JASN Abstract Supplement

Abstract Publication
More than 4,600 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 27, 2016: Page(s).

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The *Onsite Program* lists all abstract experts.

Abstract Disclaimer and Copyright
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). It is published as a service for the personal, noncommercial, and informational use only of its members and Kidney Week participants. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week 2016 program, which can be found in the *Onsite Program*, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week 2016 to complete a disclosure form. Responses are listed on the ASN website (www.asn-online.org/kidneyweek/faculty) and on the Kidney Week 2016 mobile app.

Program Builder
All abstracts and the complete Kidney Week 2016 program are viewable online through the interactive Program Builder at www.asn-online.org/KidneyWeek.

The Online Program Builder is supported by OPKO Renal.

Role of PAD4 and NETs in Ischemia Reperfusion Injury in the Kidney William Brian Reeves,[1] Wesley M. Raup-Konsavage,[1] Weiwei Wang,[1] Jinquan Sun,[2] Yanming Wang.[2] *[1]Div of Nephrology, Penn State College of Medicine, Hershey, PA; [2]Biochemistry and Molecular Biology, Penn State Univ, Univ Park, PA.*

Background: Ischemia-reperfusion injury (IRI) is a common cause of AKI. Neutrophils contribute to renal IRI though the mechanism by which they cause injury is uncertain. The formation of neutrophil extracellular traps (NETs) is a defense against infection but may also contribute to tissue injury. The role of NETs in ischemic AKI is unknown. Peptidyl arginine deiminase 4 (PAD4) is essential for NET formation and regulates gene expression through the citrullination of histones.

Methods: Wild type (WT) and PAD4 KO mice were subjected to renal ischemia. Renal function, histology and circulating cell-free DNA were measured.

Results: PAD4 KO mice were markedly resistant to ischemic injury as measured by serum BUN (WT 136±14 vs KO 49±9 mg/dl, P<0.0001) and creatinine (WT 1.54±.13 vs KO 0.43±.13 mg/dl, P<0.0001) levels. We assessed NET formation by measuring serum DNA levels. Serum DNA levels increased after IRI but were lower in KO than WT mice (1310±16 vs 1678±157 ng/ml,P<0.01). Additionally, we observed less citrullinated histone H3 in tissue from PAD4 KO vs WT mice. Kidney expression of TNF and IL-6 were lower, while IL-10 was higher, in KO vs WT mice. DNase I has been used to reduce NET formation in vivo. Therefore, we treated WT mice with DNaseI just prior to ischemia and again 8 hrs after reperfusion. DNaseI treatment resulted in better preservation of kidney function (BUN: veh. 130±6 vs DNase 86.6±12 mg/dl and creatinine: veh. 1.48±.24 vs DNase 0.84±.06 mg/dl, P<0.05). To determine if neutrophils were the major site of action for PAD4 in IRI, we transferred WT or PAD4 KO neutrophils into PAD4 KO mice prior to IRI. PAD4 KO mice which received WT neutrophils developed much greater injury than mice which received PAD4 KO neutrophils (BUN 136±9 vs 63±10 mg/dl, P<0.001). In contrast, neutrophils lacking TNFR1 did not increase injury (BUN 73±6 mg/dl).

Conclusions: Our findings suggest that formation of NETs mediates IRI and that inhibition of PAD4 or degradation of NETs may reduce the severity of ischemic AKI. Moreover, neutrophils are targets of TNF in IRI, perhaps leading to NET formation.

Inhibition of Signal Transducer and Activator of Transcription 3 (STAT3) Protects against Renal Ischemia-Reperfusion Injury Jae Wook Lee,[1] Sun Moon Kim,[2] Seung Hee Yang,[3] Yon Su Kim.[3] *[1]National Cancer Center, Korea; [2]Chungbuk National Univ Hospital, Korea; [3]Seoul National Univ, Korea.*

Background: STAT3 promotes survival of naïve T cells and differentiation of T helper 17 (Th17) cells. Cln three requiring 9 (Ctr9), a subunit of RNA polymerase II-associated factor complex, functions as a negative regulator of Th17 cells by repressing IL-17 transcription. On the other hand, STAT3 in tubular epithelial cells (TECs) is activated by ischemia-reperfusion (IR) injury and compromises adaptation to hypoxia. Here, we investigated the role of STAT3 and Ctr9 in renal IR injury.

Methods: IR injury was induced in wild-type mice, wild-type mice pre-treated with CADPE (a STAT3 inhibitor), and mice with T cell-selective STAT3 deletion (*Stat3*$^{\Delta/\Delta}$). Renal injury was assessed by serum creatinine and immunohistochemistry at 48 h. Activation of intrarenal Th17 cells was determined by intrarenal IL-17 concentrations and flow cytometry for CD4$^+$ T cells. Changes in the proportions of Th17 cells following RNA interference of Ctr9 (Ctr9-siRNA) were analyzed using flow cytometry. Primary human TECs were grown under hypoxia (1% O_2 for 6 h) with or without CADPE. Cytokine production was quantified using real-time PCR and ELISA.

Results: Renal injury was significantly reduced in mice pre-treated with CADPE and *Stat3*$^{\Delta/\Delta}$ mice, both of which exhibited a significant reduction in intrarenal Th17 cells. Ctr9-siRNA treatment on intrarenal T cells further enhanced differentiation of Th17 cells, consistent with the inhibitory role of Ctr9 in Th17 differentiation. In cultured TECs, hypoxia upregulated STAT3, IL-17 receptor, and other markers of cell injury (e.g. IL-18). CADPE treatment significantly reduced STAT3 activation and the markers of cell injury. Interestingly, Ctr9 expression was also observed in TECs of normal kidneys and repressed with IR injury. Ctr9-siRNA treatment reduced the expression of STAT3 and Th17-related transcripts in TECs under hypoxia.

Conclusions: Inhibition of STAT3 protects against renal IR injury by reducing activation of Th17 cells and production of pro-inflammatory cytokines from TECs. Ctr9 is a negative correlate of STAT3 activity and functions as a negative regulator of IR-induced inflammation in both cell types.

Vagus Nerve Stimulation-Conditioned CD11b+F4/80+ Cells Protect from Kidney Ischemia-Reperfusion Injury Tsuyoshi Inoue,[1] Chikara Abe,[2] Liping Huang,[1] Hong Ye,[1] Diane L. Rosin,[1,2] Patrice G. Guyenet,[2] Mark D. Okusa.[1] *[1]Div of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, Univ of Virginia, Charlottesville, VA; [2]Dept of Pharmacology, Univ of Virginia, Charlottesville, VA.*

Background: We recently showed that prior vagus nerve stimulation (VNS) protects the kidney from ischemia-reperfusion injury (IRI) through the cholinergic anti-inflammatory pathway. The phenotypic change of macrophages (VNS induces M2 phenotype) in the kidney was observed by flow cytometry, however the causal role of these conditioned macrophages in vivo was not established.

Methods: CD11b+ splenocytes (MACS-enriched; 85% CD11b+) or peritoneal macrophages (70% CD11b and F4/80 double positive) were isolated from wild type mice and alpha 7 nicotinic acetylcholine receptor (α7nAChR) knock out (α7KO) mice 24 hr after electrical VNS (5 Hz, 50 μA for 10 min), then CD11b+ splenocytes or C11b+F4/80+ peritoneal macrophages were transferred into the recipient mice. Kidney IRI was performed 1 hr after the adoptive transfer and kidney injury was evaluated 24 hr later using plasma creatinine (PCr), kidney Kim-1 mRNA expression and histology (H&E).

Results: Adoptive transfer of CD11b+ splenocytes (1x10^5 cells) from VNS-treated mice to recipient mice subjected to IRI provided greater protection than CD11b+ splenocytes from mice who received sham VNS stimulation (PCr: 0.14 and 1.01 mg/dl (P<0.001) for VNS- and sham VNS-treated CD11b+ splenocytes from spleen, respectively, n=6). When peritoneal macrophages (1x10^5 cells) from donor mice were transferred, a similar protective effect was observed (PCr: 0.62 and 1.57 mg/dl (P=0.001) for VNS- and sham VNS-treated peritoneal macrophages, respectively, n=7). In addition, α7KO mice were used to evaluate the role of α7nAChR+ macrophages. The protective effect in recipient mice was much smaller if they received peritoneal macrophages from VNS-treated α7KO mice than from VNS-treated WT mice.

Conclusions: These data demonstrate that activation of CD11b+F4/80+ cells through α7nAChR is important for the protective effect of VNS in AKI and extend our findings on the role of neuroimmune regulation of kidney injury through the inflammatory reflex pathway.

Iron-Retaining Splenic Myeloid Cells Are Central for Hepcidin-Induced Protection in Renal Ischemia-Reperfusion Injury Yogesh M. Scindia,[1] Ewa U. Mandziak,[1] Liping Huang,[1] Mark D. Okusa,[1] Diane L. Rosin,[2] Sundararaman Swaminathan.[1] *[1]Medicine, Univ of Virginia, Charlottesville, VA; [2]Pharmacology, Univ of Virginia, Charlottesville, VA.*

Background: We showed previously that pretreatment with hepcidin mitigates kidney ischemia-reperfusion injury (IRI) by increasing the splenic iron content. We have further demonstrated that transfer of hepcidin-treated splenocytes into naïve recipients protects against renal IRI. In this study we have explored the role of different splenic immune cells responsible for this protective effect. In addition, we evaluated the therapeutic potential of hepcidin after the onset of IRI.

Methods: C57BL/6 (WT) and *Rag1*$^{-/-}$ mice were injected with saline or 50mg hepcidin, and 24 hours later subjected to bilateral renal IRI (24-27min). Some Rag1$^{-/-}$ mice were treated with a Thy1.2 depleting antibody to deplete nature killer (NK) and innate lymphoid cells (ILC). In some experiments WT mice were injected with hepcidin after 2 h of reperfusion. Outcomes (renal function, injury markers, histopathology and inflammation) were examined after 1-30 d of reperfusion.

Results: Hepcidin significantly reduced kidney injury in Rag1$^{-/-}$ mice as measured by plasma creatinine (Rag1$^{-/-}$ P_{Cr}: IRI; 2.6±0.13 vs hepcidin + IRI; 0.26±0.01 mg/dl, $p < 0.005$), NGAL, acute tubular necrosis and immune cell infiltration. Rag1$^{-/-}$ mice depleted of Thy1.2$^+$ cells were also protected by hepcidin pretreatment. In a separate experiment, WT mice injected with hepcidin 2 h after the onset of AKI had significantly lower plasma creatinine than saline-treated animals, after 3 days of reperfusion (WT P_{Cr}: IRI; 1.2±0.38 vs hepcidin + IRI; 0.47±0.06 mg/dl, $p < 0.05$). The kidneys of hepcidin-treated mice had more M2 macrophages and fewer inflammatory cells and survived for up to 30 d after reperfusion. In contrast, the majority of saline-treated mice died after 3 d of reperfusion.

Conclusions: Our results demonstrate that hepcidin-mediated protection against renal IRI is critically dependent on iron retention in myeloid cells and is independent of Tregs, lymphocytes, NK cells and ILC. The ability of hepcidin to protect when administered after the onset of IRI highlights its therapeutic potential.

Tamm-Horsfall Protein (Uromodulin) Regulates the Number and Function of Macrophages in the Kidney Radmila Micanovic, Shehnaz Khan, Pierre C. Dagher, Takashi Hato, Tarek M. El-Achkar. *Medicine Nephrology, Indiana Univ and Indianapolis VA Medical Center, Indianapolis, IN.*

Background: Tamm-Horsfall protein (THP also known as Uromodulin) is a kidney specific protein produced by cells of the thick ascending limbs (TAL). While predominantly secreted apically towards the urinary lumen, THP is also released basolaterally by TAL cells, towards the interstitium and the systemic circulation. We previously showed that THP mediates an anti-inflammatory tubular cross-talk between TAL and S3 proximal tubules. It has been proposed that THP also functions as an immuno-modulator, but the exact role of THP in regulating the function of renal macrophages is still unclear.

Methods: Various methodologies described below.

Results: Using THP-/- and THP+/+ mice, we show that THP deficiency is associated with partial macrophage depletion which is limited to the kidney and not other organs such as the liver or spleen. This depletion occurs mostly in the inner stripe of the outer medulla, the site of maximum THP abundance. After ischemia-reperfusion injury (IRI), THP-/- mice exhibit an impaired macrophage response and chemokine profile, and are more susceptible to renal neutrophil infiltration and acute kidney injury (AKI). Treatment of THP-/- mice with purified THP restores the number of kidney macrophages. In addition, treatment of THP-/- mice 24 hours after IRI mitigates subsequent worsening of AKI. Intravital 2-photon microscopy in CXCR3GFP+ mice shows that, intravenously injected, fluorescently-labeled THP is taken up by resident renal macrophages. In vitro, THP stimulates the proliferation of SC human macrophage cells in a concentration dependent manner. This effect, which was not due to inhibition of apoptosis, was explained by specific activation of AKT but not ERK or NFkB. Finally, THP-/- renal macrophages show resistance to the depleting effect of liposomal clodronate in vivo, suggesting impaired phagocytosis with THP deficiency.

Conclusions: Taken together, our data support that THP positively regulates macrophage proliferation and phagocytic activity. In addition to its effect on the epithelium, this emergent immuno-modulatory role could explain the protection conferred by THP in the setting of AKI.

Macrophage Extracellular Traps Induced by Mac-1 (CD11b/CD18) Dependent Platelet-Macrophage Interactions Promotes Acute Kidney Injury in Rhabdomyolysis Koshu Okubo, Matsuhiko Hayashi, Junichi Hirahashi. *Apheresis and Dialysis Center, Keio Univ, School of Medicine, Tokyo, Japan.*

Background: Rhabdomyolysis-induced acute kidney injury (AKI) is a critical complication after breakdown of skeletal muscles. Crush syndrome, an emergency condition caused by traumatic rhabdomyolysis, occurs commonly in natural disasters such as earthquakes and man-made disasters such as wars or terrorism. Recently, macrophages were implicated in disease pathogenesis, however, the detailed molecular mechanism remains unclear. Leukocytes release extracellular traps (ETs) composed of chromatin fibers and granule proteins to eliminate invading pathogens. However, ETs may also cause tissue damage.

Methods: We show that macrophages released ETs in a mouse model of rhabdomyolysis, and contributed to the pathogenesis of rhabdomyolysis-induced AKI.

Results: Administration of ET inhibitors, depletion of platelets, and genetic ablation of Mac-1 (leukocyte specific β2 integrin expressed on macrophages) ameliorated rhabdomyolysis-induced AKI. Heme-activated platelets enhanced macrophage extracellular traps (METs) production, involving intracellular ROS generation and histone citrullination. These results revealed an unanticipated role for platelets in rhabdomyolysis-induced AKI, and suggested that an interaction between platelets and Mac-1 contributed to disease pathogenesis.

Conclusions: Our findings provide a novel mechanism in rhabdomyolysis-induced AKI that Mac-1 may potentially be targeted for treatment of the disease.

FTY720 Regulates Mitochondria Biogenesis in Dendritic Cells to Prevent Acute Kidney Injury Elvira Kurmaeva, Kyle J. Alexander, Liping Huang, Amandeep Bajwa. *Medicine, Univ of VA, Charlottesville, VA.*

Background: FTY720, a S1PR agonist has been shown to protect kidneys from IRI. However, systemic use is limited due to adverse side effects. Dendritic cells (DCs) have the ability of regulate innate and adaptive responses in AKI. In current study we tested if FTY720 could induce mitochondria biogenesis to induce tolerogenic DCs to use as cellular therapy to limit the off-target effects associated with systemic drug admiration in kidney IRI.

Methods: Renal injury was assessed by plasma creatinine (PCr; mg/dl). 8-wk old C57BL/6 WT mice were used for generating highly pure DCs from bone marrow precursors. Cells were treated with cocktail of GM-CSF±FTY720. On day 7 DCs were treated with 100ng/ml LPS or Veh to induce activation. All four groups (Veh/Veh, Veh/LPS, FTY/Veh and FTY/LPS) were analyzed using real-time PCR for cytokines and mitochondria: nuclear DNA ratio, facs (for activation (MHCII) and co-stimulation (CD40/80/86) markers, and mitochondrial function (mass (MitoTrackerGreen), potential (CMXRos), oxidation (MitoSOX))and Seahorse flux analyzer for MitoStress. For in vivo studies, Veh/LPS and FTY/LPS-DCs ($0.5X10^6$, i.v.) were transferred 24hrs prior to or 4hrs after IRI.

Results: FTY720-DCs have higher oxygen consumption rate (38.18 vs 107.16; $p<0.01$), ATP production (45.29 vs 101.12; $p<0.01$) and spare respiratory capacity (163.67 vs 314.82) compared to vehicle DCs. FTY/LPS-DCs have significantly lower expression of MHCII and CD40/80/86 compared to Veh/LPS-DCs. FTY/LPS-DCs also have higher mtDNA/ncDNA ratio, significantly higher MitoSox (MFI, 800±50.1 vs 152±10.3; $p<0.001$) and MitoTracker Green (515±25.1 vs 1000±16.1; $p<0.001$) signal compared to Veh/LPS-DCs. FTY/LPS-DCs have higher gene expression for IL10, S1Pr1 and PGC1α compared to Veh/LPS-DC. Furthermore, transfer of FTY/LPS-DCs to WT mice 24hrs prior (PCr, 0.17±0.02 vs 1.5±0.17, $p<0.001$) or 4hrs after IRI (PCr, 0.53±0.08 vs 1.3±0.12, $p<0.01$) significantly protects the kidneys from IRI compared to Veh/LPS-DCs treated mice.

Conclusions: FTY720 induces tolerogenic phenotype in DCs by modulating mitochondrial biogenesis and adoptive transfer of FTY720-DCs either prior to or after established ischemic injury protects kidneys from IRI.

TH-OR008

Cardiorenal Syndrome: A Novel Mouse Model Assessed Using Near-Infrared Transcutaneous Fluorescence Michael Hutchens,[1] Rumie Wakasaki,[1] Mizuko Ikeda,[1] Hak Soo Choi,[3] Sharon Anderson.[2] *[1]Anesthesiology & Perioperative Medicine, Oregon Health & Science Univ, Portland, OR; [2]Internal Medicine, Oregon Health & Science Univ, Portland, OR; [3]Radiology, Massachusetts General Hospital/Harvard Univ, Boston, MA.*

Background: Cardiorenal syndrome type 1 causes acute kidney injury (AKI). Animal models and diagnostic aids are lacking. Near-infrared fluorophores are resistant to biologic interference and thus favorable in injury models. We developed a mouse model of cardiorenal syndrome and tested a near-infrared fluorophore, ZW800-1, to assess cardiac and renal function.

Methods: ZW800-1 (MW943D)was synthesized, and mouse CA/CPR conducted, as described. Cardiac function was measured by transthoracic echocardiography, 2- and 24h after CA/CPR. GFR was assessed by inulin clearance. Tubular cell death was quantified by unbiased stereology, creatinine (sCr) by creatine aminohydrolase assay, and transcutaneous fluorescence of ZW800-1 with a whole-animal imager at 800nm emission, simultaneously with GFR. ZW800-1 fluorescence distribution was measured at 7 ROIs every 1 s for 5m and decay every 5m for 120m, after injection . Clearance was calculated from fluorescence by standard curve, modeled with delayed (55m) single-phase kinetics. Correlation and Bland-Altman analysis were performed.

Results: CA/CPR causes biventricular failure at 2h compared to sham (LV FS 8±13% vs 16±25%/RV:PA systolic notch index 0.97±0.2 vs 0±0 n=12, $p<0.05$) which resolved by 24h. CA/CPR caused severe AKI,correlating with LV>RV dysfunction (GFR sham 87±32 CA/CPR 3±3 μL/m sCr sham 0.2 CA/CPR 1.2 mg/dL n=16, $p<0.01$ 2h LVFS:24h sCr r=-0.71, n=12,$p<0.001$). ZW800-1 was not cleared in 4 mice with bilateral nephrectomy. ZW800-1 decay half time and clearance correlated with GFR (r=0.92, bias 5‡24μL/m, 95% agreement-41-52μL/m, n=32, $p<0.0001$) ZW800-1 fluorescence was lower in CA/CPR than sham animals 8-10s after injection ($p<0.01$) correlating with 2h LV function (r=0.74, $p<0.01$).

Conclusions: CA/CPR is a model of cardiorenal syndrome type 1. ZW800-1, a small near-infrared fluorophore being developed for clinical intraoperative imaging is favorable for evaluating cardiac and renal function noninvasively.

Early DNA Hypometlylation, HIF-1 α Reduction and Increased Oxidative Stress Promotes Acute Kidney Injury (AKI) to Chronic Kidney Disease (CKD) Transition Andrea Sanchez-Navarro,[1,2] Norma Gonzalez Rubio,[1,2] Rosalba Pérez-Villalva,[1,2] Norma Bobadilla.[1,2] *[1]Molecular Physiology Unit, Inst de Investigaciones Biomédicas, UNAM, Mexico City, Mexico; [2]Dept of Nephrology, Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.*

Background: AKI is now recognized as an independent risk factor for CKD development. The mechanisms involved in the AKI to CKD transition are poorly understood and even less is known about the temporality of renal alterations along the transition. The aim was to analyze the time course response of inflammation, oxidative stress, hypoxia, and fibrosis, as well as, epigenetic modifications in the AKI to CKD transition.

Methods: Fifty-two male Wistar rats were divided in: sham operated (S), right nephrectomy (UNx) and nephrectomy plus left renal ischemia (45 min, UNx+IR) groups. The animals were sacrificed and studied at 1, 2, 3 or 4 months. At the end of each period, mean arterial pressure, creatinine clearance, and renal blood flow were determined. Proteinuria and oxidative stress was evaluated monthly. In the kidney, the mRNA levels of inflammation, hypoxia and fibrosis markers, as well as, the global DNA methylation were assessed since 1 to 4 months. Renal histopathological alterations were also examined.

Results: After 4 months, the UNx+IR group developed CKD characterized by progressive proteinuria, renal dysfunction, glomerular hypertrophy, tubular dilation and tubulointerstitial fibrosis. These alterations were not seen in S and UNx groups. Since 1-month after AKI, there was a significant increase in oxidative stress by 2-fold and a reduction in the global DNA methylation by 15% that remained along the study. HIF-1α and VEGF were completely depressed by 99% in the 1st and 2nd month, and then recovered in the UNx+IR group compared to control group. Whereas TGF-β and IL-6 were up-regulated lately and occurred when the renal fibrosis was detected.

Conclusions: The HIF-1α/VEGF reduction could be responsible of inducing vascular rarefaction and chronic renal hypoxia. Our results suggest that reduced HIF-1α signaling, increased oxidative stress and DNA hypomethylation play a crucial role in the early phase of AKI to CKD transition.

TH-OR010

The Gli1+ Kidney MSC Population Is Not Fixed but Dynamically Acquires Gli1 Expression after AKI Flavia G. Machado,[1] Gizely C.S. Moreira,[1,2] Eoghainín O Hainmhire,[1] Benjamin D. Humphreys.[1] *[1]Div of Nephrology, Washington Univ in St. Louis, St. Louis, MO; [2]Renal Div, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: We have shown that Gli+ expression in kidney defines a population of MSC-like pericytes that are the major myofibroblast progenitor population in kidney fibrosis. It is unclear whether this population is fixed, or if interstitial cells can dynamically gain Gli1 expression and myofibroblast differentiation capacity after injury.

Methods: We performed bilateral ischemia reperfusion injury (biIRI) in Gli1-nLacZ reporter mice and evaluated the distribution and density of Gli1+ cells, over a 14 day time course. We investigated whether the Gli1+ population proliferated or if Gli1 expression occurred in a previously Gli1- population. In vitro, we cultured fibroblasts from normal rat kidney (NRK-49F) with TGFβ and evaluated Gli1 expression.

Results: Using a moderate, reversible biIRI model (24 hr BUN, 121 + 20, avg. + SD), Gli1 mRNA was progressively upregulated during days 1, 3, 7 and 14 days after IRI reaching a maximal level of 14-fold over control mice on day 14. Quantitation of nLacZ expression by automated image analysis revealed a doubling of Gli1+ cells by day 14 in the cortex, from 0.31±0.01 cells/mm² in control *vs.* 0.57±0.08 cells/mm² in d14 biIRI. Gli1+ cell numbers were higher in the outer medulla, the site of maximal injury. There, Gli1+ cells rose from 0.50±0.05 cells/mm² at baseline to 1.64±0.15 cells/mm² by d14 biIRI. As expected, all Gli1 cells were PDGFRβ+. Gli1 cells differentiated into myofibroblasts during AKI repair as well, reflected by acquisition of αSMA expression by double immunofluorescent staining. Despite the overall increase in Gli1 cell number, there was no more than 0.5% of Gli1/Ki67 co-positive cells in cortex, and no more than 4% co-positive cells in medulla at all time points.

Conclusions: During AKI repair, stromal cells can acquire Gli1 expression de novo. Since Gli1 expression defines a myofibroblast progenitor population, these results indicate that myofibroblast progenitors are recruited from a Gli1-negative stromal cell pool, rather than the proliferation of a fixed Gli1-positive population.

Novel Biomarkers Predict Progressive Nephropathy in Patients with Type 2 Diabetes after Acute Coronary Syndrome: The EXAMINE Trial

David M. Charytan,[1] Muthiah Vaduganathan,[1] William B. White,[2] Craig A. Wilson,[3] Stuart Kupfer,[3] Faiez Zannad,[5] Christopher Paul Cannon,[1] George L. Bakris.[4] *[1]Brigham & Women's Hospital; [2]Univ of Connecticut; [3]Takeda Development Center; [4]Univ of Chicago; [5]Univ de Lorraine and Centre Hospitalier Universitaire.*

Background: Novel biomarkers may improve identification of individuals at risk of progressive nephropathy in type 2 diabetes (DM2), but prior studies are limited in size.

Methods: Filtration (Cystatin C) and urine tubular injury markers (neutrophil gelatinase-associated lipocalin [NGAL], kidney injury molecule-1, [KIM1]) were collected in >90% and urine protein/Cr ratio(PCR) in >58% of 5,380 patients with DM2 and recent acute coronary syndrome enrolled in the EXAMINE trial. eGFR was estimated with the CKD-EPI equation. End-stage renal disease was defined as a requirement for dialysis or eGFR <15 mL/min/1.73m^2.

Results: Median follow-up was 18 mo and 71% had eGFR ≥60 mL/min/1.73m^2. Increasing quartiles of Cystatin C, KIM1, NGAL, and PCR strongly associated with combined ESRD or 50% decline in eGFR and mean change in eGFR (P_{trend}≤0.03 for all comparisons).

Biomarker	Q1	Q2	Q3	Q4	P Trend
Cystatin C	(N=1272)	(N=1313)	(N=1337)	(N=1291)	
ESRD or 50% decline in eGFR	0.16%	0.23%	0.90%	6.05%	<0.001
Change in eGFR (mL/min/1.73m^2)	0.02 ± 10.6	0.06 ± 11.6	-0.9 ± 13.4	-0.7 ± 12.4	0.03
KIM-1/Cr	**(N=1199)**	**(N=1235)**	**(N=1217)**	**(N=1224)**	
ESRD or 50% decline in eGFR	0.58%	1.38%	1.48%	3.68%	<0.001
Change in eGFR (mL/min/1.73m^2)	0.7 ± 11.7	-0.2 ± 11.7	0.4 ± 12.1	-1.4 ± 2.6	<0.001
NGAL/Cr	**(N=1250)**	**(N=1237)**	**(N=1237)**	**(N=1238)**	
ESRD or 50% decline in eGFR	0.56%	0.89%	1.38%	4.37%	<0.001
Change in eGFR (mL/min/1.73m^2)	0.6 ± 11.2	0.2 ± 11.6	-0.7 ± 12.2	-1.5 ± 12.9	<0.001
PCR	**(N=910)**	**(N=1162)**	**(N=977)**	**(N=1000)**	
ESRD or 50% decline in eGFR	0.66%	0.52%	0.41%	6.81%	<0.001
Change in eGFR (mL/min/1.73m^2)	1.4 ± 11.1	0.1 ± 11.8	-0.8 ± 12.4	-2.9 ± 12.8	<0.001

Conclusions: This is the largest study to date of novel and traditional biomarkers and suggests they allow early identification of DM2 patients at risk for worsening kidney function.

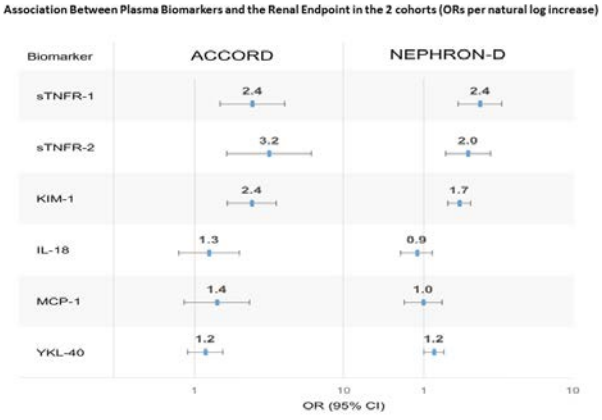
Plasma Biomarkers and Progressive GFR Decline in Early and Established Diabetic Kidney Disease: Analyses from ACCORD and VA NEPHRON-D

Steven G. Coca,[1] Girish N. Nadkarni,[1] Dennis G. Moledina,[2] Veena Rao,[2] Yuan Huang,[2] Jane Hongyuan Zhang,[2] Bart Ferket,[1] Linda F. Fried,[3] Chirag R. Parikh.[1] *[1]Icahn School of Medicine at Mount Sinai; [2]Yale Univ; [3]U Pittsburgh.*

Background: Current measures for predicting renal function decline in persons with type 2 diabetes (T2DM) are unsatisfactory. We examined inflammation, injury and repair biomarkers for risk-stratification for progressive diabetic kidney disease (DKD).

Methods: We measured 6 biomarkers: sTNFR-1 and 2, KIM-1, IL-18, MCP-1 and YKL-40 in banked baseline plasma samples from participants of two randomized, controlled trials (ACCORD, VA NEPRHON-D) in T2DM. In ACCORD, we employed a nested case-control design (n=190 cases of sustained eGFR decline≥40% and 190 controls with eGFR decline<10% over 5 years, matched on baseline eGFR, albuminuria, and BP). In the VA NEPHRON-D trial, we used the entire cohort with banked plasma (n=1156). The renal outcome in VA NEPHRON-D was 50% decline in eGFR if baseline eGFR<60 ml/min/1.73m^2 or decline of 30 ml/min if baseline eGFR>60 ml/min/1.73m^2.

Results: Median biomarker concentrations were roughly two-fold higher in NEPHRON-D vs. ACCORD. After adjusting for baseline covariates, including albuminuria and eGFR, 3 of the 6 plasma biomarkers were significantly associated with the renal outcome in both cohorts. In ACCORD, the adjusted odds ratios (ORs) for sustained eGFR decline ranged from 2.4-3.2 per log increase in sTNFR1, sTNFR2, and KIM-1.



Similarly, in VA NEPHRON-D, the adjusted ORs for sustained eGFR decline ranged from 1.7-2.4 per log increase in sTNFR1, sTNFR2, and KIM-1. The other 3 biomarkers were not significantly associated with the renal outcome in either cohort.

Conclusions: Although the absolute concentrations differed, 3 plasma biomarkers (sTNFR 1 and 2, and KIM-1) were independently associated with higher risk of eGFR decline in T2DM persons with both early (ACCORD) and established DKD (VA NEPHRON-D).

Urinary Epidermal Growth Factor Is Inversely Associated with Impaired Kidney Function in a Population-Based Lupus Cohort

Michelle R. Smith,[1] Viji Nair,[1] Sioban D. Harlow,[1] Wendy Marder,[1] William Joseph Mccune,[1] Faith M. Strickland,[1] Charles Helmick,[2] Caroline Gordon,[3] Celine C. Berthier,[1] Matthias Kretzler,[1] Afton L. Hassett,[1] Suzie Zick,[1] The Michigan Kidney Translational Core,[1] Wenjun Ju,[1] Emily C. Somers.[1] *[1]U of Michigan; [2]CDC; [3]Internal Medicine, U of Birmingham.*

Background: Over 30% of systemic lupus erythematosus (SLE) patients have kidney impairment. Urinary epidermal growth factor (uEGF), a marker representing tubular cell regenerative potential, adds prognostic value to estimated glomerular filtration rate (eGFR) and proteinuria in chronic kidney disease (CKD) patients. However, uEGF as a non-invasive biomarker for kidney function and CKD incidence in SLE has not been studied.

Methods: uEGF was measured in the MI Lupus Epidemiology & Surveillance (MILES) Cohort (394 SLE; 170 control) at baseline by ELISA. Statistical analyses included ANOVA, Pearson's correlation, and ROC curves. uEGF concentration in lupus nephritis (LN) cases (n=47) from the independent Clinical Phenotyping & Resource Biobank (C-PROBE) cohort, was used to validate our cross-sectional findings and further determine its association with *longitudinal* kidney function decline.

Results: In MILES SLE cases, uEGF was inversely correlated with baseline eGFR (r=-0.62 ,p< 0.001) and its level distinguished CKD (AUC=0.80 by uEGF vs 0.62 by proteinuria). Further, uEGF distinguished ESRD in cases and controls (AUC=0.88). In C-PROBE, the inverse correlation of uEGF with eGFR was validated in LN cases (r=0.83, p<0.001), and over 3.5 years, uEGF correlated with change in eGFR (r=0.56, p <0.001).

Conclusions: We validate significant correlation between uEGF and eGFR in SLE. For the first time, in a high CKD risk population, we show that uEGF is superior to proteinuria in distinguishing SLE cases with impaired kidney function. Whether uEGF can be used as an early biomarker that can *predict* CKD incidence in SLE requires further longitudinal follow-up.

TH-OR014

Cigarette Smoking Partially Negates the Kidney Protective Effect of ACE Inhibition in Stage 2, Non-Diabetic, Hypertension-Associated CKD

Bethany Roehm,[1] Jan Simoni,[2] Jessica Pruszynski,[3] Donald E. Wesson.[4] *[1]Internal Medicine, Tufts Medical Center, Boston, MA; [2]Surgery, Texas Tech Univ HSC, Lubbock, TX; [3]Biostatistics, Scott and White Healthcare, Temple, TX; [4]Internal Medicine, Scott and White Healthcare and Texas A&M HSC College of Medicine, Temple, TX.*

Background: Cigarette smoking appears to exacerbate nephropathy progression but by unknown mechanisms.

Methods: We recruited 108 smoking and 108 non-smoking, non-diabetic adults with CKD due to hypertension-associated nephropathy, stage 2 eGFR (60-89 ml/min/1.73 m^2), and urine albumin (mg)-to-creatinine (g) ratio (alb/cr) >200. Smokers received substance abuse counseling, nicotine patch, and oral bupropion to encourage quitting by pre-specified reduction of urine cotinine. Non-smokers (n = 108), continued smokers (n = 83), and quitters (n = 25) were followed 5 years after starting ACE inhibition with yearly eGFR (CKD-EPI), alb/cr, and urine (µg)-to-creatinine (g) isoprostane 8-isoprostaglandin $F_{2\alpha}$(8-iso/cr), a measure of oxidative stress.

Results: There was no difference in entry eGFR (p=0.53), alb/cr (p=0.30), or systolic and diastolic blood pressure (p=0.06 and 0.38, respectively) and no difference in either blood pressure at 5 years (p=0.45 and 0.25). Entry 8-iso/cr was higher (p<0.01) in continued smokers (4.3 ug/cr) and quitters (4.1 ug/cr) than non-smokers (1.6 ug/g). At 1 year, non-smokers had lower than entry alb/cr (395±143 vs 420±148, p<0.01), consistent with ACE-related reduced kidney injury. By contrast, at 1 year continued smokers had higher alb/cr (453±152 vs 426±138, p<0.01), consistent with increased kidney injury despite ACE. One-year alb/cr in quitters (356±178 vs 367±160, p=0.15) was not different from entry. One year urine 8-iso/cr was higher in continued smokers (3.6±0.8) than non-smokers (1.6±0.3, p<0.01) and quitters (1.6±0.3, p<0.01). At 5 years, eGFR was lower (p<0.01) in continued smokers (54.9±5.6 ml/min) than non-smokers (66.8±5.8 ml/min) and quitters (64.1±5.6 ml/min).

Conclusions: Continued cigarette smoking in CKD partially negates kidney protection associated with ACEI, possibly by inducing oxidative stress, an effect which appears to be ameliorated by smoking cessation.

TH-OR015

Risk and Protective Metabolomic Signatures Associated with Albuminuria in Type 1 Diabetes (T1D): A Joslin Kidney Study

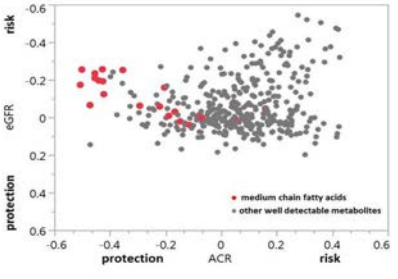
John J. Tsay,[1,2] Adam Smiles,[2] Melissa Major,[2] Stephanie E. Croall,[2] Andrzej S. Krolewski,[2] Monika A. Niewczas.[2] *[1]Medicine, Veterans Affairs Boston Healthcare System, Boston, MA; [2]Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA.*

Background: Albuminuria and renal function impairment are intermediate phenotypes of diabetic nephropathy. We aimed to investigate whether these two phenotypic features would be associated with distinct metabolomic signatures in a large study of subjects with T1D of a long duration.

Methods: Plasma metabolites were analyzed via mass spectrometry-based global platform in a cross-sectional study of 419 subjects (T1D duration: median, 25th, 75th percentile: 24, 18-31 years). We examined the associations of metabolites with albumin:creatinine ratio (ACR) and renal function (eGFR) in the following study groups with normal renal function: normoalbuminuria (Resistors, n=92), microalbuminuria (n=44) and proteinuria (n=189)) and in subjects with proteinuria and CKD stage 3 (n=94).

Results: Of the 580 detected metabolites, 383 metabolites were measured at ≥ 80% frequency in the study subjects. With Bonferroni correction, 55 metabolites were significantly associated with ACR (26↓, 29↑). Among the 26 metabolites that levels were higher in the Resistors than in subjects with microalbuminuria and proteinuria; 13 metabolites (50%) belonged to the lipid class. Top protective lipid metabolites included monocarboxylic (e.g. undecanoate) and dicarboxylic (e.g. decanedioate) medium chain fatty acids. 28 metabolites were significantly elevated in the presence of an impaired eGFR. There were 12 metabolites that were associated with both, albuminuria and eGFR.

		ACR ↑		eGFR ↓		ACR ↑ and eGFR ↓
	n [80%]	protection	risk	protection	risk	risk
Amino Acid	121	6	14	0	17	6
Carbohydrate	24	2	1	0	3	1
Lipid	167	13	10	0	1	0
Nucleotide	16	2	1	0	1	3
Other	55	3	3	0	6	2
Total	383	26	29	0	28	12



Conclusions: Metabolomic signatures associated with albuminuria and renal function impairment in diabetic kidney disease are uncoupled to a major degree. Our study suggests that medium chain fatty acids may play a protective role against albuminuria in T1D subjects.

Association between Soluble Klotho and Change in Kidney Function: The Health ABC Study

David A. Drew,[1] Ronit Katz,[2] Stephen Kritchevsky,[3] Joachim H. Ix,[4] Michael Shlipak,[5] Orlando M. Gutierrez,[6] Anne B. Newman,[7] Andrew N. Hoofnagle,[2] Linda F. Fried,[8] Mark J. Sarnak.[1] *[1]Tufts Medical Center; [2]U. of Washington; [3]Wake Forest; [4]UCSD; [5]UCSF; [6]UAB; [7]U. of Pittsburgh; [8]VA Pittsburgh.*

Background: Chronic kidney disease (CKD) is a condition of soluble klotho deficiency. Despite associations between low soluble klotho and higher degrees of oxidative stress and fibrosis, conditions that promote kidney damage, the longitudinal association between soluble klotho levels and change in kidney function has not been well studied.

Methods: Serum soluble α-klotho was assayed in 2,496 participants within the Health Aging and Body Composition Study, a cohort of well-functioning older adults. Kidney function was determined by cystatin C at baseline and years 3 and 10. Associations between baseline soluble klotho levels and rapid decline in kidney function (defined as either estimated glomerular filtration rate (eGFR) decline of greater than 30% or decline in eGFR greater than 3 ml/min/year) and incident CKD (incident eGFR < 60 ml/min/1.73 m^2 and at least 1 ml/min/year decline) were evaluated. Models were adjusted for demographics, baseline eGFR, UACR, comorbidity, and measures of mineral metabolism including FGF-23.

Results: Mean (SD) age was 75 years (3), with 52% female, and 38% African American. Median klotho level was 630 pg/ml (25^{th} – 75^{th} = 477 – 817 pg/ml). In fully adjusted continuous models, each two fold higher klotho had significant associations with lower odds of rapid decline in kidney function (30% decline: OR = 0.78 [0.66, 0.93] and > 3 ml/min/year decline: OR = 0.85 [0.73, 0.98]) but was not significantly associated with incident CKD (IRR = 0.90 [0.78, 1.04]).

Table 1. Association of the doubling of Klotho with kidney function outcomes in the Health ABC Study

Kidney Function Outcomes	Total N	N with outcome	Model 1 OR (95% CI)	Model 2 OR (95% CI)	Model 3 OR (95% CI)	Model 4 OR (95% CI)
> 30% decline in eGFR	2496	405	0.82 (0.69, 0.97)	0.81 (0.68, 0.97)	0.78 (0.65, 0.93)	0.78 (0.66, 0.93)
>3 ml/min/yr decline in eGFR	2496	702	0.92 (0.80, 1.07)	0.87 (0.75, 1.01)	0.84 (0.72, 0.97)	0.85 (0.73, 0.98)
Incident CKD	1914	536	0.90 (0.79, 1.02)	0.89 (0.77, 1.01)	0.89 (0.77, 1.02)	0.90 (0.78, 1.04)

Incident CKD = incident eGFR < 60 ml/min/1.73m^2 and at least 1 ml/min/year decline. Incident CKD group excludes those with eGFR < 60 ml/min/1.73m^2 at baseline

Model 1 = unadjusted analysis.
Model 2 = adjusted for demographics and baseline eGFR.
Model 3 = M2 + diabetes, cardiovascular disease, hypertension, and UACR.
Model 4 = M3 + calcium, phosphorus, PTH, and FGF-23.

Conclusions: Higher soluble klotho concentrations are independently associated with a lower risk of decline in kidney function. Future studies should replicate these results in those with advanced CKD and evaluate the mechanism underlying these findings.

TH-OR017

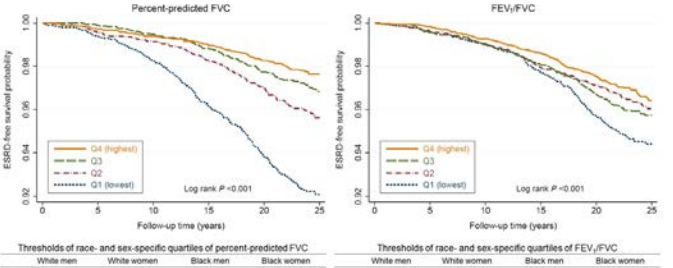
Lung Function and Incident Kidney Disease: The Atherosclerosis Risk in Communities (ARIC) Study

Keiichi Sumida,[1,2,3] Lucia Kwak,[1] Morgan Grams,[1] Kunihiro Yamagata,[2] Csaba P. Kovesdy,[3] Josef Coresh,[1] Kunihiro Matsushita.[1] *[1]Johns Hopkins Univ, Baltimore, MD; [2]Univ of Tsukuba, Ibaraki, Japan; [3]Univ of Tennessee Health Science Center, Memphis, TN.*

Background: Reduced lung function is associated with various clinical outcomes like cardiovascular disease. Little is known about its association with incident ESRD and CKD.

Methods: In 14,946 ARIC participants aged 45-64 years at baseline (1987-89), we examined the associations of race- and sex-specific quartiles of percent-predicted forced vital capacity (FVC) and the proportion of forced expiratory volume in 1 second in FVC (FEV_1/FVC) with subsequent risk of ESRD (initiation of dialysis therapy, transplantation, or death due to CKD) and CKD (ESRD, ≥25% decline in eGFR reaching <60 mL/min/1.73 m^2, or CKD-related hospitalizations) through 2012, using Kaplan-Meier method and Cox proportional hazards models with adjustment for potential confounders.

Results: During 25 years of follow-up, 526 and 3,704 cases developed ESRD and CKD, respectively. The incidence of ESRD was higher in those with lower percent-predicted FVC and FEV_1/FVC (Figure). The adjusted hazard ratio (HR) [95% CI] of incident ESRD for the lowest (vs. highest) quartile was 1.72 [1.31-2.26] for percent-predicted FVC and 1.33 [1.03-1.73] for FEV_1/FVC. Compared with normal lung function pattern, mixed pattern (3.4% of participants with percent-predicted FVC <80% and FEV_1/FVC <70%) demonstrated the highest adjusted HR of ESRD (1.97 [95% CI, 1.36-2.85]), followed by restrictive (1.77 [1.35-2.31] in 4.8% with percent-predicted FVC <80%) and then obstructive (1.28 [1.01-1.62] in 18.9% with FEV_1/FVC <70%). Similar associations were seen with incident CKD.



Thresholds of race- and sex-specific quartiles of percent-predicted FVC

	White men	White women	Black men	Black women
Q4	≥108.0	≥114.4	≥103.8	≥110.1
Q3	98.9 to <108.0	105.0 to <114.4	94.9 to <103.8	99.5 to <110.1
Q2	90.1 to <98.9	95.1 to <105.0	85.3 to <94.9	89.1 to <99.5
Q1	<90.1	<95.1	<85.3	<89.1

Thresholds of race- and sex-specific quartiles of FEV_1/FVC

	White men	White women	Black men	Black women
Q4	≥78.2	≥79.3	≥80.7	≥82.0
Q3	74.0 to <78.2	75.7 to <79.3	76.5 to <80.7	78.5 to <82.0
Q2	68.6 to <74.0	71.5 to <75.7	70.9 to <76.5	73.8 to <78.5
Q1	<68.6	<71.5	<70.9	<73.8

Conclusions: Reduced lung function, particularly lower percent-predicted FVC, is independently associated with CKD progression.

Funding: Other NIH Support - NHLBI

TH-OR018

A Peptide Transporter 2 (PEPT2) Gene Variant Predicts the Severity of Porphyria-Associated Chronic Kidney Disease Nicolas Pallet,[1] Alexandre Karras,[1] Eric Thervet,[1] Hervé Puy.[2] *[1]Hôpital Européen Georges Pompidou; [2]Centre Français des Porphyries.*

Background: CKD occurs in the majority of patients with AIP (Acute Intermittent Porphyria). During AIP, d-aminolevulinc acid (ALA) is excreted in urine, where it promotes apoptosis of proximal tubular cells, leading to tubulointerstitial damage. The peptide transporter 2 (PEPT2, also known as SLC15A2) is expressed by renal proximal tubular cells and mediates the reabsorption of ALA. A functional single nucleotide variant is associated with a lower affinity of the transporter for ALA.

Methods: To test if *PEPT2* variants impact the severity of AIP induced CKD, we follow-up a cohort of 122 patients with AIP for 10 years. *PEPT2* has been genotyped for the T/C substitution at the position 1048 in exon 13, and the T/C substitution at position 1225 (exon 15) (total linkage disequilibrium). The allelic frequency of the variants was 0.53, and the distribution was in accordance with the Hardy Weinberg equilibrium.

Results: Carriers of the *PEPT2*1*1* genotype experienced significantly worse renal function compared to **2* carriers (54.4±1, 66.6±2. and 78.1±3.8 ml/min/1.73m^2, p=0.0004). eGFR loss was -11 ml/min/1.73m^2 over the follow-up period for *PEPT2*1/*1* carriers, compared to -2.4 ml/min/1.73m^2 for the *PEPT2*1*2* genotype *and* +3.4 ml/min/1.73 m^2 for *PEPT*2*2* patients (p=0.0016). During the follwo-up, incident renal dysfunction (defined by eGFR<60 ml/min/1.73m^2) was diagnosed in up to 20% *PEPT2*1*1* patients, 14% of the *PEPT2*1*2* and 0% of the *PEPT2 *2*2* (p=0.007). At the end of the follow-up, 68% of the *PEPT2*1*1* had eGFR<60 ml/min/1.73m^2 compared with 37 % of the *PEPT2*1*2,* and 15% of the *PEPT2*2*2* (p=0.0002). In multiple regression models, *PEPT2*1*1* genotype remained significantly associated with eGFR<60 ml/min/1.73m2, with an odds ratio of 10.7. Losartan, a specific inhibitor of PEPT2, reduces ALA intracellular accumulation and inhibits ALA-induced apoptosis in proximal tubular cells in culture.

Conclusions: PEPT2 is critical the severity of AIP-induced CKD and is a potential therapeutic target. Since PEPT2 transports peptide-like molecules such as antiviral nucleoside prodrugs, it may represent a susceptibility factors for the nephrotoxicity of these drugs.

TH-OR019

Glycoprotein A (GlycA), a Pro-Inflammatory Marker of Protein Glycosilation, Is Associated to Albuminuria Independently of Cardiovascular Risk Factors and C-Reactive Protein: Results from ELSA-Brasil Silvia M. Titan,[1] Roberto Pecoits-Filho,[2] Isabela M. Bensenor,[3] Paulo Lotufo.[3] *[1]Nephrology Div, Faculty of Medicine, Sao Paulo Univ, Sao Paulo, Brazil; [2]School of Medicine, Pontifícia Univ Católica do Paraná, Curitiba, Paraná, Brazil; [3]Epidemiological and Clinical Research Center, Univ Hospital, Sao Paulo Univ, Sao Paulo, Brazil.*

Background: Systemic inflammation has been implicated in several chronic diseases. GlycA is a new nuclear mass ressonance (NMR) spectroscopy-derived biomarker of systemic inflammation that reflects protein glycosilation. We evaluated the role of GlycA in CKD, using albuminuria as a surrogate marker.

Methods: The association between GlycA, measured by NMR, LabCorp, (Raleigh, NC) and overnight 12h-albuminuria was evaluated among 5050 participants from the Sao Paulo site of the Brazilian Longitudinal Study of Adult Health (ElSA-Brasil).

Results: GlycA was higher among older, women, smokers, alcohol abstemious, obese and in those with diabetes, hypertension or dyslipidemia. In addition, albuminuria was positively associated with GlycA. In linear regression, glycA was significantly associated to log albuminuria (B 0.0008; 95%CI 0.0007–0.0009, P<0.0001), remaining significant after adjustment for age, sex, diabetes, SBP, smoking, alcohol and lipids. Importantly, the association between GlycA and albuminuria remained significant after hsCRP was added to the model. In logistic regression, GlycA was positively related to the risk of being micro or macroalbuminuric (versus normoalbuminuric), even after adjustments including hsCRP (OR 1,008, 95%CI 1,005–1,010, p<0,0001). By repeating this model with a stepwise procedure, GlycA was left in the model, while hsCRP was not. In the ROC curve, GlycA had a higher AUC in comparison to hsCRP (p=0,06, for association to micro or macroalbuminuria).

Conclusions: In conclusion, the present study demonstrates that GlycA is associated with albuminuria, independently of other major risk factors for CKD progression, including (and with a stronger association than) hsCRP. Our results suggest that GlycA may be an interesting novel marker of CKD progression, through its protein glycosylation-induced inflammation properties.

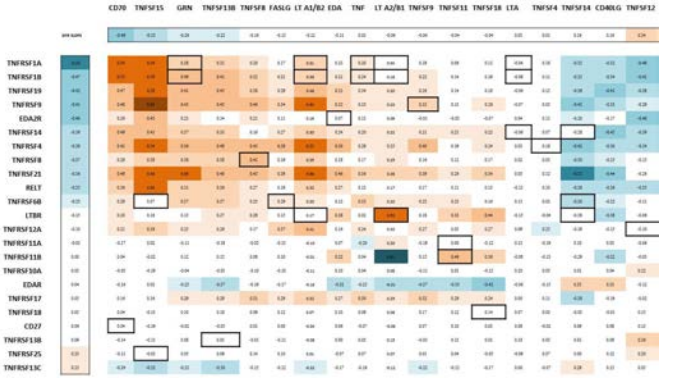
Multiple Proteins of TNF Superfamily Contribute to Progression to ESRD in Diabetes in a Global Profiling Study Monika A. Niewczas,[1] John J. Tsay,[1] Adam Smiles,[1] Melissa Major,[1] Joseph V. Bonventre,[2] Andrzej S. Krolewski.[1] *[1]Genetics and Epidemiology, Joslin Diabetes Center, Harvard Medical School, Boston, MA; [2]Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: We previously showed, using a targeted approach, that Tumor Necrosis Factor Receptors 1 & 2 (TNFRs) are robust predictors of renal function decline in diabetes. Here, we aimed to determine a comprehensive inflammatory signature associated with risk of ESRD using global profiling.

Methods: Our study group included 219 Joslin Kidney Study participants with T1D, proteinuria and CKD Stage 3 that were followed up to 12 years. Non-Progressors (eGFR decline ≤ 2.5 ml/min.1.73m^2 /yr) accounted for 34% of the cohort (n=76), whereas Rapid Progressors to ESRD (eGFR decline > 5 ml/min/1.73m^2 /yr) comprised 38% (n=84). Proteomic profiling of inflammatory proteins (n=210) was performed on an aptamer-based platform (Somascan).

Results: In the multivariate analysis 38 proteins differed between Progressors and Non-Progressors (Bonferroni corrected p value <0.05). A roster of significant proteins was enriched with TNF family members that included receptors: TNFR1 and TNFR2, TAJ, DR6, and ligands TWEAK or TNFSF15. TNFα and β were not associated with the outcome. Correlations among TNF superfamily members (figure: orange to blue) did not correspond to their known ligand-receptor interactions (figure: black open squares).



Conclusions: Our global proteomic profiling study confirmed associations of TNFRs as robust predictors of renal function decline in T1D. Further, it revealed that TNF superfamily members accounted for a major part of the inflammatory signature contributing to the progression of diabetic nephropathy. Mechanisms regulating circulating levels of this family and their contributions to the disease progression urgently need to be determined.

TH-OR021

Akt Is a Multifaceted Protein in Albumin Endocytosis Elif Erkan, Cory S. Newland. *Pediatric Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Proteins involved in endocytosis can elicit cell signaling events. Albumin in the glomerular filtrate is retrieved by receptor mediated endocytosis (RME) in proximal tubule epithelial cells. We reported a link between albumin endocytosis and cell signaling protein, protein kinase B (Akt). Akt1 and Akt2 both mediate albumin endocytosis in proximal tubule epithelial cells in cell culture. We propose that Akt mediates albumin endocytosis through its interaction with clathrin associated sorting proteins.

Methods: Inhibition of Akt1 and Akt2 in proximal tubule epithelial cells is accomplished by generation of Akt1/2 lox/lox SGLT2 cre mouse. Urinary albumin and creatinine excretion is measured with 24-hour urine collection. Renal expression of megalin, cubilin and clathrin HC is evaluated by western blotting and immunofluorescence. Protein-protein interactions are assessed by coimmunoprecipitation experiments.

Results: Global knock-out (KO) of Akt1 or Akt2 causes down regulation of megalin and cubilin expression in the proximal tubule epithelial cells associated with increased urinary albumin excretion and low molecular proteinuria. In order to eliminate systemic effects of global inhibition Akt1 and Akt2, we generated a mouse with targeted deletion of Akt1 and Akt2 (Akt1/2lox/lox SGLT2 cre) in proximal tubule epithelial cells. Akt1/2lox/lox SGLT2 cre mice displayed decreased expression of clathrin-heavy chain (clathrin-HC), megalin and cubilin in association with significant albuminuria. Coimmunoprecipitation experiments revealed an interaction between clathrin-HC, μ2 subunit of adaptor protein2 (AP2) and Akt. Furthermore KO of Akt1 and Akt2 in human proximal tubule epithelial cells resulted in a decrease in clathrin coated pits.

Conclusions: We conclude that Akt links cell signaling events to albumin endocytosis in proximal tubule epithelial cells. We propose that Akt orchestrates albumin endocytosis by recruiting clathrin to the plasma membrane and inducing formation of clathrin-coated pits. Potentially phosphorylation of clathrin HC by Akt can initiate this event. We postulate that perturbed expression of pro-survival protein Akt to limit endocytosis has implications in induction of tubulointerstitial injury in proteinuric states.

TH-OR022

Mixed Lineage Kinase Domain-Like (MLKL) Mediates Necroptosis in Humans Nina Himmerkus,[1] Hannes Olauson,[2] Ina Maria Schiessl,[3] Jan U. Becker,[4] Karl Kunzelmann,[3] Markus Bleich,[1] Joel M. Weinberg,[5] Andreas Linkermann.[6] *[1]Inst of Physiology, Christian-Albrechts-Univ, Kiel, Germany; [2]Div of Renal Medicine, CLINTEC, Karolinska Inst, Stockholm, Sweden; [3]Inst for Physiology, Univ of Regensburg, Regensburg, Germany; [4]Inst of Pathology, Univ Hospital of Cologne, Cologne, Germany; [5]Dept of Internal Medicine, VA Ann Arbor Healthcare System, Univ of Michigan, Ann Arbor, MI; [6]Clinic for Nephrology and Hypertension, Christian-Albrechts-Univ, Kiel, Germany.*

Background: Necrosis is a pathophysiological hallmark of diseases including myocardial infarction, stroke, sepsis, acute tubular necrosis, autoimmunity and cancer. Necroptosis is a form of regulated necrosis mediated by receptor-interacting protein kinase 3 (RIPK3). The pseudokinase mixed-lineage kinase domain like (MLKL), a RIPK3 target, is required for necroptosis execution *in vitro*, but the role of MLKL *in vivo* has not been investigated in preclinical disease conditions or humans.

Methods: *In vivo* mouse models, *ex vivo* investigation of freshly isolated nephron segments, human kidney transplant biopsies.

Results: We demonstrate that MLKL-deficient mice are protected from all necroptosis-related *in vivo* models such as TNFa-mediated severe inflammatory response syndrome (SIRS) and renal ischemia-reperfusion injury (IRI). Freshly isolated perfused proximal tubules of MLKL-deficient mice showed reduced single cell death events and a delayed onset in synchronized tubular necrosis. Moreover, intravital microscopy revealed a strongly elevated peritubular capillary blood flow in MLKL-deficient mice in comparison to wild type littermates. In matched human kidney transplant biopsies, the activated form of MLKL (pMLKL) was detected in endothelial cells within two hours after transplantation and in parenchymal cells within four days.

Conclusions: In summary, MLKL deficiency protects mice from renal damage by i) the prevention of parenchymal necroptosis and ii) an increase in capillary blood flow. In addition, this is the first detection of activation of the necroptosis pathway in humans.

TH-OR023

Pik3c3 Mediates Nephron Loss-Induced Compensatory Nephron Hypertrophy Ting Liu,[1] Jinxian Xu,[1] Benjamin D. Humphreys,[2] Caihong Dai,[1] Jian-Kang Chen.[1] *[1]Cellular Biology & Anatomy and Medicine, Medical College of Georgia at Augusta Univ, Augusta, GA; [2]Renal Div, Dept of Medicine, Washington Univ School of Medicine, St. Louis, MO.*

Background: Nephron loss stimulates the residual nephrons to undergo compensatory nephron hypertrophy (CNH), which is implicated in progressive nephron damage. Activation of the mechanistic (formerly mammalian) target of rapamycin complex 1 (mTORC1) mediates uninephrectomy (UNX)-induced CNH. We recently observed class 3 phosphatidylinositol 3-kinase (Pik3c3) activation in the remaining kidney after UNX. However, whether Pik3c3 activation is essential for mTORC1 activation and CNH remains undefined.

Methods: We created a *Pik3c3*-floxed mouse and crossed it to *SLC34a1.CreER^{T2}* mice to generate tamoxifen-inducible proximal tubule-specific *Pik3c3* knockout (*KO*) mice, which have a genotype of *Pik3c3$^{flox/flox}$;SLC34a1.CreER^{T2}*(+). Gender-matched *Pik3c3$^{flox/flox}$;CreER^{T2}*(-) littermates were used as controls (*Ctrl*) mice.

Results: Upon induction with tamoxifen (120 mg/kg by I.P. at 6 weeks of age), *KO* mice but not *Ctrl* mice showed Pik3c3 deletion only in the proximal tubules (mainly in the S1 and S2 segments). The *KO* mice did not exhibit any apparent phenotype, with a mean body weight and kidney-to-body weight ratio similar to those of *Ctrl* littermates. It is known that in response to UNX, all components of the nephron may hypertrophy to a certain degree but the proximal tubule undergoes the most prominent hypertrophy. Interestingly, when subjected to UNX, *KO* mice developed significantly less renal hypertrophy compared to *Ctrl* mice, revealed by UNX-induced increases in kidney-to-body weight ratio (*Ctrl*: 33.15±1.97 vs. *KO*: 15.81±2.82%; $p<0.001$, $n=7$) and protein-to-DNA ratio (*Ctrl*: 25.00±4.01 vs. *KO*: 9.78±2.88%; $p<0.05$, $n=7$). Signaling studies with immunoblotting and immunostaining indicated that Pik3c3 knockout inhibited UNX-induced mTORC1 activation in the proximal tubules, particularly in the S1 and S2 segments.

Conclusions: This study provides the first genetic evidence of Pik3c3 activation as a major mechanism mediating nephron loss-induced residual nephron hypertrophy upstream of mTORC1 activation.

NADPH Oxidase 4 Deficiency Increases Acute Renal Injury and Tubular Apoptosis during Ischemic Reperfusion Injury Romain Dissard, Stellor Nlandu Khodo, Pierre-Yves F. Martin, Sophie M. De Seigneux. *Dept of Medicine Specialties, Service of Nephrology, Univ Hospital of Geneva, Geneva, Switzerland.*

Background: NADPH oxidase 4 (NOX4) is highly expressed in kidney proximal tubular cells. NOX4 constitutively produces hydrogen peroxide, which may regulate important pro-survival and anti-oxidant pathways, or play a deleterious role. Renal ischemia reperfusion injury (IRI) is a classical model mimicking human ischemic acute tubular necrosis. We hypothesized that endogenous NOX4 may play a protective role in kidney IRI.

Methods: Wild type (WT) and NOX4 Knock-out (KO) animals were subjected to sham or 22 minutes bilateral renal artery ligation and sacrificed 24 hours after reperfusion. Stable renal tubular cells lines with transient NOX4 silencing and mouse embryonic fibroblasts issued form WT and NOX4KO mice were used for in vitro experiments.

Results: In WT animals subjected to IRI, NOX4 protein expression increased after 24 hours. Compared to WT, NOX4 KO mice displayed worst renal function, more severe tubular apoptosis, decreased Bcl-2 expression and higher histological damage scores. Activation of the NRF2 pathway was decreased in NOX4 KO mice in response to IRI. This was related to decreased baseline KEAP1 oxidation leading to decreased NRF2 stabilization. This also resulted in decreased glutathione levels at baseline. *In vitro* silencing of NOX4 in cultured tubular cells and cells derived from NOX4 KO mice showed an enhanced propensity to apoptosis, with reduced expression of NRF2, glutathione content, decreased mitochondrial membrane potential and Bcl-2 expression. Overexpression of a constitutively active form of NRF2 (caNRF2) in NOX4 depleted cells rescued most of this phenotype in cultured cells, implying that NRF2 regulation by ROS issued from NOX4 may play an important role in its anti-apoptotic property in kidney tubular cells.

Conclusions: NOX4 protein displays anti-apoptotic properties in renal tubular cells subjected to injury. NOX4 deletion aggravates IRI lesions and renal function in mice. Baseline NRF2 regulation by NOX4 may play an important role in this phenotype, whereas other pathways are not excluded. NOX4 inhibition may aggravate tubular injury in stress conditions.

Bone Marrow Is Central to the Severity of Gadolinium-Associated Systemic Fibrosis Brent Wagner,[1,2] Chunyan Tan,[2] Viktor Drel,[2] Jeffrey L. Barnes,[2] Yves C. Gorin,[2] Doug Yoon Lee.[2] *[1]Medical Service, South Texas Veterans Health Care System, San Antonio, TX; [2]Medicine (Nephrology), Univ of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Gadolinium-based magnetic resonance imaging contrast induces systemic fibrosis in humans and rodents. Cumulative doses correlate with severity. Bone marrow–derived fibrocytes accumulate in the dermis. Whether target organs liberate chemokines to recruit these cells or if they are stimulated to home to the affected tissue is unknown.

Methods: Transgenic (tagged) donor rats were treated with gadolinium–based contrast. Bone marrow was obtained from the treated animals and age–matched controls. Rats with subtotal nephrectomies were lethally–irradiated followed by salvage transplant with either the contrast–naïve or contrast–exposed bone marrow. Bone marrow recipients were randomized into control or contrast treatment.

Results: Dermal fibrosis was induced by contrast. This was exacerbated in recipients of contrast–exposed marrow. Fibronectin, the C-C chemokine receptors 2 and 7, and oxidative stress were all increased in skin from the contrast–treated animals—all parameters more severe in recipients of contrast–treated animals. The respective ligands, monocyte chemoattractant protein and C-C motif ligand 19, were both elevated in the skin from contrast–treated animals. When a C-C chemokine receptor inhibitor was co-administered with contrast, the severity of skin disease (including dermal cellularity) was reduced. Neutralizing antibody to monocyte chemoattractant protein 1 suppressed myeloid infiltration (using an *in situ* skin punch biopsy/labeled bone marrow co-culture assay).

Conclusions: These data demonstrate that the dermal liberation of specific chemokines recruits circulating myeloid cells. The systemic fibrosis is augmented by bone marrow exposure to contrast. This explains why multiple exposures correlate with severity. Furthermore, bone marrow has a memory of gadolinium exposure; these findings have serious clinical ramifications.

A Podocyte-Specific Knockout of the DNA Repair Rene Ercc1 Resembles Podocyte Aging and Leads to Proteinuria and Focal Segmental Glomerulosclerosis Fabian Braun,[1] Roman Aaron Akbar,[1] Björn Schumacher,[2] Bernhard Schermer,[1,2,3] Wilhelm Bloch,[4] Thomas Benzing,[1,2,3] Christine E. Kurschat.[1,2] *[1]Dept II of Internal Medicine and Center for Molecular Medicine Cologne, Univ of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, Univ of Cologne, Cologne, Germany; [3]Systems Biology of Ageing Cologne, SyBaCol, Univ of Cologne, Cologne, Germany; [4]Dept of Molecular and Cellular Sport Medicine, German Sport Univ Cologne, Cologne, Germany.*

Background: Chronic kidney disease is common among elderly patients. Yet, models investigating this functional decline are lacking. In a previous study, we identified a progeria mouse model of Ercc1-deficiency to exhibit expression profiles similar to those of glomerular aging in wild type mice. Ercc1 facilitates the 5' incision around interstrand cross links and other bulky DNA lesions in the nucleotide excision repair pathway. Thus, a podocyte-specific knockout of Ercc1 may help us gain new insights into glomerular and podocyte aging processes.

Methods: Ercc1$^{flox/flox}$ mice were bred with mice expressing Cre recombinase under the podocin promoter. At 7, 9, 11 and 13 weeks of age weight, urine and serum were analyzed. Kidneys were fixed in paraformaldehyde and embedded in paraffin, fresh-frozen in OCT, or prepared for electron microscopy.

Results: Ercc1^{pko} show no developmental abnormalities but die prematurely at week 13-18. 7 week old kidneys show no morphological changes in light or electron microscopy.

At 9 weeks of age foot process effacement and focal segmental glomerular sclerosis occur. This phenotype is aggravated by week 11. End-stage kidneys reveal sclerosed glomeruli, interstitial fibrosis with tubular atrophy and tubular protein casts. Cultured podocytes subjected to DNA damage exhibited an increase of mTOR phosphorylation and mTOR-Complex1 activation. This phenotype was rescued by rapamycin and was observed in both Ercc1^{pko} and 96 week old wild type glomeruli.

Conclusions: Our study underlines the critical role of podocyte DNA maintenance. Furthermore the podocyte specific knockout of Ercc1 depicts accelerated features of the podocyte aging process and will prove a crucial tool to investigate kidney aging.

KIM-1 Mediates the Uptake of Exosomes and Transfer of MHC II

Bart J. Kramers,[1] Craig R. Brooks,[1] Dhruti P. Chen,[2] Alberto Lazaro Fernandez,[3] Joseph V. Bonventre.[1] *[1]Renal Div, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Medicine, Univ Hospitals Case Medical Center, Cleveland, OH; [3]Renal Physiopathology, Hospital G.U. Gregorio Marañón, Madrid, Spain.*

Background: Urinary exosomes (EXO) are lipid membrane bound structures that mediate intercellular signaling through the transfer of proteins, miRNA and other factors. Kidney injury molecule 1 (KIM-1) acts as a phosphatidylserine (PS) receptor, inducing the uptake of apoptotic cells and necrotic debris. We hypothesize that KIM-1 acts as an endocytosis receptor, taking up EXO containing PS and mediating the intercellular exchange of signaling molecules, such as MHC II.

Methods: LLC-PK1 cells expressing KIM-1 (PK1-KIM1) and cells expressing empty vector (PK1-pcDNA) were incubated with liposomes composed of PS and fluorescently labeled phosphatidylcholine (PC) or EXO isolated from LLC-PK1 cells, mouse dendritic cells (DC) or human urine by ultracentrifugation. EXO were fluorescently labeled with CytoTracker dye or MHC II-GFP. Uptake was quantified by measuring fluorescence intensity and flow cytometry. EXO were characterized by western blot and electron microscopy. MHC-II levels in urinary EXO from healthy subjects and CKD patients were determined by western blot.

Results: PK1-KIM-1 took up significantly more liposomes than PK1-pcDNA. EXO derived from LLC-PK1 cells, DCs and urine were positive for EXO markers HSP70, Flot-1 and TSG101. The diameter of EXO were between 30-150 nm. KIM-1 expressing cells took up significantly more EXO than empty vector expressing cells independent of the source of EXO. Urinary EXO from CKD patients were found to carry MHC II while EXO from healthy subjects were MHC II negative. We found the transfer of MHC II to primary PTCs to be greater in cells expressing KIM-1 after incubation with DC-derived EXO.

Conclusions: KIM-1 is a PTC receptor for EXO. Urinary EXO from CKD patients carried MHC-II, while urinary EXO in healthy subjects did not. MHC-II on EXO can be transferred to and presented by KIM-1 positive cells, suggesting EXO may serve to link DC activation to PTC MHC II expression and antigen presentation cells in inflammatory settings.

RTN1A Is a Key Mediator for Progression of Acute Kidney Injury to Chronic Kidney Disease through Increased Endoplasic Reticulum Stress

Ying Fan,[1] Wenzhen Xiao,[2] Kyung (Kim) Lee,[2] Jiejun Wen,[1] Jing Zhang,[1] Niansong Wang,[1] John C. He.[2] *[1]Dept of Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Dept of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: A large body of evidence suggests that severe acute kidney injury (AKI) could progress to chronic kidney disease (CKD). ER stress has been considered as a key pathological process leading to tubular cell injury in AKI. However, it remains unclear whether sustained and maladaptive ER stress contributes to the progression from AKI to CKD. Recently, we reported that RTN1A expression is highly associated with the progression of human kidney disease and increased RTN1A expression in renal tubular epithelial cells (RTECs) induces apoptosis and renal fibrosis in the UUO mice through induction of ER stress. Based on these findings, we hypothesized that RTN1A mediated the progression of AKI to CKD through induction of maladaptive ER stress in RTECs.

Methods: To test this, we generated doxycycline-inducible RTN1A RTEC-specific knockdown and over expression mice. Meanwhile, we studied the expression of RTN1A and other ER Stress markers in kidney biopsies of 50 AKI (ATN and AIN) patients at various disease stages.

Results: We found that induction of RTN1A knockdown in RTECs had reduced ER stress and apoptosis of RTECs at the AKI stage and minimal renal fibrosis at the late stage in mice with folic acid nephropathy (FAN) or aristolochic acid nephropathy (AAN). In contrast, induction of RTN1A overexpression in RTECs at the AKI stage resulted more ER stress and apoptosis of RTECs at the AKI stage and more renal fibrosis at the late stage in these mice with FAN or AAN. Then, we validated that in patients with AKI there was also a significant association between renal expressions of RTN1A and ER stress markers (Phosphor-PERK and CHOP). Interestingly, we found in 10 patients with progression of AKI to CKD, RTN1A and CHOP expressions were significantly higher than those without progression to CKD.

Conclusions: In conclusion, our data suggest that RTN1A is a key molecule mediating the progression of AKI to CKD through induction of sustained and maladaptive ER stress in renal tubular epithelial cells.

Proximal Tubule Deletion of Dynamin Related Protein 1 Protects against Renal Ischemia-Reperfusion Injury

Heather M. Perry,[1] Hong Ye,[1] Liping Huang,[1] David Kashatus,[2] Mark D. Okusa.[1] *[1]Dept of Medicine, Div of Nephrology, Center for Immunity, Inflammation and Regenerative Medicine, UVA; [2]Dept of Microbiology, Immunology and Cancer Biology, UVA, Charlottesville, VA.*

Background: Mitochondrial dysfunction plays a crucial role in the pathogenesis of kidney disease. A key mediator of mitochondrial function is the GTPase, dynamin related protein 1 (DRP1). Pharmacological inhibition of DRP1 in mice has shown to protect against ischemic mediated AKI. Yet, the specific cellular target of DRP1 inhibition in AKI has not been determined. Proximal tubule cells are highly dependent on mitochondrial function. Thus, we hypothesize that the genetic deletion of DRP1 in proximal tubules (PT) protects against renal ischemia-reperfusion injury (IRI) in mice.

Methods: *PepckCre+ Drp1$^{f/f}$* (PT-Drp1 KO, n = 9) and littermate control *PepckCre- Drp1$^{f/f}$* (n = 8) mice were subjected to 26' of bilateral renal ischemia or sham operation. After 24hr of reperfusion, plasma was collected to quantify PCr as a measure of kidney function and kidneys were prepared for assessment of acute tubular necrosis (ATN) by H&E staining, TUNEL and Ki67 positivity by immunofluorescence, quantification of mRNA transcripts by RT-qPCR and neutrophils (CD45$^+$CD11b$^+$Ly6G$^+$) by flow cytometry.

Results: PT-Drp1 KO mice had attenuated IRI-induced PCr levels compared to control mice (1.44 vs. 0.35 mg/dl respectively, $p < 0.001$). Consistent with preserved kidney function, PT-drp1 KO mice had attenuated renal injury indicated by reduced ATN and transcript levels of tubule injury markers *Kim1* and *Ngal* compared to controls. Lastly, PT-Drp1 KO mice had reduced renal inflammation characterized by fewer neutrophils and transcript levels of *Il6* and *Ccl2* compared to control mice. Mechanistically, kidneys from PT-Drp1 KO mice had fewer TUNEL+ and increased Ki67+ epithelial cells.

Conclusions: Loss of PT DRP1 directs epithelial cells from IRI induced cell death pathways to proliferation, enhancing renal recovery. Recovered tubules prevent tubular damage and subsequent necroinflammation. Targeting DRP1 and mitochondrial function may be a therapeutic strategy to divert PT cells from cell death to recovery pathways, mitigating AKI.

An Intracellular Matrix Metalloproteinase-2 Isoform Induces Tubular Regulated Necrosis: Implications for Acute Kidney Injury in the Elderly

David H. Lovett, Carla Speroni Ceron, Sunil Kumar Joshi, Shaynah Wanga, Joy Walker, Sang Heon Song. *Univ of California San Francisco.*

Background: Acute kidney injury (AKI) causes severe morbidity and mortality and chronic kidney disease (CKD). Mortality is particularly marked in the elderly and with pre-existing CKD. To date, therapeutic targets based models of AKI have failed to translate into preventative or therapeutic treatments. Oxidative stress is a common theme in models of AKI induced by ischemia/reperfusion injury (I/R/I) or sepsis. We recently characterized an intracellular isoform of matrix metalloproteinase-2 (MMP-2) induced by oxidative stress-mediated activation of an alternate promoter in the first intron of the MMP-2 gene. This generates an **N**-**t**erminal **t**runcated MMP-2 isoform (NTT-MMP-2) that is retained intracellularly and is localized to the mitochondria. Significantly, the NTT-MMP-2 isoform is expressed in the proximal tubules of older mice (14 months) and in models of CKD. We recently determined that NTT-MMP-2 is induced in human renal transplants with delayed graft function and that NTT-MMP-2 expression correlates with tubular epithelial cell injury, validating NTT-MMP-2 as a potential target.

Methods: To determine mechanism(s) of action, we generated proximal tubule cell-specific NTT-MMP-2 transgenic mice.

Results: While morphologically normal at the light microscopic level at 4 months, there was evidence for increased mitochondrial oxidative stress. Ultrastructure studies revealed foci of epithelial cell necrosis, loss of the mitochondrial permeability transition and mitophagy. To determine if NTT-MMP-2 expression enhances sensitivity to I/R injury, we performed limited unilateral I/R/I sufficient to induce mild tubular injury in wild type mice. In contrast, expression of the NTT-MMP-2 isoform resulted in a dramatic increase in tubular cell necrosis, inflammation and fibrosis. NTT-MMP-2 mice had enhanced expression of innate immunity genes and prolonged release of danger associated molecular pattern (DAMP) molecules.

Conclusions: We conclude that NTT-MMP-2 "primes" the kidney to enhanced susceptibility to I/R injury via induction of mitochondrial dysfunction. NTT-MMP-2 may be a novel AKI preventative or treatment target.

TH-OR031

Treatment of Myeloma Cast Nephropathy: A Randomized Trial Comparing Intensive Hemodialysis with High Cutoff or Standard High-Flux Dialyzers (The MYRE Study) Frank Bridoux,[1] Pierre-Louis Carron,[2] Eric Alamartine,[3] Marie-Noelle Peraldi,[4] Alexandre Karras,[5] Cecile M. Vigneau,[6] Alain Wynckel,[7] Nolwenn Rabot,[8] Christian Combe,[9] Sylvie Chevret,[10] Jean-Paul Fermand.[11] *[1]Nephrology, CHU Poitiers; [2]CHU Grenoble; [3]CHU Saint Etienne; [4]Hopital Saint Louis, Paris; [5]HEGP, Paris; [6]CHU Rennes; [7]CHU Reims; [8]CHU Tours; [9]CHU Bordeaux; [10]Biostatistics, Hopital Saint Louis, Paris; [11]Immunology, Hopital Saint Louis, Paris, France.*

Background: Multiple myeloma (MM) is often revealed by acute kidney injury (AKI) usually related to cast nephropathy (CN). Recovery of renal function is a key prognostic factor. With novel anti-myeloma agents, hemodialysis (HD) independence occurs in about 30% of patients (pts) with severe AKI, advocating for the use of additional strategies to rapidly remove serum monoclonal free light chains (FLC).

Methods: We designed a prospective randomized phase III trial to compare the HD independence rate in pts with inaugural severe AKI secondary to biopsy–proven CN, treated with intensive HD (8 sessions of 5 hours over the first 10 days, then thrice a week) using either high cutoff (HCO) or conventional high-flux dialyser. In both groups, pts received 21 day-courses of bortezomib and dexamethasone (BD) reinforced by cyclophosphamide after 3 cycles in the absence of hematological response.

Results: Between 2011 and 2015, 98 pts were randomized. One pt withdrew consent and 3 had main exclusion criteria. Baseline characteristics in the control arm (n=48) and HCO arm (n=46) were close, including similar high FLC levels (median 6,015 mg/L). HD independence was achieved in 33% and 43% (P=0.31) at 3 months, and in 37.5% and 60% (P=0.03) at 6 months in control and HCO arms, respectively. Rate of hematologic very good partial response or above at 3 months, based on FLC, was 48% in control and 59% in HCO arm (p=0.29). Tolerance of HD schedule and chemotherapy was acceptable in both arms. At 12 months, 10 and 8 pts had died, respectively.

Conclusions: This randomized trial demonstrates that in MM pts with CN and severe AKI treated with bortezomib-based chemotherapy, intensive HCO HD increases renal response rate at 6 months, compared to similar HD dose with conventional high-flux dialyzers.

TH-OR032

European Trial of Free Light Chain Removal by Extended Haemodialysis in Cast Nephropathy (EuLITE); Survival and Renal Outcomes Colin A. Hutchison,[2] Paul Cockwell,[1] Nils Heyne,[3] Katja C. Weisel,[3] Lesley B. Fifer,[1] Julian D. Gillmore,[4] Arthur R. Bradwell,[5] Mark Cook.[1] *[1]Queen Elizabeth Hospital, Birmingham, United Kingdom; [2]Hawke's Bay District Health Board, Hawke's Bay, New Zealand; [3]Univ of Tuebingen, Tuebingen, Germany; [4]National Amyloidosis Centre, Univ College London, London, United Kingdom; [5]Univ of Birmingham, Birmingham, United Kingdom.*

Background: Myeloma cast nephropathy (MCN) is caused by a pathogenic immunoglobulin serum free light chain (sFLC). High cut-off haemodialysis (HCO-HD) can remove large quantities of sFLC and retrospective uncontrolled clinical trials report better outcomes; however it is uncertain if these were associated with HCO-HD or novel chemotherapy regimens.

Methods: We carried out a prospective multi-centre RCT in patients with newly diagnosed MM and associated MCN who required acute dialysis, comparing HCO-HD to standard high flux (HF)-HD, and using bortezomib based chemotherapy. 90 patients were randomised and followed for 2-years. Results are reported as intention to treat (ITT).

Results: The groups were similar for demographics, myeloma type (light chain only vs intact Ig), and sFLC isotype. At 3 weeks sFLC levels were similar between groups. 24/43 patients (55.8%) in the HCO-HD group and 24/47 (51.6%) in the HF-HD group recovered renal function by 3 months (not significant, NS). There were more lung infections in the first 3-months in the HCO-HD group (12 vs 3, P=0.014). Overall recovery of renal function was 62%; 58.1% in the HCO-HD group, 66% in the HF-HD group (NS). Overall survival at 2-years was 24 (55.8%) in the HCO-HD group and 36 (76.6%) in the HF-HD group. 82.1% who became independent of dialysis were alive at 2 years compared to 41.2% who remained dialysis dependent (P<0.001). Following renal recovery there was no subsequent difference in eGFR between groups; overall median eGFR (range) at 2-years was 34 ml/min/1.73m^2 (13-90).

Conclusions: In this RCT, HCO-HD compared to HF-HD did not improve outcomes in patients requiring acute dialysis for MCN.

Funding: Pharmaceutical Company Support - Baxter Gambro, Janssen, The Binding Site, Government Support - Non-U.S.

TH-OR033

Effects of Intensive SBP Lowering on Incident Chronic Kidney Disease (CKD) and Cardiovascular (CV) Outcomes in Non-CKD Subgroup in Systolic Blood Pressure Intervention Trial (SPRINT) Srini Beddhu, Michael V. Rocco, Robert D. Toto, Timothy Craven, Tom Greene, Alfred K. Cheung, Paul L. Kimmel, Paul K. Whelton. *For SPRINT Research Group.*

Background: The public health significance of the reported higher incidence of CKD with intensive SBP lowering in high-risk hypertensive adults without CKD in SPRINT is unclear.

Methods: In 6662 SPRINT participants without CKD (eGFR ≥ 60 ml/min/1.73 m^2) at baseline, the effects of intensive SBP control (goal <120 vs. standard <140 mm Hg) on incident CKD and the composite of CV outcome or all-cause death were examined. Incident CKD was defined as a >30% decrease in eGFR to a value <60 ml/min/1.73m^2. CV outcome was defined as the first occurrence of MI, ACS, stroke, heart failure, or CV death.

Results: Mean age was 66 ± 9 yrs, 34% were women and 34% were Black. Mean eGFR was 81 ±16 mL/min/1.73 m^2. The SBP difference between the two arms after 6 months of follow-up was 15±0.2 mm Hg. The slopes of eGFR were -5.42±0.50 (intensive) vs. 0.23±0.50 (standard) mL/min/1.73m^2 in the first 6 months (p<0.001). After 6 months, eGFR slopes were similar (-0.79±0.13 vs. -0.68±0.13; p=0.51). Numbers needed to treat for harm (NNTH) for incident CKD and the numbers needed to treat for benefit (NNTB) for CV event/death over the 3.26 yrs of median follow-up are summarized in Table.

Outcome	Intensive arm incidence*	Standard arm incidence*	Hazard ratio [95% CI]	% Absolute risk reduction (increase) [95% CI]	NNTB (NNTH) [95%CI]
Incident CKD	1.32 (140/10583)[$]	0.37 (40/10750)[$]	3.55[2.52, 5.11]	(3.01) [(3.78), (2.26)]	(34) [(45), (26)]
CV event or all-cause death	1.80 (192/10674)[$]	2.51(266/10604)[$]	0.72[0.60, 0.87]	2.17 [1.03, 3.69]	47 [27,97]
* events per 100 person years of follow-up, [$] (N events/ total years of follow-up)					

For each CV event/ death prevented, there were 1.4 incident CKD events (3.01/2.17). None in either arm reached ESRD.

Conclusions: As asymptomatic incident CKD is much more benign than CV event/ death, the risk of incident CKD appears to be outweighed by CV benefits. When the SPRINT intervention is adopted in routine clinical practice, the incidence and consequent prevalence of CKD will need to be determined over the long-term.

Folic Acid Therapy Delays the Progression of Chronic Kidney Disease: The Renal Substudy of the China Stroke Primary Prevention Trial (CSPPT) Xin Xu,[1] Xianhui Qin,[1] Youbao Li,[1] Yong Huo,[2] Fan Fan Hou.[1] *[1]Renal Div, Nanfang Hospital, Southern Medical Univ; National Clinical Research Center for Kidney Disease; [2]Dept of Cardiology, Peking Univ First Hospital.*

Background: The efficacy of folic acid therapy on renal outcomes has not been previously investigated in populations without folic acid fortification. This study was to test whether treatment with enalapril and folic acid is more effective in slowing renal function decline than enalapril alone among Chinese adults with hypertension.

Methods: A randomized, double-blinded clinical trial was conducted in 20 communities in Jiangsu province in China, enrolling 15104 eligible CSPPT participants with an eGFR≥30 ml/min/1.73m^2, including 1671 patients with CKD. Participants were randomized to receive a single tablet daily containing 10mg enalapril and 0.8mg folic acid (n=7545) or 10mg enalapril alone (n=7559). The primary outcome was progression of CKD, defined as a decrease in eGFR of ≥30% and to a level of <60 ml/min/1.73m^2 if the baseline eGFR was ≥60 ml/min/1.73m^2, or a decrease in eGFR of ≥50% if the baseline eGFR was <60 ml/min/1.73m^2; or ESRD. Secondary outcomes included a composite of the primary outcome and all-cause death, rapid decline in renal function, and rate of eGFR decline.

Results: Median followup was 4.4 years. There were 164 and 132 primary events in the enalapril group and the enalapril-folic acid group, respectively. Compared with the enalapril group, enalapril-folic acid group had a 21% reduction in the odds of the primary event (OR,0.79; 95%CI,0.62-1.00), and a slower rate of eGFR decline (1.28% vs 1.42% per year, P=0.02). Among the participants with CKD at baseline, folic acid therapy resulted in a significant reduction in the risks for the primary event (OR,0.44; 95%CI,0.26-0.75), rapid decline in renal function (0.67;0.47-0.96) and the composite event (0.62;0.43-0.90), and a 44% slower decline in renal function (0.96% vs 1.72% per year, P=0.0002). Among those without CKD at baseline, there was no between-group difference in the primary endpoint.

Conclusions: Enalapril-folic acid therapy, compared with enalapril alone, can significantly delay the progression of CKD among patients with mild to moderate CKD.

Funding: Government Support - Non-U.S.

TH-OR035

Effect of Folic Acid Supplementation on the New-Onset Proteinuria: New Insight from a Randomized Controlled Trial Youbao Li,[1] Xianhui Qin,[1] Binyan Wang,[1] Yong Huo,[2] Fan Fan Hou,[1] Xin Xu.[1] *[1]Nanfang Hospital, Southern Medical Univ; National Clinical Research Center for Kidney Disease; [2]Peking Univ First Hospital.*

Background: The efficacy of folic acid supplementation for the preventing the new-onset proteinuria was still inconclusive. We aimed to test the hypothesis that treatment with enalapril and folic acid is more effective in preventing the new-onset proteinuria than enalapril alone among Chinese adults with hypertension.

Methods: This report was a sub-study of the China Stroke Primary Trial (CSPPT).A total of 14538 eligible CSPPT patients without overt proteinuria, including 1866 patients with diabete, were randomized to receive a single tablet daily containing 10mg enalapril and 0.8mg folic acid (n=7212) or 10mg enalapril alone (n=7326) in 20 communities in Jiangsu province in China. The primary outcome was the new-onset proteinuria, defined as a urine dipstick reading ≥1+ at exit visit.

Results: Median followup was 4.4 years. The primary event occurred in 260 (4.4%) and 242 (4.1%) participants, respectively, in the enalapril group and the enalapril-folic acid group. Compared with the enalapril group, the enalapril-folic acid group had no significant effect on the primary event (OR, 0.93; 95% CI, 0.77, 1.11). Among the participants with diabetes at baseline, folic acid therapy resulted in a significant reduction in the risks for the primary event (8.5% in the enalapril group vs. 5.6% in the enalapril-folic acid group; OR, 0.63; 95%CI, 0.42-0.94). Among those without diabetes at baseline, there was no between-group difference in the primary endpoint.

New-onset proteinuria	No. of event (%)		Odds ratios (95% CI)		P	P for interaction
	Enalapril	Enalapril-Folic acid	Unadjusted	Adjusted		
Total	260 (4.4)	242 (4.1)	0.93 (0.78, 1.11)	0.93 (0.77, 1.11)	0.405	
Non-diabetes	194 (3.7)	200 (3.8)	1.03 (0.84, 1.26)	1.02 (0.84, 1.25)	0.828	ref
Diabetes	66 (8.5)	42 (5.6)	0.64 (0.43, 0.95)	0.63 (0.42, 0.94)	0.024	0.035

Conclusions: Enalapril-folic acid therapy, compared with enalapril alone, can significantly preventing the new-onset proteinuria in hypertensive patients with diabetes.

Correction of Metabolic Acidosis Improves Insulin Resistance in Chronic Kidney Disease Antonio Bellasi,[1] Lucia Di Micco,[2] Luca Di Lullo,[3] Mario Cozzolino,[4] Biagio Raffaele Di Iorio.[2] *[1]ASST-Lariana; [2]PO Landolfi; [3]Ospedale Parodi Delfino; [4]Univ of Milan.*

Background: Correction of metabolic acidosis (MA) with nutritional therapy or bicarbonate administration is widely used in chronic kidney disease (CKD) patients. However, it is unknown whether these interventions reduce insulin resistance (IR) in diabetic patients with CKD. We sought to evaluate the effect of MA correction on endogenous insulin action in diabetic type 2 (DM2) CKD patients.

Methods: Sub-study evaluation of the first 145 CKD subjects (83 men e 62 women) with DM2 treated with oral antidiabetic drugs recruited in the ongoing BIC study (NCT01640119) who completed 12 months followup. All patients were randomly assigned 1:1 to either open-label (A) oral bicarbonate to achieve serum bicarbonate levels of 24-28 mmol/L (treatment group) or (B) no treatment (control group). The Homeostatic model assessment (HOMA) index was used to evaluate IR at study inception and conclusion. Parametric and non-parametric tests as well as linear regression were used.

Results: At baseline no differences in demographic and clinical characteristics between the 2 groups was observed. Average dose of bicarbonate in the treatment group was 0.7±0.2 mmol/kg. Treated patients showed a better metabolic control as confirmed by lower insulin levels (13.4+5.2 vs 19.9+6.3; for treated and control subjects respectively; p<0.001), Homa-IR (5.9[5.0-7.0] vs 6.3[5.3-8.2]; p=0.01) and need for oral antidiabetic drugs. The serum bicarbonate and HOMA-IR relationship was non-linear and the largest HOMA-IR reduction was noted for serum bicarbonate levels between 24-28 mmol/l. Adjustment for confounders, suggests that serum bicarbonate rather than treatment drives the effect on HOMA-IR.

Conclusions: Serum bicarbonate is related to IR and the largest HOMA-IR reduction is noted for serum bicarbonate between 24-28 mmol/l. Treatment with bicarbonate influences IR. However, changes in serum bicarbonate explains the effect of treatment on HOMA index. Future efforts are required to validate these results in diabetic and non-diabetic CKD patients.

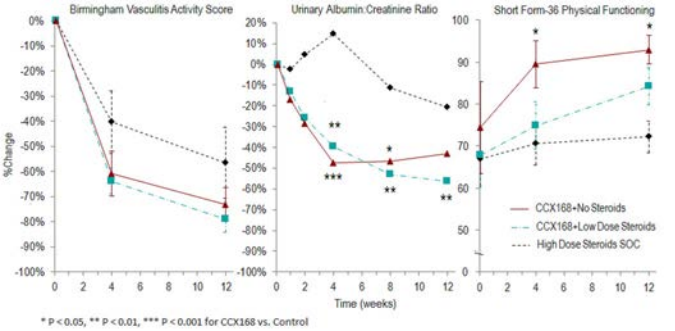
Rapid Onset of Action of Orally Administered C5aR Inhibitor CCX168 in Randomized Clinical Trial in ANCA-Associated Vasculitis (CLEAR) Vladimir Tesar,[9] David R.W. Jayne,[1] Annette Bruchfeld,[2] Lorraine Harper,[3] Matthias Schaier,[4] Patrick Hamilton,[5] Volker Rolf Burst,[6] Franziska Grundmann,[6] Michel Y. Jadoul,[7] Istvan Szombati,[8] Antonia Potarca,[10] Thomas J. Schall,[10] Pirow Bekker.[10] *[1]Univ of Cambridge, United Kingdom; [2]Karolinska Inst, Sweden; [3]Univ of Birmingham, United Kingdom; [4]Univ Hosp Heidelberg, Germany; [5]Manchester Univ, United Kingdom; [6]Univ of Cologne, Germany; [7]Cliniques Saint-Luc, Belgium; [8]Budai Irgalmasrendi Korhaz, Hungary; [9]Charles Univ, Czech Republic; [10]ChemoCentryx, Inc.*

Background: CCX168 is being developed for anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitis (AAV).

Methods: This was a randomized, placebo-controlled trial in AAV. The aim was to reduce or replace steroid treatment with CCX168 without compromising efficacy. There were 3 treatment groups: (1) High dose (60 mg) prednisone standard of care control, (2) CCX168 30 mg b.i.d.+low dose (20 mg) prednisone, and (3) CCX168 30 mg b.i.d.+no prednisone. All patients received CYC, 15 mg/kg IV q2 to 4 wks, or RTX, 375 mg/m^2 IV weekly for 4 wks. Primary endpoint: treatment response at wk 12, based on Birmingham Vasculitis Activity Score (BVAS) decrease from baseline of ≥50% and no worsening in any body system.

Results: 67 patients were enrolled. Mean age was 57-59 yrs, BVAS 13 to 14. The primary endpoint was met: BVAS response at wk 12 was higher and statistically non-inferior to SOC control (P = 0.002 and P = 0.01 for each CCX168 group vs. control), with a rapid onset of action (see figure).



The incidence of events likely associated with steroids, e.g., diabetes, psychiatric disorders, weight gain, fracture, and cataract was lower in patients on CCX168 (34%) vs. control (65%), P = 0.02. CCX168 was generally well tolerated.

Conclusions: CCX168 successfully replaced glucocorticoid treatment, with a more rapid onset of action based on BVAS, UACR, and HRQOL, and a lower incidence of steroid-related adverse effects.

Exercise Training in Hypertensive Patients with Chronic Kidney Disease: A Randomized Controlled Trial Franklin Correa Barcellos,[1,2] Annelise Reges,[2] Maristela Bohlke.[2] *[1]Medicine Faculty, Univ Federal of Pelotas, Pelotas, Brazil; [2]Medicine School, Univ Catholic of Pelotas, Brazil.*

Background: Chronic kidney disease (CKD) is a progressive illness that leads to end-stage renal disease and renal replacement therapy. These patients are at increased risk for cardiovascular events and progression to kidney failure. Observational studies have found that higher physical activity is associated with slower rates of glomerular filtration rate (GFR) decline. However, there is no definitive evidence on exercise-structured programs. The purpose study was evaluated the effects of exercise in cardiovascular risk factors and progression of kidney disease in hypertensive patients with CKD non-dialysis.

Methods: Randomized controlled trial. **Participants:** Non-diabetic patients with high blood pressure and renal disfunction. Among 935 eligible individuals, 150 individuals were randomized into the intervention or control group. **Intervention:** Exercise training of the resistance and aerobic exercises, three times per week for 16 weeks. **Outcomes:** Glomerular filtration rate estimated, blood pressure, weight, fasting glucose, lipid profile, high-sensitivity C-reactive protein, hemoglobin levels and health-related quality of life. Data were examined using linear mixed-effects models for repeated measures over time.

Results: 76 participants were allocated to the intervention and 74 to the control group. The decrease in GFR was faster in the control group than in intervention group (-2.6 against -1.9 mL/minute/1.73m^2), but the between-groups difference was not significant (+0.7; -4.0 to +5.4 mL/minute/1.73m^2) considering time and intervention interaction. C-reactive protein, mean body weight and fasting glucose levels had a significant reduction (p< 0.01) throughout the study in the intervention, but not the control group. Blood pressure decreased in both groups, physical fitness increased in the intervention group and there were no changes in quality of life.

Conclusions: Sixteen weeks of physical training exercise reduced C-reactive protein, body weight and fasting glucose levels in this high-risk population. However,have no impact on eGFRs decline in non-diabetic hypertensive patients with renal disfunction.

TH-OR039

A Randomized Controlled Trial of Care Management in Late Stage CKD – Preparation for ESKD Candice Halinski,[1] Sofia Agoritsas,[1] Vipulbhai Sakhiya,[1] Leah Balsam,[2] Steven Fishbane.[1] *[1]Div of Nephrology, Hofstra Northwell School of Medicine, Great Neck, NY; [2]Div of Nephrology, Nassau Univ Medical Center, East Meadow, NY.*

Background: Healthy Transitions (HT) is a care management and informatics program to improve late stage CKD care (stages 4/5). Nurses partner with nephrologists guided by a clinical informatics system. A primary goal is improved education / preparation for ESKD. In the current analysis, the program impact on ESKD initiation was evaluated.

Methods: Patients with stage 4/5 CKD were randomized to the HT intervention or usual care (UC) at four clinical sites. The only exclusions were for dementia, metastatic cancer or no consent. All patients were followed for up to 18 months. The primary outcome of this analysis was the proportion of patients reaching ESKD who initiated treatment with home dialysis or kidney transplantation with secondary outcomes including initiating hemodialysis (HD) without hospitalization and access type for HD.

Results: 65 patients were randomized to each group. There were no significant differences in baseline characteristics. The mean eGFR at baseline was 18.5±6.4 ml/min and 19.9±6.7 ml/min (HT/UC). 25 HT patients and 23 UC patients initiated RRT. The primary outcome was achieved in 10 of 25 (40%) HT (6 PD and 4 transplantation), 3 of 23 (13.0%) UC (1 PD and 2 transplantation) (P=0.05). Of patients who initiated HD, a non-hospital outpatient start occurred in 8/15 (53.3%) HT and 3/20 (15%) UC (P=0.03). For HD, a catheter was the sole access in 3/15 (20%) HT and 8/20 (40%) UC (p=0.28). A working AVF or AVG was in place in 8/15 (52.3%) HT 6/20 (30%) UC (p=0.18).

Conclusions: The HT intervention significantly increased utilization of home dialysis and kidney transplantation and outpatient, nonhospital starts compared to UC. Further studies will help evaluate the cost effectiveness and scalability of the HT approach.

Impact of a Primary Care Registry on Chronic Kidney Disease Management in a Safety-Net Setting Delphine S. Tuot, Charles E. McCulloch, Alexandra Velasquez, Dean Schillinger, Chi-Yuan Hsu, Neil R. Powe. *Univ of California, San Francisco, San Francisco, CA.*

Background: Early stage CKD is asymptomatic; detection by primary care providers (PCPs) is critical to prevent disease progression via blood pressure (BP) control, minimization of albuminuria and prescription of angiotensin-converting enzyme inhibitors (ACEi)/angiotensin receptor blockers (ARB). In a randomized control trial (KARE, NCT01530958), we examined the impact of implementing a primary care CKD registry on delivery of guideline-concordant care in a racially/ethnically diverse low-income patient population. At point of care, the registry identified patients with CKD, those with uncontrolled BP (>140/90 mmHg), those were not on ACEi/ARBs, and those whose albuminuria had not been quantified in the past year. Quarterly feedback pertinent to these metrics was also provided to PCPs/health care teams.

Methods: PCPs were randomized to receive the registry or usual care for one year. Mixed models and generalized estimating equations adjusted for age, gender, race/ethnicity and clinic, were used to account for PCP and patient clustering and repeated measures, to assess the impact of the registry, time, and their interaction on change in systolic BP and change in proportion of patients with BP control, prescription of ACEi/ARB and quantification of albuminuria in the prior year.

Results: Patients whose providers were randomized to the registry (n=22 PCPs, 263 patients) had no significant change in systolic BP or change in proportion of patients with BP control compared to those randomized to usual care (n=61 PCPs, 551 patients). Randomization to the registry was associated with greater prescription of ACEi/ARB over time ($p_{time\ x\ registry}$=0.01) with a post-intervention average of 82% for patients with registry vs 72% without registry, p=0.04 and increased albuminuria quantification over time ($p_{time\ x\ registry}$ =0.009), with a change from 7% to 43% with registry vs. 10 to 34% without registry, p=0.04.

Conclusions: A primary care CKD registry can improve processes of care (ACEi/ARB use and albuminuria quantification) for safety-net patients with CKD.

TH-OR041

Cognitive Function and Kidney Disease: Baseline Data from the SPRINT Trial Daniel E. Weiner,[1] S. Gaussoin,[8] John W. Nord,[2] Alexander P. Auchus,[10] G. Chelune,[2] Michel Chonchol,[3] Laura H. Coker,[8] William E. Haley,[4] Anthony Alexander Killeen,[5] Paul L. Kimmel,[6] Alan J. Lerner,[11] Mohammad G. Saklayen,[7] Yelena Slinin,[5] Clinton Wright,[8] Manjula Kurella Tamura.[9] *[1]Tufts; [2]Utah; [3]Colorado; [4]Mayo; [5]Minnesota; [6]NIH; [7]Dayton VA; [8]Wake Forest; [9]Stanford; [10]Mississippi; [11]Case Western.*

Background: People with kidney disease are at high risk of cognitive impairment. The nature of this relationship remains uncertain.

Methods: To explore the relationship among kidney disease, cognitive function, and cerebrovascular disease, we evaluated baseline data from the Systolic Blood Pressure INTervention (SPRINT) cognition substudy, SPRINT-MIND. Five cognitive domains were defined based on 11 cognitive tests using z-scores, and the associations of both urine albumin to creatinine ratio (ACR) and estimated GFR with cognitive performance and and brain abnormal white matter volume quantified by MRI were evaluated using linear and quantile regression, respectively.

Results: Among 9361 SPRINT-MIND participants, 2800 were administered an expanded cognitive battery at baseline and 2707 had complete data; 637 had brain imaging. Mean age was 69 years, 37% were women, 30% were black, and 20% had known CVD. Mean eGFR was 71±21 ml/min/1.73 m^2 and median urine ACR was 9.7 (IQR 5.7, 22.5) mg/g. In analyses adjusted for demographic and clinical characteristics, higher ACR was associated with worse performance on tests of global cognitive function, executive function, memory and attention, such that each doubling of urine ACR explained similar declines in cognitive performance as with 7 months, 10 months, 6 months, and 14 months of increasing age, respectively per domain. Lower eGFR was independently associated with worse performance on tests of global cognitive function and memory. In adjusted models, higher ACR (p=0.001) but not lower eGFR (p=0.38) was associated with larger abnormal white matter volume; the association was present at low ACR levels (30 mg/g).

Conclusions: In older adults, higher urine ACR and lower eGFR have additive effects on global cognitive performance with different patterns of affected domains. Albuminuria, even at low levels, identifies a higher burden of abnormal brain white matter disease, suggesting that vascular disease may mediate these relationships.

Serum Bicarbonate Level and Cognitive Dysfunction in Hypertensive Adults with and without CKD Mirela A. Dobre,[1] S. Gaussoin,[2] Jeffrey T. Bates,[3] Michel Chonchol,[4] Debbie L. Cohen,[5] Thomas H. Hostetter,[1] Kalani L. Raphael,[6] Addison A. Taylor,[3] Alan J. Lerner,[1] Jackson T. Wright,[1] Mahboob Rahman.[1] *[1]Case Western Reserve Univ; [2]Wake Forest School of Medicine; [3]Baylor College of Medicine; [4]Univ of Colorado; [5]Univ of Pennsylvania; [6]Univ of Utah.*

Background: Acid base balance is intimately involved in cerebral autoregulation, and hydrogen ions are important signals for neuronal function. We evaluated the association between serum bicarbonate and cognitive dysfunction in hypertensive adults with and without CKD.

Methods: A total of 2853 participants in the Systolic Blood Pressure Intervention Trial (SPRINT) were included in the study. Five cognitive summary scores were created: Global Cognitive Function, Executive Function, Memory, Attention/Concentration and Language. Multivariable linear regression models adjusted for demographics, clinical center network, education level, comorbidities, systolic blood pressure, diuretics, anti-acidosis medications, eGFR and albuminuria were built to evaluate the association between bicarbonate level and above cognitive scores. For those who underwent brain MRI (N=681), the models were also adjusted for structural and functional cerebral measurements, including white matter hyperintensity volume, vascular reactivity and cerebral blood flow.

Results: The mean age (SD) was 68.3 (8.5) years. Participants with bicarbonate ≤24mEq/L were more likely to smoke, have CKD and high albuminuria. Global Cognitive Function and Executive Function summary scores were significantly associated with serum bicarbonate (Estimate (SE): 0.014(0.006), p=0.01, and 0.018(0.006), p=0.003, respectively). The positive association with Global Cognitive Function persisted after adjustment for MRI measurements (Estimate (SE):0.03 (0.01), p=0.01). There was no association between serum bicarbonate level and Memory, Attention/Concentration and Language summary scores.

Conclusions: In a large cohort of hypertensive adults with and without CKD, we found a positive linear association between serum bicarbonate level and global cognitive and executive functions, suggesting that a low bicarbonate level may be detrimental to neuronal function.

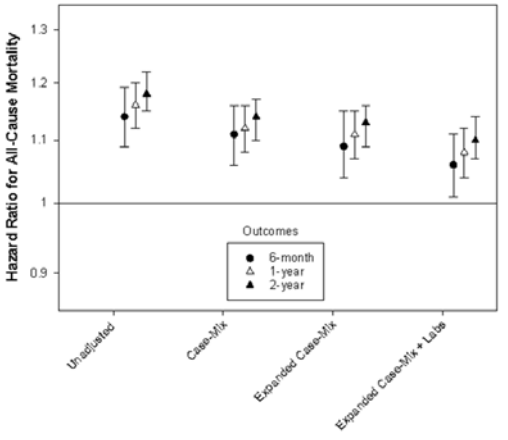
TH-OR043

Association of Pre-ESRD Depression with Post-ESRD Mortality: A Transition of Care in CKD Study Vanessa A. Ravel,[1] Melissa Soohoo,[1] Connie Rhee,[1] Elani Streja,[1] Miklos Zsolt Molnar,[2] Danh V. Nguyen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: Depression in CKD patients is often undiagnosed, empirically overlooked, and often associated with worse outcomes including higher mortality; however, prior studies have been limited to either pre- or post-ESRD diagnoses of depression separately. We sought to examine the association of pre-ESRD depression with post-ESRD mortality in patients who transition to dialysis.

Methods: From a nation-wide cohort of 46,877 US veterans who transitioned to dialysis between 10/2007-09/2011, we identified 13,565 patients with a pre-dialysis depression diagnosis (from ICD9 codes) during the prelude (pre-dialysis) period and modeled it as a predictor of all-cause mortality within the first 6 months, 1 and 2 years upon maintenance dialysis therapy initiation using Cox hazards models adjusting for case-mix covariates, residential region, initial dialysis modality, BMI, and averaged laboratory values including eGFR.

Results: Patients were 72±11years old (mean±SD) and included 5% females, 45% diabetics, and 23% African Americans. 29% of the cohort had be previously diagnosed with depression prior to transition to ESRD. Compared to those not reporting depression, depressed patients had a 16% higher 1-yr mortality risk in the unadjusted model [HR (95% CI): 1.16 (1.12, 1.20)]. Upon further adjustment for demographic characteristics and labratory measures, this risk was attenuated to 8% [1.08 (1.04, 1.12)].



Conclusions: Pre-ESRD depression is associated with increased risk of post-ESRD mortality in veterans transitioning to dialysis. Intervention studies are warranted to examine whether management of pre-ESRD depression can improve ESRD outcomes.

Funding: NIDDK Support

TH-OR044

Cognitive Impairment (CI) in Patients with ESRD and Family Psychoeducation for Reducing Readmissions: Preliminary Results from a Randomized Clinical Trial Matthew James Jasinski,[1] Mark A. Lumley,[1] Sandeep S. Soman,[2] Jerry Yee,[2] Mark W. Ketterer.[2] *[1]Wayne State Univ; [2]Henry Ford Health System.*

Background: CMS has mandated reducing early hospital readmissions as a pathway to improving patient care while lowering costs. Patients with End-Stage Renal Disease (ESRD) have the highest 30-day hospital readmission rates of any medical condition. Studies have found that CI and health illiteracy predict readmissions. In patients with ESRD, interventions targeting these factors as a means for improving patient adherence and health post-discharge, and reducing early readmissions, have not been tested.

Methods: 120 patients (*M* Age= 57.5 years, *SD* = 14.4 years; 86% Black, 12% White; 60/60 women/men) were recruited from an inpatient nephrology unit in Detroit. All patients were assessed for CI and social support at baseline, and then randomized into a family meeting intervention (FMI) group or treatment-as-usual (TAU) control. Family meetings (~8 minutes) were conducted either via phone or at bedside. Meetings involved educating family members about patients' cognitive deficits and compensatory patient care at home. 30-day readmission rates were retrieved from charts. Chi-square tests and logistic regressions were used to identify predictors of readmissions.

Results: FMI patients had less early readmissions than TAU (χ = 2.13, 1-tailed p = .072). Including emergency department (ED) visits, patients in the FMI group had fewer ED visits or admissions within 30-days post-discharge compared to those in the control group (χ = 3.48, 1-tailed p = .031). Readmission and ED visits were 30% for the FMI vs 47% for TAU. However, this effect was of borderline significance when controlling for patient substance abuse history (OR = 0.545; 95% CI, 0.25-0.97, 1-tailed p = .061).

Conclusions: Results are the first to demonstrate that a brief psychosocial intervention can decrease readmissions in patients with ESRD, and the effect size of the reduction appears to be greater than other interventions that have been attempted. Implementing interventions such as this would help decrease health care expenditures while improving patient outcomes. Larger, more integrated replications of this intervention need to be studied.

TH-OR045

Medicare Payments for Parts A and B Claims in Home Hemodialysis, In-Center Hemodialysis, and Peritoneal Dialysis Patients Eric D. Weinhandl,[1,2] Allan J. Collins.[2] *[1]NxStage Medical, Inc., Lawrence, MA; [2]Univ of Minnesota, Minneapolis, MN.*

Background: The United States Renal Data System (USRDS) annually publishes Medicare costs per person per year (PPPY) for hemodialysis (HD) and peritoneal dialysis (PD) patients, but does not publish costs for home HD (HHD) and in-center HD (IHD). Such costs are relevant to the Comprehensive ESRD Care Model. We assessed Medicare Parts A and B payments for HHD, IHD, and PD during 2012.

Methods: We analyzed USRDS data. We identified all patient-days in 2012 that were marked by HHD, IHD, or PD treatment and coincided with Medicare as primary payer (MPP). HHD patient-days were identified from NxStage records, which were linked to the USRDS registry, whereas IHD and PD patient-days were identified from USRDS data. Payments were ascertained from Medicare Parts A and B claims.

Results: Cumulative MPP patient-years for HHD, IHD, and PD were 2,659; 273,848; and 24,007, respectively. Medicare payments PPPY are shown in the table. Compared to IHD, HHD was associated with lower inpatient/post-acute and physician/supplier payments, but higher outpatient dialysis payments. Compared to PD, HHD was associated with similar inpatient/post-acute payments and higher payments for other cost centers. Excluding outpatient dialysis payments, HHD was roughly $10,000 PPPY less than IHD and $5,000 PPPY more than PD.

	HHD	IHD	PD	HHD - IHD	HHD - PD
Inpatient/post-acute	$26,533	$33,301	$26,550	($6,768)	($17)
Outpatient dialysis	$39,974	$28,294	$29,076	$11,679	$10,897
Other institutional	$5,329	$5,392	$3,073	($63)	$2,256
Physician/supplier	$10,914	$14,991	$8,363	($4,077)	$2,551
Parts A/B	$82,750	$81,979	$67,063	$771	$15,687
Parts A/B, minus outpatient dialysis	$42,776	$53,685	$37,987	($10,098)	$4,789

Conclusions: Medicare payments for HHD, IHD, and PD are heterogeneous. Home dialysis modalities are associated with lower inpatient/post-acute and physician/supplier costs, whereas HHD is associated with higher outpatient dialysis costs, likely due to payment for extra HD sessions. Additional analyses are needed to characterize geographic variability of between-modality cost differentials, as well as Medicare Part D payments with each dialytic modality.

TH-OR046

Gender Disparities in CKD Progression: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study Ana C. Ricardo, Wei Yang, Lawrence J. Appel, Esteban A. Cedillo-Couvert, Jing Chen, Marie Krousel-Wood, Mahboob Rahman, Sylvia E. Rosas, Milda Renne Saunders, Daohang Sha, Kumar Sharma, Susan P. Steigerwalt, Jackson T. Wright, Martha L. Daviglus, James P. Lash. *CRIC Study Group.*

Background: In the US, men have 1.5 times higher incidence of end-stage renal disease (ESRD), despite having lower prevalence of chronic kidney disease (CKD) compared with women. Prior studies suggest that men have more rapid CKD progression, but this finding has not been consistent. We evaluated gender differences in CKD progression.

Methods: In this prospective, longitudinal study of 1778 women and 2161 men enrolled in the CRIC Study, we used Cox-proportional hazards models to investigate the association of gender (women vs. men) with incident ESRD (dialysis or transplantation), and linear mixed effects models to evaluate gender differences in estimated glomerular filtration rate (eGFR) slope.

Results: Mean age was 58 years, 42% were non-Hispanic black and 13% Hispanic. At entry, women were significantly more likely to have never smoked (53 vs 39%), be physically inactive (33 vs 28%), have higher body mass index (33 vs 31 kg/m^2), lower eGFR (44 vs 46 ml/min/1.73m^2), and lower proteinuria (113 vs 268 mg/24h). Over median follow up of 6.9 years, 844 participants developed ESRD. In fully-adjusted mixed effects models, the difference in eGFR slope in women vs. men was -0.17 ml/min/1.73m^2/year (p=0.05). The table summarizes failure-time analyses.

Outcome	HR (95% CI) Women vs. Men	P interaction Gender*Age
ESRD model		
1[a]	0.80 (0.69-0.93)	
2[b]	0.81 (0.69-0.96)	
3[c]	0.92 (0.78-1.09)	0.03
Adjusted[c] HR (95% CI) stratified by age		
21-45 y	1.36 (0.96-1.93)	
46-60 y	0.87 (0.68-1.12)	
61-74 y	0.79 (0.61-1.03)	

[a]Adjusted for clinical site, demographics, nephrology care and health insurance.
[b]Model 1+systolic BP, diabetes, history of CVD, LDL, ACEi/ARB, aspirin, statin, serum FGF23, calcium, phosphorus, baseline eGFR and proteinuria.
[c]Model 2+ lifestyle factors (smoking, physical activity and BMI)

Conclusions: In this large and diverse CKD cohort, the lower risk of ESRD in women relative to men was explained by differences in lifestyle factors, and this association was modified by age.

Funding: NIDDK Support

TH-OR047

Food Environment and Risk of Kidney Function Decline among Urban African Americans: The Achieving Blood Pressure Control Together (ACT) Study Deidra C. Crews,[1] Patti Ephraim,[1] Yang Liu,[1] Raquel C. Greer,[1] Jessica Ameling,[2] Kathryn A. Carson,[1] Lapricia Lewis Boyer,[2] Lisa A. Cooper,[2] L. Ebony Boulware.[3] *[1]Johns Hopkins U, MD; [2]U Michigan, MI; [3]Duke U, NC.*

Background: Studies suggest that dietary factors influence risk of kidney function decline. Barriers may hinder urban African Americans' (AAs) abilities to follow healthful diets that could mitigate their increased risk of kidney function decline, yet these barriers have not been well-examined.

Methods: In a randomized trial of urban AAs with uncontrolled hypertension, we assessed, at enrollment, food environment factors including healthy food access [Healthy Food Availability Index (HFAI) of stores near participants' homes; higher=better] and participants' dietary patterns [food insecurity (i.e. skipping meals due to lack of money), directly assessed presence of fresh or frozen fruits/vegetables in participants' homes; and Block fruit/vegetable screener (measure of dietary intake; higher=better)]. We used logistic regression to quantify the association of each factor with eGFR decline >4 ml/min/1.73m^2 (ml) over 1 yr, adjusting for age, sex, diabetes, albuminuria, and study arm.

Results: A majority (120 out of 159 participants) had eGFR>15ml at baseline and completed follow up labs. Mean age was 58, 74% were female, 41% had diabetes. Many lacked fresh/frozen fruits (40%) or vegetables (22%) in their homes. Median baseline eGFR was 85ml (IQR 67-104) and 16% had eGFR<60ml. Median eGFR decline over 1 year was 4ml and 46% declined >4ml.

Food Measure at Enrollment	Median score or % for measure	Adjusted Odds Ratio (95% CI) for eGFR decline >4ml over 1yr
HFAI (highest v. lowest tertile)	8.1 (out of possible 28.5)	0.38 (0.14-1.01); p=0.05
Food insecurity (yes v. no)	45%	1.13 (0.53-2.41); p=0.7
Fruit/vegetable screener (highest v. lowest tertile)	13 (out of possible 33)	0.45 (0.16-1.21); p=0.1

Conclusions: Among urban AAs, greater availability of healthful foods in neighborhood stores and healthful dietary intake patterns were associated with a trend towards lower risk of eGFR decline. The impact of the food environment on kidney function in vulnerable populations warrants further study.

Emergency Department Use among Patients with Chronic Kidney Disease: A Population-Based Analysis Paul E. Ronksley, Robert G. Weaver, Chandra Mary Thomas, Jennifer M. MacRae. *Univ of Calgary, Calgary, AB, Canada.*

Background: While prior studies have observed high resource use among patients with chronic kidney disease (CKD), there is limited exploration of emergency department (ED) use in this population and the proportion of encounters related to CKD care.

Methods: We identified all adults (≥18 years) with eGFR<60 mL/min/1.73m^2 (including dialysis-dependent patients) in Alberta, Canada between Apr 1, 2010 and Mar 31, 2011. Patients with CKD were linked to administrative data to capture clinical characteristics and frequency of ED visits, and followed until death or end of study (Mar 31, 2013). Within each CKD category we calculated adjusted rates of overall ED use, as well as rates of potentially preventable ED encounters (defined by 4 CKD-specific ambulatory care sensitive conditions (ACSCs); heart failure, hyperkalemia, volume overload, malignant hypertension).

Results: During mean follow-up of 2.4 years, 111087 patients had 294113 ED encounters; 64.2% of patients had category 3A CKD and 1.6% were dialysis dependent. Adjusted rates of overall ED use increased linearly by CKD category, with dialysis patients having 1798 (95% CI: 1686-1911) visits/1000 p-yrs. 5.8% of all ED encounters were for CKD-specific ACSCs with approximately one-third resulting in hospital admission. Heart failure accounted for over 80% of all potentially preventable ED events among patients in categories 3A, 3B, and 4 CKD, while hyperkalemia accounted for almost half (48%) of all ACSCs among dialysis patients. Adjusted rates of ED events for heart failure showed a U-shaped relationship with rates peaking among category 4 CKD patients (61 (95% CI: 56-66) visits/1000 p-yrs. In contrast, rates of ED use for hyperkalemia increased in parallel with CKD category; rates were highest among category 5 patients who were dialysis-dependent (22 (95% CI: 17-28) and those not receiving dialysis therapy (23 (95% CI: 17-29) visits/1000 p-yrs.

Conclusions: ED use is high among patients with CKD, although only a small proportion of these encounters are for potentially preventable CKD-related care. These findings suggest that strategies to reduce ED use among CKD patients will need to target other conditions besides CKD-specific ACSCs.

Trajectories of Multidimensional Quality of Life among Patients Receiving Chronic Dialysis: Fluctuation, Gradation, and Improvement over Time Mi-Kyung Song,[1] Sudeshna Paul,[1] Sandra E. Ward,[2] Constance A. Gilet,[3] Gerald A. Hladik.[3] *[1]School of Nursing, Emory Univ, GA; [2]School of Nursing, Univ of Wisconsin-Madison, WI; [3]UNC Kidney Center, Univ of North Carolina at Chapel Hill.*

Background: Other than dialysis patients, no population must receive an invasive treatment every day or every other day to sustain life, yet inadequate attention has been paid to patient-reported multidimensional QOL over time in these patients.

Methods: 227 patients on chronic dialysis recruited from 12 clinics completed hour-long monthly measures of physical functioning, physical and emotional symptoms, cognitive functioning, and spiritual wellbeing for 12 months. Sessions were conducted by phone on a non-dialysis day if patients were on hemodialysis (n=216, 95.2%). Mean patient age was 59 years (SD=12.6) and they had been on dialysis for M=4.3 years (SD=5.3). 74% (n=168) were African Americans. Baseline Charlson Comorbidity Index (CCI) score was M=7.3 (SD=2.1). Linear mixed models were used in analysis.

Results: Patient-reported physical functioning, symptoms, cognitive functioning, and spiritual wellbeing fluctuated severely from month to month. Activities of Daily Living (ADL) gradually worsened over time (p=.035) while Instrumental ADL was unchanged. Moderate to severe pain remained unchanged (n=129, 56.8%) while fatigue slightly improved over time (p<.001). Anxiety symptoms (STAI) improved gradually (p<.001) whereas depressive symptoms (CESD-10) were stable. Baseline CCI predicted these physical functioning and symptom scores (all p<.01) while months on dialysis did not. Self-reported cognitive functioning and spiritual wellbeing (FACT-Sp) slightly improved over time (all p<.001). White race was associated with higher fatigue and lower spiritual wellbeing, and older age was associated with lower anxiety and depression and higher spiritual wellbeing.

Conclusions: While physical functioning worsened over time, older and African American patients reported improved emotional and spiritual wellbeing, possibly reflecting adaptation to their situation. Further analysis is needed to glean hypotheses regarding ways to direct clinical management.

A Comparison Study on Clinical Features and CKD Related Quality of Life between CKD G3a and CKD G3b Patients in China Zhangzhe Peng,[1] Qiongjing Yuan,[1] Jinwei Wang,[2] Luxia Zhang,[2] Qiaoling Zhou.[1] *[1]Renal Div, Dept of Medicine, Xiangya Hospital, Central South Univ, Changsha, Hunan, China; [2]Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: A new classification of chronic kidney disease (CKD) was proposed by the Kidney Disease: Improving Global Outcomes (KDIGO) in 2012. The major point of revision of this classification was the previous CKD stage 3 was subdivided into two stages (G3a and G3b). Furthermore, a two-dimensional staging of the CKD according to the level of albuminuria in addition to the GFR level was introducted.We compared the clinical features and CKD related quality of life between CKDG3a and CKDG3b patients in China to validate the neccesity of the new classfication.

Methods: Data of patients with CKD3 collected at baseline of the Chinese Cohort of Chronic Kidney Disease (C-STRIDE) which was performed in 3 000 pre-dialysis CKD patients aged between 18 and 74 years from 2011.09 to 2015.02.

Results: A population of 1277 patients with CKD3 was recruited for the study. 499(39.08%) patients were classified as CKD G3a group, 778(60.92%) patients were classified as CKD G3b group. We compared the clinical characteristics, laboratory parameters and overall rating of quality of life between CKD G3a and G3b patients. We found that serum PTH, uric acid, hemoglobin, serum HDL cholesterol and systolic blood pressure were significantly elevated in the G3b group compared with G3a group (P<0.05). Serum bicarbonate, serum total cholesterol were significantly decreased in the G3b group compared with G3a group (P<0.05). The proportions of subjects with hyperuricemia, anemia were significantly higher in the G3b group than in the G3a group (61.41% vs.52.03%, 26.35% vs.17.85 %, P<0.05). Most importantly, the overall rating of quality of life was significantly decreased in the G3b group compared with G3a group (P<0.05). Subsequently, we classified patients with CKD G3a and G3b according to the levels of ACR. We found that hyperuricemia, anemia were significantly more common in the later stages of both the eGFR and albuminuria (P < 0.01) .

Conclusions: There are differences in the clinical features and quality of life between CKDG3a and CKDG3b patients in China.

TH-OR051

Results from the ATLAS Trial: A Phase 2 Study to Evaluate Efficacy and Safety of BIIB023 in Subjects with Lupus Nephritis Brad H. Rovin,[1] David Wofsy,[2] David R.W. Jayne,[3] Eduardo Mysler,[4] Karen V. Smirnakis,[5] Jeremy Stuart Duffield,[5] Nathalie Franchimont,[5] Fei Shih.[5] *[1]Nephrology, The Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Rheumatology, Univ of California San Francisco, San Francisco, CA; [3]Vasculitis and Lupus Service, Addenbrooke's Hospital, Cambridge, United Kingdom; [4]Organizacion Medica de Investigacion, Buenos Aires, Argentina; [5]Biogen, Cambridge, MA.*

Background: BIIB023 is a humanized monoclonal antibody against TNF-related weak inducer of apoptosis (TWEAK). TWEAK has been linked to inflammation, mesangial proliferation, tubular cell death and fibrosis in lupus nephritis (LN). TWEAK acts through its receptor, Fn14. Fn14 is upregulated in LN kidney, but not expressed on T or B cells. Blocking TWEAK/FN14 pathway may attenuate inflammation and enhance the renal response (RR) to standard-of-care (SOC) therapy without adding to immunosuppression.

Methods: ATLAS was a phase II, placebo controlled, double blind, RCT to determine whether addition of BIIB023 (3 mg/kg or 20 mg/kg q4wk) to MMF+steroids improved complete or partial RR at 1yr. Patients had biopsy proven (centralized) proliferative LN, UPCR >1 and were treated with SOC for 12 wks. Only patients with a UPCR >0.5 after 12 wks of SOC were randomized.

Results: ATLAS enrolled 188 subjects. 145 finished BIIB023/placebo infusions through wk 44 before the trial was terminated for lack of efficacy. This group was designated the modified-ITT group, with 48 patients on placebo, 49 patients on 3 mg/kg and 48 patients on 20 mg/kg. At wk 52, complete and partial RR were seen in 25% (95% CI 15-35) of placebo patients, 16% (8-25) of the 3 mg/kg group and 31% (20-42) of the 20 mg/kg group. There was no difference in RR between placebo or BIIB023-treated patients nor in the time to RR. BIIB023 decreased serum and urine TWEAK dose-dependently. Serious adverse events were reported in 11% and 17% of placebo and BIIB023-treated patients, respectively.

Conclusions: The addition of BIIB023 to SOC LN therapy did not improve 1yr RR in proliferative LN. This was a unique trial design which excluded patients who responded rapidly to SOC therapy and this may have been a particularly resistant LN population.

Circulating Lymphocyte Subsets and Disease Relapse in Lupus Nephritis Desmond Y.H. Yap, Paul Lee, Susan Yung, Daniel Tak Mao Chan. *Dept of Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong.*

Background: Repeated renal flares herald adverse long-term outcomes in lupus nephritis (LN) but the mechanisms pertaining to relapse remain poorly understood. Lymphocyte subset abnormalities have been implicated in the pathogenesis of LN, but their relationship to LN relapse has not been investigated.

Methods: We compared circulating lymphocyte subsets and serum cytokine profiles during disease quiescence between patients with Class III/IV±V LN who are multiple relapsers (MR, defined as >=3 relapses within 36 months unrelated to non-compliance) and non-relapsers (NR, defined as no relapse after the presenting episode).

Results: 37 patients were included (MR n=24; NR n=13). MR showed lower percentage of circulating naïve B and memory B cells compared with NR (0.48%, IQR 0.24%-3.15% vs. 4.52%, IQR 3.18%-8.25%; and 0.51%, IQR 0.26%-0.67% vs. 0.96%, IQR 0.86%-1.91%; p=0.014 and 0.014 respectively), while the two groups had similar percentage of circulating plasma cells (0.61%, IQR 0.31%-0.77% vs. 0.38%, IQR 0.33%-0.79%, p=0.883). The plasma cell-to-naïve B cell ratio was higher in MR (1.52±2.19 vs.0.21±0.33, p=0.011). MR and NR did not differ in the percentage of circulating Th1, Th2, Th17 and Treg cells, nor the level of IL-6, IL-18, IL-21, IL-23, BAFF, IFN-α, IFN-γ or IP-10 (p>0.05 for all).

Conclusions: Our results suggest that altered prevalence of distinct circulating B cell subsets might be related to the pathogenesis of disease flares in LN patients.

TH-OR053

Urine Exosome Micro-RNA Profiling in Lupus Nephritis Xiaolan Zhang, Huijuan Song, Samir Parikh, John P. Shapiro, Brad H. Rovin. *Nephrology, Ohio State Univ, Columbus, OH.*

Background: Micro-RNA (miRNA) has emerged as a potentially important class of disease biomarkers as they play a key role in posttranscriptional regulation of gene expression. miRNA profiling has been done in the plasma, PBMC and kidey tissue of lupus nephritis (LN) patients, but thus far not in urine exosomes. The feasibility of measuring miRNA in urine exosomes was tested.

Methods: Urine exosome miRNA from 6 healthy control, and 12 biopsy-proven LN ISN/RPS class IV patients was screened for 800 miRNAs using the Nanostring nCounter® miRNA expression technique. Differentially-expressed miRNAs were confirmed by TaqMan gene expression real-timeRT-PCR. miRNA expression was normalized to a spiked-in miRNA control and urine creatinine, and analyzed by ANOVA followed by nonparametric Wilcoxon ranked-sum testing and multiple linear regression.

Results: The number of urine exosomes and their RNA content were significantly higher in LN than controls (p=0.006 and 0.008, respectively). The number of exosomes correlated with urine protein concentration (r^2=0.36, p=0.0040). miRNA profiling showed that 19 miRNAs were significantly increased in LN compared to control. These included some miRNAs previously identified in LN, such as miR-155-5p and miR-451a, and other miRNAs not previously described in LN, such as miRNA-21-5p and miRNA-1285. RT-PCR confirmed the Nanostring findings. For example, miRNA-451 was 30-fold higher in LN (p=0.0098). miRNA-21-5p and miRNA-1285-5p were over 200-fold higher in LN than control (p=0.0072 for both). miRNA-21-5p and miRNA-1285-5p were correlated with r^2=0.77 and p<0.0001. miRNA-451 showed a significant correlation with urine protein (r^2=0.31, p=0.008).

Conclusions: Urine exosome miRNA profiling was carried out in proliferative LN patients and healthy controls. Several differentially-expressed miRNAs were identified in LN exosomes and verified by RT-PCR. These data demonstrate the feasibility of developing urine exosomes as non-invasive biomarkers of LN activity.

TH-OR054

Molecular Imaging of Glomeruli from Serial Kidney Biopsies in Lupus Nephritis Samir Parikh,[1] Ana Malvar,[2] Huijuan Song,[1] John P. Shapiro,[1] Valeria Gabriela Alberton,[2] Jianying Zhang,[1] Michael T. Eadon,[3] Brad H. Rovin.[1] *[1]Nephrology, The Ohio State Univ Medical Center, Columbus, OH; [2]Nephrology, Hospital Fernandez, Buenos Aires, Argentina; [3]Nephrology, Indiana Univ, Indianapolis, IN.*

Background: Proliferative lupus nephritis (LN) is managed using only clinical and histologic data. We postulated that molecular profiling of kidney biopsies could provide novel information to improve management strategies. Here we present results of glomerular profiling.

Methods: A kidney biopsy was done at flare (Bx1) and after induction therapy (Bx2) in 5 patients with proliferative LN. Biopsies of living donor kidney transplants were controls (n=2). Glomeruli were isolated using laser capture microdissection, and glomerular RNA was extracted. The expression of 569 immune-response genes was profiled using Nanostring technology. Clinical response after induction was assessed by proteinuria and serum creatinine (SCr), and all patients achieved complete or partial remission.

Results: At Bx1 34 transcripts were differentially-expressed in LN glomeruli compared to control glomeruli. The top upregulated transcripts included *CCL2* (25-fold>control, P=0.0005), *IL21R* (11.2-fold, P=0.0002), *IL18RAP* (10.6-fold, P=0.009), *IL18R1* (4.1-fold, P=0.018), *IL7R* (9.5-fold, P=0.004), *ICAM1* (9.4-fold, P=0.0001), and *ITGAL* (5.3-fold, P=0.008). After treatment these levels fell but did not return to control levels. Comparing Bx2 to Bx1, TNF-related genes became upregulated during treatment, including *TRAF5* (3-fold>Bx1, P=0.015) *TNFSF12* (3.5-Fold, P=0.017), and *TNFRSF1B* (3.7-Fold, P=0.019).

Conclusions: LN glomeruli at flare express a dominant inflammatory molecular signature. This signature is attenuated but not eliminated with standard induction treatment, despite improvements in proteinuria and SCr. Unexpectedly, after treatment, a TNF-signature emerged in glomeruli. These data suggest that induction therapy may be improved by focusing efforts on abrogating inflammation. Furthermore, after a LN flare is initiated the TNF pathway may play an immunomodulatory as opposed to pro-inflammatory role. Because several cytokines have dual roles, the timing of anti-cytokine therapies in LN may be critical for therapeutic efficacy.

TH-OR055

Microbiota Profile in IgAN Is Associated with Differences in Immunologic Function and Disease Severity Heather N. Reich,[1] David Guttman,[1] Bryan Coburn,[1] Jan Novak,[3] Ping Lam,[1] Scott Gray-Owen,[1] Christoph Licht,[2] Stuart Yang,[1] Michelle A. Hladunewich,[1] Sean Barbour,[3] Daniel C. Cattran,[1] Rulan S. Parekh,[2] Krzysztof Kiryluk,[5] Pauline Wang,[1] Rupert Kaul,[1] Kenneth Croitoru,[1] Jennifer Gommerman.[1] *[1]Univ of Toronto, Univ Health Network; [2]Hospital for Sick Children; [3]UBC; [4]Univ of Alabama; [5]Columbia Univ.*

Background: There is a reciprocal relationship between host commensal microbiota and the immune system, suggesting that study of microbiota can reveal functional differences in immune responses that underlie susceptibility to IgA nephropathy (IgAN) and disease progression. To better understand the immunopathogenesis of IgAN, we characterized the tonsil microbiota of patients with IgAN and healthy control subjects. We characterized the immune and clinical phenotype associated with microbiota profile.

Methods: The cohort included 120 adults with IgAN and 60 healthy controls (primarily household-matched). Tonsil microbiota were characterized using V4 16s rRNA gene sequencing and qPCR. Galactose-deficient (Gd) IgA1 was quantified using ELISA.

Results: Overall abundance of *Neisseria* genus is significantly increased in tonsils of IgAN patients (p<0.01) however *N.Meningitidis* (*Nme*) is underrepresented in IgAN (0.23 vs.0.17 p=6.5x10^{-5}). *Nme* carriage is associated with a milder clinical phenotype as characterized higher eGFR, and by lower levels of Gd-IgA1(Fig1).

Conclusions: IgAN is associated with differential tonsil colonization by *Neisseria* and *Nme*. The association of *Nme* carriage with milder clinical phenotype and decreased Gd-IgA1 is compelling and merits further exploration. Non-pathogenic (non-*Nme*) *Neisseria* may contribute directly to pathogenesis of IgAN and/or *Nme* carriage may be a biomarker of a milder immunologic phenotype. Current work to investigate mechanisms explaining these associations includes evaluating complement and cytokine profiles in relation to *Neisseria* status.

TH-OR056

Systematic Analysis of IgA1 Glycosylation in IgA Nephropathy, Membranous Nephropathy and Healthy Subjects and the Effects of Ethnicity Karen Molyneux,[1] David Harry John Wimbury,[1] Daniel P. Gale,[2] Patricia Higgins,[1] Peiran Yin,[3] Xueqing Yu,[3] Jonathan Barratt.[1] *[1]Infection, Immunity & Inflammation, Univ of Leicester, Leicester, United Kingdom; [2]UCL Centre for Nephrology, Univ College, London, United Kingdom; [3]Inst of Nephrology, SunYat-Sen Univ, Guangzhou, China.*

Background: IgA nephropathy (IgAN) is characterised by the deposition of galactose deficient IgA1 (Gd-IgA)-containing immune complexes in the mesangium. IgAN is especially common in East Asia, and while the diagnostic criteria are the same worldwide, there are marked regional differences in gender distribution and clinical outcomes, suggesting that the biology of the condition is not uniform. The aim of this study was to compare levels of Gd-IgA in serum from Caucasian and Chinese patient and control cohorts.

Methods: An ELISA-based method was used to measure binding of the lectin Helix aspersa agglutinin to IgA captured from serum from: 1091 UK IgAN patients, 998 Chinese IgAN patients, 360 UK membranous nephropathy (MN) patients, 193 UK controls and 80 Chinese controls.

Results: UK IgAN patients exhibited higher Gd-IgA levels than UK controls with levels highest in patients with progressive renal damage ($p<0.05$ compared with non-progressors). Gd-IgA was lower in UK MN patients compared to both IgAN patients ($p<0.0001$) and the healthy subjects ($p<0.0001$) from the UK. Among Chinese individuals, Gd-IgA levels were higher in IgAN patients compared to healthy controls ($p<0.05$), but levels were lower in the Chinese compared to the UK cohort, in both IgAN patients ($p<0.0001$) and controls ($p<0.0001$).

Conclusions: Gd-IgA1 levels are associated with IgAN in Caucasian and Chinese patients but the difference in prevalence of IgAN cannot be attributed to differences in Gd-IgA levels between these populations. Results also presented at this meeting show that a C1GALT1 haplotype, common in Caucasians but rare in Chinese people, is strongly associated with elevated Gd-IgA1 levels and the reduced Gd-IgA in the Chinese population is consistent with reduced frequency of this haplotype. These data support the hypothesis that the causes of IgAN vary across the world.

TH-OR057

The MEST Kidney Biopsy Score Predicts Renal Outcome in STOP-IgAN Trial Patients - A Post-Hoc Study Jürgen Floege,[1] Thomas Rauen,[1] Judith Isabel Schimpf,[1] Christina Fitzner,[2] Frank Eitner,[3] Hermann-Josef Groene,[4] Ralf-Dieter Hilgers.[2] *[1]Nephrology, RWTH Aachen, Aachen, Germany; [2]Medical Statistics, RWTH Aachen, Aachen, Germany; [3]Bayer AG, Wuppertal, Germany; [4]German Cancer Research Center, Heidelberg, Germany.*

Background: Since the Oxford-MEST classification of IgA nephropathy (IgAN) was introduced, still there is limited information on its predictive power in randomized clinical trials.

Methods: We retrospectively re-analyzed renal biopsies from STOP IgAN trial participants (Rauen *et al*, NEJM 2015) using the MEST criteria (available biopsies in 70/162 patients) . The analyses were performed by researchers blinded to the clinical outcome of patients. Biopsies had been obtained at a median of 9.4 months prior to randomization. MEST scores were correlated with trial endpoints. Analyses were done by *Welch,* ANCOVA and *Fisher 's exact* tests.

Results: Mesangial hypercellularity (M1 score) significantly correlated with the subsequent annual eGFR loss during the 3 year trial and showed a weak association with full clinical remission and an eGFR-loss≥15 ml/min. T1/2 scores were significantly associated with ESRD onset in the group with additional immunosuppression, but not in the group with supportive-care only. Baseline eGFR was significantly lower when tubulointerstitial fibrosis (T1/2) was present (45.2±15.7 vs. 74.6±28.2 ml/min; $p<0.0001$), whereas initial proteinuria did not differ between the histological groups. Endocapillary hypercellularity (E) or glomerular segmental sclerosis (S) had no influence on any clinical outcome parameter.

	M0 (events/ total)	M1 (events/ total)	p-value	T0 (events/ total)	T1/2 (events/ total)	p-value
Full clinical remission	8/48 (17%)	0/17 (0%)	0.099	6/39 (15%)	2/26 (8%)	0.460
GFR-loss≥15 ml/min	14/51 (27%)	9/18 (50%)	0.092	11/40 (28%)	12/29 (41%)	0.302
ESRD	7/51 (14%)	1/18 (6%)	0.671	1/40 (3%)	7/29 (24%)	0.008
Absolute annual GFR change - ml/ min/1.73m² (mean±SD)	-0.79±4.50	-5.06±5.17	0.002	-2.05±5.40	-2.01±4.54	0.362

Conclusions: This post-hoc analysis of STOP IgAN biopsies indicates that the presence of a M1-score is associated with a worse eGFR course whereas a T1/2 score predicts ESRD.

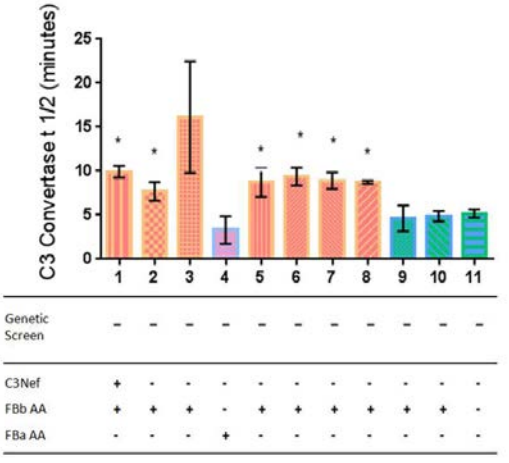
TH-OR058

C3 Glomerulopathy Associated Complement Factor B Autoantibodies Stabilize the C3 Convertase Alexandria Isabeau Clarissa Leonhardt,[1] Yuzhou Zhang,[1] Dingwu Shao,[1] Richard J. Smith,[2] Carla M. Nester.[2] *[1]Molecular Otolaryngology and Renal Research Laboratory, Univ of Iowa, Iowa City, IA; [2]Dept of Internal Medicine and Pediatrics, Univ of Iowa, Iowa City, IA.*

Background: C3 Glomerulopathy (C3G) can be a devastating glomerular disease for which targeted therapeutics are not available. The underlying disease mechanism is dysregulation of the alternative pathway of complement (AP), driven by either genetic factors or acquired autoantibodies. The most common of the latter are C3 nephritic factors, which stabilize the C3 convertase and are identified in the majority of patients. We hypothesized that antibodies to other complement proteins may also be associated with C3G. Their identification has treatment implications.

Methods: Comprehensive complement and genetic studies were completed on 87 patients with a biopsy diagnosis of C3G and 300 controls. FB autoantibodies (FBAA) were subtyped (ELISA) and evaluated by surface plasmon resonance (SPR) on a CM5 chip. After the formation of C3bBb, test IgG (x3) was flowed across the chip (dilutions, 25-400ug/ml). Interactions were analyzed with BIAcore software.

Results: FBAA were found in 9 of 87 patients and 4 of controls; 8 patients had sufficient sera for further testing. 7 of 8 patients had FBbAA (1 patient had FBaAAs). FBbAA increased convertase half-life (native convertase t ½ = 5.1 min; FBbAA stabilized, t ½ = 7.69 – 10.55 min, p = <0.05). With control IgG, FBbAA from control (subjects 9 and 10), and FBaAA from C3G patient 4, convertase t ½ was not increased. C3G patients with functionally significant FBAAs had AP biomarker abnormalities; no controls with FBAA had biomarker abnormalities.



Conclusions: FBbAA from C3G patients stabilize convertase. Nonstabilizing FBAAs can be identified in normal controls. Our data implicate FBAA as drivers of C3G.

Funding: NIDDK Support

TH-OR059

Characterization of C3 in C3 Glomerulopathy Sanjeev Sethi,[1] Fernando C. Fervenza,[1] Julie A. Vrana,[1] Richard J. Smith.[2] *[1]Mayo Clinic, Rochester, MN; [2]Carver College of Medicine, Iowa City, IA.*

Background: C3 glomerulopathy (C3G) is caused by over activity of the alternative pathway of complement that results in bright glomerular C3 and minimal/no Ig staining. Laser microdissection/mass spectrometry (MS) of the 2 subtypes, C3 glomerulonephritis (C3GN) and dense deposit disease (DDD), have identified C3 as the predominant glomerular complement protein. C3 plays a central role in complement activity, with its proteolytic cleavage first generating C3a and C3b, followed by inactivation of C3b generating iC3b (which includes C3α and C3β), and further breakdown yielding C3c and terminal breakdown product C3dg. The composition of C3 breakdown products in C3G is not known.

Methods: We chose 6 cases each of C3GN and DDD to analyze the composition of glomerular C3 deposits. We analyzed the amino acid sequence of C3 spectra detected by MS to determine the percentage coverage and relative abundance of C3 products. Thus, we were able to determine the amino acid sequences mapping to the various C3 products including C3dg, C3α (C3-α1 and 2) and C3-β.

Results: C3dg is the predominant cleavage product detected with the highest amino acid coverage. The amino acid coverage of C3dg ranged from 15.4% to 50% (avg 30.7%). The remaining amino acids were present in much lesser abundance and mapped to C3-α1 (avg 6.5 %), C3-α2 (avg 6.5 %) and C3-β (avg 7.3 %). Amino acids mapping to C3a and C3f were absent. Taken together, the C3α and C3-β amino acids represent iC3b prior to or C3c after cleavage of C3dg. The C3 spectra for C3GN and DDD were surprisingly similar.

Conclusions: The finding of large amounts of C3dg suggests that C3b deposition is an active process triggered by thioester binding of C3b to the glycocalyx over the endothelial cells and GBM. Regulatory protein-mediated inactivation of C3b results in the generation of iC3b. After additional cleavages and release of C3c, mostly C3dg remains.

Eculizumab in Secondary Atypical Hemolytic Uremic Syndrome
Teresa Cavero Escribano,[1] Santiago Rodriguez de Cordoba,[2] Manuel Praga.[1]
[1]Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain; [2]Centro de Investigaciones Biológicas, Consejo Superior de Investigaciones Científicas, Madrid, Spain.

Background: Complement hyperactivity can be observed in thrombotic microangiopathies (TMA) other than atypical hemolytic uremic syndrome (aHUS), which may explain why some patients with aHUS associated with secondary TMA (secondary aHUS), have been successfully treated with eculizumab.

Methods: We present a series of 29 secondary aHUS patients treated with eculizumab: 15 drug-induced, 8 associated with systemic diseases (lupus erythematosus 3, systemic scleroderma 2, ANCA vasculitis 2, antiphospholipid syndrome 1), 2 associated with post-partum, 2 cancer-related, 1 associated with acute humoral rejection and 1 with intestinal lymphangiectasia. Prior to eculizumab treatment all patients showed severe anemia, thrombocytopenia and renal function impairment (14 requiring dialysis) and 11 presented severe extrarenal manifestations. Unsuccessful plasmapheresis was performed in 24 patients (83%). A positive outcome (TMA response) to the eculizumab treatment was defined by a normalization of hemoglobin and platelet counts and a renal function recovery with a ≥25% reduction in serum creatinine.

Results: A remarkable TMA response was observed in 20 patients (68%), with only 4 requiring dialysis and 15 (51%) showing a ≥50% serum creatinine reduction at the last follow-up. Patients with systemic diseases presented the worst outcomes with only 2 patients (one ANCA vasculitis, one antiphospholipid syndrome) showing a TMA response. Comprehensive genetic and molecular studies in 22 patients identified complement pathogenic variants in only 2 patients. With these two exceptions, eculizumab treatment was discontinued after a median of 8 weeks without the occurrence of TMA relapses.

Conclusions: Eculizumab may be an effective treatment in most patients with secondary aHUS.

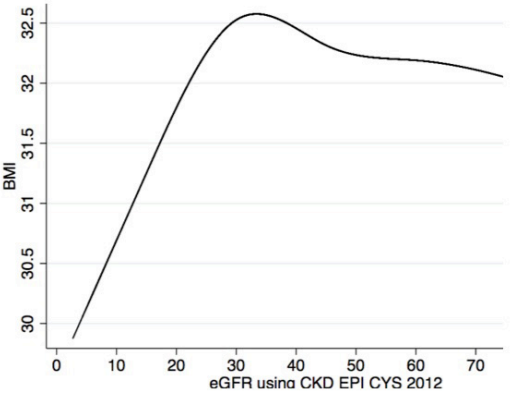
BMI Trajectory with Decline in Kidney Function: Results from the CRIC Study
Elaine Ku,[1] Kirsten L. Johansen,[1] Charles E. McCulloch,[1] Joel D. Kopple,[3] Alan S. Go,[2] Dawei Xie,[2] L. Lee Hamm,[2] Jiang He,[2] John W. Kusek,[2] Sankar D. Navaneethan,[2] Ana C. Ricardo,[2] Hernan Rincon-Choles,[2] Chi-Yuan Hsu.[1] *[1]UCSF; [2]CRIC; [3]Harbor-UCLA.*

Background: Protein-energy wasting is associated with poor prognosis for CKD and ESRD patients. However, few studies have rigorously described the relationship between CKD progression and weight changes. We compared longitudinal weight trajectory, assessed by changes in body mass index [BMI] in the Chronic Renal Insufficiency Cohort (CRIC) participants, with decline in renal function.

Methods: We included 3933 participants with CKD in CRIC for longitudinal analysis. Weight, height, and cystatin C were measured annually. We used segmented, mixed effects regression for modeling the repeated measures of BMI as a function of estimated GFR (using 2012 CKD-EPI cystatin C equation). We then examined the association between weight loss and risk factors including age, race, sex, diabetes, and heart failure.

Results: During mean longitudinal follow-up over 7.6 years, BMI increased by 0.15 kg/m^2 (95% CI 0.11-0.18) with every 10 mL/min/1.73 m^2 decline in renal function until eGFR of approximately 30 mL/min/1.73m^2. When eGFR dropped below 30 mL/min/1.73 m^2, a 0.9 kg/m^2 (95% CI 0.88-1.1) decline in BMI was noted with every 10 mL/min/1.73 m^2 decline in eGFR. (An 0.9 point decline in BMI is ~3 kg loss in a 5'10" adult.) The associations between eGFR and BMI before and after an eGFR of 30 mL/min/1.73 m^2 were statistically significantly different (p<0.001).



Of the risk factors assessed, only black race and diabetes were risk factors that were statistically significantly associated with greater weight loss (p<0.001).

Conclusions: In adults with CKD, weight loss mostly occurs when eGFR is ≤30 mL/min/1.73 m^2. Further research is needed to determine whether interventions to prevent weight loss during advanced stages of CKD may improve outcomes.

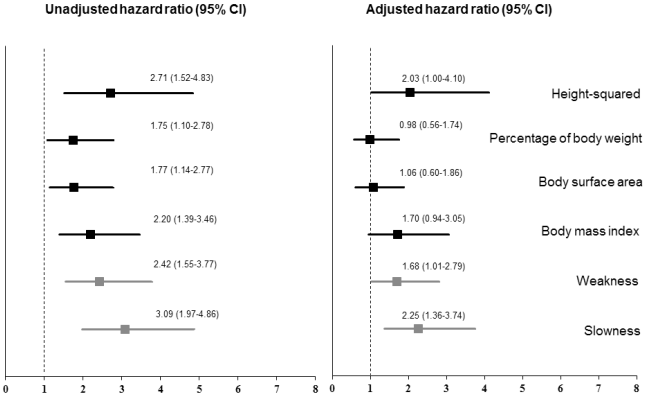
Associations of Sarcopenia and Its Individual Criteria with Mortality among Patients on Hemodialysis
Piyawan Kittiskulnam,[1] Glenn Matthew Chertow,[2] Juan Jesus Carrero,[3] Cynthia Delgado,[1] George A. Kaysen,[4] Kirsten L. Johansen.[1] *[1]UCSF; [2]Stanford Univ; [3]Karolinska Inst; [4]UC Davis.*

Background: Sarcopenia is defined as low muscle mass combined with reduced strength or physical performance. The relative importance of sarcopenia and its individual components as independent predictors of mortality in dialysis population have not been determined.

Methods: ACTIVE/ADIPOSE enrolled prevalent HD patients from San Francisco and Atlanta from 2009 to 2011. We estimated whole-body muscle mass using bioimpedance spectroscopy (n=645;age 56.7±14.5 years). We defined low muscle mass as>2SD below sex-specific means for young adults from NHANES and indexed to height^2, body weight, BSA, or BMI. We evaluated the association of sarcopenia, low muscle mass by four indexing methods, weak grip strength, and slow gait speed with mortality outcome.

Results: Seventy-eight deaths (12.1%) were observed during a mean follow-up of 1.9 years. Sarcopenia was not associated with mortality after adjusting for covariates. No muscle mass criteria were associated with death, regardless of indexing metrics. In contrast, having weak grip strength or slow gait speed was associated with mortality in adjusted model.



Only slowness improved the predictive accuracy for death with an increase in C-statistic from 0.63 to 0.68, p=0.004. However, both slowness and weakness significantly improved the continuous net reclassification index (cNRI) compared to the adjusted models without performance measures (overall cNRI of 50.5% for slowness and 33.7% for weakness) but models with muscle size did not.

Conclusions: Sarcopenia was not a better predictor of mortality than functional limitations alone in HD patients. Low muscle mass was not associated with mortality regardless of indexing method. In contrast, physical performance measures (slow gait speed and weak grip strength) were associated with mortality even after adjustment for confounders.

Healthy Eating Patterns, Mortality, and End-Stage Kidney Disease: A Meta-Analysis of Cohort Studies Suetonia Palmer,[1] Jaimon T. Kelly,[2] Shu Ning Wai,[2] Marinella Ruospo,[3,4] Juan Jesus Carrero,[5] Giovanni F.M. Strippoli,[3,6,7] Katrina L. Campbell.[2,8] *[1]Univ of Otago Christchurch; [2]Bond Univ; [3]Diaverum Medical Scientific Office; [4]Amedeo Avogadro Univ of Eastern Piedmont; [5]Karolinska Inst; [6]Univ of Sydney; [7]Univ of Bari; [8]Univ of Queensland.*

Background: Patients with CKD are advised to follow dietary recommendations that restrict individual nutrients. Emerging evidence suggests that whole dietary patterns may be more important than single nutrients in influencing clinical outcomes. RCTs in the general population showed that adherence to a Mediterranean diet lowers mortality in people at high risk of cardiovascular disease. This meta-analysis aimed to evaluate the association between dietary patterns and risks of mortality and end-stage kidney disease (ESKD) among patients with CKD.

Methods: A systematic review and meta-analysis of cohort studies of dietary patterns in adults with CKD was conducted. Electronic databases (Medline, Embase, Cochrane) were searched without language restriction in November 2015 by two independent authors. Risk ratios were summarized using random effects meta-analysis. Primary outcomes were all-cause mortality and ESKD.

Results: Seven studies (n=15,285 patients) were included. Healthy eating patterns were higher in fruit and vegetables, fish, legumes, cereals, whole grains, and fiber, and lower in red meat, salt, and refined sugars. Health eating patterns were consistently associated with lower mortality (relative risk 0.73, CI 0.63-0.83; absolute risk 46 fewer deaths (CI 29-63) per 1000 patients over 5 years). There was no evidence of a significant association between healthy eating patterns and risks of ESKD (RR 1.04, CI 0.68-1.40).

Conclusions: Healthy eating patterns are associated with clinically-important reductions in mortality for people with CKD. Dietary advice on whole food approaches encouraging increased fruit and vegetable, fish, legume, whole grains, and fiber intake, and reduced red meat, sodium, and refined sugar consumption could be an effective strategy to lower mortality in CKD. A randomized trial of interventions to support healthy eating would be of clinical relevance in the CKD population.

TH-OR064

Protein Intake and Long-Term Change in eGFR in the Jackson Heart Study Rakesh Malhotra,[1] Loren Lipworth,[1] Kerri L. Cavanaugh,[1] Bessie A. Young,[2] Adolfo Correa,[3] Talat Alp Ikizler,[1] Edmond Kato Kabagambe.[1] *[1]VUMC; [2]UW; [3]UMMC.*

Background: Dietary protein intake could have deleterious renal effects in populations at risk for chronic kidney disease such as those with diabetes. Here, we examined whether higher protein intake($\geq 80^{th}$vs.$<20^{th}$ percentile of energy from protein) is associated with decline in kidney function and whether this decline varied by diabetes status.

Methods: Participants were African Americans(n=5301) who enrolled in the Jackson Heart Study between 2000 and 2004. Dietary intake was assessed using a validated FFQ at baseline and sCR was measured at baseline(visit1) and 8 years later(visit3). Estimated glomerular filtration rates(eGFRs) at baseline and follow-up were computed using the CKD-EPI equation. Participants with an eGFR<60 mL/min/1.73 m^2 at baseline or missing dietary data or sCR at visit 1 or visit 3 were excluded from the analyses. The change in eGFR was computed by subtracting eGFR at visit 1 from that at visit 3. ANOVA was used to determine whether long-term change in eGFR significantly varies by protein intake.

Results: Of 3,165 subjects,64% were women,57% hypertensive and19% diabetic. The median percent energy intake from protein was 14.3(12.4,16.4). During a median follow-up of 8.0(7.4,8.3) years, eGFR declined by 10.5% from a mean(SD) of 97.4(17.5) to 86.9(21.3) mL/min/1.73 m^2. Consumption of protein was positively associated with decline in eGFR, particularly among those with diabetes at baseline. In the fully adjusted model, protein(P=0.03) and diabetes(P <0.0001) main effects and their interaction term(P=0.01) were statistically significant.

Figure 1. Adjusted mean decline in eGFR by diabetes status and quintiles of percent energy from protein intake in the JHS

		Quintiles of energy from protein intake				
		1(n=633)	2(n=633)	3(n=633)	4(n=633)	5(n=633)
Protein intake, %*		10.7	12.7	14.3	16.0	18.7
Model 1†	Diabetic	-15.8 ± 2.7	-16.1 ± 2.3	-10.3 ± 1.6	-17.3 ± 1.8	-17.8 ± 1.6
	Non-diabetic	-10.6 ± 0.6	-8.8 ± 0.5	-9.6 ± 0.6	-8.8 ± 0.6	-8.2 ± 0.7
Model 2‡	Diabetic	-15.9 ± 2.8	-16.7 ± 2.3	-12.0 ± 1.6	-19.1 ± 1.8	-20.0 ± 1.7
	Non-diabetic	-11.1 ± 0.8	-10.0 ± 0.7	-11.4 ± 0.7	-10.8 ± 0.8	-11.3 ± 1.0

*Median protein intake in a given quintile. Other values are means ± s.e.m and are adjusted for the variables in the model.
† Model 1 includes age, diabetes(yes, no), energy from protein intake and diabetes*protein interaction term.
‡ Model 2 includes model 1 plus sex, smoking, BMI, alcohol use, SBP, DBP, years between creatinine measurements, total energy intake and percent energy from saturated fat, polyunsaturated fat, trans fat, and carbohydrate.

Conclusions: Our results show that among African Americans with diabetes at baseline, protein intake is positively associated with greater decline in eGFR after accounting for risk factors for kidney disease. Further studies are warranted to corroborate these findings and to elucidate the underlying mechanism.

TH-OR065

Sarcopenia, Obesity, and Mortality in U.S. Adults with and without Chronic Kidney Disease Matthew K. Abramowitz,[1] Lagu A. Androga,[1] Afolarin Ayomide Amodu,[2] Deep Sharma.[1] *[1]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [2]Seton Hall Univ School of Health and Medical Sciences, St. Francis Medical Center, Trenton, NJ.*

Background: In pre-dialysis chronic kidney disease (CKD), the association of muscle mass with mortality is poorly defined, and no study has examined outcomes related to the co-occurrence of low muscle mass and excess adiposity (sarcopenic-obesity). We hypothesized that associations of sarcopenia and sarcopenic-obesity with death would be stronger in persons with CKD than in those without, as CKD-induced muscle wasting is likely a poor prognostic factor.

Methods: We examined abnormalities of muscle and fat mass using dual-energy x-ray absorptiometry measurements in adult participants of the National Health and Nutrition Examination Survey 1999-2004 to define sarcopenia, obesity, and sarcopenic-obesity. Cox proportional hazard models were created to determine whether associations of body composition with all-cause mortality differed between participants with CKD compared to those without.

Results: CKD modified the association of body composition with mortality (p=0.01 for interaction). In participants without CKD, both sarcopenia and sarcopenic obesity were independently associated with increased mortality compared with normal body composition (hazard ratio (HR) 1.44 (95%CI 1.07-1.93) and 1.64 (95%CI 1.26-2.13), respectively). These associations were not present among participants with CKD (HR 1.24 (95%CI 0.89-1.71) and 1.05 (95%CI 0.75-1.46) for sarcopenia and sarcopenic-obesity, respectively; p-value for interaction by CKD status: sarcopenia, p=0.22; sarcopenic-obesity, p=0.003). Conversely, obese persons had the lowest adjusted risk of death among persons with CKD, with an increased risk among those with sarcopenia (HR 1.43 (95%CI 1.05-1.95)) but not sarcopenic-obesity (HR 1.21 (95%CI 0.89-1.65)), compared with obesity.

Conclusions: In conclusion, sarcopenia associates with increased mortality regardless of eGFR, but excess adiposity modifies this association among people with CKD. Future studies of prognosis and weight loss and exercise interventions in CKD patients should consider muscle mass and adiposity together rather than in isolation.

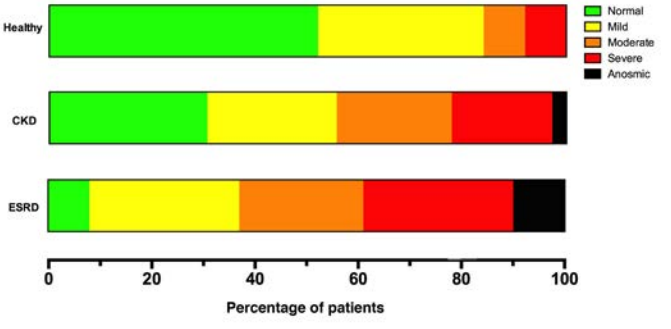
Olfactory and Nutritional Impairment in Patients with Kidney Disease: Assessment and Intervention Teodor G. Paunescu, Jeremy Weiser, Joshua Wibecan, Sahir Kalim, Dihua Xu, Kristin M. Corapi, Nwamaka Denise Eneanya, Dennis Brown, Ravi I. Thadhani, Sagar U. Nigwekar. *Mass. General Hospital, Boston, MA.*

Background: Malnutrition is common in chronic kidney disease (CKD) and especially end-stage renal disease (ESRD) patients and may be partially mediated by olfactory defects. We characterized these defects in renal patients and tested a novel intervention to improve olfaction.

Methods: We quantified olfaction in CKD (n=36) and ESRD patients (n=100) and healthy volunteers (HV, n=25) using the validated Univ. of Penn. Smell Identification Test (UPSIT, through which subjects were categorized as normosmic; mildly, moderately or severely microsmic; or anosmic) and the Smell Threshold Test for 2-phenylethanol detection (Sensonics, Inc.). We then performed a pilot study to test the effect of nasal theophylline on olfactory impairment.

Results: Most HVs were normosmic or mildly microsmic. CKD patients were equally distributed among normal and mild, moderate and severe microsmic categories, and 1 patient was anosmic. Strikingly, only 8% of ESRD patients were normosmic and 10% were anosmic.



Odor threshold was not affected in CKD, but was impaired in ESRD patients (p=0.015 vs. CKD). Nutritional markers (total cholesterol, LDL, albumin and transferrin) showed a modest but statistically significant association with UPSIT categories (R^2 range: 0.10-0.16; p range: <0.001-0.006). We next enrolled 6 ESRD patients in a 6-week pilot clinical trial for nasal theophylline (CT.gov:NCT02479451). Compared to baseline, the mean UPSIT score increased in 5 patients by 2-10% during treatment. Patients reached maximum scores of 12±3% above baseline; 3 patients improved by 1 UPSIT category.

Conclusions: CKD and ESRD patients have olfactory defects that may correlate with malnutrition. Nasal theophylline should be further tested to determine if this novel intervention improves olfactory defects and potentially nutritional status.

TH-OR067

Intradialytic Protein Supplementation Increases Protein Intake in Older, but Not Younger, Hemodialysis Patients and Is Associated with Improved Hip Bone Mineral Density Annabel Biruete,[1] Peter J. Fitschen,[1] Jin Hee Jeong,[1] Pei-Tzu Wu,[2] Emily Tomayko,[3] Ken Wilund.[1] *[1]Univ of Illinois, Urbana, IL; [2]Univ of California, Los Angeles, CA; [3]Oregon State Univ, Corvallis, OR.*

Background: Hemodialysis (HD) patients have elevated risk of bone fractures, partly due to impaired bone metabolism and protein-energy wasting. Protein supplementation has shown to improve bone health in older adults, but this effect has not been explored in HD patients.

Methods: We performed a post-hoc analysis of the IHOPE trial. In short, HD patients (n=138; <60y: 48±9y, 54% male, 88% African American; ≥60y: 67±7y, 63% male, 80% African American) were randomized for 12 months to: placebo (CON), protein supplementation (PRO) or protein + exercise training (PRO+EX). Patients in PRO and PRO+EX received 30 grams of whey protein every HD session, while the PRO+EX group also cycled at moderate intensity for 30-45 minutes during HD. Patients where then divided into <60y (n=88) and ≥60y (n=50). Dietary intake and bone and body composition by DEXA were assessed at 0, 6 and 12 months. No differences were observed between PRO and PRO+EX in the variables measured, so the groups were collapsed for analysis.

Results: In patients ≥60y, PRO had higher total protein intake on dialysis days compared to CON at 6 and 12 months (≥60y CON: 0.58±0.33, 0.51±0.25 and 0.59±0.35 vs. PRO: 0.73±0.26, 0.98±0.32 and 1.07±0.34 g/kg/day for 0, 6 and 12 months, respectively, p interaction=0.009) with no effect in <60y (p=0.48) Furthermore, the ≥60y PRO maintained hip bone mineral density (h-BMD), while there was a decrease in CON (CON 0.87±0.13 and 0.84±0.13 vs. PRO 0.87±0.16 and 0.86±0.16 g/cm^2 at 0 and 12 months, respectively; interaction p=0.02) with a similar trend in the femoral neck BMD (p=0.07); this effect was not seen in <60y (p=0.826). Finally, there was no effect of PRO on body composition or blood markers of bone metabolism (calcium, phosphorus and parathyroid hormone) in either age group (p>0.05).

Conclusions: Intradialytic PRO supplementation improved protein intake and attenuated the decrease in h-BMD, a predictor of fractures, in older HD patients. Future studies should aim to explore the effect of whey protein on fracture rates in older HD patients.

TH-OR068

An Open Label Randomized Clinical Study to Evaluate Impact of Soy-Protein Powder in Malnourished Dialysis Patients (IMPROVES STUDY) Anita Saxena,[1] J. Kothari,[2] M. Gokulnath,[3] Amit Gupta,[1] Juan Jesus Carrero,[4] Chandra M. Pandey.[1] *[1]Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, India; [2]Nephrology, Hinduja Hospital, Mumbai, Maharashtra, India; [3]Nephrology, St. John's Medical College, Bangalore, Karnatak, India; [4]Renal Medicine, Karolinska Inst, Karolinska Inst, Stockholm, Sweden.*

Background: Protein energy wasting (PEW) affects survival in patients on maintenance dialysis. Objective to evaluate effect of oral nutritional supplement on hypoalbuminemic dialysis patients.

Methods: Multicenter randomized intervention on maintenance dialysis (MD) patients with serum albumin <3.8g/dL. 180 patients were randomly assigned to 1:1 standard treatment (1.2 g/kg/d and 35 kcal/kg/d control) or standard treatment plus an oral nutritional supplement (ONS) for 6 months. The supplemented group received in addition 30 g/d of a renal-specific ONS (Proseventy©) containing 70% soya protein. At month 0, 3 and 6 routine biochemistry, subjective global assessment (SGA), dietary recalls, and skinfold thickness (SFT) were done.

Results: At inclusion, no difference was found in age, sex,dietary intake, SGA, CRP and biochemistry. Control group had significantly higher serum albumin (3.2±0.41 and 3.37±0.36 p 0.013) and subscapular SFT (14±6.0, 12.1±5.0 p 0.032) than supplemented group. At month 3, the supplemented group significantly increased their albumin (3.3 ±0.48 vs 3.4 ±0.43) and illiacSFT (15.5 ±8.5 and 18.1 ± 8.6 0.043). Protein intake was significantly higher in supplemented group compared to controls at 3 and 6 months (64± 21.5 54. ±1 16.3 p 0.004 and 69 ±28.4 and 53.5 ±15.1 p 0.000) respectively. In supplemented group subscapularSFT (16 ±5 12±5.1 p 0.000) was significantly high and albumin increased to 3.4± 0.049 versus 3.3 ±0.51 in controls at 6 months but difference in albumin was not significant. Serum phosphorus and lipid were not altered.

Conclusions: Addition of protein-rich renal specific ONS to standard nutritional counseling raised serum albumin and increased SFT in PEW patients undergoing dialysis. However, despite supplementation the serum albumin did not rise to ≥3.8 g/dL (ISRNM criteria). To correct PEW, ONS has to be given for longer period.

TH-OR069

Intramuscular Myostatin Gene Expression following Aerobic and Combined Exercise in Chronic Kidney Disease Douglas W. Gould,[1] Emma L. Watson,[1] Thomas James Wilkinson,[1] Soteris Xenophontos,[1] Alice C. Smith,[1,2] Joao L. Viana.[2] *[1]Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; [2]Univ Inst of Maia.*

Background: Muscle wasting is common in chronic kidney disease (CKD) and is associated with poor physical function and mortality. Myostatin (MSTN) is a potent negative regulator of muscle mass. It acts through the Activin 2B Receptor (AC2BR), eliciting both increased protein catabolism and reduced protein synthesis. The differential effects of aerobic exercise (AE) and resistance exercise (RE) on catabolic and anabolic pathways in CKD are poorly understood. Therefore we investigated the effects of AE or combined aerobic and resistance exercise (CE) on MSTN and AC2BR expression, and muscle hypertrophy in CKD.

Methods: 20 CKD patients (eGFR 25 ml/min/1.73m^2 [range 9-41]; age 59.6yrs [range 27-80]) were randomised to AE (3x/week for 12 weeks, n=9) or CE (AE + RE 3x/week for 12 weeks; n=11). Rectus femoris cross-sectional area (RF-CSA) was measured by ultrasound at baseline and 12-weeks. In 12 patients (AE n=5, CE n=7) muscle biopsies were obtained from the vastus lateralis at baseline (B1) and at 24h after the first (B2) and final (B3) exercise sessions. MSTN and AC2BR expression was analysed by RT-PCR and reported as % change from B1.

Results: RF-CSA was unchanged by AE (baseline 8.76±2.62cm^2, 12wks 9.21±2.44cm^2; p=.121) but significantly increased after CE (baseline 8.15±2.96cm^2, 12wks 9.25±3.15cm^2 p<.001). AE downregulated MSTN by 72% at B2 (p=.046) and 58% at B3 (p=.008). After CE, MSTN expression was downregulated by 69% (p=.005) at B2, but was non-significantly upregulated by 73% (p=.435) at B3. AC2BR expression mirrored this pattern but no significant interactions were seen between timepoints (AE; F=2.298, p=.163 & CE; F=1.099, p=.155).

Conclusions: These data suggest that AE can suppress MSTN expression in non-dialysis CKD, thereby potentially attenuating muscle catabolism. However, hypertrophy was only observed following CE, demonstrating that suppression of MSTN alone is insufficient to increase muscle size, and that an additional anabolic stimulus (RE) is required to achieve hypertrophy. These findings indicate the importance of RE in CKD and will inform guidelines for effective exercise in this underinvestigated population.

Impact of L-Carnitine Pretreatment on Intravenous Iron Administration-Induced Oxidative Stress and Inflammatory Response in Patients with CKD Zaher Armaly,[1] Kamal Hassan,[2] Nayef Mohamed Habbashe,[3] Rawi Ramadan,[4] Gattas Naser,[5] Raymond Farah,[6] Zaid Abassi.[7] *[1]Nephrology, EMMS, Nazareth, Nazareth, Israel; [2]Nephrology, Western Galilee Hospital-Nahariya, Nahariya, Israel; [3]Nephrology, HaEmeq Medical Center, Afula, Israel; [4]Nephrology, Rambam Health Campus, Haifa, Israel; [5]Internal Medicine, Western Galilee Hospital-Nahariya, Nahariya, Israel; [6]Internal Medicine, Ziv Medical Center, Safed, Israel; [7]Physiology, Faculty of Medicine, Technion, IIT, Haifa, Israel.*

Background: Anemia is a common in CKD patients. It is attributed to decreased erythropoietin (EPO) production, low iron stores, and chronic inflammationy. Therefore, therapy includes not only recombinant EPO, but also iron replenishment. However, the latter induces oxidative stress/inflammation. L-carnitine supplementation might have positive effects on the response to EPO in HD patients. However, there is no evidence whether this approach is also beneficial in earlier-stage CKD patients. Thus, the present study examined whether long term L-carnitine therapy prevents IVIR-induced oxidative stress and whether it improves response to EPO.

Methods: This study included 32 anemic CKD patients (stages 2-4) that were divided into 2 subgroups: Group 1: 16 patients were given a weekly IVIR (Sodium ferric gluconate, [125 mg/100 ml]) for 12 weeks. Group 2: 16 patients received the same IVIR regimen but also carnitine (20 mg/kg, IV) was administered weekly prior to IVIR administration through the whole study. Weekly blood samples were drawn before and after each IVIR for C-reactive protein (CRP), advanced oxidative protein products (AOPP), TBARS, fibrinogen, NGAL, in addition to routine complete blood count and biochemical analyses.

Results: Combined administration of IVIR and carnitine increased Hb more profoundly (+8%) than those treated with IVIR alone (+13%). While IVIR alone induced oxidative and inflammatory responses, patients who received carnitine did not exhibit these adverse effects, as was evident by abolishing IVIR-induced elevation in CRP, NGAL, AOPP, TBARS and Fibronectin.

Conclusions: Our findings demonstrate that co-administration of carnitine with IVIR preferentially attenuates the adverse consequences of IVIR in CKD patients, suggests a role for carnitine therapy in these subjects.

TH-OR071

A CRISP(e)R View on Kidney Organoids Cecilia Borestrom, Anna Jonebring, Marcello Maresca, Barbara Valastro, Anna Collén. *Innovative Medicines & Early Development, AstraZeneca, Mölndal, Sweden.*

Background: Development of physiologically relevant cellular models, with strong translatability to human pathophysiology, is critical for identification and validation of novel therapeutic targets. Induced pluripotent stem cells (iPSCs) are an invaluable resource for modeling complex tissues, and tools to optimize differentiation protocols are crucial for progression of this promising field.

Methods: Utilizing CRISPR/Cas9 in hiPSCs we have established a model system, in which kidney commitment, glomerular maturation and podocyte health can be monitored in living cells using fluorescently tagged kidney lineage markers. Evaluation of differentiation and maturation has been confirmed using qPCR, flow cytometry, confocal microscopy, immunohistochemistry and electron microscopy.

Results: The presented work focuses on two kidney lineage markers; SIX2 and NPHS1, for tracing early nephron commitment and glomerular maturation in the same cell. Utilizing this dual reporter cell line, we have optimized progenitor formation and confirmed 3D culturing as a critical component in maturation of podocyte-containing kidney organoids. These organoids show expression of key markers of kidney biology, as well as renal cortical structures with microvilli, tight junctions and podocyte foot processes visualized by electron microscopy.

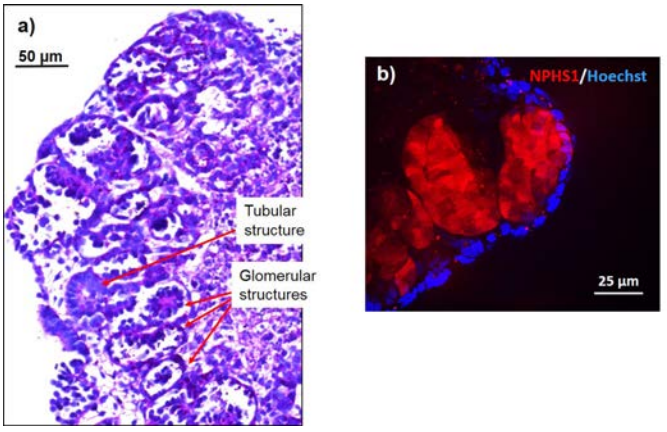

Figure a) PAS-stained section of organoid showing glomerular and tubular structures b) live image of organoid showing glomerular structures visualized by expression of NPHS1-reporter.

Conclusions: This work builds on the published kidney organoid work from the Small and Bonventre labs and extends it to build a system for live imaging in 3D, where we are able to assess longer term glomerular maturation and health. Furthermore, development of human nephron-like structures in vitro fills a major gap in assessing effectiveness of CKD-treatments and also in the possibility of clinical translations.

Monitoring and Improving Kidney Organiod Development through the Generation of Human Pluripotent Stem Cell Reporter Lines

Sara E. Howden,[1,2] Jessica May Vanslambrouck,[1] Andrew G. Elefanty,[1,2] Ed G. Stanley,[1,2] Melissa H. Little.[1,2] *[1]Murdoch Childrens Research Inst, Parkville, Vic, Australia; [2]Dept of Peadiatrics, Univ of Melbourne, Parkville, Vic, Australia.*

Background: We have recently established a robust protocol for the generation of kidney organoids from human pluripotent stem cells (Takasato et al, 2015). While such organoids appear to accurately model early human kidney, containing evidence of nephrons, vasculature and surrounding interstitium, further characterization of individual component cell types is required to both investigate and optimize their identity and function. One approach is the use of specific reporter lines to facilitate isolation and visualization of renal sub-compartments within kidney organoids.

Methods: We report the generation of reporters to characterise two key subcompartments; cap mesenchyme (CM), which represents the nephron progenitor population, and vasculature.To mark CM, the mCherry reporter gene (linked by a T2A sequence) was fused to the 3' end of human CITED1 using a previously described protocol (Howden et al, 2015) that enables reprogramming and gene targeting to be performed simultaneously in human fibroblasts. To mark vasculature we used an established (HES3) reporter line that carries mCherry targeted to the Sox17 locus (SOX17:mCherry).

Results: Seven CITED1-mCherry iPSC clones were correctly targeted according to PCR analysis of genomic DNA using primers flanking the recombination junction. During differentiation, mCherry expression could be detected several days after the initiation of differentiation and peaked around day 7 but declined as nephron differentiation proceeded. A SOX17:mCherry endothelial network was also visible early in organoid development, with vasculature increasing as the organoids matured.

Conclusions: We have demonstrated the utility of the CRISPR/Cas9 system for tagging key genes involved in kidney organogenesis. These reporter lines represent important tools for optimizing culture conditions for CM maintenance / self renewal and optimal vascularization within organoids.

Kidney Organoids Generated from Human Pluripotent Stem Cells under Defined Conditions Become Vascularized upon Transplantation In Vivo

Cathelijne W. Van den Berg,[1] Minoru Takasato,[2,3] Ellen Lievers,[1] Cristina Avramut,[1] Danielle Leuning,[1] Loes E. Wiersma,[1] Melissa H. Little,[2] Ton J. Rabelink.[1] *[1]Leiden Univ Medical Center, Leiden, Netherlands; [2]Murdoch Children's Research Inst, Melbourne, Australia; [3]Riken Center for Developmental Biology, Kobe, Japan.*

Background: Human embryonic and induced pluripotent stem cells have the unique ability to differentiate into all lineages offering innovative approaches for regenerative medicine, such as the generation of transplantable organs. We aimed to derive kidney organoids from pluripotent stem cells (PSCs) under defined conditions. Recent studies have shown the ability to differentiate these cells into nephron progenitor populations; however these methods were based on PSC cultures on mouse embryonic fibroblasts.

Methods: We maintain PSCs on defined substrates in culture medium Essential 8 (E8). Adaptation of PSCs from passaging in clumps to single cells offered higher differentiation reproducibility due to more precise seeding of cell numbers. We generated kidney organoids by applying the temporospatial mechanisms that regulate the induction of renal structures during development. The 3-dimensional structures are formed by re-aggregation and contain structures derived from both ureteric epithelium and metanephric mesenchyme progenitor populations.

Results: The self-organizing organoids are positive for markers of the glomerulus, proximal and distal tubule, and collecting duct. In addition to this, we identified endothelial cell networks in the organoids. Scanning electron microscope analysis demonstrated the presence of glomerular-like structures containing podocytes with foot processes. However, we did not detect vascularization inside the glomerular structures. To further explore the possibility of vascularization of the organoids, we transplanted them under the renal capsule. Preliminary analysis showed the integration of mouse endothelial cells into the PSC-derived organoid, possibly promoting further maturation of the glomerular-like structures.

Conclusions: We demonstrated the generation of kidney organoids and their vascularization upon transplantation. These mini-kidneys are an important step forward for future applications in the development of a bioengineered kidney.

TH-OR074

Kidney Organoids Derived from Human Pluripotent Stem Cells Contain Multiple Kidney Compartments and Model Polycystic Kidney Disease

Ryuji Morizane,[1,2] Navin R. Gupta,[1] Albert Q. Lam,[1,2] Benjamin S. Freedman,[1,2] M. Todd Valerius,[1,2] Joseph V. Bonventre.[1,2] *[1]Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Harvard Stem Cell Inst, Cambridge, MA.*

Background: We generated nephron progenitor cells (NPCs) from human pluripotent stem cells (hPSCs) with 80~90% purity. These NPCs subsequently formed segmented nephron structures containing podocytes, proximal tubules, loops of Henle, and distal tubules juxtaposed to interstitial cells. To utilize this novel platform for studies of human kidney diseases, we further characterized kidney organoids and demonstrated the feasibility of modeling polycystic kidney disease.

Methods: Kidney organoids were evaluated by qRT-PCR and immunostaining for solute transporters and region specific proteins to evaluate the existence and functionality of multiple kidney compartments. We developed modified differentiation protocols for hiPSCs derived from patients with autosomal recessive polycystic kidney disease (ARPKD). Kidney organoids were generated from hESCs H9, hiPSCs HDF, and three lines of ARPKD hiPSCs.

Results: Kidney organoids highly expressed erythropoietin, 1-α-hydroxylase, ciliary proteins (PKD1, PKD2, PKHD1), and proximal tubule (AQP1, SGLT2, MDR1), distal tubule (SLC12A3), and collecting duct (AQP2) transporters. Immunostaining revealed CDH1+AQP2+ tubular cells, Endomucin+ or PDGFRβ+ vascular structures, and α-SMA+ or ICAM1+ interstitial cells, indicating the presence of collecting duct cells, endothelia, pericytes, myofibroblasts, and fibroblasts. More than 80% of organoids derived from ARPKD hiPSCs exhibited cyst formation in response to forskolin within 4 weeks of differentiation while control lines formed cysts rarely. Cysts were formed from CDH1+ tubules and were negative for LTL and KIM-1, indicating distal nephron derivation.

Conclusions: Kidney organoids derived from hPSCs contained nephron glomerular and tubular structures with many transporters present in the adult human nephron. In addition the organoids contained collecting duct and interstitial cells with multiple functional proteins. ARPKD patient-derived hiPSCs exhibited cystic phenotypes at high enough frequency serve as models of ARPKD.

Directed Differentiation to Kidney Organoids Represents a Reproducible and Developmentally Accurate Model of Human Kidney Development

Melissa H. Little,[1,2] Belinda Phipson,[1] Minoru Takasato,[1] Pei Xuan Er,[1] Jessica May Vanslambrouck,[1] Alicia Oshlack.[1] *[1]Murdoch Childrens Research Inst, Parkville, Victoria, Australia; [2]Dept of Pediatrics, The Univ of Melbourne, Parkville, Victoria, Australia.*

Background: We recently reported the generation of kidney organoids comprised of nephrons, collecting duct, vasculature and surrounding interstitium; bringing closer the prospect of personalised drug testing, disease modelling and regenerative medicine. The directed differentiation protocol relies upon replication of stepwise differentiation from pluripotency to kidney seen in embryogenesis. The utility of the protocol for these applications will rely implicitly on the reproducibility of the directed differentiation, the transferability between iPSC lines and the authenticity of the human cell types generated.

Methods: Here we report extensive RNA-seq based transcriptional analyses across the differentiation timecourse from pluripotent iPSC to kidney organoid. We also examined transcriptional variation between individual organoids, distinct differentiation experiments and between iPSC lines.

Results: Gene ontology interrogation of unsupervised clusters of synexpression, as well as pairwise temporal changes in gene expression, show a clear transition through appropriate intermediate developmental patterning events, including primitive streak, intermediate mesoderm, metanephric commitment and nephrogenesis. This confirms the high correlation between human and mouse metanephrogenesis, and provides a framework for quality control. A transcriptional correlation of >95% was observed between organoids and >90% between distinct differentiation experiments. Distinct iPSC clones also conformed to a matching transcriptional program. An examination of the most variable genes shows that these represent genes characteristic of nephron patterning, suggesting differential organoid maturation as the major source of both inter-experimental and intra-clonal variation.

Conclusions: This data provides a framework for removing sources of unwanted experimental variation in the analysis of expression data, thereby increasing the utility of this approach for personalised medicine and functional genomics.

Isolation and Maturation of Glomeruli in Human Induced Pluripotent Stem Cell-Derived Kidney Organoids Lorna J. Hale, Peter Farlie, Pei Xuan Er, Jessica May Vanslambrouck, Ed G. Stanley, Andrew G. Elefanty, Minoru Takasato, Thomas A. Forbes, Irene Ghobrial, Melissa H. Little. *Murdoch Childrens Research Inst, Melbourne, Victoria, Australia.*

Background: An essential function of the glomerular filtration barrier (GFB) is to limit the permeability of proteins from the blood to the urinary space. The GFB is composed of two highly specialised cell populations, the glomerular endothelial cells and podocytes, both of which contribute to the formation of the basement membrane, completing this three-layer structure. Defects in this barrier are a common feature of glomerulopathies, including Alport syndrome and nephrotic syndrome, however the cellular and structural complexity makes modelling of glomerulopathies *in vitro* challenging. We have generated kidney organoids from human iPSC that contain developing nephrons. These segment into distal tubules, proximal tubules and glomeruli with a primitive Bowman's capsule and podocytes with forming primary and secondary foot processes.

Methods: Glomeruli were isolated from human iPSC kidney organoids using mechanical disruption and sieving, followed by *in vitro* culture. The kidney organoids contain a network of endothelial cells, however there is only limited vascularisation of the glomeruli. To investigate whether we can overcome this issue, kidney organoids were transplanted onto the chorioallantoic membrane (CAM) of chicken embryos *in ovo*.

Results: When placed into culture, podocyte outgrowth from glomeruli was comparable to that seen from glomeruli isolated from postnatal human or mouse kidney. These podocytes form confluent monolayers with accurate polarity and podocyte-specific markers including CD2AP, Podocin, Synaptopodin and WT1. Organoids transplanted onto CAMs showed vascular ingrowth from the host embryo within 24-36hr, with organoid vascularisation increasing over time. The capacity for this exogenous blood supply to form glomerular capillaries and facilitate podocyte and GBM maturation was then investigated.

Conclusions: In conclusion, we have developed an *in vitro* method for the vascularisation of iPSC-derived kidney organoids. This will facilitate the modelling of human glomerular disease using patient-derived iPSC.

TH-OR077

Human Pluripotent Stem Cell Derived Kidney Model for Toxicity and ADME Studies Piyush Bajaj, Claire Steppan, David Rodrigues, Thomas Schroeter. *PDM-NCE, Pfizer Inc, Groton, CT.*

Background: In vitro models of kidney function have been challenging to develop. Both primary and immortalized kidney cells quickly lose the apicobasal transporters and key proteins when grown in conventional culture systems. Therefore, a need exists to develop more physiologically relevant in vitro human cell models which could be used to support efficacy, safety and ADME testing.

Methods: Pluripotent stem cells were differentiated into podocytes and proximal tubule cells (PTCs) by mimicking elements of renal developmental biology and prior literature. The stem-cell derived cells were characterized in terms of gene expression, immunocytochemistry, and functionality. Presence of several key renal transporters was confirmed by gene expression. Finally, the in vitro model was subjected to 10 compounds and expression of renal biomarkers such as KIM-1 and HO-1 was monitored at different doses.

Results: Human embryonic stem cells (H9) were differentiated in a 6-step process over 24-days to yield both podocytes and PTCs by mimicking in vivo nephrogenesis. PTCs showed megalin-dependent cubilin-mediated endocytosis of fluorescently labeled dextran and active gamma-glutamyl transpeptidase enzyme. Several key renal transporters such as OATP4C1, PEPT1/2, MRP4, MATE1, P-gp, OCTN1/2, SLC34A1/3, etc. were present at physiological levels in the differentiated cells. Most current in vitro models only express a much smaller set of these transporters. Uptake studies using small molecules confirmed the functionality of a subset of these transporters. The in vitro cell model was also subjected to 7 nephrotoxic compounds and 3 benign compounds. The system correctly predicted 9 of the 10 compounds by showing dose-dependent changes of KIM-1 and HO-1.

Conclusions: By mimicking in vivo nephrogenesis, stem-cell derived podocytes and PTCs were generated and characterized. The model system showed physiological expression of several key renal transporters making it a useful platform for ADME studies. The model could also distinguish nephrotoxic compounds from benign compounds by monitoring key renal biomarkers showing its applicability for safety studies as well.

PiggyBac Transposon-Mediated Direct Transcriptional Reprogramming to Nephron Progenitors Jessica May Vanslambrouck,[1] Lauren Elizabeth Woodard,[2] Norseha Suhaimi,[1,3] Matthew H. Wilson,[2] Melissa H. Little.[1] *[1]Murdoch Childrens Research Inst, Royal Children's Hospital, Melbourne, Australia; [2]Dept of Veterans Affairs and Dept of Medicine, Div of Nephrology and Hypertension, Vanderbilt Univ School of Medicine; [3]School of Biomedical Sciences, The Univ of Queensland, Brisbane, Australia.*

Background: Reprogramming holds great promise for the development of desperately needed novel treatments for chronic kidney disease (CKD). All nephrons in the kidney arise from embryonic nephron progenitors (NPs). However, this population is depleted near birth rendering the mature kidney unable to form new nephrons regardless of damage or disease. Recreation of NPs may allow regeneration of entire nephrons, making them an ideal target for reprogramming approaches to generate alternate CKD treatments. Using a lentivirus-mediated screen, we previously identified 6 transcription factors (*SIX1, SIX2, HOXA11, OSR1, EYA1* and *SNAI2)* sufficient to re-impose a NP-like state when co-expressed in adult human kidney epithelial cells (Hendry *et al.*, JASN, 2013). To improve reprogramming and transferability to *in vivo* models, we have developed a multicistronic transposon construct.

Methods: The transposon was generated by engineering reprogramming factors into a *piggyBac* construct with intervening 2A sequences, a tetracycline response element for doxycycline inducibility and a fluorescent reporter (mCherry) for enrichment. To assess functionality, the transposon was co-transfected with tetracycline-activator and *piggyBac* transposase constructs. Reprogramming was induced with doxycycline exposure in combination with brief valproic acid treatment.

Results: Transfected adult kidney cells showed tightly regulated, inducible mCherry expression. When exposed to the NP reprogramming protocol, these cells displayed key markers of NPs and epithelial-to-mesenchymal-transition, as well as morphological and functional characteristics of endogenous NP cells.

Conclusions: These results not only demonstrate the feasibility of transposon-based direct reprogramming, but also bring us closer to realizing patient-specific reprogramming to NPs for cellular therapies, bioengineering applications and nephrotoxicity screening.

Convoluted Proximal Tubule Modeling Enabled by Microfluidics and Bioprinting Kimberly Homan,[1] David Kolesky,[1] Jessica E. Herrmann,[1] Annie Moisan,[2] Jennifer A. Lewis.[1] *[1]The Wyss Inst, Harvard Univ, Cambridge, MA; [2]Roche Pharma Research and Early Development, Roche Innovation Center Basel, Basal, Switzerland.*

Background: Three-dimensional models of kidney tissue that recapitulate human responses are needed for drug screening, disease modeling, and, ultimately, kidney organ engineering.

Methods: We present a bioprinting method for creating functional 3D human renal proximal tubules in vitro that are fully embedded within an extracellular matrix and housed in perfusable tissue chips, allowing them to be maintained for greater than four months. Their convoluted tubular architecture is circumscribed by proximal tubule epithelial cells and actively perfused through the open lumen at physiological shear stresses.

Results: These engineered 3D proximal tubules exhibit significantly enhanced epithelial morphology and functional properties relative to the same cells grown on 2D surfaces with or without perfusion. The proximal tubule cells in 3D printed and perfused conditions deposit their own basement membrane over time and develop a brush border. Additionally, epithelial cells in curved regions of the convoluted tubule uptake albumin more than nearby straight regions. Lastly, upon introducing the nephrotoxin, Cyclosporine A, the epithelial barrier is disrupted in a quantifiable, dose-dependent manner.

Conclusions: In addition to the enhancement in morphology and function of tubule cells observed in our chips, the bioprinted platform is versatile can be customized to incorporate perfusable vasculature and multiple cell types in predefined locations, enabling both drug screening and drug toxicity mechanistic studies at user-defined levels of complexity.

Rapid Iterative Development of Blood Conduits for Artificial Kidney Eliminates Thrombosis Rachel C. Forbes,[1] Clark David Kensinger,[1] Joseph J. Groszek,[2] Daniel Colvin,[3] Shuvo Roy,[4] William Henry Fissell.[2] *[1]Surgery, Vanderbilt Univ, Nashville, TN; [2]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [3]Inst for Imaging Sciences, Vanderbilt Univ, Nashville, TN; [4]Bioengineering and Therapeutic Sciences, Univ of California San Francisco, San Francisco, CA.*

Background: Implanted blood contacting devices, particularly dialyzers, tend to require pharmacologic anticoagulation of the patient to avoid local thrombosis and distant thromboembolism. Macrovascular encapsulation of islet cells utilizing a U-shaped device as a bioartifical pancreas was largely abandoned due to complications such as thrombosis. Improved design and manufacturing of devices might avoid the risks and costs of chronic anticoagulation and allow for the successful development of an artificial organ. Computational modeling and in vitro imaging facilitated rapid iterative development of a low-thrombosis blood conduit.

Methods: Following 3-90 day sustained preclinical implantation trials of hemofilter cartridges, correlations between low shear rates in silicon and areas of clot nucleation in vivo

led to modifications of outflow tract geometry. Computational fluid dynamics simulations of unsteady flow in design variations were followed by flow field imaging in vitro. The design with least recirculation and stasis was machined from medical grade polycarbonate and implanted in a Class A dog for 30 days without warfarin or heparin. Serial Doppler ultrasound examinations verified patency of the blood conduits. At postoperative day 30, the device was harvested and examined for thrombosis.

Results: Optimized designs had increased curvature radius and decreased taper in the outflow tract. The animal suffered no complications of surgery. No hemolysis or distal embolization was noted. The optically transparent cartridge had no visible thrombosis.

Conclusions: Meticulous attention to the flow fields in a blood contacting device, such as a bioartificial kidney, can reduce thrombosis and eliminate the need for systemic anticoagulation.

Women Have Higher Urine pH Than Men due to Increased Gastrointestinal (GI) Alkali Absorption

Kristin J. Bergsland, Fredric L. Coe, Elaine M. Worcester. *Nephrology Section, Univ of Chicago, Chicago, IL.*

Background: Calcium phosphate stones form at higher urine pH (UpH) and are more common in women (W) than in men (M). If UpH is higher in W, it may explain this disparity. In a General Clinical Research Center, we investigated whether W have higher UpH than M when eating identical diets and if so, what components of acid-base metabolism are responsible for the difference.

Methods: We measured UpH and determinants of acid-base regulation in 14 normal subjects (7 M). We collected 15 urines and 20 blood samples over a 15 hour day; diet was fixed. GI anion excretion (GIAE) = [(Na+K+Ca+Mg) - (Cl+P)] in urine (mEq/hr).

Results: UpH of W exceeded that of M; UpH rose with meals in W but not M (Table). Serum ultrafilterable (UF) CO_2 and GIAE rose with meals in W, not M; urine CO_2 excretion and GIAE exceeded M. Lower UpH in M was accompanied by higher net acid excretion (NAE), urine titratable acid (TA) and NH_4. Urine citrate (cit) and fractional excretion (FE) of cit was higher in W even adjusted for filtered load (FL) of cit, indicating reduced renal reabsorption of cit in W vs M.

	WOMEN		MEN	
	FAST	FED	FAST	FED
UpH	6.3±0.1	6.7±0.1*	5.8±0.1#	6.1±0.1#
UF CO_2	22±1	23±1*	22±1	22±1
U CO_2	0.6±0.2	1.4±0.1*	0.6±0.3	0.6±0.1#
U TA	0.36±0.08	0.35±0.04	0.46±0.08	0.65±0.04*#
U NH_4	0.9±0.1	0.9±0.1	1.1±0.1	1.2±0.1#
U NAE	0.7±0.4	-0.1±0.2*	1.0±0.4	1.3±0.2#
FL Cit	1.5±0.1	1.7±0.1	1.5±0.1	2.0±0.1*
U Cit	0.17±0.02	0.21±0.01*	0.12±0.02	0.15±0.01#
FE Cit	0.07±0.04	0.09±0.04	0.03±0.04#	0.03±0.03#
Adj U Cit	0.13±0.05	0.16±0.05	0.08±0.04#	0.08±0.04#
GIAE	2.5±0.5	3.9±0.3*	1.9±0.5	1.8±0.3#

Mean±SE, adjusted for age and weight; Adj U Cit also adjusted for FL cit. Excretions and FL are mmol/hr/BSA; UF CO_2 is mmol/L.*p<0.05 vs FAST same sex; #p<0.05 vs W same food period.

Conclusions: W have higher GI alkali absorption and GIAE than M which translates into increased urine CO_2 and higher UpH. The sex difference in UpH is not due to diet, but is related to ingestion of food.

TH-OR082

Comparison of Furosemide/Fludrocortisone with Ammonium Chloride Test in the Diagnosis of Incomplete dRTA in Recurrent Stone Formers: A Prospective Study

Nasser Dhayat, Ganesh Pathare, Bruno Vogt, Daniel G. Fuster. *Bern Univ Hospital, Div of Nephrology, Hypertension and Clinical Pharmacology, Bern, Switzerland.*

Background: Incomplete dRTA (idRTA) is a frequently encountered entity in recurrent stone formers (SF). IdRTA cannot be discerned by conventional clinical criteria but requires unmasking by a provocative urinary acidification test. Since the original description by Wrong and Davies in 1959, the short ammonium chloride (NH4Cl) loading test is considered the gold standard for the diagnosis of idRTA. The furosemide/fludrocortisone (F/F) test has recently been proposed as a test with improved tolerability. Due to the lack of comparative prospective studies, however, the validity of the different provocative tests employed is currently unknown. In addition, it remains currently unclear which group of recurrent SF should undergo testing for idRTA.

Methods: We performed a prospective study in an unselected group of recurrent SF referred to our stone clinic to assess the reliability of the F/F test in the diagnosis of idRTA. All patients underwent metabolic work up for stone disease and sequential F/F and NH4Cl testing, at least 1 week apart.

Results: 142 recurrent SF were recruited for the study over a period of 3 years. Mean age was 45.7 ± 13.4 years, 73.2% of participants were men. Prevalence of idRTA was 22.6% with the F/F test and 9.2% with the NH4Cl test. Assuming failure to lower urinary pH <5.3 during the NH4Cl test as gold standard for diagnosis, the F/F test had a positive predictive value of 37% and a negative predictive value of 97 % for the diagnosis of idRTA. Furthermore, comparison of fasting urinary pH and urinary acidification capacity during F/F and NH4Cl tests indicates that only a morning fasting urinary pH of <5.3 reliably excludes idRTA.

Conclusions: Thus, the F/F test is an excellent screening test for idRTA diagnosis in recurrent SF with a high negative predictive value. Due the low positive predictive value, however, patients with a pathological F/F test need confirmation by the NH4Cl test for idRTA diagnosis. In the absence of provocative testing, a diagnosis of idRTA can only be ruled out confidently with a morning fasting urinary pH <5.3.

TH-OR083

Hydroxyproline Metabolism and Oxalate Synthesis in Primary Hyperoxaluria

Sonia Fargue,[1] John Knight,[1] Dawn S. Milliner,[2] Julie B. Olson,[2] W. Todd Lowther,[3] Ross P. Holmes.[1] *[1]Dept of Urology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Hyperoxaluria Center, Mayo Clinic, Rochester, MN; [3]Dept of Biochemistry, Wake Forest School of Medicine, Wake Forest, NC.*

Background: The primary hyperoxalurias (PH) are severe inherited diseases of glyoxylate metabolism characterized by increased endogenous production of oxalate. A major source of glyoxylate in humans is hydroxyproline (Hyp), a collagen breakdown product. To quantify the contribution of Hyp turnover to oxalate synthesis, we infused labeled Hyp in fasting PH patients and healthy subjects.

Methods: Patients with PH type 1 (n: 7), 2 (n: 4), 3 (n: 8), and normal subjects (n: 9) were infused with ^{15}N-$^{13}C_5$-Hyp (750 nmol/kg/h) for 6 h continuously. Urine and plasma were collected hourly for analysis of ^{15}N-$^{13}C_5$-Hyp by GC/MS, total Hyp by HPLC, ^{12}C- and ^{13}C-oxalate and glycolate by IC/MS.

Results: Basal plasma Hyp concentrations and fluxes were lower in PH patients compared to controls [figure1A,B]. The contribution of Hyp metabolism to urinary oxalate excretion was 45% in PH2 patients compared to PH1 patients (16%) and controls (11%) [figure1C]. The contribution of Hyp to urinary glycolate was significantly decreased in PH2 and PH3 and marginally decreased in PH1 [figure1D].

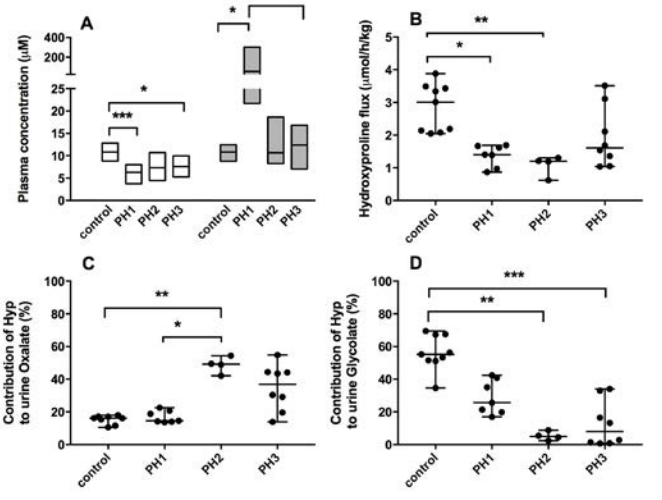

*Fig (1A) Plasma concentration of Hyp (white) and glycolate (grey) before infusion; (1B) Hyp flux; (1C) contribution of Hyp to urinary oxalate and (1D) glycolate. Results (median, range); */**/*** p<0.05/0.01/0.001 with Kruskall-Wallis test.*

Conclusions: Hydroxyproline contributes to glycolate and oxalate metabolism in humans confirming its potential as a therapeutic target in PH and the potential usefulness of dietary restrictions in PH2. The heterogeneity seen between PH3 patients highlights the complexity of oxalate synthesis in PH3. These data suggest other yet to be determined pathways are important to the increased synthesis of oxalate in PH.

TH-OR084

Enhanced Gastrointestinal Passive Paracellular Permeability Contributes to Hyperoxaluria in Obese Mice

Hatim A. Hassan,[1] Mohamed H. Bashir,[1] Daniel Y. Jung,[1] Kim Le,[2] Ruhul Amin,[4] Ignacio Granja,[3] Mustafa Satti,[1] Jon Meddings,[2] John R. Asplin.[3] *[1]Univ of Chicago; [2]Univ of Calgary; [3]Litholink; [4]UIC.*

Background: Most kidney stones (KS) are composed of calcium oxalate, and small increases in urine oxalate affect the stone risk. Obesity is a risk factor for KS and obese stone formers often have mild hyperoxaluria. A positive correlation between increased body size and elevated urinary oxalate excretion was reported. To define the underlying mechanisms, we previously found the obese *ob/ob* mice to have hyperoxaluria (>2.9-fold) and increased paracellular jejunal (>46%) and ileal (>30%) oxalate absorption *ex vivo*.

Methods: *In vivo* intestinal oxalate absorption was assessed by giving the *ob* mice and their controls ^{13}C-oxalate by oral gavage, followed by 6 h urine collection. Gastrointestinal paracellular permeability was assessed *in vivo* by giving the *ob* mice and their controls a solution containing sucrose, mannitol, lactulose, and sucralose by oral gavage, followed by 24 h urine collection to determine the fractional urinary recovery of these sugar probes.

Results: *ob* mice have significantly higher (>5-fold) urine ^{13}C-oxalate compared to controls, indicating increased intestinal oxalate absorption *in vivo*. Observing a greater oxalate absorption *in vivo* compared to *ex vivo* suggest the possibility of increased paracellular permeability along the entire gut. *ob* mice have significantly higher urinary excretion of sucrose (>1.7-fold) and sucralose (>2.2-fold), reflecting increased proximal gut (including the stomach) and colonic paracellular permeability, respectively. *ob* mice also have significantly higher urinary excretion of lactulose (>4.4-fold), mannitol (>3-fold), and lactulose:mannitol (>1.52-fold), reflecting enhanced small intestinal paracellular permeability. Using qpcr, significantly reduced mRNA expression of the tight junction proteins occludin (37-90%) and ZO-1 (28-62%) is observed in the stomach, duodenum, jejunum, ileum, cecum, and distal colon of *ob* mice.

Conclusions: We conclude that obese mice have significantly higher paracellular permeability along the entire gut, which would likely contribute to the observed hyperoxaluria, since there is a favorable transepithelial oxalate concentration gradient.

A Dose Finding Study with ALLN-177 in a Porcine Model of Mild Hyperoxaluria (20HO) Induced by a Human-Like Western Diet

Danica Grujic,[1] Craig B. Langman,[2] Kateryna Goncharova,[3] Lee Brettman,[1] Stefan Pierzynowski.[3] *[1]Allena Pharmaceuticals; [2]Northwestern Univ; [3]Lund Univ, Sweden.*

Background: Secondary hyperoxaluria is a known risk factor for recurrent urolitihiasis and progressive chronic kidney disease. Dietary modifications have limited effectiveness and no pharmacological therapies are available to reduce dietary hyper-absorption of oxalate. ALLN-177 is an oral, crystalline oxalate-degrading enzyme therapy (Rx) that specifically degrades dietary oxalate in the GI with the potential of reducing stone episodes.ALLN-177 was tested in a porcine dietary model of 2^{0}HO induced with a Western like diet (WLD) with average oxalate and calcium levels. Pigs were chosen due to their physiological similarities to humans in GI and renal functions.

Methods: To induce mild hyperoxaluria 24 pigs were fed the WLD for an initial pre-treatment period of 7 days and then randomized based on daily urinary oxalate (Uox) in a parallel 7d study to one of three treatment arms: ALLN 22,500 units/day (high dose, HD, n=8), 11,250 units/day (low dose, LD, n=8), or no treatment (n=6).The primary endpoint was the within-pig mean difference in 24h Uox (mg/g cr/24h) calculated from days 3,5,and 7 collected during the pre-treatment and treatment periods. A control group of 6 pigs was fed a regular pig feed (RF) to assess the impact of Rx on Uox vs RF alone and to establish normal Uox excretion.

Results: Twice daily oral Rx with ALLN-177 significantly reduced mean Uox by 15mg (17%) and 11mg (12%) with HD and LD respectively, when compared to WLD alone (HD: 85.08±15.0 to 70.60±10.1; LD 87.94±15.0 to 77.23±10.1 mg/gCr/d, p<0.001) whereas the mean Uox did not change in the WLD control group. Importantly, with the HD Rx, Uox excretion decreased to the normal range recorded on RF diet (66.2 ± 9.1mg gCr/d). Therapy was well tolerated without adverse symptoms.

Conclusions: Orally administered ALLN-177 with meals was well tolerated and normalized Uox with the 22,500 units/d. This porcine model that mimics 2^{0}HO in patients, and the positive efficacy results with ALLN-177, provided proof of concept for subsequent human studies that are underway.

TH-OR086

Claudin-2 Knockout Mice Spontaneously Develop Calcium Phosphate Deposition within the Renal Papilla

Alan S.L. Yu,[1,2] Joshua N. Curry,[1,2] Lei Pei,[1,2] Peter S.N. Rowe.[2] *[1]Molecular and Integrative Physiology, Univ of Kansas Medical Center, Kansas City, KS; [2]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; [3]Anatomy and Cell Biology, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: The proximal tubule (PT) is where the majority of calcium reabsorption in the kidney occurs by an unknown mechanism. Physiologic studies have shown this reabsorption to be predominantly passive. The tight junction proteins called claudins are important determinants of paracellular permeability and passive reabsorption in the kidney. In the PT, the highest claudin expression is that of claudin-2, which forms cation-selective pores in *in vitro* studies. Previous studies have shown that claudin-2 KO mice have an increase in urine calcium. We hypothesize that claudin-2 loss leads to defective PT calcium reabsorption and nephrocalcinosis.

Methods: Renal calcification was quantified by micro-CT (Scanco). Mineral composition of renal stones was determined by micro-Fourier Transform infrared spectroscopy. Transmission electron microscope was performed on 2% glutaraldehyde fixed papillary sections.

Results: We found that Cldn2-KO mice develop nephrocalcinosis concentrated within the renal papilla that is absent from wild type littermates. Using micro-FTIR analysis, these deposits were determined to be composed primarily of hydroxyapatite (calcium phosphate). Localization of these deposits was determined to be intraluminal by immunohistochemistry and transmission electron microscopy.

Conclusions: Randall's plaques are hydroxyapatite plaques which develop within the renal papilla in human kidney stone formers. Cldn2$^{-/y}$ mice may develop nephrocalcinosis in a similar manner. Physiologic analyses will help us further determine whether the observed increase in urine calcium is due to a defect in PT calcium reabsorption in Cldn2$^{-/y}$ mice.

Insulin Resistance and the Risk of Calcium Kidney Stone

Zeyar Myint,[1] Jie Tang.[2] *[1]Nephrology, Brown Univ, Providence, RI; [2]Nephrology, Univ Medicine, Brown Univ, Providence, RI.*

Background: Insulin resistance is associated with a higher risk of uric acid kidney stone. But its role in calcium kidney stone formation is not clear.

Methods: We performed a cross-sectional study of 43 non-diabetic calcium kidney stone formers, and examined the associations between insulin resistance and 24-hour urine stone risk parameters. The homeostatic model assessment (HOMA)-IR and HOMA-B were used to quantify insulin resistance and pancreatic beta-cell function respectively. Both HOMA-IR and HOMA-B were log transformed and were modeled using univariate and multiple linear regression methods.

Results: All study participants had confirmed calcium kidney stones. Among them, 61% were male, 86% were Caucasian, 33% had prevalent hypertension and 12% had prevalent dyslipidemia. The median age was 53 years (range 21-76), and the average body mass index (BMI) was 29 (Standard Deviation, ±5). The mean serum 25-OH-vitamin D level was 25 ng/ml, the median HOMA-IR was 5.25 (range 1.4-68.4), and the median HOMA-B was 176.9 (range 52.25-2421). Both HOMA-IR and HOMA-B associated significantly with BMI, even after adjusting for hypertension, dyslipidemia and 25-OH-vitamin D (P<0.02). HOMA-IR associated significantly with urine calcium (P=0.011), urine uric acid (P=0.001) and urine ammonium (P=0.033) in univariate linear models. After adjusting for age, gender, race and BMI, only urine uric acid associated significantly with HOMA-IR (P=0.009). HOMA-B associated significantly with urine calcium (P=0.039) and urine uric acid (P=0.017) in univariate linear models. After adjusting for age, gender, race and BMI, the associations were no longer significant. Neither HOMA-IR nor HOMA-B had significant associations with urine pH, sodium, phosphorus, oxalate, and citrate in univariate analysis (P>0.05).

Conclusions: Neither HOMA-IR nor HOMA-B appeared to be associated with an increased risk of calcium kidney stone formation. The significance of the association between HOMA-IR and urine uric acid among calcium stone formers is not clear.

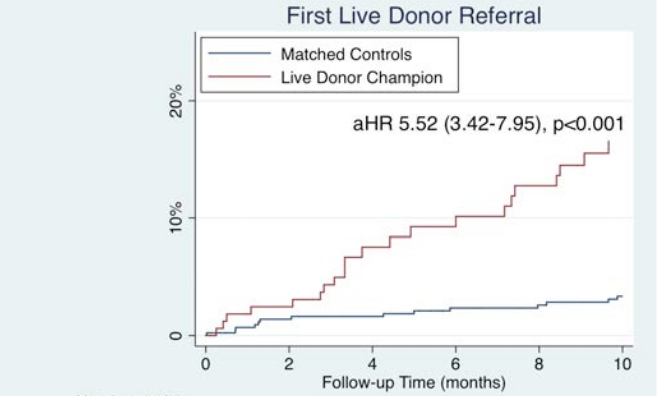
The Live Donor Champion Program: A Novel Approach to Identifying Live Kidney Donors

Elizabeth A. King, Dorry L. Segev. *Surgery, Johns Hopkins Univ, School of Medicine, Baltimore, MD.*

Background: The Live Donor Champion (LDC) program is a clinical program offered to kidney waitlist candidates at our transplant center. The five-month program provides education and advocacy training for candidates and a friend or family member chosen to serve as an advocate, or "Live Donor Champion", on each candidate's behalf. The goal of the program is to increase awareness of live donation and to identify potential live donors.

Methods: We studied 163 adult kidney transplant candidates that have participated in the LDC program at Johns Hopkins Comprehensive Transplant Center between October 2013 and May 2016. Paired t-tests were used to estimate the difference in knowledge about live donation and comfort approaching others about live donation before and after participation in the LDC program. We compared time to first live donor referral for candidates that participated in the program with matched controls from our waiting list using a cox proportional hazard model. We used 1:3 iterative expansion radius matching to choose controls based on age at listing, time on waitlist without a live donor, sex, race, and ABO blood type.

Results: Participation in the LDC program was associated with a statistically significant increase in knowledge of live donation among candidates participating alone, candidates participating with a LDC, and LDCs (all p- values <0.001). Comfort approaching others about live donation also increased significantly among all three groups (all p-values <0.001). Among LDC participants, there were a total of 81 live donor referrals. Participation in the LDC program was associated with 5.5-fold increase in having at least one donor referral compared to matched controls (aHR 5.52, 95% CI 3.42-7.95, p<0.001).



Conclusions: The LDC program is associated with increased knowledge of live donation, comfort approaching others about live donation, and live donor referrals.

The Live Kidney Donor Aotearoa (LDKA) Program: A Health Services Initiative to Increase Kidney Transplantation in New Zealand (NZ) Disadvantaged Populations Mark R. Marshall,[1,2] Denise Ann Beechey,[1] Caran Barratt-Boyes,[1] Nora Van der Schrieck,[3] Lisa Frances Hoyle,[1] Catherine Anne Tracy,[1] Hari Manoharlal Talreja.[1] *[1]Dept of Renal Medicine, Counties Manukau District Health Board, Auckland, New Zealand; [2]School of Medicine, Univ of Auckland, Auckland, New Zealand; [3]Kidney Society Auckland, Auckland, New Zealand.*

Background: Kidney transplantation (KT) is associated with the best outcomes for ESKD patients. NZ has a low rate of KT, especially in Māori and Pacific People (PP). We evaluate LDKA, a NZ government-funded 3-year demonstration program involving Counties Manukau District Health Board (CMDHB) - NZ's largest nephrology service - and Kidney Society Auckland - a patient support group. The LDKA aims to increase LDKT and thereby overall KT, particularly in disadvantaged NZ ethnic groups.

Methods: The LDKA program was initiated in April-2013 and consists of 6 projects (1) Culturally-sensitive and health literacy-appropriate educational resources on LDKT (www.ldka.org.nz) (2) A "Home & Kidney first" policy as part of CMDHB predialysis education to focus on transplantation (followed by home dialysis) as treatment of choice (3) Home-based LDKT education of family / social networks using culture-specific educators to build health literacy skills and understanding (4) Development of an engagement framework for targeted communities and their leaders (5) Educational programs for primary care providers (6) Peer-to-peer support for potential LDKT recipients and donors. We perform time series analysis using autoregressive Poisson regression to estimate the effect (IRR, 95% CI) of the LDKA program on KT and LDKT.

Results: Using the 5 years prior to the LKDA as baseline, there were 11 LDKTs from CMDHB in this period, 4 of which were in Māori or PP. In 2015 alone, there were 7 LDKTs, 4 of which were in Māori or PP. Accounting for underlying prior 5-year trends in KT or LDKT, the LDKA program is associated with an increase in KT by 1.84 (1.21-2.79) fold, and in LDKT by 3.60 (1.73-7.49) fold.

Conclusions: A whole-systems approach with a multi-faceted health service delivery improvement program is an effective way of increasing LDKT, particularly in disadvantaged populations.

Funding: Government Support - Non-U.S.

TH-OR090

Pre-Transplant Recipient Transcriptomic Profile May Predict Delayed Graft Function (DGF) in Kidney Transplantation Paola Pontrelli,[1] F. Rascio,[2] Francesco Pesce,[1] Matteo Accetturo,[1] Giuseppe Castellano,[1] Gianluigi Zaza,[3] Marco Fiorentino,[1] Loreto Gesualdo,[1] G. Stallone,[2] Giuseppe Grandaliano.[2] *[1]Univ of Bari; [2]Univ of Foggia; [3]Univ of Verona.*

Background: DGF is associated with a reduced long-term graft survival. Ischemia-reperfusion damage and donors' features have been always considered as key pathogenic factors in this setting. The aim of our study was to evaluate the role of recipients' characteristics in the development of DGF.

Methods: We prospectively enrolled 538 kidney graft recipients, 176 of whom experienced DGF. We selected 10 couples of DGF/early graft function (EGF) recipients for high throughput analysis. Peripheral blood mononuclear cells (PBMC) were harvested before transplantation. Transcriptomic profile was investigated by HG-U133A microarray (Affymetrix). The results were evaluated by statistical (Genespring software) and functional pathway analysis (Ingenuity Pathway Analysis).The transcriptomic data were validated by qPCR in an independent group (DGF n=10; EGF n=10).

Results: In 38 cases both recipients from the same donor presented with DGF (C group), whereas in 138 cases only one recipient/donor experienced DGF (D group), suggesting a key role of recipients features in the pathogenesis of this condition. We did not observe any difference in donors' features between C and D group, further supporting our working hypothesis. In the D group, DGF was independently associated (logistic regression) only with number of mismatches (OR 1.867, p=0.01) and dialysis vintage (months, OR 1.009, p=0.03). The transcriptomic profile demonstrated that, considering a fold change>2, 273 genes were differentially expressed between the 2 groups. The main biological functions were inflammatory disease (p range=9.8E-05-1.4E-14, 65 genes) and inflammatory response (p range=3.6E-04-3.2E-14, 80 genes), featuring the immunological profile of dialysis patients. Interestingly, the two main upstream regulators identified were TNF-alpha (p=4.6E-19) and TGF-β (p=4.0E-17), two key inflammatory mediators modulated by dialysis.

Conclusions: Our results suggest that recipients' immunological features, modulated by dialysis, are significantly associated with the development of DGF independently of donors' features.

Crossing the Valley of Death: A Validation Study of Noninvasive Diagnosis of Acute Cellular Rejection by a Composite Signature of 3-mRNAs and 4 Metabolites in Urine Mohamad M. Alkadi, Catherine Snopkowski, Carol Y. Li, Liana S. Perry, Matthew Magruder, Karan Jatwani, John R. Lee, Steven Salvatore, Darshana Dadhania, Surya V. Seshan, Hua Yang, Adhirai Muthukumar, Karsten Suhre, Manikkam Suthanthiran. *Weill Cornell Medicine.*

Background: Most biomarkers fail to be validated in an independent cohort- the valley of death encountered also during transitions from Phase I safety to Phase III efficacy trials. We investigated whether our 3-gene urinary cell RNA signature and the metabolite signatures for the noninvasive diagnosis of acute cellular rejection (ACR) are validatable in an independent cohort of kidney graft recipients.

Methods: We collected 118 biopsy-matched urine specimens from 95 kidney recipients (22 from 22 recipients with ACR; 96 from 73 recipients with no rejection). We isolated RNA from the urine cell pellets and quantified the absolute abundance of CD3ε mRNA, CXCL10 mRNA and 18S rRNA using qPCR assays. We measured the metabolites 3-silalyllactose, xanthosine, quinolinate and X-16397 in the corresponding cell-free urine supernatants using comprehensive GC/MS and LC/MS/MS platforms.

Results: Urinary cell 3-gene signature discriminated patients with ACR from no rejection (AUC: 0.81). The ratio of 3-silalyllactose/xanthosine (AUC: 0.65) and quinolinate/X-16397 (AUC: 0.74) discriminated ACR from no rejection. The combined mRNA and metabolite signature also discriminated patients with ACR from those with no rejection (AUC: 0.86).

Signature	Area Under the Curve (AUC)	
	Discovery Study	Validation Study
Urinary cell 3-gene mRNA signature: [−6.1487+0.8534 log(CD3ε/18S)+0.6376 log(IP-10/18S) +1.6464 log(18S)] *(Suthanthiran et al. NEJM 2013: 369:20-31)*	0.85	0.81
Metabolite signature: [log 3-sialyllactose/xanthosine] *(Suhre et al. JASN 2016: 27:626-36)*	0.75	0.65
Metabolite signature: [log quinolinate/X-16397] *(Suhre et al. JASN 2016: 27:626-36)*	0.71	0.74
Combined signature: [mRNA signature+1.1164* log(3-sialyllactose/xanthosine)+0.6937* log(quinolinate/X-16397)] *(Suhre et al. JASN 2016: 27:626-36)*	0.93	0.86

None of the AUCs differed significantly from the AUCs in our original biomarker studies (P>0.05, DeLong test).

Conclusions: To our knowledge, this is first-in-kind validation of urine-based biomarkers diagnostic of ACR using: (i) an independent cohort of kidney recipients, and (ii) a locked prediction model, i.e., using the same discovery study equation in the validation study. Our observations support consideration of these biomarkers in the clinical management.

TH-OR092

Urine Fibrosis Markers and Risk of Cardiovascular Events and Death in Kidney Transplant Recipients: The FAVORIT Trial Meyeon Park,[1] Ronit Katz,[2] Michael Shlipak,[1] Daniel E. Weiner,[3] Vasantha Jotwani,[1] Jan M. Hughes-Austin,[4] Francis B. Gabbai,[4] Chi-Yuan Hsu,[1] Nisha Bansal,[2] Andrew Bostom,[5] Orlando M. Gutierrez,[4] Mark J. Sarnak,[3] Andrew S. Levey,[3] Joachim H. Ix.[4] *[1]UCSF; [2]U. Washington; [3]Tufts; [4]UCSD; [5]Rhode Island Hospital.*

Background: Cardiovascular disease (CVD) risk is high in kidney transplant recipients (KTR) despite improvement in eGFR after transplant. Urine markers of kidney fibrosis may help to reveal mechanisms of this risk.

Methods: In a case-cohort study among stable KTR who participated in the FAVORIT trial, we measured 4 urine proteins known to correlate with kidney biopsy tubulo-interstitial fibrosis (alpha 1 microglobulin [α1m], monocyte chemoattractant protein-1 [MCP-1], procollagen type I [PINP] and type III [PIIINP] N-terminal amino peptide). We used spot urine specimens collected at baseline in a randomly selected subcohort (N=488) and in cases with CVD events [composite of CV death, myocardial infarction, resuscitated sudden death, and stroke] (N=282) and death (N=359) during 3.46 mean years of follow-up. We used weighted Cox proportional hazards regression.

Results: Urine α1m, MCP-1, and PINP were strongly associated with CVD events and death, after adjusting for demographics, CVD/CKD risk factors, eGFR, and ACR (Table 1). Relative to the lowest quartile, the highest quartile of urine α1m [HR 2.83 (1.43, 5.57)] and PINP [HR 2.88 (1.61, 5.16)] were associated with CVD events. All 3 markers were also associated with death in adjusted models: HR Q4 v. Q1 α1m 3.89 (2.05, 7.23), MCP-1 1.95 (1.02, 3.75), PINP 2.27 (1.35, 3.79). After adjustment, urine PIIINP was not associated with CVD events [HR Q4 v. Q1 0.97 (0.52, 1.82)] or death [1.63 (0.92, 2.90)] in either continuous or quartile analyses.

Adjusted associations of urine biomarker with outcomes (per log2 increase) [HR (95% CI)]		
	CV events	Death
α1m	1.43 (1.21, 1.69)	1.59 (1.36, 1.85)
MCP-1	1.26 (1.07, 1.47)	1.40 (1.20, 1.64)
PINP	1.23 (1.09, 1.39)	1.15 (1.03, 1.27)
PIIINP	1.04 (0.91, 1.18)	1.13 (0.99, 1.28)

Conclusions: Higher concentrations of urine α1m, MCP-1, and PINP identify KTR at risk for CVD events and death. Fibrotic processes in the transplanted kidney may reflect systemic fibrosis and CVD risk in KTR.

TH-OR093

Emerging Safety and Tolerability with Obinutuzumab, a Type 2 Anti-CD20 Monoclonal Antibody for the Desensitization of Renal Transplant Candidates

Robert R. Redfield,[1] Stanley C. Jordan,[2] Thomas Schindler,[3] Ha N. Tran,[4] Caroline Looney,[4] Cherie Green,[4] Alyssa Morimoto,[4] Richa Rajwanshi,[4] Paul Brunetta,[4] Dominic Borie.[4] *[1]Univ of Wisconsin, Madison, WI; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]F. Hoffmann-La Roche AG, Basel, Switzerland; [4]Genentech, South San Francisco, CA.*

Background: Allosensitization in end-stage renal disease (ESRD) patients (pts) may restrict the deceased donor pool, resulting in long waiting times, or prevent living donor kidney transplantation. B-cell depletion with rituximab (RTX) appears to be effective in desensitizing pts and enabling transplantation; however, B-cell depletion is incomplete in lymphoid organs despite complete peripheral depletion, and high antibody titers are only moderately reduced. Greater B-cell depletion in tissue may be more effective in alloantibody reduction. Obinutuzumab (Obi) is a glycoengineered anti-CD20 monoclonal antibody that binds CD20 differently from RTX and displays increased antibody-dependent cellular cytotoxicity and enhanced direct cell death compared with RTX, resulting in increased in vitro and in vivo B-cell depletion.

Methods: The open-label, phase 1b THEORY study assessed the safety, pharmacokinetics, and pharmacodynamics of Obi in hypersensitized ESRD pts awaiting renal transplantation. The first cohort of patients (n=5) received 1,000 mg Obi on day 1 and high-dose IVIG on days 22 and 43. Safety and tolerability were reviewed when the last enrolled patient had 4 weeks of follow-up.

Results: Most (4/5) pts were women, aged 34-54 years, who had been waitlisted for 2-11 years and had calculated panel reactive antibody values of 74%-100%. Obi resulted in depletion of peripheral B cells by FACS (5/5) and to less than or equal to the lower limit of quantification of high-sensitivity flow cytometry (3/5). Obi appeared well tolerated and safe. Main adverse events (AEs) were grades 1 and 2 infusion-related reactions in 3 pts that were manageable and did not prevent complete Obi administration. A serious AE of community-acquired pneumonia resolved on treatment with IV antibiotics.

Conclusions: Emerging experience with Obi indicates acceptable tolerability in ESRD patients requiring desensitization.

Efficacy and Safety of 3 Different Treatment Regimen in De Novo Renal Transplant Patients: 5 Year Follow-Up Data of the HERAKLES Trial on Everolimus-Based Immunosuppression

Ingeborg A. Hauser,[1] Oliver Witzke,[1] Petra Reinke,[1] Claudia Sommerer,[1] Frank Lehner,[1] Thomas Rath,[1] Volker Kliem,[1] Bruno Vogt,[2] Martina Porstner,[3] Rolf A. Stahl,[1] Klemens Budde,[1] Wolfgang Arns.[1] *[1]Herakles Study Group, Germany; [2]Herakles Study Group, Switzerland; [3]Novartis Pharma GmbH, Germany.*

Background: To compare safety and efficacy of 3 different immunosuppressive regimen at month (Mo) 60 after kidney transplantation (KTx) with or without everolimus (EVR).

Methods: 802 patients (pts) were included in this 1 year, prospective, open-label, randomized, controlled multi-center study with observational follow-up (FU) to Mo60 post KTx. After induction all pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3Mo post KTx, 499 pts were 1:1:1 randomized to either a) continue standard CsA(100-180ng/mL)+ EC-MPS (n=166) (STD) or convert b) to an EVR-based (5-10ng/mL) calcineurin inhibitor (CNI)-free regimen + EC-MPS (n=171) or c) to a CNI-reduced regimen (CsA 50-75ng/mL) with EVR (3-8ng/mL) (n=162); (steroids according to center praxis). In total 81% of pts completed the Mo60 FU visit.

Results: Efficacy events during FU to Mo60: BPAR reported in 8% STD, 8% CNI-free and in 7% CNI-reduced pts (p=ns). 7 deaths (4%) occurred in STD, 4 (2%) in CNI-free and 9 (6%) in the CNI-reduced group; 7 (4%) graft losses in the STD, 7 (4%) in the CNI-free and 3 (2%) in the CNI-reduced group. Composite failure occurred in 38(23%) STD, 35(20%) CNI-free and in 36(22%) CNI-reduced treated pts. GFR (Nankivell) was significantly improved by +6.7mL/min in favor of the CNI-free regimen at Mo60 (ITT, p<0.001). Safety profile did not differ between groups.

Overview on efficacy events during follow-up (ITT population)

Frequencies, n (%)	Standard (N=165)	CNI free (N=171)	CNI reduced (N=161)
Events starting after Month 12			
Biopsy-proven acute rejection (BPAR)	13 (7.88)	13 (7.60)	12 (7.45)
Graft loss	7 (4.24)	7 (4.09)	3 (1.86)
Death	7 (4.24)	4 (2.34)	9 (5.59)
Lost to follow-up	17 (10.30)	15 (8.77)	13 (8.07)
Toxicity	10 (6.06)	8 (4.68)	4 (2.48)
Therapy failure (composite endpoint)*	38 (23.03)	35 (20.47)	36 (22.36)
p-value (Fisher's exact Test): no significant differences found			

*Treatment failure as composite endpoint is defined as occurrence of at least one of the events: biopsy proven acute rejection, graft loss, death, lost to follow-up, discontinuation due to toxicity.

Overview on adverse and other safety relevant events during follow-up (Safety population)

Event	Standard N=165 n (%)	CNI-free N=171 n (%)	CNI-reduced N=161 n (%)
Death, n (%)	7 (4.2)	4 (2.3)	9 (5.6)
Hospitalization, n (%)	99 (60.0)	102 (59.6)	107 (66.5)
Discontinuation due to AE [a], n (%)	10 (6.1)	8 (4.7)	4 (2.5)
Infection, n (%)	83 (50.3)	85 (49.7)	81 (50.3)
Severe Infection, n (%)	19 (11.5)	21 (12.3)	19 (11.8)
Infection leading to hospitalization, n (%)	50 (30.3)	50 (29.2)	54 (33.5)
Of these the most common:			
Urinary tract infection, (%)	10.9%	9.4%	10.6%
Pneumonia, (%)	6.1%	9.9%	4.3%
Urosepsis, (%)	6.1%	4.7%	5.0%
CMV, (%)	3.0%	2.9%	3.1%
Gastroenteritis	3.0%	1.8%	4.3%

[a] documented as primary reason for prematurely discontinuation of follow-up period (reported at any follow-up visit); Footnote: The CRF and the clinical data base do only include serious adverse events for the follow-up period. Nevertheless, AEs were reported to Novartis drug safety but are not included in this analysis.

Conclusions: HERAKLES 5 year data show that immunosuppressive regimen using EVR with reduced-dose or without CNI reflect an efficacious and safe therapeutic approach offering the opportunity for an individualized immunosuppression to minimize CNI-exposure.

TH-OR095

Timing of Eculizumab Treatment and the Need for Dialysis in Patients with aHUS Who Receive a Kidney Transplant

Andrew M. Siedlecki,[1] Nicole Isbel,[2] Johan Vande Walle,[3] Varant Kupelian,[4] David J. Cohen.[5] *[1]Brigham and Women's Hospital; [2]The Univ of Queensland and Princess Alexandra Hospital, Australia; [3]Ghent Univ Hospital, Belgium; [4]Alexion Pharmaceuticals, Inc.; [5]Columbia Univ Medical Center.*

Background: Patients (pts) with atypical hemolytic uremic syndrome (aHUS) are at risk of thrombotic microangiopathy (TMA) and graft loss following transplantation. Eculizumab (Ecu), a complement C5a inhibitor, is effective in preventing and treating TMA and is increasingly used post-kidney transplant (KTx) in pts with aHUS. We report data on the timing of Ecu initiation and subsequent dialysis and TMA in aHUS patients undergoing KTx.

Methods: Our analyses utilized data from a Global aHUS registry (NCT01522183) with 1122 pts enrolled as of March 2016, of whom 252 (24%) had at least one KTx. Overall, 94/252 pts had a KTx between December 1, 2011 and December 1, 2014) and received Ecu. Pts were grouped by use of Ecu (prior to or at time of transplant [pre-transplant; n=57] vs started post-KTx [n=36]). Pts were monitored for up to 12 months post-KTx.

Results: Pts starting Ecu post-KTx were older, less likely to have a family history of aHUS, and had undergone fewer prior transplants (Table). Fewer pts treated pre-KTx with Ecu required any dialysis (4% vs 33%) and the median time to any dialysis was longer (15.3 vs 1.6 months) than in pts receiving Ecu post-KTx. Those pts starting Ecu post-KTx had a higher rate of TMA (61% vs 4%) and TMA occurred earlier (after a median of 3.0 vs 11.4 months), compared with those starting Ecu pre-KTx.

Table. Characteristics of pts with their last transplant between 01 December 2011 and 01 December 2014

	Ecu initiated at or prior to transplant (N=57)	Ecu initiated post-transplant (N=36)
Median age at diagnosis, years (IQR)	27.6 (5.4–35.4)	34.4 (24.6–45.7)
Family history, n (%)	18 (32)	3 (8)
Prior transplant, n (%)	19 (33)	3 (8)
Any dialysis post-transplant, n (%)*	2 (4)	12 (33)
Median time to dialysis, months (IQR)	15.3 (12.8–17.9)	1.6 (0.1–15.0)
Deaths, n (%)	1 (2)	0 (0)
TMA post-transplant, n (%)	4 (7)	22 (61)
Median time to TMA, months (IQR)	11.4 (4.3–21.5)	3.0 (0.2–8.7)

*Any dialysis includes patients who received either acute or chronic dialysis. Ecu, eculizumab; IQR, interquartile range; TMA, thrombotic microangiopathy

Conclusions: This retrospective analysis shows that fewer pts with aHUS who received Ecu prior to KTx compared with after KTx required dialysis or had TMA. This suggests initiating Ecu pre-transplant may be associated with better renal outcomes after KTx.

Acknowledgments: We wish to thank the patients and registry investigators.

Funding: Pharmaceutical Company Support - Alexion Pharmaceuticals, Inc.

TH-OR096

Effect of Denosumab on Peripheral Compartmental Bone Density, Microarchitecture and Estimated Bone Strength in De Novo Kidney Transplant Recipients: The POSTOP-HRpQCT Bone Microarchitecture Ancillary Study Rudolf P. Wuthrich,[1] Ursina Meyer,[2] Diana P. Frey,[3] Nicole Graf,[4] Heike A. Bischoff-Ferrari,[2] Marco Bonani.[1] *[1]Div of Nephrology, Univ Hospital, Zurich, Switzerland; [2]Dept of Geriatrics and Aging Research, Univ Hospital, Zurich, Switzerland; [3]Div of Rheumatology, Univ Hospital, Zurich, Switzerland; [4]Graf Biostatistics, Winterthur, Switzerland.*

Background: In a randomized controlled clinical trial in kidney transplant recipients (NCT01377467) we have recently shown that RANKL inhibition with denosumab significantly improved areal bone mineral density (aBMD) when given during the first year after transplantation. The effect of denosumab on skeletal microstructure and bone strength in kidney transplant recipients is not known.

Methods: The purpose of the present analysis was to investigate high-resolution peripheral quantitative computed tomography (HRpQCT) data from the distal tibia and distal radius in 24 study patients that had been randomized to receive either two injections of denosumab 60 mg at baseline and after 6 months (n=10) or no treatment (n=14).

Results: Denosumab reduced biomarkers of bone turnover, and significantly increased aBMD at the lumbar spine (median difference of 4.7%; 95% CI 2.6 – 7.8; p<0.001). Bone quality as assessed by total and cortical volumetric bone mineral density (Tot.vBMD, Ct.vBMD) and cortical thickness (Ct.Th) increased significantly at the tibia, while changes at the radius were less pronounced. The trabecular volumetric BMD (Tb.vBMD), thickness (Tb.Th), separation (Tb.Sp) and number (Tb.N) and the cortical porosity (Ct.Po) at the tibia and the radius did not significantly change in both treatment groups. Micro-finite element analysis (mFEA) showed that bone stiffness increased significantly at the tibia (median difference 5.6%; 95% CI 1.8% – 9.2%; p=0.002) but not at the radius (median difference 2.9%, 95% CI -3.7% – 9.1%; p=0.369). Likewise, failure load increased significantly at the tibia (median difference 5.1%; 95% CI 2.1% – 8.1%; p=0.002) but not at the radius (median difference 2.4%, 95% CI -3.2% – 8.5%; p=0.336).

Conclusions: Denosumab improves bone density and bone quality in first-year kidney transplant recipients at risk to develop osteoporosis.

TH-OR097

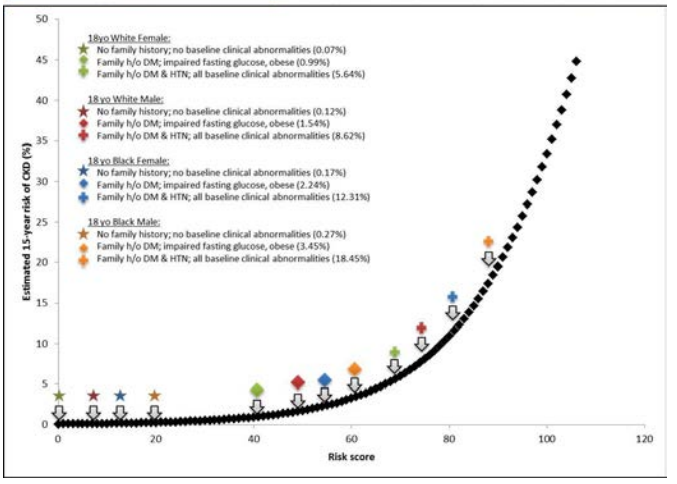
Kidney Failure Risk Projection for the Young Living Kidney Donor Candidate Jayme E. Locke,[1] Rhiannon D. Reed,[1] Deirdre L. Sawinski,[2] Paul A. Maclennan,[1] Vineeta Kumar,[1] Shikha Mehta,[1] John Jeffrey Carr,[3] James Gregory Terry,[3] Allan Massie,[4] Meredith Kilgore,[1] Robert S. Gaston,[1] Roslyn B. Mannon,[1] Dorry L. Segev,[4] Cora E. Lewis.[1] *[1]Univ of Alabama at Birmingham; [2]Univ of Pennsylvania; [3]Vanderbilt Univ; [4]Johns Hopkins Univ.*

Background: Living kidney donor selection practices aim to identify risk for chronic kidney disease (CKD). Assessment has evolved from examination of individual risk factors to a risk calculator that incorporates multiple candidate characteristics. Due to limited long-term data, current risk tools lack precision with regard to young living kidney donor candidates (LKDC).

Methods: We identified a cohort of potentially acceptable, young (18-30yo) LKDCs with no absolute contraindications to kidney donation (diabetes, hypertension, malignancy, heart disease, kidney problems, or pregnancy at year 0 exam) from the longitudinal cohort study CARDIA. Risk associations for CKD were identified and assigned weighted points, resulting in calculation of a risk score (c-statistic: 0.74).

Results: 3,554 LKDCs were identified; mean age 24.8yrs; 48.8% black; median follow-up of 24.9yrs (IQR: 24.5-25.2). For an 18yo LKDC 15-yr projection of the risk of CKD varied according to race and sex even in the absence of baseline clinical abnormalities; risk was 0.07% for white women, 0.12% for white men, 0.17% for black women, 0.27% for black men. Risk projections were higher among LKDCs with baseline clinical abnormalities - eGFR<100cc/min, obesity, impaired fasting blood sugar, family history of hypertension and/or diabetes.

Table. Risk calculator	aHR	95% CI	p-value	ß	Risk points
Age (per 1-year increase)	1.07	0.99-1.15	0.10	0.06279	1 per year > 18
Male sex	1.59	0.94-2.66	0.08	0.46031	7
Black race	2.26	1.28-4.02	0.005	0.81690	13
Impaired Fasting Glucose (FBG 100-125)	3.14	0.97-10.20	0.06	1.14312	18
Family history of DM	2.18	1.23-3.86	0.001	0.77817	12
Family history of HTN	1.94	1.09-3.47	0.02	0.66492	11
Obese (BMI ≥ 30 kg/m²)	1.99	1.04-3.82	0.04	0.69017	11
eGFR 90-99 mL/min at baseline	2.84	1.19-6.79	0.02	1.04277	17



Median time to CKD was 20.7yrs (IQR: 15.1-25.0).

Conclusions: Baseline health characteristics may be used to develop a risk prediction tool for projecting the long-term risk of CKD among young LKDCs. Risk tools may improve informed consent and LKDC autonomy in medical decision making.

TH-OR098

Cultural Competency of a Mobile, Customized Patient Education Tool for Improving Potential Kidney Transplant Recipients' Knowledge and Decision-Making Crystal Anderson,[1] David A. Axelrod,[2,3] David Wojciechowski,[3] Marie Jacobs,[3] Krista L. Lentine,[4] Mark Schnitzler,[4] John Devin Peipert,[1] Amy D. Waterman.[1] *[1]David Geffen School of Medicine, Univ of California, Los Angeles, Los Angeles, CA; [2]Xyn Management Inc., Boerne, TX; [3]Dept of Medicine, Massachusetts General Hospital, Boston, MA; [4]Dept of Internal Medicine, St. Louis Univ, St. Louis, MO.*

Background: After Kidney Allocation System (KAS) reforms, patients have to decide between deceased donor kidney transplant (DDKT), living donor kidney transplant (LDKT) and dialysis. My Transplant Coach (MTC) is a mobile, iOS based tablet education tool that presents didactic animated videos and individualized charts derived from multivariate models of pre-transplant mortality rate, median waiting time to transplant, and post-transplant survival based on kidney donor profile index (KPDI) and transplant type. We assessed whether patients found the application helpful and culturally sensitive; whether transplant knowledge and informed decision-making improved; and how patients' race and comfort with technology were associated with changes.

Methods: In two US transplant centers, 81 patients (White: 27%, African American: 25%, Hispanic: 15%, Asian: 25%) varying in their experience with technology (51% were comfortable using internet) viewed the animated content and their own graphs and completed pre- and post- intervention knowledge assessments (0-20 scale) and usability questionnaires.

Results: 86% reported MTC helped them understand their options, 85% would recommend the app, and 78% felt more comfortable talking to their doctor about their treatment options. High proportions of patients said the app was suitable for people of their race/ethnic group (67%-85%, P=0.79). After reviewing MTC, patients reported having a greater ability to make informed DDKT (27%-52%, P<.0001) and LDKT decisions (40%-72%, P<.001). Knowledge increased (9.1 to 13.8 questions correct, P<.0001), with similar increases for patients of all races and levels of comfort with technology levels.

Conclusions: MTC was helpful for a diverse group of transplant candidates and resulted in increased transplant knowledge and informed decision-making.

TH-OR099

Impact of Patient Navigators and Enhanced Personal Health Records on Health Literacy in Those with CKD Stacey Jolly,[1] Sankar D. Navaneethan,[2] Jesse D. Schold,[1] Susana Arrigain,[1] Georges Nakhoul,[1] Victoria Konig,[1] Jennifer Hyland,[1] Yvette K. Burrucker,[1] Priscilla Davis Dann,[1] Barbara H. Tucky,[1] Joseph V. Nally.[1] *[1]Cleveland Clinic; [2]Baylor College of Medicine.*

Background: The recognition of and education for patients with CKD is a public health need as patients with limited health literacy may have difficulty processing medical information and traversing an increasingly complex health system. There is a lack of

translational research in CKD that incorporates educational tools. We developed a CKD Patient Navigator program and an enhanced online personal health record (PHR) with links to publicly available NKDEP and NKF education materials. We report CKD health literacy survey results from our randomized-controlled clinical (RCT) trial.

Methods: 209 patients with CKD from 6 outpatient clinics were randomized in a 2x2 factorial design to CKD Patient Navigator or enhanced PHR, their combination, or usual care. Baseline survey was done at time of enrollment in person. An exit phone survey was done at the end of the 2-year follow-up. Survey included literacy, computer skills, and detailed CKD knowledge items.

Results: Mean age was 66.7 years with 75% whites and 22% blacks. Majority were CKD Stage 3b n=156 (76%) at enrollment. 194 completed exit survey (deceased = 11; declined/no response/unable to reach =4). Some pre-/post-survey results are shown in Table 1.

Pre	Navigator (n=53)	ePHR (n=50)	Both (n=49)	Control (n=57)
need help with medical forms	11(21%)	10(20%)	12(24%)	8(14%)
difficulty understanding when doctor talks about CKD	21(40%)	18(36%)	20(41%)	20(34%)
know your eGFR (yes)	9(17%)	10(20%)	9(18%)	9(16%)
Post	Navigator (n=50)	ePHR (n=47)	Both (n=45)	Control (n=52)
need help with medical forms	3(6%)	4(8%)	5(11%)	3(6%)
difficulty understanding when doctor talks about CKD	2(4%)	7(15%)	3(6%)	3(6%)
know your eGFR (yes)	12(24%)	6(12%)	9(20%)	4(7%)

Conclusions: We successfully conducted a RCT trial using educational tools. Health literacy improved in all groups. Future analyses are needed to evaluate the tools, such as which CKD educational links were most utilized, CKD Patient Navigators role in addressing barriers, and patient satisfaction with the intervention.

Pediatric Nephrology Training Worldwide in 2016: Quantum Educatus?

Dorey A. Glenn,[1] Kevin E.C. Meyers,[2] William A. Primack.[1] *[1]Univ of North Carolina at Chapel Hill; [2]Children's Hospital of Philadelphia.*

Background: Perceived adequacy of the pediatric nephrology (PN) workforce varies considerably worldwide. Likewise, training for qualification as a pediatric nephrologist varies from country to country. No compendium of these requirements exist. In the United States (US), PN workforce concerns have generated a discussion of whether a 2 year option, as opposed to 3 years, is advisable in order to increase the number of trainees. The purpose of our study is to synthesize and compare PN training requirements worldwide, and describe the opinions of pediatric nephrologists on the value of a 2 versus 3 year fellowship.

Methods: In the spring of 2013, survey invitations were sent to members of the American Society of Pediatric Nephrology (ASPN) and American Academy of Pediatrics (AAP) section on Pediatric Nephrology. In the Fall of 2015, survey invitations were sent to members of International Pediatric Nephrology Association (IPNA). E-mail messages were sent to pediatric nephrologists in countries with ≥ 25 contacts listed in the online IPNA member directory. Qualitative and quantitative analyses were performed, and data cross-referenced when possible.

Results: The AAP survey was sent to 766 pediatric nephrologists and had a 66% response rate. Forty nine percent of respondents favored a 2 year option for PN fellowship training and 34% were opposed to a change in training duration. Prominent themes in support of a 2 year fellowship were a perceived need for more clinicians in the PN workforce and a desire to limit the financial and time burdens of the third year of training. The IPNA survey was sent to 2304 valid e-mail addresses and had a 15% response rate. In some countries the duration and intensity of training varies with the PN responsibilities that the graduates are anticipated to assume.

Conclusions: We summarize the requirements for PN training in most areas of the world as of the beginning of 2016. Three years is the most common duration of PN fellowship and recently has become the new minimal recommendation in Europe, Australia, and New Zealand. Due to concerns of a potentially inadequate workforce, many U.S. pediatric nephrologists wonder if a 2 year clinical track should be considered.

TH-OR101

The Impact of Health Literacy in Transition Readiness

Laura Castellanos,[1] Helena Juditha Villalobos,[1] Allison L. Parente,[2] Jeffrey M. Saland,[1] Rachel A. Annunziato.[1,2] *[1]Pediatric Nephrology, Icahn School of Medicine at Mount Sinai, New York City, NY; [2]Psychology, Fordham Univ, Bronx, NY.*

Background: With medical and technological advances, the prevalence of youth with chronic diseases surviving into adulthood has become an important public health issue. This is especially true in the field of transplantation, in which transition has been identified as a vulnerable period for adolescents. Transition of care has been defined as a process that involves purposeful, planned efforts to prepare the pediatric patient to move from caregiver-directed care to disease self-management in the adult unit. Different approaches are currently being implemented to improve this process mainly centered on improved coordination and facilitation of the transition. Health literacy (HL) is known to be associated with poor clinical outcomes in adults and yet little is known about the relationship in the pediatric population and its contribution to difficulties during transition. Specifically, research is needed to determine if HL may be a factor in poor self-management acquisition in order to inform targeted interventions to improve transition.

Methods: Participants (N=75)are patients above 13 years of age with a diagnosis for at least 6 months of Chronic Kidney Disease (CKD), Hypertension (HTN) or kidney transplantation followed at Mount Sinai Medical Center. HL and self-management were measured with three screening tools, the S-TOFHLA (shortened version of The Test of Functional Health Literacy Assessment), Single Item Literacy Screen and the Developmentally Based Skills Checklist. Transition readiness was assessed using a center-specific checklist used for patients age 15 or older and medical record review for clinical outcomes.

Results: Based on the S-TOFHLA, HL was adequate (mean=33.31, SD=4.20). S-TOFHLA score was significantly correlated with team-rated transition readiness, r=.51, p=.01. When measured by the SILS, more patients displayed poor HL; 35% "sometimes" or more often have trouble reading medical instructions.

Conclusions: Preliminary findings suggest that HL is highly correlated with transition readiness. Therefore, pediatric preparation for transition should include assessment of and efforts to bolster HL.

TH-OR102

Macrophage: An Online Adaptive Learning Platform for Renal Physiology

Patrick H. Van Nieuwenhuizen,[1] Karambir Khangoora.[2] *[1]Columbia Univ College of Physicians and Surgeons; [2]Albert Einstein College of Medicine.*

Background: Many educators now use online learning tools (videos, interactive modules, etc.) in place of traditional lectures to deliver content to medical students. Relative to lectures, online learning tools have the potential to be more interactive and adaptive (delivering content specially tailored to each individual, based on their empiric performance). We sought to study student satisfaction with an interactive, adaptive, online learning tool relative to traditional lectures.

Methods: We created "Macrophage" (https://macrophage-app.herokuapp.com/), an online platform for medical education that serves as a scaffold for courses consisting of short videos and questions. For each individual user, a learning algorithm models the probability of each individual user getting questions correct, such that it can deliver content in an individualized fashion. We created a renal physiology course for Macrophage, consisting of 60 videos with an average length of 3 minutes and 238 questions, which was used by the Columbia University first-year class as a supplemental resource during the traditional renal course. Afterwards, students were surveyed on the efficacy of Macrophage and lecture for their learning of renal physiology, using a 5-point Likert scale ("very effective", "somewhat effective", "undecided", "not very effective", "not at all effective"). Data were analyzed with the Wilcoxon signed-rank and Fisher exact tests.

Results: Out of 160 students, 84 (52.5%) used both Macrophage and lecture, and rated Macrophage as more effective than lecture (p = 0.0013, Wilcoxon signed-rank test). Students were also more likely to rate Macrophage "very effective", "somewhat effective", or "undecided", with an odds ration of 5 (p-0.00079 Fisher exact test) compared to lecture. Among the 84 students who used macrophage, 69.2% rated it as "very effective" or "somewhat effective", while 7.4% rated it as "not very effective" or "not at all effective."

Conclusions: Macrophage allowed medical students to learn more effectively as compared to lecture. Online learning tools represent a promising method to teach renal physiology to medical students.

An Integrated Pathology and Ultrasonography-Based Simulation Is an Effective Educational Tool for the Performance of a Kidney Biopsy

Juan Carlos Q. Velez,[1] Vandana Niyyar,[2] Kevin D. Phelan,[3] Nithin Karakala,[3] Manisha Singh,[3] Kelly W. Bulloch,[3] John M. Arthur,[3] Shree G. Sharma.[4] *[1]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Renal Div, Emory Univ, Atlanta, GA; [3]Div of Nephrology, Univ of Arkansas Medical Sciences, Little Rock, AR; [4]Arkana Laboratories, Little Rock, AR.*

Background: Proficiency in performance of percutaneous kidney biopsy (PKB) is required for accreditation in nephrology. Medical practice trends and limitations in trainees' duty hours have diminished the interest and exposure of nephrology fellows to PKBs. We hypothesized that a novel integrated nephrology-pathology-led simulation may be an effective educational tool.

Methods: A 4-hour PKB simulation workshop (KBSW) was led by 2 ultrasonography (US)-trained nephrologists and 1 pathologist and consisted of 6 stations: diagnostic kidney US with live patients, kidney pathology with embedded torso cross sections, US-based PKB simulation with mannequin (Blue Phantom™), kidney pathology with dissected cadavers, US-based PKB simulation in lightly-embalmed cadavers and tissue retrieval adequacy examination by microscope. A 10-question survey [6 multiple-choice questions assessing knowledge acquisition, 4 five-scale questions assessing procedural confidence gain] was administered pre and post KBSW.

Results: Twenty-one participants (4 nephrologists, 17 trainees) attended the KBSW and completed the surveys. The percentage of correct answers increased numerically in 5 of 6 knowledge questions, reaching statistical significance in 3 of them (p=0.0003–0.04). The overall percentage of correct answers increased from 55 to 83% (p=0.016). The number of Extremely Confident answers increased from 0-5% to 19-28% in all 4 questions (p=0.02–0.04), and the number of Not At All Confident answers significantly decreased from 14-62% to 0-5% in 3 out of 4 questions (p=0.0001–0.03).

Conclusions: A KBSW utilizing US-based training on patients, mannequins and cadavers, along with simultaneous pathology instruction, is an effective educational tool to gain proficiency in PKB performance. This novel approach could regain interest among trainees in performing PKBs.

TH-OR104

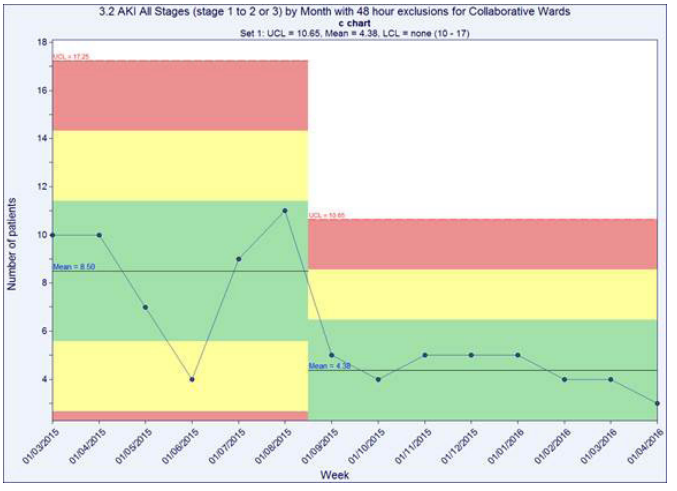
A Novel Quality Improvement Collaborative to Reduce Acute Kidney Injury Incidence and Progression in a Large Teaching Hospital in England

Lynne F. Sykes, Robert Nipah. *Clinical Research, Salford Royal Foundation Trust, Salford, United Kingdom.*

Background: Acute kidney injury (AKI) is a common condition which is associated with significant mortality and cost according to the NCEPOD report of 2009. The Quality Improvement Collaborative was established to review and improve both the recognition and management of AKI.

Methods: We designed a program of education and learning events to reduce all cause AKIs by 10%, reduce hospital acquired AKIs by 25% and reduce progression of AKI 1 to either AKI 2 or 3 by 50%. A driver diagram was developed for this improvement program based on the Institute for Healthcare Improvement's Breakthrough Series Collaborative Model. An information banner was inserted into the electronic patient records, modifications made to the admission document, post take ward round and discharge summary forms, and an AKI review template introduced. A team of selected doctors, nurse champions, pharmacists and quality improvement staff implemented an AKI bundle, based on the acronym 'SALFORD', to the collaborative wards.

Results: Whilst there was an increase overall in AKI seen, especially AKI 1, over the study (November 2015 to May 2016), there were several statistically significant results following the interventions made by the collaborative. A 15.56% reduction in overall hospital acquired AKI, with a 22.32% reduction on collaborative wards. Although there was normal variation shown for the overall hospital rates of progression of AKI 1 to AKI 2/3 there was a 48.47% reduction in AKI progression on the collaborative wards.



Conclusions: This is the first quality improvement project of its kind focussing on AKI. It has achieved statistically significant reductions of hospital acquired AKI and AKI progression particularly on the collaborative wards and is a testament to an effective quality improvement programme that is universally applicable and a step towards tackling AKI.

Funding: Other NIH Support - National Institute for Health Research Collaboration for Leadership in Applied Health Research and Care (NIHR CLAHRC)

TH-OR105

Estimating Sodium Intake in Hemodialysis Patients to Help Assist Dietary Habits

Amar V. Patel,[1] Jenna M. George,[1] Sania Tahir,[2] Carla Boutin-Foster,[3] Subodh J. Saggi.[1] *[1]Div of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; [2]Long Island Univ, Brooklyn, NY; [3]Div of Internal Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Sodium restriction is encouraged in almost all patients on hemodialysis due to its easy and effective preventative therapy, which facilitates control of thirst, water overload, inter-dialytic weight (IDW) gains, hypertension, and cardiac failure. However this strategy is often neglected by patients. Our primary aim was to validate salt intake estimating equation in ESRD patients on dialysis and making these patients aware and our secondary aim was to evaluate changes in sodium intake after being counseled on their sodium restriction diet to 2g/day.

Methods: In this pilot study, data regarding sodium intake of 13 patients on hemodialysis was gathered during 3 consecutive months (January 2016 to March 2016). Each patient was counseled regarding sodium restriction in the first month and the subsequent two months were recorded to evaluate response to counseling. Sodium intake was estimated using the following formula: Sodium intake = $V \times ([Na]_{pre} - [Na]_{post}) + (\Delta W \times [Na]_{pre})$ where V= total body water and ΔW = interdialytic weight gain.

Results: Referring to table 1 you will see that the mean sodium intake was 3.7 ± 1.3 g in January, 4.1 ± 1.2 g in February, and 4.2 ± 1.3 g in March.

Variable	N	Mean	Standard Deviation	Median	Lower 95% CI	Upper 95% CI
January	13	3678.08	1271.44	3435	2909.75	4446.40
February	13	4104.31	1175.73	4322	3393.82	4814.80
March	13	4200.85	1270.48	4193	3433.10	4968.59

There was tremendous variability in salt intake and a single counselling session over 3 month period was not associated with adherence to salt restriction ($p = 0.54$) or IDW gains.

Conclusions: Further solutions to improve sodium intake need to be considered such as motivational behavioral therapy and provide access to low salt foods. We have assumed that the participants were anephric and had insignificant amount of GI and insensible fluid loss.

TH-OR106

Therapeutic Game-Based Exercise during Hemodialysis to Improve Balance: A Pilot Randomized Controlled Trial

Abdullah Hamad,[1] Fadwa S. Al-Ali,[1] He Zhou,[2] Talal Talal,[3] Sergio Nicolas Sardon Melo,[3] Mohamed Amin Elesnawi,[1] Rania Abdelaziz Ibrahim,[1] Bijan Najafi.[2] *[1]Nephrology, Hamad Medical Corporation, Doha, Qatar; [2]Baylor College of Medicine, Houston, TX; [3]Podiatry, Hamad Medical Corporation, Doha, Qatar.*

Background: Balance, mobility and falls are serious problems for older patients with end stage renal disease on hemodialysis (HD) especially with diabetic neuropathy. HD visit time provides an optimal opportunity for exercise intervention to improve balance and mobility and decrease falls.

Methods: Eleven HD subjects (age: 65±6 years) with confirmed diabetic peripheral neuropathy were consented and recruited. They were randomized to intervention (IG: n=7) and control group (CG: n=4). Both groups underwent a 4 weeks' ankle and knee exercise program, twice per week for duration of 30 minutes during HD. The IG received exercise via the Exergame platform developed by our team, which integrates data from wearable sensors attached to subject's feet and legs into a human-computer interface designed for game-based motor adaptation training. The CG received same exercises without technology. The feasibility, acceptability, perception of benefit, and enhancement in balance in different conditions were examined.

Results: One subject in IG was dropped out due to travelling. The rest finished all exercise sessions during HD sessions indicating its feasibility. The participants gave on average score of 3.7 out of 4 for entertainment and ease of usage of the Exergame platform. All participants in IG felt more energetic at home and perceived the balance program effective. Balance improved in IG compared to baseline almost in all tested balance conditions with highest effect size (improved by 57%, d=1.20) observed for hip stability during semi-tandem eyes closed test. The improvement in tested balance conditions in IG was on average 32% higher than CG with the highest effect size difference observed for semi-tandem eyes-closed (d=1.26).

Conclusions: Our pilot trial provide proof of concept for the feasibility and benefits of an interactive ankle and knee exercise program based on wearable technology. The program was perceived to be beneficial, easy and enjoyable to perform during hemodialysis sessions by target subjects.

Funding: Government Support - Non-U.S.

"Home Run" Results of a Chronic Kidney Disease Telemedicine Patient Education Study

Andrea K. Easom, Manisha Singh, John M. Arthur. *U of AR for Medical Sciences, Mabelvale, AR.*

Background: Comprehensive pre-dialysis patient education (CPE) facilitates the choice of renal replacement therapy modalities and can slow progression of disease but it is not clear if education via telemedicine is comparable to face-to-face education (FTF). We present the two year results of a pilot randomized controlled study evaluating the effectiveness of CPE through telemedicine TM to FTF in patients with stage 4-5 CKD.

Methods: An 82 page CKD Workbook was created with corresponding slides and used to provide education to 82 patients in the FTF group and 58 patients in the TM group over three, 2-3 hour visits. Patient choice of dialysis modality is the primary endpoint of the study. Three assessment tools were utilized to compare groups: CKD Knowledge Questionnaire (based on the workbook and completed pre on visit 1 and post on all visits), S-TOFHLA on visit 1 and KDQoL on visits 1 and 3. All groups have quarterly phone follow-up. There are 7 telemedicine sites across the state.

Results: Of the 170 patients enrolled, 25 (15%) were initial drop outs. These results include data from 118 patients. Most patients were interested in transplant initially (90% FTF, 92% TM). This decreased slightly by visit 3 (86% FTF, 90% TM). Initially, about half felt they did not have enough information to choose a modality (46% FTF, 50% TM) but this decreased significantly by visit 3 (3% FTF, 15% TM). Home modalities choices increased from 16 to 25% home hemodialysis (HHD) and 14 to 46% peritoneal dialysis (PD) in the FTF group and from 11 to 20% HHD and 6 to 35 % PD in the TM group, resulting in home modalities chosen by 71% of the FTF group and 55% of the TM. Of the 26 patients completing at least one visit and needing to start therapy, 58% either started on home dialysis or received a pre-emptive transplant (HHD 12%, PD 42%, TXP 4%).

Conclusions: By the end of their 3rd visit, 97% of the FTF group and 85% of the TM group were able to choose a modality. Home modalities were chosen by 71% of the FTF group and 55% of the TM group, 58% of the patients that started therapy were either transplanted or started a home modality. The results show that TM can be an effective educational tool for CPE.

CD44 Is Required for the Pathogenesis of Experimental Crescentic Glomerulonephritis and Collapsing Focal Segmental Glomerulosclerosis
Bart Smeets,[1] Shagun Sharma,[2] Jack F. Wetzels,[2] Brigith Willemsen,[1] Vikram Sharma,[2] Marinka Bakker-van Bebber,[2] Tammo Ostendorf,[3] Marcus J. Moeller,[3] Henry Dijkman,[1] Johan Van der Vlag.[2] *[1]Pathology, Radboud UMC, Nijmegen, Netherlands; [2]Nephrology, Radboud UMC, Nijmegen, Netherlands; [3]Nephrology and Clinical Immunology, RWTH Univ Aachen, Germany.*

Background: Activation, migration and proliferation of parietal epithelial cells (PECs) is a key feature of glomerular diseases such as crescentic glomerulonephritis and focal segmental glomerulosclerosis. CD44-positive activated PECs have been identified in proliferative cellular lesions in glomerular disease. However, it remains unknown whether CD44-positive PECs contribute to the pathogenesis of scarring glomerular diseases.

Methods: Here, we evaluated experimental crescentic glomerulonephritis and the transgenic anti-*Thy1.1* model for collapsing focal segmental glomerulosclerosis in CD44-deficient (*cd44-/-*) and wild type (WT) mice.

Results: For both models albuminuria was significantly lower in *cd44-/-* mice compared to WT mice. The number of glomerular Ki67-positive proliferating cells was significantly reduced in *cd44-/-* mice compared to WT mice, which was associated with a reduced number of glomerular lesions in crescentic glomerulonephritis. In collapsing FSGS, the extracapillary proliferative cellular lesions were smaller in *cd44-/-* mice, but the number of glomerular lesions was not different compared to WT mice. For crescentic glomerulonephritis the glomerular influx of granulocytes and macrophages was similar. *In vitro*, human CD24, CD133, CD44-positive PECs displayed haptotactic responses towards collagen I in a CD44 dependent manner.

Conclusions: In conclusion, CD44-positive proliferating glomerular cells, most likely PECs, are essential in the pathogenesis of scarring glomerular disease.

Funding: Private Foundation Support, Government Support - Non-U.S.

TH-OR109

Compound Effects of Aging and Experimental FSGS on Glomerular Parietal Epithelial Cells and Podocytes in Mouse Kidneys
Remington Schneider, Diana G. Eng, Jeffrey W. Pippin, Stuart J. Shankland. *Nephrology, Univ of Washington, Seattle, WA.*

Background: Impaired kidney function is more common in the elderly, and occurs disproportionately in people >65yrs. Glomerular parietal epithelial cells (PECs) and podocytes (podo) undergo substantial changes with advanced age. This study tested the hypothesis that advanced aged adversely impacted PEC and podo responses in mice with FSGS.

Methods: Experimental FSGS was induced in young adult (Y-FSGS)(2-3m) and aged (A-FSGS)(24m) mice with a cytotoxic anti-podo antibody. Young (Y-BL) and aged (A-BL) mice without FSGS served as respective baselines. Podo density was measured by unbiased stereology on p57/PAS stained kidney sections; Desmin marked podo injury. Fibrosis was quantified using Collagen IV staining. Activated PECs ($Pax8^+CD44^+$) were examined for their localization along Bowman's Capsule (BC) and migration onto the glomerular tuft. PEC epithelial to mesenchymal transition (EMT) was measured by staining for a-smooth muscle actin and vimentin.

Results: As expected, podo density was lower in A-BL mice ($P<0.01$ vs. Y-BL). Upon induction, podo density decreased by >40% in both Y-FSGS and A-FSGS mice ($P>0.05$). However, Desmin expression increased further in podo in A-FSGS mice. Although the density of activated PECs along BC was higher in A-BL mice ($P<0.05$ vs. Y-BL), PEC increase along BC was 4 fold higher in A-FSGS mice ($P<0.01$ vs. Y-FSGS). The number of activated PECs on the tuft was also higher in A-FSGS mice. Notably, although Collagen IV staining was elevated in PECs in A-BL mice compared to Y-BL mice, staining in PECs increased in A-FSGS mice ($P<0.001$ vs. Y-FSGS). Despite A-BL mice having fewer PECs ($PAX8^+$ cells), the percentage of glomeruli with PECs expressing EMT markers was greatest in A-FSGS mice.

Conclusions: These data support the notion that, compared to young mice, aged mice are prone to more extensive glomerular damage in an experimental model of FSGS. Although the magnitude of podo depletion was similar between Y-FSGS and A-FSGS mice from their respective baselines, PECs were disproportionally more injured in A-FSGS mice, manifested by the extent of their activation, migration to the glomerular tuft, EMT and fibrosis.

Glomerulosclerosis, Imploding Glomerulopathy and Podocytes
Christopher Lund O'Connor, Jian Shi, Jeffrey B. Hodgin, Roger C. Wiggins, Markus Bitzer, Rakhi Modak. *Univ of Michigan.*

Background: We have recently shown that podocyte density decreases with age in humans and identified imploding glomeruli (shrunken glomerular tuft, proteinaceous meterial and and detached podocytes in the Bowman's space) in human kidney tissue (Hodgin et al. JASN 2015). Very little is known about the etiology and relevance of this phenotype.

Methods: We performed quantitative morphometric and transcriptomic analysis of 47 kidney tissue samples from patients undergoing radical nephrectomy. 16 glomerular and tubule-interstitial parameters were assessed through routine and immunohistochemical stains and quantitative image analysis in FFPE sections. All glomeruli present in each sample were assessed (mean=199, stdev=98). mRNA (Affymetrix human ST 2.1) and small RNA expression (Illumina tru-seq) were assessed in micro-dissected glomeruli (approx. 30 from each sample) and tubule-interstitium and associated with morphometric parameters.

Results: We confirmed the age-associated decline in podocyte density ($p<0.01$) and increase in globally sclerosed glomeruli ($p<0.01$) in this cohort. The number of imploding glomeruli was positively associated with the number of global glomerulosclerosis ($p<0.0001$), mesangial index ($p<0.001$), interstitial fibrosis (Sirius red, Trichrome) ($p<0.01$) and eGFR ($p<0.001$), and negatively associated with podocytes/glomerulus ($p<0.01$) and podocyte density ($p<0.001$). Transcriptomic analysis of glomeruli identified 260 genes whose expression was highly significantly associated with the number of imploding glomeruli (FDR<0.001; Pearson correlation analysis). This transcriptomic signature was highly similar to those detected in diabetic nephropathy, focal segmental glomerulosclerosis, and IGA nephropathy (FDR<0.001) (www.nephroseq.org) and with podocyte damage but not endothelial cell injury (Ingenuity Pathway Analysis; Genomatix).

Conclusions: The frequency of imploding glomeruli is strongly correlated with phenotypes of glomerular damage and decreased eGFR. The morphometric and transcriptomic findings suggest high similarity to other glomerular diseases linked to podocyte stress and loss. Therefore we speculate that imploding glomerulopathy is a phenotype of accelerated podocyte damage in disease and aging.

Sonic Hedgehog Links Podocyte Injury to Mesangial Cell Activation in Glomerular Disease
Dong Zhou, Haiyan Fu, Youhua Liu. *Dept of Pathology, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Glomerular disease is often characterized by podocyte injury-triggered proteinuria, followed by glomerulosclerosis caused by mesangial activation and matrix over-production. However, how podocyte injury is linked to mesangial cell activation remains largely unknown. In this study, we have identified sonic hedgehog (Shh) as a novel factor that mediates podocyte-mesangial communication (PMC), which plays a crucial role in the pathogenesis of glomerulosclerosis after initial podocyte injury.

Methods: See results section.

Results: Shh was specifically induced in podocytes in animal models of glomerular diseases induced by adriamycin (ADR) and anti-GBM antibody, and in kidney biopsy specimens from patients with glomerular diseases. Using $Gli1^{LacZ}$ knock-in mice, we identified mesangial cells as the major Shh-responding cells in diseased glomeruli. Incubation of mesangial cells with Shh activated canonical Shh/Gli1 signaling pathway and promoted cell proliferation and extracellular matrix (ECM) accumulation in a time- and dose-dependent manner, as assessed by cell counting, MTT and BrdU incorporation assay, and induced numerous proliferation- and fibrosis-related genes. Furthermore, Shh promoted mesangial cells activation and ECM deposition in cultured glomeruli. However, Shh had little effects on podocyte proliferation. We further generated mice with podocyte-specific deletion of Shh, and found that conditional ablation of Shh had little effect on proteinuria in 1 and 5 weeks after ADR injection. However, loss of Shh in podocyte markedly ameliorated glomerulosclerosis. Consistently, blockade of Shh signaling by cyclopamine, an inhibitor of Smoothened, inhibited mesangial cells proliferation, reduced ECM accumulation and attenuated glomerulosclerosis after ADR injection at 5 weeks.

Conclusions: These studies demonstrate that podocyte-derived Shh acts as a previously unrecognized mediator to activate and promote mesangial cell expansion and matrix production, leading to glomerulosclerosis. Our studies uncover a novel pathway by which podocyte injury leads to glomerulosclerosis, and should have significant implication in designing future therapy for glomerular diseases.

Single Kidney Cell Transcriptomics Applying Microfluidic Droplet Generation Technology (Drop-Seq)
Edgar A. Otto, Rajasree Menon, Celine C. Berthier, Matthias Kretzler. *Internal Medicine - Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: Microfluidic droplet-based technology (Drop-Seq) allows to uniquely barcode mRNA transcripts of thousands of individual cells derived from a complex tissue for downstream RNA-Seq expression analyses. The technique is based on combining single-cells with barcoded beads in separate nanoliter-sized droplets in the course of flowing oil, beads, and cells through a droplet-generator device via three syringe pumps[1].

Methods: Healthy adult kidney tissue derived from tumor nephrectomies was enzymatically and mechanically dissociated into single cell suspensions. Cells were processed according to the DropSeq workflow described by the McCarroll lab[1]. Individual cells were identified by barcodes, and all transcripts were tagged with Unique Molecular Identifiers (UMIs) in order to determine absolute transcript abundance. Paired-end RNA-Seq was performed on a HiSeq2500 platform. Bioinformatics analysis o was done using the tools embedded in Picard tools developed by the Broad Institute and unsupervised clustering algorithms were executed using the R package toolkit "Seurat" from the Satija lab.

Results: Single cell transcriptome analyses of 3,000 cells enabled the distinction of various cell types which correspond to specific nephron segments according to the of the "RNA-seq Analysis of Microdissected Rat Kidney Tubule Segment" database. Principal component analysis revealed cells showing high expression of *ALDOB* and *GBX3* corresponding most likely to segment S1 of the proximal convoluted tubules, *SLC12A3* and *WNK1* indicates distal convoluted tubule (DCT) and *UMOD* and *EGF* indicates cTAL nephron segment cell origin. About 10% of the cells expressed hemoglobin indicating the presence of red blood cells in the preparation.

Conclusions: We have implemented the DropSeq technique to establish transcriptome profiles on the single-cell level of human adult kidney tissue. Single cell transcriptomics may help to better define nephron cell type composition, identify cell type specific biomarkers for diagnostics, renal disease progression, and for potential therapeutic interference. Degradomic Analysis Dissects Intracellular Protease Signaling in Podocytes Markus M. Rinschen,[1] Pitter F. Huesgen,[2] Thomas Benzing.[1] *[1]Internal Medicine, Univ Hospital Cologne, Germany; [2]Forschungszentrum Juelich, Germany.*

Background: Proteases are successful therapeutic targets in many human diseases. Proteases are also crucial for maintenance of a physiological podocyte function. Based on previous system-wide analyses, threonine proteases are expressed at very high levels in podocytes both on the proteome and transcriptome levels. However, the intracellular protease targets are not completely characterized. The aim this study was to delineate posttranslational protease networks in podocytes.

Methods: Terminal Amine Isotope Labeling of Substrates (TAILS) is an innovative technology that allows identification and quantification of cleavage and native protein N-termini in various conditions using high-accuracy tandem mass spectrometry. We applied this technology to native glomeruli perfused with protease inhibitor to demonstrate the physiological presence of novel proteoforms originating from posttranslational proteolytic processing. Second, we performed a quantitative degradomic analysis of cultured podocytes under normal and stressed (PAN injury) conditions.

Results: In renal glomeruli, we discovered thousands of termini by TAILS proteomic analysis. Among these, we found a novel podocin proteoform lacking its N-terminal 60 amino acids. Novel proteoforms were also discovered for Nephrin, Synaptopodin and Actinin-4. Degradomic analysis of stressed podocytes demonstrated a distinct perturbation of protease signaling. Differentially regulated protease substrates were mainly cytoskeletal proteins, including ACTN4, further actin-associated and intermediary filament proteins. The data also determined preferential protease motifs during this damage and indicated that specific protease classes are activated during PAN injury. Novel proteoforms were also confirmed by differential migrational behavior on SDS PAGE gels.

Conclusions: The technology utilized here is crucial to identify protease classes and their intracellular targets involved in renal and podocyte disease. We demonstrate that a tightly regulated protease network strongly affects cytoskeletal and slit diaphragm proteins in podocytes.

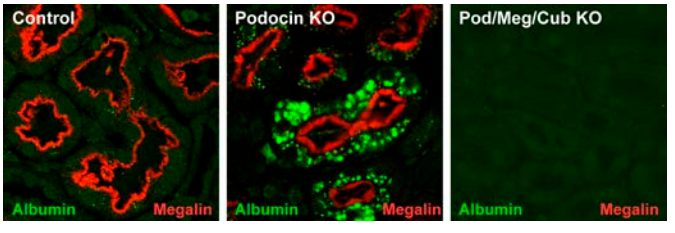
Albumin Handling in Mice with Genetic Knockout of Megalin/Cubilin and Nephrotic-Range Proteinuria Kathrin Weyer,[1] Henrik Birn,[1] Geraldine Mollet,[2] Corinne Antignac,[2] Rikke Nielsen,[1] Erik I. Christensen.[1] *[1]Biomedicine, Aarhus Univ, Aarhus, Denmark; [2]INSERM U1163, Univ Paris Descartes, Inst Imagine, Hôpital Necker Enfants Malades, Paris, France.*

Background: It has been proposed that a high-capacity pathway for transtubular transport of albumin exists for recovery of large amounts of albumin in normal kidneys, with impact for plasma albumin levels. The megalin/cubilin receptor complex is essential for tubular uptake and degradation of filtered albumin. To determine whether a high capacity retrieval pathway exists, we investigated if knockout of the receptors under normal and nephrotic states is reflected in plasma albumin levels.

Methods: Inducible podocin knockout (KO), megalin/cubilin KO, megalin/cubilin/podocin KO mice, and controls, were followed for five weeks where urine, plasma, liver, and kidney tissue were collected. Albumin levels were determined in urine and plasma samples by ELISA. Liver albumin mRNA was quantified by qRT-PCR. Kidney albumin uptake was evaluated by immunostaining.

Results: Immunostaining of kidney slices from megalin/cubilin/podocin KO mice demonstrated an efficient blockade of albumin uptake in proximal tubule cells, whereas podocin KO mice displayed excessive albumin uptake compared to controls. Megalin/cubilin/podocin KO mice had increased urinary albumin excretion compared to podocin KO mice (albumin/creatinine: 31.1±5.1 vs. 19.6±6.1 mg/mg). Albumin plasma levels were similarly reduced in megalin/cubilin/podocin and podocin KO mice (11.0±0.9 vs. 9.1±1.0 g/L), compared to controls (24.8±1.0 g/L) and megalin/cubilin KO (22.4±2.4 g/L). Liver albumin mRNA was similarly increased in megalin/cubilin/podocin and podocin KO mice, compared to controls and megalin/cubilin KO.



Conclusions: Blockade of proximal tubular albumin reabsorption causes no changes in plasma albumin levels under normal and nephrotic states, and we thus find no evidence of a major renal retrieval pathway for albumin.

Endothelial SIRT1 Inactivation Enhances Capillary Rarefaction and Fibrosis following Kidney Injury through Notch Activation Yujiro Kida,[1] Joseph A. Zullo,[1,3] Michael S. Goligorsky.[1,2,3] *[1]Medicine, New York Medical College, Valhalla, NY; [2]Pharmacology, New York Medical College, Valhalla, NY; [3]Physiology, New York Medical College, Valhalla, NY.*

Background: Peritubular capillary (PTC) rarefaction, along with tissue fibrosis, is a hallmark of progression of chronic kidney diseases (CKD). Although previous studies have demonstrated that functional loss of endothelial sirtuin 1 (SIRT1) aggravates renal fibrosis, mechanisms that afford renal protection are not completely elucidated. Recently, SIRT1 was found to deacetylate Notch intracellular domain-1 (NICD1, active form of Notch1) and accelerate its degradation. In this study, we hypothesized that impaired endothelial SIRT1 function induces Notch activation, which enhances kidney injury.

Methods: We created mice with deleted SIRT1 catalytic domain in endothelial cells (Sirt1 mutant mice). Both wild-type (WT) control and Sirt1 mutant mice were subjected to unilateral ureteral obstruction (UUO). For in vitro studies, we isolated microvascular endothelial cells (MVECs) from WT and Sirt1 mutant kidneys.

Results: In Sirt1 mutant mice, kidney injury enhanced apoptosis and senescence of PTC endothelial cells with impaired endothelial proliferation and expanded myofibroblast population and collagen deposition. Compared to WT kidneys, Sirt1 mutant kidneys showed increased expression of DLL4 (a potent Notch ligand), Hey1 (Notch target gene), and NICD1 in PTC endothelial cells post-injury. Sirt1 mutant primary MVECs reduced motility and enhanced senescence compared to WT MVECs. This phenotypical difference was negated with Notch inhibition. DLL4 and TGF-β1 synergistically increased transdifferentiation of primary kidney pericytes into myofibroblast.

Conclusions: Functional loss of endothelial SIRT1 aggravates PTC rarefaction via excessive Notch activation and tissue fibrosis through increased expression of endothelial DLL4. Endothelial SIRT1-Notch1 axis could be a novel therapeutic target to prevent progression of CKD.

Osteopontin Deficiency Reduces Alport Pathology Wen Ding, Keyvan Yousefi, Jayanti Singh, Stefania Goncalves, Bradley J. Goldstein, Lina Shehadeh. *Univ of Miami.*

Background: Alport Syndrome is characterized by progressive renal failure, hypertension, proteinuria, hearing loss, and cardiovascular dysfunction. The COL4A3$^{-/-}$ mouse phenocopies these symptoms, making it an ideal Alport model. Osteopontin (OPN), a secreted phosphoproprotein, has never been studied in Alport Syndrome. We elected to investigate the role of OPN in Alport pathology.

Methods: OPN protein expression from wild type (WT) and Alport mice (n=3-6) was analyzed by western blot. We generated Alport mice with hetero-or homo-zygous OPN deletion and evaluated effect on life span. At 8-9 weeks of age, WT, OPN$^{-/-}$, COL4A3$^{-/-}$, COL4A3$^{-/-}$OPN$^{-/-}$ and COL4A3$^{-/-}$OPN$^{+/-}$ mice (n=7-22/group) were studied. Urine from all groups was analyzed by Albumin and Creatinine Elisas, blood was analyzed for mean corpuscular hemoglobin concentration (MCHC), plasma was analyzed by Gelactin-3 Elisa, kidney injury molecule-1 (KIM-1) protein expression was analyzed by immunofluorescence, blood pressure was recorded by a tail cuff system, and hearing thresholds were determined by auditory brainstem responses to pure tone (4-16 kHz) or click stimuli. Heart function was assessed by echocardiography. Basement membrane morphology in kidneys and cochleas was analyzed by electron microscopy.

Results: OPN was increased in plasma (FC=1.4, p=.03) and kidneys (FC=2.1, p=.003) of Alport versus WT mice. COL4A3$^{-/-}$OPN$^{-/-}$ and COL4A3$^{-/-}$ OPN$^{+/-}$ mice significantly outlived the Alport mice (16 versus 10 weeks), with increase in body weight (FC=1.2, p=.02), MCHC (FC=1.3, p=.001) and endocardial stroke volume (FC=1.4, p=.003), while decrease in Albumin/Creatinine ratio (FC=.5, p=.01), Gelactin-3 (FC=.62, p=.01), renal Kim-1 (FC=.1, p=10^{-6}), and blood pressure (systolic FC=.81, p=.0002; diastolic FC=.78, p=.0001). COL4A3$^{-/-}$OPN$^{+/-}$ mice showed significantly improved hearing in response to 16 kHz stimuli. COL4A3$^{-/-}$OPN$^{-/-}$ mice had reduced thickness of glomerulus- and stria vascularis capillary- basement membrane.

Conclusions: This is the first study reporting that reduction of OPN can improve lifespan, proteinuria, hypertension, renal and cochlear histology, cardiac function and hearing ability in Alport mice. Our data suggest OPN as a therapeutic target for Alport Syndrome.

TH-OR117

Role of Macula Densa Cells in Tissue Remodeling in Renovascular Hypertension Toshiki Doi, Anne Riquier-Brison, Janos Peti-Peterdi. *Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.*

Background: Renovascular disease (RVD) accounts for an important proportion of secondary hypertension and is associated with progressive renal dysfunction. There is no specific cure for RVD and the resulting progressive, chronic kidney disease. Since robust alterations in tissue composition and renin are established features in RVD, this study tested the hypothesis that cells of the juxtaglomerular apparatus (JGA) play an important role in vascular and glomerular remodeling in RVD.

Methods: Genetic cell fate tracking using in vivo serial multiphoton microscopy (MPM) of the same glomeruli, and histology in tamoxifen-induced NG2CreERT2-Tomato mice and Ren1dCre-Confetti mice was performed to evaluate mesenchymal progenitor cell-

mediated tissue remodeling. Mice underwent either sham operation or renal artery cuffing (two-kidney, one-clip, 2K1C model of RVD) and were treated with specific inhibitors of macula densa (MD) cell-specific nitric oxide synthase (NOS1, 7-Nitroindazole (7-NI), 20 mg/kg/day ip), and cyclooxygenase (COX-2, 6 mg/L SC58236 in drinking water), or control (vehicle) groups, and sacrificed 3 weeks later.

Results: 2K1C mice showed high blood pressure, a significant decrease in the weight of the clipped kidney, and a significant increase in the weight of the non-clipped kidney compared with sham group. The number of NG2-derived cells, Ki-67 or renin positive cells increased more than 2-fold in the JGA in the clipped kidney. Some NG2-derived cells were co-labeled for Ki-67 or renin. On the other hand, 7-NI and COX-2 inhibitor attenuated these alterations. At baseline, Ren1d-Confetti cells existed at glomerular vascular pole, mesangium, Bowman's capsule, and in the proximal tubule. Serial MPM showed the migration of Ren1d-Confetti cells from vascular pole into glomerulus.

Conclusions: Our results suggest that mesenchyme-derived cells, including cells of the renin lineage have important roles in vascular and glomerular remodeling in RVD. Also, MD-derived (from COX-2 and nNOS) paracrine factors promote the migration of these cells to the JGA and glomerulus. In conclusion, MD cells may be important regulators of vascular and glomerular remodeling in RVD.

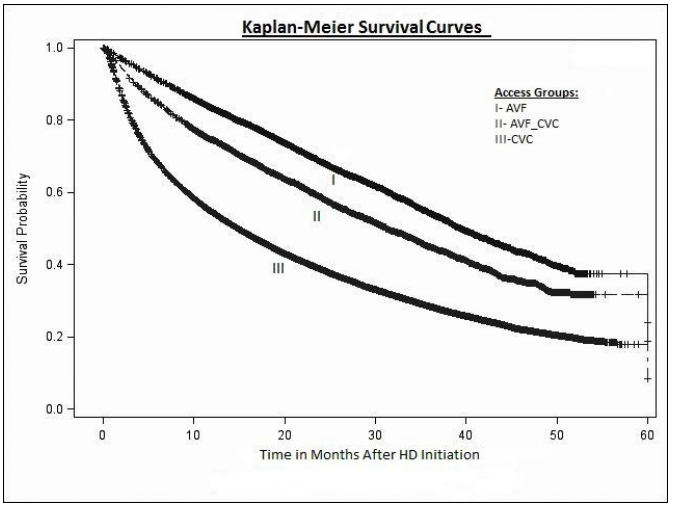
TH-OR118

'Patient First': The Survival Benefit of 'Fistula First, Catheter Last' in Hemodialysis Is Primarily due to Patient Selection Robert S. Brown,[1] Bhanu K. Patibandla,[2] Alexander S. Goldfarb-Rumyantzev.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Oregon Health & Science Univ, Portland, OR.*

Background: Patients needing hemodialysis (HD) are advised to have an arteriovenous fistula (AVF) rather than a catheter because of significantly lower mortality rates. However, disparities in AVF placement raise a question of the role patient selection plays in this apparent mortality benefit.

Methods: A cohort of 115,425 incident HD patients ≥67 years was derived from the United States Renal Data System with linked Medicare claims to identify the first predialysis vascular access placed. We compared mortality outcomes in patients initiating HD with a fistula placed first, a catheter after a fistula had been placed first, or a catheter placed first.

Results: Of 21,436 patients with an AVF placed first, 9,794 initiated HD with that AVF (AVF group) and 8,230 with a catheter rather than their AVF (AVF-CVC group). 90,517 patients initiating HD with a catheter (CVC group) served as the reference group. Those in the AVF group had the lowest mortality over the 58 month study period [HR 0.50, CI 0.48-0.52, p<0.0001] with mortality at 6, 12 and 24 months of 8.7%, 16.7% and 31.4%, respectively, compared to 31.6%, 45.6% and 62.3% in the CVC group. Surprisingly, those initiating HD with a catheter after AVF placement also had significantly lower mortality rates [HR 0.66, CI 0.64-0.68, p<0.0001] than the catheter group with 15.1%, 25.4% and 41.6% dying at 6, 12 and 24 months. Furthermore, analyzing the data in the AVF-CVC group by age, race, sex, comorbidities or whose 'failed' AVF was placed <4 or >2, 4, 6, or 9 months predialysis all showed similar mortality benefit compared to the CVC group.



Conclusions: Patient selection factors affecting fistula placement even when hemodialyzed with a catheter may explain at least two-thirds of the lesser mortality rates seen in those with a fistula compared to a catheter.

TH-OR119

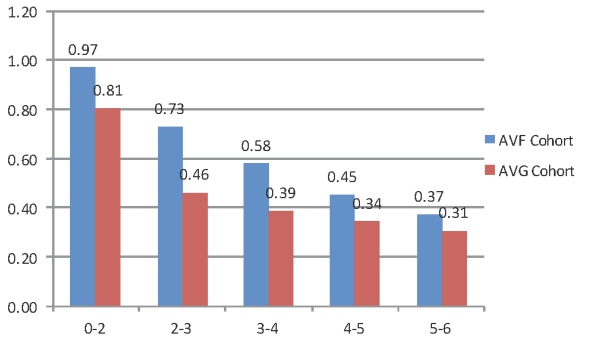
Choice of Vascular Access (VA) and Clinical Outcomes among Elderly Hemodialysis Patients Timmy C. Lee,[1] Mae Thamer,[2] Qian Zhang,[2] Michael Allon,[1] Yi Zhang.[2] *[1]Univ of Alabama at Birmingham; [2]Medical Technology and Practice Patterns Inst.*

Background: Current guidelines recommend placing an AVF rather than an AVG in HD patients. Our observational study compared VA and patient outcomes among elderly patients who initiated HD with a dialysis catheter (CVC), and subsequently had an AVF or AVG placed.

Methods: Using an observational equivalent of an intention-to-treat design, we identified ESRD patients from the USRDS age ≥67 who initiated HD from 7/1/2010-6/30/2011 with a CVC and no secondary VA, and who received an AVF (n=7,016) or AVG (n=2,228) within the ensuing 6 months. We evaluated CVC dependence during the 6 months after VA placement and used propensity score (PS)-weighted Cox proportional hazard models to evaluate the association of AVF vs AVG use with patient survival.

Results: Patients receiving an AVG were more likely to be female, black, and have high comorbidities. Those receiving an AVG had lower CVC use in the first 6 months after VA surgery (figure1).

Figure 1. Percentages of CVC dependence in AVF and AVG cohorts by months after surgery



In the PS-adjusted analysis of the entire cohort, patients with an AVF had a lower risk of death versus those with an AVG (OR 0.79, 95% CI 0.74-0.83). The survival difference between AVF and AVG persisted when patients were stratified by age and race (table 1).

Table 1. Adjusted Kaplan-Meier survival curve results based on VA type: AVF vs. AVG (ref)

Cohort	*Hazard Ratio (HR) 95% CI*
Whites 67 – 80 yrs	0.77 (0.70-0.85)
Whites >80 yrs	0.81 (0.73-0.91)
Blacks 67 – 80 yrs	0.71 (0.60-0.85)
Blacks >80 yrs	0.66 (0.53-0.83)

Conclusions: AVG placement in patients initiating HD with CVC is associated with significantly shorter duration of CVC dependence. Patient survival was significantly better in patients receiving an AVF despite longer CVC dependence, suggesting the survival advantage of patients with AVFs may be due to unmeasured clinical characteristics of these patients, rather than to presence of CVC.

TH-OR120

Cost Comparisons of Hemodialysis Access Modalities among Patients Starting with Tunneled Catheters Jason Kane Wagner, Larry Fish, Theodore H. Yuo. *Vascular Surgery, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Arteriovenous fistula (AVF) is the ideal hemodialysis (HD) access, but most patients start with tunneled dialysis catheter (TDC). AVF and arteriovenous graft (AVG) surgery may reduce TDC use and also increase procedural expenses. We compared Medicare costs associated with AVF, AVG, and TDC.

Methods: Using the US Renal Data System (USRDS), we identified incident HD patients in 2008 who started with TDC, survived at least 90 days, and had adequate Medicare records for analysis. We followed them until death or end of 2011; access modality was based on billing evidence of AVF or AVG creation. We assumed patients without such records remained with TDC. We generated multivariate linear regression models predicting Medicare expenditures, censoring costs when patients died; we included all payments to physicians and institutions. We also created algorithms to identify access-related costs.

Results: There were 113,505 patients in the USRDS who started HD in 2008, of whom 51,002 Medicare patients met inclusion criteria. Of that group, 41,532 (81%) began with TDC; 27,064 patients were in the final analysis file. In the first 90 days after HD initiation, 6,100 (22.5%) received AVF, 1,813 (6.7%) AVG, and 19,151 (70.8%) stayed with TDC. Annualized access costs by modality were: TDC $13,625 (95% CI $13,426-13,285); AVF $16,864 (95% CI $16,533-17,194); and AVG $20,961 (95% CI $20,967-21,654) (P<.001). Multivariate linear regression demonstrated that staying with TDC had lowest access-related costs, AVF was intermediate, and those who underwent AVG surgery were highest (P<.021). Access type was not significantly associated with total costs. Additional AVF and AVG

creation ($3,525 and $3,804 per access per year, respectively) and open and endovascular access-related interventions ($3,102 and $3,569 per procedure per year, respectively) (all P<.001) were important predictors of increased cost.

Conclusions: Among patients starting HD with TDC, continued TDC use is associated with lowest access-related cost. Both endovascular and open interventions are associated with significant additional costs. Further investigation is warranted to develop efficient patient-centered strategies for HD access.

TH-OR121

Access Blood Flow Surveillance in Native Arteriovenous Fistula: Reduction in Thrombosis Rate and Improvement in Assisted and Secondary Patency. A Randomized Clinical Trial Ines Aragoncillo,[1] Soraya Abad,[1] Silvia Caldés,[2] Antonio Cirugeda,[2] Almudena Vega,[1] Cristina Fernandez,[4] Cristina Moratilla,[3] Nicolás Macías,[1] Juan Manuel Lopez Gomez,[1] Fernando De Alvaro Moreno.[2] *[1]Nephrology, H Gregorio Marañon, Madrid, Spain; [2]Nephrology, H Infanta Sofia, Madrid, Spain; [3]Nephrology, Clinica Fuensanta, Madrid, Spain; [4]Nephrology, H Clinico, Madrid, Spain.*

Background: Stenosis is the main cause of arteriovenous fistula (AVF) failure. It is still unclear if surveillance based on Vascular Access Blood Flow (Q_A) enhances AVF function and longevity.

Methods: 3-year follow up randomized, controlled, multicentric, open-label trial, comparing Q_A surveillance (pre-emptive repair of subclinical stenoses with angioplasty and/or open surgery) with standard monitoring/surveillance (intervention based on classic criteria) in mature autologous AVFs. AVFs were randomized to either control group (surveillance based on venous pressure, recirculation, dialysis dose…; n=104) or to Q_A group [Q_A was measured quarterly using doppler ultrasound (*M-Turbo®*)and ultrasound dilution method (Transonic®)n=103]. The criteria for intervention in Q_A group were 25% reduction in Q_A, Q_A <500 ml/min or significant stenosis with >50% reducción in vessel lumen and haemodinamic repercussion [Peak Sistolic Velocity (PSV) >400ml/min or PSV stenosis/PSV pre-stenosis > 3).

Results: Significant reduction in thrombosis rate (0,025 thrombosis/patient/year in the Q_A group compared with 0,086 thrombosis/patient/year in control group. p= 0,007) Significant improvement in assisted primary patency rate and secondary patency rate in Q_A group (HR 0,30 CI 0,11-0,82. P=0,011 / HR 0,49 CI 0,26-0,93. p=0,030) No differences in non-assisted primary patency rate between groups (HR 0,98 CI 0,57-1,61. p=0,935). Higher needs of central venous catether and hospitalizations related with VA in control group (p<0,001 / p=0,003). - Higher total VA related costs in control group (217.845 € vs 124.186 €. p=0,029).

Conclusions: QA based surveillance combining doppler ultrasound and ultrasound dilution method prevents thrombosis, increases assisted and secondary patency rate in AVF and it is cost effective.

TH-OR122

Comparison of Postoperative Ultrasound Criteria to Predict Unassisted Clinical Arteriovenous Fistula (AVF) Maturation Timmy C. Lee,[1] Michelle L. Robbin,[1] Steven K. Burke,[2] Andrew T. Blair,[2] Missy Magill,[2] Michael Allon.[1] *[1]Univ of Alabama at Birmingham; [2]Proteon Therapeutics.*

Background: AVF maturation failure is a major clinical problem. A postoperative ultrasound (US) may provide objective measures to predict unassisted clinical AVF maturation and guide interventions to salvage nonmaturing AVFs. We compared predictive values of the NKF K/DOQI and University of Alabama (UAB) maturation criteria for unassisted clinical AVF maturation from data in a multicenter, randomized-clinical trial.

Methods: We analyzed prospective data from "A Study of PRT-201 Administered After Arteriovenous Fistula Creation in Patients with Chronic Kidney Disease.", which enrolled 151 subjects. We excluded 14 subjects with a missing 6-12 week postoperative US and 32 subjects with indeterminate clinical AVF maturation. The remaining 105 subjects were analyzed. Two US criteria were assessed:(1) NKF:AVF diameter ≥6 mm and blood flow ≥600 mL/min) and (2) UAB:AVF diameter ≥4mm and blood flow ≥500mL/min. Unassisted clinical AVF maturation was defined as successful cannulation for ≥90 days without requiring prior surgical or percutaneous interventions. Sensitivity and specificity were calculated for both criteria.

Results: 44% of AVFs were radiocephalic (RCF) and 56% brachiocephalic.

Table 1	Sensitivity	Specificity
All AVF (N=105)		
UAB Criteria	0.83	0.48
NKF Criteria	0.60	0.74
Radiocephalic AVF (N=46)		
UAB Criteria	0.82	0.85
NKF Criteria	0.39	0.92

Table 1 summarizes the sensitivity and specificity of both US criteria for unassisted clinical AVF maturation. Collectively, the UAB criteria had higher sensitivity and lower specificity for unassisted AVF maturation, as compared to the NKF criteria. For patients with a RCF AVF, the UAB criteria had higher sensitivity and similar specificity to the NKF criteria.

Conclusions: In the total population, the UAB criteria would minimize unnecessary early interventions in AVFs likely to clinically mature without an intervention, but delay interventions that may be indicated in AVFs that are unlikely to be clinically mature. However, for RCF AVFs, using the UAB criteria would reduce unnecessary early interventions without delaying necessary interventions.

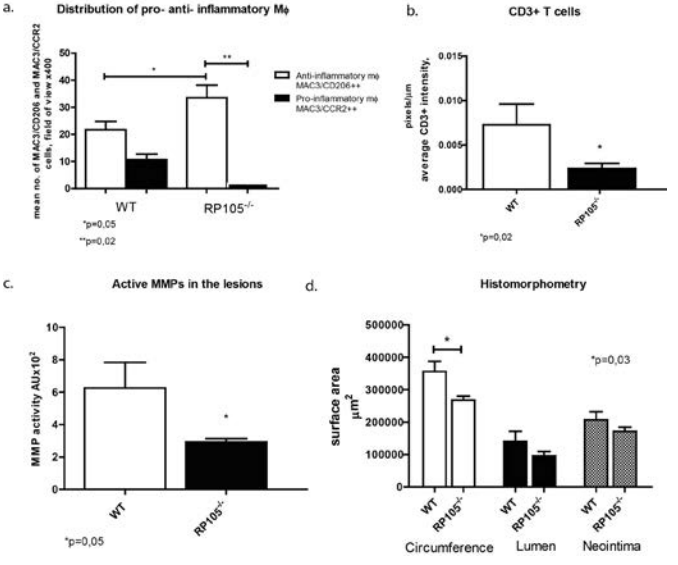
Deficiency of TLR4 Homologue RP105 Aggravates Outward Remodelling in a Murine Model of Arteriovenous Fistula Failure Taisiya Bezhaeva, ChunYu Wong, Margreet R. De Vries, Eric P. van der Veer, Carla van Alem, Joris I. Rotmans, Paul Quax. *Nephrology and Vascular Surgery, Leiden Univ Medical Centre, Netherlands.*

Background: The pathophysiology of arteriovenous fistula (AVF) maturation failure is unknown but impaired outward remodeling and intimal hyperplasia are both considered to contribute. RP105 is an important regulator of inflammatory TLR4 signalling, expressed on numerous cell types. In the present study, we defined cell specific effects of RP105$^{-/-}$ on vascular smooth muscle cells (VSMCs) and macrophages (mΦ) *in vitro* and *in vivo* effects of RP105$^{-/-}$ on AVF maturation in a murine model of AVF failure.

Methods: All *in vitro* experiments were performed on primary cells isolated from RP105$^{-/-}$ and wild type (WT) mice. AVFs were created in an end-to-side manner between *v.jugularis* and *carotid a.* in RP105$^{-/-}$ (n=13) and WT (n=11) mice. AVFs were harvested at day 14 and processed for morphometric analysis and immunohistochemistry. MMPSense probe was used to measure *in vivo* MMPs activity.

Results: *In vitro*, anti-inflammatory (M2) mΦ of RP105$^{-/-}$mice showed increased IL10 (ELISA) compared to WT. Venous VSMCs from WT mice exhibited increased mRNA of RP105 and TLR4 compared to arterial VSMCs, whereas proliferation rate of venous VSMCs was 50% lower in RP105-/- cells. *In vivo,* a shift towards M2 mΦ and a 70% reduction in CD3+ T cells was observed in RP105$^{-/-}$ mice(fig.a,b). MMP-activity was reduced by 50% in RP105$^{-/-}$(fig.c). Amount of SMA/Ki67^{++} VSMCs was decreased by 31%. Overall, RP105-/- mice showed 26% smaller circumference of the external jugular vein (fig.d).

fig.1



Conclusions: Deletion of RP105 results in a marked decrease in venous outward remodeling in AVF. The latter might relate to a shift towards M2 mΦ, reduction in MMP activity and decreased VSMCs proliferation in the venous outflow tract of AVF, illustrating the complex interactions between inflammation and VSMC biology in AVF maturation.

Loss of GSTA4 Enhances CKD-Induced Arteriovenous Fistula Failure Ming Liang, William E. Mitch, Jizhong Cheng. *Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Background: A functioning arteriovenous fistula (AVF) is the "dialysis lifeline" but progressive neointima formation reduces AVF functions leading to AVF failure.We have found that chronic kidney disease (CKD) accelerates AVF failure. CKD induces oxidative stress leads to accumulation of the uremic toxin, 4-hydroxynonenal (4-HNE). This process is linked to CKD-suppressed expression of α-glutathione transferases (GSTs).

Methods: we created CKD and AVFs in GSTA4 KO mice and mice overexpressing GSTA4, we studied how GSTA4 can suppress CKD-induced AVF failure. In cultured VSMCs, we examined how 4-HNE induces VSMC proliferation and whether GSTA4 modulates these responses.

Results: GSTA4 expression measured as mRNA or protein was decreased and 4-HNE level was increased in AVFs in CKD mice. In GSTA4 (GSTA4 KO) mice, CKD increased both 4-HNE and pc-JUN levels in VSMCs, and stimulated VSMC proliferation and neointima formation in AVFs. Using a combined Tet-On/Cre induction system, a transgenic mice was generated to transiently overexpress GSTA4 in VSMCs. The overexpression of

GSTA4 resulted in lower levels of 4-HNE and decreased MAPK activation. There were reduced accumulation of SMA-α^+ VSMCs and PCNA positive cells in neointima in AVFs created in GSTA4 transgenic mice. The outcome was a reduction in the CKD-induced neointima formation and improved AVF maturation. In ex-vivo experiments, the loss of GSTA4 expression is accompanied with increased VSMC migration and outgrowth. In cultured VSMCs, treatment with 4-HNE was found to exclude $p27^{kip1}$ from the nuclei to promote VSMC proliferation. 4-HNE also upregulated MAPK activation (pERK1/2 and pJNK). Both responses were amplified when GSTA4 was knocked down, but were blocked when GSTA4 was overexpressed.

Conclusions: CKD complications decrease GSTA4 expression resulting in 4-HNE accumulation in AVFs. This increase in 4-HNE stimulates the proliferation of VSMC to stimulate the MAPK signaling pathway. When GSTA4 were specifically overexpressed in VSMCs, there was suppression of CKD-induced 4-HNE accumulation and VSMC proliferation. These results demonstrate that increased expression of GSTA4 can suppress CKD-induced neointima formation and AVF failure.

Usability of the Endovascular Arteriovenous Fistula: 6m Results of the Novel Endovascular Access Trial (Neat) Charmaine E. Lok, Dheeraj K. Rajan. *On Behalf of NEAT Investigators, Univ Health Network, Toronto, Canada.*

Background: Recent high arteriovenous fistula (AVF) failure rates (20-60%) may be associated with vessel trauma incurred at the time of surgery. Vessel trauma may be mitigated by a novel approach to AVF creation endovascularly (endoAVF) using magnet-based catheter technology and radiofrequency energy (RFE). NEAT aimed to evaluate the safety and efficacy of this new technology in a prospective, multi-center study. We report key 6 mo outcomes.

Methods: 80 CKD V patients (60 study cohort;20 roll-in) from sites in Canada, Australia and New Zealand were enrolled. EndoAVFs were created using two magnetic catheters to create a channel between a vein and artery using RFE. Key inclusion criteria included: ineligibility for a distal forearm AVF, target vein and artery diameters > 2.0mm, no central vein stenosis. Primary endpoint was percentage of endoAVF physiologically mature (brachial artery flow >500 ml/min, vein diameter > 4mm) or 2 needle cannulation within 3 months. Patient satisfaction was evaluated via a validated survey (SF-VAQ). Only study cohort patients (n=60) were evaluated and reported.

Results: 65% of patients were men, mean age 60 yrs, mean BMI 28, 65% had diabetes and 57% were predialysis at the time of procedure. An endoAVF was successfully created in 98% (59/60) of patients; 5 (8.3%) patients had a serious device or procedure-related adverse event. Physiological maturation was 91% (52/57) of endoAVFs within 3 months. Mean brachial artery flow rate was 918ml/min at 3 months and sustained to 6 months. Cephalic, basilic, and median cubital vein diameters (mm) increased to 5.4, 5.8 and 6.1 at 6 months, respectively. 2-needle cannulation of endoAVF occurredin 90% (9/10) of predialysis patients who required dialysis and 73% (16/22) of patients who were already on dialysis at baseline. 6mo primary and secondary patency rates were 79% and 90%, respectively. 83% of patients were satisfied with their endoAVF at 6 months.

Conclusions: The NEAT reveals that endoAVF results in high physiological maturation success and ability to cannulate with 2 needles for dialysis. Patients were satisfied with their endoAVF. Ongoing follow-up will reveal the long-term durability of the endoAVF.

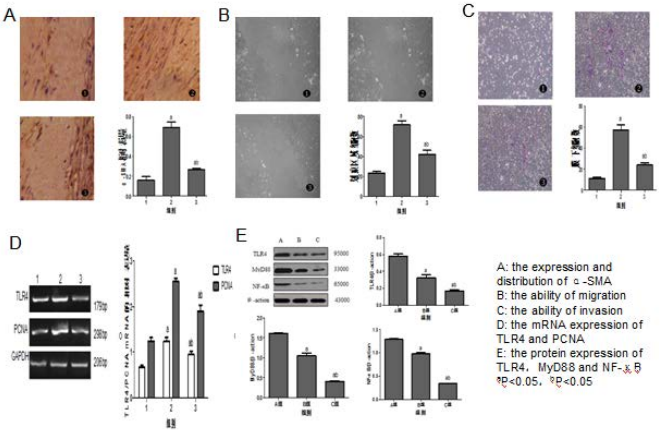
The Effect and Mechanism of Chitosan Inhibiting Vascular Smooth Muscle Cells Hyperplasia of Uremia Patients Yan Yan. *Nephrology, The First Affiliated Hospital of Nanchang Univ, NanChang, JiangXi, China.*

Background: The most common complication of arteriovenous fistula(AVF) is stenosis. The pathological characteristic of stenosis is intimal hyperplasia.Our previous studies have found that chitosan can inhibit the internal jugular fistula intimal hyperplasia of rabbit.Our aim was to investigate the effect and mechanism about chitosan have on cultured vascular smooth muscle cells(VSMCs) of uremia patients with AVF.

Methods: Adopting the the second generation VSMCs of uremia patients with AVF and normal person which cultured with improved adherent method of tissue explants, VSMCs from normal person cultured with 20%FBS was blank control group, VSMCs from uremia patients cultured with 20%FBS and 100 ug/ml chitosan respectively were control group and experimental group. α-SMA were detected by immunohistochemistry method. The migration and invasion's ability of VSMCs were detected by scratches and transwell method, The mRNA expressions of TLR4 and PCNA were measured by Real-time PCR. VSMCs of uremia patients with AVF were intervened with different doses of chitosan(10, 100, 500ug/ml), the protein expressions TLR4, MyD88 and NF-κB were detected by Western blotting.

Results:



α-SMA was staining compared to blank control group. Compared experimental group with control group, the level of α-SMA was significantly decreased. The ability of migration and invasion of VSMCs after the intervention of chitosan were decreased significantly ($P < 0.05$), The mRNA expressions of TLR4 and PCNA decreased($P < 0.05$).TLR4, MyD88 and NF-κB protein expression were reduced by chitosan in the certain concentration range.

Conclusions: Chitosan not only decreases the ability of migration and invasion but also inhibits the proliferation of VSMCs of uremia patients with AVF, the mechanism may be concerned in the decreased expression of TLR4,MyD88 and NF-κB.

Taurolidine/Urokinase Based Locking Regimen Significantly Reduces Catheter-Related Blood Stream Infections and Dysfunction of Tunneled Haemodialysis Catheters when Compared to 4% Citrate Wolfgang Winnicki, Gurkan Sengoelge. *Dept of Medicine III, Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria.*

Background: Catheter infections and dysfunctions cause morbidity and mortality in haemodialysis patients. There are data showing that taurolidine containing catheter lock solutions may reduce the risk of both of these complications. Yet, there are no consistent guidelines for the use of lock solutions in haemodialysis patients with tunneled central lines. We aimed to study whether a TauroLock™ based locking regimen reduced the incidence of catheter-related blood stream infections (CRBSI, at least one positive blood culture with no other source of infection) and catheter malfunction (inadequate blood flow during dialysis - defined as blood flow < 200ml/min or >30% less than the average of the previous 10 sessions or necessity of catheter rescue with alteplase).

Methods: In this randomized controlled trial with 106 haemodialysis patients with a newly inserted tunneled central line a taurolidine based locking regimen with TauroLock™-Hep500 2x/week after the first two dialysis sessions and TauroLock™-U25.000 1x/ week before the long interval was compared to 4% citrate (CitraFlow™) used after each dialysis 3x/week.

Results: 52 patients were assigned to TauroLock™ (8982 catheter days) and 54 patients to 4% citrate (6708 catheter days). Catheter-related blood stream infections occurred in 11.4 % of patients in TauroLock™- and in 33.3 % of patients in 4% citrate-group, corresponding to rates of 0.67 and 2.6 episodes of CRBSI per 1000 catheter days, respectively (p= 0.003). Similarly, the rates of catheter dysfunctions were significantly lower in the TauroLock™ regimen (18.7 /1000 catheter days) vs. 4% citrate (44.3/ 1000 catheter days; p= 0.001). As a consequence, patients in the citrate 4% group needed alteplase rescue intervention in a significantly higher rate (38 vs. 3.8/ 1000 catheter days Citrate 4% versus TauroLock™; p= 0.001).

Conclusions: The use of a taurolidine based locking regimen significantly reduced the incidence of catheter-related blood stream infections as well as catheter malfunction in tunneled central venous haemodialysis catheters when compared to 4% citrate.

Renal Olfactory Receptor 1393 Contributes to Glucose Reabsorption Blythe D. Shepard,[1] Lydie Cheval,[3] Zita Peterlin,[4] Stuart Firestein,[4] Hermann Koepsell,[2] Alain Doucet,[3] Jennifer L. Pluznick.[1] *[1]Johns Hopkins Univ SOM, Baltimore, MD; [2]Univ Wurzburg, Julius-von Sachs-Inst, Wurzburg, Germany; [3]Centre de Recherche des Cordeliers UMRS 872, Paris, France; [4]Columbia Univ, New York, NY.*

Background: Olfactory receptors (ORs) are G protein-coupled receptors that detect odorants in the nose but also have functions beyond odorant detection; we previously determined that ORs (including Olfr1393) are expressed in the kidney.

Methods: Olfr1393 renal localization was determined by RT-PCR on RNA from microdissected renal segments and with overexpressed MDCK cells. We generated whole-animal knockout mice (KO) and measured plasma electrolytes by iStat, blood pressure by tail cuff, GFR by elimination of plasma sinistrin, blood glucose by glucometer and

urinary glucose and creatinine by VetACE Clinical Chemistry System. Sodium-glucose co-transporters (Sglt1 and Sglt2) were examined by western blotting and confocal microscopy of kidney cryosections.

Results: Olfr1393 is expressed in the renal proximal tubule (S1, S2, S3, n=3 mice), and is found on the apical plasma membrane, but not cilia, when expressed in polarized MDCK cells. Olfr1393 KOs are similar to wild-type (WT) with regards to plasma electrolytes, blood pressure and GFR. However, KOs exhibit urinary glucose wasting (1.4x increase in glucose/creatinine vs WT; P = 0.01) despite normal blood glucose (fed and fasted) and insulin levels. KOs also perform better in a glucose tolerance test (area under curve: WT 20.4±1.6 vs KO 16.3±1.1; P = 0.008) implicating a role in renal glucose handling. In support of this, KOs have a 22% decrease in luminal Sglt1, but not Sglt2, in the proximal tubule (confocal) despite similar total renal expression (western blot). Olfr1393 and Sglt1 co-immunoprecipitate when overexpressed. KO of the Sglts has been shown to attenuate diabetes-induced hyperfiltration due to increased distal Na^+ delivery. In preliminary data, the hyperfiltration induced after 16 weeks on high fat diet in WT mice appears to be attenuated in KO (GFR/BW: WT 576ml/min n=4; KO 435ml/min n=9; P=0.09).

Conclusions: These data suggest that Olfr1393 is a regulator of Sglt1 and presents a novel signaling pathway modulating renal glucose reabsorption.

Analysis of Vasopressin V1a Receptor Distribution and Function in the Mammalian Kidney Torsten Giesecke,[1] Taka-Aki Koshimizu,[2] Katsumasa Kawahara,[3] Sebastian Bachmann,[1] Kerim Mutig.[1] *[1]Charité Universitätsmedizin Berlin, Dept of Anatomy, Berlin, Germany; [2]Jichi Medical Univ, Dept of Molecular Pharmacology, Shimotsuke-shi, Tochigi-ken, Japan; [3]Kitasato Univ School of Medicine, Dept of Physiology, Kitasato, Sagamihara Kanagawa, Japan.*

Background: Apart from its effect on the renal concentrating mechanism, vasopressin (AVP) may affect acid-base regulation through its binding on the V1a receptor (V1aR). Activation of the V1aR appears to stimulate renal proton secretion, but information on this receptor is generally scarce. To extend available data we have analyzed segmental and cellular distribution of V1aR in mouse, rat, and human kidneys and performed functional studies using a V1aR agonist.

Methods: Antibody to V1aR was generated and controlled using V1aR knockout tissues. Its segmantal and cellular distribution along mouse, rat, and human renal tubule was characterized by immunofluorescence and high-resolution immunocytochemistry. Functional studies were performed in AVP-deficient Brattleboro rats using V1aR-specific agonist, AO-4-67.

Results: The V1aR antibody produced basolateral signal in α-type intercalated cells of connecting tubules and collecting ducts across the studied species. In contrast, beta-type intercalated cells showed punctate perinuclear and subapical V1aR signal which was partially colocalized with clathrin and the lysosomal marker, LAMP1. In the mouse kidney, macula densa cells were V1aR-positive as well. Administration of AO-4-67 to Brattleboro rats for 4h resulted in luminal trafficking of V-ATPase in alpha-type intercalated cells, whereas basolateral V-ATPase of luminal pendrin signals of beta-type intercalated cells were not affected by the stimulation.

Conclusions: In summary, the divergent cellular distribution patterns of V1aR in alpha- vs. beta intercalated cells provide morphological support for distinct responsiveness of these cells to the V1aR-agonist. These results corroborate and extend data on the role of AVP in the renal acid-based handling.

TH-OR130

Physiological Study of Urea Transporters Using Mice Lacking All Urea Transporters and Computational Model Baoxue Yang,[1] Tao Jiang,[1] Yingjie Li,[1] Anita T. Layton.[2] *[1]Dept of Pharmacology, Peking Univ, Beijing, China; [2]Dept of Mathematics, Duke Univ, Durham, NC.*

Background: Urea transporters (UT) are a family of transmembrane urea-selective channel proteins expressed in multiple tissues and play an important role in the urine concentrating mechanism of the mammalian kidney. UT inhibitors have been identified to have diuretic activity and may be developed as novel diuretics.

Methods: To determine if functional deficiency of all UTs in all tissues causes physiological abnormality, we established a novel mouse model in which all UTs were knocked out by deleting an 87 kb of DNA fragment containing most parts of *Slc14a1* and *Slc14a2* genes. A computational model was used to simulate the urine concentrating mechanism in wild-type and UT knockout rat.

Results: Western blot analysis and immunofluorescence confirmed the lack of expression of any urea transporter in all-UT-knockout mice. Their daily urine output was nearly 3.5-fold higher, with significantly lower urine osmolality than wild-type mice. All-UT-knockout mice were unable to substantially increase urinary urea concentration and osmolality after water deprivation, acute urea loading or high protein intake. Knocking out all UTs also decreased blood pressure and promoted the maturation of the male reproductive system. The computational model identified the contribution of each UT except for UT-A2, the knockout simulation of which yielded no significant impact on urine concentration and flow rate.

Conclusions: These results indicate that functional deficiency of all UTs may cause urea selective urine concentrating defect with little physiological abnormality in extrarenal organs.

TH-OR131

Src Kinase Inhibition by Dasatinib Induces Aquaporin-2 Membrane Accumulation in Kidney Principal Cells Richard Bouley, Pui Wen Cheung, Dennis Brown. *Medicine/Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Maintenance of water homeostasis is a vital function of the kidneys. In order to efficiently reabsorb water, the kidneys require a functional vasopressin (VP) signaling pathway to activate aquaporin-2 (AQP2). AQP2 trafficking is a balance between endocytosis and exocytosis, and src kinases are known to play important regulatory roles in membrane protein endocytosis; therefore, we explored the role of dasatinib, a src inhibitor, on AQP2 trafficking, and to investigate its potential role for treatments of water balance diseases.

Methods: We treated LLC-PK1 cells stably expressing AQP2 (LLC-AQP2) and mutant S256A cells with the src inhibitor dasatinib, and used immunocytochemistry to study AQP2 trafficking. We used western blot with specific phospho-antibodies against S256, S261 and S269 to measure phosphorylation. We treated rat kidney slices with dasatinib to follow AQP2 localization *in situ*. The effects of dasatinib treatment on AQP2 vesicle trafficking was also studied using exocytosis and endocytosis assays, actin depolymerization assay and clathrin-transferrin internalization assays to provide mechanistic information on its mode of action.

Results: Dasatinib increased apical membrane AQP2 accumulation in collecting duct principal cells in our *in situ* kidney slice model, and led to an increase in AQP2 membrane accumulation in the LLC-AQP2 cells. Western blots showed that dasatinib did not increase phosphorylation of S256, and this S256-independent effect was confirmed when dasatinib was able to induce AQP2 membrane accumulation in mutant S256A cells. Similar to VP, dasatinib increased exocytosis and decreased endocytosis, and these effects were specific to AQP2 containing cells. In contrast to VP, dasatinib did not activate PKA or MAP kinase, and did not de-phosphorylate S261. To our surprise, however, we observed a dose-dependent increase in S269 phosphorylation upon dasatinib treatment.

Conclusions: Src inhibition by dasatinib induced AQP2 membrane accumulation in a non-canonical fashion. The signaling pathway differs from that induced by VP, and represents a new approach to stimulating VP-independent AQP2 membrane accumulation.

TH-OR132

CaSR and AQP2 Interplay in Pendrin/NCC dKO and the Impact on Water Excretion and Vascular Volume Depletion Marianna Ranieri,[1] Kamyar A. Zahedi,[2] Grazia Tamma,[1] Mariangela Centrone,[1] Manoocher Soleimani,[2] Giovanna Valenti.[1] *[1]Univ of Bari Aldo Moro; [2]Univ of Cincinnati.*

Background: Pendrin/NCC double KO (dKO) mice display significant calcium (and phosphate) wasting and develop severe volume depletion despite increased circulating vasopressin levels. It is known that high concentrations of urinary calcium in the renal collecting duct counteract vasopressin action, consequently impairing the trafficking of the vasopressin-sensitive water channel AQP2. This effect is mediated by the activation of the Calcium Sensing Receptor (CaSR) expressed in the luminal membrane of collecting duct cells. Here we tested the hypothesis that the vasopressin resistance in dKO mice is due to CaSR-mediated impairment of the AQP2 expression/trafficking.

Methods: Ex vivo experiments were performed in kidney slices from pendrin/NCC dKO mice. Modulation of AQP2 phosphorylation was tested using phosphospecific antibodies. The calcimimetic NPS-R568 and the calcilytic NPS2143 were used to activate or inhibit CaSR respectively.

Results: Pendrin/NCC dKO mice exhibit significantly reduced total AQP2 both at mRNA and protein levels. Interestingly, when normalized to total AQP2, dKO mice had significantly higher levels of AQP2-pS261 vis-à-vis WT mice, which paralleled higher levels of phosphorylated p38-MAPK, an enzyme activated by CaSR and known to phosphorylate AQP2 at ser261. Specific inhibition of p38-MAPK partially reversed the increase of AQP2-pS261 in double KO mice. Conversely, upstream inhibition of CaSR with the calcilytic NPS2143 in dKO mice resulted in 100% increase in basal levels of AQP2-pS256, suggesting that in addition to the up-regulation of AQP2-p261, CaSR mediates the downregulation of AQP2-pS256. Finally, preliminary data indicate that dKO mice have significantly higher AQP2-targeting miRNA-137, which is suggested to downregulate AQP2.

Conclusions: Together, these results point to a critical role of CaSR in impairing both AQP2 abundance, possibly through miRNA-137, and short-term vasopressin response by reducing AQP2 phosphorylation at S256 and increasing AQP2 phosphorylation at S261, contributing to water excretion and vascular volume depletion observed in Pendrin/NCC dKO mice.

TH-OR133

Tamoxifen Restores Renal Fibrosis and Attenuates Reduced AQP2 and AQP3 Regulation in Response to Unilateral Ureteral Obstruction in Rats Stine Julie Tingskov Pedersen, Rikke Norregaard. *Dept of Clinical Medicine, Aarhus Univ, Aarhus N, Denmark.*

Background: Renal fibrosis is the final common pathway in chronic kidney diseases and is the most consistent predictor of irreversible loss of renal function. Previous studies have demonstrated that fibrosis reduces the amount of aquaporin (AQP)-2 and AQP3. Tamoxifen binds to estrogen receptor (ER) and has been used as an anti-estrogen for the prevention and treatment of breast cancer. In this study, we investigated the effect of tamoxifen on unilateral ureteral obstruction (UUO)-induced fibrosis and its regulation of AQPs.

Methods: Fibrosis was induced by 7 days UUO in rats. Tamoxifen (50 mg/kg) was given by oral gavage for 5 days before induction of renal fibrosis. Tamoxifen (TAM) treatment was continued for 7 days after UUO operation. Clearance experiments were performed and histologic changes were examined by HE stain and Masson's trichrome stain. Expression of α-smooth muscle actin, fibronectin, AQP2 and AQP3 were evaluated by immunohistochemistry and western blot analysis.

Results: Renal fibrosis was increased after UUO. TAM treatment significantly reduced fibrosis and fibroblast activation as well as increased the anti-fibrotic bone morphogenetic protein 7 (BMP7) in rats subjected to UUO. Furthermore, TAM decreased cross-sectional and gross-morphology changes in the obstructed kidney. In the UUO kidneys, AQP2, phosphorylated Ser256-AQP2 and AQP3 protein expression was reduced and TAM administration attenuated downregulation of the AQPs although no changed was observed in expression of the vasopressin V2 receptor. In addition, the expression of ERα, ERβ and GPER was not affected by TAM treatment in UUO rats. Urine samples collected from the pelvis of the obstructed kidney treated with TAM exhibited a higher urine osmolality compared to non-treated UUO kidneys. Plasma osmolality was not affected.

Conclusions: These findings indicate that TAM has beneficial effects on UUO-induced fibrosis and might have therapeutic potential in the management of obstruction-associated dysregulation of fluid metabolisms.

Metformin Improves Urine Concentration Ability in Rodent Models of Nephrogenic Diabetes Insipidus Orhan Efe,[1] Janet D. Klein,[1,2] Jeff M. Sands.[1,2] *[1]Dept of Medicine, Renal Div, Emory Univ; [2]Dept of Physiology, Emory Univ, Atlanta, GA.*

Background: Urine concentration is regulated by vasopressin. Congenital nephrogenic diabetes insipidus (NDI) is characterized by excessive polyuria and caused by vasopressin V2 receptor (V2R) mutations. Present treatment options are limited. We studied AMPK as an alternate pathway to stimulate transporters involved in urine concentration.

Methods: Tolvaptan (10 mg/kg/day) was given by oral gavage to rats for 4 or 10 days, +/- metformin (800 mg/kg/day). Tolvaptan (selective V2R antagonist) was used to produce a rat model of NDI. Metformin was used to stimulate AMPK. Urine volume and osmolality were measured daily. Kidneys were dissected into inner medullary (IM) tip, base, and outer medulla, and UT-A1, AQP2, pAQP2 and NKCC2 were analyzed by Western blot. Immunohistology was used to localize the same transporters. Tamoxifen-induced V2R knock-out mice (gift from Dr. Wess, NIH) were given metformin (600 mg/kg) or vehicle twice daily. Hourly and daily urine osmolalities were determined and transporter proteins analyzed.

Results: Metformin reduced urine volume in tolvaptan-treated rats by 110% in 3 days and the effect was stable for 10 days. Correspondingly, urine osmolality in tolvaptan-treated rats was restored to near control levels by metformin (mean: 1303±126 mOsM (-met) vs 2335±273 mOsM (+met), p<0.05). Metformin increased protein abundance of IM tip UT-A1 61% and AQP2 44% (p<0.05) in tolvaptan-treated rats but not in control rats. Outer medullary NKCC2 abundance was markedly increased (117%) with metformin in control rats (p=0.004) but not in V2R-blocked rats. Immunohistochemistry showed increased membrane accumulation of AQP2 and pSer256-AQP2 with acute (1 hr) and chronic (4 days) AMPK stimulation, both in control and V2R-blocked rats. Metformin treatment of V2R knock-out mice increased urine osmolality within 1 hr and was maintained for up to 10 hours. Repeated daily treatment maintained the higher 24-hr urine osmolality. Metformin increased AQP2 in the V2R knock-out mice similar to the tolvaptan-treated rats.

Conclusions: AMPK activators, such as metformin, might provide a promising treatment for congenital NDI due to V2R mutations.

TH-OR135

Genetic Deletion of ADP-Activated P2Y12 Receptor Ameliorates Lithium-Induced NDI in Mice Bellamkonda K. Kishore,[1] Noel G. Carlson,[1] Kenny M. Hansson,[2] Yue Zhang.[1] *[1]Univ of Utah & VA Medical Center, Salt Lake City, UT; [2]Cardiovascular and Metabolic Diseases, Innovative Medicines Biotech Unit, AstraZeneca AB, Mölndal, Sweden.*

Background: Previously we reported that pharmacological blockade of P2Y12 receptor (R) significantly ameliorates Li-induced nephrogenic diabetes insipidus (NDI) in rodent models. To establish that the observed protection is mediated through P2Y12-R, we evaluated the effect of genetic deletion of P2Y12-R on Li-induced NDI.

Methods: Groups (n = 5) of adult wild type (WT) C57/Bl6 and syngeneic P2Y12-R knockout (KO) mice were fed Li-added diet (40 mmol LiCl/kg food) for 12 days with free access to food and water. Cohorts of control mice (n = 4/genotype) were fed regular chow. Twenty-four hour urine samples were collected prior to and at the end of experimental period. Blood and kidney samples were collected at euthanasia.

Results: As expected, Li caused marked increases in water consumption and urine output, and decreases in urine osmolality and AQP2 protein in the kidney medulla of WT mice. These alterations were significantly ameliorated in KO mice (Table; mean ± se).

	Wild Type	P2Y12 KO	P Value
Water Intake*	366 ± 68	140 ± 63	< 0.05
Urine Output*	393 ± 50	182 ± 22	< 0.001
Urine Osmolality*	40 ± 3	60 ± 3	< 0.05
Urine Sodium**	240 ± 26	194 ± 6	< 0.05
Urine Potassium**	511 ± 63	454 ± 19	= 0.183
AQP2 Protein in Medulla†	26 ± 6	57 ± 14	< 0.05
Serum Li (mmol/l)	0.478 ± 0.031	0.462 ± 0.027	= 0.721

*terminal value as percentage of day 0 value in the same group
**terminal value (μmol/24 h/20 g body wt)
†terminal value as percent of values in WT control group

Serum osmolality and sodium levels were within the normal range in both genotypes after feeding Li. As expected, Li feeding resulted in significant increases in urinary AVP and PGE2 excretion, which were not affected by P2Y12-R deletion.

Conclusions: Thus, similar to pharmacological blockade, deletion of P2Y12-R significantly ameliorates Li-induced NDI, without reducing serum Li levels. Hence, targeting P2Y12-R offers a novel and safer method for treating NDI with fewer side effects.

Soluble (Pro)Renin Receptor Targets Renal V2 Vasopressin Receptor to Enhance Urine Concentrating Capability Fei Wang,[1,2] Nirupama Ramkumar,[2] Kexin Peng,[1,2] Xiaohan Lu,[1,2] Long Zhao,[2] Donald E. Kohan,[2] Tianxin Yang.[1,2] *[1]Inst of Hypertension, Zhongshan School of Medicine, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Internal Medicine, Univ of Utah and Veterans Affairs Medical Center, Salt Lake City, UT.*

Background: We recently discovered that soluble (pro)renin receptor (sPRR) derived from collecting duct intercalated cells acts in a paracrine fashion to regulate water transport in the principal cells. The present study attempted to define the role of sPRR in vasopressin (AVP) signaling with emphasis on V2R regulation.

Methods: Primary rat IMCD cells were used to assess the direct effect of a recombinant sPRR-His on V2R expression. The sPRR-His was infused to mice with CD-specific deletion (CD PRR KO) and nephron-specific deletion (Neph PRR KO) of PRR.

Results: In primary rat IMCD cells, sPRR-His at 10 nM induced a 2.8 –fold increase in V2R protein and a 2-fold increase in V2R mRNA. Following AVP treatment, V2R protein was increased by 3-fold, which was blunted by a PRR antagonist and a PRR neutralizing antibody. CD PRR KO mice developed a medium level of diabetes insipidus {urine volume (UV): KO: 2.2±0.4 versus Floxed: 1.2±0.3ml/d; $P<0.05$}, accompanied with a 60% reduction of renal V2R protein and a 25% reduction of urinary sPRR excretion. Administration of sPRR-His for 3 d almost completely rescued the polyuria phenotype (UV: KO+sPRR-His:1.6±0.3 vs. KO: 2.4±0.5 ml/d, $p<0.05$) associated with restoration of renal V2R and AQP2 expression. Interestingly, Neph PRR KO mice exhibited more robust polyuria (UV:KO:7.3±1.1 vs. Floxed: 1.2±0.5 ml/d, $p<0.01$) associated with suppressed renal expression of AQP2, NKCC2, and V2R. Administration of sPRR-His to Neph PRR KO mice partially attenuated polyuria (UV:KO+sPRR-His:4.1±1.2 vs. KO: 7.3±1.1 ml/d, $p<0.01$) accompanied by restored expression of V2R and AQP2. In contrast, the downregulation of NKCC2 expression in the null mice was unaffected by sPRR-His nor was the upregulation of autophagosome marker microtubule-associated protein 1A/1B-light chain 3 (LC3b).

Conclusions: The sPRR selectively targets the CD to determine V2R expression and hence AVP sensitivity and urine concentrating capability, independently of autophagosome accumulation.

Medullary Class I HDACs Are Critical for Fluid-Electrolyte Balance and Blood Pressure Control during High Salt Feeding Kelly A. Hyndman, Joshua S. Speed, Courtney M. Dugas, Andrew Abad, Chunhua Jin, David M. Pollock, Jennifer S. Pollock. *Medicine-Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Histone deacetylase enzymes play a critical role in the regulation of transcription through epigenetic modification of chromatin structure. Consequently, deranged HDAC activity is causally linked to cancer, where three HDAC inhibitors (HDACi) are approved cancer treatments. Additional evidence suggests that HDACi may be beneficial in preventing inflammation in cardiovascular disease. However, the reported adverse events of HDACi use include hypertension, hyponatremia, and hypokalemia suggesting fluid-electrolyte disturbances. Thus we hypothesized that renal medullary class I HDACs are critical for homeostatic regulation of fluid-electrolyte balance and blood pressure control.

Methods: The class I HDACi, MS275, or vehicle was chronically infused into the medullary interstitium of the male rat kidney during high salt diet diet (HSD, 4% NaCl).

Results: Class I HDACs are expressed in the human and rat kidney, and inner medullary (IM) HDAC1 is significantly increased 4-fold with HSD in normotensive rats. During HSD, renal medullary HDACi resulted in a significant 15 ± 2.0 mmHg increase in mean arterial pressure. Furthermore, HDACi resulted in polydipsia, polyuria, a significant 50% reduction in IM aquaporin-2 expression and decreased plasma potassium (control = 4.4 ± 0.1 mM, MS275 treated = 3.5 ± 0.1 mM, $P < 0.05$). Furthermore, HDACi resulted in increased vasopressin and renal ET-1 production, and renal nitric oxide deficiency that are consistent with the fluid-electrolyte abnormalities observed in clinical studies with these

drugs. Our findings point to a mechanism whereby HDAC1 promotes nitric oxide synthase expression through regulation of chromatin structure at the *Nos1* and *Nos3* promoters. In agreement, increased HDAC1 expression resulted in a significant increase in IMCD *Nos1* mRNA expression (control = 1.0 ± 0.2 and HDAC1 = 2.5 ± 0.5 A.U) and a 30% increase in *Nos3* mRNA.

Conclusions: Given the promising research of HDACi to treat cardiovascular disease, this study provides insight on the mechanisms of the adverse events, which may be fatal to critically ill patients.

Randomized, Placebo Controlled Double Blind Clinical Trial of the Somatostatin Analog Pasireotide LAR for Patients with ADPKD or ADPLD with Severe Liver Involvement

Marie C. Hogan, Tetyana V. Masyuk, Troy G. Ofstie, Carly Banks, Marie E. Edwards, Maria V. Irazabal, Lisa E. Vaughan, Walter K. Kremers, Nicholas F. LaRusso, Vicente E. Torres. *Mayo Clinic, MN.*

Background: We previously reported the somatostatin (SST) receptor analog, octreotide LAR reduced liver volume (LV), improved quality of life in symptomatic polycystic liver disease (PLD) & retarded GFR decline in ADPKD. Here we assessed safety & efficacy of another SST analog, pasireotide (SOM230) in severe PLD & in ADPKD. SOM230 has a broader binding profile & higher affinity to SST receptors with potential for greater efficacy.

Methods: Eligible participants were assigned (2:1 ratio) in a 1 year double blind randomized trial (stratified ADPKD & ADPLD) to receive SOM230 / placebo every 28 days. Primary endpoint (EP) was change in LV; secondary EPs were change in kidney volume (KV) eGFR & QOL.

Results: Forty eight subjects were randomized (ADPKD n=40; ADPLD n=8); of these, 40 completed LV measurements at 12 mo. From baseline, there was a 3.3% decrease in annualized change in LV (4271±2373 to 4104±2265ml) in SOM230 group (n=28), compared with 6.3% increase (4047±1298 to 4294±1314ml) in placebo group (n=12; p=0.001) (fig 1†). KVs decreased -1.1% on SOM230 compared with a 3.9% increase on placebo (p=0.024). Changes in eGFR were not different between groups. Common adverse events (AEs) included hyperglycemia (24/33 (73%) SOM230 vs 3/15 (20%) placebo; p=0.003) & diabetes (10/33 (30%) vs 0/15 (0%); p=0.042). Most AEs were grade 1-2. † Results: mean±std dev. P-values: Wilcoxon.

	SOM230			Placebo			P for Delta %[a,b]
	Baseline	12 mo	Delta %[a,b]	Baseline	12 mo	Delta %[a,b]	
Blood glucose, (mg/dL)	92.3 ± 12.8	124.0 ± 28.0	36.1 ± 28.3	88.7 ± 12.6	89.8 ± 7.0	3.1 ± 16.3	<0.001
Hemoglobin A1C (%)	5.43 ± 0.48	6.31 ± 0.50	16.6 ± 10.1	5.20 ± 0.23	5.27 ± 0.26	1.3 ± 2.2	<0.001
Serum Creatinine (mg/dL)	1.00 ± 0.29	1.00 ± 0.32	4.3 ± 11.9	1.11 ± 0.36	1.10 ± 0.44	4.6 ± 11.5	0.87
eGFR (CKD-EPI)	75.2 ± 21.6	71.8 ± 20.0	-3.6 ± 13.3	72.0 ± 19.4	68.9 ± 19.8	-4.7 ± 11.4	0.69
Liver volume, (mL)	4271 ± 2373	4104 ± 2265	-3.3 ± 7.5	4047 ± 1298	4294 ± 1314	6.3 ± 7.0	0.001
Kidney volume, (mL)	927 ± 591	913 ± 572	-1.1 ± 3.6	671 ± 268	706 ± 299	3.9 ± 4.5	0.024

Conclusions: SOM230 versus placebo treatment significantly decreased the annualized liver & kidney volume & significantly increased the frequency of hyperglycemia & diabetes in patients with PLD and ADPKD. The eGFR declined in both arms, thus larger studies are needed to determine the impact of SSTs analogs on eGFR. **(NCT01670110)**

Efficacy and Safety of Tolvaptan in Autosomal Dominant Polycystic Kidney Disease Including Chroninc Kidney Disease G4

Kenjiro Honda,[1] Ryo Matsuura,[1] Teruhiko Yoshida,[1] Yoshifumi Hamasaki,[2] Kent Doi,[3] Eisei Noiri,[1] Masaomi Nangaku.[1] *[1]Dept of Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Tokyo, Japan; [3]Dept of Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan.*

Background: TEMPO3:4 trial showed the effect of tolvaptan (TLV) on total kidney volume (TKV) growth and decline of renal function among ADPKD with creatinine clearance (CCr) more than 30mL/min. However, effectiveness, safety, and optimal dose of TLV were uncertain in those with CCr less than 30mL/min. In addition, there is virtually no data of TLV influence to renal dysfunction on urine volume and osmolality.

Methods: Among ADPKD patients with TLV administration from 2014 to 2016, serum creatinine and estimated glomerular filtration ratio (eGFR) were measured at 1 week, 1, 3, 6 months, and TKV was calculated immediately before and 6 months after TLV treatment. TKV was estimated using ellipsoid approximation. Urine volume at 1 day, 1, 3, 6 months and urine osmolality at 0, 1 day, and each month until 8 months were evaluated.

Results: Chronic kidney disease (CKD) G2, G3 and G4 were 22%, 45% and 33%, respectively. ΔTKV was significantly decreased 6 months after TLV administration (24.8(7.7-56.5) vs -17.8(-37.9-1.9) %/year, P<0.05) while eGFR and serum creatinine was not changed during the same period. Urine volume variation especially observed immediately after TLV administration gradually disappeared. Water intake was significantly increased 6 months after TLV administration compared with the next day (3375(2723-3958) vs 3850(3468-4000) mL, P<0.05), whereas urine volume tended to increase between the same periods (3825(3210-5638) vs 3925(3588-4000) mL, P=0.07). The dose of TLV was larger in responders than non-responders when responders were defined as patients with improvement of TKV or eGFR after TLV administration. The dosage could not be increased because of hepatic dysfunction and polyuria in non-responders. TLV was discontinued in 2 cases with CKD G4, and both of them showed hepatic dysfunction 4-8 months after TLV initiation.

Conclusions: TLV was well tolerated in CKD G4. High dose TLV may mitigate TKV outgrowth.

FR-OR003

Toll-Like Receptors in the Progression of Autosomal Dominant Polycystic Kidney Disease

Ismail Kocyigit,[1] Elif Funda Sener,[2] Serpil Taheri,[2] Eray Eroglu,[1] Fahir Ozturk,[1] Aydin Unal,[1] Gokmen Zararsiz,[3] Ilknur Ozbay,[1] Hakan Imamoglu,[4] Murat H. Sipahioglu,[1] Bulent Tokgoz,[1] Oktay Oymak,[1] Tevfik Ecder.[1] *[1]Nephrology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [2]Medical Biology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [3]Bioistatistics, Erciyes Univ Medical Faculty, Kayseri, Turkey; [4]Radiology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [5]Nephrology, Istanbul Bilim Univ Medical Faculty, Istanbul, Turkey.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary cause of chronic kidney disease. The intriguing role of innate immune system and inflammation become a target for potential therapeutically approach to slow progression. Thus, we aim to investigate the association of Toll-like receptors(*TLRs*) between progression of ADPKD.

Methods: 90 ADPKD patients and ninety matched controls were enrolled this prospective study and were followed during three years. *TLR-2* and *TLR-4* gene polymorphisms and expressions were measured. Hypertension was diagnosed with ambulatory blood pressure monitoring. Rapid progression was defined as sustained decline in estimated glomerular filtration rate (eGFR) of more than 5 ml/min/1.73 m^2/year.

Results: *TLR-4Asp299Gly* polymorphisms were significantly different between patient and control group (p<0.05).Also,*TLR-2* and *TLR-4* geneexpressions were significantly different between the ADPKD patients and the control subjects (p<0.05). The expression levels of both *TLR-2* and *TLR-4* were found to be higher in the rapid progression groups comparing the slow progression group (p<0.05). *TLR-2* gene expression, hypertension and uric acid were found to be independent risk factors in identifying rapid progression in ADPKD patients.

Conclusions: *TLR-2* and *TLR-4* gene expressions are associated with rapid progression in ADPKD patients.*TLRs* may play a role in the progression of ADPKD.

FR-OR004

Copeptin, a Surrogate for Vasopressin, Predicts Disease Progression and Tolvaptan Treatment Efficacy in ADPKD. Results of the TEMPO 3:4 Trial

Ron T. Gansevoort,[1] Maatje D.A. van Gastel,[1] Arlene B. Chapman,[2] Jaime Blais,[3] Frank S. Czerwiec,[3] Ronald D. Perrone,[4] Katrin Stade,[5] Vicente E. Torres,[6] Olivier Devuyst.[7] *[1]Groningen, Netherlands; [2]Atlanta; [3]Otsuka Phar; [4]Boston; [5]BRAHMS GmBH, Germany; [6]Rochester; [7]Zurich, Switzerland.*

Background: The TEMPO 3:4 Trial showed that 3 years treatment with tolvaptan, a vasopressin V2 receptor antagonist, slowed the increase in total kidney volume (TKV) and eGFR decline in ADPKD. We investigated determinants of baseline copeptin concentration, surrogate marker for vasopressin, to ascertain whether copeptin is associated with rate of ADPKD progression and whether treatment induced change in copeptin is associated with treatment efficacy.

Methods: Post-hoc analysis of prospective, blinded RCT including 1445 patients with ADPKD, aged 18-50, estimated creatinine clearance ≥60 ml/min and TKV ≥750 mL. Copeptin was measured by an automated immunofluorescence assay.

Results: Median baseline copeptin concentration was 6.4 (IQR 3.8-11.0) pmol/L. Baseline copeptin concentration was in a multivariate analysis associated with age, gender, BMI, plasma osmolality, eGFR and TKV (all p<0.001). In placebo treated patients baseline copeptin predicted TKV growth during 3 year of follow-up (p<0.0001). This remained significant after adjustment for sex, age and baseline eGFR. No significant association was found between baseline copeptin and eGFR change during follow-up. In subjects with higher baseline copeptin, a larger treatment effect of tolvaptan was noted with respect to TKV growth rate (p=0.008) and to some extent for eGFR decline (p=0.07). Tolvaptan induced an increase in copeptin (baseline 6.5 vs 19.6 pmol/L at yr 1,p<0.0001), whereas no change in copeptin was noted on placebo (baseline 6.5 vs 6.0 pmol/L at yr 1,p=0.15). The percent increase in copeptin from baseline to yr 1 was positively associated with tolvaptan treatment effect on TKV growth rate (p=0.02), but not on slope of eGFR decline (p=0.31).

Conclusions: In ADPKD patients higher baseline copeptin is associated with more rapid TKV growth, and with better tolvaptan treatment efficacy on TKV growth. In addition, tolvaptan induced change in copeptin predicted better treatment effect on TKV growth.

FR-OR005

A New Clinical Entity: GANAB-Related Polycystic Kidney and Liver Disease Emilie Cornec-Le Gall,[1] Vladimir Gainullin,[1] Binu Porath,[1] Yannick Le Meur,[2] Marie-Pierre Audrezet,[2] Peter C. Harris,[1] Claude Ferec.[2] *[1]Mayo Clinic; [2]CHU Brest, France.*

Background: Genic variability in ADPKD/ADPLD has recently been refined with the description of a new gene, *GANAB*, encoding the α subunit of the glucosidase II; mutations impair polycystin trafficking (Porath et al, AJHG 2016). The aim of this study is to characterize the disease presentation in GANAB patients.

Methods: Molecular analysis of GANAB was conducted in 50 unresolved ADPKD/ADPLD unrelated patients. Clinical records and imaging data of recently reported and newly identified patients were reviewed.

Results: *GANAB* mutations were found in 2 new pedigrees.In the first (splice variant c.39-1G>C), a 75 y man was incidentally diagnosed with ADPKD at age 61 by a CT scan and had atrophic cystic kidneys (7.5 cm, ~20 cysts) and liver cysts. His two siblings had similar presentations at age 87 and 75 and did not require dialysis. In the second pedigree (frameshift variant c.2723del), a diagnosis of bilateral cystic kidneys was made in a 7 y.o boy following hematuria, and subsequently in his 9 y.o brother and 44 y.o father, who had normal kidney function and liver cysts. While all the 26 described GANAB patients (median age 50y (7-87), 14 males) had kidney cysts, kidney enlargement was only present in 18.5%, and was moderate, caused by a few large cysts. Kidney function was preserved, with 96% being CKD1-2 patients, and the only CKD3 patient (75y) had a partial nephrectomy at age 26. Hypertension was present in 39% of the adult patients. Liver cysts were reported in 81% of the adult patients and severe PLD was observed in 4 patients, clustered in 2 pedigrees, which suggests the existence of modifier genes modulating the severity of liver cystogenesis. Intracranial aneurysms were reported in 2 pedigrees.

Conclusions: In patients with normal-sized cystic kidneys and significant liver cysts, a GANAB diagnosis should be considered. GANAB patients typically present with milder kidney disease than PKD2 and do not seem at risk of CKD. As larger GANAB cohorts become available, better description of the disease penetrance and presentation will be possible. We are currently analyzing 200 other unresolved ADPKD/ADPLD cases.

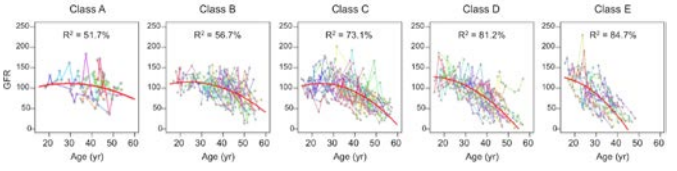
FR-OR006

Trajectory of the GFR in Autosomal Dominant Polycystic Kidney Disease Alan S.L. Yu,[1] Chengli Shen,[2] Doug Landsittel,[2] Jared J. Grantham,[1] Larry Cook,[1] Vicente E. Torres,[3] Arlene B. Chapman,[4] Kyongtae Ty Bae,[2] Michal Mrug,[6] Peter C. Harris,[3] Frederic F. Rahbari-Oskoui,[5] Michael F. Flessner,[7] William M. Bennett.[8] *[1]U Kansas; [2]U Pittsburgh; [3]Mayo Clinic; [4]U Chicago; [5]Emory Univ; [6]U Alabama; [7]NIH; [8]Legacy Good Samaritan Med Ctr.*

Background: In autosomal dominant polycystic kidney disease (ADPKD), cyst growth and kidney injury occur throughout life, leading to ESRD. The shape of the GFR trajectory over this period spanning several decades is not well defined, and the factors that influence this are unclear.

Methods: CRISP is a 13 yr observational study of 241 ADPKD pts. To predict trajectories of renal decline, a novel classification of kidney growth rates, based on age and height-adjusted total kidney volume (Irazabal, et al., 2014), was used to stratify participants into 5 classes. Within each group, a quadratic polynomial function was fit to the individual GFR trajectories using linear mixed models with a subject random effect and fixed effects for age and other covariates. Conditional R^2 is the variance explained by fixed and random factors.

Results: Irazabal classes effectively separated the cohort into individuals with similar trajectories. The overall curvilinear trend included a period of relatively stable GFR followed by accelerating decline. Increasing class (from A to E) was associated with earlier and steeper decline.



Increasing class was also associated with increased proportion of *PKD1* genotype and higher baseline urine sodium and osmolality. However, stratification effectively captured the related variability, as none of these covariates was independently associated with GFR.

Conclusions: Rate of kidney growth, as assessed by Irazabal class, is a powerful predictor of the shape and slope of the GFR trajectory. Results of the stratified polynomial linear mixed models have significant implications for predicting which individuals will more rapidly decline and where interventions should be focused.

Foam Sclerotherapy for Cystic Volume Reduction in Autosomal Dominant Polycystic Kidney Disease Ioan-Andrei Iliuta, Beili Shi, Silvio Giancarlo Bruni, John Conklin, Moumita Barua, Korosh Khalili, Eran Shlomovitz, York P. Pei. *Toronto General Hospital, Univ Health Network, Toronto, ON, Canada.*

Background: Kidney volume (KV) in autosomal dominant polycystic kidney disease (ADPKD) expands exponentially during adult life at ~5%/yr on average. Patients with total kidney volume >1,500 ml are at high risk of developing end-stage renal disease. Large cysts may be particularly detrimental by impeding regional kidney blood and urine flow. We examined the safety and effectiveness of foam sclerotherapy (FS) on KV reduction.

Methods: Thirty-one patients with typical or atypical ADPKD were treated with 3% sodium tetradecyl sulfate FS targeting 2 to 3 large (>5 cm) non-exophytic cysts in one or both kidneys between August 2014 and April 2016. Serum creatinine (sCr), measured 24 hour Cr clearance (Ccr), and KV were assessed before and after each intervention.

Results: The mean age and baseline sCr of our typical (n=27) and atypical (n=4) PKD patients were 51 vs. 63 years and 0.94 [95% CI:0.81-1.58] vs. 0.93 [0.75-1.43] mg/dL, respectively. Over a mean time of 12.5 months, the volume of kidneys targeted by FS decreased by 375 ml (-24%; p<0.0001) while the volume of non-targeted kidneys increased by 88 mL (15%; p=0.003).

	n	Pre	Post	Difference	Percentage change	p
Volume of targeted kidneys (mL)	31	1530	1155	-375	-24	<0.0001
Typical	26	1637	1293	-344	-19	0.0001
Atypical	5	973	437	-536	-48	
Volume of non-targeted kidneys (mL)	11	602	690	88	15	0.003
Typical	8	657	767	110	19	0.02
Atypical	3	457	484	27	6	
Measured CrCl (mL/min)	17	81.1 ±27.7	81.0 ±28.4	-0.1		0.96

Measured Ccr corrected for urinary Cr excretion rate was unchanged within 1 month after sclerotherapy. There were no significant complications (i.e. hypotension, bleeding, infection) other than self-limiting acute pain lasting for 2-5 days requiring analgesic treatment in ~10% of patients.

Conclusions: Foam sclerotherapy is well-tolerated in ADPKD and results in a significant kidney volume reduction. Further studies are required to examine whether this procedure can be used to improve kidney blood flow and delay kidney function decline.

Funding: Government Support - Non-U.S.

FR-OR008

Increased Risk of Kidney Cancer in Patients with Polycystic Kidney Disease: A Propensity Score Matching Analysis of a Nationwide, Population-Based Cohort Study Tung-Min Yu,[1] Kuo-Hsiung Shu,[1] Mei-Ching Yu,[2] Ya-Wen Chuang.[1] *[1]Div of Nephrology, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Pediatric Nephrology, Chang-Gung Hospital, Taoyuan, Taiwan.*

Background: Data regarding the risk of kidney cancer and cancer at other sites in patients with polycystic kidney disease (PKD) are lacking. Therefore, we conducted a nationwide cohort study to determine the risk of cancer in patients with PKD.

Methods: From the National Health Insurance Research Database (NHIRD), we included 7080 patients aged >20 years and diagnosed with PKD between 1998 and 2010 in the PKD cohort. For each patient with PKD, one patient aged >20 years who was neither PKD nor cancer was randomly selected from the NHIRD, matched on the basis of the propensity score, and included as control group. The follow-up period was from the time of the initial PKD diagnosis until the date of the cancer diagnosis, censoring, or December 31, 2011. We used Cox proportional hazard regression models to analyze the risk of cancer.

Results: The overall incidence of cancer was significantly higher in the PKD cohort than in the non-PKD cohort [17.6 vs. 11.4 per 1000 person-years; crude hazard ratio (HR) = 1.82; 95% confidence interval (CI) = 1.61–2.06]. After adjustment for comorbidities including hypertension, chronic obstructive pulmonary disease, diabetes, alcoholism, alcoholic liver damage, and obesity, the patients with PKD had a higher overall risk of cancer [adjusted HR (aHR) = 1.74; 95% CI = 1.54–1.96]. The risk of kidney cancer was significantly higher in the PKD cohort than in the non-PKD cohort (aHR = 5.00; 95% CI = 2.86–8.75). After considering death as a competing risk factor, the risk of kidney cancer remained significantly higher in patients with PKD [adjustedsubhazard ratio (aSHR) = 3.69; 95% CI = 2.41–5.67]. Of note, a significantly higher risk of kidney cancer was observed in younger patients with PKD (<49 year old; aSHR = 4.70; 95% CI = 1.78–12.4).

Conclusions: This study is the first to report the association of PKD with a higher risk of cancer, particularly kidney cancer. When treating patients with PKD, a high index of suspicion for cancer should be maintained.

Urinary Proteomic Analysis Revealed New Specific Medullary Sponge Kidney Disease (MSK)-Associated Proteins Gianluigi Zaza,[1] Antonia Fabris,[1] Maurizio Bruschi,[2] Giovanni Candiano,[2] Simona Granata,[1] Giovanni Gambaro,[3] Antonio Lupo.[1] *[1]Renal Unit, Univ of Verona, Verona, Italy; [2]Laboratory of Physiopathology of Uremia, Gaslini Inst, Genoa, Italy; [3]Renal Unit, Columbus-Gemelli Hospital/Univ, Verona, Italy.*

Background: MSK is a kidney malformation featuring nephrocalcinosis, recurrent renal stones, renal acidification and ectasias of pre-calyceal ducts. It generally occurs sporadically, but an autosomal dominant inheritance have been reported. Previous studies have suggested a putative point mutations of the *GDNF* gene as a cause of MSK but the precise molecular mechanisms leading to the disease remain poorly understood. Currently, MSK diagnosis is only radiographic and no molecular diagnostic biomarkers are available.

Methods: Therefore, we employed an innovative high-throughput methodology (proteomic analysis) to identify new specific urinary MSK diagnostic biomarkers. Briefly, urines from 21 MSK patients and 21 controls with idiopathic calcium nephrolithiasis (ICN) were collected and processed for proteomic analysis and ELISA. The urine of 11 MSK and 10 controls, randomly selected, were processed/analyzed by the mass spectrometer LTQ-Orbitrap Velos Pro. Subsequently, several statistical algorithms and bioinformatic analysis were undertaken to select most discriminative proteins between the 2 study groups. ELISA, performed on the entire patients' cohort, was used to validate proteomic results.

Results: After an initial statistical analysis, 249 (16%) and 396 proteins (26%) resulted exclusive for MSK and ICN (FC<2, p<0.001), respectively. Subsequently, several statistical algorithms and graphic representations (including Volcano Plot and ROC curve) restricted the number of proteins to 22 up- and 15 down-regulated in MSK compared to ICN. The use of a Support Vector Machine restricted the selection to 16 top ranked proteins (primarily involved in matrix remodeling and bone differentiation) hyper-expressed in urines of MSK (e.g., Glypican, Plexin). These biological elements were validated by ELISA.

Conclusions: Therefore, our study, for the first time, using a proteomic methodology was able to identify new diagnostic MSK urine biomarkers possibly employable in future in the "day by day" clinical practice.

Recessive Mutations of TTC28 Cause a Ciliopathy Ankana Daga,[1] Joao Goncalves,[2] Kinga Maria Bujakowska,[3] Daniela A. Braun,[1] Jillian Kateri Warejko,[1] Laurence Pelletier,[2] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, Canada; [3]Massachusetts Eye and Ear Infirmary, Harvard Medical School, Boston, MA.*

Background: Retinal-renal ciliopathies are characterized by dysfunction of the primary cilium and centrosomes. More than 95 genes have been discovered in these single gene-disorders; however, about 30% of cases do not have a monogenic cause identified.

Methods: To identify novel ciliopathy genes, we analyzed whole exome sequencing (WES) data in individuals with ciliopathies who had no mutations in all known ciliopathy genes. We examined the cellular localization of *TTC28* using confocal immunofluorescence analysis in HEK293 and RPE-1 cells and performed co-immunoprecipitation to test the interactions with other known ciliopathy genes. We tested defects in ciliogenesis by using siRNA directed against *TTC28* in RPE-1 cells.

Results: By WES we identified 4 different mutations in exon 7 of the *TTC28* gene in 4 unrelated families with a brain-skeletal-retinal phenotype. The first patient presented with microcephaly and seizures. A homozygous missense mutation in an amino acid residue that is evolutionarily conserved to *Drosophila melanogaster* was discovered. The second patient with severe skeletal dysplasia and intellectual disability has a homozygous missense mutation in an amino acid residue that is evolutionarily conserved to *Caenorhabditis elegans*. The third and the fourth patients both with retinitis pigmentosa have two different, rare and well-conserved compound heterozygous mutations. We show that wild type GFP-*TTC28* localizes to the centrosome. By co-immunoprecipitation, we show that wild type *TTC28* interacts with *NIN*, mutated in Seckel syndrome and *CEP120*, mutated in Jeune asphyxiating thoracic dystrophy. SiRNAs directed against *TTC28* in RPE-1 cells show reduction in number of ciliated cells.

Conclusions: We identify mutations of *TTC28* as a novel monogenic cause of ciliopathy in humans. Further studies will elucidate allele specific expression and pathogenic pathways involved.

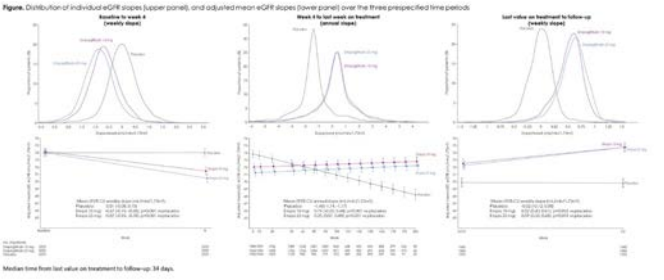
FR-OR011

Empagliflozin and Changes in Renal Function Decline in Type 2 Diabetes: Prespecified Slope Analyses from the EMPA-REG OUTCOME Trial Christoph Wanner,[1] Bernard Zinman,[2] Silvio E. Inzucchi,[3] John M. Lachin,[4] Maximilian von Eynatten,[5] Audrey Koitka-Weber,[5] Michaela Mattheus,[5] Erich Bluhmki,[5] Hans-Juergen Woerle,[5] Uli Christian Broedl,[5] Per-Henrik Groop,[6] Hiddo Jan Lambers Heerspink.[7] *[1]Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; [2]Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, Canada; [3]Section of Endocrinology, Yale Univ, New Haven, CT; [4]Biostatistics Center, George Washington Univ, Rockville, MD; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [6]Div of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; [7]Dept of Clinical Pharmacy and Pharmacology, Univ of Groningen, Groningen, Netherlands.*

Background: CKD and progressive decline of renal function are common in patients with diabetes. In the EMPA-REG OUTCOME trial, empagliflozin (EMPA) slowed CKD progression in patients with type 2 diabetes and high cardiovascular risk. Here we report treatment differences in the rate of change in eGFR by utilizing linear regression models yielding mean and individual slopes.

Methods: 7020 patients were randomized (1:1:1) to EMPA 10 mg, 25 mg or placebo on top of standard of care. Treatment differences in the average rate of change in eGFR (MDRD) for pre-specified time periods were assessed using a random intercept and time coefficient model.

Results: Mean slopes with EMPA showed an acute fall in eGFR during the first 4 weeks, followed by stable eGFR during chronic treatment and a rapid return towards baseline after drug cessation (Figure [lower panel]). Individual slopes revealed a uniform shift with EMPA compared to placebo during all three periods (Figure [upper panel]).



Conclusions: EMPA exerted a uniform treatment effect on eGFR across the entire distribution of renal function. Therefore, our findings suggest that EMPA has the potential to slow rate of GFR decline independent of the individual renal function trajectory.

Glycogen Synthase Kinase 3β Overexpression and Hyperactivity in Urinary Exfoliated Cells Predicts Progression of Diabetic Nephropathy Xianhui Liang,[1,2] Pei Wang,[1] Minglei Lu,[1] Yan Ge,[1] Zhangsuo Liu,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ; [2]The First Affiliated Hospital of Zhengzhou Univ, China.*

Background: Glycogen synthase kinase (GSK) 3β is a highly-conserved serine/threonine protein kinase that was originally identified as a key cellular signaling transducer involved in glycogenesis. Converging evidence recently points GSK3β as a key player in pathogenesis of diverse kidney diseases. However, its role in diabetic nephropathy (DN) remains unknown and was examined here.

Methods: The expression and activity of GSK3β were evaluated in kidney specimens from DN patients or db/db diabetic mouse models, and assessed in urinary exfoliated cells in patients with type 2 diabetes.

Results: In db/db mice, renal expression and activity of GSK3β were progressively elevated over time, in parallel with deterioration of signs of diabetic kidney injuries, characterized by albuminuria, extracellular matrix accumulation in glomerulus, podocytopathy and renal interstitial fibrosis. In consistency, in cultured kidney cells, including podocytes, mesangial cells and tubular epithelial cells, high glucose exposure markedly amplified GSK3β expression and activity, associated with cytopathic changes. In kidney biopsy specimens procured from patients with varying stages of DN, GSK3β expression and activity were progressively augmented in glomeruli and renal tubules, and correlated with the severity of DN, as assessed by albuminuria and glomerular pathology. In a cohort of patients with type 2 diabetes that were followed for 5 years, elevated expression of GSK3β in urinary exfoliated cells was found to precede the progression of proteinuria in patients diagnosed with diabetic nephropathy. In contrast, urinary GSK3β levels remained normal in diabetic patients with no normoalbuminuria or stable microalbuminuria. Moreover, receiver operating characteristic curve analysis revealed that urinary GSK3β was likely superior to microalbuminuria in predicting the progression of DN.

Conclusions: In aggregate, our studies demonstrated that renal expression and activity of GSK3β are amplified in animal and human diabetic nephropathy. GSK3β in urinary exfoliated cells may serve as a novel biomarker for predicting progression of DN.

BP Levels Lower Than 120/70 mm Hg Associate with Lower Risk of Renal Events in Type I Diabetes Elaine Ku,[1] Charles E. McCulloch,[1] Michael Mauer,[2] Barbara A. Grimes,[1] Chi-Yuan Hsu.[1] *[1]UCSF; [2]Univ of Minnesota.*

Background: Optimal BP targets in diabetes continue to be debated. We compared different BP levels and their associations with adverse renal outcomes in type I diabetes (T1DM), and determined whether glycemic control modifies this association.

Methods: We included 1441 participants with T1DM ages 13-39 initially randomized to intensive vs. conventional glycemic control in the Diabetes Control and Complications Trial (DCCT) and subsequently followed in Epidemiology of Diabetes Interventions and Complications (EDIC) study. The predictors were time-updated systolic (SBP) and diastolic blood pressure (DBP) categories, ascertained one year before outcomes of interest, which included macroalbuminuria,CKD stage III,and ESRD.

Results: During median follow-up of 24 years, 84 cases of CKD stage III, 169 cases of macroalbuminuria, and 26 cases of ESRD occurred. In adjusted Cox models, there was a stepwise graded association between higher BP and risk of macroalbuminuria and CKD stage III.

	Risk of Macroalbuminuria Hazard ratio (95% CI)	**Risk of CKD** Hazard ratio (95% CI)
SBP category		
≥ 140 mm Hg	**2.64 (1.62-4.29)**	**2.61 (1.44-4.71)**
130-<140 mm Hg	Reference (Ref)	Ref
120-<130 mm Hg	0.65 (0.41-1.02)	0.91 (0.49-1.71)
< 120 mm Hg	**0.46 (0.29-0.73)**	**0.23 (0.10-0.53)**
DBP category		
≥ 90 mm Hg	**1.66 (1.00-2.73)**	**3.18 (1.72-5.87)**
80-<90 mm Hg	Ref	Ref
70-<80 mm Hg	**0.55 (0.38-0.79)**	0.84 (0.49-1.44)
< 70 mm Hg	**0.56 (0.35-0.90)**	**0.40 (0.19-0.85)**

Every 10 mm Hg increase in SBP and DBP also associated with 1.73 (95% CI 1.42-2.11) and 1.67 times (95% CI 1.14-2.45) higher risk of ESRD, respectively. No interaction was noted between BP and glycemic control strategy (HbA1C <6% vs. conventional therapy) during DCCT (p> 0.10). Similar results were observed when analysis was limited to participants receiving BP medications.

Conclusions: Lower BP (<120/70 mm Hg) was associated with a substantially lower risk of adverse renal outcomes, regardless of prior assigned glycemic control strategy. These findings suggest that current guideline-recommended target of 140/90 mm Hg for T1DM may be too high for optimal reno-protection.

FR-OR014

Intensified Multifactorial Intervention in Type 2 Diabetes and Microalbuminuria Reduces End Stage Renal Disease and Mortality: 21 Years Follow-Up of the Steno-2 Study Jens Christian Øllgaard,[1,2,3] Peter Gaede,[1,2] Peter Rossing,[3,4,5] Hans-Henrik Parving.[5,7] *[1]Slagelse Hospital, Slagelse, Denmark; [2]Univ of Southern Denmark, Odense, Denmark; [3]Steno Diabetes Center, Gentofte, Denmark; [4]Univ of Aarhus, Aarhus, Denmark; [5]Univ of Copenhagen, Copenhagen, Denmark; [6]Novo Nordisk Foundation Center for Basic Metabolic Research, Univ of Copenhagen, Copenhagen, Denmark; [7]Rigshospitalet, Copenhagen, Denmark.*

Background: Despite declining rates of late diabetic complications in other organ systems, renal complication rates do not decline to the same extent according to epidemiological studies. We report renal outcomes over 21 years in patients with type 2 diabetes and microalbuminuria and the influence of intensified, multifactorial treatment including strict control of blood glucose, lipids and blood pressure.

Methods: 160 patients with type 2 diabetes and microalbuminuria assigned to conventional or intensified multifactorial intervention targeting multiple risk factors in a prospective, open-label trial. The treatment regimen was target-driven and included behavioral and pharmacological modifications. Duration of the intervention was 8 years, where after all patients were recommended intensified treatment. Total follow-up of up to 21 years of albuminuria and GFR (^{51}Cr-EDTA-clearance) assessed at 6 study visits. Outcome measures were progression to macroalbuminuria (>300 mg/24h), decline-rate of GFR and progression to ESRD or death.

Results: Progression to macroalbuminuria was reduced in the original intensive-therapy group, HR 0.45 [95% CI 0.28–0.74; p=0.003]. The decline in GFR was 3.1 ml/min/year in the intensive group vs. 4.1 in the conventional group [difference 0.5 – 1.5 ml/min/year; p < 0.001]. Progression to ESRD trended towards a decreased HR with an adjusted (age and sex) HR of 0.36 [95% CI 0.12–1.05; p=0.061] (n 5 vs. 10) in the intensive group. ESRD combined with all-cause or cardiovascular mortality was reduced in the intensive group; adjusted HR 0.53 [95% CI 0.12–0.81; p = 0.003] and 0.35 [95% CI 0.19–0.65; p=0.001], respectively.

Conclusions: Intensified, multifactorial treatment for 8 years in type 2 diabetes patients with microalbuminuria slows long-term progression in nephropathy and reduces the risk of ESRD and mortality.

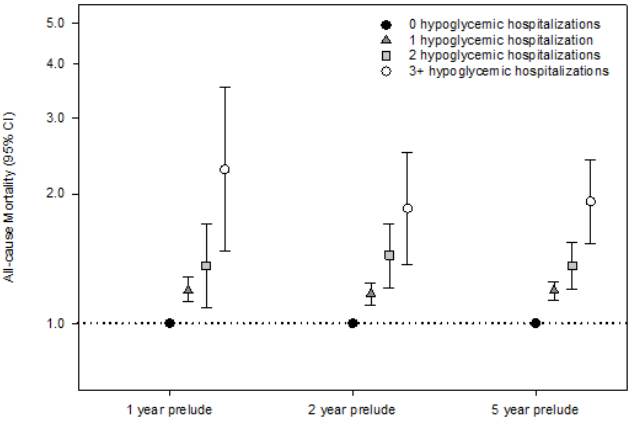
Hypoglycemia-Related Hospitalizations and Mortality among Non-Dialysis Dependent CKD Patients Transitioning to Dialysis Connie Rhee,[1] Amy Seung You,[1] Melissa Soohoo,[1] Elani Streja,[1] John J. Sim,[2] Danh V. Nguyen,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Kaiser Perm. Southern CA; [3]Univ of Tennessee Health Science Center.*

Background: Diabetic kidney disease patients with declining kidney function are at heightened risk for hypoglycemia due to impaired insulin degradation and clearance, as well as decreased renal gluconeogenesis. We sought to examine how hypoglycemia in the pre-dialysis (prelude) period impacts post-ESRD mortality in this population.

Methods: Among US veterans with diabetic kidney disease who transitioned to dialysis over 2007-11, we evaluated the occurrence and frequency of hypoglycemia-related hospitalizations during the 2-year pre-ESRD prelude interval. We then examined whether occurrence and frequency of pre-ESRD hypoglycemia-related hospitalizations are associated with post-ESRD all-cause mortality using unadjusted, minimally adjusted, and case-mix adjusted Cox models. We conducted sensitivity analyses examining 1-year and 5-year prelude intervals.

Results: Among 30,321 patients in the 2-year prelude period, occurrence of a hypoglycemia-related hospitalization was associated with higher mortality risk in case-mix analyses (ref: no hypoglycemia): HR (95%CI) 1.21 (1.14-1.28). Increasing frequency of hypoglycemia-related hospitalizations were associated with incrementally higher mortality risk in case-mix analyses (ref: no hypoglycemia): HRs (95%CI) 1.17 (1.10-1.24), 1.44 (1.21-1.70), and 1.85 (1.37-2.49) for 1, 2, and ≥3 hypoglycemia-related hospitalizations, respectively. Similar findings were observed for 1-year and 5-year prelude periods.



Conclusions: In diabetic kidney disease patients transitioning to dialysis, there is a dose-dependent relationship between frequency of pre-ESRD hypoglycemia and post-ESRD mortality. Further studies are needed to determine modifiable risk factors for hypoglycemia, and whether correction of these factors improves survival.

FR-OR016

Angiotensin Receptor Blockers Confer Cardioprotection in Males but Not in Females with Type 2 Diabetes Bauke Schievink, Dick de Zeeuw, Peter G.M. Mol, Michelle Pena, Petra Denig, Hiddo Jan Lambers Heerspink. *Univ Medical Center Groningen.*

Background: Previous studies showed that female patients with type 2 diabetes (T2D) have nearly 50% higher risk of cardiovascular (CV) complications compared to male patients. It is unclear if females also respond differently to therapy compared to males. We assessed gender differences in response to treatment with angiotensin receptor blockers (ARBs), a mainstay of cardiorenal protective therapy in T2D.

Methods: We used data from RENAAL and IDNT trials, which assessed the effect of losartan or irbesartan respectively on renal/CV outcomes in patients with T2D and nephropathy. The CV outcome in both trials was time to first event of a composite of stroke, myocardial infarction, CV death or hospitalization for heart failure. Gender differences in response to ARB treatment were assessed by a gender*treatment interaction term in a Cox model. Hazard ratios (HRs) were adjusted for baseline levels of systolic blood pressure, albuminuria, eGFR, HbA1c, total cholesterol and hemoglobin.

Results: 1737 males and 924 females were followed for a median 2.9 years. During follow-up 872 CV events were recorded. ARB treatment decreased CV risk in males (HR: 0.79, 95% CI: 0.67 - 0.94), but not in females (HR: 1.12, 95% CI: 0.88 - 1.43, p interaction=0.027). This interaction was driven by treatment differences in myocardial infarction (MI) and heart failure (Table 1). Males also had a larger, albeit non-significant, benefit for the renal endpoint of ESRD or doubling serum creatinine compared to females (Table 1).

Conclusions: ARB treatment confers cardioprotection in male but not female T2D patients. These results warrant more careful analysis of gender differences when determining treatment efficacy, as well as investigation of underlying mechanisms of drug response.

HR (95% CI) on ARB treatment			
Endpoint	Males	Females	P for gender interaction
CV composite	0.79 (0.67-0.94)	1.12 (0.88-1.43)	0.027
MI	0.60 (0.42-0.84)	1.42 (0.85-2.38)	0.007
Stroke	0.81 (0.54-1.24)	1.13 (0.64-2.01)	0.34
CV death	1.06 (0.78-1.44)	1.28 (0.83-1.98)	0.56
Heart failure	0.51 (0.38-0.70)	1.02 (0.72-1.44)	0.005
Renal composite	0.66 (0.54-0.81)	0.86 (0.69-1.09)	0.08

FR-OR017

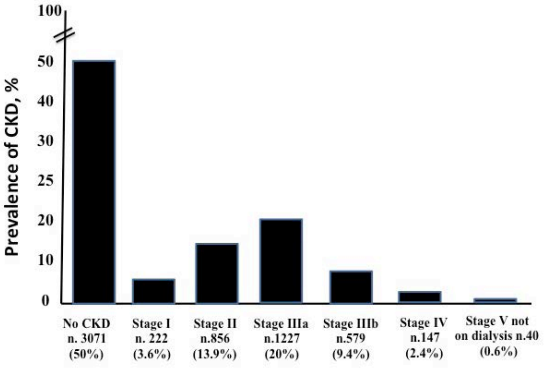
Development of a Service Interface Method (Webservice) between Family Care Physicians (FCPs) Operating in a Primary Care Setting and Nephrologists (NPs), for the Prevention, Diagnosis and Treatment of Kidney Damage in Patients with Type 2 Diabetes Mellitus (T2DM) Stefano Bianchi, Chiara Bilanceri, Elisa Poderelli, Silvia Campatelli, Francesca Nistri, Giada Santini, Roberto Bigazzi. *Nephrology and Dialysis, ASL Nordovest Toscana, Italy.*

Background: Chronic kidney disease (CKD) due to T2DM is a common and costly chronic disease and its complications are a major driver of health care (HC) costs worldlwide. Because of the large prevalence of such patients (pts), second care level of assistance (outpatient clinics and hospitals) is not able to screen and treat appropriately all of them. Information technology can be used effectively to track clinical and laboratory data and generate databases useful to follow these pts.

Methods: With this 3 years project (Italian HC system RF-2011-02346990) we realized a shared cumputerized (WEB connection) clinical chart (SCCC) allowing continuous updating of individual clinical data of pts with T2DM between NPs and FCPs. A SCCC allows an early diagnosis and would improve the treatment of DN and a reduction of cost of medications, diagnostic examinations and hospitalization rate.

Results: In the first year of the study, 106 FCPs have been enrolled, each of them caring for 1,000 pts. Therefore, the population of our study includes 106,000 subjects. We have screened 6,142 pts with T2DM, 2898 females and 3244 males, mean age 71,3±11.1 years. 3,071 out of 6,142 pts (50%) presented DN in different stage of CKD: 222 Stage I (3.6%), 856 Stage II (3.9%), 1227 Stage IIIa (20%), 579 Stage IIIb (9.4%), 147 Stage IV (2.4%) and 40 Stage V (0.6%).

Prevalence of renal damage (Stage of CKD) in 6,142 patients with type II Diabetes enrolled in the Study



Conclusions: A SCCC between NPs and FCPs is a feasible tool to early diagnose DN in pts with T2DM. DN has a high prevalence. 65% of pts with DN shows an advanced CKD stage. Screened T2DM pts with DN are now enrolled in a therapeutic protocol aimed to reduce the renal and cardiovascular complications of this high risk population.

Funding: Government Support - Non-U.S.

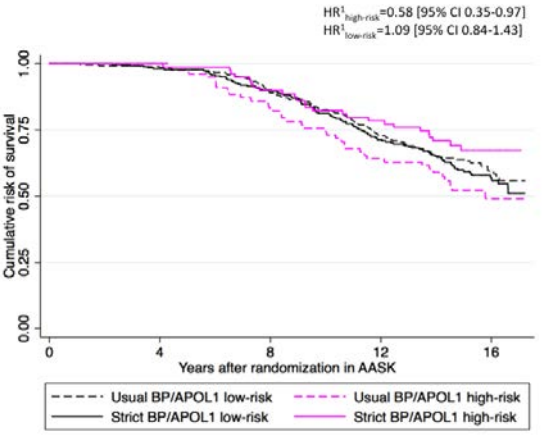
FR-OR018

Intensive Blood Pressure Control Associates with Lower Mortality Risk among Persons with High-Risk APOL1 Genotype Elaine Ku,[1] Michael S. Lipkowitz,[2] Lawrence J. Appel,[2] Afshin Parsa,[3] Jennifer J. Gassman,[2] David V. Glidden,[1] Miroslaw Smogorzewski,[2] Chi-Yuan Hsu.[1] *[1]UCSF; [2]AASK; [3]Univ of Maryland.*

Background: The association between *APOL1* and risk of death in black CKD patients is not well known. We determined whether *APOL1* status modifies the association between strict BP control and long-term mortality risk in former African American Study of Kidney Disease (AASK) trial participants.

Methods: We analyzed 682 AASK trial participants with CKD previously randomized to intensive (mean arterial pressure [MAP] ≤92 mm Hg) versus usual BP control (MAP 102-107 mm Hg) between 1995-2001. We determined risk of death by 1) *APOL1* genotype and 2) prior BP target assignment in analysis stratified by *APOL1* genotype. Deaths were ascertained through 2012 by linkage with the Social Security Death Index and US Renal Data System.

Results: During median follow-up of 14.5 years, risk of death did not differ between individuals with high- versus low-risk *APOL1* genotypes (unadjusted HR= 1.00 [95% CI 0.76-1.33]). However, an interaction was detected between *APOL1* risk group and BP control strategy during AASK trial (p=0.03). In the *APOL1* high-risk group (N=157), risk of death in long-term follow-up was 0.58 times lower comparing intensive versus usual BP control (unadjusted 95% CI 0.35-0.97), but in the *APOL1* low-risk group (N=525), risk of death was not different (unadjusted HR=1.09 [95% CI 0.84-1.43]).



In analysis adjusted for age, sex, baseline GFR, heart disease, smoking, and proteinuria, risk of death remained 0.48 times lower (95% CI 0.28-0.84) comparing intensive versus usual BP arms in the *APOL1* high-risk group, but was not different in the *APOL1* low-risk group (HR=0.98 [95% CI 0.74-1.28]).

Conclusions: Intensive BP control during CKD associates with lower risk of death in blacks with high-risk *APOL1* genotype. Knowledge of *APOL1* status may inform appropriate BP treatment targets in black CKD patients.

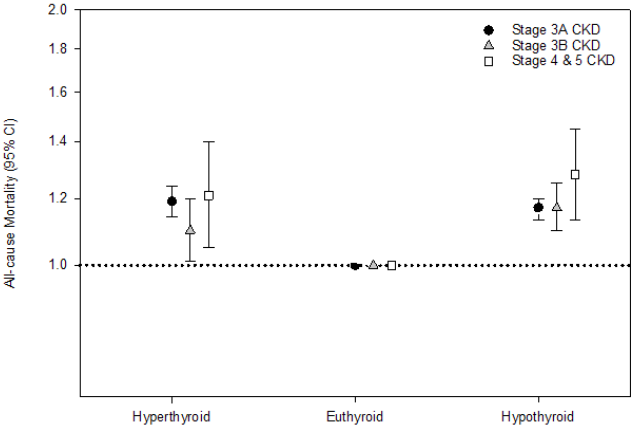
FR-OR019

Thyroid Functional Disease and Mortality in U.S. Veterans with Chronic Kidney Disease Connie Rhee,[1] Kamyar Kalantar-Zadeh,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Steven M. Brunelli,[2] Danh V. Nguyen,[1] Gregory Brent,[3] Csaba P. Kovesdy.[4] *[1]UC Irvine; [2]DaVita Inc; [3]UCLA; [4]Univ of Tennessee Health Science Center.*

Background: Epidemiologic studies show that advanced chronic kidney disease (CKD) patients have a higher prevalence of thyroid dysfunction compared to their non-CKD counterparts. While hyper- and hypothyroidism have been associated with higher mortality in the dialysis population, no studies have examined the relationship between thyroid function defined by serum thyrotropin (TSH) and death risk in non-dialysis dependent chronic kidney disease (NDD-CKD) patients.

Methods: We examined the association of thyroid function with all-cause mortality among US veterans with Stage 3-5 NDD-CKD who underwent ≥1 TSH measure(s) over 2004-12. We examined the association between thyroid status, defined as hyper-, eu-, and hypothyroid (TSH levels <0.5, 0.5-5.0, and >5.0mIU/L, respectively), with all-cause mortality across CKD strata using case-mix adjusted Cox models.

Results: Among 232,524 patients with Stage 3-5 CKD, 4% (n=8154), 90% (n=209,438), and 6% (n=14,932) of patients had hyper-, eu-, and hypothyroidism, respectively. In the overall cohort, 98% (n=227,426), 2% (n=4248), and 0.4% (n=850) had Stage 3, 4, and 5 CKD, respectively. In adjusted analyses, hyperthyroidism was associated with higher mortality risk across all CKD strata: HRs (95% CI) 1.19 (1.14-1.24), 1.10 (1.01-1.20), and 1.21 (1.05-1.40) for Stage 3A, 3B, and 4+5, respectively. Similarly, hypothyroidism was associated with higher mortality risk across all stages of CKD: HRs (95% CI) 1.17 (1.13-1.20), 1.17 (1.10-1.25), and 1.28 (1.13-1.45) for Stage 3A, 3B, and 4+5, respectively.



Conclusions: Among US veterans with Stage 3-5 NDD-CKD, hyper- and hypothyroidism were associated with higher mortality. Further studies are needed to determine whether treatment that normalizes serum TSH ameliorates death risk in NDD-CKD patients with thyroid dysfunction.

Equations Based on a Set of Novel Metabolites Markers Provide a More Precise Determination of the Glomerular Filtration Rate (GFR) Than the Standard Equations in a Swedish Population with Measured GFR

Regis Perichon,[1] Veronica Lindström,[2] Tiffany Freed,[1] Lisa Ford,[1] Ulf Nyman,[3] Jonas Björk,[2] Jacob Wulff,[1] Anders O. Grubb.[2] *[1]Metabolon, Durham, NC; [2]Univ Hospital Lund, Lund, Sweden; [3]Skane Univ Hospital, Lund, Sweden.*

Background: Creatinine and creatinine-based equations (eg, MDRD and CKD-EPI) are used in routine clinical practice to assess the kidney function. However, non-glomerular determinants affects the performance and clinical utility of creatinine-based equations. We previously identified new metabolites with high correlation with the measured (mGFR). Using quantitative assays for those new metabolites we developed equations that had better precision than the MDRD and CKD-EPI equations in a cohort of adult Swedish patients with mGFR (n=482). The aim of this study is to verify the performance of those new equations in an independent set of 803 patients with mGFR.

Methods: Plasma samples from 803 consecutive adult patients referred to the Lund Hospital (Lund, Sweden) for mGFR assessment by plasma clearance of iohexol were collected and the plasma levels of 5 metabolites were determined using quantitative mass spectrometry assays.The GFR was determined by using the new metabolite-based equations as well as with the MDRD and CKD-EPI equations. The performance of those 3 estimates of GFR was assessed against the mGFR.

Results: MDRD and CKD-EPI equations performed similarly in this patient cohort; about 78% and 64% of the GFR estimates were within 30% and 20% of the mGFR values, respectively. In contrast, with an equation based on acetyl-threonine, pseudouridine and age, 87% and 75% of the GFR estimates were within 30% and 20%, respectively. The rate of CKD Stage misclassification due to an error of more than 30% was 18% with MDRD and CKD-EPI equations. In contrast, this rate was only 8.3% (more than 50% reduction) with the equation based on the new metabolites.

Conclusions: The potential for new metabolites to provide significantly more precise and accurate estimates of GFR was verified in this large independent cohort. Full clinical validation of the new metabolite markers is underway in a larger and diverse cohort.

Multiple Metabolites Correlate More Strongly with Measured Glomerular Filtration Rate Than Creatinine: A Verification Study

Josef Coresh,[1] Lesley Inker,[2] Yingying Sang,[1] Jingsha Chen,[1] Tariq Shafi,[1] Wendy S. Post,[1] Michael Shlipak,[3] Regis Perichon,[4] Tom Greene,[5] Andrew S. Levey.[2] *[1]JHMI; [2]Tufts MC; [3]UCSF; [4]Metabolon; [5]UU.*

Background: We previously showed that in 200 individuals from AASK measured glomerular filtration rate (mGFR) was highly correlated with many metabolites. We now test whether this is also true in a higher GFR range and evaluate which metabolites are strongly correlated with mGFR at both low and high mGFR providing a foundation for improved GFR estimation.

Methods: Study Population: 265 white or African-American participants at the JHU MESA site with mGFR by plasma clearance of iohexol. **Laboratory Methods:** Untargeted GC/MS^2 and LC/MS^2-based metabolomic quantification of serum (Metabolon) followed by development of targeted assays for 15 metabolites. **Data Analysis Methods:** Log metabolites were ranked by correlation with log mGFR and compared across AASK and MESA.

Results: In semi-quantitative untargeted metabolite assays more than a quarter of measured metabolites were significantly correlated ($p<0.001$) with mGFR in AASK and MESA, and 7 of 9 metabolites more negatively correlated than untargeted serum creatinine in AASK were also more negatively correlated in MESA (Figure). Targeted assays developed for promising metabolites showed higher correlations in the combined dataset with mGFR than creatinine (r=-0.82) for: acetyl-threonine (-0.90), pseudouridine (-0.89), acetyl-alanine (-0.84) and myo-inositol (-0.83).

Conclusions: We identified several metabolites which replicated as being more correlated with mGFR than serum creatinine across both a low and high GFR populations. Validation and testing of metabolite panels is underway with the goal of developing a more precise and robust GFR estimate. [Patents pending by Drs. Levey, Inker and Coresh and Metabolon].

Weak Performances of Glomerular Filtration Rate Equations in Stable Lung/Liver Transplant Recipients Compared to 51Cr-EDTA Clearance

Emilie Navaux,[1] Thierry Gustot,[2] Judith Racape,[1] Pierre Delanaye.[3] *[1]Nephrology-Dialysis-Transplantation, CUB-ULB Hopital Erasme, Brussels, Belgium; [2]Gastroenterology, CUB-ULB Hôpital Erasme, Brussels, Belgium; [3]Nephrology-Dialysis-Transplantation, Univ of Liège, CHU Sart Tilman, Liège, Belgium.*

Background: Performance of the most common GFR equations (i.e. MDRD and CKD-EPI) is poorly described in transplant recipients. These populations exhibit frequent non-renal characteristics that influence serum creatinine. Exogenous marker, such as ^{51}Cr-EDTA, allows accurate GFR measurement but it remains cumbersome. Performance of MDRD-2006 and CKD-EPI-2009 equations was compared to the ^{51}Cr-EDTA clearance in lung or liver transplant recipients.

Methods: Retrospective monocentric study (Jan 2011-Sept 2015). GFR was measured by the intercept slope method (3 samples: 90,150 and 210 min). Bias, precision and accuracy defined the performance of GFR equations (IDMS traceable serum creatinine values). Bias was the difference between estimated and measured GFR. Precision was the standard deviation of this difference. Accuracy was rated by the percentage of estimations within 30% of the measured GFR. Risk of misclassification between chronic kidney disease categories (KDIGO 2012) was defined.

Results: 753 GFR measurements were performed for lung (n=152) and liver (n=124) transplant recipients. Mean GFR was 56±42 ml/min/1,73m², mean age was 56 years and 56% were male. Under 60 ml/min/1,73m² (n=444), bias was lower for MDRD (11±24 versus 14±25 ml/min/1,73m²; $p<0.001$). Between 60-90 ml/min/1,73m² (n=238), bias was lower for CKD-EPI (-13±25 versus -17±25 ml/min/1,73m²; $p<0.001$). Accuracy was similar but strikingly poor (43% MDRD and 41% CKD-EPI). The subsequent risk of misclassification was 75% with both equations. GFR overestimation was associated with an age <60 years, malnutrition and lung transplant. GFR underestimation was associated with an age >60 years, BMI >30 kg/m² and liver transplant.

Conclusions: Accuracy of MDRD and CKD-EPI equations was inadequate in this population precluding valid use in clinical routine. Clinicians should be aware of these limitations that may lead to a high risk of misclassification.

FR-OR023

Performance of the CKD-EPI BTP Equation in Kidney Transplant Recipients

Christine A. White,[1] Ayub Akbari,[2] Dean Fergusson,[3] Greg A. Knoll.[2] *[1]Dept of Medicine, Queen's Univ, Kingston, ON, Canada; [2]Dept of Medicine, Univ of Ottawa, Ottawa, ON, Canada; [3]Dept of Epidemeology and Community Medicine, Univ of Ottawa, Ottawa, ON, Canada.*

Background: Accurate estimation of GFR continues to be problematic in kidney transplantation. A new equation to estimate GFR based on serum concentrations of BTP has recently been proposed by the CKD-EPI consortium: BTP eGFR=55 * BTP $^{-0.695}$ * 0.998 ^{age} * 0.899 if female. The aim of this study was to examine the performance of this equation in a cohort of kidney transplant recipients and compare it to the CKD-EPI creatinine (Cr) eGFR and cystatin C (cysC) eGFR. Whether the average of the eGFRs of all three markers improves GFR estimation as compared to the average of Cr/cysC eGFR alone was also examined.

Methods: BTP, cysC, Cr and plasma clearance of ^{99m}Tc-DTPA were measured in 202 adult kidney transplant recipients. BTP and Cys C were measured using the Siemens' nephelometric assays. Equation performance was evaluated by equation bias (estimated – measured GFR), precision (standard deviation of the bias) and 10% and 30 % accuracy. Differences were assessed using paired test and McNemar's test as appropriate.

Results: Results are shown in table below.

CKD-EPI Equation	Bias (ml/min/1.73m²)	Precision (ml/min/1.73m²)	Accuracy % within	
			10%	30%
BTP eGFR	-11.9	17.4	25	65
Cr eGFR	-6.2*	14.8	29	79$^{\beta}$
CysC eGFR	1.6*	16.2	30	76$^{\alpha}$
Cr/CysC eGFR	-2.3**	12.9	37	87$^{\delta}$
Cr/CysC/BTP eGFR	-5.5	12.9	34	89

*P<0.0001 compared to CKD-EPI BTP; **P<0.0001 compared to CKD-EPI Cr/CysC/BTP; $^{\beta}$P=0.0009 compared to CKD-EPI BTP; $^{\alpha}$ P=0.02 compared to CKD-EPI BTP; $^{\Delta}$ P=0.55 compared to CKD-EPI Cr/CysC/BTP.

Conclusions: The CKD-EPI BTP equation is more biased, less precise and less accurate than either the CKD-EPI Cr or the CKD-EPI CysC equations. Incorporating the BTP equation to an average of the CysC and Cr equations does not provide any additional benefits.

Absence of Renal Hyperfiltration Imposes Adverse Pregnancy Outcome
Sehoon Park, Ho Jun Chin, Ki Young Na, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: Pre-gestational chronic kidney disease was related to worse pregnancy prognosis and failed hemodynamic adaptation was suspected to be the cause. However, the relationship between midterm renal hyperfiltration (RHF), a normal hemodynamic change during gestation, and adverse pregnancy outcome remains obscure.

Methods: This study included pregnancy cases from two tertiary hospitals in Korea from 2001 to 2015. We used CKD-EPI eGFR (estimated glomerular filtration rate, ml/min/1.73m^2) in the second trimester of each pregnancy to assess midterm RHF of mothers. Mothers were divided into four subgroups as follows: eGFR 60-90, 90-120, 120-150, and ≥150. Mothers with delivery done in the same trimester and eGFR<60 before or during pregnancy were excluded. Adverse pregnancy outcome was the composition of prematurity birth (gestational age<37 weeks), low birth weight (fetal birth weight<2.5 kilograms) and preeclampsia.

Results: A total of 1,936 deliveries were included in the study. Mothers with adverse pregnancy outcome had lower midterm eGFR than those without gestational complications, although their pre-gestational eGFR were not significantly different. When classified into subgroups, mothers with midterm eGFR 60-90 (adjusted OR 2.31, 1.41-3.79, *P*=0.001), eGFR 90-120 (adjusted OR 1.34, 1.004–1.80, *P*=0.047), and even mothers with eGFR≥150 (adjusted OR 2.31, 1.79–13.72, *P*=0.001) showed increased risk of adverse pregnancy outcome when compared to those with eGFR 120-150. Overall, midterm eGFR showed non-linear U-shape association with the risk of adverse pregnancy outcome. The results were similar with prematurity birth and low birth weight, respectively. In contrast, the risk of preeclampsia increased as midterm eGFR decreased, and was higher in the subgroup with midterm eGFR 60-90 (OR 8.27, 2.06-33.30, *P*=0.003).

Conclusions: We demonstrated a novel, non-linear, U-shaped relationship between midterm eGFR and the risk of adverse pregnancy outcome. The absence of adequate midterm RHF was a significant risk factor of worse pregnancy prognosis. Therefore, routine measurement of the midterm renal function should be considered.

Chronic Kidney Disease (CKD) and Peripheral Nerve Function in the Health, Aging and Body Composition (HABC) Study
Simit Doshi,[1] Ranjani N. Moorthi,[1] Linda F. Fried,[2,6] Sharon M. Moe,[1,6] Mark J. Sarnak,[3] Suzanne Satterfield,[4] Ann Schwartz,[5] Michael Shlipak,[5,6] Anne B. Newman,[2] Elsa S. Strotmeyer.[2] *[1]Indiana Univ; [2]Univ of Pittsburgh; [3]Tufts Med Center; [4]Univ of Tennessee; [5]UCSF; [6]Veterans Admin.*

Background: Peripheral neuropathy is prevalent in older adults and is associated with loss of mobility and balance. We hypothesize that CKD, akin to aging; will be associated with nerve function deficits.

Methods: We evaluated the cross-sectional relationship of CKD (defined by eGFR<60 ml/min/1.73 m2) with sensory, motor and autonomic function(Table) in 1483 participants of The HABC Study, a longitudinal cohort of community-dwelling white and black Medicare beneficiaries with 1997-98 baseline. Multivariable logistic regression (LR) model was used. Variables significant at p<0.1 in univariate analyses were adjusted.

Results: Mean(SD) age was 75(3) yrs, 46.1% were men, 35.7% were black and 18.5% had CKD. Participants with CKD had higher odds for having vibration detection deficit and abnormal autonomic function(Table).

Conclusions: Early CKD is associated with sensory and autonomic nerve deficits.

FR-OR026

Association of Sleep Architecture and Stage of Chronic Kidney Disease in a Large Community Based Cohort Study
Ciaran Joseph McMullan,[1] Susan Redline,[2] John P. Forman.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Div of Sleep and Circadian Disorders, Brigham and Women's Hospital, Boston, MA.*

Background: Individuals with progressive chronic kidney disease (CKD) frequently report increasing insomnia and poor sleep quality. There is also evidence that individuals with habitual sleep restriction have a more rapid decline in renal function. These finding indicate interplay between renal function and sleep which is not fully understood. To better understand the specific attributes of sleep disturbances that may associate with CKD, we performed a large cross-sectional analysis of polysomnography measures with stages of CKD.

Methods: In cross-sectional analyses of individuals from the Sleep Heart Health Study with sleep disturbances measured using polysomnography, we evaluated the association of baseline total sleep duration (primary exposure), arousal index, hypoxia index (% sleep time with oxygen saturation < 90%) , and respiratory disturbance index (secondary exposures) with baseline estimated glomerular filtration rate (eGFR,N=3597) and albuminuria-creatinine ratio (ACR, N=1567).

Results: Lower eGFR was associated with shorter total sleep duration, and higher indices of arousal, hypoxemia and respiratory disturbance, p-trend <0.005 for all. After adjustment for age, gender, race, smoking and diabetes only total sleep duration remained significantly associated with decreased eGFR, p-trend = 0.007. Higher indices for arousal, and hypoxia were associated with higher ACR, which remained significant after adjustment for age, gender, race, smoking and diabetes, p≤0.005. Neither total sleep duration nor respiratory disturbance index was associated with albuminuria.

Conclusions: Individuals with lower eGFR appear to have decreased sleep duration as measured by polysomnography, independent of age, gender or race, while individuals with more frequent arousals or hypoxemic episodes tend to have higher albuminuria. Prospective studies are required to more fully examine the direction of these associations and to better assess whether or not they may be causal.

Gait Speed Trajectory among Patients with CKD
Baback Roshanravan,[1] Kushang V. Patel,[2] Jorge Gamboa,[3] Cassianne Robinson-Cohen,[1] Jonathan Himmelfarb,[1] Ian H. De Boer,[1] Bryan R. Kestenbaum.[1] *[1]Kidney Research Inst, Univ of Washington, Seattle, WA; [2]Anesthesiology and Pain Medicine, Univ of Washington, Seattle, WA; [3]Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Gait speed is an component of frailty and strongly associated with mobility disability and mortality across populations. Understanding the trajectory of gait speed decline and its determinants is critical to preventing functional impairment among CKD patients. For the first time we describe longitudinal change in gait speed in patients with CKD.

Methods: Longitudinal study of 213 participants with CKD I-V enrolled in the Seattle Kidney Study without ADL disability, lower extremity impairment, or dialysis treatment at baseline. Gait speed was measured yearly. Generalized estimating equations were used to estimate associations with annual change in gait speed. Kidney function was measured using eGFRcysc. Multiple imputation was performed for missing variables.

Results: Mean age of participants was 57±13 years with 81% male, and 22% black. Mean eGFRcysc was 48±18. Median follow-up was 3 years IQR[2, 4]. Mean annual change was -0.002m/s IQR[-0.05, 0.04]. Those with fastest tertile decline (17.5%/yr IQR[28.3, 12]) were more likely black, and had lower eGFRcysc at baseline. After adjustment, lower eGFRcysc was associated with more rapid decline in gait speed (-0.021 m/s/yr or -2.2%/yr per 1-SD (95% CI -0.03, -0.01; P<0.001). Diabetes was independently associated with -0.019m/s/yr decline. Further adjustment for hemoglobin attenuated the estimates for eGFRcysc and diabetes.

Conclusions: Among persons with CKD, lower eGFRcysc, diabetes, and low hemoglobin are associated with faster decline in gait speed, underscoring the importance of screening for mobility impairment in more severe kidney disease.

eGFRcysc	Baseline mean (SD) (m/s)	Model slope (m/s per yr) (95% CI)

Cap Mesenchyme Cell Migration during Kidney Development Is Influenced by Attraction, Repulsion, and Adhesion to the Ureteric Tip
Alexander N. Combes,[1,2] James Lefevre,[3] Sean Wilson,[2] Nicholas A. Hamilton,[3] Melissa H. Little.[2,4] *[1]Dept of Anatomy & Neuroscience, Univ of Melbourne, Melbourne, Vic, Australia; [2]Murdoch Childrens Research Inst, Melbourne, Vic, Australia; [3]Inst for Molecular Bioscience, The Univ of Queensland, Brisbane, Qld, Australia; [4]Dept of Paediatrics, Univ of Melbourne, Melbourne, Vic, Australia.*

Background: Morphogenesis of the mammalian kidney requires reciprocal interactions between two cellular domains at the periphery of the developing organ: the tips of the epithelial ureteric tree and adjacent regions of cap mesenchyme. While the presence of the cap mesenchyme is essential for ureteric branching, how the cap mesenchyme is specifically maintained at the tips is unclear.

Methods: Using *ex vivo* timelapse imaging we show that cells of the cap mesenchyme are highly motile.

Results: Individual cap mesenchyme cells move within and between cap domains. They also attach and detach from the ureteric tip across time. Timelapse tracks collected for >800 cells showed evidence that this movement was largely stochastic, with cell autonomous migration influenced by opposing attractive, repulsive and cell adhesion cues.

Conclusions: What was formerly considered a static cellular environment has proven to be dynamic. Continuous cell movement within the niche results in a constant change in the likely signalling environment of any given CM cell. As a result, the niche does not appear to be neatly segregated into spatial subdomains required for a linear differentiation of CM cells to an induced fate. Each CM cell is being simultaneously repelled from the tip, attached to the tip and attracted to tip. These competing forces facilitate the dynamic remodelling required to maintain a domain around the ureteric tips, which is vital for continued branching and nephron induction.

The Role of Megalin in Nephrogenesis and Its Expression in the Developing Human Kidney
Jennifer R. Charlton,[1] Matthew Harer,[1] Tina Storm,[2] Kathrin Weyer,[2] Erik I. Christensen,[2] Rikke Nielsen,[2] Courtney C. Swan.[1] *[1]Univ of Virginia; [2]Aarhus Univ.*

Background: Megalin is localized in the proximal tubule (PT) and rescues ligands like retinol-binding protein (RBP) and vitamin D-binding protein (VDBP) from urinary loss. RBP transports vitamin A, critical for kidney development. Premature neonates are at risk for CKD. Considering the role of megalin in vitamin conservation, we hypothesize that kidney formation in premature neonates is compromised by a relative megalin deficiency and ligand loss. Our aim is to determine if premature neonates excrete megalin ligands due to a developmental expression of megalin and if megalin deficiency during nephrogenesis interferes with kidney development, increasing CKD risk.

Methods: To study megalin expression during human renal development along with the uptake and urinary excretion of megalin ligands, two human cohorts were assessed (1) deceased cohort (20-40 wks gestation) to quantitate tissue megalin, RBP, VDBP and mature PT and (2) living cohort (28-40 wks gestation) to measure urinary RBP and VDBP. Imaging software calculated the area of protein expression. To assess the role of megalin during nephrogenesis, we used a kidney specific megalin deficient model to analyze GFR, nephron number, PT fraction and renal morphology.

Results: Human megalin expression in the PT increased over gestation from 20 to 33 wks as does the tissue level of RBP and VDBP from 20 to 29 weeks. There was a significant correlation between megalin expression and RBP and VDBP uptake. Urinary RBP and VDBP were found in higher concentrations in the 28-32 wk group as compared to the 38-40 week group at birth (RBP: $p<0.01$; VDBP: $p<0.05$) but by term corrected age they were no different compared to the term group at birth. Our analyses showed that 3 wk old megalin KO mice have fewer glomeruli with smaller kidneys and more atubular glomeruli. By the age of 60 days, these mice have a decreased GFR (WT: 401 µl/min; KO: 184 µl/min; $p=0.017$).

Conclusions: Premature infants represent a population with relative megalin deficiency with urinary wasting of megalin ligands. In mice, PT megalin deficiency results in interference of normal nephron formation and may play a role in the development of CKD.

FR-OR030

Nrp1 Is Essential for Glomerular Development and Chemoattraction of Mesangial Cells to PDGF
Christina S. Bartlett,[1] Rizaldy P. Scott,[1] Vera Eremina,[2] Chengjin Li,[2] Yashpal S. Kanwar,[1] Jeffrey H. Miner,[3] Susan E. Quaggin.[1] *[1]Div of Nephrology/Hypertension and the Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [2]Mount Sinai Hospital, Toronto, Canada; [3]Washington Univ, St. Louis, MO.*

Background: Nrp1 is a transmembrane co-receptor for SEMA3A, VEGF, HGF, FGF2, TGF-β, and PDGF. In the kidney Nrp1 is expressed in glomerular mesangial cells (GMCs) yet little is known about its physiological role in glomerular development and disease. An antibody against Nrp1, designed as anti-angiogenic therapy, inadvertently causes significant proteinuria indicating that Nrp1 function is vital in the glomerulus.

Methods: We created conditional knockout (cKO) mouse mutants specifically lacking Nrp1 expression in GMCs and vascular smooth muscle cells (vSMCs) and assessed glomerular development, structure, and function. Cellular behavior upon PDGFB stimulation were studied in human glomerular mesangial cells (hGMCs) following siRNA-mediated knockdown of Nrp1.

Results: PDGFRb-Cre-dependent deletion of *Nrp1* resulted in cKO mice with ~86% reduction in Nrp1 protein levels in the kidney, showing that renal Nrp1 expression is largely in PDGFRb+ GMCs and vSMCs. Nrp1 deficiency causes renal insufficiency, proteinuria and early lethality. Nrp1 cKOs have simplified glomeruli with poorly elaborated capillary tufts. By 2 weeks of age cKOs show glomerular abnormalities including endothelial detachment, podocyte effacement, glomerular basement membrane distortion, and mesangiolysis. Nrp1 is required for PDGFB-dependent migration of hGMCs but not proliferation or adhesion to collagen, laminin and fibronectin. Consistently, upon PDGFB stimulation, activation of p130Cas but not Erk or Akt is dependent on Nrp1.

Conclusions: Nrp1 is essential in GMCs and its loss results in glomerular maldevelopment and glomerulosclerosis. Nrp1 is needed for the structural support function of the mesangium as the glomerular capillary tufts are poorly branched and collapsed when Nrp1 is absent. Cell culture studies suggest that impaired chemotaxis of GMCs lacking Nrp1 to PDGFB, through loss of p130Cas activation, may contribute to aberrant glomerular development in Nrp1 cKO mutant mice.

FR-OR031

A Novel Strategy to Identify the Role of Whole-Exome Sequencing Candidate Genes in Renal Hypo-Dysplasia
Olivier Niel,[1,2] Georges Deschênes,[1] Sophie Saunier,[2] Cecile Jeanpierre.[2] *[1]Pediatric Nephrology, Robert Debre Hospital, Paris, France; [2]Imagine Inst, Inserm u1163, Paris, France.*

Background: Next generation sequencing (NGS) has revolutionized genetic research, leading to fast and cost-efficient characterization of heritable pathologies. In particular, whole-exome sequencing (WES) has become the technology of choice to investigate monogenic diseases. However, WES leads to the identification of large numbers of candidate genes, which have to be individually validated. This part of the process is long and costly. Here we propose a novel approach to rapidly and inexpensively screen WES candidate genes in renal hypo-dysplasia.

Methods: Candidate genes obtained by WES were sorted in silico (functional and biological significance). The expression of each candidate gene was knocked down in murine kidney cultures, using a specific vivo-morpholino. Kidneys were analyzed after culture using a multiphoton fluorescent microscope. Candidate genes whose knockdown in culture recapitulated the phenotype observed in the families were defined as confirmed candidates.

Results: Six WES candidate genes were tested, accounting for renal hypodysplasia in 7 unrelated families. One candidate gene was identified by the presence of a heterozygous frameshift variant segregating with renal cystic dysplasia in one family. Its expression in culture was decreased by 65% ($p < 0.001$) using a specific vivo-morpholino. This finding was associated with cyst formation ($p < 0.001$). This phenotype recapitulated the patients' renal phenotype. Another gene was a candidate to account for multicystic hypodysplasia because of the identification of a homozygous, predicted as damaging missense variant in 3 fetuses from 1 family. Its expression in culture was decreased by 60%. This was associated with cyst formation. Ureteric bud branching was decreased by 45%. Tubular cell thickness was increased by 28%. The phenotype matched the patients' phenotype.

Conclusions: This novel approach is fast, inexpensive, and reliable, especially to characterize a frameshift or a loss-of-function missense mutation resulting in a decreased protein function in vivo. It is a strategy of choice to screen WES candidate genes potentially involved in renal diseases.

FR-OR032

Regulation of Kidney Field Size by Transcriptional Regulation of microRNAs
Eugenel Bermudez Espiritu,[1] Maria C. Cirio,[2] Yu Leng Phua,[3] Debora Malta C.S Santos,[3] Jacqueline Ho,[3] Neil A. Hukriede.[1] *[1]Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA; [2]Biodiversity and Experimental Biology, Univ of Buenos Aires, Buenos Aires, Argentina; [3]Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Renal progenitors arise from the intermediate mesoderm (IM), a germ layer that lies between the lateral & paraxial mesoderm. The transcription factor l*hx1* is expressed in the lateral & IM. Eventually *lhx1* becomes restricted to the IM becoming one of the earliest genes expressed in the kidney field. Lhx1 is essential to specify kidney; the molecular mechanism remains undefined and very few targets have been identified.

Methods: In *Xenopus* kidney cells, we identified proteins using tandem-affinity purified (TAP) proteins that could interact with constitutively active form of Lhx1 (TAP-LL-CA) & not a version lacking the C-terminal region (TAP-LL-delC). The C-terminal region of Lhx1 contains the functional domains necessary to confer transcriptional activity. Furry (Fry) was identified as a potential Lhx1 interacting protein that bound only to the TAP-LL-CA. In *Xenopus*, Fry acts as a transcriptional co-repressor of microRNA (miRNA) expression. We depleted Fry & Lhx1 utilizing antisense oligonucleotides & visualized their effects on the kidney by staining for pronephric kidney markers. We conducted miRNA deep sequencing on these embryos. miRNA mimics were injected into embryos and their effects on the kidney were analyzed as before.

Results: Here we show *fry* is expressed in the IM & pronephric anlagen. We determined that embryos depleted of *fry* show loss of the kidney field, phenocopying the *lhx1* depletion. We observed a synergistic requirement of these two proteins in the IM indicating the

potential interaction in the specification of the kidney field. To gain further insight of the mechanism for Fry & Lhx1 in the kidney field, we identified miRNAs regulated by the proteins using miRNA deep sequencing, & perturbed specification of the kidney field by expressing mimics for the identified miRNAs.

Conclusions: These results support a role of a Lhx1/Fry complex in specification of the kidney field by regulation of miRNAs expression.

Regulation and Function of Mural Cell-Derived p57Kip2 in Kidney Development

Jing Yu,[1,2,3] LaToya Ann Roker,[1] Faith W. Karanja.[1] *[1]Dept of Cell Biology, Univ of Virginia School of Medicine, Charlottesville, VA; [2]Center for Immunity, Inflammation and Regnerative Medicine, Univ of Virginia School of Medicine, Charlottesville, VA; [3]Child Health Research Center, Univ of Virginia School of Medicine, Charlottesville, VA.*

Background: p57kip2 (Cdkn1c) is a cyclin-dependent kinase inhibitor that is implicated in Beckwith-Wiedemann Syndrome and IMAGe Syndrome. In the embryonic kidney, p57kip2 is expressed in podocytes and the medullary interstitium. Ablation of p57Kip2 in mice led to many defects resembling the Beckwith-Wiedemann Syndrome. The kidneys of p57Kip2 mutant mouse embryos exhibited a shorter renal medulla since the onset of renal medulla formation.

Methods: Immunohistochemistry, luciferase reporter analysis and Chromatin immunoprecipitation were performed on mice and cell culture.

Results: In Wnt7b mutant kidneys, where a renal medulla failed to form, p57Kip2 expression in the medullary interstitium was reduced to undetectable levels whereas its expression in the podocytes was unaltered. In the renal medulla, p57kip2 is expressed in the mural cells associated with peri-ureteric bud capillaries, the Wnt7b/canonical Wnt target cells. Luciferase reporter analysis in vitro and Chromatin Immunoprecipitation (ChIP) of the renal interstitium showed that p57Kip2 expressed in the mural cells is a direct transcriptional target of Wnt/β-catenin signaling. Further, tissue-specific manipulation of p57Kip2 expression in the embryonic kidney showed that mural cell-derived p57Kip2 is necessary and sufficient for renal medulla elongation, whereas podocyte-derived p57kip2 did not contribute to renal medulla elongation. In the renal medulla, p57Kip2 inhibits proliferation of mural cells and endothelial cells of peri-UB capillaries, and regulates oriented cell division of collecting duct cells and collecting duct elongation.

Conclusions: Our study of p57Kip2 reveals a cross-talk between the collecting duct and the vasculature during kidney formation where the collecting duct regulates gene expression in the vascular components and the vascular component regulates collecting duct and renal medulla elongation in return.

FR-OR034

Fibroproliferative Response to Urothelial Failure Obliterates the Ureter Lumen in a Mouse Model of Prenatal Congenital Obstructive Nephropathy

Amanda J. Lee, Noemi Polgar, Josephine Andrea Napoli, Vanessa H. Lui, Brent Fujimoto, Ben Fogelgren. *Anatomy, Biochemistry, and Physiology, Univ of Hawaii, Honolulu, HI.*

Background: Congenital obstructive nephropathy (CON) is the most common cause of pediatric kidney disease and ESRD. Ureteropelvic junction (UPJ) obstructions are responsible for a large portion of CON cases. Based on histological observations the hypothesis arose that urothelial damage could be an underlying basis for some human UPJ obstructions, but this hypothesis has not been tested.

Methods: We have generated a novel genetic mouse model of prenatal UPJ obstructions by conditional deletion of Sec10, an exocyst trafficking complex subunit. We used Ksp-Cre mice to delete Sec10 in ureteric bud-derived epithelia, including the urothelial progenitor cells lining the ureters. Here, we use both *in vivo* and *ex vivo* approaches to investigate the failure of the Sec10-knockout urothelial layer to mature, the subsequent urothelial cell death, and the pathological obliteration of the ureter.

Results: $Sec10^{FL/FL}$;Ksp-Cre mice developed bilateral UPJ obstructions between E17.5 and E18.5, with severe hydronephrosis, anuria, and neonatal death. We found that without Sec10, the urothelial progenitor cells lining the ureter fail to differentiate into superficial cells, which are responsible for producing uroplakin plaques on the luminal surface. These Sec10-knockout urothelial cells undergo cell death by E17.5 and the urothelial barrier becomes leaky to urine. At E17.5, we measured an increased expression of TGFβ1 and genes associated with myofibroblast activation, increased mesenchymal cell proliferation, and found evidence of stromal remodeling. When ureters were removed at E15.5 and cultured for 72 hours, the urothelial defects persisted, but lumen obstructions did not occur in the absence of urine.

Conclusions: Our findings support the model that defective urothelial barrier allows urine to induce a fibroproliferative wound healing mechanism, which may contribute to UPJ obstructions in humans.

Epigenomic Profiles Identify Age Associated Chromatin State Transitions in Nephron Progenitors

Samir S. El-Dahr,[1] Yuwen Li,[1] Melody C. Baddoo,[1] Jiao Liu,[1] Zubaida R. Saifudeen,[1] Mazhar Adli.[2] *[1]Pediatrics, Tulane Univ, New Orleans, LA; [2]Biochemistry, Univ of Virginia, Charlottesville, VA.*

Background: $Cited1^{+}/Six2^{+}$ cells are lineage-restricted multipotent nephron progenitor cells (NPC). Unlike young NPC, which are actively engaged in self-renewal and are resistant to inductive signals, old NPC differentiate at a faster rate limiting their life span. We hypothesized that "aging" alters the epigenomic landscape of NPC, which favors differentiation over renewal.

Methods: NPC were isolated using a magnetic activated cell sorting protocol from E13 and E19 CD1 mouse kidneys and expanded in NPEM growth factor medium for 48 hrs to generate pure $Cited1^{+}/Six2^{high}$ NPC. To identify genome-wide open chromatin regions (OCR - nucleosome-free active promoters and enhancers), NPC were subjected in triplicates to ATAC-seq (Assay for Transposase-Accessible Chromatin with high throughput sequencing). Peak calling, annotation, transcription factor binding motifs and overlapping peaks between E13/E19 samples were performed using HOMER and iCis-Target. OCR were integrated with publicly available RNA-seq and ChIP-seq databases.

Results: We identified 956 and 1438 annotated genes carrying at least one OCR in E13 vs. E19 NPC, respectively, of which 5-7% are differentially expressed. OCR clustered around the transcription start site and at distant 5' or 3' or intragenic sites. Progenitor genes (e.g., c-Myc, Osr1, Six2, Meox1, Eya1, cell cycle and epigenetic regulators) featured age-related attenuation of OCR peak scores and density. Transcriptionally silent β-catenin target genes (e.g., Wnt4, Lef1, Axin2, Jag1, Pax8) consistently harbored OCR in curated enhancers as well as in novel candidate enhancers in old but not young NPC. AP-1, Six2, Sall1/2, WT1, Pax2, Smads, c-Myc, p53, and E2F were amongst the most commonly identified transcription factors in OCR footprints.

Conclusions: Young and old $Cited1^{+}$ NPC exhibit distinct epigenomic landscapes. OCR footprints identified candidate networks of transcriptional regulators in NPC. Chromatin of old NPC displays biochemical signs of epigenetic poising which may explain, at least partly, the enhanced propensity of old NPC to differentiation vs. self-renewal.

RET Signaling Is Necessary for Survival of Progenitors in the Anterior Intermediate Mesoderm and Wolffian Duct - Cloaca Joining through a Novel Trans-Cloacal Cascade of Apoptosis before Ureteric Budding

Masato Hoshi,[1] Sanjay Jain.[1,2] *[1]Dept of Medicine (Renal), Washington Univ School of Medicine, St. Louis, MO; [2]Dept of Pathology and Immunology, Washington Univ School of Medicine, St. Louis, MO.*

Background: The mammalian collecting system is derived from the ureteric bud (UB) at the caudal end of the Wolffian duct (WD). The UB progenitors originate in the anterior intermediate mesoderm (IM) at E8.5 in mouse. The specific mechanisms of how these IM progenitors generate WD and UB or join the cloaca before UB budding is not clear. These processes when disrupted are major causes of congenital anomalies of kidney and urinary tract (CAKUT). Global RET receptor tyrosine kinase signaling is required for UB induction and for WD to reach the cloaca. We recently showed that signaling through RET-Y1015 docking tyrosine inhibits ectopic UBs from WD and regulates CND apoptosis for ureter maturation after UB budding.

Methods: Here we used genetically encoded reporters, lineage tracing and mice deficient in RET-Y1062 or RET-Y1015 docking tyrosine activity to better understand the early events priming the formation of the metanephric kidney and its union with the cloaca beginning from the IM progenitors and through WD morphogenesis during the pronephros and the mesonephros stages in mice.

Results: We discovered that RET-Y1062 signaling controls IM cell number, the survival of WD leader cells and their migration to reach cloaca. We discovered a novel cascade of spatio-temporally controlled trans-cloacal apoptosis before ureteric budding and branching morphogenesis during normal development. The cloacal apoptosis at the site of putative WD insertion did not occur in WDs that do not reach the cloaca and it was dependent on RET-Y1015 signaling in WD tip cells.

Conclusions: These novel findings decipher how progenitors in IM lay this plumbing unique to amniotes and convey novel insights in the pathogenesis of CAKUT and rebuilding a kidney ex vivo.

PI3K Pathway Potentiates Nephron Progenitor Cell (NPC) Renewal by Promoting Glycolysis

Zubaida R. Saifudeen, Jiao Liu, Francesca Edgington-Giordano. *Pediatrics, Tulane Univ School of Medicine, New Orleans, LA.*

Background: Energy metabolism pathways have emerged as critical regulators of stem/progenitor cell fate. We showed an age-dependent decrease in glycolysis in young (E13.5, predominantly self-renewing) vs old (P0, poised to differentiate) NPC. Glycolysis inhibition in organ culture promotes NPC differentiation. PI3K and Bmp/MAPK signaling pathways maintain NPC in a Cited1+/Six2+ self-renewing state. PI3K inhibition or Bmp/Smad activation promotes NPC differentiation. As the PI3K pathway is a positive regulator of glycolysis, we hypothesized that PI3K and Bmp/MAPK pathways converge on glycolysis to maintain NPC in a self-renewing state. To test our hypothesis we measured the glycolytic flux in isolated NPC after PI3K or Bmp/Smad pathway modulation.

Methods: E13.5 NPC were isolated by MACS, cultured in expansion (NPEM) or differentiation (DMEM) media ± treatments followed by glycolysis flux (extracellular acidification rate, ECAR) measurement at 18h or QPCR at 24h. Treatments: 10μM PI3K inhibitor LY294002, 100nM Akt inhibitor MK2206, Wnt activator CHIR 2μM or NPEM minus Smad inhibitor LDN to activate the Bmp/Smad pathway. Glycolysis enzyme PFKFB3 inhibitor YN1 20μM was used as a positive control.

Results: Compared to NPC/NPEM, NPC/DMEM showed 3-5 fold ECAR decrease, 10- and 12-fold decreased Cited1 and Six2 expression and 6-fold increased Wnt4 expression. In comparison, inhibition of PI3K or Akt, or Smad activation in NPC/NPEM was sufficient to cause a 2-4 fold ECAR decrease. Smad activation suppressed Cited1 and Six2 expression 8- and 1.8 fold, respectively, while Wnt4 expression increased 5.2 fold. YN1 reduced ECAR 2.4-fold without affecting Cited1, Six2 and Wnt4 expression. Inhibition of glycolysis in cultured E12.5 kidneys accelerated nephrogenesis. This effect was blocked by co-treatment with the canonical Wnt response inhibitor IWR1.

Conclusions: Glycolysis flux is a pivotal determinant of NPC fate. A high glycolysis flux is an essential intermediary of PI3K-mediated NPC self-renewal. Glycolysis inhibition promotes nephrogenesis via established β-catenin dependent pathways. Reduced glycolysis in itself is insufficient to activate NPC differentiation in the absence of β-catenin.

Molecular Predictors of Proteinuria and Glomerular Filtration Rate in Patients with Focal Segmental Glomerulosclerosis Undergoing a Kidney Transplant Lilian A. Otalora,[1] Efren Alejandro Chavez,[1] Daniel J. Watford,[1] Viji Nair,[2] Dayami Hernandez,[1] Lissett Tueros,[1] Mayrin Correa,[1] Matthias Kretzler,[2] Phillip Ruiz,[1] George William Burke,[1] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Family Drug Discovery Center and Div of Nephrology and Hypertension, Univ of Miami, Miami, FL; [2]Dept of Internal Medicine - Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: We recently demonstrated that sphingomyelinase phosphodiesterase acid like 3b (SMPDL3b) is a key modulator of podocyte architecture and function. Decreased SMPDL3b expression in post-reperfusion kidney biopsies predicted post-transplant proteinuria and occurred in association with foot process effacement in retrospective studies.

Methods: Thirty-nine patients with biopsy proven FSGS undergoing a kidney transplant were enrolled in a prospective clinical trial. Pre (PRE) and post-reperfusion (POST) kidney biopsies were collected. Histological analysis, immunohistochemistry (IHC) for SMPDL3b, microarray analyses of isolated glomeruli from PRE and POST biopsies, analysis by electron microscopy (EM) to assess foot process effacement (FPE) and correlation analyses with protein/creatinine ratios (PCR) and estimated Glomerular Filtration rate (eGFR) at 12 months (eGFR-12) after kidney transplantation were performed.

Results: We found a positive correlation between SMPDL3b positive glomerular cells and eGFR-12 ($p<0.05$) in POST biopsies. The degree of FPE positively correlated with PCR and with worsened eGFR-12 ($p<0.05$). Inflammation and lipid-related pathways were found to be significantly regulated in POST when compared to PRE biopsies. Transcript levels of several genes of these pathways significantly correlated with PCR or change in eGFR. In addition, the transcript levels of a subset of genes was found to correlate with the degree of FPE.

Conclusions: Decreases in SMPDL3B positive cells in POST biopsies is significantly associated with post-transplant loss of GFR in FSGS. FPE in POST biopsies is significantly associated with post transplant proteinuria and loss of renal function. Upregulation of certain genes associated with inflammation or lipid metabolism may predict the development of proteinuria or change in eGFR after transplantation.

FR-OR039

Molecular Significance of Peritubular Capillaritis in Early Transplant Kidney Biopsies of Donor-Specific Antibody Negative Patients Maria Ajaimy, Yi Bao, Enver Akalin. *Montefiore Transplant Center, Albert-Einstein College of Medicine.*

Background: Peritubular capillaritis (PTC) is a part of microvascular inflammation seen in antibody-mediated rejection (ABMR). However, it is observed in early transplant kidney biopsies with acute tubular necrosis (ATN) due to ischemia/reperfusion injury. We aimed to investigate intragraft gene expression of transplant kidney biopsies with PTC and ATN in kidney transplant recipients without donor-specific antibody (DSA).

Methods: We identified 19 early transplant kidney biopsies with ATN for gene expression profiling comparing to 12 normal transplant kidney biopsies (Group I). Biopsies with a diagnosis of acute or chronic rejection, recurrent or de novo glomerular disease, moderate to severe fibrosis or polyoma nephropathy were excluded. The gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: Among the 19 biopsies with ATN, 7 patients (Group 2) had isolated PTC and 12 patients (Group 3) had no PTC. Both groups had similar demographics characteristics in terms of age, race, and sex, type of transplant, previous history of transplantation or acute rejection, donor characteristics, panel reactive antibody levels and immunosuppressive treatment. There was no statistically significant difference in gene expression profiles between the 3 groups including injury and response (IRIT), interferon-gamma and rejection associated transcripts (GRIT), cytotoxic T cell (CAT), regulatory T cell (TREG), B-cell (BAT) natural killer cell transcripts (NKAT) Constitutive Macrophage (CMAT), donor-specific antibody (DSAST) and endothelial cell associated transcripts.

Pathogenesis Based Transcripts	G2 vs G1	G3 vs G1	G3 vs G2
IRIT	0.57	0.58	0.18
GRIT	0.28	0.21	0.42
CAT	0.40	0.17	0.28
TREG	0.21	0.11	0.42
BAT	0.80	0.63	0.42
NKAT	0.73	0.71	0.50
CMAT	0.47	0.10	0.13
DSAST	0.48	0.88	0.93
ENDAT	0.86	0.68	0.28

Conclusions: Isolated peritubular capillaritis could be seen in early transplant kidney biopsies with ATN and intragraft gene expression profiles do not reflect immune activity.

FR-OR040

Molecular Evidence of Chronic Cellular Rejection in C4d and Microvascular Inflammation Negative Transplant Glomerulopathy Michelle Lubetzky, Yi Bao, Enver Akalin. *Montefiore Center for Transplantation, Albert Einstein College of Medicine, Bronx, NY.*

Background: Transplant glomerulopathy (TGP) is frequently found in the setting of chronic antibody mediated rejection along with microvascular inflammation (MVI) (peritubular capillaritis+glomerulitis score > 1) and/or positive c4d staining. We assessed the molecular profiles of TGP in the absence of microvascular inflammation and C4d staining as compared to TGP with positive MVI and/or C4d.

Methods: 42 for-cause renal allograft biopsies were studied using Affymetrix HuGene 1.0 ST expression arrays; 12 with normal biopsy findings (G1), 17 with a diagnosis of TGP, C4d positive and/or a MVI score >1 (G2), and 13 with a diagnosis of TGP and C4d negative and MVI score </=1 and (G3).

Results: There was no difference in sex, race, or type of transplant between the 3 groups. More patients had DSA in TGP with MVI or C4d (G2), 82.4%, as compared with normal (G1), 8.3% $p<0.001$ and TGP without MVI or C4d (G3), 38.4%, $p=0.02$. When comparing TGP with MVI and/or C4d (G2) to TGP without MVI or C4d (G3) and normal (G1), pathogenesis based transcripts revealed increased expression of gamma interferon and rejection (GRIT) and DSA associated transcripts (DSAST) consistent with the response seen in antibody-mediated rejection. However, when TGP without MVI or C4d (G3) compared to normal (G1), increased expression of Cytotoxic T cell (CAT), T-regulatory cell (TREG), and B cell associated transcripts (BAT) were observed but not GRIT or DSAST. There was no difference in expression of natural killer cell and endothelial cell associated transcripts between the 3 groups.

Conclusions: Gene expression profiles of TGP in the absence of microvascular inflammation and C4d lack molecular features of antibody-mediated rejection but suggest chronic cellular rejection.

FR-OR041

Angiotensin II Type 1 Receptor Antibodies Are Associated with Elevated TNF-α, IL-1β, IL-8, and Poor Allograft Outcomes in Pediatric Renal Transplantation Meghan Pearl,[1] Jonathan Grotts,[1] Maura Rossetti,[1] Qiuheng Jennifer Zhang,[1] Miguel Fernando Palma Diaz,[1] Patricia L. Weng,[1] Elaine F. Reed,[1] Eileen W. Tsai.[1,3] *[1]Univ of California Los Angeles, Los Angeles, CA; [2]Dept of Pediatrics, Duke Univ, Durhan, NC.*

Background: We recently found that angiotensin II type 1 receptor antibody (AT_1R-Ab) was associated with vascular injury and allograft failure in pediatric renal transplant recipients. TNF-α, IL-1β, IL-8, IFN-γ, IL-17, and IL-6 have been associated with vascular inflammation and AT_1R activity, but their role in renal transplant patients with AT_1R-Ab is unknown. We aimed to determine the relationship between cytokine profiles and AT_1R-Ab on renal function and allograft survival in pediatric kidney transplant recipients.

Methods: 65 pediatric kidney transplant recipients were monitored for 2 years post-transplant from August 2005 to November 2014. AT_1R-Ab (ELISA test, > 17 units/ml positive) and TNF-α, IL-1β, IL-8, IFN-γ, IL-17, IL-6 (Luminex assay) were measured pre-transplant and post-transplant at 6 months (m), 12m, 24m and during episodes of rejection. Renal function (Schwartz equation), rejection (2013 Banff criteria), and allograft loss were monitored.

Results: AT_1R-Ab positivity in the first 2 years post-transplant was associated with higher TNF-α (0.067), IL-1β ($p=0.055$), and IL-8 (0.006) levels (Figure 1a) but not IFN-γ, IL-17, or IL-6 (data not shown). Renal function at last follow up was worse in

patients positive for AT_1R-Ab, even in patients without rejection (p=0.049, Figure 1b). Furthermore, AT_1R-Ab positive patients with TNF-α were more prone to allograft loss (p=0.058, Figure 1c).

Conclusions: In pediatric renal transplant patients, AT_1R-Ab is associated with poor allograft function, survival and higher IL-8, IL-1β, and TNF-α levels. AT_1R-Ab monitoring used in conjunction with these cytokines may identify those at risk for poor allograft outcomes.

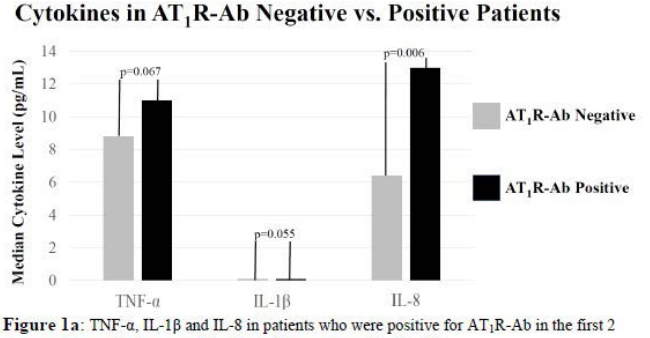

Figure 1a: TNF-α, IL-1β and IL-8 in patients who were positive for AT_1R-Ab in the first 2 years post-transplant compared to those who were negative (n=65).

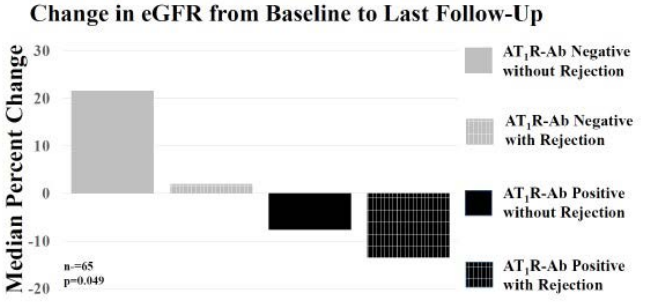

Figure 1b: Median percent change in estimated glomerular filtration rate (eGFR) between baseline and last follow up in patients with and without AT_1R-Ab with and without rejection.

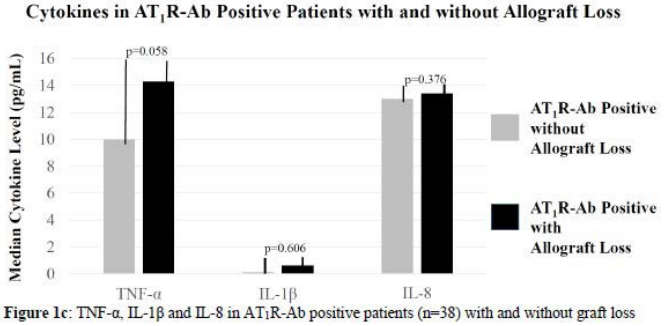

Figure 1c: TNF-α, IL-1β and IL-8 in AT_1R-Ab positive patients (n=38) with and without graft loss

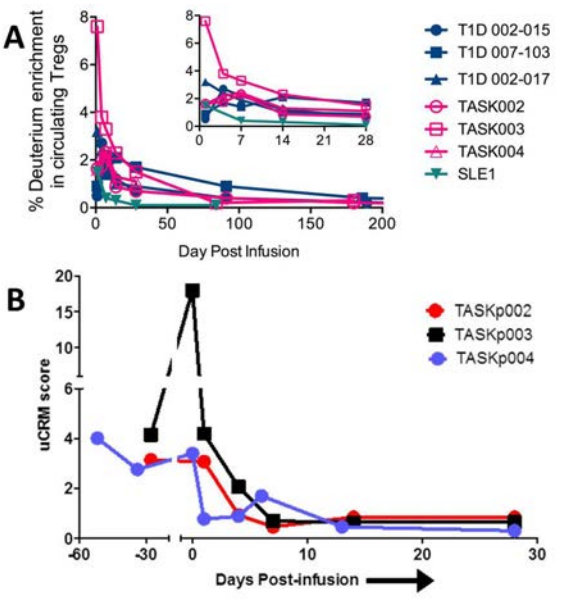
Polyclonal Treg Adoptive Therapy for Control of Subclinical Kidney Transplant Inflammation: TASK Pilot Trial

Sindhu Chandran, Qizhi Tang, Minnie Sarwal, Zoltan G. Laszik, Amy Putnam, Tara Sigdel, Erica Christen Tavares, Jeffrey A. Bluestone, Flavio Vincenti. *UCSF, CA.*

Background: Treg therapy can reverse established inflammation in animal models. We conducted a pilot safety & feasibility trial of Treg therapy for subclinical kidney transplant inflammation.

Methods: Peripheral blood $CD4^+CD25^+CD127^{lo/-}$ Tregs were isolated (FACS) & expanded *ex vivo* (anti-CD3/anti-CD28 stimulations/IL-2) in a deuterated glucose-containing medium. $320x10^6$ Tregs were infused into kidney transplant recipients with subclinical inflammation on 6-m protocol biopsy. %Deuterium enrichment by GC-MS allowed estimation of levels of infused (labeled) Tregs in circulation. Inflammation was assessed on follow-up biopsies using Banff scoring and leukocyte common antigen positive (LCA^+) cell density & in urine using common rejection module (uCRM), a biomarker of rejection.

Results: 3 patients on tac/MMF/prednisone received Treg infusions. Tregs expanded >100-fold (comparable to non-immunosuppressed patients) & met release criteria for infusion. One patient had transient lymphopenia (day 4-21) post-infusion. No infusion reactions or infections were seen & graft function remained stable. Infused Tregs peaked within week 1, up to 7.5% of all circulating Tregs. Decay of infused Tregs was similar to that seen in non-immunosuppressed patients (Fig 1A). Graft inflammation improved in two & uCRM scores improved in all cases (Table 1 & Fig 1B).



Subject	Kidney biopsy Banff score		LCA^+ cells/mm²	
	Baseline	2 weeks	Baseline	2 weeks
002	i1t1	i0t0	337	19
003	i0t1	i0t0	469	303
004	i1t1	i1t1	278	454

Conclusions: It is feasible to isolate & expand Tregs from transplanted patients. Infused Tregs were well tolerated & had pharmacokinetics similar to those in non-immunosuppressed patients. CTOT-21 will test the efficacy of Tregs for control of graft inflammation.

Funding: Private Foundation Support

FR-OR043

A Molecular Approach to Chronic Active T Cell Mediated Rejection

Layla Kamal, Michelle Lubetzky, Maria Ajaimy, Yi Bao, Graciela De Boccardo, Enver Akalin. *Montefiore Einstein Transplant Center, Bronx, NY.*

Background: Banff classification only recognizes chronic allograft arteriopathy as chronic active T cell mediated rejection. We hypothesized that T cell-mediated immune injury plays role in two conditions; donor-specific antibody (DSA) negative transplant glomerulopathy (TGP) and interstitial fibrosis and tubular atrophy (IFTA) with inflammation (i> 0). We investigated gene expression profiles of those biopsies compared to biopsies with antibody-mediated rejection (ABMR) and to biopsies with non-specific IFTA and no inflammation (i=0).

Methods: A total of 62 for-cause renal allograft biopsies were studied using Affymetrix HuGene 1.0 ST expression arrays in the following groups; G1: normal transplant kidney biopsy, n=12, G2: ABMR (including TGP with DSA), n=24, G3: TGP without DSA or IFTA with i score > 0 and G4: IFTA without inflammation (i=0), n=10.

Results: There was no difference in sex, race, or type of transplant between the 4 groups. G2 biopsies showed significantly increased expression of gamma-interferon and rejection associated (GRIT), Cytotoxic T cell (CAT), regulatory T cell (TREG), constitutive macrophage (CMAT), and DSA associated gene transcripts (DSAST) when compared to G1 biopsies. While there were no statistically significant differences in expression of any pathogenesis based transcripts studied in G4 compared to G1 biopsies, G3 biopsies showed increased intragraft expression of CAT and TREG, suggesting T cell mediated immune mechanisms in its pathogenesis.

Pathogenesis Based Transcripts	G2 VS G1	G3 VS G1	G4 VS G1
GRIT	0.055	0.17	0.33
CAT	0.005	0.017	0.13
TREG	0.025	0.04	0.14
BAT	0.15	0.10	0.13
NKAT	0.19	0.24	0.34
CMAT	0.04	0.08	0.24
DSAST	0.005	0.35	0.39
ENDAT	0.35	0.57	0.63

Conclusions: DSA negative TGP and IFTA with inflammation biopsies have a unique molecular signature with significant expression of cytotoxic and regulatory T cells. This suggests that DSA negative TGP and IFTA with inflammation could be classified as chronic T cell mediated rejection.

FR-OR044

Identification of Urinary mRNA Expression for Diagnosing Acute Rejection by Meta-Analysis of Gene Expression in Kidney Transplantation

Sang-Ho Lee,[1] Yu Ho Lee,[1] Haena Moon,[1] Yang Gyun Kim,[1] Kyung-Hwan Jeong,[1] Tae Won Lee,[1] Chun-Gyoo Ihm,[1] So-Young Lee,[2] Dong Ho Yang.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Kyung Hee Univ, Seoul, Korea; [2]Div of Nephrology, Dept of Internal Medicine, CHA Bundang Medical Center, Seongnam, Korea.*

Background: microarray data is a powerful source for identifying potential targets to diagnose acute rejection (AR) in kidney transplanted patients (KTPs). We performed a meta-analysis of gene expression profiles of stable graft function (STA) and AR from biopsy tissues in kidney transplantation and investigated expressions of candidate genes selected from meta-analysis in urine of KTPs.

Methods: The microarray data were obtained from the public repositories. Meta-analysis were conducted by 664 STA and 272 AR patients, with a total of 954 samples. 14 candidate genes selected after meta-analysis as biomarker of AR in urinary cells of KTPs. 120 urine samples (23 stable, 34 acute cellular rejection (ACR), and 17 acute antibody-mediated rejection (AMR), 23 long-term graft survival (LGS), 17 chronic antibody-mediated rejection (CAMR), and 6 tolerance (Tol)) were collected after kidney transplantation. The expression levels of transcripts were determined in urinary cells using real-time PCR.

Results: 14 candidate genes were selected by meta-analysis of gene expression for AR diagnosis, including CXCL9, PSMB9, INPP5D, LCK, ISG, RUNX3, CD3ε, IP-10, Tim-3, Foxp3, IDO1, PTPRC and C1QB. We determined expression levels of mRNA isolated from urinary cells with 14 candidates. 3 (Tim-3, CXCL9, and LCK mRNA) among them were significantly elevated in patients with acute cellular rejection, while Tim-3 was significantly higher expressed and ISG20 and OX40 were significantly decreased in patients with acute antibody-mediated rejection. In addition, the real change of CXCL9 mRNA level in biopsy tissue was confirmed by *in situ* hybridization. In ACR prediction model composed of 3 genes clearly discriminated the patients with acute cellular rejection from STA.

Conclusions: We developed ACR and AMR specific urine mRNA panel composed of 3 genes. We suggested that urinary mRNA is promising as a sensitive, non-invasive means to monitor kidney allografts.

FR-OR045

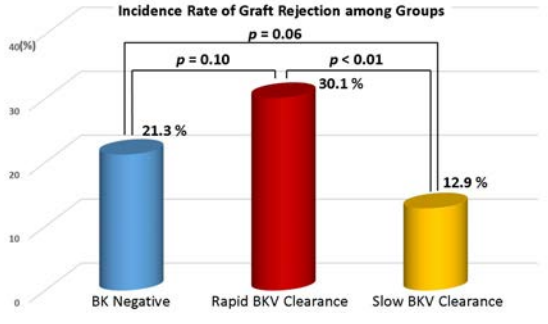
The Association between Rapid BK Viremia Clearance and Graft Rejection in Kidney and Kidney/Pancreas Transplant Recipients

Masaaki Yamada,[1] Nissreen Elfadawy,[2] Richard A. Fatica.[1] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Internal Medicine, Univ Hospital, Cleveland, OH; [3]Urology, Cleveland Clinic, Cleveland, OH.*

Background: BK polyoma virus reactivation is a serious complication after transplantation with no definitive treatment except reduction of immunosuppression. Patients are at risk of graft rejection after BK viremia (BKV) and reduction of immunosuppression. There is no published data on the association between BKV clearance rate and incidence of graft rejection. The objective of this study is to assess the relation between the rate of BKV clearance and graft rejection after kidney transplantation.

Methods: We screened 595 kidney transplants (2007-2011) for BKV by PCR in blood. One hundred and sixty two out of total 595 patients (27.2 %) developed BKV any time post-transplant. We classified BKV patients into 2 groups based on the duration from the time of peak to 50% reduction of BKV load as follows; A) rapid BKV clearance group (duration within 21 days) and B) slow clearance group (duration more than 21 days). The incidence of graft rejection after BKV was assessed among 2 BKV groups and BK virus negative group. Acute rejection was defined as Banff borderline or greater changes on either surveillance or for cause post-transplant biopsy.

Results: The rapid BKV clearance group was associated with higher incidence of allograft rejection after BKV (30.1 %) compared to the slow BKV clearance group (12.9 %), p <0.01 (Pearson's Chi-Square test). The rate of allograft rejection in BK virus negative group was 21.3 % and no statistical significance was observed in comparison to BKV groups.



Conclusions: Rapid BKV clearance is associated with higher rates of graft rejection after BKV, perhaps due to reconstitution of native immunity.

FR-OR046

20-Year Trends in Clinical Outcomes of Kidney Transplantation

William Irish,[1] Akinlolu O. Ojo,[2] Neetu Agashivala,[3] Larry M. Gache.[1] *[1]CTI Clinical Trial and Consulting Services, Inc.; [2]Univ of Arizona Health Sciences; [3]Novartis Pharmaceuticals Corporation.*

Background: The short term outcomes of KTx are excellent, but the long term outcomes have improved minimally despite advances in immunosuppression (IS). The purpose of this study was to examine historical trends using data from the United States Renal Data System (USRDS).

Methods: Adult primary Medicare beneficiaries in USRDS who received a kidney-only transplant from 1992-2012 and received pre-transplant dialysis were eligible for inclusion. Clinical outcomes included all-cause graft failure and death-censored graft loss. Trends were evaluated using transplant periods (eras 1-5): 1992-1996, 1997-2002, 2003-2006, 2007-2009, and 2010-2012. Eras were chosen to reflect major KTx milestones: tacrolimus approval (1997), organ allocation policy changes (2002), center-specific program evaluation initiative (2007), and the KDIGO guidelines (2009).

Results: 134,679 patients (77%/23% deceased [DD]/living donor [LD]) were eligible: 21%, 27%, 21%, 16% and 16% in ERAs 1, 2, 3, 4, and 5. Across ERAs**,** donors were older, prevalence of hypertension and terminal SCr>1.5 mg/dL increased, donation after cardiac death and extended criteria donor organs increased. Across ERAs, recipients were older, more often had diabetes, had higher pre-transplant Charlson Comorbidity Index scores, had more 6-antigen mismatches and were more often African American. Maintenance IS shifted from cyclosporine- to tacrolimus-based regimens with decreased use of corticosteroids. Graft survival trends are shown. Similar trends were observed for DD and LD. Death-censored graft loss at 3-years post-KTx was reduced by ~60% in ERA 5 compared to ERA 1 for DD and LD.

Conclusions: The net benefit of KTx has improved significantly across transplant eras despite worsening donor/recipient risk profiles.

Does Cognitive Function Predict Waitlisting for Kidney Transplant?

Saleem M. Al Mawed, V. Shane Pankratz, Yue-Harn Ng, Eduardo A. Alas, Christos Argyropoulos, Saeed Kamran Shaffi, Mark L. Unruh, Antonia Harford. *Dept of Internal Medicine, Div of Nephrology, Univ of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Cognitive dysfunction is common in patients with advanced kidney disease. Being cognitively intact is vital for post-transplant care and medical compliance. Few studies have examined cognitive function in pre-kidney transplant patients. We hypothesized that lower scores on the Montreal Cognitive Assessment (MoCA) would be associated with a decreased rate of transplant (TXP) listing.

Methods: MoCA was performed as a part of routine pre-kidney transplant evaluation and at annual follow-up. Demographic, comorbidity, and clinical parameters were collected on all patients. Different MoCA versions were utilized as appropriate. Scoring of the MoCA was performed as recommended by the test developers. Cox proportional hazards models were used to assess associations between baseline MoCA and the subsequent occurrence of TXP listing. Linear mixed effects models were used to test for longitudinal changes in MoCA.

Results: 329 subjects had at least 1 MoCA and 183 had 2 during a 28 month period. The baseline mean composite MoCA score was 24.3±4.2. Hispanics, Native Americans, advanced age, and ESRD secondary to diabetes were associated with lower MoCA scores. Conversely, higher education level, peritoneal dialysis, and non-Hispanic White ethnicity were associated with higher MoCA scores. In patients who underwent 2 MoCA tests (n=183), the mean score increased by 1.2 from the first to the second test (95% CI: 0.8 – 1.7, p<0.001). Among patients not already waitlisted for TXP, those with baseline composite MoCA scores below 26 had a hazard ratio for subsequent listing of 0.44 (95% CI: 0.24-0.82, p=0.01), compared to those with higher scores.

Conclusions: This study demonstrates that patients evaluated for kidney transplant suffer from mild cognitive function impairment compared to the general population. Lower MoCA scores were associated with decreased waitlisting for renal transplant. MoCA scores were stable over time among patients evaluated for kidney transplant. Further studies are warranted to define cognitive changes in patients waiting for renal transplant.

FR-OR048

The lncRNA Tug1 Interacts Directly with PGC-1α to Regulate Mitochondrial Bioenergetics in Diabetic Nephropathy Jianyin Long,[1] Shawn S. Badal,[1] Zengchun Ye,[2] Yin Wang,[1] Farhad R. Danesh.[1] *[1]Section of Nephrology, The Univ of Texas, MD Anderson Cancer Center, Houston, TX; [2]Nephrology, 3rd Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guandong, China.*

Background: The regulatory roles of long noncoding RNAs (lncRNAs) on transcriptional coactivators are still largely unknown. Here we show that the peroxisome proliferator-activated receptor γ (PPARγ) coactivator α (PGC-1α) is functionally regulated by a lncRNA, and describe a previously unknown regulatory role for this lncRNA in the regulation of podocyte mitochondrial function.

Methods: Using experimental models of diabetic nephropathy (DN), we performed unbiased RNA-Seq profiling of kidney glomeruli, and identified lncRNA *Tug1* (Taurine upregulated gene 1) as a differentially expressed lncRNA in the diabetic milieu. To test the contribution of Tug1 to the progression of DN, we generated podocyte-specific transgenic mice to overexpress *Tug1* within the diabetic millieu of Type 2 diabetic (*db/db*) mice. Mechanistically, we performed genome wide transcriptome studies, lncRNA genome wide DNA binding profiling (ChiRP-Seq) and biochemical studies to investigate novel targets/pathways under the control of *Tug1* RNA.

Results: Podocyte-specificoverexpression of *Tug1* in diabetic (*db/db*) mice improved albuminuria levels, reduced mesangial matrix expansion, improved podocyte foot process effacement and prevented podocyte loss as quantified by WT1 positive podocytes. Unexpectedly, we found that podocyte-specific overexpression of *Tug1* in diabetic mice rescued expression of PGC-1α mRNA, improved mitochondrial copy number levels and mitochondrial bioenergetics. Mechanistically, we identified a *Tug1* Binding Element (TBE) upstream of the PGC-1α gene promoter. We demonstrate that the interaction of *Tug1* with TBE serves as a genomic tether, whereby *Tug1* acts as a scaffold to recruit PGC-1α protein to its own promoter, triggering its transcription.

Conclusions: We propose that a novel, physical interaction between PGC-1α protein and *Tug1* RNA contributes to modulating mitochondrial bioenergetics in podocytes via regulation of PGC-1α gene expression.

FXR-TGR5 Agonists Prevent the Development of Diabetic Kidney Disease in Part by Increasing Mitochondrial Biogenesis and Function Xiaoxin Wang, Yuhuan Luo, Evgenia Dobrinskikh, Dong Wang, Moshe Levi. *Univ of Colorado Denver.*

Background: Diabetes mellitus continues to be the leading cause of kidney disease. Our purpose is to determine the role of the nuclear receptor farnesoid X receptor (FXR) and G protein coupled receptor TGR5 in prevention and treatment of diabetic kidney disease.

Methods: We have treated two distinct models of rodent diabetic nephropathy i) DBA/2J mice fed a western diet and made diabetic with streptozotocin and ii) db-db mice with a) FXR agonist INT-747 at 30 mg/kg/day, or b) TGR5 agonist INT-777 at 30 mg/kg/day, or c) FXR-TGR5 dual agonist INT-767 at 30 mg/kg/day, from 3 months of age until 6 months of age.

Results: All 3 agonists had no effects on the hyperglycemia but had very marked and significant effects to decrease urine albumin excretion, glomerular area and mesangial expansion, podocyte loss, inflammation, glomerulosclerosis and tubulointerstitial fibrosis (determined by Mason's trichrome and Picrosirius Red stains, immunostaining for extracellular matrix proteins, label free imaging with Two Photon Excitation and Second Harmonic Generation Microscopy, and expression of profibrotic growth factors). Further mechanistic studies indicated that these agonists also stimulate the mitochondrial transcription factors Nrf1 and Tfam, as well as AMPK, PGC-1α, Sirtuin 1, Sirtuin 3 and the nuclear receptor estrogen related receptor alpha (ERRα), major regulators of mitochondrial biogenesis and function. In fact there were increases in long-chain 3-hydroxy acyl-coenzyme A dehydrogenase (LCAD) and carnitine palmitoyltransferase IA (CPT1A) which are mediators of mitochondrial fatty acid β oxidation, resulting in decreased lipid accumulation in the kidney (as determined by lipid stains and lipid composition analysis), and mitochondrial superoxide dismutase 2 (SOD2) which is an antioxidant resulting in decreased oxidative stress in the kidney (as determined by decreases in oxidized proteins and lipids).

Conclusions: FXR and TGR5 agonists have renal protective effects independent of their effects on systemic glucose metabolism. They have a great potential for prevention and treatment of diabetic kidney disease by enhancing mitochondrial biogenesis and mitochondrial function.

Enhanced Real-Time In Vivo Mitochondrial Redox in Diabetic Nephropathy Daniel L. Galvan,[1] Shawn S. Badal,[1] Paul T. Schumacker,[2] Farhad R. Danesh.[1] *[1]Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston, TX; [2]Dept of Pediatrics, Northwestern Univ, Chicago, IL.*

Background: The role of mitochondrial reactive oxygen species (mtROS) in the pathogenesis of diabetic nephropathy (DN) remains controversial. A major gap in further addressing the role of mtROS in DN is the real-time measurement of ROS inherent to the mitochondria *in vivo*.

Methods: To monitor mtROS *in vivo*, we utilized a recently described mouse model in which a CMV-driven roGFP redox sensor was specifically expressed in the mitochondrial matrix (mts). Transgenic CMV-mts-roGFP mice were intercrossed with mice harboring the *Lepr$^{db/+}$* mutation to generate a type 2 diabetic mouse model with a genetic redox biosensor(*db/db$^{TgCMV\text{-}mts\text{-}roGFP)}$*, hereafter referred to as *db/db^{roGFP}*). We employed excitation of the roGFP biosensor at the prescribed laser wavelengths for the oxidized (720nm) and reduced (860nm) forms. Emission spectra were collected and ratios of the oxidized to reduced signals determined.

Results: Using two-photon imaging, mitochondrial redox state was assessed in the kidneys of experimental models of diabetes of 16-weeks old diabetic (*db/db^{roGFP}*) and control (*db/m^{roGFP}*) mice *in vivo*. Live animal imaging of these mice revealed increased mtROS in kidneys of diabetic mice (~5-fold ratiometric increase). Pre-treatment with mitoTEMPO (10mg/kg for 3days) restored mtROS to normal levels in diabetic mice. Podocytes isolated from diabetic animals revealed reduced complex 1 activity relative to controls suggesting that mtROS might be generated by problems with electron transport at its entry point. Ectopic expression of yeast NADH-dehydrogenase (Ndi1), a mammalian complex 1 homolog, successfully prevented high-glucose induced increases in mtROS.

Conclusions: We provide evidence that diabetic animals have increased levels of ROS within the mitochondrial matrix of the kidney *in vivo*. These increases in mtROS could be ameliorated by quenching of the mtROS, as well as bypassing electron transport at complex 1.

Pro-Oxidant Enzyme Nox5 Accelerates Renal Damage in Experimental Diabetes Jay Chandra Jha,[1] Claudine Banal,[1] Stephen P. Gray,[1] Harald H. Schmidt,[2] Mark E. Cooper,[1] Rhian Touyz,[3] Chris R. Kennedy,[4] Karin Jandeleit-Dahm.[1] *[1]Diabetes Complications, Baker IDI Heart and Diabetes Inst, Melbourne, Victoria, Australia; [2]Dept of Pharmacology, Maastricht Univ, Maastricht, Netherlands; [3]Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; [4]Dept of Medicine, Ottawa Hospital Research Inst, Ottawa, Canada.*

Background: Reactive oxygen species (ROS) play crucial role in diabetic nephropathy (DN).The more recently discovered pro-oxidant enzyme, Nox5 could play a role in DN. Nox5 is present in humans but not in rodents. Thus, there is a paucity of information about Nox5 in animal models of DN. We examined the role of Nox5 in a model of human inducible Nox5 transgenic mice expressing Nox5 selectively in vascular smooth muscle cells including the mesangial cells (SM22+Nox5+) in the setting of diabetes. In vitro, we examined the effect of Nox5 silencing in human renal cells.

Methods: SM22+Nox5- and SM22+Nox5+ transgenic mice were rendered diabetic via streptozotocin injections and followed for 10 and 15 weeks. Renal function including albuminuria and creatinine clearance, structural damage as well as gene and protein expression of markers of inflammation, fibrosis and oxidative stress were assessed. In vitro, Nox5 was silenced in human mesangial cells or in podocytes and exposed to high glucose and TGF-β for the measurement of ROS level and molecular analysis.

Results: Diabetes induced increase in albuminuria in Nox5 negative mice was further increased by 20% in Nox5 positive diabetic mice. In addition, a further increase in glomerulosclerosis and markers of fibrosis (fibronectin), inflammation (MCP-1 and F4/80) and oxidative stress (nitrotyrosine and DHE) were found in diabetic SM22+Nox5+ mice when compared to diabetic SM22+Nox5- mice. Creatinine clearance was unchanged in both group of diabetic mice. Moreover, silencing of Nox5 in human renal cells resulted in reduced ROS production and down-regulation of profibrotic and proinflammatory markers that are implicated in DN.

Conclusions: Collectively, these findings suggest that Nox5 derived ROS accelerates renal injury in diabetes and provide proof of principle for the innovation of a new renoprotective agent in diabetes.

FR-OR052

Myo-Inositol Oxygenase (MIOX) Accelerates Renal Tubular Injury via Oxidative Stress Utilizing Glucuronate-Xylulose (GX) Pathway in Experimental Diabetes Isha Sharma, Yashpal S. Kanwar. *Dept of Pathology, Northwestern Univ, Chicago, IL.*

Background: MIOX is exclusively expressed in renal proximal tubules. Subsequent to the distal events of glycolytic pathway it channels myo-inositol into glucuronic acid via G-X pathway. During the various steps of this pathway there are perturbations in the ratios of NADPH:NADP and NAD:NADP, as a result there is an excessive generation of reactive oxygen species (ROS) via G-X pathway.

Methods: A diabetic state was induced with the administration of streptozotocin in wild type (WT), MIOX transgenic (TG) and MIOX$^{-/-}$ (KO) mice to assess the degree of MIOX-induced oxidant stress that influences the outcome of tubular injury among these strains. The animals with blood glucose >250 mg/dl were evaluated and sacrificed 8 weeks after induction of diabetes.

Results: The MIOX expression was highly accentuated in diabetic MIOX TG mice compared to WT and normoglycemic untreated or KO mice. Serum creatinine and urea levels were found to be significantly elevated in MIOX TG mice. The proximal tubules had relatively more cytolysis and apoptosis with thickened basement membranes and increased interstitial fibronectin and collagen I staining in TG mice compared WT and KO mice. The cellular redox in the kidney tissues was relatively more adversely affected in TG mice compared to other strains of mice, as highlighted by increased DHE staining. Also, a markedly decreased in reduced glutathione (GSH) levels were noted TG mice. Analyses

of various signaling events revealed an increased activation of p-PDK1, p-PKC and p-Akt in kidneys of MIOX TG mice. Likewise expression of TGF-β and Smad4 along with HIF-1alpha was relatively high in TG mice. All these parameters were minimally affected in MIOX KO mice. In vitro, HK-2 cells treated with MIOX-siRNA reduced the expression of all the above indicated signaling molecules and the ROS generation, as assessed by FACS analysis and DHE staining.

Conclusions: These data indicate that MIOX is another one of the newly discovered mediator in STZ induced tubular injury via G-X with accentuated generation of ROS in diabetic tubulopathy.

FR-OR053

Stabilization of Endogenous Nrf2 by Minocycline Protects against Nlrp3-Inflammasome Induced Diabetic Nephropathy Fabian Bock,[1] Khurrum Shahzad,[1] Moh'd Mohanad Ahmad Al-Dabet,[1] Ihsan Khan Gadi,[1] Shrey Kohli,[1] Berend Heinrich Isermann.[1] *[1]Univ Klinikum Magdeburg, Inst of Clinical Chemistery und Pathobiochemistry, Magdeburg, Germany; [2]Univ of Heidelberg, Dept of Internal Medicine I and Clinical Chemistry, Heidelberg, Germany.*

Background: While a plethora of studies support a therapeutic benefit of Nrf2 activation and ROS inhibition in diabetic nephropathy, the Nrf2 activator bardoxolone failed in clinical studies in type 2 diabetic patients due to side effects. Intriguingly, the tetracycline antibiotic minocycline, which has been in clinical use for decades and limits mitochondrial dysfunction and apoptosis, has been shown to convey anti-inflammatory effects in diabetic patients. As the mechanism underlying minocycline's nephroprotection remains unknown we speculated that minocycline reduces renal ROS generation and inflammation, potentially through a Nrf2 dependent mechanism.

Methods: The effect of minocycline on inflammasome activation and oxidative stress was studied in murine models of diabetic nephropathy, db/db mice and the STZ diabetes model. We assessed albuminuria, glomerular extracellular matrix accumulation as well as expression of Nrf2 and inflammasome regulators. Nrf2-ubiquitination was analyzed by immunoprecipitation.

Results: Here we show that minocycline protects against dNP in mouse models of type 1 and type 2 diabetes, while caspase-3,-6,-7,-8 and -10 inhibition is insufficient, indicating a function of minocycline independent of apoptosis inhibition. Minocycline stabilizes endogenous Nrf2 in kidneys of db/db mice, thus dampening ROS-induced inflammasome activation in the kidney. Indeed, minocycline exerts antioxidant effects *in vitro* and *in vivo*, reducing glomerular markers of oxidative stress. Minocycline reduces ubiquitination of the redox-sensitive transcription factor Nrf2 and increases its protein levels. Accordingly, minocycline mediated Nlrp3 inflammasome inhibition and amelioration of dNP are abolished in diabetic $Nrf2^{-/-}$ mice.

Conclusions: Taken together, we uncover a new function of minocycline, which stabilizes the redox-sensitive transcription factor Nrf2, thus protecting from dNP.

FR-OR054

Renal Tubular ACE Affects Microalbuminuria in Early Diabetic Nephropathy Masahiro Eriguchi,[1] Jorge F. Giani,[1] Mercury Y. Lin,[2] Tuantuan Zhao,[1] Zakir Khan,[1] Ellen A. Bernstein,[1] Xiao Shen,[1] Romer Andres Gonzalez-Villalobos,[3] Kenneth E. Bernstein.[1] *[1]Depts of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA; [2]Pathology & Lab Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; [3]CVMET RU, Cedars-Sinai Medical Center, Groton/Cambridge, MA.*

Background: ACE inhibitors are mainstay treatment for diabetic nephropathy. Studies demonstrated that the intrarenal renin-angiotensin system plays a key role in the progression of diabetic nephropathy. However, the specific contribution of renal tubular epithelial ACE vs. other sources of ACE to diabetic nephropathy remains unknown.

Methods: To study this, we used two mouse models: it-ACE mice that specifically lack ACE in renal tubular epithelial cells and ACE 3/9 in which renal ACE is only expressed in renal tubular cells. Total renal ACE in it-ACE and ACE 3/9 mice is 48% and 83% of WT mice; GFR is equivalent to WT mice. Diabetic nephropathy was induced with streptozotocin. Glomerular filtration rate (GFR), albuminuria and urinary KIM-1, a specific marker for tubular injury, were monitored. All data are presented as % of untreated WT control mice.

Results: Total renal ACE activity was decreased in both diabetic WT and diabetic ACE 3/9 mice (54±15% and 56±7%, $p<0.001$, n=4 to 6). No changes in total renal ACE were observed between diabetic and non-diabetic it-ACE mice (46±7% and 48±6%, p=NS). After 3 months of diabetes, both WT and it-ACE mice have increased GFR (142±11% and 147±7%, $p<0.05$). In contrast, ACE 3/9 did not increase GFR (107±6%). After 4 months of diabetes, microalbuminuria and urinary KIM-1 levels were significantly higher in both diabetic WT mice (220±17% and 498±94%) and ACE 3/9 mice (292±29% and 534±147%) compared to untreated WT mice. In diabetic it-ACE mice, despite glomerular hyperfiltration, depletion of renal tubular ACE reduced both microalbuminuria and urinary KIM-1 levels (122±7% and 236±38%) compared to diabetic WT mice.

Conclusions: This study indicates that in early diabetic nephropathy, tubulointerstital injury is associated with renal tubular ACE while hyperfiltration is associated with endothelial ACE. Finally, renal tubular epithelial ACE, and not endothelial ACE, is associated with microalbumnuria.

FR-OR055

A Potent Pan-AMPK Activator Improves Renal Structure and Function in the ZSF-1 Rat Model of Diabetic Nephropathy Maarten Hoek, Xiaoyan Zhou, Robin E. Haimbach, Eric Muise, Li-Jun Ma, Olga Price, Gail M. Forrest, Kithsiri Herath, Emanuel Zycband, Zadok Ruben, Yonghua Zhu, Shirly Pinto, David E. Kelley. *Merck Research Labs, Kenilworth, NJ.*

Background: Defects in mitochondrial function and renal metabolism have been hypothesized to play a causal role in the pathophysiology of diabetic nephropathy. Non-specific AMPK activators such as AICAR improve renal function in multiple animal models, which has been attributed to the ability of these agents to improve the metabolic state of the kidney. The goal of these studies was to determine whether a potent Merck pan-AMPK activator would be beneficial in animal models of diabetic nephropathy.

Methods: An intervention study was performed in the ZSF-1 rat in which the Merck AMPK activator (Cmpd A, potency 6-60 nM, dosed at 1 and 10 mpk in feed) was compared to enalapril (10 mpk in feed). Treatment was initiated at 20 weeks, a timepoint at which renal damage was evident, and continued for another 28 weeks. Cell based studies were performed in primary human renal proximal tubule cells to assess the direct protective effects of Cmpd A in the context of a lipotoxic challenge or a challenge with TGF-β.

Results: The 10 mpk dose of Cmpd A led to improvements in uPCR (48.6 vs 18.2 mg/mg), GFR (430 vs 779 ml/min/gm kid weight) and renal histology scores compared to vehicle. These effects were comparable to enalapril treatment. Treatment with Cmpd A was accompanied by decreases in plasma glucose, body weight, and plasma lipids. Distinct renal RNA expression profiles were noted between the enalapril and Cmpd A treatments, with the endothelin axis and oxidative phosphorylation more affected by Cmpd A, suggesting that pathways affected by these treatments were at least partially orthogonal. Cmpd A protected primary human proximal tubule cells from lipotoxic stress and attenuated collagen induction in response to TGF-β.

Conclusions: Treatment with a specific AMPK activator resulted in substantial improvements in renal function in the ZSF-1 model of diabetic nephropathy. Though the effects may be secondary to systemic metabolic improvement, cell based assays and RNAseq data suggest that some of the effects might be attributed to direct action on the kidney.

FR-OR056

AdipoRon Prevents Diabetic Nephropathy through Improvement of Lipid Metabolism in db/db Mice Yaeni Kim, Sun Ryoung Choi, Ji Hee Lim, Min Young Kim, Seon Deok Hwang, Yu Ah Hong, Yong-Soo Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Adiponectin, one of the numerous adipokines produced by adipose tissue, interplays with others to exert the milieu of metabolic syndrome. Orally active synthetic molecule AdipoR agonist, AdipoRon binds to both AdipoR1 and AdipoR2 and ameliorates diabetic nephropathy (DN) in type 2 diabetes. The connection between adiponectin and lipid metabolism is apparent and the ceramide subspecies of shingolipids have been related to inflammation, cell death, and insulin resistance, so called lipotoxicity. We investigated the possible role of AdipoRon in renal physiology in the view of prevention and development of DN in diabetic mice.

Methods: Male *db/db* and *db/m* mice were fed either a regular chow or a diet containing AdipoRon (30 mg/kg/day p.o. for 4 weeks from 17 to 20 weeks of age). Serum, urine and renal tissue were analyzed for changes in metabolic parameters, relevant molecular levels and their association with regard to renal structure.

Results: AdipoRon fed *db/db* mice showed decreased amount of albuminuria and lipid accumulation in the kidney with no significant changes in the levels of serum adiponectin, glucose, creatinine, and body weight. Increased expressions of AdipoR1 and AdipoR2 in the renal cortex were observed in *db/db* mice with AdipoRon administration. Consistent up-regulations of p-AMPK, PPAR-α, p-Akt, p-ACC and p-eNOS and down-regulations of protein phosphatase 2A, SREBP-1c and iNOS levels were shown, which were related to a decrease in ceramide to sphingosine-1 phosphate ratio. In glomerular endothelial cells (GECs), AdipoRon treatment reduced lipotoxicity via attenuating palmitate-induced oxidative stress and apoptosis.

Conclusions: AdipoRon prevents lipotoxicity in the kidney as represented by decreased ceramide versus sphingosines ratio. The protective role of AdipoRon against the development of DN seems to occur through a direct action on the kidney independently of systemic effects of adiponectin. Its reduction of oxidative stress and apoptosis provides protection against renal damage via ameliorating endothelial dysfunction in DN.

FR-OR057

Fatty Kidney by Clinical 1H-Magnetic Resonance Spectroscopy: A Dietary Intervention and Validation Study in Porcine Kidneys Jacqueline Jonker,[1] Paul de Heer,[2] Evelien van Rossenberg,[1] Celine Klessens,[3] Hans J. Baelde,[3] Sietse Jan Koopmans,[4] Paulo G. Coelho,[6] Ingeborg M. Bajema,[3] Trea C.M. Streefland,[5] Ilona Alexandra Dekkers,[2] Ton J. Rabelink,[1] Patrick Rensen,[5] Hildo Lamb,[2] Aiko P.J. De Vries.[1] *[1]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Radiology, Leiden Univ Medical Center, Leiden, Netherlands; [3]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [4]Veterinary Medicine, Wageningen Univ, Wageningen, Netherlands; [5]Endocrinology, Leiden Univ Medical Center, Leiden, Netherlands; [6]New York Univ.*

Background: Renal lipid accumulation has been experimentally linked to obesity and type-2 diabetic nephropathy. Human translation has been hampered by lack of noninvasive biomarkers. ^{1}H-MR spectroscopy is an established technique to study lipids in liver, muscle and heart and feasibility was shown for kidney, but few protocols underwent validation. We assessed agreement between our ^{1}H-MRS protocol and enzymatically determined lipids in porcine kidneys.

Methods: Renal lipid content was measured in 27 porcine kidneys by ^{1}H-MRS on a 7T scanner, of which 15 mini-pigs were randomized to either 9-months control diet, cafeteria diet (CAF), or CAF with low-dose streptozotocin (CAF-S) to induce obesity and insulin-independent diabetes, with the remainder being slaughter pigs. Renal biopsies were taken at the same location and lipids were measured enzymatically.

Results: Bland-Altman analysis of normalised data of all kidneys showed good agreement with bias of 0.0 (limits of agreement -0.8; 0.8) for ^{1}H-MRS and enzymatically assessed lipid. After 9-month diet, renal triglyceride (TG) content was higher in CAF-S group (134.0 (44.7-229.8) nmol/mg protein) compared to the control group (36.0 (30.6-52.3) nmol/mg protein, P=0.02). Renal TG content was not significantly different between the control and cafeteria diet group. Notably, renal and hepatic TG showed significant positive correlation (n=14, r=0.97, P<0.001).

Conclusions: Our clinical ^{1}H-MRS protocol agreed well with gold-standard assessment of lipids in porcine kidneys, which correlated closely with hepatic lipid. This offers unique opportunity to investigate the pathophysiology of fatty kidney clinically in obesity and diabetic nephropathy.

FR-OR058

Macrophage-Derived Wnts Contribute to Kidney Fibrosis after Injury Yuan Tian, Dong Zhou, Haiyan Fu, Youhua Liu. *Dept of Pathology, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Activation of Wnt/*β*-catenin signaling plays a pivotal role in the pathogenesis of many forms of chronic kidney diseases (CKD). Wnt ligands are induced in a wide variety of kidney resident cells as well as infiltrated cells including macrophages. However, the relative contribution of Wnts from different sources in CKD progression is poorly understood. To address this issue, we utilized genetic approach by blocking Wnt secretion via conditionally knockout of Wntless (Wl), a cargo receptor that is obligatory for Wnt trafficking and secretion.

Methods: We generated Wl conditional knockout mice in macrophage by crossing Lyz-Cre mice and Wl-floxed mice. Control and macrophage-specific Wl knockout mice were then subject to renal unilateral ureteral obstruction (UUO), and kidney fibrotic lesions assessed at 7 days after UUO. Mice were also subjected to acute kidney injury (AKI) induced by ischemic/reperfusion injury (IRI). Bone marrow-derived macrophages were cultured and analyzed.

Results: Macrophage-specific ablation of Wl in mice were confirmed by Western blot analyses of bone marrow-derived macrophage. The Lyz-Wl-/- mice were phenotypically normal. We found that at 1 day after IRI, there was no difference in serum creatinine and kidney pathology betwenn control and Lyz-Wl-/- mice. In addition, the mRNA level of pro-inflammatory cytokines such as TNF-α, MCP1, RANTES in knockout mice was not significantly altered as well, compared to the controls. However, ablation of Wl in macrophage attenuated renal fibrotic lesion at 7 days after UUO, accompanied by reduction of fibronectin, plasminogen activator inhibitor-1 and Snail1. In vitro, conditioned medium derived from the bone marrow-derived macrophages of Lyz-Wl-/- mice reduced fibroblast activation and fibronectin expression, compared to the controls.

Conclusions: These results suggested that macrophage-derived Wnts does not affect the early kidney injury after ischemic AKI. However, it plays a critical role in promoting kidney fibrosis after UUO.

FR-OR059

A Critical Role for Rictor/mTORC2 in Promoting Macrophage Activation and Kidney Fibrosis Jiafa Ren, Chunsun Dai. *Center for Kidney Disease, Nanjing Medical Univ.*

Background: Our published study reported that Rictor/mTORC2 signaling mediates TGFβ1-induced fibroblast activation and kidney fibrosis. However, the role and mechanisms for Rictor/mTORC2 in macrophage activation and kidney fibrosis are not clear.

Methods: In this study, a mouse model with tamoxifen-induced macrophage-specific deletion of Rictor and primary cultural macrophages from bone marrow (BMMs) were generated.

Results: Rictor/mTORC2 signaling was activated in macrophages from mouse kidneys at 1, 2 and 4 weeks after ischemia/reperfusion (I/R). All mice were administrated with tamoxifen at 1 week and sacrificed at 4 weeks after kidney I/R. Compared with their control littermates, the knockout mice developed less kidney fibrosis and inflammatory cell accumulation in kidney tissue at 4 weeks after I/R. Rictor-/- macrophages expressed less CTGF, TGFβ1, TGFβ3, PDGFB, VEGFA and VEGFC than Rictor+/+ macrophages from kidneys at 4 weeks after I/R. Macrophage proliferation in the kidneys was enhanced after I/R, whereas it was much less in the knockouts. TGFβ1 could induce the mRNA expression of CTGF, PDGFA, PDGFB and VEGFC in primary cultured Rictor+/+ BMMs, which were much less in Rictor-/- BMMs. Conditioned cultural medium (CM) from Rictor+/+, but not Rictor-/- BMMs efficiently promoted fibroblasts to express Collagen I, FN and α-SMA. Furthermore, Rictor+/+ BMMs adoptive transfer could worsen UUO nephropathy in mice pretreated with clodronate to preclear macrophages, whereas mice with Rictor-/- BMMs adoptive transfer developed much less kidney fibrosis.

Conclusions: Together, these results suggest that Rictor/mTORC2 signaling plays an important role for promoting macrophage activation and kidney fibrosis.

FR-OR060

HIPK2 in Renal Tubules Is a Key Regulator of Kidney Fibrosis Wenzhen Xiao,[1] Ying Fan,[2] Zhengzhe Li,[1] Kyung (Kim) Lee,[1] John C. He.[1] *[1]Medicine/Div of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Renal fibrosis is the common pathway for the progression of CKD to ESRD. However, no effective treatment exists against renal fibrosis. We have shown that HIPK2 is a key protein kinase that mediates both pro-fibrotic and pro-inflammatory pathways in kidney cells. We showed previously that global knockout of HIPK2 attenuates renal fibrosis in several animal models of renal fibrosis including models of unilateral ureteral obstruction (UUO), folic acid nephropathy, and HIV-associated nephropathy. Here, we sought to further determine the role of HIPK2 specifically in renal tubular epithelial cells in contributing to renal fibrosis by using tubule-specific HIPK2 knockout and overexpression mice.

Methods: We generated floxed HIPK2 mice, which were crossed with PEPCK-Cre mice to generate renal tubular cell specific HIPK2 knockout mice. We also generated Tet-On HIPK2 overexpression mice, which were crossed with Pax8-rtTA mice to generate renal tubular cell-specific HIPK2 overexpression mice. We induced UUO in these mice and renal fibrosis was assessed at day 10 post-UUO.

Results: We confirmed that HIPK2 expression was significantly reduced in renal cortices in tubule-specific knockout mice by both real-time PCR and western blot analysis. Immunostaining also confirmed a reduction of HIPK2 in renal tubules. Using the same approach, we also confirmed that HIPK2 expression was increased in renal tubules of HIPK2 overexpression mice. After UUO, we observed that HIPK2 knockout mice developed less renal fibrosis in comparison to wildtype (WT) controls, whereas HIPK2 overexpression mice had worsened progression of renal fibrosis than in WT mice. In addition, expression of fibrosis markers such as collagen I, α-SMA, fibronectin, and Snail1 was attenuated in the HIPK2 knockout UUO mice, while increased in the HIPK2 overexpression UUO mice.

Conclusions: We conclude that increased expression of HIPK2 in renal tubular cells contributes to the development of renal fibrosis. HIPK2 could be a potential target to treat patients with renal fibrosis.

FR-OR061

Stromal Progenitor Cell Deletion of STAT3 Protects Mice from Folic Acid-Induced Kidney Fibrosis by Inhibiting Pericytes/Fibroblasts Migration, Differentiation and Proliferation Amrendra Kumar Ajay, Venkata Sabbisetti, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: STAT3 is a key transcription factor involved in inflammation, tissue regeneration, tumor growth, cell proliferation and migration. In the kidney the exact function of STAT3 remains unknown. We developed a stromal progenitor cells (pericytes/fibroblast) conditional knock out mouse to study the function of STAT3 in kidney fibrosis progression.

Methods: Breeding STAT3 floxed mice with FoxD1 Cre, we developed kidney pericyte/fibroblast knock out mice. Folic acid (250 mg/kg body weight) was injected and mice were sacrificed on day 7. Kidney fibrosis was evaluated by Masson's Trichrome and alpha-smooth muscle actin (α-SMA) staining. RT-PCR was performed to quantify fibrotic markers (fibronectin, alpha smooth muscle actin, collagen 1a1). STAT3 gain of function (constitutive active STAT3) and loss of function (siRNA mediated knock down as well as phosphorylation mutants) studies were performed in the pericyte (10T&1/2) and mouse fibroblast (NIH3T3) cell lines.

Results: Mice with STAT3 depletion in kidney pericytes were protected from folic acid-induced kidney fibrosis and had a decrease in the number of myofibroblasts as observed by Masson's Trichrome and a-SMA staining. RT-PCR analyses showed significant decreased expression of fibrotic markers in pericyte/fibroblast knock out mice as compared to the floxed littermates. Further, gain of function and loss of function studies of STAT3 in pericyte (10T&1/2) and fibroblast (NIH3T3) cell lines confirmed that STAT3 plays an important role in phosphorylation of SMAD2/3.

Conclusions: STAT3 signaling plays a crucial role in pericyte differentiation, proliferation and migration, which is one of the critical events for the progression of kidney fibrosis. Targeting STAT3 signaling in pericytes may help to slow or inhibit fibrosis progression.

Fibroblast-Specific Loss of Krüppel-Like Factor 15 Exacerbates Kidney Fibrosis Xiangchen Gu,[1] Yiqing Guo,[3] Timothy W. Miller,[3] John C. He,[2] Sandeep K. Mallipattu.[3] *[1]Nephrology, Yueyang Hospital of Integrated TCM and Western Medicine, Shanghai, China; [2]MSSM, New York, NY; [3]Medicine/Nephrology, Stony Brook Univ, Stony Brook, NY.*

Background: Regulation of fibroblast to myofibroblast differentiation in kidney fibrosis remains poorly understood. Krüppel-Like Factor 15 (KLF15), a zinc-finger transcription factor, has been demonstrated to play a critical role in progression of cardiac and kidney fibrosis. We sought to determine the mechanism by which the loss of KLF15 increases fibroblast to myofibroblast differentiation in kidney fibrosis.

Methods: To assess the role of Klf15 specifically in fibroblasts, we generated pericyte and resident fibroblast specific *Klf15* knockout mice (*Klf15$^{\Delta FoxD1}$*) by crossing *Klf15$^{fl/fl}$*mice with *Foxd1-Cre mice.* We utilized unilateral uninephrectomy (UUO for 3 and 7 days) and Angiotensin II (Ang II infusion for 4 weeks) as murine models of fibrosis. Mouse embryonic fibroblasts (MEF) with stable knockdown of *Klf15* (*Klf15*-shRNA) and empty vector (*EV-shRNA*) were generated using lentiviral delivery.

Results: *Klf15$^{\Delta FoxD1}$* mice exhibited an increase in pro-fibrotic markers (αSMA, Col1α1, fibronectin, vimentin) and fibroblast proliferation (Ki67) as compared to wildtype mice at 3 and 7 days post UUO. Similarly, we observed an increase in pro-fibrotic markers and fibroblast proliferation in AngII-treated *Klf15$^{\Delta FoxD1}$* mice as compared to AngII-treated wildtype mice. Gene-set enrichment analysis of genes with KLF15 binding sites identified an increase in the pathways involved in suppression of Wnt/β-catenin pathway. We initially confirmed that *Klf15$^{\Delta FoxD1}$* mice exhibited an increase in Wnt/β-catenin signaling (activated-phospho β-catenin, c-Myc, Lef1) as compared to wildtype mice post UUO. We also observed that *Klf15-shRNA* MEFs exhibited a significant increase in Wnt/β-catenin signaling (activated-phospho β-catenin, c-Myc), pro-fibrotic markers (αSMA, Col1α1, fibronectin), and proliferation (Ki67 and MTT assay) as compared to *EV-shRNA* MEFs after Wnt1 ligand treatment for 72 hours.

Conclusions: These data suggest that the loss of *Klf15* in pericyte/resident fibroblast-specific accelerates fibroblast to myofibroblast differentiation in models of kidney fibrosis.

Role of Lysophosphatidic Acid (LPA)/LPA Receptor in EGFR-Mediated Renal Fibrosis Jessica Marie Overstreet, Ming-Zhi Zhang, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Excessive tissue scarring or fibrosis is a critical contributor to chronic kidney disease, which ultimately leads to organ failure. We have previously demonstrated that overactivation of EGFR in the proximal tubule epithelium of mice is sufficient to promote spontaneous, progressive renal fibrosis. The role of the lysophosphatidic acid (LPA)/LPA receptor axis in epithelial-fibroblast crosstalk and renal fibrosis is less understood.

Methods: For *in vivo* analysis, we generated male C57BL/6 mice with human HB-EGF selectively expressed in the renal proximal tubule epithelia (hHB-EGF$^{Tg/Tg}$) to overactivate EGFR. hHB-EGF$^{Tg/Tg}$ mice were crossed with *Waved2* mice (hHB-EGF$^{Tg/Tg}$;*Waved2*), which have a 90% reduction in EGFR kinase activity. Human proximal tubule epithelial cell line (hRPTEC) and mouse cortical fibroblasts were used for communication studies *in vitro*.

Results: Immunohistochemical analysis revealed an increase in LPA_1 and autotaxin, an enzyme that produces LPA, in the interstitium surrounding the tubule epithelium of hHB-EGF$^{Tg/Tg}$ mice compared to wildtype mice. The increased expression of LPA_1 and autotaxin observed in hHB-EGF$^{Tg/Tg}$ mice was attenuated in HB-EGF$^{Tg/Tg}$;*Waved2* mice. EGF-treatment induced LPA secretion from hRPTEC measured by high performance liquid chromatography. Conditioned media collected from EGF-treated hRPTECs increased fibroblast proliferation and activation as indicated by increased fibronectin, α-smooth muscle actin (α-SMA), and cyclin D protein expression in comparison to fibroblasts incubated in conditioned media from untreated hRPTECs. Further, conditioned media derived from hRPTECs exposed to EGF+ Erlotinib, an EGFR kinase inhibitor, induced less fibroblast proliferation. Fibroblasts treated with EGF-induced conditioned media + Ki16425, an LPA_1/LPA_3 inhibitor, prevented the increased proliferation seen with EGF-induced conditioned media from hRPTECs.

Conclusions: These results suggest that EGFR activation in the proximal tubule promotes the secretion of paracrine factors driving fibroblast activation and proliferation, likely through a LPA/LPAreceptor-dependent pathway.

Worn-out GBM Components, Particularly the Collagen IV-Alpha1 Chain, Account for Mesangial Matrix Expansion in Diabetic Nephropathy (DN) in Humans Wilhelm Kriz,[1] Jana Loewen,[1,2] Giuseppina Federico,[2] Elisabeth Groene,[2] Hermann-Josef Groene.[2] *[1]Dept of Neuroanatomy, Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany; [2]Dept of Molecular Pathology, German Cancer Research Center, Heidelberg, Germany.*

Background: Mesangial matrix expansion is a hallmark of DN and generally believed to emerge from the overproduction by mesangial cells; other sources have so far not been considered.

Methods: Re-evaluation of 918 biopsies of DN from the years 2007-2015 (types 1 and 2 were not separated) by light and electron microscopy (LM,TEM), immunofluorescence (IF) and in-situ hybridization (ISH).

Results: As seen by LM and TEM at least a major part of the accumulated matrix in the mesangium in DN is derived from the deposition of worn-out GBM-material. The process is as follows:

The DN specific thickening of the GBM causes a narrowing of the spaces within the GBM-infoldings compromising the situation of the podocytes therein. They retract out of them leaving back shedded cytoplasmic material that becomes included into the innermost portions of the GBM. These portions disconnect from the GBM and are dropped into the mesangium. The inclusions of podocyte cytoplasmic remnants provide a label proving that this material is derived from the GBM.

As seen by IF, the collagen IV-α1, α3 and α5 chains all contribute to mesangial matrix accumulation (other components so far not studied). Whereas the staining of the α3 and α5 chains fades out with time, the staining of the α1 chain is dominant and persists even in nodules.

As seen by ISH, the synthesis of the α3 and α5 chains by podocytes seems not to be changed in DN compared to controls. In contrast, the synthesis of the α1 chain by endothelial cells seems to be substantially increased (a contribution by mesangial cells cannot be excluded); however, the crucial derangement likely consists of its failed degradation.

Conclusions: These findings put the turnover of the GBM into centre stage of the pathogenesis of DN. They support the view (Walker F. 1973, J Pathol 110: 233) that components of the GBM are synthesized by podocytes and endothelial cells and degraded within the mesangium.

FR-OR065

Erythropoietin Increases Bone FGF23 Expression and Circulating FGF23 Levels Mark R. Hanudel,[1] Maxime Rappaport,[1] Kristine Chua,[2] Erica Clinkenbeard,[3] Victoria Rivka Gabayan,[2] Tomas Ganz,[2] Kenneth E. White,[3] Isidro B. Salusky,[1] Elizabeta Nemeth.[2] *[1]Dept of Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Dept of Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Dept of Medical & Molecular Genetics, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: Polycystic kidney disease is associated with higher levels of both erythropoietin (EPO) and FGF23. Iron deficiency anemia, which is also associated with higher EPO, increases bone *Fgf23* expression. These observations raise the possibility that EPO may affect FGF23 production and metabolism.

Methods: To assess the acute effects of EPO on FGF23 parameters, wild type (WT) C57BL/6 mice, and three anemic human subjects, were injected with a single dose of human recombinant EPO, and FGF23 parameters were measured at subsequent intervals. To assess whether the effects of EPO on FGF23 are mediated by erythroferrone, an EPO-responsive, marrow-produced, hepcidin suppressing hormone, WT and erythroferrone knockout mice were treated with 3 days of saline or EPO.

Results: At 6 hours after injection of 40 μg/kg EPO, the mice had significantly increased bone *Fgf23* mRNA expression, significantly increased circulating FGF23 levels, and significantly decreased percentage intact FGF23, suggesting concurrent effects on expression and post-translational cleavage. Similarly, in the three adults, C-terminal FGF23 levels increased 1.8-fold at 12 hours after injection of 20,000-40,000 units EPO, with less of an effect on intact FGF23. Erythroferrone knockout did not ameliorate EPO-induced increases in FGF23, suggesting an erythroferrone-independent effect.

Conclusions: Independent of erythroferrone, EPO increases bone *Fgf23* expression, coupled with increased FGF23 cleavage.

FR-OR066

Cross-Talk of Anemia and Phosphate Metabolism via FGF23 in a Model of PKD Erica Clinkenbeard,[1] Hitesh Nidumanda,[1] Pu Ni,[1] Julia M. Hum,[1] Yves Sabbagh,[2] Kenneth E. White.[1] *[1]Dept Medical and Molecular Genetics, Indiana Univ, Indianapolis, IN; [2]Rare Diseases, Sanofi Genzyme, Framingham, MA.*

Background: Fibroblast growth factor 23 (FGF23) is a bone derived hormone responsible for maintaining phosphate homeostasis. We have found in addition to phosphate, FGF23 is also be significantly induced with iron-deficiency anemia. Interestingly, patients with polycystic kidney disease (PKD) maintain EPO production during anemia, whereas patients with CKD-MBD often demonstrate anemia with loss of EPO production in concert with phosphate homeostasis dysregulation. Therefore, the purpose of our study was to test the associations between FGF23 and anemia in a mouse model of PKD and to determine the molecular mechanism driving the cross-talk between iron and phosphate homeostasis.

Methods: Juvenile cystic kidney (Jck) mice harboring a *Nek8* mutation, were maintained on a normal chow and monitored from 4 to >20 weeks of age for complete blood counts, serum FGF23, erythropoietin (EPO) and total iron levels. Additionally, we tested factors important for iron handling on rat osteoblast cells (UMR-106) to determine EpoR and FGF23 mRNA levels.

Results: Serum intact FGF23 becomes significantly increased in Jck mice over normal controls during the course of disease (13-fold, $p<0.0005$). Jck mice also exhibited anemia with reductions in red blood cells, hematocrit and hemoglobin. We found a negative correlation between total iron and FGF23 ($p<0.005$), and the reciprocal strong positive correlation between serum EPO and FGF23 ($p=0.03$) in Jck mice across time. In UMR-106 cells, iron chelation stimulated EpoR mRNA expression. Human EPOR was transfected in the cells and upon EPO treatment initiated canonical JAK/STAT signaling which associated with induced FGF23 mRNA ($p<0.05$). Additionally, FGF23 promoter activity was stimulated by EPO administration.

Conclusions: During anemia, EPO is an independent regulatory factor for FGF23, and may be in part, responsible for elevated FGF23 in PKD, and EPO-treated CKD-MBD. This, in conjunction with iron deficiency may be modifiable risk factors in rare and common disorders of phosphate metabolism.

The FGF Receptor Inhibitor Decreases FGF23 Levels in Uremic Rats Maria Lerche Mace,[1,2] Eva Gravesen,[2] Anders Nordholm,[1,2] Jacob Hofman-Bang,[2] Klaus Olgaard,[2] Ewa Lewin.[1,2] *[1]Dept of Nephrology, Herlev Hospital, Copenhagen, Denmark; [2]Dept of Nephrology, Rigshospitalet, Univ of Copenhagen, Denmark.*

Background: The phosphaturic hormone fibroblast growth factor 23 (FGF23) is severely increased in uremia, where it is associated with increased cardiovascular complications and mortality. Our aim was to study whether inhibition of the FGF receptor (FGFRi) had a regulatory impact on FGF23, Klotho and PTH.

Methods: Chronic kidney disease was induced in Wistar rats by 5/6 nephrectomy. After 8 weeks of uremia, uremic rats (U) and age-matched control rats (C) were randomized to FGFRi (20mg PD173074) or vehicle. Plasma FGF23 and PTH were measured along with gene expression of *FGF23* in bone and kidney expression of α*Klotho*, *NaPi2a, NaPi2c* and *FGFR1IIIc*.

Results: Uremic rats had increased p-creatinine (72±11 vs 32±1 μM), p-phosphate (2.57±0.18 vs 2.05±0.08 mM), p-PTH (932 (355-2929) vs 224 (169-290) pg/ml) and p-FGF23 (1925±554 vs 367±21 pg/ml) (all $p<0.05$). FGFRi resulted in a significant decrease in p-FGF23 to 154±18 pg/ml in C rats and 738±174 pg/ml in U rats, and in down-regulation of the *FGF23* mRNA in bone (C rats: 1.54±0.23 to 0.15±0.03. U rats: 2.79±0.61 to 0.14±0.03) (all $p<0.01$). Despite stable p-calcium^{2+} and p-phosphate, PTH rose significantly to 392 (281-2079) in C rats and to 2719 (1579-16912) in U rats after FGFRi ($p<0.05$). The present results didn't support the concept of parathyroid resistance to FGF23 in uremia, but demonstrated renal resistance to FGF23. In the kidney of C rats FGFRi resulted in a significant increase in the expression of *αklotho* (1.40±0.05 to 1.72±0.03), *NaPi2a* (1.48±0.05 to 1.72±0.05) and *NaPi2c* (1.44±0.03 to 1.73±0.11) (all $p<0.05$). In contrast, in the kidney rudiment of U rats FGFRi had no effect on the expression of *αklotho* (0.82±0.15 vs. 0.87±0.13), *NaPi2a* (0.83±0.18 vs. 0.83±0.14) and *NaPi2c* (0.80±0.16 vs. 0.90±0.15). FGFRi did not affect the expression of *FGFR1IIIc*.

Conclusions: Inhibition of the FGF receptor has a powerful down-regulatory impact on FGF23 levels in both normal and uremic rats. The expression of Klotho was up-regulated in the normal kidney, but unchanged in the injured kidney by PD173074. These results demonstrate renal, but not parathyroid resistance to FGF23 in chronic uremia.

Acute Parathyroid Hormone (1-34) Challenge Increases C-Terminal Fibroblast Growth Factor 23 Levels but Not Intact Fibroblast Growth Factor 23 Levels Marta Christov,[1,2] Vanessa Maria Knab,[2] Braden A. Corbin,[2] Olena Andrukhova,[4] Julia M. Hum,[3] Pu Ni,[3] Seham M. Rabadi,[1] Akira Maeda,[2] Kenneth E. White,[3] Reinhold Erben,[4] Harald Jüppner.[2] *[1]Medicine, New York Medical College, Valhalla, NY; [2]Medicine, Massachusetts General Hospital, Boston, MA; [3]Medical and Molecular Genetics, Indiana Univ School of Medicine, Indiana, IN; [4]Univ of Veterinary Medicine of Vienna, Vienna, Austria.*

Background: The acute effects of parathyroid hormone (PTH) on fibroblast growth factor 23 (FGF23) *in vivo* are not well understood.

Methods: Injection of PTH into wild type and autosomal dominant hypophosphatemic rickets (ADHR) mice. Treatment of differentiated calvarial osteocytes with PTH.

Results: After a single s.c. PTH(1-34) injection (50nmol/kg) in mice, FGF23 levels were measured in plasma using assays that measure either intact alone (iFGF23) or intact/C-terminal FGF23 (cFGF23). Furthermore, FGF23 mRNA and protein levels were assessed in bone. In addition, we examined the effects of PTH treatment on FGF23 production *in vitro* using differentiated calvarial osteocytes. cFGF23 levels increased by 3- 5-fold within two hours following PTH injection, which returned to baseline by 4 hours. In contrast, iFGF23 levels remained unchanged for the first two hours, yet declined to approximately 60% by 6 hours and remained suppressed before returning to baseline after 24 hrs. Using mice that are homozygous for the ADHR-FGF23 mutation or animals treated with a furin inhibitor, we showed that cFGF23 and iFGF23 levels increased equivalently after PTH injection. These findings are consistent with increased FGF23 production in bone, yet rapid cleavage of the secreted intact protein. Using primary cultures of differentiated osteocytes, we showed that PTH increased FGF23 mRNA expression through cAMP/PKA, but not IP3/PKC signaling.

Conclusions: In conclusion, PTH injection rapidly increases FGF23 production in bone *in vivo* and *in vitro*. However, intact FGF23 is rapidly degraded. At later timepoints and through an as yet unidentified mechanism there is a sustained decrease in FGF23 production.

Paricalcitol and FGFR Blockade Synergistically Attenuate Uremic Cardiac Hypertrophy Michael Freundlich,[1] Christian Faul,[2] Saurav Singh,[2] Yasmir Quiroz,[3] Brian A. Czaya,[2] Keila Zulimi Yaguas,[3] Bernardo Rodriguez-Iturbe.[3] *[1]Pediatric Nephrology, Univ of Miami, Miami, FL; [2]Nephrology, Univ of Miami, Miami, FL; [3]Nephrology, Hospital Univ-IVIC, Maracaibo, Venezuela.*

Background: In uremic (U) rodents, FGF23 activates myocardial calcineurin/NFAT signaling causing cardiac hypertrophy (CH) that can be blocked by inhibiting FGF receptor (FGFR) 4, and paricalcitol (Pc) improves CH by suppressing the myocardial renin-angiotensin-system (RAS). Since Pc suppresses NFAT with CH attenuation in non-U animals, we studied whether Pc inhibits myocardial NFAT in U rats and if FGFR blockade amplifies the Pc effects.

Methods: 5/6 nephrectomized rats receiving Pc alone (0.3 mcg/kg x3/week) or Pc+pan-FGFR blocker PD173074 (PD; 1mg/kg), were compared to untreated (Nx) and sham (S). After 4 weeks, we analyzed heart /body weight (HW/BW) ratio, myocardial expression RT-PCR profiles, blood pressure (BP), and blood levels of creatinine and FGF23.

Results: Pc or Pc+PD versus Nx significantly attenuated renal dysfunction, hypertension and HW/BW with further elevation of FGF23. Pc+PD versus Pc significantly lowered HW/BW despite similarly elevated FGF23. Neither FGF23 nor BP correlated with HW/BW. Compared to S, myocardial expression markers for hypertrophy, fibrosis and inflammation, FGFR4, NFAT target genes (RCAN1, TRPC6), angiotensinogen and AT1R were significantly elevated in Nx and reduced by Pc and Pc+PD. Of note, some NFAT and hypertrophy markers were significantly lower in Pc+PD versus Pc, and associated with 80% higher cumulative Pc dose/prevailing log FGF23 ratio, a presumptive indicator of the anti-hypertrophic effect of Pc.

Conclusions: In addition to RAS suppression, and independently of FGF23/FGFR4 signaling, Pc suppresses cardiac NFAT in U animals. This VDR-mediated anti-hypertrophic effect is further magnified by PD co-administration, and may be dependent on the Pc dose relative to prevailing FGF23 levels. Based on the uncovered synergistic cardio-protective effects of Pc and FGFR blockade, future clinical studies should aim at targeting FGFR4 in addition to tailored Pc doses adjusted to the prevailing FGF23 levels, to effectively treat uremic CH.

FR-OR070

Endothelial Dysfunction in Experimental Chronic Kidney Disease Is Caused by FGF23 Melissa Verkaik,[1,2,3,4] Pieter M. Ter Wee,[1] Etto C. Eringa,[2] Marc G. Vervloet.[1] *[1]Dept of Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Dept of Physiology, VU Univ Medical Center, Amsterdam, Netherlands; [3]Inst of Cardiovascular Research ICaR-VU; [4]On Behalf of the NIGRAM Consortium.*

Background: Cardiovascular causes account for approximately 50% of mortality in patients with chronic kidney disease (CKD). FGF23, a phosphate-lowering protein and elevated in CKD, is associated with endothelial dysfunction and cardiovascular mortality. We hypothesized that CKD impairs vascular function and that this can be attributed to FGF23.

Methods: Seven weeks old male wild type C57Bl/6J mice were subjected to partial nephrectomy (5/6Nx) or sham-surgery. After 6 weeks resistance arteries were isolated and subjected to a pressure myograph setup to test *ex vivo* vascular function. A second non-CKD group received either PBS or FGF23 i.p. injections for 7 consecutive days twice daily. To assess whether FGF23 mediates CKD-induced endothelial dysfunction, a third group received FGF23 antibodies by i.p. injections, in combination with a low phosphate diet, 6 weeks following 5/6Nx surgery. A control group received control antibodies and a normal diet. To assess eNOS uncoupling, femoral arteries were used to determine eNOS monomer and dimer protein expression by low-temperature SDS-PAGE.

Results: Plasma FGF23 significantly increased after 5/6Nx surgery (1.7-fold p=0.01), as well as fractional excretion of phosphate (FEP) (4-fold p=0.003). 5/6Nx blunted ex vivo vasodilator responses to acetylcholine (p=0.002), whereas responses to sodium nitroprusside (SNP) or endothelin were normal. Seven days *in vivo* FGF23 injections completely mimicked this vascular endothelial defect (p=0.021), and in accordance, responses to SNP and endothelin were not altered. Short-term *ex vivo* FGF23 administration to isolated vessels did not change vascular reactivity. FGF23 antibodies in CKD mice prevented development of endothelial dysfunction (p=0.048). eNOS uncoupling was not observed after either 5/6Nx or FGF23 injections.

Conclusions: Impaired endothelium-dependent vasodilatation in CKD mice is mediated by FGF23 and can be prevented by blocking FGF23. These data corroborate FGF23 as a main target to combat in cardiovascular disease in CKD.

FR-OR071

Regulation of Phosphate Homeostasis by the Central Nervous System Daniela Egli-Spichtig,[1] Martin Y.H. Zhang,[1] Komuraiah Myakala,[2] Evgenia Dobrinskikh,[2] Moshe Levi,[2] Farzana Perwad.[1] *[1]Pediatric Nephrology, Univ of California San Francisco, San Francisco, CA; [2]Dept of Medicine, Univ of Colorado, Aurora, CO.*

Background: Phosphate (Pi) homeostasis is determined by dietary intake, intestinal absorption, renal excretion and skeletal turnover and is tightly regulated by parathyroid hormone, fibroblast growth factor 23 (FGF23) and 1,25 dihydroxyvitamin D_3. Although several Pi cotransporters have been identified, Pi sensing mechanisms are still unknown. We hypothesize that Pi sensing in the central nervous system (CNS) plays a role in the regulation of systemic phosphate homeostasis in mice.

Methods: 12 weeks old C57/BL6 mice were fed a low Pi (0.02%) diet and received intracerebroventricular (ICV) injections of either vehicle (ICV-Veh) or 20 nmol potassium dibasic phosphate (ICV-Pi).

Results: Sodium-dependent Pi (NaPi) uptake and NaPi-IIc protein abundance in the kidney were reduced by 30% and urinary Pi excretion increased by 3-fold in ICV-Pi compared to ICV-Veh injected mice after one hour. Serum Pi and FGF23 levels were not significantly different in the two groups. We next determined whether increasing cerebrospinal fluid (CSF) Pi concentrations with ICV-Pi injections or by manipulating dietary Pi intake regulates CNS Klotho expression. We observed a 35% decrease in Klotho protein expression in the choroid plexus in ICV-Pi compared to ICV-Veh injected mice. In mice fed an acute high Pi (1.65%) diet which is known to increase CSF Pi, we observed a 56% decrease in Klotho protein abundance in the choroid plexus compared to mice fed a low Pi diet. As expected, serum Pi concentrations and urinary Pi excretion increased by 6- and 300-fold, respectively, in mice fed the high Pi diet compared to the low Pi diet group.

Conclusions: ICV Pi injections stimulate urinary Pi excretion independent of serum Pi and FGF23 levels providing evidence for a CNS-kidney signaling axis. Increased CSF Pi levels and high dietary Pi intake suppress Klotho expression in the choroid plexus. Our study provides evidence that Pi regulates CNS Klotho expression and suggests Pi sensing in the CNS plays a role in the regulation of systemic phosphate homeostasis in mice.

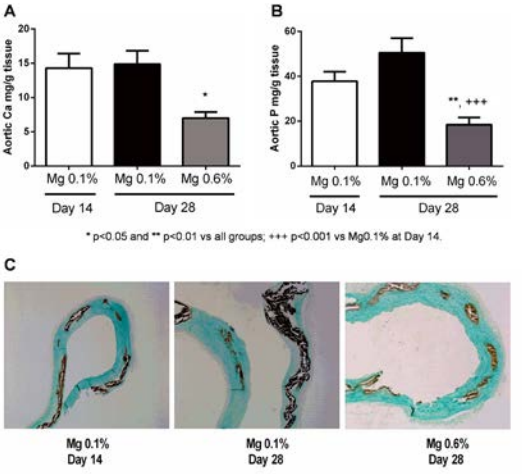
Univ Reina Sofia/Univ Cordoba and CIBEROBN, ISCIII, Cordoba, Spain; [5]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [6]Biologia Ambiental y Salud Publica, Univ Huelva, Huelva, Spain; [7]Laboratorio de Nefrología, IIS Fundación Jiménez Díaz, Madrid, Spain.*

Background: There is an association between low serum Mg and mortality in CKD patients finding an inverse correlation with cardiovascular events. Although Mg has been shown to prevent vascular calcification (VC) *in vitro*, controlled *in vivo* studies in uremic models are limited.

Methods: To investigate the effect of different levels of dietary Mg intake (from 0.1 to 1.1%) on the prevention and treatment of VC in vivo studies through 5/6 Nx rats fed with a high P diet (1.2%).

Results: A moderate increase in dietary Mg (0.3%) was associated with a reduction in aortic Ca content together with an improvement in mineral metabolism parameters. In comparison with a restricted phosphate diet (P 0.7%), Mg supplementation (0.6%) reduced more efficiently aortic Ca and P content. The effects of Mg on VC were not only limited to phosphate binder action, finding a reduction of blood pressure and improving renal function. In a second study, uremic rats with established VC (Mg 0.1%, Day 14) were fed a diet with either normal (Mg 0.1%, Day 28) or moderately increased Mg (Mg 0.6%, Day 28).Dietary Mg supplementation reduced VC and mortality.



Conclusions: Dietary Mg prevented and reversed both VC and mortality in uremic rats.

FR-OR073

The Kidney Is the Major Site for Fibroblast Growth Factor-23 Disposal in Humans Giacomo Garibotto, Daniela Verzola, Francesca Ansaldo, Samantha Milanesi, Francesca Viazzi. *Dept of Internal Medicine, Nephrology Div, Genoa Univ and IRCCS AOU San Martino-IST, Genoa, Italy.*

Background: Fibroblast Growth Factor 23 (FGF-23) accumulates in blood of patients with chronic kidney disease and is associated both with cardiovascular complications and disease progression. However, our knowledge of the sites and mechanisms which regulate plasma FGF-23 is still incomplete.

Methods: We measured plasma FGF-23 (ELISA assay Endo Millipore, Darmstadt, Germany) across the kidney, splanchnic organs and lung in nine patients (4 males, 5 females, median age 72 yrs, eGFR 65±6 ml/min) during elective diagnostic cardiac catheterizations.

Results: Arterial FGF-23 levels were in the normal range (median 14.3, range 10.5-32.7 pg/ml). Renal vein FGF-23 concentrations were remarkably lower (by ~21.6 %,$p < 0.01$) than the corresponding arterial values, indicating that plasma FGF-23 decreases substantially after a single pass across the kidney. Surprisingly, the fractional extraction (FE) of FGF-23 across the kidney was similar (p=NS) to that of creatinine (18.5%). FGF-23 level in the liver vein was quite similar (14.9±2 pg/ml) to that of arterial FGF-23. Arterial FGF 23 levels were almost identical to systemic venous (pulmonary artery) whole body levels (15.7±2 pg/ml), documenting zero balance of FGF 23 across these organs systems.

Conclusions: Our data show that the human kidney is the only site for FGF-23 removal from blood. Besides providing a better understanding of physiology of FGF-23 metabolism, the data reported in this study could be useful to understand the alterations in FGF-23 that are observed in CKD and many systemic and organ diseases.

Funding: Government Support - Non-U.S.

FR-OR074

Deletion of the Gene Encoding Transient Receptor Potential Canonical 1 (TRPC1) Channel in Mice Produces the Phenotypes of Familial Hypocalciuric Hypercalcemia (FHH) and Skeletal Parathyroid (PTH) Resistance Kai Lau,[1,2] Bonnie Eby,[1] Marybeth Humphrey,[1,2] Leonidas Tsiokas.[3] *[1]Medicine, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Medical Service, VA Medical Center, Oklahoma City, OK; [3]Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Previously we showed TRPC1 deficiency induces hypercalcemia, high PTH but increased bone mass, indicating TRPC1 controls Ca entry & cell [Ca] in concert with CaSR to regulate PTH secretion. Our 1st aim was to test the thesis that TRPC1 deficiency replicates FHH phenotypes. Our 2nd aim was to study skeletal resistance in null mice.

Methods: We studied wild-type & null mice by standard metabolic, clearance (Cl) & micro-CT techniques. Serum (S) PTH, 1,25 di(OH) vit D (1, 25 D), & calcitonin were analyzed by ELISA; alkaline (Alk) & acid phosphatases (Ptase), creatinine (creat), Ca, Mg, P & urine (U) hydroxproline (HP) by published method.

Results: We confirmed high SCa & high PTH in null males from 2nd to 12th m, without changes in S creat, 1,25 D, calcitonin, P or Mg. At 7 m, null males were normomagnesiuric but hypocalciuric [UCa (1 vs. 2 mg/d), UCa/creat (2 vs. 3), CaCl (14 vs. 26 ul/min)]. In null females, SCa (10 vs. 8.5 mg %) was up, PTH inversely related to SCa, & low urine Ca (1 vs. 1.6 mg/d), UCa/cre (2 vs. 3) & CaCl (13 vs. 22 ul/min). In null males & females, S AlkPtase was down by 20-40 % from 2nd-16th m. Osteoclastic activities were down (30% down in tartrate-resistant acid Ptase, 45% down in UHP, 3-fold up in trabecular

connectivity density, 37% more trabecular #, & 25% less trabecular spacing). At both 3 & 19 m, bone volume/tissue volume was higher in null mice. At 7th mon, their hind limbs were 25% heavier.

Conclusions: 1. TRPC1 deficiency impairs Ca entry, reduces cell [Ca] & stimulates PTH to cause hypercalcemia. 2. Similar to FHH, 1,25 D, P & Mg are normal, but hypocalciuria is prominent in both sexes like CaSR inactivation. 3. Despite chronic PTH excess, due to resistance, resorption is down & bone volume up in null mice. 4. These data support the key roles TRPC1 plays in PTH secretion, Ca absorption & bone biology.

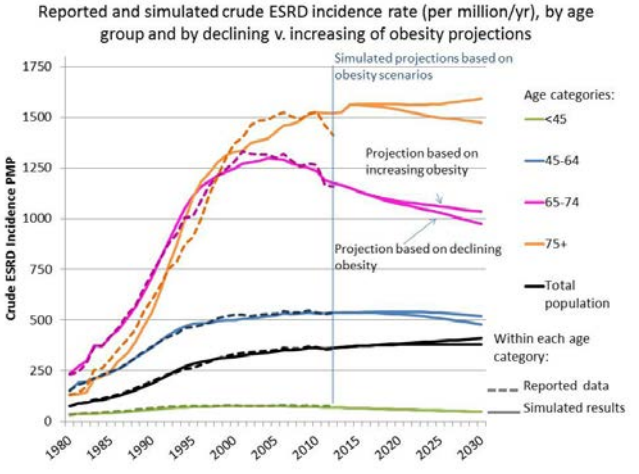
Projecting End Stage Renal Disease (ESRD) Incidence and Prevalence in the United States through 2030 Keith McCullough,[1] Hal Morgenstern,[2] William H. Herman,[2] Rajiv Saran,[2] Bruce M. Robinson.[1,2] *[1]Arbor Research Collaborative for Health; [2]Univ of Michigan.*

Background: End-stage renal disease (ESRD) can be defined by receipt of chronic dialysis or transplantation. While the age-sex-race-adjusted incidence rate of ESRD has declined slightly since 2006, the crude incidence rate has risen. Future trends in the crude ESRD incidence are important because of the impact on healthcare utilization and cost. This analysis models incidence and prevalence of ESRD in the US through 2030.

Methods: We used an open compartmental simulation model to project diabetes, hypertension, and ESRD trends stratified by age and race categories using restricted cubic spline estimates of time-varying flow parameters optimized based on annual incidence. Future trends in population-level obesity were assumed to either plateau and start to decline or increase linearly; this range should cover every reasonable obesity prevalence scenario. We assumed ESRD mortality would either remain constant at 2013 levels or to continue to decline proportionately. We used data from the National Health and Nutrition Examination Survey, Centers for Disease Control and Prevention National Health Interview Survey, US Census, and United States Renal Data System, including population projections through 2030.

Results: While age-specific rates are projected to stay relatively constant or decline, the total crude annual ESRD incidence rate is projected to rise to 381-410 per million/year, a 5-13% increase, depending on obesity trends.



The prevalence is projected to rise to 2209-2757 per million, an increase of 9-36%, depending on trends in obesity and ESRD mortality.

Conclusions: Incidence within age groups have leveled off or tended to decline, suggesting better management, but crude incidence and prevalence will both rise through 2030, due to an aging population, the increasing prevalence of obesity and diabetes, and improved ESRD survival.

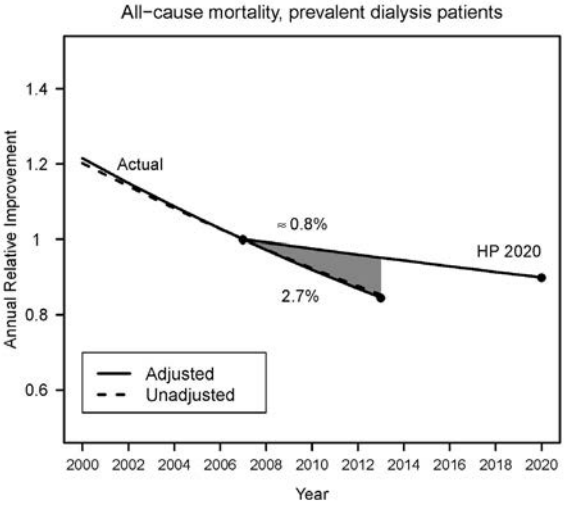
Healthy People 2020 Goals in CKD and ESRD: Measuring Progress to Date James B. Wetmore,[1] Peer Kidney Care Initiative Investigators.[2] *[1]Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; [2]Peer Kidney Care Initiative.*

Background: We assessed progress towards key Healthy People (HP) 2020 goals CKD and ESRD. We hypothesized that these goals are in the process of being met.

Methods: Using the CMS ESRD database, we created yearly cohorts of incident and prevalent dialysis patients, 2000-2013. Change in event rate or proportion change over the study years was modeled using Poisson regression with adjustment for age, race, sex, and primary cause of ESRD.

Results: For all-cause mortality in prevalent patients, HP 2020 sought a <1% relative annual improvement; actual improvement was 2.7%. Improvement was greatest for patients aged 18-44 years (3.8%, P <0.01 versus 2.8% for ages 65-74 years), and was 2.3% even for patients aged ≥75 years. For mortality in incident patients, the relative annual decrease was 2.1% overall, a 2-fold improvement over the goal; mortality decreased nearly twice as much in black as in white patients (3.2% versus 1.8%, P <0.001). Geographic variation was substantial: the relative annual decrease was 0.6% in the Midwest and >4-fold greater (2.7%) in the South. Cardiovascular mortality in prevalent patients decreased dramatically at 5.0% per year, far exceeding the annual goal of <1%; the decrease was greatest in patients aged ≥75 years (5.5%, P <0.001 versus ages 65-74 years, 5.1%). The relative annual increase in percentages of patients with a fistula at dialysis initiation was 2.4%, roughly three times the goal; the increase was greater for black than for white patients (3.2% versus 2.3%, P <0.01).

Figure 1A.



Conclusions: While progress in meeting the HP 2020 CKD and ESRD goals has exceeded the targets, not all groups of patients have benefited equally. Goal development for HP 2030 should consider ever-more-aggressive targets as well as changes in goal paradigms, such as tailoring goals by geographic region.

Optimal Outcomes with Targeted Chronic Kidney Disease Management Meghan Martin Cockrell,[1] Todd Prewitt,[1] Yanting Dong,[1] Huyi Hines,[1] Gilbert Haugh,[1] Stephen D. McMurray,[2] Eric Franco.[2] *[1]Humana Inc., Louisville, KY; [2]Village Health.*

Background: Unprepared patient transitions from chronic kidney disease (CKD) to end stage renal disease (ESRD) can result in avoidable hospitalizations and initiation of dialysis with non-preferred central venous catheters (CVC). Our objective was to evaluate the impact of integrated care management (ICM) on dialysis transitions with preferred modality (peritoneal dialysis vs. hemodialysis) and vascular access (arteriovenous fistula or graft).

Methods: Between 2012 and 2015, Humana Medicare enrollees with CKD who were most likely to transition to ESRD within a year were identified and referred to ICM using clinical rules (e.g., glomerular filtration rate ≤20) and a predictive model. The program ensured nephrologist oversight and patient education on CKD, modality and vascular access through telephone and in-person contact. For patients who transitioned to dialysis in 2015, descriptive statistics were used to report the number of transitions with preferred modality and access.

Results: In 2015, an average of 3,552 patients per month with CKD participated in ICM, with a total of 690 transitioning to dialysis. Of those who transitioned, 338 (48.9%) started dialysis with preferred modality or access. Another 151 (21.7%) started dialysis with a maturing fistula or graft, for a total of 70.9% starting dialysis with preferred modality or access option in place or underway. Among all ICM patients who transitioned to dialysis and had at least 6 months of ICM enrollment, an additional 15% had nephrologist oversight, 44% had selected a modality, 47% had a vascular access plan, and 43% had permanent access in the month prior to starting dialysis, compared to their 1st month in ICM.

Conclusions: The observed outcomes of ICM were satisfactory for the health plan to continue the program. When these findings are viewed in context of national data from the 2015 Annual Data Report by the United States Renal Data System, patients in the ICM program had a 22.4% higher rate of transition to dialysis with preferred modality or access (48.9% vs. 26.5%), which can be extrapolated to 155 avoidable CVC placements with ICM. Focused, systematic care for patients with this high risk condition can have demonstrable clinical benefits.

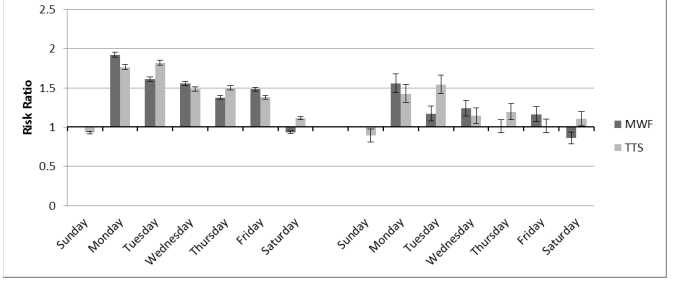
Hospitalization Rates among In-Center Hemodialysis (HD) Patients by Day of the Week Rajiv Saran,[1] Patrick J. Albertus,[1] Kevin He,[1] Francesca Tentori,[2] Brahmajee K. Nallamothu,[1] Yi Li.[1] *[1]KECC, Univ of Michigan; [2]Arbor Research Collaborative for Health.*

Background: Higher mortality on Monday/Tuesday has been reported in patients on thrice weekly hemodialysis, but the risk of other clinical outcomes remains uncertain. Therefore, we examined USRDS data to study the association of day-of-the-week with all-cause hospitalization and emergency department (ED) visits among Medicare-covered HD patients.

Methods: Prevalent in-center HD patients with Medicare as primary payer from 2013 with 3x/week dialysis sessions were identified in the USRDS database. Patients were followed through the end of 2013 for hospitalizations and ED visits, identified in Medicare claims. Poisson regression was used to calculate event rates and associated 95% confidence intervals (CI), characterized by the week day and stratified by dialysis schedule (Mon/Wed/Fri [MWF] or Tues/Thurs/Sat [TTS]), which was determined by the day of the week of a patient's first HD session. The model was adjusted for age, sex, race, ethnicity, and primary cause of ESRD.

Results: For 237,920 prevalent in-center 3x/week HD patients in 2013, 371,346 hospitalizations and 16,530 ED visits occurred. With adjustment, hospitalization rates were highest on Mondays for MWF patients (risk ratio: RR=1.92; 95% CI: [1.89, 1.96]) and on Tuesdays for TTS patients (RR=1.82 [1.79, 1.85]) (Fig. 1). Similarly, rates of emergency department visits after adjustment were highest on Mondays (RR= 1.55 [1.44, 1.68]) and on Tuesdays (RR=1.54 [1.42, 1.67]) for MWF and TTS patients, respectively.

Figure 1. Adjusted risk ratio (ref: Sunday, MWF) of (a) hospitalizations and (b) emergency department (ED) visits, by day of the week and dialysis schedule, among in-center hemodialysis patients, 2013



Conclusions: These findings, when combined with prior reports of higher mortality rates early in the week, call for a serious reconsideration of policy and practice with respect to the widely prevalent paradigm of the thrice weekly hemodialysis.

FR-OR079

Quantifying Risk of Increased All-Cause Hospitalization for Adult Hemodialysis Patients Who Skipped Seasonal Flu Vaccination Nien-Chen Li, Uddar Onta, Norma J. Ofsthun, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care, Fresenius Kidney Care North America, Waltham, MA.*

Background: It is well known that skipping seasonal flu vaccination is at a risk of increased hospitalization. The study attempts to quantify such risk for adult hemodialysis (HD) patients (pts).

Methods: We selected active HD pts aged ≥ 18 years at Fresenius Medical Care North America for three flu seasons: 2013-14, 2014-15, and 2015-16. Each season covered August 1 to July 31 of the following year. Active pts were those who had records of treatments or laboratory work within 40 days prior to August 1. We calculated hospitalization rate per patient-year and rate ratio (RR). We also estimated RR using negative binomial regression model wherein hospitalization count was the dependent variable with logarithmic link function, offset with logarithmic transform of exposure time and adjusted for age, gender, race, DM, CAD, and CHF. The model yielded estimated RR and Chi-square test for testing whether RR = 1. For each of 3 cases the exposure time at risk was calculated as follows. First, for those pts who were active throughout the season but not vaccinated, the exposure time was 12 months. Secondly, for those pts who were vaccinated, the exposure time was the duration from the vaccination date to the end of the season. Thirdly, for pts vaccinated, the exposure time prior to vaccination was calculated from the start of the season until the vaccination date, and the pts were considered not vaccinated during this time period.

Results: The total active pts were 158326, 202793, and 220203, and % pts vaccinated were 60.1, 75.6, and 80.4 for seasons 2013-14, 2014-15, and 2015-16, respectively. The estimated RR of hospitalization for non-vaccinated vs. vaccinated were 1.53, 1.87, and 2.58 (all p<.0001) in three seasons, respectively.

Conclusions: Our study showed that the risk of increased all-cause hospitalization for adult hemodialysis patients who skipped seasonal flu vaccination were 53 to 158% higher in terms of average hospitalization rate. An aggressive program for promoting flu vaccination is well warranted.

FR-OR080

The Hemodialysis Schedule Affects Hospitalization by Day of the Week for Acute Cardiovascular Diseases: 20 Years' Experience Masataka Banshodani, Hideki Kawanishi, Misaki Moriishi, Sadanori Shintaku, Shinichiro Tsuchiya. *Artificial Organs, Tsuchiya General Hospital, Hiroshima, Japan.*

Background: An increase in deaths has been identified after a 2-day break (longest interdialytic gap) in hemodialysis (HD) in previous reports, and frequent HD has recently been recommended. However, no reports have evaluated how the dialysis schedule affects day-of-week hospitalization on a long-term basis.

Methods: We analyzed 11,111 hospitalizations of 1,955 HD patients and 1,969 hospitalizations of 497 peritoneal dialysis (PD) patients to clarify the association between the day-of-week hospitalizations for acute CVDs including pulmonary edema, cerebrovascular disease, heart failure, ischemic heart disease, cardiac arrhythmia, and aortic and peripheral vascular disease (HD: 1,705 times; PD: 261 times) and the dialysis schedule at our institution between January 1995 and December 2014.

Results: In HD patients, the rate of hospitalizations for acute CVDs on 1st-HD day (Monday or Tuesday, 42%) was significantly higher than that on 2rd- (Wednesday or Thursday, 24%) and 3rd- (Friday or Saturday, 22%) HD days (P<0.001), while there was no significant difference for PD patients. However, in the HD group, the hospitalization rate on the 1st-HD day has been decreasing in recent years (1st-5th yr, 48%; 2nd-5th yr, 41%; P=0.03; 3rd-5th yr, 40%; P=0.03; 4th-5th yr, 39%; P=0.009). Moreover, the rates of acute CVD contributing to overall hospitalizations have been decreasing in HD patients (1st-5th yr, 33%; 2nd-5th yr, 19%; P<0.001; 3rd-5th yr, 13%; P<0.001; 4th-5th yr, 9.6%, P<0.001). Frequent HD (≥4 times/week) at our institution increased from 1.0% (1st-5th yr) to 5.3% (4th-5th yr) (P<0.001), and the rate of hospitalizations for acute CVDs on 1st-HD day significantly decreased from 37% pre- to 24% post-initiative (P=0.04).

Conclusions: Day-of-week hospitalization was affected by the HD schedule, but the risk decreased over time. This result may be attributed to the advantages of frequent HD. Our findings can guide clinical management practices for CVDs in dialysis patients.

FR-OR081

Obstructive Sleep Apnea in Incident Hemodialysis Patients Significantly Increases Risk for Sudden Cardiac Death and Cardiovascular Mortality Eric S. Kerns,[1] Esther D. Kim,[2] Lucy A. Meoni,[3] Stephen M. Sozio,[3] Bernard G. Jaar,[3] Michelle M. Estrella,[3] Rulan S. Parekh,[2,3] Ghada Bourjeily.[1] *[1]Brown Univ, Providence, RI; [2]Univ of Toronto, Toronto, ON, Canada; [3]Johns Hopkins Univ, Baltimore, MD.*

Background: Mortality in ESRD approaches 20% per year predominantly from sudden cardiac death (SCD). Obstructive sleep apnea (OSA) is characterized by abnormal breathing during sleep and oxygen desaturations and is highly prevalent in patients with ESRD. Whether OSA increases the risk for SCD, cardiovascular (CV) and all-cause mortality in HD is unknown.

Methods: In a prospective cohort of 558 incident HD patients from the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) study, we examined the association of OSA diagnosis ascertained by physician chart review with all-cause mortality, CV mortality, and SCD using Cox proportional hazards model. SCD was defined as out of hospital, non-ischemic coronary events adjudicated by the end point committee.

Results: Sixty-six incident HD patients (12%) were identified as having OSA. Median age and sex were similar in OSA and non-OSA groups. Those with OSA had fewer African Americans (53% vs 71%), and higher median BMI (37 [IQR 31, 42] vs 27 [IQR 24, 32]), median Charlson comorbidity index (6 [IQR 5, 7] vs 5 [IQR 4, 7]), prevalence of diabetes (76% vs 56%), coronary artery disease (47% vs 34%), and median left ventricular mass index (76 [IQR 59, 93] vs 61 [IQR 50, 79]) (all p <0.05). During 1080 person-years of follow-up, there were 104 deaths, including 30 CV and 16 SCD. OSA was associated with a higher risk of all-cause mortality, CV mortality, and SCD after adjustment.

Association of OSA compared to non-OSA with all-cause mortaltiy, cardiovascular mortality, and sudden cardiac death

Adjustment	All cause mortality	Cardiovascular mortality	Sudden cardiac death
	HR (95% CI)	HR (95% CI)	HR (95% CI)
Model 1: age, sex, ethnicity	1.27 (0.74, 2.18)	1.50 (0.66, 3.42)	3.28 (1.12, 9.57)
Model 2: model 1, Charlson comorbidity	1.10 (0.64, 1.89)	1.38 (0.60, 3.18)	3.00 (1.01, 8.86)
Model 3: model 1, BMI	1.90 (1.04, 3.46)	3.62 (1.36, 9.66)	12.12 (2.70, 54.40)

Conclusions: Incident HD patients with a known diagnosis of OSA are at significantly increased risk for all cause and CV mortality and SCD. Future studies should assess the impact of screening for OSA and OSA-targeted interventions on morbidity and mortality in ESRD.

High Efficiency Hemodiafiltration (HDF) versus Hemodialysis (HD): A Comparison of Clinical Outcomes in EuroDOPPS Angelo Karaboyas,[1] Francesco Locatelli,[2] Ronald L. Pisoni,[1] Bruce M. Robinson,[1,3] Joan Fort,[4] Raymond C. Vanholder,[5] Hugh C. Rayner,[6] Werner Kleophas,[7,8] Stefan H. Jacobson,[9] Christian Combe,[10] Friedrich K. Port,[1] Francesca Tentori.[1,11] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Alessandro Manzoni Hosp, Lecco, Italy; [3]U of Michigan, Ann Arbor, MI; [4]U Hosp Vall d'Hebron, Barcelona, Spain; [5]U Hosp, Gent, Belgium; [6]Heart of England NHS, Birmingham, United Kingdom; [7]MVZ DaVita, Dusseldorf, Germany; [8]Heinrich-Heine U, Dusseldorf, Germany; [9]Danderyd Hosp, Stockholm, Sweden; [10]Centre Hosp U de Bordeaux, France; [11]Vanderbilt U, Nashville, TN.*

Background: Online HDF is considered the most efficient dialysis technique, though only 1 of 3 recent randomized trials demonstrated a survival benefit vs. HD. Post-hoc analyses of all 3 studies showed patients who received the highest convection volumes had lower risk of adverse events. Use of high-volume HDF has consequently increased in many European countries, while online production of replacement fluid is not available in North America.

Methods: We analyzed n=8567 patients from 7 European countries in DOPPS phases 4-5 (2009-2015) with vintage >90 days. Among n=2012 (23%) HDF patients, about half had replacement fluid volume >20L. Adjusted Cox regression was used to estimate the association between mortality and HDF (vs. HD).

Results: Median follow-up was 1.6 years, and 2043 patients died. The adjusted HR (95% CI) of mortality was 1.13 (1.00-1.28) for any HDF vs. HD and 1.08 (0.92-1.28) for HDF > 20L vs. HD. Results were similar for CV and infection-related mortality. We did not observe lower mortality risk among facilities prescribing HDF to a greater % of patients.

Conclusions: Our results do not support the notion that online HDF achieves better patient survival vs. HD, even focusing on HDF with convection volumes >20L. Further trials specifically designed for testing the effect of increased convection of online HDF vs. HD on clinical outcomes are necessary before superiority of HDF can be accepted.

Adjusted HR (95% CI) of mortality: HDF vs. HD	
Overall, all-cause mortality	
Any HDF vs. HD	1.13 (1.00-1.28)
Cause of death	
CV mortality	1.20 (1.00-1.43)
Infection mortality	1.12 (0.82-1.54)
By volume replacement	
non-HDF (Ref.)	1 (Ref.)
HDF, 4-15L	1.25 (1.01-1.55)
HDF, 15-20L	1.14 (0.95-1.37)
HDF, >20 L	1.08 (0.92-1.28)
Facility % HDF use	
0%	1 (Ref.)
1-14%	1.17 (1.00-1.36)
15-49%	1.10 (0.93-1.30)
≥ 50%	1.28 (1.06-1.53)

Cox models stratified by phase*country, adjusted for age, sex, vintage, 13 comorbidities, vascular access, blood flow rate, BMI, albumin, Hgb, and accounted for facility clustering; Facility model additional adjusted for 5 fac-level confounders.

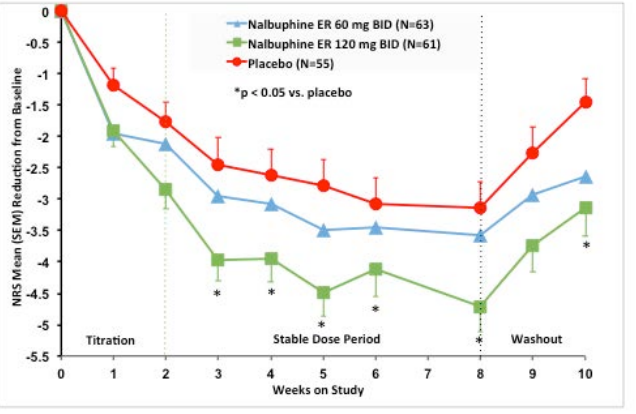
Time Course of Reduction in Itch Intensity during and following Treatment with Nalbuphine ER Tablets: A Randomized, Placebo-Controlled Trial in Patients with Uremic Pruritus Thomas Richard Sciascia,[1] Howard Hait,[1] Vandana S. Mathur.[2] *[1]Trevi Therapeutics, New Haven, CT; [2]MathurConsulting, Woodside, CA.*

Background: Clinical trials in uremic pruritus (UP) patients are typically powered to compare differences in itching intensity between the active treatment and placebo at the end of the treatment period. However, understanding the time course of loss of effect following treatment withdrawal is also important. Patients with severe baseline itching are of particular interest because they are the population with the greatest medical need.

Methods: This was a 3-arm randomized, double-blind, placebo-controlled trial comparing nalbuphine ER tablets 120 mg bid (NAL 120) and 60 mg BID (NAL 60) to placebo in 373 hemodialysis patients with UP. We measured change from baseline to the end of the treatment period (Week 8) in the worst itching intensity using an 11 point numerical rating scale (NRS) (0 = no itching; 10 = worst possible itching). The primary endpoint compared NAL 120 to placebo at the mean of Weeks 7 and 8. After completion of treatment, NRS data was additionally collected for 2 weeks.

Results: Among all patients and those with severe baseline itching (NRS >7, n = 179), NAL 120 consistently reduced itching from the end of the 2 week titration through the end of the treatment period. In the NAL 120 group, the mean (SEM) reduction in itching intensity at the end of treatment and end of washout was 3.8 (0.3) (p = 0.017 vs. placebo) and 2.2 (0.3) (p = NS vs. placebo) in the overall population and 4.7 (0.4) (p <0.01) and 3.1 (0.4) (p <0.05) in the severe pruritus population.

Reduction in Itching Intensity Among Patients with Severe Uremic Pruritus



Conclusions: In this randomized, controlled trial, NAL 120 significantly reduced itching in patients with moderate or severe pruritus. Among patients with severe pruritus, the anti-pruritic effects of NAL remained significantly better vs. placebo for at least 2 weeks after the last dose.

FR-OR084

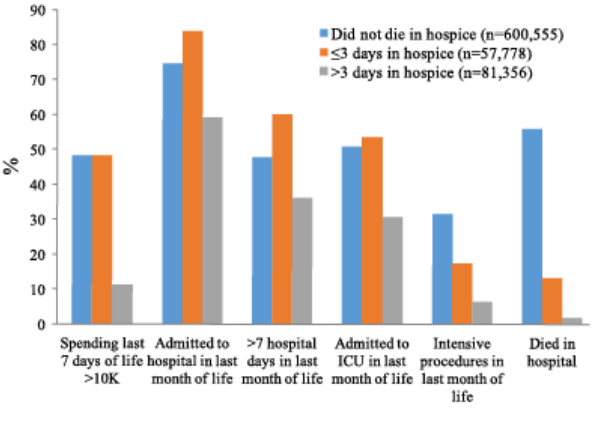
Timing of Hospice Enrollment and End-of-Life Utilization and Spending among Patients with ESRD Melissa Wachterman,[1] Susan M. Hailpern,[2] Nancy L. Keating,[1] Manjula Kurella Tamura,[3] Ann M. O'Hare.[2] *[1]Harvard Medical School; [2]Univ of Washington; [3]Stanford Univ.*

Background: Rates of hospice enrollment in patients with ESRD have increased over time, although remain low compared with the general population. Less is known about *timing* of hospice enrollment in ESRD patients. Because Medicare will not pay concurrently for dialysis and hospice for patients whose life-limiting illness is ESRD, these patients may be less often referred to hospice in a timely fashion. We examined the frequency and timing of hospice enrollment and patterns of end-of-life utilization and spending among ESRD patients.

Methods: Using USRDS data, we identified all ESRD patients who died between 2000 and 2012 who had Medicare Parts A & B. Patients were grouped according to whether and when they enrolled in hospice before death. We used a generalized linear model to examine the association of timing of hospice with healthcare utilization and spending at the end of life after adjustment for patient characteristics.

Results: Of the 739,689 ESRD patients who died, 19% were receiving hospice at the time of death, increasing from 10% in 2000 to 26% in 2012. Among hospice enrollees, 42% enrolled ≤3 days before death, decreasing slightly from 43% in 2000 to 40% in 2012. Adjusted measures of spending and utilization were significantly lower for those who received >3 days of hospice than for patients who did not use hospice (all p<.001). For patients who received ≤3 days of hospice, spending was not significantly different than for hospice non-users (p=.97), and hospital admission, length of stay, and ICU utilization were significantly higher (all p<.001).

End-of-life utilization and spending by length of time in hospice



Conclusions: While hospice use among ESRD patients has increased over time, almost half of patients enroll within 3 days before death. End-of-life spending and most measures of utilization for these patients are similar to or higher than for patients not enrolled in hospice.

FR-OR085

Efficacy of Endothelin Receptor A Blockade in Experimental Podocin Nephropathy Tanja Tamara Wlodkowski,[1] Mansoureh Tabatabaeifar,[1] Helga Denc,[1] Geraldine Mollet,[2] Corinne Antignac,[2] Franz S. Schaefer.[1] *[1]Pediatric Nephrology Div, Heidelberg Univ Hospital, Heidelberg, Germany; [2]Inserm U1163-Imagine Inst, Paris Descartes Univ, Paris, France.*

Background: Renal endothelin-1 expression is increased in various kidney diseases. Selective ET_A receptor blockade (ERA) improves renal function in various animal models of kidney disease. Here, we investigated antiproteinuric and nephroprotective effects of the ET_A receptor blocker Atrasentan in a mouse model of the most common human hereditary podocytopathy. Hemizygous R138Q-*NPHS2* knock-in mice develop heavy proteinuria, podocyte loss, focal segmental glomerulosclerosis (FSGS) and progressive renal failure.

Methods: In C57BL/6 mice with $Nphs2^{Flox/R140Q}$, Cre^{+} hemizygosity for mutant podocin was induced by tamoxifen injection. In a pilot study the animals were administered Atrasentan encompassing a sixfold dose range with food from time of induction or remained untreated (U). Furthermore, animals treated with a 4-wk delay ((D)elayed, n=14) were analyzed. Weight, blood pressure (MAP) and proteinuria were monitored weekly. Biochemical parameters and histopathological changes were examined after 4 wks treatment.

Results: Prophylactic ERA blockade demonstrated no attenuation in proteinuria and histological lesions at any dose level. Notably, intrarenal ET-1 expression increased only gradually as disease progressed, reaching significance by wk 5. When Atrasentan was administered at the time of maximal proteinuria and strong ET-1 expression, proteinuria decreased progressively and MAP was lowered significantly (wk7: 80.4 (D) v. 99.5 (U) mmHg, $p=0.001$) Preliminary histological evaluation (n=9) demonstrates attenuation in glomerulosclerosis (GSI: 1.69 (D) v. 2.27 (U wk 8), $p=0.0008$) and tubulointerstitial fibrosis (TIF % of total area: 4.18 (D) v. 7.56 (U wk 8), $p=0.008$; podocyte numbers tended to be better preserved (podocytes per glom: 54% (D) v. 32% (U wk 8) of healthy controls, n.s.). Furthermore, podocin protein abundance and mRNA expression was partly preserved in the treated animals.

Conclusions: In an *in vivo* model of hereditary podocin nephropathy, treatment with Atrasentan showed a beneficial effect on glomerulosclerosis and tubulointerstitial fibrosis.

DNA Copy Number Variations Associated with Vesicoureteral Reflux and Its Sequelae Dong Liang,[1] David S. Hains,[1] Andrew L. Schwaderer.[2] *[1]Innate Immunity Translational Research Center, Le Bonheur Children's Hospital, Memphis, TN; [2]CCTR, Nationwide Children's Hospital, Columbus, OH.*

Background: Copy number variations (CNV) represent a large class of structural genomic variations that have the ability modify susceptibility to a variety of human disorders such as cancer, obesity, schizophrenia, autism and infectious diseases. The RIVUR study followed 600 children with vesicoureteral reflux (VUR) and UTIs for two years, and DNA was collected on a subset of patients. We hypothesize that CNVs in pathways involving lower urinary tract development, innate immunity, or fibrosis will segregate to VUR patients that experience a complicated course.

Methods: Using high-resolution genome-wide, array comparative genomic hybridization (aCGH) experiment, using the genomic DNA from 298 RIVUR patients as well as 1440 matched healthy controls. The aCGH data was further processed and analyzed using Nexus 8 Copy Number software and DAVID bioinformatic resources. For each gene locus, a Fisher's Exact test was performed to access its association with disease susceptibility.

Results: Analysis identified a total of 612 common and 2659 rare CNVs differentially present in RIVUR compared to controls. 9 of the top 20 involved common pathways involved innate immunity/bacterial response. Furthermore, our analysis also revealed unique alterations (disease-specific CNVs) in genes related to renal development such as *PRKX* and *NOTCH1*, intercalated cell related genes such as *ATP6V1B1* and the bacterial defense such as *RNASE7* and *DEFA1A3* in RIVUR patients compared to controls.

Conclusions: Our study led to identification of over 3000 differentially presented rare and common CNVs in RIVUR patients compared to controls. These CNVs likely contribute to VUR sequelae and offer potential candidates for novel insights into disease pathogenesis as well as personalized medicine approaches to children with VUR.

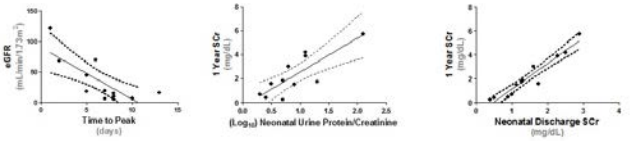
FR-OR087

Predictors of Progressive Kidney Disease after Definitive Vesicoamniotic Shunting for Lower Urinary Tract Obstruction Chryso P. Katsoufis, Marissa J. Defreitas, Wacharee Seeherunvong, Jayanthi Chandar, Michael Freundlich, Gaston E. Zilleruelo, Carolyn L. Abitbol. *Pediatrics/Pediatric Nephrology, Univ of Miami Miller School of Medicine/Holtz Children's Hospital, Miami, FL.*

Background: Lower urinary tract obstruction (LUTO) in the fetus is associated with poor postnatal outcomes, including chronic and end stage kidney disease, and high mortality. Studies of the effect of fetal intervention through vesicoamniotic shunting (VAS) are marred by a device malfunction rate of up to 60%. In this study, we delineate the postnatal course and infant renal function following definitive urinary diversion in utero.

Methods: This is a retrospective, cohort study of 17 male infants who survived the fetal intervention to birth. All had patent VAS in place at birth. Patients were followed for one year, or until demise, with serial measures of serum creatinine (SCr) and urine protein profile.

Results: Of the 17 males, 82% were non-white (35% black, 47% Hispanic). Shunts were placed at 21±3.5 weeks gestation. All neonates were born preterm (33.5±2.2 weeks) with low birth weight (2266±559 grams). 47% required respiratory support, for a duration of 2 days (IQR 0,9). Renal function at 1 year was predicted by neonatal discharge SCr [p<0.0001,r0.96] and time to peak SCr [p0.004,r-0.76]. It also correlated with neonatal random total proteinuria and albuminuria (p0.002,r0.67 and p0.02,r0.45, respectively). 3 patients died in the neonatal period, with 1 receiving renal replacement therapy (RRT). 3 additional patients required RRT at 8 months (IQR 5,28).



Conclusions: Even with definitive VAS for LUTO, postnatal morbidity and mortality remain high, emphasizing the role of renal dysplasia, in spite of urinary diversion, in postnatal kidney failure. Predictors of infant kidney function in the first year include neonatal SCr at discharge and time to peak SCr, along with neonatal proteinuria.

Genomic Imbalances Associate with Cognitive Impairment and Anxiety/Depression in Children with Chronic Kidney Disease Amy Kogon,[1,3] Miguel Verbitsky,[2,3] Matthew Matheson,[3] Stephen R. Hooper,[3] Craig S. Wong,[3] Bradley Warady,[3] Susan L. Furth,[3] Ali G. Gharavi.[2,3] *[1]Nationwide Children's Hosp; [2]Columbia Univ; [3]Chronic Kidney Disease in Children Study Group.*

Background: Children with chronic kidney disease (CKD) are at an increased risk for neuropsychiatric (NP) complications. Our ability to identify those most at risk and provide early intervention is limited. Children with CKD harbor a 10.8-fold excess of large genomic imbalances (GI) that also confer risk of NP impairment. We hypothesized that GIs predispose to both CKD and NP dysfunction.

Methods: We examined the relationship of GIs to NP performance using data from the Chronic Kidney Disease in Children Study. NP outcomes included intelligence (IQ:Wechsler Abbreviated Scales of Intelligence or Preschool and Primary Scale of Intelligence-Revised), anxiety/depressive symptoms (internalizing problems(IP):Behavior Assessment System for Children-2) and executive function (global executive composite score(GEC):Behavior Rating Inventory of Executive Function). GIs were detected by chromosomal microarrays and defined as definitively pathogenic or likely pathogenic per American College of Medical Genetics recommendations for interpretation of microarray data(Verbitsky et al,JCI'15). Linear regression determined associations of GIs with NP scores after controlling for GFR, CKD duration, maternal education, low birth weight, seizures, and genetically defined ancestry using genomic SNP data. NP measure score ≥1 standard deviation worse than the standardized mean was considered at risk.

Results: Analysis included 31 children with and 388 children without GIs. There were no demographic or kidney disease parameter differences between the groups. By adjusted regression analyses, GIs associated with a 7.6 point lower IQ score (p=0.006), 6.6 point worse IP score (p=0.003) and 5.8 point worse GEC score (p=0.01). 40% of children with GIs were at risk for intellectual disability, 46% for anxiety/depression and 57% for executive function issues compared to 22%, 23% and 29% without GIs, respectively.

Conclusions: GIs may predict NP function in children with CKD. Identifying pathogenic CNVs may provide opportunity for early diagnosis and personalized intervention for this at-risk subgroup.

Polymorphisms in Antimicrobial Peptide, Ribonuclease 7, Associate with Urinary Tract Infection Risk Keith Pierce,[1] David S. Hains,[1] Steven Creacy,[2] Andrew L. Schwaderer,[3] Brian Becknell,[3] John David Spencer.[3] *[1]Innate Immunity Translational Research Center, Children's Foundation Research Inst at Le Bonheur Children's Hospital, Memphis, TN; [2]YX Genomics, Cordova, TN; [3]CCTR, Research Inst at Nationwide Children's Hospital, Columbus, OH.*

Background: The mechanisms that maintain sterility in the urinary tract are not well understood. Recent studies emphasize the contribution of the innate immune system, which includes antimicrobial peptides (AMP), in protection from uropathogens. Previously, we have shown that the AMP, ribonuclease 7 (RNase 7), has broad-spectrum antimicrobial activity against uropathogenic bacteria and contributes to maintaining urinary tract sterility.

Methods: We used quantitative real–time PCR to investigate the prevalence of non-synonymous exonic single-nucleotide polymorphisms (SNPs) in *RNASE7* of 444 individuals with urinary tract infections (UTIs) and vesicoureteral reflux (VUR) from the Randomized Intervention for Children with Vesicoureteral Reflux (RIVUR) Study, 160 individuals with non-VUR UTIs from the Careful UTI Evaluation (CUTIE) Study, and 482 matched controls. We also used a site-directed point mutagenesis strategy to create amino acid changes in the RNase 7 peptide corresponding to these SNPs. We evaluated the antimicrobial activity of the RNase 7 peptide variants against uropathogenic *E. coli* (UPEC) using minimum inhibitory concentration (MIC) kill assays.

Results: The allele frequencies of two *RNASE7* polymorphisms, rs1263872 and rs1243469, indicated a significant difference between the cohorts studied (P<0.001 and P<0.05, respectively). Additionally, haplotype analysis revealed these polymorphisms are linked (D'=0.946) and are associated with the risk of recurrent UTI of Caucasian female patients not receiving antibiotic prophylaxis in the RIVUR and CUTIE studies (P<0.05).

Recombinant RNase 7 UPEC kill assays demonstrate that wild-type RNase 7 had a MIC of 3-4 μM while the RNase 7 variant rs1263872, encoded by an alanine to proline mutation, had an MIC of 0.25-0.5μM.

Conclusions: Our research suggests these *RNASE7* polymorphisms confer a decreased antimicrobial activity and are associated with UTI risk in children.

Prediction of Progression of Chronic Kidney Disease in Children by Various eGFR Markers in Comparison to Nuclear GFR

Janusz Feber,[1] Razgah Fajr Aldhafiry,[1] Nick Barrowman.[2] *[1]Dept of Pediatrics, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada; [2]Children's Hospital of Eastern Ontario Research Inst, Ottawa, Canada.*

Background: The accuracy of various eGFR formulas in comparison to nuclear GFR has been well documented. It is however unclear which eGFR is best suited for longitudinal follow-up and prediction of progression of chronic kidney disease (CKD). The aim of the study was to analyze the predictive power of various eGFRs obtained during follow-up for the prediction of measured GFR.

Methods: We performed a retrospective analysis of eGFR estimates in children with CKD followed in our institution over the last 8 years. All available results of urea, creatinine, cystatin C and height were used to calculate following eGFRs: Cystatin C eGFR (Pediatr Nephrol 2003;18:981), Schwartz eGFR(JASN 2009;20:629), CKiD eGFR (JASN 2009;20:629) and Lyon eGFR(NDT 2014;29:1082). Slopes of each eGFR were constructed by regression analysis in each patient; the intercepts of individual regression lines were then compared to nuclear GFR (nGFR) at the end of follow up. The ratios between predicted eGFR (PeGFR) and measured nGFR were analyzed by linear mixed effects models and intraclass correlation coefficient (ICC).

Results: A total of 366 eGFR values were collected in 23 patients (aged 11.8±5.0 years) with progressive CKD over a median of 400 follow-up days (range= 0 to 2821). There were significant differences among PeGFR/nGFR ratios (linear mixed effect model, $p<0.001$). In post-hoc Tukey tests, Cystatin C PeGFR was found to be significantly higher than Lyon PeGFR and Schwartz PeGFR (both $p<0.01$). The agreement between various PeGFR in the prediction of nGFR was modest (ICC=0.57, 95% CI=0.35 to 0.76). The most accurate prediction of the nuclear nGFR (PeGFR/nGFR ratio closest to 1) was obtained with CKiD PeGFR (mean ± SD ratio = 1.03 ± 0.20) followed by Schwartz PeGFR (0.97±0.23), Lyon PeGFR (0.95±0.23) and Cystatin C PeGFR (1.13±0.27; significantly different from 1.0, $p=0.02$).

Conclusions: There were significant differences among various eGFR formulas in the prediction of the measured nuclear GFR at the end of follow-up. The most accurate prediction of the nuclear GFR was obtained with the CKiD eGFR.

FR-OR091

Long-Term Clinical Outcomes and Risk Factors in Isolated Antenatal Hydronephrosis: A Prospective Cohort Study

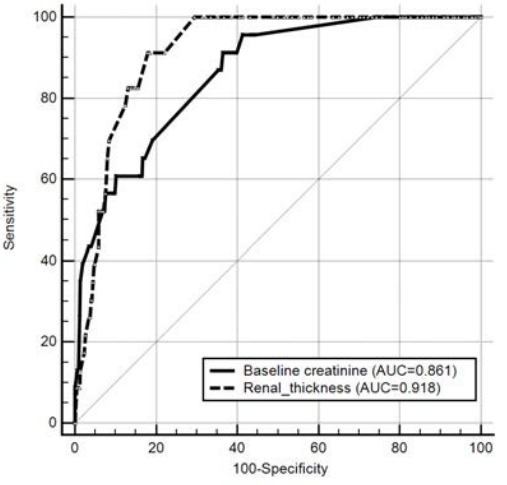
Eduardo A. Oliveira,[2] Robert H. Mak.[1] *[1]Pediatrics, UCSD, San Diego, CA; [2]Pediatrics, HC-UFMG, Belo Horizonte, MG, Brazil.*

Background: Antenatal hydronephrosis (ANH) affects approximately 1-5% of pregnancies. There are few studies on long-term clinical outcomes of infants with ANH. We evaluated the clinical outcomes of incident adverse health events (AHE) and the risk factors in a prospective cohort of 447 infants with isolated ANH in a single tertiary center.

Methods: ANH was classified according to the Society Fetal Urology (SFU) grading system into two groups (grades 0-2 vs. 3-4). The primary end-point was time until the occurrence of a composite of incident AHE, including proteinuria, hypertension and chronic kidney disease (CKD).

Results: Median follow-up time was 6.4 years (IQ range, 2.8 – 12.5). During follow-up, urinary tract infections (UTI) occurred in 89 (20%) children. Patients with SFU grades 3-4 had a greater risk of the occurrence of UTI ($P < 0.001$). Thirteen patients (3%) developed proteinuria, 6 (1.3%) hypertension, 14 (3.1%) CKD, and 23 (5%) the composite outcome. Estimated probability of occurrence of the composite outcome was 30% at 18 years. AHE occurred only in patients with SFU grades 3-4. After adjustment by Cox model, baseline creatinine, renal parenchyma thickness, and recurrent UTI were independent predictive factors of AHE. Renal parenchyma thickness at birth < 8.7 mm and a baseline creatinine > 0.37 mg/dl were strong predictors of AHE.

Risk factors	**Hazard Ratio (95% Confidence Interval)**	P-value
Baseline creatinine (mg/dl)	1.27 (1.05 - 1.56)	0.014
Renal parenchyma thickness at birth (mm)	0.78 (0.62 - 0.99)	0.042
Recurrent UTI	4.52 (1.49 - 13.6)	0.007



Conclusions: Our findings indicate a benign clinical course for ANH patients with SFU grades 0-2 without long-term AHE. Conversely, for patients with SFU grades 3-4 there is a clear increased risk of incident AHE, including proteinuria, hypertension and CKD.

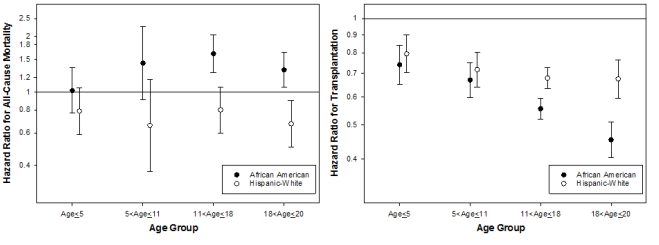
Association of Race with Risk of Mortality and Transplantation in Pediatric Dialysis Patients

Melissa Soohoo,[1] Elani Streja,[1] Marciana Laster,[2] Connie Rhee,[1] Keith C. Norris,[1] Rajnish Mehrotra,[3] Isidro B. Salusky,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UCLA; [3]Univ of Wash.*

Background: Previous studies have shown that in adults, African-Americans and Hispanic treated with dialysis have a lower likelihood of renal transplantation compared to whites and African-Americans have a higher risk of death. However, racial-ethnic disparities outcomes in pediatric dialysis patients remains understudied and often have not examined Hispanic children.

Methods: We investigated a cohort of 18,108 pediatric (age<20 years) patients who initiated dialysis between 2000-2013, according to USRDS records. We used competing risk regression to examine the association of race/ethnicity with mortality and transplantation stratified by the age at initiation of renal replacement therapy. All models were adjusted for cause of end-stage renal disease (ESRD), demographic and socioeconomic factors.

Results: The pediatric cohort included 47% white, 27% African-American and 26% Hispanic White incident ESRD patients. Compared to whites , African-Americans had a higher risk of mortality (HR[95%CI]: 1.37[1.21,1.55]), whereas Hispanic patients experienced better survival (HR[95%CI]: 0.69[0.59,0.81]) (Ref: whites). These differences were modified by age, where African-American patients ≤5 years did not experience worse mortality compared to whites. Across all levels of adjustment and age strata, both minorities had a lower probability of undergoing transplantation compared to whites.



Conclusions: The lower risk of death for Hispanic White vs. white dialysis patients extends to the pediatric age range, but for African Americans there is a reversal with higher mortality rates than their White peers. Lower transplant rates for Hispanics and African Americans also extend across adult and pediatric populations. Future studies are needed to further understand the underlying causes of these contrasting findings in adult and pediatric ESRD patients.

Antenatal Corticosteroids and the Renin-Angiotensin-Aldosterone System in Adolescents Born Preterm Andrew M. South,[1,2] Patricia A. Nixon,[1,3] Debra I. Diz,[2,4] Gregory B. Russell,[5] Beverly Snively,[5] Hossam A. Shaltout,[2,6] James C. Rose,[6] Michael H. O'Shea,[7] Lisa K. Washburn.[1,2] *[1]Pediatrics, Wake Forest School of Medicine, Winston Salem, NC; [2]Hypertension and Vascular Research Center, Wake Forest School of Medicine, Winston Salem, NC; [3]Health and Exercise Science, Wake Forest Univ, Winston Salem, NC; [4]Surgery, Wake Forest School of Medicine, Winston Salem, NC; [5]Biostatistical Sciences, Wake Forest School of Medicine, Winston Salem, NC; [6]Obstetrics and Gynecology, Wake Forest School of Medicine, Winston Salem, NC; [7]Pediatrics, Univ of North Carolina School of Medicine, Chapel Hill, NC.*

Background: Antenatal corticosteroid (ANCS) treatment hastens fetal lung maturity and improves survival of premature infants, but the long-term effects of ANCS are not well described. Animal models suggest ANCS increases the risk of cardiovascular disease through programmed changes in the renin-angiotensin (Ang)-aldosterone system (RAAS). We hypothesized that ANCS exposure alters the RAAS in adolescents born prematurely.

Methods: A cohort of 173 adolescents born prematurely was evaluated at age 14 years, of whom 92 were exposed to ANCS. We measured plasma and urine Ang II and Ang-(1-7) and calculated Ang II/Ang-(1-7) ratios. We used general linear regression models to estimate the difference in the RAAS between the ANCS-exposed and unexposed groups, adjusting for confounding variables.

Results: In unadjusted analyses, and after adjustment for sex, race, and maternal hypertension, ANCS exposure was associated with increased urinary Ang II/Ang-(1-7) [adjusted estimate 0.27 (95% CI 0.03, 0.5), $p = 0.03$], increased plasma Ang-(1-7) [0.66 (0.26, 1.07), $p = 0.002$], and decreased plasma Ang II/Ang-(1-7) [-0.48 (-0.91, -0.06), $p = 0.03$].

Conclusions: These alterations indicate an imbalance in the RAAS, promoting the actions of Ang II at the expense of Ang-(1-7), which over time may increase the risk of renal inflammation and fibrosis and ultimately hypertension and renal disease.

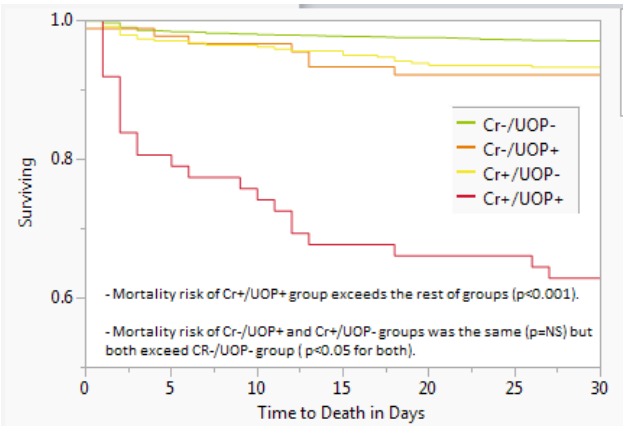
FR-OR094

Oliguria Is Independently Associated with Increased Mortality Risk amongst Critically Ill Children with Acute Kidney Injury Ahmad Kaddourah,[1,2] Rajit K. Basu,[2] Stuart Goldstein,[2] Scott M. Sutherland.[3] *[1]Sidra Medical and Research Center, Doha, Qatar; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Dept of Pediatrics at Stanford Univ, Stanford, CA.*

Background: Acute kidney injury (AKI) is associated with poor outcomes in critically ill children (CIC). While the KDIGO serum creatinine (SCr) AKI criteria have been widely applied, the urine output (UOP) criteria have not been studied. The impact of disregarding UOP criteria and effect of meeting both criteria remains unknown. We hypothesize the mortality risk associated with meeting both criteria exceeds that of meeting either alone.

Methods: We queried the database for AWARE, a prospective international multicenter study designed to assess AKI outcomes in CIC. We compared 28-mortality rates in CIC with Stage 2/3 AKI based upon whether they met both sets of criteria (SCr^+/UOP^+), SCr alone (SCr^+/UOP^-), or UOP alone (SCr/UOP^+).

Results: SCr and UOP data for 3318 CIC were available. 136(4.1%) deaths were reported. We observed poor agreement between SCr and UOP criteria to diagnose Stage 2/3 AKI (ƙ statistic 0.17, 95% CI:0.12-0.22). Kaplan-Meier survival analysis (figure 1) revealed that the mortality risk of the SCr^+/UOP^+ group exceeded all other groups (adjusted OR=20.9 [95% CI:11.7-35.6] p<0.001).



CIC meeting one but not both criteria (Cr^+/UOP^- and Cr/UOP^+) experienced similar mortality risk (p=0.21); this risk was greater than those without AKI (adjusted OR 2.4 [95% CI:1.5-3.8] and 2.8 [95%CI:1.2–5.9], respectively,p<0.05).

Conclusions: Application of the UOP criteria identified a cohort of CIC with AKI undiagnosed by SCr criteria. Notably, this cohort had similar mortality to those with SCr diagnosed AKI. Additionally, their use identified a subset of SCr diagnosed AKI with greater mortality risk. These findings underscore the importance of this definitional aspect and highlight the benefit of applying both KDIGO criteria in CIC.

FR-OR095

Loss of Serine Protease Hepsin Results in Defective Uromodulin Processing and Increased Activity of NKCC2 Eric Olinger,[1] Luca Rampoldi,[2] Ron Korstanje,[3] Olivier Devuyst.[1] *[1]Inst of Physiology, Univ of Zurich, Zurich, Switzerland; [2]San Raffaele Scientific Inst, Milan, Italy; [3]The Jackson Laboratory, Bar Harbor.*

Background: Uromodulin, the most abundant protein in healthy urine, is a zona pellucida (ZP)-type protein exclusively produced in the thick ascending limb (TAL), where it modulates NaCl handling by regulating the Na^+, K^+, $2Cl^-$ cotransporter NKCC2. The release and proper polymerization of uromodulin in urine was recently demonstrated to depend on a C-terminal proteolytic cleavage mediated by the serine protease hepsin (HPN). The functional consequences of defective HPN and uromodulin miscleavage are unknown.

Methods: We investigated an ENU mouse line harboring a splice site mutation in *Hpn,* which is predicted to reduce the transcription rate. Furthermore, we performed a knockdown of HPN using lentiviral shRNA in primary mouse TAL cells.

Results: We confirmed the predicted lack of HPN expression in the kidneys of HPN-ENU mice. In the urine of these mice, we detected a dramatic decrease of mature uromodulin excretion and evidence of miscleaved, polymerization-incompetent uromodulin isoforms. ShRNA-mediated knockdown of HPN in polarized primary mouse TAL cells led to a strong decrease in apical secretion of uromodulin as well as in the amount and size of uromodulin polymeric chains. In parallel with reduced urinary excretion, uromodulin massively accumulated both at the apical membrane and in the cytosol of TAL cells in HPN-ENU mice. These mice showed an exaggerated natriuretic response after furosemide and a better adaptation to 24h water deprivation, suggesting a hyperactivation of the TAL segment. This was supported by an increase in core and phosphorylated forms of NKCC2 in HPN-ENU kidneys, in absence of adaptations in the distal convoluted tubule.

Conclusions: These data expand the physiological role of HPN *in vivo* and in primary TAL cells, which endogenously express uromodulin and HPN. The loss of HPN results in intracellular and apical membrane accumulation of uromodulin and a specific activation of the TAL, suggesting that membrane-bound uromodulin activates NKCC2. They give new insights into the regulation of uromodulin processing and its role in the TAL.

Plasma K+ Dependent Regulation of NaCl Cotransporter in Native Distal Convoluted Tubules Involves SPAK/OSR1 and Calcineurin David Penton Ribas,[1] Jan Czogalla,[1] Agnieszka Wengi,[1] Nina Himmerkus,[2] Dominique Loffing-Cueni,[1] Olivier Staub,[3] Markus Bleich,[2] Frank Schweda,[4] Johannes Loffing.[1] *[1]Inst of Anatomy, Univ of Zurich, Zurich, Switzerland; [2]Inst of Physiology, Univ of Kiel, Kiel, Germany; [3]Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [4]Inst of Physiology, Univ of Regensburg, Regensburg, Germany.*

Background: A high dietary potassium (K^+) intake causes a rapid dephosphorylation and hence inactivation of the thiazide-sensitive NaCl cotransporter (NCC) in the renal distal convoluted tubule (DCT). Based on experiments in heterologous expression systems and in mice, it has been proposed that changes in plasma K^+ concentrations ($[K^+]$) modulate NCC phosphorylation via changes in intracellular Cl^- concentrations that control the activity of the WNK/ SPAK kinase pathway.

Methods: We used isolated perfused mouse kidneys, isolated perfused DCTs, and mouse kidney slice preparations to test the physiological relevance of this model on native DCT cells *ex vivo*.

Results: We demonstrate that changes in extracellular $[K^+]$ ($[K^+]_{ex}$) rapidly (< 30 min) modulate NCC phosphorylation by direct effects on the DCT, with the most prominent changes occurring around physiological variations of plasma $[K^+]$. The inhibition of cellular Cl^- fluxes by removing extracellular Cl^- or by blocking Cl^- channels with DIDS abolished NCC phosphorylation in response to low $[K^+]_{ex}$, but did not blunt NCC dephosphorylation in response to high $[K^+]_{ex}$. Moreover, NCC dephosphorylation under low $[Cl^-]_{ex}$ and high $[K^+]_{ex}$ was independent from any significant changes in the phosphorylation status of SPAK. However, under these conditions, inhibition of protein phosphatase 3 (calcineurin) by tacrolimus diminished $[K^+]_{ex}$ induced dephosphorylation of NCC. Inhibition of protein phosphatases 1, 2A and 4 by calyculin A did not interfere with the response to $[K^+]_{ex}$, but increased NCC phosphorylation in general.

Conclusions: In the native DCT, changes in $[K^+]_{ex}$ directly and rapidly control NCC phosphorylation by Cl^- dependent and independent pathways that involve both SPAK and calcineurin.

Funding: Government Support - Non-U.S.

FR-OR097

Calcineurin Rapidly Dephosphorylates Sodium-Chloride Cotransporter in Response to High Potassium Intake Wakana Shoda, Naohiro Nomura, Fumiaki Ando, Yutaro Mori, Takayasu Mori, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Bunkyo, Tokyo, Japan.*

Background: Dietary potassium (K^+) intake is well known for reducing blood pressure and mortality. Moreover, the sodium-chloride cotransporter (NCC) plays an important role blood pressure regulation and urinary K^+ excretion in response to K^+ intake. In previous studies, it has been reported that NCC is activated by the With no lysine kinase (WNK) - Ste 20-related proline (SPAK) cascade in a low-K^+ diet. However, the mechanism

of NCC regulation with high K^+ intake is still unclear. A previous study showed rapid dephosphorylation of NCC after acute K^+ load, suggesting the involvement of phosphatases. Protein phosphatase (PP) 1 and PP2B (calcineurin) have been reported to dephosphorylate NCC. To identify the mechanism involved in the regulation of NCC with K^+ intake, we focused on rapid decrease of NCC phosphorylation during acute K^+ load.

Methods: We used adult C57BL/6 mice, which were fed with a 1.7% K^+ solution by oral gavage. Kidneys were collected 15 min after oral gavage. The effect of WNK4, SPAK, and PP1 on acute K^+ load was evaluated by Western blotting with specific antibodies. To investigate the involvement of calcineurin and calmodulin on NCC dephosphorylation, tacrolimus (5mg/kg) or W7 (20mg/kg) was injected in each mouse intraperitoneally 1 h before K^+ oral gavage. To evaluate the urine K^+ excretion, urine samples were collected every 30 minutes after K^+ oral administration.

Results: We confirmed that acute oral K^+ load rapidly dephosphorylated NCC. The dephosphorylation of NCC induced by acute K^+ load was clearly inhibited by tacrolimus and W7 treatment. We also found that hyperkaliuria induced by high K^+ intake was significantly suppressed by tacrolimus treatment. PP1 and its endogenous inhibitor, I-1, did not show significant change after K^+ intake. There was no significant difference in WNK4, total and phosphorylated SAPK expression after high K^+ intake.

Conclusions: This study showed that calcineurin is activated with acute K^+ load, which rapidly dephosphorylates NCC, leading to increase urinary K^+ excretion. The mechanism is independent of WNK4 and SPAK kinases.

Funding: Government Support - Non-U.S.

FR-OR098

The Kidney Specific WNK1 Isoform (KS-WNK1) Is a Potent Activator of WNK4 and NCC Eduardo R. Argaiz,[1] Maria Chavez-Canales,[2] Alejandro Rodriguez-Gama,[1] Norma Hilda Vázquez,[1] Juliette Hadchouel,[2] David H. Ellison,[3] Gerardo Gamba.[1] *[1]Molecular Physiolog Unit, INCMNSZ-IIB-UNAM, Mexico City, Mexico; [2]INSERM 970, París, France; [3]Oregon Health & Science Univ, Portland.*

Background: The observation that the kidney enriched WNK1 isoform lacking exon 11 (L-WNK1-Δ11) is an activator of NCC (Hypertension, 2014) and that WNK4 can have a dual effect on NCC, which depends on the intracellular Cl^- concentration (JASN, 2015) have changed our working model of NCC regulation by WNKs. We thus revisited the effect of the KS-WNK1-Δ11 isoform on NCC and WNK4 activity.

Methods: NCC activity was assessed in *Xenopus* oocytes by measuring the thiazide-sensitive $^{22}Na^+$ uptake and the N-terminal phosphorylation by Western blot, two days after microinjection with NCC cRNA alone or together human L-WNK1-Δ11, KS-WNK1-Δ11 and/or WNK4. WNK4-S335 phosphorylation was taken as a surrogate of activity. Antibodies used were against c-myc, flag, T60-NCC, S335-WNK4, SPAK or S373-SPAK.

Results: KS-WNK1-Δ11 induced a dramatic activation of NCC by 3 fold (N=30, $p<0.001$) that was accompanied by increased SPAK/OSR1 phosphorylation as well as NCC surface expression and phosphorylation. The effect of L-WNK1-Δ11 and KS-WNK1-Δ11 on NCC was additive. The effect of L-WNK1-Δ11, but not that of KS-WNK1-Δ11 on NCC was precluded by coinjection with WNK4. The presence of KS-WNK1-Δ11 increased WNK4 phosphorylation at S335 by 7.5 fold (N=6, $p<0.01$), despite no change in intracellular Cl^- concentration. KS-WNK1-Δ11 and WNK4 interaction was confirmed by immunoprecipitation. Increased WNK4-S335 phosphorylation in the presence of KS-WNK1-Δ11 was only seen in the immunoprecipitated fraction and was not observed with the KS-WNK1-Δ11 HQ mutant that lacks interaction with WNK4.

Conclusions: Our data show that KS-WNK1-Δ11 is a powerful activator of NCC. The mechanism appears to be due to KS-WNK1-Δ11-induced WNK4 autophosphorylation and activation that in turn promotes NCC N-Terminal phosphorylation by the WNK-SPAK/OSR1 pathway. Given the high expression of KS-WNK1-Δ11 in DCT, these observations may provide a mechanism to explain why the up-regulated WNK4 in PHAII remains active despite the salt sensitive, low renin hypertension and hyperkalemia, expected to inhibit the kinase.

FR-OR099

A Cysteine-Rich Motif Regulates KS-WNK1 Protein Localization and Abundance Cary R. Boyd-Shiwarski,[1] Kara L. McClain,[1] Daniel J. Shiwarski,[1] Lubika J. Nkashama,[1] Ankita Roy,[1] Olivier Staub,[2] Arohan R. Subramanya.[1] *[1]Univ of Pittsburgh; [2]Univ of Lausanne.*

Background: WNK1 coordinates tubular NaCl and K+ transport through the concerted action of two major gene products: a ubiquitously expressed full-length "Long" isoform with intact serine-threonine kinase activity (L-WNK1), and an N-terminally truncated kinase-defective "Kidney Specific" isoform (KS-WNK1) that is highly expressed in the DCT. KS-WNK1 is transcribed from an intronic promoter that replaces the first four exons of L-WNK1 with a short unique exon, termed exon 4a. In the DCT, WNK signaling complexes form discrete puncta of unknown function. The marked expression of KS-WNK1 in DCT suggests that it may play role in the formation of these structures.

Methods: WNK1 isoform localization in kidney was assessed by immunostaining and light microscopy. The role of specific residues in KS-WNK1 trafficking and stability was determined by gBlock mutagenesis, cDNA transfection into 293 and MDCK cells, confocal microscopy, cell fractionation, and CHX chase assays.

Results: In the human and rodent DCT, C-terminal pan-WNK1 antibodies recognized a punctate signal that differed strikingly from a diffuse localization pattern in other nephron segments where KS-WNK1 expression is low. In cultured kidney epithelia, KS-WNK1 collected in similar puncta, whereas L-WNK1 was distributed diffusely throughout the cytoplasm. Mutagenesis studies revealed that KS-WNK1 puncta formation was dependent on a cysteine-rich motif harbored in exon 4a. Mutation of this signature to serines shifted KS-WNK1 diffusely, rendering the protein unstable due to enhanced sensitivity to its cognate E3 ubiquitin ligase, the KLHL3/CUL3 complex. In coexpression studies, L-WNK1 redistributed into KS-WNK1 puncta, indicating that KS-WNK1 may act as a scaffold that sequesters WNK complexes in the DCT.

Conclusions: These results suggest that exon 4a acts as a cap to protect KS-WNK1 from disposal, and that the cysteines in exon 4a are necessary for its assembly into discrete structures that participate in DCT physiology. We propose that the punctate localization of WNK kinases in the DCT may reflect a KS-WNK1 dependent signaling response during oxidative or potassium stress.

FR-OR100

Regulation of WNK4-SPAK-NCC Pathway by the Calcium Sensing Receptor Silvana Bazua-Valenti,[1] Lorena Leonor Rojas,[1] Maria Castañeda-Bueno,[1] Alejandro Rodriguez-Gama,[1] Norma Hilda Vázquez,[1] Luz Graciela Cervantes-Perez,[2] Jonatan Barrera-Chimal,[1] Paola De los Heros,[3] Gerardo Gamba.[1] *[1]Molecular Physiology Unit, INCMNSZ-IIB-UNAM; [2]Pharmacology, INCICH; [3]Faculty of Medicine, UNAM, Mexico City, Mexico.*

Background: Extracellular calcium inhibits salt reabsorption in the TAL through the basolateral Calcium Sensing Receptor (CaSR) inducing hypercalciuria. CaSR is also expressed in the apical membrane of the DCT, where we hypothesize plays a role in activating NCC via WNK4-SPAK pathway to prevent salt loss and further decrease the calcium reabsorption.

Methods: NCC activity (thiazide-sensitive $^{22}Na^+$ uptake) and the effect of the type I CaSR agonist gadolinium were analyzed in *X. leavis* oocytes in the absence or presence of mouse WNK4 and/or CaSR. Expression and phosphorylation of SPAK were assessed in HEK-293 cells co-transfected with WNK4 + wild type or mutant CaSR harboring the activating mutation E227K, in the presence or absence of the type 2 agonist R-568. Lastly, the WNK4-SPAK-NCC pathway was also studied by western blot analysis in kidneys of 12 mice administered with R-568 at 30 mg/kg or vehicle.

Results: In oocytes, gadolinium increased NCC activity by five-fold when co-expressed with WNK4 and CaSR ($p<0.001$). Absence of either WNK4 or CaSR precluded this effect. In R-568-stimulated HEK-293 cells, SPAK phosphorylation increased in a dose and time dependent manner only if both CaSR and WNK4 were present. Furthermore, co-transfection with the CaSR activating mutation, CaSR-E227K, phosphorylates SPAK in basal conditions ($p<0.05$). Interestingly, CaSR-E227K markedly increased WNK4 protein expression (almost two-fold, $p<0.0001$), a condition not observed with a WNK4 harboring PHAII mutation, suggesting a Kelch3-dependent mechanism. Finally, R-568 administration to wild-type mice showed increased NCC phosphorylation and increased WNK4 and SPAK protein expression (five-fold $p<0.05$).

Conclusions: Our results suggest that activation of CaSR can increase the activity of NCC via WNK4-SPAK pathway. It is possible that activation of CaSR by calcium in the apical membrane of DCT increases salt reabsorption via NCC to prevent salt loss and further decrease calcium reabsorption in this nephron segment.

Collecting Duct Specific Deletion of the (Pro)renin Receptor Modulates ENaC Expression Nirupama Ramkumar, Deborah Stuart, Nikita Abraham, Kai Song, Shuping Wang, Donald E. Kohan. *Nephrology and Hypertension, Univ of Utah Health Sciences Center, Salt Lake City, UT.*

Background: The renal tubular (pro)renin receptor (PRR) has been shown to modulate water balance, blood pressure and Na^+ homeostasis. We recently reported that *inducible* nephron wide deletion of the PRR results in Na^+ wasting, reduced epithelial Na^+ channel (ENaC) expression in the kidney and attenuated hypertensive response to angiotensin-II (Ang-II) infusion.

Methods: In this study, we examined the effects of PRR deletion in collecting duct (CD) specific mouse models targeting either the principal cells (PC) or intercalated cells (IC).

Results: PC-specific PRR knockout (KO) mice were obtained by crossing floxed PRR mice with mice harboring AQP-2 Cre recombinase. Compared to floxed mice, PC specific KO PRR mice had no differences in PRR immunostaining but had 50% reduction in PRR mRNA in micro-dissected cortical CDs. No differences in blood pressure were observed between the two groups at baseline or following Ang-II infusion at 600 ng/kg/min. Similarly, plasma renin concentration and renal expression of ENaC protein isoforms were comparable between the two groups. To achieve IC-specific PRR deletion, floxed PRR mice were bred with mice expressing B-1 Cre recombinase. Compared to floxed controls, IC-specific PRR KO mice were smaller (KO body weight: 5.9 ± 1.3 g vs controls: 11.1± 1.2 g) and did not survive beyond 30 days after birth. IC-specific PRR KO mice also demonstrated marked reduction in renal medullary PRR immunostaining along with decreased renal expression of ENaC-α protein (50% reduction compared to controls), similar to the findings in nephron wide deletion of PRR.

Conclusions: Taken together, these findings suggest that IC specific deletion of PRR but not PC-specific deletion modulates renal ENaC expression. Further studies evaluating ENaC activity in isolated cortical CDs from PC and IC specific PRR KO mice will help delineate the functional role of CD PRR in Na^+ homeostasis.

(Pro)renin Receptor/ATP6AP2 Is Required for V-ATPase Assembly and Function but Not for the Renin-Angiotensin System Matias Simons,[1] Magda Cannata Serio,[1] Virginie Hauser,[1] Francesco Trepiccione,[2] Michael Schwake,[3] Dominique Eladari.[4] *[1]Inst Imagine, Paris, France; [2]Second Univ of Naples, Naples, Italy; [3]Northwestern Univ, Chicago, IL; [4]PARCC, INSERM 970, Paris, France.*

Background: The proton pump vacuolar (V)-ATPase acidifies intracellular organelles and is crucial for many cellular processes. The multisubunit complex is divided into the proton pore (V0 sector) and the ATP hydrolysis domain (V1 sector). Apart from the V1 and V0 subunits, there are two accessory subunits, ATP6AP1 and ATP6AP2. While ATP6AP1 seems to participate in V0 assembly in the endoplasmic reticulum (ER), ATP6AP2 has been proposed to function as a receptor for (pro)renin in the renin-angiotensin system (RAS).

Methods: This study aimed at characterizing ATP6AP2 functions in the kidney by combining phenotypic characterization in mouse and *Drosophila* models with interaction proteomics in cultured human cells.

Results: Using an inducible conditional deletion of ATP6AP2 in the tubular nephron of the mouse, we could recently show that acid-base regulation was decreased due to impaired V-ATPase expression and activity in the intercalated cells of the collecting duct. By contrast, RAS-dependent sodium and potassium handling as well as blood pressure control was unaffected. To identify novel binding partners of ATP6AP2, we performed a mass spectrometry-based proteomic approach. Among top-ranking interactors for ATP6AP2, we found both V0 subunits and ER-based V0 assembly factors, including ATP6AP1. We were able to demonstrate ER localization of ATP6AP2 using *Drosophila* wing epithelial cells. This localization depended on an ER retention motif in the extreme cytoplasmic tail of ATP6AP2. Overexpression and knockdown of ATP6AP2 led to Xbp1-dependent ER stress in wing epithelial cells. Moreover, fly wing phenotypes caused by ATP6AP2 overexpression were completely suppressed by co-expressing ATP6AP1.

Conclusions: Taken together, our results demonstrate that ATP6AP2 interacts with ATP6AP1 in the ER to control ER homeostasis. Together with the *in vivo*-analysis, our data argue for a main role of ATP6AP2 in V-ATPase assembly and function and against a role in the renin-angiotensin system.

FR-OR103

Recombinant ApoL1 Confers pH-Dependent Anion Permeability to Phospholipid Vesicles John C. Edwards. *Internal Medicine, Saint Lousi Univ, Saint Louis, MO.*

Background: Variants in ApoL1 confer increased risk of certain types of chronic kidney disease in people of African ancestry. ApoL1 has been reported to function as an ion channel but reports vary on the nature of this activity. We sought to characterize ApoL1 channels with expectation that detailed properties of the channel activity of WT and variant ApoL1 may provide insight into the pathophysiology of ApoL1-associated kidney disease.

Methods: Recombinant N-terminal His-tagged ApoL1 was expressed in bacteria and purified by Ni-affinity and gel filtration using methods of Thompson and Finkelstein (PNAS 112: 2894 (2015)). Ion permeability was assessed using vesicle-based, voltage dependent Cl and K efflux assays employing ion selective electrodes. Single channel properties were investigated using the Tip-Dip lipid bilayer approach with ApoL1 added to the bath solution. Protein structure was probed using intrinsic tryptophan fluorescence.

Results: The purification method yields large amounts of very highly purified His-tagged ApoL1 which is active in a trypanosome killing assay. Direct addition of Apol1 to pre-formed phospholipid vesicles yields robust Cl selective permeability that supports voltage-driven chloride transport. The activity shows a strong dependence on pH at which protein and membranes interact, with a sharp drop in activity as pH is raised above 6.5. Activity is linearly dependent on mass of protein, and shows strong dependence on lipid composition of the vesicles, requiring the presence of negatively charged phospholipids. We do not find cation-selective permeability when assayed at either pH 5 or 7.5. Biophysical studies of ApoL1 in solution reveal a significant structural transition in the same range in which the channel is activated (pH 7 to 6.5). In tip-dip bilayer, ApoL1 spontaneously inserts at low pH, generating transitions with a range of single channel conductances between 2 and 10pS, and with a non-rectifying current-voltage relationship. We do not find enhanced channel activity if the bath solution is changed to pH 7.5.

Conclusions: Purified recombinant ApoL1 can insert directly into phospholipid membranes at low pH and function as an anion selective channel. Whether the disease associated variants show altered channel properties remains to be determined.

FR-OR104

Purinergic Modulation of V-ATPase-Dependent Proton Secretion in Type A Intercalated Cells Maria A. Battistone, Claire R. Barton, Rachel Nager Liberman, Anil V. Nair, Diane E. Capen, Dennis Brown, Sylvie Breton. *Prog. Membr. Biol./Nephrology Div, MGH/Harvard Med. Sch., Boston, MA.*

Background: Acid/base transport by renal intercalated cells (ICs) is central to the maintenance and regulation of blood pH. In particular, type A ICs (A-ICs) secrete protons (H^+) via the vacuolar H^+-ATPase (V-ATPase) located in their apical membrane. This process is regulated via recycling between sub-apical vesicles and the apical membrane, and activation of the cAMP/PKA pathway induces apical V-ATPase accumulation. The adenosine (Ade) P1 purinergic receptors A2A and A2B are linked to Gs and increase cAMP and we, therefore, investigated their role in the regulation of V-ATPase in A-ICs.

Methods: P1 receptor expression was evaluated by RT-PCR in $EGPF^+$ A-ICs isolated by FACS from B1-EGFP mice, and by immunofluorescence (IF) in mouse kidney. Mice were injected (i.v.) with Ade, agonists of A2A (PSB077) or A2B (BAY60-6583) (1.5 µmol/kg, 15 min) or saline. V-ATPase membrane accumulation was analyzed by IF, immunogold electron microscopy (EM), and Western blotting (WB) following cell fractionation. Moreover, isolated A-ICs were incubated for 15 min with PSB077 or BAY60-6583 (600 µM), or antagonists of A2A (ANR94) or A2B (PSB1115) (10 µM), and V-ATPase membrane accumulation and PKA substrate phosphorylation were evaluated by WB.

Results: RT-PCR revealed A2A and A2B expression in A-ICs, and IF showed their apical membrane expression in A-ICs. IF, EM, and WB following cell fractionation showed V-ATPase apical membrane accumulation (subunit A, a4) in mice treated with Ade, PSB077 or BAY60-6583, compared to control. A-ICs treated with the agonists showed an increase in PKA substrate phosphorylation, and V-ATPase redistribution from vesicles to plasma membrane. The A2A and A2B antagonists, added together with Ade, abolished these effects.

Conclusions: These results indicate the presence of an adenosine-dependent PKA activation pathway via A2A and A2B receptors, which leads to V-ATPase apical membrane accumulation in A-ICs. Our study reveals a novel mechanism by which A-ICs respond to luminal agonists via purinergic regulation, and provides new frameworks for the future development of treatments for acid/base balance disorders.

Increased Concentration of the Vasoconstriction Inhibiting Factor (VIF), an Endogenous Cofactor of Angiotensin II Acting on the AT2 Receptor, in CKD Patients Joachim Jankowski,[1] Vera Jankowski.[1] *[1]Inst for Molecular Cardiovascular Research, Univ Hospital RWTH Aachen, Aachen, Germany; [2]Charite, Berlin, Germany.*

Background: The renin-angiotensin system (RAS) and especially the angiotensin peptides play a central role in blood pressure regulation. Here, we hypothesize that a yet unknown peptide is involved in the action of Ang 2 modulating the vasoregulatory Ang II effects as a cofactor.

Methods: The peptide was isolated from bovine adrenal glands chromatographically. Chromatographic fractions with vasodilatory properties were fractionated to homogeneity, and the underlying cofactor of Ang II was identified. The effects of this peptideon vasoconstriction were evaluated *in-vitro*, *in-vivo* in an animal model, and the affinity of the peptide to the receptor mediating these effects was identified. The plasma concentration in humans was quantified in CKD patients and controlls.

Results: The amino acid sequence of the endogenous cofactor of Ang II isolated from bovine adrenal glands was HSSYEDELSEVLEKPNDQAEPKEVTEEVSSKDAAE, which is a degradation product of chromogranin A. The amino acid sequence of the peptide isolated from human plasma was HSGFEDELSEVLENQSSQAELKEAVEEPSSKDVME. Both peptides diminished significantly the vasoconstrictive effect of Ang II *in-vitro*. Based on the vasoregulatory effects on the Ang II actions, we named the peptide "*vasoconstriction inhibiting factor*" (*VIF*). The vasoregulatory effects of *VIF* are mediated by the AT-2 receptor. VIF impairs Ang II-induced phosphorylation of the p38MAPK pathway but not of ERK1/2. The vasodilatory short-term and long-term effects were confirmed *in-vivo*. The plasma concentration of *VIF* was significantly increased in CKD patients compared to controls.

Conclusions: *VIF* is a novel vasoregulatory peptide which modulates the vasoconstrictive effects of Ang II by acting on the AT2 receptor. It is likely that this increase in *VIF* may serve as a counter-regulatory effect to defend against hypertension. The identification of this new target may help us to understand the pathophysiology of renal and heart failure and may form a basis for the development of new strategies for the prevention and treatment of cardiovascular disease in these patients.

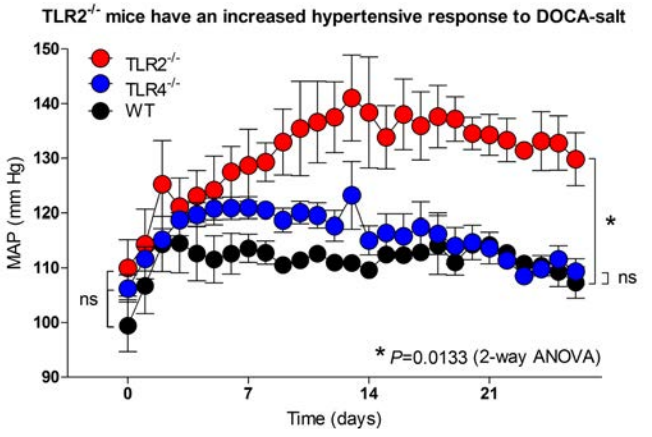
FR-OR106

Toll-Like-Receptor 2 Deficiency Exacerbates Deoxycorticosterone Acetate-Salt-Induced Hypertension David Severs, Estrellita Uijl, Alexander H. Danser, Robert Zietse, Ewout J. Hoorn. *Dept of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Emerging evidence suggests that inflammatory processes contribute to the development of hypertension. Specific damage-associated molecular patterns (DAMPs) may be increased in early stages of hypertension. Engagement of these DAMPs with Toll-like receptors (TLR) on innate immune and nonimmune cells initiates a cascade that could lead to worsening hypertension. Our aim was to assess the effect of deficiencies in TLR2 or TLR4 on the development of salt-sensitive hypertension.

Methods: We measured mean arterial pressure (MAP) in wild-type (WT, n=3), $TLR2^{-/-}$ (n=3) or $TLR4^{-/-}$ mice (n=6) by implanted radiotelemeters. We induced hypertension by deoxycorticosterone acetate and 0.9% NaCl as drinking water (DOCA-salt) during 4 weeks. We measured vascular reactivity in iliac arteries with wire myographs; these data are expressed as percentage of the maximum contractile response (E_{max}) to 100 mmol/L KCl.

Results: $TLR2^{-/-}$ mice had a much greater rise in MAP than did WT mice, while MAP in $TLR4^{-/-}$ was similar to that in WT (see figure). The angiotensin (Ang) II E_{max} did not differ between WT (60.3±6.9) and $TLR4^{-/-}$ mice (50±2.2%, P=0.41), but $TLR2^{-/-}$ mice had significantly greater contractility (93.2±5.9%, P=0.02). Irbesartan blocked Ang II-induced contractile responses in all mice, whereas the Ang II type 2 (AT2) receptor blocker PD123319 blunted the effects of Ang II only in $TLR2^{-/-}$ mice. Addition of the nitric oxide synthase blocker L-NAME did not significantly alter the contractile response to Ang II, and acetylcholine-induced vasorelaxation was similar in all mice.



Conclusions: Unexpectedly, TLR2 deficiency exacerbates experimental salt-sensitive hypertension. This effect may involve an increase in Ang II responsiveness, which may be partly explained by a constrictive rather than a vasodilatory response to AT2 receptor stimulation.

Funding: Government Support - Non-U.S.

Renal-Specific Dendritic Cell Depletion Causes Hypotension via Reduced Sodium Chloride Cotransporter Expression Brandi M. Wynne,[1,2] Gillian Grace Hecht,[2] Trinity Kronk,[1] Henrieke Jacobien van Elst,[2] Robert S. Hoover.[1,2,4] *[1]Dept of Physiology, Emory Univ, Atlanta, GA; [2]Dept of Medicine, Renal Div, Emory Univ, Atlanta, GA; [3]Veteran's Administration Research Service, Atlanta, GA; [4]Atlanta VA Medical Center, Atlanta, GA.*

Background: During hypertension, dendritic cells (DCs) have been shown to activate immune cells and secrete cytokines, such as IL-6. Recently, DCs were found to form an intricate network within the renal cortex and especially along the distal nephron. Additionally, during AngII-mediated hypertension, a subset of DCs route to the kidney. Studies have shown that loss of renal-specific DCs (rDCs) reduce glomerulonephritis and play an important role in the progression of hypertension. We hypothesize that rDCs modulate blood pressure (BP) and sodium transporter expression.

Methods: Tail-cuff measurements were performed in rDC-depleted and Wt mice. rdas loss contributed to a decreased systolic blood pressure (94mmHg ± 17mmHg *vs.* 130mmHg ± 10mmHg *Wt*, n=5, $p<0.05$) at baseline. To determine a mechanism, protein expression of phospho-NCC (pNCC) and total NCC, along with IL-6 was determined. rDC-depleted mice had a lower expression of total NCC (48% decrease), with no changes in pNCC or IL-6. There were no differences in urinary sodium excretion at baseline.

Results: Tail-cuff measurements were performed in rDC-depleted mice and Wt (C57Bl6). Renal-specific loss of DCs contributed to a decreased systolic blood pressure (94mmHg ± 17mmHg *vs.* 130mmHg ± 10mmHg *Wt*, n=5, $p<0.05$). To determine a mechanism, protein expression of phospho-NCC (pNCC) and total NCC, along with IL-6 was determined. rDC-depleted mice had a lower expression of total NCC (48% decrease), with no changes in pNCC. In addition, no detectable changes in IL-6 were observed.

Conclusions: These data suggest that baseline BP is modulated by resident innate immune cells specific to the kidney. Our data also demonstrate that rDC-depleted mice have reduced levels of the distal nephron sodium transporter, NCC, which may be contributing to this phenotype. In addition, we observed no differences in IL-6, a predominate cytokine secreted by DCs. Together, our data demonstrate that rDCs contribute to reduced NCC expression and hypotension.

FR-OR108

Atrial Natriuretic Peptide Knockout Exacerbates Hypertension in Dahl Salt-Sensitive Rat Daria Ilatovskaya, Gregory Blass, Vladislav Levchenko, Alison J. Kriegel, Alexander Staruschenko. *Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Atrial Natriuretic Peptide (ANP) encoded by the *Nppa* gene is an osmoregulatory hormone known to promote salt excretion and therefore lower blood pressure. *Nppa* knockout mice were shown to exert a salt-sensitive (SS) phenotype; furthermore, *Nppa* was identified as one of causative genes at a GWAS locus relevant to blood pressure (BP) control. The current project was designed to study the effects of ANP deficiency under the condition of SS hypertension using the *Nppa* KO developed on the Dahl SS rat background.

Methods: A combination of *in vivo* (chronic BP monitoring and GFR measurement in conscious unrestrained animals), electrophysiological (single channel patch-clamp analysis of the freshly isolated split-open CCD), molecular and biochemical approaches and echocardiography were used here to characterize the role of ANP in the development of SS hypertension in Dahl SS rats.

Results: *Nppa* KO rat is viable; there was no difference observed in the body weight or kidney to body weight ratio of the 8 week old *Nppa* KO animals compared to wild type SS rat. However, heart weight is significantly higher in *Nppa* KO rat. Echocardiography revealed a striking hypertrophy of the right ventricle, and an increase in right ventricle wall thickness and chamber diameter. Furthermore, *Nppa* KO rats have lower 24 hr urine output compared to wild type SS rats, and show decreased GFR even when fed a normal salt diet. BP measurements indicate the *Nppa* KO rats exhibit exacerbated salt-sensitivity compared to wild type SS controls (mean arterial pressure after 21 days of a 4% NaCl diet was 183 ± 9 in *Nppa* KO and 144 ± 4 mmHg in SS control group). Additionally, electrophysiological analysis demonstrated that *Nppa* KO animals have higher Epithelial Sodium Channel (ENaC) activity in the distal nephron (CNT/CCD) compared to wild type rats.

Conclusions: ANP plays a critical role in the development of SS hypertension. Knock out of *Nppa* is SS rats results in significant abnormalities in heart and kidney function.

FR-OR109

Slc26a11 Plays an Important Role in Salt Reabsorption in the Kidney Collecting Duct: Impact on Furosemide Diuresis and Salt/DOCA Hypertension Jie Xu,[1] Sharon L. Barone,[1,2] Marybeth Brooks,[1,2] Saeed Alshahrani,[1] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH.*

Background: The identity and role of trans-cellular chloride reabsorbing pathways in medullary collecting ducts are poorly understood. We have localized Slc26a11 to the apical membrane of A-intercalated cells in the CCD, OMCD and iIMCD. Functional studies in cultured cells and oocytes indicate that Slc26a11 can function as a Cl^-/HCO_3^- exchanger, chloride conductive pathway and electrogenic Na-Cl co-transporter. Expression of kidney Slc26a11 increases in response to furosemide treatment or salt loading, raising the possibility that it is important in salt reabsorption in the setting of enhanced delivery of salt to the collecting duct.

Methods: To ascertain the role of Slc26a11 in the kidney, kidney specific Slc26a11-KO mice were generated by crossing floxed-Slc26a11 mice with Cadherin promoter-driven Cre-recombinase transgenic mice.

Results: Immunofluorescence microscopy, northern and western blot analyses showed more than 90% reduction in the expression of Slc26a11 in the kidneys of KO mice. These mice exhibited significant salt wasting in response to furosemide (sodium excretion of 0.44 in KO vs 0.32 mmole/day in WT mice, $p<0.03$, n=5). Baseline salt excretion was comparable in the two genotypes (0.18 vs 0.20 mmoles/day in WT and KO mice). Slc26a11 KO mice exhibited complete abrogation of high salt/DOCA-induced hypertension vs WT mice when animals were placed on a high salt diet for 10 days and injected with a DOCA (systolic blood pressure was 98 mm Hg in KBAT KO vs. 145 mm Hg in WT mice, as measured by computerized tail cuff method (n = 5, $p<0.01$). Pendrin KO mice were used for comparison and showed a significant protection against salt/DOCA-induced hypertension.

Conclusions: We conclude that Slc26a11 plays an important role in salt reabsorption along the length of the collecting duct following increased delivery of salt and is essential for the generation of salt/DOCA hypertension. Slc26a11 could be a novel target for diuretic therapy in fluid overloaded states and in aldosterone-induced hypertension.

MiR-204 Protects the Kidney against Hypertensive Injury Yuan Cheng,[1,2,4] Dandan Wang,[1,2,4] Baorui Huang,[3,4] Maria Angeles Baker,[4] Kristie Usa,[4] Yong Liu,[4] Congxiao Zhang,[5] Lijin Dong,[5] Aron M. Geurts,[4] Niansong Wang,[3,4] Sheldon S. Miller,[5] Yongcheng He,[1,2,4] Mingyu Liang.[4] *[1]Nephrology, The First Affiliated Hospital of Shenzhen Univ and Shenzhen Second People's Hospital, Shenzhen, Guangdong, China; [2]The Center for Nephrology and Urology at Shenzhen Univ,Shenzhen Univ Health Science Center, Shenzhen Univ, Shenzhen, Guangdong, China; [3]Nephrology and Rheumatology, Shanghai Jiaotong Univ Affiliated Sixth People's Hospital, Shanghai, China; [4]Center of Systems Molecular Medicine, Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI; [5]Section of Epithelial and Retinal Physiology and Disease, National Eye Inst, National Insts of Health, Bethesda, MD.*

Background: Hypertension is the second leading cause of end-stage renal disease. The role of microRNA (miRNA) in hypertensive renal injury remains largely unknown.

Methods: Small RNA deep sequencing was performed to examine miRNA profiles in hypertensive nephrosclerosis patients. The functional role of a selected miRNA and the mechanisms involved were investigated in a rat model and a knockout mouse model.

Results: MiR-204-5p abundance was significantly lower in kidneys of hypertensive nephrosclerosis patients and Dahl salt-sensitive rats. Administration of anti-miR-204-5p in salt-insensitive $SS.13^{BN26}$ rats decreased detectable miR-204-5p in the kidneys and significantly exacerbated the thickening of interlobular artery and renal interstitial fibrosis without influencing salt-induced increases of blood pressure. Knockdown of miR-204-5p led to up-regulation of protein tyrosine phosphatase SHP2 and increased phosphorylation of signal transducer and activator of transcription 3 in the rat kidneys. The role of miR-204 was further examined in a mouse model of hypertensive renal injury induced by uninephrectomy, angiotensin II, and a high-salt diet. *Mir204* gene knockout significantly exacerbated albuminuria, renal interstitial fibrosis, and thickening of interlobular artery in this model despite an attenuation of hypertension.

Conclusions: These findings in patients, rat and mouse models indicate a new mechanism in hypertensive renal injury in which endogenous miR-204 protects the kidney against hypertensive injury.

MicroRNA-132 Regulates Renin Release via Targeting Cox-2 in the Macula Densa Roel Bijkerk,[1,2] Wendy Stam,[1,2] Sharon Van Gelderen,[1,2] Ton J. Rabelink,[1,2] Anton Jan Van Zonneveld.[1,2] *[1]Internal Medicine (Section Nephrology), Leiden Univ Medical Center, Leiden, Netherlands; [2]Einthoven Laboratory for Experimental Vascular Medicine, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Renin synthesis and release from the juxtaglomerular apparatus is the rate-limiting step in the activation of the renin– angiotensin system, which is central to the regulation of body fluid and electrolyte homeostasis and blood pressure. Generation of prostaglandin-E2 (PGE2) in a cyclo-oxygenase-2 (Cox-2)-dependent manner plays a dominant role in the stimulation of renin release.

Methods: We used miR-reporter constructs to validate Cox2 repression by microRNA-132 (miR-132) and generated antagomirs to silence miR-132 function. Mice were housed in metabolic cages and sacrificed 1 day after i.v. injection of the antagomirs or scrambled controls.

Results: We identified miR-132, using in situ hybridization, to be strongly expressed in the macula densa and found miR-132 to directly target Cox-2 *in vitro*. *In vivo* silencing of miR-132 resulted in increased PGE2 and subsequent renin production. Blocking PGE2 synthesis using the selective Cox-2 inhibitor Celecoxib abrogated the mir-132-antagonist induced increase in renin, further supporting a regulatory role for miR-132 in the Cox-2/PGE2 dependent release of renin. Previously, we found that silencing miR-132 resulted in acute diuresis by inhibiting hypothalamic AVP production, resulting in hypovolemia and increased plasma osmolality. To exclude secondary effects on PGE2 and renin production caused by this, we administered ddAVP which reversed these miR-132 mediated diuretic effects, and demonstrated that PGE2 and renin levels remained elevated independent of miR-132-antagonist induced diuresis.

Conclusions: Taken together, we demonstrated an essential posttranscriptional regulatory role for miR-132 in the synthesis and release of renin through Cox-2 mediated PGE2 synthesis in the macula densa.

FR-OR112

Detection of THSD7A Antibodies Is a Valuable Tool for the Differential Diagnosis of Membranous Nephropathy Elion Hoxha,[1] Laurence H. Beck,[2] Thorsten Wiech,[3] Nicola M. Tomas,[1] Christian Probst,[4] Catherine Meyer-Schwesinger,[1] Gunther Zahner,[1] Phillip Rolf Stahl,[3] Ulf Panzer,[1] Sigrid Harendza,[1] Udo Helmchen,[3] David J. Salant,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, UKE-Hamburg, Hamburg, Germany; [2]Boston Univ School of Medicine, Boston, MA; [3]Inst für Pathologie, UKE-Hamburg, Hamburg, Germany; [4]EUROIMMUN AG, Lübeck, Germany.*

Background: Thrombospondin Type-1 Domain-Containing 7A (THSD7A) is a target antigen in membranous nephropathy (MN) in addition to the major antigen Phospholipase A_2 Receptor 1 (PLA_2R1). The prevalence of THSD7A antibody (THSD7A-Ab) positive patients is unknown and it is unclear whether differences occur in the clinical presentation between patients positive for PLA_2R1-Ab or THSD7A-Ab.

Methods: We screened sera of 1276 patients with MN from three cohorts by Western blot and an indirect immunofluorescence test (IFT) for THSD7A-Ab. Follow-up data over at least 12 months were available for 10 THSD7A-Ab positive patients.

Results: The IFT had a 92% sensitivity and 100% specificity compared to Western blot. The prevalence of THSD7A-associated MN in a prospective cohort of 345 consecutive patients with newly diagnosed MN was 2.6%; the majority of patients was female. 40 of 1276 patients were identified to have a THSD7A-associated MN, in eight of them a malignant tumor was diagnosed within a median time of 3 months from diagnosis of MN. In one patient with THSD7A-associated MN and metastases of an endometrial carcinoma, immunohistochemistry demonstrated THSD7A expression on the metastatic cells and within follicular dendritic cells of the metastasis-infiltrated lymph node. Complete remission of proteinuria was observed in only those 4 patients in whom THSD7A-Ab disappeared from the circulation. Five patients had a partial remission of proteinuria, THSD7A-Ab became negative in one and remained positive in four patients.One patient had no remission of proteinuria and THSD7A-Ab persisted.

Conclusions: The IFT allows a sensitive and specific measurement of THSD7A-Ab in patients with MN. Patients with THSD7A-associated MN differ in their clinical characteristics from patients with PLA_2R1-associated MN. Intensive screening for malignant tumors is warranted in patients with THSD7A-associated MN.

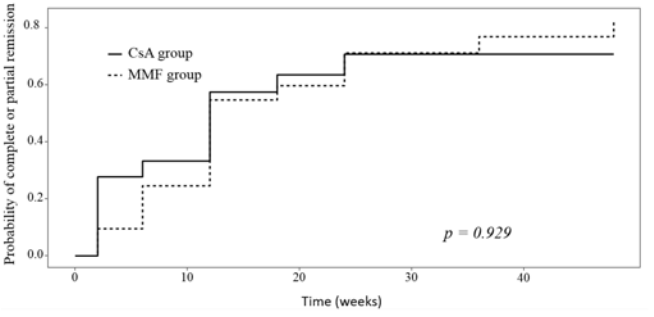
The Effect of Mycophenolate Mofetil versus Cyclosporine as a Combination Therapy to Low Dose Corticosteroid in High Risk Patients with Idiopathic Membranous Nephropathy: A Multicenter Randomized Trial Ji-Young Choi,[1] Dong Ki Kim,[2] Yang Wook Kim,[3] Tae-Hyun Yoo,[4] Jung Pyo Lee,[2] Hyun Chul Chung,[5] Kyu-Hyang Cho,[6] Won Suk An,[7] Duk Hyun Lee,[8] Hee-Yeon Jung,[1] Jang-Hee Cho,[1] Chan-Duck Kim,[1] Yong-Lim Kim,[1] Sun-Hee Park.[1] *[1]Kyungpook National Univ; [2]Seoul National Univ; [3]Inje Univ; [4]Yonsei Univ; [5]Ulsan Univ; [6]Yeungnam Univ; [7]Dong-A Univ; [8]Fatima Hospital, Daegu.*

Background: The effect of mycophenolate mofetil (MMF) versus cyclosporin (CsA) combined with low-dose prednisolone was evaluated in patients with idiopathic membranous nephropathy (MGN) in a multicenter randomized trial (NCT01282073).

Methods: Biopsy-proven idiopathic MGN patients with severe proteinuria (> 8 g/day, n=39) were randomly assigned to MMF or CsA group combined with low dose prednisolone, respectively and followed up for 48 weeks. Complete or partial remission rate of proteinuria as well as eGFR at 48 weeks were compared between the two groups.

Results: Proteinuria at baseline and 48 weeks were 8.9 ± 5.9 and 2.1 ± 3.1 g/day in the MMF vs. 8.4 ± 3.5 and 3.2 ± 5.7 g/day in the CsA group. Cumulative incidences of complete or partial remission of proteinuria at 48 weeks were 76.1% in MMF and 66.7% in CsA group, a difference of 9.4% (95% CI -0.18 to 0.38) that did not exceed the predefined 20% margin.



eGFR at baseline and 48 weeks were 73.9 ± 31.0 and 70.1±19.2 ml/min/1.73m^2 in the MMF vs. 84.9 ± 25.2 and 84.0±32.6 ml/min/1.73m^2 in the CsA group. Adverse events occurred in 12 (57.1%) and 9 (50.0%) patients in MMF and CsA group (p=0.90). There were no significant differences in changes of gastrointestinal symptom rating scale and gastrointestinal quality of life index score from baseline to 48 weeks between the two groups.

Conclusions: Combined with low dose corticosteroid, the effect of MMF was comparable to CsA in patients with idiopathic MGN with similar adverse effects including gastrointestinal symptoms.

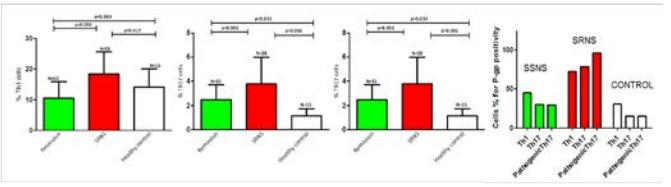
Permeable Glycoprotein Expression on Pathogenic IL-17/IFN-γ Double-Positive Th17 Cells Is Responsible for Steroid Resistance in Minimal Change Disease Narayan Prasad,[1] Akhilesh Jaiswal,[1] Vikas Agarwal,[2] Raj K. Sharma.[1] *[1]Nephrology, SGPGIMS, Lucknow, UP, India; [2]Immunology, SGPGIMS, Lucknow, India.*

Background: Th17 cells and cytokine IL-17 are involved in many autoimmune diseases. Recently, IL-17/IFN-γ double-positive Th17 cell, called pathogenic Th17 cells were found to be associated with multiple autoimmune and inflammatory diseases. P-glycoprotein (P-gp, an efflux pump) positive Th17 cells are refractory to glucocorticoids. P-gp on lymphocytes efluxes out steroid and prevents its action. We conducted this study with hypothesis that P-gp expressing Th17 and IFN-γ are one of key pharmacokinetic and pharmacodynamic modulator responsible for steroid resistance in nephrotic Syndrome(NS), As it has not been studied in NS, we studied the frequency of P-gp expressing pathogenic Th17 cells in steroid sensitive (SSNS) and steroid resistant (SRNS) patients.

Methods: We analysed the frequency of pathogenic IL-17/IFN-γ double-positive Th17 lymphocytes and P-gp expression on their surface by flowcytometry in SSNS (n=32, mean age 9.06±5.84) and SRNS (n=28, mean age 11.29±3.73) patients. We also included 15 age and sex matched healthy controls. All patients were biopsy proven MCD and all patients were treated with steroid. All patients were recruited as per criteria of ISKDC.

Results: We found a significant increase in the frequency of Th1 (p=0.001), Th17 (p=0.006) and IL-17/IFN-γ double-positive Th17 (p<0.001) cells in SRNS as compared to SSNS patients and healthy controls (p<0.001). Of the total Th1, Th17 and pathogenic Th17; 78.45%, 72.37% and 95.8% cells expressed P-gp on their surface in SRNS;45.0%, 30.27% and 30.1% cells expressed P-gp in SSNS group; and 30.91%, 15.51% and 15.62% in healthy control respectively.



Conclusions: Higher frequency of IL-17/IFN-γ double-positive Th17 cell with P-gp expression may be associated immunological and pharmacological factor for steroid resistance in minimal change disease.

Angiopoietin-Like-4 and Minimal Change Disease Gabriel M. Cara-Fuentes,[1] Alfonso Segarra,[2] Cecilia Silva Sanchez,[1] Heiman Wang,[1] Miguel A. Lanaspa,[3] Richard J. Johnson,[3] Eduardo H. Garin.[1] *[1]Univ of Florida; [2]Hospital Vall D'Hebron; [3]Univ of Colorado.*

Background: Minimal change disease (MCD) is considered a podocytopathy. It has been hypothesized that in MCD podocyte Angiopoietin-like-4 (Angplt4) lacks sialic acid, and when bound to the glomerular basement membrane (GBM) proteoglycans, decreases GBM anionic charge allowing albumin to cross the capillary wall barrier into the urinary space. Objective: To evaluate the role of Angptl4 as a biomarker and/or mediator of proteinuria in MCD.

Methods: 60, 52 and 52 patients with MCD, FSGS and MN respectively and 18 control subjects were included. Urinary and serum Angptl4 were measured by Elisa. pI of Angptl4 in urine of MCD in relapse was determined by 2D electrophoresis. Frozen tissue sections were stained for Angptl4. Statistical analysis using Kruskal-Wallis, Mann-Whitney U test and Spearman correlation.

Results: Urinary Angptl4 was increased in patients with massive proteinuria regardless of the underlying glomerular disease compared to controls. No correlation was observed between proteinuria and urinary Angptl4 in MCD patients in relapse. Serum Angptl4 was higher in normal controls compared to MCD, FSGS and MN patients in relapse. Glomerular Angplt4 expression, by immunofluorescence (IF), was absent in MCD patients in relapse. Angptl4 detected in urine in MCD had a pI of 5.4.

Conclusions: 1) Serum and urinary excretion of Angptl4 were not specific for MCD patients, and there was no correlation of urinary Angptl4 with proteinuria in MCD patients. 2) Angptl4 detected in urine in MCD is likely freely filtered circulating Angptl4 given a) its MW, b) absent glomerular staining by IF in MCD patients in relapse. 3) Urinary Angptl4 in MCD in relapse is not cationic. In summary, our data do not support a role of Angplt4 as marker and/or mediator of proteinuria in MCD. Increased urinary Angplt4 is likely the result, rather than the cause, of a leaky glomerular filtration barrier.

FR-OR116

Oxidized Low-Density Lipoprotein and Microparticle Tissue Factor Activity in the Nephrotic Syndrome Vimal K. Derebail,[1] Elizabeth J. Brant,[2] Carmen E. Mendoza,[1] Susan L. Hogan,[1] Nigel S. Key,[1] Nigel Mackman,[1] Heather N. Reich,[3] Patrick H. Nachman,[1] Donna O. Bunch.[1] *[1]Univ of North Carolina; [2]Dartmouth-Hitchcock Medical Center; [3]Univ of Toronto.*

Background: Venous thromboembolic (VTE) events are common in nephrotic syndrome (NS). Hypoalbuminemia is most consistently related to VTE risk. Profound hyperlipidemia, also characteristic of NS, leads to elevation of oxidized low-density lipoprotein (oxLDL). In turn, oxLDL stimulates monocytes to release microparticles bearing tissue factor that can initiate intravascular thrombosis. We examined the relationship between oxLDL and microparticle tissue factor activity (mpTFa) in individuals recruited to the Nephrotic Syndrome Study Network (NEPTUNE).

Methods: We included participants from NEPTUNE ages 13-80, with Membranous Nephropathy (MN), Focal Segmental Glomerulosclerosis (FSGS), or Minimal Change Disease (MCD). Inclusion required ***overt*** proteinuria ≥ 3.0 g/day by 24hr urine collection or urine protein/creatinine ratio (UPCR) ≥ 2 at screening. Baseline samples were used to measure oxLDL (by ELISA) and mpTFa (custom assay). Correlations of mpTFa, oxLDL and other clinical variables were assessed via Spearman's rank-order.

Results: 47 individuals (72.3% female, median age 47 [IQR 22, 62]) met inclusion criteria and had sample to measure mpTFa. 29.8% had FSGS, 53.2% had MN, 10.6% had MCD and 6.4% had other phenotype. Median albumin was 2.7 g/dl (IQR 2.0, 3.0), median UPCR was 4.2 (IQR 2.5, 7.1) and median mpTFa was 0.07 pg/mL (IQR 0, 0.21). oxLDL was measured in 34 individuals. Median oxLDL was 55.1 U/ml (IQR 40.5, 91.0). UPCR correlated with oxLDL (ρ=0.58, p=0.0003) and mpTFa (ρ=0.34, p=0.02). Albumin correlated negatively with oxLDL (ρ= - 0.63, p=0.0007). Only a weak correlation was noted between oxLDL and mpTFa (ρ=0.22, p=0.2) that was not statistically significant.

Conclusions: In a NEPTUNE participant sample with overt NS, serum albumin and UPCR strongly correlated with oxLDL suggesting severity of NS is pro-inflammatory; proteinuria correlated with mpTFa, indicating NS severity may also drive thrombotic risk. Future work will examine if oxLDL directly correlates with mpTFa and increased VTE risk in NS, an expected relationship limited by our sample size.

FR-OR117

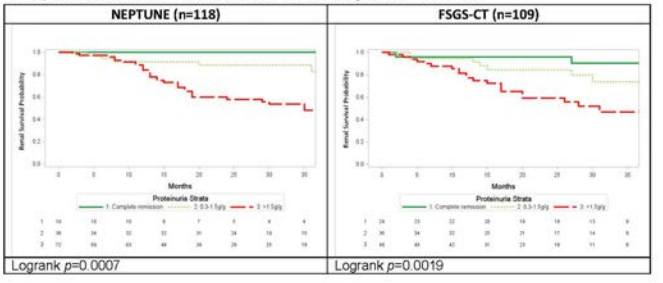
A Clinical Outcome Assessment of Proteinuria in Patients with Focal Segmental Glomerulosclerosis Jonathan P. Troost,[1] Howard Trachtman,[2] Cathie Spino,[1] Radko Komers,[3] Sarah E. Tuller,[3] Patrick H. Nachman,[4] Matthias Kretzler,[1] Debbie S. Gipson.[1] *[1]Univ of MI; [2]New York Univ; [3]Retrophin; [4]Univ of NC at Chapel Hill.*

Background: Proteinuria is used as an indicator of disease activity in FSGS, but its use as an end point for clinical trials is not universally accepted. The goal of this study is to examine the strength of the relationship between proteinuria and renal survival in patients with FSGS.

Methods: Data from 118 FSGS patients from the Nephrotic Syndrome Study Network (NEPTUNE) and 109 patients from the completed NIH sponsored FSGS Clinical Trial (FSGS-CT) were used for this discovery and replication analysis, respectively. Central measurements of urine protein: creatinine ratio (UP:C g/g) and serum creatinine were used and eGFR was calculated. Kaplan-Meier methods and log-rank tests were used to estimate the effect of proteinuria on subsequent ESRD or 40% reduction in eGFR. Proteinuria was categorized by conventional definitions of complete (UP:C<0.3, CR) and partial remission (50% reduction in UP:C and UP:C<3.5, PR). ROC analyses were performed to determine other important thresholds of proteinuria.

Results: In NEPTUNE and the CT, 40 and 47 patients progressed to ESRD or 40% reduction in eGFR, respectively. In NEPTUNE, reaching a CR, but not necessarily a PR, was associated with a decreased risk of disease progression (hazard ratio (HR) relative to no remission: CR=0.1, p<0.01; PR=1.0, p=0.90). ROC analyses identified a modified PR definition of UP:C 0.3-1.5 associated with a lower likelihood of progression to ESRD or 40% reduction in eGFR in NEPTUNE (HR=0.3 p<0.01), which was replicated in the FSGS-CT (HR=0.4, p=0.03).

FIGURE. Proteinuria Strata Using a Modified Definition of Partial Remission and Progression to ESRD/40% Reduction in eGFR. Results from NEPTUNE replicated in FSGS-CT.



Conclusions: Reaching either CR or a modified definition of PR, was associated with better long-term outcomes in patients with FSGS. From a regulatory perspective, this may help improve the feasibility of conducting clinical trials by using proteinuria as an endpoint.

Congophilic Fibrillary Glomerulonephritis: Clinicopathologic and Proteomic Characteristics Mariam P. Alexander,[1] Surendra Dasari,[1] Julie A. Vrana,[1] Glen S. Markowitz,[2] Vanesa Bijol,[3] Aviv Hever,[4] Navin Verma,[5] Julie Riopel,[6] Bhargavi Degapudi,[7] Lynn D. Cornell,[1] Mary E. Fidler,[1] Samar M. Said,[1] Sanjeev Sethi,[1] Loren Paola Herrera Hernandez,[1] Nelson Leung,[1] Paul J. Kurtin,[1] Samih H. Nasr.[1] *[1]Mayo Clinic, Rochester, MN; [2]Columbia Univ, New York, NY; [3]Brigham and Women's Hospital, Boston, MA; [4]Kaiser Permanente, Los Angeles, CA; [5]Hershey Medical center, PA; [6]L'Hotel-Dieu de Quebec, Quebec, Canada; [7]Atlantic Care, NJ.*

Background: Historically Congo red (CR) positivity has dichotomized organized glomerular deposits into amyloid and non-amyloid diseases. Fibrillary glomerulonephritis (FGN) is traditionally defined by CR negative randomly-oriented fibrils. We report the first series of Congophilic FGN (CFGN), defining its clinicopathologic and proteomic characteristics.

Methods: We identified 9 cases of CFGN from our archives from 2014-16. Histologic, clinical and outcome data were evaluated. Mass spectrometry (MS) was performed in all cases and on control cases (9 AL amyloidosis, 5 non-CFGN).

Results: Mean age was 59 yrs, 5 were female. Mean 24 h proteinuria and S. creatinine were 5.9 g and 1.5 mg/dl. 75% had hematuria. 7 of the cases were referred for amyloid typing by MS. 2 pts had hep C, 2 had carcinoma, and only 1 had monoclonal gammopathy. No pt had extrarenal amyloidosis. LM showed mesangial GN (N=6) or MPGN (N=3). All showed CR positivity with yellow (N=2) or apple green (N=7) birefringence. IF showed polyclonal staining for IgG, κ and λ. EM showed randomly-oriented fibrils (mean diameter 12-16 nm) in mesangium (N=9) and GBMs (N=7). By MS, the proteome of deposits in CFGN was identical to non-CFGN except for slightly higher spectra for ApoE in CFGN; CFGN and non-CFGN showed spectra for IgG, κ and λ, and small spectra for SAP with no/trivial spectra for ApoA4. The profile was different from AL which had abundant spectra for SAP, ApoE, ApoA4, and a single light chain. F/U was available in 8 pts (mean 13 mos, 2.5-20), including 4 treated with rituximab. 1 pt developed ESRD and none expired.

Conclusions: FGN can show CR positive deposits; therefore, Congophilia should not be the sole criterion used to distinguish FGN from amyloidosis; MS is useful in the distinction of these entities.

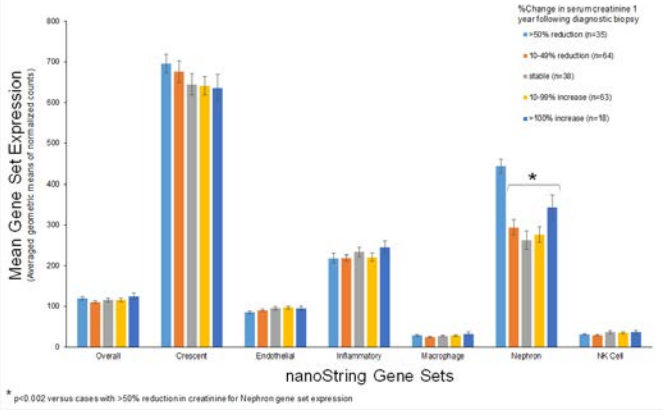
FR-OR119

Molecular Diagnostics for Glomerulonephritis in Routine Formalin-Fixed Paraffin-Embedded Native Kidney Biopsies Kristalee Watson,[1] Benjamin Alexander Adam,[1] Neesh I. Pannu,[2] Ainslie M. Hildebrand,[2] Michael Mengel.[1] *[1]Dept of Laboratory Medicine and Pathology, Univ of Alberta, Edmonton, AB, Canada; [2]Div of Nephrology, Univ of Alberta, Edmonton, AB, Canada.*

Background: Molecular diagnostics can potentially improve the classification and staging of native kidney diseases. The nanoString nCounter gene expression platform can use formalin-fixed paraffin-embedded (FFPE) tissue, representing a potential method for routine molecular diagnostics in renal pathology. We aimed to assess gene expression quantification in the diagnostics and staging in glomerulonephritis (GN) in FFPE native kidney biopsies.

Methods: A literature-derived gene set for renal injury was generated (54 genes related to nephrons, endothelium, and inflammation). RNA was isolated from 386 FFPE native kidney biopsies (275 crescentic GN, 82 non-crescentic immune complex GN, 29 non-crescentic non-proliferative disease). Gene expression was quantified with nanoString and correlated with histology, and clinical indices at biopsy and 1-year follow-up.

Results: Gene set expression was higher in cases with crescentic GN than non-crescentic GN ($p<0.001$). Gene set expression correlated with interstitial fibrosis and tubular atrophy ($r=0.34$, $p=0.001$). Expression of nephron transcripts correlated with the proportion of crescentic glomeruli ($r=0.39$, $p<0.001$). Expression of nephron transcripts was higher in patients with crescentic GN and recovery in renal function 1 year post biopsy versus those with stable or deteriorating serum creatinine ($p<0.002$).



Conclusions: The nanoString platform allows for robust gene expression quantification from FFPE native kidney biopsies. High expression of nephron genes is associated with functional recovery after crescentic GN. Molecular biopsy assessment has the potential to provide additional diagnostic and prognostic information in renal pathology.

Identification of Shared Molecular Targets across Glomerular Disease: Case Study in ANCA-Associated Vasculitis (AAV) and Nephrotic Syndrome (NS) Sean Eddy,[1,2] Viji Nair,[1,2] Hemang Parikh,[3,4] Laura H. Mariani,[1,2] Felix H. Eichinger,[1,2] Huateng Huang,[1,2] Wenjun Ju,[1,2] Casey S. Greene,[4,5] Peter C. Grayson,[4,6] Jeffrey P. Krischer,[3,4] Peter A. Merkel,[4,5] Matthias Kretzler.[1,2] *[1]Div of Nephrology, Univ of Michigan, Ann Arbor, MI; [2]NEPTUNE Consortium; [3]Univ of South Florida, Tampa, FL; [4]Vasculitis Clinical Research Consortium; [5]Univ of Pennsylvania, Philadelphia, PA; [6]Vasculitis Translational Research Program, NIAMS, NIH, Bethesda, MD.*

Background: Clinical trials in rare diseases typically test therapeutic efficacy in one disease defined by a particular clinical phenotype. An unbiased analysis of kidney diseases suggests many rare kidney diseases share common molecular profiles (Martini et al., 2014). To expand on these findings, we explored shared transcriptional responses in patients with AAV and NS to identify common targetable disease mechanisms.

Methods: Transcriptomic profiles were generated from renal biopsies from NS (MCD, FSGS and Membranous Nephropathy, n=126) from the NEPTUNE cohort and the European Renal cDNA Bank (ERCB, n=61), and from AAV (Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA)) from the ERCB cohort (n=80) and living donors (n=37) on Affymetrix U133 and ST2.1 platforms. Functional networks were assessed for cross-cutting disease mechanisms, upstream regulators and potential therapeutic targets shared between both diseases.

Results: 5%-25% of expressed transcripts were differentially regulated compared to living donor (FDR<0.05, shared directionality of change) in both NS and AAV in glomerular and tubulointerstitial compartments and replicated across expression platforms. Functional analysis identified conserved, therapeutically targetable transcriptional networks in the glomeruli from NS and AAV patients including activation of Tec kinase, IL-8 signaling, TNF, IFNG, TGFB1, and NFkappaB, while alpha catenin and LXR/RXR signaling were suppressed. A causal analysis approach predicted increase TNF pathway activity across diseases.

Conclusions: AAV and NS, two rare kidney diseases, share common intra-renal transcriptional profiles that can be readily mined to identify shared molecular targets. Shared molecular targets can be leveraged for drug development and repurposing efforts.

FR-OR121

ANCA Autoantigen Expression in Combination with ANCA Titer May Be More Useful to Assess Disease Activity Than Either Alone Jia Jin Yang,[1] Caroline J. Poulton,[1] Susan L. Hogan,[1] Yichun Hu,[1] Meghan A. Jobson,[1] Candace Henderson,[1] Britta E. Jones,[2] J. Charles Jennette,[2,1] Ronald J. Falk,[1,2] Dominic J. Ciavatta,[3] William Franklin Pendergraft.[1] *[1]Medicine, UNC-CH; [2]Pathology, UNC-CH; [3]Genectics, UNC-CH, Chapel Hill, NC.*

Background: We demonstrated aberrant up-regulation of autoantigen genes in mature neutrophils and monocytes from patients with ANCA disease (JASN 2004, 15:2103-14). Here, we compared the utility of *PRTN3* and *MPO* mRNA and ANCA titers to predict disease activity.

Methods: A total of 969 leukocyte RNA samples from 122 ANCA-patients were collected serially every 3 months over the past 6 years compared to 169 healthy controls. Levels of *PRTN3* and *MPO* gene transcripts were determined by Q-PCR and expressed as relative levels to standard curve. Active disease was defined as a Birmingham Vasculitis Activity Score (BVAS) ≥ 5 with clinical and /or laboratory evidence of disease active; remission as a BVAS=0 and no evidence of active disease. Fisher's exact test was used in this study.

Results: In samples with active disease (n=106), 60% and 67% of samples had significantly increased *PRTN3* (385±846, $p<0.0001$) and *MPO* (995±1900, $p<0.0001$) mRNA, respectively compared to healthy donors (*PRTN3*:16±33; *MPO*:57±57). Only 6% and 9% of remission samples (n=94) had increased *PRTN3* and *MPO, respectively*. In contrast, ANCA titer did not return to normal levels in 65% of PR3-ANCA (n=52) and 45% of MPO-ANCA (n=42) patients when remission was achieved. ANCA titers were increased in 92% of PR3-ANCA (n=59) and 81% of MPO-ANCA (n=47) samples with active disease. Specificity values for *PRTN3* (94%) and *MPO* (91%) mRNA were higher than PR3-ANCA (35%) and MPO-ANCA (55%) titers, while sensitivity values for *PRTN3* (60%) and *MPO* (67%) mRNA were lower than PR3-ANCA (92%) and MPO-ANCA (81%) titers. When both mRNA and ANCA titer tests were used to assess disease activity, specificity and sensitivity increased to 98% and 95% in PR3-ANCA and 98% and 89% in MPO-ANCA patients, respectively.

Conclusions: The combination of ANCA titer and ANCA autoantigen expression may be more useful to assess disease activity than either alone. Both expression of autoantigen genes and antibodies are involved in the pathogenesis of ANCA disease.

FR-OR122

Serum Klotho Levels Are Associated with Renal Function Recovery in Patients with Septic Acute Kidney Injury Undergoing Continuous Renal Replacement Therapy Ji Min Park,[1] Hyoungnae Kim,[1] Young Eun Kwon,[2] Min-Uk Cha,[1] Youn Kyung Kee,[1] Tae-Hyun Yoo.[1] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Div of Nephrology, Dept of Internal Medicine, Myongji Hospital, Seonam Univ College of Medicine, Goyang, Korea.*

Background: This study aimed to elucidate the role of klotho as a biomarker in septic acute kidney injury (AKI) patients requiring continuous renal replacement therapy (CRRT).

Methods: This is a post hoc analysis of HICORES study (HIgh-volume COntinuous REnal replacement therapy in patients with Septic AKI, NCT 01191905) conducted from January 2011 to August 2014 at two tertiary hospitals in Korea. A total of 165 septic AKI patients undergoing CRRT were eligible and serum klotho level at CRRT initiation was measured by ELISA. The patients were divided into high and low klotho groups based on the median value of klotho (244pg/ml). Primary outcome was CRRT weaning rate at 28 day and secondary outcomes were the proportion of intensive care unit (ICU) discharge at 28 day and all-cause mortality rate.

Results: Male was 110 (66.7%) and the mean age was 62.2 years. High klotho group was younger and showed significantly lower norepinephrine requirement, C-reactive protein, and log transformed interleukin (IL)-1β and IL-10 levels compared to low klotho group. Multiple Cox regression analysis revealed that the CRRT weaning rate at 28 day was significantly higher in high klotho group (hazard ratio [HR] 1.634; 95% confidence interval [CI] 1.004–2.659, P=0.048) compared to that in low klotho group. In addition, high klotho group showed more ICU discharges at 28 day (HR 2.959, 95% CI 1.493–5.864, P=0.002) than low klotho group after adjusting confounding factors. Meanwhile, the difference in all-cause mortality rate did not reach statistical significance between the two klotho groups (HR 0.709, 95% CI 0.480–1.049, P=0.085).

Conclusions: Present study suggests that baseline serum klotho might be a potential biomarker predicting renal function recovery in patient with septic AKI.

FR-OR123

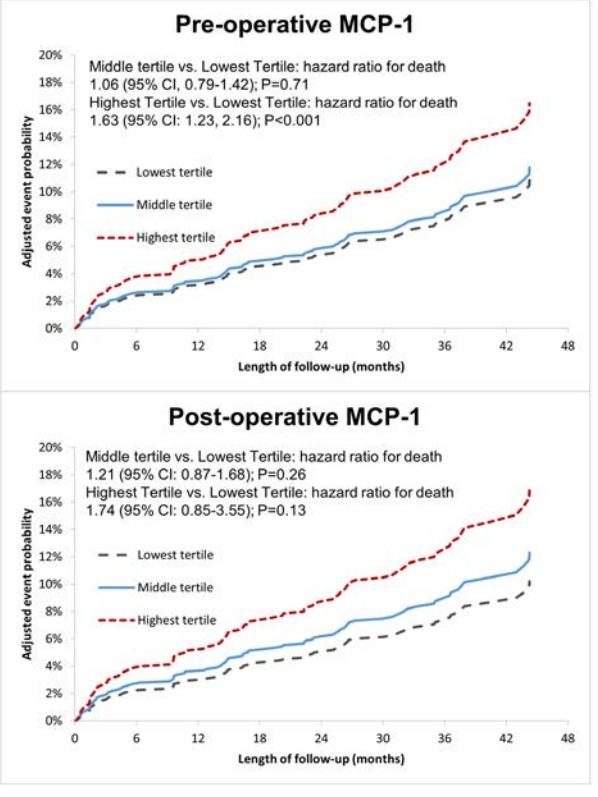
Preoperative Plasma Monocyte Chemotactic Protein-1 Is Associated with Postoperative AKI and Long-Term Mortality after Cardiac Surgery: A Multicenter Prospective Cohort Study

Dennis G. Moledina,[1] Selin Isguven,[1] Eric McArthur,[2] Heather Thiessen Philbrook,[1] Amit X. Garg,[3] Michael Shlipak,[6] Peter Kavsak,[5] Steven G. Coca,[4] Chirag R. Parikh.[1] *[1]Yale School of Medicine; [2]Inst for Clinical Evaluative Sciences; [3]Univ of Western Ontario; [4]Icahn School of Medicine; [5]McMaster Univ; [6]Univ of California.*

Background: Monocyte chemotactic protein-1 [MCP-1] is upregulated in ischemia-reperfusion injury and is a promising biomarker of inflammation in cardiac surgery. We evaluated the association of perioperative MCP-1 levels in patients undergoing cardiac surgery with AKI and mortality.

Methods: We measured pre- and postoperative plasma MCP-1 levels in TRIBE-AKI, a prospective, multicenter, observational cohort of patients undergoing cardiac surgery. Short-term outcomes were in-hospital AKI or severe AKI, and long-term outcome was all-cause mortality.

Results: Of the 972 participants in the study, 329 (34%) developed AKI and 45 (5%) developed severe AKI. Of the 957 patients alive at hospital discharge, 103 (11%) participants died during median follow-up of 2.9 (2.2-3.5) years. In fully adjusted analyses, patients with preoperative MCP-1 levels in the highest tertile (>196 pg/ml) had an increased risk of AKI as compared with the lowest tertile [<147 pg/ml; OR, 1.43(95% CI, 1.00-2.05)]; the association appeared similar but was not significant for the outcome of severe AKI [OR, 1.48 (0.62-3.54)]. As compared with patients with preoperative MCP-1 in the lowest tertile, those in the highest tertile had higher mortality risk [HR, 1.63 (1.23-2.16); P<0.001]. Postoperative MCP-1 concentrations were not associated with AKI or mortality.



Conclusions: Preoperative plasma MCP-1 level is associated with increased risk of AKI and long-term mortality after cardiac surgery. MCP-1 could be used as a biomarker to identify high-risk patients to enrich clinical trials for AKI prevention in the setting of cardiac surgery.

FR-OR124

Prediction of Acute Kidney Injury (AKI) and Clinical Outcomes Using a Combination of Routine Clinical Information and Novel Urinary Biomarkers: The Dublin Acute bioMArker Group Evaluation (DAMAGE) Study

Patrick T. Murray,[1] Marie C. Galligan,[1] Valerie Jean Logan,[1] Siobhan Elizabeth Mc Kenna,[1] Alistair Nichol,[1] Peter P. Doran,[1] Blaithin A. McMahon.[1,2] *[1]School of Medicine, Univ College Dublin, Dublin, Ireland; [2]Div of Nephrology, Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Background: Implementation of novel AKI biomarkers in practice has been hampered by a failure to integrate into routine clinical decision making, which involves standard clinical information, including demographics, acute and chronic illness information, and markers of kidney function (urine output, BUN, creatinine).

Methods: The DAMAGE Study is a prospective multicenter observational study investigating the utility of urinary biomarkers for diagnosis and prognosis of AKI in critically ill patients admitted to intensive care units in Dublin, Ireland. Clinical information and urine were collected on admission and daily for 7d. Urine biomarkers analysed were NGAL, α-GST, π-GST, KIM-1, L-FABP, Cystatin-C, creatinine, and albumin. ROC curves were constructed from logistic regression models that predicted AKI (by KDIGO) and adverse clinical outcomes (progression to death or RRT) in combination with APACHE II score, gender, admission serum creatinine, urea and urine output.

Results: The study enrolled 736 patients. 242 (37.4%) developed AKI within 7 days of ICU admission. 208 (31.6%) progressed to death or dialysis within 30d. A panel of admission biomarkers significantly improved prediction of AKI developing within 7d of admission (AUC; 95% CI: 0.77;0.72-0.82) over clinical covariates alone (0.73;0.68-0.79;p=0.029). Similarly, the admission values of Albumin and NGAL improved prediction of early AKI, developing within 48h (0.77;0.73-0.81), compared to clinical covariates alone (0.75;0.71-0.79;p=0.03). Finally, the addition of this biomarker pair improved prediction of 30d adverse clinical outcomes - RRT or death – (0.82; 0.78-0.86) when compared to clinical covariates alone (0.79; 0.75-0.83; p=0.0004).

Conclusions: Combined use of novel urinary AKI biomarkers with knowledge of patient clinical covariates on admission to the ICU significantly improved the prediction of AKI and 30d adverse clinical outcomes.

Saliva Urea Nitrogen Dipstick: A Simple Tool to Detect and Stratify Risk of Renal Disease in Low Resource Settings

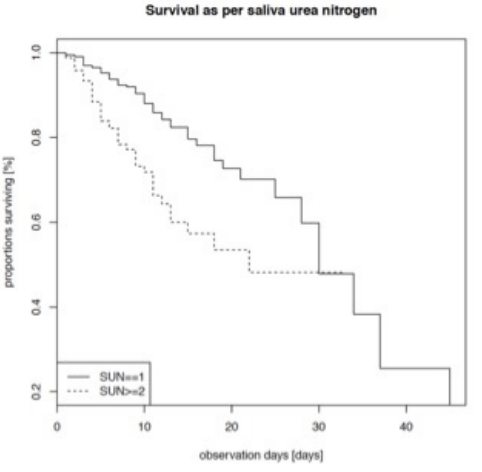
Viviane Calice-Silva,[1] Rhys David Russell Evans,[2,3,4] Jochen G. Raimann,[5] Ulla Hemmila,[2,3] Alison Craik,[3] Mwayiwathu Prince Mtekateka,[3] Fergus Hamilton,[3] Zuze Madalitso Kawale,[3] Gavin Dreyer,[6] Nathan W. Levin,[7] Peter Kotanko,[5] Roberto Pecoits-Filho.[1] *[1]Pontifícia Univ Católica do Paraná, Brazil; [2]College of Medicine, Malawi; [3]Queen Elizabeth Central Hospital, Malawi; [4]Bart's Health, United Kingdom; [5]Renal Research Inst; [6]Royal Free Hospital, United Kingdom; [7]Icahn School of Medicine at Mount Sinai.*

Background: Simple and non-expensive tools for the diagnosis of renal disease, in particular acute kidney injury (AKI), are lacking. We evaluated the diagnostic performance of a salivary urea nitrogen (SUN) dipstick and its ability to predict outcomes in a low-resource setting in Africa.

Methods: Adult patients presenting to general medicine at QECH, Blantyre, Malawi, were screened for kidney disease with serum creatinine (sCR) and SUN on admission. Patients with renal impairment were followed-up for up to 7 days. SUN level greater 14 mg/dL was the threshold to diagnose renal disease. Cox proportional hazard models were constructed to evaluate the predictors of death.

Results: 742 patients with SUN data were studied (40.9±17.3 years, 56.1% male). We diagnosed 146 patients with renal disease [114 AKI, 26 AK disease without AKI, 6 CKD] according to KDIGO sCr based criteria. The SUN performance to diagnose renal disease was good [AUC 0.83 (95% CI 0.79 to 0.87)]. SUN levels > 14 mg/dL was the optimal threshold (sensitivity 72%; specificity 87%). Out of 702 patients with complete outcome data, 104 died during hospitalization. Elevated SUN was an independent predictor of all cause mortality (**Figure 1**; HR=2.43 [95% CI 1.63 to 3.62]).

Figure 1: Kaplan-Meier curve survival analysis of all-cause mortality stratified by SUN results.



Conclusions: SUN showed good diagnostic performance to detect renal disease. SUN was an independent predictor of mortality in this population. Our data suggest that SUN may be used to diagnose kidney disease, particularly in limited health care settings.

Fluid Overload in Critically Ill Patients Is Predicted Using Single and Sequential Urinary Biomarker Measurements Erin K. Stenson,[1] Shina Menon,[2] Stuart Goldstein,[3] Rajit K. Basu.[3] *[1]Pediatric Critical Care, Cincinnati Children's Hospital; [2]Pediatric Nephrology, Seattle Children's Hospital; [3]Center for Acute Care Nephrology, Cincinnati Children's Hospital.*

Background: Fluid overload (FO) is independently associated with worsened outcomes in critically ill patients. Although urinary biomarkers have been studied in multiple populations for prediction of acute kidney injury (AKI), prediction of fluid overload has not been reported. Further, the predictive performance of biomarkers as they change over time has not been explored.

Methods: We leveraged data from a single-center, prospective study of children admitted to the intensive care unit (ICU). The primary outcome for this analysis was the development of >20% FO (derived by net fluid balance and weight) at any time from ICU admission to Day 7. Predictor variables were assessed at least 3 times during the first 36 hours of admission (urinary neutrophil gelatinase associated lipocalin (uNGAL), serum creatinine (sCr), and urine output (UOP)).

Results: 173 pts(51% male, median age 7.7 years) were included. Peak FO>20% occurred in 45 pts(26%) (Median 4 days). uNGAL was elevated over 200 in 52 pts (30%). uNGAL was persistently <200 in 115 pts (66%), intermittently elevated (spiked over 200, and then downtrended) in 29 (17%) and persistently>200 (at least 3 values over 200) in 29 (17%). Compared to UOP or sCr measurements, uNGAL levels demonstrated a significant association for prediction of FO > 20%. Persistently increased uNGAL strengthened this association (compared to persistently low uNGAL).

Variable	n	Odds for FO >20% (95% CI)	p Value
uNGAL persistently elevated	29	3.3 (1.4-7.7)	0.007
uNGAL spiked	29	1.8 (0.7-4.5)	0.205
uNGAL elevated day 1	52	2.4 (1.2-4.9)	0.016
Cr persistently elevated	12	2.7 (0.8-9.0)	0.100
Cr elevated day 1	31	1.0 (0.4-2.4)	0.977
UOP persistently decreased	21	1.1 (0.4- 3.1)	0.848
UOP decreased day 1	32	1.1 (0.5-2.7)	0.763

Conclusions: Our data suggest that >20% FO can be predicted. Single and sequential urinary biomarkers assessed early in ICU admission are predictive of FO while creatinine and urine output are not. These findings are clinically relevant as fluid accumulation is a modifiable outcome. Expanded analysis in larger populations is warranted to confirm these findings.

FR-OR127

Urinary Neutrophil Gelatinase-Associated Lipocalin Predicts Non Response to Therapy with Albumin and Terlipressin in Patients with Hepatorenal Syndrome Rafael Oliveira Ximenes,[1] Alberto Queiroz Farias,[1] Claudia Helou.[2,3] *[1]Gastroenterology, Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Nephrology, Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil; [3]LIM 12, Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Current predictors of response to hepatorenal syndrome (HRS) treatment have limited accuracy, leading to administration of ineffective therapy. The aim of the study was to evaluate the utility of urinary *neutrophil gelatinase-associated lipocalin* (uNGAL) as a predictor of non response to albumin and terlipressin treatment in patients with HRS.

Methods: Prospective study conducted at a tertiary care unit between June 2013 and November 2015. Inclusion criteria: a) cirrhosis; b) age > 18 years; c) HRS diagnosis according to International Club of Ascites criteria; d) informed consent. Exclusion criteria: a) severe systemic comorbidities; b) shock; c) chronic kidney disease; d) intrinsic nephropathy; e) nephrotoxic drug use; f) previous dialysis; g) liver transplantation recipient. uNGAL was determined in the first day of treatment.

Results: Forty-nine patients (75% male, median age 59 years) were included. 24 (49%) did not respond to treatment. Median uNGAL levels were 728.8µg/L in non-responders, and 182.9 µg/L in responders (p=0.02).

	Responders, n=25	Non-responders, n=24	p
Albumin, g/dL	2.9 (2.6-3.8)	2.7 (2.4-3.0)	0.046
INR	1.9 (1.7-2.0)	2.2 (1.9-2.5)	0.015
Bilirrubins, mg/dL	3.0 (1.7-4.0)	5.2 (2.0-16.9)	0.101
Child (B/C)	10 (40%)/ 15 (60%)	3 (12.5%)/ 21 (87.5%)	0.050
MELD	25 (21-29)	30 (27-37)	0.009
Mean blood pressure, mmHg	78 (73-87)	81 (70-86)	0.294
Fractional excretion of urea, %	24 (16-32)	14 (8-23)	0.003
uNGAL	182.9 (104.8-378.6)	728.8 (235.3-1,050)	0.020

uNGAL had an AUC of 0.69 to predict non response to combined treatment, with the optimal cut-off value of 214.4µg/L (sensitivity 0.83, specificity 0.56, positive predictive value 0.65 and negative predictive value 0.78).

Conclusions: uNGAL is a useful predictor of unresponsiveness to treatment with albumin and terlipressin in patients who fulfill HRS diagnosis criteria.

FR-OR128

Haemodialysis for Acute Kidney Injury Results in Myocardial Stunning Huda Mahmoud,[1,2] Christopher W. McIntyre,[3] Nicholas M. Selby.[1,2] *[1]Dept of Renal Medicine, Derby Royal Hospital, United Kingdom; [2]Centre for Kidney Research and Innovation, Univ of Nottingham, United Kingdom; [3]Schulich School of Medicine and Dentistry, Canada.*

Background: The circulatory stress of chronic haemodialysis (HD) results in repetitive subclinical myocardial ischaemia (myocardial stunning) contributing to adverse patient outcomes. Currently it is unknown if this process occurs during renal replacement therapy (RRT) for acute kidney injury (AKI). Acute RRT differs in both its delivery and because patients do not display the circulatory changes of chronic uraemia. We aimed to determine if acute RRT is capable of inducing myocardial stunning.

Methods: 12 patients requiring RRT for AKI participated. Serial echocardiography was performed before, during and after a single RRT session and images analysed off-line using speckle-tracking software. Myocardial stunning was defined as >2 new left ventricular (LV) regional wall motion abnormalities (RWMAs) during dialysis; global longitudinal strain (GLS) assessed LV contractility. Blood pressure (BP) and systemic haemodynamics were measured continuously.

Results: 10 patients were included in the analysis; 2 were excluded due to poor image quality. All 10 patients demonstrated dialysis-induced stunning (>2 new RWMAs), with partial recovery seen at 30min post dialysis. The median number of affected LV segments was 5 (IQR 4-6). GLS significantly declined from a pre-dialysis level of -17.8±3.7% (within normal range) to below the normal range during dialysis (-15.44±2.7%, p=0.05), remaining low at 30min post-dialysis to -14.77%±3, p=0.005. There were associations between number of stunned segments and dialysis ultrafiltrated volume (r=0.79, p=0.0061). 2 patients died at 150 and 153 days post discharge (both left HD dependant). One patient remains HD dependant.

Conclusions: HD induced myocardial stunning occurs during acute RRT in combination with reductions in LV contractility. This suggests that the process is driven by HD related factors (as opposed to patient phenotype) and opens up the possibility of therapeutic HD based interventions. Further study is required to determine whether dialysis induced stunning contributes to the very poor outcomes that are well recognised in this patient group.

FR-OR129

Effect of Acute Kidney Injury on Chronic Kidney Disease Progression and Proteinuria: Baseline Results from the ARID Study Nicholas M. Selby,[1,2] Kerry L. Horne,[1] Rebecca A. Packington,[1] Christopher Lee,[1] Timothy T. Reilly,[1] John Monaghan,[1] Nitin V. Kolhe,[1] Richard J. Fluck,[1] Maarten W. Taal.[1,2] *[1]Derby Teaching Hospitals NHS Foundation Trust; [2]Centre for Kidney Research and Innovation, Univ of Nottingham.*

Background: The long-term sequelae of acute kidney injury (AKI) on renal function and mortality are increasingly appreciated, but there remains the need for prospective studies in generalisable patient groups. We present baseline data from a large case-control study of AKI in an undifferentiated hospitalised population.

Methods: In a single UK centre, participants were identified with a hospital-wide electronic AKI detection system. Cases (hospitalised patients who sustained AKI) were matched 1:1 with controls (hospitalised patients without AKI) for age, baseline eGFR stage and diabetes. Biochemical parameters including renal function and proteinuria were measured 3 months post-AKI and will be measured at 1,3 and 5 years. Survival data will be tracked to 5 yrs. CKD progression is defined as ≥25% decline in eGFR with decline in eGFR stage.

Results: 1125 patients were recruited; 878 were successfully matched. There was no difference between cases and controls in age (70 yrs (IQR 14) vs 72 yrs (IQR 13), p=0.1) or baseline CKD-EPI eGFR (69.0±21.6 vs 69.0±21.2 ml/min/1.73m^2, p=1.0). AKI episodes were predominantly stage 1 with median duration 3 days (IQR 2.5). At 3 months, mean eGFR was lower in the AKI group than controls: 62.4±22.7 vs 72.0±20.9ml/min/1.73m^2, p<0.001. 84 cases (19%) demonstrated CKD development or progression compared with only 15 controls (3%), p<0.001. Albuminuria (ACR≥3mg/mmol) was more common in the AKI group; 184 (42%) cases had albuminuria compared with 109 (25%) controls, p<0.001. Median ACR in the AKI group was 1.9 (IQR 10.3)mg/mmol compared with 0.9 (IQR 3.0) mg/mmol in controls, p<0.001.

Conclusions: Non-recovery of renal function is common at 3 months following AKI, even in a general hospital population with predominantly AKI stage 1. Albuminuria is also common after AKI; it is currently unclear whether this reflects renal parenchymal injury at time of AKI or a pre-existing risk factor. Long-term follow-up is ongoing with the aim of developing strategies to better stratify individual risk.

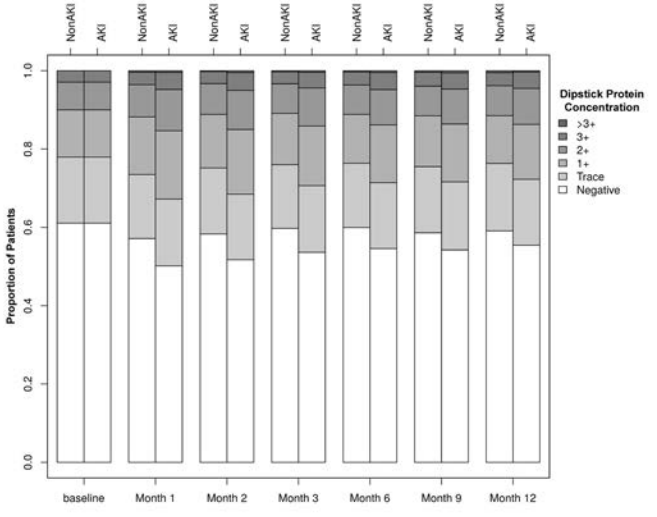
Association between Acute Kidney Injury and Subsequent Proteinuria
Sharidan Parr,[1,2] Robert Greevy,[2] Aihua Bian,[2] James Fly,[1] Guanhua Chen,[2] Theodore Speroff,[1,2] Adriana Hung,[1,2] Khaled Abdel-Kader,[2] Michael Edwin Matheny,[1,2] Talat Alp Ikizler,[1,2] Edward D. Siew.[1,2] *[1]Tennessee Valley Healthcare System, Veterans Health Administration; [2]Vanderbilt Univ Medical Center.*

Background: Acute kidney injury (AKI) is associated with progressive chronic kidney disease (CKD), but this link is not well-understood. We evaluated the association between AKI and subsequent proteinuria, as a potentially modifiable risk factor in development or progression of CKD.

Methods: We identified 657,840 patients from a national retrospective cohort of US Veterans hospitalized between 2004-2012 with baseline creatinine and urine dipstick protein measurements in the year prior to admission. Patients with and without AKI were matched on Mahalanobis distances using demographics, comorbidities, baseline proteinuria, eGFR, blood pressure, RAAS use, and inpatient exposures. We performed inverse probability sampling weighted logistic regression to evaluate changes in proteinuria over 1 year post-discharge.

Results: Matching resulted in a cohort of 90,614 AKI and non-AKI pairs. Median patient age was 66 (IQR, 59-77) years, with baseline eGFR 62 (IQR, 47-77) mL/min/1.73m^2. At baseline, 49% of patients had diabetes, 78% had hypertension, and 61% had no proteinuria. Changes in proteinuria from baseline in AKI and non-AKI groups are shown in Figure 1. Among patients with AKI, the odds of having ≥1+ proteinuria was higher during each month of follow-up than in patients without AKI; OR's ranging 1.19-1.35 (P <0.001). This risk was highest at 2 months post-discharge, OR 1.35 (95% CI: 1.30-1.41).



Conclusions: We demonstrate that AKI is a risk factor for new-onset or worsening proteinuria, suggesting a potential mechanism linking AKI and future CKD. The type of proteinuria, its mechanisms, and clinical significance warrant further study, and represent a potentially modifiable risk factor in the pathway from AKI to CKD.

FR-OR131

Use of Palliative Care Services for Patients with Acute Kidney Injury
Samuel A. Silver,[1] Kelly Chong,[2] Jin Long,[1] Yuanchao Zheng,[1] V. Shane Pankratz,[2] Mark L. Unruh,[2] Glenn Matthew Chertow.[1] *[1]Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [2]Nephrology, Univ of New Mexico School of Medicine, Albuquerque, NM.*

Background: Palliative care is underutilized in patients with chronic kidney disease, but its use in patients with acute kidney injury (AKI) is not well understood. We sought to determine the factors associated with palliative care use in hospitalized AKI patients.

Methods: Using data from the 2012 National Inpatient Sample, we identified patients with AKI and AKI-requiring dialysis (AKI-D) using validated ICD-9 codes. We compared demographics, hospital characteristics, comorbidities, and procedures between patients who did and did not receive palliative care (diagnosis code V66.7). We used logistic regression to assess associations with palliative care utilization. For the multivariable model, we used backwards selection to identify statistically significant associations.

Results: Palliative care was provided to 151,820 (5%) AKI patients and to 8370 (9%) AKI-D patients. On multivariable analysis, patients with AKI who received palliative were more likely to have cancer (OR 3.71, 95% CI 3.59-3.84), cardiogenic shock (2.39, 2.19-2.60), cirrhosis (3.50, 3.29-3.71), intracerebral hemorrhage (2.77, 2.50-3.06), or sepsis (2.00, 1.93-2.07). Several patient and hospital factors decreased the likelihood of palliative care involvement. Patient-level factors included black race (compared to white race, 0.77, 0.72-0.83), Hispanic race (compared to white race, 0.79, 0.72-0.87), chronic kidney disease (0.83, 0.81-0.86), and major surgery (0.53, 0.51-0.56); hospital-level factors included care at a rural hospital (compared to teaching hospital, 0.68, 0.59-0.78), care at a private (investor-owned) facility (compared to non-profit, 0.50, 0.44-0.57), and care at a hospital with a small number of beds (compared to large number, 0.73, 0.65-0.82).

Conclusions: Palliative care is not consistently utilized in patients with AKI, despite its many benefits in critically ill patients. More research is needed to determine reasons for patient and hospital differences in palliative care utilization, as well as to develop palliative care programs targeted at patients with AKI.

SA-OR001

The End-Stage Renal Disease Prospective Payment System Had Little Effect on Home Dialysis Usage in the United States
Eugene Lin,[1] Xingxing S. Cheng,[1] Kuo-Kai Chin,[3] Talhah Zubair,[3] Glenn Matthew Chertow,[1] Eran Bendavid,[2] Jay Bhattacharya.[2] *[1]Internal Medicine - Nephrology, Stanford Univ; [2]Centers for Health Policy and Primary Care and Outcomes Research, Stanford Univ; [3]Stanford Univ.*

Background: Home dialysis modalities (peritoneal dialysis and home hemodialysis) are touted as a way to help reduce the high cost of End-Stage Renal Disease (ESRD) in the United States. The Prospective Payment System (PPS) for ESRD, implemented by Centers for Medicare & Medicaid Services (CMS), in January, 2011, introduced financial incentives to increase home dialysis use.

Methods: In this study, we estimated the effect of the PPS on home dialysis use in adults who initiated dialysis between January 1, 2007 and August 31, 2012. We compared the estimated effect of the PPS in patients with a high incentive to use home dialysis (those with Medicare as primary insurer) with patients with a low incentive to use home dialysis (those with another primary insurer). Using a difference-in-differences method, we compared the estimated effect of the PPS in patients with Medicare as primary insurer versus those without.

Results: On average, home dialysis use increased over time in the pre-PPS era. Home dialysis use increased at a faster rate after the PPS, and by the end of the study period, the introduction of the PPS was associated with an increase in home modality use by 0.8% (CI: 0.3, 1.2%). An increase in home dialysis use was observed in both subgroups: 1.0% (CI: 0.5, 1.6%) in the Medicare as primary population and 0.4% (CI: -0.1, 1.6%) in the Medicare as secondary population. The estimated effect size was not statistically different between the two groups (p = 0.2).

Conclusions: Although the PPS was associated with an increase in home dialysis use in the United States, this increase was small relative to the baseline temporal trend, suggesting that the financial incentives for home dialysis instituted by CMS within the PPS were insufficient to yield major changes in practice.

Funding: NIDDK Support

SA-OR002

Early Technical Complications and Long Term Survival of Urgent Peritoneal Dialysis According to Break-In Period
Young Ki Son,[1] Kitae Kim,[1] Su Mi Lee,[1] Sung Hyun Son,[2] Won Suk An,[1] Seong Eun Kim.[1] *[1]Internal Medicine, Dong-A Univ Hospital, Busan, Korea; [2]Nephrology, BHS Han Seo Hospital, Busan, Korea.*

Background: Guidelines recommend a break-in period of at least 2 weeks before peritoneal dialysis(PD) start because of catheter-related technical complications. Recent study report that urgent-start PD within 14 days after PD catheter insertion is an acceptable and safe alternative to hemodialysis(HD) in patients who need to start dialysis urgently without established dialysis access. We investigated the effect of break-in periods for 48 hours less or more on early technical complications, long term PD maintenance and survival.

Methods: We included 360 patients percutaneously inserted PD catheter by surgical methods from a single center between 2007 and 2014. We excluded patients started HD before PD catheter insertion and retrospectively analyzed data of 293 PD patients. Finally we included 190 patients and grouped according to break-in period before PD solution dwell: 48 hours or less (<P2) and 2-13 days (P2-P13). We defined urgent PD patients had BUN > 100 mg/dL, creatinine >10 mg/dL, K > 6 mEq/L or pulmonary edema with a break-in period of less than 2 weeks. We defined early technical complications as malposition, leakage, obstruction, omental wrapping, change to HD within 6months after PD catheter insertion.

Results: Age of enrolled patients was 58.6, male was 62.6% and diabetes was 40.5%. 103 patients were started PD within 2 days and 87 patients within 2 to 13 days. Early technical complications was significantly higher in <P2 gorup(28.2%) than in P2-P13 group(10.3%). The incidence of re-positioning operation was higher in <P2 group(14.6%) than in P2-P13 group(3.4%). However, we observed no significant differences between the groups with respect to the prevalence of catheter dysfunction requiring change to HD within 6months or incidence of peritonitis or exit site infection. There was not significantly different in aspect of maintaining PD and survival according to break-in period.

Conclusions: Urgent PD may have few incidences of early technical complications if we avoid starting PD within 2 days after PD catheter insertion and it may warrant long term PD maintenance regardless of break-in period.

SA-OR003

Variability in Peritoneal Dialysis Patients' Training: The Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) Ana Elizabeth Figueiredo,[1,4] Junhui Zhao,[2] Brian Bieber,[2] Helen Hurst,[3,4] Francesca Tentori.[2,4] *[1]Pontificia Univ Católica do Rio Grande do Sul, Porto Alegre, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Manchester Royal Infirmary, Manchester, United Kingdom; [4]On Behalf of the PDOPPS Patient Training and Education Workgroup, Ann Arbor, MI.*

Background: Controversy exists regarding optimal training practices for PD patients. This study provides important information on international variability in PD training practices across countries participating in PDOPPS.

Methods: Launched in 2013, the PDOPPS is a prospective cohort study of PD practices and outcomes ongoing in Australia, Canada, Japan, New Zealand, Thailand, the United Kingdom (UK) and the United States (US). Data on typical training practices were reported by nurse study coordinators at each facility.

Results: At the time of submission, data were availablefor138 facilities in Australia, Canada, Japan, UK, and the US. Training practices varied internationally and were dramatically different in Japan. Japan had the greatest proportion of facilities providing training greater than one week. Home only training was unique to the UK. Across all countries, the majority of facilities provided individualized training, by a specific nurse, two weeks after catheter implantation, for 16 to 30 hours, and an oral and practical demonstration of technical procedure as a final assessment of comprehension.

Table: PD training practices by PDOPPS country*

	Australia	Canada	Japan	UK	US
Number of facilities	13	20	25	19	61
When training occurs					
Prior to PD catheter insertion	8%	5%	62%	5%	2%
1 week after PD catheter insertion	0%	30%	27%	11%	16%
2-3 weeks after PD catheter insertion	61%	65%	0%	79%	66%
Other	31%	0%	11%	5%	16%
Training location					
Facility only	46%	84%	100%	26%	53%
Combination of home and facility	54%	16%		47%	48%
Home only				26%	
Duration of training, days					
2-3	17%	22%	39%	50%	14%
4-5	67%	56%	17%	44%	29%
6-7	8%	17%	13%	6%	34%
>7	8%	6%	30%		23%
Final training assessment					
Procedure demonstration	100%	100%	100%	100%	100%
Written test	23%	30%	8%	11%	89%
Oral test	54%	40%	24%	37%	67%
Other	8%	5%	0%	0%	10%
Number of nurses training one patient					
One nurse	67%	95%	28%	84%	97%
Several nurses	33%	5%	72%	16%	3%

* As reported by the nurse study coordinator at each facility

Conclusions: Large variation exists in PD training practices across PDOPPS countries. As the study proceeds, and accrues follow-up time, patient-level training practices, and patient reported perceptions of training quality, the PDOPPS will provide unique information regarding the association of specific training practices and outcomes, thus contributing to fill this knowledge gap.

SA-OR004

Complement Activation in PD Induced Arteriolopathy Maria Bartosova,[1] Betti Schaefer,[1] Justo Lorenzo Bermejo,[2] Felix Lasitschka,[3] Silvia Tarantino,[4] Christoph Aufricht,[4] Klaus Kratochwill,[4] Bradley Warady,[5] Karel Vondrak,[6] Claus P. Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, Univ of Heidelberg, Germany; [2]Dept of Medical Biometry, Univ of Heidelberg, Germany; [3]Inst of Pathology, Univ of Heidelberg, Germany; [4]Zytoprotec GmbH, Austria; [5]The Children's Mercy Hospital; [6]Univ Hospital Motol, Czech Republic.*

Background: Exposure to high glucose concentrations and glucose degradation products (GDP) leads to angiogenesis and vasculopathy compromising ultrafiltration capacity of the peritoneum, ultimately resulting in PD failure. The underlying pathomechanisms are partly understood.

Methods: Omental arterioles were microdissected from non-uremic children, age and gender matched children at time of first PD catheter insertion and peritonitis free children on PD for 26 (2-72) months (n=6/group). Children with diseases potentially affecting vessel integrity were excluded. 4 arterioles / patient with similar morphology (EVG staining, Aperio® automated image analysis) were selected. Neighboured sections were used for transcriptome and proteome analysis.

Results: Uremia induced up-regulation of 173 and down-regulation of 117 arteriolar genes ($p<0.01$) compared to controls. In patients on low / high GDP PD, 88/139 genes were up- and 11/17 genes down regulated compared to uremic controls. Gene ontology analyses demonstrated activation of inflammatory, immunological and stress response cascades with uremia and even more with PD. In children on low GDP fluid the complement system and respective regulatory pathways were upregulated most significantly. Proteomics findings were concordant in 14 out of 15 complement factors. Findings were reconfirmed immunohistochemically in omental arterioles in independent cohorts of 15 children per group for C1q, C3c, C4d and TCC. In parietal peritoneum, we quantitated endothelial C1q, which inversely correlated with lumen/vessel ratio, i.e. vasculopathy ($r=-0.75$, $p=0.02$).

Conclusions: Omental arterioles are uniquely suited for global assessment of molecular mechanisms of uremia and PD induced arteriolopathy. Low GDP dialysis fluids predominantly activate arteriole and capillary complement cascades.

SA-OR005

The Inhibition of CTGF Ameliorates Peritoneal Fibrosis through the Suppression of Fibroblast/Myofibroblast Accumulation Miki Nakamura,[1] Norihiko Sakai,[2] Kenneth E. Lipson,[3] Taito Miyake,[2] Yasutaka Kamikawa,[2] Akihiro Sagara,[2] Shinji Kitajima,[2] Tadashi Toyama,[2] Akinori Hara,[2] Yasunori Iwata,[2] Miho Shimizu,[2] Kengo Furuichi,[2] Takashi Wada.[1] *[1]Dept of Nephrology and Laboratory Medicine, Kanazawa Univ, Kanazawa, Japan; [2]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan; [3]FibroGen, Inc., San Francisco, CA.*

Background: Peritoneal fibrosis is a severe complication of peritoneal dialysis, but the mechanisms driving it remain to be fully determined. Connective tissue growth factor (CTGF) has been known to regulate fibroblast activity such as proliferation and myofibroblast differentiation. We therefore examined if the inhibition of CTGF has anti-fibrotic effects on the peritoneal fibrosis.

Methods: Peritoneal fibrosis was induced by intraperitoneal injection of chlorhexidine gluconate (CG) in type I pro-collagen promoter-driven green fluorescent protein (GFP) mice to identify fibroblasts. The neutralizing anti-CTGF antibody (FG-3019) was used to inhibit CTGF functions.

Results: CG-induced increases in peritoneal thickness, type I pro-collagen mRNA expression and hydroxyproline content were significantly attenuated in FG-3019-treated mice (n=7). In addition, CG challenges induced a marked peritoneal accumulation of GFP^+ fibroblasts that was significantly reduced by FG-3019. To specifically identify proliferating fibroblasts, dual immunostainings of peritoneal sections were performed using anti-proliferating cell nuclear antigen (PCNA) antibody and anti-GFP antibody. The number of proliferating fibroblasts ($PCNA^+GFP^+$) in the peritoneum after CG challenges was significantly suppressed by FG-3019 (n=5). Peritoneal accumulation of a-smooth muscle $actin^+$ myofibroblasts was also reduced in FG-3019-treated mice. In addition, peritoneal CTGF expression was detected in peritoneal mesothelial cells and fibroblasts, and the levels of peritoneal CTGF expression were significantly suppressed in FG-3019-treated mice compared with those in control antibody-treated mice (n=6).

Conclusions: Our results suggest that the inhibition of CTGF by FG-3019 might be a novel treatment for peritoneal fibrosis through the regulation of fibroblast/myofibroblast accumulation.

Connective Tissue Growth Factor Is Correlated with Lymphangiogenesis in Peritoneal Fibrosis Hiroshi Kinashi,[1,2] Tri Q. Nguyen,[1] Roel Goldschmeding,[1] Yasuhiko Ito.[2] *[1]Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Nephrology and Renal Replacement Therapy, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: Lymphatic absorption in peritoneal cavity may contribute to ultrafiltration failure in peritoneal dialysis (PD). Lymphangiogenesis develops during PD-related peritoneal fibrosis (PF). Connective tissue growth factor (CTGF, aka CCN2) is an important determinant of fibrotic tissue remodeling, but its possible involvement in lymphangiogenesis has not been explored. We studied the relationship between CTGF and lymphangiogenesis in association with PD.

Methods: Messenger RNA (mRNA) for CTGF, lymphatic markers (lymphatic endothelial hyaluronan receptor-1 [LYVE-1] and podoplanin), and vascular endothelial growth factor-C (VEGF-C), a major lymphangiogenic factor, in human peritoneal biopsies (N=56) was analyzed by quantitative real-time polymerase chain reaction. CTGF and VEGF-C mRNA were assessed in human peritoneal mesothelial cells (HPMC) (N=21) treated with transforming growth factor-β1 (TGF-β1). Immunohistochemistry (IHC) for CTGF, LYVE-1, and VEGF-C in a rat chlorhexidine gluconate (CG) induced-PF model was performed.

Results: CTGF mRNA positively correlated with LYVE-1 ($R=0.638$, $P<0.001$), podoplanin ($R=0.592$, $P<0.001$), and VEGF-C ($R=0.670$, $P<0.001$) mRNA in human peritoneal biopsies. We cultured HPMC derived from 21 patients with variable peritoneal membrane transport. CTGF and VEGF-C mRNA expression were increased by TGF-β1 (5 ng/ml) treatment. There was a positive relationship between CTGF and VEGF-C mRNA increment at 12 ($R=0.722$, $P<0.001$) and 24 ($R=0.532$, $P<0.01$) hours after TGF-β1 treatment. IHC analysis indicated that the expression of CTGF ($P<0.01$), LYVE-1-positive lymphatic vessels ($P<0.001$), and VEGF-C ($P<0.01$) were increased in the rat diaphragm of CG models compared with controls. Moreover, CTGF expression positively correlated with expression of LYVE-1-positive lymphatic vessels ($R=0.775$, $P<0.05$) and VEGF-C ($R=0.952$, $P<0.001$) in the CG model. There was also a positive correlation between expression of VEGF-C and LYVE-1 in the CG model ($R=0.704$, $P<0.05$).

Conclusions: Our results suggest a close relationship between CTGF and PF-related lymphangiogenesis.

SA-OR007

The PD Membrane Microvasculature in Uremia and PD - Findings from the International Pediatric PD Biobank Maria Bartosova,[1] Betti Schaefer,[1] Stephan Macher-Goeppinger,[2] Peter Sinn,[2] Uwe Querfeld,[4] Ariane Zaloszyc,[5] Gema Ariceta,[6] Yok-Chin Yap,[7] Philipp Romero,[3] Franz S. Schaefer,[1] Bradley Warady,[8] Claus P. Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, Univ of Heidelberg, Germany; [2]Dept of Pathology, Univ of Heidelberg, Germany; [3]Dept of Pediatric Surgery, Univ of Heidelberg, Germany; [4]Univ of Charité, Germany; [5]Univ Hospital Hautepierre, France; [6]Univ Hospital Vall d' Hebron, Spain; [7]Hospital Kuala Lumpur, Malaysia; [8]The Children's Mercy Hospital.*

Background: Based on modelling and experimental findings, peritoneal microvasculature primarily defines PD membrane transport function, respective human data is scant.

Methods: 30 centers collected 332 peritoneal and 256 omental specimens from 106 healthy individuals (0.1-60 yrs), 114 patients at time of PD catheter insertion and 112 on PD (0.1-20.1 yrs), 91 treated with low GDP fluid. Aperio® and Nanozoomer/NDP Systems® were used for automated analyses.

Results: Parietal peritoneal vessel density depends on age, with highest blood capillary density / endothelial exchange area in infancy and lowest values with 7-12 yrs. Lymphatic vessel density is low, but again highest in infants. Omental blood capillary density correlates with parietal capillary density, lymphatic vessels are few. Uremia reduces omental blood vessel density by 51%, Angp-2 protein by 78%, ACTG1 by 34%. The submesothelial three vessel layer structure dissipates with low GDP PD, blood vessel density increases 2-3 fold, as do TGF-ß/pSMAD, miR21, VEGF, ASMA pos. fibroblasts and CD45/CD68+ macrophages. Mild lumen narrowing develops in 31% of blood vessels, lymphatic vessel density remains low. Similar changes develop with high GDP PD, while EMT and profibrotic $CD90^{+}$ fibroblast subpopulations are more prominent. D/P creatinine ratios correlate with peritoneal vessel density ($r=0.33$, $p<0.05$), but not with lymphatic vessel density or submesothelial thickness; vessel density with PD duration and peritonitis number ($r=0.26/0.20$, $p<0.001/0.05$).

Conclusions: Peritoneal blood vessel density defines peritoneal solute transport. Despite low GDP fluid usage, progressive blood capillarisation develops with time on PD, while lymphatic vessel density and vasculopathy remain low.

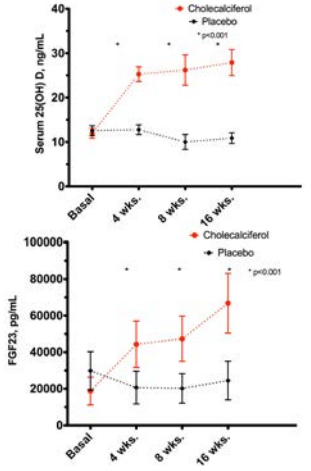
SA-OR008

Cholecalciferol Supplementation to Correct Hypovitaminosis D in Peritoneal Dialysis Patients Increases FGF23 but Not Other Osteogenic Proteins: A Randomized Clinical Trial Juan Carlos Ramirez-Sandoval, Mauricio Arvizu-Hernandez, Barbara Vazquez-Cantu, Cristinoc Cruz, Enrique Gómez, Ricardo Correa-Rotter. *Ins Nac de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.*

Background: Very low levels of 25-hydroxyvitamin D (25OHD) are common in peritoneal dialysis(PD) patients, and normalization has been advocated as potentially beneficial. The safety, eficacy, and effects of 25OHD correction on osteogenic biomarkers in this population remains uncertain.

Methods: We conducted a double-blind, placebo-controlled, randomized clinical trial to assess the effects of cholecalciferol supplementation on osteogenic biomarkers (osteoprotegerin, intact fibroblast growth factor-23[iFGF23], osteocalcin, osteopontin, iPTH) in PD patients with 25OHD<20 ng/mL;56 patients were randomized to 16 wks. of cholecalciferol (4,800 IU/daily,n=28) or placebo(n=28).

Results: Baseline characteristics were similar between groups. Mean±SD serum 25OHD increased from 10.5±3.6 ng/ml at baseline to 26.1±4.5 ng/ml in the cholecalciferol group and did not significantly change in the placebo group (11.9±4.1 ng/ml to 13.2±4.5 ng/ml). A larger proportion of the cholecalciferol supplemented subjects had an increase >30% in iFGF23 compared with placebo (95% vs 9%,p<0.0001). Extremely high iFGF23 levels (>30000 pg/ml) were observed in 74% of patients receiving cholecalciferol at 16 wks.



The observed changes in iFGF23 were not confounded by concurrent and sustained changes in urinary residual function, serum P, or iPTH levels. No difference was observed between arms in osteoprotegerin, osteocalcin, osteopontin, Ca, P, iPTH, IL-6, phosphate binder use or calcitriol dose.

Conclusions: Cholecalciferol supplementation increases serum 25OHD levels in patients on PD with levels<20 ng/mL, yet it induces an exponential increase of iFGF23 in most PD patients, which may be a major concern and contraindication for this manouever.

Peritoneal Dialysis-Related Infection Rates and Outcomes: Early Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) Jeffrey Perl,[1,6] Junhui Zhao,[2] Brian Bieber,[2] Ronald L. Pisoni,[2] Beth M. Piraino,[3,6] Yasuhiko Ito,[4,6] David W. Johnson.[5,6] *[1]Univ of Toronto, Toronto, ON, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Univ of Pittsburgh, Pittsburgh, PA; [4]Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [5]Univ of Queensland, Brisbane, Australia; [6]On Behalf of the PDOPPS Infection Prevention and Management Workgroup, Ann Arbor, MI.*

Background: Peritoneal dialysis (PD)-related infections are a major source of morbidity for PD patients. We describe preliminary peritonitis rates and outcomes among PDOPPS participants.

Methods: PDOPPS is an international prospective cohort study of PD treatment outcomes in Australia/New Zealand (ANZ), Canada, Japan, Thailand, the UK and the USA. Data was collected on peritonitis episodes, and outcomes from countries with ≥100 patient-years of follow-up.

Results: Peritonitis rates were comparable across countries with the exception of Japan which had a slightly higher peritonitis rate. Wide variation was seen in facility peritonitis rates in each country. Organism-specific information revealed: the proportion of fungal peritonitis was highest in ANZ (7%), lowest in Japan (0%), the proportion of peritonitis due to pseudomonas species was highest in Japan (7%) and ANZ (7%), and peritonitis due to CNST was lowest in Japan (13%), but culture-negative peritonitis was highest (34%). Peritonitis associated with a hospitalization was highest in Japan. The proportion of peritonitis episodes necessitating PD catheter removal was similar across countries.

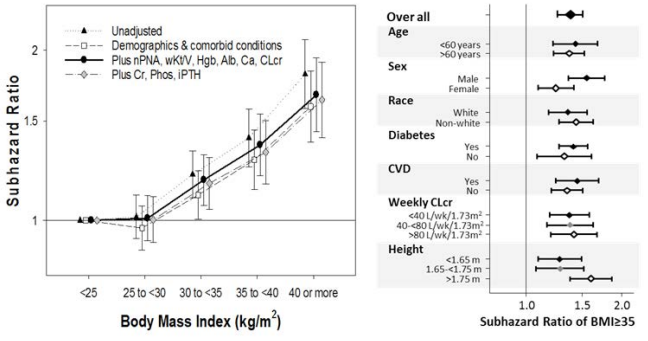
Morbid Obesity and Time to Transfer to Hemodialysis among Incident Peritoneal Dialysis Patients Yoshitsugu Obi,[1] Amanda R. Tortorici,[1] Connie Rhee,[1] Elani Streja,[1] Daniel L. Gillen,[1] Rajnish Mehrotra,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Wash.*

Background: The prevalence of obesity is increasing among dialysis patients in the USA and may be associated with higher risk of peritoneal dialysis (PD) modality interruption and transfer to hemodialysis (HD), notwithstanding the survival advantages of obesity in dialysis patients (obesity paradox).

Methods: In a national cohort of incident dialysis patients in the USA (2007–2011), we identified 15,112 patients who started PD as their 1st or 2nd dialysis modality and who had

data on body mass index (BMI) during the first 91 days. The association of BMI categories and the association of morbid obesity (BMI ≥35 kg/m^2) with transfer to hemodialysis (HD) were examined in competing risk regression models incorporating the competing risk for death and kidney transplantation. Hierarchical adjustments were employed using case-mix variables and clinically relevant laboratory variables.

Results: There was a higher likelihood of transfer to HD across higher BMI (*P*trend<0.001); BMI categories above 30 kg/m^2 were significantly associated with shorter time to transfer to HD. These associations were robust against any adjustment models (left panel). Overall the risk associated with morbid obesity (BMI ≥35 kg/m^2) was high (subhazard ratio 1.32 [95%CI, 1.21–1.45]) in the case-mix adjusted model. The risk of morbid obesity was pronounced among male or taller (height >1.75 m) patients (*P*interaction <0.05) but was consistently observed across all subgroups (right panel).



Conclusions: Obesity and morbid obesity are incrementally associated with a higher risk for PD patients to transfer to HD. This makes it imperative to identify interventions that would prolong patient time on PD in patients who are obese and morbidly obese.

IL-33 Induces Innate Lymphoid Cells and Alternatively Activated Macrophages That Reduce Kidney Ischaemia-Reperfusion Injury

Qi Cao,[1] Yiping Wang,[1] Zhiqiang Zhang,[1] Ruifeng Wang,[1] Vincent W.S. Lee,[1] Guoping Zheng,[1] Yuan Min Wang,[2] Stephen I. Alexander,[2] David C. Harris.[1]
[1]Centre for Transplant and Renal Research, Westmead Inst for Medical Research, The Univ of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.

Background: IL-33 is an important immune regulator which can promote Th2-dependent immunity, inflammation, and tissue repair in several important immune-mediated disorders. In the current study, we sought to determine whether IL-33 is an important regulator in renal ischaemia-reperfusion injury (IRI).

Methods: Renal IRI was induced in C57BL/6 mice by bilateral renal pedicle occlusion for 30 minutes. IL-33 was given by 5 consecutive daily injections starting at day 5 before IRI surgery. Separately, adoptive transfer of type 2 innate lymphoid cells into mice with IRI was used to assess their in vivo functions.

Results: IL-33 significantly improved kidney functional and structural injury in IRI mice, with lower serum creatinine and less tubular cell injury. The possible mechanisms underlying the protective effect of IL-33 were examined. IL-33 increased the levels of IL-4, IL-5 and IL-13 in serum and kidney and promoted induction of alternatively activated (M2) macrophages in kidney. Moreover, the number of NK cells and neutrophils was significantly reduced in IRI mice treated with IL-33. Of note, IL-33 increased the number of type 2 innate lymphoid cells (ILC2) and regulatory T cells (Tregs) in kidney. The depletion of ILC2 or Tregs by using CD90 or CD25 antibodies in vivo demonstrated that the protective effect of IL-33 in IRI is dependent on ILC2 cells, but not Tregs. Adoptive transfer of ILC2 not only reduced kidney injury of IRI mice but also induced M2 macrophages in kidney.

Conclusions: In conclusion, IL-33 elicits ILC2 and Tregs, regulates macrophage phenotype in kidney and prevents kidney IRI. ILC2 is primarily responsible for IL-33's protective effect in IRI.

Tubular Cell Endocycle-Related Hypertrophy and Renal Progenitor Mitosis Drive Kidney Function Recovery after AKI but Cannot Avoid Persistent Tubular Cell Loss

Elena Lazzeri,[1] Maria Lucia Angelotti,[1] Anna Julie Peired,[1] Duccio Lombardi,[1] Francesca Becherucci,[1] Hans J. Anders,[2] Laura Lasagni,[1] Paola Romagnani.[1] *[1]Excellence Centre DENOTHE, Univ of Florence, Italy; [2]Div of Nephrology, Klinikum der LMU München, Germany.*

Background: Acute kidney injury (AKI) is considered largely reversible based on an intrinsic regenerative capacity of tubules. As AKI can be followed by chronic kidney disease (CKD), we questioned this concept and hypothesized that tubular cell division is limited and other mechanisms account for kidney function recovery.

Methods: To this aim, we developed four conditional transgenic mouse models: 1. *Pax8.rtTA;TetO.Cre;R26.Confetti* (Pax8/Confetti) to track all tubular cells; 2. *Pax2.rtTA;TetO.Cre;R26.Confetti* (Pax2/Confetti) to track putative tubular progenitors; 3. *PAX8.rtTA;tetO.cre;R26.FUCCI2* (Pax8/FUCCI2) and 4. *PAX2.rtTA;tetO.cre;R26.FUCCI2* (Pax2/FUCCI2) to identify cell-cycle phase of Pax8+ and Pax2+ cells. Doxycycline administration followed by 1 week washout drove the reporters expression to track Pax2+ and Pax8+ progenies in healthy mice and after 30' of unilateral ischemia/reperfusion injury (IRI).

Results: To quantify irreversible cell loss we induced IRI in Pax8/Confetti mice where all tubular cells are tracked. Kidney function recovered, but 35% of total tubular cells were irreversibly lost. Clonal analysis disproved widespread tubular cell proliferation erroneously indicated by cell-cycle markers immunostaining. Simultaneous cell-cycle phase and DNA content assessment using Pax8/FUCCI2 mice and flow cytometry revealed endoreplication-related tubular cell hypertrophy as the predominant response and showed that cell-cycle markers indicated endoreplication but not true cell division. In contrast, Pax2/Confetti mice showed that Pax2+ tubular progenitors enriched by higher survival and clonogenic capacity after IRI. Consistently, Pax2/FUCCI2 mice demonstrated that Pax2+ tubular progenitors completed mitosis while Pax8+ cells endoreplicated.

Conclusions: These results 1. disprove common knowledge about the mechanisms of AKI recovery, 2. identify tubular cell hypertrophy related to endoreplication cycles as a critical response to AKI 3. explain the high incidence of CKD after an AKI episode.

SA-OR013

Genetic Lineage Analysis of Dedifferentiated Proximal Tubule Epithelia during Repair after AKI

Monica Chang Panesso,[1] Matthew A. Lalli,[1] Shiyo Ikeda,[1] Akio Kobayashi,[2] Andrew P. McMahon,[3] Benjamin D. Humphreys.[1]
[1]Div of Nephrology and Div of Genetics, Washington Univ in St. Louis, St. Louis, MO; [2]Div Nephrology, Univ of Washington, Seattle, WA; [3]Dept Stem Cell Biology & Reg Med. Univ Southern California, Los Angeles, CA.

Background: Proximal tubule (PT) has a remarkable capacity for repair after acute injury. Whether dedifferentiation or a fixed progenitor population is responsible for this repair remains the subject of ongoing controversy. We have generated a novel genetic mouse model to address this question.

Methods: We generated a Kim1-GFPCreER^{t2} knockin mouse line (Kim1-GCE) by homologous recombination. Kim1 is expressed exclusively in dedifferentiated PT cells. After crossing to the R26-tdTom reporter line we performed lineage analysis to evaluate the fate and characteristics of these cells during repair.

Results: Heterozygote Kim1-GCE expressed half the level of Kim1 protein after IRI, and homozygote Kim1-GCE had undetectable endogenous Kim1 protein, as expected with our ATG replacement knock in strategy.In bigenic Kim1-GCE; R26tdTom mice, there was no labeling of any cells in healthy kidney, even after tamoxifen (TAM) administration. By contrast, bilateral IRI with TAM induced robust labeling of cells in the outer medulla. These cells co-expressed Kim1, Vimentin and Pax2, indicating a dedifferentiated state. These were Ki67+, indicating proliferative repair. We performed clonal analysis using low dose TAM. At day 2, 95% of clones were single cell but this decreased to 45% single cell clones by day 14, with mostly 2, 3 and 4 cell clones however a substantial number of 10+ cell clones was observed as well. The multicellular clones continued to express Pax2 by day 14, with a decrease in Vimentin expression. Importantly, TdTom+ cells cultured on day 2 after injury formed tubular structures in a tree-like pattern resembling branching morphogenesis, whereas cells cultured after redifferentiation at day 14 lacked this capacity.

Conclusions: The mechanism of repair after AKI is by dedifferentiation of bulk proximal tubule and not by a fixed progenitor population. Dedifferentiation confers unique properties that are lacking from differentiated proximal tubule.

SA-OR014

Fibroblast-Specific Integrin-Linked Kinase Signaling Is Required for Kidney Protection and Repair after AKI

Haiyan Fu, Dong Zhou, Youhua Liu.
Dept of Pathology, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.

Background: Integrin-linked kinase (ILK) signaling plays a critical role in regulating cell proliferation, differentiation, matrix production and tissue hemostasis. Activation of ILK has been linked to the pathogenesis of tubular epithelial-mesenchymal transition (EMT) and kidney fibrosis. Whether ILK plays any role in the repair or progression after AKI is unknown.

Methods: To study this, we generated conditional knockout mice in which the ILK gene was specifically depleted in kidney fibroblasts (FC-ILK-/-) by mating ILK-floxed mice with Gli1-Cre transgenic mice. Sex- and age-matched control and FC-ILK-/- mice were subjected to ischemia/reperfusion injury (IRI).

Results: Mice with fibroblast-specific deletion of ILK (FC-ILK-/-) were phenotypically normal with no appreciable defects in kidney morphology and function. Following AKI induced by IRI, FC-ILK-/- mice developed more severe kidney injury, comparing to the controls. FC-ILK-/- mice had higher serum creatinine level and more severe morphologic injury. In addition, ablation of ILK in interstitial fibroblasts promoted chemokine expression and renal infiltration of inflammatory cells after IRI. Consistently, apoptosis was more prevalent in the kidneys of the FC-ILK-/- mice, which was accompanied by increased renal expression of soluble FasL and Fas-associated protein with death domain (FADD). Notably, the ability of fibroblasts activation and proliferation was largely abolished in the FC-ILK-/- mice, with downregulation of PDGFR-β, PCNA and increased P53 expression.

Conclusions: These results suggest that endogenous ILK in fibroblast is pivotal for proper fibroblast activation in response to acute injury. Such response from healthy fibroblasts is crucial for tubular cell survival, repair and regeneration after AKI.

SA-OR015

Renin Lineage Cells Do Not Participate in Endothelial but Mesangial Regeneration after Experimental Injury Leo Ruhnke, Jan Sradnick, Moath Al-Mekhlafi, Michael Gerlach, Florian Gembardt, Vladimir T. Todorov, Bernd Hohenstein, Christian Hugo. *Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CGC, Dresden, Germany.*

Background: In response to kidney injury renin lineage cells (RLC) can give rise to different glomerular cell types such as mesangial cells (MC) or podocytes. Endothelial cells (EC) represent another major glomerular cell type frequently undergoing primary or secondary injury during kidney disease. Up to now it is unknown if RLC can also differentiate into EC. Thus, we investigated the role of RLC in endothelial regeneration.

Methods: We used a triple transgenic lacZ reporter mouse which allows specific detection and fate mapping of RLC via X-Gal staining. LacZ labeling of RLC in healthy adult mice was induced by doxycyclin/enalapril treatment. Left sided EC injury (ECI) was caused by renal-arterial administration of concanavalin A (conA)/anti-conA. Kidneys were harvested on day 0 (healthy control (HC)), 1, 7 and 28.

Results: ECI evaluation using CD31 densitometry showed significant decrease of positive staining area at day 1 and subsequent recovery to HC levels at day 7 (HC: 11.7 ± 1.7% d1: 6.7 ± 0.3% d7: 13.7 ± 1.5%). Accordingly AFOG staining revealed glomerular fibrin thrombi at d1. In conjunction with endothelial damage we detected pronounced MC injury by PAS staining, which could be verified by α8 integrin densitometry (HC: 16.5 ± 1.7% d1: 6.2 ± 1.5% d7: 13.9 ± 1.0%). Whereas X-Gal staining was restricted to the juxtaglomerulus apparatus (JGA) in healthy controls, 15.6 ± 0.8 % of glomeruli showed migration of RLC from the JGA into the glomerular tuft at d7. Immunohistological analysis revealed that these intraglomerular RLC show a transdifferentiation to mesangial phenotype expressing α8-integrin, NG2 and GATA3, but do not co-localize with EC (CD31, ERG) or podocytes (WT-1, synaptopodin). These findings could preliminarily be confirmed using fluorescent renin lineage mice.

Conclusions: In our model of renal ECI, RLC are recruited from the JGA to the glomerular tuft upon severe injury. These RLC do not show involvement in regeneration of damaged renal endothelium. Rather, recruitment of RLC seems to be specific for the repair of concomitantly injured mesangium.

Exosomal Transfer of micro-RNA-486-5p Protects against Ischemia-Reperfusion Kidney Injury Kevin D. Burns, Joe A. Zimpelmann, Alex Gutsol, William A. Knoll, Dylan Burger, David Allan, Jose L. Vinas. *Medicine, KRC, OHRI, Univ of Ottawa, Ottawa, ON, Canada.*

Background: Exosomes derived from cord blood endothelial colony forming cells (ECFCs) reduce ischemia/reperfusion (IR) kidney injury in immuno-incompetent mice. ECFC exosomes are enriched in micro-RNA (miR)-486-5p, which we showed can transfer to cultured endothelial cells. We studied the role of miR-486-5p transfer in protection against IR kidney injury *in vivo*, and assessed phosphatase and tensin homolog (PTEN) as a potential target.

Methods: Immuno-competent mice with IR kidney injury were injected with ECFC exosomes (20 μg i.v.) at reperfusion. Some mice received exosomes derived from ECFCs that were transfected with antagomiR to miR-486-5p. After 24 h, mice were sacrificed, plasma was collected, and kidneys were analyzed by real-time PCR, immunoblots, histologic injury scores, and apoptosis assays. In cultured human umbilical vein endothelial cells (HUVECs), a luciferase reporter assay assessed targeting of PTEN by miR-486-5p, and silencing RNA determined the role of PTEN in apoptotic response to hypoxia.

Results: In mice with IR, exosomes increased kidney miR-486-5p levels, decreased PTEN, and increased phosphorylation of pro-survival Akt. These effects were blocked in mice receiving exosomes from antagomiR-transfected ECFCs. ECFC exosomes potently protected against IR kidney injury, determined by plasma creatinine and BUN, histologic injury, and apoptosis assays (plasma Cr: 117±26 μM (IR) vs 9±4 μM (IR + exosomes); P<0.01; n=5-7 mice). By contrast, the protective effects were not observed with exosomes derived from antagomiR-transfected ECFCs. In cultured HUVECs transfected with a luciferase reporter, miR-486-5p directly targeted the 3'-untranslated region of PTEN. Knockdown of PTEN in HUVECs inhibited hypoxia-induced apoptosis, to levels observed with exosome treatment (n=3).

Conclusions: In kidney IR injury, administration of ECFC exosomes causes transfer of miR-486-5p, which mediates protective effects on kidney function, histology and apoptosis. In endothelial cells, PTEN is directly targeted by miR-486-5p, which blocks apoptosis. Exosomes enriched in miR-486-5p could represent a viable strategy to protect against acute kidney injury.

Proximal Tubule-Derived Amphiregulin and TNFα Crosstalk Promotes Progressive Fibrotic Kidney Disease Eirini Kefalogianni,[1] Vaishali Krishnadoss,[1] Muthu Lakshmi Muthu,[2] Helmut G. Rennke,[2] Benjamin D. Humphreys,[1] Joseph V. Bonventre,[2] Andreas Herrlich.[1] *[1]Nephrology, Washington Univ School of Medicine, St. Louis, MO; [2]Renal, Brigham and Women's Hospital, Boston, MA.*

Background: Using global and proximal tubule (PT)-specific knockout, we previously showed in ischemic and obstructive kidney injury mouse models that the metalloprotease ADAM17 is a key regulator of fibrosis via cleavage-activation of its substrates, epidermal growth factor receptor (EGFR) ligands and TNFα. However, apart from PT, injury also induced ADAM17 upregulation in the interstitial compartment. We thus now examined the effect of stromal- or myeloid linage-specific knockout of ADAM17 on injury-induced kidney fibrosis in vivo. Further, we studied pro-fibrotic and pro-inflammatory effects of specific PT-released ADAM17 substrates in vitro. Finally, we investigated activation of the EGFR and TNFα pathways in human AKI and fibrotic CKD kidney samples.

Methods: We used SLC34a1-Cre-ERt2/ADAM17fl/fl (PT-KO), FoxD1-Cre/ADAM17fl/fl (Stroma-KO) and LysM-Cre/ADAM17fl/fl (Myeloid-KO) and respective littermates and subjected them to UUO. ADAM17 and downstream pathways were studied in PT cells *in vitro* and in AKI and chronic kidney disease (CKD) patients.

Results: UUO-induced kidney fibrosis was significantly reduced in PT-KO but not in stroma-KO or myeloid-KO mice, suggesting that ADAM17 substrate release from PT is mainly responsible for its pro-fibrotic function. Among several EGFR ligand substrates released from injured PT, we identify AREG as inducing the strongest pro-inflammatory and pro-fibrotic cytokine expression in PT cells in vitro. This effect is strongly potentiated by TNFα. This newly identified EGFR-TNFα pathway cross-talk partially depends on TNFα-induced and ADAM17-dependent AREG cleavage. Finally, both EGFR and TNFα pathways are activated in human AKI and CKD samples, and ADAM17 and AREG protein expression are very strongly correlated with fibrosis markers in CKD biopsies.

Conclusions: ADAM17 substrates released from injured PT and their cross-talk, in particular of AREG and TNFα, exert ADAM17's pro-fibrotic role. Activation of ADAM17-pathways highly correlates with injury and fibrosis in human kidney samples.

Elucidating the Cellular Mechanisms of a Pro-Regenerative Drug Therapy for Acute Kidney Injury Hwa In Han,[1] Lauren Brilli Skvarca,[1] Eugenel Bermudez Espiritu,[1] Maria Azzurra Missinato,[1] Michael Tsang,[1] Alan J. Davidson,[2] Neil A. Hukriede.[1] *[1]Dept of Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA; [2]Molecular Medicine and Pathology, Univ of Auckland, Auckland, New Zealand.*

Background: Acute kidney injury (AKI) often progresses to chronic kidney disease and end stage renal disease due to inefficient renal tubular epithelial cell (RTEC) proliferation. Therefore, drugs that can enhance proliferation in post-AKI setting are urgently in need. We have identified a small molecule, methyl-4-phenylthiobutanoate (m4PTB), an HDAC inhibitor, which increases RTEC proliferation in zebrafish and rodent models of AKI. However, the mechanisms driving proliferation are not known. Here, we show that m4PTB enhances epithelial-to-mesenchymal transition, a hallmark of dedifferentiating cells. The dedifferentiating cells provide the source of RTEC proliferation, thereby enhancing post-AKI repair.

Methods: We injected gentamicin in larval zebrafish to induce a nephrotoxic model of AKI. We utilized immunohistochemistry to visualize expression of E-cadherin and Vimentin, markers of epithelial and mesenchymal cells, respectively. We stained tubules with Pax2, and PCNA, markers for renal progenitors and proliferation, respectively. Finally, we stained tubules with kidney injury molecule-1 (KIM-1) to quantify changes in injury level after m4PTB treatment.

Results: m4PTB treatment increased expression of mesenchymal marker and decreased epithelial marker in injured RTECs. Injury stimulated Pax2 reactivation in RTECs, further increasing with m4PTB. Pax2 expression colocalized with Vimentin, suggesting that RTECs expressing the embryonic gene simultaneously undergo dedifferentiation. To investigate whether the dedifferentiating cells provide the source of proliferation, we stained tubules with Pax2 and PCNA. m4PTB increased the number of Pax2 and PCNA positive cells, of which many colocalized. Finally, we show that m4PTB lowers KIM-1 expression, thereby reducing tubular injury.

Conclusions: Our work demonstrates that m4PTB promotes dedifferentiation of RTECs to increase proliferation and reduce injury level. This mechanism of dedifferentiation and proliferation enhances regenerative responses post-AKI.

Interaction of the EGF Receptor and the Hippo Pathway in Acute Kidney Injury Jianchun Chen, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Activation of both EGFR and the Hippo signaling pathway can control cell proliferation, apoptosis and differentiation. Our previous studies have shown that activation of EGFR in renal proximal tubule epithelial cells plays a critical role in renal functional and structural recovery from Ischemia-reperfusion injury. YAP is a key transcriptional activator that associates with the highly conserved transcription factors, TEA domain (TEAD) proteins, to regulate transcription of multiple target genes.

Methods: Renal proximal tubule cell-specific EGF receptor knockout mice ($EGFR^{ptKO}$) or their wild type littermates (WT) were subjected to ischemia-reperfusion injury (IRI), and wildtype mice were subjected to IRI followed by administration with vehicle or verteporfin, an inhibitor of YAP-TEAD activation.

Results: In response to IRI, renal YAP expression and nuclear localization were markedly increased within 6 hours and persisted for at least 3 weeks after IRI. YAP activation was dramatically inhibited in $EGFR^{ptKO}$ mice. Administration of verteporfin significantly delayed renal functional and structural recovery from IRI. The BUN of vehicle-treated mice returned to basal levels (19.65 ± 1.44 mg/dl) at 7 days after IR, but remained elevated in verteporfin treated mice (43.33 ± 6.01 mg/dl, P<0.01, n=5). There was more severe proximal tubule dilation and epithelial simplification and cast formation

in verteporfin-treated mice. We also found that upregulation of cyclin D expression and phosphorylation of retinoblastoma protein (Rb) 24 h after IRI were dramatically blunted in EGFR^{ptKO} mice or in the mice given verteporfin.

Conclusions: This study demonstrates that EGFR-dependent YAP upregulation plays an important role in renal functional and structural recovery in response to acute kidney injury. The increases in cyclin D and Rb phosphorylation suggest that YAP activation is important for cell cycle activation and epithelial regeneration following AKI.

Kidney Injury Molecule-1 (KIM-1) Interacts with the Dynein Light Chain Tctex-1 to Mediate Efferocytosis Lakshman Gunaratnam,[1,2] Ola Ziyad Ismail,[1] Xizhong Zhang.[1] *[1]Matthew Mailing Centre for Translational Transplant Studies, Lawson Health Research Inst, London, ON, Canada; [2]Medicine, Western Univ, London, ON, Canada.*

Background: After tissue injury, the phagocytic clearance of apoptotic cells, or efferocytosis, attenuates inflammation and enables tissue repair. KIM-1 is an efferocytosis receptor specifically upregulated on proximal tubular epithelial cells during acute kidney injury (AKI). We previously showed that, after renal ischemia-reperfusion injury, mice deficient in KIM-1 have impaired efferocytosis, with greater tissue damage, renal dysfunction and death, compared to wild-type mice.

Methods: To uncover the phagocytic signalling pathway downstream of KIM-1, we utilized a yeast two-hybrid screening system and identified a potential KIM-1-interacting protein, the 14-kDa dynein light chain protein, Tctex-1. Tctex-1 is a component of the dynein microtubule motor complex involved in linking dynein to its cargo as an adaptor protein. It also plays dynein-independent roles in diverse cellular functions. Thus, we hypothesized that Tctex-1 is required for KIM-1-mediated engulfment of apoptotic cells.

Results: First, we confirmed the direct interaction between Tctex-1 and Kim-1 using co-immunoprecipitation, GST-Tctex-1 pull-down assay and immunofluorescence staining. When we stimulated KIM-1-expressing cells with apoptotic cells, the interaction between KIM-1 and Tctex-1 was sustained until the later stages of the efferocytosis. Knockdown of endogenous Tctex-1 expression with siRNA significantly inhibited efferocytosis by KIM-1-expresisng cells. To test if Tctext-1 the inhibitory effect caused by Tctex-1 knockdown was related to impaired cargo binding for dynein transport (i.e. dynein-dependent), we utilized a Tctex-1 mutant construct in which we replaced Threonine-94 with glutamic acid (T94E) to mimic the phosphorylated form that cannot bind dynein. Surprisingly, the phospho-mimic Tctex-1-T94E displayed decreased binding to Kim-1, but did not influence KIM-1-mediated uptake of apoptotic cells.

Conclusions: Our studies have uncovered a novel role for Tctext-1 in efferocytosis, which is crucial to tissue repair following AKI.

New Insights into the Function of Dendritic Cell Subsets in Glomerulonephritis Using Multi-Photon Imaging Sebastian Braehler,[1] Saravanan Raju,[1] Michael William Johnson,[1] Bernd H. Zinselmeyer,[1] Jeffrey H. Miner,[2] Kenneth M. Murphy,[1] Andrey S. Shaw.[3] *[1]Dept of Pathology and Immunology, Washington Univ School of Medicine, St. Louis, MO; [2]Div of Nephrology, Washington Univ School of Medicine, St. Louis, MO; [3]Genentech, South San Francisco, CA.*

Background: Glomerulonephritis (GN) is a major cause for end stage renal disease. The immunological mechanisms are not completely understood. Studies using CD11c as marker for dendritic cells (DC) have identified DCs as key players in a mouse model of GN (NTN). How to discriminate macrophages and dendritic cells in various tissues is a matter of ongoing debate. Recently, new markers allow the definition of subsets of macrophages and dendritic cells in the kidney.

Methods: Here we used multiphoton imaging of isolated kidney slices from three different fluorescent reporter mice (CD11c-YFP, ZBTB46-GFP for all classical DCs and SNX22-GFP for the CD103+ DC subpopulation) to analyze structure, migration and distribution of dendritic cells under healthy conditions and after NTN treatment. To determine the function of specialized DC subsets, we depleted the general classical DC lineage using zbtb46-DTR bone marrow chimeras and the CD103+ subset by using BATF3-knockout mice before inducing NTN.

Results: CD11c-YFP-positive cells form a continuous network with long cell processes, and with many cells in this population also expressing the macrophage markers F4/80 and CD64. In contrast, ZBTB46-GFP-positive and SNX22-GFP-positive DCs have a lower expression of these markers, exhibited shorter processes, higher motility and were found clustered around blood vessels. Depletion of ZBTB46+ DCs caused an attenuation of NTN, predominantly in the early stage, whereas depletion of only the CD103+ subset aggravated NTN with rapid crescent formation and excessive neutrophil invasion.

Conclusions: Here we provide evidence that CD11c-YFP identifies a mixed population of macrophages and dendritic cells. ZBTB46-depletion studies showed that the dendritic cells in toto have a proinflammatory effect, whereas the CD103+ subset represents an anti-inflammatory population, possibly balancing the immune response generated by their CD11b+ counterparts.

FcγRIV Is Important in the Pathogenesis of Anti-MPO Induced Crescentic Glomerulonephritis Hong Xiao, Peiqi Hu, Cheng Wan, Ronald J. Falk, J. Charles Jennette. *Pathology and Laboratory Medicaine, Univ of North Carolina, Chapel Hill, NC.*

Background: Anti-myeloperoxidase (anti-MPO) IgG causes crescentic glomerulonephritis (CGN) in mice that mimics human antineutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis in patients. Our prior studies have shown that knock out (KO) of all activating Fcγ receptors (FcγRs) prevents induction of anti-MPO CGN, but that KO of activating receptors FcγRI and FcγRIII does not prevent disease. In this study, we investigated the role of the activating receptor FcγRIV in anti-MPO induced CGN *in vivo*, as well as the effect of blocking anti-FcγRIV antibodies on neutrophil activation by anti-MPO IgG *in vitro*.

Methods: B6 mice with KO of FcγRIV (FcγRIV KO) and wild type (WT) B6 mice were injected i.v. with 50ug/g body weight anti-MPO IgG. Circulating anti-MPO IgG was determined by ELISA. Urine abnormalities were monitored, and mice were sacrificed at day 6 and kidney tissue obtained for pathologic examination. In vitro neutrophil activation by anti-MPO was measured by respiratory burst.

Results: At day 6, B6 WT and FcγRIV KO mice that received anti-MPO IgG showed similar levels of circulating anti-MPO. All WT B6 mice developed hematuria and CGN (mean 12% glomeruli with crescents). In contrast, FcγRIV KO mice had normal urine and less CGN with mean 2% crescents ($p<0.001$). Neutrophils deficient in FcγRIV-/- or treated with anti-FcγRIV blocking antibodies had less *in vitro* activation by anti-MPO than neutrophils from wild type mice as measured by respiratory burst.

Conclusions: 1) Absence of the FcγRIV greatly diminishes anti-MPO induced CGN *in vivo* and *in vitro* neutrophil activation, indicating the engagement of FcγRIV by anti-MPO IgG plays an important role in the pathogenesis of anti-MPO induced GCN. 2) Inhibitory effects of anti-FcγRIV antibody on anti-MPO induced activation of neutrophils suggests that blockade of FcγRIV engagement by ANCA may have a therapeutic role in ANCA disease.

CD11b Activation Protects against Lupus Nephritis by Suppressing TLR-Dependent IFN Responses via AKT-FOXO3-IRF7 Samia Khan,[1] Mohd Hafeez Faridi,[1] Shehryar J. Khaliqdina,[1] David J. Cimbaluk,[1] Vineet Gupta.[1] *[1]Rush Univ Medical School; [2]NIAMS, NIH.*

Background: Genetic variations in the ITGAM gene (coding for CD11b) produce defective CD11b and associate with a risk for systemic lupus erythematosus (SLE, lupus) and lupus nephritis. Elevated level of IFN I in circulation is a heritable risk factor for SLE and promotes the immune dysregulation characteristic of this disease. Whether variations in ITGAM are linked to high IFN I and whether CD11b activation could be a therapeutic strategy is not known and is explored here.

Methods: We measured serum IFN I activity in 171 SLE patients and determined their *ITGAM* genotype to test for a direct link between *ITGAM* SNPs and the IFN I pathway. Given that ITGAM SNPs result in functionally deficient CD11b, we tested whether partial CD11b activation with small molecule agonist, leukadherin-1 (LA1), can reduce IFN I responses and determined the underlying mechanistic pathways. To test the efficacy of LA1 *in vivo*, we used the MRL/*lpr* mice that develop IFN I-dependent multi-organ lupus similar to human lupus with renal injury.

Results: We show that three *ITGAM* variants significantly associate with the elevated levels of IFN I in lupus, suggesting a direct link between reduced CD11b activity and elevated inflammation in patients. Partial CD11b activation with LA1 reduced IFN I responses and protected lupus-prone MRL/*lpr* mice from kidney injury. LA1-treated mice had reduced proteinuria, IgG renal immune complex deposition, and glomerular damage as compared to controls. CD11b activation reduced TLR-dependent pro-inflammatory signaling in leukocytes and suppressed IFN I signaling, via an AKT-FOXO3-IRF7 pathway. TLR-stimulated macrophages from CD11b SNP carriers showed increased basal expression of IRF7 and IFNB, as well as increased nuclear exclusion of FOXO3, which was suppressed by LA1.

Conclusions: LA1 suppresses TLR-stimulated overproduction of cytokines *in vivo*, which have been directly linked to exacerbation of lupus nephritis. These findings suggest that pharmacological CD11b activation should be explored as a potential novel therapeutic target in SLE, particularly in patients identified as carriers of specific genetic polymorphisms.

Endothelial NF-κB Blockade Abrogates Anti-MPO Antibody-Induced Glomerulonephritis Mira Choi,[1] Adrian Schreiber,[1] Claudia Eulenberg-Gustavus,[2] Claus Scheidereit,[3] Jan A.A.M. Kamps,[4] Ralph Kettritz.[1] *[1]Nephrology, Experimental and Clinical Research Center, Berlin, Germany; [2]Experimental and Clinical Research Center, Berlin, Germany; [3]Max-Delbrueck-Center for Molecular Medicine, Berlin, Germany; [4]Dept of Pathology and Medical Biology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: ANCA vasculitis is a highly inflammatory condition where ANCA-activated neutrophils interact with endothelium resulting in necrotizing vasculitis. We tested the hypothesis that endothelial NF-κB mediates necrotizing crescentic glomerulonephritis (NCGN) and can be therapeutically targeted.

Methods: P65 siRNA was formulated in liposomes conjugated with anti-E-selectin antibodies to target activated endothelial cells (EC). Mice were injected with low dose TNFa to upregulate E-selectin on EC, followed by SOS siRNA or control compound. Anti-MPO antibodies and LPS were injected 48h later for disease induction. After 7 days urine analysis was done by dipsticks, albuminuria. Glomerular crescents and necrosis were assessed by histology. Neutrophil and monocyte influx into the kidney were measured by flow cytometry. NF-κB activity was quantified in nuclear extracts using electrophoretic mobility shift assays using EMSA and by RT-PCR for TNFa mRNA.

Results: Retrospective analysis of kidneys from murine NCGN revealed that p50/p65 NF-κB is activated in affected kidneys, resulted in increased NF-κB gene transcription, correlated with crescent formation, and possibly involved the endothelial compartment. ANCA-stimulated primed neutrophils activated endothelial NF-κB in neutrophil:endothelial cell co-cultures. This resulted in increased transcription and protein production of NF-κB dependent genes, and promoted neutrophil adhesion to an endothelial monolayer. We used a passive anti-MPO antibody transfer model for NCGN and treated mice with p65 siRNA. Active treatment significantly reduced urine abnormalities, myeloid cell influx into the kidneys, and glomerular necrosis and crescent formation. Finally, increased phospho-p65 staining in glomeruli with active lesions indicates that NF-κB is also activated in patients with ANCA-associated NCGN.

Conclusions: We suggest that endothelial NF-κB contributes to NCGN and provides a therapeutic target.

Transcriptome Analysis of CD4-Lymphocytes Specifically Deleted of NEMO or IKKβ in an Experimental Model of Rapid Progressive Glomerulonephritis

Friedrich Thaiss,[1] Meilan Chen,[1] Jiabin Huang,[2] Gunther Zahner,[1] Malik Alawi,[2] Linlin Guo.[1] *[1]Nephrology, Univ Hospital, Hamburg, Germany; [2]HPI, Univ Medical Center, Hamburg, Germany.*

Background: Experimental nephrotoxic nephritis (NTN) is a model for T-cell mediated human rapid progressive glomerulonephritis. T-cell stimulation leads to activation of transcription factors, such as NF-kappa B. Recently we published the role of a specific IKK2 (β)-inhibitor in this model. We therefore now examined T-cell specific ablation of IKK2 or NEMO.

Methods: T-cell specific ablation of IKK2 or NEMO was achieved through deletion of IKK2 or NEMO by Cre-recombinase under control of the CD4*cre* transgene. NTN-antiserum was injected and function, histology and kidney chemokines determined during a 10-days period. T cells, Th1, Th17 and Treg infiltration into the kidney were analysed by FACS. Nephritic CD4*cre* animals were used as controls. Transcriptome analysis was performed of CD4+ T-cells isolated from spleens before and after NTN induction.

Results: Nephritic CD4*cre*IKK2*fl/fl* and CD4*cre*NEMO*fl/fl* mice had an increase in albumin/creatinine-ratio at day 3 and increased glomerular crescents at day 10. Although the percentage of CD4+ T cells infiltrating kidneys was not different between the groups examined further analysis showed significantly reduced Tregs but a significant increase in Th1- and Th17-cells in CD4*cre*IKK2*fl/fl* and CD4*cre*NEMO*fl/fl* animals. As a spleen–kidney axis has been described recently next transcriptome analysis of CD4+ splenocytes was performed. Volcano plot revealed 97 genes differentially down- and 120 genes up-regulated in CD4+ splenocytes of nephritic mice. The results of DiRE analysis showed IKK2 and NEMO dependent differential transcription factors activation.

Conclusions: Our data demonstrate that ablation of IKK2 or NEMO specifically in CD4+ T-cells significantly increased Th1 and Th17 cells infiltrating kidneys after NTN. We have identified genes involved in T cell differentiation that were differentially expressed between IKK2 and NEMO deficient CD4+ T-cells. Better understanding the role of IKK2 and NEMO in T-cell regulation will help to recognize the role of IKK2- and NEMO- kinase inhibitors in patients with glomerulonephritis.

Therapeutic Induction of Antigen Specific Tolerance in MPO-ANCA GN Using MPO-Conjugated Apoptotic Splenocytes

Andrea Savina Godfrey, Poh-Yi Gan, A. Richard Kitching, Stephen R. Holdsworth. *Centre for Inflammatory Diseases, Monash Univ, Clayton, VIC, Australia.*

Background: Loss of tolerance to myeloperoxidase (MPO) results in MPO-ANCA associated glomerulonephritis (MPO-ANCA GN). Splenic clearance of senescent leukocytes by apoptosis induction is a homeostatic pathway and maintains self-tolerance. We sought to co-opt this pathway by injecting apoptotic MPO peptide conjugated splenocytes (MPO-Ap-Sp) to induce MPO tolerance in MPO-ANCA GN.

Methods: Murine Sp underwent simultaneous $MPO_{409-428}$ (the nephrogenic MPO peptide) or control, $OVA_{323-339}$ conjugation and apoptosis induction *ex vivo* using ethylenecarbodiimide; MPO-Ap-Sp and OVA-Ap-Sp respectively. MPO autoimmunity was induced by $MPO_{409-428}$ immunization and GN triggered by a subnephritogenic dose of anti-GBM Ig.

Results: Treatment of mice with MPO-Ap-Sp prior to MPO-ANCA GN attenuated MPO autoimmunity compared with control OVA-Ap-Sp mice (MPO induced DTH swelling; 0.11±0.02 vs 0.02±0.01Δmm P<0.05) and GN (43±5% of glomeruli with segmental necrosis [gsn] vs 19±1% P<0.05). Treatment of mice with established MPO autoimmunity immediately prior to inducing GN also afforded significant protection (gsn; 31±4 vs 44±4% P<0.05). Adoptive transfer of CD4+ cells from mice receiving MPO-Ap-Sp to mice with established MPO autoimmunity significantly decreased induced GN compared to mice receiving CD4+ cells from OVA-Sp treated mice (gsn; 45±4% vs 23±3% P<0.05). Confirming that MPO-Ap-Sp induces antigen specific suppressive CD4+ cells. The requirement for Tregs in mediating MPO-Ap-Sp protection against GN was confirmed by comparing GN in 1) Treg depleted mice (anti-CD25 mAb) receiving MPO-Ap-Sp, 2) Control Treg intact (irrelevant mAb) receiving MPO-Ap-Sp and 3) Untreated mice developing MPO-ANCA GN. Untreated mice developed GN with 46% gsn, not significantly different from mice given MPO-Ap-Sp but depleted of Tregs (46% gsn) whereas Treg intact mice given MPO-Ap-Sp were significantly protected (24% gsn, P<0.05).

Conclusions: MPO-Ap-Sp is a preventative and therapeutic in experimental MO-ANCA GN by enhancing antigen specific tolerance mediated by Tregs.

Funding: Government Support - Non-U.S.

SA-OR027

The Role of Th1 and Th17 CD4 T Cells in Experimental Autoimmune Myeloperoxidase ANCA Associated GN

Poh-Yi Gan,[1] Joshua D. Ooi,[1] A. Richard Kitching,[1,2] Stephen R. Holdsworth.[1,2] *[1]Dept of Medicine, Monash Univ, VIC, Australia; [2]Dept of Nephrology, Monash Health, VIC, Australia.*

Background: Current evidence suggests that CD4 T helper (Th) subsets, Th1 and/or Th17 direct MPO-ANCA GN. Defining the dominant cytokines directing this disease allows for therapeutic targeting using emerging biologicals.

Methods: Mice deficient in Th1 (IL-12p35; $p35^{-/-}$) and Th17 capacity (IL-23p19; $p19^{-/-}$) were immunized with MPO and GN triggered early (day 16) and late (day 28) with a low dose of anti-GBM Ig and culled 4 days later. Biologicals targeting the dominant cytokines (α-p35 and α-p19 monoclonal antibodies [mAb]) directing each phase were then assessed as therapeutics immediately prior to triggering GN.

Results: Early in the development of MPO autoimmunity (day 20), $p19^{-/-}$ mice were protected from the development of GN (albuminuria; 297.0±33.9vs421.1±44.5 μg/24hr and glomerular segmental necrosis; 11±2 vs 34±7%, all $P<0.05$) compared to WT mice, wherease $p35^{-/-}$ mice were not protected from MPO-ANCA GN (albuminuria; 282.9±20.6 vs WT mice 304.3±21.2 μg/24hr, $P=0.5$). Administration of α-p19 mAb starting day 16 attenuated induced GN (albuminuria; 105.3±28.2 vs IgG2a treated controls 325.4±60.5 μg/24hr, $P<0.01$). When MPO autoimmunity was established (day 32), Th1 was dominant as $p35^{-/-}$ mice had reduced MPO autoimmunity (MPO DTH swelling and *ex vivo* MPO stimulated draining lymph node cell proliferation) and attenuated GN (significantly reduced glomerular leukocytes, segmental necrosis and albuminuria). Therapeutic administration of α-p35 mAb at day 28 also attenuated GN. In $p19^{-/-}$ mice, MPO autoimmunity was not reduced (similar to WT mice), however glomerular leukocytes and albuminuria were reduced. Subsequent experiments show that IL-23 and the Th17 axis play a critical innate immune role in recruiting glomerular neutrophils and depositing MPO initiating GN, accounting for the protection from GN observed in $p19^{-/-}$ mice.

Conclusions: Established MPO autoimmunity is Th1 dominant while Th17 is important early in establishing adaptive MPO autoimmunity and playing an innate immune role in facilitating glomerular neutrophil infiltration and deposition of MPO required to induce MPO-ANCA GN.

Interferon Regulatory Factor 5 Promotes Disease in the FcgRIIB-/- Mouse Model of Lupus through TLR7-Dependent and -Independent Pathways

Hanni Menn-Josephy, Kei Yasuda, Prachi Shukla, Amanda A. Watkins, Tamar R. Aprahamian, Abraham Cohen-Bucay, Ramon G. Bonegio, Ian R. Rifkin. *Medicine - Renal Section, Boston Univ School of Medicine, Boston, MA.*

Background: Polymorphisms in interferon regulatory factor 5 (IRF5) are strongly associated with an increased risk of developing systemic lupus erythematosus. We previously demonstrated that IRF5 is required for disease development in the $FcgRIIB^{-/-}$ lupus mouse model. The exact pathways through which IRF5 acts to promote disease in this model are not known. As IRF5 plays a central role in signaling through TLR7, a TLR involved in pathogenesis in other lupus models, we investigated the relative effects of TLR7 deficiency, and combined TLR7 and IRF5 deficiency in the $FcgRIIB^{-/-}$ mouse model, on disease manifestations as well as on the severity of lupus nephritis.

Methods: We generated the following experimental groups of $FcgRIIB^{-/-}$ female mice: $TLR7^{+/+}IRF5^{+/+}$ mice, $TLR7^{+/+}IRF5^{-/-}$ mice, $TLR7^{-/-}IRF5^{+/+}$ mice and $TLR7^{-/-}IRF5^{-/-}$ mice. Mice were analyzed at the age of 8 months. Experimental groups were compared for disease manifestations including autoantibody production, serum IgG levels, and kidney disease severity.

Results: We found that TLR7 deficiency reduces disease severity and that TLR7 is required not only for the production of autoantibodies against RNA-containing autoantigens but also for autoantibodies against double-stranded DNA. $FcgRIIB^{-/-}$ mice deficient in both TLR7 and IRF5 developed less disease than mice deficient in TLR7 alone, with lower titers of anti-RNA autoantibodies, lower levels of the pathogenic IgG isotypes, and less severe renal disease.

Conclusions: We have identified TLR7-dependent and TLR7-independent roles for IRF5 in the development of lupus autoimmunity and lupus nephritis. $FcgRIIB^{-/-}$ mice deficient in both TLR7 and IRF5 developed less disease than mice deficient in TLR7 alone, with lower titers of anti-nuclear autoantibodies, lower levels of the pathogenic IgG isotypes, and less severe renal disease. This suggests that therapies targeting IRF5 may offer some additional benefit compared to therapies targeting only TLR7 for the treatment of lupus and lupus nephritis.

SA-OR029

Treatment with the Natural VEGF Inhibitor Soluble Flt-1 Reduces Renal Complications, Endothelial Activation and Inflammation in Long-Term Type 1 Diabetic Mice Pascal Bus, Marion Scharpfenecker, Jan A. Bruijn, Hans J. Baelde. *Pathology, LUMC, Leiden, Zuid-Holland, Netherlands.*

Background: It has been shown that VEGF-A is involved in diabetic nephropathy (DN). Animal models for diabetic nephropathy have shown that glomerular VEGF-A levels are increased, and that reducing VEGF-A is beneficial in preventing renal complications. Besides its role in angiogenesis, VEGF-A is also involved in endothelial activation and macrophage migration. The aim of the current study was therefore to investigate if treatment with the natural VEGF-A inhibitor sFlt-1 reduces inflammation and endothelial activation.

Methods: Diabetes was induced in C57BL/6 mice with injection of streptozotocin. After five weeks of diabetes mice were transfected with a sFlt-1 construct via electroporation. 15 weeks after the induction of diabetes mice were sacrificed. Collection of urine and blood was performed at baseline, and subsequently every other week. Albuminuria was measured using Rocket Electrophoresis. Kidneys were sectioned and stained for PAS, collagen IV, fibronectin, wt1, fa-11, tnf-a, pecam-1, vcam-1 and icam-1, and quantified using ImageJ. One-way ANOVA was performed to measure differences between groups. Differences with a probability level ($p < 0.05$ were considered statistically significant.

Results: Diabetic mice transfected with sFlt-1 had lower urine albumin/creatinine ratios compared to mice with diabetes alone and reduced glomerular damage ($p<0.001$). In addition, vcam-1 and icam-1 ($p<0.001$), the number of glomerular macrophages ($p<0.01$) and glomerular tnf-alpha expression ($p<0.001$), were reduced to basal levels in sFlt-1 treated diabetic mice compared to control diabetic mice.

Conclusions: Our results show that inhibiting VEGF-A levels by sFlt-1 has beneficial effects on inflammation, besides the effect on renal function and morphology. These effects could be attributed to a decreased number of glomerular macrophages, potentially due to the inhibitory effect of sFlt-1 on macrophage migration and by reducing endothelial activation.

SA-OR030

Absence of the Endogenous A2B Adenosine Receptor Increases Severity of Immune-Associated Inflammation Gabriela E. Garcia,[1] Luan D. Truong,[2] Kelley S. Brodsky,[3] Holger Eltzschig,[3] Richard J. Johnson.[1] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]Pathology, The Methodist Hospital, Houston, TX; [3]Anesthesiology, Univ of Colorado Denver, Aurora, CO.*

Background: Adenosine functions as a signaling molecule through the activation of four adenosine receptors. During conditions in which adenosine levels are elevated such as hypoxia, ischemia or inflammation A_{2B} adenosine receptor (A_{2B}AR) increases ischemia tolerance and attenuates acute inflammation.

Methods: Using an A_{2B}AR knockout/reporter gene-knock-in, we investigated the role of A_{2B}AR in kidney injury in the cytokine-dependent anti-glomerular basement membrane glomerulonephritis (anti-GBM GN).

Results: We found that A_{2B}AR is slightly expressed in the vascular pole and that in nephritic kidneys A_{2B}AR expression is highly induced in the vascular pole and also in glomeruli and arteries. Mice with less kidney injury expressed less A_{2B}AR. In contrast, higher expression of A_{2B}AR expression was observed with more kidney injury, suggesting that increased A_{2B}AR is a counter-regulatory response to inflammation. Importantly, nephritic kidneys from A_{2B}AR -/- mice showed more severe kidney injury compared with those in WT control mice. Glomerular proliferation, crescent formation, tubulointerstitial injury and inflammatory cell infiltration were significantly higher in A_{2B}AR -/- mice. A_{2B}AR promoter contains a binding site for the transcription factor hypoxia-inducible factor (HIF)-1 that increases A_{2B}AR expression. To investigate if HIF-1 is induced in GN and could be responsible for A_{2B}AR upregulation, we used a HIF-1α reporter mouse (ODD-Luc) and found that HIF-1 is induced in nephritic kidneys as early as day 3 after induction of the disease. Next, to determine if endothelial A_{2B}AR mediates kidney protection in GN, we compared mice with deletion of A_{2B}AR in endothelial cells with controls. Mice with endothelial-specific A_{2B}AR-/- showed increased in disease susceptibility. Moreover, use of an A_{2B}AR agonist significantly attenuated GN.

Conclusions: These findings suggest that A_{2B}AR is a natural mechanism of inhibition of inflammation and protection from tissue damage.

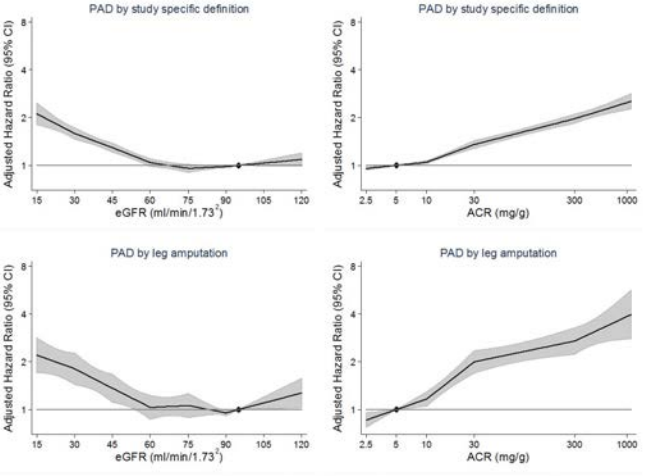
eGFR, Albuminuria, and Future Risk of Peripheral Artery Disease: The Chronic Kidney Disease Prognosis Consortium Kunihiro Matsushita, Shoshana Ballew, Josef Coresh, Hisatomi Arima, Johan Arnlov, Massimo Cirillo, Natalie Ebert, Jade S. Hiramoto, Michael Shlipak, Frank L.J. Visseren, Ron T. Gansevoort, Csaba P. Kovesdy, Varda Shalev, Mark Woodward, Florian Kronenberg. *Chronic Kidney Disease Prognosis Consortium.*

Background: Peripheral artery disease (PAD) is one of the most common cardiovascular outcomes in patients on dialysis. However, the full spectrum associations of eGFR and albuminuria with future PAD risk are yet to be investigated.

Methods: We studied 784,342 participants without a history of PAD from 13 cohorts. Cox models were used to quantify the associations of creatinine-based eGFR and urine albumin-to-creatinine ratio (ACR) with incident PAD (composite of hospitalizations with PAD diagnosis, intermittent claudication, leg revascularization, and leg amputation) beyond potential confounders such as diabetes. We also evaluated whether eGFR and ACR improve PAD risk prediction.

Results: There were 19,574 PAD cases over a median follow-up of 3.4-14.9 years across cohorts. Both low eGFR and high ACR were associated with PAD risk independently of each other and known PAD risk factors (Figure). Of note, the association of ACR appeared to be more evident with leg amputation than overall PAD. Both eGFR and ACR improved PAD risk discrimination beyond known risk factors (Δc-statistic: 0.013 [95% CI: 0.011-0.015] and 0.008 [0.006-0.010], respectively). Risk discrimination for leg amputation was improved with ACR (Δc-statistic: 0.037 [0.024-0.050]) but not necessarily with eGFR (0.012 [-0.001-0.025]).

Conclusions: Both low eGFR and high ACR were independently associated with future PAD risk and significantly improved its prediction. ACR was particularly relevant to leg amputation, even independently of diabetes. These results suggest the usefulness of CKD measures to identify patients who are at high risk of PAD and may benefit from PAD examination, monitoring, and prevention.



Adjusted for age, sex, race, smoking, diabetes, systolic blood pressure, antihypertensive drugs, total and high-density lipoprotein cholesterols, history of coronary disease, stroke, and heart failure, and each CKD measure.

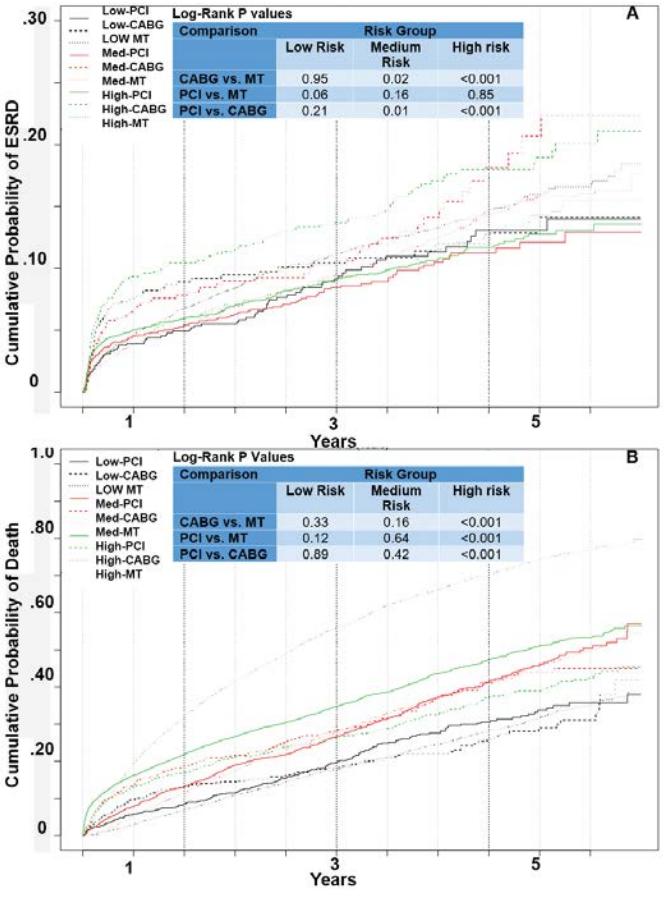
ESRD and Mortality after Medical Therapy Compared with Percutaneous and Surgical Coronary Revascularization in Individuals with CKD at Low, Medium, or High Cardiovascular Risk David M. Charytan,[1] Tanya Natwick,[2] Craig Solid,[2] Shuling Li,[2] Charles A. Herzog.[2] *[1]Brigham & Women's Hospital, Boston; [2]Chronic Disease Research Group, MMRF, Minneapolis.*

Background: Prior analyses suggest that medical therapy (MT) is inferior to percutaneous (PCI) or surgical coronary revascularization (CABG) for the treatment of coronary disease in individuals with CKD, but did not assess ESRD risks and may be confounded by definition of MT as the absence of revascularization as well as failure to stratify by baseline cardiovascular (CV) risk.

Methods: CV risk groups were defined in the 2007-2012 Medicare 20% sample. Low risk: angiography or stress testing without prior CV disease (CVD); Medium risk: stress test or angiography with prior CVD; High risk: admission for acute coronary syndrome (ACS); CKD and ESRD were defined by diagnostic codes, and PCI and CABG as procedures within 60 days of risk group entry. MT was defined as use of new CV medications.

Results: For low risk pts 1000 had PCI, 571 CABG, and 6848 MT. For medium risk 1751 PCI, 718 CABG and 9670 MT. For high risk 4542 PCI, 1481 CABG and 8287 MT. Mortality and CV outcomes increased across risk groups, consistent with excellent discrimination of our metric. Cumulative probability of ESRD was similar with CABG and MT in the low risk group, but was worse with CABG in medium and high risk groups. Notably, ESRD probability was similar with PCI and MT in all groups (figure 1) . Mortality rates per hundred patient years were lowest with MT in the low risk group—PCI 9.1, CABG 8.9, MT 8.1--and medium risk groups—PCI 13.5, CABG 14.6, MT 13.2, but was markedly better with CABG or PCI in high risk patients—PCI 18.4, CABG 13.1, MT 33.5.



Conclusions: MT, PCI and CABG benefits in CKD vary by baseline CV risk and may be equivalent in low or moderate risk. CABG is associated with improved survival but also increased ESRD risk compared to MT after ACS.

SA-OR033

Renal Impairment and Stroke: The INTERSTROKE Study Andrew Smyth,[1,2] Martin O'Donnell,[1,2] Michelle Canavan,[1] Sumathy Rangarajan,[2] Salim Yusuf.[2] *[1]HRB Clinical Research Facility Galway, National Univ of Ireland, Galway, Ireland; [2]Population Health Research Inst, McMaster Univ, Hamilton, ON, Canada.*

Background: Renal impairment and stroke share pathogenic mechanisms and risk factors, particularly hypertension. Previous studies report conflicting associations between renal impairment and stroke. In these analyses, we explore if renal impairment is an independent risk factor for stroke.

Methods: INTERSTROKE is a large, case-control study in 32 countries in Asia, America, Europe and Africa. Cases were defined as acute first stroke and were age and sex matched to controls without a history of stroke (hospital or community based). We include participants with available serum creatinine measurement, the CKD-EPI formula was used to estimate GFR and renal impairment defined as eGFR<60ml/min/1.73m^2. Multivariable-adjusted conditional logistic regression was used to explore the association between renal impairment and stroke.

Results: Of 21,127 participants, 10,610 were cases and 10,517 were controls. Mean age was 62.3 (13.4) years and 59.6% (n=16,039) were male. Mean eGFR was 79.9 (23.5) ml/min/1.73m^2 and 20.3% (n=4,296) had renal impairment, with higher prevalence in cases (23.4%, n=2,477) than controls (17.3%, n=1,819) (p<0.01). After adjustment for age, sex, ethnicity, hypertension, diabetes, cardiovascular disease, physical activity, waist hip ratio, diet, antihypertensives, analgesics and anti-inflammatories, renal impairment was associated with increased odds of all stroke (OR 1.25 [1.15-1.36]), ischemic stroke (OR 1.17 [1.06-1.29]) and intracerebral hemorrhage (OR 1.50 [1.25-1.79]). The association was similar between men (OR 1.28 [1.14-1.44]) and women (OR 1.22 [1.07-1.38]), but significant only in those <65 years of age (OR 1.73 [1.50-2.00]). Overall, there was evidence of a dose response for all stroke: eGFR>90 (Reference), eGFR 60-90 (OR 0.94 [0.87-1.03]), eGFR 30-60 (OR 1.13 [1.01-1.25]) and eGFR<30 (OR 2.01 [1.59-2.55]).

Conclusions: We report that renal impairment is associated with an increased risk of in the largest case-control study of stroke with evidence of a dose response. Importantly, there was no effect modification by gender, but those <65years of age were most vulnerable.

SA-OR034

The Incidence of Atrial Fibrillation by Chronic Kidney Disease Stage and Proteinuria Amber O. Molnar,[1] Anan Bader Eddeen,[5] Robin Ducharme,[5] Amit X. Garg,[5,6] Ziv Harel,[4] Megan K. Mccallum,[5] Jeffrey Perl,[4] Ron Wald,[4] Manish M. Sood.[2,3] *[1]Nephrology, McMaster Univ, Hamilton, ON, Canada; [2]Nephrology, Univ of Ottawa, Ottawa, ON, Canada; [3]Epidemiology, Ottawa Hospital Research Inst, Ottawa, ON, Canada; [4]Nephrology, St. Michael's Hospital, Univ of Toronto, Toronto, ON, Canada; [5]Inst for Clinical Evaluative Sciences, Ottawa, ON, Canada; [6]Medicine and Epidemiology, Western Univ, London, ON, Canada.*

Background: Prior studies examining the association of CKD with incident atrial fibrillation (AF) are limited by heterogeneous definitions of CKD. Many studies define CKD as a dichotomous outcome and most fail to include albuminuria, which is an important component of new staging systems for CKD.

Methods: In this retrospective cohort study (2002-2015), we grouped 736,666 adults ≥40 years of age with no prior history of AF by eGFR (≥90, 60 to <90, 45 to <60, 30 to <45, 15 to <30, or <15 mL/min per 1.73 m^2) and urine albumin-to-creatinine ratio (ACR >300, 30-300 or <30 mg/g) to examine the incidence of new onset AF. Cox models were used to estimate the hazard ratios (HR) for AF. Patients were censored upon death, dialysis or end of follow up.

Results: Median follow up 6 years. 45,499 (6.2%) patients developed AF, 62,243 (8.4%) died and 6,667 (0.9%) patients required dialysis. The incidence rate of AF increased more than 40 fold across declining eGFR and increasing ACR groupings (eGFR >90/ACR <30: 3.29 per 1000 person-years; eGFR <15/ACR >300: 137.3 per 1000 person-years). In adjusted models using the eGFR >90 and ACR <30 grouping as the referent, patients with an eGFR=15-<30 mL/min per 1.73 m^2 had adjusted HR's for AF of 2.4 (95% CI, 2.2-2.6) for the lowest ACR group and 5.5 (95% CI, 4.5-6.7) for the highest ACR group. Patients with an eGFR >90/ACR >300 had an adjusted HR of incident AF of 3.9 (95% CI, 2.9-5.4), higher than the adjusted HR of 2.6 (95% CI, 1.7-3.9) for patients with an eGFR <15/ACR <30. Urine ACR altered the association of eGFR with incident AF (p<0.001).

Conclusions: This study shows that declining eGFR and increasing albuminuria each independently increase the risk of AF. Strategies for the prevention of AF should consider CKD, defined by both eGFR and urine ACR, as a risk factor for AF.

SA-OR035

CKD Modifies the Association of Brain Natriuretic Peptide (BNP) and High Sensitivity-Troponin T (TnT) with CV Events and Death L. Parker Gregg,[1,2] Xilong Li,[1] Beverley Adams-Huet,[1] James Delemos,[1] Susan Hedayati.[1,2] *[1]UT Southwestern; [2]Dallas VA, TX.*

Background: Few data exist assessing associations of traditional cardiac biomarkers and outcomes in non-dialysis CKD patients. We evaluated whether associations between BNP and N-Terminal-pro-BNP (NT-BNP) ≥75th percentile for sex and TnT ≥3 ng/L with death and CV events were modified by CKD in 3,303 asymptomatic Dallas Heart Study participants followed for 10 years.

Methods: Cox proportion hazards assessed associations between biomarkers and all cause death or CV death/event, adjusted for age, sex, race, diabetes, hypertension, smoking, total and HDL cholesterol. Effect modification of CKD (eGFR<60 mL/min/1.73m^2 or ACR≥17 mg/g in men or ≥25 mg/g in women) was significant if interaction p<.1.

Results: The cohort was 50% Blacks, 31% Caucasians, 17% Hispanics, and 2% other races. Compared to 3,014 non-CKD, 289 CKD patients were older with a higher percentage of Blacks and diabetics. Proportions with stages 1, 2, 3, and 4-5 CKD were 50, 26, 20, and 3%. There were 302 deaths and 224 CV deaths/events. Of non-CKD patients 11% died and 6% had CV death/event vs. 42% and 29% of CKD patients, p<.0001 for both. The interaction between BNP and CKD on death was significant so that the aHR was intensified and significant in CKD but not significant in the non-CKD group. CKD also modified associations of BNP and TnT with CV death/event, with stronger associations in CKD (**Table**).

Conclusions: BNP, NT-BNP, and TnT provide independent prognostic information in early stage CKD, with stronger associations for BNP and TnT in CKD than non-CKD. Future studies should investigate whether these biomarkers differentially add to the prognostic ability of traditional CV risk factors in asymptomatic CKD patients.

Outcome	Main Effects aHR (95% CI)	No CKD	CKD
All-Cause Death			
BNP	1.32 (1.03, 1.68)	1.04 (0.77, 1.41)	2.11 (1.39, 3.21)*
NT-BNP	2.14 (1.67, 2.72)	1.90 (1.43, 2.53)	2.93 (1.82, 4.72)
TnT	1.67 (1.27, 2.21)	1.74 (1.29, 2.36)	1.45 (0.87, 2.44)
CV Death/Event			
BNP	1.92 (1.46, 2.52)	1.61 (1.17, 2.23)	3.02 (1.82, 5.01)*
NT-BNP	2.64 (2.01, 3.48)	2.54 (1.84, 3.50)	2.96 (1.73, 5.05)
TnT	1.83 (1.34, 2.52)	1.62 (1.15, 2.30)	3.17 (1.53, 6.56)*

*Interaction p<.1.

SA-OR036

The Association between Rate of Change in Albuminuria and Clinical Outcomes Min Jun,[1,2] Matthew T. James,[1] Braden J. Manns,[1] Marcello Tonelli,[1] Jianguo Zhang,[1] Vlado Perkovic,[2] Brenda Hemmelgarn.[1] *[1]Univ of Calgary, Canada; [2]George Inst for Global Health, Australia.*

Background: Change in albuminuria may have important prognostic utility in determining the future risk of outcomes. We sought to assess the association between change in urine albumin-creatinine ratio (UACR) and the risk of acute myocardial infarction (AMI), end-stage renal disease (ESRD), and all-cause death.

Methods: We identified 170,515 adults (age ≥18 years) in Alberta, Canada, who had ≥2 outpatient UACR measurements (1-2 years apart) within a 2-year period between May 1, 2003 and March 31, 2012. Rate of change in UACR (during a 2-year period; mg/mmol/year) was defined based on 3 groups: 1) decrease (≥-4.6 decrease; 5th percentile of change), 2) stable (-4.6 to 6.1), 3) increase (≥6.1 increase; 95th percentile of change). Follow-up for outcome (AMI, ESRD, and all-cause death) ascertainment commenced at the last UACR measurement during the 2-year period (defined as baseline). We used adjusted Cox regression models to estimate the hazard ratio for each outcome, adjusting for sociodemographic information, baseline eGFR and UACR, and comorbidities at baseline.

Results: Over the outcome ascertainment period, 4100 (2.4%) AMI events, 849 (0.5%) ESRD events, and 14450 (8.5%) deaths occurred. Compared with stable UACR, increase in UACR was associated with 56%, 721%, and 50% higher risk of AMI, ESRD, and death, respectively.

Outcome	UACR change	Adjusted HRs	
		HR	95% CI
AMI	Decrease	1.08	0.95 – 1.22
	Stable (Reference)	**1.00**	-
	Increase	1.56	1.41 – 1.74
ESRD	Decrease	3.26	2.61 – 4.08
	Stable (Reference)	**1.00**	-
	Increase	7.21	5.90 – 8.81
All-cause death	Decrease	1.33	1.25 – 1.41
	Stable (Reference)	**1.00**	-
	Increase	1.50	1.42 – 1.58

However, decrease in UACR was also associated with greater risk for ESRD and all-cause death, resulting in a U-shaped relationship between UACR change and these outcomes.

Conclusions: Change in UACR over time is associated with future risk of clinically important outcomes. However, given the observed U-shaped relationship between albuminuria change and outcomes, its utility as a prognostic tool among high-risk patient groups requires further assessment.

SA-OR037

Adverse Events in Advanced Chronic Kidney Disease: The Chronic Renal Insufficiency Cohort Study Morgan Grams,[1] Wei Yang,[2] Casey Rebholz,[1] Xue Wang,[2] Anna C. Porter,[2] Lesley Inker,[2] Edward J. Horwitz,[2] James H. Sondheimer,[2] L. Lee Hamm,[2] Jiang He,[2] Matthew R. Weir,[2] Bernard G. Jaar,[1] Tariq Shafi,[1] Lawrence J. Appel,[1] Chi-Yuan Hsu.[2] *[1]Johns Hopkins Univ; [2]CRIC Study, Univ of Pennsylvania.*

Background: People with advanced chronic kidney disease (CKD) are at risk for the development of end-stage renal disease (ESRD), but also many other adverse outcomes, including cardiovascular disease (CVD) events and death. Determination of risk factors that explain the variability in prognosis and timing of these adverse outcomes can aid patient counseling and medical decision-making.

Methods: We followed 1,798 participants with eGFR <30 ml/min/1.73 m² in the Chronic Renal Insufficiency Cohort (CRIC) study for a median of 5.5 years, evaluating risks of ESRD, CVD (congestive heart failure, stroke, myocardial infarction, peripheral artery disease), and death.

Results: Baseline age of the cohort was 60 years; 46% were women, and 46% were African American. While 52.3% of participants progressed to ESRD during follow-up, the path by which this occurred varied by baseline patient characteristics. For example, the predicted 1-year probabilities for a 60-year old white woman with eGFR 30 ml/min/1.73 m², 1.8 grams/day of proteinuria, and no diabetes or CVD (risk characteristics similar to the average participant), were 3.3%, 4.1%, and 0.3%, for first developing CVD, ESRD, and death, respectively. For a 40-year-old African-American man with similar characteristics but higher systolic blood pressure, the corresponding 1-year probabilities were 2.4%, 13.2%, and 0.1%. For all participants, the development of ESRD or CVD increased the risk of subsequent mortality, with no differences by patient race or body-mass index.

Table. 1-year probability of remaining event-free, or first developing CVD event, ESRD, or death for various hypothetical patient scenarios

Scenario	Event-Free	CVD Event	ESRD Event	Death
40-year-old white man with diabetes*	85.3%	5.4%	9.2%	0.2%
40-year-old black man with high blood pressure (systolic 150 mmHg)	84.3%	2.4%	13.2%	0.1%
60-year-old white man with EF 35% and CVD	84.2%	12.3%	3.1%	0.4%
60-year-old black man with diabetes and 5 g/day proteinuria	78.1%	8.5%	12.4%	0.9%
60-year-old white woman	92.3%	3.3%	4.1%	0.3%
60-year-old black woman with diabetes and cardiovascular disease	86.9%	7.0%	5.3%	0.8%
70-year-old white woman with 0.1 g/day proteinuria	97.2%	2.0%	0.4%	0.4%

*Unless otherwise specified, other covariates include non-Hispanic ethnicity, eGFR 30 ml/min/1.73 m², systolic blood pressure of 130 mmHg, proteinuria of 1.8 g/day, EF of 50%, BMI of 30 kg/m², no cardiovascular disease, no diabetes mellitus, and a non-smoker.

Conclusions: With replication in additional cohorts, these results can help guide personalized approaches for managing patients with advanced CKD.

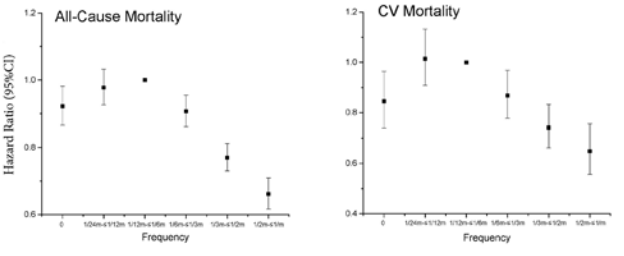
SA-OR038

Association of the Frequency of Pre-ESRD Medical Care with Post-ESRD All-Cause and CV Mortality Csaba P. Kovesdy,[1,3] Jun Ling Lu,[1] Miklos Zsolt Molnar,[1] Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Elani Streja,[2] Kamyar Kalantar-Zadeh.[2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]VA Medical Center, Memphis, TN.*

Background: Some studies found that receiving Nephrology care in the pre-ESRD period is associated with improved outcomes in dialysis patients. Less is known about the association between the frequency of pre-ESRD laboratory testing and post-ESRD mortality in incident ESRD patients.

Methods: We examined 23,089 US veterans who initiated RRT between 10/2007-09/2011, and had outpatient laboratory tests performed during the last two years prior to RRT (prelude). The association of the frequency of the combined measurement of serum creatinine, potassium and hemoglobin with post-ESRD all-cause mortality and cardiovascular (CV) mortality was examined in Cox proportional hazard regression models adjusted for socio-demographics, comorbidities, BP variability, and CV medication adherence.

Results: The mean age (SD) was 66.2 (11.3) years, and the mean estimated GFR (SD) was 46.8 (23.9) ml/min/1.73m² entering the 2-year prelude period. 32.3% of the cohort had the lab test trio performed between once-a-year to once every two years; 9.3% had no lab test trio measured during prelude, and 8.9% had the trio measured more often than every other month. Over a 2.5-year median follow-up period, 15,303 (66.3%) patients died (mortality rate: 260/1000 patient years, 95% CI: 256-264). More frequent lab testing was associated with lower post-ESRD mortality (Figure). The adjusted hazard ratio (95%CI) associated with lab testing done more than once every other month compared to once every 6-12 month was 0.66 (0.62-0.71). Associations were similar for CV mortality (Figure).



Conclusions: More frequent laboratory testing during the 2 years prior to RRT initiation is associated with lower post-ESRD all-cause and CV mortality.

SA-OR039

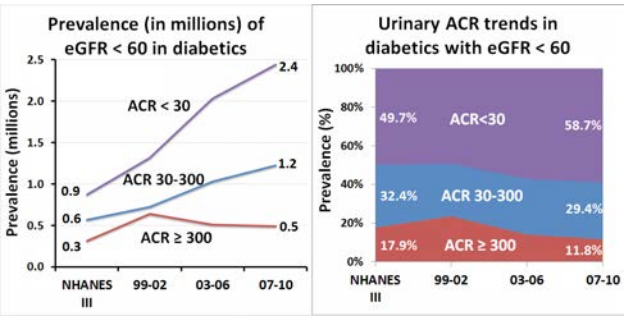
Changing Phenotype of CKD in Diabetes Mellitus (DM) and Its Implications Srini Beddhu,[1] Alfred K. Cheung,[1] Linda F. Fried,[2] Guo Wei,[1] R. E. Boucher,[1] Rabia Nadeem Kiani,[1] Julia Lewis,[3] Tom Greene.[1] *[1]Univ of Utah; [2]VA Pittsburgh; [3]Vanderbilt Univ.*

Background: Classic phenotype descriptions of CKD in DM are based upon studies conducted in the 80's and 90's. However, therapies for CKD in DM have evolved. We hypothesized that the phenotype and hence, implications of CKD in DM has changed in the US.

Methods: We examined the prevalence of CKD (eGFR < 60 ml/min/1.73 m²) and the distribution of urinary albumin-creatinine ratio (ACR) (mg/g) in DM in the US using National Health And Nutrition Examination Survey (NHANES) III (1988-1994) and recent

surveys (1999-2010). We also examined whether diabetics with eGFR< 60 and ACR < 30 compared to diabetics with eGFR ≥ 90 and ACR < 30 have ↑ risk of cardiovascular (CV) or renal events using data from NHLBI funded ACCORD Study. CV outcome was a composite of CV death, MI, CHF or stroke. Kidney outcome was a composite of 50% drop in eGFR, dialysis or serum creat >3.3 mg/dl.

Results: Prevalence of eGFR < 60 in DM has dramatically increased; in this population, nearly 60% have urinary ACR < 30 (fig).



This segment of the DM population is at ↑ risk of CV events but not CKD progression (table).

	CV composite		Kidney composite	
ACR and eGFR groups	Events /100 person-yrs	HR(95% CI)*	Events /100 person-yrs	HR(95% CI)*
ACR<30				
eGFR≥ 90	1.45	Ref	0.53	Ref
60-90	2.42	1.32(1.10, 1.59)	0.46	0.91(0.65, 1.29)
< 60	3.58	1.44(1.10, 1.89)	0.31	0.61(0.29, 1.29)
ACR ≥30				
eGFR≥ 90	3.62	2.12(1.74, 2.58)	0.63	1.08(0.72, 1.62)
60-90	4.85	2.12(1.75, 2.58)	0.85	1.49(1.02, 2.18)
< 60	6.27	2.34(1.82, 3.00)	1.79	3.17(2.02, 4.96)
*adjusted for age, gender, race, Rx arm, study network, CVD, CHF, retinopathy, HbA1C, DM duration, SBP, DBP, ACE/ ARB and statin use				

Conclusions: The phenotype of CKD in DM is changing. The most common phenotype (eGFR < 60 and ACR < 30) confers ↑ CV risk but not CKD progression risk.

SA-OR040

Glucose Targets for Renal, Mortality, and Cardiovascular Outcomes: A Meta-Analysis of Randomized Trials Marinella Ruospo,[1,2] Valeria M. Saglimbene,[1] Suetonia Palmer,[3] Salvatore De Cosmo,[4] Antonio Pacilli,[4] Jonathan C. Craig,[5] Giovanni F.M. Strippoli.[1,5,6] *[1]Diaverum Medical Scientific Office; [2]Amedeo Avogadro Univ of Eastern Piedmont; [3]Univ of Otago Christchurch; [4]Scientific Inst CSS; [5]Univ of Sydney; [6]Univ of Bari.*

Background: Blood pressure lowering and glucose control are used to reduce diabetes-associated disability including end-stage kidney disease. However, the benefits and harms of tight glycemic control on renal outcomes among patients with kidney disease are uncertain. We summarized the evidence in randomized clinical trials (RCTs) of intensive versus standard glycemic control for preventing the onset and progression of kidney disease among adults with diabetes.

Methods: A Cochrane systematic review with meta-analysis was conducted including trials in which adults with type 1 or 2 diabetes with and without kidney disease were randomly allocated to tight or less stringent blood glucose targets. Treatment effects were estimated using random-effects meta-analysis. Risks of bias were adjudicated using Cochrane methods.

Results: Eleven studies involving 29,140 patients were eligible. Trial follow up was 56.7 months on average. In moderate to high quality evidence, a tight glucose target conferred uncertain risks of serum creatinine doubling (relative risk (RR) 0.84, CI 0.59-1.18), ESKD (RR 0.88, CI 0.70-1.11); all-cause mortality (RR 0.99, CI 0.86 to 1.13), cardiovascular mortality (RR 1.19, CI 0.73-1.92), and sudden death (RR 0.82, CI 0.26-2.57). Tighter glycemic control reduced risks of nonfatal myocardial infarction (RR 0.82, CI 0.69-0.99), and onset (RR 0.85, CI 0.77-0.94) and progression of microalbuminuria (RR 0.50, CI 0.36-0.69).

Conclusions: Tight glycemic control for treatment of diabetes provided uncertain risks of ESKD, death and major cardiovascular events compared with less stringent glycemic control, while lowering risks of myocardial infarction and onset and progression of microalbuminuria. The long-term clinical benefit of glycemic management on microalbuminuria is uncertain until sufficiently powered RCTs evaluate hard renal outcomes.

SA-OR041

Generation and Analysis of KLHL3 Knockout Mice Emi Sasaki, Koichiro Susa, Takayasu Mori, Kiyoshi Isobe, Yuya Araki, Yuichi Inoue, Tatemitsu Rai, Shinichi Uchida, Eisei Sohara. *Nephrology, Tokyo Medical and Dental Univ, Bunkyo, Tokyo, Japan.*

Background: Mutations in with-no-lysine kinase 1 (WNK1), WNK4, Kelch-like 3 (KLHL3) and Cullin 3 (CUL3) genes are reported to cause PHAII. Recently, we generated KLHL3 $^{R528H/+}$ mice and demonstrated that mutant KLHL3 resulted in defective degradations of WNK1 and WNK4, leading to PHAII, indicating that KLHL3/CUL3 ubiquitin ligase complex interacts and degradates WNK kinases. However, pathophysiological roles of KLHL3 other than PHAII are still unclear.

Methods: To answer these questions, we generated two KLHL3-/- mice lines; conventional KLHL3-/- mice and KLHL3-/- mice that express β-gal under endogenous KLHL3 promoter in this study. Using these mice, we sought to determine the tissue distribution of KLHL3 and its role in regulating WNK protein level in each tissue.

Results: At first, we investigated the tissue distribution of KLHL3 using β-gal expression. Immunoblots of β-gal showed the strong expression in brain and kidney, and the lower expressions in eye, testis, heart, lung and pancreas. Strong LacZ staining was observed in hypocampus and distal tubules in brain and kidney, respectively. Next, we investigated the protein levels of WNK1, WNK3 and WNK4 in the whole tissues of KLHL3+/- and KLHL3-/- mice where KLHL3 expression was detected. In the brain and other tissues showing the lower expression levels of KLHL3, expression levels of WNK1, WNK3 and WNK4 were not increased in KLHL3+/- and KLHL3-/- mice. However, only in kidney, WNK1 and WNK4 were significantly increased in KLHL3-/- mice, but not in KLHL3 +/- mice. KLHL3-/- mice also showed PHAII-like phenotypes, but KLHL3+/- mice did not.

Conclusions: Our data clearly showed that the WNK protein levels in KLHL3-expressing tissues might not be governed only by KLHL3. Lack of PHAII phenotypes in KLHL3+/- mice clearly showed the heterozygous deletion of KLHL3 was not enough to cause PHAII in the kidney, indicating that PHAII phenotypes in KLHL3$^{R528H/+}$ heterozygous mice we previously observed are caused by the dominant-negative effect of R528H KLHL3 mutant. Dimer formation of wild-type and R528H KLHL3, which we could demonstrate, would explain the dominant-negative effect of this mutant.

KLHL3-Knockin Mice Featuring Pseudohypoaldosteronism Type II Do Not Correct the Phenotype of WNK4-Null Mice Chien-Ming Lin,[1,2] Chih-Jen Cheng,[3] Sung-Sen Yang,[2,3] Shih-Hua P. Lin.[2,3] *[1]Dept of Pediatrics, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Graduate Inst of Medical Sciences, National Defense Medical Center, Taipei, Taiwan; [3]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Enhanced SPAK/OSR1-NCC signal cascade caused by mutations in Kelch-like 3 (KLHL3) or Cullin3 (Cul3) involved in WNK1/4 ubiquitination is known to cause pseudohypoaldosteronism type II (PHAII). It remains unclear that which WNK kinases is the major regulator in the pathogenesis of KLHL3 mutation-causing PHAII.

Methods: We generated mutant KLHL3 ^{M131V} knockin mice (corresponding to human M78V)in BTB domain and WNK4 null mice. KLHL3^{M131V} mutant mice were crossed with WNK4 null mice. The genotype, phenotype, and the relevant protein expression in the kidneys were examined in these transgenic mice.

Results: Both heterozygous and homozygous KLHL3^{M131V} knockin mice exhibited typical feature of PHAII with hypertension (SBP: KLHL3$^{M131V/-}$ 118.3± 13.5 mmHg, KLHL3$^{M131V/ M131V}$119.4± 11.5 mmHg, WT 107.0± 11.3mmHg) with suppressed PRA (KLHL3$^{M131V/-}$ 4.5 ± 1.9 ng/mL/hr, KLHL3$^{M131V/ M131V}$3.8± 1.1 ng/mL/hr, WT 6.5 ± 1.4 ng/mL/hr), hyperkalemia (KLHL3$^{M131V/-}$ 5.5 ± 0.3 mmol/l, KLHL3$^{M131V/ M131V}$6.0 ± 0.6 mmol/l, WT 4.5 ± 0.3 mmol/l) with decreased FE_K, and mild metabolic acidosis. Although KLHL3 M131V protein expression was unchanged as wild type, marked increase in WNK1 and WNK4 expression and the phosphorylation of SPAK, ORS1 and NCC were observed in heterozygous and homozygous KLHL3 knockin mice. WNK4knockout mice exhibited all phenotypic features of Gitelman syndrome (GS) with an increased WNK1 expression but remarkably reduced SPAK, ORS1 and NCC phosphorylation. Of note, KLHL3$^{M131V/M131V}$, WNK4 $^{-/-}$double transgenic mice still showed the overwhelming phenotype of GS with an increased expression of WNK1 but a decreased phosphorylation of SPAK, ORS1 and NCC.

Conclusions: KLHL3 knockin mice featuring PHAII with increased expression of WNK1 and WNK4 fail to correct the GS phenotype of WNK4 null mice, indicating that WNK4 is the most paramount kinase in SPAK/OSR1-NCC cascade in the PHAII caused by KLHL3 mutation.

SA-OR043

Identification of the Cullin 3 Domain Responsible for Defective COP9 Signalosome Binding in Familial Hyperkalemic Hypertension Ryan J. Cornelius,[1] Chong Zhang,[2] Kayla J. Erspamer,[1] Jeffrey Singer,[3] Chao-Ling Yang,[1] David H. Ellison.[1] *[1]Oregon Health and Science Univ, Portland, OR; [2]Shanghai Jiao Tong Univ, Shanghai, China; [3]Portland State Univ, Portland, OR.*

Background: Familial hyperkalemic hypertension (FHHt) can result from mutations in cullin 3 (CUL3), which increase abundance of WNK kinases and activate the thiazide-sensitive NaCl cotransporter. CUL3 is a member of the cullin-RING ligase (CRL) family

that ubiquitinates proteins, targeting them for degradation. The mechanism by which deletion of exon 9 (CUL3 Δ403-459) leads to the disease is unknown, but an important feature in CRL activity is cycling between neddylated (active) and unneddylated (inactive) states. The COP9 signalosome (CSN) deneddylates CRLs utilizing the catalytically active subunit JAB1. It has been reported that the cullin 1 CSN-binding region contains the 4HB and α/β domains. Since exon 9 in CUL3 encodes the 4HB domain, we determined whether this region binds to the CSN and if the altered function of CUL3 Δ403-459 results from enhanced neddylation, caused by decreased CSN binding.

Results: Co-immunoprecipitation from HEK 293 cells of JAB1 with CUL3 or CUL3 Δ403-459 indicated that the mutant had lower binding affinity. Further, JAB1 and CUL3 constructs containing deletions in certain domains showed that removal of the α/β domain, adjacent to the 4HB domain, abrogated binding to JAB1; in contrast deletion of the 4HB domain itself did not. Suppression of JAB1 using siRNA resulted in enhanced neddylation of CUL3 and a lower abundance of KLHL3 protein. To determine whether neddylation has functional consequences, we used a neddylation-deficient CUL3 construct (CUL3 Δ403-459 K712R). The abundance of KLHL3 and WNK4 protein was higher and lower, respectively, with CUL3 Δ403-459 K712R compared to CUL3 Δ403-459.

Conclusions: The results demonstrate that (1) the CUL3 binding site for the CSN is located in the α/β domain; deletion of the 4HB domain must lead to less CSN binding by altering protein structure; and (2) the enhanced neddylation of CUL3 Δ403-459, caused by the lower affinity for the CSN, results in over activation of CUL3 leading to degradation of KLHL3 and a greater WNK abundance.

Roles of Cytoplasmic Hsp40 and Hsp70 Molecular Chaperones in NKCC2 Stability and Maturation

Elie Seaayfan,[1] Sylvie Demaretz,[1] Bodo B. Beck,[2] Martin Kömhoff,[3] Kamel Laghmani.[1] *[1]CRC, INSERM-U1138, UPMC, CNRS-ERL8228, Paris, France; [2]Univ of Cologne, Cologne, Germany; [3]Philipps Univ Marburg, Marburg, Germany.*

Background: We recently showed that MAGE-D2 mutations causes polyhydramnios with prematurity and a severe but transient form of antenatal Bartter's syndrome associated with inappropriate expression of the sodium–chloride transporters NKCC2 and NCC (Laghmani et al, N Engl J Med. 2016 May 12;374(19):1853-63). Moreover, MAGE-D2 interacts specifically with heat shock protein Hsp40/DnaJB1, raising the possibility that MAGE-D2 promotes expression of the co-transporters through this cytoplasmic Hsp40. In support of this notion, using the yeast two-hybrid system, we identified Hsp40/DnaJB1 as a specific binding partner of NKCC2. Consequently, the aim of the present study was to investigate the role of Hsp40 in NKCC2 biogenesis.

Methods: Protein-protein interaction was assessed by co-immunopreciptation (CO-IP) assay. NKCC2 protein expression was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging. NKCC2 stability was assessed by cycloheximide chase assay.

Results: CO-IP assay in renal cells showed that Hsp40 association involves only the immature form of NKCC2. Accordingly, immunocytochemistry analysis revealed that NKCC2 and Hsp40 co-localize at the ER. Hsp40 co-expression strikingly increased total cellular NKCC2 protein in a dose dependent manner. Cycloheximide chase assay showed that in cells over expressing Hsp40, NKCC2 stability and maturation are improved. Mutation of the conserved HPD motif of Hsp40 J-domain, that is essential for Hsp70 activation, abolished Hsp40 effect indicating that Hsp40-induced increase in NKCC2 maturation is Hsp70 dependent. Accordingly, similar to Hsp40, Hsp70 co-expression increased also strikingly NKCC2 expression and maturation.

Conclusions: Our data strongly suggest that Hsp40 and Hsp70 are crucial for the stability and maturation of NKCC2 . They suggest a model whereby, MAGE-D2 cooperates with Hsp40 and Hsp70 co-chaperones to protect NKCC2 from ER associated degradation and promote proper folding and maturation of the co-transporter.

The Basolateral Kidney Anion Exchanger 1 Regulates Tight Junction Integrity by Interacting with Claudin-4

Rawad Lashhab, Denis Arutyunov, R. Todd Alexander, Emmanuelle Cordat. *Physiology, Univ of Alberta, Edmonton, AB, Canada.*

Background: Patients with distal renal tubular acidosis (dRTA) have impaired renal acid secretion and, as a consequence, abnormal bicarbonate reabsorption from their distal nephron. dRTA patients develop kidney stones, hypokalemia, hyperchloremia, nephrocalcinosis, metabolic acidosis and difficulties to thrive. Mutations in the SLC4A1 gene encoding the anion exchanger 1 can cause dRTA. Kidney anion exchanger 1 (kAE1) is a transmembrane Cl^-/HCO_3^- exchanger that is expressed in a-intercalated cells in the collecting duct. Using a membrane yeast two-hybrid assay, we found that kAE1 interacts with Claudin-4 (Cldn-4). Cldn-4 is a tight junction protein, which is expressed in many tissues including intercalated cells. Cldn-4 forms a paracellular Cl^- selective pore and has been implicated in Cl^- reabsorption from the collecting duct. We therefore hypothesized that a kAE1/Cldn-4 interaction regulates pH and electrolyte homeostasis in the distal nephron.

Methods: To confirm a close proximity between the two proteins, we performed immunofluorescence and proximity ligation assays. Immunoprecipitations were used to confirm the physical interaction. kAE1 function was assessed with BCECF-based assays. Finally, the integrity of tight junctions was examined using Ussing chambers.

Results: We observed co-localization between kAE1 and Cldn-4 in polarized murine inner medullary collecting duct cells. Immunoprecipitations confirmed the physical interaction. Cldn-4 over-expression did not affect kAE1 function. Upon kAE1 expression, there was a decrease in transepithelial electrical resistance and an increase in paracellular Cl^- & Na^+ permeability, indicating that expression of the basolateral anion exchanger altered the tight junction integrity. Finally, kAE1 effect on tight junction properties was independent of changes in intracellular pH.

Conclusions: Our results demonstrate a physical interaction between kAE1 and Cldn-4 and have uncovered an un-expected role of a basolateral anion exchanger on tight junction integrity, and possibly further on electrolyte homeostasis and blood pressure regulation.

High Na Diet Causes Increased Na Retention and Impaired Dipsogenic Response in HKα1 H,K-ATPase Knockout Mice

Charles S. Wingo,[2,3] James D. Stockand,[1] Elena V. Mironova,[1] I. Jeanette Lynch,[2,3] Jonathan M. Berman,[1] Michelle L. Gumz.[2,3] *[1]UT HSC, San Antonio, TX; [2]NF/SG VHS, Gainesville, FL; [3]UF Dept of Medicine, Gainesville, FL.*

Background: Purinergic regulation of the epithelial Na channel (ENaC) is an important mechanism that regulates external Na balance. Loss of this regulation contributes to salt-sensitivity and has been implicated in mineralocorticoid escape. ENaC activity is inversely related to dietary Na intake, in part, due to inhibitory purinergic signaling in the collecting duct (CD), with increasing Na intake stimulating luminal ATP secretion. We previously showed that Na reabsorption in CD of $HK\alpha_1$ H,K-ATPase null ($HK\alpha_1^{-/-}$) mice was benzamil-insensitive, and ENaC activity in $HK\alpha_1^{-/-}$ mice was uncoupled from Na intake. ENaC activity on a 2.0% Na (HS) diet was greater in the $HK\alpha_1^{-/-}$ versus wild-type (WT), and dietary Na did not normally modulate ENaC activity in the $HK\alpha_1^{-/-}$. Purinergic signaling of ENaC was abnormal in $HK\alpha_1^{-/-}$ mice, with markedly reduced urinary ATP that did not increase in response to the HS diet. ENaC activity in the $HK\alpha_1^{-/-}$responded normally to exogenous ATP, suggesting a pre-receptor defect. The present studies tested the contribution of this uncoupling at the whole animal level.

Methods: Total Na balance was measured in $HK\alpha_1^{-/-}$ and WT mice placed in metabolic cages and fed a normal Na diet for 7 days followed by HS for 7 days. Blood hematocrit and plasma Na and vasopressin (AVP) were measured in mice on Day 1 of the HS diet.

Results: On day 1 of the HS diet, $HK\alpha_1^{-/-}$ mice had three times greater Na retention ($p<0.01$) compared to WT and markedly impaired dipsogenic response (50% lower fluid intake vs. WT, $p<0.001$) with higher urine osmolality. Hematocrit and plasma Na and AVP were significantly greater in $HK\alpha_1^{-/-}$ than WT on the HS diet. During the entire period of HS feeding, Na retention in $HK\alpha_1^{-/-}$ was greater than WT (days 1, 2&4, $p<0.05$).

Conclusions: These results suggest an important role for the $HK\alpha_1$ subunit in the regulation of purinergic signaling in the CD. $HK\alpha_1$ is physiologically important in the acute regulation of Na balance, affects the dipsogenic response to a high NaCl diet, and is part of a previously undiscovered element in Na regulation in the CD.

A Missense Mutation in the Extracellular Domain of α-ENaC Causes Liddle Syndrome

Ewout J. Hoorn,[1] Laurent Schild.[2] *[1]Erasmus Medical Center; [2]Univ de Lausanne.*

Background: Liddle syndrome or pseudoaldosteronism is an autosomal dominant form of hypokalemic hypertension that has been linked to mutations in the *SCNN1B* or *SCNN1G* gene, encoding the β- or γ-subunit of the epithelial sodium channel (ENaC). Here, we describe one generation of a family with Liddle syndrome due to a novel mutation in *SCNN1A* and functionally characterize the α-ENaC mutation.

Results: The proband (63-y.o. man) was referred because of unexplained hypertension (since age 26), hypokalemia, metabolic alkalosis, and suppressed plasma renin and aldosterone. Previous genetic testing had not identified mutations in *SCNN1B* or *SCNN1G*. Because of a positive family history for hypertension, whole-exome sequencing was performed and revealed a novel mutation in the amiloride-sensitive domain of α-ENaC. This missense mutation was identified in a highly conserved region of the extracellular domain of α-ENaC. Family analysis (5 siblings) identified one affected sister (hypertension, no hypokalemia) and showed that suppressed plasma renin and aldosterone completely segregated siblings with or without the mutation. Hypertension did not segregate because three other siblings also had (primary) hypertension. Open exome analysis did not identify additional causes of genetic hypertension in the family. A "triamterene test" was performed (adapted from the thiazide test) showing a 2-fold greater natriuresis to 100 mg triamterene (an ENaC blocker) in the two affected siblings than in healthy volunteers. Daily treatment with triamterene quickly normalized blood pressure and serum potassium in the affected siblings. Functional analysis of ENaC carrying the missense mutation in oocytes confirmed a channel gain-of-function (2-3-fold increase in Na^+ current), predominantly due to an increase in intrinsic activity of the channel.

Conclusions: We report the first mutation in the extracellular domain of α-ENaC causing Liddle syndrome. The mild phenotype correlates with the function studies. This mutation may be present in other unrecognized cases of hypertension with suppressed renin and aldosterone, and also provides novel insight in regulation of ENaC activity.

SA-OR048

Principal Cell Aerobic Glycolysis, Induced by ENaC-Mediated Lithium Entry, Likely Underlies Collecting Duct Remodeling Mohammad Alsady, Peter M.T. Deen, Theun de Groot. *Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Lithium, given to bipolar disorder patients, causes Nephrogenic Diabetes Insipidus (Li-NDI) and an increased intercalated/principal cell ratio of the collecting duct (CD remodeling). Whereas Li-NDI is due to downregulation of principal cell (PC) AQP2, The cause of CD remodeling is unknown, but has been ascribed to metabolic acidosis due to H-ATPase/H-K-exchanger inhibition in α-intercalated cells. However, as we showed that lithium induces PC proliferation, which might coincide with aerobic glycolysis-induced lactic acid formation, we investigated whether the latter process may underlie lithium-induced CD remodeling.

Methods: In Transwell grown polarized mouse collecting duct (mpkCCD) cells were exposed to LiCl on the apical (10 mM) and basolateral side (1 mM) for 1-2 days. C57BL6/J mice and rats were fed a normal diet with/without 40 mmol LiCl/kg for 10 and 28 days, respectively. 24-hrs water intake and urine output/osmolality was obtained. Kidneys were analyzed for remodeling.

Results: In mpkCCD cells and mice, lithium induced cell proliferation (increased PCNA levels) coincided with aerobic glycolysis (increased se/excretion of lactate elevated abundance of lactate dehydrogenase, and hexokinase-2, decreased ratio of phospho-pyruvate dehydrogenase (pPDH)/PDH). Lithium-increased urinary lactatewas absent in mice lacking the epithelial sodium channel ENaC, the PC entry site for lithium. Moreover, ENaC inhibition via amiloride in rats attenuated lithium-induced CD remodeling.

Conclusions: We show that ENaC-mediated lithium influx in principal cells induces aerobic glycolysis and that inhibition of principal cell lithium entry attenuates the extent of aerobic glycolysis and CD remodeling. Our data indicate that the lithium-induced aerobic glycolysis of principal cells and the consequent acidification of the micro-environment underlies CD remodeling.

Dysregulation of Acid Base (H+/HCO3-) Transport Machinery in the Kidney Collecting Duct in Cystic Fibrosis: Role in the Pathogenesis of Metabolic Alkalosis Mujan Varasteh Kia,[1] Sharon L. Barone,[1,2] Alicia A. McDonough,[3] Jie Xu,[1] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH; [3]Dept of Cell and Neurobiology, Univ of Southern California, Los Angeles, CA.*

Background: Patients with cystic fibrosis (CF) are prone to the development of metabolic alkalosis; however, the pathogenesis of this life threatening derangement remains unknown. We hypothesized that altered acid base transport machinery in the kidney collecting duct underlies the mechanism of impaired bicarbonate elimination in CF kidney.

Methods: CFTR knockout (CF) mice with the intestinal rescue were examined for acid base homeostasis in response to bicarbonate loading or salt restriction, as well as for the expression of bicarbonate transporters in the collecting duct.

Results: Baseline parameters, including acid-base status were comparable in CF and WT mice. Compared to WT animals, CF mice demonstrated a significant increase in their blood HCO_3^- concentration (21.87 in WT vs. 26.83 mEq/l in CF mice, $p<0.004$) and pH (7.33 in WT vs. 7.42 in CF mice, $p<0.003$) and exhibited impaired kidney HCO_3^- excretion (urine pH 8.10 in WT vs. 7.35 in CF mice, $p<0.002$) following a 3-day oral bicarbonate load. When subjected to salt restriction, CF mice developed a more noticeable increase in their blood HCO_3^- concentration (29.26 +/- 0.53 in CF mice vs. 26.72 +/- 0.80 mEq/l in WT; $p<0.05$). Immunofluorescence labeling demonstrated a profound reduction in the apical expression of the Cl^-/HCO_3^- pendrin in intercalated cells and the unexpected induction of the apical Na^+/H^+ exchanger, NHE3, and the basolateral $Na^+:HCO_3^-$ co-transporter, NBC-e1, in the principal cells of cortical collecting duct in CF mice.

Conclusions: We propose that patients with cystic fibrosis are prone to the development of metabolic alkalosis secondary to the inactivation of the bicarbonate secreting transporter, pendrin, and the transformation of principal cells into a bicarbonate absorbing system in the cortical collecting duct, specifically during volume depletion, which is a common occurrence in CF patients.

SA-OR050

Metabolic Acidosis Enhances Innate Immune Defense against Urinary Pathogenic *E. coli* Hu Peng, Jeffrey M. Purkerson, George J. Schwartz. *Pediatrics, Univ of Rochester Medical Center, Rochester, NY.*

Background: Intercalated cells (ICs) of the kidney mediate H^+ and HCO_3 secretion, and anion exchange. Our laboratory recently reported in collecting ducts (CDs) of kidney that adaptation to metabolic acidosis is mediated at least in part by SDF-1 signaling via CXCR12 (JCI 125:4365, 2015). SDF-1 is a target gene of hypoxia-inducible transcription factor (HIF-1α), both of which are stimulated by acidosis.

Methods: To test the effect of acidosis on pH-independent antimicrobial activity in urine, we developed an assay for activity of antimicrobial peptide (AMPs) in rabbit urine utilizing a functional model of *ex vivo* Uropathogenic *Escherichia coli* (UPEC) infection. Overnight cultured UPECs were added to diluted normal and acidotic urines (pH adjusted to 7.0), incubated at 37°C for 10 h, and bacteria growth was monitored by measuring turbidity (OD) at 600nm.

Results: Acidosis induced expression of cathelicidin (2.8 fold ±0.48, n=4), neutrophil gelatinase-associated lipocalin (NGAL) (6 fold ±2.1 n=4), and rabbit defensin neutrophil peptide 5 (NP-5) mRNA (1.76 fold ±0.42, n=6) in the CCDs micro-dissected from rabbit kidney; there was also a large increase in NP-5 mRNA (5.8 fold ±1.1, n=6) in proximal tubule (PST). Growth was attenuated in acidotic urine compared to normal. Antibody mediated blockade of cathelicidin activity promoted UPEC growth in pH neutralized acidotic urine. Conventional qRT-PCR from 4 pairs of Dolichos biflorus agglutinin (DBA)-selected kidney CDs showed that metabolic acidosis induced cytokine mRNA expression for IL-1β, TNFα, and IL-6, 2-4 fold. A rabbit cytokine/chemokine/receptor PCR array from one pair of DBA-selected kidney CDs showed induction of chemokines CXCL8 (IL-18), CXC3L, tumor necrosis factor receptor superfamily member 11b (TNFRSF-11b), and LOC100354804, a permeability factor 2-like gene, 3-7 fold by acidosis.

Conclusions: Metabolic acidosis, possibly via activation of HIF-1α, induces expression and function of innate immune defense peptides as well as pro-inflammatory cytokine/chemokine expression in renal tubules.

Kruppel-Like Factor 4 Is a Key Mediator of Renal Endothelial Injury in Antibody Mediated Rejection Chelsea C. Estrada, Edward P. Nord, Sandeep K. Mallipattu. *Medicine/Nephrology, Stony Brook Medicine, Stony Brook, NY.*

Background: Yearly mortality for patients with end-stage renal disease on dialysis is 5-times higher than their counterparts who are transplanted, however sustained graft survival is impeded by antibody-mediated rejection (ABMR) with the renal endothelium as the primary target. Mechanism(s) mediating endothelial injury in ABMR are unclear. Endothelial-associated transcripts (ENDATs), reflecting activation and injury were recently incorporated into diagnostic criteria for ABMR, and Krüppel-Like Factor(KLF4), a zinc-finger transcription factor, exhibited the highest expression by microarray in biopsies from ABMR compared to T-cell rejection (TCR). KLF4 is known to have anti-inflammatory and anti-thrombotic effects on endothelial cells in the cardiovascular system but its actions in the renal endothelium have not been delineated.

Methods: Immunofluorescence (IF) for KLF4 and isolectin B4 (endothelial marker) was performed in human and mouse control kidneys. Wild-type mice were injected with lipopolysaccharide (LPS) 10 ug/g IP or buffer and sacrificed at 48 hours. Human umbilical vein cells (HUVECs) were incubated with LPS or the endothelial specific lectin, concanavalin A (20 ug/ml, 30 minutes) followed by anti-concanavalin A, (200 ug, 6 hours).

Results: We demonstrated KLF4 has high baseline expression in all renal endothelial cells by IF. We observed a 4-fold increase in *KLF4* by rt-PCR in HUVECs treated with LPS, 1 and 10 ug/ml for 8 hours. Similarly, wild-type mice treated with LPS had a 3-fold increase in endothelial-specific expression of Klf4 as compared to controls by IF and rt-PCR. Both LPS groups exhibited an increase in the adhesion molecules *VCAM-1* and *ICAM-1*, confirming endothelial injury. Subsequently, in a model of antibody mediated endothelial injury, HUVECs incubated with concanavalin A followed by anti-concanavalin A, also demonstrated significant induction of *KLF4*. Finally, kidney biopsies from patients with ABMR demonstrated a significant increase in endothelial-specific expression of KLF4 compared to healthy donors, TCR, and non-rejecting acute kidney injury by IF.

Conclusions: Our data suggests that KLF4 is a key mediator of endothelial injury in ABMR.

Differences in Inflammation and Fibrosis in Deceased and Living Renal Donors Determine Long-Term Renal Function Montserrat M. Diaz Encarnacion, Elena Guillen-Gomez, Irene Silva, Iara Karlla Dasilva, Yolanda Arce, Jose Ballarin. *Fundacio Puigvert.*

Background: It is known that living donor (LD) transplants present better outcome than deceased ones (DD). Renal fibrosis and tubular atrophy (IF/TA) is the best predictor of renal function and it could be induce by chronic inflammation. The aim of this study is to analyze the influence of donors in renal outcome.

Methods: Pre-implantational (basal) and 4 month biopsies were analyzed by Remuzzi and Banff scores, respectively. Inflammation and fibrosis markers were quantified by qPCR and IHQ ammation. The aim of this study is to analyze the influence of donors in renal outcome.

Results: Our results show that basal inflammation measured by CD68 positive cells (24 mo, p=0.006 and 5 yr, p=0.005) and Remuzzi score (24 mo, p=0.0003; 5 yr, p=0.0468) correlate with medium- and long-term renal function in DD, whereas we did not found it in LD. At 4 months, Banff'05 inflammation (24 mo, p=0.010 and 5 yr, p=0.0233) and inflammatory and fibrosis markers in DD correlated with medium- and long-term renal function (IL-1β, 24 mo, p=0.0187 and 5 yr, p=0.0003; ICAM-1, 24 mo, p=0.0473 and 5 yr, p=0.0007; MCP-1, 24 mo, p=0.0212 and 5 yr, p=0.0011 and TNF-α, 24 mo, p=0.0209 and 5 yr, p=0.0202; TGF-β1, 24 mo, p=0.0026 and 5 yr, p<0.0001; fibronectin, 5 yr, p=0.0007). On the other hand, in LD, 4 months fibrosis but not inflammation, correlated with renal function only at 24 months, but none of the markers studied by qPCR did it. Moreover, sustained inflammation and fibrosis (Δ 4M-basal) correlated with medium- and long-term renal function (MCP1, p=0.0003; TNF-α, p=0.0241; IL-1β, p=0.0102 and ICAM-1, p=0.0026; TGF-β1, p= 0.0210; fibronectin, p=0.0258).

Conclusions: In conclusion, early and sustained inflammation in DD are predictors of long-term graft outcome and could be essential in dissimilarities between DD and LD renal outcome.

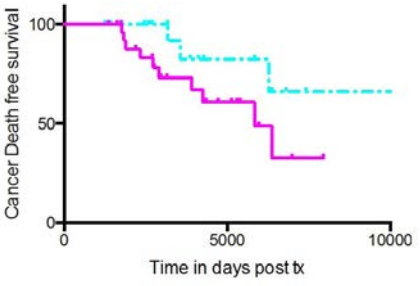
Loss of Regulatory Anti-Angiogenic Protease Activated Receptor-1 (PAR-1) Antibodies Associate with the Development of Metastatic Cancer Post Renal Transplantation and Patient Death

Rusan Catar,[1] Robert Peter Carroll,[2] Angelika Kusch,[1] Aurélie Philippe,[1] Duska Dragun.[1] *[1]Clinic for Nephrology and Critical Care Medicine, Charité, Berlin, Germany; [2]Centre for Experimental Transplantation, Royal Adelaide Hospital, Adelaide, Australia.*

Background: VEGF is crucial for neoangiogenesis in tumors. The GPCR Protease-activated receptor 1 (PAR-1) is closely involved in VEGF regulation. We hypothesized that autoimmune GPCR targeting process may disturb VEGF induced angiogenesis.*in vitro* we found that PAR-1 is a novel activating autoantibody target. We then assessed the presence of PAR-1 autoantibodies in 20 Kidney Transplant Recipients (KTR) with and 29 KTR without metastatic cancer.

Methods: Human microvascular endothelial cells (HMEC-1) were stimulated with IgG isolated from sera of kidney transplant recipients (KTx-IgG). regulation of VEGF was studied by promoter deletion assay. qRT-PCR, western blot, EMSA and cFOS knockdown. VEGF secretion was determined by ELISA. Tube formation on matrigel served to study endothelial neoangiogenic response. All 49 patients had sera for assessment of PARab and at the time of transplantation and 2014.

Results: PARab levels were lower at the time of transplant in KTR who developed metastatic cancer after transplant compared to those who did not. Levels were also different at the time of cancer diagnosis compared to those who had not developed cancer when assessed in 2014.



Time to cancer death in 49 KTR where pre transplant PARab were assessed. Upper line (dotted cyan) represents KTR (n=27) who had PARab >2.85 u/ml at the time of transplant. Lower line (pink full line) represents KTR (n=22) who had PArab <2.85 U/ml at the time of transplant. KTR with low PARab were more likely to die a cancer death (Log Rank Chi Square 3.19 p=0.074).

Conclusions: The PAR-1 receptor is a new target for functional antibodies in the context of kidney transplantation and tumor angiogenesis. KTx-IgG disturb VEGF transcriptional regulation resulting in reduced VEGF secretion and inability of endothelial cells to form tubes. KTR with low PARab <2.85 U/ml were more likely to die a cancer death, larger cohort studies are on going.

SA-OR054

Molecular Markers Predicting Delayed Graft Function in Renal Transplantation

Dagmara McGuinness,[1] Suhaib Mohammed,[1] Laura Monaghan,[1] Paul A. Wilson,[2] David Kingsmore,[3] Oliver C. Shapter,[1,3] Karen S. Stevenson,[3] Luke Devey,[4] Robert Kirkpatrick,[5] Paul G. Shiels.[1] *[1]ICS, Univ of Glasgow, MVLS, WWCRC, Glasgow, United Kingdom; [2]Target Sciences Computational Biology, GlaxoSmithKline Medicines Research Centre, Stevenage, United Kingdom; [3]Renal Transplant Unit, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [4]Metabolic Pathways Cardio Therapy Area Unit, GlaxoSmithKline, King of Prussia, PA; [5]The Pipeline Futures Group, GlaxoSmithKline, Collegeville, PA.*

Background: Ischemia reperfusion injury (IRI) occuring during peri-transplantation can lead to acute injury (AKI) and in 25-50% of cases to delayed graft function (DGF). Drug candidates identified and clinically tested to date, have not led to appreciable improvements in DGF outcome.

Methods: Cortex biopsies were taken immediately before transplant (pre-perfused) and following anastomosis after 45 minutes reperfusion (post-perfused). 22 biopsy pairs representing extreme phenotypes of immediate and delayed graft function underwent RNAseq. DESeq2 was used to identify differentially expressed transcripts while qPCR was used for target validation. Methylation status was determined in 10 paired biopsies using WGBS.

Results: 55 transcripts indicative of DGF, independent of IRI were identified, amongst them 20 were validated as related to DGF e.g. FCGR1C was upregulated (p=0.0006 and p=0.016 for pre and post-perfusion, respectively), pre-perfusion HSPB7 (p=0.007) and LPGAT1 (p=0.006) were downregulated. These represent immune, chaperone, and lipid metabolic functions, respectively. Further analyses in relation to CIT, WIT, DBD/DCD, SCD/ECD, MDRD4 at 3, 6 and 12 months post-transplant were also performed. DGF was associated with decreased methylation in promoter and intragenic regions in pretransplant biopsies.

Conclusions: Specific transcriptional and epigenome signatures provide evidence for molecular changes detectable in donor kidneys prior to transplantation and immediately following kidney transplantation independently of IRI and predict post-transplant outcomes. These signatures and pathways drive molecular events leading to impaired graft function and represent potential nodes for therapeutic intervention.

Complement Modulation Abrogated Ischemia/Reperfusion (I/R) Induced Inflammaging by Inhibiting Senescence-Associated Secretory Phenotype (SASP) in Tubular Epithelial Cells (TEC)

Giuseppe Castellano,[1] Rossana Franzin,[1] Angelica Intini,[1] Alessandra Stasi,[1] Chiara Divella,[1] Margherita Gigante,[1] Simona Simone,[1] Paola Pontrelli,[1] Giuseppe Grandaliano,[2] Loreto Gesualdo.[1] *[1]Univ of Bari; [2]Univ of Foggia.*

Background: Renal senescence is associated to the development of a subclinical, low-grade inflammatory state called inflammaging, as first described in diabetic nephropathy. This process is associated with the diminished regenerative potential of TEC. However, the role of cellular senescence and its modulation in I/R injury is not known.

Methods: Ten pigs underwent to 30min of renal warm I, followed by 24h of R (T24 CTRL). Five pigs were treated with C1-Inhibitor (C1-Inh, 500U/Kg, 5 min before reperfusion) (T24 C1-INH). Biopsies were analyzed for markers of SASP (SA-βGal, $p16^{INK4a}$, $p21^{WAF1}$ and IL-6) by IHC. In addition, TEC were exposed to C5a and then analyzed after culture in normal medium (24h, 48h) for SA-βGal, p53,NOX-4,IL-6,MCP-1 and CTGF by WB and qPCR.

Results: I/R injury induced tubular senescence by increasing SA-βGal, p21 and nuclear p16 expression (IHC T24CTRL:12.74±1.2 vs T0:3.75 ±0.84,$p<0.05$) typical of SASP accompanied by IL-6 production ($p<0.05$). Pigs treated by C1-INH efficiently antagonized SASP by restoring p16 (T24 C1-INH 4.93±0.92 vs T24 CTRL), p21, IL-6 expression and SA-βGal at basal level ($p<0.05$). In accordance, short stimulation of TEC with C5a (3h) induced senescence in vitro by up-regulating SA-β Gal (%SA-βGal+cells C5a 3h:13,5%±0.58 vs Basal 3.6%±0.8) IL-6, MCP-1 and CTGF gene expression ($p<0.05$). SASP were characterized by increase in p53 protein (WB/p53: C5a 24h: 1.45±0.84 vs basal 0.76±0.24, $p<0.05$) as sign of stable cell cycle arrest and up-regulation of p65 NF-κB subunit ($p<0.05$). Finally, NOX-4 protein levels significantly increased after C5a stimulation indicating the activation of oxidative stress pathway.

Conclusions: Renal I/R can induce TEC senescence by promoting the development of SASP. C1-INH might be a therapeutic approach to prevent graft senescence in renal transplantation.

SA-OR056

Natural Killer Cells in Renal Transplant Rejection and Ischemia

Randi Lassiter,[1] Todd D. Merchen,[1] Daniel Kleven,[2] Ryan P. Jajosky,[2] Matthew Winn,[3] N. Stanley Nahman,[3] Youli Wang.[3] *[1]Surgery, Augusta Univ, Augusta, GA; [2]Pathology, Augusta Univ; [3]Medicine, Augusta Univ.*

Background: The role of natural killer (NK) cells in induction and prevention of cellular damage relies on the balance of activating and inhibitory receptor signaling. NKp46 is a natural cytotoxicity receptor; its activation in NK cells disrupts this balance, leading to a cytotoxic phenotype. To date, the mechanism by which innate immunity contributes to kidney damage in solid organ transplant rejection remains elusive. Herein, we investigate the role of NKp46-positive NK cells in organ dysfunction using porcine models of renal ischemia and transplantation.

Methods: We performed allogeneic kidney transplantation (n=10) or auto-transplantation (n=4). Pairs of pigs were operated on simultaneously with left kidneys exchanged or reimplanted for allotransplantation and autotransplantation, respectively. All pigs underwent right nephrectomy prior to closure and transplant nephrectomy upon sacrifice at 72 hours. No immunosuppression was used. Renal function was determined by serum creatinine. Pathology was assessed with H&E. NK cells were identified with immunohistochemical staining using NKp46 receptor antibody.

Results: Creatinine was significantly elevated in the allotransplant group as compared to the autotransplants (8.18±1.80 vs 2.83±0.60 mg/dL, p=0.009). All of the allotransplanted kidneys demonstrated SLA mismatches and some degree of acute cellular rejection. Autotransplants exhibited intact renal architecture with only mild tubular necrosis. When compared to right kidney controls, autotransplants showed no significant change in baseline NK cell population. Allotransplantation with rejection but preserved renal architecture demonstrated a 2.2 fold increase in renal NK cell population. Allotransplants with severe rejection associated with tubular damage demonstrated a 6.5 fold increase in NKp46-positive NK cell population.

Conclusions: The dramatic increase in NKp46-positive cells observed in damaged renal allografts suggests that NK cells play a role in renal allograft injury and subsequent dysfunction. Thus, inhibition of NK cell infiltration of the allograft may improve transplant outcomes.

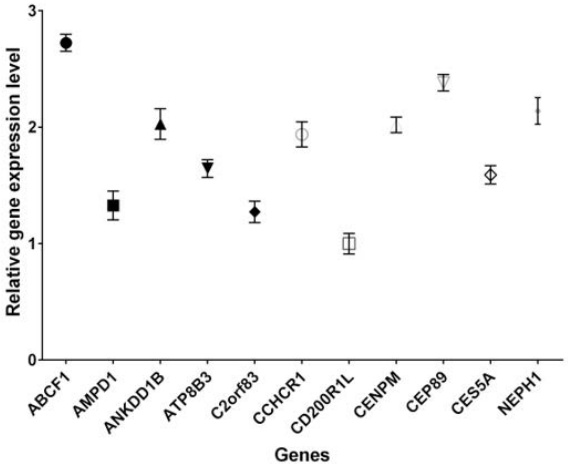
Prediction of Genome-Wide Donor-Specific Minor Histocompatibility Antigens (mHA) Based on Genotyping of Donor and Recipient Pairs Roman Reindl-Schwaighofer, Alexander Kainz, Rainer Oberbauer. *Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria.*

Background: Two random individuals differ by millions of genetic variants that include several thousands of protein polymorphisms based on sinlge nucleotide polymorphisms (SNP) as well as complete gene losses caused by "loss of function" (LoF) variants. We have established a workflow to identify genome wide genetic incompatibility based on genotyping data from donor and recipient pairs. A complete gene loss in the recipient (compound LoF variant affecting both alleles) with at least one functioning copy in the donor represents a plausible target for an alloimmune response.

Methods: We have genotyped 400 donor / recipient pairs using the iGeneTRAiN transplant array V1.0 based on Affymetrix Axiom technology that contains 750k genomic markers, including 10k specific markers for LoF variants. Following imputation we are able to cover almost 80 million different genetic markers for each individual. We then used gene expression data from kidney biopsy samples to verify if the identified proteins are expressed in transplanted kidneys.

Results: We created a candidate gene set containing more than 100 proteins with predicted homozygous gene loss. Based on the gene expression data from transplant kidney biopsies we verified that almost 70% of these proteins are transcribed in transplanted kidneys.



Conclusions: Using genomic tools new and donor-specific mHAs can be predicted on a genome-wide level.

SA-OR058

Angiotensin Receptor Antibodies Are Associated with Hypertension and Proteinuria in the Setting of Ischemia-Reperfusion Injury Gaurav Gupta, Siddhartha S. Ghosh, Todd W. Gehr, Irfan Ahmed Moinuddin, Dhiren Kumar, Anne L. King, Pam Kimball. *Nephrology, Virginia Commonwealth Univ, Richmond, VA.*

Background: Agonistic antibodies against the angiotensin II type 1 receptor (AT1R-Ab) have been linked with acute and chronic vascular kidney transplant rejection. Preliminary data has also linked AT1R-Ab with proteinuric conditions including focal segmental glomerulosclerosis and transplant glomerulopathy. In this study we investigated the effects of AT1R-Ab in an ischemia-reperfusion injury (IRI) model.

Methods: AT1R-Ab obtained from transplant patient serum was semipurified. IRI was induced in Sprague dawley rats by clamping the left renal pedicle for 45 minutes followed by reperfusion. Control animals underwent sham surgery. Alzet pumps containing AT1R-Ab (AT1R group) or human IgG (IgG group) were placed in 5 animals each with IRI. The pump was programmed to deliver 1µg/g antibody per day for 7 days. We also investigated the effect of AT1R-Ab on TGF-β secretion in a human proximal tubular (PT) cell line.

Results: Six hours after surgery, serum creatinine (SCr) in AT1R group (1.34±0.09 mg/dl) was higher than IgG group (0.78± 0.1 mg/dl) and they were both higher than in controls (0.4±0.1 mg/dl; $p<0.01$). By 7 days the SCr in IgG group dropped to normal (0.38±0.08mg/dL) but SCr in AT1R (0.8+0.1mg/dL) remained higher than in controls (0.32±0.09 mg/dl; $p<0.01$). Mean arterial pressure (MAP) of IgG group after 4 and 7 days was similar to controls at 73±12 and 71±14 mm Hg, respectively. The MAP in AT1R group after 4 and 7 days were 122+7 and 125±12 mm Hg, respectively. These were significantly higher ($p<0.01$) than the IgG group. Similarly, proteinuria in AT1R group at 7 days (227±36 mg) was also significantly higher than in IgG (44±22; $p<0.01$) and controls (24±11 mg; $p<0.01$). Finally, PT cells treated with either 75 ng of AT1R-Ab, or Angiotensin II (10^{-7}M) significantly increased production of TGF-β. This effect was abated by losartan (10^{-6}M).

Conclusions: These preliminary data suggest that AT1R-Ab is associated with worsened kidney function, hypertension and proteinuria in rats subjected to ischemia-reperfusion injury. In addition, AT1R-Ab seems to be associated with formation of pro-fibrotic TGF-β.

SA-OR059

Therapeutic Modulation of the Tie2 Receptor in Experimental Kidney Transplantation Kristina Thamm,[1] Paul Van Slyke,[2] Joon-Keun Park,[1] Hermann G. Haller,[1] Sascha David.[1] *[1]Dept of Nephrology and Hypertension, Medical School Hannover, Hannover; [2]Biological Sciences, Sunnybrook Research Inst, Toronto.*

Background: Early graft dysfunction as well as acute rejection after solid organ transplantation are characterized by a proinflammatory endothelium. The Angiopoietin/Tie2 system plays an important role in endothelial barrier function and its response to injury. Activation of the Tie2 receptor promotes endothelial homeostasis as well as anti-inflammatory properties. We therefore analyzed the potential of the Tie2 activating PEGylated 7-mer HHHRHSF, termed vasculotide (VT), as a therapeutic strategy in an MHC-mismatched renal transplant model.

Methods: We performed a murine MHC-mismatched renal transplant model (C57Bl/6 male into Balb/c female). 500ng VT was administered i.p. to C57Bl/6 1h before transplantation. Balb/c received 500ng VT i.p. directly and 3 days after surgery. Survival was monitored and remaining animals were sacrificed after 28 days. We analyzed 1) organ function, 2) Kaplan-Meier survival, 3) organ damage (PAS staining) 4) expression of endothelial adhesion molecules via immunofluorescence staining (IF), immunoblotting and qPCR, 5) infiltration of inflammatory cells (IF Gr-1, F4/80) and 6) fibrosis(IF αSMA, Sirius red staining and immunoblotting of SMAD3 activation).

Results: VT treatment resulted in diminished expression of peritubular and glomerular endothelial adhesion molecules. Consequently, infiltration of inflammatory cells (ICAM-1, Gr-1 and F4/80) was reduced in VT-treated mice compared to controls. Additionally, VT was protective against fibrogenesis. Trends towards lower serum creatinine (vehicle: 142±17 µmol/l vs. VT: 94±23 µmol/l), urea (vehicle: 76±5 mmol/l vs. VT: 60±8 mmol/l) and lactate dehydrogenase (vehicle: 1288±383 iU vs. VT: 870±275 iU) were observed. Kaplan-Meier survival analysis showed improved survival rates in the VT-treated mice (27% vs. 54%, p=0.24).

Conclusions: Exogenous activation of Tie2 via VT might reduce infiltration of inflammatory cells into renal tissue thereby protecting the renal transplant from early graft dysfunction. Thus, protection of the endothelial microvasculature via the Tie2 axis might hold promise as a therapeutic target.

SA-OR060

Effects of Anti-Human-Leucocyte-Antigen Antibodies on Endothelial Expression and Serum Levels of Thrombomodulin in Transplant Recipients Stephanie Beland, Olivier Desy, Patrice Vallin, Sacha A. De Serres. *Renal Div, Univ Health Center of Quebec, Laval Univ, Quebec, QC, Canada.*

Background: Thrombomodulin (TBM) is an anticoagulant and anti-inflammatory transmembrane protein expressed on endothelial cells. Mutations of TBM are seen in thrombotic microangiopathies due to atypical hemolytic-uremic syndrome. DSA, particularly those against HLA class II (anti-HLA-II), are involved in endothelial allograft damage during ABMR, but mechanistic knowledge is still lacking. Thus far, the effects of anti-HLA antibodies on thrombomodulin, and the differential effects of anti-HLA class I (anti-HLA-I) compared with anti-HLA-II have not been characterized.

Methods: We used human glomerular microvascular endothelial cells to examine TBM expression by fluorescence microscopy and western blot on anti-HLA-treated cells. We then tested sera from 55 kidney recipients for soluble TBM by ELISA.

Results: Treatment of endothelial cells with anti-HLA-I led to a dose-dependent increase in membrane TBM expression, whereas treatment with anti-HLA-II and TNF-α led to minimal levels of the protein. Western Blot on extracted membrane proteins confirmed these results and showed a different molecular weight for TBM in the anti-HLA-II well. Neither stimulation with anti-HLA-I nor II increased TBM levels in cell culture supernatants, but TNF-α stimulation induced high levels, suggesting different pathways between TNF-α and anti-HLA-II. We next measured cytosolic TBM and observed an accumulation upon stimulation with anti-HLA-II, but not with stimulation with TNF-α. In patients, we found a significant association between the presence of circulating anti-HLA-II DSA and low serum levels of TBM.

Conclusions: Ligation of anti-HLA-I and II produces different effects on the endothelial surface expression of TBM and on serum levels in kidney recipients. Anti-HLA-II stimulation leads to a cytosolic accumulation of TBM with little membrane expression, suggesting a modification of the protein. This phenotype may be associated with a prothrombotic state, which could explain the higher occurrence of transplant glomerulopathy and the poor outcomes observed in patients with these antibodies.

SA-OR061

Humanized Readout of Diabetic Nephropathy in Mice Using Urinary Peptidomics Joost Schanstra,[1] Julie Klein,[1] Adela Ramirez-Torres,[2] Anette E. Ericsson,[3] Yufeng Huang,[4] Benjamin Breuil,[1] Justyna Siwy,[2] Harald Mischak,[2] Xiao-Rong Peng,[4] Jean-Loup Bascands.[1] *[1]U1048, INSERM, Toulouse, France; [2]Mosaiques Diagnostics GmBH, Hannover, Germany; [3]AstraZeneca R&D, Mölndal, Sweden; [4]Univ of Utah School of Medicine, Salt Lake City.*

Background: Diabetic nephropathy (DN) is among the most frequent complications of diabetes and the first cause of end-stage renal disease. Despite being successful in animal models, the majority of clinical trials for novel drugs targeting DN failed.This lack of translational value may in part be due to an inadequate comparability of human disease

and animal models that often capture only a few aspects of disease. Here we overcome this limitation by developing a multi-molecular non-invasive humanized readout of DN based on urinary peptidomics.

Methods: The urinary peptidome of the two most frequently used models of type 2 diabetic (T2D) DN, the BTBRob/ob mice and the uninephrectomized db/db mice on a C57BLKS background (UNxdb/db), treated or not with enalapril, was analyzed using capillary electrophoresis coupled to mass spectrometry.

Results: The disease-modified urinary peptides of the two T2D DN mouse models were identified and compared with previously validated urinary peptide markers of DN in humans to generate a classifier composed of 21 ortholog peptides. This classifier predicted the response to disease and treatment with inhibitors of the renin-angiotensin system (RASi) in mice. The humanized classifier was significantly correlated with glomerular lesions. Using a human T2D validation cohort consisting of 207 patients, the classifier also distinguished between patients with and without DN, and response to RASi.

Conclusions: Our approach demonstrates that a combination of multiple molecular features similar in both human and animal disease could provide a step change in translational drug discovery research in T2D-DN nephropathy.

SA-OR062

Linking Renal Structure to Molecular Function for Outcome Prediction in Diabetic Kidney Disease Viji Nair,[1] Jennifer L. Harder,[1] Wenjun Ju,[1] Carine Boustany,[5] Kevin V. Lemley,[3] Robert G. Nelson,[2] Matthias Kretzler.[1] *[1]UM; [2]NIH; [3]Children's Hospital Los Angeles; [4]Univ of Erlangen; [5]Boehringer Ingelheim.*

Background: Genome wide transcriptional profiling identifies active regulatory and transcriptional networks in kidney disease. Integrating structural changes with molecular profiles may identify functional correlates of early structural damage that predict subsequent disease progression.

Methods: Gene expression profiling and quantitative morphometric analysis was performed on protocol kidney biopsies from 49 type 2 diabetic Pima Indians with pre-symptomatic Diabetic Kidney Disease(DKD). Transcriptional co-expression modules were generated and associated with morphometric and long term clinical traits using Weighted Gene Coexpression Network Analysis. Urinary protein Epidermal Growth Factor (uEGF) levels were assessed for their correlation with the cortical interstitial fractional volume (VvInt) and GFR.

Results: Several structural parameters were associated with molecular profiles. The degree of tubulointerstitial damage, assessed by measurement of VvInt, showed a strong association with molecular signatures and was linked to long term clinical outcomes. Enrichment for migratory, inflammatory and cell-cell/cell-matrix interaction pathways was found in the transcripts that correlated positively with VvInt and enrichment for metabolic pathways, turnover of amino acids, sugars and lipids in those that correlated negatively. A subset of VvInt associated transcripts correlated with GFR and ACR measured ~10 years after biopsy, including EGF. uEGF showed strong positive correlation with intrarenal EGF transcript and negative correlation with VvInt. uEGF was strongly associated with GFR measured at baseline and 10 years after biopsy.

Conclusions: Cortical interstitial fractional volume-associated gene expression in pre-symptomatic to early DN was associated with ACR/GFR progression. 81% of these transcripts were also regulated in a diabetic European cohort with more advanced DKD. Molecular-morphometric approaches may allow a better understanding of the molecular events activated at a early DKD stage and provide starting points for therapeutic patient stratification.

Inactivation of Placental Growth Factor Is Associated with Perirenal Inflammation and Renal Impairment Yaeni Kim, Ji Hee Lim, Min Young Kim, Eun Nim Kim, Yu Ah Hong, Sun Ryoung Choi, Hoon Suk Park, Seon Deok Hwang, Yong-Soo Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: An excess of adipose tissue displays impaired angiogenesis that can lead to local hypoxia and apoptosis, resulting in chronic inflammation. Placental growth factor (PlGF) has favorable angiogenetic activity through its interaction with VEGFR1. We investigated the role of PlGF in adipose tissue–related angiogenesis in perinephric fat and whether the inactivation of PlGF would promote renal phenotypical and functional deterioration.

Methods: Male wild-type, PlGF-deficient (PlGF KO), and PlGF transgenic mice (PlGF TG) were fed regular chow. Mice were sacrificed at 13th and 32nd weeks to compare biochemical parameters, relevant molecular expressions and phenotypes of perinephric fat and the kidney at each distinct time point.

Results: PlGF KO mice developed features of metabolic syndrome at week 32; body weight and systolic blood pressure significantly increased with concurrent increases in serum insulin level and AUC of IGTT. While perinephric fat of 13 week old PlGF KO mice showed decreased number and increased size of adipocytes with no significant difference in F4/80 positive cells as compared to the others, 32 week old PlGF KO mice revealed increased number of F4/80 positive cells. Vessel density of perinephric fat was decreased with corresponding increase in HIF-1α expression in PlGF KO mice. 32 week old PlGF KO mice showed unfavorable renal phenotypical changes as compared to PlGF TG and controls while these changes were insignificant in those at week 13. Consistent down regulations in the renal expressions of p-AMPK, LKB1, PPARα, PGC1α, ERRα, eNOS, SOD, Bcl2/Bax ratio were shown in 32 week old PlGF KO mice with increased albuminuria. Intrarenal p-AMPK-PGC1α axis was accentuated in PlGF TG mice and this was associated with attenuated albuminuria.

Conclusions: Our study suggests that PlGF-deficiency represents impaired vasculature and adipogenesis. This derangement promotes hypoxia, inflammation, and oxidative stress in the perirenal adipose tissue which deteriorates renal functional and phenotypic parameters.

SA-OR064

miR-221-Containing Exosomes from Vascular Endothelial Cells Promote Mesangial Hypertrophy in Diabetic Nephropathy Qi Sun, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Diabetic nephropathy (DN) is a major microvascular complications of diabetes that is structurally characterized by extracellular matrix (ECM) accumulation in glomeruli. Hyperglycemia-induced mesangial cell injury has been proved to play a key role in ECM expansion, but the mechanism under this progression has not been fully elucidated. Recently, exosome-associated microRNA transferring represent a newly identified mechanism of intercellular communication. Therefore, we hypothesize that miRNA expression in endothelium-derived exosomes may be critical in the crosstalk between mesangial cell injury and surrounding endothelium under DN condition.

Methods: Exosomes were isolated from endothelial cell cultures using exosome isolation reagent and characterized by electron microscopy. The uptake of exosomes by the mesangial cells was assessed by flow cytometry and flourescent microscopy. The abundance of miR-221 was measured by real-time quantitative PCR in serum, urine and kidney tissues of diabetic mice. Adeno-associated virus (AAV)-mediated miRNA inhibitor was used to explore the role of miR-221 in vivo by tail vein injection.

Results: Hyperglycemia upregulates miR-221 expression in cultured HMECs and in glomeruli from db/db type 2 diabetic mice. Incubation cultured mesangial cells with miR-221-containing exosomes can significantly downregulate matrix metallopeptidase 9 (MMP-9) expression by targeting transcription factor Ets-1. Then, we evaluated the efficacy of AAV-mediated inhibitor of miR-221 in db/db mice. AAV-anti-miR-221 reduced levels of miR-221 in kidneys of both normal and db/db mice. Inhibition of miR-221 in diabetic mice significantly increased Ets-1/MMP9 expression and promoted ECM degration.

Conclusions: In summary, our study provides the first evidence that endothelial cells can promote mesangial hypertrophy by releasing miR-221-containing exosomes, which may create a "pro-hypertrophic" microenvironment and further be delivered to mesangial cells to inhibit ECM degration by targeting Ets-1/MMP9 pathway. More importantly, we found that inhibition of miR-221 might be an effective therapy for diabetic nephropathy.

Follistatin Is a Novel Protective Agent for Diabetic Nephropathy Dan Zhang, Agata Gava, Bo Gao, Tony Nuo Wang, Richard Van Krieken, Neel Mehta, Renzhong Li, Liliana K. Wolak, Joan C. Krepinsky. *Nephrology, McMaster Univ, Hamilton, ON, Canada.*

Background: The kidney is a major site of diabetic microvascular complications. We previously showed that caveolin-1 knockout (KO) mice are protected from diabetic glomerular sclerosis, and KO mesangial cells (MC) are deficient in matrix protein synthesis in response to high glucose (HG) and the profibrotic cytokine TGFβ. A screen identified significant upregulation of the secreted antifibrotic protein follistatin (FST) in KO MC. Here we evaluated the *in vitro* and *in vivo* role of FST in DN.

Methods: *In vitro* studies used primary mouse MC and standard molecular biology techniques. For *in vivo* studies, type 1 diabetic Ins2^{Akita} or control mice were given vehicle or 3μg recombinant FST (Paranta Biosciences) IP every other day for 12 weeks and assessed for renal function, proteinuria and pathology.

Results: FST inhibited HG-induced matrix upregulation in wild-type MC, and its downregulation with siRNA enabled matrix synthesis by HG in KO MC. TGFβ is a well-recognized mediator of HG-induced matrix production. FST, however, does not inhibit its actions, but primarily neutralizes TGFβ family members called activins. HG and TGFβ increased MC production of Activin A (ActA) as assessed by ELISA. ActA was also increased in serum and kidneys of diabetic mice. Inhibition of ActA signaling by siRNA downregulation of its type I receptor ALK4 prevented HG-induced matrix upregulation. Interestingly, HG-induced TGFβ upregulation was also prevented by ALK4 siRNA and FST. Treatment of MC with recombinant ActA confirmed that it can induce the production of TGFβ. These data suggest that ActA is a key mediator of HG- and TGFβ-mediated matrix accumulation in MC. We thus tested the efficacy of FST administration in type 1 diabetic Akita mice which developed early signs of DN by 18 weeks of age. FST protected against the development of albuminuria, basement membrane thickening and collagen upregulation.

Conclusions: ActA is a major mediator of MC matrix production in response to HG. Its antagonist FST prevents matrix upregulation *in vitro* and protects against the development of DN *in vivo*. FST thus represents a novel and promising therapeutic approach to DN.

SA-OR066

CCR2 Expression in Podocytes Mediates Diabetic Renal Injury Hanning You,[1] Ting Gao,[1] Timothy K. Cooper,[2] Sarah K. Bronson,[3] William Brian Reeves,[1] Alaa S. Awad.[1] *[1]Medicine, Pennsylvania State Univ College of Medicine, Hershey, PA; [2]Comparative Medicine, Pennsylvania State Univ College of Medicine, Hershey, PA; [3]Cellular and Molecular Physiology, Pennsylvania State Univ College of Medicine, Hershey, PA.*

Background: Inflammation is a central pathophysiologic mechanism that contributes to diabetes mellitus and diabetic nephropathy (DN). Recently, we showed that macrophages directly contribute to diabetic renal injury, and that pharmacological blockade or genetic deficiency of CCR2 confers kidney protection in DN. However, the direct role of CCR2 in kidney-derived cells such as podocytes in DN remains unclear. Here, we report that CCR2 in podocytes mediates diabetic renal injury *in vivo*.

Methods: We developed a transgenic mouse expressing CCR2 specifically in podocytes (Tg(*NPHS2-Ccr2*)) in a nephropathy prone CCR2 deficient ($Ccr2^{-/-}$) background, with heterozygous $Ccr2^{+/-}$ littermate controls. Type 1 diabetes was induced by multiple low doses of intraperitoneal streptozotocin (STZ) injection.

Results: As expected, absence of CCR2 conferred kidney protection after 9 weeks of diabetes as evidenced by significantly reduced albuminuria ($p<0.05$), blood urea nitrogen (BUN) ($p<0.05$), histopathologic changes, and kidney fibronectin ($p<0.01$) and type-1 collagen expression ($p<0.05$) compared to diabetic $Ccr2^{+/-}$ littermate controls. In contrast, diabetic $Ccr2^{-/-}$ mice with podocyte-specific CCR2 expression displayed significantly increased albuminuria ($p<0.05$), BUN ($p<0.05$), histopathologic changes, and kidney fibronectin ($p<0.05$) and type-1 collagen ($p<0.05$) expression compared to diabetic $Ccr2^{-/-}$ after 9 weeks of diabetes. Of interest, there was no increase in kidney macrophage recruitment or inflammatory cytokine levels in diabetic $Ccr2^{-/-}$ mice with podocyte-specific CCR2 expression.

Conclusions: These findings support a direct role for CCR2 expression in podocytes to mediate diabetic renal injury independent of monocyte/macrophage recruitment. Targeting the CCR2 signaling cascade in podocytes could be a novel therapeutic approach for treatment of DN.

SA-OR067

Effect of Janus Kinase 2 on Kidney Serum Amyloid A in a Mouse Model of Diabetic Kidney Disease Rick L. Meek,[1] Brad Dieter,[1] Robert J. Anderberg,[1] Sheryl K. Cooney,[1] Hongyu Zhang,[2] Viji Nair,[2] Frank C. Brosius,[2] Matthias Kretzler,[2] Katherine R. Tuttle.[1,3] *[1]Providence Sacred Heart Medical Center, Providence Health Care, Spokane, WA; [2]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [3]Inst of Translational Health Sciences, Univ of Washington, Seattle, WA.*

Background: Janus kinase 2 (JAK2) signaling and expression of the pro-inflammatory mediator serum amyloid A (SAA) are increased in the kidneys of humans with diabetic kidney disease (DKD) and in diabetic mouse models. We hypothesize that JAK2 induces a mouse-kidney-isoform of SAA, SAA3, which is associated with injury in mouse DKD models.

Methods: Podocyte specific JAK2 overexpressing type 1 diabetic Akita mice were infused with angiotensin II to enhance kidney disease. A JAK2 inhibitor (LY03103801, 3 mg/kg/day) was administered for the last 2 weeks of the study. Kidney sections were immunostained for SAA3 and assessed by standard histopathology. Glomerular SAA3 mRNA (RNAseq) and urine albumin-to-creatinine ratio were measured. Cultured mouse podocytes were exposed to recombinant SAA or advanced glycation end products (AGE) with and without the JAK2 inhibitor (Tyrphostin AG 490, 50μM). JAK2 activity (Western blot) and SAA3 mRNA (qRT-PCR) were measured.

Results: Diabetes increased kidney SAA3 protein and overexpression of podocyte JAK2 augmented SAA3 protein in both the tubulointerstitium and glomeruli (19.3 fold vs control, p=0.005; 3.1 fold vs diabetic mice, p=0.003). JAK2 inhibition attenuated the increases of SAA3 protein immunostaining and reduced glomerular SAA3 mRNA. SAA3 protein correlated with increased Periodic Acid Schiff staining (r=0.51, p=0.02), mesangial index (r=0.64, p=0.001), and urine-albumin-to-creatinine ratio (r=0.49, p=0.03). Exposing podocytes to exogenous SAA or AGE increased JAK2 activity (6.2 fold, p=0.03; 3.2 fold, p=0.03, respectively) and SAA3 mRNA expression (9.0 fold, p=0.01; 8.2 fold, p=0.02, respectively), whereas inhibiting JAK2 activity attenuated the increases in SAA3 mRNA.

Conclusions: Kidney SAA3 is up-regulated downstream of JAK2 and acts locally in the kidney of diabetic mice, indicating that SAA may mediate inflammatory mechanisms in DKD.

SA-OR068

Telomerase Deficiency Increases Glomerular Endothelial Cell Senescence in Diabetic Nephropathy Huifang Cheng,[1] Xiaofeng Fan,[1] William E. Lawson,[1] Paisit Paueksakon,[2] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ School of Medicine, Nashville, TN; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ School of Medicine, Nashville, TN.*

Background: Aging is a risk factor for Diabetic Nephropathy (DN), and shorter telomere length (TL) has been observed in patients with diabetes mellitus. Both telomerase reverse transcriptase (TerT) and telomerase RNA (TerC) are essential to maintain telomere length.

Methods: To investigate the mechanism of telomerase dependent vulnerability to DN, we used streptozotocin to induce diabetes in fourth generation TerC and TerT KO mice and measured their TL and senescence in kidneys, compared with wild type (Wt) and used primary cultured glomerular endothelial cells (GEnCs) for *in vitro* studies.

Results: TL was significantly shorter in kidneys from TerC and TerT KO mice compared with Wt. STZ injection reduced TL in Wt, and further decreased it in TerC and TerT KO mice. After 26 weeks of diabetes, TerC and TerT KO mice had greater decrease in expression of renal SIRT1 and increased P53 and P16. Similarly SIRT activity was profoundly diminished in TerC /T KO mice compared to Wt. TerC /T KO mice had increased renal injury (assessed by albuminuria and GBM thickness) and glomerular senescence. Senescence was predominately detected in endothelial cells. Primary GEnCs from TerC KO mice proliferated slower. After incubation for 96 hours in high glucose (HG, 30 mM), GEnCs exhibited cellular senescence, with a marked increase in cells with TerC deletion. There was only minimal senescence with incubation in normal glucose medium or with a mannitol osmolality control. HG decreased SIRT 1 expression and activity, especially in GEnCs from TerC KO mice, with up-regulation of P16 and P53, especially acetylated P53. The SIRT1 activator, SRT1720, partially counteracted these alterations.

Conclusions: Inhibition of SIRT1 pathway contributes to telomerase deficiency-dependent susceptibility to DN progression and GEnCs senescence. Telomere shortening of aging may be a predisposing factor for development of diabetic nephropathy.

SA-OR069

Roles of Hedgehog Interacting Protein in Diabetic Nephropathy Xin-Ping Zhao,[1] Shiao-Ying Chang,[1] Min-Chun Liao,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Stephan Troyanov,[2] Julie R. Ingelfinger,[3] John S.D. Chan,[1] Shao-Ling Zhang.[1] *[1]CRCHUM, Univ of Montreal, Montreal, QC, Canada; [2]Res. Ctr., l'Hôpital du Sacré-Cœur de Montréal, Univ of Montreal, Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass. Gen. Hosp., Boston, MA.*

Background: We previously reported thathigh glucose (HG) stimulates Hedgehog Interacting Protein (*Hhip*)gene expression, impairing nephrogenesis; whether Hhip contributes to the *pathophysiology* of diabetic nephrology (DN) is unknown. Here we examined potential mechanisms of hyperglycemia induced renal Hhip gene expression, leading to endothelial to mesenchymal transition (EndoMT) related renal fibrosis. We asked if urinary soluble Hhip (sHhip) might be a marker of DN onset and/or progression.

Methods: We examined the role of renal Hhip expression in diabetic murine models—T1DM (*Akita* mice) and T2DM (*db/db* mice), as well as in kidney biopsies from T1DM and T2DM patients cf. to non-diabetic patients. We determined HG-mediated renal Hhip cleavage/shedding and HG-regulated renal Hhip expression at both transcriptional and translational levels *in vivo* and *in vitro*.

Results: Hhip expression in renal cells (glomerular endothelial cells, podocytes and glomerular and tubular epithelial cells) was significantly elevated in both murine diabetes models and diabetic patients. Urinary sHhip/Creatinine (Cre) ratio positively correlated with the time-course of diabetes in our murine models. Hyperglycemia activated ADAM 17, which subsequently cleaved/shed Hhip, contributing to urinary sHhip formation. In mouse endothelial cells (mECs) *in vitro*, H_2O_2 and angiotensin II (Ang II) directly up-regulated Hhip gene expression. HG and recombinant Hhip (rHhip) stimulated mouse Hhip and TGFβ1 promoter activity dose-dependently; recombinant TGFβ1 (rTGFβ1) had no impact on *Hhip* promoter activity, suggesting that Hhip acts upstream of TGFβ1 signaling. In sum, enhanced Hhip, via TGFβ1 receptors targets TGFβ1-Smad2/3 cascades, promoting endothelial to mesenchymal transition (EndoMT), associated with renal fibrosis.

Conclusions: Hyperglycemia induced Hhip expression is important in the pathogenesis of DN, promoting EndoMT via the TGFβ1-Smad2/3 pathway. Urinary sHhip/Cre ratio may indicate onset and/or progression.

PACSIN2 Is Increased in Podocytes in Diabetic Kidney Disease and Regulates Nephrin Turnover at the Plasma Membrane Sanna H. Lehtonen, Tuomas Aleksi Tolvanen, Sara Kuusela, Hong Wang, Sonja Lindfors, Vincent Dumont. *Univ of Helsinki, Finland.*

Background: Reduced expression or abnormal localization of nephrin has been observed in experimental models of diabetes and human diabetic nephropathy. Here we aim to define whether PACSIN2, known to participate in vesicle trafficking in various cell types, regulates localization of nephrin at the plasma membrane.

Methods: Immunohistochemistry and Western blotting were used to quantify the expression of PACSIN2 in the glomeruli of Zucker Diabetic Fat (ZDF) rats. Immunofluorescence and confocal microscopy were used to study the localization of nephrin in ZDF rat glomeruli. Complex formation between PACSIN2 and nephrin in glomeruli and podocytes overexpressing nephrin was studied by co-immunoprecipitation and *in situ* proximity ligation assay (PLA). PACSIN2 was overexpressed in nephrin-expressing podocytes followed by On-cell/In-cell Western to quantify the effect on nephrin insertion and turnover at the plasma membrane.

Results: PACSIN2 was found to be expressed in podocytes *in vitro* and *in vivo*. It colocalized with nephrin, and was found to be expressed at higher level in the glomeruli of obese, highly albuminuric ZDF rats compared to lean controls. The distribution of nephrin changed from linear to granular pattern in the glomeruli of obese ZDF rats. Co-immunoprecipitation and *in situ* PLA indicated that PACSIN2 and nephrin form a complex in cultured podocytes and in isolated human and rat glomeruli. On-Cell Western revealed that PACSIN2 overexpression reduces the amount of nephrin inserted in the plasma

membrane compared to empty vector-transduced podocytes. Furthermore, time series In-Cell Western experiments revealed quicker turnover of nephrin at the plasma membrane in PASCIN2 overexpressing cells.

Conclusions: PACSIN2 is upregulated in glomeruli in diabetes, and *in vitro* experiments revealed that PACSIN2 enhances nephrin trafficking. This suggests that increased PACSIN2 expression associates with loss of glomerular permselectivity and proteinuria. Further studies are needed to define the molecular mechanisms by which PACSIN2 regulates nephrin trafficking and whether increased expression of PACSIN2 helps in preventing or accelerates loss of renal function.

Polycystin 1 Regulates WWTR1/TAZ, a Non-Canonical WNT and Hippo Signaling Target Nikolay P. Gresko,[1] David Merrick,[2] Kavita Mistry,[1] Michael J. Caplan.[1] *[1]Cellular and Molecular Physiology, Yale Univ, New Haven, CT; [2]Univ of Pennsylvania.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in the *PKD1* and *PKD2* genes, which encode PC1 and PC2, respectively. PC1 is a 460kD multi-spanning membrane protein that undergoes multiple proteolytic cleavages, at least two of which release C-terminal fragments. One of these fragments includes the last 200 amino acids of PC1 (PC1-CTTp200) and possesses a functional nuclear localization sequence (NLS) that drives its nuclear accumulation. Nuclear PC1-CTTp200 regulates several transcription pathways.

Methods: One of the top hits in a screen for transcription factors and co-regulators whose activities are modulated by PC1-CTTp200 was TAZ (also known as WWTR1), which is an important component of several signalling cascades, including the Hippo pathway.

Results: We found that TAZ protein expression in the nephron is localized to the basolateral compartment of S3 segment epithelial cells and to the principal cells of the collecting duct. Interestingly, it has previously been shown that TAZ deficient mice develop severe renal cysts. Moreover, we find that exogenous expression of an active form of TAZ in PC1 null cells prevents them from forming cyst-like structures in the 3D Matrigel culture. Expression of the active form of TAZ also corrects the curly tail phenotype that is seen in PKD1a/b morphant zebra fish. We find that PC1 interacts with TAZ, and furthermore that PC1 expression upregulates TAZ abundance at the mRNA and protein levels. TAZ abundance and activity have been shown to be upregulated through the non-canonical Wnt signalling. A recent study demonstrates that PC1 can serve as a receptor for Wnt ligands. We find that HEK293 cells that express PC1 and PC2 respond to treatment with recombinant Wnt5a protein by increasing the abundance of TAZ mRNA as compared to wild type HEK293 cells.

Conclusions: Taken together, our data suggest that PC1 may participate in a novel signalling pathway that links detection of non-canonical Wnt ligands to the positive regulation of TAZ, a multifaceted signalling molecule whose absence is sufficient to induce renal cystic disease.

SA-OR072

Polycystin-1 Regulates EZH2 Expression through the cAMP/PKA/CREB Pathway and EZH2 Inhibition Delays ADPKD Progression Na Qi, Ming Wu, Changlin Mei. *Dept of Nephrology, Shanghai Changzheng Hospital, Second Military Medical Univ, Kidney Inst, Shanghai, China.*

Background: Enhancer of zeste homolog 2 (EZH2) plays important roles in tumor formation and growth, however it is not known whether EZH2 promotes cyst expansion in autosomal dominant polycystic kidney diseases (ADPKD). The aim of this study is to determine the effect and mechanism of EZH2 inhibition in ADPKD.

Methods: $Pkd1^{+/-}$ and $Pkd1^{-/-}$ mice were treated with 30 mg/kg/day EZH2 specific inhibitor GSK126 or vehicle from day15 to day 35 by IP injection. ADPKD cells were treated with various concentration of GSK126. The upstream signaling pathway of EZH2 was analyzed by using PKD1 siRNA, cAMP agonists or antagonists, PKA inhibitor, CREB siRNA or plasmids in control or ADPKD cells.

Results: EZH2 expression and the methylation of histone and STAT3 are increased in ADPKD kidney tissues. Four weeks of treatment by EZH2 specific inhibitor GSK126 reduced BUN and creatinine levels by 26.9% and 29.5%, respectively, in Pkd1-/- mice. Administration of GSK126 decreased two-kidney/total body weight ratio by 30.5% and cyst volume density by 36% in $Pkd1^{-/-}$ mice. Moreover, exogenous expression of human EZH2 induced pronephic cysts in zebrafishes. The effect of EZH2 inhibition *in vivo* was evaluated, GSK126 treatment reduced cell proliferation in cystic kidneys as shown by Ki-67 staining. *In vitro* study further confirmed that EZH2 ablation inhibited cell proliferation and cell cycle of ADPKD cells. Western blot analysis showed that EZH2 inhibition reduced phosphorylation of STAT3 *in vivo* and *in vitro*, which were correlated with decreased methylation of STAT3. Further *in vitro* studies showed that EZH2 is up-regulated by PKD-1 siRNA, cAMP agonists (forskolin or 8-Br-cAMP) and CREB over-expression. Moreover, the cAMP antagonist Rp-camp, the PKA inhibitor H89 and CREB siRNA down-regulated EZH2 expression in ADPKD cells.

Conclusions: Polycystin-1 regulates EZH2 expression through the cAMP/PKA/CREB pathway. Inhibition of EZH2 mediated protein methylation could be a new strategy for ADPKD therapy.

Global Profiling in Polycystic Kidney Disease Reveals a Metabolic Rewiring Reminiscent of Cancer Christine Podrini,[1,2] Isaline Rowe,[1] Roberto Pagliarini,[3] Silvia Raineri,[1] Ivano Di Meo,[4] Marco Chiaravalli,[1] Valeria Tiranti,[4] Diego Di Bernardo,[3] Alessandra Boletta.[1] *[1]DGCB, San Raffaele Scientific Inst, Milan; [2]Univ Vita-Salute San Raffaele, Italy; [3]TIGEM, Pozzuoli, Italy; [4]IRCCS Foundation Neurological Inst, Italy.*

Background: We and others have previously uncovered metabolic alterations in ADPKD including defective glycolysis. Global metabolic profiling was performed in a murine model of PKD carrying kidney-specific inactivation of *Pkd1* as to avoid confounding effects caused by inactivation in other organs.

Methods: We collected 16 newborn (P4) kidneys of *Ksp*-Cre;$Pkd1^{flox/-}$ mice and littermate controls from a total of 4 litters containing each 2 cystic and 2 control (half male, half female) kidneys. Ultrahigh performance liquid and gas chromatography followed by mass spectrometry was used.

Results: 550 metabolites were named. An unsupervised statistical analysis (PCA) revealed a clear separation between mutant and control kidneys with a significant upregulation of 196 and downregulation of 292 metabolites (total 488). Alterations include defective glycolysis, fatty acids biosynthesis, β-oxidation and TCA cycle. The last suggested a mitochondrial defect. To test this, oxygen consumption rates were measured in a 96 wells SeaHorse. $Pkd1^{-/-}$ MEFs (immortalized and primary) presented decreased maximum respiration and increased extracellular acidification rates as compared to controls, suggesting a switch from mitochondrial oxidation to glycolysis. Analysis suggested that $Pkd1^{-/-}$ cells have glutamine anaplerosis. We applied metabolic deprivation to $Pkd1^{+/+}$ and $Pkd1^{-/-}$ MEFs. $Pkd1^{-/-}$ cells were more sensitive to glucose deprivation. Deprivation of both glutamine and glucose resulted in a more detrimental effect on $Pkd1^{-/-}$ cells than $Pkd1^{+/+}$ suggesting that mutant cells are addicted to glucose and glutamine.

Conclusions: A major metabolic rewiring is identified in PKD unexpectedly similar to cancer. Defective TCA cycle and mitochondrial activity likely drive "Warburg effect" in *Pkd1* mutants which is accompanied by glutamine anaplerosis, again showing similarities with cancerous cells. Thus metabolic alterations are a hallmark of PKD. Further analysis is required to understand why transformation is not a feature of this disease.

SA-OR074

Inhibition of CamKII Reduces ER Stress, Oxidative Damage, Improves Mitochondrial Integrity, and Attenuates Polycystic Kidney Disease Nikolay Bukanov,[1] Christina M. Bracken,[3] Philippe Beauverger,[2] Olivier Duclos,[2] Ryan J. Russo,[1] Kelly A. Rogers,[1] Herve Husson,[1] Thomas A. Natoli,[1] Steven R. Ledbetter,[1] Philip Janiak,[2] Oxana Beskrovnaya.[1] *[1]Rare Diseases, Sanofi-Genzyme R&D Center, Framingham, MA; [2]Cardiovascular Research, Sanofi, Chilly-Mazarin, France; [3]Mitobridge Inc., Cambridge, MA.*

Background: Polycystic kidney diseases (PKD)s comprise a large family of cilia-associated genetic diseases characterized by formation and progressive growth of renal cysts, eventually leading to end-stage renal disease. Despite recent advances in understanding of PKD pathogenesis, the exact mechanisms of cystogenesis are not completely understood. We show a new role for calcium/calmodulin-dependent protein kinase II (CaMKII) as a pathological mediator of oxidative damage, maladaptive ER stress response and mitochondrial dysfunction in progression of cystic kidney disease.

Methods: Western blot analysis of kidney tissue was used for assessment of integral mitochondrial membrane proteins and proteins responsible for oxidative damage, mitochondria-related apoptotic pathway, and ER stress response. Mitochondrial membrane potential was assessed by MitoTracker and flow cytometry analysis of JC-1 dye uptake; mitochondrial antioxidant gene expression was evaluated with PCR. Efficacy of CaMKII small molecule inhibitor in jck mice was measured by kidney to body weight ratio, blood urea nitrogen, and cystic volume.

Results: Here we show that that CaMKII is activated in renal cystic epithelia in human ADPKD and in the jck mouse model of PKD. These data is also confirmed by western blot analysis of normal and human ADPKD and jck kidney lysates. Pharmacological blockade of pCaMKII by a novel and selective small-molecule inhibitor significantly attenuates PKD in jck mice, reducing cystic disease endpoints, namely K/BW ratio, cystic volume and BUN levels. Mechanistic analyses show that treated kidneys are characterized by decreased unfolded-protein response, oxidative stress and restoration of mitochondrial membrane potential and integrity.

Conclusions: Taken together, our data show that inhibition of CaMKII may be a viable therapeutic approach for the treatment of PKD.

SA-OR075

Re-Expression of Polycystin-1 in Polycystic Kidneys Antagonizes Cyst Progression and Prolongs Survival Stephen C. Parnell, Archana Raman, Timothy A. Fields. *Kidney Inst, Univ of KS Medical Center.*

Background: Mutations in the *PKD1* gene disrupt the function or cause decreased amounts of its protein product, polycystin-1 (PC1), and are responsible for most cases of autosomal dominant polycystic kidney disease (PKD). However, after cysts have initiated it is not known whether ongoing PC1 deficiency is necessary for cyst progression, or whether re-expression of PC1 in cystic kidneys will halt or reverse cyst growth.

Methods: To determine the effects of PC1 re-expression in cystic kidneys, we engineered an inducible functional allele of mouse *Pkd1*, $Pkd1^{NEO\ WT}$. In the absence of

Cre, *Pkd1*$^{NEO\ WT}$ is a non-functional allele. However, Cre-mediated recombination produces a re-arranged allele, *Pkd1*^{WT*}, that expresses functional PC1. *Pkd1*$^{NEO\ WT}$ mice were mated to mice with hypomorphic *Pkd1* alleles (*Pkd1*^{V} or *Pkd1*^{RC}) and ubiquitously expressed *ROSA26-Cre*^{ERT2}. PC1 re-expression was induced in 1 week-old cystic mice by tamoxifen injection, thereby converting the non-functional *Pkd1*$^{NEO\ WT}$ allele to the functional *Pkd1*^{WT*} allele, and the effects on cystic kidney disease were determined.

Results: *Pkd1*$^{NEO\ WT/V}$ and *Pkd1*$^{NEO\ WT/RC}$ pups survived embryogenesis but displayed early cystic kidney disease, with death of *Pkd1*$^{NEO\ WT/V}$ pups occurring at 3-4 weeks. Control *Pkd1*$^{WT*/WT*}$ mice were normal. Two weeks of PC1 re-expression improved cystic kidney disease in 3 week-old pups, with a decrease in kidney weight to body weight (KW/BW) and an improved cystic index compared to pups that did not re-express PC1. A single cystic mouse was sacrificed at 11 weeks following re-expression of PC1. While this mouse exhibited prominent cystic kidney disease, its KW/BW was less than that of 1 week-old *Pkd1*$^{NEO\ WT/V}$ pups. Moreover, there was significant preservation of normal parenchyma, and evidence of cystic epithelial cell apoptosis.

Conclusions: These results suggest that re-expression of PC1 provides a significant benefit to cystic mice, and further suggests that rescue of PC1 function (*e.g.*, chaperone-mediated therapy for *PKD1* mutations that result in misfolded and/or mis-localized PC1, or small molecules that stimulate polycystin-2 channel activity for *PKD1* loss-of-function mutations) may be an ideal therapeutic approach for PKD.

Loss of Cilia Does Not Inhibit Pkhd1 Dependent Cyst Growth in the Liver

Rachel Gallagher,[1] Sorin V. Fedeles,[1] Matteus Krappitz,[1] Ming Ma,[1] Stefan Somlo.[1,2] [1]*Internal Medicine, Yale School of Medicine, New Haven, CT;* [2]*Dept of Genetics, Yale School of Medicine, New Haven, CT.*

Background: Loss of polycystin in ADPKD and complete removal of cilia by inactivation of intraflagellar transport-related proteins both give rise to cysts in the kidney and liver. Recently it has been shown that inactivation of both polycystin and cilia concurrently results in a protective effect on ADPKD dependent cystogenesis, revealing the existence of a novel signaling pathway of polycystin-dependent inhibition and cilia-dependent cyst activation (CDCA). We and others have previously shown that there is a genetic interaction between *Pkhd1* and *Pkd1* dosage, we proposed to inactivate cilia in the livers of the ARPKD mouse model *Pkhd1*$^{del4/del4}$ to determine if the CDCA pathway plays a role in cyst progression in ARPKD.

Methods: The animals models used in this study are *Pkhd1*^{del4}, *Kif3a* floxed allele and ERT2;UBCCre. All animals used in this study were induced with Tamoxifen at postnatal day 28 for 5 days and then aged to 17 weeks. The livers and kidneys were examined for disease progression.

Results: At the start of cilia inactivation, the *Pkhd1*$^{del4/del4}$ livers show mild bile duct proliferation. At 17 weeks, the body weights of the *Kif3a*$^{fl/fl}$*:UbcCRE* were higher than the *Pkhd1*$^{del4/del4}$ animals [33.39 ± 5.592 g compared to 25.98 ± 2.584 g]. It has been well described that loss of cilia results in increased body weight.The body weight of the double knockout were similar to the *Kif3a* single knockouts at 30.44 ± 1.304 g. No significant difference was detected in kidney weights across all genotypes. The liver cystic disease progression which is evident in the *Pkhd1*$^{del4/del4}$ animals at 17 weeks, remained unchanged in the absence of cilia: *Pkhd1*$^{del4/del4}$(1.63 ± 0.28), *Kif3a*$^{fl/fl}$*:UbcCRE* (1.69 ± 0.50), *Pkhd1*$^{del4/del4}$*;Kif3a*$^{fl/fl}$*;UbcCRE* (1.71 ± 0.43). The slight increase in liver weights in the cilia mutant animals was due to fat deposits and not increased cyst formation.

Conclusions: Taken together our data demonstrate that loss of cilia in an ARPKD mouse model is not sufficient to slow disease progression. These data suggest that the cyst formation in the liver due to loss of *Pkhd1* is not dependent on the presence of intact cilia.

Funding: NIDDK Support

Primary Cilia Regulate Interstitial Macrophage Proliferation and Polarization in an Acute Kidney Injury Model of Polycystic Kidney Disease

Cheng 'Jack' Song,[1] Kurt Zimmerman,[1] Michal Mrug,[2] Bradley K. Yoder.[1] [1]*Cell Developmental, and Integrative Biology, Univ of Alabama at Birmingham, Birmingham, AL;* [2]*Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: The mechanism responsible for renal cyst formation often involves defects in primary cilia related proteins including intraflagellar transport proteins (e.g., IFT88) or polycystins. Induction of cilia loss in adult mice leads to slow and focal cyst formation; however, rapid cyst formation can be initiated in these mice by ischemic reperfusion (IR) injury. Over the last two decades, studies have demonstrated that inflammatory cells, including macrophages, are involved in the pathogenesis of IR injury suggesting a role for inflammation in IR induced cyst formation.

Methods: To better define the role of macrophage populations prior to and during cyst formation, we studied effects of IR injury in adult induced Ift88^{tm1Bky} (Ift88$^{fl/fl}$), CAGG-Cre/Esr1/5Amc/J (CAGG-CreER) cilia mutant mice.

Results: Following the primary cilia loss, cyst formation began ~14 days following IR and gradually progressed to post-injury day 28. Throughout the time course, there is a persistent increase in the level of pro-inflammatory and pro-fibrotic cytokines including MCP-1, TNF-α, activin A, IL-1β, and TGF-β in the injured cilia mutant mice. We also observed significantly higher number of interstitial resident macrophages at post-injury day 7 (prior to cyst initiation). Compared to controls, resident macrophage subtypes (F4/80^{hi}, CD11b^{lo}, CD11c^{-}) and their proliferation was increased in the cilia mutant mice. Interestingly, membrane bound CSF-1, which is a cytokine responsible for resident macrophage proliferation, was overexpressed in proximal tubule epithelial cells isolated from cilia mutant mice suggesting that cilia on epithelial cells may regulate resident macrophage proliferation and kidney repair after injury.

Conclusions: In conclusion, defects in communication between cilia containing epithelial cells and resident macrophages through upregulated CSF-1 results in persistent resident macrophage proliferation that contributes to initiation and progression of polycystic kidney diseases.

Tubule-Expressed Mcp-1 Promotes Macrophage Homing and Cyst Growth in Polycystic Kidney Disease (PKD)

Marcelo Ferreira Cassini, Arnaud Marlier, Elizabeth Y. Chen, Lonnette Diggs, Kyung Pyo Kang, Tinika Anita Montgomery, Ming Ma, Stefan Somlo, Lloyd G. Cantley. *Internal Medicine, Yale School of Medicine, New Haven, CT.*

Background: Macrophages accumulate around cysts in models of polycystic kidney disease (PKD), and macrophage depletion with clodronate has been shown to slow cyst growth. Macrophage chemoattractant protein-1 (MCP1) is highly expressed in orthologous mouse models of ADPKD and by polycystin-1 null renal tubular cells in culture, leading us to hypothesize that loss of tubular cell PC1 leads to over-expression of MCP1 and promotes MCP1 receptor (CCR2) dependent macrophage homing and cyst growth.

Methods: *Mcp1*$^{(fl/fl)}$*;Pkd1*$^{(fl/fl)}$*;Pax8TetOn-Cre* mice (termed DKO) were generated and induced from 4-6 weeks of age with doxycycline to simultaneously knock-out tubular cell MCP-1 and PC1 expression and compared to *Pkd1*$^{(fl/fl)}$*;Pax8TetOn-Cre* mice (SKO) induced at the same age. Some SKO mice were given daily IP injections of the CCR2-antagonist INCB3344 for 6 weeks beginning at the completion of doxycycline induction. Kidneys were analyzed at 12 weeks of age.

Results: DKO mice demonstrated significantly reduced Mcp1 expression, macrophage numbers, kidney weight/body weight, cystic index, and BUN at 12 weeks of age (table 1) with improved survival at 18 weeks (94% vs. 50%).

*p<0.05 **p<0.01 ***p<0.001

12 weeks of age	n	*Mcp-1* expression (dCt)	Macrophage number (%)	Kidney/ Body ratio	Cystic Index (%)	BUN (mg/ dL)
SKO	5	0.1705 (+/- 0.013)	22.47 (+/-2.11)	0.0592 (+/- 0.013)	38.88 (+/- 2.23)	53.6 (+/- 3.7)
DKO	8	0.0207 (+/- 0.013)***	2.97 (+/- 0.75)***	0.0127 (+/-0.003)**	22.32 (+/-2.25)*	35.1 (+/- 3.0)*
SKO (Vehicle)	5	NA	NA	0.0571 (+/- 0.009)	38.04 (+/- 2.13)	44.7 (+/- 3.8)
SKO (INCB3344)	6	NA	NA	0.0191 (+/-0.007)**	25.65 (+/-2.37)*	26.9 (+/- 1.3)*

Similarly, daily injection of INCB3344 resulted in a significant decrease in cyst growth and BUN at 12 weeks of age as compared to vehicle controls.

Conclusions: The Mcp1-CCR2 pathway appears to be critical for macrophage homing to murine polycystic kidneys and interruption of this pathway slows cyst growth and loss of renal function.

SA-OR079

Investigating the Role of T Cells in Autosomal Dominant Polycystic Kidney Disease Progression

Emily K. Kleczko, Kenneth H. Marsh, Michel Chonchol, Raphael A. Nemenoff, Katharina Hopp. *Univ of Colorado Denver - AMC.*

Background: While ADPKD is the most common monogenic renal disease, no treatment exists to slow its progression. Much research has focused on aberrations in epithelial cell signaling, but little is known about the role of the microenvironment in disease progression. Specifically, the role of T lymphocytes in ADPKD is unknown.

Methods: We used flow cytometry and immunofluorescence to identify distinct immune cell populations in mouse models of ADPKD. We used the slower progressing *Pkd1* p.R3277C (RC) model in the C57Bl/6,129S6, and Balb/c strain, which show increasing disease severity, respectively, and the rapidly progressive *Pkd1*$^{RC/-}$ model in the C57Bl/6 strain.

Results: We observed a significant increase in immune cells in all ADPKD mice compared to their respective wildtype mice. In the *Pkd1*$^{RC/-}$ model at P20, this increase was primarily mediated by macrophages, while in 9-month-old *Pkd1*$^{RC/RC}$ mice, the increase was driven by T lymphocytes (CD4 and CD8 T cells), which accumulated around cystic lesions. Importantly, the increase in T cell populations correlated with severity of disease. We also observed higher numbers of T regulatory cells (T_{Regs}) in the *Pkd1*$^{RC/RC}$ model, which generally are immunosuppressive. In a preliminary experiment, antibody depletion of CD8+ cells from 1-3 months in C57Bl/6 *Pkd1*$^{RC/RC}$ mice, resulted in a significant increase in %kidney weight/body weight compared to IgG-control, suggesting a protective role for CD8 cells in ADPKD progression. Furthermore, *Pkd1*$^{RC/RC}$ CD8 and epithelial cells expressed more PD1 and PD-L1 respectively, indicating activation of an immune checkpoint, leading to inhibition of CD8 function. Targeting this pathway has shown great promise as a cancer therapeutic, and antibodies against PD1 and PD-L1 have been approved by the FDA for multiple cancers.

Conclusions: Together, these data indicate that T cells are upregulated in ADPKD and likely play an important role in slowly progressive cystogenesis. Here, CD8 cells may play an important protective role, which could be disrupted by checkpoint activation, hence leading to more rapidly progressive disease. Targeting T cells may represent a novel therapeutic approach to inhibit ADPKD progression.

New In Vitro Model for the Study of Phenotypes Associated with Polycystic Kidney Disease: "Pseudonephrons" and "Pseudovessels" Generation

Vanesa Calviño,[1] Carmen Rial-Tubio,[2] Candido Diaz-Rodriguez,[1] Alvaro Gil,[2] Miguel A. Garcia-Gonzalez.[1] *[1]Group of Genetics and Developmental Biology of Renal Diseases, Health Research Inst of Santiago de Compostela (IDIS), Santiago de Compostela, Spain; [2]Inst of Ceramics (Univ of Santiago de Compostela-USC), Santiago de Compostela, Spain.*

Background: Polycystic kidney disease (PKD) is a group of genetic disorders that cause renal failure and are originated by abnormal tubular morphology by the presence of multiple cysts along the nephron. PKD is associated with other extrarenal manifestations (hepatic and pancreatic cysts, aneurysms…). Up to the moment, *in vitro* studies of PKD are based on 2 dimensional (2D) culture or 3 dimensional (3D) collagen culture. An *in vitro* culture model that mimic the shape or the arrangement of cells, cell-to-cell junctions or extracellular matrix environment (ECM) applying a fluid shear stress (FSS) is essential to replicate more accurately the *in vivo* conditions.

Results: We have developed a 4 dimensional (4D) culture where flow is the fourth dimension. This model is based on creation of channels embedded in collagen by 3D bioprinting of filaments of gelatin (within or without cells). This gelatin is a temporary material that leaves a hollow channel inside collagen where cells can grow. This technic allow us replicated pseudonephrons and pseudo-blood vessels to monitor different mechanisms related to cell flow sensing and orientation/organization. We have designed a device where can to apply a flow through these channels. We were able to print in a tube different serial nephron segment cell types, identifying phenotypical specific characteristics like ciliated cells. Same strategy was applied for endothelial and epithelial cells, and extended to immortal conditional primary cells derived from Pkd mouse models, allowing us to induce the inactivation of pkd genes.

Conclusions: This new 4D model of collagen channels will allows to study molecular mechanisms underlying cystogenesis and aneurysms, in a context where flow can be apply and mutations can be induce under controlled mimicking in vivo conditions.

Cross Talk between Myostatin and BMP Signaling Regulates Muscle and Bone Mass in CKD

Liping Zhang, Zihong Chen, William E. Mitch. *Nephrology Div, Baylor College of Medicine, Houston, TX.*

Background: metabolic defects in CKD include losses of muscle and bone but if and how these defects are linked. We have found that muscle of CKD mice expresses myostatin to cause muscle wasting and now we examine if myostatin-induced intracellular signaling interacts with bone morphogenetic protein (BMP) signaling, regulates muscle and bone mass.

Methods: CKD mice with BUN >80 mg/dL were treated with an antimyostatin peptibody. We monitoring body weight, bone mass, mineral density and muscle strength. Cell signaling pathways were assessed in C2C12 myoblasts and MC3T3 osteoblast cells.

Results: mice with CKD had increased myostatin expression but decreased muscle mass and reduced bone mineral density. When the peptibody blocked myostatin in mice with CKD, both body weight and bone mineral density (g/cm^2) were 18% higher vs. CKD mice treated with PBS. Skeletal muscle mass was increased 15-32% and blood glucose was decreased as was glucose tolerance. There were no changes in fat mass vs. control, CKD mice. Muscle grip strength of myostatin-blocked, CKD mice were 21% higher vs CKD mice treated with PBS. The changes were independent of serum PTH levels. To explain how myostatin changes both muscle and bone, we examined tissue lysates and found that the peptibody decreased p-Smad2/Smad3 and increased p-Smad1/5, p-S6, p-mTOR, and p-Akt in both tissues of mice with CKD. We hypothesized that myostatin could influence bone responses by changing BMP signaling. It was tested in both C2C12 myoblasts or MC3T3 osteoblastswhen myostatin production was blocked using a SiRNA to myostatin. In the absence of myostatin, both osteoblasts and myotubes exhibited increased p-Smad1/5, p-mTOR, p-Akt plus the differentiation of both osteoblasts and myotubes. Likewise, treatment of myotubes with recombinant BMP7 produced increases in p-Smad1/5, mTOR and p-Akt.

Conclusions: our results indicate that in CKD mice, myostatin exhibits cross talk with BMP to regulate intracellular signaling, inhibiting differentiation of myoblasts and osteoblasts. The result is reduced muscle and bone mass. Anti-myostatin peptibody may be a potent therapeutic strategy for improving muscle and bone growth in CKD.

A Ligand of the Activin Receptor Type IIA Mediates Osteoclast Stimulation of Bone Remodeling in Diabetic Mice with CKD

Toshifumi Sugatani,[1] Yifu Fang,[1] Hartmut H. Malluche,[2] Keith A. Hruska.[1,3] *[1]Renal Div, Pediatrics, Washington Univ, Saint Louis, MO; [2]Renal Div, Medicine, Univ of Kentucky, Lexington, KY; [3]Renal Div, Medicine, Washington Univ, Saint Louis, MO.*

Background: Dysregulation of skeletal remodeling is a component of renal osteodystrophy. We have reported that activin receptor signaling is differentially affected in various tissues in CKD, and here, using a ligand trap for the activin receptor type 2A (RAP-011), we demonstrate that inhibition of skeletal activin receptor signaling has efficacy in the CKD-MBD osteodystrophy.

Methods: CKD, with 70% reduction in GFR, was induced at 14 weeks of age in the *ldlr-/-* high fat fed model of atherosclerotic vascular calcification and diabetes. CKD mice, with hyperphosphatemia, hyperparathyroidism, and elevated activin A, were treated with RAP-011 10mg/kg (n=20) or vehicle (Veh, n=19), injected SC twice weekly beginning at 22 weeks of age until euthanasia at 28 weeks and study by skeletal histomorphometry, micro CT, mechanical testing and *ex vivo* bone cell cultures.

Results: Results were compared to sham operated *ldlr-/-* high fat fed mice (Sham, n=16). Sham mice had a low-turnover osteodystrophy and skeletal frailty that was converted by CKD to a higher turnover bone remodeling state with increases in osteoclast and osteoblast numbers and bone resorption, p<0.01. RAP-011 treatment eliminated the CKD induced increase in these histomorphometric parameters and increased trabecular bone fraction compared to CKD and sham mice. RAP-011 increased cortical bone area and thickness, p<0.05. Activin A enhanced osteoclastogenesis was mediated through p-smad2 association with c-fos and activation of NFATc1.

Conclusions: In conclusion, an ActRIIA ligand trap reversed CKD stimulated bone remodeling, likely through inhibition of activin A induced osteoclastogenesis.

In Uremic Rats, the Calcimimetic Maintains Bone Turnover in a Parathyroid Hormone-Independent Manner

Mariano Rodriguez,[1] Juan M. Diaz Tocados,[1] Maria Encarnacion Rodriguez Ortiz,[2] Yolanda Almaden Peña,[3] Carmen Pineda,[4] Eduardo C. Salido,[5] Victor Lorenzo,[5] Catarina Carvalho,[6] Joao M. Frazao,[6] Juan R. Munoz-Castaneda,[1] Escolastico Aguilera-Tejero,[4] Ignacio Lopez.[4] *[1]Nephrology S., IMIBIC/R Sofia Univ Hosp, REDinREN, Cordoba, Spain; [2]Nephrology L., IIS-F Jiménez Díaz, Madrid, Spain; [3]Lipid-Atherosclerosis, IMIBIC/R Sofia Univ Hosp, CIBEROBN, Cordoba, Spain; [4]Med and Anim Surg, UCO, Cordoba, Spain; [5]Nephrology S., Univ Hosp, Tenerife, Spain; [6]Nephrology-Inf. Res. Group, INEB/I3S, Porto, Portugal.*

Background: Calcimimetics decrease PTH secretion resulting in reduction of bone turnover. Here we evaluated the effects of CaSR activation by calcimimetic (AMG641) on bone in uremic rats with clamped high PTH levels.

Methods: Rats on a 0.9%P, 0.6 %Ca diet were divided in four groups: **Sham**; **5/6Nx**; **5/6Nx+PTx+PTH** (5/6Nx rats underwent parathyroidectomy and received constant infusion of PTH and vehicle) and **5/6Nx+PTx+PTH+AMG641**. After 28d, animals were euthanized and blood and bone were collected. Mineralization was assessed by double-calcein labeling.

Results: In 5/6Nx, PTH increased, bone volume decreased and bone turnover was augmented as compared with sham. In 5/6Nx+PTx+PTH rats, AMG641 increased bone cells activity , while bone volume was similar vs vehicle. Moreover, bone formation rate was slight but not significantly higher in rats on AMG641 than vehicle.

	Sham	5/6Nx	5/6Nx+PTx+PTH	5/6Nx+PTx+PTH+AMG641
	n=5	n=7	n=8	n=5
BV/TV (%)	30.9±1.75	21.3±1.28[a]	20.6±2.29[a]	20.1±1.21[a]
OS/BS (%)	2.89±1.01	20.7±2.06[a]	13.9±2.39[a]	23.3±1.27[ac]
Ob.S/BS (%)	0.27±0.11	13.0±0.99[a]	4.36±0.46[b]	11.7±1.44[ac]
Oc.S/BS (%)	1.02±0.20	6.42±1.22[a]	2.25±0.42[b]	5.23±1.38
BFR/BS (%/year)	192±5.80	463±46.4[a]	253±28.6[b]	379±24.6[a]

Bone Histomorphometry. Values are mean±SEM. [a]p<0.05 vs Sham; [b]p<0.05 vs 5/6Nx; [c]p<0.05 vs 5/6Nx+PTx+PTH. **BV**: Bone Volume. **TV**: Tissue Volume. **OS** Osteoid Surface. **BS**: Bone Surface **Ob.S**: Osteoblast Surface **Oc.S**: Osteoclast Surface. **BFR**: Bone Formation Rate.

Conclusions: In conclusion, the calcimimetic AMG641 increases bone turnover in uremic rats with clamped PTH. These results are in agreement with in vitro studies that demonstrate a bone anabolic effect of CaSR activation.

SA-OR084

Metabolic Acidosis Increases IFRD1 Expression in Primary Mouse Osteoblasts

Nancy S. Krieger, Sean D. Deboyace, Felix M. Ramos, David A. Bushinsky. *Medicine, Univ of Rochester School of Medicine, Rochester, NY.*

Background: Chronic metabolic acidosis (MET), a systemic increase in proton concentration [H^+], stimulates cell-mediated net calcium (Ca) efflux from bone. This Ca efflux is mediated primarily through increased osteoblastic cyclooxygenase 2, leading to prostaglandin E_2-induced stimulation of RANKL and increased osteoclastic bone resorption.

The response to MET is initiated through OGR1, a specific osteoblastic proton receptor, which results in increased intracellular Ca. To further understand the intracellular signaling events involved in the osteoblastic response to MET, we utilized primary osteoblasts to study potentially important gene expression pathways, including IFRD1, interferon-related developmental regulator 1. IFRD1 modulates the wnt/β-catenin signaling pathway and has recently been shown to play a pivotal role in activating osteoclastic bone resorption.

Methods: Confluent osteoblastic cells isolated from neonatal mouse calvariae were incubated in neutral (NTL, pH=7.50, Pco_2=39 mmHg, [HCO_3^-]=30 mM) or acid (MET, pH=7.20, Pco_2=39 mmHg, [HCO_3^-]=14 mM) medium up to 24h. Specific RNA gene expression was analyzed by real time PCR with expression normalized to RPL13A and calculated relative to non-incubated cells.

Results: MET-induced significant stimulation of IFRD1 mRNA expression in osteoblasts after 6h in culture (NTL=1.60±0.08 vs MET=1.95±0.11, p<0.05). We have previously shown that MET-induced bone resorption, as well as MET induced stimulation of FGF23 is inhibited by treatment with 50 μM 2-APB, which blocks intracellular Ca signaling or by treatment with 1 μM NS398, which blocks cyclooxygenase 2, both integral steps in MET stimulation of bone resorption. Comparable inhibition of MET-induced IFRD1 was also observed after incubation of osteoblasts with 2-APB or NS398.

Conclusions: Thus, IFRD1, a transcription factor which modulates the wnt/β-catenin pathway, was stimulated by MET and may be important in the mechanism of MET-induced bone resorption as well as MET-induced stimulation of FGF23 production. These results suggest that the wnt/β-catenin pathway could be a therapeutic target to decrease MET-induced bone loss.

The Association between Skeletal Muscle Mass Surrogates and the Risk of Bone Fracture in Patients Undergoing Hemodialysis: The Q-Cohort Study Shunsuke Yamada,[1] Masatomo Taniguchi,[3] Masanori Tokumoto,[2] Narihito Tatsumoto,[1] Hideki N. Hirakata,[3] Takanari Kitazono,[1] Kazuhiko Tsuruya.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Dept of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [3]Fukuoka Renal Clinic, Fukuoka, Japan.*

Background: CKD is an independent risk factor for bone fracture. There is a close interplay between bone and skeletal muscle. It still remains unknown whether lower skeletal muscle mass increases the risk of bone fracture in hemodialysis (HD) patients.

Methods: The present study was an prospective, observational study consisting of 3030 outpatients undergoing HD. As surrogates of skeletal muscle mass, we used both serum creatinine (Cr) and Cr index. Cr index was calculated using age, sex, serum Cr level, and Kt/V for urea. The association between the incidence of bone fracture and the baseline creatinine (Cr) index or serum Cr level was examined. Patients were stratified by sex-specific quartiles based on serum Cr or Cr index. Cox proportional hazard model was used for analyses.

Results: During the median observational period of 3.9 years, 140 patients developed bone fracture. In the multivariable analysis, the risk of bone fracture was significantly higher in the lowest Cr index quartile (Q1) compared to the highest Cr index quartile (Q4) as the reference value in both male and female (multivariable-adjusted hazard ratio [95% confidence intervals]: men; Q1, 6.26 [1.87-23.66]; Q2, 4.33 [1.49-14.62]; Q3, 1.68 [0.55-5.75]; Q4, 1.00; *P*=0.008 for trend, women; Q1, 4.25 [1.45-13.77]; Q2, 3.00 [1.19-8.23]; Q3, 1.92 [0.81–4.93]; Q4, 1.00; *P*=0.007 for trend). Similarly, lower serum Cr level was associated with the increased risk of bone fracture in both men and women. Effects modification regarding the association between bone fracture and Cr index or serum Cr level was not observed across baseline characteristics.

Conclusions: Lower skeletal muscle mass surrogates were associated with the increased risk of bone fracture in HD patients. Further studies are required to know whether maintaining skeletal muscle mass prevents bone fracture in HD population.

SA-OR086

Progression of Medial Arterial Calcification in End-Stage Renal Diseaase W. Charles O'Neill, Shumila Manzoor, Syed Mustafa Ahmed. *Renal Div, Emory Univ, Atlanta, GA.*

Background: Medial arterial calcification is an important lesion in end-stage renal disease (ESRD) but little is known about its progression and the effect of different treatments because of the inability of previous studies to quantify it and distinguish it from atherosclerotic calcification. Breast arterial calcification, which is readily apparent on mammograms (MGs), exclusively medial, and correlates with peripheral arterial calcification and clinical outcomes, provides a unique opportunity to follow the progression of medial calcification.

Methods: Women with at least 2 MGs performed while receiving hemodialysis (HD) or peritoneal dialysis (PD), or after renal transplantation were identified from a computerized search of medical records. Warfarin use was an exclusion. Lengths of calcified arteries were summed and expressed as mms per breast (+/- SE). Intraobserver and interobserver correlations were 0.99 and 0.98, and interstudy variability was 9.8%. Significance was by nonparametric testing.

Results: Progression of breast arterial calcification (BAC) was 8.7 +/- 4.4 mm/y pre-ESRD (mean: 0.36 yrs; n=30) and 30.4 +/- 7.1 mm/y during HD (n=42; p<0.01). The rate during PD was 4.7 +/- 2.5 mm/y (n=24) and did not differ from the pre-ESRD rate. To exclude other patient effects, rates were compared in the same patients before and after initiation of HD and increased from 3.6 +/- 1.8 to 18.9 +/- 8.8 mm/y (n=17; p<0.05). Progression was less frequent (25% vs. 95%) and slower (3.5 +/- 1.5 vs. 44.9 +/- 11.4 mm/y) in patients with no baseline BAC, but was still greater during HD (4.5 +/- 2.2 mm/y) than PD (1.3 +/- 0.8 mm/y; p=0.01). After renal transplantation, BAC rate was 3.8 +/- 1.8 mm/y (n=27; mean serum creatinine 1.17 +/- 1.2 mg/dl), less than the pre-ESRD rate (p<0.01). There was no significant reversal of BAC in any patient.

Conclusions: Medial arterial calcification accelerates in patients on hemodialysis but not peritoneal dialysis. Renal transplantation slows progression to below pre-ESRD rates but does not reverse calcification. These results indicate that hemodialysis or related factors promote medial arterial calcification and that calcification persists when normal renal function is restored.

Small Vessel and Soft Tissue Histology in End-Stage Renal Disease: Specificity of Diagnostic Criteria for Calciphylaxis Carla L. Ellis,[1] W. Charles O'Neill.[2] *[1]Pathology and Laboratory Medicine, Emory Univ, Atlanta, GA; [2]Renal Div, Dept of Medicine, Emory Univ, Atlanta, GA.*

Background: Calciphylaxis (calcific uremic arteriolopathy) is a rare disease characterized by skin ulceration and tissue necrosis presumably resulting from vascular calcification that typically occurs in end-stage renal disease (ESRD). Histologic criteria include intimal hypertrophy, medial calcification, and/or thrombosis of small arteries, and extravascular (soft tissue) calcification, but their specificity is unknown. These features were examined in tissue from the margins of amputations performed in ESRD patients.

Methods: 26 amputations above (11) and below (15) the knee in 21 ESRD patients were identified from pathology records for 2014-2015. Sections from the margins were retrieved and both H & E and von Kossa stains were prepared and reviewed by a single pathologist. Chart review was performed by a single nephrologist.

Results: None of the patients had a clinical presentation suggestive of calciphylaxis. Average age was 63.7 years (range 43-83), 16 (76%) were male, 14 (67%) had diabetes, and 5 (24%) were treated with warfarin. Bulky, large vessel calcifications were identified in 24/26 (92%) of specimens, consistent with peripheral arterial disease (PAD). However, 8/26 (31%) also showed dermal/epidermal arteriolar calcification, and 11/26 (42%) showed extravascular soft tissue calcification. Intimal hyperplasia and small vessel thrombosis were observed in 3 and 4 cases respectively (12 and 15%). Arteriolar calcification and thrombosis were observed in 5 and 3 of the 13 patients with diabetes mellitus but only 1 and none of the 8 patients without diabetes. There was no association with warfarin use.

Conclusions: Histopathologic findings historically associated with calciphylaxis on skin biopsies can also be seen in viable tissue from unaffected ESRD patients. While the results are not necessarily applicable to patients without PAD, they do indicate that histologic findings ascribed to calciphylaxis can be seen in the absence of clinical manifestations, particularly in diabetics. This calls into question the specificity of the histologic diagnosis of calciphylaxis.

SA-OR088

Gli1+ Adventitial MSC Are Vascular Smooth Muscle Cell Progenitors and Key Drivers of Vascular Calcification in CKD Rafael Kramann,[1] Janewit Wongboonsin,[2] Nadine Kaesler,[1] Christoph Kuppe,[1] Benjamin D. Humphreys.[2] *[1]Div of Nephrology, RWTH, Aachen, Germany; [2]Div of Nephrology, Washington Univ, St. Louis.*

Background: We recently demonstrated that Gli1 expression defines perivascular mesenchymal stem cells (MSCs). A role for adventitial MSCs in vascular injury, repair and calcification has been hypothesized but the absence of a specific *in vivo* marker for MSCs has prevented progress.

Methods: We used genetic lineage analysis to trace the fate of $Gli1^+$ cells in Gli1CreER;tdTomato mice subjected to femoral artery wire injury. Triple transgenic Gli1CreER;tdTomato;ApoEKO and Gli1CreER;iDTR,ApoEKO mice subjected to subtotal nephrectomy or sham surgery followed by western diet versus standard chow were used for fate tracing and ablation experiments during vascular calcification.

Results: We demonstrate that FACS isolated adventitial $Gli1^+$ cells are MSC that can differentiate into mature VSMCs *in vitro*. Single cell qPCR of adventitial $Gli1^+$ cells indicates a heterogeneous population that gradually loses expression of progenitor markers and acquires expression of VSMC markers. *In vivo* genetic fate tracing experiments demonstrate that adventitial $Gli1^+$ MSC migrate into the vascular media to become mature VSMCs during aging. Following acute injury to the femoral artery >50% of newly formed VSMCs in media and neointima are derived from adventitial $Gli1^+$ MSC. During chronic arterial injury with vascular calcification $Gli1^+$ cells robustly migrate into media and neointima where they differente into $Runx2^+$ calcifying vascular cells (CVCs). Costaining experiments with markers of secretory and contractile VSMCs suggest that $Gli1^+$ cells first acquire a VSMC phenotype but subsequently maldifferentiate to CVCs during vascular calcification. Genetic ablation of $Gli1^+$ cells by diphtheriatoxin before onset of CKD in Gli1CreER;tdTomato;ApoEKO mice completely abolished calcification of both media and intima.

Conclusions: Adventitial $Gli1^+$ MSC are progenitors of VSMCs during aging and acute arterial injury repair. However, in CKD with vascular calcification $Gli1^+$ cells are the key progenitors of CVCs in media and intima. They represent an important and novel therapeutic target.

SA-OR089

Coronary Calcification and Mortality in Patients with Advanced Chronic Kidney Disease: A 10-Year Follow-Up Marta Cano Megías,[1] María Perez Fernandez,[1] Gabriel De Arriba,[2] Diego Rodriguez Puyol,[1] Concepcion Alvarez Sanz,[4] Patricia De Sequera,[3] Hanane Bouarich.[1] *[1]Nephrology, Hospital Univ Principe de Asturias, Alcalá de Henares, Madrid, Spain; [2]Nephrology, Hospital Univ de Guadalajara, Guadalajara, Spain; [3]Nephrology, Hospital Univ Infanta Leonor, Madrid, Spain; [4]Radiology, Hospital Univ Principe de Asturias, Alcalá de Henares, Madrid, Spain.*

Background: Haemodialysis and advanced CKD patients have a higher prevalence of coronary calcification (CC) than general population. Previous studies have suggested a potential predictive value of CC on mortality, regardless of traditional cardiovascular (CV) risk factors. However, this mortality predictive ability is not well defined in long-term follow-up in CKD population.

Methods: A 10-year prospective longitudinal study was conducted in 137 CKD patients (stage IV-V and dialysis). A non-enhanced multi-slice coronary computed tomography was performed at baseline. CC was assessed with the Agatston method. Patients were stratified according to its coronary calcium score (CCS): CCS<400, n=53;and CCS≥400,n=84. Patients were followed for median 88 months (30-111), all-cause and CV mortality were recorded.

Results: The median age was 66 years. The median CCS was 600 (70-1794). The overall mortality rate was 58% (40% to CV events). Patients with severe calcification (CCS≥400) showed higher total and CV mortality than those with lower calcification (CCS<400); 75% vs. 30% and 34,5% vs. 5,6% respectively (p<0.001). Patients with CCS≥400, were older, have a previous history of type 2 DM and cardiac events, and lower serum albumin levels. In a multivariate Cox model, severe CCS (≥400) was a significant predictor of total mortality in haemodialysis patients (HR 4.12; 95%CI 1.83 to 9.3,p=0.001), whereas it reached significance in the CV mortality in the whole serie (HR 5.01; 95%CI 1.28 to 19.59,p=0.02). The Kaplan-Meier curves of total and CV mortalities were statistical different according to CCS (p<0,001).

Conclusions: During 10-years follow-up period mortality rate was higher among patients with severe coronary calcifications, especially CV mortality. Coronary calcifications might be a proper marker to estimate cardiovascular risk in CKD patients.

SA-OR090

Assessment of Arterial Calcification, Vascular Inflammation, Bone Mineral Density and Metabolism Using Fluorodeoxyglucose-PET/CT in Patients on Maintenance Dialysis: Focused on Relationship with PTH Level Young-Joo Kwon, Jieun Kim, Gang Jee Ko, Yoonkyung Song. *Div of Nephrology, Korea Univ, Seoul, Republic of Korea.*

Background: Aims of our study are to find factors associated with, and relationships between, aortic and coronary vascular calcification, vascular inflammation, vertebral bone mineral density(VBMD) and bone metabolism in patients on maintenance dialysis with FDG PET-CT, focused on the relationships with PTH level. Furthurmore, we tried to assess simple X-ray methods in predicting vascular calcification scores.

Methods: Thirty patients on hemodialysis (HD, n=15) or peritoneal dialysis (PD, n=15) were enrolled (both >6month). Calcification scores of thoracic (TCS), abdominal (ACS), total aorta (TACS), coronary arteries (CCS) were assessed by Agatston method. Right carotid SUV and target-to-background-ratio(CSUV/CTBR) was used for vascular inflammation measurement and L-spine maximal SUV(MSUV) for bone metabolism. VBMD was measured as 'trabecular' and 'total' by single slice QCT method. Patients were classified into 3 groups based on K/DOQI and KDIGO PTH target level. In addition, L-spine lateral and chest PA/Lateral films were used to assess various scoring methods in predicting CT-based scores.

Results: Significant calcification was found in 93%(aorta) and 62%(coronary) of the patients. The calcification scores were significantly related to one another. CCS correlated with HbA1c, and was higher in HD patients. Aortic calcification score(AC) was associated with age and serum calcium level. 'Optimal' PTH group by KDOQI tended to have lower CCS and AC. VBMD was only related to duration of dialysis. MSUV was not related to other variables. CSUV/CTBR correlated with LDL level. Simple X-ray scores well correlated with AC.

Conclusions: It seems reasonable to maintain optimal PTH levels according to KDOQI, not KDIGO guideline, in terms of vascular calcification. Our patients on maintenance dialysis had no significant vascular inflammation but showed highly prevalent vascular calcifications. The relationship between bone mineral density/bone metabolism and vascular calcification is unclear by FDG-PET/CT. Simple X-ray methods can predict CT-based aortic calcification scores.

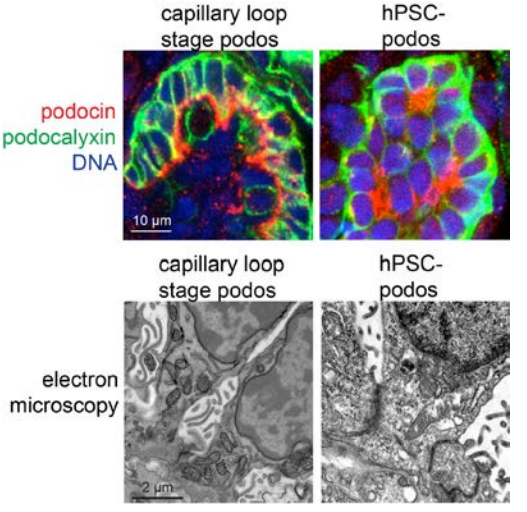
Modeling Podocyte Development with Human Kidney Organoids Derived from Pluripotent Stem Cells Yong Kyun Kim,[1] Ramila E. Gulieva,[1] Stefan Czerniecki,[1] Nelly M. Cruz,[1] Laura V. Islas,[1] Craig R. Brooks,[2] Benjamin S. Freedman.[1] *[1]Div of Nephrology, Kidney Research Inst, and Inst for Stem Cell and Regenerative Medicine, Dept of Medicine, Univ of Washington, Seattle, WA; [2]Renal Div, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: Podocytes derived from human pluripotent stem cells (hPSC-podos) have recently been generated in kidney organoids, with great potential for modeling complex development and regeneration. We investigated the structure and function of hPSC-podos, compared to developing mammalian podocytes.

Methods: hPSC-podos in kidney organoids were analyzed by confocal immunofluorescence and transmission electron microscopy. CRISPR/Cas9 was applied to hPSCs to knock out podocalyxin, a heavily sialylated podocyte glycoprotein. Kidney sections from wild-type or *Podxl*$^{-/-}$ mice were also examined.

Results:



Localization of nephrin, podocin, synaptopodin, podocalyxin, and WT1 in kidney organoids closely resembled developing capillary loop stage podocytes *in vivo*. Ultrastructurally, hPSC-podos formed basement membrane junctional domains containing slit diaphragm components. The apicolateral membranes of hPSC-podos were covered with microvilli and podocalyxin, and did not form junctions. Genetic knockout of podocalyxin resulted in ablation of apicolateral microvilli and failure of junctional components to migrate basally. These features precisely phenocopied developing mammalian podocytes in wild-type and *Podxl*$^{-/-}$ mice.

Conclusions: hPSC-podos *in vitro* correspond to capillary loop stage podocytes *in vivo*. Podocalyxin-mediated microvillus formation regulates podocyte cell spacing and junctional migration in mouse and man. The capacity of hPSC-podos to reveal and recapitulate developmental mechanisms makes them a powerful new tool for kidney disease modeling and regeneration. (Supported by Northwest Kidney Centers).

Localized mRNA Translation Mediated by Staufen Is a Novel Mechanism Regulating Cytoskeletal Reorganization in Response to Podocyte Injury Valerie A. Schumacher,[1] Jessica J. Harris,[1] Astrid Weins,[2] Britta George,[3,4] Benjamin D. Humphreys,[5] Shuang Yang.[1,6] *[1]Urology, Boston Children's Hospital, Boston, MA; [2]Pathology, Brigham and Women's Hospital, Boston, MA; [3]Renal-Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA; [4]Medizinische Klinik und Poliklinik D, Universitätsklinikum Münster, Muenster, Germany; [5]Renal Div, Washington Univ School of Medicine, St. Louis, MO; [6]Medical College of Nankai Univ, Tianjin, China.*

Background: Podocytes sometimes recover from foot process effacement indicating that there is an intrinsic plasticity inherent in foot process architecture. Our study focuses on the role of localized mRNA translation as a mechanism to dynamically regulate reorganization of the actin cytoskeleton in foot processes and modulate podocyte cell-matrix adhesion, thereby maintaining the glomerular filtration barrier during injury.

Methods: A cell biological and gene targeting approach was used to study the role of local mRNA translation in podocytes.

Results: We show that the RNA-binding protein Staufen2, previously demonstrated to mediate RNA transport and localized translation in neurons, is expressed in podocytes and localizes to focal adhesions *in vitro* and foot processes *in vivo*. Moreover, Staufen2 and translating ribosomes are increased in areas of foot process effacement. Next, we show that Staufen2-bound RNAs in podocytes are enriched for cytoskeletal assembly and cell-matrix adhesion regulators, one example being the GEF *Dock5*. *Stau2* knockdown in immortalized

podocytes affects *Actb* mRNA localization and *Dock5* mRNA stability and results in cell detachment as well as impaired re-establishment of actin stress fibers upon recovery from injury. Lastly, we generated *Stau2* single and *Stau1/2* double knockout (DKO) mice; these mice had normal baseline kidney function but DKO mice developed massive proteinuria and foot process effacement in response to Adriamycin, far greater than observed in control, or *Stau1* and *Stau2* single knockouts.

Conclusions: Localized mRNA translation mediated by Staufen represents a novel mechanism to regulate cytoskeletal reorganization and cell-matrix adhesion in response to podocyte injury.

Novel Mat of Contractile Actin Filaments Formed at the Base of Podocytes during the Process of Foot Process Effacement

Hani Suleiman,[1] Jeffrey H. Miner,[1] Andrey S. Shaw.[2] *[1]Renal Devision, Washington Univ, Saint Louis; [2]GenenTech, San Francisco.*

Background: Because the diffraction limit of light microscopy restricts the resolution of structures smaller than 200 nm such as podocyte foot processes and slit diaphragms, imaging the podocyte cytoskeleton is challenging. Traditional tissue preparation methods don't preserve the actin cytoskeleton enough, further restricting our ability to view changes after podocyte injury. We developed a new method of cytoskeletal preservation that allowed us to image actin and actin-associated molecules in kidney glomeruli. 2D and 3D superresolution imaging enabled us to study the architecture of the podocyte in normal and diseased states.

Methods: Two superresolution methods, STORM and Airyscan, were used to study the changes of the podocyte foot process in healthy and injured mouse glomeruli. Antibodies used are: synaptopodin (synpo), α-actinin-4 (Actn4), myosin IIa (myh9), nephrin, podocin.

Results: Synpo and Actn4 stained the center of healthy podocytes foot processes, while nephrin and podocin labeled between the foot processes. In injured podocytes, slit diaphragm proteins moved apically inside the effaced foot processes. While synpo and Actn4 clusters did not change upon injury, there was robust recruitment of myh9 to the base of the podocytes. Myh9 stained in alternating stripes with synpo and Actn4, suggesting the formation of contractile actin fibers during podocyte foot process effacement. 3D superresolution imaging confirmed that myh9 is part of sarcomere-like structures near the GBM in different injury models. In contrast, normal podocytes show myh9 staining only in primary podocyte processes. En face views of effaced foot processes showed that myh9, intertwined with synpo, covered the entire effaced area.

Conclusions: Using a new way of imaging the actin cytoskeleton, we visualized podocyte foot processes in healthy and diseased conditions. In the normal podocyte, contractile actin cables are present in primary processes, while the actin filaments in the foot processes are non-contractile. After foot process effacement, a mat of actin filaments form at the base of effaced podocytes and arrange in a sarcomere-like contractile network near the GBM.

Dynamics and Importance of Slit Diaphragm Molecules in Adulthood

Florian Grahammer,[1] Corinne Antignac,[2] Alessia Fornoni,[3] Jeffrey H. Miner,[4] Tobias B. Huber.[1] *[1]Dept of Medicine IV, Univ Hospital Freiburg, Freiburg, Germany; [2]Laboratory of Inherited Kidney Diseases, Necker-Enfants Malades Hospital, Paris, France; [3]Peggy and Harold Katz Family Drug Discovery Center and Div of Nephrology and Hypertension, Univ of Miami Miller School of Medicine, Miami, FL, Germany; [4]Dept of Internal Medicine, Div of Nephrology, Washington Univ School of Medicine, St. Louis, MO.*

Background: Little is known on the inherent dynamics of the slit diaphragm proteins NEPHRIN, PODOCIN and NEPH1. While constitutive deletion of any of these genes leads to early perinatal lethality adult knock-out has so far only been described for *Nphs2*. We therefore generated inducible, podocyte-specific *Nphs1, Nphs2* and *Neph1* knock-out mice to assess whether adult deletion leads to divergent phenotypes.

Methods: 5 week old, inducible *Nphs1*NEFTA8rtTA*TeTOCre* (*Nphs1$^{\Delta pod}$*), *Nphs2*NEFTA8rtTA*TeTOCre* (*Nphs2$^{\Delta pod}$*) and *Neph1*NEFTA8rtTA*TeTOCre* (*Neph1$^{\Delta pod}$*) mice were treated with oral doxycycline for 7d and were analyzed functionally, biochemically and histologically.

Results: Kinetics of proteinuria considerably differed between the 3 genes. While *Neph1$^{\Delta pod}$* mice were the first to show proteinuria after 7d of treatment, *Nphs2$^{\Delta pod}$* mice followed at 11d. In both lines proteinuria rose quickly. Although proteinuria had reached an ACR of ~70 after 4w in *Neph1$^{\Delta pod}$* no histological changes were detectable, while *Nphs2$^{\Delta pod}$* showed severe glomerulosclerosis. Most interestingly *Nphs1$^{\Delta pod}$* mice despite a knock-out efficacy of 95% on mRNA and protein level at 1w did not show any proteinuria until 5w post induction, after which proteinuria only rose very slightly till 12w where a considerable acceleration could be noted. IF indicated that the remaining NEPHRIN resided within the plasma membrane pointing to potentially different pools of NEPHRIN within podocytes.

Conclusions: Adult inducible knock-out of *Nphs1, Nphs2* and *Neph1* revealed that especially NEPHRIN has a different dynamic and turnover than PODOCIN and NEPH1. While *Nphs2$^{\Delta pod}$* and *Neph1$^{\Delta pod}$* mice developed proteinuria after 50% of their protein content had vanished, *Nphs1$^{\Delta pod}$* mice could maintain a tight barrier with as little as 5% of protein.

Mechanical Overload May Lead to Podocyte Damage by Increasing Podocyte [Ca2+] through TRPC6 Channels and P2Y2 Receptors

Georgina Gyarmati, Ildiko Toma, Janos Peti-Peterdi. *Depts of Physiology and Biophysics, and Medicine, Univ of Southern California, Los Angeles, CA.*

Background: TRPC6 channels are known to be one of the important Ca^{2+} influx pathways. The effect of extracellular nucleotides by the activation of TRPC6 through P2Y receptors on podocyte [Ca^{2+}] has also been reported. However, the molecular mechanism how mechanical overload leads to podocyte injury is still elusive. We aimed to study and quantitatively visualize the dynamic effects of high intra-glomerular capillary pressure, a solely mechanical stimulation on podocyte [Ca^{2+}] and the role of TRPC6 and P2Y2 receptors in mechanosensation.

Methods: Time-lapse high resolution multiphoton microscopy imaging on intact living kidneys and freshly dissected in vitro microperfused glomerulus of wild type (WT), TRPC6 transgenic (TG), TRPC6 knockout (KO), and P2Y2 KO mice was used to directly visualize the changes in podocyte [Ca^{2+}] after acute isolated intra-glomerular capillary pressure elevation. All mice expressed the intensely green calcium indicator, GCaMP3, only in podocytes. Changes in single cell GCaMP3 fluorescence intensity were used as an indicator for podocyte [Ca^{2+}] changes.

Results: Acute intra-glomerular capillary pressure elevation was induced by obstructing the efferent arteriole with laser induced microthrombus in vivo and by a micropipette in vitro. In WT mice GCaMP3 fluorescence intensity in podocytes increased 2.9-fold in vitro and more than 2-fold in vivo as compared to baseline. Podocyte GCaMP3 fluorescence intensity in TRPC6 TG mice increased more than 5-fold. In TRPC6 KO and P2Y2 KO mice the effect of acute mechanical overload on podocyte [Ca^{2+}] was significantly reduced, the increase in GCaMP3 fluorescence intensity was 1.3-fold and 1.41-fold, respectively.

Conclusions: This study demonstrated direct visual evidence of the effect of high intra-glomerular capillary pressure on podocyte [Ca^{2+}] and the important pathological role of TRPC6 channels and P2Y2 receptors in the related podocyte injury. Podocyte TRPC6 and P2Y2 are promising therapeutic targets in conditions with high intra-glomerular capillary pressure, such as diabetic and hypertensive nephropathy for the prevention of CKD.

Dynamic Control of Focal Adhesions in Podocyte Health and Disease

Christoph Schell,[1] Manuel Rogg,[2] Tobias B. Huber.[2] *[1]Univ Hospital Freiburg, Dept of Pathology, Freiburg, Germany; [2]Univ Hospital Freiburg, Internal Medicine, Nephrology, Freiburg, Germany.*

Background: Pericyte-like podocytes form the outer part of the glomerular filter where they have to withstand the enormous transcapillary filtration forces driving glomerular filtration. Detachment of podocytes from the glomerular basement membrane is a common hallmark and final pathway in various glomerular diseases. However, little is known about the regulation of podocyte adhesion in response to continous physical filtration and under disease conditions *in vivo*.

Methods: We screened for podocyte specific focal adhesome (FA) components employing genetic reporter models in combination with iTRAQ-based quantitative mass spectrometry. Applying bioinformatic filtering algorithms allowed for the idenfitication of podocyte specific FA components. Super resolution microscopy (STORM) was employed to validate candidates. In vivo characterization was performed using newly generated mouse models for EPB41L5 and CORO2B. CRISPR/CAS9 genome edited immortalized podocyte cell lines as well as primary podocytes were analyzed *in vitro* using life imaging.

Results: The MS-based FA mapping approach led to the identification of two novel podocyte specific FA components, the FERMT protein EPB41L5 and the WD40 protein CORO2B. Genetic deletion of *EPB41L5 in vivo* resulted in severe proteinuria, detachment of podocytes and development of FSGS. By binding and recruiting the RhoGEF ARGHEF18 to the leading edge EPB41L5 directly controls actomyosin contractility and subsequent maturation of focal adhesions. Furthermore, these effects were mediated in an ECM-dependent manner. Surprisingly, deletion of CORO2B *in vivo* prevented podocyte damage in two different stress models, via modulating focal adhesion disassembly.

Conclusions: Collectively, these observations support a novel concept of podocyte intrinsic balancing of FA turnover to maintain the integrity of the kidney filtration barrier.

SA-OR097

The Podocyte-Specific Induction of Krüppel-Like Factor 15 Attenuates Glomerulosclerosis in FSGS

Yiqing Guo,[1] Zhengzhe Li,[3] Timothy W. Miller,[1] Monica Patricia Revelo Penafiel,[2] Xiangchen Gu,[4] John C. He,[3] Sandeep K. Mallipattu.[1] *[1]Medicine/Nephrology, Stony Brook Univ, Stony Brook, NY; [2]Univ of Utah, Salt Lake City, UT; [3]MSSM, New York, NY; [4]Nephrology, Yueyang Hospital of Integrated TCM and Western Medicine, Shanghai, China.*

Background: Krüppel-Like Factor 15 (KLF15) is a critical regulator of podocyte differentiation. Klf15 is also required for steroid-induced restoration of podocyte differentiation markers. Podocyte-specific loss of *Klf15* exacerbates podocyte injury in proteinuric murine models. Furthermore, the level of KLF15 expression in podocytes correlates with steroid-responsiveness MCD and primary FSGS. We now hypothesize whether the podocyte-specific induction of *hKLF15* in mice attenuates FSGS.

Methods: Full-length ORF cDNA of *KLF15* was cloned into a TRE plasmid. Mice with *TRE-hKLF15* and *Nphs2-rtTA* transgenes (*ΔhKLF15*) exhibited doxycycline (DOX) inducible podocyte-specific KLF15mRNA and protein expression. HIV-1 transgenic (Tg26) mice were crossed with *ΔhKLF15* mice to assess the role of KLF15 in FSGS murine model.

Results: DOX-treated Tg26;*ΔhKLF15* exhibited a significant reduction in albuminuria (40-fold), foot process effacement, glomerulosclerosis, serum BUN and creatinine, interstitial inflammation, glomerular epithelial cell proliferation (Claudin1, Ki67), podocyte differentiation markers (Nephrin, Synaptopodin, Podocin, WT1), kidney fibrosis (αSMA, Col1α1, Fibronectin, Vimentin) as compared to DOX-treated *Tg26* mice. In addition, DOX-treated Tg26;*ΔhKLF15* exhibited a 50% increase in survival as compared to DOX-treated *Tg26* mice at 10 weeks of age. TRANSFAC promoter analysis was performed to identify genes with binding sites for KLF15. Gene-set enrichment analysis of these genes identified a significant increase in the pathways involved in suppression of Wnt/β-catenin pathway. Finally, we validated that DOX-treated *Tg26;ΔhKLF15* exhibited a reduction in Wnt/β-catenin pathway (*C-myc, Lef1*) compared to DOX-treated *Tg26* mice in isolated glomeruli.

Conclusions: Taken together, these data suggest that upregulation of *KLF15* in the podocyte abrogates FSGS, kidney fibrosis, and overall mortality by inhibiting Wnt/β-catenin signaling in HIV-1 transgenic mice.

Excessive Proliferator-Activated Receptor Gamma Coactivator 1a (PGC1a) Expression and Mitochondrial Biogenesis in Podocytes Results in Cell Cycle Entry and Collapsing Glomerulosclerosis Szu-Yuan Li,[1,2] Jihwan Park,[1] Chengxiang Qiu,[1] Matthew Palmer,[3] Katalin Susztak.[1] *[1]Medicine, Univ of Pennsylvania, Philadelphia, PA; [2]Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [3]Pathology and Laboratory Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: Mutations in mitochondrial genes can result in FSGS. Acquired mitochondrial defects in podocytes have been described in other forms of glomerular disorders. We hypothesized that increasing mitochondrial biogenesis in podocytes would be beneficial for glomerular disease. Pgc1a is the main transcriptional regulator of mitochondria biogenesis and tubule specific expression of PGC1a has been beneficial in acute and chronic kidney injury.

Methods: Gene expression were analyzed in microdissected human glomeruli using Affymetrix gene expression arrays. Podocyte specific inducible PGC1a transgenic mice were created by breeding Nephrin rtTA with tetO-PGC1α mice. We have studied PGC1α function in cultured murine podocytes using an adenoviral expression system.

Results: Glomerular expression of mitochondrial specific genes and PGC1a showed significant positive correlation with kidney function, indicating that mitochondrial content likely decreased with GFR. PGC1a expression was also decreased in diabetic mouse models. Cell type specific inducible expression of PGC1a in podocytes increased mitochondrial number and size, however, animals developed albuminuria. Histologically examination showed glomerular hypercellulcarity, cellular crescent formation and glomerular sclerosis and podocytes were positive for proliferation marker PCNA, resembling collapsing FSGS. Overexpression of PGC1a in cultured podocytes resulted in an increase in metabolism related gene expression and oxygen consumption rate. Excess PGC1a also caused uncontrolled mitochondria biogenesis and fusion, accompany with cell cycle reentry.

Conclusions: Decreased podocyte PGC1a expression and mitochondrial content is a consistent feature of chronic glomerular disease. While PGC1a improves podocyte energy metabolism, excessive activation promotes podocyte proliferation and result in glomerulosclerosis, indicating that there is a narrow therapeutic window for PGC1a.

SGPL1 Mutations Lead to Sphingosine-1-Phosphate Lyase 1 Deficiency with Nephrotic Syndrome, Deficiency of Cellular Immunity, Adrenal Insufficiency, and Ichthyosis in Humans Svjetlana Lovric,[1] Sara Gonçalves,[2,5] Heon Yung Gee,[1] Babak Oskouian,[3] Shazia Ashraf,[1] Won-Il Choi,[1] David Schapiro,[1] Martin Zenker,[4] Corinne Antignac,[5] Julie D. Saba,[3] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Imagine Inst, Paris, France; [3]Children's Hospital, Oakland Research Inst, Oakland, CA; [4]Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; [5]Dept of Genetics, Necker Hospital, Paris, France.*

Background: SGPL1 *(*sphingosine-1-phosphate lyase) is an intracellular enzyme responsible for the final step in sphingolipid breakdown, converting S1P into ethanolamine phosphate and hexadecenal. S1P functions as a ligand for G protein coupled receptors that mediate autocrine and paracrine signals controlling cell migration and proliferation. Mouse models of *Sgpl1* exhibit proteinuria and mild acanthosis with orthokeratotic hyperkeratosis.

Methods: We performed homozygosity mapping (HM) and WES to identify loss of function mutation in >200 individuals with steroid resistant nephrotic syndrome (SRNS). The function and localization of SGPL1 protein were examined in podocytes and mesangials cells.

Results: We identified 6 different recessive mutations in *SGPL1* (p.S3Kfs*11, p.R222Q, p.S346I, p.Y416C, p.E132G and p.R278Gfs*17) in 5 families. Affected individuals exhibited SRNS, acanthosis and orthokeratosis, deficiency of cellular immunity and facultative adrenal insufficiency. All identified mutations resulted in reduced or absent SGPL1 protein and/or enzyme activity. Overexpression of cDNA representing mutations of SRNS patients resulted in subcellular mislocalization of SGPL1. Immunofluorescence revealed SGPL1 expression in mouse podocytes and mesangial cells. Knockdown of Sgpl1 in rat mesangial cells (RMC) reduced cell migration rate, which was partially rescued by VPC23109, an S1P receptor antagonist. Knockdown of SGPL1 in RMC resulted in a decrease of active RAC1.

Conclusions: We have identified *SGPL1* mutations as a novel cause of human SRNS, acanthosis and adrenal insufficiency. Our findings delineate a new RAC1-mediated molecular pathogenesis of syndromic SRNS that may be amenable to treatment.

APOL1 Risk Alleles (G1, G2) Induced Kidney Disease Development Is Dose Dependent and Reversible Jing Bi Karchin,[1] Pazit Beckerman,[1] Ae Seo Deok Park,[1] Matthew Palmer,[2] Jeffrey H. Miner,[3] Katalin Susztak.[1] *[1]Div of Renal-Electrolyte and Hypertension, Univ of Pennsylvania, Philadelphia, PA; [2]Dept of Pathology and Laboratory Medicine, Univ of Pennsylvania, Philadelphia, PA; [3]Div of Nephrology, School of Medicine, Washington Univ, St. Louis, MO.*

Background: Two coding variants (G1 and G2) in the Apolipoprotein L1 (APOL1) gene increase the risk of developing chronic kidney disease (CKD) by 2-80 fold in African Americans. However, it remains unclear what triggers disease development in 2 risk allele carriers. Endogenous APOL1 expression can be stimulated by inflammatory cytokine interferon γ (IFNγ), which also triggers albuminuria in 2 risk allele subjects. Therefore, we hypothesized that the APOL1-associated kidney disease development depends on risk allele APOL1 expression levels.

Methods: We generated conditional inducible G0, G1 and G2 APOL1 transgenic animals and crossed them with the nephrin rtTA to induce podocyte specific expression. In these animals transgene expression can be controlled by doxycycline. Renal function was evaluated by albumin ELISA and structural changes by light and electron microscopy. *In vitro* cytotoxicity was analyzed by propidium iodide and intracellular ATP content.

Results: APOL1 expression levels showed significant variations between the different founder lines. Risk allele APOL1 levels (G1 and G2) strongly correlate with the severity of albuminuria, which was 20 fold higher than in mice expressing reference allele (G0). Similarly, glomerulosclerosis was more severe in mice with higher expression of risk allele APOL1. *In vitro* experiments supported the *in vivo* results and indicated that risk allele APOL1 causes an increased inflammatory type cell death (pyroptosis) in a doxycycline-dose dependent manner. Furthermore, initial studies indicated that albuminuria development was reversible; upon discontinuation of doxycycline diet, APOL1 expression and albuminuria returned to baseline.

Conclusions: APOL1 risk (G1 or G2) variant levels likely play an important role in disease development. Our results suggest that reducing risk allele APOL1 expression could be a realistic targeting strategy in patients with high-risk genotype.

Does Acute Declines in Renal Function during Intensive BP Lowering Associate with Higher Risk of ESRD during Long-Term Follow-Up? Elaine Ku,[1] Kirsten L. Johansen,[1] Vito M. Campese,[2] Jennifer J. Gassman,[3] Miroslaw Smogorzewski,[2] Chi-Yuan Hsu.[1] *[1]UCSF; [2]USC; [3]AASK.*

Background: Intensive blood pressure (BP) lowering frequently leads to acute declines in renal function, which was demonstrated in the recent Systolic Blood Pressure Intervention Trial (SPRINT).The long-term implications of such declines–which have been thought to be "hemodynamic"/functional in nature -are unclear. We determined whether acute declines in renal function during the first three months of intensive BP lowering in the African American Study of Kidney Disease (AASK) trial (1995-2001) were associated with a higher long-term risk of ESRD.

Methods: The percent decline in renal function (by CKD-EPI equation) in AASK CKD trial participants (N=899) randomized to mean arterial pressure (MAP) target of <92 mm Hg (Strict BP arm) versus 102-107 mm Hg (Usual BP arm) was determined between time of randomization and month 3 of the trial (period of intensive BP lowering to achieve MAP goals). Risk of ESRD (ascertained through 2012) was compared among those with a <5%, 5-<20%, versus ≥20% decline in eGFR in adjusted Cox models.

Results: Up to a 20% decline in eGFR during anti-hypertensive therapy intensification in the Strict BP arm was not associated with a statistically significantly higher risk of ESRD during mean follow-up of 14.4 yrs, compared to the reference group of <5% decline in the Usual BP arm (HR 1.16; 95% CI 0.79-1.69). In contrast, a ≥5% decline in the Usual BP arm and ≥ 20% decline in Strict BP arm was associated with a higher risk of ESRD.

% decline in renal function	N	ESRD incidence (per 100 person years)	Hazard ratio (95%CI)	N	ESRD incidence (per 100 person-years)	Hazard ratio (95%CI)
	Usual BP Arm			Strict BP Arm		
<5%	307	2.8	1.0 (Reference)	265	2.9	1.05 (0.78-1.40)
5-<20%	76	5.8	2.14 (1.48-3.09)	107	3.2	1.16 (0.79-1.69)
≥ 20%	68	7.5	2.77 (1.92-4.00)	76	6.0	2.23 (1.53-3.24)

Conclusions: Acute declines in eGFR up to 20% during intensive BP lowering appears to be safe and is not associated with a higher long-term risk of ESRD.Further studies are needed to confirm the long-term safety of a <20% decline in eGFR during intensive BP lowering.

SA-OR102

Blood Pressure Parameters and Their Associations with Various Causes of Death in Chronic Kidney Disease Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Susana Arrigain,[2] Stacey Jolly,[2] Matthew F. Blum,[2] Wolfgang C. Winkelmayer,[1] Joseph V. Nally.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Cleveland Clinic, Cleveland, OH.*

Background: Previous observational studies reported higher risk for death with lower blood pressure levels in CKD. However, recent clinical trial evidence suggest targeting BP <120/80 mm Hg results in better cardiovascular outcomes even among those with CKD. We examined the associations of different BP levels with various causes of deaths in a CKD population.

Methods: We included 45,433 patients with eGFR 15-59 ml/min/1.73 m^2 (twice 90 days apart) with underlying hypertension and taking at least one antihypertensive agent. We ascertained overall and cause-specific deaths from State department of health mortality data and classified deaths into three major categories: a) cardiovascular b) malignancy and c) non-cardiovascular/non-malignancy conditions. We fitted Cox models for overall mortality and separate competing risk regression models for each major cause of death categories to evaluate their associations with various SBP (<110, 110-119, 120-129, 130-139, 140-149 and >150 mm Hg) and DBP levels (<50, 50-59, 60-69, 70-79, 80-89, >90 mm Hg) adjusting for relevant covariates.

Results: During a median follow-up of 3.9 years, 13,343 patients died. SBP <110,110-119 and >150 mm Hg (vs. 130-139) were associated with all-cause mortality and cardiovascular mortality (Table). DBP <50, 50-59 mm Hg (vs. 70-79 mm Hg) were associated with all-cause and non-cardiovascular/non-malignancy related deaths. DBP >90 mm Hg was associated with higher cardiovascular mortality.

Table. Associations of systolic blood pressure with all-cause and cause-specific mortality

SBP levels (mm Hg)	Overall* HR (95%CI)	Cardiovascular deaths SHR (95% CI)	Malignancy related deaths SHR (95% CI)	Non-cardiovascular/Non-malignancy deaths SHR (95% CI)
<110 mm Hg	**1.32 (1.24, 1.41)**	**1.42 (1.28, 1.58)**	1.07 (0.94, 1.21)	1.16 (1.04, 1.29)
110-119	**1.14 (1.07, 1.21)**	**1.19 (1.07, 1.31)**	0.92 (0.81, 1.04)	1.09 (0.98, 1.20)
120-129	0.99 (0.94, 1.05)	1.00 (0.91, 1.10)	0.95 (0.86, 1.06)	0.97 (0.89, 1.07)
130-139	Ref	Ref	Ref	Ref
140-149	1.01 (0.95, 1.07)	1.07 (0.97, 1.19)	0.98 (0.87, 1.10)	1.01 (0.92, 1.12)
> 150	**1.09 (1.03, 1.15)**	**1.24 (1.13, 1.36)**	1.01 (0.90, 1.13)	1.00 (0.91, 1.11)

Conclusions: Among non-dialysis dependent CKD population, SBP <120 and >150 mm Hg were associated with all-cause cardiovascular deaths, and DBP <60 mm Hg was associated with all-cause and non-cardiovascular/non-malignancy related deaths. Additional studies examining the differential associations with cause-specific death are needed.

Funding: Pharmaceutical Company Support - Development of CCF CKD registry is supported by an unrestricted grant to the Department of Nephrology and Hypertension, Cleveland Clinic from Amgen

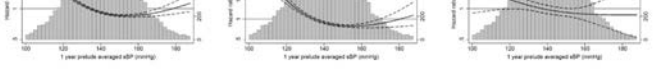
SA-OR103

Pre-ESRD Systolic Blood Pressure and Post-ESRD Mortality in Advanced CKD Patients Transitioning to Dialysis Keiichi Sumida,[1,2] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Connie Rhee,[3] Elani Streja,[3] Kunihiro Yamagata,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of Tsukuba, Ibaraki, Japan; [3]Univ of California, Irvine, CA; [4]VA Medical Center, Memphis, TN.*

Background: Previous studies of non-dialysis dependent (NDD)-CKD patients have shown a J-shaped association of systolic blood pressure (SBP) with mortality. However, the association of SBP in late-stage NDD-CKD with post ESRD mortality remains unknown.

Methods: We identified 17,994 US veterans with advanced CKD transitioning to dialysis between 10/2007-9/2011 who had at least 3 outpatient BP measurements within 1 year prior to dialysis initiation. Associations of 1-year averaged pre-ESRD SBP categories (<120, ≥160 mmHg; and increments of 10 mmHg in between) with all-cause and cause-specific mortality during the 2-year period following dialysis initiation were examined using Cox (for all-cause) and competing risk (for cause-specific mortality) regressions and cubic splines adjusted for demographics, comorbidities, medications, CV medication adherence, and BMI, eGFR, and access type at dialysis initiation.

Results: The mean±SD of SBP was 141±16 mmHg. There was a reverse J-shaped association of SBP with all-cause and CV mortality (Figure). The lowest mortality was associated with SBP of 140-149 mmHg (multivariable adjusted hazard/subhazard ratios [95% CI] for SBP <120 [vs. 140-149] mmHg: 1.64 [1.51-1.79] and 2.01 [1.72-2.35] for all-cause and CV mortality, respectively). There was an inverse linear trend of association between SBP and infectious mortality, none of which were statistically significant.



Conclusions: Low SBP in late-stage NDD-CKD are associated with higher post-ESRD all-cause and CV mortality, but not infectious mortality. Further studies are needed to clarify ideal SBP levels among these patients.

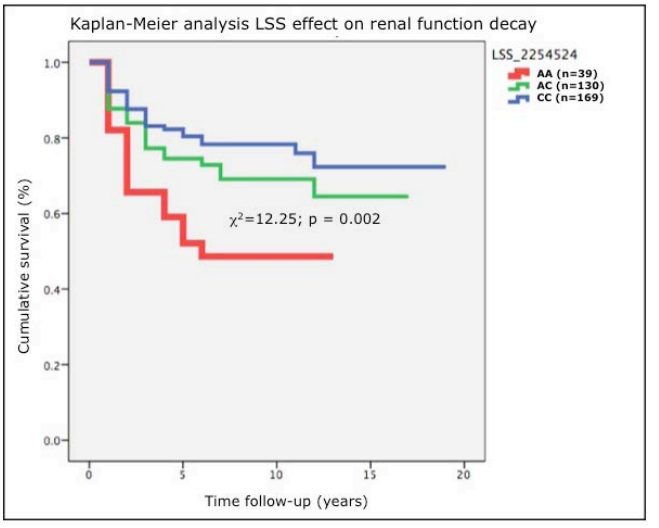
SA-OR104

Lanosterol Gene Polymorphisms Impact the Decline in Renal Function among Hypertensive Patients: A Follow-Up Study Simone Fontana,[1] Chiara Lanzani,[1] Rossella Iatrino,[1] Lorena Citterio,[1] Marco Simonini,[1] Simona Delli Carpini,[1] John Hamlyn,[2] Elena Brioni,[1] Stefano Tentori,[1] Paolo Manunta.[1] *[1]H San Raffaele, Italy; [2]Univ Maryland.*

Background: Cholesterol is an essential component of mammalian cell membranes and serves as a precursor for bile acids and various steroid hormones. The gene for Lanosterol (LSS), the first committed intermediate in cholesterol biosynthesis, has a missense polymorphism that affects EO biosynthesis in adrenocortical cells. Recently, we reported *(Hypertension 2016)* that the LSS AA genotype is associated with salt-sensitive hypertension. Exposure to increased circulating EO causes glomerular damage, and is a risk factor for acute kidney injury (*Cri Care Med 2015*). Furthermore, LSS gene is transcribed in discrete nephron sites (*JASN 2015*). In this report, we explore the importance of LSS in the progression of chronic kidney disease (CKD).

Methods: A cohort of 421 naïve hypertensive patients (female 188, male 233, age 42.7 ± 8.41 years), were enrolled in a follow-up study (5.32 ± 4.37 years) in which BP values were kept at goal with ACEi plus diuretic and, when needed, a Ca^{2+} channel antagonist. Renal function and other kidney parameters were evaluated every six months.

Results: BP values (SBP/DBP) after 4.6 years of follow-up were at target (LSS AA 138/85 AC 140/86 CC 141/85, respectively). The slope in eGFR (CKD-EPI) was 1.43±0.47 ml/1.73m^2/yr in the whole study population. When analysed according to the LSS genotype, the decline in renal function was double in the AA homozygotes (LSS AA -2.01±2.4 vs CC 2.23 ± 1.20 ml/1.73m^2/yr;p= 0.024). The impact of LSS polymorphisms was also reflected in patient renal survival (see Fig. 1).



Conclusions: Our findings further support the role of LSS polymorphisms and circulating EO in the progression of CKD. This metabolic pathway may accelerate the decline in renal function via its effects on glomerular podocyte and tubular components.

SA-OR105

Prevalence of White-Coat (WCH), Masked (MH), and Sustained Hypertension (SH) Using Uniform Definitions across Multiple Cohorts - The International Database of Ambulatory Blood Pressure in Renal Patients (I-DARE) Collaborative Group Paul E. Drawz,[1] Luca De Nicola,[2] Naohiko Fujii,[3] Francis B. Gabbai,[4] Jennifer J. Gassman,[4] Jiang He,[5] Satoshi Iimuro,[3] James P. Lash,[5] Roberto Minutolo,[2] Robert A. Phillips,[4] Luis M. Ruilope,[5] Susan P. Steigerwalt,[5] Raymond R. Townsend,[5] Dawei Xie,[5] Mahboob Rahman.[4,5] *[1]Univ of Minnesota; [2]Italian Cohort; [3]CKD-JAC; [4]AASK Cohort; [5]CRIC Cohort.*

Background: Differences in ABPM profiles based on ethnicity and geography have not been well studied. In addition, differences in definitions have made it hard to compare the prevalence of WCH, MH, and SH across cohorts.

Methods: A database of demographic, clinical, and ambulatory BP (ABP) data from renal patients from AASK, CRIC, Italy, CKD-JAC, and Spain was established. Participants with CKD, either eGFR <60ml/min/1.73m^2 or proteinuria, were included in this cross-sectional analysis. Cutoffs for controlled clinic and 24h ABP were 140/90 and 130/80mmHg, respectively.

Results: Characteristics of the 9,293 participants are shown in the table. The prevalence of MH was higher in AASK, CRIC, and CKD-JAC (30-38%) compared to the Italian and Spanish cohorts (7-10%) in which WCH was higher.

Covariate	Overall	AASK	CRIC	Italy	CKD-JAC	Spain
N	9293	581	1306	444	1017	5945
Age	64.5 (12.3)	62.1 (10.4)	63.8 (10.1)	65.3 (13.9)	61.2 (11.3)	65.5 (12.9)
Male (%)	51.8	62.5	56.6	59.0	63.3	47.2
eGFR (CKD-Epi)	46.7 (22.6)	34.4 (14.8)	38.3 (15.0)	38.5 (18.1)	34.2 (15.9)	52.5 (23.8)
Proteinuria (% pts)	35.1	48.0	49.7	71.4	40.7	26.9
BP category (%)						
- Controlled BP	23.7	30.8	46.6	21.2	37.3	15.8
- WCH	22.0	2.2	4.4	28.6	5.3	30.1
- MH	15.1	38.2	30.5	10.1	32.8	6.7
- SH	39.2	28.7	18.3	40.1	24.4	47.3

Conclusions: This international database of ABP in renal patients reveals a large heterogeneity of BP profiles across countries. This project represents an important advance in our ability to study racial/ethnic/geographic variations in ABP profiles. Future analyses will evaluate factors that contribute to elevated ABP, the effect of elevated ABP on adverse cardio-renal outcomes, and whether there are any ethnic or geographic differences in these associations.

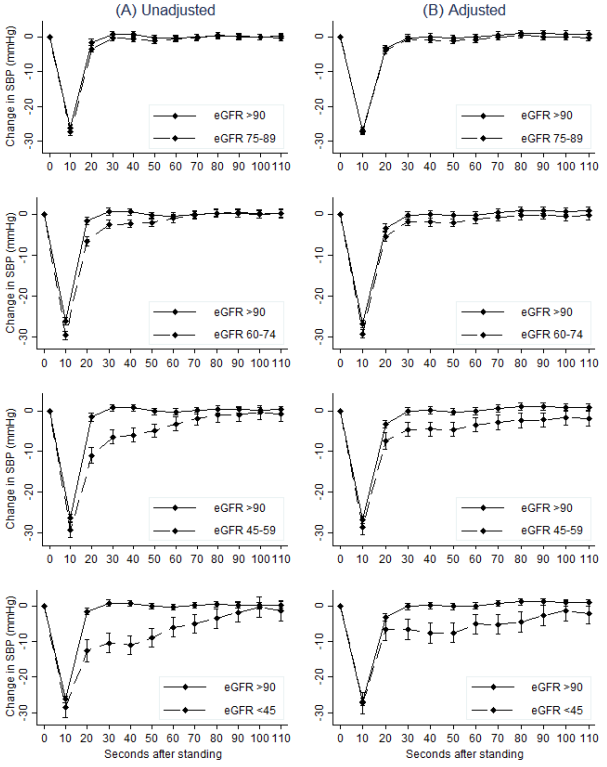
Graded Association between Kidney Function and Postural Blood Pressure Instability

Mark Canney,[1,2] Matthew D.l. O'Connell,[1] Donal J. Sexton,[1,2] Neil O'Leary,[1] Rose Anne M. Kenny,[1] Mark Alan Little,[2] Conall M. O'Seaghdha.[3] *[1]The Irish Longitudinal Study on Ageing, Trinity College Dublin; [2]Trinity Health Kidney Centre, Trinity College Dublin; [3]Nephrology Dept, Beaumont Hospital, Dublin.*

Background: Postural blood pressure (BP) instability is a predictor of cognitive dysfunction, falls and mortality. We sought to characterize postural BP behavior across the spectrum of estimated glomerular filtration rate (eGFR) in older adults.

Methods: Cross-sectional analysis of 4204 participants from The Irish Longitudinal Study on Ageing, a representative national cohort of community-dwelling adults aged ≥50yrs. Beat-to-beat BP was measured by finometry during a 2 minute active stand test. The primary predictor was cystatin C eGFR categorized as follows (mL/min/1.73m^2): ≥90(ref);75-89;60-74;45-59;<45. We used multivariable linear regression to model the association between eGFR groups and postural BP behavior, defined as the change from baseline in mean systolic BP (SBP) at 10 second(s) intervals. In a secondary analysis we modeled the association between creatinine eGFR and postural BP behavior.

Results: Mean(sd) age was 61.6(8.2)yrs, 53% were female and mean(sd) eGFR was 81(17.6)mL/min/1.73m^2. We observed a graded association between postural BP instability and cystatin C eGFR. This was evident within 20s of standing and was robust to multivariable adjustment.



At 40s participants with eGFR<45 had a mean SBP deficit of 8(95%CI, 5 to 11)mmHg vs the reference group. There was no evidence of effect modification by antihypertensive therapy. The association between creatinine eGFR and postural BP behavior was comparatively modest.

Conclusions: We report a novel relationship between postural BP instability and eGFR in a large representative sample of older adults using beat-to-beat data. This graded association was marked within the first minute of standing, a time window not captured by conventional BP measurements.

SA-OR107

Intensive Blood Pressure Lowering Will Prevent over 100,000 Deaths Annually

Tisha Joerla M. Tan,[1] Adam Bress,[3] Richard Cooper,[1] Paul Muntner,[2] Srini Beddhu,[3] Holly J. Kramer.[1] *[1]Loyola Univ; [2]Univ of Alabama; [3]Univ of Utah.*

Background: The Systolic Blood Pressure Intervention Trial (SPRINT) trial randomized 9,361 adults aged ≥50 years at high cardiovascular disease (CVD) risk without diabetes or stroke to intensive systolic blood pressure (SBP) lowering (≤120 mmHg) or standard SBP lowering (≤140 mmHg). After a median follow up of 3.26 years, all-cause mortality was 27% (95% CI 40%, 10%) lower with intensive SBP lowering. We estimated the potential number of prevented deaths with intensive SBP lowering in the U.S. population meeting SPRINT criteria.

Methods: SPRINT eligibility criteria were applied to the National Health and Nutrition Examination Survey 1999-2006, a representative survey of the U.S. population, linked with the mortality data through December 2011. Eligibility included (1) age ≥50 years with (2) SBP 130-180 mmHg depending on number of antihypertensive classes being taken, and (3) presence of ≥1 CVD risk conditions (history of coronary heart disease, estimated glomerular filtration rate (eGFR) 20 to 59 ml/min/1.73 m^2, 10-year Framingham risk score ≥15%, or age ≥75 years). Adults with diabetes, stroke history, >1 g/day proteinuria, heart failure, or eGFR<20 ml/min/1.73m^2 were excluded. Annual mortality rates for adults meeting SPRINT criteria were calculated using Kaplan-Meier methods and the expected reduction in mortality rates with intensive SBP lowering in SPRINT was used to determine the number of potential deaths prevented. Analyses accounted for the complex survey design.

Results: An estimated 18.1 million U.S. adults met SPRINT criteria with 7.4 million taking blood pressure lowering medication. The mean age was 68.6 years and 83.2% and 7.4% were non-Hispanic white and non-Hispanic black, respectively. The annual mortality rate was 2.2% (95% CI 1.9%, 2.5%) and intensive SBP lowering was projected to prevent 107,453 deaths per year (95% CI 45,374, 139,490). Among the estimated 4.1 million adults with eGFR 20-59 ml/min/1.73 m2 meeting SPRINT criteria, the annual mortality rate was 2.9% (95% CI 2.3%, 3.6%) and intensive SBP lowering was projected to prevent 32,145 deaths per year (95% CI 25,493 - 39,903) in this group.

Conclusions: We project intensive SBP lowering could prevent over 100,000 deaths per year of intensive treatment.

SA-OR108

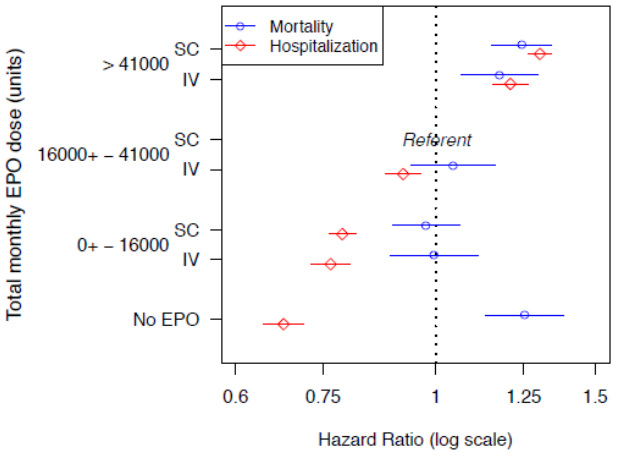
Dose Requirements, Hospitalization, and Mortality Are Similar with Subcutaneous versus Intravenous Erythropoietin Administration

Ambreen Gul,[1] R. Schrader,[1] D. Miskulin,[1,2] S. Paine,[1] Antonia Harford,[3] Philip Zager.[1,3] *[1]DCI; [2]Tufts; [3]UNM.*

Background: Erythropoietin (EPO) is indicated for the treatment of the anemia of ESRD. Results of the CREATE and CHOIR trials as well as implementation of the bundle payment system led many providers to switch from intravenous (IV) to subcutaneous (SC) EPO administration. A retrospective analysis of hemodialysis (HD) patients enrolled in the CMS Clinical Performance Measures Project from 1997 to 2005 found that IV vs. SC EPO administration was associated with 25% higher doses and an increased risk for the composite outcome of death or cardiovascular hospitalization. However, only 8% of patients received SC EPO. Since then, target hemoglobin (Hgb) values, EPO doses and the percent of patients treated with IV EPO have decreased significantly. Therefore, it is unknown if the alleged advantages of SC over IV are still operative.

Methods: We conducted a retrospective study of 24,957 HD patients treated between 2011 and 2014 at DCI facilities. The majority of SC and IV doses were administered once and thrice weekly, respectively. We used linear mixed models to compute mean weekly EPO doses and associated Hgb levels. To assess the relationships of IV and SC EPO to hospitalization and mortality, we constructed Cox models with time varying covariates to adjust for age, vintage, race, sex, BMI, albumin and Hgb.

Results: From 2011 to 2014, the proportion of patients treated with SC EPO increased from 41% to 69%. For a given achieved Hgb there were no significant differences between SC and IV mean weekly EPO doses. High doses, whether IV or SC, were associated with increased risks of hospitalization and mortality. However, there were no differences in hospitalization or mortality risk by route of administration.



Conclusions: Mean weekly doses of EPO and the risks for hospitalization and mortality were similar for IV and SC EPO administration.

SA-OR109

Mortality among Undocumented Hispanic ESRD Patients with Different Availability to and Access for Dialysis Lilia Cervantes,[1] Delphine S. Tuot,[2] Rajeev Raghavan,[3] Jeff Zoucha,[1] Lena C. Sweeney,[2] Chandan Vangala,[3] Madelyne L. Hull,[1] Mario Andres Camacho,[1] Jessica B. Kendrick,[1] Neil R. Powe,[2] Stuart L. Linas.[1] *[1]Univ of Colorado; [2]Univ of California, San Francisco; [3]Baylor College of Medicine.*

Background: Treatment strategies for undocumented end-stage renal disease (ESRD) patients in the U.S. varies between and within states. Most states provide dialysis to undocumented patients only when they present to an emergency department with life-threatening complications. We sought to determine whether the frequency of available treatment and access to AVF/AVG placement yielded mortality differences in three cities.

Methods: We conducted a retrospective cohort study of undocumented Hispanics who initiated hemodialysis January 2007 through July 2014 at three sites with different approaches: Denver Health (DH) (n = 45) in Colorado, Harris Health (HH) (n = 47) in Texas, and Zuckerberg San Francisco General (ZSFG) (n = 119) in California. Standardized mortality ratios (SMR) were calculated using participant gender and age at initiation. Sites were individually and collectively compared to the documented Hispanic population in the U.S. Renal Data System (USRDS). A Kaplan-Meier curve described one, three, and five year survival across sites.

Results: Compared to the USRDS Hispanic population, undocumented Hispanics had greater risk of mortality at three and five years following dialysis initiation (Table). SMRs show patients who received emergent dialysis with either a catheter or AVF/AVG experienced higher rates of mortality compared to counterparts who received routine dialysis with access to AVF/AVG placement. Kaplan-Meier curves were consistent.

	1-year		3-year		5-year	
Treatment group	Gender	Age	Gender	Age	Gender	Age
HH: Emergent care with non-permanent access	0.62	0.95	1.55	2.35	1.80	2.77
DH: Emergent care with access to AVF/AVG placement	1.04	1.31	1.77	2.23	2.36	3.00
ZSFG: Routine care with access to AVF/AVG placement	0.53	0.63	0.90	1.08	0.93	1.12
All undocumented Hispanics	0.69	0.96	1.46	1.99	1.74	2.40

Conclusions: Availability of routine dialysis and permanent vascular access for undocumented Hispanics is strongly associated with improved mortality.

Anemia and Iron Management over the First 5 Years after Dialysis Start: Results from the DOPPS Angelo Karaboyas,[1] Bruce M. Robinson,[1,2] Yvonne Meier,[3] Lisa Loram,[4] Masaaki Inaba,[5] Stefan H. Jacobson,[6] Raymond C. Vanholder,[7] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]U of Michigan, Ann Arbor; [3]Vifor Pharma Ltd, Glattbrugg, Switzerland; [4]Keryx Biopharmaceuticals, Boston, MA; [5]Osaka City U, Japan; [6]Danderyd Hosp, Stockholm, Sweden; [7]Univ Hosp, Gent, Belgium.*

Background: Hemodialysis (HD) patients are at an especially high risk of adverse events in the period following HD initiation. Optimizing treatment practices before, during, and after this transition is paramount, particularly for anemia management. Hemoglobin (Hgb) levels typically rebound on HD due to substantial ESA and IV iron dosing, but the trajectory of ferritin and TSAT levels after the transition to dialysis has not been well-studied.

Methods: Restricted cubic splines were used to model the mean (SE) of ferritin, TSAT, Hgb, IV iron and ESA dose over the first 5 years of HD using longitudinal data from 6612 patients in phase 5 (2012-2015) of the Dialysis Outcomes and Practice Patterns Study (DOPPS) in Europe (EUR), Japan, and the US.

Results: In the first year after HD initiation, IV iron and ESA doses were higher in the US vs. EUR, but achieved mean Hgb levels were lower in the US. In contrast, iron parameters increased more quickly in the US and remained high, reaching a mean plateau of 900 ng/mL (ferritin) and 32% (TSAT) after 2 years, despite IV iron doses declining to EUR levels. Anemia treatments and measures were generally more stable across HD vintage in Japan.

Conclusions: Regional differences in anemia management are accentuated during the early HD period, when US patients receive the highest IV iron and ESA doses and have larger, sustained increases in ferritin and TSAT levels. Because early HD mortality is high, future investigation is needed including identifying pre-HD practices that can support the use of lower IV iron and ESA doses soon after HD start, and what effect if any this might have on clinical outcomes.

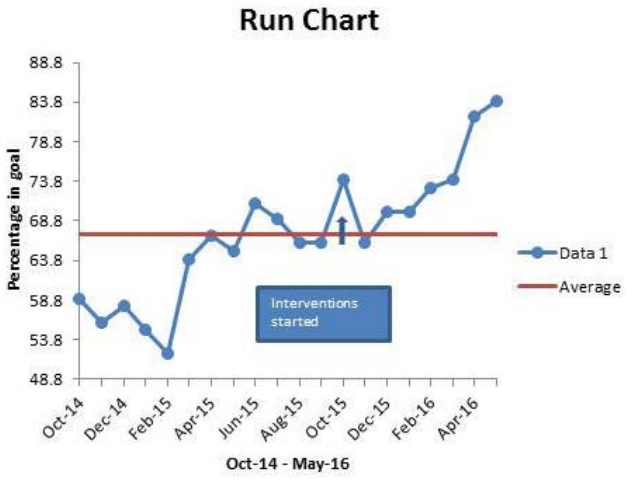
Improving Interdialytic Weight Gain in Dialysis Patients Chandandeep Takkar,[1] Karen D. Burchell,[1] Laura Montes,[2] Wajeh Y. Qunibi.[1] *[1]Nephrology, UTHSCSA, San Antonio, TX; [2]UHS, San Antonio, TX.*

Background: UF Rate (UFR) above 13 ml/Kg/ hour (vs 10-13 ml/kg/hour) in hemodialysis (HD)patients is associated with increase in mortality. Moreover, UFR is being considered as a reportable quality measure for HD by the CMS. Aim of our project is to improve interdialytic weight gain (IDWG) to keep UFR <12ml/Kg/hour in at least 65% of HD patients.

Methods: A multidisciplinary team was convened in Sept 2015. Baseline IDWG (average of 13 /month/ patient) was recorded from 10/2014-9/2015. Goal IDWG was calculated for each patient to keep maximum UFR<12ml/Kg/hour as follows: 12 X Estimated Dry Weight X treatment duration (in hr)-Rinse back. Patients met goal the preceding month if their average IDWG was at/below maximum goal. Volume overload-related admissions, pre-and post-dialysis BP and hypotensive episodes during dialysis were recorded. A fishbone diagram was used to identify barriers to goal IDWG and a driver diagram to identify key actionable items. We counseled patients extensively regarding sodium and fluid restriction, adjusted their dialysate sodium (DNa) prescription according to the 3-month pre dialysis average serum sodium concentration (SNa), in order to reduce the DNa to SNa gradient. Standardized educational process and material for counseling was also developed. For sustainability, IDWG calculation, maximum goal and monthly average IDWG report was incorporated in EMR.

Results:



Compared to baseline, average percentage of patients at goal increased from 62% pre intervention to 74% by May 2016. Average UFR improved from 11.4 ml/kg/hour pre intervention to 9.7 ml/kg/hour. We noticed fewer hypotensive episodes, decreased use of antihypertensive agents, and improved staff and patient engagement.

Conclusions: A team based approach involving intensive patient counseling and attention to dialysis prescription are effective means to reduce IDWG in dialysis patients.

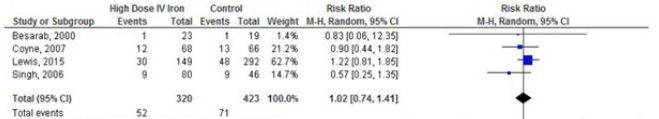
SA-OR112

Intravenous Iron Dosing and the Risk of Adverse Events in End Stage Renal Disease: A Systematic Review and Meta-Analysis Ingrid Hougen, Mathieu Bourrier, David Thomas Collister, Thomas W. Ferguson, Paul Komenda, Claudio Rigatto, Navdeep Tangri. *Max Rady College of Medicine, Univ of Manitoba, Winnipeg, MB, Canada.*

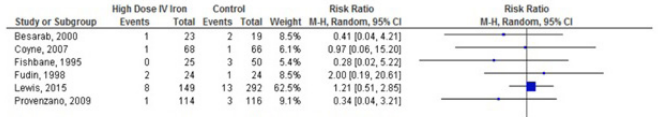
Background: Anemia and relative iron deficiency are common in patients with end stage renal disease (ESRD) and contribute to morbidity and mortality. The optimal intravenous (IV) iron dosing strategy in dialysis patients is unclear with controversy regarding the safety of high versus low dosing. We performed a systematic review and meta-analysis in order to assess the safety of IV iron dosing in adults with ESRD on dialysis.

Methods: A search strategy was developed for searching Medline, PubMed, EMBASE, Cochrane Central and CINAHL databases from inception until July 15, 2015. We included randomized controlled trials that compared high dose IV iron to low dose IV iron in the adult ESRD population on hemodialysis (HD) or peritoneal dialysis (PD) with follow-up of at least 30 days. Outcomes included infections, hospitalizations, cardiovascular events, and mortality.

Results: Seven studies met the criteria for inclusion with five in HD, one in PD, and one in both HD and PD. Four studies reported infections (n=743) and six reported mortality (n=970). Only two studies reported hospitalizations and none reported cardiovascular events. Meta-analysis with a random effects model showed that higher doses of IV iron were not associated with an increased risk of infection (HR 1.02 [95% C.I. 0.74, 1.41]) or mortality (HR 0.93 [95% C.I. 0.47, 1.84]). No significant statistical heterogeneity was detected.



Meta-Analysis Comparing the Safety of High Dose IV Iron versus Control for Relative Risk of Infection Events.



Meta-Analysis Comparing the Safety of High Dose IV Iron versus Control for Relative Risk of Mortality Events.

Conclusions: High dose IV iron does not appear to increase the risk of infection or mortality in adult ESRD patients on dialysis. However, our results are limited by the generally low quality of included studies and clinical heterogeneity among anemia management, as well as possible publication bias. Additional studies are needed to elaborate on these findings.

SA-OR113

Continuous ECG Recording of Cardiac Rhythm Shows That Pre-Hemodialysis (HD) Potassium (K+) Levels Need To Be Tightly Controlled between 4 to 5.5 mM Christian Combe,[1,2,6] Antoine Benard,[3,6] Hélène Savel,[3,6] Virginie Rondeau,[4,6] F. Sacher.[5,6] *[1]Nephrologie, CHU Bordeaux, Bordeaux, France; [2]INSERM 1026, Univ Bordeaux, Bordeaux, France; [3]Sante Publique, CHU Bordeaux, Bordeaux, France; [4]INSERM 1219, Univ Bordeaux, Bordeaux, France; [5]LYRIC Inst, CHU Bordeaux, Bordeaux, France; [6]Rythmodial, Study Group, France.*

Background: Sudden cardiac death is the commonest mode of death in HD patients (pts). Our objective was to identify mechanisms which may lead to SCD using an implantable loop recorder (ILR).

Methods: Pts from 9 HD centers were included. Cardiac rhythm was monitored with the ILR. Clinical, biological, & HD parameters & medications were recorded for ≥1 year. General joint frailty model for recurrent event data were used to analyze associations between these parameters & the occurrence of cardiac rhythm events (RE).

Results: 71 pts (65.1±8.6 y, 52M) have been included, with diabetes (n=32) & hypertension (n=19) as ESRD causes. 22 pts had ischemic cardiomyopathy. 66.2% pts had at least one RE, with a 198.8 patients-years (py) incidence (95%CI 196.3-201.4). Incidence was 55.6 py (54.2-56.9) for conduction abnormalities (CA); 9.6 py (9.0-10.1) for ventricular arrhythmias (VA); 100.7 py (98.9-102.6) for atrial fibrillation >2min (AF); 33.0 py (31.9-34.0) for bradycardia. In multivariate analyses, CA was linked to high K+ (K+>5mM, RR=4.0, p<0.0002), to high hemoglobin (Hb>11.5, RR=3.3, p<0.005), & to ischemic cardiopathy (RR=18.3, p<0.01), to a high-risk day for HD (RR=6.4, p<10-9), to a history of any RE (RR=9.3, p<10-7). VA incidence was higher with low K+ (<4mM, RR=12.8, p<0.005), & lower with anti-arrhythmic drugs (RR=0.1, p<0.005). AF was more frequent in males (RR=73.0, p<0.002), with low K+ (<4mM, RR=2.5, p<0.02), & high phosphorus (>45mg/L, RR=1.9, p<0.01). Bradycardia was linked to high K+ (>5mM, RR=13.7, p<0.002), to low K+ (<4mM, RR=9.2, p<0.05), & to shortened HD sessions (RR=7.6, p<0.02. In 6 SCD pts, ILR showed bradycardia followed by asystole.

Conclusions: Serum K+ levels need to be tightly controlled, since levels>5mM are associated to CA and bradycardia, while levels <4mM are associated to VA, AF, and bradycardia. Pts treated with anti-arrhythmic drugs had a much lower rate of VA.

SA-OR114

Daprodustat, a HIF-Prolyl-Hydroxylase Inhibitor, Maintains Hemoglobin Levels over 24 Weeks in Anemic Hemodialysis Subjects Switching from Recombinant Human Erythropoietin Alexander Ralph Cobitz,[1] Amy M. Meadowcroft,[1] Borut Cizman,[1] Louis Holdstock,[1] Nandita Biswas,[1] Delyth Jones,[1] Brendan M. Johnson,[2] John J. Lepore,[1] A. Kaldun Kaldun Nossuli.[3] *[1]GlaxoSmithKline; [2]Roivant Sciences; [3]Nossuli Research.*

Background: This study examined the relationship between daprodustat (GSK1278863) dose and hemoglobin (Hgb) level at 4 weeks (4w), and the efficacy and safety of daprodustat over 24 weeks (24w), in 216 subjects on hemodialysis (HD) previously receiving a stable dose of recombinant human erythropoietin (rhEPO).

Methods: Subjects with a baseline Hgb of 9-11.5 g/dL discontinued rhEPO and were randomized to receive daily oral daprodustat 4, 6, 8, 10, 12 mg or control (placebo for 4w; then open-label rhEPO as required). After 4w, doses were titrated to a Hgb target of 10-11.5 g/dL.

Results: Mean baseline Hgb was 10.4 g/dL. Switching from rhEPO to daprodustat produced dose-dependent mean changes in Hgb (g/dL) from baseline after 4w (placebo: -0.72; 4mg: -0.29; 6mg: 0.18; 8mg: 0.40; 10mg: 0.69; 12mg: 0.69). The mean change from baseline in Hgb at 24w for the combined daprodustat group was 0.03 g/dL (control: -0.11 g/dL). Mean hepcidin levels were reduced from baseline at 24w by 20.6% in subjects in the combined daprodustat group (control: 3.6%). The median maximum observed plasma EPO levels in the control group during rhEPO therapy were ~14-fold higher than the combined daprodustat group (control: 522.9 IU/L; daprodustat: 36.5 IU/L). There was no effect on plasma VEGF for either group. Daprodustat demonstrated an adverse event profile consistent with the HD population; however, the incidence of overall mortality and major cardiovascular events were lower than expected across all treatment arms.

Conclusions: These data inform the Hgb dose-response relationship of daprodustat in anemic HD subjects who were switched from a stable dose of rhEPO and demonstrate daprodustat can maintain Hgb at target levels for 24w. In the same time frame, daprodustat reduced hepcidin levels, maintained physiologic levels of plasma EPO, and there was no effect on plasma VEGF. These data support future long-term clinical studies in the dialysis population using daprodustat to treat anemia of CKD.

Effects of Hemodialysis and Dialysate Potassium on Maximum P Wave Duration and P Wave Dispersion Yi-Lun Zhou. *Dept of Nephrology, Tian-Tan Hospital, Capital Medical Univ.*

Background: Atrial fibrillation (AF) is a frequent arrhythma in hemodialysis (HD) patients and is associated with increased morbidity and mortality. Maximum P wave duration (Pmax) and P wave dispersion (Pd) are effective electrocardiographic predictors of AF. This study was designed to evaluate the influence of HD session and dialysate potassium concentration (K_d) on Pmax and Pd.

Methods: 117 chronic HD patients with sinus rhythm and 50 healthy controls were included. K_d 2.5mmol/L (K_d 2.5) was normally used and then once raised to 3.0mmol/L (K_d3.0). Blood samples were drawn and twelve-lead electrocardiograms (ECG) were recorded immediately before and after HD session. Pd was defined as the difference between the maximum and minimum P-wave duration on ECG. Home blood pressure monitoring was performed and home systolic blood pressure (home-SBP)≥150mmHg was defined as uncontrolled hypertension. Left atrial diameter was measured by ultrasound.

Results: Pmax and Pd were significantly increased in HD patients than healthy controls. Multiple stepwise regression analysis relveald that left atrial enlargement ($p< 0.001$) and uncontrolled home blood pressure ($p=0.030$) were indiependent predictors of prediaysis Pmax and Pd among HD patients. Pmax significantly increased during both HD sessions compared with prediaylsis values (121.1±11.6 vs. 105.4±11.6ms, 115.8±10.7 vs. 106.1±11.3ms, respectively, $p<0.001$), either did Pd (46.2±10.3 vs. 32.8±8.8ms, 40.4±9.7vs. 33.2±8.4ms, respectively, $p<0.001$) after HD sessions. Furthermore, postdiaysis Pmax and Pd were decreased in K_d3.0 group than K_d2.5 (115.8±10.7 vs. 121.1±11.6ms, 40.4±9.7ms vs. 46.2±10.3ms, respectively).

Conclusions: Pmax and Pd increase significantly after HD sessions. Raising dialysate potassium concentration can shorten postdialysis Pmax and Pd, and this may help to decrease the incidence of AF among HD patients.

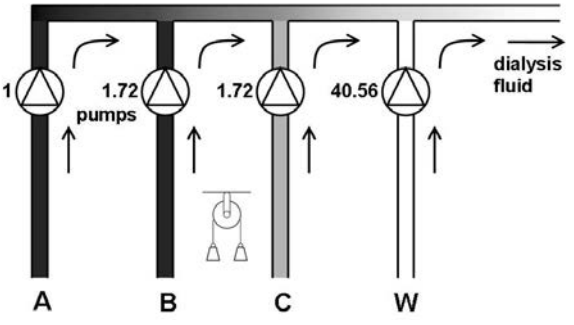
A Novel Method of Delivering Bicarbonate-Based Dialysis Fluid: A 4-Stream Approach Susie Q. Lew,[1] Yuk Lun Cheng,[2] Todd S. Ing.[3] *[1]Medicine, George Washington Univ, Washington, DC; [2]Medicine and ICU, Alice Ho Miu Ling Nethersole Hospital, Hong Kong, China; [3]Medicine, Stritch School of Medicine, Loyola Univ Chicago, Maywood, IL.*

Background: A conventional 45X, 3-stream method of delivering a bicarbonate-based dialysis fluid (DF) uses an acid concentrate stream (CS), **A**; a bicarbonate (BIC) CS, **B**; & H_2O stream, **W**. The flow rate ratios (FRR) for **A**:**B**:**W** are: 1:1.72:42.28, respectively (totaling 45 or 45X). By altering the **B** flow rate, BIC level in the final DF ranges from 20 to 40 mM. Variations beyond these limits leads to excessive reciprocal changes in the DF levels of **A** ingredients.

Methods: We have devised a 4-stream method to overcome the above range limitation by adding a NaCl CS, **C**. **B** & **C**'s FRR are controlled by an electronic pulley-like mechanism.



Results: The FRR for the 4-streams **A**:**B**:**C**:**W** are: 1:1.72:1.72:40.56 (45X). Contributions to the final DF are: **A:** Chlorides of Na (63 mM), K, Ca, & Mg, & glucose; **B:** 37 mM $NaHCO_3$; **C:** 37 mM NaCl, and **W**: H_2O. With **B** & **C**, when the FRR changes in 1 stream, the other changes by the same magnitude but in the opposite direction. For example, **B**'s FRR decreases by 0.2 to 1.52 in order to lower the DF $NaHCO_3$ level to 32.7 mM to treat metabolic alkalosis, then **C**'s FRR will reciprocally increase by 0.2 to 1.92 to raise the DF NaCl level to 41.3 mM. The opposite sequence of events occur if FRR of **B** increases to treat metabolic acidosis. The 2 fluid volumes responsible for diluting the ingredients derived from **A**, namely, the sum of the FRR for **B** & **C** (3.44) and the FRR for **W** (40.56) remain unchanged. Hence, the levels of **A** ingredients in the final DF will remain untouched. Since **B** & **C** are isonatric, their reciprocal changes described will not affect the final DF Na level either.

Conclusions: This 4-stream approach allows a wider [BIC] range in the final DF without changing the levels of Na or **A** ingredients.

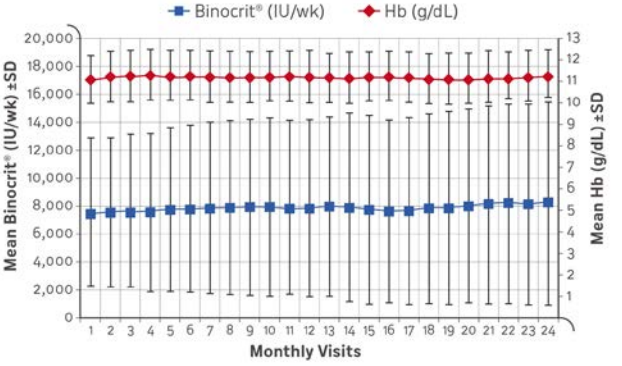
Real-World Effectiveness of Biosimilar Epoetin α: 2-Year Outcomes in the Monitor-CKD5 Study Johannes F. Mann,[1] Gerard M. London,[2] Christian Combe,[3] David Goldsmith,[4] Philippe Zaoui,[5] Frank Dellanna,[6] Michael Gorray,[7] Nadja Hoebel,[7] Karen Macdonald,[8] Ivo Abraham.[9] *[1]Friedrich Alexander Univ Erlangen-Nürnberg, Erlangen, Germany; [2]Centre Hospitalier F.H. Manhés, Fleury-Mérogis, France; [3]Centre Hospitalier de Bordeaux, Bordeaux, France; [4]Guy's and St. Thomas' NHS Foundation Hospital, London, United Kingdom; [5]Univ de Grenoble-Alpes, Grenoble, France; [6]Dialysezentrum, Düsseldorf, Germany; [7]Sandoz/Hexal AG, Holzkirchen, Germany; [8]Matrix45, Tuscon, AZ; [9]Univ of Arizona, Tuscon, AZ.*

Background: Biosimilar erythropoiesis-stimulating agents (ESAs) are not yet available in the US, but longitudinal evidence on real-world use abroad is growing. MONITOR-CKD5 is a European study examining long-term safety and effectiveness of biosimilar epoetin α (Binocrit®) in hemodialysis (HD) patients (pts).

Methods: Prospective 24-month (24m) pharmacoepidemiological study of 2023 HD pts with renal anemia treated with Binocrit® in 10 European countries. Binocrit® dosing and hemoglobin (Hb) outcomes over 24m are presented.

Results: Mean±SD age was 64.8±14.95y; 59.3% were male. Mean time on HD was 3.8±4.6y. Most had received an ESA previously (82.5%). Primary CKD etiology: diabetic nephropathy (25.4%), chronic glomerulonephritis (20.4%), renal vascular disease (16.4%). At enrollment 73.0% had adequate iron stores, 22.2% had functional and 4.8% absolute deficiency. Over 24m, mean serum ferritin ranged from 466±320 to 581±434ng/mL; supplemental iron was given to 59.7-67.5% and transfusion to 0.3-1.2% of pts. Baseline Hb was 11.1±1.1g/dL, with 68% between 10-12g/dL; mean weekly Binocrit® dose at baseline was 106.5±78.7 IU/kg. Mean Hb and Binocrit® dose remained stable over 24m (both *p*=ns)



Conclusions: In this real-world study Binocrit® maintains stable Hb over 24m, consistent with originator. This is the first 2-year evidence of the effectiveness of Binocrit® in HD.

Discontinuation of Eculizumab in a Patient with Atypical HUS Mamta Shah, Juan Calderon, Anushree C. Shirali. *Dept of Nephrology, Yale School of Medicine, New Haven, CT.*

Introduction: Since atypical HUS (aHUS) is a disease of disordered serum complement activation, eculizumab has been used successfully in its treatment. While this approach has been beneficial in the acute treatment of aHUS, the optimal duration of therapy remains unknown, particularly in patients with mutations of complement regulatory proteins. We report a case of aHUS in a patient with a membrane cofactor protein (MCP) mutation who was successfully treated with eculizumab and remains without disease recurrence after its discontinuation.

Case Description: A 26 year-old man was diagnosed with aHUS after presenting with influenza, non-bloody diarrhea, hematuria and a serum creatinine (Cr) of 5.1mg/dL. He had 4gms of proteinuria, hemolytic anemia and thrombocytopenia. He showed improvement in hematologic parameters with steroids and plasmapheresis but had persistently elevated Cr prompting initiation of eculizumab. Within 6 months his Cr was 1.1mg/dL with minimal proteinuria. Direct sequencing analysis revealed that he had a heterozygous MCP missense mutation c.586G>A (G196R). Two years later, in consultation with hematology, eculizumab was stopped. He is being followed with monthly labs. Over the past year, he has shown no evidence of disease recurrence, with stable Cr at 1.1mg/dL and no significant proteinuria, hematuria or hemolysis.

Discussion: Approximately 60%-70% of aHUS patients have mutations in the genes encoding complement factor H (CFH), factor I, MCP, factor B, thrombomodulin or C3. In a study of 10 aHUS patients with different mutations who were taken off eculizumab maintenance, 3 patients had recurrent disease, all of whom had CFH mutations. Immediate improvement was seen with reinstitution of eculizumab. Our patient with a MCP mutation has been recurrence free for a year following discontinuation of eculizumab. The rationale for this approach includes avoiding high drug cost,and minimizing risk of meningococcal infection and immune-mediated drug reactions. Frequent laboratory testing is necessary for early detection of recurrence. Improved understanding of specific genotypes and aHUS recurrence will help tailor therapy individually and maximize benefit while minimizing risk.

Two Cases of Adult Onset Henoch-Schönlein Purpura with Acute Kidney Injury and Severe Gastrointestinal Manifestations: Successful Treatment with Factor XIII Replacement Therapy Takeyuki Takamura, Fumihiko Furuya, Kenichiro Kitamura. *Third Dept of Internal Medicine, Univ of Yamanashi, Chuo, Yamanashi, Japan.*

Introduction: Gastrointestinal involvement occurs in 50-75% of Henoch-Schönlein Purpura (HSP) patients. Several prior studies have identified a correlation between the decreased FXIII activity and the severity of gastrointestinal manifestations or kidney injury in HSP patients.

Case Description: [Case 1] A 48-year-old-woman was hospitalized with purpura, gastrointestinal hemorrhage, proteinuria, and macroscopic hematuria. Kidney biopsy revealed granular deposition of IgA and C3 in the mesangial region with crescent formation. She was initially treated with intravenous methylprednisolone pulse therapy followed by oral prednisolone 40mg daily, but her symptoms were not improved. Since her plasma level of FXIII was substantially decreased, we added FXIII replacement therapy and intravenous cyclophosphamide (IVCY) on oral prednisolone therapy. Her gastrointestinal manifestations and renal function were significantly ameliorated. [Case 2] A-78-year-old-man was admitted complaining of purpura, melena, proteinuria, and macroscopic hematuria. His pathological findings indicated leukocytoclastic vasculitis and IgA deposition of vessel walls. Nine severe gastrointestinal hemorrhages occurred and he received red blood cell transfusion and endoscopic clipping therapy. He was also treated with intravenous methyl prednisolone pulse therapy, IVCY, intravenous immunoglobulin, and plasma exchange. His plasma level of FXIII was significantly reduced and FXIII replacement therapy was performed. His kidney function and gastrointestinal bleeding were improved.

Discussion: We report 2 cases of HSP with acute kidney injury and severe gastrointestinal manifestations and successfully treated with FXIII replacement. In both cases, immunosuppressive therapy did not improve the kidney or gastrointestinal injury, but FXIII replacement therapy or combination of plasmapheresis and FXIII replacement substantially ameliorated the both injury. These findings strongly suggest the possibility that FXIII plays critical roles in the pathogenesis and the progression of kidney and gastrointestinal injury that are associated with HSP.

TH-PO003

A Case of Nephrotic Syndrome Secondary to Kimura Disease Divya Raghavan,[1] Mazdak A. Khalighi,[2] Laith Al-Rabadi,[1] Josephine Abraham.[1] *[1]Dept of Nephrology, Univ of Utah, Salt Lake City, UT; [2]Dept of Pathology, Univ of Utah, Salt Lake City, UT.*

Introduction: Kimura disease (KD) is a rare chronic inflammatory disorder typically presenting with head and neck masses, peripheral eosinophilia and elevated serum IgE levels. Etiology is unclear and it is usually seen in East Asians. A multitude of renal lesions have been described with KD, including membranous glomerulonephritis (GN), mesangioproliferative GN, minimal change disease (MCD) and IgA nephropathy. We report a case of KD in a Caucasian male patient who initially presented with MCD.

Case Description: A 70 year old Caucasian man with a history of diabetes mellitus and recurrent skin lesions (lymphocytoma cutis on biopsy) was admitted to the hospital with complaints of leg swelling and dyspnea on exertion. Physical exam revealed pitting pedal edema and enlarged right post-auricular and right cervical lymph nodes. Labs showed a serum creatinine (SCr) of 2.44 mg/dl (baseline 1.1mg/dl), eosinophilia (14%), and urine total protein-to-creatinine ratio of 8.8 g/g. Kidney biopsy showed MCD. Prednisone 1mg/kg PO QD was started soon after he underwent a CT scan of head, neck, chest, abdomen and pelvis to evaluate for lymphoma as the etiology of MCD. A large infiltrative soft tissue mass involving the right parotid gland was identified. Patient underwent an ultrasound-guided fine needle aspiration of the post-auricular lymph node which showed atypical lymphoid cells but no monoclonality. Patient declined biopsy of the parotid mass after discussing potential surgical complications. Dermatopathology obtained slides of previous skin lesions (''lymphocytoma cutis'') which showed numerous eosinophils with dilated vascular spaces, a finding consistent with KD. IgE level was elevated at 1084 kU/L (<214). Patient was discharged on oral prednisone. SCr improved to 1.1 mg/dl three months later (peak value 4.9 mg/dl) with resolution of proteinuria.

This is a unique case of KD causing nephrotic syndrome in a 70 year old Caucasian man. A multidisciplinary approach was important in identifying the etiology of the patient's nephrotic syndrome. This unifying diagnosis obviated the need for further invasive procedures.

TH-PO004

Effect of Single-Dose Rituximab in IgA Nephropathy Presenting as Nephrotic Syndrome: A Report of Two Cases Roxana Adriana Jurubita, Bogdan Obrisca, Florentina Wagner, Andreea Andronesi, Bogdan Marian Sorohan, Nicu Caceaune, Gener Ismail. *Nephrology and Internal Medicine, "Carol Davila" Univ, Bucharest, Romania.*

Introduction: Nephrotic syndrome (NS) is a rare manifestation of IgA nephropathy (IgAN) usually associated with widespread proliferative lesions or coexistent minimal-change disease. Rituximab has shown efficacy in the treatment of membranous nephropathy and ANCA-associated vasculitis, but wasn't evaluated as a therapeutic option for IgA nephropathy.

Case Description: Case 1: A 27 year-old male presented with edemas, NS (proteinuria of 8 g/day), altered renal function with estimated glomerular filtration rate (eGFR-CKD-EPI) of 63 ml/min and microscopic hematuria. Kidney biopsy revealed IgAN with fibrocellular crescents involving more than 50% of the examined glomeruli, with no endocapillary hypercellularity. The serologic studies (ANA, pANCA, cANCA, anti-GBM antibodies) were negative. After an initial 6-month course of corticosteroid therapy, the NS persisted. In this setting, 500 mg of Rituximab was administered. Subsequent check-ups are shown in table. Case 2: A 21 year-old male is admitted for edemas and hypertension. Initial testing revealed NS with proteinuria of 8,74 g/day, serum albumin 2,8 g/dl, eGFR 58 ml/min and microscopic hematuria. Kidney biopsy showed intense mesangial IgA staining on immunofluorescence and fibrocellular crescents in less than 50% of the examined glomeruli. The patient received a 6-month course of corticosteroid therapy and mycophenolate mofetil 2g/d, with partial remission of the NS. However, after completing the immunosuppressive regimen, the NS relapsed and eGFR decreased to 41 ml/min, so it was decided upon administration of 500 mg of Rituximab. Subsequent check-ups are shown in table.

Variables	Case 1				Case 2		
	Baseline	3 months	6 months	9 months	Baseline	3 months	6 months
eGFR (ml/min)	75	58	50	56	41	34	39
Serum Albumin (g/dl)	3.3	3.6	4	4.2	2.9	3.5	3.7
Proteinuria (g/day)	5.53	2.5	1	0.7	10	7	4

Discussion: In the cases described, Rituximab treatment was associated with a clear improvement of NS and stabilization of renal function. Still, randomized clinical trials to assess the efficacy of rituximab in IgAN treatment are needed.

TH-PO005

Acute Kidney Injury and Possible Thrombotic Microangiopathy Associated with EGFR Inhibitor Osimertinib Nuha Ibrahim, Antoney Joseph Ferrey, Yongen Chang. *Nephrology, UC Irvine, Orange, CA.*

Introduction: Osimertinib is a small molecule inhibitor of epithelial growth factor receptor (EGFR) tyrosine kinase approved to treat non-small cell lung cancer (NSCLC). Here, we report a case of acute kidney injury (AKI) associated with the use of osimertinib.

Case Description: A 68 year old female with metastatic NSCLC presented with dyspnea, hypertension and swelling after taking osimertinib for one month. Exam was remarkable for +JVD and peripheral edema. Serum creatinine (SCr) was 4.4mg/dL from baseline 0.89mg/dL. Urine protein creatinine ratio was 3.9 g/g and albumin creatinine ratio was 1905mg/g. Urine sediment revealed many nondysmorphic RBCs but no casts. Echocardiogram showed ejection fraction of 33%. Patient was oliguric and hemodialysis was initiated. Renal biopsy was performed. Light microscopy showed severe acute tubular epithelial cell injury with tubular basement membrane rupture and secondary interstitial inflammation. Both LM and electron microscopy showed extensive glomerular and arteriolar endotheliosis and glomerular basement membrane (GBM) wrinkling. No endocapillary fibrin thrombi were observed. There was also mild effacement of podocyte foot processes. Given the severity of endotheliosis, the possibility of early TMA was considered. Further laboratory studies showed no thrombocytopenia or evidence of hemolysis. On hospital day 7, her urine output improved and dialysis was held. Her SCr was 2.8mg/dL upon discharge and 1.3 mg/dL two months later. Repeat urine PCR was 0.57g/g and ACR 208mg/g. Osimertinib was held indefinitely.

Discussion: In summary, we presented a case of new onset heart failure (HF), AKI and proteinuria in association with osimertinib use. HF is a known adverse effect of osimertinib. Unlike vascular endothelial growth factor (VEGF) receptor inhibitors, EGFR inhibitors were not known to be nephrotoxic. To our knowledge, this is the first report of EGFR inhibitor associated AKI. Interestingly, renal biopsy not only demonstrated ATN but also features of TMA and podocyte injury. This case expands the current knowledge of the renal effects of tyrosine kinase inhibitors in the era of biologics.

TH-PO006

A Report of 3 Cases of MPGN Type III, Strife and Anders Type: A Definitive Diagnosis by EM-PAM Proposes a Negative Application to C3 Glomerulonephritis Naomi Sato,[1] Yasuhiro Nakamura,[2] Takashi Takaki,[1] Kensuke Joh.[1] *[1]Pathology, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Pathology, Tohoku Medical and Pharmaceutical Univ, Sendai, Miyagi, Japan.*

Introduction: C3 glomerulopathy is an umbrella term comprising of dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). C3GN is composed of primary membranoproliferative GN (MPGN) type I and type III after differentiation of DDD. Since primary MPGN type III, second form, "Strife and Anders" type (MPGN III S&A) can be a candidate of C3GN. We experienced 3 cases of MPGN III S&A, which were definitely diagnosed by electron microscope with Periodic Acid-Methenamine-Silver stain (EM-PAM) according to the original articles of Strife and Anders. The purpose was to analyze these rare cases and to estimate whether MPGN III S&A can be categorized into C3GN.

Case Description: Patients (pts) were 57 yrs male, 23 yrs male and 20 yrs female, respectively. All pts showed no clinical symptoms of secondary GN. Only one presented C3 hypocomplementemia. Renal biopsy revealed MPGN-like lesion with double contour. Immunoglobulins (heavy and light chains) besides C3 deposition were demonstrated as glomerular peripheral pattern. In EM, all cases showed a large amount of lumpy intramembranous continuous dense deposits in the glomerular basement membrane (GBM) with mesangial interposition, whereby a continuity of lamina rara externa was well preserved. EM-PAM demonstrated a disruption of lamina densa of the GBM, which may relate to immunoglobulins deposition.

Discussion: EM-PAM proposed substantial reasons to diagnose these all cases as MPGN III S&A, which consists of first, a disruption of lamina densa, which can differentiate a diagnosis of DDD without GBM disruption and second, intact lamina rara externa, which can differentiate MPGN type III Burkholder with epimembranous deposits showing destruction of lamina rara externa. The term C3 GN is coined to describe glomerular lesions in which there is glomerular accumulation of C3 with little or no immunoglobulin. Since our all 3 cases showed immunoglobulins deposition, which may relate to a disruption of lamina densa as a definition of MPGN III S&A, C3 GN may not be applied to MPGN III S&A.

TH-PO007

A Complex Case - Solitary Kidney with Crescentic IgA Nephropathy during Pregnancy Rekha Kambhampati, Daphne Harrington Knicely. *Nephrology, Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Introduction: IgA nephropathy is the most common glomerular disorder. We present a complex case of successfully treated crescentic IgA nephropathy in a solitary kidney diagnosed in early pregnancy.

Case Description: A 28 year old Caucasian G1P0101 at 14 weeks and 5 days gestation with a past medical history of left donor nephrectomy and gestational hypertension presented with acute kidney injury. Fifteen days prior to admission, her creatinine was 0.95 and 24-hour urine protein was 4448 mg. Five days prior to admission, she developed group A streptococcal infection. One day prior to admission, her creatinine rose to 2.4 with gross hematuria. On admission, she was found to be hypertensive with a creatinine of 3.2 and 36 red blood cells per high power field on urinalysis. A renal biopsy revealed 70% crescentic and necrotizing proliferative glomerulonephritis with IgA dominant deposits.

She was treated with methylprednisolone 1 gram daily for three days and then transitioned to prednisone 60 mg daily. Her creatinine improved to 1.0-1.1. Her pregnancy was complicated by variable fetal heart decelerations requiring delivery of a live infant at 28 weeks gestation. Post-partum, her prednisone was tapered at monthly intervals. Her creatinine remained stable at 1.5-1.7. Maximum 24-hour urine protein was 14.6 gm and improved to 1 gram. Post-partum, she was started on an ACE inhibitor.

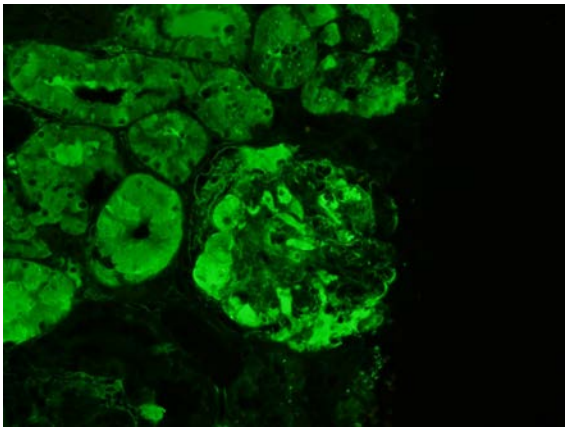
Discussion: There is very little literature on treatment of crescentic necrotizing glomerulonephritis in pregnancy. Current recommendations advise for corticosteroids and cyclophosphamide as initial therapy in non-pregnant individuals. However, given its teratogenic side effects, cyclophosphamide was not a feasible option for our patient. A case report by Komatsuda, et al (1994) revealed successful treatment of a patient with crescentic IgA nephropathy diagnosed at 21 weeks gestation with corticosteroids. No literature currently exists regarding treatment of crescentic IgA nephropathy in a solitary kidney during pregnancy. We were able to successfully treat our patient with pulse dose steroids followed by high dose oral steroid therapy for the duration of her pregnancy with favorable post-partum outcomes.

TH-PO008

Proliferative Glomerulonephritis with Masked Monoclonal Deposits Responsive to Myeloma Chemotherapy Anjuman A. Howlader,[1] Amy Nicole Sussman,[1] Erika R. Bracamonte,[2] Samih H. Nasr,[3] Bijin Thajudeen.[1] *[1]Nephrology, Banner Univ of Arizona, Tucson, AZ; [2]Pathology, Banner Univ of Arizona Medical Center, Tucson, AZ; [3]Pathology, Mayo Clinic, Rochester, MN.*

Introduction: MPGN with masked monotypic immunoglobulin(IG) deposits is a recently described entity. In the absence of an electron microscopy(EM), some of these patients can be misdiagnosed as having post-infectious glomerulonephritis(PIGN).

Case Description: A 48-year-old Hispanic male transferred to our institution with a diagnosis of biopsy-proven PIGN. His lab evaluation: urine 82 RBC/HPF, urine pro/cr 6100 mg/gm, alb/cr 5403 mg/gm, BUN 208 mg/dl, serum: Cr 4.6 mg/dl. Serum electrophoresis: monoclonal gammopathy(MG) with predominant IgG kappa on immunofixation. Serum free kappa elevated(1246 mg/l) and lambda fraction normal. A repeat kidney biopsy was performed. LM demonstrated diffuse endocapillary proliferative GN. IF was negative except for trace granular staining for C3. EM showed large non-organized intraluminal electron dense deposits. In view of histopathology and MG, IF study on pronase-digested, paraffin embedded tissue was performed which showed bright (2-3+) staining for IgG kappa.



The findings were consistent with diffuse endocapillary proliferative GN with masked monoclonal IgG kappa deposits. Bone marrow aspiration showed myeloma, treated with revlimid-velcade-dexamethasone. He also received HD support for 3 weeks with subsequent improvement in renal function. The most recent serum Cr and urine pro/cr ratio were 0.8 mg/dl and 300 mg/gm respectively.

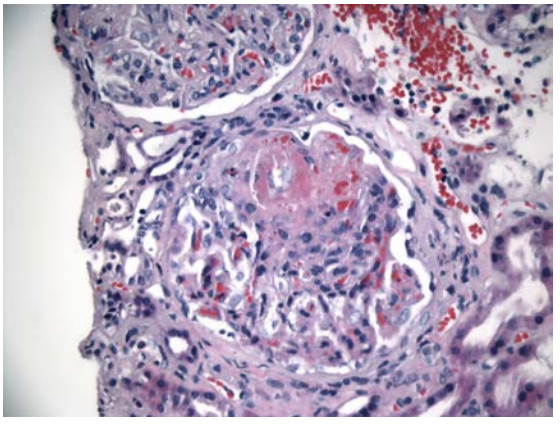
Discussion: This case highlights the importance of performing paraffin IF for GN associated with C3 deposits in adults, especially in the presence of MG regardless of the ultrastructural appearance and location of deposits. It is also recommended when the findings by routine IF do not match either the clinical scenario or EM findings.

TH-PO009

Concomitant Heparin Induced Thrombocytopenia and Hemolytic Uremic Syndrome Sarthak Virmani,[1] Ari B. Geller.[2] *[1]Internal Medicine, Univ of Connecticut School of Medicine, Farmington, CT; [2]Div of Nephrology, St. Francis Hospital, Hartford, CT.*

Introduction: Thrombotic microangiopathy (TMA) with renal failure has a broad differential including TTP, HUS, DIC, APLS and renal scleroderma crisis.

Case Description: A 54 year old female presented with with blurry vision, unilateral leg weakness and altered mental status 11 days after a bio-prosthetic valve repair for critical aortic stenosis. Initial blood work showed hemolytic anemia (Hb 10.7 g/dl, haptoglobin < 6 mg/dl), AKI (Cr 2.4 mg/dl, baseline 0.9 mg/dl) and thrombocytopenia (60,000/mm^3). MRI of the brain showed multifocal acute infarcts of the anterior and posterior circulation. ANA titers were found to be 1:160. Plasma exchange (PLEX) therapy was initiated for a clinical diagnosis of TTP while awaiting ADAMTS13 levels. After 5 days of therapy, her initial ADAMTS13 measured 50% activity and her heparin PF4 antibody screen was positive. This effectively ruling out TTP and established a diagnosis of Heparin Induced Thrombocytopenia (HIT).PLEX therapy was then stopped and Argatroban was initiated. Soon after this intervention, her platelet counts, LDH and other hemolysis markers improved. However, progressive renal failure (Cr 5.0 mg/dl) prompted a biopsy which demonstrated thrombotic microangiopathy. This raised a concern for concomitant atypical HUS.



She received a total of 4 weekly doses of Eculizumab for presumptive diagnosis of atypical HUS. She had significant improvement of her renal function (Cr 1.9 mg/dl). She was continued on anticoagulation. On follow up, she reports improvement in all her symptoms, with improving hemolysis parameters. She will be continued on Eculizumab for 6 months.

Discussion: This case not only highlights the need to have a broad differential diagnosis for TMAs and renal failure, but also the complex management of a patient with overlapping syndromes of HIT and HUS.

TH-PO010

Association of Atypical ANCA with Glomerular Disease Ali I. Gardezi, Tripti Singh, Sana Waheed. *Div of Nephrology, Univ of Wisconsin SMPH, Madison, WI.*

Introduction: Anti neutrophilic cytoplasmic antibodies (ANCA) include a wide range of antibodies directed against cytoplasmic antigens of neutrophils. Indirect Immunofluorescence (IIF) is commonly used to identify ANCA with different patterns. Cytoplasmic pattern (cANCA) is mostly caused by proteinase-3 (PR3) whereas perinuclear pattern (pANCA) is mostly caused by Myeloperoxidase (MPO) antibodies. Any pattern other than these two is labeled atypical ANCA (aANCA). Whereas cANCA & pANCA have been associated with small vessel vasculitis in the kidneys, aANCA has never been associated with any glomerular pathology.

Case Description: We reviewed cases of 7 patients who had aANCA positive on serological testing with negative MPO and PR3 antibodies on ELISA. The details of clinical course and biopsy findings are mentioned in the table included.

Sr. No	Clinical presentation	Initial Creatinine mg/dl	Urine Protein g/g	Hematuria	ANA	Biopsy findings	Treatment and outcome
1	29 y/o male, SLE with flare, mucositis, leukopenia	0.5	0.5	Present	1:640	Class IV Lupus Nephritis	Steroids and IV Cyclophosphamide. Stable creatinine and proteinuria
2	65 y/o male, Hypertension, CKD, Proteinuria & family h/o autoimmune disease	1.26	0.5	Absent	1:320	Secondary membranous nephropathy due to mixed connective tissue disorder	Creatinine and Proteinuria has remained stable without any immunosuppressive treatment
3	44 y/o female, h/o Lung transplant, CKD 4, New onset nephrotic range proteinuria	2.26	4.1	Absent	Negative	Mesengial Proliferative Glomerulonephritis with IgM deposits	Already on immunosuppression for lung transplant. Progression to End stage renal disease within four months of diagnosis.
4	64 y/o male, AKI on CKD 3, Hypertension, NSAIDs	1.56	14	Present	Negative	Membranoproliferative Glomerulonephritis with Cryoglobulins	Rituximab. Significant improvement in serum creatinine and proteinuria
5	76 y/o male, AKI	2.79	2.21	Present	Negative	Pauci Immune Glomerulonephritis	Cytoxan initially, then switched to Rituximab. Significant improvement in creatinine and proteinuria
6	57 y/o male, Nephrotic range proteinuria, Sarcoidosis	0.8	4.36	Present	1:640	Pauci Immune Glomerulonephritis	Oral Cytoxan. Creatinine has been stable, Proteinuria is improving
7	40 y/o male, AKI on CKD 3, DM, Nephrotic range proteinuria	4.58	14.7	Present	Not checked	Pauci Immune Glomerulonephritis	IV Cytoxan, Steroids & Plasma Exchange. Required dialysis on presentation and never came off.

Discussion: As opposed to cANCA and pANCA, target antigens for aANCA have not been identified but have been associated with inflammatory bowel disease, autoimmune hepatitis, primary sclerosing cholangitis, rheumatoid arthritis and certain chronic infections. All seven patients with aANCA showed glomerular damage but no common pattern was identified. A strongly positive antinuclear antibody (ANA) can lead to cross reactivity with ANCA and three of our patients had concurrent ANA positivity. Interestingly, three patients were diagnosed with pauci-immune glomerulonephritis despite having a negative MPO and PR3 antibodies. The presence of aANCA in our patients could be due other antibodies implicated in ANCA negative vasculitis like leukocyte associated membrane protein 2 (LAMP-2) or anti-pantrexin 3 antibodies and might have been the direct pathogenic cause of the disease process. Even though, historically, a positive aANCA test with negative PR3 and MPO antibodies is ignored; findings of glomerular damage with positive aANCA warrants further studies to explore this association.

TH-PO011

Catastrophic Hemodialysis Failure Secondary to Hydroxocoblamin Exposure Kenneth Lim,[1] Eliot C. Heher,[1] David J.R. Steele,[1] Andrew Z. Fenves,[1] Ravi I. Thadhani,[1] Kenneth Christopher,[2] Nina E. Tolkoff-Rubin.[1] *[1]Div of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Renal Div, Brigham and Women's Hospital, Boston, MA.*

Introduction: Hydroxocobalamin is an antidote for the treatment of cyanide poisoning. We describe a case of a young patient administered empiric hydroxocobalamin due to suspected cyanide overdose with failure of emergent hemodialysis secondary to interference from hydroxocobalamin.

Case Description: A 24 year old man was found unresponsive and profoundly hypotensive. On arrival to the emergency room, he was in extremis with significant agonal breathing. Following emergent intubation and despite IV fluid resuscitation, he required rapid escalation to multiple vasopressor requirements. Due to profound acid-base disturbance and concern for intentional overdose, emergent dialysis was considered. Physical examination was notable for a glasgow coma scale of 3, temp 35.3°C, BP 60/46 mm Hg, HR 74 beats/min, RR 24 breaths/min, and cool extremities. Laboratory investigations revealed a Cr of 1.3mg/dL, Na 145mmol/L, K+ 4.6mmol/L, HCO3 10mmol/L, AG 39, phos 4.9, lactate 21.3mmol/L, WBC 27.3K/uL. A rapid bedside echocardiogram showed severely diminished cardiac function. Blood and urine toxicology screen were negative. Hemodialysis was initiated emergently using a Fresenius 2008K machine, however this was confounded by a recurrent "blood leak alarm" that repeatedly shut down the machine. Following multiple trials to initiate hemodialysis, this was aborted with plans to initiate CVVH. Emergent salvage extracorporeal membrane oxygenation (ECMO) was commenced, however the patient expired prior to CVVH initiation. Collateral history later revealed likely sodium azide intoxication.

Discussion: Hydroxoobalamin causes orange/red discoloration of bodily fluids and can permeate dialysate. This can lead to catastrophic dialysis failure due to defraction of light from discolored dialysate, resulting in triggering of the blood leak sensor in certain hemodialysis machines. The case highlights the need for increased awareness of hydroxocobalamin effects in hemodialysis and its potential to delay initiation of emergent dialysis in critically-ill patients.

TH-PO012

Focal Segmental Glomerulosclerosis Associated with Mitochondrial Disease Kenneth Lim,[1] David J.R. Steele,[1] Ravi I. Thadhani,[1] Eliot C. Heher,[1] Amel Karaa.[2] *[1]Div of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Pediatrics, Massachusetts General Hospital, Boston, MA.*

Introduction: Primary mitochondrial diseases (MD) are complex, heterogeneous inherited diseases caused by mutations in either the mitochondrial or nuclear DNA. Glomerular diseases in MD have been reported with tRNA mutation m.3243A>G causing a syndrome of mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes (MELAS). We present a case of focal segmental glomeruloscerosis (FSGS) associated with a new tRNA mutation site.

Case Description: A 34 year old man with a history of ESRD s/p living related kidney transplantation, diabetes, hearing loss and developmental delay presented to outpatient clinic with complaints of new behavioral changes. At age 12 he developed hearing loss and at age 14 non-nephrotic range proteinuria secondary to FSGS. He now presents with new behavioral difficulties and disorganized thought processes. Based on this set of clinical circumstances, concern for an underlying genetic abnormality was raised. Physical examination was remarkable for difficulty hearing, a pattern of dysarthric speech and cerebellar gait. Laboratory investigations including lactate levels were unremarkable. Serial brain MRIs revealed multiple areas of abnormal signal intensity in the basal ganglia and deep white matter, prominent 4th ventricle and cerebellar atrophy. Multiple metabolic testings were unremarkable and whole exome sequencing revealed a mitochondrial MT-TW tRNA change at position m.5538G>A as well as a PDGFRB p.R695C variant. This gene is associated with primary familial brain calcification. Genotype-phenotype correlations in this case are more consistent with a tRNA mutation as a cause of his symptoms. Biochemical investigations are currently in process to further evaluate the pathogenicity of the mutation found.

Discussion: Patients presenting with deafness and proteinuria can be misleadingly diagnosed with Alport's syndrome. Consideration of an underlying MD should be made in patients presenting with deafness, neurologic changes, diabetes and renal failure. To the best of our knowledge, this is the first case describing FSGS-associated MD caused by a m.5538 G>A mutation.

TH-PO013

A Confounding Case of Type 1 Cryoglobulinemic Vasculitis Nishkarsh Saxena, Tripti Singh, Sana Waheed. *Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) associated with cryoglobulins (CG) is often seen in the setting of hepatitis C (HCV) infection, hematologic malignancies or autoimmune conditions. Rarely, no etiology is found, limiting therapeutic options in these patients. We present a case of type 1 CG associated GN caused by monoclonal IgM heavy chain (HC) successfully treated with rituximab.

Case Description: A 64-year-old white male with history of hypertension and sporadic NSAID use presented to the kidney clinic with a creatinine (Cr) of 4.2mg/dL and a spot urine protein to Cr ratio (UPCR) of 9g/g with dysmorphic RBCs. Serologic work up was significant for normal complements, negative ANA and negative HCV antibody and PCR.

His CG test was positive for type 1 CG (monoclonal IgM HC). His serum immunofixation (IF) showed three distinct monoclonal bands – two IgG kappa and one IgG lambda. Bone marrow biopsy and CT scan of the chest, abdomen and pelvis were negative for malignancy. Renal biopsy showed MPGN pattern of glomerular injury with a full-house immunofluoresence pattern and subendothelial deposits with electro-lucent areas inside and severe podocyte foot process effacement. He was treated with pulse dose steroid followed by 4 weekly doses of rituximab 375 mg/m^2. His renal function improved to a Cr of 1.97mg/dL and UPCR 0.43g/g.

Most cases of CG associated GN are seen in the setting of mixed CG. Type 1 CG associated GN without an underlying hematologic malignancy is rare. Interestingly our patient had multiple oligoclonal bands of IgG on regular IF but his renal disease was likely caused by IgM HC. This monoclonal IgM HC was detectable only on IF done on serum for testing of CG due to its precipitation at a lower temperature. Data regarding optimal therapy for such patients is scarce. A study of 23 patients with type 1 CG treated with rituximab had shown a response rate of 80%, however, one-third had relapse by 12 months. Another case series of 2 patients with type 1 CG, rituximab therapy was associated with treatment failure.

Discussion: Further data is needed to evaluate the efficacy of rituximab monotherapy for type 1 CG associated GN, which was successful in our patient.

TH-PO014

The Importance of Renal Biopsy in the Diagnosis of Fabry Nephropathy

Eduarda Tenorio Leite,[1] Luiz Antonio Magnata Da Fonte Filho,[1] Jose Edevanilson Gueiros,[1] Ana Paula Gueiros,[1] Luiz A. Moura.[2] *[1]Nephrology, IMIP, Recife, Brazil; [2]Pathology, UNIFESP, Sao Paulo, Brazil.*

Introduction: Fabry disease (FD) is caused by mutations in the α-galactosidase A gene resulting in progressive accumulation of globotriaosylceramide (GL-3) in various tissues including the kidney, brain and heart. The current challenge is the search for biomarkers that allow early identification of patients with progressive disease, mainly in asymptomatic young people. In this context, the renal biopsy (RB) is gaining importance in the diagnosis of Fabry nephropathy, in the indication and evaluation of the response of enzyme replacement therapy (ERT).

Case Description: A female patient was diagnosed as a carrier of the p.R356W mutation at 14 years old through family screening after her father, (already on hemodialysis) had been diagnosed with FD. At first, the asymptomatic patient rejected the diagnosis and only later at 17 years old, sought medical help. She remained asymptomatic, denied having neuropathic pain, hypohidrosis or anhidrosis or gastrointestinal symptoms. She not had angiokeratoma. Laboratory tests showed serum creatinine 0.64mg/mL, urinary albumin-creatinine ratio 29 mg/g and normal urinalysis. Normal echocardiography. With the medical history of the father, coupled with the fact that a cousin had a kidney transplant at age 32 (daughter of a deceased uncle), we opted to do a RB. Light microscopy revealed vacuolization of podocytes, tubules with small and sparse atrophy foci and discreet interstitial fibrosis. Small-size arteries showed discrete fibrous intimal hyperplasia. In electron microscopy, podocytes were observed with large cytoplasm containing inclusions in concentric lamellar (myelin figures) and periodic band (zebra bodies) configuration. In these, there is effacement of foot processes. When evaluated by the renal scoring system for FD Proposed by Fogo, the podocytes received a GL-3 score 2 and 3.2 in PAS and semi thin sections, respectively. The percentage of interstitial fibrosis was 5%. On the findings of RB the patient was advised to start ERT.

Discussion: RB is of fundamental importance for early therapeutic intervention in FD in order to mitigate or prevent progressive nephropathy and other life threatening complications.

TH-PO015

Novel Treatment of HCV Induced Cryoglobulinemia Glomerulonephritis

Saed Shawar, Sandhya S. Thomas. *Nephrology Dept, Baylor College of Medicine, Houston, TX.*

Introduction: Current standard treatment of HCV-induced cryoglobulinemia GN (Cryo GN) in severe cases include plasmapheresis plus steroids with induction immunosuppressive (IS) (i.e. cytoxan), but in era of the antiviral therapy with 96-100% Sustained virologic response, it is unclear if standard therapy remains the best option.

Case Description: 66 year old white man with history of HTN, HLD, history of bladder cancer s/p resection, presented to renal clinic for evaluation of elevated creatinine (Cr) [6.3 mg/dl] from his baseline 1mg/dl [4month ago], he was complaining from generalized fatigue, joint pain, no joint swelling, redness, mouth ulceration, skin rash, no fever, no history of NSAID or herbal medication. His physical examination was unremarkable. His labs revealed elevated serum Cr, pyuria, hematuria, proteinuria (1.3 g/g), small monoclonal spike 0.57, free light chain normal 1.9, rheumatoid factor 85, HCV viral load 170K , kidney biopsy revealed a diagnosis of Cryo GN. The patient was treated with plasmapheresis, pulse steroids and initiated on the newer antiviral therapy [Elbasvir,grazoprevier], without induction IS. Patient's serum Cr decreased from 6.3 to 3.4 in less than 1month preventing him from being dialysis dependent.

Discussion: The treatment of cryoglobulinemia depends upon the underlying disorder and upon the severity and nature of the renal involvement. In this patient he responded well to plasmapheresis, steroids, and newer antiviral therapy alone. Raising the question in Cryo Gn secondary to HCV, the treatment may include standard therapies plus the new antiviral treatment with or without the need for induction immunosuppressive medication. To our knowledge this is the first case using newer antiviral treatment strategies and plasmaphereses without immunosuppressive medication in Cryo GN with a good response.

TH-PO016

Do Genetic Defects in Complement Regulation Underlie Invasive *S. pneumoniae* - Associated HUS?

Selasie Goka, Joshua Zaritsky. *Pediatrics, Nemours, Wilmigton, DE.*

Introduction: *Streptococcus pneumoniae*- associated HUS (Strep-HUS) has been thought to be a result of neuraminidase activity of pneumococci leading to endothelial damage and thrombotic microangiopathic anemia (TMA). However recent data suggests that mutations in the genes encoding complement proteins may potentiate complement dysregulation leading to the full clinical manifestation of HUS. We present a case of Strep-HUS associated with a known gene mutation of complement factor I (CFI).

Case Description: An otherwise healthy 10 month old male presented with 5 days of fever, and 2 days of vomiting and diarrhea. Initial and subsequent lab findings were significant for a TMA (Table) with a peripheral smear significant for helmet cells and RBC schistocytes and severe AKI with anuria.

	Presentation	6h later	40h later
Hemoglobin (g/dL)	11.4	9.5	6.7
Platelets (k/uL)	18	12	57 (post transfusion)
Sodium (mm/L)	136	146	144
Potassium (mm/L)	5.1	5.4	5.7
Chloride (mm/L)	102	114	114
TCO2 (mm/L)	24	22	19
BUN (mg/dL)	16	23	55
Creatinine (mg/dL)	0.5	0.6	1.6

Blood culture was positive for *S. pneumoniae.* Given an ADAMTS13 activity of 41%, a haptoglobin of 109 mg/dl and a LDH of 14, 645 U/L the patient was diagnosed with Strep-HUS. The patient was admitted to the PICU due to altered mental status with bradycardia and hypertension necessitating intubation. MRI brain demonstrated restricted diffusion, multiple hemorrhagic foci and elevated lactate on spectroscopy concerning for HUS. Unfortunately despite rapid treatment with eculizumab the patient developed brainstem herniation within 18 hours of presentation and was pronounced dead 4 days after admission. Genetic testing showed patient to be positive for a heterozygous missense mutation (c. 355G>A, p. Gly119Arg) in exon 3 of CFI, which has been previously shown to be associated with aHUS.

Discussion: This case suggests that underlying congenital abnormalities of complement regulation may play a significant pathogenic role in the development of Strep-HUS. Future studies are needed to clarify this association as rapid identification of these genetic abnormalities may allow for targeted therapy and improved patient outcomes.

TH-PO017

Renal Medullary Angiitis: Another Manifestation of ANCA - Associated Vasculitis

Swetha Rani Kanduri, Jorge Luis Castaneda. *Div of Nephrology, Univ of Mississippi, Jackson, MS.*

Introduction: Renal Medullary Angiitis is a lesion involving the vasa recta of the medulla. It has been reported previously in association with and without Anti-Cytoplasmic Neutrophil antibodies (ANCA). This lesion can be easily mistaken for acute interstitial nephritis owing to the acute inflammatory infiltrate. We report a case of Pulmonary-Renal Syndrome associated with ANCA and Myeloperoxidase antigens (MPO) with medullary involvement and no significant glomerular involvement.

Case Description: Our patient was a 74 years old AAF with previous history of Diabetes and HTN and no renal disease, who presented with 2-week history of shortness of breath, hemoptysis and AKI with a Serum Creatinine of 2.5mg/dl. The Urine analysis was positive for hematuria and minimal proteinuria. The bronchoscopy revealed a diffuse alveolar hemorrhage. She was immediately started on pulse dose steroids while the renal biopsy was prepared. Serology was positive for ANA, MPO-ANCA and negative for Anti-dsDNA, anti-GBM and normal Complement levels. Renal Biopsy showed mostly unremarkable glomeruli with only one cellular crescent formation, several areas of interstitial inflammatory infiltrates and one area of medullary angiitis, IF was negative. Renal function recover even before the institution of Rituximab as induction of remission regimen.

Discussion: Medullary angiitis is a lesion seen on kidney biopsy characterized by the combined morphologic findings of interstitial hemorrhage in the medulla with associated polymorphonuclear leukocyte infiltrate. The presence of karyorrhectic debris surrounding peritubular capillaries and interstitial hemorrhage may be the clue to distinguish from interstitial nephritis. The exact pathogenesis of medullary angiitis is unknown however we want to stress the importance of recognition of this presentation since it may be the only clue suggesting the presence of systemic vasculitis.

TH-PO018

Treatment of Fibrillary Glomerulonephritis with Use of Repository Corticotropin Injections (Acthar®) Sharon Reuben,[1] Natallia Maroz.[1,2] *[1]Dept of Medical Education, Kettering Medical Center, Kettering, OH; [2]Wright State Univ, Dayton, OH.*

Introduction: Fibrillary glomerulonephritis (FG) is a rare idiopathic condition, which is linked to malignancy, autoimmune disorders, or monoclonal gammopathies in a third of the cases. It carries a poor prognosis resulting in progression to end stage renal disease (ESRD) within 2-6 years depending on severity of disease and histological findings. Immunosuppressive agents (IA) have been used in uncontrolled studies with inconsistent results.

Case Description: A 66 year old African American male with a history of hypothyroidism and hypertension was referred to outpatient nephrology consultation in 10/2013 for worsening renal insufficiency over the prior of 2 years. Physical exam was notable for uncontrolled HTN, obesity, and 2+ pitting edema of lower extremities. Elevated creatinine of 2.7mg/dl and nephrotic range proteinuria 5.9gm/day prompted renal biopsy in 12/2013, which showed advanced fibrillary glomerulonephritis with proliferative features, extensive interstitial scarring, and tubular atrophy. Serological work up was negative for autoimmune disorders, hepatitis C or monoclonal gammopathy. No malignancy was identified. Initially, treatment was deferred due to patient preference, advanced disease, and consideration of adverse effects of IA. Four months later, he was started on *Acthar*®80 units three times weekly in hopes to slow progression to ESRD while avoiding the potentially more severe systemic immunosuppressive effects of alternative cytotoxic agents. Within 8 months he had resolution of nephrotic range proteinuria (from a peak of 8.1gm/day to 600mg/day). *Acthar*® was further tapered to 40 units twice weekly and eventually 20 units twice weekly. Creatinine peaked at 3.8mg/dl in 09/2015 but improved to 2.8mg/dl within 8 months and remained stable over subsequent 18 months.

Discussion: FG has no standardized treatment regimen owing to the lack of clinical trials. The use of corticotrophin injections have been seen to mitigate nephrotic proteinuria in variety of glomerular diseases. We report a case of partial remission in FG with complete resolution of nephrotic syndrome and stabilization of renal function over 26 months of therapy.

TH-PO019

Nephrotic Syndrome in a Patient with Mitochondrial Trifunctional Protein Deficiency Bakri Alzarka, Avi Rosenberg, Larry T. Patterson. *Nephrology, Children's National Medical Center, Washington, DC.*

Introduction: Mitochondrial trifunctional protein (MTP) deficiency is a rare autosomal recessive disorder of mitochondrial fatty acid β-oxidation caused by mutations in HADHA or HADHB. Nephrotic syndrome is not a reported feature of MTP deficiency.

Case Description: An 18 month old female had developed severe hypoglycemia and acidosis after birth. Her acylcarnitine profile was consistent with long-chain-3-hydroxyacyl-CoA dehydrogenase deficiency or MTP deficiency. She was found to have a heterozygous deletion, c.1059delP, in HADHB that is predicted to cause truncation and loss of MTP function. Her father had the same mutation, but is asymptomatic. At 18 months of age, she developed nephrotic syndrome. Her renal biopsy contained segmental and global sclerosing glomerular lesions. Her renal function rapidly declined leading to dialysis and nephrectomies. Collapsing glomerulopathy (CG) was seen on microscopy. Gene analysis showed a heterozygote variant in COQ6, which is predicted to have abnormal function.

Discussion: Our patient had a heterozygous mutation in COQ6, an enzyme needed for production of an integral member of the mitochondrial electron transport chain. Homozygous and compound heterozygote mutations in COQ6 cause coenzyme Q10 deficiency and nephrotic syndrome. Susceptibility genes for CG in mouse encode proteins directly involved in mitochondrial function suggesting that the glomerulopathy can be induced by mitochondrial dysfunction. A mutation in COQ2, which encodes an enzyme in CoQ10 pathway, leads to collapsing lesions resembling those in a murine model having a mutation in a gene with homology to the human PDSS2, another member of the CoQ10 synthesis pathway. We speculate that heterozygosity for both HADHB and COQ6 in our patient led to the metabolic disease as well as the nephrotic syndrome. Neither mutation alone would be expected to cause disease, but together could alter mitochondrial function. Collapsing glomerulopathy, which is found in other conditions with mitochondrial dysfunction, supports this idea. Further study will be needed to evaluate the effect of a combined HADHB and COQ6 heterozygosity and to determine whether supplementation might effectively treat disease.

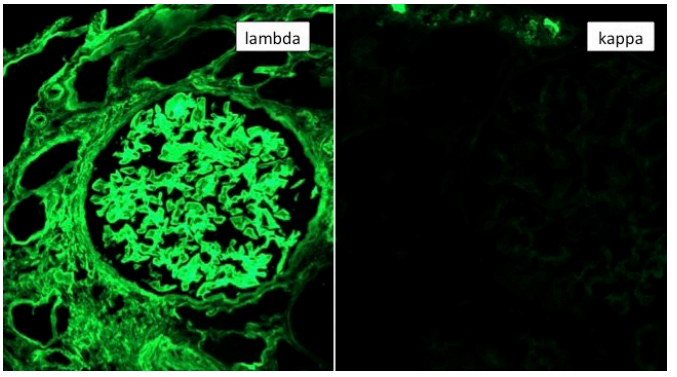
TH-PO020

De Novo Multiple Myeloma in a Kidney Transplant Recipient Presenting with Asymptomatic Proteinuria Anne D. Sebastian,[1] William Luke Whittier,[2] David J. Cimbaluk.[3] *[1]Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Nephrology, Rush Univ Medical Center, Chicago, IL; [3]Pathology, Rush Univ Medical Center, Chicago, IL.*

Introduction: Multiple myeloma (MM) is a plasma cell malignancy that can cause renal failure in native kidneys and recur in kidney transplants (RT) but is rarely reported *de novo*. We present a case of an asymptomatic RT recipient with proteinuria whose biopsy revealed *de novo* light chain deposition disease.

Case Description: A 65 y.o. black man with a PMH of HTN, DM2, and ESRD due to FSGS s/p RT in 1982 presented for routine follow up in 2015. His baseline SCr was 2.0 mg/dL from chronic allograft nephropathy (CAN) on biopsy in 1990. Microalbumin/Cr and p/c ratio in 2014 were 53 mcg/mg and 170 g/g respectively. Physical exam was normal. SCr: 2.1 mg/dL, Calcium: 10.4 mg/dL, total protein: 7.0 g/dL, albumin 4.4 g/dL. UA: 2+protein, 1+blood. Urine p/c 2.1 g/g.

Renal biopsy in 2015 redemonstrated CAN without nodularity or acute rejection. Congo red was (-). IF revealed strong, linear staining of glomerular and tubular basement membranes for lambda (λ) light chain and no staining for kappa (κ) (see Figure). EM contained no deposits or granules in the GBM.



SPEP showed κ 1.96 mg/dL, λ 93.0 mg/dL, and κ/λ 0.021. UIEP had monoclonal free lambda light chains. Marrow bx confirmed lambda light chain MM with 25% plasma cells. After starting bortezemib and dexamethasone, SCr and lambda light chains improved to 1.8 mg/dL and 34 mg/dL respectively. Treatment was held after a cavitary lung lesion was found. He eventually expired due to infectious complications.

Discussion: We present a patient found to have *de novo* lambda light chain nephropathy from MM 33 years after his renal transplant. This case highlights the importance of considering *de novo* pathology in transplant patients presenting with proteinuria.

TH-PO021

Successful Treatment of Resistant Mixed Class IV/V SLE with Adrenocorticotropic Hormone (ACTH) Amtul Aala,[1] Ali Yalcindag,[2] M. Khurram Faizan.[2] *[1]Dept of Medicine, Rhode Islad Hospital, Providence, RI; [2]Dept of Pediatrics, Hasbro Children's Hospital, Providence, RI.*

Introduction: Numerous immunosuppressive medications have been used in the treatment of resistant mixed class IV/V lupus nephritis (LN) such as mycophenolate mofetil (MMF), cyclophosphamide, cyclosporine, rituximab and tacrolimus. We present a 13 y.o. girl with resistant mixed class IV/V lupus nephritis treated successfully with ACTH.

Case Description: 13 y.o. African American girl presented with new onset proteinuria with urine protein to creatinine ratio (UPCR) of 2.7, creatinine 0.5 mg/dL, ANA 1:10240, C3 52.0 (low), C4 10.9 (low) and serum albumin (Alb) 2.7 g/dL. Renal biopsy revealed diffuse proliferative and membranous glomerulonephritis consistent with Mixed Class IV/V LN. She was started on oral prednisone and MMF 1000 mgs bid. Due to persistent proteinuria, MMF was increased to 1500 mg bid, prednisone was increased to 20 mg bid and Lisinopril to 20 mg daily with minimal improvement. Repeat renal biopsy 3 yrs later showed focally proliferative and predominantly membranous glomerulonephritis, consistent with LN classes III (A/C) and V, with <10% interstitial fibrosis. This time Rituximab was given (2 doses) with no change in serologies and worsening UPCR to 4. Tacrolimus was added, but UPCR increased to 6 with Alb 1.9 gms/dL and patient remained persistently nephrotic. ACTH (Acthar Gel) 80 units IM twice a week was added to her previous immunosuppressive regimen. Her UPCR improved remarkably to 4.1 in 6 months, and to 2.06 in 10 months on ACTH. She reports marked improvement in fatigue, swelling and joint stiffness with improved but low complements (C3 66, C4 18), ANA titer 1:2560, and creatinine 0.79 mg/dL.

Discussion: Patients with concurrent membranous LN and proliferative or diffuse LN are treated according to the proliferative lesion. Such patients have a worse prognosis. Numerous immuno-suppresive drugs have been used but none of these treatments produce a satisfactory response on class IV/V LN. So far, there is no known data on the use of ACTH in such patients. We hypothesize that for select patients with resistant mixed LN with proteinuria, adding ACTH to their immunosuppressive regimen may be beneficial with improvement in lupus symptoms.

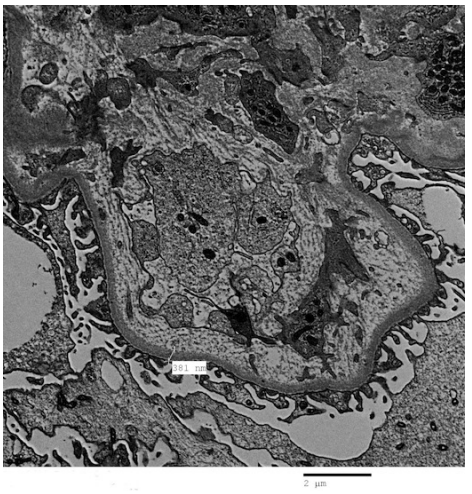
TH-PO022

Preeclampsia in a Man? Idiopathic Endotheliosis Successfully Treated with Plasmapheresis Jennifer A. Lazor, William Luke Whittier, David J. Cimbaluk. *Nephrology, Rush Univ Medical Center, Chicago, IL.*

Introduction: Glomerular endotheliosis is a distinct lesion characterized by endothelial swelling. The glomeruli are "bloodless" due to endothelial swelling causing occluded capillary lumens. We report a case of anasarca, hematuria and AKI with biopsy findings characteristic of endotheliosis. Our patient failed Rituxan therapy but responded rapidly to plasmapheresis.

Case Description: A 50 yo male presented with anasarca. Past medical history was significant for colon CA treated by surgical resection alone (no chemotherapy). On physical exam, BP 112/70 mmHg. He had rales, ascites, and 3+ leg edema. SCr 1.9 mg/dl, UA 3+ prot, 1+ bld, P/C ratio of 0.5 g/g. Secondary serological workup was negative. Biopsy revealed

glomerular capillaries occluded by swollen endothelium without thrombi. IF was negative. On EM, the capillary lumen was occluded by endothelial swelling, electron-lucent widening and subendothelial flocculent material. Podocyte foot processes were preserved (Figure 1).



Therapy with Rituxan was unsuccessful. His SCr rose to 2.9 mg/dl and plasmapheresis was initiated. With 8 treatments over 10 days, his SCr was 1.3 mg/dl and his anasarca resolved. After 6 months, he remains in remission.

Discussion: Circulating endogenous anti-angiogenic substances such as sFLt-1 and KDR antagonize VEGF when over-expressed. This dysregulated signaling deprives the glomerular endothelium of growth factors needed for maintenance. The patient had an excellent sustained response with resolution of AKI and edema following plasmapheresis. We theorize there is an auto-antibody against the VEGF receptor, excess levels of sFLt-1 or KDR, or another anti-endothelial vascular protein that is removed with plasmapheresis allowing restoration of glomerular maintenance.

TH-PO023

Antineutrophil Cytoplasmic Antibodies-Positive Pauci-Immune Crescentic Glomerulonephritis Associated with Acquired Angioedema Siwadon Pitukweerakul, Sai Prasad Gadapa, Sree V. Pilla, Pye Phyo Aung. *Medicine, Presence Saint Francis Hospital, Evanston, IL.*

Introduction: The association of hereditary angioedema with different types of glomerulonephritides has been previously reported. To our knowledge, there has been no reports of acquired or hereditary angioedema associated with pauci-immune vasculitis or glomerulonephritis.

Case Description: A 76 years old African American man with past medical history significant for hypertension and diabetes presented with 2 years of recurrent lip and tongue swelling. He had similar symptoms in the past over past 2 years which required multiple hospitalizations. Physical examination revealed upper lip swelling tongue swelling. Comprehensive metabolic panel revealed Blood urea nitrogen of 49 mg/dL, creatinine of 3.8 mg/dL. Urine analysis was significant for hematuria and proteinuria without casts or abnormal cells. His last known historic creatinine was 1.5 mg/dL 6 months prior to admission. Vasculitis workup was positive for Myeloperoxidase(MPO) ANCA, negative for anti-Glomerular basement membrane(GBM)and proteinase 3(PR3) ANCA. Serum C3 was normal. Serum C4, Serum C1 and C1q were decreased. These complement profiles were compatible with diagnosis of acquired angioedema(AA). According to rapid decline in kidney function he underwent left core needle kidney biopsy which showed focal necrotizing and crescentic glomerulonephritis, pauci-immune type. Patient was started on methylprednisolone and cyclophosphamide. At 1-month follow up and 6-month follow up, creatinine decreased to 2.7 and 1.7 mg/dL,respectively. He also denied episodes of lip and tongue swelling.

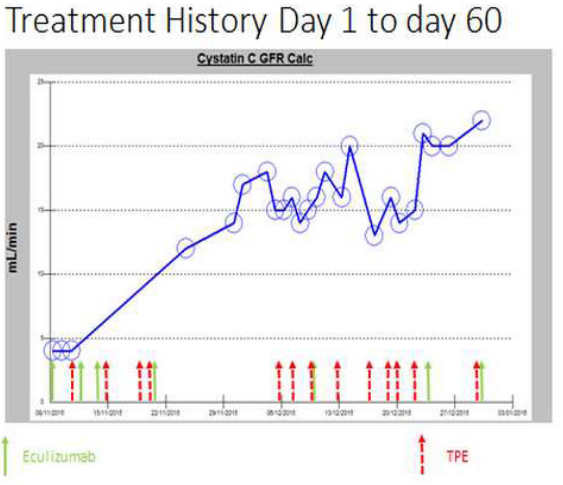
Discussion: Common causes of acquired angioedema(AA) includes non-Hodgkin's lymphoma, monoclonal gammopathy. Other nonhematologic malignancy, infections, and a variety of autoimmune diseases have also been reported as causes of AA. In our case, compatible chronology, complement level and lack of other possible causes of angioedema made pauci-Immune crescentic glomerulonephritis likely the cause of AA. The exact mechanism of recurrent angioedema in this case remains unclear. We would like to add this pauci-immune vasuculitis as a rare cause of AA.

TH-PO024

Atypical Histopathological Findings in a Child with Atypical Hemolytic Uremic Syndrome Treated Successfully with Eculizumab Gurinder Kumar,[1] Bassem Soliman Mohamed Hendawy,[2] Zubaida Al-Ismaili,[1] Omar Nihad Al Masri,[1] Eslam Mohamed Saleh Tawfik,[1] Eihab Al Khasawneh.[1] *[1]Dept of Pediatric Nephrology, Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates; [2]Dept of Pathology, Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare disease due to dysregulated alternate complement pathway. Histologically it is rare to have crescents on renal biopsy in aHUS. We report a case of 9 year old male presenting with renal failure and renal biopsy showed diffuse crescentic glomerulonephritis(GN) with only few glomeruli showing rare tiny intracapillary fibrin thrombi. Child subsequently developed features of thrombotic microangiopathy(TMA) and successfully treated with eculizumab(Ecu).

Case Description: We report a case of a 9-year-old male presenting with oligoanuric renal failure. Initial labs did not suggest TMA. He required hemodialysis for 2 weeks. Renal biopsy on day 2 showed more than 75% of glomeruli with cellular crescents and negative immunofluorescence. However subsequent labs showed TMA. ANA,ANCA, antiDsDNA were negative and C3 was low. Course in hospital was complicated with seizures and severe hypertension. Repeat renal biopsy after 10 days showed clearing of crescents(60%). He was started on Ecu and plasmapheresis with good response. Genetic testing for aHUS showed hetereozygous variance in genes coding for CFH, CFB,CFI,CFHR5. Currently child improved with gfr of 75 ml/min/1.73m2 and on regular follow up with Ecu q2weeks.



Discussion: Though unusual, aHUS may rarely present histologically with crescentic morphology rather than the expected TMA like picture. aHUS may be considered as a cause of diffuse crescentic GN, especially if ANCA serology is negative and with the presence of other supportive histologic, serologic and clinical signs of TMA. Testing for gene mutations may be helpful for confirmation.

TH-PO025

A Case of Hereditary Fibrinogen A-α-Chain Amyloidosis: Clinical and Counseling Challenges Alison F. Fitzgerald, Alan Segal. *Nephrology, Univ of Vermont Medical Center, Burlington, VT.*

Introduction: Hereditary fibrinogen Aα-chain renal amyloidosis—characterized in 1993—is a form of autosomal dominant renal amyloidosis. Patients invariably present with proteinuria and usually progress to ESRD in their 50s. Our asymptomatic patient first developed isolated proteinuria at age 52. A few months later, her fraternal twin brother developed proteinuria. Four other members of their family (father, older brother, uncle, and uncle's son) had previously developed ESRD and are deceased. Her father had a kidney biopsy in 1971 (age 51) that showed "amyloidosis," which recurred in 2 kidney transplants over the next 6 years.

Case Description: In light of her family history, our patient was convinced that she would "develop ESRD and die of amyloidosis" and was terrified that one or both of her children would meet the same fate. As she feared and predicted, her kidney biopsy showed enlarged glomeruli stuffed with amyloid. No extraglomerular amyloid was apparent. Analysis of the tissue at Mayo Clinic revealed a mutation (E545V) in the fibrinogen Aα-chain made by the liver. Learning this and realizing the significance, this sophisticated patient immediately rejected the idea of "waiting for kidney failure just to have a kidney transplant fail within a few years" and instead advocated that she should pursue a curative liver transplant now, before she gets sick. Yet, a liver transplant is based on a MELD score, which she does not have.

Discussion: It is unclear why this genetic disease does not become clinically evident for 45-55 years, but then recurs within 5 years in a transplant kidney. Should we advocate for pre-emptive liver transplantation for our patient and her children (while their livers can be used for domino transplants), or have them wait for a liver-kidney transplant when they have advanced kidney disease? Finally, when would be the ideal time to transplant her children if they do in fact have the mutation?

TH-PO026

IgA-Dominant Acute Post-Infectious Glomerulonephritis in a Kidney Transplant Recipient Hassan Alhalabi, Manish Anand, Juan Pablo Arroyo, Timothy E. Thayer, Mark Lusco, Anthony J. Langone, Beatrice P. Concepcion. *Vanderbilt Univ Medical Center.*

Introduction: IgA-dominant acute post-infectious glomerulonephritis (IgA-APIGN), a morphologic variant of APIGN, is a rare disease in which IgA is the dominant immunoglobulin found in glomerular immune deposits. All prior reported cases have been in native kidneys. Here we present the first reported case of IgA-APIGN in a kidney transplant recipient, successfully treated with steroids.

Case Description: A 62/M with ESRD secondary to DM underwent kidney transplantation in 2012 and was maintained on tacrolimus and MMF. He was admitted in 2015 with right foot osteomyelitis and MSSA bacteremia and was treated with antibiotics and BKA. Twelve days after initial presentation, he was readmitted with oligoanuric AKI with a Cr of 8.2 mg/dL (baseline 1.4 mg/dL), low C3 and normal C4, UA 2+ protein, 122 WBC's, 133 RBC's, and urine PCR of 1. Biopsy was performed and LM revealed diffuse global endocapillary hypercellularity with frequent neutrophils and 2/10 glomeruli with fibrinoid necrosis. By IF, IgA was the dominant Ig with stronger C3 staining in a diffuse global granular mesangial and irregular chunky capillary loop pattern. By EM, there were frequent mesangial, scattered subendothelial and rare subepithelial deposits. He was given pulses of methylprednisolone (1.5 g) then prednisone 40 mg daily. Renal function improved rapidly with a discharge Cr of 2.1 mg/dL. Steroids were tapered over 3 months and on last follow-up 5 months after presentation Cr was 1.7 mg/dL, UA 1+ protein, 1 RBC, 18 WBC's, urine PCR 0.3.

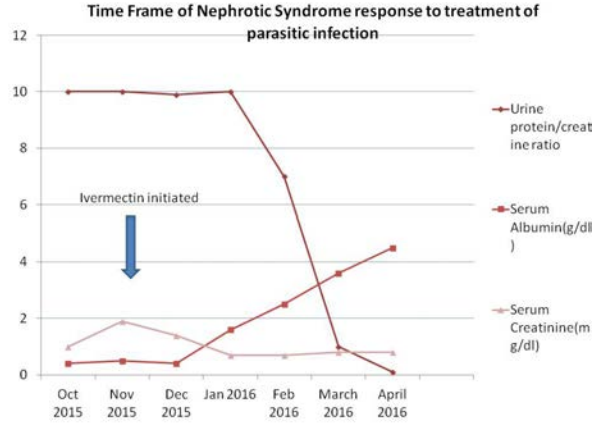
Discussion: IgA-APIGN is often associated with a staphylococcal infection and usually presents with AKI, hematuria and proteinuria. Antibiotics are the mainstay of treatment and prognosis is generally poor. All prior 85 reported cases of IgA-APIGN have been in native kidneys. This is the first reported case of IgA-APIGN in a kidney transplant recipient, illustrating that this disease can occur despite ongoing immunosuppression. Early recognition of IgA-APIGN is an important first step in determining appropriate management. Steroids may have a therapeutic role in cases where renal function continues to deteriorate despite appropriate management of infection.

TH-PO027

Tip Variant Focal Segmental Glomerulosclerosis Associated with Strongyloides Stercolaris Massini Merzkani,[1] Vivette D. D'Agati,[2] Pranisha Gautam-Goyal,[3] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra Medical School; [2]Pathology, Columbia Univ Medical Center; [3]ID, Hofstra Medical School.*

Introduction: Although parasitic infections are known to be associated with glomerular lesions, strongyloidiasis-associated glomerulopathy has not been well documented. We report a case of tip variant focal segmental glomerulosclerosis(FSGS) associated with strongyloides stercorali (SS).

Case Description: A 36 year old male from Guatemala presented with sudden onset of lower extremity and facial edema. Lab data revealed urinary protein/creatinine ratio of 10.6 g with serum albumin(Alb) 0.4 g/dl and serum creatinine 0.5mg/dl. Past medical history included tip variant FSGS in childhood that had responded to steroids. A repeat kidney biopsy showed tip variant FSGS with marked podocyte effacement. A detailed history revealed that the patient had recently traveled and had suffered episodic abdominal pain and diarrhea with peripheral eosinophilia of 41 % (2.7 k/ul). His stool studies confirmed SS. Conservative management with lisinopril, atorvastatin and diuretics was initiated with no improvement in edema. He was not given steroids. Ivermectin was initiated to treat the parasitic infection. His edema improved one month after ivermectin treatment, and his nephrotic syndrome resolved in 2 months. Changes in proteinuria, Alb and creatinine over time are graphed below.



Discussion: This is the first case report of tip variant FSGS secondary to SS. Given his predilection for podocytopathy, the parasitic infection was likely the precipitating immune stimulus as "second hit". Surprisingly, the nephrotic syndrome resolved with antihelminthic therapy alone. This case suggests a possible causal relationship between SS infection and FSGS. Even in primary podocytopathies, it is important to consider precipitating infectious triggers that can be specifically treated without resorting to steroid therapy.

TH-PO028

IgM Nephropathy: Achievement of Steroid Free Remission with Rituximab Fatima Khalid,[1] Catherine A. Moore.[1] *[1]Nephrology, Univ of Rochester; [2]Nephrology, Univ of Rochester.*

Introduction: Immunoglobulin M (IgM) nephropathy often presents as nephrotic syndrome in childhood which is poorly responsive to steroids. Likelihood of steroid free remission is very low in the long term, and this exposes individuals to long term complications of steroid therapy. Rituximab has been successfully used in cases of steroid resistant/refractory nephrotic syndrome. However, there are only a few case reports of use in IgM nephropathy, all early in the course of disease.

Case Description: We present a case of a 22 year old female with history of nephrotic syndrome, initially diagnosed at age 20 months. Her first biopsy was at age 6 year old, revealed minimal change disease and possible early cyclosporine nephrotoxicity. Immunofluorescence was not performed on this specimen. Subsequent biopsies have revealed mesangial hyper-cellularity with mesangial IgM consistent with IgM nephropathy. Her most recent biopsy, performed at age 17, revealed 40% global glomerulosclerosis and mild interstitial fibrosis with tubular atrophy. She was steroid-resistant until age 8, and subsequently was steroid dependent. Cyclophosphamide and cyclosporine therapy were used without clear response. This was followed by a trial of tacrolimus and mycophenolate mofetil. She was in complete remission with the above regimen and steroid free for two years. She then relapsed and was steroid dependent again. Infections, particularly upper respiratory infections, tend to trigger relapses. She has experienced significant toxicity from her chronic immunosuppression. Considering steroid dependence with chronic glucocorticoid toxicity, and lack of remission with tacrolimus and mycophenolate mofetil, we decided to initiate rituximab treatment. The patient underwent induction with 2 doses of rituximab 375 mg/m^2, with mycophenolate mofetil as maintenance. The patient has been in remission on less than 20 mg of steroids in the last 6 months and completely off of steroids in the last 6 weeks with no evidence of relapse.

Discussion: We describe a case demonstrating achievement of steroid-free remission using rituximab in a patient with longstanding IgM Nephropathy.

TH-PO029

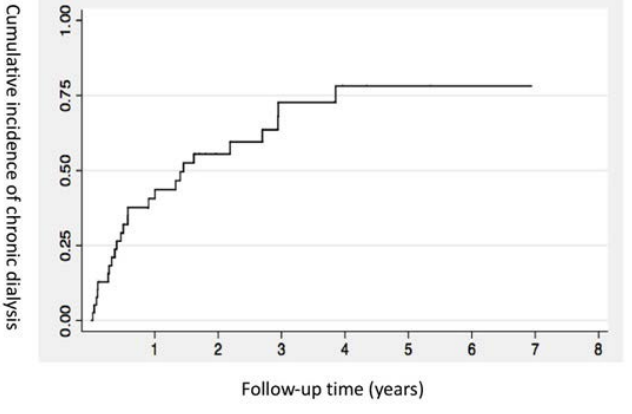
Intravenous Heroin Use Associated with AA Amyloidosis Arjun V. Sharma, Priyanka Govindan, Bryan R. Kestenbaum. *Dept of Nephrology, Univ of Washington, Seattle, WA.*

Introduction: Secondary (AA) renal amyloidosis is characterized by the deposition of serum amyloid A within the glomerular basement membrane, mesangium, tubules, and blood vessels. Affected patients typically present with nephrotic range proteinuria and rapid loss of kidney function. We and others have observed renal AA amyloidosis among patients who use intravenous (IV) heroin; however, the association of IV drug use and renal AA amyloidosis is incompletely described.

Case Description: We evaluated all biopsy proven cases of renal AA amyloidosis within native kidneys at the University of Washington Medical Center and Harborview Medical Center, in Seattle Washington, from 2005-2015. We extracted medical data via chart review. We used Kaplan-Meier estimation to describe renal and overall survival of affected patients.

We identified 43 patients who had biopsy proven renal AA amyloidosis from 2005-2015. Among this group, 42 patients (97%) had chart documentation of IV heroin use with 29 (67%) with use within 6 months prior to biopsy. In addition to IV heroin use, "muscling" and "skin-popping" were also common (83% and 70%, respectfully). Cocaine (72%) use was frequent. Renal co-morbidities included hepatitis C (81%), HIV (9%), and rheumatic disease (5%). At time of biopsy, the mean protein to creatinine ratio was 13.3 ±8.1 g/g and the mean serum creatinine concentration was 4.0 ±2.6 mg/dL. Among 39 of the 43 patients who were not receiving dialysis at the time of biopsy, 25 initiated dialysis over a maximum of 6.9 years of follow-up. Overall patient survival at 5 years was 47%.

Figure. Time to dialysis initiation among 39 patients with AA amyloidosis.



Discussion: Nearly all patients who have renal AA amyloidosis in Seattle, WA use IV heroin. The marked geographical variation in the association of IV heroin use with AA amyloidosis strongly suggests that specific components of street heroin and/or local patterns of use are a cause of this disease.

TH-PO030

Membranous Nephropathy Related to the Checkpoint Inhibitor Nivolumab Jonathan T. Lin,[1] Morgan A. Schiff,[2] Steven Salvatore,[3] Alexander N. Shoushtari,[4] Ilya Glezerman.[5] *[1]Div of Nephrology, New York Presbyterian / Weill Cornell, New York, NY; [2]Critical Care Service, Memorial Sloan Kettering, New York, NY; [3]Pathology and Laboratory Medicine, New York Presbyterian / Weill Cornell, New York, NY; [4]Melanoma and Immunotherapeutics, Memorial Sloan Kettering, New York, NY; [5]Renal Service, Memorial Sloan Kettering, New York, NY.*

Introduction: Programmed cell death (PD) inhibitors are novel anti-cancer immunotherapy, and cases of autoimmune nephritis have been described. We report the first case of nephrotic syndrome with membranous nephropathy associated with the IgG4 PD-1 inhibitor nivolumab.

Case Description: A 75 year-old male presented with metastatic melanoma of unknown primary. He was treated with nivolumab and tolerated bi-weekly infusions with few adverse effects, including mild pruritus and mild colitis. After his fifth treatment, he noted scrotal and lower extremity edema. Subsequent labs revealed hypoalbuminemia to 1.4 (4-5.2) mg/dL with stable creatinine at 1.2 (0.6-1.3) mg/dL. Urine studies were notable for 12 g proteinuria/24 hours, without RBCs, WBCs, or casts on urine microscopy. Serological workup including Anti-Phospholipase-A2-Receptor (PLA_2R) antibody testing was negative. Nivolumab infusions were held, and the patient was started empirically on steroids with prednisone 0.5 mg/kg for presumed autoimmune nephritis. A renal biopsy was performed, with electron microscopy revealing scattered subepithelial electron dense deposits with nearly complete podocyte effacement and immunofluorescence revealing predominantly granular IgG capillary wall staining, consistent with membranous nephropathy. PLA_2R staining was negative. Imaging one month later showed interval decrease in size of both masses. Repeat spot urine protein-to-creatinine was 4.0, plasma albumin was 3.2 g/dL, and his edema resolved.

Discussion: Membranous nephropathy has been linked to solid malignancies including melanoma, but the timing of nephrotic syndrome in this patient coincided with treatment with nivolumab. Clinicians should be aware of this risk, and additional cases may help elucidate alterations in the immune response and mechanisms of renal injury by therapy with PD-1 inhibitors.

TH-PO031

Spontaneous Clinical Resolution in Dense Deposit Disease Anna Lane Baldwin, Katherine D. Westreich, Akhil Hegde, Volker Nickeleit, Harsharan Kaur Singh, Gerald A. Hladik. *UNC Kidney Center, UNC Hospitals, Chapel Hill, NC.*

Introduction: Dense deposit disease (DDD) is often progressive and incurs high morbidity. We present two atypical cases of DDD that are somewhat atypical with spontaneous remission of proteinuria and renal dysfunction.

Case Description: Case 1: 24-year-old white woman with acute kidney injury (AKI) and nephritis. She had a recent minor skin infection of the hand that resolved. C3 was <40 mg/dl and anti-DNAse B titer was elevated at 862 U/ml. Biopsy: DDD, with proliferative GN, C3 deposits, and electron dense deposits (EDD) within the glomerular basement membrane (GBM). C3 nephritic factor (C3NeF) was detected; extensive testing of the complement system, including sequencing of 6 genes with known mutations causing C3GN/DDD, was normal. Serum creatinine (Scr), C3, and urine protein normalized in 1 month without treatment; microscopic hematuria persists. **Case 2:** 8-year-old white girl with AKI and nephritis during an upper respiratory infection; anti-streptococcal antibodies were[-]. 1st Biopsy: proliferative GN, C3 deposits, scattered EDD. Scr, C3, and urine protein normalized in 3 months after a short course of steroids. 7 months later developed recurrent nephritis during confirmed strep pharyngitis. 2nd biopsy: DDD with no significant chronic tissue injury. Complement analysis as described in case 1 showed elevated C3NeF and no other abnormality. Creatinine, cystatin C, C3, and urine protein all normalized within 6 weeks.

Discussion: The two patients under discussion had DDD with self –limited clinical findings. Both had increased C3NeF with relatively limited intramembranous deposits . In Case 2, a second biopsy showed no evidence of chronic kidney injury. The underlying etiology remains undetermined. We speculate that infection, autoimmune, or inflammation-related complement activation may cause transient and rudimentary forms of DDD in patients with elevated C3NeF. Alternatively, these might reflect early clinical expression of DDD. Overall, these cases illustrate that the clinical manifestations may largely resolve without treatment Similar cases require further study to identify distinguishing features in order to avoid immunosuppression (IS) in cases that improve, at least in the short term, without IS.

TH-PO032

Membranous Nephropathy in a Patient with Common Variable Immune Deficiency Teena Zachariah, Syed Ali Husain, Jordan Gabriela Nestor, Renu Regunathan-Shenk, Glen S. Markowitz, Andrew S. Bomback. *Nephrology, Columbia Univ Medical Center, New York, NY.*

Introduction: Secondary membranous glomerulonephritis occurs in patients with systemic lupus erythematosus, infections such as hepatitis B and C, and solid tumors. There have been no prior case reports of membranous nephropathy in adult patients with common variable immune deficiency (CVID).

Case Description: A 36 year old Caucasian woman with CVID on weekly subcutaneous immunoglobulin G (IgG) therapy presented with fluid overload. Labs were notable for 8 g/day proteinuria, albumin 2.0 g/dL, and creatinine of 0.6 mg/dL. She underwent renal biopsy revealing membranous nephropathy (MN) with negative staining for anti-PLA2R on immunofluorescence. She was initially treated conservatively; within two weeks, she was admitted for worsening lower extremity edema, abdominal pain, and nausea. Her creatinine had risen to 2.0 mg/dL on admission, and she subsequently developed oliguric renal failure with a peak creatinine of 5.8 mg/dL. Serologic test for PLA2R antibody was negative. A repeat renal biopsy revealed acute tubular injury in addition to prior findings of PLA2R negative membranous nephropathy. She was treated with 6 sessions of hemodialysis, two doses of intravenous rituximab (1 g), and a prednisone taper. At 2 months after starting treatment, her creatinine had returned to 0.6 mg/dL, urine microalbumin:creatinine ratio was 345 mcg/mg, and serum albumin was 3.4 g/dL.

Discussion: The treatment of membranous glomerulonephritis in an immunocompromised patient poses a challenge. A previous case report of MN in a child with CVID reported remission of proteinuria with cyclosporine, and here we report successful response to rituximab-based therapy. CVID, a rare disease, may be an even rarer etiology of secondary membranous nephropathy that, nonetheless, appears to respond to immunosuppressive therapy.

TH-PO033

Kidney Disease and Neurologic Deficits from a Rare Collagen Type 4 Mutation Dominique Dorsainvil, Jeffrey M. Turner. *Nephrology, Yale School of Medicine, New Haven, CT.*

Introduction: Type 4 collagen is the main component of the basement membrane in the filtration barrier of the glomerulus. Mutations in the genes coding for the six alpha chains lead to various disorders with renal and non-renal manifestations. Mutations in COL4A5 cause Alport syndrome, the most common inherited type 4 collagen disorder. Recently an autosomal dominant disorder termed hereditary angiopathy with nephropathy, aneurysms and muscle cramps (HANAC) has been described due to mutations in the COL4A1 gene.

Case Description: 24 year old female with isolated persistent microscopic hematuria in the setting of recurring acute intermittent headaches with transient neurologic deficits. Her neurologic symptoms began as migraine episodes as a teenager. They severely worsened at the age of 22 during the postpartum period of her second pregnancy. MRI was notable for periventricular and deep subcortical white matter changes. Her family history is notable for several family members with neurologic deficits ranging from migraines to strokes at a young age. Two maternal aunts had end stage renal disease of unknown etiology. Kidney biopsy in this patient showed thin basement membrane with an average thickness of 139nm and diffuse foot process effacement on electron microscopy. Whole exome sequencing showed a heterozygous mutation of the COL4A1 gene leading to amino acid changes G->E at codon 805.

Discussion: Case series have reported a wide spectrum of renal manifestations from COL4A1 mutations, ranging from no proteinuria, persistent hematuria, cystic disease to end stage kidney disease with diffuse fibrosis. Our patient had persistent hematuria with a preserved glomerular filtration rate, consistent with the previous descriptions. Electron microscopy findings in published case series have shown irregularities in the basement membrane structure, also present in our case. Unique to our case, as it has not yet been described in the literature, is the finding of diffuse podocyte foot process effacement. For that reason, this case expands our understanding of the different renal patterns of injury associated with COL4A1 mutations.

TH-PO034

Patient with Thrombotic Microangiopathy: Thrombotic Thrombocytopenic Purpura and Atypical Hemolytic Uremic Syndrome at the Same Time Ahmed Daoud, Lauren L. Pacheco, Umbar Ghaffar. *Nephrology, UAMS, Little Rock, AR.*

Introduction: Thrombotic microangiopathy (TMA) is a pathological process characterized by microangiopathic hemolytic anemia, thrombocytopenia and microvascular occlusion. TMAs are classified into 4 major syndromes: Hemolytic uremic syndrome (HUS), Atypical HUS (aHUS), Thrombotic thrombocytopenic purpura (TTP) and other disorders including malignant hypertension. We are reporting a case of a patient presenting with clinical features of a TMA who was diagnosed with both aHUS & TTP at the same time.

Case Description: A 24-year-old African American man with a past medical history of Klinefelter Syndrome and hypertension was transferred from an outside facility with the chief complaint of generalized fatigue. Labs showed renal failure, thrombocytopenia, and hemolytic anemia. He underwent workup for TMA which revealed low ADAMTS13 level of 15% with a positive ADAMTS13 inhibitor screen. The ADAMTS13 inhibitor Bethesda titer was elevated at 5.2. His genetic testing revealed CFHR1/CFH3 homozygous deletion, which is strongly associated with the presence of Factor H auto-antibodies and a heterozygous, missense variant in exon 20 of CFH which was recently cited as a mutation associated with aHUS. Patient was treated with plasmapharesis, eculizumab, rituximab, vincristine, cyclophosphamide, and prednisone with resolution of thrombocytopenia and anemia. However, he remained dialysis dependent for his renal faliure. Near discharge, his ADAMTS13 level was 31% with a negative inhibitor. He was discharged home on infusions of cyclophosphamide and prednisone and with follow-up appointments for labs and on weekly eculizumab.

Discussion: TTP is an uncommon TMA-related disorder that occurs mainly in adults, and is associated with acquired (or rarely genetic) severe deficiency of the cleaving protease for Von Willebrand Factor (vWF), ADAMTS13. aHUS is a rare disease associated with genetic or acquired factors that cause defective regulation of the alternative complement pathway. This patient had low ADAMTS 13 levels indicating TTP & complement gene mutations indicating aHUS. The occurrence of both these conditions together is extremely rare,and has not been reported before.

TH-PO035

A Case of Glomerular Capillary Endotheliosis due to Multicentric Castleman's Disease Vahagn A. Zakaryan, Anjali A. Satoskar, Tibor Nadasdy, Brad H. Rovin, Samir Parikh. *The Ohio State Univ Medical Center.*

Introduction: Glomerular capillary endotheliosis (GE) is the result of severe endothelial cell injury and manifests histologically with endothelial swelling, glomerular hypertrophy, and capillary lumen narrowing. GE has been previously associated with thrombotic microangiopathy and pre-eclampsia. Here, we report a case of severe GE causing acute renal failure in a patient with Multicentric Castleman's Disease (MCCD).

Case Description: A 59-year-old male presented with anasarca, hypoalbuminemia, and orthostatic hypotension consistent with systemic capillary leak syndrome (SCLS). He developed acute renal failure requiring hemodialysis. Workup was negative for autoimmune disease, infection, or malignancy. A kidney biopsy showed severe glomerular capillary endothelial swelling with acellular closure of capillary loops consistent with GE. Empiric treatment with high dose prednisone led to remission but disease relapsed after steroids were stopped. He had nephritic urine sediment and 750mg/d proteinuria. A second renal biopsy showed severe GE. Remission was again achieved after 6 months of oral cyclophosphamide and prednisone taper. Maintenance mycophenolate mofetil was given for 3 years without relapse. Therapy was stopped and disease relapsed but this time with diffuse lymphadenopathy and a circulating monoclonal IgG-kappa light chain in addition to SCLS and nephritis. A lymph node biopsy was consistent with MCCD. IL-6, CRP, and VEGF levels were markedly elevated. Anti-IL-6 antibody therapy was started and a complete remission was achieved after 2 months of treatment.

Discussion: This is the first report of GE as a manifestation of MCCD. MCCD is a rare, life threatening lymphoprolfierative disease associated with hyperactivation of the immune system causing excessive release of IL-6 and similar cytokines. The hypercytokinemia seen in MCCD is likely responsible for the increased vascular permeability and GE seen in this case. In summary, MCCD should be considered in patients found to have acute glomerulonephritis due to capillary endotheliosis. If recognized, therapy with immunosuppression is effective and may prevent life-threatening complications.

TH-PO036

Using Steroids for Nephrotic Syndrome in Proliferative Glomerulonephritis with Monoclonal IgG Deposits Sean Verma,[1] Emmanuel Bassily,[1] Claude Bassil.[3] *[1]Internal Medicine, Univ of South Florida; [2]Nephrology, Univ of South Florida.*

Introduction: Proliferative Glomerulonephritis with Monoclonal IgG Deposits (PGNMID) is a rare disorder associated with monoclonal gammopathy of renal significance (MGRS) that has unique pathological and glomerular histological features from other MGRS disorders. The pathogenesis and best treatment options remain unknown.

Case Description: A 57-year-old man was found to have nephrotic range proteinuria of 8 grams/24 hours. On exam he had 2+ pitting edema to the knees. Labs showed hemoglobin 12.2 mg/dL, creatinine 1.3 mg/dL, calcium 8.6 mg/dL, and albumin 2.7 mg/dL. Renal biopsy revealed glomerular basement membranes (GBM) with irregular thickening with "tram tracking" and diffuse moderate mesangial expansion. Immunofluorescence showed 3+ granular staining for IgG3, 3+ kappa light chains, 2-3+ C3, and 2-3+ C1q. Electron microscopy showed irregular thickness of the GBM with subendothelial electron dense granular deposits and podocyte foot process effacement. Serum and urine protein were negative for monoclonal proteins. Skeletal survey had no lytic lesions and bone marrow biopsy showed plasma cells less than 5% of total cellularity. He was started on lisinopril and prednisone taper. His 24-hour urine protein was 800 mg at 6 month follow up.

Discussion: We report an uncommon case of PGNMID responding to steroid therapy and renin angiotensin-system (RAS) blockade. PGNMID has been associated with myeloma, chronic lymphocytic leukemia, parvovirus and hepatitis C infection. In a study of 37 PGNMID patients, Nasr et al. suggest PGNMID is not a precursor to hematological malignancies in most patients. However, the best treatment option remains elusive and prognosis typically is poor. Biopsy may show endocapillary proliferation, membranoproliferative features, membranous features, or mesangial proliferation. Possible treatments include, RAS blockade alone, cyclophosphamide, rituximab, and bortezomib. Komatsudu et al. described the first case of steroid responsive nephrotic syndrome in PGNMID with pure mesangial features, and it is unclear whether this unusual form has a better response to steroids.

TH-PO037

Characteristics of Genetic and Biomolecular Backgrounds in Patients with LAMB2 Related Nephropathy Shogo Minamikawa,[1] Kandai Nozu,[1] Tomohiko Yamamura,[1] Takeshi Ninchoji,[1] Yuko Shima,[2] Koichi Nakanishi,[2] Kazumoto Iijima.[1] *[1]Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Hyogo, Japan; [2]Dept of Pediatrics, Wakayama Medical Univ, Wakayama, Japan.*

Introduction: Null mutations in *LAMB2* cause Pierson syndrome (PS), a severe congenital nephrotic syndrome with ocular and neurologic defects, and show completely negative expression of laminin β2 on glomerular basement membrane (GBM). However, recently some cases with milder phenotypes in *LAMB2* mutations have been reported. Here we report 3 cases with milder phenotypes who were diagnosed as PS by next generation sequencing (NGS). We also identified characteristics of genetic and biomolecular backgrounds in these patients.

Case Description: Case 1 is a 3 yo boy; developed nephrotic syndrome at 6 mo. Case 2 is a 1yo girl, younger sister of the case 1. She presented nephrotic syndrome at 1 mo. Case 3 is 2 yo boy, exhibited hematuria and non-nephrotic range proteinuria at 1 mo. None of these three patients showed kidney dysfunction, ocular or neurological defects until now. Renal biopsy showed mesangial proliferation, and electron microscopy findings showed thinning and Basket-weave change of the GBM in all cases. As a result of genetic analysis by NGS, novel frameshift mutation: c.225delC and known pathogenic missense mutation: p.Gly699Arg in *LAMB2* were detected in case 1 and case 2. In case 3, novel frameshift mutation: c.5073-5076dupCCAG and novel splicing-site mutation: c.3797+5G>A in *LAMB2* were detected whichresulted in whole intron 24 (96bp) insertion between exon 24 and exon 25 at the transcript level. Laminin β2 positive expression on GBM was evaluated by immunohistochemistry in all cases.

Discussion: We detected compound heterozygous mutations in *LAMB2* gene in all patients. One family showed missense mutation and another showed in-frame mutation. We proved laminin β2 positive expression in all cases. These results might reflect milder phenotypes for PS in our cases. In conclusion, we clarified the genetic and biomolecular backgrounds for milder phenotypes in our cases with *LAMB2* mutations. NGS is a powerful tool to make genetic diagnosis of inherited kidney diseases showing atypical phenotypes.

TH-PO038

ANCA Vasculitis Induced Aortitis Rawan T. Al-Odat, Faisal Anwar, Hafiz Ali Sroya, Saeed Kamran Shaffi. *Nephrology, UNM, Albuqerque, NM.*

Introduction: ANCA vasculitis primarily affects small vessels; however, large vessel involvement has been reported in literature. We present a case of aortitis caused by ANCA vasculitis.

Case Description: We evaluated a 49 years old male with history of granulomatosis with polyangitis (GPA), that was diagnosed 15 years ago and was treated with induction therapy (steroids, cyclophosphamide and plasmapheresis) followed by maintenance therapy (azathioprine) for 5 years, in the nephrology clinic. He was recently admitted to the hospital for chest pain that had been worsening over the last few days with a chest CT showing an ascending aortic aneurysm that mandated urgent repair. Physical examination during the clinic visit was unremarkable. Pertinent diagnostic data is shown in Figure 1. The patient is currently receiving induction therapy for anti-proteinase 3 (PR3) positive ANCA vasculitis with monthly intravenous cyclophosphamide doses and oral steroids.

Figure 1

Lab data	Result
BUN (mg/dL)	40
Cr (mg/dL)	2.16
ANCA	Positive for PR3*
PR3*	4.4 (normal 0.0-0.9)
Urine analysis	Protein 2+, Blood 3+
Urine microscopy	> 5 dysmorphic RBCs per high power field
Spot urine protein to creatinine ratio (g/g)	1.3
Kidney ultrasound	Normal sized kidneys with preserved cortices.
Kidney biopsy	Few crescents with focal necrosis, and scarring; Pauci-immune
* PR3; Anti proteinase 3 antibody	

Discussion: The pathogenesis of large vessel involvement by ANCA vasculitis is not entirely clear. Intimal injury may be the initial insult followed by the inflammation of the media and adventitia resulting in trans-mural aortitis. It occurs in both myeloperoxidase (MPO) and PR3 ANCA vasculitis. The presentation is varied with instances of stenosing large vessel arteritis, aneurysmal disease, aortic dissection, and aortic rupture reported in literature. Most of the reported cases were managed with an extended period of immunosuppression using corticosteroids and cyclophosphamide with good outcomes.

TH-PO039

Mixed Cryoglobulinemic Glomerulonephritis Associated with Ulcerative Colitis in a Liver Transplant Patient Rungwasee Rattanavich, Ali I. Gardezi, Dr Salahuddin, Arjang Djamali, Didier A. Mandelbrot. *Div of Nephrology, Dept of Medicine, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Introduction: Mixed Cryoglobulinemic vasculitis is most commonly associated with Hepatitis C infection but rarely reported in chronic autoimmune disorders. We present a patient who developed cryoglobulinemic vasculitis with membranoproliferative glomerulonephritis after ulcerative colitis (UC) flare.

Case Description: 47 y/o male with ulcerative colitis, primary sclerosing cholangitis s/p post liver transplant, CKD III presented with an ulcerative colitis flare which was treated with adalimumab and prednisone with improvement in symptoms. He was also found to have AKI on CKD with new onset nephrotic range proteinuria, hematuria. He also developed violaceous discoloration of his toes. Hepatitis B & C panel, HIV, CMV, EBV, ANA and ANCA were negative. LFTs and serum free light chain ratio were normal. C3 was low but C4 was normal. Serum cryoglobulins were negative. Kidney biopsy showed Membranoproliferative glomerulonephritis. Electron microscopy showed electron dense deposits with ultrastructural features of cryoglobulinemic glomerulonephritis. Skin biopsy of the rash was consistent with cryoglobulinemic vasculitis. He developed anuric AKI requiring temporary hemodialysis. He was given rituximab due to severity of his AKI and no improvement with treatment of ulcerative colitis. He subsequently came off dialysis and his GFR improved back to baseline. His urine protein to creatinine ratio improved from 4.81 to 0.73.

Discussion: This case highlights the rare association between ulcerative colitis(UC) and cryoglobulinemia. Studies have shown the presence of autoantibodies to Saccharomyces cerevisiae (ASCA) in patients with UC as well as in those with cryoglobulinemia which could explain the association. Although this is rare, but clinicians treating IBD should have a high suspicious for cryoglobulinemic vasculitis especially in patients with vasculitic rash or AKI. Rituximab has been shown to be effective in treating both Hepatitis C and Non HCV related cryoglobulinemic vasculitis and should be considered in severe glomerulonephritis with nephrotic range proteinuria.

TH-PO040

Rituximab Therapy Worsens Hepatitis C Associated Cryoglobulinemic MPGN Post Kidney Transplant Despite HCV Eradication Samuel Chakola,[1] Nomsa Musemwa,[1] Swati Rao,[1] Mythili Ghanta,[1] Duncan B. Johnstone,[1] Xu Zeng,[2] Serban Constantinescu,[1] Avrum Gillespie,[1] Crystal A. Gadegbeku,[1] Iris J. Lee.[1] *[1]Section of Nephrology and Transplantation, Temple Univ, Philadelphia, PA; [2]Section of Pathology, Temple Univ, Philadelphia, PA.*

Introduction: Chronic Hepatitis C virus infection (HCV) is prevalent in end stage renal disease and kidney transplant recipients (KTR). Polyclonal B-cells stimulation by HCV leads to cryoglobulin and rheumatoid factor (RF) production, manifesting as systemic vasculitis and/or MPGN in KTR. Standard of care is therapy with steroids, Rituximab (RTX), plasmapheresis (PP) and eradication of HCV with anti-viral regimens. We report a case of persistent cryoglobulinemia with vasculitis and MPGN, despite eradication of HCV in a KTR.

Case Description: A 63 year old AA male with HCV on hemodialysis received a cadaveric KT from a HCV positive donor. Proteinuria, HCV, high RF and low complement levels prompted an allograft biopsy which showed cryoglobulinemic MPGN. Therapy was initiated with steroids, PP, and RTX (375mg/m2) for 2 doses, with remaining doses of RTX held due to sepsis. Despite rapid resolution of HCV with an IFN-free regimen cryoglobulinemia persisted. Work up for a monoclonal lymphoproliferative disorder was negative. A third dose of RTX was given but the patient subsequently developed gross hematuria, proteinuria, acute kidney injury and a purpuric rash. Allograft biopsy showed progressive MPGN with crescents improved by aggressive PP and steroids. We reasoned that RTX triggered an acute vasculitis and MPGN, and therefore opted to give 2 cycles of Bortezomib along with PP and achieved complete clinical remission.

Discussion: RTX is a chimeric molecule possessing a humanized IgG tail, a potential target for IgM with RF activity. The resulting increase in IgG-IgM complex could have precipitated acute vasculitis and organ damage in our patient. In addition, RTX alters B-cell populations by upregulating BAFF receptor on B-cells favoring mature B-cell development, counter-productive to treatment goals. Our case highlights the complications of RTX in HCV cryoglobulinemia and suggests studying the role of bortezomib in resistant cases likely driven by plasma cell dyscrasia.

TH-PO041

Hydralazine-Induced ANCA Vasculitis with Glomerulonephritis and Diffuse Alveolar Hemorrhage Josef Bautista, Katherine Mikovna Scovner. *Section of Kidney Diseases and Hypertension, Brown Univ - Rhode Island Hospital, Providence, RI.*

Introduction: Hydralazine is known to cause drug-induced lupus. However, this entity has very limited renal involvement. In contrast, hydralazine-induced ANCA vasculitis, a rarer pathology, may result in catastrophic renal and pulmonary disease.

Case Description: This is a 71-year-old woman with hypertension who had been on hydralazine 50 mg twice daily for 2.5 years. She presented with hematuria, acute renal failure, hemoptysis and hypoxic respiratory failure. Physical exam was notable for hypertension, coarse lung sounds and bilateral pitting edema. Serum creatinine was 5.4 mg/dL. Her UA showed 3+ blood and 100mg/dL protein. ANA was 1:1,280, p-ANCA was 1:80, anti-histone antibody was elevated to 2.8, anti-double-stranded (ds) DNA antibody was elevated at 155, and C3/C4 were low. Renal ultrasound showed increased echogenicity concerning for medication-induced renal disease. Renal biopsy showed diffuse acute tubular necrosis with RBC casts and active vasculitis in 5 of 23 glomeruli. 10 of 18 glomeruli had fibrocellular crescents. Immunofluorescence was negative for immune complex deposition while electron micrograph showed no deposits in the glomerular basement membrane or mesangium. Hydralazine was discontinued. The patient received stress dose steroids and was started on plasmapheresis. She was also started on rituximab 375 mg/m2 weekly for 4 weeks for induction immunosuppression. 1 week after the diagnosis, labs showed improvement in her ANA, anti-histone and myeloperoxidase titers. Her complement levels remained low. After 2 months, she remained dialysis-dependent.

Discussion: This case illustrates an exceedingly rare complication of hydralazine. Hydralazine may alter the expression of MPO and other neutrophilic antigens (e.g. histone, ANA, anti ds DNA) by inhibiting DNA methyltransferases in the neutrophils. The presence of P-ANCA, positive anti-histone antibodies, and pauci-immunity are consistent with drug-induced ANCA vasculitis rather than with drug-induced lupus or primary vasculitis. Treatment of this condition is similar to that of idiopathic ANCA vasculitis but, in addition, the offending agent must never be reintroduced to the patient.

TH-PO042

Rituximab for Proliferative Glomerulonephritis with Monoclonal IgG Deposits in Two Kidney Allografts Josef Bautista, Basma Omar Merhi. *Section of Kidney Diseases and Hypertension, Brown Univ - Rhode Island Hospital, Providence, RI.*

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposit (PGNMID) in the allograft is a rare condition with IgG3 Kappa being the most common subtype. It could be de novo or recurrent disease. There is no standardized treatment protocol yet due to the limited case reports published. Here, we present 2 cases of PGNMID in the allograft and their response to Rituximab.

Case Description: We present two kidney transplant cases of nephritic syndromes with sub- and nephrotic-range proteinuria and allograft dysfunction. Serologies for hepatitis B & C, anti-nuclear antibodies, cryoglobulins, SPEP/UPEP were negative in both patients. Allograft biopsy of the two patients met the pathologic criteria for PGNMID with IgG1 kappa subtype in one case and IgG3 kappa subtype in the second case. Both cases were treated with two doses of 375mg/m2 of Rituximab given two weeks apart. Both had improvement in their hematuria, proteinuria and allograft function after 2 years of follow-up with improving pathologic biopsy one year after Rituximab in one patient.

Discussion: PGNMID in the allograft creates a diagnostic and therapeutic dilemma to the clinician. The pathophysiology appears to be persistence of monoclonal IgG molecule that is readily fixed by the complement system and subsequent glomerular deposition and activation of downstream inflammatory reaction. B cell apoptosis by rituximab, a chimeric anti-CD20 monoclonal antibody, decreases immunoglobulin production and this is the rationale behind its use in the transplant population especially in the treatment of steroid-resistant antibody mediated rejection, post-transplant lymphoproliferative disorder, recurrent glomerular disease after transplant. Its use in our 2 cases seems promising as a potential treatment of PGNMID after transplantation.

TH-PO043

Acquired Gitelman Syndrome from Bendamustine Josef Bautista, Jie Tang, Andrew Rogers. *Section of Hypertension and Nephrology, Dept of Medicine, Rhode Island Hospital - Brown Univ, Providene, RI.*

Introduction: Gitelman's syndrome, caused by loss-of-function mutations in the thiazide-sensitive Na-Cl cotransporter (NCC), is characterized by hypokalemic metabolic alkalosis, hypomagnesemia, and hypocalciuria. Acquired Gitelman-like syndromes have also been described, commonly with cisplatin use. Bendamustine is a nitrogen mustard routinely used in the treatment of chronic lymphocytic leukemia (CLL) and indolent B-cell non-hodgkin lymphoma (NHL). Although hypokalemia has been observed in about 5% of patients taking it, the underlying causes have never been established, the mechanism is unknown.

Case Description: Herein, we report a case of bendamustine-induced hypokalemia that satisfied the diagnostic criteria for Gitelman's syndrome. The patient is a 51-year-old male who had recently completed bendamustine and rituximab therapy for follicular lymphoma who presented to the hospital with leg cramps and with serum potassium 1.6 mEq/L, magnesium 1.6 mEq/L and bicarbonate 36 mEq/L. Physical exam showed hypotension, dry mucosa, and poor skin turgor. Laboratory test prior to his chemotherapy showed serum creatinine of 0.9 mg/dl, potassium of 3.7 meq/L and bicarbonate of 27 meq/L. Subsequent work-up revealed 24-hour urine potassium 88 meq, sodium 206 meq and calcium 8 mg. Serum aldosterone was undetectable while the renin activity was elevated at 6.82 ng/mL/hr. Diuretic screen was negative. The patient was treated with oral and intravenous potassium, which normalized his serum potassium and improved his symptoms. Follow-up laboratory test after one month showed a potassium of 5.4 meq/L and a bicarbonate of 22 meq/L while still on 80 meq/day of oral potassium.

Discussion: To our knowledge, this is the first documented case of acquired Gitelman's syndrome from bendamustine. Now that bendamustine is more commonly used, this rare but serious complication with hypokalemia should be recognized. Future studies are needed to elucidate mechanisms of the pathophysiological effects of bendamustine on the distal tubule.

TH-PO044

Successful Treatment with Spironolactone and Acetazolamide for Severe Metabolic Alkalosis and Hypokalemia Secondary to Ectopic Adrenocorticotropic Hormone-Secreting Extrapulmonary Small Cell Neuroendocrine Carcinoma of the Rectum Luis A. Vazquez, William Chastant, Jonathan G. Owen. *Nephrology and Hypertension, Louisiana State Univ Health Sciences Center, New Orleans, LA.*

Introduction: Metabolic alkalosis is life threatening with reported mortality of 45% with arterial blood pH of 7.55. We present a case of severe metabolic alkalosis and hypokalemia secondary to an ACTH-secreting neuroendocrine tumor.

Case Description: 58 year old man with hypertension and HIV on HAART therapy, presented to his PCP with edema, hypertension and fatigue after no improvement from doubling his valsartan-HCTZ. Labs showed creatinine 5.6 mg/dL, hypokalemia (2.3 mmol/L) and serum CO2 level of 42mmol/L, prompting admission. Arterial blood gas showed pH 7.57, HCO3 42.8 mmol/L, pCO2 45.8 mmHg. Nephrology consulted after no improvement with a liter of normal saline and 80 meq potassium chloride (KCl). Exam was notable for buffalo hump and striae and mineralocorticoid excess was suspected; patient started on spironolactone 25mg daily, and hydration and KCl replacement continued. After 24 hours, despite improving creatinine, the pH peaked at 7.596. Spironolactone increased to 50mg daily, oral KCl 40meq started thrice daily, and acetazolamide 500mg IV started q12 hours for two doses, followed by acetazolamide 500 mg orally q12 hours for 4 doses.

His pH improved to 7.577 at 24 hours, 7.505 at 48 hours, and to 7.442 at 72 hours upon completion of acetazolamide. He was maintained on spironolactone 50mg daily and KCl 40meq orally thrice daily with no return of severe alkalosis or hypokalemia. Creatinine improved to 1.2 mg/dL. Cortisol level resulted greater than 110 µg/dL, and ACTH level of 1585 pg/mL. Work-up suggested non-pituitary source, and CT-imaging revealed concern for metastatic involvement of rectum and liver. Biopsy of the rectal mass confirmed extrapulmonary small cell ACTH-secreting neuroendocrine carcinoma.

Discussion: Severe metabolic alkalosis and hypokalemia secondary to mineralocorticoid effects of cortisol in ACTH-secreting neuroendocrine tumors has been rarely reported. Our case demonstrates the potential severity and a treatment regimen that has not previously been reported in this rare condition.

TH-PO045

Novel Treatment: Nephrogenic DI Swapna P. Vantzelfde, Jean M. Francis, Craig E. Gordon. *Boston Medical Center, Boston, MA.*

Introduction: A patient with lithium-induced nephrogenic diabetes insipidus (NDI) was treated with acetazolamide. This was modeled after a trial in mice.

Case Description: 49 year old male with bipolar disorder on chronic lithium therapy, admitted for resection of acoustic schwannoma due to ipsilateral hearing loss. Post-operatively, he was delirious with limited water intake. Lithium was discontinued on day 3 for worsening mental status. Serum sodium ranged from 153mmol/L to 164mmol/L and urine output ranged from 8 to 12L per day. Urine osmolality was 150mosm/kg H20. The free water deficit was initially treated with D5W IV without improvement. His mental status continued to deteriorate and his serum sodium remained elevated. DDAVP was administered with no change in the urine osmolality or serum sodium, conferring the diagnosis of complete NDI. Hydrochlorothiazide was started, and 4 days into treatment his urine output had increased to 14L per day. On day 18, acetazolamide started and hydrochlorothiazide stopped. By day 20 of admission there were dramatic improvements; urine output dropped to 3 to 5L per day, urine osmolality increased to 330mosm/kg H20 and serum sodium normalized. The beneficial effects of acetazolamide persisted, but were confounded by recent cessation of lithium and thus the acetazolamide was stopped which led to rise in urine output, to 7L per day. The acetazolamide was resumed on day 34, with marked reduction in polyuria to 1.5-3.5L per day for the duration of admission.

Discussion: The most common cause of NDI is chronic lithium use. Traditionally, the therapeutic approach emphasizes reduced sodium intake and thiazide diuretics with or without amiloride. Recent data from animal models of lithium-induced NDI delineate that hydrochlorothiazide reduces polyuria in mice lacking the thiazide-sensitive sodium-chloride co-transporter. This suggests an alternative mechanism of action than previously accepted. Carbonic anhydrase inhibition was proposed and a trial utilizing mice and collecting duct cells showed that acetazolamide was at least as effective for treatment of NDI. We utilized acetazolamide monotherapy in a patient with severe lithium-induced NDI and to our knowledge this is the first case with successful use of acetazolamide in humans with NDI.

TH-PO046

Attempt to Treat Anti-Brush Border Antibody-Mediated Tubulointerstitial Nephritis with Rituximab Emily Dryer,[1] Robert B. Colvin,[2] Ivy A. Rosales,[2] A. Bernard Collins,[2] Katherine Westin Kwon.[1] *[1]Lakeland Health, Saint Joseph, MI; [2]MGH Pathology, Boston, MA.*

Introduction: A case of immune complex tubulointerstitial nephritis due to autoantibodies to the proximal tubule brush border was recently described. We describe a second case, identified prior to the onset of end stage renal disease, and the lack of response to therapy with rituximab.

Case Description: A 76 year old man was referred to nephrology for evaluation after routine labs revealed his serum creatinine had risen from 1.1 to 1.5 over a year's time. He had 510 mg of proteinuria and transient microhematuria. He had no history of diabetes or hypertension. His blood pressure was 118/56, and physical exam revealed no edema. Kidney biopsy showed segmental membranous glomerulopathy. Immunofluorescence identified immune complex deposits along tubular basement membranes (TBM). This was consistent with a primary immune complex tubulointerstitial nephritis associated with anti-brush border antibodies (ABBAs). To confirm, the patient's serum was incubated with normal renal tissue and similar immune complexes developed. The patient was treated with prednisone 40 mg daily and rituximab 375 mg/m2 weekly for four weeks. Over the next five months, his serum creatinine rose further, reaching 3.5 mg/dL. He had profound functional decline, and his BMI fell from 18.8 to 15.9, ultimately requiring inpatient evaluation for failure to thrive. Admission was complicated by respiratory failure due to pneumonia in the setting of advanced chronic obstructive lung disease, and he expired in the hospital. Postmortem evaluation revealed no occult malignancy or extrarenal autoimmune disease. The kidneys had widespread tubular injury and atrophy with extensive diffuse fibrosis, progressive from prior biopsy. Interstitial inflammation was mild, but immune complex deposits were present in the TBM and Bowman's capsule. Serum was positive for ABBAs.

Discussion: In this case of anti-brush border antibody-mediated tubulointerstitial nephritis, administration of rituximab and prednisone early in the course of the disease did not halt the progression of renal decline. In the future, alternative therapy options should be considered for this disease process.

TH-PO047

Inherited Salt-Losing Tubulopathy: A Case Series Zhen Cheng,[1,3] Jing Lin,[2,3] Qi Qian.[3] *[1]Nephrology, Jinling Hospital Nanjing Univ, Rochester, MN; [2]Nephrology, Zhongshan Hospital Fudan Univ, Rochester, MN; [3]Nephrology and Hypertension, Mayo Clinic College of Medicine, Rochester, MN.*

Introduction: Two major syndromes of salt-losing nephropathy are Bartter syndrome (BS) and Gitelman syndrome (GS). We presented a series of GS and BS with unique mutations and some atypical presentations.

Case Description: Clinical data were collected through Mayo Clinic Electronic Medical Records with the IRB approval.

Five cases were identified (2010-2015). Average age was 37.2 yr (range: 20-50), BP 113.2/65.2 mmHg (96-140/48-88), common presentations were fatigue/muscle cramps and hypokalemia 2.82 mmol/L (2.0-3.3) while on K supplementation. Mutation analysis showed SLC12A3 gene mutations in 4 patients, consistent with GS, and CLCNKB mutation in 1, consistent with classic BS (cBS). The SLC12A3 mutations were (1) novel combination of double heterozygous c.184G>C and c.1964G>A; (2) novel combination of double heterozygous c.533C>T and c.815T>C; (3) homozygous mutations in two positions c.2221G>A and c.791C>G; and, (4) novel combination of heterozygous c.1315G>A and c.1964G>A. The remaining patient had CLCNKB mutation c.508G>A combined with an allelic deletion. Atypical presentations included (1) normotensive and hypertensive in 4 cases, 2 were on treatment; (2) erythrocytosis requiring phlebotomy in 1; (3) reversible hypercalcemia (11.5 mg/dL) associated with Ca supplement (1250 mg 2xdaily) and with fixed low urine Ca excretion (65 and 67 mg/24 hr urine before and after serum Ca correction [9.6 mg/dL]) by discontinuation of Ca intake; and, (4) the most severe hypokalemia (1.8-2.0 mmol/L on 160 mmol KCl/day) in a GS patient and the mildest hypokalemia (3.5-4.0 mmol/L on 20 mmol KCl/day) in the cBS patient. Combination treatments of oral KCl (20-160 mEq daily), amiloride (5-10 mg daily), and MgOx (400 -1800 mg daily) improved symptoms and serum K rose to 3.27 mmol/L (2.1-4.1).

Discussion: We describe unique mutant alleles in five unrelated adults. 8 mutations were predicted to be pathogenic, of which 7 missense mutations and 1 deletion. Differentiation of BS and GS based on clinical presentations is difficult. Normotension and hypertension are common. Genetic testing is informative.

TH-PO048

Pseudonormalization of the Serum Anion Gap in a Patient with Ketoacidosis Caused by Bromvalerylurea Intoxication Yatsumu Saito, Akiko Soda, Shuichiro Yamanaka, Kyoko Kishida, Yasuyuki Nakada, Taketo Uchiyama, Izumi Yamamoto, Ichiro Ohkido, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan.*

Introduction: Although nonsteroidal anti-inflammatory drugs (NSAIDs) containing bromvalerylurea are prohibited in the United States, such drugs are commonly available over-the-counter in Asian countries. The clinical features of acute intoxication include nausea, vomiting, and disturbed consciousness. Chronic intoxication induces irreversible neurological deficits and cerebellar atrophy. Importantly, the commonly used assays cannot distinguish bromides from chlorides, with the result that serum hyperchloremia may be a key feature of bromvalerylurea intoxication.

Case Description: A 50-year-old woman had a history of Neuro-Behçet's disease from the age of 48 years. She felt nauseous, and vomited repeatedly for 3 weeks prior to admission. These symptoms and her disturbance of consciousness became gradually worse to the point where she could not eat. On admission, ketone body levels in urine and blood were markedly elevated and her serum levels of bicarbonate were extremely low at 8.8 mmol/L. However, blood gas analysis revealed a paradoxical normal anion gap of 7.7 with hyperchloremia (127 mmol chloride/L). Furthermore, a magnetic resonance imaging brain scan revealed severe cerebellar vermis atrophy compatible with chronic bromvalerylurea intoxication. A medical interview revealed a history of common use of NSAIDs containing bromvalerylurea. Ultimately, we diagnosed her with acute to chronic bromvalerylurea intoxication. Prohibition of drug use resolved the digestive symptoms quickly, resulting in normalization of chloride levels and the metabolic acidosis. She was discharged, ambulating, 21 days after admission.

Discussion: Bromvalerylurea intoxication is uncommonly encountered in modern practice but has not disappeared; cases are still reported in Asian countries. Our case suggests that pseudohyperchloremia and pseudonormalization of the anion gap in patients with severe acidosis could be key features in the diagnosis of bromvalerylurea intoxication.

TH-PO049

Succinylcholine Induced Hyperkalemia in Pregnancy: A Unique Clinical Presentation Maria Theodorou, Jennifer K. Bond, Kavitha Vellanki. *Loyola Univ Medical Center, Maywood, IL.*

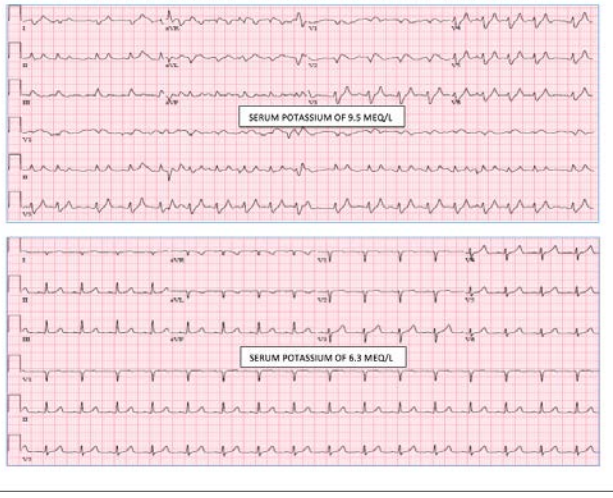
Introduction: Succinylcholine is used as a paralytic for endotracheal intubation, especially when rapid onset and offset of effect is needed. One adverse effect in certain patients is acute onset hyperkalemia and associated cardiovascular instability. Little is known about such effects in pregnancy. Here we report one such rare case.

Case Description: A 38 year old primigravida at 16 weeks with poorly controlled asthma presented with severe acute asthma exacerbation. Over 36 hours, she deteriorated despite maximal medical support, requiring emergent intubation for severe hypercapnic respiratory failure with succinylcholine and propofol induction. 7 hours post-intubation, wide QRS complexes were noted on cardiac monitor. STAT workup revealed a serum potassium of 9.5 MM/L (Table 1).

Table 1: Laboratory Data Pre & Post Succinylcholine Induction		
	Pre-Induction	7 Hours Post
Na (136-144 MM/L)	138	133
K (3.3-5.1 MM/L)	3.6	9.5
HCO3 (20-32 MM/L)	24	30
Cl (98-108 MM/L)	107	103
Glucose (70-100 MG/DL)	96	226
BUN (7-22 MG/DL)	6	11
Cr (0.6-1.4 MG/DL)	0.49	0.79

EKG showed wide QRS complexes. She was treated with calcium gluconate, sodium bicarbonate, insulin drip, sodium polystyrene sulfonate, and inhaled isoflurane. Hyperkalemia and EKG abnormalities improved in 4 hours (Figure 1).

FIGURE I : EKG CHANGES WITH SEVERE HYPERKALEMIA AND POST TREATMENT



Her hospital course was complicated by severe hypercapnia requiring extracorporeal membrane oxygenation, however she was eventually extubated and delivered a healthy child.

Discussion: Succinylcholine induced hyperkalemia in pregnancy has rarely been described. Cardiac arrest was reported in a pregnant female who had recovered from Guillain-Barre syndrome and developed hyperkalemia and cardiac arrhythmia within 1 minute of receiving succinylcholine. The 7 hour time delay to hyperkalemia and absence of neuromuscular disorder make our patient's clinical presentation unique.

TH-PO050

Persistent Hyperkalemia Post-Adrenalectomy Rami Mouayad Azem,[1,2] George Thomas.[1] *[1]Nephrology, Cleveland Clinic Foundation, Cleveland, OH; [2]Internal Medicine, Summa Health System, Akron, OH.*

Introduction: Primary aldosteronism should be suspected in resistant hypertension with hypokalemia. Adrenal vein sampling (AVS) can differentiate unilateral from bilateral secreting lesions. Adrenalectomy should result in normalization of potassium (K) levels. We describe a patient with adrenal adenoma who underwent unilateral adrenalectomy, with subsequent persistent hyperkalemia.

Case Description: A 62 year old male with resistant hypertension and hypokalemia presents with a plasma aldosterone (PA) level of 203 ng/dl and plasma renin activity (PRA) of 0.4 ug/dl/hr. CT showed a 1.5 cm right adrenal adenoma with left adrenal hyperplasia. AVS showed lateralization to the right, and the patient underwent right adrenalectomy. ACTH stimulation test showed appropriate cortisol response. He was discharged 2 days post-operatively on nifedipine XL, lisinopril, and K supplementation because of a persistently low K of 3.0 mmol/l and hypertension. On follow-up after 3 days, his K was 5.4 mmol/l and creatinine was 1.5 mg/dl from pre-operative level of 1.1 mg/dl. His lisinopril and K supplementation were discontinued. His post-operative PA and PRA levels were 3 ng/dl and 3.5 ug/l/hr respectively. Because of persistent hyperkalemia with K up to 5.8 mmol/l and creatinine up to 2.6 mg/dl 2 weeks post-operatively, he was hydrated with IV normal saline. His renal function and K improved, but on follow-up one month post-operatively, he was persistently hyperkalemic with K of 5.3 mmol/l. Fludrocortisone 0.1 mg daily was started.

Discussion: Unilateral adrenalectomy should correct hypokalemia in primary aldosteronism. Case series have described hyperkalemia post-adrenalectomy. Incidence is 16-29 percent and hyperkalemia can persist from 1 week to 46 months. Fludrocortisone is needed in rare cases. The etiology is likely selective hypo-aldosteronism due to suppressed contralateral adrenal gland, along with volume depletion. Factors that increase risk include long duration of hypertension and decreased eGFR. Patients who undergo unilateral adrenalectomy for primary aldosteronism should increase fluid intake, liberalize dietary sodium, and have close follow-up of renal function and electrolytes.

TH-PO051

Hyperphosphatemia, Normal eGFR, and Complete Tubular Phosphate Reabsorption Leading to a Pituitary Tumor Diagnosis Jwalant R. Modi, Ghurulakshmi Moorthy, Michael T. Eadon. *Medicine, Indiana Univ, Indianapolis, IN.*

Introduction: The classic presentation of a pituitary tumor is comprised of hormonal symptoms related to gonadal hormone deficiency or neurological symptoms including diplopia, headache, or visual field defects. However, these tumors may be dormant clinically, be found incidentally on brain imaging, or provide subtle clues which can be easily overlooked.

Case Description: A 49 year old African American woman was seen following hospitalization for sudden-onset hand cramping and facial contracture due to hypokalemia for evaluation of hypokalemia induced nephrogenic diabetes insipidus. History was notable for hypertension, normal eGFR, fibroids, colonic polyps, wrist fracture and a 15 lb weight loss in 1 year. She complained of diffuse body aches, fatigue, and poor appetite, but denied any nipple discharge, major headaches, or visual symptoms. She no longer menstruated as she had undergone hysterectomy. On lab studies, she had hypokalemia, recurrent hyperphosphatemia, hypomagnesemia, TTKG 6.5, urine K+/Creatinine ratio 20 meq/g; Fractional excretion (FE) of Mg 1.3% and FE-phos 0%. Her aldosterone level was low with a normal renin level. The most differential-focusing aspect was the complete tubular reabsorption of phosphate in the setting of hyperphosphatemia and normal eGFR. Her 25-OH and 1,25-OH vitamin D were suppressed. It is known that acromegaly with IGF-1 secretion may lead to phosphorus reabsorption. Even though she had no phenotypic features of acromegaly, we checked growth hormone, IGF-1, and IGF-BP3, as well as an MRI brain. Her growth hormone axis was suppressed, but the MRI revealed a heterogeneous sellar mass, suspicious for a pituitary macro adenoma. Her endocrine work-up revealed pan-hypopituitarism, except for a prolactin level of 72.4 - elevated, but atypical for a prolactinoma. She was started on hydrocortisone and levothyroxine and will undergo transsphenoidal tumor removal.

Discussion: Since this patient had hyperphosphatemia with normal eGFR and complete tubular reabsorption of phosphate, this case raises the question of whether pituitary hormones (other than IGF-1) contribute to the regulation of FGF-23 and the sodium phosphate co-transporter.

TH-PO052

TB or Not TB.. That Is the Question Miraie Wardi,[1] Angelica Aurora Nunez,[2] Dubier Matos,[2] Hasan Joseph Salameh.[1] *[1]Internal Medicine - Div of General Internal Medicine, TTUHSC Paul L. Foster School of Medicine, El Paso, TX; [2]Internal Medicine - Div of Nephrology, TTUHSC Paul L. Foster School of Medicine, El Paso, TX.*

Introduction: *Mycobacterium wolinskyi* , a member of the *Mycobacterium smegmatis* group of rapidly growing mycobacteria (RGM), is a rare cause of infection in humans. To date, less than 20 cases have been reported, most of which are associated with post-traumatic and post-surgical wound infections. We report a case of *M.wolinskyi*-induced peritoneal dialysis (PD) catheter exit-site infection, an entity never before reported in the literature.

Case Description: A 46 year old female with a past medical history of end-stage renal disease secondary to lupus nephritis on chronic PD presented for constant abdominal pain of 3 days duration after manual exchanges. Pain was localized in the epigastrum and lower abdomen with no radiation with associated nausea and vomiting. Upon initial evaluation, she was found to be afebrile and normotensive. Abdominal examination was significant for a tender abdomen in the lower and epigastric regions with thick purulent discharge easily expressed from the exit site. A CT of the abdomen failed to show infectious changes tracking along the catheter tunnel. Peritoneal fluid analysis was unremarkable. Bacterial and AFB cultures of the purulent discharge were taken and the patient was initiated on empiric levofloxacin. Initial cultures were negative. The patient with discharged home on topical gentamicin. Upon follow up, the purulent discharge remained. Analysis of exit-site cultures at 168 hours revealed growth of *M. wolinksyi*. Long-term dual antibiotic therapy was initiated and currently pending follow up.

Discussion: M. wolinskyi was discovered in 1999 using 16sRNA sequencing. Only 19 cases of *M.wolinskyi* infections in humans have been described, the majority of which are associated with post-orthopedic surgical site infections, although a few cases of post-operative *M. wolinskyi* bacteremia have been described. It has also been described in one case of PD catheter-related acute peritonitis within 6 months of surgical placement of PD catheter. To our knowledge, this is the first case of M. wolinskyi-induced PD catheter exit-site infection.

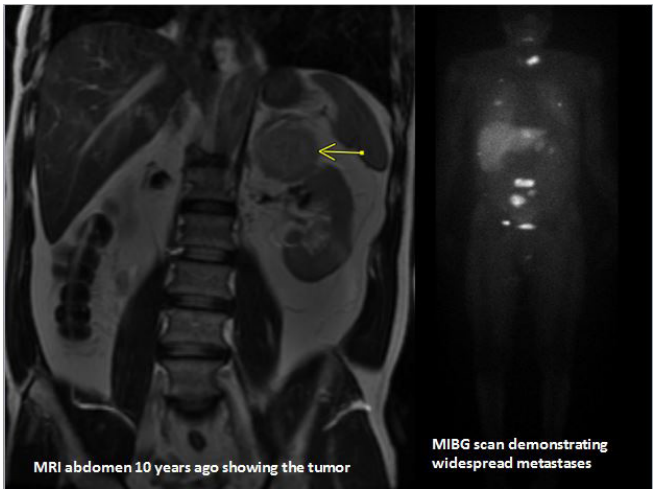
TH-PO053

The Tale of a Forgotten Tumor Abhilash Koratala, S. Irfan Qadri, Vikrampal Bhatti, Volodymyr Chornyy. *Nephrology, Univ of Florida.*

Introduction: Pheochromocytoma (PCC) is a rare catecholamine-secreting neuroendocrine tumor that arises from chromaffin cells of the adrenal medulla. Approximately 10% are malignant, often diagnosed as a result of local invasion into surrounding organs or distant metastases. We present a case of an apparently benign PCC that presented 10 years after diagnosis as metastatic disease.

Case Description: A 64 year old Caucasian man was seen by us for hypertension (HTN) and an adrenal mass. 10 years prior to presentation, he was diagnosed with a left adrenal mass while undergoing work up for uncontrolled HTN. He underwent laparoscopic left adrenalectomy and pathology confirmed PCC. The tumor was 8.3 cm in size with focal areas of hemorrhage and necrosis, but confined to the adrenal gland. His BP normalized

and he was tapered off of anti-hypertensives a few weeks later. He was then lost to follow up. 3 months ago, he saw his primary care physician for a 40 lbs unintentional weight loss. He was found to be hypertensive & hyperglycemic. He denied headache, palpitations or sweating. 24 hour urine studies confirmed elevated (~1,000x normal) metanephrines & normetanephrines. CT revealed a 3.8cm left adrenal mass with focal calcification. PET CT identified multiple areas of bony involvement suggestive of metastatic disease. Biopsy of the sacral mass was attempted, but the blood pressures rose to 240/124. He was started on phenoxybenzamine & labetalol with good response. He is currently being treated with I-131 metaiodobenzylguanidine. Prior MRI and current MIBG are shown.



Discussion: Malignant PCCs are histologically and biochemically similar to benign ones with the only reliable clue to malignancy being local invasion or distant metastases, which may be missed during initial diagnosis. Although benign appearing PCCs are completely excised, we recommend continued follow up of these patients until reliable predictors of malignancy are defined.

TH-PO054

Severe Hypertriglyceridemia and Fasting Ketoacidosis Associated with Clevidipine

Daniel Dudenkov,[1] Insara Jaffer Sathick,[1] Robert C. Albright.[1] *[1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic, Rochester, MN; [3]Nephrology, Mayo Clinic, Rochester, MN.*

Introduction: Clevidipine (CLV) is a newer intravenous calcium channel blocker used to treat high blood pressure in acute settings. Although CLV is generally considered safe, clinical experience is limited, especially pertaining to rare adverse effects.

Case Description: Patient is a 60 year-old male with a history of allogenic cardiac transplantation for ischemic cardiomyopathy, immunosuppressed with mycophenolate mofetil and cyclosporine. He gradually developed cardiac allograft vasculopathy and cyclosporin-related nephrotoxicity. On hospital day (HD) 1, he underwent kidney allotransplantation and second cardiac allotransplantation. On HD3, he was initiated on CLV drip for hypertension. Over the next two days he developed progressive metabolic acidosis with bicarbonate 13 mmol/L and anion gap 23 (Figure 1). Due to increased work of breathing, he was placed on BiPAP support, with arterial blood gas showing pH 7.37, pCO2 27, and pO2 81. Other labs revealed a lactate 1.0 mmol/L, creatinine 1.0 mg/dL, glucose 121 mg/dL, beta-hydroxybutyrate (BHB) 5.9 mmol/L, and triglycerides (TG) 2000 mg/dL. Due to concern for CLV toxicity, he was transitioned to a nicardipine drip. He was also given IV dextrose with insulin. Within 24 hours, the patient's acidosis resolved with a repeat BHB 0.2 mmol/L and TG 280 mg/dL.

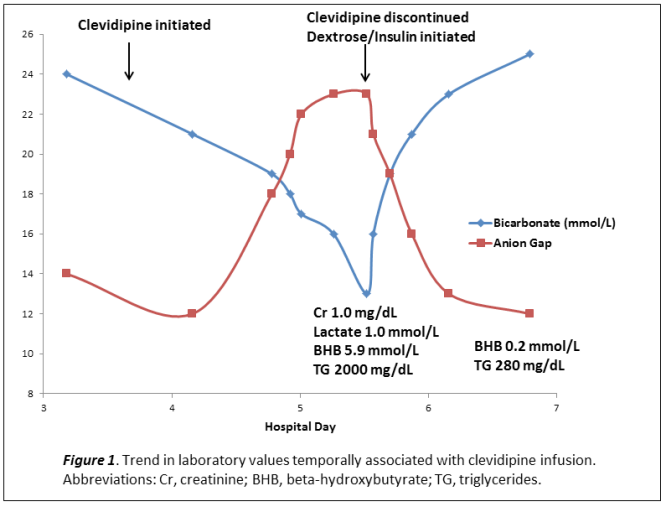


Figure 1. Trend in laboratory values temporally associated with clevidipine infusion. Abbreviations: Cr, creatinine; BHB, beta-hydroxybutyrate; TG, triglycerides.

Discussion: To our knowledge this is the first reported case of severe hypertriglyceridemia and fasting ketoacidosis associated with intravenous CLV. CLV is formulated within a 20% fat emulsion. For patients with low insulin states from fasting, the production of ketoacids is potentiated by a high lipid load. For fasting patients receiving CLV, close monitoring of triglycerides and administration of glucose with insulin should be considered.

TH-PO055

Coexistence of Proximal and Distal Renal Tubular Acidosis

Soham Gohil, Hemant J. Mehta, Jhoomar R. Makhija, Wasi Shaikh. *Nephrology, Lilavati Hospital & Research Center, Mumbai, India.*

Introduction: Renal tubular acidosis (RTA) is a group of transport defects in the reabsorption of bicarbonate, the excretion of hydrogen ion (H+), or both, resulting in systemic acidosis and hypokalemia with a normal glomerular filtration rate. Isolated proximal (type 2) or distal (type 1) tubular pathologies are well characterized, a combined pathology leading to type 3 RTA is very rare. We report a case with features of type 1 and type 2 RTA. We wonder if this is a case of type 3 RTA, a term, which is not in use.

Case Description: 20 years old female presented with diarrhea and weakness of all 4 limbs. She had 5 episodes of weakness over past 10 years, and fracture of left shaft of femur. She had growth retardation, left genu valgum, power was 4 in all 4 limbs. She was 1st of 4 siblings of parents, and no family history of similar disease. Clinical diagnosis: renal tubular acidosis with rickets. Investigations: isosthenuria, urine pH 9.0; urine protein creatinine ratio 0.47 mg/mg, normal renal function, hypokalemia, hypocalcemia, hypophosphatemia, normal blood sugars, glycosuria, phosphaturia, bicarbonaturia, with venous bicarbonate of 18 mEq/L. Specific aminoaciduria could not be demonstrated. Urinary calcium excretion, serum Vit D and PTH levels were normal. X-rays showed fractures and looser's zone in many bones. CT KUB showed non obstructing renal calculi and amorphous chunky calcification in renal medulla suggestive of medullary nephrocalcinosis. Patient was treated with potassium, calcium, phosphorus and alkali supplements. Her power returned to normal and she could walk with support.

Discussion: Our patient has features of proximal (p) and distal (d) RTA. The term Type 3 RTA is not in use, but it is an extremely rare autosomal recessive syndrome. Combined dRTA and pRTA is also observed in inherited carbonic anhydrase II deficiency. Patients with pRTA may have high urinary calcium excretion; however, nephrocalcinosis and renal calculi are rare in type 2 but common in type 1 RTA. Stunted growth is a prominent clinical feature in children. Rickets and osteomalacia are never observed unless hypophosphatemia is present as occurs in the Fanconi syndrome. We feel this patient has Type 3 RTA.

TH-PO056

Acute on Chronic Osmotic Demyelination in Binge Alcoholism

Mark A. Kleman, Ion D. Bucaloiu. *Nephrology, Geisinger Health System, Danville, PA.*

Introduction: Osmotic Demyelination is a devastating neurological complication of hyponatremia and a consequence of rapid increase in serum tonicity in patients with chronic hyponatremia. We present a rare case of acute on chronic pontine and extra pontine demyelination in the setting of binge alcoholism.

Case Description: A 24-year-old male admitted with ataxic gait, slurred speech, nausea, and vomiting of five days duration. He also had blurred vision and fell several times but denied significant head injury or loss of consciousness. He was habitually drinking 24 bottles of beer per weekend over the last year. He also reported craving and licking salt upon regaining sobriety. His medical history was significant only for depression. On physical examination he was hypotensive and appeared hypovolemic. Neurological examination revealed significant dysmetria, ataxic gait, and intentional tremor. Initial laboratory data showed serum sodium level of 118, serum osmolality 263, urine osmolality 565, and urine sodium <10. Computed Tomography of the head showed a lucent area in the central pons concerning for myelinolysis. The patient was treated with normal saline infusion, followed by 5% dextrose in normal saline infusion containing thiamine and folic acid. Serum sodium level corrected to 123 mEq/dL (5 mEq/dL) over the next 6 hours. Desmopressin was administered and the rate of correction of serum sodium stabilized to an average rate of 7 mEq per 24 hours over the next three days. Neurologic symptoms resolved during the first 48 hours of admission. Magnetic resonance imaging scan of the brain showed T2 hyperintensity and restricted diffusion in the middle cerebellar peduncles suggestive of acute osmotic demyelination and myelomalacia in the central pons likely secondary to remote episodes of osmotic demyelination.

Discussion: It is unlikely that the radiological findings were caused by the presenting hyponatremic event, rather prior episodes of alcohol binges may have caused rapidly correcting hypotonic states, resulting in the chronic demyelinating lesions. This case underscores the the spectrum of demyelination that can be present in the setting of repeated osmotic injury associated with the pattern of binge alcoholism.

TH-PO057

Tubulointerstitial Nephritis and Renal Tubular Acidosis Are Important Complications of Primary Biliary Cirrhosis - A Case Report

Anjushree Kumar, Pooja Budhiraja, Amna Ilahe. *Nephrology, Kansas Univ Medical Center, Kansas City, KS.*

Introduction: Primary biliary Cirrhosis (PBC)is a liver disease that is characterized by the progressive destruction of the bile ducts.T cell dependent immune reaction has been thought as the major mechanism of bile duct destruction.This mechanism may play role in renal dysfunction in these patients.We describe a case of Renal Tubular acidosis (RTA) and tubulointerstitial nephritis (TIN) associated with PBC.

Case Description: A 53 years old female was diagnosed with PBC with elevated antimitochondrial antibodies(AMA)of 1:320 and high IgM levels(500 mg/dl).Laboratory results at the time of diagnosis-

Serum Creatinine-3.1 mg/dl	Serum Potassium -3.4 mEq/L	Serum Phosphate -2.6 mg/dl	Serum bicarbonate -15 mEq/L	Serum uric acid -2.0 mg/dl
Serum alkaline phosphatase-134 U/L	Urine PH -5.5	Glycosuria ++	Proteinuria ++	Aminoaciduria +
RBC in urine -0-2 cells/hpf	WBC in urine -0-2 cells/hpf	Protein /cr -2.9 g/g	SPEP-absent	UPEP-absent

She underwent kidney biopsy which showed normal Glomeruli.Interstitial edema,marked tubulo-interstitial inflammatory infiltrates and significant fibrosis were present.Significant deposits of calcium phosphate were also noted in the tubules. Immunofluorescence showed C3 activity in arterioles.EM showed extensive mononuclear infiltrate.Proximal and distal RTA and TIN was likely related to PBC in this patient. Patient was started on potassium citrate.Due to significant fibrosis steroids were not given.Later her renal function worsened and she needed dialysis.

Discussion: PBC can be associated with TIN and RTA which can be easily missed. Possible mechanisms include autoreactive T lymphocytes driven by abnormal antigen expression in both hepatocytes and similar antigen expression in renal tubules might be involved leading to T lymphocyte infiltration into the interstitium.Also,AMA by reducing activity of mitochondrial enzymes in renal tubular cells may also play a role in genesis of TIN and RTA.Physician acquaintance regarding these mechanisms is needed as these processes can cause renal dysfunction in subjects with PBC and early treatment with steroids may prevent further renal damage.

TH-PO058

A Heterozygous Mutation in NPT2c (SLC34A3) Is Associated with Marked Hypercalciuria and Kidney Stones during Infancy Maryam Gondal, Olivera Marsenic Couloures, Neera K. Dahl, Clemens Bergwitz. *Yale Univ School of Medicine, New Haven, CT.*

Introduction: The SLC34A3 gene encodes for the renal sodium-phosphate co-transporter NPT2c. A homozygous or compound heterozygous inactivation results in Hereditary hypophosphatemic rickets with hypercalciuria (HHRH, OMIM#241530). Affected individuals present with hypophosphatemia and hypercalciuria . Heterozygous carriers of SLC34A3 mutations often present with idiopathic hypercalciuria (IH). Here we present the case of a child with multiple kidney stones and hypercalciuria since birth. His father was also found to have marked hypercalciuria.

Case Description: The child was born prematurely (29GW), and presented as a new born with hypertension.Renal imaging revealed bilateral kidney stones and nephrocalcinosis. Urine analysis showed calcium oxalate crystals with calcium excretion of 4.9mg/kg/day.His most recent laboratory studies at age 10 yrs show serum calcium of 9.8mg/dl , phosphorous 4.9 mg/dL, PTH 12 pg/ml, 1,25-OH vitamin D 78 pg/ml and 25-OH vitamin D 27 pg/ml. His 24-hr urine calcium is 8.6 mg/kg/day. Prompted by his son's findings, the father's evaluation at age 43 was significant for urine calcium 609 mg/day and urine oxalate 40mg/day. Serum Parathyroid hormone (PTH) was 13pg/ml, 1-25 OH vitamin D was 105pg/ml, 25 OH vitamin D 53 pg/ml, phosphate 3.7mg/dL and calcium was 10mg/dL. An ultrasound of his kidneys revealed a left calcified renal cyst and left sided renal mass, found to be renal cell cancer and he underwent partial nephrectomy. Whole exome sequencing (WES) of the child revealed a heterozygous mutation SLC34A3: c.575C>T (p.S192L).

Discussion: SLC34A3: c.575C>T (p.S192L) was previously reported in compound heterozygous individuals affected by HHRH and has a minor allele frequency in the general population of 0.03%. This mutation likely contributes to the idiopathic hypercalciuria in the current kindred. Interestingly, penetrance appears variable, causing early onset nephrocalcinosis and symptomatic stone disease in the son, while only a calcified cyst was found upon ultrasound in the father. Based on genetic diagnosis, son is managed on high phosphorous diet with resolution of hypercalciuria. The father is monitored off therapy.

TH-PO059

Nephrolithiasis and Nephrocalcinosis Associated with 1,25(OH)2D-24 Hydroxylase Deficiency M. Lourdes Gonzalez Suarez,[1] Robert A. Wermers,[2] Ravinder Singh,[3] Stephen B. Erickson.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Endocrinology, Mayo Clinic; [3]Lab. Medicine and Pathology, Mayo Clinic College of Medicine.*

Introduction: Vitamin D plays a major role in calcium (Ca) homeostasis. $1,25(OH)_2D$-24 Hydroxylase is the enzyme that converts active vitamin D to its inactive metabolites. It is codified by the gene CYP24A1. If deficient, it may cause hypercalcemia, nephrolithiasis, nephrocalcinosis and renal failure. We describe two cases of $1,25(OH)_2D$ mediated hypercalcemia associated with nephrolithiasis and nephrocalcinosis with biochemical evidence of possible biallelic CYP24A1 mutation.

Case Description: Case 1: 50 year old man with kidney stones (Ca phosphate) since age 14 with a strong family history of kidney stones. He had persistent hypercalcemia (13 mg/dL), PTH 22 pg/mL, serum creatinine (sCr) 1 mg/dl, and hypercalciuria (349 mg/24h). $1,25(OH)_2D$ 77 ng/ml, 25(OH)D 32 ng/ml, $24,25(OH)_2D$ 0.3 ng/ml; 25(OH) $D/24,25(OH)_2D$=107(ratio >80 consistent with biallelic CYP24A1mutation). Patient was treated with fluconazole attempting to downregulate conversion of 25(OH)D to $1,25(OH)_2D$, prednisone and potassium citrate. **Case 2:** 33 year old man with failure to thrive as a child. He had chronic hypercalcemia (13-14 mg/dL), sCr 2.6 mg/dl, PTH 62 pg/ml, $1,25(OH)_2D$ 38 ng/ml, 24h urinary Ca 152 mg/dl. Kidney biopsy showed nephrocalcinosis. Parathyroid scan showed left lower adenoma -removed without improvement. Repeat scan showed right lower adenoma, he underwent a second partial parathyroidectomy. 25(OH)D 35 ng/ml; $24,25(OH)_2D$ 0.1 ng/ml; $25(OH)D/24,25(OH)_2D$=350. Drug therapy included furosemide, prednisone and cinacalcet. He was approved for kidney transplant. Genetic testing is pending.

Discussion: This study highlights the importance of recognizing clinical presentation of patients who may have CYP24A1mutations. This may have a varied presentation including longstanding $1,25(OH)_2D$mediated hypercalcemia, nephrocalcinosis and nephrolithiasis, progressive chronic kidney disease (CKD). Case 2 presented signs of CKD –lower $1,25D_2$ level and lower 24h urine calcium–as CYP24A1 gene is expressed in the kidney, kidney transplant should be curative.

TH-PO060

Glucocorticoid Therapy for the Treatment of Oxalate Nephropathy Dominique Dorsainvil, Bryan Tucker, Randy L. Luciano. *Nephrology, Yale School of Medicine, New Haven, CT.*

Introduction: Oxalate nephropathy is an uncommon form of kidney injury marked by calcium oxalate crystals in kidney tubules leading to acute tubular injury and interstitial inflammation. Supportive treatment includes intravenous fluids to flush crystals out of the tubules. However in severe injury, renal replacement therapy may be required. No studies report the use of anti-inflammatory medications to treat oxalate induced kidney injury. Here we present two patients who presented with acute kidney injury (AKI) attributed to oxalate nephropathy. Both patients had significant acute interstitial inflammation resulting in prolonged AKI that improved with glucocorticoids.

Case Description: The first patient was a 54 year old man with bipolar disorder who presented obtunded after ethylene glycol ingestion. He had AKI, a high anion gap metabolic acidosis and an osmolar gap in the setting of high serum ethylene glycol. The patient was treated with intravenous fluids but kidney injury was so severe that he required hemodialysis. Six weeks into hemodialysis recovery was not apparent. At that time a biopsy revealed persistent calcium oxalate crystals and interstitial inflammation. The patient was pulsed with intravenous solumedrol and transitioned to prednisone 60 mg with a gradual taper over 4 weeks. Two weeks after starting glucocorticoids the patient was able to stop hemodialysis. The second patient was a 71 year old gentleman with hypertension, non insulin dependent diabetes mellitus, mild dementia, prior stroke, and CKD stage III presenting with AKI of unclear origin. Creatinine increased from 1.5 mg/dL to 8.4 mg/dL, all the while receiving intravenous isotonic fluid and antibiotics for a pneumonia. Due to the continued rising creatinine a biopsy was performed and unexpectedly revealed diffuse oxalate crystals with a reactive peri-tubular interstitial infiltrate. The patient was started on prednisone 60 mg daily. His renal function subsequently improved. In retrospect, it was noted that he ate copious amount of chocolate and peanut butter.

Discussion: Both cases demonstrate the importance of identifying oxalate nephropathy early and treating inflammation with glucocorticoids if there are no underlying contraindications.

TH-PO061

Xanthine Oxidase Deficiency: A Very Rare Cause of Recurrent Nephrolithiasis Madhura S. Borikar, Kevin Fleming. *Internal Medicine, Mercy Catholic Medical Center, Darby, PA.*

Introduction: Xanthine Oxidase deficiency with resulting xanthinuria causing nephrolithiasis is a very rare disorder. We present a rare such case which exemplifies importance of understanding pathophysiology of purine metabolism and clinical correlation to pathophysiology.

Case Description: A 32 year old African-American female with PMHx of recurrent renal stones, presented with 2 day history of right flank pain radiating to RUQ, fevers and nausea. She was previously diagnosed with nephrolithiasis with hydronephrosis requiring ureteral stent. Her physical examination was notable for an elevated temperature, tachycardia, RLQ and CVA tenderness. A CT scan of the abdomen and pelvis showed a staghorn calculi in the right pelvicalyceal system, along with the previously placed stent and perinephric stranding. She underwent lithotripsy and stone extraction. The chemical analysis revealed that the stone was composed of 100% Xanthine. Serum uric acid level was less than 0.2 mg/dl, which was consistent with Xanthine Oxidase deficiency. Her treatment involved aggressive intravenous hydration and alkalization of the urine, recurrent lithotripsy and stone extraction procedures.

Discussion: Xanthine oxidase deficiency is extremely rare autosomal recessive disease resulting in hereditary xanthiuria. The enzyme is a catalyst of the final two steps in the metabolism of Purine leading to the formation of Xanthine and Uric Acid. Its deficiency causes increased urinary excretion of relatively insoluble xanthine which leads to development of xanthine stones in approximately one-third of patients. Diagnosis is suspected by hypouricemia (uric acid level less than 1.0 mg/dl), reduced urinary uric acid levels and increased xanthine excretion and is confirmed by liver or intestinal biopsy with measurement of enzyme activity. Management of xanthine stones involves intravenous isotonic saline administration to increase urine output. Although alkanization of the urine with sodium bicarbonate anecdotally successful, xanthine is poorly soluble in both acidic and alkalized urine. Anecdotally, aggressive fluid intake and low purine diet helps prevent such stones.

TH-PO062

Combined Liver/Kidney Transplantation in a Patient with Primary Hyperoxaluria Type 2 Tsering Dhondup, Elizabeth C. Lorenz, Dawn S. Milliner, John C. Lieske. *Dept of Nephrology and HTN, Mayo Clinic, Rochester.*

Introduction: Liver transplantation is an accepted therapy for primary hyperoxaluria type 1 (PH1), but has not been shown to correct the enzyme defect causing PH2. Unlike PH1, the enzyme deficiency in PH2 is found not only in the liver, but also in cells in multiple body organs. To date, the question of whether liver transplantation can provide sufficient correction of the metabolic deficiency in PH2 has remained unanswered. We report a case of a 44-year-old man with PH2 who had successful reduction in plasma oxalate (POx) and urine oxalate (UOx) after combined liver/kidney transplantation.

Case Description: Born with a solitary kidney, the patient's first symptomatic stone event occurred at the age 6. The next symptomatic nephrolithiasis was at age 37 when he presented with an elevated creatinine and a large obstructing renal stone requiring endoscopic removal. Progressive chronic kidney disease ensued and he underwent a preemptive living donor kidney transplant elsewhere. Allograft dysfunction occurred 6 months post-transplant and a biopsy revealed oxalate nephropathy. Urine studies showing elevated urine glycerate and normal glycolate suggested PH2. Multiple stone events and progressive allograft dysfunction followed. Genetic testing confirmed PH2 with a nonsense mutation in *GRHPR (*c.139C>T; p.R47X). Creatinine was 4.1 and both UOx (1.51 mmol/24hr) and POx (22.1 umol/L) were markedly elevated. Because of the marked hyperoxaluria, frequency of stone events, and loss of the first renal allograft to oxalate nephropathy, he was listed for combined liver/kidney transplant at our center. The combined transplant occurred 1 year later at age 44 before dialysis was required. He developed delayed renal allograft function and received hemodialysis daily for the 1st 9 days post-transplant. By postoperative day 26, creatinine had improved to 1.4 and both POx and UOx had normalized [1.2 umol/L (reference < 1.8 umol/L) and 0.23 mmol/ 24 hr (reference 0.11-0.46 mmol/ 24hr)] respectively.

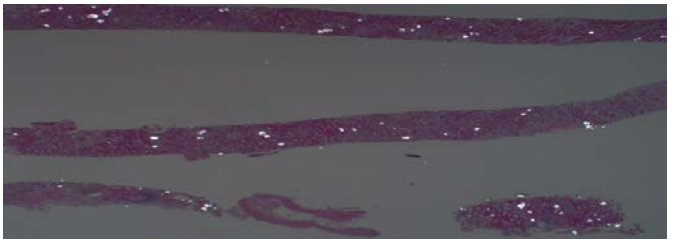
Discussion: Although GR/HPR is expressed throughout the body, this case suggests that a liver transplantation may normalize oxalate generation in PH2. Thus the role of liver transplantation in PH2 merits further study.

TH-PO063

Alternative Chemotherapy Resulting in Pancreatitis, Ketoacidosis and Oxalate Nephropathy Caroline Johnson, Lindsay Sanders, Ayan Sen, Mira T. Keddis, Leslie F. Thomas. *Nephrology, Mayo Clinic Hospital, Phoenix, AZ.*

Introduction: Alternative treatments for cancer are used increasingly in the United States. Unintended harms of these novel regimens may be profound but underreported. Here,we describe a non-diabetic patient with solitary kidney who developed pancreatitis, ketoacidosis and oxalate nephropathy quickly following the use of high dose vitamin C and 3-bromopyuruvate.

Case Description: A 72 year old man presented with progressive fatigue,nausea,and mid-epigastric pain.Two weeks prior to admission,he initiated an 8-day course of an alternative chemotherapeutic regimen for metastatic bladder cancer consisting of oral vitamin C 2g daily,IV vitamin C 50g daily, and IV 3-bromopyruvate 90mg daily. CT and laboratory studies confirmed pancreatitis(lipase >3,000 U/L).A high anion gap metabolic acidosis(pH 7.14, AG 36),elevated beta-hydroxybutyrate(15.6mmol/L (<0.4))and elevated oxalate (23.4mmol/L (<1.8)) were noted. Acute kidney injury was revealed by the serum creatinine (3.8mg/dL (patient's baseline 1.7)).Kidney biopsy revealed acute tubular necrosis and diffuse oxalate crystal deposition.



Lack of meaningful renal recovery led to initiation of hemodialysis.

Discussion: We posit the infusion of cellular stressors vitamin C and 3-bromopyuruvate induced his pancreatitis.Severe ketoacidosis in this non-diabetic patient may be explained by the acute pancreatitis and exacerbated by the direct effect of 3-bromopyuruvate on inhibition of glycolysis and diverting ATP production to fatty acid utilization.This is the first reported case of the triad of pancreatitis,oxalate nephropathy, and non-diabetic ketoacidosis secondary to alternative therapy.Complications associated with alternative therapies needs further reporting in literature.This would enable active evidence-based discussion and improved risk counseling to patients regarding harm associated with unproven alternative therapies.

TH-PO064

Hypervitaminosis A: A Rare Case of Hypercalcemia Divya Sharma, Ramapriya Sinnakirouchenan. *Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Serum Vitamin (Vit) A levels are raised in chronic kidney disease (CKD). Chronic Vit A toxicity occurs with ingestion of 10 times the recommended daily allowance. It occurs at lower doses in patients with CKD. We present a case of hypercalcemia in a CKD patient taking toxic levels of beta-carotene.

Case Description: A 59 year old male presented for routine nephrology follow up. His past medical history was significant for CKD stage 3 and liver transplant 10 years prior for alcoholic cirrhosis. He had no complaints and felt well overall. Routine labs revealed an elevated serum calcium level of 12.4 mg/dL. Subsequent workup for hypercalcemia showed 25 hydroxy Vit D of 50.7 ng/mL (normal 32-100), 1,25 hydroxy Vit D of 92.1 pg/mL (normal 10-75), intact parathyroid hormone (PTH) of 11.0 pg/mL (normal 15-72), and an undetectable PTH related peptide level. Hypercalcemia persisted despite discontinuing calcium and Vit D supplements. On further review, the patient reported he started taking 50,000 units of beta-carotene daily 3 months prior. Hypercalcemia resolved after cessation of the Vit A supplement.

Discussion: While hypervitaminosis A is a well-documented cause of hypercalcemia, the association is rarely seen in clinical practice. Vit A stimulates osteoclastic resorption and inhibits osteoblastic formation. Patients with underlying CKD are more sensitive to its effects and have higher Vit A concentrations even if ingested below toxic doses. Possible explanations include decreased retinol and retinol binding protein excretion by the kidneys. This case illustrates the importance of obtaining a complete history, including all nonprescription medications. Additionally, as illustrated by our patient taking 50,000 units of beta-carotene daily instead of the recommended 3,000 units daily, the clinician must be mindful of recommended doses as patients may unknowingly be taking toxic doses of seemingly benign substances. Nephrologists should be especially vigilant of this phenomenon, as risk for toxicity remains higher in our patients with underlying CKD. Care should be taken in prescribing multivitamins with Vit A to CKD patients.

TH-PO065

Stone or Pseudo-Stone? S. Irfan Qadri,[1] Abhilash Koratala,[1] Vincent G. Bird,[2] Rupam Ruchi.[1] *[1]Nephrology, Univ of Florida; [2]Urology, Univ of Florida.*

Introduction: We report a case of Keratinizing Desquamative Squamous Metaplasia (KDSM) of the upper urinary tract, which is an uncommon and under-recognized condition that mimics Nephrolithiasis in symptomatology.

Case Description: 66 year old Caucasian male with history of hypertension, hyperlipidemia, osteoarthritis and 16 pack-year smoking was referred to us for evaluation of recurrent right sided flank pain and suspected Nephrolithiasis. He had the first episode of pain about 2 years prior to presentation that was recurrent. There was no associated hematuria, dysuria, fever, chills, urinary hesitancy or incontinence. No family history of stones or other kidney disease. He saw multiple urologists and underwent multiple ureteroscopies some of which showed glistening, soft, acellular debris in the upper ureter. Last available pathology showed minute fragments of acellular keratin debris. Interestingly, he never had imaging evidence of renal stone, though had mild hydronephrosis one time. During the episodes of flank pain, he can feel 'something' sloughing off and traversing through the ureter. Excreted material is shown.

We diagnosed KDSM and managed conservatively with adequate hydration and supportive measures.

Discussion: KDSM is a condition in which the urothelium of the urinary tract is replaced with keratinized squamous epithelial cells. It can be confused with nephrolithiasis and/or neoplasia based on symptoms and appearance on imaging. It has been associated with chronic infection or irritant exposure including smoking. Management is largely conservative with invasive treatment reserved for those with ureteral obstruction by desquamated keratinous material. Renal parenchymal involvement is rare. KDSM has been associated with squamous cell carcinoma without any proven causative relationship. Given the unlikely, but possible transition to SCC, it is prudent to monitor these patients with annual imaging.

TH-PO066

Refractory Hungry Bone Syndrome in a Patient with Prior Roux-en-Y Gastric Bypass Surgery Jared Crisafi,[1] Natallia Maroz.[2,3] *[1]Kettering Medical Center; [2]Boonshoft School of Medicine, Wright State Univ; [3]Univ of Florida.*

Introduction: Hungry bone syndrome (HBS) with hypocalcemia is a known complication following parathyroidectomy (PTX) for hyperparathyroidism with incidence reported up to 20%. Risk factors include volume of resected adenoma, age, azotemia, and elevated alkaline phosphatase. Few cases have attributed prolonged hypocalcemia to prior gastric bypass surgery.

Case Description: A 64 year-old-female with past medical history of chronic kidney disease stage IV (CKD) and Roux-en-Y gastric bypass (RYGB) underwent subtotal PTX for primary hyperparathyroidism. Pathology revealed three hyperplastic glands and an adenoma. PTH was reduced from 1,452.9 pg/ml to 187 pg/mL. She subsequently developed symptomatic hypocalcemia with facial and acral paresthesias secondary to HBS with calcium <5 mg/dl and urine calcium <5mg/dl. During this time she became dialysis dependent. Patient's symptomatic hypocalcemia was unresponsive to oral therapy necessitating intravenous calcium replacement for 253 days to date.

Days from PTX	Calcium mg/dl	Ionized Calcium mmol/L	PTH pg/ml	Therapy (dose/day)
Reference	8.5-10.5	1.09-1.3	15-65	
Preoperative	7.7		788	Calcitriol 0.5 µg
Day 1	5.7	0.90	187	Calcitriol 0.5 µg
Day 30	5.3	0.88	49.4	Calcitriol 0.5 µg Calcium carbonate 15 g
Day 253	6.7	0.96		Calcitriol 2 µg Calcium carbonate 5 g Calcium acetate 6003 mg Calcium gluconate IV 3-8g three times per week High-calcium dialysate bath

Discussion: This case demonstrates HBS in a patient with prior RYGB lasting 253. The duration of hypocalcemia is unlikely due to CKD given an undetectable urine calcium suggesting minimal renal calcium loss. Additionally, Mittendorf demonstrated HBS in patients with CKD had a mean duration of only 4.7 days. We propose that prior surgical diversion of the duodenum where intestinal calcium is preferentially absorbed resulted in calcium malabsorption which impaired bone mineralization and lead to hypocalcemia refractory to oral calcium. Prior case reports by Petras and by Panazolla have also attributed prolonged HBS to prior gastric bypass. History of bariatric surgery should be considered a risk factor for development of HBS.

TH-PO067

Pancreaticobiliary Adenocarcinoma Secreting Fibroblast Growth Factor 23 Valerie Suzanne Barta, Mala Sachdeva. *Hypertension, Northwell Hofstra School of Medicine, Great Neck, NY.*

Introduction: Oncogenic renal phosphate wasting secondary to fibroblast growth factor 23 (FGF23) secretion is a rare paraneoplastic syndrome, causing tumor induced osteomalacia (TIO). The majority of cases reported are benign mesenchymal tumors. Malignant FGF23 secreting tumors have been reported in lung, colon, prostate, ovarian cancer, osteosarcoma, multiple myeloma and lymphoma. We report the first case of a malignant pancreaticobiliary tumor secreting FGF23.

Case Description: We present a 71yr old female with no past medical history who was admitted for progressively worsening abdominal pain and weight loss over 6 weeks. Labs were pertinent for calcium 11.6 mg/dL, albumin 2.8 g/dL, magnesium 2.0 mg/dL, and phosphorus ranging from 1.4 to 2.4 mg/dL with supplementation. Further workup revealed intact PTH 6 pg/mL, 25-hydroxyvitamin D 18.9 ng/mL, 1-25-hydroxyvitamin D level 28.6 pg/mL, and normal PTHrP, Kappa/Lambda ratio and SPEP. Fractional excretion of phosphorous was 48%. Abdominal CT showed cirrhosis with multiple hepatic masses. Biopsy of the liver mass revealed pancreaticobiliary adenocarcinoma. Due to hypophosphatemia being persistent and refractory, an FGF23 level was checked and returned as 1310 RU/mL (normal <= 180). A diagnosis of oncogenic renal phosphate wasting was made.

Discussion: TIO is characterized by oversecretion of FGF23 by tumor cells causing marked hypophosphatemia. We report the first case of malignant pancreaticobiliary related oncogenic renal phosphate wasting. In our patient, the hypophosphatemia and the pancreatobiliary malignancy were diagnosed simultaneously. There was no evidence of osteomalacia, likely because the short duration of hypophosphatemia had not yet impaired bone mineralization. She had typical biochemical features of TIO however atypical was her slight Vitamin D insufficiency, which was unlikely the sole cause of her hypophosphatemia. Hypercalcemia was thought to be malignancy related.

TH-PO068

B-Type Natriuretic Peptide and Renal Physiology Taranpreet Kaur,[1] Joseph V. Nally,[1] Hernan Rincon-Choles.[1] *[1]Nephrology and Hypetension, Cleveland Clinic, Cleveland, OH; [2]1; [3]1.*

Introduction: B- Type natriuretic peptide (BNP) related peptides are mainly produced by ventricular myocytes in response to stretch. Its production is upregulated in cardiac failure. However its exact effect on renal function is poorly understood. Total artificial heart (TAH) implantation provides a unique scenario where the role of BNP in renal physiology is highlighted.

Case Description: A 60 year old Amish male with end stage heart disease from familial hypertrophic cardiomyopathy and cardio renal syndrome underwent total ventriculectomy and TAH implantation as a bridge to heart transplantation. Two weeks prior to surgery, amino-terminal pro-BNP (NT-proBNP) level was 1318 pg/ml and serum creatinine (SCr) was 1.8 mg/dl. Nesiritide infusion was started on post- operative Day 2 (POD) after surgery when he failed to respond to intravenous high dose diuretics. Immediately the urine output improved and over the next few days SCr improved to a nadir of 1.2 mg/dl. Blood NT-proBNP level was 349 pg/ml on POD 4. On POD 6 Nesiritide was stopped and again he did not respond to high dose diuretics. Nesiritide was resumed after 24 hours with marked improvement in urine output. Further attempts of weaning off Nesiritide drip were futile and led to worsening of renal function. Unfortunately, he developed acute tubular necrosis (ATN) and had to be started on dialysis. He ultimately succumbed to sepsis before heart transplant could take place.

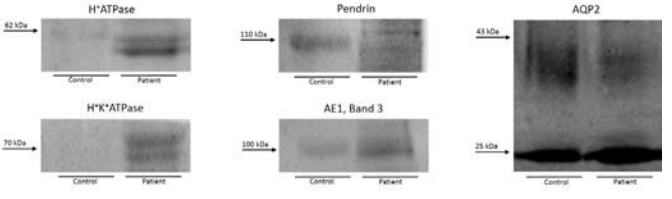
Discussion: In heart failure, BNP and intracellular cyclic GMP synthesis is upregulated, causing vasodilation, diuresis and inhibition of the renin–aldosterone system. With total ventriculectomy as part of TAH implantation, there is a sudden marked decline in endogenous BNP production. Thereupon, renal function declines and diuretic resistance develops. Low-dose BNP infusions post operatively restores the urine output. This finding suggests that BNP has direct renal effects in patients with congestive heart failure. Literature review showed that Nesiritide can be weaned off once endogenous production of BNP from extra cardiac tissue (e.g., brain) is restored usually between POD 7 to 30. In our case, it could not be stopped even 8 weeks after surgery until patient develop ATN and needed dialysis.

TH-PO069

An Atypical Case of Renal Tubular Acidosis Type I Laura Onuchic, Talita R. Sanches, Camila Eleuterio Rodrigues, Antonio C. Seguro, Lucia Andrade. *Nephrology, Univ of São Paulo, Brazil.*

Introduction: Distal renal tubular acidosis (RTA type I) is characterized by impaired urine distal acidification and can be associated with multiple etiologies, including autoimmune diseases, hereditary disorders and drugs.

Case Description: A 34 y/o male presented with a year history of diffuse weakness, vomiting and a 20-kg weight loss. He denied relevant medical history other than alcohol abuse. Laboratory data at admission revealed: serum creatinine 3.9 mg/dL, BUN 47.2 mg/dL, Na 114 mEq/L, K 1.2 mEq/L, Mg 1.8 mg/dL, iCa 3.9 mg/dL, pH 7.22, bicarbonate 9 mEq/L, CPK 1039 IU/L and urinary pH 7.0. TTKG was 10 and the FEK was 25%, extremely high considering low serum K. CT scan revealed a slightly enlarged pancreas and no renal abnormalities. He was started on intravenous saline 0.9% and electrolyte reposition, presenting no recovery of laboratory abnormalities within the following 5 days. Further on he was started on metimazol based on a TSH of 0.02 mU/L and free T4 of 2.2 mg/dL.Due to uremic symptoms he was submitted to a dialysis session, followed by electrolyte normalization and renal function improvement. Urine analysis revealing K loss and RTA type I excluded the hypothesis of pancreatitis associated with hypokalemia, leading to protein expression evaluation of the main H+ transporters located in the final distal tubule and collecting duct cells through urinary exosome western-blot analysis.



Discussion: This case is consistent with RTA type I, possibly associated with a systemic disease such as Sjogren's or IgG4, considering hypothyroidism as a manifestation of his underlying disease. Exosome analyses, in turn, revealed an appropriate physiological response to a severe metabolic acidosis: H+ATPase, H+K+ATPase and AE1 overexpression and pendrin underexpression. We hypothesize that defects in other distal nephron transporters may have significantly impaired urinary acidification.

Funding: Government Support - Non-U.S.

TH-PO070

Effect of Lowering Hemoglobin S Level to Less Than 30 Percent on Renal Physiology and Pathology in Sickle Cell Disease Olorunkemi O. Oluwole,[1] Julie Kanter Washko,[2] Milos N. Budisavljevic,[1] Ndidiamaka O. Obadan.[1] *[1]Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Pediatric Hematology & Oncology, Medical Univ of South Carolina, Charleston, SC.*

Introduction: Sickled red blood cells in sickle cell disease (SCD) cause repeated episodes of ischemia and reperfusion in all organs, including the kidney.The most common marker of nephropathy from SCD is albuminuria, occurring in 19% of children age 10 and older and 68% of adults. Red blood cell exchange (RBCE) has been documented to prevent stroke, acute chest syndrome, and recurrent pain crises. Thus we investigated the role of RBCE on renal function in SCD patients.

Case Description: Charts of 61 patients with SCD undergoing monthly prophylactic RBCE were reviewed. Excluded were patients with diabetes (1), advanced chronic kidney disease (1), missing data (12), the deceased (2) and those less than 15 years old (7). Variables collected on the remaining 42 patients included age, sex, number of RBCEs, albuminuria, urine specific gravity, blood pressure, and serum chloride and bicarbonate concentrations.

Parameters of the 20 males and 22 females were: mean age 21 ± 5 years, time on therapy (median 8 years, range 2 - 10), and median RBCEs 100, microalbuminuria (median 34 mg/g creatinine, range 4 – 1772) present (ie > 30) in 19%, mean systolic and diastolic blood pressure 120 ± 16 and 75± 8 mmHg respectively, mean urine specific gravity of 1.013 ± 0.003, and mean serum chloride and bicarbonate concentrations 107 ± 3 and 23 ± 2 respectively. Albuminuria was not different between patients receiving RBCE for less than 6 years (N = 9) of therapy compared to those receiving RBCE for more than 6 years (N = 33). Diastolic blood pressure and serum bicarbonate concentrations dropped with duration of RBCEs ($p < 0.04$, $p < 0.001$, respectively).

Discussion: This study establishes relevant renal clinical and laboratory data in a cohort of SCD patients who received RBCEs over an extended period of time. We did not find that RBCE reduced albuminuria over time. Currently we are matching our patients with SCD patients not undergoing prophylactic RBCE, to determine if RBCE protects the kidney against SCD nephropathy.

TH-PO071

A Rare Case of End Stage Renal Disease Chidinma N. Enyinna, Amir Abdi Pour. *Medicine, Loma Linda Univseristy Medical Center, Loma Linda, CA.*

Introduction: Chronic tubulointerstitial nephritis (CTIN) is a type of renal injury associated with progressive decline in renal function characterized histopathologically by epithelial tubular cell atrophy, tubular dilation, interstitial fibrosis, and lymphocyte-and macrophage-predominant cell infiltration. Multiple conditions including medications, metabolic disorders, immune-mediated disease, infection, and hematologic disease can result in CTIN.

Case Description: A 69 year old male with history of hypertension, basal cell skin cancer, prostate cancer, and recently diagnosed small cell lymphocytic leukemia was seen for elevated creatinine. He exhibited features of Fanconi syndrome with mild proteinuria. Except for mildly decreased C4, all serologic tests including anti-GBM were negative. Abdominal CT showed a retroperitoneal mass encasing multiple vessels including bilateral renal arteries. Kidney ultrasound was unremarkable. Kidney biopsy showed advanced interstitial fibrosis and tubular atrophy without significant glomerular abnormalities. Immunofluorescence demonstrated diffuse linear IgG staining of tubular basement membranes, but no staining of glomeruli (Figure 1). Electron microscopy showed proximal tubular basement membrane thickening without significant glomerular disease. A diagnosis of anti-tubular basement membrane (anti-TBM) nephritis was made based on these collective biopsy findings.

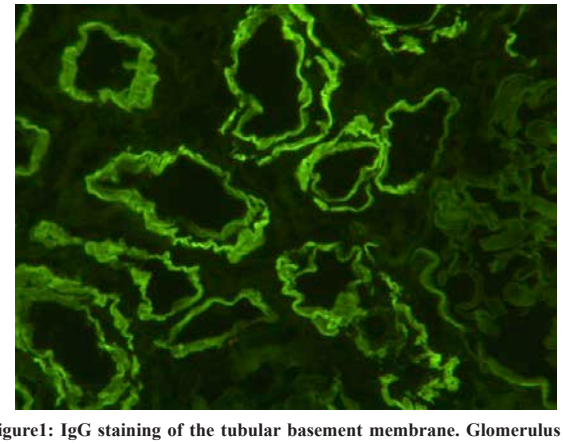


Figure1: IgG staining of the tubular basement membrane. Glomerulus on the right shows no staining of the basement membranes.

Discussion: Primary anti-TBM nephritis is a rare disease and has been associated with membranous nephropathy in children. Circulatory anti-TBM antibody has been seen in many renal diseases including post-infectious,lupus and drug-induced nephritis, and also post-kidney transplant. We report a case of advanced renal failure due to anti-TBM nephritis. It is not clear if his underlying leukemia may have played a role.

TH-PO072

A Rare Case of Calciphylaxis in a Renal Transplant Patient with a Glomerular Filtration Rate of More Than 60ml/min/1.73m2 Jean Luc Franck, Abduljalil Elfasi, Jason Cobb. *Nephrology, Emory Univ Hospital, Atlanta, GA.*

Introduction: Calcific Uremic Arteriolopathy (CUA) or calciphylaxis is a life-threatening ischemic vasculopathy confined primarily to patients with ESRD. We report a case of calciphylaxis in a renal allograft recipient with a GFR of more than 60ml/min/1.73m2.

Case Description: A 55 year old female patient with a transplanted kidney was referred to our institution for evaluation of multiple necrotic skin lesions in her legs. Her past medical history beside hypertension, diabetes mellitus type 2, coronary artery disease was significant for being on hemodialysis for five years before receiving a cadaveric renal transplantation two years prior to presentation. Her post surgical course was uneventful and her current immunosuppressant regimen consisting of tacrolimus, mycophenolate mofetil, and prednisone. Her physical exam was remarkable for a functioning left brachio-cephalic arteriovenous fistula and the presence of multiple necrotic ulcerations with eschar formation in her lower extremities, the largest measuring 13cmx8cm in her left crural region. Admission labs notable for a BUN/Cr (mg/dl)18/0.8, calcium 8.9mg/dl, phosphorus 3.6mg/dl, PTH 128pg/ml and albumin 2.4g/dl. An incisional skin biopsy was performed and the histopathological findings were consistent with CUA by the presence of dermal fibrosis with prominent calcium deposition within the vessel walls and lumina of small to medium sized blood vessels. Despite intensive combined management with wound care and hyperbaric oxygen therapy, the patient expired within a year from sepsis.

Discussion: Risks factors implicated in the development of calciphylaxis include perturbation of the calcium and phosphate homeostasis, type 2 diabetes mellitus, Vitamin K antagonists, hypoalbuminemia and more recent evidence also suggests the use of prednisone. The disease is almost always described in ESRD patients and despite intensive combined treatments, the prognosis of CUA remains poor. This case of calciphylaxis in a renal transplant patient was reported to emphasize the need to maintain a high degree of suspicion in the renal transplant population even more when other risk factors are present.

TH-PO073

Hypokalemic Flaccid Paralysis Induced by Distal RTA Associated with Primary Hyperparathyroidism: Case Report Adriana Belo Lopes Prazeres, Marclebio M.C. Dourado, Ana Paula Gueiros, Jose Edevanilson Gueiros. *Nephrology, UFPE, Recife, Pernambuco, Brazil.*

Introduction: Primary hyperparathyroidism (PHP) is a condition in which one or more of the parathyroid glands becames overactive due to an abnormal regulation by calcium and produce parathyroid hormone (PTH) in excess. The prevalence of PHP is 21 cases per 100.000 person-year, with hyperfunctioning single adenoma of the parathyroid accounting for approximately 85% of cases of PHP. The major renal clinical presentation includes polyuria, nephrolithiasis, hypercalciuria and rarely nephrocalcinosis and renal tubular acidosis (RTA).

Case Description: A 30 year-old man was admitted in the emergency department with subtle weakness in lower limbs. Laboratory studies revealed normal renal function, serum sodium 142 mEq/L, serum potassium 2mEq/L, serum chloride 116 mEq/L and CPK 116 U/L. Venous blood gas analysis showed hyperchloraemic metabolic acidosis. Urinalysis with density 1010, pH 6,5 and negative proteinuria and hematuria. He had no known diseases and was not taking any medication. He had a family history of nephrolithiasis. The weakness improved with venous potassium replacement. Subsequent laboratory studies revealed PTH 601 pg/ml, phosphate 1,9 mEq/L, calcium 11,7 mEq/L, albumin 4,5 mg/dL, 25-hydroxyvitamin D 19,9 ng/mL, thyroid stimulating hormone 2,2 nUI/mL and a 24 hour urine calcium of 449mg. The sestamibi parathyroid scintigraphy showed hyperfunction of the lower left gland. After partial parathyroidectomy (PTX) the patient had resolution of the distal RTA.

Discussion: The type 1 RTA represents the inability of the distal tubule to acidify the urine. The major acquired causes of distal RTA includes Sjögren syndrome, HIV, hyperthyroidism, use of amphotericin or lithium and vitamin D intoxication. PHP is a rare cause of distal RTA with 5 previous reports (4 indian and 1 philippine) and in 4 of these, PTX solved the RTA. In our case, PTX also treated the patient.

TH-PO074

IgG4-Related Kidney Disease in HIV Infection: Coincidence or Something More? Christina L. Bradshaw,[1] Brian Y. Young.[1,2] *[1]Nephrology, Stanford Univ, Palo Alto, CA; [2]Nephrology, Santa Clara Valley Medical Center, San Jose, CA.*

Introduction: IgG4-related disease (IgG4-RD) is characterized by tissue lymphoplasmacytic infiltration with IgG4-positive plasma cells and CD4+ T lymphocytes. The role of IgG4 in the pathogenesis of the disease is poorly understood and association with autoimmune or infectious triggers is unclear. We describe here an unusual presentation of IgG4-RD in an HIV-positive patient.

Case Description: A 68-year-old male patient with history of HIV infection (CD4 count >600, viral load undetectable) presented with elevated creatinine (Cr) to 1.8 mg/dL from a baseline of 0.8 mg/dL. No inciting event was evident from review of medical history and HAART regimen did not include a tenofovir-based agent. Urinalysis was bland with urine protein/Cr ratio of 0.44 mg/mg and no microalbuminuria. UPEP showed a monoclonal IgA kappa band and serum free light chain ratio was abnormal. Other serologic markers included a positive ANA, reduced C3 and C4 levels, and negative HBsAg and anti-HCV Ab. An increase in Cr to 3.3 mg/dL prompted a kidney biopsy, which showed an interstitial

lymphoplasmacytic infiltrate and no significant glomerular abnormalities. Immunostaining showed >100 IgG4-positive cells per HPF and serum IgG4 level was >300 mg/dL. Bone marrow biopsy performed to rule out lymphoma was unremarkable and lymph node biopsy showed an average of 130 IgG4 cells per HPF. Once malignancy was excluded and undetectable HIV viral load confirmed, patient was started on prednisone 0.6 mg/kg/day for IgG4-related tubulointerstitial nephritis. Cr level thereafter improved from 3.1 mg/dL to 2.6 mg/dL over the first 10 days of therapy.

Discussion: IgG4-RD is a rare multi-systemic disorder, initially described as a cause of autoimmune pancreatitis. To our knowledge, this is the first report of IgG4-RD in an HIV-positive patient, with its only manifestation being renal dysfunction. HIV is known to target CD4+ T cells and some reports have suggested abnormal IgG4 regulation. Given that many patients are now surviving with a long-term diagnosis of HIV, further investigation may be warranted to determine if IgG4-RD is a more frequent, yet less considered, cause of renal dysfunction in HIV.

TH-PO075

Apolipoprotein L1 and Soluble Urokinase Receptor in the Activation of Integrin Avb3 and Incident Kidney Disease Salim Hayek,[1] Kwi Hye Koh,[2] David Changli Wei,[2] Cheryl Ann Winkler,[3] Jeffrey B. Kopp,[4] Jochen Reiser.[2] *[1]Emory Univ; [2]Rush Univ Medical Center; [3]NCI, NIH; [4]NIDDK, NIH.*

Introduction: Apolipoprotein L1 (APOL1) genetic variants are strongly associated with but only partially explain the increased risk of chronic kidney disease (CKD) in African Americans (AA). Immunologic factors such as HIV may synergistically increase the risk of CKD associated with APOL1. Soluble urokinase receptor (suPAR) is a marker of immune activation and a predictor of CKD. Mechanistically, suPAR activates podocyte αvβ3 integrin. An interaction between suPAR and APOL1 with regards to kidney disease is however unknown.

Case Description: We measured plasma suPAR and characterized APOL1 genotype in 825 AA patients (mean age 58±12, male 52%, eGFR<60 in 27%) enrolled in the Emory Cardiovascular Biobank. Follow-up serum creatinine was collected (median measures =7, median follow-up =10 years). We characterized the cross-sectional association between suPAR and APOL1 genotype and determined the interaction between future eGFR decline, suPAR and APOL1 risk alleles. We studied the biochemical interaction between APOL1, suPAR, and integrin β3 by co-immunoprecipitation (Co-IP) and surface plasmon resonance (SPR).

Patients with 2 APOL1 risk alleles (14%, median suPAR 3300 pg/mL) had significantly higher levels of suPAR compared to those with 1 (44%, median suPAR 2770 pg/mL) or 0 (42%, median suPAR 2827 pg/mL), after adjusting for baseline eGFR, age, gender and BMI. In longitudinal analyses, patients with 2 APOL1 risk alleles and high suPAR levels had a steeper decline in eGFR compared to those with 1 or no alleles (β-2.96, P=0.04 for three-way interaction). Co-IP data show that APOL1 wild type protein binds both suPAR and integrin β3. In SPR analysis, APOL1 directly binds suPAR (K_D ~11.71 nM). APOL1 binds strongly to integrin αvβ3 (K_D ~6.27 nM) but not α3β1. Interestingly, the binding affinity of APOL1 to integrin αvb3 increased 100-fold upon activation of the integrin.

Discussion: A synergistic, eGFR independent relationship between suPAR and APOL1 explains the heightened risk for kidney disease in patients with 2 APOL1 risk alleles. suPAR mediated integrin αvb3 activation facilitates a high affinity binding of APOL1.

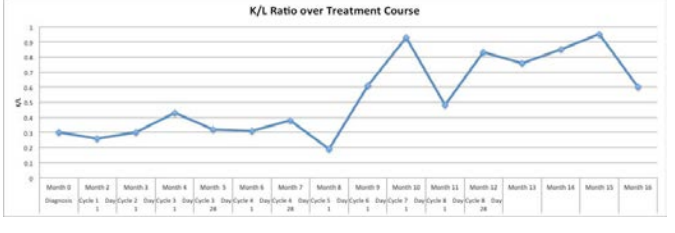
TH-PO076

Serum Free Kappa/Lambda Ratio in Primary Amyloidosis: Can It Be Abnormally Normal? Arouna Senthilkumar, Saud Rana, Kavitha Vellanki. *Loyola Univ, Maywood, IL.*

Introduction: Free light chain quantification is considered to be highly sensitive for diagnosis of primary renal amyloidosis, reported sensitivity as high as 95 to 100%. Here we report a rare case of Primary renal amyloidosis with normal serum and urine free light chain ratio.

Case Description: A 67 year old male with no past medical history was referred for evaluation of worsening lower extremity swelling after negative cardiac work up. He reported generalized fatigue and exam revealed diffuse anasarca with dark macular lesions on bilateral shins. Initial work up revealed nephrotic range proteinuria (25grams) with serum albumin of 1.1. Further serological work up is shown in Table 1. Serum free K/L ratio was within normal range for few months as shown in figure 1.



Kidney biopsy revealed lambda light chain amyloidosis and subsequent bone marrow biopsy revealed lymphoplasmacytic lymphoma.

Lab (reference range)	Result
Sodium (136-144mmol/L)	140
Potassium (3.3-5.1mmol/L)	3.7
Bicarbonate (20-32 mmol/L)	27
Chloride (98-108 mmol/L)	107
Glucose (70-100 mg/dL)	109
Blood Urea Nitrogen (7-22mg/dL)	16
Creatinine (0.6-1.4mg/dL)	1.07
Albumin (3-5 gm/dL)	1.1
24 hr urine Protein	25.3 grams
Serum free light chain K/L ratio (0.26-1.65)	0.3
Urine free light chain K/L ratio (0.46-4.00)	3.23

Discussion: Free light chain quantification may abnormally be normal in lambda light chain amyloidosis and hence, should not be used as a sole criteria to rule out paraproteinemias.

TH-PO077

A Case of IgG4-Related Kidney Disease with Predominantly Unilateral Renal Atrophy Akari Wada,[1] Kazunori Yamada,[1] Ichiro Mizushima,[1] Satoshi Hara,[1] Kiyoaki Ito,[1] Hiroshi Fujii,[1] Kazuaki Mizutomi,[2] Mitsuhiro Kawano.[1] *[1]Div of Rheumatology, Kanazawa Univ Graduate School of Medicine, Kanazawa, Ishikawa, Japan; [2]Internal Medicine, Kaga Medical Center, Kaga, Ishikawa, Japan.*

Introduction: Patients with IgG4-related kidney disease (IgG4-RKD) may reveal various renal abnormalities on imaging tests, such as multiple low-density lesions on contrast-enhanced computed tomography (CE-CT), diffuse bilateral renal swelling, and hypovascular solitary nodules, as well as renal atrophy. Here, we describe a patient with IgG4-RKD manifesting as predominantly unilateral renal atrophy.

Case Description: A 73-year-old woman with obstructive jaundice was first referred to our hospital 6 years prior. At that time, an elevated serum IgG4 level (378 mg/dL) was found and CE-CT revealed a mass in the pancreatic head. Renal lesions were absent. The patient was diagnosed with autoimmune pancreatitis (AIP) and treated with prednisolone (PSL) 30 mg/day. As her AIP symptoms improved and serum IgG4 level decreased, the PSL dose was gradually tapered to 5 mg/day. Her renal function had been normal (Cr 0.7 mg/dL) until 1 year before the current admission, and CT showed no renal atrophy. During the intervening 12 months her renal function declined (Cr 1.1 mg/dL), and she was admitted to our hospital. A urinalysis showed no abnormality. CE-CT revealed marked right renal atrophy and multiple low-density lesions on both kidneys. Serum IgG4 level was elevated (204 mg/dL). A renal biopsy was not performed because of the right renal atrophy and malformation of the left renal vein. Through careful examination, we ruled out vascular diseases and clinically diagnosed IgG4-RKD. PSL dose was increased to 30 mg/day. One month later, her renal function improved, with no obvious change in CE-CT findings. Six months later, PSL dose was tapered to 10 mg/day. Her renal function was stable, and no worsening of renal atrophy was seen.

Discussion: Bilateral renal atrophy sometimes occurs in patients with IgG4-RKD. However, this patient presented with predominantly unilateral renal atrophy. Renal lesions are sometimes asymptomatic in patients with IgG4-RKD; therefore, when caring for such patients, careful examination is required if the patients' renal function declines.

TH-PO078

Adenovirus Related Granulomatous Interstitial Nephritis Masquerading as Sarcoidosis in Renal Transplant Recipient Dilek Yarar,[1] Pradeep Vaitla,[2] Stephen O. Pastan,[2] Carla L. Ellis.[3] *[1]Nephrology Dept, Emory Univ, Atlanta, GA; [2]Transplant Nephrology Dept, Emory Univ, Atlanta, GA; [3]Renal Pathology Dept, Emory Univ, Atlanta, GA.*

Introduction: Granulomatous interstitial nephritis is an uncommon entity in kidney transplant recipients.

Case Description: A 42 year-old African-American female with a history of sarcoidosis, and end stage renal disease presumed secondary to hypertensive nephrosclerosis, received a deceased donor renal transplant in 2012. The immunosuppresssive regimen was prednisone, mycophenolate mofetil and belatacept. She was admitted in 2016 with fever, chills, myalgia, gross hematuria and acute kidney injury. The patient's creatinine was 2.6 on admission with baseline creatinine of 1.2-1.5. Workup showed no growth on urine and blood cultures, serum PCR was negative for BK and CMV viruses. Renal ultrasound showed hydronephrosis, but renal function did not improve with percutaneous nephrostomy. She continued to experience fever spikes and intermittent gross hematuria despite broad spectrum antibiotics. Renal biopsy showed severe granulomatous interstitial nephritis with focal areas of necrosis. Given the history of sarcoidosis, she was started on high dose Prednisone. Serum angiotensin converting enzyme level, vitamin D and calcium were normal. Kidney tissue stained positive for adenovirus in the areas of the granulomas; serum PCR was strongly positive for adenovirus. The patient's symptoms significantly improved with steroids and supportive care. The infectious disease specialist recommended brincidofovir, which the patient refused due to her clinical improvement. She was discharged home on steroid taper. The hematuria resolved and the creatinine decreased down to baseline.

Discussion: We report a case of granulomatous interstitial nephritis affecting a renal transplant secondary to adenovirus infection, a known but uncommon entity

that can be confused with sarcoidosis. Adenovirus infection should be considered in immunocompromised patients with acute kidney injury, hematuria and granulomatous inflammation on renal biopsy.

TH-PO079

Reno-Cerebral Reflex Activates Renin-Angiotensin System and Promotes Renal Damage after Ischemia-Reperfusion Injury Wei Cao, Fan Fan Hou. *Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China.*

Background: A kidney-brain interaction has been described in AKI but the mechanisms are uncertain. Since we recently described a reno-cerebral reflex, we tested the hypothesis that renal ischemia-reperfusion injury activates a sympathetic reflex that interlinks the renal and cerebral renin-angiotensin axis to promote oxidative stress and progression of the injury.

Methods: Ischemic AKI in C57BL/6J mice was induced by bilateral clamping of the renal pedicles for 45 minutes. The status of renin-angiotensin system, oxidative stress, and activity of sympathetic nervous were studied in AKI mice with or without various inhibitors.

Results: Bilateral ischemia-reperfusion activated the intrarenal and cerebral, but not the circulating, renin-angiotensin system, increased sympathetic activity in the kidney and the cerebral sympathetic regulatory regions, and induced brain inflammation and oxidative stress, and kidney injury. Central blockade of central renin-angiotensin system or oxidative stress by intracerebroventricular losartan or tempol reduced the renal ischemic injury score by 65% or 58%, respectively, and reduction of renal efferent sympathetic signal by intracerebroventricular clonidine decreased the score by 52% (all $P<0.05$). Remarkably, selective blockade of renal afferent sympathetic signal by capsaicin inhibited the upregulation of the brain renin-angiotensin system, and decreased brain oxidative stress, sympathetic activity and inflammation after ischemia-reperfusion injury. Ischemia-reperfusion-induced renal damage and dysfunction persisted after controlling blood pressure with hydralazine.

Conclusions: In conclusion, this study demonstrates that ischemia-reperfusion induces AKI in a mouse model, at least in part, by activation of a reno-cerebral RAS axis interlinked by renal afferent and efferent sympathetic nerves. This identifies a novel mechanism underlying reno-cerebral interaction in response to renal ischemia-reperfusion, and thereby could lead to new interventional approaches, such as the use of RAS inhibitors, sympatholytic agents or even renal nerve ablation.

TH-PO080

The Effect of Circulating Extracellular Vesicles on the Response of the Kidney Proximal Tubule to Injury Emma E. Morrison, Marion Rook, Iqbal Singh Toor, Alexandra Inés Thompson, Neil Henderson, Gillian A. Gray, Matthew A. Bailey, James W. Dear. *Univ of Edinburgh, Edinburgh, United Kingdom.*

Background: Acute kidney injury can complicate liver or heart failure and increase mortality. Acute liver injury (ALI) causes a characteristic microRNA (miRNA) signature in blood.[1] Circulating miRNAs are encapsulated in extracellular vesicles (EVs) that can be taken up by kidney tubules with subsequent delivery of functional miRNA into the cell.[2] We hypothesized that circulating miRNA changes that accompany liver and/or cardiac cell death could affect the response of the kidney proximal tubule (PT) to injury.

Methods: To complement our ALI profiling data [1], the circulating miRNA response to cardiac injury was determined by small RNAseq. Samples were collected from patients undergoing cardiac bypass surgery (CABG n=23) and orthopedic surgery (control n=23). MiRNAs of interest were quantified in additional human samples and in mice. In mouse models, miRNA containing circulating EVs were isolated after myocardial infarction (MI) or paracetamol-induced acute liver injury (ALI). Murine kidney primary PT cells were co-cultured with fluorescently-labeled EVs and their uptake was quantified by flow cytometry. PT cells exposed to EVs were injured and their viability was determined.

Results: 333 miRNAs increased or decreased more the 1.5 fold after CABG compared with control. miR-22, -30a, -30d, -145, -140, -99b, -499, -1, -133a, -23 were successfully back-translated into mice. EVs from MI and ALI models entered PT cells (control EVs: mean fluorescence intensity±SD 12,989±8282a.u.; ALI: 17,689±10782a.u.; MI: 23,541±26915a.u.). ALI EVs reduced PT cell injury induced by cisplatin (10μM) (ATP luminescent assay ALI:142,300±17307u; control: 84,373±13861u; n=6; P=0.03). MI EVs had no effect.

Conclusions: Liver and cardiac injury induced significant but distinct changes in circulating miRNA. Only EVs from mice with ALI protected PT cells. EVs represent a potential mechanism of liver to kidney signaling that is amenable to therapeutic modulation. 1. Vliegenthart, A.D., et al. Sci Rep, 2015. 5: p. 15501. 2. Oosthuyzen, W., et al. J Am Soc Nephrol, 2016.

TH-PO081

Long-Acting Albumin-Thioredoxin Fusion Protein Prevents AKI-Associated Acute Lung Injury Kento Nishida,[1] Hiroshi Watanabe,[1] Masafumi Fukagawa,[2] Toru Maruyama.[1] *[1]Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan; [2]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Respiratory complications are frequently occur after acute kidney injury (AKI), and are associated with increased mortality. Therefore, an effective strategy for preventing AKI-induced acute lung injury (ALI) due to increasing oxidative stress and inflammatory response is highly desirable. Thioredoxin-1 (Trx) is a redox-active protein that has anti-oxidative and anti-inflammatory properties. Although, Trx has great potential for use as a therapeutic agent against several types of oxidative stress-related diseases, its short half-life limits its clinical application. To overcome this problem, we produced a recombinant fusion protein that is comprised of human serum albumin and Trx (HSA-Trx), and examined its preventive effect against AKI-induced ALI.

Methods: Recombinant HSA-Trx was expressed using *Pichia* expression system. AKI-induced ALI mice were produced by renal ischemia/reperfusion (I/R).

Results: A pharmacokinetic study of HSA-Trx or Trx in mice showed that the plasma retention and lung distribution of Trx were markedly increased by fusion with HSA. Renal I/R mice showed not only an increase in BUN and serum creatinine levels, but also an increase in neutrophil infiltration in lung and protein concentration in bronchoalveolar lavage fluid (BALF)compared to sham mice. In contrast, systemic administration of HSA-Trx significantly decreased the number of neutrophils in lung and BALF protein compared with PBS administration. HSA-Trx also suppressed the elevation of plasma IL-6 level, CXCL1/CXCL2 chemokine and oxidative stress in lung.

Conclusions: HSA-Trx has potential for use in the treatment of AKI-induced ALI via its extended effects of modulating oxidative stress and inflammation.

TH-PO082

Prevention of Liver Inflammation in a Rodent Model of Acute Kidney Injury following Selective Gut Decontamination Chen Yu, Jiangtao Li. *Dept of Nephrology, Tongji Hospital, Tongji Univ School of Medicine, Shanghai, China.*

Background: Recent studies have indicated that the intestinal integrity and barrier function is disrupted during acute kidney injury(AKI)and blood from the intestines containing endotoxin and inflammatory mediators are presumed to activate Kupffer cell and further augment the systemic consequences of AKI . We investigated the effects and underlying mechanisms of oral norfloxacin on liver inflammation in renal ischemia reperfusion (RIR) model of AKI.

Methods: Sprague–Dawley rats were divided into 3 groups: Sham, RIR+saline and RIR + norfloxacin. The RIR animals were treated with oral norfloxacin 20 mg/kg/day or saline for 2 weeks before operation. For RIR induction, the bilateral kidneys were subjected to 60 min of ischemia and followed by 24h reperfusion. Plasma biochemistry and cytokines were measured. Endotoxemia was measured using Limulus amoebocyte lysate (LAL) assays. Protein expression of CD68, NFκB and cytokines were measured in the liver homogenate.

Results: Severity of endotoxemia was reduced in norfloxacin treated animals($p<0.05$). The RIR group treated with norfloxacin showed significant attenuation of the increasing liver TNF-a and IL-6($p<0.05$). The increased expression of CD68 and NFκB of liver tissues in the untreated animals was significantly attenuated in the norfloxacin treated animals.

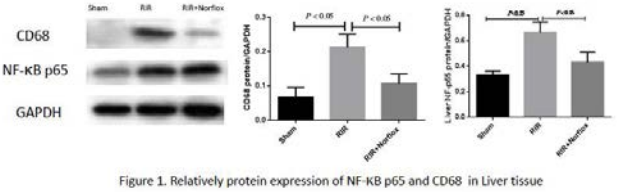

Figure 1. Relatively protein expression of NF-KB p65 and CD68 in Liver tissue

However, norfloxacin administration failed to improve the liver and renal function and down-regulate the circulation level of cytokines ($p<0.05$).

Conclusions: The results showed for the first time that translocation of endotoxin from the gut can contribute to endotoxinemia in AKI. As a result, the liver becomes an important affected organ system in the context of remote organ injury. Liver inflammatory insult due to AKI can be prevented with selective decontamination, providing novel insights into the cross-talking between gut and liver in AKI.

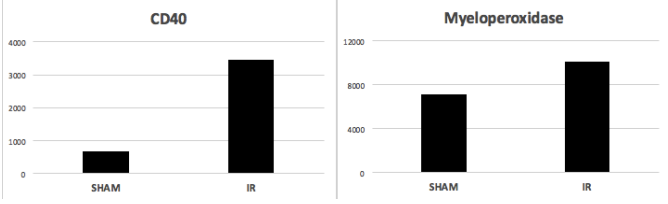
TH-PO083

Pulmonary CD40 Levels Are Increased 24 Hours after Ischemia-Reperfusion Kidney Injury Mark Hepokoski,[1] Laura E. Crotty Alexander,[1] Prabhleen Singh.[2] *[1]Div of Pulmonary and Critical Care Medicine, Univ of California San Diego, La Jolla, CA; [2]Div of Nephrology and Hypertension, Univ of California San Diego, La Jolla, CA.*

Background: Pulmonary complications are known to significantly increase the mortality of acute kidney injury (AKI) up to 80%. Multiple mediators of lung injury after AKI have been identified, the majority of which induce damage within 24 hours. The purpose of this study was to identify mediators of lung injury that are present 24 hours after AKI, as this is potentially a more useful time point for interventions.

Methods: Mice were randomized to ischemia-reperfusion (IR) kidney injury via 15 minutes of bilateral renal arterial clamping or sham operation (n=4 for each group). Pulse oximetry measurements were obtained prior to surgery and at harvest. At 24 hours, the pulmonary arteries were perfused with PBS to wash out blood and lung parenchyma was harvested, lysates prepared, and levels of 111 common inflammatory mediators were analyzed (Proteome Profile Mouse XL Cytokine Array, R&D Systems).

Results: Only 10 inflammatory mediators showed increased levels at 24 hours in IR mice compared to sham controls. Of these, CD40 had the most robust change with a 5-fold increase. There was no difference in mean pulse oximetry measurements between groups, 96.2% in sham compared to 95.8% in IR. However, lung myeloperoxidase, an indicator of neutrophil influx and thus a marker of lung injury, was elevated 30% compared to sham.



Conclusions: CD40 is a costimulatory protein known to amplify inflammatory cascades, such as NF-κB, a previously described mediator of lung injury after AKI. We show that IR kidney injury leads to a remarkable increase in pulmonary CD40 expression at 24 hours. CD40 may be a mediator of lung injury in the later phases of AKI, and further research into the role of CD40 in lung injury after AKI is warranted.

TH-PO084

Antithrombin III Protects against AKI following Acute Severe Pancreatitis and Contrast Medium Administration Feng Wang,[1] Zeyuan Lu,[1,2] Jianyong Yin,[1] Nian-Song Wang.[1] *[1]Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: We previously reported that insufficiencies of antithrombin III (ATIII), the major anti-coagulation molecule in vivo, exacerbated renal ischemia-reperfusion injury in animal models and possibly humans.

Methods: In the present study, we investigated the relationship between ATIII levels and two additional types of acute kidney injury in patients and examined therapeutic effects of ATIII in animal models.

Results: Patients with low ATIII activity presented a higher incidence of acute kidney injury (AKI) following severe acute pancreatitis (SAP). Intravenous injection of ATIII (500μg/kg) before or after the induction of SAP in Sprague-Dawley rats did not attenuate pancreatic injury, but significantly attenuated the elevation of serum creatinine, blood urea nitrogen, and renal histological injury. The beneficial effects of ATIII were accompanied with diminished renal inflammatory response, oxidative stress, and tubular cell apoptosis. Similarly, patients with low ATIII activity showed a higher incidence of contrast induced nephropathy (CIN), and the ATIII treatment significantly attenuated contrast induced AKI and improved renal blood flow in rats. In cultured renal tubular epithelial cells, ATIII attenuated tumor necrosis factor α (TNFα) -stimulated intercellular cell adhesion molecule 1(ICAM)-1 and monocyte chemotactic protein 1 (MCP-1) upregulation.

Conclusions: In conclusion, ATIII administration may represent a promising strategy for the prevention and treatment of SAP or contrast-induced AKI.

Transcutaneous Measurement of Glomerular Filtration Rate to Assess the Progression from Acute to Chronic Kidney Disease following Bilateral Ischemic Injury in Mice Danielle Soranno, Chris Altmann, Sarah Faubel. *Univ of Colorado, Aurora, CO.*

Background: AKI is common and predisposes patients to developing CKD. Biomarkers used to estimate kidney function (BUN and Cr) are less accurate than measurement of GFR.

Methods: 8-10 week WT C57BL/6 mice underwent bilateral ischemia-reperfusion with clamp-time of 22 minutes. Mice received 0.5 mL saline resuscitation subcutaneously daily for 5 days. tGFR measurement: Mice were put under anesthesia via 2% inhaled isoflurane and the hair was removed from the dorsum. The NIC-Kidney device was attached to the dorsum of the mouse. After 1-5 minutes, FITC-sinistrin (15 mg/100 g body weight) was injected via tail vein injection. The mouse was monitored for 1 hour; the device was removed. The half-life of the FITC-sinistrin was calculated using MPD Lab Version 1.0a software, and the tGFR was calculated: tGFR [μL· min ·100 g body weight] = 14616.8 [μL/100g body weight]/$t_{1/2}$ FITC-sinistrin[min]. tGFR was measured pre-AKI, 1 day after and then weekly until 28 days. BUN (BioAssay Systems) and serum Cr (Point Scientific) were analyzed per manufacturer instructions. Picrosirius Red staining was performed tissue using standard histological staining procedures and imaging software was used to calculate the percent area of fibrosis.

Results:

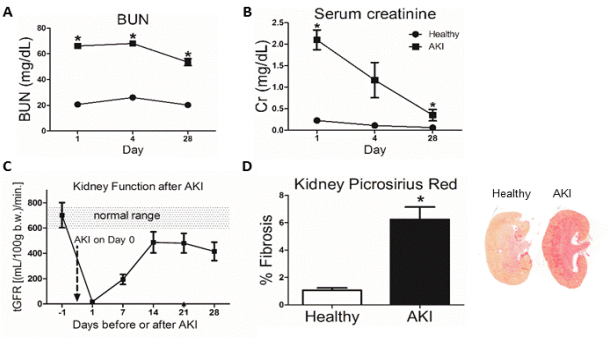

Figure 1: Assessment of kidney function 28 days following acute kidney injury (AKI). Serial (**A**) blood urea nitrogen (BUN) and (**B**) serum creatinine (Cr) to *estimate* kidney function over time. (**C**) Serial tGFR to *measure* function over time. (**D**) Quantification and representative images of Picrosirius Red stain 28 days following AKI. n = 5, p < 0.01.

Serial BUN and Cr used to estimate kidney function, demonstrates a persistent elevation in BUN and a mild increase in Cr 28 days after AKI. Serial tGFR used to measure kidney function demonstrates a persistent decrease in GFR 28 days following AKI. Picrosirius Red staining demonstrates the presence of cortical fibrosis 28 days following AKI.

Conclusions: We have demonstrated both histological and functional evidence of CKD in a murine model of bilateral ischemia-reperfusion AKI. The utilization of non-invasive tGFR monitoring allows for accurate, serial measurements of kidney function following injury.

Mir-219 Is a Pro-Fibrotic MicroRNA That Is Hyper-Methylated and Suppressed in Kidney Injury Associated Fibrosis Qingqing Wei,[1] Chunyuan Guo,[1] Xiao Xiao,[1] Huidong Shi,[3] Zheng Dong.[1,2] *[1]Cellular Biology & Anatomy, Medical College of Georgia, Augusta Univ, Augusta, GA; [2]Charlie Norwood VA Hospital, Augusta, GA; [3]Georgia Cancer Center, Medical College of Georgia, Augusta Univ, Augusta, GA.*

Background: Epigenetic regulation, including DNA methylation, plays important roles in gene expression under various patho-physiological conditions.

Methods: To understand DNA methylation after kidney injury, we analyzed the global DNA methylation change in different mouse kidney injury models.

Results: Interestingly, in addition to protein coding genes, the global analysis revealed the hyper-methylation of mir-219-2 in kidney tissues of 3 days of cisplatin nephrotoxicity, 25 minutes of ischemia with 1 week or 1 month reperfusion, and 1 week of unilateral urinary obstruction (UUO). The hyper-methylation was associated by a significant decrease in mir-219 expression in the injured kidneys. In vitro, 48 - 72 hours of hypoxia also led to a decrease in mir-219 in BUMPT proximal tubular cells. Overexpression of mir-219 in BUMPT cells enhanced the pro-fibrotic reaction during hypoxia or TGF-β treatment, as shown by significantly higher induction of fibronectin. Though immunoblotting did not show obvious difference of TGF-β signaling pathway activation, GSK-3beta phosphorylation was significantly increased by mmu-mir-219 overexpression. The KEGG pathway analysis of the predicted mmu-mir-219 targets from TargetScan indicated that mmu-mir-219 may regulate several important pathways related to renal fibrosis regulation, which include insulin signaling pathway, phosphatidylinositol signaling system, MAPK signaling pathway, and WNT signaling pathway.

Conclusions: These results suggest that intrinsic anti-fibrotic mechanisms are activated in response to kidney injury and fibrosis. DNA hyper-methylation of mir-219 may be one of these anti-fibrotic mechanisms, which is activated to repress mir-219, a pro-fibrotic microRNA.

Expression of Endomucin, an Endothelial-Specific Sialomucin in Normal and Injured Kidneys Li Li, Xiaoyan Xiao, Takaharu Ichimura, Hong Liu, Seiji Kishi, Joseph V. Bonventre. *Brigham and Women's Hospital, Boston, MA.*

Background: Endomucin (EMCN) is a membrane bound O-sialoglycoprotein expressed on the surface of endothelial cells. Its role in inflammation has been controversial. Early studies reported that EMCN bears a peripheral node addressin (PNAd) epitope and binds to L-selectin on high endothelial venules (HEVs) in lymph nodes. Recent studies suggest that EMCN is part of endothelial glycocalyx and maintains the anti-adhesive property of normal endothelium. The role of EMCN in kidney injury is unknown.

Methods: We investigated the expression of EMCN and PNAd using immunofluorescence in both normal and injured kidneys. In male BALB/c mice, ischemia-reperfusion injury (IRI) was induced by clamping the renal pedicle of both kidneys for 27 min at 37.0 °C. Aristolochic acid nephropathy (AAN) was induced by a one-time intraperitoneal injection AA (5 mg/kg BW).

Results: EMCN stained glomerular and peritubular capillaries in normal kidney, co-localizing with CD 31. In post-ischemic mouse kidneys, EMCN staining became significantly thicker and more intense at 1 day. EMCN continued to co-localize with CD31, but did not overlap with F4/80 (macrophages), Ly6G (neutrophils), KIM-1 (injured tubules) and PDGFRβ (pericytes and fibroblasts) staining. A similar pattern of EMCN staining was observed at day 2, 4, 7 and 9 post-ischemia. At day 28 post-ischemia, EMCN staining returned to baseline thin capillary morphology as observed in normal kidney. In contrast,there was significant loss of the EMCN staining in the AAN model associated with much more fibrosis at day 21 and 42. EMCN co-localized with CD 31 in AAN model. On the other hand, PNAd was not expressed in the day 2 post-ischemic kidneys.

Conclusions: These data suggest that EMCN is expressed in normal and injury kidney. Up-regulation of EMCN expression after ischemic injury suggests that EMCN might serve as a specific marker for activated remodeling endothelium. Loss of EMCN in AAN may facilitate endothelial rarefaction. No PNAd expression in ischemic kidney suggests EMCN bears a different glycosylation epitope and may serve different function in kidney compared to EMCN in HEVs in lymph node.

Stromally Derived Endothelial Progenitors Mediate Injury after Acute Kidney Injury Katherine V. Maringer,[1] Jeffrey S. Isenberg,[2] Sunder Sims-Lucas.[1,2] *[1]Pediatric Nephrology, Rangos Research Center Childrens Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]Vascular Medicine Inst, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Acute Kidney Injury (AKI) is characterized by an abrupt decrease in renal function leading to renal failure, and contributing to high percentages of morbidity and mortality. The kidney contains a complex and high degree of vascularization making it susceptible to ischemic injury. We have identified a subset of stromally derived endothelium (SDE) that is important for kidney vascular development. We hypothesize that SDE are critical to the kidneys ability to recover from AKI.

Methods: To confirm the importance of SDE following ischemia reperfusion injury (IRI) we performed lineage tracing, using a TdTomato reporter (permanently labeling all SDE cells) and interrogated the percentage of SDE cells that were present in the IRI and contralateral control kidneys. Furthermore, we generated mice with a conditional deletion of Flk1 (floxed) in the Foxd1cre positive renal stroma ($Flk1^{SY-/-}$), and evaluated the tissue after IRI, focusing on the recovery phase (7 days) post injury.

Results: We determined in control mice following IRI that stromal genes were re-expressed suggesting that the stroma may be undergoing de-differentiation and subsequently driving SDE proliferation. Furthermore, using lineage tracing we found that SDE preferentially increase during the repair phase (7 days) of IRI. To evaluate the role of SDE during IRI we used $Flk1^{SY-/-}$animals subjected to IRI and found that mutants had less perfusion and an increase in hypoxia at 7 days. This was coupled with inappropriate continued expression of de-differentiation markers in the proximal tubules, which failed to re-differentiate in the hypoxic environment causing exasperated kidney damage in the mutant animals.

Conclusions: Taken together we determined that SDE are important mediators of vascular perfusion after kidney injury. Furthermore, SDE play a vital role in reestablishing normal oxygen concentrations after AKI to regulate the repair of the de-differentiated proximal tubules.

Genetic Deletion of Endogenous Proangiogenic Factor Vasohibin-2 Exacerbates Renal Ischemic Reperfusion Injury Katsuyuki Tanabe, Kana Masuda, Yuka Arata, Hitoshi Sugiyama, Jun Wada. *Dept of Nephrology, Rheumatolgy, Endocrinology and Metabolism, Okayama Univ Graduate School of Medicine, Okayama, Japan.*

Background: During the progression of acute kidney injury (AKI), dramatic alteration in the expression of various mediators including angiogenesis-related factors has been reported. Understanding the role of such mediators in AKI may lead to development of novel therapeutic strategies. Vasohibin-2 (VASH2) was originally identified as a proangiogenic factor secreted by bone marrow-derived mononuclear cells and it has been shown to be upregulated in various malignant tumor tissues. However, its pathogenic role in kidney diseases has not been elucidated yet. In the present study, we examined the effects of lacking endogenous VASH2 deficiency on renal function and histology in murine AKI model.

Methods: Ischemic-reperfusion (I/R) injury was induced by clumping bilateral renal pedicles for 25 min in eight to nine week-old C57BL6/J wild type (WT) and VASH2 knockout ($VASH2^{-/-}$) mice (n=6 in each group). Blood samples were collected and kidneys were harvested 24 hours after the reperfusion.

Results: I/R injury caused marked increase in serum creatinine and blood urea nitrogen in WT mice, and such increase was significantly accelerated in $VASH2^{-/-}$ mice (1.05±0.51 vs 2.20±0.41mg/dl and 143±26 vs 203±25mg/dl, respectively). Histologically, renal tubular injury (ATN score) following I/R in $VASH2^{-/-}$ mice was significantly exuberated compared with WT mice. Likewise, increased oxidative stress associated with the accumulation of malondialdehyde and 4-hidroxynonenal was more prominent in $VASH2^{-/-}$ I/R mice. VEGF mRNA level was significantly reduced after I/R in both WT and $VASH2^{-/-}$ mice. By immunostaining, VASH2 expression was observed in fibroblast-like cells in normal kidney interstitium. In the course of I/R, renal VASH2 mRNA markedly elevated on 24 hours but not six hours. Increased immunoreactivity of VASH2 on injured tubules 24 hours after I/R was observed.

Conclusions: These results suggested that endogenous VASH2 was upregulated in late phase of I/R injury, and thus may exert certain beneficial effects on the tubular repair process.

Activated CD47 Dysregulates Metabolic Pathways and Cellular Reprogramming in Acute Kidney Injury Natasha M. Rogers,[1,4] Takuto Chiba,[1,2] Elina Mukherjee,[2] Zheng Jenny Zhang,[3] Jiao-Jing Wang,[3] Angus W. Thomson,[4,5] Dennis Kostka,[3,6] Sunder Sims-Lucas,[1,2] Jeffrey S. Isenberg.[1] *[1]Medicine, Univ of Pittsburgh, PA; [2]Children's Hospital, Univ of Pittsburgh, PA; [3]Comprehensive Transplant Center, Northwestern Univ, Chicago, IL; [4]Starzl Transplantation Inst, Univ of Pittsburgh, PA; [5]Immunology, Univ of Pittsburgh, PA; [6]Developmental Biology, Univ of Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is a serious disorder that is identified in 50% of ICU patients. We have previously shown that 1) TSP1-CD47 signaling exacerbates ischemia reperfusion (IR)-mediated AKI in mice, 2) in some non-renal tissue beds, absence of CD47 was associated with improved mitochondrial function, and that 3) multiple self-renewal factors including Oct4, Sox2, Klf4 and c-Myc (OSKM) are increased in murine $CD47^{-/-}$ primary renal tubules. We hypothesize that AKI-induced TSP1-CD47 signaling dysregulates PTEC metabolic pathways and cellular reprogramming to limit kidney healing.

Methods: To localize TSP1-CD47 signaling, we utilized antibodies bound to magnetic beads to selectively enrich for PTEC and renal arterial endothelial cells as compared to whole kidneys from age/ gender matched $CD47^{-/-}$ and wild type (WT) mice. RNA sequencing (RNA-seq) was performed with whole kidneys of age/ gender-matched WT and $CD47^{-/-}$ mice 24 hours after IR.

Results: TSP1 and CD47, mRNA levels were increased in WT PTEC and endothelial cells compared to whole kidneys. Conversely, cMyc and Klf4 mRNA expression was elevated in $CD47^{-/-}$ PTEC as was VEGF mRNA in $CD47^{-/-}$ renal arterial endothelial cells compared to WT cells. *In vitro*, hypoxic $CD47^{-/-}$ PTEC maintained enhanced OSKM levels in the face of TSP1 induction and showed increased proliferation under normoxia. OSKM protein and mRNA levels were increased in whole kidneys from $CD47^{-/-}$ mice at day1, 3 and 7 post-IR. RNA-seq followed by a pathway analysis revealed that genes of oxidative phosphorylation pathway as well as of mitochondrial and glycolysis were upregulated in $CD47^{-/-}$ kidneys.

Conclusions: TSP1-CD47 signaling is maladaptively upregulated in IR-mediated AKI in a cell type specific fashion, suppresses expression of self-renewal factors OSKM, dysregulates oxidative phosphorylation, and suppresses proliferation of PTEC to limit tubule repair.

Role of IL-17 in the Induction of Fibrosis and Neutrophil Recruitment in Post AKI Rats Fed on High Salt Diet Purvi Mehrotra, Jason Andrieu Collett, Seth D. Mckinney, Jackson Stevens, David P. Basile. *Cellular and Integrative Physiology, Indiana School of Medicine, Indianapolis, IN.*

Background: T cells have been implicated in the pathogenesis of acute kidney injury (AKI) as well as its progression to chronic kidney disease (CKD). Previous studies from our laboratory suggest that a specific subset of T helper cells, Th17, characterized by IL-17 secretion, is the predominant subtype activated during AKI to CKD transition. Further, inhibition of T cell activity by mycophenolate mofetil (MMF) or losartan, protected from fibrosis in post AKI rats fed on high salt diet, but the role of Th17 cells in AKI-CKD transition is not clear. We hypothesized that T cell deficient rats, may have reduced cytokine levels leading to decrease fibrosis.

Methods: Ischemia and reperfusion was performed on T cell deficient athymic rats ($Foxn1^{rnu-/rnu-}$) and control heterozygote control euthymic rats ($Foxn1^{rnu-/+}$) and allowed to recover for 35 days. CKD progression was hastened by unilateral nephrectomy and high salt diet for an additional 4 weeks. These rats were also treated with MMF or vehicle along with high salt diet.

Results: As expected, I/R and high salt diet increased fibrosis in euthymic rats (206%;p³0.05) as indicated by an increase in picosirus red staining, which was reduced by MMF treatment (66%; p³0.05). However, the degree of fibrosis was similar in the athymic rat (266%) as compared to euthymic controls (206%). Surprisingly, MMF treated had no effect on AKI induced fibrosis in athymic rats. This may be due to the compensatory role, MMF-insensitive natural killer (NK) T-cells in IL-17 production in athymic rats. Blockade of IL-17 activity using IL-17RC soluble receptor (150ng/day), significantly decreased fibrosis in both euthymic (66%) and athymic (71%) rats as compared to vehicle treated controls. Further, we also observed a significant decrease in neutrophil recruitment in IL-17RC-treated rats as compared to vehicle-treated rats.

Conclusions: Taken together, we conclude that IL-17 cytokine secretion from any source plays a central role in the pathogenesis of fibrosis during AKI to CKD transition.

TH-PO092

Adenine Overload Causes Severe AKI Progressing to CKD by Activation of Innate Immunity in Rats and Mice Gizely C.S. Moreira,[1,2] Flavia G. Machado,[2] Clarice K. Fujihara,[1] Benjamin D. Humphreys,[2] Roberto Zatz.[1] *[1]Renal Div, Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Div of Nephrology, Washington Univ in St. Louis, St. Louis, MO.*

Background: Adenine (ADE) overload is a known model of kidney injury due to precipitation of crystals in the tubular lumen leading to epithelial damage and interstitial expansion. Here we investigated glomerular filtration rate (GFR), the role of innate immunity and tubular damage in both rat and mouse models of tubulointerstitial nephritis.

Methods: Adult male Munich-Wistar rats were fed with chow containing 0.5% of ADE for 1 week and analyzed 4 and 24 weeks after cessation of ADE. A separate group of mice were fed with 0.25% ADE chow for 10 days and evaluated 4 weeks after ADE cessation. GFR was measured through transcutaneous elimination kinects of FITC-Sinistrin.

Results: At the end of 1 week under ADE overload in rats, innate immunity components such as IL1β, IL6, NLRP3 and TLR4 were upregulated. After 4 and 24 weeks of ADE cessation intratubular rare crystals could be observed and innate immunity protein expression had fallen back to normal levels, translating a foreign body reaction against ADE crystals in tubulointerstitial compartment. At 24 weeks, glomerulosclerosis and collagen interstitial deposition indicating irreversible tubulointersititial fibrosis. A similar overall pattern was observed in mice, where ADE induced KIM-1 and NGAL mRNA expression to 620-fold and 3810-fold over control. Four weeks after ADE, their expression fell but remained elevated at 20-fold and 555-fold over control. Fibronectin, collagen 1α1, αSMA and F4/80 mRNA were also induced over the 4 weeks time course. Importantly, acute ADE overload in mice caused a 64% reduction in GFR (1049±96 µl/min/100*g* bw at baseline vs. 380±60 µl/min/100*g* bw ADE 10d, $p<0.05$) that made an incomplete recovery 4 weeks after discontinuation of ADE (792±18 µl/min/100*g* bw, $p>0.05$ *vs.* baseline).

Conclusions: ADE overload causes severe AKI that progresses to CKD in both rats and mice. This is mediated by activation of innate immunity. The ADE model is an attractive one to study AKI to CKD transition because it is associated with GFR reduction.

TH-PO093

Effects of Acute Coxsackievirus Infection on the Kidneys of Non-Obese Diabetic Mice Debra L. Walter,[1,4] Kelly D. Mccall,[2,4] Karen T. Coschigano.[3,4] *[1]Biological Sciences, College of Arts and Sciences, Athens, OH; [2]Specialty Medicine, Heritage College of Osteopathic Medicine, Athens, OH; [3]Biomedical Sciences, Heritage College of Osteopathic Medicine, Athens, OH; [4]The Diabetes Inst at Ohio Univ, Athens, OH.*

Background: Enteroviruses, like coxsackievirus, are one of the most common virus genera infecting humans worldwide. Enterovirus infections have been documented to mediate a wide range of insults including direct injury as well as indirect injury through mechanisms such as autoimmune disease. Chronic kidney disease (CKD) can result from each type of damage (direct or indirect), however, little work has been done to differentiate the effects of each type of damage as a cause of CKD. This study, therefore, evaluates acute coxsackievirus infection in the kidneys of non-obese diabetic (NOD) mice that are genetically susceptible to develop autoimmune diseases that can ultimately result in CKD. Characterizing the effects of an acute viral infection in the kidneys of these mice will strengthen our understanding of direct virus-induced injury which can then be used to understand chronic kidney disease with respect to virus infection and autoimmune disease both alone and together.

Methods: In the current study, NOD mice were infected with coxsackievirus at 8 weeks of age and euthanized 3, 7, 10 and 14 days post infection.

Results: Coxsackievirus infection within the kidneys of NOD mice peaked at 3 days and disappeared by 14 days post infection. While morphological evaluation has not yet revealed any significant changes, genes involved in kidney damage and the inflammatory response (e.g. IL-6, TLR3, TNFα, CCL2, and others) were found to be significantly upregulated 3 days post infection.

Conclusions: Characterizing the direct effects of an acute virus infection within the kidneys of these mice will strengthen our understanding of the nature of virus-induced acute kidney injury that may trigger CKD resulting from either virus infection (direct), autoimmunity (indirect) or both together. Together, these data will help identify how CKD develops in different situations and reveal potential treatment strategies for each causative agent.

TH-PO094

Macrophage Promoted Kidney Repair in the Ischemia-Reperfusion Injury via the Activation of IKKα Xin Wan, Changchun Cao. *Dept of Nephrology, Nanjing First Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Macrophage played a notable role in the renal ischemia-reperfusion injury(IRI). IKKa, a key mediator of NF-κB nonclassical pathway was considered could inhibit the progression of imflammation. The roles and underlying mechanisms of IKKa in macrophage was not clear in kidney IRI.

Methods: To investigate the performance of IKKa in macrophages, we generated a *chuk* knock mouse ($IKK\alpha^{F/F}$:MlysCre, $IKK\alpha^{MKO}$) and they were submitted to unilateral renal IR or sham operation. Histomorphological, immunohistochemical methods were performed to judge the kidney samples.

Results: Compared to WT, KO mouse was smaller ($P<0.05$). After IRI, the ratio of left kidney and whole weight was higher in KO mouse then they survived more than WT (Figure 1, 2). KO group showed less SDF-1, IL-10 expression in renal epithelial cells than another group, accompanied with a higher injury score (Figure 3, 4).

Conclusions: The IKKα in macrophage was essential for the restoration of kidney injury.

Funding: Government Support - Non-U.S.

TH-PO095

Splenic Marginal Zone Macrophages Regulate NKT Cell Activation in Acute Kidney Injury Elvira Kurmaeva, Liping Huang, Amandeep Bajwa. *Medicine, Univ of VA, Charlottesville, VA.*

Background: Marginal zone macrophages (MZM) are present in lymphoid and non-lymphoid organs and regulate innate immune responses. In spleen MZM are arranged around the marginal sinus lining and consist of several subsets: $CD169^+$, $CD209^+$ or $MARCO^+$. $CD169^+$ MZM are involved in erythropoiesis, capture blood born particles and target endogenous glycolipids to activate splenic NKT cells. In kidney ischemic reperfusion injury (IRI), NKT cell activation through production of IFN-γ is crucial in initialing innate injury. Depletion of NKT cells or use of NKT KO mice protects kidneys from injury. We functionally evaluated the role of splenic $CD169^+$ MZM to present endogenous glycolipid to activate NKT cells to initiate injury in kidney IRI.

Methods: Renal injury was assessed by plasma creatinine (PCr; mg/dl). 8-wk old $CD169^{WT/WT}$ and $CD169^{DTR/WT}$ male mice were used for all IRI studies. Mice were injected with 10ng/g of diphtheria toxin (DT) one day prior to 24 mins or 26 mins of IRI. For NKT functional studies, α-galactosylceramide (α-GalCer, 10µg/mouse, i.p.) was administered 2 days after CD169-depletion and all samples were collected after 2 hrs.

Results: CD169-depleted mice are partially protected compared to WT mice (PCr; 0.8±0.2 vs 0.6±0.01; 26-mins). However, with sub-threshold clamp time of 24 mins, CD169-depleted mice have significantly lower PCr compared to littermates (2.14±0.15, $p<0.001$). Sham and CD169-depleted IRI mice had comparable injury (PCr; 0.23±0.05 vs 0.27±0.01). Additionally, CD169-depleted mice have less infiltration of $CD11b^+Gr1^{high}Ly6C^{int}$ (neutrophils) and $CD11b^+Gr1^{neg}Ly6C^{high}$ (monocyte) in IRI kidneys compared to controls. Additionally, administration of α-GalCer to CD169-depleted mice results in two times less IFN-γ production by splenic NKT cells (%NKT^+, 38.28 ± 2.831vs 14.74 ± 4.103, $p=0.0003$).

Conclusions: Depletion of $CD169^+$ MZM in CD169-DTR mice reduced IFN-γ production by NKT cells, neutrophil and monocyte infiltration into IRI kidneys. Due to prime location of $CD169^+$ macrophages at the MZ of the spleen, our data further demonstrates that endogenous glycolipid presentation takes place in the spleen to regulate ischemic injury and depletion of $CD169^+$ MZM protests kidneys from IRI.

TH-PO096

Acute Splenic Iron Loading Protects against Ischemic AKI Yogesh M. Scindia, Ewa U. Mandziak, Liping Huang, Saleh Mohammad, Sundararaman Swaminathan. *Medicine, Univ of Virginia, Charlottesville, VA.*

Background: We have previously demonstrated that hepcidin (*Hamp*) mitigates renal ischemia reperfusion injury (IRI) by inducing splenic iron retention. In these studies, we observed that renal protection was associated with splenic iron accumulation that far out weighed that in the liver and kidney. We therefore hypothesized that strategically iron overloading the spleen with iron preparations known to be targeted to splenic macrophages may be beneficial in renal IRI.

Methods: Mice, C57Bl/6 (WT), and $Hamp^{-/-}$ (on B6 background) were injected with saline or 14 mg/kg Ferumoxytol (Feraheme™) (i.v.), a FDA approved iron nanoparticle preparation in current use for treating anemia of chronic kidney disease. Twenty-four hours later, mice were subjected to renal IRI (24-26 min). In some experiments, WT mice were injected with Ferumoxytol, 2 h post reperfusion. Outcomes (renal function, injury markers, histopathology and inflammation) were examined after 24-72 h of reperfusion.

Results: Ferumoxytol significantly reduced IRI-induced kidney injury in WT mice as measured by plasma creatinine (WT P_{Cr}: IRI; 2.5±0.32 vs Ferumoxytol+IRI; 0.38±0.01 mg/dl, $p < 0.005$), NGAL, acute tubular necrosis score and immune cell infiltration. Ferumoxytol protected hepcidin-deficient ($Hamp^{-/-}$) mice against renal IRI despite the presence of kidney iron overload. Splenic iron accumulation was a common feature in the protected WT and $Hamp^{-/-}$ mice. In contrast, the spleens of injured mice were iron depleted. Mice injected with Ferumoxytol after the onset of AKI had significantly lower plasma creatinine, after 72 h of reperfusion (WT P_{Cr}: IRI; 1.2 vs Feraheme+IRI; 0.50 mg/dl, $p < 0.05$). The kidneys of the protected mice had more M2 macrophages and less neutrophils.

Conclusions: Our results reveal a novel protective effect of Ferumoxytol in renal IRI. Moreover, its actions are independent of hepcidin or kidney iron content. The ability of Ferumoxytol to protect against IRI even when administered after the onset of injury highlights its therapeutic potential. These observations validate our previous studies suggesting the critical importance of splenic iron content for inducing protection in ischemic AKI.

A Novel Mice Model of Acute Kidney Injury Induced by Hemorrhagic Shock Lei Wang, Jin Wei, Shaohui Wang, Jie Zhang, Ruisheng Liu. *Molecular Pharmacology and Physiology, Univ of South Florida, Tampa, FL.*

Background: Current animal models for hemorrhagic shock-induced acute kidney injury (HS-AKI) need extensive surgery and monitoring which are very time consuming. The goal of the present study is to develop an easy and reliable mouse model of HS-AKI.

Methods: C57BL/6J mice were implanted with radio-transmitters for mean arterial pressure (MAP) measurement. Hemorrhagic shock was induced by left retro-orbital bleeding of 0.4 ml blood. After 30 min, bilateral pedicels were clamped for 18 min at 36.8-37.0^{0}C. One group of mice were then resuscitated with 0.2 ml of collected blood 2-fold diluted with Lactate Ringer's solution. Another group was not given resuscitation. The clamps were then released to start the reperfusion. Renal blood flow (RBF) was measured in separate non-survival experiments.

Results: Hemorrhagic shock reduced MAP from 77 ± 4 to 35 ± 3 mmHg, which returned to 90% of baseline in 3 hours in the resuscitation group and in 8 hours in the non-resuscitation group. Plasma creatinine levels increased from 0.09 ± 0.01 mg/dl to 1.71 ± 0.08 mg/dl in the resuscitation group and from 0.08 ± 0.01 mg/dl to 2.03 ± 0.12 mg/dl in the non-resuscitation group 24 h after HS-AKI. GFR was decreased by 69% in the resuscitation group and by 78% in the non-resuscitation group. ($p<0.05$, resuscitation group vs non-resuscitation group, n=6/group) All of the above parameters returned to near baseline at 4 weeks after HS-AKI. Hemorrhagic shock reduced RBF from 0.68 ± 0.13 to 0.24 ± 0.09 ml/min. RBF was returned about 92% of baseline with resuscitation, but remained low in the non-resuscitation group. ($p<0.01$ resuscitation group vs non-resuscitation group, n=5/group).

Conclusions: We propose to generate this HS-AKI mouse model without MAP and RBF monitoring by: 1) retro-orbital bleeding 0.4 ml blood; 2) bilateral pedicles clamping for 18 min at 36.8-37 °C; 3) with or without resuscitation of 0.2 ml LR + blood via retro-orbital sinus. This new HS-AKI model is a well-controlled, easy and reliable mouse model, which may facilitate investigators to further investigate and understand the mechanisms of HS-AKI.

Development of a Cellular Assay for Ischemic Acute Kidney Injury David J. Rickard,[1] Robert S. Geske,[1] Cathy Simmons,[1] Jean-Louis D. Klein,[1] Robert Kirkpatrick,[2] Craig Leach,[3] Luke Devey.[4] *[1]Target Sciences, GlaxoSmithKline R&D, Collegeville, PA; [2]Pipeline Futures Group, GlaxoSmithKline R&D, Collegeville, PA; [3]Platform Technology and Science, GlaxoSmithKline R&D, King of Prussia, PA; [4]Heart Failure DPU, GlaxoSmithKline R&D, King of Prussia, PA.*

Background: In AKI, tubular epithelia respond to ischemia-induced hypoxia and nutrient deprivation with oxidative and metabolic stress, leading to cell death, inflammation and impaired kidney function in severe cases. A possible reason for the failure of several promising therapeutic approaches is poor predictability of preclinical models of renal ischemia. We sought to develop a cellular model of renal tubular ischemia amenable to the identification of potential therapeutic targets and agents. Precision-cut kidney slice cultures were used for comparison with the cell model.

Methods: HK-2 proximal tubule and primary human renal epithelial cells subjected to chemically-induced redox, hypoxic, metabolic and fibrotic stresses were analyzed for changes in mitochondrial activity, cell death, as well as expression of genes associated with hypoxia, nephrotoxicity and genes identified from patient samples exhibiting delayed graft function (DGF) after renal transplant (see abstract by Kirkpatrick R, et al).

Results: HIF hydroylase inhibitors (hypoxia mimic) and TGFβ1 (fibrosis) both had little effect on cell death, while ATP and glucose deprivation (metabolic stress) induced apoptosis and hydrogen peroxide (oxidative stress) increased necrosis. Despite differing effects on cell death, metabolic and hypoxic stressors caused time-dependent mitochondrial damage. Consistent with their divergent effects on cell health, each stress treatment produced distinct changes in gene expression. Importantly however, the effect of each stressor in epithelial cell culture correlated poorly with the DGF-induced change for a subset of differentially expressed genes. Moreover, gene expression analysis in cultured cortical slices demonstrated a greater number of hypoxia rather than DGF-mediated changes.

Conclusions: The DGF tissue dataset indicates that our in vitro models may require an immune component to better recapitulate the complex pathology of AKI.

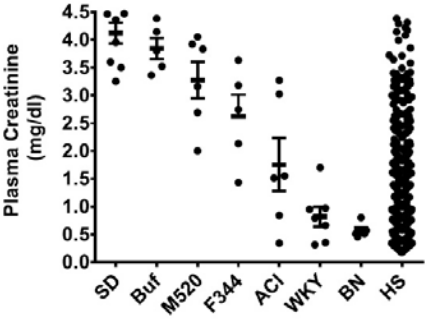
Differential Susceptibility to Renal Ischemia-Reperfusion Injury in Heterogeneous Stock Rats David Charles,[1] David Houser,[1] Bohan Xing,[1] Leah C. Solberg Woods,[2] Kevin R. Regner.[1] *[1]Nephrology; [2]Pediatrics, Medical College of Wisconsin.*

Background: Renal ischemia-reperfusion injury (IRI) is a common cause of acute kidney injury (AKI). In animal models of AKI, we and others have demonstrated that genetic factors may play a role in modulating the severity of AKI. Heterogeneous stock (HS) rats are outbred from eight inbred founder strains and can be used to fine map genes involved in complex traits. The aim of the present study was to evaluate the range of phenotypes in HS rats and HS founder strains following renal IRI.

Methods: Groups of eight week old male outbred Sprague-Dawley (SD), inbred HS founder (ACI, BN, BUF, F344, M520, WKY), and outbred HS rats underwent 30 min bilateral renal ischemia and 24 hrs reperfusion or sham surgery. Renal function was assessed by measurement of serum creatinine (sCr) by LC-MS/MS. Tubular injury (TI) was assessed by histologic analysis in kidney sections and immunblot analysis of neutrophil gelatinase-associated lipocalin (NGAL) expression.

Results: TI scores and sCr did not significantly differ between groups 24 hrs after sham surgery. Following IRI, sCr was 4.1 ± 0.22 mg/dl in SD rats. In comparison to SD rats, sCr was significantly lower in the BN and WKY founder strains (see Figure). As expected, sCr in HS rats varied across the range found in the inbred HS founder strains (see Figure). Similar trends in TI scores were found in HS founder strains and HS rats. NGAL expression correlated with sCr ($r = 0.7$, $P < 0.01$) and with renal cortex TI scores ($r = 0.5$, $P<0.01$) in HS rats.



Conclusions: In conclusion, we found that susceptibility to renal IRI varied between HS founders and that HS rats exhibited a high degree of variability in response to renal IRI, with some rats completely protected from AKI. This variability indicates that HS rats can be used to fine-map genetic loci and to uncover the causal genes that alter susceptibility to AKI in HS founder strains.

Estrogen Receptor Alpha Mediates Female Protection from Renal Ischemia-Reperfusion Injury David Dean Aufhauser,[1] Douglas R. Murken,[1] Zhonglin Wang,[1] Guanghui Ge,[1] Tricia Bhatti,[2] Matthew H. Levine.[1] *[1]General Surgery, Hospital of the Univ of Pennsyvania and the Childrens's Hospital of Philadelphia, Philadelphia, PA; [2]Pathology and Laboratory Medicine, Hospital of the Univ of Pennsyvania and the Childrens's Hospital of Philadelphia, Philadelphia, PA.*

Background: Female protection from renal ischemia-reperfusion injury (IRI) is observed in both mouse and human renal transplantation. We have previously shown that both estrogen and androgens contribute to the gender dichotomy following this injury pattern. We wished to assess the role of estrogen receptor alpha (ERα) in mediating this process.

Methods: Wild type (WT) and ERα knockout (ERαKO) C57BL/6 mice underwent standardized 28-min (female) or 15-min (male) warm IRI with clamping of the left renal pedicle and contralateral nephrectomy. BUN was measured daily for 4 days following injury and kidneys were collected for histology after 28 days.

Results: Female ERαKO mice demonstrated significantly diminished survival after renal IRI compared to WT controls with universal lethality from renal failure within 96 hours of the ischemic injury (n=5 per group, $p<0.01$, Fig 1). Male ERαKO mice demonstrated equivalent biochemical renal injury (n=5 per group, $p=0.81$, Fig 2) and fibrosis compared to WT controls.

Figure 1. Survival After 28-min IRI

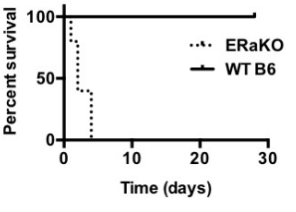

Figure 2. Renal Function after 15 min IRI

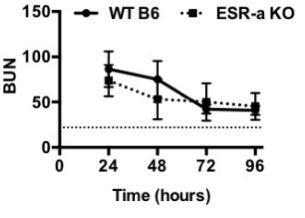

Conclusions: Genetic deletion of ERα leads to profound reduction in renal IRI tolerance in female but not male mice. This finding confirms that gender-specific phenotypes in renal IRI arise from both protective actions of estrogens and detrimental effects of androgens and suggests that ERα plays a mechanistic role in female protection. Further investigations are necessary to identify specific actions of ERα responsible for protection and possible avenues to translate the protective action of ERα after renal transplantation and in other clinical scenarios of AKI.

Influence of Gender and Regulatory T Cells on Acute Aristolochic Acid Nephropathy in Mice Gilbert R. Kinsey, Brian K. Stevens, Mana Yang. *Div of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, Univ of Virginia.*

Background: Aristolochic acid has been identified as the cause of several outbreaks of ESRD around the world. Clinical studies revealed extensive inflammation in kidneys of patients with aristolochic acid nephropathy (AAN). AAN involves acute toxic injury to tubular epithelial cells that leads to immune cell infiltration and progressive fibrosis over time. Regulatory T cells (Tregs) protect the kidney from acute and chronic disease in other models and we sought to test the role of Tregs in AAN.

Methods: Male and female C57Bl/6 mice were treated with AA 5 – 10 mg/kg/day for 1 to 3 days by i.p. injection. Tregs were partially (~50%) depleted using the anti-IL-2 receptor antibody PC61. Five to 14 days after initiating AA treatment renal function, injury and inflammation were assessed.

Results: Male mice developed dose-dependent renal dysfunction, inflammation and tubular necrosis by day 5, whereas female mice were markedly resistant to renal injury. For example, one dose of 5 mg/kg in males induced consistent kidney injury and dysfunction in males at day 5, whereas 2 doses of 10 mg/kg caused no significant renal injury in females. Renal inflammation at day 5 in males consisted mainly of monocyte/macrophages ($CD11b^{+}F4/80^{int}$) and to a lesser extent neutrophils ($CD11b^{+}SSC^{high}Ly6G^{high}$), with few T or B cells observed. At day 14, a significant increase in the abundance of renal $CD4^{+}$ and $CD8^{+}$ T cells was noted in males ($CD3^{+}CD4^{+}$ T cells per gram: Veh 49,000 ± 22,000; AA 440,000 ± 123,000) . In contrast, AA treatment in female mice did not increase renal immune cells above control levels at 5 or 14 days after AA treatment. Treg depletion in males had no effect on plasma creatinine or BUN levels, but led to elevated tubular necrosis, KIM-1, NGAL, CXCL1 and MCP-1 expression in the kidney compared to non-Treg-depleted mice treated with AA at day 5.

Conclusions: These results demonstrate a significant difference in the acute response to AA between male and female mice. In males, Tregs appear to act as a barrier to kidney damage in the acute phase of this nephrotoxic injury model.

Gender Differences in Response to Ischemia-Reperfusion as Determined by RNA Sequencing of Pre- and Post-Ischemic Human Kidney Biopsies Hannes Olauson,[1] Johan E. Nordström,[2] Julia Wilflingseder,[1] M. Todd Valerius,[1] Lars Wennberg,[2] Annika Wernerson,[2] Joseph V. Bonventre.[1] *[1]Div of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]CLINTEC, Karolinska Inst, Stockholm, Sweden.*

Background: Ischemia-reperfusion injury (IRI) is implicated in many common diseases, including acute kidney injury (AKI). Patients with AKI are seldom biopsied, and most of our knowledge about the kidney's response to ischemia-reperfusion is derived from animal studies.

Methods: Twenty paired kidney biopsies were obtained before and after 3-15 min warm ischemia, 60-120 min cold ischemia and ca 60 min reperfusion during living donor transplantation. Glomeruli were removed and mRNA was extracted from the tubulointerstitial fraction and subjected to RNA Sequencing. Genes with a 2-fold up- or downregulation and a FDR < 0.05 were considered to be differentially expressed.

Results: Histological analysis showed no major differences between pre- and post-ischemic samples. RNA Sequencing, however, revealed a robust tissue response to ischemia-reperfusion, with upregulation of 259 genes, and downregulation of 72 genes. When compared to published datasets, there was a significant overlap with the transcriptional profile in rodents subjected to IRI. Shared pathways included the MAPK pathway and the transcription factors KLF4 and KLF6. Furthermore, we systematically analyzed gender differences between samples. Genes located on the male-specific region of the Y chromosome and their X-linked homologues were differentially expressed and accounted for a large portion of the variability between samples. When these genes were removed from the analysis the gender differences disappeared.

Conclusions: This study demonstrates that RNA Sequencing is a feasible and sensitive method to study genome-wide gene expression changes in kidney biopsies, and establishes living donor transplantation as a suitable human model to study the immediate response to ischemia-reperfusion. Additionally, we demonstrate that differences between genders were largely driven by sex-specific genes, and that the response to ischemia-reperfusion appears similar in men and women when these sex-specific gene expression differences are removed.

Age and Sex Dependent HO-1 Expression Regulates Autophagy in Cisplatin Induced AKI Ravindra Boddu,[1] Sunil Rangarajan,[1] Bhuvana Sunil,[1] Lisa M. Curtis.[1,2] *[1]Medicine, Univ of Alabama at Birmingham; [2]Birmingham VA Medical Center, Birmingham, AL.*

Background: Cisplatin (Cp)-induced AKI is a major complication of chemotherapy in patients with solid organ cancers. Previous studies using pharmacological and genetic manipulations in animal models have demonstrated a protective role for heme oxygenase-1 (HO-1), an inducible heme catabolizing enzyme, in Cp-induced AKI, effects that are mediated via anti-oxidant, anti-apoptotic, and anti-inflammatory properties.

Methods: To study the influence of age and sex on HO-1 expression in response to AKI, 4 month (young) and 16-17 month (aging) old male and female C57BL/6 mice were injected with a single intra-peritoneal injection of Cp (20 mg/kg body weight) or saline as control. 1 and 3 days post injections, the kidneys were processed for western blot analyses. Serum creatinine (SCr) was measured by LC-MS/MS. Data and statistical values indicate mean±SEM using one way ANOVA with Tukey's post-test.

Results: SCr values in aging males (3.64±0.40 mg/dL) and females (3.40±0.44 mg/dL) showed worsening of kidney function as compared to the young males (1.69±0.66 mg/dL) and females (0.61±0.12 mg/dL)($p<0.01$ and $p<0.0001$, respectively), after 3 days post Cp injection. Western blot data from kidney lysates indicate that young males had significantly higher HO-1 induction as compared to young females 1 day post Cp injection. Young females and males had significantly higher HO-1 induction as compared to aged females and males, respectively, at 1 day after Cp. 3 days post Cp, in contrast to aging females, HO-1 expression in young females returned to values comparable to baseline saline control treated levels. The increased HO-1 protein levels persisted in young and aging males 3 days after Cp as compared to saline treated control mice. ATG5, a marker of autophagy, was significantly decreased in aging females compared to young females at 3 days post Cp. Levels of p62 were significantly higher in all the aging mice as compared to their younger counterparts after 1 and 3 days of Cp injection.

Conclusions: These results indicate that age and sex influence renal HO-1 expression and alter the autophagy pathway after Cp-induced AKI and may contribute to worse outcomes in this setting.

TH-PO104

Protective Effects of Heme Oxygenase-2 in Ischemic Acute Kidney Injury Karl A. Nath,[1] Joseph P. Grande,[2] John D. Belcher,[5] Anthony J. Croatt,[1] Gianrico Farrugia,[3] Zvonimir S. Katusic,[4] Gregory M. Vercellotti.[5] *[1]Div of Nephrology and Hypertension, Mayo Clinic; [2]Dept of Pathology, Mayo Clinic; [3]Div of Gastroenterology and Hepatology, Mayo Clinic; [4]Dept of Anesthesiology, Mayo Clinic, Rochester, MN; [5]Div of Hematology, Oncology and Transplantation, Univ of MN, Mpls., MN.*

Background: Heme oxygenase (HO) exists as an inducible (HO-1) and a constitutive (HO-2) isoform. HO-1 is widely recognized as a protectant against ischemic and nephrotoxic AKI. Our prior studies demonstrate that HO-2 protects against heme protein-induced AKI. The present study examined whether HO-2 is protective in ischemic AKI.

Methods: Bilateral renal ischemia (15 minutes) was imposed on young (18-19 wk) and old (80-85 wk) $HO\text{-}2^{+/+}$ and $HO\text{-}2^{-/-}$ mice of either gender. Renal function (BUN and serum creatinine) and relevant gene expression were then assessed.

Results: We observed no significant differences in BUN or serum creatinine in young $HO\text{-}2^{+/+}$ and $HO\text{-}2^{-/-}$ mice (either male or female) on days 1 and 2 following ischemic AKI. However, for aged male mice, HO-2 deficiency significantly worsened renal function: BUN on day 1 (73 ± 10 vs 113 ± 6 mg/dl) and day 2 (94 ± 15 vs 156 ± 17 mg/dl); serum creatinine on day 1 (0.9 ± 0.1 vs 1.5 ± 0.2 mg/dl) and day 2 (0.9 ± 0.2 vs 1.9 ± 0.3 mg/dl). No significant differences in function were observed in similarly aged female $HO\text{-}2^{+/+}$ and $HO\text{-}2^{-/-}$ mice. In aged male mice, HO-2 deficiency also significantly increased the upregulation of a number of genes at day 2 after ischemia, including proinflammatory genes which contribute to ischemic AKI, such as CCL2 (9.8 ± 1 vs 18.3 ± 1.8 AU) and IL-6 (18.9 ± 1.6 vs 36.8 ± 8.3 AU).

Conclusions: We conclude that the protective effects of HO-2 in ischemic AKI are evinced in aged male mice and involve, at least in part, suppression of proinflammatory pathways. These effects of HO-2 are not observed in aged female mice, or in young mice of either gender. These studies underscore the exacerbatory effects of age and male gender as determinants of the severity of AKI, and support the recent emphasis that analyses of putative protective and exacerbatory pathways in AKI should accommodate studies of age and gender.

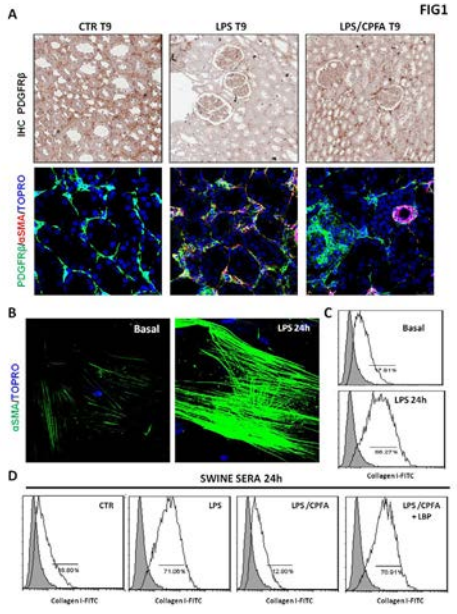
LPS Binding Protein (LBP) Amplifies TLR-4 Signaling and Pericyte (PC) to Myofibroblast Trans-Differentiation (PMT) in LPS-Induced Acute Kidney Injury (AKI) Giuseppe Castellano,[1] Alessandra Stasi,[1] Rossana Franzin,[1] Chiara Divella,[1] Alessandra Spinelli,[1] Margherita Gigante,[1] Paola Pontrelli,[1] Giuseppe Grandaliano,[2] Giovanni B. Pertosa,[1] Loreto Gesualdo.[1] *[1]Univ of Bari; [2]Univ of Foggia.*

Background: During sepsis, serum LBP levels increase and maximize the activation of TLR4-signaling leading to AKI. PC are pivotal in myofibroblasts generation during chronic kidney disease but little is known in AKI.

Methods: AKI was induced by i.v. LPS infusion in 8 pigs (LPS group). After 3h from LPS infusion, 8 pigs were treated with coupled plasma filtration adsorption (CPFA) to remove LBP. Renal biopsies, performed at 9h from LPS infusion (T9), were analyzed by IHC and IF. PC (PDGFRβ+) were stimulated in vitro and analyzed by FACS, IF and WB. Serum LBP and TGFβ were quantified by ELISA.

Results: In endotoxemic pigs, we found the occurrence of acute PMT by reduction of PDGFRβ expression and αSMA increase in peritubular PC (**Fig.1A**, T9LPS vs CTR). CPFA treatment restored PDGFRβ expression and significantly decreased $\alpha SMA^{+}PC$ (**Fig.1A**, T9LPS/CPFA vs T9LPS) in accordance with reduced serum levels of LBP and TGF-β ($p<0.05$). LPS and endotoxemic sera led to PMT in vitro with Collagen I synthesis and αSMA ($p<0.05$) reorganization in contractile fibers (**Fig.1B-C**). The removal of LBP from septic plasma ($p<0.05$) maintained Collagen I and αSMA expression ($p<0.05$) at basal

level. On the contrary, LBP supplementation completely reversed CPFA effects (**Fig.1D**). Finally, LPS induced acute PMT by both canonical TGFβ-Smad2/3 dependent and non-canonical TGF-β-Smad independent signaling (MAPK), by increased phosphorylation of Smad2/3 and ERK1, respectively ($p<0.05$).



Conclusions: PC might be pivotal in the generation of renal myofibroblasts by PMT during AKI upon LPS/TLR4 signaling pathways. Removal of LBP might represent a potential novel strategy to hamper the acute development of renal fibrosis.

TH-PO106

Role of Adenosine 1a Receptor Signaling on GFR Early after the Induction of Sepsis Jonathan Street, Erik H. Koritzinsky, Peter S.T. Yuen, Robert A. Star. *NIDDK, Bethesda, MD.*

Background: Sepsis is a common condition with a high mortality and morbidity. Organ dysfunction, including acute kidney injury (AKI), strongly predicts adverse outcomes. Kidney injury is diagnosed by a reduced glomerular filtration rate (GFR). The mechanisms underlying a reduced GFR are poorly characterized and have been proposed, in part, to be an adaptive, protective response limiting the metabolic demand on the kidney tubules. The extent of reabsorption by the tubules can be sensed at the macula densa, and adenosine 1a receptor (A1aR) signaling reduces GFR via tubuloglomerular feedback (TgF). We tested whether TgF contributes to sepsis-AKI using A1aR knockout mice.

Methods: Cecal ligation and puncture (CLP) was used as a model of sepsis in A1aR knockout (KO) and wild type (WT) littermate control mice. GFR was monitored using a miniaturized fluorimeter on the back of a mouse measuring the plasma disappearance of FITC-Sinistrin. Hemodynamics were monitored in conscious mice using implantable pressure transducer telemetry devices.

Results: In WT, GFR was stable for the first hour following CLP surgery to induce sepsis and then declined rapidly over the next 4 hours. In the KO, GFR was lower immediately following CLP surgery ($p=0.0226$) and declined gradually over the next 4 hours. Mean arterial pressure and heart rate declined during the third and fourth hours, respectively, and were not significantly different between WT and KO. Systemic hemodynamics cannot account for the difference in GFR at 1 hour.

Conclusions: In the absence of A1aR, unexpectedly, GFR began to decrease immediately after CLP surgery. The sudden decrease in GFR in the WT mice 2 hours after surgery occurs before clinical symptoms or hemodynamic changes and does not occur in the A1aR KO mice. GFR may initially be supported by A1aR signaling (GFR is initially higher in WT) and is only later suppressed.

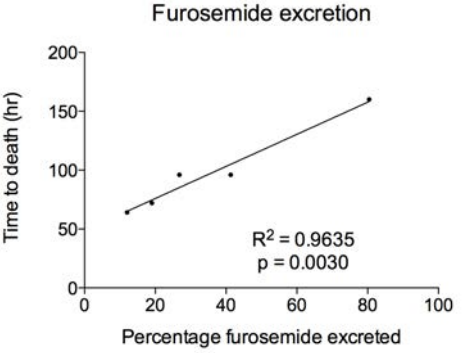
A Furosemide Excretion Stress Test (FEST) Predicts Mouse Mortality after Sepsis Jonathan Street,[1] Erik H. Koritzinsky,[1] Tiffany R. Bellomo,[1] Hiroshi Kojima,[1] Lakhmir S. Chawla,[2] Peter S.T. Yuen,[1] Robert A. Star.[1] *[1]NIDDK, Bethesda, MD; [2]VA, Washington, DC.*

Background: The furosemide stress test (FST) measures urine production after a furosemide bolus. FST is a sensitive and specific predictor of mortality and a need for renal replacement therapy in the ICU. Furosemide must be actively secreted into the proximal tubule lumen to then inhibit NKCC2 in the thick ascending limb, causing a diuresis. Tubule damage should thus reduce furosemide excretion (FEST) and prevent a subsequent increase in urine volume (FST). As filtration markers have limited predictive value of sepsis mortality in mice, we tested FST and FEST in a murine model of sepsis.

Methods: We developed a sensitive reverse phase HPLC assay for urine furosemide. Male CD-1 mice underwent cecal ligation and puncture (CLP) to induce sepsis. 48 hrs post-CLP 1 mg/kg furosemide was given s.c. and urine was collected for the next 12 hrs to allow for intermittent urination. The mice were monitored every 8 hrs and euthanized if their clinical score exceeded the protocol threshold.

Results: A moderate severity of CLP injury was used; 20 of 32 mice survived to 48 hr and underwent FST/FEST, and 15 mice survived 7 d. Urine production during 12 hr varied from 0.08 to 2.62 ml. Both urine production and the fraction of furosemide recovered in the urine predicted mortality [AUC ROC values of 0.92 ($p<0.01$) and 0.87 ($p<0.05$), respectively]. There was a strong correlation between time to event and fraction of furosemide recovered in the urine among mice that died, $R^2=0.96$ ($p<0.01$).



Conclusions: The furosemide excretion stress test and furosemide stress test strongly predict post-sepsis mortality in mice, allowing for early stratification by severity in future drug studies.

TH-PO108

RIPK3 Is a Mediator of Oxidative Stress, Mitochondrial Dysfunction and Necroptosis in Sepsis-Induced Kidney Injury in Mice Sureshbabu Angara, Oleh M. Akchurin, Sung Il Kim, Augustine M.K. Choi, Mary E. Choi. *Weill Cornell Medicine, New York City, NY.*

Background: Sepsis causes multi organ dysfunction including acute kidney injury (AKI). Recent studies have identified Receptor Interacting Protein Kinase-3 (RIPK3) and Mixed Lineage Kinase domain-Like protein (MLKL) as key mediators of necroptosis.

Methods: We sought to investigate the role of RIPK3 in sepsis-induced AKI using cecal ligation and puncture (CLP) sepsis model in mice.

Results: We showed that RIPK3 deficiency (*Ripk3*$^{-/-}$ mice) significantly decreased intracellular vacuolization and improved brush border in proximal tubular epithelial cells compared to *Ripk3*$^{+/+}$ mice at 24 h CLP. Furthermore, proteinuria and lipocalin-2 (both in urine and serum) induced in *Ripk3*$^{+/+}$ mice at 6 h CLP were significantly reduced in *Ripk3*$^{-/-}$ mice. We showed increased expression of p-RIPK3, RIPK3, p-MLKL and NOX4 upon 6h LPS treatment in human proximal tubular epithelial (HK-2) cells. Pharmacological inhibition of RIPK3 and NOX4 significantly reduced lactate dehydrogenase levels as compared to LPS treatment alone in HK-2 cells. Knock down of RIPK3 by specific siRNA in HK-2 cells decreased expression of NOX4/1 but not NOX2 as compared to scrambled siRNA-treated cells after LPS treatment. Similarly, kidney tissue lysates of *Ripk3*$^{-/-}$ mice showed decreased expression of NOX4 and MLKL as compared to *Ripk3*$^{+/+}$ mice at 6h CLP. Also, elevated mitochondrial DNA levels in the plasma of *Ripk3*$^{+/+}$ mice at 6h CLP were reduced in *Ripk3*$^{-/-}$ mice. Using transmission electron microscopy, we noted increased swelling of intracellular organelles, rupture of outer mitochondrial membrane and poorly defined mitochondrial cristae in proximal tubular epithelial cells of *Ripk3*$^{+/+}$ mice compared to *Ripk3*$^{-/-}$ mice at 24 h CLP. Using immunohistochemistry, we noted decreased nitrotyrosine staining in tubular epithelial cells in *Ripk3*$^{-/-}$ mice compared to *Ripk3*$^{+/+}$ mice at 6h CLP. Furthermore, kidney tissue lysates of *Ripk3*$^{-/-}$ mice showed significantly reduced ROS and MDA levels as compared to *Ripk3*$^{+/+}$ mice at 6h CLP.

Conclusions: Together, our data suggest that RIPK3 acts as mediator of oxidative stress and mitochondrial dysfunction and resultant necroptosis in CLP-induced kidney injury in mice.

TH-PO109

Sphingosine Kinase-2 Inhibitor ABC294640 Attenuates Endotoxin-Induced Acute Kidney Injury Zhi Zhong,[1] Yasodha Krishnasamy,[1] John J. Lemasters,[1] Rick G. Schnellmann.[1,2] *[1]Medical Univ of South Carolina; [2]Ralph H. Johnson VA Medical Center.*

Background: Sepsis is the most common cause of acute kidney injury (AKI), and mortality of septic AKI is up to 70%. Inflammatory responses and mitochondrial dysfunction contribute to septic AKI. ABC294640, a specific sphingosine kinase-2 (SK2) inhibitor, suppresses inflammatory responses in many diseases and prevents mitochondrial dysfunction after hepatic ischemia/reperfusion. The purpose of this study was to examine if ABC294640 decreases endotoxin-induced AKI.

Methods: Mice were treated with lipopolysaccharide (LPS, 10 mg/kg, ip), and ABC294640 (50 mg/kg) was gavaged 2 h later.

Results: At 24 h after LPS treatment, renal pathological changes were mild. Tubular necrosis was absent, but cast formation and inflammatory cell infiltration occurred. TUNEL-positive cells, cleaved caspase-3, and NGAL expression increased, and serum creatinine increased 2.6 folds, indicating LPS-induced AKI. ABC294640 decreased kidney injury and

serum creatinine after LPS treatment. LPS increased NFκB p65 phosphorylation and TLR4 and ICAM-1 expression, indicating increased inflammatory signaling. Myeloperoxidase, F4/80, and CD4, markers of neutrophils, monocyte/macrophages, and T lymphocytes, respectively, also increased, confirming leukocyte infiltration. ABC294640 decreased these inflammatory responses and inflammatory cell infiltration. In control mice by intravital imaging, TMRM fluorescence, a marker of mitochondrial membrane potential, was bright and punctate in tubular cells, indicating mitochondrial polarization. Depolarization occurred in >60% tubular cells after LPS, indicating mitochondrial dysfunction. Reactive nitrogen species are known to cause mitochondrial dysfunction. iNOS expression increased in the kidney after LPS treatment. ABC294640 blunted iNOS expression and mitochondrial depolarization.

Conclusions: SK2 inhibition by ABC294640 attenuates endotoxin-induced AKI, most likely by inhibition of inflammatory responses and prevention of mitochondrial dysfunction.

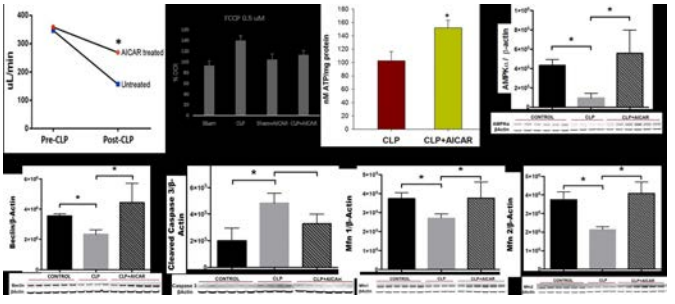
TH-PO110

Protective Role of AMPK in Sepsis-Associated AKI Ying Li, Elanore Hall, Hai Pham, Prabhleen Singh. *Medicine, UC San Diego & VASDHS, San Diego, CA.*

Background: Sepsis-associated acute kidney injury (s-AKI) significantly contributes to morbidity and mortality in critically ill patients. Effective therapeutic strategies for s-AKI are limited due to incomplete understanding its pathogenesis.

Methods: We performed FITC inulin clearance to examine renal function and other functional and molecular analyses to examine mitochondrial dysfunction in the pathogenesis of sepsis using a model of cecal ligation and puncture (CLP) 24 hours post-injury. Mitochondrial function was evaluated in fresh isolated proximal tubules by assessing oxygen consumption rates (OCR) during oxidative phosphorylation with a high-throughput XF96 Seahorse® analyzer.We also evaluated the role of AMPK in mitochondrial function in sAKI.

Results:



At 24 hours post-CLP, GFR was significantly reduced in CLP mice (345±19 vs. 155±35 uL/min; p=0.004). AICAR (AMPK activator) treatment 24 hours prior to CLP significantly improved GFR. CLP mice displayed elevated basal OCR rates, and significantly increased maximal respiratory OCR in the presence of uncoupler, FCCP. This was eliminated by pre-treatment with AICAR. AMPK was decreased in CLP kidney, along with decreased fusion proteins (Mfn1 and Mfn2). Expression of an autophagy protein Beclin was decreased while apoptosis protein cleaved caspase 3 was increased. Pre-treatment with AICAR increased AMPK and ATP levels in CLP kidney and increased fusion and autophagy proteins in the CLP kidney.

Conclusions: Our findings indicate cellular stress with decreased AMPK is associated with abnormal regulation of signaling pathways involving autophagy, apoptosis, mitochondrial function and mitochondrial biogenesis, which may play an important role in the pathogenesis of sepsis associated AKI. AMPK and its signaling pathway may serve as novel therapeutic targets in s-AKI.

Oxidative Stress and HMGB1 Redox during Acute Kidney Injury Wasan Abdulmahdi, Devika Patel, Rahul N. Pawar, Tala F. Azar, Anitsire Collado-Polanco, May M. Rabadi, Brian B. Ratliff. *New York Medical College.*

Background: A common factor in many forms of kidney disease is increase of reactive species of oxygen (ROS) and nitrogen (RNS). Enhanced production of ROS/RNS affects the redox state of molecules such as the alarmin high mobility group box 1 (HMGB1). HMGB1 is released from the kidney following sepsis-induced acute kidney injury (AKI), and can promote repair or damage depending on its redox state. We hypothesize that during sepsis-induced AKI, elevated ROS/RNS cause an imbalance of antioxidants and promote HMGB1 oxidation and its pro-damage effects.

Methods: After injection of either a low or high dose of lipopolysaccharide (LPS) to induce sepsis in mice, kidney samples were fractionated, and the redox of HMGB1 and antioxidant activity measured. Experiments also measured cytokine release in mice plasma after injection of reduced or oxidized HMGB1. In cell culture experiments, endothelial and proximal tubule cells were treated with LPS and glutathione/thioredoxin inhibitors, with subsequent analysis of HMGB1 redox.

Results: High dose LPS enhanced ROS/RNS and blunted thioredoxin activity in the kidney, while lower dose caused less pronounced ROS/RNS increase and enhanced thioredoxin activity. Glutathione activity paralleled thioredoxin, except demonstrated less nuclear activity. High LPS dose enhanced HMGB1 oxidation in the cytoplasm, plasma and especially in the nucleus. Administration of oxidized HMGB1 to healthy mice triggered release of anti-inflammatory cytokines, while reduced HMGB1 stimulated release of reparative anti-inflammatory cyto-/chemokines. In cell culture experiments, glutathione and thioredoxin activity inhibitors augmented HMGB1 oxidation. However, glutathione inhibition was more effective in endothelial cells, while thioredoxin inhibition was more effective in proximal tubular cells.

Conclusions: Low dose LPS upregulated antioxidants, while higher dose enhanced ROS/RNS, increased oxidation of HMGB1, and altered levels of antioxidants which maintain HMGB1 in a reduced state. Release of pro-inflammatory cytokines after injection of oxidized HMGB1 is indicative of the alarmin's role in inflammation, while reduced HMGB1 promotes reparative processes.

TH-PO112

Real-Time Quantification of Temporal and Cell Specific Oxidative Stress in the Ischemic Kidney Tomoaki Miyazaki, Yun-Wei A. Hsu, Neal A. Paragas. *Medicine, Univ of Washington, Seattle, WA.*

Background: A key factor in acute kidney injury (AKI) has been oxidative stress (OS) after the ischemic event. A classic model of AKI is renal ischemia and reperfusion (I/R) which leads to OS due to hypoxia during ischemia and subsequent generation of reactive oxygen species (ROS) during reperfusion. A major ROS is hydrogen peroxide (H202) and excess H202 can be injurious, however to date, there has never been a cell-specific, non-invasive, real-time, and longitudinal method to quantitate this H202 after an acute kidney injury.

Methods: We created the following mice expressing the luciferase (luc) gene in a cell specific manner: Aquaporin2, HoxB7, Podocin, and E2a. Luc cell-specific reporter mice were injured by 30 min bilateral I/R and H202 activity imaged at 3, 6, 12 and 24 hrs after perfusion using an optical imaging system. Using a novel H202 sensitive caged-luciferin substrate, that only releases luciferin to react with luciferase in the presence of H202, we quantified cell specific changes of H202 after I/R.

Results: Aqp2-Luc, HoxB7-Luc, and E2a-Luc H202 activity peaked 6 hours after surgery while Podocin-Luc2 showed increasing H202 activity after 24 hrs. At the peak, E2a-Luc2 mice, the global luciferase expressers, had 10^8 increase in H202-luminescent flux while both Aqp2-Luc2- and HoxB7-Luc2 both had 10^6 increase in H202-luminescent flux. Podocin-Luc2 mice had log orders less increase in H202-luminescent flux within the 24 hr reperfusion period.

Conclusions: For the first time, we demonstrate the feasibility of quantifying kidney ROS non-invasively and longitudinally in the living animal in a cell-type specific manner. These early data reveal that the cells of the nephron and the collecting duct have logarithmic order differences in ROS generation after AKI. Here we prove that the ability to monitor H202 generation non-invasively in a cell-specific manner will permit the identification of cell-types susceptible to OS during an AKI and ultimately lead to mapping the time-course of kidney OS. This is a powerful new system to better understand the pathophysiology of renal disease progression and to test the specificity and efficacy of novel therapeutics.

Interleukin(IL)-36 Axis Is Modulated in Mice Acute Kidney Injury Model and Human Urine Hirofumi Nishikawa, Naoki Arima, Tatsuki Matsumoto, Yoshiko Shimamura, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Shimpei Fujimoto, Yoshio Terada. *Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan.*

Background: IL-36 is a newly named cytokine of the IL-1 cytokine family comprising three members, IL-36α, IL-36β and IL-36γ. All three IL-36 isoforms bind to a heterodimer consisting of IL-36 receptor (IL-36R). IL-36 axis plays roles in inflammation in psoriasis. However, little is known about the role of IL-36 axis in acute kidney injury (AKI) pathogenesis.

Methods: We evaluated the role of IL-36 in renal function in bilateral renal ischemia (28 min)/reperfusion injury (IRI) model using IL-36R knock-out (KO) and wild type (WT) mice. We evaluate the localization of IL-36R in WT mice kidney by confocal microscopy. Plasma was evaluated creatinine (PCr), BUN, IL-6 and kidneys were prepared for histology. Total kidney tissue mRNA was measured by RT-qPCR. The effects of IL-36α on NF-κB and Erk activities were examined in cultured renal tubular cells. In clinical study, we measured urine IL-36α in AKI patients, and immunohistological examination of IL-36α in AKI and minimal change renal biopsy sample.

Results: IL-36R was expressed in mainly proximal tubules in WT mice. IL-36R KO mice had significantly lower PCr (0.41+0.12 versus 1.08 + 0.21 mg/dl), BUN (65.3+14.8 versus 158+31.5 mg/dl) and IL-6 (24.3 + 5.7 versus 39.6+7.9 pg/ml) at 24h after IRI compared to WT. Immunohistological examination showed mild tubular injury in IL36R KO mice compared to WT mice. IL-36α, IL-36β, and IL-36γ expression were up-regulated at 24h post IRI. IL-36α expressions were observed at neutrophil (7/4+) and proximal tubules. IL-6 and TNF-α expressions after AKI were lower in IL36R KO mice compared to WT. In vitro experiments, up-regulation of NF-κB and Erk activity was observed by IL-36α in NRK-52E cells. Urinary IL-36α levels and renal staining of IL-36α were increased in AKI patients (n=7).

Conclusions: These data demonstrate that IL-36 axis plays pathological roles IRI induced mice AKI. IL-36α is up-regulated in renal tissue not only mice AKI but also human AKI. These results indicate that IL-36 blockage could be a potential therapeutic target of AKI.

Dysregulated Chromogranin A Expression in Acute Kidney Injury
Saiful A. Mir, Jacob Story, Anneke Arlene Stenger, Linda Awdishu, Prabhleen Singh, Ravindra L. Mehta, Sucheta M. Vaingankar. *Medicine, Univ of California at San Diego, La Jolla, CA.*

Background: Chromogranin A (CHGA) is a component of the adrenergic pathway and the index granin protein in dense core vesicles of the adrenal medulla and sympathetic axons. It is co-stored and co-released with catecholamine and is elevated in human hypertension and renal failure. Hypertension is a complication associated with AKI, therefore CHGA expression was investigated in AKI patients. Mouse model over-expressing CHGA was employed to understand the consequence of dysregulated CHGA expression.

Methods: Serum samples from AKI patients and healthy controls were tested for CHGA expression and kidney injury biomarkers by multi-plex and elisa assays. Mouse models 'humanized' for the *CHGA* loci expressing *CHGA* at normal and excess levels were phenotyped for BP and HR by telemetry; eGFR; adrenal ultrastructure and *in vivo* and *in vitro* analysis of dense core vesicles.

Results: Sympathetic over-activity established by higher BP, HR and circulating CHGA accompanied elevated creatinine, albumin, b-2 microglobulin, cystatin C, NGAL, NAG, KIM-1 in AKI patients. Mice mimicking this human phenotype of elevated CHGA, also displayed higher BP and HR contrasting with mice expressing normal levels of CHGA. The adrenal medullary cells of mice expressing excess CHGA showed an increase in total number and size of vesicles and mitochondrial abundance. This resulted in elevated expression of electron transport chain enzymes but surprisingly 2-fold decrease in ATP. This was delineated to be due to higher expression of mitochondrial uncoupling protein 2 (UCP2). This was recapitulated *in vitro* in which, CHGA overexpression in the PC12 cell line, caused upregulation of UCP2.

Conclusions: CHGA the catecholamine storage protein is elevated in the circulation of AKI patients and has predictive potential for consideration as a biomarker for the disease. The physiological consequences of elevated CHGA is increased adrenergic tone in humans and mice. We hypothesize that elevated CHGA disrupts mitochondrial electron transport chain causing ATP decline through the upregulation of UCP2 protein.

JNK Signaling in the Proximal Tubule Is Critical for Renal Ischaemia Reperfusion Injury
Keren Grynberg,[1,2] Elyce Ozols,[1,2] William R. Mulley,[1,2] Frank Yuanfang Ma,[1,2] David J. Nikolic-Paterson.[1,2] *[1]Nephrology, Monash Medical Centre, Clayton, VIC, Australia; [2]Dept of Medicine, Monash Univ, Clayton, VIC, Australia.*

Background: Activation of the JNK signalling pathway in tubular epithelial cells is evident in most forms of acute and progressive renal injury, including renal I/R injury. However, the specific contribution of tubular JNK signalling in kidney disease remains to be established. Kidney cells express the two main JNK isoforms (Jnk1 and Jnk2), with considerable redundancy. We created mice lacking the *Jnk1* gene in proximal tubules (via gamma-glutamyl transpeptidase Cre) with global *Jnk2* gene deletion (termed Jnk^{PT}). These mice are viable with normal kidney structure and function but lack JNK expression in the S3 segment of the proximal tubule.

Methods: Bilateral warm I/R injury was induced in groups (n=8) of; Jnk^{PT}, $Jnk2^{-/-}$, and wild type (WT) mice. Mice were killed 24hr after I/R surgery. Controls underwent sham surgery.

Results: Renal I/R injury caused acute renal failure in both WT and $Jnk2^{-/-}$ mice (178±6 and 170±23 umol/L serum creatinine, respectively; both $P<0.001$ vs 12±4 umol/L in sham operated). In contrast, Jnk^{PT} mice undergoing I/R showed marked protection from renal failure (61±21 umol/L; $P<0.01$ vs other I/R groups). This protection was associated with reduced tubular damage [79±3% WT, 75±4% $Jnk2^{-/-}$, 61±8% Jnk^{PT}; $P<0.01$ vs other I/R groups and a 35% reduction in KIM-1 mRNA levels in JNK^{PT} vs other I/R groups; $p<0.05$]. A 60% reduction in infiltrating neutrophils and a 40% reduction in macrophages was evident in JNK^{PT} vs other I/R groups ($p<0.01$). Up-regulation of mRNA levels for pro-inflammatory molecules (CCL2, NOS2, IL-6) was substantially reduced in JNK^{PT} vs other I/R groups ($p<0.05$).

Conclusions: This study establishes that JNK signalling in proximal tubular epithelial cells plays a critical role in cell damage and renal dysfunction in acute I/R injury.

P2X7 Receptor Activation Induces Renal Tubular PAD4 to Exacerbate Ischemic AKI
H. Thomas Lee,[1] Mihwa Kim,[1] Vivette D. D'Agati,[2] May M. Rabadi.[1] *[1]Anesthesiology, Columbia Univ, New York, NY; [2]Pathology, Columbia Univ, New York, NY.*

Background: Acute kidney injury (AKI) due to ischemia and reperfusion (IR) is a major clinical problem without effective therapy. We recently demonstrated that peptidylarginine deiminase-4 (PAD4) is induced after renal IR to exacerbate ischemic AKI. Moreover, ATP is a recently recognized DAMP molecule and exacerbates ischemic AKI via P2X7 purinergic receptor (P2X7R) activation. Here, we tested the hypothesis that ATP released from necrotic kidney cells activates P2X7R to induce renal tubular PAD4.

Methods: To test whether ATP induces renal tubular PAD4, cultured mouse or human proximal tubule cells were treated with vehicle, with 0.5-1mM ATP or with 100-500μM ATPγS for 1-24hr. To determine whether P2X7R is involved in ATP-mediated PAD4 induction, some proximal tubule cells were pretreated with 20μM A804598 (a selective P2X7R antagonist) before ATP treatment or treated with 50μM BzATP (a selective P2X7R agonist) in lieu of ATP. To determine whether P2X7R activation directly exacerbates ischemic AKI by inducing PAD4, PAD4 WT or PAD4 KO mice were pretreated with 5mg/kg BzATP or with vehicle 24 hr prior to 20 min renal IR injury.

Results: ATP and ATPγS induced PAD4 expression and activity in mouse and human renal proximal tubule cells. Implicating a critical role for P2X7R activation, A804598 blocked and BzATP mimicked the ATP-mediated induction of renal tubular PAD4, respectively. Consistent our *in vitro* findings, BzATP significantly increased mouse kidney PAD4 expression and activity *in vivo*. Supporting a critical role for PAD4 in ischemic AKI, PAD4 KO mice were protected against ischemic AKI (Cr(mg/dL)=0.6±0.1, N=5) when compared to PAD4 WT mice (Cr=1.4±0.2, N=5). Finally, supporting a critical role for P2X7R-mediated induction of PAD4 in the pathogenesis of ischemic AKI, pretreatment with a selective P2X7R agonist BzATP exacerbated ischemic AKI in PAD4 WT mice (Cr=2.4±0.3, N=5) but not in PAD4 KO mice (Cr=0.7±0.2, N=5).

Conclusions: Taken together, our studies show that ATP via P2X7R activation induces renal tubular PAD4 *in vitro* and *in vivo*. We also show here a critical role for P2X7R-mediated exacerbation of ischemic AKI via induction of PAD4.

Benefit of Mineralocorticoid Receptor Antagonism in Acute Kidney Injury (AKI): Role of Smooth Muscle Rac1
Jonatan Barrera-Chimal,[1] Gwennan André-Grégoire,[1] Sonia Prince,[1] Peter Kolkhof,[2] Vincent Sauzeau,[3] Frederic Jaisser.[1] *[1]INSERM, U1138, Centre de Recherche des Cordeliers, Paris, France; [2]BAYER Pharma AG, Cardiology Research, Wuppertal, Germany; [3]INSERM U1087, CNRS U6291, l'Inst du Thorax, Nantes, France.*

Background: Renal ischemia/reperfusion (IR) is a major cause of AKI. The benefit of novel non-steroidal MR antagonists such as finerenone in the IR context has not been evaluated and the mechanisms underlying the benefit of MR antagonism remain unclear. Here we tested the efficacy of finerenone in ischemic AKI and to evaluate the specific contribution of the MR expressed in endothelial or smooth muscle cell (SMC) in renal IR injury.

Methods: We included 18 male C57/B6 mice that were divided in: sham, renal ischemia for 20 min and IR plus treatment with finerenone (10 mg/kg) by gavage once a day at -48, -24 and -1 h before IR. Alternatively, MR inactivation in endothelial cells (MR^{endoKO} mice / Vecadh-cre) or in smooth muscle cells (MR^{SMCKO} mice/SMA-cre) was induced in 3-month-old mice. Sham surgery or bilateral renal IR for 20 min was performed and mice were studied 24 h after reperfusion. Primary rat SMC cultures were used to assess the signaling pathways modulated by MR.

Results: In C57/B6 WT, $MR^{fl/fl}$ and MR^{endoKO} mice, IR induced kidney dysfunction and tubular injury. After IR, Finerenone-treated mice and the MR^{SMCKO} mice presented normal renal function and a significant reduction of histological alterations, while MR^{endoKO} mice were not protected. The benefit of finerenone and MR KO in SMC was associated with reduced oxidative stress-mediated lipid peroxidation as compared to $MR^{fl/fl}$ or WT mice. In aldosterone-stimulated rat SMC, we observed a 100% increase in hydrogen peroxide production and a 2-fold increase in Rac1 activity; MR and Rac1 antagonism blunted these effects. Moreover, mice deficient of Rac1 in SMC were also protected against ischemic AKI.

Conclusions: Finerenone limits renal injury induced by IR. Moreover, genetic deletion of MR in SMC only has similar effects. This benefit was associated with reduced oxidative stress, by affecting oxidative stress production via SMC Rac1.

Renal Afferent Neurons Are Altered by Lipopolysaccharides
Kristina Rodionova,[1] Tilmann Ditting,[1] Sonja Loosen,[1] Christian Ott,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[2] Roland Veelken.[1] *[1]Medical Dept 4, Univ of Erlangen, Erlangen, Bavaria, Germany; [2]Nephropathology, Univ of Erlangen, Erlangen, Bavaria, Germany.*

Background: Sympathetic renal nerve activity (RSNA) is increased in lipopolysaccharide (LPS)-induced SIRS probably due to altered properties of renal afferent nerves (RANs), which exert complex sympatho-modulatory and paracrine effects. We tested the hypotheses that LPS alters the firing patterns and acid dependant inward currents in cultured renal neurons as well as CGRP release from afferent renal nerves.

Methods: In rats treated with LPS (E.coli O127/B8,20mg/kg iv) blood pressure (BP), heart rate (HR)and RSNA were measured. Dorsal root ganglion neurons (Th11-L2) of rats with renal afferents were cultivated and incubated with LPS 12h before patch clamp recordings. Inward currents were assessed during neuronal stimulation with protons (pH 6,9 and 5,0). Current clamp recordings were also done after 12h LPS-incubation and in controls. Neurons were characterized as tonic, i.e. sustained AP firing or phasic, i.e.<5 APs in response to current injections. In an organ bath of kidney slices (with/without LPS) Capsaicin, a TRPV1 receptor agonist, was used to induce CGRP release.

Results: LPS induced high increases of RSNA (+250%, $p<0.05$) and HR (+25%, $p<0.05$), BP remained unchanged. Under control conditions, acidic superfusion of 246 renal neurons was followed in 59% by tonic firing patterns, a portion that were significantly reduced to 49 % after LPS exposure ($p<0,05$) suggesting altered sympathetic control by renal afferents in vivo. LPS exposure significantly increased acid dependant inward currents in renal neurons (-793,18+/-66pA vs.-1224+/-200pA,$p<0,05$) putatively involved in paracrine functions of neurons. Neurogenic CGRP release from kidney slices due to capsaicin was significantly increased after LPS incubation (LPS: 58+20 pg/ml, control: 14+2, $*p<0.05$).

Conclusions: LPS significantly decreased the ease of AP production of renal neurons while the responsiveness to acidic milieu was increased. Neurogenic renal CGRP release was also increased by LPS. These finding may contribute to the complex sympatho-paracrine alterations seen in SIRS affecting kidney and the cardiovascular system.

Resolvin D1 Modulates Renal Cell Apoptosis in Lipopolysaccharide-Related Acute Kidney Injury Yuliang Zhao, Ping Fu. *Nephrology, West China Hospital, Chengdu, Sichuan, China.*

Background: Resolvin D1 (RvD1) is a newly found anti-inflammatory bioactive compound derived from polyunsaturated fatty acids. Our previous research revealed a renal protective effect on Lipopolysaccharide (LPS) -related AKI of RvD1 by down-regulating NF-κB signaling pathway. The current study aims to observe the influence of RvD1 on renal cell apoptosis during LPS-related AKI *in vivo* and *in vitro*.

Methods: Male BALB/c mice and human proximal tubule epithelial cells (HK-2) were randomly divided into control group (saline), LPS group (LPS) and RvD1 group (LPS+ RvD1) and blockage group (LPS+ RvD1+Boc-MLP). Boc-MLP is a RvD1 receptor blocker. The drugs were intraperitoneally injected or added into culture medium at targeted concentrations. The mice kidneys and HK-2 cells were harvested at different time points respectively.

Results: In *in vivo* experiment, RvD1 inhibited the up-regulation of Bax/Bcl-2 mRNA ratio by LPS, which was mitigated in blockage group. LPS activated the expression of Caspase-3 mRNA in mice kidney, but RvD1 inhibited its activation. TUNEL staining indicated RvD1 suppressed cell apoptosis in mice kidney. In *in vitro* study, RvD1 was effective in down-regulating Caspase-3 mRNA expression in renal tubular epithelial cells. Interestingly, RvD1 also increased Bax/Bcl-2 mRNA ratio. Flow cytometry recorded a higher proportion of apoptosis in RvD1 group than in LPS group (P=0.002) and control group (P<0.001)(figure 1).

Conclusions: In LPS-related AKI, the effect of RvD1 on renal cell apoptosis is complex. RvD1 imposed a pro-apoptotic influence directly on tubular epithelial *in vitro*, while showing a general anti-apoptotic effect *in vivo. T*he underlying mechanism needs further research.

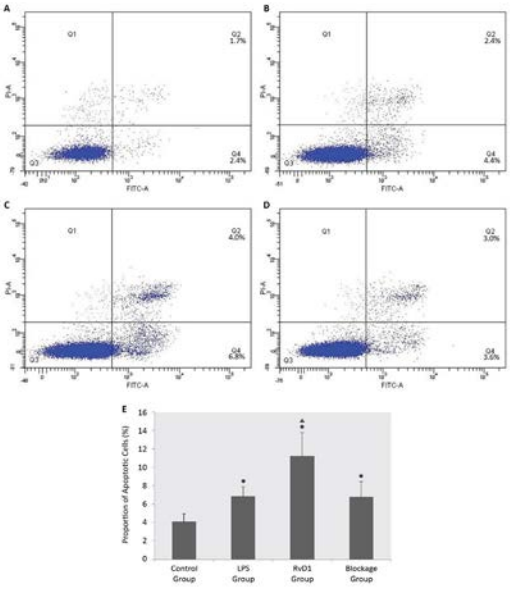

Figure 1. flow cytometry of HK-2 cell apoptosis (A: control group; B: LPS group; C: RvD1 group; D: blockage group; *indicates P<0.05 compared with control group; Δindicates P<0.05 compared with LPS group; time point: 24h).

TH-PO120

Shikonin Elicits a Nephropreventive Effect in a Murine Model of LPS-Induced Septic AKI by Triggering Nrf2 Activation with Anti-Oxidative Responses Go Yoneda,[1] Madoka Kawara,[1] Yuko Yamamoto,[1] Rika Matsunaga,[1] Hirofumi Jono,[1,2] Hideyuki Saito.[1,2] *[1]Dept of Clinical Pharmaceutical Sciences, Kumamoto Univ Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Dept of Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.*

Background: Sepsis-induced AKI is developed frequently in the patients with decreased immunocompetence, resulting in severe renal failure. For the effective treatment of septic AKI, infusion therapy and/or anti-inflammatory treatments are provided, however, the efficacy is insufficient to reach recovery of survival rates, requiring development of therapeutics. Shikonin is a naturally occurring herbal medicine extracted from the red-root gromwell, possessing proteasome inhibition and antioxidant effects. The present study explored a preventive effect of shikonin against LPS-induced septic AKI and its molecular events.

Methods: Septic AKI was induced in C57BL mice with intraperitoneally administration of LPS (20 mg/kg). Shikonin (5 mg/kg) was administered intraperitoneally to mice 1 h before the LPS treatment. Development of AKI, Nrf2 expression and anti-oxidant responses (HO-1 and NQO1) in LPS-treated mice with or without shikonin were compared 48 hr after the treatment.

Results: Survival rates of LPS-treated mice and LPS & shikonin-treated mice were 36 and 82%, respectively. Histochemical examination revealed that glomerular and tubular injuries in LPS-mice was partially restored by shikonin treatment. Serum levels of creatinine (SCr), BUN, IL-6 and TNF-α were markedly elevated in LPS-mice. Shikonin treatment resulted in significant decreases in the elevated SCr (P<0.05), BUN (P<0.05), and serum levels of IL-6 (P<0.01) and TNF-α (P<0.01). Shikonin significantly suppressed serum hydroperoxide and malondialdehyde levels evoked by LPS treatment. Shikonin treatment induced a marked expression of Nrf2 protein in the nuclear fraction of kidney, which was associated with a significant induction of mRNA expressions of HO-1 (P<0.01) and NQO1 (P<0.01) in LPS-mice kidney.

Conclusions: These results suggested that shikonin could have a renopreventive potency against septic AKI, at least in part, through the transient activation of renal Nrf2 followed by the downstream antioxidant responses.

TH-PO121

Paricalcitol Pretreatment Attenuates Lipopolysaccharide-Induced Inflammation in Human Renal Proximal Tubule Cells through the EP4 Receptor Yu Ah Hong, Yoon-Kyung Chang, Cheol Whee Park, Chul Woo Yang, Suk Young Kim, Hyeon Seok Hwang. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Republic of Korea.*

Background: Paricalcitol is thought to exert protective effects on various renal diseases, but the underlying molecular mechanism remains unclear. We investigated whether paricalcitol attenuates renal proximal tubule cell injury after lipopolysaccharide (LPS)-exposure, and evaluate the prostaglandin E_2 receptor (PGE_2) EP4 pathway as an anti-inflammatory mechanism of paricalcitol.

Methods: Human renal tubular epithelial cells (HK-2 cells) were exposed to LPS with or without paricalcitol pretreatment. The effects of paricalcitol and its protective mechanisms were investigated using EP4 antagonist or small interfering RNA EP4.

Results: Paricalcitol pretreatment significantly increased the expression of vitamin D receptor and cyclooxygenase-2 in LPS-exposed HK-2 cells. The PGE2 and cellular membrane expression of EP4 was increased in paricaliol-treated cells. Paricalcitol prevented cell death induced by LPS exposure, and the co-treatment of EP4 antagonist offset these cell-protective effects. The phosphorylation and nuclear translocation of p65 nuclear factor-κB (NF-κB) were decreased in LPS-exposed cells with paricalcitol pretreatment. EP4 antagonist and EP4 siRNA reversed the inhibitory effects of paricalcitol on p65 NF-κB nuclear translocation.The production of regulated upon activation normal T cell expressed and secreted (RANTES), tumor necrosis factor-a (TNF-a), interleukin-1b (IL-1b), interferon-g (IFN-γ), and macrophage inflammatory protein-1a (MIP-1a) were attenuated by paricalcitol pretreatment in LPS-exposed HK-2 cells. The co-treatment with EP4 antagonist abolished all of these suppressive effects on inflammatory cytokine productions.

Conclusions: Paricalcitol prevents LPS-induced renal proximal tubule cell injury, and EP4-dependent pathway isone of the anti-inflammatory mechanisms of paricalcitol.

TH-PO122

Curcumin Therapy Attenuates the Severity of Acute Kidney Injury in a Mouse Model of Hepatorenal Syndrome Type 1 Sindhura Bobba, Manoj Das, Siddhartha S. Ghosh, Todd W. Gehr, Daniel E. Carl. *Div of Nephrology, Virginia Commonwealth Univ Health System, Richmond, VA.*

Background: Hepatorenal syndrome (HRS) type 1 is a life threatening complication of cirrhosis with limited therapeutic options. We hypothesized that Curcumin will attenuate severity of HRS by improving intestinal barrier function, via tight junctions (TJ). We tested this hypothesis in a mouse model of HRS. TJ proteins, such as Zonula occludens protein-1 (ZO-1), are responsible for restricting the paracellular movement of compounds across the intestinal mucosa. Therefore, impaired intestinal barrier function can result from decreased TJ protein expression.

Methods: C57BL/6 mice received 1ml/kg of carbon tetrachloride (CCl4) biweekly for 12 weeks to induce cirrhosis. A 6 mg/Kg of Lipopolysaccharide (LPS) was given intraperitoneally to induce acute kidney injury by simulating the inflammatory stressor caused by acute infection. Curcumin 100mg/ kg body weight was co-administered with CCL4 for 4 weeks. Four mouse populations were studied: (1) control mice (2) CCl4 treated mice (3) CCl4 + LPS mice (4) CCl4+LPS+curcumin mice (N=4 per group). Urine output, urinary sodium, and serum creatinine (SCr) were measured 10 hrs after LPS. Mice intestines were homogenized, and ZO-1 expression determined by western blot.

Results: Control and CCl4 treated mice showed no change in renal function. CCL4+LPS treated mice had renal phenotype suggestive of HRS, including a higher SCr, lower UNa and UOP compared to CCL4 mice (p<0.05). Moreover, CCl4+LPS+curcumin treated mice had a significant improvement in renal function (p<0.05) compared with CCl4+LPS mice. ZO-1 protein expression was significantly low (p<0.05) in both CCL4 and CCL4+ LPS groups compared with control. ZO-1 expression was significantly increased (p<0.05) in CC4+LPS+ curcumin mice compared to CCL4+LPS.

Conclusions: CCL4 induced cirrhotic and in CCL4+LPS (HRS) mice have decreased ZO-1 protein expression compared to controls. Curcumin administration attenuates the severity of AKI in this mouse model of HRS. Moreover, the expression of ZO-1 protein was increased in this cohort of mice, suggesting improved intestinal barrier function compared to cirrhotic and HRS mice.

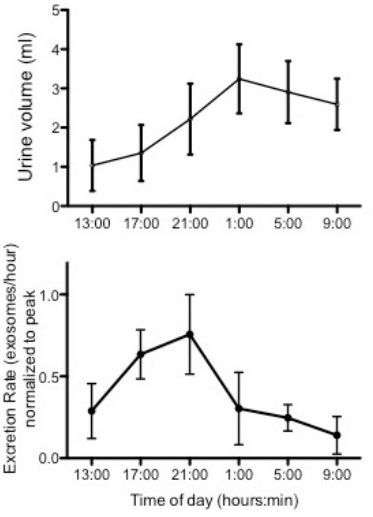
TH-PO123

Urine Exosome Excretion Varies Diurnally in Rats Erik H. Koritzinsky, Jonathan Street, Robert A. Star, Peter S.T. Yuen. *NIDDK, Bethesda, MD.*

Background: Urine exosomes are a promising source of non-invasive biomarkers for kidney health. Kidney transport and function have circadian patterns. Normalization by urine creatinine is thought to account for most physiologic diurnal variation in kidney function, allowing for diagnosis using a spot urine collection rather than a timed 24 hr collection. It is unknown if urine exosome excretion similarly varies throughout the day in normal animals.

Methods: Timed 4-hour urine collections were obtained from healthy, untreated male SD rats over a 24 hour period with free access to food and water and housed in a facility with a 24 hr light/dark cycle [Light: 6AM – 6PM; Dark: 6PM – 6AM]. Exosomes were isolated from 4 hr urine fractions by ultracentrifugation. Quantification of exosome concentration (number/mL) was assessed by Nanosight analysis. Because of variability in total 24 hr urine exosome excretion rate between animals, hourly exosome excretion rates for each 4-hour fraction were normalized to peak exosome excretion in each animal.

Results: The normalized urine exosome excretion rate increased during the light period, peaking at the start of the dark period, then subsequently fell during the dark period. The observed circadian pattern of exosome excretion did not temporally correspond to that of urine flow rate. The relative amplitude of the variation (peak to trough ratio) was 5.4-fold for exosome excretion and 3.85-fold for urine flow.



Conclusions: Urine exosome excretion in rats displayed a circadian pattern that was not directly linked to that of urine flow. Because of a large daily variation in normal urine exosome excretion rates, the time urine of collection must be considered. Prospective urine exosomal biomarkers should be evaluated for circadian rhythms. As exosomes serve as a form of cell-cell communication in other contexts, the functional significance of this circadian pattern in urine exosome excretion is unknown.

TH-PO124

Enrichment of miR192 in Urinary Exosomes following Ischemia-Reperfusion Injury in Rats Erik H. Koritzinsky, Jonathan Street, Tiffany R. Bellomo, Hua Zhou, Robert A. Star, Peter S.T. Yuen. *NIDDK, Bethesda, MD.*

Background: We previously identified urine exosomal miR192 as a candidate biomarker for renal ischemia-reperfusion injury in rats (Zhou et al, ASN 2008). Two hypotheses arose from these observations: a) the number of exosomes were increasing with a constant abundance of miR192 or b) the number of exosomes was relatively unchanged with an increased abundance of miR192 per exosome. We used Nanosight analysis to determine exosome number, and then measured the temporal excretion of exosomes by collecting timed urine fractions.

Methods: Male Sprague-Dawley rats (250-290 g) underwent bilateral ischemia-reperfusion injury (IRI) with a 40 minute clamp. Acute kidney injury was confirmed by a rise in BUN 24 hours after surgery. Urine was collected in metabolic cages for 24 hours before (baseline) and immediately following IRI surgery. Six 4-hour urine samples were collected by an automated fraction collector. Urinary exosomes were isolated by ultracentrifugation. After isolation of miRNA by miRNeasy, the absolute concentration of miR192 was determined by RT-qPCR using purified, synthetic miR192. The concentration of exosomes was determined by Nanosight analysis.

Results: Exosomal excretion rate varied from 6.89 x 10^9 to 1.04 x 10^{11} exosomes per hour and was not significantly different between baseline and post-AKI, nor across the 24 hour period. Similarly, miR192 excretion rate was not significantly different between baseline and AKI, nor across the 24 hour period. However, the number of miR192 molecules per exosome increased at the earliest time point, and persisted throughout the 24 hr period ($p<0.05$). The average number of miR192 molecules/exosome over the 24 hour collection after ischemia-reperfusion was 62-fold higher than baseline ($p<0.05$).

Conclusions: Ischemia-reperfusion injury does not significantly change exosome excretion rates, nor does it significantly change the excretion of miR192; however, the abundance of miR192 per exosome increases 62-fold, consistent with an enrichment of miR192 within urinary exosomes.

Stoichiometry of the Protein TSG101 in Urine Exosomes Erik H. Koritzinsky,[1] Jonathan Street,[1] Tiffany R. Bellomo,[1] Angel M. Aponte,[2] Robert A. Star,[1] Peter S.T. Yuen.[1] *[1]NIDDK, Bethesda, MD; [2]NHLBI, Bethesda, MD.*

Background: Novel biomarkers for kidney health, including miRNAs, have been identified in urine exosomes. Surprisingly, miRNAs are stoichastically present in a small fraction of biofluid-derived exosomes (≤1%), making miRNA unsuitable to normalize exosomal biomarkers. As TSG101 is a protein in the ESCRT complex involved in exosome biogenesis, it is assumed to be present in exosomes in high copy number, and thus is commonly used as a surrogate marker for exosome number. However, the number of molecules of TSG101 per exosome is not known, nor is it known to be constant.

Methods: Spot urine samples were obtained from 7 healthy volunteers (3 M, 4 F; Age 21-55) then treated with protease inhibitors. Urine exosomes were isolated by ultracentrifugation. Absolute quantification of molecules of exosomal TSG101/mL was assessed by Western blot using a 4 point dilution series (standard and samples) with a TSG101 standard of known concentration. Quantification of exosome concentration (number/mL) was assessed by Nanosight Nanoparticle Tracking Analysis.

Results: In 7 healthy adults, values ranged from 4.39x10^9 to 7.87x10^{10} exosomes/mL urine and 3.37x10^{10} to 1.08x10^{12} exosomal TSG101 molecules/mL urine. The stoichiometry of molecules of TSG101 per exosome in urine averaged 10.2 ± 4.0 (SD) copies per urine exosome (range of 5.2 to 15.8).

[Exosome] (number/mL urine)	[Exosomal TSG101] (molecules/mL urine)	TSG101 Molecules/Exosome
7.67 x 10^{10}	1.08 x 10^{12}	13.4
7.87 x 10^{10}	4.34 x 10^{11}	5.2
4.06 x 10^{10}	4.72 x 10^{11}	11.8
2.40 x 10^{10}	1.93 x 10^{11}	6.9
4.39 x 10^{9}	3.37 x 10^{10}	6.6
1.07 x 10^{10}	1.45 x 10^{11}	15.8
1.94 x 10^{10}	2.02 x 10^{11}	11.3

Conclusions: Exosome concentration and TSG101 concentration varied 18-fold and 32-fold from person to person, but the stoichiometry of TSG101 per urine exosome was relatively stable across healthy human subjects. There were ~10 TSG101 molecules/urine exosome. TSG101 may be a valid surrogate for exosome number to normalize urine exosomal biomarkers. Normalization using TSG101 is easier and less costly than Nanosight analysis, and easier to interpret than normalization using miRNA.

Urinary Activin A: A Novel Urinary Biomarker for Acute Kidney Injury Shunsuke Takahashi, Akito Maeshima, Yoshinori Takei, Masao Nakasatomi, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: Activin A, a member of TGF-β superfamily, is known to regulate cell growth and differentiation in various tissues. We previously reported that activin A, which was absent in normal kidney, was increased in the post-ischemic rat kidney and negatively regulates the repair process of renal tubules after injury (Maeshima et al. JASN 2001). This study was conducted to examine whether activin A can be detected in the urine from mice with renal ischemia-reperfusion injury and patients with acute kidney injury (AKI).

Methods: Ischemia-reperfusion injury was induced in C57BL/6 mice. Mice were sacrificed at 6, 24, 48, 72, 120 hours after operation, and the kidneys and urine were collected for analysis. Urine samples were collected from ten patients with AKI as well as from eight healthy volunteers. Urinary activin A was measured by ELISA. Correlation of urinary activin A with urinary N-gal, urinary KIM-1, and clinical parameters were analyzed.

Results: The expression of activin A was markedly up-regulated in the post-ischemic mouse kidney. Immunoreactive activin A was detected in KIM-1-positive proximal tubular cells of the outer medulla in ischemic kidneys, but not in normal kidneys. Activin A was absent in the urine of normal mice. In contrast, activin A was detectable in the urine of ischemic mice. Urinary activin A was almost undetectable in healthy volunteers, but was significantly increased in patients with AKI (9.6 ± 2.3 vs. 257.9 ± 174.6 ng/gCr, $p<0.001$). There was a significant correlation of urinary activin A level with urinary N-gal and follistatin (activin antagonist), but not with urinary KIM-1 or eGFR.

Conclusions: Activin A can be detected in the urine of patients with ATN and may serve as a useful biomarker for renal proximal tubule injury.

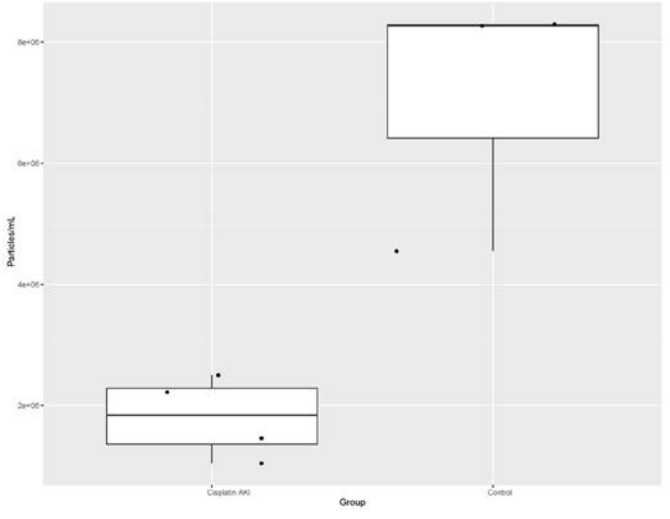
Profile of Urinary Microparticles in Cisplatin Nephrotoxicity in Mice Gabor Bodonyi-Kovacs, Christine Rudy, Thu H. Le, Uta Erdbruegger. *Renal Div, Univ of Virginia, Charlottesville, VA.*

Background: Acute kidney injury (AKI) is associated with increased mortality and risk of progression to chronic kidney disease. Its diagnosis is based on rising levels of serum creatinine - a late and nonspecific marker of reduced kidney function. Urinary microparticles (uMP) are candidate biomarkers for earlier and non-invasive diagnosis and prognosis of AKI. We hypothesized that a distinct uMP profile characterizes cisplatin-induced AKI.

Methods: 11-19 week old 129S6 male mice received either ip. injection of 25 mg/kg cisplatin or equal volume of saline. Serum and urine were collected 72 hours later. Serum creatinine was measured using an enzymatic, colorimetric kit (Crystal Chem). Urine was frozen and stored in -80 C. A uMP pellet was generated from thawed urine with differential centrifugation. Enumeration and phenotyping of uMPs was performed with imaging flowcytometry using the following markers: podocalyxin (podocyte derived), Insulin-like growth factor-binding protein 7 (IGFBP7, inducer of G1 cell cycle arrest, implicated in AKI), collectrin (tubular cell marker) and Annexin V. Results were analyzed by a two sided t-test.

Results: The cisplatin treated mice had significantly elevated serum creatinine (n=4, 2.35 ± 0.54 mg/dl) compared to saline treated controls (n=4, 0.1 ± 0.07 mg/dl), p=0.003. Animals with AKI had lower level of IGFBP7 positive microparticles compared to controls, 1.8 x 10^6 and 7 x 10^6 particles per ml respectively, (p=0.044), Figure 1.



Urinary concentrations of MPs stained with other markers were not statistically different between AKI and control groups.

Conclusions: Severe cisplatin induced AKI is associated with significantly lower IGFBP7 positive uMP levels. Future studies are needed to examine the diagnostic role of these vesicles in earlier stages of AKI and assess their potential mechanistic and prognostic roles.

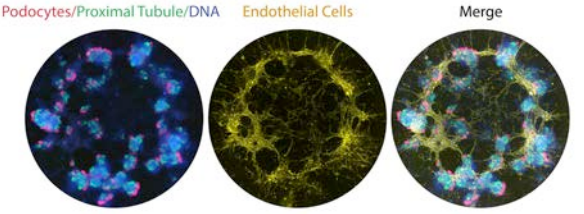
Differentiation of Human Kidney Organoids in High Throughput-Compatible Formats Modeling Nephrotoxic Injury Stefan Czerniecki, Ramila E. Gulieva, Laura V. Islas, Yong Kyun Kim, Neal A. Paragas, Benjamin S. Freedman. *Div of Nephrology, Kidney Research Inst, and Inst for Stem Cell and Regenerative Medicine, Dept of Medicine, Univ of Washington, Seattle, WA.*

Background: Kidney organoids derived from human pluripotent stem cells (hPSCs) are a potentially powerful tool for high throughput discovery, but their complexity poses a challenge for miniaturization and automation. We tested whether kidney organoids could be generated in high throughput formats for modeling nephrotoxicity.

Methods: hPSCs were seeded and differentiated in 96-well and 384-well plates both 1) manually, using multi-channel pipettors, and 2) automatically, using liquid handling robots to perform all steps. Kidney markers were characterized by high content imaging analysis, compared to kidney tissue sections. Injury biomarker induction was monitored in cisplatin-treated organoids by ELISA and immunofluorescence.

Results: Differentiation was robustly achieved in 96-well and 384-well formats with several hPSC lines using both manual and fully-automated protocols. Each 384-well contained ~ 30 miniature kidney organoids (~ 300 organoids/cm^2). Analysis of > 20 tubular and podocyte markers revealed transporters and nephron sublineages similar to developing kidneys. Cisplatin treatment induced 4-fold upregulation of kidney injury molecule 1 (KIM-1) in proximal tubules, using a high throughput-compatible assay.



Conclusions: hPSC-derived kidney organoids can be generated and analyzed in fully-automated, high throughput-compatible formats. Miniaturized cultures retain sufficient complexity to model nephrotoxicity in proximal tubules. High throughput compatibility, coupled with human specificity, makes this platform an attractive starting point for screening approaches focusing on therapeutic discovery, toxicology, and regenerative medicine. Probiotics Attenuate Progression of CKD via Expanding Tregs in Mesenteric Lymph Node Sang-Kyung Jo, Jihyun Yang, Sung Yoon Lim, Young Ju Na, Myung-Gyu Kim, Won-Yong Cho. *Dept of Internal Medicine, Div of Nephrology, Korea Univ Medical College, Seoul, Republic of Korea.*

Background: Emerging evidence showed the presence of kidney-gut crosstalk and alterations in intestinal barrier or dysbiotic gut microbiota have been demonstrated in diverse pathological processes including chronic kidney disease (CKD). Regulatory T cells (Tregs) exert anti-inflammatory effect and the decrease of Tregs has been shown to be associated with inflammatory phenotype and disease severity. The purpose of this study was to investigate the effect of probiotics on the progressive CKD and also the mechanisms.

Methods: CKD was induced in 6 week old C56BL/6 mouse by 5/6 nephrectomy. *Lactobacillus Rhamnosus* R0011 and *Lactobacillus Acidophilus* R0052 and proton pump inhibitor mixture were administered via oral gavage starting 1 day after the operation and continued for 8 weeks following intestinal decontamination. Biochemical, histological as well as flow cytometric analyses were performed at 4 weeks after 5/6 nephrectomy.

Results: Increased serum creatinine and substantial fibrosis in CKD mice were associated with increased plasma and kidney TNF-a, IL-6 level. In addition, significantly decreased percentage of mesenteric LN Tregs, colonic Foxp3 mRNA expression as well as increased colon epithelial cell apoptosis were observed in CKD mice. Treatment with probiotics resulted in significantly decreased serum creatinine level as well as kidney fibrosis. The beneficial effect on progressive CKD was also associated not only with reduction of systemic and kidney iniflammation, but also with partial expansion of mesenteric lymph node Tregs, increase of colonic Foxp3 expression and also decreased colon epithelial cell apoptosis.

Conclusions: This study first demonstrated that alteration of normal intestinal immune homeostasis (decreased Tregs in colon, mesenteric LN) and barrier disruption (colon epithelial cell apoptosis) was associated with inflammation, progression of CKD. Probiotics seem to be promising as one therapeutic strategy in progressive CKD via their immune modulatory mechanisms.

Toll-Like Receptor 4 Is Dominantly Expressed Compared to Toll-Like Receptor 2 and 9 in Kidneys of Patients with Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis Kim M. O'Sullivan,[1] Sharon Lee Ford,[1] A. Richard Kitching,[1,2] Stephen R. Holdsworth.[1,2] *[1]Centre for Inflammatory Diseases, Dept of Medicine, Monash Univ, Clayton, Australia; [2]Dept of Nephrology, Monash Health, Clayton, Australia.*

Background: Infections can initiate and exacerbate disease in patients with anti-neutrophil cytoplasmic antibody associated vasculitis (AAV). Toll-like Receptors (TLRs) may be the link between infection and autoimmunity. This study investigates the distribution of kidney TLR2, 4 and 9 and evaluates altered TLR expression in relation to the severity of renal injury.

Methods: Kidney biopsies from patients with a first presentation of AAV (38), Lupus (8), and controls (minimal change and thin membrane disease, 10) were examined by confocal microscopy for the distribution of TLR2, 4 and 9 and co-localized with CD34, CD68, CD15, nephrin, and TLR ligands fibrinogen and high mobility group box 1(HMGB1).

Results: AAV+ renal biopsies had significant glomerular and tubular expression of TLR2, 4 and 9 compared to controls (all, P<0.05). TLR2 and 4 co-localized with endothelial cells, podocytes and leukocytes, whereas TLR9 was predominantly expressed by podocytes. The functional relevance of TLR2, 4 and 9 expression was supported by the observation that TLR expression was co-localised with known endogenous TLR ligands HMGB1 and fibrinogen. Infiltrating neutrophils were highly positive for TLR4, however the largest degree of TLR staining was observed within intrinsic renal cells. The predominant glomerular TLR assessed by percentage area was TLR4 (31.2±3.8%), compared to TLR2 expression (5.2±1.9%) and TLR9 expression (13.5±2.1% P<0.0001). Tubulointerstitial TLR4 was significantly more expressed (29.3 ±3.3%) than TLR2 (9.1±1.8%) and TLR9 (17±2.5%, P<0.05). Glomerular TLR2 correlated with glomerular segmental necrosis (SN) (r=.44,

P<0.05) and TLR4 correlated with SN and cellular crescents (r= .57, P<0.01). Increased glomerular TLR 2 and 4 inversely correlated with presenting eGFR (r=-.39, P=0.02 and r=-3.9, P=0.01, respectively).

Conclusions: The extent of TLR4 expression correlates with renal injury and is the predominant TLR expressed within intrinsic renal cells, and may be a potential target for therapeutics.

Elevated Microparticle Tissue Factor Activity Predicts Venous Thromboembolism in ANCA Vasculitis Elizabeth J. Brant,[1,2] Carmen E. Mendoza,[1] Matthew L. Mcdermott,[1] Yichun Hu,[1] Susan L. Hogan,[1] J. Charles Jennette,[1] Ronald J. Falk,[1] Patrick H. Nachman,[1] Vimal K. Derebail,[1] Donna O. Bunch.[1] *[1]UNC Kidney Center; [2]Dartmouth-Hitchcock Medical Center.*

Background: Venous thromboembolism (VTE) is a complication of ANCA vasculitis (AAV). Mechanisms of VTE and the cells involved have not been elucidated, but tissue factor (TF)-bearing microparticles (MP) may play a role. We hypothesized that elevated microparticle tissue factor activity (MPTFa) is associated with VTE in AAV and explored the cellular source.

Methods: Patients without VTE (VTE^{neg}, n=21) were enrolled during active disease. Patients with VTE (VTE^{pos}, n=11) were included whether active or in remission at the time of VTE. Longitudinal platelet-free plasma samples were assayed for MPTFa and compared to 15 healthy controls (HC). Isolated MP were incubated with Factor VIIa and Factor X. Absorbance was measured after adding Factor Xa chromogenic substrate. Recombinant, relipidated human TF was the standard used to determine TF concentration. Values were expressed as percent relative to positive controls. Surface expression of TF was measured by flow cytometry. A Mann-Whitney test was used to compare continuous variables.

Results: Demographics were similar among patients and HC. VTE^{pos} and VTE^{neg} patients did not differ in ANCA serotype or titer, BVAS, D-dimer or other laboratory data, or organ involvement. VTE^{pos} patients had significantly higher peak MPTFa than VTE^{neg} patients (median 16.1 vs 3.4; p<0.0001). MPTFa of VTE^{neg} patients was similar to HC (2.4, p=0.3). Four of 6 VTE^{+} patients with available stored samples had elevated MPTFa within 6 months prior to VTE. VTE^{pos} patients had higher $\%TF^{+}$ $CD14^{+}$ monocytes than HC (median 19.9 vs 1.8; p=0.009), and $CD14^{+}CD16^{+}$ inflammatory monocytes than HC (23.8 vs 9.5; p=0.03) and VTE^{neg} patients (4.1, p=0.04). Our other preliminary in vitro data show that ANCA IgG triggers release of MP with TFa in HC blood.

Conclusions: Patients with AAV who develop VTE have increased MPTFa, whereas those without VTE rarely exhibit MPTFa higher than HC. Our data suggest that elevated MPTFa identifies AAV patients at high risk for VTE and that effects of ANCA IgG on monocytes may contribute to thrombogenesis.

Quantification of the Average Creatinine-Clearance and Proteinuria per Nephron in Murine Nephritic Kidneys by Tissue Clearing and Light Sheet Microscopy Christian Kurts.[1] *[1]Inst for Experimental Immunology, Rheinische Friedrich-Wilhelms-Univ, Bonn, Germany; [2]Inst for Experimental Immunology and Imaging, Univ Duisburg-Essen, Essen, Germany.*

Background: The number of nephrons is a fundamental parameter of kidney function, but very difficult to determine using standard methodology. This precludes analysis of kidney function per nephron.

Methods: Here we enumerated nephrons by a combination of in vivo fluorescence labeling of endothelial cells, a novel tissue clearing technique, light sheet microscopy and automated enumeration of glomeruli by a computer algorithm. Our clearing technique is superior to other reagents because of its non-toxicity and because its maintenance of fluorescence over weeks.

Results: The average creatinine-clearance per nephron declined already in the first week of murine nephrotoxic nephritis, whereas nephron numbers started doing so after day 7. Focal glomerular inflammation was accompanied by periglomerular accumulation of dendritic cells. Only inflamed glomeruli showed protein leakage, indicating that large proteinuria may result from damage to a few glomerular filters only. Finally, using a model of crystal proteinuria by alimentary adenine overload, we quantified the number of intrarenal microstones.

Conclusions: Our novel technique delivers fundamental parameters of renal function and should facilitate the analysis of various models of experimental kidney disease.

Myeloid-Specific Deletion of MRP8 Ameliorates Glomerulonephritis through Affecting Macrophage Characterization Takashige Kuwabara,[1,3] Kiyoshi Mori,[2] Manabu Hayata,[1] Shuro Umemoto,[1] Hideki Yokoi,[3] Masashi Mukoyama.[1,3] *[1]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Our previous report indicated that myeloid-related protein 8 (MRP8) and toll-like receptor 4 (TLR4) play an important role in diabetic nephropathy in mice. We observed that glomerular-infiltrated macrophages (Mφ) expressed MRP8 much more robustly than tubulointerstitial Mφ in diabetic mice, which has also been observed in human diabetic kidney and glomerulonephritis. However, these mechanisms and roles are still unknown.

Methods: We generated myeloid-lineage cell-specific conditional knockout mice (MRP8cKO), and induced experimental nephrotoxic glomerulonephritis (NTN). Co-culture of Mφ with mesangial cells (Mes) or proximal tubular cells (PT) was performed to investigate potential mechanisms of intraglomerular crosstalk. The effects of MRP8 on Mφ were evaluated with phalloidin staining in bone marrow-derived Mφ (BMDM) generated from MRP8cKO. Mφ were characterized as M1/M2 ratio determined by real-time PCR.

Results: Effective 60-80% reduction of MRP8 was achieved in target organs of MRP8cKO. Ablation of MRP8 in myeloid-lineage cells significantly ameliorated glomerulonephritis as indicated by proteinuria, glomerular exudative lesions and pro-inflammatory gene expressions in isolated glomeruli. In vitro study revealed that MRP8 expression in Mφ was dramatically induced by co-culture with Mes but not with PT. Such results were recapitulated by stimulation with Mes-cultured supernatant (Mes-sup). Mes-sup stimulation tended to increase M1/M2 less in BMDM generated from MRP8cKO than that from wild-type. M1/M2 was also significantly suppressed in isolated glomeruli of MRP8cKO NTN mice in vivo. Phalloidin staining of Mφ revealed that deletion of MRP8 resulted in less stress fiber formation.

Conclusions: Myeloid-lineage cell-derived MRP8 potentially contributes to glomerular injury through intraglomerular cell-cell crosstalk affecting Mφ characterization.

TH-PO134

NLRP3 Inflammasome Activation Contributes to Aldosterone-Induced Podocyte Injury Aihua Zhang,[1] Mi Bai,[1] Yue Zhang,[1] Zhanjun Jia,[2] Songming Huang.[1] *[1]Dept of Nephrology, Nanjing Children's Hospital affiliated to Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Lab of Pediatrics, Nanjing, China.*

Background: Recently, the pathogenic role of NLRP3 inflammasome in mediating renal tubular damage was identified, while its role in podocyte injury still needs evidence. Thus the aim of the present study was to investigate the role of NLRP3 inflammasome in aldosterone (Aldo)-induced podocyte damage.

Methods: Aldo was administered to the cultured podocytes and NLRP3 WT and KO mice. Renal biopsy specimens and urine samples from nephrotic syndrome patients were used to test the activation of NLRP3 inflammasome.

Results: In vitro, exposure of podocytes to Aldo enhanced NLRP3, caspase-1 and IL-18 expressions in dose and time-dependent manners by around 2 to 4 folds, respectively, indicating an activation of NLRP3 inflammasome. Silencing NLRP3 by a siRNA approach strikingly attenuated Aldo-induced podocyte apoptosis and nephrin protein downregulation in line with the blockade of caspase-1 activation and IL-18 production. In NLRP3 WT mice, since day 5 of Aldo-infusion, NLRP3 inflammasome activation and podocyte injury evidenced by nephrin reduction occurred concurrently. More importantly, immunofluorescence analysis showed a significant induction of NLRP3 in podocytes of glomeruli following Aldo infusion. In the mice with NLRP3 gene deletion, Aldo-induced downregulation of nephrin(-53%) and podocin (-50) and podocyte foot processes (electron microscopy) were largely diminished. Consistently, a 5-fold increase of urinary albumin output was blocked by 55% in the KO mice, indicating a protective role of NLRP3 deletion in Aldo-induced podocyte injury. Finally, we observed a striking induction of NLRP3 in both glomeruli and renal tubules in line with an enhanced urinary IL-18 output (around 5.5 folds) in nephrotic syndrome patients with pathological feature of MCD or FSGS.

Conclusions: These results demonstrated an important role of NLRP3 inflammasome in mediating the podocyte injury induced by Aldo.

ABIN1 Contributes to the Severity of Antibody-Mediated Glomerulonephritis via an Intrinsic Podocyte-Neutrophil Axis David W. Powell,[1] Erik Korte,[1] Dawn J. Caster,[1,2] David J. Salant,[3] Kenneth R. McLeish.[1,2] *[1]Nephrology, Univ of Louisville; [2]Dept of Veterans Affairs; [3]Boston Univ Medical Center.*

Background: Transcription factor (NF)-κB regulates expression of hundreds of genes that control inflammation and NF-κB is activated in glomerular cells in glomerulonephritis (GN). We previously identified genetic variants for a NF-κB regulatory, ubiquitin binding protein ABIN1 as risk factors for GN in autoimmune diseases. The goal of the current study was to determine if disruption of glomerular ABIN1 function contributes the development of GN.

Methods: Nephrotoxic serum nephritis (NTN) was induced in wild-type (WT) and ubiquitin binding null ABIN1[D485N] mice; and proteinuria, kidney pathology, glomerular leukocyte accumulation, and glomerular inflammatory mediator expression were assessed 24 hours post nephrotoxic serum injection. Proteinuria was also measured in ABIN1[D485N] mice transplanted with wild-type mouse bone marrow and following administration of recombinant TAT-SNAP-23 protein, an inhibitor of neutrophil degranulation. The interaction of neutrophils with WT and homologous ABIN1 mutant cultured podocytes was assessed by functional assays.

Results: Disruption of ABIN1 function exacerbated proteinuria, podocyte injury, glomerular expression of inflammatory mediators, and glomerular recruitment and retention of neutrophils, but not mesangial cell proliferation, in NTN. Bone marrow transplantation of WT bone marrow did not prevent increased proteinuria. TAT-SNAP-23 attenuated proteinuria and foot process effacement in WT and ABIN1 mice. TNF-stimulated supernatant from homologous ABIN1 mutant podocytes stimulated neutrophil chemotaxis and degranulation. Incubation with neutrophil granule contents disrupted cytoskeletal organization and morphology of ABIN1 mutant podocytes.

Conclusions: We conclude that ABIN1 dysfunction mediates a novel intrinsic podocyte-neutrophil inflammatory axis that determines the severity of podocyte injury in GN. Our data suggest that genetic regulation of podocyte NF-κB activity controls injury through release of cytokines that recruit neutrophils. Inhibition of neutrophil granule release is a novel therapeutic intervention for preventing podocyte injury in GN.

TH-PO136

Function of the Atypical Chemokine Receptor 2 in Murine Immune Complex Glomerulonephritis Andrei Bideak, Volker Vielhauer. *Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Univ, Munich, Germany.*

Background: The atypical chemokine receptor 2 (ACKR2), also named D6, is unable to induce cell signaling but can regulate local chemokine levels by internalization and degradation. Here we characterize the role of ACKR2 in murine autologous nephrotoxic nephritis (NTN).

Methods: NTN was induced in C57/BL6 wild-type and Ackr2-deficient mice by injection of sheep antibodies against mouse glomerular basement membrane.

Results: At 2 weeks Ackr2-/- mice showed increased albuminuria, serum creatinine and urea levels than wild-type controls. Histological analysis revealed increased structural damage in the glomerular and tubulointerstitial compartment of Ackr2-/- kidneys. By flow cytometry these findings correlated with a higher renal leukocyte infiltration of CD4+ T cells and mononuclear phagocytes in Ackr2-/- mice. As a possible cause, Ackr2-/- mice demonstrated higher levels of inflammatory chemokines CCL2 and CCL5 in nephritic kidneys. Further histological analysis revealed that increased leukocyte infiltration resulted from higher numbers of T cells and macrophages in the tubulointerstitial compartment of Akcr2-/- mice, whereas leukocyte numbers in glomeruli were comparable. Accordingly, in-vitro experiments with TNF-stimulated renal cells showed that increased chemokine levels in Ackr2-/- mice resulted from a reduced ACKR2-mediated chemokine degradation in the tubulointerstitial compartment. Furthermore, Ackr2-/- mice showed decreased T-cell activation resulting in a reduced adaptive cellular immune response.

Conclusions: These results are consistent with the known expression of Ackr2 in interstitial lymphatic endothelial cells, assuring efflux of activated leukocytes into locoregional lymph nodes. However, the decreased adaptive immune response did not result in decreased renal inflammation during NTN because of simultaneously increased tubulointerstitial chemokine levels and a higher renal leukocyte infiltration in Ackr2-deficient mice. Our data indicate that ACKR2 plays an important role in limiting renal inflammation in NTN and therefore identifies ACKR2 as a potential target molecule for therapeutic approaches in immune complex-mediated glomerulonephritis.

A Novel Targeting Strategy to Inhibit Deleterious TNF Signaling in Nephrotoxic Nephritis Rudolf Lucas, Maggie McMenamin, Nino Kvirkvelia, Supriya Sridhar, Maritza J. Romero, Istvan Czikora, Michael P. Madaio. *Vascular Biology Center and Dept of Medicine, Medical College of Georgia, Augusta Univ, Augusta, GA.*

Background: Activation of the p38 MAPK pathway by TNF in glomerular endothelial cells (GEC) represents a central mechanism of renal inflammation in nephrotoxic serum (NTS)-induced nephritis (NTN). Strategies to inhibit TNF receptor signaling, using neutralizing antibodies or soluble TNF receptors, can impair host defense to infection. In this study, we evaluated the therapeutic potential of the TNF-derived TIP peptide in NTN. This peptide mimics the lectin-like domain of TNF, blunts acute lung injury in several species and does not affect TNF receptor-mediated anti-bacterial activities.

Methods: TIP peptide or inactive mutant peptide were evaluated when applied systemically in murine NTN (13.5 µl/g NTS). To determine whether the effects were local or systemic, glomerular targeting was evaluated after linking the peptide to the human F1.1 mAb directed against α3(IV) collagen, in more severe NTN (14.5 µl/g NTS). All agents were given i.p. after induction of nephritis every second day from day 2 on (n=10 per group). To further evaluate the glomerular specific effects of TIP peptide its actions on TNF-induced p38 MAPK activation in GEC were assessed using Western blotting analysis of the phospho-p38/total p38 ratio.

Results: Systemic delivery of active, but not mutant TIP peptide significantly reversed nephritis (histology, proteinuria, BUN, macrophage infiltration) on day 7, and this was associated with reduced plasma levels of TNF, IL-6, IL-1β and MCP-1. Renal delivery of TIP peptide-F1.1 complex reduced mortality from 100% to 20% on day 6 and improved pathology in more severe NTN. In culture, TIP peptide abrogated hTNF-induced activation of p38 MAP kinase in GEC.

Conclusions: Local actions of TNF-derived TIP peptide ameliorate ongoing nephritis, at least in part due to direct effects on glomerular cells. Therefore, application of strategies that specifically target deleterious effects of TNF in acute glomerulonephritis (GN) locally, without either interfering with beneficial anti-bacterial activities of the cytokine or inciting inflammation, has therapeutic potential.

Funding: NIDDK Support

TH-PO138

APOL1 mRNA Is Partially Retained in the Nucleus and Is Associated with Increased Levels of Phosphorylated Protein Kinase R Koji Okamoto,[1] Maarten Hoek,[2] Myung Shin,[2] Jeffrey B. Kopp.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]Merck Research Laboratories, Kenilworth, NJ.*

Background: APOL1 coding variants G1 and G2, compared to ancestral G0, are strongly associated with glomerular diseases. We have previously found that APOL1 renal risk variants contribute to podocyte injury by activating interferon-inducible, double-stranded RNA-activated protein kinase (PKR). Cytoplasmic PKR is central to the cell stress pathway, activating the metabolic inflammasome and suppressing protein synthesis. PKR also resides in the nucleus where its function is unclear, although nuclear PKR levels are increased in leukemia and neurogenerative disease (e.g. Huntington disease, in which PKR preferentially binds mutant *huntingtin* transcripts).

Methods: BAC/APOL1 transgenic mice bear the APOL1 gene locus. We conducted knock-down experiments using conditionally immortalized human podocyte cell lines established from human urine and we generated stable HEK293 cell lines over-expressing *APOL1* variants.

Results: In BAC/APOL1 transgenic mice, the amount of nuclear phosphorylated PKR was increased, G1=G2>G0. By confocal microscopy, phosphorylated PKR formed nuclear speckles. APOL1 G1/G2 heterozygous podocytes manifested strong signals for nuclear phosphorylated PKR (intensity: 759±169), which was lacking in G0/G0 podocytes (intensity: 328±119). In APOL1 G1/G2 dual heterozygous podocytes but not in G0/G0 podocytes, knock down of APOL1 RNA reduced nuclear phosphorylated PKR by 28.7%. In APOL1 over-expressing HEK293 cells, APOL1 nuclear mRNA was increased with the G1 (152±9%)and G2 variants (176±8%) compared to cells that were transfected with the G0 variant (106±13%) (100% set as nuclear ratio in housekeeping genes). Nuclear mRNA retention was 70-fold higher than housekeeping genes (β-actin, GAPDH), and APOL1 nuclear RNA levels were 12-fold higher following transfection of the coding sequence and 3' UTR, compared with transfection of coding sequence alone.

Conclusions: APOL1 mRNA and phosphorylated PKR were present in the nucleus, at higher levels with the risk variants. The APOL1 3' UTR contributes to nuclear localization of mRNA. Nuclear PKR may serve as a reservoir for delivery to the cytoplasm, contributing to the stress response.

Funding: NIDDK Support

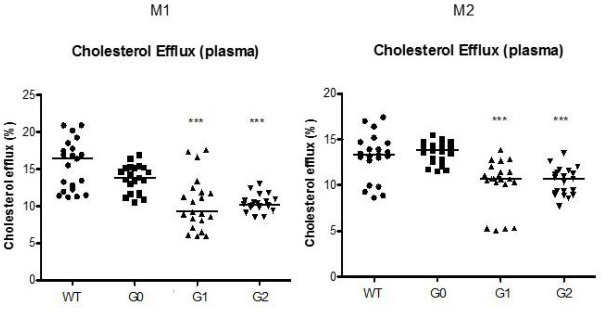
APOL1 Renal Risk Variant Alleles Reduce Cholesterol Efflux in Murine Bone Marrow-Derived Macrophages Jung-Hwa Ryu,[1] Hidefumi Wakashiu,[1] Alex Dinh,[1] Alan Remaley,[1] Maarten Hoek,[2] Myung Shin,[2] Alessia Fornoni,[3] Jeffrey B. Kopp.[1] *[1]NIDDK, National Insts of Health, Bethesda, MD; [2]Merck, Kenilworth, NJ; [3]Univ of Miami School of Medicine, Miami, FL.*

Background: Apolipoprotein L1(APOL1) genetic variants G1 and G2, compared to the common allele G0, are major risk factors for non-diabetic kidney disease in African descent populations. APOL1 is a protein component of HDL. Reverse cholesterol transport(RCT) involves the transport of cholesterol to HDL by cellular ABCA1, with subsequent delivery from peripheral tissues to the liver. With impaired RCT, macrophages become foam cells, releasing inflammatory factors. We asked whether the APOL1 risk variants alter macrophage cholesterol efflux.

Methods: Bone marrow monocytes were isolated from wild-type mice(WT) and from BAC-APOL1 transgenic(G0, G1, and G2) mice, which carry a bacterial artificial chromosome with the human *APOL1* genomic region. Monocytes were differentiated into macrophages using M-CSF(50 ng/mL) for 7d. Macrophages were stimulated for 24h with IFN-γ(20 ng/mL) to induce the M1 phenotype or with IL-4(20 ng/mL) to induce the M2 phenotype. For cholesterol efflux assays, cells were incubated with [^{3}H]-cholesterol for 24h. After incubation with efflux ligands for 4h, [^{3}H]-cholesterol in the supernatant and cell lysates were quantified.

Results: M1 and M2 macrophages showed the expected polarization according to cytokine stimulation. M1 and M2 macrophages derived from APOL1 G1 and G2 mice showed significantly decreased cholesterol efflux compared to WT or G0 macrophages.



N=6 mice per group, 3-5 samples per mouse. ***$P < 0.001$ vs. WT and vs. G0.

Conclusions: M1 and M2 macrophages from APOL1 G1 and G2 mice showed decreased cholesterol efflux compared to cells from WT or G0 mice. This process would tend to promote macrophage foam cell formation, driving inflammation in the glomerulus and interstitium.

Spleen Tyrosine Kinase Inhibitor Ameliorates Tubular Inflammation in IgA Nephropathy Wai Han Yiu, Dickson W.L. Wong, Haojia Wu, Kam Wa Chan, Yang Liu, Loretta Y.Y. Chan, Joseph C.K. Leung, Kar Neng Lai, Sydney C.W. Tang. *Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong.*

Background: Spleen tyrosine kinase (Syk) is a non-receptor tyrosine kinase involved in signal transduction in a variety of immune responses. It has been demonstrated that inhibition of Syk has renoprotective effects in antibody mediated glomerulonephritis and this protein tyrosine kinase plays a pathogenic role in orchestrating inflammatory responses and cell proliferation in human mesangial cells in IgA nephropathy (IgAN). However, the therapeutic potential of Syk inhibition in tubulointerstitial damage in IgAN remains unknown.

Methods: Cultured human proximal tubular epithelial cells (PTECs) were stimulated with conditioned medium prepared from human mesangial cells incubated with polymeric IgA (IgA-HMC) from patients with IgAN or healthy control subjects. The effect of Syk inhibitor R406 on the expression of inflammatory cytokines was detected by real-time qPCR and ELISA, and NFκB signal transduction in activated PTECs was determined by Western blotting. Furthermore, expression of phosphorylated Syk protein was examined on renal biopsies from patients with IgAN and normal control by immunohistochemistry.

Results: The synthesis of IL-6, IL-8 and ICAM-1 in PTECs were upregulated at both mRNA and protein levels after incubating with IgA-HMC conditioned medium from IgAN patients when compared to that from healthy control subjects. Pretreatment with R406 significantly suppressed IgA-HMC conditioned medium-induced pro-inflammatory cytokine production and also attenuated the phosphorylation of NFκB p65 subunit in the activated PTECs. Finally, the phosphorylated level of Syk was increased in renal tubules of patients with IgAN compared to that of the healthy controls.

Conclusions: Syk mediates inflammatory responses in tubular cells, suggesting a role for this kinase in tubulointersitial damage of IgAN. These data also supported a therapeutic potential of Syk inhibitor in treating IgAN. Fund support: Hong Kong Society of Nephrology and Hong Kong Kidney Foundation Research Grant (2015).

TLR9 Activation Induced Overproduction of Aberrantly Glycosylated IgA via Activation of BAFF in Patients with IgA Nephropathy Yuko Makita,[1] Hitoshi Suzuki,[1] Toshiki Kano,[1] Akiko Takahata,[1] Bruce A. Julian,[2] Jan Novak,[2] Yusuke Suzuki.[1] *[1]Nephrology, Juntendo Univ Faculty of Medicine; [2]Univ of Alabama at Birmingham.*

Background: Involvement of Toll-like receptor9 (TLR9) has been discussed in the pathogenesis of IgA nephropathy (IgAN). There is increasing evidences that galactose-deficient IgA1 (Gd-IgA1) and immune complexes (ICs) consisting of Gd-IgA1 are important players in the pathogenesis of IgAN. We recently demonstrated that IL-6 can enhance the production of Gd-IgA1 by IgA1-producing cells. Moreover, B-cell activating factor (BAFF) and A proliferation-inducing ligand (APRIL) may be involved in the overproduction of nephritogenic IgA1. However, the mechanisms leading to overproduction of nephritogenic IgA and progression of IgAN are still unclear. In present study, we studies the mechanisms of TLR9-mediated activation of IgA-producing cells.

Methods: Commercially available quiescent ddY mice were divided into two groups with (n=18) or without (n=18) stimulation by TLR9 agonist (CpG-ODN) for 12 weeks. Renal histological lesions and serum levels of IgA, IgG, IgA-IgG ICs and aberrantly glycosylated IgA were evaluated. The expression of TLR9, MyD88, BAFF, APRIL, and BCMA were quantitatively evaluated. We also examined the mechanisms of production of Gd-IgA1 in human IgA1-secreting cell lines with or without stimulation of TLR9.

Results: Mice treated with CpG-ODN showed overexpression of TLR9, MyD88, BAFF, APRIL and BCMA. These mice had elevated serum levels of aberrantly glycosylated IgA and IgA-IgG ICs. Serum levels of aberrantly glycosylated IgA and IgA-IgG IC correlated with BAFF expression. *In vitro*, CpG-ODN stimulation induced secretion of soluble BAFF *via* elevation of IL-6, resulted in production of aberrantly glycosylated IgA. The production of aberrantly glycosylated IgA correlated with increase of soluble BAFF. In human IgA1-secreting cell lines, TLR9 activation enhanced production of Gd-IgA1 through the same pathways, *i.e.,* IL-6-mediated BAFF production.

Conclusions: TLR9 activation exacerbated murine IgAN by enhancing production of aberrantly glycosylated IgA and nephritogenic ICs. This TLR9-mediated activation involved IL-6 and BAFF overproduction in murine as well as human IgA-secreting cells.

TH-PO142

(Pro)renin Receptor-Mediated ERK1/2 and Wnt Signaling Pathway in Crescent Glomerulonephritis Maki Urushihara,[1] Takashi Nagai,[1] Shuji Kondo,[1] Yasumasa Ikeda,[2] Toshiaki Tamaki,[2] Shoji Kagami.[1] *[1]Dept of Pediatrics, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan; [2]Dept of Pharmacology, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.*

Background: (Pro)renin receptor ((P)RR)-bound renin and (pro)renin not only become enzymatically active but also cause intracellular signaling pathway activation. We recently showed that direct renin inhibition ameliorated the magnitude of crescent glomerulonephritis (GN) using rat experimental model and suggested that inflammation and cell proliferation via (P)RR involved in the pathophysiology of glomerular crescent formation.

Methods: To clarify the mechanism of (P)RR-mediated intracellular signaling in glomerular crescent formation, we induced crescentic GN model by anti-glomerular basement membrane antibodies in WKY rats and treated with direct rein inhibitor (DRI). Furthermore, we examined the signal transduction in cultured mesangial cell (MCs) and parietal epithelial cell (PECs) transfected with (P)RR specific small interference RNA (siRNA).

Results: Anti-GBM nephritis model developed severe glomerular crescent, accompanied by increased CD68 positive macrophage infiltration and glomerular expression of (P)RR and phospho-ERK1/2 by immunohistochemistry, and mRNA levels of MCP-1 and Wnt4 in isolated glomerulus. Treatment with DRI markedly suppressed those augmentations. Recombinant renin (rRenin) stimulation induced cell proliferation in cultured PECs and increase of monocyte chemoattractant protein-1 (MCP-1) mRNA in cultured MCs, but not in (P)RR siRNA transfected PECs or MCs. PECs stimulated with rRenin showed ERK1/2 phosphorylation and MEK1/2 inhibitor PD98059 abolished cell proliferation, suggesting that (P)RR-mediated ERK1/2 regulated cell proliferation of glomerular crescent. Wnt4 siRNA transfected MCs suppressed the elevation of MCP-1 mRNA by stimulation with rRenin, indicating that (P)RR-mediated Wnt4 signal regulated MCP-1 expression leading to macrophage infiltration into glomerular crescent.

Conclusions: These data suggest that ERK1/2 and Wnt4 signaling pathways via (P)RR are involved in cell proliferation and macrophage infiltration in crescentic GN.

TH-PO143

Autotaxin Inhibition Decreases Inflammation and Fibrosis in Experimental Model of Crescentic Glomerulonephritis Marco Prunotto,[1] Solange Moll,[2] Christos Chatziantoniou,[3] Susanne Raab,[1] Laura Badi,[1] Christoph Ullmer.[1] *[1]Roche Basel Innovation Center, Hoffmann- La Roche, Basel, Bs, Switzerland; [2]Clinical Pathology Dept, Univ of Hospital of Geneva, Geneva, Ge, Switzerland; [3]INSERM UMR S 1155, Hôpital Tenon, Paris, France.*

Background: Autotaxin (ATX) is a secreted enzyme catalyzing the conversion of lysophosphatidyl choline to produce the majority of extracellular lysophosphatidic acid (LPA), a bioactive phospholipid that exerts its action through binding to specific LPA activated G-protein coupled receptors (LPARs). In a number of organs, elevated plasma levels of LPA have been associated to fibrosis. Specifically in kidney, preclinical evidence in the UUO model showed LPA levels to be associated to fibrosis and causal role has been demonstrated in the same model where fibrosis was significantly attenuated in LPA1R-KO mice compared with wild type mice. In addition to that specific role in fibrosis, LPA has been associated by a vast number of papers to inflammation. All findings let us investigate the role of autotaxin inhibition in preserving renal function and its specific mode of action (MoA) in that model.

Methods: Sv129 mice were injected with nephrotoxic serum (NTS) and a selective ATX inhibitor was administered 1 day prior lesion induction. Functional assessment was carried out at 4, 7 and 14 days post NTS injection with evaluation of blood urea nitrogen, proteinuria or urine cystatin C. Mice were euthanized 14 days post NTS injection and kidney collected for histology, immunohistochemical and morphometric analysis. Gene expression profile was performed for all mice.

Results: ATX inhibition significantly improved renal function measured by proteinuria or urine cystatin C. These functional results were paralleled by a correspondent effect on tubule-interstitial fibrosis, tubular injury or total number of infiltrating inflammatory cells. Gene expression profile of all treated animals pointed out to a key role of ATX inhibition on T-cell recruitment.

Conclusions: Our findings support a key role of LPA axis in renal function preservation in NTS model of crescentic glomerulonephritis and possibly in other renal diseases.

TH-PO144

DDR1 Inhibition Decreases Experimental Induced Glomerulosclerosis Marco Prunotto,[5] Takeshi Murata,[1] Hideaki Shimada,[1] Akira Maeda,[1] Naoshi Fukushima,[1] Christos Chatziantoniou,[2] Marcus J. Moeller,[4] Diana Rubel,[3] Oliver Gross,[3] Yukari Yasui.[1] *[1]Fuji-Gotemba Research Labs, Chugai Pharmaceutical Co., Ltd., Gotemba, Japan; [2]INSERM UMR S 1155, Hôpital Tenon, Paris, France; [3]Clinic of Nephrology and Rheumatology, Univ Medicine Goettingen, Goettingen, Germany; [4]Dept of Nephrology and Clinical Immunology, RWTH Univ, Aachen, Germany; [5]I2O, Clinical Development, Roche Product Ltd., Basel, Switzerland.*

Background: Discoidin Domain receptor 1 (DDR1) is tyrosine kinase collagen receptor that has been shown to be involved in progression of cancer and fibrosis. Specifically in kidney, an impressive series of papers highlighthed a major role for this receptor in the pathogenesis of renal fibrosis, crescentic glomerulonephritis and in Alport syndrome. The present abstract describes the effects of selective DDR1 pharmacological inhibition in experimental-induced glomerulosclerosis models.

Methods: Selective DDR1 pharmacological inhibition on progression of experimental-induced glomerulosclerosis by injection of alloimmune sheep nephrotoxic serum (NTS) in Sv129 mice and in a model of acquired progressive glomerular sclerosis (NEP25) was tested. Functional parameters were collected during the study and tissues submitted to histology, immunohistochemistry and gene expression profile.

Results: DDR1 selective inhibition, assessed by reduction of DDR1 phosphorylation in renal parenchyma, showed a dose-dependent decrease in disease severity assessed by blood urea nitrogen and albuminuria in both models. This functional improvement was paralleled by a marked reduction of expression levels of the principal fibrotic markers. Network analysis on gene expression profile from all treated mice showed a preserved renal tissue gene signature and a decreased signature of inflammation & fibrosis in both anti-GBM and NEP25 model with a marked effect on podocin/nephrin network preservation.

Conclusions: Our preclinical data suggest DDR1 inhibition as a possible therapeutic intervention strategy in treating glomerulosclerosis and in advanced stages of chronic kidney disease.

TH-PO145

Intraglomerular Crosstalk between Mesangial Cells and Macrophages in Glomerular Injury Shuro Umemoto, Takashige Kuwabara, Manabu Hayata, Daisuke Fujimoto, Tomoko Kanki, Yuichiro Izumi, Yutaka Kakizoe, Masashi Mukoyama. *Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto City, Kumamoto, Japan.*

Background: We previously reported that myeloid-related protein 8 (MRP8: S100A8)–toll-like receptor 4 (TLR4) signaling activated by ER-stressed macrophages (Mφ) could be involved in the progression of diabetic nephropathy. Besides, ER stress associated with glucolipotoxicity might contribute to diabetic complications along with the MRP8/TLR4 upregulation in the kidney. Since glomerular infiltrated Mφ showed obviously high MRP8 positivity compared to tubulointerstitial Mφ, we speculated the intraglomerular crosstalk between infiltrated Mφ and resident cells in glomeruli. However, detailed mechanisms remain to be elucidated.

Methods: Macrophages (mouse RAW264.7 cells) were co-cultured or stimulated with rat mesangial cells (Mes) or Mes-conditioned media (Mes-sup), respectively. Expressions of mRNA of MRP8, pro-inflammatory genes and ER stress-associated genes were determined with TaqMan real-time PCR. Inflammation and ER stress were evaluated using THP1-dual reporter cell line enabling to monitor activation of both NFκB and interferon regulatory factor (IRF) pathways. Furthermore, the effects of a TLR4 antagonist on this crosstalk were also examined.

Results: MRP8 and pro-inflammatory genes in Mφ were dramatically induced by co-culture with Mes (by 25-fold and 12-fold, respectively). These results were mostly reproduced by stimulation with Mes-sup, rather than that with proximal tubular cell-conditioned media. Furthermore, experiments using the dual reporter assay revealed that Mes-sup stimulation induced IRF signaling, which could cause ER stress, as well as NFκB pathway in a concentration-dependent manner. Such induction was partially (by ~50%) abrogated by the TLR4 antagonist.

Conclusions: These results indicate that humoral factors secreted from Mes would contribute to the intraglomerular crosstalk between Mes and Mφ during the course of MRP8 activation, which might play an important role in the inflammation and ER stress partly through TLR4 signaling.

TH-PO146

CXCL10-Deficient Mice Reveal a Pro-Proliferative Role for IP-10 in Mesangial Proliferative Glomerulonephritis Xiang-Mei Chen, Lingling Wu. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing.*

Background: IFN-γ-inducible protein 10 (IP-10, CXCL10), a small chemokine belonging to the CXC chemokine family, has been widely documented to be involved in chemokine activity, cell proliferation and angiogenesis inhibition. It has also been pointed out that the CXCL10 expression increased significantly in patients with mesangial proliferative glomerulonephritis (MesPGN). However, the role and the underlying mechanism of CXCL10 in MesPGN reminds unclear.

Methods: MesPGN was induced in both CXCL10-/- and CXCL10+/+ mice. The glomerular lesions were examined by PAS staining. Immunohistochemistry staining of PCNA was performed to detect the cell proliferation in glomerulus. The expression levels of cell cycle-related proteins were determined by western blotting.

Results: Typical pathological phenotypes were observed in both CXCL10-/- and CXCL10+/+ mice, but the CXCL10-/- mice showed more severe accumulation of extracellular matrix and proliferation of mesangial cells. The PCNA-positive cells in the CXCL10+/+ mice were much more than that in CXCL10-/- mice at day 7. In addition, the results of western blotting showed that the expression levels of cell cycle-related proteins, including Cyclin D3, Cdk2 and Cdk4, were all higher in CXCL10+/+ mice compared with those in CXCL10-/- mice. Furthermore, we observed that CXCL10-/- mice showed less activation of PI3K-AKT signaling pathway than that in CXCL10+/+ mice at day 7.

Conclusions: CXCL10 may aggravate the mesangial proliferation in MesPGN through activating the PI3K-AKT signaling pathway. These results provide a novel insight into the mechanism and a potential therapy target of MesPGN.

TH-PO147

Transcriptome Analysis Suggests That Vorinostat Is Antiapoptotic and Anti-Inflammatory in Experimental Alport Syndrome Vanessa R. Williams,[1] Eun Hui Bae,[2] Ana Konvalinka,[3] York P. Pei,[3,4] James W. Scholey.[1,3] *[1]Medical Science, Univ of Toronto, Canada; [2]Internal Medicine, Chonnam National Univ, Korea; [3]Nephrology, Univ Health Network, Canada; [4]Genomic Medicine, Univ Health Network, Canada.*

Background: Alport syndrome (AS) is a hereditary disorder characterized by early proteinuria and progressive chronic kidney disease (CKD). Currently few effective treatments are available. We previously identified vorinostat, a lysine deacetylase (KDAC) inhibitor, as a novel therapeutic approach to AS. Here, we used systems biology to examine effects of vorinostat treatment on molecular mechanisms affecting progression of AS.

Methods: *Col4a3*$^{-/-}$ (KO) and wild-type (WT) mice on a congenic 129 background were treated with vorinostat (50 mg/kg/day) or vehicle from 4 to 7 weeks of age ($n = 8$ per group). Plasma and urine samples were collected, and kidney histological analyses were performed. Global RNA expression profiling of renal cortical samples was performed with Affymetrix Mouse Gene 2.0 ST arrays at 7 weeks, followed by differential expression, gene ontology (GO), and pathway analyses.

Results: KO mice developed proteinuria, elevated plasma creatinine and blood urea nitrogen, glomerulosclerosis, and tubulointerstitial fibrosis, however vorinostat treatment tended to attenuate these changes. Transcriptional profiles of untreated KO mice compared to WT mice showed enrichment of genes involved in activation of NF-κB, toll-like receptor, and TNF inflammatory signaling pathways. Genes involved in apoptosis, and lipid and carbohydrate metabolism were also enriched. Interestingly, vorinostat-treated KO mice showed downregulation of pathways involved in apoptosis, particularly p53 signaling, compared to untreated KO mice. GO analysis of vorinostat-treated KO mice revealed enrichment of biological processes involved in negative regulation of inflammation and metabolism.

Conclusions: Unbiased transcriptome analysis suggested that vorinostat exerts therapeutic effects by reversing changes in gene expression and biological processes contributing to progression of CKD in AS, particularly apoptosis, inflammation, and metabolism. Future studies will thoroughly investigate specific mechanisms of KDAC inhibition in AS.

TH-PO148

Capillary Mechanical Tension Cause Glomerular Injury through Activation of Innate Immunity in the Remnant Kidney Simone C.A. Arias, Victor F. Avila, Camilla Fanelli, Denise M. Malheiros, Niels O.S. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo.*

Background: Mechanical tension (MT) is thought to initiate and perpetuate glomerular injury, a notion supported by in vitro studies. The mechanisms of the deleterious action of MT remain unclear. We hypothesized that at least part of these effects may be mediated by innate immunity (InIm), activated as part of a nonspecific cell response to aggression.

Methods: We analyzed retrospectively, by IHC, renal tissue from 15 sham-operated (S) and 30 adult male Munich-Wistar rats subjected to 5/6 renal ablation (Nx). For each experiment, glomerular transcapillary hydraulic pressure difference (ΔP), glomerular volume (V_G) and glomerulosclerosis index (GSI) had been obtained 30 (Nx30) or 60 (Nx60) days after Nx. The ($\Delta P \times V_G^{1/2}$) product was used as a simple estimate of mean glomerular wall MT (GWMT), according to Laplace's law. We assessed the glomerular infiltration (cells/mm^2) by PCNA+ cells and macrophages (MΦ), and the glomerular content (% area) of zonula occludens-1 (ZO-1), α-actin and TGF-β. Glomerular InIm activation was evaluated by the % area of Caspase-1, TLR4, IL-1β and NLRP3.

Results:

	S	Nx30	Nx60
GWMT	40±1	63±2[a]	91±3[ab]
GSI	0±0	10±4[a]	30±11[ab]
TGF-β	3±2	22±6[a]	31±9[a]
α-actin	2.1±0.3	3.8±0.9[a]	11.3±2.5[ab]
MΦ	1.4±0.3	3.0±0.4[a]	4.3±0.7[a]
PCNA	0.7±0.2	2.4±0.3[a]	3.4±0.8[a]
ZO-1	59±2	50±5	42±4[a]
Caspase-1	0.4±0.1	1.8±0.4[a]	4.1±0.1[ab]
TLR4	0.3±0.1	2.0±0.3[a]	2.3±0.3[a]
IL-1β	5±2	11±1[a]	24±3[ab]
NLRP3	0.9±0.6	3.9±0.7[a]	7.1±0.7[ab]
Mean±SE, [a]p<0.05 vs. S; [b]p<0.05 vs. Nx30			

Among Nx rats, GWMT correlated positively with GSI ($p<0.02$) and α-actin ($p<0.005$), and negatively with ZO-1 ($p<0.03$), indicating that it may participate in glomerular inflammation and podocyte injury. In addition, GWMT correlated with % area for Caspase-1 ($p<0.05$), NLRP3 ($p<0.05$), IL1β ($p<0.001$) and TLR4 ($p<0.05$), suggesting that glomerular MT activated InIm.

Conclusions: InIm activation may mediate the adverse effects of GWMT and participate in the initiation and perpetuation of progressive glomerular injury in the Nx model. FAPESP/CNPq.

Suppression of Inflammation by Leukadherins Ameliorates Diabetic Kidney Disease Mohd Hafeez Faridi,[1] Samia Khan,[1] Shehryar J. Khaliqdina,[1] Alessia Fornoni,[2] Vineet Gupta.[1] *[1]Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Div of Nephrology and Hypertension, Miller School of Medicine, Univ of Miami, Miami, FL.*

Background: Systemic Inflammation governs the pathology of several diabetic complications including diabetic nephropathy (DN). Increased infiltration of inflammatory leukocytes in the glomerular milieu has been reported in DN in recent studies. We recently described that CD11b activation using a novel compound, Leukadherin-1 (LA1), suppresses tissue infiltration of leukocytes by reducing transmigration. Here, we tested our hypothesis that CD11b-activation mediated suppression of leukocyte kidney infiltration reduces diabetic kidney injury.

Methods: BTBR ob-/ob- mice were treated with LA1 at 2mg/kg/day for 8 weeks. Blood glucose level, body weight, and urine albumin-creatinine ratio were measured weekly. Histochemical and immunofluorescence analyses were used to quantify LA1 treatment mediated tissue protection.

Results: Diabetic BTBR ob-/ob- mice showed increased albuminuria with age that correlated with leukocyte infiltration into the kidney. LA1 treatment of diabetic mice

significantly reduced albuminuria and improved renal function. Histochemical analyses showed that LA1 significantly reduced leukocyte infiltration and glomerular injury, including mesangial sclerosis, as compared to the untreated animals.

Conclusions: Pharmacologic activation of CD11b with allosteric agonists can be a therapeutically relevant strategy to reduce leukocyte kidney infiltration and inflammatory injury in the setting of diabetes.

Integrative Analysis of Transcriptome Alterations in Kidney Tissues of Diabetes Nephropathy Revealed Significant Enrichment of M1 Macrophages, Mature Dendritic Cells and Activated Helper T Cells Tao Wei, John N. Calley, Philip Ebert, Suntara Cahya, Zhonghua Qi, Bhaskarjyoti Sarmah, Matthew D. Breyer, Kevin L. Duffin. *Eli Lilly and Company, Indianapolis, IN.*

Background: Recent studies suggested tissue inflammation may play a significant pathogenic role in diabetes kidney disease (DKD). We carried out an integrative analysis with objectives to identify major cellular players associated with diseased kidney tissues.

Methods: Multiple independently generated DKD transcriptome datasets involving different cohorts of human subjects were analyzed to identify a consensus set of differentially expressed genes (DEGs) in kidney tissues (glomeruli and tubuli) associated with DKD. Pathway analysis and leukocytes specific gene signatures were employed to identify major pro-inflammatory leukocytes.

Results: ~2000 genes were identified as DEGs by at least two different studies. Pathway enrichment and coherence analysis revealed significant up-regulation of inflammatory pathways and down-regulation of metabolism and mitochondrial activities. Leukocyte specific gene signatures for macrophages, dendritic cells (DCs), neutrophils, natural killer cells (NKs), T cells and B cells were developed from a published human immune cell transcriptome profile. Enrichment analysis, together with pathway analysis, revealed significant enrichment of macrophages, DCs and helper T cells in diseased kidney tissues. Further analysis revealed significant enrichment of pro-inflammatory M1 macrophages when compared to M2 macrophages, and mature or activated DCs when compared to immature or tolerogenic DCs. Metabolic and mitochondrial activity profiles of M1 and mature dendritic cells are similar to what was observed in DKD kidney tissue, further confirming the involvement of M1 macrophages and mature dendritic cells in DKD development.

Conclusions: Integrated analysis confirmed the significant association of chronic tissue inflammation with DKD. We discovered the dis-regulated enrichment in kidney tissues of M1 macrophages, mature DCs and activated helper T cells is the main cellular basis that underlies the chronic tissue inflammation observed in DKD kidney.

A Macrophage COX-2/PGE2/EP4 Axis Protects against Development of Diabetic Nephropathy Xin Wang,[1] Yinqiu Wang,[1] Suwan Wang,[1] Xiaofeng Fan,[1] Haichun Yang,[2] Agnes B. Fogo,[2] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ School of Medicine, Nashville, TN; [2]Pathology and Microbiology and Immunology, Vanderbilt Univ School of Medicine, Nashville, TN.*

Background: Alterations of intrinsic kidney cyclooxygenase-2 (COX-2) expression are observed in development of diabetic nephropathy (DN), and increased COX-2 expression in macula densa contributes to hyperfiltration in the early stage of diabetes. More advanced DN is characterized by increased infiltration of macrophages. COX-2-derived PGE2 plays an important role in macrophage polarization. In the present studies, we investigated the potential roles of macrophage COX-2 in development of DN.

Methods: Mice with hematopoietic cell COX-2 knockout (129J/sv) and mice with deletion of macrophage COX-2 (CD11b-Cre; COX-$2^{flox/flox}$) or EP4 receptors (CD11b-Cre; $EP4^{flox/flox}$) on an FVB background were used. Type I diabetes was induced by streptozotocin.

Results: At 20 weeks of diabetes, hematopoietic cell COX-2 deletion increased albuminuria, in association with increased renal profibrotic and fibrotic markers (CTGF, fibronectin) and macrophage infiltration. Similarly, macrophage COX-2 deletion also significantly increased albuminuria (ACR: 314 ± 43 vs. 137 ± 32 μg/mg of WT, $P < 0.01$, $n = 5$-9) with increased renal fibrotic markers (α-SMA, collagen I) and macrophage infiltration. Macrophage COX-2 deletion also led to greater glomerulosclerosis index (0.48 ± 0.09 vs. 0.24 ± 0.04 $P < 0.05$, $n = 5$) and podocyte loss (podocytes/glomerulus: 13.65 ± 0.54 vs. 21.34 ± 0.95, $P < 0.001$, $n = 4$). Macrophage COX-2 deletion resulted in decreases in mRNA levels of M2 markers (mannose receptor and YM-1) as well as the number of M2 macrophages (mannose receptor positive macrophages). Finally, macrophage COX-2 deletion caused reduction in autophagy (lower LC3A expression) and increases in endoplasmic reticulum (ER) stress (higher CHOP expression). Similar results were also observed in mice with macrophage EP4 deletion.

Conclusions: Our studies indicate that macrophage COX-2 protects against development of DN through multiple mechanisms, including modulation of macrophage polarization and infiltration, decreases in autophagy and increases in ER stress.

High Glucose Induces Dedifferentiation in Podocytes but Prevents Parietal Epithelial Cells Transition through Up Regulation of Micro-RNA193a Manoj K. Tembhre,[1] Waqaar Khawar,[1] Seyedeh Shadafarin Marashi Shoshtari,[1] Judith Eng,[1] Catherine Meyer-Schwesinger,[2] Ashwani Malhotra.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Medicine, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: In recent studies, MicroRNA (miR) 193a has been implicated for the development of glomerulosclerosis in several models of chronic kidney diseases. miR193a is a regulator of Wilms tumor (WT1) suppressor gene. Enhanced expression of WT1 in glomerular epithelial cells is associated with the expression of podocalyxin and nephrin, markers of podocytes. On the other hand, down regulation of WT1 enhances the expression of PAX2, a marker of parietal epithelia cell (PEC). A subset of PECs acts as progenitor cells to replenish injured podocytes. We hypothesize that high glucose milieu up regulates miR193a contributing to dedifferentiation of podocytes and preventing the transition of PECs to podocytes.

Methods: Renal tissues of 8 week wild type and $BTBR^{ob/ob}$ mice were evaluated for the expression of WT1, nephrin, and PAX2. In *in situ* hybridization studies, renal cortical sections of control and diabetic mice were labeled for miR193a. In *in vitro* studies, human podocytes and human parietal epithelial cells were incubated in media containing either normal glucose (5mM) or high glucose (30 mM) for 48 hours and probed for miR193a. In other sets of experiments, control and high glucose treated (48 hours) podocytes were evaluated for the expression of podocalxin, PAX2, and nephrin.

Results: *In situ* hybridization studies revealed podocyte expression of miR193 in diabetic mice. In *in vitro* studies showed enhanced miR193a expression in high glucose treated podocytes and PECs. Renal tissues of diabetic mice displayed attenuated expression of WT1 and nephrin. High glucose treated podocytes also displayed attenuated expression of podocalyxin and nephrin. High glucose did not alter PAX2 expression in PECs.

Conclusions: High glucose down regulates podocytes's but preserves PECs's molecular phenotype through modulation of miR193a. The present study provides mechanistical insight into the development of glomerulopathy in majority of diabetic patients.

IL17A Blockade Improves Renal Damage en BTBR ob/ob Animal Model Carolina Lavoz,[1] Yenniffer Sanchez,[1] Maria Alejandra Droguett,[1] Paola Krall,[1] Daniel Carpio,[1] Marta Ruiz-Ortega,[2] Sergio A. Mezzano.[1] *[1]Div of Nephrology, School of Medicine, Univ Austral, Valdivia, Chile; [2]Renal Diseases Laboratory, Univ Autónoma Madrid, Madrid, Spain.*

Background: Chronic inflammation is a main feature of the progressive renal diseases, including diabetic nephropathy (DN), the most prevalent chronic kidney disease. Among potential therapeutic targets of diabetic renal damage the Interleukin 17A might be a promising one. IL17A is the hallmark cytokine of the T helper 17 cell. The mouse model strain BTBR obob (leptin deficiency mutation) has been widely used for the study of DN, develops histological features that resembles human DN, and offer an opportunity to study the mechanisms that may lead to more specific therapies aimed at regression of DN. Our aim was to investigate the involvement of the Th17 effector cytokine IL17A in the pathogenesis of DN.

Methods: To evaluate the direct effects of IL17A on DN progression, a neutralizing antibody against IL17A (osmotic mimipumps, 5 ng/gr of b.w) was administered to mice between 15 and 20 weeks (sacrifice) . The results were analyzed by Western blot, ELISA, and RTPCR.

Results: In the obob animal model, IL17A renal production was observed at 16 weeks, sustained up to 20 weeks as well as activated RORγT. Moreover, positive IL17A expressing CD4 lymphocytes, mastocytes and tubular epithelial cells were found. IL17A neutralization diminished blood glucose and body weight compared to IgG control-treated mice, whereas renal weight and serum creatinine levels were not affected. Importantly, IL17A blockade improved Albumin/Creatinine Ratio during all period of study. Moreover, downregulation of the kidney damage markers (KIM1 and Ngal) and the proinflammatory factors (MCP1 and Rantes) were found in response to IL17A neutralization. Podocytes markers like WT1 and Pdcn tend to recover after treatment. Histologically was observed a decreased inflammatory infiltrating cells in anti-IL17A-treated mice. In biopsies of DN patients we have detected IL17A expression in tubular epithelial cells.

Conclusions: These data demonstrate that IL17A participates in diabetic-mediated renal damage and could be a novel therapeutic target for ND. PAI 82140017.

Tissue Plasminogen Activator Modulates Macrophage Polarity Shift Ling Lin, Kebin Hu. *Medicine, Penn State Univ College of Medicine, Hershey, PA.*

Background: Macrophage polarization plays an important role in tissue inflammation and fibrogenesis. Generally, M1 macrophages promote inflammation, whereas, M2 macrophages are anti-inflammatory and promote tissue remodeling. Recent work indicates that macrophages, in response to kidney injury, can shift their polarity. However, the underlying mechanisms remain largely unknown.

Methods: We investigated the role of tissue plasminogen activator (tPA) in macrophage polarity shift using integral in vivo and in vitro approaches.

Results: We found that there were more $CD11b^+TNF\alpha^+$ or $CD11b^+F4/80^{lo}$ M1 macrophages in the obstruction-induced fibrotic kidneys from wildtype mice than that from tPA knockout mice. tPA also induced M1 chemokines expression, including IFN-γ, IL-1β, and TNF-α, both in vivo and in vitro, suggesting that tPA may be an endogenous factor that modulates M2 macrophages shift towards M1 phenotype. J774 macrophages were treated with IL-4 to induce M2 phenotype as indicated by de novo expression of arginase 1, SOCS3, and Ym1. Intriguingly, it's found that IL-4-induced M2 macrophages, after tPA treatment, lost their M2 markers such as arginase 1 and SOCS3, indicating that tPA promotes a polarity shift of macrophages from M2 skewed towards M1. Possible contamination of endotoxin was also excluded as heat-inactivated tPA lost its effect. Additionally, knockdown of LRP-1 by siRNA, one of the known tPA receptor, had little effect on tPA-induced macrophage polarity shift. Instead, it's found that annexin A2 mediated tPA-induced macrophage polarity shift, because annexin A2 siRNA abolished tPA effects.

Conclusions: Thus, it's clear that tPA promoted macrophage polarity shift from M2 to M1 through annexin A2-mediated pathway.

Cell Specific Targeted PCR and RNA Sequencing of Renal Collecting Duct Epithelial Cells Reveals Novel Innate Immune Signature in Murine Intercalated Cells Andrew L. Schwaderer,[1] Vijay Saxena,[1] Raoul D. Nelson,[3] George J. Schwartz,[4] David S. Hains.[2] *[1]CCTR, Nationwide Children's Hospital, Columbus, OH; [2]Pediatrics, Le Bonheur Children's Hospital, Memphis, TN; [3]Pediatrics, Univ of Utah, Salt Lake City, UT; [4]Pediatrics, Univ of Rochester Medical Center, Rochester, NY.*

Background: The urinary tract is usually culture negative despite its close proximity to microbial flora. The precise mechanisms by which the kidneys and urinary tract defends against infection is not well understood. The initial kidney cells to encounter ascending pathogens are the collecting tubule cells which consist of principal cells (PC) that express the aquaporin 2 (AQP2) and intercalated cells (IC) which express vacuolar H^+-ATPase (V-ATPase). We have previously shown that intercalated cells are involved in the innate immune defense of the kidney in humans.

Methods: In this study we generated two reporter mice, V-ATPase-cre^+Tdt^+ mice to fluorescently tag IC and AQP2-cre^+Tdt^+ mice to fluorescently tag PC and enriched them by flow sorting to ≥90% purity. Isolated IC and PC cells were studied for targeted anti-microbial peptide mRNA expression. Unbiased RNA sequencing (RNA-Seq) was performed on IC and non-IC cell fractions.

Results: ICs were significantly enriched for anti-microbial peptides (AMPs), *Defb1*, *Defb26* and *RNase4*. ICs responded rapidly to uropathogenic *E. coli* challenge *in vitro* by rapidly up-regulating *RNase4* gene expression. Pathway analysis of RNA-Seq data identified, LPS/IL1 mediated inhibition of retinoic acid receptor function as the primary pathway involved in the collecting tubule compared to the remainder of kidney cells. Additionally AMP and/or innate immune gene expression including *Defb11*, *Scg5*, *Cav1*, *Cav2*, *IL-17RE*, *IL-23R* and *CXCR4* was increased in ICs.

Conclusions: Key collecting tubule innate immune genes include *Defb1*, *Defb11*, *SCG5*, *Cav1*, *Cav2* and *RNase4*. To our knowledge, this is the first report of isolating murine collecting tubule cells and identifying their innate immune gene profile.

BET Bromodomain Inhibition Ameliorates Experimental Renal Damage Jose Morgado-Pascual,[1] Beatriz Suarez-Alvarez,[4] Sandra Rayego-Mateos,[1] Raúl R. Rodrigues Díez,[1] Pierre-Louis Tharaux,[2] Jesus Egido,[3] Alberto Ortiz,[3] Carlos Lopez-Larrea,[4] Marta Ruiz-Ortega.[1] *[1]Univ Autónoma Madrid, Spain; [2]Paris Cardiovascular Centre, France; [3]ISS Fundacion Jimenez; [4]Hospital Univ Central de Asturias, Spain.*

Background: Renal inflammation plays a key role in the onset and progression of immune and non-immune renal diseases. Here, we evaluated whether the epigenetic inhibitor of bromodomain and extraterminal (BET) proteins JQ1 could modulate renal inflammation.

Methods: In vitro studies were done in TNF-α treated tubuloepithelial cells. Experimental models of unilateral ureteral obstruction (UUO), infusion of Angiotensin II and anti-glomerular basement membrane nephritis induced by nephrotoxic serum (NTS) administration were used. Mice were treated with JQ1 (100 mg/ mouse/day).

Results: The *in vitro* evaluation of JQ1 on cytokine-inducible genes in renal cells showed that BET inhibition modulates several biological processes, including inflammation and immune response. Gene silencing of BDR4, one of the most important BET proteins, and chromatin immunoprecipitation assays demonstrated that JQ1 alters the direct association of BRD4 with acetylated histone-packaged promoters and reduces the transcription of proinflammatory genes (IL-6, CCL-2 and CCL-5). These data suggest that JQ1 by chromatin remodelling might regulate renal inflammation. Interestingly, several JQ1-downregulated genes were under nuclear factor-kB (NF-κB) control, a key inflammatory signaling pathway. The RelA NF-κB subunit is activated by acetylation of lysine 310. In damaged kidneys and in cytokine-stimulated renal cells, JQ1 inhibited RelA/NF-κB nuclear levels and down-regulated NF-κB-mediated gene expression. Additionally, JQ1 dampens the activation of the Th17 immune response in experimental renal damage.

Conclusions: Our results demonstrate that BET inhibition reduces renal inflammation by several mechanisms: chromatin remodeling in promoter regions of specific genes, blockade of NF-κB pathway activation and modulation of the Th17 immune response. These results suggest that BET inhibitors could have important therapeutic applications in inflammatory renal diseases.

Cisplatin(CP)-Induced Chronic Kidney Disease (CKD): Failed Healing and the Conversion of AKI to CKD Robert L. Safirstein,[1,2] Heino Velazquez,[1,2] Richard Torres,[2] Gilbert W. Moeckel,[2] Gary V. Desir.[1,2] *[1]Medicine/Nephrology, CVAHS, West Haven, CT; [2]Medicine/Nephrology, Yale Univ, New Haven, CT.*

Background: CP causes AKI and CKD but the mechanism of this conversion is unknown. We have shown that the induction of CKD after 2 doses of CP is characterized by changes in physiologic, molecular, and three dimensional histologic parameters. We report now the molecular and morphologic events that mark this interface.

Methods: We compared changes evident 1,3,5 days and 2 and 4 week after a single dose to those noted after two CP doses given 2 weeks apart. Function by inulin clearance and morphology by light and electron microscopy (EM), and multiphoton microscopy was evaluated. Molecular changes were assessed by cDNA microarrays, PCR, western blotting, and immunohistochemistry (IHC).

Results: Mice given 1 dose of CP recover nearly completely. By contrast, CKD develops fully 2 weeks after the 2nd dose of CP. 3-D morphology shows the same degree of capsular cuboidal cell loss and atubular glomeruli at 2 weeks as that seen after 9 weeks following the second CP dose. The renal transcriptome was similar between acutely and chronically injured kidneys and include activation of stress response, inflammatory, cell cycle, and cell death genes. Expression of the damage markers NGAL and KIM-1, which had returned to normal after 1 dose, was re-activated in a sustained manner after the second dose. Proximal tubule Ki67 staining was reduced compared to single dose exposure and the cell cycle inhibitor p21 gene was activated as well. IHC showed widespread molecular responses in the PT, distal tubule and collecting duct. EM of PT cells revealed severe injury and autophagy and pericytes in the outer medulla showed evidence of transdifferentiation.

Conclusions: These studies show that persistent injury and inflammatory responses characterize the transition from AKI to CKD. The failure to replace damaged and dying tubule cells suggests a causal relationship between failed repair of this segment and the conversion of AKI to CKD. We propose that the source of the continued injury response and the check on cell cycle activity are linked and is central to the development of CKD.

Role of Claudins in Tumor Necrosis Factor-Induced Permeability and Migration Changes in Tubular Cells Katalin Szaszi,[1,2] Shaista Anwer,[1] Yasaman Amoozadeh,[1] Emily Branchard,[1] Qinghong Dan.[1] *[1]Keenan Research Center St. Michael's Hospital, Toronto, ON, Canada; [2]Surgery, Univ of Toronto, Toronto, ON, Canada.*

Background: Tumor Necrosis Factor-α (TNF) is a key pathogenic cytokine in kidney disease. We showed that TNF causes a biphasic transepithelial resistance (TER) change in tubular cells that consists of an early drop followed by recovery (1-3h), and a late increase (>8h). TNF also enhances tubular cell migration. However, the underlying mechanisms are not fully known. TER is determined by the claudin (Cldn) family of tight junction proteins. The combination of claudin isoforms expressed determines paracellular permeability of a cell. Claudins were also shown to affect migration. The aim of this work was to assess how claudins contribute to TNF-induced changes in permeability and motility of tubular cells.

Methods: We used LLC-PK1 tubular cells. TER and cell migration was quantified by Electric Cell-substrate Impedance Sensing (ECIS). Claudin expression was followed using western blotting. Specific claudins were silenced using siRNA.

Results: TNF alters expression of several claudins. It causes a biphasic change in Cldn-2 and 3 expression. Specifically, an initial transient increase due to reduced degradation (1-3h) is followed by a drop in mRNA and protein levels (>8h). Prolonged TNF treatment also increases claudin-1, 4 and 7 protein and mRNA . The ERK and JNK pathways are required for the expression changes of Cldn-1, 4 and 7, and have a key role in the late TER increase. To correlate TNFα-induced claudin expression and TER changes, we silenced each claudin and monitored TER using ECIS. Cldn-1 is necessary for the early TNFα-induced TER change. In contrast, Cldn-2 decrease is the main contributor to the late TER increase, with only minor roles for Cldn-1, 4 and 7. Finally, we assessed the role of the various claudins in migration. Silencing Cldn-1, 2 or 3 significantly slowed wound healing in LLC-PK1 cells. Our ongoing studies explore the role of these claudins in migration-associated cytoskeleton remodeling.

Conclusions: Altered claudin expression may have consequences beyond permeability changes. By affecting epithelial regeneration following injury claudins may contribute to the pathogenesis of kidney disease.

Fibroblast CD73 Controls the Interstitial Adenosine Microenvironment, Inflammation and Fibrosis after Kidney Ischemia-Reperfusion Injury (IRI) Nicole Görldt,[1] Sun-Sang J. Sung,[1] Liping Huang,[1] Jessica R. Lawler,[1] Hong Ye,[1] Jurgen Schrader,[3] Diane L. Rosin,[2] Mark D. Okusa.[1] *[1]Div of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, Univ of VA; [2]Dept of Pharmacology, Univ of Virginia, Charlottesville, VA; [3]Inst of Molecular Cardiology, Heinrich-Heine-Univ, Duesseldorf, Germany.*

Background: Molecular mechanisms after IRI are poorly understood. ATP, released by apoptotic/necrotic cells, promotes pro-inflammatory responses but is rapidly metabolized by CD39 to AMP and then by CD73 to adenosine, which activates its specific receptors to regulate immune response and healing processes. Loss of CD73 increases inflammation

after IRI, but its contribution to late kidney fibrosis has not been examined. We hypothesize that CD73 mediates fibrosis after AKI by blocking inflammation-induced fibroblast-myofibroblast transformation.

Methods: *Foxd1^{Cre}CD73$^{fl/fl}$* (fibroblast CD73KO) and *Foxd1^{Cre}* (control; C) mice were subjected to 20' unilateral IRI, and kidney function, immune cell infiltration and histology were assessed at 14d. In a subset of mice simultaneous unilateral IRI and contralateral nephrectomy were performed to compare initial effects of IRI after 24h.

Results: 24h after IRI, fibroblast CD73KO and C mice had similar initial injury as assessed by plasma creatinine (PCr), KIM-1 and NGAL mRNA, but 14 d after IRI, PCr was higher in fibroblast CD73KO. Collagen formation, myofibroblast marker expression and the area occupied by PDGFR-β^{+} cells were higher in fibroblast CD73KO 14d after IRI, suggesting a role of CD73 in regulating fibroblast-myofibroblast transformation. Furthermore inflammation was higher in fibroblast CD73KO 14d after IRI resulting in impaired resolution of immune cell infiltration. Fibroblasts from *CD73$^{-/-}$* mice cultured *in vitro* showed a hyperproliferative phenotype.

Conclusions: These results demonstrate that mice with fibroblasts deficient in CD73 have increased fibrosis after injury and enhanced fibroblast-myofibroblast transformation, and their fibroblasts have a hyperproliferative phenotype. Understanding the molecular mechanism of regulation by fibroblast CD73 on phenotype transformation could provide an important therapeutic approach to blocking progressive kidney fibrosis.

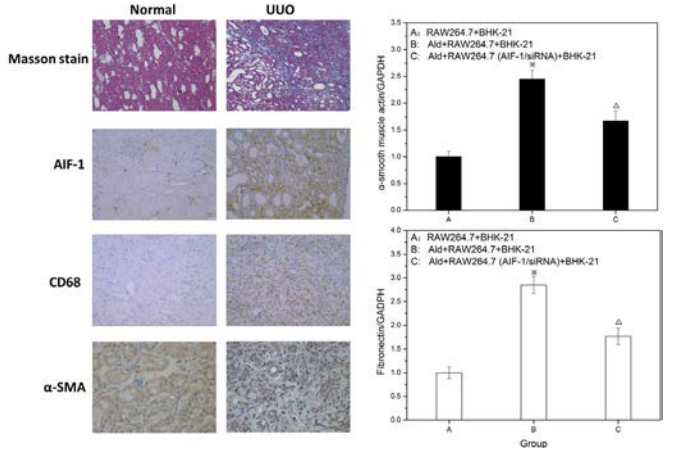
AIF-1 Expression in Macrophages Promotes Fibroblasts to a Pro-Fibrotic Phenotype and Renal Interstitial Fibrosis Yushu Li, Lirong Hao, Xingzhi Wang. *Nephrology, The 1st Hospital Affiliated of Harbin Medical Univ, Harbin, Heilongjiang, China.*

Background: Macrophages have been identified as key cells in the pathogenesis of renal interstitial fibrosis, but the mechanism is still unclear.This research focus on effects and possible mechanism of Allograft Inflammatory Factor-1 (AIF-1) in promoting of renal interstitial fibrosis.

Methods: Mice were subjected to Unilateral Ureteric Obstruction (UUO), and sacrificed after 14 days. Kidney sections were analyzed by Masson stain. Presence of AIF-1, CD68 and α-smooth muscle actin (α-SMA) were analyzed by immunohistochemistry. Double immunofluorescence stain of AIF-1 and CD68 was also used. AIF-1 expression in RAW264.7 stimulated by aldosterone was detected in vitro. To identify the role of AIF-1 in promoting fibrosis, AIF-1 expression was reduced by transfection of AIF-1 small interfering RNA (siRNA) in RAW264.7. Expressions of α-SMA, Phosphorylation P38 kinase (P-P38) and fibronectin (FN) in BHK-21 (fibroblasts cell line) were examined after co-culture with normal or AIF-1/siRNA RAW264.7.

Results:



Expressions of AIF-1, CD68 and α-SMA were up-regulated in UUO model. AIF-1 expression colocalized with CD68-positive macrophages in kidneys. The increase of AIF-1 expression (above basal levels) was confirmed in RAW264.7 responsed to aldosterone. After 24 hours of co-culture between fibroblasts and macrophages, the α-SMA expression was induced in BHK-21 with increasing expressions of FN and P-P38.Expressions of α-SMA,P-P38 and FN were reduced in BHK-21 co-cultured with RAW264.7 with AIF-1/siRNA.

Conclusions: The expression of AIF-1 in macrophages is critical for the activation of renal fibroblasts to a pro-fibrotic phenotype. AIF-1 expression could be up-regulated in macrophages, and it is a novel mechanism linking macrophages to the promotion of renal interstitial fibrosis, which should be via P38 pathway.

TH-PO161

Nrf2 Dependent Inflmmasome Activation Contributes to Maintain M1 Macrophage but Not M2 Infiltration in Kidney Disease Model Yuji Sogawa, Hajime Nagasu, Atsushi Uchida, Seiji Itano, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Inflammasome activation contributes progression of chronic kidney diseases (CKD) in animal disease model but the molecular mechanism was unknown. We focused on the transcription factor Nrf2 to reveal the mechanism of inflammasome activation in kidney injury. Nrf2 is a master transcription factor for cellular defense against oxidative stress, on the other side, Nrf2 play an important role in inflammasome activation. We investigated the contribution of Nrf2 dependent inflammasome activation for the progression of CKD.

Methods: (1) Male Nrf2 knockout mice (Nrf2$^{-/-}$) and Wild-type mice (WT) underwent UUO (unilateral ureteral obstruction). Histological change, inflammasome activity and fibrotic changes in kidney were examined. The polarity of the macrophages were assessed using FACS. (2) Bone marrow cells were harvest from WT or Nrf2$^{-/-}$ as a donor, then injected to tail vein of WT which were irradiated lethal dosage (Nrf2$^{-/-}$-BMT and WT-BMT). Two weeks after BMT, UUO were performed. Kidney were harvested to examine kidney damage at 14 days. (3) WT were also treated with AtRA (all trans retinoic acid) which is known as Nrf2 inhibitor, for daily 2 weeks after UUO.

Results: (1) Expression of inflammasome related genes is increased in 7 days, and fibrosis-related gene was increased to one-way from 3 days to 14 days in WT. These was reduced in Nrf2$^{-/-}$. Although inflammatory macrophage (M1; CD11b^{+}F4/80^{low}) was increased to one-way in both group until 7 days,it was significantly reduced in Nrf2$^{-/-}$ to 14 days. Anti-inflammatory macrophage (M2; CD11b^{+}F4/80^{high}) was similar in both group. (2) Fibrosis was histologically remarkably suppressed in Nrf2$^{-/-}$-BMT group compared with WT-BMT group.Furthermore expression of fibrosis-related gene and inflammasome-related gene has been suppressed in Nrf2$^{-/-}$-BMT group. (3) Compared to Control, fibrosis is suppressed histologically in AtRA group. Inflammasome activation and fibrosis-related genes was also suppressed.

Conclusions: Inflammatory macrophages sustain infiltrating by Nrf2-dependent inflammasome activation and contribute to kidney disease progress.

TH-PO162

eNOS-NO Pathway Attenuates Chronic Inflammation via Nitric Oxide in Hypertensive Kidney Disease Yuji Sogawa, Hajime Nagasu, Atsushi Uchida, Seiji Itano, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Medical School, Nephrology and Hypertension, Kurashiki, Okayama, Japan.*

Background: It is widely known that chronic inflammation is a common pathway of various progressive kidney diseases (CKD). We previously reported that NLRP3 inflammasome activation plays an important role in the progression of CKD. However, it is unclear how NLRP3 inflammasome is regulated in the kidney. We investigated whether or not NO suppresses inflammasome activation in hypertensive kidney disease because it is well known that endothelial dysfunction promotes progressive kidney disease. We used wild-type (WT) and enos knockout (eNOS$^{-/-}$) mice to determine the role of endothelial function, especially with nitric oxide, for inflammasome dependent chronic inflammation of the kidney.

Methods: [1] WT and enos$^{-/-}$ underwent unilateral nephrectomy (Nx). After NX, these mice were divided into four groups (WT-Nx, WT-Nx-Ald, eNOS-Nx, and eNOS-Nx-Ald). Aldosterone (Ald) was continuously administered with 1% NaCl drinking water. The mice were sacrificed after four weeks of Ald administration, and the kidney tissue was examined. [2] We used bone marrow-derived macrophages (BMDMs) to examine the molecular mechanism. After LPS priming, the BMDM were stimulated with ATP to activate NLRP3 inflammasome. We simultaneously primed with S-nitrosoglutathione (GSNO) as an NO donor or Bay41-2272 as a sGC stimulator.

Results: [1] In the WT-Nx-Ald, blood pressure increases were seen after administration of Ald. Fibroses were observed in the kidneys of the WT-Nx-Ald but not the WT-Nx. These changes were much more exacerbated in the eNOS-Nx-Ald compared with the WT-Nx-Ald. Expression of inflammatory genes was also much higher in the eNOS-Nx-Ald than in the WT-Nx-Ald. [2] ATP stimulation with LPS priming caused NLRP3 inflammasome-dependent cell death and IL1beta secretion. While GSNO inhibited this activation, it did not affect the sGC stimulator. This data suggests that NO can suppress NLRP3 inflammasome activation directly in macrophages.

Conclusions: Endothelial cell-induced NO inhibits inflammasome activation, which regulates chronic intra-renal inflammation. Additionally, endothelial dysfunction might promote chronic inflammation in CKD.

TH-PO163

Role of TLR4-MyD88 Regulation in the Renal Inflammation and Fibrosis Induced by C-Reactive Protein Jiao Hai Bao, Zi Li. *Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: Our previous study indicated CRP was not only a biomarker, but also a mediator of the pathogenesis of early renal fibrosis and inflammation. TGF-β/Smad and NF-κB signaling pathways activation but the underlying mechanism remains unclear. In present study, we hypothesis inflammation triggered by the NF-κB signaling pathway would subsequently activate Toll-like receptor 4, and then activates TGF-β/Smad and to mediates the acfute renal fibrosis and inflammation induced by CRP.

Methods: The expression of TLR4, MyD88 , NF-κB signaling pathway and TGF-β/Smad pathway, renal inflammation and fibrosis factors in both human renal proximal tubular epithelial cells(HK2) and human CRP-transgenic mice were detected. HK2 were cultured and stimulated with CRP, TLR4 siRNA, pyrrolidine dithiocarbamate (PDTC) (inhibitor for NF-kapa B). TLR4, MyD88 and other cytokines were assessed by real-time PCR and westernblot analysis . In vivo, unilateral ureteral obstruction model was mad in human CRP-transgenic and wild-type mice. Assessment of renal inflammation, fibrosis,NF-κB signaling pathway and TGF-β/Smad pathway, expression of TLR4 were evaluated by realtime PCR and immunohistochemistry staining.

Results: We found that HK2 incubation with CRP induced an significantly increase in expression of TLR4, MyD88, pro-inflammatory cytokines (IL-1β, TNF-α), chemokines (MCP-1) and pro-fibrotic growth factors (TGF-β, collegen-1,α-SMA) . Silencing of TLR4 with siRNA attenuated CRP-induced TGF-β/Smad signaling pathways activation, inhibited the downstream synthesis of MyD88, TGF-β, collegen-1 and α-SMA. Block NF-κB signal pathway inhibited expression of TLR4, MyD88, and all the inflammation and fibrosis cytokines. Compared with wild-type (Wt) mice at 3 days after UUO, CRPtg mice expressed more TLR4, MyD88 and developed more severe renal inflammation and fibrosis with a significant upregulation of proinflammatory cytokines , chemokines and pro-fibrotic growth factors.

Conclusions: CRP induced early renal inflammation by activating NF-κB signaling pathway, then lead to renal fibrosis through TLR4-MyD88-TGF-β/Smad dependent pathway.

TH-PO164

Activation of Angiotensin II Receptors on T Cells Attenuates Renal Fibrosis

Nathan Rudemiller, Jiandong Zhang, Alexander David Jeffs, Steven D. Crowley. *Medicine/Div Nephrology, Duke Univ and Durham VA Medical Centers, Durham, NC.*

Background: Most forms of chronic kidney disease (CKD) culminate with renal fibrosis that heralds organ failure. Although global blockade of type 1 angiotensin (AT_1) receptors attenuates hypertension and kidney fibrosis, we have recently discovered that activating AT_1 receptors directly on T lymphocytes limits their differentiation toward a pro-inflammatory Th1 phenotype by blunting expression of the Th1 transcription factor TBET. As activated T cells have recently been implicated in the pathogenesis of kidney fibrosis, we hypothesized that AT_1 receptor activation on T cells may ameliorate kidney fibrosis.

Methods: We subjected mice with GFP^+ T cells (Lck Cre mT/mG) or T cell-specific deletion of the dominant murine AT_1 receptor isoform, AT_{1A}, (Lck Cre $Agtra^{flox/flox}$; "TKO"; 90% deletion) and wild-type (WT) controls to the unilateral ureteral obstruction (UUO) model of kidney fibrosis.

Results: In Lck Cre mT/mG reporter mice, renal infiltration of GFP^+ T cells peaked at day 14 UUO. Compared to WTs, obstructed TKO kidneys at day 14 had increased expression of mRNA for TGF-B (1.0 ± 0.1 vs 1.6 ± 0.4 au; P = 0.04) and more collagen 1 protein deposition (1.8 ± 0.4% vs 3.7 ± 0.9% of section; P = 0.05). Obstructed TKO kidneys also had elevated mRNA levels for TNF-α (1.0 ± 0.1 vs 1.6 ± 0.3 au; P = 0.03) and interleukin-1B (IL1B) (1.0 ± 0.1 vs 2.2 ± 0.6 au; P = 0.02), suggesting that activation of the AT1 receptor on infiltrating T cells mitigates renal fibrosis by suppressing their generation of profibrotic Th1 cytokines. To test the contribution of the Th1 response to kidney fibrosis, we examined kidney scar formation in TBET deficient (KO) mice and controls. At day 14 after UUO, TBET KO kidneys contained less collagen 1 mRNA (1.3 ± 0.1 vs 1.0 ± 0.1 au; P = 0.01) and protein (P<0.006) and expressed lower levels of IL1B (1.5 ± 0.2 vs 1.0 ± 0.1 au; P = 0.02).

Conclusions: We conclude that activating the T cell AT_1 receptor mitigates renal fibrogenesis by inhibiting their elaboration of pro-inflammatory and pro-fibrotic cytokines. These studies illustrate important tissue-specific actions of the renin angiotensin system in modulating the progression of CKD.

Factor XII Deficiency Confers a Modest Renal Beneficial Effect in 5/6 Nephrectomy-Induced Chronic Kidney Disease in Rats

Xiaoyan Zhou,[1] Zhu Chen,[1] Maarten Hoek,[1] Wei Zhu,[1] Weizhen Wu,[1] Gino A. Castriota,[1] Emanuel Zycband,[1] Yonghua Zhu,[1] Haihong Zhou,[1] Ying Chen,[1] Ye Tian,[2] Yanqing Kan,[1] Dan Xie,[1] Stephen F. Previs,[1] Olga Price,[3] Gail M. Forrest,[3] Dietmar Alfred Seiffert,[1] Shirly Pinto.[1] *[1]Cardiometabolic Diseases, Merck & Co., Kenilworth, NJ; [2]In Vivo Pharmacology, Merck & Co., Kenilworth, NJ; [3]Drug Metabolism, Merck & Co., Kenilworth, NJ.*

Background: Coagulation Factor XII (FXII) was previously reported as one of the candidate genes in proximity of the single-nucleotide polymorphisms (SNPs) significantly correlated with GFR. FXII mRNA levels in the kidney are negatively correlated with eGFR in chronic kidney disease (CKD) patients. We therefore were interested in evaluating whether FXII plays a causal role in CKD development and progression by studying the FXII knockout (KO) rat in a CKD model. The present study was designed to assess blood pressure, renal function and histology in wild type (WT) and FXII KO rats with surgically induced CKD via 5/6 nephrectomy (NX).

Methods: Four experimental groups were included: WT sham surgery; WT with 5/6 NX; FXII KO sham surgery; FXII KO with 5/6 NX. Blood pressure was measured by radiotelemetry. Renal function was assessed in metabolic cage studies. Kidney fibrosis was assessed by collagen synthesis rate and collagen trichrome staining. Kidney gene profiling was determined by RT-PCR. Plasma bradykinin was measured by ELISA and LC/MS.

Results: FXII KO animals exhibited markedly prolonged activated partial thromboplastin time (aPTT) and lower basal and stimulated bradykinin levels than WT animals, as expected. WT 5/6 NX animals developed hypertension, kidney hypertrophy, proteinuria, GFR reduction, kidney fibrosis and tubular injury, consistent with our understanding on the model. FXII KO 5/6NX group displayed significantly lower blood pressure and proteinuria, and a trend toward less GFR declining and less severe kidney fibrosis than the WT 5/6NX group.

Conclusions: Our data suggest that FXII deficiency confers a modest renal beneficial effect in 5/6 NX rat model. Future studies will be necessary in further determining the role of FXII-mediated activation of Plasma Kallikrein-kinin system (PKKS) in CKD development in the 5/6 NX rat model.

Renal Pharmacology and Preclinical Attributes of Sparsentan, a Dually Active Endothelin A and Angiotensin 1 Receptor Antagonist

Kevin Leach, Xin-Ru Pan-Zhou, Wayne Deats, Maria Beconi. *Retrophin, Inc., Cambridge, MA.*

Background: Sparsentan (RE-021) is a first-in-class, potent, dual endothelin A (ET_A) and angiotensin 1 (AT1) receptor antagonist currently in clinical development to treat focal segmental glomerular sclerosis (FSGS). Here we report the results of in vitro potency studies and in vivo toxicology studies and the effects of sparsentan in 2 different renal pharmacological models.

Methods: In vitro potency was assessed by competition with the appropriate ligand. Pharmacological activity was measured in either the 5/6 nephrectomy or Passive Heymann Nephritis models in rats. Long-term toxicology studies were performed in the Sprague Dawley rat and the Cynomolgus monkey.

Results: In vitro, sparsentan is a potent antagonist of the AT1 receptor (Ki=0.9 nM) and the ET_A receptor subtype (Ki=13 nM), with selectivity over the endothelin B subtype (Ki=6582 nM). In the 5/6 nephrectomy rat model of glomerular sclerosis, where animals received a single daily oral dose of sparsentan at 6, 18, or 60 mg/kg/day for 8 weeks, sparsentan reduced systolic blood pressure compared with the 5/6 nephrectomized control rats at the 18- and 60-mg/kg/day doses. At 60 mg/kg/day, sparsentan significantly reduced proteinuria compared with the control group after 4 (-65%, $P<.05$) and 8 weeks (-84%, $P<.05$) of treatment. The 18-mg/kg/day dose showed a positive trend toward reduction in proteinuria at 8 weeks. In the anti-FX1A-induced passive Heymann Nephritis model, 60 mg/kg/day oral sparsentan led to a 59% ($P=.009$) decrease in proteinuria, significant preservation of podocytes in the glomeruli ($P=.02$) and significant reduction in fibrosis in the kidney ($P=.03$) as measured by alpha smooth muscle actin staining. In long-term toxicology studies the no observed adverse effect level for sparsentan was 50 mg/kg/day in Cynomolgus monkeys and 80 mg/kg/day in Sprague-Dawley rats; the corresponding $AUC_{0\text{-last}}$ were 14 and 209 μg×hr/mL, respectively.

Conclusions: The combined preclinical characteristics of sparsentan—potency, selectivity, pharmacology, and toxicology—are consistent with a molecule that may be safe and effective to treat FSGS.

Funding: Pharmaceutical Company Support - Pharmacopeia, Inc. funded the long-term toxicity studies. Retrophin, Inc. acquired sparsentan from Ligand Pharmaceuticals (formerly Pharmacopeia) and funded the other preclinical studies. Retrophin, Inc., participated in the writing, reviewing, and approving this abstract for presentation

T-Type Calcium Channel Blocker Attenuates Renal Interstitial Fibrosis Induced by Unilateral Ureteral Obstruction via Activating the Nrf2 Antioxidant Pathway

Seok Joon Shin, Soojeong Kim, Minyoung Kim, Eun Sil Koh, Sungjin Chung. *Nephrology, The Catholic Univ of Korea, Seoul, Korea.*

Background: T-type calcium channel blocker has been reported to have a renoprotective effect in experimental models of renal fibrosis. We investigated whether the renoprotective effect of T-type calcium channel blocker is associated with modulation of the signaling of oxidative stress-induced renal fibrosis.

Methods: Treatment with a non-hypotensive dose of efonidipine, a T-type calcium channel blocker, or nifedipine, an L-type channel blocker, was initiated one day before unilateral ureteral obstruction (UUO) in C57BL6/J mice, and was continued until 3 and 7 days after UUO. Oxidative stress, inflammation and fibrosis in renal tissues were evaluated.

Results: In the obstructed kidneys, treatment with efonidipine significantly attenuated interstitial fibrosis, collagen deposition and inflammatory cell infiltration compared with those of treatment with nifedipine on day 7 after UUO. Additionally, efonidipine significantly increased the expression of the antioxidant enzymes heme oxygenase-1, NAD(P)H:quinone oxidoreductase 1 and superoxide dismutase 1 on day 3 and 7 after UUO, and Nox4 and catalase on day 3 after UUO. Increased apoptotic cell death and decreased Bcl-2 were also significantly ameliorated by efonidipine. Furthermore, the expression of the histone acetyltransferase p300/CBP-associated factor (PCAF), a regulator of inflammatory molecules, was significantly inhibited by efonidipine, on the contrary, nifedipine decreased the expression of PCAF. These beneficial effects of efonipidine were attributed to the increased nuclear expression of nuclear factor-erythroid-2-related factor 2 (Nrf2) on UUO day 3 and the increased expressions of both total and nuclear Nrf2 with elevated Kelch-like ECH-associated protein 1 on UUO day 7.

Conclusions: T-type calcium channel blocker could attenuate UUO-induced renal tubulointerstitial inflammation and fibrosis, via increased expression of PCAF and activation of the Nrf2 followed by upregulation of its subsequent antioxidants.

HDAC1 Inhibition Ameliorates Renal Inflammation in Unilateral Ureteral Obstruction Induced Renal Fibrosis Jin Han Lim,[1,2] Kyung Pyo Kang,[1] Tung Nguyen-Thanh,[1] Won Kim,[1] Sik Lee,[1] Sung Kwang Park.[1] *[1]Dept of Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Korea; [2]Dept of Internal Medicine, Research Inst of Clinical Medicine, Chonbuk National Univ Hospital.*

Background: Renal fibrosis begins from localized activation of inflammatory processes, which include infiltration of inflammatory cells and production of proinflammatory cytokines and chemokines. Histone deacetylases can remove acetyl-residue from histones and result transcriptional regulation of DNA. Inhibition of these histone deacetylase (HDAC) might have potential protective effect against fibrosis of the liver, heart and kidney. However, modulation of renal inflammation by HDAC inhibition was still elusive in renal fibrosis process. Therefore, we evaluate whether class I HDAC inhibitor have anti-inflammatory effect on unilateral ureteral obstruction (UUO)-induced renal fibrosis.

Methods: Renal fibrosis was induced by UUO in the six-week-old C57BL/6 mice for 14 days. Class I HDAC inhibitor, vaproic acid (VPA, 300 mg/kg), was treated by intraperitoneal injection for 5 days before induction of renal fibrosis and continued for 14 days. Tubular injury, fibrosis and macrophage infiltration were evaluated by histologic examination. Expression of inflammatory cytokines and chemokines were evaluated by Western blot analysis and ELISA.

Results: After 14 days of ureteral obstruction, renal tubular injury and fibrosis were significantly increased compared to sham operation group. VPA treatment group has significantly attenuated the UUO-induced renal tubular injury and fibrosis. The number of F4/80 (+) macrophage infiltration after UUO surgery was significantly decreased after VPA treatment. In immunohistochemistry study, VPA treatment significantly decreased UUO-induced increase of ICAM-1 and MCP-1 expression in the tubule-interstitial area. We also found that total kidney ICAM-1 and MCP-1 expression were decreased after VPA treatment in UUO model by Western blot analysis and ELISA.

Conclusions: In conclusion, VPA have anti-inflammatory effect on UUO-induced renal inflammation through regulation of ICAM-1 and MCP-1 expression and decreases renal fibrosis.

D-Pinitol Alleviates Cyclosporine-Induced Renal Fibrosis via the Activation of Sirt1 and Nrf2 Antioxidant Pathways Minyoung Kim,[1] Soojeong Kim,[2] Eun Sil Koh,[1] Hyung Wook Kim,[1] Sungjin Chung,[1] Seok Joon Shin.[1] *[1]Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Dept of Biochemistry, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: D-Pinitol, 3-methoxy analogue of D-chiroinositol, is one of the most abundant cyclitol present in soybean seeds, legumes and soy food. According to previous studies, D-pinitol has been suggested to possess multifunctional properties including anti-inflammatory, anti-lipidemic and anti-diabetic effects. The aim of this study was to evaluate of the effect of D-pinitol on renal fibrosis through the antioxidant signaling pathway in an experimental model of cyclosporine A (CsA)-induced nephropathy.

Methods: Renal effect of oral treatment of D-pinitol at 50 mg/kg body weight for 28 days was evaluated against CsA-induced renal injury in male ICR mice.

Results: Treatment with D-pinitol significantly prevented the rise in albuminuria, urine volume and urine osmolality and the decrease in renal function as compared to CsA control group. Additionally, D-pinitol attenuated CsA-induced tubulointerstitial fibrosis and inflammation as assessed by Masson's trichrome and α-SMA staining. Administration of D-pinitol increased the expression of heme oxygenase-1, NAD(P)H:quinone oxidoreductase 1 and catalase in CsA-treated kidneys. These renoprotective effects of D-pinitol were attributed to the increase in level of sirtuin 1 (Sirt1) and total and nuclear expressions of nuclear erythroid factor 2-related factor 2 (Nrf2), as well as an elevated level of Kelch-like ECHassociated protein 1, indicating that Sirt1 increased by D-pinitol regulates Nrf2 and in turn the activated Nrf2 affects the cellular antioxidant system.

Conclusions: These findings show that the renoprotective effect of D-pinitol against renal fibrosis in CsA-induced nephrotoxicity may result from the inhibition of oxidative stress through Sirt1 and Nrf2 activation and subsequent enhancement of antioxidant enzymes.

TH-PO170

Ligand-Bound Thyroid Hormone Receptor on Macrophages Ameliorate Kidney Injury via Inhibition of Nuclear Factor-κB Activities Toshihisa Ishii, Fumihiko Furuya, Kenichiro Kitamura. *Third Dept of Internal Medicine, Univ of Yamanashi, Chuo, Yamanashi, Japan.*

Background: In chronic kidney disease (CKD) patients, inflammation plays a pivotal role in the tubulointestitial injury and the progression of renal fibrosis, however it remains unclear how its processes are initiated and regulated. Hypothyroidism is associated with an increased occurrence of atherosclerosis and inflammation, suggesting the protective roles of thyroid hormones and its receptors against inflammatory processes. However, the contribution of thyroid hormone receptors to the macrophage differentiation has not been well documented.

Methods: We focused on the endogenous thyroid hormone receptor α (TRα) in macrophages and examined the role of ligand-bound TRα in the macrophage polarization-mediated anti-inflammatory effects.

Results: TRα-deficient irradiated chimeric mice exacerbated tubulointerstitial injury in the UUO model when compared with wild type mice. Macrophages isolated from obstructed kidneys of mice lacking TRα were mainly derived from bone marrow and displayed increased expression of proinflammatory cytokines such as IL-1β. In bone marrow-derived macrophages from wild type mice, T3-depleted culture medium augmented the phosphorylation of IκBα and enhanced the translocation of p65 to the nucleus via MAPK/MAPK phosphatase pathway. TRα-deficient macrophages also increased the release of proinflammatory cytokines accompanied with the increased nuclear translocation of p65. Evaluation of TRα-deficient bone marrow-derived macrophages confirmed the propensity of these cells to produce exaggerated levels of IL-1β, and co-culture of TRα-deficient bone marrow-derived macrophages with renal epithelial cells induced more severe damages to the epithelial cells via IL-1 receptor (IL1R) activation compared with wild type bone marrow-derived macrophages.

Conclusions: Our study indicates that ligand-bound TRα on macrophages plays protective roles in the kidney inflammation through the inhibition of NF-κB pathway, possibly by affecting the pro- and anti-inflammatory balance that controls the development of CKD.

TH-PO171

Canonical Wnt Signaling Promotes Macrophage Proliferation and Migration and Potentiates Kidney Fibrosis in Mice with Obstructive Nephropathy Ye Feng, Jiafa Ren, Chunsun Dai. *Nanjing Medical Univ.*

Background: Macrophage accumulation plays a critical role for kidney fibrosis in chronic kidney diseases. However, the underlying mechanisms regulating macrophage accumulation during kidney fibrosis remain to be investigated.

Results: In this study, we found that canonicalWnt/β-catenin signaling was robustly activated in macrophages from the fibrotic kidneys after UUO or IRI. A mouse model with specific deletion of β-catenin in macrophages was generated by using the Cre-LoxP system. Compared to control littermates, the knockouts developed less kidney injury, interstitial extracelluar matrix deposition, macrophage accumulation or macrophage proliferation in kidney tissue at 2 weeks after UUO. In the primary cultured bone marrow–derived macrophages (BMMs), compared with wild type macrophages, cell proliferation and cyclin D1 expression stimulated by M-CSF were markedly decreased in β-catenin–deficient macrophages. Additionally, cell motility for β-catenin–deficient macrophages was also largely inhibited compared to the wild type macrophages.

Conclusions: Taken together, this study suggests that Wnt/β-catenin signaling may regulate macrophage proliferation and migration, which may potentiate kidney fibrosis in mice with UUO nephropathy.

Inhibition of Inflammasomes Activation Attenuates Hypertensive Renal Injury Satoru Oka,[1] Yoko Obata,[1] Kenta Torigoe,[1] Miki Sawa,[1] Takehiko Koji,[2] Tomoya Nishino.[1] *[1]Dept of Nephrology, Nagasaki Univ Hospital, Nagasaki, Japan; [2]Dept of Histology and Cell Biology, Nagasaki Univ Graduate School of Biomedical Sciences, Nagasaki, Japan.*

Background: Chronic inflammation is closely linked to the development of organ damage by hypertension. Inflammasomes are involved in the production of IL-1b and play an important role in the progression of inflammation. Thus, inflammasomes may be involved in the development of hypertensive renal injury.

Methods: Using the Dahl salt-sensitive (DS) rats as a model of hypertensive renal injury, we examined the involvement of inflammasomes in the development of hypertensive renal injury and investigated whether colchicine (Col), an inhibitor of tubulin polymerization which is essential for activation of inflammasomes, attenuated hypertensive renal injury. We divided three groups: (1) DS rats fed a normal-salt diet, defined as DS + NS group, (2) DS rats fed a high-salt diet, defined as DS + HS group, (3) DS rats fed a high-salt diet with oral Col administration, defined as DS + HS + Col group. After 6 weeks salt loading, we collected renal tissue, blood and urine sample. We examined the morphological changes, the expression of inflammasomes associated protein (NLRP3 and caspase-1) by immunohistochemistry, and measured the urinary IL-1b by ELISA.

Results: Systolic blood pressure significantly elevated from 2 weeks after salt loading, but Col administration did not affect blood pressure. Serum creatinine, interstitial fibrosis and glomerulosclerosis significantly increased in the DS + HS group than those in the DS + NS group. These changes were significantly suppressed by Col administration. NLRP3 and caspase-1 expressions were limited to renal tubules and these expressions in the DS + HS group were significantly enhanced than those in the DS + NS group. Col administration significantly suppressed these expression. Moreover, urinary IL-1b was significantly increased in the DS + HS group than that in the DS + NS group, but Col tend to decrease urinary IL-1b levels.

Conclusions: Our results suggest that the inhibition of inflammasomes activation may be a therapeutic target in the hypertensive renal injury.

TH-PO173

shRNA Mediated Knockdown of DPP4 in the Kidney Ameliorates Kidney Inflammation and Proteinuria Ravi Nistala, Jianzhong An. *Medicine, Univ of Missouri-Columbia, Columbia, MO.*

Background: Dipeptidyl peptidase 4 (DPP4) inhibition is widely used for type 2 diabetes mellitus (T2DM) management. The Saxagliptin Assessment of Vascular Outcomes Recorded in Patients with Diabetes Mellitus - Thrombolysis in Myocardial Infarction 53

(SAVOR-TIMI 53) trial showed that DPP4 inhibition improves proteinuria in T2DM subjects with chronic kidney disease (CKD). Our lab and others have observed that kidney DPP4 activation in rodents is associated with proteinuria in conditions of RAAS activation including diabetes and obesity. However, the role of kidney DPP4 is not clear.

Methods: To test our hypothesis, we uninephrectomized mice, knocked down DPP4 via lentiviral based shRNA injections into the contralateral kidney through the renal veins. After a recovery period of 2-3 wks, we implanted Ang II osmotic pumps (1000ng/kg/min), DOCA pellet (50mg) and provided 0.9% NaCl in drinking water for an additional 2 wks.

Results: Ang II-DOCA salt caused heart hypertrophy (Ang II/DOCA salt, 174±16mg vs. Saline, 140mg±8.2mg) as expected accompanied by left kidney hypertrophy. DPP4 knockdown was not protective of this hypertrophy. However, DPP4 knockdown prevented kidney injury as assessed by reduction in albuminuria (Sham controls+Ang II/DOCA 80.18 ug/mg crt vs. DPP4shRNA+Ang II/DOCA 25.76 ug/mg crt). Flow cytometry assessment showed that DPP4 knockdown prevented activation of CD4+ T-cells by Ang II/DOCA salt as indicated by reduced expression of DPP4 on CD4+, CD44+CD127+ central memory and CD44+CD127- effector cells. In addition, DPP4 knockdown prevented the Ang II/DOCA salt mediated infiltration of Ly6ChiCD11bhiF4/80lo macrophages and decreased CD11bloF4/80hi resident dendritic cells. DPP4 knockdown decreased pro-fibrotic markers such as Col1A and CTGF. Lastly, DPP4 knockdown decreased glomerulomegaly, mesangial expansion and interstitial inflammation as assessed by trichrome stain.

Conclusions: In summary, RAAS activation is a prominent mechanism for kidney injury in diabetes and obesity and kidney DPP4 is an important effector of RAAS mediated effects. Kidney specific DPP4 inhibition may ameliorate kidney injury and proteinuria through reduction in activation of the immune system and pro-fibrotic markers.

Allopurinol Diminished NLRP3 and Attenuated Hypertension and Renal Inflammation in the Chronic NO Inhibition and Salt Overload Model

Fernanda F.F. Zambom, Karin C. Oliveira, Victor F. Avila, Simone C.A. Arias, Camilla Fanelli, Orestes Foresto-Neto, Denise M. Malheiros, Niels O.S. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

Background: Chronic NO synthase (NOS) inhibition with Nω-nitroarginine methylester (NAME) is a model of renal inflammation leading to hypertension (HT). Concomitant salt overload (HS) aggravates renal injury/inflammation and exacerbates HT. The pathogenesis of these processes remains unclear. Here, we investigated whether in this model: 1) Innate immunity (InIm) is activated; 2) Allopurinol (Allo), which has been reported to inhibit the NLRP3 inflammasome, attenuates renal damage.

Methods: Male Munich-Wistar rats received oral NAME (32 mg/Kg/d) and HS (HS+NAME, N=10). Other rats received HS+NAME and Allo, 36 mg/kg/d, (HS+NAME+Allo, N=10). Control rats received HS only (N=9). Tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d) and glomerulosclerosis (GS, %) were assessed after 4 weeks. In addition, we evaluated % interstitial collagen 1 (COLL1) and α-actin, and macrophages (MΦ, cells/mm^2). Glomerular (%area) and interstitial (cells/mm^2) NLRP3 was estimated by IHC. Renal content of IL1β (pg/mg), Caspase1, TLR4 and nuclear p65 (NFκB) were also measured (x HS).

Results:

	HS	HS+NAME	HS+NAME+Allo
TCP	148±2	211±4[a]	192±4[ab]
ALB	11±3	144±13[a]	79±18[ab]
GS%	0.3±0.2	4.5±1.2[a]	3.8±1[a]
COLL1%	1±1	3±1[a]	2±1[ab]
MΦint	23±2	133±7[a]	88±10[ab]
α-actin	0.7±0.1	10±1[a]	5±1[ab]
NLRP3int	0.8±0.1	2.4±0.3[a]	1.1±0.2[b]
NLRP3glom	1.4±0.2	4.5±0.8[a]	2.1±0.4[b]
IL1β	1.6±0.3	4.5±0.8[a]	2.0±0.3[b]
Caspase1	1.0±0.2	1.6±0.3	1.8±0.3
TLR4	1.0±0.1	2.6±0.4[a]	1.7±0.4
p65	1.0±0.1	2.9±0.3[a]	2.7±0.3[a]
Mean±SE;[a]p<0.05 vs HS,[b]p<0.05 vs HS+NAME			

These results suggest that severe HTN and renal inflammation/injury were associated with activation of both NLRP3/IL1β and TLR4/NFkB pathways. Allo normalized renal NLRP3/IL1β, attenuating HTN, ALB, renal inflammation and fibrosis, although NFkB remained activated.

Conclusions: Allo prevented NLRP3 activation and attenuated HT and renal injury in the HS+NAME model. Allo may exert renoprotection by mechanisms additional to, or independent of, its effect on uric acid. FAPESP/CNPq.

TH-PO175

Role of Innate Immunity in the Progressive Nephropathy That Ensues after Brief NO Inhibition and Salt Overload

Karin C. Oliveira, Fernanda F.F. Zambom, Lais Braga, Victor F. Avila, Simone C.A. Arias, Camilla Fanelli, Claudia R. Sena, Vivian L. Viana, Denise M. Malheiros, Niels O.S. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

Background: NO inhibition by L-NAME plus salt overload (HS) leads to marked hypertension (HT) and renal injury. With cessation of treatment, most of these changes subside, but progressive renal injury/inflammation develops. Here we investigated whether activation of innate immunity (InIm) is involved in this process.

Methods: Male Munich-Wistar rats received HS and L-NAME, 32 mg/Kg/d. Control rats received HS only. Treatments ceased at 4 wk (18 rats studied). Additional rats (N=36) were studied at 8 and 28 wk. Assessed at each time point: tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), glomerulosclerosis (GS, %), ischemic glomeruli (IG, %), interstitial collagen 1 (COLL, %), AngII+ and macrophages (Mø), cells/mm^2, and the renal protein content of IL1β (pg/mg), Casp1, TLR4, and NFkB (x HS).

Results:

	4wks		8wks		28wks	
	HS	HS+N	HS	HS+N	HS	HS+N
TCP	146±3	213±3*	146±3	164±4*[#]	131±2	162±8*
ALB	9±2	160±27*	5±1	25±6[#]	18±4	68±13*[&]
GS%	0±0	2±1*	0±0	1±0*	1±1	7±2*[&]
GI%	0±0	17±2*	0±0	7±1*[#]	0±0	4±0*[&]
COLL	1±0	4±1*	2±0	4±0*	1±1	4±0*
MΦ	26±4	225±19*	34±5	85±15*[#]	34±4	104±17*
AngII	2±0	10±1*	3±0	14±3*	3±1	10±2*
Casp1	1±0	4±1*	1±1	2±1	1±1	2±1
IL1β	2±0	4±1*	2±1	2±1	1±1	2±0.1
NFκB	1±1	2±1	1±1	2±1	1±1	1±1
TLR4	1±1	2±1*	1±1	2±1*	1±1	2±1*
*p<0.05 vs HS [#]p<0.05 vs 4 wk [&]p<0.05 vs 8 wk						

Expectedly, 4 wk HS+N caused severe HT, ALB and renal injury and increased Casp1, IL1β and TLR4. At 8 wk, renal injury/inflammation regressed partially, but InIm remained activated. At 28 wk, GS worsened, while inflammation and InIm activation persisted.

Conclusions: InIm activation may contribute to the initiation of renal injury in the HS+L-NAME model, and for autonomous progression of the nephrophaty even after cessation of the original insult. FAPESP/CNpq.

Funding: Government Support - Non-U.S.

TH-PO176

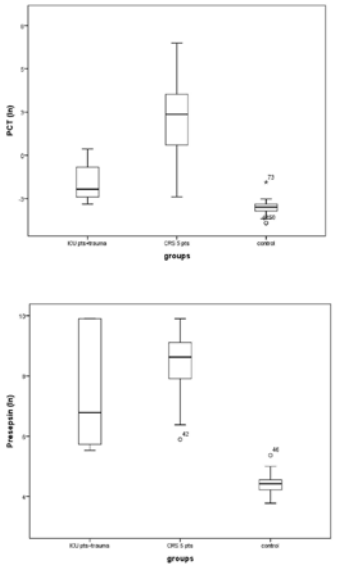
Useful of Presepsin and Procalcitonin in Cardiorenal Syndrome Type 5 Diagnosis

Alessandra Brocca, Grazia Maria Virzì, Anna Clementi, Massimo de Cal, Claudio Ronco. *IRRIV.*

Background: Procalcitonin (PCT) has been shown to predict bacteremia and bacterial DNAemia. Presepsin is the soluble N-terminal fragment of CD14, which is the receptor for LPS and LPS-binding protein complexes; its level increases in response to bacterial infections, and it is considered a new, emerging, early marker for sepsis. The aim of this study was to investigate the role of Presepsin and PCT in the diagnosis of patients with Cardiorenal Syndrome Type 5 (CRS5).

Methods: we enrolled 8 ICU patients with trauma (4 male; age 61.6±22.9), 36 CRS5 patients (30 male; age 64.8±15.7) and 19 healthy controls (CTR) (10 male; age 42.3.±11.4). Plasma levels of Presepsin and PCT, IL6; IL18, TNFα, NGAL and endotoxin level were detected at diagnosis. Serum endotoxin activity was measured by the EAA^{tm}.

Results: Accordingly to EAA levels, patients were divided into two groups: 25% of patients had low endotoxin activity level (negative EAA), while 75% of patients showed high endotoxin activity level (positive EAA). Plasma PCT in CRS5 patients were significantly higher than those in ICU patients with trauma and CTR (both p=0.000). PCT levels was higher in pts with positive EAA results compared to negative EAA pts (p=0.000). Presepsin was significantly higher in trauma and in CRS5 patients than in CTR (both p=0.000). There were a positive correlations between Presepsin and IL6 (rho=0.583), TNFα (rho=0.411), IL18 (rho=0.636) and NGAL (rho=0.646)(all p<0.001).



Conclusions: Our results suggest that the levels of PCT are increased in CRS5 patients compared to trauma patients and CTR and PCT discriminate patients with positive EAA from the others. Presepsin correlates with pro-inflammatory cytokines and NGAL level, but it cannot discriminate between CRS5 and trauma pts in our ICU population. In conclusion, presepsin may underline an inflammatory process and PCT may be useful as a biomarker of systemic process and in particular of septic condition.

TH-PO177

Identification of Myeloid-Derived Fibrosis-Inducing Cells Presumably Accounting for Cardiorenal Connection in Chronic Kidney Disease Akihiro Sagara,[1] Norihiko Sakai,[1] Yasunori Iwata,[1] Kengo Furuichi,[1] Yasuhiko Yamamoto,[2] Takashi Wada.[1] *[1]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan; [2]Dept of Biochemistry and Molecular Vascular Biology, Kanazawa Univ Graduate School of Medical Sciences, Kanazawa, Japan.*

Background: Chronic kidney disease (CKD) is a serious risk factor for cardiovascular diseases, which is known as cardio-renal syndrome (CRS). Dysregulation of tissue repair such as fibrosis is a pathological process leading to the end stage of organ failure. However, fibrosis mediators in CRS under CKD are not fully defined.

Methods: To seek the functional cell mediator, unilateral ureteral obstruction (UUO) plus angiotensin II (AII) infusion (AII+UUO) CRS model was established and used with employing CAG-GFP mice and Col1a2 (Col)-GFP mice along with procedures of parabiosis and bone-marrow transplantation (BMT). We performed flow cytometry to identify newly recruited cells into hearts or kidneys and gene expression analyses followed by cell sorting. We also used immunohistochemistry and co-culture system of sorted cells with mouse embryonic fibroblasts (MEFs) from Col-Luciferase mice.

Results: We newly identified a cluster of myeloid cells, which was tracked by GFP using mouse parabiosis or BMT and thereby found to be double-positive for CD45 and Sca1 in hearts as well as kidneys of the CRS model. The cells of the cluster were oval-shaped and mononuclear and significantly increased in number in proportion to heart fibrosis. Gene chip analyses further led to subdividing the population and then identifying fibrosis-triggering cells using Col-reporter MEF co-culture system. The number of the fibrosis-inducing cells in peripheral blood was also significantly increased in the CRS model.

Conclusions: We identified a new population of myeloid-derived fibrosis-inducing cells which were associated with cardiac and kidney fibrosis using our CRS mouse model. Novel strategies targeting the cell population would be therapeutic means against CRS in CKD.

TH-PO178

Lineage Tracing Analysis Elucidating the Behaviors of Erythropoietin Producing Cells Keiichi Kaneko, Misako Asada, Motoko Yanagita. *Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto-shi, Kyoto-hu, Japan.*

Background: We previously reported that resident fibroblasts in the kidney including erythropoietin (Epo)-producing cells transdifferentiate into myofibroblasts with concomitant loss of Epo production during renal fibrosis. However, previous reports including ours cannot distinguish current Epo-producing cells from resident fibroblasts, and the behavior of Epo-producing remains unclear.

Recently Epo-Cre mice were generated which enabled the lineage tracing of the cells with the history of Epo production. With Epo-Cre mice, the transdifferentiation of Epo-Cre labeled cells into myofibroblasts during fibrosis has been demonstrated. As Epo-Cre mice labeled Epo-producing cells from fetal period to adult life, we tried to narrow down the period of labeling and trace current Epo-producing cells at desired time points.

Methods: We generated a novel mouse strain in which inducible form of Cre, Cre^{ERT2} is knocked-in at the locus of Epo gene (Epo-Cre^{ERT2} mice). Epo-Cre^{ERT2} mice were crossed with R26TdTomato mice, and tamoxifen was administered to activate Cre^{ERT2}.

Results: Epo-Cre^{ERT2} labeled cells were located in the interstitium of the cortex and corticomedullary region of the kidney, and expressed PDGFRb and CD73, indicating that these cells are resident fibroblasts. Double in situ hybridization confirmed that Epo-Cre^{ERT2} labeled cells expressed Epo mRNA, indicating that Epo-Cre^{ERT2} mice labeled Epo-producing cells faithfully. The numbers of Epo-Cre^{ERT2} labeled cells were increased with the induction of anemia. After unilateral ureteral obstruction, Epo-Cre^{ERT2} labeled cells expressed aSMA and increased in parallel with the progression of fibrosis, indicating the transdifferentiation to myofibroblasts.

Conclusions: We generated a novel mouse strain, Epo-Cre^{ERT2} mice, which faithfully label current Epo-producing cells at desired time points. Epo-Cre^{ERT2} labeled cells transdifferentiated into myofibroblasts and increased during renal fibrosis. Further analysis of Epo-producing cells with this strain will provide clues to the unsolved questions whether Epo-producing cells are distinct population in resident fibroblasts.

microRNAs Are Essential for Maintenance of Postnatal Collecting Duct Homeostasis Sachin S. Hajarnis,[1] Matanel Yheskel,[1] Darren Williams,[1] Michel G. Baum,[1] Olivier Devuyst,[2] Vishal Patel.[1] *[1]UT Southwestern Medical Center, Dallas, TX; [2]Univ of Zurich, Zurich, Switzerland.*

Background: miRNA biogenesis involves the sequential processing of primary miRNA transcripts by two enzymes Dgcr8 and *Dicer*,while miRNA-induced gene silencing is aided by Argonautes1,2,3 and 4.In embryonic kidney,*Dicer* knockdown produces tubular cysts. In contrast,*Dicer* ablation from postnatal proximal tubules (PT) has no effect on kidney histology.However, whether miRNAs are required for maintenance of other segments of postnatal renal tubule is not known.

Methods: To study the role of miRNAs in renal tubule homeostasis,we ablated *Dicer* specifically from postnatal collecting ducts (CD) using the Pkhd1/Cre driver.Dicer is also involved in repair of damaged DNA and generation of small non-coding RNAs.To exclude miRNA-independent effects of *Dicer* deletion,we generated and analyzed CD-specific *Dgcr8*-KO,CD-specific *Ago*2-KO,Ago1,3,4-null,and combined Ago1-4-KO mice.

Results: *Dicer*-KO mice were born with histologically normal kidneys.By postnatal day(P)21,*Dicer* deletion evoked an increase in kidney injury markers *Ngal* and *Kim1*,which led to progressive interstitial fibrosis,tubular atrophy and inflammatory infiltration.*Dicer*-KO mice exhibited gradual increase in serum creatinine levels and shortened life-span (median survival of ~6 months).*Dgcr8*-KO mice were born with histologically normal kidneys but eventually developed progressive chronic kidney disease (CKD).While adult CD-*Ago2*-KO and global *Ago*1,3,4-KO mice had histologically normal kidneys,CD *Ago*1-4-KO recapitulated the *Dicer* and *Dgcr8*-KO phenotype.Microarrays on microdissected (MD) postnatal renal tubules revealed that CD have a unique miRNA expression pattern compared to PT.miR-200c was ~80-fold more enriched in CDs compared to PTs.miR-200c levels were reduced in MD *Dicer*-KO CDs compared to ctrl CDs.Levels of miR-200c targets *Zeb1 and Zeb2*,two regulators of epithelial-to-mesenchymal transition (EMT),were increased in CDs of *Dicer*-KO compared to ctrl kidneys but levels of epithelial markers Hnf-1β and E-cadherin were unchanged.

Conclusions: Inhibition of miRNAs in CD produces progressive CKD.Loss of CD-enriched miRNAs is associated with partial EMT,inflammatory and pro-fibrotic response.

Serum Levels of a Type VI Collagen Fragment Predict Mortality in Chronic Kidney Disease Daniel Guldager Kring Rasmussen,[1] Anthony Fenton,[2] Mark David Jesky,[2] Charles Ferro,[2] Morten Asser Karsdal,[1] Paul Cockwell,[2] Federica Genovese.[1] *[1]Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; [2]Dept of Nephrology, Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Chronic kidney disease (CKD) is associated with increased mortality. Systemic fibrosis may be a central component of this increased risk. Collagen type VI (COL6) is a major extracellular matrix protein that is over-expressed in fibrosis and mechanistically associated with vascular and myocardial injury. We hypothesized that increased COL6 expression represents a novel pathway for early mortality.

Methods: We used an immunoassay that binds a specific fragment of COL6, which is cleaved off after secretion from the cell (Pro-C6) and reflects COL6 formation. Serum Pro-C6 levels were measured in 500 patients from the Renal Impairment In Secondary Care (RIISC) study, which is a prospective cohort of patients with high risk of CKD progression as defined by the UK NICE criteria (2008). Patients were followed up for mortality; Cox regression analysis was used to assess risk of death.

Results: The cohort was 61.6% male, with a median age of 64 years (IQR 50-76), and 72.2% Caucasian. Median eGFR was 26.5 mL/min/1.73m^2 (19.5-34.6), and median ACR was 32.4 mg/mmol (6.2-128.0). Median follow-up time was 37 months. 66 (13.2%) patients had died at time of analysis. Median Pro-C6 level was 23.1 ng/mL (IQR 16.8-30.0) and on log transformation had a linear association with CKD-EPI eGFR ($r=-0.74$, $p<0.0001$). An increase in Pro-C6 of 10 ng/mL was associated with a mortality hazard ratio of 1.60

(95% CI 1.35-1.89, p<0.0001), and patients in the highest quartile had a 12-fold increase in hazard relative to the lowest quartile. After adjusting for confounding variables (age, eGFR, ACR, blood pressure, co-morbidities), Pro-C6 was independently associated with mortality (HR 1.51 [1.07-2.12], p=0.019).

Conclusions: Serum Pro-C6 is an independent marker for mortality in CKD after adjustment for confounders, and may reflect a pathological role for COL6 in the increased mortality associated with CKD.

TH-PO182

Selective Tubular Activation of Hypoxia-Inducible Factor-2α Has Dual Effects on Renal Fibrosis Kyoung Hye Kong,[1] Seung-Jung Kim,[2] Duk-Hee Kang,[2] Kyu Bok Choi,[2] Dong-Ryeol Ryu.[2] *[1]Graduate School, Ewha Womans Univ, Seoul, Korea; [2]Dept of Internal Medicine, Ewha Womans Univ, Seoul, Korea.*

Background: Hypoxia-inducible factor (HIF) is a key transcriptional factor in the response to hypoxia. This study aimed to investigate the effects of HIF-1α or HIF-2α activation on renal fibrosis according to activation timing in inducible tubule-specific transgenic mice with non-diabetic chronic kidney disease (CKD).

Methods: Mice with tubular selective HIF activation were generated by multiple breeding strategies. For the induction of renal fibrosis and CKD, the mice were fed a custom-made diet containing 0.2% adenine for 4 weeks, and HIF activation was done at day 0 or day 14. Mice were sacrificed at 4 weeks, and the kidneys were removed for histological evaluation and molecular analysis. We also performed in vitro experiments with cultured renal tubular epithelial cells.

Results: In transgenic mice with CKD, activation of HIF-2α at the beginning of CKD significantly aggravated renal fibrosis, whereas activation at a late-stage of CKD abrogated renal fibrosis, which was associated with restoration of renal vasculature and amelioration of hypoxia. Similarly, renal function assessed by serum creatinine in mice with HIF-2α activation at the beginning of CKD was comparable to that of wild-type CKD mice, but serum creatinine in CKD mice with activation at a late-stage was significantly lower than in wild-type CKD mice. HIF-2α activation in renal tubular cells upregulated mRNA expression of VEGF, PAI-1, lysyl oxidase, Bnip3, type I collagen, fibronectin, and PGK1, suggesting that it induced both profibrotic and antihypoxic pathways. However, tubule-specific HIF-1α activation had no significant effect on increased serum creatinine level or on histologic change in CKD mice, though its late activation decreased fibronectin expression.

Conclusions: Renal tubular HIF-2α activation has dual effects on renal fibrosis, and it could represent a therapeutic target in late-stage CKD when HIF-2α expression is not sufficient to maintain renal vascular integrity.

Instructive Role of the Microenvironment in Preventing Renal Fibrosis (RF) Kei Matsumoto,[1] Sandhya Xavier,[2] Jun Chen,[2] Yujiro Kida,[2] Mark Lipphardt,[2] James R. Dutton,[3] Brian B. Ratliff,[2] Stefan Rose-John,[4] Michael S. Goligorsky.[2] *[1]Showa Univ, Tokyo, Japan; [2]New York Medical College, Valhalla, NY; [3]Univ of Minnesota, MN; [4]Christian-Albrechts Univ, Kiel, Germany.*

Background: Accumulation of myofibroblasts is a hallmark of renal fibrosis (RF). A significant proportion of myofibroblasts has been reported to originate via endothelial-mesenchymal transition. We initially hypothesized that exposing myofibroblasts to the extract of endothelial progenitor cells (EPC extract) could reverse this transition.

Methods: Studies were performed in cultured renal fibroblasts and in α-SMA mice subjected to UUO or folic acid-induced nephropathy (FAN).

Results: In vitro EPC extract prevented expression of α-SMA in TGF-β1-activated fibroblasts, however, it did not enhance expression of endothelial markers. In two models of RF, (UUO) and chronic phase of FAN, subcapsular injection of EPC extract to the kidney prevented and reversed accumulation of α-SMA-positive myofibroblasts and reduced fibrosis. Screening the composition of EPC extract for cytokines revealed that it is enriched in LIF and VEGF, but only LIF reduced fibroblast-to-myofibroblast transition of TGF-β1-activated fibroblasts. In vivo subcapsular administration of LIF reduced the number of myofibroblsts, improved the density of peritubular capillaries, however, it did not reduce the degree of RF. A receptor-independent ligand for gp130/STAT3 pathway, Hyper-IL-6, not only induced a robust downstream increase in pluripotency factors Nanog and c-Myc, but also exhibited a powerful anti-fibrotic effect.

Conclusions: 1) EPC extract prevents and reverses fibroblast-to-myofibroblast transition and RF. 2) The component of EPC extract, LIF, was capable of preventing development of the contractile phenotype of activated fibroblasts, but did not eliminate TGF-β1-induced collagen synthesis in cultured fibroblasts and models of RF. 3) In contrast, a receptor-independent gp130/STAT3 agonist, Hyper-IL-6, prevented fibrosis. 4) These studies through the evolution from EPC extract to LIF and then to Hyper-IL-6 demonstrate the instructive role of microenvironmental cues and may offer a strategy to prevent and reverse RF.

TGF-β1 Represses Expression of the Antifibrotic Protein Follistatin in Mesangial Cells Neel Mehta, Tony Nuo Wang, Dan Zhang, Renzhong Li, Bo Gao, Joan C. Krepinsky. *Nephrology, McMaster Univ, Hamilton, ON, Canada.*

Background: The TGF-β superfamily member Activin A is emerging as an important mediator of the development and progression of renal fibrosis in chronic kidney disease (CKD). Follistatin (FST) is a secreted glycoprotein inhibitor of activin A. The balance between FST and activin A is an important determinant of fibrosis. Here we determined whether TGF-β1, a known key mediator of fibrosis in CKD, influenced the expression of FST.

Methods: Studies used primary mouse mesangial cells (MC) and standard molecular biology techniques including immunoblotting, qRT-PCR and luciferase reporter assays. Immunohistochemistry was used to assess FST in CKD mouse kidneys.

Results: Renal FST expression was decreased in the 5/6 nephrectomy mouse model of CKD. In MC, TGF-β1 potently suppressed FST transcript as early as 2 hours, associated with decreased FST protein expression. Inhibition of methyltransferase activity using 5-azacytidine reversed the repression of FST transcript by TGF-β1. Histone deacetylase inhibition with TSA and sodium butyrate also reversed this repression, suggesting that epigenetic mechanisms are involved in TGF-β1 regulation of FST. Interestingly, TGF-β1 did not affect activity of a FST mouse promoter (-2.9kb) reporter. However, TGF-β1 destabilized the FST 3'UTR as assessed by activity of a reporter construct. This was found to be dependent on Smad3 in studies using the Smad3 inhibitor SIS3 and MC from Smad3 knockout mice.

Conclusions: We show for the first time that TGF-β1 is a potent repressor of FST expression in MC through epigenetic regulation of its 3'UTR. Importantly, FST is decreased in CKD. This reduction of a major antifibrotic protein likely contributes significantly to the development of renal fibrosis. Future studies will delineate the molecular mechanism by which this occurs, and test the use of FST as a novel antifibrotic agent in CKD.

Hippo-YAP Signaling in the Regulation of Fibroblast Activation and Renal Fibrosis Zhengmao Zhang,[1] Yanlin Wang.[1,2] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Center for Translational Research on Inflammation Diseases, Michael E. DeBakey VA Medical Center, Houston, TX.*

Background: Renal fibrosis is characterized by fibroblast activation and excessive accumulation of extracellular matrix proteins. However, the molecular mechanisms underlying fibroblast activation are incompletely understood. In this study, we investigated the role of Hippo-YAP signaling in fibroblast activation and fibrogenesis.

Methods: Fibroblasts were used to examine the role of Hippo-YAP signaling in fibroblast activation. To examine the functional role of YAP in vivo, we generated mice with fibroblast-specific deletion of YAP by crossing $YAP^{flox/flox}$ mice with tamoxifen-inducible collagen type I promoter/enhancer-driven Cre recombinase transgenic mice. Unilateral ureteral obstruction (UUO) and ischemia-reperfusion injury (IRI) models were used to induce renal fibrosis.

Results: In cultured fibroblasts, TGF-β1 led to phosphorylation of YAP at serine 127 and cytoplasmic translocation of YAP. Knockdown of YAP with shRNA enhanced α-smooth muscle actin (α-SMA) protein expression and promoter activity and ECM protein expression. Conversely, expression of constitutively active YAP (YAP-5SA) suppressed α-SMA protein expression and promoter activity and ECM protein expression. Mechanically, YAP interacted with Smad3 and inhabited its transcriptional activity. Mice with fibroblast-specific deletion of YAP were born normal and had no obvious morphological abnormality in the kidney. Compared with Cre negative, floxed YAP control mice, mice with fibroblast-specific deletion of YAP exhibited larger number of α-SMA-positive myofibroblasts and expressed higher levels of α-SMA protein in the kidneys following UUO or IRI. Furthermore, fibroblast-specific deletion of YAP significantly enhanced total collagen deposition and increased expression of extracellular matrix proteins in the kidneys in response to UUO or IRI.

Conclusions: Our results have shown that YAP functions as a corepressor in fibroblast activation through inhibition of Smad transcriptional activity. Therefore, activation of YAP signaling may represent a novel therapeutic strategy for fibrotic kidney disease.

The Ins and Outs of Nuclear TAZ Transport: More Than Retention Andras Kapus,[1,2] Pamela Speight,[1] Katalin Szaszi,[1,2] Michael M. Kofler.[1] *[1]Keenan Research Centre, St. Michael's Hospital, Toronto, ON, Canada; [2]Surgery & Biochemistry, Univ of Toronto, Toronto, ON, Canada.*

Background: Yap and TAZ are cell fate-determining transcriptional coactivarors, with key roles in the pathogenesis of organ (kidney) fibrosis. Their main regulators include the Hippo pathway and mechanical factors (via cytoskeleton remodeling), which impact their nucleocytoplasmic shuttling. According to the current view, Yap/TAZ traffic is controlled by stimulus-regulated binding to cytosolic or nuclear "retention factors" (e.g. 14-3-3 in the cytosol or TEAD transcription factors in the nucleus). However, several major aspects of Yap/TAZ shuttling remain unknown. It is unclear if nuclear entry occurs via an active process or passive diffusion, and neither the potential nuclear localization and efflux signals (NLS, NES) nor their putative regulation have been identified. Further, a simple retention model seems inadequate since the sequestering partners also shuttle.

Methods: To address these questions and identify key regions responsible for nucleocytoplasmic TAZ traffic, we generated a "molecular-mass ruler" toolkit fusing wild type or mutant TAZ or its fragments to a large tag (5mCitrine) that cannot passively diffuse through the nuclear pore. We expressed these in LLC-PK1 proximal tubular cells and tested their distribution under various conditions.

Results: We show that TAZ transport is active. We identify a conserved and unique (non-canonical), *negatively* charged NLS in the C-terminal half. The NLS is both necessary and sufficient for nuclear TAZ entry; its uptake is mediated in an unusual, Ran-GTPase activity-independent manner; and is mitigated by charge neutralization. Importantly cyclic stretch or the expression of active Rho promote the nuclear entry of the 5mCitrine-NLS, which binds neither 14-3-3 nor TEAD. Using mutagenesis and rapamycin-sensitive TAZ constructs, we also identify an N-terminal NES, which is masked by TEAD binding, but exposed through 14-3-3 mediated displacement of TEAD.

Conclusions: Thus, we have found a unique NLS in TAZ that is mechanosenstive and an NES which is controlled by a masking mechanism. Our findings shed light on fundamental aspects of TAZ regulation and offer new ways for pharmacological interventions.

Gremlin1 Signaling in Kidney Development and Disease Derek P. Brazil,[1] Rachel H. Church,[1] Imran H.A. Ali,[1] Mitchel Tate,[1] Deborah P. Lavin,[1] Ellen Kok,[2] Roel Goldschmeding.[2] *[1]Centre for Experimental Medicine, Queen's Univ, Belfast, Northern Ireland, United Kingdom; [2]Dept of Pathology, Univ Medical Centre Utrecht, Utrecht, Netherlands; [3]UCD Conway Inst, Univ College Dublin, Dublin, Ireland.*

Background: Grem1 is a secreted glycoprotein antagonist of bone morphogenetic proteins (BMPs) that is found in the extracellular matrix. Grem1 homodimers bind to and antagonise BMP homodimers, regulating normal limb, kidney and lung formation. *Grem1*-/- mice on a C57Bl/6 background die at birth due to renal agenesis, and display lower limb abnormalities. Grem1 is implicated in fibrotic diseases of kidney, lung and other tissues. Recent data has demonstrated increased levels of Grem1 in a range of cancers of the colon, brain and pancreas. Levels of Grem1 are elevated in rheumatoid arthritis in both synovial fluid and chondrocytes. Grem1 has also been suggested to drive angiogenesis via activation of VEGFR2 signalling.

Results: We generated *grem1*-/- mice on a mixed C57Bl6J/FVB background, and showed that levels of Grem1 were highest in colon, brain and spleen. In contrast, levels of Grem2 were highest in kidney, followed by colon, brain and liver. Only 8 % of *grem1*-/- offspring were viable, and these surviving *grem1*-/- mice were, on an average, 33 % smaller in size and weight compared to wild-type. Grem1 staining was evident in the muscularis layer of the colon, and elevated pSmad1/5/9 levels were detected in *grem1*-/- colon. The right kidney was absent in the majority of *grem1*-/- mice of both genders, with an enlarged left kidney evident, likely explaining the survival of these animals. Mice lacking Grem1 specifically in the kidney tubule epithelial cells (Grem1-TEC-/-) developed normal kidneys and were partially protected from acute kidney injury induced by folic acid. Compensatory increases in Grem2 expression were seen in Grem1-TEC-/- kidneys. Grem1 and Grem2 displayed differing affinities for BMP-2, 4 and 7 using C2C12 BRE-luciferase readouts, with Grem2, but not Grem1 inhibiting BMP-7.

Conclusions: We also show that Grem1 but not Grem2 are weak activators of VEGFR2 activation, suggesting that the current model of Grem1-mediated angiogenesis needs to be reconsidered.

TH-PO188

Extracellular Matrix Alterations Induced by Renal Fibrosis Perturb Epithelial Tubulogenesis in a Decellularized Whole-Kidney Model Joseph S. Uzarski,[1] Ryan C. Hill,[2] Kirk Hansen,[2] William M. Miller,[3] Jason Wertheim.[1,4] *[1]Comprehensive Transplant Center, Northwestern Univ Feinberg School of Medicine, Chicago, IL; [2]Dept of Biochemistry and Molecular Genetics, Univ of Colorado Denver, Denver, CO; [3]Dept of Chemical and Biological Engineering, Northwestern Univ, Evanston, IL; [4]Dept of Surgery, Jesse Brown VA Medical Center, Chicago, IL.*

Background: The growing number of patients suffering from renal failure has led to a severe shortage of donor kidneys for transplantation. Development of functional renal tissue by combining recipient cells with a scaffold derived from an unsuitable kidney would alleviate this shortage and create new platforms for modeling diseases or drug-induced nephrotoxicity.

Methods: Rat kidneys with or without 7 days of ureteral obstruction to induce extracellular matrix (ECM) accumulation were decellularized to produce normal or fibrotic ECM scaffolds. Proteomic analysis was performed for quantitative comparison of various protein fractions comprising normal, fibrotic, and decellularized kidney matrices. Scaffolds were repopulated with human distal tubule-derived renal cortical tubular epithelial cells (RCTECs) and cultured in a perfusion bioreactor for 7 days.

Results: Decellularization reduced the cellular fraction of kidneys by >97%, yet scaffolds retained fibrillar collagens (types I, III) basement membrane proteins (collagen IV, laminin), and proteoglycans (perlecan) organized in a 3D framework. Fibrotic ECM scaffolds were characterized by excessive interstitial collagen deposition. RCTECs cultured within normal ECM scaffolds formed tubules displaying proper basolateral (Na^+/K^+-ATPase, E-cadherin) and apical (a-tubulin+ cilia) protein expression. In contrast, RCTECs injected into fibrotic ECM scaffolds formed non-polarized, multi-layered interstitial aggregates.

Conclusions: ECM scaffolds derived from healthy or diseased kidneys are useful to investigate cell-matrix interactions that mediate renal tubule development or degeneration. These studies will also inform on the use of healthy or abnormal kidney scaffolds as 3D biological templates for generating patient-customized renal tissue for transplantation.

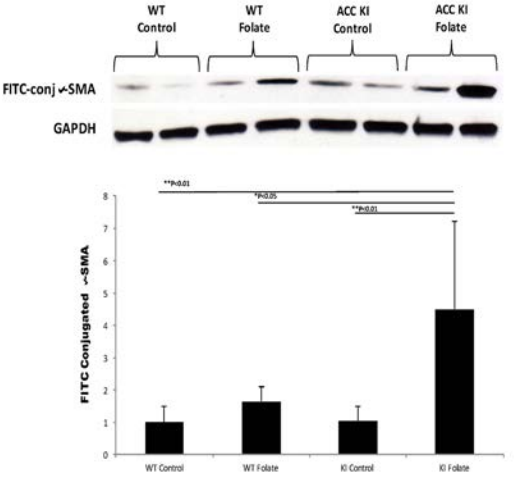
Deletion of AMPK Regulatory Sites in ACC 1 and 2 Increases Epithelial Mesenchymal Transformation following Renal Injury Mardiana Lee,[1,2] Peter F. Mount,[1,2] Marina Katerelos,[1] Kurt Gleich,[1] David A. Power.[1,2] *[1]Nephrology, Austin Health, Melbourne, Victoria, Australia; [2]Medicine, The Univ of Melbourne, Heidelberg, Victoria, Australia.*

Background: AMP-activated protein kinase (AMPK) is a major regulator of fatty acid oxidation in tissues, mainly through phosphorylation of acetyl CoA carboxylase 1 and 2 (ACC1 and 2), which increase fatty acid (FA) oxidation and reduce FA synthesis. Previous studies have shown that activation of AMPK reduces renal fibrosis following injury, and also has an effect on epithelial-mesenchymal transformation (EMT). It is not known, however, whether these effects are mediated through regulation of fatty acid metabolism by AMPK. The aim of this study is to determine the effect of phosphorylation of ACC by AMPK on renal interstitial fibrosis and EMT in a model of renal tubular injury.

Methods: Male C57/BL6 mice with a combined knock-in mutation of the regulatory S79 and S212 phosphorylation sites in ACC1 and 2, respectively (ACC1/2 KI mice), were given an intraperitoneal injection of folic acid to induce renal injury. Kidneys were removed for analysis after 2 weeks.

Results: There was increased expression of α-smooth muscle actin (α-SMA) by Western blot analysis in the ACC1/2 KI mice when compared to the WT folate group (P<0.01).



There was no difference in expression of E-cadherin by Western blot. Interstitial fibrosis was not increased in the ACC1/2 KI mice, as determined by Sirius Red staining measured by image analysis. Measurement of the expression of key regulatory enzymes by PCR suggested that FA oxidation (ACox1, CPT1) and glycolysis (PK) were reduced in the mice receiving folate compared to untreated controls, but there was no difference between WT and ACC1/2 KI mice.

Conclusions: The data suggests that control of energy metabolism by AMPK following tubular injury is of particular importance in preventing EMT, and that EMT and fibrosis are controlled separately in these mice.

TH-PO190

Loss of β-1 Integrin in Collecting Duct Principal Cells Downregulates AQP2 Expression and Induces Severe Renal Fibrosis and Kidney Failure Fahmy Mamuya,[1,2] Lei Lei,[1] Dongping Xie,[1] Kenji Tsuji,[1,2] Diane E. Capen,[1] Teodor G. Paunescu,[1,2] Hua Ann Jenny Lu.[1,2] *[1]Program in Membrane Biology and Div of Nephrology, Massachusetts General Hospital; [2]Harvard Medical School, Boston, MA.*

Background: Renal collecting duct principal cells are highly regulated epithelial cells and play a major role in salt and water transport via ENaC sodium channels and aquaporin-2 (AQP2) water channels, respectively. Understanding their signaling mechanisms is crucial for developing therapeutic approaches to enhance and support the role of the kidney in homeostasis. A major cause of kidney failure is renal fibrosis, and β-1 integrin has been shown to play a role in fibrosis in the kidney and other organs. Recent studies are now showing interaction between AQP2 and β-1 integrin in principal cells, suggesting that β-1 integrin is involved in AQP2 trafficking.

Methods: To investigate the role of β-1 integrin in principal cells we conditionally deleted β-1 integrin in mouse medullary principal cells under a specific AQP2 Cre promoter. We investigated water homeostasis in these mutant mice by urine osmolarity measurements, and occurrence of fibrosis through histopathological analyses and transmission electron microscopy. We also characterized AQP2 expression by immunohistochemistry, immunoblotting, and RT-PCR.

Results: Although the mutant mice appeared normal at birth and successfully grew into adulthood, they died around 10 to 12 weeks, weighing about half of their wild type littermates' weight. Remarkably, the mutant mice exhibited very low urine osmolarity (404 ± 52 mOsm/kg, compared to 2403 ± 203 mOsm/kg in wild types). Starting around 5 weeks of age, we observed a steep time-dependent decrease in AQP2 protein levels in the mutant mouse collecting ducts along with increased evidence of fibrosis and cell death. Towards the end of their lives, AQP2 expression was barely detectable in mutant mice. This phenotype progressed to renal medullary fibrosis, which ultimately caused kidney failure and premature death.

Conclusions: Our data strongly suggest that β-1 integrin is required for maintaining AQP2 expression in medullary collecting duct principal cells, and that its loss induces renal medullary fibrosis and kidney failure.

TH-PO191

Muscle-Kidney Crosstalk via A Myokine, Irisin, Suppresses Renal Metabolic Reprogramming and Fibrosis in Mice Hui Peng,[1,2] Qianqian Wang,[1,2] Yanlin Wang,[2] William E. Mitch,[2] Zhaoyong Hu.[2] *[1]Div of Nephrology, Dept of Medicine, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Div of Nephrology, Dept of Medicine, Baylor College of Medicine, Houston, TX.*

Background: Beneficial effects of exercise on muscle metabolism are associated with improved survival of patients with ESRD but the mechanisms underlying this observation are unknown. Potential mediators are myokines which are released from muscle by exercise. We hypothesized that myokines could mediate muscle-kidney crosstalk to limit the development of renal fibrosis and chronic kidney disease (CKD).

Methods: Since skeletal muscle-specific PGC-1a overexpression (mPGC-1a) stimulates myokines expression, we created several CKD models in the transgenic mice and evaluated the kidney function and the degree of fibrosis. Using a metabolomics approach, we accessed energy metabolic reprogramming in kidneys of wild-type and mPGC-1a with or without CKD. We also performed a PCR-based myokines array in muscle of PGC-1a mice and serum fraction assay to identify renal protective myokines.

Results: In mPGC-1α mice with CKD, we found that serum creatinine was lower than it in wild-type mice with CKD, this response was associated with less degree of interstitial fibrosis and glomerulosclerosis. Using a metabolomics approach, we found that CKD-induced energy metabolic reprogramming in kidney cells was blocked in kidney of mPGC-1a mice. To identify renal protectivemyokines present in serum of mPGC-1a mice, we divided serum from mPGC-1a mice into 4 fractions and found that only the fraction3 (10kD~30kD) significantly increased mitochondrial respiration capacity in kidney cells. We then analyzed the myokines array in muscle of PGC-1a mice and identified that irisin was the most likely candidate to protect kidney. The underneath mechanism is that irisin counteracts TGF-β1 signaling by competitive inhibiting TGF-β1 type 1 receptor.

Conclusions: Based on previous identification that metabolic reprogramming in kidney cells contribute to the development of fibrosis and CKD, we conclude that myokine irisin can block metabolic reprogramming in kidney cells and limit the development of renal fibrosis and CKD.

Oral Treatment with PBI-4050 Reduces Kidney Fibrosis Lyne Gagnon,[1] Brigitte Grouix,[1] Ming-Zhi Zhang,[2] Martin Leduc,[1] Mikaël Tremblay,[1] François Sarra-Bournet,[1] Lilianne Geerts,[1] Kathy Hince,[1] Liette Gervais,[1] Marie-Pier Cloutier,[1] Shaun Abbott,[1] Jean-Simon Duceppe,[1] Boulos Zacharie,[1] Raymond C. Harris,[2] Pierre Laurin.[1] *[1]ProMetic BioSciences Inc., Laval, QC, Canada; [2]Vanderbilt Univ School of Medicine, Nashville, TN.*

Background: PBI-4050 is a first-in-class novel orally active compound which displays anti-inflammatory/antifibrotic activities via a novel mechanism of action. PBI-4050 also displays metabolic properties by reducing blood glucose levels. In a double-blind single ascending dose (400 to 2400 mg) in healthy volunteers, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant adverse effects (SAEs). Similarly, PBI-4050 was well tolerated in chronic kidney disease (CKD) patients with no SAEs observed at 800 mg. PBI-4050 is presently in Clinical Phase II in diabetes (T2D) associated with metabolic syndrome and in idiopathic pulmonary fibrosis (IPF). Preliminary data from the open-labeled T2D associated with metabolic syndrome clinical phase shows that PBI-4050 significantly reduced glycated hemoglobin (HbA1c, -0.77%, $p<0.001$), and biomarkers (IL-18, resistin, and pentraxin-3) from the first 12 enrolled patients.

Results: PBI-4050 has demonstrated strong anti-fibrotic activities in different kidney models: 5/6-nephrectomized rats (end-stage renal failure, early and late treatment), doxorubicin-induced nephrotoxicity (acute kidney injury), renal ischemia, db/db and db/db eNOS-/- mice (diabetic kidney disease), DTR (a spontaneous tubulointerstitial fibrosis in homozygous HB-EGF mice), and unilateral ureteral obstruction (UUO). PBI-4050 plays a key role in inflammation/fibrosis regulation by reducing pro-fibrotic cytokines and growth factors (MCP-1, CTGF, CCL11, IL-5, endothelin 1 (EDN1), EGF, PDGFα, VEGFα, Inhibin βE, TGF-β2), myofibroblast activation and epithelial-to-mesenchymal transition markers (α-SMA, collagen III, ILK, MMP2, MMP9, and TGF-β1, 2 and 3), remodeling enzymes (LOX, MMP1, MMP2, MMP9, MMP13, uPA, PAI-1, TIMP3 and ILK) and fibrotic markers, resulting in improvement of organ function.

Conclusions: Taken together, these pre-clinical results suggest that PBI-4050 offers the potential as a novel therapy for the treatment of kidney fibrosis.

TH-PO193

Imaging Renal Fibrosis with Two Photon Excitation (TPE), Second Harmonic Generation (SHG), and Fluorescence Lifetime Imaging Microscopy (FLIM) Evgenia Dobrinskikh,[1] Xiaoxin Wang,[1] Yuhuan Luo,[1] Suman Ranjit,[4] Avi Rosenberg,[3] M. Scott Lucia,[1] Vivette D. D'Agati,[2] Moshe Levi.[1] *[1]Univ of Colorado; [2]Columbia Univ; [3]NIH; [4]UC Irvine.*

Background: Glomerulosclerosis and tubulointerstitial fibrosis occurs in many diseases and signals poor renal functional outcomes. In view of recent therapies aimed at the pathogenesis of fibrosis, sensitive and quantitative techniques for documenting fibrosis have become highly desirable. Current stains have limited use for 3D imaging and they do not allow for determination of the metabolic state of the kidney.

Methods: We have applied TPE, SHG, and FLIM for label-free imaging of kidney sections. We have then applied the phasor approach for FLIM analysis, which allows for the determination of collagens and other extracellular matrix components, and metabolic state of the kidney (free to bound NADH ratio) taking advantage of the specific autofluorescence characteristics of these molecules. These techniques can be used in fresh or frozen or FFPE tissues. We have furthermore applied the novel multiphoton imaging microscope known as the DIVER which enables for imaging of thick tissues.

Results: In kidney biopsies obtained from diabetic humans, compared to biopsies obtained from nondiabetic subjects, we have determined that there is a strong SHG signal around the glomerulus and tubulointerstitial areas, which indicates presence of fibrosis. FLIM shows shift to the shorter lifetime in diabetic kidneys that corresponds to different metabolic state of the tissue and different matrix composition. FLIM also may determine relative degree of the disease progression based on differential lifetimes in diabetic compared to nondiabetic control kidneys. Application of the DIVER allows for 3D imaging of thick sections made from biopsies, which should give a better vision of the kidney ultrastructure and disease progression.

Conclusions: TPE, SHG and FLIM imaging allows for label-free and 3D imaging of the extracellular matrix and metabolic state of the kidney based on the autofluorescence of the corresponding molecules. In addition to the quantitative advantage it also allows for further processing of the same kidney biopsy slides for additional histochemical stains or biochemical studies.

PHF14 as an Innate Brake to the Progression of Renal Fibrosis following Acute Kidney Injury Bo Yang, Zhiguo Mao. *Div of Nephrology, Changzheng Hospital, Shanghai, China.*

Background: PHF14 is a newly identified regulator of mesenchyme growth in embryonic tissues. Studies showed that PHF14-null mutants were neonatally lethal due to interstitial tissue hyperplasia in major organs including kidney. We hypothesize that PHF14 may plays a protective role in renal fibrosis progression after the pro-fibrotic insults. It will help to elucidate the interactions of mediators in the process of renal fibrogenesis by illuminating the function of PHF14.

Methods: We determined the expression profile of PHF14 in fibrotic kidneys after folic acid (FA) injection in mice. Then, we generated PHF14 inducible knockout mice to explore the biological role of PHF14 in the progression of renal fibrosis following FA administration. Relationship of PHF14 expression with TGF-β signaling pathway was also examined in rat renal fibroblast cells. We also validated whether PHF14 performed as negative regulator of platelet-derived growth factor receptor-α (PDGFR-α) and eventually suppressed the expression of fibrosis related biomarkers.

Results: PHF14 was upregulated in fibrotic kidneys after FA insults in mice. Compared with sham control, induced PHF14 deletion in adult mice exacerbated renal fibrosis following FA associated renal injury. TGF-β stimulation induced the upregulation of PHF14 *in Vitro*, and p-smad3 acts as transcription factor to enhance the PHF14 expression, which was proved by immunoprecipitaion assay. Lack of PHF14 expression enhances collagen I and α-SMA synthesis induced by TGF-β *in Vitro.*

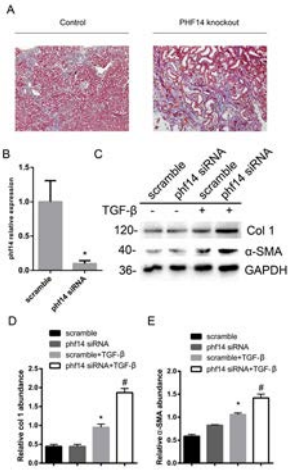

Figure 1: (A) Representative Masson (200x) images demonstrating the severity of renal fibrosis in the PHF14 knockout mice at day 28 after FA administration compared with sham control. (B) Q-PCR demonstrating the transcriptional activity of PHF14 mRNA. (C-E) Lack of PHF14 expression enhances collagen I and α-SMA synthesis induced by TGF-β. * P < 0.05 compared with NRK-49F cells untreated with TGF-β; # P < 0.05 compared with NRK-49F cells pretreated with scramble control siRNA and cultured in the media with TGF-β.

PHF14 was involved in the inhibition of the PDGF signaling overactivation by selectively repressing PDGFR-α transcription.

Conclusions: PHF14 expression was upregulated in fibrotic models *in vivo* and *in vitro* with anti-fibrotic functions. The TGF-β /smad3/PHF14 pathway acted as a self-limiting mechanism in TGF-β dominated renal pro-fibrotic signaling by suppressing PDGFR-α expression.

A Step Towards Clinical Application of Acellular Matrix: A Clue from Macrophage Polarization

Astgik Petrosyan,[1,2] Stefano Da Sacco,[1] Nikita Tripuraneni,[1] Ursula Kreuser,[1] Maria J. Lavarreda-Pearce,[1] Riccardo Tamburrini,[3] Roger E. De Filippo,[1,2] Giuseppe Orlando,[3] Paolo Cravedi,[4] Laura Perin.[1,2] *[1]Univ of Southern California; [2]GOFARR Laboratory, Children's Hospital Los Angeles; [3]Wake Forest School of Medicine; [4]Icahn School of Medicine at Mount Sinai.*

Background: The outcome of tissue engineered organ transplants depends on the capacity of the biomaterial to promote a pro-healing response once implanted in vivo. Multiple studies, including ours, have demonstrated the possibility of using the extracellular matrix (ECM) of animal organs as a platform for tissue engineering and more recently, discarded human organs have also been proposed as a scaffold source. It is known that natural matrices present diverse immune properties when compared to artificial biomaterials. However, how these properties compare between diseased and healthy ECM and artificial scaffolds has not yet been defined.

Methods: We used decellularized renal ECM derived from WT mice and from mice affected by Alport Syndrome as a model of renal failure with extensive fibrosis, at different time-points of disease progression. We characterized the morphology and composition of these ECMs and compared their in vitro effects on macrophage activation with that of synthetic scaffolds commonly used in the clinic (collagen type I and poly-L-(lactic) acid, PLLA).

Results: We showed that ECM derived from Alport kidneys differed in fibrous protein deposition (col I, col IVα1,2 and fibronectin) and cytokine content (Resistin, TIM-1/KIM-1, DPPIV/CD26 and Reg3G) when compared to ECM derived from WT kidneys. Yet, both WT and Alport renal ECM induced macrophage differentiation mainly towards a reparative (M2) phenotype (reduced CD80), while artificial biomaterials towards an inflammatory (M1) phenotype. Anti-inflammatory properties of natural ECMs were lost when homogenized, hence three-dimensional structure of ECM seems crucial for generating an anti-inflammatory response.

Conclusions: Together, these data support the notion that natural ECM, even if derived from diseased kidneys promote a M2 protolerogenic macrophage polarization, thus providing novel insights on the applicability of ECM obtained from discarded organs as ideal scaffold for tissue engineering.

TH-PO196

Human Discarded Kidneys as a Source of Protolerogenic Extracellular Matrix Scaffolds for Bioengineering

Astgik Petrosyan,[1] Stefano Da Sacco,[1] Chiara Donadei,[2] Giuseppe Orlando,[3] Laura Perin,[1] Paolo Cravedi.[2] *[1]Children's Hospital Los Angeles; [2]Icahn School of Medicine at Mount Sinai; [3]Wake Forest School of Medicine.*

Background: Human extracellular matrix (ECM) scaffolds produced through the decellularization of discarded kidneys represents a potential platform for kidney bioengineering. Studying their immune properties is crucial for their future implementation in the clinic.

Methods: We decellularized adult human kidneys not suitable for transplantation, dissected medulla from cortex and evaluated their relative immune effects on human naïve T cell proliferation (CFSE dilution in response to aCD3/aCD28 mAb) and conversion into functional regulatory T cells (cells were cultured with aCD3/aCD28 mAb, IL2 and no TGF-β, since we previously showed the TGF-β is present in ECM). We also seeded human macrophages on ECM and evaluated their cytokine expression.

Results: ECMs obtained from the cortex of discarded human kidneys inhibited expansion of activated human naïve CD4+ T cells and promoted their conversion into FoxP3+ regulatory T cells (Treg) (Figure) . Macrophages adhered onto human ECM and showed cellular activity including survival and proliferation. In addition after 5 days they secreted significant amounts of anti-inflammatory cytokine such as IL10, but no pro-inflammatory cytokines like INFγ and TNFα.

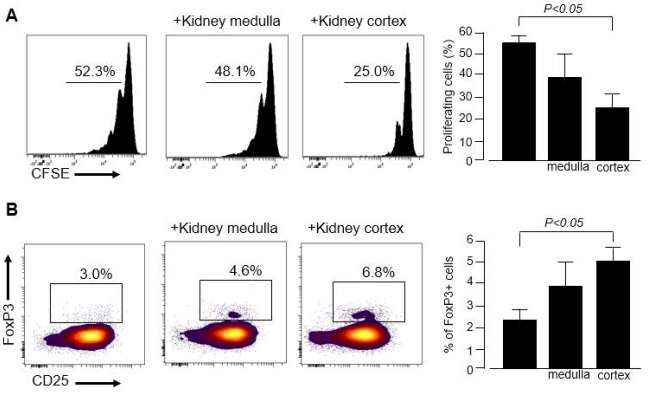

Figure. Human renal ECM inhibits naïve CD4+ T cell expansion and promotes their conversion into regulatory T cells. (A) CFSE-labeled naïve CD4+ T cells were activated with anti-CD3/anti-CD28 mAb with or without ECM from kidney medulla of cortex. Cell division was quantified on day 5 with CFSE dilution by flow cytometry. Representative histograms (left) and data quantification (right) of 6 independent experiments from 6 different donors. (B) Naïve CD4+ T cells were activated with anti-CD3/anti-CD28 mAb and IL-2 with or without ECM from kidney medulla of cortex. On day 5, the percentage of CD4+CD25+FoxP3+ regulatory T cells was quantified by flow cytometry. Representative histograms (left) and data quantification (right) of 4 independent experiments from 4 different donors.

Conclusions: Our data demonstrate that hrECMs inhibit effector T cell expansion and promote naïve CD4 T cell conversion into FoxP3+ Treg, possibly through a TGF-β mechanism. They stimulate macrophages to secrete anti-inflammatory cytokines, supporting further studies for their clinical use.

Podocyte-Derived Microparticles Induce Pro-Fibrotic Responses in Human Promote Proximal Epithelial Cells: Role of Scavenger Receptors

Dylan Burger, Mercedes N. Munkonda, Shareef Akbari, Maddison Turner. *Kidney Research Centre, Ottawa Hospital Research Inst, Ottawa, ON, Canada.*

Background: Tubulo-interstitial fibrosis (TF) is a hallmark of advanced diabetic kidney disease that is linked to renal decline. Cross-talk between podocytes and the tubular epithelium has been implicated in TF however the pathogenic mechanisms are poorly understood. Microparticles (MPs) are 100-1000 nm membrane vesicles shed from stressed/injured cells that have been implicated in cell-cell communication. Our lab recently showed that podocytes release MPs following stress/injury and that urinary podocyte MPs are increased in animal models of diabetes. The purpose of the present study was to assess whether podocyte MPs play a role in podocyte-epithelial cell cross-talk.

Methods: MPs were isolated from the media of cultured human podocytes (hPODs) and administered to cultured human proximal tubule epithelial cells (PTECs). PTEC/MP interaction was assessed by fluorescence microscopy and intracellular signaling responses were assessed by Western blot analysis.

Results: Podocyte MPs physically interacted with PTECs immediately after administration and continuing over 24 hours. Podocyte MP treatment increased phosphorylation of protein kinases p38 and Smad3 and increased expression of the extracellular matrix (ECM) proteins fibronectin and collagen type IV. All MP-induced responses were attenuated by co-treatment with the p38 inhibitor SB202190 (10 uM). The transforming growth factor beta (TGF-β) receptor inhibitor (SB431542, 10 uM) blocked MP-induced Smad3 phosphorylation and ECM protein expression but not p38 phosphorylation suggesting that these responses occurred downstream of p38. Finally, inhibition of the class B scavenger receptor CD36 with Sulfo-N-succinimidyl oleate (10 uM) completely blocked

MP-mediated effects on PTECs. Similarly, MP-induced activation of p38 and Smad3 was attenuated by a neutralizing antibody to kidney injury molecule-1, a putative scavenger receptor linked to tubular injury.

Conclusions: Taken together, our results suggest that podocyte MPs induce pro-fibrotic responses in PTECs. Such effects may involve activation of scavenger receptors and contribute to fibrosis and renal decline in diabetes.

TH-PO198

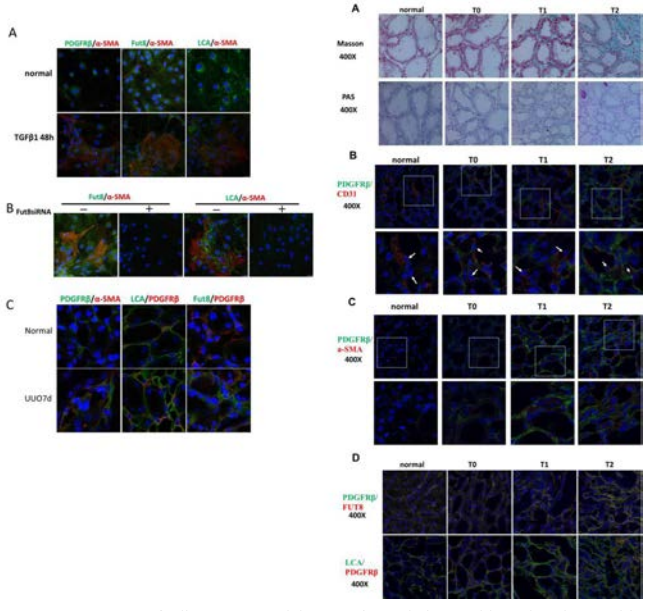
Core Fucosylation Regulates the Transition of Pericytes to Myofibroblasts in Renal Interstitial Fibrosis

Nan Wang. *Nephrology Dept, The First Affiliated Hospital of Dalian Medical Univ, Dalian, Liaoning Province, China.*

Background: Chronic kidney diseases are irreversible diseases with high mortality. Renal interstitial fibrosis is the final common outcome of CKD. While myofibroblasts are the main contributors to the progress of RIF. Recently pericytes have been confirmed as the main source of myofibroblasts in RIF. Cross-talks of multiple signaling pathways, such as TGF-β, PDGF pathways, are known to activate pericytes in the process of RIF. Researches have found that single receptor blockage of these pathways can alleviate RIF. Our previous researches have found that some key receptors of these pathways are modified by fucosyltransferase 8-regulated core fucosylation.

Methods: Pericyte-myofibroblast transition and the expressions of core fucosylation were observed in renal biopsies of IgAN patients, UUO mice model and primary pericytes cultivation *in vitro*. *FUT8*shRNA-Adenovirus and *FUT8*siRNA were used for the knockdown of FUT8 *in vivo* and *in vitro*, Pericyte-myofibroblast transition and the expressions of core fucosylation were then observed.

Results: We found that core fucosylation of pericytes was increased with the severities of renal interstitial injuries in IgAN patients. Similar elevations of core fucosylation were found in UUO mice model and pericytes-myofibroblasts transition model *in vitro*. Adenoviral-mediated *FUT8*shRNA *in vivo* and *FUT8*siRNA *in vitro* were then used to inhibit the expressions of FUT8. Interestingly, we found that the inhibitions of core fucosylation could alleviate RIF dramatically and prevent pericytes transition both *in vivo* and *in vitro*.



Conclusions: Our findings suggested that core fucosylation could regulate the transition of pericytes to myofibroblasts in the progress of RIF. We believed that glycosylation may provide a novel hub target to prevent RIF and CKD.

The BET Bromodomain Inhibitor JQ1 Diminished Renal Fibrosis

Sandra Rayego-Mateos,[1] Jose Morgado-Pascual,[1] Beatriz Suarez-Alvarez,[4] Pierre-Louis Tharaux,[2] Alberto Ortiz,[3] Carlos Lopez-Larrea,[4] Marta Ruiz-Ortega.[1] *[1]Univ Autónoma Madrid; [2]Paris Cardiovascular Centre, France; [3]ISS-Fundación Jimenez Diaz; [4]Hospital Univ Central de Asturias, Spain.*

Background: Bromodomain and extraterminal domain (BET) proteins participates in tumor development, autoimmunity, inflammation, and fibrosis. BET proteins bind to acetylated lysine residues on proteins to regulate the transcriptional program. Sex determining region Y-box 9 (SOX9) is a transcription factor involved in kidney regeneration, proliferation and migration. JQ1, a selective BET inhibitor, have demonstrated beneficial effects on murine pulmonary and liver fibrosis, but there is no data in renal fibrosis.

Methods: Experimental models of anti-glomerular basement membrane nephritis, induced by nephrotoxic serum (NTS) administration and unilateral ureteral obstruction (UUO) were used. Mice were treated with JQ1 (100 mg/mouse/day). In vitro studies were done in TGF-β-treated mesangial cells and renal fibroblasts.

Results: NTS-injected mice presented extracapillary proliferation and increased of podocyte damaged (evaluated by WT-1 levels) and gene upregulation of biomarkers of renal injury (*Ngal* and *Kim-1*) after 10 days. JQ1 restored changes in renal function (as serum creatinine and urinary albumin), downregulated renal injury biomarkers and fibronectin expression, and ameliorated glomerular lesions. Obstructed kidneys presented tubulo-interstitial fibrosis after 5 days. JQ1 markedly diminished gene overexpression of profibrotic factors (TGF-β and PAI-1) and renal overproduction of matrix components (Fibronectin and type I collagen). In vitro, JQ1 dose-dependently inhibited TGF-β-mediated Fibronectin and type I collagen gene expression and protein production. In injured kidneys of both models, Sox9 activation was found. In obstructed kidneys nuclear Sox9 was colocalized with SMA-positive cells, mainly in areas of matrix accumulation. JQ1 blocked Sox9 nuclear localization in injured kidneys and in TGF-β-treated cells.

Conclusions: Our results demonstrate that JQ1 regulates profibrotic and matrix-related components and reduces experimental renal fibrosis. These results suggest that BET inhibitors could have important therapeutic applications in chronic kidney diseases.

Niclosamide Ameliorates Fatty Acid Metabolism Disturbance of Tubular Epithelial Cells in Renal Fibrosis

Qi Yuan, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Renal fibrosis is the common pathological and histological pathway of chronic kidney disease.Mitochondrial dysfunction promotes tubular epithelial cells injury, playing a vital role in the progress of renal fibrosis. As the mitochondria rich cells, tubular epithelial cells are mainly using fatty acid oxidation (FAO) as the energy fuel. Uncoupling proteins function as mitochondrial fatty acid anion exporters, modulating cellular fatty acid homeostasis. Niclosamide is a teniacide mediating the uncoupling of mitochondria. In this study, we investigate the role of niclosamide in the fatty acid metabolism of tubular epithelial cells in renal fibrosis.

Methods: C57BL/6J mice were randomly assigned into control group and three folic acid groups, mice in the folic acid groups sacrificed in the day 1,day 7 and day 30. The bilateral kidneys were used for morphology, western blot and RT-PCR analysis. C57BL/6J mice after injecting folic acid were treated with niclosamide, while the morphology of renal sections and the function of fatty acid oxidation were observed.

Results: 1.Folic acid induced the mitochondrial injury and fatty acid oxidation defect of the tubular epithelial cells. 2. The fibrotic matrix was expanded and the markers of collagen fibrils such as α-SMA, fibronectin (FN), Collagen I were increased in the kidneys after folic acid injecting in a time depended manner. 3.Niclosamide restored the structure and function of the tubular epithelial cells' mitochondria after folic acid injecting. The fatty acid oxidation of the tubular epithelial cells was resumed by niclosamide treatment. 4.Niclosamide could alleviate the progress of renal fibrosis induced by folic acid.

Conclusions: These results demonstrate that mitochondrial dysfunction leading to fatty acid metabolism disturbance in the tubular epithelial cells contribute to renal fibrosis. Niclosamide-induced mitochondrial uncoupling improves the mitochondrial structure and the fatty acid oxidation in the progress of renal fibrosis, and finally resisting the lesion of renal fibrosis. Targeting mitochondrial uncoupling may be a potential treatment for renal fibrosis.

Proteomic Analysis of Glomerular Extracellular Matrix Demonstrates Differences between FSGS Variants

Liliane Hobeika,[1] Michelle T. Barati,[1] Michael Merchant,[1] Kenneth R. McLeish.[1,2] *[1]Medicine, Univ of Louisville; [2]Robley Rex VAMC, Louisville, KY.*

Background: Histologic evidence for abnormal remodeling of the glomerular extracellular matrix (ECM) is a prominent feature of FSGS, however, the differences in glomerular ECM composition are unknown. The current study used laser capture microdissection (LCMD) of glomeruli from human biopsy specimens and mass spectrometry (MS) to compare glomerular ECM composition among patients with FSGS NOS, collapsing FSGS (CFSGS), and normal subjects.

Methods: Glomerular sections were obtained by LCMD from de-identified formalin-fixed paraffin embedded renal biopsy tissue from 6 patients with FSGS NOS, 7 patients with CFSGS, and from 2 kidneys retrieved, but not used, for transplantation. Proteins were extracted by sequential decellularization with NH4OH/triton X-100 and extraction of the remaining matrix with protease MAX surfactant. Peptides obtained by proteolysis with trypsin were identified by MS. Peptide data was analyzed by Mascot/Sequest, and label-free quantification compared among groups.

Results: Of the 1271 unique proteins identified, 161 were determined to be ECM proteins by comparison to the matrisome database and previously published glomerular ECM identification. 110 ECM proteins were identified from normal glomeruli, 136 from FSGS NOS, and 155 from CFSGS. 106 ECM proteins were common between normal and FSGS NOS, while 30 proteins were unique to FSGS NOS. 109 ECM proteins were common between normal and CFSGS, while 46 were unique to CFSGS. 130 ECM proteins were common between FSGS NOS and CFSGS, 6 unique to FSGS NOS, and 25 unique to CFSGS. Protein quantification identified 8 proteins differentially expressed in CFSGS and 10 proteins differentially expressed in FSGS NOS, compared to the other two groups.

Conclusions: Proteomic analysis of glomeruli isolated by LCMD from renal biopsy tissue successfully identified differences in ECM protein expression in FSGS NOS and CFSGS. Differential ECM protein expression provides targets for biomarker identification for specific FSGS variants and suggests unique differences in ECM remodeling between FSGS NOS and CFSGS.

Fibroblast Growth Factor 23 Exacerbates Kidney Fibrosis Involving β-Catenin Signaling Activation and Extracellular Matrix Production in Tubular Cells Xin Liu, Chunsun Dai. *Nanjing Medical Univ.*

Background: The concentration of fibroblast growth factor 23 (FGF23) in the circulation is closely correlated with the decline of renal function in patients with chronic kidney diseases. However, whether FGF23 can directly promote kidney fibrosis and its underlying mechanisms are not clear.

Methods: In this study, we generated a mouse model with ectopic expression of exogenous FGF23 in CD-1 mice through tail vein hydrodynamic injection of FGF23 expression plasmid once a week.

Results: FGF23 was largely increased at as early as one day and maintained at high level in the circulation during the observation period. The mice developed hypertension, anemia and hypokalemia but little kidney morphological damage after four times of pFGF23 injection. We then generated mouse models with kidney fibrosis including UUO nephropathy, adriamycin nephropathy and ischemia/reperfusion injury. The mice with ectopic FGF23 expression developed more severe kidney fibrosis and inflammatory cell accumulation in kidney tissue after UUO, adriamycin injection or ischemia/reperfusion compared to those injected with control plasmid. In cultured NRK-52E cells, FGF23 treatment could exacerbate TGFβ1-induced extracellular matrix production with a time and dose dependent manner. Additionally, in both FGF23 treated NRK-52E cells and UUO kidneys from mice with ectopic FGF23 expression, p-β-catenin (Ser675), an active form of b-catenin, was robustly elevated.

Conclusions: Thus, these results suggest that FGF23 exacerbates UUO nephropathy in mice, which may be associated with b-catenin signaling activation and extracellular matrix production in tubular cells.

TH-PO203

Proximal Tubule Specific COMP-Angiopoetin-1 Overexpression Decreases Renal Injury in a Mouse Unilateral Ureteral Obstruction Model Woong Park, Yujin Jung, Tung Nguyen-Thanh, Kyung Pyo Kang, Won Kim. *Dept of Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Korea.*

Background: Preservation of renal endothelial cells is one of promising strategies for renal fibrotic process. Angiopoietin-1 (Ang1) is an angiogenic factor through its endothelial receptor tyrosine kinase, Tie2. We have reported that adenoviral transfer of cartilage oligomeric matrix protein(COMP)-Ang1 decreases the progression of renal fibrosis by regulation of Tie2 and Akt phosphorylation in mouse unilateral ureteral obstruction (UUO) model. It also has been demonstrated that Ang1 is expressed on renal tubular epithelial cells of normal mice. In this study, we investigated whether the COMP-Ang1 in the mouse proximal tubules has protective effect on UUO-induced renal inflammation and fibrosis.

Methods: We generated proximal tubule specific COMP-Ang1 overexpression mice, constitutively expressing COMP-Ang1 under the control of a gamma-glutamyltransferase 1 (gGT1, a proximal tubular cell marker) promotor (COMP-Ang1 TG mice). Renal fibrosis was induced by UUO in the six-week-old COMP-Ang1 TG and WT mice for 7 days. Histologic examination and Western blot analyses for alpha-smooth muscle actin (α-SMA), intercellular adhesion molecule 1 (ICAM-1), F4/80 and *granulocyte* receptor-1 (Gr-1) were performed.

Results: COMP-Ang1 overexpression from renal proximal tubular epithelial cell ameliorated the UUO-induced decrease of PECAM-1-positive endothelial cells. After ureteral obstruction, tubular dilatation, desquamation and mononuclear cell infiltrations were increased in WT mice. However, UUO-induced tubular injury and fibrosis were significantly decreased in proximal tubular COMP-Ang1 overexpression mice. Immunofluorescence data for neutrophils (Gr-1-positive cells) and macrophages (F4/80 positive cells) showed that proximal tubular COMP-Ang1 overexpression mice suppressed UUO-induced increase of Gr-1 and F4/80 positive cells infiltration. In Western blot analyses, α-SMA and ICAM-1 expression were significantly decreased in proximal tubular COMP-Ang1 overexpression mice compared to WT mice.

Conclusions: Proximal tubular COMP-Ang1 overexpression might have a protective role in UUO-induced renal fibrosis and inflammation.

Funding: Government Support - Non-U.S.

TH-PO204

ErbB4 Deletion Accelerates Renal Fibrosis and Inflammation after Unilateral Ureteral Obstruction Fenghua Zeng,[1] Lance A. Kloepfer,[1] Tomoki Miyazawa,[2] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ Medical Center, Nashville, TN; [2]Pediatrics, Kindai Univ School of Medicine, Sakai, Osaka, Japan.*

Background: Tubulointerstitial injury/fibrosis is a histological feature involved in the progression of chronic kidney disease (CKD) regardless of etiology. Our preliminary results showed increased ErbB4 expression in the glomeruli and tubular epithelium of CKD kidneys. However, its role in the tubulointerstitial injuries remains to be determined.

Methods: Heart rescued ErbB4 deletion (ErbB4^{del}ht^{+}) and wild-type (WT) mice were subjected to unilateral ureteral obstruction (UUO) or sham operation. Renal function and pathological changes were examined.

Results: ErbB4^{del}ht^{+} mice tended to have higher BUN levels compared to WT mice after UUO, but the levels were not significantly different. However, in UUO kidneys, ErbB4^{del}ht^{+} mice displayed accelerated interstitial fibrosis as early as 3 days after UUO, whereas similar levels of fibrosis shown by trichrome staining were only evident after 6 days of UUO in WT mice. ErbB4^{del}ht^{+} kidneys had increased collagen I, SMA, and FSP-1 immunoreactivity. Macrophage infiltration as shown by F4/80 immunostaining and renal cell apoptosis by cleaved caspase 3 levels were also increased in ErbB4^{del}ht^{+} kidneys.

Conclusions: ErbB4 deletion accelerates the development and progression of renal fibrosis in obstructive nephropathy. Increased expression of ErbB4 seen in the kidneys of CKD may reflect a compensatory effect to overcome the tubulointerstitial injury.

Funding: NIDDK Support, VA Support

TH-PO205

Serum Levels of a Type VI Collagen Fragment Predict Progression of Chronic Kidney Disease Signe Holm Nielsen,[1] Anthony Fenton,[2] Mark David Jesky,[2] Charles Ferro,[2] Morten Asser Karsdal,[1] Paul Cockwell,[2] Federica Genovese.[1] *[1]Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; [2]Dept of Nephrology, Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Progressive renal fibrosis is the dominant process that leads to end stage renal disease (ESRD) in patients with chronic kidney disease (CKD). Collagen type VI (COL6) is over-expressed in progressive fibrosis, with prominent expression in renal disease. Pro-C6 is a COL6 fragment which reflects COL6 expression. We hypothesized that Pro-C6 levels were associated with CKD progression.

Methods: We measured Pro-C6 levels in the serum of 500 patients from the Renal Impairment in Secondary Care (RIISC) study. This is a prospective cohort study of patients with high risk CKD, as defined by the UK NICE criteria (2008). Participants were followed up and data collected at 12 months for progression of CKD, defined as either commencement of RRT or decline in eGFR of >30%. Logistic regression was performed to assess Pro-C6 as a marker of progression of CKD at 12 months.

Results: The cohort was 61.6% male, with a median age of 64 years (IQR 50-76), and 72.2% caucasian. Median eGFR was 26.5 mL/min/1.73m^2 (19.5-34.6), and median ACR was 32.4 mg/mmol (6.2-128.0).

417 patients had 12-month follow-up, and of these 46 (11.0%) had experienced progression of CKD at 12 months. Median Pro-C6 level was 23.1 ng/mL (IQR 16.8-30.0), and on log transformation had a linear association with CKD-EPI eGFR ($r=-0.74$, $p<0.0001$). An increase in Pro-C6 of 10 ng/mL was associated with a hazard ratio of 1.96 (95% CI 1.50-2.55, $p<0.0001$) for CKD progression, and participants in the highest quartile had a 9-fold higher risk than those in the lowest quartile. After adjusting for eGFR and ACR, a significant association between Pro-C6 and CKD progression at 12 months remains (HR 1.44 [01.02-2.04], $p=0.039$).

Conclusions: Serum Pro-C6 is an independent marker for CKD progression at 12 months. This indicates a potential pathological role for collagen type VI in progressive CKD.

TH-PO206

Inhibition of K-Ras in the Peri-AKI Period in a Murine Model of Aristolochic Acid Nephropathy Reduces Long-Term Progression to CKD in a Murine Model of Aristolochic Acid Nephropathy Sujit Kumar Saha, Bruce M. Hendry, Claire C. Sharpe. *Dept of Renal Sciences, King's College London, London, United Kingdom.*

Background: Acute Kidney Injury (AKI) is a recognised early forerunner of Chronic Kidney Disease (CKD). K-Ras expression is up-regulated in renal fibrosis and chronic K-Ras inhibition post-injury prevents scarring. Our aim was to investigate whether transiently reducing K-Ras expression prior to an AKI reduces progression to CKD.

Methods: CD1 mice received intra-peritoneal injections of 3.5mg/kg Aristolochic Acid (AA) or saline (NS) on Day 1 & on Day 5. A treatment group also received a single subcutaneous dose of 100mg/kg K-Ras murine Antisense Oligonucleotide (ASO) 2 days prior to the 1st AA dose. A vehicle group received NS 2 days prior instead. Blood urea nitrogen (BUN), Creatinine (Cr), Haemoxygenase 1 (HO-1) and urinary NGAL were measured at multiple time points. The degree of fibrosis was ascertained through a Hydroxyproline assay, Western blot (WB) for alpha SMA and Picrosirius Red (PSR) & Masson Trichrome (MT) staining. The effect on K-Ras was determined by QPCR and WB.

Results: Mice given AA transiently developed an AKI at day 5-20 before then recovering. There was a further rise in both BUN & Cr at day 80 indicating CKD. Administration of Murine K-Ras ASO reduced both the BUN & Cr at day 80 compared to vehicle by 37%. Fibrosis quantification through PSR & MT staining showed AA caused a 5 fold increase in collagen deposition by day 80. ASO treatment halved this amount of fibrosis at day 80 and reduced both hydroxyproline & αSMA. AA resulted in raised K-Ras expression throughout the model. ASO only transiently reduced K-Ras at day 0 as it was raised again by day 12 and remained elevated throughout the model before falling again at day 80. It is this initial fall in K-Ras with ASO that has resulted in the reduction in the CKD demonstrated at day 80.

Conclusions: Transiently reducing K-Ras expression in the peri-AKI period in a murine model of AA nephropathy reduces downstream fibrosis and prevents the decline in renal function. Targeting K-Ras may provide a future therapeutic option for preventing renal fibrosis and CKD following AKI.

TH-PO207

Lipoxins Attenuate Kidney Disease Progression in Diabetic ApoE-/- Mice Phillip Kantharidis,[1] Mark E. Cooper,[1] Muthukumar Mohan,[1] Aaron D. McClelland,[1] Karin Jandeleit-Dahm,[1] Catherine Godson,[2] Eoin P. Brennan,[1,2] Stephen P. Gray,[1] Raelene J. Pickering,[1] Chris Tikellis.[1] *[1]JDRF Danielle Alberti Memorial Centre for Diabetes Complications, Baker IDI Heart and Diabetes Insitute, Melbourne, Victoria, Australia; [2]UCD School of Medicine and Medical Sciences, UCD Conway Inst of Biomolecular & Biomedical Research, Dublin, Ireland.*

Background: Strategies based on the resolution of inflammation are an attractive approach for the treatment of diabetic kidney disease (DKD). Endogenous lipid mediators including Lipoxins (LXs) actively promote the resolution of inflammatory responses. Here we investigated the potency of endogenous (LXA_4) and stable LX analogues (Benzo-LX) in attenuating kidney disease in diabetic $ApoE^{-/-}$ mice.

Methods: 6-week-old apolipoprotein E ($ApoE^{-/-}$) mice were randomly divided into control and diabetes groups. Diabetes was induced with low-dose streptozotocin. Mice in both groups were randomly divided into vehicle, LXA_4, and Benzo-LX analogue groups, and followed for 10 or 20 weeks.

Results: Diabetic $ApoE^{-/-}$ mice presented with DKD, as evidenced by albuminuria and renal injury. Diabetes-induced glomerular expansion and mesangial matrix expansion were significantly attenuated by LXA_4 and Benzo-LX (Glomerulosclerotic index: control 1±0.1, diabetic+vehicle 2.3±0.2, diabetic+LXA4 1.8±0.01, diabetic+Benzo-LX 1.5±1 arbitrary units, $p<0.01$ Benzo-LX vs vehicle; n=9). The increase in renal cortical collagen (COL1, COL3, COL4), alpha-smooth muscle actin (α-SMA), transforming growth factor beta 1 (TGF-β1), ICAM-1, VCAM-1, MCP1, IL-6 and TNFA seen in diabetic $apoE^{-/-}$ mice was attenuated by both LXA4 and Benzo-LX. The Lipoxins had no significant effect on albuminuria.

Conclusions: Taken together, our data demonstrate that LXs may be used as novel anti-fibrotic and anti-inflammatory therapeutics in DKD.

Funding: Government Support - Non-U.S.

TH-PO208

Smad Anchor for Receptor Activation, which Regulates Wnt/β-Catenin Signaling, Is Transcriptionally Suppressed by Dec1 Constance Runyan, Tomoko Hayashida, H. William Schnaper. *Pediatrics, Northwestern Univ, Chicago, IL.*

Background: We previously reported that cultured renal epithelial cells (HKC) lacking Smad Anchor for Receptor Activation (SARA) spontaneously undergo mesenchymal transition and become more fibrogenic, expressing higher TGF-β-stimulated COL1A2 mRNA content . In unilateral ureteral obstruction-mediated renal fibrosis, SARA is significantly downregulated, suggesting that SARA loss is a key event for progression. At least four mRNA species for human SARA exist and one major form, Z2.1 lacks the FYVE domain, thought to be required for SARA membrane localization. The Smad-binding domain and following C-terminal portion remain intact. Functions of the Z2.1 isoform are not well characterized. Here we evaluate transcriptional regulation of SARA, and compared effects of Z2.1 and full-length SARA on Wnt/β-catenin signaling.

Methods: The SARA promoter region from -1036 to TSS or its truncation mutants were cloned into pGL2-basic vector. Expression vectors carrying the full-length or Z2.1 form of human SARA cDNA were transfected in HKC. β-catenin or Smad2/3 dependent transcriptional activity was evaluated using TOPflash/FOPflash or ARE/SBE-luciferase reporter systems.

Results: Consistent with our previous finding that TGF-β decreases SARA mRNA expression, SARA -1036 promoter activity was reduced by TGF-β by 50%. A -814 promoter construct demonstrated 3-fold higher basal transcriptional activity compared to the -1036 promoter. Analysis identified a binding site between -814 and -1036 for Dec1, and Dec1 knockdown yielded higher levels of SARA protein and resistance to TGF-β-mediated SARA downregulation. Cells expressing either Z2.1 or full-length SARA suppressed Wnt3a-induced β-catenin activity to a similar degree, while neither Smad2-dependent ARE nor Smad3-dependent SBE reporter was affected by Z2.1 or full-length SARA overexpression. Both SARA isoforms interacted with β-catenin and rendered β-catenin for degradation.

Conclusions: Dec1 ablation inhibits TGF-β-stimulated SARA downregulation. Despite lacking the membrane localization sequence, Z2.1 suppresses Wnt/β-catenin signaling. These findings suggest possible novel approaches to suppressing progression of renal fibrosis.

Renoprotective Effects of Angiotensin III: Role of Oxidative Stress and Extracellular Matrix Expansion Rita de Cassia Cavaglieri, Doug Yoon Lee, Robert T. Day, Yves C. Gorin, Denis Feliers. *Dept of Medicine/Nephrology, Univ of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Glomerular injury is a prominent pathological feature of diabetic nephropathy (DN). Hyperglycemia promotes extracellular matrix protein accumulation by glomerular mesangial cells (MCs) and oxidative stress plays an important role in the pathogenesis of glomerular fibrotic lesions in DN.

Results: Type 1 diabetic mice displayed higher renal angiotensin (Ang) II and lower renal levels of Ang III, which correlated with a downregulation of aminopeptidase-A, which generates Ang III from Ang II. Mice lacking Ang II type 2 receptor (AT2R) lower renal Ang III even in the absence of diabetes. Reduced Ang III was associated with enhanced oxidative stress and glomerular fibrotic injury in these mouse models, suggesting that Ang III may be protective in DN. We studied the effect of Ang III on high glucose (HG)-induced oxidative stress and fibrotic injury in cultured MCs. Ang III blocked rapid upregulation of Nox4 NADPH oxidase expression and reactive oxygen species (ROS) generation induced by HG in the cells and the mitochondrial fraction. Ang III negatively regulated HG-mediated Nox4 expression via inhibition of Nox4 mRNA translation, and significantly attenuated upregulation of fibronectin induced by HG at 24 h. All these effects of Ang III were reversed by pharmacologic or genetic inhibition of the AT2R. The relevance of this pathway was confirmed by the finding that Nox4 expression, ROS production and fibrotic injury are exacerbated in both control and type 1 diabetic mice lacking AT2R. The signs of renal disease in these mice are linked to a reduction in Ang III generation in the kidney.

Conclusions: We provide the first evidence that Ang III, acting through the AT2R, protects MC from HG-induced oxidative stress and fibrotic injury via inhibition of Nox4 expression. Our data unveil the anti-oxidant and anti-fibrotic effects of Ang III and demonstrate that a functional interplay between AT2R and Ang III accounts for these renoprotective action in the diabetic environment. Targeting of Ang III/AT2R axis may represent a promising therapeutic approach for the treatment of DN.

The Cys-Knot C Terminal Motif of CTGF Modulates Fibrotic Effects in Proximal Tubule Cells Alone and in Concert with TGFβ1 Matthew Pottle, Mysore Keshavmurthy Phanish, Mark E. Dockrell. *Renal, SW Thames Inst for Renal Research, Carshalton, Surrey, United Kingdom.*

Background: Connective tissue growth factor (CTGF, CCN2) and Nov(CCN3) are both members of the CCN family of matricellular proteins; they are structurally similar, both consist of an IGFBP motif and a von Willebrand factor type C motif linked by a hinge region to the thrombospondin and CYS knot motifs. CTGF in particular has been shown to play an important role in cell proliferation and extracellular matrix remodelling regulated by different motifs and is widely recognised as a key mediator of glomerular and tubulointerstitial fibrosis in the context of renal disease. Work by ourselves and others supports the hypothesis that CCN3 acts in opposition to CTGF with regard to the regulation of fibrosis.

Methods: Primary human PTEC were cultured on collagen IV in supplemented medium. At 75-80% confluence cells were treated with: the 11 kDa C-terminus form of CTGF (Peprotech, 0.5-50 nMol) for 24hr and 48 hr; or both TGFβ1 (30 pMol) and C-terminus CTGF (0.5-50 nMol) for 60min and 24hr. The medium was collected and cells lysed. Western Blotting was used to detect protein expression and qPCR for mRNA expression. Antibodies (Ab) to the hinge regions of CCN3 and CTGF were used for protein detection.

Results: Exogenous Cys Knot C-terminus CTGF treatment at 24hr resulted in a dose dependent increase in CCN3 expression ($p<0.05$) in contrast to U – shaped response by CTGF with a trough at 5nMol. Cys Knot CTGF also caused a dose dependent inhibition of cell proliferation as determined by by expression of proliferating cell nuclear antigen (PCNA) No intracellular signalling by Cys Knot CTGF was detected but a selective increase in phosphor-Smad3 induction by threshold concentrations of TGFβ1was observed.

Conclusions: Primary human PTEC in culture are sensitive to the effect Cys Knot CTGF protein. The effects observed were distinctively different from those reported for the c-terminus CTGF including the hrombospondin but possibly consistent with the binding of the 11 KDa Cys Knot protein.

Mechano Growth Factor Stimulated Collagen IV Expression Is Dependent on Connective Tissue Growth Factor Yongxin Gao,[1] Raafat Farag Makary,[2] Leighton R. James,[1] Charles W. Heilig.[1] *[1]Dept of Medicine, Div of Nephrology and Hypertension, Univ of Florida, Jacksonville, FL; [2]Dept of Pathology and Laboratory Medicine, Univ of Florida - Jacksonville, Jacksonville, FL.*

Background: Increased extracellular matrix production is a hallmark of diabetic and hypertensive nephrosclerosis, yet the pathogenesis of nephrosclerosis is incompletely understood. Amongst various signaling pathways associated with sclerosis, connective tissue growth factor (CTGF) has been implicated in mediating extracellular matrix production in diabetic and hypertensive kidney disease. Mechano growth factor (MGF) is implicated in skeletal and cardiac muscle growth and survival; MGF has proliferative and anti-apoptotic properties. We have shown that MGF is glucose-response in that its expression is increased by high glucose in culture and in kidney of diabetic mice models.

Methods: To ascertain the interaction between CTGF and MGF in expression of matrix protein, we examined collagen IV and fibronectin levels in mesangial cells expressing MGF sense (MGF-S) and anti-sense (MGF-AS) transcripts. Immunohistochemistry (IHC) was performed for MGF, GLUT1, Type IV Collagen (Col-IV), Fibronectin, CTGF, NFkB p50 and NFkB p65 in cultured mouse MC's, +/- MGF-overexpression or MGF-suppression.

Results: Both CTGF and collagen IV protein levels were increased in MGF-S cells (1.5 and 2-fold respectively, $P<0.001$) and significantly reduced in MGF-AS cells. NF-κB (p50 and p65) was translocated to the nuclei (activated) in MGF-S MC's. Activated NFkB p50 was increased 2.4-fold in MGF-S MC's, while activated NFkB p65 was increased 2.1-fold in MGF-S vs MGFEV control MC's. In human kidneys from patients with interstitial fibrosis and tubular atrophy, CTGF and MGF were increased. Treatment of MGF-S cells with anti-CTGF antibody attenuated expression of collagen and fibronectin in MGF-S cells.

Conclusions: Thus, both CTGF and MGF expression associate with increased matrix protein levels and NF-KB nuclear translocation. Attenuation of ECM protein by CTGF antibody, suggest that CTGF may mediate part of the increased collagen production seen in MGFS cells.

TH-PO212

Rac1 Is a Novel Fibrotic Transducer of TGF-β Pathway in Chronic Kidney Disease Rohan Samarakoon,[1] Samik H. Patel,[1] Lucas Falke,[2] Jessica Marie Overstreet,[3] Jiaqi Tang,[1] Roel Goldschmeding,[2] Paul J. Higgins.[1] *[1]Dept of Regenerative and Cancer Biolgy, Albany Medical Center, Albany, NY; [2]Dept of Pathology, Univ Medical Center Utrecht, Uttecht, Netherlands; [3]Div of Nephrology and Hypertension, Vanderbilt Medical School, Nashville, TN.*

Background: Rac-GTPase, a major regulator of cytoskeletal remodeling, is a subunit of NADP(H) oxidases which generate reactive oxygen species. While the causative role of Rac in cancer progression and skin fibrosis is documented, whether Rac relays profibotic TGF-β1 signals and contributes to CKD progression is not known.

Methods: We used both genetic and pharmacological approaches in vitro and in vivo to definitively implicate Rac1 in renal maladaptive repair responses associated with fibrosis.

Results: TGF-β1 promotes rapid Rac-GTP loading in HK-2 human renal epithelial cells. Pharmacological blockade of Rac activation with a specific inhibitor, EHT1684 abrogated the expression of a battery of TGF-β1 induced genes, including fibronectin, PAI-1, CTGF, p21 and vimentin in renal epithelial cells and fibroblasts. Stable Rac1 silencing in HK-2 cells eliminated not only fibrotic gene expression but bypassed growth arrest induction by TGF-β1 evident in control transductants. ROS generation by TGF-β1 is also substantially retarded in epithelial cells with Rac1 depletion, consistent with the role of Rac1 in the assembly of free radical generating NOX1/2 complexes. Expression of Rac1b isoform is significantly elevated in mouse models of UUO compared to contralateral controls, correlating with fibrosis gene expression. Intraperitoneal administration of EHT-1684 significantly attenuated UUO-induced fibrosis compared to vehicle treated control mice with ureteral ligation.

Conclusions: Rac1 is novel non-SMAD control element of the TGF-β1 pathway necessary for ROS generation and subsequent induction of epithelial fibrogenesis and growth arrest. Pharmacological targeting of Rac pathway suppressed obstructive nephropathy, strongly implicating Rac as a novel therapeutic target against CKD.

Autotaxin Promotes Renal Interstitial Fibrosis by Inducing Vascular Leak and Fibroblast Accumulation Norihiko Sakai,[1] Gretchen Bain,[3] Miki Nakamura,[2] Taito Miyake,[1] Yasutaka Kamikawa,[1] Akihiro Sagara,[1] Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[1] Yasunori Iwata,[1] Miho Shimizu,[1] Kengo Furuichi,[1] Andrew M. Tager,[4] Takashi Wada.[2] *[1]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan; [2]Dept of Nephrology and Laboratory Medicine, Kanazawa Univ, Kanazawa, Japan; [3]PharmAkea, Inc., San Diego, CA; [4]Pulmonary and Critical Care Unit, Massachusetts General Hospital, Boston, MA.*

Background: The expansion of fibroblasts is an important step in the development of organ fibrosis, but the mechanisms driving this in renal fibrosis remain to be fully clarified. Lysophosphatidic acid (LPA), a bioactive lipid, has been reported to promote organ fibrosis by regulating multiple fibroblast functions. Autotaxin (ATX) is a major LPA-producing enzyme, and we hypothesized that ATX contributes to the development of renal fibrosis through LPA-mediated fibroblast accumulation.

Methods: Renal fibrosis was induced by unilateral ureteral obstruction (UUO) in type I pro-collagen promoter-driven green fluorescent protein (GFP) mice to identify fibroblasts. The selective ATX inhibitor was used to inhibit ATX activity.

Results: Renal activity and protein levels of ATX increased with the progression of fibrosis, despite concurrent reductions in renal ATX mRNA levels. UUO enhanced vascular permeability in the renal interstitium, and ATX protein localized to areas of vascular leak, suggesting that ATX enters the renal interstitium from the circulation in this model. Pharmacological inhibition of ATX activity protected mice from UUO-induced fibrosis, reducing the accumulation of fibroblasts. Renal vascular leak was also suppressed by ATX inhibition. *In vitro* studies showed that ATX induced the migration and proliferation of renal fibroblasts and enhanced the vascular permeability of endothelial monolayers.

Conclusions: These results suggest that during the development of renal fibrosis, ATX accumulates in the renal interstitium, and ATX produces LPA that drives fibroblast accumulation and further exacerbates renal interstitial vascular leak, thereby creating a vicious circle that amplifies fibrosis. Taken together, ATX inhibition may be a novel therapeutic strategy to combat renal fibrosis.

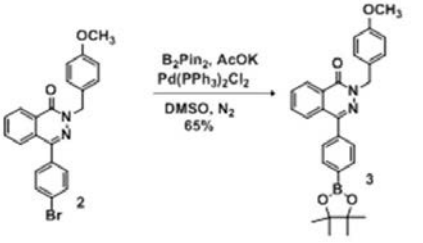
TH-PO214

Development and Synthesis of Boron Containing Low Molecular Weight Candidate Mimetics of Hepatocyte Growth Factor (HGF) for Treating Renal Fibrosis Sasmita Das,[1] Anna Fantinati,[2] Ram Sharma,[3] Bhaskar Chandra Das,[1] Mukut Sharma.[1,3,4] *[1]KU Medical Center, Kansas City, KS; [2]Univ of Ferrara, Ferrara, Italy; [3]KCVA Medical Center, Kansas City, MO; [4]MBRF, KCVA Medical Center, Kansas City, MO.*

Background: Renal fibrosis is associated with chronic kidney disease progression. HGF activates c-Met to initiate anti-fibrotic effects through opposing TGFβ1-Smad signaling. HGF mimetics are promising therapeutic agents for treating renal fibrosis. However, available HGF-derived peptide and c-Met activating protein mimetics are unstable and expensive. Introduction of boron in suitable scaffolds provides stable and versatile compounds for receptor-activation by hydrogen and covalent binding.

Methods: Computational Limited Rational Design Approach (LRD) was used. Protein crystal structures and their predicted ligands from protein-ligand data banks (PBB and EBI) were used to identify compatible small molecules with drug properties based on similarity search methods and Tanimoto similarity scores. Initial search identified phthalazin-1(2H)-one based heterocyclic compounds containing pharmacophore groups that complex with HGF and also bind c-Met. We synthesized compound based on phthalazinone scaffold and the product was used for borylation (3).

Results: Phthalazinone scaffold (Compound 2, Figure) developed by us was used for Miyaura borylation reaction. Bis (pincoloto) diboron (B_2pin_2)was used with potassium acetate as the base and $Pd(PPh_3)_2Cl_2$ as the catalyst to obtain the boron-containing derivatives (Compound 3) as a white solid in 65% yield at 99.9% purity. Structure was confirmed by Proton NMR, Carbon NMR and High Resolution mass spectrometry.



Conclusions: This novel approach for the first time provides boron-containing phthalazinone derivatives as potential HGF mimetics.

Pro-Inflammatory Mediator Exocytosis from Murine Primary Macrophages Is Dependent on Protein Kinase C-θ Anna Bertram,[1] Natalia Ronkina,[2] Yulia Kiyan,[1] Hermann G. Haller,[1] Nelli Shushakova.[1] *[1]Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Physiological Chemnistry, Hannover Medical School, Hannover, Germany.*

Background: The cooperation of several cell types is critical for a functioning inflammatory response to different kinds of injury. Protein kinase C-theta (PKC-θ) is well-known for its role in T-cells. Recently we could demonstrate a function for PKC-θ in neutrophil adhesion and recruitment, as well as cytokine release in chemical peritonitis in mice. Since the release of pro-inflammatory mediators from resident macrophages is a critical initial step in inflammation, we investigated the role of PKC-θ in this process.

Methods: Resident peritoneal macrophages isolated from healthy wild type (WT) or PKC-θ knockout (KO) mice were stimulated with LPS or vehicle with or without brefeldin A. Levels of the pro-inflammatory mediators TNF-α, CXCL1 and CXCL2 were measured by ELISA in conditioned cell culture medium and by Western Blots in cell lysates. Immunofluorescence microscopy in adherent stimulated macrophages and Western Blots were performed for evaluation of p38 MAPK activation and NFkB nuclear translocation. mRNA analysis was performed by RT-PCR.

Results: The release of pro-inflammatory mediators from LPS-stimulated KO macrophages was strongly impaired compared to WT, but no clear difference could be detected in mRNA levels. In line with the latter finding, neither activation of p38 MAPK nor nuclear translocation of NFkB was impaired in KO macrophages, suggesting a downstream target of PKC-θ. The analysis of exocytosis of WT and KO macrophages was further performed for TNF-α. LPS stimulation of WT macrophages resulted in transient intracellular accumulation of TNF-α with a maximum at 1h and declining within 2-4h. In line with the reduced TNF-α levels in conditioned medium from stimulated KO macrophages, intracellular TNF-α accumulation was significantly increased compared to WT starting 1h after stimulation. This difference was abrogated by co-incubation with brefeldin A, suggesting a defect in cytokine transport and exocytosis.

Conclusions: Our data demonstrates a role for PKC-θ in exocytosis of pro-inflammatory mediators from LPS-stimulated resident peritoneal macrophages.

Suppressed microRNA-214 (miR-214) Dictates IGF-1 Receptor (IGF-1R) Expression to Stimulate mTORC1 Signaling for Proliferation of Renal Cancer Cells Falguni Das,[1] Nandini Ghosh-Choudhury,[2] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: Elevated expression of IGF-1R in renal cell carcinoma correlates with tumor development and progression. The mechanism of hyper-expression of IGF-1R is not known.

Methods: VHL positive and negative renal cancer cells, immunoblotting, real-time qRT-PCR, site-directed mutagenesis, reporter transfection assays, DNA synthesis and proliferation assays were used.

Results: VHL positive and deficient renal cancer cells (ACHN, 786-O, RCC4 and A498) showed significantly reduced expression of mature, pre- and pri-miR-214 as compared to normal proximal tubular epithelial cells (HK2 and HRPTEC). Interestingly, in the 3'UTR of IGF-1R we identified a miR-214 recognition element (MRE) that responded to miR-214. When the MRE was mutated, the miR-214 responsiveness was abolished confirming its specificity. Overexpression of miR-214 inhibited IGF-1R mRNA and protein expression. IGF-1 increased phosphorylation of PRAS40 by Akt, leading to the activation of mTORC1

and phosphorylation of S6 kinase and 4EBP-1. miR-214 blocked the phosphorylation of PRAS40, S6 kinase and 4EBP-1. Phospho-deficient mutants of PRAS40 and 4EBP-1 and overexpression of miR-214 significantly inhibited IGF-1R-induced proliferation of renal cancer cells. Finally, expression of a 3'UTR-less IGF-1R or constitutively active mTORC1 reversed the miR-214-mediated inhibition of IGF-1-induced renal cancer cell proliferation.

Conclusions: These results provide the first novel evidence that reduced expression of miR-214 causes IGF-1-induced renal cancer cell proliferation via mTORC1 activation. Furthermore, we uncover the requirement of phosphorylation of PRAS40 and 4EBP-1 for IGF-1-stimulated proliferation of renal carcinoma cells. Thus we propose that use of miR-214 may represent an attractive therapy to test in preclinical models of renal carcinoma.

The Contribution of Transient Receptor Potential Channel 6 to Motility and Adhesion in the Podocyte and Identification of Novel Binding Partners

Louise K. Farmer,[1] Moin Saleem,[1,2] Gavin Iain Welsh.[1] *[1]Bristol Renal, Univ of Bristol, Bristol, United Kingdom; [2]Children's Renal Unit, Bristol Children's Hospital, Bristol, United Kingdom.*

Background: Several genetic mutations in TRPC6 have been linked to familial forms of FSGS, identifying it as a treatment target for nephrotic syndrome. TRPC6 is a membrane expressed calcium channel and it has previously been suggested that several of these mutations cause a gain of function and subsequent increase in calcium influx. However the role of TRPC6 in disease progression is still unclear.

Methods: Conditionally immortalised podocyte cell lines have been generated from TRPC3 KO, TRPC6 KO and TRPC3/TRPC6 double KO C57Bl/6 mice. GFP tagged TRPC6 was stably reintroduced into the KO cell line through generation of a lentiviral construct. These cell lines were then characterised to determine cell motility and adhesion using scratch and adhesion assays. GFP TRAP beads were used to pull down TRPC6 and proteomics was performed to identify novel binding partners. These interactions were confirmed through immunoprecipitation.

Results: Glomeruli from TRPC6, TRPC3 and TRPC3/6 KO mice were isolated and used to generate conditionally immortalised podocyte cell lines. All three cell lines appeared morphologically normal and expressed podocyte markers. Adhesion assays showed a significant increase in the adhesiveness of TRPC6 KO cells, whilst the TRPC3 KO and double KO cells were unaltered. The TRPC6 KO cells were also significantly less motile in a scratch assay. Reintroduction of GFP-TRPC6 to the TRPC6 KO cells returned the adhesive and motility phenotype towards that of the WT cell line. Immunoprecipitation with GFP TRAP beads identified interactions between TRPC6 and a number of calcium regulated proteins and proteins involved in regulating actin dynamics.

Conclusions: These results suggest that TRPC6 plays a considerable role in the adhesion and motility of the podocyte. This contribution could be occurring through the novel protein interactions that have been identified in this study, giving new insight into the role of TRPC6 in glomerular injury.

TH-PO218

The N-Recognin Ubr4 Controls Posttranslational Stability of Podocin/MEC-2 Supercomplexes

Markus M. Rinschen, Thomas Benzing. *Internal Medicine, Univ Hospital Cologne.*

Background: The PHB-domain protein podocin maintains the renal filtration barrier. Podocin mutation causes hereditary nephrotic syndrome. Podocin and its Caenorhabditis elegans orthologue MEC-2 are components of mechanosensitive membrane protein signalling complexes. Whereas podocin resides at a specialized cell junction at the podocyte slit diaphragm, MEC-2 is found in neurons required for touch sensitivity.

Methods: We performed mass-spectrometry based interactome analysis of podocin in vivo and in vitro to determine its interaction partners. We performed knockdown and knockout studies of Ubr4 in cell culture and C. elegans to determine its effect on podocin/MEC-2. We performed mass-spectrometry based ubiquitylomic analysis (using a Di-gly-gly antibody) to determine native podocin ubiquitylation sites in vivo. We modeled the biophysical effect of podocin ubiquitylation on the podocin structure using molecular dynamics simulations.

Results: Ubr4 was a key component of the podocin interactome purified both from cultured podocytes and native glomeruli. It localizes at the slit diaphragm and to the leading edge of podocytes in cell culture. Ubr4 regulates podocin stability in cell culture. In C. elegans, this process is conserved. Ubr4 knockdown or knockout increased the expression of Mec-2, the podocin orthologue. Ubr4 is also responsible for the degradation of mislocalized MEC-2 multimers. Ubiquitylomic analysis of mouse glomeruli revealed that podocin is ubiquitylated at two lysine residues. These sites were increasingly ubiquitylated in the presence of Ubr4 and were conserved across species, also based on mass-spectrometry dependent evidence. Molecular dynamics simulations revealed that ubiquitylation of one site, K301, does not only target podocin/MEC-2 for proteasomal degradation, but may also affect stability and disassembly of the multimeric complex. Mutation of K301 and K370 shifted podocin to the lysosomal compartment, indicating that K301 and K370 are essential for degrading podocin.

Conclusions: We suggest that podocin degradation is tightly controlled and that Ubr4 is a key regulator of podocyte foot process proteostasis.

HGF, a Novel Activator for Neph1 Signaling

Deepak Nihalani,[1] Pankaj Srivastava,[1] Prince Mohan,[1] Ashish K. Solanki,[1] Ehtesham Arif,[1] Darpan Gandhi,[1] Peifeng Deng,[1] Matthew J. Lazzara.[2] *[1]Medical Univ of South Carolina, 1, Charleston, SC; [2]Univ of Pennsylvania, 2, Philadelphia, PA.*

Background: Podocytes are the critical components of the glomerular filtration system and signaling from podocyte proteins Nephrin and Neph1 contributes towards their function. Despite numerous advancements, an extracellular ligand/s involved in their activation remains unknown. This is the first report demonstrating that the Hepatocyte Growth Factor (HGF) may induce Neph1 and Nephrin signaling in podocytes.

Methods: Proteomics, substrate trapping and mRNA profiling approaches were used to identify and investigate the role of HGF ligand in Neph1 signaling.

Results: HGF is known to signal through the phosphatase SHP2 and our preliminary results demonstrate that SHP2 may directly regulate Nephrin and Neph1 activation. Using a large scale mass spectrometric-based screen, we found that SHP2 interacts with Nephrin and Neph1 in a phosphorylation dependent manner. Using a substrate trapping mutant we demonstrate that SHP2 binds Neph1 in a substrate-specific manner, providing direct evidence that Neph1 is a substrate for SHP2. Additionally, HGF that stimulates SHP2 pathway was found to increase Neph1 phosphorylation only in SHP2 knock down cultured podocytes, suggesting that Neph1 participates in HGF induced signaling in podocytes. Since injury to podocytes has been shown to induce Neph1 phosphorylation we hypothesized that such induction may affect SHP2 expression. Indeed, mRNA profiling of cultured podocytes treated with puromycin aminonucleoside showed fivefold reduction in SHP2 expression. These results are consistent with a role for SHP2 in regulating Neph1 phosphorylation and activation. We further hypothesized that HGF induced Neph1 phosphorylation may initiate Neph1 endocytosis and to test this we created a chimeric Neph1 where Flag tag was introduced in the N-terminus of Neph1 that allows Neph1 to be extracellularly labeled with Flag antibody. Indeed, treatment of podocytes with HGF but not with other growth factors induced Neph1 endocytosis.

Conclusions: Collectively, these results provide compelling evidence that HGF can stimulate the signaling of slit diaphragm protein Neph1 in podocytes.

TH-PO220

Nephrin Tyrosine Phosphorylation Regulates Its Endocytosis through the Nck Adaptor Proteins

Claire E. Martin, Laura A. New, Nina Jones. *Molecular and Cellular Biology, Univ of Guelph, Guelph, ON, Canada.*

Background: Nephrin is a key structural component of the podocyte slit diaphragm, and proper expression of nephrin on the cell surface is critical to ensure integrity of the blood filtration barrier. Maintenance of nephrin within the slit diaphragm is proposed to require endocytic recycling, although the molecular mechanisms that regulate such trafficking are poorly understood. We have recently demonstrated that tyrosine phosphorylation of nephrin is central to its function, via recruitment of intracellular signaling proteins including the Nck family of SH2/SH3 domain-containing cytoskeletal adaptors. We now reveal that Nck provides a connection between phosphorylated nephrin and the endocytic machinery, and that changes in nephrin tyrosine phosphorylation dynamically alter its expression on the cell surface.

Methods: Mice expressing a nephrin variant that cannot undergo tyrosine phosphorylation (nephrin-Y3F) were used to characterize trafficking dynamics in healthy and injured podocytes. Complementary cell-based approaches were employed to assess molecular interactions that regulate nephrin endocytosis.

Results: We demonstrate that the nephrin-Y3F protein is overexpressed on the cell surface, and localized within tubulated pits both *in vitro* and *in vivo*. Remarkably, mutations in the SH3 domain of Nck2 induce a similar pattern of nephrin localization, and fusion of the intact Nck2 SH3 domains to the nephrin-Y3F protein can rescue this phenotype. We confirm that Nck2 preferentially associates with the endocytic regulator dynamin, and that disruption of dynamin GTPase activity promotes accumulation of nephrin on the cell surface. Lastly, we show that nephrin is transiently hyperphosphorylated and removed from the cell surface in a reversible model of proteinuric kidney injury, and that nephrin-Y3F mice are protected from this injury.

Conclusions: Together these findings underscore the link between actin signaling and endocytosis in podocytes, and they suggest that precise regulation of nephrin tyrosine phosphorylation is required to maintain barrier homeostasis.

Ephrin-B1 Interacts with the Basal Site of the Extracellular Domain of Nephrin in Cis and Regulates the Barrier Function and the Signal Transduction Pathway of the Slit Diaphragm

Yoshiyasu Fukusumi, Ying Zhang, Hiroshi Kawachi. *Dept of Cell Biology, Kidney Research Center, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: We have previously reported that Ephrin-B1 is the component of the slit diaphragm (SD) (KI, 2008) and plays a role in the arrangement of the SD molecules (ASN, 2015). However, the role of Ephrin-B1 in regulating the SD function is not well understood.

Methods: (i)The molecular association between Ephrin-B1 and nephrin was analyzed with HEK cells. (ii) The phenotype of the podocyte-specific Ephrin-B1 knockout (KO) mice induced by tamoxifen administration was precisely analyzed. (iii)To explore novel molecules associated with Ephrin-B1, gene expression profile of glomeruli of the KO mice was analyzed by the RNA-seq with next-generation sequencer.

Results: (i)Ephrin-B1 interacted with the basal site of the extracellular domain (7th immunoglobulin (Ig) domain-fibronectin domain) of nephrin and did not interact with the tip (N-end-1st Ig domain) of the extracellular domain or cytoplasmic domain of nephrin. Tyrosine residue (324/329) at the most C-terminal region of Ephrin-B1 was phosphorylated by the stimulation to nephrin by an anti-nephrin antibody in the HEK cells co-transfected with Ephrin-B1 and nephrin. (ii)The mice of which Ephrin-B1 gene was knocked out after birth showed disarrangement of the SD molecules and proteinuria (KO 5.33 mg/24 h vs. control 1.55, p<0.0001). Although the expression of Ephrin-B2 was not increased in the mice knocked out after birth, Ephrin-B2 expression was increased (to compensate the lack of the Ephrin-B1) in the mice knocked out at E18.5. The mice knocked out at E18.5 showed disarrangement of the SD molecules, but proteinuria was not observed in these mice. (iii) Five transmembrane proteins, of which expressions in glomeruli were evidently downregulated (< 30%) in the KO mice, were identified by the RNA-seq analysis.

Conclusions: Ephrin-B1 interacts with the basal site of the extracellular domain of nephrin in cis and plays a crucial role in the accumulation of the SD molecules and in the maintenance of the barrier function and the signal transduction system of nephrin.

TH-PO222

KIBRA Promotes Podocyte Injury by Inhibiting YAP Pro-Survival Signaling Kristin Meliambro, Jenny Wong, Justina Ray, John C. He, Evren U. Azeloglu, Kirk N. Campbell. *Nephrology/Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: KIBRA, an upstream regulator of the Hippo signaling pathway encoded by the *Wwc1* gene, shares the pro-injury properties of its putative binding partner dendrin and antagonizes the pro-survival signaling of downstream Hippo pathway effector YAP (Yes-associated protein) in *Drosophila* and MCF10A cells. Our group recently identified YAP as an essential component of the glomerular filtration barrier that promotes podocyte survival by inhibiting dendrin pro-apoptotic function. Despite recent advances, the signaling pathways that mediate podocyte survival and injury remain poorly understood. Here we test the hypothesis that similar to its role in other model systems, KIBRA promotes podocyte injury and death.

Methods: KIBRA/*Wwc1* was overexpressed in murine podocytes using retrovirus and high content image analysis characterized YAP localization, focal adhesion metrics, and actin cytoskeleton. KIBRA/*Wwc1* was silenced in human podocytes using lentivirus. Apoptosis was assessed via caspase 3/7 activity assay. Quantitative PCR determined expression levels of YAP-associated genes. Albuminuria was qualitatively assessed via Coomassie staining. Mouse kidneys were harvested following pericardial perfusion with HBSS or protamine sulfate and/or 4% PFA. Foot processes were quantified using transmission EM images.

Results: We found increased KIBRA/*Wwc1* gene expression in patient cohorts with biopsy-proven FSGS and CKD. Constitutive KIBRA/*Wwc1* knockout mice were protected from protamine-sulfate induced foot process effacement and KIBRA/*Wwc1* silencing in podocytes protected against adriamycin-induced apoptosis. Conversely, KIBRA/*Wwc1* overexpression enhanced podocyte susceptibility to staurosporine-induced apoptosis, disrupted actin cytoskeletal architecture, and reduced focal adhesion size and number. KIBRA promoted LATS phosphorylation leading to subsequent YAP S127 phosphorylation, YAP cytoplasmic sequestration, and reduction in target gene expression.

Conclusions: These findings suggest an important role for KIBRA in the pathogenesis of podocyte injury and the progression of proteinuric kidney disease.

SLIT2-ROBO2 Signaling Pathway Inhibits Non-Muscle Myosin IIA Activity and Destabilizes Kidney Podocyte Adhesion Xueping Fan,[1] Hongying Yang,[2] Sudhir Kumar,[1] Kathleen Tumelty,[2] Anna Pisarek-Horowitz,[1] Hila Milo Rasouly,[1] Richa Sharma,[1] Stefanie Chan,[1] Edyta Tyminski,[2] Michael Shamashkin,[2] Mostafa Belghasem,[1] Joel M. Henderson,[1] Anthony J. Coyle,[2] David J. Salant,[1] Stephen Berasi,[2] Weining Lu.[1] *[1]Nephrology and Pathology, Boston Univ Medical Center, Boston, MA; [2]Pfizer Centers for Therapeutic Innovation, Pfizer Inc, Boston, MA.*

Background: The repulsive guidance cue SLIT2 and its receptor ROBO2 are required for kidney development and podocyte foot process structure, but the SLIT2-ROBO2 signaling mechanism regulating podocyte cellular function is not known. Here we report that a novel signaling pathway of SLIT-ROBO Rho GTPase activating protein 1 (SRGAP1) and non-muscle myosin IIA (NM-IIA) regulates podocyte adhesion downstream of ROBO2.

Methods: We performed yeast two-hybrid assay, co-precipitation and western blot analyses, immunofluorescent staining, podocyte cell culture and adhesion assays, MRLC phosphorylation assay, in vivo mouse genetic interaction studies, and deoxycorticosterone (DOCA)-salt-uninephrectomy injury model study.

Results: We found that the myosin II regulatory light chain (MRLC), a subunit of NM-IIA, interacts directly with SRGAP1 and forms a complex with ROBO2-SRGAP1-NM-IIA in the presence of SLIT2. Immunostaining demonstrated that SRGAP1 is a podocyte protein and is co-localized with ROBO2 on the basal surface of podocytes. In addition, SLIT2 stimulation inhibits NM-IIA activity, decreases focal adhesion formation, and reduces podocyte cell attachment to collagen. In vivo studies further showed that podocyte-specific knockout of *Robo2* protects mice from hypertension-induced podocyte detachment and albuminuria and also partially rescues the podocyte loss phenotype in *Myh9* knockout mice.

Conclusions: We have identified SLIT2-ROBO2-SRGAP1-NM IIA as a novel signaling pathway in kidney podocytes, which may play a role in regulating podocyte adhesion and attachment. Our findings also suggest that inhibition of SLIT2-ROBO2 signaling could be beneficial for kidney diseases associated with podocyte detachment and loss.

Novel Mouse Models Overexpressing TRPC5 Xuexiang Wang, Hao Yu, Ranadheer Dande, Beata Tryniszewska, Mehmet M. Altintas, Jochen Reiser. *Dept of Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: Transient receptor potential channel (TRPC) family is a nonselective calcium–permeable cation channels that is widely expressed in cells and critical to cell behavior, physiology and pathology. The subfamily 5 of TRPC (TRPC5) is highly expressed in brain and kidney, and it mediates Ca2+ influx induced promoted cell migration. In the kidney, TRPC5 is related to podocyte cytoskeletal remodeling and filtration barrier modulating. One study suggested that knockout of TRPC5 in mice protects podocytes and the kidney filter. However, the effect of TRPC5 overexpression in mice has never been shown and the pathogenic role of TRPC5 in causing proteinuria is not clear.

Methods: Two novel transgenic mouse models (C57BL/6 background) were developed by overexpressing either wild-type TRPC5 (TG) or the dominant negative TRPC5 (DN, pore mutant) respectively. Overexpressed animals were validated by genotyping. TRPC5 level in the animal tissue was measured through mRNA expression, western blot and glomerular immunofluorescence (IF). Urinary albumin levels were measured and histology analysis was performed up to 6 month. LPS-induced albuminuria was quantified and compared among TG, DN and Bl/6 at baseline (0 hour), and at 24 hours and 48 hours after injection.

Results: In our transgenic mice, TRPC5 mRNA was significantly higher than control. Western blot exhibited abundant TRPC5 protein throughout various tissues. IF demonstrated stronger staining of TRPC5 in glomeruli of TG and DN compared with Bl/6. Histology analysis of TG and DN appeared to have no abnormalities at birth and after month 6. Neither TRPC5 mouse line did develop proteinuria. Kidney injury after LPS injection was similar among TG, DN and Bl/6 at 0, 24 and 48 hour with no significant differences in albumin/creatinine ratio (ACR).

Conclusions: TRPC5 was overexpressed in our novel transgenic mice. However, overexpression of TRPC5 does not cause kidney damage per se. LPS treatment resulted in similar levels of glomerular injury among TG, DN and Bl/6.

The Mechanisms of Dendrin Nuclear Translocation in Kidney Podocytes Naritoshi Shirata,[1,2] Kan-Ichiro Ihara,[3,4] Motoko Yanagita,[1,5] Katsuhiko Nishimori,[4] Katsuhiko Asanuma.[1,5] *[1]Medical Innovation Center, TMK Project, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan; [2]Research Unit/Nephrological & Endocrinological Science, Sohyaku, Innovative Research Div, Mitsubishi Tanabe Pharmaceutical Corporation, Toda, Saitama, Japan; [3]Dept of Molecular Genetics, Inst of Biomedical Sciences, Fukushima Medical Univ, Fukushima, Japan; [4]Dept of Molecular and Cell Biology, The Laboratory of Animal Breeding and Genetics, Graduate School of Agricultural Science, Tohoku Univ, Sendai, Miyagi, Japan; [5]Dept of Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan.*

Background: Previously we reported that dendrin, which is a component of the slit diaphragm, translocates to the injured podocyte and that nuclear translocated dendrin promotes podocyte apoptosis. We also demonstrated that dendrin nuclear translocation was detected in human renal diseases with glomerulosclerosis. However, the regulatory mechanisms of dendrin localization have been still unknown.

Methods: In this study, we investigated the regulatory mechanisms of dendrin nuclear translocation using yeast two hybrid screening, Co-IP and newly generated the podocyte specific MAGI-2 KO mice.

Results: We identified Fyn (tyrosine kinase) and Nedd4-2 (ubiquitin ligase) as putative interacting proteins with dendrin. Proteolysis of dendrin was regulated by Fyn-mediated phosphorylation and Nedd4-2-mediated ubiquitination. Dendrin was downregulated and accumulated in the nuclei in podocyte of MAGI-2 KO mice. These KO mice exhibited podocyte apoptosis leading to glomerulosclerosis. Dendrin at the slit diaphragm was phosphorylated and that in the nuclei was dephosphorylated.

Conclusions: Localization and expression of dendrin is controlled by Fyn, Nedd4-2 and MAGI-2.

New Structural and Biomechanical Insights Reveal the Importance of α-Actinin-4 Phosphorylation in Mediating Cytoskeletal Network and Glomerular Podocyte Function Di Feng,[1] Ramaswamy Krishnan,[2] Gabriel Birrane,[3] Johannes S. Schlondorff,[1] Martin R. Pollak.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA; [2]Emergency Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [3]Experimental Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Mutations in the alpha-actinin-4 gene (ACTN4) cause podocyte injury and familial focal segmental glomerulosclerosis (FSGS) in humans. We recently found that in cultured human podocytes, ACTN4 can be phosphorylated at the serine 159 site (S159), which is within the same actin-binding domain (ABD) as all of the known disease-causing ACTN4 mutations. Phosphomimetic S159D ACTN4 protein (which mimics the effect of phosphorylation at S159), recapitulates the altered actin bundling activity of FSGS-associated mutant ACTN4. This study seeks to further investigate the mechanism by which phosphorylation of ACTN4 affects podocyte function.

Methods: We used x-ray crystallography to solve the structure of the ACTN4 ABD protein, and traction force microscopy to quantify contractile forces exerted by human podocytes transfected with different ACTN4 constructs.

Results: We crystalized the ABD of phosphomimetic S159D ACTN4 protein. Similar to the previously solved crystal structures for the disease-causing K255E ACTN4, S159D ACTN4 showed a compact conformation with altered charge distribution compared to WT ACTN4. Across time, contractile force was consistently higher in S159D ACTN4 podocytes (commensurate with K255E podocytes) than in non-phosphorylatable S159A ACTN4 podocytes. However, WT ACTN4 podocytes initially exerted similar contractile force as S159D and K255E podocytes, but later decreased to lower levels comparable with S159A podocytes. This decrease in force could be in part due to decreased phosphorylation of WT ACTN4.

Conclusions: Our results suggest that phosphorylation of ACTN4 at S159 alters ACTN4 protein characteristics and podocyte biomechanical force. These observations support our hypothesis that an intracellular signal "switch" can convert normal ACTN4 to a form similar to the human mutation associated forms, therefore mediating podocyte injury in non-genetic forms of FSGS.

Physiological Roles of Ezrin in the Regulation of Podocyte Foot Process Formation Ryo Hatano, Kotoku Kawaguchi, Shinji Asano. *Dept of Molecular Physiology, Ritsumeikan Univ, Kusatsu, Shiga, Japan.*

Background: Ezrin is highly expressed in the glomerular podocytes, and is reported to form multi-protein complex with a scaffold protein Na^+/H^+ exchanger regulatory factor 2 (NHERF2), and podocalyxin, a major sialoprotein. Podocalyxin deficient mice died within 24 hrs after birth with anuric renal failure, whereas NHERF2 knockout mice did not show apparent renal phenotype. On the other hand, physiological roles of ezrin in glomerular podocytes still remain unclear.

Methods: To investigate the physiological roles of ezrin in the regulation of glomerular podocyte function, ezrin knockdown mice ($Vil2^{kd/kd}$) were used in this study. Histological analysis of glomerulus was performed by H&E staining and electron microscopy. Western blotting and immunofluorescent analysis were performed to investigate the expression and localization of related proteins in the podocytes. Rho activities were investigated by ELISA-based pull down assay using isolated mouse glomeruli from WT and $Vil2^{kd/kd}$ mice before and 7 days after adriamycin treatment.

Results: $Vil2^{kd/kd}$ mice did not exhibit apparent glomerular dysfunction, morphological defects, and disturbance in the localizations of podocalyxin and NHERF2 in podocytes. In $Vil2^{kd/kd}$ glomeruli, RhoA activity was increased 1.3-fold compared to WT glomeruli, while Rac1 and Cdc42 activities in $Vil2^{kd/kd}$ glomeruli were comparable with those in WT glomeruli at baseline. Interestingly, in adriamycin-induced nephrotic condition, $Vil2^{kd/kd}$ mice showed reduced susceptibility to the drug-induced glomerular injury. In $Vil2^{kd/kd}$ glomeruli after adriamycin treatment, RhoA activity was increased 1.5-fold, but Rac1 activity showed 2-fold decrease compared to adriamycin-treated WT mice. Furthermore, interaction of ezrin with Rho GDP dissociation inhibitor (RhoGDI), a key regulator of Rho activities, was confirmed by coimmunoprecipitation in WT glomeruli.

Conclusions: Our results suggest that loss of ezrin protect the podocytes from injury-induced dynamic morphological change, and ezrin plays important roles in the regulation of podocyte motility by regulating Rho activities via the interaction with RhoGDI in glomerular podocytes.

TH-PO228

ARF6 Activation Is Necessary for Nephrin-Dependent Changes in Podocyte Cytoskeletal Dynamics Jamie Lin,[1] Qingfeng Fan,[1] Hetty N. Wong,[1] Jin Seok Jeon,[2] Lawrence B. Holzman.[1] *[1]Renal-Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA; [2]Dept of Nephrology, Soon Chun Hyang Univ Hospital, Seoul, Korea.*

Background: Nephrin is a slit diaphragm protein that regulates podocyte actin dynamics and cell signaling. Nephrin is tyrosine-phosphorylated and undergoes endocytosis subsequent to podocyte injury. This triggers cellular remodeling necessary for podocyte effacement. The functional significance of nephrin endocytosis remains uncertain. We hypothesized that ARF6, a small GTPase necessary for endocytic trafficking and cell motility, is necessary for nephrin activation-induced podocyte cytoskeletal dynamics that results in injury-induced effacement.

Methods: These experiments were performed in an inducible nephrin-expressing podocyte cell culture model or in a newly engineered podocyte-specific ARF6 null mouse model.

Results: ARF6 is enriched in human podocytes *in vitro* and *in vivo*. In culture, nephrin activation resulted in increased ARF6 activity. Following nephrin activation, ARF6 was necessary for nephrin endocytic recycling, but not early nephrin trafficking, and was necessary for focal adhesion turnover and cellular ruffling. Mice deleted of ARF6 in podocytes had normal glomerular development and developed no evidence of proteinuria even when aged to eight months. When challenged with protamine sulfate, podocyte-specific ARF6 null mice exhibited protection from injury.

Conclusions: Our data show that nephrin tyrosine phosphorylation dependent focal adhesion turnover and cellular ruffling in cell culture are ARF6 dependent. *In vivo*, ARF6 appears to be dispensable for normal podocyte development and maintenance, yet is necessary for changes in podocyte morphology following injury with protamine sulfate. More studies are necessary to clarify the specific role and mechanism of ARF6 involvement in podocyte pathophysiology.

Von Willebrand Factor Release and Weibel-Palade Body Fusion Maintain Endothelial Cell Homoeostasis after Complement Activation Magdalena Riedl,[1] Daniel Schlam,[1] Damien Gerard Noone,[2] Christoph Licht.[1,2] *[1]Cell Biology, The Hospital for Sick Children, Toronto, Canada; [2]Nephrology, The Hospital for Sick Children, Toronto, Canada.*

Background: Complement dysregulation on endothelial cells causes EC activation and injury and leads to thrombotic microangiopathy. Different from previous concepts, our data demonstrate that complement dysregulation does not result in EC death. The current study focuses on EC complement evasion strategies, especially plasma membrane (PM) repair. We particularly focused on von Willebrand Factor (VWF), which we recently identified as new complement regulator on ECs. VWF is stored in EC Weibel-Palade bodies(WPB) and known to be released by ECs due to activation.

Methods: Complement was activated via a previously established protocol on blood outgrowth endothelial cells (BOECs) from healthy controls and patients with two types of von Willebrand disease (VWD): VWD type 2a with dysfunctional VWF, and VWD type 3 lacking both VWF and their storage organelle WPBs. Calcein release was used to determine plasma membrane (PM) integrity.

Results: Complement activation resulted in PM insertion of C5b-9 pores in control followed by rapid intracellular Ca^{2+} elevation. In response, VWF was recruited to the EC surface via WPBs merging with the PM and releasing VWF multimers. Importantly, only BOECs with WPBs (control and VWD type 2a BOECs) were able to reseal the PM within 30 min. VWD type 3 BOECs - lacking WPBs - were not able to reseal. In control BOECs known cellular mechanisms for PM repair (endocytosis of C5b-9, lysosomal recruitment) were not critically involved in PM repair. Defective or missing VWF also resulted in increased C3b deposition on the EC surface.

Conclusions: ECs have evasion strategies allowing for survival of complement attack. We have identified a new mechanism of complement evasion via VWF: release of VWF reduces complement activation on ECs, and PM fusion of WPBs repairs complement induced PM injury. This repair mechanism may contribute to EC homoeostasis beyond complement-mediated injury.

TH-PO230

Activated Neurotrophin-3 Receptor TrkC Transmits Signals to the Podocyte Actin Cytoskeleton Sascha Gromnitza, Hermann Pavenstaedt, Britta George. *Molecular Nephrology, Inst of Internal Medicine D, Univ Hospital Münster, Münster, Germany.*

Background: Podocyte malfunction is central to glomerular disease and is characterized by defective podocyte intercellular junctions and actin cytoskeletal dynamics. Recently, TrkC was shown to be located at the podocyte slit diaphragm. TrkC knockout mice developed proteinuria shortly after birth (Lefevre et al., PLoS Genet., 2010). The aim of this study is to further investigate the role of TrkC in podocytes and its relevance in glomerular disease.

Methods: Mouse podocyte lines were generated that inducably express wild-type TrkC or TrkC with mutations of specific tyrosine-residues known to mediate TrkC signaling. Wound healing assays following live cell imaging were performed. Glomeruli were isolated from murine kidneys and treated with Lipopolysaccharide (LPS) or Adriamycin (ADR) to induce podocyte injury.

Results: We confirmed that TrkC was expressed in mouse glomerular podocytes and co-localized with the slit diaphragm marker Nephrin. Activation of endogenous TrkC by adding the ligand Neurotrophin-3 (NT-3) to cultured mouse podocytes resulted in tyrosine-phosphorylation of TrkC as well as activation of the downstream target proteins Erk and Akt. Activation of overexpressed or endogenous TrkC by NT-3 lead to increased formation of filopodia in cultured mouse podocytes. Increased filopodia formation could not be observed in podocytes expressing kinase dead TrkC. Consistently an increased migration of podocytes *in vitro* was observed upon TrkC activation. Injury induced by treating isolated murine glomeruli with ADR or LPS resulted in a significant increase in tyrosine-phosphorylation of endogenous TrkC.

Conclusions: Currently, genetic mouse models with the potential to conditionally express or knockout TrkC in podocytes or nephrons are generated to test whether TrkC is essential for the podocyte and to dissect TrkC signaling in vivo. These mouse models will be employed to test whether TrkC can be therapeutically-targeted to treat glomerular disease. Our results imply that TrkC is activated during glomerular injury, signals to the podocyte actin cytoskeleton and regulates cell migration.

Dasatinib Induces Nephrotoxicity through Selective Disruption of Podocyte Biomechanics Rhodora C. Calizo,[1] Johan G.C. Van Hasselt,[1] Gomathi Jayaraman,[1] Jenny Wong,[2] Kirk N. Campbell,[2] Evren U. Azeloglu.[1] *[1]Pharmacological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Nephrology (Medicine), Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The toxicity induced by kinase inhibitors (KIs) is a bottleneck in targeted oncological therapies, where it may limit the efficacy of treatment or lead to the failure of a trial. It is thought that KIs lead to nephrotoxicity through nonspecific inhibition of VEGF; however the exact mechanisms are poorly understood.

Methods: We used retrospective data mining of FDA Adverse Event Reporting System (FAERS) to rank clinical nephrotoxicity of all FDA-approved KIs. We then used atomic

force microscopy (AFM), high-content imaging, and differential phospho-proteomics to assess the cytoskeletal biomechanics of cultured podocytes under different KI treatments and to identify the mechanisms through which dasatinib induced podocyte cytoskeletal remodeling.

Results: Dasatinib had the highest odds ratio for glomerulonephritis within FAERS compared to other KIs. Interestingly, VEGF inhibitor vandetanib was ranked very low as well as other Bcr-Abl inhibitors such as imatinib. High-content imaging of cultured podocytes showed significant and specific alterations to the actin cytoskeleton, number and size of focal adhesions, and cell morphology under dasatinib but not with other VEGF or BCR-Abl inhibitors. AFM elastography also revealed that elastic modulus of podocytes was significantly reduced under dasatinib treatment alone. Network analysis of differential phospho-proteomics of dasatinib treated podocytes showed "protein-protein interaction in the podocyte" and "regulation of actin cytoskeleton" as the highest enriched terms, and highlighted a number of upstream kinases that may be responsible for dasatinib's effects.

Conclusions: We conclude that dasatinib induces nephrotoxicity independent of VEGF inhibition. Its unique mechanism of action is specific to podocytes, and it acts through altered cellular cytoskeleton and biomechanics. Our results suggest that leukemia patients that are receiving targeted therapy with dasatinib should be monitored closely for nephrotoxicity.

Mediation Complex Protein 22 Is Essential for the Maintenance of the Glomerular Filtration Barrier Patricia Rodriguez,[1,2,3] Jing Guo,[1,3] Lwaki Ebarasi,[1] Jaakko Patrakka.[1,2] *[1]KI/AZ Integrated CardioMetabolic Center, Dept of Medicine, Karolinska Inst, Huddinge, Stockholm, Sweden; [2]Clinical Research Center, Dept of Laboratory Medicine, Karolinska Inst, Huddinge, Stockholm, Sweden; [3]Div of Matrix Biology, Dept of Medical Biochemistry and Biophysics, Karolinska Inst, Stockholm, Sweden.*

Background: Mediator complex protein 22 (Med22) is a component of the mediator complex, a multisubunit assembly that mediates signals from DNA bound transcription factors to RNA polymerase II. The role of Med22 in the biology of cells and organisms is not known. In this study, we identified Med22 as a highly podocyte-enriched transcript.

Methods: To establish its biological role in podocytes, we inactivated Med22 in zebrafish and mouse.

Results: In zebrafish larvae, Med22 knockdown prevents the formation of pronephros capillary loops and proper kidney filtration at 4dpf. Dye filtration assay shows that Med22 knockdown results in proteinuria in zebrafish larvae. Mice lacking Med22 specifically in podocytes develop normal kidneys and appear healthy until 8 weeks of age. After this the mice develop progressive albuminuria and renal insuffiency resulting in death by 16 weeks of age. Histologically, Med22-deficient mice exhibit large cytoplasmic vacuoles in podocytes that are positive for endosomal marker caveolin and lysosomal marker LAMP2.

Conclusions: Thus, Med22 is critical for the maintenance of podocyte homeostasis probably by regulating endosomal trafficking. This is the first time that a component of the mediator complex is shown to have a critical role in the kidney.

TH-PO233

Nanoscopy of Slit Diaphragm Proteins in Optically Cleared Kidney Tissue David Unnersjö-Jess,[1] Lena Scott,[2] Hans Blom,[1] Hjalmar Brismar.[1,2] *[1]Applied Physics, Royal Inst of Technology, Solna, Sweden; [2]Women's and Children's Health, Karolinska Inst, Solna, Sweden.*

Background: Previously, the finest elements of the filtration barrier have only been possible to visualize using electron microscopy. However, electron microscopy is mostly restricted to ultrathin two-dimensional samples, and the possibility to simultaneously visualize different proteins is limited. With the advent of super-resolution light microscopy new possibilities are available. We have developed a fluorescence-based protocol for studying the filtration barrier in human and rat kidneys. The strict requirements of staining quality needed for super-resolution imaging are normally hard to meet when working with tissue samples due to high background. We overcome this by applying an optical clearing protocol, drastically increasing the signal-to-noise ratio as well as the staining homogeneity.

Methods: Our hydrogel-based optical clearing protocol can be applied to both human and rat kidney samples to remove lipids without interfering with tissue integrity. Samples are stained by immunohistochemistry, mounted in a saturated fructose solution and imaged using a Leica SP8 3X STED system.

Results: We show that an optical clearing protocol in combination with super-resolution microscopy allows us to resolve the slit diaphragm and the localization of proteins in this region. In non-cleared samples the slit diaphragm could not be resolved, showing that optical clearing is a necessary part of the protocol. We compared the localization of proteins in control samples to samples from rats with induced nephropathy, and observed alterations of the nanoscale distributions.

Conclusions: We show that optical clearing in combination with super-resolution microscopy can be used as a tool to study the finest parts of the slit diaphragm in kidney tissue. We also show alterations of slit diaphragm protein localizations under pathological conditions, making our protocol a possible tool for diagnosis.

Funding: Government Support - Non-U.S.

TH-PO234

Angiomotin Mutation in Rats Causes Proteinuria and Podocyte Foot Process Effacement Yaochun Zhang, Isaac Liu, Chang-Yien Chan, Hui Kim Yap, Kar Hui Ng. *Paediatrics, National Univ of Singapore, Singapore.*

Background: Using next generation sequencing, we identified in a Singapore Chinese family with X-linked recessive nephropathy a putative missense mutation in the *AMOT* gene which codes for angiomotin. The mutation segregates with renal disease, is not present in the exomes of healthy population and public databases. It changes a hydrophilic to hydrophobic amino acid. Although the amino acid is not conserved across different species, all species carry hydrophilic amino acids. *AMOT* occurs in the X chromosome in humans and rats and is known to affect tight junctions and actin cytoskeleton in epithelial cells. This study aimed to elucidate the function of *AMOT* in rat kidneys.

Methods: Using CRISPR/Cas9 system, we created a founder rat with a missense mutation corresponding to the human mutation. The phenotypes of the mutant F2 generation rats were compared with control rats. Total RNA were extracted from peripheral blood mononuclear cells and sent for RNA-Seq.

Results: All male mutant rats developed significant proteinuria by 6 months old and had significantly higher body weight than controls at 10 months old. Light microscopy showed minor glomerular changes but electron microscopy confirmed podocyte foot process effacement at 8 months old. There appeared to be no involvement in other organ systems. The renal tubular function was normal in mutant rats as shown by similar serum electrolytes and acid-base compared to controls. In contrast, both heterozygous and homozygous mutant females had no or very mild proteinuria, affirming the X-linked recessive inheritance. RNA-Seq results showed more than 300 differentially expressed genes including Smad7, Rac1 and pdlim1. Analysis using IPA revealed altered effector pathways in glomerular injury, renal necrosis, and nephritis.

Conclusions: To our knowledge, this is the first study that suggests that *AMOT* play important roles in podocytes. AMOT may exert its function in podocytes through Rich1/Gap complex affecting activation status of Rho GTPases or via interactions with slit diaphragm and actin cytoskeleton proteins. More studies are needed to further elucidate the mechanism.

Funding: Government Support - Non-U.S.

TH-PO235

Podocyte-Based HCS Assays Identify Paullone Derivatives as Novel Reno-Protective Agents Ha Won Lee,[1] Ehtesham Arif,[2] Deepak Nihalani,[2] Vineet Gupta.[1] *[1]Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Dept of Medicine, Nephrology Div, Medical Univ of South Carolina, Charleston, SC.*

Background: Injury and loss of podocytes are early hallmarks of a variety of glomerular diseases. Targeting podocytes is an approach for the kidney-directed therapeutics. Damaged podocytes change their morphology and skeleton structure. To identify small molecules that protect podocytes from injury, we performed cell-based high content screening (HCS) using a phenotypic assay. The HCS assay revealed a family of small molecules, paullones, which are GSK3β inhibitors as potent podocyte-protective agents.

Methods: Phenotypic changes of podocytes were analyzed using automated methods. For in vitro podocyte damage, murine podocytes were treated with puromycin aminoglycoside (PAN). qPCR was used for the quantification of mRNA expression. Caspase 3/7 activities were measured using luciferase substrate-based system. Annexin V-positive cell population was quantified using flow cytometry. For glomerular injury in zebrafish, Adriamycin was added in growth medium. Pericardial edema was calculated by dividing cardiac area by whole body area.

Results: 3 paullone derivatives showed dose-dependent protection of podocytes from PAN-induced injury. Alsterpaullone, which showed most protective effects reduced the expression of a podocyte damage marker, *Desmin*, and inhibited PAN-induced increase in podocyte migration. Furthermore, alsterpaullone reduced PAN-induced apoptosis of podocytes. As a control, GSK3β inhibitor, SB216763, also protected podocytes from PAN-mediated injury apoptosis. Both alsterpaullone and SB216763 protected zebrafish from Adriamycin-induced glomerular damage.

Conclusions: Screening of a chemical library using our newly developed podocyte-based HCS assay resulted in identification of paullone family of compounds as novel podocyte-protective compounds. Paullones mediate their protective effects by targeting GSK3β, a well-known protein target in podocytes and showed protection of podocytes from injury in both in vitro and in vivo assays.

A T2A-Peptide Based Knock-In Mouse Model for Enhanced Cre Recombinase Activity and Fluorescent Labeling of Podocytes
Sybille Köhler,[1] Sebastian Braehler,[1,4] Fabian Braun,[1] Markus M. Rinschen,[1,2] Bernhard Schermer,[1,2,3] Thomas Benzing,[1,2,3] Paul T. Brinkkoetter.[1] *[1]Dept II of Internal Medicine and Center for Molecular Medicine, Univ of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Univ of Cologne, Cologne, Germany; [3]Systems Biology of Ageing Cologne (Sybacol), Univ of Cologne, Cologne, Germany; [4]Dept of Pathology & Immunology, Div of Immunobiology, Washington Univ School of Medicine, St. Louis.*

Background: Podocyte injury is a key event in glomerular disease leading to proteinuria and opening the path towards glomerular scaring. As a consequence glomerular research strives to discover molecular mechanisms and signaling pathways affecting podocyte health.

Results: Here, we generated a novel podocyte-specific Cre mouse model combining enhanced Cre efficiency and fluorescent cell labelling. To this end, we targeted the *Nphs2* locus to generate a tricistronic mRNA linking *Nphs2* to a codon improved Cre recombinase (iCre) via a viral 2A sequence followed by a second 2A sequence and mTomato allowing direct podocyte labelling. Podocin.T2A, iCre.T2A and mTomato are expressed in equimolar amounts under the control of the endogenous *Nphs2* promoter. Immunofluorescence and FACS-analysis revealed exclusive mTomato expression in podocytes. Nphs2.T2A.iCre.T2A.mtTomato mice did not develop glomerular disease confirming that the knock-in *per se* was not harmful. We assessed Cre recombinase efficiency by mating the mice to $Phb2^{fl/fl}$ mice. $Phb2^{fl/fl}$;$Pod2ACre^{tg/wt}$ mice presented with aggravated glomerular injury already evident after 2-3 weeks of age and premature lethality after 4 weeks while the onset of disease in conventional $Phb2^{fl/fl}$;$Pod.cre^{tg/wt}$ mice was delayed by approximately 7 days.

Conclusions: Taken together, we generated a tricistronic podocyte reporter mouse that combines improved Cre recombinase activity and expression of a membrane-tagged tomato for easy visualisation and identification of podocytes.

TH-PO237

VEGFA Expression by the Stromal Lineage Is Critical for Glomerular and Peritubular Capillaries in Kidney
Henrik Dimke,[1,2] Rizaldy P. Scott,[2,3] Yoshiro Maezawa,[2] Vera Eremina,[2] Paul S. Thorner,[4] Yashpal S. Kanwar,[5] Susan E. Quaggin.[2,3] *[1]Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; [2]Lunenfeld-Tanenbaum Research Inst, Toronto, ON, Canada; [3]Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL; [4]Dept of Pediatric Laboratory Medicine, Hospital for Sick Children, Toronto, ON, Canada; [5]Depts of Pathology and Medicine, Northwestern Univ, Chicago, IL.*

Background: VEGFA produced by podocytes and renal tubular epithelial cells is essential for the glomerular endothelium and peritubular capillaries, respectively. Given the important role of VEGFA in maintaining select microvascular beds, we aimed to determine whether the stromal compartment in kidney could be important for renal microvasculature by modulating the VEGFA system.

Methods: Expression of *Vegfa* in kidney was visualized using reporter mice with a *LacZ* gene inserted downstream of the *Vegfa* locus. Stromal-specific *Vegfa* deficient mice ($Vegfa^{Foxd1}$) were generated through crosses between Foxd1-Cre transgenic mice and floxed *Vegfa* animals, resulting in deletion of the *Vegfa* gene in interstitial pericytes and mesangial cells.

Results: During renal embryogenesis *Vegfa* was highly expressed in stromal cells. Elimination of *Vegfa* from the $Foxd1^{+}$ stroma resulted in proteinuria by postnatal day 14 (P14). Kidneys from $Vegfa^{Foxd1}$ showed abnormal mesangial expansion and thickening of the glomerular basement membrane at P7. Progressive worsening of the phenotype followed in $Vegfa^{Foxd1}$ with loss of glomerular endothelial cells, obliteration of the capillary lumen, and severe expansion of the mesangium. By P21, glomeruli appeared hypocellular with collapse of capillary tufts. Additionally, reduced peritubular capillary density was observed in $Vegfa^{Foxd1}$ kidneys.

Conclusions: VEGFA produced by renal $Foxd1^{+}$ stromal derivatives appear critical for proper maintenance of glomerular and peritubular microvasculature. The present data suggest that VEGFA may act as a paracrine factor mediating cellular communication towards renal endothelial cells by adjacent pericytes and mesangial cells.

Unbiased Phosphoproteomic Approach Identifies Podocyte Protective Pathways Downstream the Melanocortin-1 Receptor
Lovisa Bergwall,[1] Johannes Elvin,[2] Hanna Ilse Wallentin,[1] Borje Haraldsson,[2] Jenny C. Nystrom,[1] Lisa Buvall.[1] *[1]Dept of Physiology, Inst for Neuroscience and Physiology, Sahlgrenska Academy, Univ of Gothenburg, Gothenburg, Vastergotland, Sweden; [2]Dept of Molecular and Clinical Medicine, Inst of Medicine, Sahlgrenska Academy, Univ of Gothenburg, Gothenburg, Vastergotland, Sweden.*

Background: Adrenocorticotropic hormone (ACTH) has shown to be efficient in treatment of patients with nephrotic syndrome. Activation and upregulation of the ACTH receptor in podocytes, the melanocortin-1 receptor (MC1R), following renal damage has been proposed to be the protective mechanism of action.

Methods: To further understand the effector pathways downstream of the MC1R in podocytes, phosphoproteomic mass spectrometry was used on podocytes overexpressing wt-MC1R treated with the MC1R agonist, BMS. Stress fiber rearrangement was studied in real-time using LifeAct on podocytes treated with protamine sulfate, either overexpressing a constitutively active MC1R or a wt-MC1R treated with BMS.

Results: 299 significant MC1R regulated phosphoproteins were identified, with the top ranked regulated pathways at the early timepoint (15 min of BMS exposure) being actin cytoskeleton signaling followed by integrin, paxillin, FAK and RhoGTPase signaling. At a later stage (60 min of BMS) the activated pathways were shifted to tight junction followed by integrin, actin cytoskeleton and adherent junction signaling. The regulation of the actin cytoskeleton signaling by MC1R was further supported by LifeAct experiments where both BMS activation of wt-MC1R overexpressing cells and overexpression of the constitutively active MC1R showed a protective effect against PS induced stress fiber rearrangement.

Conclusions: This study presents the mechanisms behind the beneficial effects of MC1R-activation, with the top ranked function being actin cytoskeleton stabilization in podocytes, which is known to be crucial for the maintenance of kidney filtration barrier function. It also demonstrates how an unbiased phosphoproteomic approach can be used to identify regulated signaling pathways important in podocyte function.

Epidermal Growth Factor Receptor Augments Nephrin Tyrosine Phosphorylation
Jimmy J. Qian,[1,2] Shannon Keenan,[3] Amar Bansal,[4] Lawrence B. Holzman,[4] Matthew J. Lazzara.[5] *[1]Chemistry, Univ of Pennsylvania (UPenn), Philadelphia, PA; [2]Physics, UPenn, Philadelphia, PA; [3]Chemical & Biomolecular Engineering, UPenn, Philadelphia, PA; [4]Renal Electrolyte & Hypertension Div, Perelman School of Medicine, UPenn, Philadelphia, PA; [5]Chemical Engineering & Biomedical Engineering, Univ of Virginia, Charlottesville, VA.*

Background: Phosphorylation of nephrin cytoplasmic tyrosines is thought to regulate podocyte morphology and actin cytoskeletal dynamics by inducing downstream signaling events. Here, we studied the ability of epidermal growth factor (EGF) receptor (EGFR) to participate in nephrin signaling.

Methods: Human podocytes were engineered with stable expression of chimeric nephrin (CD16 extracellular domain, CD7 transmembrane domain, and nephrin cytoplasmic domain). Nephrin phosphorylation was induced through antibody-mediated clustering (AMC) of nephrin and EGFR was activated with recombinant human EGF. Protein phosphorylation and protein complex formation were measured by immunoblotting and immunoprecipitation. Formation of endocytic structures and protein colocalization were quantified through analysis of fluorescence microscopy images.

Results: We found that the tyrosine phosphorylation that occurs normally in response to AMC was significantly augmented by concurrent EGFR activation. This effect was most apparent when EGFR and nephrin colocalization had increased substantially above baseline levels (≥10 min of AMC+EGF). The augmentation was abrogated through inhibition of Src family kinases (SFK), which were activated by EGFR and trafficked with EGFR-containing endosomal vesicles. Across all signals, phospho-nephrin signal correlated linearly with colocalization of nephrin and phospho-SFK ($R^2 = 0.87$). Interestingly, at early time points (≤2 min), concurrent EGFR activation suppressed nephrin tyrosine phosphorylation. This effect appeared to result from EGFR, which internalizes faster than nephrin, sweeping active SFK away from nephrin.

Conclusions: EGFR augments nephrin phosphorylation in a SFK-dependent manner by bringing active SFK into physical proximity of nephrin through EGFR–nephrin colocalization in endosomal compartments. EGFR's ability to influence nephrin signaling could play a role in slit diaphragm integrity.

Role of the Rac1 Guanine Nucleotide Exchange Factor, Trio, in the Regulation of Rac1 Activity in Podocytes
Mirela Maier, Cindy Baldwin, Lamine Aoudjit, Tomoko Takano. *Experimental Medicine, McGill Univ, Montreal, QC, Canada.*

Background: Hyperactivation of the small GTPase, Rac1, has been shown to contribute to podocyte injury and development of focal segmental glomerulosclerosis (FSGS). We hypothesize that Rac1 is activated by one or more guanine nucleotide exchange factors (GEFs).

Methods: Nephromine was used to identify genes that are differentially expressed in FSGS and minimal change disease (MCD). Immuoblotting (IB) and immunofluorescence (IF) staining were used to detect proteins. Focal adhesion complex (FAC) was detected by vinculin IF. Trio knockout human podocyte (HP) lines (Trio KOs) were generated by the Cas9/CRISPR system. HP expressing Cas9 alone was used as control. Cell proliferation was studied by MTT assay. Motility was studied by wound healing. GST-bound Cdc42-Rac1 Interactive Binding domain (GST-CRIB) was used to pull-down (PD) active Rac1, followed by IB. GST-Rac1G15A was used to PD active Trio, followed by IB.

Results: RNA-seq showed high mRNA expression of the Rac1-GEF, Trio in two lines of HP. Glomerular mRNA of Trio was significantly upregulated in FSGS (1.24 fold) and MCD (1.18 fold) in the Ju podocyte dataset. Trio protein expression was detected by IB in HP and mouse glomerular lysates, and by IF staining in the mouse kidney, most notably in podocytes colocalizing with WT1. In HP, TGFβ1 activated Trio and Rac1 by 60 min and induced FAC relocalization toward the cell periphery. Compared to control, Trio KOs showed lower basal (24 ± 5% of control, n=3, $p<0.001$), as well as TGFβ1-induced (control: 1.72 ± 0.21 fold increase from basal, Trio KOs: 0.59 ± 0.13 fold from basal, n=4, $p<0.01$)

Rac1 activity. Trio KOs showed decreased motility (control: 21.4 ± 0.6 %, Trio KOs: 17.3 ± 1.0 %, wound closure at 5 h, n=4, p<0.05), while cell size, proliferation rate, and F-actin pattern were comparable to control HP. When the active form of Trio (GEF-D1 domain) was expressed in HP, it increased cell size and relocalized FAC to the cell periphery.

Conclusions: Trio contributes to basal and TGFβ1-induced Rac1 activity and regulates motility and FAC localization in podocytes. Trio may be one of the GEFs that contribute to the pathogenesis of FSGS and MCD via Rac1 activation.

TGF-β1-Induced Changes of DNA Methylation Levels in Promoter and Enhancer Regions of WT1 Gene in Human Podocytes Hiroko Hamatani, Toru Sakairi, Hidekazu Ikeuchi, Yoriaki Kaneko, Akito Maeshima, Yoshihisa Nojima, Keiju Hiromura. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Japan.*

Background: Wilms' Tumor Suppressor (WT1) is essential for normal podocyte function. Previous reports have shown that WT1 promoter is often methylated in cancers, leading to transcriptional silencing. We have reported that TGF-β1 downregulates WT1 expression in podocytes. Based on the hypothesis that epigenetic modification plays a role in this process, we examined if TGF-β1 changes WT1 methylation levels in its promoter and three enhancer regions.

Methods: Conditional immortalized human podocytes were treated with 3 ng/ml of TGF-β1 for 10 days. A human renal tubular epithelial cell line (HK-2) was used as the control cells, which do not express WT1. The degree of DNA methylation was determined by quantitative methylation-specific PCR (Q-MSP), bisulfate sequencing, and pyrosequencing.

Results: Both WT1 mRNA and protein expression were reduced by the treatment of TGF-β1, as previously reported. Interestingly, TGF-β1 reduced mRNA expression of WT1 +KTS isoform, but not of -KTS isoform. The examination of methylation status of WT1 promoter by Q-MSP revealed that higher levels of methylation in HK2 (99.1±1.0% P<0.01) compared to untreated podocytes (2.9±4.5%), and that TGF-β1-treated podocytes tended to increase DNA methylation (14.3±10.5%, P=0.16, vs untreated podocytes). In contrast, examination of WT1 5' enhancer and intron 3 enhancer showed lower levels of methylation in HK2 (10.7±2.8% and 47.3±13.1%, P<0.01 and P<0.05) compared to untreated podocytes (53.7±10.3% and 74.5±8.9%), and that TGF-β1 tended to reduce or significantly reduced methylation at 5' enhancer and intron 3 enhancer (40.7±6.0% and 43.1±16.0%, P=0.13 and P<0.05, vs untreated podocytes). Bisulfite sequencing and pyrosequencing showed similar results. Finally, methylation levels at 3' enhancer did not differ among HK2, untreated podocytes and TGF-β1-treated podocytes.

Conclusions: Our data suggest that TGF-β1 changes the methylation levels of WT1 promoter and enhancers of podocytes. The reduction of WT1 expression by TGF-β1 may be partly due to the DNA methylation changes.

TH-PO242

FRMD3/Protein 4.1O Is a Novel Linker of Nephrin to the Actin Cytoskeleton Eva Koenigshausen,[1] Aida Bajraktarevic,[1] Sinja Ohlsson,[1] Klaus Stahl,[2] Marie Schönberger,[1] Magdalena Woznowski,[1] Ivo Quack,[1] Mario Schiffer,[2] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Univ Hospital Duesseldorf, Germany; [2]Hannover Medical School, Germany.*

Background: FRMD3 has been proposed as a candidate gene for susceptibility of diabetic nephropathy (DN). FRMD3 encodes for protein 4.1O, which is a member of the 4.1 protein family. Members of the protein 4.1 family link membrane proteins to the actin cytoskeleton. The molecular function of protein 4.1O is unknown so far. Linkage of the slit diaphragm protein nephrin to the actin cytoskeleton via adapter proteins like nck are essential for the integrity of the slit diaphragm.

Methods: FRMD3 expression was analyzed in human podocytes. The interaction of nephrin with protein 4.1O and its truncations was examined by co-immunoprecipitation. Phospho-specific antibodies to nephrin and PP2 were used to investigate the role of nephrin Y-phosphorylation. Zebrafish larvae were treated with morpholinos against the orthologue of FRMD3 in zebrafish. Injection of fluorescently labeled FITC-dextran was monitored via eye fluoescence. A reduction of fluorescence was an indirect sign of glomerular tracer loss. For rescue experiments, morpholino treated larvae were injected with protein 4.1O truncations.

Results: Protein 4.1O is expressed in human podocytes and interacts with nephrin. Truncation mapping reveals the interaction domain of nephrin to protein 4.1O AA 506-554. Nephrin-protein 4.1O interaction is dependent on Src-family kinases. Interestingly, protein 4.1O reduces nephrin Y-phosphorylation at nephrin-nck binding sites and reduces nck binding to nephrin. Protein 4.1O directly interacts with actin. Injection of FRMD3 orthologue morpholinos in zebrafish larvae leads to yolk sac edema, slit diaphragm disruption and increase in glomerular permeability. This increase can be rescued by reconstitution of protein 4.1O AA 506-554, the nephrin binding domain.

Conclusions: Protein 4.1O is a novel linker of nephrin to the actin cytoskeleton and essential for the integrity of the glomerular filtration barrier. Our data point to a protective role of protein 4.1O in podocytes. Understanding of the physiological role of protein 4.1O will help to understand its role in diabetic nephropathy that has been implicated by GWAS.

c-Abl Is Involved in the Cytoskeleton Remodeling of Podocytes via Interaction with Nephrin Yiqiong Ma, Qian Yang, Dingping Yang, Guohua Ding. *Div of Nephrology, Renmin Hospital of Wuhan Univ, Wuhan, Hubei, China.*

Background: Previous studies have showed that nephrin is required for cytoskeleton remodeling in podocytes. However, the molecular mechanism remains incompletely understood. c-Abl is a non-receptor tyrosine kinase involved in cytoskeleton regulation, which may be a candidate of signaling proteins interacting with SH2/SH3 domains of nephrin. The present study has explained whether c-Abl contributes to nephrin-dependent cytoskeleton remodeling of podocytes.

Methods: Colocalized expression of nephrin and c-Abl was evaluated in glomeruli of patients with nephrotic syndrome (NS) by double immunolabeling analysis. In *vitro*, Angiotensin II (Ang II) was used to promote cytoskeleton remodeling of podocytes. Differentiated murine podocytes were exposed to Ang II for 24 h. Cytoskeleton configuration was evaluated by FITC-phalloidin staining. Western blotting was performed to evaluate the expression of nephrin and c-Abl. Colocalization of nephrin and c-Abl was determined by confocal microscopy and co-immunoprecipitation analysis. Cell migration assays were used to evaluate the function of cytoskeleton remodeling. Co-immunoprecipitation was conducted in COS7 cells co-transfected with CD16-CD7-nephrin and SH2/SH3-defective c-Abl vectors to identify the domain of c-Abl binding with nephrin.

Results: The glomerular staining of nephrin and c-Abl indicated that the colocalization in patients with NS was decreased compared with that in control patients. In cultured podocytes, Ang II exposure induced dephosphorylation of nephrin and diminished the interaction between nephrin and c-Abl. In addition, F-actin disruption was aggravated by exposure of both Ang II and overexpression of c-Abl. Furthermore, the disorganized cytoskeleton stimulated by cytochalasin D in COS7 cells was restored by cotransfection with phosphorylated CD16-CD7-nephrin and c-Abl full-length constructs. Co-immunoprecipitation showed that phosphorylated CD16-CD7-nephrin interacted with wild type c-Abl, not with SH2/SH3-defective c-Abl.

Conclusions: This study suggests that phosphorylated nephrin is able to recruit c-Abl in a SH2/SH3-dependent manner, which modulates cytoskeleton remodeling in podocytes.

TH-PO244

Novel Role of Proteasomes in Glomerular Disease Radhakrishna Baliga,[1] Allyson E. Bradley,[1] Himanshu Vashistha,[1] Sudhir V. Shah.[2] *[1]Inst of Translational Research, Ochsner Clinic Foundation, New Orleans, LA; [2]Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Proteasomes have been implicated in the pathophysiology of several disease processes in part through its action on a crucial transcription factor, nuclear factor-kappa B (NF-KB). NF-KB is a transcription factor that regulates the expression of a wide variety of inflammatory genes including cytochrome P450 (CYP). We have shown that CYP plays a major role in glomerular injury in a model of Minimal Change Disease (MCD). The role of proteasomes in MCD has not been explored. The current study examined the role of proteasomes in vitro utilizing cultured human podocytes (HP) and in vivo in a model of MCD.

Methods: MCD was induced in rats by injecting puromycin aminonucleoside (PAN) and the effect of proteasome inhibitors (PI) on proteinuria was measured as urinary albumin to creatinine ratio (ACR)(μg/mg) until day 10. Protein from PAN treated HP were analyzed by Western Blot. CYP2B6 was identified to the human kidney by immunohistochemistry and in cultured HP by W-B and RT-PCR.

Results: Exposure of HP to PAN resulted in nuclear translocation of NF-KB, activation of IL-6 and upregulation of CYP2B6. There was marked generation of H_2O_2 associated with significant increase in 8-oxo-2-deoxyguanosine (8-oxo-dG) accompanied by disorganization of actin cytoskeleton. PI, MG-132, significantly increased the expression of Nrf2 and its downstream antioxidant enzyme heme oxygenase-1 (HO-1), blunted the nuclear translocation of NF-KB and activation of IL-6 with no further upregulation of CYP2B6. There was marked reduction in H_2O_2 release and 8-oxo-dG expression with preservation of actin cytoskeleton. Administration of two PI, Carfilzomib(CAR) and MG-132, to rats resulted in marked and significant protection against PAN-induced ACR (Day 4:PAN 75 ±14, MG + PAN 31 ±1, CAR + PAN 36 ±6 ;Day 10:PAN 147 ±13, MG + PAN 97 ±16, CAR + PAN 75 ±9).

Conclusions: These studies indicate a pivotal role of proteasomes in the pathophysiology of MCD most likely through its effects on NF-KB and CYP2B6. Carfilzomib, a novel irreversible PI, is currently used in humans and may be potentially useful for the treatment of glomerular disease.

Targeting mTOR Signaling Can Prevent the Progression of Focal Segmental Glomerulosclerosis Tillmann Bork, Stefan Zschiedrich, Wei Liang, Nicola Wanner, Markus Gödel, Tobias B. Huber. *Dept of Nephrology, Univ Hospital Freiburg, Freiburg, Germany.*

Background: Mammalian Target of Rapamycin (mTOR) signaling is involved in a variety of kidney diseases. Clinical trials administering mTOR inhibitors to patients with focal segmental glomerulosclerosis (FSGS), a prototypic podocyte disease, led to conflicting results ranging from remission to deterioration of kidney function.

Methods: Here we combined complex genetic titration of mTORC1 levels in murine glomerular disease models, pharmacologic studies and human studies to precisely delineate the role of mTOR in FSGS.

Results: mTORC1 target genes were significantly induced in both human FSGS cohorts and murine FSGS models. Mouse models with constitutive mTORC1 activation closely recapitulated human FSGS. Unexpectedly, the complete knockout of mTORC1 by induced deletion of both *Raptor* alleles accelerated the progression of murine FSGS models. However, curtailing mTORC1 signaling by genetically deleting just one *Raptor* allele ameliorated progression of glomerulosclerosis in murine FSGS model. This non-linear mTORC1 gene dosage effect was further substantiated by low dose Rapamycin treatment of murine FSGS models ameliorating disease progression. Mechanistically, complete mTOR inhibition shifted the cellular energy metabolism towards reduced rates of oxidative phosphorylation and anaerobic glycolysis, which was linked to an increased reactive oxygen species production. Moderate mTOR inhibition however preserved mitochondrial function in the presence of FSGS.

Conclusions: Together these data suggest that podocyte injury and loss is initially followed by an adaptive mTOR activation precluding the use of long-term and high dose mTOR inhibition. However as prolonged mTOR activation results in podocyte dedifferentiation and cellular stress with our models we propose incomplete mTOR inhibition as a novel and individualized treatment rationale.

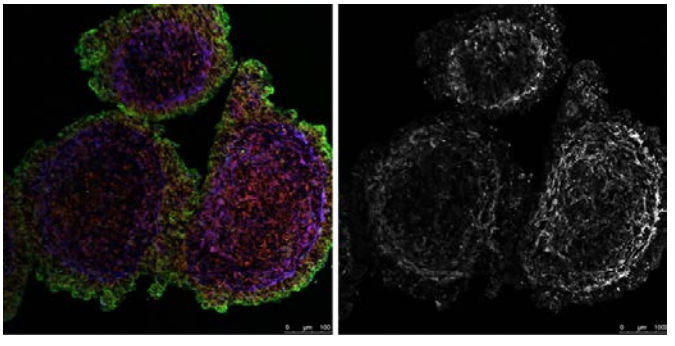
An In Vitro Model of the Glomerulus Jack P. Tuffin,[1] Gavin Iain Welsh,[1] Moin Saleem,[1] Simon C. Satchell.[1] *[1]Bristol Renal, Univ of Bristol, Bristol, United Kingdom; [2]UCB Pharma Ltd, Slough, United Kingdom.*

Background: Our lab has previously developed conditionally immortalised human podocytes and glomerular endothelial cell (GEnC) lines. The purpose of this project has been to develop a 3D in-vitro model of the glomerulus for the purpose of developmental research as well as pharmaceutical-compound screening.

Methods: Cells were cultured using a variety of scaffold culture techniques including a novel gel/scaffold hybrid platform utilizing cocultured, growth factor-treated cells. Magnetic levitation as well as magnetic bioprinting techniques were also used. Cell types were identified using stable GFP/RFP labelling. Cultured tissues were paraffin embedded, sectioned and stained for confocal immunofluorescence microscopy.

Results: Experiments show that 3D cocultured podocytes and GEnCs reorganise in a similar, glomerular-like manner regardless of the culture platform used. Podocytes were seen to wrap around GEnCs, with tube formation identified. Magnetic spheroids were used to manually and rapidly organise cells in this way to form glomerulus sized tissues that express the glomerular basement membrane protein collagen IV in a location concurrent with its in-vitro deposition.



Conclusions: We have developed an in-vitro 3D coculture model of human podocyte and GEnC glomerular cell lines, with self organizing properties, that show early hallmarks of GBM formation.

Akt Pathway Plays a Critical Role in Podocyte Injury and Recovery in Glomerular Disease Tetsuya Kitao,[1,2] Melinda A. Chanley,[1] Kazunari Kaneko,[2] William E. Smoyer,[1,3] Shipra Agrawal.[1] *[1]CCTR, The Research Inst at Nationwide Children's Hospital, Columbus, OH; [2]Pediatrics, Kansai Medical Univ, Osaka, Japan; [3]Pediatrics, The Ohio State Univ, Columbus, OH.*

Background: Tight regulation of mTOR and Akt pathways has recently been reported in the context of chronic kidney disease and in apoptosis control of podocytes. Furthermore, we have previously reported the beneficial roles of glucocorticoids (GCs) and pioglitazone (Pio) in nephrotic syndrome (NS). We hypothesized that Akt pathway downstream of PI3K and/or mTOR plays a critical role in podocyte injury and recovery in NS.

Methods: Phosphorylated and total forms of Akt and Mdm2 were analyzed in the glomeruli or kidney sections of rats and mice injured with single puromycin aminonucleoside (PAN) and Adriamycin (Adr) injections, respectively. In vitro, differentiated immortalized human podocytes were injured with PAN and Adr at various time points and treated with GCs and Pio. Apoptosis was analyzed by TUNEL assay in the presence or absence of Akt activator (SC79) and inhibitor (MK2206).

Results: Akt phosphorylation was inhibited under the mTORC2 (site Ser473) pathway in PAN-treated rat glomeruli which correlated with proteinuria and inhibited under both mTORC2 and the PI3K (site Thr308) pathways in differentiated human podocytes which was restored by GC and Pio treatment. Adr-treated human podocytes also showed decreased Akt phosphorylation at earlier time point while it was activated in the Adr- treated mice cortices at 7 and 21 days. This activation was however attributed to proximal tubule cells and not podocytes as assayed by immuno-fluorescence microscopy. Moreover, while PAN induced apoptosis in cultured differentiated human podocytes and treatment with GCs inhibited apoptosis, activator of Akt at Ser473/Thr408 enhanced the anti-apoptotic effects while the inhibitor at Ser473/Thr408 enhanced apoptosis and reduced the anti-apoptotic effects of GCs.

Conclusions: Akt regulation by both mTORC2 and PI3K pathways is associated with podocyte injury and recovery in glomerular disease and its activation provides beneficial protective effects.

TH-PO248

Glomerular Podocyte to Endothelial Cell Cross-Talk in Kidney Disease Jia Fu,[1] Kyung (Kim) Lee,[1] Stuart J. Shankland,[2] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai, New York; [2]Univ of Washington School of Medicine, Seattle.*

Background: Podocytes and glomerular endothelial cells (GECs) are major components of the glomerular filtration barrier, and cross-talk between these two cell types is critical for maintaining this barrier. Recent studies suggest that podocyte injury leads to the progression of glomerular disease. It is hypothesized that podocyte injury could cause GEC injury through a cross-talk mechanism. Here, we sought to test this hypothesis in vivo using RNA sequencing of GECs in an animal model of podocyte injury.

Methods: We used a transgenic mouse model in which GECs are labeled with yellow-fluorescent protein (YFP) in the nuclei which allowed us to effectively sort GECs by flow cytometry. Podocyte injury was induced by injection of mice with a specific anti-podocyte antibody generated in Dr. Stuart Shankland's laboratory. Mice were sacrificed at day 14 after antibody injection, glomeruli were isolated and YFP-positive GECs were sorted for RNA sequencing. The key pathways were validated by real-time PCR, western blot analysis, and functional assays for apoptosis and ROS production.

Results: Antibody-injected mice developed significant proteinuria, focal glomerulosclerosis, and podocyte depletion. Interestingly, number of GECs was also reduced and appeared detached from glomerular basement membrane. GECs were sorted from these mice and expression of endothelial cell-specific markers was confirmed in the sorted cells. Analysis of the differentially expressed genes (DEGs) in GECs between the diseased and control mice revealed significant alteration of the pathways related to apoptosis, tight-junction, and oxidative stress. Expression of key DEGs was confirmed by real-time PCR and western blot analysis. We validated that apoptosis and production of ROS increased in the GECs of the diseased mice.

Conclusions: Podocyte injury can propagate to GEC injury through a crosstalk mechanism that mediates the progression of glomerular disease.

TH-PO249

Mutant Actinin-4 in the Pathogenesis of Focal Segmental Glomerulosclerosis Albert Yee, Joan Papillon, Julie Guillemette, Daniel Robert Kaufman, Andrey V. Cybulsky. *Medicine, McGill Univ, Montreal, Canada.*

Background: Mutations in actinin-4 are associated with heritable focal segmental sclerosis (FSGS) in humans. Previously, we showed that actinin-4 K256E is a misfolded protein that undergoes aggregation and degradation in cultured glomerular epithelial cells (GECs). There is associated proteotoxicity, i.e. induction of endoplasmic reticulum (ER) stress and "choking" of the proteasome. The present study examined whether small molecules could improve the folding and function of mutant actinin-4, and if autophagy is upregulated by actinin-4 K256E and is responsible for its degradation.

Methods: GFP-tagged actinin-4 wild type (WT) or K256E were expressed in GECs or COS-1 cells by transfection. Interaction of actinin-4 with the cytoskeleton was assessed by detergent-extraction of cells and monitoring actinin-4 by immunoblotting. Autophagy was monitored by immunoblotting of endogenous LC3II or by expression of RFP-LC3 and quantifying formation of LC3II puncta.

Results: After extraction of cells with Triton X-100, actinin-4 WT was found mainly in the Triton-soluble fraction (69.8%); however, K256E was predominantly Triton-insoluble (81.6%), reflecting abnormally tight binding to F-actin. Incubation of cells with the chemical chaperone, 4-phenylbutyrate, decreased the proportion of Triton-insoluble actinin-4 K256E (from 81.6% to 68.6%), but celastrol, a drug that enhances expression of cytosolic and ER chaperones, had no effect. After treatment of cells with chloroquine (to block fusion of autophagosomes with lysosomes), actinin-4 K256E stimulated autophagy, as reflected by a 1.5-fold greater accumulation of endogenous LC3II, compared to WT. Moreover, RFP-LC3II puncta occupied a 45% greater area in cells expressing actinin-4 K256E, compared to WT. Surprisingly, actinin-4 K256E did not colocalize with RFP-LC3II, and was not degraded by autophagy, but rather by the proteasome.

Conclusions: A small molecule chemical chaperone improved the function of actinin-4 K256E. Mutant actinin-4 stimulated autophagy, but this process was not responsible for its degradation. The combination of a chemical chaperone and proteasome inhibitor may become a novel therapeutic approach to actinin-4-mutant associated FSGS.

TH-PO250

CD147/Basigin Deficiency Prevents the Development of Podocyte Injury through the Integrin/FAK Signaling Pathway Tomoki Yoshioka, Tomoki Kosugi, Kayaho Maeda, Tomohiro Masuda, Yuka Sato, Hiroshi Kojima, Noritoshi Kato, Takuji Ishimoto, Shoichi Maruyama. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya-shi, Aichi-ken, Japan.*

Background: CD147/Basigin (Bsg) is a glycosylated transmembrane protein belonging to the immunoglobulin superfamily. Bsg contributes to cell survival, migration, cancer invasion and inflammation. We have so far demonstratedits pathophysiological roles in the kidney diseases, ranging from the occurrence of acute kidney injury accompanied by ischemia and inflammation to progression of renal fibrosis and lupus nephritis. However, little is known in the development of proteinuria. We therefore investigated the role of Bsg in the development of podocyte injury leading to the augmentation of proteinuria, using adriamycin nephropathy mice model.

Methods: Wild-type ($Bsg^{+/+}$)or Bsg-deficient ($Bsg^{-/-}$)mice were injected with adriamycin (16mg/kg BW), and were then sacrificed at 2 weeks later for histological and biochemical analyses. Blood, urine samples and kidney tissues were analyzed. In *in vitro* study, conditionally immortalized human podocyte cell lines were used.

Results: $Bsg^{-/-}$ mice ameliorate the development of proteinuria compared to $Bsg^{+/+}$ mice in adriamycin nephropathy.Marked podocyte injuries and the progression of foot process effacement were observed in $Bsg^{+/+}$ mice. Podocyte rarely expressed Bsg, but began to exhibit Bsg induction upon adriamycin exposure, using in situ hybridization and immnohistochemistry. Furthermore, Bsg expression was observed in immortalized human podocyte cells, and Bsg silencing with siRNA in podocyte cells suppressed the phosphorylation of focal adhesion kinase (FAK) under TGF-β stimulation. Interestingly, Bsg expression in podocyte has the association of integrin. Additionally, Bsg silencing on podocytes after TGF-β stimulation caused the decreases of endothelin-1 and MMP expressions, which are regarded as key molecules in the development of podocyte and glomerular injuries.

Conclusions: Bsg plays an indispensable role in the development of podocyte injury leading to the augmentation of proteinuria through the activation of FAK signaling pathway.

TH-PO251

Podocyte Effacement Precedes Albuminuria and Glomerular Hypertrophy in CD2 Assosicated Protein Deficient Mice John M. Basgen,[1] Susanne B. Nicholas,[2] Jenny Wong,[3] Kirk N. Campbell.[3] *[1]Charles Drew Univ, LA, CA; [2]Univ of California, Los Angeles, Los Angeles, CA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: CD2AP-deficient mice show podocyte foot process effacement, mesangial expansion, massive proteinuria and decreased kidney function by 4 weeks of age eventually resulting in glomerulosclerosis and death. We previously demonstrated crosstalk between podocytes and mesangial cells in this model but it is unclear which cell type was affected first. Here we sought to determine the sequence of early structural podocyte and mesangial changes in $Cd2ap^{-/-}$ mice at 2 weeks of age.

Methods: At age 14 days urine was collected and the mice perfused with fixative. After genotyping five $Cd2ap^{+/+}$ and four $Cd2ap^{-/-}$ mice were available for analysis. Urine albumin and creatinine were measured using appropriate ELISA kits. The albumin/creatinine ratio (ACR) was calculated for each animal and log-transformed for statistical analysis. Glomerular volume was measured by light microscopy using the Cavalieri principle. The volume densities of glomerular components (mesangium, podocyte and capillary) were measured on low magnification electron microscopy images using the Delesse principle. The volume of a component was then calculated by multiplying the volume density of the component by the glomerular volume. Foot process width was measured on high magnification EM images. Five glomeruli were measured per kidney.

Results: There was no difference in ACR between the $Cd2ap^{+/+}$ group (median [range] mg/g): 183 [160-1138] and the $Cd2ap^{-/-}$ group: 242 [176-388]. Foot process width was increased (p-value = .008) in the $Cd2ap^{-/-}$ group (mean [SD] nm): 1128 [286] vs. $Cd2ap^{+/+}$ group: 374 [42]. There was no difference in glomerular volume between $Cd2ap^{+/+}$ (mean [SD] μm^3): 68,307 [10,931] and $Cd2ap^{-/-}$: 66,844 [13,022] or the volumes of the glomerular components.

Conclusions: Podocyte effacement precedes albuminuria and changes in glomerular volume and the volumes of glomerular components in the CD2AP-deficient mouse. These findings suggest that podocyte injury is the initiating event in CD2AP-deficient mice leading to subsequent mesangial volume expansion and disease progression.

Podocyte Vitamin D Receptor Deficit Induces Activation of Renin Angiotensin System via SIRT1 Modulation Nirupama Chandel, Vinod Sharma, Waqaar Khawar, Nairuti H. Shah, Vinita Vishnoi, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: Vitamin D receptor (VDR) deficient status has been shown to be associated with the activation of renin angiotensin system (RAS). However, the involved mechanism is not clear. We hypothesized that lack of VDR would enhance p53 expression in podocytes through down regulation of SIRT1; the former would enhance the transcription of angiotensinogen (Agt) and angiotensinogen type 1 receptor (AT1R) leading to the activation of RAS.

Methods: Renal tissues of 4 week old control and VDR mutant (M, n=4) were analyzed for expression of p53, angiotensinogen (Agt), renin, SIRT1, PPAR--y and AT1R (mRNA and proteins). Human podocytes (HPs) were transfected with either scrambled or VDR siRNAs and evaluated for expression of above mentioned molecules. Renal tissues from VDR(M) and HPs lacking SIRT1 were evaluated for acetylation of p53 and lysine (K) 382 residues.

Results: Renal tissues of VDR mutant (M) mice displayed increased expression of p53, Agt, renin, PPAR-y, and AT1R. *In vitro* studies, VDR knockout podocytes not only displayed up regulation p53 but also displayed enhanced expression of Agt, renin and AT1R. VDR deficient podocytes also displayed an increase in mRNA expression for p53, Agt, renin, and AT1R. Interestingly, renal tissues of VDR-M as well as VDR heterozygous (h) mice displayed attenuated expression of deacetylase SIRT1. Renal tissues of VDR-M mice showed acetylation of p53 at lysine (K) 382 residues inferring that enhanced p53 expression in renal tissues could be the result of ongoing acetylation, a consequence of SIRT1 deficient state. Notably, podocytes lacking SIRT1 not only showed acetylation of p53 at lysine (K) 382 residues but also displayed enhanced p53 expression. Since renal tissues of VDR-M mice also showed enhanced expression of PPAR-y, it is plausible that either the deficit of SIRT1 has de-repressed expression of PPAR-y or enhanced podocyte expression of PPAR-y (in the absence of VDR) has contributed to the down regulation of SIRT1.

Conclusions: VDR deficit activates the RAS via SIRT1 modulation.

Mapping Podocyte Mechanical Force In Vitro Kathryn E. Haley,[1] Nils Michael Kronenberg,[2] David James Harrison,[1] Malte C. Gather,[2] Paul Reynolds.[1] *[1]School of Medicine, Univ of St. Andrews, United Kingdom; [2]SUPA, School of Physics and Astronomy, Univ of St. Andrews, United Kingdom.*

Background: Podocyte damage is a pivotal event underlying the pathogenesis of multiple glomerular diseases. When damaged podocytes lose the ability to adhere to the glomerular basement membrane, they detach, resulting in impaired glomerular filtration. However, the mechanism underlying podocyte detachment remains poorly understood. In this study we sought to characterize the mechanical forces exerted by differentiated podocytes by using a novel force detection assay.

Methods: A human podocyte cell line containing a SV40/hTERT temperature-sensitive transgene was differentiated over the course of 12 days at the non-permissive temperature of 37°C. Differentiated podocytes were treated with 25μg/mL Puromycin Aminonucleoside (PAN) for 24 hours, followed by washout with fresh RPMI for 5 days. Podocyte mechanical forces were assessed with a novel continuous force detection assay, Elastic Resonator Interference Stress Microscopy (ERISM).

Results: Podocytes demonstrated a pulling force at focal points around the cell periphery that co-localized with foot processes. A pushing force was observed under the cell body that was 3 times greater than the force exerted by 3T3 fibroblasts (n=18). PAN treatment resulted in foot process effacement and membrane blebbing as evidenced by scanning electron microscopy, F-actin rearrangement, and a reduction in expression of NPHS1, NPHS2, CD2AP, and SYNPO. PAN treatment resulted in an initial increase in podocyte force transmission by a factor of 1.4, followed by a complete loss of either pushing or pulling force (n=4), despite continued cell attachment. Following PAN washout, partial recovery of force transmission of up to 60% of the initial value was observed.

Conclusions: Herein we present a novel biological application of the ERISM force detection assay. Our results indicate that, in a PAN model of glomerular injury, loss of podocyte mechanical force transmission is partially reversible. These results highlight podocyte mechanical force transmission as an integral feature of healthy podocytes, and suggest that changes in mechanical force play a pivotal role in the development of podocytopenia.

TH-PO254

Functional Interaction of USP40 with Nestin in Podocyte Shohei Takahashi, Yukino Nishibori, Kunimasa Yan. *Pediatrics, Kyorin Univ School of Medicine, MKtaka, Tokyo, Japan.*

Background: We previously showed that gene knockdown of ubiquitin specific protease-40 (USP40) leads to disorganized glomerulus in zebrafish morphants. Nestin is currently speculated to be a protective molecule against podocyte injury. The aim of the present study was to explore a functional role of USP40 in the acquired podocyte disease.

Methods: USP40 KO mice were generated and assessed for the kidney morphology and urinary abnormality. The isolated glomeruli from 3 KO mice and 3 wild type mice were analyzed to integrate the data of proteomic analysis. Cultured mouse podocytes were subjected to dual-labeling immunofluorescence, immunoprecipitaion and gene knockdown experiments to determine a functional relationship between USP40 and nestin. Glomeruli and kidney sections from adriamycin nephropathy and control mice were analyzed to compare protein expression of USP40 and nestin in podocytes.

Results: KO mice did not reveal pathological proteinuria and apparent alterations in kidney morphology. However, proteomic analysis revealed a predominant increase of nestin in KO mice compared to wild type. In the cultured podocytes, apparent protein binding and colocalization between USP40 and nestin were determined. Gene knockdown of USP40 revealed significant decrease of nestin in cultured podocytes. Finally, colocalization between USP40 and nestin was also apparent in the glomerular podocytes in the control mice. In the podocytes of adriamycin nephrosis, the expression of both USP40 and nestin were reduced in the sclerotic region whereas those were predominantly increased in the hypertrophic region.

Conclusions: Our findings collectively show that USP40 is a novel ligand protein for nestin and suggest that their interaction may be involved in the pathophysiology of the acquired podocyte disease. Absence of phenotypic change of USP40 KO mice suggests the possible presence of the compensatory mechanism for nestin protein turnover in podocytes.

Mechanism of TIMAP Action: Competition with MYPT1 for the PP1c Catalytic Subunit Xin Wang,[2] Laiji Li,[1] Barbara J. Ballermann.[1] *[1]Medicine, Univ of Alberta, Edmonton, AB, Canada; [2]Nephrology, The First Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, China.*

Background: Actomyosin activation by phosphorylated myosin-light chain 2 (MLC2) increases endothelial permeability in glomeruli and other capillaries, and myosin phosphatase inhibition maintains MLC2 phosphorylation (pMLC2). Myosin phosphatase consists of regulatory (MYPT1) and catalytic protein phosphatase I (PP1c) subunits, and is inhibited by Rho-kinase-dependent phosphorylation of MYPT1. TIMAP is an endothelial cell (EC)-predominant member of the MYPT family. Surprisingly, overexpression of TIMAP increases pMLC2 in glomerular EC by inhibiting myosin phosphatase activity without activating Rho or MYPT1 phosphorylation. We investigated how TIMAP inhibits MYPT1/PP1c action in EC.

Methods: Western blots (WB) with densitometric quantification were performed on lung (rich in EC) lysates from wild-type and TIMAP deficient mice, and cultured human glomerular EC lysates. Glomerular EC were transduced with Adenoviruses (Ad) expressing GFP (Ad-GFP), GFP-TIMAP (Ad-GFP-TIMAP^{WT}) or the PP1c binding mutant Ad-GFP-TIMAP^{PP1-}. PP1c was specifically precipitated with microcystin sepharose.

Results: Similar to our findings of increased pMLC2 in glomerular EC overexpressing TIMAP^{WT}, the pMLC2:Actin ratio was higher in lung lysates of WT than TIMAP deficient mice (0.56 ± 0.19 *vs.* 0.32 ± 0.07, mean ± SD, n=4, *P*=0.019). The MYPT1:Actin ratio was 57 ± 23% (mean ± SD, n=3, *P*=0.026) lower in glomerular EC expressing GFP-TIMAP^{WT} vs. GFP. GFP-TIMAP^{PP1-}, which cannot bind PP1c, had no discernable effect on pMLC2 or MYPT1 abundance. Microcystin co-precipitated PP1c and MYPT1, but not TIMAP, from EC expressing GFP or GFP-TIMAP^{PP1-}, but co-precipitated only PP1c and TIMAP, and not MYPT1 from EC expressing GFP-TIMAP^{WT}, even when equivalent MYPT1 was loaded.

Conclusions: The data indicate that TIMAP competes for PP1c with MYPT1, implying that PP1c regulatory subunits like MYPT1 and TIMAP exist in excess over their catalytic subunits in EC, and that TIMAP inhibits, while MYPT1 potentiates PP1c activity towards pMLC2. Also, expression of TIMAP^{WT}reduces the MYPT1 abundance in EC. Hence, pMLC2-dependent EC permeability may be controlled in a Ying-Yang fashion by TIMAP and MYPT1.

Loss of Nonmuscle Myosin II in Postnatal Mouse Renal Tubules Results in Chronic Kidney Disease Indra Chandrasekar,[1] Karla L. Otterpohl,[1] Ryan G. Hart,[1] Kameswaran Surendran,[1] Bruce A. Molitoris.[2] *[1]Sanford Children's Health Research Center, Sanford Research, Sioux Falls, SD; [2]Dept of Medicine, Indiana Univ, Indianapolis, IN.*

Background: Nonmuscle myosin II (M2) is an actin associated motor protein that contributes to the cellular processes of migration, adhesion, and division and is essential for brain and heart development. Our recent work demonstrated that MII function (isoforms M2A and M2B) is critical for both compensatory and constitutive receptor mediated endocytosis. Previous studies have shown that point mutations in the M2A gene, *MYH9*, are associated with human diseases involving blood, eye, ear and kidney disorders. Additionally, two genome wide association studies have identified *MYH9* as a major locus for susceptibility to end-stage renal disease.

Methods: We hypothesized that the underlying mechanism in M2 related kidney disorders is compromised renal tubular endocytosis resulting in decreased protein reabsorption. We inactivated one or both M2 genes, *Myh9* and *Myh10*, within the postnatal renal tubules using the doxycycline inducible Pax8->rtTA; Tet-O-Cre system. Doxycycline was administered in the drinking water to mice at 1 month of age to inactivate the Myh9 and Myh10 genes.

Results: Urine analysis revealed proteinuria as early as two months after starting doxycycline. Histological evaluation of kidney from single MII gene knock-out revealed mild tubular dilation and inflammation younger mice, that progressed to glomerular sclerosis, loss of cytosolic staining in the proximal tubules and the presence of polymorphonuclear leukocytes and macrophages. Interestingly, knockout of both *Myh9* and Myh10 in the postnatal tubules results in dysplastic kidney disease within two months of starting doxycycline treatment.

Conclusions: Our data support the hypothesis that postnatal loss of M2 in renal tubules results in tubular dysfunction and progresses to chronic kidney disease.

mPGES-1-Derived PGE2 Stimulates Stat3 to Promote Podocyte Injury Jing Yu,[2] Zhanjun Jia,[2] Wei Gong,[2] Shuzhen Li,[2] Yue Zhang,[1] Guixia Ding,[1] Aihua Zhang,[1] Songming Huang.[1] *[1]Dept of Nephrology, Nanjing Children's Hospital affiliated to Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Lab of Pediatrics, Nanjing, China.*

Background: We previously reported that microsomal prostaglandin E synthase-1 (mPGES-1) contributed to Adriamycin (Adr)-induced podocyte injury (Yu et al. AJP-renal, 2015). However, the molecular mechanisms mediating mPGES-1 effect on inducing podocyte damage is still unknown. Here to performed experiments to test the role of mPGES-1/PGE2 cascade in activating Stat3 and its contribution in PGE2- and Adr-induced podocyte injury.

Methods: PGE2 and Adr were administered to the podocytes to induce podocyte injury. Specific Stat3 inhibitor and mPGES-1 siRNA were used to determine the roles of Stat3 and mPGES-1-derived PGE2 in this pathological process.

Results: By administration of PGE2 to podocytes, we observed a dose- and time-dependent upregulation of p-Stat3 (>3folds), indicating an activation of Stat3, in line with the significant podocyte injury as evidenced by the remarkable cell apoptosis and the reduction of nephrin expression. Consistently, Stat3-drived cytokines like IL-6, IL-17, and MCP-1 were enhanced by 2-4 folds ($p<0.05$) by PGE2 treatment. By inhibiting Stat3 with a specific Stat3 inhibitor S3I-201, PGE2-induced podocyte apoptosis was blocked by 51% ($p<0.05$) in parallel with attenuated nephrin downregulation by 55% ($p<0.05$). Then the podocytes were further subjected to the Adr treatment. As expected, Adr remarkably elevated p-Stat3 levels by more than 3-folds after 6 h treatment in line with the stimulation of mPGES-1/PGE2 cascade. Blockade of Stat3 by S3I-201 significantly ameliorated Adr-induced cell apoptosis by 60% and nephrin reduction by 45%. More interestingly, silencing mPGES-1 in podocytes by mPGES-1 siRNA almost abolished Adr-induced increments of Stat-3 phosphorylation, PGE2 production, and Sta3-drived inflammatory cytokines.

Conclusions: The current study highly suggested that mPGES-1-derived PGE2 could activate Stat3 signaling to promote podocyte injury. Targeting mPGES-1/PGE2/Stat3 signaling might be a potential strategy for the treatment and prevention of podocytopathy.

Tracking the Fate of Single Glomerular Endothelial Cells with Serial Multiphoton Imaging in a New Cdh5-Confetti Mouse In Vivo Dorinne Desposito, Anne Riquier-Brison, Janos Peti-Peterdi. *Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.*

Background: Endothelial cells are critical in the maintenance of a healthy glomerular filter and in the development of glomerular disease. However, the origin, proliferation, migration and regeneration of glomerular endothelial cells have been difficult to study in vivo. We aimed to develop a direct visual approach to track the fate of single endothelial cells over several days-weeks in the same glomerulus in vivo.

Methods: Endothelial cell-specific confetti mice featuring tamoxifen-inducible expression of 4 different fluorescent proteins (CFP/GFP/YFP/RFP) were developed by crossing Cdh5 (VE-cadherin) CreERT2 and floxed confetti reporter mice. Cdh5-Confetti mice (3 to 5 weeks of age) were subjected to implantation of a dorsal abdominal imaging window, which allowed non-invasive multiphoton microscopy (MPM) of the same kidney volume in vivo on a daily basis. To induce kidney injury, the streptozotocin (STZ) model of diabetes and L-NAME treatment, or unilateral ureteral ligation (UUO) were applied.

Results: MPM imaging of Cdh5-Confetti mice revealed strong expression of all confetti FPs (colors) at baseline. Individual glomerular endothelial cells were clearly identifiable based on their unique color, with random distribution of all four colors. High resolution MPM imaging observed thickened cytoplasmic ridges of endothelial cells that appeared as primary and secondary cell processes. Endothelial injury by STZ+L-NAME triggered rapid cellular remodeling of the glomerular endothelium judged by the changing confetti colors. Within four days of injury, multi-cellular endothelial cell tracing units developed in the same color suggesting that the newly formed cells were daughter cells of the same parent endothelial cell. Entirely monochromatic glomeruli developed. In UUO mice, multi-color afferent arterioles were seen transitioning into monochromatic glomeruli, suggesting rapid proliferation of single endothelial precursor cells within glomeruli.

Conclusions: In summary, glomerular endothelial cells show highly dynamic and robust proliferation/migration after injury, which may be consistent with glomerular and vascular regeneration.

TH-PO259

The Role of FcRn in the Expression of MHC II and Trafficking of Antibody-Antigen Complexes to Lysosomes in Glomerular Endothelial Cells James Francis Dylewski, Evgenia Dobrinskikh, Linda Lewis, Judith Blaine. *Dept of Medicine, Div of Renal Disease and Hypertension, Univ of Colorado, Aurora, CO.*

Background: Glomerulonephritis (GN) has been shown to occur via activation of CD4+ T cells by intrinsic renal cells expressing MHC II. Glomerular endothelial cells can express MHC II but it is unclear if they are able to process antigen for presentation. Neonatal Fc receptor (FcRn) is a trafficking protein that is required for antigen processing & presentation in dendritic cells. Renal endothelial cells are known to express FcRn and it has been demonstrated that when FcRn is knocked out of the kidneys, GN is prevented. We believe that glomerular endothelial cells can traffic antibody-antigen complexes utilizing FcRn for presentation on MHC II. Furthermore, we hypothesize that if FcRn is absent, antibody-antigen complex trafficking & antigen presentation via MHC II is altered.

Methods: We first isolated & purified glomerular endothelial cells (GECs) from wild type (WT) & FcRn knockout (KO) mice by isolating glomeruli. We then grew the cells and used von Willebrand factor coated dynabeads to isolate endothelial cells. The cells were then characterized using IF for vWF & a podocyte specific marker (WT1) to check for podocyte contamination. After characterization, WT and KO GECs were treated with INFγ. Flow cytometry was used to evaluate the expression of MHC II. To study antigen-antibody trafficking, we treated both WT & KO cells with antigen-antibody complexes, then used IF to identify co-localization of lysosomes with antibodies.

Results: We demonstrated that endothelial cells isolated from both WT & KO mice can express MHC II when treated with INFγ but the percentage of cells that express MHC II in the KO cells was significantly less than that in WT cells. We also discovered that WT cells had a higher rate of co-localization of antibody-antigen complexes with lysosomes than in the KO cells suggesting that FcRn directs lysosomal trafficking of immune complexes in glomerular endothelial cells.

Conclusions: These findings suggest that FcRn is needed to optimize the expression of MHC II as well as facilitate trafficking of antigen-antibodies to lysosomes.

C14orf142 Is the 5th Member of the Highly Conserved KEOPS Complex and Is Mutated in Galloway-Mowat Syndrome (GMS)

Geraldine Mollet,[1] Bruno Collinet,[2] Christelle Arrondel,[1] Olivier Gribouval,[1] Olivia Boyer,[1] Patrick Revy,[1] Daniella Magen,[3] Daniela A. Braun,[4] Friedhelm Hildebrandt,[4] Herman Van Tilbeurgh,[2] Corinne Antignac.[1] *[1]Inserm U1163, Imagine Inst, Paris Descartes Univ, Paris, France; [2]Inst de Biologie Intégrative de la Cellule, CNRS, Univ Paris Sud, Orsay, France; [3]Pediatric Nephrology Inst, Rambam Health Care Campus, Technion Faculty of Medicine, Haifa, Israel; [4]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston.*

Background: The evolutionarily conserved KEOPS complex is composed of at least 4 subunits (LAGE3, OSGEP, TP53RK and TPRKB), Gon7 being the 5th subunit in yeast. In model organisms, KEOPS was shown to catalyze an essential tRNA modification, and in yeast it plays a role in transcription and telomere maintenance. However, KEOPS function in humans is unknown. We have recently identified mutations in all four members of KEOPS in patients with GMS associating nephrotic syndrome with microcephaly and neurological impairment.

Methods: To identify new genes involved in GSM and characterize new potential partners of the KEOPS complex, we performed exome sequencing, proteomic and coIP/co-purification experiments. To assess one of the known functions of KEOPS, we performed Telomere Restriction Fragment analysis and Telomere dysfunction-Induced Foci.

Results: We identified 2 homozygous truncating mutations in the *C14orf142* (C14) gene in 5 families with GMS and showed that the C14 protein, which is predicted to be largely unstructured and of similar size as Gon7, strongly interacts with LAGE3. We further demonstrated that his-tagged C14 co-purified with all KEOPS members when over-expressed in bacteria and that this complex is stable during gel filtration purification. We did not find any telomere length modifications or telomere dysfunction suggesting that telomere maintenance is not the primary function of KEOPS in humans.

Conclusions: Here, we identified C14 as being the 5th element of the human KEOPS complex binding to the LAGE3 subunit, in a similar way as does Gon7 in yeast. The role of C14 within the KEOPS complex and the role of this complex in the pathogenesis of GMS remain unclear.

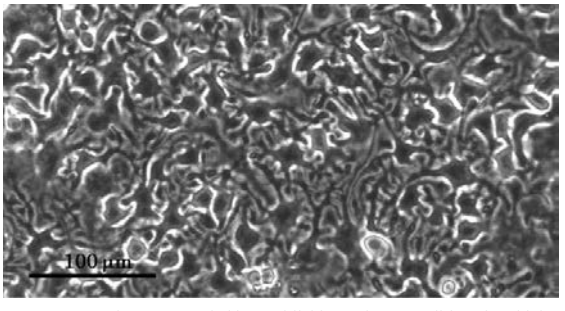
Induction of Interdigitating Cell Processes in Cultured Podocytes

Eishin Yaoita, Yutaka Yoshida, Hiroki Takimoto. *Dept of Structural Pathology, Kidney Research Center, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Interdigitating cell processes characterize glomerular podocytes in vivo. However, podocytes in primary culture and in cell lines have a simple morphology lacking cell processes, especially upon reaching confluence. Some culture conditions have been reported to upregulate podocyte-specific gene expressions, but no reports have succeeded in inducing morphology close to that of in vivo conditions. In this study, we tried to establish culture conditions under which cultured cells spread cell processes at confluence.

Methods: Rat primary cultured podocytes were used to investigate the effects of cell density, low concentrations of fetal bovine serum (FBS), heparin, retinoic acid (RA), and extracellular matrices (collagen type I, fibronectin and laminin) on their morphology.

Results: Cell processes were extensively induced when cells were seeded at a cell density equivalent to in vivo and cultured in the presence of heparin and RA on laminin-coated dishes, and in decreasing concentration of FBS as shown in the phase-contrast micrograph figure. Cell seeding density and decreasing FBS concentrations were critical to interdigitating cell process formation. Without laminin coating, heparin or RA, cell processes were formed, although limited to a small area. Like primary processes in vivo, the processes contained vimentin filaments, occasionally overlapping each other, and stretched under adjacent cell bodies. Intercellular junctions as shown by staining for podocin, nephrin or ZO-1 were located between the cell processes and under cell bodies as elaborate squiggles, where actin filaments accumulated, suggesting primitive foot processes. Local formation of slit diaphragms was demonstrated by electron microscopy.



Conclusions: We have succeeded in establishing culture conditions in which cultured cell phenotypes are closer to those in vivo.

TH-PO262

A Small Molecule Screening to Detect Potential Therapeutic Targets in Human Podocytes

Weizhen Tan,[1] Eugen Widmeier,[1,2] Merlin Airik,[1] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Dept of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Medicine, Univ of Freiburg Medical Center, Freiburg, Germany.*

Background: Steroid resistant nephrotic syndrome (SRNS) inevitably progresses to end-stage kidney disease, requiring dialysis or transplantation for survival. However, treatment modalities and drug discovery remain limited. Mutations in over 30 genes have been discovered as monogenic causes of SRNS. Most of these genes are predominantly expressed in the podocyte, placing it at the center of the pathogenesis of SRNS. Podocyte migration rate (PMR) represents a relevant intermediate phenotype of disease in monogenic causes of SRNS (Gee 2013; Ashraf 2013; and Gee 2014). We therefore adapted PMR in a high-throughput manner to screen small molecules as potential therapeutic targets for SRNS.

Methods: We performed a high-throughput drug screening of an NIH Clinical Collection (NCC) library (n=725 compounds) measuring PMR by video-microscopy. We used the Woundmaker™ to perform individual 96-well scratch wounds and screened compounds using a quantitative kinetic live cell imaging migration assay using IncuCyte ZOOM® technology.

Results: Using a normal distribution for the average PMR in wild type podocytes with a vehicle control (DMSO), we applied a 90% confidence interval to define "outliers" (5% faster/slower PMR) and found that 12 of 725 compounds (at 10 μM) reduced PMR. Clusters of drugs that alter PMR included actin/tubulin modulators such as the azole class of antifungals and anti-neoplastic vinca-alkaloids.

Conclusions: We hereby identify compounds that alter PMR. The PMR assay provides a new avenue to test therapeutics for nephrotic syndrome. Positive results may reveal novel pathways in the study of glomerular diseases such as SRNS.

The Donnai-Barrow Syndrome, Megalin Deficiency: A New Context

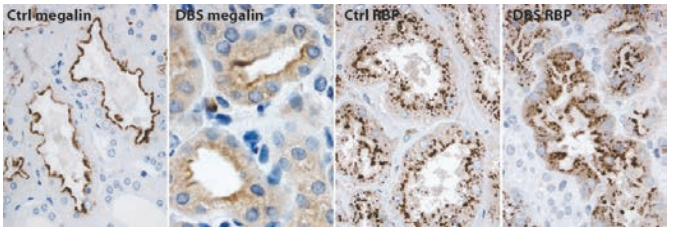
Weizhen Tan,[1] Ghaleb H. Daouk,[1] Lisa Teot,[2] Seymour Rosen,[2,3] Erik I. Christensen,[4] Rikke Nielsen.[4] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Dept of Pathology, Boston Children's Hospital, Boston, MA; [3]Dept of Pathology, Beth Israel Deaconess Medical Center, Boston, MA; [4]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: Donnai-Barrow syndrome (DBS) is caused by deficiency of the endocytic receptor megalin and is characterized by low-molecular weight proteinuria, craniofacial, CNS, and ocular abnormalities. Herein we present a family with DBS who harbor a missense mutation in the megalin encoding gene, *LRP2*, and whose protein reabsorptive capacity has largely continued.

Methods: In a consanguineous Arabic family, a homozygous mutation (p.Y2522H) in exon 41 of *LRP2* was detected in two sisters who have the phenotype of the DBS: hypertelorism, broadened forehead, enlarged globes, high degree of myopia, bilateral sensorineural hearing loss and developmental delay. Both demonstrate proteinuria with urine protein to creatinine ratios from 1.8-3 mg/mg and high levels of β2-microglobulin. The mutation segregates completely with affected status.

Results: The immunohistochemical findings in both sisters were similar. The brush border megalin staining was largely reduced, while its functional conjoiner cubilin was maintained. The "normal" tubular content of albumin, α-1 microglobulin (megalin/cubilin ligands) and retinol binding protein (megalin ligand) was present in the proximal tubule, implying appropriate binding with endocytotic receptors (Fig. 1).

Conclusions: The missense mutation may allow for continued endocytic function of the largely intact protein; but to some extent has lost its immunohistochemically recognized epitope(s). The case is complicated by the fact that both sisters have an immune complex glomerulonephritis, which in one could be categorized as IgA nephropathy, a finding which may have broader implications (Kiryluk JASN epub, May 17, 2016).



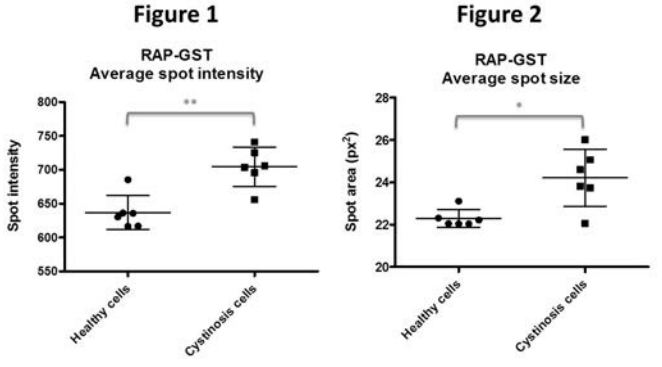
TH-PO264

High Throughput In Vitro Drug Screening Assay for Proximal Tubule Cell Function in Cystinosis Manoe J. Janssen,[1] Nienke Van Andel,[1] Martijn J. Wilmer,[2] Elena N. Levtchenko,[3] Rosalinde Masereeuw.[1] *[1]Pharmacology, UIPS, Netherlands; [2]Pharmacology-Toxicology, Radboudumc, Netherlands; [3]Pediatric Nephrology & Growth and Regeneration, KU Leuven, Belgium.*

Background: Cystinosis is a lysosomal storage disorder caused by mutations in cystinosin (*CTNS*). Patients develop renal Fanconi syndrome at 6 months and kidney failure before the age of ten. Here we developed a high-throughput *in vitro* assay to evaluate proximal tubular cell function for identification of potential drugs.

Methods: Receptor-mediated endocytosis was determined in conditionally immortalised proximal tubular cells (ciPTEC) from cystinotic patients and healthy controls by uptake of receptor associated protein (RAP-GST). RAP-GST uptake and transport to early endosomes (EEA1 staining) and late endosomes/lysosomes (LAMP1 staining) was quantified using a CV7000 high-content confocal imager. Cell viability was determined by PrestoBlue conversion.

Results: RAP-GST was efficiently taken up by ciPTEC in a vesicular pattern co-localizing with endosomes and lysosomes. After 1 hr incubation RAP-GST staining was significantly increased in cystinotic cells (28% ±10, $p<0.03$) and vesicles were prone to forming larger clusters (Figure 1, $p<0.02$) with higher intensity (Figure 2, $p<0.003$). This suggest a delay in protein degradation rather than protein uptake in cystinotic cells. Next, we determined the toxicity of two potential drug candidates selected after Prestwick library screening and found that the TC50 values after 7 days exposure were 49±2 and 54±3 µM ($R^2>0.99$). Pathological cystine accumulation is reduced at 10 µM, suggesting that the compounds will be non-toxic in the pharmacological range in cystinotic patients.



Conclusions: Our assay provides insight into lysosomal patterning and protein degradation in proximal tubule cells and can be used as a functional readout to identify drug compounds that may improve kidney function in cystinosis.

Funding: Government Support - Non-U.S.

TH-PO265

Determination of Plasma 2,8-Dihydroxyadenine with Ultra-Performance Liquid Chromatography-Mass Spectrometry (UPLC-MS/MS) Vidar O. Edvardsson,[1,2] Unnur A. Thorsteinsdottir,[2,3] Hrafnhildur L. Runolfsdottir,[1,2] Inger M. Agustsdottir,[1] Finnur Freyr Eiriksson,[3] Margret Thorsteinsdottir,[2,3] Runolfur Palsson.[1,2] *[1]Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland; [2]Univ of Iceland, Reykjavik, Iceland; [3]ArcticMass, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase deficiency (APRTd) is a hereditary disorder of purine metabolism characterized by excessive urinary 2,8-dihydroxyadenine (DHA) excretion, causing nephrolithiasis and crystal nephropathy. Allopurinol treatment reduces DHA production and ameliorates renal manifestations in affected individuals. We have recently developed a UPLC- MS/MS method for quantification of urinary DHA for diagnosis of the disorder and therapeutic monitoring. The objective was to modify this method for determination of DHA in plasma.

Methods: A UPLC- MS/MS plasma DHA assay was optimized utilizing chemometric approach. Experimental screening was conducted using D-optimal design in both negative and positive ionization mode. Optimization of the DHA response was performed by applying central composite face design, including 3 quantitative variables, and related to peak area of DHA utilizing partial least square regression. Protein precipitation (PPT) plate was used for clean-up of plasma samples from 2 patients with APRTd and one healthy subject. Following PPT, the plasma samples were evaporated and redissolved in 10 mM NH_4OH prior to analysis. Plasma specimen from a healthy control spiked with 1000 ng/mL of the DHA standard was included in the measurements for relative quantification.

Results: DHA was detected in plasma samples from the 2 APRTd patients and in the spiked control sample, but not in a plasma sample from the healthy control. The DHA signal intensity observed in the 2 patient samples indicated a concentration of 786 and 371 ng/mL, respectively.

Conclusions: For the first time, DHA was detected in plasma samples from patients with APRTd. This new assay may enhance the diagnosis and monitoring of pharmacotherapy in APRTd, particularly in patients with kidney failure.

2,4-Dihydroxybenzoic Acid Improves Survival and Demonstrates Reno-Protective Effect in a Podocyte-Specific Coq6-Knockout Mouse Model of Nephrotic Syndrome Eugen Widmeier,[1,2] Merlin Airik,[1] David Schapiro,[1] Hadas Ityel,[1] Rannar Airik,[3] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Medicine, Univ of Freiburg Medical Center, Freiburg, Germany; [3]Div of Nephrology, Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Steroid resistant nephrotic syndrome (SRNS) inevitably progresses to end-stage renal disease. Human mutations in the *COQ6* gene cause SRNS (Heeringa *JCI* 121:2013, 2011). To study the function of *COQ6* in podocytes we generated a podocyte-specific *Coq6*-knockout mouse model.

Methods: *Nphs2.Cre* mice were crossed with $Coq6^{lox/lox}$ mice, to generate podocyte specific *Coq6*-knockout mice ($Coq6^{\Delta Podocyte}$) on a C57BL/6 background. Treatment with 2,4-dihydroxybenzoic acid (2,4-diHB) at a 25 mM concentration in the drinking water was started at 5 months. Kidneys were harvested for histological and ultrastructural analysis at 10 months, and urine was collected monthly for metabolic studies.

Results: $Coq6^{\Delta Podocyte}$ mice displayed an onset of proteinuria at 4 months. Non-treated $Coq6^{\Delta Podocyte}$ mice displayed a significant reduction in survival, with all mice being moribund at 10 months of age (n=5). In contrast, $Coq6^{\Delta Podocyte}$ mice treated with 2,4-diHB (n=5) showed significantly improved survival, comparable to their untreated $Coq6^{\Delta Podocyte}$ and wild type littermates. Histological analysis of $Coq6^{\Delta Podocyte}$ kidneys at 10 months demonstrated severe global and focal segmental glomerular sclerosis (FSGS) with extensive interstitial fibrosis and tubular atrophy. Electron microscopy studies revealed severe foot process effacement and disturbed podocyte cell morphology. In contrast, treatment of $Coq6^{\Delta Podocyte}$ mice with 2,4-diHB significantly reduced the levels of urinary protein and prevented the development of FSGS as well as foot process effacement in all treated mice (n=5).

Conclusions: Our data demonstrate that 2,4-diHB, an intermediary metabolite of the CoQ10 biosynthesis pathway efficiently ameliorates proteinuria and prevents FSGS in $Coq6^{\Delta Podocyte}$ mice. Further, our study reveals a potential novel treatment strategy for human SRNS caused by dysfunction in the CoQ10 biosynthesis pathway.

A Genetically Defined RhoA-Regulating Protein Module Elucidates Effects of Steroid Treatment in Steroid-Dependent Nephrotic Syndrome Friedhelm Hildebrandt, Jia Rao, Jennifer A. Lawson, Weizhen Tan, Eugen Widmeier, Svjetlana Lovric, Jillian Kateri Warejko, Daniela A. Braun, Shazia Ashraf. *Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA.*

Background: Nephrotic syndrome (NS) is categorized into steroid sensitive (SSNS) and steroid resistant forms (SRNS). For SRNS no efficient treatment exists. And mechanisms of steroid action in SSNS are still unknown. We recently identified multiple novel recessive genes as causing NS if mutated: *MAGI2, TENC1, DLC1, CDK20,* and *ITSN1*. We showed that DLC1 molecularly interacts with TENC1 and CDK20. Interestingly, the affected individuals had steroid-dependent nephrotic syndrome (SDNS).

Methods: Because the individuals with mutations in these genes shared the clinical phenotype of SDNS, and because DLC1 is a known GTPase activating protein of RhoA/Rac1/Cdc42, and ITSN1 is a known GTPase exchange factor of the same, we hypothesized that the pathogenesis of mutations in these genes involves steroid-dependent dysregulation of RhoA/Rac1/Cdc42 activation. We performed a G-LISA assay to quantitate the active components of RhoA/Rac1/Cdc42 in a HEK293Ts, following knockdown (kd) *versus* overexpression (oe) of *MAGI2, TENC1, DLC1,* or *CDK20.*

Results: No effects were observed for the active Rac1 and Cdc42. However, we found that kd of *DLC1* increased active RhoA, while oe of *DLC1* decreased active RhoA. Kd and oe of the *DLC1* interaction partners *MAGI2*, *TENC1* and *CDK20* behaved opposite to the effects of *DLC1*, revealing a RhoA regulatory cluster of interacting proteins in HEK293Ts. We then demonstrated that steroid treatment with dexamethasone at >50 uM abolished the effects on RhoA activation by kd or oe of *TENC1, DLC1,* or *CDK20.* This indicates that the beneficial effect of steroids in patients with SDNS and mutations in these genes is likely mediated by the RhoA-regulating module *MAGI2, TENC1, DLC1,* and *CDK20.* We are seeking the direct target of steroid action, which is likely part of this genetically defined RhoA regulating module.

Conclusions: Our findings for the first time may elucidate cell autonomous podocytic mechanisms of treatment response in SDNS, and may make specific genetic variants of NS amenable to treatment.

Mutation in Human Class II α-Isoform of Phosphatidylinositol 3-Kinase Cause a Syndrome with Kidney, Bone and Retinal Involvement

Markus Schueler,[1] Karl Knaup,[1] Parisa Westergerling,[1] David R. Powell,[2] Johanna Stoeckert,[1] Kai-Uwe Eckardt,[1] Michael Sean Wiesener.[1] *[1]Dept of Nephrology and Hypertension, Friedrich-Alexander Univ of Erlangen-Nuernberg, Erlangen, Germany; [2]Lexicon Pharmaceuticals, Inc, TX.*

Background: Phosphatidylinositol 3-kinases (PI3Ks) are lipid kinases involved in a large set of biological processes, including membrane receptor signaling, cytoskeletal organization, and endocytic trafficking. PI3KC2A has been proposed to play an important role in endothelial cells, where it promotes endosomal trafficking and regulation of PtdIns3P levels. Whole exome sequencing (WES) provides a novel means of establishing an etiologic diagnosis. By revealing the causative monogenic mutation, it thereby contributes to our knowledge of the gene function, biological mechanisms and pathways, and will provide important knowledge about disease mechanisms the underlying pathophysiology.

Methods: In one affected child of consanguineous parents we performed WES to identify the underlying single-gene disease-causing mutation. We then harvested fibroblasts from skin biopsies of the affected individual and healthy control for performing immunofluorescence and immunoblotting studies.

Results: Through WES we detected a homozygous obligatory splice site mutation (c.1640+1 G>T) in the gene *PIK3C2A* (phosphatidylinositol-4-phosphate 3-kinase catalytic subunit type 2 alpha) in the affected individual. The mutation segregated with the affected status in this family and was absent from healthy controls. The affected individual showed right kidney agenesis and a complex tubulopathy, retinal degeneration with severe and progressive visual impairment,skeletal dysplasia, dental anomalies, brachydactyly and disproportionate short stature. By immunofluorescence studies we demonstrate that *PIK3C2A* localizes in endosomes, the trans-Golgi network and clathrin-coated vesicles, whereas the mutation of PIK2C2A lacks this. By immunoblotting we show that the mutation alters the phosphorylation status of GSK3beta, a major player of Wnt signaling.

Conclusions: We show that in humans *PIK3C2A* is critically involved in development and function of the kidney, bone and retina.

Variant-Prioritization Coupled with Ontology-Based Algorithm Identified Disease-Causing Mutation in a Family with Atypical Hemolytic Uremic Syndrome

Masafumi Tsuchida, Shin Goto, Hirofumi Watanabe, Ryohei Kaseda, Suguru Yamamoto, Yoshikatsu Kaneko, Ichiei Narita. *Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare form of thrombotic microangiopathy. Recently, personal genome sequence analysis identified numerous disease-causing variants in aHUS, mainly in complement-related genes. However, variant-prioritization tools are needed to effectively discriminate true causative variants from a number of non-related variants, especially in a small family. To dissect causative genes in a family with aHUS, we applied prioritization strategies (pedigree VAAST) coupled with an ontology-based algorithm (Phevor) to whole exome sequence analysis.

Methods: We carried out an exome sequence analysis of a Japanese multiplex family composed of three patients diagnosed with aHUS in infancy, clustered in a dominant transmission mode. Variants identified by exome sequencing were prioritized by pVAAST, which combines variant frequency data, mutation severity, and conservation into a single score with linkage analysis, that is compared genome wide. Then, the prioritized gene ranking were re-ranked by Phevor, based on the phenotype information in the biomedical ontologies.

Results: Exome sequencing in this family detected a total of 83 heterozygous and non-synonymous variants shared only by the affected individuals. Filtering against several variant databases, we identified 20 variants, which have been reported in allele frequencies of less than 1%. To determeine which of the shared variants were most likely causative, pVAAST was carried out and 18662 genes were ranked according to the scores. Then, Phevor re-ranked the genes, and *C3* (p.W1034R) was selected as a top candidate gene with Phevor score of 7.4. p.W1034R in *C3* have been reported in aHUS patients (Blood 2015;125:2359), and predicted to have substantial effect on the protein C3d structure or function.

Conclusions: We identified *C3* mutation in a family with aHUS using prioritization and ontology-based algorithm. Functional analyses of the mutation in C3d domain are in progress to uncover the role in the pathogenesis of aHUS.

TH-PO270

A Recessive ETV4 Mutation Causes Urinary Tract Malformation via Abrogation of its DNA Binding Affinity

Amelie van der Ven,[1] Jing Chen,[1,2] Asaf Vivante,[1,3] Nina Mann,[1] Shirlee Shril,[1] Hadas Ityel,[1] Johanna Magdalena M. Schmidt,[1] Elijah O. Kehinde,[4] Friedhelm Hildebrandt.[1] *[1]Dept of Medicine, Boston Children's Hospital/Harvard Medical School, Boston, MA; [2]Dept of Nephrology, Children's Hospital of Fudan Univ, Shanghai, China; [3]Talpiot Medical Leadership Program, Sheba Medical Center, Tel-Hashomer, Israel; [4]Div of Urology, Dept of Surgery, Kuwait Univ, Safat, Kuwait.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the most common reason for chronic kidney disease in children. Although over 30 monogenic causes have been implicated in isolated forms of human CAKUT so far, the vast majority of causes for the development of CAKUT remain elusive.

Methods: To identify novel monogenic causes of CAKUT we applied homozygosity mapping, together with whole exome sequencing (WES) to a patient of consanguineous descent with isolated CAKUT. We performed electrophoretic mobility shift assay (EMSA) to analyze the DNA binding affinity of the mutated protein, and dual-luciferase reporter assay to test its transcriptional activity. Furthermore, we investigated a potential impact of the mutant protein onto cell migration by using scratch wound migration assays in two different stable knock-down cell-lines.

Results: We identified a highly conserved homozygous missense mutation (p.R415H) of the *Ets Variant Gene 4* (*ETV4*) in a CAKUT patient from consanguineous descent. The transcription factor ETV4 is a downstream target of the GDNF/RET signaling pathway and plays a crucial role in kidney development. By means of EMSA we show that the R415H ETV4 mutant causes loss of the DNA binding affinity of ETV4, and fails to activate transcription in a cell-based luciferase reporter assay. Unlike wildtype *ETV4*, the *ETV4* R415H mutant fails to rescue migration defects observed in stable ETV4 knock-down PC3 and U-2OS cells.

Conclusions: We identified and functionally characterized a recessive mutation in *ETV4* as a novel monogenic cause of isolated CAKUT. Possible pathomechanisms include impairment of proper GDNF/RET/ETV4 signaling. A.vdV. and J.C. are co-first authors.

A Dominant Mutation in NRIP1 Causes Urinary Tract Malformations via Dysregulation of Retinoic Acid Signaling

Asaf Vivante,[1,2] Nina Mann,[1] Hagith Yonath,[3] Maike Getwan,[4] Tobias Bohnenpoll,[5] Michael Kaminski,[4] Anna-Carina Weiss,[5] Jing Chen,[1] Shirlee Shril,[1] Amelie van der Ven,[1] Hadas Ityel,[1] Weining Lu,[6] Daniella Magen,[7] Velibor Tasic,[8] Robert Kleta,[9] Yair Anikster,[10] Benjamin Dekel,[10] Andreas Kispert,[5] Soeren S. Lienkamp,[4,11] Friedhelm Hildebrandt.[1] *[1]Dept of Med, BCH, HMS, Boston, MA, USA; [2]Talpiot, Israel; [3]Int Med A, Sheba & Sackler Faculty-TAU; [4]Univ Med Cent, Faculty of Med-ALU, Freiburg, Germany; [5]Med Univ Hannover, Germany; [6]BUMC, Boston, US; [7]Rambam & Technion, Haifa, Israel; [8]Med Faculty Univ Children's Hospital, Skopje, Macedonia; [9]Centre for Neph-UCL, UK; [10]Sheba & Sackler Faculty-TAU, Israel; [11]BIOSS, ALU, Freiburg, Germany.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the most common cause of chronic kidney disease in the first three decades of life. Identification of monogenic mutations that cause CAKUT permits insights into related disease mechanisms.

Methods: We performed whole exome sequencing, transcriptional reporter assay, protein-protein interaction studies, as well as in vivo studies in *Xenopus laevis*.

Results: We investigated a three-generation Yemenite Jewish family with an autosomal dominant form of CAKUT. By whole exome sequencing, we identified a heterozygous truncating mutation (c.279delG, p.Trp93fs*) of the *NRIP1* gene in all seven affected members. *NRIP1* encodes a nuclear receptor transcriptional co-factor, which directly interacts with the retinoic acid receptors to modulate retinoic acid transcriptional activity. By functional studies we reveal that the NRIP1 altered protein does not translocate to the nucleus, does not interact with retinoic acid receptor alpha (RARα) and fails to inhibit retinoic acid dependent transcriptional activity. In addition, we show that both *NRIP1* expression and its binding to RARα, are enhanced in the presence of retinoic acid. By expression and knockdown experiments in *Xenopus laevis* we confirm an evolutionary conserved role for *NRIP1* in renal development.

Conclusions: These data indicate that dominant *NRIP1* mutations cause CAKUT by interference with retinoic acid transcriptional signaling, thus shedding light on the well documented association between abnormal vitamin A levels and renal malformations in humans, and suggest a possible gene environment pathomechanism.

Misidentification of Dihydroxyadenine Kidney Stones by Conventional Stone Analysis Techniques

Hrafnhildur L. Runolfsdottir,[1,5] David S. Goldfarb,[2] John Andrew Sayer,[3] Mini Michael,[4] Runolfur Palsson,[1,5] Vidar O. Edvardsson.[1,5] *[1]Univ of Iceland, Iceland; [2]NYU Langone Medical Center; [3]Newcastle Univ, United Kingdom; [4]Texas Children's Hospital; [5]Landspitali – The National Univ Hospital of Iceland, Iceland.*

Background: Adenine phosphoribosyltransferase deficiency (APRTd) is an inherited disorder of purine metabolism that leads to excessive renal excretion of 2,8-dihydroxyadenine (DHA), resulting in kidney stones and crystal nephropathy. Analysis of crystal or kidney stone material using infrared (IR) spectroscopy has been considered diagnostic of APRTd. Recently, we have encountered cases misidentified as DHA stone formers by IR spectroscopy. The objective of this study was to examine the accuracy of stone analysis for identification of DHA kidney stones.

Methods: Records of all 40 patients referred to the APRTd Research Group of the Rare Kidney Stone Consortium from 2010 to 2016 were reviewed.

Results: Fifteen patients were referred to our program with the presumptive diagnosis of APRTd based on stone analysis. Seven of these 15 patients did not have APRTd as DHA had been misidentified as a stone component in 2 cases from the US, 2 from the UK, 2 from South Africa and 1 from Australia. The median age at referral was 26.6 (6-45) years. IR spectroscopy was the stone analysis technique used in 6 cases, yielding 12-100% (median of 60%) DHA in stone samples from 5 patients, while only trace amounts were found in a stone from 1 individual. X-ray diffraction was applied in one case suggesting 90% DHA.

None of the 7 patients had APRTd, demonstrated by undetectable DHA in spot urine samples using a novel mass spectrometry assay. The absence of APRTd was further confirmed by APRT enzyme activity measurements in 4 cases and genetic testing in 1 case.

Conclusions: Misidentification of kidney stones as DHA stones using gold standard stone analysis techniques appears to be more common than previously thought. The results of kidney stone analysis are based on human interpretation of different spectra and thus subject to error. The diagnosis of the APRTd should be confirmed by more reliable diagnostic methods, such as enzyme activity measurements or genetic testing.

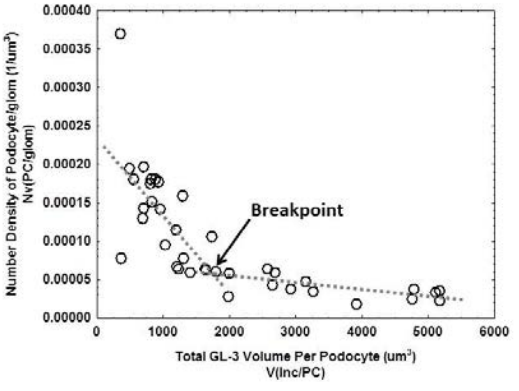
Podocyte Hypertrophy and Globotriaosylceramide (GL-3) Accumulation Are Strong Predictors of Podocyte Loss in Enzyme Replacement Therapy Naïve Male Patients with Fabry Disease

Behzad Najafian,[1] Camilla Tøndel,[2] Einar Svarstad,[2] Michael Mauer.[3] *[1]Univ of Washington; [2]Haukland Univ; [3]Univ of Minnesota.*

Background: Podocyte (PC) injury and loss play crucial roles in progressive chronic kidney disease (CKD) in Fabry disease. While PCs accumulate more GL-3 than other renal cells, they are far more resistant to GL-3 clearance following enzyme replacement therapy (ERT). Identifying parameters associated with PC loss may be crucial to halt CKD in Fabry disease. We assessed the relationship between PC GL-3 accumulation and PC number density per glomerulus [Nv(PC/glom)].

Methods: Biopsies from 38 male ERT-naïve Fabry patients aged 33[13-60], median [range], years with GFR 114±45 ml/min/1.73 m^2 were studied using electron microscopy unbiased stereology, including modified point-sampled intercept method.

Results: By linear regression, age correlated directly with protein creatinine ratio (PCR) (r=0.55, p=0.001) and inversely with GFR (r=-0.47, p=0.006). Nv(PC/glom) correlated inversely with mean PC volume (VPC) (r=-0.77, p=0.0001) and total GL-3 inclusion volume/PC [V(Inc/PC)] (r=-0.69, p=0.0001), but not with GL-3 volume fraction [Vv(Inc/PC)] or foot process width (FPW). Using piecewise linear regression analysis, 88% of Nv(PC/glom) variability was explained by VPC and V(Inc/PC), p=0.000001, with the V(Inc/PC) breakpoint at 1965 um^3 and the VPC breakpoint at 5201 um^3, beyond which the slope of decline in Nv(PC/glom) was markedly increased.



PCR correlated with VPC (r=0.44, p=0.01) and V(Inc/PC) (r=0.40, p=0.02), but not with Vv(Inc/PC) or FPW.

Conclusions: PC enlargement and total GL-3 accumulation are important determinants of PC loss in Fabry disease. The observed V(Inc/PC) and VPC breakpoints suggest thresholds beyond which PC hypertrophy and GL-3 content are associated with marked acceleration of PC loss. Such thresholds may suggest new treatment targets for Fabry nephropathy.

TH-PO274

Aging Is Associated with Reduced %Podocytes (Podo), but Not %Parietal Epithelial Cells (PECs) with Fabry Phenotype in Females with Fabry Disease

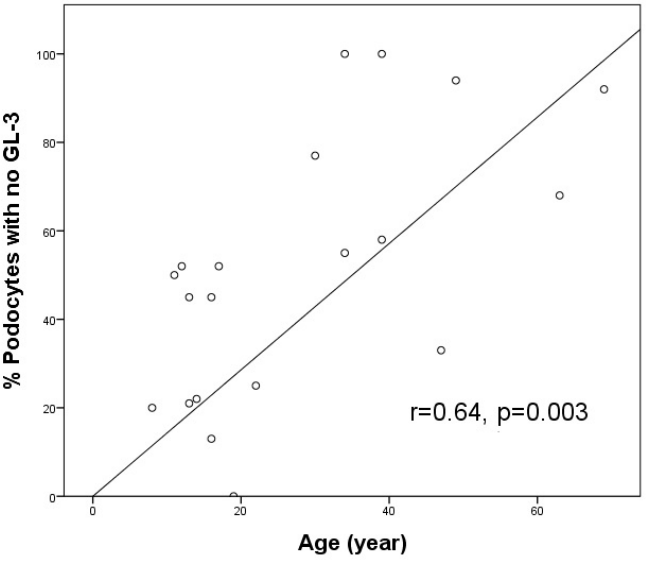
Fu-Pang Chang,[1] Michael Mauer,[2] Luiz A. Moura,[3] Behzad Najafian.[1] *[1]Univ of Washington; [2]Univ of Minnesota; [3]Univ Federal de São Paulo, Brazil.*

Background: In Fabry nephropathy (FN), globotriaosylceramide (GL-3) accumulation in Podo leads to disease progression. In females with FN, due to X-inactivation, the distribution of GL-3 inclusions in Podo is heterogeneous, and related to Podo injury. Recent studies suggest PECs may replace lost Podo. Thus, PECs may be important in pathophysiology of FN. We studied the distribution of Podo and PEC involvement in female Fabry patients, and their relationships to clinical parameters.

Methods: Kidney biopsies from 20 treatment-naïve female Fabry patients (age 20.5 [8–69], median [range]) were studied by electron microscopy. Urine protein excretion (UPE) was estimated by urine protein creatinine ratio (UPCR) (n=12) or total urine protein/day (n=8).

Results: GFR was 96.64±21.01 ml/min/1.73 m^2. UPE was 61 (0-1150) mg/day. In all 20 biopsies, 51±30% (mean ± SD) of Podo per glomerulus contained no GL-3 inclusions, classified as non-Fabry Podo (NFPodo). In 14 biopsies which allowed reliable evaluation of PECs, 47±31% of PECs per glomerulus had no GL-3 inclusions, classified as non-Fabry PECs (NFPEC). %NFPodo per glomerulus (%NFPodo/glom) was directly correlated with age (r=0.64, p=0.003), but %NFPEC per glomerulus (%NFPEC/glom) was not. %NFPodo/glom and %NFPEC/glom were not correlated. Neither %NFPodo/glom nor %NFPEC/glom showed relationships with GFR or UPE. The inter-glomerular variation in %NFPodo/glom in a given patient's biopsy was smaller than %NFPEC/glom.

Conclusions: Direct relationship between age and %NFPodo/glom is suggestive of a survival disadvantage for Podo with Fabry phenotype. The differential relationships of %NFPodo/glom and %NFPEC/glom to patients' age may reflect different regeneration capacity or injury response to GL-3 inclusions in Podo and PECs.



TH-PO275

High Prevalence of Proteinuria and Reduced Renal Function in 14 Adolescents and Young Adults with Antenatal and Classic Bartter Syndrome

Martin Kömhoff,[1] Stefanie Weber,[1] Günter Klaus.[2] *[1]Univ Children's Hospital, Dept of Pediatric Nephrology, Philipps-Univ, Marburg, Germany; [2]Kuratorium für Heimdialyse, Marburg, Germany.*

Background: Antenatal Bartter syndrome (aBS) and classic BS (cBS) are characterized by renal salt wasting resulting in hypokalemia, enhanced production of prostaglandin E_2, renin and aldosterone as well as hypercalciuria in aBS. The long-term outcome of glomerular and tubular function in adolescents and young adults is largely unknown. We here describe extensive follow-up data based on our single center experience with aBS and cBS.

Methods: 14 adolescents and young adults (seven females and males; aBS type I: n=7; aBS type II: n=3; and cBS: n=4), with a mean age of 21.2 years. All subjects were continously treated with prostaglandin synthesis inhibitors and supplemental electrolytes. We analyzed retrospectively endogenous creatinine clearance (CCR), the urinary excretion of electrolytes and protein and 24 h-ABDM.

Results: The average renal excretion of sodium and chloride were 153±75.1 and 185.5 ± 90.6 mmol/d, respectively. FE_{Na} correlated with systolic day blood pressure SDS (r=0,46, p=0.015). CCR was 81.5 ± 29.9 ml/min/1,73m², ten patients had a CCR<90, three patients < 50ml/min/1.73m². Proteinuria was detected in 11/14 patients (Alb/Crea 189 ± 288,6 mg/g), of these, five patients had tubular proteinuria. CCR correlated negatively with proteinuria (r=-0.4, p<0.01). Patients with aBS type I showed the most pronounced renal impairment (CCR: 68.5 ± 15.6, Alb/Crea 290 ± 379 mg/g), followed by patients with aBS type II (CCR: 77.6 ± 15.1, Alb/Crea 171 ± 261 mg/g) and patients with cBS (CCR: 107 ± 44, Alb/Crea 50 ± 40 mg/g). Two patients had increased blood pressure on 24 h-ABDM.

Conclusions: Reduced CCR and proteinuria were present in the majority of patients and clearly exceeded values from two previously published case series describing younger patients (Reinalter et al., 2001; Puricelli et al, 2010). Genotype, chronic renal salt wasting with continuous activation of renin and aldosterone synthesis and the cumulative exposure to prostaglandin synthesis inhibitors may all contribute to this so far unanticipated impairment in renal function.

TH-PO276

Defects in N-Glycosylation of Cubilin Result in Tubular Proteinuria

Tomohiro Udagawa,[1] Ken-Ichiro Miura,[3] Akihiko Saito,[2] Yutaka Harita.[1] *[1]Pediatrics, Graduate School of Medicine, The Univ of Tokyo, Tokyo, Japan; [2]Applied Molecular Medicine, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [3]Peidatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Mutations of either cubilin (*CUB*) or amnionless (*AMN*) cause low-molecular weight proteinuria and megaloblastic anemia, due to defects in endocytosis through cubilin-amnionless receptor complex (IGS: Imerslund-Gräsbeck Syndrome). The pathogenic mechanism of IGS is largely unknown. We found a novel missense G653R mutation of *CUBN* in a boy with IGS. Renal histology demonstrated that cubilin and amnionless were not targeted to brush border of proximal tubular cells in the patient.

Methods: To analyze the pathogenic mechanism of the mutations found in IGS, we quantitatively determined the membrane targeting of cubilin and amnionless in cultured cell by flow cytometry. We analyzed the effect of mutations causing IGS on glycosylation and membrane targeting of cubilin and amnionless.

Results: While wild-type cubilin and amnionless were interdependently targeted to the cell membrane, G653R and previously reported missense mutations of *CUBN* inhibited amnionless-dependent glycosylation, membrane expression of cubilin and amnionless, and endocytosis. Notably, all the previously reported missense mutations of *AMN* also inhibited cubilin glycosylation, and causes ER retention of amnionless and cubilin. N-linked glycosylation of cubilin did not affect cubilin-amnionless interaction, but was required for transport from ER to Golgi. Mass spectrometric and mutagenesis analysis identified the combination of glycosylations in CUB domain of cubilin which are crucial for surface expression of cubilin and amnionless.

Conclusions: N-glycosylation of cubilin is essential for endocytosis in renal and intestinal epithelial cells, and its defects result in tubular proteinuria.

TH-PO277

Morphological and Immunohistochemical Presentation of Complement Disorders in Native and Transplant Renal Biopsies Christof Aigner,[1] Martina M. Gaggl,[1] Zoltan Prohaszka,[2] Ahmad Altaleb,[3] Gere Sunder-Plassmann,[1] Alice Schmidt,[1] Renate Kain.[3] *[1]Dept of Medicine III, Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria; [2]IIIrd Dept of Internal Medicine, Research Laboratory, Semmelweis Univ, Budapest, Hungary; [3]Clinical Dept of Pathology, Medical Univ of Vienna, Vienna, Austria.*

Background: Complement-mediated Thrombotic Microangiopathy (TMA), C3-glomerulonephritis (C3GN) and Dense Deposit Disease (DDD) are diseases of the alternative complement pathway and associated with the same genotypic background. However, the reasons for the different phenotypes remain unexplained.

Methods: We analysed 35 biopsies of 5 patients followed for an average of 14 years. All underwent renal transplantation (KTX) and analysis of morphologic and immunohistochemical parameters included light-, electron-microscopy, and detection of immunoglobulins and proteins of the complement pathway (C1q,C3c,C3d,C4d,C5b-9).

Results: We identified 5 patients with complement associated disorders, all of which developed C3GN in the transplants**.** Treatment followed standard regimens in patients with biopsy proven rejection and 3 patients with persistent TMA received Eculizumab. All patients developed GN with a range of morphological presentation and variable C3d,C4d, no C5b-9, but prominent C3c deposits.

Pat	Muta-tion	Presen-tation	KTX1	Rejection (BANFF)	KTX2	Rejection	KTX3	Rejec-tion
1	THBD	TMA	TMA+C3GN	vascular(II)				
2	C3	TMA	TMA+C3GN					
3	-	TMA	C3GN					
4	CFH	TMA	TMA+C3GN					
5	CFH	DDD	TMA	vascular	TMA	ABMR, vas-cular (IIb), interstitial	C3GN	vascular (IIa), ABMR (II)

Conclusions: We present 5 patients, all of which developed C3GN after KTX, which indicates a phenotype-switch between complement associated disorders. Neither mutations nor deposition of complement products in renal biopsies allowed to predict presentation or outcome of disease. Our data indicate that a phenotype-switch may not be as rare as reported however morphological presentation may be influenced by therapies or immunological events in graft rejection.

TH-PO278

Focal Global Glomerulosclerosis Is Common in Dent Disease and Associates with Kidney Function Xiangling Wang,[1] Franca Anglani,[2] Lada Beara Lasic,[3] Anila Mehta,[1] Lisa E. Vaughan,[1] Loren Paola Herrera Hernandez,[1] Andrea G. Cogal,[1] Steven J. Scheinman,[4] Gema Ariceta,[5] Lawrence A. Copelovitch,[6] Felicity T. Enders,[1] Peter C. Harris,[1] John C. Lieske.[1] *[1]Mayo Clinic; [2]Uof Padua; [3]NYU; [4]TCMC; [5]U Hospital Vall d'Hebron; [6]U Penn.*

Background: Dent disease (DD) is a rare X-linked disorder characterized by low molecular weight proteinuria and considered a tubular disorder. However, focal global glomerulosclerosis (FGGS) was recently reported in several patients.

Methods: To characterize pathological findings in a cross section of DD patients, renal pathology reports and slides (where available) were obtained from 30 male patients in eight countries who had undergone clinically indicated renal biopsy.

Results: Median (25th, 75th) age at biopsy was 7.5 (5, 19) years with an estimated glomerular filtration rate (eGFR) of 69 (44, 94) ml/min/1.73m^2 and a 24hr protein excretion of 2000 (1325, 2936) mg. A repeat biopsy for steroid-resistant proteinuria was performed in 13% (4/30) of the patients. Prominent histological findings included FGGS in 83% of patients (25/30) affecting 16% ± 19% glomeruli, mild segmental foot process effacement in 57% (13/23), focal interstitial fibrosis in 60% (18/30), interstitial lymphocytic infiltration in 53% (16/30) and tubular damage in 70% (21/30).

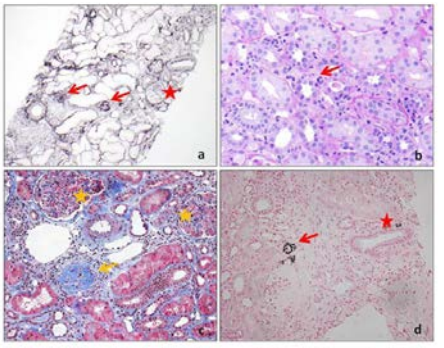


Figure 1. Renal histopathological features in Dent Disease 1. (a) Glomeruli with global sclerosis (arrows) and intact glomerulus (star). **(b)** Tubulitis (arrow). **(c)** Globally sclerotic glomerulus adjacent to the interstitium with lymphocytes infiltration (arrow) and intact glomeruli (stars). **(d)** Calcium phosphate crystals in the tubule (arrow) and interstitium (star).

Lower eGFR at biopsy associated with a higher percentage of globally sclerotic glomeruli, foot process effacement, and interstitial inflammation, while steeper annual eGFR decline during follow-up was associated with foot process effacement.

Conclusions: Glomerulosclerosis is common in DD. Glomerular pathology, specifically involving the podocyte,may play a role in disease progression in DD, which deserves further studies to understand the underlying mechanism(s). Furthermore, Dent disease should be suspected in unexplained proteinuric male patients with focal global glomerulosclerosis and segmental foot process effacement on renal biopsy.

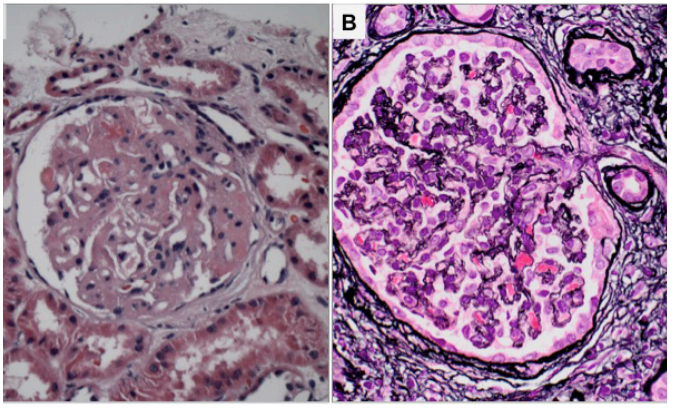
Thrombotic Microangiopathy: A Novel Presentation for TREX1 Mutation Ashima Gulati,[1] Gabriel M. Danovitch,[2] Margaret J. Bia,[1] Allen E. Bale,[1] Gilbert W. Moeckel,[1] Stefan Somlo,[1] Neera K. Dahl.[1] *[1]Yale Univ School of Medicine, CT; [2]David Geffen School of Medicine at UCLA, CA.*

Background: Thrombotic microangiopathy (TMA) is a systemic condition with predilection for the kidney. Genetic determinants have been identified mainly related to complement dysregulation. Since a significant proportion of TMA remains etiologically undefined, exome sequencing may uncover novel genotype correlations.

Methods: Genomic DNA from proband with familial TMA was subjected to exome sequencing and variant filtering using bioinformatics pipeline and data analyzed on *a priori* suggestion for autosomal dominant TMA.

Results: Proband is a Caucasian male (5th decade) with persistent proteinuria (1g/d) and gradual serum creatinine elevation during 3-yr follow up (eGFR 48 ml/min/1.73m^2) with controlled hypertension. He had no neurologic or visual symptoms and unremarkable physical examination. Kidney biopsy (fig.A) showed TMA with duplication of glomerular basement membrane. Family history is significant for kidney transplant in deceased father; retinal hemorrhage and chronic kidney disease with TMA in his brother (fig.B). CBC, CFH, CFI, C3, antiphospholipid panel were unremarkable. Proband exome sequencing revealed a heterozygous 4 bp duplication in carboxyl terminus of *TREX1* (Three Prime Repair Exonuclease) resulting in a non-truncating frame shift (NM_033629:exon1: c.828_831dupGAAG:p.D278Efs*48).

Conclusions: C-terminal mutations in *TREX1* known to alter its subcellular localization while preserving exonuclease activity cause microangiopathy predominantly of retina and brain. We report an exclusive renal phenotype of TMA and chronic kidney disease with mutation in *TREX1* in absence of symptomatic multisystem microangiopathy. While awaiting familial genetic testing, we emphasize the clinical importance of recognizing *TREX1* mutation as a cause of non complement mediated TMA and an opportunity for delineating novel TMA pathophysiology.



TH-PO280

Clinical Follow-Up of Female Fabry Disease Patients Receiving Enzyme Replacement Therapy for up to 2 Years Fellype C. Barreto,[1,2] Tammy Vernalha Rocha Almeida,[1] Bruna Fernanda de Castro,[1] Felipe T.M. Novak,[2] Lidio Derossi,[3] Caroline de Paula Cassanego,[1] Mariza G. Rosa,[3] Gilson Biagini.[1] *[1]Pontificia Univ Católica do Paraná; [2]Univ Federal do Paraná; [3]Health Center Clinic - Tapejara.*

Background: Fabry disease (FD) is an X-linked lysosomal storage disorder resulting from a deficiency of the hydrolytic enzyme α-galactosidase A (α-Gal-A). Heterozigous female patients may develop clinical manifestations and require enzyme replacement therapy (ERT) as homozygous males.

Methods: A review of clinical and laboratorial data of females FD patients followed up in Tapejara - Brazil, with serum creatinine and albuminuria measured before ERT (agalsidase-beta; 1 mg/kg; eow) Cardiac and cerebral involvements were evaluated by echocardiography and/or magnetic resonance imaging. The follow up period was divided in two time points. T1: up to 12 months (6.1±2.8 months, n=17); T2: up to 24 months (22.1±3.3 months, n=7) of ERT.

Results: Seventeen female patients (age: 29.1 ± 16.2 years) were included. The median age at diagnosis was 21 (13-65) years. The most frequent clinical manifestations were as follows: left ventricular hypertrophy (59%), septal hypertrophy (29%), cardiac fibrosis (35%), white matter lesion (43%), acroparesthesia (59%) and nephropathy (59%). 6/17 and 2/17 patients were at CKD stage 2 and 3a at baseline, respectively. ERT was initiated after 5 yrs (median) of the diagnosis. All patients received antiproteinuric medication. Renal function remained stable for most patients at the two different time points of follow up, including the patient with the lowest eGFR (49.5 ml/min) and the highest proteinuria (2500mg/24h) at baseline. Kidney biopsy performed before ERT in a patient without overt proteinuria and normal eGFR unveiled effacement of foot processes of the podocytes. No cardiac or cerebrovascular event was observed during the follow up.

Conclusions: Heterozygous female FD patients may present a broad spectrum of clinical manifestations of FD and should not be neglected. ERT, combined with renin-angiotensin system blockade, seems to be a safe and effective strategy to prevent progression of Fabry nephropathy in females.

TH-PO281

Proteogenomic Analysis of a Disease-Causing Actinin-4 Mutation Markus M. Rinschen,[1] Malte P. Bartram,[1] Caroline Pahmeyer,[1] Thomas Benzing,[1] Bodo B. Beck.[2] *[1]Internal Medicine, Univ Hospital Cologne, Cologne, Germany; [2]Human Genetics, Univ Hospital Cologne, Cologne, Germany.*

Background: In children, genetic diseases are the most important cause for end-stage renal disease. Mutations in the ACTN4 gene are a rare cause of autosomal dominant familial focal segmental glomerulosclerosis (FSGS). We here identified a novel, disease-causing ACTN4 mutation (p.G195D, de novo) in a sporadic case of childhood FSGS.

Methods: We utilized next generation sequencing to identify a novel ACTN4 mutation in a sporadic case of childhood FSGS. In vitro studies (actin sedimentation assay, immunofluorescence analyses and migration assays) were used to judge actin cytoskeleton function. Primary urinary epithelial cells of the patient were subjected to proteomic analysis. Results were complemented with interactomic and ubiquitylomic analyses of ACTN4 G195D in vitro.

Results: In vitro studies demonstrated that ACTN4 G195D had a detrimental effect on actin cytoskeletal function. Proteome analysis by quantitative mass spectrometry of patient-derived urinary epithelial cells indicated that ACTN4 levels were significantly decreased when compared with healthy controls. By resolving the allele bearing the mutated residue on a protein level, we demonstrated that the mutant protein is less abundant when compared with the wild-type protein. Molecular dynamics simulations revealed a decrease in ACTN4 CH-domain stability upon mutation. Further analyses revealed that the decreased stability of p.G195D is associated with increased ubiquitylation in the vicinity of the mutation site. We next defined the ACTN4 interactome, which was predominantly composed of LIM domain proteins. Interestingly, this entire group of proteins, including several ACTN4 interactors, was globally decreased in the patient-derived cells. Further ACTN4 mutations may demonstrate a similiar phenotype.

Conclusions: Our findings advance the understanding of dominant effects exerted by ACTN4 mutations in FSGS. This study illustrates the potential of genomics and complementary, high-resolution proteomics analyses to study the pathogenicity of rare gene variants (“proteomendeliomics”).

Recessive Mutations in 5 Novel Genes of Interaction Partners Elucidate Steroid Sensitivity in Nephrotic Syndrome Shazia Ashraf,[1,2] Jia Rao,[1] Jennifer A. Lawson,[1] Weizhen Tan,[1] Eugen Widmeier,[1] Svjetlana Lovric,[1] Jillian Kateri Warejko,[1] Daniela A. Braun,[1] Heon Yung Gee,[1] Mohamad Aman Jairajpuri,[2] Martin Zenker,[3] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Boston Childrens’ Hospital, Harvard Medical School, Boston, MA; [2]Dept of Biosciences, Jamia Millia Islamia, New Delhi, India; [3]Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany.*

Background: Idiopathic nephrotic syndrome is a common pediatric kidney disease. 80% of all cases are steroid sensitive (SSNS). First insights into the pathogenesis of steroid-resistant nephrotic syndrome (SRNS) came from identification of ~30 single-gene causes. However, mechanisms of treatment sensitivity *vs.* resistance remain unknown.

Methods: We performed homozygosity mapping (HM) and whole exome sequencing (WES) to identify novel disease-causing genes in a worldwide cohort of ~2,000 individuals with severe NS.

Results: By WES and high-throughput sequence analysis, in families who mostly had steroid-dependent NS (SDNS), we identified multiple recessive mutations in the following genes: *MAGI2, TENC1, DLC1, CDK20,* and *ITSN1* in 2, 5, 4, 1, and 3 unrelated families, respectively. Knockout mice of *Magi2* or *Tenc1* have been previously shown to develop NS. By Co-IP, we now show that MAGI2 interacts with TENC1 and DLC1 and these interactions are abrogated by the two MAGI2 mutants. Knockdown of *MAGI2*, *DLC1* or *ITSN1* in cultured podocytes exhibited a decreased podocyte migration rate. Immunofluorescence studies showed that TENC1 and DLC1 colocalize with phosphotyrosine at focal adhesions in human podocytes. We discover CDK20 as a novel renal regulator of DLC1. In addition, we discover ITSN as a novel GEF for Cdc42, relevant for podocyte function.

Conclusions: Thus, by identification of 5 novel monogenic causes of NS we define a functional network of proteins at the intersection between steroid sensitivity *vs.* steroid resistance of NS. These findings for the first time may elucidate cell autonomous podocytic mechanisms of treatment response in NS and will make specific genetic variants of NS amenable to treatment.

TH-PO283

IgA Glomerulonephritis Caused by ENTPD3 Mutations; and with Drusen Suggesting Low Grade Complement Activation Judith A. Savige,[1] Terence L. Kirley,[2] Deb J. Colville.[1] *[1]Medicine and Nephrology, The Univ Dept of Medicine, Melbourne, VIC, Australia; [2]Dept of Pharmacology and Cell Biophysics, Univ of Cincinnati College of Medicine, Cincinnati, OH; [3]The Univ of Queensland, QLD, Australia.*

Background: IgA disease is the commonest glomerulonephritis worldwide affecting 1% of the population, one third of whom go on to develop end-stage renal failure. The aim of this study was to use whole exome sequencing and bioinformatics analysis in a family with biopsy-proven IgA glomerulonephritis to identify the mutant gene.

Methods: Nine members of the family provided DNA that underwent whole exome sequencing (Otogenetics, Atlanta). The results were analysed for variants that segregated with affected status in an in-house bioinformatics pipeline. Pathogenicity was then confirmed with protein modelling experiments and functional assays using cells from family members.

Results: The whole exome sequencing demonstrated a missense mutation (R143C, rs 369719510) in the ectonucleoside triphosphate diphosphohydrolase 3 (*ENTPD3*) gene that segregated with disease in this family. ENTP3 is important in purinergic signalling, with roles in phagocytosis, inflammation and apoptosis. The R143C variant is very rare (0.0001%, www.exac.broadinstitute.org/). It affected enzyme function in modelling experiments, and in an in vitro transfection system. Affected peripheral blood monocytes from family members with the R143C mutation also demonstrated reduced enzyme activity and abnormal phagocytosis. We identified a further pathogenic variant (rs34266806, R264Q) that resulted in the same phagocytic defects in an unrelated individual with apparently sporadic IgA disease.

Conclusions: These results indicate a novel gene locus for IgA glomerulonephritis, and that some apparently sporadic cases also have a genetic basis. *ENTPD3* mutations impair phagocytosis which potentially contributes to the development of mesangial deposits. This represents the second gene identified in IgA glomerulonephritis, and the corresponding proteins belong to interacting pathways.

TH-PO284

Retinal Temporal Thinning Is More Pronounced in Males with X-linked Alport Syndrome and Early Onset Renal Failure Judith A. Savige, Yan Hong Chen, Andrew S. Talbot, Deb J. Colville. *Medicine and Nephrology, The Univ of Melbourne (MH and NH), Melbourne, VIC, Australia.*

Background: Alport syndrome is an inherited disease characterised by renal failure, hearing loss, and ocular abnormalities including retinal temporal thinning. This study examined retinal thinning in Alport syndrome.

Methods: Alport syndrome was diagnosed on renal biopsy or genetic testing, and the mode of inheritance was determined by genetic testing. Age at end-stage renal failure and current eGFR were recorded. Retinal thinning was determined from optical coherence tomography (OCT), using the formula of temporal thickness index (TTI) = (nasal – temporal thickness) ÷ nasal thickness x 100% compared with the normal range for age group (Ahmed, 2013). Statistical analysis was performed using Stata (StataCorp).

Results: Temporal thickness index was 11.47 + 5.3% in males (n=20) and 7.51 + 1.79% in females (n=28) with X-linked disease; 14.5 + 1.36% (n=5) in recessive disease; 7.03 + 2.12% (n=12) in Thin membrane nephropathy ; and 6.34 + 2.53% (n=12) in other causes of renal failure. In X-linked disease, 15 males (75%) and 19 females (68%) had retinal thinning, and thinning was more pronounced in males ($p< 0.01$), and, in males, correlated with early onset renal failure ($p<0.01$). Thinning did not correlate with eGFR in females ($R2 = 0.016$). The degree of thinning did not distinguish X-linked disease in women from Thin basement membrane nephropathy. Overall the sensitivity of retinal thinning for Alport syndrome was 72% and specificity was 58%.

Conclusions: The difference in retinal thinning in males and females with X-linked Alport syndrome and renal failure suggests that the loss of the collagen IV a5 chain from affected membranes contributes to renal failure in men, but that there is a further non-genetic contribution to renal deterioration in women such as hypertension.

TH-PO285

Function of Focal Segmental Glomerulosclerosis Disease Protein Inverted Formin 2 (INF2) in Podocytes

Balaji Karthick Subramanian,[1,2] Paul Yan,[1] Johannes S. Schlondorff,[1,2] Martin R. Pollak.[1,2] *[1]Div of Nephrology, Beth Israel Deaconnes Medical Center, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Mutations in Inverted formin 2 (INF2) gene cause an autosomal dominant human kidney disease characterized by focal segmental glomerulosclerosis (FSGS) with or without Charcot-Marie-Tooth disease. Aberration in actin dynamics are manifested due to pathogenic mutations *in vitro* and have been hypothesized to play a major role in INF2 mediated FSGS. In addition, recent studies with a human pathogenic R218Q knockin mutant mouse model showed impaired podocyte recovery with protamine sulfate followed by heparin sulfate treatments, which associates with defective cell protrusions and actin structures in mutant podocytes. While these studies highlight the importance of INF2 in actin dynamics, its correlation with podocyte structure and function remains largely unknown. The purpose of this study was to understand the INF2 function in podocytes, and advance our knowledge in INF2 associated FSGS.

Methods: Human podocyte specific INF2 splice variant expressions were analyzed both by RT-PCR and Immunoblotting. CRISPRed INF2 knockout cells were generated and evaluated for changes in cytoskeleton and lipid raft trafficking using migration assays.

Results: Splice variant analysis of INF2 in human podocytes showed the expression of INF2-CAAX isoform (NCBI ID: NM_022489.3) and a short splice-isoform corresponding to a region from N-terminus exon 1 start to exon 5 end (NCBI ID: NM_032714.2). Unlike in normal cells, CRISPRed INF2 knockout podocytes lacking these isoforms exhibited polyglutamylated tubulin and cortactin structure defects in the lamellipodium region during migration. In addition, lipid raft trafficking, an actin and polyglutamylated tubulin structure dependent process, as measured through GM1 marker also exhibited defects in INF2 knockout podocytes.

Conclusions: INF2 functions in podocytes are associated with the regulation of podocyte cytoskeleton and lipid raft trafficking. Further understanding of INF2 function in these processes and their relation to slit diaphragm proteins would provide the critical mechanistic insights into INF2 associated FSGS.

The Acadian Variant of Fanconi Syndrome Is Caused by Mitochondrial Respiratory Chain Complex 1 Deficiency due to a Non-Coding Mutation in NADH Dehydrogenase Complex 1 Assembly Factor 6 (NDUFAF6)

Anthony J. Bleyer,[1] Yves Thibeault,[2] Philip D. Acott,[3] Stanislav Kmoch.[4] *[1]Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Section on Nephrology, Dr. Georges L. Dumont Univ Hospital Centre, Moncton, New Brunswick, Canada; [3]Section of Pediatric Nephrology, Dalhousie Univ, Halifax, NS, Canada; [4]Inst for Inherited Metabolic Disorders, First Faculty of Medicine, Charles Univ, Prague, Czech Republic.*

Background: The Acadian Variant of Fanconi Syndrome (AVFS) occurs in the Acadian population of Canada and is characterized by autosomal recessive inheritance of Fanconi syndrome and progressive CKD with ESRD between age 21 and 40.

Methods: 12 individuals with AVFS were identified and phenotyped. Fibroblasts were obtained from a skin biopsy of an affected patient. Whole exome sequencing, homozygosity mapping, whole genome sequencing (WGS), and Sanger sequencing were performed.

Results: Whole exome sequencing identified a region on chromosome 8(chr8:90958422-95690579) that was homozygous in 3 affected but not present in one unaffected family member. Using WGS, we identified one ultra-rare noncoding variant, chr8:96046914T>C in the gene *NDUFAF6* that was homozygous in the 9 affected individuals, whereas 13 healthy siblings were either heterozygotes or lacked the mutant allele. *NDUFAF6* encodes assembly factor 6 of the NADH dehydrogenase (ubiquinone) complex1 (NDUFAF6). This variant is located in intron 2. Mutation interpretation software predicted that the c.298-768 T>C nucleotide change would create a novel splice acceptor site. Western blot analysis of affected and control skin fibroblasts revealed loss of the mitochondrial NDUFAF6 isoform V-1 in affected fibroblasts, while the NDUFAF6 isoform V_2 was reduced but present in the cytoplasmic fraction. Affected fibroblasts had defects in mitochondrial respiration and complex 1 biogenesis that corrected with *NDUFAF6* cDNA transfection. All affected individuals had progressive pulmonary fibrosis leading to death.

Conclusions: AVFS is caused by a mutation in *NDUFAF6* that results in mitochondrial respiratory chain complex 1 deficiency. Progressive pulmonary fibrosis occurs in all affected individuals.

Funding: Clinical Revenue Support

TH-PO287

Prevalence of UMOD and MUC1 Mutations in Families with Autosomal Dominant Tubulo-Interstitial Kidney Disease

Anthony J. Bleyer,[1] Kendrah O. Kidd,[1] Anna Greka,[2] Stanislav Kmoch.[3] *[1]Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Broad Inst of Harvard-MIT, Harvard Medical School, Boston, MA; [3]First Faculty of Medicine, Charles Univ, Prague, Czech Republic.*

Background: Mutations in *UMOD*, *MUC1*, *REN*, and *HNF1beta* genes are known causes of autosomal dominant tubulo-interstitial kidney disease (ADTKD). We analyzed the relative prevalence of these conditions in ADTKD.

Methods: Since 1996 we have been referred 698 families. We suspected ADTKD in 446 of these families and were able to obtain 2076 DNA samples on 1702 individuals from 308 families. These families underwent analysis for *UMOD*, *MUC1*, *REN*, and *HNF1beta* mutations. We also obtained information regarding a family history of gout. *UMOD* mutational analysis was performed at Athena Diagnostics, Worcester, MA, or the First Faculty of Medicine, Charles University, Prague, Czech Republic. Genetic analysis for a cytosine duplication in the variable number of tandem repeat region of the *MUC1* gene was performed at the Broad Institute, Cambridge, MA. Other mutational analyses were performed at Charles University.

Results: Of the 308 families, 140 (45.5%) had *UMOD* mutations, 59 (19.2%) *MUC1* mutations, 11(3.7%) *REN* mutations, one family (0.3) had an *SEC61A1* mutation and 1 (0.3%) a *hepatocyte nuclear factor one beta* mutation. 86 of 140 families with *UMOD* mutations (62%) had a strong family history of gout, and 21 of 59 (36%) families with *MUC1* mutations had a strong history of gout. All 11 *REN* families had a history of gout. We also performed mutational analysis in 23 individuals with tubulo-interstitial kidney disease of unknown cause and no family history of kidney disease; one individual(4.3%) was found to have a *MUC1* mutation, while no mutations were found in the other individuals.

Conclusions: *UMOD* and *MUC1* mutations make up the majority of mutations causing autosomal dominant tubulo-interstitial kidney disease, though the cause of inherited kidney disease remains unclear in a number of families. Gout is more prevalent in *UMOD* families, but can be seen in both disorders. Patients with tubulo-interstitial kidney disease and no family history of ADTKD rarely are found to have a *UMOD* or *MUC1* mutation.

The Genetic and Phenotypic Spectrum of DGKE Nephropathy

Mathieu Lemaire,[1] Karolis Azukaitis,[2] Eva Simkova,[3] Baerbel Lange-Sperandio,[4] Anuradha A. Gajjar,[5] Hae Il Cheong,[6] Zoltan Prohaszka,[7] Veronique Fremeaux-Bacchi,[8] Franz S. Schaefer.[9] *[1]Nephrology Div & Cell Biology Program, Univ of Toronto, Toronto, ON, Canada; [2]Clinic of Pediatrics, Vilnius Univ, Vilnius, Lithuania; [3]Pediatric Nephrology Dept, Dubai Hospital, Dubai, United Arab Emirates; [4]Pediatric Nephrology Dept, Ludwig-Maximilian-Univ, Munich, Germany; [5]Div of Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [6]Dept of Paediatrics, Seoul National Univ, Children's Hospital, Seoul, Korea; [7]Dept of Internal Medicine, Semmelweis Univ, Budapest, Hungary; [8]Dept of Immunology, Hôpital Européen Georges-Pompidou, Paris, France; [9]Div of Paediatric Nephrology, Heidelberg Univ Hospital, Heidelberg, Germany.*

Background: Diacylglycerol kinase ε (DGKE) is a recently discovered gene that causes a novel form of glomerulopathy. Our objective is to combine data from 9 new cases with previously published reports to gain insights into the phenotype and natural history of DGKE nephropathy.

Methods: Genetic testing was done in certified laboratories. Previously reported cases were identified with PubMed search. Time to ESRD was assessed by Kaplan-Meier analysis.

Results: We present the clinical characteristics for 9 patients from 8 unrelated kindreds. Novel disease-causing genotypes were found in Polish, Emirati, Korean and Indian kindreds. Published reports contained data on 34 children. Renal biopsies were consistent with thrombotic microangiopathy (TMA) in 15 patients, MPGN-like features in 9, and mixed TMA/MPGN in 1. While 30/33 of patient with aHUS were diagnosed in the first year of life, patients with MPGN were diagnosed later (range 2-17 years). Thus far, 11 children have progressed beyond CKD stage 3. Of these, 5 were transplanted with excellent outcomes. The phenotype of patients harboring the same pathogenic genotypes - in particular, mutation-concordant siblings - was more heterogenous than expected. Mild hypocomplementemia was observed in 8/43.

Conclusions: DGKE nephropathy presents either as infantile aHUS or pediatric MPGN, usually without hypocomplementemia. Substantial phenotypic disconcordance between affected siblings was observed. The risks of CKD/ESRD are high but kidney transplantation is a safe option.

Acute and Stable CRISPR/Cas9 Zebrafish Models of KEOPS Protein Defects Recapitulate Microcephaly of Galloway-Mowat Syndrome Tilman Jobst-Schwan,[1] Johanna Magdalena M. Schmidt,[1] David Schapiro,[1] Daniela A. Braun,[1] Corinne Antignac,[2] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Imagine Inst, Univ Paris Descartes, Sorbonne Paris Cité, Paris, France.*

Background: Galloway-Mowat syndrome (GMS) is a severe neurorenal disorder that combines nephrotic syndrome with microcephaly. We performed whole exome sequencing and homozygosity mapping on a cohort of GMS patients and identified in a total of 31 families recessive missense mutations in the 4 genes *LAGE3*, *OSGEP, TP53RK* and *TPRKB* which constitute the evolutionary conserved KEOPS complex. To study the pathogenesis of this newly defined disease entity, we generated zebrafish animal models.

Methods: We used CRISPR/Cas9 to develop an acute knockdown (KD) approach based on injections of multiple guide RNAs to study larval-onset developmental phenotypes for the zebrafish orthologues *osgep, tp53rk* and *tprkb*. Also by CRISPR/Cas9, we generated stable knockout (KO) zebrafish lines for *osgep* and *tprkb*. Survival curves were generated by monitoring larvae twice a day until reaching a steady state. The microcephaly phenotype was determined by measuring the head diameter to body length ratio (HD/BL-R).

Results: All gene specific groups in the acute KD show a significant reduction of HD/BL-R and long term survival compared to scrambled and uninjected controls for *osgep, tp53rk* and *tprkb*. Immunoblotting shows efficient KD of all 3 proteins in protein extracts from pooled zebrafish larvae. DNA damage response (DDR) is induced in the *osgep* group compared to controls. Stable zebrafish KO lines reproduce the microcephaly phenotype for *osgep* and *tprkb*. No larvae homozygous for truncating mutations survived for more than 15 days.

Conclusions: CRISPR/Cas9 zebrafish models of KEOPS protein defects partially reflect the human disease phenotype in GMS patients, including microcephaly and early mortality. Early death in zebrafish may mask a nephrotic phenotype. Acute CRISPR/Cas9 KD reproduces the early phenotype in stable KO lines and provides a viable alternative to morpholino KD. Our zebrafish models implicate DDR in the pathogenesis of KEOPS related GMS.

"Humanize" Zebrafish to Model Nephrotic Syndrome Weibin Zhou, Mi-Sun Lee, Sulochana Devi. *Pediatrics and Communicable Diseases, Univ of Michigan, Ann Arbor, MI.*

Background: Nephrotic syndrome (NS) is a disease characterized by proteinuria caused by disruption of the glomerular filtration barrier (GFB). The *NPHS1* gene encodes NEPHRIN, a protein component of the interpodocyte-spanning slit diaphragm essential for the normal GFB. Our objective is to study the function of *nephrin* mutations *in vivo* and model NS in zebrafish.

Methods: Zebrafish *nphs1* mutants were made using CRISPR targeted to exon 2 of *nphs1*. *nphs1* heterozygotes were crossed to obtain *nephrin* homozygotes for morphological and histological analyses. The pathogenic human NPHS1 mutations were introduced into zebrafish *nphs1* and specifically expressed in the podocytes of zebrafish.

Results: We have established two zebrafish *nphs1* mutant lines carrying 5 bp or 28 bp deletion that leads to ORF shifts and hence a premature stop-codon. Different from a previous report that morpholino-mediated knockdown of *nphs1* in zebrafish resulted in pericardial edema at 4 days post fertilization (dpf), these mutants did not show any morphological abnormality until after 5 dpf, when periorbital edema (POE) (similar to the phenotype seen in children with NS) was observed. The edematous phenotype become progressively severe and led to whole-body edema and lethality within two weeks of age. We generated transgenic fish expressing wild-type zebrafish *nphs1* in podocytes to rescue the edematous phenotype. We also generated transgenic fish to model two new NPHS1 mutations discovered in NS patients (p.Asp105Asn and (p.Tyr638Cys) to demonstrate their functional consequences *in vivo*.

Conclusions: The zebrafish *nphs1* mutants generated by CRISPR genome editing avoid the possible off-target effect by morpholino-mediated knockdown and thus demosntrate a more reliable and convicing nephrotic phenotype for zebrafish, which is consistent with that of the zebrafish model of inducible podocyte injury previously published by us. Given the efficiency of generating transgenic zebrafish, our new zebrafish model is potentially a useful platform to perform functional studies of pathogenic alleles for *nphs1* and other genes related to podocyte diseases. The "humanized" zebrafish model of NS will be used to screen for therapeutical compounds for this disease.

OSGEP and TP53RK, Two Novel Monogenic Causes of Steroid Resistant Nephrotic Syndrome, Interact with Components of the ARP2/3 Complex and Regulate Cell Migration David Schapiro,[1] Daniela A. Braun,[1] Jennifer A. Lawson,[1] Jia Rao,[1] Geraldine Mollet,[2,3] Olivier Gribouval,[2,3] Christelle Arrondel,[2,3] Weizhen Tan,[1] Tilman Jobst-Schwan,[1] Olivia Boyer,[2,3] Johanna Magdalena M. Schmidt,[1] Svjetlana Lovric,[1] Shazia Ashraf,[1] Shirlee Shril,[1] Martin Zenker,[4] Corinne Antignac,[2,3] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]INSERM, Laboratory of Hereditary Kidney Diseases, Paris, France; [3]Univ Paris Descartes, Sorbonne Paris Cite, Imagine Inst, Paris, France; [4]Inst of Human Genetics, Univ Hospital of Magdeburg, Magdeburg, Germany.*

Background: Steroid resistant nephrotic syndrome (SRNS), an inherited disease of the renal glomerular filter, is one of the most frequent causes of end-stage renal disease in childhood. We have recently identified mutations of *OSGEP* and *TP53RK*, two components of the highly conserved KEOPS complex, as novel monogenic causes of SRNS and microcephaly in humans. The role of the KEOPS complex in higher organisms is not well understood.

Methods: We generated human podocyte cell lines with stable knockdown of *OSGEP* and *TP53RK,* and examined the effect of loss-of-function of these genes on cytoskeletal architecture and cell migration using videomicroscopy.

Results: We show that knockdown of *OSGEP* and *TP53RK* impairs cell migration as well as lammelipodia formation in immortalized human podocytes. Both proteins show distinct localization to lammelipodia and co-localize with components of ARP2/3 complex in this compartment. Upon overexpression, OSGEP and TP53RK interact with four proteins of the ARP2/3 complex, which was confirmed with half-endogenous CoIP.

Conclusions: We have recently identified mutations of *OSGEP* and *TP53RK* as novel monogenic causes of SRNS. Here, we show that OSGEP and TP53RK interact with components of the ARP2/3 complex and that knockdown of these genes impairs cell migration, a well-established surrogate phenotype of SRNS. We thus show for the first time that the KEOPS complex may regulate cytoskeletal architecture and cell migration *via* ARP2/3 in human podocytes and that this might represent the pathogenic link between *OSGEP* and *TP53RK* mutations and SRNS in humans.

Background: Steroid resistant nephrotic syndrome (SRNS) is the second most frequent cause of end-stage renal disease in the first 3 decades of life. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis.

Methods: We combined homozygosity mapping with whole exome sequencing (WES) in 100 families with SRNS. To identify additional mutations, we screened a cohort of ~800 individuals with SRNS by microfluidic multiplex PCR and next generation sequencing.

Results: By WES and next generation sequencing, we identified 4 recessive mutations of the *advillin* (*AVIL*) gene in three unrelated families with SRNS.A homozygous missense mutation in *AVIL* was found in an individual of consanguineous parents with SRNS, deafness, cataracts, microcephaly, mental retardation. The other two individuals had compound heterozygous mutations in *AVIL*. AVIL is a member of the gelsolin superfamily of actin binding proteins with 6 gelsolin domains. We show that AVIL localizes to WT1 positive podocytes in rat kidney. Molecular dynamics stimulations with enhanced sampling for changes of AVIL indicate that the two missense mutant alleles potentially influence the structure and therefore the function of AVIL. In human podocytes the truncating mutant allele of *AVIL* caused miscolocalization of F-actin. We identified PLCε1 and ARP2/3 as new interaction partners of advillin which regulate podocyte migration through the EGF-induced DAG signal pathway.

Conclusions: We identified recessive mutations of *AVIL* as a novel monogenetic cause of SRNS. Further genetic and functional studies will shed light on the pathogenic pathway involved.

Mutations in Genes Encoding Members of the KEOPS Complex Are a Novel Cause of Nephrotic Syndrome with Microcephaly Daniela A. Braun,[1] Jia Rao,[1] Geraldine Mollet,[2,3] Olivier Gribouval,[2,3] David Schapiro,[1] Christelle Arrondel,[2,3] Weizhen Tan,[1] Tilman Jobst-Schwan,[1] Olivia Boyer,[2,3] Johanna Magdalena M. Schmidt,[1] Jennifer A. Lawson,[1] Svjetlana Lovric,[1] Shazia Ashraf,[1] Shirlee Shril,[1] Martin Zenker,[4] Corinne Antignac,[2,3] Friedhelm Hildebrandt.[1] *[1]Nephrology, Boston Children's Hospital, Boston, MA; [2]Laboratory of Hereditary Kidney Diseases, INSERM, Paris, France; [3]Imagine Inst, Univ Paris Descartes, Paris, France; [4]Inst of Human Genetics, Univ Hospital of Magdeburg, Magdeburg, Germany.*

Background: Galloway-Mowat syndrome (GMS) is an autosomal-recessive disorder that manifests with steroid-resistant nephrotic syndrome (SRNS) and severe developmental anomalies of the central nervous system. So far, mutations in the gene *WDR73* are the only identified monogenic disease cause.

Methods: To identify novel mongenic causes of GMS, we performed whole exome sequencing, homozygosity mapping, and targeted exon sequencing. To investigate molecular mechanisms of 4 newly identified GMS genes *in vitro*, we generated immortalized human podocyte cell lines with stable knockdown of the genes of interest.

Results: By next-generation sequencing, we identified mutations of the genes *LAGE3, OSGEP, TP53RK,* and *TPRKB* that encode proteins of the evolutionary highly conserved KEOPS complex (Kinase, Endopeptidase and Other Proteins of Small size) in 31 families with microcephaly and childhood-onset nephrotic syndrome. We show that knockdown of *OSGEP, TP53RK,* and *TPRKB* results in severe proliferation defects, and upregulation of the CDK inhibitor p21 in human podocytes. To confirm pathogenicty of the idenitified alleles, we show that wildtype but not mutant constructs rescue the proliferation deficiency. Furthermore, knockdown of *OSGEP, TP53RK,* and *TPRKB* increased phosphorylation of γH2AX as an indicator of activated DNA damage response signaling, and ultimately resulted in apoptotic cell death.

Conclusions: We here identified recessive mutations of all four members of the KEOPS complex, i.e. *LAGE3, OSGEP, TP53RK,* and *TPRKB* as novel monogenic causes of GMS. We generate evidence that the disease phenotype is caused by defects in cell proliferation, accumulation of DNA damage, and induction of apoptosisupon loss-of-function of *OSGEP*, *TP53RK*, and *TPRKB*.

Applying the Drosophila Garland Cell Nephrocyte to Model Mechanisms of Monogenic Forms of Human Nephrotic Syndrome Tobias F. Hermle, Daniela A. Braun, Friedhelm Hildebrandt. *Nephrology, Boston Children's Hospital/Harvard Medical School, Boston, MA.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is characterized by podocyte dysfunction. The Drosophila garland cell nephrocyte (GCN) is a podocyte-like cell that forms membrane invaginations bridged by autocellular slit diaphragms (SD). GCN represent a potential *in vivo* model to study the pathogenesis of SRNS. However, relevant pathomechanisms of SRNS such as interaction with the extracellular matrix (ECM) or CoQ_{10}-deficiency have not been studied in GCN.

Methods: RNAi and CRISPR/Cas9 in larval GCN, transmission electron microscopy, confocal imaging of immunostainings of SD-proteins and uptake of fluorescent tracers.

Results: Drosophila SD-proteins colocalize within a fingerprint-like staining pattern that correlates with ultrastructural morphology of SD. Using RNAi and conditional CRISPR/Cas9 in GCN we found this pattern to be mutually dependent on the orthologues of *NPHS1* and *KIRREL*. We show that tracer endocytosis occurs through Cubilin and also reflects size selectivity analogous to mammalian glomerular function. Thus we establish significant tools to study GCN. Using RNAi for gene silencing and tracer endocytosis as a read-out of GCN-function we screened 29 Drosophila orthologues of human monogenic causes of SRNS. Silencing of 15 genes mainly involved in the SD-complex, ECM-interaction, and CoQ_{10}-synthesis impaired GCN-function. This supports the usefulness of GCN to study SRNS pathogenesis. We focused on the CoQ_{10}-biosynthesis gene *Coq2,* whose silencing by RNAi we found to disrupt SD morphology and function. Restoration of CoQ_{10}-synthesis by vanillic acid resulted in partial rescue of the phenotype of *Coq2*-RNAi. We show that *Coq2* resides in mitochondria and *Coq2*-silencing increased formation of reactive oxygen species (ROS). We observed phenocopy of *Coq2*-RNAi by knockdown of *ND75,* a subunit of the mitochondrial respiratory chain complex that controls ROS formation CoQ_{10}-independently. Moreover, ROS scavenger glutathione partially rescued *Coq2*-RNAi.

Conclusions: Drosophila GCN represent a useful model to study the pathogenesis of SRNS, and our findings implicate ROS formation as a potential pathomechanism of *COQ2*-nephropathy.

Ctns Loss-of-Function Zebrafish Mutant Shows Early Larval Glomerular and Tubular Dysfunction: A New Animal Model for Nephropathic Cystinosis Mohamed A. Elmonem,[1,2] Ramzi Khalil,[3] Ladan Khodaparast,[4] Laleh Khodaparast,[4] Hans J. Baelde,[3] Lambertus P.W.J. Van den Heuvel,[1,5] Elena N. Levtchenko.[1] *[1]Pediatric Nephrology & Growth and Regeneration, Univ Hospitals Leuven, KU Leuven, Leuven, Belgium; [2]Clinical and Chemical Pathology, Faculty of Medicine, Cairo Univ, Cairo, Egypt; [3]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [4]Cellular and Molecular Medicine, Univ Hospitals Leuven, KU Leuven, Leuven, Belgium; [5]Pediatric Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: The human ubiquitous protein cystinosin is essential for transporting the amino acid cystine out of the lysosomal compartment into the cytosol. Pathogenic mutations of the coding gene *CTNS* lead to defective cystinosin function and the intralysosomal accumulation of cystine. kidneys are first affected with renal Fanconi syndrome; however, unless properly treated the diseases progresses rapidly towards end stage renal disease and multiple organ dysfunction. Animal models to study nephropathic cystinosis are limited, with only a *Ctns*-knockout mouse reported, showing cystine accumulation and signs of tubular dysfunction but lacking the early glomerular phenotype.

Methods: In our study we used a morpholino injected knock-out model (MO) and established a stable model ($ctns^{-/-}$) with a homozygous nonsense mutation in exon 8 of the zebrafish *ctns* gene. We evaluated early development, morphology, motor activity and cystine levels in mutant larvae. We further investigated the glomerular and tubular renal functional involvement.

Results: $ctns^{-/-}$ mutant larvae showed cystine accumulation, delayed development, signs of glomerular and tubular proteinuria and significantly reduced glomerular filtration rate, which closely resemble the early phenotype observed in cystinotic patients. Furthermore, $ctns^{-/-}$ larvae showed a gradual and significant decrease in cystine levels when treated with increasing concentrations of cysteamine, the only available cystine depleting therapy for human patients.

Conclusions: Taken together, Our Ctns loss-of-function zebrafish mutant seems like a suitable animal model for studying the mechanisms involved in the pathogenesis of the disease and for the experimentation of potential new therapeutic agents.

Early Induction of MMCP-4 in Podocytes May Underlie Endothelin-1 Activation in Alport Glomeruli Dominic E. Cosgrove, Daniel T. Meehan, Brianna M. Dufek, Duane C. Delimont. *Genetics, Boys Town National Research Hospital, Omaha, NE.*

Background: We recently showed that active endothelin-1 protein, but not mRNA, is elevated in glomeruli and urine of pre-proteinuric Alport mice. In this same study we showed that endothelin-1 activation of endothelin A receptors plays a key role in the initiation of glomerular pathogenesis in this same model. The mechanism underlying elevated active endothelin-1 peptide was unclear. Here we show induction of the murine homologue of human chymase, mast cell protease-4 (mMCP-4) in podocytes of pre-proteinuric Alport mice. mMCP-4 processes big endothelin to the active peptide, and is thus as a likely candidate for elevated endothelin-1 in Alport glomeruli.

Methods: Isolated glomeruli from (pre-proteinuric) 2 week-old 129 Sv autosomal Alport mice and 7 week old C57Bl/6 X-linked Alport mice and wild type littermates were analyzed by real time RT-PCR and by western blot for mMCP-4 mRNA and protein. Cryosections from these same mice were analyzed by immunofluorescence for mMCP-4 expression. Glomerular podocyte, endothelial, and mesangial cell lines were analyzed for mMCP-4 mRNA expression.

Results: mMCP-4 mRNA and protein were significantly elevated in glomeruli from both the autosomal and X-linked Alport mouse models before the onset of proteinuria. The mMCP-4 protein localized to the podocyte foot processes and the GBM. Cultured podocytes and glomerular endothelial cells express mMCP-4 mRNA. Expression was not detected in cultured mesangial cells.

Conclusions: Elevated expression of mMCP-4 in pre-proteinuric Alport glomeruli may account for elevated active endothelin-1 at this same time-point. Drugs that block endothelin receptors are toxic. Targeting the protease that processes big endothelin-1 to active endothelin-1 might provide a less toxic alternative.

COL4A3/4/5-Sequencing by NGS in Chilean Alport Patients: Significant Applications in Diagnosis and Renal Transplant Paola Krall,[1] Daniela Paz Nualart,[1] Daniel Carpio,[2] Carolina Lavoz,[1] Sergio A. Mezzano.[1] *[1]Unidad de Nefrologia, Univ Austral de Chile, Valdivia, Region de los Rios, Chile; [2]Inst de Anatomia Patológica, Univ Austral de Chile, Valdivia, Region de los Rios, Chile.*

Background: Alport syndrome (AS) is an inherited kidney disease associated with mutations in COL4A3/4/5 genes. Altogether the three genes contain 151 exons turning genetic analysis by Sanger sequencing (SS) a challenge. NGS emerges as a cost-time-labor effective tool to identify mutations in benefit of AS patients and their families.

Methods: 7 Chilean males with AS clinical diagnosis were recruited; 6 of them were in dialysis and/or waiting for cadaveric donor transplantation. Genomic DNA was extracted

from blood samples and analyzed with the ALPORT MASTR kit covering COL4A3/4/5 in 149 amplicons, combined with Illumina MID barcodes and sequenced with MiSeq Reagent Kit (600c).

Results: 100% of exonic and exon-intron regions in COL4A3/4/5 were covered with more than 100x. Data analysis resulted in the identification of 345 SNV, which represent 86 different SNV. After filtering procedures, 6 different SNV were identified as "disease causing" (table 1) and confirmed by SS.

Case	Mutation	Protein prediction effect
#1	*COL4A5* (IVS36) c.3246 +1G>A	p.Pro1037TyrfsX560
#2	COL4A5 (IVS48) c.4688 +5G>A	p.Gly1504AspfsX11
#3	COL4A5 (EX9) c.525 T>A	p.Tyr175*
#4	COL4A3 (EX38) c.3270 A>C	p.Pro1090Pro
#5	COL4A3 (IVS15) c.888 +2T>C	p.aaΔ297-316
#6	COL4A3 (IVS15) c.888 +2T>C COL4A3 (EX3) c.172 G>A	p.aaΔ297-316 p.Gly58Ser
#7	-	-

In silico tools predicted truncating, missense, in-frame deletion and synonymous mutations. In case #1, skipping of exon 36 was observed by cDNA(RNA) sequencing in blood and hair root. Genetic analysis by SS of the mutated exon was offered to families.

Conclusions: NGS is being implemented worldwide as a very useful tool to identify mutations. To our knowledge, NGS has never been offered to AS patients in Chile. Our results allowed as to confirm diagnosis in 6 AS patients carrying different mutations. Additionally, we were able to identify three first-degree relatives as safe kidney donors, discard AS in one patient´s sister and provide early diagnosis in one patient´s son. FONDECYT #11140242.

Pathogenicity of the Human LamininB2 S80R Mutation Revealed by Its Impact on Alport Syndrome

Steven Daniel Funk, Jeffrey H. Miner. *Internal Medicine, Renal Div, Washington Univ, St. Louis, MO.*

Background: Mutations that affect the GBM component laminin β2 (LAMB2) cause either Pierson syndrome or isolated congenital nephrotic syndrome, depending on the severity of the mutation. We investigated the pathogenicity of LAMB2-S80R, a mutation reported as homozygous in a child with nephrotic range proteinuria, ocular abnormalities, and mild diffuse mesangial sclerosis, which are all features consistent with Pierson syndrome. LAMB2-S80R resides in the laminin polymerization domain and is predicted to affect GBM integrity.

Methods: *Lamb2*-/- mice were engineered to express a rat Lamb2-S80R transgene driven by the nephrin promoter (Neph-Lamb2-S80R) or mated to mice carrying the S80R point mutation that was knocked into *Lamb2* with CRISPR technology (*Lamb2*-S80RCr). To determine if the LAMB2-S80R mutation could exacerbate kidney disease in another GBM disease model, *Lamb2*-S80RCr mice were mated to *Col4a3*-/- Alport mice and analyzed for proteinuria and GBM defects.

Results: *Lamb2*-/- mice with uniform Neph-Lamb2-S80R expression or exclusively *Lamb2* S80RCr expression never showed signs of proteinuria up to ~1 year of age. Interestingly, the *Lamb2*-S80RCr allele exacerbated proteinuria in *Lamb2* S80RCr/+; *Col4a3*-/- mice, and all *Lamb2* S80RCr/+; *Col4a3*-/- mice reached ESRD at 36-63 days, earlier than *Lamb2*+/+; *Col4a3*-/- littermates and pure 129 *Col4a3*-/- mice (typically 75 to 90 days).

Conclusions: A lack of significant proteinuria in mice expressing only the LAMB2-S80R mutant protein was unexpected. This result could stem from an inherent difference between human and mouse laminin or GBM biology, a resistance to proteinuria in the mixed C57BL/6 x CBA strain background being used, or a lack of pathogenicity of the homozygous LAMB2-S80R point mutation despite the Pierson-like features of the patient. However, the enhanced proteinuria and reduced survival of Alport mice harboring just one Lamb2-S80RCr allele indicates that the LAMB2-S80R variant is pathogenic in the context of glomerular stress. Our results demonstrate the power of modelling specific human variants in mice and using genetic interactions to identify pathogenicity that would otherwise be missed.

Functional Assessment of a Novel COL4A5 Splice Region Mutation in an Alport Family

Andrew F. Malone, Steven Daniel Funk, Jeffrey H. Miner. *Nephrology Dept, Washington Univ School of Medicine, St. Louis, MO.*

Background: Alport syndrome is a hereditary disease caused by mutations in *COL4A5* in 85% of cases. Approximately 13% of variants described in Alport Syndrome patients are splice site or splice region variants. Many of these have not been validated as pathogenic by functional studies.

Methods: Targeted-exome sequencing was performed on the proband of a family with biopsy-confirmed Alport syndrome. Sanger sequencing was performed on all affected family members and married-in individuals. In silico splicing analyses and an in vitro splicing reporter minigene assay were used to assess the functional consequences of the *COL4A5* variant discovered in this family.

Results: Our family is a 3 generational family with X-linked Alport Syndrome. There are no extra-renal manifestations of disease in this family. Targeted-exome sequencing revealed a novel splice region variant, c.1780-6T>G, in *COL4A5*. There were no other pathogenic variants found in *COL4 genes*. This variant was confirmed by Sanger sequencing and segregated with disease. Different in silico models were inconsistent with respect to the likely impact of the variant on splicing. However, the splicing reporter minigene assay clearly showed that c.1780-6T>G causes frequent skipping of exon 25. Skipping of exon 25 appeared incomplete, as the variant minigene assay showed some properly spliced transcript (exon 25 retained).

Conclusions: We identified a novel splice region variant in *COL4A5* in a family with X-linked Alport Syndrome. We confirmed that this variant causes frequent but incomplete skipping of the downstream exon 25. We hypothesize that the variable expression of normal and abnormal transcripts may explain phenotypic variation within this family.

Appropriate Use of a Rapid Genetic Assay to Confirm the Diagnosis of Complement-Mediated Thrombotic Microangiopathy

Jan C. Hofmann. *Dept of Medicine, California Pacific Medical Center, San Francisco, CA.*

Background: Improved diagnostic tests and greater understanding of thrombotic microangiopathy (TMA) have led to rapid differentiation of various types of TMAs. Availability of "Next-Gen" aHUS genetic testing (GT) allowing rapid detection (2-5 days) of >230 known or suspected polymorphisms possibly associated with aHUS, including 12 common mutations, (sensitivity ~70%) has enabled faster assessment of TMA cases.

Methods: From 4/14-4/16, we evaluated 124 patients (pts) with TMA. 86/124 (69%) pts had TTP (ADAMTS13 activity <5%), 9/124 (7%) pts had shiga-toxin ecoli (STEC) HUS, and 29/124 (24%) pts had neither. TTP pts presented with (p/w) mean platelet count (plt ct) 14 x 10^9/L (5-27 x 10^9/L), LDH 2816 U/L (844-5213), creatinine (Cr) 0.9 mg/dl (0.5-2.2); 32/86 (37%) had CNS abnormalities (abn), 9/86 (10%) had renal insufficiency (RI) (Cr>1.5). STEC HUS pts p/w mean plt ct 44 x 10^9/L (33-57 x 10^9/L), LDH 567 (390-694), Cr 3.1 (2.6-4.1); 2/9 (22%) had CNS abn, 9/9 (100%) had RI. Non-TTP/non-STEC TMA (TMA) pts p/w mean plt ct 59 x 10^9/L (18-153 x 10^9/L), LDH 827 (457-1336), Cr 4.3 (2.0-17.7), and ADAMTS13 of 78% (15-130%); 9/29 (31%) had CNS abn, 27/29 (93%) had RI.

Results: TTP pts received mean 14.8 plasma exchange (PE) treatments (txs) (5-43 txs); 63/86 (73%) received rituximab. STEC HUS pts received supportive care, including mean 5.3 PE txs (4-7). TMA pts received mean 6.1 PE txs (0-13); 17/29 (59%) required hemodialysis, 6/29 (21%) had RI which resolved. 14/29 (48%) TMA pts with unexplained, persistent RI received aHUS GT; 15/29 (52%) pts did not get aHUS GT and were treated for assoc. conditions: sepsis/DIC (3 pts), SLE flare (3 pts), malignant HTN (3 pts), pre-eclampsia (2 pts); HIV TMA, gemcitabine-assoc. TMA, CAPS, and scleroderma renal crisis (1 pt each). 10/14 (71%) of aHUS GT were positive (CFH, CFI, C3, MCP, DGKE, thrombomodulin, or plasminogen genetic abn) or equivocal; 29% were negative. 11/14 (79%) pts received eculizumab.

Conclusions: With development of improved genetic testing (ie, increased speed and sensitivity), aHUS genetic assays may represent a "real-time" diagnostic tool enabling more rapid assessment of complex TMA cases.

TH-PO302

A Monogenic Cause in Half Cases of Autosomal Dominant FSGS

Olivia Boyer, Olivier Gribouval, Raphaelle Campait, Olivier Alibeu, Cecile Fourrage, Marie-Josèphe Tête, Aude Servais, Geraldine Mollet, Corinne Antignac. *Inserm U1163, Inst Imagine, Univ Paris Descartes, Centre de Référence MARHEA, Hôpital Necker-Enfants Malades, Assistance Publique-Hôpitaux de Paris (APHP), Paris, France.*

Background: The advent of next generation sequencing (NGS) has tremendously facilitated the genetic diagnosis in hereditary FSGS, and podocyte gene panels are increasingly used as the first step of genetic analyzes in familial cases.

Methods: We aimed to determine the causative gene mutations through Sanger sequencing and NGS in a large worldwide cohort of 140 families (253 patients) with FSGS starting during childhood or adulthood and an apparent autosomal dominant (AD) inheritance.

Results: Monogenic cause was identified in 67 families (48%). The mutation rate did not differ according to the size of pedigrees or the number of affected generations. The most prevalent gene mutations were the following: INF2 (20/67 families, 30%), COL4A3-5 (17/67, 25%), and WT1 (10/67, 15%). ACTN4 and TRPC6 mutations were detected in only 1 and 5 families (1.5% and 7.5%) respectively. An X-linked transmission was also possible in the 8 families with COL4A5 mutations and at least one affected relative had microscopic hematuria in 5/8, but no deafness was reported. Interestingly, we identified WT1 mutations in families with late-onset FSGS diagnosed at a median age of 19 years and no Wilm's tumor, including 3 pedigrees with fertile males who transmitted the mutation. Among the 60 different mutations identified, 30 were published pathogenic mutations (50%), 6 were novel truncating mutations (10%), 12 were novel missense variants in functional domains of the protein (20%) and 12 were predicted damaging missense variants (20%).

Conclusions: We conclude that 1) a high mutation rate is observed in families with AD-FSGS 2) isolated FSGS could result from mutations in collagen and developmental podocyte genes that should be included in all NGS diagnosis approaches to FSGS 3) a third of mutations are only probably pathogenic requiring further segregation/functional studies. This highlights the complexity of mutational analysis in identifying the true and nothing but the true pathogenic mutations in hereditary FSGS.

Funding: Government Support - Non-U.S.

TH-PO303

Novel TRPC6 Loss-of-Function Mutations Associated with FSGS Mario Kassmann,[1] Marc Riehle,[2] Anja K. Büscher,[3] Björn-Oliver Gohlke,[1] Jan H. Braesen,[4] Mato P. Nagel,[5] Jan U. Becker,[6] Peter F. Hoyer,[3] Robert Preissner,[1] Dietmar Krautwurst,[7] Maik Gollasch,[1] Christian Harteneck,[2] Stefanie Weber.[8] *[1]Experimental and Clinical Research Center (ECRC), Charité Univ Medicine Berlin, Berlin, Germany; [2]Eberhard Karls Univ Tubingen, Tubingen, Germany; [3]Univ of Duisburg-Essen, Essen, Germany; [4]Univ Hospital of Hannover, Hannover, Germany; [5]Center of Nephrology and Metabolism, Weisswasser, Germany; [6]Univ Hospital of Cologne, Cologne, Germany; [7]Deutsche Forschungsanstalt für Lebensmittelchemie, Molekulare Zellphysiologie und Chemorezeption, Freising, Germany; [8]Philipps-Univ Marburg, Marburg, Germany.*

Background: FSGS is a CKD with heavy proteinuria that eventually progresses to ESRD. Hereditary forms of FSGS have been linked to mutations in the transient receptor potential cation channel, subfamily C, member 6 (TRPC6) gene encoding a nonselective cation channel. Most of these TRPC6 mutations cause a gain-of-function phenotype, leading to calcium–triggered podocyte cell death, but the underlying molecular mechanisms are unclear.

Methods: We studied the molecular effect of disease-related mutations using tridimensional in silico modeling of tetrameric TRPC6. Our results indicated that G757 is localized in a domain forming a TRPC6-TRPC6 interface and predicted that the amino acid exchange G757D, a mutation which was found in FSGS-affected patients earlier, causes local steric hindrance and disruption of the channel complex. Notably, functional characterization of model interface domain mutants suggested a loss-of-function phenotype.

Results: Characterizing 19 human FSGS–related TRPC6 mutations by Ca2+-fluorescence measurements, we found that the majority caused gain-of-function mutations. However, five mutations (N125S, L395A, G757D, L780P, and R895L) caused a loss-of-function phenotype. For G757D and L780P these findings were confirmed by electrophysiology.

Conclusions: Our comprehensive analysis of human disease–causing TRPC6 mutations reveals loss of TRPC6 function as an additional concept of hereditary FSGS and provides molecular insights into the mechanism responsible for the loss-of-function phenotypes of TRPC6 G757D and L780P in humans.

The Prevalance of Fabry Disease in Patients with Chronic Kidney Disease in Turkey: The Results of Multicentric TURKFAB Study Kultigin Turkmen,[7] Aydin Guclu,[1] Garip Sahin,[2] Ismail Kocyigit,[3] Faruk Turgut,[4] Hilmi Umut Unal,[5] Cengizhan Açikel,[6] Mahmut Ilker Yilmaz,[5] Alberto Ortiz.[8] *[1]Nephrology, Kirsehir Ahi Evran Univ, Kirsehir, Turkey; [2]Nephrology, Eskisehir Univ, Eskisehir, Turkey; [3]Nephrology, Erciyes Univ, Kayseri, Turkey; [4]Nephrology, Mustafa Kemal Univ, Hatay, Turkey; [5]Nephrology, GATA Univ, Ankara, Turkey; [6]Epidemiology and Biostatistics, GATA Univ, Ankara, Turkey; [7]Nephrology, Necmettin Erbakan Univ, Konya, Turkey; [8]Nephrology, Unidad de Dialisis, HS-Fundaction Jimenez Diaz, U Automatica de Madrid, IRSIN, Madrid, Spain.*

Background: Fabry disease (FD) is a multisystemic X-linked disorder characterized by the accumulation of lysosomal globotriaosylceramide. In the literature, there has been no data regarding the prevalance of FD in Turkish CKD patients. We aimed to investigate the prevalance of FD in CKD population in Turkey.

Methods: This was a prospective study involving 313 stage 1-5 CKD patients not receiving hemodialysis or peritoneal dialysis. Patients with FD were confirmed by α-Gal A activity via DBS test and α-Gal A gene mutation analysis.

Results: Three patients among 313 CKD patients (0.95%) were identified as CKD patients with FD. After family screening of the 3 index patients, 11 patients (7male,4female) with CKD were diagnosed FD. Median age at onset of first symptoms of FD was lower in males compared to females (26years vs 38 years, respectively). The most frequent presenting symptoms in male patients were fatigue (100%), tinnitus (85%), acroparestesia (85%), vertigo (85%), hot intolerance (71%), abdominal pain (57%), cold intolarance (57%) The most frequent presenting symptoms in female FD patients were fatigue (50%), tinnitus (25%) and vertigo (25%). Male patients with FD had cornea verticillata (50%), cataract (25%), and angiokeratoma (25%). EM revealed Zebra bodies and miyeline figures. 6 male patients had started agalsidase-α, 1 male had started agalsidase-β along with previously prescribed RAS blockers. None of the female patients did not receive ERT. After six months of ERT, proteinuria significantly decreased in male patients.

Conclusions: FD was not uncommon among CKD patients in Turkey.

Multigene Panels Resolve Clinical Diagnosis for Multiple Inherited Kidney Disease Phenotypes in a Multidisciplinary Laboratory Service Andrew John Mallett,[1] Hugh J. Mccarthy,[2] Gladys Ho,[2] Amali Mallawaarachchi,[3] Chirag Patel,[1] Elizabeth Ann Farnsworth,[2] Cathy Quinlan,[4] Bruce Bennetts,[2] Stephen I. Alexander,[2] Katherine Jane Holman.[2] *[1]Royal Brisbane and Women's Hospital, Australia; [2]Children's Hospital Westmead, Australia; [3]Nepean Hospital, Australia; [4]Royal Children's Hospital, Australia.*

Background: Inherited kidney disease (IKD) spans a wide variety of phenotypes. Achieving genetic diagnosis is hypothetically feasible for many patients. The Australian Renal Gene Panels (ARGP) was established to realise this. Here we aim to describe its process and results (approval LNR/15/SCHN/505).

Methods: Consecutive patients (12/2013-03/2016) were referred for diagnostic genetic sequencing (10 multilane panels; 137 genes). DNA was sequenced (Illumina TruSightOne, HiSeq2500) and variants assessed with bioinformatic filters and a multidisciplinary team (MDT). Pathogenic variants were confirmed (Sanger). MLPA/microarray were utilized to identify copy number variants.

Results: 135 families (140 patients) were referred from all Australian states/territories. Probands were paediatric in 68/135 families (50%). Median/mean ages were 18/24yrs (IQR 33yrs, range 0-71yrs). 53% were female. Panels most requested were atypical haemolytic uraemia syndrome/C3 glomerulopathy (aHUS/C3GN, n=33), Alport Syndrome/thin basement membrane nephropathy (AS/TBMN n=27), nephrotic syndrome (NS, n=28), and nephronophthisis/related disorders (NPHP-RD, n=17). Pathogenic variants were confirmed in 58/135 families (43%). There was not a significant difference between paediatric and adult cohorts (31/68 vs 27/67, p0.53). The subcohorts with the greatest diagnostic rate were paediatric AS/TBMN (7/8, 88%), tubular (5/6, 83%) and adult AS/TBMN (15/19, 79%). Variants of uncertain significance (VOUS) were identified in an additional 22/135 (16%) families. Median age and gender proportion were similar between adults and children respectively with pathogenic, VOUS or negative results.

Conclusions: The diagnostic rate of this nephrogenetic service is 43% demonstrating the utility and cost-effectiveness of a MDT variant assessment approach. The absence of diagnostic rate difference between adults and children challenges dogma that such testing is less successful amongst adults.

TH-PO306

Whole Exome Sequencing in a Large International Cohort of 430 Pediatric Patients with Nephrotic Syndrome Jillian Kateri Warejko, Weizhen Tan, Svjetlana Lovric, Ankana Daga, Jia Rao, Shazia Ashraf, David Schapiro, Jennifer A. Lawson, Daniela A. Braun, Tobias F. Hermle, Tilman Jobst-Schwan, Eugen Widmeier, Shirlee Shril, Friedhelm Hildebrandt. *Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA.*

Background: Steroid resistant nephrotic syndrome (SRNS) inevitably progresses to end-stage renal disease, requiring dialysis or transplantation for survival. To date, more than 40 monogenic causes of SRNS have been identified. Prior work (Sadowski et al, *JASN*, 26, 2015, pp 1279-89.) with targeted panel sequencing has shown that approximately 30% of cases of SRNS can be explained by a monogenic cause. However, panel sequencing can be limited by a high false positive rate and large numbers of Sanger sequencing required to confirm variants.

Methods: We therefore studied the underlying genetic cause of 382 patients from 295 families with nephrotic syndrome (NS) by employing whole exome sequencing (WES).

Results: Samples were recruited from April, 1998 to July, 2015 (17 years). WES was performed at the Yale Center of Mendelian Genomics. By using a candidate gene approach, we examined the sequenced exome data for mutations in 40 genes known to cause proteinuria and SRNS. During the time frame of the study, 10 of these genes were identified, characterized, and published by our laboratory. In 99/382 individuals (26.1%), we identified mutations in 27 of the known genes with this approach. There were also 8 genes that were identified as phenocopies of SRNS. In addition to an overall molecular solving rate of 26.1% of cases, we recapitulated what has been previously published with a 39% solve rate in consanguineous individuals and 15.5% solve rate in non-consanguineous individuals (Sadowski 2015).

Conclusions: This study confirms that ~26% of families with NS in our cohort are due to monogenic causes. WES is a viable and now cost-effective way to diagnose the underlying cause of NS in children. With our candidate gene approach, our report is the largest and most in-depth study of monogenic causes of NS in children using WES to date.

Whole Exome Sequencing of 121 Unrelated CAKUT Patients Identifies Novel Pathogenic Variants in Kidney Development Genes and in Genes Previously Not Associated with CAKUT Madhurima Kaushal, Amy B. Wilfert, Donald Conrad, Sanjay Jain. *Washington Univ in Saint Louis.*

Background: Congenital anomalies of the kidneys or lower urinary tract (CAKUT) encompass a spectrum of more than 10 different kidney malformations and are collectively the biggest cause of renal failure in children. These are genetically heterogeneous disorders with high heritability. The prevailing view is that these are monogenic or single pathway disorders. While a number of CAKUT genes have been implicated from discoveries in animal models or large pedigrees (mainly outside the US) the pathogenic variations in these genes or novel causes are largely undefined in US cohorts. By drawing on concepts

and discoveries in mechanisms of early kidney development and resulting defects , we focused on CAKUT phenotypes that are more likely due to defects in UB induction, ureter maturation and branching morphogenesis.

Methods: We performed Whole Exome Sequencing using Illumina platform and 50Mb Agilent clinical exome kit on 121 unrelated CAKUT cases with renal agenesis, hypoplasia, dysplasia and ureter defects to identify pathogenic rare or novel variants.

Results: By first interrogating 81 genes implicated in kidney development or CAKUT we found pathogenic variants identified by at least 3 different tools in 28 of these 81 genes in 48 cases. Many of these variations occurred in key functional domains that explain the likely mechanisms of these defects. While the common polymorphism frequencies in CAKUT cases and public datasets were similar, there was significant difference in rare variants in our cases compared to controls. We then used an unbiased approach that combined the prediction tools above, survey of large public datasets including 1000 genome, ESP6500, and Population Sampling Probabilities or PSAP tool that ranks pathogenicity from variant data of > 60000 exomes in ExAC and found pathogenic variants in 24 novel genes in additional 22 cases with a PSAP probability <1E-05. The novel ones includes genes important in histone and tRNA modification and apoptotic signalling.

Conclusions: Our work provides one of the first reports of the exomic landscape of CAKUT cohort that informs on pathogenetic mechanisms and diagnosis of these disorders.

Exome Sequencing in Patients with Rhabdomyolysis Reveals Heterogeneous Single-Gene Etiology in 47% of Cases

Hadas Ityel,[1] Asaf Vivante,[1,2] Ben Pode Shakked,[2,3,4] Jing Chen,[1] Shirlee Shril,[1] Amelie van der Ven,[1] Nina Mann,[1] Johanna Magdalena M. Schmidt,[1] Yuval E. Landau,[4] Yair Anikster,[3,4] Friedhelm Hildebrandt.[1] *[1]Dept of Medicine, Boston Children's Hospital,Harvard Medical School, Boston, MA; [2]The Dr. Pinchas Borenstein Talpiot Medical Leadership Program, Sheba Medical Center, Tel-Hashomer, Israel; [3]Sackler Faculty of Medicine, Tel-Aviv Univ, Tel-Aviv, Israel; [4]Metabolic Disease Unit, Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Tel-Hashomer, Israel.*

Background: Rhabdomyolysis is a clinical emergency accounting for around 10% of all cases of acute kidney injury (AKI) in the US. Rhabdomyolysis can be acquired or due to single-gene causes. In the clinical setting, identifying the underlying molecular diagnosis is challenging, due to nonspecific presentation, high number of causative genes and lack of data regarding the prevalence of monogenic forms.

Methods: We employed whole exome sequencing (WES) to reveal the percentage of rhabdomyolysis cases that can be explained by single-gene mutations. We investigated a cohort of 19 unrelated families, in whom no underlying etiology was previously established.

Results: Using WES, we identified the causative mutation in nine of the 19 families (47%). We detected disease causing mutations in eight different known genes which can be grouped into the following categories: 1) disorders of glycogen metabolism (*PFKM* and *PGAM2*), 2) disorders of fatty acid metabolism (*CPT2*), 3) disorders of abnormal skeletal muscle relaxation and contraction (*RYR1*, *SCN4A*, *CACNA1S* and *MYH3*), and 4) disorders of purine metabolism (*AHCY*).

Conclusions: Our findings suggest a high prevalence for monogenic etiologies as well as broad genetic heterogeneity for rhabdomyolysis. This highlights the importance of molecular genetic diagnostics by WES of rhabdomyolysis to allow for personalized therapy. In addition, it helps establishing an etiologic diagnosis for an important subgroup of recurrent acute kidney injury.

Exome Sequencing Discerns Syndromes in Patients from Consanguineous Families with Congenital Anomalies of the Kidneys and Urinary Tract

Shirlee Shril,[1] Asaf Vivante,[1] Daw-Yang Hwang,[1] Stefan Kohl,[1] Jing Chen,[1] Julian Jakob Schulz,[1] Amelie van der Ven,[1] Ghaleb H. Daouk,[1] Neveen Soliman,[2] Velibor Tasic,[3] Friedhelm Hildebrandt.[1] *[1]Dept of Medicine, Boston Children's Hospital, Boston, MA; [2]Dept of Pediatrics, Kasr Al Ainy School of Medicine, Cairo Univ, Cairo, Egypt; [3]Medical Faculty Skopje, Univ Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the leading cause of CKD in children, featuring a broad variety of malformations. A monogenic cause can be detected in around 12% of patients. Nevertheless, in clinical practice, the genetic basis of most patients with CAKUT is elusive because of a very weak genotype-phenotype correlation.

Methods: To determine the likelihood of detecting causative recessive mutations, we performed whole exome sequencing (WES) and homozygosity mapping to identify such mutations that might also cause CAKUT. We screened and analyzed individuals with CAKUT from 33 different consanguineous families.

Results: Using homozygosity mapping and WES, we identified the causative mutations in nine of the 33 families studied (27%). We detected recessive mutations in nine known disease–causing genes: *ZBTB24*, *WFS1*, *HPSE2*, *ATRX*, *ASPH*, *AGXT*, *AQP2*, *CTNS*, and *PKHD1*. Notably, when mutated, these genes cause multiorgan syndromes that may include CAKUT as a feature (syndromic CAKUT) or cause renal diseases that may manifest as phenocopies of CAKUT. None of the above monogenic disease–causing genes were suspected on clinical grounds before this study. Follow-up clinical characterization of those patients allowed us to revise and detect relevant new clinical features in a more appropriate pathogenetic context.

Conclusions: Applying WES to the diagnostic approach in consanguineous families with CAKUT provides opportunities for an accurate and early etiology–based diagnosis and improved clinical management.

The Circadian Clock Provides Beneficial Effects against the Endothelial Dysfunction to Promote Atherogenesis by Regulating PDGF and TGF Generation

Hideyuki Negoro. *Medicine, Harvard Medical School, The Graduate School of Project Design, Tokyo, Japan.*

Background: The circadian clock is a molecular mechanism that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influencegrowth factors, such as platelet-derived growth factor (PDGF) and transforming growth factor (TGF)-β which play an important part in the progression of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of PDGF and TGF-β in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was an increase in PDGF and TGF-β expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include PDGF and TGF-β, which are significantly elevated in Bmal1 KO mice. We also confirmed that plasminogen activator inhibitor-1 and PDGF levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating PDGF and TGF-β generation. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

Therapeutic Restoration of Endothelial Glycocalyx in Sepsis

Jong Wook Song,[1] Joseph A. Zullo,[1] Matthew A. Dragovich,[2] X. Frank Zhang,[2] Michael S. Goligorsky.[1] *[1]New York Medical College, Valhalla, NY; [2]Lehigh Univ, Bethleham, PA.*

Background: Endothelial glycocalyx (EG) is disintegrated during sepsis. We (Zullo et al. Am J Pathol, 2016) showed that this occurs very early in the course of sepsis and its prevention improves survival of mice with sepsis. The goal of the present study was to investigate pharmacologic tools capable of accelerating the restoration of disintegrated EG in sepsis.

Methods: We used a soilage injection model to induce sepsis in C57/Bl6 mice. We measured total body EG by comparing the dilution curves of dextran-40 and dextran-500 and their subtraction approximated the volume of EG. *En face* aortic preparations were used for staining with antibodies against heparan sulfate (HS) and atomic force microscopy (AFM) was used in vitro to measure EG.

Results: In vitro studies conducted in cultured endothelial cells exposed to LPS showed a robust ability of HS, sulodexide [Alfa Wassermann S.p.A., Alanno (PE), Italy], or high-molecular weight hyaluronic acid (HA) to accelerate EG regeneration (immunofluorescence and AFM). In vitro studies revealed the potential for inhibitors of hyaluronidase (Hase) and heparanase (HEPase) to accelerate EG regeneration. We demonstrated through In vivo studies showed that total volume of EG in control mice averaged 57±24 um^3, whereas in septic mice it was reduced to 1±30 um^3 within 24 hours of sepsis. Administration of components of the EG such as HA or HS did not produce dramatic acceleration of EG restoration. When HA or HS were administered in combination with inhibitors of Hase and HERase, the restoration of EG was remarkably accelerated. Notably, a heparan-sulfate like compound resistant to HEPase degradation, sulodexide, demonstrated a remarkable capacity for regeneration in vitro and in vivo. This combined treatment instituted 24 hr after induction of severe sepsis was also associated with the improved animal survival.

Conclusions: 1) EG is disintegrated in sepsis, the event which contributes to animal survival; 2) the process of endogenous restoration of EG is protracted; 3) pharmacologic acceleration of EG restoration can be achieved using the combination of hyaluronan and sulodexide with inhibitors of hyaluronidase and heparanase.

Thrombospondin-1 and Its Glycocalyx Binding Partners Are Enriched in Endothelial Microparticles Formed under High Glucose Conditions

Maddison Turner, Mercedes N. Munkonda, Shareef Akbari, Dylan Burger. *Kidney Research Centre, Ottawa Hospital Research Inst, Ottawa, ON, Canada.*

Background: Diabetes is typified by the development of endothelial dysfunction; an independent predictor of poor prognosis linked to renal and cardiovascular disease. Microparticles are small (0.1-1.0 μm) membrane vesicles secreted following cell stress/

injury. Our previous work has shown that endothelial microparticles (eMPs) are sensitive markers of vascular injury and shown that eMPs themselves promote endothelial injury. However the effect of high glucose and diabetes on eMPs is unclear.

Methods: eMPs were isolated by centrifugation from the media of cultured human umbilical vein endothelial cells treated with normal D-glucose (5.6 mM), 25 mM D-glucose, or L-glucose (osmotic control, 5.6 mM D-Glucose + 19.44 mM L-Glucose). eMP levels were then assessed by nanoparticle tracking analysis. To assess the protein composition of eMPs formed under each condition, eMP protein lysates were separated by SDS-Page and the tryptic digests were analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Relative differences in protein levels between the conditions were assessed by label-free spectral counting and candidate proteins were verified by Western blot analysis.

Results: MP formation increased following 24 hour treatment with D-glucose (25mM) compared to the normal D-glucose or osmotic controls (~3-fold, $P<0.05$). LC-MS/MS analysis identified 14,631 unique peptides and 220 independent proteins with at least 2 peptides per protein and an average sequence coverage of ~16%. Amongst the 10 proteins most highly enriched in high glucose eMPs were the pro-coagulant protein thrombospondin-1 (~4-fold increase vs normal glucose eMPs) and its glycocalyx binding partners Versican (~8-fold enrichment), Agrin (~5-fold), and Perlecan (~11-fold). These observations were confirmed via Western blot analysis.

Conclusions: In summary we show that high glucose increases the formation of eMPs and leads to alterations in their molecular composition including the enrichment in thrombospondin-1. Such alterations may contribute to the development of vascular and renal injury in diabetes.

TH-PO313

CD4+CD28- T-Cells Are Cytomegalovirus Specific Cytotoxic Endothelial Targeting Cells and Are Independently Associated with Increased Arterial Stiffness in Renal Disease Dimitrios Chanouzas, Lovesh Dyall, Michael Sagmeister, Charles Ferro, Paul Moss, Matthew David Morgan, Lorraine Harper. *Univ of Birmingham, UK.*

Background: CD4+CD28- T-cells have been linked to cardiovascular disease (CVD) in inflammatory conditions. We previously showed that in ANCA associated vasculitis (AAV) they are associated with mortality and are specific to Cytomegalovirus (CMV) seropositivity. Using AAV as a model, we sought to characterize these cells further and determine their contribution to arterial stiffness, an independent predictor of CVD.

Methods: Peripheral blood mononuclear cells from 53 CMV seropositive AAV patients with renal involvement in remission and 30 age-matched healthy volunteers (HV) were cultured overnight with CMV lysate and stained for surface and intracellular markers by flow cytometry. Pulse wave velocity (PWV) was measured using the Vicorder device.

Results: AAV patients had higher % of CD4+CD28- cells compared to HV (median 11.3%[IQR 3.4-19.8] vs 6.7%[2.3-8.9],p=0.02). In comparison to CD4+CD28+ cells, CD4+CD28- cells displayed a CXCR3+CCR6- Th1 phenotype (80.5%[65.0-89.8] vs 31.0%[25.0-35.4],p<0.01) and expressed the Th1 transcription factor T-bet (83.5%[47.5-89.9] vs 12.9%[4.7-22.2],p<0.01). They expressed endothelial receptors (CX3CR1+CD49d+CD11b+ 51.6%[42.7-64.4] vs 4.9%[1.7-6.3],p<0.01) and cytotoxic molecules (perforin+granzymeB+ 74.5%[63.5-92.7] vs 2.9%[1.8-5.4],p<0.01) at high levels and produced IFN-γ (21.2%[8.2-37.0] vs 0.7%[0.3-1.4],p<0.01) following CMV lysate stimulation compared to CD4+CD28+ cells. The CD4+CD28- % was independently linked to increased PWV in AAV after controlling for age, mean arterial pressure, proteinuria, CD4 count and CD8+CD28-% ($R^2$0.482, B=0.075[0.018-0.132],p=0.01).

Conclusions: CD4+CD28- cells are a CMV specific, cytotoxic, proinflammatory Th1 subset that possess endothelial targeting receptors and are independently associated with increased arterial stiffness in renal disease. In a linked clinical trial submitted for ASN 2016, we also show that blocking subclinical CMV reactivation in AAV led to a reduction in CD4+CD28- cells, implicating CMV as the driving force behind their expansion and offering novel therapeutic opportunities in inflammatory renal disease.

TH-PO314

Creation of the CD148-Specific TSP1 Fragment and Its Effects in Glomerular Endothelial Cells Keiko Takahashi, Rachel H. Kim, Katherine Sumarriva, Ray Mernaugh, Takamune Takahashi. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: CD148 is a transmembrane tyrosine phosphatase expressed in renal endothelium including glomerulus. Previous studies showed its role in negatively regulating cell growth and growth factor signaling. Furthermore, we recently found that thrombospondin-1 (TSP1) serves as a ligand for CD148 (PNAS 109:1985), then characterized its interaction and created the CD148-specific TSP1 fragment (148-TSP1) (PLoS One 11:e0154916). This study aimed to define its effects in glomerular endothelial cells (GECs).

Methods: Human GECs were treated with monomeric or trimeric 148-TSP1 fragments and its effects on GECs proliferation and tube formation were assessed. CD148 catalytic activity was measured by IP/PTP assay and oligomerization status was assessed by immunostaining. GEC growth factor signaling was assessed by Western or IP/Western using phospho-specific antibodies. The effect on angiogenesis was assessed by mouse sponge assay using VEGF as an inducer. Specificity of the effects was evaluated by CD148 knockdown or knockout (mice).

Results: Trimeric, but not monomeric, 148-TSP1 fragment; 1) increased CD148 catalytic activity with its accumulation on cell surface in GECs, although both forms bound to CD148 effectively, indicating CD148 oligomerization is required for this effect.; 2) dose-dependently inhibited GEC proliferation (~80%) and tube formation (~50%) in culture; 3) remarkably (~80%) suppressed VEGF angiogenesis *in vivo*. These effects were largely attenuated or abolished by CD148 knockdown or knockout (mice). Furthermore, the 148-TSP1 fragment reduced tyrosine phosphorylation of VEGFR2, HGFR, Tie2, ERK1/2, and Src pY529 in GECs, while it showed no effects for EphA2, FGFR, Akt, and Src pY416.

Conclusions: The trimeric 148-TSP1 fragment increases CD148 activity and inhibits GEC proliferation and tube formation in culture and angiogenesis *in vivo*. This fragment suppresses multiple growth factor signaling (VEGFR, HGFR, Tie2, ERK1/2) in GECs without altering Akt or Src activity. Given the fact that Akt cell survival signal is preserved, this agent and pathway may provide a new and safer strategy for inhibiting glomerular angiogenesis.

TH-PO315

Vascular Endothelial Growth Factor Augments Arginine Transport and Nitric Oxide Generation via a KDR Receptor Signaling Pathway Idit F. Schwartz, Moshe Shashar, Doron Schwartz. *Nephrology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.*

Background: Vascular endothelial growth factor (VEGF) is an endothelium-specific peptide that stimulates angiogenesis via two receptor tyrosine kinases, Flt-1 and KDR. Endothelial nitric oxide synthase (eNOS) plays a major role in VEGF signaling. Delivery of arginine to membrane bound eNOS by the cationic amino acid transporter-1 (CAT-1) has been shown to modulate eNOS activity. The current studies were designed to test the hypothesis that VEGF enhances eNOS activity via modulation of arginine transport by CAT-1.

Methods: Using radio-labeled arginine {[^{3}H] L-arginine} uptake was determined in HUVEC following incubation with VEGF with and without silencing the VEGF receptors Flt-1 or KDR. Subsequently, western blotting for CAT-1, PKCα, ERK 1/2, JNK, and their phosphorylated forms were performed. NO generation was measured by the Griess reaction.

Results: VEGF (50 and 100 ng/ml) significantly augmented endothelial arginine transport in a time dependent manner, an effect which was prevented by Sunitinib (2 μM), a multi targeted receptor tyrosine kinase inhibitor.

The increase in arginine transport velocities by VEGF was not affected by silencing Flt-1 while silencing KDR abrogated VEGF effect. Furthermore, incubating cells with 50 and 100 ng of VEGF for 30 minutes significantly augmented CAT-1 abundance. The expression of PKC-α, JNK, and ERK1/2 and their phosphorylated forms were unchanged following incubation of HUVEC with VEGF. The concentration of NO2/NO3 following incubation with VEGF was significantly higher than from untreated cells.

Conclusions: VEGF increases arginine transport via modulation of CAT-1 in endothelial cells. This effect is exclusively dependent on KDR rather than Flt-1.

Akt Signaling Modulates a Novel Transcription Factor to Promote the Re-Vascularization of Kidney Microvascular Endothelial Cells following Injury Lan Dang, Bryce Gordon Johnson, Graham Marsh, Ivan G. Gomez, Jeremy Stuart Duffield. *Cell Stress and Innate Immunity, Biogen, Cambridge, MA.*

Background: Acute kidney injury and chronic kidney disease are characterized by the progressive loss of kidney peritubular capillaries, which leads to local areas of hypoxia, induction of profibrotic responses, and ultimately the deterioration of renal functions. While many vascular beds have significant regenerative potential following tissue injury, the renal microvasculature fails to adequately regenerate. The unique property of the kidney microvasculature has prompted the investigation of new tissue-specific regulatory mechanisms that can provide new therapies for promoting re-vascularization following injury and thereby minimize the progression to chronic kidney disease.

Methods: We have developed new methods to isolate and study mouse and human Kidney Microvascular Endothelial Cells (KMVECs) *ex vivo*. Using *in vitro* and *ex vivo* assays that recapitulate features of angiogenesis, we demonstrated that both mouse and human derived KMVECs fail to generate new vascular sprouts in response to VEGF stimulation, compared to endothelial cells isolated from large vessel beds, such as Human Umbilical Vascular Endothelial Cells.

Results: Western blotting analysis showed that the PI3K/Akt pathway in KMVECs was severely attenuated in response to VEGF. PI3K/Akt signaling plays a critical role during endothelial invasion and sprouting and its activation is inhibited by the phosphatase PTEN. We observed that KMVECs treated with the PTEN inhibitor showed an increased capacity to invade and form new sprouts compared to the untreated control. Furthermore, we evaluated whether the inhibition of PTEN can ameliorate the re-vascularization capacity of KMVECs following ischemia re-perfusion injury in adult mice. Interestingly, PTEN inhibition greatly enhanced the capacity of KMVECs to form new blood vessels *in vivo,* as shown by the increase in vessel density.

Conclusions: These results provide critical insight into the role of the PI3K/Akt signaling pathway in regulating functional re-vascularization of injured kidneys to prevent progressive capillary regression and chronic kidney disease.

Increased Angiogenic Potential of Endothelial Cells Isolated from Patients with End-Stage Kidney Disease Using Combined Cell Therapy
Brooke M. Huuskes,[1] Peter G. Kerr,[2] Chrishan S. Samuel,[3] Sharon D. Ricardo.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Victoria, Australia; [2]Dept of Medicine, Monash Medical Centre and Monash Univ, Clayton, Victoria, Australia; [3]Dept of Pharmacology, Monash Univ, Clayton, Victoria, Australia.*

Background: We have recently shown that the administration of the anti-fibrotic hormone, relaxin (Rln) in combination with mesenchymal stem cells (MSCs) abrogates fibrosis in a model of obstructive nephropathy, yet their effect on revascularization is still to be elucidated. Endothelial progenitor cells (ECPs) play a key role in this process and it is known that patients on dialysis have reduced circulating EPCs. Therefore, enhancing angiogenic potential of end-stage kidney disease (ESKD) patients warrants investigation.

Methods: Mononuclear cells were isolated from patients with ESKD and control subjects. Colony forming units (CFU) were quantified and Dil-AC-LDL/lectin binding confirmed endothelial cell function. Endothelial lineage was determined using immunocytochemistry and confirmed with flow cytometry. Tube formation in matrigel was assessed over 6hours using live cell time-lapse microscopy in the presence of MSCs/Rln. Wound healing over 24hours and proliferative capacity with/without MSC or Rln further quantifed angiogenic potential. All assays were replicated and compared with primary human endothelial cells (HECs).

Results: Patient EPCs were positive for Dil-AC-LDL/lectin and had impaired CFU compared to controls. EPCs transitioned into mature endothelial cells as confirmed by morphology and positive immunolabelling for vWF, CD31 and VEGFR2. Flow cytometry identified CD34+CD31+KDR+CD45- cells confirming endothelial lineage. HECs cultured directly with MSCs and Rln had a significant increase in branch points and length in tube forming assays ($p<0.05$). Additionally, wound closure was accelerated ($p<0.01$) and proliferation capacity was increased ($p<0.05$) when combination therapy was used.

Conclusions: EPCs can be successfully isolated from patients with ESKD and matured into endothelial cells. Their angiogenic potential can be modulated and enhanced with MSCs and Rln, which may have implications in kidney revascularization after injury.

Funding: Government Support - Non-U.S.

Direct Evidence of Vascular Oxidative Stress and Inflammation in Chronic Kidney Disease
Kristen L. Nowak,[1] Wei Wang,[1] Laurel Thur,[1] Heather Farmer-Bailey,[1] Anna Jeanette Jovanovich,[1,2] Michel Chonchol.[1] *[1]Univ of Colorado Anschutz Medical Campus; [2]Denver VA Medical Center.*

Background: Chronic kidney disease (CKD) is associated with vascular dysfunction, as indicated by impaired vascular endothelial function and increased large-elastic artery stiffness. Vascular dysfunction in CKD is thought to be related to vascular oxidative stress and inflammation, but direct evidence is lacking.

Methods: We studied 21 patients (60±12 years) with stage 3-4 chronic kidney disease (CKD; mean estimate glomerular filtration rate (eGFR) 34±11 ml/min/1.73 m^2) and 15 healthy controls (42±4 years; eGFR 102±12 ml/min/1.73 m^2) and assessed brachial artery flow-mediated dilation (FMD_{BA}), aortic pulse-wave velocity (aPWV), and the carotid artery β-stiffness index. Vascular endothelial cells were collected from a peripheral vein and were available for analysis in 18 CKD patients and 11 controls. Vascular endothelial cell protein expression of the oxidant enzyme NADPH oxidase and pro-inflammatory cytokine interleukin-6 (IL-6) were measured using quantitative immunofluorescence.

Results: Consistent with previous evidence, FMD_{BA} was lower and aPWV and the β-stiffness index were higher in CKD patients ($p<0.01$) compared to healthy controls. Vascular oxidative stress was also higher in CKD patients, as indicated by greater endothelial cell protein expression of NADPH oxidase (0.94±0.06 vs. 0.80±0.08 [intensity relative to human umbilical vein endothelial cell (HUVEC) control; $p<0.001$). Vascular inflammation was also higher, as indicated by greater endothelial cell protein expression of IL-6 (0.87±0.06 vs. 0.66±0.05 [intensity vs. HUVEC control; $p<0.001$). These differences persisted after statistical correction for age ($p<0.001$). Participants with NADPH oxidase above the median had lower FMD_{BA} and higher aPWV and β-stiffness index compared to those below the median.

Conclusions: These results provide direct support for the hypothesis that endothelial oxidative stress and inflammation develop with CKD and are related to vascular dysfunction. Therapies targeting a reduction in oxidative stress and/or inflammation may improve vascular dysfunction in CKD.

Elevated Serum Platelet Microparticles Contribute to Aorta Endothelial Injury: A Potential New Mechanism for Atherosclerosis in Diabetes
Gui Hua Wang, Kun Ling Ma, Yang Zhang, Zebo Hu, Liang Liu. *Inst of Nephrology, Southeast Univ, Nan Jing City, JIang Su Province, China.*

Background: An early complication in diabetes is the development of endothelial dysfunction, characterized by altered endothelial cell function, impaired nitric oxide (NO) bioavailability and accelerated thrombosis. Platelet microparticles (PMPs) are arousing interest due to their pro-inflammatory effects. This study aimed to investigate the role of PMPs in aortic endothelial injury in diabetes.

Methods: Eight-week old male *Sprague-Dawley* rats were divided into three groups: nondiabetic rats (control), streptozotocin-induced diabetic rats (DM), and diabetic rats treated with Aspirin (DM+ Aspirin). The determination of PMPs was used by flow cytometry and confocal microscopy. The inflammatory cytokines released from PMPs was checked by protein microarray, immunohistochemical staining, or Western blot. The aortic endothelial injury was evaluated through determination of NO concentration, measuring the expression of endothelial nitric oxide synthase (eNOS), the change of glycocalyx and aortic endothelial permeabilityby electron microscopy, immunofluorescent staining and Western blot.

Results: Compared to the control, the serum level of PMPs increased significantly in DM rats, which was inhibited by Aspirin. Aspirin treatment decreased the production of inflammatory cytokines from serum PMPs and aorta. Using confocal microscopy, the enhanced interaction between PMPs and aortic endothelium was observed in DM rats, which was inhibited by Aspirin. Interestingly, the elevated PMPs and production of inflammatory cytokines from PMPs were correlated with the aortic endothelial injury by decreasing the NO excretion, the expression of eNOS, glycocalyx thickness and increasing endothelial permeability in DM rats. Decreased serum PMPs and production of inflammatory cytokines by Aspirin ameliorated the aortic endothelial injury compared to the DM group.

Conclusions: Elevated serum PMPs contribute to aorta endothelial injury through the release of inflammatory cytokines from PMPs, which accelerate the progression of atherosclerosis in diabetes.

TH-PO320

Myeloperoxidase and Altered Arginine Methylation Drive Chronic Kidney Disease Accelerated Atherosclerosis
Anna V. Mathew, Lixia Zeng, Jaeman Byun, Subramaniam Pennathur. *Internal Medicine-Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: Atherosclerosis is the leading cause of morbidity and mortality in chronic kidney disease (CKD) patients, but the underlying factors are not fully understood. In this study, we sought to determine the specific role of myeloperoxidase (MPO) mediated oxidative stress and the arginine -nitric oxide pathway in CKD accelerated atherosclerosis in a pathophysiologically relevant mouse model.

Methods: Male LDL receptor deficient mice were subjected to sham (CTL) or 5/6 nephrectomy (CKD) surgery and maintained on either low fat diet (LFD) or high fat diet (HFD) for up to 24 weeks. In addition to biological parameters, the extent of atherosclerosis was assessed at 24 weeks. Expression of MPO and its oxidation products 3-chlorotyrosine, 3-nitrotyrosine and *o,o'*-dityrosine were demonstrated using both immunohistochemistry and immunofluorescence and quantified using liquid chromatography / mass spectrometry (LC/MS). Targeted LC/MS was also utilized to profile the arginine metabolome.

Results: As anticipated, the CKD mice had significantly higher plasma creatinine, urea nitrogen, and intact parathyroid hormone while having lower hematocrit and body weight when compared to CTL mice. The CKD mice had similar blood pressure as CTL mice but had decreased cholesterol and triglycerides in the VLDL and LDL fractions. CKD mice on HFD had significantly increased aortic plaque area fraction compared to the CTL mice on similar diet. Additionally, CKD animals on HFD demonstrated increased MPO expression, and co-localization of macrophages, MPO and its specific oxidation products in the atherosclerotic lesions when compared to the CTL mice. Importantly, these modified aortic proteins were markedly elevated in the CKD HFD mice ($p<0.05$) when quantified by MS and consistent with increased MPO-mediated oxidation. Also, higher asymmetric dimethyl arginine (ADMA) levels in CKD mice correlated with atherosclerotic lesion area implicating altered arginine methylation and ADMA accumulation in these mice.

Conclusions: Together, these findings demonstrate the important role of macrophage derived MPO and its oxidants and altered arginine methylation in CKD accelerated atherosclerosis.

Scavenging of Lipid Aldehydes Lessens Kidney Injury-Driven Atherosclerosis
Yan Shen,[1] Sean Stephen Davies,[2] Macrae F. Linton,[2] Valentina Kon.[1] *[1]Pediatrics, Vanderbilt Univ Medical Center, Nashville, TN; [2]Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Chronic kidney disease (CKD) accelerates atherogenesis. Reactive aldehydes, including isoprostanes and isolevuglandins (IsoLG) are lipoxidation products carried by high density lipoprotein (HDL). These aldehydes promote cellular dysfunction underlying atherosclerosis and their levels are increased in CKD. We previously used aldehyde scavenger, eg., IsoLG scavenger - salicylamine (SAM)) to lessen lipoxidation-induced cytotoxicity and now investigate the impact of this treatment on kidney-injury driven acceleration of atherosclerosis.

Methods: 11 week old female apolipoprotein E-/- mice underwent 5/6 nephrectomy (sNx) or sham-operation (sham), then treatment with SAM (1g/L) or vehicle for 6 weeks. Extent and characteristics of atherosclerotic lesions were assessed; cultured THP-1 macrophages were used to examine effects of IsoLG modified HDL on macrophage inflammatory response.

Results: Compared to sham, sNx increased atherosclerosis. SAM reduced the atherosclerotic lesion area in sNx ($121100 \pm 18760 \mu m^2$ *vs* 217600 ± 19890 in sNx+vehicle, $P<0.01$), but had little effect in sham. Assessment of plaques revealed greater necrotic area in sNx than sham ($9.4 \pm 0.8\%$ *vs* 3.7 ± 1.2, $P<0.01$). SAM significantly lessened necrotic areas in sNx+SAM ($6.2 \pm 0.5\%$, $P<0.01$), and did not affect the macrophage area or collagen content of plaques. Amelioration in atherosclerosis in sNx was not accompanied by changes in body weight, blood pressure, serum cholesterol, triglycerides, or BUN. In vitro, compared

to significant dampening of LPS-induced macrophage cytokine (IL-6) response to normal HDL, oxidative modification of HDL with IsoLG caused significant amplification in the inflammatory response (2.22 ± 0.16*vs* 0.78 ± 0.27in normal HDL, P<0.05).

Conclusions: Aldehyde scavengers ameliorate renal injury-induced acceleration in atherosclerosis and reduce necrotic area in plaques.These benefits are independent of effects on blood pressure or renal function but are linked to HDL aldehyde modification of macrophage inflammatory cytokine response.

TH-PO322

Extracellular Nucleosomes, Markers of Cell Death, Are Elevated in End-Stage Renal Disease Independent of Circulating Microparticle-Associated Tissue Factor Trung Phan,[1] Ryan Mcmillan,[1] Amanda Walborn,[1] Debra Hoppensteadt,[1] Jawed Fareed,[1] Vinod K. Bansal.[2] *[1]Pathology, Loyola Univ Medical Center, Maywood, IL; [2]Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Background: Extracellular nucleosomes in plasma (PNs) are complexes of DNA and histones that are released during cell death. In acute kidney injury, there is an increased release of nucleosomes with decreased nucleosome clearance. Nucleosomes mediate inflammatory and thrombotic responses and could serve as biomarkers in chronic kidney diseases. Microparticle-associated tissue factor (MP-TF) are released during cell death and mediate thrombosis.

Methods: The concentrations of PNs in ESRD patients (n = 90) and healthy volunteers (n = 50) were measured using the Cell Death Detection ELISA PLUS assay (Roche Diagnostics, Mannheim, Germany). MP-TF levels were measured using the ZYMUPHEN MP-TF kit (Hyphen BioMed, Neuville-sur-Oise, France). The levels of both PNs and MP-TF were also correlated with WBCs, RBCs and platelets to determine their origin.

Results: In comparison to the plasma from healthy volunteers (6.74 ± 13.7 Arbitrary Units (AU)), the levels of PNs in ESRD patients were higher (15.5 ± 14.1 AU; $p < 0.0001$). Similarly, MP-TF levels were elevated in ESRD patients (3.00 ± 1.42 pg/mL; $p < 0.0001$) compared to normal (0.363 ± 0.263 pg/mL). There was no correlation between PNs and MP-TF in ESRD patients ($r = 0.077$; $p = 0.501$). Moreover, there was no correlation between PNs and platelets ($r = 0.067$; $p = 0.543$) and RBCs ($r = 0.083$; $p = 0.447$). However, the PNs showed a positive correlation with WBCs ($r = 0.223$; $p = 0.042$). There was no correlation between MP-TF and WBCs ($r = -0.057$; $p = 0.632$) and RBCs ($r = -0.042$; $p = 0.722$), but a positive correlation was observed between MP-TF and platelets ($r = 0.237$; $p = 0.042$).

Conclusions: PNs were elevated in ESRD patients, indicating an increased release of nucleosomes, suggesting increased cell death. The observed correlation between PNs and WBCs suggests that the detected PNs are derived from WBCs. A lack of correlation between PNs and MP-TF suggests that the MP-TF increase is independent of the pathogenesis responsible for abnormal PN generation in ESRD patients.

FGF-23/Klotho System and Inflammation in Atherosclerotic Disease Ernesto Martín, Javier Donate, José Cruz, Angel López-Castillo, Sergio Rodríguez, Purificación Cerro, Nayra Pérez-Delgado, Anabel Rodriguez, Virginia Dominguez, Carmen Mora, Juan F. Navarro-Gonzalez. *Univ Hospital Nuestra Señora de Candelaria (Santa Cruz de Tenerife).*

Background: Several studies have shown the cardiovascular implications of the FGF-23/Klotho system. The aim of this work was to characterize the relationship between FGF-23/Klotho system, atherosclerotic disease and the underlying inflammatory process.

Methods: Forty-five patients with atherosclerotic vascular disease and 17 healthy organ donors (control group) were included in this work. The mRNA expression levels of *KLOTHO*, *FGF-23*, *TNF-α*, *IL-6* and *IL-10* were measured in vascular tissue samples and peripheral blood mononuclear cells (PBMC). Serum levels of KLOTHO, FGF-23 and IL-6 were also determined.

Results: Regarding vascular expression, *FGF-23* transcript was not detected in any individual in the control group, whereas it was present in 29 subjects (64.4%) with atherosclerosic vascular disease. *KLOTHO mRNA* levels were significantly lower in atherosclerotic patients ($P<0.05$). Regarding inflammatory cytokines, atherosclerotic patients had a lower expression of *IL-10* ($P<0.05$), with no differences in *IL-6* and *TNF-α*. Concerning gene expression in PBMC, atherosclerotic subjects had significantly lower mRNA levels of *KLOTHO* ($P<0.0001$) and *IL-10* ($P<0.001$), with higher expression of *TNF-α* ($P<0.001$). There were no differences for *IL-6* or *ADAM-17*. Finally, serum concentrations of KLOTHO and IL-6 were significantly lower in the atherosclerotic group ($P <0.0001$ and $P <0.05$, respectively).

Conclusions: These results indicate a relationship between vascular atherosclerotic disease and the regulation of FGF-23/KLOTHO system. The lower expression levles of *KLOTHO* in vessels and PBMCs, as well as the reduced serum concentrations of this protein, point to the atherosclerotic disease as a state of KLOTHO deficiency. In addition, *FGF-23* expression in vessels from atherosclerotic patients as compared with the lack of FGF-23 expression in control subjects might suggest that vascular tissue affected by the atherogenic process is a potential extra-bone source of this factor.

TH-PO324

KLOTHO Expression in Different Vascular Territories and Its Relationship with Atherosclerosis Ernesto Martín, Javier Donate, Angel López-Castillo, Raúl Portas, Anabel Rodriguez, Sergio Rodríguez, Purificación Cerro, Nayra Pérez-Delgado, Carmen Mora, Juan F. Navarro-Gonzalez. *Univ Hospital Nuestra Señora de Candelaria (Santa Cruz de Tenerife).*

Background: The anti-aging factor Klotho has been related to protective effects on the vascular wall, while a decrease on its serum levels has been related with the presence and severity of coronary artery disease and an increased mortality in hemodialysis patients. The objectives of this study are (i) to determine the relationship between vascular expression of *KLOTHO* and the presence of atherosclerotic disease, and (ii) to assess potential differences in *KLOTHO* gene expression among different vascular territories.

Methods: Vascular tissue samples were collected from 44 patients with atherosclerotic disease under elective vascular surgery, and from 10 healthy organ donors (control group). Samples were obtained from different vascular territories: aorta (n=13), carotid (n=15) and femoral (n=16). *KLOTHO* gene expression levels were assessed by qPCR with TaqMan probes.

Results: In the overall group of patients with atherosclerotic disease, *KLOTHO* gene expression levels were significantly lower compared to healthy individuals [0.276 (-0,193 - 0.642) vs. 2.239 (0.017-2.756); $p<0.0001$]. Likewise, *KLOTHO* expression in every vascular territory was lower respect to controls (femoral, $p<0.05$; aorta and carotid, $p<0.01$). Within the group of patients affected of atherosclerosis, *KLOTHO* expression levels were significantly higher in the femoral territory respect to aorta [0,577 (0,29-0,93) vs. -0,053 (-0,17- 0,52); $p<0,01$] and to carotid [-0,234 (-0,46- 0,66); $p<0,01$], whereas there was no difference between the latter two regions.

Conclusions: The lower *KLOTHO* expression in patients with established vascular disease suggests a relationship between this factor and the pathophysiology of the atherosclerotic process. In addition, the differences observed in the expression of the *KLOTHO* gene among different vascular territories might suggest the existence of mechanisms of regulation dependent on the specific vascular territory.

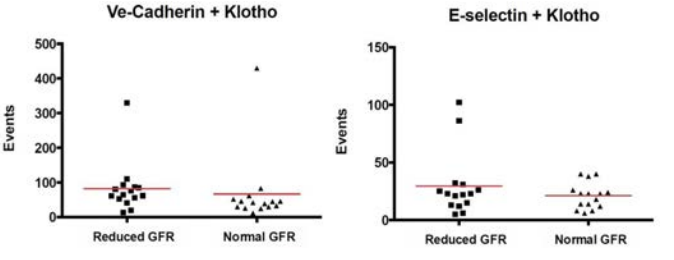
Expression of Klotho on Endothelial Derived Microparticles Josefin L.G. Mörtberg, Fariborz Mobarrez, Kristina Lundwall, Hakan Wallen, Stefan H. Jacobson, Jonas Spaak. *Dept of Clinical Sciences, Danderyd Hospital, Karolinska Inst, Stockholm, Sweden.*

Background: Klotho is mainly expressed in the renal tubules, but also exists in a soluble form, where reduction is associated with renal disease, increased oxidative stress, endothelial dysfunction, and diffuse vascular calcification. Overexpression of Klotho promotes cardiovascular and renal protection. Endothelial derived microparticles (EMP) is considered a micro-biopsy of the endothelium. We investigated wheter Klotho is found on endothelial cells in patients with myocardial infarction and renal failure, by measuring Endothelial derived microparticles.

Methods: Blood samples were collected from 30 patients (21 men, 9 women), after acute myocardial infarction. Patients were stratified according to renal function, above or below eGFR 60 ml. Cystatin C eGFR was 81±7 ml/min/m^2, and 34±14 respectively in the groups. EMP:s were detected with antibodies towards CD144 (VE-cadherin), and also towards CD62E (E-selectin), a cell adhesion molecule expressed on cytokine activated endothelium. Klotho was identified on endothelial cells using a KLH conjugated polyclonal IgG antibody against human Klotho. All samples were analyzed using a Beckman Coulter Gallios flow cytometer and microparticles were defined as particles less than 1.0 µm in size.

Results: Our result indicate that Klotho is exposed on endothelial cells and on cytokine-activated vascular endothelium, (figure 1) without significant correlation with kidney function. There was no significant correlations between Klotho EMP levels and CRP, phospate, urea, urate, calcium, or urinary albumine excretion levels.



Conclusions: Klotho is found on endothelial cells and on cytokine-activated vascular endothelium, but levels do not correlate with kidney function. Further studies are warranted to investigate whether endothelial cells express trans-membrane Klotho, or Klotho receptors for soluble klotho.

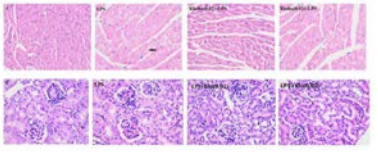
α-Klotho Alleviates LPS Induced Cardiorenal Syndrome Type 5 Chen Yu, Xi Liu. *Dept of Nephrology, Tongji Hospital, Tongji Univ School of Medicine, Shanghai, China.*

Background: Cardio-renal syndrome type 5occurs when an overwhelming insult leads to the simultaneous development of acute kidney injury and acute cardiac dysfunction. The α-klotho protein is a pleiotropic protein with a multitude of renal and extrarenal effects. Whether α-klotho can alleviate cardiorenal syndrome type 5is lack of research. We designed this study to study the effect and mechanism of α-klotho on cardiorenal syndrome type 5.

Methods: C57BL/6 micewere randomly assigned to following four groups: The CON group; the LPS group; the LPS+α-klotho (0.01mg/kg) group; and the LPS+α-klotho (0.02mg/kg) group. The dose of LPS is 10mg/Kg. Plasma creatinine, NGAL, BNP and troponin was measured at 24hours after LPS treatment, as same as myocardial apoptosis, inflammation, oxidation stress and endoplasmic reticulum stress levels.

Results: The result showed that Klotho gene was highly expressed in kidney but undetectable heart tissue. LPS induced the reduction of the klotho expression in kidney as early as 6 hours after LPS injection. The α-klotho protein (0.01~0.02mg/kg) reduced the levels of plasma creatinine, NGAL, BNP and troponin, and the protective effects were dose-dependent.

The α-klotho protein alleviates LPS induced cardiorenal syndrome type 5



α-klotho also reduced myocardial apoptosis and regulated the balance of proinflammation/anti-inflammation in both plasma and heart tissue. α-klotho reduced oxidative stress and increased endoplasmic reticulum stress level in myocardial tissue.

Conclusions: The α-klotho protein ameliorated the cardiac injury and renal injury in cardiorenal syndrome type 5 induced by LPS. The mechanism included reducing myocardial apoptosis and oxidative stress, regulating inflammatory cytokine and improving endoplasmic reticulum stress levels.

p66Shc Mediates ET-1 Induced Intracellular Calcium Mobilization in Renal Resistance Arteries Bradley S. Miller,[1] Oleg Palygin,[2] Alexander Staruschenko,[2] Andrey Sorokin.[1] *[1]Medicine Div of Nephrology, Cardiovascular Center, Medical College of Wisconsin, Milwaukee, WI; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Increased renal perfusion pressure activates renal autoregulation mediated in part by vasoconstriction of smooth muscle cells of preglomerular vessels, leading to reduction of blood flow to normal levels. The Dahl salt-sensitive (SS) rat model of hypertension is characterized by loss of renal vascular responsiveness upon increased dietary salt intake despite elevated levels of circulating Endothelin-1 (ET-1), a potent vasoconstrictor peptide. ET-1 mediates smooth muscle cell (SMC) contraction via elevated intracellular calcium signaling. In addition, ET-1 induction of p66Shc phosphorylation on serine 36 is essential for the promotion of mitochondrial oxidative stress, a potential factor in vascular dysfunction. The purpose of this study was to determine the role of p66Shc in ET-1 induced intracellular calcium mobilization in intact smooth muscle cells in isolated renal microvessels.

Methods: p66Shc knockout and p66Shc Ser36Ala substitution knock-in rats were generated on the SS genetic background using engineered Zinc Finger nucleases. Renal microvessels dissected from hypertensive WT SS rats and p66Shc mutant rat strains were loaded with calcium-sensitive fluorescent dye Fluo4-AM. Localization and quantification of calcium signaling was evaluated using two-photon excitation microscopy.

Results: We report that SMC, embedded in vascular wall of renal resistance arteries from p66Shc knockout rats, demonstrate an elevated level of intracellular calcium concentration in response to ET-1, when compared to SMC of renal resistance arteries isolated from wild type SS rats.

Conclusions: Our data suggest that the increased expression of p66Shc contributes to reduced vascular responsiveness which accompany the progression of salt-sensitive hypertension in SS rats through p66Shc-dependent modulation of intracellular calcium levels. It appears that p66Shc inhibitory effect occurs independently of its mitochondrial action. The p66Shc deficiency restores or enhances intracellular calcium levels, resulting in increased vascular response to ET-1.

TH-PO328

Cholecalciferol Supplementation Improves Vascular Function in Non-Diabetic Chronic Kidney Disease Patients with Vitamin D Deficiency: A Self-Controlled Study Ashok Kumar Yadav,[1] Vivek Kumar,[1] Manphool Singhal,[2] Vivekanand Jha.[1,3] *[1]Nephrology, PGIMER, Chandigarh, India; [2]Radiodiagnosis, PGIMER, Chandigarh, India; [3]George Inst for Global Health, New Delhi, India.*

Background: Vitamin D deficiency is common and associated with mortality in chronic kidney disease (CKD) patients. Its supplementation might improve endothelial and vascular function in patients with CKD. We studied the influence of vitamin D supplementation on vascular function and inflammatory biomarkers in patients with non-diabetic CKD stage 3-4 and vitamin D deficiency.

Methods: In this self-controlled study, 31 patients with non-diabetic stage 3-4 CKD and vitamin D deficiency [serum 25(OH)D levels <20 ng/ml] were assessed at 0, 16, and 32 weeks. All patients received directly observed cholecalciferol supplementation (300,000 I.U.) at 16 and 24 weeks. Endothelium dependent brachial artery flow mediated dilatation (FMD), pulse wave velocity (PWV) and circulating biomarkers were analyzed at 0, 16 and 32 weeks. The primary outcome was change in FMD at 16 and 32 weeks.

Results: 25(OH)D levels remained similar to baseline at 16 weeks but significantly increased at 32 weeks (13.0±5.4, 15.7±9.8 and 34.7±15.2 ng/ml at 0, 16 and 32 weeks, respectively, p<0.0001). FMD, PWV and biomarkers were similar at 0 and 16 weeks (table 1). However, after cholecalciferol supplementation at 16 and 24 weeks, FMD increased significantly at 32 weeks (p<0.0001). Similarly, significant changes in $1,25(OH)_2D$, IL-6, FGF-23 and PWV were seen at 32 weeks.

	Baseline	16 weeks	P value	32 weeks	P value
$1,25(OH)_2D$ (pg/ml)	22.3±13.9	21.4±20.2	0.974	40.1±18.9	**0.001**
iFGF-23 (pg/ml)	82.7±58.1	70.3±50.5	0.151	48.9±45.6	**0.005**
IL-6 (pg/ml)	5.5±5.8	5.0±4.0	0.653	3.3±2.5	**0.002**
E-selectin (ng/ml)	57.9±25.2	54.2±22.0	0.281	51.6±18.0	0.581
vWF (mU/ml)	1128±656	1076±379	0.689	1225±253	0.103
FMD (%)	7.6±2.3	8.0±2.7	0.231	13.8±4.3	**<0.0001**
PVW (ng/ml)	7.9±1.4	8.0±1.3	0.092	7.3±1.3	**0.005**

Conclusions: Cholecalciferol supplementation corrected vitamin D deficiency, improved FMD and PVW, and decreased serum levels of FGF-23 and IL-6 in subjects with non-diabetic CKD.

Funding: Government Support - Non-U.S.

TH-PO329

The Impact of Dietary Phosphate on Erectile Function in an Experimental Model of CKD Mandy E. Turner, Melanie Wilson, Cynthia M. Pruss, Emilie C. Ward, Paul S. Jeronimo, Bruno Svajger, Rachel M. Holden, Martin P. Petkovich, Michael A. Adams. *Biomedical and Molecular Sciences and Medicine, Queen's Univ, Kingston, ON, Canada.*

Background: CKD patients are at a markedly increased risk of CVD and CVD-related mortality. Phosphate dysregulation and pathological consequences, such as vascular calcification(VC), are key to this increased CVD risk. Erectile dysfunction(ED) is one of the earliest predictors CVD and ~80% of CKD patients self-report ED. Erectile function is a complex process dependent endothelial and vascular health, both of which are negatively impacted by phosphate. In a model of CKD, we sought to determine the impact of increased dietary phosphate on the development of ED and VC.

Methods: CKD was induced in male Sprague-Dawley rats(N=51, 15 wks) for 5 weeks using a 0.5% PO_4 0.25% adenine diet. They were then stratified by serum creatinine and phosphate in to either low(0.5%,N=14), medium(1%,N=13) or high (1.5%,N=15) phosphate diets for 3 weeks. ED was characterized using a pharmacological erectile bioassay (apomorphine 80ug/kg; no. of erectile responses(ER) per 30 min). Serum PTH, FGF23, creatinine, and phosphate were measured weekly. At sacrifice, vessels were harvested and calcium was measured. Urinary NO metabolites were measured in 10 animals.

Results: During the induction of CKD(0-5 wks), animals incurred a severe decline in erectile function (3.0±1.5 to 1.2±1.2 ER, p<0.001), while controls were constant. Serum phosphate was significantly elevated at week 3 despite low dietary phosphate. At week 5, the severity of ED was associated with higher serum phosphate but not with increased FGF23 or PTH. Increasing dietary phosphate (1.0, 1.5%) elevated serum phosphate, aortic and pudendal VC and decreased NO metabolites(p<0.05), however, there was no difference in ER between phosphate groups.

Conclusions: Increased serum phosphate was linked to early ED, however, increasing dietary phosphate at late stages of CKD did not have an impact on already declined erectile function. This occurred despite the higher phosphate diets worsening VC and markers of endothelial dysfunction. These results suggest that early interventions in CKD, possibly in phosphate, are more likely to impact ED.

Transcriptomic Analysis Reveals Molecular Mechanisms Underlying the Beneficial Effect of Lipoprotein-Apheresis (LA) in Blunting Atherosclerosis Progression in Familiar Hypercholesterolemia

Simona Simone,[1] Annarita Chieti,[1] Maria Grazia Zenti,[3] Matteo Accetturo,[1] Paola Pontrelli,[1] F. Rascio,[2] Gianluigi Zaza,[3] Antonio Lupo,[3] Loreto Gesualdo,[1] Giuseppe Grandaliano,[2] Giovanni B. Pertosa.[1] *[1]Univ of Bari; [2]Univ of Foggia; [3]Univ of Verona.*

Background: LA is a potentially valuable treatment applied to conventional therapy-resistant hypercholesterolemic patients. Several clinical studies suggest that LA may reduce the recurrence of cardiovascular events, but the molecular mechanisms underlying this effect are still unknown. The aim of the study was to identify the modulation of peripheral blood mononuclear cell (PBMC) transcriptomic profile induced by LA.

Methods: The transcriptomic profile was evaluated in PBMCs isolated from 6 FH patients before and after LA by Microarray (Agilent Technologies). The results were evaluated by statistical (Genespring software) and functional pathway analysis (Ingenuity Pathway Analysis, IPA). The transcriptomic data were validated by real-time PCR in an independent testing-group (n=10).

Results: Using a fold-change (FC)≥2, we demonstrated that LA modulates the expression of 240 genes. The top canonical pathways were: communication between innate and adaptive immune cells (p=.00004), natural killer cell signaling (p=.00004) and atherosclerosis signaling (p=.0003). Many pro-inflammatory cytokines involved inthe development and progression of the atherosclerotic process were significantly down-regulated: Interleukin 1 (IL-1 FC=-2.97), IL-6 (FC=-2.07), IL-8 (FC=-3.56) ed Amphiregulin (AREG FC=-3.5). Quantitative real-time PCR confirmed that IL-1 (-84%; p=0.0004) IL-6(-69%; p=0.01) IL-8 (-75%; 0.005) ed AREG (-96% p=0.0002) were down-regulated after LA.

Conclusions: Our data suggest that LA may contribute to cardiovascular risk reduction through the modulation of different pathways involved in the progression of atherosclerotic disease and improvement of microcirculation. This observation might open new perspectives in the prevention of cardiovascular risk in patients with FH.

Adipose-Derived Mesenchymal Stem Cells (MSCs) from Human Atherosclerotic Renovascular Disease (RVD) Have Increased DNA Damage and Lower Angiogenesis as Compared with Normal Kidney Donors That Can Be Modified by Hypoxia

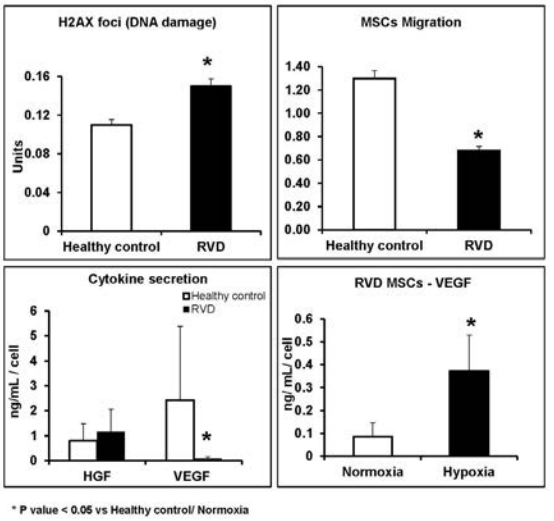
Ahmed Saad, Allan B. Dietz, Sandra Herrmann, LaTonya J. Hickson, Andre J. Van Wijnen, Lilach O. Lerman, Stephen C. Textor. *Mayo Clinic.*

Background: MSCs support angiogenic and immuno-modulatory processes. Whether these properties are modified in older patients with RVD is not known. Hypoxic conditions modify functional and growth characteristics of MSCs and may affect their role in ischemic kidney tissue. We tested the hypothesis that MSCs from RVD patients differ from MSCs from healthy kidney donors, and that hypoxia changes their functional and molecular properties to promote angiogenesis.

Methods: MSCs obtained from adipose tissue of 11 patients with RVD (age =74.5 ±3.9) and 10 healthy subjects (age= 51.2±16.7) cultured under normoxia (20% O_2) or hypoxia (1% O_2) for 3-4 days. Expression of genes and microRNAs analyzed using RNA-sequencing and rt-Quantitative PCR, H2AX and MSC migration using western blot. Secretion of VEGF and HGF was quantified in supernatant using ELISA, and apoptosis using Annexin-V flow cytometry.

Results: MSCs from RVD patients proliferated normally, but exhibited increased DNA damage and reduced migration. VEGF protein secretion was lower in RVD MSCs ($p< 0.05$) while HGF was slightly higher. Both patterns were reversed during growth under hypoxic conditions.

Figure



* P value < 0.05 vs Healthy control/ Normoxia

Hypoxia upregulated expression of pro-angiogenic mRNAs in MSCs (VEGF, FGF, STC and ANGPTL4) and downregulated expression of related miRNAs (e.g., miR-15a, miR-16, miR-93 and miR-424) whereas miR-210 was upregulated.

Conclusions: Adipose derived MSCs from older patients with RVD had more DNA damage and reduced migration and angiogenic properties, yet hypoxia stimulated pro-angiogenic responses by increasing expression of angiogenic genes and VEGF secretion. These data support a potential role for hypoxic preconditioning as a maneuver to enhance the angiogenic potency of MSCs in patients with RVD.

TH-PO332

Intraarterial Autologous Mesenchymal Stem Cells (MSC) Increase Renal Blood Flow and Preserve Kidney Function in Patients with Atherosclerotic Renovascular Disease (RVD)

Ahmed Saad, Sandra Herrmann, Alfonso Eirin, LaTonya J. Hickson, Michael A. Mckusick, Allan B. Dietz, Lilach O. Lerman, Stephen C. Textor, James Glockner, Andre J. Van Wijnen. *Mayo Clinic.*

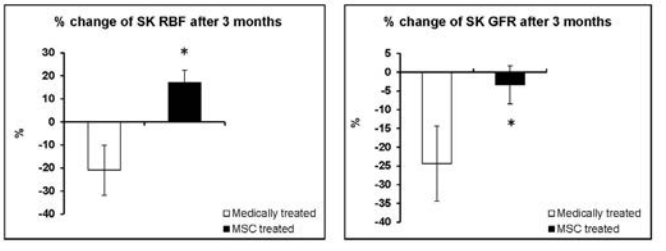
Background: Atherosclerotic RVD reduces renal blood flow (RBF), GFR and accelerates both hypertension and post-stenotic kidney (SK) tissue injury. Preclinical studies indicate that MSCs stimulate angiogenesis and modify immune function in experimental RVD. We tested the hypothesis that autologous MSCs would be safe and improve SK perfusion and function in a phase-I study of patients with RVD.

Methods: Adipose derived MSCs were collected from 14 RVD patients and expanded in platelet lysate media. Inpatient studies performed during fixed Na+ intake and ACE/ARB Rx before and 3 months after unilateral intra-arterial injection of 1.0-2.5 x 10^5/kg MSCs into the SK. Patients with RVD treated with standardized medical therapy alone (n=14), matched for age, severity of stenosis, and GFR, served as a control group. SK cortical perfusion and RBF were measured using multidetector CT, GFR by iothalamate clearance, and renal tissue oxygenation by BOLD-MRI at 3T.

Results: Age, GFR, and degree of stenosis did not differ between groups. MSC infusions were well-tolerated with no adverse effects. SK-RBF and cortical perfusion increased after 3 months ($p<0.05$). Fractional hypoxia (%R2*>30 sec-1) decreased in MSCs group. Iothalamate SK-GFR remained stable during 3 months after MSC, but fell in the control group.

	MSCs + Medical Rx (N=14)		*Medically Rx alone (N=14)*	
Age (years)	74.4 ± 3.4		71.1 ± 6.9	
Baseline iothalamate clearance GFR (mL/min)	51.2 ± 18.6		54.9 ± 20.4	
SK artery U/S Doppler velocity (cm/sec)	303.7 ± 64.5		331 ± 119.4	
Stenotic kidney	***Baseline***	***3 months***	***Baseline***	***3 months***
Cortical perfusion, mL/min/mL tissue	2.02 ± 0.69	2.4 ± 1*	2.1 ± 0.76	2.0 ± 0.53
RBF, mL/min	151.8 (63.7, 222)	185.5 (72.3, 259)*	132.5 (96, 255)	128.1 (77.2, 233)
Cortical flow, mL/min	125.6 (54.7, 192)	138.3 (60.3, 226)*	114 (75.7, 221)	106 (54, 186.3)
Medullary flow, mL/min	31(14.8, 38.9)	29.4(14.5, 36.9)	26.3(11.5, 42.3)	20.3(17.8, 36.4)
Renal hypoxia (% R2* > 30 sec^{-1})	12.1 (3.3, 17.8)	6.8 (1.8, 12.9)*	10 (6.3, 25.1)	9.6 (2.4, 37.7)

*P< 0.05 vs baseline (Wilcoxon signed-rank test). Values are presented as mean ± SD or median (IQR)



* P<0.05 vs Medically treated kidneys (Wilcoxon signed-rank test)

Conclusions: In this "first-in-man" study in 14 patients with atherosclerotic RVD, a single infusion of MSCs into the SK increased cortical perfusion and RBF after three months. Increased perfusion was associated with reduction in tissue hypoxia and preserved GFR. Our results demonstrate the capability of MSCs to improve oxygenation and RBF in the human kidney in-vivo and support a potential role for MSCs in the management of ischemic renal disease.

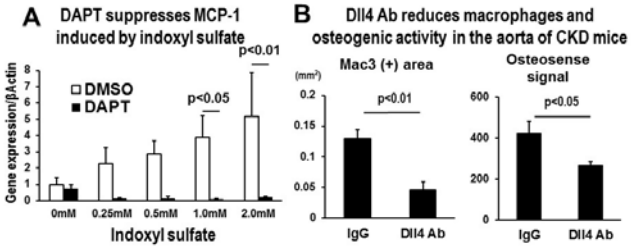
Notch Signaling Mediates Indoxyl Sulfate-Induced Atherogenesis in Chronic Kidney Disease

Toshiaki Nakano, Mingxian Chen, Diego Vinicius Santinelli Pestana, Shunsuke Katsuki, Elena Aikawa, Masanori Aikawa. *Dept of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: Chronic kidney disease (CKD) increases cardiovascular risk, however, the mechanisms of atherogenesis in CKD remain obscure. We previously demonstrated that the Notch signaling ligand Delta-like 4 (Dll4) promotes macrophage activation. We investigated the causal role of the Dll4-Notch pathway in vascular inflammation in CKD.

Methods: We examined pro-inflammatory effects of indoxyl sulfate in human primary macrophages and C57BL/6 mice. To evaluate the role of Notch signaling in atherogenesis in CKD, we performed 5/6 nephrectomy in high fat-fed LDL receptor-deficient (Ldlr-/-) mice and administered Dll4 neutralizing antibody (Ab) or control IgG for 19 weeks (n=13-14/group).

Results: [In vitro] In human macrophages, clinically relevant concentrations of indoxyl sulfate (0.5-1.0 mM) induced the expression of pro-inflammatory molecules IL-1β, TNFα, and MCP-1 and Notch-related genes (e.g., Dll4, Notch1, Hey2), which was suppressed by Notch inhibition with the γ-Secretase inhibitor DAPT (fig.A). [In vivo] Indoxyl sulfate administration in C57BL/6 mice (100mg/kg/day, 7 days) induced activation of peritoneal macrophages, which Dll4 Ab treatment suppressed. In Ldlr-/- mice, 5/6 nephrectomy induced IL-1β, IL-6, TNFα, and MCP-1 in splenic macrophages, and accelerated aortic atherosclerosis and calcification. Dll4 blockade reduced the size of atherosclerotic lesions and macrophage accumulation as compared to IgG treatment (fig.B). Dll4 Ab also suppressed aortic calcification as gauged by alkaline phosphatase activity and molecular imaging of osteogenic activity (OsteoSense, fig.B).



Conclusions: Dll4-Notch signaling mediates indoxyl sulfate-induced macrophage activation and promotes atherosclerotic plaque inflammation and calcification in CKD.

Atherosclerosis a Circulatory Disease: The Pivotal Role of Primed Neutrophils Eynav Kliger,[1,3] Shifra Sela,[1,3] Ronit Geron,[2,3] Galina Shapiro,[1] Batya Kristal.[2,3] *[1]Eliachar Research Laboratory, Galilee Medical Center, Nahariya, Israel; [2]Nephrology Dept, Galilee Medical Center, Nahariya, Israel; [3]Bar-Ilan Univ Faculty of Medicine in the Galilee, Safed, Israel.*

Background: Endothelial dysfunction and monocytes transmigration and differentiation underlie the development of atherosclerosis. Increased counts and priming of circulating neutrophils are associated with atherosclerosis however, the role of neutrophils in the accelerated atherosclerotic process of hemodialysis (HD) patients is still unclear. We hypothesize that atherosclerosis is a circulatory disease, where peripheral primed neutrophils activate monocytes and endothelium concomitantly, at the blood-tissue interface. Our aims were to examine monocytes transmigration through endothelial layer and their post-transmigration activation, induced ex-vivo by primed neutrophils, separated from HD patients.

Methods: A unique ex-vivo co-culture system of 3 cell types was developed in this study, enabling interactions among: primary endothelial cells (HUVEC), monocytes (THP-1, cell line) and in-vivo primed neutrophils from HD and Healthy Controls (HC), in order to mimic the initiation of the atherosclerotic process. The interactions among these cells were examined at the cellular, protein and gene expression levels.

Results: Pre-exposed HUVEC to HD/HC neutrophils showed a significant monocytes transmigration yield, 120-170% above HC. Monocyte exposure to HD neutrophils induced pre- and post-transmigration activation compared to HC. When the 3 cell types were co-cultivated at the same time, MCP-1 protein levels released from HUVEC, activation markers on HUVEC (CD54, CX3CL1) and monocytes (CX3CR1, CCR2) were increased. We have found that when the 3 cell types were co-cultivated with HD neutrophils at the same time, monocytes transmigration yield decreased to 70% (compared to HC) due to adherence and aggregation of monocytes to HUVEC.

Conclusions: We conclude that peripheral primed neutrophils play a pivotal role in the initiation of the atherosclerotic process suggesting atherosclerosis as a circulatory disease. Primed neutrophils can be used as a mediator and a biomarker of atherosclerosis even before plaque formation.

TH-PO335

Cardiac and Inflammatory Biomarkers and Their Role in the Pathogenesis of Heart Failure in ESRD Ryan Mcmillan,[1] Vinod K. Bansal,[2] Debra Hoppensteadt,[1] Jawed Fareed.[1] *[1]Pathology, Loyola Univ Medical Center, Maywood, IL; [2]Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Background: Heart failure (HF) is highly prevalent in patients with End-Stage Renal Disease with a presence of approximately 40 %. HF is characterized by left ventricular hypertrophy, diastolic and systolic left ventricular dysfunction and cardiomyopathy. The purpose of this study was to determine the role of cardiac and inflammatory biomarkers in the pathogenesis of HF in ESRD patients.

Methods: Blood samples from maintenance hemodialysis patients were collected and stored at -70° C. Fifty plasma samples from healthy individuals were used as control. These samples were used to profile KIM-1, NT-pro BNP, NGAL, IL-18, PDGF, Vitamin D, PTH, Endothelin, Endocan, MPTF, Heparin anti Xa, Lp(a) using commercial sandwich and competitive ELISA kits and assays (R&D Systems, Minneapolis, MN | RayBiotech, Norcross, GA | Hyphen Biomed, Neuville-sur-oise, France).

Results: All biomarkers, except PDGF, Endothelin and Vitamin D, were increased in ESRD compared to normal ($P < 0.05$). Vitamin D was decreased in patients with ESRD compared to normal ($P < 0.05$). HF patients with ESRD, as compared to non-HF patients with ESRD, had significantly elevated NT-pro-BNP ($P = 0.0194$ | % change = 52.9) and KIM-1 ($P = 0.0485$ | % change = 58.5%). There were no differences found between age groupings, except <60 y.o KIM-1 vs 60-69 y.o KIM-1. NT-pro-BNP in ESRD patients with HF was found to correlate with K+ ($P = 0.023$ | $R = -0.39$), Ca+ ($P = 0.029$| $R = -0.38$), and Heparin anti Xa ($P = 0.045$ | $R = 0.35$). KIM-1 in ESRD patients with HF was found to correlate with Creatinine ($P = 0.0175$ | $R = -.41$), EGFR ($P = 0.008$ | $R = 0.45$), Phosphate ($P = 0.002$ | $R = -0.51$), Intact PTH ($P = 0.043$ | $R = -0.36$), Calcium Phosphate Product ($P = 0.002$ | $R = -0.52$), and Vitamin D ($P = 0.037$ | $R = 0.36$).

Conclusions: Elevated plasma NT-pro-BNP and KIM-1 in all of the ESRD patients and ESRD patients with HF suggest that natriuretic peptides and KIM-1 may contribute to the pathogenesis of HF in ESRD patients. Elevated NT-pro-BNP further supports previous studies demonstrating NT-pro-BNP's potential diagnostic and prognostic utility.

TH-PO336

Glomerular Hyperfiltration Is Associated with Elevated Urinary Mitochondrial-DNA Copy Number in African American Hypertensive Patients Alfonso Eirin,[1] Ahmed Saad,[1] John R. Woollard,[1] Luis A. Juncos,[2] Hui Tang,[1] Amir Lerman,[1] Lilach O. Lerman.[1] *[1]Mayo Clinic; [2]Univ of Mississippi.*

Background: Glomerular hyperfiltration may contribute to the high incidence of renal disease in African Americans essential hypertensive (AAEH) patients, but the precise mechanisms responsible for renal injury have not been elucidated. Mitochondria are important determinants of renal injury in hypertension, and increased levels of mitochondrial DNA (mtDNA) in the urine may indicate renal mitochondrial injury. We hypothesized that urine mtDNA copy numbers would be higher in AAEH compared to Caucasian essential hypertensive (EH) patients.

Methods: We prospectively measured systemic and urinary copy number of the mtDNA genes COX3 and ND1 by quantitative-PCR in Caucasian EH and AAEH patients during constant sodium intake and anti-hypertensive regimens, and compared them with healthy volunteers (HV) (n=23 each). Urinary mtDNA levels were corrected to the nuclear control gene RNAse-P and expressed as mtDNA/nDNA to identify mitochondrial-specific cellular damage.

Results: Blood pressure was similarly elevated in EH and AAEH, yet body mass index (BMI) and estimated glomerular filtration rate (eGFR) were higher and age lower in AAEH versus HV and EH (Table). Urinary (but not plasma) COX3 and ND1 were higher in EH compared to HV, and further elevated in AAEH patients (Figure). In AAEH patients, urinary COX3 and ND1 directly correlated with eGFR. In multivariate analysis, eGFR remained the only predictor of elevated urinary COX3 and ND1 levels.

Conclusions: Urinary fragments of the mitochondrial genome are elevated in AAEH patients and correlate with glomerular hyperfiltration. These results are consistent with mitochondrial injury that may aggravate renal damage and accelerate hypertension-related morbidity/mortality rates in AAEH.

	HV	EH	AAEH

VE-PTP Inactivation Enhances TIE2-AKT-ENOS Signaling Lowering Blood Pressure and Elevating GFR Isabel Anna Carota,[1,2] Christina S. Bartlett,[1] Rizaldy P. Scott,[1] Sunday S. Oladipupo,[2] Yazan M. Alia,[1] Matthew D. Breyer,[2] Susan E. Quaggin.[1] *[1]Div of Nephrology,Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [2]Bio TDR, Eli Lilly & Co, Indianapolis, IN.*

Background: Chronic kidney disease affects 26 million Americans. Hence, discovery of novel therapeutic targets to slow its progression is urgently needed. Disruption of the angiopoietin-TIE2 signaling pathway occurs in CKD and is often associated with worsened outcomes in inflammatory diseases such as diabetic nephropathy and macular edema,

and sepsis. An imbalance between TIE2 ligands, specifically an increase in antagonistic ANGPT2 at the expense of agonistic ANGPT1 levels, is linked to vascular destabilization, leakage, and inflammation. We evaluated how augmentation of TIE2 activation, through genetic deletion of its inactivating phosphatase VE-PTP (PTPRB), affects renal function and blood pressure.

Methods: Using an inducible knockout mouse model, we induced deletion of VE-PTP in neonates and assessed potentiation of TIE2 autophosphorylation. Glomerular filtration rates (GFR) were determined by FITC-sinistrin clearance while blood pressure (BP) values were measured by tail cuff plethysmography. Nitric oxide production was reduced in mice by blocking the enzyme ENOS through a week-long administration on the drug L-NAME in drinking water.

Results: TIE2 phosphorylation is elevated in VE-PTP iKO mice versus control littermates. GFR increased 53.1±9% while systolic BP dropped 25±8% in VE-PTP iKO mutants relative to control cohorts. AKT and ENOS phosphorylation were also higher in VE-PTP iKO mutant kidneys suggesting that increased NO production might underlie altered GFR and BP. Consistently, L-NAME treatment normalized GFR and BP values in VE-PTP iKO mutants to wild-type control levels.

Conclusions: Genetic loss of VE-PTP causes increased TIE2 activity leading to sustained AKT-dependent ENOS signaling and eventual rise in circulating levels of NO. Loss of VE-PTP thus promotes vasodilation and vascular compliance resulting in lower BP and enhanced renal blood flow and glomerular filtration. Targeted inhibition of VE-PTP therefore holds promise in maintaining renal function in conditions such as CKD.

Novel Mechanism for Cardiovascular Protective Effect of Vitamin D and ACE-Inhibitors in Chronic Kidney Disease: Correction of Impaired Cholesterol Efflux Induced by Plasma from Patients with Chronic Kidney Disease Nobuyuki (Bill) Miyawaki, Nicolle Marie Siegart, Heather Anne Renna, Hirra A. Arain, Farah Daccueil, Joseph Mattana, Joshua De Leon, Allison B. Reiss. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

Background: In chronic kidney disease (CKD) and dialysis, ACE-inhibitors (ACEi) and Vitamin D (Vit D) reduce mortality/cardiovascular disease (CVD) risk while statins lose efficacy. Hence the atherosclerotic mechanism with advancing CKD likely differs from the general population. Macrophage lipid handling defect may be a pivotal proatherogenic factor in CKD. This study aims to detect changes in reverse cholesterol transport gene expression and foam cell accumulation in the setting of CKD in the presence and absence of Vit D or ACEi.

Methods: Following THP-1 human macrophage (10^6/ml) incubation for 24h with pooled plasma from 5 CKD Stage 4+5 patients or with control media ± Vit D (calcitriol, 10^{-8} M), or ACEi (enalapril, 50 μM), mRNA was isolated and reverse transcribed. The resulting cDNA was subjected to quantitative real-time PCR using specific primers for ATP binding cassette transporter (ABC)A1 and G1 (cholesterol efflux proteins). Foam cell quantification using Dil-acetylated-LDL with VectaShield mounting medium was used.

Results: CKD plasma suppressed ABCA1 in macrophages while concurrent Vit D restored ABCA1 mRNA, increasing it by 44±2.8% ($p<0.0001$). Concurrent exposure to CKD plasma + ACEi increased ABCA1 dramatically by 148±4.9% ($p<0.001$). ABCG1 expression did not increase (8±5.8%, nonsig) with Vit D, but increased 52±15% ($p<0.0001$) with ACEi. In control media, neither Vit D nor ACEi elicited significant response. In macrophages exposed to CKD plasma, foam cell accumulation decreased with addition of Vit D by 54±22% ($p<0.01$).

Conclusions: This is the first direct demonstration of an atheroprotective mechanism from Vit D and ACEi in the CKD milieu. ACEi and Vit D each promote cholesterol efflux with ACEi affecting ABCA1 and G1, while Vit D restored ABCA1 alone. Vit D reduced foam cell accumulation; ACEi study is planned. Further studies of mechanism, synergy of Vit D + ACEi and cholesterol handling in CKD are planned. This novel insight may define viable therapeutic targets.

Differential Role of Vascular Contractile Reactivity in Salt Wasting- and Salt Restriction-Induced Hypotension Saeed Alshahrani,[1,2] Robert Rapoport,[1] Manoocher Soleimani.[1,2] *[1]Pharmacology and Cell Biophysics, Univ of Cincinnati, Cincinnati, OH; [2]Nephrology and Hypertension, Univ of Cincinnati, Cincinnati, OH.*

Background: Although both salt wasting and salt restriction associated with Na-Cl-Co-transporter (NCC) dysfunction result in hypotension, whether decreased vascular contractility *per se* contributes to the hypotension in these models of volume depletion has not been entertained. This study investigated vascular contractility in mouse aorta in models of 1) sodium wasting due to double knockout (KO) of NCC and pendrin (the apical chloride/bicarbonate exchanger in B-intercalated cells) and 2) NCC KO with salt restricted diet, both of which are associated with hypotension.

Methods: To determine vascular contractility, aorta was removed from 8-12 months male and female mice, and 4-5 mm ring segments placed in an isometric contractile apparatus under optimal resting tension of 3 g-force. Vessels were then challenged with maximal or near maximal agonist concentrations.

Results: Maximal contraction of aorta segments to KCl and phenylephrine in the NCC/pendrin double KO compared to wild type were decreased by 30% and 55%, respectively. Sensitivity to these agents remained unaltered. In contrast, maximal contractions to KCl, and to phenylephrine, were similar in NCC KO with and without salt restricted diet and sensitivity also remained unchanged.

Conclusions: These findings suggest that decreased vasoreactivity associated with severe salt wasting contributes to the hypotension. The decreased reactivity occurs post receptor and does not involve membrane hyperpolarization.We suggest that compensatory vasoconstriction due to elevated circulating constrictors (angiotensin II) in response to hypovolemia may result in lowered amounts of contractile proteins while constrictor mechanisms remain intact. Lack of decreased vasoreactivity under conditions of NCC dysfunction and salt restriction reflect lower levels of circulating constrictor factors due to less severe hypotension and volume depletion.

TH-PO340

Role of AT1a Receptor in 2K1C Model of Renovascular Hypertension and Its Impact on Renal ACE2 and NEP Protein Expressions Nadja Grobe, Laale F. Alawi, Rucha Fadnavis, Khalid M. Elased. *Pharmacology & Toxicology, Wright State Univ, Dayton, OH.*

Background: Angiotensin (Ang) II is the major biologically active peptide of the renin angiotensin system (RAS). Elevated formation of Ang II contributes to initiation and progression of chronic kidney disease via its action as a vasoconstrictor through binding to the Ang II type 1 receptor (AT1R). Ang II is antagonized by the vasodilator Ang (1-7), partly generated by angiotensin converting enzyme 2 (ACE2) and neprilysin (NEP). The two-kidney, one clip (2K1C) Goldblatt model is an experimental approach designed to mimic renovascular hypertension. We tested the hypothesis that renovascular hypertension in the 2K1C model is mediated by AT1AR and investigated its role on renal ACE2 and NEP.

Methods: For blood pressure (BP) measurements, a radiotelemetric probe was inserted into the left carotid artery of $AT1_AR$ knockout (KO) and wild type (WT) mice. 2K1C was induced by constricting the left renal artery using a u-shaped silver clip leaving a 0.12 mm gap for ischemic blood flow. Histochemistry, Immunofluorescence, Western blot, and RAS enzyme assays were used to study renal histology, protein expression and activity.

Results: At baseline, BP was significantly lower in KO compared to WT (90.4± 8.4 mm Hg vs. 152.1± 5.9 mm Hg, $p<0.05$). BP measurements revealed a significant increase of 46.1±3.6 mm Hg in 2K1C WT compared to 2K1C KO (145.3 ± 12.9 mm Hg vs 92.3 ± 6.4 mmHg, $p<0.05$). Renal pathologies were exacerbated in the 2K1C model as revealed by a significant increase in mesangial expansion and renal fibrosis. Immunofluorescence demonstrated that ACE2 and NEP were mainly co-localized in the proximal and distal renal tubules. Western blot analysis showed renal ACE2 and NEP were significantly reduced in clipped 2K1C kidneys in both WT and KO compared to the unclipped kidneys or to sham controls. However, renal and urinary ACE2 activity was not altered by 2K1C.

Conclusions: Taken together, these results suggest that renovascular hypertension are mediated via $AT1_AR$, and that the receptor has no impact on the decreased expression of renal ACE2 and NEP in renovascular hypertension.

TH-PO341

Impact of Soluble Epoxide Hydrolase Inhibition on the Cardiovascular Consequences of Chronic Kidney Disease Dominique Guerrot,[1,2] Clothilde Roche,[2] Mouad Hamzaoui,[1,2] Valéry Brunel,[3] Vincent Richard,[2] Jeremy Bellien.[2] *[1]Nephrology, Rouen Univ Hospital, Rouen, France; [2]U1096, INSERM, Rouen, France; [3]Biochemistry, Rouen Univ Hospital, Rouen, France.*

Background: Cardiovascular (CV) events are the leading cause of morbi-mortality in chronic kidney disease (CKD). Epoxyeicosatrienoic acids (EETs) are endothelium-derived metabolites of arachidonic acid, with vasodilatory, anti-inflammatory, natriuretic and antiproliferative properties. The aim of this project is to study, in experimental CKD, the cardiac impact of the pharmacological inhibition of soluble epoxide hydrolase (sEH), which degrades EETs.

Methods: 129/Sv mice were subjected to 5/6 nephrectomy, and were assigned to t-AUCB, amiloride or placebo for 10 weeks. Echocardiography was performed before sacrifice. Hearts were weighed and histological analyses were performed to evaluate fibrosis. Vascular function was studied ex vivo on the mesenteric artery. Sequential blood and urine tests were performed to assess kidney function.

Results: Following 5/6 Nx, mice developed CKD. The CV consequences were heart hypertrophy (heart weight/tibia length Nx vs Sham 7.9±0.3 vs 6.5±0.5 mg/mm, $p<0.05$), diastolic dysfunction (E/A ratio Nx vs Sham 1.29±0.05 vs 0.97±0.04, $p<0.001$) and diffuse fibrosis (Nx vs Sham 57.8±8.8 vs 1.8±1.8 %, $p<0.001$). t-AUCB significantly prevented left ventricular hypertrophy (Nx t-AUCB 6.7±0.2 mg/mm, $p<0.05$ vs Nx), diastolic dysfunction (Nx t-AUCB 1.12±0.04 $p<0.05$ vs Nx), while effects on fibrosis were not significant. These effects were independent of plasma FGF-23 concentrations. No beneficial effects were present with amiloride. No vascular dysfunction was observed in our study.

Conclusions: Inhibition of sEH reduces the cardiac hypertrophy and diastolic dysfunction associated with CKD. These beneficial effects of inhibiting sEH hold a therapeutic potential in CKD patients to treat type 4 cardiorenal syndrome.

TH-PO342

Rats with Adenine-Induced Chronic Renal Failure Develop Left Ventricular Hypertrophy with Selective Diastolic Dysfunction Pavlos Kashioulis,[1] Emman Shubbar,[1] Lisa Nguy,[1,2] Cecilia W. Guron,[1] Gregor S. Guron.[1] *[1]Dept of Molecular and Clinical Medicine, Inst of Medicine; [2]Dept of Physiology, Inst of Neuroscience and Physiology, the Sahlgrenska Academy at the Univ of Gothenburg, Sweden.*

Background: Rats with adenine-induced chronic renal failure (ACRF) develop severe renal insufficiency and metabolic abnormalities characteristic of uremia. The aim of the present study was to analyze left ventricular (LV) morphology and function in rats with ACRF.

Methods: Male Sprague-Dawley rats received either chow containing adenine or were pair-fed an identical diet without adenine (controls, C). After 9 weeks rats were anesthetized with isoflurane and cardiac function was assessed by echocardiography. At 12-13 weeks isoflurane-anesthetized rats were instrumented for measurements of aortic and LV pressures.

Results: Rats with ACRF showed an increase in mean arterial pressure (115±6 vs. 106±7 mmHg, P<0.05) and LV weight (3.4±0.3 vs. 2.5±0.2 mg/kg, P<0.05) vs. controls. Rats with ACRF had reduced early diastolic tissue Doppler velocities, enlarged left atrial diameter (4.8 ±0.8 vs. 3.5±0.4 mm, P<0.05) but increased cardiac output (211±66 vs. 149±24 ml/min, P<0.05). LV end-diastolic pressure was elevated in ACRF rats (15±5 vs. 8±1 mmHg, P<0.01). In the LV of ACRF animals there were statistically significant (P<0.05) increases in cardiomyocyte diameter, proliferation and apoptosis vs. controls.

Conclusions: Rats with ACRF develop LV hypertrophy, increased cardiomyocyte apoptosis, and diastolic dysfunction with preserved systolic function. These cardiac abnormalities resemble those in uremic patients making this a promising animal model for future studies of uremic cardiomyopathy.

TH-PO343

Disruption of Angiopoietin-TIE2 Signaling Causes Cystic Kidney Disease Yael Kenig-Kozlovsky, Rizaldy P. Scott, Benjamin R. Thomson, Shinji Yamaguchi, Hyea Jin Gil, Christine Jiang Wu, Susan E. Quaggin. *Feinberg Cardiovascular Research Inst, Chicago, IL.*

Background: The angiopoietin ligands ANGPT1 and ANGPT2, and their cognate receptor TIE2 are well recognized for their important roles in the development and remodelling of blood and lymphatic vessels. In this study, we sought to determine how angiopoietin-TIE2 signaling regulates the development and organization of the complex renal vasculature. Surprisingly, we found that loss of ANGPT1 and ANGPT2, or TIE2 causes a rapid onset of cystic kidney disease.

Methods: Using a Cre-based inducible gene targeting strategy we deleted *Angpt1*, *Angpt2,* and *Tie2* at mid-gestation or postnatally in the mouse in order to overcome null mutant embryonic lethality.

Results: Compound ablation of *Angpt1* and *Angpt2*, or *Tie2* leads to a reduction of renal blood vascular density. Unexpectedly, mice lacking *Angpt1* and *Angpt2*, or *Tie2* develop renal cysts evident early as P10. These cysts are lined by myofibroblast-like cells. Cysts do not express epithelial, endothelial, or lymphatic markers. Vascular-specific deletion of these genes postnatally (P1-P3) does not lead to cysts suggesting that TIE2 signaling within late gestation is likely mitigating abnormal vascular development and cysts if perturbed. While investigating the lymphatic vasculature in the kidney using Prox1 reporter mice we discovered novel "hybrid" vessels that co-express lymphatic (Prox1) and blood vessel (CD31, CD34) markers, but not other classic lymphatic markers like Lyve1 and podoplanin.

Conclusions: Inactivation of ANGPT-TIE2 signaling affects the gross architecture and density of the renal vasculature, and a subsequent emergence of renal cysts. Newly identified novel hybrid vascular bundles in the kidney raises the question of whether such vessels are deficient, in a manner reminiscent of Schlemm's canal defects in the eye, when ANGPT-TIE2 signaling is absent. These findings highlight a hitherto unidentified link between attenuated angiopoietin-TIE2 signaling and the pathogenesis of renal cysts suggesting a potential therapeutic target that can be used to treat cystic kidney disease.

TH-PO344

CPAP Treatment for Obstructive Sleep Apnea Improves the Heart Rate Variability Response to Angiotensin II David Donald McTavish Nicholl,[1] Patrick Hanly,[1] Michelle C. Mann,[1] George Handley,[2] Darlene Y. Sola,[1] Sofia B. Ahmed.[1] *[1]Univ of Calgary, Calgary, AB, Canada; [2]Healthy Heart Sleep Company, Calgary, AB, Canada.*

Background: Obstructive sleep apnea (OSA) is common in chronic kidney disease (CKD). Both conditions are associated with decreased heart rate variability (HRV) and increased renin-angiotensin system activity, each a risk factor for progression of kidney and cardiovascular disease.

Methods: We aimed to determine the effect of continuous positive airway pressure (CPAP) treatment on HRV at baseline and in response to a physiological stress. Twenty normotensive, non-diabetic, newly diagnosed OSA subjects with normal kidney function (75% male; 50±2y; respiratory disturbance index [RDI] >15hr^{-1}) and hypoxia (oxyhemoglobin saturation [SaO_2] <90% for >12% of night) were studied in high-salt balance pre- and post-CPAP (≥4h/night x 1 month). Utilizing a 3-lead Holter monitor with a sampling frequency of 125Hz, HRV was calculated by spectral power analysis (low-frequency [LF], high-frequency [HF], standard deviation of the normal R-R wave [SDNN]) at baseline and in response to graded Angiotensin II (AngII) infusion (3ng/kg/min•30min, 6ng/kg/min•30min).

Results: CPAP corrected OSA and hypoxia (RDI, 43.1±4.1 vs 3.8±0.6hr^{-1}, p<0.001; SaO_2<90%, 36.3±5.0 vs 5.6±2.0%, p<0.001). There was no change in baseline LF (45±2 vs 46±3nu [normalized units], p=0.4) or HF (81±4 vs 83±10nu, p=0.8), but there was trend to improved SDNN (63±6 vs 75±9ms, p=0.087) post-CPAP. There was a greater reduction in LF (Δ30min, -1±2 vs -6±2nu, p=0.047; Δ60min, -2±3 vs -6±2nu, p=0.2), no change in HF (Δ30min, -7±5 vs -16±7nu, p=0.3; Δ60min, -9±5 vs -16±10nu, p=0.5), and SDNN was decreased (Δ30min, 14.1±6.8 vs 8.2±8.2ms, p=0.022; Δ60min, 14.9±6.1 vs 5.5±7.7ms, p=0.082) in response to AngII post-CPAP therapy. Norepinephrine decreased post-CPAP (2.6±0.3 vs 1.9±0.2nmol/L, p=0.001).

Conclusions: Treatment of OSA, a common condition in CKD, with short-term CPAP improved HRV and may have important implications in mitigating cardiovascular risk in CKD patients.

Normalization of Arterial Pressure in Rats with Adenine-Induced Chronic Renal Failure Does Not Attenuate the Defect in Aortic Relaxation Gregor S. Guron, Olof Arvidsson, Emman Shubbar, Lisa Nguy. *Molecular and Clinical Medicine, Medicine, Sahlgrenska Academy at Gothenburg Univ, Gothenburg, Sweden.*

Background: Cardiovascular disease is the major cause of death in chronic kidney disease. We have previously shown that rats with adenine-induced chronic renal failure (CRF) develop a markedly reduced rate of aortic relaxation. The aim was to examine whether reduced aortic relaxation rate in rats with adenine-induced CRF was caused by hypertension.

Methods: Experiments were carried out on male Sprague Dawley rats and CRF was induced by feeding rats an adenine-containing diet. Rats were randomized into 4 Groups (n=10 per group); adenine diet (adenine-induced CRF, A); adenine diet plus antihypertensive therapy (A-AHT); control diet (Controls, C); control diet plus antihypertensive therapy (C-AHT). Antihypertensive drugs (hydrochlorothiazide, metoprolol, and reserpine) were provided in the drinking water. Systolic arterial pressure (SAP) was measured weekly by tail-cuff plethysmography. Ex-vivo analyses of thoracic aortic function was assessed after 7 weeks using myography. Aortic relaxation rate was determined in vessels precontracted by KCl by calculating the area under the curve (AUC) for the initial 50% reduction in force following washout of KCl. Values are means±SEM.

Results: Antihypertensive triple therapy normalized SAP in rats with adenine-induced CRF. Average SAP during the treatment period was 126±4, 141±4 and 121±3 mmHg in groups C, A, and A-AHT, respectively. Groups A and A-AHT developed severe renal failure and showed similar plasma concentrations of creatinine, phosphorous and calcium. Aortic relaxation rates were significantly reduced (corresponding to increased AUCs for force) in groups A and A-AHT vs. controls (AUCs: 1980±292, 2440±929, and 960±105 s%, in groups A, A-AHT and C, respectively, P<0.01 ANOVA for adenine effect). Antihypertensive therapy had no statistically significant effect on aortic relaxation rate.

Conclusions: Normalization of SAP in rats with adenine-induced CRF did not attenuate the reduction in aortic relaxation rate. Hypertension does not seem to be the primary cause of reduced aortic relaxation rate in rats with adenine-induced CRF.

Epigenetic Control Mechanisms Explain the Two Distinct CD177/mPR3 Subsets of Human Neutrophils with Relevance to ANCA Vasculitis Claudia Eulenberg-Gustavus,[1] Sylvia Bähring,[1] Friedrich C. Luft,[1] Ralph Kettritz.[1,2] *[1]Experimental and Clinical Research Center, a Joint Cooperation between the Charité Medical Faculty and the Max-Delbrück Center for Molecular Medicine at the Charité, Berlin, Germany; [2]Nephrology and Intensive Care Medicine, Campus Virchow, Medical Faculty of the Charité, Berlin, Germany.*

Background: The CD177 receptor presents the ANCA autoantigen PR3 on the neutrophil surface. Individuals can be either CD177-deficient, or harbor two distinct $CD177^{neg}/mPR3^{low}$ and $CD177^{pos}/mPR3^{high}$ neutrophil subsets. A larger percentage of the latter is clinically important in ANCA vasculitis. The molecular genetic mechanisms that control subset-restricted CD177, and therefore bimodal mPR3 expression, are not known.

Methods: We performed haplotype analyses, methylation studies,chromatin immunoprecipitation (ChIP) analyses, immunoblotting, and CD177 expression studies (TaqMan), reporter assays, as well as transcription factor transfection studies in hematopoietic stem cells, neutrophils, and HeLa cells.

Results: In our healthy cohort, 94 % of 165 individuals showed a $CD177^{pos}$ neutrophil subset with a median size of 60 %. $CD177^{pos}$, but not $-^{neg}$ neutrophils, produced CD177 protein and mRNA. Haplotype analysis indicated parental-inherited monoallelic CD177 gene expression. Hematopoietic stem cells silenced one CD177 allele during neutrophil differentiation. A HeLa cell model recapitulated key neutrophil findings of CD177 transcription and allowed reporter assays that characterized the CD177 promoter in euchromatin configuration containing a TATA box, 16 CpGs, CG-rich regions, and several binding sites for the AP-1 transcription factors (TFs) c-Jun and c-Fos. Reporter activity declined with vector methylation *in vitro* and CD177 monoallelic expression became biallelic with HeLa cell demethylation. c-Jun and c-Fos bound to the CD177 promoter and transfection with both TFs upregulated CD177 mRNA. Most importantly, $CD177^{pos}$, but not$-^{neg}$ neutrophils, exhibited euchromatin configuration, demethylated CpGs, c-Jun, and c-Fos binding in the CD177 promoter.

Conclusions: We propose that epigenetic mechanisms are responsible for the two distinct CD177 neutrophil subsets.

The Effect of Resveratrol on the Vascular Renin-Angiotensin-System in Aging Mice Hye Eun Yoon, Eun Nim Kim, Min Young Kim, Ji Hee Lim, Seok Joon Shin, Cheol Whee Park, Bumsoon Choi. *Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Aging is a major risk factor of cardiovascular disease and the renin-angiotensin system (RAS) is the key player in cardiovascular diseases. Resveratrol is known to have protective effects on inflammation and oxidative stress. This study evaluated the effect of resveratrol on arterial aging and the vascular RAS in mice.

Methods: Histologic changes and expressions of collagen IV, fibronectin, angiotensin II (Ang II), Ang II type 1 receptor (AT1R), Ang II type 2 receptor (AT2R), prorenin receptor (PRR), Mas receptor (MasR), angiotensin converting enzyme (ACE), ACE2, endothelial nitric oxide synthase (eNOS), NADPH oxidase 2 and 4 (NOX2 and NOX4), superoxide dismutase 1 and 2 (SOD1 and SOD2), silent information regulator T1 (SIRT1), peroxisome proliferator-activated receptor (PPAR)ɣ co-activator 1α (PGC-1α), and PPARα were measured in the thoracic aortas from 24-month-old C57/BL6 mice with or without resveratrol treatment.

Results: The aorta media thickness significantly decreased in the resveratrol-treated mice compared to the control mice (77.07±15.90 μm vs. 95.20±18.55 μm, $P < 0.001$). The aortic expressions of collagen IV and fibronectin decreased in the resveratrol-treated mice compared with the control mice. Resveratrol treatment decreased the aortic expressions of Ang II, ACE, AT1R and PRR, and increased those of AT2R and MasR. The expressions of eNOS, SOD1, SOD2, PPARα, SIRT1, PGC-1α increased with resveratrol treatment, while the expression of NOX4 decreased.

Conclusions: The results suggest that resveratrol has protective effects on arterial aging by amelioration of oxidative stress and inflammation, which was associated with the reduction in the PRR-ACE-Ang II-AT1R axis and enhancement of the ATR2-MasR axis.

TH-PO348

Erythropoiesis-Stimulating Agent for Treatment of Anemia Ameliorates Deterioration of Erythrocyte Deformability Associated with Chronic Kidney Disease Ken Aizawa, Ryohei Kawasaki, Yoshihito Tashiro, Kumiko Kondoh, Yasushi Shimonaka, Michinori Hirata, Hideyuki Yasuno. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan.*

Background: Erythropoiesis-stimulating agents (ESAs) are commonly used to treat anemia associated with chronic kidney disease (CKD). Although ESAs contribute to increasing erythrocytes, erythrocyte lifespans in CKD patients are thought to be shortened by qualitative changes such as deterioration of deformability and stability, and shortened erythrocyte lifespans in CKD patients may result in poor prognosis. Therefore, ensuring appropriate hemoglobin (Hb) levels may not be sufficient to provide an effective treatment for CKD-associated anemia. However, it is not yet clear whether therapeutic treatment of anemia with ESAs affects erythrocyte quality in CKD.

Methods: CKD model rats were produced by anti-Thy1.1 antibody injection plus uninephrectomy (Week 0). After the surgery, vehicle or epoetin beta pegol (C.E.R.A., 0.6 μg/kg) was intravenously injected every 2 weeks from Week 4 to 16. Blood and urine was collected until Week 18. Therapeutic control of anemia was assessed by Hb level, and deformability and stability of erythrocytes was quantified by laser diffraction ektacytometry and hemolysis test, respectively. To explore the effect on kidney and cardiovascular status, total urinary protein (uTP) and heart weight/body weight (HW/BW) were assessed, respectively.

Results: CKD model rats showed anemia and impaired erythrocyte deformability and stability. Deformability significantly improved and stability tended to recover by C.E.R.A. treatment. In the sham-operated group, C.E.R.A. treatment did not change erythrocyte deformability or stability. In this experimental procedure, C.E.R.A. treatment did not change the significant increase in uTP and HW/BW in the CKD model rats.

Conclusions: In CKD rats, not only did Hb decrease but qualitative deterioration of deformability and stability in erythrocytes was also observed. These aspects were improved by therapeutic administration of C.E.R.A. The appropriate ESA therapy for anemia may contribute to a better understanding of the therapeutic benefits of ESA treatment in CKD-associated anemia.

Far Infrared Irradiation Inhibits Platelet Adhesion through the Induction of ADAMTS-13 Wen-Yi Chen,[1] Daw-Yang Hwang,[1,3] Shang-Jyh Hwang.[1,2,3] *[1]Divsion of Nephrology, Dept of Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [2]Faculty of Renal Care, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [3]Faculty of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: Far-infrared Ray (FIR) is an invisible electromagnetic waves with wavelength between 3-1000μm, which has multiple effects on the cardiovascular system. FIR irradiation improved dialysis fistula function through diverse mechanisms. We ever reported FIR irradiation reduced Thromboxan A2 recetor (TBXA2R)and von Willebrand factor (vWF) protein expression of on the surface of endothelial cells, which decreased platelet adhesion to HUVECs. VWF can be cleaved by the metalloprotease ADAMTS13, and the cleavage site in the VWF A2 domains is also cryptic in normal circulating plasma VWF. We hypothesize that FIR may induce ADAMTS-13 release and decrease platelet adhesion to endothelial cells.

Methods: Cultured HUVECs were treated with or without FIR irradiation for 30 minutes. In culture media, the levels of VWF and ADAMTS-13 were measured by immunoassay. The VWF on the surface of endothelial cells was detected by immunofluorescence staining. To examine platelet-HUVEC interactions, we co-cultured calcein AM-labeled platelet with FIR-treated or controlled HUVECs, followed by fluorescence microscopy analysis. Peripheral blood samples were obtained from healthy adult volunteers before and after FIR irradiation for 40 minutes, which were analyzed for the concentrations of ADAMTS-13 by immunoassay.

Results: The immunoassay results showed increased level of ADAMTS13 and VWF D4-CK domain in culture media after FIR irradiation. Significant reduced VWF D4-CK terminal expressions of on the surface of endothelial cells were observed after FIR irradiation. The platelet binding to HUVEC cells was significantly less in FIR-treated versus control. The ADAMTS-13 levels in healthy adult were significantly higher after FIR-treated.

Conclusions: These data suggest that far infrared Irradiation inhibits platelet adhesion to endothelial cell through the induction of ADAMTS-13. Our results may provide information for further exploring the mechanisms of FIR in the prevention of thrombus formation.

Not All Elastic Fibers Are Created Equally: Differential Role of Fibulin-4 in Large versus Small Arteries Carmen M. Halabi,[1] Robert P. Mecham.[2] *[1]Pediatrics, Washington Univ School of Medicine, Saint Louis, MO; [2]Cell Biology and Physiology, Washington Univ School of Medicine, Saint Louis, MO.*

Background: Homozygous or compound heterozygous mutations in Fibulin-4 (*FBLN4*) lead to autosomal recessive cutis laxa type 1B (ARCL 1B), a multisystem disorder characterized by inelastic skin, arterial tortuosity, aortic aneurysms, and pulmonary emphysema and thought to be the result of aberrant elastic fiber formation. We sought to determine the consequences of a disease-causing mutation in *FBLN4* (E57K) on the cardiovascular system and vascular elastic fibers in a mouse model of ARCL 1B.

Methods: The vasculature of mice homozygous for E57K *Fbln4* (*Fbln4*$^{E57K/E57K}$) were examined by visual inspection, histology and electron microscopy. Blood pressure and large artery compliance were assessed, as were vascular elastin and collagen levels and smooth muscle cell (SMC) organization.

Results: *Fbln4*$^{E57K/E57K}$ mice were hypertensive and developed arterial elongation, tortuosity and ascending aortic aneurysms. SMC organization within the wall of conduit arteries was abnormal and elastic fibers were fragmented and had a moth-eaten appearance. *Fbln4* E57K homozygosity led to a modest increase in elastin content in large arteries without a change in extracellular matrix gene expression. Surprisingly, elastin and smooth muscle cells in the mesenteric, saphenous, and renal arteries of homozygous mutant mice were normal and seemingly unaffected by the E57K mutation. In addition, elastin content of *Fbln4*$^{E57K/E57K}$ mesenteric arteries was unchanged.

Conclusions: These results suggest a differential role of FBLN4 in elastic fiber assembly, not only between different tissues, but also between conduit and resistance arteries. Future studies investigating tissue-specific elastic fiber assembly may lead to novel therapeutic interventions for ARCL 1B and other disorders of elastic fiber assembly.

Single Cell Gene Expression of Adventitial Gli1+ MSC Indicates a Heterogeneous Pool of Myofibroblast and VSMC Progenitors Janewit Wongboonsin,[12] Rafael Kramann,[3] Harald Grove,[2] Prapat Suriyaphol,[2] Benjamin D. Humphreys.[1] *[1]Div of Nephrology, Washington Univ in St. Louis; [2]Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; [3]Div of Nephrology and Clinical Immunology, RWTH Aachen Univ, Aachen, Germany.*

Background: Progenitor cells are known to reside in the vascular adventitia but their precise cellular potential and gene expression profile remains unknown. We identified Gli1 as a marker of perivascular MSC that are important progenitors both of myofibroblasts in fibrosis but also vascular smooth muscle cells (VSMC). Whether Gli1^{+} stem cells are homogeneous, or alternatively represent a heterogenous population of myogenic and myofibroblast progenitors remains unknown. To address this question, we performed single cell gene expression analysis and looked for cell subpopulations expressing perivascular or smooth muscle gene markers.

Methods: 10 days after tamoxifen was given to bigenic Gli1CreER;tdTomato mice, the aorta was harvested and dissociated. Single Gli1+ progenitor cells were sorted and single cell qPCR was performed using TaqMan expression probes on a 96.96 Fludigm array for 32 genes of interest. Data was analyzed using the R package SINGuLAR Analysis Toolset.

Results: Three distinct cell clusters were identified from this gene panel. Seventeen genes were differentially expressed between the clusters (ANOVA, $p<0.0016$): Ly6a,Endoglin,Tek, IGF2,Kdr,Tagln,CD34,Ccnd2,TSC22d3,Nestin,Smtn,Ptch1,CD140a, CD140b,Sox10,Msx1 and CNN1. Principal component analysis showed the top four most influential genes were CNN1(calponin),Tagln(SM22),CD140a and CD34. Tagln, a VSMC gene, was negatively correlated with MSC markers such as CD140a ($R2 = -0.32$) and CD34 ($R2 = -0.13$). Cross validation confirmed a subpopulation of cells that always clustered together providing strong evidence that Gli1+ cells are heterogeneous. This subpopulation had low expression of CD140a and Thy1, and high expression of Kdr,Tek,IGF2 and Tagln.

Conclusions: Single cell qPCR strongly suggests the presence of distinct subpopulations among adventitial Gli1^{+} MSC. As VSMC marker expression increases, MSC marker expression decreases reflecting differentiation and commitment to the VSMC lineage of Gli1+ progenitors.

TH-PO352

Association of Vascular Injury Markers with Rate of GFR Decline in Type 2 Diabetes Alexander Mohtadi, Olufemi B. Aina, Ameet Kumar, Candace D. Grant, Joseph Mattana, Shayan Shirazian. *Winthrop-Univ Hospital.*

Background: Urine microalbumin levels are the most commonly used biomarker for vascular injury and progression of chronic kidney disease (CKD) in patients with type 2 diabetes (T2DM). However, nonalbuminuric patients with T2DM and CKD are also prone to vascular injury and CKD progression, warranting study of additional biomarkers. This study examines the association between vascular injury markers and CKD progression in patients with T2DM and CKD.

Methods: This is a retrospective study of 40 subjects with T2DM and stage 3 CKD with prior vascular injury marker testing including urine microalbumin to creatinine ratio (UACR), von-Willebrand factor antigen, high sensitivity C-reactive protein, uric acid and circulating endothelial cell (CEC) levels. CEC levels were tested by Veridex® using an immune-magnetic bead based assay. The primary outcome, slope of estimated glomerular filtration rate (GFR) decline, was calculated in subjects with over 16 months of follow-up from vascular injury marker testing, and at least 3 measured creatinines separated by 3 months using a line of best fit. Pearson correlations were performed between slope of eGFR decline and other demographic and clinical predictors including vascular injury markers.

Results: Of the original 40 subjects, 30 had sufficient follow-up data for slope of eGFR decline calculation. This group was 53.3% male, 70% Caucasian, 23.3% African American, 6.7% Asian, and had a mean age of 69.8±8.1 years, diabetes duration of 16.5±5.9 years, UACR of 393.5±896.1 mcg/mg, slope of eGFR decline of -1.5±4.25 mL/min/1.73m^2/year, and median follow-up time of 23 months. UACR levels (r=-0.37, p=0.042) and hemoglobin $A1_c$ (r=-0.3198, p=0.08) were negatively correlated with slope of eGFR decline. There were no significant correlations between slope of eGFR decline and other vascular injury markers.

Conclusions: In this pilot study, only urine microalbumin levels showed a significant negative correlation with slope of eGFR decline in patients with T2DM and stage 3 CKD over a median of 23 months of follow-up. Longer term follow-up is needed to determine whether other vascular injury markers associate with eGFR decline in this population.

TH-PO353

IRE1 Activation Is Required for Collagen Secretion by Vascular Smooth Muscle Cells Victor Tat, Jeffrey G. Dickhout. *Dept of Medicine, Div of Nephrology, McMaster Univ and St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

Background: Vascular stiffening is positively associated with both hypertension and aging and is a strong predictor of end-organ damage. Fibrotic remodeling of the extracellular matrix by vascular smooth muscle cells (VSMCs) contributes to the stiffening of conduit arteries such as the aorta. Activation of the IRE1 pathway within the unfolded protein response (UPR) results in adaptive programs that increase protein folding capacity. We hypothesize VSMCs transitioning to a collagen-secreting phenotype in response to TGF-β1 require the activation of IRE1. Inhibition of this pathway is hypothesized to reduce collagen secretion and hence prevent the development of fibrosis in the aorta.

Methods: Aortic smooth muscle cells were isolated from Wistar-Kyoto rats. Small molecule inhibitors of the IRE1α endonuclease domain, 4μ8c and STF-083010, were used to block IRE1 activity. Collagen production was measured using a dot blot for Type I collagen and a Picrosirius red-based microplate assay. Markers of UPR activation and ER stress were assessed with Western blot. Aortic rings were harvested from 5-7 week old WKY rats and cultured for 5 days in the presence of TGF-β1 (5 ng/ml) and 4μ8c (30 μM). Arterial compliance was measured using a wire myograph.

Results: Inhibition of IRE1 endonuclease activity dose-dependently reduced the production of collagen by VSMCs in response to either L-ascorbic acid or TGF-β1. 4μ8c blocked the splicing of the transcription factor XBP1 and prevented the induction of the collagen-folding chaperones GRP78, GRP94 and PDI by tunicamycin. Aortic rings incubated with TGF-β1 had reduced compliance, which was improved by co-treatment with 4μ8c.

Conclusions: These results suggest that activation of the IRE1 pathway is required for the secretion of collagen by VSMCs, leading to vascular fibrosis and stiffening. It is hypothesized that IRE1 blockade will have similar antifibrotic effects in other tissues such as the kidney by limiting the secretory capacity of collagen-producing cells. This presents a novel target for the treatment of fibroproliferative diseases. Funding:CIHR MOP-133484, Kidney Foundation of Canada Krescent New Investigator (Dr. Dickhout).

TH-PO354

Role of Interleukin 17 Receptor A in Enhanced Atherosclerotic Inflammation in Renal Impairment Johannes Nordlohne,[1] Shuwang Ge,[1] Ari Waisman,[2] Hermann G. Haller,[1] Sibylle Von Vietinghoff.[1] *[1]Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Inst of Molecular Medicine, Inst of Molecular Medicine, Mainz, Germany.*

Background: Patients with chronic kidney disease (CKD) suffer from increased atherosclerosis and its complications. This is only partly amenable to control of traditional risk factors. The T cell cytokine Interleukin (IL)-17A enhances myeloid inflammation via IL-17 receptor A. This project investigated the role of IL-17 receptor A in enhanced atherosclerotic inflammation in renal impairment.

Methods: LDL receptor (LDLr-/-) deficient mice with and without IL-17 receptor A (Il17ra-/-) underwent unilateral nephrectomy or sham surgery and were maintained on a high-fat diet. Bone marrow transplantation was conducted after lethal irradiation. Aortic leukocyte infiltration was determined by flow cytometry. Interaction of myeloid cells with aortic explants in response IL-17A was studied in vitro.

Results: Unilateral nephrectomy significantly decreased GFR in LDLr-/- mice. The number of aortic total leukocytes, CD11b+ myeloid cells and among them, both neutrophils and CD11c+ and MHCII high-expressing cells, both indicators of antigen presenting function, increased significantly in renal impairment after 10 weeks of high fat diet. This was completely abolished in the absence of IL-17 receptor A. In vitro, IL-17A enhanced adhesion of myeloid cells to aortic explants. Aortic myeloid cell homing in atherosclerosis was investigated in mixed bone marrow chimeric mice (50% wt/50% *Il17ra*$^{-/-}$ bone marrow). In the identical environment of mixed bone marrow chimeric mice, *Il17ra*$^{-/-}$ cells had a significant aortic homing defect in renal impairment.

Conclusions: IL-17 receptor A is instrumental in prevention of enhanced atherosclerotic inflammation in renal impairment. IL-17 inhibition should be further tested as an anti-inflammatory target in atherosclerosis and CKD.

TH-PO355

Myostatin: A New Player in Uremic Vascular Remodelling and Fibrosis in Uremia Pasquale Esposito,[1] Daniela Verzola,[2] Edoardo La Porta,[1] Samantha Milanesi,[2] Maria Antonietta Grignano,[1] Antonio Dal Canton,[1] Giacomo Garibotto.[2] *[1]Nephrology, Dialysis and Transplantation, Fondazione IRCCS Policlinico San Matteo, and Univ of Pavia, Pavia, Italy; [2]Nephrology, Dialysis and Transplantation, Genoa Univ IRCCS AOU San Martino-IST, Genoa, Italy.*

Background: Myostatin (MSTN), a member of the TGFβ superfamily that exerts pleiotropic effects on skeletal muscle and bone, has been recently recognized as a mediator of cardiovascular cachexia, heart dysfunction and fibrosis. Accordingly, in this study we assessed the role of MSTN in arterial vascular remodelling and fibrosis in patients with end-stage renal disease (ESRD).

Methods: We studied gene expression (RT-PCR) and protein (immunohistochemistry) of myostatin, smoothelin-A (a marker of the smooth muscle cell contractile phenotype), klotho and periostin (an early marker of vascular calcification) in aortic patches from ESRD patients (n=16, 9M, 56.4±7.9 years) at the time of renal transplantation, and from paired deceased kidney donors–(Controls) (n=15, 8M, 55.4±12.1 years) at the time of organ removal. Von Kossa stain was used to quantify vascular calcium deposition. In addition we tested, *in vitro,* the effect of uremic serum on the expression of MSTN, klotho and smoothelin in primary human Vascular Smooth Muscle Cell line (VSMC), obtained from a kidney donor.

Results: There was a 15-fold increase in myostatin-mRNA levels in ESRD patients compared with age-matched control subjects ($P < 0.05$), while klotho was markedly downregulated ($p<0.001$). In addition, smoothelin-A and klotho immunohistochemical signals were lower in ESRD than in controls ($P<0.001$-$P<0.01$). Moreover, MSTN m-RNA was inversely correlated with klotho and smoothelin-A m-RNA (r=-0.5, p=0.05; r=0.6, p=0.01, respectively). In vitro studies on VSMC showed that uremic serum increased MSTN-mRNA (+ 70% respect to normal serum), and downregulated smoothelin and klotho (both - 40%), suggesting that the uremic milieu is responsible for inducing the observed changes.

Conclusions: Uremia increases MSTN gene expression in vascular tissues and blunts Klotho and smoothelin, suggesting that MSTN has a role in uremic-related vascular remodelling and fibrosis.

TH-PO356

Aryl Hydrocarbon Receptor Signaling Is an In Vivo Targetable Antithrombotic Pathway Mostafa Belghasem,[1] Moshe Shashar,[2] Jamaica Siwak,[2] Faisal F. Alousi,[2] Anqi Zhang,[3] Jean M. Francis,[2] Joel M. Henderson,[1] Vipul C. Chitalia.[2] *[1]Dept of Pathology, Boston Univ Medical Center, Boston, MA; [2]Nephrology, Boston Univ Medical Center, Boston, MA; [3]Metabolomics Core, Boston Univ Medical Center, Boston, MA.*

Background: CKD is characterized by the retention of several solutes of which indoxyl sulfate (IS) is highly thrombogenic. It enhance thrombosis by activating AHR to increase tissue factor levels, a key procoagulant. Though AHR inhibitors (AHRi) significantly suppressed thrombosis in an *ex vivo* model, there is a dearth of *in vivo* proof of AHRi as antithrombotics. There are limitations to current CKD animal models in that they retain numerous solutes precluding specific examination of IS and also fail to recapitulate the prothrombotic phenotype of human CKD.

Methods: We generated a uremic thrombosis model by combining IS administration along with the inhibition of its urinary excretion using Probenacid (Prob) in C57BL/6 mice. The protocol with high IS levels similar to stage 5 CKD was used. The effect of AHRi was examined in three groups **I**: Prob (CTL), **II**: IS + Prob, and **III**: IS + Prob+ AHRi (CH223191 10 mg/kg IP). Plasma IS levels were measured on day 0, 2, and 5 using LC/MS, and the animals were subjected to ferric chloride-mediated carotid injury. The onset of thrombosis was defined as the reduction of blood flow to the background and time to thrombosis served as a primary end point.

Results: IS in water (4mg/ml) along with Prob IP (150mg/kg) twice daily for 5 days resulted in a significant increase in IS levels greater than stage 5 CKD patients. The IS levels remained significantly higher from day 2 onwards. The time to thrombosis was significantly lower in IS + Prob (315.9±163.3 sec) compared to Prob (673.7±395.6 sec), and was significantly prolonged with AHRi (655.7±342.8 sec), despite similar IS levels in group II and III (p=0.49).

Conclusions: With the IS levels similar to stage 5 CKD patients, this first uremic thrombosis model faithfully recapitulates enhanced thrombotic phenotype in humans CKD. Validating IS as a thrombogenic uremic solute *in vivo*, the above observations confirm the *in vivo* druggability of AHRi as a novel class of antithrombotic.

TH-PO357

Disruption of Glomerular Permeability Barrier Increases Apolipoprotein AI (ApoAI) Ultrafiltration which Regulates Interstitial Lymphangiogenesis
Jianyong Zhong,[1] Haichun Yang,[1] Yohei Tsuchida,[1] Taiji Matsusaka,[2] Agnes B. Fogo,[1] Valentina Kon.[1] *[1]Vanderbilt Univ Medical Center, Nashville, TN; [2]Molecular Life Science, Tokai Univ, Isehara-shi, Kanagawa, Japan.*

Background: Lymphatics not only return fluids/lipoproteins from the periphery to the circulation but have critical pathophysiologic/therapeutic roles in disease e.g., atherosclerosis, cancer, hypertension. Lipoproteins themselves appear to regulate lymphangiogenesis, however, little is known about lipoprotein modulation of the intrarenal lymphatic network. We examined ApoAI modulation of lymphangiogenesis in proteinuric kidney injury.

Methods: We studied Nphs1-hCD25 mice (NEP25) expressing human CD25 in podocytes which can be injured by immunotoxin, LMB2. Six weeks after LMB2, we assessed glomerular filtration, excretion of albumin and ApoAI, examined the intrarenal lymphatic network with podoplanin, localized endogenous ApoAI, and stained for lipoprotein transporters (scavenger receptor class B member 1, SRB1). In vitro, we examined lymphatic endothelial cells exposed to ApoAI with/without transporter blocker.

Results: Lymphatic endothelial cells exposed to ApoAI showed increased cell viability, lower migration, and reduced lymphangiogenesis compared to vehicle-exposed cells. Blocking SRB1 with BLT1 reduced cell viability and promoted more migration than ApoAI alone. In vivo, NEP25 mice had glomerulosclerosis, albuminuria and increased ApoAI excretion. Podocyte injury also caused more tubulointerstitial injury and more ApoAI localized to tubular epithelial cells and interstitium. After injury, tubular cells showed more SRB1 and VEGF-C, a powerful lymphaniogenic stimulus, compared to nonproteinuric mice. NEP25 mice had a dramatically more dense and complex lymphatic network than wild type mice. Lymphatic vessels expressed SRB1 that co-localized with reabsorbed ApoAI.

Conclusions: Proteinuric glomerular injury leads to more ApoAI in the ultrafiltrate, greater reabsorption by the proximal tubules into the interstitium and more ApoAI uptake by lymphatic endothelial cells via SRB1. We conclude that tubular VEGF-C secretion and lymphatic ApoAI absorption promote renal lymphangiogenesis.

TH-PO358

Abnormalities in Cholesterol Flux Pathway Induced by Plasma from Patients with Chronic Kidney Disease
Farah Daccueil, Allison B. Reiss, Nicolle Marie Siegart, Joseph Mattana, Iryna Voloshyna, Lora Kasselman, Joshua De Leon, Nobuyuki (Bill) Miyawaki. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

Background: The mechanism underlying chronic kidney disease (CKD) as a major risk factor for atherosclerosis and cardiovascular disease (CVD) has not been elucidated. Lipid profile is less predictable of CVD risk and statins lose benefit with advancing CKD. This study aims to detect changes in cholesterol transport gene expression and to determine if such changes adversely affect macrophage lipid handling in CKD leading to atheromatous foam cell formation.

Methods: THP-1 human macrophages (10^6/ml) were incubated for 18h-24h with plasma from 10 CKD patients not on dialysis and non-renal transplant or 10 healthy control (HC) subjects. Post-incubation, mRNA was isolated and reverse transcribed to cDNA, and subjected to quantitative real-time PCR using specific primers for ATP binding cassette transporter (ABC)A1 (cholesterol efflux protein) and CD36, (a scavenger receptor with the capacity to endocytose oxidized LDL). Foam cell quantification using Dil-acetylated-LDL with VectaShield mounting medium was used on 5 samples from each group.

Results: PCR analysis showed that ABCA1 mRNA was reduced by 28±5% ($p<0.0001$) while CD36 mRNA was decreased by 35±6% ($p<0.0001$) in macrophages exposed to CKD plasma as compared to HC. Increase in foam cell accumulation in macrophages exposed to CKD plasma by 36±11% as calculated by total fluorescence per cell corrected for total nuclei in frame ($p<0.01$).

Conclusions: A different mechanism of lipid dysregulation in CKD based on impaired efflux, through proatherogenic suppression of ABCA1, differs from our finding in autoimmune rheumatic diseases where, in addition to lowering of ABCA1, augmentation of CD36 influx was observed. In CKD, oxidized lipid uptake appears less dependent on macrophage CD36. Statins reduce lipid influx via down regulation of CD36 but low CD36 expression in CKD would limit its benefit from this mechanism. These changes to ABCA1 and CD36 may explain the pathogenesis of elevated CVD risk accompanied by reduced statin efficacy in advanced CKD. Defining lipid handling changes in CKD could lead to novel, targeted CVD treatments in the CKD population.

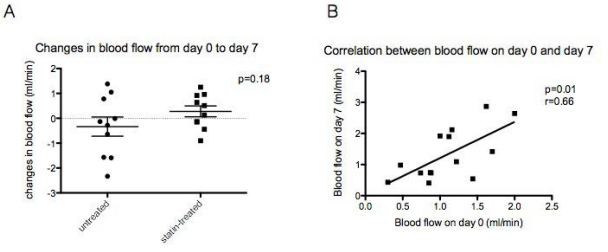
Atorvastatin Decreases Vascular Wall Inflammation following Arteriovenous Fistula Creation in a Murine Model
Jie Cui,[1,2] Harkamal Singh Jhajj,[2] Chase Kessinger,[2] Farouc Amin Jaffer.[2] *[1]Nephrology Div, Massachusetts General Hospital, Boston, MA; [2]Cardiovascular Research Center, Massachusetts General Hospital, Boston, MA; [3]Center for Systems Biology, Massachusetts General Hospital, Boston, MA.*

Background: The most common cause of AVF failure is inflammation-driven neointimal hyperplasia and thrombosis. Statins have well-recognized anti-inflammatory and anti-thrombotic properties. Here, we investigated whether statin therapy can improve murine AVF patency, and assessed the anti-inflammatory effects using in vivo nanoparticle-based fluorescence molecular imaging.

Methods: AVFs were created using internal jugular vein and carotid artery (n=20). AVF blood flow was measured 15 minutes post-surgery. On day 6, an inflammatory cell targeted fluorescent nanoparticle, CLIO-VT680 (10mg/kg) was administered. 24 hours later, *in vivo* epifluorescence imaging was performed to visualize inflammatory response of the mobilized vein. In the statin treated group, 1.14mg/kg atorvastatin was administered daily. Changes in blood flows (BF) were compared in both statin treated (SG) and untreated control group (CG).

Results: AVF BFs on day 0 and day 7 were similar between the SG and CG ($p>0.05$). The day 7 adventitial AVF inflammation signal (CLIO-VT680) assessed by in vivo epifluorescence imaging was significantly lower in the SG compared to the CG (6.3±0.98 vs 3.4±0.2, $p=0.002$). There was a nonsigificant trend to increased BFs from day 0 to day 7 in the SG compared to the CG (0.28 vs -0.33 ml/min, $p=0.18$).



The day 7 AVF BF strongly correlated with the day 0 BF ($r=0.66$, $p=0.01$).

Conclusions: Oral statin therapy decreases adventitial inflammation in experimental AVF as assessed by in vivo nanoparticle-based molecular imaging. There was a trend to improve AVF blood flow with statin therapy. Further studies are indicated to determine if statin therapy can improve AVF patency and maturation.

Impact of HIV Infection on Arteriovenous Fistula Outcomes: A Retrospective Analysis
Juan Camilo Duque Ballesteros,[1] Laisel Martinez,[3] Adriana Dejman,[2] Marwan Tabbara,[3] Roberto I. Vazquez-Padron,[3] Loay H. Salman.[2] *[1]Internal Medicine, Jackson Memorial Hospital / Univ of Miami, Miami, FL; [2]Nephrology and Interventional Nephrology, Jackson Memorial Hospital / Univ of Miami, Miami, FL; [3]Surgery, Jackson Memorial Hospital / Univ of Miami, Miami, FL.*

Background: Multiple conditions have been associated to the elevated AVF failure rates. One of the influenced factors but less studied is the effect of the immunosuppression on the AVF vascular wall. In AVF, immunosuppression has been related with higher failure rates of newly created AVF in animal models.

Methods: This retrospective study assessed for the impact of HIV infection on one-stage and two-stage hemodialysis AVF outcomes. The study included 494 patients (HIV=42 patients) who underwent an AVF creation at the University of Miami/Jackson Memorial Hospital from 2008 to 2014. The effects of HIV on primary failure were determined using multivariate logistic regressions and Cox proportional hazard models adjusted for 10 clinical and demographic covariates.

Results: A positive predictors of primary failure are HIV infection ($p=0.004$) and previous AVF ($p=0.002$), but HIV does not correlate with primary patency after excluding primary failure cases. We could not find a correlation with any of the T-cell subsets counts (CD3, CD4, or CD8). In HIV patients a prior dialysis catheter is the only clinical factor that predisposes for AVF primary failure ($p=0.012$).

Conclusions: Our results suggest that immunosuppression might play a role in AVF outcomes. HIV infection show increased rate of AVF failure but this is not explained by the T-cell subsets counts and should be a different immunological relationship between AVF failure and vascular remodeling.

TH-PO361

Pro- and Anti-Inflammatory Factors and Vascular Stiffness in Chronic Hemodialysis Patients Botond Csiky,[1,2] Attila Peti,[5] Orsolya Lakatos,[4] Endre Sulyok.[3] *[1]FMC Dialysis Center Pecs, Pecs, Hungary; [2]Dept of Nephrology, Univ Medical School of Pecs, Pecs, Hungary; [3]Faculty of Health Sciences, Univ of Pécs, Pecs, Hungary; [4]Univ Medical School of Pecs, Pecs; [5]Siofok Hospital, Hungary.*

Background: In this cross-sectional study we addressed the accelerated arteriosclerosis in patients with chronic renal failure (CRF) on hemodialysis (HD) by measuring arterial stiffness parameters and attempted to relate them to pro-inflammatory and protective factors.

Methods: 96 consecutive patients receiving regular HD were included in the study. 20 adult patients without major renal, cardiovascular or metabolic morbidities served as controls. Arterial stiffness parameters (carotid-femoral pulse wave velocity – PWV, aortic augmentation index) were measured by using applanation tonometry (SphygmoCor, AtCor Medical,Sidney). In addition to routine laboratory tests 25(OH)vitamin D_3 (vitamin D_3) and hsCRP were quantified by immunometric assay; whereas fetuin-A, α-Klotho, TNF-α and TGF-β1 were determined by ELISA using commercially available kits (IBL International GmbH, Hamburg and BioVendol Laboratory Med. Inc Brno).

Results: Pro-inflammatory biomarkers (hsCRP, TNF-α and TGF-β1) were markedly elevated ($p<0.01$), while anti-inflammatory factors (fetuin-A: $p<0.05$, α-Klotho: $p<0.01$, vitamin D_3: $p<0.01$) significantly depressed in CRF patients on HD when compared to control patients. PWV was significantly affected only by total cholesterol, fetuin-A and dialysis time. Multiple linear regression analyses revealed that several clinical and laboratory parameters were associated with pro-and anti-inflammatory biomarkers rather than arterial stiffness.

Conclusions: Our results provide additional information on the pathomechanism of accelerated atherosclerosis in patients with CRF but failed to document direct influence of pro- and anti-inflammatory biomarkers studied on the complex interplay between uremic milieu and vascular health.

TH-PO362

Morphological and Immunohistochemical Characterization of Thrombotic Microangiopathy (TMA) in Native and Transplanted Kidney Biopsies: A Multicenter Study Jessica Schmitz,[1] Wei Dai,[1] Abedalrazag Ahmad Khalifa,[1] Jan Menne,[2] Ulrich Kunzendorf,[3] Oliver Witzke,[4] Hermann G. Haller,[2] Hans Heinrich Kreipe,[1] Jan H. Braesen.[1] *[1]Inst for Pathology, Hannover Medical School, Hannover, Germany; [2]Nephrology, Hannover Medical School, Hannover, Germany; [3]Nephrology, Univ Clinic Schleswig-Holstein, Campus Kiel, Kiel, Germany; [4]Nephrology, Univ Clinic Essen, Essen, Germany.*

Background: Thrombotic microangiopathy (TMA) is defined as microvascular endothelial injury and thrombosis, thrombocytopenia and MAHA, often affecting the kidney. Correct diagnosis of TMA in kidney biopsies is demanding since TMA may manifest without thrombi.

Methods: Using routine paraffin sections, accepted morphological criteria were analysed in TMA cases from the archives of the Insitute for Pathology at Hannover Medical School in 163 kidney biopsies from the last three years.

Results: Patient (female 45%) age ranged from 4 to 81 (mean 47) years. 45% of TMA cases occured in kidney transplants (KTx), 53% of these revealed rejection (cellular 7%, humoral 34%, mixed 12%). Thrombi were identified in 71% of KTx TMA cases (glomerular 41%, arteriolar 40%, arteries 25%) compared to 67% of native kidneys (glomerular 38%, arteriolar 53%, arteries 41%). Most useful histological TMA criteria were fragmented red blood cells (glomerular 65%, arterioles/arteries 67%), fibrillar appearance of mesangium (66%), endothelial swelling (glomeruli 68%, arterioles 67%), thickened capillary walls (66%), collapse of capillary tuft (92%) and arterial intimal mucoid edema (arteries 78%, arterioles 47%). Grouping of well-characterized patients regarding the underlying cause for the TMA showed differences between morphological criteria comparing genetically verified atypical HUS (more arteriolar/hilar involvement), humoral transplant rejection and medication induced injury (e.g. gemcitabine, more glomerular and overall thrombi). Stainings using antibodies for thrombomodulin, heparanase-2, CD34 and lectin stains for evaluation of the glycocalyx do not seem to mirror the morphological differences so far.

Conclusions: One third of TMA cases do not display thrombi in kidney biopsies. Certain morphological criteria vary in their diagnostic value and differ between causes of TMA.

TH-PO363

Matrix Metalloproteinase-10 in Glomeruli of Aldosterone-Infused Systemic and Podocyte-Specific Guanylyl Cyclase-A Knockout Mice Keisuke Osaki,[1] Yukiko Kato,[1] Naohiro Toda,[1] Akira Ishii,[1] Kiyoshi Mori,[2] Moin Saleem,[3] Taiji Matsusaka,[4] Masashi Mukoyama,[5] Motoko Yanagita,[1] Hideki Yokoi.[1] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]School of Pharmaceutical Sciences, Univ of Shizuoka, Shizuoka, Japan; [3]Academic and Children's Renal Unit, Univ of Bristol, United Kingdom; [4]Dept of Molecular Life Sciences, Tokai Univ School of Medicine, Kanagawa, Japan; [5]Dept of Nephrology, Kumamoto Univ Graduate School of Medical sciences, Kumamoto, Japan.*

Background: Natriuretic peptide receptor/guanylyl cyclase-A (GC-A) signaling exerts renoprotective effects by eliciting natriuresis and reducing blood pressure. We previously reported that high salt-fed systemic GC-A knockout mice with aldosterone, uninephrectomy and high salt showed accelerated hypertension and severe glomerular injury with massive albuminuria. However, genes involved in glomerular injury are elusive.

Methods: By using microarray analysis, we compared gene expression in the glomeruli of systemic GC-A knockout mice and wild-type mice with aldosterone. Furthermore, we constructed podocyte- specific GC-A KO mice to examine the role of GC-A in podocytes, and analyzed gene expression in systemic and podocyte-specific GC-A knockout mice.

Results: We identified 85 upregulated and 48 downregulated genes in GC-A knockout mice by more than 8-fold compared with wild-type mice. One of upregulated genes in GC-A knockout mice was matrix metalloproteinase-10 (MMP-10). Podocyte-specific GC-A KO mice with aldosterone exhibited albuminuria by 13-fold, mesangial expansion and footprocess effacement compared to control mice with aldosterone. We confirmed that the expression of MMP-10 from the glomeruli in systemic and podocyte-specific GC-A knockout mice was 200 and 3 times higher than that from control mice by real-time PCR, respectively. Podocyte-specific GC-A KO mice with aldosterone exhibited albuminuria, mesangial expansion and footprocess effacement. *In vitro*, the expression of MMP-10 was increased in podocytes as well as mesangial cells with TNF-α.

Conclusions: These results suggest that glomerular MMP-10 is increased in aldosterone-infused GC-A KO mice, and could play a role on inflammation during glomerular injury.

TH-PO364

Gender-Dependent Hypertension-Induced Kidney Injury in Cystathionine γ Lyase Knock Out Mice; Amelioration by Sodium Hydrosulfide Hak Joo Lee,[1,2] Denis Feliers,[1] Jeffrey L. Barnes,[1] Goutam Ghosh-Choudhury,[1,2] Rui Wang,[3] Balakuntalam S. Kasinath.[1,2] *[1]Medicine, Univ of Texas Health Science Center, San Antonio, TX; [2]Medicine, South Texas Veterans Health Care System, San Antonio, TX; [3]Lakehead Univ, Thunder Bay, ON, Canada.*

Background: Hydrogen sulfide (H2S) is constitutively synthesized in the kidney by cystathionine γ lyase (CSE) and cystathionine β synthase (CBS). Although CSE knock out (KO) mice develop hypertension (HT) (Yang G et al, Science, 2008), whether they develop kidney injury is not known.

Methods: Male and female 2.5 to 4.5- month old wild type (WT) and CSE KO mice were randomized to receive water alone or 30 umoles/L of sodium hydrosulfide (NaHS, a source of hydrogen sulfide) in drinking water for 12 weeks (n=4-6 mice in each group).

Results: Compared to WT mice, male CSEKO mice had significantly higher blood pressure and albuminuria. NaHS robustly reduced the blood pressure and albuminuria in male CSEKO mice to WT levels (Systolic BP: WT water 114±19, WT NaHS 121±12, KO water 141±9, KO NaHS 122±8, $p<0.05$ ANOVA). Similar trends were seen in female CSEKO mice. However, the renal cortical expression of TGFβ, phospho-Smad3, collagen Iα2 and laminin was increased in male but not female CSEKO mice; NaHS restored these changes to normal. Renal cortical renin-angiotensin system assays in male CSEKO vs. WT mice showed higher Ang II, Ang III, AT1 receptor and low ACE2 levels; NaHS restored ACE2 to normal without affecting other parameters. There were no changes in renal cortical contents of renin, ACE, AT2, and Mas. Blood glucose and serum cystatin C levels were unchanged in CSEKO mice vs. WT mice. At the beginning of the study, both male and female CSE KO mice were smaller than the respective WT mice but equalled WT mice weight by the end of the study. In WT mice NaHS did not affect blood pressure, albuminuria, and the above parameters.

Conclusions: Our data show that male CSEKO mice are more susceptible to HT associated renal injury than female CSEKO mice. HT in male CSEKO mice is associated with complex changes in renal parenchymal renin-angiotensin system. Administration of H2S ameliorates HT and associated renal injury suggesting exploration of H2S as a treatment tool in HT.

Sustained Reduction in Blood Pressure and Improvement in Kidney Function in Hypertensive Sheep with Chronic Kidney Disease following Radio-Frequency Catheter-Based Renal Denervation Reetu R. Singh,[1] Lindsea C. Booth,[2] Karen M. Moritz,[3] Kate M. Denton.[1] *[1]Monash Univ, Clayton, VIC, Australia; [2]Florey Inst of Neuroscience and Mental Health, Parkville, VIC, Australia; [3]School of Biomedical Sciences, The Univ of Queensland, St Lucia, VIC, Australia.*

Background: Clinical trials investigating the effectiveness of radio-frequency catheter-based renal denervation (cDNX) in reducing blood pressure in hypertensive patients have yielded conflicting results. Additionally, the long-term efficacy of the procedure is unclear. The present study examined the consequences of cDNX on basal mean arterial pressure (MAP) and renal function at 2, 5 and 11 months following cDNX procedure in sheep with hypertension and chronic kidney disease (CKD).

Methods: Sheep with established hypertension and CKD (H-CKD) with an appropriate control group were used. At 10 months of age, some animals underwent cDNX (H-CKD-cDNX (*N*=7); control-cDNX (*N*=8)) while the remaining underwent sham procedure (H-CKD-intact (*N*=7); control-intact (*N*=6)). At 2, 5 and 11 months MAP was assessed continuously over 72 hours in unanesthetised sheep and glomerular filtration rate (GFR) was measured via clearance of ^{51}Chromium-EDTA.

Results: Following cDNX MAP in H-CKD sheep was significantly reduced at 2 months (~6mmHg, P<0.001), 5 months (~5mmHg, P<0.01) and at 11 months (~6mmHg, P<0.001) compared to MAP prior to cDNX. GFR was unchanged at 2 months post-procedure but was significantly increased in H-CKD sheep at 5 months (P<0.01) and at 11 months (P<0.001) compared to their pre-cDNX GFR.

Conclusions: In sheep with hypertension and CKD, cDNX caused a sustained reduction in blood pressure from 2-11 months post procedure and caused an increase in GFR from 5-11 months post procedure. These findings are interesting because in normotensive healthy sheep, at 5 and 11 months post-cDNX, both structural and functional reinnervation has been demonstrated. The sustained reduction in blood pressure and improvement in renal function in the present study suggests the rate and degree of reinnervation may be dissimilar in sheep with hypertension and CKD compared to normotensive.

TH-PO366

Role of Adenosine A1 Receptor in Renal Afferent Arteriolar Constriction Induced by Hyperuricemia Lin Liu,[1] Xiaoyan Peng,[1] Qian Huang,[2] Jinling Hao,[1] Liang Zhao,[2] Xuewang Li,[1] En Yin Lai,[2] Limeng Chen.[1] *[1]Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China; [2]Physiology, Zhejiang Univ School of Medicine, Hangzhou, Zhejiang, China.*

Background: Hyperuricemia is known as an independent risk factor of hypertension with prominent cortical vasoconstriction and renin activation. Adenosine and A_1 adenosine receptor (A_1AR) play an important role in regulating the constriction of afferent arterioles (AAs), known as a part of tubuloglomerular feedback. However, there is no direct pathogenic proof of AAs constriction induced by uric acid and the role of A_1AR has not been studied yet.

Methods: We investigated the effects of A_1AR in AAs remodeling during hypertension induced by mild hyperuricemia in mice model. Renal arteriolopathy was evaluated by α-SMA staining. The protein expression of adenosine receptors in mice kidney was detected. The direct role of A_1AR in the AAs constriction induced by uric acid was observed by microperfusion technique and the diameter of AAs was monitored.

Results: Hyperuricemia induced by oxonic acid(OA) gavage effectively increased systemic systematic blood pressure in WT mice, associated with an increase in total medial area of the renal arteriolar wall and up-regulated A_1AR protein expression in renal tissues(1.50±0.10 vs 1.00±0.15, *P*=0.020). Hypertension and preglomerular arteriolopathy were abolished in A_1AR deficient mice. A_{2b}AR, another receptor of adenosine expressed on AAs and in charge of AA dilation, was obviously increased under hyperuricemia condition (1.12±0.02 vs 1.0±0.04, *P*=0.006) in A1AR$^{-/-}$ mice. AAs constriction was dose dependently increased by uric acid, when the concentration of uric acid increased from 10^{-7}mol/L to 10^{-3}mol/L, the AA luminal diameter diminished from (10.03±1.85)μm to (8.49±1.69)μm *(P*=0.005, paired t test). This constriction effect was abolished in $A_1AR^{-/-}$ mice(the average AA diameter increased from 10.46±1.00μm to 12.81±1.23μm, *P*<0.001), suggesting that uric acid induced hypertension possibly via directly activating AAs constriction.

Conclusions: Adenosine A_1 Receptor played an important role in renal afferent arteriolar constriction and remodeling induced by mild hyperuricemia.

TH-PO367

Renal Blood Flow Measurements Using Invasive Flow Probe Measurements in Humans Can Identify Subjects with Poor Autoregulation Branko Braam,[1] Alexander Kiepas,[1,4] Nick Mitrou,[2] William A. Cupples,[3] Daniel H. Kim.[1] *[1]Medicine/Nephrology, Univ of Alberta, Edmonton, AB; [2]Western Univ, London, ON; [3]Physiology and Kinesiology, Simon Fraser Univ, Burnaby, BC; [4]McGill, Montreal, QB, Canada.*

Background: Autoregulation of renal blood flow (RBF) is well established in animals and is regarded important to stabilize renal function when BP fluctuates preventing functional/structural impairment during low BP, but also to protect the glomerulus from transmission of high pressures to the glomerulus. This study, in humans, tested whether renal autoregulation exists and can fail in humans, and whether imprints of myogenic response (MR) and tubuloglomerular feedback (TGF) can be detected in the pressure-flow relationship.

Methods: In 15 subjects who were undergoing cardiac catheterization, we also assessed RBF at 50 Hz using a Doppler-based flow velocity measurement by introducing a FloWire (Volcano) catheter into the renal artery for 5-10 minutes and using renal artery diameter. Renal artery pressure (RAP) was measured in the abdominal aorta at the origin of the renal artery. The BP/RBF relationship was analyzed using moving 10s windows for autoregulation efficiency and with time series analysis to investigate myogenic response.

Results: Of the 15 (1F/14M) recordings 14 could be analyzed. Average MAP was 80+8 mmHg, RBF 463+208 ml/min, and slope of 10s windows with a significant change in MAP 5 ml/min/mmHg. When divided into better and poorer autoregulation, RBF was significantly higher in the group with worse autoregulation. MR and TGF signatures could be identified in the Gain, Coherence and Phase plots.

Conclusions: The use of this newly developed method to assess autoregulation efficiency established by MR revealed good efficiency among half of the individuals. In summary, this approach makes it possible to investigate RBF dynamics, MR and TGF and efficiency of autoregulation in humans. Further studies are being undertaken to refine the analytical methodology for these human samples and to compare patients with and without heart failure with respect to RBF dynamics. In the future, this methodology may provide a more physiological parameter to assess diagnosis, prognosis and therapeutics in patients with heart or circulatory failure.

TH-PO368

Deletion of Endothelial Mineralocorticoid Receptors Confers Protection Toward Altered Contractility in Renal Vessels during Endothelial Dysfunction Henrik Dimke,[1] Sidsel Brandt Laursen,[1] Stine Louise Høyer Finsen,[1] Susan E. Quaggin,[2] Pernille B. Hansen.[1] *[1]Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; [2]Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Background: Aldosterone blockade confers substantial cardiovascular protection. The effects of aldosterone on mineralocorticoid receptors (MR) expressed in endothelial cells (EC) within the renal vasculature have not been delineated. We hypothethized that lack of MR in EC may be protective in renal vasculature in models of hypertension and endothelial dysfunction.

Methods: To examine the role of the MR in EC we utilized transgenic Tie2-Cre mice to ablate the MR gene (EC-MR). Blood pressure, heart rate and PAH clearance were measured using indwelling catheters in conscious mice. The role of the MR in EC on constriction and relaxation was investigated in the renal artery and in perfused afferent arterioles. Urinary sodium excretion was determined by use of metabolic cages after 4 weeks of AngII infusion.

Results: EC-MR transgenics had markedly decreased MR expression in isolated aortic endothelial cells as compared to littermates (WT). Baseline as well as the rise in blood pressure and renal plasma flow following one week of AngII infusion was similar between WT and EC-MR. No differences in constriction and relaxation was observed in isolated renal arteries between groups during baseline. Endothelial dysfunction, as evidenced by decreased acetylcholine-induced relaxation was evident in both genotypes after 4 weeks of AngII infusion. However, increased contractility of renal arteries was seen only in WT, but not EC-MR mice after infusion. The constriction of afferent arterioles from untreated mice was not different. No differences were found between the groups with respect to urinary and fractional excretion of sodium after 4 weeks on AngII infusion.

Conclusions: Deletion of the MR in EC does not confer protection towards the development of AngII-induced hypertension and endothelial dysfunction in renal arteries. However, loss of MR in EC prevents an augmented contractile response to constrictors under these conditions.

TH-PO369

Anti-Hypertensive Effect of Thiazides Shifts from Salt Excretion to Vasorelaxation during Salt Restriction or Volume Depletion Saeed Alshahrani,[1] Kamyar A. Zahedi,[1] Min Jiang,[2] Michelle L. Nieman,[3] Sharon L. Barone,[1] John N. Lorenz,[3] Jack Rubinstein,[2] Manoocher Soleimani.[1] *[1]Divs of Nephrology, Univ of Cincinnati; [2]Cardiology, Univ of Cincinnati; [3]Cellular and Molecular Physiology, Univ of Cincinnati.*

Background: Thiazide derivatives, including hydrochlorothiazide (HCTZ), are specific inhibitors of the $Na^+.Cl^-$ Co-transporter (NCC), and the most commonly used diuretic to treat mild hypertension. Both renal (natriuretis) and extra renal (vasorelaxation) mechanisms have been proposed as major mediators of blood pressure reduction by HCTZ but the circumstances under which the renal or extra renal mechanism predominates remain unknown.

Methods: Systemic blood pressure was monitored by intra-arterial catheter and computerized tail cuff in transgenic mice lacking NCC under varying conditions. Pendrin KO or pendrin/NCC double KO (dKO) mice were used to ascertain the compensatory role of pendrin in salt reabsorption in response to HCTZ.

Results: Pendrin KO mice were the only group which showed enhanced salt excretion in response to HCTZ, with salt excretion increasing by ~30% in pendrin KO vs. WT mice (p<0.05). In mice lacking NCC, HCTZ significantly reduced the systemic blood pressure only during salt restriction and without enhancing salt excretion. In volume depleted but not in volume resuscitated NCC/pendrin dKO mice, HCTZ caused dramatic reduction in systemic blood pressure from 72.13± 5.1 at baseline to 51.06 ± 6.6 mm Hg in dKO mice

within 20 minutes of HCTZ administration (p<0.01 vs. baseline) with no significant effect in WT mice (p>0.5 vs. baseline) or in salt resuscitated NCC/pendrin dKO mice. There was no enhancement in salt excretion and no reduction in cardiac output in pendrin/NCC dKO mice in response to HCTZ. The antihypertensive effects of HCTZ were abrogated in the presence of paxilline, a specific blocker of BK channel, which is upregulated in arterial vasculature of volume depleted mutant mice.

Conclusions: Thiazides reduce blood pressure predominantly via vasorelaxation during salt restriction/volume depletion; whereas, they enhance salt excretion during salt replete state and specifically in conditions associated with pendrin inactivation.

TH-PO370

The Metabolic Syndrome Does Not Affect Development of Collateral Circulation in the Post-Stenotic Swine Kidney

Xin Zhang,[1] Christopher M. Ferguson,[1] Behzad Ebrahimi,[1] Ahmad Fahim Hedayat,[1] Amir Lerman,[2] Lilach O. Lerman.[1,2] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Cardiology, Mayo Clinic, Rochester, MN.*

Background: Development of collateral circulation around a stenotic renal artery contributes to maintenance of renal blood flow (RBF) in the ischemic kidney. Stenotic kidney RBF is elevated in the metabolic syndrome (MetS) compared to lean pigs, but the underlying mechanism is unclear. We hypothesized that MetS increased collateral circulation around renal artery stenosis (RAS).

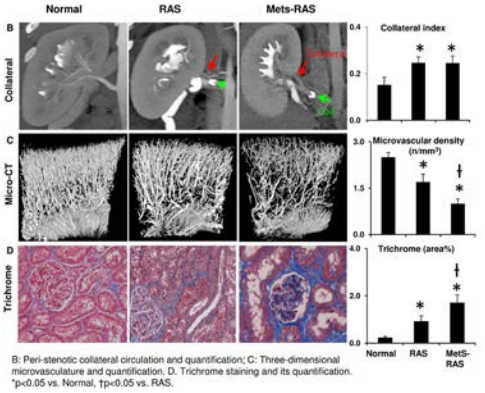
Methods: Unilateral RAS was induced using a coil [figure1B] in 14 domestic pigs after 6 weeks of either an atherogenic (high-fat/fructose, MetS-RAS) or standard diet, which then continued for 10 more weeks. Pigs on standard diet served as controls (n=7 each group). At completion of diet, RBF, glomerular filtration rate (GFR), and the peri-stenotic collateral index (CI) were assessed in vivo using multi-detector computed tomography (CT). CI was assessed as the fractional vascular volume in the zone encompassing visually discernible collaterals around the stenotic segment of the renal artery. The intrarenal microcirculation was examined ex vivo by micro-CT by the spatial density of microvessels, and renal fibrosis by trichrome staining.

Results: MetS-RAS developed obesity, dyslipidemia, and insulin resistance [figure1A]. RBF and GFR were decreased in RAS, but not in MetS-RAS, whereas their peri-stenotic CI's were similar [figure1B]. Conversely, intra-renal microvascular loss and fibrosis were greater in MetS-RAS [figure1C-D].

A

	Normal	RAS	MetS-RAS
MAP (mmHg)	89.6±2.1	97.2±2.0*	129.6±9.1*†
Total cholesterol (mg/dl)	103±34	102±27	377.7±84.6*
HOMA-IR (μU/ml×mg/dl)	0.6±0.1	0.8±0.1	1.9±0.1*†
Renal blood flow (ml/min)	676.9±34.6	544.6±42.7*	648.6±10.9†
Glomerular filtration rate (ml/min)	97.9±5.3	85.8±6.2*	95.2±3.4
Degree of stenosis (%)	-	64.8±3.8	65.0±5.0

MAP: mean arterial pressure; HOMA-IR: homeostasis model assessment insulin resistance.
*p<0.05 vs. Normal, †p<0.05 vs. RAS.



B: Peri-stenotic collateral circulation and quantification; C: Three-dimensional microvasculature and quantification. D. Trichrome staining and its quantification.
*p<0.05 vs. Normal, †p<0.05 vs. RAS.

Conclusions: The unaltered collateral vessel formation in the stenotic MetS compared to lean kidneys argues against a major contribution of the collateral circulation to preservation of RBF, which might be secondary to hemodynamic factors in MetS-RAS. Nevertheless, despite preserved RBF, the post-stenotic kidney shows microvascular loss, possibly due to MetS-induced fibrosis.

Renal Nerves Mediate Increased Renal Vascular Resistance in Response to Moderate but Not Severe Elevation of Renal Venous Pressure in Rats

Shereen M. Hamza,[1,2] Xiaohua Huang,[1] William A. Cupples,[3] Branko Braam.[1,2] *[1]Medicine/Nephrology, Univ of Alberta, Edmonton, AB, Canada; [2]Physiology, Univ of Alberta, Edmonton, AB, Canada; [3]Physiology and Kinesiology, Simon Fraser Univ, Burnaby, BC, Canada.*

Background: Heart failure (HF) often coincides with renal dysfunction, leading to significant and unexplained mortality, thus emphasizing the intricate connection between cardiac and renal systems. HF-induced elevation of central venous pressure translates to increased renal venous pressure (RVP) which may, in turn, impair renal function. We hypothesized that increases in RVP lead to increased renal vascular resistance (RVR) modulated by renal nerves. **Objectives:** (1) Determine the impact of selective RVP increase (10 or 20 mmHg) on renal hemodynamics, (2) Elucidate the contribution of renal nerves.

Methods: Blood pressure and RVP were assessed in anesthetized rats (300-400g, n=38). FITC-inulin was infused i.v. and urine collected to assess GFR; renal arterial blood flow (RBF) was directly measured. Rats were intact or subjected to bilateral renal denervation (RD). Following baseline measurements, RVP was selectively increased to either 10 or 20 mmHg by partial occlusion of the left renal vein for 120 min or not manipulated (time controls).

Results: Moderate elevation of RVP (1.1±0.3 to 11.3±0.4 mmHg, n=10) decreased RBF in intact rats with a concomitant increase in RVR (p<0.001, n=5). RD did not prevent a fall in RBF, but completely abolished the RVR increase (p<0.05, n=5). GFR remained unaltered in each group. Augmented RVP elevation (0.5±0.1 to 20.1±0.2 mmHg, n=12) similarly decreased RBF and increased RVR in intact rats (p<0.05, n=8), however, this was not prevented by RD (p<0.001, n=4). GFR dropped in both intact (1.2±0.1 to 0.3±0.1 mL/min, p<0.001) and RD (1.4±0.1 to 0.1±0.07 mL/min, p<0.001) rats.

Conclusions: Elevated RVP directly modulates renal hemodynamics, inducing significant reduction of RBF and GFR as well as a sustained increase in RVR, which appears to be differentially mediated by renal nerves at moderate and high levels of RVP.

SH and XH equally contributed to this work.

Transglutaminase Is a Critical Link between Inflammation and Hypertension

Renna Luo.[1,2,3] *[1]Dept of Nephrology, The First Affiliated Hospital of Dalian Medical Univ, Dalian, Liaoning, China; [2]Dept of Biochemistry and Molecular Biology, Univ of Texas Houston Medical School, Houston, TX; [3]Dept of Nephrology, Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

Background: The pathogenesis of essential hypertension is multifactorial with different underlying mechanisms contributing to disease. We have recently shown that TNF superfamily member 14, LIGHT (also known as TNFSF14), induces hypertension when injected into mice. Research reported here was undertaken to examine the role of transglutaminase (TGase) in LIGHT induced hypertension.

Methods: Six to eight mice for each group were infused with LIGHT by minipump. Recombinant mouse LIGHT (R&D Systems, Minneapolis) was delivered at a rate of 4ng/day into mice for 14-days. Cystamine treated mice were provided drinking water containing 0.9 g/L cystamine dihydrochloride throughout the 14 days. Control mice were infused with saline. We collected urine and measured blood pressure at 0,3,7,10,14 days. After treatment for 14-days, mice were sacrificed.

Results: Initial experiments showed that plasma and kidney TGase activity was induced by LIGHT infusion and was accompanied with hypertension and renal impairment. The increase in renal TGase activity corresponded to an increase in RNA for the tissue Tgase isoform, termed TG2. Pharmacologically we showed that LIGHT-induced hypertension and renal impairment did not occur in the presence of cystamine, a well-known competitive inhibitor of TGase activity. Genetically we showed that LIGHT-mediated induction of TGase, along with hypertension and renal impairment, was dependent on IL-6 and endothelial HIF-1α. We also demonstrated that IL-6, endothelial HIF-1α and TGase are required for LIGHT induced production of angiotensin receptor agonistic autoantibodies, AT_1AA.

Conclusions: Thus, LIGHT induced hypertension, renal impairment and the production of AT_1-AA require TGase, most likely the TG2 isoform. Our findings establish TGase as a critical link between inflammation, hypertension and autoimmunity.

Renal Cortex and Medulla Oxygenation during Chronic Angiotensin II Infusion in Conscious Rats

Tonja Emans,[1,2] Maarten P. Koeners,[3] Jaap A. Joles,[2] Ben Janssen,[4] C.T.P. (Paul) Krediet.[1] *[1]Internal Medicine-Nephrology, AMC-UvA, Netherlands; [2]Nephrology & Hypertension, UMC Utrecht, Netherlands; [3]Physiology and Pharmacology, Univ Bristol, United Kingdom; [4]Pharmacology and Toxicology, Univ Maastricht, Netherlands.*

Background: Angiotensin II (AngII) infusion persistently increases renal vascular resistance. We previously found reduction in renal cortical oxygenation during acute infusions of AngII in conscious rats [EDTA 2014]. Experiments under anaesthesia suggested impaired renal oxygen delivery. Here we characterize chronic effects of AngII infusion on tissue oxygen levels of kidney cortex and medulla in conscious rats using telemetric pO_2 recording.

Methods: Telemetric oxygen-sensitive carbon paste electrodes were implanted in Sprague-Dawley rats (250-300 g), either in renal cortex (n=7) or medulla (n=7). In vivo hyperoxia/hypoxia inhalation was performed weekly to test signal responsiveness. After recovery and baseline oxygen level assessment, 300ng/kg/min AngII was infused for 2 weeks by s.c. osmotic minipumps. Losartan (300mg/L) was added to drinking water for 2 days. Blood pressure was monitored by telemetry in a separate group (n=5).

Results: Hyperoxia/hypoxia confirmed sensitivity for reproducibly detecting changes in tissue oxygen throughout the experiment. Upon hyperoxia, oxygen increased more in cortex than in medulla (peak change relative to baseline at 100% oxygen was 297±56% in cortex vs. 131±5% in medulla). There was sustained increase in blood pressure during AngII infusion (from 95±2 to 168±12mmHg, P<0.01). Renal oxygen decreased transiently during the first 20 hours of AngII infusion in both cortex and medulla. Losartan increased oxygen levels during the first 8 hours (peak change compared to 12 hours before losartan was 121±19% in cortex and 125±20% in medulla, P≤0.05).

Conclusions: Our data suggest that less oxygen reaches medulla than cortex during hyperoxia, possibly due to countercurrent vasa recta that enable oxygen shunting. Chronic AngII exposure at levels that induce hypertension only causes transient hypoxia in both cortex and medulla. This suggests renal adaptation to hypoxia either by altered metabolic demand due to decreased blood flow or increased efficiency of oxygen consumption.

TH-PO374

Circadian Rhytm in Kidney Tissue Oxygenation Tonja Emans,[1,2] Jaap A. Joles,[2] C.T.P. (Paul) Krediet.[1] *[1]Internal Medicine-Nephrology, AMC-UvA, Amsterdam, Netherlands; [2]Nephrology & Hypertension, UMC Utrecht, Netherlands.*

Background: Blood pressure, renal hemodynamics, electrolyte and water excretion all display diurnal oscillation. Disturbance of the renal circadian clock is associated with hypertension. Kidney oxygenation is dependent on oxygen delivery and consumption that in turn are regulated by renal hemodynamics and metabolism. We hypothesized that i) kidney oxygenation also demonstrates 24h periodicity, and ii) this periodicity is disturbed during angiotensin (Ang)II infusion.

Methods: Telemetric oxygen-sensitive carbon paste electrodes were implanted in Sprague-Dawley rats (250-300g), either in renal medulla (n=7) or cortex (n=7). Rats were housed in a 12h light-dark cycle. Arterial pressure (MAP) was monitored by telemetry in a separate group (n=5). After 2 weeks of stabilization and recovery, hypertension was induced by s.c. osmotic minipumps containing 300ng/kg/min AngII. Both at baseline and during AngII 5 consecutive days were analysed for periodicity. The first 3 days of AngII were not analyzed.

Results: MAP was 97±2 mmHg during active dark phase and 94±2 mmHg during daytime (P<0.01). During the dark oxygen levels increased to 106±2% in cortex and 104±4% in medulla (vs. baseline; P≤0.05). During the light oxygen levels decreased to 95±2% in cortex and 98±3% in medulla. Data was analysed for rhythmicity by curve fitting and 95% confidence intervals (rectangles in figure). During AngII rhythmicity for oxygenation was lost in cortex but not in medulla. There was a shift in MAP pattern.

Conclusions: We detected significant 24h periodicity in cortex and medulla oxygen based on curve fitting. Possibly oxygen levels in the kidney follow renal blood flow, which determines oxygen delivery and peaks in the active phase (at night) and troughs during the resting phase [Pons *et al.* AJP 1996;271:R1002]. Periodicity in cortex oxygen was disturbed by AngII, possibly by persistent vasoconstriction.

The Ablation of Dendritic Cells Prevents Hypertension and Enhances Natriuresis in Angiotensin II and High-Salt Diet Treated Mice Patricio A. Araos,[1] Daniel E. Hevia,[1] Carolina E. Prado,[2] Rodrigo Pacheco,[2] Luis F. Michea.[1] *[1]Millennium Inst on Immunology and Immunotherapy, ICBM Facultad de Medicina, Univ of Chile, Santiago, Chile; [2]Laboratory of Neuroimmunology, Fundación Ciencia & Vida, Santiago, Chile.*

Background: Angiotensin II (AngII) and high salt diet (HS) cause hypertension, endothelial dysfunction and the upregulation of renal sodium transporters. Our previous studies showed that the ablation of Dendritic Cells (DCs) in mice prevented hypertension and the increased expression of renal sodium transporters. In the present study we evaluated if the ablation of DCs modified natriuresis and arterial function in AngII+HS treated mice.

Methods: We studied wild type (WT) mice and CD11c.DOG transgenic mice (CD11c) for the selective elimination of DCs by Diphteria Toxin (DT) injection. WT and CD11c mice were divided into 3 groups: AngII+HS (AngII=1.042 µg/Kg/min+1% NaCl in drinking water), AngII+HS+DT (DT=8ng/g) and control. Blood pressure (BP) and urinary sodium excretion was analyzed. At days 4 and 14, we made saline challenge test (injection of isotonic saline; 10% of BW) and measured 4h natriuresis. We obtained aortic rings at day 14 for vascular reactivity and endothelial function studies.

Results: WT mice of AngII+HS and AngII+HS+DT groups showed similar increase of SBP. However, the injection of DT prevented the increase of SBP in CD11c mice. Telemetric studies confirmed high BP of AngII+HS CD11c mice (PAM=144±21 mmHg; SBP=160±26 mmHg, day14) that was prevented by the ablation of DCs (PAM=92.7±20 mmHg and SBP=104±26 mmHg). The AngII+HS treatment increased 24h natriuresis (19.4±7.6 µEq/g BW); the ablation of DCs further increased natriuresis (30±7.9 µEq/g BW; n=5; P<0.05) in CD11c mice. Natriuresis after saline challenge test in AngII+HS mice was similar in WT and CD11c mice at day 4. However, the DT injection in CD11c mice increased natriuresis in 27% compared to the other AngII+HS groups (P<0.05). Aortic rings showed similar vascular reactivity and endothelial function in all AngII+HS groups.

Conclusions: The results suggest that DCs modulate tubular sodium reabsorption in response to AngII and high salt diet. FONDECYT1130550, IMII P09-016-F, BECA CONICYT 21130482.

Central Nervous System Expression of Epithelial Sodium Channels and Regulatory Proteins in Secondary Hypertension following Renal Artery Stenosis Md. Shahrier Amin,[1] Mazen Osman,[2] Karen R. Lien,[2] Zeng Hu,[2] Sonu Kashyap,[2] Joseph P. Grande.[1,2] *[1]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [2]Mayo Foundation for Medical Research, Mayo Clinic, Rochester, MN.*

Background: Central pathways involving epithelial sodium channels (ENaC) contribute to sympathetic hyperactivity in salt sensitive hypertension. Whether or not these pathways are involved in the pathogenesis of secondary hypertension due to renal artery stenosis (RAS) has not been studied.

Methods: We studied protein distribution by immunohistochemistry of ENaC α, ENaC β, ENaC γ, mineralocorticoid receptor (MR) and serum and glucocorticoid regulated kinase-1 (SGK1), in brain areas involved in sodium homeostasis and regulation of BP in C57BL6 mice with unilateral RAS (n=9) compared to sham controls (n=5) at 4 weeks. RAS was achieved by placement of a 0.2 mm polytetrafluoroethylene cuff on the right renal artery.

Results: Unilateral RAS for 4 weeks was associated with decreased kidney weight (32±14 g) and global atrophy (88±21%) in the stenotic kidney vs non-stenotic kidney (184±20 g, no atrophy), and a modest increase in BP (124±9 mm Hg vs 90±15 mm Hg at baseline). Increased cytoplasmic abundance of all three ENaC sub-units was noted in the sub-fornical organ, supra-optic nucleus, para-ventricular nucleus and hippocampus, compared to other brain areas. RAS did not cause a significant change in staining intensity or distribution in these areas. However, increased apical staining in microvilli was noted for ENaCγ only in the choroid plexus. Staining for MR was mostly nuclear and cytoplasmic, and was not affected by RAS. Strong cytoplasmic immunostaining for SGK1 was noted in the magnocellular neurons, which also remained unaffected by RAS.

Conclusions: We noted increased staining for ENaCγ in the apical membrane and microvilli of the choroid plexus epithelia following unilateral RAS. Redistributed ENaCγ may contribute to formation of functionally active channels and act as a compensatory mechanism to reabsorb Na from the cerebrospinal fluid. No changes in protein expression in the hypothalamic nuclei, supports the observations that central MR-ENaC regulated pathways are primarily involved in salt sensitive hypertension.

Dietary Potassium Regulates Renal Kallikrein, Renin and Cyclooxygenase-2: Morphological Evidence Carlos P. Vio,[1] Natalia A. Mendez,[1,2] Daniela P. Salas,[1] Jessica Diaz-Elizondo,[1] Mariana Labarca,[1] Carlos Cespedes.[1] *[1]Center for Aging and Regeneration, Dpt Physiology, Pontificia Univ Catolica de Chile, Santiago, Chile; [2]Inst of Anatomy, Histology, Pathology, Univ Austral de Chile, Valdivia, Chile.*

Background: The importance of dietary potassium in health and disease is underscored compared with that placed on dietary sodium. Much effort has been placed on reduction of sodium intake and less on the adequate dietary potassium, although natural food contains 10-15 times more potassium than sodium. The benefits of a potassium-rich diet are known, and recent evidence showed that high potassium diet dephosphorylate NCC resulting in acute natriuresis. With the hypothesis that dietary potassium regulates renal sodium excretory hormonal systems at long-term, we studied the effect of high potassium diet on kallikrein (Kall), renin and cyclooxygenase-2 (COX-2).

Methods: SD male rats on a normal sodium diet received normal potassium (0.9%, NK) or high potassium diet (3%, HK) for 4 weeks. Urine was collected in metabolic cages for measurement of electrolytes and enzyme activities. Renal tissue was used to analyze protein (Western blot) and mRNA (RT-qPCR) levels, and immunohistochemistry for morphometric analysis.

Results: Kall was restricted to connecting tubule cells, HK increased the Kall positive cell size and immunostaining area; cells were hypertrophied with increased Golgi and secretory-like vesicles. Cell changes were associated with increased enzyme activity (p<0.005), increased protein (p<0.05) and mRNA levels (p<0.01). Renin staining was restricted to granular cells of the afferent arteriole; a HK diet decreased the number of renin positive cells and renin mRNA levels (p<0.01). COX-2 containing cells were restricted to a subset of thick ascending limb segment and in response to HK decreased number of COX-2 cells was observed with decreased protein (p<0.01) and mRNA levels (p<0.05).

Conclusions: The increased renal kallikrein and decreased renin are consistent with the their contribution to the natriuretic and renoprotective effect of potassium. Downregulation of COX-2 could be compensatory and requires further study.

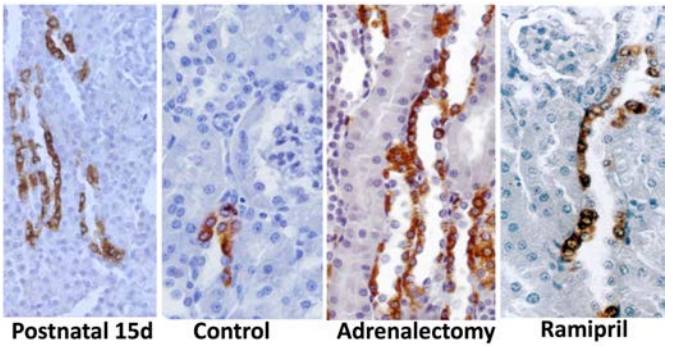
TH-PO378

Cyclooxygenase-2 Increases Its Expression by Recruitment of Neighboring Epithelial Cells from the Thick Ascending Limb of Henle Carlos P. Vio,[1] Natalia A. Mendez,[1,2] Carlos Cespedes.[1] *[1]Center for Aging and Regeneration, Dept Physiology, Pontificia Univ Catolica de Chile, Santiago, Chile; [2]Inst Anatomy, Histology and Pathology, Univ Austral de Chile, Valdivia, Chile.*

Background: Cyclooxygenase-2 (COX-2) is an enzyme that contributes to regulation of renal function via local prostaglandins. We described its origin in a subset of cells from the thick ascending limb of Henle (TALc). COX-2 is regulated in physiological conditions by dietary sodium, glucocorticoids, postnatal development and a negative feedback loop mediated by PGE_2 EP3 receptor. COX-2 increases its expression along the axis of the TAL segment and we hypothesize that this follows a recruitment pattern.

Methods: We used renal tissue from a wide variety of conditions, some are new experiments such as SD adult rats with adrenalectomy (ADX), or treated with coxibs (rofecoxib), or with ACEi (ramipril), or AT1 blockers (ARBs, losartan), or EP3 antagonist (L-798106). Other tissue was obtained from our collection of stored tissue: microdissected nephrons from treated rats, or early postnatal ages (5 to 15 days). The tissue was stained by immunohistochemistry, the levels of the enzyme quantified by its protein by Western blot and mRNA by RT-qPCR.

Results: A wide variety of stimuli produced the same pattern of recruitment of epithelial cells from TAL, with highest levels during early postnatal age, lowest levels in adult, and increased in ADX, ACEi, ARBs or EP3 antagonist. This axial recruitment was confirmed in microdissected nephrons.



Conclusions: Regardless of the stimuli, when COX-2 increases, a recruitment phenomenon was observed. The recruitment phenomenon is rare, and the most studied is a similar recruitment observed with renin expression in the afferent arteriole. Both COX-2 and renin recruitment share similarities like regulation by sodium, postnatal development, ACEi and ARBs. Funding Fondecyt 1130741, CONICYT PIA/Basal PFB12, SQM.

TH-PO379

TLR4/NFkB Inhibition Strongly Attenuated Renal and Vascular Injury in the Chronic NO Synthase Inhibition/Salt Overload Model Fernanda F.F. Zambom,[1] Karin C. Oliveira,[1] Victor F. Avila,[1] Camilla Fanelli,[1] Simone C.A. Arias,[1] Flavia G. Machado,[2] Claudia R. Sena,[1] Vivian L. Viana,[1] Denise M. Malheiros,[1] Niels O.S. Camara,[1] Roberto Zatz,[1] Clarice K. Fujihara.[1] *[1]Univ of Sao Paulo, Brazil; [2]Washington Univ.*

Background: Chronic NO inhibition by Nω-nitroarginine methylester (NAME) combined with salt overload (HS) leads to severe hypertension (HT), albuminuria (ALB) and renal/vascular injury. The mechanisms of inflammation and tissue injury in this model remain poorly understood. We investigated the role of innate immunity in HS+NAME and the possible salutary effects of inhibiting NFκB with pyrrolidine dithiocarbamate (PDTC).

Methods: Male Munich-Wistar rats received oral NAME, 32 mg/Kg/d, and HS (N=11), or HS+NAME+PDTC, 60 mg/kg/d (N=13). Rats given HS only were controls (N=12). After 4 wk, we assessed tail-cuff pressure (TCP, mmHg), ALB (mg/d), glomerulosclerosis (GS, %), glomerular ischemia (GI, %), arteriolar onion skin lesions (OSL, %), interstitial α-actin, collagen 1 (COLL1, %), AngII+ cells and macrophages (MΦ), cells/mm^2. Renal content of IL1β (pg/mg), caspase-1 (Casp1), TLR4 and nuclear p65 (NFκB) was also measured (x HS).

Results:

	HS	HS+NAME	HS+NAME+PDTC
TCP	149±2	209±4[a]	174±4[ab]
ALB	9±3	147±12[a]	37±8[ab]
GS%	0.2±0.1	4.1±1.0[a]	0.7±0.3[b]
GI%	0.6±0.5	11.6±1.9[a]	2.6±1.1[b]
OSL%	1±1	23±3[a]	6±2[b]
COLL1	1±1	3±1[a]	2±1[ab]
MΦint	23±2	131±7[a]	34±6[b]
AngII	2±1	13±1[a]	3±1[b]
α-actin	0.7±0.2	10±1[a]	2±1[b]
IL1β	1.5±0.2	4±1[a]	2±1[b]
Casp1	1.0±0.2	1.6±0.3	1.8±0.5
TLR4	1.0±0.1	2.6±0.4[a]	1.3±0.2[b]
p65	1.0±0.1	2.9±0.3[a]	1.4±0.3[b]
Mean±SE;[a]p<0.05 vs HS, [b]p<0.05 vs HS+NAME			

Expectedly, HS+NAME promoted severe HT, ALB and renal/vascular injury/inflammation. Renal IL1β was increased along with activation of the TLR4/NFκB pathway. PDTC normalized renal IL1β and TLR4, reversed NFκB activation, prevented inflammation and strongly attenuated HT, ALB and renal injury.

Conclusions: Activation of the TLR4/NFκB pathway may promote, and its inhibition may reverse, renal injury in the chronic NOS inhibition model. The participation of other aspects of innate immunity, such as the Casp1/NLRP3 pathway, cannot be excluded. FAPESP/CNPq.

TH-PO380

The Effects of Pitavastatin on Renal Nitric Oxide System in Spontaneously Hypertensive Rats and Wistar-Kyoto Rats Gaizun Hu, Osamu Ito, Masahiro Kohzuki. *Internal Medicine and Rehabilitation, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: Clinical trials have demonstrated renoprotective effects of atorvastatin (ATV) and pitavastatin (PTV), which belong to the strong statins, are more potent than other statins. We reported previously that ATV attenuated the development of hypertension in SHR with increasing the endothelial and neuronal nitric oxide synthases (eNOS, nNOS) expressions in the kidney, inhibited the eNOS phosphorylation at serine1177 and did not affect expressions in Wistar-Kyoto rats (WKY) . To clarify the mechanisms of antihypertensive and renoprotective effects of PTV, the present study examined the effects of PTV on blood pressure and NO system in the kidney of SHR and WKY.

Methods: Five-week-old, male SHR and WKY were given orally PTV (2mg/kg•day^{-1}) or vehicle for 8 weeks. The renal eNOS, nNOS expressions and eNOS phosphorylation were examined by westernblot.

Results: PTV attenuated the hypertension (220 ± 8 vs. 177± 4 mmHg) and albuminuria(684 ± 66 vs. 398 ± 42 mg/day) without changing plasma total cholesterol or creatinine, but did not change the parameters in WKY. PTV tended to increase NO_x concentration in plasma both in SHR and WKY and significantly increased urinary NO_x excretion in WKY. PTV increased the renal eNOS and nNOS expressions in the medulla of SHR (eNOS; by 182% and 186%, nNOS; by 315% and 194%), PTV increased the renal eNOS and nNOS expressions in the cortex and inner medulla of WKY (eNOS by 181% and 45%, nNOS by 45% and 125%). PTV significantly stimulated the eNOS phosphorylation at serine1177 in the inner medulla (98%) and inhibited the eNOS phosphorylation at threonine495 in the medulla of SHR (50% and 58%). PTV also enhanced the eNOS phosphorylation at serine1177 in the medulla (306% and 158%) and inhibited eNOS phosphorylation at threonine495 in inner medulla of WKY (39%).

Conclusions: PTV attenuates the development of hypertension and albuminuria in SHR. PTV increases the expressions, and activates the eNOS phosphorylation in the kidney of both in hypertensive and normotensive rats. The antihypertensive and renoprotective effects of PTV may be mediated in part by an upregulation of NO system in the kidney.

TH-PO381

Role of Angiotensin II Type 1b (AT1b) in Renal Injury in the DOCA-Salt Hypertension Model Using AT1a Deficient Mice Mikako Hisamichi,[1] Atsuko Ikemori,[1,2] Takeshi Sugaya,[1] Daisuke Ichikawa,[1] Kenjiro Kimura,[3] Yugo Shibagaki.[1] *[1]The Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki City, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki City, Japan; [3]JCHO Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Angiotensin II (Ang II) type 1 (AT1) receptors exist as two isoforms, designated AT1a and AT1b, in rodents. Although AT1a receptors play a major role in myogenic vasoconstriction of afferent arterioles for renal autoregulation and are the murine homologue of the single human AT1 receptor, AT1b receptors were reported to be more related to myogenic response in vascular smooth muscle than AT1a receptors. The aim of this study is to reveal the role of the AT1b receptor on myogenic vasoconstriction in pressure-dependent renal injury.

Methods: Female AT1a deficient($AT1a^{-/-}$) mice were subjected to left nephrectomy and were divided into three groups; the DOCA group received systemic DOCA ($75\mu g/kg^{-1}.min^{-1}$) using tablets and were provided with drinking water containing 1% NaCl for 28 days. We used losartan as a blocker of all AT1 receptors. The DOCA+losartan group was given an oral dose of 25mg/kg/day in addition to injections of DOCA and NaCl, while the control mice underwent sham operations and were provided with only tap water.

Results: Systolic blood pressure was significantly increased on day 28 in the DOCA group, but was not reduced by the losartan treatment. Expansion of the mesangial matrix and increase in urinary albumin induced by DOCA-salt tend to be slightly prevented by the losartan treatment. Both the glomerular size and the score for glomerular sclerosis induced by DOCA-salt were not aggravated by losartan. These results suggested that blocking the AT1b receptor in addition to the AT1a receptor did not increase vulnerability to pressure-dependent glomerular injury.

Conclusions: The AT1b receptor might not contribute to myogenic vasoconstriction of afferent arterioles in the DOCA-salt hypertension model using AT1a deficient mice.

Renal Afferent Peptidergic Neurons – What Are Primary Stimuli? Tilmann Ditting,[1] Kristina Rodionova,[1] Sonja Loosen,[1] Christian Ott,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[2] Roland Veelken.[1] *[1]Medical Dept 4, Univ of Erlangen, Erlangen, Bavaria, Germany; [2]Nephropathology, Univ of Erlangen, Erlangen, Bavaria, Germany.*

Background: Renal afferent nerves comprise a complicated neuro-paracrine regulatory system influencing the sympathetic nervous system. We tested the hypothesis that the activity of renal afferent neuronal units is primarily altered by inflammatory processes in cardiovascular disease.

Methods: In rats, hypertension was induced by unilateral clipping of one renal artery (2K1Cl model), normotensive renal inflammation (anti Thy-1) by i.v. injection of 1.75 mg/kg BW Thy-1 antibody . Retrograde labelling (DiI) identified renal afferent neurons in the dorsal root ganglion (DRG) (Th11-L2). Patch clamp recordings, i.e. current clamp allowed to characterize neurons as highly active or "tonic" with sustained action potential (AP) firing versus low active or "phasic" (<5 Aps) upon current injections. Electrophysiological parameters and AP properties were determined in all experimental groups, proteinuria and renal morphology for all kidneys.

Results: In renovascular hypertension (mean arterial pressure: 173+12 mmHg) only neurons with projections to the clipped kidneys showed a significant decrease in tonic firing (30.6% [23/75]), the non-clipped kidney showed an unaffected proportion of tonically firing neurons (67.5% [50/74], $p<0.05$). In nephritis, neurons with a tonic, more active response pattern decreased significantly (43,4% vs. 64,8%, $p<0.05$) compared to controls. There was no increase in blood pressure (BP) in nephritic animals. Rats with nephritis exhibited albuminuria (61±6 µg/24h), infiltration of macrophages in the interstitium (26 ± 4 cells/high-power field) and glomeruli (3.7±0.6 cells/glomerular cross-section). In 2K1Cl hypertension, renal inflammation occurred mainly in the glomeruli and interstitium of the nonstenotic kidneys, in clipped kidneys signs of inflammation were signifcantly less.

Conclusions: Inflammation (and hypertension) may play less important roles for the decreased activity pattern of afferent renal neurons in cardiovascular disease. Rather altered perfusion occurring in a clipped kidney with renal stenosis and likely also present in nephritis might be of importance.

TH-PO384

Febuxostat Suppresses High Salt-Induced Hypertension and Renal Damages in Dahl Salt-Sensitive Rats Takahiro Miura, Akihiro Sakuyama, Masahiro Kohzuki, Osamu Ito. *Dept of Internal Medicine & Rehabilitation Science, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: Several clinical studies reported that febuxostat (Fx), a xanthine oxidase (XO) inhibitor, has anti-hypertensive and renal protective effects. However, their mechanisms are not elucidated. We studied whether Fx affects the blood pressure and renal damages in Dahl salt-sensitive (Dahl-S) rats fed a high-salt diet (HS).

Methods: Eight-week-old, male Dahl-S rats were divided into three groups, normal salt diet (0.6% NaCl) group, HS (8% NaCl) group and HS+Fx (3 mg/kg/day, po) group. Every 2 weeks, 24 hours urine sample was collected, and the systolic blood pressure (SBP) was monitored by the tail-cuff method. After 8 weeks, the kidney was removed for XO activity measurement, Western blot analysis, and histologic analysis.

Results: HS intake significantly increased the SBP, urinary protein (UP), plasma creatinine (Cr), uric acid (UA) and urinary H_2O_2 excretion. Fx significantly improved the HS intake-induced hypertension, renal dysfunction and oxidative stress (SBP 209±4 vs.174±6 mmHg, UP 324.5±40.3 vs.152.4±20.9 mg/day, Cr 0.41±0.03 vs.0.29±0.01 mg/dl, UA 1.67±0.21 vs.0.53±0.06 mg/dl, urinary H_2O_2 483.8±47.4 vs.339.6±27.8 nmol/day, $P<0.01$ respectively, HS group vs.HS+Fx group). HS intake increased the XO activity and expression in the renal cortex, outer medulla, andproximal tubules, but not in the medullary thick ascending limbs. Immunohistochemical analysis showed that HS intake increased the XO expression in the proximal tubules and outer medullary interstitium. HS intake significantly increased index of glomerular sclerosis (IGS), desmin-positive area of glomeruli, relative interstitial volume (RIV) and ED-1 infiltration, and Fx significantly suppressed the HS intake-induced renal damages.

Conclusions: Fx suppresses the HS intake-induced hypertension and renal damages in Dahl-S rats. Fx may have anti-hypertensive and renal protective effects in patients with salt-sensitive hypertension.

Fetal Programming of Renal Function and Blood Pressure by Maternal Circadian Disruption Natalia A. Mendez,[1,2] Karina Vergara,[1] Carlos Spichiger,[1] Diego Halabi,[1] Carlos P. Vio,[2] Hans Richter,[1] Claudia Torres-Farfan.[1] *[1]Anatomy, Histology and Pathology, Univ Austral de Chile, Valdivia, Chile; [2]Center for Aging and Regeneration, Dept Physiology, Pontificia Univ Catolica de Chile, Santiago, Chile.*

Background: A potential harmful condition for fetal development is the alteration of the maternal circadian system a novel determinant for fetal programming related to modern 24/7 society. We have demonstrated that gestational chronodisruption (maternal exposure to constant light) affects fetal growth with consequences in adult offspring (endocrine, metabolic and cognitive function). Currently, a number of studies in fetal programming describe hypertension and renal diseases as key targets linked to fetal programming of adult disease, however, the consequences of gestational chronodisruption on blood pressure (BP) control and renal function remain unknown.

Methods: Pregnant rats were housed under chronic rotation of photoperiod (CPS) during gestation until delivery. We studied in males CPS **(CPS)** and control males, gestated in standard photoperiod (1) heart rate (HR), temperature and activity by telemetry (2) gene expression in the kidney and circadian rhythms of hormones (3) BP by tail cuff method, and its response to 4%NaCl as well renal expression of kallikrein.

Results: We found that animals gestated in CPS condition had an increase in the variation of heart rate (measured as standard deviation-SD) during day and night, and that the acrophase of HR was advanced in almost one hour versus control. CPS group display changes in corticosterone, aldosterone and melatonin rhythms and effects on expression of *Sgk1*, *NHE3* and *αENaC* in kidney. Both groups showed circadian rhythms of BP, however adult CPS displayed larger amplitude of the rhythm during night, and responded to 4%NaCl with a significant increase of BP. Decreased protein expression of renal kallikrein was observed in adult CPS in basal condition and after 4%NaCl, relative to control rats.

Conclusions: Our findings show that gestational circadian disruption affects renal function at different levels, including transporters, vasoactive enzymes and blood pressure control.

Catechol-O-Methyltransferase Deficiency Leads to Hypersensitivity on the Pressor Response against Angiotensin II Norikazu Ueki,[1,2] Satoru Takeda,[1] Daisuke Koya,[2,3] Keizo Kanasaki.[2,3] *[1]Obstetrics and Gynecology, Juntendo Univ, Tokyo, Japan; [2]Diabetology and Endocrinology, Kanazawa Medical Univ, Japan; [3]Div of Anticipatory Molecular Food Science and Technology, Medical Research Inst, Kanazawa Medical Univ, Japan.*

Background: Women with preeclampsia (PE) exhibit hypersensitivity on the pressor response against angiotensin II (AngII). Catechol-O-methyltransferase (COMT) metabolizes 2-hydroxyestradiol (2-OHE2) into 2-methoxyestradiol (2-ME) and COMT deficiency has shown to be associated with PE. We have hypothesized that COMT deficiency is reasonable to explain the molecular mechanisms of the hypersensitivity on the pressor response against AngII.

Methods: We utilized C57BL/6 male mice for all experiments. Mice were subjected to COMT inhibitor (COMTi: 25 mg/kg/day) or olive oil (Control) for 4 weeks, with or without low-dose AngII infusion (ANGII: 70ng/kg/min) for last 3 weeks. The AngII-infused mice were treated with 2-ME (10 ng/day), 2-OHE2 (10 ng/day), or vehicle for last 1 week. We obtained following 6 experimental groups; Control, ANGII, COMTi, COMTi+ANGII, COMTi+ANGII+2-ME, and COMTi+ANGII+2-OHE2. Also we performed similar experiments utilizing in vivo administration of siRNA (20 nmol/week) of COMT instead of COMTi.

Results: NeitherANGII nor COMTi alone exhibited significant alteration in blood pressure compared with Control. When compared to ANGII or COMTi alone, COMTi+ANGII displayed significantly higher blood pressure, increased albuminuria and glomerular endotheliosis; 2-ME normalized such physiological and pathological alterations. 2-OHE2 did nothing in all parameters. Similar phenotypes were observed in COMT siRNA treated mice. In human aortic smooth muscle cells, AngII (100nM) significantly increased AngII receptor type 1 (AT1R) mRNA and protein levels; 2-ME (500nM) suppressed either basal or AngII-induced AT1R levels.

Conclusions: Deficiency in COMT and 2-ME are associated with the hypersensitivity on the pressor response against AngII infusion. Similar mechanisms could be relevant to pregnant status and PE.

TH-PO387

Cyclosporin A Differentially Induces Activation of Renal Salt Transporters in the Distal Nephron Katharina Ilse Blankenstein,[1] Aljona Borschewski,[1] Kerim Mutig,[1] David H. Ellison,[2] Sebastian Bachmann.[1] *[1]Inst für Vegetative Anatomie, Charité Universitätsmedizin, Berlin, Germany; [2]Div of Nephrology & Hypertension, Oregon Health & Science Univ, Portland, OR.*

Background: The calcineurin inhibitor cyclosporin A (CsA) is broadly used for immunosuppression but may cause severe side effects including hypertension and electrolyte imbalance. Mechanisms of CsA-induced hypertension are complex and include renal

effects on salt transporters of the distal nephron. This study was designed to investigate the impact of local and systemic calcineurin inhibition on the function of renal cation-chloride cotransporters, NKCC2 of thick ascending limb and NCC of distal convoluted tubule.

Methods: Normal Wistar rats, vasopressin (AVP)-deficient Brattleboro rats or cultured distal convoluted tubule (DCT) cells (mpkDCT4) were treated with CsA at short (30 mg/kg for 4h) or long term (14 days). Urine was collected in metabolic cages. NKCC2, NCC and their activating kinases (WNK1, WNK4, and SPAK) were evaluated by quantitative PCR, immunoblotting, immunofluorescence and morphological analysis.

Results: Short term CsA administration to Wistar rats induced posttranslational activation of NCC and NKCC2 by increasing their phosphorylation (+ 200 % and + 500 %; $p<0.05$) and surface expression. Activating SPAK phosphorylation was augmented as well (+ 100 %; $p<0.01$). After 14 d of CsA, the diuretic responses to furosemide was higher than in controls (+ 100 %; $p<0.05$) and sodium excretion was diminished (- 20 %; $p<0.05$). CsA (4h) augmented SPAK and NCC phosphorylation in cultured mpkDCT4 cells as well. In the absence of AVP, CsA increased phosphorylation of SPAK and NCC but not NKCC2 in Brattleboro rats, suggesting that AVP is required for the activation of NKCC2 but not NCC in this setting.

Conclusions: Our data suggest that CsA augments the function of NKCC2 and NCC via posttranslational regulatory mechanisms. In contrast to NCC, however, NKCC2 requires baseline stimulation by AVP.

TH-PO388

Comparative Distribution and Localization of Renal Outer Medullary Potassium Channel in Rat, Dog, Rhesus Monkey, and Human Kidney Yonghua Zhu, Yan Cui, Emanuel Zycband, Yan Ni, Maya Dajee, Kathleen A. Sullivan. *Cardiometabolic Disease, Merck Research Laboratories, Kenilworth, NJ.*

Background: The renal outer medullary potassium channel (ROMK) mediates potassium recycling and facilitates sodium reabsorption in renal tubule. Accumulated evidence supports the promise of ROMK inhibitors as a novel target in the treatment of hypertension and heart failure. We set out to explore the distribution and localization of ROMK protein in the kidney of different species in order to facilitate preclinical animal model design and mechanism of action studies, and to ensure the translatability of data from bench to bedside.

Methods: Immunohistochemistry (IHC) allows the localization of proteins to specific regions of the nephron. Using a specific antibody (R80, provided by Welling PA & Wade JB) against rat ROMK and antibodies against Tamm-Horsfall Glycoprotein, a thick ascending limb (TAL) marker, and against Aquaporin 2, a collecting duct (CD) marker, IHCs were performed on normal kidney from rat, beagle dog, rhesus monkey, and human.

Results: Our IHC study revealed that ROMK is conservatively expressed on the apical membrane of tubular epithelial cells of TAL and macula densa (MD) across the four species. However, there are interspecies differences in ROMK expression in CD. In CD of rat and human kidney, ROMK positive stain was found on the apical membrane of cortical CD and medullary CD, consistent with published reports. On the contrary, ROMK positive stain in dog kidney was undetectable in cortical CD and relatively weak in medullary CD. In Rhesus kidney, the expression pattern of ROMK is similar to that of dog kidney.

Conclusions: This study provides comprehensive data demonstrating the localization of ROMK in kidney tissue originating from four different species. Our data revealed that ROMK is primarily expressed in the epithelial cells of TAL and MD and exhibits interspecies expression variability in the collecting ducts. In conclusion, these data suggest a molecular basis for potential species difference in the transporter handing of potassium to further the field's understanding of therapeutic benefit of ROMK inhibitors.

Most SUCNR1 Missense Variants Demonstrate Impaired Activity; Implications for Disease Susceptibility? Claudia Carmone, Peter M.T. Deen. *Physiology, Radboud UMC, Nijmegen, Netherlands.*

Background: The succinate receptor 1 (SUCNR1) is activated by succinate, a mitochondrial metabolite released from cells under metabolic or oxidative stress. In the kidney, the SUCNR1 is expressed in the macula densa cells and yields reduced renin and renal sodium uptake in unstressed mice. In type-1 diabetic (T1DM) mice, with elevated urinary succinate levels due to metabolic stress, the SUCNR1 was essential for T1DM-related renin release and hypertension, but a role for SUCNR1 in human diseases has not been reported yet. Database analysis, however, revealed many missense variants in the human SUCNR1 gene. Here, we tested the functionality of 18 of these.

Methods: Mutations were introduced in the hSUCNR1-mCherry construct. SUCNR1 variant functionality, expression and subcellular localization were tested in transiently-transfected HEK293 and stably-transfected MDCK cells using Ca2+ imaging, immunoblotting (IB) and immunocytochemistry (ICC), respectively.

Results: L26F, I32T, T42A, G47S, T75I, D92Y, I118T, K125R, R129Q, T166I, D174N, A211V, R252Q, R255T, I273L, R281Q, R281W, and Y295C variants were introduced. After succinate stimulation, Ca2+ imaging in HEK293 revealed 9 variants as functional as wild-type (wt). IB analysis revealed that only I32T and wt had similar banding patterns. When expressed at physiological levels in MDCK, the functionality, expression and plasma membrane localization of only I32T was similar to wt. All other variants showed weak IB signals and a different pattern from wt, dispersed subcellular staining and no Ca2+ imaging signal when stimulated with succinate.

Conclusions: Our data reveal that, except for I32T which is like wt, all other 17 missense single nucleotide polymorphisms lead to non-functional, misfolded and endoplasmic reticulum-retained SUCNR1 proteins. If occurring in homozygosity or compound heterozygosity in humans, these mutants are expected to cause hypotension and to prevent development of hypertension in T1DM, and possibly T2DM, variants.

Response of Renal Podocytes to High Hydrostatic Pressure: Pathophysiologic Cascade in a Model of Malignant Hypertension Ramzia Abu Hamad,[1] Moshe Stark,[1] Yafit Hachmo,[1] Fadia Hassan,[1] Keren Doenyas-Barak,[1,2] Shai Efrati.[1,2] *[1]Research & Development Unit, Assaf-Harofeh Medical Center; [2]Nephrology Div, Assaf-Harofeh Medical Center.*

Background: Renal injuries induced by increased intraglomerular pressure coincide with podocyte detachment from the glomerular basement membrane. We investigated the pathophysiologic cascade responsible forpodocyte detachment and the cascade's relationship with mesangial cells.

Methods: Rat renal mesangium and podocytes were exposed to high hydrostatic pressure for 1h to simulate malignant hypertension. In some cultures, podocytes were placed in milieu of mesangial cells pre-exposed to pressure, or treated with excessive angiotensin-II, TGF-β1 or the blockers. The resultant detachment, apoptosis and podocyte expression of adhesion proteins, podocin and integrin-β1, were evaluated.

Results: Pressure resulted in increased angiotensin-II production. Via AT1 receptors, this reduced the expression of podocin (54.3±6.06 vs. 84.8±15.6, $p< 0.05$) and integrin-β1 (27±11.3 vs. 55.8±10.5, $p< 0.05$), and culminated in detachment of viable and apoptotic podocytes. Mesangial cells, pre-exposed to pressure, resulted in a greater increase in angiotensin II production than podocytes exposed to pressure (2999.5 ±580 vs. 367±14.1, $p< 0.05$pg/ml). The massively increased concentration of angiotensin by mesangium, together with increased TGF-β1 production (20.5±4.5 vs. 84±30, $p< 0.05$), resulted in increased apoptosis, and considerable detachment of non-viable apoptotic podocytes, with no change in adhesion protein expression.

Conclusions: Malignant hypertension induces podocyte detachment by autocrine and paracrine effects. In direct response to pressure, podocytes increase angiotensin-II production. This leads, via AT1 receptors, to structural changes in the manifestation of adhesion proteins, culminating in detachment of viable podocytes.Further, the adjunct mesangial cellsrespond to pressure by increasing angiotensin-II and TGF-β_1 production, leading to massive apoptosis and detachment of non-viable podocytes.

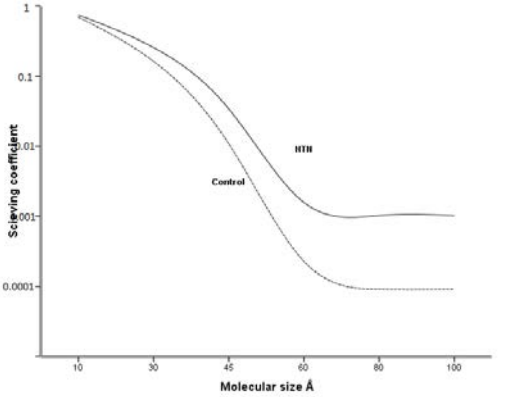
Functional Alterations in the Glomerular Filtration Barrier in Rats Infused with Angiotensin II Omran Bakoush,[1] Charu Sharma,[1] Nima Nalin,[1] Subramanian Dhanasekaran,[2] Abderrahim Nemmar.[3] *[1]Internal Medicine, College of Medicine and Health Sciences, United Arab Emirates Univ, Al Ain, AbuDhabi, United Arab Emirates; [2]Pharmacology and Therapeutics, College of Medicine and Health Sciences, United Arab Emirates Univ, Al Ain, AbuDhabi, United Arab Emirates; [3]Physiology, College of Medicine and Health Sciences, United Arab Emirates Univ, Al Ain, AbuDhabi, United Arab Emirates.*

Background: Chronic infusion of angiotensin II leads to progressive hypertension and podocyte injury, however, the effect of chronic angiotensin infusion on the glomerular perm-selectivity have been less well characterized. In this study we evaluated the changes in the function of the glomerular filtration barrier caused by chronic angiotensin II infusion.

Methods: Male Wistar rats (n = 5) were fitted with an osmotic minipump and angiotensin II was infused for 7 days at 200 ng/kg/min. The glomerular sieving coefficient was measured for polydisperse inert ficoll molecules with a radius of 10-90 Å. Ficoll is a neutral polysaccharide that is not significantly reabsorbed by proximal tubules, which enables its use for determination of the filtrate-to-plasma concentration ratios for a broad spectrum of molecular radii (10–90 Å).

Results: The glomerular sieving coefficient for Ficoll was significantly increased in rats following chronic angiotensin II infusion compared to control animals. The sieving coefficient increased 1.6 fold for ficoll-20 Å, two-fold for ficoll-35 Å, six-fold to ficoll-50 Å, and ten-fold for ficoll-70 Å.



According to the two-pore theory, these changes are compatible with an increase in the number of large pores and shunts in the glomerular filtration barrier.

Conclusions: Angiotensin II infusion severely impairs the glomerular perm-selectivity to cause a ten-fold increase in the urinary leakage of large molecular weight molecules in the size range of IgG and IgM proteins.

TH-PO392

Effect of Diet-Induced Vitamin D Deficiency on Renal Sodium Transporter Expression, Intrarenal RAS and Oxidative Stress Weverton M. Luchi,[1,2] Renato Crajoinas,[1] Antonio C. Seguro,[1] Adriana C.C. Girardi.[1] *[1]Nephrology, Medical School Univ of São Paulo; [2]Federal Univ of Espírito Santo, Brazil.*

Background: Vitamin D Deficiency(VDD) has been linked to hypertension in experimental and clinical studies. Thus, we aimed to test the hypothesis that high blood pressure in VDD rats is associated with altered expression of sodium transporters along the nephron.

Methods: Wistar rats were fed for 30 days with a vitamin D-free(VDD_{30}) or standard diet(controls). Blood Pressure(BP) was measured by tail cuff plethysmography. The expression of sodium transporters and intrarenal Renin-Angiotensin System(RAS) components were evaluated by immunoblotting. Serum concentration of vitamin D and urinary excretion of angiotensinogen(AGT) were determined by ELISA. Intrarenal redox status were analysed by the ratio of thiobarbituric acid reactive substances and glutathione levels(TBARS/GSH).

Results: Compared to controls, VDD_{30} rats had lower serum levels of 25(OH)D(48.0±2.5 vs. 4.2±1.0 ng/mL, p<0.01) and higher BP(153±2 vs. 119±3mmHg, p<0.01). Urinary flow and sodium excretion were not affected by VDD, but it slightly reduced GFR. VDD_{30} rats exhibited higher expression of NKCC2 in medulla(147±12 vs.100±10%, p<0.05) and cortex(157±12 vs.100±10%, p<0.05). No significant changes were observed in cortical levels of NHE3, NCC, NCC phosphorylated at Thr 53 and in cortical and medullary α, β and γ ENaC subunits between groups. However, the levels of NHE3 phosphorylated at Ser 552 were higher in cortex of VDD_{30} rats(200±12 vs.100±11%, p<0.01). Renin expression was only markedly elevated in the medulla of the VDD_{30} rats(207±28 vs.100±25%,p<0.05). Higher expression of cortical AGT(160±18 vs.100±19%,p<0.05) and urinary AGT/Cr ratio(0.35±0.08 vs.0.12±0.01ng/mg,p<0.05) were found in VDD_{30} rats. Angiotensin II concentration was higher in cortex(1.22±0.04 vs.0.60±0.07,p<0.01) and medulla(2.32±0.15 vs.1.55±0.10ng/g,p<0.01) of the VDD_{30}. Also, VDD_{30} rats showed higher TBARS/GSH ratio in cortex(11.5±0.9 vs.1.8±0.4,p<0.01) and medulla(6.9±0.5 vs.3.2±0.3,p<0.01).

Conclusions: These data suggest that VDD leads to altered renal sodium handling and high BP by upregulating NKCC2 coupled with intrarenal RAS activation and oxidative stress. CNPq

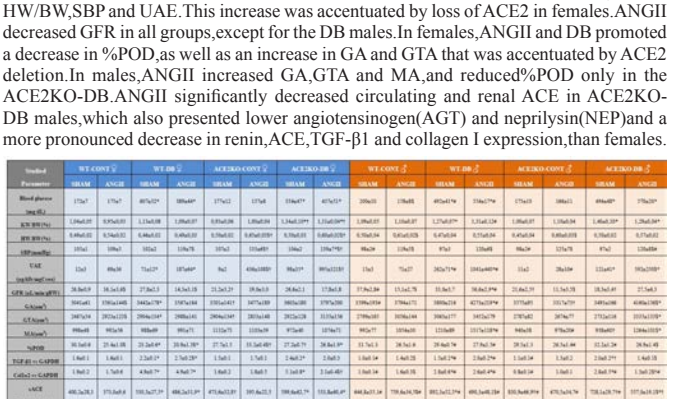
TH-PO393

Sexual Dimorphism in the Diabetic Kidney in Response to ACE2 Down-Regulation and ANGII Infusion Sergi Clotet-Freixas,[1] Maria Jose Soler,[1] Vanesa Palau,[1] Lidia Anguiano,[1] Marta Rebull,[1] Javier Gimeno,[2] Julio Pascual,[1] Marta Riera.[1] *[1]Nephrology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona, Spain; [2]Pathology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona, Spain.*

Background: Loss of ACE2 exacerbates hypertension in ANGII-infused male mice. Sex influence on the effects of ACE2 deletion in diabetic(DB)mice with ANGII-induced hypertension has not been studied.

Methods: We evaluated wild-type(WT)and ACE2KO streptozotocin(STZ)-induced female and male mice.At week8 of follow-up,minipumps for ANGII infusion were implanted.Kidney/body weight(KW/BW),heart/body weight(HW/BW),systolic blood pressure(SBP),urinary albumin excretion(UAE),GFR,glomerular area(GA),glomerular tuft area(GTA),mesangial area(MA),podocyte number(%POD),circulating(c)and renal(r)ACE activity,and renal mRNA levels of TGF-β1,collagen I,and RAS components were studied.

Results: ACE2KO-DB females showed increased KW/BW than WT.ANGII augmented HW/BW,SBP and UAE.This increase was accentuated by loss of ACE2 in females.ANGII decreased GFR in all groups,except for the DB males.In females,ANGII and DB promoted a decrease in %POD,as well as an increase in GA and GTA that was accentuated by ACE2 deletion.In males,ANGII increased GA,GTA and MA,and reduced%POD only in the ACE2KO-DB.ANGII significantly decreased circulating and renal ACE in ACE2KO-DB males,which also presented lower angiotensinogen(AGT) and neprilysin(NEP)and a more pronounced decrease in renin,ACE,TGF-β1 and collagen I expression,than females.



$ P<0.05 vs SHAM; * P<0.05 vs CONT; † P<0.05 vs WT; # P<0.05 vs FEMALE

Conclusions: Our results suggest a sexual dimorphism in relation to the role of ACE2 in diabetic and hypertensive kidney disease.Loss of ACE2 exacerbated ANGII-induced hypertension,albuminuria and cardiac,renal and glomerular hypertrophy in diabetic females(hemodynamic effect).In diabetic males,ANGII promoted mesangial expansion and podocyte loss in the context of ACE2 deficiency(tissue effect).

TH-PO394

Role of Innate Immunity in a Model of Malignant Hypertensive Nephrosclerosis Victor F. Avila, Orestes Foresto-Neto, Simone C.A. Arias, Camilla Fanelli, Lisienny C.T. Rempel, Mariliza V. Rodrigues, Claudia R. Sena, Vivian L. Viana, Denise M. Malheiros, Jose E. Krieger, Niels O.S. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

Background: NFkB inhibition by PDTC during rat lactation ($PDTC_{lac}$) promotes moderate hypertension (HT) with no apparent renal injury. With salt overload (HS) and uninephrectomy (UNx), severe HT, glomerulosclerosis (GS), onion-skin renal arteriolar lesions (OSL) and NFκB activation develop. We further investigated the role of innate immunity (InIm) in this model.

Methods: Male newborn rat pups received PDTC or no treatment (C) for 20 d, underwent UNx at 10 wks of age, and were divided in: **C**, standard diet (NS); **$PDTC_{lac}$**, NS; **$PDTC_{lac}$+HS**, HS. After 3 mo, we assessed tail-cuff pressure (TCP, mmHg), GS index (GSI), %OSL, interstitial (I) collagen 1 (%COLL) and macrophages (MØ, cells/mm^2) and, by IHC, TLR4, Caspase1 (Casp1) or IL1β in glomeruli (G, %area) and I (cells/mm^2), as well as the renal content of IL1β, Casp1, TLR4 and nuclear p65.

Results:

	C	$PDTC_{lac}$	$PDTC_{lac}$+HS
TCP	145±2	167±3[a]	193±4[ab]
GSI	3±1	2±1	38±10[ab]
%OSL	0±0	1±1	17±5[ab]
%COLL	3±1	3±1	8±1[ab]
MØ	33±3	35±4	146±23[ab]
Casp1, G	0.7±0.1	1.2±0.2[a]	2.9±0.5[ab]
Casp1, I	3±1	5±1	12±2[ab]
IL1β, G	1.0±0.1	1.4±0.2	2.6±0.4[ab]
IL1β, I	3±1	4±1	8±1[ab]
TLR4, G	0.2±0.1	0.2±0.1	1.0±0.2[ab]
TLR4, I	0.3±0.1	0.6±0.2	2.9±0.6[ab]
p65	1.0±0.1	1.7±0.4	2.6±0.5[a]

Mean±SE, [a]p<0.05 vs C, [b]p<0.05 vs $PDTC_{lac}$.

Even without renal injury, Casp1 was upregulated in $PDTC_{lac}$, whereas TCP correlated with MØ and IL1β, suggesting incipient InIm activation. Expectedly, HS enhanced HT, renal injury/inflammation and the renal content of IL1β, TLR4 and p65 (p<0.05). Casp1 was prominent in OSL. MØ (both G and I) correlated with the respective Casp1, IL1β and TLR4 expressions, suggesting both inflammasome and TLR4/NFkB activation.

Conclusions: InIm is activated early in $PDTC_{lac}$, perhaps reflecting incipient vascular injury. HS enhances InIm, aggravating HT and renal/vascular injury. InIm may be an important mediator of renal injury by HT. FAPESP/CNPq.

Bimodal Action of Intrarenal Afferent Stimulation by Bradykinin on RSNA: Tonic Inhibition after Short Excitation Martin Hindermann,[1] Tilmann Ditting,[1] Kristina Rodionova,[1] Sonja Loosen,[1] Christian Ott,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[2] Roland Veelken.[1] *[1]Dept of Nephrology and Hypertension, Friedrich-Alexander-Univ, Erlangen, Germany; [2]Dept of Nephropthology, Friedrich-Alexander-Univ, Erlangen, Germany.*

Background: Renal afferent nerves (RANs) play an important role in the modulation of renal sympathetic nerve activity (RSNA). We recently reported tonic sympatho-inhibitory action due to intrarenal afferent nerve stimulation by the TRPV1 agonist capsaicin. However, some studies indicate sympatho-excitatory RANs, stimulated by Bradykinin (BK). Since BK is known to augment TRPV1 effects we hypothesized that intrarenally applied BK would rather inhibit than excite RSNA.

Methods: 3 groups of anesthetized rats (n=8, each) were equipped with arterial and venous catheters for blood pressure (BP) and heart rate (HR) recording and drug application; left sided renal arterial catheter for intrarenal administration (IRA) of Bradykinin (BK; group 1) or the TRPV1 agonist capsaicin (CAP, pos. control; group 2) to stimulate RANs (CAP 3.3, 6.6, 10 and $33*10^{-7}$M, 10µl each; BK $10*10^{-6}$M, 20µl and BK $10*10^{-5}$ M; 2.5, 5, 10µl at 30, 45, 60, 75min). Normal saline (IRA NS) served as neg. control (group 3); right sided electrode for RSNA recording; After 105min the NK_1-receptor blocker RP67580 ($10*10^{-3}$M, 15µl).

Results: IRA BK and IRA CAP decreased RSNA from 4.2±0.8 to 1.3±0.2µV*sec (BK, *P*<0.01) and 3,6±0,5 to 0.9±0.2µV*sec (CAP, *P*<0.01) while maximum inhibition was reached within 70 minutes. IRA NS had no effect. Tonically suppressed RSNA (CAP & BK group) was transiently but completely unmasked by systemic (IV) administration of the NK_1-blocker (1.6±0.5 to 8.6±2.9µV*sec; *P*<0.01 (BK); 1.0±0.2 to 6.1±1.5µV*sec; *P*<0,01 (CAP)). IRA BK was associated with short lived (1-2 sec) increases of RSNA (up to 13.3±2.4µV*sec; *P*<0.01).

Conclusions: The effect of intrarenal BK was similar to CAP. Thus, the net effect of intrarenal stimulation of RANs by BK is sympatho-inhibitory in nature. The similarity of NK_1-blocker effects indicates a common final pathway of intrarenal afferent stimulation. However, the nature of the short-lived BK induced RSNA increase remains unclear. Nociceptive effects or differential central processing are possible.

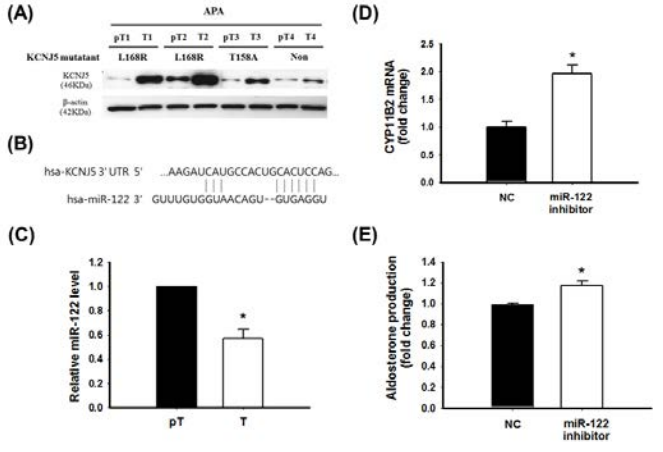
TH-PO396

MicroRNA-122 Regulates Aldosterone Production by Targeting KCNJ5 in Aldosterone-Producing Adenomas Kang-Yung Peng, Vincent Wu. *Dept of Internal Medicine, National Taiwan Univ, Taipei, Taiwan.*

Background: It has been identified that 40%–60% of aldosterone-producing adenoma (APA) patients carry somatic mutations in *KCNJ5* gene. Theses *KCNJ5* mutations lead to reduced K^+/Na^+ channel selectivity *in vitro* and result in increased calcium influx and expression of genes promoting aldosterone synthesis. In this study, we investigate the role of miR-122 in the pathogenesis of APA through targeting *KCNJ5*.

Methods: The expression level of miR-122 in APA and cultured adrenal cells were validated by using quantitative reverse transcriptase polymerase chain reaction (qPCR). Radioimmunoassay (RIA) was used to measure the aldosterone concentration in the culture supernatants. Liposome-mediated transfection of miR-122 inhibitor was constructed into HAC15 human adrenocortical cells. The expression of KCNJ5 was assessed by immunoblotting and qPCR.

Results: Our data showed that KCNJ5 protein was upregulated in APAs compared with peri-tumor tissue. Besides, the upregulated ratio of KCNJ5in APAs tissues than their conterpart with *KCNJ5* mutations were much higher than APA tissues without *KCNJ5* mutations. miR-122 was chosen based on its possible functions, and target prediction by multiple algorithms. The expression of miR-122 was down-regulated in APA when compared to the adjacent non-tumor tissues (p= 0.0207). In cultured HAC15 cells, miR-122 inhibitor augmented aldosterone synthase (CYP11B2) and promoted aldosterone production.



Conclusions: Our findings suggest that miR-122 may mediate some of hyperaldosterone in aldosteronism, in part via regulating KCNJ5 expression. The novel results add another dimension to accumulating evidence regarding further development of new therapies and diagnosis in APA.

Trend Toward Lower Exosomal Thiazide-Sensitive NaCl Co-Transporter Expression after Renal Denervation in Resistant Hypertensive Humans Olivier Bonny,[1,2] Candice Stoudmann,[2] Fanny Durussel,[2] Marc P. Maillard,[1] Johannes Loffing,[3] Grégoire Wuerzner.[1] *[1]Service of Nephrology, Lausanne Univ Hospital, Lausanne, Switzerland; [2]Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [3]Inst of Anatomy, Univ of Zurich, Zurich, Switzerland.*

Background: The renal sympathetic nervous system is implicated in most forms of hypertension. It has recently been shown in animals that norepinephrine activates the thiazide-sensitive NaCl cotransporter (NCC), which participates to sodium retention in the distal part of the nephron (DCT). However, no data are available in humans. Now, we used human urinary exosomes from timed urine collection before and after renal denervation (RDN) and investigated the acute effect of renal denervation on NCC abundance and phosphorylation.

Methods: Baseline 24 hours blood pressure and sodium excretion were measured before RDN. Timed urines were collected the morning before and the morning after renal denervation. Exosomes were freshly isolated by ultracentrifugation and stored at -80°C. NCC abundance and phosphorylation were analyzed by Western blot. Detection of TSG101 was used to confirm exosome quality and equality of loading.

Results: Thirteen patients (7 women/6 men) with proven resistant hypertension and an estimated GFR ≥ 30 ml/min/1.73m^2 were included in the study. Mean age was 58.2±7.6 years, mean body mass index was 32.9±4.5 Kg/m^2, mean daytime systolic and diastolic blood pressure were respectively 146±17 mmHg and 87.6±12.3 mmHg. In the isolated urinary exosomes, the levels of total and phosphorylated NCC normalized to TSG101 varied considerably at baseline (pre-denervation), but showed a trend towards lower expression levels post-denervation, but without reaching significance though.

Conclusions: Thus, RDN may reduce total NCC abundance and phosphorylation and urinary exosome analysis may represent a mean to monitor the acute effects of RDN. Additional studies are necessary to confirm these initial observations and to assess the long term effects of RDN on renal NCC and possibly other renal transport proteins involved in blood pressure control.

A Novel Chronic Kidney Disease Mouse Model with Hypertension Jin Wei,[1] Jie Zhang,[1] Gensheng Zhang,[1] Shaohui Wang,[1] Lei Wang,[1] Jacentha Lynn Buggs,[2] Ruisheng Liu.[1] *[1]Molecular Pharmacology & Physiology, Univ of South Florida, Tampa, FL; [2]Tampa General Hospital.*

Background: Chronic kidney disease (CKD) affects 26 million American adults and may eventually develop into end-stage renal disease. Hypertension is a leading cause and a common consequence of CKD. Subtotal nephrectomy is a widely used low-nephron CKD model. This model creates hypertension in rats, however, the mouse model exhibits strain-dependent outcomes following subtotal nephrectomy. In particular, C57BL/6 mice are normotensive. The goal of the present study is to create a new CKD model with low nephron numbers and hypertension in C57BL/6 mice.

Methods: The reduction of renal mass was performed by ligating either upper (LU) or lower (LL) branches of the renal artery in the left kidney plus a nephrectomy (UX) of the right kidney. The mean arterial pressure was measured with a telemetry system and glomerular filtration rate (GFR) was measured in conscious mice.

Results: Eight weeks after surgery, there was no significant difference in body weight among LU, LL and control mice. The left kidney weight decreased by 22.7% in LU group (184.3±12.9 mg), and by 22.1% in LL group (185.7±13.2 mg) compared with control mice (238.4±19.1 mg) (n=4/group, p< 0.05 vs control). Both LU and LL mice had a significant decrease in GFR (LU: 128.41±21.47 µl/min and LL: 144.71±23.92 µl/min) compared with the control mice (193.76±13.94 µl/min). Plasma creatinine increased from 0.08±0.01 to 0.18±0.02 mg/dl in LU group; from 0.09±0.01 to 0.17±0.03 mg/dl in LL group; and from 0.08±0.03 to 0.11±0.02 in controls (n=4/group, p<0.05 vs control). The MAP increased and remained elevated at 131.5±12.7 mmHg in LU and 126.8±11.4 mmHg in LL mice. The MAP in control mice did not change (n=3/group, p<0.05 vs control). Proteinuria increased from 2.7±0.3 to 8.1±3.4 mg/24 h in LU; from 2.3±0.9 to 6.7±3.1 mg/24 h in LL mice; and from 2.5±0.9 to 2.7±0.7 in control mice (n=4/group, p<0.05 vs control). Glomerular injury score was 1.4±0.4 in LU mice, 1.2±0.5 in LL mice, and 0.2±0.1 in controls.

Conclusions: In summary, we developed a new CKD model with low-nephron and hypertension by a combination of ligation in renal artery branch and UX in C57BL/6 mice.

Screening for HLA Linear Epitopes Using Personalized Peptide Array: A Feasibility Study of Alloantibody Specificity in Transplantation Jing Jin, Pan Liu, Tomokazu Souma, Andrew Z. Wei. *Dept of Medicine - Nephrology, Northwestern Univ, Chicago, IL.*

Background: HLA molecules are highly polymorphic cell receptors, posing a major obstacle to the success of organ transplantation. The allorecognition of mismatched donor HLA directly contributes to chronic rejection. DNA typing for HLA is widely used in the clinic and one of the most important challenges is to determine which mismatched transplants will fare well and which should be avoided. Therefore it is desirable to specify antibody reactivity to individual mismatched epitopes.

Methods: We use peptide antigens of donor sequences to probe for antisera specificity in kidney transplant subjects. A large custom panel of 15-residue HLA peptides was synthesized in an array format following one of the two designs: a standard array of a fixed panel of peptides or personalized arrays. The standard array contains 420 peptides derived from a predetermined set of HLA-DQ allelic antigens. The personalized arrays that each includes donor-derived peptides of HLA-A,B,C,DQ and DR sequences were separately synthesized for individual transplant subjects. These arrays were used to probe pre- and post-transplant patients' sera for alloantibodies against the peptide antigens.

Results: The array method detected distinct antiserum patterns among transplant subjects and revealed epitope-levels of specificity largely in accordance with the Luminex single-antigen results. Collective mapping of alloantibody epitopes in five kidney transplant patients revealed a highly antigenic "hotspot" of reactive epitopes in HLA-DQB1 across individual patients and their allelic variants, provided donor-recipient mismatch(es) present within this ~15 amino acid segment.

Conclusions: The peptide arrays robustly detected *de novo* antibodies following transplantation, directly revealing epitope-levels of antibody specificity associated with HLA mismatches. The array method also showed superior sensitivity to the Luminex single-antigen assay. Collectively, our pilot study proved the feasibility of personalized design to achieve high-resolution detections of linear HLA epitopes associated with distinct donor-recipient mismatches.

Anti-Fibrotic MicroRNA Strategies in a Mouse Model of Chronic Renal Allograft Dysfunction Celina Schauerte,[1] Song Rong,[2] Michael Mengel,[3] Hermann G. Haller,[2] Thomas Thum,[1] Johan Lorenzen.[1,2] *[1]Inst of Molecular and Translational Therapeutic Strategies (IMTTS), Hannover Medical School, Germany; [2]Dept of Nephrology & Hypertension, Hannover Medical School, Germany; [3]Dept of Laboratory Medicine & Pathology, Univ of Alberta, Canada.*

Background: Pro-fibrotic microRNA-21 (miR-21) is upregulated in chronic allograft dysfunction (CAD), which is characterized by fibrotic remodeling, renal injury and chronic inflammation. This study investigates miR-21 inhibition as a therapeutic approach in an evaluated murine model of CAD.

Methods: Allogenic kidney transplantation (KTx) was performed from male C57BL/6 into female Balb/c. Recipients were treated at day -1 and day 7 either with LNA-scr (control) or LNA-21 (inhibitor of miR-21) (20mg/kg BW, i.p.). Kidneys were analyzed 6 weeks after KTx, e.g. by qRT-PCR, PAS-, Picrosirius Red- and immunostaining. *In vitro* analyses were performed in renal fibroblasts (NRK49F) and macrophages (RAW264.7).

Results: We determined via qRT-PCR increased expression of fibrosis (αSMA, Col1, Col3, FSP-1) and inflammation (IL-6) markers in KTx kidneys which were rescued by miR-21 inhibition. Moreover, Picrosirius Red staining and BANFF scoring (ci and ct) revealed significantly less fibrosis and injury development due to miR-21 inhibition. Besides, allografts of LNA-21 treated mice showed less infiltrated T-cells (CD3) and macrophages (F4/80) visualized by immunostaining. *In vitro* we found LPS-activated macrophages to produce and secrete high levels of IL-6. IL-6 activates the transcription factor STAT3, which has a putative binding site in the miR-21 promoter. We hypothesize, that infiltrating macrophages produce IL-6 which affects resident renal cells causing fibrosis and injury progress. Co-culture assays confirmed a crosstalk between macrophages and renal fibroblasts with increased expression levels of miR-21, primary miR-21, IL-6 and CTGF in fibroblasts. Similar results were observed due to IL-6 treatment of fibroblasts. Furthermore, EMSA verified IL-6-mediated activation of STAT3 in fibroblasts.

Conclusions: MiR-21 antagonism could reduce allograft rejection due to less inflammation and fibrosis and suggests a new essentially needed anti-fibrotic treatment strategy against CAD.

TH-PO401

Role of Brain-Derived Neurotrophic Factor in Chronic Cyclosporine Nephropathy Long Ye Zhang, Shang Guo Piao, Ji Zhe Jin, Can Li. *Nephrology, YanBian Univ Hospital, YanJi, JiLin, China.*

Background: Increasing evidence suggests that Brain-derived neurotrophic factor (BDNF) induces a variety of psychiatric and neurological disorders. However, the role of BDNF in the kidney has yet to be determined. The present study examined the expression of BDNF and tropomyosin-related kinase (Trk) receptors in the kidney in a rat model of chronic cyclosporine A (CsA) nephropathy.

Methods: SD rats were maintained on a low-salt diet and treated daily for four weeks with vehicle or CsA. Basic parameters, histology (tubulointerstitial fibrosis and apoptosis), concentration of the oxidative stress marker 8-OHdG, and expression of BDNF and Trk receptors (TrkB and TrkC) were compared between groups. The effect of vasopressin infusion on the urine-concentrating ability was examined by measuring the expression of AQP-2 and BDNF and urine profiles in normal and CsA-treated rats.

Results: Compared with the vehicle-treated rats, rats given CsA showed renal insufficiency,increased urine volume and number of apoptotic cells, decreased urinary osmolality, and tubulointerstitial fibrosis. Immunohistochemistry showed that BDNF and Trk receptors TrkB and TrkC were constitutively expressed in the collecting duct of thecortex and medulla in vehicle-treated kidneys. This was confirmed by double immunofluorescent stainingfor Na-K-ATPase-α1, AQP-1, and AQP-2. By contrast, the expression of these factors decreased significantly in kidneys from CsA-treated rats. Donwregulation of BDNF and Trk receptors was accompanied by increase in urine volume and decrease in urine osmolality. These changes were reversed by exogenous infusion of vasopressin (all $p<0.05$), whereas AQP-2 expression was unchanged. The number of apoptotic cells correlated closely with BDNF protein expression ($r = 0.-866$, $p<0.001$) and urinary 8-OHdG excretion ($r = 0.884$, $p< 0.001$).

Conclusions: Our findings strongly suggest that long-term CsA treatment suppresses renal BDNF and Trk receptor expressionand thatthese changes are associated with impairment of the urine-concentrating ability in chronic CsA nephropathy. Renal tubular cell apoptosis at least partially accounts for the CsA-induced decrease in BDNF expression.

Quantitative Proteomic Analysis of the Calcineurin Inhibitors-Induced Nephrotoxicity Using the iTRAQ Approach Bastien Burat,[1] Julien Gonzalez,[1] Emilie Pinault,[2] Pierre Marquet,[1] Marie Essig.[1] *[1]UMR INSERM 850, Univ of Limoges, Limoges, France; [2]SCRABL, Univ of Limoges, Limoges, France.*

Background: In solid organ transplantation, Calcineurin Inhibitors (CNI), Cyclosporine A (CsA) and Tacrolimus (Tac), are the backbones of immunosuppressive drugs given to counteract allograft rejection. However, their great efficacy is undermined by their deleterious side effects such as nephrotoxicity whose mechanisms remain widely unknown. Despite their calcineurin similar target, Tac and CsA seem to have each specific nephrotoxicity, which would be of utmost interest to decipher to design new immunosuppressive drugs without such toxicity.

Methods: This study used the untargeted iTRAQ approach, allowing relative proteomic quantitation, to decipher specific modifications of proximal tubular cells induced by CsA or Tac or VIVIT, a specific NFAT pathway inhibitor. LLC PK-1 cells were exposed for 24 hours to CsA (5µM), Tac (0,05µM) or VIVIT (5µM). After cell lysis and trypsin digestion, peptidic samples from the different conditions were labelled with isobaric tags and analyzed by tandem mass spectrometry. Bioinformatic analysis was done through a custom-made and personalized process from the source material to the final bioinformatics steps.

Results: 131 proteins have been identified mainly from the following pathways: protein synthesis and maturation, cytoskeleton organization, metabolism or cell cycle . A third of the proteins were not altered by CNI or VIVIT; 15 proteins were equally overexpressed/repressed by CsA, Tac or VIVIT; most of the proteins were impacted in a Calcineurin-independent CNI-specific way. Na/K-ATPase α-1 subunit, Polypyrimidine Tract-Binding Protein-1 (PTBP-1), High Mobility Group protein B1 (HMGB1), Cofilin and Thymosin β10 were among the most CsA-sensitive. CsA seems to set up new actin cytoskeleton dynamics through RhoGTPases pathways and Calcium-dependent signaling.

Conclusions: Through iTRAQ technology, we demonstrated that each CNI altered the phenotype of tubular proximal cells in a unique and specific way. This bias-free approach is the first step to design new immunosuppressive drugs able to inhibit calcineurin activity without the current CNI nephrotoxic side effects.

Evaluation of CCR6 Expression on T Cells from Monkeys Tolerant of Kidney Allografts Achieved via Mixed Hematopoietic Chimerism Ruichao Yu, Gilles Benichou, Joren Madsen. *Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA.*

Background: Chemokine receptor 6 (CCR6), which is constitutively expressed by immature dendritic cells (DCs) and by T cells, regulates the migration and recruitment of DCs and T cells during inflammation and immunological responses. CCR6 is expressed by both T helper 17 cells (Th17) and regulatory T cells (Tregs), as well as by T cells with a dual Th17/Tregs phenotype. Tregs co-expressing FoxP3 and IL-17 retain their suppressive function in humans and mice. It is, however, unclear whether $FoxP3^+IL\text{-}17^+$ T cells represent a transitional stage in regulatory T cell differentiation or they display stable suppressive functions in non-human primates (NHPs).

Methods: Mononuclear cells were isolated from the peripheral blood of cynomolgus monkeys (PBMCs). First, the expression of CCR6 on $CD4^+FoxP3^+$ Tregs was compared among tolerant and rejecting animals using flow cytometry. Second, cytokine IL-17 secretion was measured after polyclonal activation of PBMCs by anti-CD3/CD28 Ab-coated beads. Next, we compared CCR6 expression of dual Tregs/Th17 cells isolated from the PBMCs of 1) naïve monkeys, 2) monkeys undergoing rejection of kidney allografts and, 3) monkeys which had been rendered tolerant of kidney allografts following donor mixed hematopoietic chimerism induction (consisting of leukodepletion, costimulation blockade and donor bone marrow transplantation) and short term immunosuppression.

Results: Naive monkey PBMCs expressed CCR6 on Th17 and Tregs, as well as on $FoxP3^+IL\text{-}17^+$ T cells. CCR6 expression was higher on Tregs as compared to T effector cells. After polyclonal activation, the expression of CCR6 was much higher among dual $FoxP3^+IL\text{-}17^+$ T cells (but not Th17 and Tregs) of tolerant monkeys as compared to rejecting animals.

Conclusions: Our data indicate that expression of CCR6 on dual Th17/Tregs is associated with tolerance induction/maintenance of kidney allografts in NHPs treated with our mixed chimerism procedure via regulating the migration and recruitment of T cells.

TH-PO404

Targeting Histone Deacetylase in Renal Tubular Epithelial Cells Reduces T Cell-Mediated Inflammatory Responses Byeongwoo Kim, Sunwoo Kang, Tae Hee Kim, Yeong Hoon Kim. *Div of Nephrology, Dept of Internal Medicine, Inje Univ Busan Paik Hospital, Busan, Republic of Korea.*

Background: More studies are focusing on renal tubular epithelial cells (RTECs) as a new target to restore inflammatory environment as clarifying their immune regulatory function. Here, we investigated whether histone deacetylases (HDACs) are activated in RTECs during T cell-mediated inflammation and their blockade is able to reducethe inflammatory responses.

Methods: Human renal proximal tubular epithelial cell line HK-2 was cultured in the presenceor absence of recombinant IFN-γ (200 U/ml) plus TNF-a(5 ng/ml). The HDAC activity was determined on the expression levels of acetylated H3 and a-tubulin by immune blot assay. To determine the functional activity of HDAC inhibitor SB939, we analyzed the immune stimulatory phenotype of HK-2 cells such as class II MHC molecule, CD80, CD86, and CD40 by flow cytometry. In addition, the culture supernatants were used for measuring cytokines and chemokines by ELISA assay.

Results: We found that HDAC activity was markedly increased in HK-2 cells by treatment of IFN-γ/TNF-a within 12h. Treatment of pan-HDAC inhibitor SB939 in HK-2 cells completely prevented HDAC activity increased by IFN-γ treatment. SB939 treatment predominantly inhibited up-regulating CD40 expression but not MHC class II, CD80, and CD86. In addition, MCP-1 was significantly inhibited more than IL-6 and TNF-a by SB939 treatment.

Conclusions: Our results demonstrate that 1) HDAC activity is increased in RTECs in response to IFN-γ, 2) which further facilitates T cell-mediated inflammatory responses through CD40 and MCP-1. Therefore, our study suggests that HDAC inhibitor has a therapeutic potential for the treatment of acute renal inflammatory diseases such as allograft rejection in transplantation.

High Dose Belatacept Is Diabetogenic and Toxic to Pancreatic Islet Cells Long Jin, Jian Jin, Chul Woo Yang. *Convergent Research Consortium for Immunologic Disease, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: Belatacept is a promising immunosuppressant for replacing calcineurin inhibitors in kidney transplantation, but its side effect is not fully studied. We evaluated whether belatacept is diabetogenic at therapeutic dose.

Methods: Three doses of belatacept (1,2, 4mg/kg) were chosen based on previous animal studies that 2 mg/kg of belatacept is effective in preventing acute rejection in rats. Belatacept was administered intravenously via tail vein on a weekly basis for 4 weeks in rats, and VH group rats received a saline via tail vein injection on the weekly basis for 4 weeks. Body weight, urine volume, and water intake were measured daily before sacrifice. The diabetogenicity of belatacept was evaluated by intraperitoneal glucose tolerance test (IPGTT) and area under the curve for glucose (AUCg) calculated by trapezoidal estimation. Pancreatic beta cells were isolated from experiment animals then AO/PI staining, which was explained viability of islet cells and glucose-stimulated insulin secretion (GSIS) were performed in isolated beta cells.

Results: After four weeks, there is no significant difference in body weight, water intake and 24hr-urine volume between control and belatacept-treated groups. Belatacept 1mg/kg and 2mg/kg treatment increased AUCg from the values obtained during the IPGTT, which was not statically significant. However, received 4mg/kg of belatacept group showed significantly increased blood glucose level at 30 min compared with VH group. Consistently, AO/PI staining showed PI-positive cell death were increased in belatacept 1mg/kg and 2mg/kg treatment groups. However, only treatment with belatacept 4mg/kg significantly increased PI-positive cell death compared with VH group. GSIS also showed a high dose of belatacept significantly decreased insulin secretion.

Conclusions: Our preliminary study clearly defines that belatacept (therapeutic dose) increased blood glucose level gradually and diabetogenic at the high dose. Further evaluation is needed to confirm diabetogenicity of belatacept in clinical practice.

TH-PO406

Addition of a DPP-IV Inhibitor to Metformin Decreases Sirolimus-Induced Oxidative Stress and Improves Mitochondrial Respiration in Pancreatic Islet Cells Long Jin, Jian Jin, Chul Woo Yang. *Convergent Research Consortium for Immunologic Disease, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: The guideline for the management of new-onset diabetes after transplantation recommends metformin (MET) as a first-line drug, and the addition of a second-line drug is needed to better control of hyperglycemia. We tested the effect of the addition of a DPP-IV inhibitor to MET on sirolimus (SRL)-induced diabetes mellitus (DM).

Methods: Male Sprague-Dawley rats were treated initially with SRL for 3 weeks and then started to treat with DPP-IV inhibitor (LC15-0444) and/or MET for further 3 weeks. The effect of combined treatment of LC15-0444 and MET was evaluated by pancreatic islet function. The influence of oxidative stress and apoptotic cell death was evaluated by serum and pancreas tissue. An in vitro study was also performed by INS-1 cells. Pancreas beta cell death and production of ROS were evaluated by INS-1 cells. At the subcellular level, mitochondrial respiration was also evaluated in INS-1 cells.

Results: In an animal model of SRL-induced DM, MET treatment improved pancreatic islet function and attenuated oxidative stress and apoptotic cell death. The addition of a DPP-IV inhibitor to MET improved these parameters more than MET alone. An in vitro study showed that SRL treatment increased pancreas beta cell death and production of ROS, and pretreatment of ROS inhibitor or p38MAPK inhibitor effectively decreased SRL-induced islet cell death. Exendin-4 (EXD), a substrate of DPP-IV, or MET significantly improved cell viability and decreased ROS production compared with SRL treatment, and combined treatment with the two drugs improved both parameters. At the subcellular level, impaired mitochondrial respiration by SRL was partially improved by MET or EXD, and much improved further after addition of EXD to MET.

Conclusions: Our data suggest that addition of a DPP-IV inhibitor to MET decreases SRL-induced oxidative stress and improves mitochondrial respiration. This finding provides a rationale for the combined use of a DPP-IV inhibitor and MET in treating SRL-induced DM.

Regulation of IFNγ Production by IL-10 May Predict Functional Outcome in Chronic Antibody-Mediated Rejection Hatty A.A. Douthwaite, Hannah E. Wilkinson, The Dorling Group. *MRC Centre for Transplantation, King's College London, London, United Kingdom.*

Background: Kidney transplants do not last for the natural lifespan of most recipients. The single biggest cause of renal allograft failure is chronic rejection (CR). Surprisingly little is known about the mechanisms that underpin CR. HLA antibodies are important but multiple lines of evidence suggest that it is the cognate interactions between donor-specific CD4+ T and B lymphocytes that underpin CR. Th1 effector CD4+ T cells, which produce interferon-gamma (IFNγ), mediate chronic rejection. Regulation of Th1 cells by IL-10 is essential, as unchecked IFNγ production results in severe tissue damage and death. We demonstrate that ELISPOT patterns (detecting indirect CD4+-T cell alloresponses) are significantly associated with functional outcome after renal transplantation.

Methods: PBMCs were analysed by ELISPOT assay & Flow Cytometry from two patient cohorts undergoing renal transplant biopsy (PROTOCOL: 19 patients & FOR CAUSE: 46 patients) at baseline and 9-12 months later.

Results: IFNγ production that is dependent on donor alloantigen presentation by B cells ("Bdep" pattern) is correlated with kidney transplant dysfunction. Where IFNγ production becomes detectable after B cell (CD19+) depletion ("Breg" pattern); these patients have a better outcome. In these Breg samples we also found associations with IL- 10 cytokine production after polyclonal stimulation. These independent associations were found to be significant at two separate time points in both cohorts.

Conclusions: These data establish the utility of this ELISPOT assay and suggest that mechanisms that regulate IFNγ production appear to be critical determinants of transplant success. Moreover the significant associations with regulatory cytokine IL-10 give support to further investigation of the contribution of the Th1 lifecycle in CR.

Effect of Sodium Glucose Transporter 2 Inhibitor on Tacrolimus Induced Diabetes Mellitus Jian Jin, Long Jin, Sun Woo Lim, Chul Woo Yang. *The Catholic Univ of Korea.*

Background: Empagliflozin (Em) is an inhibitor of sodium glucose transporter and is recommended in type 2 diabetic patients. But, its effect on tacrolimus (TAC) - induced diabetes mellitus (DM) is undetermined.

Methods: Experimental model of Tac-induced DM in rats was induced by treating TAC (1.5mg/kg) subcutaneously for 3 weeks, and two doses of Em (5 and 10mg/kg) was injected for additional 3 weeks. Control rats were treated with Em only. Body weight, urine volume and water intake were measured every week. The effect of Em on TAC-induced DM was evaluated by assessing intraperitoneal glucose tolerance test (IPGTT), serum insulin level, glucose stimulated insulin secretion (GSIS), and pancreatic islet size. The effect of Em on kidney function was evaluated by assessing serum creatinine (Scr), creatinine clearance (Ccr), urine glucose excretion, urine albumin excretion and kidney tubulointerstitial fibrosis. In addition, we measured the expression of SGLT2, oxidative stress and apoptosis in each group.

Results: TAC treatment decreased delta body weight, increased urine volume and water intake compared with controls. TAC caused elevated IPGTT level, reduced serum and GSIS and pancreatic islet size compared to controls. But, Em treatment reduced blood glucose level, increased plasma insulin level, and recovered pancreatic islet size compared to the TAC group in a dose-dependent manner. Em treatment decreased SGLT2 expression in a dose-dependent manner. TAC impaired renal function, increased urine glucose and albumin excretion, and increased renal tissue fibrosis. But, Em treatment improved these parameters. In addition, Em treatment reduced oxidative stress and apoptosis caused by TAC.

Conclusions: Em is effective in control TAC-induced hyperglycemia and renal dysfunction. This finding provides clinical usefulness of Empa in renal transplant patients with TAC-induced DM.

Genes Causing Post-Transplant Lymphoproliferative Disease Philip Webster, Joanna Dawes, Katalin Takacs, Hamlata Dewchand, Barbara Iadarola, Anthony Uren. *MRC Clinical Sciences Centre, Imperial College London, United Kingdom.*

Background: Post-transplant lymphoproliferative disease (PTLD) is an important complication after renal transplantation. The anti-apoptotic BCL2 is frequently overexpressed in Non-Hodgkin's Lymphoma, and the limited genetic profiling of PTLD shows overexpression in these tumours. Epstein Barr Virus drives PTLD via oncoproteins that alter gene expression, including upregulating *MYC* and *BCL2*, and downregulating *p53*, thus creating an aberrantly expanding B cell population. BCL2 inhibitors have demonstrated some success in treating lymphoma, and in treating autoimmune disease and preventing transplant rejection in mice, however limited efficacy means there is a requirement for additional therapeutic targets.

Methods: We performed a retroviral insertional mutagenesis screen using Moloney murine leukaemia virus in *Vav-BCL2* C57BL/6 mice as our lymphoma model, with Next-Generation Sequencing to identify mutations that cooperate with BCL2. To validate candidate genes, we created a model of PTLD by overexpressing *Myc* in splenic B cells from *Vav-BCL2 p53*$^{+/-}$ C57BL/6 mice by retroviral transduction. Candidate genes are cotransduced and these cells are injected via tail vein into immunodeficient NOD scid gamma mice or irradiated C57BL/6 mice which are monitored for lymphoma.

Results: The screen identified 3,000 clonal and 700,000 subclonal mutations. Many genes were mutated more frequently in *Vav-BCL 2* mice than controls, including genes already implicated in PTLD e.g. *Bcl6a* and *Pax5* (2-tailed Fisher's exact p=0.0028 and 0.0224 respectively) and also lymphoma drivers novel to PTLD e.g. *Ebf1* and *Ikzf3* (2-tailed Fisher's exact p<0.0001 for both). In the validation model, mice developed lymphoma from 30 days and latency was modified by altering expression of candidate genes.

Conclusions: We have identified new *BCL2* cooperating mutations for further study in PTLD. We have developed a new model of PTLD to validate candidate genes, with disease generated in an immunodeficient state comparable to renal transplant. This furthers insight into disease mechanism, and identifies putative therapeutic targets, with implications that may extend to treating autoimmune disease and preventing transplant rejection.

Long Term Renal Allograft Survival and Inhibitory KIR Receptors Raj K. Sharma, Swayam Prakash, Suraksha Agarwal. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.*

Background: NK cell is regulated by KIR like inhibitory and activating cell surface receptors. We evaluated allelic diversity of KIR3DL1/3DS1 and effect of its HLA-Bw4 ligand affinity on long term transplant outcome.

Methods: KIR3DL1/3DS1 allelic diversity was examined in 100 renal transplant cases and 100 controls. All samples were positive for KIR3DL1 or/and KIR3DS1 and possessed HLA-Bw4 ligand. PCR-SSP was used to determine incidence of KIR3DL1/3DS1 genes and sequence based typing method evaluated the pattern of KIR3DL1/3DS1 allele distribution. HLA class-I genotyping was performed using PCR-SSP kits. Quantification of KIR3DL1/3DS1 mRNA expression was done by $2^{-\Delta\Delta Ct}$ algorithm with GAPDH as the housekeeping gene.

Results: We observed presence of 84 KIR3DL1/3DS1 alleles in the north Indian cases and controls. 6 inhibitory KIR3DL1 alleles and 4 activating KIR3DS1 alleles with incidence > 1% were noted. For KIR3DL1*0010101, no-risk (OR=0.37, p=0.0072) association was observed with increased mRNA expression among ABMR (Fold change=1.48±0.32, p=0.031), and antibody mediated chronic rejection (Fold change=1.12±0.15, p=0.042) cases. Risk was found for KIR3DS1*049N (OR=5.16, $p \leq 0.0001$) and KIR3DS1*01301 (OR=4.27, $p \leq 0.0001$). Both KIR3DS1*049N and KIR3DS1*01301 showed a decreased mRNA level. Looking at the ligand affinity, 3DS1*01301/HLA-Bw4+ (OR=2.12, p=0.0120) and 3DS1*049N/HLA-Bw4+ (OR=3.42, p=0.0051) combinations showed susceptibility. Kaplan-Meier survival analysis performed on a 15 year follow-up data revealed highest overall survival of 11 years for KIR3DL1*0010101-HLA-Bw4 (cumulative survival=63%). Less prolonged survival of 10 years for 3DS1*01301/HLA-Bw4+ (cumulative survival=36%) and 8 years for 3DS1*049N/HLA-Bw4+ (cumulative survival=18%) combinations. Inhibitory signal transmitted by KIR3DL1 induces the ITIM motifs giving rise to inhibitory signaling in KIR positive cells. Inhibition leads to higher T cell response due to protection of T cell from activation induced death.

Conclusions: Survival of renal allograft depends on presence of inhibitory KIR receptors. Suppressing KIR3DS1 like activating NK cell surface receptors may improve long term survival of kidney allografts.

TH-PO411

ATG Induction Is Associated with Increased De Novo Donor Specific Antibodies (d-DSA) in Living Related Transplantation Raj K. Sharma, Sonia Mehrotra, Mahabaleshwar Mayya, Amit Gupta, Narayan Prasad, Dharmendra Bhadauria, Anupama Kaul. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.*

Background: Post transplant DSA monitoring needs to be correlated with clinical outcome of renal transplant in patients receiving induction with ATG or Basiliximab.

Methods: Present study is comparison of two methods (single antigen bead (SAB) assay and solid phase cross match luminex assay using donor lysate), their sensitivity and specificity.121 living donor kidney transplant recipients were prospectively evaluated after transplantation for development of de-novo DSA against Class I and Class II HLA. All recipients were complement dependant cytotoxicity (CDC) cross match negative at time of kidney transplant. 87 recipients (72%) were given induction with either Basiliximab (62) or ATG (25) at time of kidney transplant.

Results: 26 recipients (21.4%) out of 121 developed dn-DSA within 1 to 3 months post-transplant by lysate based cross match. Of patients who were dn-DSA+ive, 11 were given Basiliximab and 9 got ATG induction. Sixteen out of 26 dn-DSA positive recipients (61%) developed only Class II DSA and seven patients (27%) developed only Class I DSA positivity; while in three patients (12%), both Class I and Class II dn-DSA developed. Eight recipients(31%) developed AR in positive group; 6 (75%) of these patients with AR had evidence of antibody mediated rejection (ABMR) with glomerulitis (5 C4d–ve, one C4d +ve), while 2 patients (25%) had T cell mediated AR. In the DSA negative group (78.5%): 18 recipients out of 95 (19%) developed AR. 22 (18.2%) recipients out of 121 were positive for dn-DSA by SAB assay and 99 (81.8%) were negative. On comparison of these two methods; the sensitivity of lysate assay was 100% (95% confidence interval 84.56 % to 100%) and specificity was 95.96% (95% confidence interval 89.98% to 98.89%) against SAB assay.There was increased dn-DSA development with ATG induction (36%) as compared to Basiliximab (17.7%) and no induction (17.6%).

Conclusions: Development of de-novo DSA was associated with more AR and ABMR. Lysate based solid phase cross match which is cheaper than SAB assay can be useful for post-transplant DSA monitoring.

Effect of Inflammation on Intracellular Concentration of Tacrolimus Eunjin Bae,[1] Seung Seok Han,[2] Yon Su Kim.[2] *[1]Internal Medicine, Gyeongsang National Univ Changwon Hospital, Republic of Korea; [2]Internal Medicine, Seoul National Univ College of Medicine, Republic of Korea.*

Background: Calcineurin inhibitors improved the prognosis of transplant recipients. CNI is the substrate of ABCB1, which transports drugs from the intracellular to the extracellular domain. ABCB1 expression and function are controlled by CD44. We evaluated the effect of inflammation on intracellular concentration of tacrolimus (TAC), and its associations between ABCB1 and CD44.

Methods: We enrolled 9 kidney recipients with AR between 2015 and 2016. We measured both whole blood and intracellular concentration of TAC (BC-TAC and IC-TAC) in patients with AR and stable status. IC-TAC were measured using LC-MS/MS. The TAC ratio was defined as the ratio between IC-TAC and BC-TAC. Jurkat T cell line was treated with TAC by dose dependent manners for 21 hours and stimulated with PMA/ionomycin for 3hours. IL-2, 8 and IFN production were measured by RT-PCR. Furthermore, we analyzed the expression of CD44+and ABCB1+cells by FACS to examine the change of IC-TAC respect to treated TAC level and stimulation.

Results: In human data, only one person's TAC-ratio was lower at the time of AR than that of stable status. The other patients' TAC-ratio were higher at inflammatory status (infection: n=3, rejection: n=5) than stable status. The person who had lower level of TAC-ratio at the time of AR experienced recurrent inflammatory conditions, pneumonia and AR, during 1month. Other patients did not experience an inflammatory conditions at least 6 months before this event. In vitro data, the levels of IC-TAC increase proportionally with the levels of treated TAC in Jurkat T cells. After stimulation, the proportion of T cells producing IFN-γ, IL-2 and 8 was higher in the 0, 2.5 ng/ml TAC treated groups than the 5ng/ml TAC treated group. In addition, the levels of IC-TAC were decreased after stimulation. Under the same conditions, the frequency of CD44+ABCB1+cells were increased with TAC treatment and stimulation in FACS.

Conclusions: This study supports a hypothesis that chronic or recurrent inflammation such as rejection, infection, can decrease the IC-TAC level. This could be explained by drug efflux function of CD44+ABCB1+ cells.

TH-PO413

The Effects of Coenzyme Q10 in Sirolimus-Induced Pancreatic Islet Injury In O. Sun,[1] Kwang Young Lee,[1] Chul Woo Yang.[2] *[1]Internal Medicine, Presbyterian Medical Center, Jeonju, Republic of Korea; [2]Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: This study was performed to investigate the effect of addition of coenzyme Q_{10} (CoQ_{10}) to metformin (MET) on sirolimus (SRL)-induced diabetes mellitus (DM).

Methods: Animal model of SRL-induced DM was induced with daily treatment of SRL (0.3 mg/kg, s.c.) for 28 days, and CoQ_{10} (20mg/kg, p.o.)or metformin (250mg/kg, p.o.) was treatment alone or combination for 14 days. The effect of MET and CoQ_{10} on SRL-induced DM was evaluated by assessing by measuring of pancreatic islet function (blood glucose level and insulin secretion) and oxidative stress and apoptosis.

Results: SRL treatment induced pancreatic islet dysfunction and islet morphology with a higher level of 8-hydroxy-2'-deoxyguanosine (8-OHdG), the number of apoptotic death and depletion of the level of manganese superoxide dismutase. MET and MET + MET and CoQ_{10}

decreased blood glucose level and increased plasma insulin level significantly. These improvements were accompanied by a reduction in oxidative stress and apoptosis and were more prominent MET and CoQ_{10} than MET alone. At the subcellular level, shrunken mitochondria in the islet cells of SRL-treated rats was restored by the addition of CoQ_{10} to MET.

Conclusions: Combined use of MET and CoQ_{10} had more protective effect against SRL-induced pancreatic injury than MET alone therapy.

TH-PO414

Hypercapnic Acidosis Attenuates Ischemia-Reperfusion Injury Associated Acute Kidney Injury in Rats Ming-Tso Yan,[1] Chih-Jen Cheng,[1,2] Shih-Hua P. Lin.[1,2] *[1]Cathay General Hospital; [2]National Defense Medical Center; [3]Tri-Service General Hospital.*

Background: Hypercapnic acidosis (HCA) preconditioning was suggested to attenuate ischemia-reperfusion (IR) injury of brain and lung, and underlying mechanism is uncertain. No study has assessed renoprotective effect of HCA preconditioning on renal IR injury. Here we investigate the effect and mechanism of HCA preconditioning on renal IR injury in rats.

Methods: Adult Sprague-Dawley rats are randomly exposed to humidified gas containing either FiCO2 of 5% or room air only for 30 minutes before sham operation or clamping renal artery for 30 minutes. Three or 24 hours reperfusion followed. Urine, blood and kidney tissue were obtained for biochemistry and histology. Protein level was determined by immunoblot.

Results: Histologically, less IR-related tubulointerstitial injury, leukocyte infiltration and tubular cell apoptosis were disclosed after HCA preconditioning. Functionally, HCA preconditioning preserved renal function after IR injury, reflected by better concentrating ability as well as low serum creatinine and urea nitrogen. Circulating TNF-α, interleukin (IL)-1β and IL-6 levels in response to IR is suppressed significantly in HCA group. HCA preconditioning demonstrated anti-apoptotic effect by downregulating TRAF6-ASK1-p38/JNK pathway and reducing the cleavage of caspase 3 and PARP. HCA also suppressed NF-κB pathway to achieve anti-inflammatory effect and enhanced anti-stress ability by raising expression of heat shock protein 70 and heme oxygenase-1.

Conclusions: These results suggest that protective effect of HCA preconditioning on renal IR injury may be mediated by complex mechanisms including anti-apoptosis, anti-inflammation and anti-stress.

TH-PO415

Development of Experimental Model of Renal Thrombotic Microangiopathy in Rat Allogeneic Bone Marrow Transplantation Takafumi Kanemitsu, Yusuke Okabayashi, Michiko Aoki, Yusuke Kajimoto, Kiyotaka Nagahama, Akira Shimizu. *The Dept of Analytic Human Pathology, Nippon Medical School, Bunkyo, Tokyo, Japan.*

Background: The thrombotic microangiopathy (TMA) after bone marrow transplantation (BMT) is a severe complication that carries a high risk of renal dysfunction. In TMA after BMT, total body irradiation, use of immunosuppressants, and chronic graft-versus-host-disease (GVHD) have been proposed as risk factors in inducing endothelial cell injuries and causing TMA. The skin, gut and liver are well-known primary target sites in GVHD. In our previous study, the kidney was a primary target organ of acute GVHD after BMT. In TMA after BMT, the involvement of the kidney is not well-understood. We are focusing on the pathogenesis of TMA after BMT affecting the kidney.

Methods: We induced TMA in irradiated BN rat by transplanting BM cells from allogeneic Lewis rats without immunosuppression. For chimerism analysis, FCM was performed. We examined the clinical and pathological characteristics of TMA in several organs including kidney at 9 months after BMT.

Results: Almost all blood cells were replaced by the donor cells. Mild to moderate GVHD in the skin, gut and liver was developed at 9 months after BMT. The serum creatinine levels were mildly increased. Renal pathology at 9 months after BMT showed the increase number of collapsed and sclerotic glomeruli with endothelial cell injuries in all rats. In addition, in half of the rats, renal TMA developed, that were characterized by the glomeruli with mesangiolysis, double contour of the GBM with widening of subendothelial spaces, and fibrin thrombi formation in some glomerular capillaries. Exudative lesions in small arteries were also seen. These renal findings were quite similar to renal TMA after BMT in humans. RT-PCR showed that mRNA levels of Th2 cytokines are strongly expressed than Th1 cytokines in glomeruli.

Conclusions: We have developed the animal models of renal TMA after BMT in rats. In this model, renal TMA is accompanied with mild to moderate GVHD in the skin, gut, and liver. These findings may be indicated that renal TMA after BMT is one of the findings of chronic GVHD in the kidney. Further studies are also needed to assess the mechanism of TMA after BMT.

TH-PO416

Drug Repurposing: In Vitro Validation of In Silico Predicted Transcriptomic Changes in Primary Human Mesangial Cells Induced by Calcineurin Inhibitor FK 506 Constantin Aschauer,[1] Andreas Heinzel,[2] Judith Sunzenauer,[1] Paul Perco,[2] Rainer Oberbauer.[1] *[1]Dept of Nephrology, Medical Univ of Vienna, Vienna, Austria; [2]Emergentec Biodevelopment GmbH, Vienna, Austria.*

Background: Network based drug repurposing is an emerging area in systems pharmacology utilizing Omics-derived network-based models of disease pathophysiology and drug mechanism of action(MoA) in order to identify new indications for established drugs. The calcineurin-inhibitor FK 506 shows potential positive effects in a set of diseases outside the area of transplantation.

Methods: A FK 506 MoA molecular model was constructed using two published transcriptomics datasets and a set of molecular features affected by FK 506 based on a literature mining approach. This model was screened against an in-silico library of ~2000 phenotype molecular models. We set up an in-vitro experiment studying the effect of FK 506 on mesangial cells as diabetic nephropathy (DN) was among the hit phenotypes. Primary human mesangial cells were cultured in 6 well plates and treated for 24h with 1 µM FK 506 and changes in gene expression were analyzed using Affymetrix microarrays.

Results: A set of 222 transcripts mapping to 204 unique protein coding genes were found deregulated. Pathway enrichment analysis identified the TGF-β signaling pathway (p-value: 0.0210) and a set of cell adhesion molecules (p-value: 0.0217) as relevant. Although TGFB1 was upregulated (1.32 fold), also one major inhibitor of the TGFB signaling cascade, SMAD7, was upregulated (1.31 fold). Other drug targets in the context of diabetes and DN as JAK2 (0.81 fold) and DPP4 (0.76 fold) were downregulated. On the other hand, NOX4 and EDN1 were both significantly upregulated being detrimental for DN.

Conclusions: Our in-silico drug screening approach identified DN as one of the key hit candidates showing interference on a molecular level with FK 506. In an in-vitro experiment we could validate the effect of FK 506 on TGFB signaling as well as other drug targets currently being addressed in clinical practice or trials. A set of predictive markers might guide on the use of FK 506 in DN thus identifying those patients potentially benefitting from a low-dose tacrolimus therapy.

Allogeneic Neo-Islets, Composed of Equal Numbers of Mesenchymal Stem and Islet Cells, Are Immune Protected and Cure Auto-Immune Type 1 Diabetes Mellitus in NOD Mice Christof Westenfelder,[1,2] Anna Gooch,[2] Jon D. Ahlstrom,[2] Zhuma Hu,[2] Ping Zhang.[2] *[1]Medicine, Nephrology, Univ of Utah and VA Medical Centers; SCT, LLC, Salt Lake City, UT; [2]Medicine, VA Medical Center and SCT, LLC, Salt Lake City, UT.*

Background: Globally, individuals with autoimmune Type 1 Diabetes mellitus (T1DM) continue to depend for survival on insulin injections. While pancreas and intrahepatic pancreatic islet transplants can produce insulin-independence and ameliorate serious complications, both therapies depend on potentially toxic anti-rejection drugs. Furthermore, the scarcity of pancreas donors, islet transplant failures, and the inability to adequately culture expand insulin-producing β-cells significantly limit the general availability of such and other cell-based interventions. Encapsulation of islets to protect them from allo- and auto-immune destruction has shown both promise and failures, and there remains a critical need for curative therapies of T1DM.

Methods: Here we tested the hypothesis that the need for anti-rejection drugs or encapsulation devices, the shortage of pancreas donors can be overcome by harnessing the robust immune-modulating and complex trophic activities of Mesenchymal Stem Cells (MSCs). This was investigated with *ex vivo* generated islet-sized "Neo-Islets" (NIs) in which culture-expanded islet cells, via Epithelial-Mesenchymal-Transition (EMT), were aggregated in cell clusters with equal numbers of MSCs.

Results: The minimally invasive intraperitoneal administration of allogeneic NIs durably normalized blood glucose levels in Non-obese Diabetic (NOD) mice with auto-immune T1DM, a model of human T1DM. This was achieved, without anti-rejection drugs, by the spontaneous engraftment of NIs in the animals' omenta, redifferentiation of NI-intrinsic islet cells that physiologically secrete insulin into the hepatic portal vein, and omental and splenic upregulation of Tregs.

Conclusions: NIs, as engineered here, provide a novel therapy that, we posit, has significant translational relevance to clinical T1DM.

Arctigenin Attenuates Podocyte Injury in Diabetic Kidney through Activation of PP2A Yifei Zhong,[1] Ruijie Liu,[2] Xueling Li,[1] Kyung (Kim) Lee,[2] John C. He.[2] *[1]Dept of Nephrology, Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China; [2]Div of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Arctigenin (ATG) is a major extract of Fructus Arctii which has been commonly used alone or in combination with other Chinese herbal Medicines to treat patients with diabetic kidney disease (DKD). However, it remains unknown whether ATG alone has renal protective effects for DKD.

Methods: To determine this, we treated streptozotocin (STZ)-induced diabetic $eNOS^{-/-}$ mice with either ATG or vehicle from 10 weeks post-STZ injection to 18 weeks. To understand the mechanism, we performed RNA sequencing of glomeruli from these mice. To explore the mechanism of ATG action in podocytes, we used *drug affinity responsive target stability* (*DARTS*) method combined with mass spectrometry analysis to identify ATG-bound proteins.

Results: We found that ATG markedly attenuated proteinuria, glomerular hypertrophy, mesangial expansion, foot process effacement and podocyte loss in diabetic mice as compared to those treated with vehicle. RNA sequencing of glomeruli revealed that ATG significantly affects cell cytoskeleton, cell migration, oxidative stress and inflammatory pathways in diabetic glomeruli. We confirmed that ATG reduced lamellipodia, inhibited migration, and attenuated superoxide production and pro-inflammatory gene expression in cultured podocytes. We identified that protein phosphatase 2A (PP2A) is an ATG-bound protein. The interaction between ATG and PP2A was also confirmed by structural analysis. Interestingly, ATG-PP2A interaction led to increased PP2A activity, suggesting that ATG is a natural agonist for PP2A. We demonstrated that ATG was able to reduce MAPK and p65 phosphorylation to have anti-inflammatory effects in cultured podocytes through enhanced PP2A activity. ATG also regulated RACK1 to inhibit podocyte migration through increased PP2A activity.

Conclusions: In conclusion, we demonstrated a renal protective effect of ATG in DKD and its novel mechanism of action in podocytes.

TH-PO419

Hormone-Like Function of Coagulation Protease Rescue Defective Insulin Signaling in the Kidney Sanchita Ghosh,[1] Madhusudhan Thati,[2] Moh'd Mohanad Ahmad Al-Dabet,[3] Jayakumar Manoharan,[4] Andi Marquardt,[5] Berend Heinrich Isermann.[6] *[1]IKCP, Otto-von-Guericke Univ, Magdeburg, Germany; [2]Thrombosis and Hemostasis, Univ Medical Center Mainz, Mainz, Germany; [3]IKCP, Otto-von-Guericke Univ, Magdeburg, Germany; [4]IKCP, Otto-von-Guericke Univ, Magdeburg, Germany; [5]IKCP, Otto-von-Guericke Univ, Magdeburg, Germany; [6]IKCP, Otto-von-Guericke Univ, Magdeburg, Germany.*

Background: Impaired insulin signaling in the kidney contributes to the progressive failure in glomerular filtration, the loss of the specialized glomerular epithelial cells (podocytes), and subsequent proteinuria in diabetic kidney disease (DKD).

Methods: We recently established that the coagulation protease activated protein C (aPC) protects mice from diabetic nephropathy, but the intracellular signaling mechanism remains unknown.Here we show that the aPC rescues defective insulin signaling by activating the unfolded protein response (UPR) arm of the multistep ER-stress response in podocytes. Analogous to insulin, physiological levels of aPC regulate homeostatic-UPR in podocytes by maintaining nuclear levels of sXBP1 while downregulating the transcription factors responsible for the maladaptive ER-stress response (ATF6 and CHOP). This cytoprotective mechanism of nuclear translocation of sXBP1 occurs via the interaction with regulatory subunits of PI3Kinase (p85α and p85β).

Results: Type I diabetic mice with podocyte specific deletion of the insulin receptor ($INSR^{\Delta Pod}$) develop enhanced albuminuria, glomerular basement membrane (GBM) thickening and podocyte foot process effacement compared to the wild type $INSR^{\Delta Pod}$ mice. Transgenic overexpression of protein C or treatment with aPC, protects the $INSR^{\Delta Pod}$ mice from DKD by restoring the nuclear sXBP1 and attenuating maladaptive ER-stress response.

Conclusions: Taken together, due to signaling redundancy aPC efficiently alleviates defective INSR signaling in podocytes, suggesting that aPC or its receptors could prove to be an excellent therapeutic adjunct for DKD.

Funding: Government Support - Non-U.S.

TH-PO420

Podocyte Specific Knockout (KO) of COX2 Exacerbates Kidney Disease in Diabetic Akita Mice Liming Wang,[1] Yonggang Sha,[1] Jingyi Bai,[1] William Eisner,[1] Anne Buckley,[2] Robert F. Spurney.[1] *[1]Medicine, Duke Univ and Durham VA Medical Centers, Durham, NC; [2]Pathology, Duke Univ Medical Center, Durham, NC.*

Background: Induction of COX2 expression in podocytes has been implicated in promoting podocyte injury in diabetic kidney disease (DKD).

Methods: To investigate the role of COX2 in DKD, we deleted COX2 specifically in podocytes in a mouse model of type 1 diabetes mellitus (male 129/SvEv Akita mice) by expressing Cre recombinase under the regulation of the podocyte specific podocin promoter.

Results: Wild type (WT) Akita mice and podocyte specific knockout (KO) Akita mice had similar levels of hyperglycemia at 8, 12, 16 and 20 weeks of age as well as similar levels of systemic blood pressure at 12 and 20 weeks of age. Albuminuria was significantly increased in both groups of Akita mice compared to non-diabetic controls at the 16- and 20-week time points. The increase in albuminuria was significantly greater in KO Akita mice compared to WT Akita mice at 16 weeks of age (138 ± 12 [WT Akita] vs 300 ± 48 [KO Akita] ug/24H; P<0.05) and at 20 weeks of age (158 ± 25 [WT Akita] vs 305 ± 50 [KO Akita] ug/24H; P<0.05). At the 20-week time point, mesangial expansion was significantly increased in both groups of diabetic mice compared to non-diabetic controls; but the degree of mesangial expansion was similar in WT and KO Akita mice. Tubular dilation and casts as well as tubulointerstitial inflammation and fibrosis were not significantly different in either group of diabetic mice compared to non-diabetic controls. Because systemic KO of COX2 causes developmental defects of the kidney, we also examined kidneys from non-diabetic WT mice and non-diabetic KO mice for abnormalities. There were no differences detected in kidney weights, kidney histology or glomerular ultrastructure between WT and KO groups.

Conclusions: These data suggest that deletion of COX2 specifically in podocytes has adverse effects on DKD in Akita mice. Some basal level of podocyte COX2 expression may be necessary to protect podocytes from injury in diabetes.

TH-PO421

Paricalcitol Prevents Glucose Induced-Podocyte Injury by Inhibiting Wnt/β-Catenin Pathway Xuan Xiong, Shi Xiao Zhong. *Dept of Nephrology, Guangzhou Red Cross Hospital, Jinan Univ, Guangzhou, Guangdong, China.*

Background: Diabetic nephropathy (DN) is one of the most important causes of end-stage renal disease and Wnt/β-catenin pathway is highly activited in diabetes.Paricalcitol has been reported to prevented podocyte demage, but its role in diabetic nephropathy remain unknow. This study was designed to investigate whether Paricalcitol could ameliorate high glucose induced podocyte injury and the underlying mechanisms.

Methods: The podocytes were cultured under different conditions for 24h, which were divided into 6 groups of normal glucose control(NG), mannitol Group(MG),high glucose group(HG), Paricalcitol group(PG),losartan group(LG) and Paricalcitol+LiCL group(PLG). Cell proliferation was detected by methyl thiazolyl tetrazolium(MTT). The podocyte injury induced by high glucose and the effect of Paricalcitol on it were evaluated by measuring the nephrin,wt1,Tgf-beta,Col IV,VDR and β-catenin expression.The wnts mRNA expression and Apoptosis rate of the podocytes were detected using reverse transcription PCR and flow cytometry, respectively. The nuclear translocation of VDR and β-catenin were evaluated too.β-catenin agonists (LiCL) were used to analyze the role of this pathway.

Results: The podocyte injury induced by HG was characterized by upregulated tgf-β and Col IV expression; increasing Apoptosis rate;with downregulated expressions of both wt1 and nephrin, which paralleled the increasing wnts mRNA expression and β-catenin nuclear translocation.Our data demonstrated that paricalcitol preserved the expression of nephrin,wt1,reduced the expression of tgf-βand Col IV,prevented apotosis in podocyte. It promoted VDR nuclear translocation and blocked β-catenin nuclear translocation.The expression of wnt4,wnt10a,wnt10b were inhibited at RNA level.We found that paricalcitol protect podocytes from high glucose by surpressing wnt pathway.LiCL,as a WNT/β-catenin Signaling pathway agonist, could abolish the effects of paricalcitol.

Conclusions: The results suggests that Paricalcitol attenuates high glucose-induced podocyte injury in vitro partly through inhibiting the wnt/β-catenin pathway.

TH-PO422

RTN1A Induces Podocytes Injury through Increased ER Stress and Is Ameliorated by Tauroursodeoxycholic Acid in Diabetic Nephropathy Ying Fan,[1] Jing Zhang,[1] Wenzhen Xiao,[2] Jiejun Wen,[1] Kyung (Kim) Lee,[2] Zhengzhe Li,[2] Li He,[1] John C. He,[2] Niansong Wang.[1] *[1]Dept of Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Dept of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Diabetic nephropathy (DN) remains the leading cause of chronic kidney disease (CKD) in most countries. Podocyte injury contributes to the progression of DN. Our previous studies reported a critical role of reticulon (RTN) 1A in mediating endoplasmic reticulum (ER) stress in kidney tubular cells and contributed to the progression of CKD. However, how ER stress mediates podocyte injury in DN remains largely unknown.

Methods: In the present study, we explored the role of ER stress in vivo using an accelerated murine model of advanced diabetic nephropathy, which is db/db mouse with early uninephrectomy. We also assessed the role of RTN1A in mediating ER stress in podocyte injury *in vitro*.

Results: We found that the expression of RTN1A and ER stress markers was upregulated in the kidney of diabetic mice. Administration of tauroursodeoxycholic acid (TUDCA), an inhibitor of ER stress, suppressed RTN1A and ER stress marker expression, attenuated kidney injury, preserved glomeruli function and protected podocytes from apoptosis in uninephrectomized db/db mice. *In vitro*, overexpression of RTN1A in human podocytes induced ER stress and cell apoptosis, whereas knockdown of RTN1A attenuated human serum albumin-induced podocyte ER stress and apoptosis. Interestingly, overexpression of RTN1A induced CHOP expression while knockdown of CHOP expression led a suppression of RTN1A expression, suggesting a positive feedback loop between RTN1A and CHOP to enhance the ER stress signaling.

Conclusions: In conclusion, ER stress is a key event for podocyte injury in DN. RTN1A might be a crucial mediator of ER stress in podocytes, probably through a positive feedback loop between RTN1A and CHOP.

TH-PO423

Huangkui Capsule Protects against Podocyte Injury in Diabetic Nephropathy via Regulating Insulin Resistance and IRS1/PI3K/Akt2 Signaling Pathway, Compared with Rosiglitazone Wei Wu, Yigang Wan. *Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School.*

Background: Huangkui capsule (HKC) has been applied extensively for treatment of proteinuria in patients with early diabetic nephropathy (DN) in China. However, its mechanism is fully unclear. In the process of early DN, insulin resistance (IR) and low activation of IRS1/PI3K/Akt2 signaling pathway in kidneys lead to podocyte lesion, which further results in proteinuria. This study thereby aimed to investigate effects and mechanisms in vivo of HKC on podocyte damage, compared withrosiglitazone (ROS)as an insulin sensitizer in clinic, by regulating IR and IRS1/PI3K/Akt2 signaling activity.

Methods: Rats were randomly divided into 5 groups, sham-operated group, vehicle-given group, low dose of HKC-treated group, high dose of HKC-treated group and ROS-treated group. HKC, ROS and saline were daily administrated for 8 weeks after the induction of DN by streptozotocin (STZ)with unilateral nephrectomy. Albuminuria, biochemicalindicators, IR-related markers (HOMA-IR), podocyte form, glomerular pathological changes, as well as the key protein expressions inIRS1/PI3K/Akt2 signaling pathway and podocyte structural molecules in kidneys including nephrin, podocin, CD2AP and neph1 were examined,respectively.

Results: The results showed that, urinary albumin, HOMA-IR, foot process effacement, glomerularsclerosis and the decreased protein expressions of p-IRS1, p-PI3K, p-Akt2, nephrin and podocin in the DN model rats were ameliorated in different extent in the HKC and ROS treated groups, especially in the high dose of HKC-treated group. More notably, HKC synchronously up-regulated IRS1/PI3K/Akt2 signaling activity and nephrin protein expression, whereas, ROS only increased nephrin and podocin protein expressions in kidneys.

Conclusions: In conclusion, by DN model rats, we demonstrated that IRcontributes topodocyte damage and IRS1/PI3K/Akt2 signaling activity inhibition. HKC, as a natural regulator in vivo, can improve IR-related podocyte injury via up-regulating the protein expressions of p-IRS1, p-PI3K, p-Akt2 and nephrin, which is different from ROS.

TH-PO424

Dysregulation of LDL Receptor by Cyclooxygenase-2 Contributes to Podocyte Injury in Streptozotocin Induced Diabetic Rats Liang Liu, Kun Ling Ma, Yang Zhang, Gui Hua Wang, Zebo Hu. *Inst of Nephrology, Southeast Univ, Nan Jing City, JIang Su Province, China.*

Background: Podocyte injury and resulting microalbuminuria are early hallmarks of diabetic nephropathy(DN). Lipid disorder play crucial roles in podocyte injury of DN. This study was designed to investigate whether cyclooxygenase-2 (COX-2)is involved in podocyte injury by disrupting the low-density lipoprotein receptor (LDLr) pathway.

Methods: Eight-week old male *Sprague-Dawley* rats were treated for 12 weeks by dividing into three groups: nondiabetic rats (control), streptozotocin-induced diabetic rats (DM), and diabetic rats treated with Aspirin (DM+ Aspirin). The ratio of urinary microalbumin to creatinine (ACR) was detected by enzyme-linked immunosorbent assay. Intracellular lipid accumulation was evaluated by Oil Red O staining, Filipin staining, and a free cholesterol quantitative assay. The glomerular podocyte injury and the expression of molecules related with LDLr pathway was evaluated by, immunohistochemical staining, immunofluorescent staining, and Western Blot.

Results: There were increased levels of plasma lipid, serum creatinine, and urinary ACR in diabetic rats compared with control rats. Moreover, there was significant mesangial matrix expansion, basement membrane thickening, podocyte foot process effacement and phenotypic alteration in the diabetic rats. Additionally, lipid accumulation in the kidneys of diabetic rats was increased, due to increased protein expressions of LDLr, sterol regulatory element–binding protein (SREBP), cleavage activating protein (SCAP), and SREBP-2. The podocytes in kidneys of diabetic rats underwent epithelial-mesenchymal transition, which was closely associated with the increased expression of LDLr pathway components and subsequent cholesterol accumulation. Interestingly, COX-2 protein expression in kidneys

of diabetic ratswas markedly increased and closely correlated with increased LDLr protein expression, compared with the controls. However, these change was significantly inhibited by a nonselective inhibitor of COX-2, Aspirin.

Conclusions: Dysregulation of LDLr pathway contributes to podocyte injury in diabetic nephropathy, which might be mediated through the increased COX-2 expression.

TH-PO425

Multiglycoside of *Tripterygium wilfordii* Hook.f. Attenuates Podocyte Damage in Diabetic Nephropathy Rats via Regulating mTORC1 Signaling Pathways, Compared with Rapamycin Ge Shi,[1] Yigang Wan.[2] *[1]Nanjing Univ of Chinese Medicine; [2]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School.*

Background: Multiglycoside of *Tripterygium wilfordii* Hook.f. (GTW) has been applied extensively for treating podocyte injury in patients with early diabetic nephropathy (DN) in China. Activation of mTORC1 plays a critical role in podocyte damage under hyperglycemia, which can be realized by the combined actions of Akt activation and AMPK inhibition. This study thus aimed to investigate effects and mechanisms in vivo of GTW on podocyte lesion, compared with rapamycin (RAPA) as an mTORC1 inhibitor, by regulatingAkt/mTORC1 or AMPK/mTORC1 signaling activities.

Methods: Rats were randomly divided into 4 groups, the sham-operated group, the GTW-treated group, the vehicle-given group and the RAPA-treated group, and sacrificed at week 8 after theinduction of DN by 2 consecutive intraperitoneal injections of streptozotocin (STZ) with an interval of 1 week following unilateral nephrectomy. Daily oraladministration of GTW, RAPA and saline were started after the second injection of STZ until sacrifice.

Results: The results indicated that, after p-Akt was up-regulated and p-AMPK was down-regulated respectively, mTORC1signaling pathways wereconcurrentlyactivated in kidneys of the DN model rats. GTW, similar to RAPA, markedly regulated the protein expressions of p-Akt, p-AMPK, p-mTOR and p-p70S6 kinase in kidneys, and ameliorated albuminuria, foot process effacement, podocyte loss and glomerularsclerosis. In addition, the recuperative protein expressive levels of podocin and CD2AP and the rasied protein combinative levels between nephrin and neph1 in kidneys in the GTW-treated group were also observed, while RAPA only up-regulated the protein expression of podocin and the protein combinative levels between nephrin and neph1 in kidneys.

Conclusions: In summary, using the DN model rats, we clarified that GTW, as a natural regulator in vivo, effectively attenuates podocyte damage by the potential mechanisms involving the repair of podocyte structural molecules and the regulation of Akt/mTORC1 and AMPK/mTORC1 signaling activities.

TRIM72-Containing Microvesicles Protect Podocyte in Diabetic Nephropathy via TWIST Pu Duann,[1] Haichang Li,[4] Elias A. Lianos,[3] Pei-Hui Lin.[2] *[1]Medicine, OSU Wexner Medical Center, Columbus, OH; [2]Surgery, OSU Wexner Medical Center, Columbus, OH; [3]Medicine/ Nephrology Div, Rutgers RWJ Medical School, New Brunswick, NJ; [4]DHLRI, OSU Wexner Medical Center, Columbus, OH.*

Background: Glomerulonephropathy is the major kidney complication in diabetes. GBM thickening caused by disrupted ECM homeostasis, is a prominent feature in DN with the disrupted regulation with Type IV collagen, the main structural component of GBM. We previously reported a glocose intolerance phenotype with a TRIM72-null transgenic mice, which show proteinuriua and DN feature with reduce glucose uptake in podocyte. We also observed deliver TRIM72 by microvesicles reduced proteinuria and attenuate DN features. Apply TRIM-72 containing microvesicles on cultured podocytes, we observed cytoproting effects yet with unclear mechanism.

Methods: TRIM72(+)-microvesciles, isolated by ultracentrifuge, were applied on cultured podocytes, pulsed with normal- or high- glucose media. Effects on genes with TGF-β1 signal pathway, stress responsive cytokines or proinflammatory genes were assessed by Q-PCR and western blot analysis. Mic-tagged TRIM 72 and FLAG-tagged TWIST1 were co-transfected to HEP293 to verify immunoprecipitation. Contribution of individual genes, e.g. TWIST, was validated by mutant or knockdown by siRNA.

Results: TRIM72-null mice showing DN feature with thickened GBM and proteinuria. TRIM72 containing microvessicles attenuate proteinuria and partially rescue DN phenotype. TRIM72 co-precipitated with wild type- but not mutant TWIST lacking binding motif. Cultured podocyte treated with TRIM72-containg microvessicle displayed a altered expression pattern on genes including TGF b1, Smad2/3, but not COL4A. When TWIST knocking down by siRNA, TRIM72 lost its gene modulation effect.

Conclusions: We have shown that TRIM72-containing microvessicles modulate TGF-β signal pathway via TWIST. Though the synthesis COL4A was not directly altered, TGFb1 Smad2/3 are cleared changed. TRIM72-containing microvesicle are a powerful vehicle, readily uptake by cultured podocyte and modulate disease related genes. These findings suggest pharmacological targeting to ECM homeostasis against diabetic nephropathy.

Pigment Epithelium Derived Factor (PEDF) Is Protective for Podocytes, and Global Genetic Ablation Exacerbates Glomerular Lesions in Mice with STZ-Induced Diabetes Minghao Ye, Olga V. Volpert, Jan A. Wysocki, Daniel Batlle. *Div of Nephrology and Dept of Urology, Northwestern Univ, Feinberg School of Medicine, Chicago, IL.*

Background: Pigment Epithelium Derived Factor (PEDF) encoded by *SERPINF1* gene is a multifunctional protein that has anti-angiogenic and cytoprotective activities. It has been reported that PEDF protein levels are reduced in the kidneys of rodents with experimentally induced diabetes and 44mer PEPF fragment may be renoprotective. We used SERPINF1 KO mice to examine the impact of global PEDF deficiency on kidney pathology and tested a short PEDF fragment for protective effects in cultured podocytes.

Methods: The potential protective effects of a novel PEDF peptide PMD-427 was tested in cultured podocytes exposed to high glucose or genotoxic stress (cisplatin, CPT). Podocyte apoptosis was measured by TUNEL assay and ROS levels were assessed using DHFR fluorescent dye. Metabolic activity was evaluated in cells exposed to control vehicle and PMD-427 using Seahorse analyzer in the presence of free log-chain fatty acids (Palmitate).

Results: Twelve weeks after diabetes induction by STZ, *SERPINF1* KO mice showed a significant increase in mesangial matrix (2.8±0.14 vs. 1.2±0.14 arbitrary units, $p<0.01$) and ~ 20% decrease in podocyte counts (8.2±0.0.4 vs. 9.7±0.2 podocytes/glomerulus, $p<0.01$) compared to the WT controls. In vitro, PMD-427 decreased apoptosis of cultured podocytes by 72±17% in hyperglycemic conditions and by 30±9% when exposed to CPT. The decreased apoptosis was associated with 70-90% decrease in ROS production. A significant 1.7 fold increase in fatty acid oxidation was also observed.

Conclusions: Global PEDF deficiency results in worsening of glomerular lesions in the STZ-induced mouse model of diabetes A short fragment of PEDF derived from its active epitope has a marked protective effect in vitro. This peptide attenuates ROS, and increases fatty acid oxidation in podocytes and may have therapeutic potential for diabetic kidney disease.

Mitochondrial Dynamic Alterations Mediated by P66Shc Signaling Promotes Diabetes-Induced Tubular Cell Injury and Apoptosis Ming Zhan,[1] Yashpal S. Kanwar,[2] Lin Sun.[3] *[1]Medicine, Ningbo First Hospital, Zhejiang Univ, China; [2]Pathology, Northwestern Univ; [3]Medicine, Second Xiangya Hospital, Central South Univ, China.*

Background: Renal tubular injury is an early characteristic of diabetic nephropathy (DN), mitochondrial damage and the adaptor protein p66Shc-mediated oxidative stress are both critical during diabetic tubular cell injury and death, their correlation is unclear.

Methods: We investigate mitochondrial morphological changes in renal tissues from DN and MCD patients, and explore the involvement of p66Shc-mediated mitochondrial pathway in high glucose (HG)-induced mitochondrial dynamic alterations and cell apoptosis in human renal tubular cells.

Results: Elongated mitochondria became fragmented in renal tubules of patients with DN, compared with the control group. The levels of mitochondrial shaping proteins Drp1 and Fis1 were increased and Mfn1 decreased in DN tissues, these changes were accompanied with the elevation of p66Shc level and oxidative stress. In HK-2 cells, alterations in mitochondrial dynamics and its related protein levels was observed under HG ambience, together with upregulation of p66Shc and phosphorylated p66Shc at Ser36. Notably, siRNA knockdown of p66Shc alleviated HG-induced mitochondrial fragmentation, down-regulated Fis1 but increased Mfn1 expression under HG, and reduced the protein interactions between Mfn1 and proapoptotic protein Bak, resulting in decreased mitochondrial $\Delta\Psi$, mROS production and apoptosis. Oppositely, over-expression of p66Shc could exacerbate HG-induced mitochondrial fragmentation and apoptosis, whereas transfection with dominant-negative Ser36 p66Shc mutant in HK-2 has marginal similar effects.

Conclusions: Clinical evidence of mitochondrial fragmentation in human diabetic nephropathy was presented in our study. P66Shc activation and phosphorylation mediated mitochondrial dynamic alterations through regulating mitochondrial shaping proteins, and leading to tubular oxidative injury and apoptosis via p66Shc/Mfn1/Bak pathway under HG ambience.

Human Kidney Biopsies Gene Expression Reveals Changes in Mitochondrial and Lipid Metabolic Pathways in Obesity-Related Glomerulopathy Michal Herman-Edelstein,[1] Talia R. Weinstein,[1] Vivette D. D'Agati,[3] Avry Chagnac,[1] Moshe Levi.[2] *[1]Nephrology, Rabin -Felsenstein, Israel; [2]Colorado, Denver; [3]Columbia, New-York.*

Background: Obesity-related glomerulopathy (ORG) is an emerging complication of the obesity epidemic. However, pathways through which obesity may cause renal injury are not well understood. Potential mechanisms include metabolic maladaptive pathways, lipid accumulation, podocyte hypertrophy and dysfunction, adipokine dysregulation, oxidative and inflammatory stress.

Methods: To obtain insight into molecular mechanisms underlying obesity-induced kidney injury we studied metabolic target gene expression in amplified mRNA of laser captured microdissection (LCM) isolated glomeruli and tubules. We studied FFPE renal biopsies of patients with clinical and pathological established obesity- related

glomerulopathy (ORG), compared to normal kidneys. We also investigated lipid content and markers of podocyte injury and hypertrophy (Immunohistochemistry analysis of GLEPP1/WT1).

Results: ORG manifests a benign course with slow eGFR deterioration compare to DN. Glomerular surface area was markedly enlarged in ORG and was accompanied by significant decreases in the podocyte marker and genes with only limited compensatory podocyte hypertrophy. There was marked lipid accumulation in both glomeruli and tubules. The most prominent difference in lipid metabolism gene expression was down-regulation of fatty acid β oxidation genes in both glomerular and tubulointerstitial fractions, possibly secondary to reduced transcription of nuclear genes involved in mitochondrial respiration (PGC1α) and decreased expression of adiponectin receptors 1 and 2. Furthermore, increases were observed in genes contributing to cholesterol and triglyceride uptake (CD36) and decreases in cholesterol efflux (ABCA1) with a parallel decrease of liver X receptor alpha (LXRα) and an increase in sterol-regulatory element binding protein-2 (SREBP-2) mRNA content, mainly in the tubular fraction.

Conclusions: The major finding of this study is that lower expression of the mitochondrial respiratory pathway and defective regulation of lipid metabolism pathways involved in obesity- induced kidney injury.

PGC1 α, Increases HO-1 Gene Expression Resulting in the Restoration of Mitochondrial Mfn1/2 Signaling and Prevention of Obesity-Induced Hypertension via Recruitment of Renal NaCl Co-Transporter

Joseph Schragenheim, Nader G. Abraham. *Pharmacology, New York Medical College, Valhalla, NY.*

Background: Elevated blood pressure (BP) was frequently observed in subjects with midlife weight gains and in obese mice. Elevation of mitochondrial dysfunction is associated with obesity induced BP elevation. Previously we and others have shown that an EET agonist (EET-A), reduced adiposity and ROS resulting in normalization of BP by unknown mechanisms. We hypothesized that EET-A may attenuate BP in mice fed high caloric intake diets by NCC Channel by recruiting PGC1a-HO-1 that resulted in restoring mitochondrial function and fusion.

Methods: C57/B16 mice at the age of 5 wks., fed a HF diet that for 24 wks. when all mice had established pre-diabetic stage (12-wks), EET-A was administered intraperitoneally, 1.5 mg/100g BW. (Blood was collected, glucose and visceral fat and renal tissues were harvested, HO-1, NKCC2, ENaC, NCC, insulin receptors, PGC1a Mito-fusion protein markers and VO_2 consumption were determined in group: A) Control, B) HF, C) HF-EET-A and D) EET-A-Ln-PGC1α (sh).

Results: Renal PGC1a, HO-1, pAMPK, and mitochondrial fusion protein Mfn 1/2, and Opa1 were decreased in obese mice and restored by EET-A treatment. VO_2 consumption were impaired in control obese mice compared to mice treated with either EET-agonists or vehicle solution $p<0.05$. A HF diet increased levels of NaCl co-transporter (NCC) but not type 2 Na-K-Cl co-transporter (NKCC2) or epithelial Na channel-alpha subunit ENaC while treatment with EET-A decreased NCC expression ($p<0.05$) that was associated with normalization of BP. Electron transport and mitochondrial citrate carrier ($p<0.05$) were lowered in mice fed a HF diet compared to EET-A.

Conclusions: EET-A restores cortical NCC channel function is associated with recruitment of PGC1α HO-1, mitochondrial Mfn1/2 and Opa1, mitochondrial function that is associated with normalization of BP. Pharmacological targeting mitochondrial fusion protein and increase of HO-1-derived antioxidant activity via increase bilirubin and CO may be a promising therapy in prevention of renal function and amelioration of hypertension.

Acute Mitochondrial Response to High Glucose Exposure in Primary Renal Cells Studied with Super Resolution Microscopy

Linnéa M. Nilsson,[2] Lena Scott,[1] Jacopo Maria Fontana,[1] Liang Zhang,[1] Kristoffer Bernhem,[2] Hjalmar Brismar,[1,2] Anita Aperia.[1] *[1]Karolinska Inst, Stockholm, Sweden; [2]Royal Inst of Technology, Stockholm, Sweden.*

Background: Hyperglycemia is a major cause of diabetic complications. Many aspects of mitochondrial dysfunction are reported in studies of experimental diabetic nephropathy. Yet, little is known about the immediate mitochondrial response to high glucose (HG) in primary renal cells.

Methods: Acute response of primary renal cells, proximal tubule cells (RPTC), mesangial cells (MC) and podocytes, to HG (15-20mM) exposure was studied with immunocytochemistry, TUNEL stain, Stimulated Emission Depletion (STED) and Stochastic Optical Reconstruction (STORM) microscopy.

Results: First we compared the 8 h response to HG in RPTC and MC, which express both Glut transporters and SGLT 2 or 1 respectively, and in podocytes which only express Glut transporters. We observed significant increase in apoptotic index in RPTC and MC but not in podocytes, associated with an increased expression of apoptotic factor Bax and decreased expression of anti-apoptotic factor Bcl-xL. Next we used STED to visualize initiation of apoptosis in RPTC exposed to HG. In control cells, Bax in inactive form was found in cytoplasm, while Bcl-xl was found on mitochondria. After 6 h of HG, clusters of active Bax was found on mitochondria, while Bcl-xl remained on mitochondria. STORM revealed progressive co-localization between Bax and the voltage–dependent anion channels (VDAC) in approximately 10% of cells. Bax-VDAC interaction permitted an uncontrolled mitochondrial calcium influx, marking the point of no return in the apoptotic process. Previously we have described how ouabain/Na,K-ATPase signaling exerts an anti-apoptotic effect. Here we show that this signal halts initiation of the apoptotic process.

Conclusions: We conclude that exposure to glucose in concentrations not uncommon in poorly controlled diabetes promptly initiates an apoptotic process in SGLT expressing renal cells and would require preventive anti-apoptotic treatment.

Apoptosis Signal-Regulating Kinase 1 (ASK1) Pathway Activation in Diabetic Kidney Disease (DKD) Patients and db/db eNOS-/- Mice

John T. Liles,[1] Haichun Yang,[2] Ted Sullivan,[1] Erik G. Huntzicker,[1] Dorothy French,[1] Agnes B. Fogo,[2] David G. Breckenridge.[1] *[1]Gilead Sciences, Inc, Foster City; [2]Vanderbilt Univ Medical Center, Nashville.*

Background: ASK1 is a serine/threonine kinase activated by pathological oxidative stress that drives renal inflammation, apoptosis, and fibrosis via the downstream MAPK kinases p38 and c-Jun N terminal kinase (JNK). GS-4997 is a selective ASK1 inhibitor in clinical development for the treatment of DKD. We quantified p38 activation (p-p38) in kidney biopsies from patients with DKD and renal ASK1 activation (p-ASK1) and p-p38 levels in the db/db eNOS$^{-/-}$ model of DKD. A selective ASK1 inhibitor was used to determine the role of ASK1 in p38 activation and progressive GFR decline in db/db eNOS$^{-/-}$ mice.

Methods: p-p38 levels in renal biopsy tissue from patients with DKD (n=10) and healthy subjects (n=7) were determined by IHC. Slide images were analyzed with Definiens Developer XD and expressed as an H-Score that quantifies intensity and distribution. Masson's trichrome, PAS, and H&E stains were done to assess fibrosis and morphology. 10 week old db/db eNOS$^{-/-}$ mice were treated with a structural analog of GS-4997 (GS-444217) or vehicle for 8 weeks (n=8-10). Endpoints included p-p38 and p-ASK1 in kidney lysates, histology, and GFR by inulin-FITC clearance.

Results: Compared to normal subjects, p-p38 levels were significantly elevated in DKD biopsies (144 ± 49 vs 15 ± 9 H-Score, $p<0.00001$). In glomeruli with mild to severe mesangial expansion, p-p38 expression was prominent and localized to mesangial cells, podocytes, and parietal epithelial cells. Tubule epithelium and areas of interstitial fibrosis/inflammation also had prominent p-p38. p-p38 staining was similarly distributed in kidneys of db/db eNOS$^{-/-}$ mice. Treatment of db/db eNOS$^{-/-}$ mice with an ASK1 inhibitor suppressed p-ASK1 by 80% ($p<0.05$) and p-p38 by 84% ($p<0.0005$), and decreased albuminuria, glomerulosclerosis, and GFR decline (365± 31 vs 212± 21 ml/min, $p=0.0007$) compared to vehicle.

Conclusions: p-p38 is elevated in the glomerulus and tubulointerstitium of patients with DKD. A selective ASK1 inhibitor strongly suppresses p-ASK1 and p-p38 levels and halts GFR decline in db/db eNOS$^{-/-}$ mice.

Involvement of Endoplasmic Reticulum Stress, Autophagy, and Apoptosis in Advanced Glycation End Products-Induced Glomerular Mesangial Cell Injury

Chih-Kang Chiang,[1,2] Shing-Hwa Liu.[1] *[1]Graduate Inst of Toxicology, National Taiwan Univ, College of Medicine, Taipei, Taiwan; [2]Dept of Integrated Diagnostics & Therapeutics, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Advanced glycation end-products (AGEs)-induced mesangial cell death is one of major causes of glomerulosclerosis in diabetic nephropathy. Both endoplasmic reticulum (ER) stress and autophagy are adaptive responses in cells under environmental stress and participate in the renal diseases. The role of ER stress and autophagy in AGEs-induced mesangial cell death is still unclear. Here, we investigated the effect and mechanism of AGEs on glomerular mesangial cells.

Methods: Mouse mesangial cells (MMCs) were obtained from Food Industry Research and Development Institute. MMCs were treated with AGEs to evaluate the cell viability by MTT assay and flow cytometry. The protein expressions were measured by Western blot assay. Furthermore, MMCs were treated with 3-Methyladenine (3MA), siATG5 and 4-phenylbutyric acid (4PBA) to study the influence of autophagy and ER stress.

Results: AGEs dose-dependently decreased mesangial cell viability and induced MMCs apoptosis. AGEs also induced ER stress signals (GRP78, IRE1α, eIF2α, ATF4, and CHOP) in a time- and dose-dependent manner. Inhibition of ER stress with 4PBA significantly inhibited the activation of eIF2α and CHOP signals and reversed AGEs-induced apoptosis. AGEs also significantly activated LC3 cleavage, decreased p62 expression, and increased Atg5 expression in a time- and dose-dependent manner, which indicated the autophagy induction in mesangial cells. Inhibition of autophagy by Atg5 siRNA transfection aggravated AGEs-induced MMCs apoptosis. Moreover, ER stress inhibition by 4PBA significantly reversed AGEs-induced autophagy, but autophagy inhibition (Atg5 siRNA) did not influence the AGEs-induced ER stress-related signals activation. These results suggest that AGEs induce MMCs apoptosis via an ER stress-triggered signaling pathway. The Atg5-dependent autophagy plays a protective role in AGEs-induced MMCs apoptosis.

Conclusions: ER stress is capable of interfering with the function of autophagy, which may offer a new strategy against AGEs toxicity in the diabetic kidney.

TH-PO434

Modification of Renal Macrophage Signaling via MCP-1 Inhibition Reduces Albuminuria in Diabetic Nephropathy in Mice Daphne Thomas-Ijpelaar,[1] Margien G.S. Boels,[1] Angela Koudijs,[1] Cristina Avramut,[1] Wendy Sol,[1] Gangqi Wang,[1] Annemarie Van Oeveren-Rietdijk,[1] Anton Jan Van Zonneveld,[1] Hetty C. de Boer,[1] Johan Van der Vlag,[2] Cees van Kooten,[1] Dirk Eulberg,[3] Bernard van den Berg,[1] Ton J. Rabelink.[1] *[1]LUMC, Netherlands; [2]RadboudUMC, Netherlands; [3]NOXXON Pharma AG, Germany.*

Background: Recently, inhibition of the pro-inflammatory chemokine monocyte-chemotactic protein 1 (MCP-1) with Emapticap was found to reduce albuminuria in patients with type 2 diabetic nephropathy (DN). MCP-1 regulates inflammatory cell recruitment and differentiation of macrophages. Pro-inflammatory macrophages express cathepsin L (CTSL), which activates heparanase (HPSE), thereby degrading heparan sulphates, one of the components of the glomerular endothelial glycocalyx (GEG). Presence of GEG is essential to prevent albuminuria. Therefore, we hypothesized that MCP-1 inhibition reduces albuminuria via influencing macrophage function, resulting in reduced HPSE activity and restoration of GEG.

Methods: DN was induced in 6 weeks old ApoE-KO mice with STZ (5x 60mg/kg) and a high cholesterol diet (0.15%). At week 18 mice were treated for 4 weeks with mouse specific MCP-1 inhibitor mNOX-E36 (20mg/kg, s.c.) or control Spiegelmer. Cationic ferritin (CF) binding to the GEG was imaged using transmission electron microscopy. Glomeruli were analysed for F4/80, CTSL and HPSE protein expression. Macrophages were isolated from the kidney with FACS and *ex vivo* cytokine production was measured.

Results: Treatment with mNOX-E36 attenuated albuminuria, without changes in blood glucose and blood pressure. This was accompanied by reduced CTSL and HPSE expression and increased binding of CF to the GEG. The number of glomerular macrophages did not change upon treatment. However, functional *ex vivo* analysis showed a reduced LPS-induced IL-6/IL-10 ratio, demonstrating an anti-inflammatory phenotype.

Conclusions: MCP-1 inhibition by mNOX-E36 decreases albuminuria in diabetic apoE-KO mice. The accompanied anti-inflammatory phenotype of macrophages and GEG restoration, suggest that MCP-1 inhibition attenuates albuminuria in DN by restoration of the GEG via polarization of renal macrophages.

TH-PO435

The Role and Mechanism of Alternatively Activated Macrophage in Renal Fibrosis of Diabetic Mice Ning Su, Jiang Zongpei. *Dept of Nephrology, The Six Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong Province, China.*

Background: The effect and mechanisms of alternatively activated macrophage (M2) on renal fibrosis in diabetic mice has not been elucidated.

Methods: M2 macrophages(F4/80+CD206 double positive cells) and the accumulation of fibronectin in the kidney were observed in diabetic C57BL/6J mice after eight weeks of diabetic mellitus with intraperitoneal injection of streptozocin. Liposome-encapsulated clodronate (LC, the specific scavenger of macrophages) was used to treat the diabetic mice by intraperitoneal injection (10μl/1g bodyweight) twice one week from the third to the eighth week to investigate the effect of M2 on renal fibrosis. Furthermore, Raw 264.7 cells were induced to M2 phenotype with high ambient glucose(30mmol/L) and TGF-β1(5ng/ml). The special inhibitor of Smad2(SB431542) and Erk(U016) were used to investigate the mechanism involved in the process of M2 differentiation.

Results: M2 macrophages in kidney were eliminated and the accumulation of fibronectin was improved in those diabetic mice treated with LC. Furthermore, the activation of Smad2 and Erk were all involved in the transformation of M2 macrophage, and not only the inhibitor of Smad2 but also Erk partially inhibited the process of M2 macrophage. However, no crosstalk between the Smad2 and Erk signal pathway was found in this process.

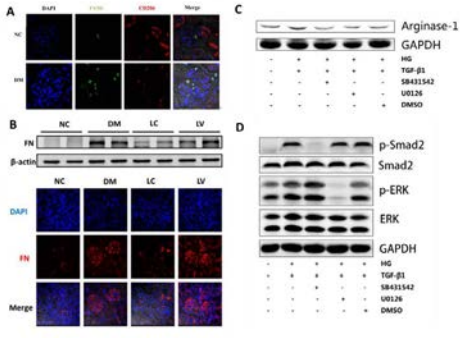

Figure1: A. M2 macrophage emerged in the kidney of diabetic mice after eight weeks of diabetic mellitus with intraperitoneal injection of streptozocin. B：LC (the specific scavenger of macrophages) was used to treat the diabetic mice by intraperitoneal injection (10μl/1g bodyweight) twice one week from the third to the eighth week. As a result, the accumulation of fibronectin were improved in those treated with LC. C: Not only the block of Smad2(with the inhibitor SB431542) but also Erk（with the inhibitor U0126）partially inhibit the transformation of M2 macrophage stimulated by high ambient glucose(30mmol/L D-glucose) and TGF-β1(5ng/ml), however. D:No crosstalk between the Smad2 and Erk signal pathway was found in this process. Abbreviations: NC: normal control group. DM: diabetic mice. FN: fibronectin. LC: Liposome-encapsulated clodronate. LV: Liposome-encapsulated vehicle(PBS). HG: high ambient glucose.

Conclusions: M2 macrophages aggravate the renal fibrosis of diabetic mice, and the Smad2 and Erk signal pathways independently involve in the transformation of M2 phenotype.

TH-PO436

De-Nitrosylation of Laminin 521 in Diabetic Nodular Glomerulosclerosis Alda Tufro, Qi Li, Pablo A. Ortiz-Pineda. *Pediatrics/Nephrology, Yale Univ, New Haven, CT.*

Background: We showed that glomerular basement membrane laminin 521 is nitrosylated in normal glomeruli. Laminin S-nitrosylation, a reversible post-translational modification controlled by nitric oxide availability and by VEGF-A in mouse kidneys and podocytes. Laminin 521 is increased in glomerular nodules observed in experimental diabetic nephropathy (DN) and likely involved in the pathogenesis of nodular glomerulosclerosis. We examined α5 and β2 laminin S-nitrosylation function in podocytes and DN.

Methods: We assessed S-nitrosylation (SNO) of α5-and β2-laminin using dual immunohistochemistry, biotin switch assay and proximity link assay in tissue and cultured cells. Kidneys from normoglycemic and T1D mice with mild DN and advanced DN were compared. SNO-α5-laminin and SNO-β2-laminin, secretion of each laminin chain, and cell migration were evaluated in human podocytes exposed to medium with normal glucose, high glucose, or mannitol.

Results: We determined that α5- and β2-laminin are S-nitrosylated in kidneys from non-diabetic mice and from mice with mild DN, whereas SNO-α5-laminin and SNO-β2-laminin decrease dramatically in advanced DN, inversely correlating with glomerular nodules. Podocytes cultured in normal glucose or mannitol medium express abundant SNO-α5-laminin and SNO-β2-laminin, while podocytes exposed to high glucose showed minimal SNO-α5-laminin and SNO-β2-laminin, as assessed by 3 independent methods. This SNO-α5-laminin and SNO-β2-laminin decrease was associated with several fold increase in α5- and β2-laminin secretion to the medium, which was abolished by nitric oxide (NO) donors. Wound assays showed that podocyte migration is impaired when α5-laminin and β2-laminin is de-nitrosylated by high glucose, and that NO donors rescue this migration defect.

Conclusions: De-nitrosylation of α5-laminin and β2-laminin leads to increased laminin secretion by podocytes, impairs their migration and contributes to development of glomerular nodules in advanced diabetic nephropathy. Nitric oxide donors reverse the podocyte increased α5-laminin and β2-laminin secretion and migration defect induced by high glucose. The inherent S-nitrosylation reversibility implies that this pathogenic mechanism may be a therapeutic target in DN.

TH-PO437

Periostin-Binding DNA Aptamer Attenuates Diabetic Nephropathy-Induced Renal Fibrosis Seonghun Kim,[1] Jae Eun Um,[1] Hae-Ryong Yun,[2] Boyoung Nam,[1] Seung Hyeok Han.[1,2] *[1]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Diabetic nephropathy is the major cause of chronic kidney disease, and is associated with progressive renal fibrosis. Recently, accumulation of periostin, an extracellular matrix, was shown to be implicated with renal fibrosis. Aptamers, a novel oligonucleotide which binds to specific target molecules, have been proved to have higher binding affinity without developing the common side effects of antibodies. In addition, the costs of aptamer productions are cheaper than small molecules making them a promising pharmaceutical candidate. This study was aimed to examine the therapeutic role of periostin-binding DNA aptamers (PA) on renal fibrosis under diabetic conditions.

Methods: *In vitro*, immortalized mouse distal convoluted tubule cells (mDCTs) were exposed to TGF-β1 (5 ng/ml) to induce fibrosis with or without PA (100nmol/l). *In vivo*, C57BL/6 mice were intraperitoneally injected with saline (C group, N=16) or streptozocin (50mg/kg/d) (DM group, N=16). Eight mice from each group were treated with PA (500μg/kg/d). mRNA and protein expressions of periostin, fibronectin, collagentype I (col-I) in mDCTs and mouse kidney were examined by real-time polymerase chain reaction and western blot analysis, respectively. Immunohistochemistry (IHC) was conducted with renal tissues.

Results: *In vitro*, TGF-β1 treatment significantly up-regulated periostin, fibronectin and col-I. PA treatment significantly ameliorated the TGF-β1 induced fibronectin and col-I expressions ($P < 0.05$). *In vivo*, fibronectin and col-I was significantly up-regulated in kidney samples of diabetic mice ($P < 0.05$). IHC staining revealed that the number of fibronectin and col-I (+) cells were significantly higher in diabetic mice ($P < 0.05$). These increases were clearly ameliorated by PA treatment ($P < 0.05$).

Conclusions: These findings suggest that inhibition of periostin using a DNA aptamer could be a potential therapeutic strategy against renal fibrosis in diabetic nephropathy.

TH-PO438

Susceptibility of Renal Fibrosis in Early Diabetes Shuqin Mei,[1,2] Qingqing Wei,[2] Man J. Livingston,[2] Changlin Mei,[1] Zheng Dong.[2] *[1]Shanghai Changzheng Hospital, Shanghai, China; [2]Augusta Univ, Augusta, GA; [3]Augusta Univ, Augusta, GA; [4]Shanghai Changzheng Hospital, Shanghai, China; [5]Augusta Univ, Augusta, GA.*

Background: The diabetic complication in kidneys is traditionally characterized as pathological alterations in glomeruli. However, tubulo-interstitial fibrosis (TIF) frequently occurs earlier than glomerular pathology in diabetic kidney disease (DKD). It is largely unclear how TIF is induced in DKD. We hypothesize in diabetes, renal tubulo-interstitium is predisposed to fibrogenesis and, upon stress, is highly sensitive to the development of TIF. To test this possibility, we examined renal fibrosis induced by unilateral ureteral obstruction (UUO) in diabetic models.

Methods: Two diabetic mouse models were tested: (1) Akita model. C57BL/6-*Ins*^{Akita}/J (Akita) mice were monitored to reach diabetic hyperglycemia at ~6-7 weeks of age and then were subjected to UUO along with matched wild-type littermate mice. The mice were sacrificed 7 and 14 days later for analysis. (2) STZ model. Mice were injected with 50mg/kg body-weight of STZ for 5 consecutive days at the age of 4 weeks. After verification of hyperglycemia 2-3 weeks, the mice were subjected to UUO for 7 or 14 days. For tissue analysis, Masson staining was used to detect collagen deposition and TUNEL staining was used to examine kidney injury. Fibrotic proteins were analyzed by immunoblotting. For in vitro study, mouse tubular BUMPT cells were incubated with high or normal glucose media under hypoxia for 48, 72, and 96h to examine pro-fibrotic changes.

Results: UUO induced higher fibronectin and α-SMA expression after 7and 14 days in Akita and STZ-induced diabetic mice than non-diabetic mice. Consistently, Masson staining showed more collagen deposition in Akita and STZ-induced mice. TUNEL staining also showed more apoptosis after UUO in Akita and STZ-induced mice. In cultured BUMPT cells, hypoxia induced fibronectin accumulation, which was significantly higher in high glucose cells than normal glucose group.

Conclusions: The results suggest that diabetes sensitize kidney tissues and renal tubular cells to fibrogenesis. Hyperglycemia exposure appears to contribute to this sensitivity.

Aerobic Exercise(EXE) Reduce Proteinuria, Fibrosis and Renal Inflammatory Factors, in Diabetic Rats Rodolfo Rosseto Rampaso, Rafael DaSilva Luiz, Kleiton Augusto Santos Silva, Luciana Jorge, Edson Andrade Pessoa, Mario Luis Ribeiro Cesaretti, Nestor Schor. *Nephrology Div, Escola Paulista de Medicina/UNIFESP, São Paulo, Brazil.*

Background: We evaluated the role of EXE in controlling the progression of diabetic nephropathy as proteinuria, fibrosis, inflammatory factors, and thus, its possible renoprotective effects.

Methods: Wistar rats divided into 4 groups (n=8): Sedentary controls (SED), Diabetes+Sedentary (DM-SED), Diabetes+Exercise (DM-EXE) and Exercise+Controls (EXE). DM was induced with streptozotocin, 50mg/kg i.v. EXE was done on treadmill 60min/day/5 days/week/8 weeks. Weekly it was determined the Maximal Exercise Test(MEtest). Fibrosis,Glycemia 24h post training(glycemiapt), creatinine clearance/BW(CrCl/BW), mean arterial pressure(MAP), proteinuria(uProt), renal inflammatory factors were measured.

Results:

	SED	DM-SED	DM-EXE	EXE
uProt(mg/24h)	17±0.9	46±2.1 *#&	18±0.7	16±1.0
IL6(pg/ml)	541±98	993±40*#&	768±74*&	391±22
IL10(pg/ml)	545±86	876±34*#&	654±31*&	453±28
