mediated MB is unknown. It has been proposed that ERK1/2 is a negative regulator of MB and eNOS activation induces MB through cGMP generation. Therefore, we investigated the role of ERK1/2 and eNOS in 5-HT_{1F} receptor induced MB.

Methods: Mitochondrial respiration (FCCP-OCR, a marker of MB) was measured in renal proximal tubule cells using a Seahorse instrument. Signaling pathways were explored using pharmacological inhibitors and immunoblot analysis. cGMP levels were measured using an ELISA.

Results: LY increased p-Akt at 15-30 min and was attenuated by the Gβγ inhibitor gallein. eNOS, a downstream target of Akt, was measured following LY in the presence and absence of gallein or the Akt inhibitor GDC-0068 (GDC). LY increased p-eNOS at 1 hr, that was attenuated by gallein or GDC. cGMP was also increased at 1 hr. Pretreatment with gallien, GDC, the nitric oxide synthase inhibitor L-NAME or the guanylate cyclase inhibitor ODQ attenuated LY-induced increases in FCCP-OCR.

In parallel to the Akt/eNOS/cGMP pathway, p-ERK1/2 was decreased at 1 hr following LY exposure and gallein and GDC blocked this reduction, indicating that both Gβγ and Akt mediate LY reduction of p-ERK1/2. c-Raf phosphorylation by Akt is known to reduce MEK/ERK signaling. A 30 min exposure to LY elevated p-c-raf and GDC blocked this increase. The inactive form p-FOXO3a, a downstream phosphorylation target of ERK1/2 and transcription factor involved in MB, was decreased following LY at 2 hr. Akt phosphorylation of c-raf decreased p-ERK1/2, reducing p-FOXO3a and increasing PGC-1α.

Conclusions: This study reports the novel finding that Gβγ heterodimer initiates renal MB by increasing Akt/eNOS/cGMP and decreasing ERK/FOXO3a pathways. Thus, 5-HT_{1F} receptor agonists are potent and efficacious inducers of MB and potential therapeutics for renal injury.

Acute Kidney Injury in Patients with Severe Sepsis or Septic Shock: A Comparison between the Risk, Injury, Failure, Loss of Kidney Function, End-Stage Kidney Disease (RIFLE), Acute Kidney Injury Network (AKIN) and Kidney Disease Improving Global Outcomes (KDIGO) Classifications

Iolanda Nunes Godinho,[1] Marta Pereira,[1] Natacha Rodrigues,[1] Joana Gameiro,[1] Marta R.A. Neves,[1] Joao Gouveia,[2] Zelia Costa-e-Silva,[2] António Gomes da Costa,[1] Jose António Lopes.[1] *[1]Div of Nephrology and Renal Transplantation, Dept of Medicine, Hospital de Santa Maria, Lisbon, Portugal; [2]Div of Intensive Medicine, Dept of Medicine, Hospital de Santa Maria, Lisbon, Portugal.*

Background: Using the RIFLE, AKIN and KDIGO systems, the incidence of acute kidney injury (AKI) and their ability in predicting in-hospital mortality in severe sepsis or septic shock was compared.

Methods: Retrospective analysis of 457 critically ill patients with severe sepsis or septic shock hospitalized between January 2008 and December 2014. Multivariate logistic regression was employed to evaluate the association between RIFLE, AKIN and KDIGO with in-hospital mortality. Model fit was assessed by the goodness of-fit test, and discrimination by the area under the receiver operator characteristic (AuROC) curve. Statistical significance was defined at a P <0.05.

Results: RIFLE (84.2%) and KDIGO (87.5%) identified more patients with AKI than AKIN (72.8%) (P<0.001, respectively). AKI defined by AKIN and KDIGO was associated with in-hospital mortality (AKIN - adjusted OR 2.3, 95%CI 1.3-4, P=0.006; KDIGO - adjusted OR 2.7, 95%CI 1.2-6.2, P=0.021) while AKI defined by RIFLE was not (adjusted OR 2.0, 95%CI 1-4, P=0.063). The AuROC curve for in-hospital mortality was similar between the three classifications (RIFLE 0.652, P<0.001; AKIN 0.686, P<0.001; KDIGO 0.658, P<0.001).

Conclusions: RIFLE and KDIGO diagnosed more patients with AKI than AKIN however the prediction ability for in-hospital mortality was similar between the three systems.

Non-Critical Care Hospital-Acquired Acute Kidney Injury: Risk Factors and Clinical Outcomes

Camilo Gonzalez, Paola Garcia, Kateir Contreras, Patricia Rodriguez, Luis Vera, Jorge Sotelo, Maria Vasquez, Paola A. Acuna, Melissa Accini, Maite Hurtado. *Nephrology, Hospital Univ San Ignacio, Bogota, Colombia.*

Background: Non-critical care Hospital-Acquired Acute Kidney Injury (Non ICU HA-AKI) is a common complication associated with worse clinical outcomes. We analysed the risk factors and outcomes in this condition.

Methods: Paired case-control 1:2 study was carried out from April-December 2014 at a University Hospital in Bogotá, Colombia. Non ICU HA-AKI was defined by creatinine KDIGO criteria after 24 hours of hospitalization. Controls was paired by date and type of attention. We analysed outcomes and performed univariate and multivariate analysis of risk factors.

Results: Of 16368 admissions, 101 patients fulfill criteria. Mean length of hospitalization to AKI was 7.9±8.8 days, 44.2% fulfilled KDIGO1 criteria and 32.7% KDIGO2, 4.9% requiered dialysis. Hospital length of stay was longer in patients with AKI (p<0.01) 13 vs 6 days, ICU admission was higher in cases OR 2.43 [95%CI 1.2-4.7 p=0.004] as well as mortality OR 26.2 [95%CI 8.8-104 p<0.01]. In multivariate analysis, sepsis OR 3.6 [95%CI 1.3-10.1 p=0.01], dehydration OR 14,4 [95% CI 4.5-46.2 p=0.0001], baseline eGFR OR 0.96 [95% CI 0.94-0.98 p=0.0001], contrast OR 4.33 [95% CI, 1.60-11.66 p=0.004], recently NSAIDs use OR 3.23 [95% CI 1.22-8.52 p=0.017] and Charlson comorbidity index OR 1.23 [95% CI 1.05-1.43 p=0.007] were independent risk factors.

	Cases (101) %	Controls (202) %	All (303) %
Diabetes	13.8	17.3	16.1
Hypertension	48.5	42.5	44.5
Cardiac failure	26.7	18.3	21.1
CKD	21.7	6.9	11.8
COPD	22.7	11.8	15.5
Neoplasm	41.5	29.7	33.6
NSAIDs use	37.6	15.8	23.1
ACEi/ARBs	47.5	48.5	48.2
Sepsis	52.5	16.3	28.4
Dehydration	56.4	6.4	23.1
Diuretics	39.6	18.3	25.4
Contrast	48.5	32.2	37.6
eGFR	73.5±30.4	91.4±22.4	85.4±26.7
Charlson index	5.2±2.3	3.2±2.9	3.8±3.1

Conclusions: Non-ICU HA-AKI is associated with a longer hospital stay, ICU requirement and high mortality rate. The majority of risk factors are potentially preventable.

PUB035

Incidence and Characteristics of Acute Kidney Injury in Children and Adolescents with Diabetic Ketoacidosis

Arushi Verma, Poonam Thakore, Tetyana L. Vasylyeva. *Pediatric, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

Background: Diabetic ketoacidosis (DKA) is a potentially lifethreatening acute complication of type 1 diabetes mellitus (T1DM). DKA is also associated with numerous acidbase, hydration and electrolytes derangements. Acute kidney injury (AKI) is a known complication of DKA, mainly resulting from hypovolemia due to glucoseinduced osmotic polyuria. However, there is paucity of knowledge about acute kidney injury in children with DKA.

Methods: Retrospective chart review of 21 children (with median age of 12 years) hospitalized consecutively with DKA over a oneyear period at Northwest Texas pediatric hospital was done after IRB approval. Patients were classified as per the pRIFLE classification into Risk of AKI, AKI and acute kidney failure. Pearson correlation was used to correlate clinical and laboratory parameters in these populations.

Results: Among the 21 children hospitalized with DKA, 4 children (19%) were at risk of AKI, 7 (33.33%) had AKI, 7 (33.33%) had acute renal failure (ARF). No patients required renal replacement therapy or dialysis. Only 2 of 21 patients had an admission diagnosis of AKI. Twentyeight percent of patients with either AKI or acute kidney failure had severe DKA. Median time of resolution for AKI was 11 days. Admission eGFR was negatively correlated with age (r = 0.35; p=0.12). No correlation was found between admission eGFR and blood glucose on admission or severity of DKA.

Conclusions: For the first time we showed that there is a high incidence of AKI in pediatric DKA population. AKI is a frequently associated, but underdiagnosed condition in children with DKA. Older age may be a risk factor for AKI. However, it is usually transient and resolves by fluid replacement as per DKA management.

PUB036

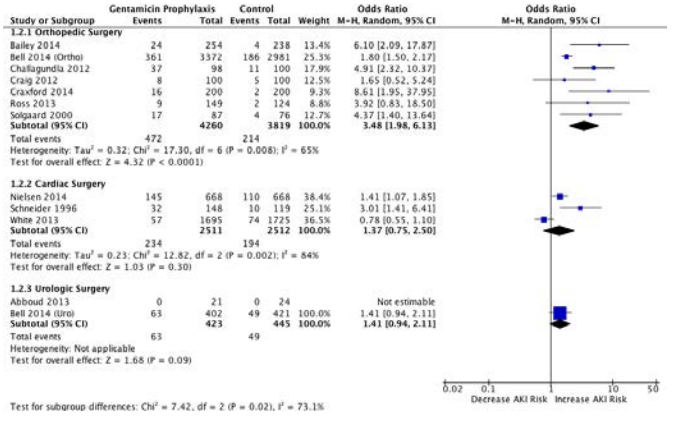
Surgical Prophylaxis with Gentamicin and Acute Kidney Injury

Weeraporn Srisung,[1] Jirapat Teerakanok,[1] Pakpoom Tantrachoti,[1] Amputch Karukote,[2] Kenneth Nugent.[1] *[1]Internal Medicine, TTUHSC; [2]Mahidol Univ.*

Background: Gentamicin has been increasingly used instead of cephalosporins for surgical prophylaxis in an attempt to reduce the rate of "Clostridium difficile" infection. There are limited data regarding nephrotoxicity related to gentamicin in these patients.

Methods: We have conducted a meta-analysis to evaluate the risk of acute kidney injury (AKI) in gentamicin-containing surgical prophylactic regimens, compared to regimens without gentamicin, in several types of surgery. Electronic searches were performed using PubMed and Embase. Statistical analysis was then performed using a random-effect model; heterogeneity (I^2) was calculated.

Results: Eleven studies with fifteen cohorts with 18,354 patients are included in the analysis. Subgroup analysis was performed according to surgery type. We have found that antibiotic prophylaxis with gentamicin containing regimen has significant risk for developing postoperative AKI in orthopedic surgery (OR [95%CI] = 3.48 [1.98,6.13]). The results were inconclusive in other types of surgery .



Conclusions: Therefore, physicians should consider risks and benefits of using this regimen in individual patients.

PUB037

Factors Associated with Renal Recovery from Acute Kidney Injury Requiring Renal Replacement Therapy

Katsuhito Ihara, Madoka Kimura, Yukiko Tanaka, Atsuki Ohashi, Hitomi Tanaka, Seiji Inoshita. *Internal Medicine, Tokyo Metropolitan Bokutoh Hospital, Tokyo, Japan.*

Background: Recovery of renal function after an episode of acute kidney injury (AKI) is an important clinical measure of morbidity, but factors associated with the renal recovery are currently not clear.

Methods: In this single center retrospective cohort study, we studied AKI patients who were admitted to the ICU or general wards, and required renal replacement therapy (RRT) during 1 January 2010 and 31 December 2013. Patients were excluded if they underwent RRT prior to the admission including those on chronic RRT, or they were cardiopulmonary arrest on admission. Demographic data, co-morbidities, clinical history, cause of AKI, and laboratory data were collected at the time of RRT initiation, and patients were followed until death or discharge. The primary outcome was RRT withdrawal, which was defined as being free from RRT. A priori determined covariates of age, gender, vasopressor use, mechanical ventilation, oliguria (urine output <0.5 mL/kg/h), cardiovascular disease, diabetes mellitus, surgery, sepsis, contrast agent, and pre-existing CKD (eGFR <60 mL/min/1.73 m^2) were included in Cox hazard models to estimate hazard ratio (HR) of RRT withdrawal.

Results: A total of 337 patients were enrolled. The mean age was 66 years, 28.8 % were female, and 46.3 % had sepsis. During follow-up (median 6 days, IQR 2-22 days), 159 patients achieved RRT withdrawal, and 146 died. In multivariable Cox analysis, significant factors associated with RRT withdrawal were pre-existing CKD (HR 0.52 [95 % confidential interval {CI} 0.33-0.82]), male (HR 0.68 [95 % CI 0.47-0.99]), mechanical ventilation (HR 0.57 [95 % CI 0.35-0.93]), and oliguria (HR 0.60 [95 % CI 0.41-0.86]).

	HR [95% CI]
Age (+ 1 year)	0.99 [0.98-1.01]
Male	0.68 [0.47-0.99]
Use of vasopressor	1.77 [1.04-3.01]
Mechanical Ventilation	0.57 [0.35-0.93]
Oliguria	0.60 [0.41-0.86]
CVD	0.99 [0.65-1.51]
CKD	0.52 [0.33-0.82]
Diabetes	1.23 [0.81-1.88]
Use of contrast agent	1.14 [0.76-1.69]

Conclusions: Among individuals with AKI requiring RRT, male gender, pre-existing CKD, mechanical ventilation, and oliguria were negatively associated with RRT withdrawal.

PUB038

Improvements in Recognizing and Managing Medications in Patients with AKI, Better Long-Term Management and Follow-Up Needed

Gang Xu, Dipesh Patel, Richard J. Baines. *Dept of Nephrology, Univ Hospitals of Leicester, Leicester, United Kingdom.*

Background: Care bundles, education programs, and electronic alert systems have all been cited as possible ways to improve care. However, it is still unclear just how much impact these interventions have in a real life clinical setting, or in which areas valuable resources should be focused on in order to improve outcomes.

Methods: Our hospital has implemented an electronic altering system for patients with AKI along with a structured education program for clinicians. To assess the effectiveness of these inventions we audited medication and IV fluid prescriptions in patients with AKI over a period of 3 months.

Results: We identified 397 patients with AKI stage 2/3 from August to October 2015. 40% of AKI was identified on admission units, 38% on medical wards. The number of patients prescribed a diuretic, Angiotensin converting enzyme inhibitor(ACE)/ Angiotensin receptor blocker(ARB), Non-steroid anti-inflammatory drugs (NSADS), or given Intravenous fluids pre-admission, 24 hrs post admission, and at point of discharge are shown in Figure 1.

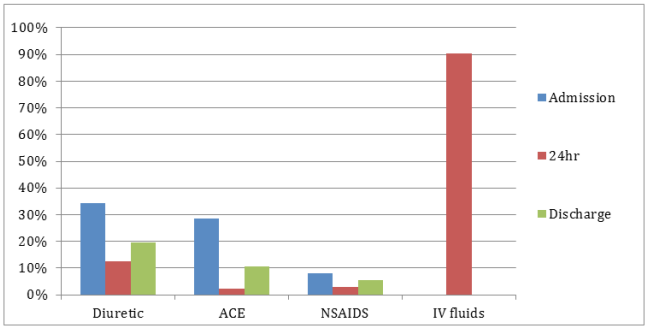


Figure 1: Changes in Medication and intravenous fluid prescription for patients with AKI.

For patients who survived to discharge, 17% had a repeat blood tests carried out in a non-hospital setting with-in 4 weeks of discharge, 59% if patients did not have any repeat blood test with-in 4 weeks of discharge.

Conclusions: The majority of patients with AKI and on potentially nephrotoxic medications pre-admission had their medications altered with-in 24hr of admission and was given intravenous fluid. The percentage of patients with AKI identified on the medical wards is higher than reported in the literature, suggesting changes in practice regarding investigating AKI in our hospital. The vast majority of patients who suffered AKI are not been followed up in secondary or primary care with follow up blood tests. More resources and research is needed to focus on improving AKI follow up care.

PUB039

Comparison of Tziakas Risk Score versus Mehran Risk Stratification in Predicting Contrast-Induced Acute Kidney Injury among Patients Undergoing Coronary Angiography and/or Percutaneous Coronary Intervention

Frederick Elises Ogbac, Michelle Jane Aguirre Buaron, Russel Redoblado Semeniano, Oscar D. Naidas. *St. Luke's Medical Center - Quezon City, Quezon City, Philippines.*

Background: Contrast-induced acute kidney injury (CI-AKI) is a form of acute kidney injury (AKI) that occurs after the administration of contrast media. In patients who underwent percutaneous coronary intervention (PCI), there was a 3.3% to 19% incidence of CI-AKI. Among these patients, dialysis was needed in 0.3% to 3%. Furthermore, they have a higher mortality rate of 7.1% to 81.2%. It is therefore necessary to measure the patient's risk to develop CI-AKI in order to prepare them for the procedure.

Methods: This was a cross-sectional analytic study conducted at St. Luke's Medical Center - Quezon City. Patients aging >18 yrs old who underwent coronary angiography or PCI were included in the study. The following patients were excluded: incomplete data, already on renal replacement therapy, and underwent multiple procedures. Included patients were stratified using both tools. The study outcomes were the occurrence of CI-AKI or need to do dialysis. CI-AKI was defined as an increase in serum creatinine >0.5mg/dL or >25% from baseline.

Results: A total of 414 patients were included. 55 patients (13.28%) developed CI-AKI. Comparing the accuracy indices, Tziakas Risk Score (84.5 {81.1-88.0}) has a higher over-all accuracy than Mehran Risk Stratification (81.6 {77.9-85.4}). Sub-group analysis of patients who underwent coronary angiography showed no statistical difference (*p*-value=0.51) between the Area Under the Curve (AUC) of the 2 stratification tools. But the sub-group analysis of patients who underwent PCI showed a statistically higher (*p*-value=0.03) AUC for Tziakas Risk Score (AUC-0.79;SE-0.5) than Mehran Risk Stratification (AUC-0.71;SE-0.06).

Conclusions: In conclusion, Tziakas Risk Score or Mehran Risk Stratification can be used to stratify patients who will undergo coronary angiography. For patients who will undergo PCI, Tziakas Risk Score has a better predictive value compared to Mehran Risk Stratification. In clinical practice, we recommend Tziakas Risk Score as the risk stratification tool.

PUB040

Cytokine Clearance in Continuous Venovenous Hemofiltration and Continuous Venovenous Hemodialysis

Ling- Xin Chen,[1] Sevag Demirjian,[2] Suneel M. Udani,[1] Sharon A. Trevino,[1] Jay L. Koyner.[1] *[1]Nephrology, Univ of Chicago Hospitals, Chicago, IL; [2]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: In the past, it was believed that Continuous Venovenous Hemofiltration (CVVH) provided improved middle molecule and cytokine clearance compared to Continuous Venovenous Hemodialysis (CVVH).

Methods: We conducted a multicenter prospective unblinded randomized trial of patients with severe acute kidney injury. Patients were randomized to CVVH or CVVHD. Blood, urine and effluent were collected at 0, 4, 24 and 48 hours after initiation of CVVH or CVVHD with collections stopping at the time of the first circuit change. Levels of electrolytes and cytokines were tested in both groups of patients and compared. Clearances of each cytokine was calculated and compared between groups and across time-points.

Results: We enrolled 21 patients with 11 patients receiving CVVH and 9 receiving CVVHD. There was no difference in baseline demographics, baseline renal function or ICU type across the 2 groups. The mean(SE) time to first filter change for the cohort was 30.4(6.7) hours. No significant differences were found between the two modalities in terms of cytokine concentrations at enrollment, 4 and 24 hours. We had sufficient samples to calculate 4 hour cytokine clearances in 19 patients and found no difference in 4 hour cytokine clearances.

	Mean 4 hour dialysis clearances (mL/min)		
	CVVHD (n=8)	CVVH (n=11)	p
IL-1 beta	38728.6 (108357.1)	28781.95 (65434.52)	0.82
IL-1 RA	30.22 (48.25)	8.81 (4.30)	0.25
IL-6	11.50 (9.41)	18.79 (13.75)	0.19
IL-10	72.20 (55.88)	38.14 (28.22)	0.15
TNF-alpha	58.21 (34.76)	54.01 (26.22)	0.78
Creatinine	61.58 (25.43)	51.39 (21.14)	0.37
BUN	138.08 (54.42)	93.65 (26.20)	0.06

Conclusions: In our randomized multicenter study, there was no significant difference in cytokine clearance between CVVH and CVVHD.

PUB041

Poor Nutritional Status Is Associated with the Incidence of Acute Kidney Injury in the Treatment of Head and Neck Cancers with Concurrent Chemoradiotherapy Using High-Dose Cisplatin Akihiko Kato,[1] Takayuki Tsuji,[2] Naro Ohashi,[2] Hideo Yasuda.[2] *[1]Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; [2]Internal Medicine 1, Div of Nephrology, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Identifying potential risk factors is critically important for reducing the burden of acute kidney injury (AKI) in cancer patients receiving cisplatin (CDDP) treatment. We aimed this study to explore the risk factors for CDDP-induced AKI in head and neck cancer patients with concurrent chemoradiotherapy.

Methods: We retrospectively reviewed medical records for 40 head and neck cancer patients who underwent chemoradiotherapy including 66-70 Gy with CDDP 80 mg/m^2 on Days 1, 22 and 43 (age: 60±10 years old, male/female=38/2). We also evaluated the association of nutritional parameters with CDDP-induced nephrotoxicity in the first-line setting of CDDP.

Results: CDDP-induced AKI developed in 11 out of 40 (27.5%) patients in the first course, 6 out of 35 (17.1%) patients in the second, and 2 out of 34 (5.9%) patients in the third. Serum creatinine levels were increased from 0.76±0.16 in the first to 0.92±0.23 mg/dL in the last administration. No difference was found in basal creatinine clearance (79.5±21.0 vs. 87.3±26.7 ml/min) and CDDP dosage (120±19 vs. 132±32 mg) between patients with AKI development and those without. Dairy dietary food intake and anthropometric parameters were also identical between the two groups. However, there was a significantly lower level of serum albumin (3.5±0.6 vs. 3.9±0.5 g/dL, p<0.01), cholinesterase (237±49 vs. 299±85 IU/L, p<0.03) and hemoglobin (11.8±1.3 vs. 12.9±1.5 g/dL, p<0.05) in patients with AKI than those without. The Geriatric Nutritional Risk Index (GNRI) was also significantly lower in AKI patients (86±9 vs. 96±10, p<0.01). In patients having high nutritional risk (GNRI<92), the incidence of CDDP-induced AKI was significantly higher than those not having (47.1 vs. 13.0%, p<0.02).

Conclusions: These findings suggest that poor nutritional status just before chemoradiotherapy was associated with CDDP-induced AKI in advanced head and neck cancer patients. GNRI less than 92 may be useful in predicting the risk of AKI in these patients.

PUB042

Acute Kidney Injury after Laparoscopic Abdominal Surgery Nattachai Suwachittanont, Thaksa-On Wirotwan, Passisd Laoveeravat, Nattachai Srisawat. *Excellence Center for Critical Care Nephrology, Faculty of Medicine, Chulalongkorn Univ and King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Laparoscopic abdominal surgery can induce many physiologic changes including renal function. Many studies demonstrating the relationships of pneumoperitoneum and renal function disturbance were conducted in animal models and showed controversial conclusions. Therefore our objectives were (1) to describe incidence of acute kidney injury (AKI) in patients underwent laparoscopic abdominal surgery and (2) to identify risk factors associated with development of AKI in these circumstances.

Methods: In this prospective cohort study, the medical records of patients who underwent laparoscopic abdominal surgery at King Chulalongkorn Memorial Hospital, Thailand from June 2012 to December 2013 were reviewed. Demographic data (gender and age), preoperative clinical characteristics (body weight, height, heart rate, blood pressure, serum creatinine, estimated glomerular filtration rate and co-morbidities including hypertension, diabetes mellitus and hyperlipidemia) and intraoperative data (operative time, inflation time, mean intra-abdominal pressure and duration of intraoperative hypotension) were collected. We used AKIN criteria to diagnose AKI. Therefore, we collected blood samples, urine samples and we also monitored daily urine output of all patients.

Results: A total of 62 patients were included in this study. Twelve patients (19%) developed AKI. Patients with postoperative AKI had more body weight (p=0.04), more height (p=0.002), more inflation time during surgery (p=0.035) and more exposure index defined as the product of operation time and intra-abdominal pressure (p=0.03). In addition, we found that duration of intraoperative hypotension (mean arterial pressure < 65 mmHg) was independently associated with AKI (adjusted OR=1.19, 95%CI= 1.02-1.37, p=0.022).

Conclusions: Our incidence of AKI was 19% which higher than reported in previous studies. Intraoperative hypotension was the independent factor of AKI associated laparoscopic surgery. Therefore, awareness of physician about intraoperative hypotension should be considered in order to reduce the risk of AKI.

PUB043

Prompt Reversal of Acute Renal Failure (ARF) by Large-Volume Diuresis in 36 Consecutive Patients with Anasarca: Evidence for Congestive Kidney Failure as Suggested by Animal Data Showing Impaired Function by Renal Vein Hypertension/Congestion Grant Meltzer,[1,2] Kai Lau.[1,2] *[1]Dept of Nephrology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Medical Service, VA Medical Center, Oklahoma City, OK.*

Background: Fluid overload in ICU patients is known to link to greater ventilator dependency, longer hospital stay, worse mortality & more ARF. But a causal relationship is not proven. Animal studies showed renal vein hypertension with or without saline loading impairs function. In patients with anasarca & unexplained ARF, we tested the hypothesis that fluid overload was causative & diuresis curative.

Methods: We studied 36 consecutive patients with acute gain of >3 kg weight or ≥3 L fluid, ≥50% acute drop in creatinine clearance (CrCl) or ≥2 x rise in serum creatinine (Scre) without known or identifiable causes. They got IV furosemide at rates without causing hypotension or unstable hemodynamics. All relevant data like weights, fluid balance, volume markers & renal responses were noted, reviewed & statistically analyzed.

Results: Primary etiologies of fluid overload were heart failure (40%), liver failure (22%), CKD (16%), proteinuria (9%) & iatrogenic causes (10%). In the evolution of ARF, weight rose by 12.5 kg in 14 d. Scre rose from 1.3 to 4.4 mg%. CrCl fell from 76 to 25 ml/min. The falls in CrCl correlated with weight gains (p<0.02). Furosemide caused 15.2 kg diuresis in 12 d, dropped Scre to 1.45 mg% & raised CrCl to 67 ml/min. ARF fully resolved in 33 patients. In 3, Scre was stable despite >4 kg diuresis. Gains in CrCl correlated with diuresis volume (p<0.04). At a diuretic rate of 1.5 kg/d, no adverse events occurred.

Conclusions: Our data support the entity of Congestive Kidney Failure (CKF) as induced by acute & major salt retention or fluid overload but resolved by diuresis. 2. CKF is likely mediated by reduced cardiac output, systemic or renal venous congestion, renal interstitial edema &/or intra-abdominal hypertension. 3. It can alone induce or aggravate ARF by other causes. 4. Likely under-recognized, CKF is preventable & treatable. 5. Diuresis in cohorts at rates & monitored as ours should be safe & effective.

PUB044

The Relationship between Cancer and Acute Tubular Necrosis in Patients with Chronic Kidney Disease Gregory John Wilson,[1,2] Andrew John Mallett,[1,2,3] Adrian Lawrence Kark,[1,2] Ken-Soon Tan,[2,4] Rajitha Asanga Abeysekera,[1,2] Zaimin Wang,[2,3] Helen G. Healy,[1,2] Wendy E. Hoy.[2,3] *[1]Dept of Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Australia; [2]CKD.QLD & NHMRC CKD.CRE, Univ of Queensland, Brisbane, Australia; [3]Centre for Chronic Disease, Univ of Queensland, Brisbane, Australia; [4]Dept of Renal Medicine, Logan Hospital, Brisbane, Australia.*

Background: Acute tubular necrosis (ATN) occurs commonly in patients with cancer, yet it is not known how these conditions and other comorbidities influence the development and progression of chronic kidney disease (CKD).

Methods: Patients enrolled (with informed consent) in the RBWH and Logan CKD.QLD registries (n=2,367) were assessed for a diagnosis of an acute kidney injury (AKI) as either the primary cause of their CKD or an acute on chronic kidney injury. From this group, patients with ATN as either the primary cause of CKD (primary ATN) or as an acute on chronic kidney injury (ATN on CKD) were selected, and compared with CKD patients without AKI (CKD only).Changes in estimated glomerular filtration rates (eGFR) at one and two years after consent, where available, were calculated.

Results: 823 patients (35%) had a diagnosis of AKI and among them 97 patients (4% overall) had a diagnosis of ATN. 31 patients had a diagnosis of primary ATN (mean age 59; 61% male), and 66 had ATN on CKD (mean age 66; 55% male). 1544 patients had CKD only (mean age 67; 50% male). 19% of CKD only patients had cancer: rates were higher in those with primary ATN (42%, OR 3.03, p= 0.002), and marginally higher in those with ATN on CKD (29%, OR 1.7, p=0.06). Diabetes (DM) and hypertension (HTN) were recorded in 52% and 80% of CKD-only patients: rates were significantly lower for patients with primary ATN (DM 19%, p<0.001 and HTN 55%, p=0.001), but were not for patients with ATN on CKD (DM 41%, p=0.1, and HTN 74% p= 0.3. The mean rate of eGFR decline (ml/min/1.73m^2/yr) in patients with cancer and CKD only was 0.91 (SD=5.12), for patients with primary ATN and cancer was 3.63 (SD=4.90) and for ATN on CKD and cancer was 0.88 (SD=5.56).

Conclusions: These findings suggest that ATN in patients with cancer may be an independent risk factor for developing CKD. However an effect on progression is not yet clear.

PUB045

Increased Levels of uPAR Correlate with Disease Severity in Hantavirus-Induced Acute Renal Failure Stefan Hägele,[1] David Changli Wei,[2] Jochen Reiser,[2] Martin G. Zeier,[1] Ellen Krautkrämer.[1] *[1]Dept of Nephrology, Univ Hospital Heidelberg, Heidelberg, Germany; [2]Dept of Medicine, Rush Univ, Chicago, IL.*

Background: Hantavirus disease caused by Puumala and Dobrava-Belgrade virus is characterized by acute kidney injury (AKI) with often massive proteinuria. The underlying mechanisms for renal failure are not completely understood. Recently, serum soluble urokinase-type plasminogen activator receptor (uPAR) has been identified as one of the key factors for proteinuria in focal segmental glomerulosclerosis (FSGS) by impairing podocyte function.

Methods: We analyzed levels of uPAR and its ligand urokinase-type plasminogen activator (uPA) in serum samples of patients with acute hantavirus disease and of healthy control persons. Serum uPAR levels were correlated with hantaviral clinical parameters.

Results: Serum uPAR levels were significantly higher in hantavirus-infected patients. In contrast, levels of the ligand uPA were not elevated. The concentration of serum uPAR correlated with clinical parameters and highest uPAR levels were observed in patients with severe AKI.

Conclusions: The correlation between increased serum uPAR levels and laboratory parameters indicates a possible role of uPAR in the severity of hantavirus-induced AKI. Elevated levels of soluble uPAR may contribute to podocyte dysfunction and may be relevant in the pathogenesis of proteinuria induced by hantavirus infection.

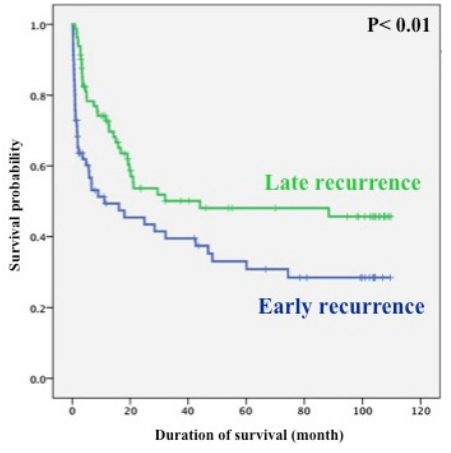
PUB046

Patients with Early Recurrence of Acute Kidney Injury Are Poor Prognosis
Keisuke Sako, Kengo Furuichi, Yasunori Iwata, Norihiko Sakai, Takashi Wada.
Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.

Background: Preventing recurrent AKI would improve kidney dysfunction and mortality. However, it is still unclear how long should we follow the AKI cases after the kidney injury. In this study, we evaluate interval of recurrent AKI and prognosis of these cases.

Methods: This study was observational cohort study. An entry criterion of this study is all cases admitted and visited to Kanazawa University Hospital from November 1st, 2006 to October 31st, 2007. A total of 21,939 cases were evaluated retrospectively from November 1st, 2006 to December 31st, 2015. Primary end point was death. Observation time after index AKI were two years for short-outcome and ten years for long-outcomes. Recurrent AKI was defined as re-increase of serum creatinine after index AKI.

Results: One hundred fifty one cases occurred recurrent AKI within two years. Cases recurred AKI within 28 days were defined as the early recurrence group (n=70), and others were defined as the late recurrence group (n=81). Their clinical factors were almost no difference between two groups. However, rates of all-cause mortality were higher in the early recurrence group (p<0.01; Log-rank test). Multiple cox regression analysis revealed that AKI stage III in first AKI showed high HR for death in early recurrence group (HR 3.269; p<0.05), and AKI Stage III in recurrent AKI showed high HR for death in late recurrence group (HR 5.600; p<0.01).



Conclusions: Patients with recurrent AKI within 28 days after index AKI showed poor prognosis. Careful follow-up for at least 28 days after AKI would be required to detect recurrence of AKI and predict prognosis after AKI.

PUB047

Metformin Associated Lactic Acidosis with Acute Kidney Injury: Results of a French Observational Multicenter Study Carried Out in 2015
Alain Wynckel,[1] Anthony Corchia,[1] Zoubir Djerada,[2] Thiery Trenque,[3] Philippe Rieu.[1] *[1]Nephrology, CHU, Reims, France; [2]Pharmacology, CHU, Reims, France; [3]Pharmacovigilance, CHU, Reims, France.*

Background: Metformin associated lactic acidosis (MALA) remains a controversial issue in the literature.

Methods: Our observational multicenter study focused on MALA (pH <7.35, blood lactate > 2 mmol/L) associated with acute kidney injury (AKI), occurring from January to December 2015. The same questionnaire was sent to 67 nephrology departments (ND) and 17 intensive care units (ICU). Clinical characteristics, baseline chronic treatment, precipitating factors, need for vasoactive drugs, extrarenal support, renal recovery, mortality and the worst biological values were recorded for all the patients. Plasma metformin levels were collected if available.

Results: 42 ND did not observe MALA. 158 MALA were collected. Mean age was 70 ± 12 years. Preexistent eGFR was less than 60ml/min per 1.73m^2 in 38 patients and was unknown in 20 patients. The mean pH was 7.13 ± 0.20. Mean serum creatinine and blood arterial lactate were 604 ± 360 µmol/L and 10.2 ± 8.1 mmol/L respectively. A septic or cardiogenic shock was documented in 34 patients. Gastro intestinal disorders or acute cardiac dysfunction were observed in 79 of the 97 patients who did not need vasoactive drugs. Plasma metformin level was positively correlated with blood lactate level and negatively correlated with pH. Need for vasoactive drugs, baseline mean pH and lactate concentration did not differ significantly between survivors (n=137) and non survivors (n=21). Death was related to septic or cardiogenic shock in 12 patients. Hemodialysis was performed in 119 patients. The correction of lactic acidosis was obtained in 48 hours in 109 patients. Complete renal recovery was observed in 91% of the patients with a previous eGFR > 60ml/min per 1.73m^2.

Conclusions: MALA occurred mainly in patients without preexistent renal failure. Septic shock was not the predominant triggering factor. The majority of patients with MALA survived when hemodialysis was performed early despite a mean pH that is usually thought to be fatal. Temporary metformine withdrawal is recommended in dehydrated patient.

Can We Blame Vitamin D for Contrast Induced Nephropathy? A Prospective Single Center Study
Ashraf Omar Oweis,[1] Sameeha A. Alshelleh.[2]
[1]Internal Medicine, Jordan Univ of Science and Technology, Irbid, Jordan; [2]Internal Medicine, Univ of Jordan, Amman, Jordan.

Background: Contrast induced nephropathy (CIN) is one of the major causes of acute kidney injury (AKI) for hospitalized patients, few mechanisms were suggested to cause CIN, one of which is the anti-oxident, anti-inflammatroy effect of vitamin D on the kidney. Our study is to evaluate the factors associated with CIN including vitamin D deficiency.

Methods: in a tertiary referral hospital, we prospectively collected data, blood and urine samples for all patients admitted to our cardiology unit, and signed the consent form to participate in our study. all consented patients were asked to have a creatinine level withdrawn 48-72 hours after the procedure. CIN was defined as increase in serum creatinine by 25% from the baseline within 48-72 hours after the contrast administration. we excluded patients with advanced CKD (stage 4,5), patients with recent contrast administration.

Results: between June 1.2015 - January 10. 2016, we approached 1810 patients, 327 patients agreed and signed the consent to participate in the study, 123 patients did not come back for follow up creatinine,for baseline characteristics see table 1, the contrast media used was low osmolality for all patients, the average contrast used was 99.8 ml (SD 68.7) for the CIN group and 99.2 ml (SD 65.7) for the other group. mean creatinine for CIN group was 73.3 mmol/l vs. 87.6 mmol/l for the other group,78.2% of all patients were vitamin D defificent (mean 13.6 ng/ml). in our study only 10.4% received pre procedure hydration, the incidence of CIN was 14.9%, admission creatinine (P=0.001) and the use of diuretics (P=0.047) were associated with CIN, vitamin D was not associated with increase incidence of CIN in our study (P=0.097).

Conclusions: incidence of CIN is high among hospitalized patients, in many cases its a preventable complication of contrast media if adhered to general recommendation of adequate pre contrast hydration.

PUB050

Study Protocol Renal Function Measurements Are Comparable to Clinical Care Measurements in a Cardiac Surgery Cohort
Eric McArthur,[1] Amit X. Garg,[1] Steven G. Coca,[2] Chirag R. Parikh,[3] Heather Thiessen Philbrook.[3]
[1]Inst for Clinical Evaluative Sciences, ON, Canada; [2]Icahn School of Medicine at Mount Sinai, NY; [3]Yale Univ, CT.

Background: In the era of electronic medical records, it is appealing to utilize measurements available from routine clinical care instead of laborious and expensive study protocol visits. However, clinically obtained lab values are prone to ascertainment bias. It is not known if renal function measured during clinical care is comparable to protocol-based visits.

Methods: The TRIBE-AKI cohort is comprised of adults undergoing cardiac surgery. We examined a subset of the cohort in Ontario, Canada who had estimated glomerular filtration rate (eGFR) measured in follow-up as per study protocol, with a clinical care eGFR collected from an outpatient laboratory within one year of the study protocol visit (using CKD-EPI equation). Comparability of the eGFRs was assessed using Pearson's correlation, concordance correlation, and a Bland-Altman plot.

Results: Overall, 224 adults had a study protocol visit a median 3.0 years (IQR 2.9-3.2) after surgery, of which 88 (39%) had their eGFR measured in clinical care. The mean eGFR in clinical care was 66 mL/min/1.73m^2 (SD 18) and was 59 mL/min/1.73m^2 (SD 17) at protocol visits. A correlation of 0.90 (95% CI 0.85, 0.93) and concordance of 0.84 (95% CI 0.77, 0.89) indicated strong correlation and moderate concordance. The Bland-Altman plot showed, among those with mild or no chronic kidney disease, clinical care may slightly overestimate eGFR relative to protocol-based eGFR.

Conclusions: Clinical care eGFR may be marginally higher compared to study protocol eGFR, but the values were largely comparable in follow-up after cardiac surgery. Supplementing research studies with eGFR collected from electronic medical records may help minimize costs and loss to follow-up, but further research should confirm these findings.

Analysis of Kidney Injury Markers in Children with Cancer Marcelo Rodrigues Bacci, Marina M. Sonnenfeld, Carolina Y. Tamashiro, Fernando Luiz Affonso Fonseca. *General Practice, ABC Medical School, Santo Andre, São Paulo, Brazil.*

Background: Children are subjected to develop acute kidney injury(AKI) when in a chemotherapy(CT) routine basis. Still, when the AKI is not present the pattern of glomerular biomarkers of renal dysfunction is not known. The association between its levels before the initiation of CT could predict the occurrence of AKI later on.The aim of the study is to evaluate AKI in pediatric oncology patients in current CT.

Methods: It is a cross-sectional study. Individuals from 2 to 18 years-old with a confirmed diagnosis of acute lymphoblastic leukemia, acute myeloid leukemia and any solid tumors receiving CT were included. Exclusion criteria involved patients with end stage renal disease or in dialysis and with an eGFR less than 60 mL/min/1.73m^2 and also with any other immunodeficiency. Individuals with prior organ transplants were excluded as well. Blood samples were collected in order to analyze the following variables before and after CT : serum creatinine,C cystatin, NGAL, interleukin-6, TNF-alpha, C-reactive protein and homocysteine.

Results: A total of 26 children were included. About 17 had acute lymphoblastic leukemia, 2 had acute myeloid leukemia, 3 with neuroblastoma, 1 with testicle neoplasia, 1 with adrenaloma, 1 with osteosarcoma and 1 with rabdomiosarcoma. About 61.5% were male and the mean age was 9,48 years. NGAL and C cystatin in blood were measured with the following median results in the sample:0.3 and 6.6. Serum creatinine median was 0.6 mg/dL. Spearman correlation test analysed the correlation between C cystatin and inflammatory and renal dysfunction biomarkers. The correlation was not significant between NGAL and creatinine (p=0.213) and between C cystatin and creatinine (p=0.113). The correlation between C cystatin and NGAL was also not significant with a p=0.464. The performance in the receiver operating characteristics analysis the area under the curve for NGAL in detecting acute kidney injury was 0.280. The performance of C cystatin had the value of 0.565 .

Conclusions: This model could not predict AKI in patients receiving CT. NGAL and C cystatin were not correlated with the development with AKI in children receiving CT.

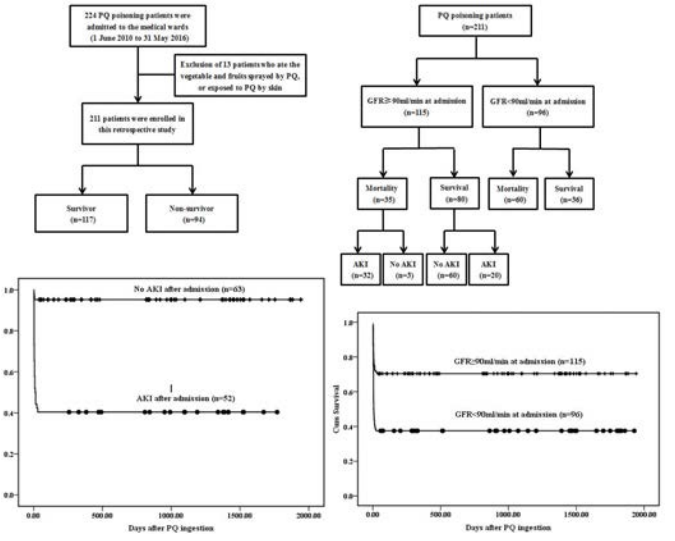
PUB052

Analysis of Prognostic Factors in Patients with Paraquat Poisoning for Optimal Therapy Regimen Ying Xu, Jingyun Le, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital, School of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Paraquat (PQ) is an effective quaternary nitrogen herbicide which is highly toxic to human. The purpose of this study was to identify prognostic factors after PQ poisoning and discuss the efficacy of current therapy regimen.

Methods: In this retrospective study, 211 cases admitted to our hospital between 1 June 2010 and 30 April 2016 were enrolled. The demographic characteristics, medical records of clinical features, laboratory parameters, therapy regimen and the prognosis were retrospectively analyzed.

Results: The overall survival rate was 55.45%. The mean age was 35.85 years with 55.45% being female. The average amount of PQ ingestion was 30.79 ml. Twelve Patients who ingested PQ combined with alcohol had a higher survival rate. The patients in survival group ingested less amount of PQ, presented with lower serum creatinine level and higher glomerular infiltration rate at admission, developed lower incidence of acute kidney injury and pulmonary CT deterioration. As to the therapy regimen, the survivors were treated with higher dosage of methylprednisolone, daily dose of aspirin, daily dose of rapamycin and lower daily dose of vitamin C. The frequency of hemoperfusion was much more in the survival group. The Cox regression analysis demonstrated that larger amount of PQ ingested (HR 1.006, *P*=0.003), abnormal renal function at admission (HR 12.540, *P*=0.001) or developed AKI after admission (HR 21.327, *P*<0.001) were the independent risk factor. Higher dose of methylprednisolone (HR 0.577, *P*<0.001) and aspirin (HR 0.998, *P*=0.027) were independent protective prognostic factor .



Conclusions: The non-survivor characteristics are larger amount of PQ ingestion, manifestation of abnormal renal function at admission or developed AKI after admission, whereas the survivor characteristics are higher dose of methylprednisolone and aspirin.

PUB053

Ionomic Profile as a Biomarker for Acute Kidney Injury after Cardiac Surgery Ziyan Shen,[1,2,3] Xiaoyan Zhang,[1,2,3] Jie Teng,[1,2,3] Xiaoqiang Ding.[1,2,3] *[1]Dept of Nephrology, Zhongshan Hospital, Shanghai Medical College, Fudan Univ, Shanghai, China; [2]Kidney and Dialysis Inst of Shanghai, Shanghai, China; [3]Kidney and Blood Purification Laboratory of Shanghai, Shanghai, China.*

Background: Ion transportation, one of the fundamental renal tubular functions, is veiled during acute kidney injury (AKI). This study is aimed to map the urinary ionomic profile of patients with AKI after cardiac surgery in order to screen out representative ions and set up an ionomic model to early diagnose AKI after cardiac surgery.

Methods: A total of 261 patients undergoing cardiac surgery were recruited. Urine samples of pre-operation and 2h, 12h, 24h and 48h after operation were collected. Urinary concentration of 18 ions were measured by inductively coupled plasma spectroscopy (ICP-MS) and adjusted by urinary creatinine. AKI was diagnosed according to KDIGO guideline.

Results: Urinary concentration of 18 ions changed dynamically during perioperative period of cardiac surgery, especially at 2h after operation. The urinary concentrations of Cu, Pb, Al, Zn, Cd, Co, Tl, Ba, V, Ga, Se, W, U at 2h after operation were significantly higher than those of pre-operation, whereas B, As, Sr, Pd at 2h after operation were significantly lower than pre-operation. At 48h after operation, urinary ionic concentration gradually recovered to preoperative levels. There was remarkable difference in urinary ionomic profile between AKI and non-AKI groups during the perioperative period. Urinary Ion Index (UII) model to early diagnose AKI was established by bioinformatic method. Prediction equation is as following: 0.21× lg(urinary Fe at 2h after operation) + 0.32×lg(urinary Cd at 2h after operation). The cutoff value of UII was 1.85 and AUC was 0.76±0.11, while the sensitivity, specificity and accuracy were 0.61±0.17, 0.97±0.09 and 0.82±0.08, respectively.

Conclusions: Urinary ionic concentrations change dynamically during perioperative period of cardiac surgery. There is remarkable difference in urinary ionomic profile between AKI and non-AKI groups. Urinary Fe and Cd at 2h after operation can be used efficiently to construct the early diagnosis model for AKI after cardiac surgery with considerable accuracy.

PUB054

A Case of Atypical Hemolytic Uremic Syndrome Presenting as Dermatomyositis and Complicated with Viral Infections I-Ru Chen,[1] Han-Mou Tsai,[2] Hsin Hung Lin,[1] Chiu-Ching Huang.[1] *[1]Kidney Inst and Div of Nephrology, Dept of Internal Medicine, China Medical Univ Hospital, Taichung City, Taiwan; [2]MAH Hematology Associates, New Hyde Park, New York.*

Background: Atypical hemolytic uremic syndrome (aHUS) usually presents with the triad of acute renal failure, thrombocytopenia and microangiopathic hemolytic anemia (MAHA). It is unusual to present with features of dermatomyositis without the triad.

Methods: A 41 years old woman was admitted for fever, polyarthralgia, proximal limb weakness, erythematous rashes, heliotrope rashes, periungual erythema and Gottron's papules. Her LDH, ALT, CPK, amylase, lipase and CRP were elevated but her platelet count and serum Cr were not. Serology testing failed to detect any autoantibodies. Four days later she lost her left visual acuity, platelet count decreased to 53x10^9/L, Cr increased to 1.64 mg/dL and LDH increased to 1659 from 537 IU/L. Despite daily plasma exchange her platelet count further decreased. Hemodialysis was started for oliguria and pulmonary edema. She then developed seizure, altered mental status and respiratory failure that required endotracheal intubation. Eculizumab was given on day 20, her general status improved and her leukocytosis resolved. Yet her fever persisted and her platelet count, after increasing

to a maximum of $58x10^9$/L, failed to normalize after two weekly doses of eculizumab. Extensive microbiological investigation revealed by PCR herpes simplex virus type 1 and CMV viremias. Neither was detected in a saved blood sample of day 14.

Results: Four days after adding acyclovir, before ganciclovir was instituted, her platelet count normalized. Fever resolved after 3 weeks of anti-CMV therapy. Her skin rashes subsided and her Cr normalized after 8 doses of eculizumab therapy. Kidney and skin biopsies showed thrombotic microangiopathy. Gene sequence analysis detected a CFH miss-sense mutation (G936A).

Conclusions: aHUS may present with features mimicking dermatomyositis. Our case is also unusual in that its course was complicated with viremia of HSV and CMV. In a case of aHUS, lack of expected responses to anticomplement therapy should prompt rigorous searches for concurrent illnesses.

PUB055

Phenotype of Proton Pump Inhibitor Associated Drug Induced Kidney Disease (DIKD): Results from the DIRECT Study Linda Awdishu,[1] Rajasekara Chakravarthi Madarasu,[2] Stuart Goldstein,[3] Ashita J. Tolwani,[4] Melanie S. Joy,[5] Etienne Macedo,[1] Dinna Cruz,[1] Jorge Cerda,[6] David T. Selewski,[7] Michael Zappitelli,[8] Andrew J.P. Lewington,[9] Maria Ostermann,[10] Vivekanand Jha,[11] Ravindra L. Mehta.[1,12] *[1]Univ of California, San Diego; [2]Star Kidney Centers; [3]Cincinnati Children's Medical Center; [4]Univ of Alabama at Birmingham; [5]Univ of Colorado, Denver; [6]Albany Medical College; [7]Univ of Michigan; [8]McGill Univ Health Centre; [9]Leeds Teaching Hospital; [10]Guy's and St. Thomas' Hospital; [11]Postgraduate Inst of Medical Education and Research; [12]On Behalf of the DIRECT Investigators.*

Background: Proton pump inhibitors (PPIs) have strong evidence for efficacy and a favorable side effect profile. However, there are concerns given overprescription and recent association of chronic kidney disease with PPI use.

Methods: DIRECT is an international multi-center study which enrolled 634 patients with DIKD to identify drug-related polymorphisms by GWAS studies that were associated with standardized phenotypes. Each presumed PPI case was adjudicated by 2 nephrologists.

Results: PPI associated DIKD cases (N=28) were confirmed by adjudication (21 adult and 7 pediatric patients). Implicated PPI's were omeprazole (N=9,22.2±6.7mg), esomeprazole (N=3,20 mg), lansoprazole (N=5,27±6.7mg) and pantoprazole (N=10,38±6.3mg). Patients were 43% male with mean age of 51.6±20 years in adults and 12.6±3.3 years in pediatrics. Subjects were 79% white, 11% black and 11% asian. Co-morbidities included hypertension, diabetes and cancer in adults and hypertension, cancer and liver disease in pediatrics. The mean Scr increased from 0.99±0.47 to 3.76±2.22mg/dL in adults and 0.34±0.22 to 1.14±0.46 mg/dL in pediatrics. Median (IQR) time to onset was 6 (3-14) days. Common risk factors were hyperglycemia and additional nephrotoxic exposures. Biopsies were performed in 29% demonstrating interstitial nephritis in 75% of cases. However, blood eosinophils were within normal range (2.0±1.5%). Dialysis was required for 14.3% of cases. Mortality was 3.7% and 13.6% at hospital discharge and 90 days.

Conclusions: PPIs may cause interstitial nephritis in susceptible caucasian patients at standard doses.

PUB056

Biomarkers Utilization to Detect Subclinical Kidney Injury in Acute Stroke: Organ Cross-Talk Begoña Campos, Anthony C. Leonard, Charuhas V. Thakar. *Nephrology, Univ of Cincinnati, Cincinnati, OH.*

Background: Acute kidney injury (AKI) affects 25% of patients admitted with stroke, predicts high mortality. Recent study shows that 10% of stroke patients have unrecognized chronic renal insufficiency, which predicts poor outcomes. Neutrophil gelatinase associated lipocalin (NGAL) has been used as a reliable kidney injury biomarker, which predicts both AKI and clinical outcomes. Animal studies show that this protein is expressed early and highly induced in the kidney after ischaemic or nephrotoxic AKI. In this study we evaluate if NGAL could be used to detect subclinical Kidney injury in patients suffering from other vital organ ischemia; acute stroke.

Methods: Based on the established knowledge of NGAL, we studied the occurrence of subclinical kidney injury. In a prospectively collected biological repository of eligible acute stroke subjects (2013-14), there were 38 cases of stroke (14 Ischemic; 24 hemorrhagic). Demographic, comorbid and laboratory variables were collected at the time of admission with stroke, along with de-identified plasma samples for biomarker assays. We assayed the samples for NGAL based on established methods.

Results: Based on literature, we chose 150 ng/ml as the upper limit of normal baseline NGAL in plasma. As shown in Table 1 of the 31 patients with baseline creatinine of < 1.2 at the time of stroke, 4 (12%) already had positive biomarker levels (range 151 to 248 ng/ml) indicating subclinical kidney injury. 1/4 patients with subclinical injury went on to develop clinically apparent AKI. Median NGAL levels were significantly different across stroke patients with baseline creatinine of < or >/= 1.2 mg/dl (71.2 vs 154.5, p = 0.01).

	Biomarker -ve (NGAL < 150 ng/ml)	Biomarker +ve (NGAL >/= 150 ng/ml)	N
Creatinine <1.2	27	4 (subclinical Injury)	31
Creatinine >1.2	3	4	7
TOTAL	30	8	38

Conclusions: NGAL levels at the time of acute stroke may indicate subclinical kidney injury and suggest vital organ cross talk. Biomarker utilization can discriminate those patients with subclinical kidney injury. Larger studies with longitudinal follow up are needed to examine the biomarker-based risk stratification in vital organ ischemia.

PUB057

Acute Kidney Injury Result from Rhabdomyolysis and Continuous Renal Replacement Therapy Meng Wang, Hongli Jiang, Hua Liu, Quan He. *Blood Purification, The First Affiliated Hospital of Xi'an Jiaotong Univ, Xi'an, Shaanxi, China.*

Background: Rhabdomyolysis(RM) can lead to acute kidney injury(AKI) as a life-threatening complication. Whether to use continuous renal replacement therapy(CRRT) or not for RM is still controversial. We aim to assess risk factors for AKI and evaluate further if the CRRT is effective.

Methods: 57 cases of RM were selected from our hospital (August 2013 - May 2016). Logistic regression analyses were performed to determine risk factors for AKI by collecting the medical records. All patients received etiological and rehydration therapy. Meanwhile, 32 patients received more than 24 hours of CRRT. Laboratory datas such as concentrations of myoglobin (MB), creatine kinase (CK), creatine kinase isoenzyme-MB (CK-MB), lactic dehydrogenase (LDH), aspartate aminotransferase (AST), lanine transaminase (ALT) in blood and CRRT effluents were collected.

Results: The incidence of AKI was 40%. Logistic regression analysis showed hypoalbuminemia, hypocalcemia, urine protein test positive were independently associated with AKI (p<0.05). Duration of CRRT and hospital stay were significantly higher among patients with AKI, compared with patients without AKI (p<0.05). After 24 hours of treatment, comparing with the conventional treatment patients, the concentrations of serum MB, CK, CK-MB, LDH, AST, were significantly decreased in the CRRT intervention patients (p<0.05), but there was no statistically significance in ALT level. Concentrated CRRT effluents were detected that the concentrations of the CK, CK-MB, LDH, AST, and ALT were trace amounts.

Conclusions: Prevention of AKI is important for RM patients, especially for patients with hypoalbuminemia, hypocalcemia and urine protein test positive, for whom CRRT could be a benefical intervention. CRRT could remove MB out of blood circulation directly, while the macromolecular metabolism products such as CK, CK-MB, LDH, AST, couldn't remove directly, but their serum levels were significantly decreased in CRRT intervention patients. It was suspected associating with retarding progression and helping improving metabolic function of body. Further studies and more datas are required to confirm the mechanism.

PUB058

The Impact of Elevated Preoperative Serum Creatinine on Acute Kidney Injury following Cardiac Surgery and the Protective Role of Dopamine Xuxia Gao,[1] Xinbao Yao.[2] *[1]Internal Medicine, Beijing Anzhen Hospital, Capital Medical Univ, Beijing Inst of Heart, Lung and Blood Vessel Diseases, Beijing, China; [2]Pharmacy, Beijing Anzhen Hospital, Capital Medical Univ, Beijing Inst of Heart, Lung and Blood Vessel Diseases, Beijing, China.*

Background: Preoperative renal function is an independent risk factor for Acute kidney injury (AKI) following cardiac surgery. The objective of this study is to investigate the impact of elevated preoperative serum creatinine (Scr) on AKI, and the protective effect of dopamine.

Methods: 1700 patients undergoing cardiac surgery in Beijing Anzhen Hospital from March 2008 to October 2008 were analyzed retrospectively. AKI was defined as a ≥ 50% or 26.5μmol/L increase in Scr from the preoperative value. The AKI patients (n=264) were divided into normal (n=191) and elevated Scr group (n=73) according to preoperative Scr; 124 patients with elevated Scr and complete clinical records were divided into Control (n=18) and Dopamine group (n=106, dopamine was administered postoperatively in 10 to 15mg/h for 1 to 5 days). The prevalence, the recovery of AKI, and the length of stay in the intensive care unit (ICU) were compared by chi-square test or student t-test; Risk factors were determined by multivariable logistic regression analysis.

Results: 264 of 1700 cases (15.5%) suffered from AKI. Compared to the normal Scr group, the prevalence of AKI increased (44.2% vs 12.4% , P<0.05), and the recovery rate of AKI (postoperative Scr went down to the preoperative level in 7 days)decreased (30% vs 68.8%, P<0.05) significantly in the elevated Scr group. Multivariable analysis revealed that elevated Scr (OR: 1.39, 95% CI: 1.22, 1.57)and older age (OR: 1.08, 95% CI: 1.00, 1.16) were risk factors for this difference. Between Dopamine and Control groups, pre- and intra-operative variables were comparable. Compared to Control, the prevalence of AKI decreased (36.8% vs 66.7%, P<0.05), and the length of stay in ICU was shortened (33±3.6h vs 74±45.5h, P<0.05) significantly in Dopamine group.

Conclusions: Elevated preoperative Scr increases the prevalence of AKI and make AKI more difficult to recover. Lower dose of dopamine may have protective role on AKI in patients with elevated preoperative Scr.

Prevalence and Severity of Depression among Patients with Pregnancy Related AKI Presenting to a Tertiary Care Hospital of a Developing Country
Syed Rizwan A. Bokhari,[1] Zumar Sardar,[1] Sidra Saleem,[1] Khalid Tahir,[1] Abeera Mansur.[2] *[1]Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Pakistan; [2]Nephrology, Doctors Hospital and Medical Center, Pakistan.*

Background: Acute kidney injury (AKI) in pregnant women is commonly seen in developing countries. It is associated with significant morbidity, social and personal implications. We conducted a study to assess the prevalence and severity of depression in patients with pregnancy related AKI (PRAKI) in a tertiary care center.

Methods: Patients with PRAKI admitted from 1-16 to 6-16 under Nephrology service, Jinnah Hospital, Lahore, Pakistan were included in this cross sectional study. The Hamilton Rating Scale for Depression (HAM-D) version translated and adapted in Urdu, was used to assess the study population. These patients were interviewed with the (HAM-D) questionnaire on their first encounter with Nephrology. Previous history of psychiatric illness was excluded. The diagnosis of AKI was based on the classification of the Acute Kidney Injury Network group.

Results: The mean age of the patients was 24±5 years. Seventeen (57%) patients were multipara and 13(43%) were prim gravida. Of the 30 patients with AKI, 8 (27%) presented before 28-weeks and 22 (63%) patients after 28-weeks of gestation. The cause of AKI included postpartum hemorrhage in 9 (30%), sepsis in 8 (27%), preeclampsia/eclampsia in 6(20%), shock in 4(13%) and coagulopathy in 3(10%) of patients. Alive and heathy fetus was found in only 15 (50%) of patients. Twenty-one (70%) patients received average of 5-8 hemodialysis sessions during their hospital stay. Twenty-three (76 %) had no depression (0-7 score), 2 (7%) had mild (8-13 score), 3 (10%) had moderate (14-18 score) and 2 (7%) had severe (19-22 score) depression according to HAM-D score.

Conclusions: Our study depicted considerable depression of varying degrees in women with PRAKI. Increased awareness and effective monitoring for depression should be integrated into regular maternal care to decrease morbidity associated with it.

PUB060

Incidence of Chronic Renal Replacement Therapy after Acute Kidney Injury at a University Hospital in Northeastern Mexico
Mara Cecilia Olivo, Lilia Maria Rizo Topete, Jesus Cruz Valdez. *Nephrology, Hospital Univ Dr. Jose Eleuterio Gonzalez, Monterrey, Nuevo Leon, Mexico.*

Background: Acute kidney injury (AKI) is a condition that affects 1 in 7 patients admitted to hospital and it can be prevented. AKI can occur in any clinical condition, increasing mortality and hospital costs.

Methods: Prospective, cross-sectional, descriptive study. Hospitalized patients who requires interconsultation by the Nephrology Department from March 2015 to March 2016 were included.

Results: 942 patients were included, 387(41%) developed AKI or AKI over Chronic Kidney Disease (CKD),56% were male, mean age 52.1 years (SD 17.5). The most frequently comorbidities: Diabetes Mellitus 39%, Hypertension 38.2% and obesity 13.9%. The main causes of AKI: 32% pre-renal, 27% infectious and 17% heart disease. Mortality in critical ill patients with AKI was 63%. 198 patients developed AKI, 46.5% required acute renal replacement therapy (RRT), 43.4% died, 30.4% of them recovered renal function without RRT and 26% requiring chronic RRT. 189 patients developed AKI over CKD, 46.5% of them required acute RRT, 28.5% died, 31.8% recovered renal function without RRT required with an average creatinine of 2.5(SD 1.22) at discharge and 39.7% developed ESRD requiring chronic RRT.

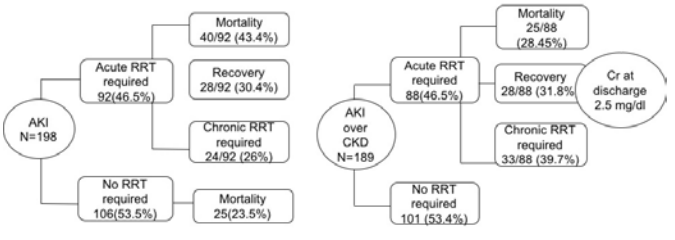

Figure 1. Renal Replacement Therapy in patients with AKI

Chi square was used to find the difference between the need of RRT among patients with AKI vs AKI over CKD (p=0.15). The global mortality associated with AKI was higher (32.8%) than in patients with AKI over CKD (13.3%) (p=0.001).

Conclusions: No difference between group AKI and AKI over CKD to continue in chronic RRT, however in relation to mortality there is a significant difference between AKI against AKI over CKD, beeing higher in the fist one. This relates in our hospital with the critically ill patient, and can be compared with other international statics.

PUB061

Rituximab Is Effective Treatment for Small Vessel Vasculitis in Absence of Circulating ANCA
Leanne A. Ogden, Ajay Prabhakar Dhaygude. *Renal Unit, Royal Preston Hospital, Preston, United Kingdom.*

Background: The antibody depleting monoclonal antibody Rituximab has been shown to be effective in ANCA associated vasculitis, as shown by the RAVE and RITUXVAS studies. Rituximab, apart from B cell depletion, facilitates B cell/T cell interaction. B cells are also known to be present in tissue infiltrate without being detected peripherally. Literature suggests ANCAs are absent in up to 10% of cases and the efficacy of Rituximab in these patients is a rarely studied group.

Methods: This retrospective, single centre study reviewed the case notes of all patients with vasculitis who were treated with rituximab and were ANCA negative at the time of treatment.

Results: 10 patients were identified, all Caucasian. Results shown in table

ANCA status at presentation (%)	Anti-PR3 (50) Anti-MPO (10) ANCA negative (40)
Organ Involvement (%)	Renal (60) Multisystem (70)
Dialysis Required (% of those with renal involvement) - at presentation	50
Mean eGFR at treatment commencement (renal involvement, dialysis independent) (mls/min)	28
Mean eGFR at follow up (renal involvement, dialysis independent) (mls/min)	32

Indications for rituximab were cyclophosphamide resistance in 9(90%). 1(10%) patient had suspected urothelial malignancy. Mean age at presentation was 60 (range 35-77 years). 1g of Rituximab was given fortnightly, with a mean cumulative dose of 4.5g of rituximab. 7 (70%) patients achieved remission following rituximab treatment. 2 (20%) patients achieved partial remission (1 had destructive ENT granulomatous disease and 1 developed AA amyloid secondary to vasculitis). 1 (10%) died whilst receiving rituximab treatment as a result of a perforated bowel.

Conclusions: This retrospective study supports the use of rituximab in the absence of circulating autoantibodies and has shown:70% complete remission; 20% partial remission; 10% mortality. Of those with renal involvement 1(16%) has remained dialysis dependent. The treatment was tolerated well with no infections requiring hospital admission. To the best of our knowledge this is the largest published series in use of rituximab in ANCA negative patients.

PUB062

The Relationship between the Hourly Urine Output and the Clinical Outcome in Nontraumatic Exertional Rhabdomyolysis
Won Jae Shin, Young-Il Jo. *Div of Nephrology, Dept of Internal Medicine, Konkuk Univ Medical Center, Seoul, Republic of Korea.*

Background: Early and aggressive fluid resuscitation is required for the prevention of acute kidney injury (AKI) in rhabdomyolysis. However, the optimal fluid and rate of repletion are unclear. The purpose of this study is to evaluate the relationship between the degree of diuresis and the clinical outcomes in nontraumatic exertional rhabdomyolysis.

Methods: We reviewed the medical records of patients who were diagnosed with nontraumatic exertional rhabdomyolysis from January 2011 to December 2015 in Konkuk university medical center. Total 40 cases were analyzed.

Results: Patients were categorized according to the hourly urine output during initial 48 hours; the low urine output (< 200 mL/hr) and the high urine output (>200 mL/hr) group. No significant differences were noted between two groups in initial levels of CPK, serum myoglobin, and creatinine. The hourly urine output was significantly high in the high urine output group (143.7±36.71 vs 291.0±79.08, p<0.001). The clinical outcomes including maximal level of CPK, incidence of AKI and mean hospital stay showed no significant differences between two groups.

Table 1. Group comparison

	The low urine output group(< 200ml/hr)	The high urine output group(> 200ml/hr)	P-value
Number	13	27	
Hourly urine output (ml/hr)	143.74 (121.56-165.92)	291.07 (259.79-322.36)	0.000
Amount of initial hydration (ml/kg/hr)	2.51 ± 0.73	4.62 ±1.58	0.000
CPK, initial (U/L)	45097.00 ± 44495.17	59969.78 ± 41900.85	0.309
CPK, maximum (U/L)	46853.15 ± 44439.95	56263.85 ± 38803.11	0.497
Creatinine, initial (mg/dL)	1.25 ± 1.32	1.04 ± 0.96	0.566
AKI, initial (number [%])	2 (15.38)	2 (7.41)	0.584
AKI, developed (number [%])	1 (7.69)	0 (0.00)	0.325
Use of bicarbonate for treatment (number [%])	3 (23.08)	10 (37.04)	0.484
Mean hospital stay (day)	8.38 ± 8.04	7.07 ± 2.87	0.451

Conclusions: Our results indicated that we should not effort to maintain the desired diuresis of approximately 200 to 300 mL/hour for prevention of AKI in nontrumatic exertional rhabdomyolysis.

PUB063

Kidney Function in Patients with Acquired Thrombotic Thrombocytopenic Purpura: Initial Presentation and Long-Term Outcomes Dustin J. Little,[1] Evaren E. Page,[2] Lauren M. Mathias,[2] Sara Vesely,[2] James George.[2] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Little is known about the incidence, severity, and significance of AKI among TTP patients. In 2003, we used a simple SCr- and RRT-based OK AKI criteria to report low rates of AKI among TTP patients in the Oklahoma TTP registry. A recent report of high rates of severe AKI among TTP patients may be limited by referral bias as all subjects were admitted to the ICU of a single tertiary care medical center. Additionally, long-term renal and health outcomes following TTP complicated by AKI have not been reported. We analyzed kidney function of patients enrolled in the OK TTP registry, using both the OK and KDIGO criteria for AKI diagnosis and staging, and investigated for associations between AKI and subsequent CKD.

Methods: Acquired autoimmune TTP was diagnosed among patients referred to the Oklahoma Blood Institute, by identifying severe (<10%) ADAMTS 13 deficiency with the presence of an inhibitor or increased ADAMTS13 activity to >10% during remission. AKI was diagnosed and staged via the previously published OK and KDIGO criteria. eGFR was calculated using the CKD-EPI equation.

Results: The diagnosis of TTP was confirmed in 75 patients enrolled in the registry from 1995-2014. Rates of overall and severe AKI were 59% and 9% by KDIGO and 50% and 7% by OK criteria, respectively. Compared to subjects without AKI, initial mortality rates were significantly increased in OK (8/40 vs. 1/35; p=0.03) but not KDIGO AKI patients. eGFR of <60 mL/min/1.73m^2 at follow-up was more common among survivors with AKI by OK criteria (6/32 vs. 0/32 without AKI; p=0.02), but not by KDIGO criteria.

Conclusions: AKI is common among TTP patients, but severe AKI is rare. A simple, SCr-based OK criteria better identified patients at risk for early mortality and decreased eGFR at follow-up, when compared to KDIGO. Our study provides the most complete and comprehensive description of AKI and long-term renal outcomes in TTP patients, and provides clinicians with important information to facilitate prognostic discussions and inform monitoring strategies in patients with a history of TTP.

PUB064

Incidence and Risk Factors of Acute Kidney Injury after Femur Fracture Surgery Young Ju Na, Sang-Kyung Jo, Won-Yong Cho, Myung-Gyu Kim, Sung Yoon Lim, Jihyun Yang. *Nephrology, Korea Univ Anam Hospital, Seoul, Korea.*

Background: As the aging population increases, the number of patients with femur fractures caused by falling and traffic accidents is also increasing. It is known that mortality is high as well as the clinical course and prognosis are not good when acute kidney injury(AKI) is shown in the femur fracture patients. Nevertheless, there are not enough studies about AKI from the femur fracture patients. In this study, we want to show the correlation between the incidence and risk factors of AKI in patients with femoral fracture.

Methods: We retrospectively evaluated the medical records of 311 patients who were operated on for femoral fracture at Korea University Anam Hospital between January 2012 and October 2015. We evaluated the Incidence and Risk factors of AKI after Femur Fracture surgery and compared between AKI and normal kidney function (NKF) groups.

Results: The overall incidence of AKI was 9.2%. When compared to the normal kidney function (NKF) groups, the AKI group had a higher incidence of anemia (86.4% vs 51.6%, p = 0.001), hyponatremia (31.8% vs 13.4%, p = 0.021), ESR (45.5% vs 10.6%, p = 0.000), use of contrast agent (27.3% vs 6.9%, p = 0.001).

In logistic regression analysis of risk factors, age (p = 0.049), lower estimated glomerular filtration rate levels (p = 0.05), contrast use(p = 0.04), diabetes mellitus (p = 0.002), heart failure (p = 0.012) were statistically significantly correlated with the development of AKI.

Conclusions: AKIafter femur fracture was associated with longer hospitalization, morbidity and mortality. It is recommended that close evaluation and monitoring is needed for patients who have the risk factor of AKI after operation for femur fracture to reduce the possibility of AKI. In the future, We need prospective studies including biomarkers.

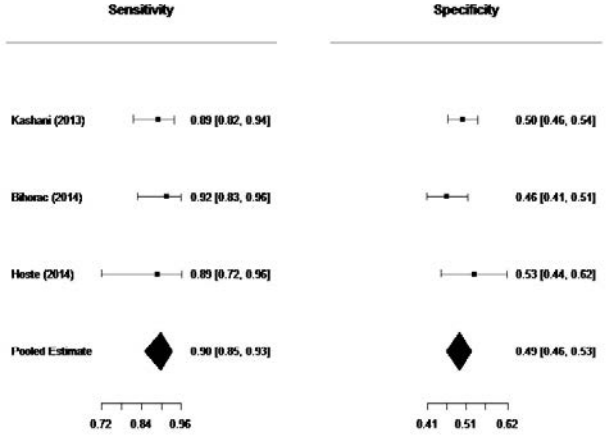
Diagnostic Accuracy of the NephroCheck for Acute Kidney Injury in Critical Care: Systematic Review and Meta-Analysis Andrew J.P. Lewington,[1,2] Elizabeth D. Mitchell,[3] Judy M. Wright,[3] David Allan Cairns,[3] Michelle Hutchinson,[3] Michael P. Messenger,[2,3] Claire Louise Corps,[1] David M. Meads,[3] Alison F. Smith,[2,3] Rebecca L. Kift,[1,2] Linda Sharples,[3] Patrick Hamilton,[4] Aleksandra Sobota,[3] Peter S. Hall.[2,5] *[1]Leeds Teaching Hospitals NHS Trust, United Kingdom; [2]NIHR Diagnostic Evidence Cooperative Leeds, United Kingdom; [3]Uni of Leeds, United Kingdom; [4]Uni of Manchester, United Kingdom; [5]Uni of Edinburgh, United Kingdom.*

Background: New diagnostics for early diagnosis of acute kidney injury (AKI) are needed. The Nephrocheck® test (ASTUTE Medical, San Diego, CA) combines two urine biomarkers metalloproteinase inhibitor 2 and Insulin-like growth factor-binding protein 7. Independent analysis is needed for evidence-based clinical adoption policy. We therefore conducted a systematic review and meta-analysis of clinical validity, efficacy, utility, and cost-effectiveness in critical care.

Methods: The search looked at 12 databases and 2 trials registers in Nov 2015 with pre-defined eligibility criteria and quality assessment (QUADAS-2) by 2 reviewers. Meta-analysis used Bayesian hierarchical regression to estimate joint pooled sensitivity and specificity for AKI KDIGO stages 2–3 within 12 hours. Prospectively registered on PROSPERO ref. CRD42014013919.

Results: The search identified 122 original articles of which 29 were subject to full text review. Ten studies were included in the review; and 3 in the meta-analysis. The mean participant median age was 64 years and 58% were male. Using the high sensitivity cut-off (0.3), pooled sensitivity was estimated as 0.90 (95% CI 0. 85-0.93) and pooled specificity as 0.49 (95% CI 0.46-0.53) (Figure 1). No clinical efficacy, clinical utility or cost-effectiveness studies were identified.



Conclusions: Nephrocheck has high sensitivity and moderate specificity for AKI in adult critical care settings. Further research to estimate clinical utility and cost-effectiveness is worthwhile.

PUB066

The Lifespan of CRRT Dialyzer Is Proportional to Bleeding Diathesis in DIC Jae Seok Kim,[1] Byoung Geun Han,[1] Seung-Ok Choi,[1] Min Keun Kim,[1] Minseob Eom,[2] Jae Won Yang.[1] *[1]Internal Medicine, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea; [2]Pathology, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea.*

Background: CRRT needs continuous systemic anticoagulation to maintain extracorporeal circuit. But, frequent dialyzer clotting reduces the efficiency of CRRT. Therefore, we aim to investigate which conditions contribute to frequent dialyzer clotting and dialyzer lifespan.

Methods: We investigated retrospectively the medical records of thirty patients who had been received CRRT. Heparin was used primarily for circuit anticoagulation in 4 patients, and nafamostat mesilate was used alternatively in 26 patients. We investigated clinical situations, CRRT prescriptions and basic blood tests including DIC profile. Dialyzer lifespan was calculated as: CRRT maintenance time (hours) divided by the frequency of dialyzer membrane clotting. In addition, we estimated DIC severity by ISTH DIC scoring system.

Results: The results showed that D-dimer and FDP had significant positive correlations with dialyzer lifespan respectively (r=0.38, p=0.048 / r=0.40, p=0.041), while hemoglobin concentration, platelet count, PT and activated PTT did not show the relationships with diaylzer lifespan. Transfusion of packed RBC, fresh frozen plasma and platelet concentrate did not show the relationships with dialyzer lifespan, and clinical severity including initial mean blood pressure, urinary amount and APACHE score also had no relationships. CRRT prescription including CRRT dose, blood flow and type of anticoagulation had no correlations with diaylzer lifespan. When compared with non-DIC group (n=20), DIC group (n=10) had longer dialyzer lifespan, but did not quite achieve statistical significance (DIC vs. non-DIC, 48.0±19.5 vs. 33.4±18.3 hours, p=0.052). When compared with non-sepsis group (n=11), sepsis group (n=19) had shorter dialyzer lifespan significantly (sepsis vs. non-sepsis, 32.2±16.1 vs. 48.8±21.3 hours, p=0.022).

Conclusions: Our study indicates that the more DIC gets worse, the less dialyzer clotting is frequent in CRRT. We believe that local predisposition to bleeding in DIC may play a role in preventing dialyzer clotting although PT and activated PTT had no significant relationships with it.

PUB067

Clinical Case with Interstitial Nephritis Induced by Mycophenolate Mofetil Valentin Ch. Ikonomov, Miroslava Stancheva Benkova, Aleksandar Aleksandrov Petrov, Iliana Georgieva Teodorova, Petar Petrov. *Clinic of Nephrology Acute and Peritoneal Dialysis with Apheresis and Transplantation, Univ Hospital "St. Marina" , Medical Univ Varna, Varna, Bulgaria.*

Background: Acute interstitial nephritis (AIN) is an inflammatory disease, characterized with generalized or local infiltration of the renal interstitium with T-lymphocytes, macrophages, eosinophilia and plasmic cells. The most common causes

of AIN are: drug-induced nephropathy, infections, autoimmunology diseases, cancer, and idiopathic interstitial nephritis. The cell-mediated response is more important than the humoral induced acute interstitial nephritis. For the definite diagnosis, a kidney biopsy is indicated. Microscopic linear or granular deposition of immunoglobulins and complement in the interstitium and/or on the tubule basal membrane is characteristically linked to AIN. Key in the treatment is to identify the agent/drug, causing the disease and apply low-dose steroid therapy for 4 to 6 weeks. Alternative to corticosteroids is MMF.

Methods: Here we introduce the clinical case of a 45-years old woman with previously proven chronic membranous nephropathy, treated with Mycophenolate mofetil for 3 months. The patient worsened her renal function (urea 22,5 mmol/l, creatinine 909 µmol/l), which led to additional acute morphological examination. The renal biopsy has shown focal lymphocyte infiltration in the interstitium and tubular atrophy, without immunofluorescent deposition of globulins.

Conclusions: Discontinuation of the treatment with Mycophenolate mofetil, corticosteroid infusion and dialysis improved the renal function, reaching the normal levels for the patient – creatinine 200 µmol/l.

PUB068

Epidemiology of Acute Kidney Injury in an American Inner City Population

Justin Lee Loy,[1] Gayatri Lessey,[1] Osezua J. Olear,[1] Michael A. Fischman,[1] Bhupinder K. Prajapati,[1] Muner Mohamed,[1] Asana Anderson,[1] Alan D. Weinberg,[2] Jonathan M. Barasch,[3] Subodh J. Saggi.[1] *[1]Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; [2]Biostatistics, Mount Sinai School of Medicine, New York, NY; [3]Nephrology, Columbia Univ, New York, NY.*

Background: Data on incidence of AKI in hospitalized patients can be extracted based on ICD codes. While these databases give insight into distributions of AKI across different populations, age groups, gender and race during different time periods, they are limited in being retrospective with fragmented information on patient details. We prospectively conducted a study on hospitalized patients with specific details over a 3 year period to define our population phenotype to validate roles of biomarkers in AKI. We report the epidemiological characteristics of our predominantly African American (AA) inner city population who developed AKI.

Methods: Patients had their initial plasma, serum and urine stored for bio-banking. We gathered data on age, gender, race, BMI, DM, HTN, CKD, CHF, length of stay and medications given. Analysis was done by SAS 9.3, Chi square analysis and student "t" test.

Results: Mean age was 59±18 years, male:female ratio 1.4:1, 93% were AA, mean BMI 28±7.4, 33% DM, 69% HTN, 17% CHF and 25% CKD (eGFR <60 ml/min/1.73^2 BSA). AKI was identified in 8.82%, was associated with DM p=0.05, HTN p=0.005 and polypharmacy p= 0.0003. Average number of medications in patients with AKI was 12. CKD and DM were strongly associated p=0.012 but CKD with new AKI was not p=0.15. Incidence rate ratio of AKI was 25% at baseline, 30.4% on admission, 32% on Day 3.

Conclusions: There was a higher rate of AKI on admission in our population (~2%) and a 2% increase in incidence rate ratio by Day 3. An association was found between being diabetic and hypertensive. Preexisting CKD was not associated with AKI perhaps due to the inability to detect AKI by traditional methods at baseline or by day 3 using AKIN criteria. This suggest the value of using biomarkers to capture this population. It seems that patients on more than 8 medications and with hospital stays beyond 3 days are specifically vulnerable to AKI, the latter due to excess pharmacological exposure.

PUB069

Incidence of Hypocalcemia in Pediatric Patients Receiving Continuous Renal Replacement Therapy and Tandem Therapeutic Plasma Exchange

Tara Haworth,[1] Ji Yeon Lee,[1] Jennifer L. Morris,[1] Katharine Sigler,[1] Ayse Akcan Arikan,[1,2] Poyyapakkam Srivaths.[1,2] *[1]Texas Children's Hospital, Houston, TX; [2]Baylor College of Medicine, Houston, TX.*

Background: Therapeutic plasma exchange (TPE) is often performed in tandem with dialytic therapy in pediatric patients as vascular access and need for continuous dialysis would limit separate procedures. There is dearth of data regarding the incidence of hypocalcemia with tandem procedures.

Methods: Retrospective review to evaluate the incidence of hypocalcemia during continuous renal replacement (CRRT) and tandem TPE performed at our institution from January 2012 through December 2014.

Results: Twenty-three patients underwent 115 procedures; median of 4 tandem sessions (IQR 2.5-5.5) were instituted per patient. Demographics: Median age 2.5 yrs [IQR 0.96-9.50], 35% male, wt 14.7 kg [IQR 10.0-36.2], and BSA 0.56 m^2 [IQR 0.45-1.14]. Liver failure with coagulopathy was the most common indication (64.5%). Continuous venovenous hemodialfiltration and centrifugal based TPE was performed in all patients. The median CRRT flow rate was 2,163 ml/1.73 m^2/hr [IQR 1,985-3,364] and apheresis duration 50 minutes [IQR 30.5-102.5]. Fresh frozen plasma (FFP) was the most common replacement fluid (96.5%); median FFP replacement volume 700 mL [IQR 500-2350]. Regional anticoagulation with 3% citrate solution (ACD-A) was used to provide anticoagulation for both CRRT and TPE. Median ACD-A rate was 90 ml/hr [IQR 70-165]; intravenous (IV) calcium chloride infusion rate (2.16 mg/mL of elemental calcium) 60 ml/hr [IQR 40-100]; inlet flow rate 38.5 ml/min [IQR 26.3-50.0]; ratio 1.8 [IQR 1.2-2.3]. During tandem therapy, median ionized calcium (iCa) was 1.12 mmol/L [IQR 0.96-1.19]; hypocalcemia (iCa <1.0 mmol/L) occurred in 52 procedures (45%). Calcium boluses were given during 40 procedures (35%). Hypocalcemia was not affected by diagnosis, age, or inlet flow. Earlier institution data had shown only 3% hypocalcemia with non-tandem TPE.

Conclusions: Hypocalcemia occurred in nearly half of TPE procedures in tandem with CRRT even with IV calcium replacement at 1.8 x inlet flow. Exogenous calcium supplementation should be increased in patients undergoing tandem therapy to prevent hypocalcemia.

PUB070

AKI in Heart Failure Admissions and Impact of Non-Specialist Care

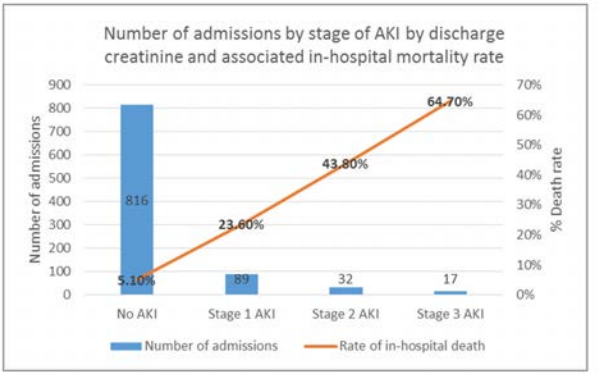
Rebeka E. Jenkins, Saraniga Gugathas, Juan Carlos Kaski, Lisa J. Anderson, Debasish Banerjee. *St. George's Hospital.*

Background: Persistent AKI in heart failure (HF) can be associated with poor outcome, but the effect of specialist care is not clear. We investigated the impact of persistent AKI and specialist care on mortality, length of stay (LOS) in a inner-city UK hospital.

Methods: Data were analysed for all HF admissions between 1/3/2013-31/3/2015. Discharge creatinine[crt] and crt>3months prior to admission determined persistent AKI using KDIGO criteria.

Results: Data on baseline crt were available in 953 out of 1056 admissions with acute HF. 138 [10%] of the 953 admissions were associated with AKI; 89-stage 1, 32-stage 2, 11-stage3. Patients with AKI were similar compared to non-AKI in age [77±10 vs 77±13 years; p=0.961], diabetes [42% vs 40%; p=0.393], presence of systolic dysfunction [65% vs 57%; p=0.122], pre-existing stage 4/5 CKD [10% vs 12%, p=0.404], haemoglobin [11±2 vs 12±2 g/L; p=0.453]. AKI admissions had higher potassium (K) [4.7±0.9 vs 4.3±0.6 mmol/L; p=0.000], higher BNP, longer (LOS) [13±12 vs 10±12 days; p=0.002], less ACEi/ARB therapy [46% vs 59%; p=0.006], higher in-patient mortality [33% vs 5%; p=0.000]. Mortality increased with worsening AKI Stage 1-24%, stage 2-43%, stage 3-64% [see figure]. In logistic regression age, AKI, CKD 4/5 were independent predictors of in-hospital mortality adjusted for each other, diabetes, systolic dysfunction and specialist care. AKI-HF admissions under the non-specialist care were older than those under specialist cardiology care [79±10 vs. 73±10 years; p=0.002], with less systolic dysfunction [59% vs 79%; p=0.023], similar diabetes, higher K [4.8±1 vs 4.5±1; p=0.030]; with no significant increase in LOS or in-hospital mortality [39% vs 24%; p=0.068].

Conclusions: Persistent AKI during acute HF admissions was a strong independent predictor of mortality, which worsened with severe AKI, with longer admission, which was not significantly affected by non-specialist care.



PUB071

Fatal Milk Acid

Tokameh Entezari. *Internal Medicine, 1, Reno, NV.*

Background: Metformin associated lactic acidosis has been described but delayed presentation of this condition has not been recognized. We present a case of severe lactic acidosis in a patient with acute renal failure 24hrs after admission.

Methods: A 65 year old diabetic woman on metformin was admitted due to abnormal renal function on routine labs and inability to urinate for 48hrs. Creatinine was 7.72, bicarbonate 17 and anion gap 16. She was hemodynamically stable, but decompensated 24 hrs after admission with acute respiratory distress and severe metabolic acidosis. Arterial ph was 6.88, bicarbonate of 3 and lactate of 14mmoles. She was intubated for and received 200mmoles of intravenous bicarb push. An emergent hemodialysis was performed with normalization of blood pH and reduction of lactate to 5mmoles.

Results: Acidosis and lactate normalized with repeat dialysis. Throughout her hospital course, her blood pressure was normal to high and did not require any vasopressors. Her renal function eventually improved and dialysis was discontinued. Renal biopsy showed ATN, nephrosclerosis with features of focal global glomerulosclerosis. Metformin is actively excreted, un-metabolized, via transporters in the proximal tubules of the kidneys with an estimated half-life of 5hrs. In renal failure, metformin accumulates and leads to lactic acidosis by enhancing anaerobic metabolism and inhibiting pyruvate dehydrogenase. Also renal failure further leads to reduced excretion of lactic acid. This patient is unusual given her development of lactic acidosis almost 24 hrs after admission to hospital. She had no other concurrent reason for developing lactic acidosis. This case highlights the importance of carefully monitoring and recognizing delayed development of lactic acidosis in patients taking metformin and acute renal failure. Appropriate treatment could be lifesaving in these patients.

Conclusions: Delayed development of life-threatening lactic acidosis is uncommon complication in diabetic patients who stopped metformin with acute severe renal failure.

PUB072

Application of Cardiothoracic Bioimpedance Hemodynamics and Volemic Parameters in Acute Kidney Injury Francisco Javier Lavilla, Nuria Garcia-Fernandez, Maria Jose Molina Higueras, Pelayo Moiron Fdez-Felechosa, Christian Israel Alfaro Sanchez, Paloma L. Martin Moreno, Pedro Errasti. *Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: Evaluate appplication of cardiothoracic bioimpedance (CTBIA) hemodynamics and volemic parameters in Acute Kidney Injury (AKI).

Methods: Cohort 50 patients (mean age 71.2 years SD 1.6, 79.6% males) with AKI. Evaluate hemodynamic parameters (cardiac output –CO-, cardiac output index –COI- and systemic vascular resistance index –SVRI-), thoracic volemic parameters (Thoracic fluid volumen TFV-, Thoracic fluid volumen index –TFVI-) and impedance (Z),analytical (c-reactive protein –CRP-, brain natriuretic factor -BNF-) and clinical parameters (hypotension, respiratory failure, renal replacements requeriments and Karnofsky index –K-).

Results: Patients with lower vascular resistance and higher cardiac work, are associated with hypotension (¿inflammatory state, hipovolemia?). Patients with higher BNF have low cardiac output with high vascular resistences (¿heart failure?). Lower cardiac output are associated with hypoalbuminemia. Patients with higher thoracic volumen have higher risk of respiratoy failure and higher renal replacement therapy requeriments (¿hyperexpansion?). Thoracic hypervolemia are associated with poor impedance (TFV r=-0.931 p= 0.001; TFVI r=-0.885 p=0.001) and poor chronic health status.

	CO l/min	COI l/min/m2	TFV l/kOhm	TFVI l/kOhm/m2	SVRI dyn s cm-5 m2	Z Ohm

RRT. p. NO/YES	ns	ns	0.005 37/49.2	0.037 20.2/25.1	ns	ns

Conclusions: CTBIA can be used to evaluate clinical evolution and theraphy in AKI, as a patients with vasoplegic state (inflammatory origen and higher multiorgan failure risk) or thoracic hypervolemia (higher respiratoy failure and intubation risk).

PUB073

Role of TIMP-2 and IGFPB7 in Predicting Outcomes of Post-Hospitalization Dialysis-Dependent AKI (PHD-AKI) Emaad M. Abdel-Rahman, Jitendra K. Gautam. *Nephrology, Univ of Virginia, Charlottesville, VA.*

Background: Predicting outcomes of patients with PHD-AKI is important to ensure adequate medical management. This is becoming more crucial with CMS reversing their clarification, allowing AKI patients to be dialyzed at outpatient ESRD facilities. Tissue inhibitor of metalloproteinases-2 (TIMP-2) and insulin-like growth factor-binding protein 7(IGFBP7) are expressed in renal tubular cells during cellular stress and injury. Studies showed these biomarkers as being superior to exisiting markers in predicting AKI .We hypothesize that a decrease in these biomarkers in PHD-AKI will signal less renal epithelium stress and possible renal recovery. We aim to evaluate the value of TIMP-2, and IGFBP7 as predictors of renal recovery of PHD-AKI within 90 days post hospital discharge (PHD).

Methods: In this pilot study, 10 patients with PHD-AKI were studied. Within the 90 days PHD, 5 remained dialysis dependent (group 1) and 5 recovered their kidney function (group 2). Blood and urine were obtained from each patient on their first hemodialysis session PHD. TIMP-2 and IGFBP7 in plasma and urine were determined using the R & D Systems (Minneapolis, MN, USA) sandwich ELISA as per manufacturer's recommendations. Frozen samples were thawed and brought to room temperature, appropriate dilutions were tested for the biomarkers along with known standard. Final absorbance at 450 nm was read using Synergy2 from Biotek Corp (Winooski, VT, USA). Microsoft Excel and OriginPro 7.5 from Origin Labs (Northampton, MA, USA) were used for graph plotting and statistical analysis.

Results: The mean plasma level of plasma TIMP-2 x IGFBP7 were 26.5 $(ng/ml)^2/1000$ and 10.6 $(ng/ml)^2/1000$ for groups 1 and 2 respectively. The mean urine TIMP-2 x IGFBP7 were 138.2 $(ng/ml)^2/1000$ and 8.4 $(ng/ml)^2/1000$ for groups 1 and 2 respectively.

Conclusions: Biomarkers TIMP-2 and IGFBP7 may have a role in predicting recovery in patients with PHD-AKI. Further data is needed to elicit the role, if any, for these biomarkers as predictors of renal recovery. Currently, we continue to recruit more patients, obtaining plasma and urine samples twice/week from patients along with recording patients' demographics and comorbidity data.

PUB074

Acute Kidney Injury. Unicentric Observational Prospective Study. Identification Parameters to Reduce Mortality and Hospitalization Francisco Javier Lavilla, Nuria Garcia-Fernandez, Maria Jose Molina Higueras, Pelayo Moiron Fdez-Felechosa, Christian Israel Alfaro Sanchez, Paloma L. Martin Moreno, Pedro Errasti. *Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: Evaluate prognosis in acute kidney injury (AKI). Identificate parameters to reduce mortality and hospitalization.

Methods: In a cohort of 2714 patients (62 years-old SD 0.3, 71.6 % male) with a diagnosis of ARF (creatinine increase > 20%). Inclusion period: 3/1996 to 3/2016. We evaluate individual severity (ISI), multiple organ failure index (MFO), Karnofsky, ECOG, analytical parameters, and renal replacement therapy requirement (RRTR).

Results: The death rate was 17.1%. ISI and MOFI are associated with mortality risk, ROC curve analysis showed high sensitivity and specificity: ISI (0.838, SD: 0.011, 95% CI:0.816-0.860), MOFI (0.868, SD: 0.009, 95% CI:0.850-0.886).Multivariate logistic regression analysis showed that variables included in ISI: oliguria (OR 6.241, 95% CI4.894-7.96) and coma (OR 8.218, 95% CI6.04-11.1) influenced independently. Evaluating MOFI, the respiratory failure showed, as well, an independent correlation (OR 4.378, 95% CI 3.822-5.016). Karnofsky (69.6 SD 0.3 vs 62.2 SD 0.6) and ECOG (1.86 SD 0.02 vs 2.77 SD 0.07) was higher in death patients (p<0.001). Analytical parameters observed differences.

	Initial creatinine	Peak creatinine	Creatine increment	Lower Albumin	Lower hemoglobin	Lower Platelets	Basal C reactive protein	Peak Brain Natriuretic Factor
No exitus	1.73	2.12	1.30	2571	9.1	120.802	9.1	7129
Exitus	1.92	2.23	1.55	2407	8.0	83127	13.2	12673
p	0.007	<0.001	0.005	0.058	0.032	>0.001	<0.001	<0.001

Treatment: Exitus rate was higher in replacement therapy (no requeriment: 8.5%, IHD 30.6%, CRRT 45%, and IHD with CRRT 40.6%) (p<0.001).

Conclusions: ISI and MOFI are good prognostic predictors of outcome. Oliguria and respiratory failure correlates to mortality. Prognostic depends on health state prior to injury and evolution of creatinine, hematological, protein, inflammatory and cardiac congestion status. Use of renal replacement therapy predicts a worst prognosis.

PUB075

Intradialytic Hypotension in Acute Kidney Injury: A Systematic Review Adrianna Douvris,[1] Swapnil Hiremath,[2,3] Edward George Clark.[2,3] *[1]Dept of Medicine, Univ of Ottawa; [2]Kidney Research Centre, Ottawa Hospital Research Inst; [3]Div of Nephrology, The Ottawa Hospital.*

Background: Intradialytic hypotension (IDH) is a frequent complication of hemodialysis in end-stage kidney disease. Most studies on current interventions have focused on this chronic population. IDH is also an important concern for critically ill ICU patients with acute kidney injury (AKI) requiring renal replacement therapy (RRT), complicating an estimated 30% of treatments. We undertook a systematic review to synthesize the evidence surrounding dialysis-related interventions used to minimize IDH in critically ill patients with RRT-requiring AKI. Our outcomes included the incidence of IDH, RRT-related complications, in-hospital mortality and renal recovery.

Methods: We searched MEDLINE, EMBASE and CENTRAL databases using a comprehensive search strategy. We had performed an initial search of these databases and Prospero, which yielded no prior or ongoing systematic reviews on this topic. Study quality was assessed using the Newcastle Ottawa Scale and ROBINS-I tool for observational studies and the Cochrane Collaboration's Tool for assessing risk of bias for RCTs.

Results: A total of 14 studies were identified for qualitative synthesis: 7 randomized controlled trials (RCTs) and 7 observational studies. Our search identified only 1 to 2 studies per dialysis-related intervention, which included sodium modeling, ultrafiltration profiling, blood volume and temperature control, blood volume monitoring, extended duration of dialysis, CRRT pump speeds at initiation, dialysate solutions, and dialyzer membranes. Some strategies were employed in combination. Variable definitions of IDH were employed. We were unable to do a formal meta-analysis due to the heterogeneity of interventions, dialysis modalities, and outcomes assessed. Study quality was generally low.

Conclusions: Little high-quality evidence exists with respect to interventions for reducing IDH in RRT-requiring AKI. Standardization of the definition of IDH in this context could help facilitate future studies that seek to minimize the persistently high rates of mortality and dialysis-dependence after RRT-requiring AKI through a reduction in IDH.

PUB076

Fractional Excretion of Sodium (FeNa) <1 Is Sensitive but Not Specific for Hepatorenal Syndrome (HRS) Diagnosis in Cirrhotic Patients Hani Wadei, Ali Alsaad.[2] *[1]Transplantation, Mayo Clinic, Jacksonville, FL; [2]Medicine, Div of Nephrology and Hypertension, Mayo Clinic, Jacksonville, FL.*

Background: FeNa<1 favors HRS diagnosis in cirrhotic patients with renal dysfunction however FeNa<1 has not been previously correlated with renal histology . **Aim:** correlate FeNa<1 with histological findings on renal biopsy and determine the accuracy of FeNa in diagnosing HRS.

Methods: 88 liver transplant candidates with renal dysfunction and/or proteinuria underwent percutaneous kidney biopsy, iothalamate GFR, 24-hr urine collection for urinary Na and protein excretions and random urine Na and creatinine. FeNa was calculated using the equation [(urine sodium x serum creatinine)/(serum sodium x urine creatinine)] x 100. Patients on renal replacement therapy were excluded.

Results: Table 1 represents patients' characteristics

Age	60 ± 7
Male gender	57 (65)
HCV infection	40 (45)
History of diabetes	35 (40)
History of hypertension	40 (45)
Iothalamate GFR ml/min	28 ± 14
Serum creatinine (mg/dl)	1.9 ± 0.9
Serum Na (mEq/dl)	137 ± 5
24-hr urinary protein excretion (mg/d)	87 (0-13625)
FeNa<1	**77 (87)**
Hematuria	40 (45)
Diuretic use	64 (72)
Kidney Biopsy	
HRS	10 (11)
ATN	12 (14)
MPGN	13 (15)
Minimal histology	15 (17)
≥30-40% IF/GS	38 (43)

77 (87%) had FeNa<1. FeNa<1 was present in 10/10, 10/12, 11/13, 12/15 and 34/38 in patients with HRS, ATN, MPGN, minimal histological findings and advanced (≥30-40%) interstitial fibrosis (IF) and/or glomerulosclerosis (GS), respectively (P=0.6). FeNa<1 was 100% sensitive and 14% specific in diagnosing HRS. ROC confirmed that FeNa <1 performs poorly in diagnosing HRS, AUC=0.58.

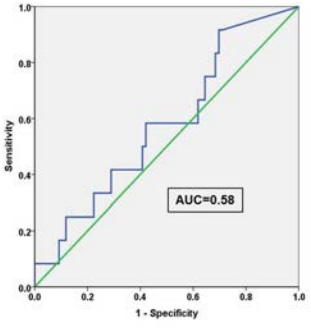

Figure 1: ROC curve demonstrates the poor diagnostic performance of FENA<1 in diagnosing HRS. AUC= 0.58

Conclusions: FeNa<1 is common in cirrhotic patients with renal dysfunction and does not differentiate between HRS and other causes of renal dysfunction.

PUB077

The Recognition of Acute Kidney Injury and Referral to a Nephrology Unit Influence the Outcomes of Hospital-Acquired Acute Kidney Injury

Takayuki Tsuji,[1] Naoko Tsuji,[1] Naro Ohashi,[1] Akihiko Kato,[2] Hideo Yasuda.[1]
[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan.

Background: Several studies have shown an increasing incidence and high mortality of hospital-acquired acute kidney injury (HA-AKI). Although AKI criteria of KDIGO has been widely used to detect AKI events early and avoid development of AKI in hospitalized patients, it is not unclear where and how often HA-AKI events are recognized and whether the recognition and referral to a nephrology unit influence their outcomes.

Methods: We searched retrospectively the incidence of AKI events from electronic database of Hamamatsu University Hospital (Shizuoka, Japan) that provides all major medical and surgical specialities, and reviewed medical records of the patients. AKI was defined as more than 1.5 times increasing from baseline of serum creatinine within 7 days based on KDIGO AKI criteria. The study population consisted of 5,591 adult patients who were admitted to the hospital from April to September 2015. All HA-AKI events were analysed.

Results: 135 HA-AKI episodes (128 patients, 2.41%) were detected during the study period. 84 episodes (62.2%) as stage 1, 30 episodes (22.2%) as stage 2, 21 episodes (15.6%) as stage 3 were classified, respectively. 43.7% of the HA-AKI patients suffered from cancer. All hospital mortality was 33.6% (43 patients). 86 episodes (63.7%) of the HA-AKI were recognized by the attending doctors. Only 15 episodes (17.4%) of the recognized cases were referred to nephrology. Whereas the referred cases had more severe AKI compared to non-referred cases, these referred cases were significantly less short-term of hospital mortality compared to the non-referred cases (0 vs. 25.4%, p<0.05). Nephrologist contributed to discriminate between intrinsic and pre-renal AKI, and induce renal replacement therapy properly.

Conclusions: AKI was common in hospitalized cancer patients and associated with high mortality. Recognition of AKI and referral to a nephrology unit might improve hospital mortality after HA-AKI.

PUB078

Dapsone Induced Methemoglobinemia: A Case Series

Sohail Abdul Salim, Iasmina Craici, Swetha Rani Kanduri, Yougandhar Akula. *Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Dapsone, a sulfone antibiotic, has been used in renal transplant recipients for prophylaxis of Pneumocystis Carinii Pneumonia in patients with documented sulfa allergy. Acquired Methemoglobinemia caused by dapsone is not uncommon in transplant patients with normal G6PD levels. Discrepancy between pulse oximetry (PO) and arterial oxygen saturation (SpO**2**) readings, a phenomenon known as "saturation gap" is noted.

Methods: None

Results: Case 1:72 Male with Deceased Donor Renal Transplant (DDRT) with sob for 2-3 weeks on mild to moderate exertion, found to have Pulse oximetry saturation of 82% and arterial Po2 of 100 with methemoglobin level of 21.3%Case2: 24 female with lupus nephritis and hemolytic anemia. Few weeks prior she was switched from Bactrim to dapsone. Pt methemoglobin level was 4.6% and came down to normal levels as soon as dapsone was stopped. Case 3: 52 y/o Female DDRT admitted for worsening SOB and dyspnea on exertion with methemoglobin level of 7.2%.

Conclusions: Dapsone might be reasonable alternative in TMP/SMX intolerance, but clinicians should have a higher suspicion of Methemoglobinemia. Symptoms can occur at Methemoglobin levels ranging from 1.9% to 26.8%, mostly at the 100 mg dose and could be worse in patients with preexisting coronary and chronic lung disease. Adequate level of suspicion with appropriate labs could lead to early recognition, which is key to effective management.

PUB079

The Activation of Notch3 in Endothelial Cell Aggravate Renal Fibrosis in Obstructive Nephropathy

Hui Xu, Jin Zhang, Ting Ding. *Nephrology Dept, Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Notch3 has been showed to be protective in generating functional arteries. But the role of notch3 activation in chronic kidney injury (CKD) is controversial. Angitensin II (AngII) plays a key role in arteries function and the progression of kidney diseases. This study was to assess the expression of notch3 in obstructive nephropathy.

Methods: The expression of Notch3 in injured kidney of obstructive nephropathy patients was analyzed by immunohistochemistry. The expression of Notch3 and (AngII) was detected in 3, 7, 14 and 21 unilateral ureteral occlusion (UUO) rats by western blot or realtime PCR. After the stimulation of AngII, the expression of notch3 in proximal tubular or endothelial cell lines was assessed by western blot or realtime PCR.

Results: The expression of notch3 is upregulated in the renal cortex of obstructive nephropathy patients. Consistently, the expression of notch3 and AngII increased time-dependently in the renal cortex of UUO rats. Moreover, after the stimulation of AngII, the expression of notch3 was up-regulated in endothelial cells but not the proximal tubular epithelial cells.

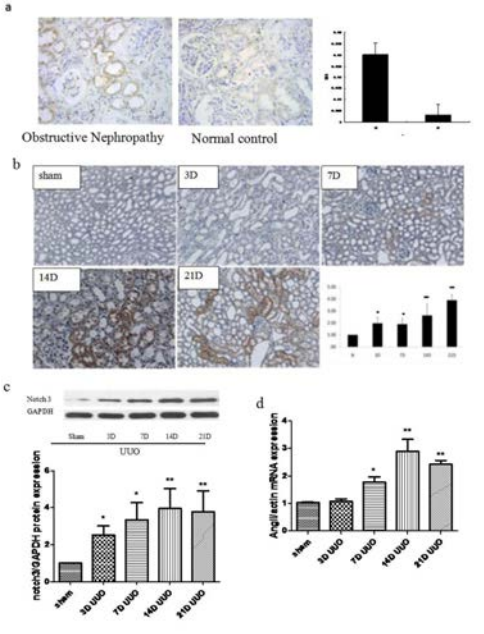

Figure1 a. Notch3 in the renal cortex of obstructive nephropathy patients and normal control by immunohistochemistry; b. Notch3 in the renal cortex of UUO rats by immunohistochemistry; c. Notch3 in the renal cortex of UUO rats by western blot; d. AngII in the renal cortex of UUO rats by realtime PCR.

Conclusions: The activation of notch3 plays a role in obstructive nephropathy and renal fibrosis. AngII is an important physiological factor in triggering the expression of notch3 expression. Blocking the expression of notch3 may be a potential therapeutics for renal fibrosis.

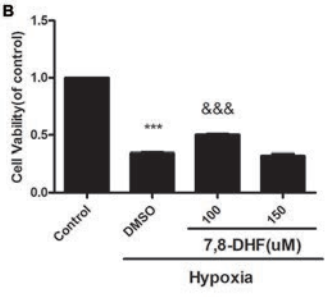
PUB080

7,8-DHF Treatment Induces Cyr61 Expression to Suppress Hypoxia Induced ER Stress in HK-2 Cells Yan Xu, Rui Ma. *Dept of Nephrology, Affiliated Hospital of Qingdao Univ, Qingdao, Shandong, China.*

Background: Hypoxia is the leading cause to AKI and the proximal renal tubular cells are the most damaged part in kidney. In this study we explored function of 7,8-DHF in protecting human proximal tubular cell line HK-2 from hypoxia insults.

Methods: The cultured HK-2 cells were pretreated with 7,8-DHF and exposed to 12 h hypoxia. Then the cytotoxicity of 7,8-DHF and cell viability were determined. The protein expression of the possible downstream biomarker as cysteine-rich protein 61 (Cyr61) and endoplasmic reticulum (ER) stress marker as CCAAT/enhancer-binding protein homologous protein (CHOP) were identified by western blot analysis. Real-time PCR was selected to test the mRNA expression of ER stress associated signaling pathway, such as protein kinase-like ER kinase(PERK),Glucose-regulated protein 78(GRP78),splicing X-box–binding protein-1(xbp1s),activating transcription factor 6(ATF6). In study of overexpression of Cyr61, apoptotic rate, mRNA and protein levels of ER stress markers and apoptotic parameter as cleaved Caspase-3 were detected.

Results: In hypoxia induced HK-2 cells, 7,8-DHF improved cell viability.



Mechanistically, 7,8-DHF could elevate the expression of cysteine-rich protein 61 (Cyr61), a protective immediate early gene in AKI. In addition, treatment of 7,8-DHF decreased CCAAT/enhancer-binding protein homologous protein (CHOP) expression, which is a mark protein during endoplasmic reticulum (ER) stress activation. Intriguingly, overexpression of Cyr61 significantly reduced CHOP expression.

Conclusions: 7,8-DHF could protect HK-2 cells from hypoxia insult by activating Cyr61 signaling and suppressing ER stress and have potential clinical implications for the treatment of AKI.

PUB081

Activation Inhibits but Deactivation of the Renin Angiotensin System Accelerates Differentiation of Human Podocytes Vinita Vishnoi, Abheepsa Mishra, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: Activation of renin angiotensin system (RAS) has been shown to play a role in the development of focal glomerulosclerosis (FSGS). Loss of critical number of podocytes has been incriminated for the development of FSGS. Usually, a subset of parietal epithelial cells (PECs) or cells of renin lineage serve as progenitors cells and are differentiated into podocytes to repopulate the glomerular basement membrane. We asked whether activation of the RAS in adverse milieus such as high glucose would prevent but inhibition of the RAS would accelerate differentiation of podocytes.

Methods: Immortalized proliferating human podocytes (HPs) which proliferate at 33˚C but differentiate at 37˚C (differentiation complete on 10th day). HPs were incubated at 37˚C either for 3 days (short duration, SD) or for 8 days (long duration, LD). HPs were reincubated in media containing either buffer or high glucose (HG, 30 mM) for the next 48 hours. HPs were treated under similar conditions with variable concentrations of HG (5, 10, 15, 25, 30 mM). Protein blots and cDNAs of SD/HPs were probed for podocalyxin. Protein blots and cDNAs of LD/HPs were probed for nephrin. To evaluate the role of RAS, SD/HPs and LD/HPs were incubated in media containing either buffer, losartan (an Ang II blocker, 10^{-7}M)/aliskiren (renin inhibitor, 10^{-6}M)/ captopril (an angiotensin converting enzyme inhibitor (10^{-6}M), or losartan/aliskiren/captopril with or without HG (30 mM) for 48 hours. Protein blots and cDNAs were probed for podocalyxin and nephrin.

Results: HG down regulated podocalyxin in SD/HPs in a dose dependent manner. Similarly, HG down regulated nephrin in LD/HPs in a dose dependent manner. Losartan, captopril, and aliskiren up regulated expression of podocalyxin as well as of nephrin both at basal and HG-stimulated states.

Conclusions: Activation of the RAS in high glucose milieu prevents whereas inhibition of RAS accelerates differentiation of podocytes.

PUB082

How Many Podocyte Autophagosomes in Two Kinds of Nephropathy: IgAN and IMN? Shikai Liang. *Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: The aim of this study was to investigate the number of autophagosomes in podocyte from kidney tissue of immunoglobulin A nephropathy (IgAN) and idiopathic membranous nephropathy (IMN).

Methods: The changes of kidney tissue pathology were detected after hematoxylin and eosin (HE), periodic acid-Schiff (PAS), Masson's trichrome and immunofluorescence (IF). The autophagosomes of podocyte were analysed by transmission electron microscopy (EM). Clinical data, including age, gender, edema, serum creatinine, estimated glomerular filtrating rate (eGFR), hematuria, urine protein excretion and serum albumin, were collected from inpatient medical record.

Results: It was found that the number of autophagosomes in podocyte of nephropathy group were lower when compared with the control group. At the same time we did not find the difference of the parameter between these two kinds of nephropathy. Further study showed that the index was affected by two factors: eGFR and gender.The cases with worse eGFR (eGFR<60 ml/min) and male patients presented more autophagosomes. Furthermore, each nephropathy had its own character. The phenomena of reduced autophagosomes was found in IMN cases, did not change from male to female, and further aggravated from pathological stage I to II. By contrast, IgAN cases with less eGFR exhibited more autophagsomes.

Conclusions: Therefore, the results of the present study indicate that autophagy participates in podocyte injury and the progression of IgAN and IMN.

PUB083

Mechanisms of Graphene Toxicity to Kidney Tubular Epithelial Cells Tariq Fahmi,[1] Alena Savenka,[1] Alexei G. Basnakian.[1,2] *[1]Dept of Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Graphene is a new nanomaterial that is extremely light, flexible and strong. It is expected to be commonly applied in the future due to its versatility. However, since it is a carbon-based nanomaterial, its potential toxicity is a health and environmental concern. Kidney is one of the primary organs for the assessment of nanomaterial toxicity.

Methods: By using a near infrared fluorescence (NIRF) DNase activity probe, we have established that graphene induces nephrotoxicity that occurs mainly through DNA destruction. A non-modified graphene (50 μg/ml) exposed with cultured rat kidney tubular epithelial NRK-52E cells induced an LDH release and a TUNEL-type DNA fragmentation usually associated with cytotoxicity.

Results: Dark-field and phase-contrast microscopy showed that TUNEL-positive cells have significantly higher graphene content than TUNEL-negative cells. DNase activity quantified in live cells using the oligonucleotide-based NIRF probe was increased in the presence of graphene in parallel with the TUNEL. Cell death DNases, such as caspase-activated DNase (CAD), endonuclease G (EndoG), and DNase I, and the marker of oxidative stress, heme oxygenase-1 (HO-1) were shown to be elevated. We then applied specific chemical inhibitors to determine whether the DNase and oxidative pathways are mechanistically involved in the graphene toxicity.

Conclusions: The hypothesis was confirmed by the fact that all of the inhibitors abolished the graphene toxicity. In summary, the measuring of DNase activity by using NIRF probe in combination with TUNEL assay and are appropriate tools for the assessment of graphene toxicity, and oxidative injury and DNases are the mechanisms of the latter.

PUB084

Calcitriol Mitigates Advanced Glycation End Product (AGE)-Elicited Imbalance between Th17 and Treg Cells via VDR-State3- RORγt/Foxp3 Pathway in Diabetic Nephropathy Ao Cheng, Yanlin Zhang. *Dept of Nephrology, The First Affiliated Hospital of Xiamen Univ, Xiamen, Fujian, China.*

Background: Our previous studies have found AGE-HSA can induce the initial T CD4+cells to generate Th17 cells by RAGE- RORgt signaling. In addition to regulate calcium and phosphorus metabolism, Calcitriol has immunomodulatory effects. The main purpose of this experiment is to explore whether calcitriol could regulate advanced glycation end products elicited Imbalance between Th17 and Treg Cells.

Methods: (1) Recruitment of 20 healthy adults and 50 diabetic nephropathy patients and detection activited Vitamin D content and ratio of Th17 cells / Treg cells to verify the correlation. (2) Prepared AGE-HSA in vitro and isolated and cultured the initial CD4+T cells from healthy volunteers peripheral blood: a) AGE-HSA stimulated initial CD4+T cells, or pretreatment with calcitriol, and to detect the ratio of Th17 cell and Treg cells and determine the expression mRNA and protein of RORgt, Foxp3, STAT3 and HIF-1α; b) Pretreatment initial CD4+T cells with VDR siRNA, AGE-HSA and or not calcitriol stimulated initial CD4+T cells to detect the ratio of Th17 cell and Treg cells and the expression of RORgt, Foxp3, STAT3 and HIF-1α.

Results: (1)In patients with diabetic nephropathy, there is lower of vitamin D and increasing of Th17 cells and the reduction of Treg cells. The ratio of Th17 cells and Treg cell is imbalance (increase in the proportion). There was a negative correlation between the concentration of vitamin D and ratio of Th17 cells and Treg cells; (2) the AGE-HSA induced the initial CD4+ T cells to differentiate Th17 cells, and calcitriol could migitated effects of AGE-HSA; (3) After the suppression VDR, it can reduce the effects of Calcitriol.

(4) AGE-HSA up-regulated expression RORγ. With pretreatment of calcitriol, there was reduced the expression of RORγt, HIF-1α and STAT3 induced by AGEs and increased expression of Foxp3.

Conclusions: In patients with diabetic nephropathy, there was negatively correlated between the content of vitamin D and the proportion of Th17 cells and Treg cells, and calcitriol mitigates AGE-HSA elicited imbalance between Th17 and Treg Cells via VDR-State3- RORγt/Foxp3 Pathway.

Enrichment of Collecting Duct Cells by FACS Sorting from Whole Kidney Using L1-CAM

Yasunobu Ishikawa,[1] Sorin V. Fedeles,[2] Chao Zhang,[2] Saori Nishio,[1] Stefan Somlo.[2] *[1]Medicine II, Hokkaido Univ, Sapporo, Hokkaido, Japan; [2]Internal Medicine, Yale Univ School of Medicine, New Haven, CT.*

Background: The sensitivity for discovering *in vivo* biological effects of gene mutations in whole kidney tissue is compromised by the complexity resulting from cell type heterogeneity in tissue. For example, inactivation of *SEC63*, one of genes that causes human autosomal dominant polycystic liver disease, is known to result in increased spliced XBP1 (XBP1s), a transcription factor involved in the unfolded protein response. However, when using whole kidney protein and RNA (ASN, 2015 TH-OR066), this response was undetectable in whole kidney tissue following inactivation of *Sec63* only in collecting ducts (CD). We therefore investigated cell type specific enrichment of CD from whole kidney by FACS sorting.

Methods: WT (wild type), SKO (*Sec63$^{fl/fl}$; Pkhd1-cre*), DKO (*Sec63$^{fl/fl}$; Xbp1$^{fl/fl}$; Pkhd1-cre*) kidneys at postnatal day 35 were harvested and a single cell suspension was made. L1-CAM, a transmembrane glycoprotein belonging to the Ig superfamily of cell adhesion molecules, was conjugated to Alexa Fluor 647. Cells were stained with L1-CAM-647 (L1) and LTL-FITC (LTL) (a proximal tubule maker) prior to analysis using MoFlo cell sorters.

Results: IF showed that L1-CAM co-localized with THP positive and AQP2 positive tubules, indicating L1-CAM is expressed in murine thick ascending limb of loop of Henle and CD. L1^{+}/LTL^{-} and L1^{-}/LTL^{+} cells were separated by FACS. In whole kidney mRNA, expression of megalin (proximal tubule) is ~3-4 fold higher than AQP2 and ENaC (CD). L1^{+}/LTL^{-} cells showed ~3 fold higher expression of AQP2 and ENaC relative to megalin, indicating a ~10-fold enrichment of CD cells relative to proximal tubules. qRT-PCR analysis of whole kidney from WT, SKO and DKO showed no difference in gene expression of ERdj4 which is transcriptional target gene of Xbp1s whereas expression of ERdj4 in L1^{+}/LTL^{-} cells from SKO kidneys was increased 1.4-fold compared with WT and DKO.

Conclusions: FACS sorting by L1-CAM and LTL achieves ~10-fold enrichment of collecting duct cells relative to proximal tubules, enabling detection of modest cell type specific changes in gene transcription.

PUB086

Up-Regulation of Liver Hnf1α Gene Expression-a Possible Cause of Elevated CRP Biosynthesis Accompanied Inflammation in Experimental Chronic Renal Failure

Elzbieta Sucajtys-Szulc, Marek Szolkiewicz, Boleslaw Rutkowski, Alicja Debska-Slizien. *Dept of Nephrology, Transplantology and Internal Medicine, Medical Univ of Gdansk, Gdansk, Poland.*

Background: High sensitivity C-reactive protein (hsCRP), a marker of inflammation and predictor of cardiovascular risk is usually elevated in CKD patients. Regarding that HNF1α activates *Crp* gene expression through binding to specific site present in promoter of this gene, we examined HNF1α and CRP mRNA levels in the liver and serum CRP concentration in rats with experimentally induced chronic renal failure (CRF).

Methods: Rats underwent 5/6 nephrectomy or a sham surgery. Liver expressions of *Crp, Hnf1α* genes were quantified by qPCR. Serum CRP concentration were estimated with an immunoassay.

Results: Experimental CRF was associated with significant increase of liver HNF1α mRNA (approx. 2-fold greater that in controls (CON) and pair-fed (PF) rats). The pattern of changes in liver HNF1α mRNA levels strictly resembles the pattern of changes in liver CRP mRNA. These differences in liver CRP mRNA levels were paralleled by differences in serum CRP concentration (179±19 μg/ml in CON; 219±41 μg/ml in PF; 392±42 μg/ml in CRF respectively). We found positive correlations between the liver levels of HNF1*α* mRNA and: the liver levels of CRP mRNA ($r=0.78$, $p<0.01$) and serum CRP concentration($r=0.83$, $p<0.01$). Moreover, strong positive correlation between the liver levels of CRP mRNA and serum CRP concentrations ($r=0.85$, $p<0.01$) was found.

Conclusions: The results presented hereby indicate that up-regulation of *Hnf1α* gene expression was associated with significant increase of liver CRP mRNA and serum CRP concentrations in rats with CRF. Considering the above discused data, it is likely that HNF1α plays an important role in controlling CRP biosynthesis in CRF. Our finding provide a new information about coordinated up-regulation of *Hnf1α and Crp* genes in liver and association of this events with inflammation in chronic renal failure.

PUB087

The Explorative Analysis for Characteristics and Classification According to C4d Staining in Glomerulonephritis

Na Kyoung Hwang, Jong Man Park, Harin Rhee, Il Young Kim, Eun Young Seong, Dong Won Lee, Soo Bong Lee, Ihm Soo Kwak, Sang Heon Song. *Internal Medicine, Pusan National Univ School of Medicine, Busan, Korea.*

Background: The C4d is widely used as a footprint of the complement activation by classic or lectin pathway. It has mainly applied to antibody mediated rejection in kidney transplantation. A few studies have suggested that the C4d would have an important role in glomerulonephritis. This study aimed to analyze the C4d staining status at the time of renal biopsy and its association with clinical characteristics in glomerulonephritis.

Methods: This retrospective study included 392 patients who underwent renal biopsy between 2009 and 2016. We categorized the patients according to the C4d deposit and compared the baseline characteristics.

Results: The C4d deposits were detected in 29.1% (69/237) with IgA nephropathy (IgAN), 67.1% (47/70) with membranous nephropathy (MN), 39.5% (17/43) with minimal change disease (MCD), 57.1% (8/14) with membranoproliferative glomerulonephritis (MPGN), and 71.4% (20/28) with lupus nephritis (LN). It deposits mainly in the mesangium (IgAN, MCD, LN) and the glomerular capillary wall (MN, MPGN, LN). Clinically, the group having mesangial C4d deposit had higher proteinuria level compared with C4d-negative group in IgAN ($p=0.045$). However, there was no significant difference with baseline clinical characteristics in other glomerulonephritis. Interestingly, IgM was co-localized with C4d in IgAN (43.5% vs. 30.4%; $p=0.053$), MN (38.3% vs. 14.3%; $p=0.048$), MCD (40.0% vs. 7.1%; $p=0.008$), and LN (61.5% vs. 13.3%; $p=0.008$) compared with C4d-negative groups. The C4d-positive group has lower frequency of C3 staining and higher frequency of C4 staining in IgAN. There was no relationship between IF staining and serum level of Immunoglobulin or complements.

Conclusions: The C4d positively deposited with high frequency in glomerulonephritis and the C4d-positive area was so variable according to the type of glomerulonephritis. Additionally, IgM was co-localized with the C4d and the further evaluation for the role of IgM is necessary. In the future, extended study is needed for the prognostic role of the C4d through long-term follow-up.

PUB088

Podocyte Adhesion to Collagen-Coated Surface Is Affected after Exposure to Serum of Patients with Preeclampsia

M. Lourdes Gonzalez Suarez,[1] Allan W. Ackerman,[1] Sonu Kashyap,[1] Muthuvel Jayachandran,[1] Natasa Milic,[2] Wendy White,[1] Joseph P. Grande,[1] Vesna D. Garovic.[1] *[1]Mayo Clinic, Rochester, MN; [2]Medical Faculty Univ of Belgrade.*

Background: Podocyte proteins, such as nephrin, podocin, and synaptopodin maintain the structure and function of the slit diaphragm. Injury to this structure causes proteinuria and foot process effacement. Podocyturia has been described in preeclampsia. It remains unclear the mechanism of injury that causes podocytes detachment from the glomerular basement membrane in preeclampsia.

Methods: We conducted cell adhesion assays on collagen-coated plates, using an immortalized human podocyte cell line after 3-4 weeks of differentiation. Podocytes were exposed to serum of patients with preeclampsia (n=7) and normotensive pregnancy (n=10) at delivery. Fetal bovine serum (FBS) was used as control. Non-attached living podocytes were detected by flow cytometry. For Western blots, lysates of podocytes were incubated with antibodies against nephrin, podocin, synaptopodin, and integrin β1. Experiments were done in triplicates. Statistical analysis was done using paired t- test and Wilcoxonsign-rank.

Results: There was a significant increase ($p=0.03$) in number of living podocytes that were not able to adhere to the surface after incubation with preeclamptic versus normotensive sera. Expression of podocin in suspended cells was decreased after incubation with preeclamptic versus normotensive sera. Integrin β1 expression was increased, and expressions of nephrin and synaptopodin were decreased in suspended compared to attached cells in all three conditions.

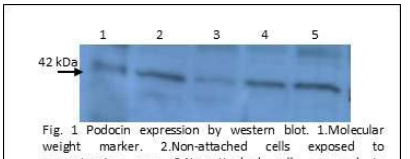

Fig. 1 Podocin expression by western blot. 1.Molecular weight marker. 2.Non-attached cells exposed to normotensive sera. 3.Non-attached cells exposed to preeclamptic sera. 4.Attached cells exposed to normotensive sera. 5.Attached cells exposed to preeclamptic sera

Conclusions: Podocin expression is decreased in non-attached cells after exposure of preeclamptic serum and may represent a disease-specific mechanism for podocyte detachment that may contribute to podocyte dysregulation in preeclampsia.

PUB089

Renoprotective Effect of the Xanthine Oxidoreductase Inhibitor, Topiroxostat, in Addition to Inactivation of RAS, on Adenine-Induced Renal Injury Atsuko Ikemori,[1,2] Takeshi Sugaya,[2] Mikako Hisamichi,[2] Kenjiro Kimura,[3] Yugo Shibagaki.[2] *[1]Anatomy, St. Marianna Univ School of Medicine; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine; [3]Tokyo Takanawa Hospital.*

Background: The aim of this study is to reveal the effect of a xanthine oxidoreductase inhibitor, Topiroxostat (Top), compared to Febuxostat (Feb), in addition to inactivation of RAS on an adenine-induced renal injury model.

Methods: Angiotensin II type 1a receptor (AT1a) hetero deficient and human L-FABP chromosomal transgenic mice (L-FABP$^{+/-}$AT1a$^{+/-}$) mice, and urinary liver type fatty acid binding protein (L-FABP), a biomarker of tubulointerstitial damage, were used. These male mice (n=48) were fed a 0.2% w/w adenine-containing diet. Four weeks after starting this diet, renal dysfunction was confirmed and the mice were divided into six groups: the adenine group was given the diet containing adenine and the control group was given only the diet. The Febuxostat-high (Feb-H) or low (Feb-L) groups and Topiroxostat-high (Top-H) or low (Top-L) groups were given diets containing Feb-H (3mg/kg), Feb-L (1mg/kg), Top-H (3mg/kg), and Top-L (1mg/kg) in addition to adenine for another 4 weeks.

Results: Serum creatinine levels, urinary L-FABP, urinary 15-F2t-isoprostane levels and urinary angiotensinogen were significantly lower in the Feb-H and Top-H groups compared to the adenine group. The degree of macrophage infiltration, tubular damage, renal fibrosis, and renal xanthine oxidoreductase (XOR) activity were significantly attenuated in the Feb-L, Feb-H, Top-L and Top-H groups compared to the adenine group. The tubular damage, urinary angiotensinogen, and the renal xanthine oxidoreductase activity (XOR) in the Top-H group, were significantly lower than those in the Feb-L group. Because the dosages of high-dose Top group are equivalent to dosages of the low-dose Feb group, Top with stronger XOR inhibitory potency might prevent the progression of CKD more than Feb.

Conclusions: Top may be useful as add-on therapy to the RAS inhibitors for preventing the progression of CKD.

PUB090

Role of Nuclear 1 Factor Related Factor 2 (Nrf2) Activator, Bardoxolone Methyl, in Hypertensive Renal Injury Mikako Hisamichi,[1] Atsuko Ikemori,[1,2] Takeshi Sugaya,[1] Kenjiro Kimura,[3] Yugo Shibagaki.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; [3]JCHO Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Nuclear 1 factor related factor 2 (Nrf2) activators have an anti-oxidant effect and might be a new treatment strategy for chronic kidney disease. Aldosterone (Ald) causes renal damage via generation of oxidative stress in hypertensive renal injury. The aim of this study is to reveal the renoprotective effect of the Nrf2 activator in a systemic Aldo infusion model.

Methods: To evaluate the degree of tubulointerstitial damage using the urinary liver type fatty acid binding protein (L-FABP), known as a biomarker of tubulointerstitial damage, we used human L-FABP chromosomal transgenic (L-FABP$^{+/-}$) mice because L-FABP is not expressed in the kidneys of wild-type mice. Male L-FABP$^{+/-}$ mice were divided into three groups: the Ald group received systemic aldosterone infusions via an osmotic minipump and were given 1% NaCl water for 35 days. The Ald-Nrf2 group was given Bardoxolone Methyl intraperitoneally in addition to an injection of aldosterone and salt. The dose of the Nrf2 activator was gradually increased every 7 days, reaching 10mg/kg/daily and continued for 14 days. The control group was given only a vehicle.

Results: The gene expressions of MCP-1, RANTES, and collagen typeIand type III, as well as the degree of macrophage infiltration, and collagen type Iand type III-positive areas were significantly greater in the kidneys of the Ald group compared to those in the control. In the Ald-Nrf2 group, such renal inflammatory reaction and renal fibrosis were significantly attenuated. Although the degree of renal human L-FABP gene expression and urinary human L-FABP levels significantly increased in the Ald group compared to the control, such an increase was suppressed in the Ald-Nrf2 group. The same trend can be observed in urinary albumin levels.

Conclusions: The Nrf2 activator, Bardoxolone Methyl, ameliorated the degree of hypertensive renal disease, and thus may be an effective treatment for hypertensive renal disease.

PUB091

Antiphospholipase A2 Receptor Antibody Titer Is Associated with Idiopathic Membranous Nephropathy Disease Activity Regardless of Pathological Grading Juan Jin. *Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: Membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults, and anti-M-type phospholipase A2 receptor (anti-PLA2R) antibodies are found in the majority of patients with idiopathic MN (IMN). We investigated the assocation of anti-PLA2R antibody titer with IMN disease activity and pathological grading.

Methods: A total of 131 patients with biopsy-proven IMN who had not received immunosuppressive treatment at the time of renal biopsy and serum sample collection were included in the study. Forty-two patients had IMN, 9 patients had secondary MN (sMN) and 223 had other glomerulonephritis.Circulating anti-PLA2R antibodies were analyzed by ELISA analysis.

Results: Anti-PLA2R antibodies were detected in 69.0% (29/42) of patients with IMN, 3.0% (1/33) of patients with mesangial proliferative glomerulonephritis, and 0% (0/223) of patients that had other glomerulonephritis. The prevalence of anti-PLA2R antibodies was higher in patients with (91.2%) compared to patients without (42.1%) nephrotic syndrome. Urinary protein was significantlylower ($p = 0.002$), while total protein and albumin were significantly higher ($p < 0.001$ and $p = 0.002$, respectively) in patients with anti-PLA2R antibodies.The sensitivity, specificty, positive predictive value and negative predictive value were 71.4%, 99.6%, 96.7% and 94.7%, respectively.

Conclusions: Our results indicate that anti-PLA2R titersreflect MN disease activity and can therefore be used as a specific marker of IMN. However, we did not identify any relationship between anti-PLA2R antibody titer and MN pathological stage.

PUB092

The Study of Syndrome Differentiation Based on Renal Biopsy Pathology of Diabetic Kidney Disease Maosheng Chen. *Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: Research the distribution of syndrome differentiation in Traditional Chinese Medicine(TCM) on diabetic kidney disease (DKD) and its relationship with pathological stage of DKD.

Methods: Bring into the DKD patients through pathological diagnosis which have more than one year disease course, to classify by the Tervaet criterion of pathological stage of DKD, to differentiate the syndrome differentiation in TCM by collecting clinical data, and have a statistical processing at last.

Results: We collected 353 DKD patients meeting the criterion in total, classified by the pathological stage criterion of DKD, among them there were 52 patients with phase I, 90 patients with phase IIa, 29 patients with phase IIb,141 patients with phase III, 41 patients with phase IV. About syndrome differentiation, there were 13 patients with Yin-Xu-Zao-Re type, there were 151 patients with Qi-Yin-Liang-Xu type, there were 140 patients with Pi-Shen-Qi-Xu type, there were 49 patients with Yin-Yang-Liang-Xu type, there were 19 patients with Han-Shi type, there were 68 patients with Shi-Re type, there were 212 patients with Yu-Xue type, there were 54 patients with Tan-Yu type. In the patients with Yin-Xu-Zao-Re type, the renal interstitial inflammation was more serious than other typs. In the patients with Pi-Shen-Qi-Xu type,the glomerular segmental sclerosis, nodular changes, and fibrinoid exudation were more serious than other groups. In the patients with Yu-Xue syndrome differentiation, interstitial fibrosis and tubular atrophy (IFTA), interstitial inflammation, hyaline degeneration, angiosclerosis,and fibrinoid exudation were more serious than other types significantly. Multivariate COX analysis showed that syndrome differentiation were independent risk factors for renal prognosis.

Conclusions: Among the syndrome differentiation of DKD, Qi-Yin-Liang-Xu type and Yu-Xue type were more frequently than other tyes. The result showed that syndrome differentiation was correlated significantly with pathological stage of DKD, Yin-Yang-Liang-Xu type and Tan-Yu type were independent risk factors for renal prognosis in DKD.

PUB093

ZNF268 Mediates Podocyte Response to PAN through Interaction with NF-κB Pathway Khaldoun Al-Romaih,[1] Khalood Aldosari,[1,2] Zakia M. Anwar Shinwari,[1] Basma Mohammed Alahideb,[1] Maram Alwahebi,[1] Rabab Hassan Allam,[1] Ayodele Alaiya.[1] *[1]Stem Cell and Tissue Re-Generation Program, King Faisal Specialist Hospital and Research Centre; [2]College of Medicine, Alfaisal Univ, Riyadh, Saudi Arabia.*

Background: Nephrotic Syndrome (NS) is a progressive kidney disease that is characterized by protein leakage into the urine. In vivo induced nephrosis by puromycine aminonucleoside (PAN) leads to the onset of proteinuria. The glomerular visceral epithelial cells (podocytes) and their injury are central to the development of proteinuria. Nuclear factor κB (NF-κB) has been implicated in the podocyte injury and onset of proteinuria. Observation, in systems other than podocytes, suggested the involvement of transcription regulation of zinc finger protein ZNF268 in mediating NF-κB pathway.

Methods: ZNF268 protein expression was analyzed in differentiated human podocyte cells. The interaction between ZNF268 and NF-kB and family members in the context of podocyte response to sub-lethal doses of PAN treatment was also studied.

Results: Expression of different isoforms of ZNF268 was seen by Immunoblotting in differentiated podocytes including ZNF268a, and ZNF268b. ZNF268 showed diffused cytoplasmic localization and focal nucleus localization. Sub-lethal doses of PAN treatment (5, 10, and 20 ug/ml) caused accumulation of ZNF268 and NF-kB-p65 in the nucleus. Also an interaction between ZNF268 and NF-kB -p65 was seen in the PAN-treated differentiated podocytes.

Conclusions: These observations highlight the potential role of ZNF268 as a mediator of response to PAN treatment in human cultured differentiated podocytes.

PUB094

Chemical Induction of Proteinuria in Larval Zebrafish Using Puromycin
Philipp Niggemann,[1] Patricia Ann Schroder,[2] Heiko Joachim Schenk,[1] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Hanover Medical School; [2]MDI Biological Laboratory.*

Background: Zebrafish have become a widely used model organism in glomerular kidney research. Developing a method that produces a standardized glomerular proteinuria phenotype in zebrafish through treatment via the fishwater would be an asset to high throughput testing of potential beneficial drugs. Thus far such a method does not exist.

Methods: We induced glomerular proteinuria phenotypes in zebrafish of different genetic backgrounds by treating the zebrafish embryos with Puromycin Aminonucleoside (PAN) in the fishwater at varying timepoints. Treatment with PAN was conducted at timepoints from 44hpf to 50hpf. Different crosses of Tg(l-fabp:DBP-EGFP) zebrafish backcrossed onto AB or *nacre* background were examined.

GFP fluorescence content was measured in 96hpf embryos' eyes as a readout of their proteinuria phenotype.

Results: Embryos homozygous for the *nacre* mutation were more susceptible to PAN treatment compared to embryos with an AB background. Moreover, we noted that a treatment at 46hpf reliably yields consistent phenotypes. Treatments at later timepoints were less effective in proteinuria induction. This specific line crossing is a good starting point for testing of drugs potentially beneficial for the treatment of proteinuria.

Conclusions: The basis of *nacre* is a mutation in the *Mitf* transcription factor regulating the formin-homology protein Dia1. Further studies are on the way to examine the relation between the *Mitf* mutation and a higher susceptibility for a disruption of the filtration barrier.

PUB095

Peroxisome Proliferator-Activated Receptor α-Dependent Renoprotection of Murine Kidney by Irbesartan
Yuji Kamijo,[1,2] Makoto Harada,[1,2] Yosuke Yamada,[1,2] Akinori Yamaguchi,[1] Koji Hashimoto.[1] *[1]Dept of Nephrology, Shinshu Univ School of Medicine, Matsumoto, Nagano, Japan; [2]Dept of Metabolic Regulation, Shinshu Univ Graduate School of Medicine, Matsumoto, Nagano, Japan.*

Background: Activation of renal peroxisome proliferator-activated receptor α (PPARα) is renoprotective, but there is no safe PPARα activator for patients with chronic kidney disease (CKD). Studies have reported that irbesartan (Irbe), an angiotensin II receptor blocker (ARB) widely prescribed for CKD, activates hepatic PPARα. However,Irbe's renal PPARα-activating effects and the role of PPARα signaling in the renoprotective effects of Irbe are unknown.

Methods: Herein, these aspects were investigated in kidneys of wild-type (WT) and *Ppara*-null (KO) mice and in the murine protein-overload-nephropathy (PON) model, respectively. The results were compared with those of losartan (Los), another ARB that does not activate PPARα.

Results: PPARα and its target gene expression were significantly increased only in the kidneys of Irbe-treated WT mice and not in KO or Los-treated mice, suggesting that the renal PPARα-activating effect was Irbe-specific. Irbe-treated-PON-WT mice exhibited decreased urine protein excretion, tubular injury, oxidative stress, and pro-inflammatory and apoptosis-stimulating responses, and they exhibited maintenance of fatty acid metabolism. Furthermore, the expression of PPARα and that of its target mRNAs encoding proteins involved in oxidative stress, pro-inflammatory responses, apoptosis, and fatty acid metabolism was maintained upon Irbe treatment. These renoprotective effects of Irbe were reversed by the PPARα antagonist MK886 and were not detected in Irbe-treated-PON-KO mice.

Conclusions: These results suggest that Irbe activates renal PPARα and that the resultant increased PPARα signaling mediates its renoprotective effects.

PUB096

Drug Treatment Response in Patients Diagnosed with Membranoproliferative Glomerulonephritis in a Fourth-Level Hospital at the City of Barranquilla-Colombia
Gustavo Aroca Martinez,[1,2] Andres A. Cadena,[1,2] Alex A. Domínguez,[2] Diana Carolina Silva,[2] Jossie E. Fontalvo,[2] Henry J. Gonzalez Torres.[2] *[1]Clinica de la Costa, Barranquilla, Colombia; [2]Univ Simón Bolívar, Barranquilla, Colombia.*

Background: The Membranoproliferative Glomerulonephritis (MPGN) is the third of fourth leading cause of End-stage renal disease among the glomerulonephritides. However, the benefits of immunosuppression treatment and the prognosis in patients with MPGN are often unknown due to a lack of controlled clinical trials.

Methods: The retrospective study was conducted in a fourth-level hospital at Barranquilla and included medical records of patients with MPGN who underwent renal biopsies from 2007 to 2014. Patients were classified according to the type of Treatment response in Responders and Non-responders. The Responders were those with Partial remission (Improvement of at least 50% of the 24hrs proteinuria and active urinary sediment) and Complete remission (24hrs proteinuria <0.5g and inactive urinary sediment). Non-responders were those who had no change in the 24hrs proteinuria or increase of 25% from the same, End-stage kidney disease and active urinary sediment. The immunosuppressive treatment included Mycophenolate and Cyclophosphamide alone and/or conjugated steroids. The treatment response was evaluated at 6 and 12 month.

Results: Of the 58 patients, 30 (52%) were females and 28 (48%) were males, with an overall mean age of 35 ± 13 years. The Nephrotic syndrome was the most common clinical presentation (70%) and 63% of the patients developed CKD at year to be evaluated. Serum Creatinine and 24hrs proteinuria did not change significantly over 6 months of treatment both males and females. 15 (25.8%) patients achieved remission (22.4% partial and 3.4% complete) and 43 (74.1%) failed to enter remission. 39.6% of females and 37.9% of males failed to achieve remission at 6 months. At 12 months, only 5 Patients (8.6%) achieved response (partial or complete) compared to 13 Patients (22.4%) of the previous semester.

Conclusions: MPGN is a major cause of CKD among the study population. Immunosuppressive drug therapy revealed no statistically significant benefits in remission of the impaired renal function at 6 and 12 months.

PUB097

An Enzyme-Linked Immunosorbent Assay (ELISA) for the Quantification of Mouse Endostatin as a Marker of Decreased Kidney Function in ETV6/RUNX1 and BCL2 Transgenic Mice
Jacqueline Wallwitz,[1] Dagmar Stoiber.[2] *[1]The Antibody Lab GmbH, Vienna; [2]Ludwig Boltzmann Inst of Cancer Research, Vienna.*

Background: Endostatin is a protein with approximately 20 kDa produced by proteolytic cleavage of collagen XVIII. It is one of the most potent endothelial cell-specific inhibitors of angiogenesis with influence on proliferation, migration and apoptosis. In order to investigate the biological functions of Endostatin in more depth this work presents the development and validation of a specific, high-quality ELISA for detecting mouse Endostatin.

Methods: We developed an immunoassay which is based on a sandwich type format with an immobilized polyclonal antibody used to capture mouse Endostatin which is subsequently detected with a horseradish peroxidase labelled polyclonal anti-Endostatin antibody. To investigate the importance of Endostatin as a potential biomarker for impaired kidney function we determined serum concentration of Endostatin in ETV6/RUNX1 and BCL2 transgenic mice.

Results: The novel sample-saving Endostatin ELISA is optimized for mouse serum and plasma. Assay characteristics such as precision, dilution linearity and spike-recovery as well as sample stability meet high quality standards. In this study we demonstrate that the glomerulonephritis phenotype of ETV6/RUNX1 and BCL2 transgenic mice is also accompanied with higher Endostatin serum concentration.

Conclusions: In conclusion, this high-quality ELISA provides a reliable and accurate tool for the quantitative determination of mouse Endostatin in serum and plasma samples.

PUB098

Deficiency of Purinergic P2X7 Receptor Protects against Progression of Chronic Renal Injury
Fabian Srugies,[1] Clemens L. Bockmeyer,[2] Lars C. Rump,[1] Sebastian Alexander Potthoff.[1] *[1]Nephrology, Medical Faculty - Heinrich-Heine Univ, Duesseldorf, Germany; [2]Pathology, Univ Clinic Erlangen, Erlangen, Germany.*

Background: Chronic kidney disease (CKD) is defined as progressive loss of renal functional. The ionotropic ATP-gated receptors the P2X7-receptor (P2X7R) is detected on immune cells like lymphocytes, macrophages and dendritic cells. P2X7R mediates Ca2+ and Na+-influx and mediates the release of pro-inflammatory cytokines (IL1β and IL18). Here, we test whether P2X7-receptor deficiency prevents progression of CKD after subtotal nephrectomy (SNX).

Methods: SNX was performed in wild type (control) and P2X7R knock out (KO) mice and assessment was performed at different time points for 35 days. Kidneys were removed on day 35 for further assessment (quantitative PCR (qPCR), Western Blot (WB), histology).

Results: On day 35, remnant-kidney-mass was significantly lower in P2X7R-KO mice. In P2X7R-KO mice urine urea level was significantly higher on day 5 and day 35, urine creatinine level was higher throughout day 5 to 35 and albumin-creatinine ratio was lower throughout day 10 to 35 compared to controls. Systolic blood pressure was significantly lower in P2X7R-KO mice. qPCR analysis showed reduced expression of collagen1, MCP-1 and NFκB in P2X7R-KO mice. WB showed a significantly lower levels collagen1 in P2X7R-KO mice. There was a significantly reduced number of sclerosed glomeruli in P2X7R-KO mice compared to controls.

Conclusions: These data indicate reduced compensatory hypertrophy in P2X7R-KO kidneys. Urine samples suggest a preserved tubulo-interstitial function in P2X7R-KO mice. Despite small difference in systolic blood pressure, heart weight showed no difference, indicating blood pressure independent effects on organ injury. Reduced collagen1-expression in qPCR and WB indicate lower fibrosis, possibly contributing to reduced hypertrophy. The reduced number in sclerosed glomeruli and reduced proteinuria indicate a preserved glomerular function. Reduced inflammatory response indicated by lower MCP-1 and NFκB expression are likely the underlying cause for the attenuated progression of renal injury in this model. Therefore, P2X7 deficiency protects against progression of chronic renal injury.

PUB099

PEDF Protein as a Potential Therapeutic Candidate for Diabetic Nephropathy: Bioinformatic Analysis of Transcriptional and Posttranscriptional Elements Associated with Personalized Gene Expression
Mohammed A. Al-Obaide, Tetyana L. Vasylyeva. *Pediatric, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

Background: Pigment epithelium-derived factor (PEDF) protein is encoded by SERPINF1 gene. PEDF is a multifunctional 50 kDa glycoprotein that belongs to the non-inhibitory Serine Protease Inhibitor (SERPIN) subfamily. It has renoprotective, neuroprotective, anti-angiogenic, anti-inflammatory and anti-apoptotic properties. We hypothesized that PEDF might be a potential therapeutic target for diabetic nephropathy (DN).

Methods: PubMed and publicly available databases, NCBI-GenBank, UCSC Genome Bioinformatics, Ensembl, ENCODE, FANTOM5, DBTSS, EPD, and MpromDB were systematically utilized for search and bioinformatic analysis of PEDF regulatory sequences. The structural features of PEDF regulatory sequences were analyzed using DNALive tool. Algorithm Fold of "RNA structure" Webservers software was used to predict the secondary structure and stem-loops for the SERPINF1 mRNA transcript. Identification of un-reported mature sequences of miRNA was performed by using miRBase BLASTN search tool.

Results: We identified twenty three tissue specific transcription starting sites (TSS) and several specific enhancers for SERPINF1 gene, which showed variable expression patterns in Kidney.SERPINF1 genomic space also contains promoter flanking, enhancers and CTCF regions. Many SNPs were identified within promoter flanking and enhancer regulatory sequences. Analysis of sequence-dependent physical properties of the SERPINF1 promoters' DNA sequences showed specific correlation with the high and low expressed TSS. Stem-loops in the SERPINF1 mRNA secondary structure were also identified that are likely candidates for posttranscriptional regulation by miRNA.

Conclusions: This study provides further insight into the regulatory features that govern PEDF expression and reveals novel regulatory sequences associated with transcription process in kidney and might play a role in pathogenesis of DN. The SERPINF1 regulatory elements could be exploited in targeted therapy.

Identifying Late-Onset Nephropathic Cystinosis Cases Using Electronic Health Records (CystEHR)
Robert M. Haws,[1] Elizabeth Mcpherson,[1] Krishna Reddy Polu,[2] Gregg C. Checani,[2] Nils F. Confer,[2] Jeremy Pomeroy,[1] Burney Kieke,[1] Robert Steiner,[3] Jeffrey J. Vanwormer.[1] *[1]Marshfield Clinic Research Foundation; [2]Raptor Pharmaceuticals Inc; [3]Univ of Wisconsin.*

Background: Nephropathic cystinosis (NC), a rare autosomal recessive disorder, typically presents with Fanconi syndrome by 1 year of age. Caused by lysosomal cystine accumulation, NC contributes to 5% of pediatric renal failures and affects multiple organs. The estimated 15 cases diagnosed annually in the US are believed to represent half of actual cases, as less severe atypical variants presenting in adolescence and young adulthood may be missed. The frequency of late onset cystinosis (LOC) cases is unknown and clinical recognition/treatment is likely suboptimal.

Methods: Reusable logic is being developed to identify LOC cases using electronic health records (EHR) from Marshfield Clinic Health System (MCHS). Stage 1 involves retrospective EHR screening to identify suspected NC cases from patients 1-30 years of age. Renal and extra-renal features indicative of NC were ascertained via clinical experience, literature search, and chart review of existing cystinosis cases within MCHS. Patients with NC clinical features were extracted from EHR based on diagnostic codes, lab values, and natural language processing. This algorithm will be validated using data from Stage 2, where suspected NC cases will be confirmed using prospectively collected leukocyte cysteine levels, genetic analysis, and ocular examination.

Results: Approximately 600,000 patients were screened for cystinosis clinical features. An initial EHR screen identified 950 patients with ≥1 renal plus ≥1 extra-renal feature. The screening algorithm, based on chart review of these cases, is being refined to determine the precise combinations of clinical features, including number and severity, and to identify potential LOC patients for Stage 2. Results of Stage 1 will be available at the time of presentation.

Conclusions: CystEHR is the first known study to develop an EHR-based algorithm for cystinosis identification, which will help determine the degree to which LOC is missed. Once validated, this algorithm could be used in other large EHR systems to update cystinosis incidence and improve clinical recognition.

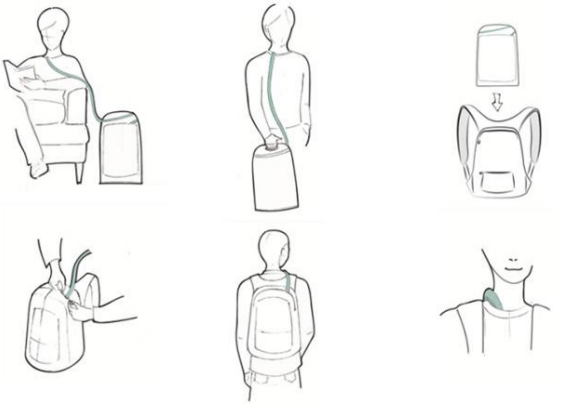
A Backpack Design Is the Best Solution for a Conceptual Design of a Wearable Artificial Kidney
Mauro Neri, Alessia Buffagni, Francesco Garzotto, Marta Zaccaria, Fiorenza Ferrari, Alessandra Brendolan, Federico Nalesso, Claudio Ronco, Anna Lorenzin. *Nephrology, Dialysis and Transplantation, International Renal Research Inst of Vicenza (IRRIV), S.Bortolo Hospital, Vicenza, Italy.*

Background: For hemodialysis patients, a miniaturized wearable artificial kidney (WAK) would allow for more freedom of movement and maintenance of a higher quality of life. In order to be truly wearable (and not only portable), not only single components, but even the device as a whole has to be designed in a convenient layout. The aim of this abstract is to propose a new concept of layout for wearable artificial kidney and to compare it with previous proposals.

Methods: The WAK general layout has to be designed providing ergonomics and low-weight, respecting the consequential phases of blood ultrafiltration process. Furthermore, the patient should not be hindered while performing daily activities and should not feel embarrassed wearing the device. Assuming a vascular access placed in jugular vein, four main proposals of layout have been considered, also based on previous proposals from literature: Belt-like device (horizontal arrangement); Jacket device (frontal arrangement); Sling shape device (frontal and vertical arrangement); Backpack device (rear and vertical arrangement).

Results: The last option seems to meet the requirements better than the others. A backpack design (commonly used in everyday life) would offer more space for the components and cause less discomfort for the patient. A schematic preliminary draw of the device is represented in Fig.1 .



Conclusions: With a backpack design, hemodialysis patients would use their own personal device only, in which all the disposable components could be replaced as a unique cartridge, designed to be extremely easy to fit and dispose. Furthermore, the backpack shape can be re-arranged into a "sleep station" to perform night treatments as well.

PUB102

A Novel Electronic Device for Measuring Urine Flow Rate
Aliza D. Goldman,[1] Hagar Azran,[1] Dafna Willner,[1] Mor Grinstein.[2] *[1]Dept of Anesthesiology and CCM, Hadassah-Hebrew Univ Hospital, Jerusalem, Israel; [2]Massachusetts General Hospital.*

Background: Most vital signs in the ICU are electronically monitored. However, clinical practice for urine output (UO) measurements still requires manual recording of data subject to human errors. UO is an underutilized biomarker for monitoring kidney function, fluid balance and hemodynamic status. Diuretics must be administered with caution and when appropriate. The use of a medical device that provides accurate data of UO in real-time can aid in defining kidney function, patient fluid status, and response to diuretic treatments.

Methods: RenalSense has developed the *Clarity RMS™ sterile sensor kit* for electronic UO monitoring. The sensor, incorporated within a standard sterile urinary catheter drainage tube, monitors urine flow in real-time as it exits the foley catheter. The sensor, connected by a cable to a laptop computer, uses software designed by RenalSense (Clarity RMS™ monitor). The drainage bag was placed on a scientific scale (gold standard) to validate the sensor measurements. For comparison of sensor data to the manual records, a standard urinometer was incorporated into the RenalSense drainage bag for the nursing staff to record UO as per standard practice. Sensor measurements and nurses' records of UO were compared to the scale data. 1635 hours of UO data from 40 patients were collected.

Results: The *Clarity RMS™* device identified 40% more of cases of acute kidney injury (AKI), as defined by the AKIN (Acute Kidney Injury Network) criteria for UO, than nursing staff records. Common human errors with regard to the UO information included missing hours of data, imprecise records of hourly output, and an incomplete picture of patient fluid balance. Graphical presentation of electronic data showed real-time response to repeated diuretic administration, as well as response to fluid bolus.

Conclusions: An electronic device for recording UO has been shown to be crucial for identifying AKI. Automated urine monitoring documented diuretic response in real-time with continuous graphic monitoring of UO; highlighting possible applications of this tool for future decisions as to timely diuretic administration, furosemide stress tests, and dose response.

Remote Monitoring of Home Dialysis Patients: Leveraging Policies for Other Chronic Diseases in U.S. and Europe
Katherine Rojahn, Suzanne Laplante, James A. Sloand. *Baxter Healthcare Corporation, Deerfield, IL.*

Background: Remote monitoring (RM) has shown to be useful in managing chronic disease patients. RM may represent an opportunity to better manage end-stage renal disease (ESRD) patients treated by home dialysis. Research was conducted to identify public policies of RM in the US and 4 European countries (Germany, Italy, Spain, UK), which potentially could be leveraged for ESRD.

Methods: Medical literature, internet, and targeted Ministry of Health websites were searched to identify RM policies for ESRD and chronic diseases such as diabetes,

heart failure, chronic pulmonary obstructive disease, and hypertension. RM was defined as patients' clinical data collection and transmittal to a hospital or physician's office, for monitoring and clinical action. Original searches were conducted Q1-2014 and complemented by 1-hour interviews with 4-5 payers/policymakers per country. Searches were updated Q4-2015/Q2-2016. Selection criteria included: policies focusing on telehealth or related terms. Data extracted consisted of: date of issue, disease areas covered, geographic scope, type of policy, and details. Each was rated according to criteria of successful public health policy including: targeted scope, identified criteria for decision-making framework, and evidence collection.

Results: Overall, more than 43 policies were identified: US=10, Italy=11, Germany=5, Spain=9, UK=8. 20 policies were nationally funded and 23 were regional. Most policies included funding for research (22) and financial incentives (13). 4 countries had policies to invest in health IT infrastructure (4) and RM guidelines (6). 24 policies were identified that may be leveraged for ESRD, of which 6 ranked the highest (US=3, Italy=1, Spain=2) for being an ongoing initiative involving data tracking, and/or established financial incentive for healthcare professionals. 10 were identified as potential long term opportunities, which included hospital or research programs (US=2, Italy=2, Germany=2, Spain=2, UK=2).

Conclusions: Our research identified policies that may be leveraged for ESRD population. Short term and long term opportunities will help to generate evidence of the benefit of RM for home dialysis.

PUB104

In Vitro Characterization of Qidni-X1, an Implantable Renal Replacement Therapy (Artificial Kidney) Device with Animal Blood Morteza Ahmadi. *Qidni Labs Inc., San Francisco, CA.*

Background: There are over 650,000 patients with End Stage Renal Disease in US. More than 100,000 patients are in the waiting list for kidney transplant and only 25,000 kidney transplants are performed each year. Qidni-X1 is an implantable renal replacement therapy under development for patients with end stage renal disease. We report on in vitro characterization of Qidni-X1 for hemodialysis and hemofiltration of animal blood.

Methods: Blood was pumped into Qidni-X1 under normal blood pressure and the hemofiltrate was collected. For hemodialysis, dialysate was pumped into the device. The composition of blood was measured using VetScan VS-2 chemistry analyzer.

Results: 75 ml of fluid was removed in each hour of hemofiltration. In hemodialysis, reduction in urea and creatinine was recorded while no significant change in the level of albumin was observed.

Conclusions: In in vitro experiments with animal blood, Qidni-X1 has been effective in removing fluids during hemofiltration and reduction of urea and creatinine without significant change in albumin level in hemodialysis.

PUB105

Podocyte-Specific Deletion of the Vitamin D Receptor Gene Did Not Increased Albuminuria Excretion under Physiologic Condition in a Short Time Li Ni, Xinxin Jiang, Jing Chen. *Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

Background: Vitamin D and its analogues possess important beneficial activity in podocytes. To understand the role of vitamin D in regulating podocytes structure and function, the vitamin D receptor (VDR) gene was selectively deleted in podocytes using the Cre-LoxP system.

Methods: Exon 3 in the VDR gene was the target sequence. The recombinant VDR allele with the loxP bordered exon 3 was maintained in the C57/BL6J background.Mice harboring the recombinant allele (VDR loxP/loxP) were bred with EIIa-Cre to verify the efficiency of VDR knockout. Then, a podocyte-specific VDR knockout mice were generated by mating VDR-floxed mice with Nestin-CreER^{T2} mice. Urine albumin excretion rate(UACR) was measured and the kidneys were obtained for immunofluorescence staining and HE staining.

Results: VDR-KO mice were generated by mating VDR-floxed with EIIa-Cre mice. Intestinal DNA from VDR-KOmice was extracted and an transcript in the 830bp band was detected by PCR. After sequencing and comparing with VDR gene, the transcript was confirmed a null allele of exon 3. Immunofluorescence, Western blot and RT-PCR all confirmed the absence of VDR expression in the intestine of VDR^{KO} mice. These results suggested that the deletion of exon3 in VDR gene caused the loss of VDR expression. Double-transgenic VDR $^{fl/fl}$/nestin-CreER^{T2} mice were treated with tamoxifen. After tamoxifen induction, expression of VDR in glomerlus of VDR$^{fl/fl}$/nestin-Cre^{+} mice was decreased significantly. Before tamoxifen induction, UACR was in VDR$^{fl/fl}$/nestin-Cre^{+} mice and wide-type mice was 77.79±42.39mg/g and 37.15±27.25mg/g, respectively, without statistical significance(p=0.08). After tamoxifen induction, UACR of VDR$^{fl/fl}$/nestin-Cre^{+} mice was increaseed but did not reach statistical significance. Serum BUN, creatinine, calcium and phosphate levels were normal and had no difference in these groups. The histology of the kidney by HE staining did not observed abnormality.

Conclusions: The model of VDR gene knockout in podocyte was successfully generated. Under physilogic condition, podocyte VDR knockout had no obvious effect on proteinuria in a short time. The long-term effect required further observation.

A New View on Glomerular Filtration Wilhelm Kriz,[1] Kevin V. Lemley.[2] *[1]Neuroanatomy, Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany; [2]Div of Nephrology, Children's Hospital Los Angeles, Los Angeles, CA.*

Background: The glomerular filtrate flow represents the highest extravascular fluid flow in the body. It consists of the outflow from glomerular capillaries, through the GBM and into Bowman's space. This latter step creates a problem: in contrast to its exit from capillaries, its entry tends to separate the podocytes from the GBM. This problem has become clear since we learned that podocytes are lost by detachment from the GBM as viable cells. This also disproved the idea that foot processes (FPs), like pericyte processes, counteract the pressure driven expansion of the GBM. Their interdigitating pattern provides the channels (filtration slits), through which the filtrate enters Bowman's space. They are bridged by the slit diaphragm (SD), a unique adherens junction. So far no satisfying hypothesis has been proposed that would explain the complexity of this structure.

Methods: Traditional view The pattern of FPs and filtration slits bridged by the SD is considered to restrict the passage of plasma proteins. It is a sensitive structure that is lost early in pathological situations leading to FP-effacement, consistently associated with the loss of permselective function. Supporting the high filtrate flow has never been considered as a function of the SD.

Results: New view The slits between FPs channel the flow of filtrate into Bowman's space. A filtrate flow of 25 nl/min (rat) creates a shear stress on the FPs as high as 8 Pa (Endlich and Endlich, Sem Nephrol 2012). Much lower values of shear stress (0.5 Pa) on podocytes in culture lead to their detachment. The SD, mechanically connecting opposite FPs, "utilizes" the shear stress on one FP to balance the shear stress on the opposite FP. This is supported by the observation that loss of the SD-connection between adjacent FPs represents the earliest failure starting detachment of a podocytes.

Conclusions: Consequence The elastic GBM continually adapts in area to capillary pressure fluctuations. In consequence, the FPs steadily change in area, shown by us in the isolated perfused rat kidney. This ensures that the flow rate per unit area of SD, the source of local shear stress, does not change with varying filtration pressure.

Angiotensin Receptor Blockers Prevent Kidney Injury by Preserving Podocytes Katherine Mikovna Scovner, Minglei Lu, Lance D. Dworkin, Rujun Gong. *Nephrology, Rhode Island Hospital, Brown Univ, Providence, RI.*

Background: Angiotensin receptor blockers (ARB) prevent chronic kidney disease. We assess blood pressure (BP) and proteinuria (UprotV) in spontaneously hypertensive rats (SHR) given variable doses of ARB therapy. To further assess glomerular injury, podocyte number is also evaluated.

Methods: SHR were untreated (C) or given 3 doses of candesartan daily (standard 5 mg/kg (T5), high 25 mg/kg (T25), and very high 75 mg/kg (T75)). Tail-cuff BP and 24-hour urine protein excretion were measured monthly for 14 months after which time the rats were sacrificed. Podocyte number was then measured by quantifying cells positive for WT-1 in each glomerulus based on immunohistochemistry staining.

Results: BP was very high in C but normal and not different in all treatment groups. UprotV was reduced in T5 and completely prevented in T25 and T75. Podocyte number was greatest in T75, fell with decreasing doses of ARB, and was least in C (means for T75: 18.2; T25: 15.0; T5: 12.9; C: 11.3. P value < 0.0001).

Conclusions: BPs are controlled in all doses of ARB therapy administered to SHR. However, high and very high doses of ARBs completely prevent UprotV. Increasing doses of ARB therapy are also associated with better preservation of podocytes. The reduced destruction of podocytes may be the reason for decreased UprotV seen at higher doses of ARB therapy. Loss of podocytes leads to uncovering of the basement membrane and increased protein filtration ultimately causing glomerulosclerosis. ARB therapy may thus be renal protective for its protection of the podocytes. BP is normal in all treated groups, but there is decreased UprotV and increased podocytes seen at the higher doses compared to standard dose of ARB therapy. Therefore, the mechanism of protection of podocytes and decreased UprotV may be independent of hemodynamic changes. It may instead be related to the therapy's suppression of inflammation as has previously been theorized.

PUB108

Sirtuin 3 Deficiency Mediates Mitochondrial Dysfunction of Podocytes in Diabetic Mice Zengchun Ye, Ming Li, Wenbo Zhao, Meijun Si, Cheng Wang, Tan-Qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Mitochondria play essential roles in many aspects of biology, and their dysfunction has been linked to podocytes injury in diabetic nephropathy. Sirtuin 3 (SIRT3) is a nicotinamide adenine dinucleotide (NAD+)-dependent deacetylase, which mediates the deacetylation of various metabolic and antioxidant enzymes, in turn controlling energy metabolism and mitochondrial function. This study is to investigate the roles of Sirt3 in mitochondrial dysfunction of podocytes in diabetic mice.

Methods: To assessthe expression of Sirt3 and mitochondrial complex activity, mitochondria were isolated from podocytes of16-week-old diabetic (*db/db*) and non-diabetic (*db/m*) mice. Moreover, diabetes was induced in Sirt3-knockout mice by streptozotocin (STZ) injection. The expression of Sirt3 was measured by western blotting. Mitochondrial complex I activity was detected by microplate assay kit purchased from Abcam.

Results: We found that Sirt3 was decreased significantly in podocytes of db/db mice when compared to db/m mice. Furthermore, Sirt3-deficient diabetic mice induced by STZ experienced more severe mitochondrial dysfunction in podocytes, including reduced complex I activity and decreased level of mitochondrial DNA. And *in vitro* studies, we also found that high glucose could reduce the expression of Sirt3 in podocytes and lead to decrease of mitochondrial complex I activity. Overexpression of Sirt3 in cultured podocytes can restore the activity of mitochondrial complex I.

Conclusions: Collectively, these data suggest that Sirt3 plays an important role in regulating the mitochondrial function in podocytes. Decrease of Sirt3 expression in podocytes lead to reducing mitochondrial complex I activity in diabetic mice. Our study uncovers a previously unrecognized role of Sirt3 in the pathogenesis of diabetic nephropathy, thus implicating Sirt3 as a new potential therapeutic target to treat diabetic nephropathy.

Fibrinogen A α Type Amyloid: A Rare Entity Ankita Tandon,[1] William F. Glass,[1] Ala Abudayyeh.[2] *[1]Renal Diseases and Hypertension, The Univ of Texas Medical School at Houston; [2]Div of Internal Medicine, Section of Nephrology, The Univ of Texas MD Anderson Cancer Center.*

Background: With the help of laser micro dissection and mass spectrometry, patients that were initially misdiagnosed with AL amyloid can now be found to have sporadic hereditary amyloidosis. We describe a case of a patient who was initially diagnosed with AL amyloid and later found to have fibrinogen A alpha type amyloid.

Methods: 77 year old man with atrial fibrillation was referred by his urologist for proteinuria. Lab work indicated IgG 921 mg/dL, IgM 43 mg/dL and IgA 475 mg/dL. Serum and urine protein electrophoresis was negative for an M protein. Kappa light chain was 26.1 mg/L, lambda light chain was 12.9 mg/L with a kappa to lambda light chain ratio of 1.72 (normal 0.26 - 1.65). Bone marrow biopsy showed normal trilineage hematopoiesis with no evidence of plasma cell dyscrasia. It was also negative for amyloid deposition by congo red staining. Fat pad biopsy was also negative for amyloid. Bone survey showed no evidence of lytic lesions. The patient continued to have 8 g of proteinuria during this time. Due to the unclear etiology of the amyloidosis, repeat renal biopsy was performed for laser microdissection and mass spectrometry to identify the amyloid protein. Mass spectrometry demonstrated fibrinogen A alpha type amyloid.

Conclusions: A high index of awareness is necessary for the diagnosis of hereditary sporadic amyloidosis. It can be misdiagnosed as AL amyloidosis, which carries significant implications for the patient, as he is now being treated for a condition he doesn't have, and for family members, who then remain unaware that a hereditary amyloidosis runs in their family.

PUB110

Ischemia Leads to Increases in Tight Junction Mobility following FRAP In Vivo Alexander Louis Kolb,[1] Josephine Axis,[3] Robert L. Bacallao,[2] Kurt Amsler.[3] *[1]Biology, Indiana Univ Purdue Univ Indianapolis, Indianapolis, IN; [2]Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [3]Biomedical Scienes, New York Inst of Technology College of Osteopathic Medicine, Old Westbury, NY.*

Background: After an injury to a cells tight junction it is hypothesized that these junctions become immobile and have a slow turnover rate contributing to leak and polarity changes leading to cell death. However, our in vivo data indicates ischemia increases the rate of tight junction turnover compared to pre ischemic tight junctions.

Methods: In vivo- Adenoviral GFP occludin was hydrodynamically delivered through the renal vein. Four days later the kidney was exposed and labeled tight junctions were selected for FRAP. FRAP was conducted on both pre and post ischemic tight junctions and on non-tight junction regions. In vitro-GFP occludin transduced MDCK cells were serum starved overnight. Cells were treated with 0 μM H_2O_2, 55 μM H_2O_2 or 110 μM H_2O_2 for 2 hours at 37° C before FRAP.The tight junction region or a non-tight junction region of the apical membrane was selected for FRAP.

Results: In vivo- The immobility of pre ischemic tight junctions is 93% (SD 9%). The immobility of ischemic tight junctions is 34% (SD 24%). The average half-life for recovery of ischemic tight junctions is 23.13 seconds (SD 1.07). The pre ischemic tight junctions show minimal recovery at 180 seconds post FRAP. In vitro: Control cells treated with 0 μM H_2O_2 have an immobility of 43% (SD 14%;) with a half-life of 68.2 seconds (SD 17.3 seconds). Cells treated with 55 μM H_2O_2 have an immobility of 32% (SD 16%) with a half-life of 88.5 seconds (SD 23.7 seconds). Cells treated with 110 μM H_2O_2 have an immobility of 37% (SD 15%) with a half-life of 82.3 seconds (SD 21.03 seconds). Results are statistically significant, p value <0.05.

Conclusions: In vitro tight junction turnover following FRAP occurs much faster in wild type cells then it does in injured cells. This data indicates that injury actually slows down tight junction turnover compared to control cells. However, these results are contradictory to the in vivo data that indicates ischemic injury increases tight junction turnover.

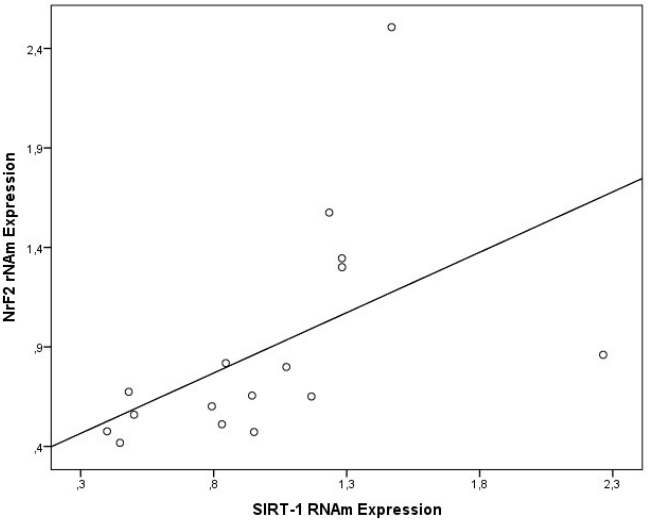
PUB111

Sirtuin-1 (Sirt-1) and Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2) Interplay in Nondialysis CKD Patients Denise Mafra,[1] Juliana Saldanha,[1] Felipe Rizzetto Santos,[2] Viviane Oliveira Leal,[4] Alex Sandro Duarte Albuquerque.[3] *[1]Federal Fluminense Univ; [2]Federal Hospital of Lagoa; [3]Federal Univ of Rio de Janeiro; [4]Univ of the State of Rio de Janeiro.*

Background: The transcription factor nuclear factor-erythroid 2-related factor 2 (Nrf2) is responsible for the expression of antioxidant response element-regulated genes and is recognized to be a major cellular defense mechanism. The high Nrf2 expression might be mediate by Sirt1 activation. Sirtuins (SIRTs), a family of NAD-dependent histone deacetylases, regulate DNA repair and recombination, chromosomal stability, and gene transcription. In particular, SIRT-1 activation is associated with longevity and attenuation of metabolic disorders. There is no report about association between SIRT-1 and Nrf2 gene expression in CKD patients. The aim of this study was to verify the possible association between SIRT-1 and nuclear factor erythroid 2-related factor 2 (Nrf2) expression in nondialysis CKD patients.

Methods: Sixteen nondialysis CKD patients (65 ± years old, 11 women, estimated glomerular filtration rate (eGFR) of 33.1 ± 13.7mL/min/1.73m^2, and body mass index (BMI) of 28.5 ± 7.5kg/m^2) were studied. The peripheral blood mononuclear cells were isolated and processed for the evaluation of expression of Nrf2 and SIRT-1 by quantitative real-time polymerase chain reaction.

Results: Nrf2 and SIRT-1 mRNA expression was 0.65 (1.01) and 0.91 ± 0.39, respectively. SIRT-1 mRNA expression was negatively correlated with age (r= -0.53; p = 0.03); however, it was positively correlated with Nrf2 mRNA expression (r= 0.77; p = <0.001).



The linear regression analysis showed that age was an independent predictor for SIRT-1 expression after adjustment of gender, BMI, and eGFR(B = -0.54, p = 0.04).

Conclusions: Gene expression of SIRT-1 and Nrf2 are directly associated and age may be negatively related to antioxidant protection in nondialysis CKD patients.

PUB112

Effects of a Medical Food (ErgoD2) on the Progression of Chronic Kidney Disease Marvin Stanley Hausman,[1] Michael Herman Hermelijn,[2] Alvaro Mercado,[3] Kyle H. Ambert,[4] Bruno Michel Jedynak,[5] Hector J. Rodriguez.[6] *[1]Entia Biosciences, Portland, OR; [2]Bonaire Medical Clinic, Kralendijk, Bonaire, Netherlands Antilles; [3]Savia Salud, Medellin, Colombia; [4]Intel Corporation, Life Sciences, Hillsboro, OR; [5]Portland State Univ, Portland, OR; [6]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Current standard of care overlooks the fact that Chronic Kidney Disease (CKD) is a multisystem functional disorder involving free radicals, inflammatory molecules, as well as catalytic metals, such as iron, that promote free radical production. This study proposes a novel non-pharmacologic approach to reno-protection through the use of a natural mushroom-based medical food, ErgoD2, which contains two potent antioxidants not produced by humans, L-Ergothioneine and vitamin D2. Two previously completed pilot studies in patients with type 1 and 2 diabetes and stage 5 CKD, treated with ErgoD2, revealed a significant decrease in plus 3 free radical iron.

Methods: 60 stage 3 and 4 CKD patients are under evaluation and following 2 stable values for eGFR, HbA1C and blood pressure receive two-500 mg capsules of ErgoD2 twice daily for 12 months. Patients are re-evaluated every 3 months with repeat physical and blood biomarker measurements standard in these disease stages, as well as Kidney Disease Quality of Life (KDQOL) questionnaires.

Results: To date, 24 patients are receiving ErgoD2 and 11 patients have completed three months of therapy. Three-month treatment results in the initial small group of patients showed eGFR improvement in 8 patients, stabilization in 1 patient and decline in 2 patients (see table below).

		eGFR	eGFR	%
Patient	Sex	Baseline	Treated	Change
1	F	54	66	22.2
2	F	15	15	0.0
3	F	17	19	11.8
4	F	45	47	4.4
5	M	50	46	-8.0
6	M	38	40	5.3
7	M	43	59	37.2
8	F	44	48	9.1
9	M	48	50	4.2
10	M	56	50	-10.7
11	F	40	45	12.5

Conclusions: The medical food, ErgoD2, represents a novel, non-pharmacologic approach to reno-protection. Continuation of the current open clinical trial is warranted and further data will be presented.

PUB113

Treatment of Metabolic Acidosis in CKD Yields Better Overall Outcomes and at Lower Per Patient Cost when Done with Fruits and Vegetables Than $NaHCO_3$

Nimrit Goraya,[1,2] Jan Simoni,[3] Jessica Pruszynski,[4] Pin Xiang,[5] Donald E. Wesson.[1,2,6] *[1]Internal Medicine, Baylor Scott and White Healthcare, Temple, TX; [2]Texas A&M HSC College of Medicine, Temple, TX; [3]Surgery, Texas Tech Univ HSC College of Medicine, Lubbock, TX; [4]Biostatistics, Baylor Scott and White Healthcare, Temple, TX; [5]Pharmacy, Baylor Scott and White Health, Temple, TX; [6]Diabetes Health and Wellness Inst, Dallas, TX.*

Background: Both $NaHCO_3$ and base-producing fruits and vegetables (F+V) improve metabolic acidosis (MA) in CKD and provide kidney protection but whether they differ in overall outcomes and management costs is unknown.

Methods: We randomized 108 subjects with CKD stage 3 eGFR (30-59 ml/min/1.73 m^2) and MA with plasma TCO_2 >22 but <24 mM as follows: F+V (n=36) to reduce dietary potential renal acid load (PRAL) 50% in the patient but was given to all household members, oral $NaHCO_3$ (HCO_3, n=36) to reduce PRAL 50%, or no alkali (Usual Care n=36). All were treated with antihypertensive and cholesterol-lowering drugs and followed 5 years with twice-yearly assessments of deaths, myocardial infarction (MI), cerebrovascular accident (CVA), and management costs. We used retail F+V cost although they were given free of charge, pharmacy drug costs, and Diagnosis Related Group costs for hospitalizations.

Results: There were 3 deaths in Usual Care, 1 in HCO_3 (all from MIs), and none in F+V. There were 6 MIs in 5 patients in Usual Care, 2 MIs in 2 patients in HCO_3, none in F+V, and one CVA in Usual Care but none in HCO_3 or F+V. Five-year cost per household was higher for F+V ($385,809) than HCO_3 ($231,981) and Usual Care ($263,634) but 5-year per patient cost was lower in F+V ($198,124) than the remaining groups. Lower per patient costs for F+V than HCO_3 and Usual Care was due to offsetting lower costs for hospitalizations ($0 vs. $50,074 vs. $95,360) and management of hypertension ($79,760 vs. $155,372 vs. $152,305) and serum cholesterol ($8,477 vs. $16,447 vs. $16,169).

Conclusions: Treating metabolic acidosis in this CKD population with F+V yielded fewer deaths, fewer cardiovascular events, and lower overall per patient management costs compared to HCO_3 and Usual Care over 5 years.

PUB114

An Open-Label Pilot Study of New Spherical Carbon Adsorbent Renamezin: Efficacy in Reducing Indoxyl Sulfate in Chronic Kidney Disease

Seung Kyu Kim,[1] Seok-Hyung Kim,[1] Hoon Young Choi,[1] Sang-Ho Lee,[2] So-Young Lee,[3] Dong Ho Yang,[3] Joo-Hark Yi,[4] Sang-Woong Han,[4] Young-Il Jo,[5] Hyeong Cheon Park.[1] *[1]Gangnam Severance Hospital, Yonsei Univ College of Medicine, Republic of Korea; [2]College of Medicine, Kyunghee Univ, Republic of Korea; [3]CHA Bundang Medical Center, CHA Univ, Republic of Korea; [4]Hanyang Univ Guri Hospital, Republic of Korea; [5]Konkuk Univ Hospital, Republic of Korea.*

Background: Reduced renal function in chronic kidney disease(CKD) causes systemic accumulation of indoxyl sulfate (IS), which has been shown to promote CKD progression. Renamezin® (Daewon Pharmaceutical Co., Korea) is a newly developed oral spherical carbon adsorbent with modified micropores that has high specificity for adsorbing indoles in the gastrointestinal (GI) tract. Aim of the study was to investigate whether oral administration of Renamezin® would reduce serum IS levels in CKD patients.

Methods: A total of 35 stable pre-dialysis CKD patients [mean age: 62 years, 82.9% male, serum creatinine (SCr) 1.5 ~ 5.0 mg/dL] were enrolled in this open-label pilot study. Renamezin® (7 capsules, t.i.d., 6 grams/day) was administered for 4 weeks. Serum IS as well as other parameters were measured at baseline and after 4 weeks. Wilcoxon Rank test was used to assess differences in IS before and after Renamezin® treatment.

Results: The mean SCr and estimated glomerular filtration rate (eGFR) was 2.58±0.98 mg/dL and 29.5±12.8 ml/min per 1.73 m^2, respectively. Serum IS negatively correlated with renal function(r=-0.478, p=0.003). Four weeks of Renamezin® treatment significantly reduced serum IS from baseline of 0.369±0.243 mg/dL to 0.322 ± 0.303 mg/dL (mean reduction of 14.6%, p=0.02) that was independent of baseline renal function. During the 4-week treatment period, Renamezin® did not adversely affect other renal parameters (SCr and eGFR) and was well tolerated (mean drug compliance: 92.1%). No severe side effects were reported except for GI symptoms (vomiting and diarrhea) in 4 patients (11.6%) and skin rashes in 1 patient (2.9%).

Conclusions: Our results suggest that newly developed carbon adsorbent Renamezin® significantly reduces serum indoxyl sulfate levels in moderate to severe pre-dialysis CKD patients.

Safety, Tolerability and Pharmacokinetics of KBP-5074 in Patients with Mild-to-Moderate Chronic Kidney Disease: A Randomized, Open-Label Study

Bin Zhang,[1] Paul W. Crawford,[2] William B. Smith,[3] Kenneth Lasseter,[4] Fred Yang,[1] Xiaojuan Tan,[1] Peter Pelka.[1] *[1]KBP Biosciences USA Inc; [2]Research by Design Inc.; [3]New Orleans Center for Clinical Research; [4]Clinical Pharmacology of Miami, Inc.*

Background: Chronic kidney disease (CKD) is one of the leading causes of morbidity and mortality in the United States. Albuminuria and hypertension are two key risk factors for the development of end-stage renal disease. Effective therapy to combat these risk factors in CKD patients remains elusive. KBP-5074 is a novel, non-steroidal, highly selective mineralocorticoid receptor antagonist being developed for CKD.

Methods: In this randomized, open-label study, 14 patients with mild-to-moderate CKD (estimated glomerular filtration rate [eGFR] ≥30 and ≤89 mL/min/1.73 m^2, using the modification of diet in renal disease formula), albuminuria (urine albumin to creatinine ratio [UACR] ≥30 mg/g and ≤3,000 mg/g), and normal serum potassium (≤4.8 mmol/L at baseline) were randomized to either KBP-5074 0.5 mg (n = 8) or 2.5 mg (n=6) once daily and treated for 8 weeks. Safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) measures were assessed throughout this study.

Results: The mean age of the participants was 64 years; 35.7% were male. Baseline eGFR, blood pressure, and UACR values were similar in the 2 arms. Dose-dependent PK measures were observed, which was similar to healthy adults who received the same dose of KBP-5074. Compared to baseline, UACR was reduced by 58.9% in the KBP-5074 0.5 mg group and by 50.7% in the 2.5 mg group by Week 8. PK/PD analysis showed a trend toward a decrease in both systolic and diastolic blood pressures. Adverse events related to KBP-5074 were mild and infrequent. 2 subjects in the 2.5 mg group developed hyperkalemia (serum potassium >5.5 mmol/L); 1 subject in the 0.5 mg group with baseline serum potassium 5.0 mmol/L also developed hyperkalemia on study. These three subjects continued in the study. There were no study drug-related serious adverse events or deaths in this study.

Conclusions: This study demonstrated that KBP-5074 at a dose of 0.5 mg QD was safe and showed potential to reduce UACR and blood pressure in patients with mild-to-moderate CKD.

PUB117

Influence of Depression, Anxiety and Stress on Dialysis Decision-Making

Cicero Italo Leite Bezerra, Bruno C. Silva, Glauce Rejane dos Santos, Keisy Lima Rizzetto, Rosilene M. Elias. *Nephrology, Univ de Sao Paulo, Sao Paulo, SP, Brazil.*

Background: The choice of renal replacement therapy (RRT) modality and the sharing-decision making is a situation that often involves anxiety and stress, which could influence on the modality choice. Depression is another factor highly prevalent among these patients that could also influence on this decision. However, only few studies have addressed the impact of these factors on the modality choice, which was the main objective of this current prospective study.

Methods: Patients were approached while attending the structured Pre-Dialysis Multidisciplinary Education Programme, with information session to help on the RRT modality decision-making. Scales of anxiety, depression and stress (Hospital anxiety and depression scale and perceived stress scale, respectively) were applied after the mentioned session and repeated later on when patients were already on peritoneal dialysis-PD or hemodialysis-HD. Demographic, clinical, biochemical and personal characteristics were also assessed.

Results: Sixty-three patients were enrolled (age 53 ± 15 years, 56% men, 59% Caucasian, 56% married, and 41% diabetic). Demographic, clinical and biochemical characteristics did not distinguish patients who choose PD or HD as their initial RRT modality. Women presented higher scores of depression (p=0.039), stress (p=0.050) and had a tendency toward to present higher scores of anxiety (p=0.064) than men. Scores of depression, anxiety and stress did not have any impact on the RRT modality. A small sample of the study population who already initiated dialysis was re-evaluated showing significant reduction of anxiety, depression and stress scores (p=0.004, p=0.012 and p=0.0016, respectively). Family support was the main determinant of PD choice.

Conclusions: Although women have presented high scores of depression, anxiety and stress, none of these factors have affected the decision-making process between PD and HD. Despite high levels of depression, anxiety and stress while on the process of RRT decision-making, these factors may be alleviated after the dialysis initiation.

PUB118

Mild Cognitive Impairment Is Highly Prevalent and Strongly Associated with Physical Function in Elderly Patients with Pre-Dialysis Chronic Kidney Disease Yuhei Otobe,[1] Koji Hiraki,[1] Chiharu Hotta,[1] Yasuhiro Taki,[2] Naohiko Imai,[2] Tsutomu Sakurada,[2] Yugo Shibagaki.[2] *[1]Dept of Rehabilitation Medicine, St. Marianna Univ School of Medicine Hospital, Kawasaki, Japan; [2]Div of Nephrology and Hypertension, Dept of Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan.*

Background: Chronic kidney disease (CKD) has been reported to be a risk factor for cognitive decline. However, the prevalence of mild cognitive impairment (MCI), a prodrome of dementia, and its risk factors remain to be determined. The purpose of this study is to clarify the prevalence and to elucidate the risk factors of MCI in elderly patients with pre-dialysis CKD.

Methods: The subjects were 122 elderly (≥ 65 years old) pre-dialysis CKD patients of our outpatient nephrology clinic (average age 77.7 years old with 96 males). Mini Mental State Examination (MMSE) and Japanese version of Montreal Cognitive Assessment (MoCA-J) was used as cognitive function tests. Patients with MMSE>23 and MoCA-J≥26 were diagnosed as normal, those with MMSE>23 and MoCA-J<26 were diagnosed as having MCI, and those with MMSE≤23 diagnosed as having dementia. Grip strength, knee extension strength, 4m comfortable walking speed, one leg stance time, the skeletal muscle index were measured as physical function. We investigated the presence of diabetes, history of smoking/drinking, and blood biochemical test as patients' characteristics.

Results: 47 cases were identified as normal, 71 cases MCI, and 4 cases dementia, thus, 58.2 % of the elderly pre-dialysis CKD patients had MCI, and this prevalence was much higher than the prevalence of 18.8 % in community dwelling elderly Japanese. Characteristics of Normal group and MCI group were compared. Age was 74.9 vs 78.9 years ($p < 0.01$), hemoglobin was 12.4 vs 11.6 g/dL ($p < 0.01$), walking speed was 124.5 vs 103.6 cm/sec ($p < 0.01$), one leg stance time was 28.9 vs 12.7 sec ($p = 0.01$). By logistic regression analysis, age and walking speed were significantly associated with MCI ($p < 0.01$).

Conclusions: Mild cognitive impairment is highly prevalent (58.2%) and strongly associated with physical function in elderly patients with pre-dialysis chronic kidney disease.

PUB119

Disease Awareness Significantly Impacts the Quality of Life in CKD Patients Colin A. Hinkamp,[1] Emma Rebecca Segal,[1] Xuerong Wen,[1] Ashutosh M. Shukla.[2,1] *[1]Medicine, Univ of Florida, Gainesville, FL; [2]NF/SG VHS, Gainesville, FL.*

Background: Despite established value in the management of many chronic conditions, there is limited data correlating disease awareness to quality of life (QoL) in CKD patients.

Methods: We conducted a cross sectional study of patients attending a university nephrology practice with the aim of assessing the effect of demographic, socioeconomic, literacy and disease awareness states on QoL. All consenting subjects were administered a set of surveys aimed to gather demographics, Charlson Comorbidity Index (CCI), REALM-SF, KDQoL-36, and a novel CKD disease awareness questionnaire.

Results: Initial findings of an ongoing study with the first 108 enrollees is presented. We found high health literacy and mildly elevated comorbidity indices across the spectrum of CKD. Despite these, average CKD patients displayed poor CKD awareness (19.6 ± 9.2, out of 45) and average physical (39.6 ± 11.7) and mental (49.5 ± 10.4) QoL. Univariate analysis showed that physical QoL had the strongest positive correlation with CKD awareness ($R=0.27$; $p=0.009$) and strongest negative correlation with comorbidities indices ($R=-0.45$; $p<0.001$). Multivariate analysis, adjusting for age, gender, health literacy, economic affluence and renal function, showed that amongst the factors affecting mental QoL, male gender, African American race, and economic affluence had the strongest positive impact. Multiple comorbidities and poor CKD awareness had the strongest negative impact on physical QoL. Duration of renal care was found to be insignificant after adjusting for other risk factors.

	Significant Risk Factors	Estimates ± SE	p
KDQoL Physical Score	CKD Awareness	0.36 ± 0.12	0.003
	Length of Renal Care	0.27 ± 0.17	0.12
	CCI score	-2.43 ± 0.44	<0.0001
	R^2	0.32	
KDQoL Mental Score	Household Income	6.01 ± 2.27	0.01
	Race	7.61 ± 2.66	0.005
	Gender	5.27 ± 2.33	0.03
	R^2	0.17	

Conclusions: Our results show that disease awareness and not just the nephrology care is a significant modifiable risk-factor affecting CKD patients' QoL. It provides rationale for elucidating the viability of improving outcomes by adding an educational component to standard treatment.

PUB120

Quality of Life of Non-Dialysis Chronic Kidney Disease Patients: Comparative Reports of Nephrologists and Patients According to the First Results of MAEVA Gilbert Deray,[1] Jean-Philippe Bertocchio,[2] Myriam Rouchon Isnard,[3] Philippe Zaoui,[4] Thierry Baranger.[5] *[1]SITEGPR Nephrology, La Pitié-Salpêtrière Hospital, Paris, France; [2]Renal and Metabolic Diseases Unit, European Georges-Pompidou Hospital - Paris Descartes Univ, Paris, France; [3]Dialysis Unit, AURA Auvergne, Chamalières, France; [4]Nephrology, Grenoble Univ Hospital, La Tronche, France; [5]Nephrology-Dialysis, Bordeaux Nord Aquitaine Polyclinic, Bordeaux, France.*

Background: The quality of life (QoL) of non-dialysis chronic kidney disease (CKD) patients is impaired, but very little has been specifically published. The French study MAEVA aimed to evaluate this clinical aspect and to compare the opinion of nephrologists and patients on the comprehensive management of CKD patients in France.

Methods: A self-completion questionnaire was sent by mail to 1,282 French nephrologists. A "mirror" self-completion questionnaire was given to CKD patients (stages 3, 4 and 5) by nephrologists. Data were collected prospectively and anonymously.

Results: Between February and August 2015, 261 nephrologists and 172 patients completed the questionnaires. Responding patients (22%) stated their renal condition had a major impact on QoL. CKD affected energy (77%), physical capacity (75%), mood (64%), sleep (55%), sexuality (45%), and appetite (33%). However, nephrologists did not systematically investigate QoL impairment: only 51% of respondents questioned their patients on QoL, and approximately one third probed them on sleep disorders, depression or anxiety (39%, 38% and 30%, respectively). Sexuality was rarely discussed by nephrologists, with only 16% stating that they investigated possible sexual disorders. This figure was confirmed by patients, of whom 17% only mentioned that they have been questioned on this issue during follow-up. However, 59% of patients felt comfortable with discussing such topic with their nephrologist.

Conclusions: Regarding QoL, communication between non-dialysis CKD patients and nephrologists could be improved by the use of tools, such as an adapted questionnaire completed by patients before visit.

Magnetic Resonance Spectroscopy and Psychological Status in CKD Stage 4-5 Patients Chun Zhang, Ying Chen, Shan Chen, Cheng Wan, Hua Su. *Nephrology, Union Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: The study aimed to explore magnetic resonance spectroscopy (MRS) and psychological status in CKD stage 4-5 patients.

Methods: This study enrolled 35 patients with stage 4-5 CKD, including 10 pre-dialysis patients, 15 hemodialysis (HD) patients and 10 peritoneal dialysis (PD) patients. Dialysis duration, dialysis sufficiency, hemoglobin (Hb), and parathyroid (PTH) were recorded as baseline data. All the patients accepted psychological assessment by SDS, SAS, SCL-90 and MRS for bilateral amygdalae, hippocampi and anterior cingulate cortices (ACC).

Results: The positive rates of SDS and SAS were 20%, while that of SCL-90 was 34.29% in CKD stage 4-5 patients. SDS score, F1 somatization, F7 terror were negatively correlated with N-acetyl Aspartate (NAA)/Creatinine (Cr) in right amygdala. F9 psychosis was negatively correlated with Myo-inositol (MI)/Cr in left hippocampus, and Glutamate complex (Glx)/Cr in ACC. Compared to HD patients, pre-dialysis patients got higher scores in SCL-90, F2 force, F3 relationship, F5 anxiety, F8 paranoid, and F9 psychosis. In addition, the pre-dialysis patients graded higher in F9 psychosis than the PD patients. The HD patients had a lower NAA/Cr in left amygdale and a higher Glx/Cr in ACC than pre-dialysis patients. Among all patients, the HD patients had the highest Choline-containing compounds (Cho)/Cr and MI/Cr in ACC. Moreover, the HD patients' Cho/Cr in left amygdala was higher than PD patients'. PTH was negatively correlated with F9 psychosis, while dialysis duration, Cho/Cr, MI/Cr, and Glx/Cr in left amygdala were positively correlated. Dcr4/Pcr was negatively associated with MI/Cr in left amygdala. Hemoglobin level showed a negative correlation with NAA/Cr in left amygdala and a positive correlation with MI/Cr in left hippocampus.

Conclusions: CKD stage 4-5 patients are inclined to suffer from many psychological problems, especially the pre-dialysis patients. HD patients present the most obvious alterations in MRS. PTH might influence F9 psychosis, while dialysis duration, dialysis sufficiency, and Hb level have certain effects on MRS.

Kidney Disease in Type 2 Diabetes Is an Independent Risk Factor for Peripheral Artery Disease: A Cross-Sectional Analysis Niraj Desai, Nivetha Subramanian, Krishna H. Patel, Jennifer W. Xu, Michael S. Simonson. *Nephrology, Case Western Reserve Univ School of Medicine, Cleveland, OH.*

Background: Diabetic kidney disease (DKD) affects more than 7 million adults in the United States, is the most common cause of end stage renal disease, and doubles the risk of coronary artery disease and death. Patients with DKD also suffer from disproportionately high rates of critical limb ischemia and amputation. We asked whether DKD is a risk factor for peripheral artery disease (PAD).

Methods: We conducted a cross-sectional analysis of patients with type 2 diabetes and glomerular filtration rate (eGFR) ranging from 7-146 ml/min/1.73 m2. PAD was diagnosed

by standardized physical examination and history. eGFR was calculated from the serum creatinine-based MDRD equation. Potential confounders of the relationship between eGFR and PAD were assessed by multivariable logistic regression.

Results: Of 96 participants (median age 58 (range 30 - 84); median eGFR 72.4 ± 33.0 ml/min/1.73 m2), 43 % had PAD. Duration of diabetes (7.0 ± 7.2 years) and HbA1c (7.7 ± 1.8 %) were similar in patients with and without PAD (P = 0.901 and 0.196, respectively). eGFR < 60 ml/min/1.73 m2 was associated with increased risk of PAD (odds ratio ± SE) 2.7 ± 1.3, P = 0.034. Association of low eGFR with PAD was stronger (3.7 ± 2.1, P = 0.023) after adjustment for PAD risk factors in the general population: systolic blood pressure, smoking, duration of diabetes and HbA1c. PAD was not associated with albuminuria defined as albumin/creatinine ratio (1.0 ± 0.001, P = 0.425).

Conclusions: Our results suggest that kidney disease in type 2 diabetics is a risk factor for PAD. For timely diagnosis and risk factor modification, patients with DKD should be screened for PAD.

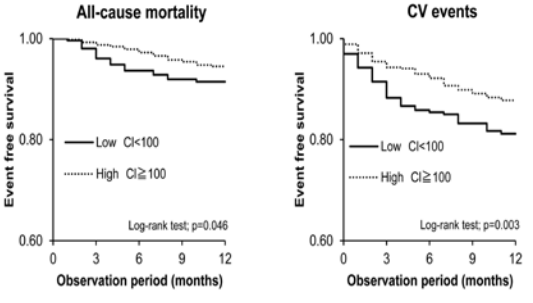
PUB123

Serum Chloride Levels Predict Cardiovascular Morbidity and Mortality in Patients on Incident Dialysis Yosuke Saka,[1] Tomohiko Naruse,[1] Daijo Inaguma.[2] *[1]Internal Medicine, Kasugai Municipal Hospital, Kasugai, Aichi, Japan; [2]Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan.*

Background: Patients with advanced chronic kidney disease (CKD) have an electrolyte imbalance due to impaired kidney function. Several studies have associated increased morbidity and mortality with abnormalities in serum sodium, potassium and phosphate among patients with CKD. However, whether serum chloride levels are associated with morbidity and mortality in such patients, especially those on incident dialysis, remains obscure. We investigated whether serum chloride levels can predict morbidity and mortality after starting dialysis in the AICOPP study (Aichi Cohort Study of Prognosis in Patients Newly Initiated into Dialysis).

Methods: Among 1,525 patients who started dialysis between October 2011 and September 2013 and were enrolled in the retrospective, multicenter cohort AICOPP study, 278 were excluded from analysis due to incomplete data. We followed up the remaining participants for 12 months after enrollment. The primary and secondary endpoints were all-cause mortality and cardiovascular (CV) events, respectively. Serum chloride levels were categorized as low or high (Cl < 100 and ≥ 100 mEq/L, respectively) and data were analyzed using the Kaplan-Meier method and Cox hazards models.

Results: The mean serum chloride level was 103.9 mEq/L. Approximately 20% of the patients had low serum chloride levels that were significantly associated with all-cause mortality and CV events.



Multivariate Cox hazards models selected low serum chloride as an independent risk factor for CV events (adjusted hazard ratio [HR], 1.68; 95% confidence interval [CI], 1.08 – 2.59, p < 0.05).

Conclusions: Serum chloride levels might serve as a practical biomarker to predict morbidity and mortality, especially CV events, in patients on incident dialysis.

PUB124

Effect of Methoxy Polyethylene Glycol – Epoetin β (Mircera) on Plasma Levels of sE-selectin, sICAM-1, sVCAM-1, NT-proBNP and Left Ventricle Structure and Function in Patients with Chronic Kidney Disease Jacek Rysz,[1] Ewa Majewska,[2] Beata Franczyk,[1] Zbigniew Baj,[2] Piotr Bartnicki.[1] *[1]Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Lodz, Poland; [2]Dept of Pathophysiology and Immunology, Medical Univ of Lodz, Lodz, Poland.*

Background: Anemia and endothelial dysfunction may be involved in pathogenesis of atherosclerosis, disadvantageous changes in left ventricle structure and function and cardiovascular complications in CKD patients. In this study we aimed to determine effect of Mircera on chosen plasma and echocardiographic parameters in CKD.

Methods: 28 patients with stage IV of CKD and anemia, treated with Mircera, were enrolled to the study. Control group included 15 volunteers. Plasma levels of sE-selectin, sICAM-1, sVCAM-1 were measured with ELISA kits. Echocardiographic examination was performed (EF – ejection fraction, LVM – left ventricle mass, LVESd – left ventricle end systolic diameter, LVEDd - left ventricle end diastolic diameter).

Results:

	CKD before treatment	CKD after treatment	Control group
Hb [g/dl]	9.5 (9.0 – 10.1)*	11.5 (11.0 – 12.1)* •	14.5 (13.3 – 14.9)
NT-proBNP [pg/ml]	355.6 (282.3 - 432.7) *	302 (182.1 – 401.3)* •	75 (49 – 101)
sE-selectin [ng/ml]	33.1 (25.6 – 36.4) *	29.3 (24.8 – 33.9)* •	16.1 (11.9 – 22.2)
sICAM-1 [ng/ml]	460.1 (352 – 519.2)*	409.1 (371.3 – 501)* •	245 (232 – 281)
sVCAM-1 [ng/ml]	2640 (1790 – 4052)*	2340 (1450 – 2945)* •	890 (680 – 1340)
EF [%]	34 (29 – 40)*	41 (36 – 49)* •	58 (50 – 64)
LVM [g]	286.4 (218.3 – 359)*	278.1 (186 – 352.1)*	208.2 (165 – 249)
LVESd [mm]	41.2 (35.1 – 47.4)*	39.2 (33.1 – 45.2) * •	36.1 (30.2 – 40.9)
LVEDd [mm]	49.1 (41.3 – 54.9)*	46.9 (40.1 – 51.9)* •	40.6 (32.9 – 47)

*p < 0.05 to control group, •p < 0.05 to CKD before treatment.

Conclusions: Evaluated plasma and echocardiographic parameters were significantly increased but EF was significantly decreased in CKD patients compared to controls. Anemia treatment with Mircera may diminish endothelial dysfunction as well as improve left ventricle structure and function in these patients.

PUB125

The Association between Insulin Resistance and Atrial Fibrillation: A Cross-Sectional Analysis from the Systolic Blood Pressure Intervention Trial Monique E. Cho,[1] Timothy Craven,[2] Alfred K. Cheung,[1] Stephen P. Glasser,[3] Mahboob Rahman,[4] Elsayed Z. Soliman,[2] R. Stafford,[5] Karen C. Johnson,[6] Jeffrey T. Bates,[7] Anna Marie Burgner,[8] Addison A. Taylor,[7] Leonardo Tamariz,[9] Rocky Tang,[10] Srini Beddhu.[1] *[1]Univ of Utah; [2]Wake Forest School of Medicine; [3]Univ of Alabama at Birmingham; [4]Case Western Reserve Univ; [5]Stanford Prevention Research Center; [6]Univ of Tennessee Health Science Center; [7]Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine; [8]Vanderbilt Univ; [9]Univ of Miami; [10]Columbia Univ.*

Background: Observational studies conducted in the general population have suggested that metabolic syndrome (MetS), which is closely linked to insulin resistance (IR), is associated with atrial fibrillation (AF). It is less clear, however, if IR is associated with AF in an older population with greater cardiovascular (CV) risk, including chronic kidney disease (CKD). We thus investigated the association between MetS and IR with AF in the participants of the Systolic Blood Pressure Intervention Trial (SPRINT).

Methods: We limited our analyses to 8263 SPRINT participants with all available covariates for analyses. We defined IR as fasting glucose ≥100 mg/dL and increased serum triglycerides-to-HDL-cholesterol ratio levels ≥ 3.0 for whites and Hispanics and ≥2.0 for non-Hispanic blacks. MetS was defined based on the Modified Third National Cholesterol Education Program. We used body mass index >30 kg/m^2 as a substitute for waist circumference, which was not collected. CKD was defined as MDRD eGFR <60 ml/min/1.73m^2. Multivariable logistic regression models were used to examine the strength of association between the risk factors and AF.

Results: The baseline prevalence rates for IR and MetS were 60% and 55%, respectively, while 8.2% of the participants had AF. In multivariate regression analyses, only age, white race, history of CV disease, decreased serum triglyceride level, and albuminuria remained significantly associated with AF risk. AF was not associated with IR or presence of MetS in CKD or non-CKD subgroups.

Conclusions: In contrast to the general population, IR and MetS were not associated with AF in the older population with increased CV risk studied in SPRINT.

PUB126

Serum Free Light Chains Predict All-Cause Mortality in Chronic Kidney Disease: A Systematic Seview and Meta-Analysis Simon D.S. Fraser,[1] Anthony Fenton,[2] Scott Harris,[1] Anne Burmeister,[5] Adam Shardlow,[4] Sophie Liabeuf,[6] Ziad Massy,[7] Martin J. Landray,[8] Jonathan R. Emberson,[8] Philip A. Kalra,[3] Paul Cockwell,[2] Maarten W. Taal.[4] *[1]Southampton Univ; [2]Univ Hospitals Birmingham; [3]Manchester Univ; [4]Nottingham Univ; [5]Binding Site; [6]Amiens Univ Hospital; [7]Ambroise Paré Univ Hospital & Inserm; [8]Oxford Univ.*

Background: Serum immunoglobulin (Ig) free light chain (FLC) assays are used in identifying and monitoring clonal FLC (kappa (κ) or lambda (λ) in paraproteinaemia. In the absence of a paraprotein, high serum levels of polyclonal combined (c)FLC (κ and λ) have been associated with increased mortality in CKD. The study aimed to synthesise current evidence for cFLC as a mortality risk predictor in CKD.

Methods: Four databases (Medline, Embase, CINAHL, PubMed) were searched using terms for CKD and Ig light chains. Inclusion criteria: quantitative CKD studies, FLCs measured, mortality as outcome. Excluded: paraproteinaemia and dialysis associated terms. Two reviewers independently assessed study inclusion and quality. Individual patient data obtained from all included studies were combined for common variables and Cox regression models used to explore the relationship between cFLC>43.3mg/L (95th percentile normal range) and all-cause mortality using fixed effect for study ID.

Results: 5 cohort studies were included (combined n=3688). All had used the Freelite™ assay. Studies were moderate to high quality. Mean age was 67 (SD 14) years, 1842 (50%) were male, 810 (22%) had diabetes and 1229 (33%) had cardiovascular disease (CVD).

Mean eGFR was 41.8 ml/min/1.73m2 (SD 17.4). On multivariable analysis adjusted for age, sex, diabetes, CVD, MDRDeGFR, albumin, calcium and renin angiotensin system inhibitors, elevated serum cFLC was independently associated with all-cause mortality.

	HR	95% CI	p
Age(years)	1.06	1.05-1.06	<0.001
Male(y/n)	1.28	1.10-1.51	0.002
Diabetes(y/n)	1.31	1.12-1.53	0.001
CVD(y/n)	1.59	1.36-1.85	<0.001
eGFR (ml/min/1.73m2)	0.98	0.97-0.98	<0.001
Albumin (g/L)	0.95	0.94-0.97	<0.001

Conclusions: In this first meta-analysis of patient-level data cFLCs predicted all-cause mortality across the full spectrum of CKD and may be useful for risk-stratification.

PUB127

HDL and LDL Cholesterol Subfractions in Chronic Kidney Disease Patients

Jacek Rysz,[1] Anna Gluba-Brzózka,[1,2] Beata Franczyk,[1] Magdalena Górzynska-Rysz.[1,2] *[1]Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Lodz, Poland; [2]Healthy Aging Research Center, Medical Univ of Lodz, Lodz, Poland.*

Background: Chronic kidney disease (CKD) is a worldwide public health problem which is associated with increased cardiovascular risk. Recent studies indicate that the level of individual LDL and HDL subfractions may be more important that their total concentration. Moreover, some points that in pathological conditions HDL may lose its protective functions.

Methods: The study group consisted of a total of 115 patients with CKD (25 with stage II, 25 - stage III, 25 – stage IV, 40 – stage V), and control group consisted of 25 healthy volunteers. Complete medical history was obtained from all subjects. Subfractions of LDL (7) and HDL (10) cholesterol were analysed with the use of Lipoprint™ system (Quantimetrix Corp.) according to the manufacturer's instructions.

Results: Differences in nearly all LDL and HDL subfractions distribution were observed between CKD stages and between CKD patients and controls. HDL1-HDL4 and large HDL subfractions were significantly more abundant in patients with end-stage renal disease, while their amount was lower in controls (HDL1 - P<0.0001; HDL2- p=0.013; HDL3 – p=0.003; HDL4 – p=0.004). The highest concentration of HDL7- HDL10 and small HDL subfractions were found in control group, and it gradually decreased along with worsening kidney function (HDL7 – P=0.001; HDL8- P<0.0001; HDL9 – P<0.0001; HDL10 – P<0.0001). Moreover, the concentration of IDL-C, IDL-B and IDL-A were higher in patients with CKD V, while LDL2 and LDL3 concentration were higher in control group (IDL-C – P=0.010; IDL-B- p=0.001; IDL-A – p<0.0001; LDL2 – P<0.0001; LDL3 – P=0.007).

Conclusions: This study indicated higher prevalence of large HDL subfractions in CKD V patients. Predomination of larger HDL particles in patients with coronary artery disease was observed in other studies. Despite the fact that role of individual HDL subfractions remains unknown, it can be hypothesized that the abundance of large HDL or decreased concentration of small HDLs may participate in increased cardiovascular risk observed in CKD.

PUB128

The Association between Creatinine versus Cystatin C-Based eGFR and Cardiovascular Risk Using PDAY Risk Score in Children with Chronic Kidney Disease

Sheena Sharma, Michelle Denburg, Susan L. Furth. *Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Children with CKD have a high prevalence of cardiovascular disease (CVD) risk factors. Among adults with CKD, cystatin C-based eGFR demonstrate a stronger predictive value for cardiovascular events compared to creatinine-based eGFR. The PDAY (Pathobiological Determinants of Atherosclerosis in Youth) risk score is a validated tool used to estimate the probability of atherosclerotic lesions within coronary arteries in adults. The objective was to assess the association between cystatin C- vs creatinine-based eGFR and cardiovascular risk using modified PDAY risk score as a proxy for CVD in children and young adults.

Methods: We used cross-sectional data from 71 CKD subjects (15.5 yrs, (13, 17), eGFR creatinine 50mL/min/1.73m^2 (27, 74), eGFR cystatin C 53mL/min/1.73m^2 (32, 74)), and 33 controls (15.1 yrs (13, 17), eGFR creatinine 112mL/min/1.73m^2 (85, 128), eGFR cystatin C 114mL/min/1.73m^2 (87, 135)). eGFR was calculated using age-appropriate creatinine and cystatin C-based formulas. PDAY risk scores (include sex, age, serum lipoprotein, obesity; modified by smoking, hypertension, hyperglycemia) were used to determine probability of coronary artery atherosclerosis. Spearman's correlation, chi-square, and ordinal logistic regression were used.

Results: PDAY scores ranged from -2 to 16 (higher score equals greater risk). The correlation between eGFR creatinine and eGFR cystatin C with coronary PDAY scores were -0.26 (p<0.007) and -0.27 (p<0.005), respectively. Ordinal logistic regression showed similar association between higher eGFR creatinine and eGFR cystatin C and lower PDAY scores. Chi-square between CKD severity (stage 1-4) and PDAY categories (low 0,-1; moderate 1-5; high risk ≥5) was not significant for eGFR creatinine (p=0.09) but was significant for eGFR cystatin C (p=0.03).

Conclusions: The correlation between eGFR by cystatin C or creatinine with PDAY risk score was similar. A slightly stronger association between CKD stage and PDAY score was seen with eGFR cystatin C when assessed by chi-square. Further studies should explore the association between cystatin C and cardiovascular risk in children with CKD.

PUB129

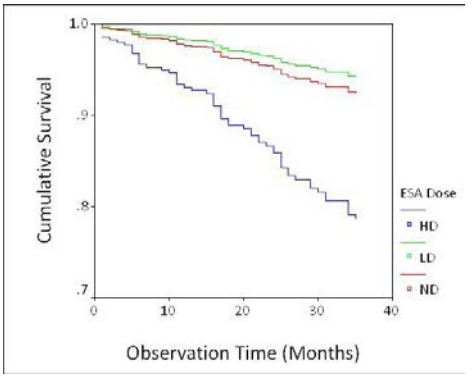
Higher-Dose Erythropoiesis-Stimulating Agents (ESA) to Maintain Higher Target Hemoglobin Is Associated with Higher Risk of Mortality and Cardiovascular Event Risk in Patients with Chronic Kidney Disease (CKD): The CKD-ROUTE Study

Seiko Ishikawa,[1] Soichiro Iimori,[2] Shotaro Naito,[2] Eisei Sohara,[2] Tomokazu Okado,[2] Sei Sasaki,[2] Tatemitsu Rai,[2] Shinichi Uchida.[2] *[1]Nephrology, Tokyo Kyosai Hospital, Japan; [2]Nephrology, Tokyo Medical and Dental Univ, Japan.*

Background: Recent studies showed that the use of ESA for treatment of renal anemia to achieve high hemoglobin (Hb) levels was associated with an increased risk of adverse events in CKD patients. We evaluated the relationships among ESA doses, mortality, and risk of CV events.

Methods: This prospective cohort study was comprised of 776 pre-dialysis patients with CKD G2-G5 enrolled from 2010 to 2011. Patients were followed up until ESRD, death, transfer, or the end of 3-years follow-up. The outcome was a composite of all-cause mortality or CV events. We categorized patients into 3 groups according to ESA doses : no dose group (ND) ; lower dose group (LD) (<3111 IU/month) ; higher dose group(HD) (≥3111 IU/month). Three groups were compared using the log-rank test and the adjusted hazard ratio (aHR) was estimated using multivariate cox hazards model.

Results: During a median follow-up of 36 months, 64 CV events occurred, 40 patients died, and 97 patients reached the outcome. HD was associated with greater mortality and risk of CV events than both LD and ND (HD vs LD: aHR 2.05 [95% confidence interval (CI) 1.04-4.06], HD vs ND: aHR 1.94 [95%CI 1.00-3.75]). When patients were further stratified according to their achieved Hb levels, ESA dose did not affect the outcome in patients with Hb < 10 g/dl. However, in patients with Hb ≥ 10 g/dl, higher ESA dose increased mortality and CV event risk (HD vs LD: aHR4.01 [95%CI 1.28-12.6], HD vs ND: aHR 3.03 [95%CI 1.32-6.99]).



Conclusions: Use of higher-dose ESA to achieve higher target Hb levels in CKD patients was associated with greater risk of mortality and CV events.

PUB130

Undiagnosed and Uncontrolled Hypertension in Primary Care: The Role of Awareness of the Renal Risk

Marco Sartori,[1] Luca Valerio,[2] Silvia De Rosa,[1] Faeq Husain-Syed,[1] Stefano Cattin,[1] Mirella Zancato,[3] Claudio Ronco.[1] *[1]Nephrology, St. Bortolo Hospital, Italy; [2]Medicine, Univ of Amsterdam, Netherlands; [3]Pharmacy, Univ of Padua, Italy.*

Background: To assess the distribution and features of pts with undiagnosed and uncontrolled arterial hypertension(AHT)in the community setting,we have conducted a cross-sectional survey of the general population through community pharmacies in the North-Eastern area of Italy.In addition,we assessed awareness among pts of the role of AHT as a risk factor for chronic kidney disease(CKD).

Methods: The survey was carried out between Oct-2014 and Feb-2015.Participants were selected among the pts of 35 pharmacies.All participants were interviewed by using a structured questionnaire(18-items),and their blood pressure(BP)was measured.The survey included previous diagnosis of AHT,risk factors for CKD,and knowledge of AHT as risk factor for CKD.We identified factors associated with awareness of the renal risk associated with AHT.

Results: The sample included 2036 subjects aged ≥18 yrs(39.2% male;24% below age 45;31.4% older than 65;44.6% between age 45 and age 65).40.1% of subjects was in treatment for AHT;awareness of the renal risk associated with AHT was reported by 48.4% of the participants.Non-white ethnicity,smoking,higher BMI were all associated with lower awareness of the hypertensive renal risk.In contrast, diagnosis of AHT,family history of AHT,and family history of renal disease were all associated with higher awareness of the hypertensive renal risk,with family of history of renal disease displaying the strongest association(OR 2.32[1.70-3.15];p<0.05).All associations were statistically significant for p<0.05.Of 1219(59.9%)participants without diagnosis of AHT 29.0% were found to have AHT upon BP mesurement.In this group awareness of the hypertensive renal risk has a protective effect against undiagnosed AHT(OR 0.69[0.52-0.92];p<0.05).In contrast, awareness of the hypertensive renal risk has not protective effect against uncontrolled AHT among hypertensive pts.The rate of uncontrolled AHT was 58.0% of hypertensive pts.

Conclusions: The rate of awareness of the renal risk associated with AHT demands more attention in the primary care setting due to its potential benefit on undiagnosed AHT.

Hypertriglyceridemia and Inflammatory Markers as Predictors of Survival in Cohort of Patients with Chronic Kidney Disease Maristela Bohlke,[1] Gabriela Araujo Duarte,[1] Alexia Schuch,[1,2] Jamile Gardin Dos Santos,[1] Luiza Morrone Gastaud,[1] Mateus De Mamann Vargas,[1] Annelise Reges,[1] Franklin Correa Barcellos.[1,2] *[1]Medicine School, Univ Catolic of Pelotas, Pelotas, Brazil; [2]Medicine Faculty, Univ Federal of Pelotas, Pelotas, Brazil.*

Background: Systemic inflammation, dyslipidemia and other metabolic disorders has been associated with increased cardiovascular mortality. Exercise is a non-drug intervention with positive effects on metabolic profile and inflammation in individuals with chronic diseases and the general population. Objective is correlate inflammatory and metabolic markers with the long-term prognosis of a cohort of patients with chronic kidney disease (CKD) who suffered an intervention with exercise.

Methods: Hypertension and nondiabetic patients with GFR ≤60 mL/min/1.73m2 were included in a randomized clinical trial (RCT) that evaluated effects of an exercise program on cardiovascular disease markers. demographic factors and clinical (blood glucose, lipid profile, C-reactive protein (CRP), body mass index (BMI), ankle brachial index (ABI) at baseline and after 4,8 and 16 weeks of exercise. At the end of the intervention patients were followed-up to investigate the exercise long-term effects and identify quality predictors of life and mortality.

Results: A total of 150 patients allocated to the RCT, 65 patients had CKD. The long-term follow-up lasted for an average of 2.75 (1:06 to 4:29) years. Predictors of mortality were elevated CRP levels (OR 1.16 95% CI 1:00 to 1:34) and triglycerides (OR 1.1 95% CI 1:00 to 1:01). Other markers such as LDL cholesterol, BMI and blood glucose showed no detectable impact on mortality, as well as intervention with physical exercise. The ITB tended (OR 0 .027 0 95% CI .00 to 2.44) to be associated with mortality. Among the 65 patients with CKD were recorded 10 deaths during the follow-up period.

Conclusions: Larger studies with adequate samples are needed to confirm the prognostic impact of hypertriglyceridemia and elevated CRP for patients with pre-dialysis CKD, as well as the tendency of association between peripheral arterial disease as with ABI and mortality in this population increase.

PUB132

Change in Albuminuria and Incident Cardiovascular Events among Diabetic Patients: Results from the Kailuan Study in China Jinwei Wang,[1] Shouling Wu,[2] Luxia Zhang.[1] *[1]Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China; [2]Dept of Cardiology, Kailuan Hospital, Tangshan, Hebei, China.*

Background: Albuminuria is one of the biomarkers to define chronic kidney disease. However, there are few studies concerning pattern of albuminuria change in relation to adverse outcomes.

Methods: Our study is based on a cohort study among 101510 employees of Kailuan group in Tangshan of China. Diabetic patients without a history of cardiovascular disease(CVD) at baseline(2006-2007) and also available at the second circle of examination(2008-2009) were included(n=5002). Definition of diabetes was based on glucose concentration or self-reported diagnosis. Albuminuria was measured by dipstick test from morning spot urine. CVD was a composite of myocardial infarction and stroke and followed-up until December 31, 2010. A total of 4954 participants were included in the final analysis after excluding 48 CVD events occurred baseline through the second circle of examination. Latent mixture modeling was used to identify albuminuria trajectories. Multivariate Cox proportional hazards regression model was fit to assess the association of albuminuria trajectories with CVD. The covariates included age, gender, education, smoking, body mass index, mean arterial pressure, and estimated glomerular filtration rate.

Results: The mean age of the study participants was 52.5±9.5 years with 78.16% of males. Three discrete trajectory groups of albuminuria were identified: persistent negative(74.2%[95% confidence interval[CI] 72.8-75.6], n=3799), positive to negative(8.6%[95%CI 7. 6-9.7], n=363) and persistent positive(17.2% [95%CI 16.1-18.4], n=792). With a median of 1.95 years (0.08-2.56 years) of follow-up, 63 composite CVD were recorded with 39, 5 and 19 events in the three groups, respectively. Using the persistent negative group as reference, persistent positive group showed an increased risk of CVD with the multivariate adjusted hazard ratio(HR) of 2.2(95%CI 1.3-3.9), while positive to negative group did not show an association with CVD(HR=1.2 [95%CI 0.5-3.0]).

Conclusions: Persistent albuminuria was found as a risk factor for CVD, while transient albuminuria shows no risk among diabetic patients.

PUB133

Echocardiographic Evaluation of Left Atrial Volume Index in Patients with Chronic Kidney Disease Syed Rizwan A. Bokhari,[1] Muhammad Zaman Khan Assir,[2] Shahbaz Sarwar,[3] Afshan Ittifaq,[1] Zumar Sardar,[2] Abeera Mansur.[1] *[1]Nephrology, DHMC, Pakistan; [2]Medicine, AIMC/JHL, Pakistan; [3]Cardiology, DHMC, Pakistan.*

Background: Chronic kidney disease (CKD) patients are at high risk of developing cardiovascular disease (CVD) predominantly ischemic heart disease (IHD) and cardiomyopathy. Left atrial volume index (LAVi) is an indicator of left ventricular diastolic dysfunction independent of volume status. A high LAVi is an independent poor prognostic factor in patients with CVD. We conducted this study to find out correlation of LAVi and other echocardiographic parameters with eGFR.

Methods: We prospectively enrolled 153 subjects, 72 (47%)patients with and 81 (53%) control subjects without CKD. Demographic, clinical and Echocardiographic parameters including systolic and diastolic volumes, Left atrial volume, left atrial volume index (LAVI), Ejection fraction (EF), Pulmonary artery systolic pressure (PASP) and E/e ratio were measured in all participants.

Results: From the total of 153 individuals, males with and without CKD were 42 (58.3%) Vs 54(66.7%) (p.value 0.318), Females with CKD were 30 (41.7%) Vs 27 (33.3%) without CKD (p-value 0.287). Median age of patients with CKD was 67 (range 27-90years), and 35 (range 17-90) years in control group. Hypertension was seen in 38 (52.8%) with CKD Vs 10(12.3%) in control group p-value <0.001, Diabetes Mellitus (DM) was found in 35 (48.6%) with CKD vs 8 (9.9%) without CKD (p-value <0.001) and Coronary artery disease (CAD) was present in 26 (36.1%) as compared to 8 (9.9%) patients in control group (p-value <0.001). Patients with CKD had significantly higher median LAVi (31.5 [range 9-69] vs 22 [range 10-31]; p value <0.01), higher median E/e ratio (10 [range 4-16] vs 7 [range 4-15]; p value <0.01), higher median PASP (40 [range 27-82] vs 26.5 [range 20-55]; p value < 0.01) and lower EF (60 [range 15-72] vs 65 [range 32-70], p value of 0.01). There was a significant negative correlation of eGFR with LAVi (r=-0.577; p value< 0.001), PASP (r=-0.466; p value <0.001) and E/e ratio (r=- 0.383; p vale <0.001).

Conclusions: Patients with CKD have higher LAVi, PASP and E/e ratio and lower EF as compared to those without CKD. There is significant negative correlation between eGFR and LAVi.

PUB134

Interleukin-18 May Predict Cardiovascular Mortality in Chronic Kidney Disease among Non-Diabetic Post-Myocardial Infarction Patients in 2-Year Follow-Up Maria Wanic-Kossowska,[1] Dorota Formanowicz,[2] Elzbieta Pawliczak,[1] Krzysztof Schwermer.[1] *[1]Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland; [2]Dept of Clinical Biochemistry and Laboratory Medicine, Poznan Univ of Medical Sciences, Poznan, Poland.*

Background: The incidence and severity of cardiovascular (CV) complications in patients with chronic kidney disease (CKD) is disproportionate compared to well-known traditional atherosclerosis risk factors profile. The aim of our study was to investigate whether and how non-traditional risk factors, such as interleukin-18 (IL-18), due to its pleiotropic properties, is prospectively associated with CV deaths in patients with CKD in the 2-year follow-up.

Methods: The study was carried out in a group of 200 non-diabetic patients, aged 45-80 years, with different stages of CKD and the history of myocardial infarction in the past. They have been followed for 2-years for having CV-related deaths. At the beginning of this study hsCRP, NT-proBNP, GFR, albumins, ferritin, and IL-18 in the serum have been measured. Additionally, all patients had an assessment of carotid intima media thickness. Moreover, a formal model of the involvement of IL-18 in the atherosclerotic plaque formation, expressed in the language of Petri nets theory, has been built and analyzed.

Results: In our study we found that an increase in serum concentration of IL-18 above the cut-off point (1584.5 pg/ml) was characterized by 20.63-fold higher risk of CV deaths among studied patients. IL-18 serum concentration was found to be superior to the studied well-known CV risk parameters.

Conclusions: IL-18 seems to be important indicator and predictor of cardiovascular death in two-year study among non-diabetic patients with different stages of CKD. The importance of IL-18 in the process of atherosclerotic plaque formation has been confirmed by systems analysis based on a formal model.

PUB135

End-Stage Renal Disease versus Death in a Portuguese Cohort of Elderly Patients: An Approach Using Competing Event Analysis Josefina Lascasas,[1] Isabel Fonseca,[1] Jorge Malheiro,[1] Idalina Beirão,[1] Sofia Correia,[1] Andreia Campos,[1] Pedro Oliveira,[2] Luisa Lobato,[1] António Cabrita.[1] *[1]Nephrology Dept, CHP, Porto, Portugal; [2]Inst Ciências Biomédicas Abel Salazar, Univ Porto, Porto, Portugal.*

Background: Portugal is facing an increasingly ageing, and has the highest incidence of end stage renal disease(ESRD)among European countries. Chronic kidney disease(CKD) prevalence is higher in elderly, but mortality outweighs the risk of progression to ESRD, which makes it a challenge to determine each patient's risk for requiring renal replacement therapy(RRT) in relation to the competing risk of death.

Methods: Longitudinal cohort study, with consecutive CKD patients aged≥ 65 years(yrs) referred to outpatient clinic during 2012, followed until the time of the first event(RRT or death) or until April 30, 2016. A competing risk analysis using STATA statistical software was performed between those two mutually exclusive endpoints.

Results: Among 416 patients,age 76±8 yrs(36%≥80 yrs), 52% male, mean eGFR EPI 32ml/min, 49.7% had diabetes, and 71% cardiovascular disease. Median follow-up was 3.6 yrs(min-max:0.02-4.3), during which 36 patients progressed to ESRD(8.7%) and 103 died(24.8%). The rate(per 100 person-yrs) was 2.7 for ESRD and 7.8 for death. The independent predictors for RRT with competing risk of death were:lower age(sHR=0.97; P=0.029),creatinine>2mg/dl(sHR=2.48, P=0.012),and peripheral vascular disease(sHR=2.50, P=0.011) at baseline;and having one or more hospitalizations during the follow-up (sHR=4.07, P=0.002). The independent predictors for patient death with competing risk of RRT were: age>80 yrs(sHR=2.22; P<0.001), creatinine>1.6 mg/dl(sHR=2.59, P=0.003)and having one or more hospitalizations during the follow-up(sHR=4.55, P<0.001).

Conclusions: During a median follow-up of 3.6 yrs, older CKD are near 3-fold more likely to die from any cause than progress to ESRD. Age,late nephrology referral(higher creatinine at the first observation) and hospitalizations are the most important predictors of the competing events ESRD and death. A greater burden of vascular disease, present in our cohort, as a predictor for RRT, highlights the importance of strategic targeting vascular risk reduction in these patients.

PUB136

P2Y12 Antagonists for Acute Coronary Syndrome in Chronic Kidney Disease: A Meta-Analysis of Randomised Controlled Trials Peter J. Gallacher. *Centre for Cardiovascular Sciences, Univ of Edinburgh, Edinburgh, United Kingdom.*

Background: Chronic kidney disease (CKD) patients are under-represented in cardiovascular trials and less likely to receive secondary prevention. Dual antiplatelet therapy with aspirin and $P2Y_{12}$ antagonists (e.g. clopidogrel) is standard treatment following acute coronary syndrome. We aimed to determine how reduced eGFR influences major adverse cardiovascular events (MACE) and bleeding risk in patients treated with these agents for acute coronary syndrome.

Methods: Central, Embase, and Medline databases were searched from 1946 through to June 2016 for randomised controlled trials (RCTs) comparing $P2Y_{12}$ antagonists with another antiplatelet agent, standard care or placebo in adults with acute coronary syndrome in the presence or absence of CKD, defined as an eGFR of $\leq$60mL/min/1.73m^2. Two assessors independently screened relevant studies. The primary outcome was MACE; a composite of cardiovascular death, myocardial infarction (MI) or stroke. The secondary outcome was TIMI major bleeding. Publication bias was determined using Eggers regression test and heterogeneity was calculated using the I_2 test. Summary effects of relative risk (RR) ratios were collated using a random-effects model.

Results: Of 4,382 studies, five international, multi-centre, double-blinded RCTs with low risk of bias studies were included in the analysis. From 57,611 patients, eGFR data were available for 88.6% (n=51,031). CKD patients comprised 21.2% of the population (n=10,480), of whom 1.1% (n=560) had an eGFR <30mL/min/1.73m^2. Treatment reduced MACE in both those with CKD (n=10,840; RR 0.89 [CI 0.69-1.18]) and those without (n=40,191; RR 0.79 [CI 0.63-1.00]). TIMI major bleeding risk was increased in both those with (n=9,350; RR 1.04 [CI 0.63-1.72]) and those without CKD (n=28,301; RR 1.39 [0.94-2.07]).

Conclusions: $P2Y_{12}$ antagonists after acute coronary syndrome confer benefit to CKD patients, although to a lesser degree than in those with normal renal function. They are associated with a lower risk of major bleeding in CKD; this may reflect premature mortality due to other causes. Those with severe CKD, and so the greatest cardiovascular risk, are vastly under-represented in cardiovascular trials.

PUB137

The Clinical Characteristics and Therapy in Aortic Dissection Patients with Chronic Kidney Disease Zhen Su. *Nephrology, The First Affiliated Hospital of Wenzhou Medical Univ, Wenzhou, Zhejiang, China.*

Background: Chronic kidney disease (CKD) is a common condition that elevates the risk of adverse outcomes including cardiovascular disease. Aortic dissection (AD) is one of the most frequent life-threatening cardiovascular diseases. AD in CKD is rarely reported. This study aimed to evaluate the features and therapy in AD with CKD.

Methods: A retrospective analysis of 412 AD patients who admitted to our hospital during January 2005 to June 2015. 40 patients (34 males; mean age, 60.47± 16.05 years) were identified as CKD. We collected their baseline data as well as clinical features and followed up their outcomes. We compared them with 372 AD patients without CKD (268 males; mean age, 55.73±14.71 years). All patients underwent contrast-enhanced computerized tomography (CT) (nonionics and low-osmolarity contrast were used) to confirm the diagnose of AD.

Results: The most common etiologies of these CKD patients were glomerulonephritis, benign hypertensive nephrosclerosis and gouty nephropathy. 21 patients were medically treated, 13 received endovascular repair and 6 were surgically treated. During the median follow-up of 20 months (range, 1-124 months), 5 patients developed Acute renal failure on CKD after surgical treatment, and all of them required CRRT. Those who received endovascular therapy seemed to have a more favorable outcome than who maintained conservative medical therapy, though without significance (1-year survival 88% vs 68.6%, respectively; log-rank test p = 0.07). We classify dissections that involve the ascending aorta as type A and all other dissections as type B. In type B AD patients with CKD, endovascular treatment patients significantly had a favorable survival (1-year survival 100% vs 60% medically treated, respectively, log-rank test p = 0.011). Compared with those without CKD, AD cases with CKD had more hypertension (P <0.001), less likely to present with abrupt onset pain (p = 0.001), more often diagnosed incidentally (p =0.002) and more patients prone to medical treated (p=0.005).

Conclusions: endovascular treatment has acceptable outcomes in CKD patients when they suffered AD and such patients had their atypical features which need the physicians pay more attention.

PUB138

The Impact of Admission Serum Creatinine on Major Adverse Clinical Events in ST-Segment Elevation Myocardial Infarction Patients Undergoing Primary Percutaneous Coronary Intervention Mohamed Khayata, Mohit Gupta, Shyam Bhakta, Rupesh Raina. *Internal Medicine, Akron General Medical Center, Akron, OH.*

Background: Impaired renal function has been shown in previous studies to be an independent predictor of cardiovascular adverse events amongst patients admitted for percutaneous coronary intervention (PCI). We will investigate the impact of admission serum creatinine on major cardiovascular outcomes among STEMI patients undergoing PCI.

Methods: A Retrospective Institutional Review Board approved study of patients admitted for STEMI was conducted using the National Cardiovascular Database Action Registry (NCDR) at Cleveland Clinic Akron General (CCAG) Hospital. The primary outcome was a composite of major clinical events (cardiogenic shock, atrial fibrillation, ventricular tachycardia/fibrillation, heart failure, bleeding, mechanical ventilation). Creatinine was an independent and continuous variable. Statistical analysis was performed via the Mann Whitney U test.

Results: 1452 subjects who were admitted to CCAG hospital between January 2011 and September 2015, with the diagnosis of STEMI were included. The cohort consisted of primarily older Caucasian males with creatinine levels from 0.83 mg/dL to 1.2 mg/dL. Higher levels of creatinine on admission was associated with an increased incidence of the composite clinical outcome (p<0.001), atrial fibrillation (p=0.021), cardiogenic shock (p=0.002), bleeding (p<0.001), and heart failure (p<0.001).

Characteristics	N=1452	Major Adverse Event During Hospital Stay	p Value
Age (Mean +/- SD)	64 +/- 14	Atrial Fibrillation	0.021
Gender (Male%)	64	Ventricular Tachycardia / Ventricular Fibrillation	0.884
Race (Caucasian%)	85	Dialysis	0.713
Hypertension	72	Mechanical Ventilation	0.731
Diabetes Mellitus	29	Cardiogenic Shock	0.002
History of Heart Failure	13	Heart Failure	0.000
Current Smoker	40	Bleeding	0.000
Creatinine (Median (IQR))	1(0.83-1.2)	Composite Event	0.000

Conclusions: In the setting of STEMI, elevated creatinine was associated with an increased risk of developing major clinical events including cardiogenic shock, atrial fibrillation, bleeding and heart failure.

PUB139

The Error of Estimated GFR in Patients with Acute Heart Failure: The Cardiologist in the Mist Sergio Luis Lima,[1] Pablo Jorge,[1] Martin L. Garcia,[1] Ana Aldea Perona,[1] Natalia Negrín,[1] Federico J. Gonzalez-Rinne,[1] Esteban Porrini.[2] [1]*Hospital Univ de Canarias, La Laguna, Spain;* [2]*Univ de La Laguna.*

Background: In diverse populations, estimated GFR (eGFR) showed a wide error in predicting real renal function. This error has never been tested in patients with acute heart failure (AHF).

Methods: We analyzed 30 patients (12 women) with AHF in whom GFR was measured by iohexol plasma clearance (mGFR) and estimated with 52 formulas (creatinine and cystatin-based) 48 hours after admission in a condition of clinical stability. The agreement between mGFR and eGFR was assessed by the Total Deviation Index (TDI), Concordance Correlation Coefficient (CCC) and coverage probability (cp).

Results: Age 63±12 yr; DM 55%; HTA 74%; dyslipidemia 78%; previous ischemic disease 44%; new-onset AHF 59%; creatinine 1.36±0.69mg/dl; NT-proBNP 6048±4915pg/ml; troponin-I 0.05ng/ml (median). 58% received high doses of furosemide (>125mg) in the first 24 hours. 44.4% had left ventricular ejection fraction<35%. Formulas showed poor agreement with mGFR: CCC~0.70; TDI from 106,8% to 49,6% (~62%), indicating that 90% of eGFR showed an error of ±62%. No formula included 90% of eGFR within a cp of ±10% Table 1 shows a sub-group of formulas.

	CCC (95%CI)	TDI (95%CI)	CP (95%CI)	N
Creatinine based formulas				
aMDRD	0.70 (0.51)	69 (94)	22 (18)	30
CKD_EPI	0.72 (0.55)	70 (95)	22 (17)	30
RuleMC	0.61 (0.43)	107 (145)	15 (11)	30
Effersoe	0.63 (0.42)	80 (108)	20 (16)	30
Cystatin-C based formulas				
Hoek	0.73 (0.54)	50 (67)	29 (22)	30
RuleCisc	0.75 (0.56)	52 (70)	28 (22)	30
CKD_EPI_cisc	0.75 (0.57)	54 (74)	27 (21)	30
Creatinine and cystatin-C based formulas				
Stevens	0.73 (0.53)	55 (75)	27 (21)	30
Ma	0.63 (0.43)	72 (98)	21 (15)	30
CKD_EPI_crecisc	0.75 (0.57)	56 (76)	26 (20)	30

Errors in CKD classification were observed: one in three patients with eGFR>60 ml/min (stage 1-2) had mGFR<60 ml/min (stage 3).

Conclusions: Formulas do not accurately reflect the GFR in patients with AHF. The clinical consequences of this error must be evaluated in prospective studies.

Funding: Government Support - Non-U.S.

PUB140

Serum 1,25 Dihydroxyvitamin D Is Independently Associated with Left Ventricular Hypertrophy and Diastolic Dysfunction in Patients with Chronic Kidney Disease Il Young Kim, Jong Man Park, Harin Rhee, Sang Heon Song, Eun Young Seong, Dong Won Lee, Soo Bong Lee, Ihm Soo Kwak. *Dept of Internal Medicine, Pusan National Univ School of Medicine, Yangsan, Republic of Korea.*

Background: Cardiovascular disease is the leading cause of death in chronic kidney disease (CKD) patients. Increased left ventricular mass and diastolic dysfunction is known for the predictors of the cardiovascular complications in these patients. This study investigated the association between serum 1,25 dihydroxyvitamin D [$1,25(OH)_2D$] and left ventricular mass/diastolic dysfunction in pre-dialysis CKD patients.

Methods: This study included 246 patients with pre-dialysis CKD [glomerular filtration rate (GFR) < 60 ml/min/1.73m^2]. Two-dimensional echocardiography was performed to measure the left ventricular mass index (LVMI). Tissue Doppler imaging was used to measure the early mitral inflow velocity (E) and the peak early mitral annular velocity (E'). Diastolic dysfunction was estimated by the ratio of E to E' (E/E').

Results: In univariate analysis, LVMI was significantly correlated with the presence of hypertension, GFR, $1,25(OH)_2D$, and parathyroid hormone (PTH). E/E' was significantly associated with the presence of hypertension, $1,25(OH)_2D$, and PTH. In multivariate analysis, LVMI was independently associated with the presence of hypertension (β = 0.175, P = 0.003), $1,25(OH)_2D$ (β = -0.140, P = 0.025), and PTH (β = 0.351, P < 0.001). PTH (β = 0.160, P = 0.016) and $1,25(OH)_2D$ (β = -0.135, P = 0.039) were independent predictors of E/E'.

Conclusions: This study shows that $1,25(OH)_2D$ is independently associated with left ventricular hypertrophy and diastolic dysfunction in pre-dialysis CKD patients. Further studies are needed to determine whether the therapy with vitamin D supplement prevents these cardiac changes in them.

PUB141

Non-Dipping Status in 24-H Ambulatory Blood Pressure Monitoring Is Associated with Left Ventricular Hypertrophy in Patients with Non-Dialysis Chronic Kidney Disease Patrick Saudan,[1] David Antoine Jaques,[2] Hajo Mueller,[3] Sophie M. De Seigneux,[1] Pierre-Yves F. Martin,[1] Belen Ponte.[1] *[1]Div of Nephrology, Geneva Univ Hospitals, Geneva, Switzerland; [2]Div of General Internal Medicine, Geneva Univ Hospitals, Geneva, Switzerland; [3]Div of Cardiology, Geneva Univ Hospitals, Geneva, Switzerland.*

Background: Few studies have assessed the role of 24-h ambulatory blood pressure monitoring (ABPM) in non-dialysis CKD adults. We conducted a study to examine the association of ABPM dipping status with the development of left ventricular hypertrophy (LVH) in this population.

Methods: Within a prospective cohort of 242 patients with stage IIIb-IV CKD, 72 had both ABPM and transthoracic echocardiography performed simultaneously in addition to usual renal function tests. Dipping status ≥10% was considered normal.

Results: Mean age and eGFR were 69 yrs and 36ml/min/1.73m respectively in this cohort. There were 67% male, 49% diabetics and 42% presented LVH. Median left ventricular mass index was119 (109-136) vs 82 (63-91) g/m^2 in patients with and without LVH respectively. Mean ABPM systolic and diastolic BP did not differ between patients with and without LVH (132/78 vs 133/75 mm Hg). Normal systolic and mean BP dippings were present in 57 and 62% in patients without LVH and 23 and 33% in patients with LVH. Multivariate logistic regression analysis showed that systolic and mean dipping status remained associated with LVH: OR 0.21 (p<0.01) and OR 0.26 (p=0.014). Diastolic dipping was not associated with LVH (OR 0.71, p 0.52). No other variable was associated with LVH in this model adjusted for GFR, anti-hypertensive medication, smoking, hemoglobin, PTH and diabetic status.

Conclusions: These data confirm the high incidence of LVH amongst CKD patients. Systolic and mean BP non-dipping status are associated with LVH in patients suffering from non-dialysis CKD.

PUB142

Impact of Anticoagulation and Antiagregation on the Anemia and Hemorrhagic Events in Patients with Chronic Kidney Disease Stage 3 and 4 Ana M. Garcia Prieto, Marian Goicoechea, Tania Linares, Ursula Verdalles, Eduardo Verde, Maria Soledad Garcia de Vinuesa, Jose Luno. *Nephrology, Gregorio Marañón Hospital, Madrid, Spain.*

Background: There is controversy about the risk/benefit of anticoagulation/antiagregation in chronic kidney disease (CKD) patients not in dialysis. We analyze the impact of anticoagulation/antiagregation on the anemia and bleeding risk in CKD patients.

Methods: 232 CKD patients stage 3 and 4 were followed in the outpatient clinic of Nephrology with a mean follow-up of 36.7 +/- 11.6 months. 81 patients did not receive anticoagulation or antiagregation, 91 received acenocumarol and 60 patients received antiagregation. Hemorrhagic and cardiovascular events were collected.

Results: There were no differences between groups regarding age, renal function or inflammatory parameters (CRP and fibrinogen). Hemoglobin and ferritine levels were significantly higher in patients who did not receive anticoagulation or antiagregation. During follow up 36 hemorrhagic events occurred: 4 in the control group, 17 in the anticoagulation group and 7 in the antiagregation group (log Rank: 9,010, p=0,011). In a Cox model adjusted by age, renal function and hemoglobin levels, the anticoagulation increased the risk of bleeding almost four times (HR 3,7(1,6-8,5), p=0,002) and antiagregation almost three times (HR 2,6 (1,1-5,9), p=0,025). 64 cardiovascular events were registered, 21 were classified as atherosclerotic events: 10 in the antiagregation group, 8 in the control group and 2 in the anticoagulation group (log rank: 8.351; p=0.015). In a Cox model adjusted by age, renal function and previous cardiovascular events, the anticoagulation reduced the risk of atherosclerotic events in 86% (HR 0.136 (0.033.0.551), p=0.005).

Conclusions: Anticoagulation and antiagregation increase the hemorrhagic risk in patients with CKD and worsen the anemia, fact that must be taken on account to optimize treatment and valuate the risk/benefit in the prescription of these drugs. Anticoagulation reduces the atherosclerotic events in more than 85%. Antiagregation does not prevent atherosclerotic events and increases the risk of bleeding, thus it should not be a first election treatment neither in primary nor secondary prevention.

PUB143

Association of Vascular Disease with Mortality and Development of End Stage Renal Disease in Patients with Chronic Kidney Disease Olufemi B. Aina, Candace D. Grant, Farah Daccueil, Nobuyuki (Bill) Miyawaki, Shayan Shirazian, Joseph Mattana. *Medicine, Winthrop-Univ Hospital, Mineola, NY.*

Background: Patients with chronic kidney disease (CKD) are disproportionately affected by atherosclerotic vascular disease (AVD). AVD can plausibly contribute to progression of CKD to end stage renal disease (ESRD) but AVD also predisposes to cardiovascular mortality and may therefore reduce the risk of ESRD via the competing risk of death. In this study we evaluated the relationship between AVD, the development of ESRD, and mortality in patients with CKD.

Methods: We conducted a prospective observational study of 623 patients with stage 3 and 4 CKD. Demographic, clinical and laboratory variables were recorded and patients divided into two groups based on the presence or absence of AVD, defined as having a diagnosis of coronary artery disease, myocardial infarction and/or peripheral vascular disease. Development of ESRD and death without ESRD were recorded over 2 years of follow up.

Results: Out of 623 patients with CKD 285 had AVD. Patients with AVD were older than those without (75.8 ±10.0 vs 65.6 ±15.0 y, p<0.001) and had lower eGFR (33.8 ±11.5 vs 36.4 ±11.7 mL/min/1.73 m2, p<0.01). Mortality was higher in patients with AVD (16.8 vs. 5.3%, p<0.0001) and increased with age. There was a trend toward higher ESRD incidence in AVD patients but in contrast with mortality, ESRD incidence decreased with age though remained higher in AVD patients. ESRD incidence in AVD patients <65 was 17.1 vs 9.5% in those without and for AVD patients ≥65 the incidence was 6.6 vs 3.3% though these differences did not reach statistical significance.

Conclusions: Our findings suggest that despite significantly higher mortality rates in patients with CKD who have AVD, they may also experience an increased risk of development of ESRD. This effect may be especially pronounced in younger patients with CKD and AVD where the competing risk of death is lower. This observation may be helpful in decision making such as planning for renal replacement therapy in patients with CKD and AVD and suggests shared pathophysiological mechanisms contributing to both cardiovascular death and progression of CKD to ESRD.

PUB144

Fracture Risk Assessment (FRAX) in Chronic Kidney Disease (2-5ND) Sarcopenia's Role Secundino Cigarran,[1] Ana Maria Sanjurjo Amado,[1] Mª Milagros López Hernández,[1] Juan Latorre,[1] Jesus Calvino.[2] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Hospital Lucus Augusti, Lugo, Spain.*

Background: A higher risk fractures has been well recognized among patients with chronic kidney disease (CKD).FRAX is a well-accepted tool for fracture risk assessment in the general population.In CKD many pts are frail and prone to falling which predisposes to suffer a fracture.Bone changes in CKD are over impose to normal aging evolution, as sarcopenia.The aim of this cross-sectional study is to assess the relationship of body composition and sarcopenia in CKD (2-5ND) pts with FRAX.

Methods: 411 pts >70 yo were enrolled, (mean age 75 yo, 40% diabetic status, 44.4% female) from our CKD unit. (Stage 2 19%; Stage 3A 39%; Stage 3B 73%; Stage 4 25% and Stage 5ND 2%). Spanish FRAX was use to calculate the 10-year probability of a major osteoporotic fracture. Vertebral score was >10% at 10 yr and hip fractures risk score >3% as at risk.Body composition assessment was performed with vectorial bioelectrical impedance (EFG, Akern Fl. ITA and multifrequency Bioscan 920, Maltron,London UK). Handgrip strength in both arms was performed with (Handgrip Akern. FL. Ita).Biochemical markers of CKD-MB, nutrition,renal function (CKD-EPI & ACR),inflammation and CV risk were performed.

Results: 170 pts (39.8%) were in risk of hip & vertebral fractures and 256 pts (61%) in risk of hip fracture alone.In bivariate analysis female (p<0.001) and older (p<0.001) evidenced high risk of fractures.

Variable	No Fracture risk	Fracture (vertebral/hip) risk	P
Muscle Mass (%)	40.2±7.34	36.31±6.64	.000
TBW (%)	51.27±5.89	46.8±6.37	.000
ECW(%)	48.78± 5.46	50.25±4.97	.006
ICW (%)	51.28 ± 5.44	49.74±4.98	.006
Interstitial Fluid (L)	13.06± 2.55	11.13±2.68	.001
Plasma volume (L)	3.72±0.73	3.18±0.77	.001
Fat Mass (%)	35.42± 7.55	41.24±8.05	.001
Phase Angle (°)	5.48±1.14	5.19±0.94	.007

No other significances were met.HGS was lower in the fracture risk group (29.2 ± 8.7 Kg vs 20.4± 7.0 kg; p<0.001).

Conclusions: FRAx is a useful tool to predict fracture risk in CKD pts.Our study reflects bone-muscle cross talk.Importance of physical exercise should not be underestimated.

PUB145

Muscle-Kidney Crosstalk through microRNA-29a in Mice with Chronic Kidney Disease Aiqing Zhang, Haidong Wang, Bin Wang, Faten Hasounah, Xiaonan H. Wang. *Renal Div, Emory Univ, Atlanta, GA.*

Background: Kidney fibrosis is a progressive process that ultimately leads to end-stage renal failure. Muscle wasting is a serious complication of chronic kidney disease (CKD) and contributes substantially to the morbidity and mortality of patients. Exosomes, natural carriers of many signaling molecules including microRNA (miR), mediate organ to organ communication. Our studies have suggested that MiR-29 could be a therapeutic target to treat muscle wasting but it also has anti-fibrotic activities. We hypothesized that miR-29 could benefit both unilateral ureteral obstruction (UUO)-induced muscle wasting and kidney fibrosis through exosome-mediated muscle-kidney crosstalk.

Methods: UUO was induced by left ureteral ligation. A NanoSight instrument was used to quantify exosomes. A miR deep sequencing assay and qPCR were used to identify microRNA. We used Adeno-Associated Virus (AAV) for miR overexpression. Immunohistochemistry (Mason Trichrome) identified renal fibrosis.

Results: We found that serum-derived exosomes from UUO mice are larger than control exosomes. MiRNAdeep sequencing showed that miR-29a-5p was significantly increased in serum exosomes but decreased in skeletal muscle and kidney tissue of UUO vs controls. Uremic serum enhanced exosome/miR29a secretion by cultured skeletal muscle cells. When we overexpressed miR-29a by injecting AAV into tibialis anterior muscle, the cross-sectional area increased and UUO-induced up-regulation of muscle atrogin-1 and MuRF1 decreased. Interestingly, kidney fibrosis was also partially depressed in these mice, confirmed with decreased α-smooth muscle actin (αSMA), vimentin, fibronectin and collagen1α. Exosomes containing miR-29a secreted by cultured skeletal muscle cells were able to transfer miR-29a to human kidney cells and attenuate uremic serum-induced up-regulation of αSMA, providing indirect evidence of muscle-kidney crosstalk.

Conclusions: Overexpression of miR29a in muscle not only attenuated skeletal muscle atrophy but also ameliorated UUO-induced renal fibrosis through exosome-mediated muscle-kidney crosstalk.

PUB146

Childhood IgA Nephropathy Presenting Acute Nephritic Syndrome at Onset Yuko Shima,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Masashi Sato,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Hiroshi Kaito,[2] Kandai Nozu,[2] Ryojiro Tanaka,[3] Kazumoto Iijima,[2] Hiroyuki Suzuki,[1] Norishige Yoshikawa.[4] *[1]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [2]Pediatrics, Kobe Univ, Kobe, Japan; [3]Pediatric Nephrology, Kobe Children's Hospital, Kobe, Japan; [4]Clinical Research Center, Wakayama Medical Univ, Wakayama, Japan.*

Background: Acute nephritic syndrome (ANS) is a rare manifestation of IgA nephropathy (IgAN). Clinical characteristics and long-term outcomes of childhood IgAN presenting ANS (ANS-IgAN) at onset are not clear.

Methods: Retrospective analysis of 538 consecutive biopsy-proven IgAN children from July 1976 to June 2013 to compare clinical and pathological findings between ANS-IgAN and others.

Results: Nine ANS-IgAN (1.7%) at onset, all were due to edema. Clinical findings showed significant differences (ANS vs. non-ANS) in mean blood pressure (91 vs. 75 mmHg; p=0.03), proteinuria (2.1 vs. 0.5 g/day/m^2; p=0.0005), and duration from onset to renal biopsy (2.0 vs. 8.0 months; p=0.016). There were no significant differences in MEST score or patient/glomerular ratios showing crescent and global sclerosis, but there were significant differences in patient ratios showing diffuse mesangial proliferation. Logistic analysis suggested a significant independent relationship between proteinuria and tubular atrophy/interstitial fibrosis area and ANS-IgAN. Kaplan-Meier analysis suggested that patients with ANS-IgAN had significantly lower renal survival rates than the others (p<0.001). ANS-IgAN at 5 years was 64.8% (95% CI: 33.8–88.4). Prognostic factors for renal survival were proteinuria disappearance (p<0.001) and ANS at onset (p=0.002). Among nine ANS-IgAN patients, four were treated with combination therapy (PSL and immunosuppressants), three had no medication (from before the early 1980s), and two were unknown. Three patients (33.3%) reached CKD III–V (eGFR <60) during the observation period (6.8 ± 2.9 years). Two patients demonstrated heavy proteinuria even after 2-year combination therapy. One patient showed remarkably deteriorated renal function with severe tubular atrophy at diagnosis.

Conclusions: Patients with ANS-IgAN showing evident chronic lesion at onset have a poor prognosis as a consequence of refractoriness to treatment.

PUB147

A "Mini-Epidemic" of Anti-GBM Disease: Epidemiological, Clinical and Immunological Study Umesha Lingaraj. *Dept of Nephrology, Inst of Nephrourology, Bangalore, Karnataka, India.*

Background: Acute glomerulonephritis due to anti-GBM antibody disease is rare, estimated to occur in fewer than one case per million population & accounts for less than 20% of RPGN. It accounts for fewer than 3 percent of all kidney biopsies done with crescentic glomerulonephritis. Cases of Anti-GBM disease occurring in cluster have rarely been reported.

Methods: A Cross-sectional Observational study. All biopsy proven anti-GBM disease cases were collected from January-2015 to March-2015 at our Institute. All cases were analysed for demographic & clinical profile, pathological findings, treatment received and special search for any common environmental antigenic source.

Results: Total of 11 new biopsy proven anti-GBM cases were collected. Age group varied from 17-80years. 7 were males & 4 were females. All were dialysis dependant at presentation. Seven had active cellular crescents and three had fibrocellular. Only one patient was a smoker and none had history of exposure to any forms of hydrocarbons. The peak was seen from January 2015 to March 2015, which does not correlate with any of the infections seasonal occurrence in southern India. Though there was clustering of cases to southern territories of Karnataka state, no common etiological agents could be identified. No patient had any previous urological surgeries. All patients received Methylprednisone with Plasmapharesis 5-7 sessions and Cyclophosphamide. All 11 patients were dialysis dependant at the end of 3 months.

Conclusions: Anti-GBM disease cannot be regarded as a rare cause of renal failure and lung hemorrhage. With the occurrence of such epidemics within a short period of time, suggest a possible unidentified environmental factor like infection or occupational agents as inciting agents. Identification of possible inciting agents could help us in instituting appropriate preventing measures.

PUB148

Are We Slowing the Rate of CKD Progression in Children? A Single Center Study Isabel Roberti, Shefali Vyas. *BarnabasHealth Children's Kidney Center, Barnabas Health Medical System, West Orange, NJ.*

Background: CKD progresses to ESRD with a variable decline in eGFR from 1.3 to 4.2 ml/min/1.73 m^2/yr depending on etiology, proteinuria and HTN.

Methods: Retrospective study of all children with CKD (eGFR: 20 to 70 ml/min/1.73m^2)* diagnosed by age 10 yrs and followed for ≥3 yrs. Etiology of CKD, eGFR at presentation, clinical data, meds used and rate of eGFR decline were reviewed. Children with AKI at presentation were included if CKD was diagnosed and eGFR reached >20*. All children received ACEis and rigorous control of acidosis, nutrition, growth, anemia, iPTH, HTN and proteinuria was done as per center protocol.

Results: 37 children had CKD, diagnosed from birth (N=7) to age 10 yrs (5.8±3 yr). 26 males, 15 C, 11 AA, 8 H, 3 other. **Mean eGFR at presentation:** 46.2 *(SD=2.99). Ten (27%) had eGFR ≤29 *. **Etiology**: 31 CAKUT (6 dysplasia), 2 aHUS, 1 twin transfusion, 1 GN, 2 tubular diseases. **AKI at presentation** =10 (27%); 4 required PD. **Follow-up time**: 3 to 18 yrs (8.7±3.9yrs). **eGFR change:** 10 increased, 2 unchanged, 25 deteriorated (rate of eGFR decline/yr =1.31±0.88*). **Children with initial eGFR ≤ 29*** (N=10) 4 either improved or were stable at last f/u; 3 progressed to ESRD (after mean f/u of 13 yrs) and received pre-emptive txp (8% of all children). No decrease >50% from baseline eGFR or progression to ESRD was seen in others - p=0.03. **Meds/therapies used**: GH =12, erythropoeitin =7, GT feeds =12. **Co-morbidities**: HTN =5, obesity =7, hyperlipidemia =5, malnutrition =1, CIC =7, VP shunt =2, UTIs =10, other congenital malformations = 11, single kidney =9, neurodev. delay = 2; Uprot/Cr≥1 =7; UAc>7.5 =12. **No single factor including AKI, single kidney, prematurity, CKD stage or age at presentation predicted eGFR changes overtime.**

Conclusions: 30% of our children with CKD had increase or stable eGFR* (including 40% of those with initial eGFR<29). Progression to ERSD was only seen in 3 (all had initial eGFR<29*). We report a lower than expected rate of eGFR decline and attribute it to rigorous control of nutrition, underlying condition and co-morbidities. Prediction of eGFR change can't be made at time of CKD diagnosis except for children with eGFR ≤29% who are at a significantly higher risk for ESRD.

PUB149

The Evaluation of the Associations between Measures of Kidney Dysfunction and Oral Health Status Jun-Beom Park,[1] Hye Min Choi.[2] *[1]Periodontics, The Catholic Univ of Korea, Seoul, Republic of Korea; [2]Internal Medicine, Seonam Univ Myongji Hospital, Goyang, Republic of Korea.*

Background: Urinalysis was considered an important part of the physician's diagnosis. Urinary sodium was considered an indicator of dietary sodium intake.The purpose of the present study was to investigate the association between urinary sodium, urinary sodium/creatinine, and urinary sodium/urine specific gravity and oral health behavior using nationally representative data.

Methods: Data from the Korea National Health and Nutrition Examination Survey conducted between 2008 and 2010 were used; the sample analyzed in this study consisted a total of 15,013 respondents over 19 years old who had no missing values for the urinalysis or outcome variables.

Results: Urinary sodium level was significantly lower in females ($P<0.05$). The rate of hypertension and diabetes was significantly lower in females ($P<0.05$). Adjusted odds ratios of urinary sodium and their 95% confidence intervals in relation to the frequency of tooth brushing (≤1, 2, and ≥3 times per day, respectively) were 1, 0.963 (0.794, 1.168), and 0.897 (0.741, 1.086) for males ($P>0.05$) and 1, 0.898 (0.704, 1.145), and 0.734 (0.573, 0.939) for females ($P<0.05$). Adjusted odds ratios and their 95% confidence intervals of urinary sodium regarding the number of secondary oral hygiene products used per day (0, 1 and ≥2, respectively) were 1, 0.986 (0.839, 1.158), and 0.766 (0.542, 1.081)for males ($P>0.05$) and 1, 0.851 (0.735, 0.985), and 0.798 (0.63, 1.01) for females ($P<0.05$).

Conclusions: Poor oral hygiene behavior was associated with higher sodium consumption in females. This association between sodium uptake and oral health behavior was independent of various potential confounding factors such as age, body mass index, smoking, drinking, exercise, diabetes, hypertension, and metabolic syndrome. Oral hygiene behavior may be considered an independent risk indicator for high urinary sodium level in Korean females.

PUB150

A Tale of Two Endpoints: Pre-Dialysis Education and Beyond
Prasad Rajendran, Sagar Jujjavarapu, Biju John, Terence Samuel, Shiva Kumar. *Dudley Group NHS Foundation Trust, United Kingdom.*

Background: Renal Replacement Therapy (RRT) planning in CKD patients should ideally happen 3 to 6 months prior to anticipated start of RRT to enable dialysis access and pre-emptive transplant work up to be done in time for start of dialysis through a permanent access. Our study aims were to analyse trends and timelines in referral to our Pre-dialysis education service, the subsequent patient choice of RRT, access creation, transplantation and RRT start.

Methods: 76 patients were referred following clinician review for pre-dialysis education given by the CKD nursing team between July 2014 and June 2015 where both modalities of dialysis, transplantation and conservative care was discussed. Data collection from clinic letters for timelines and the hospital IT system for results was performed in January 2016, therefore individual follow up varied from 6 to 18 months. Analysis was done using EPI-INFO 7.

Results: 45(59%) were males. Mean age was 68. 68(88%) were white. 24 patients had hypertension, 18 had Diabetes.

Timelines & Trends	Mean ± SD	Median	Range
eGFR at referral for education (ml/min)	15.5 ± 5.37	16	5 to 49
Time to access referral in months *n=42/61(69%)[Choice HD:31;PD:30]*	4.1 ± 3.68	3.5	0 to 15
eGFR decline/change at access referral (ml/min)	2.3 ± 3.13	2	+4 to -13
Time to access creation after access referral in months *n=29(48%)*	2.6 ± 3.18	1	0 to 14
Time to start of dialysis after education in months *n=19(25%) [10:PD;9:HD]*	5.8 ± 4.83	4	-2 to 16
eGFR at dialysis start (ml/min)	7.1 ± 3.58	6	3 to 19

6 patients started HD with a line. For a cut off eGFR for referral towards education at >=15ml/min, we derived a non-significant p value of 0.36 for an odds ratio of 3.0 for starting HD via line with referrals to education at a lower eGFR.

Conclusions: Due to variable rate of decline in renal function in varied age groups and with multiple comorbidities, a timely referral for pre-dialysis education and access creation would have to depend on individual assessment and clinical judgement. Even with early education, there may be a small risk of rapid decline in a group of patients and other factors influencing RRT start via alternative access or modality.

PUB151

Risk of Developing CKD at Any Given Blood Pressure Is Higher in Patients with Antihypertensive Medication Than in Those without in the Japanese General Population: An Analysis from Large Database of National Health Check-Up
Masaru Murasawa,[1] Ryo Kido,[1] Hiroo Kawarazaki,[1] Daisuke Uchida,[1] Shouichi Fujimoto,[2] Kunitoshi Iseki,[2] Toshiki Moriyama,[2] Kunihiro Yamagata,[2] Kazuhiko Tsuruya,[2] Tsuneo Konta,[2] Ichiei Narita,[2] Masahide Kondo,[2] Masato Kasahara,[2] Koichi Asahi,[2] Tsuyoshi Watanabe,[2] Yugo Shibagaki.[2] *[1]Inagi Municipal Hospital, Tokyo, Japan; [2]Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkup, Japan.*

Background: Higher systolic blood pressure (SBP) may increase the risk of developing chronic kidney disease (CKD) in the general population, but it remains unknown how different the risks conferred are in those with antihypertensive medication (med+) and in those without (med-).

Methods: Using national health check-up database from 2008 to 2011 in the general Japanese population aged 39 to 74 years, we evaluated the association of SBP with incidence of CKD 2 years later in 128,005 participants without CKD (proteinuria and/or eGFR <60, ml/min/1.73m2). SBP was categorized by every 10mmHg from the lowest (<100mmHg) to the highest category (>180mmHg), with further stratification into med+/-. We calculated odds ratio (OR) for estimating adjusted risk of developing CKD using logistic regression model.

Results: Participants including 62% of female and 25.9% of med+ had mean age of 63 years. Two years later, 12,379 (9.7%) developed CKD. Multivariate analysis showed the risk of developing CKD increased as SBP rose up in both med- and med+ (P for trend 0.001, <0.001), having the highest risk in each of the highest category (OR 1.75, 2.01) as compared with med- with SBP 100 to 109mmHg. Estimated risk in med+ with any SBP were higher than those in med- within the same SBP category, especially showing statistically significance in med+ with SBP ranging 110 to 160mmHg.

Conclusions: In the general population, the risk of CKD conferred by any given SBP was higher in those with antihypertensive medication than in those without. This result indicates that risk stratification by SBP requires to take use of antihypertensive medication into consideration.

PUB152

Low Serum Uric Acid Level Is a Risk Factor for 5-Year Mortality in Incident Hemodialysis Patients
Yoshiko Nishizawa,[1] Sonoo Mizuiri,[1] Mariko Asai,[1] Kyoka Ono,[1] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Takao Masaki.[2] *[1]Div of Nephrology, Ichiyokai Harada Hospital, Hiroshima, Saeki-ku, Japan; [2]Nephrology, Hiroshima Univ Hospital, Hiroshima, Minami-ku, Japan.*

Background: 'J-shaped' association between uric acid and mortality has been controversial in maintenance hemodialysis patients. However, low serum uric acid (UA) level at the initiation of dialysis has not been fully clarified as a risk factor for mortality.

Methods: A retrospective study was conducted on 252 consecutive incident hemodialysis (HD) patients who started HD between 2005 and 2010. Data collection was terminated either at the 5-year observation of the study or at the time of death. Age, sex, presence of diabetes mellitus (DM), hemoglobin (Hb), serum uric acid (UA), creatinine (Cr), blood urea nitrogen (BUN),C-reactive protein (CRP), albumin (Alb),phosphate(P),albumin-adjusted calcium (Ca), phosphate,and geriatric nutritional risk index (GNRI) at the initiation of dialysis were recorded.The cumulative 5-year survival rate was estimated in the each UA quartile group. The hazard of survival rate between the each group was also evaluated by Cox regression analysis. For 5-year all-cause mortality and the lowest UA quartile (Q1≤5.9 mg/dl), risk factors including age, sex, DM, Hb, UA, Cr, BUN, CRP, Alb, Ca, P and GNRIwere assessed by univariate and multivariate logistic regression analysis.

Results: The cumulative 5-year survival rate of the patients in Q1 (45.5%) was significantly lower than those of the patients in Q2 (5.9-7.2 mg/dl, 68.3%), Q3 (7.2-8.3 mg/dl, 68.7%), and Q4 (≥8.3 mg/dl, 67.8%). Comparing with UAin Q4 as a reference group, the hazard ratio of patients with UA in Q1 was 2.3 ($p<0.01$). Age ($p<0.05$), BUN ($p<0.001$), UA ($p<0.01$), Cr ($p<0.01$) and Alb ($p<0.05$) were associated with 5-year all-cause mortality. The lowest UA quartile(QI) was significantly associated with age($P<0.01$), sex($P<0.05$), Cr ($P<0.01$), BUN ($p<0.01$), P ($P<0.01$), and GNRI ($P<0.05$) in univariate logistic regression analysis. In the multivariate model, Cr ($P<0.05$) was detected.

Conclusions: Low serum uric acid (≤5.9 mg/dl) level at the time of initiation of dialysis is a risk factor for 5-year mortality.

PUB153

Median Nerve Thickness Related to Renal Impairment in Inflammatory Arthritis
Suad Ma Hannawi,[1] Issa A.L. Salmi.[2] *[1]Internal Medicine, Ministry of Health, Dubai, United Arab Emirates; [2]Renal Medicine Dept, The Royal Hospital, Muscat, Oman.*

Background: Autoimmune processes, contribute to the burden of kidney disease. The reported kidney disease prevalence in patients with rheumatoid arthritis (RA) is 5-15%. Subclinical decreased kidney function has been identified as an independent risk factor for CV events with increase mortality in RA. On the other hand, both RA and renal impairment associated with increase prevalence of carpal tunnel syndrome. This study aims to establish the the relation of the to the median nerve thickness to the renal function in RA.

Methods: 120 RA patients recruited through a specialized rheumatology clinic. 8–16 MHz linear array transducer probe was used. The median nerve was examined at the entrance of the carpal tunnel, between the pisiform bone and the tubercle of the scaphoid bone, where the distal volar crease is an external pisiform landmark. The cross-sectional area of the median nerve was calculated directly by the software of the US equipment. Each median nerve was measured three times, and the mean value was used for further analyses. GFR calculated used DMARD formula. The average median nerve thickness was used when exploring bivariate correlations to the renal variables (Pearson's correlation coefficients). All statistics were performed using STATA program.

Results: The mean (SD) age of participants was 49 (13) years and female were 82%. The average median nerve thickness was 9.79 ±2.6 mm2 (Range 1.5 -22.25). The average GFR was 122 ± 20 ml/min(59.6-286). Thickness of the median nerve was positively associated with the age of the participants (p=0.03, CI:0 .00, 0.08), body mass index (p=0.04, CI: 0.00, 0.21), uric acid level (p= 0.033, CI:0.00, 0 .01), & urine microalbumin (p=0.04, CI 0.00, 0.01). GFR showed no significant relation to the median nerve thickness.

Conclusions: RA patients without symptoms or clinical signs have a median nerve thickness that is positively correlated to the level of microalbumin and uric acid. Whether sosnographic examination of the median nerve would be helpful in anticipating who is going to have a deteriorated renal function need to be explored in a larger study.

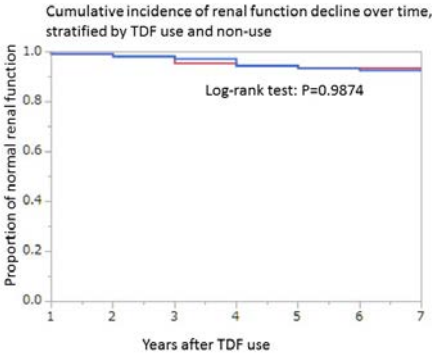
PUB154

Long-Term Exposure to Tenofovir Is Not Linked with Increased Risk of Renal Dysfunction: A Propensity Score-Matched Analysis Minoru Ando,[1,2] Kumiko Momoki,[2,3] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Dept of Medicine, Fu-chu Medical and Welfare Center, Tokyo, Japan; [2]Dept IV of Internal Medicine, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Dept of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan.*

Background: Tenofovir disoproxil fumarate (TDF) has nephrotoxicity; however, it has not been validated in the clinical setting for HIV care. A retrospective cohort study with a propensity score (PS)-matched analysis is considered comparable to randomized control trials.

Methods: A retrospective cohort study was performed in 661 HIV-infected patients receiving antiretroviral therapy from 2008 to 2014. PS matching using a multivariate logistic regression model was performed to match each TDF user with TDF non-user in a 1-to-1 fashion, and 214 patients (107 in each) were eligible for analysis. Baseline covariates that would relate significantly to the decision to use or not to use TDF were chosen in the PS scoring. A decline in eGFR was defined as an eGFR decline ≥30% from baseline. The difference in proportion of eGFR decline between the PS-matched groups was analyzed by McNemar test. A multivariate Cox proportional hazards model was constructed to calculate hazard ratio (HR) with its 95% confidence interval (CI) of TDF use for eGFR decline. Cumulative incidence of eGFR decline over time was drawn by Kaplan-Meier method.

Results: eGFR decline developed in 8 and 7 in the TDF users and the non-users, respectively; moreover, the proportions were not significantly different between the groups (7.48% versus 6.54%; p = 0.7889). The Kaplan-Meier estimates were not different between the groups .



The HR (95% CI) of TDF use was not statistically significant (HR, 0.88 [95%CI, 0.31-2.46], p = 0.8112).

Model	HR (95% CI)	P value
Unadjusted	0.87 (0.31-2.45)	0.8039
Adjusted for PS	0.88 (0.31-2.46)	0.8112

Conclusions: Long-term exposure to TDF is less likely to develop renal dysfunction.

PUB155

Dialysis Therapy and Conservative Management of Advanced Chronic Kidney Disease: A Meta-Analysis Paweena Susantitaphong,[1] Supakanya Wongrakpanich,[2] Wikrom Chaiwatcharayut,[2] Suramath Isaranuwatchai,[1] Jirat Chenbhanich,[1] Natanong Thamcharoen,[3] Kearkiat Praditpornsilpa,[1] Somchai Eiam-Ong,[1] Bertrand L. Jaber.[4] *[1]Div of Nephrology, Dept of Medicine, Chulalongkorn Univ, Thailand; [2]Einstein Medical Center, Philadelphia; [3]Dept of Medicine, Bassett Medical Center, Cooperstown; [4]Dept of Medicine, St. Elizabeth's Medical Center, Boston.*

Background: Dialysis in the elderly with advanced chronic kidney disease (CKD) and multiple co-morbidities may not be associated with improved life expectancy compared to conservative non-dialytic management.To inform clinical practice,we performed a quantitative meta-analysis of all available studies examining this question.

Methods: A systematic literature search was conducted in MEDLINE,Scopus,Cochrane,and ClinicalTrials.gov to identify cohort studies examining the association of dialysis vs.conservative management of stage5 CKD with clinical outcomes. Random-effect models were used to compute the pooled adjusted hazard ratio (HR) for all-cause mortality, and the weighted mean difference (WMD) for continuous variables.

Results: In the 11 cohort studies (11,120 patients) that were identified,patients initiating dialysis were significantly younger by approximately 7 years compared to conservative management.The mean GFR of patients initiating dialysis was 10.4 mL/min/1.73m2 (95%CI 8.4 to 12.4),which was significantly lower than those receiving conservative management (WMD-1.04 mL/min/1.73m2;95%CI-1.94 to-0.13). By meta-analysis, while dialysis was associated with a significantly lower age-adjusted risk of death compared to conservative management (age-adjusted pooled HR 0.65;95%CI 0.46 to 0.91;P=0.01), after adjustment for co-morbidities,dialysis was marginally associated with improved survival (adjusted pooled HR 0.54;95%CI 0.29 to 0.99;P=0.05).

Conclusions: Initiation of dialysis therapy in older patients with co-morbidities might not be associated with a lower adjusted mortality risk compared to conservative management. We were unable to compare the two strategies in terms of patient centered quality of life measures. Efforts must focus on promoting patient values and preferences, shared decision-making, and symptom burden alleviation.

PUB156

Prevalence of Proteinuria in Patients Requiring Hyperbaric Oxygen Therapy (HBOT) Melissa L. Swee, Douglas L. Somers. *Nephrology, Univ of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Hyperbaric Oxygen Therapy is a medical treatment using high levels of pressurized oxygen (100%) in order to treat a variety of conditions, including decompression sickness, poorly healing skin ulcers, radiation cystitis, and carbon monoxide poisoning. Despite gaining popularity in recent decades, there is little data about the effects of hyperbaric oxygen therapy on the kidneys.

Methods: Approval by the Institutional Review Board was obtained. This is a retrospective chart review investigating the degree of proteinuria on urine dipstick on all patients undergoing hyperbaric oxygen therapy at the University of Iowa from January 2010 to May 2015. Other variables that were investigated included serum creatinine, age, sex, and co-morbid medical conditions. Descriptive statistics were utilized in order to calculate the prevalence of proteinuria among these populations.

Results: The records of 326 patients were examined. In this population, 201 did not have urine dipstick performed and therefore were excluded from analysis. Among those examined, proteinuria (1+ or higher) was found in 7 of 33 patients with carbon monoxide poisoning (21%), 31 of 67 patients with non-healing soft tissue infection or osteomyelitis (46%), 9 of 33 patients with a history of cancer of the head and neck (27%), and 8 of 11 patients with radiation cystitis (73%).

Conclusions: To our knowledge, this is the largest study to date examining proteinuria in patients who are undergoing hyperbaric oxygen therapy. Our results indicate that there is a higher than expected rate of proteinuria in these patients, particularly in those with carbon monoxide poisoning and history of cancer of the head and neck. The reasons for this are unclear and require further research. A prospective study measuring proteinuria prior to and after sessions of hyperbaric oxygen therapy has been approved by the IRB at the University of Iowa and is forthcoming.

Glomerular Filtration in Patients with Advanced Chronic Kidney Disease by Berlin Study Initiative Equation Marisol Poma Tapia,[1] Fernando Tornero,[1] Jose A. Herrero,[1] Jose Maria Bautista,[1] Amir Shabaka,[1] Marta Calvo,[1] Virginia López de la Manzanara Pérez,[1] Fabio Procaccini,[1] Mauricio Alejandro Miranda Cam.[1] *[1]Nephology, Hospital Clínico San Carlos, Madrid, Spain; [2]Nephology, Hospital Clínico San Carlos, Madrid, Spain; [3]Nephology, Hospital Clínico San Carlos, Madrid, Spain.*

Background: We estimate the glomerular filtration rate (eGFR) using formula based on serum creatinine (Cockroft-Gault, MDRD and CKD-EPI). These equations are poorly developed in the elderly population. Recently described new equations specifically designed in this population as the Berlin Initiative Study (BIS 1). Our goal is to assess the difference in measured GFR by CKD-EPI and BIS1 in patients in advanced chronic kidney disease (CKD).

Methods: We studied 182 patients, 117 over 70 years old and 65 under of the advanced chronic kidney disease program with eGFR <20 ml / min according CKD-EPI equation. We compare the difference between CKD-EPI and BIS 1 equations.

Results: The mean age of patients over 70 years was 80.88 +/- 5.98 (66 males, 51 females) and under 70 was 58.84 +/- 5 (39 men, 26 women). The eGFR measured by CKD-EPI was similar in both groups (15.92 + 0.5 ml / min in patients over 70 years VS 16.2 + 0.8 ml / min in younger, p NS). However, when we use the BIS1 equation older patients have a significantly lower GFR that younger (19.6 + 0.4 ml / min vs 24.16 + 1.0 ml / min; p <0.001). When equate both equations CKD-EPI gives lower values of eGFR in 96.5% of patients with lower levels (16.03 + 0.45 ml / min vs 21.3 + 0.50 ml / min; p <0.001). If we analyze the difference between the two equations by the age we note that CKD-EPI gives lower values in patients under 70 years, being the difference between the two equations of -7.94 + 0.45 ml / min for under 70 years and -3.67 + 0.16 ml / min for over 70 years (p <0.011).

Conclusions: The eGFR by BIS1 equations in patients over 70 years old gives higher than estimated by CKD-EPI equations, although it is more correlated than younger patients. patients under 70 years, being the difference between the two equations of -7.94 + 0.45 ml / min for under 70 years and -3.67 + 0.16 ml / min for over 70 years (p <0.011).

PUB158

A Randomized Controlled Trial Comparing In-Person and Wiki-Inspired Nominal Group Techniques for Engaging Stakeholders in Chronic Kidney Disease Research Prioritization Meghan J. Elliott,[1] Sharon Straus,[1] Neesh I. Pannu,[2] Sofia B. Ahmed,[3] Helen Tam-Tham,[3] Maoliosa Donald,[3] Erin Lillie,[1] Braden J. Manns,[3] Brenda Hemmelgarn.[3] *[1]Univ of Toronto; [2]Univ of Alberta; [3]Univ of Calgary.*

Background: Few studies have evaluated stakeholder engagement in chronic kidney disease (CKD) research prioritization. In this randomized controlled trial, we sought to compare an in-person nominal group technique (NGT) approach with an online wiki-inspired alternative to determining the top 10 CKD research priorities.

Methods: Participants included adults ≥18 years with access to a computer and Internet, high health literacy, and from one of the following stakeholder groups: patients with non-dialysis CKD, their caregivers, CKD health care providers, or CKD health policymakers. 56 participants were randomized to a wiki-inspired modified NGT that occurred over 3 weeks *vs.* a one-day in-person NGT workshop, informed by James Lind Alliance methodology, to determine the top 10 CKD-related research priorities. The primary outcome was the pairwise agreement between the two groups' final top 10 ranked priorities, evaluated using Spearman's correlation coefficient. Secondary outcomes were participant engagement and satisfaction and wiki tool usability.

Results: Spearman's rho for correlation between the two lists was 0.139 (95% CI -0.543 to 0.703, p=0.71), suggesting low correlation between the top 10 lists across the two groups. Both groups ranked the same item as the top research priority, with 5 of the top 10 priorities ranked by the wiki group within the top 10 for the in-person group. In comparison to the in-person group, participants from the wiki group were less likely to report: satisfaction with the format (73.7% vs.100%, p=0.011); ability to express their views (57.9% vs 96.0%, p=0.0003); and perception of meaningful contribution (68.4% vs 84.0%, p=0.004).

Conclusions: A CKD research prioritization approach using an online wiki-like tool identified low correlation in rankings compared with an in-person approach, with less satisfaction and perceptions of engagement. Modifications to the wiki tool are required before it can be considered an alternative to an in-person workshop for engaging patients in research prioritization.

PUB159

Clinical Predictors of Maternal and Fetal Outcomes in Pregnancy of Chronic Glomerulonephritis Patients Yuehong Li, Jiaxuan Lv. *Nephrology, Beijing Tsinghua Changgung Hospital, Medical Center of Tsinghua Univ, Beijing, China.*

Background: Analysing the predictors of maternal and fetal outcomes in pregnancy of chronic glomerulonephritis (CGN) patients is helpful to acknowledge the effects of pregnancy on chronic kidney diseases. Decreased kidney function, uncontrolled hypertension and serious proteinuria are unfavorable pregnancy outcomes observed in some cohorts, but not enough studies on outcomes of pregnancies in CGN patients. The aim of the study was to define the predictors of adverse maternal and fetal outcomes in CGN patients.

Methods: Maternal and fetal outcomes in 60 pregnancies of CGN patients from Jan. 2006 to Jan. 2016 were retrospectively analyzed. Clinical manifestations, laboratory data, medication and outcomes before and during pregnancies of these patients were analyzed by univariate and logistic regression.

Results: 1. CGN patients were associated with more adverse pregnancy outcomes. The gestational ages were shorter, the incidents of preeclampsia and gestational hypertension were increased. The rates of premature delivery and low birth weights were higher. 2. Prenatal proteinuria (1.8±2.1 g/d vs 0.6±0.8 g/d, *P*=0.032) and blood pressure (11.7% vs 3.3%, *P*=0.001) significantly increased compared with pre-pregnancy stage. 3. Proteinuria ≥1.0 g/d (OR 12.22, 95%*CI* 3.16~47.32, *P*=0.001) was the predictor of adverse maternal outcomes. Blood pressure ≥140/90 mmHg (OR 8.97, 95%*CI* 1.69~47.53, *P*=0.010) and uric acid ≥363 umol/l (OR 7.35, 95%*CI* 1.88~28.76, *P*=0.004) were the predictors of adverse fetal outcomes. 4. Proteinuria of 6-months after delivery are slightly increased.

Items	Pre-pregnancy	Post-6months delivery	*P*
Proteinuria (g/d)	0.6±0.8	0.8±0.6	0.032
Plasma albumin (g/l)	36.5±4.0	37.0±4.2	0.531
Creatinine (umol/l)	67.0±7.5	70.2±7.9	0.296
Uric acid (umol/l)	313.0±86.3	316.4±89.3	0.585

Conclusions: Maternal-fetal risks are increased in pregnancies of CGN patients. Proteinuria ≥1.0 g/d is the predictor of adverse maternal outcomes. Blood pressure ≥140/90 mmHg and uric acid ≥363 umol/l are the predictors of adverse fetal outcomes.

PUB160

Specialists' Perspectives on the Management of Patients with Systemic Lupus Erythematosus: A Mixed-Methods Study David J. Tunnicliffe,[1,2] Davinder Singh-Grewal,[1] Jonathan C. Craig,[1,2] Shilpa Jesudason,[4] Daniel Sumpton,[1,2] Allison Tong.[1,2] *[1]Univ of Sydney; [2]Centre for Kidney Research, Children's Hospital at Westmead; [3]Central and Northern Adelaide Renal and Transplantation Service, Royal Adelaide Hospital.*

Background: Different specialists are involved in the management of patients with systemic lupus erythematosus (SLE) but unwarranted variation in practice remains unexplored. We aimed to describe specialists' attitudes and perspectives on the management of SLE.

Methods: Immunologists, nephrologists and rheumatologists (n=43) caring for adult patients with SLE in Australia completed a face-to-face semi-structured interview and seven clinical vignettes on the management of lupus nephritis. Descriptive statistics were calculated for responses to vignettes and qualitative data were analyzed thematically.

Results: Nephrologists were less likely to report the use of mycophenolate mofetil in the management of class II lupus nephritis, while there was no difference in the use of hydroxychloroquine. Five themes underpinned management of SLE: safeguarding patient priorities (emphasizing patient goals, protecting fertility, preventing cosmetic side-effects, maximizing adherence); persisting through ambiguity (uncertainty in etiology, inapplicable evidence, comprehending information dispersion); fundamental instincts and habits (learnt familiarity, empathy for the vulnerable); defining responsibility (core educator role, retaining disease control, avoiding severe outcomes, maintaining versatility of skills, protecting specialists' interests); and optimizing nuances of the health system (capitalizing on multi-disciplinary care, accessing effective therapies, improving specialists decisional-confidence).

Conclusions: Clinicians aim to achieve optimal outcomes for patients with SLE, but specialists often felt constrained by an unclear understanding of SLE, poor-quality evidence, and competing priorities to standardize practice. In order to help guide decisions and help eliminate unwarranted variation in practice, we recommend that future collaborative multidisciplinary efforts be undertaken to ensure improved models of shared care across specialties, and a clear direction for future research.

PUB161

Healthcare and Research Priorities of Adolescents and Young Adults with Systemic Lupus Erythematosus - A Mixed-Methods Study David J. Tunnicliffe,[1,2] Davinder Singh-Grewal,[1,3,4] Jonathan C. Craig,[1,2] Martin Howell,[1,2] Ming-Wei Lin,[5] Angelique F. Ralph,[1,2] Allison Tong.[1,2] *[1]Univ of Sydney; [2]Centre for Kidney Research, Children's Hospital at Westmead; [3]Dept of Rheumatology, Sydney Children's Hospital Network; [4]Faculty of Medicine, Univ of New South Wales; [5]Dept of Immunology, Westmead Hospital.*

Background: The care of adolescents and young adults with systemic lupus erythematosus (SLE) is particularly challenging. The disease may be severe, adolescent patients have complex medical and psycho-social needs, and they must navigate the transition to adult services. To inform patient-centered care, we aimed to identify the healthcare and research priorities of adolescents and young adults with SLE and describe the reasons underpinning their priorities.

Methods: Face-to-face, semi-structured interviews and focus groups were conducted with patients with SLE, aged from 14 to 30 years, from five centers in Australia. In five allocation exercises, participants allocated ten tokens (i.e. votes) to 1) research topics (medical management, prevention and diagnosis, lifestyle and psychosocial), 2-4) research questions associated with research topics, and 5) healthcare specialties, and discussed the reasons for their choices. Descriptive statistics were calculated for votes and qualitative data was analyzed thematically.

Results: From the 26 participants, there was an undifferentiated allocation of votes to research topics and associated research questions. They allocated their votes towards medical and mental health specialties in the management of SLE, whilst fewer votes were given to allied health. Seven themes underpinned participants' priorities: improving service shortfalls, strengthening well-being, ensuring cost efficiency, minimizing family/community burden, severity of comorbidity or complications, reducing lifestyle disruption, and fulfilling future goals.

Conclusions: Young patients with SLE value comprehensive care, in particular rheumatology, nephrology, and mental health. Research on improving psychological health and self-management of symptoms may improve treatment satisfaction and health outcomes for adolescents and young adults with SLE.

PUB162

Impact of an On-Line Course for Primary Health Care Physicians on Patients at Risk for Chronic Kidney Disease (CKD) Maria Alejandra Guzman,[1,2] Alfonso M. Cueto-Manzano,[1] Cristina Chavez,[3] Hector Martinez Ramirez,[1] Jorge Lopez-Leal,[1] Roxana Marquez-Herrera,[1] Norma Palacios,[3] Enrique Rojas-Campos.[1] *[1]Unidad Investigación Médica en Enfermedades Renales, HE-CMNO IMSS, Guadalajara, Mexico; [2]ISN-Fellowship Program, ISN; [3]Coordinación Nacional de Educación en Salud, IMSS, DF, Mexico.*

Background: On-site education increases clinical competence of family physicians (FP) and preserves renal function of early CKD patients; on-line learning might have higher impact, however, this has not been probed. Aim: to assess the impact of an on-line course for FP on patients at risk for CKD.

Methods: Fifty FP from 2 Family Medicine Units were registered in an on-line course implemented during Aug-Oct/2015. One-hundred forty-seven patients attended by those FP registered, with diagnosis of diabetes mellitus and/or hypertension, were retrospectively studied (from medical charts). Patients were divided in 2 groups: those whose physician approved the course (G1), and those whose physician did not approve (G2).

Results: Main results are shown in Table.

	G1(n60)		G2(n87)	
Variable	**Baseline**	**Final**	**Baseline**	**Final**
FP Advice to improve				
Diet(%)	37	58*	58**	68
Physical activity(%)	32	52*	41	49
Emotion management(%)	8	33*	20	21
Referral to dietitian(%)	10	17	7	18*
Referral to self-help group(%)	3	10	7	16
Creatinine request(%)	50	60	37	31**
GFR estimation(%)	27	40	11	11**
Urinalysis request(%)	33	35	10	24**
Clinical-Biochemical				
Systolic blood pressure(mmHg)	126±13	123±12*	123±13	122±11
Diastolic blood pressure(mmHg)	76±8	75±8	77±8	76±7
Creatinine(mg/dL)	0.9(0.7-1)	0.8 (0.7-1)*	0.9(0.7-1)	0.8(0.7-1)
Glucose(mg/dL)	130±40	120±41*	124±44	123±61
eTFG(mL/min/m^2)	79(68-95)	74(62-91)*	82(75-97)	86(63-107)
*p<0.05 vs baseline same group;**p<0.05 vs group 1 same evaluation				

Conclusions: FP who successfully completed the on-line course significantly increased advice to patients to improve diet, physical activity, emotional management, levels of systolic blood pressure and glucose. Although kidney function remained clinically stable in both groups, FP who successfully completed the course tended to request serum creatinine and estimate GFR more frequently than the others.

PUB163

Impact of an On-Line Course about Prevention, Diagnosis and Tratment of Early Chronic Kidney Disease (CKD) in the Primary Health-Care
Maria Alejandra Guzman,[1,2] Alfonso M. Cueto-Manzano,[1] Cristina Chavez,[3] Hector Martinez Ramirez,[1] Jorge Lopez-Leal,[1] Roxana Marquez-Herrera,[1] Norma Palacios,[3] Enrique Rojas-Campos.[1] *[1]Unidad Investigación Médica en Enfermedades Renales, HE-CMNO IMSS, Guadalajara, Mexico; [2]ISN Felloship Program, ISN; [3]Coordinación Nacional de Educación en Salud, IMSS, DF, Mexico.*

Background: The Mexican Institute of Social Security (IMSS) is the major health care provider. On-site education increases clinical competence of family physicians (FP) and preserves better renal function of early CKD patients; on-line learning might have higher impact, however, this has not been probed. Aim: to report the experience in implementing an on-line course on early CKD in primary health care.

Methods: An on-line course was developed in collaboration with IMSS Educational Experts. It was focused on early CKD, containing 5 units: General Aspects, Prevention, Diagnosis, Treatment, and Follow-up/Referral to Nephrologist. Each unit contained relevant information, clinical cases, homework, summary, and final test; all the latter, together with a final course evaluation, had to be approved to obtain credits. The course was implemented in Aug-Oct/2015.

Results: One-hundred eight FP from 3 Family Medicine Units (FMU No. 53, 78, and 171) of Guadalajara city, were initially registered; roughly, one third of physicians belonged to each FMU. Forty-four FP never started (terminal efficiency 58%), half of them were male, and their age was 45±9 yrs. At the end of Unit 1, 14 FP dropped out (70%), 2 (10%) at the end of Unit 2, 3 (15%) at Unit 3, and 1 (5%) at Unit 5; 43% were male and age was 45±8 yrs. Forty-four FP completed the course, and all of them finally approved it (modified terminal efficiency 100%); these latter subjects were younger 43±8 yrs (p=0.008), and tended (NS) to have more men (68%) in the group than those who did not approved.

Conclusions: An on-line course about early CKD was successfully developed and applied in FP of the primary health-care. A significant proportion of physicians dropped out before starting; however, those physicians who remained finally approved the course. Terminal efficiency was adequate; however, it is needed to implement strategies to increase it in order to improve tools against kidney disease.

CKD.QLD: Management of Chronic Kidney Disease through Tele-Health in Queensland, Australia
Sree Krishna Venuthurupalli,[1,2,3] Andrea Rolfe,[3] Anne Cameron (Salisbury),[1,2] Zaimin Wang,[1,2] Wendy E. Hoy.[1,2] *[1]NHMRC CKD CRE and CKD.QLD, Brisbane, Queensland, Australia; [2]School of Medicine, Univ of Queensland, Brisbane, Queensland, Australia; [3]Renal Services, Darling Downs Hospital and Health Service, Toowoomba, Queensland, Australia.*

Background: In some areas of Australia, access to specialists is limited by geographical location and resources. We explored a Tele-heath program for management of chronic kidney disease (CKD) patients in rural, regional and remote Queensland.

Methods: Patients were among those attending renal clinics in Toowoomba Hospital, but living at some distance. Their first review was at Toowoomba Hospital to ascertain their clinical profile and to discuss the process. Tele-health clinics in Kingaroy & Cherbourg were coordinated by the renal nurse practitioner. Other hospital locations were managed by local nursing personal. At each clinic the patients' health records and relevant investigations are assembled in advance. Consultations are conducted through Queensland Health (QH) facilities.

Results: 151 patients were seen between November 2011 and May 2016, with over 400 consultations. Total distance traveled by all patients to specialist clinics at Toowoomba for their first consultation was 55,619 kilometers (range 63.5 to 672). Mean age was 64.0 (SD13.9) years, median 67 yr, and 48.3% were males. A quarter (27.8%) were Aboriginal. Major risk factors include hypertension (94%), smoking (current or former) (64.2%), diabetes (58.2%) and obesity (58.2%). Diabetic nephropathy (40.7%) was the dominant cause for CKD followed by renovascular (18.5%) and glomerular disease (9.9%) There were 4 transplant patients. Co-morbidities included coronary artery disease (30.4%), chronic lung disease (19.2%), cerebrovascular (15.8%) and peripheral vascular disease (9.9%). On follow up 21 (13.9%) have died without dialysis and 4 (2.6%) started planned RRT. About half of patients who died were identified for conservative therapy.

Conclusions: CKD patients from regional and remote areas have multiple risk factors and co-morbidities. They can be managed successfully by Tele-health with significant savings in distance traveled and resources utilized.

PUB165

Knowledge, Attitude and Practices of Immediate Blood Relatives/ Spouse(s) of Patients with End Stage Renal Disease Toward Organ Donation
Chander Shekher Aggarwal, Om Prakash Kalra, Alpana Raizada, Anil Kumar Yadav, Sunil Agrawal. *General Medicine, Univ College of Medical Sciences, Delhi, India.*

Background: A strong relationship between knowledge and organ donation has already been established. Despite the various available options of Renal Replacement Therapy (RRT), majority of the patients with End Stage Renal Disease (ESRD) do not receive any RRT.In the absence of a well-organized deceased donor program, living donors constitute the major donor source.With this premise, a cross sectional study was done to assess the knowledge, attitude and practices (KAP) in immediate blood relatives and spouse(s) of ESRD patients and to assess the factors influencing KAP.

Methods: 379 subjects from attendants of 238 ESRD patients were administered a pre-tested questionnaire. All consenting attendants (aged 18 years and above) of CKD stage 5 ESRD patients were included. Assessment of factors influencing the KAP was done using Pearson Chi-Square test.

Results: 91.8% attendants had heard about organ donation. 67.5% had knowledge about organ donation which was significantly associated with the relationship with patient [spouse (p=.001), son (p=.005)], education status [graduates and above (p=.001)] and higher socioeconomic status (p=.004). 50.6% had positive attitude towards organ donation which was significantly associated with gender [females (p=.002)], relationship with the patient [mother (p=.0254), spouse (p=.001), son (p=0.02)] and the number of dependants [6-8 (p=.04)]. 41.2% subjects had positive attitude towards practicing organ donation which was significantly associated with marital status [Single (p=.04)-more motivated], education status [graduates and above (p=.001)].

Conclusions: More knowledge about organ transplantation can be transformed into better attitude which can lead to increased number of organ donations. More and more people should be educated and made aware of the importance of organ donation.

PUB166

Patient Partnership as the Core of a National Patient-Oriented Kidney Research Network: Can-SOLVE CKD
Helen Chiu,[1,3] Mila Tang,[1] Heather A. Harris,[1] Adeera Levin,[2,3] Braden J. Manns.[4] *[1]PHCRI; [2]Dept of Medicine, UBC; [3]BC Renal Agency, BC; [4]Dept of Medicine & Community Health Sciences, U of Calgary, AB, Canada.*

Background: Patient-oriented research (POR) focuses on priorities that matter to patients, seeking to engage them throughout the research process, and to generate results that can rapidly advance improvements in health and care. The Canadians Seeking Solutions and Innovations to Overcome (Can-SOLVE) CKD Initiative embraces a national partnership strategy with patients across Canada to transform kidney research and care.

Methods: The James Lind Alliance method was adopted to discern top research priorities with patients and families with CKD. Patient partners, researchers and policy-makers developed in workshops research proposals and various components in Can-SOLVE CKD. A national Patient Council was formed to lead all aspects of Can-SOLVE CKD. The extent and impact of patient engagement is continually assessed with surveys and testimonials.

Results: The priority-setting workshops identified research questions for early and advanced CKD, resulting in a 3-themed research program in Can-SOLVE CKD (early identification, access to novel therapies, and models of care). A diversely representative Patient Council of >30 members is a key strength, secured federal funding support and has become the core driver of the research agenda. Quantitative and qualitative survey results demonstrated that the patient partners are highly engaged and appreciative of having a voice in research, along with concrete insights on needs for training and other supports for effective partnership in research. In their qualitative feedback, patient partners expressed that they were empowered in their involvement, while allowing peer support and giving back.

Conclusions: Patients are making a unique and important contribution to Can-SOLVE CKD. They are critical partners in kidney research, and feel a sense of hope in the partnership in transforming kidney care and therapy. Meaningful engagement with patients enables a new era in kidney research to co-create better kidney health and care with researchers and policy-makers across Canada.

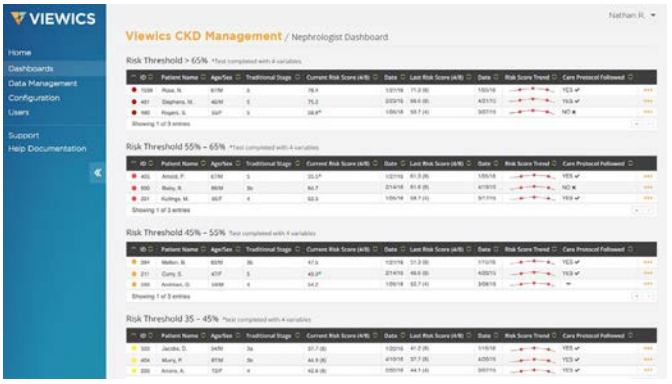
PUB167

Development of an Automated CKD Risk Management System
Navdeep Tangri,[1] Eleanor Herriman.[2] *[1]Medicine, Seven Oaks Hospital, Winnipeg, MB, Canada; [2]Viewics Inc., Sunnyvale, CA.*

Background: CKD is managed according to eGFR based stages rather than risk of progression, resulting in variable and suboptimal care. Here we describe the development of an automated system that actualizes the highly accurate Kidney Failure Risk Equation (KFRE) via a practical, automated clinical solution.

Methods: We defined a four-step protocol based on the KFRE that recommends referral to nephrologist, multidisciplinary care enrollment, dialysis discussion and education and fistula placement at specific risk thresholds. Utilizing the Viewics platform (Figure 1), we automated the input of patient's lab results and demographic information and calculation of the KFRE algorithm. A series of dashboards was created to enable primary care and nephrologist clinicians, as well as program managers to track patient

results, protocol recommendations, and required actions. Finally, custom patient education reports were automatically created, which detail individual risk of renal failure and care recommendations, designed to reduce anxiety and better engage patients in their care.



Results: Our solution is a cloud-based, HIPAA compliant, end-to-end program which readies the risk score prediction for clinical adoption and improved CKD management. It comprises a lab and EMR integration platform, personalized risk prediction for renal failure, automated and integrated care management recommendations for primary care physicians and nephrologists, and customized patient education reports.

Conclusions: This program accurately predicts the risk of progression from CKD to ESRD for at least five years, and its integration into practice allows for more appropriate care and improved outcomes. Total annual cost savings to an ACO with a population of 25,000 covered lives was estimated at $2 million as a result of delaying stage 3 progression, reclassifying stage 4s, and providing earlier nephrologist care for patients with a high risk of progression.

PUB168

Incidence of Cisplatin-Induced Nephrotoxicity among Patients Using Saline Hydration, Potassium Chloride, Magnesium Sulfate and Mannitol

Kristine Tan Gapuz, Maria Kristina Alolod. *Dept of Medicine, Section of Nephrology, St. Luke's Medical Center, Quezon City, Metro Manila, Philippines.*

Background: Cisplatin is the standard drug for treating solid-organ malignancy however, can cause tubular toxicity, decrease in GFR, and increase creatinine causing AKI, interstitial injury and probably CKD. To prevent nephrotoxicity that can lead to CKD, maintenance of adequate hydration and replacement of electrolytes are necessary but no standardized hydration protocols available. Determination of the incidence of cisplatin-induced nephrotoxicity using isotonic saline, KCl, $MgSO_4$ and mannitol can help improve the hydration regimen for the prevention of nephrotoxicity.

Methods: A retrospective study evaluating the incidence of nephrotoxicity among patients using cisplatin-based chemotherapy hydrated with isotonic saline, KCl, $MgSO_4$, and mannitol from January 2011-2015. Estimated GFR was calculated using CKD-EPI. Nephrotoxicity is defined as lower GFR, higher creatinine, and reduced magnesium and potassium levels. Descriptive statistics were done. Any associated p-values <0.05 will be considered statistically significant.

Results: Total of 53 patients were analyzed which showed an increasing trend in creatinine and decreasing trend in eGFR until 3 months after chemotherapy. The baseline creatinine, eGFR, and serum electrolytes compared with the results 3 months post-chemotherapy were found to be significantly different.

	Chemotherapy Cycle (n=53)		
	Baseline	3 months post	p-Value
Creatinine (mg/dl)	0.9 (0.57-1.54)	1.07 (0.55-1.78)	**0.0000***
Sodium (mmol/L)	136 (127-143)	135 (114-142)	**0.0000***
Potassium (mmol/L)	4 (2.8-5.1)	3.80 (2.9-4.8)	**0.0008***
Magnesium (mg/dL)	2.1 (1.4-2.5)	1.7 (1.1-2.4)	**0.0000***
Ionized Calcium (mg/dL)	1.19 (0.95-1.37)	1.15 (0.89-1.39)	**0.0076***

The incidence of decreased renal function after 3 months from the last chemotherapeutic cycle was 33% (n=18).

Conclusions: Despite judicious hydration, Cisplatin therapy may induce permanent nephrotoxicity with an incidence of 33% three months after 3 chemotherapeutic cycles. Cisplatin induces nephrotoxicity as evidenced by electrolyte imbalance, increased mean serum creatinine and decreased estimated GFR.

PUB169

Urinary Procollagen Type-III Amino Terminal Propeptide (PIIINP) Predicts End Stage Kidney Disease (ESKD) and All-Cause Death in Non-Dialysis CKD Patients

Hiroaki Yonishi,[1] Akira Suzuki,[1] Shihomi Maeda,[1] Aiko Kugimiya,[1] Eriko Iwahashi,[1] Kenji Yokoyama,[1] Terumasa Hayashi.[2] *[1]Internal Medicine, Japan Community Health Care Organization Osaka Hospital, Osaka, Japan; [2]Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan.*

Background: Tubulointerstitial fibrosis is the final common pathway to ESKD. Since urinary PIIINP is correlated significantly with the severity of fibrosis in renal biopsy, it could be a marker of progressive kidney diseases. Recent cross-sectional study demonstrated that the urinary PIIINP was correlated with the progression of CKD in the community based population. In this prospective study, we investigated whether urinary PIIINP was associated with renal outcome and mortality in pre-dialysis advanced CKD patients.

Methods: A total of 132 CKD patients were recruited from January 2011 to December 2014. Patients with liver disease, lung fibrosis, and malignancies were excluded. Urinary PIIINP was measured using the radioimmunoassay at baseline. Multivariate Cox regression analysis and log-rank test were adopted using urinary PIIINP/Cr as the explanatory variable and initiation of RRT and all-cause death as the primary composite endpoint.

Results: The study population included 71, 51, and 10 patients with CKD stage 3, 4, and 5, respectively. The mean age of the overall patients were 68 years and 70.5% were male sex. Forty-four patients (33.3%) had diabetes. A total of 14 patients (11%) started RRT and 8 patients died during the follow-up period (mean, 40.1 months) The patients were stratified into two groups based on the cut-off value of urinary PIIINP/Cr determined by the ROC analysis. The Kaplan-Meier survival curves showed that the patients' group with higher urinary PIIINP had significantly poorer outcomes ($p = 0.000$). Furthermore, multivariate Cox regression analysis revealed that higher urinary PIIINP wassignificantly associated with increased risk of RRT and all-cause death adjusted for the age, gender, the etiology of diabetes, blood pressure, eGFR, and urinary protein. (HR; 3.177, 95%CI; 1.018–9.915, $p = 0.046$).

Conclusions: Urinary PIIINP in pre-dialysis and anvanced CKD patients might be a novel prognostic marker for ESKD and all-cause death.

PUB170

Neck Circumference Predicts Renal Function Decline in Overweight Men and Women: A Community-Based Prospective Cohort Study

Youn Kyung Kee, Chang-Yun Yoon, Changhwan Seo, Hae-Ryong Yun, Dae-Suk Han. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Upper body subcutaneous fat, commonly estimated by neck circumference (NC), has recently been noticed as the main determinant of systemic free fatty acid concentrations in overweight patients. Therefore, the association between upper body subcutaneous fat, represented by NC, and incident chronic kidney disease (CKD) was explored.

Methods: The data was retrieved from the Korean Genome and Epidemiology Study (KoGES) cohort. Overweight was defined as body mass index ≥ 23 kg/m^2, and subjects were followed at a 2-year interval from 2003 to 2012. Incident CKD was defined as the composites of estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2 or development of proteinuria. A total of 35,709 cohort subjects were screened. After exclusion, 2,268 overweight subjects were eligible for final analysis.

Results: The mean age was 36.3±3.0 years, and 1,285 patients (56.7%) were male. The subjects were divided into two groups according to the median value of NC in male and female subjects, respectively. High NC showed significantly high prevalence of hypertension (male, P<0.001; female, P=0.009) and diabetes (male, P=0.002; female, P<0.001), while eGFR was significantly low only in male subjects with high NC (male, P<0.001; female, P=0.167). In multiple Cox analysis, higher NC values were independently associated with incident CKD development in female subject after adjusting for multiple confounding factors [NC, 1 cm increase, male; hazard ratio (95% confidence interval)=0.989 (0.89-1.10), P=0.841, female; 1.159 (1.02-1.31), P=0.019]. However, a significant relationship was not found in male subjects.

Conclusions: NC is independently associated with the incidence of CKD in overweight female subjects. Upper body subcutaneous fat, chiefly represented by NC, could be considered as a practical risk factor for CKD.

PUB171

Early Emergence of Proteinuria Portends Subsequenct Development of Kidney Function Decline or Nephrotic Syndrome after Stem Cell Transplantation

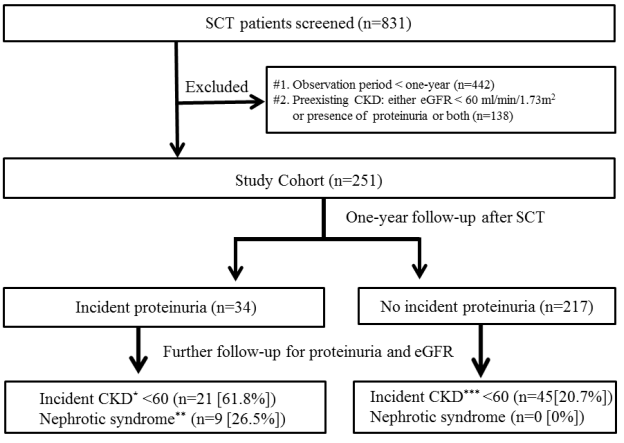
Kumiko Momoki,[1,2] Minoru Ando,[2,3] Masaki Hara,[1,2] Akihito Ohta,[1] Masamitsu Ubukata,[1,2] Kosaku Nitta.[2] *[1]Div of Nephrology, Dept of Medicine, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Tokyo, Japan; [2]Dept IV of Internal Medicine, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan; [3]Dept of Medicine, Tokyo Metropolitan Fu-chu Medical and Welfare Center, Fu-chu-shi, Tokyo, Japan.*

Background: Stem cell transplantation (SCT) places a heavy burden on the kidneys. New proteinuria after SCT may portend the subsequent development of kidney insults.

Methods: A total of 831 patients who received allogeneic SCT between August 2004 and July 2015 were surveyed. Excluding those with prior kidney disease and those who were not followed over one year, 251 were eligible for the study. A historical cohort study was

performed. Dipstick proteinuria ≥1+ within one year after SCT with persistence at least for 3 months was defined as 'incident proteinuria', and subsequent persistence of an eGFR of < 60 mL/min/1.73m^2 for 3 months or longer was defined as 'incident CKD'. Additionally, kidney-biopsied tissue was investigated in all patients who developed nephrotic syndrome.

Results: The mean duration of follow-up was 3.4 (1.7-5.7) years [median (interquartile range)], and 34 patients (13.5%) developed incident proteinuria. Sixty-six of 251 (26.3%) developed incident CKD, and 9 (3.6%) developed nephrotic syndrome due to membranous nephropathy in 8 (89%) or minimal change disease in one (11%). The incidence of such kidney disease was extremely greater in patients with incident proteinuria than those without (61.8% vs 20.7% in incident CKD, and 26.5% vs 0% in nephrotic syndrome).



Figure

Conclusions: SCT patients who manifest incident proteinuria are more predisposed to incident CKD or nephrotic syndrome thereafter. Dipstick urinary protein test is a simple measure to predict the ensuing emergence of kidney disease that should be treated by nephrologists.

PUB172

Accumulation of Proatherogenic Metabolite Trimethylamine-N-Oxide and Gut Microbiome in Patients with Type 2 Diabetes Mellitus and Chronic Kidney Disease Tetyana L. Vasylyeva, Ruchi Singh, Palika Datta, Kathleen A. Rewers-Felkins, Mohammed A. Al-Obaide. *Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

Background: Increased trimethylamine N-oxide (TMAO) levels have been causally linked with chronic kidney disease (CDK) progression and cardio-vascular disease development. TMAO is produced in liver from gut microbial product trimethylamine (TMA). Our previous data showed significant gut microbial dysbiosis in patients with T2DM and advance CKD (stages 4-5) secondary to diabetic nephropathy. We hypothesized that TMAO levels in patients with T2DM and CKD are influenced by gut microbiome and FMO3 gene expression.

Methods: Twenty T2DM CKD 4-5 (not on dialysis) patients and 20 healthy adults with no significant medical issues and normal renal function were recruited. Age, gender, and dietary habits were recorded. High throughput sequencing method (the bacterial 16S rRNA) was used to study gut microbiome. TMAO concentrations were quantified by MS and analyzed by the two-samples t-test. FMO3 transcript expressions were extracted from FANTOM 5 database.

Results: The ratio of the phyla Firmicutes to Bacteroidetes were significantly increased in the CKD group compared to the healthy group ($p < 0.001$). Firmicutes represented by abundance of TMAO producing bacteria and Bacteroidetes were inversely associated with TMA and TMAO levels. TMAO level in T2DM patients was 2.7 ±1.46 µg/ml compared to 0.43± 0.20 µg/ml in healthy subjects ($p < 0.001$). FANTOM 5 database showed one of FMO3 promoters is most active in liver, whereas other promoters showed low activity or were inactive.

Conclusions: The elevated level of TMAO in T2DM CKD patients is associated with increased number of TMA producing bacteria in addition to poor renal clearance. Restoration of normal gut microbiome and control of FMO3 expression could significantly modulate thisproatherogenic metabolite.

PUB173

Risk Factors for Sleep-Disordered Breathing in Chronic Kidney Disease Mari Okada, Takahiro Masuda, Atsushi Miki, Takuya Miki, Erika Hishida, Marina Kohara, Takuya Murakami, Tomoyuki Yamazaki, Taro Sugase, Yuko Watanabe, Takahisa Kobayashi, Tetsu Akimoto, Shigeaki Muto, Daisuke Nagata. *Div of Nephrology, Dept of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.*

Background: Sleep-disordered breathing (SDB) in chronic kidney disease (CKD) predicts the progression of CKD, cardiovascular events and mortality (Sakaguchi et al. CJASN 2013; Masuda et al. NDT 2011). However, the risk factors associated with SDB in CKD patients remains unclear.

Methods: Fifty CKD patients who have not yet received dialysis were enrolled in this study. Overnight pulse oximetry was performed to diagnose SDB. Patients were divided into two groups according to 3% oxygen desaturation index (3%ODI) by pulse oximetry: normal (3%ODI<5 events/h) and SDB (5 events/h≤3%ODI). We examined predictors of SDB using multivariable logistic regression analysis.

Results: Average age was 49.8±16.5 years, male was 46.0%, body mass index (BMI) was 25.4±5.9kg/m^2 and estimated glomerular filtration rate (eGFR) was 55.9±4.8 mL/min/1.73m^2. Average 3%ODI was 12.2±16.2 events/h and twenty-nine patients (5≤3%ODI<15 events/h, 15 patients; 15 events/h≤3%ODI, 14 patients) were diagnosed as SDB. Age (normal 41.5±15.2 vs SDB 55.7±14.9* years, *P<0.05), BMI (22.3±3.9 vs 27.7±6.1* kg/m^2), systolic blood pressure (122±4 vs 135±4* mmHg) and urine protein (1.2±1.2 vs 2.8±3.4* g/day) were higher, and eGFR (72.3±6.9 vs 49.4±5.7* mL/min/1.73m^2), serum albumin (3.6±0.7 vs 3.1±0.9* g/dL), serum calcium (Ca) (9.2±0.4 vs 8.8±0.8* g/dL) and urine Ca (81±62 vs 49±45* mg/day) were lower in the SDB group than those in the normal group. Multivariate logistic regression analysis including age, gender, BMI, systolic blood pressure, eGFR, serum albumin, serum Ca, urine protein and urine Ca showed that BMI (odd ratio [OR] 1.85: 95% confidence interval [CI]: 1.20–3.69, P=0.003) and systolic blood pressure (OR 1.11: 95% CI: 1.02–1.28, P=0.009) are independently associated with SDB.

Conclusions: These results suggest that high blood pressure and BMI are risk factors for SDB in CKD.

PUB174

Blockade of P2X7 Receptor Is Protective in the Adriamycin Model of Chronic Kidney Disease Yuan Min Wang,[1] Geoff Yu Zhang,[1] Andrew Sawyer,[1] Jianheng Zhou,[1] Min Hu,[2] Guoping Zheng,[2] Qi Cao,[2] Yiping Wang,[2] Simon C. Robson,[3] David C. Harris,[2] Stephen I. Alexander.[1] *[1]Centre for Kidney Research, The Children's Hospital at Westmead; The Univ of Sydney, Sydney, NSW, Australia; [2]Centre for Transplantation and Renal Research, Univ of Sydney, Westmead Inst of Medical Research, Sydney, NSW, Australia; [3]Transplant Inst, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.*

Background: Extracellular purines have both protective and damaging effects on the immune system and on the kidney. ATP is released from injured tissues through its major receptor P2X7 (P2X7R) to induce inflammation and release pro-inflammatory cytokines, such as interleukin-1β. Extracellular ATP and P2X7 appear to be involved in early stages of damage in nephritis. A804598 (A8) is a potent competitive P2X7R antagonist. Blockade of P2X7 by A8 could potentially limit kidney injury. The aim of the study is to evaluate the role of extracellular ATP and P2X7R in Adriamycin Nephropathy (AN, a toxin-induced model of proteinuric kidney disease) by increasing extracellular ATP or blockade of P2X7R.

Methods: AN was induced with Adriamycin (ADR) in three groups: ADR, ADR+A8, ADR+ATP and a normal control group. ATP or A8 was injected prior to and 24 hours after ADR injection, followed by a further 4 weekly injections. Four weeks after AN induction, renal function and histology were assessed. Serum cytokines were measured using Cytometric Bead Array (CBA) and apoptosis was assessed by TUNEL assay in primary tubular cells.

Results: Mice receiving P2X7R antagonist A8 had significantly less kidney injury with reduced proteinuria and serum creatinine, less glomerulosclerosis and tubular damage than mice receiving ATP or ADR alone. *In vitro* TUNEL assay showed direct pro-apoptotic effects of ATP on renal tubular cells with apoptosis peaking at 2 hours with 3mM ATP. There was significantly less apoptosis in tubular cells exposed to P2X7R antagonist A8 after ATP treatment.

Conclusions: P2X7R blockade protects against kidney injury through inhibition of tubular cell damage by ATP in Adriamycin Nephropathy.

PUB175

High-Intensity Exercise Did Not Adversely Affect the Renal Function or Proteinuria in Stable Patients with IgA Nephropathy after the Initial Treatment Tatsuyuki Inoue, Hitoshi Sugiyama, Masashi Kitagawa, Jun Wada. *Dept of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama Univ, Okayama, Japan.*

Background: IgA nephropathy (IgAN) often occurs in young adults. In IgAN, proteinuria and hypertension are the main risk factors for end-stage kidney disease and can be caused by lifestyle-related diseases. Although patients with stable IgAN are generally young or middle-aged with a high level of daily activities, the actual lifestyle of these patients has not been explored, particularly with respect to their exercise regimen.

Methods: We surveyed the outpatients with IgAN at Okayama University Hospital via a questionnaire about their lifestyle. The degree of exercise was evaluated using the method of the Washington University and divided into five categories. We also investigated the kind of each exercise and further analyzed the relationships between the subjects' lifestyle and data extracted from the medical record. The severity of IgAN was determined by the Japanese clinical and histological grading system.

Results: We obtained valid responses from 81 patients, including 57 with stable IgAN who were not taking corticosteroids. Males accounted for 46% if the subjects, the mean age was 43.7 years old, the mean estimated glomerular filtration rate (eGFR) was 68.7 ml/min/1.73 m^2, and the mean daily protein excretion was 0.28 g/gCr. 91% practiced some form of diet therapy, usually salt restriction (79%). Most (54%) engaged in moderate exercise (category 4). A significantly positive correlation was noted between daily proteinuria at diagnosis and exercise intensity ($r^2 = 0.18$, $p = 0.01$). However, this correlation had disappeared at the final observation. We did not observe any relationships

between exercise intensity and daily proteinuria, change in the protein excretion, or the eGFR at the final observation. Some (34%) felt that their quality of life had been increased by the improvement in their diet after the diagnosis.

Conclusions: This study showed that stable IgAN patients are conscious of their risk of developing lifestyle-related diseases. High-intensity exercise during the period when initial treatments for IgAN are essential did not appear to affect patients with stable IgAN adversely.

PUB176

Apparent Disparity between Renal Cortical Blood Flow and Oxygenation in Diabetic Nephropathy as Evaluated by Magnetic Resonance Imaging

Pottumarthi V. Prasad,[1] Luping Li,[1] Jon Thacker,[1] Ying Zhou,[1] Orly F. Kohn,[2] Stuart M. Sprague.[1] *[1]NorthShore Univ HealthSystem, Evanston, IL; [2]Univ of Chicago, Chicago, IL.*

Background: A role for hypoxia in the progression of chronic kidney disease (CKD) has gained attention mostly based on pre-clinical data [PMID: 9551436]. Translation to humans has been challenging due to the lack of accepted markers of hypoxia in humans. Blood oxygenation level dependent (BOLD) MRI is the only known non-invasive method currently available to evaluate relative oxygenation status of the kidney. Chronic hypoxia theory also suggests the cause for the increased hypoxia is due to loss of peri-tubular capillaries. Arterial spin labeling (ASL) based renal perfusion MRI has shown reduced blood flow in CKD [PMID: 23447145].

Methods: A group of subjects with diabetes and stage 3 CKD (n=32; eGFR=50.9 ml/min/1.73 m^2) participated. Subjects were instructed not to take NSAIDs for 3 days and ACEi/ARB 1 day prior to MRI. For reference, similar data was acquired in a group of healthy subjects (n=29; eGFR=99.3 ml/min/1.73 m^2). Both groups were instructed to fast after midnight on the day of the MRI and take half the dose of insulin if applicable. BOLD and ASL perfusion MRI data was acquired on 3.0 T scanner. Reduced blood oxygenation should result in increased R2*.

Results: While cortical blood flow showed significant reduction in CKD compared to control (115.0±36.2 *vs.* 206.3±44.0, $p<0.0001$) and a significant correlation with eGFR ($\rho=0.68$, $p<0.0001$), cortical R2* did not change (18.9±2.4 vs. 18.0±1.6, $p=0.09$; $\rho=-0.26$, $p=0.05$). Since age was significantly correlated with eGFR ($\rho=-0.60$, $p<0.0001$), we performed multiple linear regression to rule out age as a confounder.

Conclusions: The reason for the apparent discrepancy between the reduced cortical blood flow and preserved oxygenation may be due to the corresponding reduction in both GFR and solute load reabsorption, resulting in reduced oxgyen consumption. Further, if blood flow reduction is primarily due to reduction in blood volume (loss of vasculature), that may also support a reduction in R2* compensating any increase due to reduced blood oxygenation. Future studies are needed to better understand this apparent disparity.

PUB177

Characterization of the Novel Kidney Function Markers C-Mannosyltryptophan and Pseudouridine

Peggy Sekula,[1] Katja Dettmer,[2] Gabi Kastenmüller,[3] Wolfram Gronwald,[2] Karsten Suhre,[3,4] Peter J. Oefner,[2] Anna Kottgen.[1] *[1]Medical Center - Univ of Freiburg, Germany; [2]Univ of Regensburg, Germany; [3]Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany; [4]Weill Cornell Medicine - Qatar, Doha, Qatar.*

Background: C-Mannosyltryptophan (CMT) and pseudouridine (PU) were previously identified as novel kidney function markers using an untargeted mass-spectrometry based metabolomics approach that provided semi-quantitative measurements. We here aimed to obtain absolute concentrations of these markers to provide reference values in blood and urine and to evaluate the agreement of their semi-quantitative and targeted measurements.

Methods: Paired samples (blood, urine) were obtained in 2012 from control participants in the Qatar Metabolomics Study on Diabetes. CMT, PU and creatinine (CREA) were measured using targeted liquid chromatography tandem mass-spectrometry based assays with stable isotope-labeled standards and semi-quantitatively on the Metabolon metabolomics platform version 3. Concentrations were evaluated in both biosamples separately and as their fractional excretion (FE).

Results: Absolute concentrations were available for 111 participants (41% male, mean age 38.3, mean BMI 28.3). The table shows the median and interquartile range of the two markers in blood and urine.

median (interquartile range)	Blood (µmol/l)	Urine (µmol/mmol creatinine)	FE (%)
CMT	0.25 (0.22-0.29)	3.4 (2.7-3.9)	70.8 (65.6-77.8)
PU	2.9 (2.5-3.2)	39.7 (35.1-43.2)	76.0 (68.6-82.4)

The FE of both PU and CMT supports their net reabsorption. Among 77 participants with both absolute and semi-quantitative measurements, both measurement types showed a good correlation for CMT, PU and CREA in blood and urine (Spearman correlation range 0.67-0.89).

Conclusions: We provide reference values for novel markers of kidney function in blood and urine for use in future studies. Semi-quantitative and absolute concentrations show good agreement in blood and urine. A comparison of FE across methods and marker characterization in CKD patients is currently ongoing and will be ready at the time of the conference.

PUB178

An Association between Remodeling of Large Arteries and Arteriosclerosis of Small Renal Arteries in Chronic Kidney Disease

Kentaro Kohagura,[1,2] Tsuyoshi Miyagi,[2] Ryo Zamami,[2] Yusuke Ohya.[1,2] *[1]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: Remodeling of large arteries may promote organ damage by leading to arteriosclerosis of small arteries. In the present study, we examined the association between arteriosclerosis of small renal arteries and remodeling of large arteries in patients with chronic kidney disease (CKD).

Methods: A total of 174 consecutive patients who underwent renal biopsy at our department between 2010 and 2013 were considered for the study. We excluded patients with vasculitis etc., leaving us with 102 patients. Using pathological specimens, the intimal thickening of the renal small arteries (RSA-IT) was semiquantitatively evaluated. Remodeling of large arteries and endothelial function were assessed by brachial–ankle pulse wave velocity (ba-PWV) and percentage flow-mediated dilatation (%FMD) of the brachial artery.

Results: The mean values for age, blood pressure, and estimated glomerular filtration rate (eGFR) were 40 years, 124 /74 mm Hg, and 72 ml/min/1.73 m^2, respectively. There was a positive correlation between the Log RSA-IT score and Log ba-PWV and a negative correlation between %FMD and both Log RSA-IT and ba-PWV. Patients with high ba-PWV, which was defined as a ba-PWV score equal to or more than the median value, were characterized by older age, higher incidence of comorbidities such as hypertension and diabetes mellitus, higher high-sensitive C-reactive protein (hs-CRP), lower %FMD, and higher RSA-IT score. We conducted multivariate logistic analysis for high RSA-IT, which was defined as a score equal to or more than the median value. High ba-PWV was significantly associated with high RSA-IT independent of age, sex, eGFR, and comorbidities such as hypertension. However, its significance disappeared upon additional adjustment with hs-CRP. Subgroup analysis revealed that patients with a combination of high RSA-IT and ba-PWV had relatively high urine protein.

Conclusions: Remodeling of large arteries may lead to the development of CKD because arteriosclerosis of the small renal arteries is promoted in association with inflammation.

PUB179

Monocyte Count and the Risk of Incident Chronic Kidney Disease and Progression to End Stage Renal Disease

Benjamin Charles Bowe,[1] Yan Xie,[1] Hong Xian,[1,2] Ziyad Al-Aly.[1,3,4] *[1]Clinical Epidemiology Center, Research and Education Service, VA Saint Louis Health Care System, St. Louis, MO; [2]Dept of Biostatistics, College for Public Health and Social Justice, Saint Louis Univ, St. Louis, MO; [3]Div of Nephrology, Dept of Medicine, VA Saint Louis Health Care System, St. Louis, MO; [4]Dept of Medicine, Washington Univ School of Medicine, St. Louis, MO.*

Background: Experimental evidence suggests a role for monocytes in the biology of kidney disease progression; however, whether monocyte count is associated with risk of incident CKD, CKD progression, and ESRD has not been examined in large epidemiologic studies.

Methods: We built a cohort of 1,594,700 United States Veterans and used survival models to examine the association between monocyte count and risk of incident CKD and risk of CKD progression (defined as doubling of serum creatinine, eGFR decline ≥ 30%, or the composite outcome of ESRD, dialysis or renal transplantation). Monocyte count was categorized into quartiles (Q): Q1 >0.00 to ≤0.40, Q2 >0.40 to ≤0.55, Q3 >0.55 to ≤0.70, and Q4 >0.70 k/cmm.

Results: Over a median follow up of 9.16 years (IQR: 8.26-9.42); in adjusted models, there was a graded association between monocyte counts and risk of renal outcomes. Compared to Q1, Q4 was associated with increased risk of incident eGFR<60 ml/min/1.73m^2 (HR=1.13; CI:1.12-1.14) and risk of incident CKD (HR=1.15 ; CI:1.13, 1.16). Q4 was associated with increased risk of doubling of serum creatinine (HR=1.22; CI:1.20-1.24), ≥30% eGFR decline (HR=1.18; CI:1.17-1.19), and the composite renal endpoint (HR=1.19; CI:1.16-1.22). Cubic spline analyses of the relationship between monocyte count levels and renal outcomes showed a linear relationship where risk was increased with higher monocyte count.

Conclusions: Our results demonstrate a significant association between high monocyte count and risks of incident CKD and CKD progression.

Toll Like Receptors, Cytokines, and Cathelecidin as a Complex Inflammatory Mechanism in HD and PD Patients

Caren Cristina Grabulosa,[1] Jacqueline Ferritto Rebello,[2] Beata Marie Redublo Quinto,[1] Marcelo Costa Batista,[1,3] Maria Dalboni.[1,2] *[1]Medicine, Univ Federal de São Paulo, Sao Paulo, Brazil; [2]Medicine, Univ Nove de Julho, Sao Paulo, Brazil; [3]Medicine, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: It has been reported that Toll-like receptors (TLR) expression on neutrophils and monocytes are associated with increase cytokines synthesis and may result in more inflammation. However, the TLRs expression, cytokines and Catelecidin on PMN

and PBMC from chronic kidney disease patients is unclear. **Objective**: To evaluate TLR-2, TLR-4, TNF-α, IL-6,IL-10,MCP-1 and Catelecidin on expression in neutrophils (PMN) and monocytes (MN) from HD and PD patients.

Methods: Blood samples from 43 HD patients, 46 PD with creatinine clearance between 15 a 60 mL/min/1,73 mm^2 and 71 age-and gender-matched healthy volunteers (CONT). TLR2 and TLR4 were analyzed by Flow cytometry. The TNF-α, IL-6, IL-10 MCP-1 and Cathelecidin were analyzed by ELISA.

Results: The expression of TLR2 and TLR4 on neutrophils from HD patients was higher than PD and CONT patients ($p<0.001$). In monocytes, TLR-2 expression was higher in HD patients compared to others groups ($p<0.001$) and TLR4 expression was higher inPD patients compared to the CONT and HD patients ($p<0.001$). Regarding to cytokines, we observed that HD and PD patients showed an increase of TNF, IL-6 , IL-10 and MCP-1 levels compared to CONT. In relation to Cathelecidin levels observed in HD patients that had higher levels compared to CONT and PD groups,We also observed a significant correlation between TLR4 and IL-10, MCP-1 and cathelecidin on neutrophils. In monocytes, observed a significant correlation only between TLR4 and MCP-1.

Conclusions: It is possible that the high expression ofTLR2 and TLR4 on neutrophils and monocytes caused by the effect by uremic toxins and the dialysis procedures. Besides, the high expression of TLR2 and TLR4 in these cells resulted in an increase of TNF-α,IL-6, IL-10, MCP-1 and cathelecidin levels, suggesting that TLRs are associated with inflammatory mechanisms in uremic patients. So, these results suggest that TLRs could be a novel target to therapeutic strategic to reduce the inflammation .

Hydration Status Assessment and Phase Angle Estimation by Multi-Frequency Bioimpedance in Patients with Chronic Kidney Disease

Ioannis Griveas.[1] *[1]Nephrology, 417 Veterans Army Hospital of Athens (NIMTS), Athens, Greece; [2]Dialysis Unit, NEFROIATRIKI, Athens, Greece; [3]Private Renal Clinic, Athens-Nephrology, Athens, Greece.*

Background: Body composition assessment has the potential to improve the care of patients with chronic kidney disease (CKD). Bioimpedance (BIA) is the most widespread method for estimating body composition due to its safety, ease of use, low cost and portability. The aims of this study were to determine the hydration status and the phase angle at 50KHz (PA) by BIA in patients with CKD, and to analyse the association between them and common biochemical characteristics.

Methods: The study group consisted of 32 patients (70±13 years, 16 males) with eGFR in between 6-68 mls/min, no one yet on dialysis. Body composition and PA at 50kHz were assessed by BIA (In Body S10). The following parameters of body composition were collected for the study with the help of BIA: total body water , intracellular water, extracellular water, ratio of extracellular water/total body water, body fat mass, soft lean mass, fat free mass, skeletal muscle mass and body mass index . Parameters such as urea, creatinine, albumin, sodium, potassium, ferritin, parathormone, calcium, phosphorus, urine protein and e GFR (MDRD-formula) were collected.

Results: 16 (50%) of our patients had diabetes. 18/32 (56%) were taken diuretics. Patients with oedemas or uncontrolled arterial hypertension showed mean estimate fluid overload significantly higher than that of the other study patients. PA was positively associated with albumin (r=0,465), e GFR (r=0,462) and negatively correlated with creatinine (r=-0,311) and urea (r=-0,500). Ratio extracellular water/total body water was positively correlated with body mass index (r=0,276), age (r=0,543) and negatively correlated with ferritin (r=-0,352) and urea (r=-0,511).

Conclusions: Estimating body composition, hydration status and PA by BIA provides useful information for treating patients with CKD.The 50kHz phase angle seems to represents an overview of nutritional, inflammatory and metabolic status of the patient with CKD.

PUB182

Renal Impairment: Global Prevalence and Risk Factors. Control Participants from the INTERSTROKE Study

Andrew Smyth,[1,2] Martin O'Donnell,[1,2] Michelle Canavan,[1] Sumathy Rangarajan,[2] Salim Yusuf.[2] *[1]HRB Clinical Research Facility Galway, National Univ of Ireland, Galway, Ireland; [2]Population Health Research Inst, McMaster Univ, Hamilton, ON, Canada.*

Background: Chronic kidney disease is increasingly prevalent and well described in some regions of the world. However, it is likely that there are significant differences in prevalence and risk factors between regions. In these analyses, we explore the prevalence of renal impairment (an indicator of CKD) and risk factors in an international population.

Methods: INTERSTROKE is a case-control study (of acute first stroke) in 32 countries in Asia, America, Europe and Africa. In these analyses, we include only the controls (without a history of stroke) with available serum creatinine measurement. The CKD-EPI formula was used to estimate GFR and renal impairment (RI) was defined as eGFR<60ml/min/1.73m^2. Multivariable-adjusted logistic regression was used to explore risk factors for RI.

Results: Of 10,517 included participants, mean age was 61.9 (13.3) years and 58.8% (n=6,181) were male. Mean eGFR was 81.6 (22.2) ml/min/1.73m^2 and 17.3% (n=1,819) had RI. There were significant variations in age-adjusted RI prevalence between regions: Western Europe & North America 8.4%, Eastern & Central Europe 11.9%, Africa 11.8%, South Asia 23.2%, China 24.1%, South East Asia 19.9% and South America 15.4%. After multivariable adjustment, factors that were associated with increased odds of RI included age (OR 1.08 [1.08-1.09]), female gender (OR 1.33 [1.18-1.49]), hypertension (OR 1.39 [1.19-1.63]), diabetes (OR 1.63 [1.40-1.90]) and cardiovascular disease (OR 1.44 [1.18-1.77]). There were regional differences in the association between RI and risk factors: (i) age was significant in all regions; (ii) female gender was significant only in Africa, South Asia and China; (iii) hypertension was significant only in South East Asia and South America; (iv) diabetes was significant in Western Europe / North America, Eastern & Central Europe / Middle East, South Asia, China and South East Asia.

Conclusions: We report an overall RI prevalence rate consistent with previous studies, but significant regional variations in prevalence and risk factors.

PUB183

Predictors of Rapid Progression in Women with X-linked Alport Syndrome

Michelle N. Rheault,[1] Shelley Dunn,[2] Paul C. Grint,[2] Jacqueline Blem,[2] Michael Huang,[2] Clifford E. Kashtan.[1] *[1]Univ of Minnesota; [2]Regulus Therapeutics, Inc.*

Background: Females with X-linked Alport syndrome (AS) have a wide variability in disease course. Predictors of rapid kidney disease progression in this population are unknown.

Methods: ATHENA (NCT02136862) is a non-interventional, global, multicenter study enrolling patients with CKD due to AS. Urine and plasma biomarkers and estimated GFR (eGFR) were assessed at baseline and every 12 weeks thereafter. P-values for categorical variables were calculated based on Fisher's Exact test. P-values for continuous variables were based on t-tests.

Results: We analyzed 28 women with X-linked AS enrolled to date with at least 3 eGFR values. Women were categorized as a slow progressor if eGFR slope declined <5ml/min/1.73m2 per year and a rapid progressor if eGFR declined ≥5ml/min/1.73 per year. Proteinuria, genotype, urine biomarkers, blood biomarkers, hearing loss, or hypertension were not predictive of rapid progression.

Baseline	Slow progressor (N=20)	Rapid progressor (N=8)	P-value
Age (mean, SD)	49.6 (14.9)	50.0 (11.3)	0.95
$eGFR_{CKD-EPI}$ (ml/min/1.73m^2; mean, SD)	60.3 (22.1)	71.3 (20.1)	0.26
Proteinuria >1gm/24 hours	6 (31.6%)	3 (42.9%)	0.66
Genotype			0.22
Missense	9 (45%)	6 (75%)	
Other	11 (55%)	2 (25%)	
Urine biomarkers (mean, SD)			
KIM-1 (pg/mL)	899 (760)	1223 (1180)	0.42
B2-microglobulin (ng/mL)	157 (244)	158 (139)	0.99
Clusterin (ng/mL)	304 (187)	641 (648)	0.05
NGAL (ng/mL)	16 (13)	19 (11)	0.65
Blood biomarkers (mean, SD)			
TGF-β1 (pg/mL)	10132 (3121)	10506 (3052)	0.78
NGAL (ng/mL)	141 (47)	130 (45)	0.57

Conclusions: In this small cohort of women with X-linked AS we have thus far been unable to identify traditional clinical or novel biomarker predictors of rapid decline in GFR.

PUB184

Hormone Therapy and Urine Protein Excretion: A Systematic Review and Meta-Analysis

Andrea G. Kattah,[1] M. Lourdes Gonzalez Suarez,[1] Natasa Milic,[2] Vesna D. Garovic.[1] *[1]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Inst for Medical Statistics & Informatics, Univ of Belgrade, Serbia.*

Background: Animal models suggest estrogen has a renoprotective effect, but human studies have had variable results.

Methods: We performed a systematic review and meta-analysis of observational studies and randomized controlled trials (RCTs) that evaluated the association of hormone therapy (HT) and urine protein excretion (albuminuria/proteinuria) in post-menopausal women. We searched Medline, Embase, Cochrane Register of Controlled Trials and Scopus. Two reviewers screened all abstracts/texts and assessed quality. Dichotomous (odds ratios (ORs)) and continuous measures (mean differences) of the association between HT and urine protein excretion were converted to standardized mean differences (SMDs).

Results: We identified 1088 abstracts - 143 full texts were reviewed and 12 studies were included. The quality of studies was low to moderate. The SMD of the effect of HT on urine protein excretion was -0.11 (95% CI -0.27-0.05, p=0.16). Pooling adjusted ORs, the odds of having elevated albuminuria in HT users was 0.84 (95% CI 0.60-1.18, p=0.31) as compared to non-users. Pooling continuous measures, urine protein excretion was lower in HT users as compared to non-users (SMD -0.25, 95% CI -0.31- -0.19, $p<0.001$). There were no differences in pre-defined subgroups.

Subgroup	# of studies	I^2(%)	Standardized Mean Difference (95% CI)	p-value for interaction
Study Design				
Randomized Controlled Trials	3	0	0.02 (-0.29 – 0.33)	0.38
Observational Studies	9	81	-0.14 (-0.31 – 0.04)	
Women with Diabetes				
Includes	7	70	-0.02 (-0.22 – 0.17)	0.18
Excludes	5	81	-0.30 (-0.64 – 0.05)	
Quality				
High/Moderate	8	78	-0.06 (-0.36 – 0.25)	0.25
Low/Very Low	4	44	-0.25 (-0.36 - -0.13)	

In a post-hoc analysis, the OR for HT use and elevated albuminuria was 1.13 (95% CI 0.76-1.68) in population-based and 0.63 (95% CI 0.53-0.75) in non-population-based cohorts (p=0.007 for interaction).

Conclusions: HT is associated with decreased urine protein excretion, but the observed benefit may be due to study design, reported outcomes and unmeasured confounders.

Differential Diagnosis of Thrombotic Microangiopathy: Survey Results from 16 Countries Hermann G. Haller,[1] T. Sakari Jokiranta,[11] Oguz Soylemezoglu,[2] Jack F. Wetzels,[3] Michel Tsimaratos,[4] Saleh Ali Al Shurafa,[5] Mohan Shenoy,[6] Ondrej Viklicky,[7] Manuel Macia,[8] Tatiana Pankratenko,[10] Rosanna Coppo.[9] *[1]Medical School Hannover, Germany; [2]Baskent Univ, Turkey; [3]Radboud Univ Medical Centre, Netherlands; [4]Hôpital Necker-Enfants Malades, France; [5]Hospital Qatif Central Hospital, Saudi Arabia; [6]Royal Manchester Children's Hospital, United Kingdom; [7]Inst for Clinical and Experimental Medicine, Czech Republic; [8]Hospital Virgen de la Candelaria, Spain; [9]Fondazione Ricerca Molinette, Ospedale Regina Margherita, Italy; [10]M.F. Vladimirskiy Moscow Regional Research and Clinical Inst, Russian Federation; [11]Univ of Helsinki, Finland.*

Background: The differential diagnosis of thrombotic microangiopathy (TMA) is complex but important to inform treatment decisions. A survey was devised with the objective of understanding current practices across Europe.

Methods: Over 450 clinicians, from 16 European countries were invited to complete an online survey.

Results: Of 254 respondents, 82% were nephrologists, 69% had >10 years' experience in their specialty, and 89% had diagnosed a patient with TMA. Results show a differential diagnosis of TMA is usually made within 1-2 (53%) or 3-4 days (26%) of presentation. Similarly, therapy is usually initiated within 1-2 (44%) or 3-4 days (30%), however 13% report treatment initiation >1 week post-presentation. Thrombocytopenia, hemolytic anemia and acute renal failure are the main diagnostic criteria used. Extrarenal symptoms and a panoply of other conditions are considered when assessing the differential diagnosis. 70% and 78% of respondents stated they always request complement protein levels and ADAMTS13 activity. However, only 65% agree that an ADAMTS13 activity >10% rules out thrombotic thrombocytopenic purpura. For the diagnosis of atypical hemolytic uremic syndrome, 93% request ADAMTS13 activity and 83% request complement protein levels. Variability in available guidelines and extent of family history taken was evident.

Conclusions: This survey highlights the variability of current practices of European physicians in differentially diagnosing TMA and the need to increase awareness of diagnostic tests and international guidelines available.

Acknowledgements: The authors wish to thank the survey participants.

PUB186

Nutritional and Inflammatory Parameters during Transition from Pre-Dialysis Chronic Kidney Disease to End Stage Renal Disease Dugan Maddux,[1] Frank van der Sande,[2] Jeroen Kooman,[2] Jochen G. Raimann,[3] Jennifer A. Vosburgh,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Terry L. Ketchersid,[1] Len A. Usvyat,[1] Peter Kotanko,[3,4] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Maastricht Univ Medical Center, Maastricht, Netherlands; [3]Renal Research Inst, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Malnutrition and inflammation during transition from chronic kidney disease (CKD) to end stage renal disease (ESRD) has not been characterized. We investigated longitudinal trajectories of albumin levels (Alb) and white blood cell counts (WBC) in patients (Pts) during their transition from CKD to ESRD.

Methods: We analyzed data from the Fresenius Medical Care CKD Data Registry on 14,095 Pts who transitioned to ESRD treated by dialysis between 2008 and 2016. Mean Alb and WBC were captured during 12 months before and after transition to ESRD. We analyzed Alb and WBC in Pts who survived, or died during the first year of dialysis.

Results: We observed mean Alb declined at transition to and 1 month after starting dialysis; thereafter Alb gradually rebounded (Figure 1A). Pts who died during the first year of dialysis generally had lower Alb 3 months before and 1 month after transition to dialysis, compared to survivors (Figure 1B). In survivors, mean WBC increased slightly in pre-dialysis months and decreased after dialysis start (Figure 1C). In those who did not survive, WBC tended to be higher than survivors during the year before, and more notably after starting dialysis (Figure 1D).

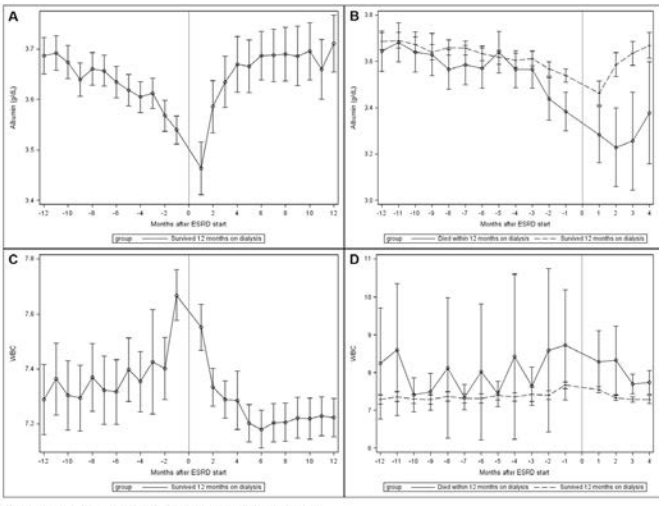

Figure 1. Error bars represent the 95% confidence intervals.

Conclusions: These results suggest the emergence of a pro-inflammatory phenotype in the months before dialysis initiation. These changes were more pronounced in Pts who died in the first year on dialysis, while in contrast Alb and WBC counts improved in survivors. Factors underlying the pre-ESRD pro-inflammatory surge deserve further research.

PUB187

Potential Association of Hyperhomocysteinemia with Target-Organ Damage in Patients with Primary Glomerulonephritis Zengchun Ye, Wenbo Zhao, Meijun Si, Ming Li, Cheng Wang, Tan-Qi Lou. *Div of Nephrology, Dept of Medicine, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

Background: Hyperhomocysteinemia (HHcy) leads to increased oxidative stress and decreased antioxidant capacities in vascular endothelial cells, which are related to increased cardiovascular risk. This study is to investigate the prevalence of hyperhomocysteinemia in patients with primary glomerulonephritis and its relationship with target-organ damage.

Methods: This study included 601 patients with primary glomerulonephritis who were enrolled in the Third Affiliated Hospital of Sun Yat-sen University from May 2010 to March 2015. Demographic and laboratory data were collected. Plasma homocysteine was detected and estimated glomerular filtration rate (eGFR) was calculated. Doppler ultrasound was used to evaluate the changes of cardiac structure and function. Multiple linear regression analyses were used to evaluate the correlation between plasma homocysteine and target-organ damage.

Results: The prevalence of hyperhomocysteinemia was 45.92% (276/601) in patients with primary glomerulonephritis. And the incidence of hyperhomocysteinemia in CKD stage 1, stage 2, stage 3, stage 4, and stage5 was 10.34%, 24.53%, 57.58%, 72.55% and 89.53%, respectively. With the deterioration of renal function, the incidence of hyperhomocysteinemia increased significantly. eGFR in patients with hyperhomocysteinemia was significantly lower than those of normal homocysteine, and the left ventricular mass index and carotid artery intima media thickness were significantly increased. Multiple linear regression analysis shown that homocysteine was associated with impaired renal function. Plasma homocysteine concentration is related to eGFR, calcium×phosphorus, serum uric acid, LDL-C, gender and hemoglobin.

Conclusions: The prevalence of hyperhomocysteinemia in patients with primary glomerulonephritis was 45.92%. Hyperhomocysteinemia was associated with impaired renal function in these patients. Further prospective randomized clinical trials are needed to clarify whether lowering homocysteine treatment has a beneficial effect in attenuating the progression of renal failure in primary glomerulonephritis patients.

PUB188

A Prospective Study of Cutaneous Manifestations in Patients of Advanced Chronic Kidney Disease in a Tertiary Care Centre in Eastern India Pinaki Mukhopadhyay. *Dept of Nephrology, NRS Medical College, Kolkata, India.*

Background: A wide variety of skin diseases occur in patients with chronic kidney diseases(CKD). Dermatological manifestations vary from age, region, race , severity of CKD and also basic disease or etiology. There is no such detail study regarding cutaneous manifestations in advanced CKD patients in Eastern India.We aim to evaluate the spectrum and frequency of dermatological manifestations in CKD patients, and also to compare cutaneous manifestations in CKD, between patients on dialysis and not on dialysis.

Methods: All patients with CKD stage 3 and beyond including patients in hemodialysis having dermatological manifestations were included. Detailed epidemiological, clinical and biochemical parameters were recorded. All patients were followed up three years. Patients with renal transplant, cutaneous diseases prior to CKD and , patients below the age of 12 years were excluded.

Results: A total of 225 patients were included in this study in which 64% were male and 36% were females, showing high male predominance. Their age ranged from 12 to 68 with mean age being 46.8 years. Majority of patients belonged to the age group of 50-70 years(60%).The means of hemoglobin, blood urea, serum cretinine were 8.9 gm% (S.D±2.05gm%), 98.07 mg/dl (S.D ±63.2 gm/dl) and 5.03 gm/dl (S.D±3.77 gm/dl) respectively. The most common skin manifestations observed were pruritus (52%) , followed by infections (36%) , xerosis (16%), acquired perforating dermatosis (16%) and others like vesicobullous diseases, adenoma sebaceum (8%).Bacterial infection(20%) is more prevalent than fungal(8%) and viral (8%) infection among study population. No significant differences in frequency and type of skin manifestations have been found between hemodialysis and without hemodialysis group. Severity of pruritus increases with duration of chronic kidney disease. Cutaneous manifestations increases with severity of kidney disease ($p<0.01$).

Conclusions: CKD is associated with a complex array of cutaneous manifestations and there distribution and frequency is closely related to the duration and fall in glomerular filtration rate.

PUB189

CKD and Prevalence of Strongyloidiasis in a Community-Based Hospital in Okinawa, Japan Takayuki Adachi,[1] Kunitoshi Iseki.[2] *[1]Internal Medicine, Tomishiro Central Hospital, Tomigusuku, Okinawa, Japan; [2]Clinical Research Center, Tomishiro Central Hospital, Tomigusuku, Okinawa, Japan.*

Background: Strongyloides stercoralis (strongyloidiasis, S) is an intestinal helminth that infects humans when they come in contact with soil containing the larvae. In advanced stages ofchronic kidney disease(CKD), patients often are associated with decreased cell-mediated immunity, under-nutrition, and anemia. The prevalence of S has been reported to be 6.3% among the Ryukyu University hospital patients in Okinawa from 1991 to 2004. However, the current prevalence is not known nor the effect of CKD;estimated glomerular filtration rate <60 mL/min/1.73 m^2.

Methods: We analyzed hospitalized patients who had undergone a stool test between September 2005 and June 2015 in Tomishiro Central Hospital, Okinawa, Japan. Also, background data such as renal function, proteinuria, anemia, nutritional status, and comorbid conditions were collected. Anemia was defined as hemoglobin level <13 g/dL in men and <12 g/dL in women.

Results: A total of 2,184 patients (median age, 74.0 [61.0-81.0] years; male ‘ 52.8%) were tested and 8% of them (median age, 75.0 [71.0-80.8] years; male ‘ 66.1%) were positive for S. In patients with S, 31.8% had CKD, 32.2% diabetes, 59.8% hypertension, 63.3% anemia, 65.4% eosinophilia, and 32.5% proteinuria. The mortality rate of S patients was 27.6% and the median survival period was 20.5 [1.0-42.3] months.

Conclusions: Large doses of steroids and/or immunosuppressants are usually indicated for nephrotic syndrome, rapidly progressive glomerulonephritis, renal transplants, and so on. CKD is often associated with protein energy wasting and immunodeficiency. In such cases, work-ups, such as stool tests to rule out S, are mandatory. Results suggest that S is still prevalent and common in elderly men who have CKD in Okinawa.

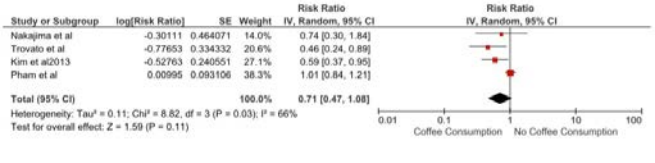
PUB190

Association of Coffee Consumption and Chronic Kidney Disease: A Meta-Analysis Natanong Thamcharoen,[1] Karn Wijarnpreecha,[1] Panadeekarn Panjawatanan,[3] Wisit Cheungpasitporn,[2] Charat Thongprayoon.[1] *[1]Dept of Medicine, Bassett Medical Center, Cooperstown, NY; [2]Dept of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [3]Dept of Biochemistry, Faculty of Medicine, Chiang Mai Univ, Chiang Mai, Thailand.*

Background: The risk of chronic kidney disease (CKD) in patients who regularly drink coffee is controversial. The aim of this meta-analysis was to evaluate the association between coffee consumption and CKD.

Methods: A literature search was performed using MEDLINE, EMBASE, and Cochrane Database of Systematic Reviews from inception until 30 April 2016. Studies that reported odd ratios or hazard ratios comparing the risk of CKD in patients consuming significant amount of coffee versus those who did not consume coffee were included. Pooled risk ratios (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method.

Results: Four observatioal studies with 14,898 individuals were included in our analysis to assess the association between coffee consumption and CKD. Coffee consumption was defined as 1 cup of coffee per day or greater. The pooled RR of CKD in patients consuming coffee was 0.71 (95% CI, 0.47-1.08).



The subgroup analysis showed the pooled RRs of CKD of 1.10 (95% CI, 0.94-1.29) in males and 0.81 (95% CI, 0.58-1.13) in females, respectively.

Conclusions: Our study demonstrates no significant association betweern coffee consumption and CKD in males. However, future studies are required to assess a potential inverse association between coffee consumption and risk for developing CKD in females.

PUB191

Plasma Convertase Subtilisin/Kexin Type9(PCSK9) Concentration in Elderly Patients with Chronic Kidney Disease Hoichi Amano,[1] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertension, The Jikei Univ Hospital, Hospital, Tokyo, Japan; [2]Div of Internal Medicine, Kanagawa Prefectural Shiomidai Hospital, Hospital, Kanagawa, Japan; [3]Dialysis center Fukushima Medical Univ, Hospital, Fukushima, Japan.*

Background: The elderly patients with chronic kidney disease (CKD) are at high risk for cardiovascular events in spite of lower level of low density lipoprotein cholesterol (LDL-C). The reason why plasma LDL-C concentration is relatively lower is not fully explained. As PCSK9 plays an important role in regulating plasma LDL-C by the mechanism which secreted PCSK9 binds to the LDL receptors (LDLR) and promotes LDLR degradation. Thus, we investigated the relationship between the magnitude of renal impairment and plasma PCSK9 levels.

Method: Concentrations of fasting serum PCSK9, lipids, creatinine and cystatin-C were measured in 219 Japanese elderly outpatients with CKD including patients receiving peritoneal dialysis (PD) or hemodialysis (HD).

Result: Plasma PCSK9 concentrations (215±76ng/mL ng/ml [SD]) did not correlate with baseline eGFR in the study population. Mean plasma PCSK9 levels in PD patients (344 ± 145 ng/ml) were significantly higher than other CKD stages ($p< 0.001$, ANOVA). Those in HD patients (165 ± 56 ng/ml) were significantly lower than other CKD stages ($p< 0.001$, ANOVA).

Conclusion: Plasma PCSK9 levels did not correlate with kidney function. PD is associated with higher plasma PCSK9 concentration and HD is lower.

PUB192

Patients Transitioning into Dialysis without Pre-Dialysis Nephrology Care Tend to Have Lower Comorbidity Index Sheetal Chaudhuri, Len A. Usvyat, John W. Larkin, Marta Reviriego-Mendoza, Chris Churchill, Lisa Dombro, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: More than 50% of patients who start dialysis do not have prior nephrology care; those patients are also reported to have poorer outcomes. We aimed to understand whether patients who start hemodialysis (HD) without prior nephrology care also have a higher comorbidity index prior to dialysis initiation.

Methods: We analyzed data from 142 patients' ≥65 years of age who transitioned to dialysis and received HD for at ≥3 months at FMCNA facilities within a selected Universal American ACO. Comorbidities were captured for the patients during the first 3 months of HD, and we calculated the non-ESRD hierarchical condition category (HCC) score to estimate the patients' comorbidity index. Patients were stratified based on whether they received pre-HD nephrology care.

Results: Of the 142 patients studied, 49 had pre-HD nephrology care. We found that patients with pre-HD nephrology care had a mean HCC score of 4.1, which was higher than the mean HCC score of patients with no pre-HD nephrology care who had a HCC score of 2.9 (Table 1).

Table 1	Number of Patients	Mean HCC Score
No Pre-ESRD Encounters	93	2.9
With Pre-ESRD Care	49	4.1

Conclusions: Given that patients with no pre-HD nephrology care have poorer outcomes, we would have expected that they would also have a higher disease complexity based on their comorbidities; this analysis suggests the opposite. Further studies are needed to investigate if outcomes differ in patients with and without pre-ESRD nephrology care controlled for their comorbidity index at the dialysis initiation.

PUB193

Self-Reported Medication Non-Adherence Association with End-Stage Renal Disease and All-Cause Mortality in Adults with Chronic Kidney Disease Esteban A. Cedillo-Couvert, Ana C. Ricardo, Jinsong Chen, Michael J. Fischer, Marie Krousel-Wood, John W. Kusek, Swati Lederer, Eva Lustigova, Akinlolu O. Ojo, Anna C. Porter, Lisa Sharp, James H. Sondheimer, Clarissa Jonas Diamantidis, James P. Lash. *The Chronic Renal Insufficiency Cohort (CRIC) Study Group.*

Background: In the general population, medication non-adherence contributes to poorer clinical outcomes. However, little is known about medication non-adherence among adults with chronic kidney disease (CKD). We evaluated the association of self-reported medication non-adherence with incident end-stage renal disease (ESRD) and all-cause mortality among adults with CKD.

Methods: Prospective observational study of 3428 adults with CKD enrolled in the CRIC Study at seven clinical centers in the U.S. Baseline self-reported medication adherence was based on responses to questions assessing unintentional (forgetting) and intentional (purposely missing or adding a pill) nonadherence in the past week. We performed Cox proportional hazard regression analyses (adjusted for clinical center, socio-demographic characteristics, clinical factors, use of cardiovascular medications and depressive symptoms) to relate type of non-adherence with incident ESRD and all-cause mortality.

Results: At baseline,mean age was 60 years, 45% were women, mean eGFR was 43.4 ml/min/1.73 m^2, and participants were on a mean of 9.3 medications/day. One-quarter of

participants reported unintentional and 15% intentional (10% purposefully missing a pill, 5% added a pill) non-adherence. Over a median follow-up of 6 years, 823 individuals experienced ESRD and 675 died. Hazard ratios are shown in the following table:

Adjusted Hazard Ratio (95% CI)			
Outcome	Forgetting a Pill	Purposely Missing a Pill	Purposely Adding a Pill
ESRD	1.09(0.92,1.29)	1.34(1.08,1.67)	1.07(0.79,1.46)
All-cause mortality	1.10(0.90,1.33)	1.32(1.04,1.68)	1.26(0.92,1.74)

Conclusions: Baseline self-reported intentional non-adherence characterized by missing a pill, but not purposefully adding a pill or forgetting a pill, was associated with an increased risk for ESRD and all-cause mortality in CRIC Study participants. Future work is needed to better understand reasons for this association.

PUB194

Analysis of Autonomic Nervous Dysfunction Characteristic in Chronic Kidney Disease Patients with Acute Ischemic Stroke Wenbo Zhao, Zengchun Ye, Ming Li, Meijun Si, Hui-Qun Li, Tan-Qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Autonomic nerve function damage is a common symptom of stroke, but there is little about its effects on stroke patients with renal insufficiency. This study explored the association between autonomic function and renal impairment in patients with acute stroke.

Methods: etrospective analysis of 232 cases (67.22 years old, male, 57.8%.) , Autonomic function evaluated by heart rate variability using 24 hours dynamic electrocardiogram. Renal impairment evaluated by glomerular filtration rate (EPI - eGFR). The national institute of health stroke scale (NIHSS) scores to measure the severity of the stroke.

Results: SDANNindex VLF value, LF and LF/HF significantly reduced ($P < 0.05$) in moderate eGFR group. Autonomic function lower significantly ($P < 0.05$) in severe stoke patients compared with mild-to-moderate groups .Multiple linear regression analysis found that the NIHSS score, history of diabetes associated with SDANN index and LF. Gender, NIHSS score, history of diabetes associated with VLF. But eGFR was not included in the regression model.

Conclusions: eGFR associated with autonomic nerve dysfunction in acute stoke patients, but not the main factors that influence the effect of autonomic nerve dysfunction; History of diabetes, NIHSS score, gender differences are the main influencing factors of autonomic nerve dysfunction in patients with acute ischemic stroke accompany renal insufficiency.

PUB195

Early Pre-Operative, and Prolonged Post-Operative Nephrological Consultation Might Prevent the Worsening of Renal Impairment in Renal Cancer Patients Candidates to Nephrectomy Laura Cosmai,[1] Wanda Liguigli,[2] Camillo Porta,[3] Maurizio Gallieni,[4] Marina Foramitti,[1] Fabio Malberti.[1] *[1]Nephrology, Istituti Ospitalieri, Cremona, Italy; [2]Oncology, Istituti Ospitalieri, Cremona, Italy; [3]Oncology, IRCCS San Matteo Univ Hospital Foundation, Pavia, Italy; [4]Nephrology, San Carlo Borromeo Hospital, Milan, Italy; [5]Nephrology, Istituti Ospitalieri, Cremona, Italy; [6]Nephrology, Istituti Ospitalieri, Cremona, Italy.*

Background: Partial nephrectomy (PN) is recommended as the preferred surgical option in organ confined renal tumours measuring up to 7 cm, whilst radical nephrectomy (RN) is the preferred option for tumors of more than 7 cm; RN is also recommended if PN is not technically feasible. RN in particular may affect renal function, expecially in patients (pts) with pre-existing chronic kindey disease (CKD).

Methods: From December 2012 to January 2015, 97 pts candidates to RN were referred to our Ambulatory of Onco-Nephrology; of these pts, 21 had a pre-existing stage III to V CKD. Nephrological consultation was performed before surgery, immediately post surgery, and then every 3 months for the first 3 years post-RN. Primary endpoint of this single-arm, prospective, pilot study was the percentage of pts who developed some worsening of kidney function over the 3-years follow-up. Interventions during Nephrological consultations included management of co-morbidities and risk factors (e.g. hypertension, diabetes …), prevention of further renal damage from potentially nephrotoxic drugs (e.g. NSAIDs) and protocols of hydration before contrast medium administration for routine Oncological follow-up.

Results: Immediately post-RN, 46 pts presented a reduction in eGFR (9 within the group with pre-existing CKD, and 37 in the group without known renal impairment). Of these 46 pts, at a 3-months post-RN 30 recovered to their pre-nephrectomy renal function, while the remaining 16 did not show any further decrease in eGFR. Only 5 pts (out of 97) were lost at follow-up during the 3 years subsequent to RN. Of the 92 pts who reached the 3 year post-RN mark, just 2 showed a decline in eGFR.

Conclusions: An early and prolonged Nephrological consultation in cancer pts candidates to RN might prevent kidney impairment.

PUB196

Quality of Perceived Physician-Patient Interaction and Risk of End-Stage Renal Disease and Hospitalization in Hispanics with Chronic Kidney Disease Esteban A. Cedillo-Couvert, Jesse Yenchih Hsu, Ana C. Ricardo, Michael J. Fischer, Ben Gerber, Edward J. Horwitz, John W. Kusek, Eva Lustigova, Amada Renteria, Sylvia E. Rosas, Milda Renne Saunders, Daohang Sha, Anne M. Slaven, James P. Lash. *Chronic Renal Insufficiency Cohort (CRIC) Study Group.*

Background: Quality of physician patient interaction influences health outcomes in the general population but little is known about this in chronic kidney disease (CKD). We evaluated the association of perceived quality of physician-patient interaction with risk of end stage renal disease (ESRD) and all-cause hospitalization in Hispanics with CKD.

Methods: We studied Hispanics with CKD enrolled in the prospective observational Hispanic CRIC Study**.** Quality of interaction with primary care providers was ascertained using the Ambulatory Care Experiences Survey sub-scales (range of score 0-100 with higher score indicating better performance) of communication quality, health promotion, interpersonal treatment, and patient trust. Outcome measures were incident ESRD and all-cause hospitalization.

Results: The mean age of the 289 participants was 56 yrs, 38% were women, 70% had health insurance, and the mean eGFR was 38.4 ml/min/1.73 m^2. Baseline subscale scores and hazard ratios are shown below:

Association of High vs Low* Physician-Patient Interaction Scores with Incident ESRD and Hospitalization			
ACES Sub-scale	**Median (IQR)**	**ESRD Hazard Ratio† (95% CI)**	**Hospitalization Rate Ratio‡ (95% CI)**
Communication Quality	100 (80-100)	0.63 (0.37-1.08)	0.62 (0.50, 0.76)
Health Promotion	80 (60-100)	0.83 (0.50-1.39)	0.77(0.63, 0.94)
Interpersonal Treatment	100 (80-100)	0.87(0.52-1.47)	0.65 (0.52, 0.79)
Patient Trust	93.3 (73.3-100)	0.76 (0.45-1.30)	0.79 (0.64, 0.97)
*100 vs < 100 due to highly skewed score distribution †Cox models ‡Poisson regression Adjusted for socio-demographic characteristics, hypertension, diabetes, cardiovascular disease, kidney function, quality of life, and depression			

Conclusions: Among HCRIC participants, higher perceived quality of physician-patient interaction was associated with a lower rate of hospitalization but not ESRD. How these interactions influence this outcome requires further study.

Parental Health Literacy and Progression of Chronic Kidney Disease in Children Ana C. Ricardo, Vivien H. Goh, Adam S. Hamidi, Lynn N. Pereira, Aisha Betoko, Bradley Warady, Marva M. Moxey-Mims, Susan L. Furth, James P. Lash. *On Behalf of the Chronic Kidney Disease in Children (CKiD) Cohort Investigators.*

Background: Although health literacy has been associated with adverse outcomes in children, this association has not been evaluated in the setting of chronic kidney disease (CKD).

Methods: We conducted a parental health literacy assessment of 367 children enrolled in the prospective multicenter observational Chronic Kidney Disease in Children (CKiD) cohort study. Using parametric failure-time models, we evaluated the association between parental health literacy and CKD progression, defined as time to the composite event of renal replacement therapy (RRT, dialysis or kidney transplant) or 50% decline in estimated glomerular filtration rate (eGFR). Parental health literacy was measured once using the Short Test of Functional Health Literacy (STOFHLA) that included 2 reading passages and 4 numeracy items (possible range from 0 to 100). Clinical and demographic characteristics of the cohort were measured at baseline. Literacy levels were assumed to remain relatively stable over time.

Results: Median patient age was 9.5 years, 63% were male, and 59% non-Hispanic white. A glomerular diagnosis was present in 32% of participants. Median eGFR at baseline was 63 ml/min/1.73m^2, and median urine protein-to-creatinine ratio was 0.22. The median (IQR) STOFHLA score was 98 (93-100). Over a median follow-up of 5.9 years, the overall composite rate of RRT or 50% eGFR decline was 2.8 per 100 person-years. Results of multivariable models are presented in the table.

Relative time (95% CI) to CKD progression per 1 SD increase in STOFHLA score	
Model 1[a]	1.25 (1.11, 1.41)
Model 2[b]	1.29 (1.13, 1.48)
Model 3[c]	1.30 (1.08, 1.56)
[a]Adjusted for clinical center, baseline age, gender and race. [b]Variables in model 1 plus baseline GFR, proteinuria, glomerular diagnosis, age at CKD onset, bmi z-score, small for gestational age, albumin and dyslipidemia. [c]Variables in model 2 plus baseline maternal education, income and health insurance.	

Conclusions: In this cohort of children with CKD, high parental health literacy was associated with 30% longer time to the composite CKD progression outcome.

PUB198

Application of Urinary Albumin: Creatinine Ratio to Predict Renal Replacement Therapy and All-Cause Mortality in a CKD Cohort
Zaimin Wang,[1,2] Jianzhen Zhang,[1,2] Helen G. Healy,[1,3] Ken-Soon Tan,[1,2,4] Sree Krishna Venuthurupalli,[1,2,5] Anne Cameron (Salisbury),[1,2,3] Wendy E. Hoy.[1,2,3] *[1]NHMRC CKD.CRE and CKD.QLD, The Univ of Queensland, Brisbane, Queensland, Australia; [2]School of Medicine, The Univ of Queensland, Brisbane, Queensland, Australia; [3]Kidney Health Service (RBWH), Metro North Hospital and Health Service, Brisbane, Queensland, Australia; [4]Renal Services (Logan), Metro South Hospital and Health Service, Brisbane, Queensland, Australia; [5]Renal Services (Toowoomba Hospital), Darling Downs Hospital and Health Service, Toowoomba, Queensland, Australia.*

Background: This study aims to examine the association of albuminuria with RRT and mortality in CKD patients.

Methods: Subjects were patients with CKD and not on kidney replacement therapy enrolled in renal clinics in Queensland, Australia. Informed consenting of patients began in 2011. The categories of albuminuria were defined by gender-specific ACR values recommended by Australasian Proteinuria Consensus Working Groups. Events of RRT and death without RRT were recorded until end of 2015. Cox regression analyses were applied.

Results: A total of 1,615 patients were eligible, with 788 (49%) females. They were followed for a total of 3,397 person years. Age at consent ranged from 18 to 96 years, mean of 65 years (SD: 15 years). The percentages of patients with CKD stage 1, 2, 3A, 3B, 4 and 5 at consent were 6.6%, 12.5%, 20.8%, 30.8%, 25.6% and 3.7%, respectively. The prevalence of microalbuminuria and macroalbuminuria at consent was 32.1% and 34.7%, respectively. 69 patients started RRT and 111 patients died without RRT.After adjusted age, gender and CKD stage, the hazard ratio (HRs) (95% CI) of macroalbuminura for RRT (combined non-albuminuria and microalbuminuria as reference group) was 10.5 (4.2-26.6). The HRs (95% CI) of microalbuminuria and macroalbuminura for death were 2.1 (1.1-3.7) and 3.4 (1.9-6.0) (non-albuminuria as reference group), respectively.

Conclusions: In this cohort,macroalbuminuria was a significant predictor of future RRT whilst both micro- and macroalbuminuria increased mortality risk.

Novel ELISA for the Measurement of Human Periostin in Patients with Impaired Kidney Function
Jacqueline Wallwitz, Manfred Tesarz. *The Antibody Lab GmbH, Vienna, Austria.*

Background: Periostin (osteoblast-specific factor OSF-2) is a soluble extracellular matrix protein that is associated in kidney development and kidney injury. Periostin consists of a conserved N-terminus and a C-terminal region which is affected by different splicing variants. Currently, at least seven splicing isoforms of human Periostin have been identified.

Methods: We developed a sandwich ELISA, which also enables the detection of all known human circulating Periostin isoforms. Our novel assay utilizes monoclonal and purified polyclonal antibodies and recognizes epitopes that are conserved between human and animal species e.g. mouse, rat, cynomolgus macaque, dog, and cat Periostin.

Results: The novel Periostin ELISA assay is optimized for human serum and plasma (citrate, heparin, EDTA) and covers a wide calibration range between 125 to 4,000 pmol/l. Assay characteristics such as precision, dilution linearity and spike-recovery as well as sample stability meet the standards of acceptance. Periostin serum and plasma concentration in apparently healthy individuals, show mean values of 864 +/- 269 pmol/l (n=24) and 817 +/- 170 pmol/l (n=20), respectively. Patients with impaired kidney function show an increase of Periostin compared to healthy individuals, suggesting that Periostin is a mediator in CKD and perhaps a promising biomarker for kidney injury in clinical renal disease.

Conclusions: In conclusion, this high-quality ELISA provides a reliable and accurate tool for the quantitative determination of Periostin in human healthy and diseased samples.

PUB200

Mexican Chronic Renal Insufficiency Cohort (MCRIC) Study: Baseline Characteristics
Magdalena Madero,[1] Ana C. Ricardo,[2] Esteban A. Cedillo-Couvert,[2] Carlos A. Linares-Koloffon,[2] Martha L. Daviglus,[2] Mayank Kansal,[2] Ricardo Duarte,[1] Ipsae E. Melgoza,[1] James P. Lash.[2] *[1]Inst Nacional de Cardiología Ignacio Chavez; [2]Univ of Illinois.*

Background: Chronic kidney disease (CKD) represents a major public health problem in Mexico. Despite the magnitude of this problem, little is known about risk factors for progression of kidney disease for individuals with CKD living in Mexico. The objective of this study is to describe the baseline characteristics of MCRIC Study participants, and to compare these characteristics with Mexican-American and non-Hispanic white individuals enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study.

Methods: We conducted a cross-sectional analysis of 249 adults with CKD (entry estimated glomerular filtration rate [eGFR] 20-60 ml/min/1.73 m²) enrolled in MCRIC. We compared demographic and clinical characteristics of MCRIC participants with all Mexican-Americans in CRIC and Hispanic CRIC (HCRIC), and with 249 non-Hispanic (NH) white CRIC participants matched for age, gender, diabetes status, and eGFR.

Results: Results are summarized in the table.

Variable	Mexican CRIC N=249	HCRIC/CRIC Mexican-Americans N=341	CRIC NH-Whites[a] N=249
Age, years (mean)	56	56	56
Female (%)	29	43 [b]	28
< High School Education (%)	59	69 [b]	4 [b]
Current Smoker (%)	10.8	6 [b]	13
Diabetes (%)	54.2	70 [b]	55
Systolic Blood Pressure, mmHg (mean)	123	139 [b]	122
Diastolic Blood Pressure mmHg (mean)	74	73	69 [b]
Blood Pressure < 140/90 mmHg (%)	78	54 [b]	81
Body Mass Index≥30 kg/m2 (%)	30	55 [b]	56 [b]
eGFR, ml/min/1-73m2 (mean)	40	38 [b]	40 [b]
Urine to Protein ratio g/g (median)	0.63	0.95	0.22

[a] Age, gender, diabetes and eGFR matched to MCRIC
[b] p<0.05 (MCRIC is the reference group for all comparisons)

Conclusions: Compared with Mexican-Americans with CKD, Mexicans with CKD living in Mexico are less likely to be obese and have better blood pressure control. Longitudinal follow-up is ongoing and will provide insights into differences in risk for CKD progression.

The Impact of Diabetes on the Progression of Renal Disease in the Elderly
Cláudia Tótoli, Adriano Luiz Ammirati, Maria Eugenia F. Canziani. *Nephrology, Univ Federal de São Paulo, São Paulo, Brazil.*

Background: Elderly and diabetes are risk factors for chronic kidney disease (CKD). Diabetics patients have a faster decline of renal function. There are few data regarding the progression of CKD in elderly especially those with diabetes. The aim of this study was to compare progression of renal disease in diabetic and non-diabetic elderly CKD patients.

Methods: A retrospective observational study that evaluated elderly CKD stage 2-5 non-dialysis patients followed in a CKD Unit Care from April 2011 to April 2015. Renal disease progression was evaluated by the change in eGFR using BIS formula, divided per years of follow-up (mL/min/year), stratified in rapid progressors (≥ 5 mL/min/year); slow progressors (≥ 1 mL/min/year to < 5 mL/min/year), stable (≥ 0 and <1 mL/min/year) and improved function (< 0 mL/min/year). Proteinuria was measured in a spot urine sample.

Results: A total of 340 patients [73 (69-79) years, 56% male, 65 % white, 41% diabetics] were evaluated. In comparison to non-diabetics, diabetic patients had a higher proteinuria at baseline. There were no differences in age, blood pressure, kidney function between the two groups at baseline. The change of eGFR during the follow up was higher in the diabetic group [1.10 (-1.53 – 3.46) vs. 0.57 (-1.54 – 2.51) mL/min/year, p = 0.09], without statistical significance but with a trend p. Proportion of rapid progressors and dialysis initiation was significantly higher in diabetic group (15 vs 8%, p = 0.04; and 10 vs 3%, p=0.03; respectively).

Conclusions: There was no statistical significance in renal progression between the groups, but there is a tendency (p trend) to a faster progression in the diabetics group. The presence of diabetes affected the need for dialysis and the number of rapid progressors.

Double-Hit of Advanced Age and Lung Cancer Leads to Increased Fibrosis and Decreased Overall Survival in a Repeated Low-Dose Regimen of Cisplatin Nephrotoxicity
Cierra Sharp,[1] Mark A. Doll,[1] Deanna L. Siow,[1] Levi J. Beverly,[1,2,3] Leah J. Siskind.[1,3] *[1]Pharmacology/Toxicology, Univ of Louisville, Louisville, KY; [2]Dept of Medicine, Univ of Louisville, Louisville, KY; [3]James Graham Brown Cancer Center, Louisville, KY.*

Background: Cisplatin-induced acute kidney injury (AKI) has a high mortality rate and poor long-term prognoses, including a 30x greater risk of developing chronic kidney disease (CKD). Understanding processes involved in the cisplatin-induced AKI to CKD transition is essential for developing novel therapeutics. We have developed a repeated, low-dose cisplatin model that allows for long-term survival of mice, and better recapitulates the type of dosing regimen humans receive. In this model, fibrosis is the main pathology associated with repeated, low-dose administration of cisplatin, and thus the transition from AKI to CKD can be studied. While this model better recapitulates the dosing regimen humans receive, it does not take into account comorbidities present in patients receiving cisplatin, namely advanced age and cancer, which is important as only individuals with cancer receive cisplatin and the majority of cancer patients are diagnosed at 60 years of age or older. It is believed that renal function declines and with normal aging and that processes of maladaptive repair also occur during aging.

Methods: Here, we determined the impact of age and cancer on the cisplatin-induced AKI to CKD transition. We compared saline and cisplatin-treated 8 wk old and 40 wk old FVB mice and found that fibrosis and renal function were not affected by aging alone. However, aged mice with mutant Kras driven lung cancer had decreased overall survival and significantly increased kidney fibrosis as compared to age matched control mice.

Results: Preliminary data suggest this the exacerbated kidney fibrosis in aged mice with lung cancer may be mediated by activation of EGFR signaling pathways in the kidney cortex.

Conclusions: Thus, understanding the mechanisms by which the comorbidities of aging and cancer impact the cisplatin-induced AKI to CKD transition may uncover novel therapeutic targets for improving long-term outcome and quality of life.

Rehydration with Fructose Worsens Dehydration-Induced Renal Damage

Tamara Milagres,[1] Gabriela E. Garcia,[1] Takuji Ishimoto,[1] Miguel A. Lanaspa,[1] Ana Andres-Hernando,[1] Takahiko Nakagawa,[1] L. Gabriela Sanchez-Lozada,[2] Masanari Kuwabara,[1] Richard J. Johnson,[1] Carlos Alberto Roncal-Jimenez.[1] *[1]Div of Renal Diseases and Hypertension, Univ of Colorado, Aurora, CO; [2]Inst Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico.*

Background: We reported that recurrent heat stress and dehydration induces chronic kidney disease due to polyol-induced fructose generation with metabolism by fructokinase. Here we test if there is a significant difference for kidney injury in mice between two different rehydration methods:pure water and fructose water.

Methods: We used two groups of mice.Mice were recurrently exposed to heat(39.5 C^0 for 30 min/h 5x/d for 5 wks).After mice became dehydration condition,we gave these mice rehydration with pure water(n=9, W) or 10% fructose water(n=9, F)consisting of 6 ml each night.Furthermore we made a control group (C),which did not have dehydration. We compared kidney function among three groups.

Results: Dehydration conditions was similar between W and F group[serum osmolality(sOsm)of W:344mOsm/kg; F:340 mOsm/kg].sOsm was significantly different between dehydration groups and control group(307 mOsm/kg)(P<0.001).Urine osmolality (uOsm) had also significant differences between dehydration groups(W: 3095,F: 2825 mOsm/kg) and control group(1976 mOsm/kg)(P<0.001).Serum copeptin level(vasopressin marker)in F group(22 pg/ml)was significantly higher than W(16 pg/nl) and C(12.5pg/ml) groups(P<0.001).Urine NGAL(ng/mg creat)in F group (156)was significantly higher than W (141) and C(47)groups(P<0.01).Interstitial fibrosis area in glomeruliin F group(0.53%) was significantly larger than W(0.43%) and C(0.33%)groups(P<0.001).Macrophage (F4/80) infiltration area in gromerulus in F(0.22%)was significantly larger than W(0.080%) and C(0.048%) groups(P<0.001).Kidney MCP-1 level in F group(28.4 pg/mg) was significantly higher than that in C group(24.8pg/mg).(P=0.031).MCP-1 level had no significant difference between F and W group(26.1 pg/mg).

Conclusions: Rehydration with fructose in heat stressed,dehydrated mice caused renal damage,likely due to higher vasopressin levels.This result suggests rehydration with soft drinks in the setting of heat stress and dehydration may not be good for the kidney.

Impact of Direct Acting Antiviral Agents on Kidney Function in Hepatitis C Virus Infected Patients

Javier Pagan, Antonio A. Armstrong, Vanessa Blumer, Roberto J. Echeverri, Maria Del Pilar Hernandez, Fernando E. Pedraza, Marco A. LadinoAvellaneda, David Roth. *Nephrology, Univ of Miami / VAMC, Miami, FL.*

Background: Hepatitis C virus (HCV) infection is a public health issue with approximately 170 million individuals infected worldwide. The prevalence of HCV infection is higher in patients with chronic kidney disease (CKD) and data suggests that it is a risk factor for CKD progression. The new direct acting antivirals (DAA) have transformed the treatment of HCV with high (>90%) sustained virologic response (SVR) rates achieved. The objective of this study is to evaluate the relationship of DAAs treatment and kidney function.

Methods: We used a retrospective and descriptive design. Consecutive patients with HCV and on DAA's were identified at the Miami VAMC from 2015 to 2016 (n=397). The following DAA agents were used: ledipasvir, sofosbuvir, simeprivir, ribavirin and daclastavir. Serum creatinine with estimated glomerular filtration rate calculations (eGFR/MDRD formula) were obtained. The following data was obtained: gender, age, creatinine (Cr) and eGFR before and at 12 weeks following completion of therapy were obtained. Blood pressure (BP) measurements before starting and after therapy were also analyzed.

Results: 397 patients were identified, 380 males and 17 were females. The mean age was 63 years old (range 36-84). Most of the patients were treated with a combination of drugs: sofosbuvir (390/396:98.5%), ribavirin (201/396:50.8%), ledipasvir (195/396:49.2%), simeprivir (155/396:39.1%) or daclastavir (8/396:2%). The mean Cr before therapy was 1.4 mg/dl and eGFR was 53 ml/min, after DAA therapy the mean Cr was 1.2 mg/dl and eGFR was 64 ml/min (p=0.001), the mean systolic BP before therapy was 130 mmHg and 134 mmHg after, the diastolic BP before and after therapy was 80 mmmHg.

Conclusions: The use of DAA agents to treat HCV was associated with a statistically significant improvement in eGFR. No significant changes were seen in systolic or diastolic BP at the end of treatment. Prospective long-term studies are needed to establish a clear relationship between renal function and treatment of HCV-positive patients with DAA.

PUB205

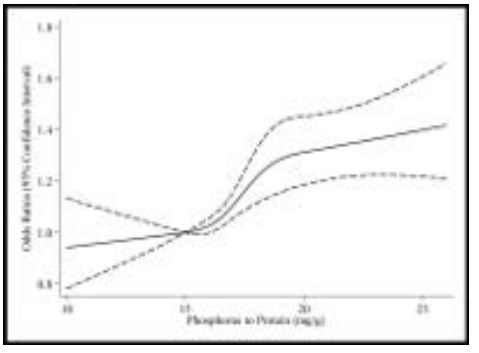
The Association of Dietary Phosphate to Protein Ratio with Metabolic Syndrome: Analysis of KNHANES Data

Jong Cheol Jeong,[1] Han Ro,[2] Inwhee Park,[1] Gyu Tae Shin,[1] Heungsoo Kim.[1] *[1]Dept of Nephrology, Ajou Univ Hospital, Suwon, Korea; [2]Dept of Nephrology, Gachon Univ Gil Medical Center, Incheon.*

Background: To keep adequate phosphate to protein ratio of dietary intake is important for the control of hyperphosphatemia among hemodialysis patients. However, whether dietary phosphate to protein ratio (p/prot) is also important in general population was unknown. We investigated the association of p/prot with metabolic syndrome.

Methods: We used The Korean National Health and Nutrition Examination survey (KNHANES) 2005 – 2014 data (n = 45,648). Metabolic syndrome was defined by fulfilling 3 or more criteria of the modified National Cholesterol Education Program Adult Treatment Panel III. Data available for estimated GFR, nutritional survey, metabolic syndrome were used. (n = 16,576).

Results: Dietary p/prot were divided by quartiles: mean dietary p/prot were 13.4 ± 1.5 mg/g, 16.2 ± 0.6 mg/g, 18.4 ± 0.7 mg/g, 21.9 ± 2.3 mg/g, respectively. Age was showed linear association with p/prot (β=0.058, p<0.001). Protein intake was inversely associated with increased p/prot (β=-0.041, p<0.001). A sigmoidal association of p/prot with metabolic syndrome was found.



P/prot higher than 18mg/g had odds ratio (OR) of 1.280 to metabolic syndrome [95% confidence interval (C.I.) 1.192 – 1.374]. Adjusted with sex, body mass index, low educational status, number of moderate-vigorous activities per week and smoking, p/prot showed adjusted OR of 1.262 to metabolic syndrome [95% C.I. 1.163 – 1.370]. However, when age was added in the model, the impact of high p/prot was reduced. [Adjusted OR, 1.084, 95% C.I 0.997 – 1.179].

Conclusions: In KNHANES population, ingestion of food with high p/prot was associated with metabolic syndrome. High p/prot was associated with low protein intake, which requires further dietary pattern analysis. Impact of p/prot could be different in different age group.

PUB206

Correlation Analysis of Renal Ultrasound Elastography and Clinical and Pathological Changes in Patients with Chronic Kidney Disease

Qiuling Fan. *Dept of Nephrology, The First Hospital of China Medical Univ.*

Background: To analyze the correlations with the Estimates of tissue Young's modulus (YM) of renal cortex, medulla and clinical biochemical indicators and pathological changes in patients with chronic kidney disease (CKD).

Methods: A total of 113 cases of CKD patients were enrolled in this study. Pearson's correlation analysis was used for the Young's modulus values and various related factors. In the correlation analysis, the variables showing significant correlation with the Young's modulus were introduced into the regression equation for multivariate linear regression analysis.

Results: The YM of CKD patients was significantly higher than that of the control group; and with the progression of CKD, the YM of the renal cortex and medulla gradually increased.The Young's modulus of the renal cortex was positively correlated with serum creatinine, urea nitrogen, cystatin C, serum phosphorus, calcium and phosphorus product, iPTH and uric acid levels and was negatively correlated with urinary MA, urinary NAG, eGFR, and hemoglobin levels. The YM of the renal medulla was positively correlated with SBP, serum creatinine, BUN, iPTH, and UA and was negatively correlated with urinary MA, urinary NAG, eGFR, and hemoglobin levels. Serum cystatin C, uric acid, and iPTH levels were independently correlated with the YM of the renal cortex. Serum creatinine, uric acid levels and smoking were independently correlated with the YM of the renal medulla. The YM of the renal cortex in the patients with phases IV and V based on the Lee grading system of IgA nephropathy were significantly higher than phases II and III. According the Oxford classification , the YM of the renal cortex and medulla in the T1 and T2 patients were significantly higher than those of the T0 patients. The YM of renal medulla in focal segmental glomerulosclerosis was significantly higher than that in minimal change nephropathy.

Conclusions: Renal ultrasound elastography is expected to provide a new indicator for determining CKD progression and the extent of kidney fibrosis and to distinguish between focal segmental glomerulosclerosis and minimal change nephropathy.

PUB207

Left Atrial Function: A Cardiac Computed Tomography Study of Patients with Chronic Kidney Disease Laust Dupont,[1] Simon Winther,[2] Hanne Skou Joergensen,[1] My Svensson,[3] Per R. Ivarsen.[1] *[1]Dept of Nephrology, Aarhus Univ Hospital, Aarhus N, Denmark; [2]Dept of Cardiology, Aarhus Univ Hospital, Aarhus N, Denmark; [3]Dept of Nephrology, Oslo Univ Hospital, Akershus Univ Hospital, Oslo, Norway.*

Background: Previous studies using 2-dimensional-echocardiography show that left trial end-diastolic volume (LaEDV) is predictive for CV outcomes and mortality in CKD patients. Cardiac computed tomography (CCT) angiography measure LaEDV more precise than echocardiography.

Hypothesis: LaEDV and left atrial ejection fraction (LaEF) measured by CCT is predictive of major adverse cardiac events (MACE), and is positively correlated to functional metrics of left ventricular (Lv) function and plasma-pro-brain natriuretic peptide (pro-BNP) in CKD.

Methods: 167 kidney transplant candidates from 9 regional centres underwent CCT angiography prior to kidney transplantation. La and Lv volume and function were determined using CCT. MACE and mortality data were extracted from Western Denmark Heart Registry, review of patient records and patient interviews.

Results: LaEDV was significantly associated with pro-BNP ($p<0.05$, $r=3.98$), Lv end-diastolic volume ($p<0.05$, $r=0.14$) and mass ($p<0.05$, $r=0.05$). LaEF was significantly associated with age ($p<0.05$, $r=-0.003$) and pro-BNP ($p<0.05$, $r=-0.03$). During a median follow-up of 3.3 years (*range:* 0.3-5.1), 22 (15.0%) patients suffered MACE and 24 (16.4%) died. MACE and survival analysis showed no relation to LaEDV (*survival*: HR=0.99, p=0.53 – *MACE*: SDHR=1.00, p=0.92) and LAEF (*survival*: HR=0.50, p=0.74) – *MACE:* SDHR=0.16, p=0.45), whereas Lv ejection fraction was solely associated to increased MACE risk and not mortality (*survival:* HR=0.98, p=0.46– *MACE:* SDHR=0.94, p<0.05).

Conclusions: Using CCT, LaEDV correlates to functional parameters of Lv in CKD. The association does not apply to LVEF. We failed to detect any association between LaEDV, MACE and mortality in this cohort of kidney transplant candidates. Similar results were found for LaEF. Lv ejection fraction was solely associated to MACE.

PUB208

Timing and Pregnancy in ESRD Patients: When Is Conception Better? Amelia Rita Bernasconi,[1] Liliana Susana Voto,[2] Alicia M. Lapidus,[2] Rosa Alejandra Waisman,[2] Ricardo M. Heguilen.[1] *[1]Medicine, Hospital J.A. Fernández, Caba, Buenos Aires, Argentina; [2]Materno-Fetal, Hospital J.A. Fernández, Caba, Buenos Aires, Argentina.*

Background: Pregnancy (P) in women with renal disease (CKD) implies significant risk for adverse maternal and fetal outcomes. Although advances in antenatal and neonatal care continue to improve them, risks remain proportionate to the degree of underlying renal dysfunction.There is evidence to suggest that pt with 1-2 CKD, normal bp, and no urinary protein, P is safe. Trying to stablish better timing of pregnancy in further ESRD pt is still controversial.

Methods: we compared the outcome of Pt in 3 different CKD groups. Group A:(10 ESRD 4-5 p pt); Group B: 10 P in HD (pt in dialysis between 1-10 years); Group C: 10 P in renal transplant women (4 w/related donor).

Results: All groups mean age was similar, no DBT, no SLE. Folic acid, rHuEpo and IS maintained stable mothers H^{to} (28%) and HB (8.7 g/dl) in all groups. Aimed at improving fetal lung maturity, intramuscular betamethasone was administered at 32 weeks. Methylprednisone pulse was given peripartum to avoid intra and postpartum stress in Group C. Amlodipine and or labetalol were used when necessary in the three groups. GA: pt entered in an intensified HD schedule (> 20 h/w) when SCR increased to 3,5 mg/dl. GB: intensified dose was prescribed. GC: all pt received appropriate medication for P. Main data are shown in table one.

	GA (n: 10)	GB (n: 10)	GC (n: 10)	p
Age, *y*	25.5 ± 5.6	31.4 ± 4.6	26.2 ± 6.7	NS
Gestational age, *w*	31.8 ± 4.3	32.0 ± 3.9	36.6 ± 1.6	0.03
Weight at birth, *g*	1495 ± 744	1418 ± 436	2714 ± 545	0.001

Conclusions: better timing for conception maybe during transplantation according to our data. In preconception counselling patients should be advised of the high risk of fetal demise and early Hd start in ESRD 4-5, intensified Hd schedule in those previously in RRT, and graft loss in declining renal function pt, and adverse pregnancy outcome in. According to our study the administration of human recombinant erythropoietin has a beneficial effect in pregnancy without side effects. Preterm delivery, IUGR and low birth weight are common in this population.

PUB209

Comparison of Different Definitions of Progression of Chronic Kidney Disease and Predisposing Factors in a Public Renal Practice: Queensland, Australia Rajitha Asanga Abeysekera,[1,3] Zaimin Wang,[1,2] Jianzhen Zhang,[1,2] Helen G. Healy,[1,3] Anne Cameron (Salisbury),[1,2,3] Wendy E. Hoy.[1,2] *[1]NHMRC CKD.CRE and CKD.QLD, 1, Brisbane, Queensland, Australia; [2]School of Medicine, Univ of Queensland, 2, Brisbane, Queensland, Australia; [3]Kidney Health Service (RBWH); Metro North Hospital and Health Service, 3, Brisbane, Queensland, Australia.*

Background: We compared different definitions of CKD progression and assessed factors associated with progression.

Methods: Annual data ofCKD patients in the public renal practice of the RBWH, who were enrolled in the CKD.QLD registry were analysed from consent until 31st July 2015. 905 and 682 patients were studied at 1 and 2 years follow up. Six definitions of progression were evaluated- Definition **i:** loss of EGFR of >2ml/min/1.73m^2/year, **ii**: loss of >5ml/min/1.73m^2/year, **iii**: change of CKD stage, **iv**: combination of CKD stage change & 25% eGFR reduction, **v**: 20% eGFR reduction, and **vi**: start of renal replacement therapy. Age, gender, renal diagnosis, AKI, presence of diabetes, and number of comorbidities were evaluated as potential predictors over the first year.

Results: Proportions defined as progressing at one year, in descending order, were: Definition **i** 42.8%, **ii** 26.7%, **iii** 18.5%, **iv** 14.7%, **v** 7.9% and **vi** 3.3%. At two years, the proportions were 38%, 15.5%, 23.2%, 21.9% and 12% and 2.2% respectively, representing a similar rank order, except for the lesser frequency of Definition **ii.** Among the four major groups of renal diagnoses, proportions who progressed, regardless of definition, were, in descending order, diabetic nephropathy, renovascular disease, genetic renal disease, and glomerulonephritis. More patients with >8 comorbidities progressed, versus those with <4 comorbidities. Compared to stage 1, 2 and 3A, more patients in CKD stage 3B, 4 and 5 progressed. More patients with any diagnosis of AKI progressed compared to patients without AKI ($p<0.005$). Patients <40 years old had the lowest rates of progression. Males tended to more often be progressors, although this was not significant.

Conclusions: There is some consistency of the different definitions of progression. The choice of a particular expression should be context specific. These data give valuable insights into progression of CKD.

PUB210

The Effects of Pazopanib versus Sunitinib on Renal Outcome in Metastatic Renal Cell Carcinoma Eun Jeong Lee, Subin Hwang, Hye Ryoun Jang, Wooseong Huh, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Jung Eun Lee. *Nephrology Div; Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

Background: Pazopanib and sunitinib are used as the first-line treatment of metastatic renal cell carcinoma (RCC). Several studies have reported similar efficacy with a favorable safety profile of pazopanib. The aim of this study was to examine the renal outcome after pazopanib versus sunitinib treatment in patients with metastatic RCC.

Methods: We reviewed medical records of 304 patients with metastatic renal cell carcinoma who received pazopanib (n=103) or sunitinib (n=201) therapy from 2007 to 2016. The primary outcome was chronic kidney disease (CKD) progression, defined as a drop in glomerular filtration rate (GFR) category accompanied by a 25% or greater drop in GFR from baseline, during treatment. Secondary outcome was disease progression-free survival.

Results: Overall, 47% of subjects had CKD stage 3 or 4 at baseline. Distributions of CKD stage were similar between two treatment groups. Treatment durations were 363 (129 ~ 504) days in pazopanib group and 360 (91 ~ 510) days in sunitinib group. Incidence of CKD progression was 19% in pazopanib group 17% in sunitinib group at 1 year after treatment ($p = 0.083$ by log rank test). Lower serum albumin levels and older age were independent risk factors of CKD progression. Progression-free survival was higher in pazopanib group than in sunitinib group ($p = 0.04$ by log rank test, 53% vs 42% at 1 year after treatment). In sunitinib group, dose reduction was conducted more often than in pazopanib group during treatment (68% vs 40%, p=0.032).

Conclusions: The effects of pazopanib versus sunitinib treatment on CKD progression were similar in real-world practice. However, higher percentage of pazopanib group continued the regular dosage of drugs and more favorable cancer outcome was observed in pazopanib group.

PUB211

Urinary N-Acetyl Cysteine and Kidney Disease Progression in HIV-Infected Patients: A Prospective Study Clara Dias,[1] Lucília N. Diogo,[1] Pedro Pereira Campos, Ana R. Lemos,[1] Emília C. Monteiro,[1] Karina Soto,[1,2] Sofia Pereira.[1] *[1]CEDOC, NOVA Medical School/Faculdade de Ciências Médicas, Lisbon, Portugal; [2]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal.*

Background: Chronic kidney disease has emerged as a major health concern in HIV-patients, its early diagnosis is paramount to prevent progression. Screening and searching for new non-invasive pathophysiologic markers are a key challenge. *N*-acetyl cysteine-disulfides conjugates are products of *N*-acetyltransferase 8, an enzyme mainly expressed in proximal tubular cells that has been pointed out as a candidate for renal regulation and nephrotoxic response. *N*-acetyl-cysteine conjugates were identified in urine open the possibility of using as surrogate of *N*-acetyl cysteine-disulfides conjugates. The aim of the present study was to determine if urinary *N*-acetyl-cysteine (uNAC) can be uses as biomarker of kidney disease progression.

Methods: As a part of an ongoing prospective study of HIV+ population, a 1-year analysis was performed in a cohort of patients under combined antiretroviral therapy, with visits at 0 (M0), 6 (M6) and 12 (M12) months. Glomerular filtration rate (eGFR) was estimated by CKD-EPI equation, expressed in mL/min/1.73m^2. Patients were divided in 2 groups according their eGFR evolution: Group1, stable eGFR; Group2, decline in eGFR≥10% at M12.uNAC was quantified by HPLC with fluorescence detection. Data are presented as percentage relative to M0.

Results: A total of 24 HIV-infected patients were included (67% men, 33% Black, 54 [IQR47-62] years old at M0). Patients with eGFR≥90 had higher uNAC at M0 than patients with kidney disease (*Unpaired t*-test, p=0.005). Among patients with stable eGFR, the levels of uNAC remained unchanged after 12 months in opposite to patients with a declined eGFR (*Two-way RM ANOVA* with *Bonferroni* post-test, p<0.05). Ten patients had a pronounced declined eGFR (83±SD7%), at M12 (*Paired t*-test, p=0.010). Correlated with a significant decrease in uNAC (60±40%) (*Wilcoxon signed rank* test, p=0.006).

Conclusions: Kidney disease progression was associated with a significant decline in uNAC. The present results suggest that uNAC has a role as a newly non-invasive indicator of kidney disease progression in HIV.

PUB212

Risk Factors Involving CKD Progression – Brazilian Perspective

Paula Ferreira Orlandi,[1] Naohiko Fujii,[1] Roberto Zatz,[2] Harold I. Feldman.[1] *[1]Center for Epidemiology and Biostatistics, Univ of Pennsylvania, Philadelphia, PA; [2]Nephrology Div, Univ de São Paulo, São Paulo, São Paulo, Brazil.*

Background: Few data are available about CKD progression in the Brazilian population . This study evaluates the association between established risk factors for CKD progression and the development of ESRD in a retrospective cohort of individuals followed in an outpatient CKD Unit in São Paulo, Brazil.

Methods: A total of 2290 individuals with mean age of 63±15 yrs were followed by a median of 4 years. All had at least 2 consecutive eGFR measurements <=60 ml/min/1.73m2 in an interval >=3 months. Clinical and laboratorial assessments included standardized serum creatinine and urinary protein to creatinine ratio (PCR), obtained from electronic medical records. Main outcome was ESRD, defined as initiation of dialysis, transplantation or eGFR<10ml/min/1.73m2. We performed survival analyses with the Cox proportional hazards model. Creatinine based CKD-EPI equation was used to estimate eGFR.

Results: Participants were predominantly white (79%), with history of hypertension in 88.6% and diabetes in 39.9%. Incidence rate of ESRD was 3.2 per 100 persons-year. Among the most significant factors associated with ESRD were: baseline eGFR (HR 2.27 [95%CI 1.14, 4.55] for eGFR 30-45 and 4.7 [2.3, 9.3] for eGFR<30; Ref: eGFR 45-60; P<0.001); PCR (HR 2.7 [1.17, 6.27] for PCR 30-300 mg/gCr and 8.3 [3.8, 18.2] for PCR>300; Ref: PCR<30; P<0.001); age (HR 0.57 [0.43, 0.76] for age 55-75 and 0.19 [0.10, 0.35] for age>75; Ref: age<55; P<0.001); systolic blood pressure (sBP) (HR 1.67 [1.15, 2.43] for sBP 120-140 mmHg and 2.28 [1.57, 3.31] for sBP≥140; Ref: sbp<120, P=0.001); and serum albumin (Alb) (HR 0.63 [0.43, 0.91], 0.49 [0.34, 0.70], and 0.47 [0.30, 0.74] for Alb 4.1-4.4 g/dL, 4.4-4.6, and ≥4.6, respectively; Ref: Alb<4.1, P=0.0002).

Conclusions: This is one of the first studies analyzing renal outcomes in a cohort of Brazilian patients. A significant association of risk factors such as ethnicity, diabetes and BMI with ESRD was not observed, whereas older age, sbp, and albumin were significantly associated with ESRD.

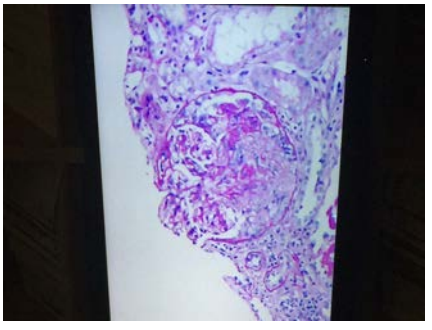
PUB213

A Fascinating Case of Anti Glomerular Basement Membrane (GBM) Disease with Coeexisting Anti Neutrophil Cytoplasmic Antibody (ANCA) following Aortic Dissection

Sadeem Ali, William A. Davila, Reginald Ifeanyi Obi. *Nephrology and Hypertension, East Carolina Univ/ECU, Greenville, NC.*

Background: About 30% of patients with anti-GBM disease have co existing ANCA positivity. The occurrence of this disease after aortic dissection has not been reported in literature. We describe this case of a "double positive serology" presenting with Rapidly Progressive Glomerulonephritis & diffuse alveloar hemorrhage (DAH) after an aortic dissection.

Methods: 45yrs woman with controlled hypertension presented with sudden chest & back pain. **Exam** found tachypnic, even on oxygen. **CT** confirmed type A aortic dissection extending to the upper pole of left kidney. After repair, she was **discharged**. She **represented** 2 weeks later with hemoptysis & dyspnea. **Creatinine** rose to 2.2, & urine had dysmorphic RBCs. **Bronchoscopy** confirmed DAH. **Renal biopsy** found 75% glomeruli with cellular crescents in the same stage.



Immunofluorescence stain revealed 2+ linear GBM staining. Anti GBM & p-ANCA **titers** were elevated. Patient was **treated** with plasma exchanges, steroids & IV Cyclophosphamide over 3 months that lead to resolution of hemoptysis and significant improvement of renal function.

Conclusions: Our patient presentation & renal biopsy findings support more an Anti GBM disease with co existing p- ANCA positivity. Anti GBM disease & ANCA associated vasculitis are diseases characterized by circulating antibodies. The principal target for the anti-GBM antibodies is the alpha-3 chain of type IV collagen. Type IV collagen is also in subintimal membrane of aorta . We postulate that the aortic dissection exposed the hidden antigenic domain of type IV collagen resulting in antibody formation that resulted in this anti GBM disease few weeks later. **CONCLUSION:** Aortic dissection could be a risk factor for developing anti GBM disease in future.

PUB214

Twenty-Six Cases Treated by Short Term Steroid Regimen for Adult Steroid Sensitive Nephrotic Syndrome

Takaya Ozeki, Takayuki Katsuno, Sawako Kato, Yoshinari Yasuda, Shoichi Maruyama. *Dept of Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: The appropriate treatment duration for adult steroid sensitive nephrotic syndrome (SSNS) is not clear. In pediatric field, recent trials revealed that 2 months short term steroid regimen for SSNS children is not inferior than extended course of steroid in the occuerence of frequent relapse or steroid dependent disease. This is the case series of 26 adult steroid sensitive nephrotic syndrome patients treated by 2 months short term steroid regimen.

Methods: Among the biopsy-proven adult MCNS or FSGS cases in Nagoya university affiliated hospitals during Feb. 2015 to Jan. 2016, patients satisfied the following criteria: over 20 years old, first time episode of nephrotic syndrome, acieved remission within 4 weeks and concent of the patient was obrained. Treatment plan of short term steroid regimen is as below; (1) prednisolone 0.8-1.0 mg/kg/day as initial dose and continued for 4-6 weeks. (2) prednisolone reduced to 0.5-0.6 mg/kg/alternative day and continued for 4 weeks. We compared the patients with histrical control from our retrospective cohort (140 cases).

Results: There were 26 cases (male: 13, median age: 50.0). The initial steroid dose was 50 mg/day in the midian. All the patients except 1 was finished steroid administration without relapse. Throughout the observation period (median: 204.5 days), 14 cases (53.9%) experienced relapse and 1 patinet (3.8%) developed to frequent relapse. The adverse events were observed in 2 cases (3 incidents). None had an episode of adrenal insufficiency. Compared with the histrical cintol, patients treated by short term regimen relapsed earlier from the baseline (131 vs 357 days, p<0.001), but the cumulative steroid dose at 3, 6 and 9 months from the baseline were significantly lesser in short term regimen patients (1822 vs 2855 mg, 2160 vs 4095 mg and 1781 vs 4887 mg respectively).

Conclusions: Although the timing of relapse in short term regimen is earlier than conventional one, short term steroid regimen may detect the frequent relapse or steroid dependent cases in SSNS earlier and lesser steroid exposure. For further comparison, it is necessary to analyze by extending observation period.

PUB215

Monotypic Atypical Anti-GBM Nephritis in a 9/11 First Responder

Neeraj Sharma,[1] Hone S. Kaw,[1] Hiba M. Ahmed,[1] Mandeep Samra,[1] Farah Piracha,[1] Ananea Adamidis,[2] Jennine Michaud,[1] Michael Yudd.[1] *[1]Renal Section, Dept of Veterans Affairs NJ Healthcare System, East Orange, NJ; [2]Renal Medicine Associates, Teaneck, NJ.*

Background: Atypical anti-GBM nephritis (AAGN) is rare, and is characterized by bright linear anti-GBM immunoglobulin staining in the absence of circulating anti-GBM antibodies. As opposed to typical anti-GBM, the clinical course of AAGN is frequently renal-limited and indolent. Nasr et al described 20 patients with this – we add another.

Methods: 44 year old white man, a first responder at the World Trade Center in 9/11, developed gross hematuria in 2007. Urologic work up was negative. In 2010, labwork showed creatinine 1.4 mg/dL, urinalysis 2+ protein and large blood, urine protein/creatinine ratio 0.8, with the following negative or normal studies: ANCA, anti-GBM, SPEP, κ/λ ratio, complements, hepatitis B/C and HIV. First renal biopsy, in 2010, showed mild endocapillary proliferation with linear IgG1λ deposits and no electron dense deposits. He was started on steroids, but could not tolerate them and stopped. Ace inhibitor was started. Six years later, labwork showed moderate worsening: creatinine 1.7mg/dL, urine protein 2.9 g/day, urinalysis 2+ protein, large blood. Repeat biopsy in 2016 showed similar findings: mesangial proliferative GN with MPGN features, the same monotypic-restricted bright linear deposits on IF, and no electron dense deposits, with mild increase in chronicity. Bone marrow biopsy showed no monoclonality.

Conclusions: Our patient had an indolent renal-limited course over at least 9 years. Biopsies showed mild proliferative changes and diffuse linear GBM staining with a monotypic IgG1λ, and no electron-dense deposits. Monoclonal gammopathy was not present. Environmental factors may trigger anti-GBM disease, particularly hydrocarbon exposure . Whether toxic exposure at 9/11 could have played a role is not known. The cause of the linear Ig accumulation in the GBM is uncertain. Potential mechanisms include: antibodies reactive to a GBM antigen, likely different from the conventional 3NC1 of anti-GBM nephritis; physicochemical properties of the Ig chains independent of antigen, similar to MIDD findings; abnormalities of the GBM.

PUB216

Glomerular Diseases Associated with Malignancies: Clinical Presentation, Histopathology and Outcome Sophia Lionaki,[1] Konstantinos Panagiotellis,[1] Joan Vlahadami,[2] Ioanna Tsoubou,[1] Chrisovalantis Vergadis,[3] George Liapis,[4] Petros P. Sfikakis,[5] Athanasios Tzioufas,[2] John Boletis.[1] *[1]Nephrology, Laiko Hospital, National & Kapodistrian Univ, Athens, Greece; [2]Pathophysiology, National & Kapodistrian Univ, Athens, Greece; [3]Radiolody, Laiko Hospital, Athens, Greece; [4]Pathology, Laiko Hospital, Athens, Greece; [5]Propeudeutic and Internal Medicine, National & Kapodistrian Univ, Athens, Greece.*

Background: To study the glomerular diseases, associated with malignancies (GDAM), with respect to clinical characteristics and histopathological findings.

Methods: We retrospectively studied the medical charts of all patients with GDAM, diagnosed in our hospital between 2008-2015 and recorded demographic, clinical, laboratory and histopathological findings, as well as the type of malignancy and the outcomes at end of follow up.

Results: Twenty nine biopsy proven cases with GDAM were identified, with a mean age of 62.4(±12.0) years at kidney biopsy. Renal histopathology revealed: membranous nephropathy in 9 cases (31.0%), membranoproliferative glomerulonephritis in 5(17.2%), lupus-like nephritis in 4(13.8), minimal change disease in 4(13.8%), pauci-immune glomerulonephritis in 3(10.3%), IgA nephropathy with crescents in 1(3.4%), amyloidosis in 1(3.4%) and interstitial nephritis in 2(6.9%). 13(44.8%) patients presented with acute nephritic syndrome and 4(30.8%) with rapidly progressive glomerulonephritis. 12(41.4%) patients developed acute renal injury within 2.85(±2.83) months from kidney biopsy and 5(17.2%) required dialysis. 14(48.3%) cases had a solid tumor and 15(52.7%) a hematologic malignancy.

Characteristic	Median (range) or (mean±sd) or N (%)
24h proteinuria (g/day)	4.2 (0.12-16.9)
Hematuria	19 (65.5)
Ser creatinine (mg/dl)	1.2 (0.8-9.6)
Immunosuppressive therapy	14 (48.3)
GDAM outcome Remission Treatment resistance ESRD Death	 13(44.8) 8(27.6) 4(13.8) 7(24.1)
Follow up time (months)	30 (±26.05)

Conclusions: Patients with GDAM may present with various clinical pictures, combined with diverse histopathological patterns. Prompt and accurate diagnosis, recognition of the specific characteristics of each patient and individualized management are critical for renal and patient outcome.

PUB217

Improving Administration Rate of Pneumococcal Polysaccharide Vaccine (PPSV23) in Children > 2 Years with Nephrotic Syndrome: A Single Center Experience Siddharth A. Shah. *Pediatric Nephrology, Univ of Louisville, Louisville, KY.*

Background: Pneumococcal infections are major cause of morbidity and mortality in children with nephrotic syndrome. Apart from pneumococcal vaccines, other strategies have not shown to decrease the risk of pneumococcal infections. Previous study showed high serological response to pneumococcal vaccine in nephrotic children even at disease onset on high-dose prednisone therapy. IgM is less likely to be lost in urine in active disease state given its high molecular weight compared to IgG. The challenges to improve coverage with PPSV23 vaccine include vaccine availability, compliance to clinic visits and patient education.

Methods: A standard protocol was established to administer PCV13 and PPSV23 vaccine as per ACIP guidelines. All patients with clinical diagnosis of nephrotic syndrome and age range between 2 and 18 years were included in the study. Two strategies were implemented including: 1) Inpatient administration of PPSV23 vaccine at time of initial diagnosis of nephrotic syndrome or during hospital admission for relapse or infection 2) Outpatient administration of PPSV23 vaccine. Letters were mailed to family. PPSV23 documentation and alerts were added to Clinical Notes to help improve patient education.

Results: Overall, 58 children and adolescents with clinical diagnosis of nephrotic syndrome were included in the study. The PPSV23 immunization rate had improved to 80% after 2 years compared to 32% at beginning of study. Hospital administration of PPSV23 vaccine helped achieve better immunization rates. The PPSV23 vaccine administration rate was only 60% in children who received vaccines at outpatient basis even with patient letter and clinic visit reminders.

Conclusions: PPSV23 (Pneumovax) is readily available across major hospitals in United States in contrast to local pediatrician offices. PPSV23 vaccine should be administered as early as possible in children>2 years of age with nephrotic syndrome. PPSV23 administration at time of initial hospital admission for nephrotic syndrome or hospital admission for relapse may be an effective strategy to help improve immunization coverage in children with nephrotic syndrome.

PUB218

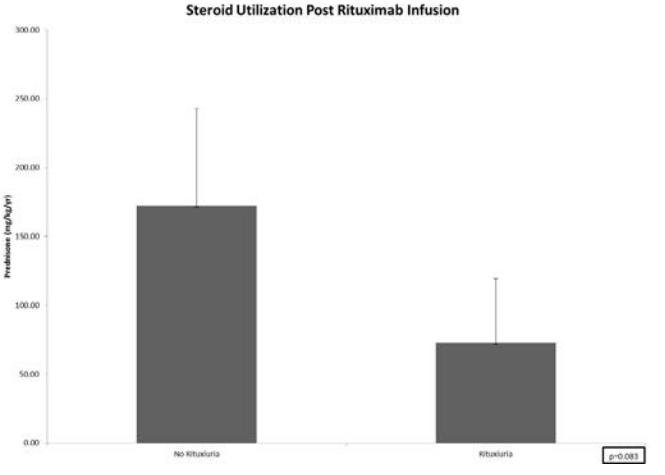
Study of Urinary Excretion of Rituximab in Pediatric Nephrotic Syndrome Jason Peter Thomas,[1] Teri L. Crumb,[2] Tracy J. Koehler,[3] Alejandro Quiroga.[2] *[1]Pediatric Residency, Grand Rapids Medical Education Partners, Grand Rapids, MI; [2]Pediatric Nephrology, Helen DeVos Children's Hospital, Grand Rapids, MI; [3]Research Dept, Grand Rapids Medical Education Partners, Grand Rapids, MI.*

Background: Rituximab (RTX) is a monoclonal antibody used in patients with steroid dependent nephrotic syndrome as an alternative to cyclophosphamide. As a protein, it is susceptible to excretion in the urine of patients with nephrotic range proteinuria.

Methods: This is a pilot pediatric clinical research trial (n=7) which enrolled patients prior to their clinically indicated RTX infusion. Serial urine samples were obtained pre/post-infusion to evaluate for RTX via ELISA. Patients received 2 doses of RTX (375 mg/m^2) 2 weeks apart.

Results: Rituximab was found in 3/7 patient's serial samples. There is a non-statistically significant increased likelihood of rituxiuria in patients with higher levels of proteinuria. Two weeks after infusion, 85% of the patients had no proteinuria. Two of three patients that excreted RTX in the urine were able to wean off steroids. Patients with rituxiuria required a lower cumulative dose of prednisone/kg/year post infusion (p=0.083).

Subject	Pre-Infusion (ug/mL)	1-3hr (ug/mL)	Infusion Completion (ug/mL)	24hr Post Infusion (ug/mL)
1	Not Detected	Not Detected	Not Detected	Not Detected
2	Not Detected	Not Detected	Not Detected	Not Detected
3	Not Detected	Not Detected	Not Detected	Not Detected
4	Not Detected	Not Detected	Not Detected	Not Detected
5	Not Detected	0.34	0.37	0.21
6	Not Detected	Not Detected	0.19	Not Detected
7	Not Detected	Not Detected	31.67	2.20



Conclusions: Patients with nephrotic range proteinuria receiving RTX developed rituxiuria in 42% of the cases. There is an increased likelihood of response to RTX as measured by cumulative steroid dose 1 year after therapy in patients with rituxiuria.

PUB219

IgA Nephropathy (IgAN) in Patients over 64 Years Old: A Devastating Disease with No Effective Treatment Angel M. Sevillano, Eduardo Gutierrez-Martinez, Manuel Praga. *On Behalf of Glosen, Grupo de Estudio de las Enfermedades Glomerulares de la Sociedad Española de Nefrología (G.L.O.S.E.N.), Spain.*

Background: Recent data from the Spanish Registry of Glomerulonephritis show that the incidence of IgAN is increasing among elderly subjects. Limited information about clinical characteristics, response to treatments and outcomes of elderly IgAN has been published.

Methods: Retrospective cohort study performed in 21 nephrology departments that collected data from patients over 64 years with biopsy-proven IgAN who were identified at each participating center in the period 1990-2015. This time interval was divided into five consecutive five-year periods. 142 patients with a mean follow-up of 48±52 months were included in the study.

Results: The incidence of IgAN in patients over 64 years increased in the last years, from 6 cases in 1990-1995 to 56 in 2011-2015 (p=0.00). Patients were divided according to the type of clinical presentation: 1) asymptomatic proteinuria and hematuria (n = 80, 56%) 2) Hematuria-induced AKI (n = 48, 34%) 3) Crescentic IgAN (> 50% crescents) (n = 7, 5%) and 4) nephrotic syndrome (n = 7, 5%). When comparing the two most common types of presentations (1 and 2), patients with hematuria-induced AKI were older, had higher serum creatinine at baseline, a higher number of cases with gross hematuria and more patients receiving oral anticoagulants (all significant). For the whole group of patients, renal and

patient survival at 1,3 and 5 years were 85%, 80% and 66%, and 95%, 84% and 75.7% respectively. At 5 years 49% of patients had died or reached ESRD. Most patients (83%) received RAAS blockade and 45% were treated with corticosteroids alone or accompanied by other immunosuppressive drugs. Among patients with hematuria-induced AKI, 56% received immunosuppressive treatments. There were no differences in the outcomes of treated and untreated patients.

Conclusions: Prevalence of IgAN is increasing among subjects over 64 years. Hematuria-induced AKI is a frequent type of presentation and oral anticoagulants may play a triggering role. Renal and patient survival is poor and immunosuppression does not improve prognosis.

PUB220

Significance of M2 Macrophage in Tubulointerstitial Disease Secondary to Primary Sjogren's Disease Jun Li,[1] Ya-Fen Yu,[1] Chang-Hua Liu.[2] *[1]Dept of Nephrology, The Affiliated Hospital of Jiangnan Univ, Wuxi, Jiangsu, China; [2]Dept of Nephrology, Clinical Medical College, Yangzhou Univ, Yangzhou, Jiangsu, China.*

Background: The study aims to observe the clinicopathologic significance of M2 macrophage in tubulointerstitial injury secondary to primary sjogren's disease.

Methods: Renal tissue samples from patients with tubulointerstitial disease secondary to primary sjogren's disease (SS, n =8), chronic tubulointerstitial nephritissecondary to drug (CIN, n =8), normal control kidneys (n =3) were included in this study. The expression of CD163 and CD68 was detected by immunohistochemistry or immunofluorescence.

Results: (1) Renal involvement was the first manifestation in six of eight (6/8) patients with pSS, including proteinuria, renal dysfunction, renal tubular acidosis and multiple renal stone; and one patient had intractable hypokalemia. (2)In the normal kidneys samples, CD163 and CD68 were occasionally expressed in tubulointerstitial tissue. (3) There were more CD163 and CD68 positive cells infiltration in tubulointerstitial injury of pSS, especially in patients with hypokalemia. CD68 positive cells were expressed around chronic tubulointerstitial injury and proteinuria casts. There was a negative correlation between the number of CD68-positive cells in tubulointerstitial lesions and estimated glomerular filtration rate(r=-0.700, p=0.004).CD163 positive cells were mainly expressed in acute tubulointerstitial injury of pSS, which positively correlated to N-acetyl-β-D-glucosaminidase(NAG, r=0.627, p=0.012)and beta2-microglobulin(r=0.602, p=0.018) separately. (4)Compared with CIN, patients with pSS had higher serum globulin level, ESR and lower urinary osmotic pressure. During follow-up of one year, four patients with pSS and acute tubular injury acquired improved renal function on therapy of middle dose of steroid and total glucosides of paeony. The remaining four patients with pSS had stable renal function.

Conclusions: M2 macrophage are involved in acute tubular injury in patients with primary sjogren's disease. Early intervention can improve renal function of tubulointerstitial injury secondary to primary sjogren's disease.

PUB221

Regional Incidence and Outcomes of Anti-GBM Disease Andrew Nixon, Ajay Prabhakar Dhaygude. *Renal Medicine Dept, Royal Preston Hospital, Preston, Lancashire, United Kingdom.*

Background: Anti-GBM disease is a rare autoimmune disorder characterised by rapidly progressive glomerulonephritis.[1] The estimated incidence is 1 case/million.[1] Renal survival is poor in those that present with severe acute kidney injury.[2]

Methods: Clinical records of all patients diagnosed with anti-GBM disease between 1/1/2010 and 11/1/2015 were reviewed.

Results: Eighteen patients were diagnosed giving a regional annual incidence of 3.4/million. The median age was 65yrs (M:F::1:1). The majority (16) were Caucasian. Five patients were also ANCA positive. Pulmonary haemorrhage was present in 3. A renal biopsy was performed in 7. The average percentage of crescents on biopsy was 94%. Steroids, cyclophosphamide and plasma exchange were administered to 12. Table 1 demonstrates 1yr patient and renal survival.

	Patients N (%)	1-Year Patient Survival N (%)	1-Year Renal Survival N (%)
Creat <500µmol/L	4 (22)	3 (75)	1 (25)
Creat >500µmol/L	14 (78)	11 (79)	2 (14)
-Dialysis first 72hrs	8 (57)	7 (88)	1 (13)
-No dialysis first 72 hrs	6 (43)	4 (66)	1 (17)
Total	18	14 (78)	3 (17)

There was no significant difference in 1yr renal (P>0.999) or patient survival (P>0.999) for those presenting with a creat<500µmol/L and those presenting with a creat>500µmol/L. There was also no significant difference in 1yr renal (P>0.999) or patient survival (P=0.539) for patients with a creat>500µmol/L that required dialysis within 72hrs and patients with a creat>500µmol/L that did not require dialysis within 72hrs.

Conclusions: This single centre study shows that the incidence of anti-GBM disease is over three-fold higher in the North West of England than reported elsewhere in the literature.[1] Furthermore, this study demonstrates that 1yr renal survival remains poor irrespective of presenting creatinine or initial dialysis requirement. **References:** 1. Twelve Hints and Tips for the Management of STEC-HUS Outbreaks Gianluigi Ardissino,[1] Francesca Tel,[1] Damiano Picicco,[1] Laura Daprai,[1] Valentina Bianchini,[2] Antonella Dodaro,[1] Milena Arghittu,[1] Mario Vittorio Luini.[2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano; [2]IZLER, Sezione di Lodi, Italy.*

Background: Shigatoxin-producing Escherichia Coli(S)Hemolytic Uremic Syndrome(HUS)is an endemo-epidemic thrombotic microangiopathy (TMA)and the management of outbreaks(O)is very challenging for both clinicians and public health(PH) professionals as shown in Germany in 2011. In SO, health care providers should be guided by clear and integrated(clinical/PH, hospital/community, human/veterinary/environmental) indications on priorities and most appropriate actions to protect individuals and the community.

Methods: Based on the experience gained in the management of 2 S-HUS O, which took place in Northern Italy in 2013 and 2015 (8 S-HUS, 41 infected), new recommendations were developed and tested; theese may worth being shared with the nephrology scientific community, the front line in S-HUS O.

Results: In case of proven or supected SO(2 or more S infections or S-HUS temporally/spatially related):1.The event must be immediately reported to the relevant health authority (HA);2.HA must promptly inform physicians operating in the involved area in order to have patients(pts)with diarrhea(bloody or watery)tested for a.hemoglobinuria(uHb)with urine dipstick to actively identify pts with ongoing TMA and b.for the presence of Shigatoxin(Stx) in the stools with PCR; 3.Pts with positive dipstick will be immediately addressed to blood testing to rule in/out the signs of TMA(platelet consumption, hemolysis, renal damage);4.If stools are Stx+ or HUS is confirmed, a stool sample must be sent to the appropriate lab for S isolation and serotyping; 5.Stx+Pts must continue daily testing for uHb to early detect TMA onset;6.Family members of Stx+Pts should be tested for Stx regardless of symptoms;7.A sample collecting point should be identified for easy access of pts to tests;8-12 continues.

Conclusions: This relatively novel approach to the management of a S-HUS O provides the best opportunity for early identification of S-HUS during an O and for protecting both the individuals and the community from the possibly devastating effect of infection spreading while enhancing the likelihood of identifying the source of the infection.

PUB223

Clinical Investigation of Preeclampsia in Patients with IgA Nephropathy Miho Karube, Shinya Kaname, Hideki Shimizu, Yoshinori Komagata, Yoshihiro Arimura. *The First Dept of Internal Medicine, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.*

Background: To evaluate the effect of preeclampsia on the renal prognosis in patients with IgA nephropathy.

Methods: In 15 patients with IgA nephropathy that experienced childbirth in the past 5 years in our hospital, 5 patients developed preeclampsia (PE) or superimposed preeclampsia (SPE), thus the 5 patients (IgAN group)were retrospectively analyzed for clinical features including onset time of PE, the child weight and childbirth weeks, blood pressure, renal function, degree of proteinuria, and uric acid levels, and were compared with 20 patients that had no known renal disease before pregnancy and were complicated by PE or SPE (non-IgAN group).

Results: No significant differences were observed in childbirth ages (35 years), blood pressure levels, delivery weeks and body weight of children between both groups. The primipara rate was higher in the non-IgAN group, although the premature infants were seen in both groups. However, the onset of hypertension was earlier in IgAN group than in non-IgAN group (22 vs. 27 weeks). Although proteinuria, serum Cr and uric acid levels were transiently worsened after delivery in both groups, the recovery was delayed in patients of IgAN group. Moreover, in 60% of the patients of IgAN group, renal function progressively worsened one year after delivery.

Conclusions: These results shows that although proteinuria may increase in IgAN and non-IgA groups, proteinuria may appear earlier and may be sustained longer, resulting in worsening renal function in IgAN. patients with PE or SPE.

PUB224

Effect and Security of Azathioprine in Maintenance Therapy for Refractory Nephropathy Mengjun Liang, Yajuan Huang, Xing Zhang, Jiafan Zhou, Rui Zhang, Jiang Zongpei. *Dept of Nephrology, The Six Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, China.*

Background: Refractory nephropathy relates to steroid resistant or frequently relapsing nephritis. Maintenance therapy has been called for lupus nephritis(LN). Effect and security of azathioprine in maintenance therapy are still controversial.

Methods: We conducted a retrospective study enrolling patients treated with azathioprine(50mg/d) and low-dose prednisone as nephritic maintenance therapy in our center from 2013.01 to 2016.01.

Results: Forty-four patients were enrolled, with 10 minimal-change disease(MCD), 9 idiopathic membranous nephropathy(IMN), 12 IgA nephropathy(IgAN), 3 focal segmental glomerulosclerosis(FSGS), 1 ANCA glomerulonephritis(ANCA-GN) and 9 LN. Relapse frequency of MCD patients was 3.5(Min-Max, 1-8). Eight IMN patients(88.9%) were treated with steroid plus cyclosporine as initial therapy with remission duration of 6.7±2.4months. Cellular crescent scale in IgAN patients was 11.4(5.0-72.4)%. Among them, 39 patients(88.6%) had persistent remission with efficiency of 80%, 88.9%, 100%, 33.3%, 100% and 100% in MCD, IMN, IgAN, FSGS, ANCA-GN and LN, respectively(p=0.030). The maintenance remission duration was 13(1-36)months. Relapse occured in 5

patients(11.4%) with 1 due to self-withdrawal. Nine patients(20.5%) met side effects with 2 dyshepatia, 2 leukocytopenia, 3 upper respiratory infection, 1 dermapostasis and 1 paramenia that were cured readily, and 5 patients dropped out of azathioprine therapy.

Conclusions: Our research indicates that azathioprine plus low-dose prednisone will do good to maintenance therapy for refractory nephropathy. The low dose of azathioprine, 50mg/d, may be effective and secure for Chinese patients.

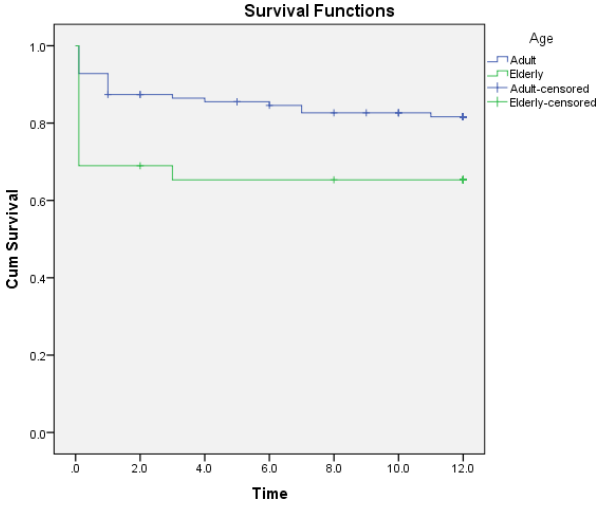
PUB225

IgA Vasculitis: Renal Outcomes in the Elderly James Stanway,[1] Patrick Hamilton,[2] Els Van de Perre,[4] James Tollitt,[5] Edmond O'Riordan,[5] Matthew David Morgan,[3] David R.W. Jayne,[4] Michael Venning,[2] Alan D. Salama.[1] *[1]UCL; [2]Manchester Royal Infirmary; [3]Univ of Birmingham; [4]Univ of Cambridge; [5]Salford Royal NHS Trust.*

Background: IgAV in adults has a poorer renal outcome compared with children. There are no data on renal prognosis in the elderly, in whom other forms of small vessel vasculitis fare worse. We investigated the renal outcomes in IgAV patients categorized according to age in a UK population.

Methods: We retrospectively analysed renal outcomes in patients from 5 UK sites with biopsy proven IgAV, defined as IgA GN on renal biopsy and evidence of vasculitis, including vasculitic lesions on renal or skin biopsy or purpuric rash. Primary outcome was progression to ESRD at 1 year, defined as doubling of serum creatinine from biopsy or use of renal replacement therapy. Secondary outcome was progression to ESRD at 5 years and eGFR at 1 year.

Results: We identified 111 18-65 year olds and 29 over 65s. Renal survival was 71.4% overall, 73.9% in the <65s and 61.7% in the 18-65s, p=0.21. Log-rank test showed significantly poorer 1 year survival in the >65s, p=0.035, but similar outcomes at 5 years. All >65s progressing to ESRD did so in the first year, 82% presented at ESRD compared to 28% of 18-65s. Mean eGFR at biopsy was 80mls/min and 56mls/min in 18-65 and >65 groups respectively p=0.014. An eGFR at biopsy below 30mls/min was associated with poorer 1 and 5 year survival; HR 9.8 (p<0.001) and 6.7(p<0.001) respectively. In those not reaching ESRD, there was a small increase in eGFR over the first year, no significant difference between age groups. Timing of biopsy with regard to eGFR and treatment given varied between sites.



Conclusions: In the short term, renal outcome is worse in patients aged over 65 years. An eGFR less than 30mls/min at biopsy is an important predictor for renal survival. Earlier biopsy and diagnosis may improve renal outcome in older subjects.

PUB226

Proliferative Glomerulonephritis with Monoclonal Ig Deposits: A 21 Cases Report Marc Ulrich,[1] Viviane Gnemmi,[2] Francois Glowacki,[1] Arnaud Lionet,[1] Cécile Lemoine,[1] Cyrille Vandenbussche,[1] Laurence Vrigneaud,[3] Christian Noel,[1] Celine Lebas.[1] *[1]Néphrologie et Transplantation, CHRU Lille, Lille, Nord, France; [2]Anatomopathologie et Cytopathologie, CHRU Lille, Lille, Nord, France; [3]Néphrologie, Dialyse et Médecine Interne, CH Valenciennes, Valenciennes, Nord, France.*

Background: Proliferative glomerulonephritis with monoclonal Ig deposits (PGNMID) was described by Nasr in 2004 with limited information on prognosis and treatment.

Methods: We retrospectively identified patients with histological PGNMID (strictly glomerular monoclonal immune deposits without organization on electronic microscopy (EM)) without cryoglobulinemia.

Results: We included 21 cases of PGNMID with 1 recurrence and 3 de novo occurrence on allograft. Mean age was 54,6 years. At diagnosis, mean creatininemia was 3,1 mg/dL, mean proteinuria 3,7 g/24h and haematuria was present in 90,5%. Eight patients had monoclonal spike. Main pathological presentation was membrano-proliferative glomerulonephritis (n=16) with IgG3 Kappa immune deposits in 62%. EM revealed non organized deposits, mostly sub-endothelial. Fourteen patients received chemotherapy 16,6 months after diagnosis meanly, 10 before end stage renal disease (ESRD). ESRD occurred in a mean time of 27,5 months in 4 of 7 non-treated patients and 6 of 14 treated patients. One patient experienced partial response (proteinuria 0,5g/24h and creatininemia 1,7 mg/dL versus 2,3 mg/dL, without histologic features of PGNMID at 6 months) without chemotherapy. Five patients deceased (mean time from diagnosis 44 months), one of them, transplanted, died of infectious complications.

Conclusions: This cohort confirms published data. PGNMID outcome is variable with nearly 50% of patients progressing to ESRD. A spontaneous partial response raises the matter of multiple diseases under PGNMID term. Nevertheless, nothing differentiated this case from the others. Even if early chemotherapy treatment may be valuable, there was no renal survey difference between chemotherapy and abstention group in this series, maybe because of the small sample size. Chemotherapy in transplanted patients may lead to infectious complications and Rituximab could be an alternative for them.

PUB227

Kidney Biopsy in aHUS May Be Misleading as to Final Renal Outcome Gianluigi Ardissino, Donata Cresseri, Francesca Tel, Michela Perrone, Stefania Salardi, Martina Sgarbanti, Silvana Tedeschi, Piergiorgio Messa. *Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milano, Italy.*

Background: Kidney biopsy (KB) is an important tool for diagnosis, staging and defining disease prognosis but in thrombotic microangiopathies (TMA) but in many centers (particularly in pediatrics) the diagnostic process relies upon lab findings, only.

Methods: Herein we describe 2 patients (pt) with aHUS in which KB was performed and the results, as to opportunity of renal recovery, were strikingly different compared to the ultimate (favorable) outcome obtained.

Results: A 42 yo woman was diagnosed aHUS 58 days (d) after delivery. Firstly addressed to plasmaexchange (PEX) the pt started Eculizumab (E) while on dialysis 18 d after diagnosis. TMA promptly improved and 3 mutation were detected on complement regulatory genes (CFH,CFI,THBD). KB performed for the persisting anuria on d 28 showed:diffuse thickening and reduplication of capillary walls, severely ischemic glomerular tuft and marked vascular intimal thickening. Nevertheless, E was continued, the pt was exposed to last dialysis on d 35, sCr peaked to 9.1 mg/dL, reached the nadir of 1.4 mg/dL 11 months later and so far it remains stable after 5 years of observation. A 28 yo girl was diagnosed aHUS following few weeks of generalized malaise. The pt was first addressed to PEX but the disease rapidly progressed to a peak sCr of 9.4 mg/dL. E was started on d 8 and KB was performed for the persistent anuria, on day 17 with the following findings: diffuse ischemic and segmental sclerotic glomerular lesions associated with vascular intimal fibrosis and lumen reduction. No mutation, nor AntiCFHAb, were detected. Renal function slowly improved and the patient remained dialysis dependent for 6.5 months, the nadir of sCr (1.3) was reached 3.1 yrs later and now has a stable renal function (sCr 1.3) after 3.6 yrs.

Conclusions: The presented observations rise the issue that KB in TMAs may not be informative and sometimes is frankly misleading for the decision making process on whether to address/continue complement inhibition. In our experience E is worth being tried anyhow as long as TMA is ongoing.

PUB228

Unique Case of Renal Amyloidosis: Leukocyte Chemotactic Factor 2 (Lect2) Deepti D. Torri, James J. Wheeler. *Park Nicollet Health System, St. Louis Park, MN.*

Background: The LECT2 associated renal amyloidosis is a recently recognized and unique clinical entity that primarily involves the kidneys, liver, spleen and adrenal gland. The most clinically significant feature is the slow progressive renal failure with an ethnic predominance in Mexican Americans or Middle Easterns.

Methods: A 68-year-old Mexican female presented to urgent care with throbbing headaches for the past two weeks. Her exam was significant for lower extremity pitting edema and hypertensive urgency, BP of 182/112. Her laboratory data revealed serum creatinine (Scr) of 4.2, with no prior baseline serum creatinine available for comparison. She was then seen in the nephrology clinic for evaluation of renal failure, volume overload and uncontrolled hypertension. Her additional laboratory testing,showed a spot urine total protein to creatinine ratio (TP/CR) of 8 gm. Serological workup was negative. She then underwent kidney biopsy that showed renal amyloidosis with marked diffuse involvement of glomeruli, interstitium and vessels. Liquid chromatography tandem mass spectrometry was done, which detected peptide profile consistent with LECT2. Her ultrasound of abdomen showed no splenomegaly or hepatomegaly and her echocardiography showed normal ejection fraction of 60%. She had no other organ involvement. Given her uremic symptoms and volume overload status she was initiated on dialysis.

Conclusions: LECT-2 associated renal amyloidosis represents a unique and perhaps not uncommon disease, especially in Mexican Americans.The pathogenesis and prognosis remain to be determined.The primary involvement is the kidneys. It typically does not involve the heart or the bone marrow. Liver involvement is typically isolated and, thus, does not likely occur in conjunction with kidney involvement. There is no treatment per se for renal LECT2 amyloidosis. The management is a kidney transplant or initiation of dialysis if they develop end stage renal failure.

PUB229

Efficacy of Steroid Monotherapy for Pure Membranous Lupus Nephritis Frank Ward, Mohammad Saad Alkhowaiter, Joanne M. Bargman. *Nephrology, United Health Network, Toronto, ON, Canada.*

Background: The benefit of combination immunosuppressive therapy over steroid monotherapy in pure membranous lupus nephritis (MLN) is unclear. Steroid monotherapy could reduce unnecessary exposure to additional immunosuppressive agents. We reviewed patient characteristics and outcomes in pure MLN at our institute in those treated with steroid monotherapy or combination therapy.

Methods: In a retrospective, observational cohort study we identified all patients with biopsy-proven pure MLN (ISN/RPS class V) treated since 1990. Inclusion criteria were 17 years or older, baseline proteinuria of at least 2g/day and minimum follow-up of 2 years. Combination therapy consisted of corticosteroids and at least one other agent. Outcomes were complete remission (CR), partial remission (PR) or no response based on serial proteinuria measurement. Categorical data were analysed by Fisher's Exact test and continuous data by Student's t-test.

Results: Steroid monotherapy and combination therapy groups were similar in terms of gender, age, duration of SLE, initial serum albumin and proteinuria levels, proportion of sub-nephrotic patients, estimated GFR, C3/C4/dsDNA titres, use of renin-angiotensin blockade and initial prednisone dosing. Combination therapy patients were more likely to have had extra-renal manifestations (100% vs. 40%, p=0.02). CR or PR was achieved in all steroid monotherapy patients and 88% of combination therapy patients. Time to remission (CR or PR) was significantly shorter in the steroid monotherapy group (6.4 months vs. 27.7 months, p=0.007). There was a non-significant trend towards a higher relapse rate in steroid monotherapy treated patients (60% vs 25%, p=0.26). Follow-up duration was similar between groups (mean 79.4 months vs. 60.7 months, p=0.44) and estimated GFR did not differ at latest follow-up (111ml/min/1.73m^2 vs. 112ml/min/1.73m^2, p=0.92).

Conclusions: Steroid monotherapy appears to be efficacious in pure MLN, and may be an appropriate first-line treatment in renal-limited disease. The relapse rate may be higher than that observed with combination therapy. Although limited by study design and sample size, these findings warrant further investigation by a larger, prospective, randomized clinic trial.

PUB230

Risk Factors for Renal Scarring in Children with Myelomeningocele Fatma Lale Sever, Yesim Kucukkagnici, Nur Canpolat, Salim Caliskan. *Pediatric Nephrology, Istanbul Univ, Cerrahpasa Medical Faculty, Istanbul, Turkey.*

Background: Most of children with myelomeningocele have neurogenic bladder. Bladder dysfunction predisposes patients to urinary tract infections, renal scarring and renal failure. We aimed to evaluate risk factors for renal scarring in these patients.

Methods: This single center study involves 53 children with neurogenic bladder due to myelomeningocele (28 male; mean presentation age 18±19 months; current age 7.0±3.6 years), followed-up at least for one year after urodynamic testing. Anthropometric indices, spinal lesion levels, shunt status, ambulatory ability, urinary tract infection (UTI), ultrasound and urodynamic parameters, eGFR and serum cystatin-C levels were recorded. 47 patients (89%) were performing clean intermittent catheterization (CIC). Patients applying at least >75% of CIC suggestions were defined as "compliant". Low bladder capacity was defined as<65% of expected volume by urodynamic test. Renal scarring was diagnosed by current DMSA scans.

Results: The mean follow-up period was 66±34 months. 24 patients (45%) had VP shunt. Spinal lesion levels were as follows: lumbosacral region in 28, lumbar in 13, sacral in 7 and thoracolumbar in 5. DMSA scintigraphy revealed renal scarring in 9 (17%) patients, which was not associated with gender, presentation, CIC initiation and current age, level of spinal lesion, ambulatory disability or none of urodynamic parameters except low bladder capacity. Significant risk factors for renal scarring are shown in Table 1.There was no difference between eGFR values of the patients with or without scarring, whereas serum cystatin C levels differ significantly (0.80±0.2 vs 0.63±0.09 mg/dL, p=0.03).

	All patients n=53	Scarring (+) n=9	Scarring (-) n=44	p
No. of UTI between 0-2 years	0.9±1.4	3.0±1.9	0.6±1.0	0.007
UTI >3, n(%)	8 (15%)	4 (44%)	4 (9%)	0.008
VUR (+), n(%)	9 (17%)	5 (56%)	4 (9%)	0.001
CIC compliance, n(%)	38 (71%)	4 (44%)	34 (90%)	0.002
Low bladder capacity	10 (19%)	5 (56%)	5 (11%)	0.002

Conclusions: CIC compliance and avoidance of UTI may prevent renal scarring in patients with myelomeningocele.

PUB231

Unusal Cause for Headache in Lupus Nephritis Patient Viswanathan S. Iyer. *Nephrology, Pinnacle Health, Harrisburg, PA.*

Background: Therapy with mycophenolate is the norm in the care of lupus nephritis. Here we report an unusual complication of treatment with this drug.

Methods: Known lupus nephritis with class 4 disease-had worsening of renal functions and proteinuria after being stable for 3 years when mycophenolate mofetil was omitted for a month. Repeat kidney biopsy showed collapsing lesions and focal glomerulosclerosis consistent with a podocytopathy. Mycophenolate was restarted at her tolerated dose of 750 mg twice a day along with full dose of steroids. Up to six months into the therapy patient complained severe headache and a MRI done showed multiple bilateral brain masses with surrounding vasogenic edema, most extensive in the right temporal lobe (Fig 1). CSF was not obtained due to mass effects and uncal herniation on the right side. Neurosurgeon did an open brain biopsy that showed multiple organisms largely tachyzoites seen in H&E and immunohistochemistry for toxoplasma. HIV test was negative but her CD4 count was low at 175/cumm at that time. She was started on hemodialysis waiting for her PD catheter to mature. Anti-toxoplasmosis regimen chosen was sulfadiazine 1g four times a day,Dara prim 50 mg daily and leucovorin 20 mg daily. A repeat MRI was performed 2 weeks later as patient had persistent headache despite an initial improvement,showed a right posterior temporal mass and associated vasogenic edema worsened since the initial study when most other lesions seen initially had progressively decreased in size(Fig 2). Regimen was changed to Clindamycin 600 mg four times a day along with atovaquone 750 mg bid ,Dara prim and leucovorin. Repeat MRI after 4 weeks showed marked interim improvement in lesion in the right temporal lobe with minimal sequela of toxoplasmosis in other areas. A repeat CD4 was at 512 /cumm by then. She is now on atovaquone prophylaxis due to Bactrim allergy.

Conclusions: Non HIV toxoplasmosis itself is rare so also this infectious complication in the treatment of lupus with mycophenolate. Reactivation of dormant toxoplasmosis is a possibility and consideration need to be give for checking CD4 counts while on therapy with mycophenolate mofetil so that appropriate prophylaxis can be initiated.

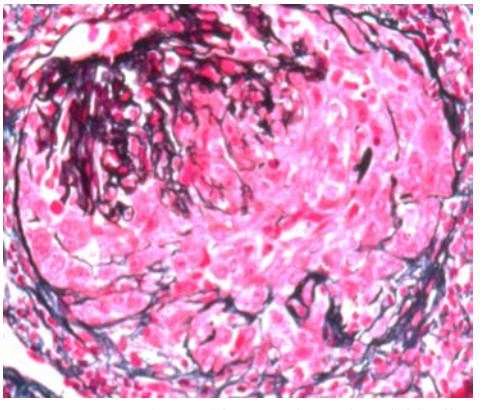
PUB232

Pauci Immune Glomerulonephritis a Case Series Giovanna Y. Arteaga Muller, Lilia Maria Rizo Topete, Allina Primavera Flores Mendoza, Elisa Maria Guerrero Gonzalez, Concepcion Sanchez Martinez, Jesus Cruz Valdez. *Nephrology, Univ Hospital José E. González of the Autonomous Univ of Nuevo León, Monterrey, Mexico.*

Background: ANCA associated vasculitis affects kidneys frequently more than half of the cases progress to ESRD with renal replacement therapy.

Methods: A retrospective observational study was made to describe pauci-immune glomerulonephritis diagnosed by kidney biopsy, from 2008 to 2015. Medical records were used to obtain demographic variables, clinical and paraclinical features of the patients.

Results: Ten patients were identified with crescent formation pauci-immune deposit glomerulonephritis,50% male with a median age of 35.5 years, 100% of patients presented malaise, microscopic hematuria and proteinuria, only 30% of proteinuria in nephrotic range,70% presented nephritic syndrome, 50% fever, 90% anemia, 40% leucocytosis, 30% alveolar hemorrhage, of histopathologic findings 80% crescent formation in more than 50% of glomeruli (Figure 1) all of then with progression to CKD.In regard to clinical diagnosis; the mean time of disease development at the time of histopathologic diagnosis was 5 months, 8 patients met criteria por microscopic polyangiitis of which 62.5% were male, 87.5% required chronic HD,75% nephritic syndrome,2 patients adenocarcinoma,2 cases overlap rheumatoid arthritis and systemic sclerosis, of the 10 patients only 1 was ANCA negative. Of the patients with polyangiitis with granulomatosis diagnosis 100% presented leucocytosis and proteinuria in nephrotic range, only 50% nephritic syndrome.



Conclusions: In our case series pauci-immune glomerulonephritis affected males and females equally, a larger number of males was affected with microscopic polyangiitis. It is relevant to identifyy clinical features of this disease to achieve early diagnosis. In our series kidney survival was only modified if the number of crescent formations were less than 50% in kidney biopsy.

PUB233

Determinants of Urinary Soluble CD163 over Time in an Intensive Care Cohort Donal J. Sexton,[1] Mark Canney,[1] Eoin Joseph Cotter,[3] Peter P. Doran,[2] Patrick T. Murray,[2] Mark Alan Little.[1] *[1]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [2]Dept of Medicine, Univ College Dublin, Dublin, Ireland; [3]Royal College of Surgeons, Dublin, Ireland.*

Background: Urinary soluble CD163 (UsCD163) holds promise in the management of patients with ANCA associated vasculitis and possibly other forms of glomerulonephritis. Little is known about the determinants of urinary UsCD163 in a critical care setting.

Methods: A consecutive sample of intensive care patients (N=438), investigating UsCD163 on repeated testing and its association with clinical parameters. Analysis was

performed using generalised linear mixed-effects models. Individual trajectories were drawn to map discernible longitudinal clusters, which identified 5(Fig 1). Cluster A was the largest. Univariate associations between time-invariant and time-varying covariates with UsCD163 were explored. 44 clinical parameters were investigated. Time-varying covariates: serum creatinine, sepsis and urinary albumin excretion.

Results: Mean (sd) age 61.9(16)yrs, 66% were male and 222 (38%) had AKI by KDIGO criteria. Median UsCD163 level was 0.06 ng/mmol (IQR 0.02-0.13, cutoff 0.3, Fig 2). Clusters A (N=224) and B (N=30) were characterised by a consistently low UsCD163 value throughout the observation period. Although a number of clinical covariates were associated with cluster membership on univariate analysis, with multiple comparison adjustment only one association remained: RRT appeared more likely in cluster C vs. A. In the mixed effects models (cluster A & B), UsCD163 levels were not associated with any of the clinical parameters studied.

Conclusions: In the setting of critical illness, UsCD163 is generally low with sporadic high values that fall into several patterns. These do not associate with any specific clinical parameters, in particular sepsis or AKI, and may be a reflection of unquantified parameters such as macroscopic haematuria.

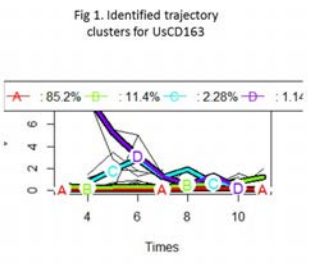


Fig 1. Identified trajectory clusters for UsCD163

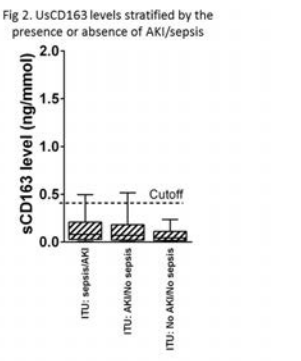

Fig 2. UsCD163 levels stratified by the presence or absence of AKI/sepsis

PUB234

Complications of Percutaneous Kidney Biopsies in Patients with or without Renal Failure: A Single Center Experience Andrea Guarnieri, Serena Bainotti, Ariaudo Claudia, Elisabetta Moggia, Carlo Ferrando, Paola Inguaggiato, Alfonso Pacitti. *Nephrology and Dialysis, S. Croce-Carle Hospital, Cuneo, Italy.*

Background: Percutaneous renal biopsy (PRB) of native kidneys is an essential tool in the diagnosis and management of renal diseases. Reduced GFR is one of the leading risk factors for complications. Aim of the study is to compare the incidence of complications in two groups of patients with different GFR.

Methods: PRB of native kidneys were performed in 188 adult patients from january 2010 through dicember 2015 in our unit. Renal biopsies were performed by two nephrologists usign real-time ultrasound with a 18-gauge automated biopsy needle. We compared 95 patients with eGFR > 60 mL/min (Group 1) with 93 patients with eGFR < 30 mL/min (Group 2).

eGFR (CKD-EPI) (mL/min/1.73mq)	Group 1 > 60	Group 2 < 30	p (t-test)
Number of patients	95	93	
Age, years	47 ± 16	64 ± 13	< 0,000
eGFR, mL/min/1.73mq	94,8 ± 21,95	15 ± 6,92	< 0,000
SCr, mg/dL	0,87 ± 0,22	4,2 ± 1,89	< 0,000
BP Systolic, mmHg	129 ± 16,2	136 ± 16,9	< 0,05
Pre-PRB Hb, g/dL	12,8 ± 1,9	10,1 ± 1,4	< 0,000
Bleeding Time, min	4,4 ± 1,7	4,8 ± 1,9	> 0,05
Kidney Length, mm	110 ± 14	107 ± 15	> 0,05
Number of glomeruli	19 ± 12	15 ± 11	> 0,05

We evaluated: 1. Minor complications: gross ematuria with rapid resolution, hemoglobin drop 1-2 g/dL, perinephric hematoma but spontaneously resolving. 2. Major complications: persistent gross hematuria, hemoglobin drop > 2 g/dL, hematoma requiring blood transfusion, loss of kidney, death.

Results: Adequate material for diagnosis was obtained in 98,9% of biopsies. Minor complications were observed in 34 patients of Group 1 (36%) and in 25 patients of Group 2 (27%). Most prevalent complication was a small symptomless hematoma assessed by ultrasound. Major complications were 2 in Group 1 (2 Hb drop > 2 g/dL) and 4 in Group 2 (3 Hb drop > 2 g/dL with one requiring blood transfusion and one loss of kidney). No statistical difference between groups was observed (Chi-square test).

Conclusions: Percutaneous renal biopsy is a low-risk procedure. In our experience reduced eGFR in not associated with an increased risk of minor and major complications.

Funding: Government Support - Non-U.S.

PUB235

Thrombotic Microangiopathy, the Broad Clinical Spectrum of the Same Lesion Lida Maria Rodas Marin,[1] Jessica Ugalde-Altamirano,[1] Luis F. Quintana,[1] Manel Sole,[2] Adriana Garcia,[2] Esteban Poch,[1] Josep Miquel Blasco Pelicano.[1] *[1]Nephrology and Renal Transplant, Hospital Clinic, Barcelona, Spain; [2]Pathology, Hospital Clinic, Barcelona, Spain.*

Background: Thrombotic microangiopathy (TMA) is a common histological lesion to multiple clinical diseases, which is characterized by the presence of endothelial cell injury and microvascular thrombi.TMA should be suspected in front the presence of hemolytic microangiopathic anemia(HMA), thrombocytopenia and kidney injury.After a clinical suspicion or histological confirmation, a broad differential diagnosis is required.

Methods: We reviewed all the renal biopsies performed in Hospital Clínic of Barcelona, in the period 2005-2015.We present the analysis of demographic, clinical and histological data of cases of TMA was identified.

Results: TMA was detected in 87 renal biopsies of 71 patients during a 10 year period: 24 patients with TMA in native kidneys,13 women and 11 men with a mean age of 46.79±15.56 years. At the onset of the disease all the patients presented signs HMA (Hb:92.08±25.61 g/L;LDH:959±709U/L) and 62% with thrombocytopenia (Platelets 128±65 10^9/L).Renal manifestations AKIN3 (Creatinine 7.33±5.57mg/dL) and proteinuria (2643±2120mg/g) in all the patients.Histological lesions included vascular involvement in 95.83% and glomerular changes in 87.5%.Transplanted kidneys:47 patients that presented histological TMA with 63 biopsies:16 women and 31 men, with a mean age of 43.66+15years.The main causes of ESRD were: 25% congenital diseases, 16% aHUS, 10% IgAnephropathy and 10% diabetic nephropathy. The onset of the disease was detected after a graft biopsy due to AKI. At that point, despite 60% of the patients manifested anemia (Hb<12 g/L),21% of the patients showed signs of hemolysis and 19% thrombocytopenia. All the biopsies demonstrated acute vascular and glomerular TMA changes (only 48% with chronic changes).

Conclusions: In our series we demonstrate the variability of clinical entities associated with TMA, especially in renal transplant patients were the renal biopsy is necessary to ensure a correct etiological diagnosis. We also observed that TMA over kidney grafts manifested with HMA and thrombocytopenia in less than 21% of the patients, complicating the clinical suspicion.

PUB236

miRNAs as Biomarkers of Kidney Damage in Patients with Systemic Lupus Erythematosus Gustavo Aroca Martinez,[1,2,3] Elkin Navarro,[1] Lisandro Pacheco,[1] Lisneth Almendrales,[2] Andres A. Cadena,[1,2] Antonio Iglesias Gamarra.[4] *[1]Nephrology, Univ Simon Bolivar, Barranquilla, Atlantico, Colombia; [2]Nephrology, Clin de la Costa, Atlantico, Colombia; [3]Nephrology, Uninorte, Barranquilla, Atlantico, Colombia; [4]Rheumatology, Univ Nacional, Bogota, Cundinamarca, Colombia.*

Background: Renal involvement is a severe manifestations of systemic lupus erythematosus (SLE). Is priority the development of diagnostic tests for kidney disease in patients with SLE through non-invasive methods, due to the date this is done by kidney biopsy, it presents complications. The microRNA's (miRNA's) are found in tissues with variable expression, and changes in expression are related to pathological processes of various diseases. The aim of this study was to identify differentially expressed miRNAs in patients with lupus nephritis (LN) potentially allow the diagnosis of renal damage in patients with SLE.

Methods: A case-control and cross-sectional study, in which we characterized the differential expression profiles of miRNAs among 14 patients with LN Class II: 4 patients, LN class III: 4 patients, LN IV: 6 patients) compared with 8 patients with LES without nephritis or with 8 healthy control individuals, by sequencing by Illumina. We validated by qPCR diagnosis by renal biopsy in 180 samples using a group of miRNAs as biomarkers.

Results: We found 89 serum miRNAs that showed statistically significant changes in the proportion of their expression, comparing patients with LN individuals with healthy controls. We find the contrast with the results of the diagnosis by renal biopsy miRNAs miR-221-5p, miR-380-3p, miR-556-5p, miR-758-3p and miR-3074-3p sensitivity averaged 97% , specificity 70.3%, positive predictive value 82.5%, negative predictive value 96% and 87.9% efficiency diagnosed.

Conclusions: Whereupon we propose that these microRNAs are potential molecular biomarkers of kidney damage in patients with SLE and request the patenting of the potential usefulness of these microRNAs diagnosed. The miR-221-5p microRNAs, miR-380-3p, miR-556-5p, miR-758-3p and miR-3074-3p are potential diagnostic biomarkers of LN in patients with systemic SLE and the differential expression pattern of microRNAs have significant implications for the pathophysiology of renal damage in LN patients.

Primary versus Secondary Recurrent Membranous Glomerulonephritis in Simultaneous Liver-Kidney Transplantation after MRSA Infection: A Diagnostic Challenge Ekamol Tantisattamo, Dilip Samarapungavan, Ping L. Zhang. *Oakland Univ William Beaumont School of Medicine, William Beaumont Hospital, MI.*

Background: Anti-PLA2R Ab and IgG4 are still useful tools in differentiating primary from secondary membranous glomerulonephritis(MGN) in kidney transplantation.

Methods: A 50-year-old man with primary MGN 7 years earlier. Urinary protein/creatinine ratio(UPCR) was 10.2 g/g of Cr. He developed ESRD. He was then diagnosed with HBV infection. Tenofovir was initiated. Despite viral load became undetectable; he had ESLD from HBV cirrhosis. He underwent SLK 6 months later. He had delayed renal allograft function. Biopsy performed 3 weeks post-transplant revealed borderline changes for acute cellular rejection. He had MRSA bacteremia concomitant with proteinuria of 8 g from 24-h urine collection. After the bacteremia resolved, the second biopsy was performed and revealed stage II MGN without features of secondary MGN. HBV viral load was undetectable. Serum anti-PLA2R Ab was undetectable. Serum IgG3 and %IgG3, but not IgG4 were elevated. Recurrent secondary MGN was diagnosed. UPCR spontaneously decreased to 1.1 g/g of Cr without intensified immunosuppression or ACEI/ARB(Figure 1).

Results: Our patient recovered from bacteremia before the biopsy was performed. Infection could trigger secondary MGN, and its resolution lead to decreased proteinuria. This is quite similar to the pathogenesis of *de novo* primary MGN which is not related to anti-PLA2R Ab or co-localized IgG4.

Conclusions: Differentiating primary from secondary MGN particularly in patients with underlying diseases commonly associated with secondary MGN(HBV) is challenging. Further studies should elucidate diagnostic and prognostic utilities of anti-PLA2R Ab and IgG4 subclass in differentiating primary vs. secondary MGN in transplantation with co-existing conditions and infection associated with secondary MGN.

PUB238

Urinary Findings Does Not Reflect Kidney Status in Chronic Glomerulonephritis after Steroid Therapy Byoung-Soo Cho,[1] Hyaejin Yun,[1] Sung Min Jung,[2] Hyun Soon Lee.[3] *[1]MIRAE ING Kidney center, Seoul, Korea; [2]EWha Women's Medical College, Seoul, Korea; [3]Korea Pathology Lab, Seoul.*

Background: Routine urinalysis, especially hematuria and proteinuria, has long been used as the most important laboratory tools in the diagnosis of glomerulonephritis and also widely adopted as a screening tool for kidney problems at school screening or health checking program. Recently other newly developed markers for kidney injury, such as cystatin-c, KIM-1, L-FABP, NGAL etc., were developed but not routinely used because lack of accumulated convincing data as yet.

Methods: We performed follow up kidney biopsy who showed normal urinalysis and serum cystatin-c for more than 3 months after steroid therapy to check the kidney status in 20 patients with chronic GN. Of the 20 patients, ten were IgAN and others were 2 allergic purpura nephritis, 2 FSGS, 2 MGN, 2 diffuse mesangial proliferative GN, nonspecific glomerulonephritis, and membranoproliferative GN. All 20 patients took long term steroid therapy more than 6 months. Mean age was 30.7 years old. Mean follow up biopsy interval was 13.6 months. All kidney biopsy were performed at the OPD level without admission. We used ACE-Cut disposable biopsy needle under the ultrasound guide(LOGIQ E9).

Results: All 20 cases showed abnormal urinalysis such as persistent hematuria, persistent proteinuria or associated with hematuria and proteinuria at initial kidney biopsy, and showed persistent normal urinalysis findings include hematuria and proteinuria more than 3 months at the time of follow up renal biopsy. However only 3 cases showed normal renal pathologies at the time of follow up biopsy. Seventeen cases showed persistent original diseases although slight to moderate degree pathological improvement. Three pathologically improved cases were 2 MGN and one focal nonspecific glomerulonephritis. These 3 cases did not show any sclerotic lesions at the initial renal biopsy, and age were 1, 23 and 28 years old.

Conclusions: Any one who showed segmental or global sclerosis, when associated with moderate to severe tubular atrophy and interstitial fibrosis at initial kidney biopsy, follow up kidney biopsy is mandatory even showed persistent normal urinalysis and lab findings before finishing steroid therapy.

PUB239

Clinical and Histological Features of Patients with Membranoproliferative Glomerulonephritis Classified by Immunofluorescence Findings Cristiane B. Dias,[1] Lectícia Jorge,[1] Leonardo Abreu Testagrossa,[2] Denise M. Malheiros,[2] Viktoria Woronik.[1] *[1]Nefrologia, Hospital das Clínicas de São Paulo, São Paulo, São Paulo, Brazil; [2]Patologia, Hospital das Clínicas de São Paulo, São Paulo, São Paulo, Brazil.*

Background: A new classification system for membranoproliferative glomerulonephritis (MPGN) according to immunofluorescence (IF) has been proposed. The aim of this study was to evaluate the clinical and biochemical characteristics of patients with MPGN grouped by IF analysis.

Methods: This was a retrospective study of patients with renal biopsy-proven MPGN unrelated to systemic lupus erythematosus (SLE), diagnosed between 1999 and 2014.

Results: We evaluated 92 patients, which were divided into three groups determined by immunofluorescence: immunoglobulin positive; C3 positive only; and negative IF. Data on diagnosis are in table 1.

Parameter	Immunoglobulin positive (n = 73)	C3 positive (n = 9)	IF negative (n =10)	P-value
Age (years)	44.9 ± 14.6	44.6 ± 20.0	43.8 ± 15.0	ns
Male gender, n (%)	45 (61.6)	6 (66.6)	7 (70.0)	ns
Creatinine (mg/dL)	1.8 (1.1–3.6)	1.8 (1.3–5.4)	2.1 (1.6–5.1)	ns
GFR (mL/min/1.73m^2)	41.0 (20.0–65.0)	42.0 (15.5–50.0)	39.5 (11.2–53.5)	ns
Proteinuria (g/day)	6.3 ± 3.4	6.0 ± 3.0	5.5 ± 3.5	ns
Serum albumin (g/dL)	2.5 ± 0.6	2.5 ± 0.3	2.7 ± 0.5	ns
Low C3, n (%)	35 (52.2)	4 (44.4)	5 (50.0)	ns
Low C4, n (%)	23 (34.3)	2 (22.2)	4 (40.0)	ns
Low C3 and C4, n (%)	18 (26.8)	2 (22.2)	3 (30.0)	ns
Arterial hypertension, n (%)	41 (56.0)	2 (22.2)	3 (30.0)	ns
Hematuria, n (%)	51 (70.0)	5 (55.5)	10 (100.0)	ns

Infection was the most common in the three groups. Hepatitis C virus (14 patients) and schistosomiasis (7 patients) located mainly in immunoglobulin positive groups. Eleven patients, despite having been diagnosed with infectious disease, autoimmune disease, or monoclonal gammopathy, showed no immunoglobulin deposition on immunofluorescence.

Conclusions: The new classification enlightens a systematic approach to evaluation of secondary causes.

PUB240

Surgical and Oncologic Outcomes of Small Renal Tumors Treated with Nephron-Sparing Surgeries - Correlation with Pathology of the Tumor-Parenchymal Interface and Status of the Surgical Margin Maria M. Picken,[1] Gopal N. Gupta.[2] *[1]Pathology, Loyola Univ Chicago, Maywood, IL; [2]Urology, Loyola Univ Chicago, Maywood, IL.*

Background: Approaches to nephron-sparing surgeries (NSS) of renal lesions include partial nephrectomy (PN) and tumor enucleation (TE). Our objective was to examine the pathology of the pseudocapsule and status of the surgical margin in small renal masses treated by NSS, and to correlate these findings with the surgical and oncological outcomes.

Methods: All consecutive renal TE and PN cases obtained between Jan 2012-Dec 2014, that also had available clinical follow-up, were included; pathologic features and clinical data were reviewed and analyzed.

Results: A total of 117 NSS specimens (59 EN, 58 PN) were reviewed. Clear cell renal cell carcinomas and paraganglioma had the thickest pseudocapsules (0.36 mm), while angiomyolipomas lacked a well-defined pseudocapsule. Other tumors were intermediate in their characteristics. The positive margin rate for TE and PN was 17.2% and 0%, respectively. Compared to PN, TE involved a significantly shorter procedure time, less blood loss and fewer post-op complications.

	TE	PN	p-value
# of patients	59	58	
mean age (range)	57 yrs (31-80)	62 (24-83)	0.781
M:F (ratio)	35:24 (1.5:1)	29:29 (1:1)	0.356
# of NSS without hilar clamp (%)	31 (52.5%)	0(0%)	<0.001
average clamping time	25 min	25 min	1
Procedure time	181 min	241 min	<0.001
Blood loss during NSS	180 ml	280 ml	<0.001
Average hospital stay	1.71 days	2.67 days	<0.001
Patients with post-op complications (%)	7/59 (12%)	15/58 (26%)	0.062
Patients re-admission within 1 month (%)	0 (0%)	7 (12.1%)	0.006
Median follow up - months (range)	22 (11-40)	19 (8-42)	
Tumor recurrence	0	0	

None of the patients from either group was found to have a local recurrence after follow-up imaging.

Conclusions: Although positive surgical margins were encountered in some TEs, local tumor recurrence was comparable to PN. Thus, TE with maximal nephron sparing, is a reasonable choice for pT1 renal tumors, especially for those without a prominent infiltrative growth pattern.

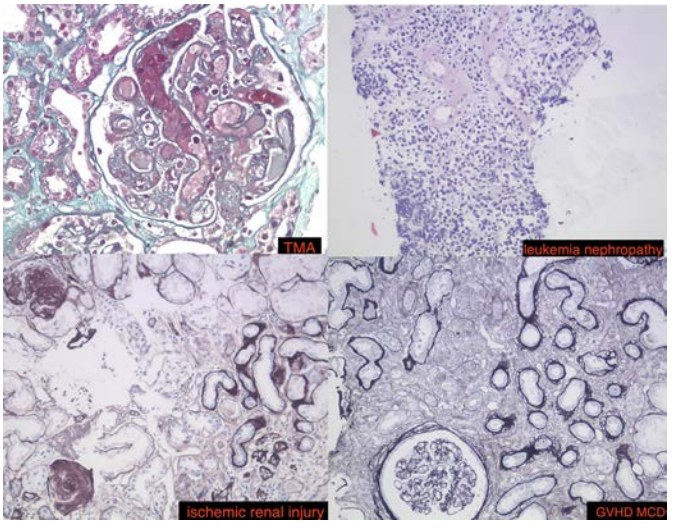
PUB241

Analysis the Clinical and Pathology of Renal Injury in Patients Received Hematopoietic Stem Cell Transplantation Jiaxuan Lv. *Beijing Tsinghua Changgung Hospital, Medical Center, Tsinghua Univ, Beijing, China.*

Background: The rate of acute and chronic renal injury is very high in patients received hematopoietic stem cell transplantation(HSCT),but not enough studies about it.Analyzing the reason of renal injury in these patients can improve the renal damage and improve the prospects of survival.

Methods: Clinical, laboratory data, treatment issue and renal pathology results of eight patients with renal injury after HSCT from July.2015 to May.2016 were retrospectively analyzed.

Results: The clinical manifestation of renal injury after HSCT showed as proteinuria, hypertension and renal function damage. The pathological damages involved in glomerulus, renal tubular interstitial and vessel, which is related with bone marrow graft versus host disease, drug damage and thrombotic microangiopathy (TMA).



Conclusions: Renal injury after HSCT varied in different kinds, renal biopsy is important for diagnosis and treatment. According to the renal pathology, early intervention can relieve kidney injury.

PUB242

Clinical and Pathological Features Analysis of Collagen Type III Glomerualopathy Shao Min Gong, Hong Liu, Weili Luo, Xiaoqiang Ding. *Nephrology, Zhongshan Hospital,Fudan Univ, Shanghai, China.*

Background: Collagen type III glomerualopathy, characterized with collagen Type III deposits in mesangial and subendothelia area, is a kind of relatively rare autosomal recessive glomerular disease with few reports of sporadic cases. The specific treatment remains unknown due to the mechanism of this disease has not been elucidated. We reported four sporadic cases in adult without extra-renal organ involvement.

Methods: We searched the database of patients receiving renal biopsy during Jan.2007 to Aug.2015 in Zhongshan Hospital,Fudan University. The clinical and pathological characteristics of 4 cases who were proven as collagen type III glomerualopathy were analyzed.

Results: Four cases comprise of 2 males and 2 females aging 45.5±10.7 years old, none of the cases were reported to have any familial history of kidney diseases. 3 cases complicated with hypertension and none of the cases was found to have extra-renal organ involvement. The quantitative of 24-hour proteinuria was 3.8±3.6g(ranging from 0.32 to 7.56g), the eGFR was 27.1±39.2ml/min/1.73m^2(ranging from 10.3-81.3 ml/min/1.73m^2, calculated by MDRD formula). The light microscopy results of each case were membranoproliferative glomerulonephritis, focal segmental proliferative and sclerosis glomerulonephritis, IgA nephropathy, nodular glomerulosclerosis, respectively. Collagen type III was detected by immunohistochemical test in four case. One case with minor declined eGFR and mild proteinuria remained stable after recieving conservative therapy. 2 cases had improvement in renal function and partial remission of proteinuria after recieving glucocorticoids and immunosuppressive agents while 1 case with severe renal impairment onset developed into end stage renal disease and received hemodialysis.

Conclusions: The sporadic cases of collagen type III glomerualopathy in adults may be underestimated. The majority of cases presented with porteinuria and multiple light microscope pathological type. Immunohistochemical analysis and electronic microscope examination are essential to confirm the diagnosis, which should not be neglected to avoid missing diagnosis this rare disease.

PUB243

The Significance of Cryoglobulin Deposition Discovered by Renal Biopsy in Patients with Lupus Nephritis Companying Cryoglobulinaemia Wen Wen, Yuehong Li. *Nephrology, Beijing Tsinghua Changgung Hospital, Beijing, China.*

Background: To investigate the relationship between cryoglobulin deposition and manifestations of patients diagnosed as lupus nephritis and cryoglobulinaemia.

Methods: Retrospectively collected the clinical materials of patients diagnosed as lupus nephritis companying cryoglobulinaemia with or without cryoglobulin deposition from October 2012 to May 2014. Their clinical data, renal pathological features and ultrastructural morphology were analysed. Statistical analyses were performed using SPSS software (version 17.0). The Mann-Whitney U test was used for the comparison of continuous variables; the Fisher exact tests were used for the comparison of proportions. A value of $P < 0.05$ indicated statistical significance.

Results: There were 12 patients suffering from lupus nephritis and cryoglobulinaemia. Eight were female, and 4 were male. Their mean age at the time of renal biopsy was 37.1±10.6 years old. The classification of lupus nephritis of them ranged from III to V. Seven of them had depositions of cryoglobulin in renal biopsy. The occurrence of acute kidney injury (AKI), IgA and complement C4 were higher in patients with cryoglobulin deposition than those without. The improvements of parameters of renal damage were fewer in patients with cryoglobulin deposition after 3 and 6 months.

Conclusions: In patients with lupus nephritis and cryoglobulinaemia, cryoglobulin deposition in kidney may increase the risk of AKI and impede the patients from recovery.

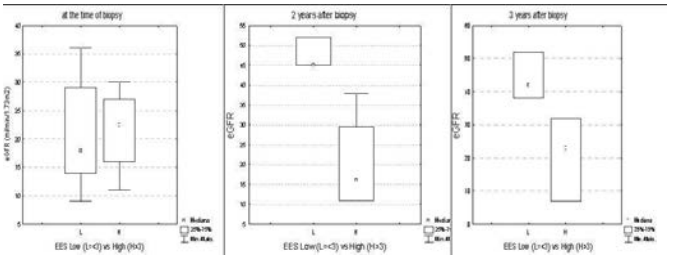
PUB244

ETAR Expression in Kidney Biopsies of Patients with ANCA-Associated Glomerulonephritis Predicts GFR Decline: Preliminary Results Olumide Olatubosun Rowaiye,[1] Piotr Donizy,[2] Mariusz Kusztal,[1] Miroslaw Banasik,[1] Magdalena Krajewska,[1] Agnieszka Halon,[2] Marian Klinger.[1] *[1]Nephrology and Transplantation Medicine, Wroclaw Medical Univ, Wroclaw, Poland; [2]Pathomorphology, Wroclaw Medical Univ, Wroclaw, Poland.*

Background: ANCA-associated glomerulonephritis (AAGN) is often characterized by a decline in renal function. Endothelin has been implicated in renal cell injury, inflammation and fibrosis. We hypothesized that degree of endothelin-1 type A receptor (ETAR) expression in renal specimen can predict decline in eGFR in AAGN patients.

Methods: Immunohistochemical (IH) evaluation for ETAR expression was performed on the renal biopsies of AAGN using anti-ETAR antibody (rabbit polyclonal, ABCAM, USA). Control reactions were performed on 5 normal kidneys. A composite ETAR expression score [EES] was calculated for each biopsy based on the intensity of expression (0 for negative, 3 for high) using the formula: g (0-3) + v (0-3) + t (0-3) + i (0-3).

Results: Cohort consisted of 5 patients with PR3-ANCA, 5 with MPO-ANCA and 1 ANCA-negative (7M, 4F). Histopathological class: 3 crescentic, 7 mixed, 1 sclerotic. Tubular epithelium revealed diffuse cytoplasmic pattern of ETAR expression in all analyzed patients. Renal vessels were negative for ETAR. In 3 patients immunoreativity of ETAR was observed only in glomerular crescents. Composite EES was in range 1-6 for all patients. In general patients with higher composite EES (>3) showed a decline in eGFR when compared to lower EES (≤3) after 24 (20 vs 47ml/min; p<0.05) and 36 months (20 vs 44ml/min;p<0.05) irrespective of histopathological class.



Conclusions: ETAR expression in renal biopsy seems to be useful in predicting decline in renal function in AAGN, irrespective of histopathological class, in long term. Further studies will elucidate relevance of ETAR expression and its antibody presence in patients with AAGN.

Glomerulopathies Secondary to *Schistosoma mansoni*: Revisiting a Forgotten Enemy Precil Diego Miranda de Menezes Neves,[1] Ramaiane Aparecida Bridi,[1] Bernardo V. Reichert,[1] Lectícia Jorge,[1] Luis Yu,[1] Viktoria Woronik,[1] Leonardo Abreu Testagrossa,[2] Denise M. Malheiros,[2] Cristiane B. Dias.[1] *[1]Nephrology Service, Univ of Sao Paulo School of Medicine, São Paulo, Brazil; [2]Pathology Div, Univ of Sao Paulo School of Medicine, São Paulo, Brazil.*

Background: Schistosomiasis mansoni is a parasitic disease caused by Schitosoma mansoni (SM). This is an endemic disease in some regions of Brazil. The kidney may be impaired, particularly in the form of glomerulopathies. We aim to make clinical and epidemiological characterization of patients with glomerulopathies secondary to SM.

Methods: Identification of cases of glomerulopathies secondary to SM in the period of 1992-2015. We revised their clinical, epidemiological and renal biopsy data.

Results: Of an initial casuistic of 21 patients, two of them were excluded due to neoplasia at the time of renal biopsy. Patients were predominantly male (79%), white (52%),mean-age 38.8±7,8 y.o. The diagnosis of SM was made through fecal analysis (94%), 64.7% had hepatosplenic disease. The most common clinical presentation was nephrotic syndrome (48%), hypertension was evidenced in 66% and 74% had hematuria. The mean of serum creatinine was 1.43±0,5mg/dL (CKD-EPI: 67.5±30ml/min/1,73m^2), mean 24h proteinuria: 6.9±3g, serum albumin: 2.1±0,7g/dL and low serum complement C3 and/or C4 in 48% of cases. The histological presentation more frequent was Membranoproliferative Glomerulonephritis (MPGN) 69%, followed by Focal Segmental Glomerulosclerosis (21%), Membranous Nephropathy (5%) and Focal Proliferative Glomerulonephritis (5%). In 60% of cases antimicrobial treatment wasn't effective to induce remission than immunossupressive therapy was required. Of these ones, 70% with diagnosis of MPGN. The follow-up was 70 (14-124) months, and at that time 26,3% of patients undergone dialysis and mortality rate was 10,5% due to non-related nephropathy causes.

Conclusions: The histological presentation as MPGN was associated with worst response to antimicrobial treatment, need for immunosuppressive treatment, higher rate of progression to end-stage renal disease/dialysis and higher mortality compared to other subtypes of glomerulopathies.

PUB246

Cohort of Native Kidney Percutaneous Biopsies in an Urban Center with a Majority of African American Patients Ravi K. Thimmisetty, Nashat Burhan Imran, Muhammad Omar Azam, Yahya M. Osman Malik. *Internal Medicine/Nephrology, Wayne State Univ, Detroit, MI.*

Background: The percutaneous biopsy of native kidneys can aid in: confirming a suspected diagnosis, anticipating recurrence post-transplant, prognosticating the kidney disease, or even deterring clinicians from committing to therapy in cases of advanced fibrosis. kidney biopsy may even alter the pre-biopsy proposed management. Indications for biopsy depends on the treating nephrologists but include: nephrotic syndrome, acute nephritic syndrome, and unexplained acute kidney injury. We are reporting our 5-year experience in an urban center with majority African American patients.

Methods: Epidemiological retrospective analysis, single-center, urban medical center with a predominant demographic of African Americans. Cohort: all non-cancer and non-transplant native kidney biopsies from February, 1st 2011 till June, 6th 2016. All biopsies were done in one center and under ultrasound guidance by either the nephrology service or interventional radiology.

Results: There was total of 561 biopsies in this time period. All transplant biopsies and onco-surgical biopsies were excluded. The final 143 biopsies were analyzed with the following findings: average age at the time of biopsy was 43.6 years (18-86), 49% male, 76.2% African Americans, average proteinuria 4.8 g/g, hypertension 76.2%. Unexplained acute kidney injury was the most common indication for biopsy (34%) followed by nephrotic syndrome (31%). Accurate pre-biopsy clinical diagnosis was accurate in 49% of the time. Focal segemental glomerulosclerosis (FSGS) and lupus nephritis classes were equally the most common diagnosis. Among African Americans, FSGS was incorrectly presumed in 53% of the cases and was not suspected in 65% of patients with histological evidence of FSGS.

Conclusions: Percutaneous native kidney biopsy in our urban center showed FSGS and lupus nephritis as the most common diagnosis. Presumption that African American patient would have FSGS was incorrect in more than half of the time and was not even suspected in 65% of the cases.

PUB247

Evaluation of microRNA Profiles in Patients with Autosomal Dominant Polycystic Kidney Disease Ismail Kocyigit,[1] Serpil Taheri,[2] Elif Funda Sener,[2] Eray Eroglu,[1] Fahir Ozturk,[1] Aydin Unal,[1] Gokmen Zararsiz,[3] Murat H. Sipahioglu,[1] Yusuf Ozkul,[2] Bulent Tokgoz,[1] Oktay Oymak,[1] Tevfik Ecder.[4] *[1]Nephrology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [2]Medical Biology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [3]Bioistatistics, Erciyes Univ Medical Faculty, Kayseri, Turkey; [4]Nephrology, Bilim Univ, Istanbul, Turkey.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the progressive hereditary disorders. Biomarkers are needed to predict clinical course of the disease. In this study, we aimed to investigate the association of microRNAs (miRNAs) with the clinical course of ADPKD and to test the availability of miRNAs as a biomarker in ADPKD patients.

Methods: Eighty ADPKD patients (52 hypertensive, 28 normotensive) and 50 healthy subjects were enrolled to the study. Ambulatory blood pressure monitoring was performed. The expressions of miRNAs were determined by Biomark Real Time PCR system in the serum samples obtained from all study participants. oRNAs (miRNAs) with the clinical course of ADPKD and to test the availability of miRNAs as a biomarker in ADPKD patients.

Results: The mean age was 44.6±12.7 in the patient group, while it was 45.4±12.7 in the control group. Altered expression in 15 miRNAs was observed in the ADPKD patients with hypertension compared to those of the healthy controls. When hypertensive ADPKD patients were compared with normotensive ADPKD patients, we determined altered expressions in 4 miRNAs. One of these was upregulated (miR-3907), while the others were down-regulated (miR-4687-5p, let-7c-5p, let-7d-3p). Also, miR-1587, miR-3907, miR-92a-3p and miR-3911 showed dynamic changes which correlated with chronic kidney disease stages in ADPKD patients.

Conclusions: We found an association of upregulation of miR-3907 and clinical course of ADPKD. We plan to assess prognostic potential of this miRNA in a follow-up analysis.

PUB248

Positive Predictive Values of International Classification of Diseases, 10th Revision Coding Algorithms to Identify Patients with Autosomal Dominant Polycystic Kidney Disease Vinusha Kalatharan,[1] York P. Pei,[4] Kristin Clemens,[1] Rebecca K. Mctavish,[1] Stephanie Dixon,[1,3] Matthew Rochon,[5] Danielle Marie Nash,[3] Arsh Jain,[2] Sisira Sarma,[1] Andrew Zaleski,[5] Andrea Lum,[5] Amit X. Garg.[1,2,3] *[1]Epidemiology & Biostatistics, Western Univ, London, ON, Canada; [2]Div of Nephrology, Dept of Medicine, Western Univ, London, ON, Canada; [3]Inst for Clinical Evaluative Sciences, London, ON, Canada; [4]Div of Nephrology, Univ Health Network, Univ of Toronto, Toronto, ON, Canada; [5]Dept of Radiology, Western Univ, London, ON, Canada.*

Background: International Classification of Disease, 10th revision (ICD-10) codes for autosomal dominant polycystic kidney disease (ADPKD) exist within several administrative databases. It is unknown whether these codes identify patients who meet strict clinical criteria for ADPKD.

Methods: We obtained a list of emergency room visits and hospital admissions in London, Canada between April 1st, 2002 and March 31st, 2014 for adults where either ICD-10 codes Q61.2 (polycystic kidney disease, autosomal dominant) or Q61.3 (polycystic kidney disease, unspecified) were assigned to a hospital encounter. From this list, we manually reviewed a random sample of patient medical charts, and determined whether ADPKD was present or not according to strict clinical criteria. We calculated the positive predictive value (95% confidence interval) for 9 different coding algorithms. We also used province wide databases to assess the number of patients in Ontario identified with different code sets.

Results: The presence of either ICD-10 code Q61.2 or Q61.3 in a hospital encounter had a positive predictive value of 85% (95% CI: 79% to 89%) for the identification of ADPKD, and identified 2981 adults in Ontario (0.02% of the general population). The presence of ICD-10 code Q61.2 in a hospital encounter had a positive predictive value of 97% (95% CI: 86% to 100%) for the identification of ADPKD, and identified 394 adults in Ontario (0.003% of the general population).

Conclusions: Most patients with ICD-10 administrative codes Q61.2 or Q61.3 assigned during their hospital encounters have ADPKD according to strict clinical criteria. These codes can be used to assemble and study cohorts of adult patients with ADPKD and hospital encounters.

PUB249

Low Serum Levels of 1,25-Dihydroxyvitamin D, Not 25-Hydroxyvitamin D, Are Associated with Greater Total Kidney Volume (TKV) in Patients with Early Autosomal Dominant Polycystic Kidney Disease (ADPKD) Kristen L. Nowak,[1] Zhiying You,[1] Myles S. Wolf,[2] Michel Chonchol,[1] Berenice Y. Gitomer.[1] *[1]Univ of Colorado Anschutz Medical Campus; [2]Northwestern Univ.*

Background: The association of circulating vitamin D with kidney growth in patients with ADPKD is currently unknown. We sought to determine whether serum vitamin D levels are related to risk of TKV progression in patients with early ADPKD and estimated glomerular filtration rate (eGFR) > 60 ml/min/1.73m^2.

Methods: 25-hydroxyvitamin D (25(OH)D) and 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) were measured in 462 hypertensive ADPKD patients who participated in the HALT-PKD trial study A. Participants were randomized to standard or low blood pressure control and to either lisinopril plus telmisartan or lisinopril plus placebo, with evaluation of height-corrected TKV (HtTKV) at baseline, 24, 48, and 60 months. The study population was divided into tertiles of 25(OH)D and $1,25(OH)_2D$ levels. We used mixed effect models to examine the associations across tertiles of 25(OH)D and $1,25(OH)_2D$ with repeated measures of HtTKV during the course of the study.

Results: At baseline, participants had a mean age of 37 ± 8 years, mean CKD-EPI eGFR of 91.4 ± 17.4 mL/min/1.73m^2, and median (IQR) 25(OH)D, $1,25(OH)_2D$ and HtTKV of 31.5 (24.1 – 38.2) ng/mL, 36.6 (30.0-44.7) pg/mL and 589 (406-860) mL/m, respectively. After adjustment for age, gender, race, randomization group, body-mass index, systolic blood pressure, eGFR, urine albumin excretion, serum calcium, phosphate and parathyroid hormone level, the lowest $1,25(OH)_2D$ tertile was associated with greater HtTKV (ß=123.05, [95% CI 44.74, 201.36]; $p < 0.0001$ compared with the highest $1,25(OH)_2D$ tertile). Similarly, when evaluated as a continuous variable, higher levels of

1,25(OH)$_2$D were associated with a lower HtTKV (ß= -167.23, [95% CI -86.81, -247.65]; p=0.002 per natural log unit increase). In contrast, there was no association between 25(OH) D levels and HtTKV (p=0.50).

Conclusions: Low serum 1,25(OH)$_2$D level, but not 25(OH)D level, is independently associated with a higher HtTKV over time in patients with early ADPKD.

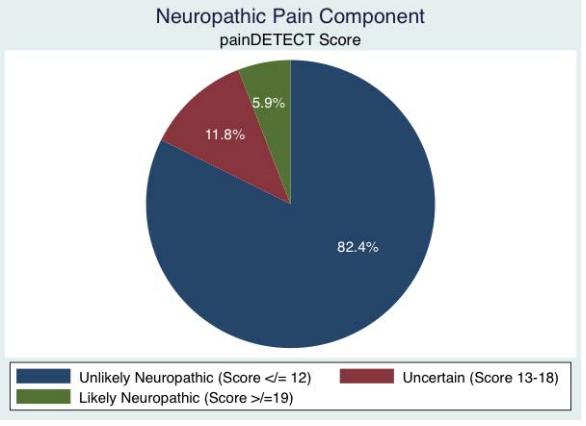
Improving Our Understanding of Pain in Autosomal Dominant Polycystic Kidney Disease Ragada El- Damanawi,[1] Tess Harris,[2] Thomas F. Hiemstra,[1] Michael C. Lee.[3] *[1]Dept of Renal Medicine, Cambridge Univ NHS Trust, Cambridge, United Kingdom; [2]Polycystic Kidney Disease (PKD) Charity, London, United Kingdom; [3]Div of Anaesthesia, Cambridge Univ NHS Trust, Cambridge, United Kingdom.*

Background: In Autosomal Dominant Polycystic Kidney Disease (ADPKD) pain is an early prominent feature affecting 60%. Multiple mechanisms result in pain, the severity of which correlates poorly with renal size. We conducted a survey to get a better understanding of patients experience of pain.

Methods: We used the painDETECT questionnaire, which was distributed to patients attending an ADPKD information day in Birmingham. 34 attendees completed the questionnaire.

Results: Participants were asked about how strong on average their pain was over the last 4 weeks using a scale 0= none to 10=maximum, 20.6% (7/34) had no pain, the majority 55.9% (19/34) scored pain between 1-5, and 23.5% (8/34) scored pain between 6-10. Of those that did experience pain (n=27), the pain quality is shown in table 1. 11.8% (4/34) said they had persistent pain with slight fluctuations, 8.8% (3/34) had persistent pain with pain attacks, most commonly 44% (15/34) had pain attacks without pain in between, and 20.6% (7/34) had pain attacks with pain between them. 82.4% (28/34) had a painDETECT score of ≤12 indicating the pain was not neuropathic-figure 1.

Pain Quality	Experienced Moderately-Very Strongly
Burning	22.2% (6/27)
Tingling or prickling	14.8% (4/27)
Light touch triggers pain	22.2% (6/27)
Sudden, electric shocks	**51.9% (14/27)**
Hot or cold painful	3.7% (1/27)
Numbness	3.7% (1/27)
Slight pressure triggers pain	**48.1%(13/27)**



Conclusions: In patients with ADPKD pain was episodic and nociceptive in quality, with not much of a neuropathic component. Our management should focus on intermittent therapy, and less on anti-neuropathic medications. There may be a role for renal denervation.

PUB251

Performance of Equations to Estimate Glomerular Filtration Rate in a Longitudinal Study of Autosomal Dominant Polycystic Kidney Disease Chengli Shen,[1] Doug Landsittel,[1] Maria V. Irazabal,[2] Alan S.L. Yu,[3] Arlene B. Chapman,[4] Michal Mrug,[5] Jared J. Grantham,[3] Kyongtae Ty Bae,[1] William M. Bennett,[6] Michael F. Flessner,[7] Vicente E. Torres,[2] The Crisp Investigators.[1] *[1]U of Pittsburgh, Pittsburgh, PA; [2]Mayo Clinic College of Medicine, Rochester, MN; [3]Kansas U, Kansas City, KS; [4]U of Chicago, Chicago, IL; [5]U of Alabama, Birmingham, AL; [6]Legacy Good Samaritan Hospital, Portland, OR; [7]National Inst of Diabetes, Digestive and Kidney Diseases, Bethesda, MD.*

Background: The reliability of estimated glomerular filtration rate (GFR) to reflect actual GFR values in clinical trials for ADPKD is controversial. Since 2001 the Consortium for Radiologic Studies of Polycystic Kidney Disease (CRISP) has followed 241 ADPKD patients (entry creatinine clearance >70 ml/min) with measurements of iothalamate clearance and serum creatinine yearly during four years and every other year afterwards. CRISP has shown a strong association of baseline height adjusted total kidney volume (HtTKV) and change in HtTKV with the rate of decline in iothalamate clearance.

Methods: We have evaluated the performance of GFR estimations by the MDRD and CKD-EPI equations relative to measured GFR using iothalamate clearance by mean bias, precision, accuracy, and strength of association with baseline HtTKV and change in HtTKV.

Results: Mean biases of MDRD GFR and CKD-EPI GFR values were large and positive (but highly variable) when measured GFR was ≥70 (10.1±26.9 and 6.2±22.6) and small and negative when it was <70 ml/min/1.73 m^2 (-1.9±9.5 and -5.0±9.9). Precision was higher when measured GFR was <70 ml/min/1.73 m^2.Measured and estimated GFR slopes and overall declines were not different. All were equally capable to detect the effect of baseline HtTKV and of change in HtTKV on the rate of GFR decline during 4, 8 or 12 years of follow-up. Beta coefficients were modestly higher with measured than with estimated GFR, but this advantage was offset by larger standard errors.

Conclusions: Determinations of estimated GFR using the MDRD or CKD-EPI equations are adequate to detect changes in kidney function over time in longitudinal studies and clinical trials of ADPKD.

PUB252

Online Survey Exploring Opinions of European Caregivers about Testing for Autosomal Dominant Polycystic Kidney Disease Stephanie Le De Rechter,[1] Djalila Mekahli,[1] Jonathan A. Kringen,[2] Elena N. Levtchenko,[1] Peter Janssens,[1] Max Liebau,[5] Carsten Bergmann,[3] Bert Bammens,[1] Pascal Borry,[1] Franz S. Schaefer.[4] *[1]Univof Leuven; [2]Univ of New Haven; [3]Bioscientia Center for Human Genetics, Ingelheim; [4]Univ of Heidelberg; [5]Univ Hospital of Cologne.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is considered an adult disease. Whether minor offspring of ADPKD patients should have diagnostic testing remains controversial. However, the attitudes of caregivers have never been studied.

Methods: We used an online questionnaire aimed for pediatric and adult nephrologists, and an adapted version for geneticists.

Results: A total of 410 caregivers responded: 151 adult nephrologists, 216 pediatric nephrologists, and 43 geneticists. All three specialities similarly agreed that it was appropriate to encourage clinical testing in adults (group mean = 5.31, sd = 1.16). While all supported that clinical testing in minors should be encouraged (group mean = 4.76, sd = 1.50), pediatric nephrologists demonstrated significantly stronger agreement (t =3.60, p < .001) than geneticists. Regarding ethical concerns, although all specialities exhibited some disagreement with the statement that "prenatal genetic diagnosis is ethically justified" (group mean = 3.08, sd = 1.76), adult and pediatric nephrologists exhibited significantly higher levels of disagreement compared to geneticists (tadult = -2.10, p < .05; tpediatric = -3.19, p < .01). Similarly, all groups disagree on the statement "termination of pregnancy for ADPKD is ethically justified" (group mean = 2.78, sd = 1.67). Finally, geneticists exhibited agreement with the statement that "pre-implantation genetic diagnosis is ethically justified" (geneticist mean = 4.48, sd = 1.63). This position was significantly different that of adult and pediatric nephrologists who exhibited disagreement (tadult = -2.51, p < .05; tpediatric = -4.43, p < .001).

Conclusions: Our survey demonstrated that most of the caregivers will support clinical testing of the offsprings of ADPKD families, however, there is no consensus on the value of genetic testing neither on the ethical issues of the family planning.

CRISPR-Cas9 Mediated Knockout of Ciliary Genes to Study PKD in Zebrafish Stephanie Jerman, Zhaoxia Sun. *Genetics, Yale Univ School of Medicine, New Haven, CT.*

Background: Polycystic Kidney Disease (ADPKD) is one of the most commonly occurring genetic disorders in the world with limited treatment modalities, resulting in many PKD patients progressing to end-stage renal disease. Thus, to understand the fundamental biology of PKD is an important area of research. Several recent studies suggest a critical role of the primary cilium, a signaling organelle with various sensory functions, in the development and manifestation of cysts in ADPKD. Notably, polycystin-2, one of the two proteins known to be mutant in Autosomal Dominant PKD, encodes a cation channel targeted to cilia. Many other ciliary proteins, including Arl13b and IFT57, when mutant lead to cyst formation. The earliest stages of vertebrate embryonic development rely on maternally supplied gene products. In zebrafish, these maternal contributions can have a protective effect on offspring, masking the true null mutant phenotype. For example, *Pkd2* homozygous mouse mutants develop kidney cyst similar to what is observed in patients with Autosomal Dominant PKD; however, *Pkd2*$^{-/-}$ zebrafish do have body curvature and left-right defects indicative of ciliary defects but do not display kidney cysts unless subjected to morpholino knockdown of *Pkd2*, which eliminates the maternal contribution. However, toxicity and off-target effect of morpholino knockdown is a concern. To address this issue and reveal the true null phonotype of ciliary mutants, this study focused on understanding the role of polycystin-2, Arl13b, and IFT57 within the primary cilium using maternal zygotic zebrafish to eliminate maternally contributed mRNA in mutant offspring. Maternal zygotic mutants were generated using CRISPR sgRNAs specific to the ciliary genes of interest and Cas9-nanos, which is preferentially expressed in the germline. These results provide novel insight into the function of *PKD2, Arl13b, and IFT57* within cilia and the role of the primary cilium in PKD and other cystic disorders.

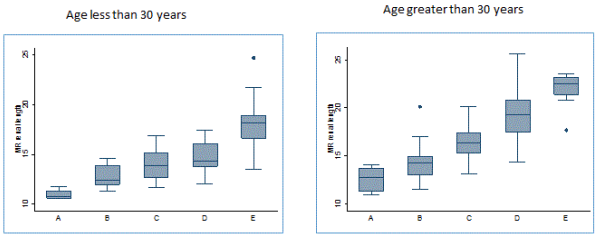
PUB254

Kidney Length Identifies Risk Categories of Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) Bharathi V. Reddy,[1] Doug Landsittel,[2] Chengli Shen,[2] Kyongtae Ty Bae,[2] Alan S.L. Yu,[3] Vicente E. Torres,[4] Maria V. Irazabal,[4] Frederic F. Rahbari-Oskoui,[5] Michal Mrug,[6] Arlene B. Chapman.[1] *[1]U Chicago; [2]U Pittsburg; [3]U Kansas; [4]Mayo Clinic; [5]Emory U; [6]UAB Birmingham.*

Background: Recently, a classification system establishing low and high risk ADPKD patients for progression to ESRD has been developed using height corrected total kidney volume (htTKV), age and serum creatinine (1A-1E, Irazabal, JASN. 2015 Jan;26(1):160-72). The Consortium for Radiologic Studies in Polycystic Kidney disease (CRISP) has demonstrated that kidney length (KL) performs as well as htTKV in predicting future Stages 3-5 CKD. Therefore we determined the corresponding MR based KL measures in participants in Classes IA-IE in CRISP.

Methods: Baseline coronal MRI maximum KL in 231 CRISP Class 1A-1E participants were assessed in those < 30 and >30 years of age.

Results: 145 participants were > and 84 patients < 30 years of age. In those < 30 years, 5, 17,29,18 and 32% of patients were in class 1A, 1B, 1C, 1D and 1E. In those >30 years, 7, 30, 30, 26 and 8% were in class 1A, 1B, 1C,1D and 1E. KL is less in all risk categories in young vs. old patients. The maximum KL observed in younger patients was 11.77, 14.58, 16.85, 17.43 and 24.66 in class 1A, 1B, 1C, 1D and 1E. In those >30 years, the maximum KL was 14.12, 20.15, 20.17, 25.65 and 23.55 in class 1A, 1B, 1C, 1D and 1E. Mean KL is < threshold to predict future stage III CKD in groups 1A-1D and 1A-1C in younger and older patients.



Conclusions: KL, which can be easily obtained by MRI and other imaging modalities show incremental change throughout the Irazabal classification of disease severity, highlighting which groups will progress to CKD.

PUB255

The Intrarenal Renin-Angiotensin System in Polycystic Kidney Disease: A Cross-Sectional Study Mahdi Salih,[1] Ron T. Gansevoort,[2] Stephan J.L. Bakker,[2] Robert Zietse,[1] Alexander H. Danser,[1] Ewout J. Hoorn.[1] *[1]Erasmus Medical Center; [2]Univ Medical Center Groningen.*

Background: Renin-angiotensin system (RAS) inhibitors are the preferred drugs for hypertension in autosomal dominant polycystic kidney disease (ADPKD). However, the relative role of the systemic and intrarenal RAS in hypertensive patients with ADPKD remains unresolved. Tubulocystic epithelium can synthesize functional renin, possibly in response to local hypoperfusion, but urinary renin has not been measured in patients with ADPKD. Therefore, we tested the hypothesis that ADPKD activates the intrarenal RAS resulting in higher urinary renin.

Methods: Patients with ADPKD (DIPAK cohort) were matched to patients with CKD (PREVEND cohort) based on gender, eGFR (CKD 3), RAS-inhibitor use, and blood pressure. Angiotensinogen (AGT), renin, and aldosterone were measured in plasma and 24h urine. Urinary renin was measured with a sensitive enzyme-kinetic assay.

Results: 69 patients with ADPKD were matched to 58 patients with CKD (43% male, 78% RAS-inhibitor use, eGFR 46 ml/min, blood pressure 131/77 mmHg). Patients with ADPKD were younger (47 vs. 69 years) and had more albuminuria (40 vs. 27 mg/day). While plasma levels of AGT, renin, and aldosterone were similar between groups, urinary AGT and renin excretion were 4.8 and 6-fold higher in ADPKD (P<0.01). These differences persisted in the subset of patients without RAS-inhibitors. A subanalysis in patients with similar age and albuminuria (31 ADPKD vs. 9 CKD patients) still showed higher urinary AGT (3.5-fold) and renin (8.7-fold) excretion in ADPKD. In a multivariable analysis, ADPKD, plasma renin, and albuminuria were identified as independent predictors for urinary renin. Urinary renin did not correlate with blood pressure or total kidney volume. In three patients with available plasma, cyst fluid, and urine, analysis of the concentration ratios indicated that relatively more renin than albumin was excreted in urine, suggesting local renin release from cysts.

Conclusions: In addition to plasma-derived urinary renin, the consistently higher urinary renin excretions in patients with ADPKD also supports the possibility of activation of the intra-renal RAS.

PUB256

Patient Survey of Current Water Intake Practices in Autosomal Dominant Polycystic Kidney Disease: The WIPP Survey Ragada El-Damanawi,[1] Tess Harris,[2] Thomas F. Hiemstra.[1] *[1]Dept of Renal Medicine, Cambridge Univ NHS Trust, Cambridge, Cambridge, United Kingdom; [2]Polycystic Kidney Disease (PKD) Charity, London, United Kingdom.*

Background: Vasopressin drives cyst growth in Autosomal Dominant Polycystic Kidney Disease (ADPKD). It can be suppressed through high water intake, although the effects of this approach on renal outcomes are unproven. We conducted a survey of ADPKD patients to determine current fluid intake practices and willingness to participate in a randomised water intake trial.

Methods: In collaboration with the PKD Charity, we developed and distributed an online patient questionnaire. Participants were arbitrarily divided into those reporting a high water intake (>2 litres/day) and those reporting a lower intake. Responses were compared between groups.

Results: 89 ADPKD patients responded [65 female (73%); 84 caucasian (94%); 80 British (93%)]. The median age range was 45-49 years. One third (30/89, 33.7%) received a diagnosis of ADPKD during the 4th decade of life. More patients in the high water intake group (47 of 54, 87%) reported regularly drinking beyond thirst compared to the low water intake group (18 of 35, 32%, p=0.001). Reports of nocturia were not different between groups (p=0.663) and both groups equally believed high water intake was beneficial - table1.

	Low Intake ≤ 2 Litres/ day (N= 35)	High Intake > 2 Litres/day (N=54)	p value
Intake Beyond Thirst	52% (18/35)	87% (47/54)	0.001
Nocturia	63% (22/35)	57% (31/54)	0.663
Believe high water intake beneficial	49% (17/35)	52% (28/54)	0.099

Despite only 15 (17%) living with affected family members, the majority (70 of 89, 79%) regularly discussed management with their relatives. Most patients (80 of 89, 90%) indicated willingness to participate in a randomised trial of high versus *ad lib* water intake.

Conclusions: Current water intake practices vary widely among UK patients with ADPKD. A trial of high versus standard water intake in ADPKD is urgently needed and likely to be supported by patients. Many patients regularly discuss their condition with affected family members, suggesting that contamination between trial arms is possible and may require cluster randomisation.

PUB257

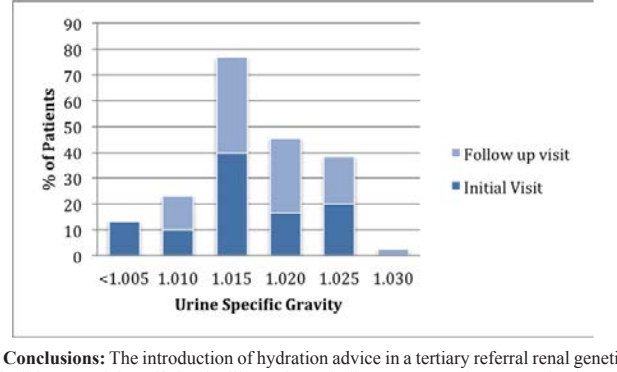
Influencing Urine Specific Gravity in the Management of Autosomal Dominant Polycystic Kidney Disease Ragada El-Damanawi, Richard N. Sandford, Fiona E. Karet, Thomas F. Hiemstra. *Dept of Renal Medicine, Cambridge Univ NHS Trust, Cambridge, United Kingdom.*

Background: Vasopressin receptor blockade slows cyst growth in Autosomal Dominant Polycystic Kidney Disease (ADPKD). High water intake readily suppresses vasopressin release, and may be an alternative to Vasopressin antagonists. Patients are often advised to drink beyond thirst. However, the effect of this advice is unknown. As vasopressin suppression results in water diuresis with a urine specific gravity (uSG)<1.010, uSG provides a surrogate for vasopressin suppression. We assessed uSG in a cohort of ADPKD patients to establish prevalent hydration status.

Methods: High water intake advice for ADPKD was introduced in our centre in 2013. In this single-centre retrospective cohort study, we determined adherence to hydration advice by assessing uSG. Data were extracted from patient case records.

Results: Data were available for 77 patients [41(53%) male; 56 (73%) Caucasian; 5 (6%) PKD2 mutation]. The mean (SD) age at diagnosis was 29±14 years, and at referral 40±14 years. 59 patients (77%) had a family history of ADPKD. At baseline 40 (52%) has CKD1 or 2; 13 (17%) CKD3 and 3 (4%) CKD4. CKD5 patients were referred to Low Clearance services and thus not included.

Baseline median uSG was 1.015 (IQR 1.015-1.020), 41 patients (53%) demonstrating uSG>1.010. Serial uSG data was available for 48 patients. There was no difference (p=0.1154) in mean uSG at first visit [1.016±0.006(SD)] and follow-up visit [1.018±0.005], despite hydration advice (figure 1). Renal function did not differ (p=0.1053) between initial visit [eGFR 75.5ml/min±23.5 (SD)] and follow up [72.2ml/min±26.7].



Conclusions: The introduction of hydration advice in a tertiary referral renal genetics clinic did not result in sufficiently dilute urine to indicate vasopressin suppression in many patients. Further studies assessing strategies to promote hydration are warranted.

PUB258

Autosomal Dominant Polycystic Kidney Disease in the Southwest of Ireland Michael Keyes, Dearbhla Kelly, Edward Philip Mcmonagle, Liam F. Casserly. *Dept of Nephrology, Univ Hospital Limerick, Limerick, Ireland.*

Background: Autosomal dominant polycystic kidney (ADPKD) is the most common genetic cause of chronic kidney disease (CKD). In a recent cross-sectional survey, it accounted for 7.3% of patients with CKD in the Republic of Ireland. ADPKD is caused by mutations of either PKD1 (which encodes polycystin-1), on chromosome 16, or PKD2 (which encodes polycystin-2), on chromosome 4.

Methods: This was an observational study of all patients with ADPKD who attended the Nephrology services in University Hospital Limerick from January 2000-June 2016. Patients were identified by interrogation of the departmental database. Retrospective chart review enabled documentation of demographic and clinical characteristics along with treatment course and outcome. Water intake and access to genetic counseling were also recorded.

Results: 99 patients with ADPKD were identified. The mean age of the population was 58.7 years (SD ± 13.9, range 29-88 years). 56.7% were female. 13 patients (13.1%) had no family history of ADPKD but only 1 patient had genetic testing for PKD1 and PKD2 genes performed. 76.8% of patients developed hypertension and 51.5% of patients were treated with renin-angiotensin system [RAS] inhibitors. The mean delta glomerular filtration rate (GFR) was -1.2ml/min (SD ± 2.8). 28.3% were dialysis-dependent and 21.2% of patients received a renal transplant. No patient was counseled regarding increased water intake and no patient was in receipt of a vasopressin receptor antagonist. 37.4% were screened for cerebral aneurysms with only 2 positive cases.

Conclusions: Genetic testing for patients with ADPKD without a family history should be performed to ensure that other hereditary or acquired ciliopathies are not misdiagnosed. Only half the population in this study received a RAS inhibitor but the rate of progression of kidney disease was slow. Vasopressin receptor antagonists are not yet in widespread use in Irish patients. Patients with APDKD should receive counseling regarding increased water intake in order to adequately suppress anti-diuretic hormone levels to inhibit cyst growth. There was a low incidence of cerebral aneurysms in this population.

PUB259

Renal Angiomyolipoma: Outcomes of Selective Arterial Embolization on Glomerular Filtration Rate Ammar Almehmi,[1] Alian Albalas,[3] Ahmed Kamel Abdel Aal.[2] *[1]Nephrology and Radiology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Radiology, Univ of Alabama at Birmingham, Birmingham, AL; [3]Nephrology, Univ of Alabama at Birmingham.*

Background: Selective arterial embolization (SAE) is a surgery-sparing treatment for renal angiomyolipoma (AML). However, limited data are available on the effects of SAE on glomerular filtration rate (GFR). Further, the outcomes of contrast exposure on GFR during SAE procedure remain unknown. The aim of this study was to evaluate the change in serum creatinine and GFR in patients with AML who underwent SAE.

Methods: This is a retrospective review of AML cases that were treated with SAE procedure at our center from 2004 to 2015. Data collected from medical records included demographics, tumor side and size, and other laboratory parameters. Serum creatinine and calculated GFR were collected immediately prior and 3 months after SAE procedure.

Results: This study included 42 patients who underwent SAE. Indications for SAE included back pain, hematuria and retroperitoneal hemorrhage. Baseline characteristics were: age (median +/- 25^{th}-75^{th} interquartile) 42 (32-64) year; 81% females; 66% whites. Hypertension and tuberous sclerosis were present in 33% and 42.9% of patients, respectively. Tumor size (median +/- 25^{th}-75^{th} interquartile) was 5.9 (4.7-8.5) cm. Two episodes of acute kidney injury occurred post SAE with complete renal recovery. Although mean serum creatinine increased from 0.98 mg/dl to 1.15 after SAE procedure, no statistically significant difference was noted in post SAE GFR (60 vs 70 ml/min; p=0.125).

Conclusions: Selective arterial embolization is a safe, surgery-sparing treatment for renal AML. Despite contrast exposure and partial parenchymal loss, renal function (i.e. GFR) remained well preserved after SAE procedure.

PUB260

Genome Editing-Based Cell Culture Models for Studying ADPKD Alexis Hofherr, Tilman Busch, Andreas Nold, Albert Bohn, Amandine Viau, Frank Bienaime, E. Wolfgang Kuehn, Michael Kottgen. *Renal Div, Dept of Medicine, Faculty of Medicine, Univ of Freiburg, Freiburg im Breisgau, Baden-Wuerttemberg, Germany.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic cause of end-stage renal disease. Mutations in two genes, *Polycystic Kidney Disease 1* (*PKD1*) and *PKD2*, cause ADPKD. Data from humans and animal models show that both genes are part of a morphogenetic program to maintain kidney structure. However, the molecular functions of the respective proteins, Polycystin-1 (PC1) and transient receptor potential Polycystin-2 (TRPP2), have remained elusive.

Methods: Analyses of polycystin-dependent events driving cystogenesis *in situ* are complicated by a complex interplay of endogenous and environmental factors. *In vitro*, wild-type renal cell lines, including Madin-Darby Canine Kidney (MDCK) and mouse Inner Medullary Collecting Duct 3 (mIMCD3) cells, have been well-characterized. But a lack of differentiated ADPKD mutant cell lines has confounded molecular studies of polycystin function: the majority of isolated primary cells are heterogenous and have a finite replicative capacity; the generation of immortalized differentiated renal epithelial cells from ADPKD patients or mouse models has proven difficult; murine embryonic fibroblasts (MEFs) from genetically modified ADPKD mice lack the epithelial characteristics of renal tubular cells; and the physiological relevance of heterologous expression systems has been questioned. We therefore hypothesized that the manipulation of native proteins in differentiated renal epithelial cell lines may accelerate novel insights into polycystin function.

Results: Here we present ADPKD-specifc *in vitro* models of varying complexity. Based on MDCK and mIMCD3 cells we generate ADPKD models with: 1) deletion of PKD genes; 2) rescue of polycystin expression; 3) introduction of highly antigenic epitope-tags into the *Pkd1* genomic locus; and 4) combination of multiple alleles.

Conclusions: We hope that our genome-edited cell culture models may help to clarify the function of polycystin proteins in renal epithelial cells.

PUB261

Efficient Genome Editing of Differentiated Renal Epithelial Cells Alexis Hofherr,[1] Tilman Busch,[1] Nora Marie Huber,[2] Sebastian Arnold,[2] Michael Kottgen.[1] *[1]Renal Div, Dept of Medicine, Faculty of Medicine, Univ of Freiburg, Freiburg im Breisgau, Baden-Wuerttemberg, Germany; [2]Experimentelle und Klinische Pharmakologie und Toxikologie, Faculty of Medicine, Univ of Freiburg, Freiburg im Breisgau, Baden-Wuerttemberg, Germany.*

Background: The recent advent of highly efficient genome editing technologies has enabled a new paradigm in which genomes can be precisely manipulated. This includes the targeted introduction, alteration, and/or removal of genomic sequences. However, respective methods have been described mainly in haploid or non-differentiated cells. The application in well-differentiated renal epithelial cells has been hampered by a range of technological issues, including optimal design, efficient expression of multiple genome editing constructs, attainable mutation rates, and best screening strategies.

Methods: Here we show how to overcome these challenges to rapidly generate heterozygous and homozygous genomic sequence alterations in renal cells using transcription activator-like effector nucleases (TALENs) and the clustered regularly-interspaced short palindromic repeat (CRISPR) system.

Results: The cell lines most widely used to study renal epithelial biology are Madin-Darby Canine Kidney (MDCK) cells and mouse Inner Medullary Collecting Duct 3 (mIMCD3) cells. Both cell lines retain core epithelial characteristics, are phenotypically stable, and develop clear apico-basolateral polarity. We therefore developed a genome editing-based framework to efficiently expand on the genetics of wild-type MDCK and mIMCD3 cells. Applications include, but are not limited to, large genomic deletions, loss-of-function mutations, and knock-ins by homologous recombination. Furthermore, we describe how to translate these genetic alterations into complementary mouse models. Notable features of genome edited cell lines are, a high degree of differentiation, phenotypic and genetic stability, experimental tractability, and suitability for small and high throughput screening.

Conclusions: We anticipate that the developed genome editing workflow may help to clarify gene functionality in differentiated renal epithelial cells in health and disease.

Funding: Government Support - Non-U.S.

PUB262

Serum from Diabetic-End Stage Renal Disease (DM-ESRD) Patients Affects Endothelial Reparative Ability María Marques Vidas,[1] Estefanya Garcia Menendez,[1] Matilde Alique,[3] Elena Corchete,[2] Jeanette Nora Fernandez C.,[1] Patricia De Sequera,[2] Rafael Perez-Garcia,[2] Rafael Ramirez,[3] Jose M. Portoles.[1] *[1]Nephrology, H U Puerta de Hierro Majadahonda, Majadahonda, Madrid, Spain; [2]Nephrology, HU Infanta Leonor Vallecas, Madrid, Spain; [3]Physiology Lab, U Alcalá de Henares, Alcalá de Henares, Madrid, Spain.*

Background: Chronic renal disease and diabetes mellitus are associated with higher rates of cardiovascular disease. Circulating micoparticles (MPs) are intercellular communication mediators that module mechanisms of vascular endothelium lesion and reparation. The aim of this study was to evaluate the effect of the MPs from DM-ESRD patients on the vascular endothelium.

Methods: We used pooled serum obtained from DM-ESRD patients stage 4 (n=5), on peritoneal dialysis (PD, n=5), on haemodialysis pre-session (pre-HD, n=5) and post-session (post-HD, n =5), and healthy volunteers (n=5). MPs were isolated, and HUVEC were incubated with and without the addition of MPs. We analysed proliferation and apoptosis averages and ICAM and VCAM expression.

Results: The serum from DM-ESRD patients on any stage induced an increase on the expression of both ICAM and VCAM on HUVEC ($p< 0.001$*). Treatment with HD or PD did not modify this effect with respect to VCAM; however, the pre-HD serum pool induced a higher expression of ICAM ($p< 0.01$**). The presence of MPs decreased ICAM up-expression on all study groups (p ns). DM-ESRD serum was less effective on inducing cellular proliferation than control serum, especially on HD groups when tested without MPs. Finally, DM-ESRD serum induced a significant increase on apoptosis rate, especially on HD groups. The presence of MPs seemed to increase apoptosis rate in every study group but PD (p ns).

Conclusions: We conclude that the serum from DM-ESRD patients induces inflammatory changes and modification of the endothelial proliferative and apoptosis rates. The uraemia correction with the different types of renal substitutive therapy did not restore this effect and HD even seemed to exacerbate it. The presence of MPs protects the endothelial reparative ability even though they induced an increase on the apoptosis average on HUVEC, probably pointing towards a dual effect on endothelial reparative mechanisms.

PUB263

SGLT2 Inhibitor Ipragliflozin Increases Fluid and Food Intake to Maintain Body Fluid Volume and Weight Takahiro Masuda,[1] Yuko Watanabe,[1] Minami Watanabe,[1] Keiko Fukuda,[1] Akira Onishi,[2] Volker Vallon,[2] Daisuke Nagata.[1] *[1]Div of Nephrology, Dept of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [2]Univ of California San Diego & VA San Diego Healthcare System, San Diego, CA.*

Background: We previously reported that sodium-glucose cotransporter (SGLT) 2 inhibitor Ipragliflozin increases urine volume (UV) and Na excretion, whereas body fluid volume is maintained possibly due to an increase in fluid and food intake (ASN Kidney Week 2015). We therefore evaluated whether preventing the increase in fluid and food intake during SGLT2 inhibition induces body fluid reduction.

Methods: Male Sprague-Dawley rats (average 20.5±0.5 weeks of age) were treated with vehicle (Veh), 0.01% (in diet) Ipragliflozin (Ipra) and 0.01% Ipra by pair-feeding and drinking with Veh (Pair-Ipra) (n=8) for 7 days. Rats were placed in metabolic cages to measure UV and food and fluid intake. Bioimpedance spectroscopy (ImpediVet) was used to assess body water on day 0 and day 7.

Results: Compared with Veh, Ipra increased food and fluid intake; Pair-Ipra prevented the increase (food intake: 20.3±0.9, 29.2±1.2*, 21.9±0.6# g/day, fluid intake: 41.1±3.6, 78.4±7.9*, 43.7±1.4# ml/day, *P<0.05 vs Veh, #P<0.05 vs Ipra). Pair-Ipra decreased body weight (BW) vs Veh and Ipra (ΔBW: Veh -5.4±0.5, Ipra-4.1±0.6, Pair-Ipra -11.2±0.5*# %). Serum glucose was similar among groups (210±16, 176±13, 178±3mg/dl, P=0.11). Ipra and to a lesser extent Pair-Ipra increased UV (19.3±1.9, 53.7±3.6*, 31.6±1.8*# ml/day), Na excretion (2.2±0.1, 3.5±0.1*, 2.6±0.1*# mEq/day), Cl excretion (2.9±0.1, 4.7±0.2*, 3.6±0.1*# mEq/day) and K excretion (4.1±0.1, 5.5±0.2*, 5.0±0.2*mEq/day). Pair-Ipra decreased fluid balance (fluid intake - UV) (Δfluid balance: -2.2±10.0, 27.3±16.0, -42.8±6.5*# %). Pair-Ipra decreased total body water (-9.8±1.6%¶, ¶P<0.05 day 0 vs day 7), extracellular water (-11.5±1.7%¶) and intracellular water (-8.6±2.6%¶), while Ipra or Veh had no significant effect.

Conclusions: SGLT2 inhibitor Ipragliflozin increases fluid and food intake in euglycemic rats. Preventing the increase in fluid and food intake causes body fluid and weight reduction. Thus, SGLT2 inhibition increases fluid and food intake to maintain body fluid volume and weight.

Protective Effect of ApoAI/ABCA1 on Kidney inflammation of STZ Induced Diabetic Nephropathy Rats Tong Li,[1] Ricong Xu,[2] Huanfang Yang.[3] *[1]Shenzhen No.2 People's Hospital, Shenzhen; [2]Shenzhen No.2 People's Hospital, Shenzhen; [3]Shenzhen No.2 People's Hospital, Shenzhen.*

Background: To discuss the protective effect of ApoAI/ABCA1 pathway on kidney inflammation of STZ-induced diabetic nephropathy rats.

Methods: Forty Sprague-Dawley male rats were randomly divided into 4 groups: Normal group,DN group(diabetic nephropathy),DN+GFP group and DN+ApoA-I group. The DN rats model were injected by abdominal streptozotocin(STZ) (65 mg /kg). The successful models were defined as FBG> 16.7 mmol/L, UGLU >3+ . DN+GFP group and DN+ApoA-I group were injected with AdV-GFP or AdV-AI (1×1011v.p./mice/d) by tail vein . After 4 weeks, kill the rats and get out the kidneys, and then test the expression of ABCA1 mRNA and TTP protein in the kidney by RT-PCR and Western blot; Collect blood in postcava, and then test the content of TNF-α and MCP-1in serum respectively by ELISA.

Results: Compared with the control group, the expression of ABCA1 mRNA and TTP protein in the kidney were reduced in the DN group($P < 0.05$);There were no differences of ABCA1 mRNA and TTP protein in the kidney between the DN group and DN+GFP group; However, Compared with DN+GFP group, the contents of serum TNF-α and MCP-1 were reduced ,what's more, the expression of ABCA1 mRNA and TTP protein in the kidney were increased in the DN+ApoA-I group($P < 0.05$).

Conclusions: Activation of ApoA-I / ABCA1 pathway could protect STZ-induced diabetic nephropathy rats from inflammatory injure , This effect may be through down regulation of TNF-α,MCP-1 and over xpression of ABCA1 mRNA ,TTP protein in the kidney.

PUB265

The Protect Effect of Ouabain in Diabetic Nephropathy Dong Li,[1] Xiaowei Wang.[2] *[1]Pediatric Dept, Dalian Municipal Women and Children's Medical Center, Dalian, Liaoning, China; [2]Basic Medicine Dept, Dalian Medical Univ, Dalian, Liaoning, China.*

Background: Diabetic nephropathy is the main cause of kidney injury. As a plant-derived cardioglycoside, ouabain was well-established inhibitor of Na-K-ATPase activity. Recent investigations demonstrate at nanomolar concentrations, ouabain increases Na-K-ATPase activity, and increase cell proliferation. We aim to study the potential protect effect of Ouabain in diabetic nephropathy.

Methods: Primary tubular cells of rats were cultured and treated with glucose (5mM, 10mM, 15mM and 25mM) to perform the diabetic nephropathy model, meanwhile 5nM ouabain was added and incubated together for 8hrs, 18hrs and 24hrs separately. Cells were observed under imaging, Apoptosis data was performed with TUNEL method.

Results: With the 10mM glucose incubation for 8hrs, 18hrs and 24hrs separately, the PTCs were damaged under imaging, and 18hrs was the top point, TUNEL showed the mean index of apoptosis was 2.9%±0.3%(control)and for 18hrs treatment apoptotic index was increased to 21.2%±4.1% (P<0.01). In the co-incubated with ouabain 5nM for 18hrs group, Ouabain significantly alleviated the apoptosis, apoptosis index was 6.5%±1.3%.

Conclusions: Apoptosis play a role in Diabetic Nephropathy, Ouabain may perform as an anti-apoptotic factor and play a protect effect on it.

Renoprotective Effect of Uremic Clearance Granules in Streptozotocin-Induced Diabetic Nephropathy Hua Jin, Shang Guo Piao, Ji Zhe Jin, Long Ye Zhang, Can Li. *Nephrology, YanBian Univ Hospital, YanJi, JiLin, China.*

Background: Uremic Clearance Granules (UCG), a compounded Chinese patent medicine, has been shown to exert beneficial effects on chronic renal failure. However, its role in diabetic nephropathy (DN) has not to be illustrated. The present study investigated the renoprotection of UCG in a rat model of streptozotocin (STZ)-induced DN.

Methods: Diabetes was induced with STZ (65 mg/kg) by intraperitoneal injection in male Wistar rats. Two weeks after STZ injection, diabetic rats were treated daily for 12 weeks with UCG (5g/kg). Basic parameters (body weight, fasting blood glucose level, 24h urinary protein excretion, and renal function), histopathology, inflammatory (ED-1 and Toll-like receptor-2 [TLR-2]) and glomerulosclerotic factors (Transforming growth factor-beta inducible gene-h3 [βig-h3] and connective tissue growth factor [CTGF]), and oxidative stress (8-hydroxy-2¢-deoxyguanosine, 8-OHdG) were studied at 4, 8, 10, and 12 weeks.

Results: UCG treatment significantly improved body weight loss, 24h urinary protein excretion, and renal dysfunction induced by diabetes in a time-dependent manner (all p<0.05). These changes were accompanied by a significant attenuation of glomerulosclerosis. Increased expression of inflammatory (ED-1 and TLR-2) mediators and glomerulosclerotic (βig-h3 and CTGF) factors in diabetic rat kidney wasmarkedly reduced by treatment with UCG (all p<0.01). Moreover, increased urinary 8-OHdG excretion in diabetic rats was decreased by treating UCG. There was no significant between-groupdifference in blood glucose level.

Conclusions: UCGtreatment may confer renoprotection by anti-inflammatory and anti-fibrotic actions in STZ-induced DN.

High Fat Diet Given with Low Doses of Streptozotocin Induces Type 2 Diabetic Nephropathy in Endothelial Nitric Oxide Synthase Knockout Mice M-Altaf Khan,[1,2] Federico Jose Teran,[1,2] Kathleen S. Hering-Smith,[1,2,3] Molly Fisher,[4] Dewan S. Majid,[2] L. Gabriel Navar,[2] Vecihi Batuman.[1,2,3] *[1]Medicine, Nephrology & Hypertension, Tulane Univ, School of Medicine; [2]Physiology/THRCE, Tulane Univ, School of Medicine; [3]VA, SLVHCS, New Orleans, LA; [4]Medicine/Nephrology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Wild type (WT) mice are usually resistant to the development of diabetic nephropathy (DN). We hypothesized that aged eNOS$^{-/-}$ mice fed a high fat diet (HFD) are more susceptible to streptozotocin (STZ) induced DN than mice fed a regular diet (RD) or HFD only.

Methods: Male eNOS$^{-/-}$mice were fed a HFD (52% fat Kcal) for 9 - 12 weeks to develop β-cell resistance and low doses of STZ (50 mg/kg b.w., ip) were administered for 3 days to induce diabetes. Control eNOS$^{-/-}$ or WT (C57Bl6/J) mice were fed a RD and all mice were sacrificed at 16 - 20 weeks of age.

Results: All eNOS$^{-/-}$ mice on HFD, after the 3rd STZ injection, developed diabetes with non-fasting blood glucose levels > 300 mg/dl that continued to increase with age. The diabetic (DB) eNOS$^{-/-}$ mice had significantly higher blood hemoglobin A1C levels (9.21 ± 0.18% SE) compared to non-diabetic (ND) eNOS$^{-/-}$ mice on RD (4.4 ± 0.4%) or on HFD alone (5.4 ± o.4%), and WT mice on RD (4.7 ± 0.05%) only. Aged DB eNOS$^{-/-}$ mice developed significant polyuria, glucosuria, albuminuria and proteinuria compared to ND eNOS$^{-/-}$ mice. Diabetic eNOS$^{-/-}$ mice showed higher systolic blood pressure and significantly higher pulse rate, and a significant increase in serum creatinine (ND = 0.11 ± 0.1 vs DB = 0.252 ± 0.05 mg/dl). These mice showed a significant increase in urinary angiotensinogen (AGT) (DB = 275.2 ± 44.5 vs ND = 29.8 ± 8.2 or ND WT = 12.04 ± 2.5 ng/day) reflecting augmentation of the intrarenal renin-angiotensin system (RAS). Urinary kidney injury biomarkers (NGAL and KIM-1) were significantly increased in association with glomerulosclerosis. Aged DB eNOS$^{-/-}$ mice also showed metabolic acidosis with significantly lower blood HCO_3 and urinary pH values.

Conclusions: Aged eNOS$^{-/-}$ mice on HFD and STZ develop diabetes and nephropathy with increased serum creatinine, albuminuria, urinary AGT and metabolic acidosis. These mice can be used as a model of type 2 DN with hypertension.

PUB268

Effect of CS-3150, a Non-Steroidal Selective Mineralocorticoid Receptor Antagonist, on Blood Pressure and Renal Injury in High Salt-Treated Type 2 Diabetic Mice Akira Nishiyama, Hirofumi Hitomi, Daisuke Nakano. *Dept of Pharamacology, Kagawa Univ Medical School, Japan.*

Background: The aim of the study was to examine the effect of CS-3150, a non-steroidal selective mineralocorticoid receptor (MR) antagonist, on blood pressure and renal injury in high salt diet-treated type 2 diabetic KKAy mice, and compare the effects with spironolactone, a steroidal MR antagonist.

Methods: Male 11-week-old KKAy mice were treated with normal salt diet (NS: 0.3% NaCl, n = 5), high salt diet (HS: 4% NaCl, n = 8), HS + CS-3150 (1 mg/kg/day, p.o., n = 8), or HS + spironolactone (20 mg/kg/day, p.o., n = 7) for 8 weeks. Renal oxidative stress was evaluated by dihydroethidium florescence intensity assay.

Results: As compared with NS-treated KKAy mice, HS-treated diabetic KKAy mice demonstrated hypertension, albuminuria, glomerular injury (glomerular PAS staining-positive area) and tubulointerstitial fibrosis (Azan staining-positive area) with increased oxidative stress at 19 weeks of age. Treatment with CS-3150 and spironolactone decreased blood pressure to a similar extent in HS-treated KKAy mice. In contrast, CS-3150 caused greater attenuation of albuminuria, glomerular injury and tubulointerstitial fibrosis as compared with spironolactone.

Conclusions: These data indicate that CS-3150 elicits antihypertensive and renal protective effects in HS-treated type 2 diabetic mice.

PUB269

L-Carnitine Protects against Streptozotocin-Induced Diabetic Nephropathy Ji Zhe Jin, Long Ye Zhang, Shang Guo Piao, Can Li. *Nephrology, YanBian Univ Hospital, YanJi, JiLin, China.*

Background: We have recently demonstrated that L-carnitine confers renoprotective effect on cyclosporine-induced nephropathy in the rats. The present study investigated whether L-carnitine protects against streptozotocin (STZ)-induced diabetic nephropathy (DN).

Methods: Diabetes was induced with STZ (65 mg/kg) by intraperitoneal injection in male Sprague-Dawley rats. Two weeks after STZ injection, diabetic rats were treated daily for 10 weeks with vehicle or L-carnitine (50 or 200mg/kg). The renoprotective effects of L-carnitine were studied by evaluating the expression of fibrotic cytokine-transforming growth factor-beta1 (TGF-β1) inducible gene-h3 (βig-h3), of apoptosis or autophagy-related gene-active caspase-3 or LC3, and the concentration of oxidative stress. In addition, renal function, fasting blood glucose level, and 24h urinary protein excretion were also compared for different groups.

Results: L-carnitine induced dose-dependent decreases in the expression of βig-h3, caspase-3, and LC3, and in the concentration of urine 8-OHdGCG. These were accompanied by a significant attenuation of glomerulosclerosis.Renal function and 24h urinary protein excretion significantly improved with administration of L-carnitine at different time points, although fasting blood glucose level was unaffected.

Conclusions: L-carnitinetreatment protects against STZ-induced DN.

The Effect of miR-29c on Inflammation through Tristetraprolin in Diabetic Nephropathy Jing Li,[1,2] Jing Zhao,[1,2] Jia Guo,[1,2] Zhanzheng Zhao.[1,2] *[1]The Nephrology Center of the First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China; [2]Zhengzhou Univ Inst of Nephrology, Zhengzhou, Henan, China.*

Background: Inflammation is a key factor of diabetic nephropathy (DN). Emerging evidence has demonstrated that miRNAs play a mediatory role in the inflammation of diabetic nephropathy. Tristetraprolin(TTP) could modulate the mRNA expression of inflammatory cytokines. In this study, we investigated the repertoire of miRNAs in the blood plasma, urinary sediment and kidney tissues of patients with DN and their potential regulatory role in inflammation invloved in DN.

Methods: The miRNA expression profiling of the blood plasma, urinary sediment and renal biopsy samples was performed by a microarray analysis, which showed that miR-29c was significantly differential expression. Mice podocytes were cultured under different conditions, and the protein expressions were examined by western blot or ELISA. The real-time PCR was used to detect the miR-29c or mRNA expressions. Dual luciferase reporter assay kit was used to detect the interaction between TTP 3'UTR and miR-29c.

Results: 1. The expression of miR-29c was significantly increased in the blood plasma, wherease, decreased in the urinary sediment and kidney tissues of the DN patients compared with the controls. The miR-29c expression in blood plasma was closely negatively correlated with the TTP level ($R = -0.9$, $P < 0.05$) and positively with the inflammatory cytokine IL-6 level ($R = 0.879$, $P < 0.05$). 2. The expressions of miR-29c and inflammatory cytokines IL-6 and TNF-α were up-regulated under high glucose in mice podocytes, with the decreased expression of TTP. 3. Up-regulation of miR-29c by mimics led to the increased expressions of inflammatory cytokines IL-6 and TNF-α and a decreased expression of TTP. However, inhibition of miR-29c by inhibitor exerted the opposite effect. 4. The dual-luciferase reporter assay showed that miR-29c directly targeted the TTP 3'UTR. 5. The expression of TTP could be increased wherease inflammatory cytokines IL-6 and TNF-α decreased after miR-29c inhibitor transfected in high glucose-treated podocytes.

Conclusions: These findings suggested that miR-29c accelerated high glucose-induced inflammation through directly down-regulating TTP.

PUB271

Carbamylation of Albumin Reduces Binding to FcRn and Cubilin Mark C. Wagner,[1] Jered Myslinski,[1] Shiv Pratap Singh Yadav,[3] Silvia B. Campos-Bilderback,[1] Sudhanshu Kumar,[1,2] George Rhodes,[1] Ruben M. Sandoval,[1] Sarah E. Wean,[1] Fnu Ashish,[3] Bruce A. Molitoris.[1,2,4] *[1]Medicine, Indiana Univ School of Medicine, Indianapolis, IN; [2]Cellular & Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN; [3]CSIR-Inst of Microbial Technology, Chandigarh, India.*

Background: Elevated urea levels in CKD patients leads to carbamylation, a chemical modification of lysines within proteins. This irreversible non-enymatic posttranslational modification results in formation of e-amino-carbamoyl-lysine (homocitrulline) a hallmark of aging as evidenced by carbamylation of skin and matrix proteins. Elevated serum urea also promotes albumin carbamylation, a known risk factor for mortality in CKD patients, and was recently found to be associated with heart failure and mortality in diabetic patients with ESRD.

Methods: Since cubilin/megalin and FcRn interact to mediate PT transcytosis of albumin we investigated if carbamylated albumin would be handled differently by the kidney by quantifying binding to both FcRn and cubilin.

Results: Independent binding (K_D) to either FcRn or cubilin was measured using Microscale Thermophoresis and found to be markedly reduced, $p<0.0001$ (FcRn 2.0 ±0.5 to 37.0 ±1.7 mM, Cubilin 0.16 ± 0.007 to 2.4 ± 0.14 mM). Since the isoelectric point of carbamylated albumin was more anionic than unmodified albumin we also determined how other charge modifications impacted binding. Alterations in albumin charge are likely to occur when different drugs such as antibiotics and other molecules interact with albumin. Binding analysis showed similar binding for cationic albumin to both FcRn (1.2 mM) and cubilin (0.12 mM) while anionic albumin had weaker binding to cubilin (5.4 mM, $p<0.0001$) and FcRn (>100 mM, $p<0.0001$).

Conclusions: To further understand the molecular cubilin-albumin interaction we performed molecular docking of cubilin 7, 8 domains with albumin. This revealed a lysine residue in albumin likely to be carbamylated that could contribute to the weaker binding observed. Studies are presently underway to quantify serum clearance and *in vivo* handling of these albumins in order to better understand their physiological processing.

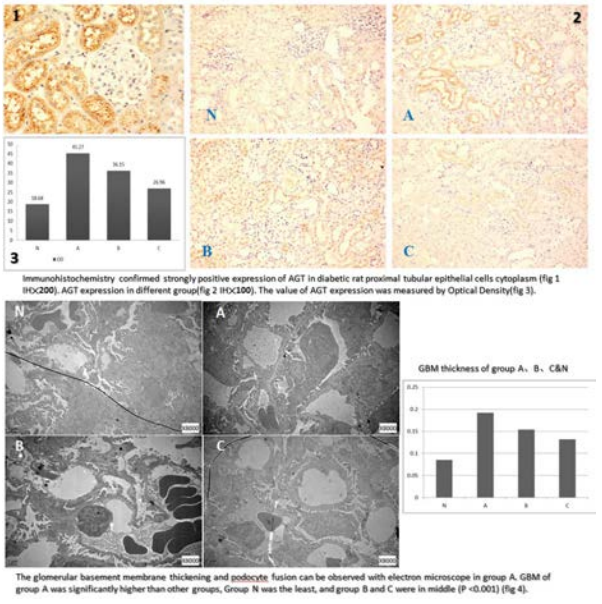
PUB272

Urinary Angiotensinogen Is a New Biomarker of Early Renal Pathological Change in Diabetic Rats Zhuang Zhen, Jiaxuan Lv. *Nephrology, Beijing Tsinghua Changgung Hospital, Beijing, China.*

Background: Urinary angiotensinogen might be a marker for activation of renin-RAS of DN. The purpose of this study was to investigate the relationship between AGT in blood, urine and renal tissue with renal function, renal pathological changes in diabetes animal models with the intervention of ARB drugs, to explore the functional roles of UAGT changes in the pathogenesis of DN and possible mechanisms.

Methods: 41 rats,4 groups, diabetic group and healy controll,the other two diabetic groups were treated with different doses of losartan.In a 12-week investigation, we detected the changes of AGT in all rats' blood and urine and the association between RAS activation and urinary proteins were analyzed in this study. After 12 weeks, we made renal tissue specimens, and stained observe pathological changes. By immunohistochemistry we detected the expression of AGT.

Results: The serum AGT had no significant differences. The urinary AGT of the diabetic rats was significantly different from the control group, the UAGT of the diabetic rats under different treatments was also obviously different. The level of UAGT was positively associated with urinary protein ($r=0.493$, $P<0.01$) and negatively correlated with CCr ($r=-0.474$, $P=0.007$). Further immunohistochemistry confirmed strongly positive expression of AGTin diabetic rat proximal tubular epithelial cells cytoplasm. The value of AGT expression was measured by Optical Density. Group A was significantly higher than other groups, group B and C expression decreased gradually($P<0.001$). The GBM thickening and podocyte fusion can be observed with electron microscope in group A. GBM of group A was significantly thicker than other groups ($P<0.001$).



Conclusions: In the early stage of DN, rising UAGT reflects renal local RAS activation and is associated with proteinuria, and damaged renal function. UAGT is a new biomarker of early pathological changes in diabetic rats.

PUB273

Meprin β-Associated Changes in Serum and Urine Metabolite Profiles of Mice with Streptozotocin (STZ) Induced Type 1 Diabetes
Jessica Gooding,[2] Jean-Marie V. Niyitegeka,[1] Susan Mcritchie,[2] Susan Sumner,[2] Elimelda Moige Ongeri,[1] Courtney Whitaker.[2] *[1]Biology, North Carolina A&T State Univ, Greensboro, NC; [2]NCTraCS Metabolomics Core, RTI International, Research Triangle Park, NC.*

Background: The pathophysiology of diabetic nephropathy (DN) is not fully understood. Meprin metalloproteinases are the most abundantly expressed proteins in the brush border membranes of proximal kidney tubules. Meprin ß has been implicated in the pathophysiology of DN in humans and mice. Single nucleotide polymorphisms (SNPs) in the meprin ß gene were associated with human DN in the Pima Indians, a US ethnic group with extremely high rates of diabetes and DN. The mechanism(s) by which meprins modulate the progression of DN are not known.

Methods: Low dose STZ was used to induce type 1 diabetes in 8 week old male wild-type (WT) and meprin ß knockout (ßKO) mice. Control mice were injected with sodium citrate buffer. Urine and blood samples were collected at 4 and 8 weeks post-STZ injection. Enzyme-linked immunosorbent assays (ELISA) were used to determine the levels of creatinine and two protein-based kidney injury markers, neutrophil gelatinase-associated lipocalin (NGAL) and kidney injury molecule 1 (KIM-1). For metabolomics analysis, plasma and urine samples were loaded onto a UPLC-QTOF system for separation by HILIC chromatography and detection in MS^E mode.

Results: Diabetic meprin ßKO mice had significantly higher levels of plasma NGAL at 4 weeks but not at 8 weeks post STZ injection. The levels of urinary KIM-1 were significantly higher in meprin ßKO mice at both 4 weeks and 8 weeks when compared to their WT counterparts. Multivariate data analysis (OPLS-DA) showed urine metabolites important to differentiating meprin ßKO mice and WT, including four metabolites that have previously been shown to be indicators of kidney injury (*Hippuric acid, Methyladenosine, L-Carnitine, and Nicotinic acid).*

Conclusions: Meprin ß partially protects mice from the tubular kidney injury associated with diabetes. Meprin β expression and/or activity impacts the levels of plasma and urine metabolites in DN. The identities of these metabolites will advance understanding of the metabolic pathways impacted by meprins in DN.

PUB274

Carbamylation Is a Potent Competitor of Glycation for Protein Modifications In Vitro Et In Vivo
Camille H. Nicolas, Christine Pietrement. *Laboratory of Biochemistry and Molecular Biology, CNRS/URCA UMR N° 7369 MEDyC, Reims, France.*

Background: Chronic kidney disease (CKD) and diabetes mellitus accelerate protein aging through nonenzymatic post-translational modifications like glycation (addition of sugars) and carbamylation(addition of isocyanic acid, mainly generated from urea dissociation) occurring on the same binding sites. Our objective was to evaluate their potential competitive effect.

Methods: *In vitro*, albumin was incubated for three weeks with glucose, urea or cyanate. *In vivo*, carbamylation was amplified by subtotal-nephrectomy or oral cyanate consumption for 6 weeks in diabetic (*db/db*) or non-diabetic mice. LC-MS/MS was used for measuring carbamylation (homocitrulline, carbamylated hemoglobin) and glycation (furosine) markers. Fructosamine and HbA1c were measured by colorimetry and immunoassay, respectively.

Results: A reciprocal inhibition of 30% between glycation and carbamylation was evidenced *in vitro*. *In vivo*, after 5 weeks of CKD, plasma HCit concentrations were indifferently increased in diabetic or control mice. On the contrary, fructosamine and HbA1c were decreased in CKD-diabetic compared to diabetic mice. These decreases, (-16% and -35% respectively, $p<0.05$) were confirmed, in cyanate vs water drinking diabetic mice.

Conclusions: *In vitro* glycation and carbamylation inhibit reciprocically. However, *in vivo*, carbamylation gets the upper hand. Thus, classical markers of diabetes metabolic control should be interpreted with caution in diabetic patients with CKD because of this competitive effect.

PUB275

Association between Body Mass Index, Abdominal Circumference and Blood Pressure, Fasting Blood Sugar, HbA1c in Retired People of a Japanese Company
Kyoko Kikuchi,[1] Masahiko Ando,[2] Sawako Kato,[1] Takaaki Kondo,[3] Shoichi Maruyama,[1] Hiroyuki Honda,[4] Yasuko Yoshida.[4] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Center for Advanced Medicine and Clinical Research, Nagoya Univ Hospital, Nagoya, Japan; [3]Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [4]Innovative Research Center for Preventive Medical Engineering, Nagoya Univ, Nagoya, Japan.*

Background: Body mass index(BMI) and abdominal circumference(AC) is associated with blood pressure(BP),fasting blood sugar(FBS),and HbA1c. However, reference values of BMI,AC as risk factors to BP,FBS,HbA1c remain controversial in Japanese. We analyzed results of medical check up in retired people of a Japanese company to disclose association between BMI,AC and BP,FBS,HbA1c.

Methods: We recruited total 24781 person retired of a Japanese company who are 50-74years old between 2004 and2014 and analyzed their results of medical check up to check the correlations between BMI,AC and BP,FBS,HbA1c.We used linear mixed model. BMI was divided into 5 subgroups:A;<18.5,B;18.5≤BMI<22,C;22≤BMI<25,D;25≤BMI<30 ,E;≥30kg/m^2. AC was divided into 4 subgroups:F<80,G;80≤AC<85,H;85≤AC<90,I;≥90cm.

Results: BMI and systolic BP became linear relation.(CvsA ,estimated value[;EV];-5.65mmHg, P<0.0001.CvsB,EV-2.63, P<0.0001. CvsD,EV3.00,P<0.0001. CvsE,EV7.87,P<0.0001.)After correct by BMI,AC and systolic BPbecame linear relation. (FvsG,EV1.12mmHg,P<0.0001.FvsH,EV2.21,P<0.0001.FvsI,EV3.35,P<0.0001.) BMI and FBS became linear relation.(CvsA ,EV-1.87mg/dl, P<0.0001.CvsB,EV-1.12, P<0.0001. CvsD,EV1.97,P<0.0001.CvsE,EV7.84,P<0.0001.)BMI and HbA1c became linear relation.(CvsA ,EV-0.04%, P<0.0001.CvsB,EV-0.03,P<0.0001. CvsD,EV0.06,P<0.0001. CvsE,EV0.28,P<0.0001.)After correct by BMI,AC and FBS became linear relation. (FvsG,EV0.94mg/dl,P<0.0001.FvsH,EV2.04,P<0.0001.FvsI,EV3.15,P<0.0001.) After correct by BMI,AC and HbA1c became linear relation.(FvsG,EV0.02%,P<0.0001. FvsH,EV0.05,P<0.0001.FvsI,EV0.09,P<0.0001).

Conclusions: The elevation of SBP,FBS andHbA1c was observed for a AC of 80cm and up,and a BMI of 25 kg/m2 and up in middle-aged and elderly Japanese.

Renal Biopsy Findings in Patients with Diabetes: Experience in our Centre
Virginia Cabello,[1] Nestor Gabriel Toapanta,[1] Manuel Lopez Mendoza,[1] Rocío Cabrera-Pérez.[2] *[1]Nephrology, Virgen del Rocio Univ Hospital, Seville, Spain; [2]Pathology, Virgen del Rocio Univ Hospital, Seville, Spain.*

Background: The prevalence of renal disease unrelated to diabetes(NDRD)in patients with diabetes mellitus(DM)is variable.To be able todistinguish between both categories is an important issue given their prognostic and therapeutic implications.The sudden onset of nephrotic syndrome(NS),late age at diagnosis of the disease,the short duration of DM,the absence of retinopathy or hematuria and acute kidney injury(AKI)are considered as predictors of NND.The aim of our study is to assess renal biopsies performed in diabetic patients and correlate histological findings with clinical and laboratory parameters,in order to know which variables are associated with NND.

Methods: We retrospectively reviewed the medical records of patients who underwent kidney biopsy from January 2008 toDecember 2015.The indications of renal biopsy included:AKI,chronic kidney disease(CKD)and NS.Based on the biopsy findings the patients were categorized as:isolated diabetic nephropathy(DN,group 1);NDRD superimposed on DN(DNNDRD,group 2);isolated NDRD(group 3).

Results: A total of 54 patients underwent renal biopsy.Indications for kidney bio psy:AKI(64.4%),NS(20.3%),CKD(13.4) and nephrotic proteinuria(1.9%).In 72% of cases we found histological lesions different to DN.Glomerulonephritis(GN,27.5%),ac ute interstitial nephritis(AIN,18.5%),acute tubular necrosis(ATN,18.5%),hypertensive nephrosclerosis(5.5%) and myeloma cast nephropathy(1.8%).Proteinuria was significantly higher in patients with DN alone when compared to patients with NDRD or DNNDRD. Longer duration of DM and presence of retinopathy was more prevalent in groups 1 and 2 compared to group 3.Hematuria and leukocyturia was more common in patients with NDRD or DNNDRD.GN,AIN and ATN were the most common findings seen in all NDRD.

Conclusions: 70% of biopsies in diabetic patients revealed NDRD,most of them would alter treatment decisions.Tubulointerstitial lesions were a common biopsy finding with higher incidence of ATN and AIN.The shorter duration of DM and no previous CKD were the main predictors of NDRD.An active urinary sediment and the absence of diabetic retinopathy suggests a different lesion to DN.

PUB277

Cortical Distribution Pattern of Renal Histopathological Lesions in Type 2 Diabetes Takaya Sasaki, Kentaro Koike, Nobuo Tsuboi, Go Kanzaki, Kotaro Haruhara, Yusuke Okabayashi, Tetsuya Kawamura, Yoichi Miyazaki, Makoto Ogura, Takashi Yokoo. *Div of Kidney and Hypertension, The Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan.*

Background: The renal histopathological findings in diabetic nephropathy show some variation in severity within the same kidney specimen of each individual. However, the potential mechanisms involved in such variation remain largely unknown. We previously reported the zonal distribution patterns of renal lesions in non-diabetic kidneys (2015 ASN). The aim of this study was to examine whether or not the distribution of diabetic renal lesions is related to the renal anatomical organization.

Methods: We examined both the juxtamedullary (JM) and superficial (SF) cortices of autopsied kidneys with a history of type 2 diabetes. The renal histopathological findings closely related to diabetes were evaluated in 50 glomeruli per cortex. The cortical distribution index (CDI) was defined as follows to quantify the distribution pattern: CDI = (SF - JM) / (mean value of SF and JM).

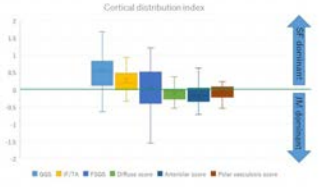
Results: A total 42 autopsy kidneys were analyzed. The average values were age of 74 years and estimated glomerular filtration rate (eGFR) of 71 ml/min/1.73 m^2. Some diabetes-specific lesions showed significant zonal differences, while other lesions did not (Table). The scores for diffuse lesion, arteriolar hyalinosis and polar vasculosis were significantly higher in the JM cortex than in the SF cortex (Figure). Neither age nor eGFR nor hypertension were found to be independent factors associated with the CDI of each lesion in multivariate analyses.

Table

Variables	Value		
	SF cortex	JM cortex	p-value*
Global glomerulosclerosis (%)	22.1±11.1	14.8±10.6	<0.001
Interstitial fibrosis/tubular atrophy (%)	24.6±14.9	20.1±14.3	<0.001
Segmental glomerulosclerosis	5.05±3.90	4.88±3.78	NS (0.426)
Diffuse score	1.05±0.71	1.15±0.71	0.002
Arteriolar hyalinosis score	1.22±0.55	1.40±0.59	0.020
Polar vasculosis	0.522±0.179	0.563±0.200	0.050
Nodular lesion	2.60±6.15	2.88±7.00	NS (0.186)
Duplication	14.7±10.1	16.0±8.8	NS (0.051)
Mesangiolysis	2.28±3.20	3.05±4.85	NS (0.240)
Exudative lesion	1.55±2.03	1.83±2.42	NS (0.409)

*: Wilcoxon signed-rank test

Figure



Conclusions: These results suggest that the glomeruli in the JM cortex may be more susceptible to specific renal histopathological lesions in diabetes than those in the SF cortex. The structural and/or functional differences, which are independent of age, renal function, and blood pressure, may have marked influence on the development of such lesions.

PUB278

Dialysis in Vancomycin Toxicity Jason M. Kidd, Andinet Gizaw, Todd W. Gehr. *Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ Medical Center, Richmond, VA.*

Background: Vancomycin is a glycopeptide antibiotic used to treat gram positive infections including MRSA. Therapeutic monitoring of serum levels is widely performed by clinicians with the expectation this will lead to improvement in treatment as well as minimize toxicity.Known adverse effects of include infusion related reactions as well as nephrotoxicity. Nephrotoxicity is more common in patients receiving other nephrotoxins or who have altered hemodynamics. The molecular weight of vancomycin is 1450 Da and it is 10-50% protein bound. We present a case utilizing high efficiency dialysis to remove vancomycin in a patient with oliguric renal failure due to vancomycin nephrotoxicity.

Methods: A 58 year old female with myelodysplastic syndrome was admitted with neutropenic fever. She was empirically treated with intravenous vancomycin 1 g every 12 hours for 4 days. Dose was then increased to 1250 mg every 8 hours for the next 5 days based on initial clearance data. The patient's serum creatinine was 0.4 mg/dl on the day of admission. On day 11, her serum creatinine had increased to 0.8 mg/dl. A vancomycing level was checked and was found to be 400 mg/l. She was oliguric. She had no eosiniophilia and urine sediment was bland. In the setting of her renal failure and toxic vancomycin level, dialysis was initiated.

Results: The patient was initially treated with high flux, F-180 dialyzer for an 8 hour treatment after which her vancomycin level decreased to 113 mg/l. The following day, she was dialyzed again for 4 hours and level was 61 mg/l. The next morning, her vancomycin level had increased to 81 mg/l, likely related to tissue rebound. Dialysis was repeated on this day for a 6 hour treatment and level the next morning was 42 mg/l. Her urine output subsequently increased and vancomycin level slowly decreased over the next several days without further dialysis sessions.

Conclusions: Hemodialysis with a high flux dialyzer removes significant amounts of vancomycin. Nephrotoxicity from vancomycin is generally self limited. This case illustrates a potential use of high flux hemodialysis in patients with severe toxicity.

PUB279

Safety and Efficacy of Citrate Anticoagulation for Continuous Renal Replacement Therapy for Acute Kidney Injury following Liver Transplantation: A Single Centre Experience Nicoletta Pertica, Paolo Ria, Gianluigi Zaza, Antonio Lupo. *Nephrology, AOUI, Verona, Italy; Nephrology, AOUI, Verona, Italy; Nephrology, AOUI, Verona, Italy; Nephrology, AOUI, Verona, Italy.*

Background: Acute kidney injury (AKI) following liver transplantation (LTx) is a frequent and serious complication with an high incidence of requiring continuous renal replacement therapy (CRRT). KDIGO guidelines indicate the use of citrate as loco-regional anticoagulant drug for CRRT regardless patient's hemorrhagic risk, however, the use of citrate is still under debate in patients with liver failure and/or LTx because of the potential risk of plasmatic citrate accumulation due to reduced liver clearance. Aim of the study wash to evaluate the safety and efficacy of citrate as locoregional anticoagulation drug in CRRT for AKI following LTx.

Methods: A retrospective analysis was performed in 5 patients with AKI post Ltd who were tremate in out transplant centre with CRRT using citrate as local anticoagulant. No patients with very high liver enzimes after LTx (more than double the normal range) were included. All the patients were treated with CVVHDF, using Trisodiumcitrate solution with a concentration of 18 mmol/l each bags.

Results: All the patients developed AKI during the early peri-operative corse. The main indication to CRRT was fluidi overload. No patients showed complications related to citrate accumulation. 4 patients were treated at the beginning with heparine as anticoagulant and then shifted to citrate caused by circuits coagulazione. Treatments with citrate was interrupted where it was no longer needed or when other examinations had to be made. None were stopped due to circuit coagulation.

HEPARIN						
	Total number of dialysis sessions	Sessions number	Heparin dose (U/h)	Protamine	Average time (Hours)	Number of session interrupted for clotting
Patient 1	7	3	750	YES	7	3
Patient 2	2	NO SESSIONS WITH HEPARINE				
Patient 3	22	16	500	YES	20,5	16
Patient 4	4	1	750	NO	22	1
Patient 5	3	4	750	YES	9,75	3
Median Value			550		14,8	

CITRATE						
	Total number of dialysis sessions	Sessions number	Citrate dose (U/h)	Metabolic complications	Average time (Hours)	Number of session interrupted for clotting
Patient 1	7	4	2,4	NO	24,5	0
Patient 2	2	2	2,4	NO	72	0
Patient 3	22	6	2,5	NO	55,3	0
Patient 4	4	4	2,5	NO	42,25	0
Patient 5	3	1	3	NO	48	0
Median Value			2,56		48.4	

Tab 2: CRRT data

Conclusions: Our result, even if in a small series of patents, evidence that CRRT with citrate can be a safe and promising treatment for AKI after Ltx.

PUB280

Administration of Iron Sucrose and Ferric Carboxymaltose during Hemodialysis (HD) Does Not Accelerate Lipid Peroxidation Jaromir Eiselt,[1] Daniel Rajdl,[2] Lukas Kielberger.[1] *[1]Internal Dept 1, Charles Univ, Plzen, Czech Republic; [2]Dept of Biochemistry, Charles Univ, Plzen, Czech Republic.*

Background: Intravenous iron (Fe_{iv}) may induce oxidative stress. Isoprostanes, specifically 8-iso-Prostaglandin $F_{2\alpha}$ (8-iso-$PGF_{2\alpha}$), represent a reliable biomarker of *in vivo* lipid peroxidation. We sought to determine whether administration of two Fe_{iv} formulations and a sham comparator affect the level of 8-iso-$PGF_{2\alpha}$ in HD patients.

Methods: A total of ten maintenance HD patients received intravenous infusion of a) 200 mg of iron sucrose in 100 mL of normal saline, b) 200 mg of ferric carboxymaltose in 100 mL of normal saline, c) 100 mL of normal saline without iron (sham comparator) from minute 60 to 90 of HD. Plasma levels of 8-iso-$PGF_{2\alpha}$ were assessed before infusion (minute 60 of HD), after infusion (min. 90), 1 hour after infusion, at the end of HD and before the next HD session using enzyme immunoassay.

Results: We did not detect significant changes in the level of 8-iso-$PGF_{2\alpha}$ after administration of two different Fe_{iv} agents. Moderate decrease of 8-iso-$PGF_{2\alpha}$ documented after infusion of the sham comparator could reflect an imbalance between elimination of the free fraction of 8-iso-$PGF_{2\alpha}$ without concomitant formation of this substance in the absence of Fe_{iv}. Results are presented in table 1.

Plasma 8-iso-prostaglandine $F_{2\alpha}$ (pg/L) before and after iron infusion during hemodialysis					
	Before Fe_{iv} infusion (min. 60 of HD)	End of Fe_{iv} infusion (min. 90 of HD)	1 h after Fe_{iv} (min. 150 of HD)	2.5 h after Fe_{iv} (min. 240 of HD)	46 h after Fe_{iv} (before next HD)
Iron sucrrose	27 (24-30)	33 (26-35)	31 (29-33)	24(23-27)	35 (24-38)
Ferric carboxymaltose	20 (17-28)	21 (18-25)	19 (18-22)	20 (18-23)	23 (20-25)
Isotonic saline (sham comparator)	22 (18-31)	18 (16-25) [a]	24 (17-30)	25 (19-31)	26 (21-29)
Data are expressed as median (interquartile range); Friedman test; [a] $p<0.05$ *vs.* min. 60, min. 240 and before next HD					

Conclusions: The study did not prove any acute effect of tested iron preparations on oxidative stress. Single infusion of iron sucrose or ferric carboxymaltose administered during hemodialysis does not cause measurable elevation of 8-iso-$PGF_{2\alpha}$.

PUB281

Impact of Comorbidities on Hemoglobin Stability in CKD Patients on Hemodialysis, Treated with C.E.R.A. in Current Practice: Is the Comorbidity Scoring Still Useful? The MIRIADE Study

Luc Frimat,[1] Philippe Zaoui,[2] Jean-Paul Jaulin,[3] Mustapha Amirou,[4] Gilles Sinnasse-Raymond,[5] David Pau,[5] Guy Rostoker.[6] *[1]Nephrology, Nancy Univ Hospital, Vandoeuvre, France; [2]Nephrology, A Michallon Hospital, Grenoble, France; [3]Nephrology, Les Oudairies Hospital, La Roche sur Yon, France; [4]Nephrology, Jacques Puel Hospital, Rodez, France; [5]Medical Dept, Roche, Boulogne Billancourt, France; [6]Claude Galien Private Hospital, Quincy sous Sénart, France.*

Background: The MIRIADE study assesses the real-life impact of comorbidities on hemoglobin (Hb) stability in patients (pts) with chronic kidney disease on hemodialysis (HD), treated with C.E.R.A., its use, and safety.

Methods: In this French prospective and multicenter cohort, a 6-month data collection was performed from C.E.R.A. initiation following erythropoietin stimulating agent (ESA) treatment, in HD pts with Hb level between 10 and 12 g/dL. Comorbidities were defined by the Charlson Index (CCI adjusted on age) and Hb stability as a variation of +/- 1g/dL after the 6-month treatment period.

Results: From the 585 pts included in efficacy analysis in 2014, 58% were men. The CCI distribution was as follows: CCI ≤3 (12% of pts), 4 ≤ CCI ≤5 (17%), 6 ≤ CCI ≤7 (31%) and CCI ≥8 (40%). At C.E.R.A. start, its median monthly dose was always under the theoretical conversion dose defined according to the previous ESA, and with a 100 µg/monthly dose over follow-up (little variation according to the CCI). Hb level was stable in 56% of pts (67% if CCI ≤3). Pts with stable Hb were more numerous to have Hb level between 10 and 12 g/dL at M6 (85% vs. 46% if non-stable Hb). Pts with inflammatory syndrome (CRP >5 mg/L, p=0.04), those having received more than 200 mg of IV iron (p=0.03), or those transfused prior to C.E.R.A. start (p=0.03) were less likely to reach stable Hb under C.E.R.A. at M6. Among the 644 C.E.R.A.-treated pts, 4 pts had one serious adverse event related to treatment.

Conclusions: In HD pts, a stable Hb level within the therapeutic target was observed in current practice with a lower C.E.R.A. dose, regardless of comorbidities scores.

Factors That Condition the Response to Erythropoietin in Patients on Hemodialysis

Natalino Salgado Filho,[1] Elton Jonh Freitas Santos,[2] Joyce S. Lages,[1] Gyl Barros-Silva,[1] Dyego José Araujo Brito,[1] Bernardete Jorge Leal Salgado,[1] Alcione Santos.[1] *[1]Federal Univ of Maranhão, São Luis, Brazil; [2]EBSERH - HUUFMA, São Luis, Brazil.*

Background: Anemia is an inevitable complication of hemodialysis patients, the main cause is erythropoietin deficiency. Several erythropoiesis-stimulating agents (ESAs) are available for treating anemia. However, part of the patients on hemodialysis remains anemic even using ESAs. This study was aimed at determining clinical-laboratorial factors associated with maintenance of hemoglobin levels < 10 g/dL in hemodialysis patients treated with recombinant human erythropoietin (EPO).

Methods: This was a prospective longitudinal analytical study that spread over a period of six months. Anemia was characterized as a hemoglobin level < 10 g/dL. A longitudinal logistic regression model with random effects was used to analyze the relationship clinical-laboratorial parameters with the anemia. To evaluate the dose-response effect of EPO therapy, we used the erythropoietin resistance index (ERI), calculated as the weekly weight-adjusted dose of EPO divided by the hemoglobin level.

Results: The prevalence of anemia in the study period ranged from 23.91% to 43.80%, in the adjusted analysis. The increase in the probability of anemia was negatively associated with age (**-0.016; p=0.039**) and the body mass index (**-0.057; p=0.032**). Positively with: the presence of hypertension (**1.040; p=0.019**), the ferritin (**0.318; p=0.005**), the erythropoietin resistance index (**0.184;p<0,001**) and the C-reactive protein (**0.270; p=0.002**).

Conclusions: We observed a high anemia prevalence and the factors associated were: age, nutritional status, hypertension, inflammation and recombinant human erythropoietin resistance.

PUB283

Utilization of Darbepoetin Alfa as an Erythropoiesis Stimulating Agent in Patients Receiving In-Center Hemodialysis

Mahmoud T. El-Khatib,[1,2] Heather Duncan,[1] Kotagal Shashi Kant.[1,2] *[1]Internal Medicine, Nephrology & Hypertension, Univ Cincinnati Coll Med, Cincinnati, OH; [2]Dialysis Clinic, Inc, Cincinnati, OH.*

Background: Previous studies have compared Epoetin alfa with Darbepoetin alfa and demonstrated equivalence in safety and efficacy for the treatment of anemia in chronic kidney disease. Other studies indicate that the cost of using Darbepoetin alfa is higher than Epoetin alfa. These studies have compared the two Erythropoiesis Stimulating Agents (ESAs) with intravenous (IV) administration of both drugs, but no subcutaneous (SC) route comparison is available. This study compares differences in hemoglobin and ESA dose, as well as IV iron dose and resulting iron stores after switching the entire dialysis unit from Epoetin alfa given SC to Darbepoetin alfa given IV.

Methods: Records for 78 patients who dialyzed in the same unit between January to April 2015 (Epoetin) as well as January to April 2016 (Darbepoetin) were reviewed for labs and medication administrations. To compare doses of these two drugs, a conversion of 3000 units of Epoetin to 10 mcg Darbepoetin was used to create ESA equivalent doses in mcg. Patients served as their own controls so that Paired t-tests could be used to analyze the differences.

Results: A statistically higher hemoglobin was found in the Darbepoetin period compared to the Epoetin period. Ferritin was lower in the Darbepoetin period, while T-sat and albumin were equivalent. ESA equivalent doses were lower with Darbepoetin, but more iron was used. While controlled by DCI algorithms, the number of ESA dose changes in the four month period was lower in the Darbepoetin period.

all data are the mean of 4 months	Hemoglobin (g/dL)	Ferritin (ng/mL)	T-Sat (%)	Albumin (g/dL)	IV Iron use (mg/month)	ESA dose (mcg/month)	total dose changes in 4 months
2015-Epoetin	11.20	1202.6	28.5	3.94	103.5	89.1	4.8
2016-Darbepoetin	11.39	1075.6	29.2	3.96	142.8	76.5	3.7
p	**0.02**	**0.015**	0.42	0.28	**0.005**	**0.03**	**.008**

Conclusions: Hemoglobin was higher and dose changes were less frequent when Darbepoetin was used and less ESA was needed to maintain hemoglobin levels. More iron was given with Darbepoetin, yet ferritin was lower.

PUB284

Differential Oxidative Stress and Endothelial Dysfunction Induction by Brand and Generic Sodium Ferric Gluconate Formulations

Amy Barton Pai,[1] Paul H. Neumann,[2] Teresa Marie Regis.[2] *[1]Univ of Michigan College of Pharmacy, Ann Arbor, MI; [2]Albany College of Pharmacy and Health Sciences, Albany, NY.*

Background: Intravenous iron products are colloidal nanoparticle suspensions making formulation of bioequivalent generics challenging. Differences in oxidative stress induction with generic iron sucrose outside the US compared to the reference listed drug (RLD) have been shown. There are no data comparing oxidative stress by the RLD Ferrlecit® and the only FDA approved generic, sodium ferric gluconate complex (SFGC).

Methods: Human umbilical vein endothelial cells were incubated with Ferrlecit® and SFGC in dose response (0 to 200 mcg/mL for 24 h) and time (0 to 24 h) studies. Induction of the transcription factor nuclear factor erythroid-2-related factor 2 (Nrf2), a master regulator of detoxification and heme-oxygenase 1 (HO-1) a Nrf2-regulated enzyme were determined in lysate by immunochemistry. Intracellular labile iron (ILI) was determined the Phen Green SK fluorescent probe. Endothelial cell monolayers were treated with each product at 50 µg/ml for 24 h and permeability was measured by the clearance rate of labeled albumin between the luminal and abluminal compartments.

Results: ILI significantly increased dose dependently with both formulations. Ferrlecit® treated cells had higher ILI at all studied doses except 50 µg/ml ($p<0.01$). Induction/stabilization of Nrf2 by Ferrlecit® was greater than SFGC at all doses, significancant at the 100 mcg/mL dose ($p<0.05$). Similarly, Ferrlecit®-induced upregulation of HO-1 was greater than SFGC at all doses, significantly at the 100 and 200µg/mL doses ($p<0.001$). At 50µg/ml, both compounds induced significant stabilization of Nrf2 by 3 to 6 hours ($p<.0001$). HO-1 increased with SFGC at 24 hours ($p<0.0001$) but was lower than Ferrlecit® ($p<0.0004$). Both IV iron formulations increased endothelial barrier permeability, which was significant for Ferrlecit® ($p<0.05$), compared to untreated controls.

Conclusions: The generic SFGC was associated with a lower oxidative stress response and endothelial permeability despite being a "bioequivalent" product. These differences may be due, in part, to different labile iron release profiles and requires further study.

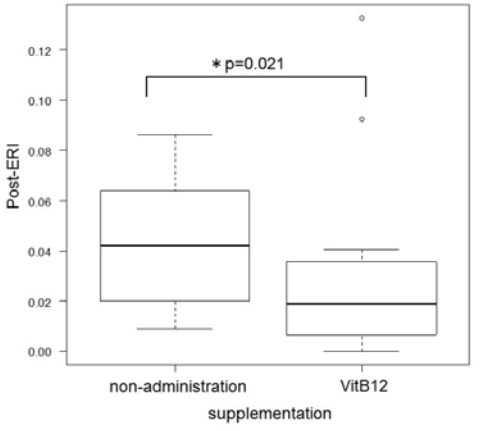
PUB285

Vitamin B12 Can Reduce Dose of Erythropoietin Even in Elderly Hemodialysis Patients Suspected for Potential Vitamin B12 Deficiency Shunichi Shibazaki, Katsuji Tuda, Kohei Miura, Makoto Araki. *Nephrology, Suwa Central Hospital, Chino, Nagano, Japan.*

Background: Potential vitamin B12 deficiency is often overlooked, even though it is a common nutritional deficiency in elderly hemodialysis patients because aging itself is a risk factor and dialysis removes vitamin B12. We attempted to evaluate whether a vitamin B12 supplement can reduce a dose of erythropoietin even with suspected potential vitamin B12 deficiency, which is diagnosed with homocystine and Vitamin B12 values.

Methods: A cohort study was conducted by collecting data from September 2015 to March 2016 at Suwa Central Hospital. Inclusion criteria were: outpatients in maintenance hemodialysis, over 65 years old, suspected potential vitamin B12; vitamin B12 < 400 pg per milliliter (lower limit of normal range), and homocysteine > 13.5 nmol per milliliter. We divided participants into two groups: a vitamin B12 supplementation group (injections of more than 500 µg per week) and a non-supplementation group. We evaluated the erythropoietin resistance index (ERI) between the two groups at the start and three months later. ERI was determined as the weekly weight-adjusted dose of darbepoetin (µg/kg/week) divided by hemoglobin concentration (g/dL).

Results: 24 patients were included. There was no difference in hemoglobin concentration, vitamin B12 concentration and frequency of iron deficiency at the start. There was also no difference in ERI; both groups were 0.04. Vitamin B12 concentration became higher in the supplementation group (> 1,500 pg per milliliter) than in the non-supplementation group (297 pg per milliliter) after three months. ERI improved in the supplementation group (0.02), but deteriorated in the non-supplementation group (0.05, p = 0.021) .



Conclusions: Vitamin B12 supplement can improve ERI and reduce dose of erythropoietin even in elderly hemodialysis patients with suspected potential vitamin B12 deficiency.

PUB286

Algorithm Based Erythropoiesis Stimulating Agents Dosing to Improve Anemia Management in a Pediatric Hemodialysis Population Shagun Berry,[1] Beth A. Vogt,[2] Robert J. Cunningham,[2] Tamar Y. Springel.[2] *[1]Dept of Biology, Case Western Reserve Univ, Cleveland, OH; [2]Dept of Pediatric Nephrology, Rainbow Babies Children's Hospital at Univ Hospitals, Cleveland, OH.*

Background: Dialysis providers attempt to maintain hemoglobin (Hgb) levels within a goal range. We set out to improve the number of patients meeting the Hgb target, which we set at 10-12 g/dL, with a computer-based algorithm for dosing of erythropoiesis stimulating agents (ESA) in a pediatric hemodialysis (HD) population.

Methods: Population: Chronic HD patients at our institution from 2013 until 2015. Algorithm: We utilized a Microsoft Excel based program that recommended an ESA dose based on the current and previous month's Hgb levels. Outcome: Our primary outcome was Hgb divided into three categories: <10, 10-12, and >12. Our secondary outcome was ESA dose in u/kg. Explanatory variables: We included race, age, Kt/V urea, intact PTH (iPTH), nPCR, percent iron saturation, and albumin. Statistic: Pre- and post-algorithm periods were compared. The association of the algorithm with Hgb category and ESA dose was tested by multinomial logistic regression and linear regression respectively. We adjusted for the explanatory variables.

Results: We had 17 patients, 7 pre- and 10 post-algorithm, with 55 Hgb values pre- and 94 post-algorithm. There were significant differences in age, iPTH, and albumin, however not in Hgb or ESA dose. The algorithm was associated with an increased risk of Hgb >12 (RRR=1.03, p=0.03).

Conclusions: This algorithm was not associated with improvement in Hgb 10-12 and was associated with an increased risk of Hgb >12. The increased risk was not associated with higher doses of ESA or higher iron saturation, which may indicate a more efficient ESA utilization. The retrospective nature and small size limit this study, however more at goal patients may result from adjustment of the algorithm.

PUB287

Intermittent Low Dose of Iron Supplementation Improves Erythropoietic Resistance Index and Reduces Hemoglobin Cycling in Chronic Hemodialysis Patients Tatsuo Tsukamoto, Motoko Yanagita. *Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan.*

Background: We have measured iron loss by iron contents of residual blood in the blood tubing set and dialyzer, and estimated that 500mg of iron would be lost by routine hemodialysis procedure in Japan (Am J Nephrol 2016,43,32-38). In this study, we show here the stable iron status as well as hemoglobin (Hb) level by an intermittent low dose of iron supplementation. Moreover, we demonstrate the improvement of erythropoietic resistance index (ERI) and the reduction of Hb cycling by the iron supplementary protocol in chronic hemodialysis patients.

Methods: 156 patients of Otowa Memorial Hospital were enrolled after informed consent. Men were consisted in 64.7%, and the mean age was 69.2±13.5 (m±SD). 40.4% was diabetic. 40mg of iron (saccharated ferric oxide) was administered once a month or every four weeks after hemodialysis session. Hb, TSAT (transferrin saturation), and ferritin were monitored every month before and after the intermittent iron supplementation. Erythropoiesis-stimulating agents (ESAs) used in this study were human recombinant erythropoietin (rHuEPO), darbepoetin-α (DA), and continuous erythropoietin receptor activator (CERA). DA was converted to 200U, and CERA was 240U of rHuEPO, respectively. ERI was calculated with rHuEPO dose in a month divided by Hb and body weight (dry weight). The dose of ESA was determined by an attending physician along the Japanese guideline for renal anemia in chronic kidney disease 2008.

Results: Hb levels kept from 11.2±1.0g/dL at the beginning to 10.9±1.0g/dL after 12 months. TSAT and ferritin did not change from 26.3±12.2% and 88.9±86ng/mL to 25.7±9.9% and 77.6±94.6ng/mL, respectively. ERI significantly reduced from 36.8±36.8 to 30.3±21.1. Hb cycling reduced from 123 times per 6 months before the supplement to 103 times after 6 months and 68 times after 1 year.

Conclusions: Intermittent iron supplementation (total 500mg a year) could improveERI and reduces Hb cycling with stable iron status in chronic hemodialysis patients.

Similar Anemic Control between Chronic Kidney Diseases Patients with and without Transplantation on Entry to Dialysis Ken Sakai,[1] Yasushi Ohashi,[3] Masaki Muramatsu,[1] Yoshihiro Itabashi,[1] Hiroki Hase,[2] Seiichirou Shishido.[1] *[1]Nephrology, Toho Unversity Ohmori Hospital, Tokyo, Japan; [2]Nephrology, Toho Unversity Ohashi Hospital, Tokyo, Japan; [3]Nephrology, Toho Unversity Sakura Hospital, Chiba, Japan.*

Background: Transplant recipients are supposed to be more anemic at re-entering hemodialysis due to chronic rejection. This study aimed to clarify how transplant recipients can re-enter dialysis safely by focusing on anemic control.

Methods: From 2012 to 2014, a total of 29 transplant recipients entered hemodialysis again by chronic rejection (Chronic Kidney Disease with Transplant: CKDT). At the same time, in 2014, a total of 30 CKD patients without transplantation entered dialysis as control group (CKD). CKDT recipients (age41.9±11.8yrs , m:f=18:10, diabetic 10%, duration of graft survival 12.5±4.3y) were younger and less diabetic compare to CKD (age53.2±10.5yrs , m:f=21:9, diabetic 36%). We analyzed both patient characteristics at entering dialysis by retrospective chart review.

Results: At entering dialysis, there was no significant differences for the dose of darbepoetin (DA:µg/month), Hb (g/dl), albumin(g/dl), CRP (mg/dl), CTR (%), eGFR (ml/min/1.73m^2), BUN (mg/dl), Cr (mg/dl) and initial ultrafiltration (UF: L/session) between CKD and CKDT. The only difference between groups was mean body weight (BW) at entry to dialysis (CKDT group, 58.5±15.1 kg; CKD group, 67.1±14.8 kg; P=0.03). However, DA dose per kilogram of BW did not differ between groups (CKDT, 2.28±2.03 µg/kg; CKD, 2.12±1.6 µg/kg; P=0.95) in the final month before entry to dialysis.

Conclusions: Safely re-initiation of dialysis is also important for recipients survival. Anemia was supposed to be higher in transplant recipients by immunosuppression, this single center analysis did not show any difference of anemia compare to CKD with well using ESA.

PUB289

MicroRNA 499 Gene Expression in Patients on Hemodialysis with Cardiovascular Complications Magdy M. Elsharkawy, Amr Mohab, Haitham Ezzat, Hesham Elsayed. *Nephrology Dept, Ain Shams Univ, Cairo, Egypt.*

Background: MicroRNA 499 is an evolutionarily conserved muscle-specific microRNA that is encoded by an intron of the myh7 gene and is likely to play a role in myosin gene regulation. It has been shown to be involved in inhibiting apoptosis and myocardial infarction. It is unknown whether levels of microRNAs are affected in patients undergoing hemodialysis.

Methods: The aim of this study was to assess circulating levels of microRNA 499 in hemodialysis patients and whether the levels are affected by dialyzer membranes (high flux vs low flux). The studied population consisted of 32 ESRD patients (22 males and 10 females) with an age ranged from 38-75 years on regular hemodialysis (4 hours, 3 times weekly) for at least one year duration with cardiovascular events in the last 6 months and 32 healthy controls (20 males and 12 females) with an age range from 54-60 years. Patients

were involved into a two-stage sequential study; high flux hemodialysis stage (stage I), then low flux hemodialysis stage (stage II). Expressed levels of plasma microRNA 499 have been measured by Real Time-PCR.

Results: Statistically significant higher levels of circulating microRNA 499 were observed in all the studied patients compared to the levels found in healthy controls ($p<0.0001$). MicroRNA 499 was found to be a dialyzable marker. A significant decrease in plasma levels of microRNA 499 was obtained after either high flux or low flux dialysis compared to plasma levels of microRNA 499 found before dialysis ($p<0.0001$). On comparing both types of hemodialysis membranes with respect to microRNA 499 clearance, we found that low flux membrane showed better clearance for microRNA 499 than high flux membrane with a statistically significant difference between them ($p<0.001$).

Conclusions: In conclusion microRNA 499 levels are elevated in patients with ESRD with cardiovascular complications. High flux membrane seems to be less efficient in microRNA 499 clearance in cardiac patients on hemodialysis.

PUB290

Lower Limb Vascular Disease in Patients on Chronic Hemodialysis Treatment Lene Boesby,[1] Julie Broesen,[1] Pernille Moerk Hansen.[2] *[1]Dept of Cardiology-Nephrology-Endocrinology, Hilleroed Hospital, Hilleroed, Denmark; [2]Dept of Nephrology, Herlev Hospital, Herlev, Denmark.*

Background: Patiens receiving chronic hemodialysis (HD) treatment have an elevated risk of developing vascular disease. The primary aim of this study was to evaluate the cause and frequency of lower limb arteriel ischaemia leading to surgical interventions, in a well characterized center-HD population. The secondary aim was to evaluate whether having diabetes mellitus (DM) influenced the result.

Methods: This is a single center retrospective study covering a 4-year period from 6.1.2008 - 6.1.2012. Combining registration codes for lower extremity amputation (digital, metatarsal, crus and femoral amputation (LEA)) and HD, patients were indentified and included in the study. Further data were registered from electronic patient files. Patients were excluded from the study if HD treatment was started < 3 months prior to LEA.

Results: We registered 180 HD-patients per year. 18 patients had ≥1 LEA during the investigation period, 8 (44%) of these patients had DM. There were no significant differences between gender, age, systolic or diastolic blood pressure, previous cardiovascular events, HD vintage or mineral metabolic control comparing LEA-patients with or without diabetes. In the group af patients with DM one was smoking at the time of LEA compared to four in the non-DM group. The number of re-amputations and patients who died within six months after LEA was higher in non-DM patients. Of the non-DM patients 63% had no previous record of consultations with chiropodist, orthopedic or vascular surgeon prior to LEA, whereas all of the DM patients had.

	non-DM (n=10)	DM (n=8)
Profylactic intervention	3	8
Re-LEA	4	2
Death < 6 months after LEA	8	5

Conclusions: In our population more than half of the patients who underwent LEA did not have DM. Only 37% of these patients have had an evaluation by chiropodist, orthopedic or vascular cunsultation prior to LEA, despite long HD vintage. To further explore these results a nationwide study is planned.

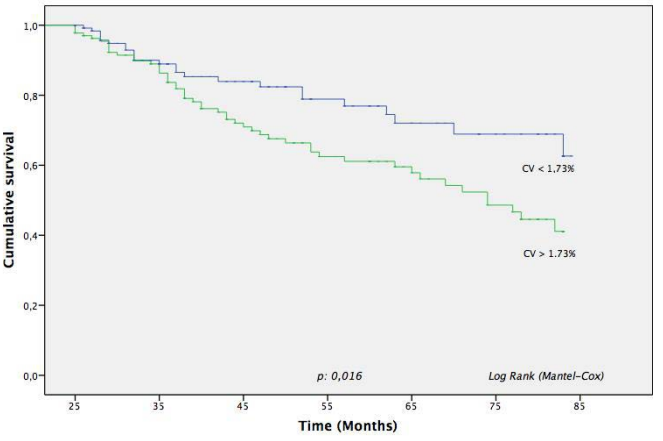
PUB291

Sodium Variability and Survival in Hemodialysis Patients Eduardo Baamonde, Nicanor Vega-Diaz, Elena Oliva-Damaso, Patricia Pérez Borges, Jose C. Rodriguez-Perez. *Nephrology, Hospital General Univ de Gran Canaria Dr. Negrin, Las Palmas, Spain.*

Background: The concentration of serum sodium (SNa^{+}) prehemodialisis (pre-HD) not always responds to the classic "set point" pattern. Recent evidence has shown that, variability of key laboratory parameters such as hemoglobin are also associated with important outcomes such as survival in HD patients Aims: we investigate the relationship between SNa^{+} preHD variability and survival in a population of HD patients.

Methods: Retrospective analysis of 261 prevalent HD patients (60.9% male; 51.7% diabetics; mean age 60.04 ± 14.09 years, time in HD: 69.64 ± 50.53 months; follow-up time: 48.78 ± 19.09 months). SNa^{+} concentration was corrected for glucose concentration. The first 24 SNa^{+} monthly measures were used for the study. SNa^{+} variability was calculated by the SD and coefficient of variation (CV).Crude mortality rates were computed. Kaplan-Meier, Log rank test and Cox regression were used to analyze the survival rate.

Results: 6221 determinations of SNa+ were analyzed. The average concentration of SNa^{+} was: 138,26 mEq/L (range: 151,65-120,86 mEq/L).The median of SNa^{+} SD and CV was 2,37 mEq/L and 1,73% respectively. The survival rate in the low CV group was significantly higher than in the other group.



Sodium variability low (blue) vs high (green)

This finding was corroborated in the adjusted Cox regression.

	Hazard Ratio	95% CI	p value
Age (years)	1,03	1,01 to 1,05	,020
KT/V	0,10	0,01 to 0,33	,000
IDGW (%)	0,43	0,24 to 0,76	,004
Albumin (g/dL)	0,11	0,01 to 0,31	,000
SNa^{+}CV (%)	0,57	0,35 to 0,94	,028
UF rate (ml/Kg/mn)	1,20	1,01 to 1,43	,044
Gender	0,67	0,39 to 1,12	,129
Diabetes	0,65	0,39 to 1,09	,103

Conclusions: Patiens with highest SNa^{+} variability show reduced survival compared with those with SNa^{+}lower variability. The relationship persisted after adjustment for potential confounders.

PUB292

Aldosterone Levels Elevated in Dialysis Patients: Are We Underused Blockers Renin Angiotensin-Aldosterone System? Ramiro Callejas,[1] Manuel M. Heras,[1] Carmen Rita Martin Varas,[1] Leonardo Calle,[1] Alvaro Molina,[1] Maria Astrid Rodriguez Gomez,[1] Olaia Rodriguez Fraga,[2] Vanesa Lopes-Martin,[1] Maria Jose Fernandez Reyes.[1] *[1]Dept of Nephrology, General Hospital Segovia, Segovia, Castilla y Leon, Spain; [2]Dept of Clinical Analysis, Univ Hospital La Paz, Madrid, Spain.*

Background: Serum aldosterone system (AS) is a marker of cardiovascular (CV) risk in the general population. **Objective:** To analyze AS levels in dialysis patients and its relationship with characteristics of dialysis; comorbidity ; blood pressure and use of blocking the renin angiotensin aldosterone system (BSRAA).

Methods: We determined AS in 102 patients (81 hemodialysis and 21 peritoneal dialysis); mean age 71.4 ± 12 years; 54.9% male; 29.4% diabetics; time on dialysis 59.3 ± 67meses. In 44 hemodialysis patients plasma renin (RP) was measured.

Results: The mean was 72.6 ± AS 114.9 ng / dl (vn 1.17-23.6 ng / dl). 57.8% of patients had levels above normal which were not related to dialysis characteristics or comorbidity. Twenty five treated with BSRAA had significantly lower levels of AS. Only 21% of patients with heart failure and and 19.2% with ischemic heart disease used BSRAA. There is an inverse correlation between AS and systolic blood pressure (BP) and direct with RP. The logistic regression analysis to see associated factors with AS levels above the median, systolic BP was the only independent risk variable in the overall population (OR 0.97; p = 0.022); in the 44 patients in whom RP was determined this was the only independent risk factor (OR 2.24; p = 0.012).

Conclusions: A high percentage of dialysis patients have elevated levels of AS that are not related to characteristics of dialysis and if with decreased systolic and activation of the RAAS. In patients with a history of heart disease the BSRAA are underused.

PUB293

Dual Control of Blood Pressure and Hemodynamics in Hemodialysis Patients Dan Sapoznikov, Michal Dranitzki Elhalel, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.*

Background: Systolic blood pressure (SBP) is dually controlled by baroreflex (BARO) and non-baroreflex (NON-BARO) sympathetically mediated central mechanisms.

Methods: To assess the relative contribution of these mechanisms during hemodialysis (HD), beat-to-beat SBP and interbeat interval (IBI) monitoring using Finometer device was performed during a 4 hr regular stable HD session in 49 non-diabetic patients (Pt), age 52±15 y. Cardiac output (CO), stroke volume (SV) and total peripheral resistance (TPR)

were calculated using the Modelflow simulation method. BARO and NON-BARO activity episodes were evaluated by two regression coefficients: 1. Calculation of the slope of the regression line between IBI and SBP in 1 min sequences; a positive regression coefficient was considered to be representative of BARO activity, and 2. A positive correlation between power spectrum of SBP in the low frequency range and SBP was considered to represent NON-BARO sympathetic activity. LFα coefficient, a measure of BARO function was calculated as the square root of the ratio between average IBI power and average SBP power in the low frequency band (0.04-0.15 Hz).

Results: The averaged variables for the 1st and the 4th HD hr (median and interquartile range) are shown in Table 1.

	HD 1st hr	HD 4th hr	p
SBP (mmHg)	132 (27)	132 (31)	NS
IBI (ms)	811 (170)	800 (190)	NS
% BARO episodes	35 (31)	43 (48)	0.006
% NON-BARO episodes	47 (60)	41 (50)	NS
CO (L/min)	6.94 (2.13)	5.68 (2.21)	0.001
SV(ml)	89 (26)	76 (36)	0.001
TPR (mmHg.s/ml)	0.863 (0.936)	0.998 (0.410)	0.001

During HD LFα increased from 3.73 (2.24) in the 1st to 3.98 (2.90) the last hr (p=0.013).

Conclusions: Our data show :1.During a stable HD session, the maintenance of constant SBP is achieved by a transition from centrally mediated sympathetic activity to activation of the baroreflex. 2.The decrease in CO and SV during ultafiltration is compensated by an increase in TPR.The interaction between BARO and NON-BARO mechanisms seems to be critical for intradialytic hemodynamic stability and prevention of hypotensive episodes.

PUB294

Percutaneous Perfusion Monitoring Provides Accurate and Timely Detection of Hemodialysis Induced Multi-Organ Injury

Claire J. Grant,[1] Anne M. Brumfield,[2] Marcus Mianulli,[2] Lori L. Poole,[2] Christopher W. McIntyre.[1]
[1]The Kidney Clinical Research Unit, The Univ of Western Ontario, London, ON, Canada; [2]Intelomed Inc., Wexford, PA.

Background: The safe delivery of hemodialysis (HD) faces dual challenges: (1) the accurate detection of systemic circulatory stress producing cardiovascular (CV) injury and (2) doing so within a time frame sufficient to enable effective proactive intervention. Non-invasive, real-time monitoring of CV stability is now available. We performed a pilot study to directly examine the capability of such technology to detect deleterious effects of HD upon two crucial vulnerable vascular beds (heart, kidney), using advanced multi-modal imaging.

Methods: 8 patients were repeatedly evaluated during HD with cardiac (echocardiography) and renal perfusion imaging (256-slice CT). Continuous CV physiologic monitoring was performed throughout using oximeter-based pulse waveform analysis [CVInsight® Monitoring System (CVI), Intelomed]. Longitudinal strain (LS) values for 12 left ventricular segments were generated using speckle-tracking software [EchoPac, GE], to assess the presence of HD-induced myocardial stunning. Renal perfusion was evaluated for the entire kidney.

Results: A reduction in pulse strength (PS) of >40% detected by CVI was associated with renal and cardiac ischemic challenge. This reduction occurred in 6/8 patients, all of whom exhibited myocardial stunning and a significant reduction in renal perfusion (p=0.04). The remaining 2 patients tolerated HD with maintained renal perfusion, no evidence of myocardial stunning or reduction in PS. The decrease in PS began early during HD (median 12 min, range 2-23 min). Earlier onset was associated with increased evidence of HD-induced multi-organ injury, with respect to both the degree of myocardial stunning (r=0.80, p=0.02) and fall in renal perfusion (r=0.78, p=0.04).

Conclusions: CVInsight® appears useful to identify patients vulnerable to circulatory stress during HD. Detection of the propensity for organ injury occurs early in HD and may potentially enable timely and pre-emptive intervention to prevent previously undetected recurrent insults to both residual renal function and the heart.

PUB295

Erythrocyte Sodium Sensitivity (ESS) Is Significantly Elevated in Hemodialysis Patients

Viktoriya Kuntsevich,[1] Anna Meyring-Wosten,[2] Chiarra Marie Ornillo,[1] Israel Campos,[2] Jie Ma,[2] Samir D. Patel,[2] Schantel Williams,[2] Stephan Thijssen,[2] Nikolas B. Harbord,[1] Peter Kotanko,[2] James F. Winchester.[1]
[1]MSBI, NY, NY; [2]RRI, NY, NY.

Background: Hemodialysis (HD) patients exhibit elevated vascular dysfunction compared to the general population. Disturbances in the endothelial glycocalyx, which selectively buffers sodium, can damage the erythrocyte glycocalyx and lead to elevated ESS. ESS, which can be estimated by a novel "salt blood test" (SBT), reflects glycocalyx damage of both the vascular wall and the erythrocyte (RBC) surface. In parallel, senescent and damaged RBCs lose membrane asymmetry with exposure of phosphatidylserine (PS) on the outer surface, which is an early sign of suicidal erythrocyte death (eryptosis) and is related to RBC life span. We explored the distribution of ESS and levels of eryptosis in HD patients compared to healthy subjects (HS).

Methods: Blood samples were collected from chronic HD patients before mid-week treatment and from HS. ESS was measured by SBT [Oberleithner and Wilhelmi, Pflugers Arch 2013] in triplicates. Percentage of reticulocytes and eryptotic RBC with elevated PS exposure were assessed by BD FACSCalibur™ with RETIC-Count™ (BD Biosciences, USA) and Annexin-V-Fluos (ROCHE, Germany) respectively, and used for calculation of absolute eryptotic RBC (A-ERYPTO-RBC) and absolute reticulocyte count (A-RETIC) from absolute RBC count.Two-tailed homoscedastic TTEST was used to explore associations between parameters (P<0.05). Data is presented as M±SD.

Results: We analyzed data from 20 HD patients (age 28-76 years, 11 males, 11 white, 10 diabetic) and 11 HS (age 30-71 years, 5 males, 9 white). SBT was significantly higher in HD compared to HS group (3.93±1.5 vs 1.95±0.51). While A-RETIC was significantly lower in HD group (4.95±1.76 vs 7.06±1.59 $x10^4$ cells/µL), there was no difference in A-ERYPTO-RBC between HD and HS (2.26±1.58 vs 2.35±1.38 $x10^4$ cells/µL).

Conclusions: Higher levels of ESS in HD patients reflect disturbed endothelial glycocalyx and might be related to increased vascular damage in this population. Difference between the groups in absolute reticulocyte count but not in eryptotic RBCs likely indicates higher turnover of RBC in HD population.

PUB296

Brain Natriuretic Peptide as a Sensitive Cardiac Biomarker for Hypervolemia in Hemodialysis Patients

Amr Mohab, Aber Baki, Chery Reda, Islam Ismael. *Nephrology Dept, Ain Shams Univ.*

Background: Evaluation of volume status is sometimes a clinical dilemma in hemodialysis (HD) patients. BNP is an important biomarker in patients with CKD.

Methods: We enrolled 40 ESRD patients older than 20 years, on regular HD 3 times weekly with duration of HD more than 12 months. Inclusion criteria for patients: 1) Ejection fraction> 55%, LV end systolic (2-4 cm) and diastolic (3.7-5.5 cm) internal dimensions on ECHO. 2) Patients with mild LVH; intraventricular wall thickness in diastole < 1.3 cm. 3) Hypertensive patients with or without antihypertensive medications. Exclusion criteria: Patients with volume or pressure overload due to other causes than fluid overload (ex. anemia, heart failure, valvular lesions). In addition to full history taking and thorough clinical and cardiac examination, lab. investigations were done including CBC, renal and liver functions, with serum BNP samples collected post dialysis. Radiological studies done included: Echo, IVC collapsibility index for assessment of volume status.

Results: Our results showed no statistical substantial differences between hyper and normovolemic patients concerning patients' characteristics as gender, smoking, and presence of DM or hypertension. Moreover, no significant association was existing between BNP levels and patients' characteristics (ex: age and sex) or lab results (ex: creatinine, Ca, HgB), however, there was an inverse relationship between BNP and IVC collapsibility index (mean was 29.248 %). In addition, patients with hypervolemia had significantly higher BNP levels, as compared to euvolemic ones, with a significant difference (p value = 0.011) and the most pertinent level of BNP was (17.650 pg/ml) to discriminate hyper/normovolemic patients, with a sensitivity of 71%, and a specificity of 77.8%.

Conclusions: our study would appear to provide an evidence that plasma BNP levels were correlated to the degree of fluid retention in HD patients indicating that elevated levels may possibly be regarded as a marker of volume overload in absence of other causes and even before being clinically evident.

PUB297

The Study of Death Risk Factor and Survival among Maintenance Hemodialysis Patients

Ming Li,[1] Zengchun Ye,[1] Huiqing Chen,[2] Wenbo Zhao,[1] Tanqi Lou.[1]
[1]Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sun Univ, Guangzhou, Guangdong, China; [2]Div of Pediatrics, The First Affiliated Hospital of Sun Yat-sun Univ, Guangzhou, Guangdong, China.

Background: To identify the cause and the risk factors associated with death and evaluate the survival among maintenance hemodialysis(MHD) patients.

Methods: All of the patients undergoing maintenance hemodialysis in the dialysis center of the 3rdAffiliated Hospital of Sun Yat-sen University for at least 3 months from Jan 1st, 2013 to Dec 31st, 2015 were analyzed. The baseline variables and laboratory results were collected,death and survival were recorded. Logistic regression and multivariate COX regression were used to detect the relative factors.

Results: A total of 183 patients were included in the study.The mean age was 58.21±16.45.Male 113,female 70. Death were recorded in 36 cases after average 32months followed.The main cause of death were cardiovascular disease (33.3%), infectious disease(25%), cerebro-vasculardisease(13.9%),potassemia(11.1%), tumor(5.6%). Logistic regression showed that age (HR=1.068,95%CI:1.026-1.113), HBP(HR=3.660, 95%CI:1.187-11.286),hypoproteinemia (HR=0.886, 95% CI:0.788-0.994), acidosis (HR=0.816, 95% CI: 0.687-0.969) , hyperuricemia(HR=0.996, 95% CI: 0.992-0.999) were risk factors for death. The average survival time in death cases were 47.8months after hemodialysis.Cox proportional hazards regression model showed that age(HR=1.033, 95%CI:1.000-1.066), acidosis (HR=0.863, 95% CI:0.760-0.979), hyperuricemia(HR=0.997, 95% CI: 0.994-1.000)were risk factors for death.

Conclusions: To maintenance hemodialysis patients,the main cause of death were cardiovascular or cerebrovascular disease and infection.Age, hypoproteinemia, acidosis, hyperuricemia are risk factors for death.

PUB298

Serum Nitric Oxide and Natriuretic Peptides Have a Relationship with Whole Blood Viscosity in End-Stage Renal Disease Undergoing Hemodialysis

Jong-Hwan Jung,[1] Kyung Pyo Kang,[2] Sung Kwang Park,[2] Young I. Cho,[3] Won Kim.[2] *[1]Dept of Internal Medicine, Wonkwang Univ Hospital, Iksan, Jeonlabukdo, Korea; [2]Dept of Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Jeonlabukdo, Korea; [3]Mechanical Engineering and Mechanics, Drexel Univ, PA.*

Background: A change of whole blood viscosity (WBV) may increase risk of major atherosclerotic events. NO regulates the renal function through the modulation of the vascular tone. WBV related with vascular shear stress may be linked to production of NO. WBV is also associated with volume status during hemodialysis. Atrial natriuretic peptide (ANP) and B type natriuretic peptide (BNP) may be linked to WBV because they can be indicators of blood volume. This study was planned to investigate correlation between WBV at several shear rates during hemodialysis and serum levels of NO, ANP, and BNP in ESRD patients.

Methods: This study included 31 end-stage renal disease patients who were enrolled. We measured WBV using a scanning capillary tube viscometer pre- and post- dialysis to quantify viscosity. Serum NO, ANP, and BNP level before hemodialysis was assayed using an ELISA method.

Results: The mean WBV variations at shear rates of 1, 5 and 300 s^{-1} for pre-dialysis were 168.5±62.5, 76.9±20.6, and 33.3±3.8 mP, respectively. The mean values of post-dialysis WBV obtained at a shear rate of 1, 5 and 300 s^{-1} were 240.4±84.4, 100.8±28.0, and 38.5±6.4 mP, respectively. Mean serum levels of NO, ANP, and BNP were 13.97±10.34 µg, 198.85± 61.56 pg/mL, and 1233.32± 280.81 pg/mL. Serum NO levels was positively correlated with WBV at a shear rate of 1, 5 and 300 s^{-1} at pre-dialysis. (p=0.09, p=0.015, and p=0.010, respectively). There was also statistical significance at post-dialysis. Serum ANP levels were negatively correlated with WBV at a shear rate of 1, 5 and 300 s^{-1} at only pre-dialysis (p=0.014, p=0.008, and p=0.009, respectively). However, BNP levels did not show any correlation with WBV.

Conclusions: Correlation between serum NO, ANP levels and WBV may indicate an important role of endothelial dysfunction in ESRD patients. However, whether monitoring of ANP, BNP, and NO has a relationship with WBV requires further controlled study.

PUB299

Reactive Hyperemia Index and Its Clinical Correlates in Dialysis Patients

Wenjin Liu, Meijuan Meng, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Reactive hyperemia index (RHI), as a reflection of endothelial function, has been suggested to be an independent predictor of adverse outcome both in the general population and patients with chronic kidney disease. However, its value in risk stratification in patients on maintenance hemodialysis remains inexplicit.

Methods: This is a cross-sectional analysis of midterm baseline data from a cohort study. Two-hundred and fifty six dialysis patients from four tertiary hospitals in East China were recruited.Reactive hyperemia index was measured by peripheral arterial tonometry (EndoPAT 2000) on a midweek nondialysis day. Blood pressure level was determined by ambulatory blood pressure monitoring. Demographic and clinical information, as well as routine laboratory results were also recorded. Stepwise linear regression analysis was used to determine independent clinical correlators with natural logarithm of RHI (LnRHI).

Results: Among the 258 patients, peripheral arterial tonometry results were available for 218 patients. Average value of LnRHI was 0.57±0.31. In univariate correlation analysis, systolic blood pressure, diastolic blood pressure and heart rate were positively correlated with LnRHI, while age and body mass index (BMI) were inversely related to LnRHI. Stepwise linear regression analysis results demonstrated that systolic blood pressure (ß=0.004, $p<0.001$) and age (ß=-0.004, $p=0.015$) were independently correlates of LnRHI.

Conclusions: Our results indicate that reactive hyperemia index was affected by blood pressure and age in patients on maintenance hemodialysis. The prognostic value of RHI remains to be explored by follow up of this study population.

Do Patients in Chronic Hemodialysis Have Another Atherogenic Phenotype

Magdalena Dusejovska,[1,2] Barbora Stanková,[2] Marek Vecka,[2] Jana Rychlíková,[2] Lucie Vávrová,[2] Magdaléna Mokrejsová,[3] Ales Zak,[2] Ivan Rychlik.[1,3] *[1]Dialysis Unit, Fresenius Medical Care, Prague, Czech Republic; [2]4th Dept of Internal Medicine, 1st Faculty of Medicine Charles Univ and General Teaching Hospital, Prague, Czech Republic; [3]3rd Faculty of Medicine Charles Univ, Prague, Czech Republic.*

Background: High cardiovascular morbidity and mortality is observed in patients (PTS) with end-stage renal disease (ESRD). Dialysis patients revealed nearly 20 times higher the risk of dying from cardiovascular disease in comparison with the general population. There is growing evidence that dysregulation of lipid metabolism is connected with CKD. The research is now focused on the lipoprotein classes and subclasses and on the possible role of small dense LDL and small HDL particles in the atherogenesis. The aim of our study was to examine differences in individual lipoprotein classes and subclasses between chronic high volume hemodiafiltration (HD HDF) PTS and healthy volunteers (CON).

Methods: 60 PTS on HD HDF for at least 12 months and 60 CON were included into the study. PTS and CON were age-matched. Individual lipoprotein classes and subclasses (resp.) were analysed by Quantimetrix Lipoprint (TM) System using Lipoprint LDL and HDL subfractions Kit and Lipoware software.

Results: PTS differed from CON by decreased levels of total-, LDL-, and HDL-cholesterol (all P<0.001) that was connected with increased triacylglycerol concentration (P<0.001). Decreased HDL-C level in PTS were connected with fall of intermediate and small HDL levels (both P<0.001). PTS had increased VLDL levels (P<0.01) that was associated with opposite changes in concentration of large (P<0.001) as well as small dense LDL (P< 0.05).

Conclusions: The results of the study showed different atherogenic phenotype of HD HDF PTS and implicated delayed VLDL/LDL catabolism and remodelling connected with changes in HDL homeostasis that warrant further research. *The study was supported by research from the Ministry of Health of the Czech Republic (project RVO-VFN64165/2012), and the Ministry of Education, Youth and Sports of the Czech Republic (research project PRVOUK-P25/LF1/2 of Charles University in Prague, the 1st Faculty of Medicine).*

Comparison of 3D Echocardiographic and Cardiac MRI Measurements of Left Ventricular Structure and Function in Hemodialysis Patients

Daniel Scott March,[1,2] Matthew P.M. Graham-Brown,[2] Anna-Marie Marsh,[3] John Mcadam,[3] Gerry Patrick Mccann,[3] James Burton.[1,2,3] *[1]Dept of Infection Immunity and Inflammation, Univ of Leicester, Leicester, Leicestershire, United Kingdom; [2]John Walls Renal Unit, Univ Hospitals Leicester, Leicester, Leicestershire, United Kingdom; [3]Dept of Cardiovascular Sciences, and NIHR Leicester Cardiovascular Biomedical Research Unit, Univ of Leicester, Leicester, Leicestershire, United Kingdom.*

Background: This study compared left ventricular (LV) end diastolic volume (LVEDV), LV end systolic volume (LVESV), LV diastolic mass (LVDM) and ejection fraction (EF) in hemodialysis (HD) patients using transthoracic 3D echocardiography (3DE) and cardiac MRI (CMR).

Methods: 3DE and CMR (3 Tesla) scans were performed on 25 prevalent HD patients. CMR LV volumetric and mass analysis was undertaken using the software package CMR[42]. 3DE apical four chamber full volume 3DE images (iE33, Philips) were obtained and analysed with vendor specific software. Dependent sample t-tests were performed to compare LV volumes, mass and EF by 3DE and CMR. Pearson's correlation coefficient was performed to assess correlations between variables (LVEDV, LVESV, LVDM and EF) from 3DE and CMR. Statistical significance was accepted at $P < 0.05$ level.

Results: Eight patients were excluded from the analysis due to poor image quality from the 3DE. LVEDV (189.58 mL ± 60.88 mL versus 91.42 mL ± 25.86 mL, $P<0.001$) and LVESV (94.37 mL ± 39.60 mL versus 39.50 mL ± 12.93 mL, $P<0.001$) were significantly higher for CMR compared to 3DE. There was no significant correlation between LVEDV (r=0.479, $P=0.052$) for CMR and 3DE. There was a significant correlation between LVESV (r=0.743, $P=0.001$) for CMR and 3DE. LVDM (108.05 g ± 35.31 g versus 163.48 g ± 35.32 g, $P<0.001$) and EF (51.30% ± 6.72% versus 56.45% ± 8.63%, $P=0.011$) were significantly lower for CMR compared to 3DE. Both LVDM (r=0.735, $P=0.001$), and EF (r=0.559, $P=0.020$) significantly correlated between CMR and 3DE.

Conclusions: This study suggests 3DE underestimates LVEDV and LVESV compared to CMR. While LVDM is overestimated by 3DE compared to CMR. EF was comparable when measured by both imaging tools.

PUB302

Coronary Artery Calcification Score (CACS) and Cardiovascular Events in Maintenance Hemodialysis Patients

Yoshiko Nishizawa,[1] Sonoo Mizuiri,[1] Kyoka Ono,[1] Mariko Asai,[1] Kenichiro Shigemoto,[1] Takao Masaki.[5] *[1]Div of Nephrology, Ichiyokai Harada Hospital, Hiroshima, Saeki-ku, Japan; [4]Nephrology, Hiroshima Univ Hospital, Hiroshima, Minami-ku, Japan.*

Background: Coronary artery calcification is known as a frequent complication in patients with chronic renal failure and contributes to their excess death with cardiovascular events. We examined the relationship between the coronary artery calcification score (CACS) and cardiovascular events in maintenance hemodialysis patients .

Methods: A retrospective study was conducted on 322 patients who received maintenance hemodialysis within 5 years between2011 and 2015. The Agatoston's CACS>400, age, sex, dialysis vintage, presence of diabetes mellitus (DM), history of smoking, hemoglobin, serum creatinine(Cr), uric acid, phosphate, intact parathyroid hormone(iPTH), total cholesterol (T-CHO), CRP, β2-microglobulin (β2MG), albumin-adjusted serum calcium (Ca), geriatric nutritional risk index (GNRI) and PCR were used as independent variable. Risk factors related to cardiovascular events were assessed by univariate and multivariate logistic regression analysis using the above variables. Risk factors related to CACS >400H and serum β2MG >30mg/l were also evaluated.

Results: CACS(2378±2228 vs 1307±1938H, P<0.01), DM (77 vs 69%, P<0.01), β2MG(28±9 vs 25±8mg/l, P<0.05) were significantly higher in patients who had cardiovascular events than patients who did not, While iPTH and CRP were significantly lower (P<0.01). DM (OR 0.34, 95% CI 0.15-0.72, P<0.01), CACS >400 (OR 0.32, 95% CI 0.12-0.72, P<0.05), and β2MG (OR 0.96, 95% CI 0.92-1.00, P<0.05) were detected as cardiovascular events-associated factors. Age (OR 0.95, 95% CI 0.92-0.97, P<0.01), DM (OR 0.30, 95% CI 0.18-0.50, P<0.01) were detected as CACS >400 -associated

factors. Dialysis vintage (OR 0.97, 95% CI 0.96-0.99, P<0.01), Cr(OR 0.80, 95% CI 0.73-0.88, P<0.01) and iPTH (OR 1.00, 95% CI 1.00-1.01, P<0.01) were related to serum β2MG>30mg/l.

Conclusions: DM, CACS >400, and high β2MG levels were risk factors for cardiovascular events in the patients who received maintenance hemodialysis within 5 years.

PUB303

The Relationship between Arterial Stiffness and Brain Small Vessel Disease in Dialysis Patients Ke Zheng,[1] Xuemei Li.[2] *[1]Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Dialysis patients have high prevalence of cardiac and cerebral vascular diseases .Our previous study showed the prevalence of brain small vessel diseases (SVDs) increased significantly. The mechanisms of this phenomenon was still unknown. Arterial stiffness has close relationship with cardiac vascular diseases. PWV can reflect the degree of arterial stiffness, and it was considered to be a prediction index of cardiac events. Whether abnormal PWV will have impact on brain SVDs? By now, there is no data about this.

Methods: (1) Subjects:427 convenient subjects who were on chronic hemodialysis and/or peritoneal dialysis in PUMCH dialysis center were screened. (2)Arterial stiffness assessment: PWV was assessed by SphygmoCor® on femoral-carotid artery .(3) Brain SVDs were evaluatied by 3T-magnetic resonance imaging.

Results: (1)202 subjects entered this study, male47.6%, average age56.3yrs, average dialysis vintage 59.9 moths, HD61.4%.(2)Average BP136.9/78.4mmHg, Hgb 112.0g/L, Alb38.0g/L,Calcium and phosphamid product 3.87±1.08mmol^2/L^2.(3) Average PWV10.6±2.3 m/s. 47.2% participants could be diagnosed as arterial stiffness (PWV>10 m/s). (4) By MRI, the prevalence of microbleeds was 42%, lacuna infarct was 39.5% and abnormal white matter lesions 51.5%. (5) Compared to patients with normal PWV, patients with abnormal PWV had more lesions in all kinds of SVDs (P<0.05). (6) PWV was relative with WML scores (r=0.410), lacunar infarct (r=0.281)and weakly relative with microbleed (r=0.164, P=0.029). Age was also relative with PWV,WML and lacunar infarction. By multiple linear regression analysis, after adjusted for dialysis vintage, calcium and phosphamid product and hsCRP, PWV still was an independent risk factor of WML but no longer risk factor of lacuna infarct. After adjusted age on above model, PWV was no longer risk factor of WML.

Conclusions: In our dialysis patients, there were a high prevalence of arterial stiffness. Patients with arterial stiffness had more severe SVDs. PWV was relative to WML and lacunar infact. Intervention of arterial stiffness maybe can be an alternative method to alleviate dialysis patients' brain SVDs.

PUB304

Patient Survival on Peritoneal Dialysis Compared with Hemodialysis Jwa-Kyung Kim,[1] Sun Ryoung Choi,[2] Sung Gyun Kim.[1] *[1]Internal Medicine, Kidney Research Inst, Hallym Univ Sacred Heart Hospital, Anyang, Korea; [2]Internal Medicine, Sahmyook Medical Center, Seoul, Korea.*

Background: It was recently reported that the overall mortality rate of incident peritoneal dialysis (PD) patients was constantly higher compared to hemodialysis (HD) patients in Korea. We aimed to investigate whether the overall survival of patients with PD is still inferior among patients who were cared at university hospitals in Korea.

Methods: We included all patients who had started dialysis between January 1, 2006 and October 31, 2013 at 5 general hospitals of Hallym University Medical Center (Gangnam, Gangdong, Chunchun, Hangang, Hallym Sacred Heart Hospital) in South Korea. Patients were followed up until October 31, 2014.

Results: We analyzed eligible 846 patients (461 HD patients and 385 PD patients). Median follow-up time was 46.1 months (range, 3.0-106 months). The crude incidence rates of all-cause mortality in PD and HD patients were 86.1 and 82.8 per 1000 patient-years, respectively. The overall survival rate of PD patients was similar with that of HD patients (Fig 1, $P = 0.960$). The 2-year and 5-year survival rates were 87.8% and 65.1% in patients with PD, and 86.5% and 64.3% in patients of HD. At the time of dialysis start, PD patients showed lower age, lower systolic blood pressure, lower Charlson comorbidity index (CCI), lower hemoglobin levels, lower serum creatinine levels, and lower blood glucose levels than HD patients. In multivariate Cox analysis, adjusting age, sex, body mass index, blood pressure, primary renal disease, CCI, hemoglobin levels, albumin levels, and serum creatinine levels, hazard ratio of peritoneal dialysis on all-cause mortality was 1.509 (95% CI, 1.160-1.962, $P = 0.002$). Among female patients or patients without diabetes mellitus, hazard ratio of peritoneal dialysis was not significantly increased [1.114 (0.703-1.767) and 1.785 (0.965-3.302), respectively].

Conclusions: The overall survival of patients with PD might be inferior compared to the survival of HD. Among female patients or the patients without diabetes mellitus, the survival rate of PD might be similar to those of HD.

PUB305

The Study of Cardiac Valve Calcification in Maintenance Hemodialysis Patients and Its Related Risk Factors Ming Li,[1] Huiqing Chen,[2] Zengchun Ye,[1] Wenbo Zhao,[1] Tan-Qi Lou.[1] *[1]Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sun Univ, Guangzhou, Guangdong, China; [2]Div of Paediatrics, The First Affiliated Hospital of Sun Yat-sun Univ, Guangzhou, Guangdong, China.*

Background: To explore the cardiac valve calcification(VC) in maintenance hemodialysis(MHD) patients and to analyze the risk factors.

Methods: Patients with MHD aged>14 years without history of heart valve disease and heart surgery were enrolled in the study. The color doppler uhrasonography was performed on 181 MHD patients to detect the cardiac VC.The patients were divided into two groups:VC group and no VC group.General clinical information, blood biochemical results were collected for analyzation among different groups.

Results: Of all the patients, male 112, female 69, the average age were 57.9+16.3 years. VC was found in 72 patients(39.8%),60(33.1%) with aortic valve calcification,30(16.5%) with mitral valve calcification,and 18(9.9%) with both. Compared with patients with no VC, patients with VC were older, more obesity,had longer hemdialysis duration, higher proportion of patients with hypertension and DM, higher plasma phosphate and serum uric acid, serum triglyceride.Multivariate Logistic regression showed that age(β=1.109,*P*=0.000), hemdialysis duration(β=1.390,*P*=0.001),BMI (β=1.187,*P*=0.008) were independently correlated with VC.VC also was founded positive correlation to pulmonary artery hypertension(PAH)(*P*=0.006).

Conclusions: cardiac valve calcification(VC) is common phenomenon in MHD patients,and aortic valve calcification is more common than mitral valve calcification.The major risk factors for cardiac VC are age, hemdialysis duration and BMI. VC is positive correlation with PAH.

PUB306

Cyclophilin A and Sclerostin as Markers of Atherosclerosis in Dialysis Patients Yoo Jin Lee, Yang Wook Kim, Sihyung Park, Bongsoo Park. *Internal Medicine, Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: Systemic inflammation and oxidative stress caused by endothelial dysfunction are related to atherosclerosis, which is one of major cause of death in dialysis patients. In addition, vascular calcification is an additional important factor of atherosclerosis in dialysis patients. Cyclophilin A (CyPA) is secreted by vascular smooth muscle cells in response to oxidative stress, which makes vascular inflammation and calcification by Wnt pathway. Sclerostin is known to as an antagonist of the Wnt pathway in bone modeling and vascular calcification.

Methods: Sixty patients (control n=20, hemodialysis n=20, peritoneal dialysis n=20) were enrolled in this cross sectional and single-center study.Serum CyPA, sclerostin were analyzed by ELISA. Ankle-brachial index (ABI) and carotid intima-media thickness (carotid IMT) were performed to measure atherosclerosis of peripheral and carotid arteries. Presence of atherosclerosis was defined as ABI ≤ 0.9 and carotid IMT ≥ 0.754 mm.

Results: Four patients (ABI ≤ 0.9 and carotid IMT ≥ 0.754 mm) had atherosclerosis and 35 patients did not have atherosclerosis (ABI > 0.9 and carotid IMT < 0.754 mm). The level of CyPA was higher in atherosclerosis group (42.8 ± 17.4 ng/mL vs. 32.21 ± 13.5 ng/mL, $p = 0.21$). The level of sclerostin was also higher in atherosclerosis group (3.98 ± 1.51 pg/mL vs. 3.45 pg/mL ± 3.1, $p = 0.33$). In subgroup analysis with non-atherosclerosis group, CyPA was highest in hemodialysis (control 30.23 ± 11.6 ng/mL; hemodialysis: 41.7 ± 16.4 ng/mL; peritoneal dialysis: 27.0 ± 10.2, $p = 0.57$). Sclerostin was higher in dialysis group than control (control: 0.91 ± 0.2 pg/mL; hemodialysis group: 5.99 ± 3.18 pg/mL; peritoneal dialysis group: 4.83 ± 2.98, $p = 0.01$).

Conclusions: This study did not prove the clinical usefulness of CyPA and sclerostin on prediction of atherosclerosis in dialysis patients because of small sample size. However, CyPA and sclerostin would be good biochemical parameters for assessing atherosclerosis in dialysis patients.

PUB307

A Validation Study of the Quick Sequential Organ Failure Assessment (qSOFA) for Japanese Patients Undergoing Hemodialysis Hiroki Nishiwaki, Sho Sasaki, Takaya Ozeki, Hiroo Kawarazaki, Shun Minatoguchi, Masahide Furusho, Masahiko Yazawa, Daisuke Uchida, Kenichiro Koitabashi, Takeshi Hasegawa. *JOINT-KD Group, Japan.*

Background: Hemodialysis (HD) patients are high risk population for bloodstream infection, due to daily punctures to vascular access. As the previous study, qSOFA had predictive validity (AUROC = 0.81; 95%CI, 0.80-0.82) among non-ICU encounters without hemodialysis. This study aim is to examine the performance of qSOFA proposed as an easy-to-use score which rapidly identify sepsis in general population for patients undergoing HD.

Methods: This was a multi-center retrospective observational study of patients undergoing HD. The study subjects were maintenance HD patients over 18 years old suspected with bloodstream infection who had blood cultures drawn in outpatient setting or within 2 days after admission from August 2011 to July 2013 in 11 Japanese tertiary care centers in JOINT-KD group. We did complete data analysis in this study. Main outcome measure was in-hospital mortality. As the previous study, qSOFA was defined as the score range was 0-3 points, with 1 point each for systolic hypotension [100mmHg], tachypnea [22/min], or altered mentation [GCS<13]. The cutoff point defined as 2 and more. The performances of qSOFA were evaluated using the areas under the receiver operating characteristics curves (AUROC) for discrimination, and Hosmer–Lemeshow test for calibration.

Results: Data from 220 consecutive patients were analyzed for qSOFA evaluation. The in-hospital mortality was 14.6%. AUROC of qSOFA was 0.648 (95% CI 0.57 to 0.73). The sensitivity and specificity were 36.8% and 92.9%, respectively. The logistic regression analysis showed that the pseudo R2 was 0.100. The Hosmer-Lemeshow test showed $p<0.01$.

Conclusions: qSOFA may not be useful in identifying sepsis in Japanese HD patients compared to that in the general population.

PUB308

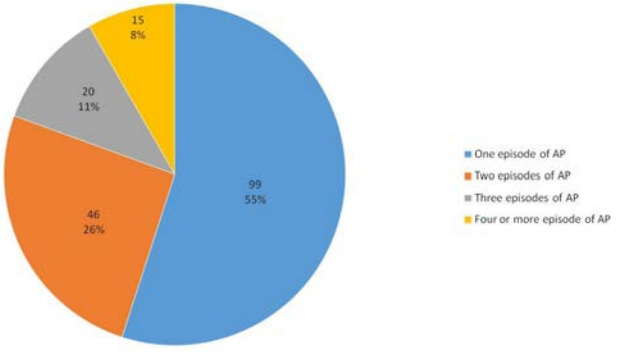
Recurrent Peritonitis in Peritoneal Dialysis in Qatar, an 8-Year Epidemiologic Study

Mostafa Fottoh Elshirbeny,[1] Abdullah Hamad,[1] Rania Abdelaziz Ibrahim,[1] Hany Ezzat Ismail,[1] Ahmad Kaddourah,[2] Hanaa Ahmed,[1] Ahlam Ali,[1] Mohamed Elsayed,[1] Fadwa S. Al-Ali.[1] *[1]Nephrology, Hamad Medical Corporation, Doha, Qatar; [2]Sidra Medical and Research Center, Doha, Qatar.*

Background: Acute peritonitis (AP) is a common and devastating complication in end stage renal disease patients on Peritoneal Dialysis (PD). We are reporting an epidemiologic study of recurrent AP in PD patients in Qatar over 8 years follow up.

Methods: We retrospectively reviewed the medical records of all PD patients in the biggest dialysis center in Qatar from 2007 to 2014. The analysis was conducted to repot the epidemiology, outcome and associated risk factors of recurrent AP.

Results: We had a total of 318 AP episodes in 180 patients between 2007 and 2014. 99 (55%) patients had single AP while 81 (45%) had 2 episodes or more (recurrent AP) .



Patients on automated PD carried a higher risk of developing recurrent AP (OR= 1.46, 95% CI:1.01-1.71). First episode of AP caused by gram positive (G+) cocci carried a significant risk of recurrent AP (OR= 4.3, 95 % CI: 2.2-8.2). Multivariate logistic regression model including both Gram + infection and automated PD as predictors of recurrent AP revealed the same predictive value of the G+ cocci infection to have at least another AP episode (OR = 3.9, 95% CI: 2.0-7.7). Additionally, negative-culture AP carried a significant protective role from a repeated AP (OR= 0.35, 95% CI: 0.19 – 0.66). Most deaths occurred with the first episode of peritonitis (4 out of six). Gram negative- associated AP carried the highest risk of death while no deaths was reported in association with G+ AP.

Conclusions: In this 8 year follow up epidemiologic study, recurrent AP was prevalent (45%) among all AP cases. and its risk increases with G+ cocci infections. However, G- infections were associated with increased mortality risk. Our results signify the importance of implementing more efficient care bundles to prevent recurrent AP.

PUB309

Factors Associated with Foot Ulceration and Lower Extremity Amputation in Adults with End-Stage Renal Disease on Dialysis: A Cross-Sectional Observational Study

Michelle R. Kaminski,[1] Anita Raspovic,[1] Lawrence P. McMahon,[2] Katrina A. Lambert,[3] Bircan Erbas,[3] Peter F. Mount,[4] Peter G. Kerr,[5] Karl B. Landorf.[1] *[1]Discipline of Podiatry, La Trobe Univ, Melbourne, Victoria, Australia; [2]Dept of Renal Medicine, Monash Univ, Melbourne, Victoria, Australia; [3]Dept of Public Health, La Trobe Univ, Melbourne, Victoria, Australia; [4]Dept of Nephrology, Austin Health, Melbourne, Victoria, Australia; [5]Dept of Nephrology, Monash Health, Melbourne, Victoria, Australia.*

Background: Dialysis patients are at increased risk for foot ulceration, which often precedes more serious lower limb complications. Limited data exist regarding the prevalence and factors associated with foot disease in this patient group. The aim of this study was to investigate factors associated with foot ulceration and amputation in the dialysis population.

Methods: This multi-centre cross-sectional observational study recruited 450 adults on dialysis from satellite and home-therapy dialysis units in Melbourne, Australia. Data collection involved a participant interview, medical record review, a health-status questionnaire and a foot examination. Logistic regression analyses were conducted to evaluate associations between screened risk factors and the primary and secondary outcomes.

Results: Mean age was 67.5 ± 13.2 years, 64.7% were male, 94% were on haemodialysis, the median dialysis duration was 36.9 (IQR, 16.6 to 70.1) months, and 50.2% had diabetes. There was a high prevalence of previous ulceration and amputation (21.6% and 10.2%), and 10% had current ulceration. Foot examination identified 50% with neuropathy and/or peripheral arterial disease. Factors significantly associated with foot ulceration were previous amputation (OR, 10.19), peripheral arterial disease (OR, 6.16) and serum albumin (OR, 0.87). For amputation, previous and current ulceration (OR, 167.24 and 7.49) and foot deformity (OR, 15.28) were significant factors.

Conclusions: Dialysis patients have a high burden of lower limb complications. Those with markedly higher risks of foot ulceration and/or amputation include those with lower serum albumin, previous/current ulceration or amputation, peripheral arterial disease, and foot deformity.

PUB310

Description of Kuwait Dialysis Population - 2015

Ali Alsahow,[1] Anas M. AlYousef,[2] Bassam A. Alhelal,[3] Monther M.A.M.H. Alsharekh.[4] *[1]Medicine, Jahra Hospital, Jahra, Kuwait; [2]Medicine, Farwanyea, Farwanyea, Kuwait; [3]Medicine, Adan, Ahmadi, Kuwait; [4]Medicine, Mubarak, Hawalli, Kuwait.*

Background: Dialysis population is growing, but basic data is lacking.

Methods: Brief data on dialysis patients presented.

Results: Population Health: Population in 2015 was 4.3 million, 30% Kuwaitis. Population is young (29.5 median age) plagued with risk factors for chronic kidney disease (CKD) development; diabetes (17.9% prevalence), hypertension (20% prevalence), obesity (42% obese), and smoking (20% of adults smoke). **Dialysis Services:** Ministry of health (MoH) centers provide dialysis freely for Kuwaitis, children of Kuwaiti women married to non-Kuwaiti men and residents from other Gulf states. Bedoons (Stateless people) get dialysis for a fee per hemodialysis (HD) session. Other expatriates leave as chronic dialysis is not provided in MoH units even when cost is covered, but some may access peritoneal dialysis (PD) for a fee. Military hospital has a small HD unit for defense ministry personnel and their families. One private center provides HD for $250 per session not including medications, which they get from MoH hospitals. **Dialysis Population:** Number increased by 4%from 1650 in 2014 to 1720 in 2015. Patients starting dialysis in 2015 were 410 (85% Kuwaitis). Non-Kuwaiti are 70% of the population, but 70% of dialysis patients are Kuwaitis as expatriates access to dialysis is minimal. So, incidence is 95 PMP and prevalence is 405 PMP for total population, and prevalence is 930 PMP and incidence is 275 PMP for Kuwaitis only (1.3 Million Kuwaitis, 1200 Kuwaitis on dialysis and 355 Kuwaitis started dialysis in 2015). More than 45% on dialysis due to DM. Mortality increased from 11.5% in 2014 to 13.5% in 2015. Hepatitis C found in 7%, and hepatitis B found in 2% of patients. Access was arteriovenous fistula in 42%, arteriovenous graft in 7.5%, and tunneled catheters in 50%. Low flux HD used in 32%, and high flux HD in 20%, and hemodialfiltration in 48% of patients. PD usage increased from 9.5% in 2013, to 10.5% in 2014, and to 12% in 2015, with automated PD used in 56% of cases.

Conclusions: Young society plagued with CKD risk factors. Incidence and prevalence rates are high, and PC use is high. Hepatitis C is a problem. Mortality is reasonable.

PUB311

Longer Haemodialysis Sessions Improved Clinical and Biochemical Markers Compared to Conventional Sessions: A Non-Randomised Trial

Darren R. Churchward,[1] Matthew P.M. Graham-Brown,[1] Warren Paul Pickering,[2] Robert C. Preston,[2] Gerry Patrick Mccann,[3] James Burton.[1,3] *[1]John Walls Renal Unit, Univ Hospitals of Leicester, United Kingdom; [2]Northampton General Hospital, United Kingdom; [3]Cardiovascular Biomedical Research Unit, Leicester, United Kingdom.*

Background: Data suggest extended haemodialysis (HD) provides significant physical and psychological benefits, including reduced mortality. Home HD patients have more opportunity than those in-centre to undergo extended treatments. Additionally, increasing HD incidence is resulting in an increased demand for HD. In-centre nocturnal HD (INHD) delivers extended HD sessions in addition to daytime slots, but is not routinely provided.

Methods: This non-randomised controlled trial enrolled 10 patients who elected to begin INHD (3x5-8hours) and 12 control patients receiving standard therapy (3x4hours) matched for age, gender and dialysis vintage. Clinical parameters relating to dialysis quality —such as ultrafiltration volumes (UFvol; Litres) absolute (absUFrate; mL/hour) and relative (relUFrate; mL/hour/Kg) UF rates, volumes cleared (mL) and urea reduction ratios (%) – were collected at baseline and following six months of treatment. Phosphate and haemoglobin levels were also compared. A mixed 2-way ANOVA was used to analyse main effects of time, treatment group and interaction.

Results: Our analysis showed significant time effects of volume cleared (p=0.005), AbsUFrate (p=0.001), relUFrate (p=0.001), phosphate (p=0.009) and haemoglobin (p=0.035). We found UFvol to have a significant group*time interaction (p=0.024) and URR to have both significant interaction and time effects ($p\leq0.001$). Post hoc analysis revealed no significant changes to any parameters in the control group, however the INHD group showed significant increases in volume cleared, UF volume, URR and haemoglobin over the study ($p\leq0.048$); and significant reductions in absUFrate, relUFrate and phosphate over the same period ($p\leq0.008$).

Conclusions: Over 6 months of INHD, patients show significant improvements in all clinical and biochemical parameters reported. Although patients were less strict with fluid restrictions, rates of fluid removal were still significantly reduced, clearance higher and biochemistry improved.

PUB312

Incidence of Hepatitis C Virus Infection in a Large Cohort of Dialysis Patients in the United States Pablo E. Pergola, Rebecca Vincent Rokosky, Navid Saigal. *Renal Associates PA, San Antonio, TX.*

Background: Rates of Hepatitis C Virus (HCV) chronic infection in dialysis patients are unknown. Published data are based only on HCV antibody (Ab) testing. Until the recent approval of direct acting antiviral agents (DAAs) with high efficacy and limited toxicity, no effective therapies were available for dialysis patients. Routine testing for HCV Ab and PCR is not standard of care on all dialysis facilities. Studies testing for HCV Ab and PCR are needed to determine the true incidence of chronic HCV infection in the dialysis population.

Methods: Observational, population-based cohort of prevalent dialysis patients, from 8 dialysis centers belonging to a large dialysis organization. All patients were tested as part of routine care between Sept 2015 and May 2016 for Hepatitis C Ab and if positive, a HCV PCR was performed.

Results: 687 patients were tested (626 in-center HD, 54 PD, 7 home HD), 48 were found to be HCV Ab+ (6.7%); 34 of the HCV Ab+ patients were PCR+ (66% or 4.7% of the total). None of the HCV PCR+ patients were co-infected with either Hep B or HIV. Only 10/48 patients were aware of the HCV Ab+ diagnosis. Mean age 61 (range 30-92), Male 33 (70%), Hispanic 32 (70%), Black 5 (10%). Of the HCV PCR+ patients, by zip code analysis, mean income was $43,116, high school graduation 75.2%, and poverty rate 23.8%. At the time of this report, only 5 patients were actively being treated (14% of HCV PCR+; genotypes 1A and 1B). Since this observation began, of the HCV PCR+ patients, 1 died from metastatic hepatocellular carcinoma (HCC), 1 was diagnosed with HCC and 1 with renal cell carcinoma (8.8% of HCV PCR+ had malignancies detected so far).

Conclusions: Rates of HCV infection in dialysis patients appear significantly higher than the general population (0.7/100,000 per CDC, 1.0% per NHANES 2003-2010). All dialysis patients should be tested for HCV Ab with reflex PCR, at dialysis initiation and every 6 months (CDC). All infected patients without contraindications should be offered treatment with approved therapies. All should have abdominal imaging due to long HX of untreated infection (until now no treatment offered or possible) and overall higher rates of malignancy in dialysis patients.

Funding: Clinical Revenue Support

PUB313

Association of Potassium Gradient with Near-Term Clinical Outcomes in Hemodialysis Patients Steven M. Brunelli,[1] Nina Oestreicher,[2,3] Charles Du Mond,[2] David M. Spiegel,[2] Csaba P. Kovesdy.[4] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Relypsa Inc, Redwood City, CA; [3]Univ of California San Francisco, San Francisco, CA; [4]Univ of Tennessee Health Science Center, Memphis, TN.*

Background: A high serum to dialysate potassium (K) gradient leads to rapid lowering of K during dialysis and may confer a greater risk of adverse events. Here, we examined the near-term association of K gradient with key clinical outcomes.

Methods: This retrospective (2010-2011) study considered 830,741 patient-intervals, each defined by a measurement of serum K made among adult Medicare Parts A & B enrollees who received in-center hemodialysis on a Monday/Wednesday/Friday schedule at a large US dialysis organization. K gradient was considered based on the difference in K concentration (serum - dialysate) on the date of measurement; analyses account for multiple observations per patient. Outcomes considered over the day of the qualifying gradient and the next day were: hospital admissions (all-cause and cardiovascular [CV]), emergency department (ED) visits, and deaths.

Results: Higher K gradient was associated with younger age, greater fistula use, lower comorbidity scores, and better nutritional indices. Adjusting for patient differences, higher K gradient was associated with greater risk of all-cause hospitalization and ED visit. A similar but non-significant trend was seen for CV hospitalization. No associations were observed with mortality, possibly due to the low number of events. Results were similar when the outcome window was limited to the date of measurement only.

	Potassium Gradient Category (mEq/L)

PUB314

Validation of an Anthropometric Model to Predict Brain Mass: Relevance for the Assessment of Brain Oxygen Demand Natasha Sharda,[1] Hanjie Zhang,[2] Israel Campos,[2] Stephan Thijssen,[2] Peter Kotanko.[2] *[1]Western Univ, London, ON, Canada; [2]Renal Research Inst of New York, NY.*

Background: Evidence indicates that HD patients suffer from structural brain damage. While the exact basis of these pathologies is unknown, poor oxygen delivery relative to brain oxygen demand may be a contributing factor. Brain oxygen demand depends critically on oxygen consumption which can be estimated if mass is reliably known. To that end we computed brain mass using published anthropometric formulae and compared the results to that actually measured in a large cohort of U.S subjects.

Methods: A Pubmed literature search revealed two papers of interest to our research question. Mehrpour reported a regression model utilizing age, gender, and height to predict brain mass determined from autopsies of non-pathological specimens in an Iranian population (Mehrpour, *J Forensic Leg Med*. 2010). We validated that model in a U.S population for both genders, aged 18-84 yrs with heights ranging from 140-190cm (Dekaban, *Ann Neurol*. 1978). The mean data points in the Dekaban paper were used as predictors in the Mehrpour model.

Results: The Mehrpour model consistently underestimated average brain mass in males (mean difference 78g) and overestimated it in females (mean difference 40g). The maximum absolute difference between estimated and measured brain mass was 100g for both sexes.

Figure 1. Difference between estimated and measure brain mass as a function of age and gender.

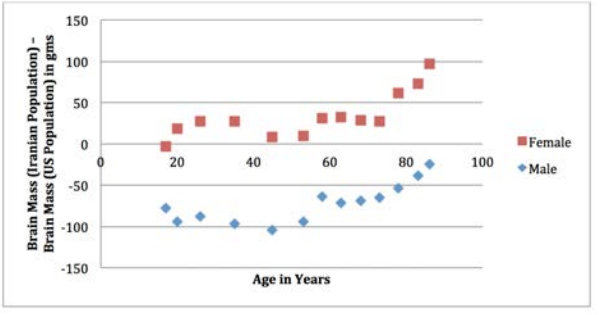

Figure 1 shows the average differences as a function of age and gender. When data is restricted to an age range of 55-74 yrs representing 90% of the U.S HD population, a further reduction in variation is noted.

Conclusions: The Mehrpour regression model provides a fair estimate of brain mass within a U.S population. Given an average brain mass of 1,311g in males and 1,285g in females, the average difference is 5.9% and 3.1%, respectively. Further studies are needed to validate the Mehrpour model in HD patients.

PUB315

Associations between Sleep Quality/Depressive Symptoms and Albumin/Phosphate Level Nien-Chen Li, Stephanie Johnstone, Joy R. Lutz-Mizar, Felicia N. Speed, Marta Reviriego-Mendoza, John W. Larkin, Norma J. Ofsthun, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Patients (pts) undergoing hemodialysis (HD) often complain about poor sleep quality (SQ) and are known to be at an increased risk for experiencing depressive symptoms. As a function of a Fresenius Medical Care North America Social Worker (SW) Quality Improvement Program, we investigated whether profiles of SQ and depressive symptoms are associated with alterations in levels of albumin (Alb) and phosphate (PO4).

Methods: We investigated 1,244 HD pts enrolled in the 8-week SW program from 7/1/13 and 2/28/14. SQ was assessed upon enrollment to the SW program. The SQ survey included 5 items, which were reduced to 3 by factor analysis that included: difficulty sleeping, difficulty awakening, and restless legs during sleep. Each item was scored on a scale from 1-10, with 10 indicating the worst score. For depressive symptoms, the Center for Epidemiologic Studies Depression Scale-10 (CESD-10) questionnaire was utilized. Means of Alb and PO4 were calculated over 30 days before the SW program. Correlations between SQ factors/CESD and albumin/PO4 mean levels were calculated.

Results: Pts had a mean age of 55.3 ± 13.9 years, 52.4% were males, 68.7% were white, 57.6% with diabetes, 19.8% with coronary artery disease, and 37.5% with congestive heart failure. The mean levels of Alb and PO4 were 3.9±0.4 and 5.9±1.6, respectively. Mean scores of CESD, difficulty sleeping, difficulty awakening and restless legs during sleep were 9.7±6.6, 4.4±2.8, 2.3±2.4, 3.2±3.1, respectively. We found that Alb was negatively correlated with CESD (r=-0.06, p=0.045) as well as restless legs during sleep (r=-0.07, p=0.02); however, PO4 was positively correlated with restless legs during sleep (r=0.06, p=0.03).

Conclusions: This study indicates that low levels of Alb are associated with worse depressive symptoms and restless leg syndrome in HD patients, while high PO4 levels are associated with restless leg syndrome. Social work interventions that can improve SQ and depressive symptoms may have the potential to improve HD pts outcomes.

PUB316

Body Temperature and Systolic Blood Pressure Patterns before Vancomycin Treatment in Hemodialysis Patients Sophia Rosen,[1] Yue Jiao,[1] Sheetal Chaudhuri,[1] Hao Han,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Ravi I. Thadhani,[2] Peter Kotanko,[3,4] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Massachusetts General Hospital Div of Nephrology, Boston, MA; [3]Renal Research Inst, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Infection is the second leading cause of death for dialysis patients (pts). Predicting infection before occurrence of apparent clinical markers would be desirable. We examined patterns of body temperature (BT) and systolic blood pressure (SBP) in hemodialysis (HD) pts before vancomycin treatment for an infection.

Methods: The analysis included 3,510 HD pts from the Fresenius Medical Care Data Warehouse from Jan 2010 to Sep 2015 who were treated with vancomycin for about 2 weeks. Data for predialysis BT and SBP measurements was collected 1 month before and after the vancomycin course. We compared several combinations of time points prior to vancomycin treatment using a repeated measures analysis of variance.

Results: We observed slight, but significant increases in average BTs during the time points 6-4, 3-1, and the mean of 6-1 days before starting vancomycin, as compared to the mean or any individual time point 30-7 days prior to pts receiving vancomycin (all $p<0.01$; Figure 1A). This change coincides with a subtle decrease in SBP one week before starting vancomycin as compared to earlier period ($p<0.001$; Figure 1B). Albeit significant increases were observed in BT before starting vancomycin, the mean BTs rose to a maximum of clinically normal levels of 97.5°F.

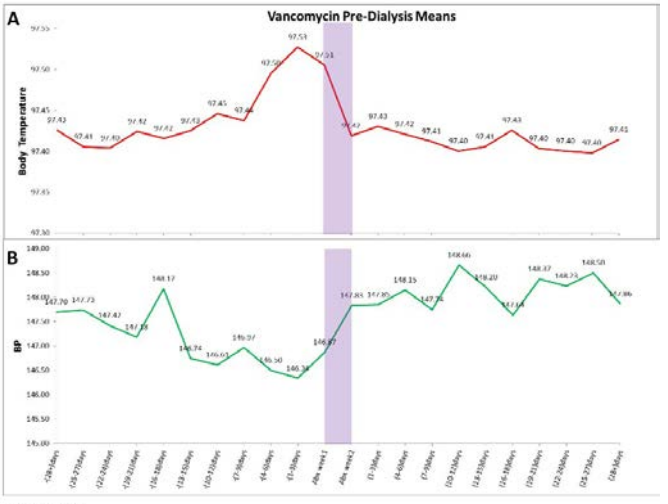

Figure 1

Conclusions: Small but measurable increases in BT and decreases in SBP prior to vancomycin treatment in HD patients likely antedate clinical infection.

PUB317

Bilateral Breast Pyoderma Gangrenosum in an Hemodialyzed Patient Cured by Corticosteroids with Wound Care Achour Laradi, Francois Babinet, Stephanie Lanoiselee. *Nephrologie Dialyse, ECHO-DIALYSE CMCM, Le Mans, France.*

Background: Pyoderma Gangrenosum(PG) is a rare neutrophilic but destructive and painful cutaneous disease with progressive ulcerations and necrosis of the skin.The typical lesions appear generally on the extremities.PG is associated with with specific diseases such as inflammatory bowel and myeloproliferative diseases .There are rare reports on Hemodialyzed Patients (HD).

Methods: A 62 -year -old female HD since 13 years with a medical history of a monoclonal gammapathy Ig G Lambda (2007) and Multiple Myeloma treated in 2016 , parathyroidectomy and adnexectomy.She was taken Cinacalcet, Sevelamer and Vitamin D.She presented in April 2015 with multiple bilateral breast painful cutaneous large ulcerations with elevated borders that gradually expanded surrounded by indurated violaceous plaques.The causes of cutaneous ulcerations were ruled out such as adverse drug effects, ,mycobacteries infection ,calciphylaxis,vasculitis and arteriosclerotic ulcers. Mammography was normal.Histological lesions showed a diffuse neutrophilic infiltration consistent with PG surinfected with Escherichia Coli and Streptococcus Agalactiae. Systemic corticosteroids were started (1 mg/kg) combined with antibiotics and advanced wound care with negative-pressure wound dressing.

Results: A positive response to therapy on the left breast was obtained within 3 months with a wound recovery with the wound depth decreasing from 5 cm to 2 cm and the diameter from 4 cm to 1 cm after 4 months.The right lesions are almost cleared after 8 months of .This is in accordance with previous reports showing that the majority of patients cleared witn the first six months of treatment and 95 % of patients attained remisssion within 3 years.Plastic surgery was not performed.

Conclusions: PG warrants attention in HD patients who accumulate multiple comorbidities and underlying conditions such myeloma and are at higher risk of PG which could be an overreactive inflammatory response linked to a neutrophil dysfunction with an overexpression of interleukin-8 and 18 .Diagnosis is based on clinical feature .Corticosteroid therapy needs a mean period of 11.5 months to achieve remission.Surgical approaches should be excluded.

PUB318

Effects of Dialysis Modalities on Markers of Mineral and Bone Disorders in ESRD Patients Melissa Soohoo,[1] Matthew B. Rivara,[2] Elani Streja,[1] Scott V. Adams,[2] Vanessa A. Ravel,[1] Onyebuchi A. Arah,[3] Kamyar Kalantar-Zadeh,[1] Rajnish Mehrotra.[2] *[1]UC Irvine, Irvine, CA; [2]Kidney Research Inst, Seattle, WA; [3]UCLA, Los Angeles, CA.*

Background: Mineral and bone disorders (MBD) are highly prevalent in patients undergoing maintenance dialysis, and are associated with adverse clinical outcomes. There are limited data on the effects of implementation in clinical practice of hemodialysis with either longer treatment time or higher frequency on markers of MBD.

Methods: This cohort study used data from 132,523 incident dialysis patients treated with any of the following modalities: conventional thrice-weekly in-center hemodialysis (HD), nocturnal in-center HD (NICHD), home HD (HHD), or peritoneal dialysis (PD). We analyzed the data using marginal structural models fitted with inverse probability weights to adjust for confounding due to fixed and time-varying covariates. We estimated the effects of treatment with different dialysis modalities on time-varying serum concentrations of four markers of MBD: calcium, phosphorus, parathyroid hormone (PTH) and alkaline phosphatase.

Results: Compared to conventional HD patients, patients treated with NICHD had lower mean PTH (21 pg/mL [95% CI 6 to 37] lower), whereas PD and HHD patients had higher mean PTH (44 pg/mL [95% CI 36 to 51] higher and 52 pg/mL [95% CI 34 to 69] higher, respectively). Compared to conventional HD patients, serum phosphorus was lower for patients treated with NICHD (0.45 mg/dL [95% CI 0.38 to 0.53] lower), PD (0.15 mg/dL [95% CI 0.12 to 0.18] lower) or HHD (0.33 mg/dL [95% CI 0.27 to 0.40] lower). There were no clinically significant associations between dialysis modality and concentrations of calcium or alkaline phosphatase (Table).

Conclusions: Among incident dialysis patients, treatment with dialysis modalities with longer treatment times or higher frequency was associated with altered patterns of serum phosphorus and PTH compared to conventional HD.

Abstract Withdrawn

PUB320

Prognostic Significance of the Interval Change of Plasma Neutrophil Gelatinase-Associated Lipocalin Level during the First 48 Hours in Patients Starting Continuous Renal Replacement Therapy Ha Yeon Kim, Tae Ryom Oh, Eun Hui Bae, Soo Wan Kim, Seong Kwon Ma. *Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: The present study investigated the clinical significance of the interval change of plasma neutrophil gelatinase-associated lipocalin (pNGAL) during the first 48 hr in acute kidney injury (AKI) patients starting continuous renal replacement therapy (CRRT).

Methods: This retrospective observational study included 404 AKI patients treated with CRRT. The patients were divided into two groups; renal recovery (n=120, 29.7%) vs. renal non-recovery (n=284, 70.3%) or survivor (n=193, 47.8%) vs. non-survivor group (n=211, 52.2%). The cut-off value of pNGAL was 200 ng/mL, and that of serum cystatin C (sCysC) was 1.0 mg/L. The estimated glomerular filtration rate (eGFR) was calculated by CKD-EPI equation. Exclusion criteria was a patient less than 18 years old, death with 24 hr after CRRT starting or a patient with maintenance renal replacement therapy.

Results: The volume of hourly urine output during the first 48 hr was significantly higher in the renal recovery group compared with the renal non-recovery group, and in the survivor group compared with the non-survivor group. The level of pNGAL at baseline or at 48 hr did not differ between renal recovery group and non-recovery group, and survivor group and non-survivor group. However, the value of ΔpNGAL was significantly higher in the renal recovery group compared with the renal non-recovery group (90.6 ± 82.9 vs. 33.8 ± 53.7, p<0.001), and in the survivor group compared with the non-survivor group (129.8 ± 182.4 vs. -98.5 ± 162.6, p<0.001). The level of sCysC at baseline, at 48 hr or ΔsCysC did not differ between the both groups. That of sCr at baseline, at 48 hr or ΔsCr also did not differ.

Conclusions: The interval change of pNGAL during the first 48 hr may predict renal outcome and survival of AKI patients undergoing CRRT although the value of pNGAL per se has a limitation on the prediction of outcomes. Urine output is also a robust prognostic biomarker in these patients.

PUB321

An Effect That Parameters Using Body Composition Monitor Have on Hemodialysis Patients: A Systematic Review and Meta-Analysis of Observational Studies Seon Deok Hwang,[1] Jin Ho Lee,[3] Woo Yeong Park,[2] Moon-Jae Kim,[3] Seoung Woo Lee.[4] *[1]Inha Univ College of Medicine; [2]Keimyung Univ Kidney Inst; [3]Bongseng Memorial Hospital; [4]Inha Univ College of Medicine; [5]Inha Univ College of Medicine.*

Background: It is reported that, with regard to assessment of patients' nutritional status, the interest in sarcopenia has recently risen, and an effect is produced on mortality as well, and overhydration in dialysis patient has an effect not only patient's cardiovascular mortality but also prognosis. The purpose of this study is to examine what effect is produced on dialysis patient by the measurement of tissue index and overhydration degree, using body composition monitor. .

Methods: A systematic review and meta-analysis using a random-effects model was performedWe searched the Cochrane Central Register, OVID MEDLINE, EMBASE, and Pubmed until March 15, 2016. We reviewed the reference lists of relevant reviews, registered trials, and relevant conference proceedings. Definition of overhydration group >15% and low LTI group <10% compare with reference group.

Results: Six trials were included, consisting of a total of 39615 patients In the pooled analysis, In overhydration group, The pooled hazard ratio (HR) for overall survival of overhydration vs.non overhydration was 2.01 ([95% confidence interval (CI): 1.397-2.890, P[thinsp]=[thinsp]0.001). HR for mortality in Low LTI Group was 1.53 (95% CI), 1.407 to 1.670]; P=0.001) in a random-effects model respectively. In the sensitivity analysis, the result from the most recent study showed the most heterogeneity.

Conclusions: Being diagnosed with low lean tissue index and determining whether to be overhydrated by using BCM may become a factor in increasing mortality in dialysis patients.

PUB322

Treatment Outcomes for Calcific Uraemic Arteriolopathy: One Centre's Experience Andrew Nixon, Annabel Roberts, Ajay Prabhakar Dhaygude. *Renal Medicine Dept, Royal Preston Hospital, Preston, Lancashire, United Kingdom.*

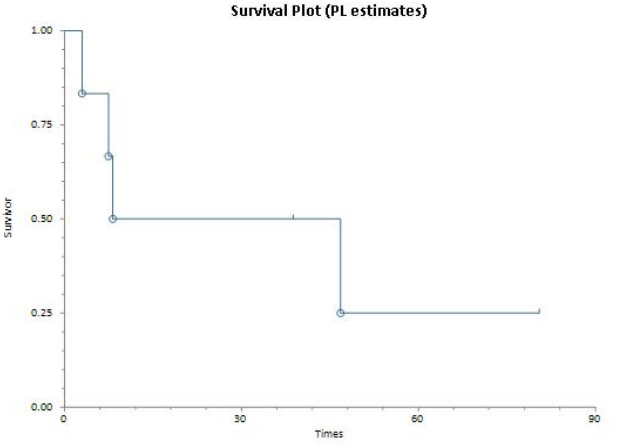
Background: Calcific Uraemic Arteriolopathy (CUA), also known as calciphylaxis, is a rare disorder that primarily affects patients with dialysis-dependent end-stage renal disease.[1] It is characterised histologically by medial calcification of arterioles.[1] It is associated with severe pain, skin ulceration and a significantly increased mortality risk.[1]

Methods: Clinical records were reviewed for all patients diagnosed with CUA between 2009 and 2015.

Results: Six patients were diagnosed. Table 1 demonstrates patient demographics and clinical characteristics.

Demographics and Clinical Characteristics	
Median Age	61
M:F	1:1
Dialysis	5
Median Dialysis Vintage (range)	39 months (12-109)
Previous Renal Transplant	4
Diabetes Mellitus	2
Warfarin	3
Mean Calcium Phosphate Product	3.8 $mmol^2/L^2$
PTH Above KDOQI Targets	4
Lower Limb Lesion(s)	6

Treatment included: increasing dialysis dose(6), IV sodium thiosulphate(6), dietary/ pharmacological hyperphosphataemia management(6), cinacalcet if uncontrolled hyperparathyroidism(3), stopping contributory medications(3) and regular wound care(6). Wound debridement was performed for 3 patients. Amputation was required for 1 patient. Lesions resolved in 4 patients. One-year survival rate was 50% with a median survival of 8.2 months. No deaths were directly due to CUA. Figure 1 demonstrates survival analysis (months).



Conclusions: This single centre study reports a median survival over three-fold greater than that published previously in the literature.[2] Thus, providing support for a multi-modal, multi-disciplinary approach to the management of CUA. **References:** 1. PUB323

Hemodialysis and Hemodiafiltration Affect VAP-1 and Endocan Levels in Regards to Type of Anticoagulant Jolanta Malyszko,[1] Ewa Koc-Zorawska,[1] Jacek S. Malyszko.[2] *[1]2nd Dept Nephrology, Medical Univ, Bialystok, Poland; [2]1st Dept Nephrology, Medical Univ, Bialystok, Poland.*

Background: Traditional anticoagulants used in hemodialysis-HD are heparin and low molecular weight heparins-LMWHs. Repeated and prolonged exposure to UFH and/ or LMWHs may further disturb hemostasis in uremic patients. VAP-1 (vascular adhesion protein) is secreted by vascular smooth muscle cells, adipocytes, and endothelial cells with functional monoamine oxidase activity and is elevated in atherosclerosis, diabetes mellitus and obesity. Endocan is a novel soluble dermatan sulfate proteoglycan derived from endothelium. Its elevated level is connected with endothelial activation, inflammation or carcinogenesis In this cross-sectional study we aimed to assess the effects of UFH and LMWHs on VAP-1and endocan in 80 hemodialyzed patients and 17 patients treated by means of hemodiafiltration-HDF. We also assessed the effects on single HD session on VAP-1 land endocan evels in regard to the type of anticoagulant.

Methods: Patients were selected from the group of hemodialyzed subjects who had been receiving enoxaparine (n=42), dalteparine (n=10), nadroparine (n=6) or unfractionated heparin –UFH (n=20) as an anticoagulant during their HD sessions. VAP-1 was assessed using kits from BioVendor, Modrice, Czech Republic. Endocan was assessed using commercially available kits from Lunginov, France.

Results: Diabetic patients had higher serum VAP-1 and endocan than non-diabetic. Patients on HDF had significantly lower VAP-1snd endocan when compared with HD patients. We found that VAP-1 and endocan concentration in patients dialyzed by using LMWH or UFH were similar. HD session was associated with a significant increase in endocan level (p<0.001), however, there was no effect on HD session on VAP-1 concentration.

Conclusions: HDF is associated with lower VAP-1and endocan levels indicating less pronounced endothelial cell injury and more favorable effect of this type of treatment. Dialysis session affect endothelial function reflecting by a significant rise in endocan levels. Type of heparin seem to have no effect on VAP-1 and endocan levels in hemodialyzed patients. However, the cross-sectional but not prospective design is a limitation of this study.

PUB324

Comprehensive Analysis of Support Interventions on Quality of Life in Patients with End Stage Renal Disease on Hemodialysis May Christine Zeta,[1] Jennie Z. Ma,[2] Uta Erdbruegger,[1] Emaad M. Abdel-Rahman.[1] *[1]Nephrology, Univ of Virginia, Charlottesville, VA; [2]Public Health Sciences, Univ of Virginia, Charlottesville, VA.*

Background: Decreased health-related quality of life (HRQOL) is common in chronic hemodialysis (HD) patients and is associated with mortality, complications and reduced compliance with treatment. Interestingly, achievement of widely accepted clinical performance targets is not related to HRQOL of hemodialysis patients. The effectiveness of a multidisciplinary team approach in support interventions targeting adult patients with ESRD has not been systematically assessed. The aim of this study was to comprehensively describe these interventions and QOL measures from a pilot study with intensified HRQOL testing.

Methods: This is a pilot study of 8 adult patients on hemodialysis who consented to perform the Kidney Disease and Quality of Life questionnaire (KDQOL™36) on an intensified schedule (months 0, 3, 6, 9, and 12). Interventions normally given as standard

of care were documented for each time period (T1=0-3 months, T2=4-6, T3=7-9, T4=10-12). Five intervention categories were determined—nutrition, education/counselling, psychosocial, medical management/treatments, and rewards/gifts.

Results: 40 KDQOL questionnaires completed by 8 patients during the 1-yr study period were analyzed. The average KDQOL scores were: Physical=35.6, Mental=49.6, Burden of Disease=51.6, Symptoms/Problems=80, and Effects of Kidney Disease=65. During the study the mean scores over the 1-yr study period did not change markedly. The average number of interventions for each time period was 7, most of which were related to nutrition, followed by medical management. Overall no change in number of interventions were observed over time.

Conclusions: The HRQOL scores and number of interventions did not change markedly during the study period. Interestingly, most interventions were related to nutrition counseling. More patients are needed to assess the effectiveness of these support interventions on patient's quality of life and to determine the optimal frequency of its testing.

PUB325

Impaction Factors for Mortality of Maintain Hemodialysis Patients Chang Wang, Yuan Yang, Fang Yuan, An Zhou, Youming Peng, Xing Chen, Hong Liu. *2nd Xiangya Hospital, Central South Univ.*

Background: The mortality of hemodialysis in the five-yearon hemodialysis is still high, despite progression of hemodialysistechnological and applicationof different dialysis techniques. The study of the long time survival outcome and risk factors for maintain hemodialysis (MHD) of Chinese mainland patient are currently lacking.

Methods: A retrospective cohort study of 91 death MHD patients wascarried out, and data was collected by the 2nd Xiangya hospital hemodialysis center from 2011 to 2015. The Kaplan-Merier test was used to analyze risk factors associated with 48m survival. Multivariate Cox regression was used to analyze independent risk factors of all-cause death.

Results: Results revealed the median survival time of 91 maintenance dialysis patient (25 female and 66 male) is 46 months. The Kaplan-Merier analysis showed the age of initiation dialysis >70y, diabetic nephropathy, cerebrovascular comorbility, eGFR<7 ml/min/1.73m^2 or > 10 ml/min / 1.73 m^2 at the initiation of dialysis were risk factors of mortality. While the serum albumin≥30g/l, or with haemoglobin≥100g/l at the initiation of dialysis, using high-flux dialyzer, AVF, HDF+HD dialysis model, Kt/V ≥1.2, dialysis frequency>2/w, or haemoglobin ≥110g/l, or iPTH ≥300 pg/ul, or prescript β-receptor blocker treatment had significantly longer survival time. Further, multivariate analyses showed baseline eGFR<7 ml/min/1.73m^2,diabetes, cerebrovascular disease, age of initiation dialysis >70y , baseline eGFR>10 ml/min/1.73m^2 were significant independent risk factors of higher all cause death in MHD patients; and using AVF vascular access, pre-dialysis hemoglobin≥100g/l, using high-flux dialyzer, and dialysis frequency>2 times/week were independent factors of reducing all-cause death in MHD patients.

Conclusions: In this study, old age, diabetes and CVD co-morbidity lead to an increased risk of death in MHD patients. Low hemoglobin and too high or low eGFR at the commencement of dialysis are associated with the poor survival time. Fortunately, dialysis frequency>2/w, fistula access and high-flux dialyzer are associated with better survival outcome.

PUB326

Increased Prevalence and Morbidity of *Clostridium difficile* Infection in Patients with End-Stage Renal Disease on Hemodialysis Hong Joo Lee. *Dept of Nephrology, Seoul Red Cross Hospital, Seoul, Republic of Korea.*

Background: Patients with end-stage renal disease(ESRD) on hemodialysis have impaired host defense mechanisms and frequently require antibiotics for various infective complications. Despite increasing efforts to prevent infection, the prevalence of hospital-associated *Clostridium difficile* infections (CDI) is increasing. Heightened awareness prompted this study of the prevalence and morbidity associated with CDI in ESRD patients on hemodialysis.

Methods: This was a single-center, retrospective case-control study. A total of 85 patients with CDI were identified based on a retrospective review of *Clostridiumdifficile* toxin assay or histology recordsat Seoul Red Cross Hospital from January 2011 to January 2015. CDI was diagnosed by enzyme immunoassay for toxins and, more recently, polymerase chain reaction (PCR) testing.In 85 patients with CDI, 15 patients with end-stage renal disease on hemodialysis included as cases and 60 patients without hemodialysis were used as controls. We compared the baseline characteristics and identified independent risk factors that could predict the development or prognosis of CDI. Hospital outcomes and survival were also compared between cases and controls.

Results: Independent risk factors for occurance of CDI included age, duration of antibiotics and ESRD on hemodialysis. Hemodialysis patients with CDI had more baseline comorbidities and received more blood products than non-hemodialysis patients with CDI. All were treated with metronidazole or vancomycin. Patients on hemodialysis with CDI showed poorer responses to the initial metronidazole therapy. Hemodilalysis patients with CDI had more septicemia, longer hospital stay, and lower 3-year survival than non-hemodialysis patients with CDI.

Conclusions: The prevalence of CDI is increasing, contributing importantly to morbidity and mortality in ESRD patients on hemodialysis.

PUB327

The Increase of Serum Myostatin Level Was Suppressed by Intra-Dialytic Exercise in Hemodialysis Patients Shigeichi Shoji,[1] Hisayo Yokoyama,[2] Kiyonori Takai,[1] Senji Okuno,[1] Tomoyuki Yamakawa,[1] Eiji Ishimura,[3] Yoshiki Nishizawa,[4] Masaaki Inaba.[4] *[1]Internal Medicine, Shirasagi Hospital, Osaka, Japan; [2]Dept of Environmental Physiology for Exercise; [3]Dept of Nephrology; [4]Dept of Metabolism, and Molecular Medicine, Osaka City Univ Graduate School of Medicine, Osaka, Japan.*

Background: Myostatin is a TGF-β family member that act as a negative regulator of skeletal muscle mass. In healthy people, aerobic exercise and resistance training decreased the level of serum myostatin. (Hittel DS, et al, Med Sci Sports Exerc, 2010). But there was no reports of the effects of intra-dialytic exercise on muscle and bone metabolism with the change of the serum myostatin levels.

Methods: This study is a non-randomized controlled trials; 12 exercised group and 10 no exercised group. Pre and after exercise, body composition were measured by DXA (QDR-4500; Hologic Inc, Waltham,MA), exercise capacity was measured by cardio pulmonary exercise test, and the serum levels of myostatin (time-averaged concentration: TAC) were measured.

Results: After 12 weeks intra-dialytic, aerobic and resistance exercise, serum myotatin levels increased in both groups. But the statistically significant suppression of serum myosttin levels by exercise was found by two-way (group x intervention) ANOVA with repeated measurements.

	Control(pre)	C(post)	Exercise G(pre)	E(post)	group effect	Inter-vention effect	Inter-action
Myostatin ng/mL	10.5 ±4.0	22.9 ±2.5#	17.4 ±4.5*	23.8 ±6.9#	0.077	<0.001	0.007
P1NP ug/L	323 ±155	406 ±258	267 ±125	250 ±87	0.135	0.175	0.047
TRACP-5b mU/dL	470 ±274	584 ±392	503 ±292	477 ±236	0.779	0.294	0.108
FGF-23 pg/mL	4416 ±3860	3770 ±3448	2937 ±2793	2490 ±1978	0.307	0.134	0.778
Sclerostin pmol/L	249 ±151	198 ±123#	184 ±77	157 ±55#	0.278	<0.001	0.146

Exercise has significant interventional effect on handgrip strength and PINP. 10m gait speed, peak VO2 and heart rate recovery has significantly improved in only exercise group. Body composition, bone mineral density, and muscle mass and muscle strength (knee extension strength) have no change after exercise.

Conclusions: In hemodialysis patients, intra-dialytic exercise suppress the increase of serum myostatin level.

PUB328

Can We Use Cellulose Triacetate Membrane for Postdilution Online-Hemodiafiltration? Marta Albalate,[1] Patricia Martínez-Miguel,[4] Lourdes Bohorquez,[2] Patricia De Sequera,[1] Rafael Ramirez,[2] Hanane Bouarich,[4] Guillermina Barril,[3] Rafael Perez-Garcia.[1] *[1]Nephrology, Infanta Leonor Hospital, Madrid, Spain; [2]Physiology, Alcalá de Henares Univ, Alcalá de Henares, Madrid, Spain; [3]Nephrology, La Princesa Hospital, Madrid, Madrid, Spain; [4]Nephrology, Principe de Asturias Hospital, Alcalá de Henares, Madrid, Spain.*

Background: Synthetic membranes have been the only used in the postdilution online-HDF. We have a new asymmetric cellulose triacetate (ACT) (Solacea®, Nipro) suitable for this technique (Kuf 76/ml/h/mmHg). The aim is to describe ACT performance and behaviour to identify: purifying efficiency, use in clinical practice, biocompatibility and inflammatory effect.

Methods: Prospective observational multicentre study. Twelve patients (9 men, 65 (41-85)years) were included. Each patient was treated with ACT for a month without changing their previous schedule. 127 full sessions were collected. Effective time (EfT), Qb, Qd, ultrafiltrate volume (UF), infusion volume (IV), Kt, maximum PTM and technical or coagulation problems during treatment were collected. At the first treatment, blood samples were taken before and after dialysis to determine RR of urea, creatinine, β2microglobulin, myoglobin and retinol binding protein (PTR). At 30' one second blood was removed. Monocyte subpopulations were measured before the start of the first and the last dialysis session.

Results: 1) Efficiency: EfT 248.9(10.3)', effective Qb 371(28.2) ml/min, UF 2.6(0.6) l, IV 26.7(2.8) l, Kt 57.3(4.3) l, maximum PTM 83(22.6) mmHg, RRurea 81(5.2), Cr 74.7(4.6), mioglobin 71(6.8), β2m 76.5(4.8) and PTR 18.6(7.6)% 2) Clinical use: There were no complications or alarms or need to change dosage of heparin. 3) Biocompatibility: Leukocyte and platelet initial vs. 30' didn't change 4) Inflammation: After ACT percentage of CD14+CD16++ was lower (33.8(13) vs. 26.4(13.1), p<0.04) (%), no differences were found in other subpopulations.

Conclusions: ACT achieved adequate Kt, IV and RRs without technical problems, making it a potential treatment for post-HDF and a solution to allergic patients to synthetic membranes. Also, our preliminary results show that ACT seems to be a biocompatible membrane that selectively decreases the percentage of pro-inflammatory monocytes.

Factors Associated with Dialysis Withdrawal Billie Axley, Michael R. O'Connell, Dugan Maddux, John W. Larkin, Marta Reviriego-Mendoza, Stephanie Johnstone, Michelle L. Gilliland, Rebecca L. Wingard, Tammy C. Green, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Little is known about the factors that may influence discussions with patients about withdrawal from hemodialysis (HD). To explore this we surveyed a group of HD staff including nephrology nurses, social workers, and dietitians.

Methods: A voluntary, electronic survey was offered to staff at 20 Fresenius Medical Care North America HD clinics during February of 2016. The survey questions identified: 1) most common reasons for a patient/family to initiate a conversation about HD withdrawal, 2) when a patient/family request(s) for HD withdrawal is most often made, and 3) describe process(s) in place to support the patient/family when a decision is made to withdraw from HD. Responses from 28 HD staff were analyzed.

Results: We found that clinic staff reported decreased quality of life and failure to thrive as the most common reasons for a patient/family member to initiate a conversation about withdrawal from HD (89% & 79%, respectively) (Figure 1A). Withdrawal requests by the patient/family were mostly made during hospitalization, followed by requests being made during HD (57% & 21%, respectively) (Figure 1B). Most common processes in place supporting patients requesting dialysis withdrawal were hospice referral (68%), and home care arrangements via social workers and clinic managers (43%); 14% reported there was not a specific process in place (Figure 1C).

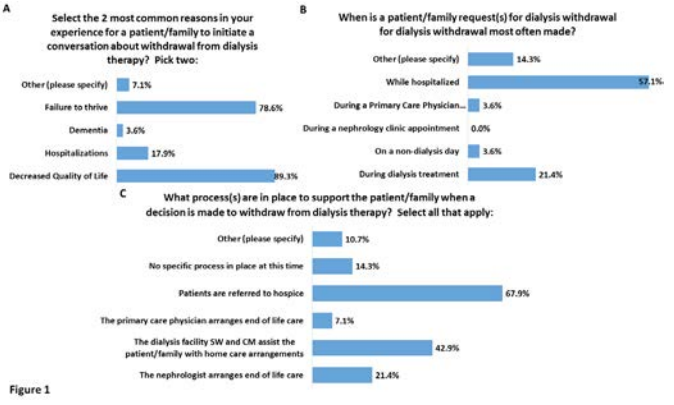

Figure 1

Conclusions: Survey results from a multidisciplinary group of dialysis clinic staff suggest that the most common reasons for patients and families to request dialysis withdrawal were decreased quality of life and failure to thrive, and these requests were commonly made while patients were hospitalized. These findings support the need for strategies that focus on the patients' values and wishes.

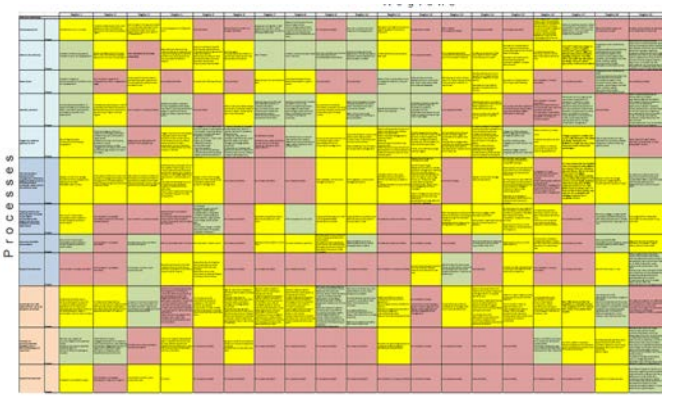
Provincial Initiatives to Implement a Palliative Approach to Renal Care across Ontario Sarbjit Vanita Jassal,[1,3] Marnie MacKinnon,[3] Sharon Gradin,[3] Tea Palamarevic,[3] Peter G. Blake.[2,3] *[1]Div of Nephrology, Faculty of Medicine, Univ Health Network, Toronto, ON, Canada; [2]Div of Nephrology, Univ of Western Ontario, London, ON, Canada; [3]Ontario Renal Network, Toronto, ON, Canada.*

Background: The Ontario Renal Network (ORN) provides policy, financial, and governance oversight to individuals receiving renal care in the Province of Ontario. Through their planning work with patients and family members, the ORN identified palliative and end of life care as a priority. We present the provincial strategy used to develop an integrated process for the early identification and provision of a palliative approach to renal care.

Methods: Information about current practices was collected from all renal centres across the province through a process mapping exercise. Process maps were collated and synthesized using aggregate gap analysis. Clinician understanding of palliative care was evaluated by questionnaire.

Results: The current state mapping process showed a number of clinical initiatives had been initiated across a number of centres, suggesting heightened clinical awareness of the need for a palliative approach to renal care.



Processes were, however, often inconsistently delivered, and at risk due to poorly coordinated community engagement. Informal survey results suggest practicing clinicians are aware of the need to include a palliative care approach to renal care, but they do not feel enabled or sufficiently trained.

Conclusions: Key opportunities to effectively roll out provincial-level initiatives can be identified from the process maps. A provincial level initiative can facilitate clinician driven initiatives to improve the provision of renal services to patients.

PUB331

Development of a Medical Writing Elective for Nephrology Fellows Amir Kazory, Abhilash Koratala, Maryam Sattari. *Univ of Florida.*

Background: While half of the American medical schools provide formal training in writing history and physicals, less than 15% offer any type of formal medical writing courses designed to teach the skills needed to write grant proposals and peer-reviewed journal articles. Similarly, although faculty development in the "effective writing of grants and manuscripts" continues to be a perceived need for academic physicians, there has been minimal documented progress in improving the availability of formal writing education in the recent years. To address this gap, a "medical writing elective" (MWE) was designed at the University of Florida specifically for nephrology fellows.

Methods: Based on the published literature and our own experience with development and directorship of MWE for medical students and internal medicine residents, we constructed an interactive multimodality curriculum for nephrology fellows. The goals of this renewable 2-week MWE are to (1) provide fellows with knowledge and experience about various aspects of medical writing (e.g. case reports, clinical vignettes, and poster/oral presentations in scientific meetings), (2) enhance their education by advancing their medical writing skills and editing abilities, and (3) increase and enrich their scholarly output in order to improve their future career opportunities. Teaching methodology of the MWE includes (1) didactic lectures, (2) writing assignments, and (3) small group sessions with the faculty. Fellows are also assigned a writing project for the elective, for which they prepare a clinical vignette abstract and/or a case report.Examples of planned topics include introduction to writing various types of manuscripts, plagiarism/self-plagiarism, patient privacy, journal rankings, and submission/revision requirements.
