Iron Deficiency Induces Cystic Chronic Kidney Disease Rongjia Deng,[1] Jacob Stauber,[1] Christian Hinze,[2] Christian Rosenberger,[2] Andong Qiu,[1] Jonathan M. Barasch.[1] *[1]Medicine/Nephrology, Columbia Univ, New York, NY; [2]Nephrology, Max Delbrueck Center for Molecular Medicine, Berlin, Germany.*

Background: Iron deficiency is a threat to embryonic and early postnatal development.

Methods: We investigated dietary and transferrin iron deficiency during embryogenesis and in the immediate postnatal period.

Results: Iron malnutrition produced a severe phenotype with nearly complete loss of the proximal tubule (E15) while TfR1-/- produced only a mild glomerular and tubular insufficiency (E15). However, after birth both iron deficiency and TfR1 -/- produced fulminant phenotypes reflected by severe disruption of the proximal tubule and severe deficits in TALH development. TfR1 -/- (Six2Cre) demonstrated striking hypoplasia, tubular dilation, interstitial fibrosis and widespread cortical cystic transformation with Bardet-Biedel (BBS) or Nephronothesis (NPHP) deficiency. These defects were due to iron deficiency because introduction of NTBI (venofer) normalized the growth abnormalities. In addition, relocating the TfR1 knockout to the TALH (KspCre), relocated cystogenesis to the cortical-medullary junction, confirming a direct effect of defective iron traffic in cystogenesis. RNAseq revealed that both dietary and genetic models induced the HIF-1 pathway. TfR1 -/- resulted in a decrease in kidney Epo and the duodenal iron transporters Dcytb and Dmt1, as well as an increase in Liver Hamp1. In contrast, after small molecule activation of HIF (FG-4592) the hypoplastic cystic phenotype was dramatically rescued, EPO increased in the kidney, HAMP expression decreased in liver, and iron transporters were normalized in the duodenum. Indeed, HIF activation rescued body weight, kidney weight, and serum creatinine.

Conclusions: In sum, while TfR1 was not absolutely essential for embryonic development, kidney TfR1 was critical after birth; TfR1-/- disrupted systemic iron balance and induced kidney cystic hypoplasia. These changes resulted from dysregulation of HIF and altered iron-dependent gene expression. The phenotype was rescued with iron and HIF modulators which increased systemic iron. These results demonstrate an unexpected connection between iron deficiency and cystic CKD and point to two therapeutic interventions for the treatment of cystic CKD.

FR-PO107

A Clinical Perspective of Glomerular Hyperfiltration in Health and Disease Go Kanzaki,[1,2] Victor G. Puelles,[1] Luise A. Cullen-McEwen,[1] Yusuke Okabayashi,[2] Nobuo Tsuboi,[2] Akira Shimizu,[3] Takashi Yokoo,[2] John F. Bertram.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Australia; [2]Dept of Internal Medicine, The Jikei Univ School of Medicine, Japan; [3]Dept of Analytic Human Pathology, Nippon Medical School, Japan.*

Background: It has been proposed that a nephron deficit marks the risk for renal disease. This hypothesis is supported by the development of glomerular hyperfiltration in settings of nephron deficiency. However, the clinical study of human glomerular hyperfiltration is problematic, mostly due to limited access to adequate tissue samples and functional data. This study combines for the first time clinical and morphological data for a comprehensive analysis of glomerular hyperfiltration in human health and disease.

Methods: Autopsy kidneys from 25 Japanese subjects were collected and were divided into three age-matched groups: normotensives (n=9;eGFR>70), hypertensives (n=9;eGFR>60), CKDs (n=7;eGFR<52). Total nephron number (Nglom) and mean glomerular volume (Vglom) were estimated by design-based stereology. Hyperfiltration was assessed by glomerular hypertrophy, single nephron GFR (snGFR;eGFR/Nglom) and the ratio of eGFR per glomerular volume (eGFR/Vglom).

Results: Nglom was significantly lower in hypertensives (423,498±89,716) than in normotensives (666,140±159,755), even though eGFR was similar in the two groups. CKDs (312,277±91,160) had significantly fewer nephrons than hypertensives and normotensives. Nglom was the best morphological predictor of eGFR (R^2;0.46,P<0.001). Glomerular hypertrophy was associated with hypertension and CKD. SnGFR was elevated in hypertensives (P<0.05 vs normotensives), but was similar in normotensives and CKDs. eGFR/Vglom was reduced in hypertensives (P<0.05 vs normotensives) and in the CKDs (P<0.0001 vs hypertensives, P<0.001 vs normotensives).

Conclusions: This study shows for the first time in humans that nephron number predicts eGFR. Physiological markers of glomerular hyperfiltration elevated snGFR were observed in hypertensive subjects. While CKD patients showed glomerular hypertrophy and reduced eGFR/Vglom, snGFR was unaltered. This suggests these glomeruli have already exhausted their physiological capacity to compensate for glomerular loss.

Impact of Enzyme Replacement Therapy on Cardiac and Renal Tissues: A Post-Mortem Case Series Andrew S. Talbot,[1] Kathleen M. Nicholls,[1,3] Moira J. Finlay.[2,3] *[1]Nephrology, Royal Melbourne Hospital, Melbourne, Victoria, Australia; [2]Anatomical Pathology, Royal Melbourne Hospital, Melbourne, Victoria, Australia; [3]Medicine, Univ of Melbourne, Melbourne, Victoria, Australia.*

Background: Fabry Disease an X-linked lysosomal storage disease, caused by deficiency in alpha-galactosidase (aGAL), leads to accumulation of globotriaosylceramide (Gb3) within vascular endothelial cells. Limited long-term pathology on enzyme replacement therapy (ERT) is available. We describe post-mortem findings of 3 patients after ≥ 12 yrs ERT.

Methods: Post-mortem cardiac and renal samples were compared with tissue collected prior to initiation of ERT. Renal function was determined by annual ^{51}Cr-EDTA clearance while cardiac function by echocardiography.

Results: Demographics

	Case 1	Case 2	Case 3
Age Mutation aGAL Level	65yo Male Mis-sense 0.01%	45yo Male Mis-sense Undetectable	68yo Female Nonsense 0.24nmol/ml/mg
ERT (Years)	13	13	12
Renal Stage Proteinuria (g/24hr) GFR Decline (ml/min/1.73m^2/yr)	CKD 4 0.5 1.91	Renal Transplant x 2	CKD 3 2.5 1.77
Diastolic Dysfunction Systolic Function Cardiac Wall Thickness (mm) pre & Post ERT	Moderate Grade 1 14/12 & 10/10	Severe Grade 1 10/12 & 21/17	Moderate Grade 3 14/12 & 14/12
Brain MRI	Basal Ganglia Infarcts White Matter Lesions	Severe Dolichoectasia Cerebellar Infarcts	Basal Ganglia Infarcts White Matter Lesions
Cause of Death	Cardiovascular	Cerebrovascular	Cardiovascular

Renal Histology: Male 1: Biopsies pre-ERT and post-mortem showed similar glomerular sclerosis, podocyte vacuolation and interstitial fibrosis. Male 2: Transplant parenchyma - no vacuolation with moderate renovascular disease. Female: Minimal vacuolation, moderate interstitial fibrosis and hyaline thickening due to renovascular disease. Cardiac Histology: All patients showed hypertrophied cardiomyocytes, intracellular vacuolation and patchy interstitial fibrosis. No glycosphingolipid inclusions in cardiomyocytes on electron microscopy.

Conclusions: Initiation of ERT prior to CKD5 leads to stabilisation of function with renal parenchyma remaining viable. Long-term ERT resulted in clearance of Gb3 from cardiomyocytes but did not prevent cardiac events or diastolic dysfunction.

FR-PO109

Comprehensive Analysis of IgA1 Hinge-Region *O*-Glycoforms in Patients with IgA Nephropathy Kazuo Takahashi,[1] Hisateru Yamaguchi,[1] Yukako Ohyama,[1] Akihiro Kato,[1] Tomohiro Mizuno,[1] Yoshiyuki Hiki,[1] Matthew B. Renfrow,[2] Jan Novak,[2] Yukio Yuzawa.[1] *[1]Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan; [2]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: The serum level of IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans (Gd-IgA1) is elevated in the majority of IgA nephropathy (IgAN) patients. To characterize the involvement of IgA1 in the pathogenesis of IgAN, *O*-glycan microheterogeneity and attachment sites should be analyzed, as each HR has nine potential sites for *O*-glycosylation. Recently, a relative quantitative workflow was developed for the analysis of IgA1 HR *O*-glycoforms, including for identification of attachment sites of *O*-glycans, using high-resolution liquid chromatography-mass spectrometry (LC-MS) and electron-transfer dissociation (ETD) tandem MS. A limitation of this protocol is throughput, as the sites of attachment of Gal-deficient *O*-glycans in all the *O*-glycoforms should be assigned.

Methods: To increase the throughput of the analysis, we developed a sequential enzymatic deglycosylation protocol, which leaves only Gal-deficient *O*-glycans on HR; this workflow was tested to analyze the *O*-glycoforms of serum IgA1 from a patient with IgAN.

Results: After neuraminidase treatment, 13 glycopeptides corresponding to HR variants with 3-6 *O*-glycans attached to the His^{208}-Arg^{245} backbone amino acids were detected. Nine of the 13 glycopeptides possessed up to 3 Gal-deficient *O*-glycans. After sequential enzymatic treatment, only Gal-deficient *O*-glycans remained on HR, and the sites with Gal-deficient *O*-glycan, including structural isomers, were successfully identified based on the amino-acid position of the attached glycans by on-line LC ETD tandem MS. The results show that Gal-deficient *O*-glycan is attached at specific sites. Once the attachment sites of Gal-deficient *O*-glycans are localized by ETD tandem MS, comparison of the isomeric distributions can be easily accomplished in a large number of samples.

Conclusions: Our new workflow using high-resolution LC-MS with ETD tandem MS after removal of galactosylated *O*-glycans is a promising powerful method to identify specific glycoforms and specific sites for Gal-deficient *O*-glycans in IgA1 from patients with IgAN.

FR-PO110

The Levels of Urinary J Chain-Containing IgA-IgG Complexes Are Elevated in Patients with IgA Nephropathy Guanhong Li, Ruitong Gao, Xuemei Li. *Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: IgA nephropathy (IgAN) is characterized by polymeric IgA (pIgA) containing immune complexes deposition in the renal mesangium, inducing kidney injury. Only one previous study has demonstrated that the elevation of urinary IgG anti-IgA autoanbibodies (IgA-IgG) of some patients with IgAN. It is known that J chain is critical in the structure of pIgA, but there has no report about the urinary J chain-containing IgA-IgG complexes (J-IgA-IgG) in patients with IgAN.

Methods: Spot morning urine samples were collected from 10 patients with biopsy-proven IgAN (IgAN group), 11 patients with non-IgA nephropathies (diseases control group) and 33 healthy volunteers (healthy control group). The levels of urinary IgA-IgG and J-IgA-IgG complexes were measured by sandwich enzyme-linked immunosorbent assay (ELISA), and the latter was measured with J chain specific monoclonal antibody generated by our laboratory.

Results: The levels of urinary IgA-IgG and J-IgA-IgG complexes were higher in IgAN group than that in diseases control group (1.55±0.35 vs. 0.76±0.12, *P*=0.0377; 2.54±0.29 vs. 1.82±0.17, *P*=0.0380, respectively) and healthy control group (1.55±0.35 vs.0.35±0.03, *P*< 0.0001; 2.54±0.29 vs. 0.90±0.07, *P*< 0.0001, respectively). We observed that higher levels of urinary IgA-IgG complexes were significantly associated with higher levels of J-IgA-IgG complexes (r=0.92, *P*=0.0001) in patients with IgAN. Both the levels of urinary IgA-IgG and J-IgA-IgG complexes in patients with IgAN were associated positively with serum creatinine (r=0.92, *P*=0.0002; r=0.84, *P*=0.0025, respectively) and negatively with eGFR (r= -0.70, *P*= 0.0251; r= -0.65, *P*=0.0438, respectively), but not significantly associated with 24-hour urine protein (r= 0.62, *P*= 0.0558; r=0.50, *P*=0.1462, respectively).

Conclusions: Our results suggested urinary IgA–IgG and J-IgA–IgG complexes were higher and negatively associated with renal function in patients with IgAN. However, further research with larger sample sizes is needed to identify the role of urinary IgA–IgG and J-IgA–IgG complexes in IgAN.

FR-PO111

Serum BCMA Levels Are Elevated in IgA Nephropathy Karen Molyneux,[2] David Harry John Wimbury,[1] Jonathan Barratt.[1] *[1]Dept of Infection, Inflammation and Immunity, Univ of Leicester, Leicester, Leicestershire, United Kingdom; [2]The John Walls Renal Unit, Leicester General Hospital, Leicester, Leicestershire, United Kingdom.*

Background: IgA nephropathy (IgAN) is a glomerulonephritis characterised by the mesangial deposition of IgA1-containing immune complexes. Two of the key events in the pathogenesis of IgAN are the appearance in the serum of poorly galactosylated IgA1 molecules and IgA and IgG anti-IgA1 autoantibodies directed against the aberrant O-galactosylation. In this study we determined whether levels of serum biomarkers, with particular focus on factors known to be important in B-cell activation, are associated with the development of IgAN and the risk of progressing to ESRD.

Methods: Serum samples from patients with progressive IgAN (a doubling of serum creatinine or ESRD during follow-up), non-progressive (NP) IgAN, (<10% change in serum creatinine over 10 years), membranous nephropathy (MN) and healthy controls were selected from the UK Glomerulonephritis DNA Bank and the concentrations of 49 candidate biomarkers were measured using a bead-based multiplexing immunoassay (Luminex). We analysed the relationship of biomarker concentration with:renal function (eGFR), a diagnosis of IgAN, risk of progression in IgAN, specificity of biomarker changes in IgAN by comparison with matched MN.

Results: There was a clear correlation between the majority of the selected biomarker serum concentrations and eGFR, suggesting that as renal function falls the levels of these biomarkers rise independent of the underlying primary renal disease. With regard to B-cell specific factors; levels of soluble BCMA (sBCMA, TNFRSF17, a receptor for B-cell survival factors BAFF & APRIL) were significantly higher in IgAN and MN compared to healthy subjects, independent of eGFR.

Conclusions: Our results suggest levels of sBCMA are significantly elevated in patients early in the natural history of IgAN (patients with normal renal function) and elevated levels mark out a group of patients at high risk of developing progressive renal disease. Our results highlight the importance of B-cell activation in IgAN and suggest shedding of BCMA by plasma cells may provide a valuable biomarker for B-cell involvement in IgAN.

FR-PO112

VIS649-A Highly Potent Anti-APRIL Antibody for the Treatment of IgA Nephropathy James Myette, Hedy Adari, Gregory Babcock, Ketan Deotale, Karthik Viswanathan, Andrew M. Wollacott. *Visterra, Inc., Cambridge, MA.*

Background: IgA Nephropathy (IgAN) is the most prevalent cause of primary glomerular disease worldwide. There are currently no effective, disease specific therapies for treatment. The cytokine APRIL (A Proliferation Inducing Ligand, TNFSF13) is emerging as a potentially key player in IgAN pathogenesis and disease progression based on a compilation of genetic, biochemical, and clinically relevant data. We report here the discovery and optimization of VIS649, a highly potent, fully humanized anti-APRIL antibody for therapeutic consideration.

Methods: The VIS649 antibody scaffold was identified through epitope-targeted screening of a mouse hybridoma library designed for achieving maximal antagonism of APRIL-receptor interactions. Full humanization of antibody variable regions was successfully achieved using both standard and proprietary computational methods.

Results: The attributes of VIS649 include picomolar APRIL binding affinity and sub-nanomolar receptor blocking activity to both TACI and BCMA *in vitro*. VIS649 likewise demonstrates functional interference of APRIL mediated downstream cellular signaling through the canonical NFkB activation pathway. Further biological characterization of VIS649 *in vitro* demonstrates effective reduction of B cell proliferation and directly relevant inhibition of APRIL-mediated IgA production. Early *in vivo* data indicate effective neutralization of biological activity based on targeted reduction in serum IgA levels with minimal perturbation of overall B and T cell homeostasis indicating a selective immunomodulatory mechanism of action. VIS649 has been successfully engineered as an IgG2 subtype for purposes of clinically mitigating against antibody-dependent exacerbation of complement recruitment in the kidneys of IGAN patients.

Conclusions: APRIL (TNFSF13) represents a logical biological target for the treatment of IgA nephropathy. Toward this end, VIS649, a fully humanized IgG2 based anti-APRIL antibody with high biological potency and low complement activation is currently under pre-clinical development.

MicroRNA-155 Induced T Lymphocyte Subgroup Drifting in IgA Nephropathy Wei Qin, Yi Tang. *Dept of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: This study was performed to explore the relationship between miR-155 in peripheral blood mononuclear cells (PBMCs), T lymphocyte subgroups, T lymphocyte regulators and clinical manifestations of IgAN patients.

Methods: Sixty IgAN patients and 25 healthy controls were included. Expression of miRNAs in PBMCs was determined using microRNA microarray and real-time RT-PCR. T lymphocyte subgroups (Th1, Th2, Treg and Th17), differentiation regulators (c-Maf, STATA-6, GATA-3, SOCS-1 and Fxop3), cytokines (IFN-γ, IL-5, IL-10 and IL-17), serum IgA1 glycosylation level and Cosmc expression level were measured using flow cytometry, qPCR and ELISA. PBMCs from IgAN patients were cultured with miR-155 mimic or inhibitor with LPS in vitro.

Results: Microarray analysis and qPCR suggested that miR-155 level of PBMCs in IgAN patients was significantly lower than healthy controls ($p<0.01$). Expression level of Gata3, SATA-6 and SOCS-1 in IgAN patients were significantly higher, while Foxp3 and Cosmc expression were remarkably lower. Flow cytometry found that peripheral blood Th1 and Treg cells percentages in IgAN patients were significantly lower. However, Th2 and Th17 cells percentages were remarkably higher. ELSIA results indicated that serum Th1 cytokine INF-γ and Treg cytokine IL-10 levels were apparently lower, while Th2 cytokines IL-5 and Th17 cytokine IL-17 were significantly higher in IgAN patients than normal controls. Significant correlations were found between miR-155 levels and Foxp3, Cosmc level, 24hr urine protein amount, urine RBC count, serum IgA concentration and IgA1 dys-glycosylation level. In vitro study, we also found that miR-155 mimic treatment will reverse T lymphocyte drifting and decrease the IgA dys-glycosylation level; while miR-155 inhibitor treatment will aggrevated the T lymphocyte drifting and increase the IgA dys-glycosylation level.

Conclusions: Remarkable lower expression of peripheral lymphocytes miR-155 was observed in IgAN patients, which leads to T lymphocyte subgroup drifting (increase of Th2 and Th17 along with decrease of Th1 and Treg), which inhibits Cosmc gene expression and worsen the aberrant glycosylation of IgA1 molecular in IgAN patients.

T-follicular Like Helper Cells Drive the Proliferation and Expansion of IgA Antibody Secreting Cells in IgA Nephropathy Nicholas J. Steers, Jason Mccutchan, Stacy E. Piva, Drew A. Bradbury, Michael Divecchia, Maddalena Marasa, Ali G. Gharavi. *Columbia Univ, New York, NY.*

Background: Dysregulated IgA1 response is a central defect in the development of IgA nephropathy (IgAN), but it is not clear if the altered IgA1 response is solely attributable to dysregulation of IgA-antibody secreting B-cells (ABS) or whether additional immune cells contribute.

Methods: We studied peripheral B-cells in 8 IgAN patients, 8 healthy controls (HC), 5 lupus nephritis (LN), and 5 CKD controls.

Results: In the steady state, IgAN individuals had an increased number of IgA-ABS (88 per 1000 activated B-cells) in the peripheral blood compared to the HC, LN and CKD controls (20, 58 and 27, per 1000 activated B-cells, respectively), correlating with increased levels of IgA and IgA1 detected in the serum. *In vitro* stimulation with IL-4, IL-6, IL-21 and CD40L demonstrated increased IgA-B cell proliferation of IgAN patients was heavily influenced by IL-21, facilitated through the increased surface expression of IL-21R on non-class switched B-cells compared to the controls. We next asked the question whether this enhanced proliferative capacity was attributable to T-follicular (T_{FH}) like helper cells, a subset of T-cells that secrete IL-21 upon contact with naive B-cells, and have been shown to drive naïve cells into immunoglobulin secreting cells *in vitro*. Co-culturing T_{FH} likecells and naïve B-cells, an enhanced capacity to drive the naïve B-cells to activated B-cells *in vitro* was observed using cells isolated from IgAN patients, resulting in 13.5% of the B-cell population having an activated B-cell phenotype (vs 6.9% of the B-cell population in HC). IgA was detected in the supernatants of the cell co-cultures of IgAN patients (658ng/ml vs 518ng/ml of HC cell co-cultures ($p < 0.05$).

Conclusions: Collectively our data suggest that an altered balance of T_{FH} likecell and B-cell interactions may contribute to increased expansion and proliferation of IgA-ABS in IgAN, leading to greater numbers of IgA-ABS in the peripheral blood in the steady state.

FR-PO115

Cationic Lipids Enhance Autoantigen Production in IgA1-Producing Cells from IgA Nephropathy Patients and Healthy Controls Colin Reily,[1] Koshi Yamada,[3] Dana Rizk,[1] Bruce A. Julian,[1,2] Jan Novak.[1,2] *[1]Medicine, UAB; [2]Microbiology, UAB; [3]UAB; Juntendo Univ Faculty of Medicine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is an autoimmune disease characterized by elevated production of autoantigen, IgA1 with some *O*-glycans deficient in galactose (Gd-IgA1). Increased pro-inflammatory cytokines, such as IL-6, have been shown to increase synthesis of Gd-IgA1, but only in cells from patients with IgAN. Here we show, for the first time, that a cationic lipid can enhance Gd-IgA1 production in IgA1-producing cells of patients with IgAN as well as healthy controls.

Methods: Peripheral blood mononuclear cells were isolated from IgAN patients and healthy controls, EBV immortalized, and IgA1producing cells were subcloned using limiting dilution. IgA1-secreting cells from IgAN patients and healthy controls were stimulated with cationic lipids, and IgA1 production and *O*-glycosylation were assessed.

Results: Cationic lipids were supplemented to the cell-culture medium of a panel of IgA1-producing cells from IgAN patients and healthy controls. This supplementation enhanced production of Gd-IgA1 (HC 3.81 *vs.* HC+Lipid 7.84 U Gd-IgA1, and IgAN 4.32 *vs.* IgAN+Lipid 6.48 U Gd-IgA1) without affecting total IgA1 production. Together, these data for the fist time identified a general mechanism controlling galactosylation of IgA1 *O*-glycans.

Conclusions: This is the first studythat revealed an effect of cationic lipids on glycosylation. Specifically, these lipids reduced galactosylation of IgA1 *O*-glycans without affecting total IgA1 production. Ongoing experiments will identify mechanisms involved. Understanding of the pathways controlling glycosylation in IgA1-producing cells may identify targets for manipulation of IgA1 *O*-glycosylation in patients with IgAN.

FR-PO116

Circulating CD89-IgA Complex Does Not Predict Progression of IgA Nephropathy Ji Min Park, Hyoungnae Kim, Youn Kyung Kee, Jong Hyun Jhee, Min-Uk Cha, Seung Hyeok Han. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Pathogenesis of IgA nephropathy (IgAN) is a multi-step process. CD89 is a soluble receptor and CD89-IgA complex facilitates the formation of immune-complex. However, there is lack of evidence supporting circulating levels of CD89-IgA complex is associated with disease progression. Thus, this study aimed to delineate whether circulating CD89-IgA levels can predict the renal outcome in patients with IgAN.

Methods: A total of 344 patients with biopsy-proven IgAN between 2005 and 2014 were included in this study. Patients with estimated glomerular filtration rate (eGFR) < 30 ml/min/1.73m^2 were excluded from the analysis. Demographic and laboratory data were recruited from the Glomerulonephritis Registry of Yonsei University Health System. Circulating CD89-IgA complex levels were determined by sandwich ELISA method. The study outcome was a 30% decrease of eGFR during the follow-up.

Results: The median value of CD89-IgA complex was 7.20ng/ml (inter-quartile range 4.25 to 12.98). Patients were categorized into 3 groups by tertiles of circulating CD89-IgA complex levels. Circulating CD89-IgA complex levels were not correlated with eGFR at the time of biopsy and did not differ among chronic kidney disease stages. During follow-

up, 23 (34.3%), 25 (37.3%), and 19 (28.4%) patients in the lowest, middle, and highest tertiles reached the study endpoint, respectively (P=0.59). In a multiple Cox model adjusted for confounding factors, circulating CD89-IgA complex levels were not associated with developing a 30% decrease in eGFR [lowest versus middle, HR 0.95, 95% CI 0.44-2.07, P=0.89 and lowest versus highest, HR 1.14, 95% CI 0.49-2.61, P=0.76).

Conclusions: Although CD89-IgA complex mediates formation of immune complex, our findings suggest that its circulating level is not a predictor of adverse renal outcome in IgAN.

FR-PO117

Deficiency of C3a/C5a Receptors Reduce Renal Injury in IgA Nephropathy In Vivo and C3a/C5a Receptors Antagonism Inhibit Mesangial Cells Proliferation In Vitro Guolan Xing, Ying Zhang. *Dept of Nephrology, First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.*

Background: Complement activation has a deep pathogenic influence in IgA nephropathy (IgAN). C3a and C5a,as key pro-inflammatory effectors of complement system, contribute to the development of IgAN. Therefore, C3a, C5a and their receptors are potential therapeutic targets for the disease. This study aimed toinvestigate whether deficiency of C3a/C5a receptors could attenuate renal injury in IgAN mice model, and define the effect of C3a/C5a receptors inhibition on cultured human mesangial cells (HMCs).

Methods: An IgAN mice model induced by Sendai virus (SV) infection was employed on wild type and several knockout mouse strains ($C3aR^{-/-}$ or $C5aR^{-/-}$). Mice were immunized with inactivated SV at gradually increasing dose intranasally for 14 weeks, combined with 6.25×10^8 dose challenge intravenously twice. Urine protein, renal function and renal histologic lesion are assessed. Expression of pro-inflammatory cytokines and chemokines in kidney tissue were detected by immunofluorescence and RT-qPCR. Cultured HMCs were stimulated with 100ug/L IgA. Cell proliferation was measured by MTT assay. Production of cytokines and chemokines in response to C3aR/C5aR antagonists were analyzed by Western blot and RT-qPCR.

Results: In the SV-induced IgAN model, C3aR/C5aR deficient mice had significantly reduced proteinuria than WT mice, but not lower levels of BUN and SCr. C3aR/C5aR deficient mice also showed remarkable lower renal IgA and C3 deposition, less histologic damage and reduced mesangial proliferation compared to the WT mice. Furthermore, both C3aR and C5aR deficiency significantly inhibited the gene expression and protein synthesis of TNF-α, TGF-β, IL-1β, IL-6 and MCP-1, especially C3aR deficiency. *In vitro*, C3aR/C5aR antagonism prevented IgA-induced HMCs proliferation and TNF-α, TGF-β, IL-1β, IL-6, MCP-1 production.

Conclusions: These results demonstrate that deficiency of C3a/C5a receptors reduce renal injury in IgAN mice model, and verify the inhibition of HMCs proliferation by C3a/C5a receptors antagonism *in vitro*. Our findings suggest that pharmaceutical targeting of C3aR/C5aR may have potential in the treatment of IgAN.

FR-PO118

Anti-Symmetric Dimethylarginine Autoantibodies (anti-sDMA) in Systemic Lupus Erythematosus Andrew Z. Wei, Pan Liu, Cybele Ghossein, Jing Jin. *Nephrology/Hypertension, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Systemic lupus erythematosus (SLE) is a complex multi-system autoimmune disease characterized by the loss of tolerance to self-antigens and subsequent production of self-reactive antibodies. The most well-known and clinically-tested class of antibodies are the anti-nuclear antibodies (ANA), which include antibodies against ribonucleoproteins (anti-RNPs) such as the smith proteins (anti-Sm). Glycine-arginine (GR) dipeptide repeats of the Sm protein contain symmetrical dimethylarginines (sDMA), a post-translational modification, which form an antigenic epitope for autoantibodies. The presence of anti-Sm has been associated with an increased risk of kidney involvement due to production of immune complex deposits. The purpose of this ongoing study is to elucidate the potential involvement of arginine methylation of GR repeats in neoantigenic responses of lupus.

Methods: Serum from 31 SLE patients with renal involvement and 6 healthy controls was collected (28 females and 3 males, age = 23-66yrs, median= 42yrs). Through the use of peptide-array technology, we generated an array containing 270 distinct antigen peptides (all 15 amino acids in length) derived from 76 human proteins, and screened SLE patient sera for antibody reactivity towards sDMA and non-modified epitopes. Serum from healthy subjects, antibody standards such as Y12 and SYM10 were used as negative controls.

Results: 17/31 SLE patients demonstrated strong selectivity of sDMA-containing vs. non-methylated epitopes. Anti-sDMA positive serum reacted to a wide range of proteins with low sequence specificity. Selectivity for sDMA epitopes were not seen in heterogeneous healthy controls.

Conclusions: Anti-sDMA that preferentially target sDMA epitopes are seen in a large subset of patients with SLE. These antibodies bind to a wide variety of sDMA-containing epitopes found in human cells and may contribute to the pathogenesis of SLE and development of immune complexes in lupus nephritis. The EBNA-1 protein of the Epstein Barr virus contains a region rich in GR and provides an interesting hypothesis through the generation of anti-sDMA through molecular mimicry.

FR-PO119

Annexin II-Binding Immunoglobulin Level Correlates with Renal Histological Features in Lupus Nephritis Kwok Fan Cheung, Susan Yung, Mel Chau, Desmond Y.H. Yap, Daniel Tak Mao Chan. *Dept of Medicine, The Univ of Hong Kong, Hong Kong.*

Background: Annexin II on the surface of mesangial cells mediates anti-dsDNA antibody binding and downstream inflammatory and fibrotic processes in lupus nephritis. We investigated the relationship between annexin II-binding immunoglobulins and renal histology in lupus nephritis.

Methods: Archived serial serum samples from 28 patients with Class III/IV lupus nephritis were retrieved, and annexin II-binding immunoglobulin level was measured with an in-house ELISA. Glomeruli were isolated from NZBWF1 mice, and annexin II gene and protein expression was investigated by real-time PCR and cytochemical staining respectively. Ultrastructural localization of annexin II was determined by immunogold staining and electron microscopy.

Results: Associations between serum annexin II-binding IgG level, anti-dsDNA level, and disease activity were observed in 42% of lupus nephritis patients. Annexin II-binding IgG level correlated with activity index (r=0.44, p=0.04), leukocyte infiltration score (r=0.52, p=0.01), and karyorrhexis/fibrinoid necrosis score (r=0.66, p=0.002) as stated in the patients' renal biopsy reports, and also the semi-quantitative mesangial electron-dense deposit score (r=0.63, p=0.009). Glomerular annexin II expression increased with active nephritis and decreased with glomerulosclerosis in NZBWF1 mice. Annexin II expression co-localized with electron-dense deposits in the mesangium, along the glomerular basement membrane and around podocytes.

Conclusions: The association between annexin II-binding IgG level and histological features of severe nephritis and the co-localization of annexin II with electron-dense deposits both implicate annexin II in the pathogenesis of lupus nephritis.

Interferon Regulatory Factor 5 Signaling in Myeloid Cells Is Not Required for the Development of Lupus and Lupus Nephritis Abraham Cohen-Bucay, Kei Yasuda, Barry K. Horne, Prachi Shukla, Ian R. Rifkin, Ramon G. Bonegio. *Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Recent genetic studies have associated systemic lupus erythematosus (SLE) and gain-of-function polymorphisms in the interferon regulatory factor 5 (IRF5) gene. In lupus prone mice, IRF5 knockouts develop less active lupus and less severe lupus nephritis (LN). A growing body of literature indicates a critical role for myeloid cells including macrophages, monocytes, and neutrophils in the pathogenesis of autoimmunity. This led us to hypothesize that IRF5 signaling in myeloid cells may play a critical role in the development of autoimmunity and end-organ damage in SLE.

Methods: We generated an IRF5 conditional knockout (cKO) targeting myeloid cells using the Cre-loxP system in lupus-prone FcγRIIb-/- knockout (R2) mice. Littermate R2 (R2-/-.IRF5fl/fl.LysMCre-/-) and R2.IRF5cKO (R2-/-.IRF5fl/fl.LysMCre+/-) mice were evaluated for evidence of SLE by measuring splenomegaly, lymphadenopathy, and antinuclear antibodies (ANA) titers. Albuminuria, renal histopathology and analysis of immune cell infiltrate of the kidney by flow cytometry were used to compare the severity of lupus nephritis.

Results: SLE developed in both the R2 (n=22) and R2.IRF5cKO (n=19) littermates as evidenced by similar degrees of spleen and lymph node enlargement and similar titers of ANA. Analysis of the lupus nephritis revealed that all mice had severe immune complex glomerulonephritis (glomerular score 2.03 vs 2.17, on a scale of 0 to 4), with severe proteinuria (urine protein/creatinine ratio 133.59 ± 63.07 mg/mg vs 32.24 ± 25.04 mg/mg, p=0.18). Analysis of the renal immune cell infiltrate by flow cytometry demonstrated that myeloid and lymphoid cell infiltrated the kidney during the course of SLE however; the infiltrate was similar in the R2.IRF5cKO and R2 control mice.

Conclusions: IRF5 signaling in neutrophils, monocytes and macrophages is not required for the development of SLE or damage to end organs like the kidneys in lupus-prone R2 mice.

Growth Factor Midkine Exacerbates Lupus Nephritis by NFAT-Regulated Activation of T Cells Tomohiro Masuda,[1] Kayaho Maeda,[1] Tomoharu Watanabe,[1] Tomoki Yoshioka,[1] Hiroshi Kojima,[1] Yuka Sato,[1] Tomoki Kosugi,[1] Yukio Yuzawa,[2] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya Univ, Nagoya, Aichi, Japan; [2]Nephrology, Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan.*

Background: Midkine (MK), a heparin-binding growth factor, regulates cell growth, cell survival and migration in nephrogenesis and development. Its pathophysiological roles are diverse, ranging from the occurrence of acute kidney injury to progression of chronic kidney disease, often accompanied by hypertension and diabetes. In autoimmune diseases, however, molecular mechanism involving MK is unknown. In current study, we elucidated the role of MK in the activation and differentiation of T cellsubset in lupus nephritis (LN).

Methods: *In vivo* study, LN was induced in MK-deficient ($Mdk^{-/-}$) or wild-type mice ($Mdk^{+/+}$) with an intraperitoneal injection of pristane.Mice were sacrificed at 6 months later. Serum, urine, kidney and spleen were analyzed. *In vitro* study, we examined the activation of $CD4^+$ splenocytes and differentiation of T cell subset.

Results: *In vivo* study: Glomerular injuries in $Mdk^{+/+}$ mice were severer than those of $Mdk^{-/-}$ mice. $CD68^+$ macrophages and $CD4^+$ T cells infiltration were prominent in glomeruli of $Mdk^{+/+}$ mice, consistent with the profiles of albuminuria and renal function. In proportion to LN disease activity, the frequency of splenic $CD69^+$ T cells and T helper (T_H) 1 cells, but not regulatory T cell (Treg), was augmented in $Mdk^{+/+}$ mice with skewed cytokine production. MK expression was also enhanced in activated $CD4^+$ T cells. *In vitro* study: MK induction in splenocytes was found during the activation of T cells, and supplemental administration of MK protein to $Mdk^{-/-}$ activated T cells induced the activation of the nuclear factor of activated T cells (NFAT) signaling and CD69 expression with a profile similar to that in $Mdk^{+/+}$ activated T cells. In addition, MK selectively regulates population and differentiation into T_H1 cells, which is independent of Treg population.

Conclusions: MK serves an indispensable role in the NFAT-regulated activation of $CD4^+$ T cells and T_H1 cell differentiation, eventually leading to the exacerbation of LN.

FR-PO122

Gene-Environment Interactions Promote Nephritis-Associated Autoimmunity Amy G. Clark,[1,2] Emma Zhao,[1] Anastasiya Birukova,[1] Elizabeth Sarah Buckley,[1,2] Jeffrey Ord,[1,2] Yohannes G. Asfaw,[1] Robert Matthew Tighe,[1,2] Mary H. Foster.[1,2] *[1]Medicine, Duke Univ Med Ctr, Durham, NC; [2]Durham VAMC, Durham, NC.*

Background: Occupational exposure to inhaled crystalline silica dust is clearly associated with autoimmune diseases such as lupus and ANCA-associated vasculitis with glomerulonephritis where autoantibody (autoAb) production is a prominent disease component. A key question is how lung exposure to silica breaks tolerance and unleashes autoreactive B cells and autoAb that destroy kidneys and other organs. We hypothesize that pathogenic B cell dysregulation occurs in ectopic/tertiary lymphoid structures (ELS) that form during relevant environmental exposures in genetically susceptible individuals.

Methods: Wildtype (WT) and autoAb transgenic (Tg) mice of C57BL/6 (B6) and genetically distinct lupus-prone NZB, MRL, and BXSB backgrounds were exposed to inhaled silica or vehicle. After 1-3 months, lung pathology and lymphocyte infiltration were scored using H&E, PAS and immunofluorescent stained sections. AutoAb levels in bronchoalveolar lavage fluid (BALF), supernatants from cultured lung and spleen cells, and serum were assayed by ELISA.

Results: All WT and autoAb Tg+ silica-exposed strains showed extensive lung pathology with B and T cell infiltrates and ELS compared to vehicle controls. The percentage lung area containing ELS following silica exposure varied by strain (WT BXSB>MRL>B6>NZB, p=0.03). Significant increases in autoAb production (anti-DNA and anti-MPO) with silica exposure were observed in WT BALF, lung cell supernatants, and serum, in a strain-dependent manner. In autoAb Tg+ mice, Tg+ B cell counts in lung were significantly higher from silica- vs vehicle-exposed B6 (6.6±1.4 vs 3.0±0.7) and BXSB (35.8±20.0 vs 6.8±2.3) backgrounds (cell #, $x10^3$, mean±SD, $p<0.05$). Tg+ Ig levels in BALF were significantly higher in silica-exposed mice in these strains ($p<0.05$).

Conclusions: In genetically susceptible subjects, pulmonary exposure to silica leads to B and T cell accumulation with ELS formation in lung, enhancing local as well as systemic autoAb production. This data suggests that a gene-environment interaction leading to autoAb production is a potential mechanism promoting nephritogenic autoimmunity.

FR-PO123

Major Glomerular Infiltrating Alternatively Activated Macrophage in Lupus Nephritis and Emigration Dependence on CD11b Sun-Sang J. Sung,[1] Yan Ge,[1] Chao Dai,[1] Hongyang Wang,[1] Jing Yu,[2] Rahul Sharma,[1] Young Hahn,[3] Thu H. Le,[1] Mark D. Okusa,[1] Kline Bolton,[1] Jessica R. Lawler.[1] *[1]Medicine, CIIR, U of Virginia, Charlottesville, VA; [2]Cell Biology, U of Virginia; [3]Microbiology, U of Virginia.*

Background: Despite the general acceptance that glomerulus-infiltrating leukocytes play critical roles in glomerulonephritis (GN), studies on the dynamics of leukocyte emigration into the glomerulus during disease progression and functional attributes of the leukocyte populations are lacking.

Methods: The lupus-prone NZM2328 (NZM) mice developing spontaneous LN with chronic GN (cGN) or anti-GBM-induced LN with acute GN (aGN) were studied. Confocal microscopy were used to identify marker expression. Highly purified glomeruli obtained from magnetic bead trapping were used to prepare single cell suspensions for flow cytometry analysis.

Results: $MHCII^{dim}$ and $F4/80^{dim}$ macrophages expressing high levels of the M2 markers Mac2, PD-L1, MMR, and Mgl1/2, and other macrophage markers CD11b, CD14, and SLAMf9 constituted the largest population of infiltrating leukocytes in NZM mice with cGN, comprising 60% - 80% of total $CD45^+$ cells and their numbers correlated with proteinuria severity. $I\text{-}A^+CD11b^+$ DC-like cells constituted the next largest leukocyte population (10%-20%). PMN and T cells were only about 2% of total leukocytes. Leukocytes in young NZM mice lacking GN have 10 - 30 times fewer infiltrating leukocytes and lower percentages of PMN. In anti-GBM-treated NZM mice, $CD11b^+I\text{-}A^-$ macrophages remained the largest glomerular leukocyte population (50%) whereas PMN increased to 30% of $CD45^+$ cells at the expense of reduced $CD11b^+$ DC numbers (4%). Blocking of CD11b, the predominant marker on both macrophages and PMN with anti-CD11b or anti-ICAM-1 mAb reduced macrophage and PMN infiltration by 80% and 70% respectively, and reduced proteinuria by 95%.

Conclusions: The results showed that in cGN, M2 macrophages are the predominant glomerular infiltrating leukocytes whereas higher contribution of infiltrating PMN and reduced numbers of DC occur in aGN. Infiltration of both macrophages and PMN are heavily dependent on CD11b-ICAM-1 interaction. Controlling macrophage infiltration and function is potentially beneficial in GN treatment.

Macrophage Mediators of Tissue Fibrosis Are Found in Murine Kidneys after Experimental Glomerulonephritis Gaia Muallem.[1,2] *[1]Renal, Hypertension, and Electrolyte Div, Univ of Pennsylvania, Philadelphia, PA; [2]Dept of Pathobiology, Univ of Pennsylvania, Philadelphia, PA.*

Background: Crescentic glomerulonephritis (GN) is an important cause of kidney injury, and immune-mediated damage is thought to be a significant contributor to chronic kidney fibrosis. A transition in macrophage phenotype from classical (M1) to alternative (M2) activation has been associated with tissue fibrosis in other organ systems, and limiting this transition has attenuated fibrotic lung and liver injury in preclinical studies. Understanding whether this pathway contributes to renal fibrosis in GN could have significant implications for monitoring and abrogating disease progression.

Methods: Wild type (WT) C57BL/6 mice were treated with sheep IgG on day 0. Nephrotoxic serum (NTS) or control IgG was then injected intravenously on day 5 to induce immune complex deposition at the glomerular basement membrane. Kidneys were harvested at day 9. Half of the kidney was fixed in formalin for histology and half was preserved in Trizol for qPCR. Paraffin-embedded slides were stained with fluorescent antibodies against the macrophage marker CD68 and the M2 macrophage marker Ym1. qPCR was performed to evaluate for macrophage markers and regulatory cytokines.

Results: Preliminary experiments confirm an influx of M2 macrophages in the glomerulus, as identified by the markers CD68 and Ym1 that occurs as early as 3 days after NTS injection. Furthermore, qPCR analysis of whole kidney tissue reveals an increase in transcripts of the cytokine IL-13, which is produced by M2 macrophages, and of Fizz1 and Ym1, two markers of alternative activation in macrophages.

Conclusions: This work identifies a clear population of M2 macrophages in inflamed kidneys during GN. These macrophages are important mediators of fibrosis in other organs, and their presence suggests that they may drive chronic renal injury after acute immune-mediated disease. Further work will focus on manipulating endogenous regulatory pathways to limit M2 polarization in the kidney after GN. A better understanding of the immune pathways that contribute to renal fibrosis will facilitate the development of therapies to slow or reverse disease progression.

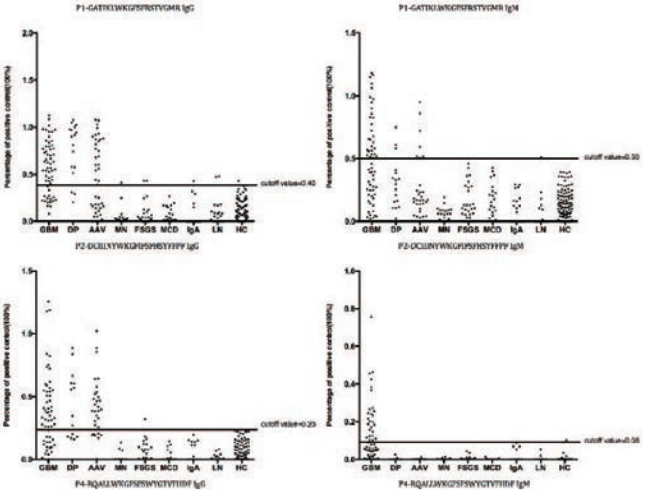
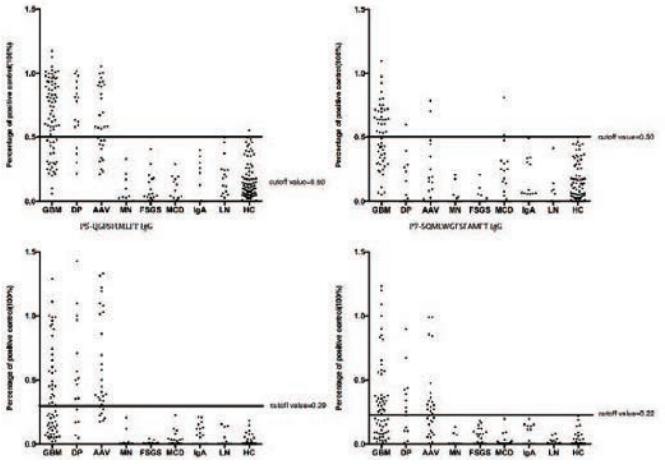
Plasma from Patients with Anti-Glomerular Basement Membrane Disease Could Recognize Microbial Peptides Jian-Nan Li, Xiao-Yu Jia, Zhao Cui, Ming-Hui Zhao. *Renal Devision, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: Infection has long been suspected as one etiology of anti-glomerular basement membrane (GBM) disease, however, the evidence is insufficient and the mechanism is unclear. Molecular mimicry to the T cell and B cell epitopes on α3(IV)NC1 was hypothesized in this study.

Methods: Microbe originated peptides were searched from Uniprot database based on a previously defined critical amino acid motif within α3(IV)NC1, which is $\alpha3_{136-146}$, with five critical amino acid residues, isoleucine137, tryptophan140, glycine142, phenylalanine143 and phenylalanine144. Seven human-infected microbial peptides were identified and were further synthesized. Circulating IgG and IgM antibodies against these peptides were detected using ELISA from plasma of 76 patients with anti-GBM disease.

Results: Four peptides were recognized by both IgG and IgM antibodies, and one peptide was recognized by IgG antibodies only. Peptides from Bacteroides, Saccharomyces cerevisiae, and Bifidobacterium thermophilum possessed the highest recognition frequency with the prevalence of 73.7%, 61.8% and 67.1% for IgG, and 56.6%, 44.7% and 67.1% for IgM, respectively.





Patients with antibodies against these microbial peptides showed more severe kidney injury, including higher serum creatinine and higher percentage of crescents formation. Circulating antibodies against the microbial peptides were also detected from patients with ANCA associated vasculitis with similar clinical associations, but not from patients with idiopathic membranous nephropathy, primary focal segmental glomerular sclerosis, minimal change disease, IgA nephropathy, lupus nephritis, or healthy blood donors.

Conclusions: In summary, antibodies against microbial peptides were identified in plasma of human anti-GBM disease, implying its etiological mechanism through molecular mimicry to the epitopes on α3(IV)NC1.

Pathogenesis of Antimicrobial Peptides LL-37 and CpG-ODN in ANCA Associated Vasculitis Guangqun Xing. *Nephrology Dept, Affiliated Hospital of Qingdao Univ, Qingdao, Shandong, China.*

Background: We hypothesized that AAV patients have ANCA-producing B lymphocytes in the circulation, and that these cells can be triggered and prone to produce ANCA in response to LL-37 and (or) CpG-ODN both of which related to infection.

Methods: 15patients with AAV were enrolled. 16 patients with chronic bronchitis (CB) were selected as disease control groups. 15 cases of healthy people were as healthy control group. PBMC collected from those groups were cultured and stimulated by LL-37and (or) CpG-ODN for 7 days.The IFN-α and ANCA in vitro were measured by ELISA.The serum IFN-α and LL-37 was measured also.

Results: The serum level of IFN-α in AAV group much higher than that in CB group, and that in healthy control group .The serum level of LL-37 in AAV group was much higher than that in CB group, and that in healthy control group .Also the level of IFN-α showed a significant positive relationship with ANCA in AAV group whether in serum or in supernatants of PBMC culture stimulated by LL-37 and (or) CpG-ODN.In AAV patients, the level of IFN-α by supernatant in PBMC culture stimulated by LL-37 and (or) CpG-ODN was higher than that without stimulating factor ($p<0.05$).The supernatant level of IFN-α in cultured PBMC stimulated by LL-37only was lower than that stimulated by CpGA only. But The supernatant level of IFN-α in cultured PBMC stimulated by LL-37only was higher than in that stimulated by CpGB only .The supernatants level of IFN-α in cultured PBMC stimulated by both LL-37 and CpG-ODN was higher than that stimulated by LL-37 or CpG-ODN only. Whether it is stimulated by LL-37 or CpG-ODN or both the level of IFN-α by supernatant in PBMC culture in AAV patients was highest , that in healthy controls was the lowest.Whether stimulated by LL-37 or CPG-ODN ,or both, the levels of ANCA production in vitro in AAV groups were statistically significantly higher than that in CB group and that in healthy control group.

Conclusions: There was higher level of LL-37and IFN-α in the peripheral blood of AAV patients. IFN-α could reach a higher level stimulated by LL-37 and CpG-ODN. AAV patients have ANCA-producing B lymphocytes in the circulation and that these cells can be triggered by infection.

Atypical Glycosylation of the Constant and Variable Domains of Immunoglobulin G from Patients with ANCA-Associated Systemic Vasculitides: Relation to Disease Activity Olivier Lardinois,[1] Leesa Deterding,[2] Caroline J. Poulton,[1] Candace Henderson,[1] Patrick H. Nachman,[1] J. Charles Jennette,[1] Ronald J. Falk.[1] *[1]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [2]Collaborative Mass Spectrometry Group, National Inst of Environmental Health Sciences, Research Triangle Park, NC.*

Background: Anti-neutrophil cytoplasmic autoantibodies (ANCA) directed against myeloperoxidase (MPO) and proteinase 3 (PR3) are considered pathogenic in ANCA-associated vaculitides (AAV). The aim of the present study is to investigate the changes in Fc and Fab glycosylation with disease activity in detail, and examine the association of glycosylation aberrancies with disease parameters in a cohort of AAV patients.

Methods: IgGs were isolated from serum samples from 30 patients with AAV and 23 control subjects. Isolated IgGs were digested with trypsin and the released glycopeptides were analyzed for subclass-specific Fc glycosylation by LC-MS. Fab glycosylation was determined by fluorescence labeling and chromatography of glycans released by PNGase treatment. The hydrazide glycoprotein capture approach and MS were used to determine the exact localization of *N*-glycans on Fc and Fab fragments.

Results: IgG1 Fc galactosylation and sialylation of total IgG purified from plasma was significantly reduced in AAV patients compared to controls. The levels of galactosylated and sialylated glycoforms on Fc portion of total IgG from PR3-ANCA patient significantly increased during disease remission. In contrast, Fc *N*-glycans levels of total IgG from MPO-ANCA patient did not correlate with disease activity. Hydrazide capture and LC-MS/MS analysis identified six *N*-glycosylation sites on Fab fragments of anti-MPO specific IgGs.

Conclusions: Significant differences exist between MPO and PR3-ANCA diseases regarding the changes in amounts and types of glycans on Fc portion of total IgGs with disease activity. A major fraction of anti-MPO specific IgGs isolated from serum samples of MPO ANCA patients harbor extensive glycosylation within the variable domain on the Fab portion. These differences may contribute to significant clinical differences in the disease course, severity, or relapse rate observed between the two diseases.

FR-PO128

Assessment of HLA-DPB1*04:01 and Time to Relapse in an Evenly Divided Cohort of PR3-ANCA and MPO-ANCA Vasculitis Patients Katherine G. Stember,[1] Yichun Hu,[2] Susan L. Hogan,[2] Caroline J. Poulton,[2] Candace Henderson,[2] J. Charles Jennette,[1,2] Ronald J. Falk,[2] Meghan E. Free,[2] Dominic J. Ciavatta.[2,3] *[1]Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [2]UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Genetics, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: GWAS identified HLA-DPB1 as a risk factor for ANCA-associated vasculitis (AAV), specifically for patients with PR3-ANCA. Whether specific HLA-DPB1 alleles predict patient outcome is unclear. One recent study (Arthritis & Rheum. 2016 DOI 10.1002/art.39620) found that carriers of HLA-DPB1*04:01 (DPB4) had a significantly increased risk of relapse compared to non-carriers, regardless of ANCA subtype.

Methods: We sequenced the HLA-DPB1 gene in 203 patients with AAV. Differences in DPB4 genotype (null, heterozygous, or homozygous) between ANCA subtype were analyzed by Fisher's exact test. Kaplan-Meier estimates and log rank test were used to analyze the relapse probability of DPB4 genotypes in all AAV patients and ANCA subtypes alone.

Results: In our cohort the DPB4 allele frequency was 81% and 68% among patients with PR3-ANCA and MPO-ANCA, respectively, compared to 43% among US Caucasians (Allele Frequency Net Database). Patients with PR3-ANCA were more likely to be homozygous for DPB4 compared to patients with MPO-ANCA ($p=0.0012$). In our cohort of 96 PR3-ANCA and 107 MPO-ANCA patients, the risk of relapse was not different based on DPB4 genotype ($p=0.5$). When stratified by ANCA subtype, PR3-ANCA patients showed a trend toward increased risk of relapse in DPB4 heterozygotes and homozygotes compared to non-carriers ($p=0.06$). In contrast, MPO-ANCA showed no difference in risk of relapse, regardless of DPB4 genotype ($p=0.6$).

Conclusions: Contrary to previous work, in our cohort of AAV patients, DPB4 carriers did not have a significantly greater probability of relapse. The difference may be a consequence of 65% MPO-ANCA patients in our cohort compared to 25% in the previous cohort. We conclude that DPB4 carrier status may be informative for PR3-ANCA patients, but is not predictive of relapse in a combined or MPO-ANCA only cohort.

FR-PO129

Circulating Complement Activation Products in MPO and PR3 ANCA Vasculitis Eve Wu, Sonia Brigitte Boyer, Elizabeth Alderman McInnis, Yichun Hu, Susan L. Hogan, Caroline J. Poulton, Peiqi Hu, Hong Xiao, Ronald J. Falk, J. Charles Jennette, Patrick H. Nachman, Donna O. Bunch. *Univ of North Carolina.*

Background: An anti-MPO murine model suggests complement activation is important in ANCA-associated vasculitis (AAV). Correlation between complement activation products and disease activity has also been shown in an MPO-AAV cohort. These observations have not been confirmed in others, and complement activation has not been studied in PR3-AAV. We investigate complement activation in MPO- and PR3-AAV.

Methods: Subjects included 31 active AAV (BVAS>3, 14 MPO, 17 PR3), 36 remission AAV (BVAS=0, 15 MPO, 21 PR3), and 27 age- and gender-matched healthy controls (HC). Plasma samples were obtained on ice in EDTA tubes including no or 100mcg/mL of futhan. Properdin (Hycult) and Bb, C3a, C5a, and sC5b-9 (Quidel) were measured by ELISA. No futhan samples were used for analyses except Bb and sC5b-9, where futhan significantly affected values. Group comparisons were made using Wilcoxon two-sample test. After Bonferroni correction, $p<0.0083$ was considered statistically significant.

Results: In PR3-AAV, Bb, C3a, and sC5b-9 were higher in active disease compared to HC (Table, median values). Bb and C3a were higher in remission compared to HC. C3a in remission was lower than in active disease, but Bb did not differ by disease state. C5a was not different. In MPO-AAV, C3a, C5a, and sC5b-9 were higher in active disease compared to HC. Bb and C3a were higher in remission compared to HC, but did not differ from active disease. There was no difference in properdin among groups.

	HC	Active PR3	Remission PR3	Active MPO	Remission MPO
Bb(mcg/mL)	0.58	0.74[A]	0.73[A]	0.63	0.69[A]
C3a(ng/mL)	32.84	84.99[A,B]	41.05[A]	68.18[A]	80.89[A]
C5a(ng/mL)	6.47	8.24	7.74	12.36[A,B]	8.21
sC5b-9(ng/mL)	114.46	194.60[A,B]	115.98	154.21[A]	141.41
[A]Significant difference from HC					
[B]Significant difference from remission					

Conclusions: Complement activation occurs in MPO- and PR3-AAV. The complement activation profile differs by ANCA serotype and disease activity. We are confirming results with larger sample size. Complement's role in AAV pathogenesis and disease monitoring warrants more study.

FR-PO130

The Role of Myeloperoxidase as a Critical Mediator of Damage in Diverse Forms of Crescentic Glomerulonephritis Marilina Antonelou, Alan D. Salama. *Centre for Nephrology, Univ College London.*

Background: Myeloperoxidase(MPO) is a heme-containing peroxidase stored in neutrophils and monocytes. It is a key component of innate immune defense, a major autoantigen in ANCA associated vasculitis but also a potential mediator of tissue damage in renal diseases that can lead to crescentic glomerulonephritis(CGN).

Methods: We examined the MPO deposition in renal biopsies of patients with various forms of glomerulonephritis(GN). Clinical and laboratory data were obtained from hospital records and pathology archives. Sections were stained for MPO and a neutrophil marker, CD15. Extra- and intracellular MPO deposition was quantified using Image J analysis software and expressed as a percentage of the total biopsy area. Intracellular MPO was defined as MPO co-expressed with CD15, while extracellular MPO was independent of CD15 staining.

Results: Immunohistochemistry was performed on 14 biopsies from patients with first presentation of glomerulonephritis: 10 with pauci-immune GN, (5 MPO-ANCA, 3 PR3-ANCA, 2 ANCA-negative), 2 anti-GBM disease and 1 post-infectious GN. The median(IQR) age was 57(30-78) years. Nine (64.3%) patients were male. The median number of glomeruli on each biopsy was 16(9-34). We demonstrated intra- and extracellular MPO staining, irrespective of MPO-ANCA positivity.[figure1] The median urine protein creatinine ratio(uPCR) was 257(10-1747) mg/mmol and serum creatinine (sCr) 169(87-694) µmol/L. There was a positive correlation between total MPO deposition and disease severity as defined by uPCR (Spearman's r=0.55,p=0.44) and sCr (Spearman's r 0.55, p=0.04).

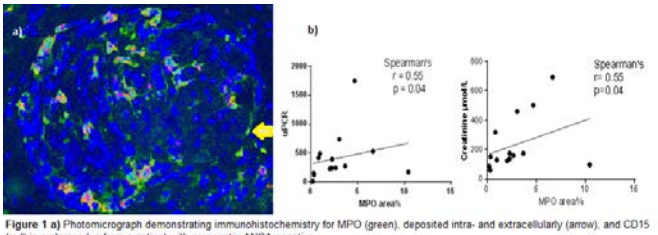

Figure 1 a) Photomicrograph demonstrating immunohistochemistry for MPO (green), deposited intra- and extracellularly (arrow), and CD15 (red) in a glomerulus from a patient with crescentic ANCA negative glomerulonephritis (x630) (DAPI nuclear stain blue), **b)** correlation between MPO deposition and disease severity expressed as proteinuria (uPCR) and serum creatinine (µmol/L).

Conclusions: We have shown that MPO can be detected both intra- and extracellularly in inflamed glomeruli from patients with various forms of CGN. This suggests the role of MPO as a critical mediator of tissue injury, not only as a key autoantigen in MPO-ANCA disease but as a generalised phenomenon in all forms of CGN.

FR-PO131

Granzyme B Producing B-Cells Have Immunoregulatory Function and Are Diminished in Patients with ANCA-Vasculitis Benjamin Wilde,[1] Zhu Jiqiao,[1] Sebastian Dolff,[1,2] Oliver Witzke.[1,2] *[1]Dept of Nephrology, Univ Duisburg-Essen, Univ Hospital Essen, Essen, Germany; [2]Dept of Infectious Diseases, Univ Duisburg-Essen, Univ Hospital Essen, Essen, Germany; [3]Immunology, Maastricht Univ, Maastricht, Netherlands.*

Background: Regulatory B-cells **(**Breg) have recently been identified as a cell population with immunoregulatory capacity and play a role in autoimmunity. Breg suppress pro-inflammatory T-cell responses. The exact mechanisms of suppression are unknown.The aim of this study was to investigate mechanisms of Breg-mediated immunoregulation.Thus, the immunoregulatory properties of Granzyme-B-secreting B-cells were further studied and also characterized in patients with ANCA-vasculitis (AAV).

Methods: 19 patients with inactive AAV were recruited and PBMC were isolated from peripheral blood. B-cells and peripheral blood mononuclear cells (PBMC) from 20 healthy blood donors (HC) were isolated. Purified B-cells/PBMC were stimulated with CpG or IgG+IgM or CD40L in presence of varying cytokines. After 24-72 hours of culture,B-cells/PBMC were analyzed for IL-10 and granzyme B (GrB) expression.

Results: In HC, CpG or IgG+IgM or CD40L stimulation without additional cytokines induced IL-10 in B-cells. Under these conditions, IL-10^{pos}Breg and IL-10^{neg}B-cells did not produce GrB. In contrast, CpG or IgG+IgM or CD40L stimulation in presence of IL-2/IL-21 induced an additional, separate GrB^{pos}IL-10^{neg}B-cell subset. GrB^{pos}B-cells were able to suppress anti-CD3-induced T-cell proliferation. In patients with inactive AAV, B-cells showed a diminished production of GrB upon IgG+IgM/CD40L stimulation in presence of IL-21 (AAV vs. HC; IgG+IgM: 21.1±17.8% vs. 29.4±15.2%,p=0.0427; CD40L: 3.4±2.6% vs. 6.5±3.8%,p=0.0111).

Conclusions: Depending on the cytokine environment, a separate GrB producing B-cell population can be induced. GrB confers cytotoxic capacity to B-cells and allows suppression of T-cells. Thus, GrB^{pos} B-cells can be regarded as an additional Breg subpopulation. This GrB^{pos} B-cell-population is diminished in patients with ANCA-vasculitis.

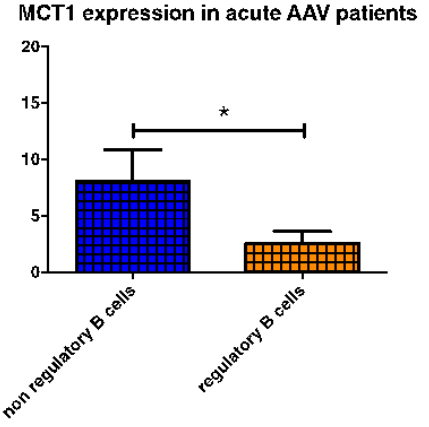
Investigating the Role of MCT Pathway in ANCA Associated Vasculitis Fernanda Florez-Barros,[1] Graham Paul Belfield,[2] Alan D. Salama.[1] *[1]Centre for Nephrology, UCL Medical School, Royal Free Hospital, Univ College London, London, United Kingdom; [2]Respiratory, Inflamation, Autoimmunity, iMed, AstraZeneca, Sweden.*

Background: Monocarboxylate transporters (MCT) are critical for exporting lactate from actively proliferating cells and if inhibited lead to an intracellular accumulation of lactate and cell death. MCT1 inhibitors are currently in clinical oncology trials, but there is only limited knowledge of their role in the context of kidney inflammation and autoimmune disease. The aim of this study was to investigate MCT1 inhibition in vasculitis and glomerulonephritis.

Methods: a)*In vitro* experiments with samples from acute and remission ANCA vasculitis patients and healthy controls. We studied MCT1&4 expression in B and T cells, and also the effect of MCT1 inhibition on cytokine production and changes in B and T subsets. b)*In vivo* experiments using the MCT1 inhibitor in the nephrotoxic nephritis model, evaluating the potential benefit on different parameters of renal function.

Results: a)There was a significantly lower expression of MCT1 in regulatory B cells compared with non-regulatory B cell subsets in patients with acute disease ($p<0.05$).



b)We found a decrease in IL17 production, both in patients and healthy controls. c)MCT1 inhibitor was not toxic to the mice over a week of treatment. We found an improvement in renal function associated with a benefit on tubulointerstitial damage and a decrease in the humoral response.

Conclusions: The differential expression of MCT1 in B cell subsets, suggests that its inhibition may produce a favorable immune regulatory profile. A non-significant reduction in IL-17 production needs further investigation. On-going research will determine the effect of MCT1 inhibition on antigen-specific and non-specific T and B cell activation. Together, these preliminary data suggest MCT1 may be a useful adjunctive immunotherapy in inflammatory renal disease.

FR-PO133

Annexin A1 Plays a Protective Role in Myeloperoxidase Anti-Neutrophil Cytoplasmic Antibody Associated Glomerulonephritis Takeshi Fujita,[1] Poh-Yi Gan,[2] A. Richard Kitching,[3] Stephen R. Holdsworth.[3] *[1]Nephrology, Hirosaki Univ, Hirosaki, Aomori, Japan; [2]Dept of Medicine, Monash Univ, Melbourne, Victoria, Australia; [3]Dept of Nephrology, Monash Univ, Melbourne, Victoria, Australia.*

Background: Myeloperoxidase-ANCA associated glomerulonephritis (MPO-ANCA GN) results from autoimmunity to MPO. To date, corticosteroids are still first line therapy despite their adverse effects. Annexin A1 (AnxA1) is an endogenous anti-inflammatory protein ubiquitously expressed by glomerular cells and significantly overexpressed in inflammatory diseases. This study aimed to assess the role of AnxA1 and its importance in immunomodulating this disease model.

Methods: We compared the development of anti-MPO autoimmunity and the extent of induced GN in C57BL/6 (WT, n=8) and AnxA1$^{-/-}$ (n=7) mice developing experimental MPO-ANCA GN.MPO autoimmunity was induced by immunizing mice with MPO in Freund's adjuvant and GN triggered using subnephritogenic dose of anti-glomerular basement membrane globulin.

Results: AnxA1 deficiency significantly augments MPO-ANCA GN. AnxA1$^{-/-}$ mice developed more severe functional renal injury as measured by urinary albumin/creatinine ratio (2±0.5 vs 5±1, P<0.01) and structural glomerular damage (glomerular segmental necrosis; 21±2 vs 60±3%, P<0.0001), compared to WT mice. Additionally, AnxA1$^{-/-}$ mice had significantly increased infiltration of glomerular macrophages (0.2±0.05 vs 0.5±0.07 cells/glomerular cross section [c/gcs], P<0.01) and neutrophils (0.4±0.2 vs 0.8±0.2 c/gcs, P<0.05) compared to WT mice. To determine the role of AnxA1 in the development of systemic MPO-ANCA GN, spleens from WT and AnxA1$^{-/-}$ mice with induced MPO-ANCA GN were assessed. AnxA1$^{-/-}$ mice had increased numbers of activated splenic CD4+ T cells (CD4+CD44+; 26±2 vs 34±2%, P<0.05 and CD4+CD69+; 27±4 vs 33±1%, P<0.05) and CD8+ T cells (CD8+CD44+; 20±0.5 vs 30±1, P<0.0001 and CD8+CD69+; 13±2 vs 20±1, P<0.05) compared to WT mice.

Conclusions: This study highlights the importance of Annexin A1 in modulating the extent of MPO-ANCA GN and deficiency in Annexin A1 increases the severity of GN.

Deoxyribonuclease 1 Treatment Attenuates Neutrophil Extracellular Trap Formation, Leukocyte Infiltration and Inflammation in Experimental Anti-Myeloperoxidase Glomerulonephritis Kim M. O'Sullivan,[1] Poh-Yi Gan,[1] A. Richard Kitching,[1,2] Stephen R. Holdsworth.[1,2] *[1]Centre for Inflammatory Diseases, Dept of Medicine, Monash Univ, Clayton, Australia; [2]Dept of Nephrology, Monash Health, Clayton, Australia.*

Background: Accumulating evidence suggests that a dysregulation of neutrophil extracellular trap (NETs) could be associated with the pathogenesis of anti-neutrophil cytoplasmic antibody (ANCA) vasculitis. This study investigates the contribution of NETs in the pathogenesis of experimental anti-myeloperoxidase ANCA associated glomerulonephritis (MPO-ANCA GN), and investigates the therapeutic possibility of deoxyribonuclease 1 (DNase1) to disrupt NET formation *in vivo*.

Methods: Experimental MPO-ANCA GN was induced using a standard protocol, by MPO immunisation and glomerulonephritis triggered using a subnephritogenic dose of anti-glomerular basement membrane globulin. Twice daily intravenous DNase 1 (10mg/kg, n=10 or saline control, n=9) was administered to disrupt NET formation after establishment of MPO autoimmunity until termination of the experiment.

Results: NET accumulation identified by co-localisation of extracellular DNA, citrullinated histone 3 (H3Cit), protein arginine deiminase 4 (PAD4), and MPO, was prominent in glomeruli of mice receiving the saline control (38±5.6%) compared to DNase 1 treated mice (2.5%±1.5%, P<0.0001). Functional kidney injury assessed by proteinuria was significantly reduced (24 hour albuminuria 1650±515.7µg in controls vs 368.7±166µg, P<0.05). Histological assessment of kidneys demonstrated prominent segmental necrosis in the saline treated group (38.5±1.5%) versus a reduction in the treated group (13.2 ±1.9%, P<0.05). Leukocyte infiltration was attenuated in the DNase 1 treated group with CD4 and CD8 T Cells, macrophages and neutrophils significantly reduced (all, P<0.05). MPO induced Delayed Type Hypersensitivity assessed by footpad swelling was significantly reduced in the DNase 1 treated group (P<0.003) as was glomerular fibrin deposition (P<0.05).

Conclusions: DNase 1 successfully attenuates *in vivo* formation of NET formation in experimental MPO-ANCA GN, and reduces functional kidney injury, glomerular pathology and inflammation.

FR-PO135

Enhancing Immunoregulation in Anti-Myeloperoxidase Glomerulonephritis by Human Amniotic Epithelial Stem Cells Andrea Savina Godfrey, Poh-Yi Gan, A. Richard Kitching, Stephen R. Holdsworth. *Centre for Inflammatory Diseases, Monash Univ, Clayton, VIC, Australia.*

Background: Human amniotic epithelial stem cells (hAECs) isolated from the placenta retain their stem cell like anti-inflammatory and low antigenicity properties, making them an attractive stem cell based therapeutic. As their use in anti- myeloperoxidase glomerulonephritis (anti-MPO GN) has not been explored, we sought to determine whether hAECs can attenuate MPO-ANCA GN by enhancing immunoregulation.

Methods: We compared disease between C57BL/6 (WT) mice receiving either hAECs or saline. Anti-MPO autoimmunity was induced by MPOimmunisations and GN triggered using a low subnephritogenic dose of anti-glomerular basement membrane globulin Ig.

Results: *In vitro* co-cultures of MPO-specific effector splenocytes and hAECs showed significant suppression of MPO-specific T cell recall responses (2.7±0.6 vs 7.5±0.8% bromodeoxyuridine^{+}CD4^{+} cells, P<0.01). *In vivo*, when used as a preventative, hAECs attenuated MPO-specific dermal delayed-type hypersensitivity (DTH; 0.1±0.03 vs 0.5±0.Δmm, P<0.05), while enhancing proliferation of foxp3^{+}CD25^{+} regulatory T cells (1.20±0.09 vs 0.84±0.13%, p<0.05). Increased IL-10 production of CD4+ cells (0.05±0.01 vs 0.26±0.09% p<0.05) and intracellular expression of indoleamine 2,3 dioxygenase^{+} (0.027±0.004 vs 0.28±0.08%, P<0.05) indicate an immunomodulatory phenotype. Therapeutic administration of hAECs attenuated the development of glomerulonephritis (segmental necrosis: 15.6±2.2 vs 40.6±2.2%, p<0.05) while enhancing CD4+ TGFβ^{+} producing cells (1.35±0.3 vs 0.46±0.07% p<0.05) and reducing anti-MPO specific CD4^{+} IL-17A^{+} cells (1.1±0.3 vs 1.9±0.21% p<0.05). hAECs reduced infiltrating glomerular leukocytes (macrophages;0.2±0.04 vs 0.4±0.06 cells/glomerular cross section [c/gcs], p<0.05, CD4+ cells (0.3±0.03 vs 0.4±0.05 c/gcs, p<0.05 and neutrophils;0.2±0.03 vs 0.4±0.03 c/gcs, p<0.01) and systemic anti-MPO autoimmunity (DTH: 0.01±0.01 vs 0.4±0.06Δmm, p<0.05).

Conclusions: hAECs successfully inhibit MPO-specific autoimmunity and glomerulonephritis by enhancing immunoregulation. These findings may be relevant in developing better and more targeted therapies for patients with MPO-ANCA glomerulonephritis.

IL-10 Receptor Signaling Empowers Tregs to Control Th17 Responses and Protects from GN Paul Diefenhardt,[1] Anna Nosko,[1] Malte A. Kluger,[1] Claudia Wegscheid,[2] Yasushi Kobayashi,[3] Gisa Tiegs,[2] Richard A. Flavell,[3] Rolf A. Stahl,[1] Oliver M. Steinmetz.[1] *[1]III. Medical Clinic, Univ Hospital Hamburg Eppendorf, Germany; [2]Experimental Immunology and Hepatology, Univ Hospital Hamburg Eppendorf, Germany; [3]Dept of Immunobiology, Yale Univ School of Medicine.*

Background: Th17 cells are central pathogenic mediators of glomerulonephritis (GN). It was recently proposed that IL-10 Receptor (IL-10R) signaling enables Tregs to suppress Th17 responses. Since, little is known about this pathway in inflammatory diseases, we studied the IL-10R function on Tregs in crescentic GN.

Methods: Specific IL-10R deletion was achieved using Foxp3Cre and CD4CrexIL-10Rfl/fl mice and nephrotoxic nephritis (NTN) was analyzed. Treg in vivo and in vitro functions were assessed. IL-10 effects on Th17 immunity were analyzed by competitive cell transfer into Rag1-/- mice.

Results: Naïve Foxp3Cre x IL-10Rfl/fl mice showed spontaneously overshooting Th17 immunity and enhanced Th17 inflammation after induction of NTN. In line, NTN was aggravated in terms of renal function, histology and inflammatory cell infiltration. Analyses of Tregs revealed unchanged numbers and percentages. In particular, expression of Th17 type chemokine receptor CCR6 was maintained on IL-10R-/- Tregs, indicating mechanisms for control of Th17 immunity, different from those of Stat3+ Treg17 cells. Instead, we found reduced suppressive capacity and selective impairment of IL-10 secretion by IL-10R-/- Tregs. In order to assess, whether reduced IL-10 production might be causative for the hyper Th17 phenotype, we co-transferred splenocytes from CD45.2 CD4Cre x IL-10Rfl/fl mice together with IL-10R intact CD45.1 splenocytes into Rag1-/- recipients and induced NTN. Confirming a crucial role for IL-10 in controlling Th17 responses, Th17 cells among IL-10R deficient T cells massively outcompeted those among IL-10R intact wild type T cells.

Conclusions: Our data indicate that IL-10R signaling enables Tregs to control Type17 immunity. As one mechanism, we hypothesize a feed forward loop, whereby IL-10R signalling enhances IL-10 secretion by Tregs. IL-10 in turn suppresses Th17 responses, protects from crescentic GN and thus represents a promising therapeutic target.

IL-17C/IL-17RE Axis Drives Renal TH17 Responses in Glomerulonephritis Sonja Krohn, Jasper Nies, Jan-Hendrik Riedel, Anna Kaffke, Anett Peters, Alina Borchers, Hans-Joachim Paust, Rolf A. Stahl, Ulf Panzer. *III. Medizinische Klinik, Univ Hamburg-Eppendorf, Germany.*

Background: The T_H17 effector cytokines, IL-17A and IL-17F have been shown to play a central role in the pathogenesis of crescentic glomerulonephritis. However the importance and function of other IL-17 family cytokines in immune responses and inflammatory diseases have not been studied so far. IL-17C acts via the activation of the IL-17RA/RE receptor complex. The role of the IL-17C/IL-17RE axis in autoimmune diseases is largely unknown. Thus the goal of this study is to elucidate the role of the IL-17C/IL-17RE axis in the inflamed kidney.

Methods: Using a mouse model of experimental crescentic GN (nephrotoxic nephritis) we studied the IL-17C mRNA expression level in the inflamed kidney. Studies using IL-17C- and IL-17RE-gene-deficient mice as well as adoptive transfer experiments into Rag1$^{-/-}$ mice were performed to study the role of the IL-17C/IL-17RE axis in renal tissue injury.

Results: Here we demonstrate an increased renal IL-17C mRNA expression level in the early course of experimental GN. In studies using IL-17C- and IL-17RE-gene-deficient mice we demonstrated that these mice developed significantly less severe disease with respect to proteinuria, renal function and histological injury, which was associated with a reduced T_H17 response. Moreover adoptive transfer experiments in Rag1$^{-/-}$ mice were performed to study the intrinsic effect of IL-17RE on CD4^{+} T cells. These studies demonstrated that CD4^{+} T cells expressing IL-17RE might play a role in driving nephrologic T_H17-cell responses in renal autoimmunity.

Conclusions: These findings indicate a specific function of the IL-17C/IL-17RE axis in the development of renal tissue injury in experimental GN and might provide the basis for a better targeting of the T_H17 pathway in crescentic GN.

FR-PO138

Inhibition of Protein Kinase C-α Restores Mitochondrial Disfunction in Kidney Endothelial Cells Nino Kvirkvelia,[1] Maggie McMenamin,[1] Marie Warren,[2] Raghavan Raju,[2] Michael P. Madaio.[1] *[1]Medicine, Augusta Univ, Augusta, GA; [2]Biological and Radiological Technology, Augusta Univ, Augusta, GA.*

Background: We have shown that glomerular targeted PKC-α inhibition in nephrotoxic nephritis (NTN) limits inflammation and enhances recovery. We aimed to understand the underlying mechanism and identify candidate proteins that were differentially affected.

Methods: Using quantitative mass spectrometry, we analyzed proteomes from mice cortexes from the following groups: 1) controls, 2) NTN, 3) NTN + PKC-α inhibitor Ro-32-0432 given i.p. after induction of nephritis on day 2, and 4) NTN + PKC-α inhibitor conjugated to the human mAb F1.1, directed against α3(IV) collagen. Mitochondrial function was investigated by measuring mitochondrial respiration (assessed as OCR), and glycolytic lactic acid production, (assessed as ECAR) in cultured kidney endothelial cells.

Results: Combined analysis of microdissected cortexes identified total of 4187 proteins in all four samples. Functional protein groups most affected by NTN were mitochondrial proteins associated with respiratory processes, such as ATP synthase, Cytochrome b-c1 complex, NADH dehydrogenase, Superoxide dismutase, which were down regulated in NTN mice (fold changes compared to the same protein levels found in healthy mice were 0.52±0.15), while their expression was restored with PKC-α inhibition (both systemic and glomerular specific, with fold changes 0.90±0.14, p≤1.054E-14), suggesting a role for proteins that regulate oxidative phosphorylation. In cultured kidney endothelial cells, NTS reduced basal oxygen consumption rates (OCR) from 225 pmol/min to 185 pmol/min and increased ECAR from 42 to 62 mpH/min. The PKC-α inhibitor (at 10nM and 50nM) normalized NTS mediated changes in OCR and ECAR levels.

Conclusions: The results suggest that PKC-α is an important regulator of antibody mediated glomerulonephritis and that targeted inhibition of this enzyme protects the kidneys from the damage associated with severe inflammation by restoring oxidative phosphorylation at the glomerular cell level. This has therapeutic implications for treatment of human disease.

Loss of DNA Methylation Triggers Transcription of Silenced Laminin Genes in Aging Kidneys Oleg N. Denisenko, Karol Bomsztyk. *Medicine, Univ of Washington, Seattle, WA.*

Background: Aging kidney is associated with aberrant gene expression of extracellular matrix components that leads to gradual structural changes and progressive decrease in glomerular filtration rates. We examined contribution of epigenetic changes to dysregulation of laminin genes in aging rat kidneys.

Methods: RT qPCR was used to examine renal expression of all 11 laminin genes in kidneys from 4, 24 and 28 months old (mo) F344 rats; and from 4, and 30 mo FBN-F1 hybrid rats. Chromatin immuno-precipitation (ChIP) and DNA methylation (MeDIP) assays were used to assess renal histone and DNA modifications, respectively.

Results: While no changes were detected in the abundant laminin transcripts Lama2, Lamb1, Lamb2, Lamc1, silenced genes Lama3, Lamb3, and Lamc2 were transcriptionally upregulated in old animals ($p<0.05$). ChIP and MeDIP analyses revealed reduction in the density of silencing marks H3K27m3 and DNA methylation (5mC) at Lamc2 gene in old kidneys. Loss of these epigenetic marks at Lamc2 gene was associated with no detectable global changes in the levels of these marks in old kidneys by Western blot analysis of histones and dot blot analysis of DNA. Mechanistic studies in renal cell culture revealed no effect of H3K27m3 loss (by Ezh2 inhibitor) on Lama3, Lamb3, Lamc2 expression, whereas treatment with DNA methylation inhibitor 2'-deoxy-5-azacytidine was sufficient to upregulate these genes *in vitro*.

Conclusions: We found that three laminin genes normally silenced in young kidney, Lama3/Lamb3/Lamc2 (components of Laminin 5), are de-repressed in old kidney. Our results suggest that loss of DNA methylation at these genes re-activates their expression during aging *in vivo*, and define DNA methylation system as a potential target for therapeutic interventions. These studies were supported by grants from Nathan Shock Center of Excellence in the Basic Biology of Aging, University of Washington, and NIH RO1 DK094934 (OD), and R01 DK083310, R37 DK45978 (KB).

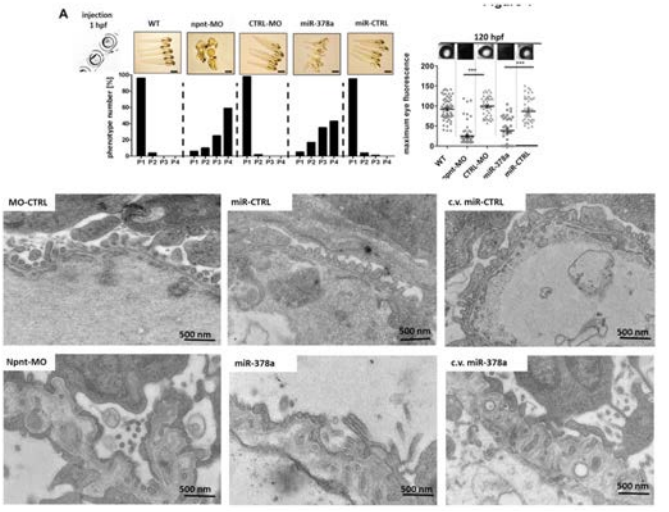
Podocytes Regulate Expression of Glomerular Basement Membrane Protein Nephronectin via miR-378a in Glomerular Diseases Janina Müller-Deile,[1] Meei-Hua Lin,[3] Jenny C. Nystrom,[2] Jeffrey H. Miner,[3] Johan Lorenzen,[1] Thomas Thum,[4] Mario Schiffer.[1] *[1]Dept of Medicine/Nephrology, Hannover Medical School, Hannover, Germany; [2]Dept of Physiology and Dept of Nephrology Sahlgrenska Academy, Washington Univ School of Medicine, Univ of Gothenburg, Gothenburg, Sweden; [3]Div of Nephrology, Washington Univ School of Medicine, St. Louis.*

Background: MicroRNAs (miRs) play an important role in gene regulation and therefore seem to be promising candidates involved in glomerular diseases.

Methods: We used the zebrafish and mice model to investigate the role of miR-378a in glomerular diseases.

Results: We identified miR-378a, as specifically increased in urine samples of patients with nephrotic primary membranous glomerulonephropathy, focal segmental glomerulosclerosis and minimal change disease. Nephronectin is a predicted target of miR-378a, which is predominantly located in the glomerular basement membrane (GBM). In patients, glomerular miR-378a expression was increased and glomerular nephronectin levels were reduced in focal segmental glomerulosclerosis and membranous glomerulonephropathy. In our zebrafish model, nephronectin knockdown by morpholino or miR-378a overexpression caused edema, proteinuria and structural impairments of the glomerular filtration barrier with podocyte effacement and widening of the lamina rara interna of the GBM.



In mice pharmacological overexpression of miR-378a confirmed the phenotype with increased levels of albuminuria, podocyte effacement and altered expression of GBM proteins.

Conclusions: In summary, we demonstrate that miR-378a is an important regulator of proteinuria development in humans, mice and zebrafish. It exerts its function through regulation of its target nephronectin. MiR-378a controlled nephronectin expression is a novel mechanism for proteinuria development in active glomerular diseases in patients.

FR-PO141

Podocyte Specific ZHX2 Overexpression Worsens Focal Segmental Glomerulosclerosis and Improves Minimal Change Disease Maria Del Nogal Avila, Hector Donoro Blazquez, Camille E. Mace, Caroline B. Marshall, Lionel C. Clement, Sumant S. Chugh. *Div of Nephrology, Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Zinc fingers and homeoboxes (ZHX) transcriptional factor family are major regulators of podocyte gene expression and are mostly expressed as heterodimers bound to transmembrane proteins. ZHX2-ZHX1 heterodimers are present mostly in the podocyte body and ZHX2-ZHX3 in the slit diaphragm. Loss of heterodimerization, is common in podocyte diseases and promotes nuclear entry of ZHX proteins.

Methods: To induce loss of heterodimerization of ZHX2 related complexes, podocyte-specific ZHX2 transgenic rats were generated. Following baseline characterization, we induced Adriamycin nephrosis, a model of FSGS, and puromycin aminonucleoside, a model of MCD.

Results: Three founder lines of ZHX2 podocyte-specific transgenic rats were characterized (TG 14, TG 142, TG 144). Glomerular RNA expression of ZHX2 in heterozygous rats showed a fold-increase of 1.13 ± 0.10 in TG 14, 1.50 ± 0.09 in TG 142 and 4.09 ± 0.69 in TG 144. Confocal characterization of heterozygous TG 144 rats revealed increase expression of ZHX2 in podocyte cell membrane distribution. Expression of ZHX3 and ZHX1 was unchanged. None of the ZHX2 transgenic rat lines had proteinuria at baseline. When compared with Sprague Dawley rat, NPHS2-promoter-ZHX2 TG rats had more proteinuria and more severe glomerular disease than controls (TG 144 and TG 142 > WT; proteinuria/18h: 310.4 ± 41.5 mg, 204.8 ± 29.9 mg and 102.6 ± 20.3 mg, respectively) ($p<0.01$). Also, backcross of the ZHX2 transgene into the Buff/Mna rat background, a model of FSGS, for 8 generations was associated with more proteinuria (301.9 ± 27.4 mg in 18 h) than the Buff/Mna at age 8 month (193.8 ±23.7 mg in 18 h) ($p<0.05$). By contrast, proteinuria in PAN was less severe 10 days after treatment (TG 144 and TG 142 < WT; proteinuria/18h 178.9 ± 13.4 mg, 169.1 ± 37.8 mg and 351.7 ± 38.9 mg, respectively) ($p<0.05$).

Conclusions: Loss of heterodimerization caused by overexpression of ZHX2 in podocytes had a protective effect in MCD but worsens the development of FSGS. These findings suggest a major role of ZHX2 in nephrotic syndrome.

FR-PO142

Nanoproteomics and 2-Photon Glomerular Micropuncture (2PGM) Reveal LRP2 Ligands in Glomerular Filtrate Michael Hutchens,[1] Rumie Wakasaki,[1] Kirsti A. Golgotiu,[1] Paul D. Piehowski,[3] Sharon Anderson.[2] *[1]Anesthesiology & Perioperative Medicine, Oregon Health & Science Univ, Portland, OR; [2]Internal Medicine, Div of Nephrology & Hypertension, Oregon Health & Science Univ, Portland, OR; [3]Biological Separations and Mass Spectrometry, Pacific Northwest National Laboratory, Richland, WA.*

Background: The proximal tubular (PT) transporter LRP2 (megalin) mediates endocytosis of >50 ligands. LRP2 ligands such as albumin and myoglobin alter tubular function and survival in kidney disease. In order to access subsurface cortical glomeruli,

we developed 2PGM and coupled this with simplified nanoproteomics (SN), developed at the Pacific Northwest National Laboratory, to test the hypothesis that LRP2 ligands may be quantified in glomerular filtrate.

Methods: Cortical glomeruli were accessed in anesthetized C57BL/6 mice with 2 photon guidance using the novel technique. Imaging excluded vascular injury. GF was aspirated, frozen, and underwent in-column trypsin digestion and inline LC/MS analysis with MS identification against the Uniprot mouse proteome. Urine from mice with mosaic PT deletion of LRP2 (LRP2 fl/fl;ApoE cre) was assessed by conventional proteomics to confirm the findings obtained with novel techniques.

Results: Cortical glomeruli (depth 63±7μm) were accessed with 100% survival. In GF, 18 proteins were identified (MW 57.5±12kD), albumin the most abundant, consistent with GF. Urine of LRP2 fl/fl;ApoE cre mice was selectively enriched in 320 proteins relative to cre- control, including all known LRP2 ligands. 38% of the GF identifications were among the 320 LRP2 deletion-selective proteins.

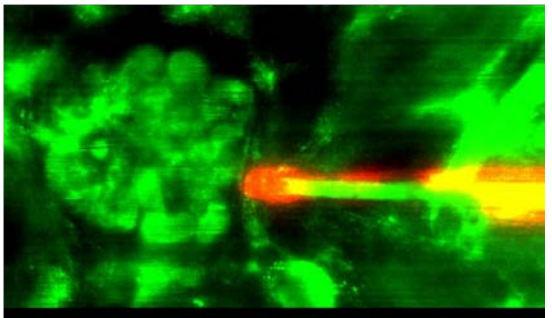

Figure: 2-photon image of red fluorophore-coated micropipette during placement in Bowman's space, 36 um below the renal capsule. The vasculature is partially opacified with fluorescein-isothiocyanate 2000kD dextran

Conclusions: We identified known and possible LRP2 ligands in glomerular filtrate using novel methodology. 2PGM allows access to subsurface glomeruli, enhancing micropuncture. 2PGM coupled with SN may provide important data regarding glomerular protein filtration.

FR-PO143

Podocyte-to-Podocyte Propagation of Damage Takes Place in an Accelerated Manner in Males Masahiro Okabe,[1,2] Masaru Motojima,[1] Yoichi Miyazaki,[2] Takashi Yokoo,[2] Taiji Matsusaka.[1] *[1]Tokai Univ School of Medicine, Isehara, Japan; [2]Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Our recent studies demonstrated that injury incurred in a fraction of podocyte population causes secondary damage in other initially intact podocytes. This podocyte-to-podocyte propagation of damage may drive the progressive nature of glomerulosclerosis. Since male patients commonly develop renal failure faster than females following various kidney diseases, we hypothesized that male podocytes are more susceptible to this secondary injury.

Methods: We established a new mosaic mouse model in which approximately 50% of podocytes express hCD25 and the other podocytes express EGFP. Injection with hCD25-targeted immunotoxin, LMB2, injured not only hCD25-positive but also -negative podocytes, and the mice developed FSGS without increase in blood pressure. To study impact of sex on secondary podocyte injury, five male and five female mosaic mice (28 weeks) were injected with LMB2.

Results: FACS analysis in mosaic mice without LMB2 revealed that the proportion of hCD25-positve podocytes was not different between the male and female mice. Seven days after the induction of podocyte injury, urinary Alb/Creatinine ratios (ACR) were similarly increased in both groups (male 84.8±14 vs. female 85.1±14 mg/mg). Thereafter, the male mice continuously showed high ACR (89.2±50 at day 21) and two died at day 18 and 24. In contrast, ACR in the female mice decreased (19.2±16 at day 21, $p<0.01$ vs. male). Renal histological analysis at day 25 revealed that male glomeruli showed severer sclerosis, higher desmin expression, and fewer EGFP-positive cells than female glomeruli. Glomerular nephrin was diminished globally in the male mice while only segmentally in the female mice. To verify that LMB2 causes similar primary podocyte injury in males vs. females, NEP25 mice (5 males and 5 females), in which all podocytes express hCD25, were injected with LMB2. No sex difference was observed in proteinuria, glomerulosclerosis, nephrin or desmin expressions.

Conclusions: Propagation of podocyte-to-podocyte injury takes place more aggressively in males, which may underlie more rapid progression of renal failure in male than female patients with kidney diseases.

FR-PO144

The Effect of Maternal Low Protein Diet on Podocyte Endowment Victor G. Puelles, Luise A. Cullen-McEwen, James William Van der Wolde, John F. Bertram. *Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Australia.*

Background: It is well established that an adverse feto-maternal environment such as a maternal low protein diet (LPD) can result in low nephron endowment – a permanent deficit in nephron number. Given that podocytes are post-mitotic cells with limited capacity for regeneration, we investigated whether a maternal LPD also resulted in reduced podocyte endowment.

Methods: Kidneys were collected at postnatal day 21 in rat offspring exposed to a maternal LPD (8%) or normal protein diet (NPD; 20%) starting at 3 weeks prior to pregnancy until weaning. Total nephron number was estimated by design-based stereology. Podocyte number was determined using a combination of immunofluorescence, confocal microscopy and optical clearing; and glomerular volume by model-based stereology. Podocyte density was also calculated. A total of 300 whole glomeruli were analysed: 10 glomeruli from the outer and 10 from the inner cortex per rat (NPD, n=8, and LPD, n=7).

Results: Body weight and nephron number were 43% ($P<0.0001$) and 32% ($P<0.0001$) lower in LPD compared to NPD offspring. Glomerular volume was 42% lower in LPD offspring ($P<0.01$; 50% for outer and 37% for inner glomeruli). Interestingly, glomeruli from the LPD group contained 13% fewer podocytes than those from the NPD cohort ($P<0.0001$; 18% for outer and 8% for inner). Consequently, podocyte density was increased by 60% in LPD offspring ($P<0.001$; 66% for outer and 50% for inner). Inner glomeruli were larger and had lower podocyte densities than glomeruli from the outer cortex in both NPD and LPD rats ($P<0.001$ for all). While there was no zonal difference in podocyte number in NPD rats, there were 14% more podocytes in glomeruli from the inner cortex in LPD rats ($P<0.0001$).

Conclusions: This is the first report that podocyte endowment is directly affected by an adverse feto-maternal environment. The observation that outer glomeruli in LPD rats had particularly low podocyte number suggests glomeruli formed in the latter stages of nephrogenesis were particularly affected. Studies focused on the adult consequences of low podocyte endowment are underway in our laboratory.

Podocyte Number Increases after Birth in Mice and Humans Victor G. Puelles,[1] James William Van der Wolde,[1] Luise A. Cullen-McEwen,[1] Peter G. Kerr,[2] David J. Nikolic-Paterson,[2] John F. Bertram.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Australia; [2]Nephrology, Monash Medical Centre, Melbourne, Australia.*

Background: Podocyte depletion is a direct cause of glomerulosclerosis and is observed in a wide range of glomerular diseases. However, the presence of postnatal podocyte gain remains a controversial topic.

Methods: Kidneys were collected from *Pod^{iCre}iDTR* mice injected with 50ng/kg of diphtheria toxin (DT) and age-matched controls (6-14 weeks of age). Total podocyte number per glomerulus was obtained using a combination of immunofluorescence, optical clearing and confocal microscopy. A total of 740 whole glomeruli were analysed (20 per mouse). Podocyte number was also estimated in human nephrectomy (n=3 adults) and autopsy tissue (n=18 children) using model-based stereology in 10-20 glomeruli per subject for a total of 350 glomeruli.

Results: Podocyte number increased approx. 20% in control mice from 6 to 14 weeks of age ($P<0.0001$). Podocyte number decreased by 13% ($P<0001$) 1 week after DT injection (7 weeks of age). However, by week 14 of age, podocyte number increased by 12% ($P<0.001$) in DT-injected mice. While there was no statistical difference in podocyte number between 6-week control mice and 14-week DT-injected mice ($P=0.59$), the difference between DT-injected and age-matched control mice at 14 weeks remained at 15% ($P<0.0001$). Body weight increased in both control (37%; $P<0.001$) and DT-injected mice (47%, $P<0.001$). Glomeruli from children 3-36 months of age and adults contained approx. 30% more podocytes than children 0-2 months of age ($P<0.0001$). Podocyte number was similar in children 3-36 months of age and adults. Body surface area increased dramatically in children 3-6 months of age (50%; $P<0.001$), 12-36 months of age (154%; $P<0.01$), and adults (680%; $P<0.0001$) compared to children 0-2 months of age.

Conclusions: These findings suggest that podocyte number increases by 20-30% after birth in both mice and humans. This increase in podocyte number may align with normal physiological growth in the early period of postnatal life. Future studies using cell fate tracking are urgently needed to confirm these findings.

Podocyte Injury Is Involved in Albuminuria in the Rat Model of Hyperuricemia Shin-Ichiro Asakawa, Shigeru Shibata, Daigo Toyoki, Yosuke Kawamorita, Yoshifuru Tamura, Yoshihide Fujigaki, Shunya Uchida. *Dept of Intern Med, Teikyo Univ School of Medicine, Tokyo, Japan.*

Background: We have recently shown that high level of serum uric acid (UA) may deteriorate kidney function in CKD patients using propensity score analysis (Uchida S et al. PLoS One 2015). In the present study, we have evaluated the kidney injury and its mechanism in a rat model of hyperuricemia.

Methods: Male Sprague-Dawley rats received 2% oxonic acid (OA group) as a uricase inhibitor to increase serum UA level. Blood pressure and urinary albumin excretion were monitored during the experiment. At 8 weeks, kidney histology and urine albumin excretion were evaluated by immunostaining.

Results: Rats received OA had significantly higher levels of uric acid than control group (1.3 ± 0.1 mg/dL vs. 0.7 ± 0.1 mg/dL, n =10; p = 0.002). OA group showed time-dependent increase in systolic blood pressure and thickening of arcuate arteries and afferent arterioles as assessed by a-smooth muscle actin staining. Of note, OA caused significant increase in urinary albumin excretion, and the immunostaining of desmin, a podocyte injury marker, showed marked increase in its positivity. The presence of podocyte injury in this model was further confirmed by electron microscopy. To address the mechanism of UA-induced kidney injury, we analyzed the levels of 8OHdG, the oxidative stress marker, and found that urinary 8OHdG levels, as well as 8OHdG staining in the glomeruli, were significantly increased in the OA group as compared with the control. Moreover, urinary 8OHdG was highly correlated with UAE ($R^2 = 0.49$; $p < 0.001$), suggesting the importance of oxidative stress as a cause of podocyte injury. However, oral administration of tempol, a potent antioxidant, decreased blood pressure but not UAE, suggesting that the cause of UAE is distinct from that of hypertension and is relevant to podocyte injury.

Conclusions: High levels of serum UA can cause arteriopathy/arteriolopathy and albuminuria, the latter of which is attributable to podocyte injury. Oxidative stress induced by higher serum UA may underlie the mechanism of the kidney injury.

FR-PO147

miR-21 Mediates Podocyte Injury and Mitochondrial Dysfunction via Targeting Mitochondrial Gene Dnm1l Aihua Zhang,[1] Mi Bai,[1] Guixia Ding,[1] Yue Zhang,[1] Songming Huang,[1] Zhanjun Jia.[2] *[1]Dept of Nephrology, Nanjing Children's Hospital affiliated to Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Lab of Pediatrics, Nanjing, China.*

Background: Emerging evidence indicated that the maintenance of mitochondrial structure and function is critical for preventing podocyte injury. Recently, some miRNAs have been proven to play roles in modulating mitochondrial function. Our preliminary data from a miRNA array analysis showed a remarkable elevation of renal miR-21 in a podocytopathy mouse model. By bioinformatics analysis, mitochondrial Dnm1l was predicted to be a direct target of miR-21. Thus we conducted experiments to determine the role of miR-21 in podocyte injury and mitochondrial dysfunction.

Methods: Puromycin aminonucleoside (PAN) or Adriamycin (ADR) was used to induce podocyte injury in cultured podocytes or animals. Genetic approaches were applied to define the roles of miR-21 in mediating podocyte injury and mitochondrial function in vitro and in vivo.

Results: Following PAN treatment in SD rats and podocytes, miR-21 was dramatically induced by 4.8-fold in kidney and 4.2-fold in cells, respectively. Strikingly, overexpression of miR-21 alone in podocytes induced mitochondrial dysfunction evidenced by the increase of ROS (+3.1 folds) and decrease of Mitochondrial membrane potential (MMP) (-27%) and mitochondrial DNA (mtDNA) copy number (-24%), and cell injury shown by increased cell apoptosis (+81%) and decreased nephrin (-70%) and podocin (-45%) expression. By luciferase reporter assay and miR-21 overexpression, we identified that Dnm1l is a direct target of miR-21. And overexpression of Dnm1l could largely abolish miR-21 effects on inducing mitochondrial dysfunction and podocyte injury. More importantly, the miR-21 inhibitor attenuated PAN/ADR-induced podocyte injury in both in vitro cells and in vivo animals shown by 70% blockade of albuminuria and remarkable amelioration of podocyte injury markers in line with markedly attenuated mitochondrial dysfunction.

Conclusions: miR-21 mediated podocyte injury and mitochodnral dysfunction via targeting mitochondrial gene Dnm1l.

FR-PO148

Succinate Receptor GPR91 Regulates Mitochondrial Metabolism and Contributes to Diabetic Nephropathy Progression Ju Young Moon,[1,2] Dorinne Desposito,[1] Anne Riquier-Brison,[1] Bahram Nadim,[1] Janos Peti-Peterdi.[1] *[1]Dept of Physiology and Biophysics, Univ of Southern California, Los Angeles, CA; [2]Dept of Internal Medicine, College of Medicine, Kyung Hee Univ, Seoul, Korea.*

Background: Succinate is traditionally known as an intermediate of the mitochondrial citric acid (TCA) cycle, but its novel signaling role as a ligand of the cell membrane GPR91 receptor (also called SUCNR1) is emerging. Succinate and GPR91 have been implicated in metabolic diseases including hypoxia (ischemia), lipolysis (obesity), and diabetic nephropathy (DN), however the pathophysiological role of GPR91 signaling in DN has been elusive. The purpose of the studies was to validate the importance of GPR91 in DN, and to investigate the pathomechanism of succinate/GPR91 signaling. We hypothesized genetic GPR91 inhibition attenuates the progression of DN by regulating mitochondrial metabolism and hypoxia response in the kidney.

Methods: Our study included four mouse groups: 1) C57/BL6 (Wild type, WT CON); 2) C57/BL6+Streptozotocin+Nω-Nitro-L-arginine methyl ester hydrochloride (Wild STZ+L-NAME, 1g/L administered in the drinking water); 3) GPR91$^{-/-}$ (KO CON); and 4) GPR91$^{-/-}$+STZ+L-NAME (KO STZ+L-NAME). Intravital multiphoton microscopy was used to measure mitochondrial metabolism in the intact kidney *in vivo*, by quantitatively visualizing mitochondrial ROS generation (using Mitosox) and depolarization of the mitochondrial membrane potential (using MitoTracker-Red).

Results: We found significant reductions in hyperglycemia-induced mitochondrial ROS generation and depolarization of the mitochondrial membrane potential in distal tubule-collecting duct epithelial cells in KO vs. WT STZ+L-NAME mice. Also,the hypoxia-inducible factor HIF1α was highly expressed in KO kidney compared to WT. These findings were also linked with attenuated systolic blood pressure, albuminuria,mesangial expansion, and Type IV collagen deposition in KO vs. WT STZ+L-NAME groups.

Conclusions: Taken together, these data support the direct role of GPR91 in activating mitochondrial ROS generation and depolarization of mitochondrial membrane potential, contributing to the progression of DN. GPR91 is a promising new therapeutic target for DN.

Over-Expression of Dynamin-Related Protein 1 Contribute to Podocyte Injury by Facilitating Mitochondria Fragmentation Na Guan, Qijiao Wei, Xiaoya Liu, Han Xu. *Pediatrics, Peking Univ First Hospital, Beijing, China.*

Background: Mitochondria fragmentation during podocyte apoptosis has been found. Dynamin- related protein 1 (Drp1) can facilitate mitochondria fragmentation. This study aimed to test the hypothesis that Drp1 might lead to podocyte injury by facilitating mitochondria fragmentation.

Methods: Thirty SD rats were divided into adriamycin nephropathy and control group. Proteinuria, podocyte mitochondria morphology and density, glomerular staining and cortical expression of Drp1 were analyzed at 2, 4 and 6 week. Glomerular expression of Drp1 in children with nephrotic syndrome was also analyzed. The effects of over-expression of Drp1 on mitochondria morphology and apoptosis were analyzed using mouse podocyte MPC5. Data was expressed as mean±SD.

Results: In adriamycin group, compared with controls, proteinuria appeared at 4 week (150.5±87.7 vs. 16.0±9.2mg, P=0.01) and 6 week (226.9±106.9mg vs. 12.0±4.4mg, P<0.01); podocyte mitochondria density increased at 2 week (0.17±0.00 vs. 0.14±0.01, P<0.01), mitochondria area density decreased (0.71±0.11 vs. 0.87±0.12, P=0.02) at 6 week; glomerular staining intensity of Drp1 increased at 4 week (0.025±0.013 vs. 0.003±0.001, P=0.02) and 6 week (0.008±0.003 vs. 0.0004±0.003, P=0.01); renal cortical Drp1 expression increased at 4 week (0.38±0.09 vs. 0.03±0.02, P=0.05) and 6 week (0.39±0.14 vs. 0.07±0.10, P=0.02).

Glomerular staining intensity (r=0.48, p=0.01) and renal cortical expression of Drp1(r=0.47, p<0.01) correlated positively with urinary protein. Glomerular staining area ratio (r=-0.44, P=0.02) and cortical expression of Drp1 (r=-0.46, p=0.01) correlated negatively with mitochondria density in podocyte. The cortical expression of Drp1 correlated negatively with podocyte mitochondria aspect ratio (r=-0.49 , P=0.01).

Glomerular staining of Drp1 increased dramatically in some children with nephrotic syndrome, and co-localized with synaptopodin.

Over-expression of Drp1 lead to increase of apoptosis in mouse podocyte MPC5 compared with control (31.2±10.4% vs. 5.7±4.0%, P=0.02) and fragmentation of mitochondria.

Conclusions: Over-expression of Drp1 lead to podocyte injury possibly by facilitating mitochondria fragmentation.

CHOP Deficiency Inhibits Proteinuria by Promoting Nephrin Expression in a Mouse Model of Chronic Kidney Disease Zahraa Mohammed-Ali,[1] Mandeep K. Marway,[1] Chao Lu,[2] Kjetil Ask,[1,3] Jeffrey G. Dickhout.[1,2] *[1]Health Sciences, McMaster Univ, Hamilton, ON, Canada; [2]Nephrology, St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [3]Firestone Inst for Respiratory Health, St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

Background: CHOP (GADD153/DDIT3) is a transcription factor that is upregulated during endoplasmic reticulum (ER) stress in chronic kidney disease (CKD). CHOP impacts protein translation during ER stress. It induces GADD34 that relieves the block in translation caused by eIF2a phosphorylation. Nephrin is the key component of the podocyte slit diaphragm maintaining the glomerular filtration barrier to albumin. Under conditions of ER stress-induced translation attenuation, predominant in CHOP knockout, nephrin has been shown to be preferentially translated. Therefore, we hypothesized that CHOP deficiency would result in higher nephrin expression, a more intact glomerular structure, and lower proteinuria in response to CKD.

Methods: Our model of CKD was based on reduced renal mass and Angiotensin II/DOCA infusion in C57BL/6 male mice. CHOP deficient mice on the C57BL/6 genetic background were used to test the effect of CHOP knockout in the CKD model. CKD was assessed using blood pressure and 24h total urinary protein and albumin excretion. On day 21 of the model, mice were sacrificed. PAS staining was used to evaluate renal pathology and glomerular damage. Nephrin mRNA levels were measured using Nanostring analysis and nephrin protein levels from renal tissue lysates.

Results: In response to the CKD model, both CHOP$^{-/-}$ and wild type (WT) mice showed similar significant increases in systolic and diastolic blood pressure. However, CHOP$^{-/-}$ mice showed significantly lower proteinuria and albuminuria. In addition, CHOP deficiency significantly decreased intertubular cast formation and glomerular sclerosis index. CHOP$^{-/-}$ mice, however, had significantly higher levels of nephrin mRNA and protein in the kidney in response to CKD.

Conclusions: CHOP deficiency resulted in a decrease in proteinuria and improved glomerular structure as well as increased nephrin expression. These findings indicate CHOP inhibition as a mechanism to maintain glomerular integrity. Funding: Government Support-MOP-133484.

Caspase-1 Activation Contributes to Hypertension-Induced Glomerular Injury and Focal Segmental Glomerulosclerosis Jinghui Luo,[1] Yingbao Yang,[1] Stephanie Wylie,[1] Tamra J. Reed,[2] J. Michelle Kahlenberg,[2] Jeffrey B. Hodgin.[1] *[1]Pathology, Univ of Michigan; [2]Rheumatology, Univ of Michigan, Ann Arbor, MI.*

Background: Hypertension is a leading cause of end-stage kidney disease and a significant determinant of focal segmental glomerulosclerosis (FSGS). However, the cellular and molecular responses to glomerular hyperfiltration are not well understood. Recent studies highlight the inflammasome in the pathogenesis of diabetic nephropathy and related podocyte injury. We find a robust upregulation (priming) of inflammasome-related gene expression in glomeruli of diabetic and non-diabetic patients with FSGS and/or hypertension. We hypothesize that caspase-1 activation contributes to hypertension-mediated albuminuria and FSGS.

Methods: Caspase-1 knockout (KO) and wildtype (WT) BALB/c mice (n=8-10 per group) were uninephrectomized, implanted with osmotic minipumps releasing Ang2 (1.2 ug/kg/min), and given 1% salt water for 4 weeks (wks). Control groups received sham, saline infusion, and normal water. Blood pressure (BP) and albumin/creatinine ratio (ACR) were measured at 2-wk intervals and kidneys harvested for histology. Immortalized human podocytes were treated with Ang2, LPS, +ATP to investigate caspase-1 activation.

Results: Ang2 similarly elevated BP in both WT and KO mice at 2 and 4 wks versus control. At 2 weeks, ACR was increased in both groups (10mg/mg), however ACR in WT >doubled by 4 wks, whereas KO mice remained stable ($p<0.01$). Histologic analysis revealed 3-fold more FSGS in Ang2 treated WT vs KO mice ($p<0.05$). In cultured podocytes, Ang2 alone (500nM & 1mM) activated caspase-1 6-8-fold vs controls, and 8-10-fold combined with LPS (Ang2 as inflammasome activator) or ATP (Ang2 as inflammasome primer). LPS+ATP increased caspase-1 activity 14-fold. Westerns showed increased caspase-1, ASC, and IL1beta with Ang2 and LPS.

Conclusions: Caspase-1 loss significantly abrogates Ang2/hypertension-mediated albuminuria and FSGS in our model, and Ang2 primes and activates the inflammasome in human podocytes. Our mouse and human data demonstrate an important role for caspase-1 activation in the pathogenesis of hypertension-mediated podocyte injury and FSGS that may prove therapeutically targetable.

RNA-seq Based Differential Expression Analysis in Rats with Slit Diaphragm Specific Dysfunction: The Glomerular Gene Expression Profiles of Nephropathy Induced by Anti-Nephrin Antibody Ying Zhang, Yoshiyasu Fukusumi, Hiroshi Kawachi. *Dept of Cell Biology, Kidney Research Center, Niigata Univ, Niigata, Japan.*

Background: Slit diaphragm (SD) dysfunction is understood to be involved in the development of proteinuria in several types of glomerular diseases. However, the pathogenic mechanism of the SD dysfunction is not well elucidated. The aim of this study is to identify novel molecules involved in the SD dysfunction.

Methods: The glomerular gene expression profiles of rat nephropathy induced by the injection of anti-nephrin antibody were examined by RNA sequencing (RNA-seq) with the Next-Generation Sequencer. Differentially expressed molecules were further analyzed by Gene Ontology (GO) and KEGG pathway analysis using DAVID.

Results: mRNA expressions of 870 genes were reduced to less than 50% at 1h when abnormal proteinuria was not detected yet, and those of 601 genes were reduced on day 5 when proteinuria peaked.mRNA expressions of 880 and 794 genes were increased to more than 2 folds at 1h and on day 5, respectively.We focused on 870 molecules which are down-regulated at 1h, since they are supposed to be potential molecules involved in the onset of proteinuria. GO analysis indicated 163 of the 870 genes were clustered in plasma membrane, and enrichment analysis revealed transmembrane receptor tyrosine kinase activity was the most significant over-represented molecular function for these 163 plasma membrane molecules. KEGG pathway analysis showed RAP1 signaling pathway is most significantly enriched. In the 870 molecules the most evidently down-regulated molecule is Hmgcs2 (3.8% to normal) and the second is Slc5a8 (4.3%). The reduction in gene expression levels of these two molecules were validated by real-time PCR. Glomerular expressions of these molecules were detected by Western blot analysis and the distribution of Slc5a8 in podocyte was observed by immunohistochemical analysis.

Conclusions: RNA-seq analysis with nephrotic glomeruli showed Hmgcs2 and Slc5a8 are involved in the early event of the SD dysfunction. GO and KEGG analyses showed the altered RAP1 pathway modulated by receptor tyrosine kinases participates in the development of proteinuria in the SD dysfunction.

Preservation of Glomerular Architecture in Aged Mice via Systemic Late-Age Intervention with SS-31 Mariya T. Sweetwyne,[1] Jeffrey W. Pippin,[1] Diana G. Eng,[1] Kelly L. Hudkins,[2] Charles E. Alpers,[2] Ying Ann Chiao,[2] Hazel H. Szeto,[3] Peter S. Rabinovitch,[2] Stuart J. Shankland.[1] *[1]Nephrology, Univ of Washington, Seattle, WA; [2]Pathology, Univ of Washington, Seattle, WA; [3]Pharmacology, Weill Cornell Medical College, New York, NY.*

Background: The mitochondrial targeted peptide, SS-31, prevents mitochondrial damage and reduces cellular injury. Mitochondrial damage and oxidative stress accumulate with age. Thus, we hypothesized that SS-31 peptide would prevent/limit the progression of glomerular disease with aging.

Methods: 24-month old mice (~70 yr-old human) received either 8w of SS-31, or saline, by osmotic pump. Animals were sacrificed at 26m (~79 yr-old human) and tissues analyzed by quantitative histology. Untreated 24m-old animals were used to perform baseline measurements.

Results: SS-31 partially but significantly, inhibited the development of glomerulosclerosis (PAS). The age-associated decrease in podocyte density was not altered, but SS-31 treatment limited podocyte injury (desmin), and improved podocyte integrity (synaptopodin). 26m-old 8w SS-31 treated mice also had higher glomerular endothelial cell density (CD31). Parietal epithelial cells (PEC) were the most protected glomerular cell as SS-31 treatment significantly increased PEC density above 24m baseline and yet decreased PEC activation markers (staining for active phospho-ERK1/2, α-smooth muscle actin, COLIV). Thus suggesting that PEC responses are still malleable at late age. Glomerular mitochondrial damage was evident in 26m-old saline treated mice by electron microscopy but was attenuated in PECs and podocytes in SS-31 treated aged mice. Consistent with decreased oxidative activity, SS-31 reduced Nox4 staining in podocytes, mesangium and PECs. Cellular senescence (p16) was also reduced in tuft cells and PECs of aged SS-31 treated mice as compared to saline controls.

Conclusions: In mice of advanced age, mitochondrial protection via SS-31 intervention lowers glomerulosclerosis, increases PEC density but lowers their activation, improves podocyte and endothelial cell integrity, and reduces senescence. This demonstrates that age-induced renal injury can be attenuated even in individuals of advanced age.

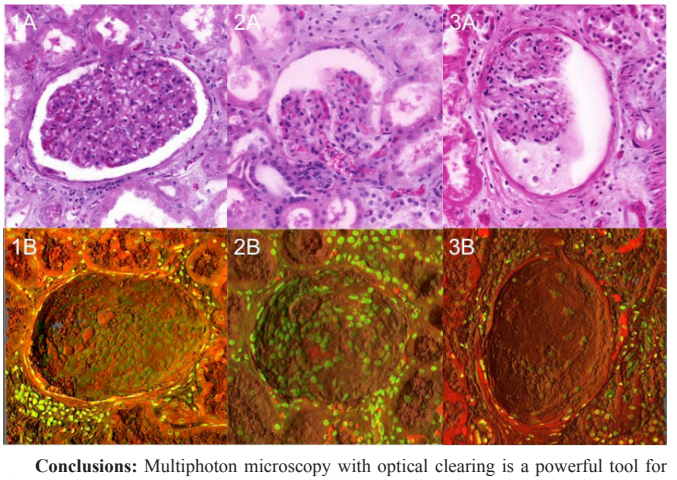
Morphologic Changes in Human Parietal Epithelial Cells Using 3D Capsular Reconstructions Parker C. Wilson,[1] Gilbert W. Moeckel,[1] Robert L. Safirstein,[2] Richard Torres.[1] *[1]Pathology and Laboratory Medicine, Yale Univ School of Medicine; [2]Nephrology, Yale Univ School of Medicine.*

Background: There has been recent interest in the role of parietal epithelial cells (PEC) in the evolution of kidney disease. However, PEC morphology cannot be adequately visualized using traditional microscopy due to the limitations of 2D histologic sections. We employed a new imaging method based on multiphoton microscopy and chemical clearing to improve glomerular capsule visualization.

Methods: High-resolution 3D microscopic images of entire glomeruli were obtained from autopsies with well-preserved kidneys and varying degrees of chronic kidney disease (CKD). Tissue clearing was performed to enable high resolution deep tissue imaging on a home-built multiphoton microscope. Glomeruli were digitally removed to reveal capsular surface morphology on 3D reconstruction.

Results: Individual kidneys showed a range of capsular morphologies. In the absence of CKD, parietal epithelial cells (PEC) had rounded nuclei and were evenly-spaced in a single layer covering the capsule (1A,1B). In patients with CKD, disorganized architecture and nuclear elongation was a feature of capsules from otherwise normal-appearing glomeruli with patent proximal tubules (2A,2B). Severely affected capsules from patients with CKD showed marked reduction in epithelial cell number and was associated with capsular thickening, fibrotic capsules with coarse contours, and damaged proximal tubules (3A,3B).



Conclusions: Multiphoton microscopy with optical clearing is a powerful tool for visualization of glomerular capsules, atubular glomeruli, and associated proximal tubule changes in human specimens. Glomerular capsule changes may be linked to proximal tubule damage in chronic kidney disease.

FR-PO155

Progressive Pathological Profile of the Passive Nephrotoxic Nephritis Model in CD1 and C57BL/6 Mice Maria Katarina Ougaard,[1,2] Peter Helding Kvist,[1] Henrik Elvang Jensen,[2] Constanze Hess,[1] Claus Haase,[1] Henrik Søndergaard.[1] *[1]Diabetes Complications Pharmacology, Novo Nordisk A/S, Denmark; [2]Dept of Veterinary Disease Biology, Uni. of CPH, Denmark.*

Background: When modelling human diseases in mice, different susceptibility to specific diseases needs to be considered. CD1 mice are a commonly used outbred stock of mice for studies of chronic kidney disease, supposedly due to their proneness to develop kidney fibrosis. In this study C57BL/6 (B6) and CD1 mice were compared for their susceptibility to develop nephropathy in the passive nephrotoxic nephritis (NTN) model.

Methods: Initially, 100 and 250 µl of sheep anti-rat GBM antibody containing nephrotoxic serum (NTS) was identified as the preferred doses to induce NTN in CD1 and B6 mice, respectively. In a longitudinal study, the urinary albumin excretion rate (UAER) was measured on day 2-3, 6-7, 16-17, and 36-37 post NTS injection. On day 7, 21, and 42 post NTS injection, kidneys were harvested and stained with Perl, PAS and collagen III by immunohistochemistry. Mesangial expansion (ME) was graded from 0 to 3, in a blinded fashion.

Results: NTN induction resulted in significantly increased UAER already on day 2-3 in CD1 and B6 mice (mean±SD 233.7mg/24h±134.4; 68.2mg/24h±75.5) compared to their healthy controls (mean±SD 97.1mg/24h±31.2; 40.1±17.7), and this continued until day 36-37. On day 2-3, 6-7, and 16-17 UAER was significantly increased in CD1 NTN mice compared to the B6 NTN mice. Both CD1 and B6 NTN mice revealed significant, but similar progressive ME on day 7, 21, and 42, suggesting that disease might exacerbate beyond day 42. Perl staining showed increased renal iron accumulation on day 21 and 42 in both CD1 and B6 NTN mice, suggesting that iron accumulation is a pathological feature in this model. An increased deposition of collagen III was observed in the renal cortex in CD1 and B6 NTN mice on day 21 and 42, suggesting a similar renal fibrosis development in CD1 and B6 mice.

Conclusions: Taken together, CD1 and B6 mice show significant, progressive, but similar renal pathology up to day 42 when subjected to passive NTN. Moreover, both murine strains are useful for studies related to UAER, ME progression, and renal fibrosis, when subjected to NTN.

FR-PO156

Gene Expression Profiling of Proximal Tubular Cells - A Novel Experimental Technique James Alexander Tomlinson,[1,2] Claire Bruce-Cobbold,[1] James M. Leiper.[1] *[1]MRC CSC, Imperial College, London, United Kingdom; [2]Renal Section, Dept of Medicine, Imperial College, London, United Kingdom.*

Background: Gene association and experimental studies implicate the proximal tubule (PT) as a major effector cell in progressive renal fibrosis but PT-specific maladaptive responses to injury *in vivo* are not well-defined. Previous techniques to isolate tubular cell genetic material remain limited by residual contamination from other kidney cell-types and gene expression changes elicited by the isolation technique itself. We have developed a novel ribosomal protein tag-and-capture technique to isolate proximal tubular cell messenger RNA (mRNA) transcripts from whole kidneys.

Methods: The *RiboTag* mouse strain has a mutated ribosomal protein L22 (Rpl22) locus with three copies of the haemagglutinin (HA) epitope after a STOP codon. When bred with a proximal tubule-specific kidney androgen-sensitive protein Cre recombinase (*KAPiCre*) strain, female mice expressed HA-tagged Rpl22 protein confined to kidney proximal tubular cells induced by testosterone treatment.

Results: Western blot analysis of whole kidney tissue showed strong HA protein expression in *Ribotag* homozygous mice, >50% less in heterozygous mice and not in the absence of either *KAPiCre* or *Ribotag* genes. Immunohistochemical staining revealed strong HA protein expression within proximal tubules and not in other kidney structures. Ribosomal immunoprecipitation yielded 100-300ng/uL of RNA from a single kidney, with negligible yield from control *KAPiCre* negative animals (<5ng/uL). Proximal tubular-specific gene markers including megalin, *NHE3* and *AQP1* were enriched (2 – 3-fold), whilst gene markers associated with other cell types, *αSMA* (mesenchymal cells/fibroblasts) and *UMOD* (thick-ascending limb cells) were reduced (upto 10-fold) compared to whole kidney extract.

Conclusions: This novel technique permits proximal tubular gene expression analysis at any given time-point during the evolution of renal fibrosis using targeted RT-qPCR or non-biased RNA sequencing. Future studies using this experimental tool will provide new insights into how the proximal tubule responds to renal injury and repair, thus making a valuable contribution to our understanding of CKD pathogenesis.

FR-PO157

Proximal Tubule-Specific Intracellular-Type Nampt Conditional Knockout Mice Exhibited Renal Fibrosis and Basement Membrane Thinking via Suppression of Sirt1 and/or 6 Hirokazu Muraoka, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Dept of Endocrinology, Metabolism and Nephrology, Keio Univ, Shinanomachi, Tokyo, Japan.*

Background: Intracellular-type Nicotinamide phosphoribosyltransferase (iNampt) cooperates with NAD-dependent deacetylase Sirtuins, to exert the potentiation of stress resistance and longevity. We previously reported that proximal tubule (PT)-specific Sirt1 transgenic mice are protected against diabetic nephropathy (DN), and that PT-conditional knockout (CKO) mice exhibited aggravation of DN (Nature Medicine,2013). We also showed that the high expression level of iNampt in PTs contributes to the sufficient supply of nicotinamide mononucleotide (NMN), a precursor of NAD, to glomeruli. In this study, we established PT-specific conditional Nampt-deficient mice to investigate the role of iNampt in DN.

Methods: We generated PT-specific, iNampt-deficient mice by crossing $Nampt^{flox/flox}$ mice with γ-GT-Cre mice. Wild-type (WT) and CKO mice were injected with saline (SAL; control) or streptozotocin (STZ) to induce DN. The phenotypes of mice, WT+Sal, CKO+Sal, WT+Sal, and CKO+STZ, were analyzed at 8 and 24 weeks after treatment.

Results: Periodic acid methenamine silver, Masson-trichrome, and Elastica van Gieson staining revealed notable thickening of the tubular basement membrane and basement membrane of Bowman's capsule. Peritubular and periglomerular fibrosis in the cortex and perivascular fibrosis surrounding interlobular arteries and veins in the medulla were clearly detected in CKO mice. DNA microarray showed that expression of tubular tissue inhibitor of metalloproteinase 1 (TIMP-1) and latent transforming growth factor beta binding protein 2 (LTBP-2) was elevated in CKO mice, which might cause the histological changes. Among all isoforms of sirtuin proteins, the activity of only SIRT1 and SIRT6 were significantly decreased in the CKO mice.

Conclusions: We revealed that iNampt deficiency in PTs has unfavorable effects on the phenotype of broad bridging fibrosis through the overproduction of TIMP-1 and LTBP-2. The decreased activities of SIRT1 and 6 would be responsible for this change. Nampt in PTs is a safeguard against the initiation and progression of DN-induced fibrotic progression.

FR-PO158

Modulation of Proximal Tubule Endocytic Capacity by Shear-Stress Stimulated Cell Differentiation Kimberly R. Long,[1] Katherine Shipman,[1] Youssef Rbaibi,[1] Megan Eshbach,[1] Ora A. Weisz.[1,2] *[1]Medicine - Renal/ Electrolyte, Univ of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Cell Biology, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Epithelial cells that line the proximal tubule (PT) of the kidney are responsible for the reabsorption of low molecular weight proteins and other small molecules from the glomerular ultrafiltrate. Efficient uptake of these filtered proteins is essential to prevent tubular proteinuria.

Methods: Because cells in the kidney are continuously exposed to flow and the accompanying fluid shear stress (FSS), we asked whether continuous growth under FSS affects cell morphology and constitutive endocytic capacity. To this end, opossum kidney cells were plated on permeable filter supports, and the following day were exposed to orbital FSS or maintained under static conditions for an additional four days.

Results: Filters exposed to FSS had roughly 25% more cells than those maintained under static conditions as quantified using DAPI staining. Additionally, cells exposed to FSS were taller, had a more extensive brush border, and contained more apical endocytic compartments than cells grown under static conditions. Endocytic capacity per cell, quantified based on uptake of fluorescently-labeled albumin, was also dramatically increased (>2-fold) in cells cultured under FSS. This effect could be reset by overnight incubation under static conditions prior to albumin uptake. Interestingly, cells exposed to twice our normal orbital speed had a 5-fold increase in endocytic capacity per cell, and albumin uptake could be rapidly modulated by changes in FSS in these cells. Ultrastructural analysis revealed striking differentiation of the apical brush border and endocytic pathway in these cells, similar to that observed in PT cells *in vivo*.

Conclusions: Growing cells under continuous FSS better replicates the characteristics of PT cells *in vivo* and may represent a more physiologic *in vitro* model system in which to study protein uptake and the endocytic pathway in PT cells.

Deleting the TGF-β Receptor in the Proximal Tubule Worsens the Response to Chronic Injury due to Altered β-Catenin Activation Stellor Nlandu Khodo,[1] Surekha Neelisetty,[1] Melanie Phillips,[1] Raymond C. Harris,[1,2] Leslie S. Gewin.[1,2] *[1]Medicine, Vanderbilt Medical Center, Nashville, TN; [2]Medicine, Veterans Affairs Hospital, Nashville, TN.*

Background: TGF-β is arguably the strongest profibrotic factor in chronic kidney disease (CKD), but its effects vary depending upon the target cell type. We previously demonstrated that blocking TGF-β signaling in the proximal tubule (PT), the main target of renal injury, protected renal function after acute kidney injury (AKI) in mice; how TGF-β signaling in the PT affects CKD progression is still unclear.

Methods: To address this, we selectively deleted the TGF-β type II receptor (TβRII) in the PT using the γGT-Cre. These conditional knockout (KO) mice and littermate controls were injured by either aristolochic acid (AA) or uninephrectomy/angiotensin II. To define the mechanism underlying the observed response, we used PT cells with and without TβRII as well as mice with conditional stabilization of β-catenin in the PT.

Results: Surprisingly, conditional KO mice had a worse response to chronic injury as assessed by increased tubular injury (histology, KIM-1 levels), fibrosis (collagen I expression), and renal function. In addition, deleting the TβRII increased epithelial apoptosis both in vivo and in PT cells treated with AA in vitro. As TGF-β signaling interacts with the β-catenin pathway, and β-catenin activation has been shown to reduce apoptosis in murine AKI, we investigated how abrogating TGF-β signaling alters β-catenin activity. Both renal cortices from injured conditional KO mice and $T\beta RII^{-/-}$ PT cells had reduced nuclear β-catenin and axin2 mRNA compared to tissue and cells with the receptor intact. The increased apoptosis in AA-treated $T\beta RII^{-/-}$ PT cells was reduced by pharmacologically augmenting β-catenin activity. We crossed our conditional KO mice with those containing conditional activation of β-catenin and injured them using AA. The activating β-catenin mutation reduced the renal injury in mice lacking TβRII in the PT.

Conclusions: In conclusion, genetically inhibiting TGF-β signaling in the PT worsened the response to chronic injury by increasing epithelial apoptosis, in part, due to compromised β-catenin signaling.

Thioredoxin Interacting Protein: A Novel Regulator of Tubular Autophagy and Mitophagy in Diabetic Nephropathy Chunling Huang, Xinming Chen, Carol A. Pollock. *Renal Lab, Kolling Inst, Univ of Sydney, Sydney, NSW, Australia.*

Background: Dysregulation of autophagy contributes to the development of diabetic nephropathy. Hyperglycemia upregulates TXNIP expression, which in turn induces the generation of reactive oxygen species (ROS), inflammatory and fibrotic responses in diabetic nephropathy. The aim of the study is to define the interaction of thioredoxin interacting protein (TXNIP) with autophagy/mitophagy in diabetic nephropathy.

Methods: Transgenic (mRen-2) rats with streptozotocin-induced diabetes were given TXNIP DNAzyme or scrambled DNAzyme for 12 weeks respectively. Total collagen deposition, type I collagen expression, mitochondrial function and mitochondrial ROS (mtROS) production were assessed. The formation of autophagosomes and autophagic clearance were determined in kidneys from both human and rats with diabetes. The colocalization of LC3 and P62 within mitochondria was used to monitor mitophagy. Autophagic signaling molecules including BNIP3, mTOR and p70S6 were examined.

Results: TXNIP DNAzyme dramatically attenuated total collagen deposition and type I collagen expression in the kidneys of diabetic rats compared to the control DNAzyme. LC3 and P62 expression were increased in the renal tubular cells of human diabetic kidneys compared to non-diabetic controls, which indicates accumulated autophagosomes and reduced autophagic clearance. The increased LC3 and P62 in the renal tubular cells of diabetic rats were reversed by TXNIP DNAzyme. High glucose induced mitochondrial dysfunction, mtROS production, and inhibited mitophagy in the renal tubular cells, which were reversed by TXNIP siRNA. Inhibition of TXNIP suppressed diabetes-induced BNIP3 expression and activation of the mTOR signaling pathway.

Conclusions: Hyperglycemia-induced TXNIP contributes to the dysregulation of tubular autophagy and mitophagy in diabetic nephropathy through activating mTOR signaling pathway.

Hypoxia-Inducible Factor Agonist Ameliorates Impact of Tubulointerstitial Injury on Subsequent Glomerular Injury Jun Zou,[1] Jianyong Zhong,[2,3] Taiji Matsusaka,[4] Volker H. Haase,[5] Haichun Yang,[2,3] Agnes B. Fogo.[2,3] *[1]Nephrology, Xin Hua Hospital, Shanghai, China; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ; [3]Pediatric Nephrology, Vanderbilt Univ; [4]Inst of Medical Science, Tokai Univ, Isehara, Japan; [5]Nephrology, Vanderbilt Univ, Nashville, TN.*

Background: We previously found that tubulointerstitial injury sensitizes to subsequent glomerular injury, with increased peritubular capillary permeability and tissue hypoxia in folic acid-induced tubulointerstitial injury. Hypoxia-inducible factors (HIFs) regulate hypoxia and angiogenesis. In this study, we evaluated whether dimethyloxalylglycine (DMOG), an inhibitor of HIF-α degradation, can ameliorate tubulointerstitial injury and its impact on subsequent glomerular injury.

Methods: Col I-luciferase mice, with luciferase in the collagen I promoter, were mated with Nep25 mice, which express human CD25 receptor on podocytes, and develop glomerulosclerosis when LMB2 toxin is administered. Mice, 12 wk old males, received folic acid (FA, 240mg/kg BW, i.p.) or vehicle (VE), and subgroups were treated with DMOG (8 mg qod, i.p.) from wk 3 till 6. Uninephrectomy was performed at wk 6 to assess extent of tubulointerstitial fibrosis, and LMB2 was injected at wk 7. Ten days later, mice were sacrificed.

Results: Kidneys from UniNx, before added glomerular injury, showed that DMOG elevated HIF-1α and HIF-2α mRNA in FA+DMOG vs FA. Pimonidazole, a tissue marker of hypoxia, was attenuated in FA+DMOG vs FA. VEGFA mRNA was significantly increased and collagen I reduced in FA+DMOG vs FA. CD31 staining, a marker of peritubular capillaries, was not different among groups. At sacrifice, body weight increase (marker of edema) was less in FA+DMOG vs FA, despite similar proteinuria. Collagen I bioluminescence signal was also decreased in FA+DMOG vs FA. Mice with FA+podocyte injury showed increased mortality, which was also reduced by DMOG (FA+DMOG 14.3 vs. FA 55.6% death rate), linked to improved renal function.

Conclusions: Our findings indicate that hypoxia contributes to tubular injury sensitizing to subsequent glomerular injury, and restoring HIFs may blunt this adverse crosstalk of tubules to glomeruli.

Darunavir Protects Renal Tubular Epithelial Cells against HIV-Induced Injury via Mechanisms Independent of Suppression of HIV Replication Xiaobo Gao, Alan Rosales, Heidi Karttunen, Michael J. Ross. *Medicine, Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: HIV-associated nephrology (HIVAN) is an important cause of end-stage renal disease (ESRD) in HIV-positive patients. HIVAN is caused by infection of renal epithelial cells, but viral replication in these cells is not necessary to induce disease. Expression of HIV Vpr and Nef proteins causes dysregulation of cellular signaling pathways, including Stat3, ERK, and Src, and activation of innate immune responses. Antiretroviral therapy (ART) markedly reduces the risk of progression to ESRD without eradicating HIV in the kidney and the mechanism(s) by which ART protects kidneys from HIVAN is poorly understood.

Methods: Described in results section.

Results: Since previous suggest that HIV protease inhibitors have pleiotropic effects on cell signaling, we tested our hypothesis that HIV protease inhibitors protect the kidneys from HIVAN via HIV-independent mechanisms. Conditionally immortalized human tubular epithelial cells (RTEC) were infected with *gag/pol*-deleted HIV (does not express HIV protease and cannot replicate), Vpr lentivirus, or control lentivirus and subsequently treated with the HIV protease inhibitor darunavir (DRV) or vehicle control. Western blotting studies demonstrated that DRV significant attenuated HIV and Vpr-induced activation of Stat3, ERK, and Src. DRV also decreased HIV and Vpr induced expression of IL-6 and IL-8, which we had previously demonstrated to be important mediators of inflammation in HIVAN. Moreover, DRV also decreased cleavage of PARP1 in HIV and Vpr-transduced RTEC, suggesting that DRV prevented caspase-induced apoptosis.

Conclusions: Since the HIV and Vpr vectors used in these studies were replication-defective and did not encode HIV protease, the protective effects of DRV were likely mediated by direct effects upon RTEC signaling pathways. Together, these data support our hypothesis that ART protects the kidney against HIV-induced injury and inflammatory response in part, via mechanisms that are independent of suppression of HIV replication.

Renin Accelerates Progression of HIVAN via Enhanced HIV Gene Expression Partab Rai, Manoj K. Tembhre, Vinita Vishnoi, Nairuti H. Shah, Judith Eng, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: The activation of renin angiotensin system (RAS) has been demonstrated to play an important role for the the progression of HIVAN. Recently, cells of renin lineage have been shown to convert into podocytes in deactivated RAS. We have previously demonstrated that HIV enhances kidney cell renin expression. We now hypothesize that HIV-induced renin production might be causing kidney cell injury through enhancement of HIV gene expression.

Methods: Human podocytes (HPs) were tranducded with either vector (V/HP) or HIV (NL4-3, HIV/HP). To increase endogenous renin production, V/HPs and HIV/HPs were transfected with siRNA vitamin D receptor (siRNA-VDR/HIV/HPs) or scrambled (Scr-siRNA/HIV/HP) siRNA; protein blots were probed for renin and actin. To evaluate the effect of renin *in vivo*, mRNA expressions of HIV genes from renal tissues of HIVAN (Tg26) mice with high endogenous renin (Tg26 mice either with 2, 3 and 4 copies of angiotensinogen [Agt] or lacking VDR) were quantified by qPCR. To down regulate renal tissue renin expression, Tg26 mice were treated with either vehicle or a VDR agonist (VDA) for 2 weeks and then renal tissues were evaluated for HIV gene expression. in addition, gene expression and progression of renal lesions were compared in Tg26 mice and Tg26 mice lacking renin.

Results: HIV enhanced renin expression in HPs. Silencing of VDR in HIV/HPs further enhanced expression of Nef, Tat, and Vif. However, VDA down regulated HIV gene expression in HIV/HPs. Renal tissues of Tg26-Agt-4 displayed 2-4 fold increase in mRNA expression of gp120, Vpr, Tat, Nef and Vpu vs. Tg26-Agt-2. Similarly, Tg26 mice lacking VDR displayed greater HIV gene expression when compared with Tg26 mice with intact VDR. VDA treatment of Tg26 mice not only down regulated renal tissue expressions of renin but also attenuated expression of HIV genes. Tg26 mice lacking renin, displayed attenuated renal tissue HIV gene expression and slowed progression of renal lesions.

Conclusions: Renin enhances renal tissue and podocyte HIV gene expression and induces accelerated progression of renal lesions.

Reciprocal Interaction between (Pro)renin Receptor and Wnt/β-Catenin Drive Kidney Injury and Fibrosis Zhen Li,[1] Lili Zhou,[1] Xue Hong,[1] Jinhua Miao,[1] Youhua Liu.[1,2] *[1]Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China; [2]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: The (pro)renin receptor (PRR) is a newly discovered, multi-functional protein that plays a critical role in the activation of the renin-angiotensin system (RAS). However, its regulation and potential role in the pathogenesis of chronic kidney disease (CKD) are poorly understood. In this study, we show that PRR not only is a downstream target but also an upstream regulator of Wnt/β-catenin signaling.

Methods: The expression of PRR in three models of kidney disease induced by ischemia/reperfusion injury (IRI), adriamycin or chronic angiotensin II infusion was assessed by Western blot and immunostaining. Human kidney tubular cells (HKC-8) were transfected with Wnt1 and/or PRR expression vectors. In vivo expression of Wnt1 and/or PRR was also carried out in mouse model of IRI.

Results: In various models of CKD, PRR was upregulated predominantly in renal tubular epithelium, and over-expression of either Wnt1 ligand or β-catenin induced PRR mRNA and protein expression *in vitro*. Interestingly, over-expression of PRR potentiated Wnt1-mediated β-catenin activation and promoted the expression of its downstream target genes such as fibronectin, plasminogen activator inhibitor 1 and α-smooth muscle actin. Conversely, knockdown of PRR by siRNA abolished β-catenin activation and its target

genes expression induced by Wnt1, suggesting that PRR is an obligatory component of the Wnt/β-catenin signaling. We found that the effect of PRR on Wnt/β-catenin signaling was independent of renin. In mouse model of IRI, expression of either exogenous PRR or Wnt1 promoted β-catenin activation and aggravated kidney dysfunction and fibrotic lesions. Furthermore, co-expression of both PRR and Wnt1 accelerated kidney function decline, and deteriorated interstitial fibrosis and inflammation after ischemic injury.

Conclusions: These results establish that PRR is both a target and an essential component of Wnt/β-catenin signaling. Our studies suggest that PRR induction and Wnt/β-catenin activation constitutes a vicious cycle, which drives kidney dysfunction and fibrosis after injury.

Renal Tissues of HIV Transgenic Mice (Tg26 and Vpr) and Parietal Epithelial Cells Display Attenuated miR-193a Expression

Waqaar Khawar,[1] Nirupama Chandel,[1] Vinod Sharma,[1] Manoj K. Tembhre,[1] Abheepsa Mishra,[1] Ashwani Malhotra,[1] Catherine Meyer-Schwesinger,[2] Pravin C. Singhal.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Medicine, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: MicroRNAs (miR) regulates gene transcription both in physiological and pathological conditions. Both parietal epithelial cells (PECs) and podocytes (PD) are derived from mesenchymal lineage during embryogenesis. miR-193a is highly expressed in matured PECs but least expressed in matured PDs. miR193a acts as a switch to determine the phenotype of both PDs and PECs via modulation of WT1, a master transcriptor of podocalyxin and nephrin. Recently, enhanced expression of miR-193a has been considered to play critical role in the development and progression of focal segmental sclerosis. However, the role of miR193a in the development of HIV associated nephropathy (HIVAN) has not been elucidated to date.

Methods: Renal tissues from 4 week old control (FVBN) and HIV transgenic mice (Tg26 mice on FVB/N background), 4 week old control and Vpr mice (treated with doxycycline for 6 weeks) were harvested. Human immortalized PECs and PDs were transduced with either HIV (NL4-3) or vector. A microarray-based approach in combination with real-time PCR to profile the miR expression patterns in HIV-1 transgenic mice. Both renal tissues and transduced cells were evaluated for expression of miR193a using the miRNeasy kits from Qiagen. Renal cortical sections of control and HIV mice were also evaluated for kidney cell expression of miR-193a utilizing *in situ* hybridization technique.

Results: 13 miRNAs, which belong to 11 miR families, were down regulated in HIVAN when compared with control mice. Expression of miR-193a was down regulated by 5 and 10 fold in renal tissues of Tg26 and Vpr transgenic mice, respectively. In situ hybridization studies revealed down regulation of miR193a in PECs in HIV transgenic mice. In vitro studies, HIV- transduced PDs as well as PECs displayed attenuated expression of miR193a when compared to respective vector-transduced cells.

Conclusions: HIV down regulates miR193 both in podocytes and PECs *in vitro* as well as *in vivo*.

PGC-1α Protects against Notch1-Induced Kidney Injury

Ji Min Park,[1] Boyoung Nam,[1] Meiyan Wu,[1] Jung Tak Park,[1,2] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Seung Hyeok Han,[1,2] Katalin Susztak.[3] *[1]Dept of Internal Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [3]Renal Electrolyte and Hypertension Div, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: PGC1α is known as a key regulator of energy metabolism and mitochondrial biogenesis. However, there is lacking of evidence on whether PGC1α provides a protective effect against kidney damage. This study evaluated the effect of PGC1α on kidney fibrosis using mice with tubule-specific double overexpression of Notch1 and PGC1α.

Methods: For animal study, we crossed mice expressing *Pax8-rtTA/tetO-ICN1* (N) with mice harboring *Pax8-rtTA/tetO-Ppargc1a* (P) to create *Pax8-rtTA/tetO-ICN1/tetO-Ppargc1a* (NP) mice. Using kidney tissues from these mice, we examined fibrotic changes, fatty acid oxidation pathway, and cell death. To delineate relationship between Notch1 and PGC1α,chromatin immunoprecipitation (ChIP) assay and luciferase assay were performed using primarily cultured tubular epithelial cells.

Results: Compared to control mice, normal renal architecture was lost and severe tubular dilatation and fibrosis developed in Nmice. In contrast, these findings were almost null in NP mice. Fatty acid oxidation was impaired in N mice and this alteration was significantly restored by PGC-1α overexpression. In addition, PGC-1α overexpression attenuated the increased apoptosis rate in N mice. ChIP assay revealed that the transcriptional repressor Hes1, a downstream target of Notch1 signaling, directly regulated PGC-1α in kidney tubular epithelial cells. Furthermore, Hes1 overexpression significantly inhibited *Ppargc1a* promoter–driven luciferase reporter activity.

Conclusions: Tubule-specific Notch1 overexpression decreased PGC-1α expression and impaired fatty acid oxidation, resulting in severe kidney fibrosis. Notch1-induced kidney injury was almost nullified by PGC-1α. In addition, PGC-1α was directly regulated by Notch signaling. Our findings suggest that restoring PGC-1α activity can be a promising therapeutic strategy in the management of chronic kidney disease.

Early Intervention through Induced Genetic Deletion of Cell Division Autoantigen 1 Attenuates Diabetes-Associated Renal Fibrosis

Pacific Huynh,[1,2] Aozhi Dai,[1] Tieqiao Wu,[1] Mark E. Cooper,[1,2] Zhonglin Chai.[1,2] *[1]Diabetic Complications, Baker IDI Heart and Diabetes Inst, Melbourne, Victoria, Australia; [2]Dept of Immunology, Monash Univ, Melbourne, Victoria, Australia.*

Background: CDA1 plays a key role in the development of diabetic nephropathy, where it enhances the profibrotic actions of the TGF-β signalling pathway. This was demonstrated *in vivo* where global CDA1 knockout mice exhibited an attenuation in renal fibrosis in a model of diabetic nephropathy. Whether inhibiting CDA1 activity after the development of disease can attenuate renal fibrosis has yet to be experimentally investigated. This study focuses on the effect of an early intervention by induced genetic deletion of CDA1 on the progression of renal fibrosis in a *streptozotocin* (STZ)-induced mouse model of diabetic nephropathy.

Methods: Male CDA1flox/ERCre mice were rendered diabetic and killed 10 weeks later for analysis of various metabolic and renal parameters. After 5 weeks of diabetes, these mice were administered either tamoxifen to delete the CDA1 gene or vehicle to leave CDA1 intact.

Results: Analysis showed that diabetic mice exhibited expected changes in metabolic parameters such as hyperglycemia, polyuria and renal hypertrophy. Tamoxifen administration, while having no effect on any metabolic parameters in both non-diabetic and diabetic CDA1flox/ERCre mice, led to a reduction of renal CDA1 mRNA expression of ~70-80% ($p<0.001$). Expression levels of profibrotic genes, such as fibronectin, collagen I and MMP2, were elevated by ~2.6-3.5 fold ($p<0.01$) in vehicle-treated/CDA1 "wildtype" diabetic mice. This increase was attenuated by ~40-70% ($p<0.05$) in CDA1 deficient diabetic mice. Additionally, renal extracellular matrix deposition as determined by Masson's Trichrome staining was increased ~40% in diabetic mice ($p=0.062$), and this increase was attenuated in CDA1 deficient mice.

Conclusions: In conclusion, reduction in CDA1 expression at an early stage of diabetic nephropathy is able to attenuate diabetes-associated renal fibrosis, emphasising the potent antifibrotic potential of utilizing this approach in diabetic nephropathy.

FR-PO168

Metformin-Induced Inhibition of Mammalian Target of Rapamycin (mTOR) Pathway Slows Down the Progression of HIVAN

Abheepsa Mishra,[1] Vinita Vishnoi,[1] Nairuti H. Shah,[1] Hanan K. Tawadrous,[2] Anil K. Mongia,[2] Seyedeh Shadafarin Marashi Shoshtari,[1] Judith Eng,[1] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Pediatrics, Down State Medical Center, Brooklyn, NY.*

Background: Since patients with HIV infection are now living almost a normal life style including the development of metabolic syndrome. we hypothesized that use of metformin in this population would not only control insulin resistance but would also slow down the progression of kidney lesions in HIV-associated nephropathy. To test our hypothesis, we studied the effect of meformin on the progression of renal lesions in a mouse model of HIVAN (doxycycline-inducible Vpr [podocyte specific] transgenic mice).

Methods: Vpr mice in groups of eight were fed either doxycycline with or without metformin for six weeks followed by evaluation for renal biomarkers (Blood urea nitrogen, urine protein:creatinine ratio, grading of severity of renal lesions and immunoblotting for phospho-mTOR and down stream molecular markers). In *in vitro* studies, mouse proximal tubular epithelial cells (MPTECs) were transduced with either empty vector (EV) or NL4-3 without *gag* and *pol* (HIV). EV/MPTECs or HIV/MPTECs were incubated in media containing either buffer or metfromin (0.5μM) for 48h. Protein blots of EV/MPTECs and HIV/MPTECs were probed for phospho-mTOR, phospho-p70S6 kinase, phospho-eEF2, p-eIF4B, and p-4EBP-1. The same blots were stripped and reprobed for actin.

Results: Vpr mice displayed sclerotic glomerular lesions, microcyst formation, proteinuria and activation of mTOR pathway; metformin not only attenuated proteinuria but also decreased severity of renal lesions. Moreover, metformin downregulated activation of the mTOR pathway. In vitro studies, protein blots of HIV/MPTEC displayed 2-fold increase in phospho-mTOR, 2.5-fold increase in phospho-p70S6K, and 2-fold increase both in p-eIF4B and p-4EBP-1when compared to EV/MPTECs. On the other hand, metformin inhibited HIV-induced mTOR phosphorylation and associated down stream signaling.

Conclusions: Metformin slows down the progression of HIVAN through down regulation of mTOR pathway.

The Effects of Aminophylline and Adenosine on the Tubular Damage Induced by Methotrexate in the Rats

Harun Akar,[1] Emin Taskiran,[1] Dilek Taskiran,[2] Oytun Erbas.[3] *[1]Internal Medicine, Tepecik Education and Research Hospital, Izmir, Turkey; [2]Physiology, Ege Univ, Izmir, Turkey; [3]Physiology, Bilim Univ, Istanbul, Turkey.*

Background: Methotrexate (MTX causes kidney damage in high doses. Adenosine is recently suggested in the prevention of tubular damage associated with diabetic nephropathy. Aminophylline is a potent peripheral vasodilator possibly due to adenosine receptor antagonism. We aimed to investigate the potential of adenosine and aminophylline for preventing MTX-induced renal tubular damage.

Methods: Twenty-eight Sprague-Dawley adult male rats were included in the study. No drug was administered to 7 rats (n=7), which served as controls. Twenty one rats were administered a single dose of 20mg/kg intraperitoneal injection of MTX to induce MTX toxicity. 21 rats with MTX toxicity were divided into 3 groups; one group was treated with 1 ml/kg saline/day (MTX + saline) intramuscularly for 5 days, second group was treated with 4 mg/kg/day adenosine (MTX + adenosine) intramuscularly for 5 days, third group was treated with 50mg/kg/day aminophylline (MTX + aminophylline) intramuscularly for 5 days. At the end of the fifth day, all animals were euthanized and blood and urine samples were collected. BUN and creatinine were measured in plasma samples. Kidneys were harvested for histopathological tubular damage scoring, determination of renal malondialdehyde (MDA) , and glutathione (GSH). Urine was examined by dipstick for proteinuria.

Results: n MTX + saline group, proteinuria, plasma BUN, creatinine, renal malondialdehyde (MDA) levels and proximal tubular damage score were found significantly increased compared to controls ($p<0.05$). In MTX + adenosine group, plasma creatinine and proximal tubular damage score were found significantly increased compared to MTX + saline group. In MTX + aminophylline group, proteinuria, plasma BUN, creatinine levels and proximal tubular damage score were found significantly decreased compared to MTX + saline and MTX + adenosine groups ($p<0.05$).

Conclusions: Aminophylline reduced proximal tubular damage score induced by MTX and aminophylline may be an useful therapeutic agent for preventing MTX toxicity.

FR-PO170

Sirt1 Prevents Age-Associated Kidney and Cardiac Dysfunction Ashley R. Bellin,[1,2] Yanling Zhang,[1] Kim Connelly,[1,2] Richard E. Gilbert.[1,2] *[1]Li Ka Shing Knowledge Inst, St. Michael's Hospital, Toronto, ON, Canada; [2]Univ of Toronto, Toronto, ON, Canada.*

Background: Aging is a major contributing factor to both chronic kidney disease (CKD) and heart failure (HF). Sirtuin 1 (Sirt1), an NAD^+-dependent lysine deacetylase, mediates health span extension in a wide range of organisms, and has been shown to be downregulated in both CKD and HF. Accordingly, we hypothesized that a genetically engineered diminution in Sirt1 activity may accelerate cardio-renal aging.

Methods: To test this hypothesis, we compared wild type CD1 mice with $Sirt1^{Y/Y}$ mice that have undetectable Sirt1 catalytic activity, examining both young (4 week) and old (14 month) animals. Glomerular filtration rate (GFR) was assessed by FITC-inulin clearance, and cardiac function was assessed using conductance catheterization. At termination, kidneys were perfusion-fixed with formalin, paraffin embedded, and stained with hematoxylin and eosin for glomerular counting.

Results: When compared with their wild type counterparts and indexed to body weight, catalytically inactive $Sirt1^{Y/Y}$ mice had lower GFR ($p=0.0004$) with fewer glomeruli ($p=0.0005$) at both time points.

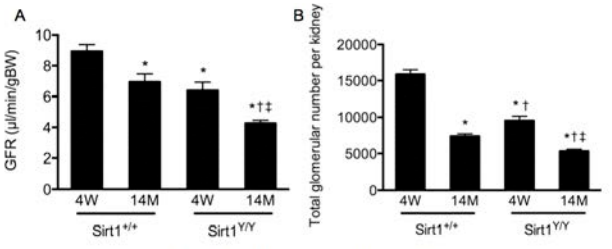

Figure 1: Comparison of the $Sirt1^{+/+}$ wild type mice and the catalytically inactive $Sirt1^{Y/Y}$ mice at 4 week and 14 month time points in regards to (A) GFR and (B) total glomerular number per kidney. * $p<0.05$ vs 4W $Sirt1^{+/+}$, † $p<0.05$ vs. 14M $Sirt1^{+/+}$, ‡ $p<0.05$ vs. 4W $Sirt1^{Y/Y}$.

Kidney weight was also lower in the $Sirt1^{Y/Y}$ mice ($p<0.0001$). Blood pressure, urinary albumin excretion, and heart weight were, however, similar in wild type and $Sirt1^{Y/Y}$ mice. Measures of cardiac function, including stroke volume (10.2±1.1 vs. 6.5±0.4µl, $Sirt1^{+/+}$ vs. $Sirt1^{Y/Y}$, $p=0.01$), ejection fraction (40.1±4.2 vs. 25.9±3.9%, $p=0.03$), and cardiac output (44±5 vs. 30±2ml/min, $p=0.02$), were lower in the 14 month $Sirt1^{Y/Y}$ mice.

Conclusions: These findings indicate that Sirt1 is both a determinant of glomerular endowment and age-associated cardio-renal disease. Strategies that increase the abundance or activity of Sirt1 may offer a new therapeutic approach to CKD and concomitant cardiac complications.

FR-PO171

Functional Characterization of the Role of the Transcription Factor Grhl2 in Cystic and Neoplastic Kidney Diseases Zeliha Yesim Yurtdas,[1,2,3] Peter Boor,[4] Klaus Jung,[3,5] Kai M. Schmidt-Ott.[1,2] *[1]Max-Delbrück Center for Molecular Medicine, Berlin, Germany; [2]Dept of Nephrology, Charité Universitätsmedizin, Berlin, Germany; [3]Berlin Inst for Urologic Research, Berlin, Germany; [4]Inst of Pathology & Dept of Nephrology, Univ of Aachen, Aachen, Germany; [5]Dept of Urology, Charité Universitätsmedizin, Berlin, Germany.*

Background: Cystic and neoplastic kidney diseases are characterized by a dysregulation of epithelial morphogenesis and epithelial hyperproliferation. Grainyhead-like 2 (GRHL2) is a transcription factor specifically expressed in distal and collecting duct epithelia of the kidney. We have previously shown that Grhl2 regulates epithelial morphogenesis and barrier formation and controls lumen expansion of kidney tubules. However, the functional role of GRHL2 in kidney disease remains unknown.

Methods: We conducted a comprehensive immunohistochemical analysis of GRHL2 expression in patient samples with renal carcinomas and cystic kidney disease and in parallel, studied GRHL2 functionally in genetic mouse models.

Results: GRHL2 expression was upregulated in chromophobe carcinomas and oncocytomas when compared with other renal carcinomas and its expression was partially lost in cyst-lining epithelia in ADPKD. To assess the role of GRHL2 in cystic and neoplastic kidney diseases *in vivo*, the proto-oncogene MYC was conditionally overexpressed in the collecting duct (HoxB7Cre;R26StopFLMYC). These mice developed cysts with epithelial hyperplasia which tended to transform to adenomas. Both cysts and adenomas displayed strong Grhl2 expression and were primarily derived from intercalated cells of the collecting duct as shown by their positivity for VATPaseB1/B2. Furthermore, conditional deletion of Grhl2 in the kidneys of these mice (HoxB7Cre; R26StopFLMYC; Grhl2 flox/flox) resulted in a marked aggravation of cyst development. While HoxB7Cre; R26StopFLMYC mice survived to advanced ages, HoxB7Cre; R26StopFLMYC; Grhl2 flox/flox mice died of renal failure 5 weeks of age, displaying massively expanded cysts.

Conclusions: Our data indicate that Grhl2 is strongly expressed in collecting duct epithelia-derived cysts and neoplasms and acts as a gatekeeper of epithelial hyperproliferation and uncontrolled cyst expansion.

Anti-Angiogenic Factors Regulate the Cytoprotective Thrombomodulin Pathway in the Kidney In Vitro and In Vivo Manon Bos,[1] Rosanne Jane Turner,[1] Maria Elisabeth Penning,[1] Pascal Bus,[1] Aiko P.J. De Vries,[2] Marion Scharpfenecker,[1] Lukas J. Hawinkels,[4] Kitty Bloemenkamp,[3] Jan A. Bruijn,[1] Hans J. Baelde.[1] *[1]Pathology, LUMC, Netherlands; [2]Nephrology, LUMC, Netherlands; [3]Gastroenterology-Hepatology, LUMC, Netherlands; [4]Obstetrics, UMCU, Netherlands.*

Background: An excess of angiogenic factors is associated with a variety of renal syndromes, e.g. preeclampsia and diabetic nephropathy. Levels of soluble thrombomodulin increase in these syndromes, but if endothelial thrombomodulin changes and if this affects anti-coagulative and cytoprotective signalling in the kidney is unknown. Hence, we investigated thrombomodulin signalling in patients and experimental models of preeclampsia and diabetic nephropathy.

Methods: HUVECs were treated with VEGF or soluble Flt-1. Kidneys from 12 mice treated with endoglin or VEGF receptor neutralizing antibodies and from 5 pigs with metabolic syndrome after a high-fat diet, 5 pigs diabetic after streptozotocin injection and 5 control pigs were collected. Kidney tissue from 22 pregnant women and 11 preeclampsia patients was collected. Gene expression of thrombomodulin, endothelial protein C receptor (EPCR) and tissue factor was measured with qPCR. Thrombomodulin protein expression was investigated with immunohistochemistry.

Results: sFlt-1 decreased endothelial thrombomodulin *in vitro*. Glomerular thrombomodulin protein was increased in diabetic pigs and in mice treated with anti-angiogenic compounds. In diabetic pigs, thrombomodulin, EPCR, and VEGF mRNA increased (all $P<0,05$), which correlated inversely with tissue factor mRNA. In preeclampsia, glomerular thrombomodulin was increased compared to pregnant controls and this correlated with podocyte nephrin expression (both $P<0.01$).

Conclusions: Angiogenic factors regulate renal thrombomodulin expression, *in vitro* and *in vivo*. Increased thrombomodulin expression is accompanied by less tissue factor expression and increased podocyte nephrin expression, indicative of a protective effect on the glomerulus. These results indicate an attempt of glomerular endothelial cells to maintain cytoprotection; investigating pathways through which thrombomodulin expression is increased in endothelial cells could reveal clues to restore or prevent endothelial kidney damage.

VEGFR1 Neutralization Reverses Murine Diabetic Nephropathy Zhonghua Qi, Dianna L. Jaqua, Yuan Su, Martin S. Cramer, Bhaskarjyoti Sarmah, Shannon Marie Harlan, Tamer Coskun, Kathleen Heinz-Taheny, Josef G. Heuer, Ying Tang, Matthew D. Breyer. *Eli Lilly and Company, Indianapolis, IN.*

Background: The role of VEGFA in the pathogenesis of renal disease remains controversial. The proangiogenic effects of VEGFA are primarily mediated by its receptor VEGFR2 whereas these effects are antagonized by ligand binding to its inhibitory receptor VEGFR1 (flt1).

Methods: A specific VEGFR1 monoclonal antibody (MF1) was studied in CKD mice.

Results: The present study demonstrated that MF1 dramatically improved albuminuria and renal histology in three distinct mouse models of CKD including uninephrectomized db/db mice, $eNOS^{-/-}$ db/db mice, and 129S6 remnant kidney mice. MF1 treatment increased circulating VEGFA levels consistent with ligand displacement from VEGFR1, and this was accompanied by increased renal VEGFR2 phosphorylation, suggesting VEGFR2 activation. Interestingly MF1 treatment was accompanied by a sustained decrease in blood pressure of approximately 10mmHg in both db/db and $eNOS^{-/-}$ db/db mice receiving MF1, showing that the decreased blood pressure was not exclusively dependent on the downstream activation of eNOS by VEGFR2. In contrast to previous reports, we found blocking either VEGFA or VEGFR2 via administration of neutralizing antibodies to VEGFA or VEGFR2 (DC101) worsened albuminuria and renal histological injury scores in db/db mice, an effect consistent with clinical observations of proteinuria and hypertension following treatment with Bevacizumab (Avastin). VEGFR1 blockade with MF1 also protected $eNOS^{-/-}$ db/db mice from serum creatinine (Scr) increases and significantly reduced mortality in these

mice. The effects of MF1 were not dependent on the VEGFR1 tyrosine kinase (tk) domain since treatment of VEGFR1 tk-/tk- remnant kidney mice with MF1 didn't significantly impair its beneficial effects on albuminuria and renal histology.

Conclusions: These data demonstrate monoclonal antibody VEGFR1 blockade prevents renal failure progression by increasing VEGFA and VEGFR2 activity in diverse mouse models of kidney disease. These findings are consistent with recent observations of reduced VEGFA levels in human DN and suggest they may contribute to the pathogenesis of DN.

Bone Marrow Myeloid Progenitor Cells Are Contributing to a Wide Variety of suPAR Associated Kidney Diseases

Eunsil Hahm,[1] David Changli Wei,[1] Jing Li,[1] Nicholas J. Tardi,[1] Shikha Wadhwani,[1] Yanxia Cao,[1] Vasil Peev,[1] Christopher Lund O'Connor,[2] Markus Bitzer,[2] Vineet Gupta,[1] Sanja Sever,[3] Jochen Reiser.[1] *[1]Rush Univ; [2]Univ of Michigan; [3]Massachusetts General Hospital.*

Background: Systemic soluble urokinase plasminogen activator receptor (suPAR) is implicated in the onset and progression of chronic kidney disease (CKD). To investigate the potential relevance of suPAR in other renal diseases, we examined the levels of suPAR and Gr-1^{lo} bone marrow (BM) myeloid cells in multiple animal models of proteinuria.

Methods: Bone marrow transplantation (BMT), adoptive transfer, ELISA, and flow cytometric analysis were performed.

Results: BM chimera and adoptive transfer studies revealed that hematopoietic cells, specifically BM myeloid cells, are responsible for suPAR production and proteinuria development in lipopolysaccharide (LPS)-induced proteinuric mouse model. In this model, BM myeloid cells increased uPAR expression , and LPS stimulation led to a significant increase in the percentage of Gr-1^{lo} cells in the BM. Next, we examined the levels of suPAR and Gr-1^{lo} BM myeloid cells in 5 additional animal models of proteinuria. i) A genetic model of podocyte injury (Pod-Rac1), in which podocyte-specific Rac1 activation causes podocyte dysfunction, ii) Adriamycin (ADR)-induced nephropathy, iii) Albumin TGF β_1 transgenic (TGF β_1 Tg) mice, iv) Nephrotoxic serum (NTS) nephritis, and v) BTBR *ob/ob* diabetic mice with nephropathy. All tested animals exhibited proteinuria. Unlike LPS model, Pod-Rac1 and ADR models, in which podocytes are the direct target of injury, were not characterized by elevated systemic suPAR levels. There was also no change in the BM Gr-1^{lo} cell population. In contrast, TGF β_1 Tg, NTS, and BTBR *ob/ob* mice, showed elevated suPAR levels, which was accompanied by an expansion in Gr-1^{lo} BM myeloid cells. Transplantation of BM from healthy into NTS mice ameliorated the degree of kidney disease.

Conclusions: Expansion of Gr-1^{lo} BM myeloid cells and their overproduction of suPAR may represent a common upstream event in immunologically associated kidney disease with high systemic suPAR. BM transplantation may be one new therapeutic strategy to combat a disturbed BM-kidney disorder.

Synergism of CD40 Autoantibodies and suPAR in FSGS Recurrence

Tara Sigdel,[1] David Changli Wei,[2] Flavio Vincenti,[1] Jochen Reiser,[2] Minnie Sarwal.[1] *[1]Surgery, UCSF; [2]Medicine, Rush Univ.*

Background: FSGS is a histopathological lesion leading to end stage kidney disease requiring dialysis and transplantation. Primary FSGS however has a 40-80% risk of recurrence of disease in the transplanted kidney, with resultant accelerated graft loss. The disease pathophysiology has been difficult to unravel despite a large body of evidence suggesting a role of circulating factors. Recent studies in recurrent FSGS (rFSGS) suggested a potential role suPAR and CD40 auto-antibody (autoAb) isolated from the sera of FSGS patients.

Methods: We evaluated affinity in between CD40 autoAb isolated from rFSGS patients with suPAR and synergistic role of suPAR and CD40 Ab from rFSGS in rodent model in causing kidney damage in terms of proteinuria. Anti-CD40 autoAb isolated from rFSGS and non-recurrent FSGS (nrFSGS) were injected (i.v.) to C57BL/6 mice with predetermined amount of CD40 autoAb isolated from rFSGS and nrFSGS. Injection of CD40 autoantibody was given 6 times, every other day. Six hours after the last dose of CD40 autoantibody, recombinant human suPAR protein was given i.v. at 5 µg/ml to all mice in order to analyze the additive effect of suPAR on proteinuria. Urine was collected before and every day after the first injection of CD40 autoantibody to analyze urinary albumin and creatinine. Surface plasmon resonance (SPR) was used to find affinity in among autoAbs, suPAR and integrin αvβ3.

Results: There was an increase in proteinuria (p=0.04) with the injection of CD40 auto Ab from rFSGS. The injection of suPAR along with CD40 autoAbs from rFSGS increased proteinuria significantly compared to CD40 autoAb alone (p=0.004). CD40 autoAbs isolated from rFSGS, nrFSGS patients directly demonstrated affinity towards integrin αvβ3 as a similar binding affinity (KD = ~26 to 84 nM). Only human CD40 autoAb from rFSGS have specific interaction as the RUmax values of those from nrFSGS and no-FSGS patients are small. Only human CD40 autoAbs from rFSGS patient, not from nrFSGS patients had specific affinity to suPAR.

Conclusions: Through this study we demonstrated that suPAR and CD40 autoAbs from rFSGS can aggravate proteinuria in mouse model and suPAR exhibits specific affinity to CD40 autoAbs isolated from rFSGS.

FR-PO176

PPARα and PPARγ Attenuate the Anti-Glomerular Basement Membrane Glomerulonephritis through the Actions on the Different Inflammatory Cells, T Cells and Macrophages

Yusuke Okabayashi, Go Kanzaki, Ai Katsuma, Takafumi Kanemitsu, Michiko Aoki, Yusuke Kajimoto, Dedong Kang, Kiyotaka Nagahama, Akira Shimizu. *Dept of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Background: Peroxisome proliferator activated receptor-alpha (PPARα) and -gamma (PPARγ) agonists modulate inflammatory responses and attenuate the renal injury in glomerular diseases, but the mechanisms are not well understood. In this study, we examined the protective effects of PPARα and PPARγ agonists, fenofibrate and pioglitazone, in anti-glomerular basement membrane glomerulonephritis (anti-GBM GN) characterized by the invasion of Inflammatory cells such as macrophages and CD8+ T cells.

Methods: Male Wister-Kyoto rats at 5 weeks of age were divided into 7 groups and received fenofibrate (30, 100, 300mg/kg/day), pioglitazone (12.5, 50, 100mg/kg/day) or vehicle (control) the day before induction of anti-GBM GN. At 7 days after the induction, 24-hr urine samples were collected and the kidneys were harvested. The expression of cytokines, chemokines and cell surface markers in isolated glomeruli were evaluated by real time PCR analysis.

Results: Both the treatments reduced the level of proteinuria, glomerular infiltration of CD8+ T cells and ED1+ macrophages and prevented the development of necrotizing and crescentic lesions dose dependently. Notably, pioglitazone showed greater reduction in infiltration of ED1+ macrophages with down-regulation of the M1 macrophage marker including TNF-α, IL-1β and iNOS, and increase in infiltration of ED2+ M2 macrophages with up-regulation of the M2 macrophage marker, TGF-β and mannose receptor. In contrast, fenofibrate showed greater reduction in infiltration of CD8+ T cells and up-regulation of Th2 cell-associated cytokines, IL-4 and IL-10.

Conclusions: PPARα and PPARγ dose-dependently attenuated glomerular inflammation in anti-GBM GN through the regulation of the different inflammatory cells. Our results suggested that PPARα suppresses CD8+ T cell infiltration with increase in the production of Th2 anti-inflammatory cytokines, and PPARγ suppresses inflammatory macrophage infiltration with promotion of the anti-inflammatory macrophage infiltration.

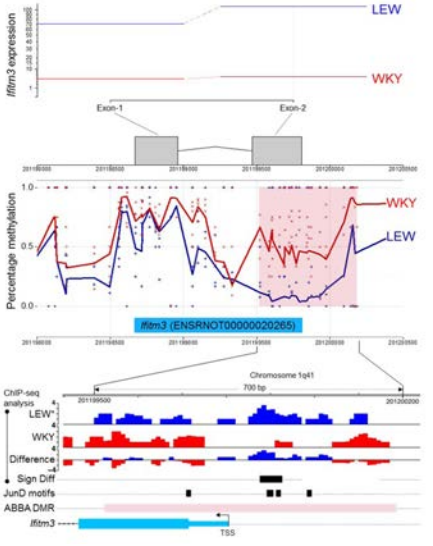
Whole Genome Transcriptome, Methylome, and Transcription Factor Binding in Nephrotoxic Nephritis

Thomas Oates,[1] Owen J.L. Rackham,[2] Sarah R. Langley,[2] Jacques Behmoaras,[3] Enrico Petretto.[2] *[1]UCL Centre for Nephrology, Univ College London, London, United Kingdom; [2]Duke-NUS Medical School, Singapore; [3]Imperial College London, United Kingdom.*

Background: Nephrotoxic nephritis (NTN) is a macrophage dependent model of crescentic glomerulonephritis in which the Wistar-Kyoto (WKY) rat is susceptible to disease and the Lewis (Lew) rat is resistant. Previous work has suggested a role for the AP-1 transcription factor (TF), JunD, in the pathogenesis of NTN. TFs are fundamental regulators of gene expression but additional regulation may result from local methylation of DNA cytosine bases. Given the interaction between TF activity, DNA methylation and gene expression, we integrated distinct whole-genome datasets to try and identify novel determinants of NTN pathogenesis.

Methods: DNA methylation data were produced in WKY and Lew bone marrow-derived macrophages (BMDMs) by whole genome shotgun bisulphite sequencing and integrated with previously generated RNA-seq, and JunD ChIP-seq data.

Results: We identified 1,004 genomic regions that showed differential methylation between WKY and Lew BMDMs. 427 of these regions overlapped with known genes and integration with RNA-seq data elucidated three genes that showed differential expression and differential methylation within their promoter region. Using the ChIP-seq dataset, we also found that, interferon-induced transmembrane protein 3 (*Ifitm3*), had differential binding of JunD within its promoter.



Conclusions: Integration of distinct whole genome datasets in NTN allows consideration of multiple determinants of gene expression and has revealed a potential new candidate gene (*Ifitm3*) for glomerulonephritis susceptibility.

FR-PO178

The Association and Its Mechanism between Microbiota Alteration and Intestinal-Barrier Function in Mice with Chronic Renal Failure Seiji Itano, Minoru Satoh, Yuji Sogawa, Atsushi Uchida, Kengo Kidokoro, Hajime Nagasu, Tamaki Sasaki, Naoki Kashihara. *Dept of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: The intestinal microbial flora consists of diverse bacterial species. These bacteria are necessary for the ontogeny, regulation of the immune system, and for intestinal homeostasis. Alterations of the intestinal barrier and intestinal bacterial flora in chronic kidney disease have been reported to affect uremic toxin influx. Antimicrobial peptides contribute to maintenance of microbiota. We examined the mechanisms of the mutual relation between intestinal bacterial flora and intestinal-barrier function by using a mouse model of chronic renal failure.

Methods: We used 13-week-old male ICR-derived glomerulonephritis (ICGN) mice as the renal-failure group and ICR mice as the control group. Gene expression patterns of the whole bacterial flora in the intestine were analyzed by means of terminal restriction fragment length polymorphism. Fecal and serum bacterial products (phenol, para-cresol, indole/indole sulfate, and skatole) were examined by quantitative chemical analysis. Intestinal tight junction protein (occludin or claudin-1) and glycocalyx were evaluated by immunostaining of the ascending colon. Expression levels of antimicrobial-peptide genes (defensin beta-1, 2, and 3) in the colon were measured by quantitative polymerase chain reaction (PCR).

Results: The proportion of pathogenic bacteria *Clostridium* increased while that of the opportunistic pathogen *Bacteroides* decreased in the intestinal bacterial flora of ICGN mice. Fecal bacterial products phenol and para-cresol were upregulated in the feces of ICGN mice, but indole concentration remained unaffected. On the other hand, serum indoxyl sulfate was upregulated in ICGN mice. Intestinal tight junction and glycocalyx were impaired in ICGN mice. The mRNA expression levels of defensins beta-1 and beta-3 in the ascending colon decreased in ICGN mice compared to those in the control mice.

Conclusions: The intestinal bacterial flora was altered and tight junctions were impaired in mice with chronic renal failure. Defensins beta-1 and beta-3 may contribute to these changes in bacterial flora.

FR-PO179

Acetate from Microbiota Contributes to Tubulo-Interstitial Inflammation and Fibrosis in Lupus Nephritis Daniel Tak Mao Chan, Qing Zhang, Mel Chau, Ping Lung Chan, Susan Yung. *Dept of Medicine, The Univ of Hong Kong, Hong Kong.*

Background: The gut microbiota is implicated in the pathogenesis of autoimmune diseases. Bacterial products could gain access into the bloodstream and exert effects on distant organs. Acetate is a short chain fatty acid (SCFA) produced by gut microbiota. We previously reported that lupus nephritis patients had higher serum acetate levels compared with healthy controls, and acetate level correlated with activity of nephritis. We further investigated the role of acetate and its receptors in inflammatory and fibrotic processes in murine lupus and cultured proximal renal tubular epithelial cells.

Methods: Renal expression of SCFA receptors GPR-41 and GPR-43 was investigated in NZBWF1 mice with progressive lupus nephritis. HK-2 cells were incubated with acetate (1-50mM) or serum-free medium for 24h, and the secretion of IL-6, IL-8 and MCP-1, and expression of fibronectin and laminin determined.

Results: GPR-41 and GPR-43 expression was markedly increased in NZBWF1 mice with active nephritis, and was predominantly localized in the tubulo-interstitium. Acetate induced ERK, p38 MAPK and JNK phosphorylation in HK-2 cells, accompanied by increased IL-6, IL-8 and MCP-1 secretion. The expression of GPR-41, GPR-43, fibronectin and laminin expression was also induced by acetate in a time- and dose-dependent manner. GPR-41 and GPR-43 upregulation was mediated in part through IL-6, IL-8 and MCP-1, which in turn increased fibronectin synthesis through activation of MAPK and PI3K signaling pathways.

Conclusions: The results show that acetate from microbiota may contribute to tubulo-interstitial inflammation and fibrosis in lupus nephritis.

Funding: Government Support - Non-U.S.

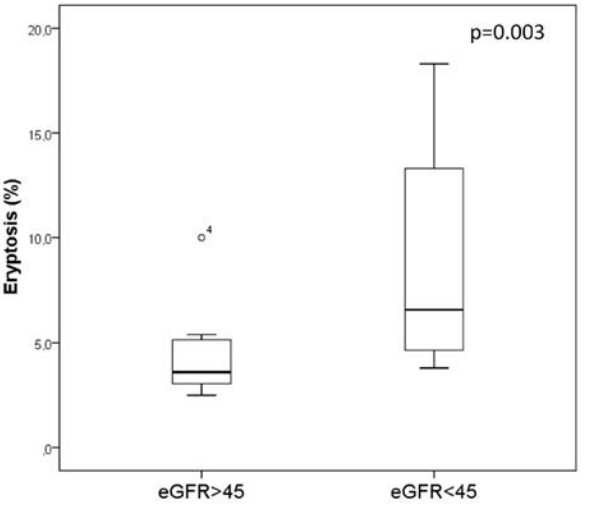
Mechanisms and Pathophysiological Significance of Eryptosis in Chronic Kidney Disease and Anemia Grazia Maria Virzì, Alessandra Brocca, Anna Clementi, Massimo de Cal, Claudio Ronco. *IRRIV.*

Background: Anemia is a common complication of CKD resulted from compromised erythropoiesis or decreased lifespan of erythrocytes(RBCs). Eryptosis, suicidal death of RBCs, is characterized by cell shrinkage and membrane scrambling with phosphatidylserine (PS)-exposure at the RBC surface. Exposed PS is recognized by macrophages that engulf and degrade the affected cells. Enhanced eryptosis is observed in CKD, which invariably leads to anemia. The purpose of this study was to assess and study eryptotic changes in RBC exposed in vitro to uremic toxins and CKD patients'plasma.

Methods: RBC from healthy subject were incubated at a hematocrit of 0.4% in RPMI solution with different concentrations of uremic toxins and with plasma from CKD patients for 24hours. CKD patients were divided in 2groups(eGFR>or<45ml/min/1.73m^2). RBC volume and morphology was estimated, PS exposure was estimatetestedd by AnnexinV-binding by flow cytometric. Each experiment was tested 5times.

Results: Increasing concentrations of uremic toxins significantly modify RBCs volume, dramatically derange their morphology and progressively enhance the percentage of PS in vitro. Moreover, the median values of eryptosis showed significant differences between the 2CKD groups.The RBCs exposed to CKD plasma from patients with eGFR<45ml/min/1.73m^2 show strong eryptotic changes and high eryptosis(p=0.003).Eryptosis increases with CKD progression.



P-cresol (mg/l)	0	5	15	20	30	40	60
Median Eryptosis %	2.7	6.4	22.1	38.9	54.8	83.5	99
Urea (mg/l)	0	50	100	150	200	250	300
Median Eryptosis %	2.3	5.4	7.9	8.7	12	19.3	24

Conclusions: In conclusion, uremic toxins induce morphological changes in RBCs and stimulate eryptosis in vitro. Increasing concentrations of these uremic toxins and their additive combination in vivo may be responsible for higher eryptosis that leads to anemia in CKD. CKD plasma contains components which trigger an increasing eryptosis;different stages of CKD may induce different levels of RBC death. Our data suggests that progression of CKD may progressively increase eryptosis and anemia in vivo.

Enzymatic Active and Inactive Ubiquitin C-Terminal Hydrolase L1 (UCH-L1) Exert Differential Effects in Podocytes Julia Reichelt, Anna Reinicke, Jan Hendrik Knop, Catherine Meyer-Schwesinger. *Nephrology, Internal Medicine, Univ Medical Center Hamburg-Eppendorf.*

Background: UCH-L1 is a major deubiquitinating enzyme of the central and peripheral nervous system. Biochemically, UCH-L1 is thought to regulate the intracellular pool of monoubiquitin, required for ubiquitination procedures. In the central nervous system oxidative-modifications and mutations (such the I93M point mutation) of UCH-L1 result in enzymatic inactivity of UCH-L1. These conditions are associated with the development of neurodegenerative disease. We could demonstrate a de novo expression of UCH-L1 in podocytes in patients with membranous nephropathy. Chemical inhibition of the enzymatic activity of UCH-L1 in a rat model of membranous nephropathy attenuated podocyte injury by increasing proteasomal activity and reducing the accumulation of polyubiquitinated proteins.

Methods: In an attempt to dissect the function of UCH-L1 in the development of podocyte injury in membranous nephropathy, we specifically overexpressed enzymatic-active (wildtype) and -inactive (I93M) UCH-L1 in podocytes in mice. We first investigated the basic phenotype of these mice by morphological and biochemical analyses. Furthermore, we investigated the effects of inducible overexpression of wildtype and I93M point mutated UCH-L1 in cultured podocytes.

Results: Inducible overexpression of I93M UCH-L1 in cultured podocytes resulted in increased levels of monoubiquitin and polyubiquitin partly through increased transcription of ubiquitin precursor proteins. No changes in ubiquitin levels were observed in podocytes overexpressing wildtype UCH-L1. Specific analyses of proteins that were polyubiquitinated in I93M-overexpressing cultured podocytes demonstrated that I93M overexpression resulted in an enhanced K48-polyubiquitination and degradation of alpha-actinin-4. In mice, overexpression of wildtype enzymatic active UCH-L1 resulted in podocyte loss and the development of proteinuria with increased proteasomal activity. Astonishingly, overexpression of enzymatic inactive I93M UCH-L1 on the other hand reduced podocyte-loss and proteinuria and decreased proteasomal activity.

Conclusions: UCH-L1 influences podocyte integrity and function through its enzymatic activity.

FR-PO182

Long-Term Selective ETA Receptor Antagonism Prevents Renal Injury in Humanized Sickle Cell Mice Malgorzata Kasztan, Carmen De Miguel, Jennifer S. Pollock, David M. Pollock. *Dept of Medicine, Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Elevated plasma endothelin-1 (ET-1) levels reported in sickle cell disease (SCD) patients correlate with microalbuminuria, suggesting a pathophysiological link between ET-1 and sickle nephropathy (SN). The current study was designed to determine if early intervention with an endothelin antagonist would prevent renal injury in a mouse model of SN.

Methods: Humanized sickle cell mice (HbSS) and genetic controls (HbAA) were treated with ambrisentan (ET_A antagonist), A-182086 ($ET_{A/B}$ antagonist) (10mg/kg/day) or vehicle for 10 weeks (beginning at the time of HbF to HbS switch into adulthood).

Results: Chronic administration of ambrisentan prevented histo-pathological lesions including hyperthrophy, sclerosis, vascular congestion and tubulointerstitial fibrosis, as well as preserved brush border thickness in HbSS mice. Also, ambrisentan reduced tubular iron deposition in HbSS mice (3.5±0.5 vs. 7.1±0.6 Mpixel/μm), and was associated with similar levels of urinary NGAL, tubular iron binding protein, compared to non-disease HbAA mice (33.3±3.3 and 29.2±9.9 in HbAA vs. 107.5±28.4 ng/24 in untreated HbSS). Correspondingly, functional analysis of renal injury revealed that ambrisentan prevented nephrinuria (15.4±3.9 vs. 53.9±5.5 μg/24h), albuminuria (16.7±3.3 vs. 67.0±18.9 μg/24h), proteinuria (1.1±0.3 vs. 3.57±0.8 mg/24h), as well as preserved glomerular permeability to albumin (0.14±0.03 vs. 0.52±0.04), GFR (231±13 and 233±8 μm/min in HbAA) and excretion of markers of tubular injury (NAG: 5.8±2.1 and 5.4±2.5 in HbAA vs.14.5±1.2 mU/24h in HbSS; KIM-1: 90.5±23.9 and 24.2±10.7 in HbAA vs. 285.3±90.3 pg/24h in HbSS) to the levels of non-disease controls. The dual $ET_{A/B}$ antagonist had some effect to reduce glomerular injury markers (nephrin, P_{alb}), but no effect on the changes in renal structure and function in HbSS mice.

Conclusions: ET-1 contributes to SN via ET_A receptor activation and long-term ET_A receptor antagonism may provide a strategy for the prevention of renal complications of SCD.

FR-PO183

Topiroxostat, a Novel Xanthine Oxidase Inhibitor, Exerts Renoprotective Role via Antioxidant Effects in Puromycin Aminonucleoside Nephrotic Rats Yosuke Kawamorita, Yoshifuru Tamura, Shigeru Shibata, Shunya Uchida. *Teikyo Univ School of Medicine, Tokyo, Japan.*

Background: Topiroxostat (Topi) is a newly developed drug for gout and hyperuricemia belonging to xanthine oxidase inhibitor (XOI) like allopurinol. It has been proposed that allopurinol not only reduces serum uric acid (UA) level but also urine protein excretion in puromycin-aminonucleoside (PAN) nephrotic rats. Topi may decrease urine protein excretion (UPE) in addition to hypouricemic action. In the present study we aimed to examine change in UPE in response to Topi and its molecular mechanism using PAN rats.

Methods: PAN nephrosis was induced by a single intraperitoneal injection of PAN (10 mg/100 g body weight). Rats were divided into four groups: Control rats (Cont); PAN rats (PAN); Control rats with Topi 0.5 mg/kg/day (Topi); PAN rats treated with Topi (PAN + Topi).

Results: Topi significantly decreased tissue UA in the kidney cortex and UPE by 30% at day 10 after PAN injection. To elucidate the protective effect of Topi we focused on the oxidative stress in the kidney. Firstly, PAN significantly decreased the number of WT-1-positive podocytes and reduced podocin immunoreactivity, both of which were partially improved by Topi. Next, nitrotyrosine and 8-OHdG in the kidney induced by PAN were significantly decreased by Topi treatment. Moreover, increased amounts of XO and NOX4 in the cortex induced by PAN were completely reverted in response to Topi. Of note was that serum UA did not vary significantly.

Rats	Tissue uric acid	Urinary protein at 10 days	Oxidative stress markers		
(n = 6)	mg/day	mg/day	Nitrotyrosine	NOX4	Xanthine oxidase
Cont	0.76 ± 0.34	7.3 ± 5.5***	1.00 ± 0.15**	1.00 ± 0.25	1.00 ± 0.06**
PAN	1.42 ± 0.35	308.2 ± 130.8	2.86 ± 1.29	2.57 ± 0.50	2.80 ± 1.58
Tx	0.78 ± 0.19	9.6 ± 7.5***	0.94 ± 0.32**	0.72 ± 0.27**	1.25 ± 0.49*
PAN + Tx	0.87 ± 0.21	201.7 ± 83.0*	1.58 ± 0.72*	1.56 ± 0.52**	1.35 ± 0.33*
*P<0.05, **P<0.01, ***P<0.001 vs. PAN.					

Conclusions: Topi ameliorates proteinuria and renal injury apart from serum UA in PAN rats, thus Topi may play a renoprotective role through antioxidant effects beyond uric acid lowering action.

FR-PO184

Pathological and Molecular Characteristics of Adenine-Induced Chronic Kidney Disease (CKD) Model in Rats Erika Abe,[1] Li Xiao,[1] Yuumi Iida,[1] Naoko Oyama,[1] Rika Fujino,[2] Hirofumi Jono,[1,2] Hideyuki Saito.[1,2] *[1]Dept of Clinical Pharmaceutical Sciences, Kumamoto Univ School of Pharmacy, Kumamoto, Japan; [2]Dept of Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.*

Background: The process leading to CKD from acute kidney injury (AKI) is known to be caused by strength and frequency of proximal tubule injury. Although attempts were made to develop experimental CKD model, a suitable animal model is not yet established. In this study, we generated the adenine-induced CKD model using rats, and characterized pathological and moelcular aspects for investigating factors involved in the CKD progression.

Methods: Wistar rats (8-weeks-old) were fed diet powdery without or with adenine (0.3, 0.5 and 0.75%, respectively) for 4 weeks, followed by control diet for 4 weeks. Rats were sacrificed after 8 weeks, and kidney tissues were collected. In adenine-induced CKD model rats, body weight, water intake, urine volume, kidney weight, index of renal function, renal tubular damage markers (Kim-1, Ngal), oxidative stress-related factors (Nrf2, 4-HNE), fibrosis marker (αSMA), uremic toxin indoxyl sulfate (IS), organic anion transporters OAT1 and OAT3 mediating basolateral uptake of serum IS, and autophagy-related factors LC3-2 were examined.

Results: Body weight was significantly decreased and urine volume/water intake were increased in adenine group. Adenine treatment caused the decreases in urine urea nitrogen, Cr and marked increases in BUN and SCr. The marked increases in renal Kim-1 and Ngal, and histochemical injury of renal tubules were evident in adenine group. In adenine rats, the elevated 4-HNE and Nrf2 levels in the kidney indicated induction of oxidative stress. Moreover, LC3-2, a maker of autophagy, which often increases with oxidative stress, was also induced. The expressions of OAT1&3 were downregulated in adenine rat kidney, resulting in serum accumulation of IS. The appearance of interstitial αSMA indicated fibrotic response in adenine rat kidney associated with Masson's trichrome positive staining.

Conclusions: Adenine-induced CKD model rats exibited a significant deterioration of renal function, severe tubule injury, elevation of oxidative stress, accumulation of serum IS and autophagic and fibrotic responses.

Funding: Government Support - Non-U.S.

Omics Characterization of Ethanol and Lipopolysaccharide Impact on the Renal Cortex Christine E. Dolin,[1] Lauren G. Poole,[1] Daniel Wade Wilkey,[2] Gavin E. Arteel,[1] Eric C. Rouchka,[3] Michelle T. Barati,[2] Michael Merchant.[1,2] *[1]Pharmacology & Toxicology, Univ of Louisville; [2]Medicine, Univ of Louisville; [3]Computer Engineering & Computer Science, Univ of Louisville.*

Background: Chronic, heavy ethanol (EtOH) consumption impacts the kidney through the hepato-renal syndrome. The direct renal effects of moderate chronic EtOH consumption and sensitization to secondary hits are unclear. We hypothesized that moderate EtOH consumption can alter renal transcriptomic/proteomic responses to acute exposure to lipopolysaccharide (LPS).

Methods: Mice were pair fed EtOH-containing Lieber-DeCarli diet for 6 weeks and/or injected i.p. with LPS 4h prior to sacrifice. Kidney cortex sections were isolated and snap frozen. Comparative Omics studies used (a) two-dimensional liquid chromatography-mass spectrometric analysis with an Orbitrap Elite and TMT labeling reagents and (b) mirVana™ isolation of total RNA, library preparation using the TruSeq Stranded Total RNA LT Sample Prep Kit-Set A with Ribo-Zero Gold and data collected using Illumina NextSeq 500/550 with the RNASeq protocol. Proteomic and transcriptomic data were filtered by Benjamini-Hochberg (BH) corrected ANOVA p-value <0.05 and fold change (FC). Ingenuity Pathways Analysis (IPA) was used to identify pathways changed by EtOH, LPS, and/or the combination. Individual protein changes were validated with immunoblot.

Results: 170 of1863 proteins were significantly different abundance at FC ≥1.2 across groups.853 of 47,719 transcripts were significantly differentially abundant at FC ≥2 across groups. The majority of these effects LPS derived. Expected increases in Fibrinogen A protein and transcript were observed in LPS-exposed samples. IPA results show EtOH attenuated LPS effects on LXR/RXR and Nrf2-mediated pathways. Immunoblots of Nrf2 target proteins validated proteomic findings.

Conclusions: This study on the effects of EtOH and/or LPS on the renal transcriptome and proteome supported expected observations andrevealed new changes in proteins, transcripts and pathways. We hypothesize these changes will provide insight into mechanisms by which EtOH affects the kidney and alters response to a second pathologic stimulus.

Near-Infrared Autofluorescence Is Useful for Non-Invasive Imaging of Injured Kidneys in Mice Isao Matsui,[1] Hiroshi Fushiki,[2] Nobuhiro Hashimoto,[1] Keiichi Kubota,[1] Tatsufumi Oka,[1] Daisuke Mori,[1] Yusuke Sakaguchi,[3] Takayuki Hamano,[3] Yoshitsugu Takabatake,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Translational Science Research Labs, Drug Discovery Research, Astellas Pharm Inc., Tsukuba, Ibaragi, Japan; [3]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Tubulointerstitial injury (TI) is a final common pathway leading to end-stage renal disease. One of the major problems in the field of TI is the lack of strategies that enable us to evaluate the progression of TI non-invasively.

Methods: Near-infrared autofluorescence (AF) of injured kidney was non-invasively evaluated by IVIS imaging system. A combination of excitation filter 710 nm and emission filter 810-875 nm was employed. Two models, unilateral ureteral obstruction and folic acid induced nephropathy, in BALB/c mice were analyzed. The origin of the renal AF was also analyzed.

Results: The AF levels were positively correlated with the degree of TI in both animal models. Microscopic analysis of the kidney sections revealed that the AF was originated from the injured tubular cells. Because porphyrins are intrinsic fluorescent substrates that have near-infrared emission peak, we analyzed renal expression levels of enzymes that participate in the metabolism of porphyrin. Among 10 enzymes, only coproporphyrinogen oxidase (CPOX) was suppressed in the injured kidneys in both animal models, suggesting that coproporphrinogen III and its spontaneously oxidized product, coproporphyrin III, were accumulated in the injured kidneys. Authentic sample of coproporphyrin III had identical fluorescent properties observed in the injured kidneys. Intraperitoneal injection of Δ-aminolevulinic acid, a substrate of porphyrin synthesis, enhanced the AF of the injured kidneys. BALB/c-nct/nct mice, a mouse strain that retains only 15% of the wild type CPOX activity, showed the identical AF observed in the injured kidneys.

Conclusions: Near-infrared AF derived from coproporphyrin III is useful for non-invasive imaging of the TI.

CTGF Is Critically Involved in Lymphangiogenesis of Obstructive Nephropathy Hiroshi Kinashi,[1,2] Lucas Falke,[1] Tri Q. Nguyen,[1] Yasuhiko Ito,[2] Andrew Leask,[3] Roel Goldschmeding.[1] *[1]Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Nephrology and Renal Replacement Therapy, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [3]Schulich School of Medicine and Dentistry, Western Univ, London, ON, Canada.*

Background: Lymphangiogenesis is correlated with the degree of renal interstitial fibrosis. TGF-β induces VEGF-C production, which is the main driver of lymphangiogenesis. CTGF (aka CCN2) is an important determinant of fibrotic tissue remodeling, but its possible involvement in lymphangiogenesis has not been explored.

Methods: Wild-type mice (WT, n=5) and CTGF knockout mice (CTGF-KO, n=9) underwent unilateral ureteral obstruction (UUO), and both the obstructed kidney (OBK) and contralateral kidney (CLK) were collected on day 14 after UUO. We analyzed the number of lymphatic vessels and VEGF-C expression by IHC and qPCR. Human proximal tubular epithelial cells (HK-2) were treated with CTGF or CTGF siRNA under the treatment with TGF-β1, and VEGF-C expression in HK-2 cells was assessed by qPCR and ELISA. Interaction of CTGF with VEGF-C was examined in a solid phase binding assay. We finally assessed the CTGF effect on VEGF-C stimulated growth and tube formation of human lymphatic endothelial cells (HMVEC).

Results: In vivo, CTGF knock-out inhibited lymphangiogenesis in OBK, as evidenced by reduction of the increase of LYVE-1-positive lymphatic vessels ($p<0.05$) and VEGF-C positive area ($p<0.001$). LYVE-1 and VEGF-C mRNA was reduced in CTGF-KO OBK as compared to WT OBK ($p<0.05$). In HK-2 cells, CTGF enhanced VEGF-C expression, while, CTGF siRNA suppressed TGF-β1-induced VEGF-C mRNA ($p<0.05$) and protein ($p<0.01$). Solid-phase binding assay revealed direct physical interaction between CTGF and VEGF-C. VEGF-C treated HMVEC efficiently formed capillary-like structures. Remarkably, this was significantly suppressed by the addition of full length CTGF ($p<0.05$). We are currently testing whether proteolysis of CTGF reverses this inhibition, as reported previously for VEGF-A inhibition.

Conclusions: CTGF is critically involved in renal lymphangiogenesis through interactions with VEGF-C.

FR-PO188

Swimming Exercise Training(EXE) Does Not Change Inflammatory Parameters but Increase Creatinine Clearance(CrCl) and Low Glomerulosclerosis and Mortality in Rats with 10 Weeks of Chronic Kidney Disease(CKD) by 5/6 Nephrectomy(5/6Nx) Rafael DaSilva Luiz, Rodolfo Rosseto Rampaso, Kleiton Augusto Santos Silva, Luciana Jorge, Edson Andrade Pessoa, Maria A. Gloria, Mario Luis Ribeiro Cesaretti, Nestor Schor. *Nephrology Div, Escola Paulista de Medicina/UNIFESP, Sao Paulo, SP, Brazil.*

Background: We evaluated the EXE effects on serum inflammatory markers, renal function and glomerulosclerosis in rats with 5/6Nx.

Methods: Adult Wistar rats were divided in groups(n=8): Control(C), Control+Exercise(E), Sedentary 5/6Nx(NS) and 5/6Nx+Exercise(NE). The protocol was employed in 5/6Nx rats after 7 days from the surgical procedures. EXE periods were 60min/day, 5 days a week/8 weeks. It was evaluated inflammatory parameters as IL1 alpha and beta, IL2, IL6 and TNF-alpha (Luminex), mean arterial pressure(MAP), maximal exercise test(MEte/st), CrCl, BUN, proteinuria(uProt), glomerulosclerosis(%) as well mortality rate.

Results: EXE did not modify the profile of inflammatory markers.

	C	E	NS	NE
IL1 alpha(pg/ml)	2.0±0.1	2.2±0.1	2.0±0.1	2.3±0.1
IL1 beta(pg/ml)	1.6±0.4	2.7±1.0	0.7±0.1	1.1±0.4
IL2(pg/ml)	0.6±0.1	0.9±0.4	0.9±0.2	0.9±0.1
IL6(pg/ml)	11.7±0.6	12.5±1.5	11.8±0.7	12.9±0.8
TNF-alpha(pg/ml)	0.1±0.0	0.1±0.0	0.1±0.0	0.1±0.0

There is an increment in MAP but prevent, at least in part, a lower decline in the MEtest caused by 5/6Nx(29±1vs16±2m/min $p<0.05$). Higher CrCl in NEvsNS, 2.3±0.3vs1.0±0.2ml/min, respectively($p<0.05$). BUN was normalized in NEvsNS(43.6±7.3vs180.6±49.2mg/dL $p<0.05$). Proteinuria was not significantly different in NEvsNS group (36.9±3.5vs40.1±2.4mg/24h). Glomerulosclerosis was 48% higher in NSvsNE($p<0.05$). A higher mortality rate was observed in NS(70%) vs NE(39%$p<0.05$).

Conclusions: Results suggested that 8 weeks of EXE did not change the inflammatory markers but minimize the impact of 5/6Nx by decreasing glomerulosclerosis and reduce the impact on CrCl. Finally, the decreasing mortality rate in NE vs NS and by minimizing the impact of 5/6Nx on CrCl indicate that exercise, at least swimming in this protocol, induced partial protection on renal function. Thus, it is reasonable to suggest that EXE could be an additional strategy to be employed in CKD.

FR-PO189

SRGAPs Is Essential for Podocyte Cytoskeletons and Its Downregulation Facilitates Podocyte Injury and Diabetic Nephropathy Yu Pan, Song Jiang, Qing Hou, Dandan Qiu, Jingsong Shi, Zhao-Hong Chen, Ming-Chao Zhang, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: Podocytes injury is involved in the development of diabetic nephropathy (DN). Disruption of cytoskeletons in podocytes underlies podocyte foot process effacement and detachment from the glomerular basement membrane, leading to podocyte loss, proteinuria and glomerulosclerosis in DN. At present, the mechanism underlying podocyte cytoskeletal damage is incompletely understood.

Methods: We performed high-throughput microarray transcriptomics analyses of the micro-dissected glomeruli samples from the patients with early or late stage type 2 diabetic nephropathy. We performed bioinformatics analyses of the data to identify the genes associated with the progression of DN. We performed a variety of molecular and cell biology studies with cultured podocytes, db/db mice and zebrafish to investigate the role of the candidate gene in podocyte injury.

Results: Systems and network analyses of the microarray data identified that actin cytoskeleton is one of the top dysregulated pathways in the glomeruli of diabetic patients and that SRGAP2 downregulation is associated with the progression of DN. We further found that SRGAP2 is mainly expressed in podocytes in glomeruli and confirmed its downregulation in the podocytes of patients with DN at protein level. Consistently, SRGAP2 was also downregulated in the cultured podocytes treated with high glucose or TGF-β1. Furthermore, SRGAP2 knockdown was found to enhance podocyte mobility through altering RhoA/Cdc42 interaction, which was reversed by exogenous SRGAP2 overexpression. *In vivo*, SRGAP2 delivery ameliorated podocyte injury in db/db mice. Lastly, SRGAP2 knockdown in zebrafish by morpholino oligonucleotide (MO) resulted in developmental defects of podocytes and proteinuria.

Conclusions: SRGAP2 is a critical regulator of RhoA/Cdc42 activity, through which it maintains cytoskeleton stability. In DN, its expression is downregulated in podocytes, leading cytoskeleton disruption and podocyte injury. It is a potential therapeutic target for the treatment of DN.

Sphingomyelinase Induces Podocyte Ferroptosis in HIV Milieu Kamesh R. Ayasolla, Waqaar Khawar, Nairuti H. Shah, Judith Eng, Seyedeh Shadafarin Marashi Shoshtari, Vinita Vishnoi, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: Loss of podocytes in HIV-associated nephropathy has been attributed to both apoptosis and pyroptosis; however, the role of ferroptosis in HIV-induced podocyte injury has not been investigated to date. Ferroptosis is a programmed caspase independent cell death initiated by cellular non-chelated iron and driven by altered lipid environment (reduced glutathione and lipid alterations) and condensed mitochondrial structures. We asked whether lipid alteration mediated ferroptosis contributes to the loss of podocytes in HIV-associated nephropathy (HIVAN). To elucidate this aspect, we examined the role of sphingomyelinase (SMase) in the induction of podocyte ferroptosis in HIV milieu, *in vivo* as well as *in vitro*.

Methods: SMase activities of renal tissues of control (FVB/N, n=5) and HIVAN (Tg26, n=6) mice and vector (V/HP) - and HIV-transduced human podocytes (HIV/HPs) were determined. To evaluate the effect of sphingomyelinase inhibitor (GW48), V/HPs and HIV/HPs were incubated in media containing either buffer or GW48 for 48 hours. Subsequently,

cells were evaluated for SMase activity and lipid peroxidation. V/HPs and HIV/HPs were evaluated for cell death with or without blockers of ferroptosis, caspase-1, and caspase-3 at different time periods. Additionally, role of PKC-ζ and NF-κB on SMase-induced HIV/HPs' downstreamBoyBoy signaling was evaluated.

Results: ζRenal tissues of Tg26 mice and HIV/HPs displayed several fold increase in SMase activity. HIV/HP-induced SMase activity could be effectively blocked by GW48. Additionally, HIV/HPs displayed increase in lipid peroxidation that could be inhibited by GW48. A vast numbers of HIV/HPs succumbed to death during 96 hours. The relative cell survival using blockers of ferroptosis, Caspase-1, and Caspase 3 were 35%, 45%, and 20% respectively. HIV activated PKC-ζ and NF-κB and inhibitors of PKC-ζ and NF-κB prevented HIV induced ferroptotic cell death.

Conclusions: HIV induces ferroptosis in podocytes through the activation SMase activity and associated downstream signaling.

APOL1 Risk Variants Down Regulate Podocytes Nephrin Protein Expression: Role of Endoplasmic Reticulum Stress Xiqian Lan, Seyedeh Shadafarin Marashi Shoshtari, Judith Eng, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: Two coding sequence variants (G1 and G2) in *APOL1* gene have been implicated for higher rates of chronic kidney diseases in African Americans when compared to European Americans. Previous studies from our group as well as from other investigators have elucidated that the APOL1 G1 and G2 variant proteins are more toxic to kidney cells when compared with wild type APOL1 G0; nonetheless, the involved mechanisms are not clear. Nephrin is an important constituent of the slit diaphragm and animals lacking this gene have been reported to develop massive proteinuria. We hypothesize that APPOL1 risk variants down regulate translation of podocyte nephrin as a consequence of endoplasmic reticulum (ER) stress.

Methods: In these studies, we used human podocytes (HPs) stably expressing APOL1G0, G1, or G2 (Vec/HPs, G0/HPs, G1/HPs, and G2/HPs). After differentiation for 7 days, the cell lysates were collected, and were subjected to Western blot to examine the protein expression of nephrin. We also isolated RNA samples from these cells, and detected the changes of nephrin mRNA levels by using real time-PCR. To study the role of endoplasmic reticulum stress, we evaluated the effect of APOL1 variants on podocyte phosphorylation of eIF-2α. To establish a causal relationship, podocytes expressing APOL1G0/G1/G2 were incubated in media containing either buffer or ER stress inhibitors (either salubrinal or 4-PBA-1) during differentiation followed by immunoblot analysis for nephrin.

Results: Expression of nephrin protein in G1 and G2 podocytes was dramatically decreased when compared with that in G0. Since the neprhin mRNA levels didn't change, it appears that APOL1 risk variants affect nephrin expression at translation step. APOL1G1 and G2 dramatically increased its phosphorylation of eIF-1α, indicating that they these cell undergoing the ER stress. ER stress inhibitors rescued nephrin expression in APOL1G1 and G2 podocytes.

Conclusions: APOL1 risk variants suppress neprhin translation through enhanced ER stress.

FR-PO192

Triptolide Attenuates Proteinuria and Podocytes Apoptosis in Zebrafish via GADD45 Ling Wang, Zhao-Hong Chen, Qing Hou, Xiao-Dong Zhu, Wei-Song Qin, Cai-Hong Zeng, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: Dysfunction or loss of podocytes causes proteinuria, which has been associated with both acute and chronic glomerular diseases. However, podocyte target treatments are still limited. Triptolide, a major active component of Tripterygium wilfordii Hook F, has dramatic antiproteinuric effect, but the mechanism is unclear. A transgenic zebrafish model of inducible podocyte injury has been established previously. In this transgenic zebrafish, the bacterial nitroreductase (NTR) is expressed specifically in podocytes under the control of zebrafish podocin promoter, the prodrug metronidazole (MTZ) can be converted into a cytotoxin only in podocytes, which leading to podocyte injury.

Methods: We examined the effect of tripolide on transgenic zebrafish model of inducible podocyte injury. We treated zebrafish embryos with triptolide, then observed edema, measured proteinuria level as well as analyzed changes of podocin expression and foot process by immunostaining and Transmission Electron Microscope respectively. Furthermore, we performed an activated caspase-3 staining and applied microarray in tripolide-treated human podocyte. Finally, we validated the result of microarray by qRT-PCR in vitro and in vivo.

Results: Triptolide effectively alleviated edema and proteinuria in zebrafish model. The antiproteinuric effect was associated with improvement of foot process effacement, restoration of podocin expression and distribution as well as inhibition of podocytes apoptosis. Comparison of the mRNA profile by microarray analysis showed GADD45 family expression was downregulated in triptolide treated human podocytes *in vitro*. GADD45B has been implicated in podocytes apoptosis. Triptolide could suppress the expression of GADD45 in both MTZ-treated zebrafish glomeruli and PAN-treated human podocytes.

Conclusions: These results demonstrate that triptolide has direct effect on podocyte. Triptolide attenuates proteinuria and podocyte injury via reversing podocyte apoptosis and downregulation of gadd45 expression.

FR-PO193

MicroRNA193a-Induced Oxidative Stress Contributes to Puromycin Aminonucleoside (PAN) Mediated Podocyte Injury Vinod Sharma, Waqaar Khawar, Seyedeh Shadafarin Marashi Shoshtari, Judith Eng, Nairuti H. Shah, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: MicroRNA193a negative regulates Wilms tumor (WT1) gene and plays an important role in the development of focal segmental glomerulosclerosis (FSGS). PAN induces FSGS through a loss of critical number of podocytes. PAN has been shown to be an inducer of apoptosis in podocytes, both *in vitro* and *in vivo* studies. We asked whether pro-apoptotic effect of PAN was mediated via miR193a-induced reactive oxygen species (ROS) generation by podocytes.

Methods: Immortalized human podocytes (HPs) were incubated in media containing either buffer or PAN (30 μg/ml) for 24 hour and 48 hours (n=3). To determine the dose response effect, HPs were treated with variable concentration of PAN (0, 10, 20, 30 μg/ml) for 24 hours. Subsequently, RNAs were extracted and cDNAs were probed for miR193a. To establish a causal relationship, HPs were incubated in media containing either buffer, PAN (30 μg/ml), miR193 inhibitor (miR, 50 nM), and PAN + miR inhibitor for 24 hours followed by apoptosis assay. In parallel sets of experiments, effect of miR193a inhibitor on PAN-induced podocyte ROS generation was measured after DCFDA loading of control and experimental cells followed by measurement of ROS by a fluorometer. In another set of experiment, mice (n=4) were administered either normal saline or PAN. After 8 days, renal cortical sections were prepared for *in situ* hybridization for miR193a expression and immuno-histochemical analysis for glomerular cell WT1 expression.

Results: PAN enhanced podocyte expression of miR193a in a dose dependent manner. PAN promoted ROS generation and apoptosis in podocytes, however, these effects of PAN were partially inhibited by an inhibitor of miR193a. *In situ* hybridization studies displayed enhanced miR193a expression by scattered podocytes in PAN mice. PAN mice also displayed decreased number of WT1 stained glomerular cells (control, 27.2 ± 7.6 vs. PAN, 13.2±3.7 +ve cells/glomerulus, $P<0.05$).

Conclusions: PAN contributes to podocyte injury through enhancing podocyte miR193a expression.

Funding: NIDDK Support

FR-PO194

DNA Hypermethylation of sFRP5 Contributes to Indoxyl Sulphate-Induced Renal Fibrosis Yanlin Yu, Jinghong Zhao. *Dept of Nephrology, Inst of Nephrology of Chongqing and Kidney Center of PLA, Xinqiao Hospital, Third Military Medical Univ, Chongqing, China.*

Background: Renal fibrosis is the most common outcome of chronic kidney disease (CKD), whereas the molecular mechanisms underlying CKD-associated renal fibrosis are not fully understood.

Methods: In this study, we used high-performance liquid chromatography (HPLC), Masson's trichrome staining, Immunohistochemistry, Methylation-specific PCR (MSP), bisulfite-sequencing PCR (BSP), Semi-Quantitative RT-PCR, Western blotting, Immunoprecipitation.

Results: In this study, we found that in CKD patients the progress of renal fibrosis was positively related to the increase in the serum indoxyl sulphate (IS), a typical protein-bound toxin, and there was a close correlation between serum IS level and β-catenin expression in the kidneys ($r=0.908$, $p<0.001$).It was then demonstrated that intraperitoneal injection with IS for 4 weeks was able to induce renal fibrosis, accompanied by significant activation of Wnt/β-catenin signaling in uninephrectomized mice. Further investigations revealed that in cultured human renal tubular HK-2 cells,IS exhibited a strong ability to silence *sFRP5*, an extracellular Wnt antagonistic gene, by increasing DNA methylation level of the promoter CpG island. A significant increase in ROS production and ERK1/2 phosphorylation, accompanied by increased expression of DNA methyltransferases (DNMTs), were detected before *sFRP5* decline in IS-treated HK-2 cells. Similar to the inhibition of ROS production and ERK1/2 activation, treatment with 5-aza-2'-deoxycytidine, the inhibitor of DNMTs, significantly constrained IS-induced sFRP5 down-regulation and Wnt/β-catenin activation. In vivo, intraperitoneal injection with recombined sFRP5 protein or 5-aza-2'-deoxycytidine could remarkably alleviate IS-induced Wnt/β-catenin activation and interstitial fibrosis in the kidney.

Conclusions: Our results demonstrate that DNA hypermethylation of *sFRP5* is involved in IS-induced Wnt/β-catenin activation that contributes to the development of renal fibrosis, which provides new insights into the pathogenesis of CKD-associated renal fibrosis.

A Novel Mouse Model Demonstrates the Role of Bone Marrow-Derived Fibrocytes in Gadolinium-Associated Systemic Fibrosis Catherine Do,[1,2] Chunyan Tan,[2] Viktor Drel,[2] Brent Wagner.[1,2] *[1]Medical Service, South Texas Veterans Health Care System, San Antonio, TX; [2]Medicine, Univ of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Intravenous gadolinium (Gd)-based contrast is now associated with a number of conditions, including 'nephrogenic' systemic fibrosis/gadolinium-associated systemic fibrosis. The pathophysiology has been largely unexplored, particularly with mouse models.

Methods: Mice with partial nephrectomies underwent lethal irradiation then salvaged with bone marrow from green fluorescent protein (GFP)-expressing donors. After an engraftment period, these recipients were randomized to control (n=5) or Gd-based contrast treatment (n=6, 2.5 mmol/kg, 20 doses intraperitoneally over 4 weeks). Gd was assessed with inductively-coupled plasma mass spectroscopy.

Results: Gd was elevated in the skin, kidney, and liver; it was barely detected in brain. Dermal cellularity was increased in contrast-treated mice. Compared to control, skin GFP, fibronectin, and type I collagen were all increased in the contrast-treated animals as assessed by Western blot and immunofluorescence. Importantly, CD45RO, a marker for myeloid fibrocytes, was abundant in the dermis of contrast-treated animals, frequently expressed by the myeloid cells. Many of these cells expressed cytoplasmic α-smooth muscle cell actin, a marker of myofibroblast activation. We also show that C-C chemokine receptor (CCR)-2 and -7 as well as CCR2 ligand monocyte chemoattractant protein-1, are all increased in skin from contrast-treated mice.

Conclusions: Systemic fibrosis can be induced by Gd contrast in mice. That GFP levels and expression increase in an involved organ, the skin, in tandem with a fibrocyte marker—CD45RO—supports the blood-borne circulating fibrocyte hypothesis of the disease. Importantly, similar to what is observed in a rat model, our data strongly suggest that inflammatory chemokines play a critical role in the pathogenesis of Gd-induced systemic fibrosis. Our study demonstrates that mice are an appropriate model to investigate the deleterious effects of gadolinium and will allow proceeding with mechanistic studies using relevant genetically-modified mice.

The Novel sGC Stimulator IW-1973 Inhibits Renal Inflammation and Fibrosis in Preclinical Animal Models Guang Liu, Courtney Shea, Renee T. Sarno, George Todd Milne, Mark G. Currie, Jaime L. Masferrer. *Ironwood Pharmaceuticals, Cambridge, MA.*

Background: Defects in NO-soluble guanylate cyclase (sGC)-cGMP signaling are implicated in several cardiovascular diseases. IW-1973, a novel sGC stimulator has been shown to reduce blood pressure and preserve kidney function in the Dahl-ss rat model (Dss) of hypertension. Mechanistically IW-1973 demonstrates direct anti-fibrotic effects through blocking TGFβ-mediated signaling in human renal proximal tubular cells. This study evaluated the effect of IW-1973 on renal inflammation and fibrosis in Dss and unilateral ureteral obstruction (UUO) rat models.

Methods: In Dss rats, IW-1973 treatment (1, 3 and 10 mg/kg/d) started 2 weeks after rats began a high salt diet and continued for 6 weeks (total 8 weeks). For the UUO model, rats underwent surgery then received IW-1973 in chow for 2 weeks.

Results: Analysis of kidneys from IW-1973-treated Dss rats demonstrated a dose-dependent reduction in the expression of inflammatory genes TNFα, NFkB-1, ICAM and VCAM. Acute administration of IW-1973 (1 and 10 mg/kg) significantly reduced LPS-induced increases in IL-6 and TNFα ($p<0.01$), and increased IL-10 levels ($p<0.01$) in C57BL/6 mice, supporting the anti-inflammatory activity observed in the Dss rat model. In the UUO model, rats had statistically significant increases in renal inflammation ($p<0.01$), tubular degeneration ($p<0.001$) and interstitial fibrosis ($p<0.001$) 14 days after surgery compared with healthy controls. Treatment of UUO rats with 10 mg/kg/d IW-1973 resulted in a reduction of interstitial fibrosis from marked (histology score=4) to mild (histology score=3) in 6 out of 8 rats, compared to a median histological score of 3.8 for the UUO vehicle control group. The reduction in histological score was consistent with decreases in Col1a1 mRNA level and hydroxyproline content in the kidneys of IW-1973-treated rats.

Conclusions: These preclinical data suggest that sGC stimulation represents a mechanism that warrants investigation for the treatment of renal inflammatory and fibrotic diseases.

FR-PO197

PGC-1α Protects TGF-β Induced Fibrosis by Suppressing TGFβRI Expression Affected to Smad2/3 Activation Hoon In Choi, Jung Sun Park, Eun Hui Bae, Seong Kwon Ma, Jong Un Lee, Soo Wan Kim. *Dept of Internal Medicine & Physiology, Chonnam National Univ Medical School, Gwangju, Republic of Korea.*

Background: Renal fibrosis results from aberrant accumulation of extracellular matrix mainly driven by transforming growth factor-β (TGF-β). This process is initiated by binding of active TGF-β1 to TGF β type I and type II receptor (TGFβRI and II) complex, which is transduced to intracellular signals for pro-fibrotic gene expression through Smad2/3 activation. Peroxisome proliferator-activated receptor gamma co-activator 1 alpha (PGC-1α) is a key metabolic regulator that stimulates mitochondrial biogenesis, and may play a role in oxidative stress and inflammation. However, the physiological effects of PGC-1α in renal fibrosis have not been fully characterized. We investigated whether PGC-1α may regulate TGF-β/Smad signal pathways in the pathogenesis of renal fibrosis.

Methods: As *in vivo* and *in vitro* model of renal fibrosis, Left kidneys of C57BL/6J mice were subjected to unilateral ureteral obstruction (UUO) for 7 or 14 days. Human proximal tubule (HK-2) cells were stable transduced with human PGC-1α expression vector ($PGC\text{-}1\alpha^{O/E}$) or empty vector ($PGC\text{-}1\alpha^{Mock}$) containing selective marker and were treated with TGF-β for the indicated time. The changes of pro-fibrotic marker proteins in TGF-β treated $PGC\text{-}1\alpha^{Mock}$ and $PGC\text{-}1\alpha^{O/E}$ HK-2 cells were assessed by western blotting and immunofluorescence.

Results: The level of PGC-1α was diminished throughout the course of ureter obstruction and conversely associated with increased levels of fibrotic cytokine and fibrotic markers, such as TGF-β, fibronectin, vimentin, and alpha-smooth muscle actin (α-SMA). Consistent with *in vivo* data, the level of PGC-1α were reduced in TGF-β treated HK-2 cells. Stable expression of PGC-1α ($PGC\text{-}1\alpha^{O/E}$) in HK-2 cells attenuated the TGF-β induced upregulation of fibrotic markers (fibronectin, vimentin, and α-SMA) and downregulation of epithelial marker (E-cadherin), compared to $PGC\text{-}1\alpha^{Mock}$. Overexpression of PGC-1α significantly suppressed TGFβRI expression, and subsequently phosphorylation of Smad2/3 was reduced.

Conclusions: PGC-1α regulates canonical TGF-β/Smad signal pathway by targeting TGFβRI expression, resulting in anti-fibrotic effect.

FR-PO198

Indoxyl Sulfate Triggers Increased Oxidative Stress and Eryptosis Gabriela Ferreira Dias,[1] Natalia Borges Bonan,[1] Viktoriya Kuntsevich,[4] Silvia Daniele Rodrigues,[3] Lia S. Nakao,[3] Stephan Thijssen,[2] Peter Kotanko,[2] Roberto Pecoits-Filho,[1] Andrea Novais Moreno-Amaral.[1] *[1]PUCPR, Brazil; [2]RRI; [3]UFPR, Brazil; [4]MSBI.*

Background: Uremic toxins increase oxidative stress and red blood cell (RBC) death (eryptosis). We explore the effect of indoxyl sulfate (IS) on reactive oxygen species (ROS) production and eryptosis, and its effect on the RBC antioxidant system.

Methods: RBC from 6 healthy subjects were incubated for 6, 12 and 24h with buffer (negative control – NC) or IS (4.49; 23.1; and 44.5mg/L) in the presence or absence of diphenyleneiodonium chloride (DPI; 10μM). Flow cytometry was used to determine eryptosis (by AnnexinV-PE staining) and ROS production (by DCFH-DA probe). Levels of reduced glutathione (GSH) were measured by spectrophotometry using tert-Butyl hydroperoxide (TBHP) as positive control. Data are presented as mean±SD.

Results: IS increased ROS in a time- and dose-dependent manner (Table 1) between 6 and 12h, and stabilized after 24h. Eryptosis increased in a dose- and time-dependent fashion (Table 1), without significant eryptosis after 6h. In the presence of DPI, ROS production and eryptosis were inhibited to levels compared to NC. IS did not change GSH concentration (Table 1).

Table 1. ROS production, Eryptosis and GSH levels

ROS (MFI)	NC	TBHP	IS 4.49	IS 23.1	IS 44.5
6h	2.9±1.2	-	8.5±5	13±2.9*	23±6.7*
12h	2.7±1.6	-	13±6.3*	21±7.4**	26±6.1**
24h	3.9±0.9	-	11±3.2*	14±4.8**	20±5.7**
Eryptosis					
12h	4.3±1	-	8.6±2.3	14±3.2*	16±4**
24h	4.5±2.6	-	9.53±2*	20±2.8**	30±7.3**
GSH					
6h	3.9±1	0.1±0.05**	3.8±1	4±0.9	4±1.1
12h	2±0.2	0.1±0.05**	2.8±0.2	2.1±0.2	2.2±0.2
24h	2.1±0.2	0.1±0.01**	1.9±0.1	2.1±0.2	1.9±0.1

Mean Fluorescence Intensity (MFI); μmol GSH/μg protein; *$p<0.05$; **$p<0.01$ *vs*. NC.

Conclusions: IS promoted ROS production and eryptosis in a dose- and time-dependent fashion, both NADPH oxidase-dependent processes. At the same time, IS did not affect RBC GSH, which indicates limited ability of RBC antioxidant enzymes to respond to high levels of oxidative stress.

Role of APE1/Ref-1 in Hydrogen Peroxide-Induced Apoptosis in Human Renal HK-2 Cells Ha Yeon Kim,[1] Jung Sun Park,[2] Eun Hui Bae,[1] Seong Kwon Ma,[1] Jong Un Lee,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [2]Dept of Physiology, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: Apurinic/apyrimidinic endonuclease 1/redox factor-1 (APE1/Ref-1) is multipotent protein that plays an essential role in the cellular response to oxdiative stress. In the present study, we investigated the role of APE1/Ref-1 in ischemia-refusion (IR) injury in rat kidney and hydrogen peroxide (H_2O_2) induced renal tubular apotosis.

Methods: Kidney IR injury in rats was established by clamping the both renal arterys for 50 minutes followed by 2 or 5 days of reperfusion.

Results: APE1/Ref-1 is predominantly localized in the nucleus in the kidney tubule cell, while there was lack of APE1/Ref-1 in the glomerulus. The fluorescence of APE1/Ref-1was most prominent in the proximal tubule. Consistenct with the expression of APE1/Ref-1, the level of APE1/Ref-1 protein also was highest in the cortex, modest in the outer meulla, and lowest in the inner medulla. In rat model of renal IR injury, the level of APE1/Ref-1 protein was increased compared with that in kidneys subjected to sham operation. We found that over-expression of APE1/Ref-1 in HK-2 cell enhanced the ratio of Bax/Bcl-2. The suppression of APE1/Ref-1 by the pharmacologic inhibitors E3330 in HK-2 cell with H_2O_2 exposure, resulted in decreased ratio of Bax/Bcl-2 and altered phosphorylation of ERK1/2, p38, JNK1/2, and NF-κB.

Conclusions: These findings suggest that APE1/Ref-1 inhibitor attenuates H_2O_2-induced apoptosis in HK-2 cells by modulating the ERK/p38 signaling pathways.

Novel Non-Coding RNA Regulated by HIF-1 Suppresses Apoptosis in Renal Tubular Epithelial Cells Imari Mimura,[1] Yosuke Hirakawa,[1] Natsuki Kushida,[1] Yasuharu Kanki,[2] Yutaka Suzuki,[3] Hiroyuki Aburatani,[4] Masaomi Nangaku.[1] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Isotope Science Center, The Univ of Tokyo, Japan; [3]Graduate School of Frontier Sciences, The Univ of Tokyo, Japan; [4]Div of GenomeScience, Div of GenomeScience, Research Center for Advanced Science and Technology, Japan.*

Background: We have reported that chronic tubulointerstitial hypoxia plays an important role as the final common pathway to end-stage renal disease. HIF-1 (hypoxia inducible factor-1) is a master transcriptional factor under hypoxia, regulating downstream target genes. Genome-wide analysis of HIF-1 binding sites using high throughput sequencers has clarified various kinds of downstream targets and made it possible to demonstrate the novel roles of HIF-1, which interacts with epigenetic histone modifiers. Our aim of this study is to identify novel HIF-1 downstream epigenetic factors which may play important roles in the kidney.

Methods: HK2 (human kidney-2) and primary cultured tubular cells (RPTEC: renal proximal tubular epithelial cells) are exposed to 1% hypoxia. We performed genome-wide analysis of RNA-seq to clarify the expressions of mRNA and large intergenic non-coding RNA (lincRNA). We also examined ChIP-seq using HIF-1 antibody to identify HIF-1 binding sites under hypoxia.

Results: RNA-seq identified 580 lincRNAs which are up-regulated under hypoxic condition in both cells. ChIP-seq analysis demonstrated that HIF-1 also binds to the lincRNAs under hypoxia. The expression of novel lincRNA, DARS-AS1 (aspartyl-tRNA synthetase anti-sense 1), is up-regulated only under hypoxia and HIF-1 binds to its promoter region, which includes two HREs (hypoxia responsive elements). Its expression is also up-regulated with cobalt chloride exposure, while it is not under hypoxia when HIF-1 is knocked down by siRNA. To clarify the biological roles of DARS-AS1, we measured the activity of caspase 3/7 using anti-sense oligo of DARS-AS1. As a result, apoptotic cell death deteriorated by knockdown of DARS-AS1.

Conclusions: We firstly identified the novel lincRNA regulated by HIF-1 under hypoxia and clarified that DARS-AS1 plays important roles in inhibiting apoptotic cell death in renal tubular cells.

Dimethyl Fumarate Treatment Regulates Macrophage Polarization upon Oxidative Stress in Renal Inflammation Yi Li, Li Wang. *Renal Div and Inst of Nephrology, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Characterized by macrophage polarization, renal inflammation represents a ubiquitous human health problem, effective therapies with limited side effects are still lacking. In this study, we examine the role of Dimethyl fumarate (DMF) in macrophage polarization induced by oxidative stress of renal inflammation.

Methods: Balb/c mice (n=10) were administrated by 50 mg/kg DMF then injected with 10 μg/kg LPS. After tested renal dysfunction and histological features upon LPS nephritis, RT-PCR detected the level of IL-6, MCP-1, TNF-α, IFN-γ, IL-10 and CD206 in murine kidney. Before stimulated with LPS, the Raw264.7 macrophage cells were respectively pre-treated with DMF, Nrf-2 agonist SFN or ROS inhibitor NAC. The results of mito-tracker staining were observed by confocal. Flow cytometry measured the production of ROS by DCF-HDA and the expression of M1 macrophage marker iNOS. Western blot detected the expression of Nrf-2 and Sirt-1 *in vivo* and *in vitro*.

Results: DMF ameliorated murine LPS nephritis on renal dysfunction by reduction of blood urea nitrogen and serum creatinine, then decreased the histological features following renal injury. DMF also reduced mRNA level of IL-6, MCP-1, TNF-α and IFN-γ after LPS injection, whereas it did not decrease the level of IL-10 and CD206. Compared with LPS induced Raw264.7 cells, DMF significantly inhibited the expression of iNOS and reduced the production of Nitrite. Current study also revealed the role of DMF in protecting against intracellular ROS accumulation and mitochondria dysfunction upon LPS induced nephritis. DMF increased the level of Nrf-2 and Sirt-1 following *in viv*o and *in vitro* LPS treatment.

Conclusions: This study showed that DMF augmented LPS-induced acute nephritis and related cellular malfunction, indicating protective effects of DMF on regulating macrophage polarization upon oxidative stress in LPS induced acute renal inflammation via Nrf-2-mediated pathway.

FR-PO202

Following Site-Selective Endothelial Injury, Endothelial Cells Die from Necrosis and Apoptosis, but Not from Necroptosis Jan Sradnick,[1] Anika Luedemann,[1] Kathleen Fischer,[1] Andreas Linkermann,[2] Bernd Hohenstein,[1] Christian Hugo.[1] *[1]Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CGC, Dresden; [2]Clinic for Nephrology and Hypertension, Univ Hospital, Kiel, Germany.*

Background: Since the introduction of our site-selective endothelial injury model in murine kidneys, we have shown that particular cell types do (platelets) or do not (extrarenal progenitor cells) play a role for the occurrence or repair of endothelial cell (EC) lesions. With respect to the initiation of disease and cellular response, the mechanism of EC death might be relevant. We here aimed to investigate EC death following EC injury (ECI) in mice.

Methods: Using renal-arterial perfusion of Concanavalin(ConA)/anti-ConA, selective ECI was induced in C57Bl/6 mice. Kidneys were harvested after 24h (n=5) and 72h (n=6), 5 mice served as controls. Flow cytometry was used to analyze inflammatory cells and different death markers in EC, defining them either as necrotic (7AAD+), apoptotic (annexinV+) or necroptotic (pMLKL+). Additionally ECI or ischemia reperfusion (I/R) was induced transgenic mice carrying a constitutive EC-specific Tie2 GFP signal. Kidneys were harvested 24h following model induction.

Results: Kidneys demonstrated EC lesions reflected by a EC reduction of 25% measured after 24h and 72h (sham 10%±2 vs d1: 7%±1; d3: 7%±1 FACS). As described previously neutrophils were increased 24h, T-cells and macrophages 72h after ECI. The amount of 7AAD+ EC was raised after 24h (14%±5; $p<0.01$) and 72h (16%±2; $p<0.01$) compared to controls (8%±1). More apoptotic EC were found after 24h (1.1% ±0.4 vs. sham 0.3%±0.1; $p<0.01$). In contrast, less necroptotic EC were found and stayed unchanged over time (contr.: 0.16%±0.1; 24h: 0.15%±0.2; 72h: 0.3%±0.2). Similar data were found in Tie2 transgenic mice injured with ECI and I/R.

Conclusions: Necrosis and apoptosis represent the dominant EC death mechanism during the initial time course of our disease model, while necroptosis is no major cell death mechanism in EC in this disease model. These findings will now have to undergo further validation using interventional strategies blocking the individual mechanisms.

FR-PO203

Tumor Necrosis Factor (TNF) α-Converting Enzyme Inhibitors Attenuate Lipopolysaccharide-Induced Reactive Oxygen Species and Mitogen-Activated Protein Kinase in HK 2 Cells Eun Hui Bae,[1] Seong Kwon Ma,[1] Jong Un Lee,[2] Soo Wan Kim.[1] *[1]Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [2]Physiology, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: Lipopolysarralide (LPS) induce acute kidney injury (AKI), which key mediator is tumor necrosis factor-1 (TNFα). TNFα-converting enzyme (TACE) is responsible for the shedding of cell surface TNF. It is also associated with ACE2 shedding. We hypothesize that LPS suppresses ACE2 by increasing TACE and TACE inhibitors attenuate LPS injury in HK 2 cells.

Methods: Intravenous LPS (10mg/kg) in male mice induced increased serum creatinine, TNFα, and urinary neutrophil gala (NGAL).

Results: LPS increased Angotension II, angiotensin II type 1 receptor, mitogen activated protein kinase (MAPK), TACE expression and TACE activity, while decreased ACE2 expression in LPS induced AKI mice model and LPS-treated HK2 cell. LPS induced reactive oxygen species (ROS) and down-regulation of ACE2 expression were prevented by TACE inhibitors in HK 2 cells. Cell vioability also increased by TACE inhibitor treatement in LPS treated in HK2 cells. TACE inhibition also attenuated mitogen activated protein kinase (MAPK), cyclooxygenase 2 (COX2), and hemoxygenase-1 (HO-1) which is oxidative stress markers.

Conclusions: Our findings indicate that LPS-induced TACE activation partially contribute to ACE2 shedding and TACE inhibitors attenuate LPS-induced ROS and MAPK pathway in HK 2 cells.

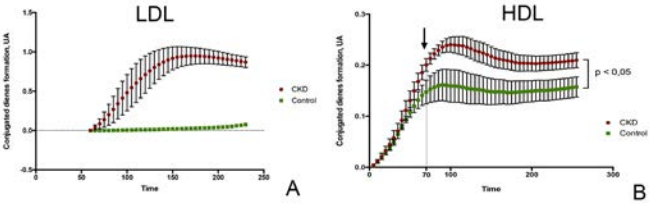
Enhanced Oxidation of HDL in a Rabbit Model of Chronic Kidney Disease Nans Florens,[1,2] Caroline C. Pelletier,[1,2] Sandrine Lemoine,[1,2] Laurent Juillard,[1,2] Christophe O. Soulage.[2,3] *[1]Nephrology, Hospices Civils de Lyon, Lyon, France; [2]INSERM U1060 - CarMeN, Villeurbanne, France; [3]INSA, Villeurbanne, France.*

Background: Recent studies have shown modified proprieties for HDL in chronic kidney disease (CKD). As the cardiovascular mortality remains the major cause of death in CKD and as oxidative stress is raised in CKD, we aimed to explore the specific role of renal dysfunction, on lipoproteins modifications in a rabbit model of CKD.

Methods: Rabbits were nephrectomized with a surgical 5/6-fold reduction technique. Lipoproteins were isolated from plasma by potassium bromide stepwise density gradient ultracentrifugation.Malondialdehyde (MDA) was measured by high performance liquid chromatography (HPLC). 4-hydroxy-nonenal (HNE) and 4-hydroxy-2-hexenal (HHE) adducts were assayed by dot-blot. Copper-induced oxidation of lipoprotein was performed with the addition of CuSO4 and formation of conjugated dienes were monitored.

Results: 8 CKD rabbits were compared with 9 Sham operated. Creatinine levels were significantly higher in CKD group (93 vs 214 μM, $p<0.001$) as well as plasmatic level of MDA (0,14 vs 1.45 μM, $p<0.001$). Anti-oxidant activity of the plasma was lower in the CKD group (0.98 vs 0.83 mM, $p<0.05$). MDA levels in LDL were not altered in the CKD group while increased in the HDL from CKD rabbits (0.89 vs 2.64 nmol/mg of proteins, $p<0.05$). HNE-adducts were also raised in the HDL of CKD group ($p<0,05$) while HHE-adducts were only raised in LDL of CKD group ($p<0,05$). Copper-induced oxidation showed higher production of conjugated dienes in LDL and HDL from CKD animals.



Conclusions: CKD rabbits exhibited extensive oxidative modifications in HDL even if LDL seemed to be more sensitive to oxidation. This observation is consistent with the modified functions of HDL in CKD reported in the literature.

FR-PO205

Antioxidant Modulates Diabetes Induced Cardiorenal Injury in an Experimental Model of Cardiorenal Syndrome Firoozeh Farahmand. *Internal Medicine, Div of Nephrology, Saint Louis Univ, Saint Louis, MO.*

Background: There is growing evidence that oxidative stress is one of the key mediators of cardiorenal syndrome (CRS), and has a key role in pathological processes in diabetic nephropathy, as well as diabetic cardiomyopathy. Therefore, an understanding of cellular pathways involved in both renal and cardiac oxidative stress is essential in the development of novel and effective therapeutic strategies to improve the survival and prognosis in CRS patients.

Methods: Diabetes was induced in rats with single injection of streptozocin (STZ). Animals were randomly divided into 4 groups: CONT, CONT+Losartan, Diabetics Control, and Diabetics+Losartan. At 4 weeks left ventricle (LV) systolic pressure (LVSP), aortic systolic (AS)pressure, LV diastolic pressure, LV hypertrophy (LVH), and LV function were measured, and the slope of the LV end-diastolic P-V relationship (EDPVR) as index of LV stiffness were calculated. After sacrificing the animals, the renal cortex and the heart were removed for histology, antioxidant enzymes, and lipid peroxidation measurement.

Results: In STZ-induced diabetics group at 4 weeks there was a significant drop in LVSP and ASP associated with increased renal and myocardial lipid peroxidation, and decreased in antioxidants enzymes. These effects were inhibited by losartan. In Diabetics+Losartan group losartan also significantly reduced renal and myocardial histopathological alterations.

Conclusions: Our results indicate diabetic nephropathy and diabetic cardiomyopathy are associated with antioxidant deficit that can be reversed with losartan. Improved cardiac function with losartan may be due to the recovery of the antioxidants in the heart. Oxidative stress, as an important trigger in diabetes complication, may offer a unique therapeutic option for the treatment of cardiorenal injury in diabetes, and benefit reducing diabetes-induced renal damage.

FR-PO206

Assessing the Impact of Primary Cilia Loss on Epithelial Phenotype and Function in a Human Renal Proximal Tubular Epithelial Cell Line Michael Higgins, Tara McMorrow. *School of Biomolecular and Biomedical Science, Conway Inst, Univ College Dublin, Dublin, Ireland.*

Background: The primary cilium is a hair-like microtubule based structure, protruding from nearly all mammalian cells. The primary cilium is well established as a crucial signalling hub with receptors for Wnt and hedgehog localized to the cilium. Primary cilia have been found to be implicated in a range of diseases collectively called ciliopathies. In recent years there has been increased interest in the link between the primary cilium and the development and progression of cancer, with several cilia associated genes dysregulated in numerous cancers. The primary cilium has been found to be absent in renal cell carcinomas, breast and pancreatic cancers. The aim of this study was to assess the impact of cilia loss on epithelial and mesenchymal marker expression and to investigate the effects on epithelial function by assessing epithelial barrier function.

Methods: A number of known deciliating chemicals were used to induce primary cilia loss. The immunofluorescent labelling of ciliary markers ARL13b and acetylated alpha tubulin were employed to confirm the absence or presence of a primary cilium in human renal cells. Western blotting and Real Time PCR were used to assess epithelial, mesenchymal and tight junction protein and gene expression following deciliation. Epithelial barrier function was also assessed by measuring trans-epithelial electrical resistance (TEER).

Results: Deciliation of human renal cells by the deciliating compounds was confirmed by acetylated alpha tubulin/ARL13B staining. Deciliation was found to cause an altering of tight junction protein expression, specifically effecting members of the claudin family. Cilia loss also caused an increasing trend in TEER, suggesting a decrease in tight junction permeability and a change in epithelial barrier function following deciliation.

Conclusions: Preliminary results suggest cilia loss in renal epithelial cause an altering of epithelial tight junctions and effect epithelial barrier function. Further analysis is currently being carried out to establish the link between primary cilia and the maintenance of epithelial phenotype and function.

Funding: Government Support - Non-U.S.

FR-PO207

Reactive Oxygen Species Control Primary Cilia Length in Kidney Tubule Cells Sang Jun Han,[1] Jee In Kim,[2] Kwon Moo Park.[1] *[1]Dept of Anatomy and BK 21 Project, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.*

Background: Primary cilium is involved in kidney function. Recent studies have demonstrated that primary cilium length changes are associated with acute kidney injury, suggesting that primary cilia may play an important role the progression of various kidney diseases. Here, we investigated whether renal mass reductions induced by unilateral nephrectomy (UNx) and transient unilateral ischemia (UI) affect primary cilia length and its molecular mechanisms.

Methods: Mice were subjected to either unilateral nephrectomy (UNx) or unilateral ischemia for 30 min (UI). Some mice were administered Mn(III) Tetrakis (1-methyl-4-pyridyl) porphyrin (MnTMPyP, a ROS scavenger) for 8 days daily beginning on 1 day after those operations. Primary cilium was visualized by immunofluorescence staining using anti-acetylated-α-tubulin antibody and its length was determined under microscope.

Results: UNx increased primary cilium length in all tubular segments including proximal, distal, Henle's loop and collecting duct, and parietal cells of the remaining kidney 9 days later. UI also increased primary cilium length in tubule cells and parietal cells of the UI-exposed kidneys. UNx and UI increased reactive oxygen species (ROS) levels in the remaining kidneys and UI-induced kidneys, respectively. Treatments of MnTMPyP prevented those elongations of primary cilia and increases of ROS production. UNx resulted in the hypertrophy of the remaining kidneys 9 days later. UI induced tubular cell damage and fibrosis in the UI-induced kidneys 9 days after the operation. Treatments of MnTMPyP prevented the hypertrophy of the remaining kidney after UNx and post-UI kidney tubule cell damage and fibrosis. In the MDCK cells, a cultured tubular epithelial cell line cells, H_2O_2 induced the elongation of primary cilium length. This elongation was prevented by MnTMPyP treatment.

Conclusions: UNx and UI elongated the length of primary cilia via increased production of ROS in the remaining kidney after UNx and UI-exposed kidney. These results suggest that ROS-induced changes of primary cilia length may play an important role for compensatory response to UNx- or UI-induced renal mass reductions.

FR-PO208

High Glucose Stimulation of Mitochondrial Metabolism and Superoxide Generation Is Mediated by Thioredoxin Interacting Protein (TXNIP) Anu Shah,[1,2] Ling Xia,[2] Lemieux Luu,[1] Michael B. Wheeler,[1] James W. Dennis,[1,2] Ivan George Fantus.[1,2] *[1]Dept of Physiology, Univ of Toronto, Toronto, ON, Canada; [2]Lunenfeld Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, ON, Canada.*

Background: Thioredoxin-interacting protein (TXNIP) is an endogenous inhibitor of thioredoxin (Trx), a thiol oxidoreductase that regulates cellular redox status. TXNIP is upregulated by high glucose (HG) and augments reactive oxygen species (ROS). We recently showed that a reduction of TXNIP inhibits HG-induced mitochondrial membrane potential and superoxide production in cultured renal mesangial cells (MCs) (JBC, 2013) and that $TXNIP^{-/-}$ mice are protected from diabetic nephropathy (DN) (JASN 2015).

Methods: To investigate mechanisms, metabolic profiling and bioenergetics of HG-treated C3H (wild type) and Hcb-19 (TXNIP deficient) MCs were assessed.

Results: Metabolomic analysis revealed higher glycolytic, but significantly reduced citrate and isocitrate, TCA cycle intermediates, in HG-treated Hcb-19 compared to C3H. As well, a 2-fold increase in malonyl CoA was observed in Hcb-19 cells suggesting that acetylCoA was driven towards lipogenesis. These data were supported by a lower PDHE1α and citrate synthase protein and activity in these cells. Assessment with the SeahorseXF analyzer revealed that Hcb-19 cells displayed lower mitochondrial oxygen consumption and a reduced respiratory capacity. Furthermore, Hcb-19 cells displayed a markedly lower protein expression of electron transport chain complexes (ETC) I, II, and III, the key generators of mitochondrial superoxide.

Conclusions: The results indicate that TXNIP promotes mitochondrial glucose oxidation via the TCA cycle and ROS generation via the ETC, thereby stimulating a HG-oxidative stress pathway mediating DN.

Funding: Government Support - Non-U.S.

FR-PO209

High Glucose-Induced Fibronectin Upregulation in Cultured Mesangial Cells Involves Caveolin-1-Dependent RhoA-GTP Activation via Src Kinase Yiqiao Li, Juan Jin. *Zhejiang Province People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: Increasing evidence indicates that diabetic-mediated renal interstitial fibrosis through extracellular matrix protein (ECM) accumulation is a key event in the development of diabetic kidney disease (DKD). High glucose (HG) promotes excessive accumulation of ECM proteins and expression of fibrotic factors in mesangial cells (MCs), which leads to subsequent diabetic renal dysfunction. The activation of RhoA and its downstream mediator Rho-kinase act as crucial mediators of strain-induced the matrix protein fibronectin (FN) secretion in MCs, which depend on intact caveolae. However, the involvement of caveolae/caveolin-1 in HG-induced dysfunction of MCs has not been assessed.

Methods: Primary MCs were obtained from Sprague-Dawley rat glomeruli by differential sieving and cultured in DMEM supplemented with supplemented with 20% fetal calf serum, streptomycin, and penicillin. Experiments were carried out using cells between passages 6 and 15. We then examined the influence of HG on caveolin-1/RhoA signaling and FN secretion in mouse MCs.

Results: We show that high levels of glucose time and dose dependently increased matrix protein FN production in primary rat MC. Rho pathway inhibition blocked HG-induced FN upregulation. HG-induced RhoA activation was prevented by disrupting caveolae with filipin III or caveolin-1 siRNA and rescued by exogenous caveolin-1. HG also increased caveolin-1/Src association and activated Src kinase, and Src inhibitor blocked RhoA activation and FN upregulation. Src mediated phosphorylation of caveolin-1 on Y14 has also been implicated in signaling responses. Overexpression of nonphosphorylatable caveolin-1 Y14A mutant prevented HG-induced RhoA activation and FN upregulation.

Conclusions: HG-induced FN upregulation require caveolae and caveolin-1 interaction with RhoA and Src kinases. Interference with Src/caveolin-1/RhoA signaling may provide new avenues for the treatment of DKD.

FR-PO210

Activation of PDGF Receptor beta (PDGFRb) by High Glucose (HG) Forces mTORC1 Signaling to Induce Proximal Tubular Epithelial Cell (PTEC) Hypertrophy and Matrix Expansion Falguni Das,[1] Nandini Ghosh-Choudhury,[2] Meenalakshmi M. Mariappan,[1] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: Increased expression of PDGF BB and PDGFRb has been reported in both glomerular and proximal tubular compartments in human and rodent diabetic nephropathy. Whether hyperglycemia activates PDGFR-mediated signaling in renal cells has not been investigated.

Methods: Human PTEC, immunoblotting, siRNA transfection, protein synthesis and cell hypertrophy assays, and mouse model of Type 1 diabetes were used.

Results: High glucose (HG) significantly increased phosphorylation of PDGFRb at the autophosphorylation site Tyr-857 and PI 3 kinase binding site Tyr-751 in a time-dependent manner. A PDGFRb-specific inhibitor JNJ-10198409 (JNJ) blocked these phosphorylations, resulting in inhibition of association of PI 3 kinase with the PDGFRb leading to suppression of Akt activation in response to HG. Similarly, siRNAs against PDGFRb abolished HG-induced Akt activation. Both JNJ and siPDGFRb inhibited HG-induced phosphorylation of two mTORC1 endogenous inhibitors PRAS40 and tuberin and, consequently suppressed mTORC1 activation, as judged by phosphorylation of S6 kinase, rps6 and 4EBP-1. Interestingly, JNJ and siPDGFRb did not have any effect on HG-stimulated MEK/Erk1/2 activation and phosphorylation of their downstream target eIF4E. Furthermore, inhibition of PDGFRb attenuated protein synthesis and PTEC hypertrophy and, expression of fibronectin and collagen I (alpha2) in response to HG. Finally, we observed increased phosphorylation of PDGFRb and its complex formation with PI 3 kinase in the renal cortex of OVE26 mice with type 1 diabetes. The renal cortical PDGFRb activation was associated with phosphorylation of Akt and mTORC1 activation, and expression of fibronectin and collagen I (a2) in the diabetic mice.

Conclusions: These results provide the first direct evidence for the requirement of PDGFRb activation in HG-induced PTEC injury found in diabetic nephropathy. Furthermore, we uncover a specific role of mTORC1 signaling downstream of PDGFRb in hyperglycemia-induced stimulation of PTEC hypertrophy and matrix protein synthesis.

mTORC2/PKCβ II Node Contributes to TGFβ (TGFβ)-Induced Twist1 Expression and Proximal Tubular Epithelial Cell (PTEC) Injury Falguni Das,[1] Nandini Ghosh-Choudhury,[2] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: TGFb contributes to renal fibrosis via the master regulator Twist1, which regulates epithelial-mesenchymal transition (EMT) in the proximal tubular epithelial cells. But the mechanistic basis by which TGFb increases Twist1 and fibrotic marker expression remains elusive.

Methods: Human PTEC, immunoblotting, siRNA transfection, plasmid-derived overexpression, protein synthesis and cell hypertrophy assays were used.

Results: TGFb time-dependently increased the expression of Twist1 in PTEC. Both PI 3 kinase inhibitor Ly294002 and mTOR inhibitor rapamycin blocked TGFb-induced Twist1 expression. Similarly, shRNAs against raptor and rictor, exclusive and required components of mTORC1 and mTORC2, respectively, individually inhibited the expression of Twist1 in response to TGFb, suggesting roles of both mTOR complexes. Importantly, overexpression of Twist1 and siRNAs against Twist1, respectively, increased and decreased the TGFb-induced protein synthesis, PTEC hypertrophy and the expression of fibronectin, collagen I (alpha2) and, the EMT marker alpha-smooth muscle actin (aSMA). Interestingly, TGFb increased the hydrophobic motif site Ser-660 phosphorylation of PKCbeta II (PKCb II) in a time-dependent manner. Use of rictor shRNA to inhibit mTORC2 blocked PKCb II phosphorylation. Importantly, siRNA against PKCbII inhibited Twist1 expression by TGFb. Similarly, the non-phosphorylatable mutant PKCbII Ser660Ala abolished TGFb-stimulated Twist1. Finally, siPKCb II or PKCb II Ser660Ala inhibited the expression of fibronectin, collagen I (alpha2) and aSMA in response to TGFb.

Conclusions: These results for the first time outline the principal mechanisms utilized by TGFb for the expression of Twist1 and its downstream effects on PTEC hypertrophy, matrix protein expression and EMT. We define a regulatory module involving mTORC2 and PKCb II for Twist1 expression and PTEC pathology induced by TGFb.

Investigating the Role of the PAR-1 Receptor and Th17 Cells in Idiopathic Nephrotic Syndrome Carl J. May,[1] Gavin Iain Welsh,[1] Moin Saleem.[1,2] *[1]Bristol Renal, Univ of Bristol, Bristol, Avon, United Kingdom; [2]Bristol Royal Children's Hospital, Bristol, Avon, United Kingdom.*

Background: There is increasing evidence that a subset of T helper (Th17) cells can survive steroid treatment and may be driving steroid resistant inflammatory conditions such as uveitis, ulcerative colitis and asthma. Additionally there is evidence to suggest a role for a circulating factor(s) released by T cells in idiopathic nephrotic syndrome. Work published previously by our group demonstrated that nephrotic plasma is capable of increasing podocyte motility. This factor signals via the PAR-1 receptor. We hypothesised that the Th17 cells are capable of signalling to the podocyte and that this signalling occurs via the PAR-1 receptor.

Methods: Th17 cells were cultured and their culture supernatants were retrieved and applied to conditionally immortalised wild-type human podocytes. Protein was extracted and used in western blotting experiments to investigate intracellular signalling. Scratch assays were performed to look at podocyte motility. A Par-1 agonist containing the sequence of the tethered ligand was used to look at the effect of PAR-1 stimulation on the podocyte.

Results: Th17 cell culture supernatant treatment of the podocytes stimulated p38 MAPK and JNK signalling pathways. Only the JNK target site (S178) of paxillin was also phosphorylated. Th17 cell culture treatment also significantly increased podocyte motility. This effect was blocked by both JNK inhibition and Protease inhibition. Suggesting that the effector molecule in the Th17 cell culture supernatant is a protease that acts via JNK. PAR-1 agonist treatment of podocytes stimulated the same signalling events. The PAR-1 agonist treatment had such a large effect on adhesion that motility could not be measured.

Conclusions: This work suggests that there is a hitherto unknown protease present in Th17 cell culture supernatant that signals via the PAR-1 receptor on the podocyte and via JNK and Paxillin phosphorylation affects podocyte motility and/or adhesion. Further inhibitor studies are required to confirm this pathway. However, if shown to be correct, this work provide multiple therapeutic targets that could be used to protect the podocyte against the circulating factor.

p70S6K Cross Talk with p66ShcA Modulates Progression of HIV-Associated Nephropathy (HIVAN) Manoj K. Tembhre,[1] Partab Rai,[1] Vinod Sharma,[1] Hanan K. Tawadrous,[2] Anil K. Mongia,[2] Seyedeh Shadafarin Marashi Shoshtari,[1] Judith Eng,[1] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Pediatrics, Down State Medical Center, Brooklyn, NY.*

Background: Down regulation of p66ShcA has been demonstrated to provide protection against HIV mediated kidney cell injury. At present there is no effective tool to inhibit p66ShcA pathway. We observed a cross talk between p66ShcA and p70S6K. On that account we hypothesize that inhibition of p70S6k would also down regulate p66ShcA pathway and would prevent progression of HIVAN.

Methods: Renal tissue lysates of sex and age matched control, Tg26/p66$^{+/+}$, Tg26/p66$^{+/-}$ mice were evaluated for phospho-p70S6K and downstream signaling. Control and Tg26 mice were administered either normal saline or PF47 (an inhibitor of p70S6K, 5mg/Kg/every other day, intraperitoneally) for 4 weeks. Urinary protein analysis was carried out and renal tissues were evaluated for severity of renal lesions. Renal tissue lysates were probed for phospho-p66ShcA and total p66ShcA. For *in vitro* studies, mouse proximal tubular cells (MTC) were transduced with either empty vector (EV/MTC) or NL4-3 (HIV/MTC) and transfected with siRNAp66, siRNAp70S6K, and scrambled siRNA. Subsequently, protein blots were probed for p66ShcA, p70S6K and actin. To study molecular binding, EV/MTC and HIV/MTC lysates were immunoprecipitated with anti- p66ShcA antibody and probed for p70S6K.

Results: TG26/p66$^{+/-}$ mice displayed attenuated renal tissue expression of phospho-p70S6K, whereas, Tg26/PF47 mice displayed attenuated expression of p66ShcA. PF47-receiving Tg26 mice displayed decreased proteinuria as well as less advanced renal lesions. HIV/MTC displayed enhanced expression of phospho-p66ShcA and phospho-p70S6K. MTC silenced for p66ShcA displayed attenuated expression of phospho-p70S6K, whereas, MTC silenced for p70S6K exhibited attenuated expression of p66ShcA both under control and HIV milieus. EV/MTC and HIV/MTC lysates immunoprecipitated with anti-p66 antibody demonstrated expression of p70S6k.

Conclusions: Cross talk between p66ShcA and p70S6K plays a role in the progression of renal lesions in HIVAN mice.

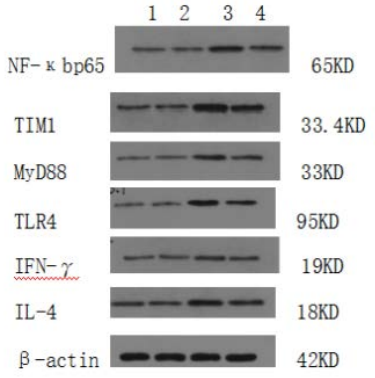
The Role of TIM-1 Signaling Pathway in the Pathogenesis of IgA Nephropathy Mouse Ying Wang. *The First Affiliated Hospital of Nanchang Univ, Nanchang, Jiangxi, China.*

Background: Studies have shown that the pathogenesis of IgAN may be related to Th1 / Th2 balance to Th2 bias related and TIM-l play an important role in regulating Th2 responses and it may influence TLR4 each other to adjust the kidney inflammation.Based on above basis,we investigate the expression of TIM ,TLR4 and IFN-γ, IL-4 in renal tissue of IgAN mouse, and explore the role and the possible mechanism of TIM-1 signaling pathway in renal injury of IgAN mouse.

Methods: 36 mice were randomly divided into normal control group,normal control + anti - TIM1 group,IgAN model group,IgAN + anti - TIM1 group,each group of 9 mice. The protein expression of TIM-1, TLR4, MyD88, NF-κB, IFN-γ, IL-4 in mice kidney was detected by Westernblot. Semi-quantitative RT-PCR was used to examine the mRNA expression of TIM1, TLR4, MyD88, NF-κB , IFN-γ,IL-4 in renal cortex.

Results:



The protein expression of TIM1、TLR4、MyD88、NF-κbp65、IL-4、IFN-γ in mice kidney tissues of four groups (Westernblot).

Note: 1 represents normal control group, 2 represents normal control + anti - TIM1 group , 3 represents IgAN model group, 4 represents IgAN + anti - TIM1 group.

Group					
Index	n	Normal Control group	Normal+anti-TIM1group	IgAN group	IgAN+anti-TIM1 group
TIM1	9	0.98±0.17	0.88±0.15	2.09±0.17[a]	1.54±0.19[a,b]
TLR4	9	1.14±0.16	0.93±0.02	1.98±0.15[a]	1.50±0.14[a,b]
MyD88	9	1.13±0.16	0.93±0.02	2.01±0.22[a]	1.50±0.18[a,b]
NF-κbp65	9	0.93±0.15	1.00±0.02	2.17±0.17[a]	1.51±0.14[a,b]
IL-4	9	0.93±0.07	1.03±0.06	1.94±0.29[a]	1.38±0.11[a,b]
IFN-γ	9	0.89±0.10	0.99±0.06	1.29±0.15[a]	1.07±0.19
Note: compared with normal control group, [a]P<0.05; compared with IgAN model group, [b]P<0.05.					

Compared with IgAN model group, the expression quantity of TIM1,TLR4, MyD88, NF-κbp65 in IgAN + anti-TIM-1 group was significantly lower(P <0.01); the protein expression of TIM1,TLR4,MyD88,NF-κbp65,IL-4,IFN-γ was lower (P<0.05); the expression quantity of TIM1,TLR4,MyD88,NF-κbp65,IL-4mRNA was lower (P<0.01).

Conclusions: In the pathogenesis of IgAN, TIM-1 signaling pathway may be involved in the pathogenesis and progression of the disease. Blocking the TIM1 signaling pathways may delay the development of IgAN through reducing the expression of TLR4, etc.

Kidney Risk Variants Apolipoprotein L1 Increase Efflux of Rubidium in Human Embryonic Kidney Cells Opeyemi A. Olabisi,[1] Jiayue Zhang,[2] David J. Friedman,[2] Martin R. Pollak.[2] *[1]Internal Medicine, Massachusetts General Hospital, Boston, MA; [2]Internal Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The proposed mechanism of trypanosome lysis by human Apolipoprotein L1 (APOL1) includes APOL1-mediated ion transport across trypanosome membranes. It is unknown if pathomechanism of APOL1 mediated kidney disease also involves aberrant ion transport by kidney risk variants APOL1 (G1 or G2). We recently reported that expression of G1 or G2 APOL1 in human embryonic kidney (HEK) cells increased efflux of cellular potassium which ultimately led to cell death via induction of stress activated protein kinase signaling. To further characterize this initial finding that G1 or G2 APOL1 or their surrogate act as potassium channels in mammalian cells, we investigate if the expression of G1 or G2 APOL1 would increase the efflux of rubidium (RB^+)—a well-established tracer of potassium movement across cell membrane.

Methods: Stably transfected HEK cells were induced to express APOL1 (G0, G1, or G2) for 5 or 9Hr. The cells were loaded with Rb^+ for 3Hr, then washed, and incubated in efflux buffer. Rb^+ content in the efflux buffer and in the cell monolayer was measured.

Results: We found that relative to G0, expression of G1 or G2 APOL1 in HEK cells for 9 Hr. results in significant increase of extracellular, but decrease of intracellular Rb^+. Expression of G1 or G2 APOL1 for 5Hr did not significantly alter transmembrane Rb^+ transport.

Conclusions: These results corroborate our prior findings and raise the possibility that aberrant depletion of cellular potassium by G1 or G2 APOL1 may be integral to APOL1 nephropathy in individuals of recent African Ancestry.

Effect of a Novel Pan-NOX Inhibitor on Phenotype Transition of Mesothelial Cells and Peritoneal Fibrosis Jiyeon Ko,[1] Eun Sun Ryu,[1] Dal-Ah Kim,[1] Sun-Hee Park,[2] Yong-Lim Kim,[2] Duk-Hee Kang.[1] *[1]Div of Nephrology, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea; [2]Div of Nephrology, Kyung-Pook National Univ School of Medicine, Dae-gu, Republic of Korea.*

Background: Oxidative stress plays a key role in the development of peritoneal fibrosis, and NADPH oxidases (NOX) substantially contribute to generation of ROS in peritoneum. However, it is not known whether each isoforms of NOX (NOX-1, -2, -4) play a differential role in peritoneal damage. Recent data suggested epithelial-to-mesenchymal transition (EMT) of peritoneal mesothelial cells is an early process of peritoneal fibrosis. Anti-oxidant effect of a novel pyrazole derivative pan-NOX inhibitor Ewha-18278 was recently reported in animal model of osteoporosis.

Methods: EMT was evaluated by an alteration of morphology and the expressions of E-cadherin and α-SMA. ROS generation & the expression of NOX isoforms were measured in TGFβ1-exposed human peritoneal mesothelial cells (HPMCs). We investigated the effect of Ewha-18278 on EMT, the expression of antioxidant [reduced/oxidized glutathione ratio (GSH/GSSG), superoxide dismutase (SOD)] and peritoneal fibrosis in animal model of peritoneal dialysis (PD) by 8-week infusion of dialysate via intraperitoneal catheter.

Results: TGFβ1 enhanced NOX activity and ROS generation. NOX-1 was the major NOX detected in HPMCs, however TGFβ1 upregulated only NOX-4 mRNA expression. Despite an absence of NOX-1 up-regulation by TGFβ1, both siNOX-1 and siNOX-4 ameliorated TGFβ1-induced EMT. Ewha-18278 decreased TGFβ1-induced ROS generation and EMT of HPMC. In animal model of PD, intraperitoneal administration of Ewha-18278 decreased the peritoneal fibrosis with an increase in GSH/GSSG and SOD activity in peritoneal dialysate whereas it decreased the expression of nitrotyrosine in peritoneum and 8-hydroxy-2'-deoxyguanosine in dialysate.

Conclusions: Increased NOX-1/2 activity with an enhanced NOX-4 expression plays a major role in ROS generation & EMT of peritoneum. Our result indicates a novel pan-NOX inhibitor as a new therapeutic agent for treatment of peritoneal fibrosis.

FR-PO217

Glycocalyx Shedding as a Novel Mechanism of Uric Acid-Induced Endothelial Dysfunction Jiyeon Ko,[1] Eun Sun Ryu,[1] Dal-Ah Kim,[1] Richard J. Johnson,[2] Duk-Hee Kang.[1] *[1]Div of Nephrology, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea; [2]Div of Nephrology, Univ of Colorado.*

Background: Recent data suggested a causative role of uric acid (UA) in the development renal disease. Endothelial dysfunction is regarded as one of the key mechanisms of UA-induced renal disease. Endothelial-to-mesenchymal transition (EndoMT) is an early process of endothelial dysfunction, and is known to play a role in the progression of renal fibrosis. Glycocalyx is a structure covering endothelium composed of membrane-bound proteoglycans and glycoproteins with adsorbed plasma components, which can cause endothelial dysfunction via intraluminal shedding.

Methods: EndoMT was evaluated by cell morphology and a comparison of the expression of VE-cadherin or CD31 and α-SMA in HUVECs and animal model of hyperuricemia (Sprague-Dawley rats fed with 2% oxonic acid for 6 weeks). NAPDH oxidase (NOX) activity, ROS generation, endothelial permeability and markers of glycocalyx shedding (syndecan-1, heparin sulfate & lectin staining) were assessed. To investigate the role of glycocalyx shedding in endoMT, the effect of GM6001 (matrix metalloproteinase inhibitor) on UA-induced endo-MT was examined.

Results: UA induced endoMT (48 hours) and ROS generation via NOX (15 min) and mitochondrial activation (6 hours) with an increase in glycocalyx shedding (6 hours). UA-induced endoMT, glycocalyx shedding and increase in vascular permeability were blocked by probenecid (500 μM). Anti-oxidant treatment ameliorated endoMT, however did not change glycocalyx shedding in HUVEC. GM6001 (10 μM) also alleviated UA-induced endoMT. In the kidney of hyperuricemic rats, endothelial staining in peritubular capillaries (PTC) was decreased with de-novo expression of α-SMA in PTC. Plasma levels of syndecan-1 & heparin sulfate were increased in hyperuricemic rats, which were ameliorated by allopurinol.

Conclusions: UA per se induced a phenotypic transition of endothelial cells via both oxidative stress and glycocalyx shedding, which could be one of the mechanisms of uric acid-induced endothelial dysfunction and nephropathy.

FR-PO218

Non-Canonical Regulation of Heterotrimeric G-Protein Subunits by Accessory Proteins in the Collecting Duct Taketsugu Hama,[1,2] Jeffrey D. Pressly,[1] Frank Park.[1] *[1]Pharmaceutical Sciences, The Univ of Tennessee Health Science Center, Memphis, TN; [2]Pediatrics, Wakayama Univ, Wakayama, Japan.*

Background: Heterotrimeric G-proteins are known to play a fundamentally central role in the biological homeostasis of renal tubular epithelial cells. Recent studies have shown that renal tubular epithelial cells can exhibit atypical modes of regulation on G-protein subunits through the actions of intracellular accessory proteins. Accessory proteins can bind to distinct G-protein α or βγ subunits to control a multitude of biological functions, including the repertoire of intracellular signaling, modulation of signaling amplitude, and alteration in protein mobilization within the cell.

Results: In this study, our group describes the ability of a novel accessory protein, thyroid receptor interacting protein 13 (TRIP13), to control MAPK signaling networks by interacting with various combinations of Gβγ dimers, most notably $G\beta_1\gamma_7$. Of the 5 known β and 12 γ isoforms, we demonstrated that only 4 β (β1, β2, β4, and β5) and 5 γ (γ5, γ7, γ10, γ11 and γ12) isoforms were expressed in collecting duct mRNA from two different mouse lines by RT-PCR analysis. Transient over-expression of $G\beta_1$ with either $G\gamma_2$, $G\gamma_5$ or $G\gamma_7$ subunits promoted MAPK activity for ERK1/2, p38 MAPK, and SAPK/JNK, but not ERK5. In the presence of TRIP13, however, $G\beta_1\gamma_7$ signaling was found to selectively regulate the phosphorylation of ERK1/2 and p38 MAPK, with no observable change in the activation status for ERK5 or SAPK/JNK. The other Gβγ dimer combinations, $G\beta_1\gamma_2$ and $G\beta_1\gamma_5$, were observed to either partially or complete lose their ability to activate ERK1/2 and p38 MAPK in the presence of TRIP13. Genetic knockdown of $G\gamma_7$ using 2 distinct short hairpin RNA constructs or over-expression of TRIP13 in collecting duct cells demonstrated accelerated wound closure by 21-47% compared to control cells, which could be partially blocked by the selective p38 MAPK inhibitor, SB203580.

Conclusions: In conclusion, TRIP13 is a newly identified accessory protein, which can selectively sequester $G\beta\gamma_7$ and accelerate cell migration following tissue damage, and may be a future therapeutic target to control wound healing of tubular epithelial cells in the kidney.

Ergothioneine Plays a Key Role in Kidney-Intestinal Interaction of CKD through Organic Cation Transporter 1 Dysfunction Yasuyuki Shinozaki, Kengo Furuichi, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: Chronic kidney disease (CKD) affects other organ damages. We hypothesized that ergothioneine (ERGO), which is the antioxidant derived from diet, was related to the progression of CKD and kidney-intestinal interaction. We focused on organic cation transporter 1 (OCTN1) and PDZ domain containing 1 (PDZK1). OCTN1 is a specific transporter for ERGO, and PDZK1 is a regulator of transporter stabilization on apical cellular membrane and modulates transporter function.

Methods: To evaluate the effects of intestinal OCTN1 function in CKD, everted sac method was used in CKD model or control mice. Furthermore, the pathological changes and oxidative stress in the kidney of OCTN1-/- or OCTN1+/+ were evaluated in the CKD model mice. Moreover, the expression of OCTN1 and PDZK1 in small intestine were confirmed by RT-PCR, Western blot and immunohistochemistry.

Results: The uptake of ERGO in everted sac significantly decreased in CKD mice than control mice. Kidney interstitial fibrosis, evaluated by azan stain, sirius red stain, and the content of hydroxyproline of injured kidney, was significantly advanced in OCTN1-/- CKD mice. Moreover, oxidative stress, assessed by 4-HNE stain and carbonyl protein ELISA, was exaggerated in OCTN1-/- CKD mice kidney. The mRNA and protein level of intestinal OCTN1 were not different in CKD mice, however, the localization on apical cellular membrane decreased in CKD mice intestine. The expression level of PDZK1 decreased in CKD mice.

Conclusions: The reduction of OCTN1 function and ERGO uptake may participate in oxidative stress and progression of kidney injury. The decreased PDZK1 expression may disturb OCTN1 function and stabilization on cellular membrane, which may relate the mechanism of kidney-intestinal network in CKD.

Indoxyl Sulfate Up-Regulates P-Glycoprotein Transporter through the Aryl Hydrocarbon Receptor Pathway Tacy Santana Machado,[1,2] Nathalie Mc Kay,[1] Pascale Paul,[1,4] Bertrand Dussol,[1,3] Francoise Dignat-George,[1,4] Philippe Brunet,[1,3] Stephane Burtey,[1,3] Claire Cerini.[1] *[1]VRCM, INSERM UMR-S 1076, Aix-Marseille Univ, Marseille, France; [2]CAPES Foundation, Ministry of Education of Brazil, 70040-020, Brasília, DF, Brazil; [3]APHM, Hôpital de la Conception, Centre de Néphrologie et Transplantation Rénale, Marseille, France; [4]APHM, Hôpital de la Conception, Service d'Hématologie et de Biologie Vasculaire, Marseille, France.*

Background: Chronic kidney disease (CKD) is associated with profound changes in drug metabolism. Reduction of drug renal clearances is a major reason, but some drugs with only hepatic metabolism have modified half life during CKD. CKD induces an accumulation of many solutes called uremic toxins. Aryl hydrocarbon receptor (AhR) is a transcription factor which is activated by indolic uremic toxins and mediates their toxic effects. It has been shown that uremia can inhibit the function and expression of hepatic drug metabolizing enzymes and drug transporters. The objective of this work is to study the effects of the indolic uremic solute indoxyl sulfate (IS), on the expression and activity of the efflux cellular transporter, P-glycoprotein (P-gp) which is encoded by ABCB1.

Methods: Levels of ABCB1 mRNA were studied by RT-PCR, the P-gp levels by flow cytometry and by western blotting. The activity of P-gp was measured with rhodamine 123 in the presence or absence of an inhibitor, verapamil. The role of AhR was studied using small interfering RNA. Transplant patients were recruited from APHM.

Results: In a human hepatocellular liver carcinoma cell line, IS increased both the mRNA and protein levels of P-gp. IS increased the efflux activity of P-gp, an effect that was partially inhibited after incubation with verapamil. The effects of IS on P-gp are AhR-dependent. Dioxin, a well known agonist of AhR, also increased the expression and activity of P-gp. In heart and kidney transplant recipients receiving cyclosporine A (n=109), a substrate for P-gp, patients with higher serum levels of IS need higher doses of cyclosporine to achieve the target blood level.

Conclusions: In conclusion, IS acting through AhR activates the xenobiotic efflux transporter P-gp and could modify the hepatic clearance of drugs such as cyclosporine.

Funding: Government Support - Non-U.S.

FR-PO221

Urinary Exosomes Contain MicroRNAs Capable of Paracrine Modulation of Tubular Transporters Fiona E. Karet,[1] Tannia Gracia,[1] Xiaonan Wang,[2] Ya Su,[1] Elizabeth Norgett,[1] Pablo Moreno,[1] Gos Micklem.[3] *[1]Medical Genetics, Univ of Cambridge, Cambridge, United Kingdom; [2]Pathology, Univ of Cambridge, Cambridge, United Kingdom; [3]Genetics, Univ of Cambridge, Cambridge, United Kingdom.*

Background: Exosomes derived from all nephron segments are present in human urine, where their full functionality is poorly understood, but is known to include direct antimicrobial activity. Although one report has suggested *in vitro* uptake of exosomes by renal cortical collecting duct cells, most studies of human urinary exosomes have focused on biomarker discovery rather than exosome function. Exosomes from other sources have been demonstrated to contain microRNA (miRNA) species.

Methods: Urinary exosomes were isolated from healthy volunteers.The miRNA repertoire of these exosomes was identified using deep sequencing of miRNA-enriched fractions. Targets for the identified miRNAs were predicted using 5 different algorithms and a selection was validated by exposing renal tubular epithelial cells to fresh urinary exosomes and measuring their protein levels. Live cell microscopy examined cellular uptake of exosomes.

Results: 276 mature miRNAs were identified in urinary exosomes, together with some miRNA precursors, mRNA and other non-coding RNAs. For the top 10 miRNAs we found an enrichment of target genes encoding a variety of channels and transporters (eg of organic molecules and mono- and divalent ions). DAVID enrichment analysis highlighted the possibility of these identified miRNAs exerting effects on regulators of key functions such as sodium reabsorption and potassium secretion in the kidney in a paracrine manner. Selected targets were validated by qRT-PCR, and to provide proof of concept, cultured renal epithelial cells were exposed to pools of urinary exosomes, cellular exosomal uptake was confirmed and downregulation of SNAT2 and ROMK protein expression levels was observed.

Conclusions: The significant presence of miRNAs in urinary exosomes demonstrated the potential regulatory roles that these noncoding RNAs could play in the kidney. These data suggest that exosomes could be suitable for biomarker development and therapeutic options for kidney diseases, which will require future *in vivo* studies.

FR-PO222

PDLIM5 Is Required for Membrane Targeting of AE1 in Kidney Fiona E. Karet,[1] Ya Su,[1] Thomas F. Hiemstra,[1] Yahui Yan,[1] Hannah Karet,[2] Pablo Moreno.[1] *[1]Univ of Cambridge, United Kingdom; [2]Univ College London, United Kingdom.*

Background: Anion exchanger 1 mediates Cl^-/HCO_3^- exchange across the plasma membranes of erythrocytes and kidney epithelial cells (kAE1). In kidney, AE1's main activity is basolaterally in type A intercalated cells of the collecting duct where it is functionally coupled with apical proton pump to maintain normal bodily acid-base homeostasis. Mutations in *SLC4A1* are associated with distal renal tubular acidosis. The major pathogenic mechanisms have been attributed to intracellular retention and aberrant membrane targeting of kAE1, but molecular basis of the mis-targeting is unclear. AE1's C-terminus (AE1C) is rich in membrane targeting motifs which are known to play an important role in its normal membrane residency. To inform disease-causing mechanisms, we sought binding partners for AE1C.

Methods: Co-immunoprecipitation-coupled mass spectrometry (co-IP-MS) screen was performed using anti-AE1 antibody to precipitate AE1 associated proteins from MDCK-kAE1 cell lysates. A potential AE1-PDZ interaction was confirmed by ELISA. Significance of the interaction was investigated by GST pulldown and overexpression/ knockdown studies in HEK293 cells.

Results: The co-IP-MS screen yielded PDLIM5, a PDZ protein, as a potential binding partner for kAE1. The interaction was confirmed *in vitro* and demonstrated to be direct, with actual binding between the PDZ domain in PDLIM5 and the PDZ binding motif in AE1C. SiRNA-mediated depletion of PDLIM5 in cell culture resulted in significant reduction in kAE1 at the cell surface, whereas overexpression of kAE1 increased PDLIM5 level, underscoring the functional importance of PDLIM5 for proper membrane residency of kAE1. GST pull-down from both human kidney tissue and HEK-kAE1 cell lysates revealed not just PDLIM5, but also integrin linked kinase, an actin associated protein, indicating formation of a multiprotein complex by these proteins.

Conclusions: These data establish both physical and functional links between kAE1 and PDLIM5 in kidney and suggest PDLIM5 as a crucial linker between kAE1 and actin cytoskeleton associated proteins; this is critical for proper movement of kAE1 to its normal functional location.

FR-PO223

Calcineurin Inhibitor-Induced Endothelial Cell Injury and Dysfunction – A Role for Complement? Chia Wei Teoh,[1] Magdalena Riedl,[1] Lisa Robinson,[1,2] Christoph Licht.[1,2] *[1]Div of Nephrology, The Hospital for Sick Children, Toronto, Toronto, ON, Canada; [2]Dept of Paediatrics, Univ of Toronto, Toronto, ON, Canada.*

Background: Calcineurin inhibitors (CNI) are widely used immunosuppressive agents which are in up to 14% of renal graft biopsies associated with thrombotic microangiopathy (TMA) (in up to 90% subclinical). Evolving evidence suggests a central role for complement dysregulation in the pathogenesis of CNI-induced TMA. It has recently been shown that CNI can induce endothelial cell (EC) release of complement-activating microparticles that lead to bystander EC injury. However, the exact mechanism of CNI-induced complement-mediated injury and possibly resulting EC dysfunction remains unknown.

Methods: EC cytotoxicity was assessed via LDH assay. Complement activation/regulation were assessed by flow cytometry for C3c and surface bound complement regulators CD46, CD55 and CD59. EC repair was assessed by scratch wound assay. Blood outgrowth endothelial cells (BOECs) were incubated with various concentrations/durations of cyclosporine (CsA) 10 microgram/ml for 24 hours and subsequently exposed to 50% normal human serum (complement active) or heat inactivated serum (complement inactive).

Results: CsA cytotoxicity was dose and duration-dependent. An optimal balance of EC survival and CNI effect was obtained with CsA 10 microgram/ml for 24 hours. The sequence of CsA incubation (above) and 50% NHS resulted in enhanced EC complement (C3c) deposition and cell death. In addition, scratch wound healing was also significantly impaired. Of note, CsAled to upregulation of CD46, CD55 and CD59.

Conclusions: CsA induced EC cytotoxicity is dose and duration dependent. CsA causes complement activation on EC with increased cell death and impaired endothelial repair. Unexpectedly, we found that CsA led to upregulation of surface-bound complement regulators CD46, CD55 and CD59. Further experiments are ongoing to unravel the mechanism of CsA induced complement activation and its effects on EC injury and dysfunction.

FR-PO224

TLR4 Links Uric Acid with the Innate Immune System to Mediate Injury in Proximal Tubule Cells Giacomo Garibotto,[1] Daniela Verzola,[1] Samantha Milanesi,[1] Barbara Bonino,[1] Francesca Cappadona,[1] Emanuele L. Parodi,[1] Abitha Murugavel,[1] Francesca Viazzi,[1] Roberto Pontremoli.[1] *[1]IRCCS AOU San Martino-IST; [2]IRCCS AOU San Martino-IST; [3]IRCCS AOU San Martino-IST; [4]IRCCS AOU San Martino-IST; [5]IRCCS AOU San Martino-IST; [6]IRCCS AOU San Martino-IST; [7]IRCCS AOU San Martino-IST; [8]IRCCS AOU San Martino-IST; [9]IRCCS AOU San Martino-IST; [10]IRCCS AOU San Martino-IST.*

Background: Hyperuricemia has been linked to the development of inflammation and progression of renal damage. However the mechanisms by which uric acid (UA) may cause these effects are poorly explored. Tubular cells (pTCs) posses both the afferent and efferent limbs of the innate immune system, including Toll like receptors (TLRs) and both early and late-phase cytokines. TLRs mediate signal transduction pathways through the activation of transcription factors that regulate cytokines.Toll-like receptor4 (TLR4)recognize pathogen-associated danger signals but is also activated *via* endogenous ligands. The aim of the present study was to examine the immune activation induced by UA in (pTCs).

Methods: Human pTCs line (HK-2) was exposed for 0-5 hours to UA (12 mg/dl). Cells were pretreated with 1 um TLR4 antagonist (Tak 242) or valsartan (5 um) or losartan (10 um). TLR4 gene and protein expression were evaluated by rtPCR and western blot; P65 activation by western blot and MCP1 and NOX4 by rtPCR.

Results: Exposure of HK-2 to UA resulted in increased gene and protein expression of TLR4 ($p<0.05$) and in upregulation of proinflammatory cytokine MCP-1 ($p<0.05$) and prooxidant NOX4 ($p<0.01$). UA induced NF-κB signaling (phosphorylated-p65) and p65 inhibition blunted the upregulation of TLR4 mRNA ($p<0.001$). Pretreatment with Tak242 attenuated the UA induced expression of both MCP-1 and NOX4 mRNA ($p<0.001$). While preincubation with valsartan did not affected the effects investigated, URAT-1 transport inhibition by losartan blunted both MCP-1 and NOX4 mRNAs.

Conclusions: Our results show that TLR4 links UA with the innate immune system to mediate injury in pTCs. These effects are prevented by inhibition of UA intracellular transport. These results might explain the chronic tubulointerstitial damage observed in hyperuricaemic states and suggest that UA transport in pTCs is necessary for urate-induced effects.

Pro224/Ala Mutation of Rat Na/K-ATPase α1 Subunit Attenuates Na/K-ATPase Signaling Functions without Affecting Na/K-ATPase Activity in Renal Proximal Tubular Cells Yanling Yan,[1] Anna P. Shapiro,[2] Zi-Jian Xie,[1] Joseph I. Shapiro,[1] Jiang Liu.[1] *[1]Marshall Univ JCE School of Medicine; [2]Univ of Toledo College of Medicine.*

Background: Cardiotonic steroids (CTS, such as ouabain) signaling through Na/K-ATPase, regulate sodium reabsorption in the renal proximal tubule (RPT). Carbonylation modification of the Na/K-ATPase α1 subunit regulates Na/K-ATPase signaling and subsequent transepithelial sodium transport in RPTs.

Methods: Expression of the Pro224/Ala of rat α1 subunit mutant in α1 knockdown pig LLC-PK1 cells. Determinations of the followings: activation of c-Src and ERK1/2, protein carbonylation, [^{3}H]ouabain binding, Na/K-ATPase activity, active $^{22}Na^+$ transport, cellular redistribution of Na/K-ATPase, etc.

Results: Comparing to control wild type cell (AAC-19, expressing rat α1 subunit in α1 knockdown pig LLC-PK1 cells) and mutation control cell (A416P, expressing Ala416/Pro mutation of rat α1 subunit in α1 knockdown pig LLC-PK1 cells), mutation of Pro224 to Ala of rat α1 subunit attenuates ouabain-stimulated activation of c-Src and ERK1/2, tyrosine phosphorylation of multiple proteins, protein carbonylation, redistribution of Na/K-ATPase, and inhibition of active transepithelial $^{22}Na^+$ transport. However, as seen in AAC-19 and A416P cells, this Pro224/Ala mutation has no effect on ouabain-induced inhibition of Na/K-ATPase enzymatic and ion-exchange activities assessed by ouabain-sensitive enzymatic activity of the Na/K-ATPase in crude membrane preparations as well as the ion-exchange activity assayed by ouabain-sensitive $^{86}Rb^+$ uptake.The data indicate that P224A mutation did not change the characteristics of ouabain-induced Na/K-ATPase inhibition but attenuated ouabain-induced signaling function.

Conclusions: Pro224 of rat α1 subunit plays an important role in ouabain-mediated Na/K-ATPase signaling and related sodium handling in RPTs.

Cardiotrophin-Like Cytokine Factor 1 (CLCF1): An Intrinsically Disordered Promiscuous Cytokine in Focal Segmental Glomerulosclerosis (FSGS) Plasma Mukut Sharma,[1,2,3] Andrew Keightley,[4] Fei Philip Gao,[5] David Genochio,[1] Jianping Zhou,[1] Alok De,[2] Tarak Srivastava,[6,2] Ellen T. McCarthy,[3] Ram Sharma,[1] Jean-Francois Gauchat,[7] Virginia J. Savin.[1,3] *[1]Research, Kansas City VA Medical Center, Kansas City, MO; [2]Research, MBRF, KC VA Medical Center, Kansas City, MO; [3]Kidney Inst, KU Medical Center, Kansas City, KS; [4]Mass Spectrometry and Proteomics Center, UMKC, Kansas City, MO; [5]Structural Biology Center, Univ of Kansas, Lawrence, KS; [6]Nephrology, CMH, UMKC, Kansas City, MO; [7]Pharmacology, Univ of Montreal, Montreal, QC, Canada.*

Background: CLCF1, an IL-6 family cytokine, detected in FSGS plasma is believed to secrete and circulate with cytokine-receptor like factor1 (CRLF1) and soluble ciliary neurotrophic factor receptor (sCNTFR). CLCF1 carries a weak net charge and aggregates at physiological pH suggesting intrinsic disorder (ID) and potential binding with multiple proteins.

Methods: ID in CLCF1 was determined using CSpritz bioinformatics tools. Surface plasmon resonance (SPR) was used to study interaction of immobilized rhCLCF1 with anti-CLCF1 antibody (Ab), apo-lipoprotein E (ApoE) and the multi-ligand receptor protein sortilin. LC-MS and Western blotting (WB) were used to compare distribution of CLCF1 in normal and FSGS sera. Glomerular albumin permeability (P_{alb}) assay and WB were used to compare the effect of monomeric CLCF1 and heterodimer CRLF1-CLCF1 on P_{alb} and JAK-STAT activation, respectively.

Results: In silico analysis showed 33.33% ID in the CLCF1 molecule due to 5 disordered segments 10-23 amino acids long. Low pH buffers favored monomeric stability of CLCF1. SPR analysis showed that CLCF1-ApoE binding was stronger (200%) but CLCF1-sortilin interaction was weaker (12%) compared to CLCF1-Ab interaction (100%). SDS-PAGE, LC-MS and WB showed that CLCF1 associated with several fractions. CRLF1-CLCF1 blocked the CLCF1-induced increase in mouse podocyte STAT3 phosphorylation and rat glomerular P_{alb} ($P<0.001$).

Conclusions: Significant ID determines the molecular characteristics of CLCF1. CLCF1 may function as a "hub" interacting with several proteins including CRLF1 and CNTFRα with varying affinity to modulate cell-type specific functions.

MicroRNA-148b Suppresses Megalin Expression and Is Associated with Downregulation of This Receptor in Mice Subjected to Unilateral Ureteral Obstruction Lu Wen,[1,2] Pia K. Andersen,[1] Dina Michelle Baarts Pedersen,[3] Rikke Norregaard,[3] Henrik Birn.[1] *[1]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark; [2]Dept of Nephrology, First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, China; [3]Dept of Clinical Medicine, Aarhus Univ, Aarhus, Denmark.*

Background: Tubular proteinuria has been observed in unilateral ureteral obstruction (UUO)–induced kidney injury. Proximal tubule uptake of filtered protein is mediated through the multiligand endocytic receptors megalin and cubilin. However, the expression of megalin and the mechanisms of its regulation in UUO-induced kidney injury are unresolved.

Methods: UUO kidney injury was induced in 10-week old male C57BL/6 mice by ligation of the left ureter for 7 days. The expression of megalin was evaluated by quantitative PCR (qPCR), Western blotting and immunofluorescence. The levels of microRNA-148b (miR-148b) were detected by qPCR. *In silico* miRNA target prediction analysis combined with dual-luciferase reporter assay in HEK293 cells was used to confirm the potential interaction between miR-148b and megalin expression. LLC-PK1 cells were transfected with miR-148b mimic or inhibitor to examine the effect of miR-148b on megalin expression *in vitro*.

Results: Megalin expression was dramatically decreased in mice kidney of UUO associated with an upregulation of miR-148b in kidneys from UUO mice. The relative luciferase activity in HEK293 cells was reduced when co-transfected with miR-148b mimic and wild type megalin-3'-UTR, whereas luciferase activity of mutant megalin-

3'-UTR was not affected. Transfection of LLC-PK1 cells with miR-148b mimic reduced both endogenous megalin mRNA and protein levels, while transfection with miR-148b inhibitor resulted in an increase.

Conclusions: MiR-148b directly suppresses megalin expression in LLC-PK1 cells. This indicates that miR-148b may negatively regulate megalin expression in UUO-induced kidney injury leading to tubular proteinuria. Thus, miR-148b may be a potential therapeutic target for modulation of tubular protein reabsorption in obstructive kidney injury. Further studies should examine if miR-148b is important for megalin expression in other conditions.

FR-PO228

Loss of Mitochondrial Heat Shock Protein, Mortalin during Renal Cold Storage and Transplantation Nirmala Parajuli, Lee Ann MacMillan-Crow. *Pharmacology/Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Long-term graft viability continues to be problematic after transplantation, especially in kidneys that require cold storage (CS). Our prior study reported that renal CS leads to increased mitochondrial injury and renal damage following transplantation (J. Kidney, 2: 114, 2016). However, the molecular mechanisms responsible for worsening mitochondrial and renal damage following transplantation of kidneys preserved with CS are poorly understood. Mortalin is a *heat-uninducible* mitochondrial chaperone within the heat shock protein 70 (mtHsp70) family that maintains proper folding of mitochondrial proteins. A reduction in mortalin expression in normal cells leads to mitochondrial fragmentation and dysfunction. The goal of this study is to evaluate if mortalin is altered during renal CS and transplantation.

Methods: Male Lewis rat kidneys exposed to CS (18 hr) followed by transplantation (*in vivo*) and a rat kidney proximal tubular cells (NRK) exposed to CS (0-18 hr) followed by rewarming (*in vitro*) models were used. MKT-077 (a rhodacyanine dye) was used to inhibit mortalin function in NRK cells. Mitochondrial function was assessed via high resolution respirometry.

Results: Mortalin expression was decreased after CS plus transplantation (*in vivo*) or rewarming (*in vitro*). NRK cells treated with the mortalin inhibitor, MKT-077 (without CS) showed a dose dependent increase in mitochondrial reactive oxygen species, cell death, and impaired mitochondrial respiration. These studies suggest that inhibition of mortalin function contributes to renal mitochondrial dysfunction.

Conclusions: These data suggest, for the first time, that renal CS leads to altered mortalin expression/activity leading to mitochondrial dysfunction, oxidative stress, and renal cell death. New studies designed to preserve the mortalin function may have promising therapeutic implications for better outcomes after renal transplantation.

Mass Spectrometry and Cellular Bioenergetics Analysis Reveals Altered Mitochondrial Function in the Kidneys of Na-H Exchanger Regulatory Factor Isoform 1 (NHERF1) Deficient Mice Amanda R. Sherwood,[1] Syed J. Khundmiri,[2] Caryl Conklin,[1] Kenneth Gagnon,[1] Michelle T. Barati,[1] Adrienne M. Bushau,[1] Michael Merchant,[1] Eleanor D. Lederer.[1,5] *[1]Dept of Medicine, Univ of Louisville School of Medicine, Louisville, KY; [2]Dept of Physiology, Howard Univ, Washington, DC; [3]Nephrology, Robley Rex VA Medical Center, Louisville, KY.*

Background: NHERF1 is a protein that plays a critical role in both defining the renal proximal tubule brush border membrane (BBM) composition and regulating ion transport through modulation of its trafficking and anchoring functions. In a NHERF1-deficient opossum kidney cell line, we have observed disrupted trafficking of transporters to the BBM.

Methods: As the role of NHERF1 in total BBM protein composition has not previously been explored in the kidney cortex, we used ID-RP (C18) nanoflow ultra high performance liquid chromatography and nanoelectrospray-mass spectrometry (MS) to examine the composition of the BBM of proximal tubule cells from 4 month old NHERF1 KO mice. To investigate the biological impact of these findings, we isolated and cultured primary proximal tubule cells from the kidney cortex of 2-month old wild-type and NHERF1 KO mice and measured both mitochondrial respiration and glycolysis rates.

Results: The BBM of NHERF1 KO mice exhibited decreased abundance of ion channels, cytoskeleton-associated proteins, and cell survival proteins, and increased abundance in proteins involved in vesicular transport. Our proteomics analysis also identified a large amount of proteins typically associated with the mitochondria with significantly decreased abundance in the NHERF1 KO BBM. NHERF1 KO proximal tubule cells also exhibited decreases of 35% in glycolytic reserve capacity, 40% in baseline mitochondrial respiration rate, 40% in mitochondrial reserve capacity.

Conclusions: NHERF1 may play a role in membrane protein composition in not only the BBM but membranes of cellular organelles such as the mitochondria, leading to a lower oxidative capacity and the potential for increased susceptibility to cell injury.

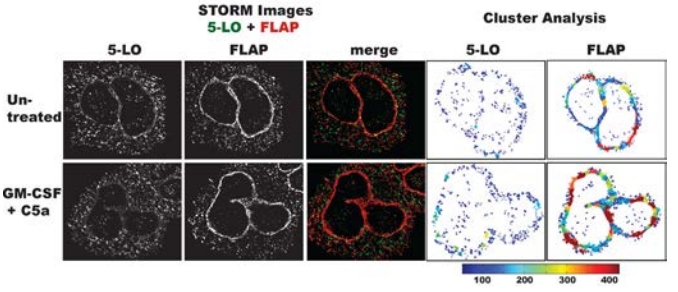
Organization of the Leukotriene Synthetic Complex in Neutrophils as an Indicator of Disease State Angela Bair Schmider,[1] Matthew Godin,[1] Hunter Elliott,[2] Roy J. Soberman.[1] *[1]Medicine, Massachusetts General Hospital, Charlestown, MA; [2]Cell Biology, Harvard Medical School, Boston, MA.*

Background: The recruitment and activation of neutrophils is a prominent component of tissue injury in anti-neutrophil cytoplasmic autoantibody-vasculitis (AAV). The chemotactic lipid, leukotriene (LT)B_4 plays a role in the initial recruitment of neutrophils from the vasculature. We previously identified the LT synthetic complex to involve multiple steps in its organization on the nuclear envelope resulting in LTB_4 synthesis. We hypothesized that organization of the core members of this structure, 5-lipoxygenase (5-LO) and 5-lipoxygenase-activating protein (FLAP), form supramolecular structures as an additional regulatory step in LTB_4 synthesis resulting in enhanced neutrophil recruitment and activation.

Methods: We paired *S*tochastic *O*ptical *R*econstruction *M*icroscopy (STORM) with cluster analysis and *F*luorescence *L*ifetime *I*maging *M*icroscopy (FLIM) to show the reorganization of 5-LO/FLAP into supramolecular clusters on the nuclear envelope in response to priming and activation from neutrophils of patients with AAV and healthy controls. Primary antibodies against 5-LO/FLAP were used for all microscopy experiments. STORM required secondary antibodies Cy3b and AlexaFluor647. To test the hypothesis that LT synthetic complexes were organized into larger groups, we developed unbiased automated cluster analysis algorithms to analyze primary STORM data. FLIM required AlexaFluor488 and 594 secondary antibodies.

Results: The priming and activation of neutrophils results in reorganization of 5-LO and FLAP into supramolecular clusters.



Conclusions: Using a novel approach we have identified novel supramolecular complexes of LT synthetic enzymes that play a major regulatory role in neutrophil activation and are potentially an indicator of disease state.

Attenuation of Na/K-ATPase Mediated Oxidant Amplification with pNaKtide Partially Reverses PNx-Induced Experimental Uremic Cardiomyopathy Jiang Liu,[1] Muhammad A. Chaudhry,[1] Kyle D. Maxwell,[1] Yanling Yan,[1] Xiaoliang Wang,[1] Preeya Tushar Shah,[1] Asad A. Khawaja,[1] Rebecca Martin,[1] Christopher A. Drummond,[2] Steven T. Haller,[2] David J. Kennedy,[2] Jiang Tian,[2] Zi-Jian Xie,[1] Joseph I. Shapiro.[1] *[1]Marshall Univ JCE School of Medicine; [2]Univ of Toledo College of Medicine.*

Background: In C57BL/6 mice, Na/K-ATPase mediated oxidant amplification is involved in 5/6 renal partial nephrectomy (PNx) induced cardiac fibrosiswith at week 4 of post-surgery. Here we report that attenuation of Na/K-ATPase mediated oxidant amplification with pNaKtide ameliorates experimental uremic cardiomyopathy.

Methods: PNx was performed and C57BL/6 mice were allowed to develop uremic cardiomyopathy for 4 weeks. At week 4 of post-surgery, the mice were randomly divided. During the fifth week post-surgery, pNaKtide was administered i.p. at a dose of either 0, 1, 5, 10 or 25 mg/kg body weight on day 0, day 2, and day 4, and the mice were sacrificed on day 7 of that week. Transthoracic echocardiography, western blot of proteins, hematocrit, heart/body weight ratio, and renal function were determined.

Results: Comparing with PNx group 5 weeks post-surgery, pNaKtide appeared to reverse PNx-induced anemia and cardiac hypertrophy based on heart weight/body weight ratio. Many (but not all) of the echocardiographic features of uremic cardiomyopathy were reversed by pNaKtide in a dose dependent fashion after one week administration. Specifically, left ventricular wall thickness (anterior, posterior and relative wall thickness) as well as left ventricular mass index (LVMI) were ameliorated by pNaKtide at the higher doses. The myocardial performance index (MPI) changes were not reversed by pNaKtide. At higher doses, pNaKtide also reversed the fibrosis as assessed by histology and collagen-1 expression. Administration of pNaKtide also attenuated left ventricular c-Src activation and ERK1/2 activation as well as oxidant stress as assessed by protein carbonylation. pNaKtide at higher doses reversed PNx-mediated increases in plasma creatinine and BUN, but not plasma cystatin C.

Conclusions: Attenuation of Na/K-ATPase mediated oxidant amplification with pNaKtide is able to partially reverse PNx-induced experimental uremic cardiomyopathy.

Activation of Gβγ-Akt Signaling Mediates the Differential Effects of β2 Adrenoceptor Agonists on Mitochondrial Biogenesis Robert Bruce Cameron, Craig Cano Beeson, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: AKI is associated with suppression of mitochondrial function, and drugs that induce mitochondrial biogenesis (MB) are effective in preclinical models of AKI. Formoterol, a β_2 adrenoceptor (β_2AR) agonist, induces MB and stimulates recovery of renal function following AKI in mice, but the β_2AR agonist clenbuterol does not induce MB. We sought to determine the differences in signaling between formoterol and clenbuterol in renal MB.

Methods: For *in vitro* studies, renal proximal tubule cells (RPTC) were treated with 30nM formoterol or 30nM clenbuterol. RPTC were also pretreated with 100nM gallein, 100nM MK2206, 10μM L-NAME, or 5μM ODQ. For *in vivo* studies, C57BL/6 mice received 0.3 mg/kg formoterol or 0.3 mg/kg clenbuterol (i.p.). MB was assessed by FCCP-uncoupled oxygen consumption rate using a Seahorse instrument and by mRNA expression of PGC-1α and NDUFS1 using RT-qPCR.

Results: In both RPTC and mice, formoterol, but not clenbuterol, increased Akt phosphorylation after 30 min. Pretreatment with the Gβγ inhibitor gallein blocked formoterol-induced increases in Akt phosphorylation in RPTC. At 1 h, formoterol, but not clenbuterol, increased eNOS phosphorylation, which was prevented by pretreatment with gallein or the Akt inhibitor MK2206 in RPTC. Both formoterol and clenbuterol increased cGMP in RPTC. Formoterol-induced MB was attenuated by pretreatment with gallein, MK2206, the NOS inhibitor L-NAME, and the sGC inhibitor ODQ in RPTC.

Conclusions: Formoterol induced MB by activating the Gβγ-Akt-eNOS-cGMP pathway, leading to increased MB gene transcription and oxidative metabolism. In contrast, clenbuterol did not activate Akt or induce MB. Because formoterol and clenbuterol increased cGMP production, cGMP is necessary but not sufficient for β_2AR-dependent MB. We propose that structural differences between formoterol and clenbuterol result in distinct receptor interactions that cause differential activation of the Gβγ-Akt pathway. Compounds that selectively activate the Gβγ-Akt pathway are efficacious inducers of MB and potential therapeutics for renal MB and injury.

FR-PO233

HIF1A Activates the TGF-β/SMAD3 Pathway in Kidney Tubular Epithelial Cells Natsuki Kushida,[1,2] Seitaro Nomura,[2] Imari Mimura,[1] Hiroyuki Aburatani,[2] Masaomi Nangaku.[1] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo, Bunkyou, Tokyo; [2]Div of Genome Science, Research Center for Advanced Science and Technology, The Univ of Tokyo, Meguro, Tokyo.*

Background: Kidney injury, including chronic kidney disease and acute kidney injury, is a worldwide health problem. Hypoxia and TGF-β are well-known factors that promote kidney injury. Hypoxia-inducible factor (HIF) and SMAD3 are their main downstream transcriptional factors. Hypoxia-HIF pathway and TGF-β/SMAD3 pathway play crucial roles in the progression of kidney injury. However, reports of their interactions are limited, and the global transcriptional regulation under their control is almost unknown.

Methods: Kidney tubular epithelial cells (HK2: human kidney-2) were cultured and stimulated by 1% hypoxia and TGF-β. We detected global binding sites of HIF1A and SMAD3 in the cells using chromatin immunoprecipitation (ChIP)-Seq, and examined genome-wide gene expression profiling by using RNA-Seq. ChIP-qPCR of SMAD3 was performed after knocking down of HIF1A to quantitatively evaluate the effect of HIF1A on the bindings of SMAD3.

Results: ChIP-Seq revealed that 2,065 and 5,003 sites were bound by HIF1A and SMAD3, respectively, with 614 sites co-occupied by the both factors.RNA-Seq showed that hypoxia and TGF-β stimulation causes synergistic upregulation of 249 genes, containing collagen type I alpha 1 (COL1A1) and serpin peptidase inhibitor, clade E, member 1 (SERPINE1), which are well-known genes related to fibrosis. Ontology of the 249 genes implied that the interaction of HIF1Aand SMAD3 is related to biological processes such as fibrosis. ChIP-qPCR of SMAD3 at HIF1Abinding sites near COL1A1 and SERPINE1 indicated that HIF1A promotes the bindings of SMAD3 induced by TGF-β.

Conclusions: These findings suggest that HIF1A induced by hypoxia activates the TGF-β/SMAD3 pathway. This mechanism may promote kidney injury, especially by upregulating genes related to fibrosis.

FR-PO234

Minichromosome Maintenance Protein 3 Regulates Renal Tubule Cell Signaling Associated with Nrf2 Activation Andrew Birton Smith, Susan M. Isaacs, Madhavi J. Rane, Jon B. Klein, Michael Merchant, Michelle T. Barati. *Kidney Disease Program, Univ of Louisville.*

Background: Altered tubule cell function contributes to progression of diabetic nephropathy (DN). Previous studies in our lab showed upregulation of minichromosome maintenance protein 3 (MCM3), a member of MCM2-7 DNA helicase, in renal tubules of diabetic mice. In addition, MCM3 protein associated with and stabilized Nrf2 in cultured tubule cells and MCM3 knockdown augmented high glucose concentration-induced caspase-3 cleavage. This study addressed the hypothesis that MCM3 regulates cell signaling pathways involved in Nrf2 stabilization and DN.

Methods: HK-11 human proximal tubule cells (PTCs) were transfected with MCM3 DNA or MCM3 siRNA to overexpress or knockdown MCM3, respectively. Total and phosphorylated-ERK and p38 MAP Kinases and glycogen synthase kinase 3β (GSK3β), MCM7 and p21 were analyzed by immunoblotting. Kidney sections of OVE26 diabetic and FVB control mice were immunostained for MCM7.

Results: Activation of ERK induces Nrf2 while p38 MAPK deactivates Nrf2 and overexpression of MCM3 in PTCs transiently increased phosphorylation of ERK1/2 followed by decreased p38 phosphorylation. Overexpression or knockdown of MCM3 in PTCs did not alter phospho-S9GSK3β, a kinase known to deactivate Nrf2. Overexpression of MCM3 increased expression of p21, a cyclin kinase inhibitor that stabilizes Nrf2 and is upregulated in DN. Alternatively, knockdown of MCM3 in tubule cells decreased p21 expression. Unlike MCM3, another member of the MCM2-7 helicase, MCM7, was not increased in renal tubules of diabetic mice, but was down-regulated in PTC following knockdown of MCM3.

Conclusions: In conclusion, regulation of ERK and p38 MAPK are likely mechanisms by which MCM3 stabilizes Nrf2 and may also serve to regulate PTC responses associated with DN. Regulation of p21 in PTC by MCM3 may also serve to stabilize Nrf2, as well as, regulating tubule cell cycle arrest and/or cell death associated with DN or other renal pathologies. Lack of MCM7 regulation in tubules of diabetic mice suggests that MCM3 induction during diabetes may have roles independent of the MCM2-7 helicase.

FR-PO235

Suppression of SIRPa Signaling Affecting Adipose Tissue and Muscle Metabolism: Evidence for Organ Cross-Talk in Chronic Kidney Disease Jiangling Dong,[1] Jiao Wu,[1] Zhaoyong Hu,[1] William E. Mitch,[1] Sandhya S. Thomas.[2,1] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Medicine, Michael E. Debakey Veteran Affairs Medical Center, Houston, TX.*

Background: A major complication of chronic kidney disease (CKD) is insulin resistance, causing metabolic dysregulation of carbohydrate, protein, and lipid metabolism. The large scope of metabolic interrelationships between fat and muscle tissues in CKD suggest there is organ crosstalk between fat and skeletal muscle tissues that worsens insulin resistance. Signal Regulatory Protein alpha (SIRPα), regulates muscle metabolism, we hypothesized that SIRPα mediates organ crosstalk in CKD.

Methods: SIRPα whole body mutant (Mt) mice and wildtype mice (WT) were compared after inducing subtotal nephrectomy. DEXA was used to assess body composition. Skeletal muscles and adipose tissues were evaluated by western blot and qPCR.

Results: Compared to WT CKD mice, SIRPα Mt mice with CKD had improved insulin sensitivity signified as increased tyrosine phosphorylation of IRS1 and pAkt in skeletal muscles and adipose tissues; there also were increased markers of white adipose tissue (WAT) browning (i.e., UCP-1, >2-fold) plus significant increases in mitochondrial activity (acetyl-CoA carboxylase, PGC-1α >5-fold). SIRPα Mt mice also had increased lean mass vs. responses of wild type mice (WT) with CKD.

Conclusions: SIRPα mediates impaired insulin signaling by interfering with intracellular insulin signaling. Suppression of SIRPα improves insulin signaling, promotes lean mass and increases browning of WAT. We conclude that in CKD, SIRPα mediates cross talk between muscle and adipose tissue promoting dysregulation of protein and lipid metabolism likely exacerbating mortality.

FR-PO236

Urinary Vesicles and Differential Centrifugation: Failure of Full Vesicle Content Recover Luca Musante,[1] Dorota Ewa Tataruch,[1] Harry B. Holthofer.[2] *[1]Centre for BioAnalytical Sciences, Dublin City Univ, Dublin, County, Ireland; [2]Freiburg Inst for Advanced Studies, Albert-Ludwigs Univ, Freiburg, Germany.*

Background: Urinary extracellular vesicles (UEVs), especially the exosome fraction, are an ideal, uninvasive source of biomarkers. The bulk of protocols designed for their isolation are based on differential centrifugations at relative centrifugation force (RCF) of 2000g (P2), 40.000g (P40) and 200,000g (P200) respectively. However, a fraction of EVs sediments already at P40 and yet another fraction is in the final supernatant (SN200) to be normally discarded. This means loss of diagnostic EVs throughout the process.

Methods: We used here hydrostatic filtration-dialysis (HFD) to enrich UEVs followed by differential centrifugation. Western blot (WB), ELISA and Tunable Resistive Pulse Sensing (TRSP) were used to characterize and quantify UEVs. Additionally, transmission electron microscopy (TEM) and mass spectrometry (MS) were employed to characterize leftover vesicles in the final ultracentrifugation supernatant. All fractions were also subjected to RNA extraction, quantification and electrophoretic profiling.

Results: Screening and relative quantification for specific UEV marker CD9 in WB and ELISA showed that ~25% of exosomes are recovered in P40, ~50% in P200 and ~25% in SN200 (normally discarded) in respect to the amount of starting material recovered with HFD. Additionally, TEM analysis showed a variety of small size vesicles remaining in SN200. MS identifications matched accurately with the protein listed in the Vesiclepedia. Finally, extraction of the small RNA (snRNA) species from vesicles confirmed that the bulk of RNA is found in P40 with no snRNA was detected in SN200 vesicles.

Conclusions: Notably, exosomes sedimenting already in P40 are grossly lost in the subsequent centrifugation at 200,000g. These results unequivocally call for serious re-evaluation of the isolation workflows used and suggest that alternative methods, like HFD, need to be used. Notably, with HFD all the losses in the conventional serial centrifugations can be avoided to guarantee the catch of the whole vesicle repertoire.

Identification of Differentially Regulated Pathways in Cellular Models of Mutant Uromodulin Expression Celine Schaeffer, Matteo Trudu, Elena Pasqualetto, Stefania Merella, Dejan Lazarevic, Davide Cittaro, Luca Rampoldi. *San Raffaele Scientific Inst, Milan, Italy.*

Background: Uromodulin is the most abundant urinary protein. It is exclusively produced and released in the urine by renal epithelial cells lining the thick ascending limb of Henle's loop (TAL). Mutations in *UMOD*, the gene encoding uromodulin, cause autosomal dominant tubulointerstitial kidney disease uromodulin-related (ADTKD-*UMOD)*. While the primary effect of all mutations, retention in the endoplasmic reticulum (ER), is well established, its downstream effects are still unknown.

Methods: To gain insight into ADTKD-*UMOD* pathogenesis, we performed transcriptional profiling and biochemical characterisation of cellular models (immortalised mouse TAL cells) of robust wild-type or mutant (C150S) GFP-tagged uromodulin expression.

Results: Similar to previous studies, mutant uromodulin is ER retained, but its expression does not impact on cell viability and proliferation. Transcriptional profiling identified 45 up- and 20 down-regulated (fold change >1.5, adjusted p-value< 0.05) genes in mutant cells relative to wild type ones. Up-regulated genes include several ER resident chaperones and protein disulphide isomerases. Consistently, pathway enrichment analysis indicates that mutant uromodulin expression affects ER function, protein homeostasis and calcium signalling. Interestingly, among the three branches of the Unfolded Protein Response (UPR), i.e ATF6, PERK and IRE1, only the one driven by IRE1 is induced, as shown by an increased splicing of XBP1. Treatment with specific IRE1 inhibitor suggests that such induction is not necessary for cell survival and could be maladaptive. Consistent with UPR induction, results obtained by co-immunoprecipitation experiments show association of mutant uromodulin with ER chaperones, as Bip and calnexin. Using metabolic labelling, we also demonstrate that while autophagy plays no role, mutant protein is partially degraded by the proteasome through ER-associated degradation.

Conclusions: Our work shows that ER stress is the main effect induced by mutant uromodulin expression. This cell model will be an interesting tool where to further dissect the molecular pathways of ADTKD-*UMOD* pathogenesis.

Funding: Private Foundation Support, Government Support - Non-U.S.

FR-PO238

A Personalized Drosophila Model of COQ2 Nephropathy Rescued by the Wild-Type Human COQ2 Allele and Dietary Q10 Supplementation Zhe Han, Patricio E. Ray, Yulong Fu, Jun-Yi Zhu, Adam Richman. *Children's National Health Systems.*

Background: Clinical studies have identified patients with nephrotic syndrome (NS) caused by mutations in genes involved in the biosynthesis of Coenzyme Q10 (CoQ_{10}), a lipid component of the mitochondrial electron transport chain and an important antioxidant. However, the cellular mechanisms through which these mutations induce podocyte injury remain obscure.

Methods: We developed *Drosophila* models of COQ-related renal diseases by exploiting the striking similarities between *Drosophila* nephrocytes and human podocytes. We performed the first systematic *in vivo* analysis for each of the 10 COQ genes using nephrocyte-specific gene silencing, with various of function assays, as well as electron microscopy.

Results: We found that silencing each of these COQ genes specifically in nephrocytes shortened the life span of flies. Moreover, nephrocyte-specific silencing of Coq2, Coq6, and Coq8, which are genes involved in the CoQ_{10} pathway that have been associated with genetic NS in humans, induced dramatic adverse changes in these cells. In particular, Coq2-silencing led to an abnormal localization of slit diaphragms, collapse of lacunar channels, and increased number of dysmorphic mitochondria. In addition, Coq2 deficient nephrocytes showed elevated levels of reactive oxygen species, and increased sensitivity to oxidative stress. These phenotypes were rescued by expressing the wild-type human COQ2 gene specifically in nephrocytes, but not the mutant allele derived from a patient with COQ2 nephropathy. Furthermore, dietary supplementation with Coenzyme Q10 reversed this phenotype.

Conclusions: We conclude that transgenic *Drosophila* lines carrying mutations in the CoQ_{10} pathway genes are a clinically relevant model to explore the pathogenesis of podocyte injury, and could serve as a new drug-testing platform for novel therapeutic approaches.

FR-PO239

Mesenchymal Stromal Cells Accelerate Epithelial Tight Junction Assembly via the AMP-Activated Protein Kinase Pathway, Independently of Liver Kinase b1 Pascal Rowart,[1] Pauline Erpicum,[1] Jean-Marie H. Krzesinski,[1] Michael Sebbagh,[2] Francois Jouret.[1] *[1]Univ of Liège, Belgium; [2]Centre de Recherche en Cancérologie de Marseille, France.*

Background: Disruption of epithelial tight junctions (TJ) is one of the earliest hallmarks of acute kidney injury (AKI). Mesenchymal stromal cells (MSC) represent a heterogeneous population of adult fibroblast-like multipotent cells capable of tissue repair properties following AKI. Hence, we hypothesized that MSC may modulate TJ. We focused on the AMP-activated protein kinase (AMPK) pathway since it participates both in energy salvation and TJ maintenance.

Methods: Madin-Darby canine kidney (MDCK) cells were cultured alone or in direct contact with rat bone marrow derived MSC (upon a 3:1 ratio) for 5 days. Next, a Ca^{2+} switch, i.e. switching cells from [5μM] Ca^{2+} (for 48h) to [1.8mM] Ca^{2+} (up to 2h), was performed. TJ formation was assessed upon ZO-1 relocation by immunofluorescence, and AMPK phosphorylation was quantified by immunoblotting. Experiments were repeated using MDCK stably expressing ShRNA against the AMPK kinase, Liver kinase b1 (Lkb1), or against Luciferase (LUC, used as control).

Results: Following Ca^{2+} switch, ZO-1 relocation occurred significantly faster in MDCK/MSC *versus* MDCK. Correspondingly, phospho-AMPK/total AMPK ratio was 1.7-fold increased in MDCK/MSC *versus* MDCK alone (n=4, p<0.001). Of note, AMPK was not detectable in MSC alone. As previously reported, Ca^{2+}-induced ZO-1 relocation to TJ was significantly delayed in Lkb1-ShRNA *versus* LUC-ShRNA MDCK. However, after 48-hour Ca^{2+} deprivation, TJ-associated ZO-1 was significantly more abundant in MSC co-culture systems of either ShRNA in comparison to corresponding ShRNA MDCK alone. Following Ca^{2+} switch, ZO-1 relocation occurred twice faster in ShRNA MDCK/MSC *versus* ShRNA MDCK alone (n=4, p<0.001). Phospho-AMPK/total AMPK ratio was 1.5-fold increased following Ca^{2+} switch in ShRNA MDCK/MSC *versus* ShRNA MDCK alone (n=4, p<0.001). No difference in phospho-AMPK/total AMPK ratio was observed between Lkb1-ShRNA *versus* LUC-ShRNA MDCK following Ca^{2+} switch.

Conclusions: Our results suggest that MSC may modulate AMPK activation in epithelial cells at the time of Ca^{2+}-induced TJ assembly, independently of Lkb1.

FR-PO240

nrip2 Is Required for Megalin-Dependent Endocytosis via Retinoic Acid Pathyway in Zebrafish Pronephric Tubule Qing Hou, Wei-Bo Le, Xiao-Dong Zhu, Ling Wang, Wei-Song Qin, Zhao-Hong Chen, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: Nuclear receptors are transcription factors which require multiple protein-protein interactions to stimulate or repress target gene expression. Nuclear Receptor Interacting Protein 2 (Nrip2) can down-regulate transcriptional activation by binding to retinoic acid receptor in the mouse brain. Retinoic acid (RA) is essential for directing the patterning of the proximodistal nephron segmentation in zebrafish. However, the role of *nrip2* and its association with RA are still unknown in zebrafish kidney.

Methods: We investigated the expression pattern of *nrip2* in zebrafish by *in situ* hybridization. To examine the role of *nrip2*, we generated *nrip2* knock-out (KO) zebrafish using CRIPSR/Cas9 system. Transmission Electron Microscope (TEM) and zebrafish pronephric tubule uptake were carried out. We also detected the expression of *megalin* by immunostaining and analyzed the promoter region of *megalin*.

Results: *nrip2* is expressed predominately and dynamically in zebrafish pronephric tubule during embryogenesis. We introduced a double-strand DNA break in exon2 of *nrip2* and established *nrip2* KO zebrafish. TEM images show *nrip2* deficiency results in reduced amount of endocytic apparatus and cilia in the pronephric tubule. Endocytosis is impaired in the *nrip2* deficiency embryos, the tracer 10KD FITC-Dextran were injected into the cardinal vein of embryos, which are efficiently taken up by the renal tubular cells of control embryos, in contrast, uptake is severely impaired in the *nrip2* deficiency embryos. The expression of *megalin* is reduced in *nrip2* deficiency embryos compared with wild-type embryos. There are two RA response elements are contained in the promoter region of *megalin*, indicating the expression of *megalin* could be altered by RA.

Conclusions: These results suggest that loss of *nrip2* results in impaired *megalin*-dependent endocytosis in zebrafish pronephric tubule and indicate that *nrip2* acts upstream regulator of *megalin* via RA pathway, which will be investigated furthermore.

FR-PO241

Glomerular Endothelial Cells Exposed to Salt-Stress and Aldosterone Loose Key Components from their Glycocalyx Resulting in Functional Impairment Matthew J. Butler, Simon C. Satchell. *Bristol Renal, Univ of Bristol, United Kingdom.*

Background: Aldosterone and salt excess exacerbate proteinuria and may contribute to the progression of kidney disease. We investigated the effects of aldosterone and salt on conditionally immortalised glomerular endothelial cell (CiGEnC) glycocalyx; a protective glycoprotein layer on cells' luminal surface which forms part of the glomerular protein barrier and contributes to laminar shear stress (LSS) detection, as a potential mechanism of damage.

Methods: CiGEnC were exposed to standard media (125mmol NaCl, no aldosterone) or supplemented media (145mmol NaCl, 0.1nM aldosterone). Glycocalyx damage was assessed using immunofluorescence. Functional damage was assessed using cells reaction to LSS; studying up-regulation of Krupple like factor 2 (KLF2) mRNA as an index of LSS response.

Results: 145 mmol NaCl and 0.1nM aldosterone for 5 days resulted in significant up-regulation of matrix metalloproteinases (MMP) 2 and 9 mRNA, but not heparanase mRNA, and significantly reduced surface expression of heparan sulphate (HS) and syndecan 4 (Synd 4). Reduced expression was associated with a functional impairment in cells ability to up-regulate KLF2 in response to LSS.

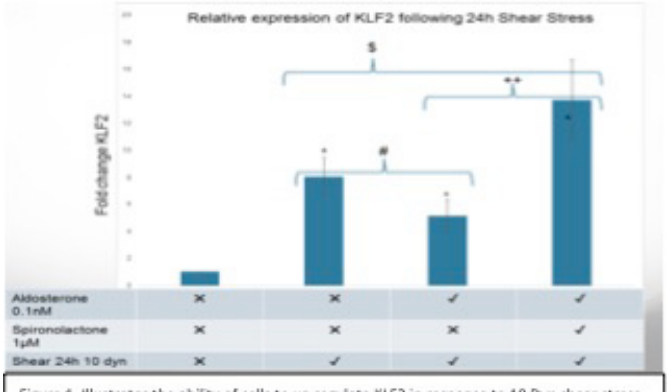

Figure 1. Illustrates the ability of cells to up regulate KLF2 in response to 10 Dyn shear stress for 24h. Aldosterone significantly reduced the response to shear stress ($p<0.05$ #). Spironolactone restored the response suggesting Aldosterone is acting via the mineralocorticoid receptor to elicit damage.

Inhibition of MMPs using the broad spectrum inhibitor Batimistat (5μm) partially restored cells surface expression of HS and Synd 4 and maintained cells ability to up-regulate KLF2 in response to LSS.

Conclusions: Physiologically relevant levels of aldosterone, when combined with elevated salt concentrations, damage CiGEnC glycocalyx. Synd 4 is a LSS sensitive molecule within the glycocalyx. MMP 2 and 9 are known to cleave Synd 4 from the glycocalyx. Inhibition of MMP 2 and 9 prevents HS and Synd 4 loss from the glycocalyx and restores the physiological response to LSS. This work suggests MMP inhibitors may protect the glycocalyx from the damaging effects of aldosterone and salt exposure.

Drug Repositioning Screening for the Discovery of Inhibitors of Keap1–Nrf2 Interaction Using Fluorescent Correlation Spectroscopy Yuki Yoshizaki, Eisei Sohara, Takayasu Mori, Eriko Kikuchi, Daiei Takahashi, Moko Zeniya, Yuya Araki, Yutaro Mori, Fumiaki Ando, Naohiro Nomura, Tatemitsu Rai, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

Background: The Keap1-Nrf2-ARE pathway signal is the major regulator of cyto-protective responses to oxidative and electrophilic stress. Recently, activation of the Nrf2 defense response has been shown to protect against several kinds of diseases, such as diabetes, cardiovascular disease, inflammation and cancer. Moreover, the Nrf2 activator Bardoxolone methyl is now clinically evaluated for the treatment of chronic kidney disease. In this study, we focused on the disruption Keap1–Nrf2 interaction, in order to up-regulate the expression of ARE-controlled cyto-protective oxidative stress response enzyme, such as HO-1. We screened the inhibitors of Keap1-Nrf2 protein-protein interaction, in terms of drug repositioning, using Fluorescent Correlation Spectroscopy (FCS).

Methods: FCS is a method capable of measuring the fluctuation rate of a fluorescently labelled single peptide as output of the diffusion times. For this screening, we used FCS to detect the inhibition of Keap1-Nrf2 binding by drugs.

Results: We succeeded to detect the protein interaction between fluorescent TAMRA-labeled small peptides of Nrf2 and GST-Keap1, and performed drug screening using chemical screening library for drug repositioning, arranged by Tokyo Medical and Dental University chemical library center. We judged that the compound had an inhibitory effect on the binding when the measured diffusion time was not increased, compared to the sample without Keap1 protein. As a result of screening 1633 drugs, we extracted 13 drugs that reproducibly disrupted the binding of Nrf2 to Keap1 in FCS. In HepG2 cells, protein level of Nrf2 was actually increased by administration of 11 of the 13 screened drugs. Furthermore, we detected the up-regulation of ARE gene promoter activity and increasing HO-1 mRNA by 2 drugs.

Conclusions: We screened the inhibitors of Keap1-Nrf2 interaction using FCS. These two compounds could be the promising drug candidates for activation of Nrf2-ARE pathway.

Funding: Government Support - Non-U.S.

The Adaptor Protein CD2AP and L-type Lectin LMAN2 Regulate GPRC5B Trafficking for Its Exosome Release Kenneth Kwon,[1] Sekyung Oh,[4] Marisa Nacke,[3] Keith Mostov,[2] Joshua H. Lipschutz.[1] *[1]Medicine, Medical Univ of South Carolina - MUSC, Charleston, SC; [2]Anatomy and Biochemistry/ Biophysics, Univ of California School of Medicine — UCSF, San Francisco, CA; [3]Cancer Research UK Beatson Inst, Glasgow, United Kingdom; [4]Stanford Univ, Palo Alto, CA.*

Background: Exosomes, 40-100 nm extracellular vesicles, transport biological macromolecules that mediate intercellular communications. While exosomes are known to originate from maturation of endosomes into multivesicular bodies (MVBs) with subsequent fusion of the MVBs with the plasma membrane, it remains unclear how cargos are selected for exosomal release. Previously we have shown that GPRC5B, an orphan G protein coupled receptor is induced during *in vitro* renal tubulogenesis and loaded on exosomes released from renal tubule cells in culture and in human kidneys. Interestingly, intercellular transfer of GPRC5B via exosomes can drive *in vitro* renal tubule growth.

Methods: Using an inducible expression system for the exosome cargo protein GPRC5B and following its trafficking trajectory, combined with CRISPR/Cas9 technology.

Results: we show here that CD2AP is required for internalization of GPRC5B for exosomal release, while LMAN2 (also known as VIP36) inhibits exosome release of GPRC5B. LMAN2 appears to be specifically required for the accumulation in the trans Golgi network (TGN), thereby restricting GPRC5B movement along the exosomal pathway by interfering with TGN-to-endosome transport of GPRC5B.

Conclusions: We propose that GPRC5B is released into exosomes through a TGN-traversing pathway in which LMAN2 critically impedes the flux of exosomes.

FR-PO244

Combinateion of Omega-3 Fatty Acids and Vitamin D Has Synergic Effect on Up-Regulation of NRF-2 Expression and Down-Regulation of SREBP-1 in 5/6 Nephrectomy Rats Young Ki Son,[1] Kitae Kim,[1] Su Mi Lee,[1] Sung Hyun Son,[2] Won Suk An,[1] Seong Eun Kim.[1] *[1]Internal Medicine, Dong-A Univ Hospital, Busan, Korea; [2]Nephrology, BHS Han Seo Hospital, Busan, Korea.*

Background: The Nrf-2 regulates antioxidant and anti-inflammatory process in kidney injury model. Recent study showed that SREBP-1 mediates angiotensin II-induced pro-fibrogenic responses. The present study aimed to investigate whether omega-3 FA and vitamin D which were related with anti- inflammatory process affects the Nrf-2 and SREBP-1expression and has anti-inflammatory, anti-apoptotic, and anti-fibrotic processes in 5/6 nephrectomy rats.

Methods: Male Sprague Dawley rats were divided into five groups: sham control (0.9% saline), 5/6 subtotal nephrectomy (Nx) (0.9% saline), 5/6 Nx treated with vitamin D (cholecalciferol 3000 IU/kg/week) group, 5/6 Nx treated with omega-3 FA (300 mg/kg/day by gastric gavage) group, 5/6 Nx treated with vitamin D and omega-3 FA groups. The expression of IK-b, transforming growth factor (TGF-β1), α-smooth muscle actin (α-SMA), E-cadherin, Smads for inflammation and fibrosis, caspase-3, caspase-7, BAX, and Bcl-2 for apoptosis, and Nrf2 and SREBP-1 were examined. The expression levels of apoptosis-associated factors were examined by western blot analysis.

Results: Serum BUN and creatinine was the lowest in 5/6 Nx treated with omega-3 FA and vitamin D group among 5/6 Nx rat models. Compared with control, 5/6 Nx group significantly up-regulated caspase 3, caspase7, IkB, a-SMA, E-cadherin, SREBP-1, TGF β and Smad2/3 expression and down-regulated Smad6 and Nrf2 expression. We found that omega-3 FA prevented these up and down regulations related with apoptosis, inflammation, and renal fibrosis. There were no significant differences on expression of these factors between 5/6 Nx with untreated group and 5/6 Nx with vitamin D group. However, increased expression of Nrf2 and decreased SREBP-1 expression was distinguished by omega-3 FA and vitamin D combination in 5/6 Nx rats.

Conclusions: Nrf-2 activation and SREBP-1 reduction are potential mechanism induced by omega-3 FA supplementation attenuating pro-inflammatory pathway, fibrotic processes and apoptosis. These mechanisms may be reinforced by additional vitamin D supplementation.

FR-PO245

Molecular Insights into the Program of Proximal Tubules Surviving a Resolving Acute Kidney Injury Aurélien Bataille,[1] Pierre Galichon,[1,2,3] David Legouis,[1] Eric Rondeau,[1,2,3] Alexandre Hertig.[1,2,3] *[1]Inserm UMR_S 1155, Paris, France; [2]Sorbonne Univs, UPMC Université Paris 06, Paris, France; [3]Urgences Néphrologiques et Transplantation Rénale, Hôpital Tenon, Assistance Publique - Hôpitaux de Paris, Paris, France.*

Background: In human beings, even a reversible episode of acute kidney injury (AKI) increases the risk of chronic kidney disease. "Maladaptive repair" was coined to name the pro-fibrotic epithelial changes observed in the aftermath of an AKI. Our aim was to interrogate the effect of a history of a reversible AKI on the transcriptomic pattern of tubular epithelial cells facing a second aggression.

Methods: Adult C57BL6/J wild-type mice were subjected to a left nephrectomy, with (AKI group) or without (Sham group) 20 minutes clamping of the right renal vascular pedicle. Histological recovery was assessed at day 28. At this time point, all mice were subjected to a second hit: angiotensin 2 was continuously administered via subcutaneous pumps (1 $\mu g.kg^{-1}.min^{-1}$). Renal fibrosis was assessed by sirius red coloration. Ex vivo isolation of proximal tubular cells at day 0, 28 and 56 was performed to access total mRNA for high-throughput sequencing.

Results: At day 2, AKI mice displayed acute tubular necrosis at the cortico-medullary junction, and impaired renal function. At day 28, histological recovery was complete, and indistinguishable from sham-operated mice. Arterial pressure and heart rate response to angiotensin 2 was similar in both groups. At day 56, mice with a previous history of AKI displayed significantly more renal fibrosis ($p<0.01$). Investigating the transcriptome of proximal tubular cells, a principal component analysis and clustering individualizes specialized transcriptomes within experimental groups. Up-regulation of metabolic pathways (oxydative phosphorylation, fatty acid metabolism, glycolysis, PPAR signalling pathway) was found in the AKI group compared to the Sham group at day 56.

Conclusions: A resolving episode of AKI poised for activation genes involved in metabolic pathways and durably sensitizes differentiated epithelial cells in a way that promotes energetic hyperactivity concurrently to organ fibrogenesis.

GDF11 Improves Tubule Regeneration after AKI in Elderly Mice Xiang-Mei Chen, Lingling Wu. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing.*

Background: The effects of GDF11 on organ regeneration and repair after injury in elderly mice are highly controversial questions. However, this does not imply the autocrine and paracrine GDF11 is without effect. GDF11 is necessary in metanephric development, and its expression level is highest in the adult kidneys. The function of GDF11 on kidney regeneration and its molecular mechanism were explored in this study.

Methods: Firstly, GDF11 was restoredin the kidney of old mice aged 23-24 months by four dose of intraperitoneal (i.p.) injection of recombinant GDF11 (0.3 mg/kg/d) 48h before bilateral kidney ischemia-reperfusion injury (IRI), and the control group was given an equal volume of vehicle. Renal function, tubular injury scores, tubule cells dedifferentiation and proliferation were assessed at IRI 72h. Next, TGF-β Pathway Phosphorylation Antibody Array was used to analyze phosphorylation events at specific sites in human primary proximal renal epithelial cells (hPTC) treated by rGDF11 or equal volume of 0.1% BSA. Finally, tubule cells dedifferentiation, proliferation and migration were assessed in HPTCs treated by rGDF11 in the presence or absence of the ERK1/2 inhibitor U0126 (10 uM).

Results: Firstly, GDF11 supplementation in the kidneys of aged mice increased dedifferentiation marker vimentin and Pax2 expression and the percentage of 5-ethynyl-2′-deoxyuridine (EdU) positive proximal tubular epithelial cells. GDF11 improved the renal repair, kidney functional recovery and survival of elderly mice at IRI 72 h. Next, GDF11 upregulated Abl1, c-Myc, ERK1/2, Smad1 and Akt phosphorylation by above 1.5 fold in hPTCs. Finally, the ERK1/2 signaling pathway was activated *in vitro* and *in vivo* after GDF11 treatment, and GDF11 regulated dedifferentiation and proliferation in proximal tubule cell via an ERK1/2-dependent pathway in vitro.

Conclusions: Our study indicated that GDF11 could increase tubule cell dedifferentiation and proliferation and improve tubule regeneration after AKI in old mice though ERK1/2 signaling pathway.

FR-PO247

Mesenchymal Stromal Cell-Elaborated Stromal Cell Derived Factor-1 (CXCL12) Is a Potency Marker, Essential for Their Migration and Renoprotective Efficacy in AKI Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]Medicine, U of Utah and VA Medical Centers, SLC, UT; [2]Physiology, U of Utah, SLC, UT.*

Background: We and others showed in preclinical and clinical studies that Mesenchymal Stem Cells (MSCs) are renoprotective when administered within hours of an acute kidney injury (AKI), due largely to (1) MSCs homing to kidneys in response to increased renal expression of SDF-1 and (2) MSC release of protective and reparative cytokines. While renal SDF-1 is upregulated in response to AKI MSCs also express SDF-1. As SDF-1 expression decreases with passaging of MSCs, and as off-the-shelf MSC therapeutic applications rely on cell passaging and banking for dose production, we investigated the role of MSC-expressed SDF-1 in MSC (1) homing and (2) renoprotection.

Methods: 1) The ability of P2 wild type (wt) MSCs vs. MSCs in which SDF-1 was knocked down by siRNA (siMSCs) to migrate toward normal or injured (ATP depleted) Normal Rat Kidney (NRK) cells was assessed in a transwell system. 2) IRI AKI was induced (renal pedicle clamp) in 3 groups of 6 Fischer344 rats. Post reflow, rats were infused i.a. with 2x10e6/kg (a) wt MSCs, (b) siMSCs or (c) vehicle. Renal function, renal and urinary SDF-1 levels and mortality were assessed.

Results: 1) siMSC migration toward ATP depleted NRK cells was significantly decreased vs. wt MSCs. 2) Renal function was protected and improved by wt MSCs, and all animals survived. Vehicle or siMSC administration was ineffective and associated with significant mortality. Parallel to worsened kidney function, renal and urinary SDF-1 levels were significantly higher post AKI in vehicle and siMSC treated rats than in wt MSC-treated rats.

Conclusions: SDF-1 is a known renal cell survival factor and distress signal. Increased renal expression post AKI promotes MSC homing through CXCR4, SDF-1's cognate receptor that is expressed on MSCs. We show here that MSCs' SDF-1 expression is also essential to homing toward injured cells by yet to be elucidated mechanisms, and to their renoprotective, therapeutic efficacy. As SDF-1 expression decreases with MSC passaging, as a potency marker, SDF-1 expression levels must be monitored in MSCs destined for renotherapeutic applications.

FR-PO248

Tenascin-C Protects Kidney against Acute Ischemic or Toxic Injury through Augmenting Wnt/β-Catenin Signaling Shuangqin Chen,[1] Lili Zhou,[1] Haiyan Fu,[1] Youhua Liu.[1,2] *[1]Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China; [2]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Tenascin-C (TNC) is an extracellular matrix glycoprotein and plays an important role in regulating cell survival, proliferation and differentiation. TNC is abundantly expressed during embryonic development and induced in a variety of organ after injury. However, the potential role of TNC and its underlying mechanism in acute kidney injury (AKI) have not been elucidated. In this study, we investigated the potential role and mechanism of TNC in AKI.

Methods: In mouse models of ischemia-reperfusion injury (IRI) and cisplatin nephropathy, renal TNC was knocked down by shRNA-mediated inhibition. Renal function and tubular injury and apoptosis were examined. In cultured tubular epithelial cells (HK-2), cisplatin and staurosporine were used to induce apoptosis, as determined by both FACS and TUNEL. The interaction between TNC and Wnt was also examined by co-transfection of TNC and Wnt1 plasmids.

Results: TNC was upregulated in the interstitial area in AKI following IRI or cisplatin treatment. Knockdown of TNC further deteriorated serum creatinine and blood urea nitrogen, aggravated tubular apoptosis, compared to AKI alone. This effect of TNC inhibition was associated with a reduced β-catenin upregulation, suggesting the relevance TNC to an altered Wnt signaling. In cultured HK-2 cells, recombinant TNC significantly inhibited cisplatin or staurosporine-induced apoptosis, as assessed by FACS and TUNEL, and inhibited caspase-3 activation and Bax and FasL expression. We found that TNC physically interacted with Wnt ligand, as shown by co-immunoprecipitation. Such an interaction augmented Wnt-induced β-catenin activation.

Conclusions: These studies indicate that TNC expression is rapidly upregulated after AKI and this induction of TNC is renal protective. Our data also suggest that the protective effect of TNC is mediated by its regulation of Wnt/β-catenin signaling via physical interaction.

FR-PO249

Age-Dependent Tertiary Lymphoid Tissue Formation in the Kidney as a Novel Therapeutic Target Yuki Sato,[1,2] Akiko Mii,[1] Hirosuke Nakata,[1] Shingo Nishiyama,[1] Motoko Yanagita.[1] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Medical Innovation Center TMK Project, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: There has been a worldwide increase in the number of patients with end-stage renal disease, predominantly in the elderly population in developed countries. Clinical studies demonstrated that the elderly show a reduced capacity for renal regeneration after acute kidney injury (AKI), yet the precise mechanism remains unclear.

Methods: To evaluate the impact of aging on the prognosis of AKI, we induced 3 different kidney injury models to young and aged mice.

Results: Aged mice developed multiple tertiary lymphoid tissues (TLTs) after AKI, whereas young mice did not. As kidney injury progressed, TLTs expanded and destroyed adjacent nephrons. The size of TLTs correlated well with impaired renal function, increased expression of pro-inflammatory cytokines and homeostatic chemokines, suggesting that TLTs in aged injured kidney are detrimental and contribute to sustained inflammation and maladaptive repair after AKI. Notably, lineage tracing analysis demonstrated that resident fibroblasts diversified into fibroblasts with distinct phenotypes, including p75 neurotrophin receptor expressing fibroblasts, retinoic acid producing fibroblasts and homeostatic chemokine producing fibroblasts. Interventions with anti-CD4 monoclonal antibody as well as dexamethasone abolished TLTs and improved renal outcomes. TLTs were also observed in aged human kidneys, whose cellular and molecular components were similar to those of mouse TLTs.

Conclusions: TLTs represent a novel therapeutic target of AKI in the elderly.

Kidney Damage Triggers a PGC1α-to-c-MYC Warburg Shift Perpetuating the Activation of Fibrogenic Progenitor Cells Dario R. Lemos,[1] Gamze Karaca,[1] Ivan G. Gomez,[1] Graham Marsh,[1] Bryce Gordon Johnson,[1] Benjamin D. Humphreys,[2] Jeremy Stuart Duffield.[1] *[1]Biogen, Cambridge, MA; [2]Div of Nephrology, Washington Univ, St. Louis, MO.*

Background: CKD is characterized by fibrosis & inflammation, two major factors impairing tissue regeneration. This inflammatory milieu is deleterious to epithelial cells. In the same environment, however, mesenchymal progenitor cells proliferate and differentiate into myofibroblasts, suggesting inflammatory signals have a positive impact on fibroblast metabolism.

Results: Whole genome analysis of kidney from patients with CKD & fibrosis revealed a unique metabolic signature characterized by reduced expression of genes involved in oxidative phosphorylation (Ox Phos), mitochondrial (mito) activity, and elevated glycolysis and autophagy. Using the kidney ischemia reperfusion model, we found a similar metabolic shift within 72hs after damage. The injured kidney displays increased autophagy, reduced levels of the autophagy cargo protein P62/SQSTM1, loss of the mito biogenesis regulator PGC1a, and the concomitant upregulation of the glycolysis master regulator c-MYC and downstream targets. Nuclear localization of c-MYC in interstitial fibrogenic cells, indicated c-MYC is active 72hs after damage. *S*timulation of PDGFRb+ fibrogenic progenitors from human and mouse kidneys *in vitro* with IL1b, TNFa and LPS, induced autophagy, loss of P62, reduced mTOR signaling, and triggered the PGC1a-to-c-MYC switch. This transcriptional shift resulted in a metabolic phenotype characterized by lower Ox. Phos. capacity and increased aerobic glycolysis. The latter driven by c-MYC as indicated by the inhibitory effect of JQ1 or 10058-F4, two previously characterized c-MYC inhibitors. Similar to observations in cancer cells, the inflammatory signals induce proliferation of PDGFRb+ progenitor cells in a c-MYC-dependent manner. Direct interaction with P62 regulates c-MYC levels in human PDGFRb+ progenitors.

Conclusions: We have identified a novel molecular mechanism driving the activation of mesenchymal fibrogenic progenitors in response to damage. The mechanism relies on a metabolic switch that resembles the Reverse Warburg effect observed in cancer associated fibroblasts.

FR-PO251

Myeloid Cell Heme Oxygenase-1 Expression Regulates the AKI to CKD Transition Jeremie M. Lever,[1] Ravindra Boddu,[1] Oreoluwa O. Adedoyin,[1] James George,[2] Anupam Agarwal.[1,3] [1]*Div of Nephrology, Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL;* [2]*Div of Cardiothoracic Surgery, Dept of Surgery, Univ of Alabama at Birmingham, Birmingham, AL;* [3]*Birmingham VA Medical Center, Birmingham, AL.*

Background: Acute kidney injury (AKI) is a major public health concern, accounting for up to 3% of hospitalized patients. Those who experience AKI requiring dialysis are at a 28-fold increased risk of chronic kidney disease (CKD). Heme oxygenase-1 (HO-1) is an inducible, ubiquitous, cytoprotective enzyme that catabolizes heme. Its induction is protective in animal models of AKI. We have demonstrated that myeloid cell HO-1 mitigates damage following renal ischemia-reperfusion injury (IRI) in the acute setting.

Methods: For this study, we modeled the AKI to CKD transition in mice using unilateral IRI, leaving the contralateral kidney intact, and followed the animals for 3 weeks. Given the importance of macrophages (MΦs) in regulating kidney damage after AKI, we *hypothesized* that HO-1 deficiency in myeloid cells would lead to worse outcomes in this model. We used cre-lox mice in which HO-1 is deleted in myeloid cell populations (LysM-HO-$1^{-/-}$).

Results: Surprisingly, we found LysM-HO-$1^{-/-}$ mice exhibited less proteinuria and renal fibrosis, when compared with floxed control mice (LysM-HO-$1^{+/+}$) (urinary ACR: 0.131 ± 0.02 and 0.188 ± 0.02 in LysM-HO-$1^{-/-}$ and LysM-HO-$1^{+/+}$, respectively, $p = 0.04$). In addition, greater absolute numbers of bone marrow-derived MΦs ($F4/80^{low}CD11b^{hi}$, $7.22x10^6 \pm 6x10^5$ vs $4.90x10^6 \pm 6x10^5$, $p = 0.03$) and NK cells ($NK1.1^+$, $4.51x10^6 \pm 6x10^5$ vs $2.44x10^6 \pm 5x10^5$, $p = 0.02$) were observed in injured kidneys from LysM-HO-$1^{-/-}$ mice, indicating these cell types may play a protective role in this model. Further, myeloid cell HO-1 deficiency resulted in a trend toward lower proportions of pro-fibrotic tissue-resident MΦs ($F4/80^{hi}CD11b^{low}$, 12.14 ± 1.3% versus 16.56 ± 1.6%, $p = 0.07$).

Conclusions: These studies demonstrate that HO-1 expression in myeloid cells regulates progression in the AKI to CKD model, having potential implications for developing cell-based therapy or strategies involving modulation of HO-1 expression in the AKI to CKD transition.

FR-PO252

Proximal Tubule-Specific Heme Oxygenase-1 Modulates the Progression of AKI to CKD Laurence Marie Black,[1] James George,[2] Anupam Agarwal,[1,3] Subhashini Bolisetty.[1] [1]*Nephrology Research and Training Center, Div of Nephrology, Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL;* [2]*Dept of Surgery, Univ of Alabama at Birmingham, Birmingham, AL;* [3]*Birmingham VA Medical Center, Birmingham, AL.*

Background: Acute Kidney Injury (AKI) is associated with high morbidity and mortality, and can to lead to chronic kidney disease (CKD), though the mechanism(s) are unclear. AKI is ameliorated by the induction of heme oxygenase-1 (HO-1), a cytoprotective enzyme that catalyzes the breakdown of pro-oxidant heme, into pro-survival by-products. Such induction of HO-1 occurs predominately in renal proximal tubules (PT), which are important for fluid, nutrient, and electrolyte homeostasis and thus consume significant energy.

Methods: To evaluate the role of PT-specific HO-1 in the transition from AKI to CKD, we used transgenic mice, generated using the cre-lox system, to manipulate HO-1 expression specifically in the PT. We examined the progression to CKD using unilateral kidney ischemic injury (30 minutes) followed by reperfusion and leaving the contralateral kidney intact.

Results: We demonstrate that selective PT-specific HO-1 deletion lessens the severity of fibrotic remodeling in the injured kidney, as evident by decreased expression of fibronectin, α-smooth muscle actin, and reduced collagen deposition. PT deletion of HO-1 also led to significantly reduced expression of inflammatory markers, such as TNF-α, in the injured kidneys compared to wild-type littermates. Interestingly, HO-1 led to decreased levels of urinary neutrophil gelatinase-associated lipocalin (NGAL), a biomarker of AKI, at 24h post-injury and reduced NGAL gene expression in the injured kidneys at day 21.

Conclusions: These results suggest a role of PT-specific HO-1 in modulating fibrotic remodeling post-ischemic injury and may provide insight into the generation of therapies for preventing progression from AKI to CKD.

Inhibition of TGF-β Activation by an RGD Small Molecule Alpha V Integrin Inhibitor Reduces Fibrosis in a Mouse Model of Nephrotoxic Injury Jeannine M. Basta,[1] Lynn R. Robbins,[1] David W. Griggs,[1] Michael I. Rauchman.[1,2] [1]*St. Louis Univ, St. Louis, MO;* [2]*St. Louis VA Medical Center, St. Louis, MO.*

Background: Targeting TGF-β activity is an attractive strategy for anti-fibrotic therapy. However, clinical trials have shown that global targeting of TGF-β signaling has serious adverse effects. A more promising approach is to disrupt TGF-β activation specifically in the injured tissue. TGF-β is held in an inactive state by binding of the Latency Associated Peptide (LAP) in the extracellular matrix (ECM). Binding of alpha v integrins to the arginine-glycine-aspartic acid (RGD) LAP motif is a major mechanism that releases biologically active TGF-β. Inhibition of integrin binding to the RGD motif prevents TGF-β activation.

Methods: CWHM-12 is novel highly potent peptidomimetic that inhibits all RGD integrins. CWHM-12 potently blocked TGF-β activation by LTC-14 myofibroblasts with a mean IC_{50} value of 1.5 nM (SD = 0.78; n=4). To determine if inhibition of RGD integrins could prevent kidney fibrosis, we tested CWHM-12 in mice exposed to the nephrotoxin Aristolochic Acid-I (AA). Active drug was infused by osmotic mini-pumps at a rate of 100 mg/kg body weight per day. Kidney injury was induced by a single intra-peritoneal injection of AA (5 mg/kg body weight) 1 day after drug infusion.

Results: 28 days after injury, serum creatinine was significantly less (0.15 vs. 0.32 mg/dl, P=0.011) in animals treated with CWHM-12 compared with vehicle, indicating partial recovery of renal function. CWHM-12 significantly attenuated the up-regulation of *Col1a1* mRNA (32 vs 7-fold), a major component of ECM deposition in injured kidneys; this was confirmed by Sirius red staining. Smooth muscle actin staining revealed a significant decrease (26% area) in drug treated kidneys versus vehicle (n=3, P <0.001). RNA-seq analysis revealed a significant decrease in many profibrotic (*Col3a1*, *Mmp2*, *Fn1*, *Ctgf*) and activated myofibroblast genes (*Rgs16*, *Crlf1*, *Gli1*, *Pdgrfb*) in injured kidneys treated with CWHM-12.

Conclusions: Inhibition of RGD integrins is a promising novel therapeutic approach to slow progressive CKD by limiting fibrosis.

Umbilical Cord-Derived Cells Protect against Maladaptive Repair in Renal Ischemia/Reperfusion Injury Camila Eleuterio Rodrigues, Jose Manuel Condor Capcha, Ana C. de Bragança, Talita R. Sanches, Priscila Queiroz Gouveia, Denise M. Malheiros, Patricia Ferreira Oliveira, Mirela Santinho, Rildo A. Volpini, Irene L. Noronha, Lucia Andrade. *Univ of Sao Paulo, Brazil.*

Background: Human umbilical cord-derived mesenchymal stromal cells (huMSCs) are a treatment option in ischemia/reperfusion injury (IRI)-induced AKI, but their role in slowing progression to CKD is unclear.

Methods: Male rats were induced to renal IRI, i.p. injected 6h later with saline or 1×10^6 huMSCs and euthanatized on day 2 (D2), D7 or D49. We evaluated plasma and urinary parameters. In kidney tissue, we performed western blotting (AQP2, βgal, p21, p16, TGFβ, klotho and heme oxygenase-1), immunohistochemistry (for macrophage) and qPCR (for miRNA expression). Data are mean±SEM.

Results: On D2, renal filtration and tubular function were better in treated rats. Recovery was similar on D7, but treated rats showed less dysfunction on D49.

Parameter	Control	IRI2	IRI+ huMSC2	IRI7	IRI+ huMSC7	IRI49	IRI+ huMSC49
Urea, mg/dl	52 ±2.5	234 ±36.3[a,b]	108 ±19.6	59.8 ±14.8	43.7 ±4.5	65 ±26.7[a,d]	52 ±5.0
Creat, mg/dl	0.3 ±0.02	2.4 ±0.4[a,b]	0.9 ±0.17	0.7 ±0.20	0.5 ±0.2	0.9 ±0.26[a,d]	0.6 ±0.03[a]
Cl Creat, ml/min/100g BW	0.59 ±0.04	0.10 ±0.02[a,b]	0.23 ±0.05[a]	0.25 ±0.06[a]	0.22 ±0.03[a]	0.29 ±0.08[a]	0.42 ±0.1
FENa, %	0.10 ±0.01	3.27 ±1.10[a,b]	0.48 ±0.09	0.38 ±0.13[a,c]	0.14 ±0.02	0.07 ±0.03[a,d]	0.03 ±0.01
Urinary flow, ml/min/100g BW	0.002 ±0.0004	0.005 ±0.0006[a]	0.006 ±0.0007[a]	0.004 ±0.0009[a,c]	0.002 ±0.0003	0.002 ±0.0009	0.005 ±0.0013

[a]p<0.05 vs. control; [b]p<0.05 vs. IRI+huMSC2; [c]p<0.05 vs. IRI+huMSC7; [d]p<0.05 vs. IRI+huMSC49

Urinary osmolality was higher in treated rats (D2: 450±23 vs. 354±24 mOsm/kg; D49: 513±39 vs. 480±61 mOsm/kg, p<0.05), as was AQP2 expression (D2: 112.0±5.6 vs. 61.9±7.2%; D49: 122.8±3.3 vs. 100.0±7.7%, p<0.05). On D2, treated kidneys showed less macrophage infiltration; lower levels of βgal, p21, p16, TGFβ, miR-29a and miR-34a; and higher heme oxygenase-1 and Klotho protein expression. On D49, treated rats showed higher renal Klotho expression, less βgal expression, and less histological damage.

Conclusions: Treatment with huMSCs might slow progression from AKI to CKD. (Supported by FAPESP).

Tenascin-C Expressing Stromal Cell Is a Potential Niche for the Injury Repairing of the Kidney following Ischemia-Reperfusion Injury Qionghong Xie, Min Zhang, Xiaoyi Mao, Da Shang, Chuanming Hao. *Div of Nephrology, Huashan Hospital, Shanghai, China.*

Background: Tenascin-C (TNC), a non-structural extracellular matrix glycoprotein, is involved in creating a specific microenvironment for cell survival, proliferation and migration. The study examined the role of tenascin-C in ischemic reperfusion (IR) induced acute kidney injury (AKI).

Methods: A TNC promoter driven inducible CreER2 knock-in mouse line with an EGFP was generated and IR was used as an AKI model. Homozygous $TNCCreER^{+/+}$ ($TNC^{-/-}$) was used to examine the role of TNC in AKI. The cellular distribution of TNC in the kidney was determined using immunofluorensce and TNC reporter transgenic mice. The double-transgenic TNC-$CreER2^{+/-}$Rosa-$tdTomato^{+/-}$ mice were used for cell lineage chasing.

Results: TNC is normally expressed in renal medullar interstitial cells (RMIC) and markedly induced in the whole kidney, especially in the outer medulla and the cortex

adjacent to medulla after IR. Increased TNC was also observed in biopsy tissues from AKI patients. Deletion of TNC significantly aggravated IR induced AKI (BUN 113 vs 11.2mmol/L at day 2) and reduced survival (5/10 vs 10/10 by 7 days following IRI). To determine the nature of TNC expressing cells, we co-stained TNC reporter eGFP with kidney cell markers and found that the TNC expressing cells were restricted in the interstitium. They did not express CD68 and F4/80, nor CD44(+), CD34(+) and FSP1(+). Some of the TNC expressing cells (40%) expressed αSMA. Cell linage-chasing experiment suggested that the TNC expressing cells in the injured area were not originated from medullary cells that normally express TNC, and TNC was induced in certain stromal cells following IR. Hypoxic response element is identified in the promoter region of TNC and a HIF stabilizer markedly induced renal TNC expression in mice and in cultured primary interstitial cells. Cell cultured studies showed that exogenous TNC induced activation of STAT3. The activation of STAT3 was also found lower in $TNC^{-/-}$ than WT mice following IR, consistence with a STAT3 signaling mechanism involved in the protective effect of TNC.

Conclusions: Matrix protein TNC alleviates IR-induced AKI by interacting with epithelial cells through STAT3 pathway.

NecroX-7, Necroptosis Inhibitor, Attenuates Cisplatin Nephropathy

Jin Young Jeong,[1,2] Hong Jin Bae,[1] Young Rok Ham,[1] Dae Eun Choi,[1] Ki Ryang Na,[1] Kang Wook Lee,[1] Yoon-Kyung Chang.[3] *[1]Nephrology, Chungnam National Univ, Daejeon, Korea; [2]Medical Science, Chungnam National Univ, Daejeon, Korea; [3]Nephrology, Catholic Univ, Seoul, Korea.*

Background: Reactive oxygen species (ROS) generation and necrosis play a important role in cisplatin nephrotoxicity. There have been developed NecroX series that can attenuate necroptosis pathway. Especially, NecroX-7 showed anti-necroptotic and anti-oxidative feature. We investigated the effect of NecroX-7 on cisplatin nephrotoxicity in mice.

Methods: C57BL/6 mice were divided into 4 groups; normal control group (n=7), NecroX-7 treated control group (n=7), vehicle with cisplatin (20mg/kg, intraperitoneal injection) treated group (n=9), and NecroX-7 (2mg/kg, intraperitoneal injection) with cisplatin treated group (n=9). We measured BUN and serum creatinine. Also we examined histologic findings (H&E and PAS stain). We examined molecular study for oxidative stress and necroptosis.

Results: The levels of BUN and serum creatinine in NecroX-7 with cisplatin treated mice were significantly lower than that of vehicle with cisplatin treated mice(p <0.05). In microscopy, NecroX-7 significantly reduced renal tubular epithelial cell necrosis and detachment in cisplatin treated mice kidney. NecroX-7 significantly reduced RIP1, RIP3, MLKL, and PARP in cisplatin treated mice kidney. Also it reduced p22phox expression and 8-OH deoxyguanosine positive cells in cisplatin treated mice kidney. It elevated UCP2 expression in cisplatin treated mice kidney.

Conclusions: NecroX-7 attenuates oxidative and necroptotic renal injury in cisplatin induced nephrotoxicity.

FR-PO257

Par1b Deficiency Leads to Polarity Defects in Acute Kidney Injury

Abhijeet Pal, Zhongfang Du, Kimberly J. Reidy. *Pediatric Nephrology, Children Hospital of Montefiore and Albert Einstein Medical College, Bronx, NY.*

Background: Partitioning defective (Par)1 is a serine threonine kinase member of Par polarity protein family, first found to be important in establishing embryonic polarity in C.elegans. Par1a and Par1b are functionally redundant mammalian homologues that are highly expressed basolaterally in the developing kidney and regulate cell adhesion and polarity. Mice with 1 of 4 copies of *Par1a* or *1b* die after birth and have hypoplastic kidneys with abnormal proximal tubular cell-cell adhesion. Increased expression of Par1a and Par1b is noted in acute kidney injury in mice and humans. Apico-basal polarity and adhesion defects are hallmarks of acute kidney injury which lead to transport defects and back-leak of toxins. We hypothesize that Par1 proteins play an important role in acute kidney injury recovery by regulating polarity and adhesion.

Methods: To test the effect of Par1a and 1b deletion on development of renal tubular injury, cisplatin was injected in *Par1a* and *1b* knockout mice. Controls were cisplatin injected wild-type (WT) and un-injected WT and knockout mice.

Results: Using immunofluorescence and western-blot, we identified increased baso-lateral Par1a/1b expression following cisplatin injury. Periodic Acid Schiff staining demonstrated increased number of dilated tubules and protein casts in cisplatin treated *Par1a* and *1b*-/- vs WT, with most severe injury in *Par1b*-/- mice. Quantification of TUNEL positive nuclei indicated a three-fold greater increase in apoptotic nuclei in *Par1b*-/- vs. WT mice following cisplatin injury (p<0.05). Severe mis-localization of basolateral adhesion molecules, E-cadherin, N-cadherin and β-Catenin, and luminal transporters Aquaporin-1 and Megalin was observed in cisplatin injected *Par1b* knockout mice that was not present in controls.

Conclusions: Mice with loss of *Par1a* or *1b* exhibited more severe tubular injury following cisplatin injection in mice. This was associated with severe mis-localization of cell-cell adhesion proteins and increased apoptosis. This experimental model suggests that Par1b in contributes to cellular polarity and renal regeneration in the setting of acute kidney injury.

Persistent Kidney Injury Molecule-1 (Kim-1) Expression Promotes AKI to CKD Transition after Severe Renal Ischemia-Reperfusion Injury (IRI)

Xiaojing Gu,[1] Xizhong Zhang,[2] Aaron R. Haig,[2] Lakshman Gunaratnam.[2] *[1]West China School of Medicine, Chengdu, Sichuan, China; [2]Schluich School of Medicine and Dentistry, Western Univ, London, ON, Canada.*

Background: Maladaptive repair after acute kidney injury (AKI) driven by renal tubular epithelial cell (TEC) secretion of profibrotic factors results in tubulointerstitial fibrosis and chronic kidney disease (CKD). Kim-1 is a phosphatidylserine receptor upregulated on proximal TECs during AKI. We showed Kim-1 mediates phagocytic clearance of apoptotic and necrotic cells and protects against renal damage acutely after bilateral renal IRI. However, transgenic overexpression of Kim-1 in TECs promotes spontaneous kidney fibrosis. We thus investigated whether Kim-1 can promote AKI to CKD transition.

Methods: We subjected Kim-1 deficient (KO) and wild-type (WT) mice to unilateralrenal pedicle clamping for 35 min (moderate) or 45 min (severe) (n=3-5/group/experiment). Mice were euthanized at 3 and 28 days. Renal damage and fibrosis were assessed by a pathologist blinded to mouse genotype using standard scales. Quantitative RT-PCR was used to detects expression of profibrotic factors (Collagen-1&4) and inflammatory cytokines (MCP-1, IL-1β, IL-6, TNF-α) and Kim-1.

Results: As expected, KO mice exhibited worse renal injury (median injury score 4/5 vs. 3/5, p<0.05) and greater MCP-1, IL-1β and IL-6 mRNA expression (p<0.05 for each) than WT mice 3 days after moderate UIRI. Surprisingly, these differences were not present 3 days after severe UIRI. At 28 days, renal fibrosis, profibrotic factors, and inflammatory cytokines were not different between KO and WT mice after moderate UIRI, but after severe UIRI KO mice had less renal fibrosis (3.5/5 vs. 5/5, p=0.016), less collagen-1&4, IL-1β and TNF-α expression (p<0.05 for each). Significantly higher renal Kim-1 expression was observed at 28 days after severe compared to moderate UIRI (p<0.05).

Conclusions: Our data suggest that KIM-1's protective role during the acute phase of AKI can be overwhelmed if the injury is severe, and that persistent KIM-1 expression after severe injury can promote long-term renal fibrosis. These results have implications when considering potential therapeutic options that target Kim-1 during AKI.

Sustained Increased microRNA-21 Drives Aristolochic Acid Induced AKI to CKD Progression

Yi Fang,[1,2] Sheng Wu,[1] Bingying Zhang,[1] Qing Kuang.[1] *[1]Nephrology, Zhangshan Hospital, Fudan Univ, Shanghai, Sha, China; [2]Shanghai Key Laboratory of Kidney Diseases and Blood Purification, Shanghai, China.*

Background: To investigate the role of microRNA-21(miR-21) in the development of renal tubulointerstitial fibrosis secondary to aristolochic acid induced acute kidney injury.

Methods: C57BL/6J male mice were intraperitoneally injected witharistolochic acid at a dose of 10 mg/kg. Blood samples and kidneys were harvested at day1, 3, 7, 14, 28 after aritolochic acid treatment. Locked nucleic acid-modified anti-miR-21 oligonucleotides (10mg/kg) were administered intravenously to mice via the tail vein less than 30mins prior to aristolochic acid exposure, and the dose was repeated at day5 and day10.

Results: Renal tubulointerstitial fibrosis developed at 14 days after aristolochic acid treatment. The abundance of miR-21 increased at day 7 after aristolochic acid dosing, peaked at day14 and thereafter maintained at a high level. Protein expression of α-SMA, vimentin and collagen I were significantly up-regulated at day 7 and peaked at day 28 (P < 0.01), while protein abundance of E-Cadherin decreased at day 14 and thereafter (P<0.01). Anti-miR-21 treatment relieved renal injury with reduced serum creatinine (P<0.05) and attenuation of renal tubulointerstitial fibrosis. Besides, the protein expression of PTEN, a target of miR-21, was up-regualted and the ratio of its downstream genes p-AKT/AKT was decreased after anit-miR21 treatment (P <0.05).

Conclusions: Sustained increased abundance of miR-21 was imperative for the development of chronic kidney disease secondary to aristolochic acid induced acute kidney injury. Renal tubulointerstitial fibrosis could be partially reversed by inhibiting miR-21 via PTEN/ p-AKT pathway.

FR-PO260

Animal Models for Progression from Acute to Chronic Kidney Injury in Mice

Kengo Mayumi,[1] Mizuki Yamano,[1] Tetsushi Yamashita,[1] Yoshifumi Hamasaki,[2] Eisei Noiri,[1] Masaomi Nangaku,[1] Kent Doi.[3] *[1]Nephrology and Endocrinology, The Univ of Tokyo, Bunkyou, Tokyo, Japan; [2]22nd Century Medical and Research Center, The Univ of Tokyo, Bunkyou, Tokyo, Japan; [3]Emergency and Critical Care Medicine, The Univ of Tokyo, Bunkyou, Tokyo, Japan.*

Background: Recently, epidemiologic studies have suggested that acute kidney injury (AKI) is one of the important precipitating factors in the progression of chronic kidney disease (CKD). However, mechanism of CKD progression after AKI has not been investigated sufficiently. Animal model that mimics clinical features of AKI-to-CKD is necessary.

Methods: We developed two mouse AKI-to-CKD models by combining renal ischemia reperfusion and nephrectomy; unilateral ischemia-reperfusion injury with contralateral nephrectomy (UIR+UNx) and without contralateral nephrectomy (UIR), and evaluated their differences of post-ischemia injury and drug responses.

Results: Serum creatinine and BUN was elevated in the UIR+UNx group, but the UIR group showed no increase. Quantitative analysis revealed that interstitial fibrosis in the kidney of the UIR+UNx group was significantly milder than that of the UIR group.

Glomerular abonormalities including sclerosis were not found in the both groups. Orally administration of telmisartan, an angiotensin II receptor blocker, improved interstitial fibrosis not in the UIR+UNx group, but in the UIR group. In addition, telmisartan administration inhibited mRNA expression of profibrotic factors (αSMA, TGF-β1, and Galectin-3) only in the UIR group. After induction of anemia by hemolysis with phenylhydrazine administration, serum erythropoietin concentration was significantly higher in the UIR group than in the UIR+UNx group, but renal EPO-mRNA expression in the ischemic kidney is higher in UIR+UNx group than in UIR group.

Conclusions: We found the differences in post-ischemic fibrosis, an anti-fibrotic effect of telmisartan, and erythropoietin producing ability in response to anemia between the two AKI-to-CKD models. These differences will suggest that careful interpretation is necessary for animal experiments that evaluate AKI to CKD progression.

FR-PO261

Human Mesenchymal Stromal Cells Derived Extracellular Vesicles Alleviate Renal Ischemic Reperfusion Injury and Enhance Angiogenesis in Rats Xiangyu Zou, Di Gu, Yingjian Zhu. *Dept of Urology, Shanghai XinHua Hospital Affiliated to Shanghai Jiaotong Univ, School of Medicine, Shanghai, China.*

Background: Mesenchymal stromal cells (MSCs) derived extracellular vesicles (EVs) were regarded as a potent medium for kidney injury repair and angiogenesis plays an important role in tissue repair. However, MSC-EVs' pro-angiogenesis effect in ischemia-reperfusion induced kidney injury and its potential mechanisms has yet to be determined.

Methods: EVs were isolated from the conditioned medium of human Wharton-Jelly mesenchymal stromal cells (hWJMSCs) (treated with RNase or not) were injected in rats intravenously after unilateral kidney ischemia. Animals were sacrificed at 24h and 2 weeks after injury respectively. Next, we examined the renal functions and histology to assess the therapeutic effect of the EVs. Moreover, we investigated the pro-angiogenesis effects and the probable mechanisms.

Results: It was observed that human MSC-EVs could reduce cell apoptosis and enhances cell proliferation 24h after kidney injury, meanwhile renal function was improved and histological lesion was mitigated. Moreover, at this time point we found VEGF was up-regulated in EVs group and HIF-1α was down-regulated. Further, the capillary vessel density was increased in EVs group after 2 weeks and the renal fibrosis was reduced as well. In vitro, EVs could both deliver human VEGF directly to renal tubular epithelial cells (TECs) and induced rats VEGF synthesis in TECs under hypoxic conditions. Most important, all the beneficial effects of MSC-EVs were abrogated by RNase treated except for the delivery of human VEGF.

Conclusions: MSC-EVs could protect against IRI kidney injury through pro-angiogenesis effects, and both the delivery of pro-angiogenesis related proteins and RNAs involve in this process.This provides the direction for future clinical applications.

FTY720 Reduced Acute Kidney Injury in a Sepsis Rat Model via Sphk1 Pathway Jun Yan Fang,[1] Lei Zhang,[2] Xin Li,[1] Feng Ding.[1] *[1]Dept of Nephrology, The 9th People's Hospital of Shanghai The Medicine College of Shanghai JiaoTong Univ, Shangha, China; [2]Dept of Nephrology, Shanghai Jiaotong Univ Affiliated First People's Hospital Baoshan Branch, Shangha, China.*

Background: Sphingosine kinase-1(Sphk-1), an enzyme which is active in neutrophils and macrophages, regulates proinflammatory responses that are important in endotoxemia and sepsis. Recent study shows that Sphk-1 and its product sphingosine-1-phosphate(S1P) promote inflammation via TNF-αsignalling and the canonical NF-κB activation pathway. FTY 720, a S1P analog, is a FDA approved sphingosine-1 phosphate (S1P) receptor agonist. Recent evidences demonstrate that FTY720 offers therapeutic potential against lung injuries in murine sepsis models. We therefore hypothesized that treatment with FTY720, could ameliorate the acute renal injury induced by sepsis through Sphk-1 pathway.

Methods: Male rats (250-300g, 2 months, n=5 for each group) underwent standardized procedures of cecal ligation and puncture (CLP) to induce sepsis. The rats were treated with 4mg/kg/day FTY720 or vehicle right after surgery by gavage for 5 days.

Results: CLP rats exhibited increased Sphk-1, S1P and TNF-a level accompanied by acute tubular cell injury. Five days FTY720 treatment improved the survival rate by 50% (80% vs 40%) and the acute tubular injury score by 53.2%(1.800±0.1144 vs 3.85±0.1163), and reduced BUN and serum creatinine levels by 23.0%(9.520 ±1.443mmol/L vs 12.37±4.139mmol/L)and 20.2%(137.5±12.50umol/L vs 172.3±17.48 umol/L)respectively in CLP rats compared with CLP rats treated with vehicle. Moreover, FTY720 inhibited Sphk-1 expression in CLP rats kidney and decreased S1P concentration of kidney by 40.6% (939.6±52.03 vs 1583.0±161.7 nmol/L) compared with CLP rats treated with vehicle. Furthermore, TNF-α levels in CLP rats kidneys was reduced by 24.8%(325.4±25.86 ng/L vs 432.7±19.03ng/L) by FTY720 treatment.

Conclusions: FTY720 reduced the mortality and prevented renal functional decline in CLP rats via down-regulation of the Sphk-1 pathway and amelioration of inflammation.

FR-PO263

Endothelial Colony Forming Cells (ECFCs) in Murine AKI: Implications for Future Cell-Based Therapies Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Clinic of Nephrology and Rheumatology, Univ Hospital of Göttingen, Göttingen, Niedersachsen, Germany.*

Background: Early Endothelial Progenitor Cells (eEPCs) have been proven as effective tool in murine ischemic AKI and in diabetic nephropathy. Only few data in contrast have been published about the role of so-called Endothelial Colony Forming Cells (ECFCs - late EPCs) in ischemic AKI. We thus aimed to investigate ECFC effects on postischemic kidney function and structure over several weeks. Our special interest focused on endothelial-to-mesenchymal transition (EndoMT), peritubular capillary density (PTCD), endothelial alpha-Tubulin (aT - cytoskeletal integrity), and endothelial p62 (marker of autophagocytic flux).

Methods: 8-12 weeks old male C57/Bl6N mice were subjected to bilateral renal pedicle clamping for 35 and 45 minutes, respectively. Donor-derived syngeneic ECFCs (0.5×1.000.000) were i.v. injected at the end of ischemia. Animals were analyzed 1, 4, and 6 weeks later.

Results: Cell therapy improved kidney function exclusively at week 1 (35 and 45 min). Ischemia-induced fibrosis was diminished in all experimental groups by ECFCs, while PTCD loss remained unaffected. Significant EndoMT was detected in only two of 6 groups (35 min, week 4 and 45 min, week 6), ECFCs reduced EndoMT only in the latter. Endothelial aT declined under almost all experimental conditions and these effects were further aggravated by ECFCs. p62 was elevated in endothelial cells, more so after 45 than after 35 minutes of ischemia. Cell therapy did not modulate p62 abundances at any timepoint.

Conclusions: ECFCs act AKI-protective in the mid- to long-term. There are certain differences in renal outcome parameters between eEPCs and ECFC. The latter do not prevent animals from peri-tubular capillary loss and they also do not further elevate endothelial p62. We conclude that differences between eEPCs and ECFCs result from certain mechanisms by which the cells act around and within vessels. Overall, ECFC treatment was not as efficient in preventing mice from ischemic mid- to long-term damage as eEPC therapy.

FR-PO264

The Role of C1q in Apoptotic Cells Phagocytosis In Vitro and Obstructive/ Ischemic Renal Injury In Vivo Eoin D. O Sullivan, Jeremy Hughes, David A. Ferenbach. *MRC Centre for Inflammation Research, Univ of Edinburgh, Edinburgh, United Kingdom.*

Background: C1q initiates classical complement activation and is implicated in glomerular disease pathology. C1q binds to antibodies/surface proteins, activates C3 binding, mediates apoptotic cell (AC) clearance and modulates macrophage phenotype. Recent studies demonstrate that C1q levels increase in aging rodents and man, and via intracellular Wnt signaling inhibits skeletal muscle regeneration in aged mice. We tested the hypothesis that increased C1q may augment fibrosis and worsen AKI/inflammation via complement-mediated injury.

Methods: Serum was obtained and used for *in vitro* studies of primary murine bone marrow derived macrophage (BMDM) phagocytosis. C57Bl6 and C1q KO animals underwent unilateral ureteric obstruction and ischaemia-reperfusion injury.

Results: *In vitro*, serum from aged mice had higher C1q levels (170.5±7.5 vs 92.7±14.8ug/mL; p<0.05 O vs Y), and augmented AC phagocytosis by BMDM (%phago 45.1±0.9 vs 27.8±1.8; p<0.05 O vs Y). AC treated with C1q depleted serum showed absent C3 labelling, which was fully restored by addition of recombinant C1q. BMDM phagocytosis of ACs was assessed with C1q replete and C1q depleted human serum. Compared to serum free the addition of C1q alone had little effect on phagocytosis (%phago 31.8±1.3 vs 34.0±1.1), the addition of human serum augmented phagocytosis (%phago 56.6±2.1 p<0.01 vs serum free), with C1q depleted serum ineffective (%phago 29.3±0.8 p<0.01 vs normal serum). The addition of C1q to C1q deplete serum augmented phagocytosis (%phago 51.6±2.1) demonstrating that serum is essential for propagation of the C1q phagocytosis signal. *In vivo*, baseline renal collagen expression in C1qKO and wild-type mice was comparable. C1qKO animals showed no protected phenotype (equal creatinine and ATN) after acute IRI and worse fibrosis after d7 unilateral ureteric obstruction (%collagen deposition 14.2±2.1 vs 8.5±1.3; C1qKO vs WT, p=0.04).

Conclusions: We found no improvement in injury levels in C1qKO mice with worsened scarring after UUO *in vivo.* I*n vitro* experiments showed major defects in AC clearance in the absence of C1q. Inadequate labeling and uptake of ACs may lead to increased tissue injury and fibrosis.

Ischemic Rat Kidneys: Alive, Dead or in Suspended Animation? Jesus H. Dominguez,[1,2] James M. Dominguez,[2] Katherine J. Kelly.[2] *[1]Medicine, VAMC, Indianapolis, IN; [2]Medicine, IUMC, Indianapolis, IN.*

Background: Severe acute kidney injury (AKI) from ischemia/reperfusion (IR) destroys nephrons. There is no cure, and recovery is uncertain.

Methods: Rats with 50 min of bilateral renal IR were treated with intravenous renal exosomes (exo) from normoxic (Norexo) or ischemic preconditioned (IPCexo) renal cells, 24 and 48 hrs post IR.

Results: ICAM1 protein ratio (n = 5) on IPCexo/Norexo was 1.85 fold (p = 0.002). IPCexo fused with renal cells. There were 312 mRNAs in exos, and 25 differentially expressed, with mRNA in IPCexo higher for Drd4 (78 fold), TMEM80 (10 fold) Ptdss2 (8 fold) among others. There were 4 rat groups, Sham, untreated IR (IRUn), IR given Norexo, and IR given IPCexo (n = 5). Renal function was negligible 24 hrs post-IR, and it

recovered in IRIPCexo by 24 hrs, but not in IRUn. Rats were terminated 6 days post IR and renal phenotypes and RNAseq genotypes obtained. Kidneys from IRUn group had severe lipid peroxidation, inflammation, fibrosis, proliferation, and loss of microvasculature, but IRIPCexo group did not, $p < 0.05$ for all. Genotypes included 12,159 genes in each group, and were compared with each other. MDS plots of log-fold changes for each transcriptome pair showed the largest separation between Sham and IRUn (3141 altered genes), a midrange between Sham and IRNorexo (1599 altered genes), and near overlap between Sham and IRIPCexo (71 altered genes), $p < 0.05$ for all. Gene pathways activated in IRUn, but not in IRIPCexo, included metabolic, proliferation, DNA replication, cell cycle, phagosome, protein digestion apoptosis, and ECM receptor interaction, $p < 10^{-7}$ for all.

Conclusions: Severe renal IRUn is followed by cell death, with deranged phenotypes and genotypes. However, IR non-functional kidneys do not change immediately from life to death, but transition to SA, with full potential to recover within a 24 hrs window. IPCexo promote near full recovery of SA kidneys, assuring integrity and function. IPCexo genetic cargo contains recovery mRNAs in the form of enzymes, receptors, or structural proteins.

Early Inhibition of p53 Leads to Renoprotection and Attenuation of Senescence Arpita Baisantry,[1,2] Birgit Berkenkamp,[1] Raj Bhayadia,[1] Inga Soerensen-Zender,[2] Hermann G. Haller,[2] Anette Melk,[1] Roland Schmitt.[2] *[1]Kidney, Liver and Metabolic Diseases, Children's Hospital, Hannover Medical School (MHH), Hannover, Germany; [2]Nephrology, MHH, Hannover, Germany.*

Background: Early inhibition of p53 has been reported to be renoprotective during acute kidney injury (AKI). These positive effects were mainly attributed to a reduction in apoptosis. Since p53 through its main transactivational target p21 is also involved in the development of senescence, we aimed to investigate the short- and long-term effects of p53 targeting siRNA in a mouse model of renal ischemia reperfusion (IR) injury.

Methods: Mice undergoing IR injury received 6 injections of p53 specific or scrambled siRNA until D10 and were harvested at Day 14 or Day 30 (early treatment groups). In an additional continuous treatment group mice received 11 doses of p53 specific or scrambled siRNA until Day 26 and were harvested at Day30.

Results: At D14, we found that p53 siRNA treatment protected against IR injury and significantly ameliorated the development of senescence (fewer senescence-associated-ß-galactosidase and γ-H2AX positive cells, less $p16^{INK4a}$ expression). The beneficial effects (less acute injury and chronic tubular atrophy, reduced inflammation, less fibrosis and better preservation of peritubular capillaries) persisted even with a prolonged observation period of D30. However, most of these positive effects were lost when p53 siRNA treatment was continued until D30.

Conclusions: Our results showing attenuated senescence through early p53 inhibition are in line with the known dual function of p53. The reversal of the renoprotective effects in the group of continuously treated animals suggests that the function of p53 differs between the early and later phase after IR and that latent expression of p53 is essential for long-term recovery. These data are important in the light of therapeutic approaches using p53 targeting siRNA to prevent AKI and delayed graft function.

ERK1/2 Rapidly Downregulates PGC-1α Expression in Renal Physiological and Pathological Conditions Justin B. Collier, Ryan Whitaker, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Previous studies demonstrated that suppression of mitochondrial biogenesis (MB) through decreased peroxisome proliferator-activated receptor gamma coactivator-1a (PGC-1a) is an important contributor to renal ischemia reperfusion (IR) injury and repair. While ERK1/2 regulates numerous cell signaling pathways, the role of ERK1/2 in renal PGC-1a regulation physiologically and after renal IR remains limited.

Methods: Renal proximal tubule cells (RTPC) were treated with the MEK1/2 inhibitor trametinib (10nM) and the epidermal growth factor receptor (EGFR) inhibitor, erlotinib (100nM). Trametinib (1mg/kg) and erlotinib (50mg/kg) were administered to naïve mice, as well as 1 hour before 18 min of IR injury. Signaling was explored using RT-qPCR, subcellular fractionation, and immunoblot analysis.

Results: Trametinib and erlotinib exposure blocked ERK1/2 phosphorylation and increased PGC-1a mRNA in RPTC after 1 and 4 hr. The mRNA levels of PGC-1a targets NDUFS1, NRF1, and TFAM increased at 1, 4, and/or 24 h after ERK1/2 inhibition. Trametinib and erlotinib administered to naive mice increased PGC-1a mRNA at 4 h in the cortex and trametinib increased PGC-1a and TFAM proteins. Trametinib decreased nuclear pFOXO3a by 60% at 30 min in RPTC and *in vivo* nuclear pFOXO1 decreased 60% in the cortex, leading to increased expression of downstream FOXO3a/1 genes, including PGC-1a. In the IR AKI model, pERK1/2 increased 4-fold at 1 and 3 h post IR and was linked to decreased mRNA levels of PGC-1a, NRF1, and TFAM. Pretreatment with trametinib attenuated the suppression of PGC-1a and NRF1 mRNA at 3 h, increased TFAM protein 2.5-fold, and attenuated renal dysfunction as measured by BUN.

Conclusions: We have linked physiological ERK1/2 phosphorylation to the regulation of PGC-1a and MB through the EGFR and subsequent FOXO3a/1 inactivation. In IR kidney injury, PGC-1a and related genes decreased and ERK1/2 inhibition restored PGC-1a. These results demonstrate that ERK1/2 regulates MB in the kidney rapidly through the pathway, EGFR/ERK1/2/FOXO3a/1/PGC-1a under physiological and pathological conditions.

IL233 Hybrid Cytokine bearing Interleukin (IL)-2 and IL-33 Activities Protects from Nephrotoxic Injury Rahul Sharma,[1] Marta Stremska,[1] Saleh Mohammad,[1] Amandeep Bajwa,[1] Gilbert R. Kinsey,[1,2] Diane L. Rosin,[2] Mark D. Okusa.[1] *[1]Div of Nephrology, Dept of Medicine, Univ of Virginia, Charlottesville, VA; [2]Dept of Pharmacology, Univ of Virginia, Charlottesville, VA.*

Background: Acute kidney injury induced by chemotherapy drugs limits their use. Earlier we showed that IL-2 and IL-33 cooperate to promote regulatory T-cells (Treg), and a hybrid cytokine (IL233) bearing these activities in a single molecule protected mice from ischemia-reperfusion Injury. Here we investigated whether immuno-modulation by IL233 also protects from nephrotoxic drugs.

Methods: Male Balb/C mice (12-wk) were injected (ip) with saline or 66pmoles/day IL233 for 5 days and 10mg/kg Doxorubicin (Dox) (iv) on day 8. In another model, 12-wk old C57Bl/6 males were injected with IL233 (66pmoles/day) or saline as above and 20mg/kg Cisplatin (Cis) on day 8. Plasma creatinine (PCr) and blood urea nitrogen (BUN) were measured (mg/dL; mean±SEM). Blood, spleen and lymph nodes (LN) were analyzed for immuno-phenotype. Kidneys were analyzed for inflammation and injury.

Results: In mice administered Dox, saline or IL233 treatment did not prevent loss of renal function initially. However, IL233-treated mice recovered rapidly and normalized PCr by day 28 (0.23±0.01), whereas all saline-treated mice were moribund and had elevated PCr (0.56±0.11). By H&E, all saline treated mice had leukocytic infiltration, tubular necrosis, proteinaceous casts, mesangial expansion and fibrosis, whereas the IL233-treated mice showed normal histology. IL233 treatment not only increased $Foxp3^{+}$ Treg in blood and renal LN and production of IL-2 and IL-10, but also lowered IFNγ and TNFα production compare to the saline-treated mice. Cis treatment in saline control mice caused an increase in BUN (95±12) and death by day 4, whereas all the IL233-treated mice survived and had comparatively preserved BUN (44±7). IL233 treatment in the Cis models also increased Treg and IL-10 production while inhibiting IFNγ and IL-17 production.

Conclusions: The novel cytokine IL233 harboring the activities of IL-2 and IL-33 promotes Treg and suppresses inflammation to protect from nephrotoxic injury and bears therapeutic potential.

FR-PO269

Finerenone Protects against the Acute and Chronic Consequences of Renal Ischemia/Reperfusion Injury Jonatan Barrera-Chimal,[1] Alan Le Mercier,[1] Soumaya El Moghrabi,[1] Peter Kolkhof,[2] Frederic Jaisser.[1] *[1]INSERM, U1138, Centre de Recherche des Cordeliers, Paris, France; [2]BAYER Pharma AG, Cardiology Research, Wuppertal, Germany.*

Background: One of the most common causes of acute kidney injury (AKI) is renal ischemia/reperfusion (IR). Mineralocorticoid receptor (MR) antagonism has shown beneficial effects against renal IR consequences. The potential benefit of novel non-steroidal MR antagonists such as finerenone has not been explored. Therefore, we evaluate the efficacy of finerenone to prevent the acute and chronic consequences of ischemic AKI.

Methods: For the acute study (24 hours), 18 rats were divided in: sham, rats subjected to bilateral renal ischemia of 25 min and rats that received three doses of finerenone at -48 h, -24 h and -1 h before the ischemia. For the chronic study (4 months), 21 rats were divided in: sham, rats with 45 min of bilateral ischemia and rats treated with Finerenone at day -2, -1 and 1h before IR. The left kidney was used for histology and the right kidney for molecular analysis.

Results: After 24 h of reperfusion, the untreated IR rats presented a 3-fold increase in plasma creatinine, accompanied by 40% of tubules presenting cell detachment and casts. Kim-1 and NGAL mRNA levels were induced by 30-fold. In contrast, the rats that received finerenone presented normal creatinine and significantly fewer injured tubules (11%) and a less pronounced induction of kim-1 and NGAL (8-fold). After 4 months, the untreated IR rats developed chronic kidney disease (CKD), evidenced by kidney dysfunction, increased proteinuria (121.6 vs. 14.3 mg/24h in sham) and renal vascular resistance (16.8 vs. 11.4 mmHg/mL in sham). Tubular dilation, extensive tubule-interstitial fibrosis and an increase in kidney TGF-ß and Collagen-I mRNA levels also characterized CKD. The transition from AKI to CKD was fully prevented by finerenone administration at the time of IR.

Conclusions: Altogether, our data shows that finerenone is able to prevent AKI induced by IR as well as the chronic and progressive deterioration of kidney function and structure.

Kidney Injury Molecule-1 Overexpression Promotes Healing of Injured Kidney Epithelial Cells and Induces Alternative Activated Macrophage Polarization Joseph C.K. Leung,[1] Loretta Y.Y. Chan,[1] Kar Neng Lai,[2] Sydney C.W. Tang.[1] *[1]Dept of Medicine, The Univ of Hong Kong, Hong Kong; [2]Hong Kong Sanatorium & Hospital, Hong Kong.*

Background: Kidney injury molecule-1 (KIM-1) acts as a double-edged sword in injured kidney. We aim to study the effects and mechanism of KIM-1 overexpression on healing of injured kidney proximal tubular epithelial cells (PTEC) and macrophage polarization.

Methods: Oxidative injury model by H_2O_2 was established in murine PTEC with KIM-1 overexpression ($KIM\text{-}1^{hi}$ PTEC). Cell viability, proliferation and apoptosis were

determined from 24 to 120 hours after injury. The expression of vimentin, N-cadherin, TNF-α, MCP-1, TGF-β1 and CSF-1; were determined by real-time PCR or ELISA. To delineate the role of humoral factors released by injured KIM-1^{hi} PTEC on macrophages (Mø) polarization, bone marrow–derived Mø were cultured with injured PTEC in transwell setup. The temporal expression of markers for classical M1 or alternative activated M2 including iNOS, TNF-α, IL-23, CD206, IL-10 and arginase-1 were evaluated.

Results: Apoptosis induced by H_2O_2 was ameliorated in KIM-1^{hi} PTEC. During recovery, injured KIM-1^{hi} PTEC exhibit enhanced cell proliferation and dedifferentiation, with up-regulated expression of TNF-α, MCP-1, TGF-β1 and CSF-1. The expression of TGF-β1 or CSF-1 by the injured KIM-1^{hi} PTEC was diminished by blockade of phagocytosis with annexin V. Injured KIM-1^{hi} PTEC promote M1 to M2 conversion as reflected by the temporally decrease of iNOS, TNF-α and IL-23, and concomitant increase of CD206, IL-10 and arginase-1 expression. Notably, this M2 polarization was diminished by blockade of soluble CSF-1, TGF-β1 or phagocytosis.

Conclusions: In acute tubular cell injury, KIM-1 overexpression accelerates the phagocytosis-dependent healing. The enhanced M2 polarization by TGF-β1 and CSF-1 released from the injured KIM-1^{hi} PTEC, further contributes to the recovery process. Persistent KIM-1 overexpression leads to sustained release of inflammatory cytokines including TNF-α and MCP-1, plus M1 polarization and infiltration. Our results implicate that enhanced KIM-1 expression is beneficial in acute but undesirable in chronic tubular cell injury.

Disruption of Hypoxia-Inducible Factor-1 Alpha Deteriorates Renal Ischemia-Reperfusion Injury through Dysregulation of Kv2.2-Induced Apoptosis in Tubules Kazuma Ota,[1] Yoshitaka Kihira,[1,2] Reina Kishibuchi,[1] Yuki Izawa-Ishizawa,[1] Yuya Horinouchi,[1] Yasumasa Ikeda,[1] Toshiaki Tamaki.[1] *[1]Pharmacology, Tokushima Univ Graduate School, Tokushima, Japan; [2]Clinical Pharmacy, Fukuyama Univ, Fukuyama, Hiroshima, Japan.*

Background: Hypoxia-inducible factor (Hif)-1α is upregulated during renal ischemia-reperfusion (I/R) and is involved in induction of apoptosis and the following proliferation in renal proximal tubular cells (PTCs). The intracellular ion homeostasis is disrupted before the I/R-induced apoptosis; increase in intracellular Ca^{2+} concentration, $[Ca^{2+}]i$, and decrease in $[K^+]i$. It is known that the voltage-gated potassium channel Kv2 activated by Ca^{2+} influx is involved in induction of neuronal apoptosis. In this study, we explored the role of Kv2 in renal I/R injury (IRI) and its relationship to Hif-1α.

Methods: Hif-1α heterozygous knockout mice (hKO) and their wild type littermates (WT) were used. For induction of IRI, the right kidney was removed and the left renal vessels were clamped for 45 min followed by reperfusion.

Results: hKO showed severer renal dysfunction and reduced expression of Kv2.2 compared with WT. The preadministration of 4-aminopyridine (4AP), an inhibitor of Kv2 channels, exacerbated renal dysfunction in C57BL/6 mice after I/R. In addition, the treatment of dimethyloxaloylglycine, a Hif-1α activator, with human PTC line HK2 increased Kv2.2 expression levels. These results indicate that Kv2.2 is involved in reduction of IRI and is regulated by Hif-1α. Moreover, the delayed induction of apoptosis in PTCs was observed in hKO mice. 4AP inhibited Ca^{2+} ionophore ionomycin-induced apoptosis in HK2 cells. Therefore, Kv2.2 is probably responsible for apoptosis induction in PTCs. Localization and molecular weight of Kv2.2 were changed by I/R in the kidney of C57BL/6 mice and the changes were mimicked by the treatment of ionomycin with HK2, indicating that Ca^{2+} influx activates Kv2.2 in renal PTCs.

Conclusions: The present study shows that Hif-1α plays an important role in recovery from IRI trough induction of Kv2.2 which leads to PTC apoptosis. PTC apoptosis mediated by Hif-1α-Kv2.2 pathway is considered a key to recovery from IRI.

Coenzyme Q10: A Potential Candidate for Contrast-Induced Acute Kidney Injury in Diabetic Rats Cassiane Dezoti da Fonseca, Maria De Fatima Vattimo, Mirian Watanabe. *School of Nursing, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Diabetic nephropathy and contrast-induced acute kidney injury (CI-AKI) involve tubular and glomerular defects, oxidative damage, mitochondrial cytopathies and the induction of protective enzymes, as coenzyme Q10 (COQ10). This study evaluated DM as a risk factor for CI-AKI and the role of COQ10 on this model.

Methods: Male Wistar rats, 250-280g, were randomized into groups: **Citrate -** citrate buffer (streptozotocin vehicle); **DM** - streptozotocin (65 mg/kg, iv).; **DM+IC -** DM animals that after 4 weeks received iodinated contrast (IC, 6 ml/kg, ip); **DM+IC+CO-Q10 -** DM preconditioned animals (COQ-10, (10 mg/kg, ip). Physiological parameters, renal function (inulin clearance).urinary neutrophil gelatinase- NGAL, oxidative profile (urinary peroxides, thiobarbituric acid reactive substances-TBARS, nitric oxide-NO in urine and thiols in renal tissue) and renal hemodynamics (renal vascular resistance- RVR) were analyzed.

Results:

Groups (n)	Inulin Clearance (mL/min/kg)	NGAL (mg/dL)	RVR (mmHg/mL/min)	Urinary Peroxides (nmol/g creatinine)	TBARS (nmol/g creatinine)	Thiols (nmol/mg protein)	NO (μM/g creatinine)
Citrate (5)	0.96 ±0.18	37.9 ±0.8	11.2 ±2.1	2.0 ±0.8	0.2 ±0.1	24.6 ±4.3	15.1 ±8.0
DM (5)	0.55 ±0.08*	53.8 ±17.8	23.9 ±8.3*	7.3 ±3.9*	14.0 ±2.6*	15.5 ±2.0*	48.7 ±24.7*
DM+IC (5)	0.17 ±0.02*#	99.8 ±18.7*#	38.4 ±9.3*#	18.5 ±3.6*	30.3 ±2.9*#	7.6 ±2.1*#	102.1 ±16.9*#
DM+IC +COQ10 (5)	0.53 ±0.08*°	61.4 ±18.5*°	18.5 ±2.9*°	3.4 ±1.2#°	12.5 ±2.8*°	17.8 ±1.9*°	43.7 ±15.6*°

*P<0.05 vs citrate; #p<0.05 vs DM; °p<0.05 vs DM+IC. Diabetic groups showed polyphagia, polydipsia, polyuria, high levels of blood glucose and reduction in body weight. IC reduced inulin clearance, increased urinary NGAL and elevated RVR. Oxidative damage was confirmed by increased urinary peroxides, nitric oxide and TBARS with the consumption of antioxidant reserve. These parameters were significantly changed by COQ-10.

Conclusions: Our results indicated that DM improves renal vulnerability to the toxicity of CI. COQ-10 showed to be a potential drug for modifying risk factor for CI-AKI in chronic disease, DM.

FR-PO273

HO-1 Gene Modification Promotes Proliferation and Differentiation of Bone Marrow-Derived Mesenchymal Stem Cells in the Acute Injured Kidney via Stimulation of AKT and ERK Signaling Nanmei Liu. *Dept of Nephrology, Jiming Hospital of Shanghai, Shanghai, China.*

Background: Bone marrow-derived mesenchymal stem cells (BMSCs) transplantation offers therapeutic potential for acute kidney injury (AKI), but with limited efficacy. Heme oxygenase-1(HO-1) possesses the cytoprotective activity. Here we tested the effect of HO-1 overexpression on the survival and differentiation ability of BMSCs under the AKI microenvironment, and its impact on the repair of AKI was also observed.

Methods: SD HO-1-BMSCs and eGFP-BMSCs were prepared by the gene transfection method. Ischemia/reperfusion (I/R)-AKI kidney homogenate supernatant (KHS) was prepared to treat BMSCs, eGFP-BMSCs and HO-1-BMSCs in vitro. The cell cycle, proliferating cell nuclear antigen (PCNA) expression, cytokeratin 18 (CK18) expression and cytokine secretions for the cultured BMSCs were all measured. Signaling pathways involved were also analyzed. In the in vivo experiment, survival and differentiation of the implanting BMSCs in the AKI rat model as well as the renal function were also assayed.

Results: HO-1-BMSCs showed a remarkable expression of HO-1. HO-1-BMSCs became better with the less proportion of cells at the G0/G1 phase, the higher proportion of cells expressing PCNA and CK 18. Levels of monocyte chemotactic protein 1 (MCP-1), tumor necrosis factor-α (TNF-α) and interleukin 1β (IL-1β) decreased significantly in supernatant of HO-1-BMSCs. Expressions of the phosphorylated Akt and phosphorylated ERK were increased in HO-1-BMSCs. Either LY294002 or PD98059 inhibited the above effects. The in vivo study showed increased proportion of $PCNA^+$ HO-1-BMSCs and $CK18^+$ HO-1-BMSCs in the injured kidneys with improved renal function and reduced ATN score.

Conclusions: HO-1 overexpression in BMSCs can enhance the survival and the renal-epithelial differentiation of BMSCs in the AKI microenvironment. Stimulations of PI3K/Akt and MEK/ERK signal pathways can be taken as the possible mechanisms. Thus, HO-1 gene-modified suggests a better kidney repair effect.

FR-PO274

Laser-Irradiation in a Closed Microcirculation System to Study Endothelial Regeneration Mechthild Roesler,[1] Florian Schmieder,[2] Jan Sradnick,[1] Udo Klotzbach,[2] Vladimir T. Todorov,[1] Frank Sonntag,[2] Christian Hugo,[1] Bernd Hohenstein.[1] *[1]Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CGC, Dresden, Germany; [2]Fraunhofer Inst for Material and Beam Technology IWS, Dresden, Germany.*

Background: Microfluidic systems are small, chip-sized platforms, which can be used as cellularized organoid systems to study cell processes and cell-cell interactions. To investigate regeneration, the generation of specific cell damage in the channels is necessary but difficult due to limited accessibility. The present project aimed to establish a well-defined lesion in a human endothelial cell (EC) layer without removing dead cells and signaling molecules.

Methods: Microfluidic platforms were produced by Fraunhofer IWS by layer laminate manufacturing according to the experimental needs, containing reservoirs, channels, valves and an integrated micropump. Human umbilical vein EC (HUVEC) and outgrowth EC (OEC) were used. Laser ablation was performed using an Olympus Spinning Disc Microscope with a laser diode at a wave length of 405nm for 5 to 15 minutes with a power of 2 - 2.4mW. EC injury was observed by phase contrast microscopy and LIVE/DEAD® Viability/Cytotoxicity Kit whereas Time-lapse recording was used to visualize the regeneration of the injured EC layer.

Results: Following an initial attachment phase (4 hours), the fibronectin-coated channels were covered with a cellular monolayer at a density of approximately $7{,}5x10^4$ cells/cm² within 3 to 6 days under pulsatile flow. Laser irradiation of 10 minutes minimum

created a selective destruction of the EC-monolayer in areas of approximately 200x200µm or 120x120µm (x40 or x60 objective, respectively). EC density showed an influence on the time needed to induce cell injury. Time-lapse recordings indicate that surrounding EC start movement and proliferation towards the damaged site and are able to fill the gap within two to three days.

Conclusions: Pre-defined EC lesions in channels of microfluidic systems can be created by laser-irradiation reproducibly. This method in combination with kidney-specific EC will allow to further understand central mechanisms of EC regeneration and signaling upon injury.

FR-PO275

The Role of IL-6 Signaling on the Transition of Acute Kidney Injury to Chronic Kidney Disease Myung-Gyu Kim, Hiroshi Kojima, Jonathan Street, Xuzhen Hu, Peter S.T. Yuen, Robert A. Star. *NIDDK, National Insts of Health, Rockville, MD.*

Background: IL-6 is a multifaceted cytokine and a novel molecular target in several inflammatory diseases (rheumatoid arthritis, asthma, colitis). Recent studies showed that trans-signaling by a IL-6/sIL-6 receptor complex (which then binds cell-attached gp130) can protect against acute kidney injury (AKI); however, the role of IL-6 signaling in renal disease remains largely unexamined. Here, we studied the role of IL-6 signaling during the AKI to chronic kidney disease (CKD) transition.

Methods: C57BL/6 mice were subjected to ischemia reperfusion injury (IRI, 28'). CD-1 mice were treated with folic acid (250mg/kg). 14 days later, glomerular filtration rate (GFR) was measured using FITC-labeled sinistrin, and renal fibrosis was evaluated by Masson's Trichrome.

Results: Serum IL-6 and sIL-6R levels significantly increased on day 1 following IRI and remained higher than sham group through day 5, whereas serum soluble gp130 level did not change. These data suggest persistent IL-6 trans-signal activation during the post-AKI recovery phase. To investigate the effect of exogenous IL-6 during recovery from IRI, rmIL-6 or PBS was administered by osmotic mini pump (0.1µg/hr) from day 2 to day 9. On day 14 after IRI, blood urea nitrogen and GFR showed no significant differences between IL-6- and PBS-treated groups. However rmIL-6 treatment significantly decreased renal fibrosis (3.2±0.1 vs. 2.3±0.3). Interestingly, renal function at day 14 post-IRI did not correlate with the degree of renal fibrosis on day 14 post-IRI. The effect of rmIL-6 treatment was also examined following folic acid-induced AKI. Folic acid was injected with 0.3M $NaHCO_3$ i.p. and then mice were treated with rmIL-6 from day 2 to 9. Treatment with rmIL-6 did not alter either renal fibrosis or GFR following folic acid exposure.

Conclusions: Increased IL-6 trans-signaling during the recovery phase may be associated with AKI to CKD transition. However treatment of IL-6 alone a) slightly altered fibrosis without detectable effects on renal function following I/R and b) had no effect in a folate nephropathy model. The dissociation of renal fibrosis and GFR was unexpected, and warrants further study.

FR-PO276

Rat and Human Renal Exosomes Protect Ischemic Rat Kidneys and Cells James M. Dominguez,[1] Jesus H. Dominguez,[1,2] Katherine J. Kelly.[1] *[1]Medicine, IUMC, Indianapolis, IN; [2]Medicine, VAMC, Indianapolis, IN.*

Background: Acute kidney injury (AKI) from ischemia/reperfusion (IR) can result in early or late loss of kidney structure and function. There is no available therapy that prevents renal cell death following severe IR.

We hypothesized that rat renal exosomes (rexo) from normal tubule cells (rNKC) limit cell death in IR rats. In order to evaluate clinical use, human renal exosomes (hexo) from hypoxia-resistant immortalized proximal tubule cells (hNKC, gift of Dr. R Bacallao) were also tested.

Methods: rNKC (4 hrs) and hNKC (24-48 hrs) were cultured in normoxia or 1 % O_2 hypoxia, and normoxic or ischemia pre-conditioned (IPC), rexo or hexo, were harvested for 72 more hours while back in normoxia. IPC rexo had higher levels of ICAM-1 protein than normoxic rexo (1.85 fold = 0.002). IPC rexos fused with target cells.

Results: IPC rexos had higher mRNAs encoding Catalase, SOD1, HSP27, and HIF (fold increase over normoxic rexos: 1.3, 1.5, 1.7, 1.6; $p < 0.05$). IPC rexos prevented rat renal cell injury given intravenously 24 hours after 50 minutes of IR. These effects included renal phenotypes and genotypes comparable to sham controls, while untreated IR rats had very advanced renal damage: damaged microvasculature, severe inflammation, scarring, and proliferation. Lipid peroxidation and cell proliferation were also elevated, $p < 0.05$. We then tested hexo from hNKC, which were resistant to 48 hrs of 1 % hypoxia. Hexos were added to rat NRK52 cells, and HLA mRNA transfer from hexos to rat cells confirmed fusion. NRK52E cells were subjected to 24 hrs of hypoxia and 24 hrs of re-oxygenation. Cell viability was unaffected by hypoxia, and increased 5.3 fold after re-oxygenation ($p < 0.05$). Hexos lowered mortality of hypoxic/re-oxygenated NRK52E cells by 55 %, $p < 0.05$.

Conclusions: IPC rexos communicate the ischemia preconditioned state and limit most renal changes from IR in rats. IR kidneys of rats treated with IPC rexos do not spend energy in regenerating de novo, and transition to a near normal state from suspended animation. Hexos from hypoxic-resistant hNKCs transfer the resistant state to rat kidney cells subjected to severe hypoxia and re-oxygenation. Hence, renal hexos are a new biological tool to treat AKI from IR.

FR-PO277

Hypoxia Inducible Factor-1α Activation Attenuates Renal Ischemia/Reperfusion Injury by the miR-21, Thrombospondin 1, and Angiogenesis Pathway Xialian Xu,[1] Nana Song,[1] Xiaoyan Jiao,[1] Jiachang Hu,[1] Mingyu Liang,[2] Xiaoqiang Ding.[1] *[1]Nephrology, Zhongshan Hospital, Shanghai, China; [2]Physiology and Center of Systems Molecular Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: Angiogenesis contributes tothe repair process after renal ischemia/reperfusion injury. In the present study, we tested the hypothesis that miR-21 induced angiogenesis by inhibiting a novel target gene thrombospondin 1.

Methods: Cobalt chloride was administered intraperitoneally 24h prior to renal ischemia/reperfusion. Human umbilical vein endothelial cells were treated by 1% O_2 for 24h. Locked nucleic acid modified anti-miR-21 or scrambled anti-miR was transfected into hypoxic cells or delivered into the mice via tail vein injection less than 1h prior to cobalt chloride treatment. Morphologic and functional parameters, vascular density, miR-21 and thrombospondin 1 expression in vivo and in vitro were assessed 24h after reperfusion or hypoxia.

Results: Hypoxia up-regulated hypoxia inducible factor-1α, vascular endothelial growth factor and miR-21, down-regulated predicted miR-21 target gene thrombospondin 1, and increased tube formation in endothelial cells. Inhibition of miR-21 led to increased thrombospondin 1 abundance and decreased tube formation in hypoxic endothelial cells. Cobalt chloride activated hypoxia inducible factor-1α and attenuated renal ischemia/reperfusion injury in mice, accompanied by up-regulation of miR-21 and increased angiogenesis. Thrombospondin 1 expression was down-regulated. These effects of cobalt pretreatment were attenuated by inhibition of miR-21.

Conclusions: hypoxia inducible factor-1α induced angiogenesis by increasing not only vascular endothelial growth factor but also miR-21 via inhibiting a novel target gene thrombospondin 1. Both of them may contribute to the protective effect of hypoxia inducible factor-1α on renal ischemia/reperfusion injury.

Rosuvastatin Treatment Ameliorated Renal Tubulointerstitial Fibrosis in Murine Model of Chronic Kidney Disease Hyeong Cheon Park,[1] Hyunwook Kim,[1] Mirae Lee,[1] Taeyeon Kim,[1] Hoon Young Choi,[1] Jung Eun Lee,[2] Hyung Jong Kim.[3] *[1]Internal Medicine, Yonsei Univ College of Medicine Gangnam Severance Hospital, Seoul, Korea; [2]Internal Medicine, Yonsei Univ College of Medicine Yongin Severance Hospital, Yongin, Gyeonggi-do, Korea; [3]Internal Medicine, Bundang Cha Medical Center, Cha Univ, Seongnam-si, Gyeonggi-do, Korea.*

Background: Tubulointerstitial fibrosis plays an important role in progressive chronic kidney disease (CKD). Lysyl oxidase like-2 (LOXL2), a member of the lysyl oxidase (LOX) family, promotes crosslinking of collagen and elastin that has been implicated in liver and lung fibrosis. Rosuvastatin (ROS)'s pleiotropic actions include anti-fibrotic effects. Aim of the study was to investigate the effect of ROS on renal LOXL2 activity and tubulointerstitial fibrosis in a murine CKD model.

Methods: Male FVB mice were subjected to 42 minutes of unilateral ischemic acute kidney injury and after 2 weeks the mice underwent contralateral nephrectomy to induce a murine model of CKD. Animals were divided into 2 groups: vehicle (methylcelluose) or rosuvastatin (10mg/kg/day) by gavage. After 4 weeks, mice were sacrificed and kidneys were harvested for analysis.

Results: Our murine CKD model showed increased BUN (47.8 ± 4.7 vs. normal 24.3 ± 3.6 mg/dL, $p<0.01$) and renal anemia (hemoglobin level: 11.0 ± 1.0 g/dL vs. normal 13.2 ± 0.4 g/dL, $p<0.01$) and overt proteinuria compared to age-matched control mice. F4/80 positive inflammatory cell infiltration in the interstitium was significantly reduced by ROS treatment (2.8 ± 1.2 vs. 39.8 ± 8.3 /HPF, $p<0.01$). The mRNA expression of TGF ß1, LOXL2 and collagen 1 was increased in CKD kidney; ROS treatment significantly decreased TGF ß1 (1.54 ± 0.42 vs. 2.91 ± 1.33, $p<0.03$, ROS vs. vehicle).and LOXL2 expression (1.29 ± 0.24 vs. 2.85 ± 0.70, $p<0.02$, ROS vs. vehicle) as well as collagen I mRNA expression (3.61 ± 1.21 vs. 7.72 ± 3.46, $p<0.03$, ROS vs. vehicle). Furthermore, tubulointerstitial fibrosis assessed, by Sirius Red staining, was significantly attenuated with ROS treatment (2.08 ± 0.49 vs. 7.75 ± 3.16, $p<0.03$, ROS vs.vehicle).

Conclusions: Rosuvastatin treatment showed significant anti-fibrotic effects via down regulation of renal LOXL2 expression.

Endothelial Colony Forming Cells and Secreted Factors Attenuate Acute Kidney Injury Jason Andrieu Collett,[1] William C. Shelley,[2] Mervin C. Yoder,[2] David P. Basile.[1] *[1]Cellular and Integrative Physiology, Indiana Univ School of Medicine; [2]Pediatrics, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: Damage to endothelial cells contributes to AKI by leading to impaired perfusion, while the loss of the capillary network has been suggested to promote CKD. Targeting endothelial impairment with endothelial progenitor cells has shown promise in preserving endothelial integrity and alleviating the severity of AKI. Endothelial colony-forming cells are endothelial precursor cells with high proliferative capacity, pro-angiogenic activity and in vivo vessel forming potential. We hypothesized that ECFCs may ameliorate the degree of AKI and/or promote repair of the renal vasculature.

Methods: ECFCs with high proliferative potential (HPP;form colonies>10,000 cells) or low proliferative potential (LPP:form colonies between 500-2000 cells) were isolated from rat pulmonary microvasculature or pulmonary artery, respectively. Human HPP ECFCs were isolated and expanded from cord blood. SD rats were subjected to 40 minutes IRI and supplemented with HPP-ECFC, LPP ECFC, ECFC conditioned media (CM) or vehicle and were allowed to recover for between 2hrs to 7 days.

Results: Serum creatinine (sCre) peaked at 5.2 ± 0.4 mg/dl at 48hrs following renal IRI in vehicle-treated rats and returned to pre-surgery values at 7 days. In rat HPP ECFC-treated rats, sCre values were significantly lower at 1, 2, 3 and and 5 days compared with vehicle, while rats treated with LPP-ECFCs were not different. Protection by HPP ECFCs was associated with significantly improved tubular morphology at 2 and 7 days. Administration of ECFCs also significantly prevented reductions in medullary blood flow 2hrs following reperfusion in vehicle treated rats (Vehicle -22.5±7% vs. ECFC +10±6%; $p<0.05$). We isolated and administered concentrated (10X) human cord blood-derived ECFC-CM. A single injection of ECFC-CM significantly reduced the severity of injury (sCre 4.5mg/dl vs. 2.8mg/dl; $p<0.05$) and promoted repair following ischemic AKI.

Conclusions: Taken together, these data suggest that HPP ECFC ameliorate AKI secondary to the production of soluble factors, in part by promoting improvement in renal vascular function.

Heme Oxygenase-1 Modulates Renal Inflammation Associated Lymphangiogenesis Sarah Ann Bowhay, Anupam Agarwal, Abolfazl Zarjou. *Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Inflammation associated lymphangiogenesis (IAL) is characteristic of many pathological conditions such as tumorigenesis, wound healing and transplant rejection. Despite its prominent role in many conditions, little is known about IAL in the kidney. Previous studies have focused on developmental lymphangiogenesis in the kidney leaving large gaps in understanding IAL in the kidney. The purpose of this study was to explore the role of heme oxygenase-1 (HO-1), a well characterized stress inducible enzyme with potent anti-inflammatory and pro-angiogenic properties, in regulating IAL in the kidney.

Methods: To study IAL in acute kidney injury and determine the role of HO-1 in this process, we induced renal injury in HO-$1^{+/+}$ and HO-$1^{-/-}$ mice via unilateral ureteral obstruction (UUO), a model of renal inflammation and fibrosis. Protein and mRNA levels of the lymphangiogenic growth factors [vascular endothelial growth factors (VEGFs), namely VEGF-C, VEGF-D, and their receptor VEGF-R3] were analyzed at baseline and on days 1 and 7 after surgery. Additionally, to determine the roles of individual cell types in this process, primary proximal tubule cells, and bone marrow derived monocytes were cultured and exposed to hypoxia to mimic ischemic conditions and the levels of lymphangiogenic markers were analyzed.

Results: Higher levels of VEGF-R3 expression were observed in the kidneys of HO-$1^{-/-}$ mice at baseline and 7 days after UUO compared to their wild-type littermates. Also, higher levels of VEGF-D were seen in the kidneys of HO-$1^{-/-}$ mice 7 days after UUO compared to HO-$1^{+/+}$ kidneys. A similar pattern of expression was found in the macrophages: in the HO-$1^{-/-}$ cells, VEGF-R3 expression was higher at baseline and this increased further after hypoxia. The expression of markers associated with lymphangiogenesis was reversed in the proximal tubule cells with a significant decrease in VEGF-R3 expression after hypoxia in the HO-$1^{-/-}$ cells.

Conclusions: These results suggest that HO-1 plays a major role in the cross-talk between tubular and inflammatory cells following kidney injury to modulate IAL and hence may serve as a major regulator of the inflammatory process and resolution following kidney injury.

Hepcidin-Dependent Dynamic Regulation of Renal and Splenic Iron Balance Dictates Outcomes of Renal Injury Ewa U. Mandziak, Yogesh M. Scindia, Saleh Mohammad, Sundararaman Swaminathan. *Medicine, Univ of Virginia, Charlottesville, VA.*

Background: Renal fibrosis is one of the major outcomes following acute kidney injury. It is a maladaptive response that leads to excess deposition of extracellular matrix components such as collagen and fibronectin. Systemic iron depletion strategies using iron chelators or diet-induced iron deficiency have been shown to reduce renal interstitial fibrosis. However, the exact mechanisms of this effect are unknown. Hepcidin is a master regulator of iron homeostasis in the body. We hypothesized that hepcidin levels and associated dynamic changes in renal and splenic iron content may modulate renal fibrogenesis.

Methods: Mice, C57BL/6J (WT), hepcidin knockout (*Hamp*$^{-/-}$) and *Hamp*$^{+/-}$ (both on C57BL/6J background) were treated with Folic Acid (FA) 250 mg/kg (i.p.). BUN was measured on day 2 to confirm the onset of kidney injury. Renal function, collagen deposition, immune cell infiltration and mRNA expression levels for fibrosis markers were examined 19 days after FA injection.

Results: Kidney function (measured by BUN) in WT mice was reduced on day 19 after folic acid treatment. This was significantly ameliorated in both *Hamp*$^{+/-}$ and *Hamp*$^{-/-}$ mice. However, renal collagen deposition (Masson's Trichrome staining) was reduced in *Hamp*$^{+/-}$ (partial hepcidin deficiency) mice but not *Hamp*$^{-/-}$ (complete hepcidin deficiency). Kidney αSMA and TGF-β paralleled the changes in collagen deposition. This reduction in renal fibrosis was associated with change in the balance of spleen and kidney iron content. *Hamp*$^{+/-}$ mice with low iron content in both splenic and renal compartments had the least fibrosis. In contrast, *Hamp*$^{-/-}$ mice with low splenic iron but high kidney iron demonstrated fibrosis comparable to WT mice.

Conclusions:

	Splenic iron	Kidney iron	Outcome
WT	High	Low	Fibrosis
***Hamp*$^{+/-}$**	**Low**	**Low**	**Protection**
***Hamp*$^{-/-}$**	Low	High	Fibrosis

Our studies reveal a novel protective role of partial hepcidin deficiency in renal fibrosis through dynamic modulation of splenic and renal parenchymal iron content thereby offering a novel therapeutic approach to prevent progression of kidney disease.

Exercise Preconditioning Reduces Acute Ischemic Renal Injury in Rats Weslei Vicente Lima, Nestor Schor, Waldemar S. Almeida. *Nefrologia, UNIFESP, São Paulo, São Paulo, Brazil.*

Background: Acute kidney injury (AKI) can be defined as the sudden loss of renal function associated with structural changes in the kidneys. Currently 13.3 million people die of AKI around the world. Normally aerobic exercise is used both as/for the treatment and prevention of high blood pressure, metabolic disease and DM. Nevertheless, exercise preconditioning must be an important resource in the prevention and mitigation of the LRA. Evaluate the effects of the exercise precontioning on renal function in Wistar rats subjected to I/R.

Methods: We used male Wistar rats with 10 weeks of life and they were separated into three groups Sham (S), control (C) and trained (T). After 4 weeks all groups were subjected to injure I/R. Moreover, the rats were recuperating for 24 hours and after that, they were placed in metabolic cages for 24 hours.We evaluate renal function from serum creatinine, urea and proteinuria. Then, renal morphological study by optical microscopy.

Results: At the end of the protocol, the T group had a lower weight than the groups S and C (S 383 vs 384 vs C T 356g $p<0.05$). After 48h of renal I/R, increased proteinuria levels (S 9 ± 1.6 vs C 20 ± 6.3 vs T 15 ± 4.2 mg/24h; $P<0.05$), creatinine (C 2,1 ± 1.6 vs S 0.53 ± 0.02 vs T 0.73 ± 0.09; $P<0.05$) and urea (S 164 ± 123.3 vs C 35 ± 2.9 vs T 59 ± 20 7; $P<0.05$) in the C and T groups. Renal histological analysis showed that 90% of the animals the group C had degrees of acute tubular necrosis (ATN) significantly greater than 90% of the animals of group T (C grade 3 and 4 vs. T 1 and 2, respectively).

Conclusions: The group that held aerobic exercise preconditioning had lesser impairment of renal function and morphology compared to the control group, suggesting that aerobic exercise preconditioning was renoprotective in this IR model.

KIM-1 Regulates the Proximal Tubular Cell Immune Response to Kidney Injury Craig R. Brooks, Melissa Y. Yeung, Takaharu Ichimura, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: We have reported that Kidney injury molecule-1 (KIM-1), the most upregulated proximal tubular cell (PTC) protein following a variety of kidney injuries, functions as a phosphatidylserine phagocytosis and scavenger receptor. Mutation of KIM-1 mucin domain (KIM-$1^{\Delta mucin}$) results in reduced binding to and clearance of apoptotic cells, increased inflammation and decreased kidney function following acute kidney injury in mice, suggesting a link between KIM-1-mediated phagocytosis and inflammation.

Methods: Primary PTCs were isolated from wild-type and KIM-$1^{\Delta mucin}$ mice. KIM-1 interaction with p85 was determined by immunoprecipitation. NFkB activity was analyzed by immunoblot and Luciferase assay. Gene expression microarray data from KIM-1 or empty vector expressing cells were analyzed via Ingenuity Pathway Analysis. MHC presentation was measured in primary PTCs directly using specific antibodies by flow cytometry. Functional implications were determined by activation of CD4+ and CD8+ T cells.

Results: KIM-1 expression limited cytokine production in primary PTCs stimulated with LPS or TNFα, which was further suppressed by KIM-1-mediated phagocytosis. Microarray analysis revealed KIM-1 expression suppressed components of the NFκB pathway. KIM-1 expression and phagocytosis was confirmed to down-modulate NFκB phosphorylation and activity. Material phagocytosed by KIM-1 was processed and presented as antigens on MHC I and MHC II in an autophagy dependent manner. While KIM-1-mediated phagocytosis lead to greater antigen presentation, the increased presentation resulted in reduced CD4+ T cell activation and increased Tregs. Mechanistically, phosphorylated KIM-1 directly interacted to the PI3 kinase p85 and knockout or inhibition of p85 reversed the anti-inflammatory phenotype associated with KIM-1-mediated phagocytosis.

Conclusions: Thus, in acutely injured kidneys, KIM-1 facilitates repair by removal of luminal debris, leading to anti-inflammatory antigen presentation, decreased CD4+ T cell activation, increased Tregs and down-regulation of the PTC immune response via NFκB suppression.

FR-PO284

Exosome Production and Its Regulation of EGFR during Wound Healing in Renal Tubular Cells Xiangjun Zhou,[1,2] Qisheng Yao,[1] Zheng Dong.[2] *[1]Dept of Urology, Taihe Hospital, Hubei Univ of Medicine, Shiyan, Hubei, China; [2]2 Dept of Cellular Biology and Anatomy, Medical College of Georgia at Augusta Univ and Charlie Norwood VA Medical Center, Augusta, GA.*

Background: Kidney repair following injury involves the reconstitution of a structurally and functionally intact tubular epithelium. Growth factors and their receptors, such as epidermal growth factor receptor(EGFR), are important to the repair of renal tubules. Exosomes are cell-produced small (~100nm in diameter) vesicles that contain and transfer proteins, RNAs and DNAs between cells. In this study, we examined exosomes production in a scratch wound healing model of renal tubular cells. We further examined the relationship between exosomes production and EGFR activation.

Methods: A scratch wound healing model was established by using renal proximal tubular cells (RPTC) cells. Rate of wound healing and EGFR activation after scratch wounding were analyzed with and without application of an EGFR inhibitor, gefitinib. Exosomes were isolated from the culture media of RPTC cells after wound with and without treatment of gefitinib. The expression of EGFR in exosomes was investigated by testing the effect of the gefitinib and the exosomes production inhibitor, GW4869.

Results: EGFR activation occurred shortly after scratch wounding. Wound repair after injury was significantly inhibited by Gefitinib . Interestingly, scratch wounding induced a significant increase of exosomes production, which was not affected by gefitinib. EGFR was observed in exosomes and EGFR expression in exosomes increased after injury. Nonetheless, inhibition of exosome release by GW4869 do not decreased the expression of EGFR in exosomes.

Conclusions: Scratch wounding in renal tubular cells leads to EGFR activation, which is critical to wound healing. Wound healing is associated with exosome production. Exosome production does not depend on EGFR, but the release of exosome may be favor to increases the rate of wound healing in renal tubular cells.

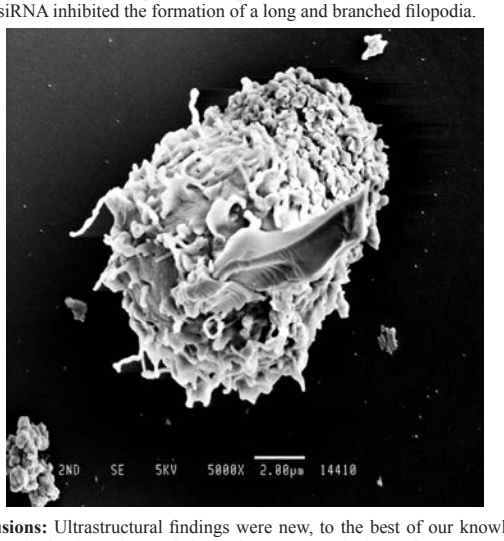
FR-PO285

Establishment of Scanning Electron Microscopic (SEM) Analysis at Various Stages of Renal Tubular Epithelium Subculture Kiyoko Inui,[1] Hiroyuki Morita,[2] Yoshihiko Inoue,[1] Tadahide Maezumi,[1] Tomohito Mizuno,[1] Fumihiko Koiwa,[1] Ashio Yoshimura.[1,3] *[1]Div of Nephrology, Showa Univ Fujigaoka Hospital, Yokohama, Kanagawa, Japan; [2]Div of Endocrinology and Metabolism, Aichi Medical Univ School of Medicine, Nagakute, Aichi, Japan; [3]Yokohama Dai-ichi Hospital, Yokohama, Kanagawa, Japan.*

Background: Renal tubular epithelium (RTE) are capable of regenerating themselves after a severe injury seen, for example, in acute kidney injury (AKI) where cell migration plays a pivotal role. RTE subculture serves as a tool to study cell migration *in vitro*. However, little is known about ultrastructure of cell migration in vitro. In the present study, we established an experimental protocol for scanning electron microscopy (SEM) in RTE subculture to study fine ultrastructural changes.

Methods: *Rattus norvegicus* kidney tubular epithelial cells, NRK-52E (ATCC® CRL-1571) were subcultured. Early floating cells and subsequent adherent ones were fixed, and subjected to SEM examinations. Minor modifications were made to the original SEM protocol. In separate experiments, small interfering RNA (siRNA) for actin related protein 3 (Arp3) was added to culture medium.

Results: We optimized SEM protocol (figure), and found that there were 2 types of floating cells: one with small sphere structures and the other with microvilli on a cell surface, that lamellipodia developed through a full 360-degree in early stages of subculture, and that very long and branched filopodia developed at later stages. Arp3 gene knockdown with exogenous siRNA inhibited the formation of a long and branched filopodia.



Conclusions: Ultrastructural findings were new, to the best of our knowledge. We claim that we obtained a tool to study how a known gene playing an important role in actin assembly influences ultrastructure in cell migration, and that further study may contribute to find a clue for constructing a new therapeutic strategy for AKI.

FR-PO286

Endothelial Nitric Oxide Synthase Gene Polymorphism in Diabetic Patients with and without Nephropathy Nishu Bhardwaj,[1] Satendra Sharma,[1] Om Prakash Kalra,[2] Anil Kumar Yadav,[2] Meera Sikka,[1] Sonal Sharma.[1] *[1]Dept of Pathology, UCMS and GTB Hospital, Delhi, India; [2]Dept of Medicine, UCMS and GTB Hospital, Delhi, India.*

Background: Nitrous oxide (NO) is a major regulator of renal hemodynamics, its production being catalysed by endothelial nitric oxide synthase (eNOS). Reduction in the generation of NO acts as a deteriorating factor for progressive renal disease. Polymorphisms in the eNOS gene may alter its expression, thus affecting the production of NO. Familial clustering in diabetic nephropathy (DN) points to a role of genetic factors in the pathogenesis of renal disease.The present study was conducted to evaluate the association of eNOS G894T gene polymorphism with the risk of developing DN.

Methods: The study comprised of 3 groups with 50 subjects in each (group 1: DN cases; group 2: diabetics without nephropathy; group 3: controls). Venous blood was collected from all subjects for measurement of serum NO level by spectrophotometry and for DNA extraction by phenol-chloroform method followed by PCR-RFLP to determine the eNOS G/T polymorphism.

Results: The frequencies of GT and TT genotypes were significantly higher in DN patients (34% and 26%, respectively) than in diabetics without nephropathy (22% and 4%, respectively) and controls (24% and 4%, respectively) ($p < 0.001$).The frequency of G allele in groups 1, 2 and 3 was 0.57, 0.85 and 0.86, respectively, whereas, that of T allele was 0.43, 0.15 and 0.14, respectively ($p < 0.001$). Thus, a positive association was observed between the eNOS G894T gene polymorphism and development of DN. Serum NO level in subjects with GG genotype ($45.1 \pm 27.8\mu M$) was significantly higher than in those with TT genotype ($26.9 \pm 18.1\mu M$) ($p = 0.029$). The carriers of T allele were seen to have significantly lower serum NO level ($35.4 \pm 24.8\mu M$) as compared to subjects with only G allele ($45.1 \pm 27.8\mu M$) ($p = 0.034$), indicating that the eNOS G894T gene polymorphism may alter the expression of eNOS.

Conclusions: This study indicates a possible role of eNOS gene polymorphism in the pathogenesis of DN. The eNOS G894T polymorphism may be a potential genetic marker for the risk of developing nephropathy in diabetic patients, and hence, may help in early identification of high-risk patients.

FR-PO287

Diabetic Nephropathy Candidate Genes Revealed by Whole-Genome Sequencing in Finnish Type 1 Diabetic Sib Pairs Discordant for Complications Miina K. Öhman,[1] Eudora Eng,[1] Yang Sun,[1] Anne-May Österholm,[2] Bing He,[2] Jing Guo,[2] Erkka A. Valo,[3] Valma Harjutsalo,[3] Niina Sandholm,[3] Carol Forsblom,[3] Per-Henrik Groop,[3] Karl Tryggvason.[1] *[1]Cardiovascular and Metabolic Disorders, Duke-NUS Medical School, Singapore; [2]Medical Biochemistry and Biophysics, Karolinska Inst, Stockholm, Sweden; [3]Folkhälsan Inst of Genetics, Folkhälsan Research Inst, Helsinki, Finland.*

Background: Diabetic nephropathy (DN) is the most devastating complication of diabetes and the most common cause of end-stage renal disease. The pathogenesis of DN is poorly understood, but epidemiologic studies support a role for genetic predisposition. To identify mutations predisposing to, or protecting from DN, we performed whole-genome sequencing (WGS) using a discordant sib pair (DSP) cohort from the homogeneous Finnish population, consisting of T1D sib pairs (n=85) who have remained discordant for complications for >30 years ("Discovery cohort"). The replication cohort consisted of 4,177 unrelated T1D patients (cases n=1,986, controls n=2,191) from the FinnDiane ("Replication") cohort and was used to screen for the variants found in the WGS.

Methods: Only sib pairs with extreme phenotypes were used for WGS: the case individuals had either persistent proteinuria, were on dialysis, had kidney transplant or died from kidney disease, and they also had retinopathy, whereas the controls had never developed a nephropathy despite 30 years of diabetes. WGS was carried out using Illumina and Complete Genomics platforms. The genetic variants found in the Discovery cohort were screened in the Replication cohort.

Results: From WGS, a total of 12,784,778 single-nucleotide variants (SNV) and 6,021,219 indels were found. Of all the SNVs, 101,734 were located in exons. We focused on the exon mutations that were either nonsense or frameshift, and narrowed them down to the mutations, which were found in homozygous form only in cases (n=15) or in controls (n=19), representing potential susceptibility or protective mutations for DN.

Conclusions: Candidate gene mutations found in the WGS are inserted into mouse genomes using the CRISPR/Cas9 technology and the mice are made diabetic by breeding with Akita mice or using streptozotocin. The mice are then monitored for potential development of DN.

FR-PO288

Epigenetic Regulation of Myo-Inositol Oxygenase (MIOX) by Hyperglycemia - A New Mechanism Relevant to the Tubulo-Interstitial Pathobiology in Diabetic Nephropathy Isha Sharma, Neel Kamal Singh, Yashpal S. Kanwar. *Dept of Pathology, Northwestern Univ, Chicago, IL.*

Background: Kidney is one of the target organs affected by biochemical and hemodynamic derangements induced by hyperglycemia. Most of the studies have focused on mechanisms relevant to glomerular pathology, while tubulo-interstitium remains under

emphasized. MIOX, an enzyme expressed in proximal tubules, is up-regulated under high glucose (HG) ambience. It channels distal intermediaries of glycolytic pathway into glucuronate-xylulose pathway with the generation of reactive oxygen species (ROS).

Methods: We investigated epigenetic regulation of MIOX to delineate various mechanism(s) that lead up to its upregulation, generation of ROS and relevant downstream events under high glucose ambience.

Results: Kidneys of mice with STZ-induced diabetes had increased expression of MIOX with hypomethylation of its promoter spanning up to -750 bp, as assessed by bisulfite sequencing. Likewise hypomethylation was observed in HK-2 cells under HG ambience. *In silico* program analysis of the promoter region revealed putative binding site for Sp-1 transcription factor, the region enriched with GC dinucleotides. EMSA studies indicated markedly increased binding of Sp-1 to MIOX promoter under HG ambience, which was significantly reduced by the selective Sp-1 inhibitor, mithramycin. A smaller 261 bp promoter DNA fragment encompassing binding region of Sp-1 was isolated to asses Luciferase activity. Activity was increased under HG ambience, while it was reduced following a single base pair substitution (C to T) in the Sp-1 binding region. Sp-1 siRNA treatment led to decreased expression of Sp-1, MIOX, HIF-1alpha, and of an ECM protein, fibronectin. Importantly, Sp-1 siRNA treatment reduced the generation of ROS, both from the mitochondrial and NADPH oxidase sources, as assessed by immunofluorescence studies and FACS analyses.

Conclusions: This study highlights the epigenetic regulation of MIOX that influences downstream events, such as, generation of ROS and accumulation of ECM proteins, both being the hallmark of tubulo-interstitial pathology relevant to the progression of diabetic nephropathy.

Cytosine Methylation and Associated Gene Expression Changes in Kidney Tubules of Patients with Diabetic Kidney Disease

Caroline A. Gluck,[1] Sang Youb Han,[2] Chengxiang Qiu,[2] Ioannis Mantzaris,[3] Ae Seo Deok Park,[2] Yi-An Ko,[2] Amit K. Verma,[3] Matthew Palmer,[2] Katalin Susztak.[2] *[1]Div of Nephrology, The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA; [3]Dept of Medicine, Albert Einstein College of Medicine, Bronx, NY.*

Background: The epigenome is a key determinant of gene expression. The epigenome is dynamic and is influenced by environment alterations, as occur in diabetes. Epigenetic modifications are maintained during cell division, thus solidifying "the memory" of environmental effects. The aim of the current project was to determine whether cytosine methylation changes can be observed in kidney tubule cells of patients with diabetic kidney disease (DKD).

Methods: Our primary data set included 91 microdissected human kidney tubule samples (22 DKD cases, 69 controls) associated with clinical and histological data. Illumina Infinium 450K Chips were used to determine genome wide cytosine methylation. Affymetrix RNA microarray was used to define transcript level changes. We used linear regression models to correlate identified changes with clinical and histological outcomes.

Results: Our analysis identified 519 probes that showed significant linear correlation with degree of interstitial fibrosis on histology after Bonferroni correction for alpha=0.05 (p-value<$1.19x10^{-7}$). To identify functionally important methylation changes we correlated differential methylation with transcript level changes. A large subset of differentially methylated probes correlated with gene expression changes (p-value=8e-5). Gene ontology analysis for methylation-expression pairs included significant enrichment for immune response, tissue remodeling and transport.

Conclusions: Human kidney tubule samples obtained from patients with diabetic kidney disease show differences in cytosine methylation patterns. The differential methylation of several probes correlated with gene expression changes, which may indicate that methylation changes are functionally important in diabetic kidney disease development.

Reversal of Epigenetic Alterations in Diabetic Nephropathy (DN) Was Associated with a Decrease in Proteinuria

Himanshu Vashistha,[1] Manoj K. Tembhre,[2] Abheepsa Mishra,[2] Nairuti H. Shah,[2] Ashwani Malhotra,[2] Leonard G. Meggs,[1] Pravin C. Singhal.[2] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Medicine, Ochsner Clinic, New Orleans, LA.*

Background: Recently, Ang II has been demonstrated to down regulate expression of podocyte neprhin via alterations in epigenetic profile. We hypothesize that blockade of Ang II would partially reverse epigenetic alterations in DN and low dose hydralazine (HYDZ, non-hypertensive dose) would further augment the effect of Ang II blockade contributing to a decrease in proteinuria in diabetic mice.

Methods: Protein blots of renal tissues/cortical sections of 2, 4, and 6 month old control and Akita mice (diabetic, n=3) were probed for methylation at histone (H)3 lysine (K)4 residues, acetylation at H3 lysine (K)9 residues, SNAIL, vitamin D receptor (VDR), and nephrin. *In vitro* studies, protein blots of control and high glucose (30 mM, HG) treated human podocytes (HPs) were probed for SNAIL, VDR, nephrin, H3K4me3, H3K9ac and actin. Podocyte VDR and nephrin gene methylation status (pyrosequencing) and SNAIL binding at VDR and nephrin promoters (ChIP assay) were determined. Control and Akita mice (n=4) were treated with losartan (an Ang II receptor blocker, 10 mg/Kg/day) with/without HYDZ (10 mg/kg/day, 4 weeks) followed by evaluation of proteinuria and renal epigenetic alterations.

Results: Protein blots of renal tissues/cortical sections of Akita mice and HG/HPs displayed enhanced expression of SNAIL and H3K4me3 but down regulation of VDR, nephrin and H3K9ac. Losartan not only decreased proteinuria but also partially reversed epigenetic alterations and associated SNAIL, VDR and nephrin expressions; HYDZ alone has similar effects on proteinuria and epigenetic markers and further augmented these effects when combined with losartan. Both nephrin and VDR displayed more than 70% cytosine methylation (CpG islands). HG/HP displayed deacetylation of nephrin and degradation via ubiquitation. ChIP assays revealed binding of SNAIL at VDR and nephrin promoters.

Conclusions: Reversal of epigenetic alterations in renal tissues contributed to decrease in proteinuria in diabetic mice.

Funding: NIDDK Support

FR-PO291

Hyperglycemia-Dependent Epigenetic and Gene Expression Profiles in Human Kidney Mesangial Cells

Akinobu Ochi,[1] Helena Kristiansson,[1] Dong Chen,[1] R. Paul Fracasso,[2] Noelynn Oliver,[2] Gilbert W. Moeckel.[1] *[1]Dept of Pathology, Yale Univ School of Medicine; [2]Boehringer Ingelheim Pharmaceuticals, Inc.*

Background: Hyperglycemia induces gene expression changes in glomeruli. Epigenetic modifications have been implicated as a mechanism contributing to dysregulated gene expression by hyperglycemia. We investigated the effects of hyperglycemia on histone and DNA methylation status in human mesangial cells (HMCs). We performed comprehensive RNA-seq analysis to assess changes in gene expression and identify candidate genes that may be affected by epigenetic modifications.

Methods: We isolated RNA, DNA and histones from cultured HMCs in osmolality-adjusted high glucose (HG, 25mM) or normal glucose (NG, 5.6mM) medium for 10 or 20 days. We compared histone3 lysine residue methylation changes by using EpiGentek ELISA plates. DNA methylation status was evaluated by Yale Center for Genome Analysis using Infinium HumanMethylation450 DNA analysis BeadChip kit. We determined gene expression by RNA-seq analysis.

Results: Most lysine residues showed increased histone methylation at the mono, di and tri methylation modification level in HG condition. Especially, H3K4me3, H3K9me1, H3K3me3, H3K36me2, H3K79me1 and H3K79me3 were strongly hypermethylated; only H3K36me1 was hypomethylated. DNA methylation analysis showed that 2279 CpG islands were hypermethylated and 995 CpG islands were hypomethylated in HG condition at day10. RNA-seq analysis showed that a total 941 mRNAs were changed in HG condition at day20. Combining results of our epigenetic and gene expression analyses identified candidate genes for epigenetic changes due to hyperglycemia. Included among them are: *CCL2,* a known marker of renal disease; *CDKN1a,* which has a role in mesangial cell hypertrophy; and *TXNIP,* known to be upregulated by hyperglycemia, thought to play a critical role in diabetic nephropathy (DN). For all of these genes, mRNA expression was strongly upregulated.

Conclusions: Hyperglycemia affects the histone and DNA methylation status, and changes expression levels of many genes in HMCs. Further analysis will clarify the precise mechanisms of these epigenetic changes and relationships among the affected genes in DN progression.

FR-PO292

ERK/MAPK Signaling-Depended Cytosolic Translocation of Dnmt3a Plays a Role in High Glucose-Induced CTGF Hypo-Methylation in Mesangial Cells

Bin Yi, Aimei Li, Wei Zhang, Hao Zhang. *Dept of Nephrology, The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Diabetic nephropathy (DN) has become a major cause of end stage renal disease. Connective tissue growth factor (CTGF), a fibrogenic factor, played an important role in the pathogenesis of DN. We have previously identified that high glucose induces the expression of CTGF by decreasing DNA methylation . Researches in tumor cells have confirmed that ERK/MAPK signaling pathway were involved in regulation of DNA methyltransferases (Dnmts), while no relevant research were reported in human mesangial cells (HMCs). The aim of this study was to investigate the mechanisms of the CTGF hypo-methylation in a ERK/MAPK signaling involved way in HMCs .

Methods: Human mesangial cells are treated with normal glucose (5mM) or high glucose (30mM) respectively. Immnofluorescence staining, real-time PCR or western blotting was performed to determine the cellular distribution and expression of CTGF and Dnmt3a. ChIP-PCR assay was applied to investigate the capability of Dnmt3a binding the CpG island of CTGF, Methylation specific PCR was used to detect the methylation state of CTGF promoter. ERK/MAPK signaling inhibitor was used to verify ERK/MAPK signaling in high glucose-induced Dnmt3a cytosolic translocation.

Results: High glucose induced both mRNA and protein expressions of CTGF ($p< 0.05$). Although the protein expression of total Dnmt3a were not altered, nuclear Dnmt3a was significantly reduced and cytosolic Dnmt3a were elevated after high glucose treatment, No significant change was observed in Dnmt1 and Dnmt3b.The binding between Dnmt3a and the CpG island of CTGF was significantly lowered ($p< 0.01$) and the methylation of CpG island of CTGF promoter was time-dependently reduced in the presence of high glucose ($p< 0.05$). Co-treated with ERK/MAPK pathway inhibitors significantly decreased cytosolic translocation of Dnmt3a and expression of CTGF induced by high glucose ($p< 0.05$).

Conclusions: High glucose induces cytoplasmic translocation of Dnmt3a, possibly through activating ERK/MAPK signaling pathway, which contributes to the decreased binding of Dnmt3a on CTGF promoter and the subsequent CTGF hypo-methylation in mesangial cells.

Activated Protein C Reverses Sustained Tubular p21-Expression and Senescence via a Methylation Dependent Mechanism Moh'd Mohanad Ahmad Al-Dabet, Khurrum Shahzad, Fabian Bock, Berend Heinrich Isermann. *Clinical Chemsistry and Pathobiochemistry, Otto-von-Guericke Univ, Magdeburg, Sachsen-Anhalt, Germany.*

Background: The importance of tubular damage in diabetic nephropathy (dNP) is increasingly recognized. Tubular damage in dNP is characterized by tubular hypertrophy and senescence, but the pathophysiological mechanistic relevance, the underlying mechanisms, and therapeutic structures allowing targeting such mechanisms are lacking. Furthermore, it is not known whether these changes are related to the hyperglycemic memory in diabetes. Interestingly, (aPC) ameliorates glomerular damage epigenetically. We hypothesized that tubular damage is epigenetically controlled and that aPC may target the underlying mechanism.

Methods: Type-1 (streptozotocin) diabetic mice were analyzed. dNP was validated based on albuminuria. A subset of mice was treated with SGLT-2 inhibitor, aPC, or 5aza-deoxycitidiene alone or in combination for 6 weeks.

Results: Gene-expression analyses identified p21 as the prominently induced gene in dNP (STZ model). Expression of p21 was further increased in mice with low aPC levels. *In-vitro* study showed that glucose induced p21 expression remains high after normalization of glucose concentration, suggesting that p21 is epigenetically controlled. Intriguingly, exposure of aPC at time of glucose normalization (25 to 5.5 mM) reversed p21 expression. In parallel, glucose reduced DNMTs activity and DNMT1/3b expression, which remained low despite glucose normalization. These glucose-induced persistent changes were reversed by aPC. Likewise, in diabetic mice (16 weeks of DM) p21 expression in renal tubular compartment remained high despite blood glucose normalization for the last 6 weeks using SGLT-2 inhibitor. aPC treatment during the last 6 weeks abolished hyperglycemia induced sustained p21 expression and protected from tubular damage (histological damage, KIM-1) and senescence (SA-βgal). Concomitant treatment with 5aza-dC abolished aPC's protective effect.

Conclusions: This suggests that p21 induces tubular senescence in dNP, which is sustained despite normalization of glucose level. Importantly, persistent p21-expression and tubular senescence can be reversed by aPC.

Transcriptome Analysis of Kidneys Identifies Novel Pathogenic Canonical Pathways in Experimental Diabetic Nephropathy Sharma S. Prabhakar, Aumyot Prongdong, E Chepchumba K. Yego. *Internal Medicine, Texas Tech Univ Health Sciences Center, Lubbock, TX.*

Background: Diabetic nephropathy (DN) is the most common cause of end stage renal disease worldwide and its current therapy remains ineffective as the pathogenesis remains unclear. In this study we examined genomic profile of kidneys from an experimental DN to obtain better insights into pathogenesis.

Methods: We used obese ZSF_1 rats, an established model of DN, and maintained from 8-26 weeks to harvest kidneys at sacrifice. Lean ZSF_1 littermates, which do not develop DN served as controls. RNA was isolated from the kidneys and processed for transcriptome analysis using Illumina HiSeq 2500. RNA from obese and lean ZSF_1 rats was compared. The differential gene list from this analysis was imported into Ingenuity Pathway Analysis (IPA) for global transcriptome analysis and pathway mapping.

Results: The top canonical pathways with a significant *Z* score include Wnt-β catenin and anti-oxidant pathway, Endothelin-1, AMP kinase, complement system, calcium signaling, eNOS signaling, cAMP, IL-1, IL-8, leptin signaling, RAS and aldosterone pathways. Significantly expressed but not hitherto reported pathways include G-protein coupled receptor, hepatic fibrosis, Ca+ transport signaling and heparin sulfate biosynthesis. The molecules significantly upregulated (fold change in parenthesis) include D4, zinc and double PHO finger family (x79), PG E receptor 2 (x28)cholinergic receptor CHRNA5 (x12), Phospholipase A PLA2G2A (x16), PLA 2G2F (x15), adrenoreceptor α1D (x10) LPS binding proteins and HMG co A. Significantly negatively regulated molecules include Cyt P450 2c8 (x2351), Heparin sulfate glucosamine HS3ST3A1 (x556) HS3ST3B1 (x334), MAP kinase 10 (x95), sulfotransferase 1E1 (x401), aldehyde dehydrogenase 3 family (x71), FABP (Fatty acid binding protein)-1 (x1359) Acyl coA synthase Acsl 6 (x39) and chondroitin 6 (x51).

Conclusions: Next Gen sequencing of kidneys with DN revealed pathways which regulate inflammation, oxidative stress, cell cycle and fibrosis. The pathogenic significance of these proteins particularly cyt P450, FABP-1, zinc finger proteins, HS3ST3 proteins adrenergic and cholinergic receptors in DN warrant more systematic investigation.

Heterogeneous Nuclear Ribonucleoprotein F Overexpression Stimulates Sirtuin 1 and Ameliorates Kidney Injury in Mice with Type 2 Diabetes Induced by High Fat-Diet/Streptozotocin Chao-Sheng Lo,[1] Anindya Ghosh,[1] Chin-Han Wu,[1] Shuiling Zhao,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]CRCHUM, Univ of Montreal, Montreal, QC, Canada; [2]Res Ctr, Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp, Boston, MA.*

Background: We investigated the impact of overexpression of heterogeneous nuclear ribonucleoprotein F (hnRNP F, a transcription factor) on the expression and signaling of the NAD+-dependent deacetylase sirtuin 1 (SIRT1) and the development of renal proximal tubular cell (RPTC) inflammation and tubulointerstitial fibrosis in mice with type 2 diabetes induced by high fat-diet (HFD) and streptozotocin (STZ).

Methods: 4-week old hnRNP F-transgenic (hnRNP F-Tg) mice overexpressing hnRNP F in their RPTCs and non-transgenic littermates (C57BL/6 strain) were fed a normal diet (ND) or a HFD for 16 weeks and received a single STZ injection (45 mg/kg, i.p.) at week 8. Body weight and blood glucose were monitored weekly. Glucose tolerance and insulin sensitivity were assessed at week 19. At week 20, kidneys were processed for histology. Renal proximal tubular (RPT) gene and protein expression were evaluated by real time-qPCR and Western blotting, respectively. In vitro studies were performed on immortalized rat PTCs (IRPTCs) stably transfected with hnRNP F cDNA or Sirt1 gene promoter.

Results: HFD/STZ-treated mice developed obesity, hyperglycemia, hyperinsulinemia, insulin resistance and tubulointerstitial fibrosis parallel with markedly increased expression of pro-inflammatory (TNF-α, MCP-1 and PAI-1) and pro-fibrotic (TGF-β1, Col IV and FN1) markers and decreased expression of SIRT1 in RPTCs. These changes were attenuated in HFD/STZ-hnRNP F-Tg mice. In vitro, hnRNP F overexpression in IRPTCs stimulated Sirt1 gene promoter activity via a DNA responsive element (nucleotides N-973 to N-962 upstream of the transcriptional start site).

Conclusions: Our findings indicate that hnRNP F overexpression can attenuate RPTC inflammation and fibrosis in type 2 diabetes induced by HFD/STZ via up-regulation of Sirt1 gene expression and signaling.

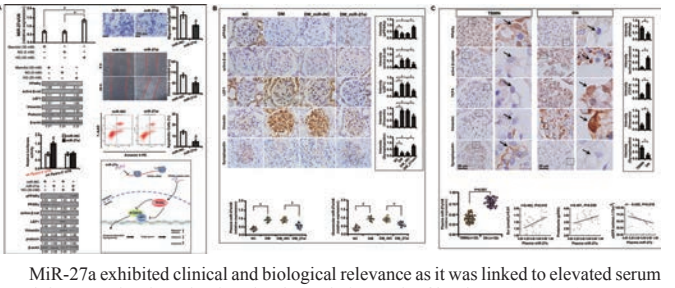
MicroRNA-27a Promotes Podocyte Injury via Suppression of PPAR gamma/β-Catenin Signaling in Diabetic Nephropathy Xiaoyan Bai. *Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China; National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Guangdong Provincial Inst of Nephrology.*

Background: Podocyte injury plays a pivotal role in diabetic nephropathy (DN). MicroRNA-27a (miR-27a) upregulation has been identified in diabetes. We asked whether miR-27a mediates podocyte injury through PPAR gamma/Wnt/beta-Catenin signaling in DN.

Methods: The expression and functional relevance of miR-27a, PPAR gamma, and beta-Catenin were investigated in cultured podocytes and glomeruli of diabetic rats and patients using in vitro and in vivo approaches. Biological parameters were analyzed using enzyme linked immunosorbent assay (ELISA).

Results: High glucose stimulated miR-27a expression and promoted podocyte injury via repression of PPAR gamma/beta-Catenin signaling. Plasma miR-27a downregulation improved renal function and attenuated podocyte injury in diabetic rats (table 1) and DN patients.

Variables	DM_miR-iNC (n=7)	DM_miR-27ai (n=7)
Scr (umol/L)	114.37±7.56	67.25±2.28*
Serum BUN (mmol/L)	15.63±4.24	11.05±1.52*
Blood glucose (mmol/L)	26.31±1.36	25.70±2.15
UAER (ug/min)	1.45±0.21	0.67±0.06#
UACR (ug/mmol)	27.32±2.32	15.35±1.16#
Ccr ($mL \cdot min^{-1} \cdot Kg^{-1}$)	3.48±0.45	7.37±0.82#



MiR-27a exhibited clinical and biological relevance as it was linked to elevated serum creatinine, proteinuria and reduced estimated glomerular filtration rate (eGFR).

Conclusions: We propose a novel role of the miR-27a/PPARγ/β-catenin axis in fostering podocyte injury in DN. Targeting miR-27a could be evaluated as a potential therapeutic approach for DN.

FR-PO297

The miR-21/PDCD4/JNK Circuit Plays a Key Role in the Pathogenesis of Diabetic Nephropathy Hao Wu,[3,4] Yonggang Wang,[1] Yunfeng Qiao,[2] Tie Li,[4] Fuchun Wang.[4] *[1]China-Japan Union Hospital of Jilin Univ, China; [2]Jilin Province People's Hospital, China; [3]The Second Hospital of Jilin Univ, China; [4]Changchun Univ of Chinese Medicine, China.*

Background: c-Jun N-terminal kinase (JNK) and microRNA-21 (miR-21) play key roles in the pathogenesis of diabetic nephropathy (DN). However, it is unknown whether the two factors have reciprocal interactions which may form a positive feedback circuit that contributes to the pathogenesis of DN.

Methods: 8-week-old male C57BL/6J mice were induced to diabetes by injection of streptozotocin. A specific JNK inhibitor, SP600125, was administrated to diabetic mice in the presence or absence of a specific miR-21 mimic (miR-21-M). In addition, a specific miR-21 inhibitor (miR-21-I) was administrated to diabetic mice to determine its effect on JNK. To determine whether programmed cell death protein 4 (PDCD4), a known target of miR-21, was the key factor through which miR-21-I inhibited JNK function, the PDCD4 siRNA was delivered to miR-21-I treated mouse mesangial cells under high glucose condition.

Results: Both SP600125 and miR-21-I markedly inhibited JNK function. Furthermore, the inhibitors decreased renal miR-21 along with increased mRNA and protein levels of *pdcd*4. As a result, they both produced similar defences against diabetes-induced renal inflammation, fibrosis and albuminuria. Interestingly, co-administration of miR-21-M abolished the inhibitory effect of SP600125 on JNK function; indicating miR-21 as the upstream of JNK. Finally, PDCD4 siRNA abolished the inhibitory effect of miR-21-I on JNK function in high glucose cultured mouse mesangial cells.

Conclusions: The present study indicates a positive feedback loop between JNK and miR-21, which may play a key role in the pathogenesis of DN.

Screening miRNAs in Urine Exosomes as New Biomakers for Diabetic Kidney Disease Jing Zhang, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Diabetic kidney disease (DKD) is the main cause of chronic renal failure, while the diagnosis of DKD is still based on proteinuria, serum creatinine, et al, which has some limitations. In this study, we would like to detect the miRNAs in urine exosomes of patients with type 2 diabetes mellitus (T2DM), to explore its correlation with proteinuria and renal function, and screening new biomarkers for early diagnosis of DKD.

Methods: Thirty inpatients with T2DM were enrolled in this study. According to the presence of microalbuminuria or clinical proteinuria, patients were randomly divided into three groups: group one is the patients without microalbuminuria or clinical proteinuria, group two is with microalbuminuria but without clinical proteinuria, and group three is with clinical proteinuria. Another ten healthy people were enrolled as control. Morning urine samples were collected from those patients, and urine exosomes were isolated by the kit and observed by transmission electron microscopy. Quantifications of urinary miRNAs were performed using stem-loop qRT-PCR followed by TaqMan PCR, and the correlations between miRNAs and proteinuria and renal function were analyzed.

Results: The exosomes isolated by the kit from 2ml of urine samples appeared as clusters of vesicles of 30-100nm in diameter under electron microscope. Compared with healthy controls, the levels of miR-21, miR-192 and miR-377 in urine exosomes of patients with T2DM were significantly increased, while the levels of miR-29a were significantly decreased ($P < 0.05$). And between each two of the three groups of T2DM, the levels of miR-21, miR-192, miR-377 and miR-29a changed significantly ($P < 0.05$). Moreover, the levels of miR-21 have a negative correlation with the estimated glomerular filtration rate (eGFR), while have positive correlations with blood urea nitrogen, serum creatinine and proteinuria ($P < 0.05$).

Conclusions: Compared with healthy control, the levels of miRNAs in urine exosomes of patients with T2DM change significantly, and have some correlations with proteinuria and renal function, which may be use as the new biomarkers of DKD.

FR-PO299

microRNAs and Epigenetic Regulation of Genes in Diabetic Nephropathy Beina Teng, Janina Müller-Deile, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hannover, Hannover, Germany.*

Background: DNA methylation and microRNAs has been identified as two key mechanisms that underlie the evolutionarily conserved phenomenon associated with developmental and pathological gene regulation, thus may cause different pathological conditions in humans. Increasing evidence suggested that dysregulation of the epigenome and miRNA is involved in diabetic nephropathy, which is a serious complication of diabetes mellitus and is associated with high mortality.

Methods: We examined the expression profiling of miRNAS by performing a screening with urin from patient with diabetic nephropathy and healthy human, or human podocytes under diabetic conditons. A genome-wide methylation was screened in human podocytes stressed for 7 days with 30 mM glucose and mannitol as osmotic control. Samples for RNA expression microarrays were isolated from glomeruli of type I diabetic mice or human podocytes treated with high glucose for no less than seven days.

Results: We found that expression of 25 miRNAs were stastically significantly different not only in the patient with diabetic nephropathy but also human podocytes under diabetic conditions. Using prediction tool, we identified top 20 targets for all the 25 miRNAs and compared the candidates with RNA expression profiling. Furthermore we analyzed miRNA expression profiles and DNA methylation in a cross-sectional study of diabetic nephropathy and was able to identify the changes in miRNA expression under diabetic conditions that are regulated by aberrant DNA methylation.

Conclusions: Diabetic nephropathy is always accociated with dyregulation of several genes, which are epigenetically regulated or by miRNAs, which could be useful as biomarkers for diagnosis of diabetic nephropathy. Using an antagonist or mimic of miRNAs could be potential therapeutic strategy for diabetic nephropathy.

FR-PO300

miRNA Expression Correlates with Fibrosis in Diabetic Nephropathy Francesca Conserva,[1,2] Mariagrazia Barozzino,[2] Paola Pontrelli,[2] Annarita Oranger,[2] Francesco Pesce,[2] Federica Giannattasio,[2] Matteo Accetturo,[2] Massimo Papale,[2] Maria Teresa Rocchetti,[2] Giuseppe Castellano,[2] Simona Simone,[2] Salvatore Di Paolo,[3] Giovanni B. Pertosa,[2] Loreto Gesualdo.[2] *[1]IRCSS, Maugeri Fundation, Cassano Murge (BA), Italy; [2]Nephrology Unit, Dept of Emergency and Organ Transplant, Univ of Bari, Italy; [3]Nephrology Unit, Dimiccoli Hospital, Barletta (BA), Italy.*

Background: Diabetic Nephropathy (DN) is the primary cause of End Stage Renal Disease. We discovered that urines of DN patients (pts) are enriched in free ubiquitin and accumulation of lysine63-ubiquitinated (K63Ub) proteins at tubular level is involved in epithelial-to-mesenchymal transition (EMT). By microarray, we identified a set of miRNAs deregulated in DN kidneys. Aim of our study was to identify miRNAs regulating the increased expression of K63Ub proteins and involved in the progression of fibrosis in DN.

Methods: Total RNA was extracted from cell free urine of 10 biopsy-proven DN pts with type 2 diabetes (T2D), 10 pts with T2D and membranous nephropathy (MN) and 10 pts with T2D and normal renal function. miRNA expression was assessed by qPCR.

Results: Among deregulated miRNAs in DN kidney, we selected 9 miRNAs deregulated in DN pts (FC >1.5) compared to controls and T2D-MN. *In silico* we found 3 miRNAs with a predicted interaction with UBE2V1, an ubiquitin-conjugating E2 enzyme variant that mediates the formation of K63Ub chains. These miRNAs downregulation was further validated on both kidney biopsies ($p<.01$, DN vs CTRL, $p<.03$ T2D-MN vs CTRL, $p<.05$ DN vs T2D-MN) and *in vitro* on tubular cells in a model of hyperglycemia (FC=-2.3). Since those miRNAs were described as correlated to EMT, we tested their prognostic strength in the progression of kidney damage by matching urinary expression with the degree of fibrosis at the tissue level. Interestingly 1 miRNA was significantly downregulated in urines of DN pts compared to other groups. Moreover, this miRNA urinary levels were independent predictors of the degree of renal fibrosis in DN ($p=.03$).

Conclusions: In conclusion we confirm the role of ubiquitination as a pathogenic mechanism in the progression of kidney damage and suggest the validation of this miRNA as diagnostic biomarker of tubular-interstitial fibrosis progression in DN.

Altered Distribution of HDL, Extracellular Vesicle and Argonaute-2 Associated Circulating microRNAs in Diabetic Nephropathy and Systemic Microvascular Damage Barend W. Florijn,[1,2] Jacques Duijs,[1,2] Geesje M. Dallinga-Thie,[3] Anita N. Böing,[4] Wendy Stam,[1,2] Ton J. Rabelink,[1,2] Marlies Reinders,[1] Roel Bijkerk,[1,2] Anton Jan Van Zonneveld.[1,2] *[1]Dept of Internal Medicine, Leiden Univ Medical Center, Leiden, Netherlands; [2]Einthoven Laboratory for Experimental Vascular Research, Leiden Univ Medical Center, Leiden, Netherlands; [3]Dept of Vascular Biology, Amsterdam Medical Center, Leiden, Netherlands; [4]Dept of Clinical Chemistry, Amsterdam Medical Center, Leiden, Netherlands.*

Background: We previously demonstrated an association between total plasma levels of specific microRNAs (miRNAs) and microvascular injury in patients with diabetic nephropathy (DN). Circulating miRNAs are carried by extracellular vesicles (EVs), RNA-binding protein Argonaute2 (Ago2) or high-density lipoprotein (HDL). Identification of the carrier specificity of these miRNAs can enhance the biomarker potential of miRNAs. In addition, carrier-specific transfer of miRNAs to vascular cells may play a causal role in vascular injury.

Methods: Here we assessed the plasma carrier distribution of miRNAs in DN (n=21), diabetes mellitus (DM; n=15; eGFR ≥ 30 mL/min) patients and healthy controls (n=15). EVs, HDL and Ago2 were isolated using size exclusion chromatography, KBr density gradient ultracentrifugation and immunoprecipitation respectively. MiRNA expression was determined using TaqMan® miRNA Arrays and correlated to markers of vascular injury, including angiopoietin-1 (Ang1), angiopoietin-2 (Ang2),soluble thrombomodulin (sTM) and capillary density.

Results: Specific miRNA-carrier complexes were identified to be associated with DN and vascular injury. EV-miR-21 and Ago2-miR-660 levels displayed a significant increase in both DM and DN groups compared to healthy controls and correlated with capillary tortuosity and sTM respectively. Furthermore, HDL-miR-132 levels decreased in DN and correlated with levels of Ang2, while both HDL-miR-152 and Ago-miR-152 levels displayed a significant increase in DN. Interestingly, only Ago-miR-152 levels correlated with levels of Ang2 and sTM.

Conclusions: Our data suggest that miRNAs in specific carriers may contribute to vascular injury and could improve selectivity and sensitivity of biomarkers for microvascular injury in DN.

FR-PO302

Characterizing the Urinary Peptidome of Early Type 1 Diabetes to Infer Protease Activity in the Kidneys Julie Anh Dung Van, Ashley Di Meo, Eleftherios P. Diamandis, James W. Scholey, Ana Konvalinka. *Medicine, Univ of Toronto, Toronto, ON, Canada.*

Background: Proteolytic activity in the kidney may induce early functional and structural changes in type 1 diabetes. Evidence suggests that this activity may be specific to some proteases and their protein substrates, and that resulting peptides generated within kidney may be excreted into the urine and provide a footprint of intrarenal proteolysis. We aim to compare urinary peptidomes of adolescents with uncomplicated type 1 diabetes and healthy peers and to infer protease activity in the kidney by using differentially excreted peptides.

Methods: We collected second-morning, midstream urines from 15 cases with type 1 diabetes and 15 age- and sex-matched controls from the observational arm of the Adolescent Diabetes Cardio-Renal Intervention Trial at The Hospital for Sick Children in Toronto. Urine volumes normalized to 90 umol of creatinine were subjected to 10kDa filter centrifugation to isolate naturally occurring peptides. Filtered peptides were then fractionated by strong cation exchange liquid chromatography and analyzed on Q-Exactive mass spectrometer. MaxQuant software was used for peptide/protein identification and label-free quantification. Peptide Extractor and Proteasix were used to infer protease activity based on the amino acid sequence of peptides.

Results: While our study is currently ongoing, our preliminary data revealed promising results. A total of 1098 peptides from 307 unique proteins were identified in a healthy volunteer urine sample. The coefficients of variation were 35% for samples processed on the same day and and 40% for samples processed on different days. Uromodulin, collagen and clusterin fragments were among the most abundant kidney-derived peptides. Bioinformatic analyses showed that proteolysis occurred near the C-terminus of the proteins and that it was perhaps carried out by plasmin and trypsin.

Conclusions: Our preliminary findings suggest that we can identify urine peptides with good reproducibility. Furthermore, we computationally predicted endogenous protease activity by examining the urinary peptidome. Future work will be conducted in a cross-sectional study of patients with diabetes and healthy controls.

FR-PO303

Global Proteomic Analysis of Insulin Action in Glomerular Podocytes Salman Hosawi,[1] Richard Coward,[2] Martin J. Humphries,[1] Rachel Lennon.[1,3] *[1]Wellcome Trust Centre for Cell-Matrix Research, Univ of Manchester, United Kingdom; [2]Academic Renal Unit, Univ of Bristol, United Kingdom; [3]Inst of Human Development, Univ of Manchester, United Kingdom.*

Background: Diabetic nephropathy (DN) is a leading cause of kidney failure world wide. In DN, there is progressive glomerular dysfunction and recent studies have demonstrated that the podocyte is a direct target for insulin action. Furthermore, deletion of the insulin receptor (IR) from podocytes leads to progressive kidney damage and eventually kidney failure. This study utilised a global unbiased proteomic approach to examine insulin signaling in podocytes under normal and resistant conditions, with the aim of identifying key molecules that could be targeted for diagnostic or therapeutic purposes.

Methods: Mouse and human immortalised podocyte cell lines were used under normal or resistant conditions (induced by the free fatty acid palmitate). The IR was isolated following whole cell immunoprecipitation (IP) or plasma membrane immunoprecipitation (PM-IP) and label-free mass spectrometry (MS) was used to detect alterations in insulin signaling. Western blotting was used for candidate validation and glucose uptake assays were employed to assess functional responses to insulin stimulation.

Results: Both human and mouse podocytes responded to insulin stimulation, and this response was abolished in the presence of 500uM palmitate. The conditions for isolating the IR using (IP) from whole cell lysates and (PM-IP) were optimised. 23 of the previously described IR interactors were detected by MS in addition to a number of potentially novel or podocyte-specific interactors. Furthermore, palmitate-induced insulin resistance altered the IR interactome in podocytes.

Conclusions: This study provides insight into the complexity and specificity of insulin signaling in podocytes, and may explain how insulin resistance can affect the integrity of the glomerular filtration barrier in diseases such as DN. The different methods of isolating the IR provided a better view on the level of disruption of the insulin signaling pathway. Selected candidates from the MS data could be targeted for therapeutic purposes, or could be used as diagnostic markers for podocyte injury.

Funding: Government Support - Non-U.S.

Silac-Based Proteomics of Primary Human Kidney Cells Reveals a Novel Link between Male Sex Hormones and Impaired Energy Metabolism in Diabetic Kidney Disease Sergi Clotet-Freixas,[1,2] Maria Jose Soler,[2] Marta Riera,[2] Julio Pascual,[2] Fei Fang,[1] Clara Barrios,[2] Eleftherios P. Diamandis,[3] James W. Scholey,[1] Ana Konvalinka.[1,3] *[1]Univ Health Network, Toronto, ON, Canada; [2]Nephrology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona, Spain; [3]Pathology and Laboratory Medicine, Mount Sinai Hospital, Toronto, ON, Canada.*

Background: Male sex predisposes to many kidney diseases.We hypothesized that dihydrotestosterone(DHT) would alter the biology of the renal tubular cell by inducing changes in the proteome.

Methods: We employed spike-in SILAC to accurately quantify the proteome in DHT- and 17β-estradiol(EST)-treated human proximal tubular epithelial cells(PTEC). Top candidate proteins were verified in vitro and in vivo by Western Blot.Renal oxidative stress(OS) was assessed by nitrotyrosine immunostaining.

Results: Of the 5043 quantified proteins, 104 were differentially regulated. Biological processes related to energy metabolism were significantly enriched among DHT-regulated proteins.SILAC ratios of 3 candidates representing glycolysis,N-acetylglucosamine metabolism and fatty acid β-oxidation, namely glucose-6-phosphate isomerase(GPI),glucosamine-6-phosphate-N-acetyltransferase 1(GNPNAT1) and mitochondrial trifunctional protein subunit alpha(HADHA),were validated in vitro and in vivo.Males showed significantly higher renal GPI,GNPNAT1 and HADHA in 2 models of diabetes.Enrichment analysis revealed a link between our DHT-regulated proteins and OS in the diabetic kidney,which was validated in vivo.

Candidate proteins for validation	Median SILAC ratio (n=3-4)		In vitro validation studies (n=3-4)		
	DHT/CONT	EST/CONT	CONT	DHT	EST
GPI	12.1±9.1*	1.2±3.2	0.32±0.2	1.30±0.2*	0.78±0.4
GNPNAT1	5.6±1.6*	2.2*±0.0	0.22±0.1	1.58±0.2*	0.40±0.4
HADHA	8.0±1.1*	0.9±0.7	0.96±0.3	2.02±0.5	1.33±0.1
	*p<0.05 according to significance A (Perseus software)		*p<0.05 vs CONT (U test)		
	In vivo validation studies (n=5-7)				
	Female-CONT	Male-CONT	Female-STZ	Male-STZ	Female-Akita	Male-Akita
Renal GPI	0.59±0.0	0.90±0.1*	0.85±0.1	1.16±0.2	0.67±0.1	1.22±0.3
Renal GNPNAT1	0.98±0.1	0.66±0.1	0.76±0.1	0.88±0.1	0.55±0.1	1.01±0.1*
Renal HADHA	0.48±0.0	0.87±0.1*	0.65±0.1	0.97±0.1*	0.65±0.1	1.25±0.2*

	*p<0.05 vs Female (U test)					

Conclusions: This is the most in depth quantitative proteomic study of human primary PTEC response to sex hormones.We suggest for the first time that male sex hormones perturbed energy metabolism in kidney cells,resulting in increased oxidative stress in the cortex.We propose a novel link that may help to understand the more rapid kidney disease progression ascribed to male sex.

Id1 Expression in Kidney Endothelial Cells Protects against Diabetes Induced Microvascular Injury Matthew D. Plotkin,[1] Shree G. Sharma.[2] *[1]Nephrology, UAMS and John L McClellan VA Hospital, Little Rock, AR; [2]Nephropath, Little Rock, AR.*

Background: The inhibitor of differentiation (Id) family of transcription regulators are induced in response to growth factors and oxidative stress and have an important role in promoting cell proliferation and inhibiting senescence. Id1 expression in endothelial cells (EC) is required for a normal response to injury. Id1 expression is limited to EC in the normal kidney. Because endothelial dysfunction is an important mechanism in the development of diabetic nephropathy, we determined if endothelial Id1 expression prevents microvascular injury and nephropathy in response to hyperglycemia.

Methods: Streptozotocin treated Id1 knockout and WT B6;129 littermates were examined at 3 and 6 months. EC were isolated from these mice by FACS and used for whole genome microarray analysis.

Results: Id1 expression was increased up to 15-fold in WT diabetic kidney EC. Id1 diabetic KO mice developed mesangial and peritubular and glomerular myofibroblast proliferation and matrix deposition. Electron microscopy demonstrated peritubular capillary endothelial cell injury and lumen narrowing. EC damage in KO mice was associated with increased albuminuria compared with WT mice. Fluorescence microangiography showed a 45% reduction in capillary perfusion area despite no significant reduction in CD31 stained areas. Gene expression microarray analysis of EC isolated from WT and KO control and diabetic mice demonstrated upregulation of type I bHLH transcription factors and activation of cell senescence pathways in KO cells. Kidneys from KO diabetic mice showed increased EC macroH2A.1.1 expression, a senescence associated heterochromatin marker. Examination of cultured EC showed that Id1 expression was induced by low level oxidative stress and KO resulted in decreased cell proliferation, increased p53 expression and expression of DNA damage and senescence markers compared with WT cells.

Conclusions: These results suggest that endothelial Id1 upregulation in response to hyperglycemia is an adaptive response that protects against microvascular injury and senescence and the development of nephropathy.

Heparanase-2 Antagonizes Heparanase-1-Induced Shedding of Endothelial Glycocalyx and Prevents Endothelial Dysfunction and Albuminuria in Zebrafish Hermann G. Haller, Yulia Kiyan, Sergey Tkachuk, Klaus Stahl, Anna Bertram, Sarah Berger, Mario Schiffer. *Clinic of Hypertension and Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Heparanase-1 is induced by hyperglycemia and mediates the deleterious effects of hyperglycemia on the endothelium. Heparanase-2, a homologue of heparanase-1, associates physically with heparanase-1 and inhibits heparanase enzymatic activity. Using (1) cultured endothelial cells in a microfluidity chamber and (2) a zebrafish model of glomerular albuminuria we have tested the hypothesis that heparanase-2 prevents heparanase-1-induced downregulation of endothelial glycocalyx and exerts ant-inflammatory effects.

Methods: Endothelial glycocalyx was assessed by confocal microscopy and dot-blot analysis in cultured microvascular endothelial cells (MEC). Gene expression was analysed by RT-PCR and microarray. Heparanase-2 was down-regulated by morpholino in transgenic zebrafish Tg(l-fabp:DBP:EGFP) and proteinuria assessed by the Fabp-eye-assay. Glomerular endothelial cells were assessed by EM. Gene and protein expression was analyzed by real-time qPCR and western blot analysis.

Results: High glucose induced expression of heparanase-1 and shedding of glycocalyx. Overexpression of heparanase-2 prevented the loss of glycocalyx, while silencing of heparanase-2 exacerbated glycocalyx loss. In addition, heparanase-2 overexpression reduced monocyte adhesion, reduced NFkB signalling and led to an anti-inflammatory cytokine pattern. In zebrafish silencing of heparanase-2 induced edema, endothelial cell swelling and massive proteinuria in the zebrafish. Rescue experiments with different heparanase-2 constructs demonstrated that the C-terminus is responsible for the protective effects on the glomerular endothelial cells.

Conclusions: Heparanase-2 stabilizes the endothelial glycocalyx and prevents heparanase-1 induced endothelial damage and dysfunction. It is the first endogenous heparinase-1 inhibitor and induction of heparanase-2 may be a therapeutic strategy in diabetic nephropathy and other glomerulopathies.

Soluble Nogo-B Improves Altered Angiogenesis: Implication for Diabetic Kidney Disease Luigi Gnudi,[1] Jiaqi Pan,[1] Xiaoyan Bai,[2] Anthea Elaine Hayward,[1] Kathryn E. White,[3] Fan Fan Hou,[2] David A. Long.[4] *[1]Cardiovascular Div, King's College London, London, United Kingdom; [2]Nanfang Hospital, Southern Medical Univ, Guangzhou, China; [3]Electron Microscopy Unit, Univ of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom; [4]Inst of Child Health, Univ College London, London, United Kingdom.*

Background: Abnormal angiogenesis is involved in the pathogenesis of diabetic nephropathy (DN). Neurite outgrowth inhibitor (Nogo)-B is expressed in endothelial cells (EC) and vascular smooth muscle cells. A soluble form of Nogo-B (sNogo-B) has been identified in the circulation and promotes angiogenesis by binding to the Nogo-B receptor NgBR on EC. We asked whether Nogo-B is expressed in glomeruli and whether its expression is modulated by diabetes, further we explored whether sNogo-B could ameliorate abnormal angiogenesis in an experimental model of DN with human cells incubated with patients' serum.

Methods: Nogo-B expression in glomeruli of control and diabetic mice was assessed with immunogold and western immunoblotting. Kidney biopsies of patients with DN and thin basement membrane nephropathy (as control) were utilised for Nogo-B expression analysis with immunoistochemistry. Angiogenesis assay was conducted with human umbilical vein endothelial cells (HUVEC) on matrigel; HUVEC were incubated with serum (4%vol/vol) of patients with type 1 diabetes with (T1DM/DN+) or without a history of albuminuria (T1DM/DN-); T1DM/DN+ and T1DM/DN- patients had similar clinical characteristics. sNogo-B was overexpressed with viral vector.

Results: Full length Nogo-B was expressed in glomerular EC and podocytes; Nogo-B was downregulated in glomeruli of diabetic mice and of patients with DN ($p<0.04$). Overexpression of sNogo-B rescued the altered angiogenesis (reduced tube length/number) observed in HUVEC incubated with T1DM/DN+ serum ($p<0.02$), while no effect was observed in the angiogenesis of HUVEC incubated with serum from T1DMDN-patients. Overexpression of sNogo-B in HUVEC was paralleled by a decrease in AKT^{Ser473} phosphorylation ($p=0.02$), no change was observed in AKT^{Thr308} phosphorylation.

Conclusions: Nogo-B is downregulated in diabetic glomerulopathy. sNogo-B could represent a potential treatment of abnormal angiogenesis in DN.

FR-PO308

Expression of Complement Components in Primary Human Glomerular Endothelial Cells after a Diabetic-Like Insult Julie Williams,[1] Troels Krarup Hansen,[2] Kamilla Pajecka.[1] *[1]Diabetes Complications Research, Novo Nordisk A/S, Måløv, Denmark; [2]Dept of Endocrinology and Diabetes, Aarhus Univ, Aarhus, Denmark.*

Background: Low-grade inflammation (e.g. elevated serum TNFα and IL1β), hypoxia and dysregulated innate immunity are well-recognized contributors to diabetes mellitus (DM) and therefore diabetic nephropathy (DN). The glomerular endothelium becomes pro-inflammatory in DN patients, yet it is unclear if and to what extent the endothelium contributes to the production of complement components and regulators. In this study we analyzed complement gene expression in primary human glomerular endothelial cells (hGEnCs) with and without a DM-like insult.

Methods: Primary hGEnCs were grown in RPMI medium supplemented with either 6.5 mM (normal) or 25 mM (high) glucose. The cells were cultured for 8 days with a media change every 48 h to allow exposure to a diabetic-like environment. During the final 48 h in culture, the cells were exposed to a second insult, i.e. TNFα, IL1β or hypoxia, to mimic DN pathopysiology. The gene expression level was quantified by qPCR.

Results: Untreated hGEnCs expressed moderate amounts of C2, C3, C4, C5, C7, C8g, CFB, CFD, CFP and VTN and very low levels of C9. They also expressed high levels of CFH, CFI, CD46, CD55, CD59 and CLU. Neither unstimulated nor stimulated hGEnCs expressed C6, C8a, C8b, C4BPB, or CD35. The expression of only a very few components was regulated. C2 was increased 4x with TNFα, while C3 was greatly up-regulated by IL1β and TNFα (both approx. 500x). Neither hypoxia nor pre-treatment with high glucose had any effects. CFB was also highly regulated. Its expression increased 40x after TNFα and 20x after IL1β treatment, but remained unchanged after 48 hours of hypoxia. CFP, CLU and VTN were decreased (3-8x) after TNFα or IL1β treatment and hypoxia had a moderate effect on their expression.

Conclusions: Human GEnCs expressed the majority of the main and auxiliary complement components, but at different levels. Their expression was modulated by pro-inflammatory cytokines involved in DN pathology (TNFα and IL1β) as well as hypoxia. The cytokines caused a considerable up-regulation of C3 and CFB molecules, which are known to be up-regulated in glomeruli from DN patients.

Increased Serum Platelet Microparticle Contributes to Glomerular Endothelial Injury in Diabetic Nephropathy Yang Zhang, Kun Ling Ma, Zebo Hu, Gui Hua Wang, Liang Liu. *Inst of Nephrology, Southeast Univ, Nan Jing City, JIang Su Province, China.*

Background: The release of Platelet microparticles(PMPs) is considered to be proinflammatory and eliciting cytokine reponses. This study was undertaken to investigate the role of PMPs in glomerular endothelial injury in diabetic nephropathy (DN).

Methods: Eight-week old male *Sprague-Dawley* rats were divided into three groups: nondiabetic rats (control), streptozotocin-induced diabetic rats (DM), and diabetic rats treated with Aspirin (DM+ Aspirin). The determination of PMPs was used by flow cytometry and confocal microscopy. The inflammatory cytokines released from PMPs was checked by protein microarray contain a variety of inflammatory cytokines, immunohistochemical staining, or Western blot. The glomerular endothelial injury was evaluated through measuring the change of endothelial surface layer (ESL), endothelial fenestration, cellular junction, and glomerular permeability by electron microscope, immunofluorescence staining and Western blot. The ratio of urinary microalbumin to creatinine (ACR) was detected by enzyme-linked immunosorbent assay.

Results: Compared to the control, the serum level of PMPs was significantly increased in DM rats, while it was reduced by Aspirin. Aspirin treatment decreased the production of inflammatory cytokines in PMPs suspension, blood serum and glomerulus. Using confocal microscopy, the enhanced interaction between PMPs and glomerular endothelium was observed in DM rat, which was inhibited by Aspirin. Interestingly, the elevated PMPs and production of inflammatory cytokines from PMPs were correlated with the glomerular endothelial injury by decreasing the ESL thickness and endothelial fenestration, destroying cellular junction, increasing glomerulus permeability and the level of ACR in DM rats. Decrease of serum PMPs and production of inflammatory cytokines by Aspirin ameliorated the glomerular endothelial injury compared to the DM group.

Conclusions: Elevated serum PMPs contributes to glomerular endothelial injury in diabetic nephropathy through the release of inflammatory cytokines from PMPs.

FR-PO310

The Progression of Diabetic Nephropathy in CSE-/-, eNOS-/-, db/db, CSE-/- db/db, and eNOS-/- db/db Murine Models: A Comparative Study Eric Linville, Deborah J. McCarthy, Christopher G. Kevil, Kevin J. McCarthy. *Dept of Pathology and Translational Pathobiology, LSU Health Sciences Center, Shreveport, LA.*

Background: Targeted deletion of eNOS ($eNOS^{-/-}$ *db/db* mouse) is associated enhanced development of glomerulosclerosis. However, the role of another gasotransmitter, hydrogen sulfide, (H2S) in the onset and progression of diabetic nephropathy is still not entirely clear. The purpose of this study was to compare the development of diabetic nephropathy between $CSE^{-/-}$, $eNOS^{-/-}$,$CSE^{-/-}$*db/db,*and $eNOS^{-/-}$*db/db* models.

Methods: Age matched (16 wks) $CSE^{-/-}$, $eNOS^{-/-}$ and $eNOS^{-/-}$*db/db*, $CSE^{-/-}$*db/db* mice were used. Prior to sacrifice, blood was drawn for H2S measurement. After sacrifice, the kidneys were removed, and processed for light and electron microscopy, a segment of the kidney used for sulfide measurement. Morphology readouts included measurement of glomerular areas (AT), mesangial areas (AM), and calculation of the AM/ AT ratio. Pedicel effacement was determined by TEM. H2S levels and the presence of H2S metabolites in plasma and tissues was measured by HPLC.

Results: There were no differences in AT between $CSE^{-/-}$, $eNOS^{-/-}$ glomeruli; however an increase ($p<0.0001$) in AT was seen in $CSE^{-/-}$*db/db* and $eNOS^{-/-}$*db/db* glomeruli when compared to the former groups. There was no difference in AT between the *db/db*, and $eNOS^{-/-}$*db/db* glomeruli, but AT was less ($p<0.0001$) in the $CSE^{-/-}$*db/db* glomeruli. Mesangial areas (AM) followed a similar trend, except that AM increased ($p<0.0001$) in the $eNOS^{-/-}$*db/*

db glomeruli over all groups. The AM/ AT ratio, an indicator of mesangial expansion, was not different among the diabetic animal models. There were no differences in the ultrastructural morphology among the diabetic models. H2S metabolites were significantly reduced in plasma and kidneys of *db/db* mice. Measurement of discrete biochemical sulfide forms revealed that bound sulfane sulfur was blunted in $CSE^{-/-}$ and *db/db* mice, with $CSE^{-/-}$*db/db* mice showing the greatest reduction in bound sulfane sulfur in the kidney.

Conclusions: These reductions suggest a potential difference in sulfide dependent signaling responses, the mesangial cells appear to be most affected by changes in H2S.

Altered Hemodynamic Responses to Infused Insulin in TALLYHO/Jng Obese Mice Carolyn M. Ecelbarger,[1] Swasti Tiwari,[2] Hwal Lee,[1] Lijun Li.[1] *[1]Dept of Medicine, Georgetown Univ, Washington, DC; [2]Sanjay Gandhi Post-Graduate Inst of Medical Sciences, Lucknow, India.*

Background: Insulin resistance blunts glucose uptake in the major metabolic tissues; however, the impact of "insulin-resistance" within the cardiovascular-renal system remains unclear. Previously we showed reduced protein expression for the insulin receptor (IR) in different regions of the kidney in obese, relative to lean rats; however, the main metabolic factors driving IR expression in kidney were unclear, as well as, whether these changes were associated with altered hemodynamics.

Methods: We infused young, adult lean (C57Bl6) and obese (TALLYHO/Jng) male mice (n = 6/group) with insulin (40 U/kg bw/d) for 2 weeks while monitoring blood pressure (BP) and heart rate (HR) by radiotelemetry. In additional mice (F2 cross, 75% TALLYHO/25% C57Bl6) we correlated metabolic factors with IR protein in different regions of the kidney to determine which factors were best correlated with IR.

Results: Obese mice had significantly higher basal BP (10-12 mm Hg) with a slight fall in BP (mean 4 mm Hg) in the first 3 days of insulin infusion, which returned to basal levels by day 14. In contrast, lean mice demonstrated a mean 7 mm Hg fall in the first 3 days, followed by a fairly substantial rise (15 mm Hg). Basal HR was significantly higher in the obese mice (mean 650 versus 540 beats per minute); however, HR rose in the lean mice sharply in the first 2 days then stabilized at a higher level. This rise was not seen in obese mice. At two weeks, no significant differences existed between lean and obese mice for HR or BP. Body weight was significantly negatively correlated with IR protein in kidney cortex and outer medulla. Glucose peak during a glucose tolerance test was also negatively correlated with IR protein in the outer medulla.

Conclusions: Hemodynamic responses to insulin infusion are attenuated in obese mice indicating "insulin resistance" of these cardiovascular responses. Chronic insulin infusion abrogated differences between lean and obese mice suggesting insulin, per se was the direct cause of these differences. Reduced renal IR expression may partially explain attenuated responses to insulin infusion in obese mice.

Deficient Endothelial Heparan Sulfate Prevents Renal Inflammation and Fibrosis in Murine Diabetic Nephropathy Ditmer Talsma,[1] Kirankumar Katta,[2] Marieke A.B. Ettema,[1] Berna Kel,[1] Marion Kusche-Gullberg,[2] Coen A. Stegeman,[1] Jacob van den Born,[1] Lianchun Wang.[3] *[1]Dept of Neph., UMCG, Netherlands; [2]Dept of Biomed., Univ of Bergen, Norway; [3]Dept of Glycoconjugates in Animal Dev., Disease & Cancer, Univ of Georgia.*

Background: Recent findings suggest a role for inflammation in the development of diabetic nephropathy (DN). Endothelial heparan sulfate (HS) is known for its cytokine/chemokine binding capacities and subsequent presentation to high affinity receptors on leukocytes. For the sulfation and function of HS the enzyme N-deacetylase N-sulfotransferase-1 (NDST-1) is essential. In this study we aim to assess the role of endothelial HS in renal inflammation and fibrosis in a mouse DN model.

Methods: To induce diabetes, age matched C57Bl/6J^{-} WT and Tie2 Cre^{+} NDST-$1^{f/f}$ mice were intraperitoneally injected with streptozotocin (50 mg/kg). Control mice received citrate buffer (n=8-10/group). At baseline, two and eight weeks follow up urine and plasma was collected and plasma glucose, urinary creatinine and albuminuria were measured. Two months after diabetes induction the animals were sacrificed and kidneys were immunohistochemically stained for macrophages, collagen III and αSMA. Expression of VCAM-1, collagen I, III, IV, TGF-β1 and fibronectin was measured using qRT-PCR.

Results: Diabetes induction was evidenced by significant increased values of blood glucose and albuminuria, without differences between WT and KO animals. Compared to WT, NDST-1 KO animals showed decreased interstitial macrophages ($p<0.05$). The reduction in inflammation was confirmed by a reduced mRNA expression of VCAM-1 ($p<0.001$). KO animals also showed a reduced interstitial collagen III deposition ($p<0.001$) and myofibroblast shown by a reduction interstitial αSMA staining ($p<0.01$). The reduction in fibrosis was confirmed a reduced mRNA expression of collagen I ($p<0.001$), III ($p<0.05$), IV ($p<0.01$), TGF-β1 ($p<0.01$) and fibronectin ($p<0.001$). Furthermore, glomerulosclerosis was reduced in the NDST-1 KO animals ($p<0.001$).

Conclusions: Our results show the role of endothelial HS in the development of renal inflammation and subsequent fibrosis in DN in mice. These results suggest that HS can be a possible target for therapy in DN.

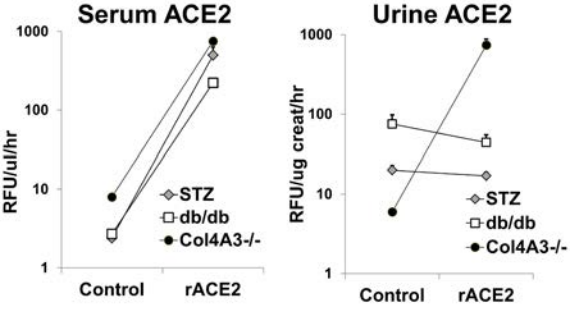
FR-PO313

Delivery of Murine Recombinant ACE2 in Different Mouse Models of Albuminuria Jan A. Wysocki, Minghao Ye, Daniel Batlle. *Northwestern Univ, Chicago, IL.*

Background: Targeting RAS is the mainstay of therapy for CKD. New approaches, based on fostering the degradation of Ang II, rather than blocking the formation or action of AngII could be complementary or even better. ACE2, the main enzyme that degrades Ang II, is a large 100kD protein that normally is not filterable by glomeruli. This study examined whether murine recombinant (r)ACE2 can increase urinary and kidney ACE2 in three models of kidney disease with different degrees of albuminuria.

Methods: *db/db* mice, mice with STZ-induced diabetes and Alport model of CKD due to *col4A3* gene deficiency that results in advanced alterations in the glomerular basement membrane and robust proteinuria were used. Serum ACE2 was overexpressed chronically using ACE2 minicircle (MC) in STZ mice or acutely via i.p. injection of rACE2 to *db/db* and *Col4A3-/-* mice. ACR was 534±70, 87±23 and 3902±495 ug/mg in *db/db*, STZ and Alport mice, respectively.

Results: In McACE2-treated STZ mice, serum ACE2 activity was markedly augmented, but urine ACE2 activity did not increase (Figure). In *db/db*, infusion of rACE2 increased serum ACE2 activity markedly without any increase in urine ACE2 activity (Figure). By contrast, in mrACE2-treated *Col4A3-/-* mice, the increase in serum ACE2 activity was associated with a marked increase in kidney (5.5 vs. 13.5±3.6 RFU/ug prot/hr) and urinary ACE2 activity (Figure).



Conclusions: A large enzyme such as ACE2 cannot be filtered in mouse models of diabetes-induced moderate glomerular injury such as in STZ and db/db with modest albuminuria. When glomerular permeability is sufficiently altered, as in the *Col4A3 -/-* model of CKD with robust proteinuria, an increase in serum ACE2 results in an increase in both kidney and urinary ACE2 activity. The potential renoprotective action of this enzyme will likely depend on local kidney delivery rather than systemic levels in the circulation.

FR-PO314

Effect of ACE2 Deletion on Circulating and Renal ACE in Non-Obese Diabetic (NOD) Mice Vanesa Palau, Heleia Roca Ho, Marta Riera, Marta Rebull, Javier Gimeno, Julio Pascual, Maria Jose Soler. *Nephrology, Hospital del Mar Medical Research Inst (IMIM), Barcelona, Spain.*

Background: ACE2 is altered in diabetic nephropathy(DN). Downregulation of ACE2 either by gene deletion or by pharmacological inhibition worsens DN in STZ and Akita model of type 1 diabetes. We demonstrated that loss of ACE2 contributes to an increase in DN progression in the non-obese diabetic(NOD) mice. We hypothesized that ACE is altered in ACE2KO mice under NOD and NOR background.

Methods: NOD and non-obese resistant(NOR) mice with a deletion on ACE2 gene compared to NOD and NOR WT mice after 30 days of diabetes were studied. Systolic blood pressure(SBP), glucose and urinary albumin excretion(UAE) were measured. ACE enzymatic activity in serum and renal cortex were assessed by a fluorometric method. Renal cortex protein expression was studied by western-blot.

Results: NOD diabetic mice present significant increase in blood glucose, SBP and UAE as compared to NOR mice. However, no differences were observed between WT and KO mice. NODACE2 KO mice showed higher serum ACE activity compared with NORACE2 KO. NODACE2 KO mice showed a decreased circulating ACE activity as compared to NODACE2 WT. Renal ACE activity was increased in NORACE2 KO as compared to NORACE2 WT.

Conclusions: Diabetes increases blood glucose, SBP, UAE and serum ACE activity. Interestingly, ACE2 deletion decreases serum ACE activity in NOD mice and increases renal cortex ACE activity in NOR mice. These results suggested that ACE2 deletion exerts a different effect on circulating and renal ACE activity in diabetic and non-diabetic mice.

FR-PO315

Effects of Angiotensin 1-7 on Klotho, mTOR and Podocyte Proteins Expression in Zucker Diabetic Fatty Rats

Jorge E. Toblli,[1] Maria Maselli,[1] Gabriel Cao,[1] Margarita Angerosa,[1] Fernando Pablo Dominici.[2] *[1]Lab. of Exp. Medicine, Hospital Aleman. UBA, Buenos Aires, Argentina; [2]Biochemistry, UBA, Buenos Aires, Argentina.*

Background: Current information indicates a link between Klotho deficiency and increased mTOR signaling which is associated with oxidative stress and inflammation/renal fibrosis in diabetic nephropathy. The RAAS blockade modulates Klotho, however, the role of angiotensin 1-7(ANG1-7) on Klotho and mTOR is still unclear. This study evaluates the effect of (ANG1-7)on Klotho, mTOR and podocyte proteins expression in kidney of Zucker Diabetic Fatty (ZDF) Rats.

Methods: ZDF and controls lean Zucker rats (LZR) were used: 1) ZDF+saline,2) ZDF+ANG1-7, 3) LZR+saline. For 4 wks, animals received either saline or ANG1–7 (100 ng·kg1·min1) by subcutaneous osmotic pumps. Kidneys were removed at the end of the experiment.Renal variables were evaluated at baseline/end of the experiment. Quantification and localization of Klotho, mTOR,WT1,Synaptopodin,Thioredoxin (Trx), Heat shock protein (HSP27)was evaluated by IHCh. Electron Microscopy was performed in order to evaluate potential GBM changes.

Results: Table1. IHCh data after four-week infusion

Mean±SD	ZDF+saline	ZDF+ANG1-7	LZR+saline
Trx¶	23.4±2.8	10.1±1.6†	2.2±0.5§

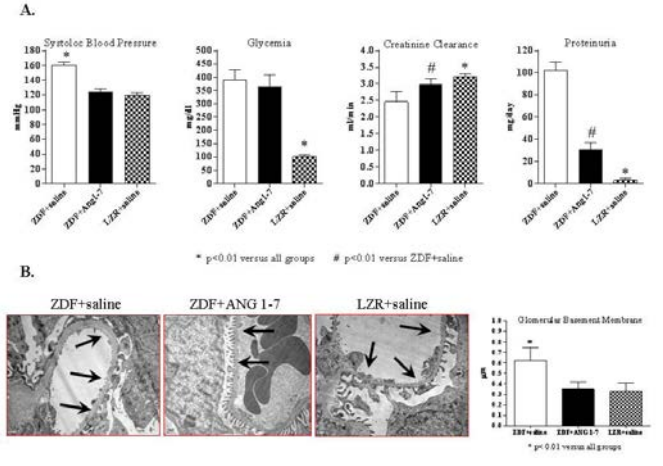

Figure 1. A.Relevant variables at the end of the experiment **B**.EM images of GBM (arrows).

Conclusions: Ang 1-7 infusion increased Klotho expression and modified favorably mTOR in kidney of ZDF rat. Furthermore, podocyte protein expression was also improved. These changes were associated with reduction in Trx, HSP27 and GBM thickness.

FR-PO316

Angiotensin Converting Enzime 2 Silencing Alters Podocyte Rearrangement

Marta Riera, Marta Rebull, Vanesa Palau, Julio Pascual, Maria Jose Soler. *Nephrology, Hospital del Mar Medical Research Inst (IMIM), Barcelona, Spain.*

Background: Renin angiotensin system(RAS) blockade has been shown to be effective in delaying diabetic nephropathy(DN) progression. Podocytes are key cells in glomerular filtration barrier with their own RAS. In the puromycin model of podocyte damage, an imbalance toward a more dynamic actin cytoskeleton and increased migration could underlie podocyte dysfunction. Our objective is to study the effect of ACE2 or InsRecp gene silencings in the growing and migration capability of podocytes. Furthermore the expression of genes related to fibrosis was also tested.

Methods: A conditionally immortalized mouse podocyte cell line proliferating was used. Differentiation was induced by non-permissive conditions removing γ-interferon at 37ºC for 10 days. Cells were then transfected with Silencer®Select siRNAs against ACE2 or InsR. After 24 hours, live time series were continuously recorded using Zeiss Cell Observer HS microscope with an incubation chamber (37°C, 5%CO2) for 17h. Comparisons were done between 0h and 17h of recording. Cells were stained for F-actin. Image processing was done by ImageJ.

Results: ACE2 gene silenced-podocytes showed a differentially cytoskeletal rearrangement as compared to the non-silenced cells. No differences were observed when InsR were silenced. This effect was correlated with a different pattern of growing after 17h. Podocytes not expressing ACE2 were significantly smaller than the control cells. On the contrary, the total perimeter of cells was similar indicating that ACE2-silenced podocytes presented more gaps between cells with fewer contact points(table). No differences were detected on TGF-β, Col4 or Fn1 gene expressions.

Conclusions: ACE2 may help to keep the shape and integrity of podocytes cytoskeleton. On DN RAS imbalance is changed and ACE2 loss may contribute to podocyte rearrangement, aggravating the disease.

Vascular Actions of AT1 Angiotensin Receptors Do Not Contribute to Albuminuria or Hyperfiltration in Diabetic Kidney Disease

Matthew A. Sparks, Stacy Alana Johnson, Susan B. Gurley, Thomas M. Coffman. *Nephrology, Duke, Durham, NC.*

Background: Blockade of the renin angiotensin system (RAS) reduces albuminuria, attenuates hyperfiltration, and slows the progression of diabetic nephropathy (DN) by preventing vasoconstriction and subsequent increases in glomerular hydrostatic pressure. Since RAS blockade disrupts Ang II signaling in all tissues, the specific contribution of vascular AT1R in DN has been difficult to delineate.

Methods: We generated 129SvEv mice with cell-specific loss of AT1A from VSMCs (SMKOs) using *Cre-loxp*. To remove AT1R from VSMCs, we crossed the SMKOs with AT1BR -/- mice, lacking the minor AT1B isoform. To study the impact of vascular AT1R in DN, we crossed AT1B-*null*SMKOs with mice having the *Ins2*^{C96Y} AKITA mutation, which develop DM1 early. To enhance kidney injury, mice underwent uninephrectomy (UNX) at 11wks.

Results: Glucose levels were elevated (~500mg/dL) and similar at 10, 16 and 24wks between the groups. Prior to UNX, albuminuria was similar between Control AKITA and (62±10 versus 107±27 µg/24hrs, P=NS). Albuminuria increased with age but with no significant differences between the groups at 16wks (307±106 Control AKITA vs 313±117 AT1B-*null*SMKO AKITA µg/24hrs; P=NS) or 24wks (494±236 versus 730±217 µg/24hrs; P=NS), despite a trend toward higher albuminuria in AT1B-*null*SMKO AKITAs. There was no significant difference in GFR (via FITC-inulin) between non-diabetic Control and AT1B-*null*SMKO (15.6±1.2 vs 14.8±0.8 µl/min/g BW), and hyperfiltration was observed in both Control AKITA (23.7±2.4 µl/min/g BW; P=0.003) and AT1B-*null*SMKO AKITA (20.7±1.7 µl/min/g BW; P=0.01) relative to their non-DM comparators. There was no difference in GFR between ControlAKITA and AT1B-*null*SMKO AKITA (P=NS). We measured mRNA levels by qPCR of putative kidney injury markers and found no differences in *Col1A1*, *NGAL*, or *TGFB1* between Control AKITA and AT1B*null*SMKO AKITA.

Conclusions: Our studies indicate that the absence of vascular AT1R responses is not sufficient to reduce albuminuria and prevent hyperfiltration in a mouse model of DN. This suggests that blockade of AT1R in other cell lineages may contribute to beneficial actions of ARBs in DN.

Altered Expression of Urate Transporters URAT1 and ABCG2 in Diabetic Rats and Their Response to Hypoglycemic Agents

Daigo Toyoki, Shigeru Shibata, Emiko Kuribayashi-Okuma, Shin-Ichiro Asakawa, Kenichi Ishizawa, Shunya Uchida. *Dept of Intern Med, Teikyo Univ School of Medicine, Tokyo, Japan.*

Background: Co-incidence of hyperuricemia is a common finding in diabetic patients, and previous studies suggest that insulin resistance is associated with the decreased renal clearance of uric acid (UA). Recent data also demonstrated that a Na^+-glucose co-transporter 2 (SGLT2) inhibitor can reduce serum UA in type 2 diabetes (Zinman et al. NEJM 2015). However, the detailed regulation of urate transporters in diabetes has remained unclear. Using rat models, we evaluated the changes in renal UA handling and urate transporters in diabetes, as well as their response to hypoglycemic agents.

Methods: SD rats received i.p. injection of streptozotocin (STZ; 70 mg/kg). Some rats received ipragliflozin (Ipra) (an SGLT2 inhibitor; 15 mg/kg chow) or insulin (s.c. *via* osmotic pump). After urine collection, kidneys were removed at day 7.

Results: Daily UA excretion was markedly increased in STZ rats as compared with controls (5.59 ± 0.32 mg/day in STZ vs. 0.46 ± 0.17 mg/day in control). Fractional excretion of UA (FEUA) was also increased, suggesting an altered tubular handling of UA. In the membrane fraction of the kidney, Slc22a12 (URAT1; urate transporter 1) was significantly decreased, whereas ABCG2 (ATP-binding cassette sub-family G member 2) was increased, consistent with the increased renal UA clearance. Moreover, treatment with insulin but not Ipra decreased UA excretion in this model together with the reversal of the changes in URAT1 and ABCG2 levels. To clarify the contribution of insulin and glycosuria to the altered UA handling, we administered insulin or Ipra to non-diabetic rats. Results showed that insulin significantly increased URAT1 and decreased ABCG2, resulting in the reduced renal UA clearance. In contrast, there were no significant changes in urinary UA in Ipra-treated rats.

Conclusions: These data show that insulin decreases renal UA clearance *via* modulation of URAT1 and ABCG2, providing a mechanism for the inverse association between hyperinsulinemia and hypouricosuria. The data also indicate that renal urate handling in diabetic patients is influenced by the types of hypoglycemic agents.

FR-PO319

Basolateral High Glucose Induces Sodium Glucose Transporter Expression via GLUT2/Importin 1 alpha/HNF 1 alpha: Pathway in Renal Tubular Cell
Hiroyuki Umino, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Internal Medicine, Keio Univ, Tokyo, Japan.*

Background: We recently reported the nephroprotective effects of sodium/glucose cotransporter 2 (SGLT2) inhibitors through the maintenance of renal sirtuin 1 expression, although, the mechanism underlying increased SGLT2 expression in diabetic nephropathy remains unknown.

Methods: We constructed a 2-chamber culture system, with the upper layer representing the renal tubular cells of the lumen and the lower layer representing the vascular lumen. Normal glucose (NG) and high glucose (HG) culture media were used for the upper or lower layer. By using cultured primary proximal renal tubular cells, we investigated the presence of polarity, i.e., whether SGLT2 expression was dependent on glycemic stimulus from an upper or lower layer.

Results: SGLT2 expression increased in HG medium in the lower chamber, indicating that hyperglycemic stimulus from vascular lumen is responsible. Using small interfering RNA to inhibit the expression of membrane proteins localized to the basolateral side of the cells, we found that decreased glucose transporter 2 (GLUT2) expression led to decreased SGLT2 expression. GLUT2 was bound to importin α1, an intranuclear transport protein, in cells maintained in NG. Reportedly, when GLUT2 sensed retrograde glucose flow which is in the opposite direction of normal glucose flow in HG, GLUT2 dissociated from importin α1, which translocated from the cytoplasm to the nucleus. We used MEGA® alignment software to predict protein binding and identified a DNA motif for HNF1α transcription factor binding to importin α1. HNF1α was present in the cytoplasm of 50% of the renal tubular cells in NG. With HG stimuli to renal tubular cells, we observed that HNF1α translocated to the nucleus via importin α1, which contributed to the increased expression of SGLT2.

Conclusions: These findings suggested that detection of hyperglycemia on the basolateral side by GLUT2 during early stage diabetes mellitus leads to retrograde signal transduction which is in a direction opposite to that of the normal glucose flow via the GLUT2-importin α1-HNF1α pathway, with subsequent upregulation of SGLT2 expression. We propose this pathway interception as a new therapeutic target.

FR-PO320

The Role of TLR4/NF-κB Signaling Pathway on Mitochondria-Related Apoptosis in Tubular Cells in Diabetic Kidney Disease
Xuejing Zhu, Shuguang Yuan, Xuemei Liu, Lin Sun, Fu-You Liu. *Dept of Nephrology, The Second Xiangya Hospital of Central South Univ, ChangSha, Hunan, China.*

Background: The role and precise mechanism of TLR4 in mitochondria-related oxidative damage and apoptosis of renal tubular in diabetic kidney disease (DKD) remains unclear.

Methods: We examined the expression of TLR4 in renal biopsy tissues and analyzed its correlation with tubulointerstitial damage of DKD patients. In HK-2 cells, we detected the expression of TLR4, NF-κB and cleaved Caspase-3 by quantitative real-time PCR and western blotting, and analyzed mitochondrial function and apoptosis by flow cytometry and immunofluorescence. PGC-1a plasmids were used for the overexpression of PGC-1a in HK-2 cells.

Results: Results showed that TLR4 was extensively expressed in the renal tubular of DKD patients, coexistent with mitochondria swelling and deformation. The level of TLR4 was positively related to the tubulointerstitial damage reflecting by tubular interstitial damage score and urinary b-NAG levels. In vitro, the expression of TLR4 increased in HK-2 cells treated with high glucose (HG), leading to activation of NF-κB, decreased expression of PGC-1α, mitochondrial deformation, cytochrome C redistribution, increased expression of cleaved caspase-3 and even apoptosis, while TLR4/NF-κB blockers and PGC-1α over-expression reversed these trends.

Conclusions: Data indicated that TLR4/NF-κB signaling pathway might be the upstream of PGC-1α and promote the tubular damage of DKD by modulating the mitochondria-related oxidative damage and apoptosis.

RhoA Activation Contributes to Hyperplastic Phenotype of Proximal Tubular Cells in the Initiation of Obesity-Related Kidney Damages
Makiko Naitoh, Hirobumi Tokuyama, Shu Wakino, Hiroshi Itoh. *Internal Medicine, Keio Univ, Shinjuku, Tokyo, Japan.*

Background: Hyperplastic phenotype is supposed to trigger the initiation of obesity-induced renal damages. A small GTP-binding protein, RhoA, and its effector, Rho-kinase, have several pathological functions including cell motility, proliferation and inflammatory response. We have previously demonstrated that excess fat intake causes obesity-induced renal injuries, which are mediated by an activated Rho/Rho-kinase pathway in proximal tubules and inflammatory process. In the present study we examined whether Rho/Rho-kinase contributes to the hyperplastic phenotypes in obesity-induced renal injury.

Methods: We created mice that overexpressed dominant negative RhoA genes specifically in proximal tubules (PT) under the control of promoter of sodium-phosphate co-transporter (PT-DN-RhoA) in C57BL/6J backgrounds. PT-DN-RhoA mice and their wild-type littermates (WT) were fed a high fat (HFD) or low fat diet (LFD) for 12 weeks.

Results: WT on HFD (WT-HFD) not only developed obesity but also manifested renal histological changes, including the enlargement in proximal tubules, tubular hyperplasia, and a marked increase in the number of PCNA and Ki-67 positive tubular epithelial cells compared with WT on LFD as early as 2 weeks after the HFD feeding, which paralleled the increase in urinary excretion of NGAL (neutrophil gelatinase-associated lipocalin). These hyperplastic phenotypes were ameliorated in HFD-fed PT-DN-RhoA mice.Among cell cycle regulators, cyclin-dependent kinase inhibitors p27 was remarkably reduced in WT-HFD, which were restored in DN-RhoA TG mice with HFD.

Conclusions: Excess fat intake causes the hyperplastic phenotype of obesity-induced renal injury, which is mediated by an RhoA activation and subsequent downregulation of p27 pathway in proximal tubules. The intervention of Rho/p27 pathway may constitute a novel strategy blocking the initiation process of obesity-induced renal damages. Urinary NGAL can be useful markers for the detection of this hyperplastic phenotype.

Subclinical Lithium Dose Attenuates Glomerulosclerosis but Causes Tubular Injury in Diabetic BTBR ob/ob Mice
Theun de Groot,[1,2] Leanne Kosse,[1,2] Lars Damen,[2] Susan Marie Sheehan,[1] Peter M.T. Deen,[2] Ron Korstanje.[1] *[1]The Jackson Laboratory, Bar Harbor; [2]Radboud Univ Med. Center, Nijmegen, Netherlands.*

Background: Type 2 diabetes mellitus (T2DM) is the most important risk factor to develop chronic kidney disease (CKD). Glycogen synthase kinase 3 (GSK3) plays an important role in the development of both DM and renal injury, as moderate GSK3 inhibition increases glucose uptake in insulin-insensitive muscle and adipose tissue, while in acute kidney injury it reduces albuminuria and glomerulosclerosis. The only clinically available GSK3 inhibitor is lithium, however in bipolar patients chronic lithium administration (0.6-1 mM in blood) increases the chance to develop tubulointerstitial nephropathy. Therefore, our aim was to investigate the effect of subclinical lithium doses on the development of DM and kidney injury in a mouse model of diabetic nephropathy.

Methods: Twelve-week old female BTBR ob/ob mice were treated for 12 weeks with 0, 10 and 40 mmol LiCl/kg after which DM parameters, urine albumin-creatinine ratio (ACR), FITC-inulin clearance, and renal histology were analyzed and compared to wild type (wt) BTRB mice on regular chow.

Results: In comparison to wt BTBR mice, ob/ob mice demonstrated elevated bodyweight, increased blood glucose/insulin levels, albuminuria, glomerulosclerosis and hyperfiltration. The lithium-10 and -40 diets did not affect body weight and resulted in blood lithium levels of respectively <0.25 mM and 0.48 mM. Lithium-40 significantly reduced non-fasting blood glucose levels, but did not affect non-fasting insulin levels or fasting blood glucose levels. Importantly, lithium-40 reduced the development of glomerulosclerosis. In contrast, lithium-40 augmented the ACR, which coincided with an increased number of atrophic tubuli. The glomerular filtration rate was not significantly altered by lithium.

Conclusions: Altogether, administration of subclinical lithium dose to BTBR ob/ob mice reduced glomerulosclerosis, but simultaneously increased tubular damage and albuminuria. These results are in agreement with recent findings that albuminuria does not always represent glomerular damage, but can also be a sign of tubular injury. Better tools to diagnose early glomerular injury are required.

FR-PO323

Metformin Ameliorates Peripheral Insulin Resistance by Inhibiting the Activity of SHIP2
Sanna H. Lehtonen,[1] Zydrune Polianskyte-Prause,[1] Tuomas Aleksi Tolvanen,[1] Sonja Lindfors,[1] Hong Wang,[1] Surjya Narayan Dash,[1] Mika Erik Anthon Berg,[1] Vincent Dumont,[1] Per-Henrik Groop,[2] Kristiina Wähälä,[1] Jukka Pekka Tienari.[2] *[1]Univ of Helsinki, Finland; [2]Univ of Helsinki and Helsinki Univ Hospital, Finland.*

Background: The expression of lipid phosphatase SHIP2 is elevated in kidney, adipose and muscle tissue in diabetes. Thus, SHIP2 is a potential therapeutic target to treat insulin resistance. To date only a few chemical compounds possessing an inhibitory effect on SHIP2 are known. All of them have poor bioavailability and none have reached clinical use.

Methods: To identify novel small molecules that inhibit SHIP2 we performed virtual screening of chemical libraries followed by validation using cultured cells, diabetic db/db mice and kidney tissue from patients with T2DM.

Results: Virtual screening of chemical libraries containing 88680 molecules revealed metformin as a potential SHIP2 inhibitor. Although metformin has been used to treat T2DM for long, the exact molecular mechanism by which it enhances peripheral insulin sensitivity has remained elusive. We found that metformin inhibits the catalytic activity of the *in vitro* produced and purified SHIP2 phosphatase domain. Metformin also inhibited the activity of SHIP2 in cultured rat skeletal muscle cells and human podocytes, and protected podocytes against SHIP2 overexpression-induced apoptosis. Metformin also enhanced glucose uptake, which was reduced by SHIP2 overexpression in these cells. *In vivo*, metformin reduced the activity of SHIP2 in skeletal muscle and kidney tissue of metformin-treated diabetic db/db mice. Furthermore, we observed that T2DM patients on insulin medication showed increased SHIP2 activity in the kidney compared to patients without T2DM. In patients receiving metformin the activity of SHIP2 in the kidney was similar to that observed in patients without T2DM.

Conclusions: Metformin inhibits the activity of SHIP2, providing a mechanism by which metformin ameliorates peripheral insulin resistance. This highlights the potential of

SHIP2 as a drug target and provides an avenue to identify and design novel molecules, such as the ones identified in our virtual screening, which can be used to develop new insulin sensitizers for future clinical trials.

Changes of DPP-4 and DPP-4 Substrates According to Aging in Kidney

Eun Nim Kim, Ji-Yeun Chang, In-Ae Jang, Ji Hee Lim, Min Young Kim, Tae Hyun Ban, Hye Eun Yoon, Cheol Whee Park, Bumsoon Choi. *Div of Nephrology, Dept of Internal Medicine, Dept of Internal Medicine, The Catholic Univ of Korea, Republic of Korea.*

Background: The incretin-based agents such as dipeptidyl peptidase IV (DPP-IV) inhibitor and glucagon-like peptide-1 (GLP-1) agonist was associated with diverse protective effect including renoprotective effect except lowering glucose. Aging kidney was characterized by decreased glomerular filtration rate, impaired electrolyte balance, decreased plasma renin activity and histological changes such as glomerulosclerosis and tubular atrophy. We investigated the renal function, albuminuria, the concentration and activity of DPP-4 and DPP-4 substrates in serum and urine, and expression of incretin hormone in renal tissue with aging in mice model.

Methods: C57BL/6 mice were divided into three groups according to age differences; 2 months-old (N=8), 12 months-old (N=8), and 24 months-old (N=8). We measured renal function, histological change in aging mice. Also, the concentrations and expressions of DPP-4 and DPP-4 substrates were measured in serum and renal tissue in aging mice.

Results: According toaging, albuminuria (16.5 ± 1.1 ng/24hr vs. 41.5 ± 8.4 ng/24hr, 65.5 ± 10.4 ng/24hr; $p < 0.05$ vs. 2M) was increased and Creatinine clearance ($p > 0.05$ vs. 12M) was decreased. There were increases in mesangial volume and tubulointerstitial fibrosis in 24-month-old mice ($p < 0.01$). There were also increases in F4/80 expression (0.11 ± 0.06% vs. 0.4 ± 0.11%, 2.5 ± 0.52%; $p < 0.01$) and in apoptosis detected by TUNEL (positive mesangial cells, 0.27 ± 0.09% vs. 0.53 ± 0.12%, 2.6 ± 0.63%; glomerulus and cortical tubular areas, 0.27 ± 0.09% vs. 0.53 ± 0.12%, 2.8 ± 0.67%.01). Urine isoprostane (7.4 ± 0.3% vs. 19.4 ± 0.78%, 21.9 ± 1.9%) excretion increased with aging. DPP-IV concentrations in serum and DPP-IV activities in renal tissue were gradually increased ($p<0.001$ and $p<0.05$, respectively). GLP-1 receptor and DPP-IV protein levels in renal tissue were significantly increased with aging in western blot ($p<0.001$ and $0<0.05$, respectively).

Conclusions: It is suggested that incretin based treatment is a possible strategy for preventing an aging process in the kidney.

FR-PO325

Sodium-Glucose Cotransporter 2 Inhibition Partly Phenocopies Calorie Restriction in Kidneys of a Type 2 Diabetes Mouse Model

Shinji Tanaka, Tetsuhiro Tanaka, Mai Sugahara, Hisako Saito, Masaomi Nangaku. *Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors lower blood glucose levels by increasing glucose/calorie loss in urine. However, the long-term effect of SGLT2 inhibition on the kidney, independent of glycemic control, is unknown. Thus, we compared renal changes induced by ipragliflozin treatment and those induced by calorie restriction (at similar blood glucose levels) in a mouse model of type 2 diabetes.

Methods: Male BTBR ob/ob mice, aged 4 weeks, were divided into three groups: vehicle, ipragliflozin (0.002%; in feed), and 70% calorie restriction. Male BTBR wild type littermates were used as controls. All mice were euthanized at 22 weeks of age.

Results: At euthanasia, HbA1c levels in the ipragliflozin (5.8±0.2%) and calorie restriction (6.2±0.3%) groups were comparable and significantly lower than those in the vehicle group (8.7±0.2%). Urinary albumin levels at 10 weeks of age in the ipragliflozin (947±228 μg/mgCr) and calorie restriction (809±142 μg/mgCr) groups were significantly lower than those in the vehicle group (3447±481 μg/mgCr), and this difference persisted until 22 weeks. Ipragliflozin treatment and calorie restriction prevented glomerular hyperfiltration at 13 and 22 weeks of age (GFR at 22 weeks: 461±13, 853±20, 753±7, and 735±44 μL/min in the control, vehicle, ipragliflozin, and calorie restriction groups, respectively) and mesangial expansion, and improved serum lipid profile at euthanasia, in equal measure. In contrast, kidney weight, glomerular tuft area, interstitial fibrosis, macrophage infiltration, and MCP-1 mRNA expression in the cortex were significantly reduced by calorie restriction but remained unaffected by ipragliflozin.

Conclusions: Our data showed that ipragliflozin treatment partly phenocopied calorie restriction toward protection in BTBR ob/ob mouse kidneys. Amelioration of glomerular hyperfiltration and reduction of albuminuria, mesangial expansion, and serum lipid profile were achieved by both interventions, while kidney/glomerular hypertrophy, inflammation, and fibrosis were improved only by calorie restriction.

Funding: Government Support - Non-U.S.

FR-PO326

Dapagliflozin Improves Glycemic Control, Hypertension and Is Neutral on Severe Renal Impairment in Uni-Nephrectomized SDT Fatty Rat, a 10-Week Model of Advanced Renal Complications and Glomerular Filtration Rate Decline

Francois Briand,[1] Masami Shinohara,[2] Emmanuel Brousseau,[1] Yasushi Kageyama,[2] Thierry Sulpice.[1] *[1]PHYSIOGENEX SAS, PHYSIOGENEX SAS, Labege, France; [2]CLEA Japan Inc., Meguro, Tokyo, Japan.*

Background: Sodium glucose cotransporter 2 inhibition (SGLT2i) represents a promising new class of glucose lowering drugs but may not be recommended in type 2 diabetic patients with severe renal impairment. To investigate the effects of SGLT2i, later in the course of diabetic nephropathy, dapagliflozin (DAPA) was evaluated in uni-nephrectomized Spontaneously Diabetic Torii (SDT) fatty rat. This novel hypertensive, obese, type 2 diabetic model, develops advanced renal complications and >50% glomerular filtration rate (GFR) decline within 10 weeks.

Methods: Male, 6-week old SDT fatty rats underwent unilateral nephrectomy (Unx; n=16) or sham operation (Sham; n=8). After a 1-week recovery, rats had free access to Purina 5008 chow diet and drinking water supplemented with 0.3% salt for 10 weeks. After 3 weeks of diet to enhance kidney complications, 8 Unx rats were treated with DAPA 1mg/kg/day for 7 weeks.

Results: After 10 weeks of diet and compared to Sham rats, albuminuria was 206% higher in Unx control rats, while plasma creatinine clearance and GFR (FITC-inulin injection) were substantially reduced by 46 and 60% ($p<0.01$ vs. Sham). Histology analysis (Periodic acid-schiff, ED1 immunostaining and Sirius Red) confirmed advanced glomerulosclerosis, inflammation and fibrosis in Unx control rats (all scores $p<0.05$ vs. Sham). The major finding was that compared to Unx control rats, DAPA treatment of Unx rats for 7 weeks did not change GFR decline, glomerulosclerosis, inflammation and fibrosis scores. We also observed reduction in HbA1c and blood pressure by 3.1% and 19%, respectively, with DAPA (both $p<0.01$ vs. control).

Conclusions: Our data suggest that SGLT2i with DAPA has no detrimental effect in uni-nephrectomized SDT fatty rat with advanced renal complications and >50% GFR decline. Whether treatment with DAPA at an earlier time point would prevent renal impairment in this model should be investigated.

FR-PO327

The Comparative Effects of a Pan-Nox Inhibitor APX-115 and Angiotensin Receptor Blocker on Diabetic Nephropathy in Type 2 Diabetic Mice

Jin Joo Cha,[1] Young Sun Kang,[1] Ji Eun Lee,[2] Hyunwook Kim,[3] Jungyeon Ghee,[1] Ji Ae Yoo,[1] Dae-Ha Kim,[1] Gyu Sik Choi,[1] Hye Sook Min,[2] Kitae Kim,[4] Jee Young Han,[5] Dae R. Cha.[1] *[1]Korea Univ; [2]Wonkwang Univ; [3]Yonsei Univ; [4]Dong-A Univ; [5]Inha Univ, Republic of Korea.*

Background: Targeting all Nox components may be a promising therapeutic strategy to ameliorate renal damage from reactive oxygen species in diabetic nephropathy. Therefore, we investigated the comparative effect of a first in class pan-Nox inhibitor, APX-115 and L158809 (angiotensin II receptor blocker, ARB) and their combination on diabetic nephropathy in type 2 diabetic mice.

Methods: 8 to 10 week old db/m and db/db mice were treated with APX-115 for 12weeks. APX-115 was administered by oral gavage at a dose of 60mg/kg/day. To compare the effects of APX-115 with ARB, other groups were treated with LC158809 (1.5mg/kg/d) or treated with both APX-115 and LC158809 for 12 weeks.

Results: Interestingly, both APX-115 group and ARB group showed significantly improved systemic oxidative stress (plasma 8-isoprostane and tissue lipid peroxidase levels), and lipid profiles compared to diabetic control group. Importantly, both APX-115 and ARB groups showed a significant decrease in urinary albumin excretion with a similar potency. Consistent with urinary albumin excretion, urinary loss of nephrin was also significantly reduced. Renal histology showed reduced mesangial expansion, fibrosis and inflammation in all treatment groups. Renal Nox1,2 and 4 protein expressions were decreased in APX-115 and combination group, whereas only Nox2 was decreased in ARB group. Although there were no additive beneficial effects in oxidative stress and lipid abnormality, combined treatment of APX-115 and ARB showed additive renoprotective effects in urinary albumin excretion and renal structural changes.

Conclusions: Our results provide evidence that pan-Nox inhibition by APX-115 may have similar renoprotective potential with ARB, and combination therapy with APX-115 and ARB may have better renoprotective potential in diabetic nephropathy. These findings suggest that an agent that simultaneously inhibits various Noxs therefore holds a considerable promise as a new antidiabetic drug.

FR-PO328

Renal Effects of LJ-2698, a Highly Selective Adenosine3 Receptor Antagonist and Combination Treatment with Angiotensin Receptor Blocker in Streptozotocin Induced Type 1 Diabetic Mice

Young Sun Kang,[1] Jin Joo Cha,[1] Jungyeon Ghee,[1] Gyu Sik Choi,[1] Ji Ae Yoo,[1] Ji Eun Lee,[2] Hyunwook Kim,[3] Hye Sook Min,[2] Jee Young Han,[4] Dae R. Cha.[1] *[1]Korea Univ; [2]Wonkwang Univ; [3]Yonsei Univ; [4]Inha Univ, Republic of Korea.*

Background: Concentration of adenosine in normal kidney increases markedly in response to cellular damage. Extracellular adenosine binds to four adenosine receptors (AR), all of which exist in the kidney. Among four subtypes, A3AR is known to be up-regulated during renal injury. In this study, we investigated the comparative effects of a novel A3AR antagonist LJ-2698 and L158809 (angiotensin II receptor blocker, ARB) and their combination on diabetic nephropathy in streptozotocin(STZ)-induced type 1 diabetic mice.

Methods: To define the mechanism of LJ-2698, we performed in vitro experiments using podocytes. For animal experiment, type I diabetes was developed using STZ injection (50mg/kg IP for 5days) in C57BL6 mice. Diabetic mice were treated with 1) LJ-2698 (10mg/kg/day by gavage), 2) LC158809 (1.5mg/kg/d mixed in drinking water) and 3) both LJ-2698 and LC158809 for 12 weeks.

Results: In cultured podocytes, high glucose(HG), palmitates(PA) and angiotensin-II(Ang-II) significantly up-regulated A3AR expression. Prior treatment with LJ-2698 markedly suppressed HG, PA and Ang-II-induced activation of TGFb1, MCP-1 and type IV collagen synthesis. In type 1 diabetic mice, treatment with LJ-2698 showed improvement in insulin resistance. Interestingly, urinary albumin excretion was significantly decreased in both LJ-2698 and ARB groups with a similar potency, and there was an additive decrease in combination treatment group. In addition, urinary nephrin excretion was significantly decreased in both LJ-2698 and ARB groups. Renal glomerular mesangial expansion, fibrosis and inflammation were decreased in all treatment groups. Renal protein expressions of TGF-β1, PAI-1, NF-kb were attenuated in LJ-2698 and combination groups compared to diabetic control.

Conclusions: Our results showed that A3AR antagonist may have a similar renoprotective effects with ARB through protection of podocyte injury. These findings suggest that targeting A3AR may have a promising potential in diabetic nephropathy.

FR-PO329

Factor Xa Inhibition with Rivaroxaban Reduces Hyperglycemia-Induced Inflammation in the Kidney by Inhibition of PAR-1 Signaling in Endothelial Cells in an Animal Model of Diabetic Nephropathy Anna Bertram, Nelli Shushakova, Joon-Keun Park, Torsten Kirsch, Jan Menne, Florence Njau, Hermann G. Haller. *Clinic of Hypertension and Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Activated factor Xa (FXa) plays an important role in the coagulation cascade. In addition, FXa binds to protease-activated receptors PAR-1 and PAR-2 and may exert cellular function in the endothelium. We tested the hypothesis that (1) treatment with a FXa inhibitor prevents or ameliorates proteinuria and inflammatory changes in diabetic mice and (2) that this effect is mediated via endothelial PAR-1 and/or PAR-2.

Methods: Streptozotocin (125 mg/kg)-treated mice (STZ) (*n*=8), and control animals were used in these experiments. They received either sham or rivaroxaban RIVA (15 mg/kg). After 2 and 8 weeks of hyperglycemia, the animals were analyzed. Albumin concentration samples was measured by ELISA. Immunohistochemistry was performed on cryostat or on paraffin sections. Gene and protein expression was analyzed by real-time qPCR and western blot. Intracellular effects of FXa were assessed in cultured microvascular endothelial cells (MEC) by measuring ERK phosphorylation (pERK) and cytokine release.

Results: Treatment with RIVA reduced the hyperglycemia–induced macrophage infiltration in the diabetic kidneys. Concomitantly, the increase in inflammatory cytokines (Il-6, TNF-alpha) and adhesion molecules (ICAM-1) in diabetic animals was also reduced by RIVA treatment. The increase in pERK in diabetic glomeruli was diminished by RIVA treatment. These changes were associated with a reduced increase in proteinuria in STZ mice. In MEC the FXa-induced pERK was reduced by RIVA treatment. Downregulation of PAR-1 abolished the effects of RIVA while loss of PAR-2 did not change the effects of RIVA.

Conclusions: Treatment with the factor Xa inhibitor rivaroxaban prevents renal inflammation in animal models of diabetes by inhibition of adhesion molecule expression and cytokine release. This effect seems to be mediated by inhibition of PAR-1 signaling by rivaroxaban in endothelial cells.

Late Intervention with PBI-4050 Offers Renoprotection in a Mouse Model of Renin-Dependent/Streptozotocin-Induced Nephropathy Jean-François Thibodeau,[1,2] Eldjonai Kamto,[2] Lyne Gagnon,[1] Pierre Laurin,[1] Richard L. Hebert,[2] Chris R. Kennedy.[2] *[1]ProMetic BioSciences Inc., Laval, QC, Canada; [2]Kidney Research Center, Ottawa Hospital, Ottawa, ON, Canada.*

Background: PBI-4050, a novel first-in-class orally active compound which is currently in clinical phase Ib/II in CKD patients, displays antifibrotic activities via a novel mechanism of action. PBI-4050 reduces functional and structural renal dysfunction in models of diabetic kidney disease. The aim of this study was to investigate the impact of PBI-4050 treatment on renal injury progression in a mouse model of diabetic kidney disease.

Methods: We used a recently developed mouse model of diabetic kidney disease in which low-dose streptozotocin (STZ)-dependant type-1 diabetes is induced in human prorenin-overexpressing mice (C57BL/6-TTRhRen) yielding a hypertensive/diabetic phenotype (HD). After 12 weeks of hypertension/diabetes, mice were treated with oral administration of vehicle or PBI-4050 (200 mg/kg) for 4 weeks, and sacrificed at 16 weeks post-STZ.

Results: At endpoint, PBI-4050 had no effect on bodyweight or blood glucose levels, but slightly increased renal hypertrophy (HD, 8.01±0.4 vs HD+PBI4050, 9.60±0.6, mg/mm, P=0.047). While PBI-4050 slightly decreased systolic blood pressure, glomerular filtration was significantly reduced to normal levels (HD, 503±42 vs HD+PBI4050, 380±27, μL/min, P=0.040). Reductions in urine albumin-to-creatinine ratios were also observed in the PBI-4050 treatment group compared to vehicle (HD, 199.3±33; HD+PBI4050, 109.7±18, μg of albumin per mg of creatinine, P=0.035), which corresponded to decreased glomerular mesangial matrix expansion, and tubulointerstitial injury. In addition, PBI-4050 treatment reduced α-smooth muscle actin (HD, 1.53±0.2 vs HD+PBI4050, 0.81±0.1, relative expression, P=0.0038) and connective tissue growth factor mRNA expression in the cortex (HD, 1.41±0.2 vs HD+PBI4050, 0.91±0.1, relative expression, P=0.055).

Conclusions: Taken together, PBI-4050 administration beginning at 12 weeks of hypertension/type-1 diabetes reduced the extent of renal injury, independently of its effects on blood glucose, which further supports its use as a potential renoprotective therapy in the context of diabetic kidney disease.

FR-PO331

Effect of an Oral Adsorbent AST-120 on Type 2 Diabetes Rats with Unilateral Nephrectomy Rieko Aoki, Yusuke Yamashita, Hiroko Iijima, Kaori Kikuchi, Mariko Kato, Yoshiharu Itoh. *Pharmaceuticals & Agrochemicals Div, Kureha Corporation, Tokyo, Japan.*

Background: Diabetic nephropathy is a major complication of diabetes and the leading cause of end-stage renal disease. An oral adsorbent AST-120 has been used clinically in Japan as a medicine for patients with chronic kidney disease (CKD) to slow down the progression of CKD. However, there is little evidence to support therapeutic efficacy of AST-120 for early stage overt diabetic nephropathy. In the ASN Kidney Week 2015 we showed that the administration of AST-120 reduced the urinary protein and albumin excretion on SHR/NDmcr-cp (SHR/ND) rats, rodent model of metabolic syndrome/ type 2 diabetes, and suppressed the podocyte injury and tubular injury. However, the renal function in SHR/ND rats didn't decrease and the effect of AST-120 on the renal function was unclear. In this study, we investigated whether the administration of AST-120 from the early stage of diabetic nephropathy is effective strategy for the suppression of the reduction of renal function using the unilateral nephrectomized (UNX) SHR/ND rats.

Methods: Male SHR/ND rats, aged 8 weeks, underwent either UNX (n=20) or sham (n=6) surgery under anesthesia. UNX rats were divided into two groups; one group was administered 8% AST-120 in their diets. WKY rats were also used as normal rats. At every 3 weeks, serum and 24-hour urine samples were collected for biomedical studies. The level of uremic toxins in serum were also measured at every 6 weeks.

Results: The levels of serum creatinine, blood urea nitrogen, serum uremic toxins, urinary protein and albumin excretion increased, and creatinine clearance decreased in UNX-SHR/ND rats compared to Sham-SHR/ND rats. Therefore, it indicated that there was the reduction of renal function in UNX-SHR/ND rats. AST-120-administered UNX-SHR/ND rats showed significantly lower levels of urinary protein and albumin excretion, serum creatinine, blood urea nitrogen and uremic toxins compared to the UNX-SHR/ND rats, and also maintained higher levels of creatinine clearance than UNX-SHR/ND rats.

Conclusions: These results indicate that the administration of AST-120 from the early stage of diabetic nephropathy has a protective effect on the reduction of renal function.

FR-PO332

CS-3150, a Novel Mineralocorticoid Receptor Antagonist, Reduces Albuminuria in Type 2 Diabetes Mice in Combination Treatment with Angiotensin II Receptor Blocker Kiyoshi Arai,[1] Yuka Morikawa,[2] Naoko Ubukata.[1] *[1]End-Organ Disease Laboratories, Daiichi Sankyo Co., Ltd., Tokyo, Japan; [2]Rare Disease & LCM Laboratories, Daiichi Sankyo Co., Ltd., Tokyo, Japan.*

Background: An angiotensin II receptor blocker (ARB) is currently recommended as first-line therapy for diabetic nephropathy (DN). Recently, it has been demonstrated that add-on treatment of a mineralocorticoid receptor (MR) antagonist with ARB shows further beneficial effects on DN patients. Our previous studies have shown that CS-3150 is a novel, highly potent and selective MR antagonist with non-steroidal structure and shows strong antihypertensive and cardiorenal protective effects in hypertension models. In this study, we evaluated the renal protective effect of CS-3150 in KK-Ay mice, a type II diabetic model, in combination with olmesartan (OLM, an ARB).

Methods: CS-3150 (3 mg/kg), OLM (1 mg/kg) or both of them was orally administered to male KK-Ay mice from 10 weeks of age for 8 weeks. At every 4 weeks, urine samples for 24 h were collected and urinary parameters (albumin, creatinine, podocalyxin and MCP-1) were measured. Systolic blood pressure (SBP) and blood glucose (BG) level were measured at 3 and 7 weeks after administration, and serum K^+ level was measured at necropsy.

Results: In KK-Ay mice at 10 weeks of age, urinary albumin-to-creatinine ratio (UACR) and BG levels were significantly higher than C57BL/6J mice, non-diabetic controls, meaning that KK-Ay mice developed DN. The combination treatment with CS-3150 and OLM significantly reduced UACR, while each monotherapy tended to reduce UACR but not significant. Urinary podocalyxin and MCP-1 excretion were also reduced. In contrast, this combination therapy did not show any significant effect on SBP, BG and serum K^+ level.

Conclusions: These results indicate that in KK-Ay mice, CS-3150 significantly reduced albuminuria without any effect on SBP, BG and serum K^+ in combination with OLM. This direct renal protective effect could be, in part, due to podocyte protective and anti-inflammatory actions. CS-3150 is currently under development as a drug candidate in the clinical phase II trials for hypertension and DN in Japan.

FR-PO333

Cyanate Improves Glucose Homeostasis and Hepatic Steatosis in Normal and High Fat-Fed Mice Seong Sik Kang,[1,2] Yaerim Kim,[1,2] Sang Mok Yeo,[1,2] Woo Yeong Park,[1,2] Kyubok Jin,[1,2] Sung Bae Park,[1,2] Seungyeup Han.[1,2] *[1]Dept of Internal Medicine, Keimyung Univ School of Medicine, Daegu, Republic of Korea; [2]Keimyung Univ Kidney Inst, Daegu, Republic of Korea.*

Background: Obesity is an important contributing factor to progression of chronic kidney disease. Cyanate, being generally known as uremic toxin, is an electrophile produced spontaneously from urea or by myeloperoxidase-catalyzed oxidation of thiocyanate.

Methods: In the current study, we explored the *in vivo* and *in vitro* metabolic effects of cyanate in normal chow diet (NCD)- and high fat diet (HFD)-fed mice.

Results: Contrary to our expectations, we found that cyanate treatment improved glucose tolerance, increased insulin sensitivity and alleviated hepatic steatosis in both NCD- and HFD-fed mice compared with corresponding control groups. Histological analyses of kidney and serum levels of blood urea nitrogen and creatinine revealed no significant differences between cyanate-treated and control mice groups. Interestingly, we found that cyanate treatment reduced appetite and body weight in both diet groups. And we also found that cyanate treatment decreased lipid peroxidation levels in the sera and kidney, attenuated reactive oxygen species (ROS) levels in the kidney. Thus we examined *in vitro* carbamylated albumin (cAlb) in Caki-2 kidney cell lines for antioxidant effects of cyanate. We found that cAlb significantly reduced ROS generation compared with Alb.

Conclusions: Taken together, the results in this study may indicate that cyanate improves glucose tolerance and hepatic steatosis possibly via exerting anorexic and antioxidative effects.

FR-PO334

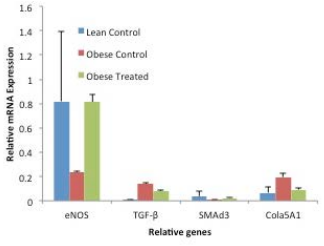
Iron Chelation Ameliorates Fibrotic Pathways in ZSF1 Obese Rat

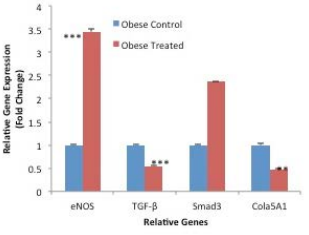
A. Bilal Malik,[1] Chhanda Bose,[2] Sudhir V. Shah.[2] *[1]Univ of Washington, Seattle, WA; [2]Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Labile iron, by virtue of its ability to participate in free-radical reactions, plays an important role in diabetic nephropathy. Chelating catalytic iron would provide beneficial effects including amelioration of oxidative and consequently fibrotic pathways involved in progression.

Methods: The oral iron chelator deferiprone was administered to ZSF1 obese rats beginning age 8 weeks over a 24 week treatment period at a dose of 125mg/kg of body weight, dissolved in drinking water. A lean and obese ZSF1 rat group was also followed simultaneously without intervention and served as control groups. Real time quantitative PCR in rat kidneys was done to determine the activity of the oxidative and fibrotic pathways. cDNA was synthesized from RNA, isolated post treatment from control and treated kidneys. Taqman PCR Gene Expression reagents were used to detect eNOS, TGF-β, Smad-3 and Collagen 5A1 chain (Cola5A1) and reference genes. cDNA and relative gene expression were calculated from Cq values using a ΔΔCq. Statistical significance relative to control is shown, **p<0.01, ***p<0.0001.

Results:





Relative mRNA Expression	eNOS	TGF-β	Smad3	Cola5A1
Lean Control [5]	0.818	0.008	0.038	0.066
Obese Control [10]	0.235	0.138	0.009	0.194
Obese Treated [10]	0.811	0.076	0.022	0.092

Conclusions: Treatment with oral iron chelator deferiprone down regulated the oxidative and fibrotic pathways in the ZSF1 obese rat, an F1 hybrid model of type 2 diabetic nephropathy. The relative gene and messenger RNA expression levels of eNOS, TGF-β, and Cola5A1 in treated obese rats returned to the levels expressed in non- diabetic lean rats with significant improvement compared with the obese non- treated group. Iron chelation may provide a new therapeutic modality for halting progression of diabetic nephropathy.

An Immunomodulatory Device Improves Insulin Resistance in an Obese Porcine Model of Metabolic Syndrome

A. Westover,[1] K. Johnston,[1] D. Buffington,[1] H. David Humes.[1,2] *[1]Innovative BioTherapies, Ann Arbor, MI; [2]Internal Medicine, Univ of Michigan Medical School, Ann Arbor, MI.*

Background: Obesity is associated with tissue inflammation which is a crucial etiology of insulin resistance (IR). This inflammation centers around circulating monocytes (MO) which form pro-inflammatory adipose tissue macrophages (ATM). Specific approaches targeting MO/ATM may improve IR without the adverse side effects of generalized immunosuppression.

Methods: An extracorporeal based biomimetic membrane leukocyte processing device, called the Selective Cytopheretic Device (SCD), was evaluated to assess the therapeutic impact in an Ossabaw miniature swine model of IR with metabolic syndrome (MetS). Pigs received three 6 hour SCD therapy (Rx) sessions over a 1 week period, with measurements for assessing changes in IR via IV glucose tolerance test (GTT) and homeostatic model assessment (HOMA)-IR scores followed up to 2 weeks post Rx. Leukocyte parameters were assessed to determine impact of SCD Rx on the inflammatory state associated with MetS. Circulating neutrophil (NE) activation was measured by CD11R3 and Ne apoptotic rates were assessed via Annexin V assay. Systemic MO numbers were determined by manual white blood cell counts.

Results: SCD Rx in this porcine model demonstrated a significant (p=0.033) effect on decreasing circulating NE activation levels as measured by CD11R3 and on returning Ne apoptotic rates toward naïve, non-inflammatory rates (p=0.023). For MO, a reduction in the absolute circulating MO counts was observed pre to post SCD Rx (p=0.007). These changes were associated with improvements in IR as determined by GTT. These improvements were also reflected in lowering of HOMA-IR scores for up to 2 weeks post SCD Rx. A decrease in TNFα was also consistently observed post SCD Rx, achieving significance at p=0.0022.

Conclusions: The above study provides strong evidence that SCD Rx reduced the chronic systemic inflammation associated with MetS as presented in this model. These results allow for the planning of first in man studies in obese type 2 diabetic patients.

FR-PO336

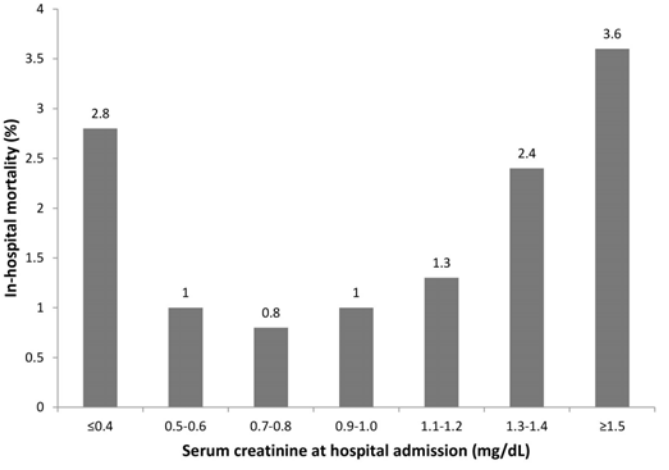
Low Admission Serum Creatinine Concentration Predicts Mortality in Hospitalized Patients Independent of Body Mass Index

Wisit Cheungpasitporn, Charat Thongprayoon, Wonngarm Kittanamongkolchai, Kianoush Banaei-Kashani. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Low serum creatinine was associated with poor outcomes in critically ill and dialysis patients. The association between low admission serum creatinine and risk of in-hospital mortality is limited. The aim of this study is to assess the independent association between low admission creatinine and in-hospital mortality in hospitalized patients.

Methods: This is a single-center cohort study conducted at a tertiary referral hospital. All hospitalized adult patients who had admission creatinine available from January 2011 to December 2013 were included. Admission creatinine was categorized into 7 groups (≤0.4, 0.5-0.6, 0.7-0.8, 0.9-1.0, 1.1-1.2, 1.3-1.4 and ≥1.5 mg/dL). The primary outcome was in-hospital mortality. Logistic regression analysis was performed to obtain the odds ratio of in-hospital mortality of various admission creatinine levels using creatinine 0.7-0.8 mg/dL as the reference group.

Results: Of 73,994 patients included, 973 (1.3%) died in the hospital. The association between different categories of admission creatinine and in-hospital mortality assumed a U-shaped curve, with both low and high creatinine associated with higher in-hospital mortality.



When adjusting for age, sex, ethnicity, principal diagnosis and comorbidities, very low creatinine (≤0.4 mg/dL) was significantly associated with increased mortality (OR 3.29; 95% CI 2.08-5.00), exceeding the risk related with markedly elevated creatinine (OR 2.65; 95% CI 2.11-3.35 for creatinine ≥1.5 mg/dL). The association remained statistically significant following adjustment for body mass index.

Conclusions: Low admission creatinine was independently associated with increased in-hospital mortality in hospitalized patients. Low serum creatinine might be a better surrogate marker of low muscle mass than a low body mass index.

FR-PO337

Free and Bound Serum Sialic Acid Profiling of End Stage Renal Disease Patients

Kunio Kawanishi,[1] Sandra Diaz,[1] Biswa Choudhury,[1] David Herold,[2] Robyn A. Cunard,[3,4] Kumar Sharma,[4,5] Ajit Varki.[1,3] *[1]Cellular & Molecular Medicine; [2]Pathology; [3]Medicine; [4]VASDHS; [5]Inst of Metabolomic Medicine, UC San Diego, La Jolla, CA.*

Background: Sialic acids (Sias) are a diverse family of molecules found at the outer tips of the glycan forest that covers all vertebrate cells. Previous studies reported increased serum total Sia associated with atherosclerosis in the general population and in patients with end stage renal disease (ESRD) undergoing hemodialysis (HD) therapy. However, there has been no profiling of the types of sialic acids in ESRD patients.The aim of this study was to analyze which types of free Sias and Sia-containing glycans accumulate in the sera of ESRD patients. Analysis focused on *N*-Acetylneuraminic acid (Neu5Ac), N-glycolylneuraminic

acid (Neu5Gc, which is not naturally made by humans), and the common lower vertebrate Sia 3-deoxy-D-glycero-D-galacto-nonulosonic acid (Kdn). Kdn is almost undetectable in normal human tissues except in some cancer.

Methods: Serum samples from HD patients (N=60) and normal controls (N=20) were analyzed for free and protein bound Sias by DMB derivatization, high performance liquid chromatography (HPLC) and matrix-assisted laser desorption/Ionization time-of-flight mass spectrometry (MALDI-TOF MS). Bound Sias were released by mild acid. Sialylated N-glycans were released by PNGase F followed by 2-aminobenzamide (2-AB) labeling. The fluorescently tagged sialoglycans were analyzed with or without sialidase pretreatment.

Results: Several unknown fluorescent DMB adduct peaks were detected only in ESRD patients, as well as much higher levels of free Neu5Ac and Kdn. No free form of Neu5Gc was detected. However, small amounts of peak corresponding to bound Neu5Gc were detected in both HD and normal control samples. N-glycan profiling using 2-AB labeling showed that sialidase resistant anionic peaks were detected only in HD serum.

Conclusions: We show accumulation of free Neu5Ac and Kdn in HD patients, and possible bound Neu5Gc (presumably of dietary origin from red meat) in HD patients and in normal controls. These findings suggest that human and non-human Sias can accumulate in HD patients and be potentially used by human cells. We are currently studying the sialidase-resistant peaks.

Bioimpedance Vectorial Analysis as a Tool for Early Diagnosis of Acute Kidney Injury Luis Ignacio Bonilla,[1,3] Sara Samoni,[2,3] Allina Primavera Flores Mendoza,[1] Jesus Cruz Valdez,[1] Claudio Ronco.[3] *[1]Nephrology Dept, Hospital Univ, Monterrey, Mexico; [2]Inst of Life Sciences, S. Anna School of Advanced Studies, Pisa, Italy; [3]International Renal Research Inst, San Bortolo Hospital, Vicenza, Italy.*

Background: Fluid overload(FO) is a frequent condition in critically ill patients.FO increases the volume of distribution of creatinine, thus decreasing serum creatinine (sCr) concentration, which may contribute to delay the diagnosis of Acute Kidney Injury (AKI) and underestimation of its severity.Our aim was to assess the incidence of AKI based on corrected creatinine according to a formula usingtotal body water(TBW) estimated by bioimpedance.

Methods: This is a prospective, dual-center study.Body fluid status was assessed in 40 adult patients during the first 24 hours after admission to ICU.Total body Bioelectric Impedance Analysis (BIA) was performed to evaluate TBW(kg) and the hydration scale with vectorial analysis (BIVA).Patients were eligible if: i)baseline sCr levels were available and ii)BIVA hydration level was more than 81% of lean body mass, indicating moderate to severe hyper-hydration.We applied the following correction formula:(measured sCr*TBW)/(0.6*Body Weight).Acute Kidney Injury was diagnosed from sCr increase, according to KDIGO criteria, before and after creatinine correction.

Results: 26 pts. (61.5% male; median age 76.5 years)were considered eligible for the study. The average baseline value of sCr was 0.93±0.36. 24 hours after admission, sCrwas 1.18±0.85. The average increase of uncorrected sCr value was 0.24±0.63.After correcting sCr for fluid overload, the average value of was 1.33±0.89 with an increase of 0.40±0.66. The incidence of AKI was 38.4% and 42.3%, respectively before and after correction. Taking into account measured sCr, 34.6%, 0% and 3.8% of patients developed AKI stage I, II and III. After correction for TBW overload, the percentages of pts. with stage I, II and III of AKI were 26.9%, 11.5% and 3.85%.

Conclusions: We suggest the utilization of TBW estimated by BIA to early diagnose AKI in hyper-hydrated patients. Further studies, including more patients, are needed to assess the correlation of AKI diagnosed with our formula with major outcomes.

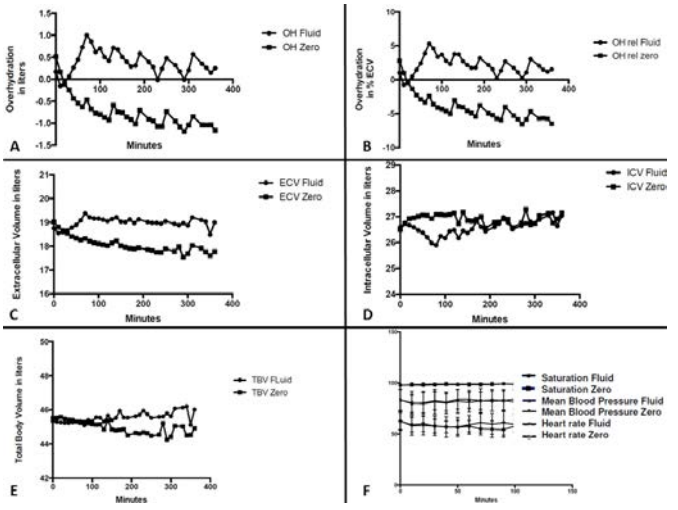
FR-PO339

Bioimpedance Spectroscopy for Assessment of Volume Changes during Intravenous Fluid Therapy: A Crossover Study in Healthy Volunteers Manfred Hecking,[1] Matthäus Ernstbrunner,[2] Peter Wabel.[3] *[1]Nephrology, Medical Univ of Vienna, Austria; [2]Anesthesiology, Medical Univ of Vienna, Austria; [3]Fresenius Medical Care Germany.*

Background: Intravenous (iv) fluid therapy is among the most common medical tasks, but its immediate and intermediate effects on the fluid compartments and hemodynamics of the human body remain enigmatic to the majority of clinicians. We therefore tested bioimpedance spectroscopy (BIS) for assessment of volume changes in healthy volunteers.

Methods: After an overnight fast, 15 males received isotonic fluid therapy (Elo-mel®, Fresenius) at a rate of 0,5ml/kg/min during 60 minutes on study day "Fluid", and no fluid therapy on study day "Zero". BIS was performed every 10 minutes using the Body Composition Monitor (Fresenius). All volunteers remained in a supine position for 350 minutes, unless urinating (every 60 minutes). Hemodynamic parameters included peripheral capillary oxygen saturation, electrocardiogram and blood pressure (NCT02296294).

Results: Mean age, height and weight of the volunteers was 29.3±5.5y, 182.7±8.8cm and 77.4±13.2kg, respectively. In minute 60, subjects on the "Fluid" day had received 2.2±0.2L iv fluid and produced 0.6±0.3L urine, while they had remained thirsting and produced 0.1±0.2L urine on the "Zero" day. Overhydration (OH) in liters and % of extracellular volume (ECV) increased to 1.0±0.9L (5.5±4.8% ECV) in minute 70 on the "Fluid" day before gradually decreasing, whereas OH decreased to -1.3±1.2L (-7.2±5.9% ECV) overall in minute 350 on the "Zero" day ($p<0.01$, panels A,B). Hemodynamics did not differ between both days (panel F). For ECV, intracellular and total body volume, see panels C-E.



Conclusions: BIS-based assessment revealed a clinically meaningful and sustained increase in ECV after iv fluid therapy, up to 50% of the infused volume. Similar studies in subjects with illness are needed to quantify the OH cut-off for worse outcomes.

FR-PO340

Residual Water Permeability: A Novel Concept Challenging Current Diagnosis of Syndrome of Inappropriate ADH Hormaz Dara Dastoor,[1] Chandra Mauli Jha,[2] Ken J. Donaldson,[3] Thalakunte Muniraju,[3] Hatem Mohyeldin Ebeid,[4] Samra Abouchacra.[5] *[1]Div of Nephrology, Rahba Hospital- Johns Hopkins International, United Arab Emirates; [2]Div of Nephrology, Burjeel Hospital, United Arab Emirates; [3]Div of Nephrology, Dumfries and Galloway Royal Infirmary, United Arab Emirates; [4]Div of Nephrology, Al Noor Hospital, United Arab Emirates; [5]Div of Medicine, Tawam Hospital, United Arab Emirates.*

Background: Residual Water Permeability (RWP) is a mechanism by which up to 5 liters of water can absorbed down the osmolar gradient between Tubular and Medullary Interstitium, and is active only in the complete absence of ADH activity. We describe a case of a patient labeled as Syndrome of Inappropriate ADH (SIADH), however by showing an active RWP system, we challenged the diagnosis of SIADH and relabelled this as a case of Reset Osmostat with concomitant Primary Polydipsia.

Methods: A 71-year-old lady presented with nausea, vomiting, Plasma Sodium (Pna)-113 mol/l and Uosm – 137mOsm/kg. She was treated with 2.4 liters of 0.9% Normal Saline over 48 hours, with improvement of Pna to 117mol/l. However over the next 24 (Day 3) hours she developed Polyuria of 5.4 liters, which was approximately 3 liters in excess of the total infused fluids with a concomitant rise in Pna to 124 mmol/l. The patient's polyuria was attributed to loss of RWP mechanism, caused by increased solute delivery in the absence of ADH secretion.

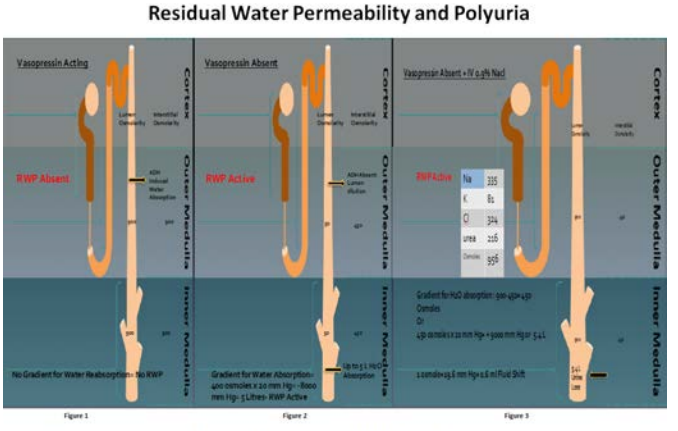


Figure 1: In the presence of vasopressin there is no absorption of water across the collecting ducts due to lack of osmotic gradient
Figure 2: In the absence of vasopressin up to 5 liters of water are absorbed across the Tubulo- Interstitial gradient
Figure 3: In the presence of vasopressin and a solute load (0.9% Nacl) , the osmotic gradient is reversed to induce a water diuresis of 5.4 liters

Results: The case highlights that an RWP system implies complete absence of ADH activity and rules out SIADH as a diagnosis despite Uosm> 100mOsm/kg.

Conclusions: This case report challenges the current diagnostic paradigm for SIADH and shifts focus to often overlooked diagnosis of Reset Osmostat, Hyper responsiveness to ADH, Age related Inability to reduce Free Water excretion as causes of Euvolemic Hyponatremia.

FR-PO341

The Effect of Vasopressin Antagonism on Renal Handling of Water and Sodium and Central and Brachial Blood Pressure during Inhibition of the Nitric Oxide System in Healthy Subjects: A Dose-Response Study

Safa Al Therwani, Jeppe B. Rosenbaek, Frank H. Mose, Jesper N. Bech, Erling B. Pedersen. *Univ Clinic in Nephrology and Hypertension, Dept of Medical Research, Holstebro Hospital and Aarhus Univ, Holstebro, Denmark.*

Background: Nitric Oxide (NO) has an effect on renal water and sodium excretion, but the effect is unknown in the principal cells of the nephron. In a dose-response study, we measured the effect of tolvaptan on renal handling of water and sodium and systemic hemodynamics during baseline and NO-inhibition with L-NMMA.

Methods: In a randomized, placebo-controlled double blind, cross over study, 15 healthy subjects received tolvaptan 15, 30 and 45mg or placebo. L-NMMA was given as a bolus followed by continuous infusion during 60 minutes. We measured GFR, urine output (UO), free water clearance (C_{H2O}), fractional excretion of sodium (FE_{Na}), urinary aquaporin-2 excretion (u-AQP2), urinary excretion of the γ-fragment of the epithelial sodium channel (u-ENaCγ), plasma vasopressin (p-AVP), and central blood pressure (cBP).

Results: During baseline, tolvaptan increased UO and C_{H2O}, whereas GFR and FE_{Na} were unchanged. P-AVP increased three fold. After NO inhibition, UO and C_{H2O} decreased, but to a lesser extent during tolvaptan. FE_{Na} decreased only after placebo. U-AQP2 decreased to the same extent during all tolvaptan doses. U-ENaCγ decreased only after placebo. Central BP increased after NO-inhibition.

Conclusions: During baseline conditions, tolvaptan increased renal water excretion in a dose dependent way. NO-inhibition antagonized the increases in renal water and sodium excretion by tolvaptan. The lack of decrease in u-AQP2 by tolvaptan could be due to a counteracting effect of elevated p-AVP.

FR-PO342

Evidence of Early Enhanced Effects of Vasopressin Type 2-Receptor Antagonist on Urinary Sodium and Potassium Excretion

Sayaka Ishigaki,[1] Takayuki Tsuji,[1] Naro Ohashi,[1] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Vasopressin type 2-receptor antagonist (V2-R antagonist) is well known to promote water diuresis by blocking the permeability to water of the collecting ducts. However, the possible effects of V2-R antagonist on sodium and potassium handling remain to be determined. Recent experimental models suggest that V2-R antagonist induce natriuresis by inhibiting V2-R mediated stimulation of epithelial sodium channel in the collecting duct, and also increase potassium excretion by a flow-dependent mechanism. This study evaluated whether the V2-R antagonist influence the sodium and potassium excretion in humans.

Methods: 5 patients with autosomal dominant polycystic kidney disease (ADPKD) were administered 45mg oral nonpeptide V2-R antagonist, tolvaptan (Tlv). Urine flow, sodium and potassium excretion in the next 3 hours were compared with basal values obtained 2 hours prior administration of Tlv.

Results: Urinary flow rate (93±33®433±112ml/hr; p<0.01), sodium and potassium excretion rate (sodium 8.2±1.8®12.3±2.8 mEq/hr; p<0.01, potassium 2.2±1.2®2.7±1.1 mEq/hr; p<0.01) significantly increased in the first 3 hours after Tlv administration. Subjects significantly lost weight (-0.49±0.30kg, p=0.02) without altering their serum sodium concentration (143.0±2.4®143.6±0.9mEq/L, p=0.61) and plasma osmolality (289.8±4.7®291.6±2.2mOsm/kg•H_2O, p=0.45).

Conclusions: Tlv rapidly increases urinary sodium and potassium excretion in patients with ADPKD.

FR-PO343

Role of Vasopressin in Dehydration-Associated Kidney Disease

L. Gabriela Sanchez-Lozada,[1] Fernando E. García-Arroyo,[1] Monica Gabriela Blas-Marron,[1] Guillermo Gonzaga,[1] Octaviano Silverio,[1] Magdalena Cristobal,[1] Virgilia Soto,[2] Richard J. Johnson,[3] Edilia Tapia.[1] *[1]Renal Physiopathology, INC Ignacio Chavez, Mexico City, Mexico; [2]Pathology, INC Ignacio Chavez, Mexico City, Mexico; [3]Renal Diseases, U of Colorado, Aurora, CO.*

Background: The role of vasopressin in rats undergoing mild thermal dehydration followed by 2 h rehydration with fructose or water, by administering conivaptan, a V1a and V2 antagonist was studied.

Methods: Four groups of male Wistar rats were exposed to hyperthermia (37°C/ 1 h/ day) and rehydrated with water (W) or 10%fructose (F) during 2 h for 30 days. Two groups received vehicle (W+Veh and F+Veh), and two received Conivaptan (C, 3 mg/kg BW, W+C, and F+C). After rehydration rats received tap water and food ad libitum. A group of normal control (NC) rats was also included. At the end of the study, plasma and urine osmolality and plasma copeptin were evaluated. In renal cortex homogenates sorbitol, fructose, uric acid, oxidative stress as well as the expression of aldose reductase, fructokinase, xanthine oxidase, Nox4, p22phox, gp91phox and vasopressin receptors V1a and V2 were assessed.

Results: Chronic recurrent heat stress was associated with mild renal functional changes (decreased CrCl, and tubular injury with systemic inflammation and renal oxidative stress as well as mitochondrial dysfunction) that were markedly exacerbated by rehydration with fructose. Fructose rehydration also markedly enhanced copeptin levels and activation of the aldose reductase-fructokinase pathway in the kidney. Treatment with C effectively blocked the amplification of injury induced by fructose, decreased oxidative stress and reduced the upregulation of the aldose reductase-fructokinase pathway as well as the V1a and V2 receptor induction that occurred in this condition.

Conclusions: Heat stress and recurrent dehydration induce renal injury by stimulating vasopressin. Importantly, this pathway is greatly amplified by fructose provided in rehydration solutions, even at small doses. Thus, these studies may provide insights into the pathogenesis of heat stress nephropathy, and also suggest that the type of rehydration solution may be critical for overall systemic and renal health.

FR-PO344

A Serine Protease Inhibitor Increases Osmotic Free Water Excretion Together with Inhibition of Urinary AQP2 Excretion

Yutaka Kakizoe,[1] Terumasa Nakagawa,[1] Yoshikazu Miyasato,[1] Yuichiro Izumi,[1] Takashige Kuwabara,[1] Masataka Adachi,[1] Kenichiro Kitamura,[2] Masashi Mukoyama.[1] *[1]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Internal Medicine III, Univ of Yamanashi Faculty of Medicine, Japan.*

Background: Serine proteases (SPs) have pivotal physiological roles in our body. In the kidney, it is reported that the epithelial sodium channel (ENaC) is activated via the proteolytic cleavage of α and γ subunits by SPs . We reported that a synthetic SP inhibitor (SPI) camostat mesilate (CM) inhibited the cleavage of γENaC and increased urinary sodium excretion in aldosterone-infused rats. These results suggest the important roles of SPs within the kidney in the regulation of sodium homeostasis and blood pressure. However, physiological roles of SPs in the kidney still remain unclear. In this study, we administered CM to normal rats in order to explore novel physiological roles of SPs in renal tubule and water homeostasis.

Methods: Six-week-old male Sprague-Dawley rats were divided into control and CM groups. CM group rats were subcutaneously implanted with sustained-release pellets of CM (14 mg/day). After 24h urine collection was performed, rats were sacrificed at day 7 to obtain blood and kidney samples. In another experiment, desmopressin (20ng/h) was infused subcutaneously to rats which were treated with CM.

Results: CM significantly increased urine volume in about two-fold throughout the experimental period independently of sodium and osmolyte excretion, indicating that CM increased osmotic free water excretion. The levels of vasopressin, potassium and calcium in blood as well as osmolality in the inner medulla, that is important for urine concentration, were not changed by CM. Urinary exosomal aquaporin-2 (AQP2) excretion was downregulated by CM, indicating that CM suppressed vasopressin signal in collecting duct. The infusion of desmopressin recovered urinary AQP2 excretion and diminished polyuria caused by CM.

Conclusions: Our results suggest that SPs are associated with water homeostasis in the kidney and that SPI could be the new class of diuretics.

FR-PO345

Role of Adenylyl Cyclase 6 in Li+-Induced Nephrogenic Diabetes Insipidus

Soren Brandt Poulsen,[1] Timo Rieg,[2,3] Robert A. Fenton.[1] *[1]Dept of Biomedicine, Aarhus Univ, Aarhus DK-8000, Denmark; [2]VA San Diego Healthcare System, San Diego 92161, CA; [3]Dept of Medicine, Univ of California San Diego, La Jolla 92093, CA.*

Background: Li^+ is a drug widely used for treating bipolar disorders. Around 50% of patients treated with Li^+ develop nephrogenic diabetes insipidus (NDI). How Li^+ treatment causes NDI is poorly understood. One mechanism that has previously been postulated is that Li^+ competes with Mg^+ as a co-factor for adenylyl cyclases (AC), leading to reduced synthesis of cAMP and dysregulation of aquaporin-2 (AQP2) in renal connecting tubule cells and principal cells. Here, we tested the contribution of AC6, the isoform mediating the majority of vasopressin-induced inner medullary cAMP formation, to Li^+-induced NDI.

Methods: We examined the effects of dietary Li^+ intake in whole body AC6 knockout ($AC6^{-/-}$) mice and in newly developed principal cell-specific AC6 knockout mice ($AC6^{loxloxCre}$; Cre expression driven by the AQP2 promotor).

Results: AC6 protein was absent from $AC6^{-/-}$ mice, and significantly reduced in the inner medulla of $AC6^{loxloxCre}$ mice. Similar to $AC6^{-/-}$ mice, $AC6^{loxloxCre}$ mice had ~50% lower urine osmolality and almost double the water intake vs. control mice. Dietary Li^+ administration for 2 weeks exacerbated these effects in $AC6^{-/-}$ and $AC6^{loxloxCre}$ mice vs. controls. Consistent with $AC6^{-/-}$ mice, medullary AQP2 and pS256-AQP2 abundances were significantly lower in $AC6^{loxloxCre}$ vs. control mice during baseline conditions, and levels were further reduced after Li^+ administration. Phosphorylation of glycogen synthase kinase-3 beta (S9-GSK3β), believed to partially mediate Li^+-induced NDI, was significantly increased in $AC6^{loxloxCre}$ vs control mice after Li^+ treatment. $AC6^{loxloxCre}$ mice had a higher number of proliferating cell nuclear antigen-positive cells compared to control mice, indicating increased cellular proliferation as commonly seen during Li^+ administration.

Conclusions: Our results suggest that AC6 plays a minor role in the development of Li^+ induced NDI. Furthermore, the results suggest that the onset of Li^+ NDI is independent of cAMP production in the inner medulla.

Inhibition of Mitochondrial Oxidative Stress Attenuates the Downregulation of AQP2 in Obstructive Kidney Disease: Role of COX-2/PGE2/V2 Receptor Pathway

Zhanjun Jia,[2] Mi Liu,[2] Yue Zhang,[1] Guixia Ding,[1] Songming Huang,[1] Aihua Zhang.[1] *[1]Dept of Nephrology, Nanjing Children's Hospital affiliated to Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Lab of Pediatrics, Nanjing, China.*

Background: Downregulation of aquaporins (AQPs) in obstructive kidney disease has been well demonstrated with elusive mechanisms. Our previous study indicated that mitochondrial dysfunction played crucial role in this process (ASN abstract, 103A, 2014). However, it is still uncertain that how mitochondrial dysfunction affected the AQPs in obstructive kidney disease.This study was undertaken to investigate the role of mitochondria-derived oxidative stress in mediating obstruction-induced downregulation of AQPs.

Methods: Mice with unilateral ureteral obstruction (UUO) or sham surgery were subjected to MnTBAP (a SOD2 mimic) or vehicle treatment by osmotic minipumps.

Results: After UUO for 7 days, renal SOD2 (mitochondria-specific SOD) was reduced by 50% accompanied by a 2.2-fold increase of oxidative stress marker TBARs. Meantime, AQP1, AQP2, and AQP4 were remarkably downregulated by 70-90% as determined by Western blotting and qRT-PCR. Administration of MnTBAP significantly attenuated AQP2 downregulation by 40% ($p<0.05$) in line with complete blockade of TBARs elevation, while AQP1 and AQP4 reduction was not affected. COX-2/PGE2 pathway has been reported to be a contributor of AQPs' reduction in obstructed kidney, thus we detected renal COX-1/2, mPGES-1/2, and PGE2 secretion in the fluid in obstructed ureter by qRT-PCR, Western blotting, or ELISA. Significantly, MnTBAP selectively reduced expressions of COX-2, mPGES-1, and renal secretion of PGE2 by 20 to 30% ($p<0.05$). Moreover, Western blotting and qRT-PCR revealed a marked decrease of V2 receptor by 80%, which was ameliorated by 35% ($p<0.05$) after MnTBAP treatment.

Conclusions: The findings suggested an important role of mitochondrial oxidative stress in mediating AQP2 downregulation in obstructed kidney possibly via modulating COX-2/mPGES-1/PGE2/V2 receptor pathway.

FR-PO348

Extracellular Vesicular Release of Aquaporins in Rats after Kidney Transplantation

Hiroko Sonoda,[1] Tomonori Nakanishi,[2] Tomoyuki Kabayama,[1] Sayaka Oshikawa,[1] Masahiro Ikeda.[1] *[1]Laboratory of Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan; [2]Laboratory of Chemistry and Technology of Animal Products, Univ of Miyazaki, Miyazaki, Japan.*

Background: Kidney transplantation is known to cause diuresis. Renal AQP2 expression has been reported to be down-regulated in an experimental kidney transplantation model, and this reduction is considered to be a cause of the diuresis. Aquaporin-1 (AQP1) and AQP2, water channel proteins, are released into urine via a subset of extracellular vesicles, exosomes. However, the level of urinary exosomal release of those AQPs after renal transplatntion is largely unknown. In this study, we investigated the urinary exosomal release of AQP1 and AQP2 in a rat syngenic kidney transplantation model.

Methods: All animal studies were approved by the committee on the Care and Use of Laboratory Animals at the University of Miyazaki. Male SD rats were used as graft recipients and donors. The donor right kidney was transplanted into the recipient rat in which the right kidney had been removed, and thereafter the remaining left kidney was removed (Tpx group). For the control animal, a simple left kidney nephrectomy was performed. Urine samples were collected at 3 (day 3) and 7 days, and kidney samples were obtained at 7 days after the surgery. Urinary exosomes were isolated by differential centrifugation.

Results: The urinary exosomal release of AQP1 on days 3 and 7, and AQP2 on day 7 were significantly lower in the Tpx group in comparison with the control group. The level of urinary exosomal AQP1 or AQP2 was positively correlated with its renal abundance in the renal cortex. The urinary exosomal release of Alix and TSG101, exosomal marker proteins, were not different in between the Tpx and the control groups.

Conclusions: Urinary exosomal release of AQP1 and AQP2 after kidney transplantation was decreased, and this reduction might be mediated by their renal expression levels but not by a lesser number of exosomes released into urine. Urinary exosomal AQPs might be useful for the estimation of their renal expression levels in renal transplantation.

FR-PO349

Genome-Wide Identification of CREB1 and CEBPB Binding Sites in Vasopressin-Responsive mpkCCD Cells

Hyun Jun Jung, Mark A. Knepper. *Systems Biology Center, NHLBI, NIH.*

Background: In collecting duct principal cells, vasopressin signaling regulates expression of several genes, including those that code for aquaporin-2 (AQP2) and ENaC (β and γ subunits), in part through differential transcription factor (TF) binding. One such TF may be cAMP-responsive element binding protein 1 (CREB1). CREB1 can heterodimerize with another basic-leucine zipper TF, CCAAT/enhancer-binding protein β (CEBPB), which translocates to the nucleus in response to vasopressin. To identify genomic binding sites for CREB1 and CEBPB in vasopressin-responsive mouse mpkCCDc11 cells, we used chromatin immunoprecipitation (ChIP) followed by deep sequencing (ChIP-Seq).

Methods: Cultured mpkCCDc11 cells were treated with the vasopressin analog dDAVP (100pM) or vehicle for 30 min (n=4 pairs for CREB1 and n=2 pairs for CEBPB). Cells were crosslinked and ChIP was performed with ChIP-grade antibodies. DNA libraries were generated and sequenced using an Illumina HiSeq 2000 sequencer. Mapping (mouse UCSC version mm10), peak calling and motif analysis were performed using standard software.

Results: For CREB1, we identified 1634 peaks in vehicle-treated cells and there was no change in response to dDAVP. 70% of these were in the promoter regions of genes. CREB1 did not bind anywhere within 390 kB of the *Aqp2* gene. For CEBPB, we identified 209 binding sites in vehicle-treated cells and the number of sites increased to 2401 with dDAVP. At the 209 sites common between vehicle and dDAVP, CEBPB binding was markedly increased by dDAVP (RPM ratio [dDAVP/vehicle]=2.25). Only about 30% of CEBPB sites were at gene promoters, but there were many intronic sites (40% of total). A strong CEBPB binding site was seen 400 bp downstream from the *Aqp2* gene body. CREB1 and CEBPB sites coincided at 20 positions in the presence of dDAVP.

Conclusions: CREB1 and CEBPB both have potential roles in vasopressin-mediated transcriptional regulation. If CREB1 is involved in regulation of *Aqp2* gene expression, its effect must be indirect since there is no binding site in the vicinity of the *Aqp2* gene. In contrast, the increase in CEBPB binding at many sites in response to dDAVP indicates a likely role for CEBPB in the broad transcriptional effects of vasopressin.

Urine AQP2 Comes from Exosome Pathway and Represents a Long-Term Regulation of Vasopressin

Sei Sasaki,[1,3] Yoko Saijo,[2] Yasukazu Ohmoto,[2] Kiyonori Katsuragi,[2] Kenichi Ishibashi,[3] Keiko Yamamoto,[4] Tadashi Yamamoto.[4] *[1]Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Dept of Research and Development, Otsuka Pharmaceutical Co Ltd, Tokushima, Japan; [3]Dept of Pathophysiology, Meiji Pharmaceutical Univ, Tokyo, Japan; [4]Biofluid Biomarker Center, Inst of Social Innovation and Promotion, Niigata Univ, Niigata, Japan.*

Background: Urine AQP2 is measured in water-balance disorders as a biomarker of vasopressin (VP) action on kidney collecting ducts. VP action consists of two time phases; a short-term regulation starts within minutes and represents increased accumulation of AQP2 at the apical membrane, whereas a long term regulation occurs in hours/days and represents increased abundance of whole AQP2 in the cell. It is unclear which time-phase effects are responsible for the effect of VP on urine AQP2 excretion.

Methods: Stably AQP2-transfected MDCK cells were grown on permeable support and excretion of AQP2 to the apical medium was measured. Human urine EVs were obtained by centrifugation and stored at -25°C to disrupt EVs membranes. Then, AQP2-bearing EVs were obtained by immunoprecipitation with AQP2 antibody and analyzed by LC-MS/MS.In 20 healthy subjects, urine AQP2 was measured by ELISA before and after 500ml water drinking. Urine samples were pretreated with alkali to disrupt EVs membranes.

Results: 1) AQP2 excretion was relatively constant and forskolin 10^{-5}M did not evoke further increases up to 3 hr. **2)** The MS analysis identified 137 proteins in the order of endocytosis pathway proteins (including TSG101, CHMP4, ALIX, VPS4)>MAPK signaling proteins=actin cytoskeleton proteins, suggesting that AQP2-EVs are endocytosis-exosome origin, and may not be ectosome origin. Western blot analysis confirmed the presence of TSG101. **3)** After water drinking, urine osmolalities, creatinine concentrations and AQP2 concentrations decreased from 750 to 371 mOsm/l, from 136.4 to 48.5 mg/dl, and from 5.07 to 1.93 ng/ml, respectively. However, after urine AQP2 values were corrected for creatinine, uAQP2/Cr were not significantly different, 3.37+0.32 and 3.43+041 ng/mg (mean+SE).

Conclusions: Urine AQP2 excretion is mediated by exosome pathway and represents a long term regulation of VP.

Depletion of Vacuolar Protein Sorting-Associated Protein 35(Vps35) Is Associated with Increased Lysosomal Degradation of Aquaporin-2

Hyo-Jung Choi,[1] Eui-Jung Park,[1,2] Tae-Hwan Kwon.[1,2] *[1]Dept of Biochemistry and Cell Biology, School of Medicine, Kyungpook National Univ, Taegu, Korea; [2]BK21 Plus KNU Biomedical Convergence Program, School of Medicine, Kyungpook National Univ, Taegu, Korea.*

Background: Carboxyl-terminus of AQP2 (AQP2c) undergoes post-translational modifications, including phosphorylation and ubiquitination, for the regulation of aquaporin-2 (AQP2) translocation and protein expression. We aimed to identify novel proteins interacting with AQP2c.

Methods: Recombinant AQP2c protein was made in *E. coli* BL21 (DE3) by exploiting the pET32 TrxA fusion system. Lysates of rat kidney inner medullary collecting duct (IMCD) tubule suspensions were interacted with rat AQP2c bound to Ni^{2+}-resin. LC-MS/MS proteomic analysis demonstrated 18 proteins, including vacuolar protein sorting-associated protein 35 (Vps35).

Results: Co-immunoprecipitation assay demonstrated that Vps35 interacted with AQP2c. Immunohistochemistry of rat kidney revealed that AQP2 and Vps35 were co-localized at the intracellular vesicles in the collecting duct cells. The role of Vps35 in the dDAVP-induced AQP2 regulation was examined in mpkCCDc14 cells. Cell surface biotinylation assay demonstrated that dDAVP-induced apical translocation of AQP2 was significantly decreased under the siRNA-mediated Vps35 knockdown. dDAVP-induced AQP2 up-regulation was less prominent in the cells with Vps35 knockdown than control. Moreover, AQP2 protein abundance was decreased to a greater extent during the withdrawal period after dDAVP stimulation under the Vps35 knockdown, which was significantly

inhibited by chloroquine (a blocker of the lysosomal pathway) treatment, but not by MG132 (a proteasome inhibitor) treatment. Immunocytochemistry demonstrated that internalized AQP2 was more associated with lysosomal marker (LAMP-1) in the primary cultured IMCD cells under the Vps35 knockdown.

Conclusions: Vps35 is an interacting protein with AQP2c and depletion of Vps35 is likely to be associated with increased lysosomal degradation of AQP2 protein.

FR-PO352

AQP2 Abundance Is Regulated by the E3-Ligase CHIP via HSP70 as Possible Anchoring Protein for the E3-Ligase MDM2 Mariangela Centrone,[1] Marianna Ranieri,[1] Sante Princiero Berlingerio,[1] Annamaria Russo,[1] Annarita Di Mise,[1] Peter M.T. Deen,[2] Olivier Staub,[3] Giovanna Valenti,[1] Grazia Tamma.[1] *[1]Univ of Bari Aldo Moro, Italy; [2]Radboud Univ Medical Center, Netherlands; [3]Univ of Lausanne, Switzerland.*

Background: AQP2 is mainly controlled by vasopressin-dependent changes in protein abundance which is in turn regulated by AQP2 ubiquitylation and degradation, but the proteins involved in these processes are largely unknown. Here, we investigated the potential role of the CHIP E3 ligase in AQP2 regulation.

Methods: Coimmunoprecipitation and Western Blotting experiments were performed to evaluate CHIP involvement on AQP2 half-life and phosphorylations.

Results: AQP2 complexes with CHIP in kidneys and renal MCD4 cells. Expression of CHIP increased proteasomal degradation of AQP2 and HSP70 abundance, a molecular signature of HSP90 inhibition. Chemical inhibition of HSP90 with 17-AAG led to increased level of HSP70 and AQP2 degradation. Increased HSP70 level, secondary to CHIP expression, promotes ERK signaling which increases of phosphorylation of AQP2 at S261. Phosphorylation of AQP2 at S256 and T269 were instead downregulated. Next, we investigated HSP70 interaction with AQP2 which is important for endocytosis. Compared with AQP2-wt, HSP70 binding decreased in AQP2-S256D and AQP2-S256D-S261D while increased in AQP2-S256D-S261A. Surprisingly, expression of CHIP-delUbox, displaying a loss of E3 ligase activity, still induced AQP2 degradation, indicating that CHIP does not ubiquitylate and degrade AQP2 itself. Interestingly, the AQP2 half-life was increased with CHIP-delTPR. Its TPR domain binds Hsc70/Hsp70 and Hsp90. So, which E3 ligase then mediates AQP2 degradation with CHIP? Importantly, HSP70 has been reported to bind other E3 ligases such as MDM2. Interestingly, we found that co-expression of CHIP and MDM2 increased AQP2 degradation, whereas co-expression of CHIP with MDM2-delRING, an inactive form of MDM2, impaired AQP2 degradation.

Conclusions: Our findings indicate CHIP as master regulator of AQP2 degradation via HSP70 that has dual functions: (1) as chaperones for AQP2 (2) as possible anchoring protein for MDM2 E3 ligase, which appears to be committed to AQP2 degradation.

FR-PO353

Use of CRISPR and Phosphoproteomics to Investigate the Role of Myosin Light Chain Kinase in Vasopressin Signaling Kiyoshi Isobe, Viswanathan Raghuram, Chin-Rang Yang, Pablo Sandoval, Chung-Lin Chou, Mark A. Knepper. *Systems Biology Center, NHLBI, NIH.*

Background: Vasopressin regulates trafficking of aquaporin-2 (AQP2) to and from the plasma membrane. We have previously reported that Ca^{2+}-calmodulin and myosin light chain kinase (MLCK) are involved in AQP2 trafficking, although the mechanisms are unclear. To address this issue, we generated MLCK knock-out (MLCK-KO) collecting duct cell lines using genome editing (CRISPR-Cas9) in mouse mpkCCD cells.

Methods: Four independent KO lines were generated using different guide RNAs. Control cells with intact MLCK were generated in the same experiments. Successful deletion was confirmed by western blotting and genomic sequencing.

Results: The MLCK-KO cells were viable and grew at approximately the same rate as control cells. However, the MLCK-KO cells were broader and flatter. Phalloidin staining revealed that vasopressin-mediated dissolution of basolateral stress fibers was slower in the MLCK-KO cells. Vasopressin-stimulated AQP2 phosphorylation at Ser256 and Ser269 did not differ versus control cells (western blotting and immunofluorescence). Upon vasopressin washout, AQP2 rapidly appeared in early endosome antigen 1 (EEA1)-positive intracellular vesicles in control cells. However, in MLCK-KO cells, AQP2-EEA1 co-localization was markedly delayed (STED microscopy), suggesting that MLCK plays a role in trafficking at the level of early endosomes. Also, EEA1-positive vesicles were much smaller in the MLCK-KO cells. To assess the signaling pathways affected, we carried out quantitative phospho-proteomics of vasopressin-treated MLCK-KO cells versus control cells (SILAC). There was a substantial decrease in phosphorylation of 18 proteins at TpS motif sites in addition to myosin regulatory light chain, identifying putative MLCK substrates. Interestingly, activation loop phosphorylation increased in several protein kinases including ERK1, ERK2, p38α, p38Δ, GSK3α and protein kinase D3, implying that MLCK may be involved in negative feedback of other kinase pathways.

Conclusions: These results indicate a role for MLCK in AQP2 trafficking at the level of early endosomes, and in signaling pathways beyond phosphorylation of myosin regulatory light chain.

Gain-Of-Function Mutations in the Vasopressin Type 2 Receptor Causing Nephrogenic Syndrome of Inappropriate Antidiuresis (NSIAD): Evidence for Vasopressin-Independent Increase in AQP2 Trafficking and Osmotic Water Permeability Marianna Ranieri, Grazia Tamma, Tommaso Pellegrino, Giovanna Valenti, Susanna Cotecchia. *Univ of Bari Aldo Moro.*

Background: Nephrogenic syndrome of inappropriate antidiuresis (NSIAD) results from gain-of-function mutations in the *AVPR2* gene coding for vasopressin receptor 2 (V2R) and is characterized by spontaneous antidiuresis and undetectable vasopressin circulating levels. Here, we investigate the effects of two mutations, R137C and F229V, on receptor-mediated intracellular signaling controlling AQP2 trafficking and function.

Methods: M1 cells were stably co-transfected with human AQP2 and wild type (WT) V2R or its mutants V2-R137C and V2R-F229V. AQP2 trafficking was evaluated by confocal studies and western blotting experiments. Osmotic water transport was evaluated by a calcein-based method. Intracellular cAMP was measured by cAMP ELISA kit.

Results: Confocal studies revealed that in cells expressing V2R-R137C, AQP2 was in part localized to the plasma membrane while a clear plasma membrane localization was found for cell expressing V2R-F229V. Functional experiments revealed a slight though significant increase in temporal osmotic response in cells expressing V2R-R137C whereas expression of V2R-F229V strongly increased the osmotic water permeability compared to cells expressing the WT receptors. Since AQP2 trafficking can be regulated by phosphorylation, we next evaluated AQP2 phosphorylation state in cells expressing the receptors. A significant increase in AQP2-S256 and AQP2-T269 phosphorylation, associated with significantly higher cAMP levels, was found in cells expressing V2R-F229V. Interestingly, in cells expressing V2R-R137C significantly lower levels of AQP2-S261 phosphorylation paralleled by decreased phosphorylation of p38-MAPK, the kinase committed to phosphorylate S261, were observed likely resulting in lower extent of AQP2 degradation.

Conclusions: These findings suggest that the constitutive activity of the V2R-R137C and V2R-F229V mutants upregulates AQP2 trafficking through two different signaling pathways. Whereas, V2R-F229V induces a cAMP-dependent increase of AQP2 phosphorylation, V2R-R137C seems to increase AQP2 abundance in cells.

FR-PO355

Acute Activation of AMPK Inhibits Aquaporin-2 Nuria M. Pastor-Soler,[1] Mohammad M. Al-Bataineh,[2] Hui Li,[1] Kazuhiro Omi,[1] Fan Gong,[2] Allison L. Marciszyn,[2] Sajid Naveed,[2] Xiaoqing Zhu,[3] Dietbert Neumann,[3] Qi Wu,[4] Lei Cheng,[4] Robert A. Fenton,[4] Kenneth R. Hallows.[1] *[1]Div of Nephrology and Hypertension, Kidney Research Center, Keck School of Medicine of USC, Los Angeles, CA; [2]Renal-Electrolyte Div, Univ of Pittsburgh, Pittsburgh, PA; [3]Molecular Genetics, Maastricht Univ, Maastricht, Netherlands; [4]Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: Aquaporin-2 (AQP2) maintains water homeostasis and traffics from intracellular vesicles to the apical membrane of principal cells in response to vasopressin (AVP), which is released with low intravascular volume. Decreased kidney perfusion activates AMP-activated kinase (AMPK), a metabolic sensor that inhibits several transport proteins. We hypothesized that AMPK inhibits AQP2 possibly to protect the interstitial gradient required for urine concentration during metabolic stress when low intravascular volume induces AVP release and there is decreased distal nephron perfusion.

Methods: We used ex vivo kidney slices, hypotonic lysis of AQP2-expressing *Xenopus* oocytes, surface biotinylation of $mpkCCD_{cl4}$ cells, phosphorylation assays, and mass spectrometry.

Results: Acute AMPK activation with 5-aminoimidazole-4-carboxamide-1-β-D-ribofuranoside (AICAR; 75 min) in kidney slices prevented baseline AQP2 apical accumulation in principal cells but did not prevent AQP2 apical accumulation in response to the AVP analog desmopressin (dDAVP). Prolonged AMPK activation prevented AQP2 cell membrane accumulation in response to forskolin in mouse collecting duct cells. Moreover, AMPK inhibition accelerated hypotonic lysis of *Xenopus* oocytes expressing AQP2. AMPK promoted Ser-261 phosphorylation and antagonized dDAVP-dependent phosphorylation of other AQP2 COOH-terminal sites. Although AMPK weakly phosphorylated immunoprecipitated AQP2 *in vitro*, no direct AMPK phosphorylation of the AQP2 C-terminus was detected by mass spectrometry.

Conclusions: Our findings suggest an increasing, time-dependent antagonism of AMPK on AQP2, as AICAR inhibits cAMP-dependent apical accumulation and AVP-dependent phosphorylation of AQP2. AMPK inhibition of AQP2 likely does not involve direct AQP2 phosphorylation by AMPK.

FR-PO356

Effects of Nephrotoxins on Claudin 2 Expression and Paracellular Water Transport Anja Wilmes, Paul Jennings. *Physiology and Medical Physics, Physiology, Innsbruck, Tirol, Austria.*

Background: Tight junction proteins are important for the selective permeability of the paracellular route and thus tissue specific function. In the proximal tubulus the pore forming claudins, claudin 2 and 10 are highly expressed, contributing to the high permeability within this part of the nephron. Recently it has been shown that claudin 2 is not only permeable to

cations, but also to water and thus has a critical role in proximal tubule paracellular water transport. We have previously shown that claudin 2 is decreased and water transport is inhibited in response the nephrotoxin cyclosporine A. Here we investigate a potential link between oxidative stress, claudin-2 regulation and paracellular water transport.

Methods: The human proximal tubular cell line RPTEC/TERT1 was cultured on micropourous growth supports (PET filters) and exposed to sub-toxic concentrations of oxidative stress inducing nephrotoxins, including diquat dibromide and potassium bromide and pharmacological Nrf2 activators, including bardoxolone methyl (CDDO methyl ester) and AI-1. Trans-epithelial electrical resistance (TEER) and apical to basolateral water transport were monitored. Claudin 2 and 10 expressions were measured by western blotting or immunofluorescence.

Results: All compounds induced downstream targets of the Nrf2 oxidative stress response pathway, including heme oxygenase 1 (HMOX1) and NQO1. Both, nephrotoxins and Nrf2 activators, affected claudin 2 expression and inhibited water transport. For most compounds neither claudin-10 nor TEER were affected.

Conclusions: The results suggest that claudin 2 expression is linked to Nrf2 activation and that oxidative stress is likely to decrease proximal tubule water reabsorption.

FR-PO357

Regulated Ser-261 Dephosphorylation Combined with Ser-256 and Ser-269 Phosphorylation in the C-Terminus of Aquaporin-2 Water Channel

Naofumi Yui, Sei Sasaki, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

Background: AQP2 has multiple vasopressin-sensitive phospho-serine sites in its C-terminus. It is known that pS261 decreases and pS269 increases stimulated by vasopressin with a constant Ser-256 phosphorylation, however; how these phosphorylation and dephosphorylation is regulated in combination remains to be clarified.

Methods: In this study, we performed combinatorial analysis of AQP2 phospho-regulation in the acute phase of forskolin (FK) stimulation. AQP2-MDCK cells were either treated or not treated with FK (20 μM) and then subjected to phospho-specific immunoprecipitation assays.

Results: First, we performed time-series analysis of phosphorylation in the initial phase of FK stimulation. A significant increase of pS269 was detectable within 1 min. A significant decrease of pS261 was detectable at 10 min, however; it was not occurred at 1 min. During the stimulation, pS256 status was constant. This demonstrated that Ser-269 phosphorylation preceded Ser-261 dephosphorylation. Next, pS256-positive AQP2 was isolated by the phospho-specific immunoprecipitation. In the steady state, pS256-positive AQP2 was strongly phosphorylated at Ser-261. After 10 min of FK treatment, pS269 signal significantly increased (1.00±0.12 to 5.62±0.25,P<0.01, n=4) and pS261 signal strongly decreased (1.00±0.05 to 0.30±0.13,P<0.01, n=4) in the pS256-positive AQP2 population. Further, pS269-positive AQP2 was isolated after 1 min or 10 min of FK treatment. At 1 min, pS261 signal was strongly detectable in the pS269-positive AQP2. After 10 min of the treatment, pS261 signal in the pS269-positive AQP2 population strikingly decreased (1.00±0.07 to 0.30±0.12,P<0.01, n=4).

Conclusions: In conclusion, pS256-positive AQP2 is strongly phosphorylated at Ser-261 to form pS256-pS261-AQP2 in the steady state. Upon FK stimulation, it quickly transformed into pS256-pS261-pS269-AQP2 and then converted to pS256-pS269-AQP2 dephosphorylated at Ser-261 a little later. These results first directly defined the basic principle of combinatorial AQP2 phospho-regulation in the cell, showing that Ser-261 dephosphorylation is involved in the pS256- and pS269-intervened acute AQP2 regulation.

FR-PO358

Protein Phosphatase 2c Is Responsible for S261 De-Phosphorylation, but Did Not Affect Aquaporin-2 Trafficking

Pui Wen Cheung, Lars Ueberdiek, Richard Bouley, Dennis Brown. *Medicine/Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Aquaporin-2 (AQP2) trafficking and degradation are regulated by phosphorylation and de-phosphorylation of 4 essential serine sites on the AQP2 c-terminus. Upon vasopressin (VP) stimulation, it is thought that S256 needs to be phosphorylated first for other serine residues (S264 and S269) to be phosphorylated or dephosphorylated (S261). We were interested in identifying the phosphatase that de-phosphorylates S261, and determining whether this process is dependent on S256, the major regulator of AQP2 trafficking.

Methods: We pretreated LLC-PK1 cells stably expressing AQP2 (LLC-AQP2) with protein phosphatase (PP) inhibitors including, okadaic acid, an inhibitor of PP1, PP2a, PP3 and PP5; cyclosporine, an inhibitor of PP2b, and sanguinarine, which inhibits PP2c. After 10 min VP treatment, we used immunocytochemistry to determine AQP2 localization, and western blot and specific phospho-antibodies against S256 and S261 to measure phosphorylation. We also treated *rat* kidney tissue slices to confirm AQP2 localization in situ by pre-treating tissues with PP inhibitors before VP.

Results: Inhibition of protein phosphatases (PP) with okadaic acid, cyclosporine or sanguinarine did not lead to a noticeable alteration of AQP2 trafficking in LLC-AQP2 cells or in our *in situ* rat kidney slice model. They also did not induce a significant change in S256 phosphorylation or S261 dephosphorylation on their own. Interestingly, we found that VP-induced de-phosphorylation of S261 occurred not only in LLC-AQP2 cells, but also S256A mutant cells. Importantly, VP induced S261 de-phosphorylation was almost completely prevented by inhibiting PP2c with sanguinarine but not the other PP inhibitors. Blocking S261 dephosphorylation with sanguinarine did not, however, affect VP-induced AQP2 membrane accumulation in either cultured cells or kidney tissue.

Conclusions: Our results show that S261 de-phosphorylation is dependent on protein phosphatase 2C activity, and is independent of S256 phosphorylation. These findings suggest an independent pattern of phosphorylation of some AQP2 C-terminal serine residues that will allow more detailed study of their physiological functions.

Proteomic Analysis of a Proximal Tubular Specific Polycystic Kidney Disease Model of AQP11 Deficient Mice

Tatsuya Saito, Yasuko Tanaka, Sei Sasaki, Kenichi Ishibashi. *Pathophysiology, Meiji Pharmaceutical Univ, Kiyose, Tokyo, Japan.*

Background: AQP11 is expressed at the ER of proximal tubular cells and its disruption leads to polycystic kidney disease (PKD) by a failure of polycystin-1 trafficking to the plasma membrane due to its defective glycosylation at the ER. As the cyst comes solely from the proximal tubule, it will be a good model to clarify whether the cystogenesis of the proximal tubule is similar to that of the collecting duct in ADPKD. Here we conducted proteomic analysis of the kidney from AQP11-null mice.

Methods: Mouse Kidneys from 3 week old AQP11-null mice and their wild-type littermates were compared at the beginning of cyst formation. Tissue samples were sonicated and digested in a sodium deoxycholate buffer. Each sample was labeled with 6-plex TMT labeling reagent, a mixture of the samples were separated by nano-flow HPLC and introduced to mass spectrometer, Q-Exactive (Thermo Fisher Scientific).

Results: A total of 755 differently expressed proteins were identified, in which 205 proteins were more abundant and 534 proteins were less abundant in AQP11-null mice. The increased proteins included transgelin (transformation sensitive actin crosslinking protein), galectin-3 (lectin family) and uromodulin (UMOD: Tamm-Horsfall protein). The enhanced UMOD may indicate a tubular injury of the distal nephron by ectatic proximal tubules or its stimulated compensatory function. AQP11-null kidney also displayed an increase of extracellular matrix-related proteins including vimentin, collagen and fibulin, and of cytoskeleton-related proteins including paladin, alpha-actinin, and keratin. On the other hand, mitochondrial proteins were decreased including succinyl-CoA ligase, lysophospholipid acyltransferase, and a Pi transporter (slc25a3), which may reflect a mitochondrial dysfunction leading to apoptosis.

Conclusions: Proteomics approach of the kidney from AQP11-null mice presented itself to be a promising tool to clarify a unique pathology of early stage of proximal tubular specific polycystic kidneys, which will lead to the discovery of key molecules for the formation and progression of the proximal tubular cysts in ADPKD.

Gender Comparison of Volume Regulating Hormones and Aquaporin-2 Excretion following Graded Central Hypovolemia

Nandu Goswami,[1] Johannes Reichmuth,[1] Annamaria Russo,[2] Mariangela Centrone,[2] Irhad Trozic,[1] Rebecca Ruedl,[1] Andreas Roessler,[1] Marianna Ranieri,[2] Annarita Di Mise,[2] Catia Ilenia Carbutti,[2] Ferdinando Sasso,[3] Natale Gaspare De Santo,[3] Grazia Tamma,[2] Giovanna Valenti.[2] *[1]Medical Univ; [2]Univ of Bari; [3]Second Univ of Naples.*

Background: Central hypovolemia induced by orthostatic loading induces reno-vascular changes that can lead to syncope. In this study we investigated volume regulating hormonal responses and reno-vascular changes in male and female subjects as they underwent central hypovolemia, induced by graded lower body negative pressure (LBNP).

Methods: 37 subjects (n = 19 males; n = 18 females. ages: 18 - 30 yrs) were subjected to graded LBNP until LBNP of 40 mmHg. Blood and urine samples were collected at rest and after 10 min recovery. The volume regulating hormones Vasopressin (measured as copetin); Brain natriuretic peptide (BNP), ACTH and adrenomedullin (ADM) were measured in the plasma using standard methods. Urinary-AQP2 excretion was measured by ELISA as biomarker for the renal system response to vasopressin.

Results: Under basal conditions, males had significantly higher vasopressin levels compared with females. However both sexes responded to the central hypovolemia with a significant reduction of vasopressin levels, as measured at 10 min of recovery. BNP, secreted by the ventricles of the heart in response to excessive stretching of heart, was higher in males than in female under basal conditions and increased significantly after the orthostatic stress only in female. Conversely, ADM, a vasodilator peptide hormone, increased significantly after orthostatic loading only in males. u-AQP2 excretion was significantly higher in females than in males at rest and did not change significantly after 10 min recovery.

Conclusions: Analysis of volume regulating hormones indicate that soon after returning to the supine position at the end of the central hypovolemia, the expected sudden volume loading should stimulate afferent inputs to the brain, leading to inhibition of vasopressin release in males and females and stimulating a preferential adaptive vascular response in males as shown by the increases in ADM, whereas females showed a preferential renal response as shown by the increases in BNP.

FR-PO361

Sex-Dependent Differences in Water Homeostasis in Wild-Type and V-ATPase B1 Knockout Mice Anil V. Nair, Teodor G. Paunescu, Richard Bouley, Dennis Brown. *Prog. in Memb. Biol. and Div of Nephrology, Mass. Gen. Hospital, Boston, MA.*

Background: Since the extent of dehydration in humans during prolonged exercise is sex-dependent, we investigated water homeostasis in male and female wild-type (WT) C57BL/6 mice. Since renal β-intercalated cells (ICs) were reported to play a role in fluid balance, we also assessed the water concentrating ability of mice deficient in the V-ATPase B1 subunit ($B1^{-/-}$ mice).

Methods: We assessed the water concentrating ability of male and female mice using urine analysis in metabolic cage experiments, immunofluorescence and immunoblotting.

Results: Baseline urine osmolality trended towards higher values in females (2756±278 mOsm/kg) than in males (2420±185 mOsm/kg). 12 h water deprivation decreased urine output by 57% in females (3664±244 mOsm/kg) and by 52% in males (3468±318 mOsm/kg). Urine output increased significantly in B1-/- mice compared to WT, by 10% in males and 29% in females. Whereas in water-deprived B1-/- mice it decreased by 46% in females, but by only 17% in males, compared to WT. AQP2 protein levels were lower in B1-/- than in WT males, but higher in B1-/- than in WT females. The baseline subcellular localization of AQP2 in principal cells (PCs) was more polarized towards the apical membrane in WT females than in males. In both genotypes, AQP2 relocates towards the apical pole of PCs to a larger extent in water-deprived females than in males. Urine output of water-deprived WT decreased, from 1.35 to 0.66 (p=0.004) in males and from 1.55 to 0.68 ml/12 h/animal (p<0.001) in females. In water-deprived B1-/- mice, urine output decreased significantly only in females, from 2.17±0.22 to 1.16±0.15 (p<0.001), whereas the decrease in B1-/- males was not significant (1.5±0.19 vs 1.24±0.14 ml/12 h/animal). Intriguingly, water deprivation caused a decrease in urine pH only in B1-/- females (7.01 to 6.71, p=0.016). We also found females to have a higher IC/PC ratio than males, and B1-/- mice of both sexes to have a higher ratio than WT.

Conclusions: Our data support the idea that ICs are involved not only in maintaining acid-base balance but also in water homeostasis, that the mechanism is at least partially mediated by the V-ATPase, and that these processes are sex-dependent.

FR-PO362

Sex-Specific Relationship of Serum Uric Acid with All-Cause Mortality in Adults with Normal Kidney Function—An Observational Study Eunjeong Kang, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: Serum uric acid (SUA) levels are associated with cardiovascular mortality and other diseases such as hypertension, diabetes, and chronic kidney disease. Although SUA possibly influences on all-cause mortality in individuals with normal kidney function, studies are lacking in normal kidney function.

Methods: Participants aged over 40 years who underwent routine health check-ups at Seoul National University Hospital between 1995 and 2006 were recruited. Individuals with estimated glomerular filtrations rates <60 mL/min/1.73 m^2 and who received lab study and colonoscopy on the same day were excluded. The association between SUA and all-cause mortality was evaluated using the COX proportional hazard regression models with adjustment for covariates including diabetes, hypertension, age, body mass index, blood pressure, creatinine, albumin, hemoglobin, C-reactive protein, smoking, and exercise.

Results: SUA levels were higher in men than in women (5.7±1.2 mg/dL for men and 4.2±0.9 mg/dL for women, $P < 0.001$). SUA levels declined as age increased in men but increased with age in women. During 12.3±3.6 years of follow-up, 1,402 deaths occurred. 6.9% of men and 3.1% of women died. The overall mortality rate had a U-shaped association with SUA levels, a J-shaped association in men, and no association in women. There was a significant interaction of sex for the SUA-mortality association (P for interaction = 0.049); therefore, survival analysis was conducted by sex. In men, the lower SUA group had a higher mortality rate after adjustment (SUA, <4.0 mg/dL, adjusted hazard ratio [HR] 1.550, 95% confidence interval [CI] 1.235–1.946, $P < 0.001$) compared with the reference group (SUA, 6.1–8.0 mg/dL). A higher SUA contributed to an insignificant increased mortality in men (>8.0 mg/dL, adjusted HR 1.305, 95% CI 0.904–1.884, $P = 0.16$). Women failed to show any significant association between SUA and mortality.

Conclusions: This study provided novel evidence that SUA-mortality association differed by sex. We demonstrated that a lower SUA was an independent risk factor for all-cause mortality in men with normal kidney function.

FR-PO363

Uric Acid Predicts Mortality and Ischemic Stroke in Subjects with Diastolic Dysfunction - The Tromso Study 1994-2013 Jon V. Norvik,[1,2] Henrik Schirmer,[1,2] Trond G. Jenssen,[2] Bjorn Odvar Eriksen,[1,2] Maja-Lisa Løchen,[2] Marit D. Solbu.[1,2] *[1]Univ Hospital of North Norway, Tromsø, Norway; [2]UiT The Arctic Univ of Norway, Tromsø, Norway.*

Background: Elevated serum uric acid is associated with cardiovascular disease and increased mortality in patients with heart failure. We investigated whether serum uric acid predicts adverse outcomes in persons with indices of diastolic dysfunction in a general population.

Methods: We performed a prospective cohort study among 1460 women and 1480 men from 1994 to 2013. Endpoints were all-cause mortality, incident myocardial infarction and incident ischemic stroke. We analyzed hazard ratios (HR) for these endpoints per 59 μmol/L increase in baseline uric acid. We stratified the analyses by echocardiographic markers of diastolic dysfunction.

Results: Multivariable adjusted Cox regression analyses showed that uric acid predicted all-cause mortality in subjects with E/A ratio < 0.75 (HR 1.12, 95% confidence interval [CI] 1.00-1.25, p = 0.04) or E/A ratio > 1.5 (HR 1.51, 95% CI 1.09-2.09, p = 0.01, p for interaction between E/A ratio category and uric acid = 0.02). Uric acid also increased mortality risk in persons with E-wave deceleration time < 140 ms or > 220 ms (HR 1.46, 95% CI 1.01-2.12, p = 0.04 and HR 1.13, 95% CI 1.02-1.26, p = 0.02, respectively; p for interaction = 0.04). Furthermore, in participants with isovolumic relaxation time ≤ 60 ms, mortality risk was far higher with increasing uric acid (HR 4.98, 95% CI 2.02-12.26, p < 0.001, p for interaction = 0.004). Finally, uric acid predicted ischemic stroke in subjects with severely enlarged left atria (HR 1.62, 95% CI 1.03-2.53, p = 0.04, p for interaction = 0.047).

Conclusions: Uric acid was a predictor of all-cause mortality in subjects with echocardiographic indices of diastolic dysfunction, and was associated with increased ischemic stroke risk in persons with severely enlarged left atria.

FR-PO364

ITM2B Inhibits the Urate Transporter GLUT9: A Link between Uric Acid Homeostasis and Neurodegeneration? Asim Mandal,[1] David B. Mount.[1,2] *[1]Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Renal Div, VA Boston Healthcare System, Boston, MA.*

Background: The level of serum uric acid (SUA) has both causative and protective roles in human disease, with protective effects of hyperuricemia in neurodegenerative diseases. Of the multiple genes associated in genome-wide association studies with SUA, variation in the SLC2A9 gene encoding the urate transporter GLUT9 is a primary determinant; basolateral GLUT9 functions as the exit pathway for urate in the proximal tubule, with widespread expression including brain.

Methods: Here we report the identification of a GLUT9-interacting protein, ITM2B, isolated from a human kidney cDNA library using the ubiquitin ligase, membrane associated yeast two-hybrid system. ITM2B is implicated in the processing of beta-amyloid in Alzheimer's disease, genetic mutations in ITM2B are furthermore associated with Danish Dementia, British Dementia and a form of retinal dystrophy.

Results: ITM2B and GLUT9 mRNAs are readily detectable in a human renal proximal tubule cell line; ITM2B protein is also detectable by immunohistochemistry in human proximal tubule. Strong physical interaction between ITM2B and N- GLUT9 isoforms was confirmed by co-immunoprecipitation followed by Western blot analysis, in both transiently co-transfected HEK-293T cells and in *Xenopus laevis* oocytes. Coexpression with ITM2B resulted in a reduction in complex N-glycosylation of GLUT9. However, N-glycosylation mutants of GLUT9 revealed that N-glycosylation of GLUT9 is redundant for interaction with ITM2B, expression at the plasma membrane, and urate transport function. However, ITM2B mutants associated with Danish and British dementia,retinal dystrophy, or defective N-glycosylation (N170Q) physically interacted with GLUT9 isoforms but were significantly less potent than wild-type ITM2B in inhibiting GLUT9-mediated urate transport.

Conclusions: ITM2B associates with GLUT9 and inhibits urate transport, with an attenuated effect for ITM2B mutants associated with neurodegenerative disorders. The interaction between ITM2B and GLUT9 provides a provocative mechanistic link between urate homeostasis and neurodegenerative disorders.

FR-PO365

Fractional Uric Acid Excretion Is Increased in Mice Lacking SGLT2 Aleksandra Novikov,[1] Yiling Fu,[1] Akira Onishi,[1] Panai Song,[1] Winnie Huang,[2] Volker Vallon.[1] *[1]Nephrology, Univ of California San Diego, San Diego, CA; [2]Nephrology, VA San Diego, San Diego, CA.*

Background: Glycosuric diabetic patients have higher urinary uric acid (UA) excretion and lower serum UA levels. This is also seen with glycosuric SGLT2 inhibitors in diabetics indicating that increased tubular glucose may facilitate urinary UA excretion. To test this further we studied A) non-diabetic mice lacking SGLT2 (Sglt2-/-) or SGLT1 (Sglt1-/-) and B) the SGLT1/SGLT2 inhibitor, phlorizin.

Methods: A) Retrobulbar blood samples and urine were collected from Sglt1-/-, Sglt2-/- and corresponding littermate wild type mice (WT). Serum and urine was analyzed for creatinine (HPLC) and UA (Amplex red uric acid assay) to calculate fractional renal excretion (FE), together with urinary glucose; n=6-10/group. B) C57 mice were saline loaded by oral gavage (30 μl/g bw) to facilitate subsequent quantitative urine collection in metabolic cages for 3 hours plus given either an i.p. injection of phlorizin (400 mg/kg) or vehicle (50% mix of propylene glycol/saline); n=5-7/group.

Results: A) Sglt1-/- presented the expected modest increase in urine glucose to creatinine ratio (Gl:Cr; μmole/mg) compared with WT (92±6 vs 4±1; P<0.005), but the FE of UA (FeUA) was not different (12±1 vs 14±3%; NS). Urine Gl:Cr was strongly increased in Sglt2-/- vs WT (4194±550 vs 3±1) and this was associated with a significant increase in FeUA (21±5 vs 2±1%)(both P< 0.001). B) In saline loaded mice, phlorizin induced glucosuria (841±109 vs 3±1 nmol/min; P<0.001), but unexpectedly reduced UA excretion (0.16±0.04 vs 1.39±0.29 nmol/min; P<0.001) while phosphate excretion remained unchanged (1.2±0.3 vs 1.8±0.7 ng/min).

Conclusions: Mice lacking SGLT2 are glucosuric and show an increase in FeUA consistent with observations using SGLT2 inhibitors in patients. Absence of SGLT1 induced

a lesser glucosuria without affecting FeUA. Unexpectedly, i.p. phlorizin application in saline-loaded mice acutely reduced urinary UA excretion despite inducing glucosuria. Further studies will test a) whether increasing plasma UA levels in mice to human levels (by blocking uricase) affects the quality of the latter response and b) the response to selective SGLT2 inhibitors.

Evidence of Phospho-Degron Regulating Expression of Urate Secretory Transporter ABCG2

Owen M. Woodward,[1] Alexis Hofherr,[2] Meng Li,[1] Michael Kottgen.[2] *[1]Physiology, Univ of Maryland School of Medicine, Baltimore, MD; [2]Nephrology, Univ Medical Centre Freiburg, Freiburg, Germany.*

Background: ABCG2 is a high capacity urate secretory transporter of the renal proximal tubule. The common Q141K ABCG2 mutation causes gout in humans through an increased instability of the nucleotide-binding domain leading to enhanced degradation and reduced function.

Results: Here, we found ABCG2 protein rescued from degradation with the proteasome inhibitor MG-132 is phosphorylated; raising the possibility that a phospho-degron regulates ABCG2 trafficking and expression. An *in silico* analysis of ABCG2 revealed a limited number of predicted phosphorylation sites, including S195, a serine conserved in the mammalian lineage. The upstream RXRXS represents a target motif for AKT1 and PKA, which both co-immunoprecipitated with ABCG2. Specifically, endogenous AKT1 pulled down both over expressed ABCG2 in HEK293 cells as well as endogenous ABCG2 in mouse kidney lysate. AKT1 and ABCG2 transcript co-localize in the proximal S2 segment of the mammalian nephron and inhibiting the AKT1 kinase cascade with PI3K inhibitor LY294002, or with growth factor receptor (RTK) inhibitor Vandetanib, dramatically up-regulated ABCG2 expression. Conversely, activating the AKT1 cascade with FBS down-regulated ABCG2 expression. Replacement of the S195 residue with a phosphomimetic aspartic acid resulted in significant reduction in ABCG2 expression, localization of ABCG2 to peri-nuclear compartments, and significant sensitivity to MG-132; confirming the S195 residue as a phospho-degron. Finally, a non-phosphorylatable S195A substitution led to the complete rescue of the Q141K gout mutant protein expression and trafficking.

Conclusions: Modeled ABCG2 structure indicates phosphorylation of the S195 residue may only be possible when the nucleotide-binding domains are separated, suggesting the S195 phospho-degron may be part of a novel regulatory mechanism for function and trafficking in ABC transporters. **American Heart Association: 14SDG18060004 & Ardea BioSciences**.

FR-PO367

Aldosterone and Vasopressin Are Erythropoietic Hormones

Hiroshi Nonoguchi,[1] Yuichiro Izumi,[2] Yukiko Yasuoka,[3] Yushi Nakayama,[2] Takanori Nagai,[4] Masayoshi Nanami,[4] Takeshi Nakanishi,[4] Masashi Mukoyama,[2] Katsumasa Kawahara.[3] *[1]Internal Medicine, Kitasato Univ Medical Center, Kitamoto, Saitama, Japan; [2]Nephrology, Kumamoto Univ, Kumamoto, Japan; [3]Physiology, Kitasato Univ, Sagamihara, Kanagawa, Japan; [4]Kidney and Dialysis, Hyogo Medical College, Nishinomiya, Hyogo, Japan.*

Background: Erythropoietin (Epo) is produced by the renal tubules in response to hypoxia and/or anemia (Nagai T, et al. BBRC 2014). We investigated the effects of aldosterone and vasopressin on mRNA expression of Epo in distal nephron segments.

Methods: Tubule suspensions (TS) of cortex (CX), outer medulla (OM) and inner medulla (IM) were prepared from 5-7 week-old rats. Nephron segments were microdissected after the incubation of kidney slices in solution containing collagenase and VRC. TS or nephron segments were incubated with 10^{-9} M and 10^{-6} M aldosterone, vasopressin or vehicle for 2 hrs at 37°C. After the RNA extraction, the expressions of GAPDH, Epo, EpoR, HIF2α, HIF1α, PHD2, mineralocorticoid receptor (MR), glucocorticoid receptor, EGFR, vasopressin V2 and V1a receptors (V2R and V1aR, respectively), GATA2 and GATA3 mRNAs were examined using real time PCR.

Results: Epo mRNA expression was detected in TS of CX, OM and IM (CX=OM>IM) and was time-dependently decreased. Aldosterone and vasopressin increased Epo mRNA expression in TS of CX and OM and vasopressin increased Epo mRNA in TS of IM. In microdissected nephron segments, Epo mRNA was decresed with time. After 2-hr incubation with vehicle, Epo mRNA expression was not observed in CAL and MAL, while its expression was remained at detectable level in the collecting ducts. Aldosterone and vasopressin stimulated the expression of Epo mRNA in CAL, MAL, CCD, OMCD and IMCD. Aldosterone and vasopressin stimulated mRNA expression of MR and V2R/V1aR, respectively. Aldosterone and vasopressin stimulated the expression of Epo mRNA along with the increase of HIF2α, GATA 2 and GATA 3 mRNAs but not with HIF1α. Aldosterone and vasopressin also stimulated EpoR mRNA expression in IMCD.

Conclusions: Epo is produced by the distal nephrons in normal condition. Aldosterone and vasopressin are erythropoietic hormones that are possibly under the control of HIF2α and GATA2/3 pathways in the distal nephrons.

Aldosterone-Regulated miRNAs and Their Target Genes in Mouse Cortical Collecting Duct Cells

Eui-Jung Park,[1,3] Hyun Jun Jung,[2] Hyo-Jung Choi,[1] Tae-Hwan Kwon.[1,3] *[1]Biochemistry and Cell Biology, Sch of Med, Kyungpook Natl Univ, Taegu, Republic of Korea; [2]NHLBI/NIH, Bethesda, MD; [3]BK21 Plus KNU Biomedical Convergence Program, Sch of Med, Kyungpook Natl Univ, Taegu, Republic of Korea.*

Background: Mature microRNA (miRNA) is a modulator in the post-transcriptional regulation. The present study aimed to identify the aldosterone-regulated miRNAs and their target genes in mpkCCDc14 cells. Target genes of the selected miRNAs and their biological functions and processes were predicted.

Methods: Microarray chip assay (Affymatrix GeneChip miRNA 4.0 array) was done in the mpkCCDc14 cells in the absence or the presence of aldosterone treatment (10^{-6} M) for 3 d. The candidate miRNAs were selected by 1) more or less than 30% of significant fold-changes (protocol 1), or 2) differential expression analysis carried out using the R package 'bridge' (Gottardo R. bridge: Bayesian Robust Inference for Differential Gene Expression. R package version 1.34.0., protocol 2). To predict putative target genes of identified miRNAs and miRNAs-enriched pathways, DIANA-mirPath program was exploited.

Results: In protocol 1, 29 miRNAs were significantly up-regulated more than 1.3 fold-change and 27 miRNAs were markedly down-regulated less than 0.7 fold-change in mpkCCDc14 cells after aldosterone treatment. In protocol 2, 5 up-regulated and 7 down-regulated miRNAs (more than 1.2 fold-change and less than 0.8 fold-change) were selected with high posterior probabilities (> 0.95). According to DIANA-mirPath program, 55 KEGG pathways (protocol 1) and 29 KEGG pathways (protocol 2) were profiled. In particular, Wnt signaling pathway, which was the most highly ranked, was selected. The quantitative changes of 7 up- and 8 down-regulated mature miRNAs enriched in the Wnt signaling pathways were further examined by qPCR and particularly miR-130b-3p was significantly increased. Six target genes (*Rock1, skp1a, Tbl1xr1, Ppp2re, Wnt2b, Plcb1*) of miR-130b-3p were identified, which need to be further evaluated for the aldosterone-induced pathophysiology.

Conclusions: Aldosterone induces significant changes in miRNA expression in mpkCCDc14 cells, which could be involved in a number of pathways including Wnt signaling.

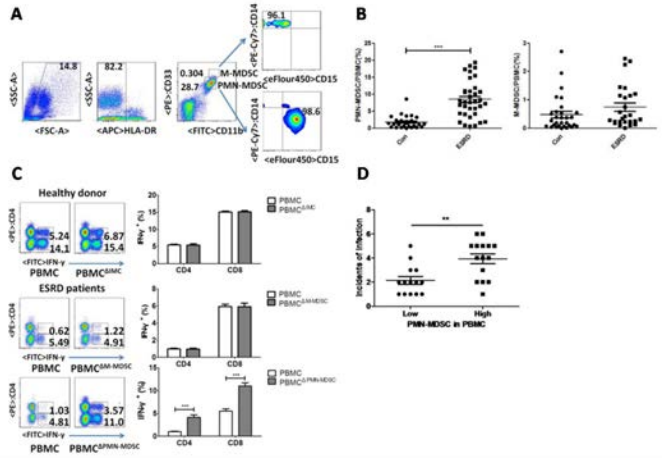
Elevated Polymorphonuclear Myeloid Deprived Suppressor Cell in Patients with End-Stage Renal Disease associated with Infectious Events

Yan-Fang Xing,[1] Xing Li.[2] *[1]Dept of Nephrology, The Third Affiliated Hospital of Guangzhou Medical Univ; [2]Dept of Medical Oncology, The Third Affiliated Hospital of Sun Yat-sen Univ.*

Background: Infectious disease is one of the common complications in patients with end-stage renal disease (ESRD) due to systematic immuno-suppression and inflammation without clear mechanism. The present study was aimed to determine the Myeloid Deprived Suppressor Cells (MDSCs) level in ESRD patients and its association with infectious events.

Methods: A total of 29 ESRD patients and 30 matched health control were tested the MDSC in peripheral blood monouclear cells (PBMC) by Flow cytometry. PMN-MDSC was defined as HLA-$DR^{-/low}CD11b^{+}CD33^{+}CD14^{-}CD15^{+}$) with M-MDSC defined as HLA-$DR^{-/low}CD11b^{+}CD33^{+}CD14^{+}CD15^{-}$ [figure1A]. MDSC depleted (Δ MDSC), or undepleted PBMCs were stimulated with anti-CD3/anti-CD28 for 3 days to test T cell responses by intracellular IFN-γ production. The association of MDSC with infectious events including respiratory tract infection, catheter related bloodstream infection and infection of digestive canal within 1 year before testing was analyzed retrospectively.

Results: The frequency of PMN-MDSCs was higher in ESRD patients as compared to healthy controls ($p<0.001$) with M-MDSC unchanged [figure1B]. Removal of PMN-MDSCs increased the expansion of antigen non-specific IFN-γ+ T cells, which indicated that PMN-MDSC suppressed immune responses. M-MDSC and immature myeloid cells (IMC) in health control were not suppressive [figure1C]. The ESRD patients were classified into two subsidiary sets according to PMN-MDSC levels. ESRD patients with higher level of PMN-MDSC >6.41845% displayed increased infectious events within 1 year before this study ($p<0.01$) [figure1D].



Conclusions: In summary, the present study firstly indentified increased PMN-MDSC in ESRD patients and its association with infectious events.

FR-PO370

Effect of Omega-3 Fatty Acids on STAMP2 Expression in 5/6 Nephrectomized Rat Model Su Mi Lee,[1] Yun Jung Oh,[2] Sung Hyun Son,[3] Young Ki Son,[1] Seong Eun Kim,[1] Won Suk An.[1] *[1]Dong-A Univ, Busan, Republic of Korea; [2]Cheju Halla General Hospital, Jeju, Republic of Korea; [3]BHS Han Seo Hospital, Busan, Republic of Korea.*

Background: Six transmembrane protein of prostate 2 (STAMP2) is known as critical modulator of inflammation and metabolism in adipose tissue. In recent study, STAMP2 had an important role in hepatic steatosis, but there is no data about the expression of STAMP2 in chronic kidney disease which is inflammatory status and related with metabolic disorder. This study aimed to investigate the STAMP2 expression of heart and kidney in 5/6 nephrectomy (Nx) rats. In addition, we evaluated the effect of omega-3 fatty acid (FA) and vitamin D which are related with inflammation and metabolic disorder on STAMP2 expression.

Methods: Sprague Dawley rats were divided into four groups: sham control (0.9% saline), 5/6 Nx (0.9% saline), 5/6 Nx treated with omega-3 FA (300 mg/kg/day by gastric gavage) group, 5/6 Nx treated with vitamin D (cholecalciferol 3000 IU/kg/week) and omega-3 FA groups. The expression of IκB, NF-κB, AMPK, SREBP1, Nox4, LXRab and STAMP2 were examined by western blot analysis.

Results: BUN and creatinine were the lowest in 5/6 Nx treated with omega-3 FA and vitamin D group among 5/6 Nx rat model. Compared with control, there was significant up-regulation of NF-κB, IκB, SREBP1, Nox4, and LXRab expression and a down-regulation of STAMP2 and phosphorylated AMPK expression in kidney and heart on 5/6 Nx model. We found that omega-3 FA prevented these up and down regulations related with inflammation and metabolic disorder of lipid. The STAMP2 expression was significantly up-regulated by omega-3 FA supplementation in both kidney and heart. In particular, STAMP2 expression was much more up-regulated in 5/6 Nx rats treated with omega-3 FA and vitamin D.

Conclusions: The STAMP2 suppression of heart and kidney was found in 5/6 Nx rats. STAMP-2 activation induced by omega-3 FA supplementation may be one of potential mechanisms attenuating inflammation and metabolic disorder.

FR-PO371

Targeted Metabolomic Analysis of Kidney from the Subtotal Nephrectomy Mouse Model of Chronic Kidney Disease Hiroaki Kikuchi,[1] Naohiro Nomura,[1] Yoji Andrew Minamishima,[2] Tatemitsu Rai,[1] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Nephrology, Tokyo Medical and Dental Univ; [2]Molecular and Cellular Biology, Medical Inst of Bioregulation, Kyushu Univ.*

Background: Metabolome analysis is a powerful tool for the identification and the quantification of the critical metabolites closely related to diseases. Little is known about the changes of metabolomic profile in chronic kidney disease (CKD).We applied a global targeted metabolome profiling approach to kidney samples obtained from C57BL/6J mice performed with subtotal nephrectomy (STN) which is the most common model of nondiabetic CKD.

Methods: Using capillary electrophoresis-time-of-flight mass spectrometry (CE-TOF-MS), we analyzed low molecular weight metabolites of kidney in the CKD mice (n=4) and sham control mice (n=4). The acquired data were analyzed using principal component analysis (PCA) followed by Kruskal-Wallis test and Dunn's post-test to assess the statistical significance.

Results: CE-TOF-MS analysis showed metabolomic profiles of kidney comprised of 278 metabolites. We found that 78 metabolites were significantly increased, and 13 metabolites were significantly decreased in kidney samples from CKD model mice. In the STN kidney, well-known uremic toxin such as 3-indoxylsulfuric acid, creatinine, and hippuric acid were significantly increased, indicating that our disease mouse model properly developed CKD. Interestingly, energy-related metabolites such as ATP, UTP, CTP were significantly decreased, compared with sham control.

Conclusions: Metabolomic analysis of kidney from CKD mice provided the useful information for identifying novel markers and elucidating the pathophysiology of CKD. The results suggested that some renal ATP-generating pathways were apparently impaired in CKD.

Calciprotein Particle Ripening Induces Mitochondrial Damage and Activates the NLRP3 Inflammasome Edward R. Smith,[1] Timothy D. Hewitson,[1] Parisa Aghagolzadeh,[2] Matthias Bachtler,[2] Andreas Pasch,[2] Stephen G. Holt.[1] *[1]Royal Melbourne Hospital, Australia; [2]Univ of Bern, Switzerland.*

Background: Calciprotein particles (CPP) accumulate and ripen from an amorphous (CPPI) to crystalline (CPPII) state in uremia and are associated with inflammation, vascular dysfunction and mortality. *In vitro* studies implicate NLRP3 inflammasome activation, but the mechanism and evidence of *in vivo* effects remains unproven.

Methods: NLRP3 priming/activation was evaluated in human monocyte-derived macrophage and in differentiated THP-1 cells. Uptake and effects on lysosomal/mitochondrial function/cell fate were assessed by flow cytometry. Live-cell imaging and particle localisation were assessed by laser-scanning confocal and super-resolution microscopy. For in vivo studies, CPPI/II or vehicle were administered to 12 week-old uremic or non-uremic Wistar rats via tail vein injection (twice daily for 5 days). Some animals received additional treatment with an NLRP3 inhibitor (MCC950) via subcutaneous minipump, or a mitochondria-targeted antioxidant (MitoQ10) via intraperitoneal injection or vehicle controls (n=6 for each treatment). Serum was collected after 6 days to assess inflammation/oxidative stress.

Results: *In vitro,* CPPI failed to prime or activate the NLRP3 inflammasome. In contrast, CPP-II primed inflammatory cytokine synthesis via Toll-like receptor 4/6/NF-κB-signalling. Binding and endocytosis of CPPII resulted in marked changes in intracellular calcium that were not apparent with CPPI. CPPII induced lysosomal destabilisation, loss of mitochondrial (mt) membrane potential, increased mtROS production and a release of mtDNA. NLRP3 activation, as well as sustained excursions in intracellular calcium, amplified mitochondrial damage via mitochondrial transition pore opening and induced interleukin (IL)-1β secretion. In uremic rats, intravenous administration of CPPII, but not CPPI, resulted in elevations in IL-1β, IL-6 and oxidative stress over 6 days, which were attenuated by concurrent treatment with MCC950 or MitoQ10 compared to vehicle controls.

Conclusions: CPP ripening drives inflammation via NLRP3 activation and effects on mitochondrial function. Targeting these pathways may have therapeutic potential in patients with CKD.

Exercise Improves Skeletal Muscle, but Does Not Alter Disease Progression in a Rat Model of Chronic Kidney Disease Keith Avin,[1,2] Neal X. Chen,[2] Sharon M. Moe,[2,3] Matthew R. Allen,[2,3,4] Jason M. Organ.[2,3] *[1]Physical Therapy, Indiana Univ, Indianapolis, IN; [2]Nephrology, Indiana Univ, Indianapolis, IN; [3]Anatomy and Cell Biology, Indiana Univ, Indianapolis, IN; [4]Veterans Affairs Medical Center, Indianapolis, IN.*

Background: Chronic kidney disease (CKD) is associated with musculoskeletal deterioration characterized by decreased skeletal muscle size (i.e. atrophy) and impaired muscle function. Currently, exercise interventions have experienced tempered success which may be the result of a lack of understanding of the pathogenesis of muscle dysfunction.

Methods: We used a slowly, progressive, naturally occurring, CKD rat model (Cy/$^{+}$ rat) and its normal littermate (NL). A graded 10- week treadmill exercise protocol began at 25 weeks of age (~CKD stage 2/3) and concluded at 35 weeks. At 35 weeks, we tested muscle strength in vivo, sacrificed and collected tissues and prepared for histology or RNA analysis using real time qPCR.

Results: Sarcopenia was first demonstrated in CKD rats (compared to NL) by reduced muscle fiber cross sectional area ($p<0.05$) and impaired strength ($p<0.05$); defined as the force produced during maximal, electrically stimulated dorsiflexion. CKD rats demonstrated altered gene expression responses in muscle regeneration (Pax-7, MyoD and myogenin ($p<0.05$)) and proteolysis (Atrogin-1 and MuRF-1 ($p<0.05$)). CKD rats who performed 10 weeks of treadmill training restored gene expression markers of skeletal muscle regeneration and muscle proteolysis similar to NL levels ($p<0.001$; CKD vs CKD exercise). At 30 weeks of age maximal torque production (20%, $p=0.05$) and power (27%, $p<0.01$) were higher, when comparing CKD to CKD-exercise although there were no differences at 35 weeks of age. Aerobic exercise did not alter disease progression as there was no difference in PTH, BUN, calcium and phosphorous between CKD and CKD exercised rats ($p>0.05$).

Conclusions: In a progressive rat model of CKD, exercise restored the regenerative and proteolytic profile to that normal littermates with improved strength at 30 weeks of age (stage 4/5 CKD). However, exercise did not alter the disease progression or end-stage disease muscle strength.

The Role of microRNA-26 on Muscle-Heart Crosstalk in Mice with Chronic Kidney Disease Bin Wang,[1,2] Aiqing Zhang,[1] Faten Hasounah,[1] Xiaonan H. Wang.[1] *[1]Renal Div, Emory Univ, Atlanta, GA; [2]Dept of Nephrology, Huashan Hospital of Fudan Univ, Changzhou, Jiangsu, China.*

Background: Uremic cardiomyopathy and muscle atrophy contribute to CKD-induced morbidity and mortality. Exosomes, natural carriers of many signal molecules including microRNA (miR), mediate organ to organ communication. We hypothesized that miR-26 would benefit both CKD-induced muscle wasting and cardiomyopathy through exosome-mediated muscle-heart crosstalk.

Methods: CKD model in mice: 5/6 subtotal nephrectomy for 10 weeks. NanoSight instrument was used to quantify exosomes. A miR deep sequencing assay and qPCR were used to identify microRNA. Cardiac ultrasound was used to detect heart size and function.

Results: We found that serum-derived exosomes from CKD mice are larger than shams using NanoSight. MiRdeep sequencing revealed increased miR-26a-5p in serum from both CKD mice and humans. However, miR-26a-5p was decreased in CKD mouse skeletal and cardiac muscle. Uremic serum enhanced secretion of miR-26a exosomes in cultured C2C12 skeletal and H9C2 cardiac muscle cells. We injected miR-26a-5p into tibialis anterior (TA) muscle and observed increased muscle cross-section area and decreased CKD-induced upregulation of atrogin-1 and MuRF1. We saw increased miR-26a expression in the heart following TA muscle injection. Interestingly, cardiac fibrosis was partially depressed in miR-26a overexpressing CKD mice. We further confirmed that FoxO1, α-SMA, GSK-3β, CTGF, fibronectin and Collagen1α were decreased by exogenous miR-26a in CKD mice. Cardiac sonography also showed that the percentage of ejection fraction was increased in CKD mice treated with miR-26a. In a cell culture model, we showed that exosomes containing miR-26a from skeletal muscle cells can transfer miR-26a to H9C2 cardiac cells and attenuate uremic serum-induced upregulation of FoxO1 in H9C2 cell, providing indirect evidence of skeletal and cardiac muscle crosstalk.

Conclusions: Exogenous miR26a not only attenuated skeletal muscle atrophy but also ameliorated uremic cardiomyopathy by targeting multiple mRNAs, possibly through exosome-mediated muscle-heart crosstalk.

Mitochondrial Dysfunction in Uremic Muscle Maria P. Martinez Cantarin,[1] Zhao Lin,[2] Bonita E. Falkner.[1] *[1]Medicine, Thomas Jefferson Univ Hospital, Philadelphia, PA; [2]Kimmel Cancer Center, Thomas Jefferson Univ, Philadelphia, PA.*

Background: Muscle wasting is associated with uremia leading to increased mortality. Different factors have been associated with increased muscle wasting in chronic kidney disease models. Mitochondrial biogenesis is a key component of skeletal muscle function and structure. We set up to determine if inflammation and or reactive oxygen species (ROS) play a role in the uremic muscle's metabolic dysfunction.

Methods: We studied mitochondrial function in muscle of ESRD patients using the protein expression of TOMM20 by western blot. We exposed a myoblast cell line (C2C12) to uremic and normal human serum (2%, 5% and 10% serum for 24h) with and without N-acetyl cysteine (NAC) 10nM and then studied mitochondrial function by mitotracker orange. We also exposed C2C12 cells to ascending concentrations of TNFα (0.1, 1, 10 ng/ml) and IL6 (0.01, 0.1, 1 ng/ml) with and without adiponectin (1 ug/ml) and determined mitochondrial activity by mitotracker orange. We also assessed TOMM20 protein expression of C2C12 exposed to TNFα.

Results: We demonstrate lower TOMM20 protein expression in ESRD patients compared with controls by western blot analysis consistent with reduced mitochondrial function. C2C12 cells exposed to uremia show a decrease in mitotracker activity with increasing uremic serum concentrations compared to cells exposed to normal serum ($p<0.01$ for 2% and 5% serum and $p<0.05$ for 10% serum). When NAC was added to uremic serum, cells exposed to uremia and NAC were able to rescue mitotracker activity to similar levels of cells exposed to normal serum ($p<0.05$). Mitochondrial activity in C2C12 cells decreases with increasing concentrations of TNFα and IL6 ($p<0.01$ for both cytokines). Exposure to TNFα and the anti-inflammatory adiponectin results in an increase in mitochondrial function compared to cells exposed to TNFα alone although only at low TNFα doses (1 ng/ml, $p<0.05$). Similar to human muscle exposed to uremia, we demonstrated that TOMM20 protein expression decreases in C2C12 exposed to high concentrations of TNFα.

Conclusions: In summary, our data suggest that inflammation and oxidative stress promote mitochondrial dysfunction in ESRD.

Adipose Tissue Inflammation in ESRD Maria P. Martinez Cantarin,[1] Diana Whitaker Menezes,[2] Bonita E. Falkner.[1] *[1]Medicine, Div of Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA; [2]Medical Oncology, Kimmel Cancer Center, Thomas Jefferson Univ, Philadelphia, PA.*

Background: ESRD patients have increased inflammation with high levels of circulating inflammatory markers. Systemic inflammation is associated with poor outcomes in patients with ESRD. Multiple mechanisms have been proposed to explain why ESRD is a chronic inflammatory state but each one's contribution is unknown. Adipose tissue is a major source of immune cell-derived inflammatory factors so we set up to study if the adipose tissue of ESRD could contribute to systemic inflammation in ESRD.

Methods: Participants were recruited from the Thomas Jefferson University Hospital (TJUH) transplant program. Criteria for inclusion in the study included having ESRD and undergoing kidney transplantation at our institution. The control group consisted of kidney donors with normal kidney function. While the participants were under general anesthesia for kidney donation or kidney transplantation, 250 mg of omental visceral fat and 250 mg of subcutaneous fat were obtained. Fixed adipose tissue samples were paraffin embedded. Paraffin-embedded sections of visceral and subcutaneous adipose tissue were immunostained for the macrophage marker CD163. Adipose tissue macrophage infiltration was measured as the number of CD163+ cells in 10 randomly chosen 40X areas (high power field) by 2 independent pathologists. Number of CD163+ cells was normalized by 100 adipocytes.

Results: Compared to controls, ESRD patients have increased macrophage infiltration in visceral and subcutaneous adipose tissue, as determined by the quantification of CD163+ cells per 100 adipocytes ($p<0.001$ for both adipose tissues). After participants were stratified by BMI as obese (BMI>30) versus non-obese (BMI<30), non-obese ESRD patients continue to present higher macrophage infiltration in subcutaneous and visceral adipose tissue compared to controls ($p<0.01$ for both tissues).

Conclusions: Our study demonstrates that the adipose tissue of uremic patients has increased macrophage infiltration, including in non-obese individuals. We propose that adipose tissue is a potential source of inflammation in ESRD that is not related to increased adiposity.

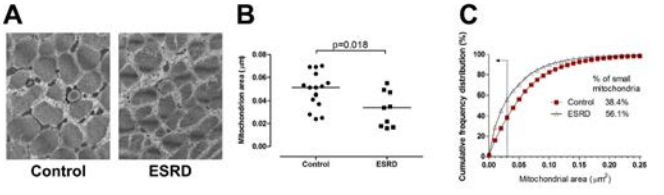
FR-PO377

Mitochondrial Fragmentation in Patients on Maintenance Hemodialysis Jorge Gamboa,[1] Theodore F. Towse,[2] Emily C. Bush,[2] Baback Roshanravan,[3] Serpil Muge Deger,[1] Talat Alp Ikizler.[1] *[1]Medicine, Vanderbilt Univ Medical Center, Nashville, TN; [2]Physical Medicine and Rehabilitation, Vanderbilt Univ Medical Center, Nashville, TN; [3]Medicine, Univ of Washington, Seattle, WA.*

Background: Frailty and sarcopenia, defined as a reduction in muscle mass and/or muscle strength, are common in patients on maintenance hemodialysis (MHD). Mitochondria are important for proper muscle function. Mitochondria are organelles that are constantly undergoing either fusion, to become larger structures, or fission, a process of mitochondrial division. A balance between mitochondrial fusion and fission is essential for proper mitochondrial function. Increased mitochondrial fission will result in mitochondrial fragmentation and smaller mitochondria. Thus, we evaluated the hypothesis that mitochondrial fragmentation is increased in patients on MHD.

Methods: We measure mitochondrial size using electron microscopy. We evaluated 10 patients on MHD and 15 controls with no CKD that were matched by age, gender, and BMI. We also measured OPA-1 and Fis-1, markers of mitochondrial fusion and fission respectively, by western blot.

Results: Controls and patients on MHD were similar in terms of age (52.8±8.7 *vs.* 50.3±15.1), BMI (30.6±7.3 vs. 29.0±5.1), and gender. We found that mitochondria are smaller in patients on MHD compared to individuals with no CKD (Figure 1A and B). Frequency distribution of individual areas showed a shift to the left in patients on MHD (Figure 1C). We did not find any difference in the abundance of either OPA-1 or Fis-1 between the groups.



Conclusions: Smaller mitochondria in skeletal muscle of patients on MHD may be the consequence of increased mitochondrial fission for segregation and elimination of damaged mitochondrial. Future studies are required to study how changes in mitochondrial dynamic and function may impact frailty and sarcopenia in patients on MHD.

Renoprotective Effect of Shen-Yan-Fang-Shuai Formula in Type 2 Diabetic Kidney Disease Rats Model by Inhibiting the TNF-α/NF-κB Signaling Pathway Jie Lv, Zhen Wang, Jingwei Zhou, Yaoxian Wang. *Nephrology, Dongzhimen Hospital Affiliated to Beijing Univ of Chinese Medicine, Beijing, China.*

Background: Diabetic Kidney Disease(DKD)is the leading cause of end stage kidney disease and satisfactory therapeutic strategies have not yet been established. Shen-Yan-Fang-Shuai-Formula (SYFSF), a traditional Chinese Formula composed of Astragalus, Angelica, Rhubarb and four other herbs, has been widely used as an effective treatment for DKD patients in China.Studies have shown that SYFSF components including emodin or flavonoids inhibit renal inflammation. However little is known about the underlying molecular mechanisms of SYFSF protection. In this study, we compared the renoprotective effect of SYFSF to ARB in a type 2 DKD rat model.

Methods: The male Wistar rats were divided into four groups: control group (n=10), DKD model group (vehicle treated, n=9), DKD model with SYFSF (DKD+S) group (n=10) and DKD model with Irbesartan (DKD+I) group (n=10). The type 2 DKD rat model was induced by high-fat diet, low-dose intraperitoneal injection of streptozotocin(STZ) and

uninephrectomy. Blood glucose level >16.7 mmol/l was defined as Highglucose. Rats were treated for 8 weeks with SYFSF once daily by oral gavage. The kidneys were harvested for histology, immunohistochemistry, western-blot, and real-time quantitative PCR analysis.

Results: SYFSF significantly decreases 24 hour albuminuria (10.12± 3.7 VS 40.41± 16.72 mg, P<0.01) and serum Creatinine levels, with no changes in glucose levels compared to DKD group and Irbesartan group. In addition, SYFSF ameliorates the glomerulosclerosis and interstitial fibrosis induced by DKD (P<0.01). These renoprotective affects were associated with reduced kidney cortex expression of TNF-α,NF-κB P65,TGF-β1 and Col-IV (P<0.05).

Conclusions: SYFSF provides significant renoprotective effects in type-2 DKD rats independently of glucose levels compared to Irbesartan treatment. This is associated with the inhibition of TNF-α/NF-κB inflammatory pathway. Therefore, SYFSF may be a beneficial treatment for DKD patients.

Hyperphosphate Increases the Expression of Inflammatory Factors in Monocytes via Sodium-Dependent Phosphate Cotransporter Pit-1

Minwen Ding, Mengjing Wang, Li Ni, Minmin Zhang, Jing Chen. *Dept of Nephrology, Huashan Hospital, Shanghai, China.*

Background: Hyperphosphatemia and systemic inflammation are known risk factors for cardiovascular calcification in maintenance hemodialysis (MHD) patients, however, the mechanisms of which are still under investigation. The aims of this study were to explore whether hyperphosphate could increase the secretion of inflammatory factors in peripheral blood monocytes via sodium-dependent phosphate cotransporter Pit-1 and its possible mechanisms.

Methods: Human primary peripheral blood monocytes(isolated from healthy donors' PBMCs) were cultured and divided into four groups: normal phosphate (NP), high phosphate (HP), HP+PFA and HP+PD98059 groups. Antagonists of sodium-dependent phosphate cotransporters (phosphonoformic acid (PFA)) and the ERK inhibitor (PD98059) were used to determine the possible signaling pathways caused by HP. The protein level of TNF-α and IL-6 were examined by ELISA. The mRNA expression level of TNF-α, IL-6 and Pit-1 were measured by Real-time PCR. The protein level of Pit-1, ERK1/2 and p-ERK1/2 were detected by Western Blot.

Results: 1. After 48h exposure of peripheral blood monocytes to Pi (4M), the concentration of TNF-α (pg/ml) and IL-6 (pg/ml) was increased comparedwith the NP group by ELISA (P<0.05 *vs.* NP). PFA and PD98059 could inhibit this effect significantly (P<0.05 *vs.*HP). 2. TNF-α, IL-6 and Pit-1 mRNA expression were increased compared with the NP group (P<0.01 *vs.* NP), while PFA could inhibit this effect (P<0.05 *vs.*HP). PD98059 showed similar effects in decreasing the mRNA expression of TNF-α, IL-6 and Pit-1 (P<0.05 *vs.*). 3. Pit-1 and p-ERK1/2 protein abundance were increased (P<0.05 *vs.* NP) after the treatment of Pi (4M) for 48h, and PFA could inhibit this effect (P<0.05 *vs.*). PD98059 showed similar effects in decreasing the protein abundance of Pit-1 and PERK1/2 (P<0.05 *vs.*).

Conclusions: We conclude that hyperphosphate could increase the expression of Pit-1 in peripheral blood monocytes and promoted the synthesis and secretion of TNF-α and IL-6 via ERK1/2 pathway.

Chronic Alcohol Mediated Hyper-Acetylation of Kidney Mitochondrial Proteins Causes Renal Dysfunction

Carolina Panico,[1] Zhongping Lu,[1] Raj Lakshman.[1,2] *[1]The George Washington Univ; [2]Veterans Affairs Medical Center, Washington, DC.*

Background: Studies have shown that sirtuins (SIRTs) are beneficial in kidney injury. In particular SIRT3, a NAD-dependent deacetylase, protects renal tubular cells through antioxidative and anti-inflammatory effects, especially in proximal tubular cells. Chronic alcohol exposure is known to cause protein hyperacetylation in the mitochondria that may play a critical role in the pathogenesis of alcoholic liver disease, but the mechanism through which chronic ethanol consumption damages the kidney has not been studied. We hypothesize that hyperacetylation of kidney mitochondrial proteins may be responsible for renal dysfunction during chronic alcohol consumption.

Methods: SIRT3$^{+/+}$ and SIRT3 $^{-/-}$ mice were pair-fed 6% ethanol or Control liquid diet (Lieber-De Carli, Dytes Inc, PA) for 6 weeks. 24 hour urine, collected at the start and at the end of the 6 weeks, was used to measure the albumin/creatinine ratio (ACR). The animals were then sacrificed, the kidneys aliquoted for isolation of mitochondria, immunohistochemistry and western blot analyses. Fresh renal mitochondria were used for respiration studies by Seahorse Analyzer and measurement of reactive oxygen species (ROS).

Results: The ACR was increased in both SIRT3$^{+/+}$ and SIRT3 $^{-/-}$ mice that were fed ethanol liquid diet. More importantly, the ACR was significantly higher in SIRT3 $^{-/-}$ compared to SIRT3 $^{+/+}$ (ACR 1200µg/mg vs 1008µg/mg, respectively; p<0.05). Mitochondrial state 3 and uncoupling respiration were significantly lower in both SIRT3 $^{-/-}$ and ethanol fed mice, suggesting that acetylation modification impairs mitochondrial oxidative phosphorylation. Indeed, the western blot analyses showed a significant increase of the acetylation status of renal mitochondrial proteins involved in energy metabolism and ROS production, SIRT3$^{-/-}$ mice fed with ethanol. Moreover, ROS production was significantly higher in chronic ethanol-fed SIRT3 $^{-/-}$ group compared to the ethanol-fed SIRT3 $^{+/+}$ group.

Conclusions: Chronic alcoholic-mediated hyper-acetylation of kidney mitochondrial proteins causes renal dysfunction.This study can unveil therapeutic strategies to reverse and/or delay renal damage during chronic alcohol consumption.

Evaluation of the Impact of Gut Microbiota on Uremic Solute Accumulation by CE-TOFMS-Based Metabolomics Approach

Eikan Mishima, Takehiro Suzuki, Hisato Shima, Koichi Kikuchi, Sadayoshi Ito, Takaaki Abe. *Div of Nephrology, Endocrinology and Vascular Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Japan.*

Background: Gut microbiota is involved in the metabolism of several uremic solutes. However, the precise contribution of microbiota to retention of uremic solutes in chronic kidney disease (CKD) is obscure.

Methods: To clarify this issue, we compared adenine-induced chronic kidney disease (KD) mice and control mice under germ-free (GF) or specific pathogen-free (SPF) conditions, and examined their metabolic profiles of plasma, feces and urine using CE-TOFMS-based approach.

Results: We found that GF condition demonstrated profound changes in the plasma metabolites of the KD mice. Among 57 uremic solutes that accumulated in plasma of SPF-KD, plasma levels of 11 solutes were significantly lower in GF-KD than that in SPF-KD, suggesting that these solutes were considered to be "gut microbiota-derived uremic solutes" (GM-US), including indoxyl sulfate, cholate, hippurate, *p*-cresyl sulfate, phenyl sulfate, trimethylamine *N*-oxide, phenaceturate, dimethylglycine, γ-guanidinobutyrate, glutarate, and 2-hydroxypentanoate. Metabolic pathway profiling also suggested that microbiota are involved in the metabolism of GM-US. Thus, GF condition attenuated the accumulation of the harmful uremic solutes in CKD condition: however, we revealed that renal damage was unexpectedly more severe in GF-KD than in SPF-KD, suggesting that gut microbial action such as production of colonic short-chain fatty acids played renoprotective roles and that loss of the beneficial microbial effects exacerbated renal damage in GF-KD.

Conclusions: Collectively, our findings indicated that gut microbiota largely contributes to the production of harmful uremic solutes and,meanwhile, microbiota has potential beneficial effects against CKD progression. Gut microbiota therefore would represent dual roles in the pathophysiology of CKD.

FR-PO382

25 (OH)D Treatment Improve Inflammatory Pathway on Monocytes Lineage (U937) in Uremic Environment

Rodrigo Barbosa Oliveira Brito,[2] Jacqueline Ferritto Rebello,[2] Caren Cristina Grabulosa,[1] William Rubens Oliveira,[2] Maria Dalboni.[1,2] *[1]Medicine, Univ Federal de São Paulo, São Paulo, Brazil; [2]Medicine, Univ Nove de Julho, São Paulo, SP, Brazil.*

Background: The 25(OH)D has been associated as a modulator of inflammatory response. It has been recognized that the uremic environment induce inflammation, mainly for presence of uremic toxins in plasma from uremic patients. This inflammation state in these patients is associated with a high risk for cardiovascular disease and infectionsThe aim of this study was evaluated the effect of 25(OH)D on inflammatory pathway as: toll-like receptor 4 (TLR4), oxidative stress (ROS) and expression of vitamin D receptor (VDR), 24 hydroxylase (CYP24) and hidroxilase 1-α (CYP27) on monocytes cells in uremic environment.

Methods: The human monocytes (U937 lineage) were pre-treatment with and without of 25(OH)D (30 ng/mL) (D) for 24 hours and after that these were incubated with 50% of healthy serum (HS) or uremic serum (US)for 24 hours at 37ºC and 5% CO_2.The monocytes were characterized by CD14+ expression. The TLR-4, VDR, CYP24, CYP27 were evaluated by human monoclonal antibody conjugated with different fluorophores and ROS were evaluated by DCFH-DA. The flow cytometer was used to detect the expression of these markers.

Results: We observed a high expression of TLR-4 in monocytes incubated with uremic serum (US) and low expression after 25(OH)D treatment (US = 4010±518 vs HS = 1786±403 and US+D = 3113±316 vs HS+D = 1121±221; p < 0.004) and lower expression of VDR in monocytes+US compared with HS (US = 7812±618 vs HS = 9659±908; p = 0.01). The CYP24 were higher in monocytes+ US than monocytes+HS (p < 0.008). CYP27 and ROS not showed differences.

Conclusions: These preliminary results shown that uremic environment induce inflammation by increase TLR-4 and diminish intracellular VDR and increase CYP24. The treatment with 25(OH)D indicate an improve in these parameters and may result in less inflammation in uremic environment.

FR-PO383

The Effect of Different BCG Measurement Procedures on Serum Albumin Levels in Patients with ESRD on Hemodialysis

Min Yu,[1] Brendan T. Bowman,[1] David E. Bruns,[1] Lorin Bachmann,[2] Lesley Mcphatter,[1] Emaad M. Abdel-Rahman.[1] *[1]Univ of Virginia, Charlottesville, VA; [2]Pathology, Virginia Commonwealth Univ.*

Background: Low serum albumin is associated with mortality in hemodialysis patients. The K/DOQI-recommended value for albumin is 4.0 g/dL as measured by any bromcresol green (BCG) method, but approximately 60% of dialysis patients have an albumin that is lower. To our knowledge, no study has assessed the effect of different manufacturers' BCG measurement procedures on the proportions of dialysis patients with serum albumin ≥4.0 and/or ≥3.5 g/dL.

Methods: In a previous study, we defined the relationships of albumin results of 9 commercially available BCG methods; the relationships were assessed by measurements of fresh, nonfrozen serum samples from patients in the hemodialysis centers at the University

of Virginia (UVA) (Yu M et al., Abstract A154, Annual Meeting, Am Assn Clin Chem, 2015). Linear regression equations of data from that study relate results of the 9 BCG methods to each other. In the present study, serum albumin was measured by one of the BCG methods (Abbott Architect) in blood samples from hemodialysis patients at UVA in February (n = 831 patients) and March (n = 852) of 2016. We used the regression equations developed earlier to define for each of the Architect albumin results the corresponding values by each of the other 8 measurement procedures.

Results: Depending on the assay used, the mean (±SD) albumin varied from 3.7 (±0.4) to 4.1(±0.4) mg/dL. The proportion of BCG albumin results ≥4.0 g/dL varied more than 2-fold, from 30% to 64%, depending on the assay used. Similarly, the proportion of albumin results ≥3.5 g/dL ranged from a low of 79% to a high of 93%. The differences of mean albumin results among 11 dialysis centers in the UVA system were smaller than the differences among the 9 BCG methods.

Conclusions: Serum albumin results of the most widely used BCG methods in the U.S. differ widely. Fixed decision limits for clinical decisions or for quality indicators are not appropriate.

FR-PO384

The Influence of Acute Aerobic Exercise on Immune Cell Subsets in Renal Transplant Recipients Patrick J. Highton,[1,2] Jill Neale,[1] Darren R. Churchward,[1] Charlotte E. Grantham,[1] Nicolette C. Bishop,[1,2] Alice C. Smith.[1,2] *[1]Leicester Kidney Exercise Team, Univ of Leicester, Leicester, Leicestershire, United Kingdom; [2]School of Sport, Exercise and Health Sciences, Loughborough Univ, Leicester, Leicestershire, United Kingdom.*

Background: Renal Transplant Recipients (RTRs) are immunologically vulnerable due to immunosuppression and systemic inflammation. In health, moderate exercise reduces systemic inflammation and is beneficial for immune function, but intense exercise can elicit inflammatory cytokine release and transiently suppress immunity leaving an "open window" for infection. Physical activity has many potential benefits for RTRs, but guidelines for safe and effective exercise for this unique population are lacking. In this study, we investigated the impact of exercise on immune and inflammatory cells in RTRs.

Methods: 15 RTRs (13 male; age 53±15 years) completed 20 minutes of continuous walking at 85% of individual maximum speed defined at a previous visit. Blood samples were obtained before, immediately after and 1 hour after this standardised walk. T cell and monocyte cell subsets were analysed by flow cytometry.

Results: Intermediate monocytes ($CD14^{++}16^{+}$) decreased immediately following exercise (3.80±0.31% vs 3.07±0.21%, p=.012), whilst non-classical monocytes ($CD14^{+}16^{++}$) increased (5.99±0.82% vs 7.25±1.03%, p=.022). There was no change in $CD14^{++}16^{-}$ classical monocytes. Number and % of $CD8^{+}$ T cells decreased during the hour of recovery ($0.60±0.12x10^{9}$/L vs $0.51±0.11x10^{9}$/L, p=.049; 31.62±4.07% vs 28.84±4.17%, p=.025). Regulatory T cells (T Regs) were increased by exercise (5.59±0.54% vs 6.55±0.73%, p=.005).

Conclusions: A bout of exercise exerts significant effects on monocyte and T cell populations in RTRs. Anti-inflammatory classical monocytes were unaffected, but intermediate monocytes decreased and non-classical monocytes increased. Both of these subsets are considered pro-inflammatory and elucidation of the overall inflammatory significance requires further investigation. The reduction in circulating $CD8^{+}$ T cells may represent an "open window" for infection after exercise. T Regs are anti-inflammatory and critical for graft tolerance: their increase after exercise is reassuring and may be beneficial.

FR-PO385

Loss of CD127 Expression on Circulating CD8+ T Cells in Patients with End-Stage Renal Disease and Its Association with Resistance to Erythropoiesis-Stimulating Agents Kenichiro Iio, Yutaka Ando. *Nephrology, National Hospital Organization, Osaka Minami Medical Center, Kawachinagano, Osaka, Japan.*

Background: IL-7 is important for T cell homeostasis. In response to an infection, IL-7 enhances $CD8^{+}$ T-cell proliferation and cytolytic activity. Decreased CD127 (IL-7alphaR) expression on $CD8^{+}$ T cells may contribute to the loss of $CD8^{+}$ cytotoxic T lymphocyte activity, thereby increasing susceptibility to infection. Resistance to erythropoiesis-stimulating agents (ESAs) is associated with cardiovascular disease and increased mortality in end-stage renal disease (ESRD) patients. Immune disorders such as chronic inflammation are also involved.

Methods: The present study compared the T cell phenotypes between 53 patients with stage 5 or 5D chronic kidney disease (CKD) and 16 control patients with stage 1 to 3a CKD. Furthermore, multivariate regression analysis was performed to detect the association between T cell phenotypes and the erythropoietin resistance index (ERI; μg/kg/Hb/week). Flow cytometric analysis was performed to detect $CD127^{hi}$ $CD8^{+}$ T cells, $CD3^{+}$ T cells, $CD4^{+}$ T cells, and $CD8^{+}$ T cells among the peripheral blood mononuclear cells.

Results: The proportion of CD127-expressing $CD8^{+}$ cells and the numbers of $CD3^{+}$ T cells and $CD4^{+}$ T cells were significantly lower in ESRD patients than in the controls. Based on multivariate linear regression analysis, the proportion of $CD127^{hi}$ $CD8^{+}$ cells, but not the numbers of $CD3^{+}$ cells or $CD4^{+}$ cells, was associated with the ERI ($\beta = -0.0006$; $p = 0.02$).

Conclusions: A decreased proportion of $CD127^{hi}$ $CD8^{+}$ T cells and decreased numbers of $CD3^{+}$ T cells and $CD4^{+}$ T cells may be indicators of an ESRD-related immunological abnormality. Additionally, CD127 expression on $CD8^{+}$ T cells was associated with resistance to ESAs. Immunological changes that increase susceptibility to infection may indicate resistance to ESAs.

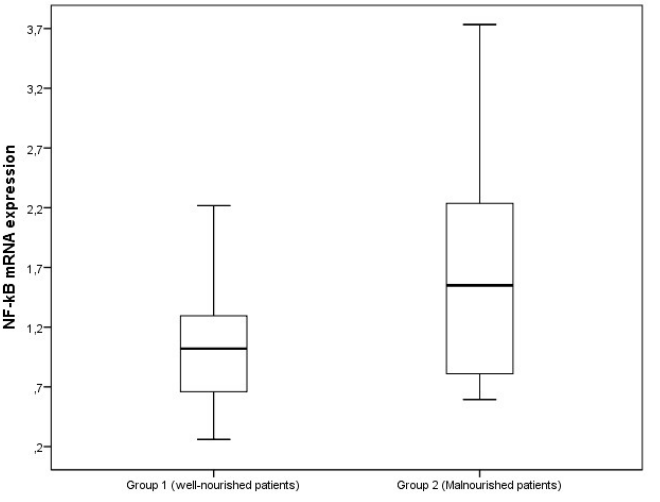
FR-PO386

Subjective Global Assessment Is Linked to Nuclear Factor-κB Expression in Hemodialysis Patients Denise Mafra,[1] Viviane Oliveira Leal,[2] Najla Elias Farage,[1] Ludmila F.M.F. Cardozo,[1] Milena Barcza Stockler-Pinto,[1] José Carlos Carraro-Eduardo,[1] Denis Fouque.[3] *[1]Federal Univ Fluminense; [2]State Univ of Rio de Janeiro; [3]Univ Claude Bernard, Lyon 1.*

Background: Wasting and inflammation are common symptoms in chronic kidney disease (CKD) patients on hemodialysis (HD). Muscle loss and malnutrition are stimulated by inflammation. Nuclear factor-kappa B (NF-κB) is a central integration site for pro-inflammatory signals that are overexpressed in HD patients and could be associated with nutritional status assessed by Subjective Global Assessment (SGA). The aim of this study was to evaluate a possible association between NF-κB expression and SGA in hemodialysis.

Methods: Eighty-three HD patients (57% men, 52.3±14.4 yr, 60 (36-108) months on dialysis, 15.7% diabetes, BMI 24.8±3.9 Kg/m^2) were enrolled. Fasting blood samples were collected and peripheral mononuclear cells were isolated. Real time PCR was performed to evaluate NF-κB mRNA expression.

Results: The 7-point SGA was performed and patients were allocated into two groups (gr1 well-nourished and gr2-malnourished). According to SGA, 32.5% presented malnutrition and a higher NF-κB expression (1.75 [0.77-2.34] when compared to well-nourished patients (1.0 [0.64 – 1.33], p=0.03).



Conclusions: In conclusion, SGA may indicate an altered NF-κB expression and an inflammatory upregulation in chronic HD patients.

FR-PO387

Lack of Polyfunctional Cytomegalovirus-Specific T Cells in Hemodialysis Patients Fang-Yun Lay,[1] Tzu-Ying Chou,[1] Kai-Hsiang Shu,[1,2] Yi-Fang Chuang,[3] Jean-San Chia,[4] Yen-Ling Chiu.[1,2] *[1]Nephrology, Far Eastern Memorial Hospital; [2]Medicine, National Taiwan Univ Hospital; [3]Epidemiology, National Yang Ming Univ; [4]Graduate School of Immunology, National Taiwan Univ.*

Background: Polyfunctional T cells are critical for maintaining protection against pathogens. Patients with end-stage renal disease (ESRD) are at increased risks for infectious complications and chronic inflammation. The current study intends to investigate T cell immunity and systemic inflammation by analyzing T cell differentiation and polyfunctionality response against cytomegalovirus (CMV) in patients with and without renal disease.

Methods: 17 healthy individuals, 13 patients with stage V chronic kidney disease (CKD) and 37 hemodialysis (HD) patients were enrolled in this study. All the donors were seropositive. Peripheral blood mononuclear cells were isolated by density gradient centrifugation. A panel of T cell differentation markers were used to identify the following T cell subsets: naive (TN), central memory (TCM), effector memory (TEM) and effector memory with RA expression (TEMRA). CMV peptide pools (IE1 and pp65) were used to stimulate PBMCs and four effector functions were measured by multicolor flow cytometry (IL-2, TNFα, IFNγ and CD107a) to identify polyfunctional T cells. Statistical comparisons were performed using Kruskal-Wallis rank test.

Results: The age of the three groups were similar (mean, 60 years old). Patients with renal disease, especially the HD patients, showed decrease in CD4+ and CD8+ TN cells and increase in CD4+ and CD8+ TEM and TEMRA cells. In addition, polyfunctional cells were dramatically reduced in HD patients. HD patient also showed higher level of systemic inflammation and CMV viral load. Among healthy individuals, CKD and HD patients, CD4+ CMV-IE1-reactive polyfunctional cell frequencies were 2.0%, 2.2%, and 0%, respectively (p=0.002) and the CD8+ CMV-pp65-reactive polyfunctional cell frequencies were 12.4%, 8.8% and 0.8%, respectively (p<0.001).

Conclusions: The lack of polyfunctional T cells in hemodialysis patients might explain the increased infectious complications in this population. Such phenomenon might contribute to subclinical cytomegalovirus activation and chronic inflammation in HD patients.

Branched-Chain Amino Acids Promote Oxidative Stress, Inflammation and Migration of Human Peripheral Blood Mononuclear Cells via mTORC1 Activation

Olha Zhenyukh,[1] Esther Civantos,[1] Enrique Bosch,[1] Marta Ruiz-Ortega,[2] Sebastian Mas,[1] Jesus Egido.[1] *[1]Fundación Jimenez Díaz, Madrid, Spain; [2]Univ Autónoma de Madrid, Spain.*

Background: Leucine, isoleucine and valine are essential aminoacids termed branched-chain amino acids (BCAA) due to its aliphatic side-chain. In several pathological and physiological conditions increased BCAA plasma concentrations have been described. Elevated BCAA levels predict insulin resistance development. Moreover, BCAA levels higher than 2 mmol/L are neurotoxic by inducing microglial activation in maple syrup urine disease. However, there are no studies about the direct effects of BCAA in circulating cells and the mechanisms involved.

Methods: We have explored whether BCAA (range 0.1 to 12 mmol/l) could promote oxidative stress and pro-inflammatory status in peripheral blood mononuclear cells (PBMCs), obtained from healthy donors.

Results: In cultured PBMCs, 10 mmol/L BCAA increased the production of reactive oxygen species (ROS), via by both NADPH oxidase and the mitochondria. BCAA activated mTOR and Akt signaling, as demonstrated by increased phosphorylation of mTORC1 and Akt, respectively. The redox-sensitive transcription factor NF-KB regulates many immune and inflammatory responses. BCAA caused p-p65 NF-KB phosphorylation, its nuclear translocation and increased p65-dependent DNA binding activity. BCAA also up-regulated several pro-inflammatory molecules under NF-KB control, such as interleukin-6, TNF-α, ICAM-1 and CD40L. Finally, we have found that BCAA induced PBMCs cell migration. By using several inhibitors and activators of these molecular pathways we have described that mTOR activation by BCAA is linked to ROS production and mitochondrial dysfunction. Moreover, BCAA, by a redox mechanism, activated the NF-KB/inflammatory pathway and regulated cell migration.

Conclusions: Elevated BCAA blood levels can promote the activation of circulating PBMCs, by a mechanism that involve ROS production and NF-KB pathway activation. These data suggest that high concentrations of BCAA could exert deleterious effects on immune cells and therefore could contribute to the pro-inflammatory and oxidative status observed in several pathophysiological conditions.

The Application of Magnetic Resonance Apparent Diffusion Coefficient in the Diagnosis of Acute Pyelonephritis

Geng-Xi Sun,[1] Hui-Qun Li,[2] Wenbo Zhao.[2] *[1]The Affiliated Hexian Memorial Hospital of Southern Medical Univ, Guangzhou, Guangdong, China; [2]The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Acute pyelonephritis (APN) is a non-specific suppurative inflammatory process secondary to ascending or haematogenous bacterial diffusion. It is widely accepted that functional Magnetic resonance imaging (MRI) provides additional information: diffusion-weighted imaging (DWI) with the apparent diffusion coefficient (ADC) represents an additional parameter which can indicate focal lesions or changes in renal function. DWI has recently been proposed as an alternative to CT for both the diagnosis and follow-up of APN. The aim of the study was to assess reliability of ADC value for differentiating normal renal parenchyma, APN and abscesses.

Methods: 56 patients (mean age 39 years) with clinical suspicion of APN were retrospectively reviewed. The contrast-enhanced MRI and DWI were applied in these patients. MRI found that 34 patients had renal abscess, and 22 had no abscess. Then ADC values which were calculated at the area of healthy parenchyma, APN and abscessed were compared in these cases.

Results: On DWI sequences inflammatory foci appeared as areas of reduced diffusivity of water molecules with high signal on DWI and low ADC values compared to healthy parenchyma (mean ADC: healthy parenchyma $(2.32\pm0.18)\times10^{-3}$ mm^2/s; APN foci $(1.52\pm0.24)\times10^{-3}$ mm^2/s; abscess $(1.16\pm0.34)\times10^{-3}$ mm^2/s, b factor=600s/mm^2).The results showed the difference between ADC values of the APN and healthy parenchyma groups ($P<0.05$), similarlythe difference between ADC values of the abscess and APN groups was significant ($P<0.05$).

Conclusions: MR ADC values showed reliable in the diagnosis and follow-up of acute pyelonephritis, and it could provide a reasonable alternative to contrast-enhanced MRI. This is especially useful when administration of contrast agent is contraindicated.

FR-PO390

Differential Effects of Angiotensin II Receptor Blocker (ARB) versus ACE Inhibitor (ACEI) on HDL Functionality in Patients on Maintenance Hemodialysis (MHD)

Ryohei Kaseda,[1] Yohei Tsuchida,[2] Jianyong Zhong,[2] Ichiei Narita,[1] Talat Alp Ikizler,[3] Valentina Kon.[2] *[1]Niigata Univ, Niigata, Japan; [2]Pediatric Nephrology, Vanderbilt Univ, Nashville, TN; [3]Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: ACEI/ARB reduce cardiovascular disease (CVD) in the general population. Although MHD are at greatly increased CVD risk, few studies have directly addressed their efficacy and recent evidence suggests differences in this population. Previously we showed HDL of MHD loses their protective function, therefore, we compared the effects of ARB or ACEI treatment on HDL functionality in MHD.

Methods: Following 3 weeks washout period, we randomly assigned 40 MHD to placebo, ramipril or valsartan. HDL was isolated at the starting point (B) and 3-6 months later (A). Cholesterol efflux was measured by cholesterol content in THP-1 cells after HDL exposure; anti-oxidative response and methylarginine were measured by HPLC; inflammatory markers were evaluated by RT-PCR and serum amyloid A (SAA) by ELISA.

Results: Compared to placebo, ARB and ACEI maintained cholesterol efflux (%)(B: 23.96 vs Placebo-A: 15.23 $P<0.01$; vs ARB-A:23.92 ns; vs ACEI-A: 22.10 ns). Cellular ROS production was reduced in response to HDL isolated from MDP on either ARB or ACEI compared to HDL of placebo-treated MHD (U/ml)(B: 21.03 vs Placebo-A 20.64 ns; ARB-A: 16.52 $P<0.01$; ACEI-A: 17.95 $P<0.01$). Neither ARB nor ACEI improved HDL anti-inflammatory effects, and ACEI rather potentiated TNF-α, IL-1β response compared to placebo or ARB. Both ARB and ACEI decreased plasma asymmetric dimethylarginine (ADMA) (μM)(B: 0.68 vs Placebo-A 0.58, ns; ARB-A 0.46 $P<0.01$; ACEI-A 0.48 $P<0.01$), but did not affect HDL content of ADMA. There was no difference in SAA levels in plasma or HDL among the groups.

Conclusions: ARB/ACEI treatment in MHD stabilized cholesterol acceptor capacity of HDL and promote its anti-oxidative effects. By contrast, neither ARB nor ACEI improve HDL's anti-inflammatory effects and ACEI may even amplify this response. ARB/ACEI did not affect postulated modulators of HDL functionality, including ADMA and SAA but reduced circulating ADMA. These results suggest a mechanism for potential superiority of ARB vs ACEI in MHD.

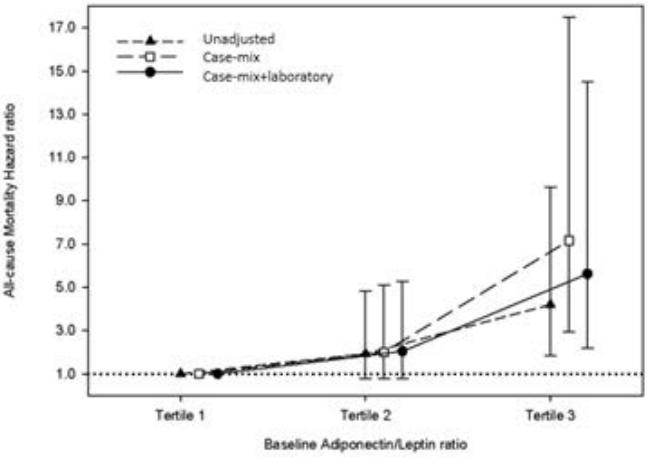
The Adiponectin/Leptin Ratio as a Predictor of Mortality in a Prospective Hemodialysis Cohort

Jerry Yu,[1] Amy Seung You,[1] Hamid Moradi,[1] Elani Streja,[1] Tracy Nakata,[1] Kavanaugh Kaji,[1] Nancy Lopez,[1] Danh V. Nguyen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Connie Rhee,[1] Frank Zaldivar.[1] *[1]UC Irvine; [2]Univ of Tennessee Health Science Center.*

Background: Adiponectin and leptin are major adipocytokines believed to play key roles in the regulation of cardiovascular and metabolic status. While animal studies show that adiponectin and leptin have inverse effects on the cardiovascular system (adiponectin reduces atherosclerosis, while leptin accelerates vascular injury), it has been suggested that the adiponectin-to-leptin (A/L) ratio may be an important predictor of cardiovascular disease and death. Despite their exceedingly high cardiovascular risk, no studies have examined the association of A/L ratio with mortality in hemodialysis (HD) patients.

Methods: Among 448 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Kidney Disease* study who underwent adiponectin and leptin measurement over 2014-15, we examined the association of A/L ratio with all-cause mortality using Cox regression with 3 adjustment levels: unadjusted, case-mix (age, sex, race, ethnicity, diabetes, vintage, vascular access), and case-mix+laboratory (albumin, creatinine, nPCR, IL-6) adjusted models.

Results: The median (IQR) of adiponectin and leptin were 15.2 (9.1, 24.2) and 16.5 (5.7, 54.6) mcg/ml, respectively. When examined as tertiles, the highest A/L ratio tertile was associated with higher death risk vs. the lowest tertile across all models: HR (95%CI) 5.63 (2.18-14.50) in case-mix+laboratory analyses. When examined as a continuous variable, higher levels were associated with higher mortality risk across all models: HR (95%CI) 1.20 (1.05-1.37) for +Δ1-standard deviation increments of the A/L ratio.



Conclusions: In a prospective cohort of HD patients, a higher A/L ratio was associated with higher mortality risk. Further studies are needed to confirm findings and to determine underlying mechanistic pathways.

FR-PO392

Pro-Inflammatory RAGE Ligand (EN-RAGE, S100A12), Circulating Soluble Receptor for AGE (sRAGE) and Mortality in Patients with Chronic Kidney Disease Stages 3-5 Marcelo M. Nascimento,[1] Shirley Yumi Hayashi,[2,3] Miguel C. Riella,[4] Bengt Lindholm.[2] *[1]Univ Federal do Parana, Curitiba, Parana, Brazil; [2]Renal Medicine & Baxter Novum, Karolinska Inst, Stockholm, Sweden; [3]KTH School of Technology and Health Research, Stockholm, Sweden; [4]Pro-Renal Foundation, Curitiba, Parana, Brazil.*

Background: Activation of the receptor for AGE (RAGE) is implicated in development and progression of vascular complications. Here we investigated associations of circulating concentrations of RAGE ligand S100A12, also known as EN-RAGE (extracellular newly identified receptor for advanced glycation end products binding protein) and soluble receptor for AGE (sRAGE) with all-cause and cardiovascular disease mortality in patients with chronic kidney disease (CKD) stages 3-5.

Methods: In 145 CKD patients (median age 61 years, 61% males) comprising 36 hemodialysis (HD), 55 peritoneal dialysis (PD) and 54 CKD stages 3-5 patients clinical characteristics were documented, and markers of mineral metabolism (including fibroblast growth factor-23; FGF-23), inflammation (s-albumin, high-sensitivity C-reactive protein; hsCRP, and interleukin-6; IL-6) as well as plasma concentrations of S100A12 and sRAGE were measured at baseline. All survivors completed 66 months of follow-up.

Results: S100A12 and sRAGE were positively associated with C-reactive protein ($\rho = 0.24$; $p < 0.05$; and $\rho=0.24$; $p<001$) and interleukin-6 ($\rho = 0.25$; $p < 0.01$, and $\rho=0.25$; $p<0.001$), respectively. After up to 66-months follow-up, the survival rate by Kaplan–Meier analysis was significantly different according to S100A12 plasma levels ($\chi2=8.09$; $P<0.01$) but not to sRAGE ($\chi2=2.19$; $P=0.13$). Finally, in Cox analysis, only S100A12 (HR=2.08 ((95% CI) 1.21-3.66) and age (HR= 1.81(95% CI 1.06-3.06) were independently associated with increased risk of death.

Conclusions: Increased concentrations S100A12 associated with inflammation - possibly reflecting activation of RAGE in the context of accelerated vascular disease - and increased all-cause mortality in CKD patients.

FR-PO393

A Malnutrition-Inflammation Score Predicts Patients Survival and Gives Strategies to Improve the Mortality of Maintenance Dialysis Patients Minoru Ito, Ikuto Masakane. *Nephrology and Dialysis Center, Yabuki Hospital, Yamagata, Japan.*

Background: Malnutrition-Inflammation Score (MIS) was reported as an assessment tool of malnutrition inflammation complex syndrome of dialysis patients. It consists of 10 components (weight change, dietary intake, gastrointestinal symptom, functional capacity, vintage and morbidity, subcutaneous fat, muscle wasting, BMI, albumin, TIBC). In this study, we validated the utility of the MIS and analyzed which component had the most effect on their mortality.

Methods: 319 hemodialysis patients (209 men, 110 women; age, 65.5 ± 12.9 years) were enrolled in this study. The MIS was assessed on all 319 patients by trained nutritionists at December 2009. They were followed up for 3 years. All patients were classified into three subgroups corresponding to each MIS points, normal nutritional group (MIS 0-3), mildly impaired group (MIS 4-7), severely impaired group (MIS over 8) respectively. The survival rates were compared among the three groups using the Kaplan-Meier analysis. The Cox's proportional hazard model was used in multivariate analyses of survival data adjusted for age and diabetes.

Results: 3-year survival rates of the 3 groups were 97.9% (normal), 94.9% (mildly impaired) and 80.3% (severely impaired) respectively. We found a significant difference in the mortality between the severely impaired group and the other two groups with a Log-Rank test. Among 10 MIS components, any component didn't affect their mortality independently. However, the total score of 10 MIS components was significant prognostic factor (HR 1.26; 95% C.I. 1.14-1.38; $p<0.0001$).

Conclusions: MIS is a comprehensive nutritional assessment tool and consists of 10 components. According to the scores of each component, we can determine treatments for each patient with malnutrition individually. Interestingly, each component was not independent prognostic factor by itself. However, the total point of MIS was a significant predictive index for their prognosis. It shows that the nutritional status can't be assessed by one parameter. In conclusion, a comprehensive andmultidisciplinary assessment procedure is required to manage the malnutrition of dialysis patents.

FR-PO394

Plasma Protein Thiolation Predicts Mortality in Maintenance Hemodialysis Patients Shweta Bansal,[1,2] Khaled Khazim,[3] Daniela Giustarini,[4] Sue Cunningham,[5] Ranieri Rossi,[4] Paolo Fanti.[1] *[1]Medicine/Renal, Univ of Texas HSC at San Antonio, SA, TX; [2]Renal Section, South Texas Veterans Healthcare System, SA, TX; [3]Faculty of Medicine in Galilee Medical Center, Bar-Ilan Univ, Safed, Israel; [4]Life Sciences, Univ of Siena, Siena, Italy; [5]UTHSC at Houston.*

Background: Oxidative stress present in CKD is implicated in the progression and complications of this disease state; however, direct measurement of oxidants such as reactive oxygen species (ROS) is difficult. Byproducts of oxidative degradation such as oxidized lipids and nucleotide etc. predict outcomes in CKD but represent the late steps in the oxidative process and therefore, may not be modifiable. We have previously shown that plasma protein thiolation index (PTI), an expression of thiol redox balance- a critical first line of defense against ROS, is altered in dialysis patients. Now, we aim to evaluate whether PTI can predict CKD outcomes.

Methods: We selected 72 clinically stable hemodialysis patients, analyzed their baseline PTI and followed them for mortality over 2.9±0.3 years. PTI is the molar ratio of protein mixed disulfides and free protein thiols in plasma and is measured by spectrophotometry. Since it is a ratio the value is not influenced by content of plasma proteins.

Results: In univariate Cox regression, death was predicted by PTI (HR 6.44;95%CI 1.07-36.7;p=0.042), serum creatinine (HR 0.75;CI 0.62-0.91;p=0.003), and Charlson comorbidity index (CCI) (HR 1.24;CI 1.01-1.53;p=0.042). In multivariate Cox proportional hazard regression (model 1: Chi-square 14.3; p=0.002), PTI predicted mortality (HR 24.6; CI 3.03-199.9; p=0.003) when adjusted for creatinine and CCI. Moreover, the model 2 including adjustments for 10 additional co-variates showed high overall predictive power (chi-square 24; p=0.008) and independent contribution of PTI (p=0.009). Furthermore, ROC curve analysis established 0.80 as cutoff value for binary PTI. High and low PTI subgroups included 33 and 38 subjects and experienced 42.5% vs. 16.2% mortality (HR 3.06; CI 1.17–7.97;p=0.02).

Conclusions: Our data supports presence of a link between oxidative stress and clinical outcome in ESRD and identifies PTI as a suitable candidate biomarker to identify dialysis patients at higher risk of mortality.

FR-PO395

Is the Association between the Malnutrition-Inflammation Score and Mortality Modified by Age, Gender and Diabetic Status? Marcelo Barreto Lopes,[1] Raissa B. Peixoto,[1] Gildete Barreto Lopes,[1] Priscila S. Carvalho,[1] Jéssica S. Fernandes,[1] Marcia T.S. Martins,[1] Luciana Ferreira Silva,[2] Antonio Alberto Lopes.[1] *[1]Univ Federal da Bahia; [2]Univ do Estado da Bahia, Salvador, Brazil.*

Background: The malnutrition-inflammation score (MIS) has been positively associated with mortality in maintenance hemodialysis (MHD) patients but it is important to show if the association is similar for patients of different subgroups. The objective was to investigate if associations of MIS with mortality vary by age, gender and diabetic status subgroups.

Methods: Prospective study of 627 patients (mean age = 48.5±14 yr) enrolled in the PROHEMO cohort, Salvador, Brazil. MIS (range 0-30) was categorized as <6 (n=364) and ≥6 (n=263). Cox regression was used to estimate adjusted hazard ratios and test for interaction.

Results: The adjusted hazard of death (Table) was 52% higher for MIS ≥6. The associations followed the same direction across subgroups, without significant interaction (P values >0.2) by age, gender, and diabetic status.

Death Rates and Hazard Ratios of Associations between MIS and Mortality in the Total Sample and by Gender, Age and Diabetic Status

		Death Rates per 100 person-years		Hazard Ratio (95% Confidence Intervals)		
	N	MIS≥6	MIS<6	Unadjusted	Adjusted*	P value for Interaction
Total Cohort	627	13.2	7.4	1.82 (1.38, 2.39)	1.52 (1.13, 2.05)	
Gender						0.918
Men	256	15.7	7.9	2.03 (1.43, 2.88)	1.36 (0.83, 2.23)	
Women	371	10.7	6.5	1.69 (1.07, 2.69)	1.68 (1.15, 2.48)	
Age (yr)						0.251
<60	485	9.4	5.6	1.71 (1.19, 2.45)	1.59 (1.08, 2.34)	
≥60	142	24.3	17.5	1.40 (0.90, 2.17)	1.28 (0.77, 2.12)	
Diabetes						0.207
Yes	122	10.5	5.9	1.81 (1.29, 2.53)	1.66 (1.15, 2.38)	
Not	505	24.7	17.7	1.53 (0.94, 2.49)	1.37 (0.74, 2.54)	

** Adjusted for age, gender, education, living with family, race, Kt/V, vintage, vascular access, hemoglobin, creatinine, erythropoietin use, diabetes, heart failure, cerebrovascular disease and peripheral vascular disease.*

Conclusions: The results of this Brazilian cohort provide support to the utility of MIS as a tool for predicting outcomes in MHD patients of different subgroups of age, gender and diabetic status.

FR-PO396

Circulating Tamm-Horsfall Protein (Uromodulin) Correlates with Sepsis Severity Varun Gaur,[1] Chadi A. Hage,[2] Ranjani N. Moorthi,[1] Simit Doshi,[1] Radmila Micanovic,[1] Sharon M. Moe,[1] Tarek M. El-Achkar.[1] *[1]Medicine-Nephrology, Indiana Univ and Indianapolis VA Medical Center; [2]Medicine-Pulm Critical Care, Indiana Univ, Indianapolis, IN.*

Background: Tamm-Horsfall protein (THP, also known as Uromodulin), is a glycoprotein uniquely expressed by the kidney and secreted in the urine. A small amount of THP also circulates in the plasma (pTHP), the significance of which remains unclear. In sepsis, invading pathogens overwhelm the host immune system, frequently leading to a maladaptive response of injurious inflammation. Mortality in THP-/- mice is significantly increased compared to THP+/+ after cecal ligation and puncture, suggesting that THP is protective in the setting of sepsis. Since THP may have immuno-modulatory functions, we hypothesized that the level of pTHP will correlate with the severity of sepsis and be a useful biomarker.

Methods: This is a prospective pilot study to measure pTHP in 26 patients with severe sepsis, at the time admission (T0), and after 48 hours (T48). Sepsis severity was assessed using the sequential organ failure assessment (SOFA) score. SOFA score incorporates 6 distinct organ associated variables, including serum creatinine.

Results: The average age was 57 ±15 years. Diabetes and hypertension were present in 42.3% and 73.1% of the study population, respectively. 30.7% of patients had CKD. Between T0 and T48, 15 patients (57.6%) had improvement in their SOFA score. The median pTHP trended lower between T0 and T48: 46.5 (32.7; 59.4) vs. 33.6 (25.5; 60.9) ng/ml, respectively (p=0.2). Although pTHP 0 and 48 did not correlate individually with SOFA 0 and 48, changes in pTHP between T0 and T48 positively correlated with SOFA 48 (p=0.03) and marginally with changes in SOFA (p=0.1). These findings suggest that an increasing pTHP level correlates with more severe sepsis.

Conclusions: We showed that increases in pTHP correlate with the severity of sepsis in this pilot study. The increase in pTHP may be reactive and part of an acute response to limit the disease. Larger studies are needed to validate the role and use of pTHP as a biomarker of clinical utility in sepsis.

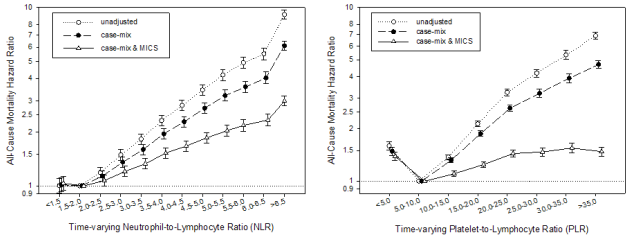
FR-PO397

Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratios and Mortality in Incident Hemodialysis Patients Christina J. Catabay, Yoshitsugu Obi, Elani Streja, Melissa Soohoo, Kamyar Kalantar-Zadeh. *UC Irvine.*

Background: Both neutrophil-to-lymphocyte ratio(NLR) and platelet-to-lymphocyte ratio(PLR), calculated from complete blood count, were suggested as oncologic prognostic markers. Recent preliminary studies indicate that NLR and PLR may be associated with inflammatory status and mortality in hemodialysis(HD) patients.

Methods: We examined the association of NLR and PLR with all-cause mortality in a cohort of 107,737 HD patients from a large dialysis organization from 2007-2011 using baseline Cox proportional hazards regression with hierarchical adjustments for case-mix (demographics, comorbidities) and markers of malnutrition and inflammation (MICS) covariates. NLR was divided into 12 categories(<1.5, ≥6.5 and ten 0.5 increments in-between) and PLR was divided into 8 categories(<5, ≥35 and six 5 categories in-between). We also conducted time-varying models to examine their short-term associations.

Results: The mean age (±SD) of the patients was 63±15 years old, and they included 44% females, 59% diabetics, and 32% African Americans. The median(IQR) NLR and PLR at baseline were 3.6 (2.7, 5.0) and 13.1 (9.5, 18.5), respectively. Both indices were positively associated with ferritin levels and negatively associated with levels of albumin, hemoglobin, and iron saturation. Unadjusted baseline Cox models showed that lowest risk at the second lower groups for both NLR and PLR and higher levels were linearly associated with all-cause mortality risk. However, these associations were attenuated in the fully-adjusted models. Time-varying models exhibited consistent trends but a more pronounced association of both NLR and PLR with mortality.



Conclusions: Higher NLR and PLR are strongly associated with higher short-term mortality risk in HD patients especially in unadjusted time-varying models, suggesting the effectiveness of these ratios as simple predictors of approaching death.

Claudia-12 Is Expressed in the Proximal Tubule and Forms a Calcium Permeable Pore R. Todd Alexander, Megan R. Beggs, Wanling Pan, Emmanuelle Cordat. *Paediatrics & Physiology, The Univ of Alberta, Edmonton, AB, Canada.*

Background: The majority of filtered calcium, approximately 2/3rds, is reabsorbed from the proximal tubule by a passive paracellular mechanism. This process depends on active sodium and water reabsorption, and a calcium permeable pore between proximal tubule cells. Claudin-12 is expressed along the intestine and forms a calcium permeable pore in Caco-2 cells. Renal localization and function is not known.

Methods: We expressed Claudin-12 in OK cells and in MDCK cells using a tet-off system. A claudin-12 knockout mouse was generated by replacing the coding exon with Beta-galactosidase from *E.Coli* and the calcium phenotype interrogated using altered diets and clearance methods.

Results: Claudin-12 mRNA was detected in microdissected proximal tubules. Expression of claudin-12 in OK cells decreased TEER and increased calcium flux, but did not alter the pNa/pCl. Over-expression of claudin-12 also decreased claudin-1 and -6 mRNA expression relative to cells expressing empty vector. Expression of claudin-12 under a tet-off promoter in MDCK cells did not alter endogenous claudin expression but decreased TEER and increased pNa/pCl. X-gal staining of claudin-12$^{+/-}$ kidney sections demonstrated exclusively cortical staining that colocalized with aquaporin-1. Claudin-12$^{-/-}$ animals weighed the same as the wild-type, had the same serum calcium, PTH and creatinine levels. Renal TRPV5, clabindin-D_{28K} and claudins -3, -10a, -14, -16 and -19 mRNA expression was not different between genotypes. Claudin-8 expression was significantly reduced in claudin$^{-/-}$ mice. Knockout mice had the same urine calcium excretion on a low, normal and high calcium diet as wild-type controls. Further, claudin-12$^{-/-}$ mice were able to reduce their urinary calcium excretion to the same extent as wild-type littermates. However, feeding claudin-12$^{-/-}$ mice a high calcium diet after fasting attenuated urinary calcium excretion relative to wild-type animals.

Conclusions: Claudin-12 is expressed in the proximal tubule where it forms a cation and calcium permeable pore, however, its genetic deletion does not alter urinary calcium excretion at steady state.

Acute Effects of Exercise on Serum A-Klotho, Phosphate and Glucose in Healthy Volunteers: A Pilot Study Sven-Jean Tan,[1,2] Melissa Minhui Chu,[1] Michael Ming Xin Cai,[1,2] Timothy D. Hewitson,[1,2] Stephen G. Holt,[1,2] Nigel David Toussaint.[1,2] *[1]Nephrology, The Royal Melbourne Hospital, Parkville, Victoria, Australia; [2]Medicine (RMH), The Univ of Melbourne, Parkville, Victoria, Australia; [3]The Royal Melbourne Hospital.*

Background: Aim: To investigate the effect of exercise on soluble α-klotho (sKl) in healthy adults. **Background:** Membrane-bound α-klotho, predominantly expressed in the kidney, functions as a co-receptor for fibroblast growth factor-23 (FGF23) to regulate phosphate excretion. Circulating sKl, derived from membrane α-klotho cleavage, has extra-renal actions. sKl can affect ion channels and insulin signaling pathways and is inversely associated with mortality. Effects of physical exercise on sKl are unknown.

Methods: Ten fasting healthy volunteers underwent a standard Bruce protocol exercise test on a treadmill. sKl, serum phosphate (sPi) and blood glucose levels were measured in samples collected 1-week prior, immediately pre (Tpre), 0 (Tpost), 30 (T30), 240 (T240) minutes and 1-week post exercise. Changes were assessed using repeat measures ANOVA or Friedman's test with Dunn's multiple comparison.

Results: Median (IQR) age of participants was 47.5 (44-51) years; five (50%) were male. All study participants achieved at least 90% predicted maximum heart rate. Compared with Tpre, an acute increase in sKl was seen at Tpost (median 483pg/mL vs 602pg/mL, p<0.01) followed by non-significant decline in sPi at T30 (mean 0.94mmol/L vs 0.83mmol/L). Exercise led to a reduction in blood glucose by T240, following an initial non-significant rise, with median glucose levels at Tpre, Tpost, T30 and T240 of 6.0, 6.5, 6.3 and 5.7mmol/L respectively.

Conclusions: High intensity exercise is associated with a transient increase in sKl, decrease in sPi levels and delayed blood glucose reduction in healthy adults. Evaluation of long-term effects of cardiovascular fitness programs on sKl and sPi in healthy individuals and disease cohorts are required to identify potential lifestyle modifications to improve chronic disease management and long-term outcomes.

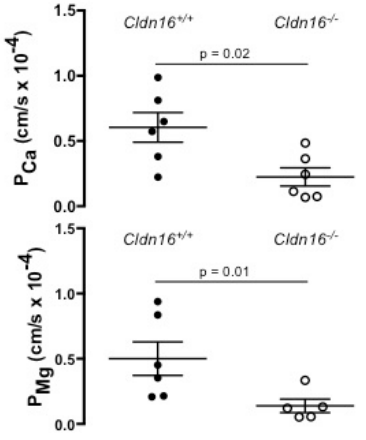
Role of Claudin-16 in Basal and PTH-Stimulated Ion Transport in the Thick Ascending Limb of Henle's Loop Marie-Lucile Figueres,[1,2] Claire Bardet,[2,3] Dominik Müller,[4] Catherine Chaussain,[2,3] Pascal Houillier.[1,2] *[1]Centre de Recherche des Cordeliers, Renal Physiology, INSERM U1138, ERL8228, Paris, France; [2]Paris Descartes Univ, France; [3]EA2496, Montrouge, France; [4]Charité Univ, Berlin, Germany.*

Background: Claudin-16 is specifically expressed at the tight junction of thick ascending limb of Henle's loop (TALH) cells. Inactivating mutations of the gene encoding claudin-16 causes Familial Hypomagnesemia with Hypercalciuria and NephroCalcinosis

(FHHNC), a rare genetic disorder responsible for a renal loss in magnesium and calcium, nephrocalcinosis and early renal insufficiency. However, the role of claudin-16 in basal and parathyroid hormone (PTH)-stimulated ion transport in the TALH remains unclear.

Methods: We used in vitro microperfusion of TALH dissected from *Cldn16*$^{-/-}$ and *Cldn16*$^{+/+}$ mice to measure paracellular ion permeabilities and to assess the effect of basolateral PTH (10^{-10} M) on transepithelial calcium absorption.

Results: Paracellular permeabilities to calcium (PCa) and magnesium (PMg) were significantly decreased in *Cldn16*$^{-/-}$ mice (PCa = 0.22x10^{-4} versus 0.60x10^{-4} cm/s in *Cldn16*$^{+/+}$ mice (p = 0.02) ; PMg = 0.14x10^{-4} versus 0.50x10^{-4} cm/s in *Cldn16*$^{+/+}$ mice (p = 0.01)). Calcium and magnesium absorption was decreased by ~50 % in TALH from *Cldn16*$^{-/-}$ mice, relative to *Cldn16*$^{+/+}$ mice.



Permeabilities to sodium, chloride and potassium were unaffected in *Cldn16*$^{-/-}$ mice. PTH significantly increased calcium reabsorption in TALH from both *Cldn16*$^{+/+}$ and *Cldn16*$^{-/-}$ mice.

Conclusions: Claudin-16 is required for normal paracellular permeability to calcium and magnesium in the TALH, under basal condition. However, the lack of claudin-16 does not prevent the PTH-elicited increase in calcium absorption.

FR-PO401

Serum Calcification Propensity Is Improved by Increased Dialysate Bicarbonate and Dialysate Magnesium: The BicMag Pilot Study

Andreas Pasch,[1,2] Matthias Bachtler,[1,2] Edward R. Smith,[4] Katarina Benackova,[3] Dominik E. Uehlinger.[3] *[1]Clinical Research, Univ Bern, Bern, Switzerland; [2]Calciscon AG, Bern, Switzerland; [3]Nephrology, Univ Hospital Bern, Bern, Switzerland; [4]Nephrology, Royal Melbourne Hospital, Melbourne, Australia.*

Background: Serum Calcification Propensity can be measured by a novel blood test, which determines the transformation time (T_{50}) from amorphous primary to crystalline secondary Calciprotein Particles. Epidemiological and in vitro data suggest that Bicarbonate and Magnesium may be of beneficial influence on T_{50}.

Methods: We conducted a 7-week prospective open label pilot study in n=12 prevalent ambulatory dialysis patients with a baseline T_{50} ≥200 min. (10 male, vintage 31 [14-92] months). T50 was determined twice at baseline, twice after increase of dialysate bicarbonate from 32 to 37 mmol/L (n=6) or dialysate magnesium from 0.75 to 1.0 mmol/L (n=6), and twice during the combined increase of bicarbonate and magnesium (n=12). Furthermore, T_{50} was determined after a washout phase of 1 week.

Results: One patient, hospitalized during this study due to an unrelated problem, was excluded from the analysis. Increasing dialysate magnesium led to an increase of serum magnesium from 1.04±0.17 to 1.15±0.17 mmol/L (p<0.01) and increasing dialysate bicarbonate led to an increase of serum bicarbonate from 20.2±1.7 to 23.4±1.8 (p<0.01). T_{50} was 242±40 min. at baseline, 265±61 min. while on increased bicarbonate, and 267±57 min. while on increased magnesium. Combining increased bicarbonate and magnesium resulted in a T_{50} of 282±67 min. (p<0.014 when compared to baseline). After 1 week washout, serum magnesium was 1.04±0.19 mmol/L, serum bicarbonate 19.6±1.7 mmol/L, and T_{50} 255±52 min.

Conclusions: Serum calcification propensity is improved by increasing dialysate bicarbonate and magnesium. Further studies with longer observation periods and individualized treatments are needed.

FR-PO402

Does Reducing Serum Phosphate in Dialysis Patients Result in Improved Clinical Outcomes - Is a Large Scale Trial Feasible?

Ramya Bhargava,[1] Philip A. Kalra,[2] Paul E. Brenchley,[1] Alastair J. Hutchison.[1] *[1]Manchester Royal Infirmary; [2]Salford Royal Hospital.*

Background: High phosphate is associated with increased mortality in dialysis patients. However no RCTs have demonstrated that reducing serum phosphate improves quality or length of life. The required size and scope of such a trial is unknown; therefore we conducted a prospective, randomised, feasibility study to inform the design of a definitive trial.

Methods: Dual centre, prospective, parallel group, RCT feasibility study. 104 HD patients were randomized to lower range (LRG phosphate target 2.5 to 4.3mg/dL) or higher range group (HRG 5.6 to 7.4mg/dL). Non-calcium containing binders, questionnaires & an adherence self-help programme were used to achieve target phosphate. End points included - number titrated to required range & maintained in range over the maintenance period, consent rates, pill burden, drop-out rates & cardiovascular events.

Results:

	HRG	LRG	P-value
N	51	53	
Age(y)	59.59 (SD 13.83)	62.70 (SD 11.19)	NS
F:M	16:35	20:33	
Serum Phosphate(mg/dL)	6.6+/-0.19	6.9+/-0.25	NS
PTH(pg/ml)	436.7+/-62.17	424.2+/-54.36	NS
Albumin(g/L)	32.97+/-0.78	32.66+/-0.75	NS
Cholesterol(mmol/L)	3.21+/-0.16	4.05+/-0.22	NS
Diabetes(Yes:No)	15:36	11:42	<0.05
CAD(Yes:No)	15:36	10:43	<0.05
RRT duration(y)	2.5 (1.5,5.0)	2.0 (1.0,5.7)	NS

Table1:Pre-randomization values. 65% patients completed the 12 month study. For phosphate the mean difference between the groups throughout maintenance period was >1.00 mg/dL, p <0.05 at weeks 10,13 and 21. 9 patients died in HRG vs only 2 in LRG. Consent withdrawal 8 LRG vs 4 HRG. Pill burden was higher in LRG. Dialysis access problems 9 in HRG vs 3 in LRG.

Conclusions: 65% retention rate is similar to other interventional RCTs in dialysis patients. 10% mortality is as expected for this cohort, but was higher in HRG. With a 13% randomization rate and 65% annual retention rate, 3 - 4,000 patients would need to be recruited for 1000 to complete 2 years follow-up. This suggests a target dialysis population of about 25,000, necessitating a multi-national approach.

Examining Risk Factors for Calciphylaxis

Rakesh Kilari,[1] Mia Wang,[1] Douglas E. Schaubel,[1] Francesca Tentori,[2] William H. Herman,[1] Rajiv Saran,[1] Vahakn B. Shahinian.[1] *[1]Nephrology, Univ of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Calciphylaxis or calcific uremic arteriolopathy (CUA) is a rare but serious disorder, occurring in dialysis patients and characterized by systemic medial calcification of the arterioles that leads to ischemia and subcutaneous necrosis. Despite its first description over 50 years ago, clinical predictors remain to be clearly identified given that much of the work done to date has consisted of smaller and single-center studies. We therefore utilized national data on dialysis patients from the United States Renal Data System (USRDS) to examine risk factors for CUA.

Methods: Patients on chronic dialysis with Medicare as primary insurance were identified from 2007 through 2014 using USRDS data. Potential risk factors were identified from the Medical Evidence Form 2728 (age, sex, race, diabetes, vintage), dialysis claims (hematocrit, BMI, IV iron) and Medicare Part D claims (warfarin, calcimimetics, calcium-based phosphate binders) in the 6 months after cohort entry. The primary outcome was the new development of CUA based on a validated claims-based algorithm. Cox regression was used to model the rate (cause-specific hazard) of CUA, treating death and transplantation as competing risks.

Results: A total of 1413 cases of CUA were identified with results comparing characteristics of cases and non-cases presented in Table 1. In the multivariable model, younger age, female sex, longer dialysis vintage, higher BMI, diabetes mellitus, calcimimetic use and warfarin use were significant predictors of CUA.

Table 1. Baseline characteristics (Risk factors) and their Hazard Ratios.

Characteristics			
	CUA cases (n=1413)	Non-Cases (n=375,658)	Adjusted HR (95%CI)
	% or mean	% or mean	
Age at cohort entry (y):			
<22	0	1	1.27 (0.38, 3.14)
22-45	23	14	2.66 (1.96, 3.67)
46-65	51	39	2.15 (1.61, 2.95)
66-80	22	36	1.30 (0.96, 1.79)
>=81	3	11	1 (ref)
Mean Age	56.5	63.0	
Female:	66	48	1.92 (1.7, 2.1)
Race:			
White	53	59	1
Black	44	35	0.90 (0.91,1.01)
Dialysis Vintage (y):			
<2 year	14	12	1
2-4	22	16	1.21 (1.01, 1.4)
>=5	19	11	1.38 (1.13, 1.7)
Mean Vintage	4.5	4.1	
Diabetes:	55	49	1.29 (1.15, 1.4)
BMI:			
19-25	17	34	1
26-30	20	25	1.42 (1.2, 1.7)

Conclusions: This represents the first truly national and the largest study to date evaluating risk factors for CUA. A better understanding of the risk factors for CUA may help identify prevention strategies for this devastating complication.

FR-PO404

Determination of Changes in Trans- and Paracellular Divalent Cation Transport Pathways in Renal and Intestinal Epithelia during Lactation
Henrik Dimke,[1] Megan R. Beggs,[2,3] R. Todd Alexander.[2,3] *[1]Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; [2]Dept of Pediatrics, Univ of Alberta, Edmonton, AB, Canada; [3]Membrane Protein Disease Research Group, Univ of Alberta, Edmonton, AB, Canada.*

Background: Significant alterations in maternal divalent cation balance occur postpartum during lactation. As such, Ca^{2+} is mobilized to breast milk by demineralization of the skeleton as well as by changes in intestinal and renal Ca^{2+} transport. However, the specific molecular alterations in divalent cation transport pathways across renal and intestinal epithelia during lactation have not been clearly delineated.

Methods: To ascertain which changes occur during lactation, female mice were divided into 3 groups, non-pregnant controls, lactating mice with litters maintained for 12 days after birth, or mice undergoing involution with litters removed after birth and maintained for 12 days.

Results: Urinary excretion and fractional excretion of Ca^{2+} and Mg^{2+} increased during lactation. Renal 1-alpha hydroxylase and 24-OHase mRNA levels increased by 900%. This was accompanied by significant increases in intestinal expression of *Trpv6* and *Calbindin-D_{9K}* in lactating mice. No significant alterations in the cation permeable claudins (-2, -12 or -15) were observed in any intestinal segments. In kidney, increased expression of *Trpv5 and Calbindin-D_{28K}* were observed during lactation. Increased Calbindin-D_{28K} and TRPV5 protein expression was found by immunohistochemical analysis, while no changes in claudin-2 were noted, consistent with the mRNA expression. Colonic *Trpm6* expression increased during lactation, while renal *Trpm6* was not significantly altered.

Conclusions: Transcellular Ca^{2+} transport pathways increase during lactation, likely due to increased Vitamin D dependent-stimulation. Increased urinary mineralexcretion can be explained on the basis of intestinal hyperabsorption and bone demineralization, despite enhanced selective transcellular renal Ca^{2+} uptake. Only transcellular Mg^{2+} absorption in intestine appeared significantly regulated during lactation, while expression of paracellular transport proteins were unchanged.

FR-PO405

Phosphate Reabsorption Is a Parabolic Function of Parathyroid Hormone and Fibroblast Growth Factor-23 Concentrations
Kenneth R. Phelps, Darius Mason. *Research Service, Stratton VAMC, Albany, NY.*

Background: The serum phosphorus concentration ($[P]_s$) is the sum of excretion and reabsorption rates of P per volume of filtrate ($E_p/C_{cr} + TR_p/C_{cr}$, C_{cr} = creatinine clearance; *Clin Nephrol* 2015;83:167). If subjects with normal and reduced GFR are considered together, TR_p/C_{cr} is a parabolic function of E_p/C_{cr}, and the horizontal limb of the parabola commences at values of E_p/C_{cr} that are typical of early CKD (unpublished data). Since [PTH] and [FGF23] are direct linear functions of E_p/C_{cr} (*Clin Nephrol* 2016;85:251), we hypothesized that TR_p/C_{cr} is a parabolic function of [PTH] and [FGF23].

Methods: We obtained morning fasting specimens of plasma, serum (s), and urine (u) from 30 subjects with CKD (eGFR 14-49 mL/min/1.73m^2) and 28 controls with eGFR > 60. [PTH]1-84 and intact [FGF23] were measured with ELISAs (Scantibodies and Immuotopics, respectively). E_p/C_{cr} was calculated as $[P]_u[cr]_s/[cr]_u$, and TR_p/C_{cr} as $[P]_s - E_p/C_{cr}$ (*Clin Nephrol* 2015; 83:167). Linear regressions of TR_p/C_{cr} on 100/[PTH] and 100/[FGF23] were sought; after significance was demonstrated, we used the regression equations to compute idealized TR_p/C_{cr} for each value of 100/[PTH] and 100/[FGF23]. We then plotted idealized TR_p/C_{cr} against [PTH] and [FGF23].

Results: TR_p/C_{cr} was a linear function of 100/[PTH] and 100/[FGF23] and thus a parabolic function of [PTH] and [FGF23]. Linear and parabolic equations, R^2, and *P*-values are summarized in the Table. TR_p/C_{cr} fell abruptly to a nadir along vertical limbs of parabolas as [PTH] and [FGF23] rose in controls. Horizontal limbs commenced at the nadir, and TR_p/C_{cr} fell minimally as [PTH] and [FGF23] rose further in CKD.

Hormone	PTH		FGF23	
Type of equation	Linear	Parabolic	Linear	Parabolic
x	100/[PTH]	[PTH]	100/[FGF23]	[FGF23]
y	TR_p/C_{cr}	TR_p/C_{cr}	TR_p/C_{cr}	TR_p/C_{cr}
Equation	$y = 0.23x + 1.97$	$y = (23/x) + 1.97$	$y = 0.063x + 2.21$	$y = (6.3/x) + 2.21$
R^2	0.26	--	0.11	--
P	< 0.001	--	0.01	--

Conclusions: TR_p/C_{cr} is a parabolic function of [PTH] and [FGF23]. Although both concentrations rise as GFR falls, the hormones inhibit P reabsorption maximally in early CKD.

FR-PO406

Low Serum Magnesium Is Associated with an Increased Risk of Prediabetes
Brenda C.T. Kieboom,[1,2] Symen Ligthart,[2] Abbas Dehghan,[2] Oscar Franco,[2] Albert Hofman,[2] Robert Zietse,[1] Bruno H. Stricker,[1,2] Ewout J. Hoorn.[1] *[1]Internal Medicine, Erasmus MC, Rotterdam, Netherlands; [2]Epidemiology, Erasmus MC, Rotterdam, Netherlands.*

Background: Previous studies identified an association between serum magnesium and incident diabetes mellitus. However, this association may be explained by reverse causality, as hyperglycemia can lower serum magnesium through urinary magnesium loss. Prediabetes is less likely to cause urinary magnesium loss, because hyperglycemia is less severe. Therefore, we studied, for the first time, the association between serum magnesium and prediabetes.

Methods: The association was analyzed in the population-based Rotterdam Study using Cox proportional hazard models adjusted for age, sex, lifestyle factors, comorbidities, kidney function, other electrolytes and diuretic use. In addition, a mediation analysis was performed to study if the risk is mediated through insulin resistance (HOMA-IR levels) or influenced by common genetic variation in eight magnesium transporter genes.

Results: 8555 participants (mean age 64.7 years) with normal glucose levels at baseline were included; the median follow-up was 7.0 years. A 0.1 mmol/L decrease in serum magnesium level was associated with an increase in diabetes risk (HR:1.15, 95%CI 1.02-1.31), confirming previous studies. Of interest, a similar association was found between serum magnesium and prediabetes (HR:1.12, 95%CI 1.01-1.26). The effect of serum magnesium on prediabetes was mediated for 34.6% through HOMA-IR levels. Genetic variation in *CNNM2* decreased prediabetes risk, which was completely mediated by increasing serum magnesium levels (indirect effect: OR:0.96, 95%CI 0.94-0.98), whereas genetic variation in *FXYD2* increased prediabetes risk, which was completely mediated by decreasing serum magnesium levels (indirect effect: OR:1.03, 95%CI 1.01-1.05).

Conclusions: The observation that lower serum magnesium levels are not only associated with diabetes but also with prediabetes makes reverse causation less likely. The effect of serum magnesium on prediabetes is partially mediated through insulin resistance. Common variants in magnesium transporter genes modify prediabetes risk by influencing serum magnesium. Hence, serum magnesium may be a modifiable risk factor for diabetes.

FR-PO407

Ghrelin Stimulates the Epithelial Magnesium Channel TRPM6 via Gαs Signaling
Matthias Wolf,[1] Mingzhu Nie,[1] Carolina Rivera,[1] Denise K. Marciano,[2] Manjot S. Bal.[1] *[1]Pediatrics, UT Southwestern Medical Center, Dallas, TX; [2]Internal Medicine, UTSW Medical Center, Dallas, TX.*

Background: Osteoporosis after bariatric surgery is an increasing health concern as the rate of bariatric surgery has risen significantly. In animal studies mimicking bariatric procedures, bone disease, together with decreased serum levels of Ca^{2+}, Mg^{2+} and the gastric hormone Ghrelin were described. Ghrelin is a 28 amino acid peptide and regulates metabolism by binding to the growth hormone secretagogue-receptor 1a (GHSR1a). GHSR1a is also expressed in the kidney. We tested the hypothesis that Ghrelin deficiency after bariatric surgery contributes to osteoporosis via reduced upregulation of the renal calcium channel TRPV5 or the magnesium channel TRPM6.

Methods: We expressed GHSR1a with TRPV5 or TRPM6 channel in HEK293 cells and treated them with purified Ghrelin. Whole-cell current density was analyzed by patch-clamp recording.

Results: After Ghrelin exposure whole-cell current density did not change for TRPV5 but increased for TRPM6 (82 ± 9 vs 255 ± 27 *p*A/*p*F for control vs Ghrelin; $p<0.001$). This effect was dose-dependent. We confirmed the stimulatory role of Ghrelin towards TRPM6 by applying the Ghrelin-mimetic (D-Trp^7, Ala^8,D-Phe^{10})-α-MSH (6-11) amide, which increased TRPM6 current density, and Ghrelin-mimetic with GHSR1a blocker (D-Lys^3)-GHRP6, which inhibited the effect (84 ± 15 vs 219 ± 13 *p*A/*p*F vs 96 ± 22 *p*A/*p*F for control vs mimetic vs mimetic+blocker; $p<0.0001$). As GHSR1a initiates downstream signaling via protein kinase A (PKA), we tested the effect of the PKA inhibitor H89 which abrogated TRPM6 stimulation by Ghrelin (204 ± 29 vs 32 ± 5 *p*A/*p*F for Ghrelin vs Ghrelin+H89; $p<0.005$). The role of PKA signaling in TRPM6 regulation was verified by the fact that only transfected $G\alpha_s$, but not the $G\alpha_s$ mutant Q227L, nor $G\alpha_i$, $G\alpha_q$, or $G\alpha_{12/13}$ upregulated TRPM6 current density.

Conclusions: Ghrelin stimulates TRPM6 channel via $G\alpha_s$-PKA signaling. Rising Ghrelin levels with hunger may contribute to increased renal Mg^{2+} reabsorption to compensate for less enteral Mg^{2+} reabsorption. Ghrelin deficiency after bariatric surgery may contribute to renal Mg^{2+} wasting and osteoporosis as 50% of total body Mg^{2+} is stored in bones.

FR-PO408

Novel VDR Gene Mutation R343H Responsible for Vitamin D-Resistant Rickets with Alopecia Min-Hua Tseng,[1] Shih-Hua P. Lin.[2] *[1]Nephrology, Pediatrics, Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Nephrology, Medicine, Tri-Service General Hospital, Taipei, Taiwan.*

Background: Hereditary vitamin D-resistant rickets (HVDRR) is an autosomal recessive disorder caused by *vitamin D receptor* (*VDR*) gene mutation featuring hypocalcemic and hypophospatemic rickets with or without alopecia. Despite more than 50 VDR mutations reported, the study of the VRD mutant on RXR-binding domains remains very rare. This study was to identify the *VDR* gene mutation in a family with HVDRR and alopecia, and determine the mechanisms of this VDR mutant causing the phenotype.

Methods: The genotype and phenotype with follow-up in a Chinese family with HVDRR were performed. In vitro studies included situ-directed mutagenesis for expression of mutant VDR constructs, fluorescence microscopy for the nuclear localization of different enhanced green fluorescent protein-tagged VDR proteins, and luciferase reporter driven by the human *CYP24A1* gene promoter for measuring transcriptional activity of VDR.

Results: A novel homozygous R343H mutation in the exon 11 of VDR were identified in the proband and his affected sister and not found in 200 healthy subjects. Supraphysiological dose of active vitamin D_3 and calcium supplement therapy improved their biochemical and radiographic abnormalities but not alopecia. This R343H mutant did not eliminate the expression of VDR and change the conformation of VDR by using antibody against HA-tag and VDR C-terminal region, respectively. This mutant also did not affect normal nuclear localization of VDR, but actually impair the *CYP24A1* promoter activity in the presence of 1,25 $(OH)_2$ vitamin D_3.

Conclusions: Although novel VDR R343H mutation in HVDRR does not affect the expression, conformation, and nuclear location of VDR, it impairs the transactivation activity of VDR on downstream transcriptional events and may account for typical clinical features with alopecia.

FR-PO409

Salivary Pi Handling May Be under the Control of Gastrointestinal Pi Sensing Kayo Ikuta, Hiroko Segawa, Shihoko Yuki, Ichiro Kaneko, Ai Hanazaki, Toru Fujii, Aoi Kushi, Sawako Tatsumi, Ken-Ichi Miyamoto. *Dept of Molecular Nutrition, Tokushima Univ, Tokushima, Japan.*

Background: A hyperphosphoric salivary content, which correlates linearly with serum inorganic phosphate (Pi), has been reported in hemodialysis (HD) patients and therefore the addition salivary Pi binding to traditional phosphate binders has been suggested to be a useful approach for improving the treatment of hyperphosphatemia in HD patients. In addition, gastrointestinal and salivary grand Pi sensing may be involved in improving hyperphosphatemia. In the present study, we investigated factors, which affect salivary Pi level.

Methods: Mice were used for hyperphosphatemic adenine-induced nephritis (adenine), acute kidney injury (AKI) models, and administration of Pi solution via oral or intravenous route. To measure salivary flow rates, osmolality, and Pi levels, mice were given an intravenous injection of pinocalpine.

Results: Hyperphosphatemic adenine mice showed high levels of salivary Pi. In contrast, AKI mice showed hyperphosphatemia, but not hyperphosphoric saliva. Adenine mice showed abnormal salivary parameter, e.g. low flow rates and high osmolality. In adenine mice, dietary P restriction significantly decreased the plasma and salivary Pi levels with the abnormal salivary parameter. It suggests that salivary Pi level is regulated by dietary Pi contents. Low Pi diet decreased plasma Pi, urinary Pi excretion and salivary Pi levels. In contrast, high Pi diet showed completely opposite results. Dietary Pi contents did not change salivary parameters. Next, we examined the effect of differential administration route on salivary Pi levels. An intravenous injection of Pi solution significantly increased plasma Pi and urinary Pi excretion, but not salivary Pi levels. In contrast, oral administration of Pi solution significantly increased plasma Pi, urinary Pi excretion, in addition to salivary Pi levels. Furthermore, only oral administration of Pi solution, but not intravenous injection, acutely changed membrane localization of salivary slc34a2.

Conclusions: Gastrointestinal Pi level may be a determinant for salivary Pi level. This study indicates that gastrointestinal Pi sensing improves salivary Pi and renal Pi excretion levels.

Calcification Propensity (Serum T50) Predicts Longitudinal Progression of Coronary Artery Calcification in CKD: The CASCADE Study Angela Yee Moon Wang,[1] Sharon Yui Ling Cheung,[1] Matthias Bachtler,[2] Ck Wong,[3] Miu Ting Chu,[3] Yat Y. Yau,[4] Andreas Pasch.[2] *[1]Medicine, Univ of Hong Kong, Queen Mary Hospital, Hong Kong, Hong Kong; [2]Clinical Chemistry, Univ Hospital Bern, Bern, Switzerland; [3]Chemical Pathology, Chinese Univ of Hong Kong, Hong Kong, Hong Kong; [4]Diagnostic Radiology, Central Biomedical Imaging Center, Hong Kong, Hong Kong.*

Background: Calcification propensity (T50) is a measure of extra-skeletal mineral stress and predicts mortality in CKD. This study aims to determine if serum T50 predicts longitudinal progression of vascular calcification over a prospective follow-up of 24 months in CKD and may thus explain its association with mortality.

Methods: 300 non-dialysis CKD 3–5 subjects (age: 60±10yrs, 56%men) underwent plain multi-slice computed tomography (MSCT) to estimate coronary artery calcium scores (CACS) and blood collection. MSCT was repeated after 24 months to determine changes in CACS over 24 months. Those with changes in CACS in the upper tertile (n=88) were defined as progressors while those in the middle and lower tertiles were defined as non-progressors.

Results: The mean T50 of all CKD subjects was 281 ± 59 mins. The progressors were older [P<0.001], had higher systolic blood pressure [P<0.001], serum phosphate [P<0.001] and intact parathyroid hormone [P=0.001], but lower serum albumin [p=0.014], T50 [268 ± 63 vs 289 ± 56mins; P=0.006], magnesium [P=0.047] and eGFR $_{CKD\text{-}EPI}$ [P<0.001]. In the stepwise multiple logistic regression adjusting for age, gender, background diabetes, atherosclerotic vascular disease, Framingham risk factors, baseline CACS, eGFR, high sensitivity C-reactive protein and intact parathyroid hormone, T50 significantly predicted CACS progression over 24 months [adjusted odds ratio [OR], 0.993, 95% confidence intervals (CI), 0.987 – 1.000, P=0.044]. Adjusting for the same covariates, phosphate, an important determinant of T_{50}, marginally lost significance in predicting CACS progression [P=0.069].

Conclusions: These data for the first time show that calcification propensity is related to progression of CACS in CKD 3-5, adding evidence to support its usefulness in reflecting mineral stress in CKD.

FR-PO411

Hepatocyte Nuclear Factor 1 Homeobox B as Novel Transcriptional Regulator of the KIR4.1/KIR5.1 Potassium Channel Joost Hoenderop,[1] Andreas Kompatscher,[1] Jeroen H.F. De Baaij,[1] Karam S. Aboudehen,[2] Peter Igarashi,[2] René J. Bindels.[1] *[1]Physiology, Radboud Inst for Molecular Life Sciences, Nijmegen, Gelderland, Netherlands; [2]Medicine, Univ of Minnesota Medical School, Minneapolis, MN.*

Background: Patients with mutations in transcription factor hepatocyte nuclear factor 1 beta (HNF1B) present with autosomal dominant tubulointerstital kidney disease (ADTKD-HNF1B), which is characterized by renal cysts and electrolyte loss. Strikingly, it was found that ~50% of mutation carriers were affected with hypomagnesemia. The origin of hypomagnesemia in patients with HNF1B mutations can be traced to the distal convoluted tubule (DCT) of the kidney, where the final urinary Mg^{2+} excretion is determined. The aim of this research is to explain hypomagnesemia in HNF1B patients by identifying target genes of HNF1B in the DCT.

Methods: To find targets of *Hnf1b* that are relevant to Mg^{2+} reabsorption in the kidney, a chromatin immunoprecipitation and subsequent sequencing (chIP-seq) was performed in an immortalized mouse DCT cell line. Luciferase assays, siRNA-mediated knockdown of *Hnf1b* in DCT cells and RT-qPCR on HNF1B mutant mouse kidneys were performed to assess the transcriptional regulation of *Hnf1b* on candidate genes *in vitro* and *in vivo*.

Results: By performing a chIP-seq on *Hnf1b*, >7000 Hnf1b binding sites were detected genome-wide, which could be mapped to >3000 unique genes. A conserved Hnf1*b* binding site was found in the promoter of the *Kcnj16* gene, encoding Kir5.1. Luciferase assays demonstrated that *Hnf1b* increases the activity of the *Kcnj16* promoter. siRNA knockdown of *Hnf1b* resulted in decreased *Kcnj16* transcript levels. Furthermore a decrease in expression of the *Kcnj10* gene, encoding Kir4.1, was observed. Decreased expression of *Kcnj10* and *Kcnj16* was also found in the kidneys of HNF1B mutant mice.

Conclusions: These results implicate HNF1B as an enhancing transcriptional regulator ofKir5.1. Active transport of Mg^{2+} in the DCT requires the constant extrusion of K^+ by the heteromeric inwardly rectifying K^+ channel Kir4.1/Kir5.1. Therefore, impaired regulation of Kir4.1/Kir5.1 by HNF1B may explain the hypomagnesemia found in HNF1B patients.

FR-PO412

Regional Expression of NaPi-IIb, PiT1 and NHE3 mRNA in the Proximal Small Intestine of Rats and Humans Evans Ohenhen Asowata,[1] Lars Fandriks,[2] Anna Casselbrant,[2] Robert J. Unwin,[1] Joanne Marks.[1] *[1]Dept of Neuroscience Physiology and Pharmacology, Univ College London, Rowland Hill Street, London, United Kingdom; [2]Dept of Gastrosurgical Research and Education, Inst of Clinical Sciences, Univ of Gothenburg, Sahlgrenska Academy, Sweden.*

Background: Previous findings have shown that the proximal small intestine is responsible for the absorption of dietary phosphate in rats and humans. Several studies investigating NaPi-IIb inhibitors, which target the transporter considered responsible for intestinal phosphate absorption, have been carried out in rats, but the effectiveness of these agents in the treatment of hyperphosphatemia in humans is still uncertain. We aimed to understand the difference in the efficacy of these therapeutic agents by comparing the mRNA levels of phosphate transporters in the different regions of rat and human proximal small intestine.

Methods: Total RNA was isolated from gut mucosa scrapes obtained from paired rat duodenum (2cm distal to pylorus) and jejunum (5cm distal to ligament of Treitz). Paired duodenal (20cm distal to pylorus) and jejunal (50cm distal to ligament of Treitz) biopsies were collected from healthy volunteers. NaPi-IIb, PiT1 and NHE3 transcript levels were established using qPCR.

Results: Our result shows that the regional profile for NaPi-IIb in humans is different from that in rats. The mRNA expression levels of NaPi-IIb were significantly higher in the human duodenum compared with the jejunum (D=0.096±0.028 *vs*. J=0.017±0.0006; p<0.05, n=5), which is in contrast to the finding of higher NaPi-IIb expression levels in the rat jejunum (D=0.0028±0.001 *vs*. J=0.028±0.004, p<0.0001, n=6). A trend for increased PiT1 expression in the human duodenum was observed, in contrast to higher PiT1 expression in the rat jejunum. The expression of NHE3, which is also a proposed regulator of phosphate transport, has a similar regional profile in both species.

Conclusions: Our results suggest that the seeming lack of therapeutic efficacy of NaPi-IIb inhibition in treating hyperphosphatemia in humans may result from differences in the regional profile of the phosphate transporters compared with rats in which NaPi-IIb inhibitors have been shown to be effective.

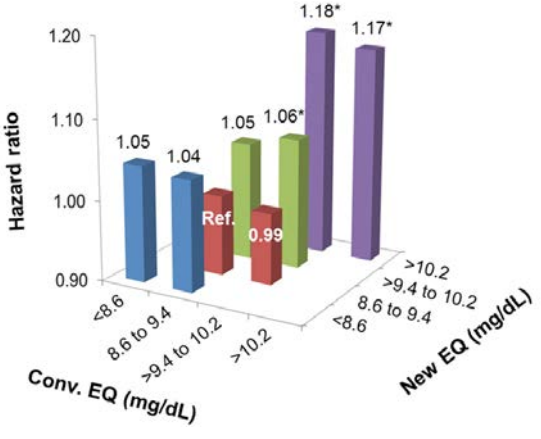
FR-PO413

Improved Mortality Predictability of Total Serum Calcium by Novel Correction Equation in Hemodialysis Patients Yoshitsugu Obi,[1] Elani Streja,[1] Matthew B. Rivara,[2] Wei Ling Lau,[1] Connie Rhee,[1] Csaba P. Kovesdy,[3] Rajnish Mehrotra,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Wash.; [3]Univ of Tenn.*

Background: Hidden hypercalcemia, characterized as high ionized calcium with normal albumin-corrected total calcium, has been reported to be associated with high mortality in hemodialysis (HD) patients. We hypothesized that the development of a new correction equation offers better mortality predictability.

Methods: In a national cohort of HD patients in the US, a novel equation comprising total calcium, albumin, and phosphorus was derived and validated among 808 hemodialysis patients with measured ionized calcium data. We then categorized 87,779 HD patients according to calcium status (i.e., low [<8.6 mg/dL], low-normal [8.6–9.4 mg/dL], high-normal [>9.4–10.2 mg/dL], and high [>10.2 mg/dL]) based on the novel vs. conventional correction equation. The association with all-cause death was evaluated using multivariable Cox regression analysis with adjustment for relevant demographics, comorbidities, and laboratory variables including albumin and phosphorus.

Results: The novel equation was expressed as 1.35×total calcium (mg/dL) – 0.65×albumin (g/dL) – 0.15×phosphorus (mg/dL) + 0.3. Adjusted R^2 was 0.79 (vs. 0.68 for the conventional equation), and net reclassification index among patients with ionized hypercalcemia was 23%. Among patients who were categorized as high-normal calcium status by the conventional equation, there appeared incremental mortality risk across higher calcium status according to the new equation. The mortality risk was consistent across calcium status according to the conventional equation within the categories by the new equation.



Conclusions: A novel equation derived for correction of total calcium performs significantly better in identifying patients with hidden hypercalcemia in HD patients than the conventional equation and helps better identify patients at high risk for mortality.

FR-PO414

Replacement of Acetate with Citrate in Hemodialysis Fluid: Effect on Calcium Balance Fabio Malberti, Laura Cosmai, Marina Foramitti. *Nephrology, Istituti Ospitalieri di Cremona, Cremona, Italy.*

Background: Bicarbonate based hemodialysis (HD) fluids require an acid component in order to balance pH and, commonly, acetic acid is used. Citric acid (Ci) has been proposed instead of acetate (A) to improve the dialysis fluid biocompatibility for its antioxidant and anti-inflammatory properties. However, Ci could reduce the diffusible Ca in dialysis fluid by binding Ca ions, resulting in more negative Ca balance compared to A at similar total Ca concentrations.

Methods: Dialysis Ca balance (CaB) was evaluated by collecting dialysis fluid during HD sessions using 4 different dialysis solutions (D) as regards Ca, A and Ci concentrations: DCi-1.0 (Ca 1.50, Ci 1.0, A 0 mmol/L); DCi-0.8 (Ca 1.50, Ci 0.8, A 0.3 mmol/L); DA1.50 (Ca 1.50, A 3 mmol/L), DA1.25 (Ca 1.25, A 3 mmol/L).

Results: Pre-HD serum ionized Ca (SiCa) was comparable with the 4 HD solutions. D ionized Ca (DiCa) was lower (P<0.001) in DCi-1.0 vs DCi-0.8 vs DA1.25 vs DA1.50 so resulting in more negative diffusion gradients between D and blood in DCi-1.0 (-0.26±0.6 mmol/L) and DCi-0.8 (-0.15±0.05 mmol/L) compared to DA1.25 (-0.02±0.07) and DA1.50 (+0.17±0.07).

	DCi-1.0	DCi-0.8	DA-1.50	DA-1.25
DiCa mmol/L	0.89±0.03	0.98±0.01	1.33±0.06	1.12±0.03
SiCa start HD mmol/L	1.15±0.05	1.14±0.05	1.16±0.07	1.14±0.05
SiCa end HD mmol/L	1.07±0.03	1.11±0.04	1.25±0.05	1.13±0.04
Diffusive CaB mg	-306±112	-155±62	404±130	65±119
Convective CaB mg	-89±42	-114±35	-138±60	-101±42
Total CaB mg	-395±134	-269±81	266±116	-36±130

Therefore, diffusive and total CaB was much more negative in DCi-1.0 compared to DCi-0.8 and DA1.25, respectively. CaB was positive in DA-1.50 (table). SiCa unchanged during HD with DA1.25, significantly increased with DA1.50 and decreased with DCi-1.0 and DC-0.8.

Conclusions: 1) Citrate-containing HD fluids have lower iCa concentrations compared to A-containing fluids at equal total Ca concentrations. This induces more negative iCa diffusion gradients between D and blood resulting in a more negative CaB. 2) Citrate fluids with 1.50 mmol/L of Ca induce more negative CaB also compared with A fluids containing 1.25 mmol/L of Ca.

FR-PO415

Effect of Dialysate Calcium Conversion on Mineral Metabolism in Maintenance Hemodialysis Pateints Han Ro, Ae Jin Kim, Ji Yong Jung, Jae Hyun Chang, Hyun Hee Lee, Wookyung Chung. *Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea.*

Background: The recommended dialysate calcium (DCa) concentration has been changed several times and the appropriate DCa concentration remains controversial. Our hemodialysis center reduced the default DCa concentration from 1.75 to 1.5 mmol/L in February 2013. This study compared the effect of DCa on serum markers of mineral bone disorders and drug requirements between conversion and no conversion (1.75 mmol/L) groups.

Methods: We retrospectively reviewed the patients undergoing maintenance hemodialysis using a consistent DCa concentration for the period between February 2012 and January 2014. We compared the serum markers of mineral metabolism and drug utilization before and after 1 year of DCa conversion between the two groups. Data were collected at 3-month intervals for 2 years. Our hemodialysis center reduced the default DCa concentration from 1.75 to 1.5 mmol/L in February 2013. This study compared the effect of DCa on serum markers of mineral bone disorders and drug requirements between conversion and no conversion groups.

Results: Thirty-two patients were maintained at a DCa of 1.75 mmol/L and 26 patients underwent conversion of DCa from 1.75 to 1.5 mmol/L. DCa conversion to low calcium increased serum phosphorus level (4.4±0.8 mg/dL vs. 4.7±0.9mg/dL, p=0.027) and parathyroid hormone level (112.6±107.2pg/mL vs. 254.0±224.5 pg/mL, p<0.001). Total amount of phosphate binder was not different in patients without conversion (p=0.993). However, DCa conversion to low calcium increased total equivalent dose of phosphate binder (p=0.012), especially calcium based phosphate binder (p=0.040).

Conclusions: In conclusion, our results demonstrate that compared with maintaining 1.75 mmol/L DCa, lowering DCa from 1.75 to 1.5 mmol/L lead to a significant change in mineral metabolism and drug requirements ofphosphate binder in maintenance hemodialysis patients. pan>224.5 pg/mL, p<0.001). Total amount of phosphate binder was not different in patients without conversion (p=0.993). However, DCa conversion to low calcium increased total equivalent dose of phosphate binder (p=0.012), especially calcium based phosphate binder (p=0.040).

FR-PO416

Tamoxifen Causes Hypophosphatemia and Phosphaturia through the Downregulation of NaPi-IIa Expression in the Rat Kidney Proximal Tubule
Hassane Amlal, Sihame Amlal, Sulaiman Sheriff. *Internal Medicine, Univ of Cincinnati, Cincinnati, OH.*

Background: Estrogen regulates renal inorganic phosphate (Pi) handling in women as well as in experimental animals. We recently showed that estrogen directly targets proximal tubule cells and downregulates NaPi-IIa in rats and both NaPi-IIa and NaPi-IIc in mice. The objective of this study was to test whether Specific Estrogen Receptor Modulators (SERMs) can also target Pi transport in the kidney proximal tubule.

Methods: Ovariectomized rats were placed in metabolic cages with free access to rodent chow and water. After acclimation period, rats were divided into 3 groups and treated with 500µg/100g BW tamoxifen (TAM) or Raloxifene (RAL) or vehicle (Control). Daily food intake, water intake and urine volume were monitored. After 3 days, rats were sacrificed for blood and kidney collection. Cortex tissues were isolated and used for molecular studies.

Results: Only rats treated with TAM exhibited a significant hypophosphatemia vs. Control animals. Blood electrolytes, acid-base and BUN are normal in all groups. Food intake decreased sharply in TAM- and only slightly in RAL-treated animals vs. Control group. Despite the reduction in food/Pi intake, Pi/creatinine excretion slightly increased in TAM over control group. The mRNA expression and protein abundance of NaPi-IIa were sharply downregulated in TAM vs. Control animal. In RAL group, Pi/creatinine excretion was decreased and correlated with food intake and NaPi-IIa protein was not significantly altered vs. Control group.

Conclusions: Tamoxifen causes phosphaturia and hypophosphatemia in female rats. This effect results from the downregulation of NaPi-IIa at both mRNA and protein levels. For the same dose, phosphaturia and hypophosphatemia are more pronounced in TAM than in RAL-treated rats. Hence, TAM is the most potent estrogen agonist with respect to its effect on Pi transport in the kidney, and could be used to correct hyperphosphatemia in chronic kidney disease with significant residual renal function or other conditions associated with impaired Pi balance.

Contributors to Mortality in Calcific Uremic Arteriolopathy: Role of Site and Severity of Skin Lesions
Chamberlain I. Obialo,[1] Alexander Quarshie.[2] *[1]Dept of Medicine, Morehouse School of Medicine, Atlanta, GA; [2]Clinical Research Center, Morehouse School of Medicine, Atlanta, GA.*

Background: Calcific Uremic Arteriolopathy [CUA] is often fatal with mortality that ranges from 50 -80%. Adverse prognostic factors include: advanced age, female gender, large body mass index [BMI], and severity of skin lesions. Survival outcome has been improved with the use of intravenous sodium thiosulfate [STS]. The relationship between mortality at 2-yrs and site/severity of skin lesions is re-examined in this study.

Methods: We retrospectively reviewed our end stage renal disease [ESRD] patient's records over a 10-year period and identified 45 biopsy confirmed cases of CUA. Skin lesions located above the elbows and knees were considered proximal while those below elbows/knees were distal. Lesions were classified as mild , moderate , or severe according to previously described criteria. Associations between mortality and various demographic, and clinical variables were assessed using t-tests, Mann-Whitney-U tests, and chi-squared as appropriate. Multivariate logistic regression models were fitted to adjust for confounders. Survival analysis utilized Kaplan-Meier plots.

Results: The mean age of the patients was 63±10 yrs, 60% were female. Mean BMI was 34±5 and mean dialysis vintage was 4±2 yrs. Patients with proximal lesions had a higher mortality (48% vs 20 %, p=0.05) and larger BMI than those with distal lesions (35±5 vs 34±6, p=0.6) respectively. Of the deceased patients, 11 0f 19 (58%) had severe skin lesions while 13 of 26 survivors (50%) had mild lesions, p=0.003. Multiple regression analysis showed a significant association between mortality and : serum phosphate level, (OR 3.4, (CI 1.1-10.5); p=0.03); proximal lesion, (OR 8.4, (CI 0.98-71.5);p=0.05); and severe lesions (OR 17.0, CI (1.3-221.9); p=0.03). Age, gender, dialysis vintage, diabetes, BMI, use of Cinacalcet, serum albumin, calcium, and PTH levels had no statistically significant associations with mortality.

Conclusions: Serum phosphorus level, proximal and severe skin lesions appear to be major determinants of survival in CUA. Phosphate levels should be monitored closely and adequately controlled in patients with CUA.

Development of Phosphatemic Index for Evaluation of Phosphate-Containing Foods in Healthy Japanese
Yoko Narasaki, Michiyo Yamasaki, Misaki Katsumoto, Yutaka Taketani. *Clinical Nutrition and Food Management, Tokushima Univ, Tokushima, Japan.*

Background: High dietary phosphorus (P) intake increases phosphorus retention or load, serum FGF23 and PTH levels, and finally causes hyperphosphatemia and poor prognosis of CKD. Therefore, decrease in dietary P intake should be required for CKD patients. Here, we propose "Phosphatemic Index: PI" to evaluate the effect of P-containing foods on serum P homeostasis.

Methods: Twenty healthy young subjects (10 men and 10 women, 20-30 y.o.) were recruited. In this study, 10 different foods (pork, ham, soy bean, tofu, milk, processed cheese, egg, buckwheat noodle, red sea bream, broccoli) containing 200 mg of P were randomly ingested with an interval of 7 days or more as lunch. Blood were collected at 0, 0.25, 0.5, 1, 2, 4, and 6 h after the food ingestion, and measured serum P and PTH level. Then, each area under the curve (AUC) of time-P concentration curve was calculated. PI of the tested food was calculated by following equation: PI = (AUC of tested food)•100/(AUC of 200 mg of sodium phosphate). This study was performed by open-label crossover study and approved by ethical committee of Tokushima University Hospital.

Results: As PI of sodium phosphate was 100, PI of milk was 108, processed cheese was 99, ham was 75, pork 54, soy bean was 33, tofu was 20. We found that PIs of vegetable foods including soy and tofu was lower than those of animal foods. In addition, PI of pork showed lower than that of ham. This result might be due to food additives containing P. Furthermore, in milk and cheese, because they showed significant low secretion of PTH and low urinary excretion of P, we discussed that high calcium in milk would suppress the secretion of PTH and urinary P excretion and resulted to show high PI.

Conclusions: PI can appropriately reflect the effect of P-containing foods on serum P level, and be useful tool to evaluate and select foods by CKD patients who need P restriction.

Green Tea Increases Urinary Excretion of Phosphorus, Magnesium and Calcium in Rats
Claudia Helou, Igor Oliveira Da Silva, Talita R. Sanches, Mirela Santinho, Lucia Andrade. *Laboratório Pesquisa Básica LIM12, Faculdade de Medicina da USP, São Paulo, São Paulo, Brazil.*

Background: The consumption of green tea (GT) is increasing worldwide, and there is a lack of data in the literature regarding its effect on renal tubular function.

Methods: Male Wistar rats were housed in individual cages and randomly assigned to have ad libitum access to GT (Feel Good©) or tap water. On day 8, we moved the rats to metabolic cages and collected 24-h urine samples under oil, in order to evaluate renal function. The rats were then anesthetized, and a catheter was placed in the abdominal aorta to measure blood pressure (BP) and collect blood samples. We quantified creatinine and electrolytes in urine and plasma samples. We removed the kidneys to quantify protein expression (PE) of ion transporters in the cortex and outer medulla (OM), by Western blot. We used unpaired t-test for statistical analyses.

Results: GT increased diuresis,as well as increasing urinary excretion (UV) of phosphorus (P), magnesium (Mg), calcium (Ca) and potassium (K).

	Control (n =11)	Green Tea (n =7)	P-value
Body weight,g	286 ± 7	295 ± 8	0.44
BP, mm Hg	103 ± 2	104 ± 4	0.90
Creatinine Clerance, ml/min.100g^{-1}	0.50 ± 0.05	0.49 ± 0.06	0.83
Liquid intake, ml/day	25 ± 2	29 ± 3	0.30
Urine output, ml/day	20 ± 2	29 ± 2	0.02
UV Na, µmol/day	0.92 ± 0.09	1.16 ± 0.15	0.17
UV K, µmol/day	2.33 ± 0.14	2.73 ± 0.15	0.07
UV Cl, µmol/day	0.61 ± 0.06	0.77 ± 0.16	0.30
UV P, µmol/day	500 ± 53	730 ± 75	0.02
UV Mg, µmol/day	148 ± 19	223 ± 24	0.02
UV Ca, µmol/day	26 ± 2	48 ± 6	0.01

However, plasma concentrations of those ions remained within the normal range, with the exception of K, which was 3.1 ± 0.1 mmol/l in the GT group. The PE of Na-Pi type IIa in the cortex was comparable between the groups. However, in the OM, the PE of ROMK channel was lower in GT rats (n =5) than in control rats (n =3) - 100 ± 13% in GT *vs.* 63 ± 7% ($p<0.02$) - as was that of the Na-K-Cl cotransporter - 100 ± 4% *vs.* 75 ± 8% ($p<0.08$).

Conclusions: Taken together, our findings indicate that GT inhibits ion transporters in the thick ascending limb of Henle's loop, which increases diuresis and ion losses.

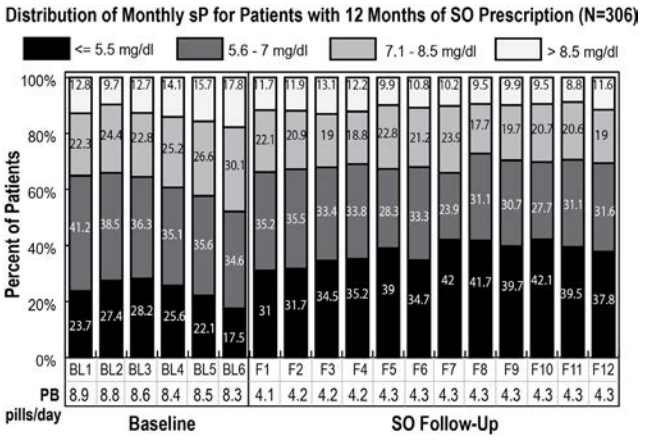
FR-PO420

Serum Phosphorus and Pill Number Per Day in Hyperphosphatemic Hemodialysis Patients (n=306) Prescribed Sucroferric Oxyhydroxide for 12 Months
Linda H. Ficociello, Vidhya Parameswaran, Carly R. Van Zandt, Norma J. Ofsthun, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: DOPPS data show that even though phosphate binders (PB) are widely used, 35% of hemodialysis (HD) patients have hyperphosphatemia (serum phosphorus (sP) levels >5.5 mg/dl). This retrospective analysis assesses the real-world effectiveness of sucroferric oxyhydroxide (SO), a chewable iron-based PB, to lower sP to ≤5.5 mg/dl over a one-year period.

Methods: De-identified data was extracted from electronic records for all adult, HD patients with first SO prescription between 3/1/2014- 3/1/2015 and SO prescription for 12 months (F1-F12). Patients on combination PB therapy were excluded. Baseline was defined as the 6 months before SO (BL1-BL6). Descriptive analyses of month to month changes are described and confirmed with linear mixed-effects regression for continuous data and Cochran's Q and McNemar's chi-square test for categorical data.

Results: At BL6, mean sP was 7.1 mg/dl and only 17.5% of patients had sP ≤5.5 mg/dl. During the months of SO follow-up (F1-F12), 31%-42.1% of patients had a sP ≤5.5 mg/dl, a 77%-141% increase (all comparisons $p<0.001$) from BL6. Mean PB pills/day decreased ($p<0.0001$) from 8.3 pills at BL6 to 4.1-4.3 pills during F1-F12. Percent of patients with sP from 5.6-8.5 mg/dl decreased ($p<0.001$) from 64.7% at BL6 to 50.6% at F12.



Conclusions: 82.5% of patients prescribed SO had hyperphosphatemia at baseline compared to a national sample of HD patients (35%). Percent of patients with sP ≤5.5 mg/dl increased from 17.5% at baseline to 31%-42.1% during the year-long follow-up, along with a mean reduction of PB pills/day of 48%-51%.

FR-PO421

Pill Burden and Serum Phosphorus in Hemodialysis Patients Switched from Calcium Acetate to Sucroferric Oxyhydroxide as Part of Routine Care Linda H. Ficociello, Vidhya Parameswaran, Carly R. Van Zandt, Norma J. Ofsthun, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America, Waltham, MA.*

Background: Although phosphate binders (PB) are widely prescribed, many hemodialysis (HD) patients do not achieve KDOQI recommended serum phosphorus (sP) levels. PB constitute a large proportion of HD patients' overall pill burden and many patients are non-adherent (Chiu et al. 2009). The current retrospective analysis examined PB pills/day and achievement of sP ≤5.5 mg/dl in patients switched from calcium acetate (CaAc) to sucroferric oxyhydroxide (SO).

Methods: Adult, HD patients with first SO prescription between 3/1/2014- 3/1/2015, recorded SO prescription for 10-12 months and CaAc prescription at baseline (previous 6 months) were included (n=139). Patients on combination PB therapy were excluded. Descriptive analyses of quarterly changes were described and linear mixed-effects regression and Cochran's Q/McNemar were used to test for statistical significance.

Results: Mean quarterly PB pills/day and percent of patients with sP ≤ 5.5 mg/dl are presented the table. Using the CaAc2 quarter as the reference (8.5 pills/day), a >47% decrease in number of PB pills/day was observed for each quarter after the switch to SO (4.0, 4.5, 4.2, 4.1 pills/day SO1-SO4, respectively). Percent of patients achieving sP ≤ 5.5 mg/dl increased by 32%, 82%, 132% and 113%, comparing CaAc2 to SO1-SO4, respectively.

	CaAc1	CaAc2 (ref)	SO1	SO2	SO3	SO4	Overall p-value
PB pills/day	8.9	8.5	4**	4.5**	4.2**	4.1**	<0.0001
% pts with sP ≤ 5.5 mg/dl	19.3	15.8	20.9	28.8[a]	36.7**	33.6*	<0.0001

**p-value <0.0001; *p-value <0.001, [a]p-value <0.05. Observation periods include 6 month CaAc and 12 month SO. Each quarter is represented as CaAc# and SO#.

Conclusions: In a cohort of patients switched from CaAc to SO, a >47% reduction in PB pills/day was observed along with improvements in the percent of patients achieving sP ≤ 5.5 mg/dl during SO follow-up.

The Effect of Ferric Citrate (Auryxia) on Serum Phosphate Control in Dialysis Patients: Real-World Data Pablo E. Pergola,[1] Debra J. Hain,[2] Meredith Marinaro,[3] David W. Koeper,[4] Melissa A. Rosenthal,[5] Salvatore Chillemi,[6] Jennifer M. Huffman,[9] Teresa Gerbeling,[7] James M. Pritsiolas.[8] *[1]Renal Associates PA, San Antonio, TX; [2]FL Atlantic Uni, Boca Raton, FL; [3]Uni CT, Farmington, CT; [4]Fox Valley Nephrology, Neenah, WI; [5]Los Alamitos HD Clinic, Los Alamitos, CA; [6]N Georgia Kidney Specialists, Marietta, GA; [7]Dialysis Center Lincoln, Lincoln, NE; [8]CarePoint Health Medical Group, Bayonne, NJ; [9]Kidney Associates of KC, Kansas City, KS.*

Background: Ferric citrate (FC) is an approved phosphate binder for use in patients on dialysis. Previous clinical trial data demonstrated FC increased iron stores, but real-world data of FC effects on both bone mineral and anemia parameters are lacking.

Methods: Adult dialysis patients (n=92, 25 peritoneal dialysis, 67 hemodialysis) taking FC for 6 mo and had data as part of routine clinical care were included in a retrospective analysis. Serum phosphate (phos), hemoglobin (Hgb), transferrin saturation (TSAT) and ferritin were extracted from medical records before & during the first 6 mo of FC treatment.

Results: When starting FC, 21 patients (23%) were binder naïve, 36 (39%) were on sevelamer only (average of 11 tablets/day), 20 (22%) were on calcium-based binder only (average of 9 tablets/day) and 15 (16%) on combination (average of 16 tablets/day) or other binder. The mean starting dose of FC was 6 tablets/day increasing to 7 tablets/day at 6 mo of treatment. Before the start of FC, 22% of patients had a serum phos within target range of < 5.5mg/dL increasing to 65% at 6 mo of FC treatment. Phos, TSAT, ferritin and Hgb values are shown in Table 1 (data presented as mean±SEM). 6 patients discontinued FC within 6 mo of treatment.

n=92	Pre-FC	Post FC (months)		
		1	3	6
Serum Phos (mg/dL)	6.5±0.2	5.9±0.2	5.8±0.2	5.4±0.2
TSAT (%)	28.2±1.2	30.3±1.5	34.8±1.5	37.1±2.0
Ferritin (ng/mL)	753±56	841±58	972±62	953±66
Hgb (g/dL)	10.6±0.2	11.0±0.2	11.2±0.1	11.1±0.2
Patients receiving IV iron	53 (47%)			31 (34%)

Conclusions: In a retrospective analysis, switching to FC lowered serum phos and raised TSAT, ferritin and Hgb. Results of serum phos and anemia markers observed in this small retrospective cohort were similar to those in previous FC data.

FR-PO423

Serum Calcification Propensity Is Largely Genetically Determined in the General Population Edward Pivin,[2] Matthias Bachtler,[1] Olivier Devuyst,[3,4] Uyen Huynh-Do,[3,5] Murielle Bochud,[3,6] Andreas Pasch.[1,3] *[1]Clinical Research, Univ Bern, Bern, Switzerland; [2]Nephrology, Univ Hosp. Lausanne, Lausanne, Switzerland; [3]NCCR Kidney.ch, Switzerland; [4]Physiology, Univ Zurich, Zurich, Switzerland; [5]Nephrology, Univ Hosp. Bern, Bern, Switzerland; [6]Social and Preventive Medicine, Univ Hosp. Lausanne, Lausanne, Switzerland.*

Background: A novel blood test (T_{50}-Test) quantifies serum calcification propensity by determining the transformation time point T_{50} from amorphous to crystalline calcium phosphate in the presence of human serum. T_{50} is associated with all-cause and cardiovascular mortality in patients with chronic kidney diseases (CKD). Here we investigated T_{50} in the general population.

Methods: T_{50} and fetuin-A were determined in 1033 sera from the Swiss Kidney Project on Genes in Hypertension (SKIPOGH) cohort, the heritability of T_{50} calculated and a genome wide association study (GWAS) and multivariate analysis performed.

Results: T_{50} was normally distributed in the population (mean±SD, 298±58 min.), and the heritability of T_{50} was estimated to be 50±8% (p<0.01). GWAS identified a strong association between T_{50} and SNPs in the *AHSG*/fetuin-A gene locus on Chromosome 3 (e.g. rs2593813 p=7.7e-28). Individuals homozygous for the minor allele had a significantly lower T_{50}-Test than those homozygous for the wildtype allele (254±54 vs. 315±54 min., p<0.01). Serum fetuin-A concentrations were lower in those homozygous for the minor allel (0.33±0.06 vs. 0.43±0.08 g/L, p<0.01). Multivariate analyses identified age, eGFR, and phosphate as determinants associated with worse (i.e. accelerated) and fetuin-A, magnesium and bicarbonate as determinants associated with improved (i.e. delayed) serum calcification propensity.

Conclusions: Serum calcification propensity (T_{50}) is highly heritable in the general population and largely depends on the same determinants as in renal patients. Calcification propensity may reflect a general physiological system of crystalization control inherent in blood.

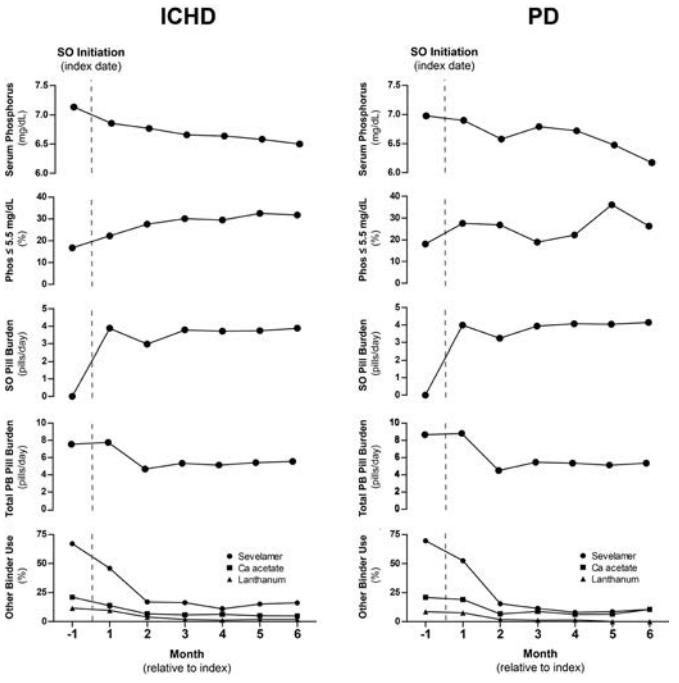
FR-PO424

Phosphorus Control and Pill Burden among In-Center Hemodialysis (ICHD) and Peritoneal Dialysis (PD) Patients Converting to Sucroferric Oxyhydroxide (SO) Kathryn S. Gray,[1] Linda H. Ficociello,[2] Claudy Mullon,[2] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Fresenius Medical Care, Waltham, MA.*

Background: SO is a new iron-containing phosphate binder (PB). In developmental studies, SO showed equivalent phosphorus reduction to sevelamer. However, the effects of SO in real-world populations have not been extensively studied. We retrospectively examined SO use among patients who converted from another PB to SO.

Methods: From among ICHD and PD patients at a large dialysis organization (LDO) receiving benefits through the LDO's pharmacy program, we identified those converting to SO from another PB: defined from prescription fill data as having had supply of another PB, receiving a first fill of SO, and subsequently not refilling the initial PB such that supply exhausted for at least 30 days. Longitudinal indices of phosphorus control and PB burden were assessed.

Results: There were 656 ICHD SO converters: mean age, 50 years; 47% female; 45% black; median vintage, 43 months. Prior to SO initiation, mean serum phosphorus was 7.1 mg/dL; during follow-up it fell to 6.6 mg/dL; percentage of patients with phosphorus ≤5.5 mg/dL rose from 17% to 32%. Daily SO pill burden was 3.0-3.9; total daily PB pill burden fell from 7.5 prior to SO initiation to 5.5 during follow-up. There were 105 PD SO converters: mean age, 47 years; 52% female; 29% black; median vintage, 33 months. Prior to SO initiation, mean serum phosphorus was 7.0 mg/dL; over follow-up it fell to 6.2 mg/dL; percentage of patients with phosphorus ≤5.5 mg/dL rose from 18% to 26%. Daily SO pill burden was 3.2-4.0; total daily PB pill burden fell from 8.7 prior to SO initiation to 5.4 during follow-up.



Conclusions: In a real-world population of ICHD and PD patients, conversion to SO coincided with reductions in serum phosphorus, higher percentage of patients with controlled phosphorus, and lower total PB pill burden.

The Dietary Adenine Rat Model of Chronic Kidney Disease Produces Hyperphosphatemia in the Absence of High Phosphate Diet

Cynthia M. Pruss,[1] Kimberly J. Laverty,[1] Emilie C. Ward,[1] Bruno Svajger,[1] Paul S. Jeronimo,[1] Mandy E. Turner,[1] Martin P. Petkovich,[1] Rachel M. Holden,[2] Michael A. Adams.[1]
[1]Biomedical and Molecular Sciences, Queen's Univ, Kingston, ON, Canada; [2]Medicine, Queen's Univ, Kingston, ON, Canada.

Background: Chronic kidney disease (CKD) induces hyperphosphatemia, which associates with cardiovascular events and vascular calcification. Animal models of CKD demonstrate similar pathologies and outcomes to CKD patients. However, a rat adenine model examining the effects of dietary phosphate (PO_4) levels after slow induction of CKD is unknown. This study is a refinement of the dietary adenine model of CKD.

Methods: Male Sprague Dawley rats (15-16 weeks) were fed a 0.25% adenine, 0.5% PO_4 diet to establish stable CKD (creatinine >250 uM), 5 weeks. At 5.5 weeks, rats were then fed 0.5%, 1% or 1.5% PO_4 diet (N=9, 10, 6). Control rats were fed 0.5% PO_4 diet (N=8). Serum creatinine, PO_4, FGF-23, and PTH were measured. At sacrifice, tissue levels of calcium and PO_4 were determined.

Results: Rats in 0.5, 1, and 1.5% PO_4 groups had similar creatinine levels throughout the experiment. From 0-5.5 weeks, all CKD rats were similar in serum PO_4 and significantly higher than control from 2 weeks. At 5 weeks, CKD rats had 3.2±0.6 mM PO_4 versus 2.5±0.3 mM PO_4 Control. When removed from adenine diet, the 0.5% group returned to control PO_4 levels by 6.5 weeks with no calcification or further increase by 7 weeks in FGF-23 (3.1±2.7 vs 0.47±0.15 ng/ml Control) and PTH (0.41±0.18 vs 0.17±0.08 Control ng/ml). The 1.0 and 1.5% groups had significant large increases by 7 weeks in PO_4 (5.0±1.0, 5.8±1.4mM), PTH (2.4±1.3, 3.1±0.6ng/ml), and FGF-23 (47±18, 35±17 ng/ml), aortic calcification in 80% of rats.

Conclusions: These results demonstrate that a high phosphate diet greater than 0.5% is required for mineral bone disorder and calcification in the rat adenine model of CKD. The dietary adenine model of CKD produced a significant increase in serum PO_4 on low PO_4 diet, that returned to normal levels within 1.5 weeks of removal of adenine. Researchers should use caution in comparing serum PO_4 levels in animals on or off adenine-containing diets.

FR-PO426

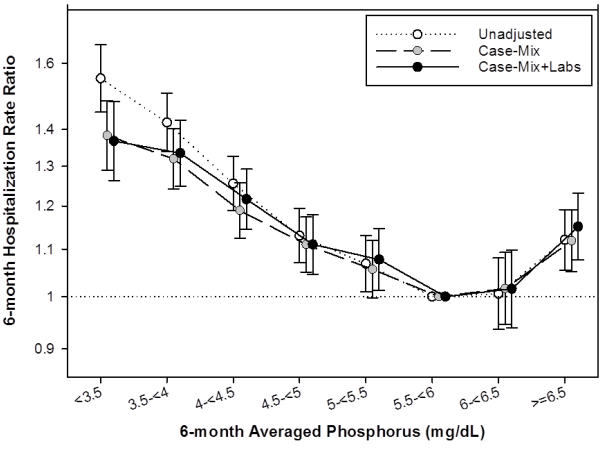
Both Normal and Very High Serum Phosphorous Levels prior to Transition to Dialysis Are Associated with Early Dialysis Hospitalization in U.S. Veterans: A Transition of Care in CKD Study

Amanda R. Tortorici,[1] Elani Streja,[1] Connie Rhee,[1] Melissa Soohoo,[1] Wei Ling Lau,[1] Yoshitsugu Obi,[1] John J. Sim,[2] Daniel L. Gillen,[1] Keith C. Norris,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Kaiser Permanente SC; [3]UCLA; [4]Univ of Tenn.*

Background: Recent studies suggest that serum phosphorous (Phos) levels are predictors of hospitalization in patients with chronic kidney disease. However, the impact of Phos levels prior to end-stage renal disease (ESRD) on post-ESRD hospitalization is unknown.

Methods: In 85,505 US veterans who transitioned to dialysis between 10/2007 and 3/2014, we identified 19,610 patients with available Phos measurements within the last 6-month prelude period (prior to ESRD). We examined the association of Phos (averaged over 6 months) as a categorical predictor of hospitalization within the first 6 months post transition, using Poisson models adjusted for demographics, comorbidities and laboratory covariates.

Results: The cohort was (mean±SD) 66±11 years old, among whom 34% were African-American, and 50% had diabetes listed as their primary cause of ESRD. The mean±SD Phos of the cohort was 5.1±1.3 mg/dL prior to ESRD. We observed a reverse J-shaped association between pre-ESRD Phos and 6-month post-ESRD hospitalization rate. Patients with Phos levels ≤5.5 mg/dL and ≥6.5 mg/dL demonstrated incrementally higher hospitalization rates compared to the referent group (Phos 5.5-<6 mg/dL).



Conclusions: Both normal and very high Phos levels were associated with higher early post-ESRD hospitalization rates. The finding of normal Phos levels being associated with increased risk was unexpected and suggests further analysis as this could impact existing recommendations of targeting an achieved Phos level to the normal range. Further studies are also needed to determine if using dietary and medication interventions to attain this Phos range confers better early dialysis outcomes in this population.

FR-PO427

Increased Phosphate Burden from Medications Prescribed to In-Center Hemodialysis Patients

Dixie-Ann Sawin,[1] Lin Ma,[2] Norma J. Ofsthun,[2] Robert J. Kossmann,[1] Franklin W. Maddux.[2] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Maintaining phosphorus balance in in-center hemodialysis (IHD) patients is problematic despite dietary restriction (800 – 1000 mg/day if serum P levels ≥5.5 mg/dL), dialysis, and phosphate (P) binder use. High-flux IHD can remove ~30 mmol (900 mg) P/session; P intake should not exceed ~750 mg/day for a 60 kg patient. Rarely is the P in prescribed medications considered part of the diet, but this source should raise concern.

Methods: Data was obtained from the Fresenius Medical Care North America (FMCNA) electronic data warehouse Knowledge Center and MedReview-eRx accessed Surescripts™, housing >80% of prescriptions filled in the US. Adult, FMCNA IHD patients prescribed ≥1 medication in the MedReview-eRx database were analyzed (695,759 prescriptions). Information collected included medication dose, dose unit, dose timing, strength, start and stop dates, refills, patients' demographic information, admission history, and modality type. The number of patients and prescriptions by drug class and individual medication, average dose/day, and phosphate content were analyzed. Average doses/day (# of pills) were calculated for each medication (open order on a randomly selected day-May 1, 2015); medications with >100 orders were reported. P content of medications taken in FMCNA clinics was assessed using routinely used pharmacology references.

Results: The top five prescribed drug classes in FMCNA dialysis patients were calcium-channel blockers (22%), proton pump inhibitors (PPIs; 18%), acetaminophen-opioid (AO; 13%), angiotensin-converting enzyme inhibitors (ACEi; 10%) and α2-agonists (9%). The top five medication orders were amlodipine, lisinopril, clonidine, acetaminophen, and

omeprazole. On average, the additional P added to patients' daily intake was 36.2 mg for amlodipine, 75-148.8 mg for lisinopril, 2.9-7.2 mg for clonidine, 0 mg for AO, and 204.8-234 mg for omeprazole per day.

Conclusions: Increased P content in medications prescribed to IHD patients may contribute to the overall daily P load, requiring more P binders, increasing the daily pill burden and affecting compliance.

FR-PO428

Pill Burden and Serum Phosphorus in Hemodialysis Patients Switched from Sevelamer to Sucroferric Oxyhydroxide Vidhya Parameswaran, Linda H. Ficociello, Carly R. Van Zandt, Norma J. Ofsthun, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America, Waltham, MA.*

Background: Recent DOPPS data show a trend towards greater phosphate binder (PB) non-adherence and higher number of prescribed PB pills per day. Also, non-adherence was associated with serum phosphorus (sP) >5.5 mg/dl (Fissell et al. 2016). The current retrospective analysis examined PB pills/day and achievement of sP ≤ 5.5 mg/dl in patients switched from sevelamer (Sev) to sucroferric oxyhydroxide (SO) as part of routine care.

Methods: Adult, hemodialysis patients with first SO prescription between 3/1/2014-3/1/2015, recorded SO prescription for 10-12 months and Sev prescription at baseline (previous 6 months) were included (n=277). Patients on combination PB therapy were excluded. Descriptive analyses of quarterly changes were described and linear mixed-effects regression and Cochran's Q/McNemar were used to test for statistical significance.

Results: Mean quarterly PB pills/day and percent sP ≤5.5 mg/dl are presented in the table. Using the Sev2 quarter as the reference (8.9 pills/day), a >50% decrease in number of PB pills/day was observed for each quarter after the switch to SO (4.0, 4.4, 4.3, 4.4 pills/day SO1-SO4, respectively). Percent of patients achieving sP ≤5.5 mg/dl increased by 45%, 93%, 131% and 119%, comparing Sev2 to SO1-SO4, respectively.

	Sev1	Sev2 (Ref)	SO1	SO2	SO3	SO4	Overall p-value
PB pills/day	9.3	8.9	4**	4.4**	4.3**	4.4**	<0.0001
% patients with sP ≤ 5.5 mg/dl	22*	15.4	22.4*	29.7**	35.6**	33.7**	<0.0001

**p-value < 0.0001, *p-value <0.05. Observation periods include 6 month Sev and 12 month SO. Each quarter is represented as Sev# and SO#.

Conclusions: In a cohort of patients switched from Sev to SO, a >50% reduction in PB pills/day was observed along with improvements in the percent of patients achieving sP ≤5.5 mg/dl during SO follow-up.

FR-PO429

Evidence for Increased Absorption of Phosphate in Experimental Adenine-Induced Chronic Kidney Disease Paul S. Jeronimo,[1] Cynthia M. Pruss,[1] Bruno Svajger,[1] Mandy E. Turner,[1] Kimberly J. Laverty,[1] Emilie C. Ward,[1] Martin P. Petkovich,[1] Rachel M. Holden,[2] Michael A. Adams.[1] *[1]Biomedical and Molecular Sciences, Queen's Univ, Kingston, ON, Canada; [2]Medicine, Queen's Univ, Kingston, ON, Canada.*

Background: Hyperphosphatemia is a common manifestation of chronic kidney disease (CKD) and is a risk factor for cardiovascular morbidity and mortality (e.g. vascular calcification). It is widely acknowledged that the kidney is a primary site of phosphate regulation, but it is poorly understood how other organs, including the gut, contribute to this control. Despite homeostatic mechanisms regulating serum phosphate within a narrow range the gut normally absorbs 70% of dietary phosphate through paracellular and sodium-dependent phosphate cotransporter (NPT2b) mechanisms. The objective of this study was to determine how disposition of phosphate is altered by impaired renal function and uremia in a rat model of CKD.

Methods: Male Sprague Dawley rats (n=42) were fed an adenine containing diet (0.25% adenine with 0.5% phosphate) for 5-6 weeks to establish moderate to severe CKD. Samples of feces (24 hours) and blood samples (1.2 mL) were collected weekly. Fecal and serum levels of phosphate, serum creatinine, FGF-23 and PTH were measured using established colorimetric assays and ELISAs.

Results: The adenine induced a moderate to severe level of CKD (serum creatinine 308 ± 141 μM), but because of the low phosphate diet serum phosphate was not elevated. Total fecal phosphate assessed at 2 time points was significantly lower in the CKD group (p=0.02), despite consuming similar phosphate. Despite the lack of increase in serum phosphate, FGF-23, which can downregulate NPT2b expression and thereby limit gut absorption, was increased in the CKD rats (p=0.02).

Conclusions: These findings demonstrate that despite the phosphate retaining CKD phenotype characterized by elevated levels of FGF-23, absorption of phosphate may be increased. However, the data indicate that the increased absorption of phosphate is not associated with increased serum levels suggesting that a maladaptive deposition of phosphate into the tissues may be enhanced at an early stage of the disease.

FR-PO430

Warfarin Induced Aorta Calcification and LV Dysfunction in a Remnant Kidney Mouse Model Ying-Ying Chen,[1,2] Szu-Yuan Li,[1,2] Der-Cherng Tarng.[1,2] *[1]Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]Faculty of Medicine, National Yang-Ming Univ, Taipei, Taiwan.*

Background: Some studies have suggested that warfarin is beneficial for stroke prevention in dialysis patients with atrial fibrillation. However, consistent with the clinical uncertainty regarding the benefits of stroke prevention with warfarin, the most recent KDIGO recommendations neither supported nor rejected the use of warfarin therapy in dialysis patients. Moreover, warfarin, a vitamin K antagonist, can inhibit γ-carboxylation of glutamic acid residues in matrix Gla protein (MGP) in arterial smooth muscle cells, and is thus involved in the process of arterial calcification.

Methods: Therefore, this study aims to explore the promoting effects of warfarin in aortic calcification *in-vivo* experiments. After 5/6 nephrectomy, B6 mice were divided into four groups: 5/6 NX, warfarin (3 mg/kg/day), Vitamin D3 (100 mg/kg/day), and Vitamin D3 plus warfarin groups (n=10~12 each group) for 4 months.

Results: In the fourth month, only the Vit-D plus warfarin group had micro-CT detectable vascular calcifications and 3-D reconstruction of the micro-CT images illustrated a pipe-like diffused calcified aorta. Histological staining confirmed the severe vascular calcification in the Vit-D plus warfarin group, but no remarkable aorta calcification in the other groups. 5/6 nephrectomy mice had a moderate left ventricular (LV) dysfunction as compared to sham operation group, however, Vit-D plus warfarin is able to induce significant LV dysfunction in remnant kidney mice [figure1].

Conclusions: Warfarin potentially promotes vascular calcification and exaggerates LV dysfunction in CKD mice.

FR-PO431

Analysis of Acidity and Phosphorus Levels in Commonly Consumed Sodas Uma D. Alappan,[1] Raj Alappan.[2] *[1]Science, Brookstone School, Columbus, GA; [2]Nephrology, Renal Associates LLC, Columbus, GA.*

Background: Increased phosphorus intake in CKD patients causes significant morbidity. The purpose of this study is to determine the prevalence of contents in commonly consumed sodas, specifically their pH, titratable acidity, phosphorus (P), phosphoric acid (H_3PO_4) and phosphate levels (PO_4), as this information is not readily available.

Methods: The Metrohm 799 GPT Titrino and the Optima 8x00 Series of ICP-EOS Spectrometers were used to estimate the pH, titratable acidity, and phosphorus content of various sodas respectively. The PO_4 and H_3PO_4 contents were calculated using proportions and the phosphorus number. A survey, inquiring soda preference, weekly intake, possible soda health effects, and consumer demographics, was administered to several high school students and faculty members, as well as to random participants in Columbus, GA.

Results: 124 participants were surveyed (n=124): Male-42 (33.9%), Female-82 (66.1%). The mean age was 31.46 years. 103 (83.1%) consumed sodas and 21 (16.9%) did not. The most frequently consumed sodas were Coca-Cola products, 62 (60.2%), Sprite products, 12 (11.7%), and Dr. Pepper products, 10 (9.7%). The weekly soda can and phosphorus consumption in those aged ≤18 years, 19-49, and 50+, was 5.6, 5.4, and 4.1 cans; and 713.0 mg/L, 748.1 mg/L, and 514.3 mg/L respectively.

	Study Mean	Overall Mean			Overall Mean			Dark Sodas		
		Dark	Light	<0.05 S	Regular	Diet	<0.05 S	Regular	Diet	<0.05 S
pH	2.90	2.75	3.05	0.61NS	2.70	3.10	0.01NS	2.48	3.02	0.01 S
T Acid	16.94	10.59	23.28	0.00 S	16.48	17.40	0.97 NS	11.41	9.77	0.17 NS
Phosphorus	70.13	125.50	6.9	0.00 S	79.00	60.00	0.59 NS	146.00	105.00	0.04 S
H_3PO_4	212.00	397.49	0.00	0.00 S	231.21	190.03	0.54 NS	462.42	332.56	0.04 S
Phosphate	205.24	384.83	0.00		223.85	183.98	0.54 NS	447.70	321.97	0.04 S
Measurements: Phosphorous, H3PO4 & PO4 in mg/L										

Conclusions: The dark regular sodas had the most acidity and phosphorus content, while the light diet sodas had the least. Coca-Cola, the commonest soda consumed, had one of the highest phosphorus contents of all sodas, suggesting high phosphorus intake. Diet Coca-Cola had the least amount of phosphorus of all dark sodas suggesting low phosphorus intake. Fanta, though a light soda, had phosphorus due to a sodium hexametaphosphate preservative. Diet 7-Up had no phosphorus and was the least acidic soda. As the survey results showed, soda intake generally decreases as one gets older.

FR-PO432

Adherence to Bone-Mineral Metabolism Guidelines among Kidney Transplant Candidates Meteb M. AlBugami,[1,2] Fahad Eid Alotaibe,[1,2] Khalid Bel'eed-Akkari.[1] *[1]Multi-Organ Transplant Center, King Fahad Specialist Hospital, Dammam, Saudi Arabia; [2]Dept of Internal Medicine, College of Medicine, Univ of Dammam, Dammam, Saudi Arabia.*

Background: Chronic kidney disease-mineral and bone disorders (CKD-MBD) is linked to cardiovascular disease (CVD). Since CVD is the most common cause of death among kidney transplant (KT) recipients, it would be prudent to optimize CKD-MBD among KT candidates. This study aimed to measure the extent to which KT candidates complied with the National Saudi Bone Biochemistry Guidelines.

Methods: All potential KT recipients evaluated at the Kidney and Pancreas Transplant Department at King Fahad Specialist Hospital-Dammam, between January 2009 and December 2013 were reviewed. Data were collected from electronic database. Blood samples were obtained during patients' initial visit to the pre-transplant evaluation clinic. For patients on hemodialysis, pre-dialysis samples were obtained.

Results: A total of 1014 candidates were evaluated, with a mean age of 43±13.7 years, and 589 (58%) of the subjects were males. Data were missing in 132 (13%) of the cases. Mean phosphorus level was 1.70±0.55 mmol/L, and 44% achieved the guideline target. Mean calcium level was 2.27±0.24 mmol/l, and 42% achieved the guideline target. Median PTH 439.2 pg/ml (IQR 243.4 – 806.75), and 19% only achieved the guideline target. 395 subjects (45%) had a PTH level >500 pg/ml, while 126 subjects (14%) had PTH less than 150 pg/ml. Only 2.3% of patients met all the 3 standards for corrected calcium, phosphorus and PTH.

Conclusions: Substantial proportion of KT candidates referred for pre-transplant evaluation failed to meet the Saudi national guideline targets of CKD-MBD. This should prompt us to place greater and more rigorous emphasis on adherence measures to the guidelines in order to improve the cardiovascular risk of transplant recipients.

FR-PO433

Acid-Base and Phosphorus Homeostasis in Chronic Kidney Disease: Results from the Chronic Renal Insufficiency Cohort (CRIC) Study Pascale Khairallah,[1] Tamara Isakova,[2] John R. Asplin,[3] L. Lee Hamm,[4] Mirela A. Dobre,[5] Mahboob Rahman,[5] Kumar Sharma,[6] Mary B. Leonard,[7] Edgar R. Miller,[8] Bernard G. Jaar,[8] Carolyn S. Brecklin,[9] Wei Yang,[10] Harold I. Feldman,[10] Myles S. Wolf,[2] Julia J. Scialla.[1] *[1]Duke Univ; [2]Northwestern Univ; [3]Litholink Corporation; [4]Tulane Univ; [5]Case Western Reserve Univ; [6]Univ of California San Diego; [7]Stanford Univ; [8]Johns Hopkins Univ; [9]Univ of Illinois; [10]Univ of Pennsylvania.*

Background: Kidneys excrete acid either as ammonium or as titratable acids (TA) that use phosphate as a buffer. In CKD, impaired ammoniagenesis promotes metabolic acidosis. I*n vitro,* acidosis stimulates phosphaturic hormones, parathyroid hormone (PTH) and fibroblast growth factor 23 (FGF23), possibly to increase buffer for TA. These *in vitro* findings have not been confirmed in humans.

Methods: In 980 CRIC participants with CKD (eGFR 44±14 ml/min/1.73m^2), we measured net acid excretion (NAE) in 24h urine, potential renal acid load (PRAL) by food questionnaire, and serum bicarbonate. Using adjusted linear and log-linear regression, we modeled associations between acid parameters and 24h urine phosphorus, serum phosphorus, FGF23, and PTH.

Results: 24h urine phosphorus was higher at higher NAE, higher PRAL, and lower bicarbonate (all p-trends<0.05). Serum phosphorus was higher with higher NAE and lower bicarbonate (both p-trends=0.001). Higher NAE or PRAL were not associated with FGF23 or PTH. PTH, but not FGF23 (p=0.2), was 26% higher (P<0.001) when serum bicarbonate was < vs. ≥22meq/L. Results were similar if stratified by eGFR categories, or if adjusted for iothalamate GFR, energy intake, urine urea nitrogen, or dietary phosphorus, where available.

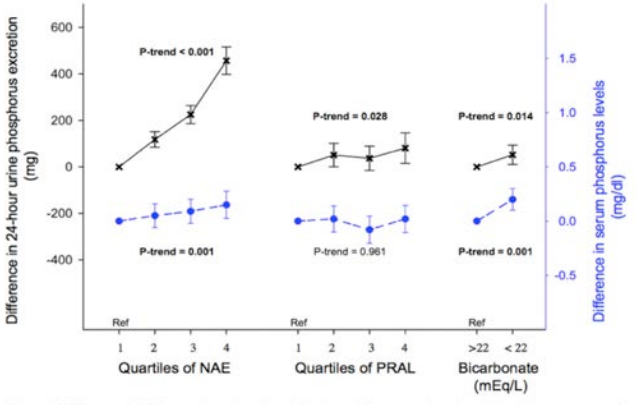

Figure 1. Difference in 24-hour urine phosphorus levels and in serum phosphorus levels by measures of acid loading.
Crosses represent the difference between 24-hour urine phosphorus levels and the reference category. Dots represent the difference between serum phosphorus levels and the reference category. Models are adjusted for age, sex, race, eGFR, 24-hour urine albumin, 24-hour urine creatinine, comorbidities, BMI, and diuretic use. The bars are 95% confidence intervals.

Conclusions: Acid loading may augment phosphaturia in CKD to maintain NAE. Mechanisms may include higher serum phosphorus and not primary increase in FGF23 or PTH. Effect of acid load on phosphorus homeostasis must be tested in trials.

FR-PO434

Novel Non-Absorbed, Calcium-Free, Highly Effective Phosphate Binders Derived from Gum Arabic J. Ruth Wu-Wong, Yung-Wu Chen, Jerry Wessale. *Vidasym, Chicago, IL.*

Background: Inadequate control of serum phosphate in chronic kidney disease can lead to pathologies of clinical importance. Effectiveness of on-market phosphate binders is limited by safety concerns and low compliance (high pill size/burden and gastrointestinal (GI) discomfort).

Methods: We have developed a series of novel, highly effective phosphate binders from metal ions and gum Arabic (GA), ingredients commonly used in food.

Results: In vitro studies show that VS-505 (Fe-GA), VS-605 (Mg-GA) and VS-705 (Zn-GA) have high densities (e.g. 1.95 g/cm^3 for VS-505 vs. 1.27 g/cm^3 for sevelamer) and low swell volumes when exposed to phosphate buffer or simulated gastric fluid (e.g. 0.4 cm^3/0.1g for V-505 vs. 4 cm^3/0.1g for sevelamer). VS-505, VS-605 and VS-705 bind phosphate within a wide physiologically relevant range of pH, enabling them to bind phosphate along much of the GI tract. In normal SD rats, increasing the dietary phosphate led to an increase in serum phosphate, which was prevented in rats treated with VS-505, VS-605, or VS-705 (0.2 - 5% in food). Urinary phosphate increased by >10-fold in the vehicle-treated group; VS-505, VS-605 or VS-705 reduced urinary phosphate, and increased fecal phosphate in dose-dependent manners. No significant changes were observed for serum calcium, while urinary calcium increased from 1.4 ± 0.2 mg/24 hr before dosing to 9.2 ± 1.0 mg/24 hr in the 5% sevelamer group, and to 3.6 ± 0.5, 3.0 ± 0.7, and 5.2 ± 1.6 mg/24 hr in the 5% VS-505, VS-605, and VS-705 groups, respectively. In SD rats made uremic by 5/6 nephrectomy (5/6 NX rats) on a high phosphate diet, urinary and serum phosphate levels were significantly elevated in untreated rats, which were reduced by VS-505 and sevelamer. VS-505 increased fecal phosphate levels in a dose-dependent manner. More aortic calcification was observed in 5/6 NX rats treated with 5% sevelamer, but not in rats treated with VS-505.

Conclusions: These results demonstrate that these novel metal ion-GA phosphate binders effectively control phosphate imbalance in rats by removing phosphate from the GI via the feces. VS-505 is currently being evaluated in a clinical trial in Australia involving hemodialysis patients (ClinicalTrials.gov #: NCT02469467).

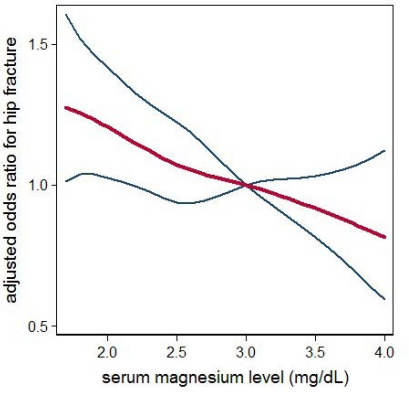
FR-PO435

Lower Serum Magnesium Levels Are Associated with an Increased Risk of Hip Fracture in Hemodialysis Patients - A Nationwide Cohort Study Yusuke Sakaguchi, Takayuki Hamano, Atsushi Wada, Masanori Abe, Eiichiro Kanda, Shunsuke Goto, Takeshi Hasegawa, Junichi Hoshino, Kan Kikuchi, Mariko Miyazaki, Shigeru Nakai, Ikuto Masakane. *Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: Hip fracture is common in dialysis patients, which leads to an increased mortality and substantial economic burden. Although magnesium is an essential mineral for normal bone metabolism, little is known about the relationship between magnesium and a risk of fractures. Here we analyzed the association of serum magnesium levels (sMg) with an incidence of hip fracture in hemodialysis patients.

Methods: We utilized a database of the Japanese Society for Dialysis Therapy-Renal Data Registry that covers nearly all dialysis patients in Japan. We included hemodialysis patients without a prior history of hip fracture. Patients living in a nursing home or aged more than 90 years old were excluded. sMg were divided into quartiles (Q1 to Q4). Primary outcome was the incidence of new hip fractures during 2-year follow-up period.

Results: Among a total of 113,086 hemodialysis patients enrolled in the analysis, a new hip fracture occurred in 2,267 patients (2.00%). The incidence rate of hip fracture decreased as sMg quartiles increased (2.61%, 2.06%, 1.74%, and 1.47% in Q1 to Q4, respectively; p <0.001 for trend) (range of sMg (mg/dL): Q1, -2.3; Q2, 2.4-2.6; Q3, 2.7-2.8, Q4, 2.9-). After an extensive adjustment for demographic and clinically relevant factors including parathyroid hormone levels, patients in Q1 had a 26% higher odds for hip fracture than those in Q4 (p = 0.004). A population attributable fraction analysis indicated that 15.4% (95%CI: 5.6-24.2; p = 0.003) of all hip fractures in this population could have been prevented by increasing sMg to the range of Q4.



Conclusions: Low sMg may be an unignorable risk factor for hip fracture among hemodialysis patients.

FR-PO436

Hypophosphatemia following Hepatectomy and Pancreatectomy: Role of the Phosphaturic Factor NAMPT Jian Zheng, Ilya Glezerman, Eran Sadot, Anjuli J. Mcneil, Vinod Balachandran, Peter Kingham, Michael D'Angelica, Peter Allen, Ronald Dematteo, William Jarnagin, Edgar A. Jaimes. *Memorial Sloan Kettering Cancer Center, New York.*

Background: Clinically significant postoperative hypophosphatemia is common and is associated with a lower risk of liver failure after hepatectomy but a higher rate of complications after pancreatectomy. The mechanisms involved are unclear but presence of

phosphaturia suggests a role for phosphaturic factors such as parathyroid hormone (PTH) or nicotinamide phosphoribosyltransferase (NAMPT). This study evaluates the role PTH and NAMPT have on development of postoperative hypophosphatemia.

Methods: Patients who underwent open liver (n=48) and pancreas (n=30) resections were enrolled, and those deemed unresectable were used as controls (n=21). Serum and urinary phosphate and creatinine were measured preoperatively and on postoperative day (POD)1-7. Serum PTH (immunoassay) and NAMPT (ELISA) were analyzed preoperatively and on POD2.

Results: Phosphate levels significantly decreased from POD1 to POD2 in all 3 groups preceded by an increase in phosphaturia. NAMPT levels were significantly increased from preoperative day to POD2 in resected patients but not in controls. PTH levels did not change in any of the groups.

	Phosphate (mg/dL)		Urine Phos/Cr		NAMPT (ng/mL)		PTH (pg/mL)	
	POD1	POD2	Preop	POD1	Preop	POD2	Preop	POD2
Hepatectomy	3.9 (3.5-4.5)	1.8* (1.5-2.2)	0.4 (0.2-0.6)	1.4** (1-1.7)	1.5 (0.7-2.9)	2.6# (1.5-5)	57 (43-83)	57 (36-76)
Pancreatectomy	4.1 (3.3-4.7)	2.0* (1.6-2.3)	0.4 (0.3-0.5)	1.7** (1.5-2.1)	0.9 (0.5-1.5)	2.5** (1.3-4.2)	47 (39-62)	48 (39-78)
Control	3.0 (2.7-3.8)	1.9* (1.6-2.2)	0.4 (0.3-0.5)	1.2** (1-1.5)	1.3 (0.6-2.9)	1.5 (1.1-3.2)	53 (37-76)	62 (39-93)

Results presented as median (IQR) and compared using Wilcoxon signed rank test (*P<0.001 vs POD1; **P<0.001 vs Preop; #P<0.05 vs Preop).

Conclusions: This study demonstrates that postoperative hypophosphatemia is linked to increased NAMPT. Downregulation of renal sodium-phosphorus co-transporters by NAMPT may be mediating these effects. The mechanisms that upregulate NAMPT and its role on the disparate clinical outcomes in these 2 groups warrant further investigation.

FR-PO437

The Serum Calcification Propensity of Hemodialysis Patients Is Strongly Modified by Serum Phosphate, Magnesium and Bicarbonate

Florian Buchkremer,[1] Andreas Pasch,[2] Andreas H. Bock.[1] *[1]Nephrology Div, Kantonsspital Aarau, Aarau, Switzerland; [2]Calciscon AG, Bern, Switzerland.*

Background: Serum calcification propensity as measured by the T50 test (Pasch, JASN 2012, 23:1744) has been validated as a strong predictor of morbidity and mortality in hemodialysis patients. We sought to identify biochemical determinants of the T50 test in a prospective cohort of hemodialysis patients.

Methods: 15 chronic hemodialysis patients (12 m, 3 f; mean age 73 ± 14 y.) treated with high volume hemodiafiltration (3 x 4 hr/wk) were studied. T50 was determined monthly over a period of 9 months (n = 122) together with midweek pre-dialysis plasma concentrations of Na+, K+, Calcium, ionized Calcium (ioCa++), Magnesium, Phosphate, Bicarbonate and Albumin. These biochemical parameters were evaluated as continuous predictors of T50 in a generalized regression model.

Results: The mean T50 value in this cohort was 260 minutes (± 72 [SD]; Range 105 - 460). In the linear model, only Magnesium, Bicarbonate, Phosphate and ioCa++ were significant predictors of T50. When the Patient ID was added to the model as a categorical predictor , ioCa++ became nonsignificant:

Parameter		Mean±SD	Beta	B	95% CI for B	p
Na^+	mmol/l	137.6 ± 3.0	-0.026	-0.6	[-4.4 3.1]	0.73
K^+	mmol/l	4.4 ± 0.5	0.013	1.9	[-16.5 20.3]	0.84
Ca^{++}	mmol/l	2.09 ± 0.14	0.456	216.1	[-383.8 816.0]	0.48
Ca^{++}_{corr}	mmol/l	2.30 ± 0.17	-0.360	-148.0	[-743.6 447.6]	0.62
$Ca^{++}_{ionized}$	mmol/l	1.10 ± 0.09	-0.136	-102.1	[-276.3 72.0]	0.25
Mg^{++}	mmol/l	0.94 ± 0.13	0.291	164.2	[83.5 244.9]	0.00012
Bicarbonate	mmol/l	25.3 ± 2.1	0.220	7.6	[2.7 12.5]	0.0027
Phosphate	mmol/l	1.49 ± 0.39	-0.246	-46.2	[-68.3 -24.1]	0.00008
Albumin	g/l	31.4 ± 3.0	0.180	5.2	[-9.9 20.3]	0.49

While Phosphate shortened the T50 precipitation time (promoting calcification), Magnesium and Bicarbonate prolonged T50, inhibiting calcification. Predicted T50 changes when altering these parameters from the minimum to the maximum measured in the study were: Bicarbonate [19 -> 30 mmol/l]: + 84 min. Magnesium [0.61 -> 1.21 mmol/l]: + 99 min. Phosphate [0.72 -> 2.66]: -90 min.

Conclusions: Several easily measurable and modifiable parameters correlate significantly with T50. Serum Phosphate appears to promote, serum Magnesium and Bicarbonate to inhibit calcification propensity. Although the present data may be influenced by individual patients' comorbidities, they constitute a basis for prospectively studying the determinants of T50.

Hepatectomy-Induced Hypophosphatemia: Mechanisms Underlying Downregulation of Phosphate Transport in the Small Intestine

Sawako Tatsumi, Atsumi Miyagawa, Osamu Fujii, Mao Ogata, Ichiro Kaneko, Hiroko Segawa, Ken-Ichi Miyamoto. *Molecular Nutrition, Tokushima Univ Graduate School, Tokushima, Japan.*

Background: Several recent clinical studies have explored the potential value of nicotinamide (NAM) in phosphate (Pi) control in dialysis patients. However, the mechanism underlying Pi regulation by NAM has not been fully elucidated. Marked hypophosphatemia is common after major hepatic resection; however, the pathophysiological mechanism remains unknown. Recently, we reported that hepatectomy-induced hypophosphatemia is due to abnormal NAM metabolism. Partial hepatectomy (PH) rats exhibited markedly decreased levels of intestinal NaPi-IIb and Na^+-dependent Pi transport activity. In the present study, we evaluated the roles of nicotinamide phosphoribosyletransferase (Nampt; catalyzes the first rate-limiting step in converting NAM to NAD) on Pi handling in the small intestine.

Methods: We used a PH rat model and $Nampt^{+/-}$ mice to investigate the molecular basis of Pi handling in the small intestine through Nampt activity.

Results: PH rats showed hypophosphatemia and hyperphosphaturia. PH rats also exhibited elevation of plasma NAM concentration and reduction of intestinal Na/Pi transport and NaPi-IIb protein. In addition, cellular Nampt protein and NAD levels were significantly increased in the small intestine. In in vitro analyses using NaPi-IIb-expressing human intestinal epithelial cells (Caco2-BBe), treatment with Nampt and NAM led to a marked decrease in the NaPi-IIb protein levels compared with treatment with NAM alone. In contrast, FK866 (a specific inhibitor to Nampt)-treated mice (C57BL/6J) showed elevated intestinal Na/Pi uptake and NaPi-IIb expression. In PH mice with FK866, urinary Pi excretion was significantly decreased. In addition, $Nampt^{+/-}$ mice showed elevation of intestinal NaPi-IIb and upregulation of intestinal Pi transport activity. These observations suggest that cellular Nampt activation is an important factor for the downregulation of intestinal NaPi-IIb levels.

Conclusions: In PH animals, the downregulation of intestinal Pi transport may be due to Nampt activation. These data suggest that intestinal Nampt is a novel potential tool for treating hyperphosphatemia in CKD patients.

Effect of Antibiotic Treatment on Oxalobacter Formigenes (OF) Colonization and Urinary Oxalate Excretion

Lama Nazzal,[1] Nora J. Henderson,[1] Sukhleen Bedi,[1] Fritz Francois,[1] Guillermo I. Perez Perez,[1] John R. Asplin,[2] David S. Goldfarb,[1] Martin J. Blaser.[1] *[1]Medicine, New York Univ, New York, NY; [2]Litholink Corp., Chicago, IL.*

Background: *OF*, a member of the human colonic microbiota, plays a major role in net colonic oxalate absorption and secretion. We now report *OF* colonization rates in a healthy population, the stability of colonization, the effects of antibiotic treatment, and *OF* colonization on urinary oxalate (Uox) excretion.

Methods: We followed 65 healthy subjects tested for *Helicobacter pylori* (HP) gastric colonization. Those who were HP+ were treated with antibiotics (amoxicillin and clarithromycin) for 2 weeks (w) for HP eradication. Using species-specific PCR, we tested for *OF* colonization. Urine samples 3h after a standard meal were analyzed for Uox, factored for creatinine (Cr). Both assessments were done at baseline and at follow-up.

Results: Of the 65 subjects (M/F: 23/42; mean age 25.2 + 5.7y) tested for *OF*, 28 (43%) were positive at baseline. Of 7 *OF*+ subjects at baseline who received antibiotics for HP elimination, 6 became *OF*- at 12 w. Of these, 2 reverted to *OF*+ at week 24, and 4 remained *OF*- at follow up (Mean 22.5 + 4.2w). For 42 untreated subjects, 18 of whom were *OF*+ at baseline, 16 (89%) remained *OF*+ at follow-up (Mean 23.0 +4.2w). Of 24 OF- subjects, only 3 (12%) were *OF*+ at follow up (Mean 20.2+ 6.8w; p=0.001 compared to initial *OF*+). We assessed Uox/Cr in 137 samples from 46 subjects with no antibiotic exposure. *OF*-positivitywas associated with 14% lower Uox/Cr compared with *OF*-negativity (17.0 ±0.0 vs 19.4 ± 0.1mg/g, p=0.04). From 5 antibiotic treated *OF*+ subjects, we assessed Uox/Cr at baseline and 24 weeks following antibiotic exposure and found no significant increase in urine oxalate (16.6 +6.7 vs 18.5 +12.6 mg/g, p=0.5).

Conclusions: We conclude that detectable *OF*-positivity remains stable over several months, but that antibiotic exposure suppresses or eliminates colonization in most subjects. In the absence of a high oxalate content meal, antibiotic exposure did not significantly increase urinary oxalate. Differences in urinary oxalate levels with respect to *OF* status are consistent with protective effects related to calcium oxalate kidney stones.

FR-PO440

Prevalence of LMWP and CLCN5 Mutations in Proteinuric Cohorts

Lada Beara Lasic,[1] Andrea G. Cogal,[1] Xiangling Wang,[1] Felicity T. Enders,[1] Ramila A. Mehta,[1] Zejfa Haskic,[1] Susan L. Furth,[2] Howard Trachtman,[3] Steven J. Scheinman,[1] Dawn S. Milliner,[1] Peter C. Harris,[1] John C. Lieske.[1] *[1]Rare Kidney Stone Consortium; [2]CHOPP, Philadelphia, PA; [3]NYU, New York, NY.*

Background: Dent disease type 1 (DD1) is a rare X-linked disorder caused by *CLCN5* mutations. Some patients present only with nephrotic range proteinuria leading to erroneous diagnosis and immunosuppressive treatment of focal segmental glomerulosclerosis (FSGS).

Methods: *CLCN5* mutations were screened using specimens from the following cohorts: Chronic Kidney Disease in Children (CKiD; n=112); Multicenter FSGS-Clinical

Trial (FSGS-CT) and Novel therapies for resistant FSGS Trial (FONT) (n=126). The CKiD cohort included patients with FSGS; chronic GN, familial nephritis, congenital nephrotic syndrome, reflux nephropathy, and medullary cystic disease. Urinary α_1-microglobulin (α_1M), albumin (A) and total protein (TP) were assessed in urine from CKiD subjects (n=104); DD1 patients (n=14) and DD1 carriers (DC; n=8).

Results: No *CLCN5* mutations were detected in the screened cohorts. TP/Cr was similar in CKiD and DD1 but lower in DC (P<0.001). A/CR was significantly less elevated in DD1 while α_1M/Cr was higher in DD1 (P<0.001) compared to CKiD cohort. α_1M/TP was similar in DD1 and DC and higher than CKiD (P<0.001), while the A/TP was lower in DD1 but similar in DC and CKiD (P=0.01).

Conclusions: *CLCN5* mutations are rare. Even though TP excretion did not differ, the protein pattern of DD1 could be distinguished from CKiD subjects due to a significantly higher α_1M/Cr and significantly lower A/TP. Although the TP excretion of DC was low, DC had proportionately more α_1M, mirroring DD1. Assessment of urinary LMWP such as α_1M is a good screen for DD1 among male patients with proteinuria. A/TP could also be considered as a simple screening test for Dent since it is readily available and provided good differentiation from other pediatric proteinuric renal diseases.

	TP/Cr (mg/g)	A/Cr (mg/g)	α_1M/Cr (mg/g)	A/TP	α_1M/TP
CKiD	2275 (3917)	1410 (2427)	34 (40)	44 (27)%	5 (5)%
DD1	1589 (837)	247 (120)	195 (91)	18 (8)%	14 (3)%
DC	80 (112)	15 (19)	5 (4)	58 (99)%	11 (6)%

Drosophila Model Indicates Role of OSR1/SPAK Signaling in Calcium Oxalate Kidney Stone Formation via Regulation of Slc26a6 Mediated Cl-/Oxalate(2-) Exchange

Jacob B. Anderson,[1] Taku Hirata,[1,2] Adam Joseph Rossano,[1,3] Greg M. Landry,[1,2,3] Michael F. Romero.[1,2,3] *[1]Physiology & Biomedical Engineering, Mayo Clinic College of Medicine, Rochester, MN; [2]O'Brien Urology Research Center, Mayo Clinic College of Medicine, Rochester, MN; [3]Nephrology & Hypertension, Mayo Clinic College of Medicine, Rochester, MN.*

Background: Kidney stones (12% male; 6% female) are costly, painful and lead to renal injury. Calcium oxalate (CaOx) are >70% of stones. Oxalate is a metabolic end-product eliminated via the kidneys and intestine. Oxalate-secretion is mediated by Slc26a6 (dPrestin in flies), a Cl^-/$Oxalate^{2-}$ exchanger. Voltage clamping of oocytes expressing dPrestin/Slc26a6 ±OSR1/SPAK indicate that these kinases ↑ Cl^-/$Oxalate^{2-}$ exchange activity. Therefore, we hypothesized that the incidence of CaOx crystals (kidney stones) could be reduced if oxalate excretion was reduced from the Malpighian tubule (MT) and shifted to the gut by reducing oxalate transport via inhibition of OSR1 in MTs.

Methods: Using a *Drosophila* model of CaOx kidney stones [Hirata, PMID22993075], we made tissue specific knockdowns (MT or gut) of *Drosophila* OSR1 (CG7693, *frayed*). Flies were used to investigate the signaling regulation of oxalate secretion , CaOx crystallization, in MTs.

Results: *Ex vivo* CaOx crystallization experiments show a 34% reduction in average crystal count when OSR1 knockdown (via RNAi: 51% knockdown) flies are compared to wildtype. *In vivo* feeding experiments with MT-specific OSR1 knockdown also reduces the crystal count recapitulating *ex vivo* experiments. Preliminary *in vivo* data for gut-specific OSR1 knockdown trends toward increasing average crystal counts.

Conclusions: From this data, we conclude that regulation of oxalate transport via OSR1 signaling is sufficient to reduce average CaOx crystal count. This data also suggests that manipulation of OSR1/SPAK signaling may be a new and important target for the development of therapeutics for the prevention of CaOx kidney stones.

FR-PO442

Development of Biomimetic Randall's Plaque Using Decellularized Porcine Kidneys

Saeed R. Khan,[1] Archana Lovett,[2] Laurie Gower.[2] *[1]Pathology, Univ of Florida, Gainesville, FL; [2]Materials Science and Engineering, Univ of Florida, Gainesville, FL.*

Background: Idiopathic calcium oxalate stones are commonly found attached to Randall's plaques (RP), calcium phosphate (CaP) deposits in the renal papillae. Plaques originate as concentrically laminated apatitic spherules, and grow by mineralization of interstitial collagen fibrils and vesicles. We hypothesize that such distinct CaP morphologies form by non-classical crystallization mechanisms, the polymer-induced liquid-precursor (PILP) process, in which highly acidic macromolecules sequester ion clusters to induce liquid–liquid phase separation of hydrated, ion-enriched nano-droplets. PILP droplets have fluidic character and thus coalesce into mineral coatings, or infiltrate into the interior of collagen fibrils, producing mineral products which differ from the classical crystallization mechanism.

Methods: Decellularized porcine kidneys were mineralized using a 4.5 mM calcium and 2.1 mM phosphate solution (pH 7.4). The PILP process was induced by addition of 50 μg/ml of poly-L aspartic-acid or osteopontin. At specific intervals, specimens were removed, and characterized using SEM and TEM.

Results: Analysis of the tissues shows features that resemble native Randall's plaques, such as concentrically laminated spherules and collagen fibrils with intrafibrillar mineral, and with differing morphologies in the basement membrane versus interstitium. In contrast, the classical crystallization produced large apatitic spherulites, which is a very different morphology, but one which is also found in some stones.

Conclusions: CaP deposition on decellularized kidney substrate appears to produce biomimetic plaque similar to the native RP with respect to calcification of collagen and production of apatitic spherules. Both classical and non-classical mechanisms might be at play. We are planning to study overgrowth of biomimetic plaques with CaOx in a rat model of hyperoxaluria.

Nephron-Segment Specific Urinary Extracellular Vesicles Containing MCP-1 and NGAL Associate with Randall's Plaque

Robin Sunny Chirackal, Majuran Perinpam, Muthuvel Jayachandran, Xiangling Wang, Timothy M. Halling, Samuel Edeh, Zejfa Haskic, John C. Lieske. *Mayo Clinic, Rochester, MN.*

Background: Randall's plaques (RP) are an important precursor of urinary stone formation. However, RP cannot be noninvasively detected. This study investigated urinary EVs as biomarkers of RP.

Methods: RP were assessed by videotape and quantitative image processing in 47 consecutive idiopathic calcium oxalate stone formers undergoing stone removal. Cell-free urinary EVs from different nephron segments carrying protein biomarkers of renal fibrosis and injury were quantified in biobanked urine by digital flow cytometry and fluorophore conjugated antibodies.

Results: Urine from 40 low RP (<5% papillary surface RP) and 7 high RP (≥5% surface RP) patients demonstrated that EVs from multiple nephron segments expressing MCP-1 and NGAL were significantly greater in the low RP group. Osteopontin-positive EVs did not differ.

Nephron Location	Marker 1	Marker 2	Low RP (n=40)	High RP (n=7)	P-value

Proximal	**NGAL**	**URAT1**	**22.4 (5.2,145.0)**	**3.9 (1.6,15.7)**	**0.02**
Thin Loop	NGAL	AQ1	8.1 (2.1,112.0)	2.9 (0.8,14.8)	0.22
Thick Loop	**NGAL**	**UROM**	**201.2 (52.2,689.9)**	**42.1 (20.6,47.6)**	**0.01**
Distal	NGAL	SLC12A3	22.2 (2.7,70.9)	7.0 (1.4,71.6)	0.52
Collecting Duct	**NGAL**	**AQ2**	**118.1 (22.1,421.5)**	**6.3 (1.3,40.0)**	**0.02**
Renal Pelvis	NGAL	CK-19	18.8 (2.0, 63.4)	5.24 (2.9,12.9)	0.50

Conclusions: Urinary EV biomarkers consistent with renal injury (NGAL) and inflammation (MCP-1) were increased in CaOx stone patients with low amounts of RP. These findings may reflect pathologic cellular events that drive stone formation in low RP patients, or perhaps protective responses that limit RP development in this group. Urinary EVs are a promising source of biomarkers for pathogenic events in USD.

Contribution of Tubular Segments to a Calcium Cortico-Papillary Gradient

Suresh Krishna Ramakrishnan,[1] Muriel Auberson,[1] Candice Stoudmann,[1] Olivier Bonny.[1,2] *[1]Dept of Pharmacology, Univ of Lausanne, Switzerland; [2]Service of Nephrology, Lausanne Univ Hospital, Switzerland.*

Background: Renal papillary calcification and Randall's plaque formation are largely dependent on urinary calcium excretion. Mathematical models of renal calcium transport predict a cortico-papillary calcium gradient in physiological conditions, but this has not been ascertained in vivo. We aimed at deciphering this gradient and at identifying which part of the nephron may contribute to its formation.

Methods: Small pieces representative of cortex, medulla and papilla were isolated from mouse kidneys, and calcium, phosphate and sodium content were measured, as well as urinary parameters. In experiment 1, C57Bl/6J mouse kidneys were harvested. In experiment 2, mice were previously injected with 1 dose of furosemide (20mg/KgBW), hydrochlorothiazide (25mg/KgBW) or vehicle. In experiment 3, mice were injected daily for 7 days with furosemide (20mg/KgBW). In experiment 4, kidneys of mice with disrupted distal calcium reabsorption (Pax8-LC1-Cre $NCX1^{fl/fl}$ mice) and WT controls were harvested. And in experiment 5, mice were fed daily dihydrotachysterol (1.5mg/kg food) for 7 days.

Results: Results showed higher calcium and sodium content in the papilla of mouse kidney compared to cortex or medulla, but lower phosphate. Acute furosemide treatment disrupted the sodium cortico-papillary gradient, but not the calcium one. Hydrochlorothiazide and disruption of renal NCX1 had no effect on any gradient. Chronic dihydrotachysterol treatment led to hypercalcemia and hypercalciuria, and blunted the calcium cortico-papillary gradient; sodium gradient was unchanged.

Conclusions: We conclude that a calcium cortico-papillary gradient exists in the mouse kidney, with higher calcium concentration in the papilla, while phosphate had a mirror gradient. Distal transepithelial calcium transport does not contribute to the calcium gradient, while thick ascending limb calcium transport may modulate it. Further studies exploring TAL and proximal tubule contribution are warranted.

FR-PO445

Urine Proteomic Analysis Confirms a Higher Degree of Bone Disease in Medullary Sponge Kidney against Nephrolithiasis Alessandra Dalla Gassa,[1] Antonia Fabris,[1] Giovanni Candiano,[2] Maurizio Bruschi,[2] Gianluigi Zaza,[1] Simona Granata,[1] Giovanni Gambaro,[3] Antonio Lupo.[1] *[1]Renal Unit, Univ of Verona, Italy; [2]Laboratory on Pathophysiology of Uremia, Istituto G. Gaslini, Genoa, Italy; [3]Div of Nephrology and Dialysis, Catholic Univ Hospital, Rome, Italy.*

Background: Medullary sponge kidney (MSK) is a genetic malformative disease characterized by cystic formations of the distal ducts, hypercalciuria, nephrocalcinosis and kidney stones. Metabolic bone disease is very frequent in MSK and idiopathic calcium nephrolithiasis (NL). We hypothesized that pathways involved in bone remodeling are more active in MSK than NL.

Methods: In 11 MSK vs 12 NL pts were studied: urine proteins (UP), 24-h urine biochemistry and bone mineral content (BMC). All pts had normal PTH and eGFR>60 ml/min/1.73m^2. UP were analyzed with STRING version 10.0. UP were selected if ≥2-fold difference in spectral counts and ≤0,05 p-value.

Results: Prevalence of F/M was 64/36% and 67/33% in MSK and NL,respectively. Mean age±ds was 53±19 yr in MSK and 54±15 yr in NL. 24-h urine(U) and BMC in MSK and NL pts, mean and (SD) are shown: U.Ca(mg/d)317(107)222(107)p=0,045, U.Na(mEq/d)204.36(49)139(47)p=0.004, Z-ScoreLS -1.4(0.5)-0.76(0.8)p=0.038, T-ScoreLS -1,65(0.45)-1.04(0.67)p=0.018. MSK differed from NL pts in 328 PP. 100 UP were overexpressed in MSK, 228 downexpressed. Some UP are involved in annotated pathways:PPP2CB,LAMB2,HSP90AA1 in PI3K-Akt pathway,CDH15,PTPRM in cell adhesion molecules. PI3K-Akt pathway induces osteoclastogenesis by activating GSK3β/NFAtc1 cascade and also promotes osteoblast differentiation. PI3Kγ was responsible for decreased BMC in a murine model. Down regulated UP: CDH1,CDH3,CDH6,CDH11,CDH13 are involved in Ca-dependent trans-dimerization of cadherin, cadherin/catenin complex; IQGAP1,CD14,RAC3,GNG12 in regulation of actin. Cadherins are linked to the actin cytoskeleton via binding to catenins in adherens junctions; this complex is essential for osteoblast differentiation and osteogenesis by controlling Wnt and PI3K/Akt signaling.

Conclusions: All these findings show that osteogenetic pathways are more active in MSK then in NL confirming their role in nephrocalcinosis and in the more severe BMC observed in MSK.

FR-PO446

Reduced BMD and Bone Quality in GHS Rats Is due to Changes in Osteoblast and Osteoclast Activity Nancy S. Krieger,[1] Hongwei Wang,[2] Murray J. Favus,[2] David A. Bushinsky.[1] *[1]Medicine, Univ of Rochester, Rochester, NY; [2]Medicine, Univ of Chicago, Chicago, IL.*

Background: To study idiopathic hypercalciuria (IH) we developed an animal model, genetic hypercalciuric stone-forming (GHS) rats, whose pathophysiology parallels that in human IH. All GHS rats form kidney stones and have decreased bone mineral density (BMD) and bone quality compared to the founder Sprague-Dawley (SD) rats. To understand this bone defect we have begun to characterize differences in osteoblast and osteoclast activity in the GHS compared to SD.

Methods: Multipotential bone marrow stromal cells (BMSC) and bone marrow monocytes (BMC) were isolated from femurs of GHS and SD rats and cultured to optimize differentiation into osteoblasts or osteoclasts. After treatment of BMSC ±60 ng/mL BMP2 for 7 to 21d, RNA was collected and specific osteoblast gene expression assessed by real time PCR. BMC were treated with 50 ng/ml M-CSF and 100 ng/ml RANKL and resultant osteoclasts were stained for TRAP or cultured in a pit formation assay to assess resorptive activity.

Results: There was increased expression of RANKL and decreased basal expression of RUNX2, alkaline phosphatase (AP), osterix (ostx) and osteocalcin (OC) in GHS compared to SD osteoblasts. Treatment of SD osteoblasts with BMP2 for 7d increased relative expression of RUNX2 (1.8x), AP (3.2x), ostx (3.0x) and OC (2.5x) compared to baseline (P<0.05) while GHS osteoblast gene expressions were unchanged. After 21d of BMP2, SD osteoblasts increased in vitro mineralization to 3.2% of the total area stained with Alizarin Red compared to baseline while only 1% of GHS surfaces were stained (P<0.001). There was increased osteoclastogenesis and increased resorption pit formation in GHS BMC compared to SD BMC cultures (23±7 vs 5±2% of surface resorbed, P<0.05).

Conclusions: These results suggest alterations in baseline characteristics of osteoblasts and osteoclasts in GHS rats that lead to decreased BMD and bone quality, perhaps due to their known increase in vitamin D receptors. Better understanding of the role of GHS bone cells in decreased BMD and bone quality may provide new strategies to prevent or reverse the low bone mass and increased fracture risk found in patients with IH.

FR-PO447

FGF23 and Its Association with Prevalent Hypertension in Calcium Kidney Stone Formers Jie Tang,[1] Michel Chonchol.[2] *[1]Medicine, Univ Medicine, Brown Univ, Providence, RI; [2]Medicine, Univ of Colorado, Aurora, CO.*

Background: As a key regulator of body calcium and phosphorus hemostasis, fibroblast growth factor 23 (FGF23) might be important for the development of hypertension in kidney stone disease.

Methods: We conducted a cross-sectional study of 91 prevalent calcium kidney stone formers, and examined the associations of C-terminal FGF23, vitamin D, intact parathyroid hormone (iPTH) and prevalent hypertension.

Results: The mean serum 25-hydroxy vitamin D [25(OH)D], 1,25-dihydroxy vitamin D [1,25$(OH)_2$D] and plasma FGF23 values were 24 ng/ml, 62 pg/ml, and 223 RU/ml, respectively. These values were different compared to those in published age matched healthy controls (33 ng/ml, 41 pg/ml and 25 RU/ml respectively). Serum iPTH, calcium, and phosphorus values were similar between the two groups, mean MDRD eGFR were both >60 ml/min. Among stone formers, plasma FGF23 had a significant reverse association with eGFR (p=0.04) after adjustment for age, gender, race, body mass index (BMI), history of diabetes, hypertension and dyslipidemia. But it failed to demonstrate significant associations with serum 25(OH)D, 1,25$(OH)_2$D, or iPTH measurements, nor was it associated with urinary fractional excretion of phosphorus. Plasma FGF23 had a strong association with prevalent hypertension from univariate analysis (p=0.002), and the association remained significant (p=0.02) after adjustment for age, gender, race, history of diabetes, dyslipidemia, BMI, eGFR, serum 25D and 1,25D. In 37 stone formers with hypertension, mean plasma FGF23 level was 340 RU/ml, compared to 123 RU/ml in 54 stone formers without hypertension, p<0.0001. In subjects with eGFR≤90 ml/min, FGF23 was a strong predictor of prevalent hypertension, odds ratio (OR) 1.013, 95% confidence interval (CI) 1.004-1.023, p=0.006. However, in subjects with eGFR>90 ml/min, FGF23 was not predictive of prevalent hypertension, OR 0.997, 95% CI 0.985-1.010, p=0.654.

Conclusions: Calcium kidney stone formers have higher plasma FGF23 levels. Plasma FGF23 is strongly predictive of prevalent hypertension among stone formers with GFR≤90 ml/min. Future studies are needed to examine the potential causal relationship and the underlying mechanism.

FR-PO448

Cystine Capacity (CysCap) and Risk of Kidney Stone Events in Cystinuria Frank Modersitzki,[1] Lisa M. Harvey,[2] Dean G. Assimos,[2] David S. Goldfarb.[1,3] *[1]Medicine, NYU Langone Medical Center, New York, NY; [2]Urology, Univ of Alambama, Birmingham, AL; [3]Nephrology, New York Harbor VAMC, New York, NY.*

Background: CysCap values may be important for the treatment of cystinuria and prevention of kidney stones. We studied if greater CysCap values, consistent with undersaturated urine, were associated with fewer stone events.

Methods: Patients were divided into Cyscap+ and Cyscap- groups based on baseline 24h urine. Undersaturated urine takes up cystine from preformed cystine crystals, giving a positive (CysCap+) value; supersaturated urine gives up cystine to added cystine crystals, giving a negative (CysCap-) value. 49 patients from 2 Rare Kidney Stone Consortium sites were enrolled and followed prospectively. Stone activity was defined as radiologic new stone or stone growth, urologic stone removal or spontaneous stone passage.

Results: Participants without 24h urine and information about stone activity were excluded. 26 participants remained: 13 male, 13 female. Mean age was 45y. A total of 17 (10F/7M) participants had a positive CysCap (mean 120 mg/L) and 9 (3F/6M) participants had a negative CysCap (mean -167 mg/L) at baseline. Table shows urine results: CysCap+ had more urine, higher pH, less cystine. Follow-up for the total group was 20 months. We identified 34 stone events that affected a total of 17 participants: fewer events were counted among those with CysCap+ values. Specific data (%) included development of a new stone: CysCap+ 29 vs. CysCap- 44; stone growth: CysCap+ 41 vs. CysCap- 22; urological stone removal: CysCap+ 29 vs. CysCap- 44, stone passage without intervention: CysCap+ 18 vs. CysCap- 33. 9 participants (CysCap+ 41 vs. CysCap- 22), had no events during observation period. Comparing CysCap groups for all stone events, CysCap+ was significantly better (p=.039, McNemar test).

*:P<0.05, Mann-Whitney	CysCap+ mean (SD)	CysCap- mean (SD)
Urine volume*	4279 (1463)	2582 (1045)
24h Cystine excretion*	820 (303)	1128 (223)
pH*	7.24 (0.29)	6.90 (0.34)

Conclusions: CysCap+ values prospectively led to fewer stone events. Achieving better, more positive CysCap values requires greater urine volume, higher urine pH and lower 24h cystine.

Selective Protein Enrichment in Calcium Oxalate Stone Matrix Jeffrey Wesson.[1,2] *[1]Medicine/Nephrology, Dept of Veterans Affairs Medical Center, Milwaukee, WI; [2]Medicine/Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Urine proteins are thought to control calcium oxalate (CaOx) stone formation, but over 1,000 proteins have been reported in stone matrix yielding little insight into their relative importance. We hypothesize that proteins critical to stone formation will be present at increased abundance in stone matrix compared to their urinary abundance, so quantitative proteomic data were acquired and compared for both stone former urine and CaOx stone matrix proteins.

Methods: Urinary proteins were isolated by ultradiafiltration (>10kDa membrane) from random urine samples from 25 CaOx stone forming patients. CaOx stone matrix proteins were isolated from 8 CaOx stone samples (>90% CaOx content) by dissolution in EDTA/SDS solution followed by ultradiafiltration. Proteomic analyses were performed on each

sample independently at the Medical College of Wisconsin Innovation Center using label-free spectral counting mass spectrometry methods. Only proteins with 2 or more peptide matches at >85% confidence were included. Keratin and redundant proteins were removed.

Results: Only 5 proteins were prominently enriched in matrix, accounting for >34% of matrix protein mass, but only 3.4% of urine protein mass. Many highly abundant urinary proteins like albumin and uromodulin were present in stone matrix, but at reduced relative abundance compared to urine. Furthermore, isoelectric point distribution analysis showed that the stone matrix proteome was highly enriched in both highly anionic (pI<5, like osteopontin) and highly cationic (pI>10, like histone) proteins; most of which are normally found in intracellular or nuclear compartments.

Conclusions: Relatively few proteins were enriched and appeared to be critically important to CaOx stone formation, while most highly abundant urine proteins found in matrix were likely included non-selectively. The presence of both highly anionic and highly cationic proteins which aggregate at low concentrations suggests that protein aggregation may trigger CaOx stone formation, while a cell injury process is implicated by the presence of many intracellular proteins. These observations present a new paradigm for CaOx stone research.

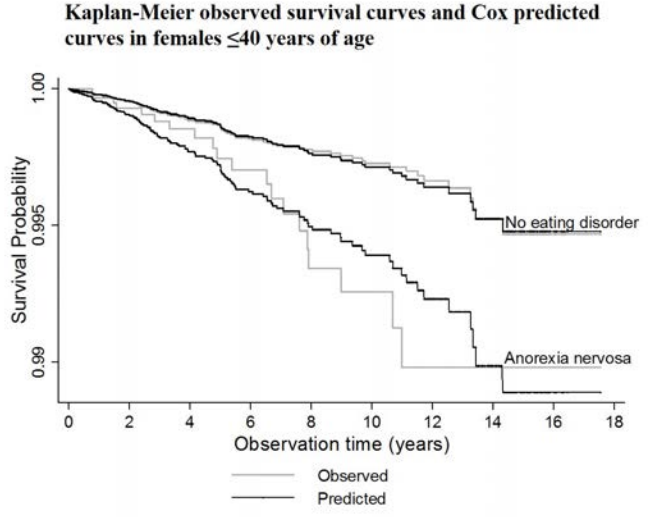
Risk of Urolithiasis in Anorexia Nervosa: A Population-Based Cohort Study Using the Health Improvement Network

Michelle Denburg,[1,2] Mary B. Leonard,[3] Thomas Jemielita,[2] Neville H. Golden,[3] Gregory Edward Tasian,[1,2] Lawrence A. Copelovitch.[1,2] *[1]Children's Hospital of Philadelphia; [2]Univ of Pennsylvania; [3]Stanford Univ.*

Background: Case reports and uncontrolled studies suggest urolithiasis is a complication of anorexia nervosa (AN). The objective of this large cohort study was to determine if AN is associated with a higher risk of urolithiasis.

Methods: We performed a population-based retrospective cohort study using The Health Improvement Network. The median calendar year for the start of the observation period was 2005. We identified 9302 females <60 years of age with AN and 92,959 randomly selected age- and practice-matched females. Multivariate Cox regression was used to estimate the hazard ratio (HR) for incident urolithiasis.

Results: Median age at start of observation was 29.8 years. 23 participants with AN (0.25%) developed incident urolithiasis compared to 154 unexposed participants (0.17%) over a median observation period of 3.6 years and 3.8 years, respectively. The risk of urolithiasis in AN varied significantly with age (interaction p=0.03). AN was associated with a higher risk of incident urolithiasis in females ≤40 years of age (HR 2.13, 95% CI: 1.32-3.45; p=0.002), but not in females over 40 years.



For participants with AN, the median time from diagnosis of AN to incident urolithiasis was 12.4 years. The distribution of diagnosis codes for urolithiasis differed significantly between the groups (p=0.04), with a higher proportion of codes for uric acid urolithiasis in the AN (16.2%) versus unexposed group (5.0%).

Conclusions: Although urolithiasis is relatively uncommon in women under 40 years of age, we demonstrated a more than two-fold greater risk in those with AN. There were more uric acid based calculi than expected among patients with AN compared to females without eating disorders. We speculate that these were likely ammonium urate stones and related to laxative abuse.

FR-PO451

Vitamin D Intake and the Risk of Incident Kidney Stones

Pietro Manuel Ferraro,[1] Eric N. Taylor,[2,3] Giovanni Gambaro,[1] Gary C. Curhan.[2] *[1]Fondazione Policlinico Univ A. Gemelli - Catholic Univ of the Sacred Heart, Rome, Italy; [2]Harvard Medical School, Boston; [3]Maine Medical Center, Portland.*

Background: Higher vitamin D intake has been purported to increase the risk of calcium-containing kidney stones, but longitudinal prospective studies of sufficient size on the association between intake of vitamin D and risk of incident kidney stones are lacking.

Methods: We performed a prospective analysis of 193,551 participants of the Health Professionals Follow-up Study (HPFS), Nurses' Health Study (NHS) I and II. Participants were divided into categories of total (<100, 100-199, 200-399, 400-599, 600-999, ≥1,000 IU/day) and supplemental (none, <400, 400-599, 600-999, ≥1,000 IU/day) vitamin D intake with updating over time. During a follow-up of 3,316,846 person-years, there were 6,576 incident kidney stone events. Cox proportional hazards regression models were adjusted for age, BMI, comorbidities, use of medications and intake of other nutrients.

Results: After multivariate adjustment, there was no statistically significant association between total intake of vitamin D and risk of incident stones in HPFS (HR for ≥1,000 vs <100 IU/day 1.08, 95% CI 0.80, 1.47, p-value for trend = 0.92) and NHS I (HR 0.99, 95% CI 0.73, 1.35, p-value for trend = 0.70), whereas there was a suggestion of higher risk in NHS II (HR 1.18, 95% CI 0.94, 1.48, p-value for trend = 0.02). Similar results were found for supplemental vitamin D intake. No interaction was found for total calcium intake.

Conclusions: Total vitamin D intake in typical amounts was not statistically associated with risk of kidney stone formation, though higher risk with substantially higher doses than those studied here cannot be excluded.

Proton Pump Inhibitors, Histamine Receptor-2 Blockers and the Risk of Incident Kidney Stones

Pietro Manuel Ferraro,[1] Gary C. Curhan,[2] Giovanni Gambaro,[1] Eric N. Taylor.[2,3] *[1]Fondazione Policlinico Univ A. Gemelli - Catholic Univ of the Sacred Heart, Rome, Italy; [2]Harvard Medical School, Boston; [3]Maine Medical Center, Portland.*

Background: Proton pump inhibitors (PPI) and histamine receptor-2 (H_2) blockers are commonly used drugs for the treatment of heartburn, gastroesophageal reflux and peptic ulcer. Although PPI and H2 blockers potentially affect urinary excretions of lithogenic factors such as calcium and magnesium, the association between use of these medications and kidney stone formation has never been explored.

Methods: 187,330 participants of the Health Professionals Follow-up Study (HPFS), Nurses' Health Study (NHS) I and II provided data about chronic PPI use. During a cumulative follow-up of 1,903,725 person-years, there were 3,245 incident symptomatic kidney stone events. Cox proportional hazards regression models were adjusted for age, race, BMI, physical activity, smoking status, comorbidities, use of medications and intake of nutrients. Multivariable linear regression models were used to analyze cross-sectional associations between PPI and H2 blocker use and 24-h urinary excretions in a subgroup of 6,520 participants.

Results: After multivariable adjustment, use of PPI was associated with higher risk of incident kidney stones (HR 1.12, 95% CI 1.02, 1.24, p-value = 0.02). HRs were similar independent of duration of use and after restricting the analysis to incident PPI users and attenuated somewhat employing a 2-year time-lag analysis. Similar results were found for use of H_2 blockers (HR 1.13, 95% CI 1.02, 1.24, p-value = 0.02). Use of PPI was associated with lower urinary excretion of calcium (-18 mg/24h, p-value <0.001), oxalate (-1 mg/24h, p-value = 0.02), citrate (-48 mg/24h, p-value <0.001), and magnesium (-10 mg/24h, p-value <0.001), whereas urine pH was not significantly different.

Conclusions: Use of PPI and H_2 blockers is associated with a small increase in risk of incident kidney stones.

FR-PO453

Intake of Zinc and Other Trace Elements and the Risk of Incident Kidney Stones

Pietro Manuel Ferraro,[1] Gary C. Curhan,[2] Giovanni Gambaro,[1] Eric N. Taylor.[2,3] *[1]Fondazione Policlinico Univ A. Gemelli - Catholic Univ of the Sacred Heart, Rome, Italy; [2]Harvard Medical School, Boston; [3]Maine Medical Center, Portland.*

Background: Recent cross-sectional [Tang J, et al. Am J Nephrol 2012] as well as pre-clinical [Chi T, et al. PLoS One 2015] studies suggest that zinc may play a role in the development of kidney stones. Other studies also hinted at the role of other trace elements such as copper and manganese [Słojewski M, et al. Adv Clin Exp Med 2012]. Longitudinal prospective studies on the risk associated with intake of zinc and other trace metals, however, have not been published.

Methods: We performed a prospective analysis of 193,551 participants of the Health Professionals Follow-up Study (HPFS), Nurses' Health Study (NHS) I and II. During a follow-up of 3,316,846 person-years, there were 6,576 incident symptomatic kidney stone events. Cox proportional hazards regression models were adjusted for age, BMI, comorbidities, use of medications and intake of other nutrients.

Results: After multivariate adjustment, there was no statistically significant association between risk of stones and intake of zinc (HR for highest compared with lowest quintile 0.94, 95% CI 0.77, 1.14, p-value for trend = 0.54), iron (HR 1.04, 95% CI 0.90, 1.20, p-value for trend = 0.48), and copper (HR 1.07, 95% CI 0.97, 1.18, p-value for trend = 0.26). Dietary manganese was associated with lower risk (HR 0.80, 95% CI 0.72, 0.90, p-value for trend < 0.001). For total manganese intake (supplemental plus dietary) the HR was 0.90 (HR 0.90, (95% CI 0.80, 1.02, p-value for trend = 0.06).

Conclusions: Intake of zinc, iron and copper is not associated with risk of kidney stone formation, whereas higher intakes of manganese may be associated with lower risk.

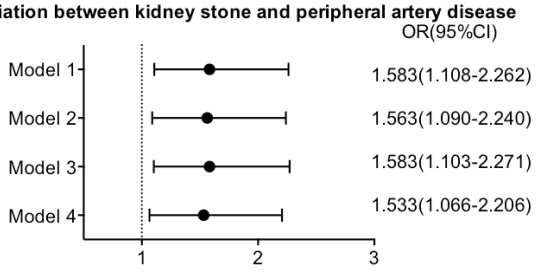
Urinary Stones Associates with Arterial Stiffness and Peripheral Artery Disease: A Population Based Study of 10,000 Chinese Participants

Xiaohong Fan,[1] Sagar U. Nigwekar,[2] Wenling Ye,[1] Sophia Zhao,[2] Jie Ma,[1] Sahir Kalim,[2] Jie Cui,[2] Rui Cui,[1] Wei Zhang,[1] Baobao Wang,[1] Ravi I. Thadhani,[2] Xuemei Li.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Previous studies investigating cardiovascular health in the context of urinary stone disease (USD) have focused on coronary artery disease and stroke. The risk associated between USD and arterial stiffness and peripheral arterial disease (PAD) has not been examined in detail.

Methods: We performed a cross-sectional study of 10,547 participants in rural China. All underwent renal ultrasound examination to detect USD, brachial-ankle pulse wave velocity (baPWV) measurement to estimate arterial stiffness, and ankle-brachial index examination to detect PAD (defined as ankle-brachial index ≤ 0.9 for at least one side of body). Univariate and multivariate regression analyses were performed to investigate associations between USD and PAD.

Results: Mean age was 55.0±10.4 years and 47.2% were males. Among participants, 5.6% had USD, mean baPWV was 1551 ± 317 cm/s, and 4.0% had PAD. Compared to subjects without USD, subjects with USD had higher baPWV (1548±316 vs. 1610±326 cm/s, p<0.01) and higher prevalence of PAD (3.9 vs. 6.0%, p=0.01). The prevalence of USD was increased with higher quartiles of baPWV (Q4 vs. Q1: 7.0% vs. 4.3%, p<0.01). In univariate and multivariable analyses, USD was associated with increased risk of PAD.



Model 1:bivariable analysis
Model 2:adjusted for age, gender, smoke
Model 3:adjusted for age, gender, smoke, MetS
Model 4:adjusted for age, gender, smoke, BMI,DM, HTN, LDL, hsCRP, CKD

MetS metabolic syndrome; BMI body mass index; DM diabetes mellitus; HTN hypertension; LDL low-density cholesterol, hsCRP hypersensitive C reactive protein; CKD chronic kidney disease.

Conclusions: USD associates with increased risk of arterial stiffness and PAD in a rural Chinese population.

Funding: Government Support - Non-U.S.

FR-PO455

Trends in the Incidence of Symptomatic Kidney Stones among the Residents of Olmsted County, MN from 1984 to 2012

Wonngarm Kittanamongkolchai,[1] Lisa E. Vaughan,[2] Felicity T. Enders,[2] John C. Lieske,[1] Andrew D. Rule.[1] *[1]Nephrology and Hypertesnion, Mayo Clinic, Rochester, MN; [2]Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN.*

Background: Studies have reported increased kidney stone incidence but lack of validation and granular detail regarding stone types.

Methods: Adult incident symptomatic stone formers in Olmsted County, MN from 1984 to 2012 were identified and validated by manual chart review. Available data included stone composition, body mass index (BMI), and medications associated with kidney stones (calcium, vitamin C, vitamin D and Topamax). The incidence rates of kidney stones per 100,000 person-years(100K py) were estimated based on the Olmsted County population census. Poisson regression models were used to calculate incidence rate ratios.

Results: There were 3,338 validated incident symptomatic stone formers (age 45±15 years, 60% male and 89% white). The overall incidence from 1984 to 2012 increased dramatically in women (39 to 118/100K py; p<0.001) and modestly in men (128 to 141/100K py; p=0.01). The increase in incidence was significant in women across all age groups (18-39, 40-59, 60+), with the highest increase observed in those 40-59 y. In men, the increase was significant only in the 18-39 age group. For each stone composition, the relative change in the incidence rate per 5-years was 1.00 (95% CI 0.99-1.01, p=0.9) for calcium oxalate monohydrate, 0.85 (95% CI 0.82-0.88, p<0.001) for calcium oxalate dihydrate, 1.10 (95% CI 1.07-1.13, p<0.001) for hydroxyapatite, 0.90 (95% CI 0.86-0.95, p<0.001) for uric acid and 1.15 (95% CI: 1.14-1.16; p<0.001) for stones of unknown composition. Calcium use, vitamin D use, Topamax use and BMI among incident stone formers increased over the time period, with Vitamin D use rising at a higher rate in women than in men (p=0.01 for interaction).

Conclusions: The incidence of symptomatic kidney stones increased dramatically in women, and more modestly in men over the last 3 decades. The increase was most evident in younger age groups. Obesity and medications associated with kidney stones may be contributing to the increased incidence of kidney stone disease in the general population.

FR-PO456

Risk of Adverse Birth Outcomes Associated with Maternal Hospitalization for Nephrolithiasis during Pregnancy

Rachel M. Engen,[1] Kelsey L. Richardson,[1] Julie Rivers,[1] Eric Chow,[1] Alyson J. Littman.[2] *[1]Seattle Children's Hospital; [2]Univ of Washington.*

Background: Nephrolithiasis is the most common non-obstetric cause of hospitalization among pregnant women, but current information on birth outcomes after hospitalization for nephrolithiasis during pregnancy is conflicting. We sought to determine if maternal nephrolithiasis hospitalization is associated with an increased risk of premature delivery, induction of labor, Cesarean delivery, low birth weight (< 2500 grams), or delivery of a small for gestational age (SGA) infant.

Methods: We conducted a population-based retrospective cohort study in Washington State using a statewide hospitalization discharge database linked to singleton birth certificate data for 2004-2013. Women hospitalized for nephrolithiasis during pregnancy were identified by ICD-9 codes (n=2083) and compared with a cohort of women without documented hospitalization for nephrolithiasis (n=8600) frequency matched 1:4 on birth year. Birth outcomes were assessed using birth certificate data and birth hospitalization ICD-9 codes. Data were analyzed using stratified analysis with Mantel-Haenszel adjustment. Subgroup analyses focused on the influence of trimester of nephrolithiasis hospitalization and procedural intervention.

Results: Nephrolithiasis hospitalization during pregnancy was associated with an increased risk for premature delivery (RR = 1.6, 95% CI 1.3-1.8) and induction of labor (RR = 1.5, 95%CI 1.3-1.6), but a decreased risk of SGA delivery (RR = 0.82, 95% CI 0.70-0.96) compared to women without hospitalization for nephrolithiasis during pregnancy. Nephrolithiasis hospitalization was not associated with low birth weight, nor was it associated with Cesarean delivery after adjusting for prior Cesarean delivery. Trimester of nephrolithiasis hospitalization and procedural intervention did not significantly alter these associations.

Conclusions: This study adds to existing evidence that maternal hospitalization for nephrolithiasis during pregnancy is associated with an increased risk of subsequent preterm delivery and induction of labor. Women hospitalized for nephrolithiasis during pregnancy should be counseled about these risks.

FR-PO457

Low Bone Density and Bisphosphonates and the Association with Kidney Stones and 24-Hour Urine Calcium Excretion

Megan Prochaska,[1] Eric N. Taylor,[2] Gary C. Curhan.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Div of Nephrology and Transplantation, Maine Medical Center, Portland, ME.*

Background: Previous studies have demonstrated lower bone density in patients with kidney stones (KS). No studies have evaluated KS risk in participants with low bone density. Small studies with short follow-up reported lower 24-hour urine calcium excretion in bisphosphonate users. We examined history of low bone density and bisphosphonate use and the association with incident KS and the association with 24-hour calcium excretion.

Methods: To evaluate the association between history of low bone density and bisphosphonate use and risk of incident KS, we conducted a prospective analysis of 98,078 women participants in the Nurses' Health Study II. We used Cox proportional hazards models to adjust for age, BMI, thiazide use, bisphosphonate use, fluid intake, and dietary factors. We also conducted a cross-sectional analysis of 2567 participants using multivariate linear regression to compare 24-hour urinary calcium excretion between participants with and without a history of low bone density and with and without bisphosphonate use.

Results: The multivariate adjusted relative risk (MVRR) of an incident KS for participants with history of low bone density compared with participants without was 1.35 (95% CI 1.13-1.61 p=0.001). The MVRR for an incident KS for bisphosphonate use was 0.90 (95% CI 0.68-1.20, p=0.47). In the cross-sectional analysis of 24-hour urine calcium excretion, the multivariate adjusted mean difference in 24-hour calcium was 13 mg/day (95% CI 4 to 22, p=0.003) higher for participants with history of low bone density. The multivariate adjusted mean difference in 24-hour calcium was 9 mg/day (95% CI -9 to 27, p=0.31) higher for participants on bisphosphonates. Results of the urine calcium analysis were similar in an analysis limited to participants with history of low bone density.

Conclusions: History of low bone density is an independent risk factor for incident KS and higher 24-hr urine calcium excretion. Bisphosphonates use was not independently associated with KS or 24-hr urine calcium excretion.

FR-PO458

Hyponatremia Is Associated with Increased Kidney Stones in a Large U.S. Health System Population Naoto Tominaga,[1] Stephen Fernandez,[2] Mihriye Mete,[2] Nawar M. Shara,[2] Joseph G. Verbalis.[1] *[1]Div of Endocrinology and Metabolism, Georgetown Univ Medical Center; [2]Dept of Biostatistics and Bioinformatics, MedStar Health Research Inst.*

Background: Kidney stones (KS) impose a large and growing public health burden. Up to 80% of KS is predominately composed of calcium oxalate (CaOx), and urinary oxalate is a major risk factor for CaOx KS formation. Previous studies have shown that hyponatremia (HN) is associated with increased risk for osteoporosis and bone fractures, which are also known to be associated with KS. It is therefore reasonable to hypothesize that HN may be related to the occurrence of KS.

Methods: To assess the potential relationship between HN and KS, we designed a matched case-control study using the electronic health records of the MedStar Health system with more than 3.2 million unique patient records accumulated as of March 2016. Data were extracted via the Explorys tool on clinical factors including labs, medications, and ICD-9 and/or ICD-10 diagnoses for patients with KS (case) and those without KS (control).

Results: Cases (n=21,232) and controls (n=21,232) were matched with a 1:1 ratio on age, sex, race and the duration of encounter window (mean age 44.3 years, 48.4% female, 61.1% Caucasian and mean follow-up days 1345 days). Case and control exposures for each of the HN variables were defined by serum [Na+] laboratory measurements reported within the encounter windows, and divided into 4 categories: prior HN, chronic HN, recent HN, and chronic and recent HN. Bivariate analyses using conditional logistic regression models confirmed increased risk of KS among patients with risk factors such as hypertension (OR=1.77, 95% CI 1.68-1.86). In addition, the risk of KS increased in all of HN categories: prior HN OR, 1.10 [95% CI, 1.03-1.18]; chronic HN OR, 1.43 [95% CI, 1.17-1.75]; recent HN OR, 2.30 [95% CI, 2.02-2.62]; chronic and recent HN OR, 5.18 [95% CI, 3.08-8.70]. Preliminary results of multivariate analyses adjusted for potential confounders confirm independent associations between HN and KS.

Conclusions: These results therefore support the hypothesis that HN is a significant and clinically important risk factor for KS in both inpatients and outpatients in the U.S.

FR-PO459

Racial Differences in Metabolic Risk Factors for Nephrolithiasis Anna L. Zisman, Kristin J. Bergsland, Fredric L. Coe, Elaine M. Worcester. *Dept of Medicine/Nephrology, Univ of Chicago, Chicago, IL.*

Background: Over the past 2 decades, the prevalence of kidney stones in black non-Hispanics has increased by 150%, yet there is a paucity of literature regarding African American (AA) stone-formers. Small studies suggest certain urinary parameters do not significantly differ between racial groups. We asked whether AA stone formers have metabolic differences when compared to Caucasians (C).

Methods: AA patients with known stone composition undergoing metabolic stone evaluation (at least 3, 24 hr urine specimens per patient and paired serum studies) were retrospectively identified by self-reported race from 1995-2016 and sex and age-matched 1:2 to C patients with known stone composition from the same year. Metabolic data were compared between groups by stone type and race using ANOVA. Majority stone type was defined as >50%.

Results: Fifty-five AA (calcium (Ca) oxalate (CaOx) =29, Ca phosphate (CaP)=9, Uric=17) and 125 matched C (CaOx=81, CaP=27, Uric=17) had complete pre-treatment metabolic data. Despite similar supersaturation (SS) for their stone type, AA had significantly lower 24-hr urine volumes than C (1.5 vs. 1.9L, p<0.001). Likewise, 24-hr calcium (Ca) levels, were significantly lower than those for C (135 vs. 225 mg , p<0.0001). Urine oxalate and citrate did not differ by ANOVA. Significant differences between races persisted in volume when analyzed by stone type. CaOx AA had lower urine Ca than C, but oxalate and citrate excretions did not differ. Urine Ca did not differ for CaP stone formers by race. For uric acid stones, AA had lower uric acid excretion and uric acid SS and higher urine pH. Serum phosphate also differed by race, and was significantly lower in AA males than in C males (3.1 vs. 3.45, p<0.001); women did not differ.

Conclusions: While physical chemistry dictates that SS drives risk for stone formation, we demonstrate racial differences in determinants of SS. Previously unknown and significant metabolic differences exist between AA and Caucasian stone formers.

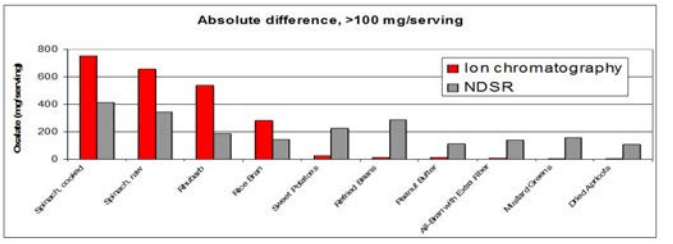
FR-PO460

Variation in Reported Oxalate Content: Implications for Research and Patient Counseling Roy A. Jhagroo,[2] Kristina L. Penniston.[1] *[1]Urology, UW Madison, Madison, WI; [2]Medicine - Nephrology, UW Madison, Madison, WI.*

Background: Hyperoxaluria is a major risk factor for calcium oxalate stone disease. For designing research studies that limit or attempt to standardize the oxalate intake of subjects, and also for the appropriate counseling of patients in the clinic setting, accurate food oxalate values are needed, and agreement on the use of standard food oxalate values is needed.

Methods: Analyze patients' reported oxalate content from 4-day weighed diet records, using standard nutrient analysis software, and compare values with the "gold standard" database for food oxalate. Assess the congruence of food oxalate data of two reputable and - Nutrition commonly-used databases. *Databases:* - Oxalate data from ion chromatography - Maintained by the Harvard School of Public Health; Nutrition Data System Research (NDSR) database, containing oxalate values for 17,820 food items > Nutrition Coordinating Center, University of Minnesota *Diet records:* Consenting patients (n= 78) completing 4-day weighed diet records. Diet records were entered for oxalate intake from the 2 databases used for this study.

Results: The mean daily oxalate intake of patients differs significantly (P = 0.0012) depending on data used. Mean daily oxalate intake assessed by NDSR and by ion chromatography, respectively, was: 108 vs 76 mg for women (min-max, 61-226 vs 40-111 mg) 163 vs 96 mg for men (min-max, 78-324 vs 63-138 mg). Particularly on high oxalate foods differences were seen.



Conclusions: Differences in databases are both clinically- and statistically-relevant(p = 0.0012). Compared to ion chromatographic analyses - the "gold standard" for oxalate analysis of foods - our study showed nearly 40% of patients incorrectly classified above or below a 90 mg oxalate/d cutoff when conventional, research-quality nutrient analysis software was used.

FR-PO461

Oxalate Stones: What Is Most Important for Oxalate Diet Modification? Roy A. Jhagroo,[1] Kristina L. Penniston.[2] *[1]Medicine - Nephrology, UW Madison, Madison, WI; [2]Urology, UW Madison, Madison, WI.*

Background: Dietary oxalate may account for up to 50% of urinary oxalate. In patients with hyperoxaluria, reducing dietary oxalate absorption is a key aspect of medical management. This requires knowledge not only of food oxalate values but also of oxalate bioavailability. Unfortunately, vast differences in the reported oxalate content of foods abound in the literature and media. Moreover, oxalate food values are typically provided in mg/100 g and not as mg per portions actually consumed.

Methods: Calcium stone formers undergoing medical management were trained to provide 4-day weighed diet records. Evaluable records from 83 subjects (M:F, 50:28; 58 and 54 years, respectively) were analyzed using the Nutrition Data System for Research nutrient analysis software (University of Minnesota). Mean oxalate intakes were calculated, and the contribution of oxalate by individual foods were assessed. Discrete food groups were defined; relative contributions to total oxalate intake were calculated.

Results: Mean oxalate intake was 161 ± 16 and 238 ± 22 SE mg/d for women and men, respectively (p = 0.02 for difference); however, when adjusted for kcal intake there was no difference. The calculated calcium:oxalate intake ratio (mg/mg), a surrogate measure for oxalate bioavailability, was 6.5 for both women and men. Nearly two-thirds of oxalate consumed was from 5 specific food groups. These were: nuts, seeds, & nut butters (26.2%); spinach (11.9%); breads, flours, & baked goods (11.0%); ready-to-eat cereals (6.7%); and potatoes & foods made from potatoes (6.3%). Other groups typically included in oxalate-reducing recommendations, e.g., tea, spices, non-spinach leafy vegetables, and fruits, collectively accounted for <10% of total oxalate consumed. The calculated calcium:oxalate ratios were lowest (p < 0.005) for 3 of these groups.

Conclusions: In our efforts to enhance patients' compliance with and the overall efficacy of medical management, dietary recommendations to reduce oxalate intake should focus on the fewest food groups possible, based not only on oxalate concentration per typical portions consumed but also on anticipated oxalate bioavailability.

FR-PO462

Effects of Citrate and Phosphate on Renal Outcomes in Primary Hyperoxaluria Dawn S. Milliner, Lisa E. Vaughan, Felicity T. Enders, Julie B. Olson, Barbara M. Seide, David J. Sas, John C. Lieske, The Rare Kidney Stone Consortium. *Mayo Clinic, Rochester, MN.*

Background: Both citrate (cit) and phosphate (P) inhibit urinary calcium oxalate crystallization and are used for treatment in primary hyperoxaluria (PH). To better understand long term treatment effects, we assessed incidence of NC and ESRD among patients (pts) in the Rare Kidney Stone Consortium (RKSC) PH Registry.

Methods: Pts with PH type 1, 2 or 3 enrolled in the RKSC PH Registry who had presented prior to ESRD were included. Nested cox proportional hazards models were used to assess main and interactive effects of P and cit separately on incident NC and ESRD.

Results: Among 290 pts, 212 had PH1, 40 PH2 and 38 PH3. Median follow-up was 8.8 yrs for ESRD and 6.6 yrs for NC. After adjusting for age at PH diagnosis, prior stone events, and pyridoxine use, neither P nor cit were strong predictors of outcomes when considered as main effects. When an interaction term was added, P use alone had a protective effect on ESRD (HR 0.57, 95% CI: 0.29-1.09), while P and cit use combined was associated with increased risk for incident ESRD (HR 2.37, 95% CI: 0.83-6.81), though results did not achieve statistical significance. Cit alone trended towards increased risk of NC (HR 1.94, 95% CI: 0.98-3.83). Results were consistent in PH1 alone.

			Model 1		Model 2	
Outcome	**Events**	**Medication***	**HR (95% CI)**	**P**	**HR (95% CI)**	**P**
ESRD	79	P	0.76 (0.45-1.28)	0.30	0.57 (0.29-1.09)	0.088
		Cit	1.33 (0.70-2.23)	0.27	0.95 (0.47-1.89)	0.88
		P*Cit	--	--	2.37 (0.83-6.81)	0.11
NC	57	P	0.80 (0.43-1.48)	0.48	1.09 (0.54-2.20)	0.81
		Cit	1.45 (0.80-2.61)	0.22	1.94 (0.98-3.83)	0.056
		P*Cit	--	--	0.32 (0.07-1.44)	0.14

Model 1 Adjusted for age at baseline, stone events, and pyridoxine
Model 2 Adjusted as Model 1 with added interaction term for P and cit
*Medications and stone events as time dependent covariates

Conclusions: There is evidence that after adjusting for stone events, P may have a protective effect on renal survival, while cit may increase risk of NC. However, the strength of these associations as well as effect of dose and duration of these medications remains to be established.

FR-PO463

Changes of Urinary Risk Profile after Short Dietary Intervention in Swiss Kidney Stone Formers Harald Seeger,[1] Pietro Manuel Ferraro,[2] Robert J. Unwin,[3] Carsten A. Wagner,[4] Nilufar Mohebbi.[1] *[1]Div of Nephrology, Univ Hospital Zurich, Zurich, Switzerland; [2]Fondazione Policlinico Univ A. Gemelli, Catholic Univ of the Sacred Heart, Rome, Italy; [3]Centre for Nephrology, Univ College London, London, United Kingdom; [4]Inst of Physiology, Univ of Zurich, Zurich, Switzerland.*

Background: Calcium-containing kidney stones are frequent with high recurrence rates. Several studies have described a significant relation between nephrolithiasis and adverse renal outcomes, including ESRD. While hypercalciuria is a well-known risk factor, restricted intake of animal protein and salt, combined with normal calcium, has been shown to be more effective in stone prevention compared with a low-calcium diet. Notably, the average salt intake in Switzerland is twice as high as the WHO recommends, while surprisingly the intake of milk and dairy products is low. Thus, we wanted to test the effect of a low salt and low calcium diet on the urinary risk profile of recurrent calcium oxalate (CaOx) kidney stone formers (rKSF).

Methods: Standardized metabolic evaluation was performed, including a first 24-hour urine collection (normal diet), followed by a second collection after a 7-day low salt and low calcium diet.

Results: Out of 215 patients, 169 patients had calcium oxalate-containing stones. Of these 169 patients, 49 were hypercalciuric at baseline. Diet produced a highly significant reduction in 24-h urinary sodium and calcium excretions: from 201±89 at baseline to 128±88 mmol/d for sodium ($p<0.0001$), and from 5.67±3.01 to 4.06±2.46 mmol/d ($p<0.0001$) for calcium. Urine volume remained unchanged. Notably, no increase in oxalate excretion occurred on the low calcium diet (0.39±0.26 vs 0.39±0.19 mmol/d, $p=0.277$). Calculated Psf values were only predictive for calcium phosphate stones.

Conclusions: In conclusion, diet low in calcium, as in the wider Swiss population, and here tested as a short intervention did not result in an increase in oxalate excretion in rKSF. The recommendation of a low salt diet in a population with too little dietary milk and dairy products does not seem to increase the risk for CaOx stone formation. However, assessment and correction of low calcium intake in hypercalciuric KSF remains important.

FR-PO464

Absence of miR-146a Increases Risk of Diabetic Glomerulopathy via Upregulation of ErbB4 and Notch-1 in Podocytes Shehryar J. Khaliqdina,[1] Samia Khan,[1] Ha Won Lee,[1] Mehmet M. Altintas,[1] Florian Grahammer,[3] Terese D. Geraghty,[1] Kwi Hye Koh,[1] Nicholas J. Tardi,[1] David J. Cimbaluk,[1] Katalin Susztak,[2] Pierre-Louis Tharaux,[4] Tobias B. Huber,[3] Matthias Kretzler,[5] Markus Bitzer,[5] Jochen Reiser,[1] Vineet Gupta.[1] *[1]Rush Univ; [2]Univ of Pennsylvania; [3]Univ Medical Center Freiburg; [4]INSERM; [5]SGBM.*

Background: MicroRNAs play a significant role in maintaining podocyte health and in glomerular disease pathogenesis. miR-146a is a negative regulator of myeloid cells. It's also expressed in podocytes, but its role is unclear. We examined the role of podocytic miR-146a in diabetic glomerulopathy (DGP). .

Methods: We used qRT-PCR to determine miR-146a expression in isolated glomeruli from a cohort of patients with type 2 diabetes (T2D) and correlated it with kidney function in these patients. We also studied miR-146a target expression levels in T2D patients, $BTBR^{ob/ob}$ mice and miR-146a deficient ($miR\text{-}146^{-/-}$) mice. To investigate the role of miR-146a in glomerular function *in vivo*, we induced hyperglycemia in WT and $miR\text{-}146a^{-/-}$ animals using streptozotocin (STZ) and tested whether ErbB4 inhibition with Erlonitib provides efficacy.

Results: We show that podocytic miR-146a expression decreased in the glomeruli of T2D patients and correlated with increased albuminuria and glomerular damage. miR-146a levels were significantly reduced in the glomeruli of $BTBR^{ob/ob}$ mice that spontaneously develop T2D. $miR\text{-}146^{-/-}$ mice displayed accelerated development of glomerulopathy upon STZ-induced hyperglycemia. miR-146a targets, Notch-1 and ErbB4, were significantly upregulated in the diseased glomeruli, suggesting induction of TGFb signaling. Treatment with Erlotinib significantly suppressed diabetic glomerular injury and albuminuria in WT and $miR\text{-}146a^{-/-}$ mice. TGFb treatment to podocytes *in vitro* resulted in increased levels of Notch-1 and ErbB4, and increased phosphorylation of ErbB4 and its partner EGFR. Increased ErbB4/EGFR signaling also increased levels of MCP-1 and MCP-1 induced protein, a suppressor of miR-146a, suggesting an autocrine loop.

Conclusions: We suggest a novel role for podocytic miR-146a in protecting against DGP. Also, ErbB4 is a novel therapeutic target for DGP intervention, especially since several ErbB4 inhibitors are clinically available.

FR-PO465

APOL1 Mediated Eukaryotic Cell Injury Involves Disruption of Conserved Intracellular Trafficking Processes Etty Kruzel Davila,[1] Revital Shemer,[2] Ayala Ofir,[1] Ira Bavli,[1] Ilona Darlyuk-Saadon,[2] Pazit Oren-Giladi,[1] Walter G. Wasser,[1,3] Daniella Magen,[1,2] Eid Zaknoun,[2] Maya Schuldiner,[4] Adi Salzberg,[2] Daniel Kornitzer,[2] Zvonimir Marelja,[5] Matias Simons,[5] Karl Leon Skorecki.[1,2] *[1]Nephrology, Rambam Health Care Campus, Haifa, Israel; [2]Rappaport Faculty of Medicine and Research Inst, Technion, Haifa, Israel; [3]Mayanei HaYeshua Medical Center, Bnei Brak, Israel; [4]Dept of Molecular Genetics, Weizmann Inst of Science, Rehovot, Israel; [5]Imagine Inst, Paris Descartes Univ–Sorbonne Paris Cité, Paris, France.*

Background: *APOL1* harbors C-terminus sequence variants (G1 and G2) which account for much of the increased risk for kidney disease in Sub-Saharan African ancestry populations. Expression of the risk variants has also been shown to cause injury to podocytes and other cell types, but the underlying mechanism is not yet understood.

Methods: We used *Drosophila melanogaster* and *Saccharomyces cerevisiae* to help clarify these mechanisms.

Results: Ubiquitous expression of the human APOL1 G1 and G2 disease risk alleles caused near complete lethality in *Drosophila* with no effect of the G0 non-risk *APOL1* allele, corresponding to the pattern of human disease risk. A congruent pattern of cellular damage was also observed with tissue-specific expression of APOL1, consistent with a cell-autonomous effect. Expression of APOL1 risk variants in *Drosophila* nephrocytes caused accumulation of the endocytic tracer ANF-RFP at early stages and nephrocyte loss at later stages. APOL1 variants inhibit endocytic trafficking in *S. cerevisiae.* Differential toxicity and impairment of vacuole acidification of the risk compared to non-risk *APOL1* variants was likewise observed in *S. cerevisiae.* Yeast strains missing key components of endosomal trafficking or acidification, but not of autophagy pathways, resulted in augmented APOL1 toxicity.

Conclusions: The congruency of differential injury by the *APOL1* risk compared to non-risk alleles across evolutionarily divergent species, is most consistent with an impairment of conserved core intracellular endosomal trafficking processes. This should facilitate the identification of specific cell injury pathways and corresponding therapeutic targets of interest in these experimental platforms.

The Calcium-Dependent Proteinase Calpain-1 Links TRPC6 Activity to Podocyte Injury Ramon Sonneveld, Jack F. Wetzels, Johan Van der Vlag, Tom Nijenhuis. *Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Transient Receptor Potential channel C6 (TRPC6) is a calcium-conducting ion channel expressed at the slit-diaphragm of podocytes. TRPC6 gain-of-function mutations and glomerular TRPC6 overexpression are associated with proteinuria. The underlying mechanisms that link TRPC6 to podocyte injury remain elusive. Activation of the calcium-dependent protease calpain-1 was suggested to mediate renal injury through cleavage of the podocyte cytoskeletal protein talin-1. We hypothesized that the calcium-dependent protease calpain-1 is involved in TRPC6-mediated podocyte injury.

Methods: Podocytes, transfected with scrambled, TRPC6 or calpain-1 siRNA, were injured using adriamycin and treated with the TRP channel activator 1-oleoyl-acetyl-sn-glycerol (OAG), calpain inhibitor calpeptin or TRPC channel blocker 2-APB. TRPC6-dependent calcium influx was measured by FURA-2. Calpain activity and talin-1 expression were determined by calpain activity assay and in situ zymography or Western blot. *In vivo*, calpain inhibition was tested in adriamycin induced nephropathy (AN), the model for human FSGS. Urine and kidney biopsies of human FSGS patients were tested for calpain activity as well as talin-1, TRPC6 and nephrin expression.

Results: Adriamycin and OAG increased calpain activity in podocytes, which was prevented in r TRPC6 KD or calpain 1 KD cells, and by 2-APB or calpeptin. TRPC6 KD in podocytes showed that adriamycin-induced calcium influx was TRPC6-dependent. The TRPC6-dependent calpain activation led to talin-1 cleavage. Calpain activity in urine and glomeruli was increased in rat AN and associated with increased proteinuria, which could be prevented by calpain inhibition. Urine and glomeruli from FSGS patients also showed an increased calpain activity, along with increased glomerular TRPC6 and reduced talin-1 and nephrin expression.

Conclusions: We have elucidated a novel mechanism that directly links TRPC6-dependent calcium influx to calpain-1 activation, talin-1 cleavage, subsequent podocyte injury, and proteinuria *in vitro, in vivo*, and in humans. Therefore, calpain-1 and/or TRPC6 inhibition could be a novel therapeutic option to treat FSGS.

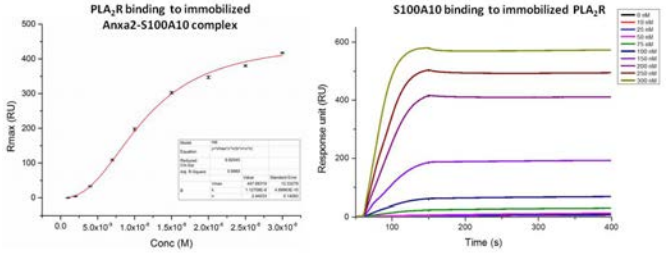
FR-PO467

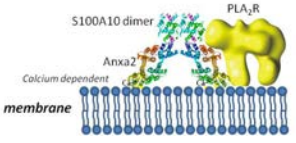
AnnexinA2-S100A10 Complex Is the Binding Partner of PLA2R in Podocytes Maryline Fresquet, Thomas A. Jowitt, Edward A. Mckenzie, Rachel Lennon, Paul E. Brenchley. *Wellcome Trust Centre for Cell-Matrix Research, Univ of Manchester, United Kingdom.*

Background: PLA_2R is the major podocyte antigen targeted by autoantibodies in membranous nephropathy (MN). We have shown that anti-PLA_2R in absence of complement activation induces change in podocyte shape, monolayer permeability, free radical production and apoptosis. How anti-PLA_2R induces these changes and disrupts PLA_2R function is unknown. PLA_2R cannot mediate intracellular signalling implying other receptors are involved. We seek to identify binding partners of PLA_2R in podocytes.

Methods: The PLA_2R binding partners were isolated from human podocytes by immunoprecipitation and analyzed by mass spectrometry. The interactions with the identified candidates were confirmed by surface plasmon resonance (SPR), quartz crystal microbalance with dissipation (QCM-D) and immunofluorescence.

Results: Pull down experiments identified an interaction between PLA_2R and AnnexinA2 (Anxa2). Anxa2 can exist as a heterotetrameric complex (A2t) coupled with S100A10, this complex being the predominant form present at the plasma membrane. We tested the binding by SPR between PLA_2R and A2t complex and found a high affinity interaction with cooperativity. We analyzed these partners individually and showed that PLA_2R interacts with A2t via S100A10 with strong affinity (K_D $8x10^{-11}$M). This is the first evidence that PLA_2R is another receptor interacting with the A2t complex. Moreover we showed using QCM-D that A2t/PLA_2R complex binds to lipids in calcium-dependent manner providing a potential mechanism for PLA_2R trafficking to the cell membrane.





Conclusions: This study describes a novel PLA_2R/A2t complex on the podocyte plasma membrane and identifies S100A10 as a potential mediator of PLA_2R translocation to the cell surface. Blocking PLA_2R expression on the cell membrane may protect the podocyte from the consequences of autoantibody attack in MN.

The Transcription Factor Dach1 Is Essential for Podocyte Differentiation and Function Nicole Endlich,[1] Felix Kliewe,[1] Katharina Schmidt,[1] Frances Kindt,[1] Nadine Artelt,[1] Maja Lindenmeyer,[2] Clemens D. Cohen,[2] Franziska Döring,[1] Regina Maciejewski,[1] Andreas W. Kuß,[3] Kerstin U. Amann,[4] Nazanin Kabgani,[5] Marcus J. Moeller,[5] Antje Blumenthal,[1] Karlhans Endlich.[1] *[1]Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, Germany; [2]Medical Clinic and Policlinic IV, LMU, Munich, Germany; [3]Human Genetics, Univ Medicine Greifswald, Greifswald, Germany; [4]Nephropathology, Univ Hospital Erlangen, Erlangen, Germany; [5]Internal Medicine II, RWTH Aachen Univ Hospital, Aachen, Germany.*

Background: Dedifferentiation and loss of podocytes are the major causes of chronic kidney disease. The locus of Dach1, a transcription factor, which is essential for cell fate, was found in genome wide association studies to be associated with glomerular filtration rate.

Methods: To investigate the role of Dach1 in transdifferentiation of parietal epithelial cells to podocytes *in vitro*, we transfected murine parietal epithelial cells (PECs) with a plasmid encoding for Dach1 and analyzed the cells by immunocytochemistry, qRT-PCR and Western blot. For studying the function of Dach1 *in vivo*, we used the zebrafish model for morpholino knockdown of dachd, the zebrafish ortholog of Dach1.

Results: We found that podocytes express high levels of Dach1 in mice and humans *in vivo* and to lower extent *in vitro*. PECs, which are able to transdifferentiate into podocytes under certain circumstances, express Dach1 only at low levels. The transfection of PECs with Dach1 induced the expression of synaptopodin, which was located along actin fibers in a punctate pattern, comparable with differentiated podocytes. Moreover, dedifferentiating podocytes of isolated glomeruli showed a significant reduction of the expression of Dach1 together with synaptopodin after 9 days in culture. Knockdown of dachd in zebrafish resulted in morphological changes of the pronephric glomerulus accompanied by a down-regulation of nephrin and a leakage of the filtration barrier. Interestingly, Dach1 and synaptopodin were significantly reduced in biopsies from patients suffering from diabetic nephropathy in contrast to biopsies from healthy controls.

Conclusions: Taken together, Dach1 is a transcription factor that is essential for podocyte differentiation and proper glomerular function.

FGF23 Play a Key Role in the Pathogenesis of Podocyte Injury in CKD Junnan Wu, Ying Fan, Niansong Wang. *Dept of Nephrology and Rheumatology, hanghai Jiao Tong Univ Affiliated Sixth People's Hospital.*

Background: Fibroblast Growth Factor 23 (FGF-23) is a bone-derived hormone involved in the regulation of phosphate homeostasis. Substantial clinical evidence has indicated that FGF23 levels extremely elevated in Chronic Kidney Disease (CKD), however, so far FGF23 has only been considered as an early biomarker of renal injury or a key hormone regulating phosphate metabolism, rather than a direct causal role in podocyte function. This research unveil a direct pathological effects of FGF23 on podocytes, providing a novel therapeutic target for podocytopathy.

Methods: Studies were performed with human podocyte cell line, FGF23-treated mice, FGF23 gene transferring *in vivo*, and CKD patients' renal biopsies.

Results: We treated cultured human podocytes with FGF23,and found treatment of FGF23 caused podocyte cytoskeletons dramatic loss and lead to podoycte apoptosis. However,podocyte injury caused by treatment with FGF23 were ameliorated by PD173074(inhibitor of FGFR). We also noticed that FGF23 induced calcium influx, calcineurin activity and NFAT nuclear translocation in podocyte. Moreover, klotho-deficient podocyte exhibited cytoskeletons damage after FGF23 treatment, Suggesting this effect was independent of klotho but via FGF receptor–dependent activation of the calcineurin-NFAT signaling pathway. *In vivo*, Intravenous injection of FGF23 in mice induces a significantly increased in proteinuria, massive foot process effacement, loss of podocin expression. And those phenotype were ameliorated by treatment of PD173074 or calcineurin inhibitor (CSA). Moreover, we injected the lentivirus-expressing FGF23 into the kidneys of mice, we found a similar phenotype as intravenous injection of FGF23.

Conclusions: Taken together, these findings demonstrate a role for FGF23 in the pathogenesis of podocyte injury by targeting calcineurin-NFAT signaling pathway. We believe that these data uncover a novel mechanism underlying podocyte injury and provide a potential target for treating podocytopathy.

Loss of APOL1 Induces Autophagy in Podocytes Ahmed Kotb,[1,2] Florian Siegerist,[1] Frank Dombrowski,[3] Kerstin U. Amann,[4] Uwe Zimmermann,[5] Johanna Chluba,[6] Tobias B. Huber,[7] Karlhans Endlich,[1] Nicole Endlich.[1] *[1]Anatomy and Cell Biology, Univ Medicine Greifswald, Germany; [2]Anatomy and Histology, Faculty of Veterinary Medicine, Asyut Univ, Egypt; [3]Pathology, Univ Medicine Greifswald, Germany; [4]Nephropathology, Inst of Pathology, Univ Hospital Erlangen, Germany; [5]Urology, Univ Medicine Greifswald, Germany; [6]INSERM, UMR 866, Univ of Burgundy, Dijon, France; [7]Renal Div, Univ Medical Center Freiburg, Germany.*

Background: *APOL1* codes for a secreted high density lipoprotein, whose variants confer resistance to Trypanosoma in Africans. APOL1 is expressed in several human cells and organs including kidney podocytes. It is known that *APOL1* variants are associated with kidney diseases like focal segmental glomerulosclerosis (FSGS) in African Americans. The aim of our study was to find out which role APOL1 plays for autophagy *in vitro* and *in vivo.*

Methods: To study autophagy *in vitro* we used human podocytes that were transfected with a plasmid encoding GFP-LC3. APOL1 knockdown was performed by siRNA. To study autophagy *in vivo* we used a transgenic GFP-LC3 zebrafish strain (Tg(CMV:EGFP-map1Lc3b)). Live imaging of the expression of GFP-LC3 in the zebrafish pronephros was performed by 2-photon microscopy. Apol1 knockdown was generated by morpholino (MO) injection in zebrafish (standard and *Vivo*-MO). Knockdown efficiencies of siRNA and MO were confirmed by RT-PCR and Western blot. Human kidney sections from FSGS patients were stained with LC3 and APOL1 antibodies.

Results: APOL1 knockdown in cultured human podocytes and in zebrafish larvae induced an increase of LC3 in podocytes. Moreover, ApoL1 knockdown in zebrafish larvae resulted in pericardial edema, a hallmark of kidney disease. Live imaging of zebrafish larvae (4 days post fertilization) that were injected with *Vivo*-MO against Apol1 showed an induction of autophagy independent of a developmental defect. Additionally, in kidney biopsies of patients suffering from FSGS, APOL1 expression was significantly decreased combined with an increase of LC3 spots in podocytes.

Conclusions: APOL1 is important for proper kidney function. Loss of APOL1 induces autophagy in podocytes as determined by an increased LC3 expression *in vitro* and *in vivo*.

FR-PO471

Role of Podocyte Receptor Podo-GPCR2 in Diabetic Nephropathy Sonia Zambrano Sevilla, Patricia Rodriguez, Jaakko Patrakka. *Laboratory Medicine, Karolinska Inst, Stockholm, Sverige, Sweden.*

Background: Podocyte injury is associated with progressive kidney disease and correlate with diabetic kidney disease (DKD). However, molecular mechanism leading to podocyte injury in DKD is still poorly understood. By using large-scale expressional profiling we have identified a novel highly podocyte-specific G-protein receptor, podo-GPCR2. Previously, this orphan GPCR has been related with the regulation of Wnt3/

βcatenin pathway in the neocortex. This pathway has been linked previously to podocyte damage in DKD. The aim of this work is to study the function of podo-GPCR2 in podocytes and its role in DKD.

Methods: *In vitro*, we generated a stable cell line of human podocytes over expressing podo-GPCR2. In these cells we carried out studies of gene expression of different component of the Wnt3/βcatenin pathway, as well as luciferase experiment using reporters for activated βcatenin. We used zebrafish and mouse as *in vivo* models. In zebrafish, podo-GPCR2 was inactivated using morpholinos. In mouse podo-GPCRC2 was inactivated using gene targeting. 6 KO and 6 control mice were challenged with LPS that is known to cause podocyte injury and proteinuria.

Results: In cultured cells, we saw that βcatenin was significantly upregulated in human podocytes overexpressing podo-GPCR2. Moreover, the gene expression of Axin3 and DKK2 (two components downstream of wnt3 pathway) was elevated in over expressing podocytes. Using a luciferase reporter we could validate that βcatenin was activated in podocytes overexpressing podo-GPCR2. In zebrafish, the inactivation of podo-GPCR2 resulted in podocyte foot process effacement, glomerular basement membrane abnormalities and proteinuria – all features of human DKD. In mouse, the absence of podo-GPCR2 did not affect normal development and function of the glomerulus. However, KO animals were more prone to LPS-induced podocyte damage as they developed higher albuminuria after LPS injection than control animals.

Conclusions: Podo-GPCR2 is a novel highly podocyte-specific GPCR that seems to be involved in the pathogenesis of podocyte injury through wnt signaling pathway. Podo-GPCR2 may be a new target molecule to treat glomerular diseases.

FR-PO472

Molecular Regulation of the Antifibrotic Protein Follistatin by Caveolin-1 in Mesangial Cells Neel Mehta, Dan Zhang, Renzhong Li, Tony Nuo Wang, Agata Gava, Pavithra Parthasarathy, Bo Gao, Joan C. Krepinsky. *Nephrology, McMaster Univ, Hamilton, ON, Canada.*

Background: Glomerular fibrosis is a key pathologic feature of chronic kidney disease (CKD), with mesangial cells (MC) being a major contributor to the excess extracellular matrix production. We previously showed that caveolin-1 (cav-1) is required for MC synthesis of matrix proteins both basally and in response to several profibrotic stimuli. Here we sought to identify the molecular basis of this protection.

Methods: MC isolated from cav-1 wild-type (WT) and knockout (KO) mice were used and studies conducted using standard molecular biology techniques.

Results: Using microarray, we identified significant upregulation of the antifibrotic secreted glycoprotein follistatin (FST) in cav-1 KO compared with WT MC. We confirmed that KO MC had significantly elevated FST transcript and protein levels. Cav-1 re-expression reduced FST expression and increased basal matrix production, which was similarly increased by FST downregulation with siRNA. The ability of KO MC to respond to Activin A, a TGFβ family member most potently inhibited by FST, was blunted. Activity of a FST mouse promoter (-1.84kb) reporter was higher in KO MC, indicative of higher transcription rates. To identify the promoter region regulated by cav-1, we created and tested a series of deletion constructs. Surprisingly, deletion to -123bp did not eliminate the higher promoter activity in KO cells. This region contains 2 potential binding sites for the transcription factor Sp1, shown to regulate FST promoter activity in intestinal epithelial cells. ChIP studies showed greater Sp1 binding to this region in KO MC, and higher Sp1 transcription activity in KO cells was confirmed using a luciferase reporter assay. Downregulation of Sp1 with siRNA attenuated FST promoter activity, and deletion of both Sp1 sites from this promoter region suppressed activity in KO MC to levels seen in WT MC.

Conclusions: We have identified a novel role for cav-1 in regulating expression of the anti-fibrotic protein FST. These studies lay an important foundation for evaluating FST as a potential novel antifibrotic agent for CKD.

Protein-Tyrosine Kinase Inhibitors as Potential Therapeutic Agents for IgA Nephropathy Zhi Qiang Huang,[1] Xianwen Zhang,[1,2] Zina Moldoveanu,[1] Qi Bian,[1,3] Stacy D. Hall,[1] Joshua Charles Anderson,[1] Rhubell T. Brown,[1] Lea Novak,[1] Christopher D. Willey,[1] Bruce A. Julian,[1] Jan Novak.[1] [1]*Microbiology, Univ of Alabama at Birmingham, Birmingham, AL;* [2]*Long Hua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China;* [3]*Changhai Hospital, Second Military Medical Univ, Shanghai, China.*

Background: Immune complexes (ICs) containing galactose-deficient IgA1 (Gd-IgA1) and anti-Gd-IgA1 antibodies play a key role in pathogenesis of IgA nephropathy (IgAN). To explore the mechanism of kidney injury and potential therapeutic targets, we assessed biological activities of circulating ICs (CICs) and engineered ICs (EICs).

Methods: CICs were isolated from sera of IgAN patients. EICs were formed by incubation of Gd-IgA1 with a recombinant antibody anti-Gd-IgA1. Cultured human mesangial cells (MCs) were incubated with ICs with or without several protein-tyrosine kinase (PTK) inhibitors. Cellular proliferation was measured by ^{3}H-thymidine uptake. Cell signaling was determined by changes in PTK activities and phosphorylation using Western blotting and Tyrosine-Kinase PamChips and Bioinformatics analyses. EICs were injected *i.v.* into immunodeficient mice every other day for a week to generate a mouse IgAN model. Mice were daily gavaged with dasatinib. Kidneys were harvested 1 d after last injection and histology was evaluated.

Results: CICs and EICs increased MC proliferation by 3.5±2.5-fold and 2.9±0.7-fold. Western blotting with phospho-tyrosine antibody revealed both ICs increased tyrosine phosphorylation of multiple proteins. Kinomic studies indicated several signaling pathways were activated by both ICs. One PTK inhibitor, dasatinib, inhibited activation of MCs induced by ICs in a dose-dependent manner. In mouse model, dasatinib inhibited MC proliferation and matrix expansion. Analysis of kidney homogenates indicated dasatinib inhibited PDGF pathway and down-stream signals.

Conclusions: Both ICs activated several signaling pathways in MCs, leading to cellular proliferation and matrix expansion. A PTK inhibitor, dasatinib, blocked these pathological changes *in vitro* and in mouse IgAN model. Dasatinib, or similar drugs, may represent a therapeutic agent(s) for IgAN patients.

APOL1 Confers Cytotoxicity through Alteration of Vesicle pH, Leading to Altered Membrane Homeostasis Jurgen Heymann,[1] Patrick D. Dummer,[1] Michael Kruhlak,[2] Alison B. Hickman,[1] Cheryl Ann Winkler,[2] Jeffrey B. Kopp.[1] [1]*NIH-NIDDK;* [2]*NIH-NCI.*

Background: Apolipoprotein L1 (*APOL1*) C-terminal mutations are risk alleles for glomerular disease in African descent populations. We studied three potential cytotoxicity mechanisms.

Methods: Experiments used HEK293 kidney cells, stably expressing APOL1 common allele G0 and risk alleles G1 and G2.

Results: APOL1 variants displayed different levels of cytotoxicity (G0<G2<G1). We examined whether APOL1 acts as a BH3-only pro-death protein based on the presence of a predicted BH3 domain. We found that the APOL1-BH3 domain is translocated into the endoplasmic reticulum (ER) lumen and, as Bcl2 is cytosolic, there was no APOL1-Bcl2 interaction. We examined APOL1 interactions with vesicle-associated membrane protein (VAMP) 8, a candidate for a functional ortholog of the trypanosomal protein SRA, which binds the APOL1 C terminus and inhibits APOL1 lytic properties. Although APOL1 trafficked to VAMP8(+) late endo-lysosomes, the predicted interaction between the two proteins is unlikely, as we show that the APOL1 C terminus has a luminal orientation, whereas the relevant, N-terminal VAMP8 domain faces the cytoplasm. Cytoplasmically-expressed APOL1 also showed co-localization with VAMP8(+) late endo-lysosomes. Deletion of the APOL1 membrane-addressing domain abolished trafficking to GFP-VAMP8(+) membranes. Together, these findings suggest that APOL1 trafficking relies on lipid interactions rather than on protein interactions. In lipid binding experiments, APOL1 preferentially bound to acidic phospholipids. APOL1 resisted extraction from microsomal membranes by alkaline sodium carbonate, which indicates strong protein-lipid interactions. However, we found that APOL1 does not span the ER membrane, and is unlikely to form pores/channels there. Dextran uptake experiments showed that APOL1 expression increased mean vesicle pH (G0<G2<G1), which would compromise vesicle trafficking. These data suggest that APOL1 toxicity is only acquired later in biogenesis, through membrane insertion.

Conclusions: These data suggest that APOL1 targets cell membranes by lipid binding and that risk alleles compromise vesicle acidification, leading to a general defect in vesicle trafficking.

FR-PO475

Silibinin Improves Mitochondrial Function of Podocytes in Diabetic Mice through Regulation of Sirtuin 3 Expression Zengchun Ye, Meijun Si, Wenbo Zhao, Ming Li, Cheng Wang, Tan-Qi Lou. *Dept of Nephrology, The Third Affiliated Hospital Sun Yat-sen Univ, Guangzhou, China.*

Background: Mitochondrial dysfunction of podocytes plays essential role in diabetic nephropathy. Our previous study shown that expression of Sirtuin 3 (Sirt3) was decreased in diabetic (*db/db*) mice, which lead to reducing mitochondrial complex I activity in podocytes. This study is to investigate the potential protective effect of silibinin and its underlying mechanisms in improving mitochondrial function of podocytes in diabetic mice.

Methods: Diabetic (*db/db*) and non-diabetic (*db/m*) mice were administrated with silibinin for 16 weeks after 8-week old. Moreover, diabetes was induced in Sirt3-knockout mice by streptozotocin (STZ) injection, and silibinin was administrated to these mice for 16 weeks after the induction of diabetes. To assess the expression of Sirt3 and mitochondrial complex I activity, mitochondria were isolated from podocytes of diabetic and non-diabetic mice. The expression of Sirt3 was measured by western blotting. Mitochondrial complex I activity was detected by microplate assay kit purchased from Abcam.

Results: We found that silibinin can increase the expression of Sirt3 in podocytes of *db/db* mice and STZ induced diabetic mice. Administration of silibinin can also ameliorate the mitochondrial function of podocytes in diabetic mice, but had no effect in Sirt3–/– mice. And *in vitro* studies, we also found that silibinin can ameliorate high glucose-induced dysfunction of mitochondria in podocytes by increasing Sirt3 expression, including the increased activity of mitochondrial complex I and the level of mitochondrial DNA.

Conclusions: Collectively, these data suggest that silibinin improves mitochondrial function of podocytes in diabetic mice through regulation of Sirt3 expression.Thus, enhancing Sirt3 by silibinin to improve mitochondrial function in podocytes has potential as a strategy for improving outcomes of renal injury in diabetes.

Expression of Thrombospondin Type 1 Domain-Containing 7A (THSD7A) in Developing Glomeruli Young-Soo Song, Hong Ma, Sudhir Kumar, Weining Lu, David J. Salant, Laurence H. Beck. *Renal Div, Dept of Medicine, Boston Univ Medical Center, Boston, MA.*

Background: Membranous nephropathy (MN) is a common cause of adult nephrotic syndrome. Autoantibodies to the podocyte proteins PLA2R and THSD7A are found in primary MN in approximately 75% and 5% of cases, respectively. Unlike PLA2R which is not expressed by the mouse, THSD7A is expressed on the basal surface of both human and mouse podocytes. The role of THSD7A is unclear, but the protein has been found in focal adhesions in human umbilical vein endothelial cells. We sought to investigate the temporal expression of THSD7A in developing mouse glomeruli to help better understand the role of the molecule.

Methods: We localized THSD7A by confocal immunofluorescence microscopy in developing mouse kidney (E14.5, E17.5, and P1) using serum from a patient with primary MN known to be anti-THSD7A positive. Specificity of the serum for THSD7A was demonstrated using blocking fragments of recombinant human THSD7A. The different stages of glomerular development (cap mesenchyme, C-shaped body, S-shaped body and capillary loop) were identified using differential interference contrast microscopy as well as commercial antibodies to SIX2 (cap mesenchyme), laminin (C-/S-shaped body) and nephrin (capillary loop).

Results: Human anti-THSD7A autoantibody did not detect THSD7A in SIX2-positive cap mesenchyme at E14.5 or in laminin-positive C-/S-shaped bodies at E17.5. However, there was very prominent linear staining of THSD7A along the basal surface of podocytes of capillary loop stage glomeruli (E17.5 and P1), in which THSD7A and nephrin partially colocalized. The specificity of THSD7A staining was shown by the complete inhibition of the glomerular signal after preincubation with the recombinant N-terminal fragment of THSD7A.

Conclusions: THSD7A appears to be first expressed by the podocyte at the capillary loop stage of mouse glomerular development. Further studies are needed to investigate its potential role at the basal surface of the podocyte.

Can Extracellular Vesicles Regulate Glomerular VEGF Homeostasis in Chronic Kidney Disease? Sargis Sedrakyan,[1] Stefano Porta,[2] Valentina Villani,[1] Nikita Tripuraneni,[1] Astgik Petrosyan,[1] Stefano Da Sacco,[1] Hasmik Soloyan,[1] Roger E. De Filippo,[1] Benedetta Bussolati,[2] Laura Perin.[1] *[1]Urology, Children's Hospital Los Angeles, Los Angeles, CA; [2]Molecular Biotechnology, Univ of Turin, Turin, Italy.*

Background: Tight regulation of paracrine VEGF signaling between podocytes and glomerular endothelial cells (GEC) is required for maintenance of the glomerular filtration barrier (GFB) structure and function. Disruption of VEGF homeostasis has been implicated in various types of glomerular diseases. However, current therapies neither specifically target the glomerulus nor the VEGF pathway but in addition present multiple side effects. Therefore, identification of new approaches aimed at restoring local VEGF remains a potential therapeutic target to treat glomerular disease. We previously showed that amniotic fluid stem cells (AFSC) are renoprotective in Alport Syndrome (AS), a model of CKD. They home within the diseased glomeruli and secrete extracellular vesicles (EVs). EVs play key role in stem cell mediated paracrine function, including the kidney. Herein, we demonstrate that AFSC derived EVs regulate VEGF/VEGFRs signaling balance in AS GEC via modulation of sFlt1, the soluble isoform of VEGFR1.

Methods: We measured VEGF activity in AS glomeruli by WB. We assessed VEGF/VEGF-Rs activity in GEC, including the sFlt1. We characterized AFSC-EVs cargo by FACS and by miRs arrays and evaluated their potential to affect VEGF biology in GEC.

Results: Glomeruli from AS mice showed increased VEGF activity through increased phosphorylation of VEGFR-2 early on during progression accompanied by modulation of sFlt1. These observations were associated with GEC damage that showed altered VEGFR signaling. Importantly, EVs presented with VEGFRs and angiomodulatory microRNA. These EVs successfully integrated within GEC and modulated VEGF activity. EVs lacking both the full and soluble VEGFR-1 failed to rescue GEC from VEGF inflicted damage.

Conclusions: In conclusion, we demonstrated for the first time the aberration of VEGF signaling within AS glomeruli. We further showed that AFSC derived EVs play important role in maintaining glomerular homeostasis of VEGF signaling, presenting with a potential for new targeted therapies in CKD.

FR-PO478

Urotensin II Contributes to Hyperproliferation and Extracellular Matrix Accumulation in High Glucose-Challenged Glomerular Mesangial Cells Adebowale Adebiyi, Hitesh Soni. *Physiology, Univ of Tennessee Health Science Center, Memphis, TN.*

Background: Glomerular mesangial cell (GMC) hyperproliferation and matrix expansion are pathological hallmarks of many kidney diseases, including diabetic nephropathy (DN). Although the circulating level of urotensin II (UII) and kidney tissue expression of UII and UII receptors are elevated in DN, it remains unclear whether UII regulates mesangial cell growth and matrix accumulation.

Methods: Using a murine GMC line, we examined the role of UII-induced Ca^{2+} signaling in the mechanisms that underlie mesangial proliferation and matrix accumulation under normal and high glucose ambience.

Results: UII promoted GMC growth and matrix production; effects dependent on TRPC4 channel-mediated store-operated Ca^{2+} entry (SOCE) and sequential activation of Ca^{2+}/calmodulin-dependent protein kinase II (CaMKII) and Ca^{2+}/cAMP response element-binding protein (CREB) transcription factor. Exposure of GMCs to high glucose (HG) concentration stimulated UII synthesis, proliferation, and type IV collagen (cIV) production in the cells. HG-induced GMC hyperproliferation and cIV synthesis were attenuated by urantide, an urotensin II receptor antagonist, ML204, a TRPC4 channel blocker, BAPTA an intracellular Ca^{2+} chelator, KN-93, a CAMKII inhibitor, and SGC-CBP30, an inhibitor of the transcriptional co-activators CREB binding protein and p300.

Conclusions: UII-induced SOCE via TRPC4 channels stimulates CaMKII/CREB-dependent GMC proliferation and matrix accumulation. Our data also suggest that increased UII synthesis contributes to HG-induced GMC hyperproliferation and matrix production. Conceivably, UII-induced Ca^{2+} signaling is involved in the pathophysiological mechanisms of mesangial matrix expansion in DN.

FR-PO479

Intermediate Filament Protein Nestin to Wilm's Tumor Suppressor WT1 mRNA Ratio in Urinary Viable Podocyte Correlated with Proteinuria Hoon Young Choi,[1] Mirae Lee,[1] Taeyeon Kim,[1] Seung Kyu Kim,[1] Seok-Hyung Kim,[1] Beom Jin Lim,[2] Jung Eun Lee,[3] Hyunwook Kim,[1] Hyeong Cheon Park.[1] *[1]Dept of Internal Medicine, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Pathology, Yonsei Univ College of Medicine, Seoul, Korea; [3]Dept of Internal Medicine, Yong-In Severance Hospital, Gyeongi-do, Korea.*

Background: Measurement of mRNA of podocyte proteins in urine sediment has been suggested as a useful tool monitoring glomerular disease activity. Nestin, an intermediate filament protein has been reported to play an important role in maintaining normal podocyte function in the human kidney. Furthermore, nestin is expressed at different stages of kidney development and regulated by the Wilms' tumor suppressor WT1. We performed this study to investigate whether the nestin-to-WT1 mRNA ratio in the urine-excreted viable podocytes could mirror disease activity and be a useful biomarker in proteinuric glomerular disease.

Methods: Fresh urine from patients with nephrotic range proteinuria was collected and urine sediments were cultured for viable podocytes. Viable cells derived from urine cultures were stained for podocyte-specific markers such as podocalyxin and WT-1. The number of cells and the duration at the time of subculture were measured. The total urine podocyte pellet RNA was purified and real-time PCR was performed.

Results: Viable and proliferating podocytes were derived from fresh voided urine. More than 70-80% of viable cells positively stained for podocalyxin and WT-1. The number of podocytes recovered at the time of first subculture was not associated with degree of proteinuria. The urine podocyte WT-1 mRNA expression showed significant negative correlation with proteinuria ($r=-0.622$, $p=0.018$), while nestin mRNA expression was not significantly correlated. Moreover, nestin-to-WT-1 mRNA ratio expression showed a significant correlation with proteinuria ($r=+0.676$, $p=0.011$).

Conclusions: Our results show that nestin-to-WT1 mRNA ratio of the viable podocytes derived from fresh voided urine could be a useful biomarker to predict degree of proteinuria in glomerular disease.

FR-PO480

Reduced ABCA1 and SOAT1 Are Required to Cause Podocyte Injury in Diabetic Kidney Disease Gloria Michelle Ducasa,[1] Christopher E. Pedigo,[1] Mayrin Correa,[1] Tahreem Hashmi,[1] Alla Mitrofanova,[1] Alexis J. Sloan,[1] Armando Mendez,[3] Robert G. Nelson,[2] George William Burke,[4] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Family Center/Div of Nephrology, Univ of Miami, Miami, FL; [2]NIDDK, Phoenix, AZ; [3]Diabetes Research Inst, Univ of Miami, Miami, FL; [4]Surgery, Univ of Miami, Miami, FL.*

Background: Decreased podocyte number and glomerular cholesterol accumulation are associated with albuminuria in diabetic kidney disease (DKD). The contribution of free and esterified cholesterol to podocyte injury remains unknown. We hypothesize that both decreased ATP Binding Cassette A1 (ABCA1) expression and sterol-o acyltransferase 1 (SOAT1) activity are required to cause free cholesterol mediated podocyte apoptosis.

Methods: Patients enrolled in the Pima Indian cohort were separated into progressors and non-progressors (dGFR -97.39±8.2,n=15 and +40.62±8.6, n=16, respectively) based on the change in glomerular filtration rate (dGFR) between enrollment and last examination (10±1.7 years). Human podocytes were treated with patient sera. ABCA1 expression, cholesterol efflux and SOAT1 activity were measured. SiRNA *ABCA1* podocytes (siABCA1p) were analyzed for cholesterol content, efflux and caspase 3 activity in the presence or absence of a SOAT inhibitor (SI) and/or cyclodextrin (CD), a cholesterol sequestering agent. Podocyte specific ABCA1 knockout mice were developed.

Results: Progressor-sera treated podocytes showed reduced ABCA1 expression ($p<0.05$), ABCA1 mediated cholesterol efflux ($p<0.01$) and SOAT1 activity ($p<0.05$). SiABCA1p showed, accumulation of esterified cholesterol and lipid droplets and no increase in apoptosis. Podocyte specific ABCA1 knockout mice did not develop albuminuria. Treatment with SI caused increased caspase 3 activity in siABCA1p ($p<0.05$), which was prevented by pretreatment with CD ($p<0.05$).

Conclusions: Our data indicate that reduced *ABCA1* expression and SOAT1 activity are required to cause podocyte injury. Podocytes with reduced *ABCA1* expression and SOAT1

activity experience free-cholesterol mediated podocyte apoptosis, which is prevented by CD suggesting that strategies to restore ABCA1 and SOAT1 function may be beneficial to inhibit podocyte loss in DKD.

Glucocorticoids and Mifepristone Provide Beneficial Effects against Nephrotic Syndrome via Similar and Different Glomerular Expression

Shipra Agrawal,[1] Melinda A. Chanley,[1] Tetsuya Kitao,[1] James Fitch,[2] Peter White,[2] William E. Smoyer.[1,2] *[1]CCTR, The Research Inst at Nationwide Children's Hospital, Columbus, OH; [2]CMP, The Research Inst at Nationwide Children's Hospital, Columbus, OH; [3]Pediatrics, The Ohio State Univ, Columbus, OH.*

Background: Glucocorticoids (GCs) are the primary therapy for nephrotic syndrome (NS), although GCs have serious side effects and are ineffective in ~20-50% of patients. We previously reported the role of the GC receptor (GR) antagonist/partial agonist mifepristone (Mif) in modulating the GR pathway in podocytes. We hypothesized that Mif could also provide reduction in proteinuria seen with GCs during NS via similar and/or different pathways.

Methods: Proteinuria was induced in Wistar rats by single PAN injections (50 mg/kg). Treatment groups received PAN+Mif (2.5-15 mg/kg) and PAN+high-dose GCs (15 mg/kg). Analyses included proteinuria and glomerular gene expression by RNA-Seq, 11 days after PAN injection. Alignment was performed to the rat reference assembly from NCBI and differentially expressed features calculated using DESeq2.

Results: PAN induced severe proteinuria, which was significantly reduced by high-dose GCs as well as low-dose Mif. PCA plots segregated the PAN-injured glomeruli from control group along the 1st principal component. The global expression pattern shifted robustly towards the control in PAN+GCs group, but only slightly in PAN+Mif group. Moreover, while 673 genes were significantly differentially expressed (fold change > 2) in PAN-inured glomeruli compared to control, and 476 in PAN+GCs compared to PAN, only 151 genes were differentially expressed in PAN+Mif compared to PAN. Furthermore, 627 genes were differentially expressed between GC and Mif treatment groups. Specific genes that were highly differentially expressed upon PAN injury, and either restored by both GCs and Mif or by GCs alone, have also been identified.

Conclusions: GR antagonists/partial agonists such as Mif may provide the same beneficial effects against NS as GCs, although via similar and/or different pathways. This may be helpful as new treatment option if they can circumvent the side effects associated with the use of GCs.

The Role of Growth Hormone Action in the Glomerulus: Studies of the Podocyte-Specific Growth Hormone Receptor Gene-Disrupted Mouse

Alison L. Brittain,[1] Ram Menon,[2] John Kopchick.[1] *[1]Dept of Biology, Ohio Univ, Athens, OH; [2]Dept of Pediatric Endocrinology, Univ of Michigan, Ann Arbor, MI.*

Background: Growth hormone (GH) has been implicated in the development of kidney disease in animal and human models of both type 1 diabetes (T1DM) and acromegaly. Evidence of increased glomerular size and sclerosis in these conditions suggests that excess GH action exacerbates glomerular damage. The podocyte is a crucial cell in the glomerular filtration barrier and is dysfunctional in many models of nephropathy. This cell is also a target of direct GH action. To explore the mechanisms by which GH impacts the glomerulus, we have developed a transgenic mouse model, the podocyte-specific GHR gene-disrupted mouse (podGHR-/-).

Methods: PodGHR-/- mice were generated on a C57BL/6J background using Cre-Lox transgenic methods. At various time points, urine and blood were collected from these mice and age-matched controls, and numerous measurements were taken, including body composition and tail-cuff blood pressure. Animals were sacrificed at 6, 18 and 30 weeks for histological studies. Supplementary cell culture studies were performed using the MPC-5 immortalized podocyte line exposed to exogenous GH.

Results: PodGHR-/- mice display significant variation in markers of fluid balance, including changes in urinary electrolyte concentration, tail-cuff blood pressure and total body fluid composition. These mice also show differences in the urinary albumin-to-creatinine ratio. Some of these differences are sex-specific and age-dependent. Our *in vitro* studies show that GH action directly increases collagen production from the podocyte.

Conclusions: Our results suggest a novel mechanism for GH action in the podocyte as a determinant of total body fluid balance, possibly through alteration of matrix proteins in the glomerular basement membrane.

Quantitative Deep Mapping of Podocytes Identifies Proteostatic Shifts during Differentiation

Markus M. Rinschen, Christina Barbara Schroeter, Sybille Köhler, Martin Kann, Thomas Benzing, Paul T. Brinkkoetter. *Internal Medicine, Univ Hospital Cologne, Cologne, Germany.*

Background: The renal filtration barrier is maintained by the renal podocyte, an epithelial postmitotic cell. Immortalized mouse podocyte cell lines – both in the differentiated (37 °C) and undifferentiated (33 °C) state - are widely utilized tools to estimate podocyte injury and cytoskeletal rearrangement processes *in vitro*.

Methods: We performed deep proteomic mapping of podocyte proteins from 50µg of protein. The method consists of protein solubilization, tryptic digestion, strong-cation exchange fractionation and analysis of peptides by nLC-MS/MS on a quadrupole-orbitrap mass spectrometer.

Results: We mapped the cultured podocyte proteome at a depth of more than 8800 proteins and quantified 7313 proteins. Copy numbers of proteins mutated in forms of hereditary nephrotic syndrome or focal segmental glomerulosclerosis (FSGS) were assessed. We found that cultured podocytes express abundant copy numbers of endogenous receptors such as tyrosine kinase membrane receptors, the ANP receptor, and several poorly characterized GPCRs. The dataset was correlated with deep mapping mRNA sequencing ("mRNAseq") data from the native mouse podocyte, the native mouse podocyte proteome and staining intensities from the human protein atlas. The generated dataset was similar to these previously published datasets, but several native and high-abundant podocyte-specific proteins were not identified in the dataset. Notably, these data detected perturbations in proteostatic mechanisms as a dominant alteration during podocyte differentiation, with high proteasome activity in the undifferentiated state and markedly increased expression of lysosomal proteins in the differentiated state. Phosphoproteomic analysis at a resolution of more than 3000 sites suggested a preference of phosphorylation of actin-filament associated proteins in the differentiated state.

Conclusions: The dataset obtained here provides a resource and provides the means for deep mapping of the native podocyte proteome and phosphoproteome in a similar fashion. Differentiation of podocytes affects cell cycle, proteostatic mechanism and phosphorylation of the cytoskeleton.

Human Mesangial Enriched Transcription in Health and Glomerular Disease

Wenjun Ju,[1] Julie Williams,[2] Lisbeth N. Fink,[2] Anna Reznichenko,[4] Tao Wei,[3] James P. Conway,[5] Felix H. Eichinger,[1] Maria Chiara Magnone,[4] Kevin L. Duffin,[3] Daniel B. Timmermann,[2] Matthew D. Breyer,[3] Carol Patricia Moreno Quinn,[5] Mark Tomilo,[1] Matthias Kretzler.[1] *[1]Univ of Michigan; [2]Novo Nordisk; [3]Eli Lilly and Co; [4]AstraZeneca; [5]MedImmune.*

Background: Mesangial cells are critical players in the initiation and progression of glomerular disease and are an attractive therapeutic target. However, we lack knowledge of specific mesangial cell function. To address this challenge we aimed to identify mesangial cell lineage-enriched transcripts using *in silico* nano dissection (ND), a genome-scale machine learning-based approach. ND leverages high-throughput transcriptomics data from human microdissected kidney biopsy homogenates, for definition of cell type specific mRNA profiles.

Methods: Lists of mesangial- and non-mesangial-specific genes were curated by 5 experts through literature mining and used as positive- and negative-standard-gene inputs for the prediction. Novel human mesangial cell-enriched transcripts were predicted using *ND*. The prediction efficiency was evaluated by AUC and density plot. Genes with a probability score above 0.8 were validated using independent public resources including HPA, GUDMAP, and PUBMED. Mesangial cell–enriched transcript levels were tested for differential regulation in glomerular disease and association with GFR.

Results: 84 genes were predicted with high probability to be novel human mesangial cell-enriched transcripts. GAS2, FHL2, AEBP1, POSTN, THBS2, GUCY1A36, and AGTR1 were genes with confirmed mesangial-enriched expression by at least one independent resource. The expression of the 84 mesangial gene signature showed significant upregulation in mesangial-proliferative glomerular diseases and in aggregate showed a stronger correlation with eGFR than a random gene set.

Conclusions: We identified human mesangial cell-enriched transcripts and reported the association of their expression with impaired kidney function in CKD. Our work can provide starting points to capture the function of this cell lineage in glomerular disease and support the development of novel treatment options.

M1 Macrophage-Induced Loss of KLF15 Promotes Chronic Podocyte Injury

Seung Seok Han,[1,2] Yong Chul Kim,[1,2] Sunhwa Lee,[1,2] Hajeong Lee,[1,2] Ran-Hui Cha,[2] Jung Pyo Lee,[1,2] Dong Ki Kim,[1,2] Yon Su Kim,[1,2] Seung Hee Yang.[2] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Kidney Research Inst, Seoul, Korea.*

Background: Krüppel-like factor 15 (KLF15), kidney-enriched transcription factor, is known to participate in the differentiation of podocyte. However, the clinical implication of KLF15 in chronic podocyte injury remains uncorroborated particularly in the relationship with the phenotypic influence of macrophage.

Methods: 5/6 nephrectomized and C-C chemokine receptor type 5 $(CCR5)^{-/-}$ mouse models were used to determine chronic podocyte injury and explore exclusive role of M1 macrophage in terms of KLF15 expression, respectively. Human primary podocytes were flow-cytometically isolated and cultured to emulate the injury process in the *in vitro* system. Biopsied kidney tissues were obtained from the patients with diabetic nephropathy (n=21) to elucidate the relationship between glomerular KLF15 expression and subsequent outcomes (i.e., doubling creatinine and end-stage renal disease).

Results: When 5/6 nephrectomy was predisposed to progressive kidney damage, the fibrosis markers (e.g., fibronectin and collagen type I) increased, but the KLF15 expressions decreased in the site of podocytes. Shrinking KLF15 was strengthened by the forced switch of macrophage to M1 subtype using a taking-off for CCR5 and subsequent Th1 milieu, which resulted in more intense fibrosis [Figure 1]. We also observed corresponding trends

in human primary podocytes, such as increase in fibrosis markers and decrease in KLF15 production after 2-day treatment of TGF-β. Baseline glomerular expression of KLF15 was lower in diabetic patients than healthy individuals. When the patients were divided into 3 groups based on the KLF15 expression, the high expression group (n=7) did not suffer any of worse kidney events during the study period (maximum of 2.5 years).

Conclusions: The KLF15 expressions in podocytes are curtailed depending on the inflexible programming of macrophages into M1 subtype, which is a critical step in chronic podocyte injury.

FR-PO486

Both HIV and Interferon (IFN)-gamma Induce APOL1 Expression in Parietal Epithelial Cells through Down Regulation of miR193a Xiqian Lan,[1] Nirupama Chandel,[1] Vinod Sharma,[1] Manoj K. Tembhre,[1] Abheepsa Mishra,[1] Vinita Vishnoi,[1] Ashwani Malhotra,[1] Catherine Meyer-Schwesinger,[2] Karl Leon Skorecki,[3] Pravin C. Singhal.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Medicine, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: Clinical reports indicate that mutation in APOL1 gene contributed to occurrence of a higher rate of glomerulosclerosis in African Americans (AAs). Notably, >50% of HIV infected AAs with the APOL1 2 risk allele genotype develop HIV-associated nephropathy (HIVAN) if not treated with anti-viral therapy. *In vitro* studies show that podocytes over expressing APOL1 risk variants displayed lysosomal injury. We have previously reported that both HIV and IFNγ enhanced podocyte expression of APOL1. Usually, parietal epithelial cells (PECs) do not express APOL1. We hypothesize that both HIV and IFN-γ have the potential to induce APOL1 expression in PECs through down regulation of mR-193a.

Methods: PECs expressing APOL1G0/G1/G2 were transduced with either vector or HIV (NL4-3) and incubated in media for 24 hours (n=4). In parallel sets of experiment, PECs were incubated in media containing variable concentrations of IFN-γ (0, 1, 5, and 10 ng/ml) for 48 hours. RNAs were extracted and cDNAs were probed for APOL1. Subsequently, cDNAs were probed with specific primers for APOL1. To determine whether IFN-γ has potential to modulate miR-193a expression and associated downstream signaling, PECs were incubated in media containing either buffer or IFN-γ (1, 5, 10 ng/ml) for 72 hours. cDNAs were probed for miR-193a, WT1 (transcription factor for podocyte molecular markers), and PAX2 (PEC marker).

Results: HIV enhanced APOL1 mRNA expression in PECs (control vs. HIV, $P<0.05$). IFN-γ also enhanced APOL1 mRNA expression in a concentration dependent manner (control vs. 0 IFN-γ, $P<0.05$; control vs. 1 IFN-γ, $P<0.05$; 1 IFN-γ vs. 5 IFN-γ, $P<0.05$). IFN-γ down regulated miR-193a and PAX2 but up regulated WT1 in PECs.

Conclusions: Since down regulation of miR193a enhances podocyte maturation, HIV/INF-γ might be enhancing APOL1 expression via down regulation of miR193a in PECs.

FR-PO487

A Role of Autophagy in Regulation of Podocyte Motility Ryusuke Yotsueda,[1] Kumiko Torisu,[1] Kazuhiko Tsuruya,[1,2] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka City, Fukuoka, Japan; [2]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka City, Fukuoka, Japan.*

Background: Podocyte-specific deletion of autophagy-related gene results in exacerbating nephrotic syndrome in mouse model of podocyte injury. Recent reports revealed that autophagy is essential for regulation of cell motility. However, the role of autophagy in podocyte motility remains poorly understood.

Methods: Cultured mouse podocyte clones (MPCs) are used for all experiments. Autophagy was inhibited by hydroxychloroquine or siRNA targeting autophagy-related 7 (Atg7). Autophagic activity and localization of autophagosome in MPCs were examined by western blot and immunofluorescence. To assess cell motility, we performed scrape motility assay and haptotaxis cell migration assay. β1 integrin expression was examined by flowcytometry and immunofluorescence. To examine signal transduction for motility, we measured small Rho-GTPase activity. The porlymerization of actin monomers into filamentous actin (F-actin) in MPCs was observed by phalloidin staining.

Results: Autophagy-inhibited MPCs became hypermotile both in scrape motility assay and haptotaxis cell migration assay. β1 integrin colocalized with autophagosome in part, within cytoplasm of MPCs. The expression of β1 integrin on cell membrane decreased, whereas increased in cytosol in autophagy-inhibited MPCs. Inhibition of autophagy resulted in the alterlation of small RhoGTPase activities and increment of F-actin.

Conclusions: Autophagy-inhibited MPCs were hypermotile in our assay. In autophagy-inhibited MPCs, β1 integrin was expressed less on cell surface, whereas accumulated in cytoplasm. We also observed colocalization of β1 integrin and autophagosomes. Taken together, our data suggest that autophagy may regulate turnover of β1 integrin in MPCs. Prevention of the decline in autophagy flux observed in podocytes pharmacologically might be beneficial to treat nephrotic syndromes.

FR-PO488

Exogenous Laminin as a Treatment for Pierson Syndrome Meei-Hua Lin, Jeffrey H. Miner. *Div of Nephrology, Dept of Internal Medicine, Washington Univ School of Medicine, St. Louis, MO.*

Background: Pierson syndrome is a congenital nephrotic disorder that targets the glomerular basement membrane (GBM), an important part of the glomerular filtration barrier. We tested the efficacy of exogenous human laminin α5β2γ1 (hLAM-521) in preventing nephrotic range proteinuria in a Pierson syndrome mouse model with a null mutation in laminin β2 (*Lamb2*).

Methods: *Lamb2-/-* mice were infused i.v. with hLAM-521 daily from P12 to P16 by retro-orbital injection. Mice were monitored for proteinuria by urinary albumin to creatinine ratios and for deposition of hLAM-521 in glomeruli, podocyte injury, and immune response by immunofluorescence and histology.

Results: Injected hLAM-521 deposited into all GBM segments of *Lamb2-/-* mice and remained there for at least 2 weeks. hLAM-521 treatment inhibited progression of proteinuria through P18 in mutants with low proteinuria prior to treatment. In contrast, all untreated mutant mice showed moderate or high proteinuria at P18. The inhibitory effect of hLAM-521 treatment on proteinuria was accompanied by reduced injury to podocytes as judged by lack of desmin, a podocyte injury marker. The ectopic deposition of laminin a1 observed in the GBM of *Lamb2-/-* mice was also reduced compared to untreated mutants. While hLAM-521 treatment was able to remedy the proteinuria of *Lamb2-/-* mice until P18, it did not inhibit progression to nephrotic range proteinuria at P25. Injection of hLAM-521 induced production of circulating antibodies against hLAM-521 and accumulation of immunoglobulins in the GBM, which likely counteracted the efficacy of hLAM-521 treatment after P18. The inability of hLAM-521 to maintain glomerular permselectivity was not associated with immune cell infiltration in glomeruli.

Conclusions: hLAM-521 treatment inhibited progression of proteinuria in *Lamb2-/-* mice with low proteinuria until the immune response caused damage to glomeruli. Future studies will include co-injection of an immunosuppressant and the use of immunodeficient *Lamb2-/-* mice. Despite the immune response, this study demonstrates the feasibility of repairing GBM defects using exogenous delivery of macromolecules.

Podocyte Injury: Role of Proteinuria, Urinary Plasminogen and Oxidative Stress as "Second Hit" in Glomerular Injury Leopoldo Raij, Runxia Tian, Jenny Wong, John C. He, Kirk N. Campbell. *Nephrology, VAMC, Univ of Miami & SFVAFRE, Miami, FL; Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Podocytes (POD) are a key target of injury in proteinuric glomerular (Glom) diseases that result in progressive POD loss, FSGS and renal failure. In animal and human nephrotic urine aberrant Glom filtration of Plasminogen (Plg) is activated to biologically active Plasmin by urokinase type plasminogen activator (uPA). In vivo, Amiloride a specific inhibitor of uPA mitigates FSGS in several proteinuric models including 5/6 nephrectomy.

Methods: We utilized human podocytes in culture and *Tg26* HIV and *Cd2ap*$^{-/-}$ mice two models of proteinuria, POD injury and FSGS.

Results: Here we show 2-3 fold urine Plg increase in *Tg26* HIV and *Cd2ap*$^{-/-}$ mice respectively and that human POD express uPA and the Plg receptors uPAR, tPA and Plg-RKT. We demonstrate that Plg treatment of POD upregulates NADPH oxidase isoforms NOX2/NOX4 accompanied by increased production of superoxide anion (O_2^-) 35cpm/μg /min +/-5,$p<0.05$). We demonstrate for the first time that Plg via O_2^- 1) augments by 70% POD expression of the B scavenger receptor CD36 with subsequent POD uptake of oxLDL with increased POD apoptosis from 9 to 15%, Plg vs. Plg oxLDL, $p<0.05$ and 2) Promotes synthesis of Endothelin-1 (200%) a molecule implicated in POD-endothelial cell crosstalk and Glom disease progression. The inhibitor of Plg/Plasmin activation EACA significantly prevented all Plg induced actions. Importantly all molecules that reduce oxidative stress (ROS) Apocynin, inhibitor of NADPH oxidase; AICAR, activator of AMPK and Mito Tempo, inhibitor of mitochondria ROS as well as Amiloride, significantly prevented ($p<0.05$) Plg induction of POD CD36 and Endothelin -1.

Conclusions: We demonstrate novel pathophysiological mechanisms suggesting that following disruption of the Glom filtration barrier at the onset of proteinuric disease, POD are exposed to Plg/ Plasmin resulting in further injury mediated by oxidative stress. We propose that chronic exposure to Plg serves as a "second hit" in glomerular diseases and that Plg is potentially an attractive target for therapeutic intervention.

p66Shc Regulates Endothelin-1 Induced Calcium Response in Glomerular Mesangial Cells Kevin D. Wright, Bradley S. Miller, Andrey Sorokin. *Dept of Medicine, Div of Nephrology, Cardiovascular Center, Medical College of Wisconsin, Milwaukee, WI.*

Background: In the kidney, glomerular mesangial cells (GMC) function to regulate glomerular filtration area and secrete extracellular matrix. Endothelin-1 (ET-1) is a critical signaling molecule which triggers an influx of calcium (Ca^{2+}) and subsequent contraction of GMC. Our goal was to assess the contribution of the adaptor protein p66Shc, a known ET-1 signal effector, in the regulation of Ca^{2+} handling and contraction in the GMC.

Methods: Primary GMC isolated from either wild type (WT) Dahl Salt-Sensitive (SS) rats, or from p66Shc mutant rats (on the SS genetic background). In these GMC

which either lacked p66Shc (M4) or have the regulatory Ser36 mutated (S36A), we measured ability of the cells to contract when embedded in a collagen matrix upon ET-1 stimulation. Additionally, we measured ET-1-mediated changes in intracellular calcium levels ($[Ca^{2+}]_i$). We also assayed GMC cells for changes in Ca^{2+} dependent signaling upon ET-1 stimulation. Lastly, in vivo assessment of glomerular filtration rate (GFR) was conducted on WT and mutant rats prior to onset of hypertension, on both high salt (1%) and low salt (0.4%) conditions.

Results: We show WT and mutant cells contract collagen disks to the same extent over 15 minutes after treatment with ET-1. There are, however, differences in collagen disks 24 hrs after ET-1 treatment. Additionally, we demonstrate that the loss of p66Shc increases $[Ca^{2+}]_i$ in ET-1 treated cells. Serum starved mutant GMC also exhibit a decreased baseline $[Ca^{2+}]_i$ than WT cells. Furthermore, the S36A GMC do not show increased $[Ca^{2+}]_i$ compared to WT cells and also exhibit a decreased baseline $[Ca^{2+}]_i$. To complement the changes in $[Ca^{2+}]_i$, there is increased phosphorylation of Ca^{2+} dependent p38 MAPK and Pyk2 in the mutant GMC. Analysis of GFR indicates increased filtration in M4 mutant compared to S36A mutant rats on a low salt (0.4%) diet.

Conclusions: These results establish a role for the adaptor protein p66Shc as a negative regulator of calcium homeostasis in GMC in vitro, where loss of p66Shc increases calcium^{2+} mobilization. Analysis of GFR suggests p66Shc may also function similarly in vivo.

MDM2 Is Implicated in High Glucose Induced Podocyte Mitotic Catastrophe via Numb/Notch1 Signaling Hui Tang, Hua Su, Chun Zhang. *Nephology, Union Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: Podocyte injury and depletion are essential events involved in the pathogenesis of diabetic nephropathy (DN). As a terminally differentiated cell, podocyte is restricted in 'post-mitosis' state and unable to regenerate. Reentering cell cycle will cause podocyte disastrous death which is defined as mitotic catastrophe (MC). Murine double minute 2 (MDM2), a cell cycle regulator, is widely expressed in renal resident cells including podocytes. Here we explore whether MDM2 involved in podocytes MC during hyperglycemia.

Methods: Patients diagnosed with DN were enrolled in this study, and DN model was constructed on C57BL/6 mice by a single intra-peritoneal injection of STZ. In vitro study human podocyte cell line was employed, and exposed to different treatments after differentiation. Nutlin-3a was used as an inhibitor for MDM2-p53 interaction. The expression of MDM2 and Notch1 was suppressed by genetic deletion.

Results: Aberrant mitotic podocytes with multi-nucleation were observed in DN patients as well as DN mice. Simultaneously the expression of MDM2 in podocytes of DN patients and mice was elevated comparing to control group. In vitro, HG exposure upregulated MDM2's abundance and forced podocytes to enter into S phase or transit G2/M phase with enhanced expression of Ki67 and mitotic markers (Aurora B, p-H3) which were partly reversed by MDM2 genetic deletion. Moreover HG-induced podocyte injury was alleviated by MDM2 knocking down but not by nutlin-3a treatment. Interestingly, we found Numb, an antagonist of Notch1, was decreased in glomeruli from DN mice and podocytes exposed to HG. Knocking down MDM2 attenuated Numb reduction and Notch1 activation. Consistently genetic silencing of Notch1 prevented HG-mediated podocyte MC.

Conclusions: Hyperglycemia upregulates MDM2 expression and leads to podocyte MC in vivo and in vitro. Knocking down MDM2 alleviates HG-induced podocyte MC and injury. Interestingly, MDM2 mediates podocyte MC not via classic p53 pathway but through Numb/Notch1signaling.

FR-PO492

Deiodinase 3 Dysfunction in Thyroid Hormone-Induced Kidney Disease Nicholas J. Tardi,[1] Chuang Chen,[1] Joao Pedro Werneck-de-Castro,[2] Jochen Reiser.[1] *[1]Int. Med., Rush Univ, Chicago, IL; [2]Endocrinology, Rush Univ, Chicago, IL.*

Background: Thyroid hormone (TH) is a circulating, lipid soluble molecule that plays an important role in physiology and development in nearly all cell types. Accordingly, precise control of TH activity is crucial to maintain homeostasis in several tissues, including the kidney where misregulation of TH can lead to tubular dysfunction and organ growth retardation. However, cases of reversible proteinuria and biopsy-proven glomerular disease associated with hyper/hypothyroidism have been reported in children and adults. TH homeostasis is maintained by deiodinases, which turn on/off tri-iodothyronine (T3), the metabolically active TH hormone. While TH regulation via deiodinases has been studied in endocrine tissues, the role of deiodinases in proteinuric kidney disease has not been addressed. Of particular interest is deiodinase 3 (D3); a catabolic enzyme that inactivates T3. We sought to determine if D3 is present and active in podocytes that regulate kidney filtration.

Methods: D3 expression and activity was analyzed in cultured podocytes treated with puromycin aminonucleoside (PAN), and in mice treated with lipopolysaccharide (LPS). qRTPCR, confocal analysis and Western blot were used to study the expression profile of D3. A cleavage assay using a radiolabeled substrate was used to measure the T3 deactivating capacity of D3.

Results: Podocyte D3 expression displays a 20-fold increase in comparison to deiodinase 1 or 2, and was significantly reduced in LPS-induced proteinuric mice up to 72 hrs, indicating persistent downregulation of D3 in injured podocytes. D3 expression and activity was downregulated in response to podocyte injury. Interestingly, D3 expression was greatly diminished at the cell membrane, yet remained concentrated in the golgi and perinuclear region where metabolically active T3 resides. Additionally, D3 is downregulated in glomeruli of kidney biopsies collected from patients with focal segmental glomerulosclerosis and minimal change disease compared to healthy donors.

Conclusions: Our data suggests D3 downregulation is the source of hyperthyroidism in podocytes, and D3 dysfunction may be a mechanism of TH induced kidney disease in humans.

FR-PO493

Mesenchymal Stem Cells Acquire Morphological and Functional Features of Mesangial Cells as They Repair the Damaged Mesangium Jiamin Teng,[1] Chun Zeng,[1] Elba Turbat-Herrera,[1,2,3] Guillermo A. Herrera.[1,3] *[1]Pathology and Translational Pathobiology, Louisiana State Univ Health Sciences Center in Shreveport, Shreveport, LA; [2]Medicine / Feist-Weiller Cancer Center, Louisiana State Univ Health Sciences Center in Shreveport, Shreveport, LA; [3]Cellular Biology and Anatomy, Louisiana State Univ Health Sciences Center in Shreveport, Shreveport, LA.*

Background: Some studies dealing with mesenchymal stem cells (MSCs) have indicated that they only provide paracrine effects when engaged in the process of tissue repair. In order to assess the specific role of MSCs in mesangial repair, a model of mesangial injury by glomerulopathic light chains was used.

Methods: A 6-D live cell imaging system was used as the in-vitro system and to address the issue. Mesangial cells (MCs) were incubated with light chains obtained from the urine of patients of AL-amyloidosis (AL-Am) and light chain deposition disease (LCDD). The light chains were also perfused through the renal artery in the ex-vivo platform. The respective lesions were reproduced in both platforms. Then, tagged MSCs were introduced. Immunofluorescence, immunohistochemistry and electron microscopy were used to evaluate samples obtained at different time frames. Stains for smoothelin, CD68 and CD29 were used to monitor phenotypic transformation of MSCs in the process of repair. Electrical field stimulation to assess the ability of cells to contract was utilized to assess functionality.

Results: MSCs transformed from an undifferentiated to a macrophage phenotype. The process showed transformed MSCs phagocytosing cellular debris resulting from apoptotic MCs, damaged matrix, amyloid, After the cleaning. MSCs acquired morphologic, functional, and immunophenotypic characteristics of MCs as they proceeded to lay down new mesangial matrix.

Conclusions: MSCs manifest great plasticity as they proceed to repair the damaged mesangium. The fact that they transform allows them to perform different crucial functions. The restored mesangium is possible as new MCs derived from MSCs are able to reproduce the normal mesangium and function as normal MCs.

Distinct and Overlapping Requirements for Nck1/2 Adaptors in Podocyte Cytoarchitecture Claire E. Martin,[1] Mira Krendel,[2] Nina Jones.[1] *[1]Molecular and Cellular Biology, Univ of Guelph, Guelph, ON, Canada; [2]Cell and Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY.*

Background: Podocytes contribute to blood filtration selectivity through a network of actin-based projections termed foot processes. The ability of these structures to withstand hemodynamic strain and maintain filtration barrier integrity is proposed to be tied to their unique and flexible cytoarchitecture. However, the molecular mechanisms that regulate such mechanotransduction are not well understood. We have previously established that the Nck1/2 family of actin adaptors is essential in podocytes for both induction and maintenance of foot processes. We have now characterized the cellular basis of this profound phenotype, and further examined the singular roles of these key adaptor proteins.

Methods: Immortalized mouse podocyte cell (MPC) cultures lacking Nck1 and/or Nck2 were generated, and rescue lines were constructed using adenoviral transduction. Complementary mouse lines deficient in Nck1 and/or Nck2 expression were also investigated.

Results: Striking disruptions in actin organization are present in Nck1/2$^{-/-}$ MPCs, characterized by loss of lamellar sheets and radial stress fibres, with remaining stress fibres appearing haphazard, shortened and highly bundled. Consistent with this, Nck1/2$^{-/-}$ MPCs display defects in cell spreading, migration and response to calcium switch injury. Molecular analysis has revealed overexpression of the actin bundling protein alpha-actinin 4 in Nck-deficient cells and animals, and mislocalization of this protein within focal adhesions. Intriguingly, intermediate and distinct phenotypes are present in Nck1$^{-/-}$ and Nck2$^{-/-}$ MPCs, with Nck1$^{-/-}$, Nck2$^{-/-}$ and Nck1$^{-/+}$; Nck2$^{-/+}$ animals all showing increased susceptibility to foot process effacement and proteinuria in multiple acute injury models.

Conclusions: We conclude that Nck proteins regulate podocyte actin bundling and focal adhesion dynamics, and that a threshold level of both Nck1 and Nck2 is required to maintain homeostasis. The ability of Nck to simultaneously associate with proteins both within the slit diaphragm and along the basal compartment positions Nck as a hub to coordinate mechanical signals within the podocyte.

The Kynurenine Pathway in Podocytes and Parietal Epithelial Cells as a Potential Contributor to Kidney Disease Patricia Bolanos-Palmieri,[1,3] Hermann G. Haller,[1,2] Patricia Ann Schroder,[2] Mario Schiffer.[1,2] *[1]Nephrology, Hannover Medical School, Hannover, Lower Saxony, Germany; [2]Mount Desert Island Biological Laboratory, Bar Harbor, ME; [3]HBRS, Hannover Medical School, Hannover, Lower Saxony, Germany.*

Background: The kynurenine pathway (KP) is responsible for the catabolism of tryptophan resulting in the generation of NAD^+ and a series of metabolically active intermediate products that participate in a number of cellular processes. In the kidneys, this pathway remains largely unexplored however an increasing amount of evidence suggests that changes in the activity and expression pattern of KP enzymes, as well as the accumulation of intermediate by-products are associated with disease. This study aims to provide an initial insight to the role played by the KP in the health and function of glomerular cells and its relationship to kidney disease.

Methods: Knock down (KD) of the enzymes in the KP was performed by morpholino injection in transgenic zebrafish Tg(l-fabp:DBP:EGFP). The phenotype of the morphants was determined according to the severity of the yolk sac edema and pericardial effusion. The maximum fluorescence in the retinal vessel plexus was taken as a measure of integrity of the glomerular filtration barrier. To assess the cellular repercussions of KP inhibition we will use UPF480 to block the pathway and analyze variations in oxygen consumption, extracellular acidification rate, as well as changes in actin cytoskeleton and response to stimuli in Podocytes and PEC.

Results: Our initial KD results show a 2-10 fold reduction in mRNA levels of the KP enzymes and by reducing their expression we are able to induce the formation of edema and detect signs of proteinuria in the MO injected fish. The proportion of fish with severe edema is higher, and the fluorescence is lower when the enzymes AFMID, KMO or KYNU are knocked down, indicating problems in the filtration barrier shown by the excretion of the fluorescent protein in the urine.

Conclusions: Taken together these results suggest that the KP is important in the maintenance and proper function of the filtration barrier, however the cellular and molecular mechanisms by which tryptophan metabolites affect cell function are yet to be elucidated.

Elucidation of the Roles of Tissue Transglutaminase in Mesangial Proliferative Glomerulonephritis Akihiro Kato,[1] Tomohiro Mizuno,[2] Kazuo Takahashi,[1] Hideki Tatsukawa,[3] Masashi Mizuno,[4] Kiyotaka Hitomi,[3] Yukio Yuzawa.[1] *[1]Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan; [2]Meijo Univ, Nagoya, Aichi, Japan; [3]Nagoya Univ Graduate School of Pharmaceutical Sciences, Nagoya, Aichi, Japan; [4]Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan.*

Background: Tissue transglutaminase (TG2) is a calcium ion-dependent protein-cross-linking enzyme that plays an important role in fibrosis and inflammation. TG2 is ubiquitously expressed enzyme and mainly distributed intracellularly as a catalytically inactive state due to low calcium concentration in the cells. We have established a method using a TG2-specific FITC-labeled highly reactive substrate peptide for the detection of TG2 activity in renal biopsy tissue. We applied this method to detect active form of TG2 in human renal biopsy tissues (n=241), and found that TG2 activities were high in mesangial areas in patients with IgA nephropathy and lupus nephritis (J Am Soc Nephrol, 2015;26:723A).

Methods: Under normal circumstances, cellular TG2 is catalytically inactive. We hypothesized that the activation of TG2 in mesangial areas may result from its shifting from the intracellular to the extracellular space by complement mediated cell damages. As a complement-mediated stimulus, human glomerular mesangial cells (HGMCs)were stimulated with normal human serum. The levels of TG2 in the culture supernatants as well as those in the intracellular compartment were measured by using ELISA. In addition, human recombinant TG2 and Platelet-Derived Growth Factor (PDGF) were added to HGMCs and cell growth was examined by performing a confluence assay.

Results: Complement-mediated stimulation of HGMCs was accompanied by a significant increase in TG2 levels in the culture supernatant and a decrease in the intracellular TG2 levels. The reaction was not observed in inactivated normal human serum, and was inhibited in the presence of C1 elastase inhibitor. When human recombinant TG2 and PDGF were added to HGMCs, cell growth was significantly promoted.

Conclusions: The extracellular shift and activation of TG2 may be due to complement activation in mesangial cells and could be involved in the progression of mesangial proliferative glomerulonephritis such as IgA nephropathy and lupus nephritis.

Puromycin Aminonucleoside Induces Endoplasmic Reticulum Stress and Apoptosis in Podocyte Tae-Sun Ha. *Pediatrics, Chungbuk National Univ, Cheongju, Chungbuk, Republic of Korea.*

Background: Puromycin aminonucleoside (PAN) is known to be a podocytotoxin, therefore, PAN-induced nephrosis is a widely studied animal model of human idiopathic nephrotic syndrome. Endoplasmic reticulum (ER) stress is the common findings under various pathogenic microenvironments, contributing to the progression of various podocyte diseases. Abnormal protein accumulation associated with ER stress in the ER of podocytes produces structural and functional damage in the cells, which in turn leads to podocyte apoptosis and severe proteinuria. In the present study, we investigated the effect of PAN on ER stress and apoptosis in *in vitro* podocytes.

Methods: We cultured rat and mouse podocytes and treated with various concentrations of PAN and evaluated ER stress markers by western blotting and apoptosis FACS and TUNEL assays.

Results: PANtreatment increased GRP78 protein, an ER chaperone,as early as at 2 hrs, which was not ameliorated by anti-oxidants. PAN also increased ER stress markers, such as, ATF6a and caspase 12 at 12 and 24 hrs, which were improved by ATF6 siRNA and chemical chaperones, such as, sodium 4-phenylbutyric acid (PBA) and TUDCA, however, not by Nox4 siRNA.PAN treatment increased oxidative stress level of podocytes significantly with the induction of Nox4. In addition, PAN induced podocyte apoptosis significantly in concentration- and time-dependent manners in FACS and TUNEL assays, which were improved by Nox4 siRNA, ATF6 siRNA, and chemical chaperones. Therefore, PAN induced ER stress, thereafter, increased oxidative stress, subsequently induced podocyte apoptosis.

Conclusions: Our studies suggest that PAN could induce podocyte ER stress of mainly ATF6a and caspase 12 pathways, which would contribute to the development of podocyte apoptosis via oxidative stress.

RNA Binding Protein Staufen 2 Is Required for Normal Podocyte Adhesion Jessica J. Harris,[1] George J. Cope,[2] Valerie A. Schumacher.[1] *[1]Dept of Urology, Boston Children's Hospital, Boston, MA; [2]Cardiff Univ, Cardiff, United Kingdom.*

Background: Podocytes are critical for the maintenance of the glomerular filtration barrier (GFB) and need to be able to adapt to changes such as variations in pressure or cellular injury, to do so they may need to alter cell-matrix interactions. Failure in the ability to respond to such changes can lead to the irreversible loss of podocytes from the GFB. Our preliminary data supports the novel concept that podocytes store mRNAs in discrete locations in the cell until protein is needed and the mRNAs locally translated to regulate cell adhesion. The localization of mRNAs within a cell can be regulated RNA binding proteins such as Staufen2. Our main focus is to determine how Staufen2 regulates the formation and maintenance of cell-matrix adhesions within the podocyte up on injury and up on adhesion of cells.

Methods: Adriamycin (ADR) treatment was used as a model of injury. siRNA was used to knockdown Staufen2 *in vitro*. Detachment of cells was monitored using a crystal violet assay. Phase contrast microscopy and ImageJ analysis were used to investigate cell spreading and western blotting used to study cell signaling.

Results: Using an *in vivo* model we show that ADR induced injury results in an increase of the phosphorylation of S6 protein indicating an increase in protein. This correlates with an increase of ribosomes within podocyte foot processes. Staufen2 is expressed in podocytes and localizes to focal adhesions *in vitro*. Podocytes lacking Staufen2 detach over time and have smaller paxillin positive focal adhesions compared to control cells. ADR induced cellular injury enhances this decrease in adhesive area. We investigated the role of Staufen2 up on podocyte adhesion to laminin and find that Staufen2 deficient podocytes show a defect in spreading. We also show that glycosylation of integrin beta1 is altered in podocytes lacking Staufen2 and that there is a reduction in phosphorylation of key adhesion related molecules.

Conclusions: Staufen2 is localized to adhesive complexes in podocytes and is required for proper spreading and maintenance of adhesion. Knockdown of Staufen2 leads to defects in glycosylation and signaling.

Diet1 Is a Novel Gene Associated with Albuminuria Jessica Ong,[1,3] Laurent Vergnes,[1] Ira Kurtz,[2] Karen Reue.[1,2,3] *[1]Human Genetics, Univ of California, Los Angeles; [2]David Geffen School of Medicine, Univ of California, Los Angeles; [3]Molecular Biology Inst, Univ of California, Los Angeles, CA.*

Background: *Diet1* is a gene previously identified from a naturally occurring null mutation in an inbred mouse strain. Studies in this mouse strain showed that Diet1 plays an important role in bile acid signaling by modulating FGF15/19 secretion. *In situ* hybridization demonstrated *Diet1* expression exclusively in the small intestine and in the renal proximal tubule. At present, nothing is known about the role of *Diet1* in the kidney, but a GWAS study for urinary albumin excretion has revealed a significant association with a polymorphism in *DIET1*.

Methods: To investigate the role of Diet1 in the kidney, we created a congenic mouse strain carrying the *Diet1* null mutation on a C57BL/6J background. Male and female $Diet1^{+/+}$ and $Diet1^{-/-}$ mice were studied on standard mouse chow and an atherogenic diet. Twenty-four hour urine samples were collected and assessed for albumin and creatinine excretion rates. In addition, on the atherogenic diet, blood chemistries and kidney tissue were obtained for histology, electron microscopy, and gene expression studies.

Results: On standard mouse chow, there was no difference in albumin excretion rates of $Diet1^{-/-}$ compared to $Diet1^{+/+}$ mice. However, on the atherogenic diet, $Diet1^{-/-}$ mice exhibited a significantly greater urinary albumin excretion compared to $Diet1^{+/+}$ (77.3% in males and 49.1% in females) without any difference in creatinine clearance. Renal histology and ultrastructural studies of the glomeruli and proximal tubules did not reveal significant differences between $Diet1^{+/+}$ and $Diet1^{-/-}$ mice, suggesting that Diet1 may have a regulatory role in albumin absorption by the kidney.

Conclusions: We have documented for the first time a role for *Diet1* in renal albumin handling in mice. Given the localized expression of *Diet1* in the proximal tubule, our results suggest a new modulatory pathway whereby Diet1 plays a role in proximal tubule albumin absorption depending on the dietary lipid content.

The Effects of Diabetes Mellitus on Cell Surface Heparan Sulfate Proteoglycans: The Uncoupling of Syndecan-4 in Podocytes due to Early Loss of N-Sulfated Heparan Deborah J. McCarthy, Kevin J. McCarthy. *Dept of Pathology and Translational Pathobiology, LSU Health Sciences Center, Shreveport, LA.*

Background: Previous work from our laboratory showed that the loss of heparan sulfate (HS) or the depletion of N-sulfated groups (NS) on HS attached to cell surface proteoglycans (PG) led to the development of podocyte (POD) foot process effacement *in vivo* and compromised cell-matrix adhesion *in vitro*, mediated by the "uncoupling" of syndecan-4 (Sdc4) from matrix protein ligands. This study extends this concept to explore the loss of NS in the glomerular basement membrane (GBM) of diabetic animals.

Methods: Control and db/db mice 16 weeks of age were sacrificed, the kidneys removed and processed for paraffin, frozen, and transmission electron microscopy (TEM). Frozen sections were double label immunostained for total HS and N-sulfated HS; Sd4 and either nephrin, synaptopodin, or a-actinin 4. Paraffin sections were stained with PAS/Alcian Blue to demonstrate glomerular hypertrophy and mesangial expansion. Tissue sections were imaged using an Olympus IX-70 microscope equipped for epifluorescent illumination or for TEM, a Hitachi TEM.

Results: PAS/Alcian Blue staining of glomeruli of db/db mice showed glomeruli ranging from normal to glomeruli having glomerular hypertrophy and early mesangial expansion. Immunostaining for NS and HS in glomeruli from control animals revealed glomerular capillaries whose GBMs stained positive for both NS and HS, indicating that the PGs contained normal HS species. GBM staining of diabetic glomeruli showed the presence of PGs lacking NS but whose total HS content remained unchanged. Capillaries in the diabetic glomeruli showed a breakdown in the linear co-distribution of Sdc4 and a-actinin-4 along the length of the GBM.

Conclusions: Our data show that in the early stages of diabetic nephropathy there is a loss of NS on HS associated with Sdc4, one of the cell surface proteoglycans that are now known to be critical in POD-matrix interactions. This change is associated with uncoupling of Sdc4 ectodomain from its GBM ligands which, in turn, leads to disruption of the a-actinin-4 cytoskeleton linkage in PODs and foot process effacement.

FR-PO501

Characterizing the Differential Regulation of Podocyte ANLN Expression by AKT1 and AKT2 Gentzon Hall,[1,3,4] Guanghong Wu,[1,4] Gina E. Kovalik,[1,4] Brandon M. Lane,[2,4] Megan Chryst-Ladd,[4] Robert F. Spurney,[1,3,4] Rasheed A. Gbadegesin.[2,3,4] *[1]Dept of Medicine, Duke Univ Medical Center; [2]Dept of Pediatrics, Duke Univ Medical Center; [3]Div of Nephrology, Duke Univ Medical Center; [4]Duke Molecular Physiology Inst, Duke Univ Medical Center.*

Background: We previously demonstrated that mutations in the F-actin bundling and cell cycle regulatory protein ANLN cause FSGS. Additionally, we have shown that: 1. ANLN expression is upregulated in podocytes in a mouse model of HIV associated nephropathy (HIVAN), 2. ANLN overexpression is sufficient to enhance proliferation and motility of cultured podocytes, and 3. ANLN gene expression is regulated by AKT. These findings suggest that the upregulation of ANLN may play role in the pathobiology of podocyte dysfunction in FSGS. Moreover, therapies that reduce ANLN gene expression might ameliorate the disease. Given the emergence of isoform-specific AKT-antisense therapies (e.g. Archexin), we sought to define the roles of AKT1 and AKT2 in the regulation of podocyte ANLN gene expression.

Methods: We used immunoblotting and cell proliferation assays to evaluate the effects of targeted AKT1 and AKT2 knockdown on ANLN expression and cell proliferation in tetracycline-inducible AKT1-shRNA and AKT2-shRNA podocyte lines.

Results: In AKT2-shRNA-expressing podocytes, ANLN expression and podocyte proliferation were significantly reduced relative to controls. Conversely, ANLN expression was significantly upregulated in AKT1-shRNA-expressing podocytes.

Conclusions: These data suggest an opposing role for AKT1 and AKT2 in the regulation of podocyte ANLN gene expression. Isoform specific modulation of AKT using genetic nanotherapies might be a novel therapeutic strategy for the treatment of FSGS.

Transcriptional Reprogramming by WT1 in Murine Podocytes Affected by Hereditary FSGS Mahdieh Rahmatollahi, Martin Kann, Maximilian O. Lenz, Bernhard Schermer, Thomas Benzing. *Dept II of Medicine, Nephrology, Rheumatology and Diabetology and Center for Molecular Medicine Cologne, Univ of Cologne, Cologne, Germany.*

Background: Mutations in several podocyte transcription factors (TF) including Wt1 are known to cause hereditary FSGS. However, the gene regulatory networks governed by these TFs in healthy and diseased podocytes are as yet poorly characterized. Here, we investigate Wt1 dependent gene regulatory reprogramming at an early stage of podocyte damage in a mouse model of hereditary FSGS.

Methods: Heterozygous deletion of Wt1 (Wt1het) was chosen as a murine model of hereditary FSGS. Wt1 gene regulatory function was assayed in Wt1het mice and control littermates by ChIPseq for Wt1 at age 4 weeks, an early proteinuric yet not sclerotic stage of glomerular damage. Results were computationally analyzed using standard ChIPseq algorithms.

Results: Wt1het mice showed a consistent phenotype of proteinuria present at age 4 weeks and glomerulosclerosis at age 15 weeks. Wt1 ChIPseq at age 4 weeks identified several thousand conserved Wt1 binding sites (peaks) in both, Wt1het and control animals. Wt1 peaks were reproducible, conserved, predominantly located in putative enhancers, and harbored the established Wt1 DNA binding motif in either condition. In principal component analysis, ChIPseq data clustered according to genotype. Differential binding analysis between Wt1het mice and controls identified changes in binding strengths corresponding to gene regulatory reprogramming events at one third of all Wt1 peaks. Reduction of Wt1 binding strengths was predominant upon glomerular damage with a small cluster of novel Wt1 peaks occurring. The majority of reprogramming events took place at putative enhancers, highlighting their importance to gene regulatory networks. Gene ontology analysis revealed key reprogramming events to be enriched at genes associated with podocyte damage signaling pathways such as Tgf-beta and Wnt, involving Wt1 in transcriptional regulation of such pathways at an early disease stage in this FSGS model.

Conclusions: In a murine model of hereditary FSGS, Wt1 is involved in gene regulatory reprogramming of signaling pathways relevant to podocyte damage at an early stage of disease.

BRAF Signalling Pathway Inhibition Causing Glomerular Injury Luca Perico,[1] Mario Mandala,[2] Arrigo Schieppati,[2] Camillo Carrara,[1] Paola Rizzo,[1] Sara Conti,[1] Lorena Longaretti,[1] Ariela Benigni,[1] Giuseppe Remuzzi.[1,2] *[1]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [2]ASST Papa Giovanni XXIII, Bergamo, Italy.*

Background: The glomerulus is uniquely susceptible to chemotherapeutic injury, though molecular targets have not been fully identified. Dabrafenib and trametinib, BRAF and MEK inhibitors, are effective targeted therapies for malignant metastatic melanoma but less is known about their nephrotoxicity. While initial trials with BRAF inhibitors suggested no renal side effects, recent case reports uncovered significant nephrotoxic events. Whereas most of the published data revealed tubulointerstitial injury as the main renal consequence of these drugs, none depicted nephrotic syndrome (NS) and glomerular damage.

Methods: Starting from the case of a patient with metastatic melanoma who developed NS during dabrafenib and trametinib treatment, we evaluated glomerular ultrastructural changes by electron microscopy analysis and the molecular mechanisms underlying the targeted therapy-induced NS by combining *in vitro* experiment in podocytes and *ex vivo* analysis in the patient biopsies.

Results: Electron microscopy analysis showed diffuse loss of podocyte cytoarchitecture, extensive foot process effacement and glomerular capillary injury in the patient's biopsy during drug treatment. Renal function and glomerular damage recovered after drug withdrawal. *In vitro* experiments documented that BRAF inhibition was the primary culprit in the podocyte slit diaphragm impairment *via* reduction of PLCξ1 and nephrin expression, leading to increased albumin permeability. BRAF and MEK inhibitors jointly altered the overall glomerular functional properties by inhibiting the podocyte VEGF system. The above mechanisms were corroborated *ex vivo* in the patient biopsies.

Conclusions: We demonstrate that MAPK pathway inhibition alters slit diaphragm architecture and we provide direct experimental evidence that this inhibition is a possible novel pathogenic mechanism leading to NS. Besides its implications for NS pathophysiology, we suggest that patients should be monitored closely for potential glomerular damage during follow-up since the dabrafenib and trametinib combination is a standard treatment for melanoma patients.

FR-PO504

The Neonatal Fc Receptor (FcRn) Is Required for IgG but Not Albumin Trafficking in Podocytes In Vitro and In Vivo Evgenia Dobrinskikh,[1] Linda Lewis,[1] Patricia M. Zerfas,[2] Avi Rosenberg,[3] Jeffrey B. Kopp,[3] Judith Blaine.[1] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]ORS, NIH, Bethesda, MD; [3]NIDDK, NIH, Bethesda, MD.*

Background: Proteinuria is strongly associated with kidney disease progression. Podocytes are key constituents of the glomerular filtration barrier (GFB), which determines protein permselectivity. By conservative estimates, 2-9 g of serum proteins pass daily through the GFB. The molecular mechanisms whereby podocytes handle albumin and IgG

remain to be fully determined. Previously, we have shown that transcytosis is the major pathway by which cultured podocytes transport albumin and IgG. In other epithelial cell types, the neonatal Fc receptor (FcRn) is required, thereby salvaging these proteins from degradative pathways.

Methods: Intracellular levels of albumin or IgG in wild type (WT) or FcRn knockout (KO) cultured podocytes were analyzed by Western blot. In vivo effects of FcRn KO on glomerular trafficking of albumin and IgG were examined in control and podocyte-specific FcRn KO mice.

Results: IgG treatment resulted in significantly increased intracellular accumulation of IgG in FcRn KO versus WT cultured podocytes. Densitometric analysis of Western blots showed more intracellular IgG in the KO 0.97 ± 0.16 (KO) compared to WT 0.51 ± 0.06 (mean ± SEM, arbitrary units), $p<0.05$. Surprisingly, FcRn KO had no effect on albumin trafficking in cultured podocytes. There was no difference between WT and KO podocytes in the amount of intracellular albumin remaining 1 h after loading (0.54 ± 0.06 in KO versus 0.38 ± 0.06 in WT, p=NS), suggesting that FcRn is not required for albumin transcytosis. In an in vivo model, there was no significant difference in albuminuria between podocyte-specific FcRn KO and WT mice. Aging resulted in increased intraglomerular accumulation of IgG but not albumin in podocyte-specific FcRn KO compared to WT mice, assessed by immunostaining. Aging also resulted in mesangial expansion in the KO mice, assessed by light and electron microscopy.

Conclusions: These studies indicate that FcRn is required for podocyte transcytosis of IgG but not albumin in vitro and in vivo and suggests that podocytes and proximal tubules handle serum proteins differently.

Loss of ABIN1 Ubiquitin Binding Function in Podocytes Alters the Exosomal Proteome to a Pro-Inflammatory Phenotype Ryan M. Sheehan, Erik Korte, Michael Merchant, David W. Powell. *Medicine/Nephrology, Univ of Louisville, Louisville, KY.*

Background: Proteomic analysis of urinary exosomes have revealed known markers for podocyte damage and unknown proteins that may play a role in glomerular disease pathogenesis. The formation and packaging of exosomes into multivesicular bodies (MVB) is coordinated by the endosomal sorting complex required for transport (ESCRT) which binds and sorts ubiquitinated proteins. We previous reported that mice with disrupted ABIN1 ubiquitin binding activity develop glomerulonephritis through enhanced pro-inflammatory NF-κB activation. The present study tested a hypothesis that ABIN1[D472N] mutation, lacking ubiquitin binding, alters the proteomic profile within exosomes released from podocytes.

Methods: Expression and secretion proteins within exosomes were assessed in wild type and ABIN1[D472N] expressing human-derived podocytes using protein arrays, qRT-PCR, and SILAC based quantitative mass spectrometry. ABIN1 expression and localization was assessed using confocal microscopy with the early endosomal marker Rab5. The interaction of ABIN1 with exosomal sorting proteins was assessed by co-immunoprecipitation.

Results: Ingenuity pathway analysis of exosomal proteomes revealed an association with kidney damage and immune response in ABIN1[D472N] podocytes. With significant increases in extracellar matrix altering proteins (FN1, SPARC), chemokines (CXCL1, IL-8), actin remodeling proteins (GSN), complement factor (C3), and acute inflammatory maker (SAA1). Two candidates, KU70 and HMGA1, were significantly down regulated in the exosomes from ABIN1[D472N] podocytes, but cytosolic protein and mRNA expression did not differ. The ABIN1 mutation did not affect colocalization with Rab5 at the early endosome, but did alter its interaction with ESCRT accessory protein Alix.

Conclusions: Our findings suggest that ABIN1 ubiquitin binding and localization at the early endosome act as a novel sorting mechanism of exosomal protein packaging. We postulate that podocytes with ABIN1 genetic variants secrete exosomes that enhance glomerular inflammation through intercellular transfer of proteins, providing biomarker candidates and novel mechanistic insight for improved therapeutics.

FR-PO506

Omentin Regulates Podocyte Function and Albuminuria Hidetoshi Kobayashi, Fumihiko Furuya, Kenichiro Kitamura. *Third Dept of Internal Medicine, Univ of Yamanashi, Chuo, Yamanashi, Japan.*

Background: Albuminuria has recently been recognized as the most significant risk factor for end-stage renal disease (ESRD) in diabetics. An adipokine, omeenin, is preferentially produced by visceral adipose tissue compared with subcutaneous adipose tissue. The aim of this study was to elucidate whether serum omentin level is associated with the progression of diabetic nephropathy (DN) and to explore the direct effects of omentin on podocyte injury to determine the mechanisms by which omentin contributes to the development of albuminuria.

Methods: The prospective follow-up study; 114 diabetes patients were followed for 6 years. Patients were divided at baseline into three groups according to their urinary albumin-to-creatinine ratio. To explore the molecular mechanisms of omentin-mediated renoprotective function, we investigated the mouse podocytes with or without recombinant omentin treatment.

Results: Progression either to the next albuminuria level in 16 patients or to end-stage renal disease ESRD occurred in 5 patients. In the patients with microalbuminuria and macroalbuminuria, progression of albuminuria was associated with higher serum omentin levels. When these covariates were inserted in a Cox regression analysis, eGFR and serum omentin levels were independently associated with progression of DN. In cultured podocytes, treatment with omentin significantly increased AMPK activities, and both omentin and AMPK activation reduced podocyte permeability to albumin and podocyte dysfunction, as evidenced by zona occludens-1 translocation to the membrane. Since omentin reduced protein levels of NADPH oxidase Nox4 in podocytes, we speculated that these protective effects of omentin were caused by the reduction of oxidative stress.

Conclusions: In conclusion, increased serum omentin levels predict the progression from microalbuminuria to macroalbuminuria and macroalbuminuria to ESRD in diabetic patients. Our in vitro findings suggest that omentin is a key regulator of albuminuria, likely acting through the AMPK pathway to modulate oxidant stress in podocytes.

FR-PO507

Microtubule and Actin Crosstalk in Podocytes Kamalika Mukherjee, Changkyu Gu, Sanja Sever. *Dept of Medicine/Div of Nephrology, Massachusetts General Hospital/Harvard Medical School, Charlestown, MA.*

Background: Podocyte injury, dysfunction and loss have been implicated in a number of diverse kidney diseases such as focal segmental glomerulosclerosis, diabetic nephropathy and HIV-associated nephropathy. It is known that structural and functional alteration of the podocyte actin cytoskeleton culminates in foot process effacement and proteinuria. The coordinated organization of the cytoskeleton is crucial for maintaining the physiological function of podocytes. The two predominant cytoskeletal proteins present in major processes and foot processes of podocytes are microtubules and actin respectively. We therefore sought to investigate the crosstalk between microtubules and actin in podocytes and identify regulatory proteins that may modulate such interactions.

Methods: Tubulin, actin and paxillin were immunostained to observe the effect of microtubule- and actin- regulating small molecules on podocytes. Dynamin oligomerization was analyzed by monitoring dynamin's ability to hydrolyze GTP over time. Microtubule polymerization and depolymerization in the presence of dynamin or small molecules were monitored using a DAPI based fluorescence assay.

Results: 1. Microtubule active ligands alter actin cytoskeleton and focal adhesion turnover in podocytes. 2. Actin-regulating drugs reorganize microtubule cytoskeleton. 3. Microtubules promote dynamin oligomerization. 4. Dynamin promotes microtubule depolymerization. 5. Dynamin inhibits tubulin polymerization.

Conclusions: Altering microtubule cytoskeleton in podocytes results in reorganization of actin cytoarchitecture and *vice versa*. This finding demonstrates the existence of a crosstalk between the two cytoskeletal proteins in podocytes. There is evidence that dynamin oligomerization promotes actin polymerization. Here, we report that dynamin self-assembles around microtubules and promotes depolymerization of microtubules and inhibits tubulin polymerization into microtubules. Taken together, dynamin oligomerization regulates polymerization activity of both microtubules and actin. Our findings therefore strongly suggest that dynamin may be one of the regulatory proteins that facilitate actin and microtubule crosstalk in podocytes.

Par3A and Par3B Exhibit Compensatory Roles to Maintain aPKC Mediated Polarity Signaling at the Slit Diaphragm Sybille Köhler,[1] Wilhelm Bloch,[5] Bernhard Schermer,[1,2,4] Thomas Benzing,[1,2,4] Paul T. Brinkkoetter.[1] *[1]Dept II of Internal Medicine and Center for Molecular Medicine, Univ of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Univ of Cologne, Cologne, Germany; [3]Dept of Dermatology and Center for Molecular Medicine Cologne, Univ of Cologne, Cologne, Germany; [4]Systems Biology of Ageing Cologne (Sybacol), Univ of Cologne, Cologne, Germany; [5]Dept of Molecular and Cellular Sport Medicine, German Sport Univ Cologne, Cologne, Germany; [6]Clinical Inst of Pathology, Medical Univ of Vienna, Vienna, Austria.*

Background: Polarity signaling through the aPKC-Par polarity complex is essential for the development and maintenance of the podocyte architecture and the function of the glomerular filtration barrier of the kidney. Despite its well-established role in aPKC-mediated signaling, Par3A appears to be dispensable for the function of the glomerular filtration barrier.

Results: mRNA seq data from primary podocytes revealed high levels of Par3B in podocytes, which were much higher in comparison to Par3A levels. Interestingly, Par3B localized to the slit diaphragm as demonstrated by immunofluorescent stainings and immunogold-labellings suggesting a role of Par3B at the slit diaphragm. To study Par3B function at the slit, we generated a novel podocyte-specific Par3B knockout mouse model. Loss of Par3B did not cause glomerulosclerosis or albuminuria. To study potential compensatory mechanisms between Par3A and Par3B, we generated podocyte-specific Par3A/B double knockout mice. Par3A/B double knockout mice were born following Mendelian rules. Within 8 weeks of age Par3A/B DKO mice developed severe proteinuria in comparison to control mice. To further study the interplay between the different Par3 proteins we utilized *Drosophila* nephrocytes and silenced expression of the Par3A/B homolog *bazooka* which also resulted in disturbed nephrocyte morphology and a severe filtration defect.

Conclusions: Taken together, these findings support the hypothesis of potential compensatory mechanisms between Par3A and Par3B to maintain aPKC mediated polarity signaling at the slit diaphragm.

FR-PO509

Regulation of Canonical Wnt Signaling by the Transcription Factor HNF-1β Siu Chiu Chan,[1] Sachin S. Hajarnis,[2] Patricia Cobo-Stark,[2] Karam S. Aboudehen,[1] Peter Igarashi.[1] *[1]Medicine, Univ of Minnesota Medical School, Minneapolis, MN; [2]Internal Medicine, Univ of Texas Southwestern Medical Center, Dallas, TX.*

Background: Hepatocyte nuclear factor-1β (HNF-1β) is a tissue-specific transcription factor that is required for kidney development and tubular function. Mutations of HNF-1β produce kidney cysts and end-stage kidney failure. Activation of canonical (β-catenin-dependent) Wnt signaling has been implicated in cystic kidney disease and has been detected in HNF-1β mutant kidneys.

Methods: HNF-1β-deficient mIMCD3 cells were produced by gene editing with CRISPR/Cas9. Gene expression was measured by RNA-seq and qRT-PCR. Transcriptional activity was measured with ChIP and luciferase reporter assays.

Results: RNA-seq and Ingenuity Pathway Analysis identified Wnt signaling as one of the most dysregulated pathways in HNF-1β-deficient cells. ChIP-seq analysis identified members of the T-cell factor/lymphoid-enhancer factor (TCF/LEF) family as novel HNF-1β transcriptional targets. Expression of Lef1 was increased in HNF-1β-deficient cells and cells expressing dominant-negative (DN) mutant HNF1β. Knockdown of Lef1 with siRNA decreased β-catenin-dependent transcription and Axin2 mRNA levels in DN-HNF1β-expressing cells. Two functional HNF-1β binding sites were identified in the Lef1 locus by ChIP and luciferase reporter assays. HNF-1β-deficient cells were hyperresponsive to Wnt3a as evidenced by upregulation of canonical Wnt targets Axin2, Sp5 and Lef1. Deletion of the β-catenin-binding domain in Lef1 partially rescued the hyperresponsiveness to Wnt3a. Increased expression of Axin2 and Lef1 was confirmed in vivo by qRT-PCR analysis of kidneys from HNF-1β mutant mice.

Conclusions: Increased expression of Lef1 contributes importantly to the activation of canonical Wnt signaling in HNF-1β mutant cells through a feed-forward mechanism. Characterization of genes that are activated by Wnt in HNF-1β mutant renal epithelial cells may identify new therapeutic targets for the treatment of cystic kidney diseases.

Funding: NIDDK Support

FR-PO510

Inactivation of Transcription Factor HNF-1β with CRISPR/Cas9 Induces Epithelial-Mesenchymal Transition Siu Chiu Chan,[1] Ying Zhang,[2] Sophia M. Vrba,[1] Svetlana Avdulov,[1] Karam S. Aboudehen,[1] Peter Igarashi.[1] *[1]Medicine, Univ of Minnesota, Minneapolis, MN; [2]Minnesota Supercomputing Inst, Univ of Minnesota, Minneapolis, MN.*

Background: Hepatocyte nuclear factor-1β (HNF-1β) is a tissue-specific transcription factor that is essential for the development of the kidney. Mutations of HNF-1β produce autosomal dominant tubulointerstitial kidney disease (ADTKD) characterized by tubular cysts, renal fibrosis, and progressive loss of kidney function. To understand the functions of HNF-1β, we generated HNF-1β-deficient mIMCD3 renal epithelial cells.

Methods: Gene editing with CRISPR/Cas9 was used to delete exon 1 of HNF-1β by non-homologous end joining (NHEJ). HNF-1β-deficient cells were characterized by RNA-seq, western blotting (WB), and assays of proliferation and cell migration.

Results: Three independent HNF-1β-deficient mIMCD3 cell lines and three paired control cell lines were established. qRT-PCR and WB confirmed the complete absence of HNF-1β expression. RNA-seq analysis of HNF-1β-deficient cells showed upregulation of 1,135 genes and repression of 759 genes compared to control cells. ChIP-seq analysis showed that 75% of the differentially expressed genes were direct targets of HNF-1β. Ingenuity Pathway Analysis (IPA) of the HNF-1β targets revealed that fibrosis and epithelial-mesenchymal transition (EMT) pathways were highly activated in HNF-1β-deficient cells. Canonical EMT markers, including vimentin, α-SMA and Zeb2, were up-regulated in HNF-1β mutant cells. HNF-1β mutant cells exhibited loss of contact inhibition and adopted a spindle-shaped morphology. Compared with control cells, HNF-1β-deficient cells had similar growth curves and rates of cell proliferation but exhibited increased cell migration. HNF-1β-deficient cells grown to confluence on Lumox discs produced a multilayered epithelium similar to the phenotype observed in kidneys from HNF-1β mutant mice and humans.

Conclusions: Loss of HNF-1β in renal epithelial cells is sufficient to induce EMT. HNF-1β-deficient mIMCD3 cells created by gene editing will be a useful reagent for unraveling the HNF-1β mutant phenotype.

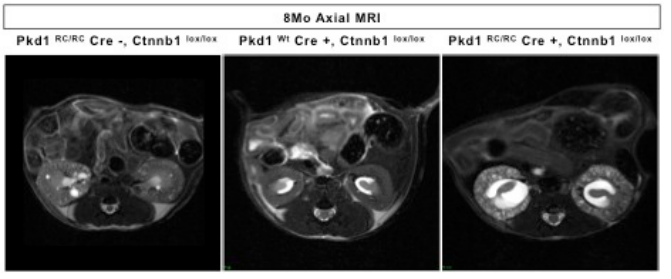
A Role for Canonical Wnt Signaling in Renal Development, Maintenance, and ADPKD Jennifer Arroyo, Cynthia J. Sieben, Vicente E. Torres, Peter C. Harris. *Nephrology & Hypertension, Mayo Clinic.*

Background: The developmental pathway, Wnt, is important for nephron development, and is suggested to be re-activated post-developmentally in response to injury, cancer and polycystic kidney disease (PKD). Increased Wnt signaling is hypothesized to contribute to increased proliferation in cystogenesis, with a possible direct interaction between Wnt ligands and the PKD1 protein, however assessments of Wnt activity in various PKD mouse models has yielded conflicting results.

Methods: To understand the contribution of Wnt signaling in PKD progression we analyzed the *TCF/Lef:H2B-GFP* transgenic Wnt reporter mouse interbred with the ADPKD mouse model, $Pkd1^{RC/RC}$. We also analyzed $Ctnnb1^{flox\ 2\text{-}6/flox\ 2\text{-}6}$, *Ksp-cadherin16 cre* mice alone and bred with $Pkd1^{RC/RC}$ to determine if loss of b-catenin expression in distal tubular segments could alter cystogenesis.

Results: As expected, *TCF/Lef:H2B-GFP* Wnt reporter mice revealed high levels of Wnt activity in tubules of P0 - P14 mice still undergoing tubule development. Interestingly, sustained Wnt activity within the medullary arrays of adult mice, 1m – 9m, was also observed. This expression was decreased by >75% in $Pkd1^{RC/RC}$, *TCF/Lef:H2B-GFP* mice as early as P2 and remained depressed for 9m. MRI analysis of $Ctnnb1^{flox/flox}$, *Ksp-cre* mice suggested Wnt signaling is needed for appropriate development of the urogenital system since all mice exhibited non-obstructive bilateral renal pelvic urine retention (Fig). This phenotype was markedly more severe in $Pkd1^{RC/RC}$, $Ctnnb1^{flox/flox}$, *Ksp-cre* mice, resulting in loss of medullary tissue. $Pkd1^{RC/RC}$, $Ctnnb1^{flox/wt}$, *Ksp-cre* mice did not exhibit this phenotype, but showed significantly increased cystic burden at 12m, compared to controls.



Conclusions: Our results show that sustained Wnt signaling in the postnatal kidney is necessary for kidney maintenance and reduced Wnt signaling may contribute to cystogenesis in ADPKD.

Stem/Progenitor Cells in Polycystic Kidney Disease Cyst Formation Timothy A. Fields, Jacqueline D. Peda, Connor J. Grantham, Ransom A. Ellis, Katherine Swenson-Fields. *Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by loss-of-function mutations in polycystins, encoded by *PKD1* (~85%) or *PKD2* (~15%). ADPKD is characterized by expanding renal tubular cysts that damage parenchyma, leading to organ failure by 5th-6th decade. Despite the fact that all cells within the nephron are predicted to contain at least one mutant *PKD1* or *PKD2* allele, only a subset of these cells form cysts. Recent data suggest that cysts form when functional polycystin expression falls below a specific threshold. Factors that may influence expression include second genetic hits, environmental stimuli, or the differentiation state of the cell. Interestingly, cyst lining cells in ADPKD have been shown to express high levels of stem/progenitor cell markers such as CD133. While it may be that CD133 expression is a secondary effect of cyst formation, it is equally possible that CD133+ progenitor cells are particularly susceptible to cystogenesis, potentially due to lowered polycystin expression.

Methods: To investigate potential roles for progenitor cells in cyst formation, we have developed a mouse model in which *Pkd1* can be inducibly deleted in cells expressing the progenitor marker CD133 (CD133-$Pkd1^{cko}$). *Pkd1* knockout was induced in CD133+ cells by tamoxifen given at post-natal day 2 and cystic kidney disease assessed.

Results: All of the CD133-$Pkd1^{cko}$ mice examined (n=9) developed cystic kidney disease by 1 month. Cyst formation was initially limited to outer medulla. Like human ADPKD, disease was worse in males and progressed slowly, involving both cortex and medulla by 2 months in males. Disease progression was characterized by injury and fibrosis, especially adjacent to cysts and areas drained by medullary regions affected by early cysts.

Conclusions: These data indicate that loss of *Pkd1* in CD133+ cells results in cystic kidney disease resembling ADPKD and imply that CD133+ progenitor cells contribute to ADPKD cyst formation. This novel orthologous ADPKD model could be a valuable tool, providing insights about mechanisms that control cystogenesis and disease progression.

Six2Frs2a Knockout Mice Are a Novel Model of Renal Cystogenesis Pawan Puri, Daniel S. Bushnell, Caitlin M. Schaefer, Carlton M. Bates. *Div of Nephrology, Dept of Pediatrics, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: *Six2cre*-mediated deletion of Frs2a (*Six2creFrs2aKO*), a docking protein for fibroblast growth factor receptors, in nephron progenitors results in progenitor loss and renal cyst formation. Our objective was to determine the molecular pathogenesis of cystogenesis in *Six2creFrs2aKO* mice.

Methods: We performed histological assays, Western blots, and quantitative PCR (qPCR).

Results: Histologically, embryonic day (E) 18.5 *Six2Frs2aKO* kidneys were hypoplastic but not cystic, P7 kidneys had a mixture of non-dilated tubules and proximal tubular (PT)-derived cysts, and P21 kidneys had cysts virtually replacing the renal parenchyma. We observed higher PT proliferation rates, progressive increases in interstitial fibrosis, and macrophage infiltration in *Six2creFrs2aKO* mutant kidneys versus controls, consistent with other polycystic kidney disease (PKD) models. Mechanistically, *Six2creFrs2aKO* kidneys showed upregulation of Wnt/b-catenin, inflammation, and hedgehog signaling pathways, additional features observed in other PKD models. Interestingly, we observed increased Gli1 (hedgehog effector) in the expanded P7 and P21 *Six2creFrs2aKO* interstitium by in

situ hybridization and aberrant increases in sonic hedgehog (Shh) ligand immunostaining in subsets of *non-dilated* P7 mutant PTs that was likely driving the stromal Gli expression. As ectopic tubular Shh is seen after acute kidney injury (AKI), we examined other AKI markers and found that increases in kidney injury molecular-1 (Kim1) and chemokine Ccl2 (macrophage chemotactic protein-1), also in non-dilated mutant PT cells in vivo. In cysts, we observed many lining cells that had lost expression of PT differentiation markers (e.g. LTL), re-expression of de-differentiation markers such as Pax2 and Ncam (often seen in regeneration after AKI), and inappropriate increases in phospho-Creb staining, a readout of cAMP/protein kinase A activity (a pathway known to drive cyst growth in PKD and that is also active after AKI).

Conclusions: Together, these observations suggest that aberrant early AKI and post AKI regenerative pathways may be driving renal pathogenesis in PKD.

FR-PO514

Smyd2 Regulates Renal Fibrosis via TGF-Beta-Smad2/3 Signaling in ADPKD Xiaoyan Li, Ewud Agborbesong, Xia Zhou, James P. Calvet, Xiaogang Li. *Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: In polycystic kidney disease (PKD), expansion of cysts and loss of renal function are associated with progressive fibrosis, which has been identified as the most significant manifestation associated with an increased rate of progression to ESRD. Anti-fibrotic therapy should be an effective adjunct to treatment of ADPKD. Smyd2, as a SET-domain-containing histone (lysine) methyltransferase, methylates both histone and non-histone proteins, including PKD associated p53, Rb and HSP90, to regulate gene expression and protein function, respectively. We found that Smyd2 promotes renal cyst growth in ADPKD via STAT3 and NF-κB signaling. However, the mechanisms by which Smyd2 regulates renal fibrosis remain unknown.

Methods: To understand the role of Smyd2 in renal fibrosis *in vivo*, we investigated renal fibrosis in *Pkd1* and *Smyd2* double conditional knockout mice (*Pkd1*$^{flox/flox}$:*Smyd2*$^{flox/flox}$:*Ksp-Cre*), and in *Pkd1*$^{nl/nl}$ *mice* and *Pkd1*$^{flox/flox}$:*tamoxifen-Cre* mice treated with a Smyd2 specific inhibitor, AZ505. To explore the pathways underlying Smyd2 mediated renal fibrosis, we also treated renal fibroblasts with AZ505.

Results: We found that knockout of Smyd2 and inhibition of Smyd2 with AZ505 not only delayed cyst growth but also decreased renal interstitial fibrosis in kidneys of *Pkd1* conditional knockout mice as examined by Trichrome Masson and Picrosirus red staining. *Pkd1* and *Smyd2* double knockout mice lived longer, to a mean age of 25 days, while *Pkd1* knockout mice died at a mean age of 17 days ($p < 0.001$). Treatment with AZ505 blocked TGF-β induced upregulation of fibrotic markers, including Col1A1, Col3A1, a-SMA and fibronectin, and decreased the phosphorylation of Smad2/3 in rat kidney interstitial fibroblasts (NRK-49F) as analyzed by qRT-PCR and Western blot. We also found that TGF-β can induce the expression of Smyd2 in a time dependent manner in these cells. Inhibition of Smyd2 with AZ505 decreased NRK-49F cell proliferation.

Conclusions: Smyd2 promotes renal fibrogenesis in ADPKD through the canonical TGF-β-Smad2/3 signaling pathway. Targeting Smyd2 with its inhibitor should not only delay cyst growth but also prevent interstitial fibrosis in ADPKD.

FR-PO515

SAHA Reduced cAMP Levels and Inhibited Renal Cyst Growth through HDAC6 Xin Li, Weiwei Shi, Ming Wu, Changlin Mei. *Dept of Nephrology, Kidney Inst, Shanghai Changzheng Hospital, Shanghai, China.*

Background: Inhibition of cyclic adenosine monophosphate (cAMP) by using Tolvaptan can delay disease progression in patients with autosomal dominant polycystic kidney diseases (ADPKD). However, it has not been approved by USA FDA because of its side effects. Recent study shows that inhibition of Histone deacetylases 6 (HDAC6) reduced cAMP levels and inhibited kidney growth in ADPKD animal models. We therefore hypothesized that treatment with suberoylanilide hydroxamic acid (SAHA), a FDA approved HDAC inhibitor, could retard PKD progression and lower cAMP levels in cystic kidneys.

Methods: Male rats were treated with 50mg/kg/day SAHA or vehicle at 4 weeks of age by gavage for 5 weeks. ADPKD cells were treated with various concentration of SAHA.

Results: Five weeks SAHA treatment reduced BUN and creatinine level by 37.7% (11.50±1.782mmol/L vs 18.15±2.988 mmol/L) and 40.8% (57.62±30.89umol/L vs 97.26±15.60umol/L) respectively in cystic Cy/+ Han:SPRD rats compared with cystic Cy/+ Han:SPRD rats treated with vehicle. Administration of SAHA decreased the two kidney weight/total body weight ratio and cystic volume density in Cy/+ rats by 25.2%(0.02056±0.004799 vs 0.02748±0.004628) and 39.7%(0.3337±0.02054 vs 0.5535±0.02214) respectively. The cell proliferation was inhibited by SAHA in cystic kidneys as shown by Ki-67 staining. SAHA reduced cAMP levels in Cy/+ kidneys, which was correlated with the down-regulation of HDAC6 expression and reduced phosphorylation of CREB. The inhibitory effect of SAHA on HDAC6 expression and cAMP levels was confirmed in ADPKD cells. In addition SAHA reduced protein levels of β-catenin and C-myc in cystic kidneys.

Conclusions: SAHA reduced cAMP levels and inhibited kidney growth in PKD, which may be mediated through HDAC6.

Structural Nephrology: 3D Analysis of Fibrocystin/Polyductin Bound to DNA Naoe Harafuji,[1] Ann C. Varano,[2] Deborah F. Kelly,[2] Lisa M. Guay-Woodford.[1] *[1]Center for Transitional Science, Children's National Health System, Washington, DC; [2]Virginia Tech Carilion Research Inst, Roanoke, VA.*

Background: ARPKD results from mutations in *PKHD1*, a transcriptionally complex gene that encodes a set of secreted and membrane-bound isoforms collectively referred to as FPC. The longest mRNA encodes a membrane-bound FPC that undergoes Notch-like proteolytic cleavage to generate a carboxy terminal domain (CTD-FPC) that translocates to the nucleus. We hypothesize that within the nucleus CTD-FPC assembles into gene regulatory complexes.

Methods: Mouse CTD-FPC was cloned into the modified p3XFLAG-CMV-7.1 vector, sequence-verified, and transfected into mIMCD-3 cells. Cell lysates were prepared and separated into cytoplasmic and nuclear fractions, with the purified nuclear fraction subjected to the "Affinity capture" technique (Sci Rep, 2015) to identify the nuclear assemblies that interact with the CTD-FPC. Captured complexes were examined using single particle Electron Microscopy (EM) methodologies.

Results: We found that Affinity-captured, natively-formed CTD-FPC nuclear assemblies were abundantly integrated into DNA networks (**Fig 1**). In parallel, we examined purified CTD-FPC assemblies using single particle EM. Classification-based computational routines revealed that these assemblies had some degree of heterogeneity, but that most complexes were ~15 nm in diameter. Representative 3D reconstruction of these complexes exhibited a ring-shaped architecture consistent with known DNA-binding motifs.

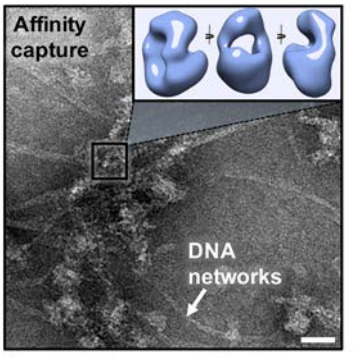

Figure 1. Affinity captured CTD-FPC assemblies integrated into DNA networks. Single particle 3D reconstruction (blue) of purified CTD-FPC assemblies in different orientations (inset). Scale bar, 50 nm.

Conclusions: The "Affinity capture" technique demonstrated that nuclear CTD-FPC is assembled into ring-shaped protein complexes, suggesting that CTD-FPC binds to DNA and plays a role in gene regulation. These initial studies provide a technical framework for elucidating the CTD-FPC nuclear structure-function relationship in renal epithelial cells. Mass spectrometry analysis of these complexes is in progress.

RNA Sequencing Analysis Reveals Upregulation of Endothelin-MAPK Signaling in Pre-Cystic Kidneys of Thm1 Conditional Knock-Out Mice Luciane M. Silva,[1] Damon T. Jacobs,[1] Bailey A. Allard,[1] Sumedha S. Gunewardena,[2] Pamela Vivian Tran.[1] *[1]Anatomy and Cell Biology, Kidney Inst, Kansas Univ Medical Center, Kansas City, KS; [2]Integrative and Molecular Physiology, Kansas Univ Medical Center, Kansas City, KS.*

Background: Primary cilia are non-motile sensory organelles that mediate signaling pathways and ciliary dysfunction leads to renal cystic disease. In mice, perinatal global deletion of *Thm1,* an intraflagellar transport–A component, causes renal cysts beginning at postnatal day 15 (P15). We aim to identify the molecular events that initiate renal cystogenesis in *Thm1* conditional knock-out (cko) mice.

Methods: We performed RNA sequencing (HiSeq2500, llumina) on whole kidney RNA lysates of pre-cystic P9 and cystic P42 *Thm1* cko mice and of controls (N=6/group), attaining 44X coverage/sample. Sequences were aligned to the mouse genome (GRCm38). Differential gene expression was calculated using Cuffdiff, and P-values were adjusted for false discovery by the Benjamini and Hochberg method. We reasoned that genes with significantly altered expression at both P9 and P42 would represent early initiation events leading to cystogenesis.

Results: We identified 10 genes significantly upregulated at P9 and further upregulated at P42 in *Thm1* cko kidneys. These included *endothelin 1* (*Edn1*), *fos* and *jun*, suggesting EDN1-MAPK signaling may play a role in renal cyst initiation and progression. Endothelial *Vcam1* and immune genes, *C3*, *Egr2* and *Adcy7*, were also upregulated, suggesting simultaneous alteration of signaling in renal epithelial, vascular and immune cells may potentiate renal cyst initiation. At P42, components of MAPK, TGF-β, mTOR, Stat, Wnt, Notch, and Hedgehog pathways were upregulated, suggesting molecular changes similar to those in Autosomal Dominant Polycystic Kidney Disease (ADPKD). These data are being validated *in vivo* in *Thm1* cko renal tissue and *in vitro* using a clonal *Thm1* knock-down collecting duct M1 cell line.

Conclusions: EDN1 is increased in serum of ADPKD patients and *EDN1* polymorphisms are associated with ADPKD severity. Our data suggest misregulation of EDN1-MAPK signaling as an early initiation event in renal cystic disease that merits further exploration.

Expression of Activated BRAF(V600E) in Collecting Ducts Accelerates Cyst Growth and Fibrosis in Renal Cystic Disease Archana Raman, Stephen C. Parnell, Aditi Khanna, Yuqiao Dai, Grant Aaron Johnson, Gail Reif, Timothy A. Fields, Darren P. Wallace. *Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: In polycystic kidney disease (PKD), aberrant cell proliferation is responsible for the growth of fluid-filled cysts leading to enlarged kidneys and progressive decline in renal function. Mutations in the PKD genes are thought to cause dysregulation of intracellular Ca^{2+}, leading to reduced basal intracellular Ca^{2+} levels in cystic cells compared to normal kidney cells and cAMP-dependent activation of the BRAF/MEK/ERK pathway. This pathway is thought to be important for driving aberrant cell proliferation in PKD.

Methods: To determine the role of BRAF on renal cyst formation, we generated mice that conditionally express $BRAF^{V600E}$, a common activating mutation in BRAF found in cancer. We used *Pkhd1-Cre* to selectively overexpress $BRAF^{V600E}$ in collecting ducts (CD) of wildtype (WT) mice. $BRAF^{V600E}$ was also expressed in cystic epithelial cells by crossing these mice with *pcy/pcy* (*pcy*) mice, a slowly progressive model of PKD that develops predominantly CD-derived cysts.

Results: CD-specific expression of $BRAF^{V600E}$ in WT mice caused hyperproliferation and cystic dilation of CD, formation of small cysts, and prominent interstitial fibrosis. CD-specific expression of $BRAF^{V600E}$ in *pcy* mice caused a striking increase in kidney weight to body weight, cyst number and size, and total cystic area compared to littermate *pcy* mice. There was also a significant increase in phosphorylated ERK and Ki-67 positive cells, consistent with elevated MEK/ERK-dependent cell proliferation. There was extensive infiltration of immune cells and a four-fold increase in interstitial fibrosis that extended through the cortex of the cystic kidneys.

Conclusions: Our results demonstrate that activation of the BRAF/MEK/ERK pathway in renal epithelial cells is sufficient to induce cyst formation and accelerate the progression of cystic disease in PKD mice.

FR-PO519

Genetic Interaction between XBP1 and Pkd1 Modulates Cyst Progression in ADPKD Sorin V. Fedeles, Yasunobu Ishikawa, Rachel Gallagher, Stefan Somlo. *Internal Medicine/Nephrology, Yale School of Medicine, New Haven, CT.*

Background: *Pkd1* is one of the two genes responsible for autosomal dominant polycystic kidney disease (ADPKD). *XBP1* encodes the main chaperone modulator of the ER unfolded protein response. *Sec63* is one of the genes mutated in isolated familial polycystic liver disease (PCLD). *Sec63* and *XBP1* interact genetically to modulate *Pkd1* function in PCLD. In the current work we investigated whether *XBP1* can exhibit a direct genetic interaction with *Pkd1* independently of *Sec63*.

Methods: $Pkd1^{fl/fl}$;*Pkhd1-Cre* (SKO) and$Pkd1^{fl/fl}$;$XBP1^{fl/fl}$;*Pkhd1-Cre*(DKO) mouse models with conditional inactivation of *Pkd1* and *XBP1* alone or together in the collecting duct were evaluated at P24 by morphological and biochemical parameters: kidney to body weight ratio (KW/BW), cystic index, creatinine and rates of apoptosis and proliferation.

Results: Deletion of *Pkd1* using *Pkhd1-Cre* in SKO leads to severe cyst formation at P24. DKO mice display decreased KW/BW as compared to the SKO animals (~2.7 fold decrease in KW/BW, 0.5+/-0.1 vs. 1.4+/-0.2 respectively, ***p<0.001). These changes were accompanied by a ~1.5-fold decrease in cystic index (42+/-1.3 vs. 70+/-1.5, ***p.0.001) and a 2-fold decrease in serum creatinine levels (0.21+/-0.02 vs. 0.45+/-0.05, **p<0.01). These effects were *XBP1* specific as restoration of spliced XBP1 expression via Cre activation of *floxstop-ROSA-XBP1s* led to morphological and functional parameters similar to the SKO mice. The cystic epithelia in the DKO mice displayed extensive apoptosis compared to SKO animals alone (4.7% vs. 0.1%, ***p<0.001) with no changes in proliferation. The level of active *XBP1s* expression was not different between the WT and SKO animals indicating that baseline levels of *XBP1s* are critical for maintaining the viability of *Pkd1* cystic cells *in vivo*.

Conclusions: Our data show that *XBP1* is a novel genetic interactor of *Pkd1* and can modulate the progression of ADPKD in murine models by protecting *Pkd1* cyst cells from apoptosis. Avenues that can reduce homeostatic XBP1 signaling *in vivo* may hold therapeutic potential by selectively promoting apoptosis in *Pkd1* deficient backgrounds.

FR-PO520

Interaction of Gα12 and Pkd1 in Renal Cystogenesis Jen Xu,[1] Tzongshi Lu,[1] Wassim El-Jouni,[2] Joseph V. Bonventre,[1] Jing Zhou,[1] Bradley M. Denker,[3] Tianqing Kong.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Nephrology Div, Massachusetts General Hospital, Boston, MA; [3]Renal Div, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common life-threatening genetic diseases and is characterized by early formation and gradual enlargement of multiple kidney cysts, which eventually results in end-stage renal disease (ESRD). Mutation of PKD1 is responsible for the majority of autosomal dominant polycystic kidney disease (ADPKD). The signaling pathways of PC1 in ADPKD are not fully understood.

Methods: Generation of inducible Pkd1 knockout mice (Mx1Cre+Pkd1flox/flox) were made by exons 2 through 6 were flanked by two LoxP sites. These mice were crossed with the mice of transgenic Cre recombinase under the control of INF-inducible Mx1 promoter (Mx1Cre mice). Gα12-deficient mice (Gα12-/-) were generated by replacement of exon 4 with reverse Neo gene. Double knockout of Pkd1 and Gα12 mice were obtained by crossing Mx1Cre+Pkd1flox/flox mice with Gα12-/- mice. Madin-Darby canine kidney (MDCK) Tet-off inducible Gα12 and Gα12QL cell lines were characterized for three-dimensional cell culture.

Results: Our results provided genetic evidence that Gα12 was essential for the development of kidney cysts induced by Pkd1 knockout. There was no phenotype in mice with deletion of Gα12 (Gα12-/-). Conditional deletion of Pkd1 (Pkd1-/-) in one week old mice resulted in multiple kidney cysts by 9 weeks, but the mice with double knockout of Pkd1 and Gα12 (Pkd1-/-Gα12-/-) had no structural and functional abnormalities in the kidneys. These mice could survive more than one year without kidney abnormalities except multiple hepatic cysts in some mice, which indicates that the effect of Gα12 on cystogenesis is kidney-specific. Furthermore, deletion of Pkd1 increased the activation of Gα12, which subsequently decreased cell-matrix and cell-cell adhesion by affecting the function of focal adhesion, and E-cadherin, respectively.

Conclusions: Our data demonstrate that Gα12 signaling is critical for renal cystogenesis in ADPKD induced by Pkd1 mutation.

FR-PO521

CU062 Is a Novel Protein That Interacts with Polycystin-1 and Activates Polycystin-2 Channels in Primary Cilia Wendy A. Lea,[1] Steven Kleene,[2] Nancy Kleene,[2] Christopher J. Ward.[1] *[1]Div of Nephrology and Hypertension, Dept of Medicine, Univ of Kansas Medical Center, Kansas City, KS; [2]Dept of Molecular and Cellular Physiology, Univ of Cincinnati, Cincinnati, OH.*

Background: Polycystin-1 (PC1), the product of the *PKD1* gene, has a large 3048 aa extracellular domain, with no known ligands. Over 30% of the protein is composed of PKD β-barrel domains. In an attempt to identify candidate interactors, we compared the proteome of a PC1 rich urine exosomal fraction (PKD-ELVs) from individuals with *PKD1* mutations with that of individuals with normal kidneys. CU062 was identified as a small glycoprotein that was decreased to 44% in *PKD1* versus controls (p = 0.001, q = 0.0001). CU062 is the product of the *C21orf62* gene in the Down syndrome critical region.

Methods: A DNA deletion series for PC1 was produced to map interactions. We also made recombinant C-terminally tandem affinity tagged CU062 in HEK-293 cells for electrophysiological studies. Recordings were performed on the primary cilia of IMCD3 cells on microcarrier beads. Recombinant CU062 was applied to the cilium via the recording pipette and currents measured 2 minutes after application for an 18 minute duration.

Results: CU062 can IP mature PC1 by recognizing PKD domains. CU062 can robustly and reciprocally IP constructs containing PKD repeats 2-17. The terminal three PKD domains (PKD15-17) have a remarkable affinity for CU062, which resists heating to 65ºC and non-reducing SDS-PAGE. CU062 is heavily glycosylated, with a mass of 42 kDa, which decreases to 21 kDa after deglycosylation, and has the ability to oligomerize on non-reducing gels. Applying recombinant CU062 to the primary cilia of IMCD3 cells activates the PC2 channel. At baseline, the current was 100.3 ±119 (SD), while the addition of 10 nM CU062 increased current to 641.1 ±801 (SD) (p = 0.014 (Welch *t*-test), p = 0.0006 (Wilcoxon rank)).

Conclusions: CU062 interacts with the extracellular PKD domains of PC1 and, when applied to primary cilia, increases currents that are due to PC2 channel opening. CU062 will be a useful tool in the investigation of PC1 signaling.

FR-PO522

The Lonidamine Derivative H2-Gamendazole Inhibits Cyst Growth in Pkd1-Deficient Kidneys by Targeting Numerous Cellular Pathways Xia Zhou,[1] Brenda S. Magenheimer,[1] Gunda I. Georg,[2] Joseph S. Tash,[1] Xiaogang Li,[1] James P. Calvet.[1] *[1]Univ of Kansas Medical Center, Kansas City, KS; [2]Univ of Minnesota, Minneapolis, MN.*

Background: Cyst growth and polycystic kidney disease (PKD) progression involve abnormal cellular processes including increases in cell proliferation, fluid secretion, inflammation, and fibrosis. H2-gamendazole (H2-GMZ) is a small molecule indazole carboxylic acid that is well-tolerated in animal studies and is currently under investigation for PKD therapy. H2-GMZ appears to function as an Hsp90 inhibitor, but also targets CFTR chloride channel activity, and the actin cytoskeleton. To better understand the extent to which H2-GMZ is able to improve kidney function we investigated global gene expression by RNA sequencing (RNA-seq) analysis.

Methods: H2-GMZ treatment was carried out on Pkd1 floxed, Pkhd1-Cre mice using daily i.p. injections of 20 mg/kg H2-GMZ from postnatal (PN) day 8 to 18. Total RNA was isolated from PN 19-day wild-type and cystic kidneys that were H2-GMZ treated or vehicle treated. Kidney tissue from three mice (2 males, 1 female) from each group was separately analyzed. RNA was sequenced and analyzed by CLC Genomics Workbench and Ingenuity Pathway Analysis (IPA).

Results: Mice treated with H2-GMZ had significantly reduced cystic index, kidney weight to body weight (KW/BW), and improved blood urea nitrogen (BUN). Continued daily treatment with H2-GMZ extended average survival from 28.8±5 days (n=8) to 67.8±23 days (n=5) (p<0.01). RNA-seq demonstrated that genes up- or down-regulated in

cystic kidneys were normalized by H2-GMZ. Among the most significant changes in cystic kidneys were upregulation of immune pathways and their effectors and downregulation of calcium signaling, among others.

Conclusions: The significant improvement in kidney function and mortality suggests that H2-GMZ may be effective in treating PKD. This was supported by RNA expression analysis which indicated that there were minimal effects on wild-type kidneys and that gene expression pathways were normalized by H2-GMZ. Of particular interest was the observation of a decrease in calcium signaling and a robust acute phase response in cystic kidneys, both of which were normalized by H2-GMZ.

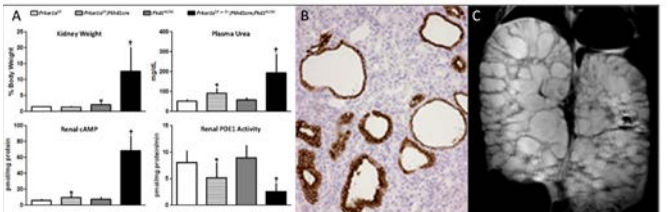
PRKAR1A Controls Renal Cystogenesis Hong Ye,[1] Xiaofang Wang,[1] Megan M. Constans,[1] Caroline R. Sussman,[1] Maria V. Irazabal,[1] William F. Young,[1] Peter C. Harris,[1] Lawrence S. Kirschner,[2] Vicente E. Torres.[1] *[1]Mayo Clinic, Rochester, MN; [2]Ohio State U, Columbus, OH.*

Background: Although cAMP signaling is thought to be upregulated in PKD, a role for PKA has not been directly demonstrated *in vivo*. PKA exists as an inactive holoenzyme with two catalytic (C) and two regulatory (R) subunits (R inhibiting C). Upon binding of cAMP to R, C subunits are released and activated. The knockout of the RIα encoding gene (*Prkar1a*) is embryonic lethal. *PRKAR1A* mutations cause autosomal dominant Carney complex (a multiorgan tumoral syndrome) which shares features with ADPKD (loss of heterozygosity and haploinsufficiency mechanisms, proliferative response to cAMP).

Methods: To investigate the role of R1α in PKD we created a kidney specific knockout by crossing *Prkar1a*$^{lox/lox}$ and Pkhd1Cre mice. This was also bred into a *Pkd1*$^{RC/RC}$ background. To ascertain whether cystic disease is associated with *PRKAR1A* mutations in humans we reviewed abdominal MR or contrast enhanced CT scans of 9 patients (2 M, 7 F; 39±18 yo, range 12-63) with Carney complex (six with proven *PRKAR1A* mutations).

Results: Kidney specific *Prkar1a* knockout by itself resulted in increased P-CREB and P-ERK levels, epithelial cell proliferation, numerous bilateral cysts (positive for THP, EMA or AQP2), interstitial inflammation and fibrosis, and elevated plasma urea (Figure 1A-B). *Prkar1a*, which contains cAMP response elements in its promoter region,was overexpressed in *Pkd1*$^{RC/RC}$ mice. *Prkar1a* renal homozygous or heterozygousknockout in *Pkd1*$^{RC/RC}$ mice markedly increased renal cAMP (likely due to PKA induced phosphorylation and inhibition of PDE1) and the severity of PKD (Figure 1A,C). Four and 7 of the 9 Carney patients had renal (3.3 per patient, range 1-9) and hepatic (3.9, range 1-8) cysts, respectively.



A) Kidney weights and labs in 16 wk old *Prkar1a*^{lox} (n=10), *Prkar1a*^{lox};Pkhd1cre (n=9) and *Pkd1*$^{RC/RC}$ (n=20) mice, and in 4-6 wk old *Prkar1a*$^{lox+/lox}$;Pkhd1cre; *Pkd1*$^{RC/RC}$ (n=6) mice; B) Immunostaining for AQP-2 in a 16 wk old *Prkar1a*^{lox};Pkhd1cre mouse; C) Coronal MR image in a 5 wk old *Prkar1a*^{lox};Pkhd1cre; *Pkd1*$^{RC/RC}$ mouse.

Conclusions: These observations confirm the importance of PKA in the pathogenesis of PKD and that the expression of *Prkar1a* controls this cystogenic pathway.

FR-PO524

Developing a Mouse Model Better Reflecting ARPKD Renal Disease Severity Rory Olson,[1] Katharina Hopp,[2] Vladimir Gainullin,[1] Peter C. Harris.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Div of Renal Diseases and Hypertension, Univ of Colorado, Denver, CO.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is the most common infantile form of PKD, associated with perinatal lethality and childhood ESRD. The disease is caused by mutations to *PKHD1,* however, the function of the *PKHD1* gene product, fibrocystin/polyductin (FCP), remains unknown. Of note, mouse *Pkhd1* null models have relatively mild renal disease and hence are unsuitable for detailed pathomechanistic analyses.

Methods: Breeding *Pkhd1* null (*Pkhd1*$^{LSL/LSL}$) animals to the *Pkd1* hypomorphic model (p.R3277C; RC) (*Pkd1*$^{RC/RC}$), we generated *Pkhd1*$^{-/-}$;*Pkd1*$^{RC/RC}$ mice, and homozygous/heterozygous combinations. The phenotype was assayed by percent kidney weight to body weight (%KW/BW), cyst index, IF of tubule markers and expression differences analyzed, including by RNA-Seq.

Results: The digenic, homozygous mice (*Pkhd1*$^{-/-}$;*Pkd1*$^{RC/RC}$) died exclusively postnatally (median survival time=P17, p=0.0001) with enlarged kidneys due to rapid expansion of collecting duct-derived cysts, a phenotype similar to human ARPKD, whereas *Pkhd1*$^{-/-}$ or *Pkd1*$^{RC/RC}$ animals presented no or mild disease (%KW/BW at P0: 2.63±0.49 vs 1.0±0.25 or 1.43±0.16, respectively, p<0.0001 [ANOVA]). Interestingly, at 6m the %KW/BW and cyst index of *Pkhd1*$^{-/-}$;*Pkd1*$^{+/RC}$ and *Pkhd1*$^{+/-}$;*Pkd1*$^{RC/RC}$ animals were not significantly different from single homozygote controls (%KW/BW: 1.57±0.12 and 2.01±0.15). These results suggested a threshold effect where 3 mutant alleles did not significantly modulate the disease phenotype, but 4 mutant alleles (no FPC and ~40% PC1) resulted in severe PKD. Targeted analysis of altered pathways in the digenic homozygous animals showed upregulation of c-MYC. To further understand the pathways altered, RNA-Seq analysis was completed, revealing signaling signatures for severe and mild cyst progression.

Conclusions: This mouse model, which reflects the human severity of ARPKD, can be effectively studied to reveal the molecular defects associated with the loss of *Pkhd1*. These results indicate shared signaling events between ARPKD and ADPKD, suggesting that therapeutic intervention for ADPKD may also be beneficial to ARPKD patients.

Fibronectin Signaling Modulates Cyst Progression in Models of Autosomal Dominant Polycystic Kidney Disease Ming Ma,[1] Rachel B. Simon,[2] Yasunobu Ishikawa,[1] Xin Tian,[1] Ke Dong,[1] Yiqiang Cai,[1] Chao Zhang,[1] Takao Sakai,[3] Stefan Somlo.[1,4] *[1]Dept of Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Barnard College, Columbia Univ, New York, NY; [3]Dept of Molecular and Clinical Pharmacology, Inst of Translational Medicine, The Univ of Liverpool, Liverpool, United Kingdom; [4]Dept of Genetics, Yale School of Medicine, New Haven, CT.*

Background: Loss of cilia suppresses cyst growth in genetic models of autosomal dominant polycystic kidney disease (ADPKD) suggesting that cilia harbor a signal that stimulates cyst progression when polycystin function is impaired. Integrin receptors for extracellular matrix (ECM) proteins have been shown to be expressed on the cilia membrane and integrin β1 (ItgB1) receptor knockout has been shown to be protective in an early onset mouse model of ADPKD. Moreover, ECM remodeling has been observed in multiple models of cystic kidney disease, including ADPKD models. We investigated whether integrin signaling is one of the drivers of cyst formation in ADPKD.

Methods: We examined expression of integrin signaling pathway components in cilia and inactivated components of integrin signaling in early onset and adult inducible *Pkd1* and *Pkd2* mouse models of ADPKD.

Results: We confirmed that ItgB1, ItgA3 and ItgA5 are expressed in the cilia of LLC-PK1 cells and that loss of ItgB1 in collecting duct cells suppresses cyst growth in an early developmental model. Surprisingly, we found that inactivation of ItgB1 does not protect, and may actually promote, cyst growth in the adult inducible mouse models of ADPKD. In contrast, inactivation of the integrin ligand fibronectin in the kidney tubules suppresses cyst growth and preserves renal function in both the early and adult onset ADPKD models.

Conclusions: ItgB1 exhibits discordant roles for cyst progression in developmental and adult models of ADPKD, excluding a role for ciliary ItgB1 as the cilia dependent signal for cyst formation in ADPKD. Fibronectin produced by kidney tubule cells promotes cyst growth in *Pkd1* and *Pkd2* models suggesting that targeting fibronectin or other ECM molecules may offer therapeutic benefits for the treatment of ADPKD.

The AAA ATPase Ruvbl1 Is Essential for the Maintenance of Tubular Architecture and Renal Function In Vivo Claudia Dafinger,[1,2] Markus M. Rinschen,[1,3] Martin Höhne,[1,3,4] Rachel H. Giles,[6] Dorien J.M. Peters,[5] Thomas Benzing,[1,3,4] Bernhard Schermer,[1,3,4] Max Liebau.[1,2] *[1]Dept II of Internal Medicine and Center for Molecular Medicine, Univ Hospital of Cologne, Cologne, Germany; [2]Dept of Pediatrics, Univ Hospital of Tuebingen, Cologne, Germany; [3]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Univ of Cologne, Cologne, Germany; [4]Systems Biology of Ageing Cologne (Sybacol), Univ of Cologne, Cologne, Germany; [5]Depts of Human Genetics, Leiden Univ Medical Center, Leiden, Netherlands; [6]Dept of Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Cystic kidney diseases are among the most common causes of end stage renal disease in childhood and adolescence. Despite the recent progress in the understanding of the underlying molecular mechanisms, the pathogenesis of cystic kidney diseases remains incompletely understood. We recently identified the highly conserved AAA ATPase Ruvbl1 as a cilia-associated protein and could show that targeted deletion of Ruvbl1 in the distal tubule leads to a severe renal phenotype in mice.

Methods: To understand the role of Ruvbl1 for maintenance of tubular function and tubular architecture beyond renal development we generated an inducible tubule-specific Ruvbl1 knockout mouse. To identify components of the Ruvbl1 protein complex we also performed label-free quantitative mass spectrometry after immunoprecipitation of Ruvbl1.

Results: Induced deletion of Ruvbl1 is associated with progressive weight loss and deterioration of kidney function as well as minor cystic tubular changes. Histological and interactome data suggest both non-ciliary and cilia-associated functions of Ruvbl1.

Conclusions: Ruvbl1 is a novel cilia-associated protein required for maintenance of tubular architecture and renal function in mice.

Microcrystals Promote Cystogenesis and Exacerbate Polycystic Kidney Disease Jacob A. Torres,[1] Mina Rezaei,[1] Louis Lin,[1] Caroline M. Broderick,[1] Saeed R. Khan,[2] Vicente E. Torres,[3] Benjamin D. Cowley,[4] Thomas Weimbs.[1] *[1]Molecular Cellular Developmental Biology, Univ California Santa Barbara, Santa Barbara, CA; [2]Dept of Pathology, Univ of Florida, Gainseville, FL; [3]Dept of Nephrology, Mayo Clinic, Rochester, MN; [4]Dept of Medicine, Oklahoma Univ, Oklahoma City, OK.*

Background: ADPKD is a slowly progressive disease characterized by the accumulation of fluid-filled cysts that slowly replace normal functioning kidney tissue resulting in renal failure. The rate of disease progression is highly variable amongst individuals suggesting that it is affected by unknown environmental factors. Individuals with ADPKD suffer from a number of renal pathologies including nephrolithiasis. Its thought that occurrences of renal calculi are secondary to ADPKD and are merely a sign of improper kidney function. Microcrystals formed in the urinary filtrate, are usually cleared through luminal passage but may lodge in tubules leading to obstruction.

Methods: Han:SPRD rats were challenged with ethylene glycol leading to CaOx crystal deposition in male rats. To investigate whether PKD progression is specific only to CaOx crystals, PCK rats were fed a high phosphate diet leading to tubular calcium phosphate crystal deposition in renal tubules.

Results: We found that calcium oxalate or phosphate crystal deposition in renal tubules of the Han:SPRD and PCK rats respectively, leads to rapid increases in tubule diameters and activation of mTOR, Src and STAT3 signaling pathways.

Conclusions: Tubule dilation and mTOR, Src and STAT3 signaling pathways are aberrantly activated in ADPKD. We hypothesized that crystal deposition may act as a trigger for cystogenesis in ADPKD. Han:SPRD rats challenged with ethylene glycol led to an increase in cyst size and cyst numbers as did CaP crystals. Together, these results suggest luminal microcrystals may act as triggers of cyst formation in PKD and that environmental factors such as diet that lead to increased crystal burden accelerate progression of PKD. These findings suggest that established therapeutic intervention for reducing renal crystal formation may prove effective in ADPKD patients.

Biochemical Changes in Cystic Epithelia of Feline Autosomal Dominant Polycystic Kidney Disease Laurie A. Smith,[1] Sarah E. Moreno,[1] Kelly A. Rogers,[1] Ryan J. Russo,[1] Hyejung Park,[2] Bing H. Wang,[2] Christine M. Adreani,[1] Leslie A. Lyons,[3] Oxana Beskrovnaya,[1] Thomas A. Natoli.[1] *[1]R&D Center, Sanofi-Genzyme, Framingham, MA; [2]Analytical R&D, Sanofi-Genzyme, Waltham, MA; [3]College of Veterinary Medicine, Univ of Missouri, Columbia, MO.*

Background: Human Autosomal Dominant Kidney Disease (ADPKD) is characterized by kidney cyst growth leading to ESRD due to a mutation in the PKD1 or PKD2 gene. Cystic epithelial cells demonstrate hyperplasia, apoptosis, and aberrant fluid secretion that together drives cyst growth. The phenotypic changes are accompanied by dysregulated cell-signaling activities, including activation of the mTOR, MAPK, Wnt, and VEGF signaling pathways, increased intracellular cAMP, glycosphingolipid accumulation, and metabolic alterations resulting in aerobic glycolysis and oxidative stress. Mice with heterozygous germline mutations in Pkd1 or Pkd2 rarely develop cysts. Murine models are widely used to test potential therapies, but testing in a relevant non-murine model of ADPKD could further de-risk clinical trials. Feline ADPKD results from an autosomal dominant nonsense mutation in the PKD1 gene and presents with clinical manifestations that resemble the human disease. However, very little biochemical characterization has been analyzed and reported. Therefore, in this study, we assessed the biochemical changes in the cystic kidneys in feline ADPKD and report analogy to human ADPKD.

Methods: Antibodies to proteins that are dysregulated in human ADPKD were screened for cross-reactivity to feline samples. Immunohistochemistry, immunofluorescence, and western blotting were used to examine protein expression. Glycosphingolipid accumulation was measured by LC/MS/MS.

Results: Cross-reactive antibodies to markers of proliferation, mTOR, MAPK, Wnt and TGFb signaling were identified. Cystic epithelium demonstrated increased proliferation, mTOR activity, MAPK activity, VEGF activation, and oxidative stress compared to surrounding normal tissue by immunohistochemical analysis. Feline cystic kidneys have increased glycospingolipid levels compared with normal.

Conclusions: Biochemical changes in cystic epithelium of feline ADPKD resemble those reported in human ADPKD.

FR-PO529

Quantitative Proteomic and Phosphoproteomic Analyses of Vasopressin V2R Dependent Signaling in Cultured Collecting Duct Cells with and without Primary Cilia Caroline Pahmeyer, Thomas Benzing, Malte P. Bartram, Bernhard Schermer, Markus M. Rinschen. *Dept II of Internal Medicine, Univ Hospital Cologne, Cologne, Germany.*

Background: The role of primary cilia in the pathogenesis of autosomal-dominant polycystic kidney disease (ADPKD) is well established. ADPKD progression is promoted by activation of the vasopressin-V2-receptor and dysregulated downstream kinase pathways. At this point the impact of cilia or ciliary signaling is ambiguous. We analyzed whether ablation of cilia *per se* could interfere with vasopressin signaling in collecting duct cells.

Methods: We generated collecting duct cell lines expressing a dominant negative Kif3A to abrogate ciliogenesis. We analyzed proteomic and phosphoproteomic perturbations of the V2-receptor signaling in both cell lines at different timepoints.

Results: Comparison of the proteome of unciliated Kif3A HL cells with control cells confirmed that membrane proteins and proteins belonging to the ciliary core, the axoneme, were altered. In the control cell line, we found that both long term (proteome) and short term (phosphoproteome) dependent changes in signaling were largely similar to previous studies. In addition, we found that ciliary ablation per se had only minor effects on the long-term response of vasopressin dependent signaling. However, analysis of short-term perturbation of the phosphoproteome revealed that ciliary ablation blunted phosphorylation of polarity dependent proteins, such as Cofilin and Marcks at known regulatory sites, without affecting subcellular localization of Marcks. Using network analysis, we found that phosphorylation sites in the control conditions were mainly present in substrates of Protein kinase A, calmodulin-dependent kinases and ERK-MAP-Kinases, whereas proteins in the ciliary ablated condition were also interactors of Map-kinases-kinases. V2R dependent ERK inhibition, however, was present in both cell lines.

Conclusions: In summary, our data reveal only subtle changes of long-term and short term response of V2R-induced signaling caused by ciliary ablation. Thus, the switch in global vasopressin signaling network which occurs in ADPKD cells might not primarily be modulated by cilia or ciliary signaling.

Mitochondrial Dysfunction Contributes to Cyst Proliferation of Autosomal Dominant Polycystic Kidney Disease Yu Ishimoto,[1] Masaomi Nangaku,[1] Masanori Kugita,[2] Shizuko Nagao,[2] Akira Shimizu,[3] Jing Zhou,[4] Reiko Inagi.[1] *[1]Nephrology and Endocrinology, Tokyo Univ, Tokyo, Japan; [2]Education and Research Center of Animal Models for Human Diseases, Fujita Health Univ, Aichi, Japan; [3]Dept of Analytic Human Pathology, Nippon Medical School, Tokyo; [4]Center for Polycystic Kidney Disease Research and Renal Div, Brigham and Women's Hospital, Harvard Medical School, Cambridge.*

Background: Pathological derangements characteristics of autosomal dominant polycystic kidney disease (ADPKD), such as continuous proliferation of cyst epithelial cells, show marked similarities to those of solid tumors. Mitochondria of tumor cells have been reported to differ functionally from those of normal cells and contribute to tumor phenotype. Therefore, we focused on mitochondrial function in ADPKD.

Methods: Comparedmitochondrial DNA (mtDNA) copy number, PGC-1α (a master regulator of mitochondrial biogenesis) expression, and mitochondrial morphology by electron microscopy utilizing ADPKD model rat (Han:SPRD Cy rat) and cultured human ADPKD cyst epithelial cell. To address the molecular mechanism of the mitochondrial alteration, mitochondrial reactive oxygen species (mtROS), ERK1/2 activity, intracellular calcium flux, and calcineurin activity were assessed in vitro. Further, the effect of mitochondria targeted therapy with MitoQ on cyst cell proliferation was evaluated.

Results: Renal mtDNA copy number was decreased with disease progression from early stage of ADPKD and PGC-1α expression was reduced in the cyst lining cells compared with normal tubules ($p<0.05$). These changes were associated with swelling and fragmentation of mitochondria in cyst epithelial cells. Similar results were observed in vitro. Of note, we found that decreased intracellular calcium level reduced PGC-1α expression through inactivation of calcineurin, and thereby deranged mitochondrial biogenesis, which induced cyst cell proliferation via increased mtROS and activation of ERK1/2. Moreover, the reduction of mtROS with MitoQ significantly suppressed the cyst cell proliferation.

Conclusions: Mitochondrial dysfunction contributes to cyst epithelial cell proliferation in ADPKD. Mitochondria may be a new therapeutic target for ADPKD.

FR-PO531

Beta-1 Integrins and Extra-Mitochondrial Electron Transport Contribute to Aerobic Glycolysis in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Wassim El-Jouni,[1] Brian D. Adair,[1] Wondong Kim,[1] Rachid Akiki,[2] Eugene P. Rhee,[1] Georges El Fakhri,[2] M. Amin Arnaout.[1] *[1]Dept of Medicine/Nephrology, Massachusetts General Hospital, Boston, MA; [2]Dept of Radiology, Massachusetts General Hospital, Boston, MA.*

Background: Increased cell proliferation in ADPKD imposes a critical requirement for nutrients, a demand achieved by increasing glucose uptake and diverting cell metabolism away from mitochondrial oxidative phosphorylation towards aerobic glycolysis. This metabolic switch converts pyruvate into lactate in the cytoplasm despite the presence of oxygen and a functional mitochondrial TCA cycle. Little is known about the cellular pathways leading to this metabolic switch in ADPKD.

Methods: We analyzed cultured DBA^+ mouse embryonic kidney cells isolated from *Pkd1*$^{-/-}$ E15.5 embryos and wild type littermates using [^{18}F]Fluoro-2-deoxy-D-glucose ([^{18}F]FDG) single cell positron emission tomography (SCPET) imaging, metabolomics, and real time measurements of cellular respiration (oxygen consumption rate, OCR, extracellular acidification rate, ECAR).

Results: We made the following observations. 1) [^{18}F]FDG SCPET revealed increased glucose uptake at the single cell level. 2) LC-MS-based metabolomics profiling of *Pkd1*$^{-/-}$ vs. WT cells showed increased glycolytic intermediates, associated with significant increases in pentose phosphate pathway metabolites and decreases in several TCA cycle intermediates in the *Pkd1* null cells. 3) An extra-mitochondrial redox pathway, located in the plasma membrane and blocked by a specific inhibitor, makes a major contribution to glucose-

driven cellular oxygen consumption and proliferation of *Pkd1*$^{-/-}$cells. 4) Stable silencing of integrin β1 inhibited OCR in *Pkd1*$^{-/-}$cells, suggesting a critical role for β1 integrin signaling in aerobic glycolysis in these cells.

Conclusions: These studies elucidate important mechanisms underlying abnormal cell metabolism in murine ADPKD, and identify potential targets for therapeutic intervention.

FR-PO532

Suppressing Both Renin and Angiotensinogen Synthesis Slows Acceleration of Cystogenesis Induced by Unilateral Nephrectomy in Pkd1 Mice Takamitsu Saigusa,[1] Yujing Dang,[1] Catalin F. Baicu,[2] Michael Zile,[2] Adam E. Mullick,[4] Wayne R. Fitzgibbon,[1] P. Darwin Bell.[3] *[1]Div of Nephrology, Medical Univ of South Carolina (MUSC), Charleston, SC; [2]Div of Cardiology, MUSC, Charleston, SC; [3]Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL; [4]Ionis Pharmaceutical, Carlsbad, CA.*

Background: Intrarenal renin angiotensin system (RAS) is activated in polycystic kidney disease. We have recently shown in *Pkd1* mouse, that Gen 2 antisense oligonucleotide (ASO) which suppresses angiotensinogen (Agt) synthesis, is efficacious in slowing kidney cyst formation compared to lisinopril. The suppression of Agt was notable for a compensatory increase in kidney renin content. Therefore, inhibiting both Agt and renin might further suppress intrarenal RAS and slow kidney cyst formation. Here we compared aliskiren+Agt ASO (Ali/Agt) to AgtASO or control in an accelerated cystic mouse model induced by unilateral nephrectomy (PMID:21493775) to test whether AgtASO slows the progression of a severe form of PKD.

Methods: Adult *Pkd1*conditional floxed allele mice expressing cre were administered tamoxifen resulting in global knockout of *Pkd1*. Two weeks after tamoxifen injection, mice underwent left unilateral nephrectomy. Mice were then treated with AgtASO (66mg/kg/wk), aliskiren (20mg/kg/d)+Agt or control (no drug) for total of 8 wks.

Results: Both AgtASO and Ali/Agt treatment significantly reduced plasma and urinary Agt levels. Compared to control mice, those receiving AgtASO had reduced Agt mRNA (liver: 80% kidney: 50%). BP was lowest in Ali/Agt among all treatment groups and control group had the highest BP. All mice developed kidney cysts at 8 wks after nephrectomy but Ali/Agt group had lower kidney/body weight, fewer kidney cysts compared to control or AgtASO. Renal pAkt, pS6 levels and apoptosis were significantly suppressed in Ali/Agt compared to AgtASO alone or control.

Conclusions: These results indicate that suppressing Agt alone is insufficient to slow an accelerated form of PKD induced by nephrectomy in *Pkd1* mice. However, concomitant use of aliskiren and AgtASO, was efficacious in slowing cyst expansion compared to AgtASO alone, likely resulting from intensive intrarenal RAS inhibition and suppression of the mTOR pathway.

FR-PO533

Loss of Primary Cilia Increases Polycystin-2 and TRPV4 Resulting in the Appearance of a Non-Selective Cation Channel at the Apical Membrane of Mouse Cortical Collecting Duct Principal Cells Takamitsu Saigusa,[1] Marlene Amjad Bunni,[1] Qiang Yue,[3] Tiffany L. Thai,[3] P. Darwin Bell,[2] Douglas C. Eaton.[3] *[1]Div of Nephrology, Medical Univ of South Carolina; [2]Div of Nephrology, Univ of Alabama at Birmingham; [3]Dept of Physiology, Emory Univ.*

Background: Polycystic kidney disease (PKD) is a ciliopathic disorder, which results in numerous kidney cyst mostly arising from the collecting duct. The mechanism by which the loss of the primary cilium promotes cyst formation is unknown. There are several TRP channels in cilia/apical membrane including polycystin (PC) 2 and TRPV4; what happens to these channels with the loss of cilia is presently unknown.

Methods: To further study ion channel activity in PKD, we measured channel activity, using the patch clamp technique, from isolated split-open collecting ducts (CCD) from adult conditional knockout mice with (*Ift88*$^{+/+}$) or without (*Ift88*$^{-/-}$) cilia. In addition, single tubules were isolated for measurements of mRNA for PC1, PC2, TRPV4, and ENaC subunits.

Results: Apical membrane channel activity from control (*Ift88*$^{+/+}$) mice had the biophysical characteristics for ENaC (5pS Na^+ selective channels with long mean open times (475.7±83.26 ms) and open probability (P_o) >0.2. However, the predominant channel activity, after the loss of cilia was a 21pS non-selective cation channel (reversal potential near 0) with short mean open time (72±17 ms), P_o <0.08 and a characteristic flickery opening. The biophysical properties of this channel in CCD's (*Ift88*$^{-/-}$) are similar to a previously reported 23pS non-selective cation channel found in mouse CCD cell line derived from an *Ift88* hypomorph (PMID:23977387). In the absence of cilia, there was over a 2-fold increase in mRNA for PC2 and TRPV4 from single isolated CCD compared to mRNA levels present in tubules with intact cilia, but there were no differences in mRNA for PC1 and ENaC subunits.

Conclusions: We interpret these results to suggest that an early event in ciliary loss is the appearance of a non-selective cation channel in the apical membrane. Whether this channel, found in freshly isolated CCD's, is a multimer of TRPV4 & polycystin 2 and the same as that identified in immortalized CCD's, remains to be determined.

FR-PO534

Increased Salt Intake Does Not Deteriorate Renal Cystic Disease Progression in High Water Loaded PCK Rats Masanori Kugita,[1] Tamio Yamaguchi,[2] Yoichi Nagamura,[2] Harold M. Aukema,[3] Shizuko Nagao.[1] *[1]Education and Research Center of Animal Models for Human Diseases, Fujita Health Univ, 1-98 Dengakugakubo Kutsukake Toyoake, Aichi, Japan; [2]Dept of Clinical Nutrition, Suzuka Univ of Medical Science, Suzuka, Mie, Japan; [3]Dept of Human Nutritional Sciences, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: We reported that high water intake (HWI) reduced the kidney/body weight ratio (KB%), improved renal function and limited serum AVP levels in PCK rats (Nagao et al: JASN 2006). However, HWI in ADPKD patients resulted in higher total kidney volume, urine sodium and urine volume, which could be a consequence of high salt intake (Higashihara et al: NDT 2014). In the current study, we loaded high salt in PCK rats with HWI.

Methods: PCK rats, an orthologous model of human autosomal recessive polycystic kidney disease, were randomly assigned to the control group (CONT: distilled water), high water intake group (HWI: 5% glucose) or high water intake with high salt group (HWS: 5% glucose+0.45% NaCl) and treated from 4 to 20 wk of age.

Results: Total water intake during the experimental period was 1.86 and 2.37 times higher in HWI (P=0.00) and HWS (P<0.01), respectively, compared with CONT, whereas total food intake was not different between all groups. Sodium intake in HWS was 5.71 or 5.94 times higher than CONT (P=0.00) or HWI (P=0.00), respectively. Systolic blood pressure (SBP) started to increase in HWS compared with HWI (P<0.05) at one week after high salt loading. SBP became significantly higher in HWS (164 ± 2 mmHg) compared with CONT (146 ± 1 mmHg, P<0.05), or HWI (146 ± 1 mmHg, P<0.05) at 20 wk of age. KB% was significantly lower in HWI (1.33 ± 0.05) compared with CONT (1.79 ± 0.11, P<0.01), and this beneficial effect was not affected by the overload of high salt in HWS (1.31 ± 0.10, HWI vs HWS: NS).

Conclusions: Although high blood pressure was induced by high NaCl intake, the effect of HWI was not adversely affected by salt in renal cyst expansion in PCK rats. This work was supported by Japan Society for the Promotion of Science Grants-in-Aid for Scientific Research.

FR-PO535

Effects of Sodium-Deficient and High Salt Diets on Cysts Formation in ARPKD Daria Ilatovskaya, Vladislav Levchenko, Jessica L. Barnett, Tengis S. Pavlov, Alexander Staruschenko. *Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Polycystic kidney diseases (PKD) are a group of nephropathies marked with the formation of fluid-filled cysts along the nephron. Generally, patients with PKD restrict their dietary sodium intake to 100 mmol/day or less, as it is expected to reduce blood pressure and albuminuria. We have shown that inhibition of Epithelial Na^+ Channel (ENaC) with benzamil aggravates cyst formation in PCK rat, a model of ARPKD. Here we hypothesize that general manipulation with sodium content in the diet can alter cyst formation.

Methods: Immunohistochemistry, Western blotting, GFR measurements in conscious animals, and routine molecular biology approaches were utilized to assess renal function in PCK rats fed a normal, high salt, and sodium-deficient (0.4% (NS), 4% (HS), and 0.01% (SD) NaCl, respectively) diets for 8 weeks (starting at 6 weeks of age).

Results: Compared to NS, both HS and SD diets resulted in a dramatic increase in the cyst formation: SD and HS diet groups exhibited 43.6% and 39.8% of cystic area compared to 28.5% in NS group). However, the development of cysts was different between HS and SD diets. HS diet provoked cyst enlargement in a manner seen in NS group. In contrast, SD diet caused extensive growth of small cysts in the cortex, and hypertrophy of the renal tissue (2K/BW ratio was 15.9 ± 0.7 when fed SD diet vs 11.5 ± 0.9 and 13.7 ± 0.8 in NS and HS). SD diet-fed PCK rats had reduced body weight (324 ± 11 compared to 517 ± 6 and 496 ± 5 g in NS and HS groups). Urinary output was significantly higher in the HS animals compared to both SD and NS groups; interestingly, food intake did not differ. GFR levels were 3.9 ± 0.5, 6.5 ± 0.3, and 9.8 ± 1.1 uL/min/BW in SD, NS and HS fed rats, respectively. Plasma electrolytes (K^+, Na^+, Cl^-, and Ca^{2+}) were significantly lower in PCK rats fed SD diet and not different between NS and HS groups. Consistent with other data, BUN was almost 130 mg/dL in the SD group compared to < 20 mg/dL in NS and HS animals.

Conclusions: Both HS and SD diets significantly increase cystic area in PCK rats, although cyst formation and its effects on kidney function are different between these two groups.

The Recessive PKD Proteins, Fibrocystin/Polyductin and Cystin, Act Independently to Regulate Myc Expression Maoqing Wu,[1] Chaozhe Yang,[1] Naoe Harafuji,[1] Jacob A. Watts,[1] Candice Wolf,[1] Avi Rosenberg,[2] Lisa M. Guay-Woodford.[1] *[1]Center for Translational Science, Children's National Health System, Washington, DC; [2]Dept of Pathology, Children's National Health System, Washington, DC.*

Background: *Myc* overexpression in renal epithelia has been reported in several PKD mouse models, as well as human ADPKD. Transgenic mice overexpressing *Myc* develop renal cystic disease. Therefore, Myc has been proposed as an inducer of cystogenesis, but little is known about *Myc* expression in recessive PKD. In previous studies, we have shown 1) cystin, encoded by *Cys1*, the gene disrupted in the *cpk* mouse, undergoes regulated nuclear trafficking; 2) cystin downregulates *Myc* expression; and 3) the *PKHD1* gene product FPC undergoes proteolytic cleavage with nuclear translocation of the carboxy terminus (CTD-FPC). In the current study, we evaluated *Myc* expression in recessive PKD kidneys and cell lines, assessed whether CTD-FPC regulated *Myc* expression, and determined the role of cystin.

Methods: Lysates and sections prepared from the *Cys1^{cpk}*, *Bicc1^{bpk}*, *Pkhd1^{cl}* mouse kidneys and lysates from wild-type and *Cys1^{cpk}* collecting duct cells were examined by immunoblotting and immunofluorescence using standard protocols. Luciferase reporter assays were conducted per our published protocol (PLOS ONE, 2013).

Results: When compared to controls, *Myc* is overexpressed in *Cys1^{cpk}* and *Bicc1^{bpk}* cystic kidneys, as well as the *Cys1^{cpk}* cell line. In addition, we observed variable levels of *MYC* upregulation in ARPKD kidneys. In contrast, *Myc* expression was not upregulated in kidneys from the spontaneously occurring *Pkhd1^{cl}* mutant, which does not express a renal cystic phenotype. In CTD-FPC overexpressing cell lines, *Myc* was upregulated and the luciferase reporter assay demonstrated that the CTD-FPC significantly enhanced the activity of *Myc* P1 promoter, a functional effect that was cystin-independent.

Conclusions: Our data demonstrate that *Myc* overexpression is a common signature of renal cystic epithelia in recessive PKD. Further, we show that in *in vitro* assays, the CTD-FPC and cystin act independently to regulate *Myc* expression. The absence of *Myc* overexpression in *Pkhd1^{cl}* kidneys may explain the absence of a renal cystic phenotype.

Differential Expressions of miR-378a-3p/ADAMTS1 in cpk Mice, a Model of ARPKD Masashi Sato,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Yuko Shima,[1] Masayasu Miyajima,[2] Kandai Nozu,[4] Shizuko Nagao,[5] Hisahide Takahashi,[5] Kazumoto Iijima,[4] Norishige Yoshikawa,[3] Hiroyuki Suzuki.[1] *[1]Pediatrics, Wakayama Medical Univ, Wakayama City, Wakayama Prefecture, Japan; [2]Laboratory Animal Center, Wakayama Medical Univ, Wakayama City, Wakayama Prefecture, Japan; [3]Clinical Research Center, Wakayama Medical Univ, Wakayama City, Wakayama Prefecture, Japan; [4]Pediatrics, Kobe Univ, Kobe City, Hyogo Prefecture, Japan; [5]Education and Research Center of Animal Model for Human Disease, Fujita Health Univ, Toyoake City, Aichi Prefecture, Japan.*

Background: The pathophysiology of cystic epithelia in polycystic kidney disease (PKD) is characterized by altered proliferative activity, secretory rather than absorptive function and abnormal matrix microenvironment. miRNA is reported to contribute to the pathophysiology in PKD, however, the details are still unknown.

Methods: To assess roles of miR-378a-3p, previously identified by our miRNA microarray, as well as ADAMTS1, a target molecule of miR-378a-3p, we investigated the expression levels of those molecules using real-time PCR, western blotting and immunohistochemistry in kidney and urine of *cpk* mice.

Results: Real-time PCR confirmed that miR-378a-3p expression was significantly down-regulated in *cpk* kidney (day 14, n=14, 20%, p<0.01; day 21, n=12, 11%, p<0.01) and that ADAMTS1 mRNA was significantly up-regulated in *cpk* kidney (day 14, n=20, 1.4-fold, p=0.01; day 21, n=12, 3.5-fold, p<0.01) compared to control. Western blotting revealed that ADAMTS1 expression was increased in *cpk* kidney (day14, n=4, 2.7-fold, p=0.02; day 21, n=4, 2.4-fold, p=0.02). Immunohistochemistry for ADAMTS1 supported these findings. Urinary miR-378a-3p expression by real-time PCR was significantly down-regulated in cpk (day 14, n=8, 15%, p<0.01).

Conclusions: Recently, dysregulation of miR-378a-3p axis is a topic in various carcinomas. Elevated ADAMTS1 promotes pro-tumorigenic changes such as increased tumor cell proliferation and altered extra cell matrix environment. Our results suggest that miR-378a-3p/ADAMTS1 axis is involved in *cpk*, and give us a rationale for future intervention studies for disease-specific treatments. Moreover, urinary miR-378a-3p might be a potential biomarker for PKD.

Deregulation of Long Non-Coding RNAs in Autosomal Dominant Polycystic Kidney Disease Karam S. Aboudehen,[1] Mohammed Shabbir Kanchwala,[2] Shayan A. Farahani,[1] Sophia M. Vrba,[1] Siu Chiu Chan,[1] Svetlana Avdulov,[1] Vishal Patel,[3] Chao Xing,[2] Peter Igarashi.[1] *[1]Dept of Medicine, Univ of Minnesota Medical School, Minneapolis, MN; [2]McDermott Center for Human Growth and Development, UT Southwestern Medical Center, Dallas, TX; [3]Dept of Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) represents the most common monogenic cause of kidney failure in humans. ADPKD is characterized by progressive cyst formation in renal tubules and is caused by mutations in *PKD1* or *PKD2*. Long non-coding RNAs (lncRNA), defined by a length >200 nucleotides and absence of a long open reading frame, have been implicated in a range of diseases. However, the role of lncRNAs in PKD has not been reported.

Methods: We performed deep RNA sequencing to identify alterations in the expression of lncRNAs in cystic kidneys from conditional *Pkd1* and *Pkd2* mutant mice. We also performed *de novo* transcriptome assembly to discover novel lncRNAs.

Results: We identified 66 known lncRNAs and 80 non-annotated transcripts that were commonly deregulated in both mouse models. The majority of the 66 annotated lncRNAs were located in intergenic regions or were antisense transcripts. Five lncRNAs were sense transcripts, and four localized to gene introns. Characterization of 44 highly deregulated lncRNAs revealed that 82% displayed developmental changes in expression between embryonic, newborn, and adult mouse kidney. Comparison of the expression in the kidney to other organs in the mouse revealed that 17 lncRNAs were widely expressed and four lncRNAs were kidney-specific. RNA fractionation experiments showed that 80% of the lncRNAs were predominantly located in the nucleus, suggesting that ADPKD-associated lncRNAs may be involved in transcriptional regulation. Consistent with this role, a subset of lncRNAs showed alterations in the expression of neighboring protein-coding genes in both mouse models.

Conclusions: Collectively, these studies identify a subset of developmentally regulated and tissue-specific lncRNA that may be involved in the pathogenesis or progression of ADPKD.

The Intron 40 Transcript from the HmPKD1 Gene Induces Major Changes in Protein Expression of NIH 3T3 Cells Robert L. Bacallao,[1] Takashi Hato,[1] Xianyin Lai,[2] Frank Witzmann.[2] *[1]Medicine, Indiana Univ, Richard Roudebush VAMC, Indianapolis, IN; [2]Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianpapolis, IN.*

Background: Informatic analysis of the HmPKD1 gene identifies 46 transcripts produced from this gene. One small transcript expressed from intron 40 of HmPKD1 is the subject of this communications. The intron 40 transcript , begins at intron 40, runs into exon 41 and then spices the 3' end of intron 41 to the 5' end of exon 43. Thereafter the sequence uses the standard splices site from full-length polycystin-1 (PC-1).

Methods: The sequence from the intron 40 cDNA was performed to confirm the identify of the clone relative to its identification in the UC Santa Cruz genome browser. To confirm the reading frame we cloned the construct into pRSET and used the proprietary XPRESS antibody to determine in frame expression. Based on sequence analysis we found significant homology between the amino acid sequence of the itron 40 transcript and 200 amino acids from the c-terminal of PC-1. Antibodies raised against c-terminal sequences of human PC-1 confirmed expression of the intron 40 transcript in NIH 3T3 cells. MS MS mass spectroscopy was performed on cell lysates obtained from mock transfected NIH 3T3 cells and intron 40 cDNA transfected NIH 3T3 cells.

Results: Immune blot analysis reveals a 40 kDA protein whose molecular weight is in agreement with the predicted open reading frame. Mas spectroscopy and 2D DIGE studies revealed over 200 proteins whose expression is changed by expression of the intron 40 transcript. Major pathways down regulated include glutathione biosynthesis, colanic acid biosynthesis, GDP-mannose biosynthesis, phagasome matureation and NRF2-mediated oxidative stress response. Upregulated pathways include cysteine degradation, glutathione biosynthesis and fatty acid oxidation.

Conclusions: Intron 40 of HmPKD1 expresses a 1200 bp message that produces a 40 kDa protein. Transfection of the intron 40 produced cDNA into NIH 3T3 cells results in significant changes in expression levels of 200 proteins .

The Roles and Mechanisms of ADP Ribosylation Factor-Like GTPase 13B in Mouse Kidney Yuanyuan Li,[1] Xin Tian,[2] Ming Ma,[2] Stephanie Jerman,[1] Stefan Somlo,[1,2] Zhaoxia Sun.[1] *[1]Genetics, Yale Univ School of Medicine, NewHaven, CT; [2]Internal Medicine, Yale Univ, NewHaven, CT.*

Background: ADP ribosylation factor-like GTPase 13B (Arl13b) encodes a small GTPase essential for cilia biogenesis in multiple model organisms. In zebrafish inactivation of arl13b leads to ventral body curvature and kidney cysts, typical phenotypes resulted from ciliary defects. In mouse null mutation of Arl13b results in disrupted neural tube patterning and defective hedgehog signaling. In human mutations of ARL13B lead to a classical form of Joubert Syndrome (JS) or retinal impairment and obesity linked by JS. However, ARL13B mutations in patients do not cause kidney cysts.

Methods: To investigate the roles of Arl13b in mammalian kidneys, we generated Arl13bFlox/Flox, Ksp-Cre mice in which Arl13b was depleted in the distal nephron at the perinatal stage.

Results: We detected rapid kidney cyst formation in the Arl13b conditional knockout model, collagen deposition and α-SMA accumulation in late stage indicative of renal fibrosis. In our model, we detected significantly upregulated Wnt7a expression as early as collecting duct dilation, before cyst formation. Valproic acid, a histone deacetylase inhibitor, inhibited the early rise of Wnt7a expression, ameliorated fibrosis, slowed cyst progression and improved kidney function.

Conclusions: Previous studies showed that, Wnt7a expression is upregulated in Pkd1-/- and unilateral ureteral obstruction (UUO) mouse model. Moreover, TGF-β activate collagen synthesis and leads to renal fibrosis through activating Wnt7a expression. In addition, NF-κB expression is upregulated significantly in folic acid induced acute kidney injury in mice. Inhibition of NF-κB activation in the UUO model reduced interstitial collagen IV deposition and α-SMA accumulation. To tease out the relationship between the different pathway in disease progression of the Arl13b model, we will investigate the roles of TGF-β and NF-κB pathway in both knockout mice and MEFs.

Centrosome Amplification Disrupts Kidney Development and Causes Cystic Kidney Disease Moe Mahjoub,[1,2] Kyuhwan Shim,[1] Lai Kuan Dionne,[1] Masato Hoshi,[1] Veronique Marthiens,[3] Amanda Knoten,[1] Renata Basto,[3] Sanjay Jain.[1] *[1]Div of Nephrology, Dept of Medicine, Washington Univ in St. Louis, MO; [2]Dept of Cell Biology and Physiology, Washington Univ in St. Louis, MO; [3]Inst Curie, Paris, France.*

Background: Cystic kidney diseases are characterized by hyperproliferation of normally quiescent renal epithelial cells, which profoundly alter the organ architecture and impair renal function over time. It is well established that defects in two essential microtubule-based organelles, the centrosome and cilium, contribute to the cystic transformation of renal epithelial cells. The centrosome-cilium complex acts as a cellular signaling center to organize and regulate the activity of various developmental signaling pathways. Recent studies have noted the presence of ectopic centrosomal structures (meaning too many centrosomes per cell) in renal epithelial cells isolated from patients and animal models of polycystic kidney disease. Surprisingly, this phenotype has been mostly ignored, and considered a potential secondary effect of cystic cell transformation and proliferation. However, we hypothesize that abnormal centrosome biogenesis may play an important causal role in the pathogenesis of the disease.

Methods: In this study, we make use of novel genetic mouse models with which we can alter centrosome biogenesis *in vivo.* We induce the formation of ectopic centrosomes in progenitor cells of the metanephric mesenchyme and the ureteric bud epithelium. Kidneys are analyzed at various stages of embryonic and postnatal development.

Results: We demonstrate, for the first time, that the formation of ectopic centrosomes disrupts embryonic kidney development and results in rapid cystogenesis. We also find that ectopic centrosomes sensitize kidneys in adult mice, causing cystogenesis following renal injury.

Conclusions: These results indicate that ectopic centrosome biogenesis alone is sufficient to trigger cyst formation and growth, even in the absence of mutations in cystic genes. These studies further our understanding of the fundamental cellular events that trigger cystogenesis, and characterize a potentially new therapeutic target for treatment of cystic kidney disease.

FR-PO542

Depletion of Ciliary Gate Protein FBF1 Promotes Cystogenesis in Pkd1RC/RC Mice Tao Xu.[1,2,3,4] *[1]Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [3]Mayo Translational PKD Center, Mayo Clinic, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic disorder resulting from mutations in either *PKD1* or *PKD2* and characterized by massive bilateral renal cyst formation. Dysfunction of sensory organelle cilia has been tightly correlated with the pathogenesis of cystogenesis. Renal cyst is a common manifestation in various ciliopathies, but intriguingly, removal of cilia also suppressed cyst growth in ADPKD rodent model, suggesting cystogenesis mechanism between ciliopathies and ADPKD may be distinctly different. We previously discovered that FBF1 is a key component of the poorly understood transition fibres (TFs), which regulates ciliogenesis initiation and selective gating of various ciliary proteins.

Methods: By combining genetics, cell biology, and model organisms, we study the conserved role of TFs in regulating polycystin pathway across ciliates species.

Results: Surprisingly, we found that *Fbf1*$^{tm1a/tm1a}$ knockout mice show negligible cystogenesis in the kidney or liver. Notably, combining *Fbf1*$^{tm1a/tm1a}$with *Pkd1*$^{RC/RC}$results in aggressive and accelerated cystogenesis in both kidney and liver. By using genetic model *C. elegans*, cultured mammalian kidney cells, and isolated MEFs from knockout mice, we demonstrated that FBF1 and its homologue play a highly conserved role in regulating the proper homeostasis of ciliary polycystins across ciliated species.

Conclusions: The defective ciliary trafficking of polycystins upon depletion of FBF1 explains the severe renal and liver manifestations of *Fbf1*$^{tm1a/tm1a}$; *Pkd1*$^{RC/RC}$double mutants, and also reveal an important role for TF-mediated cilia gating in the pathogenesis of cystogenesis.

FR-PO543

Suppressed Autophagy Leads to Increased Apoptosis in Pkd1 Knockout Models Kameswaran Ravichandran, Katharina Hopp, Andrew Thorburn, Charles L. Edelstein. *Univ Colorado Denver.*

Background: Increased proliferation and apoptosis play a role in cyst growth. The link between autophagy and apoptosis in PKD is not known. When autophagy is suppressed, there is accumulation of p62 that results in activation of caspase-8 and subsequent activation of caspase-3, the major mediator of apoptosis.

Methods: 90 (early PKD) and 150 d old mice with a kidney specific tamoxifen-inducible *Pkd1* knockout or Human *Pkd1*-/- (WT 9-12) RCTE cells with a homozygous mutated *Pkd1,* were treated with the lysosomal inhibitors, bafilomycin (Baf) or chloroquine (C), to measure autophagic flux. LC3-II (autophagic flux), cleaved caspase-3 (CC-3), cleaved caspase-8 (CC-8), p62 (autophagy/apoptosis crosstalk) were measured by immunoblot. Annexin-V staining (apoptosis) was measured by flow cytometry.

Results: Baf resulted in an increase in LC3-II in +/+ and a decrease in LC3-II in *Pkd1*-/- kidneys (decreased autophagic flux) associated with increased p62, CC-3 and CC-8. C resulted in an increase in LC3-II in control RCTE (+/+) cells but not in *Pkd1* -/- cells suggesting decreased autophagic flux. Decreased autophagic flux and increased p62 in *Pkd1* -/- cells was associated with increased apoptosis (annexin V staining), increased CC-8 and increased CC-3.

KIDNEYS	+/+	+/+ Baf	90 d old -/-	90 d old -/- Baf	150 d old -/-	150 d old -/- Baf
LC3-II	++	+++	++	+	++	+
CC-3	+	+	+++	+++	+++	+++
CC-8	+	+	+++	+++	+++	+++
p62	+	+	+++	+++	+++	+++
CELLS	+/+	+/+ C	-/-	-/- C		
LC3-II	++	+++	++	+		
CC-3	++	+	+++	+++		
CC-8	+	+	+++	+++		
p62	+	+	+++	+++		
Annexin-V (%)	9.5	6.3	15.5 *	15.9 *		
	Baf=bafilomycin	C=chloroquin	*P<0.05 vs +/+	+ - +++= density of protein expression (n=3)	+/+ = wild type	-/- = Pkd1 -/-

Conclusions: The lack of effect of the lysosomal inhibitors to increase LC3-II in *Pkd1* -/- kidneys and *Pkd1* -/- cells suggests a defect in autophagy resulting from a block of autophagosome-lysosome fusion and degradation. Suppressed autophagy is associated with increased apoptosis and apoptosis/autophagy crosstalk. Autophagy inhibition with Baf or Chloroquin leads to increased apoptosis in *Pkd1* -/- models.

FR-PO544

Identification of a Novel Ciliary Targeting Sequence in Polycystin-1 Chong Luo,[1,2] Xuefeng Su,[1] Maoqing Wu,[1] David Verkaik,[1] Jianghua Chen,[2] Jing Zhou.[1] *[1]Harvard Center for Polycystic Kidney Disease Research and Renal Div, Dept of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Kidney Disease Center, The First Affiliated Hospital, School of Medicine, Zhejiang Univ, Hangzhou, Zhejiang Province, China.*

Background: Mutations of *PKD1* cause 85% autosomal dominant polycystic kidney disease (ADPKD) cases. Previous studies by us and others have shown that many pathogenic mutations result in defective ciliary localization of polycystin-1 (PC1), suggesting that the ciliary trafficking of PC1 might be a functional assay for ADPKD. However, how PC1 traffics to primary cilia remains poorly understood. A ciliary targeting sequence (CTS) is thought to be involved in this process. The VxP motif present in the C-terminal tail of PC1 was reported to function as a CTS through an Arf4/ASAP1 dependent manner similar to rhodopsin trafficking to the primary cilia. However, this motif is dispensable for full-length PC1 targeting to cilia. The ciliary targeting motif(s) in PC1 is to be identified.

Methods: A set of chimeric constructs with different motifs in PC1 including mutations that correspond to human ADPKD patients were made. These constructs were transiently transfected into IMCD3 cells, and the ciliary trafficking ability of these constructs was evaluated by immunofluorescent staining.

Results: Here we show that an ~ 40 amino acid sequence is sufficient to drive chimeric proteins to the primary cilia. This region consists of several highly conserved motifs. Multiple deletion and point mutation analyses further led to the discovery of an eight amino acid sequence that functions at an efficiency similar to the 40 amino acid sequence in ciliary trafficking. Another motif in this region also has a milder effect on targeting chimeric protein to the primary cilia. Effects of amino acid substitutions found in ADPKD patients were analyzed.

Conclusions: Through a systemic analysis, we have identified a novel ciliary targeting motif in PC1 responsible for targeting chimeric proteins into the primary cilia. Ongoing studies include testing its function and its regulation in full-length PC1.

Primary Cilia Regulate Kupffer Cell/Resident Macrophage Activation, Monocyte Recruitment, and Hepatic Fibrosis in a Mouse Model of PKD

Kurt Zimmerman, Cheng 'Jack' Song, Bradley K. Yoder. *Cell Developmental and Integrative Biology, UAB, Birmingham, AL.*

Background: Patients with hepatorenal fibrocystic diseases (HRFD)(including PKD) develop extra-renal complications including biliary cysts and periportal fibrosis. While many HRFD genes are known, the underlying processes that drive liver cyst formation and fibrosis are not well understood.

Methods: To better define mechanisms involved in HRFD liver disease, we used an *Ift88*^{orpk} mouse model with an insertional mutation in the IFT88 gene leading to reduced IFT88 protein, short dysfunctional cilia, and severe cysts in the kidney and liver by 4 weeks.

Results: Our data indicate that 4 week old *Ift88*^{orpk} cilia mutant mice overexpress the pro-fibrotic genes *Col1a1* and *Col3a1* and have increased collagen protein in periportal regions as indicated by picrosirius red stain. In addition, livers from these mice show an accumulation of F4/80 positive macrophages in periportal regions containing smooth muscle actin positive cells. Fluorescent activated cell sorting (FACS) data indicate that a majority of the macrophages present in 4 week cilia mutant mice are the pro-fibrogenic Ly6c^{hi} monocytes. Whole liver transcript analysis shows a substantial increase in multiple pro-inflammatory and pro-fibrotic cytokines in cilia mutant mice including TGF-β, PDGF-bb, TNF-α, IL-1β and MCP-1. Preliminary data using FACS analysis of sorted liver cell populations from 4 week mutant mice show that resident macrophages/kupffer cells are the major cell type responsible for hepatic MCP-1 production whereas infiltrating monocytes are the major source of TGF-β. Importantly, resident macrophages isolated from *Ift88*^{orpk} cilia mutant mice demonstrated increased proliferation at 4 weeks compared to controls. This observation suggests that resident macrophages become activated in late stage disease progression and may be a driving force in HRFD.

Conclusions: In conclusion, we demonstrate that primary cilia defects alter hepatic immune responses including resident macrophage/kupffer cell activation. We show that activated kupffer cells overexpress MCP1, a known chemoattractant, that triggers the influx of Ly6c^{hi} pro-fibrogenic monocytes leading to development of periportal fibrosis.

FR-PO546

Unilateral Nephrectomy in Adult Pkd1 Knockout Mice Accelerates Kidney Cystogenesis

Wayne R. Fitzgibbon,[1] Yujing Dang,[1] Marlene Amjad Bunni,[1] P. Darwin Bell,[2] Takamitsu Saigusa.[1] *[1]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: One explanation for the variability in disease progression in patients with polycystic kidney disease (PKD) can be attributed to "third hit" signaling. We reported that unilateral nephrectomy induces hypertrophic signaling and accelerates kidney cyst formation in adult *Ift88* mice, a model of recessive PKD (PMID: 21493775). Whether this applies to other PKD mouse models and the mechanism of how unilateral nephrectomy accelerates cystogenesis are both unknown. Therefore, we tested the effects of unilateral nephrectomy on cystogenesis in autosomal dominant PKD mice.

Methods: Adult *Pkd1*conditional floxed allele mice (C57B6 background) without cre (*Pkd1*$^{+/+}$) and with cre (*Pkd1*$^{-/-}$) were administered tamoxifen. Some mice underwent left unilateral nephrectomy (1K) and others retained both kidneys (2K). Kidneys from all 4 groups (1K&2K *Pkd1*$^{+/+}$and 1K&2K *Pkd1*$^{-/-}$) were examined for cystic development. High-throughput RNA sequencing (RNAseq) (SE50) were performed on kidney RNA extracted using an Illumina HiSeq2500.

Results: Four weeks after nephrectomy, 1K *Pkd1*$^{-/-}$ mice had increased kidney/body weight and became cystic compared to 2K *Pkd1*$^{-/-}$ mice. Both 1K and 2K *Pkd1*$^{+/+}$ mice had no cyst in kidney and liver. Analysis of the RNAseq data from the 1K vs 2K *Pkd1*$^{+/+}$mice revealed no differences in gene regulation. However, *Pkd1*$^{-/-}$mice revealed, 1,335 significantly differentially expressed transcripts (q <0.4) when 1K was compared to 2K kidney. Gene ontology analysis demonstrated significant enrichment of terms including cell migration and regulation of cell motility (Bonferroni adjusted $p < 4.003^{E-36}$). Pathway analysis, revealed significant enrichment of genes involved in the extracellular matrix pathway (79/264 genes, Bonferroni adjusted $p< 5.560^{E-22}$).

Conclusions: In summary, unilateral nephrectomy in adult *Pkd1* conditional knockout mice results in accelerated kidney cyst formation compared to 2K *Pkd1*$^{-/-}$mice. Analysis of kidney RNAseq data demonstrated that, unilateral nephrectomy in *Pkd1*$^{-/-}$ mice, significantly enriched and upregulated transcripts and genes compared to 2K *Pkd1*$^{-/-}$ mice.

FR-PO547

Acute Kidney Injury and Polycystic Kidney Disease Share Common Signaling Mechanism

Marie Trudel, Almira Kurbegovic. *Molecular Genetics and Development, Inst de Recherches Cliniques de Montreal, Montréal, QC, Canada.*

Background: Acute kidney injury (AKI) and autosomal dominant polycystic kidney disease (ADPKD) are considered separate entities that both frequently cause renal failure. ADPKD kidneys develop multiple cysts that arise from dosage dependent mechanism with mutations in *PKD1* and *PKD2* encoding PC1, PC2. Since ischemia-reperfusion injury (IRI), a model of AKI, can promote earlier cyst formation in *Pkd1* dosage-reduced mice, we questioned whether cystogenesis could be accelerated in *Pkd1* dosage-increased and mutant mouse models via a similar mechanism.

Methods: Mice with mild overexpression of full-length *Pkd1* gene in Pkd1$_{TAG}$ dosage-increased mouse model and with a human *PKD1* mutation Pkd1$_{extra}$ develop slow progressive PKD. These transgenic mice and control littermates were subjected to unilateral renal IRI at 3-months and sacrificed at different timepoints following reperfusion. IRI kidneys were evaluated by histo-morphometry, proliferation, fibrosis and cilia length analyses. Renal transcript and protein expression was monitored by qPCR and immunoblot.

Results: All non-transgenic (n=63) and transgenic (n=36) mice relative to sham-operated (n=20) reproducibly develop moderate to severe tubular cysts and typical PKD cellular defects that is epithelial hyperplasia, immune interstitial infiltrates and fibrosis within 23 days to 3 months post-IRI. Similar onset and severity of IRI induced-cystogenesis in mice independently of their genotype revealed that IRI is sufficient to promote cyst formation and was not amplified by the transgene. IRI non-transgenic and transgenic kidneys showed from 16 days post-IRI, strikingly increased and sustained *Pkd1*/Pc1 (>3-fold) and *Pkd2*/Pc2 (>8-fold) expression that each can be cystogenic in mice. Long-term and important stimulation of *Hif1a* expression was induced as in ADPKD. While mTOR signaling is activated, stimulation of the Wnt pathway, with markedly increased active ß-catenin and c-Myc expression in IRI renal epithelium, uncovered a similar regulatory cystogenic response shared by IRI and ADPKD.

Conclusions: Our study demonstrates that AKI induces long-term cystogenesis in wild-type mice and crosstalks with ADPKD pathogenic and/or repair signaling mechanism.

Activation of Notch3 Signaling Pathway in Polycystic Kidney Disease

Madhulika Sharma, Jessica Y. Idowu, Gail Reif, Brenda S. Magenheimer, Pamela Vivian Tran, Robin L. Maser, Christopher J. Ward, Darren P. Wallace, James P. Calvet. *Univ of Kansas Medical Center, Kansas City, KS.*

Background: Polycystic kidney disease (PKD) is a genetic disease associated with fluid filled renal cysts and causes complications such as pain, hypertension and aneurysms and ultimately end stage renal disease. Despite recent advances, there is no approved treatment for PKD in United States. Notch signaling plays a key role in many chronic kidney diseases. Since the cellular processes such as proliferation and dedifferentiation are common between PKD and other kidney pathologies, we hypothesized that Notch signaling may play a critical role in PKD.

Methods: Protein expression profile of Notch pathway members in autosomal recessive PKD (ARPKD) and Autosomal dominant PKD (ADPKD) mouse models as well as patients with ADPKD was evaluated using immunolabeling techniques and Western blots. The effect of Notch inhibitor was evaluated on cysts grown on collagen gels from cells obtained from ADPKD patients.

Results: We show that Notch pathway, particularly Notch3 (N3) pathway is consistently activated in cystic cells from all the mouse models and human ADPKD samples studied. Among the ligands, only Delta like 4 (Dll4) was found to be consistently increased in all the models. N3 was expressed and upregulated in both collecting duct and proximal tubular cysts. The expression of N3 and Dll4 was maximum when the cysts were rapidly growing at earlier stage of the disease. In a slow progressing mouse model of PKD (RC/RC), there was no N3 expressed in cystic cells which had lost their structure due to de-differentiation, however N3 was found to be expressed in few cells that had retained their structure. Notch3 expression co-localized with proliferation marker, PCNA. Moreover Notch inhibition using Gamma secretase inhibitor ameliorated cyst formation when primary cells from ADPKD patients were allowed to form cysts in collagen gels.

Conclusions: We conclude that Notch3/Dll4 pathway is activated in PKD and that inhibition of Notch signaling may prevent cyst formation in PKD setting most likely by inhibiting cell proliferation.

FR-PO549

CRISPR-Mediated Knockdown of Arl3 Implicates the Functional Sequestration of Cystin as the Mechanism Underlining the Recessive PKD Phenotype in Arl3-/- Mice

Jacob A. Watts, Lisa M. Guay-Woodford. *Center for Translational Science, Children's National Health System, Washington, DC.*

Background: The *cpk* mouse, which arose spontaneously from a frameshift mutation in *Cys1*, phenocopies human ARPKD and is considered the best-characterized mouse model of recessive PKD. The overexpression of c-Myc at both the transcript and protein level is a signature of recessive PKD epithelia (Abstract No. 2290, this meeting). We have previously shown that cystin, the protein product of *Cys1*, regulates the expression of *Myc* through its nuclear interaction with necdin.

Methods: Using tandem affinity purification, we identified the ciliary GTPase Arl3 as a putative interacting partner of cystin. Previously published data demonstrated that 1) Arl3 regulates the UNC119b-mediated ciliary localization of myristoylated proteins, specifically cystin (*Genes Dev*, 2011) and 2) *Arl3*$^{-/-}$ mice express a renal cystic phenotype that closely resembles that observed in the *cpk* mouse (*Am J Pathol*, 2006). Using CRISPR technology, we generated stable *Arl3* knockdown cell lines with a Cas9 expression vector containing RNA guides targeted to the translational start site of mouse *Arl3* that were nucleofected into mIMCD-3 cells. Cells were synchronized at G_0/G_1 using simvastatin treatment.

Results: Immunoblotting confirmed that the Arl3 protein level was substantially decreased in the *Arl3*^{CRISPR} cells and c-Myc was overexpressed in these cells compared to control cell lines. The elevated c-Myc expression was rescued by over-expression of cystin$_{G2A}$, a myristoylation-deficient variant that has decreased ciliary membrane association but preserved nuclear localization and function.

Conclusions: We propose that the renal cystic phenotype observed in the *Arl3*$^{-/-}$ mouse results from functional sequestration of cystin by UNC119b due to the absence of Arl3. Our data implicate cystin-UNC119b-Arl3 in a functional complex that is required to maintain normal ciliary signaling and renal epithelial homeostasis. In this functional model, loss of either Arl3 or cystin results in renal cystic disease.

Cystin, the Protein Disrupted in the cpk Mouse, Is Implicated in Pkhd1 Transcriptional Regulation Jacob A. Watts, Candice Wolf, Chaozhe Yang, Maoqing Wu, Naoe Harafuji, Lisa M. Guay-Woodford. *Center for Translational Science, Children's National Health Systems, Washington, DC.*

Background: ARPKD results from mutations in *PKHD1*. However, gene-targeted *Pkhd1* mouse models and the spontaneous *Pkhd1*^{cl} mutant express limited or no kidney disease. In contrast, the *cpk* mouse with defects in *Cys1* phenocopies human ARPKD. This cross-species phenotypic similarity suggests that cystin (*Cys1*) and FPC (*Pkhd1*) may function in common pathway(s) that are differentially regulated in mouse and human renal epithelia. In the current study, we sought to identify cystin-binding partners, elucidate the nuclear function of cystin, and define a potential functional interaction between cystin and FPC in mouse renal epithelia.

Methods: Cystin$_{G2A}$, a myristoylation deficient variant that preferentially targets to the nucleus was cloned into a tandem affinity purification (TAP) vector. The cystin$_{G2A}$-TAP construct, double-tagged with Strep and FLAG at the N-terminus, was stably transfected into mIMCD-3 cells. Following the TAP procedure, mass spectrometry (MS), informatics analysis (STRING v10), and targeted co-IP studies were performed. Minigene assays and RT-PCR were conducted as described (*J Mol Med, 2014*).

Results: MS identified several putative cystin interacting partners, including the nuclear-entry regulatory proteins, importin α1, α2, and β2, as well as several splicing-related proteins. Our previous studies demonstrated that *Pkhd1* is transcriptionally complex and implicated the splicing regulator Srsf5 as a major factor in *Pkhd1* alternative splicing. We now show that 10 of the 12 *Srsf* genes, including *Srsf5*, are expressed in mIMCD-3 cells. Co-IP studies indicate that cystin and Srsf5 interact. In minigene assays, a construct containing *Pkhd1* exons 6-7-51 (the latter with an Srsf5 binding motif) is differentially expressed in wild-type versus *Cys1*^{cpk} collecting duct cells.

Conclusions: Our data: 1) indicate that cystin localizes to the nucleus via importin-regulated pathways and 2) implicate a role for cystin in the transcriptional regulation of *Pkhd1*. These data provide the first experimental evidence functionally linking cystin and FPC in mouse renal epithelia.

FR-PO551

Four-Jointed Knock-Out Causes a Delay in Kidney Failure in an Autosomal Dominant Polycystic Kidney Disease Model with Renal Injury Chiara Formica,[1] Hester Happé,[1] Kimberley Veraar,[2] Sandra Kunnen,[1] Marion Scharpfenecker,[2] Dorien J.M. Peters.[1] [1]*Human Genetics, Leiden Univ Medical Center, Netherlands;* [2]*Pathology, Leiden Univ Medical Center, Netherlands.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is characterized by the development of fluid-filled cysts, which leads to renal failure. In the majority of cases the disease is caused by a mutation in the *PKD1* gene. In a previous study, we demonstrated that injury-induced tubular epithelial cell proliferation accelerates cyst formation in kidneys of inducible *Pkd1*-deletion (iksp*Pkd1*^{del}) mice (Happé *et al.*, Hum. Mol. Genet. 2009). In particular, our results suggested a role for the Planar Cell Polarity (PCP) regulator Four-jointed (Fjx1), in the injury/repair mechanism. Therefore, we studied the role of Fjx1 in cyst formation and PKD progression.

Methods: We generated several mouse models, i.e. *Fjx1*$^{-/-}$mice, iKsp*Pkd1*^{del} mice as well as *Fjx1*$^{-/-}$;iksp*Pkd1*^{del} mice (double knock-out mice). After *Pkd1*-gene inactivation, we induced nephrotoxic injury using 1,2-dichlorovinyl-cysteine (DCVC) or PBS as control, and characterized tissue-repair and cyst formation in the different models.

Results: We confirmed that nephrotoxic injury is able to accelerate cyst formation in iksp*Pkd1*^{del} mice, while this was not observed in the *Fjx1*$^{-/-}$; iksp*Pkd1*^{del} mice, which showed longer survival (median survival: 14 weeks vs 20 weeks; p. value < 0.05). PCP, assessed by measuring Golgi position, was comparably aberrant in both iksp*Pkd1*^{del} and *Fjx1*$^{-/-}$;iksp*Pkd1*^{del} mice, already early after DCVC. This suggests a more complex regulation of PCP, and excludes a causal role for this pathway in prolonged survival. Also proliferation, Hippo signalling and cystic indices were comparable. However, fibrosis was significantly less in the double knock-out mice, consistent with the delayed kidney failure observed in this genotype.

Conclusions: Our data suggest that in PKD, *Fjx1* disruption is protective against renal failure by delaying fibrosis. Further analyses to unveil the mechanism are ongoing.

Ouabain Induced Differences in [Ca2+]i Response in NHK and ADPKD Cells Depend on L-type Calcium Channels Jessica D. Venugopal,[1,3] Gail Reif,[2,3] Darren P. Wallace,[2,3] Gustavo Blanco.[1,3] [1]*Molecular and Integrative Physiology, Kansas Univ Medical Center;* [2]*Internal Medicine, Kansas Univ Medical Center;* [3]*The Kidney Inst, Kansas Univ Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the progressive growth of renal cysts that alter the structure and function of the kidney. We have shown that the hormone ouabain enhances cell proliferation in cystic kidney epithelial cells from patients with ADPKD (ADPKD cells); but does not affect normal human kidney epithelial cells (NHK cells). The mechanisms involved in this dissimilar response are unclear. Due to the essential role of intracellular calcium concentration ($[Ca^{2+}]_i$) in ADPKD, we explored the effect and mechanisms of ouabain action on $[Ca^{2+}]_i$ levels in NHK and ADPKD cells.

Methods: We used the calcium dye Fura-2AM as a reporter to follow $[Ca^{2+}]_i$ changes in primary cultures of NHK and ADPKD cells, after treatment + 3 nM ouabain.

Results: Ouabain increased $[Ca^{2+}]_i$ in NHK cells, but not in ADPKD cells. Ouabain-induced $[Ca^{2+}]_i$ elevation in NHK cells was blocked by Ca^{2+} removal from the medium, suggesting that plasma membrane ion channels are involved in the response. Ouabain induced Ca^{2+} increase in NHK cells was abrogated by the L-type calcium channel (LTCC) inhibitor verapamil. Moreover, LTCC agonists restored the ouabain-dependent $[Ca^{2+}]_i$ increase in ADPKD cells to levels similar to those of NHK cells. LTCC agonists also blocked ouabain induced proliferation of ADPKD cells. Protein expression levels of full-length LTCC were lower in ADPKD cells than NHK cells. Concomitantly, ADPKD cells contained higher amounts of LTCC cleavage products and greater activity of calpain, a protease involved in LTCC cleavage.

Conclusions: Our data shows that ouabain stimulates $[Ca^{2+}]_i$ increase in NHK cells by facilitating its uptake from the extracellular space via LTCC. Instead, ouabain cannot elevate $[Ca^{2+}]_i$ in ADPKD cells, due to low LTCC levels, which may be secondary to enhanced LTCC cleavage by calpain. The lack of $[Ca^{2+}]_i$ response to ouabain in ADPKD cells helps enhance ADPKD proliferation, an event that exacerbates the ADPKD phenotype.

FR-PO553

Characterization of a P2RX7 Knockout in PCK Rats, a Model of ARPKD Tengis S. Pavlov,[1,2] Daria Ilatovskaya,[1] Vladislav Levchenko,[1] Aron M. Geurts,[1] Melinda R. Dwinell,[1] Alexander Staruschenko.[1] [1]*Physiology, Medical College of Wisconsin, Milwaukee, WI;* [2]*Hypertension and Vascular Research, Henry Ford Health System, Detroit, MI.*

Background: Over the last decade, accumulating evidence suggests that the autocrine and paracrine effects of ATP (through P2 receptors) could be detrimental for the progression of PKD. High ATP release and concentrations were reported in cystic fluid. P2X family receptors are non-selective ion channels, permeable for Ca^{2+} ions; these channels are characterized by high affinity to extracellular ATP, which makes them critical for controlling calcium dependent intracellular mechanisms. $P2X_7$ (*P2RX7* gene) is expressed in the collecting ducts (CD), as well as in cysts formed from CDs in ARPKD. We hypothesize that interfering with $P2X_7$ signaling precludes cystogenesis. To study this hypothesis we generated the knockout of the *P2RX7* gene in PCK rat strain, an established model of ARPKD characterized by a mutation in the *PKHD1* gene.

Methods: *P2RX7* knockout was performed with a CRISPR/Cas9 approach targeting exon 2 that resulted in a single base insertion of a 'T' which induced a frameshift. F2 and further litters were used to establish the colony and run pilot experiments. For characterization of the new strain, 8-weeks old animals were anesthetized and the kidneys were flushed with phosphate buffer and collected with other organs. Western blotting analysis of total kidney lysate was performed to evaluate $P2X_7$ expression. To assess severity of ARPKD, H&E histological staining of central kidney slices were analyzed to calculate cyst area as percentage of total slice area.

Results: Western Blotting revealed lower $P2X_7$ expression in heterozygous compared to wild type rats (44.7%), and lack of the protein in homozygous animals. Homozygous animals were viable and born at Mendelian ratios from intercrosses between heterozygotes. Initial characterization of the first litters showed reduction in cyst area in the homozygous compared to wild type or heterozygous male animals.

Conclusions: $P2X_7$ signaling might be involved in cystogenesis in the ARPKD rodent model.

Comprehensive Metabolomics Analysis Shows Evidence of TCA Cycle Dysregulation in a Rat Model of Polycystic Kidney Disease Ivan Vuckovic, Song Zhang, Petras Dzeja, Slobodan Macura, Peter C. Harris, Vicente E. Torres, Maria V. Irazabal. *Mayo Clinic.*

Background: Autosomal Dominant Polycystic Kidney Disease is a leading cause of end-stage renal disease. Many of the metabolic dysregulations contributing to cystogenesis remain to be elucidated. Using a comprehensive metabolomics approach (proton nuclear magnetic resonance,^{1}H-NMR and gas chromatography-mass spectrometry, GC-MS) we investigated the metabolic pathways associated with cystogenesis in the kidney of PCK compared to Sprague-Dawley (SD) wild-type rats.

Methods: We included male and female, PCK and SD rats, treated with dDAVP (PCK_D, n=16 or SD_D, n=12) to aggravate the cystic phenotype or saline solution (PCK_S, n=16 or SD_S, n=12) as controls. Kidney metabolites were identified from tissues collected at euthanasia (P37) and correlated with kidney volume byabdominal MRI (P35).

Results: Partial least squares-discriminant analysis (PLS-DA) score plots showed a significant separation between the groups (Fig 1A). Sixty five metabolites were identified by GC-MS and 42 by ^{1}H-NMR of which 30 were significantly different between PCK_S and SD_S, and 10 of the 30 remained significant ($p<0.05$) between PCK_S and PCK_D. The resulting metabolic profiles demonstrated significantly increased tissue and urine levels of most TCA cycle metabolites, including citrate, isocitrate, α-ketoglutarate, succinate, fumarate and malate in PKD (Fig 1B). Moreover, tissue TCA cycle metabolites levels correlated directly with kidney volumes (Fig 1C).

Conclusions: Comprehensive metabolomics analysis showed significant increases in TCA cycle metabolites in PCK rats. Furthermore, these levels were even higher in PCK dDAVP treated rats. Studies with state of the art stable isotope (^{13}C, ^{18}O) labeling techniques are ongoing to investigate metabolite fluxes and carbon sources, and will aid in determining dysregulations in metabolic pathways for therapeutic interventions.

FR-PO555

Characterization of Two Pkd1 Rat Models Megan M. Constans,[1] Diana L. Escobar,[1] Jessica M. Smith,[1] Aron M. Geurts,[2] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Genome Editing Rat Resource Center, Medical College of Wisconsin, Milwuakee, WI.*

Background: Rats are well established as an experimental model of renal physiology but to date no ADPKD rat model exists. In mice, Pkd1 nulls are embryonic lethal with clear PKD at ~E14.5, while heterozygotes develop few cysts, but the V2 receptor agonist dDAVP aggravates cystic disease. The CRISPR/Cas9 system allows mutants to be generated in alternative model organisms, including rats, such that novel gene knockout models can be generated which may be more experimentally tractable. Here we describe the generation and characterization of two *Pkd1* rat models.

Methods: A plasmid expressing Cas9 and short guide RNAs targeting exon 29 of the *Pkd1* gene were injected into Lewis strain embryos and founder animals with putative Pkd1 mutations were identified. Breeding to wildtypes determined germline transmission, and two mutant lines were aged to 6 months. MRI and histology characterized the heterozygous phenotype and these animals were also treated with dDAVP daily from P7 to P35.

Results: *Pkd1* models were generated with either an inframe, c.9790_9801del12; p.S3273_T3276del (del12), or a frameshifting, c.9793_9800del8, p.R3274fs (del8), deletion. Analysis for homozygotes showed no live born pups for either model from 3 litters, with embryonic analysis at E14.5 not identifying any live embryos. Heterozygotes showed no significant renal enlargement at 6 months, but MRI and histological analysis showed multiple renal cysts in the cortex and medulla (median 7, range 4 to 15) are evident at P21 from a cohort of heterozygous animals. dDAVP aggravated the development of cyst number and size by ~2-fold.

Conclusions: Analysis of these new models shows heterozygous *Pkd1* rats having more kidney cysts than the corresponding mice, which are aggravated by dDAVP as in the PCK rat model of ARPKD. Embryonic analysis suggests earlier lethality in the rat compared to mouse models. These new models will enhance the understanding of slowly progressive ADPKD in a rodent model.

FR-PO556

Microvascular Endothelial Dysfunction in a Rat Model of Autosomal Recessive Polycystic Kidney Disease David M. Pollock,[1] Anthony K. Cook,[1] Chunhua Jin,[1] Robert A. Kesterson,[3] Bradley K. Yoder,[2] Michal Mrug,[1] Edward W. Inscho.[1] *[1]Div of Nephrology, Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [2]Dept of Cell, Developmental & Integrative Biology, Univ of Alabama at Birmingham, Birmingham, AL; [3]Dept of Genetics, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Hypertension is a common early complication of polycystic kidney diseases (PKDs) including the autosomal recessive PKD (ARPKD). Hypertension is often associated with endothelial dysfunction, that is a lack of endothelial-dependent relaxation and an inability to buffer vasoconstriction. Thus, we hypothesized that the ARPKD rat should display impaired endothelial function.

Methods: Male, 2-month old ARPKD (PCK/CrljCrl-*Pkhd1*^{pck}/Crl) and control [Crl:CD(SD)] rats from Charles River were maintained on normal salt (NS 0.49% NaCl) diet prior to study. Rats were anesthetized and afferent arterioles (AA) visualized using the blood-perfused juxtamedullary nephron technique. AA diameters were measured in response to different concentrations of the endothelial dependent vasodilator, acetylcholine (ACH; 10^{-8}-10^{-4} M), or the endothelial independent vasodilator, sodium nitroprusside (SNP; 10^{-8}-10^{-4} M). An additional series of experiments were conducted in anesthetized rats surgically prepared to determine renal blood flow (RBF) responses to intravenous angiotensin II (ultrasonic flow probe).

Results: As expected, both ACH and SNP (1.0 mM) significantly increased AA diameters in kidneys from control rats (134±2% and 133±2%, respectively, n=4, $p<0.05$). The vasodilator response to ACH was significantly attenuated in ARPKD vessels (118±2%) compared to controls while the relaxation in response to SNP was similar between strains (123±2%). Decreases in RBF following intravenous bolus of angiotensin II in ARPKD rats were significantly greater in ARPKD rats compared to controls (ΔRBF -47.5±4.6% vs -27.4±3.8%, $p<0.05$).

Conclusions: These results support the hypothesis that renal microvascular dysfunction in ARPKD results from endothelial dysfunction and may contribute to vascular complications in PKDs.

FR-PO557

A Novel Aldosterone Synthase Inhibitor Ameliorates Polycystic Kidney Disease in the PCK Rat Bert Oehlen, Ping Zhou, Bin Duan, Xiaokang Zhu, Kai Jiang, Latha Paka, Itzhak D. Goldberg. *Angion Biomedica Corp., Uniondale, NY.*

Background: The renin-angiotensin-aldosterone system (RAAS) plays a critical role in renal physiology and pathology. Inhibitors of RAAS, such as angiotensin converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs) are commonly used in the management of polycystic kidney disease (PKD). However, despite initial success in reducing aldosterone, concentrations return to pretreatment levels in 30-40% of patients. This "aldosterone escape" significantly limits the therapeutic effectiveness of current RAAS

inhibitors. An attractive novel alternative approach to target RAAS is to inhibit aldosterone synthase (AS), the enzyme encoded by the CYP11B2 gene, which is directly responsible for aldosterone production. We identified a promising new series of inhibitors of AS. Lead compound ANG3586 has potent AS inhibitory activity, has excellent selectivity against other P450 enzymes, is orally bioavailable in rodents and appears to be generally well tolerated.

Methods: Male PCK rats (PCK/CrljCrl-Pkhd1pck/Crl) were treated with ANG3586 (25 mg/kg, po, bid) from the age of 6 weeks to the age of 10 weeks. A comprehensive panel of renal and liver endpoints was evaluated to assess the effect of compound treatment.

Results: Male PCK rats at the age of 6 weeks showed markedly enlarged kidneys and livers, with evident cyst formation in both organs, indicating the establishment of polycystic kidney and liver disease by this age. When these animals were treated for 4 weeks with ANG3586, the kidney weight as a percentage of body weight was reduced compared to vehicle treated animals. Progression of renal cyst formation and renal fibrosis, as well as readouts of renal function such as proteinuria were also improved. Liver fibrosis was similarly ameliorated by ANG3586 treatment.

Conclusions: In preclinical experiments, the novel aldosterone synthase inhibitor ANG3586 shows promise as a possible treatment for PKD.

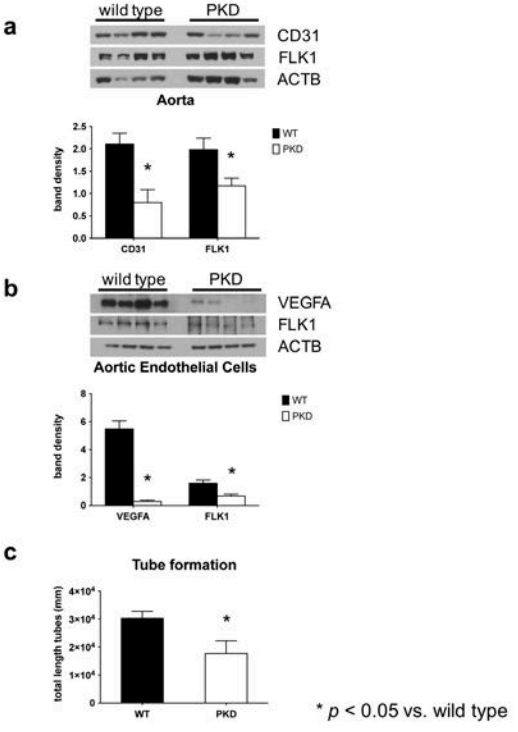
FR-PO558

The Role of Fibrocystin in the Vascular Pathophysiology of Polycystic Kidney Disease Federico Franchi,[1] Karen M. Peterson,[1] Katherine L. Quandt,[1] Peter C. Harris,[2] Martin G. Rodriguez- Porcel.[1] *[1]Cardiovascular Diseases, Mayo Clinic, Rochester, MN; [2]Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: We have previously reported that Polycystic Kidney Disease (PKD) has abnormalities in vascular structure and function even in the early stages of the disease. Here, we hypothesized that normal fibrocystin is essential for the normal function of endothelial cells.

Methods: We assessed the angiogenic profile of non-cystic organs (lung, aorta) in young (4-week old) PCK rats (model of autosomal recessive PKD – ARPKD), prior to changes in blood pressure or renal function. Then, to study the role of endothelial cells in the vascular abnormalities seen in PKD, we isolated aortic endothelial cells (AEC) from young PCK rats and characterized their angiogenic profile. Lastly, to determine if fibrocystin is responsible for the abnormal function of these cells, we used small interfering RNA (siRNA) to knockdown (KD) the expression of fibrocystin in wild type AECs and study their angiogenic profile.

Results: The aorta (fig. 1a) and lung of PCK rats had decreased expression of the vascular endothelial growth factor (VEGF) receptor, FLK1, and the endothelial marker CD31 compared to wild type, showing a significant vascular impairment of non-cystic organs in PKD. Furthermore, studies in PCK-AECs revealed a reduced expression of endothelial markers and angiogenic factors compared to wild type AECs (fig. 1b). Importantly, KD of fibrocystin in wild type AECs led to a protein expression profile similar to that observed in PCK-AECs, together with inhibition of tube formation potential (fig. 1c).



Conclusions: Here we provide evidence that ARPKD may have a primary defect in vascular function and that an intact fibrocystin is critical for the normal biology of endothelial cells. Novel interventions to reduce vascular dysfunction should be evaluated to prevent cardiovascular risk in PKD.

Does the Copy Number Variation of APOL1 Gene Associate with the Susceptibility or Clinical Manifestations of Focal Segmental Glomerulosclerosis Guisen Li, Li Wang. *Renal Div and Inst of Nephrology, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Focal segmental glomerulosclerosis (FSGS) is a primary glomerular disease characterized by diffuse fusion or effacement of podocyte foot processes.Lots of studies demonstrated that genetic mutations can be sufficient to cause or increase susceptibility to FSGS by combining the effects of environmental factors. APOL1 gene mutation (G1 and G2) in African individuals show strongly association with FSGS, but it was not replicated in Chinese FSGS patients. The copy number variation (CNV) is another type of important genetic variations. In this study, we examined the APOL1 gene copy number in chinese FSGS, and analyzed the relationship between CNV of APOL1 gene and the susceptibility to FSGS as well as clinical manifestations.

Methods: The copy number assay was custom designed to amplify and detect a 142bp region in the last exon of APOL1. The assay was performed using Applied Biosystems 7900HT quantitative real time PCR system by using 3μl of genomic DNA (50ng/μl). The results were analyzed using Copycaller software version 2. We analyzed 127 FSGS patients and 123 individuals without kidney disease for the presence of APOL1 gene duplication.

Results: The Copycaller results show that in case group and control group, 14 cases and 12 controls with one copys of APOL1, 91 cases and 92 controls with two copys of APOL1, 20 cases and 17 controls with three copys of APOL1, both cases and controls is only one sample with four copys of APOL1 and one sample didn't be detected. There was no statistical significance between the case group and control group upon the APOL1 gene copy number (p=0.34). The serum creatinine and urine proteinuria in the patients with three or four copies was obviously higher than patients with one or two copy of APOL1 gene.

Conclusions: In this study, the CNV of APOL1 gene does not associate with the susceptibility to Chinese Han FSGS patients. But the patients with high copy have higher serum creatinine and urine proteinuria.

FR-PO560

APOL1 Nephropathy Risk Variants Alter PON1 Activity in African Americans Orlando M. Gutierrez, Tamara Keenum, G.m. Anantharamaiah. *UAB.*

Background: *APOL1* nephropathy risk variants are associated with higher risk of kidney function decline and cardiovascular disease in African Americans (AA). The reasons for these associations are unclear. We reported that greater numbers of APOL1 risk variants were associated with higher circulating concentrations of small HDL subfractions linked to increased cardiovascular disease risk in population-based studies. Whether this has an impact on HDL function by *APOL1* genotype is unclear.

Methods: We recruited 11 AA with two *APOL1* risk variants (G1/G1, G2/G2, or G1/G2) and matched them by age and sex with 11 AA with one risk variant (G1 or G2) and 11 AA with zero risk variants. Participants provided plasma for HDL extraction and assessment of PON1 activity, indexed by paraoxonase/arylesterase enzymatic activity, and anti-oxidative capacity indexed by production of lipid hydroperoxides (LOOH) via dichlorofluorescein diacetate (DCFA) assay. We also measured these outputs in 11 European Americans (EA). All participants were healthy and free of kidney disease.

Results: AA participants with 2, 1 or 0 risk variants did not differ by age (33±10 vs. 36±11 vs. 35±13 years, respectively) or percentage of men (27% for each). Paraoxonase/arylesterase activity significantly increased with increasing numbers of *APOL1* risk variants in AA participants (Figure 1A). In contrast, LOOH levels did not differ by number of *APOL1* risk variants in AA participants (Figure 1B). Mean paraoxonase/arylesterase activity was lower and LOOH levels were higher in EA vs. AA participants irrespective of *APOL1* genotype status.

Figure 1A

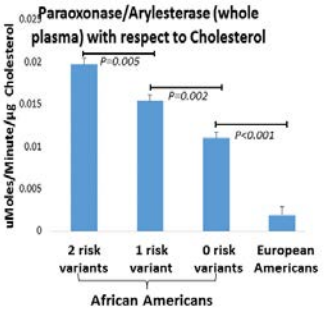

Figure 1B

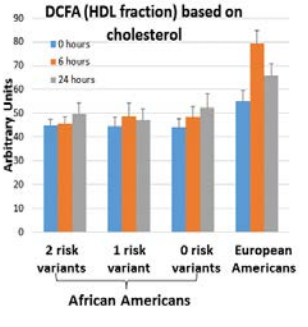

Conclusions: Greater numbers of *APOL1* risk variants associate with higher PON1 activity but no difference in LOOH levels in healthy AA. These data suggest potential resistance to the anti-oxidative action of PON1 in AA with higher numbers of *APOL1* risk variants. EA had lower PON1 activity and greater LOOH levels than AA irrespective of APOL1 risk status.

FR-PO561

APOL1 Risk Genotype in a Cohort of French FSGS Patients Aude Servais,[1,2] Olivier Gribouval,[2] Marie-Josèphe Tête,[2] Olivia Boyer,[2,3] Corinne Antignac.[2] *[1]Nephrology Unit, Necker Hospital; [2]Inserm U1163, Inst Imagine, Univ Paris Descartes; [3]Pediatric Nephrology Unit, Necker Hospital, Paris, France.*

Background: Apolipoprotein L1 (*APOL1*) G1 and G2 coding risk variants are strongly associated with sporadic FSGS in either the homozygous or compound heterozygous state in populations with African ancestry. The aim of our study was to determine the frequency of G1/G2 variants in a cohort of French steroid resistant FSGS patients with African or French West Indies origin and to analyze associations with clinical outcome.

Methods: Direct Sanger sequencing allowed the detection of three SNPs: the two missense variants p.Ser342Gly and p.Ile384Met called G1 risk allele and the 6 bp deletion p.del Asn388/Tyr389 called G2.

Results: We studied 152 patients in 139 families: 75 patients originated from French West Indies (49.0%) and 77 (51.0%) from Africa. The two risk allele (HR) genotype was considered any combination of G1 and G2 and was found in 43.1% of subjects. Patients in the HR group were more likely to originate from French West Indies than from Africa [45 (68.2%) vs 30 (34.5%), p<0.0001]. At diagnosis, patients in the HR group were more often older than 18 years than in the low risk (LR) group [34 (51.5%) vs 22 (25.6%), p=0.001] and had a lower eGFR (78.9 vs 95.2 ml/min/1.73m² by MDRD, p=0.03). All patients had similar evolution to end stage renal disease (ESRD) but patients were older at ESRD in the HR group (27.9±13.8 vs 16.6±12.3 years, p=0.007). There were more familial cases in the HR group than in the LR group [28 (42.4%) vs 13 (15.1%), p=0.0002]. Causative mutation in known monogenic steroid-resistant nephrotic syndrome genes was found in only one individual in the HR group (*NPHS1*-compound heterozygous mutation associated with G1/G1 two risk allele) and in 7 patients in the LR group. In two families, only 3/4 and 1/2 patients, respectively, had the two risk allele genotype.

Conclusions: The two risk allele genotype is found in 43% of French FSGS patients with African ancestry, compared to 13% in other population-based studies of blacks. It is more frequent in adult FSGS patients than in children and is usually not associated with other causative mutation in known monogenic steroid-resistant nephrotic syndrome genes.

Funding: Government Support - Non-U.S.

FR-PO562

APOL1 G1/G2 Down Regulates Maturation of Parietal Epithelial Cells and Immature Podocytes Xiqian Lan,[1] Nirupama Chandel,[1] Ashwani Malhotra,[1] Catherine Meyer-Schwesinger,[3] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Rambam Health Care Campus, Haifa, Israel; [2]Medicine, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Loss of critical numbers of podocytes contributes to the initiation and progression of focal segmental glomerulosclerosis (FSGS). Recently, a subset of parietal cells has been demonstrated to act as progenitor cells to replace injured podocytes in adverse milieus. Since FSGS risk is estimated to be ~17-fold higher in African Americans with compared to 0/1 copies of the APOL1 risk variants (G1, G2), we hypothesize that expression of APOL1 variants might compromise either parietal epithelial cellc (PECc) transit to podocytes or maturation of immature podocytes.

Methods: Immortalized parietal epithelial cells (PECs) were characterized by expression of PAX2, claudin 1, and notch 1 and immortalized podocytes (PDs) were characterized by expression of nephrin. These cells proliferate at 33°C and stop growing at 37°C. Both PECs and PDs differentiate at 37°C. PECs were transduced with APOL1G0/G1/G2 and incubated for 10 days at 37°C. Protein blots were probed for nephrin and reprobed for actin. Protein blots were stripped and reprboed for notch 1. Similarly, immortalized podocytes (PDs) stably expressing vector, G0, G1, and G2 were transduced with either vector with GFP or NL4-3 (HIV) with GFP. All cells were incubated at 37°C for 10 days. Protein blots were probed for nephrin and reprobed for actin.

Results: PECs expressing G1/G2 (differentiated for 10 days at 37°C) displayed attenuated expression of nephrin. Moreover, PECs expressing APOL1G0 displayed low levels of Notch 1 expression but PECs expressing APOL1 G1 and G2 displayed moderate expression of Notch 1. Differentiated APOL1G1 and G2 expressing podocytes displayed lower expression of nephrin both in the presence of vector or HIV when compared to APOL1G0. These findings indicate that expression of APOL1 G1/G2 compromises transition of PECs as well as maturation of podocytes.

Conclusions: Expression of APOL1 variants compromises transit of PECs and immature podocytes to matured podocytes.

FR-PO563

Effect of APOL1 Disease Risk Variants on APOL1 Gene Product Shabirul Haque,[1] Xiqian Lan,[1] Seyedeh Shadafarin Marashi Shoshtari,[1] Judith Eng,[1] Vinita Vishnoi,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: Gene sequence mutations may alter mRNA transcription, transcript stability, protein translation, protein stability, and protein folding. APOL1 has two sets of sequence variants which are risk factors for kidney disease development, APOL1G1 (substitution mutation) and APOL1G2 (deletion mutation). Our present study focuses on the impact of these variants on APOL1 mRNA transcription and translation.

Methods: APOL1 plasmids (EV, G0, G1, and G2) were transfected into HEK 293T cells. Podocyte cell lines stably expressing APOL1 transgenes (vector, G0, G1, and G2) were evaluated for APOL1 expression by immunoblotting (using three different commercially available antibodies) as well as FACS analysis. To determine the effect of reticulum stress or misfolded protein on APOL1 variant expression, podocytes stably expressing APOL1 and APOL1 variants were analyzed for the expression of GRP78. To determine the stability of APOL1 proteins, bioinformatics analysis (MUPro and I-Mutant 2.0) was carried out. APOL1 mRNA transcript stability was tested after actinomycin D pulsing.

Results: APOL1 variant expression was observed to be significantly lower than that of APOL1G0. Podocyte cell lines stably expressing APOL1 transgenes also showed lower levels of APOL1 expression of APOL1 variants (G1 and G2) compared to APOL1G0. The enhanced expression of GRP78 by podocytes expressing APOL1 variants suggested ongoing ER stress. Bioinformatics evaluation predicted that APOL1 variants are less stable than APOL1 G0. APOL1G1 mRNA transcript decayed 10–15 % within 0.5 to 3 hours and APOL1G2 mRNA transcript decayed 15–20% within 0.5 to 3 hours.

Conclusions: Attenuated APOL1 protein expression of APOL1 variants are due to compromised transcription and decay of the APOL1 variant transcripts.

Mother and Baby APOL1 High Risk Alleles in Births Complicated by Preeclampsia Rebecca C. Hjorten,[1] Stacy Rosenblum,[4] Joseph Myrie,[7] Bianca Lyzette Ruiz,[7] Masako Suzuki,[5] Sandra E. Reznik,[6] Cheryl Ann Winkler,[2] Jeffrey B. Kopp,[2] Frederick J. Kaskel,[1] Kimberly J. Reidy.[1] *[1]Pediatrics, Nephrology, Albert Einstein College of Medicine (AECOM), Bronx, NY; [2]Genetic and Epidemiology Studies Section, National Insts of Health, Frederick, MD; [3]Kidney Disease Section, National Insts of Health, Frederick, MD; [4]Pediatrics, Neonatology, AECOM, Bronx, NY; [5]Genetics, AECOM, Bronx, NY; [6]Pathology, AECOM, Bronx, NY; [7]AECOM, Bronx, NY.*

Background: Increased prevalence of APOL1 high-risk alleles was associated with adverse perinatal outcomes in children with chronic kidney disease. The goal of this study is to determine if APOL1 risk status is associated with risk or severity of preeclampsia, a major cause of adverse perinatal outcomes, which is more prevalent and severe in women of African Ancestry.

Methods: Clinical Looking Glass, a clinical data extraction tool, was used to identify mothers who identify as Black or African American with births complicated by preeclampsia. DNA from mothers and babies was then extracted from their placental and umbilical cord tissues and genotyped for *APOL1* SNPs (rs73885319 and rs60910145) and the G2 indel (rs717185313) by TaqMan assay.

Results: Of the 19 mothers genotyped, 2 had high-risk alleles (11%) a proportion not dissimilar to general population. Of the 24 babies genotyped, 7 were had the high-risk alleles (29%), which is significantly different from the general population (p-value 0.01, chi-square). When comparing birth outcomes, births with babies with APOL1 high-risk status have a lower gestational age, 32 versus 37 weeks gestation (p-value 0.02, Mann–Whitney test) and lower Apgar scores at 1 and 5 minutes, 5 and 7 versus 8 and 9 (p-value 0.1 and 0.02 respectively, Mann–Whitney test). They also had a lower mean birth weight, 1.8 kg versus 2.5 kg, however this difference was not statistically significant (p-value 0.21, Mann–Whitney test).

Conclusions: While limited by small sample size in this preliminary study, our results suggest that high-risk APOL1 status may be present at a higher proportion in babies born from births complicated by preeclampsia and that they are more likely to have poorer perinatal outcomes.

Detection and Validation of Epithelial-to-Mesenchymal Transition (EMT) with Increased Expression of Axl and MMP-14 in Renal Cell Carcinoma Lea Landolt,[1] Oystein Solberg Eikrem,[1] Gro Gausdal,[5] Lavina Ahmed,[5] Christian Beisland,[1,2] Kenneth Finne,[1] Andreas Scherer,[4] Mohammad Madani Ibrahim,[1] Hans-Peter Marti.[1,3] *[1]Dept of Clinical Medicine, Univ of Bergen, Bergen, Hordaland, Norway; [2]Dept of Urology, Haukeland Univ Hospital, Bergen, Hordaland, Norway; [3]Dept of Medicine, Univ of Bergen, Bergen, Hordaland, Norway; [4]Inst for Molecular Medicine Finland (FIMM), Univ of Helsinki, Helsinki, Finland; [5]Bergenbio AS, Bergen, Hordaland, Norway.*

Background: EMT is an important feature in cancer and can be used for therapeutic interventions. Recently, we described overabundance of vimentin, and underrepresentation of E-cadherin on mRNA level *(O. Eikrem, PLOS One 2016)* in clear cell renal cell carcinoma (ccRCC). In the present study, we wanted to further document and validate presence of EMT and two of its mediators or inducers, namely Axl receptor tyrosine kinase and matrix metalloproteinase 14 (MMP-14).

Methods: We have obtained perioperative core biopsies from ccRCC patients: detection cohort (n=16) and subsequent validation cohort (n=12). Paired kidney biopsies from each patient with ccRCC and adjacent non-tumorous tissue were formalin-fixed and paraffin-embedded. Next generation transcriptome sequencing (NGS), immunohistochemistry (IHC), and proteomics were performed as described *(O. Eikrem, PLOS One, 2016; K. Finne, NDT, 2014)*.

Results: In both of our NGS datasets, we found up-regulation of EMT genes, including an approx. 3-fold increased abundance of Axl tyrosine kinase and an approx. 2.7-fold overabundance of MMP-14 in ccRCC samples compared to the adjacent non-malignant tissue. Increased expression of Axl was confirmed by IHC. Up-regulation of vimentin

as well as down-regulation of E-cadherin in ccRCC were validated on mRNA level and confirmed on protein level by proteomics and IHC. Proteomic data confirmed presence of EMT, including a 3.4 fold up-regulation of vimentin and a 2.7 fold down-regulation of E-cadherin in our ccRCC samples. Proteomics, IHC and RT-PCR also confirmed up-regulation of MMP-14 in ccRCC.

Conclusions: Evidence for EMT in conjunction with up-regulation of Axl receptor tyrosine kinase and MMP-14 is a prominent feature in our ccRCC patients and offers potential therapeutic targets.

FR-PO566

An Increased Incidence of Idiopathic Membranous Nephropathy and Gene-Environment Analysis in Northern Part of China: A Cross-Sectional Study Sufang Shi,[1] Wanyin Hou,[1] Ying Li,[2] Shu Xia Fu,[3] Ming Hui Zhao.[1] *[1]Renal Div, Peking Univ First Hospital, Beijing, China; [2]Renal Div, the 3rd Hospital of Hebei Medical Univ, Shijiazhuang, China; [3]Renal Div, the 2nd Hospital of Hebei Medical Univ, Shijiazhuang, China.*

Background: Idiopathic membranous nephropathy (IMN),more common in elderly male in developed country,is becoming the most popular primary glomerula disease in China.The reason is not clear. Phosphlispase A2 receptor,PLA2R1and HLA-DQA1 genes contribute the most to IMN. It is presumed gene and air pollution were associated with the incidence of IMN. In this study, we performed a multi-center cross-sectional study in Hebei province (north China, near Beijing), to validate the increased trend of MN and the roles of gene-environment interaction.

Methods: 5785 IMN patients out of 16981 who accept renal biopsy from 28 hospitals in 11 cities since 2009 to 2013 were enrolled.374 MN and 239 controls were available of DNA samples. We classified MN patients according to age (≤20,20-40, ≥40)and air pollution level(non-risk northeast, mid-risk northwest and high-risk middle south).SNPs were genotyped by TaqMan assays. Rs4664308 within PLA2R1 and rs 2187668 within HLA-DQA1 were to validate gene roles in IMN. Gene-environment interaction was performed by epinet-calculation.

Results: From 2009 to 2013,proportion of IMN in primary glomerular disease(PGN) were 27%(258/955),36.9%(474/1283),45.6(681/1492),54.7%(1048/1917),62.6%(1409/2250) ,respectively. Younger patients (≤20) was increasing greatly from 13.9% to 31.8%. In terms of geographic and pollution level,IMN accounted for 38.6%,25.3%and23.4% of PGN in middle south(high risk), northwest (mid-risk)and northeast(non-risk)region, with the middle south mostly increased.Genetically,rs4664308 and rs2187668 were significantly associated with MN($p=4.8\times10^{-16}$ and1.0×10^{-3}, respectively),but not for rs2187668 in northwest MN(p=0.11).For PLA2R1, gene-environment interaction showed a 38 times [OR=38.72,95%CI 12.0-125.5,p<0.01,RERI 25.0(-3.4-53.4),AP 0.8(0.7-0.9),S 6.9(2.9-16.5)]of risk for developing MN.

Conclusions: IMN is the leading cause of glomerular disease in northern China. PLA2R1 gene and environment interaction might contribute to the increased MN incidence.

FR-PO567

Comprehensive RNA Sequencing Analysis of Human Diabetic and Hypertensive Kidney Disease Chengxiang Qiu,[1] Matthew Palmer,[2] Mendy Liang,[1] Melanie Sweeney,[1] Julie Hawkins,[3] Jonathan Hill,[3] Paolo Guarnieri,[3] Gregory R. Warnes,[3] Carine Boustany,[3] Steven S. Pullen,[3] Katalin Susztak.[1] *[1]Dept of Medicine, Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA; [2]Pathology and Laboratory Medicine at the Hospital, Univ of Pennsylvania, Philadelphia, PA; [3]Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: One in ten people in the United States suffers from chronic kidney disease (CKD). Progress in CKD research and drug development has been limited, and no drugs have been registered for the last 15 years. One key limitation has been that animal models do not recapitulate common forms of CKD (diabetic and hypertensive kidney disease). The aim of the current study was to collect and analyze a large number of human kidney tissue samples and identify transcript level changes in microdissected human glomeruli and tubules.

Methods: Human kidney tissue samples were collected in RNAlater from non-neoplastic regions of tumor nephrectomies. Detailed clinical information was collected using an "honest broker" system. Histologic sections were scored for 19 independent pathological parameters reflecting glomerular, tubulointerstitial, and vascular compartments. RNA sequencing of 256 human kidney tissue samples (154 control and 102 CKD) was performed on glomeruli and tubules separately using Illumina Trueseq v3 library kits and Hiseq2000 instruments. Reads were aligned using STAR aligners and annotated using Gencode human genome (GRCh37). Data analysis was performed with R/Bioconductor using a regression model.

Results: Glomerular filtration rate was best associated with tubulointersitial fibrosis. Using statistical modeling, a large number of genes showed correlation with fibrosis and glomerulosclerosis. In addition, we applied weighted gene co-expression network analysis (WGCNA) to identify key transcriptional nodules that correlate with structural and functional changes. Both analyses highlighted pathways associated with immune system activation and dysmetabolism (eg. oxidoreductase) in CKD.

The Association between Genotypes of Urate Transporter-1, Serum Uric Acid, and Mortality in the Community-Based Population Soichiro Kon, Keita Kamei, Hiroko Sato, Kazunobu Ichikawa, Tsuneo Konta, Isao Kubota. *Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan.*

Background: Hyperuricemia is a risk factor for renal and cardiovascular diseases, and serum uric acid level is affected by genetic predisposition. The function of urate transporter-1 (URAT1:SLC22A12), an important transporter in the reabsorption of uric acid in renal tubules is regulated by several single nucleotide polymorphisms (SNPs) within URAT1 gene. However it is unknown whether the genotypes in URAT1 is associated with the mortality in the community-based population.

Methods: The participants of this study were 1596 subjects (male 45%, mean age 61 years) that were registered at health checkup in Takahata, Japan and were followed up for 7 years. The association between the genotypes of SNPs (rs505802, rs475688, rs476037) in URAT1 gene, serum uric acid levels and the mortality were examined.

Results: The serum uric acid levels at baseline were significantly different between the genotypes of rs505802 (G/G: 5.1±1.3 [mean±SD] mg/dL, AG: 5.0±1.4, AA: 4.7±2.0, P=0.02), but not rs475688 and rs476037. Multiple regression model showed that the genotypes of rs505802 was independently associated with serum uric acid levels after the adjustment with confounders including gender, renal function, and comorbidities. Kaplan-Meier analysis showed that the mortality was higher in the subjects with the G/G genotypes of rs505802 than those with the A/G and the A/A genotypes. Cox proportional hazard model with the adjustment for confounders showed that the G/G genotype was an independent predictor for the mortality (hazard ratio [HR] 2.17, 95% confidence interval [CI] 1.07-5.02, [vs. A/G+A/A genotypes]). This significant association was unchanged in the analysis model adjusted with above mentioned confounders and serum uric acid levels (HR 2.16, 95%CI 1.06-5.00).

Conclusions: This study showed that the genotypes of rs505802 in URAT1 gene was independently associated with serum uric acid levels and the mortality in the community-based population. However, the link between this genotypes in URAT1 and the mortality might be due to serum uric acid-independent mechanism.

Translatability of the ZSF1 Rat to Human Diabetic Nephropathy Kathleen A. Lincoln,[1] Holly Clifford,[1] Jonathan Hill,[1] Mark Mchugh,[1] Hu Sheng Qian,[1] Steven S. Pullen,[1] Chengxiang Qiu,[2] Katalin Susztak,[2] Julie Hawkins,[1] Carine Boustany.[1] *[1]Cardiometabolic Diseases Research, Boehringer-Ingelheim Pharmaceuticals, Ridgefield, CT; [2]Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: The ZSF1 rat is utilized for preclinical screening of drug candidates due to its similarities to human diabetic nephropathy. To explore pathways dysregulated in this model, we investigated longitudinal changes in renal biomarkers, histological measures, and transcriptomics, and identified similarities with human disease. Furthermore we determined whether losartan would repair dysregulated pathways.

Methods: ZSF1 obese rats were treated with either vehicle or losartan and compared to aged-matched lean counterparts. Mean arterial pressure and urine were collected weekly. Histologic quantification of glomerular and interstitial lesions and transcriptomics were performed at 10, 25 and 41 weeks of age. For comparison to human disease we utilized transcripts derived from sequencing of human nephrectomy samples from patients with/without diabetic nephropathy.

Results: By 10 weeks of age, ZSF1 rats were obese and diabetic compared to aged-matched leans. Proteinuria preceded the onset of hypertension and was reduced by losartan treatment. The incidence of glomerulosclerosis and interstitial lesions increased with age in obese ZSF1 vs leans and was reduced by losartan at 41 weeks. Histological lesions were accompanied with increases in urinary markers of tubular damage and inflammation that were only partially reduced by losartan. Transcriptomics performed at 10, 25 and 41 weeks of age revealed 2500 genes upregulated in obese vs lean that were indicative of inflammation. In contrast, only 350 genes were downregulated in obesity and reflected dysmetabolism and oxidative stress. Losartan treatment restored a subset of these dysregulated genes. Comparison of differentially expressed genes in ZSF1 rats with those differentially expressed between healthy and diabetic nephropathy patients revealed overlapping inflammatory pathways.

Conclusions: In conclusion the ZSF1 rat displays key hallmarks of diabetic nephropathy and shares common pathways with human disease.

FR-PO570

A Single Nucleotide Polymorphism in Kidney Anion Exchanger 1 Gene Causes Incomplete Type 1 Renal Tubular Acidosis Takumi Takeuchi. *Urology, Japan Organization of Occupational Health and Safety Kanto Rosai Hospital, Kawasaki, Japan.*

Background: Various conditions including distal renal tubular acidosis (dRTA) can induce stone formation in the kidney. dRTA is characterized by an impairment of urine acidification in the distal nephron. dRTA is caused by variations in genes functioning

in intercalated cells including SLC4A1/AE1/Band3 transcribing two kinds of mRNAs encoding the $Cl^-/HCO3^-$ exchanger in erythrocytes and that expressed in α-intercalated cells (kAE1).

Methods: Sixty-eight unrelated Japanese urolithiasis patients who had previously undergone lithotripsy were investigated regarding their capacity for renal tubular acidification during hospitalization. For genomic DNAs of patients who showed urine acidification abnormality, the SLC4A1/AE1/Band3 gene was amplified in fragments encompassing all exons except exon 1 and directly sequenced. Erythroid introns 3, 7, and 17 of participants (n=13 for incomplete dRTA and n=29 for non-dRTA) were further amplified and directly sequenced. Intron 3 of the AE1 gene of an incomplete dRTA case and a non-dRTA control were amplified and subcloned into pGL4.17 [luc2/Neo] reporter vector. Those tester constructs as well as pNL1.1.TK [Nluc/TK] control vector were used to transfect MDCK and HEK293 cells. The normalized strength of the firefly luciferase activity was calculated by the firefly luciferase activity of each well divided by the NanoLuc® luciferase activity of the same well.

Results: With the acid-loading test, 25% of urolithiasis patients were diagnosed with incomplete dRTA. In erythroid intron 3 containing the promoter region of kAE1, rs999716 SNP showed a significantly higher minor allele A frequency in incomplete dRTA compared with non-dRTA patients. The promoter regions of the kAE1 gene with the minor allele A at rs999716 downstream of the TATA box showed reduced promoter activities compared with that with the major allele G.

Conclusions: Patients with the A allele at rs999716 may express less kAE1 mRNA and protein in the intercalated cells, developing incomplete dRTA. This relatively common polymorphism can cause urolithiasis frequently in population.

FR-PO571

Will Exome Sequencing Increase the Number of Patients Referred to Nephrology Clinics? Hila Milo Rasouly, David Fasel, Adele Mitrotti, Simone Sanna-Cherchi, David B. Goldstein, Ali G. Gharavi. *Medicine, Columbia Univ, New York, NY.*

Background: A growing number of individuals are undergoing whole exome sequencing (WES) for diagnosis of kidney or non-kidney disorders. We studied the prevalence of variants in genes associated with kidney diseases in healthy individuals to assess the potential for **I**ncidental **F**indings related to these disorders.

Methods: Using OMIM and Pubmed, we identified 355 genes associated with genitourinary disorders. We investigated 788 individuals of European ancestry, without any known medical issues, who had undergone WES using the Roche exome capture kit at the Institute of Genomic Medicine at Columbia University, as controls for non-kidney diseases. We used the in-house software, ATAV, to filter by minor allele frequency (MAF range 0-0.01 in ExAC and EVS databases), perform functional annotation, and select likely deleterious variants as predicted by Polyphen2 and CADD scores. We also investigated prior reports of pathogenicity in ClinVar and HGMD.

Results: 414 individuals (52.5%) carried at least 5 rare, predicted deleterious variants in the 355 kidney genes (MAF<0.01, CADD>10, Polyphen > 0.9). In 199 genes causing recessive disorders, 37 individuals (4.7%) were homozygous or potentially compound heterozygous for rare predicted deleterious variants. In 126 genes causing dominant disorders, 55% of individuals carried at least 2 such variants. Furthermore, 114 individuals (14.5%) carried **novel** predicted deleterious variants (absent in ExAC and EVS, CADD>20) and 37 individuals (4.7%) carried variants reported in HGMD and in ClinVar as **pathogenic** for dominant diseases associated with kidney diseases.

Conclusions: WES interpretation based solely on MAF and in-silico prediction algorithms may lead to misdiagnosis or erroneous assignment of multiple renal disorders to patient with nephropathy and also generate many referrals for incidental findings for individuals with no kidney disease. These data suggest the need for robust genetic criteria and consideration of prior clinical context for interpretation of genetic variants for renal disorders.

FR-PO572

Tissue-Specific MicroRNA Expression Patterns in Four Types of Kidney Disease Maria Angeles Baker,[1] Seth J. Davis,[1] Pengyuan Liu,[1] Kevin R. Regner,[2] Yong Liu,[1] Kenneth A. Iczkowski,[3] Mingyu Liang.[1] *[1]Center of Systems Molecular Medicine, Dept of Physiology, Medical College of Wisconsin; [2]Div of Nephrology, Dept of Medicine, Medical College of Wisconsin; [3]Dept of Pathology, Medical College of Wisconsin.*

Background: MicroRNAs (miRs) are small RNAs that primarily bind to target mRNA to reduce protein abundance. Several miRs have been shown to contribute to the development of kidney disease. However, previous analyses of miR expression in human kidney diseases were limited by the tissue heterogeneity of biopsy samples or the inclusion of only one pathology type.

Methods: In the present study, laser-capture microdissection was used to obtain glomeruli and proximal tubules from human needle kidney biopsies for miR expression analysis using deep sequencing.

Results: Nearly 100 patients with four different types of kidney diseases including diabetic nephropathy (DN), focal segmental glomerulosclerosis (FSGS), IgA nephropathy (IgAN) and membranoproliferative glomerulonephritis (MPGN) and a control group with minimal kidney injury were analyzed. The deep sequencing analysis detected 205 known human miRs and 173 potentially new miRs. A miR was considered differentially expressed if the adjusted p value was less than 0.05 according to an edgeR2 analysis. In the glomeruli, 21, 17, 5, and 25 known human miRs were respectively differentially expressed in DN, FSGS, IgAN, and MPGN compared to control. Fewer than 5 miRs were differentially expressed between any two of the four disease conditions. Nevertheless, miR-3182 was significantly downregulated in IgAN compared to all other conditions tested, and a combination of miRs 146a-5p and 30a-5p distinguished DN from all other conditions. In the proximal tubules, 18, 23, 11, 8 miRs were respectively differentially expressed in DN, FSGS, IgAN, and MPGN compared to control. No miR was differentially expressed in the proximal tubules between any two of the disease conditions.

Conclusions: In conclusion, we have identified tissue-specific miR expression patterns associated with several types of kidney pathologies. The identified miRs could serve as biomarkers of kidney diseases and might be involved in the disease mechanisms.

FR-PO573

Mutations of Upper Tract Urothelial Carcinoma in Chronic Kidney Disease in Taiwan Chih-Chuan Yu, Daw-Yang Hwang. *Div of Nephrology, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: Urothelial carcinoma is the most common malignant tumor of the urinary tract. In Europe and the USA, the occurrence in the bladder account for more than 85% of all urothelial carcinoma with a male to female ratio of about 2.5:1. However, the upper tract urothelial carcinoma (UTUC) accounts for 40% of all kidney cancers, and the male to female ratio was 1:1.3 in Taiwan. Furthermore, dialysis patients had more urothelial carcinoma than renal cell carcinoma in Taiwan.

Methods: Sixty-four paired cancer and normal tissues of chronic kidney disease patients who were diagnosed of upper tract urothelial carcinoma were examined. Target re-sequencing was performed by using Fluidigm 48.48. Access Array and MiSeq. The panel included 1) oncogenes (TXNIP, ELF, CDKN1A, MDM2, KLF5, ERCC, KDM6A, RUNX, NRAS, ARID1A, TP53, PIK3CA, CDKN2A, FBXW7, CTNNB1, KRAS, PTEN, FGFR1, FGFR3, NFE2L2, HRAS) and 2) potential actionable receptor tyrosine kinase (FGFR1, FGFR2, GFR3, ALK, ROS1, NTRK1, NTRK3, RET, PDGFRA, PDGFRB, FLT3). CLCbio Genomic Workbench was used to analyzed data and compared with dbSNP database and COSMIC database.

Results: A high mutation rate in TP53 (45%), RET (34%), FGFR2 (30%), FGFR3 (22%), ARID1A (21%), and FBXW7 (17%) were found in our cohort, which is in accordance to previous bladder cancer and UTUC studies. However, several tyrosine kinase mutations, including ROS1, ALK, NTRK1, ELF3, and PDGFRA, were found with relative high mutation incidence in our UTUC cohort.

Conclusions: Our study showed that the UTUC mutation profiles in Taiwan were similar in many well-known oncogenes as in the bladder cancer.However, differences existed in the possible actionable tyrosine kinases between bladder cancer and UTUC.This high throughput method provided mutation detection, drug applications, and cancer follow up.

FR-PO574

Characterization of Coding Variation in the Urate Transporter GLUT9, a Key Determinant of Serum Uric Acid: Absence of Gain-of-Function Phenotypes Asim Mandal,[1] Hyon Choi,[3] Tony Merriman,[2] David B. Mount.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Dept of Biochemistry, Univ of Otago, Dunedin, New Zealand; [3]Div of Rheumatology, Massachusetts General Hospital, Boston, MA.*

Background: Genetic variation in *SLC2A9* encoding the GLUT9 urate transporter is the single biggest genetic contributor to serum uric acid (SUA) and hyperuricemia; loss-of-function mutations also cause genetic "renal hypouricemia". Transcriptional initiation at different promoters generates GLUT9 isoforms with different N-termini and membrane targeting; the GLUT9a protein traffics to the basolateral membrane of epithelia whereas GLUT9b traffics to the apical membrane. Multiple common coding single nucleotide polymorphisms (cSNPs) in *SLC2A9* affect SUA, with considerable population heterogeneity.

Methods: We assessed the phenotypic transport function of 30 *SLC2A9* cSNPs, generating point mutants in GLUT9a/b and measuring urate transport activity in *Xenopus* oocytes under both depolarized and non-depolarized conditions. We also resequenced *SLC2A9* in ~800 subjects with extremes in SUA, i.e. hyper/hypouricemia.

Results: We identified 14 cSNPs that generated a loss-in-function, including variants in several transmembrane domains. However, mutants corresponding to five other cSNPs were no different from wild-type. Other cSNPs reduced the urate uptake activity of GLUT9a without affecting GLUT9b, i.e. isoform-specific effects. Several variants in a large intracellular loop exhibited loss of function in non-depolarized conditions that was rescued by depolarization, suggesting a voltage-sensitive conformation effect. Finally, loss-of-function mutations were detected by resequencing of subjects with very low SUA (renal hypouricemia); however, no gain-of-function mutants were discovered in hyperuricemics. No variants affected expression or N-glycosylation of GLUT9 proteins, as assessed by Western blotting.

Conclusions: In summary, "protective" cSNPs in *SLC2A9* that reduce SUA can have loss-of-function transport phenotypes, with no gain-of-function phenotypes that would explain hyperuricemia; this highlights the dominance of non-coding variation in *SLC2A9* in determining SUA.

Creation of Complement Factor H Mutations in Human C5a-Receptor Knock-In Mice as a Model to Assess the Effects of C5aR Antagonism in Complement-Mediated Renal Diseases

Chris Li, Linda Ertl, Pirow Bekker, Israel Charo, Thomas J. Schall. *ChemoCentryx, Mountain View, CA.*

Background: C3 glomerulopathy (C3G), and atypical hemolytic uremic syndrome (aHUS) are complement-mediated renal diseases. Mutations of complement factor H (CFH), a negative regulator of alternative complement activation, are associated with these diseases. In mouse, CFH deficiency results in a phenotype that resembles C3G, and C-terminal truncation of CFH leads to spontaneous development of aHUS. In this study, we aimed to generate these CFH mutations in mice whose complement C5a receptor (C5aR) was replaced with its human homolog, in order to assess the effects of C5aR antagonism using an inhibitor that is specific for human C5aR.

Methods: Using CRISPR technology, guide RNAs targeting the start codon (for complete deficiency) and Cysteine 937 (for C-terminal truncation) were injected into fertilized oocytes from human C5aR knock-in mice. Mutations were identified by PCR and DNA sequencing.

Results: gRNAs targeting the start codon lead to small deletions of this region and completely ablated CFH expression. In these CFH deficient mice, the C3 concentration in the circulation was dramatically reduced due to over-consumption, and renal function was impaired as evidenced by modest increase of urine albumin/creatinine ratio (UACR), even at young age. Effects of hC5aR antagonists in both spontaneous and accelerated disease settings are currently being investigated. The gRNA targeting Cys937 generated a larger deletion and unexpectedly resulted in the deletion of exon 17 of CFH, and produced a mutant CFH protein lacking amino acid 880-949. C3 levels in CFH exon 17 deletion mice are not significantly changed, and the functional consequence of this deletion is being further investigated.

Conclusions: These mice represent a new tool for assessing the contribution of C5a/C5aR signaling to the underlying pathophysiology for complement mediated renal diseases, and will allow assessment of the therapeutic potential of specifically blocking the C5a receptor in destructive diseases such as C3G and aHUS.

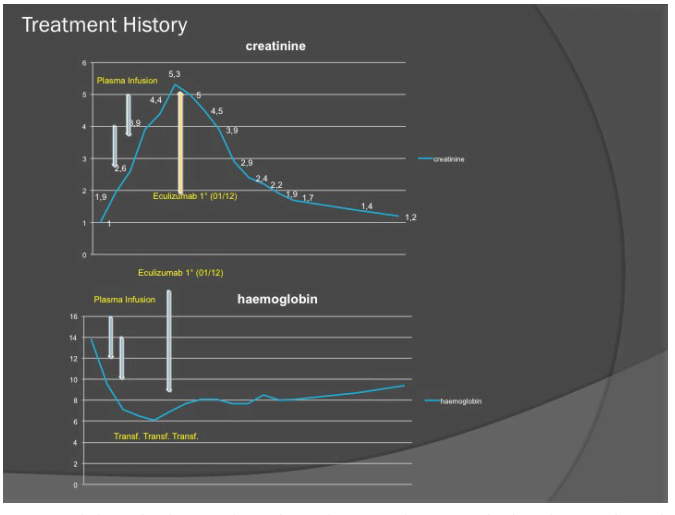
New Complement Factor H (CFH) Mutations in a Patient with Pregnancy Associated aHUS

Domenico Santoro,[1] Anna Perri,[2] Renzo Bonofiglio.[2] *[1]Univ of Messina, Messina, Italy; [2]Hospital Cosenza, Cosenza, Italy.*

Background: Pregnancy-associated thrombotic microangiopathy (P-TMA) is a rare disorder associated with a significant perinatal or maternal morbidity and mortality. P-TMA may be related to acquired or constitutional deficiency in ADAMTS13, a von Willebrand factor (vWF)-processing enzyme and gene mutations for proteins involved in regulation or activation of the alternative pathway of complement. The last one can safely and successfully treated with an anti-C5 therapy (eculizumab) to induce terminal complement blockade.

Methods: S.T. 39 years female. First pregnancy (twin pregnancy) after assisted reproduction. No therapy before pregnancy. At 32 week she referred strong pain in the epigastrium. Serum analysis showed: elevated live enzymes, acute hemolitic anemia, elevation of lactate dehydrogenase, thrombocitopenia. Twin delivery was induced (2.190Kg e 2.050 Kg). Plasma infusion and steroid therapy was started. Since no improvement was achieved , at day 5 she started Eculizumab 900 mg/week followed by 1200 every other week. Renal and clinical improvement started the day after the first infusion of eculizumab leading to complete resolution in 2-3 weeks.



Genetic investigations on alternative pathway regulatory proteins have been performed. The screening of the CFH gene showed a splicing mutation on SCR11 domain in +1G/A position of the exon 12-13, not yet described in the literature.

Conclusions: Our case show the identification of a new gene mutations coding for complement factor H (CFH). Moreover, it emphasizes the importance of a early diagnosis of aHUS for a prompt start of therapy with eculizumab in order to avoid dialysis and induce a rapid renal recovery. Future studies will help to understand how long such therapy needs to be prolonged.

FR-PO577

Apobec-1 Complementation Factor: A Novel Mediator of Renal Function

Jennie Lin, Xiao Wang, Alanna Strong, Kiran Musunuru. *Medicine, Perelman School of Medicine at the Univ of Pennsylvania, Philadelphia, PA.*

Background: A recent genome-wide association study identified rs10994860 as a genetic variant associated with higher eGFR in non-diabetic humans. This variant is located in the 5' untranslated region of *A1CF* (apobec-1 complementation factor), a RNA binding protein known to facilitate the editing of apolipoprotein B (apoB) mRNA into different isoforms in other organ systems. With little known about A1CF in the renal context, we used an unbiased approach to investigate its role in the kidney.

Methods: *A1cf* knockout (KO) mice were generated through the CRISPR/Cas9 system, with embryonic microinjection of (1) guide RNAs to target exon 9 of *A1cf* and (2) RNA encoding Cas9 nuclease. Plasma was collected for KO and wildtype (WT) male mice 12-20 weeks of age, and whole kidneys were processed for histopathology and tissue lysate immunoblotting. In addition, RNA from whole kidneys of mice from both groups was processed for RNA sequencing (N = 6 per group).

Results: *A1cf* KO mice had over 90% decrease in A1cf mRNA expression compared to their WT littermates (FDR adjusted $P < 0.01$). Mean plasma Cr values for KO (N = 10) and WT (N =14) mice were 0.84 mg/dL and 0.66 mg/dL, respectively ($P = 0.05$), although no significant differences in tissue fibrosis were observed by trichrome or Sirius red staining. Immunoblot for apoB revealed low renal apoB expression and no differences in apoB-100/apoB-48 isoform abundance between *A1cf* KO and WT mice despite elevated plasma triglycerides in the KO mice (138.4 vs. 83.4 mg/dL, $P < 0.01$). RNA-seq of whole kidneys revealed 229 differentially expressed (DE) genes (FDR adjusted $P < 0.05$) between *A1cf* KO and WT mice. We identified top canonical cell pathways enriched within these DE genes as retinoid X receptor signaling ($P = 4.8E-05$), insulin growth factor-1 signaling ($P = 6.4E-05$), and acute phase response ($P = 6.5E-05$). The top scoring gene networks for the DE genes included renal tubular injury, embryonic development, and lipid metabolism.

Conclusions: A1CF may have causal roles in renal function through metabolic pathways independent of apoB. Further studies in renal injury models are warranted.

Low Copy Numbers of FCGR3A and FCGR3B Associated with Chinese Patients with Lupus Nephritis and Anti-Neutrophil Cytoplasmic Antibody-Associated Renal Vasculitis

Yuan-Yuan Qi,[1,2] Xujie Zhou,[1,2] Ping Hou,[1,2] Jicheng Lv,[1,2] Hong Zhang.[1,2] *[1]Renal Div, Peking Univ First Hospital; [2]Peking Univ Inst of Nephrology.*

Background: Low copy number (CN) of *FCGR3B* had been implicated in systemic lupus erythematosus (SLE). However, conflicting results were reported for anti-neutrophil cytoplasmic antibody-associated systemic vasculitis. And the genetic role of CN of *FCGR3A* had seldom been addressed for these two autoantibody-mediated diseases. Here, we aimed to determine whether CNs in *FCGR3A* and *FCGR3B* were associated with lupus nephritis (LN) and ANCA-associated renal vasculitis in Chinese individuals.

Methods: A total of 1118 individuals were enrolled, including 320 LN, 95 SLE without renal involvement, 139 ANCA-associated renal vasculitis and 564 healthy controls. *FCGR3A* and *FCGR3B* CNs were determined by both paralogue ratio test and TaqMan quantitative PCR assay. The *FCGR3A* and *FCGR3B* CNV genotypes were compared between controls and cases and among patients stratified according to clinical characteristics.

Results: By comparison of results from >800 DNA samples with CN measurements by two different methods, we validated the reliability of method at first (*FCGR3A* $r=0.903$, $p<0.001$; *FCGR3B* $r=0.837$, $p<0.001$). And in susceptibility associations, a low *FCGR3B* CN was significantly associated with both LN ($p= 3.68*10^{-4}$, OR 2.02, 95% CI 1.37-2.99) and ANCA-associated renal vasculitis ($p= 0.04$, OR= 1.72, 95% CI 1.02-2.88). And a low *FCGR3A* CN was also significantly associated with both LN ($p=1.29*10^{-3}$, OR 3.26, 95%CI 1.53-6.94) and ANCA-associated renal vasculitis ($p=0.042$, OR 2.64, 95%CI 1.00-6.93). No similar associations were observed in lupus patients without nephritis. Further sub-phenotype analysis showed that lower *FCGR3A* CN associated with presence of antinuclear antibody ($p= 0.036$) and lower *FCGR3B* CN associated with anti-dsDNA and low complement ($p = 0.013$, $p = 0.035$, respectively).

Conclusions: In a large case-control study with Chinese ancestry, we identified that low CNs of *FCGR3A* and *FCGR3B* were common risk factors for LN and ANCA-associated renal vasculitis.

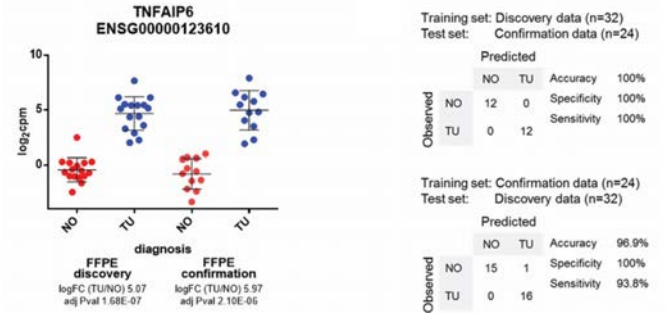
FR-PO579

Development and Confirmation of Gene Classifiers of Human Clear Cell Renal Cell Carcinoma Using Next-Generation Sequencing Oystein Solberg Eikrem,[1] Andreas Scherer,[2] Lea Landolt,[1] Hans-Peter Marti,[1] Philipp Strauss.[1] *[1]Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; [2]Spheromics, Kontiolahti, Finland.*

Background: We recently reported on the feasibility of RNAseq technology for capturing disease biology of clear cell renal cell carcinoma (ccRCC) and presented initial results for CA9 and TNFAIP6 as possible biomarkers of ccRCC ("discovery set"). To confirm these results we included another, independent cohort of 12 patients ("confirmation set") with biopsies from both cancer and peritumoral normal renal tissue.

Methods: From each of 12 patients undergoing nephrectomy, two core biopsies were obtained with a 16g needle. RNA sequencing libraries were generated with Illumina TruSeq® Access library preparation protocol. Comparative analysis was done using linear modeling (voom/limma; R Bioconductor).

Results: The FFPE discovery and confirmation data yielded 8957 and 11047 detected transcripts, respectively. Each of these two datasets shared 1193 of differentially expressed genes with each other. The average expression and the log2 fold changes of differentially expressed transcripts in both datasets correlated with R^2=0.95, and R^2=0.94, respectively. Among transcripts with the highest fold changes in both datasets were carbonic anhydrase 9 (CA9), neuronal pentraxin-2 (NPTX2) and uromodulin (UMOD). The diagnostic accuracy of CA9 was 100% and 93.9% when using the discovery set as training and the confirmation data as test set, and vice versa, respectively. Our data further support TNFAIP6 as a novel biomarker of ccRCC. On the average, TNFAIP6 had an accuracy of 98.5%. TNFAIP6 and CA9 expression abundance on the protein level was confirmed by immunohistochemistry.



Conclusions: We provide confirmatory data of potential use of CA9 and TNFAIP6 as biomarkers of ccRCC. This enables the investigation of well defined retrospective cohorts for transcriptomic analyses from FFPE kidney biopsies.

FR-PO580

Value of Genome Copy Number Variation in Predicting Responses to a Prescribed Chinese Herbal Medicine in the Treatment of Idiopathic Membranous Nephropathy(IMN) Lin Wang,[1] Shihui Li,[2] Xianwen Zhang,[1] Jianhui Tian,[1] Minping Qian,[2] Lin Wan,[3] Yiping Chen.[1] *[1]Nephrology, Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China; [2]School of Mathematical Sciences, Peking Univ, Beijing, China; [3]Academy of Mathematics and Systems Science, Chinese Academy of Sciences, Beijing, China.*

Background: IMN is one of the leading causes of nephrotic syndrome. Current treatment of IMN is far from satisfactory. ShenQi Granule (SQ) is a prescribed Chinese herbal medicine used to treat IMN in China for decades with significant efficacy but different clinical responses among patients. Clinical responses to IMN treatment may be genetically co-determined. To explore this hypothesis, we assessed a correlation between genome-wide copy number variation (CNV) and the clinical responses to SQ treatment in a cohort of IMN patients.

Methods: 80 patients were divided into 4 groups:complete remission (CR) of SQ(SCR, n=36); no remission (NR) of SQ (SNR, n=11); CR of the immunosuppressive agent (IA) (ICR, n=18); NR of IA (INR, n=15). Genomic DNA was extracted from peripheral-blood lymphocytes and genotyped with the Affymetrix Genome-Wide Human SNP Array 6.0. Samples from 270 healthy people were used as control. We analyzed a possible association of CNV and responses to IMN treatment.

Results: CNV partition called 921 CNV regions, among which 654 are gained regions, 267 are lost regions. The lengths of the CNV regions ranged from 310 bp to 3,248,859 bp, with the median size 50,365 bp. The 3 most significant CNVs regions ($p<0.05$) are located on chromosomes 5, 6 and 8, on which SCR group showed fewer loss (2, 0, and 1 on chromosomes 5, 6, and 8) while SNR group showed more loss (6, 3 and 5 on chromosomes 5, 6, and 8). The CNV of HLA gene family, located on chromosome 6, showed gain in IMN patients of SCR group, but loss on patients of SNR group. There were no significant differences in CNVs between ICR and INR groups.

Conclusions: The differences in genetic background of IMN patients may explain some of the different clinical responses to SQ treatment. The CNVs of HLA gene family may serve as a predictive factor of the response to SQ treatment.

PER1 Coordinates Kidney-Specific Sodium Trafficking and Liver-Specific Lipid Metabolism via Timing System in Nephropathy Rats Peipei Chen, Ruiyu Zhang, Lijun Mou, Xuemei Li, Yan Qin. *Renal Div, Peking Union Medical College Hospital, Beijing, China.*

Background: The circadian gene *Per1* regulates various genes involved in sodium transport in kidney and metabolism processes in liver. We have identified the circadian rhythm of blood pressure(BP) and urine sodium excretion synchronized with the core clock genes oscillating in normal rats kidney. The present study was to explore the potential role of *Per1* in communications between the peripheral organs in nephropathy rats.

Methods: Adriamycin(ADR) rats and Sprague-Dawley (SD) rats were housed in a 12:12 hour light/dark cycle and sacrificed in six time points(ZT=2,6,10,14,18,22) for 24-hr, respectively. The circadian expression of kidney and liver genes involved with clock gene *per1* evaluated by the real-time quantitative PCR and the data were analyzed by a stepwise regression.

Results: 1.*Per1* gene showed 24-hr and 4.8-hr rhythm in kidney and liver of SD rats, respectively. It is more significant difference in rhythmic features compared with other core clock genes(*Clock*, *Bmal1*, *Cry1*, *Cry2* and *Per2*) with a robust 24-hr period in both two tissues ($p<0.05$);2.The oscillated expression of *Per1* was completely disappeared in both two tissues of ADR rats. Moreover, liver presented a high level of *Per1* expression and kidney showed a low level(MESOR 5.29 vs. 0.81, $p<0.05$);3.Kidney-specific sodium trafficking genes(*αENaC*, *NCC* and *NHE3*)regulated by *Per1* with 24-hr rhythm in SD rats. However, ADR rats lost all oscillations of above clock and clock-controlled genes which were coupled with the disturbed circadian rhythm of BP and urinary sodium excretion in the nephrotic syndrome model($p<0.05$);4.In ADR rats, the disruption of rhythmic expression of liver-specific sterol regulatory element binding protein-1c (*SREBP-1c*) and ATP binding cassette transporter A1(*ABCA1*) were regulated by *Per1* involved with lipid metabolism in nephrotic syndrome.

Conclusions: The clock gene *Per1* plays a coordinating role in regulating sodium trafficking via *αENaC*, *NCC* and *NHE3* in kidney and lipid metabolism processes in liver via *SREBP-1c* and *ABCA1* genes. It shed new light on the molecular mechanisms of communications between the peripheral organs via circadian timing system in renal diseases.

FR-PO582

Mendelian Randomization Study of HDL and LDL Cholesterol as Risk Factors for Chronic Kidney Disease Matthew Lanktree,[1] Sébastien Thériault,[2,4] Michael Walsh,[1,3,4] Guillaume Pare.[1,2,3,4] *[1]Dept of Medicine, McMaster Univ, Hamilton, ON, Canada; [2]Dept of Pathology and Molecular Medicine, McMaster Univ, Hamilton, ON, Canada; [3]Dept of Clinical Epidemiology & Biostatistics, McMaster Univ, Hamilton, ON, Canada; [4]Population Health Research Inst, McMaster Univ, Hamilton, ON, Canada.*

Background: Dyslipidemia is a risk factor for vascular disease, but its role in progression of chronic kidney disease is unclear. We sought to utilize Mendelian randomization (MR) analysis of public datasets to assess a causal role for dyslipidemia in chronic kidney disease.

Methods: Using data from the Global Lipid Genetics Consortium (n = 173,000) and 1000 genomes project, the effect of independent polymorphisms ($r^2 < 0.01$) on inverse normalized high-density lipoprotein (HDL) (124 polymorphisms) and low-density lipoprotein (LDL) (97 polymorphisms) cholesterol was obtained. The effect of those same polymorphisms on log transformed eGFR (ml/min/1.73m^2), and chronic kidney disease (CKD) outcome was obtained from the Chronic Kidney Disease Genetics (CKDGen) Consortium (n = 133,000). Using a conventional MR approach, we assessed the causal effect of HDL and LDL on eGFR and CKD.

Results: A genetic increase in HDL was associated with higher eGFR ($\beta = 0.008$; P = 0.0001) and decreased CKD risk (OR = 0.68; 95% CI: 0.58 - 0.81; $P = 7.4 \times 10^{-6}$) per 1 unit increase in inverse normalized HDL. A 17 mg/dl genetic increase in HDL corresponded to a 2% increase in eGFR and 32% reduced risk of CKD. A genetic increase in LDL was weakly associated with higher eGFR ($\beta = 0.005$; P = 0.01), but no effect was seen for CKD risk (OR = 1.00; 95% CI: 0.85 - 1.17; P = 0.97) per 1 unit increase in inverse normalized LDL. Observed effects were similar if diabetic patients were excluded from analyses.

Conclusions: MR analysis supports a genetic increase in HDL as causally associated with eGFR and CKD risk. Genetically increased LDL did not change risk of CKD.

FR-PO583

HLA-DQA1 Variants and Risk of Steroid Sensitive Nephrotic Syndrome in Children Rasheed A. Gbadegesin, Christopher Esezobor, Larry A. Greenbaum, Mahmoud Kallash, Cynthia J. D'Alessandri-Silva, Tracy E. Hunley, Nilka deJesus-Gonzalez, Gentzon Hall, Brandon M. Lane, Megan Chryst-Ladd, Guanghong Wu, Adebowale A. Adeyemo. *Pediatircs, Div of Nephrology, Duke Univ Medical Center, Durham, NC.*

Background: There is relatively little known about the genetic variants underlying the risk of developing steroid sensitive nephrotic syndrome (SSNS) in children. Recently, the first exome array association study identified the missense variants C34Y (rs1129740) and F41S (rs1071630) in *HLA-DQA1* as significantly associated with SSNS in South Asian and European ancestry children. The objective of this study is to further refine this locus and evaluate its role in other ethnicities.

Methods: We screened for the C34Y and F41S in a cohort of 68 African American children with SSNS by direct sequencing. Imputation of classical alleles and amino acids of *HLA-DQA1* was done in 363 South Asian children to further refine the association.

Results: We extend our original findings to African American children (C34Y p=5.7 X 10^{-11}, OR=3.53, 95% CI 2.33,5.42; F41S p=1.23 X 10^{-13}, OR=4.08, 95% CI 2.70, 6.28). Both variants are significant *cis*-eQTLs for HLA-DQA1 in lymphoblastoid cells. Imputation of classical HLA alleles and amino acids in SA children revealed that *HLA-DQA1*0201*,*HLA-DQB1*0201,* and *HLA-DRB1*0701* (p=1-5.4 X 10^{-6}) are the most significant classical HLA-alleles. The most significantly associated amino acid positions are *HLA-DQA1* positions 56 (2.83 X 10^{-7}), 76 (p=2.83 X 10^{-7}) and 69 (p=8.11 X 10^{-7}), which are in the functional a domain of the protein and are located on the dimer interface of the structural model of the protein. Conditional analysis revealed that there was no residual association after conditioning on *HLA-DQA1* positions 56 and 76, indicating that these are most likely the functional amino acids accounting for the observed association.

Conclusions: We have demonstrated that *HLA-DQA1* is an important locus for SSNS in children of European, Asian and African ancestries and further refined the association to the critical amino acid positions of the *HLA-DQA1* molecule.

Integrative Analysis of Disease-Associated and Gene-Expression-Driving Genetic Variants Highlights Genes Likely Mediating Chronic Kidney Disease Development

Yi-An Ko,[1] Huiguang Yi,[1] Chengxiang Qiu,[1] Jihwan Park,[1] Anna Kottgen,[2] Katalin Susztak.[1] *[1]Univ of Pennsylvania, Philly, PA; [2]Univ of Freiburg, Germany.*

Background: Genome-wide association studies (GWAS) identified single nucleotide polymorphisms (SNPs) significantly associated with chronic kidney disease (CKD). These variants are localized to non-coding genomic regions and how they cause CKD is not understood. Expression quantitative trait loci (eQTL) is a method to identify gene-expression changes driven by genetic variations. We hypothesized that an integrative analysis of eQTL and GWAS could identify target genes of GWAS studies.

Methods: eQTL analysis was performed in 99 CEU control human kidney samples by correlating genotype with RNAseq gene expression levels. Genetic variants passed genome-wide significance and associated with CKD were manually curated. Other disease-trait GWAS signals were obtained from the National Human Genome Research Institute GWAS Catalog. Enrichment analysis was performed using *coloc*, a Bayesian colocalization method. Linkage disequilibrium and p-values from both GWAS and kidney eQTL were integrated in the analysis.

Results: Integrating eQTL analysis with GWAS signals identified target genes for several non-coding GWAS loci. The overlap between the kidney eQTL dataset and CKD GWAS was greater than for other disease traits (immune, cardiovascular, metabolic and other diseases), indicating variants driving CKD development are functional in the kidney. Using *coloc*, we identified 4 regions corresponding to 4 target genes for CKD-associated genetic signals, including a previously published gene, CASP9, and others including MANBA and ALMS1P. To examine the functional role of the newly identified gene MANBA, we used *Danio rerio* as a model system. eQTL analysis showed decreased MANBA expression in kidneys of subjects with risk alleles. Expression of MANBA was also decreased in kidneys of patients with CKD. Manba knockdown in zebrafish resulted in pericardial edema, a phenotype seen with kidney developmental defect.

Conclusions: Integrative analysis of genetic and transcript level data is critical to understand genes causally related to specific trait development.Our integrative analysis identified novel genes for CKD.

Rare Genetic Variants That Segregate with Familial IgA Nephropathy Belong to a Single Aberrantly Modulated Immune-Related Network

Sharon N. Cox,[1,2] Francesco Pesce,[1,3] Julia Sarah El-Sayed Moustafa,[3,4] Fabio Sallustio,[1] Grazia Serino,[5] Charalambos Kkoufou,[4] Annalisa Giampetruzzi,[1] Nicola Ancona,[6] Mario Falchi,[3,4] Francesco Paolo Schena.[1,2] *[1]Univ of Bari, Italy; [2]C.A.R.S.O. Consortium, Italy; [3]Imperial College London, United Kingdom; [4]King's College London; [5]IRCCS, Italy; [6]ISSIA, CNR, Italy.*

Background: The pathogenesis IgA nephropathy (IgAN) is still not clear but familial clustering demonstrates a strong genetic involvement. Aim of our study was to find rare, high penetrant risk variants, combining family-based linkage analysis (LA) with whole exome sequencing (WES).

Methods: Genotyping and LA were performed on 16 families of South Italian ancestry. Eight informative IgAN families containing 2 affected individuals and the most genetically discordant unaffected control were selected for WES. Variant calling and annotation were performed with GATK high standard procedures. High-priority variants in linked regions were identified and validated using Sanger sequencing. Their frequency was evaluated in external databases and with TaqMan Assays on an independent cohort of 240 IgAN patients and 113 controls. The connectivity between genes containing variants was evaluated with IPA network analysis.

Results: We found suggestive linkage signals to multiple loci. Our WES study identified 24 validated linked variants segregating with IgAN status. They were confirmed to be private or extremely rare (MAF<0.0003) and were present within coding or regulatory regions of 23 genes that merged into a IgAN-related network. The genes were interconnected by AKT, CTNNB1, NFKB, MYC and UBC, key modulators of WNT-β-catenin and PI3K/AKT pathways, notably implicated in IgAN pathogenesis. Overlaying publicly available expression data onto this network, genes/proteins whose expression is notably altered in IgAN were also included. A central role in this network was ascribed to the glucocorticoid receptor, the target of corticosteroid therapy and recommended by the KDIGO guidelines in the treatment of IgAN.

Conclusions: Our study suggests that disease could be influenced by multiple rare variants acting in a common immune related network. The analysis of IgAN related network could identify novel drug-targets for personalized therapy.

rs2576178 in Renalase Gene Is Associated with Hypertension in Type 2 Diabetic Nephropathy with Overt Albuminuria Patients

Limei Liu,[1] Xiaoxu Ge,[1] Rong Zhang,[1] Ming Li,[1] Weijing Zhao,[1] Feng Wang,[2] Niansong Wang.[2] *[1]Dept of Endocrinology & Metabolism, Shanghai Jiaotong Univ Affiliated Sixth People's Hospital, Shanghai Diabetes Inst; [2]Dept of Nephrology, Shanghai Jiaotong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: The renalase expression is related to plasma norepinephrine, systolic blood pressure (SBP) and proteinuria and renalase gene (RNLS) polymorphism is correlated with essential hypertension, type 2 diabetes and heart failure have been reported. We performed a case-control study to investigate if the rs2576178 in *RNLS* is associated with hypertension in type 2 diabetic nephropathy (DN) with overt albuminuria patients in Chinese.

Methods: The study population consists of unrelated 226 type 2 diabetic nephropathy with overt albuminuria patients (DN group) and 251 diabetes without nephropathy control subjects (Control group). According to if the hypertension (HTN) exists, the DN group was further divided into DN-HTN(+) group (n=169) and DN-HTN(-) group (n=56). Genotypic and allelic frequencies of rs2576178 as well as clinical characteristics were compared among groups. Taqman PCR assay was performed for the genotyping of all subjects.

Results: 1) Three genotypes (GG, GA and AA) of rs2576178 (G/A) were detected. The genotype distribution of rs2576178 (G/A) was in consistent with Hardy-Weinberg equilibrium. AA genotypic and A allelic frequencies were decreased in DN group when compared with Control group (P<0.05 for each). 2) AA genotype of rs2576178 is significantly associated with preventing hypertension in all subjects, by multiple logistic regression analysis, adjusted for sex, age, and BMI with OR(95% CI) of 0.48 (0.28~0.81). 3) Compared with DN-HTN (-) group, GG genotypic and G allelic frequencies were significantly increased in DN-HTN (+) group (P<0.05 for each). 4) Adjusted for sex, onset age of diabetes and BMI, AA genotype of rs2576178 is significantly associated with preventing hypertension in DN patients with OR of 0.37 (0.17~0.80) by multiple logistic regression analysis.

Conclusions: AA genotype carriers of rs2576178 in *RNLS* may decrease the risk of hypertension in overt albuminuria of type 2 diabetic nephropathy when adjusted for sex, onset-age and BMI.

FR-PO587

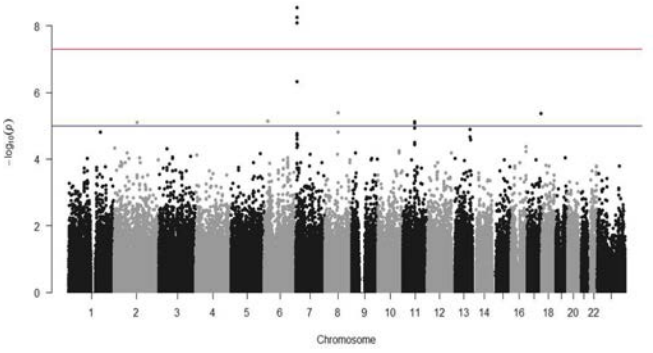
O-Glycosylation of IgA1 Is Associated with Genetic Variation of C1GALT1

Daniel P. Gale,[1] David Harry John Wimbury,[2] Peiran Yin,[3] Patricia Higgins,[2] Robert Kleta,[1] Xueqing Yu,[3] Karen Molyneux,[2] Jonathan Barratt.[2] *[1]UCL Centre for Nephrology, Univ College London, London, United Kingdom; [2]Dept of Infection, Immunity & Inflammation, Univ of Leicester, Leicester, United Kingdom; [3]Inst of Nephrology, The First Affiliated Hospital, Sun Yat-Sen Univ, Gunagzhou, China.*

Background: IgA nephropathy (IgAN) is associated with abnormal glycosylation of the IgA1 molecule. We sought factors determining IgA1 glycosylation in cohorts of patients and healthy controls.

Methods: Levels of Galactose-deficient IgA1 (Gd-IgA) were measured by lectin-binding assay in a discovery cohort of 503 UK patients with biopsy-proven IgAN with >5 year follow-up data and 250 of their healthy parents in 137 complete trios, all genotyped using a 300,000-marker array. Findings were replicated in 309 UK patients with Membranous Nephropathy (MN) genotyped on a different 330,000-marker array. Further replication was performed in 690 Chinese patients with biopsy-proven IgAN genotyped at 38 markers across the locus.

Results: Gd-IgA levels were higher in IgAN patients with progressive kidney damage (p<0.01). Heritability (h^2) was 0.28. Linear regression genome wide association study in 613 founder members of the discovery cohort identified alleles at a single locus, spanning the *C1GALT1* gene, that were strongly associated with Gd-IgA level (p<10^{-8}), with no other hits across the genome.



C1GALT1 encodes an enzyme important in galactosylation of *O*-linked glycoproteins. The association was replicated in separate cohorts of UK patients with MN ($p<10^{-6}$; combined cohorts $p<10^{-14}$) and Chinese patients with IgAN ($p<10^{-6}$). The same extended haplotype was associated with elevated Gd-IgA levels in all cohorts studied, with a frequency of 0.26 in Caucasians but only 0.02 in Chinese people.

Conclusions: In addition to providing robust validation of the assay, we conclude that genetic variation at *C1GALT1* affects Gd-IgA level in the population.

Funding: Government Support - Non-U.S.

FR-PO588

Linking Tagging SNPs with Regulatory Information in Idiopathic Membranous Nephropathy Sebastian Martini,[1] Maja Lindenmeyer,[1] Clemens D. Cohen,[1] Viji Nair,[2] Detlef Bockenhauer,[3] Paul E. Brenchley,[4] Hanna Debiec,[5] Pierre M. Ronco,[5] Jack F. Wetzels,[6] Robert Kleta,[3] Matthias Kretzler.[2] *[1]Medizinische Klinik IV, Klinikum der Univ München, Germany; [2]Dept of Internal Medicine, Univ of Michigan, Ann Arbor; [3]Centre for Nephrology, Univ College London, UK; [4]School of Biomedicine, Univ of Manchester, United Kingdom; [5]Inst National de la Santé et de la Recherche Médicale, Univ Pierre et Marie Curie Univ-Paris, France; [6]Dept of Nephrology, Radboud Univ Nijmegen Medical Centre, The Netherlands.*

Background: Genome-wide association studies have identified an association of two single nucleotide polymorphisms (SNPs) in the introns of PLA2R1 and HLA-DQA1 with idiopathic membranous nephropathy (iMN, Stanescu et al., 2011). We hypothesize that iMN SNPs with below genome wide significances can provide information on iMN disease mechanism.

Methods: An integrative strategy was devised linking less stringently ($p<10^{-5}$) selected SNPs associated with iMN to underlying mechanism. Utilizing ENCODE, HaploReg and RegulomeDB potentially regulatory SNPs (rSNPs) patterns were evaluated for their cis-transcript impact using Genomatix variant analyzer and mRNA levels from 28 iMN and 6 living donor biopsies.

Results: Starting with 525 SNPs genome-wide suggestive variants associated with iMN HaploReg identified 7,956 SNPs in linkage disequilibrium. RegulomeDB retrieved 512 potential rSNPs overlying TF binding sites. In proximity to these 512 rSNPs we identified 127 transcripts. Nineteen of those 127 genes were differentially regulated in glomeruli of iMN patients versus 6 living donors. A strong functional concept among these 19 genes was the Antigen-*presentation* pathway with non-classical human leukocyte antigens (HLA-F, HLA-G) and superfamily receptors modulating T cell function (BTN3A). Consistent with this concept several members of Antigen-*processing* pathways like PSMB9, an immunoproteasome subunit or CLIC1 regulating macrophage phagosomal functions were identified.

Conclusions: A systems genetics approach can generate a testable hypothesis of additional molecular mechanisms in iMN by integrating GWAS and gene expression information.

FR-PO589

Bi-Ethnic GWAS Refines Genetic Architecture of Membranous Nephropathy Nikol Mladkova,[1] Jingyuan Xie,[2] Justin A. D'Addario,[1] Monica Bodria,[1] Robert A. Ledesma,[1] Nicole Lester,[1] Valeria Matta,[4] Carlo Sidore,[4] Magdalena Zoledziewska,[4] Francesco SCOLARI,[3] Antonello Pani,[4] Francesco Cucca,[4] Nan Chen,[2] Krzysztof Kiryluk.[1] *[1]Columbia U *equal contribution; [2]Ruijin Hospital *Equal Contribution; [3]U of Brescia; [4]U of Monserrato, Cagliari.*

Background: Idiopathic membranous nephropathy (MN) is the leading cause of nephrotic syndrome worldwide. Common variants at PLA2R1 and HLA loci have previously been associated with MN in Europeans, but these signals have not yet been fine-mapped. Notably, PLA2R (encoded by PLA2R1) represents a known target of pathogenic autoantibodies in up to 70% of MN cases.

Methods: We performed a GWAS discovery in 1,465 East Asians and 1,685 Sardinians (654 cases & 2,496 controls). The Asian cohort was genotyped with the OmniZhongHua-8 chip while the Sardinian cohort with OmniExpress. Following stringent QC, genotype data were imputed using 1000G reference. Imputation of classical HLA alleles was performed with SNP2HLA. Ethnicity-specific results were meta-analyzed using METAL.

Results: We replicated the *HLA* signal on chr.6p21 (OR=5.56, P=9.6E-65) and *PLA2R1* locus on chr.2q23 (OR=3.23, P=2.1E-24). We also confirmed a significant genetic interaction between these loci (P=1.4E-3). We next performed conditional haplotype analyses and defined a single genome-wide significant *PLA2R1* haplotype and 3 independent *HLA* haplotypes. The analysis of classical HLA alleles revealed that the HLA signal is entirely explained by *HLA-DRB1*1501* (OR=5.34, P=7.3E-47), Arg at position 233 of *DRB1* (OR= 5.24, P=1.6E-07) and Arg at position 74 of *DRB1* (OR= 9.0, P= 2.2E-19). After conditioning on the *HLA* and *PLA2R1* loci, we identified a number of new suggestive loci across the genome that are presently being tested for replication in >1,200 additional cases.

Conclusions: We confirmed the previously implicated variants with large effects on the risk of MN, fine-mapped the MHC signal to a single gene, demonstrated that the association at the *PLA2R1* locus can be explained by a single risk haplotype, and identified several novel suggestive signals. Our genetic results confirm that the interaction between the antigen (PLA2R) and HLA-DRB1 is critical for the development of MN, confirming strong autoimmune component to the disease pathogenesis.

GWAS for Serum Galactose-Deficient IgA1 Implicates Critical Genes of the *O*-Glycosylation Pathway Krzysztof Kiryluk,[1] Yifu Li,[1] Zina Moldoveanu,[2] Hitoshi Suzuki,[3] Ping Hou,[4] Jingyuan Xie,[5] Nikol Mladkova,[1] Colin Reily,[2] Robert A. Ledesma,[1] Drew A. Bradbury,[1] Frank Eitner,[9] Thomas Rauen,[6] Jürgen Floege,[6] Nan Chen,[5] Hong Zhang,[4] Francesco SCOLARI,[7] Robert J. Wyatt,[8] Bruce A. Julian,[2] Jan Novak,[2] Ali G. Gharavi.[1] *[1]Columbia U; [2]U of Alabama at Birmingham; [3]Juntendo U; [4]Peking U; [5]Ruijin Hospital; [6]U of Aachen; [7]U of Brescia; [8]U of Tennessee; [9]Bayer Pharma.*

Background: IgA1 *O*-glycosylation defects are universally detected among patients with IgA nephropathy (IgAN). Serum level of galactose-deficient IgA1 (Gd-IgA1) represents a known heritable biomarker for IgAN, but specific genetic factors involved in its determination are not known.

Methods: We performed a quantitative GWAS for serum Gd-IgA1 in 2,633 individuals (IgAN cases and controls). In the discovery phase, we used HAA-lectin ELISA to profile sera of 1,195 individuals of Asian and European ancestry genotyped with Illumina 610q and 550v3 platforms. The association analysis of each cohort was adjusted for age, sex, ancestry and case status. Suggestive loci were followed by targeted genotyping in 1,438 additional individuals. Subsequently, all cohorts were meta-analyzed to identify novel genome-wide significant loci.

Results: The strongest association signal was mapped to chr.7p21.3 ($P=3x10^{-11}$). The top SNP intersects a B-cell specific enhancer of C1GALT1, the key enzyme of the *O*-glycosylation pathway. This variant exhibits a significant cis-eQTL effect in which the Gd-IgA1-increasing allele is associated with lower C1GALT1 mRNA levels ($P=4x10^{-23}$). The second significant locus mapped to chr.Xq24 containing C1GALT1C1 ($P=3x10^{-8}$). This gene encodes Cosmc, the molecular chaperone of C1GalT1 protein. We confirmed the role of these two genes in the production of Gd-IgA1 by iRNA knock-down experiments in IgA1-secreting cell lines. Jointly, the new loci have large effects and explain up to 7% of the overall variability in the circulating level of Gd-IgA1.

Conclusions: In the first GWAS for serum levels of Gd-IgA1, we discovered two genome-wide significant loci encoding enzymes involved in the key step of *O*-glycosylation. Our findings provide new insights into the genetic regulation of *O*-glycosylation and are relevant to IgAN as well as other human diseases, including IBD, hematologic disease, and cancer.

Genome Wide Association of Blood Pressure in Individuals of African Ancestry Identifies Novel Loci Enriched for Renal, Immune and Cardiovascular Pathways Nora Franceschini.[1,2] *[1]COGENT-BP Consortium of African Ancestry; [2]Epidemiology, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Hypertension is a leading cause of global mortality and disability, with a large burden on African Americans, who also are more likely to develop kidney and cardiovascular complications. Genetic studies in African populations can help to identify underlying biological pathways contributing to hypertension.

Methods: We used data from 21 genome wide association studies of blood pressure (BP) comprising of 31,968 African Americans and Africans. Studies used high density imputed genotypes from the 1000 Genomes Project and followed standardized protocols for analyses. We combined association summary statistics across studies using fixed effects meta-analysis, and the evidence across BP traits using the cross phenotype association analysis. We validated our significant results in additional 54,395 multi-ethnic samples of individuals of African, European, Hispanic and East Asian ancestries. Functional annotation and cell type enrichment analysis were performed using the LD score method.

Results: We identified 11 independent variants at 9 loci reaching genome wide significance ($P < 5.0\times10^{-8}$) for systolic BP, diastolic BP or hypertension. Four loci were novel (*TCF21, GPR20, FRMD3* and *LLPH/TMBIM4*), and two loci (*CDH17* and *IGFBP3*) have been reported in European ancestry but not previously replicated in African ancestry. *FRMD3* has previously been associated with diabetic nephropathy. Functional annotation identified super enhancer ($P_{Enrich} = 6.6\times10^{-6}$ for diastolic BP), enhancer ($P_{Enrich} = 3.8\times10^{-4}$ for systolic BP) and H3K27ac ($P_{Enrich} = 9.0\times10^{-4}$ for hypertension) that were significantly enriched. Cell types enrichment analysis identified immune ($P_{Enrich} = 1.4\times10^{-9}$ for diastolic BP), kidney ($P_{Enrich} = 2.4\times10^{-6}$ for diastolic BP) and cardiovascular ($P_{Enrich} = 2.3\times10^{-5}$ for systolic BP) as the three most significantly enriched pathways.

Conclusions: Our study provides new links between BP and immune, kidney and cardiovascular pathways, and illustrates the advantage of using hypertension susceptible populations of African ancestry to identify novel pathways for BP regulation.

Pregnancy Outcomes in a Racially Diverse Patient Cohort with Lupus Nephritis Meghan A. Jobson,[1] Michelle M. O'Shaughnessy,[2] Katy Sims,[1] Scarlett Murphy,[1] William Franklin Pendergraft.[1] *[1]Div of Nephrology and Hypertension, UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [2]Div of Nephrology, Stanford Univ, Palo Alto, CA.*

Background: Prior studies examining pregnancy outcomes in patients with lupus nephritis are generally restricted to white, non-US populations.

Methods: We examined maternal and fetal outcomes among patients enrolled in the Glomerular Disease Collaborative Network who received obstetric care at the UNC Hospitals between 1995 and 2015, either within the year prior to or any time after their lupus nephritis diagnosis, prior to end-stage renal disease. Our primary outcome was fetal loss (stillbirth at > 20 weeks). Secondary outcomes included: premature birth (<37 weeks), fetal weight and maternal outcomes (e.g. pre-eclampsia, disease flare). Categorical variables were compared using Fisher exact testing and continuous variables using Wilcoxon rank sum testing.

Results: We identified 32 pregnancies in 24 women with lupus nephritis. Forty-two percent were black, 34% were white and the remaining 25% were other. Mean age was 25 (SD 5.4) with black mothers being younger than white mothers ($p<0.001$). At baseline, mean serum creatinine was 0.92 mg/dL (SD 1.2) and urine protein 1.4 gm/24hrs (SD 2.2). There were 4 fetal losses, all between 20-24 weeks of gestation, 3 spontaneous and one elective due to disease severity. There were differences based on race for multiple variables including low birth weight (<0.01), preeclampsia (0.007), prematurity (0.037), having a pediatrician present at birth (0.01), NICU admission (0.004), renal flares in pregnancy (0.008) and IUGR (0.04), which were seen more often in black mothers compared to other racial groups. The median gestation was 35 weeks (IQR 34 to 37). Sixteen pregnancies (50%) developed pre-eclampsia, 8 were black, and 88% were non-white. Four required dialysis during pregnancy (3 black).

Conclusions: We identified a high frequency of adverse fetal and maternal outcomes in women with lupus nephritis, especially in black patients. We plan to evaluate this further in a multi-site study that includes lupus patients without nephritis as a control for effects seen in black and other non-white pregnancies.

FR-PO593

A Clinical Research of the Effect of Leflunomide as an Induction Treatment for Proliferative Lupus Nephritis Fei Deng, Daqing Hong, Li Wang. *Renal Div and Inst of Nephrology, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: To assess the efficacy and safety of leflunomide (LEF) as an induction treatment for proliferative lupus nephritis (PLN).

Methods: Thirty biopsy-proven PLN patients were included and randomized to LEF combined with prednisolone (LEF group) or cyclophosphamide (CTX) combined with prednisolone (CTX group) for 24 weeks. Urine routine, blood routine, blood biochemistry, quantitation of anti-ds-DNA, compliment C3, T-cell subsets and SLEDAI scoring were measured and all adverse reactions were assessed during the study.

Results: Proteinuria and SLEDAI score was reduced, and hemoglobinuria, serum albumin was increased significantly after 24-week treatment ($p<0.001$). At week 8, the efficacy was better in the CTX group than LEF group ($P<0.05$). However, at the end of treatment, there was no significant difference in efficacy between the two groups ($P>0.05$). ALT, WBC and hemoglobin were not significantly changed ($P>0.05$) in either group while T-cell subset was decreased in both groups ($P<0.001$) Although the CTX group manifested higher adverse effects in all measurements than the LEF group did, there was no statistical significance between the two groups.

Conclusions: LEF has a good efficacy as an induction treatment for PLN. LEF has the equivalent efficacy to that of CTX at the end of the induction treatment but lower adverse reactions and better patient compliance than that of CTX, indicating its further use in the treatment of PLN patients.

FR-PO594

Comparison of Clinical and Histologic Changes in Kidney Biopsies for Lupus Nephritis (LN) Repeated Early and Late after Induction Therapy Ana Malvar,[1] Valeria Gabriela Alberton,[2] Cecilia Recalde,[1] Bruno Jorge Lococo,[1] Brad H. Rovin.[3] *[1]Nephrology, Fernandez Hospital, Buenos Aires, Argentina; [2]Pathology, Fernandez Hospital, Buenos Aires, Argentina; [3]Nephology, Ohio State Univ, Columbus, OH.*

Background: Repeat kidney biopsies (Bx) done 6-9 months after starting treatment for LN often show persistence of inflammation despite complete clinical response(CR). We postulated that expanding the interval between repeat Bx may demonstrate more complete histologic resolution and a better correlation to clinical findings. To test this hypothesis we examined histologic and clinical responses at 7 and 14 months after initiating LN therapy.

Methods: SLE patients(n=53) were biopsied at first presentation of kidney involvement(Bx1) and again (Bx2) either 7 (n=30) or 14 months (n=23) after starting therapy with steroids+MMF. NIH activity(AI) and chronicity(CI) indices, proteinuria (prot, g/d) and serum creatinine (SCr) were compared.Complete Response was defined as normal SCr and prot ≤ 0.5 g/d.

Results: Clinical and histologic data are shown in the Table presented as median(range). Final prot was determined after a mean follow-up of 55±12 months.

Re -Bx months/ response	AI Bx1	CI Bx1	Prot Bx1	AI Bx2	CI Bx2	Prot Bx2	Final prot
7/CR	7.5(3-15)	3(0-6)	2.8(0.6-8)	3.5(05)	4(2-6)	0.2(1-0.5)	0.2(0.1-0.4)
7/NR	8.5 (3-13)	3(0-5)	3.6(0.7-8)	4(0-7)	4(1-7)	1.9(0.6-3.6)	0.3(0.1-1)
P(CRvsNR)	0.33	0.55	0.21	0.51	0.38	0.001	0.3
14/CR	8(4-14)	3.5(0-5)	3.1(1-7.5)	1.5(0-4)	4(3-7)	0.3(0.1-0.7)	0.2(0.1-0.8)
14/NR	7(6-12)	3(0-6)	3.4 (2-2.6)	4(0-6)	4(3-8)	0.0(0.6-3)	0.7(0.2-1.5)
P(CRvsNR)	0.83	0.68	0.99	0.16	0.9	0.001	0.007

Conclusions: Response to therapy in LN takes a long time. Even though the difference between AI-Bx2 in CR vs AI-Bx2 in NR was not significant, perhaps because of the small N, there was a tendency for AI-Bx2 in NR to be higher than AI-Bx2 in CR when the biopsy was repeated at 14 versus 7 months. Conversely, proteinuria at Bx2-7 months did not reflect long-term outcome, but at 14 months the association appeared to be better.

FR-PO595

Characteristics and Outcomes of Males with Lupus Nephritis in a Racially Diverse Patient Cohort Stephen A. Proctor, Meghan A. Jobson, Caroline J. Poulton, Keisha L. Gibson, William Franklin Pendergraft. *Div of Nephrology and Hypertension, UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

Background: Prior studies examining lupus nephritis (LN) in males have been limited to small racially homogenous cohorts or cohorts outside of the US. Little information exists on the differences between disease in males and females and in white males compared to black males.

Methods: We evaluated disease history and outcomes among patients enrolled in the Glomerular Disease Collaborative Network who were diagnosed with biopsy proven LN. Our primary outcome was end stage renal disease. Secondary outcomes include death and time to death from biopsy. Categorical variables were compared using Fisher exact testing and continuous variables using a Mann Whitney test.

Results: A total of 125 male patients with biopsy proven LN were included in the study. Forty-two percent were black, 39% were white and 19% were other. Sub-stratification by race revealed black race to be associated with positive anti-RNP ($p=0.004$), SSA ($p=0.006$), SSB ($p=0.03$), and Smith ($p=0.01$) antibodies, and present with serositis at presentation ($p=0.05$) compared to white males. White males had more intense C1q staining compared to black males ($p=0.05$) and males had more intense C1q staining compared to females ($p=0.001$). There was no difference in rates of ESRD, time from biopsy to ESRD and mortality in black patients when compared to white male counterparts; however, males time to ESRD from biopsy was shorter compared to females (2.8 vs 4.2 years, $p=0.05$). Males were more likely to die (0.008) compared to females, but time to death was similar between the two groups (males 6.2 vs females 4.7 years after biopsy, $p=0.24$).

Conclusions: We identified that male patients with lupus nephritis have higher mortality rates compared to females. Further understanding of why male presentation and serological markers vary by race and why males have a higher mortality rate need to be elucidated further to provide optimized interventions and therapeutic plans.

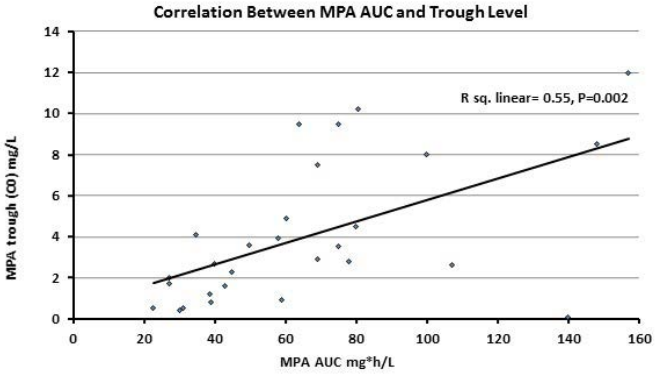
FR-PO596

Correlation between Trough Levels of Mycophenolic Acid and Area under the Curve in Patients with Lupus Nephritis Negiin Pourafshar, Rajesh Mohandas, Eric S. Sobel, Westley Reeves, Xuerong Wen, Mark S. Segal. *Univ of Florida, Gainesville, FL.*

Background: Mycophenolate mofetil is the mainstay of induction as well as maintenance therapy for lupus nephritis. Therapeutic drug monitoring appears to be particularly important in this population of patients for effective dosing and prevention of toxicity due to the high pharmacokinetic variability, however whether trough levels are the acceptable method of monitoring, remains debatable. We hypothesized that trough levels of MPA might be a poor predictor of Area Under the Curve (AUC) of mycophenolic acid in patients with lupus nephritis.

Methods: 31 patients with lupus nephritis were included in this study. We measured fasting trough levels of mycophenolic acid. Patients were then given the usual dose of oral mycophenolate mofetil. Mycophenolic acid levels were measured at 0 (C0), 1 (C1) and 2 (C2) hours. The MPA-AUC values were calculated using the linear trapezoidal rule. Pearson or Spearman correlations were used to look for correlations. Multiple linear regression and logistic regression analyses were employed to examine significant predictors of continuous and categorical dependent variables, respectively.

Results: There was a statistically significant correlation between trough levels of mycophenolic acid and area under the curve ($P=0.002$). However linear regression showed an R^2 of only 0.55. Demographic, clinical or laboratory variables did not identify subgroups in which trough levels were predictive of AUC. We were able to show that MPA trough level has a significant but moderate correlation ($r^2 = 0.55$, $P = 0.002$) and a positive linear relationship with MPA AUC.



Conclusions: Trough levels of mycophenolic acid does not show strong correlation with AUC. In clinical situations where mycophenolic acid levels are essential to guide therapy, an AUC would be a better indicator of adequate treatment.

FR-PO597

Treating Lupus Nephritis with Rituximab and Mycophenolate Mofetil (RituxiRescue Regimen) without Increasing Maintenance Oral Steroids Leads to Sustained Disease Remission and Steroid Reduction Camilla Pillay, Megan Griffith, Jeremy B. Levy, Tom Cairns, Liz Lightstone. *Imperial College Lupus Centre, London, United Kingdom.*

Background: To ↓ the morbidity caused by high-dose and long-term steroids we have used rituximab as a steroid-sparing agent in patients on maintenance steroids who develop active lupus nephritis (LN). The RituxiRescue regimen (2 x 1g rituximab ± 125-500mg methylprednisolone on d1 and 15, maintenance mycophenolate mofetil + **no** ↑ in b/line steroid dose) led to steroid ↓/cessation at 1 year in 18 patients with LN (NDT, 2009). Outcomes are now reported on 38 patients with ≥ 5 years f/up.

Methods: Inclusion: 38 patients with class III/IV/V LN on biopsy, on steroids ≥ 4 weeks at b/line, f/up ≥ 5 years, Dec 2005-Mar 2016. **Exclusion**: Requirements for dialysis ± cerebral/other life-threatening lupus features. **Remission**: **Complete** (CR): uPCR ≤ 50, eGFR ≥ 60 or ≤ 20% ↓ if > 60 at b/line. **Partial** (PR): uPCR < 50% + eGFR ↓ ≤ 20% (not nephrotic) + uPCR < 300 (if nephrotic) from b/line. **Relapse** (from CR/PR): uPCR ≥ 50% ↑ from CR/PR + >100 ± eGFR ≥ 20% ↓ from b/line.

Results: Outcomes in 38 patients by 1 and 5 years, 4 lost to f/up.

	1 year n=37(%)	5 years n=33(%)	Median time to event (months)
CR/PR	23(62.2)	31(93.9)	13.0(4.8-33.5)
No response	12(32.4)	8(24.2)	
Relapse from CR/PR	2(5.4)	7(21.2)	28.4(11.0-40.8)
↓ in eGFR ≥ 50%	3(8.1)	1(3.0)	13.2(7.1-54.6)
Mean steroid dose (mg)	7.5	5.9	
Off oral steroids	7/37(18.9)	15/33(45.5)	

1 death (28 y/o male, non-adherent) at 21.9 months. 2/37 with ↓ eGFR ≥ 50% at 1 year progressed to ESRD (from no response). By 5 years: 13/33 had not responded/relapsed before CR/PR with **no** recommencement/↑ in oral steroid dose from baseline. **Median time to steroid cessation**: 21.4 months (10.4-46.8). **Adverse events**: 19/21 episodes of infection (21 patients) required hospitalisation, 23.8% by 1 year. 42% (16/38) patients had evidence of steroid toxicity, 62.5% (10/16) bone related.

Conclusions: The RituxiRescue regimen led to sustained disease remission and a significant ↓ in steroid dose/cessation by 5 years. Poor renal outcomes were rare + adherence related. The data suggest that it is safe not to ↑ baseline oral steroids at relapse.

FR-PO598

Effect of Cyclophosphamide versus Mycophenolate Mofetil in Induction Therapy of Lupus Nephritis in Nepalese Population Arun Sedhain, Rajani Hada, Rajendra Kumar Agrawal, Anil Baral, Gandhi R. Bhattarai. *Nephrology, National Academy of Medical Sciences (NAMS), Kathmandu, Nepal.*

Background: Management of SLE and lupus nephritis (LN) comprises timely and coordinated management consisting of induction phase followed by maintenance phase. This study aimed to evaluate and compare the effectiveness and safety profile of mycophenolate mofetil and intravenous pulse cyclophosphamide in induction therapy of proliferative LN in Nepalese population.

Methods: A prospective open label randomized control trial was conducted in a tertiary hospital at Kathmandu, Nepal for a period of one and half year from January 2014 to June 2015. Fifty two patients with biopsy proven proliferative lupus nephritis were screened and 49 patients were randomized out of which only 42 patients could complete the study period of six months. Monthly intravenous injection of pulse cyclophosphamide (CYC) was given to one group and daily oral mycophenolate mofetil (MMF) to the other. Participants were followed up monthly and the results were analysed at the end of 6 months.

Results: At 6 months, serum creatinine (mg/dL) decreased from 1.73 to 0.96 in CYC and from 1.24 to 0.91 in the MMF group. Twenty four hour urinary protein (gm/1.73 m^2) reduced from 4.47 to 0.94 in CYC and from 4.5 to 0.62 in the MMF group. 19% patients in CYC and 28.6% patients in MMF group achieved partial remission (primary end point) and equal proportion (67% in each group) achieved complete remission (secondary end point). 14.3% of patients in CYC group and 4.8% in MMF group did not respond to treatment.

Efficacy measurement	CYC	MMF	P Value
Achieved partial remission (Primary end point)	4 (19%)	6 (28.6%)	0.572
Achieved complete remission (Secondary end point)	14 (66.7%)	14 (66.7%)	
Did not respond to treatment	3 (14.3%)	1 (4.8%)	

The occurrence of adverse events was higher in the CYC than in MMF group (56 vs. 15 non-infection related and 10 vs. 7 infection related events).

Conclusions: Present study found that MMF is equally effective in inducing remission with reduction of proteinuria and improvement of kidney function with lesser adverse events than CYC in proliferative lupus nephritis in 6 months therapy.

FR-PO599

Steroid-Treatment Promotes a M2 Pro-Fibrotic Macrophage Phenotypic in Lupus Nephritis Yohei Ikezumi,[1] Yuji Matsumoto,[1] Takeshi Yamada,[2] Hiroya Hasegawa,[2] Ichiei Narita,[3] David J. Nikolic-Paterson.[4] *[1]Dept of Pediatrics, Fujita Health Univ School of Medicine, Toyoake, Japan; [2]Dept of Pediatrics, Niigata Univ Medical and Dental Hospital, Niigata, Japan; [3]Dept of Nephrology, Niigata Univ Medical and Dental Hospital, Niigata, Japan; [4]Dept of Medicine, Monash Univ, Clayton, Victoria, Australia.*

Background: M1 pro-inflammatory macrophages (MQ) promote glomerular injury in lupus nephritis (LN). However, it is unclear whether steroid therapy affects macrophage phenotype in these patients. We examined the effect of steroid treatment on MQ phenotype in LN.

Methods: 46 patients with LN were divided in 2 groups; N group, underwent biopsy before steroid-treatment (N=24, 20.0±9.2 years at biopsy); S group, underwent steroid treatment (2 to 6 months) before biopsy (N=19, 20.1±9.2 years at biopsy). Macrophage number and phenotype was assessed by immunofluorescence. In vitro studies used monocyte-derived MQ from healthy human volunteers.

Results: Urine findings were comparable between the two groups, but the S group had a significantly lower eGFR (104±34 vs 125±22 ml/min/1.73m^2; p<0.05). Biopsies revealed les endocapillary proliferation (p<0.05) and greater glomerular matrix expansion (p<0.001), glomerulosclerosis (p<0.001) and interstitial fibrosis (p<0.05) in the S group. The total $CD68^+$ MQ infiltrate was comparable between N and S groups. However, the N group had fewer M1 MQ ($CD68^+CD86^+$ cells) (p<0.05) and more M2 MQ ($CD68^+CD163^+$ cells) (p<0.05), giving a 6-fold increase in the M2/M1 ratio in S vs N groups. In addition, M2 MQ correlated with glomerular matrix expansion and interstitial fibrosis (p<0.001). Steroid (dexamethasone) treatment of cultured MQ induced up-regulation of CD163 expression, increased production of anti-inflammatory (IL-10) and pro-fibrotic factors (TGF-β1, CTGF), and up-regulated the scavenger receptor, stabilin-1. We confirmed up-regulation of stabilin-1 in $CD163^+$ M2 MQ in biopsies from the S group.

Conclusions: Initial steroid treatment induces a MQ phenotypic change from pro-inflammatory M1 to pro-fibrotic M2 in LN with acute/active lesions. Promotion of fibrotic lesions via M2 MQ is a potential downside of steroid single therapy in LN.

Funding: Government Support - Non-U.S.

Clinical Features of Metabolic Indices Patients with Lupus Nephritis Hua Zhou, Lizhi Li, Congcong Jiao, Di Lu, Kong Weiwei, Lining Wang. *The First Hospital of China Medical Univ, China.*

Background: Lupus Nephritis (LN) is an autoimmune mediated disease. Metabolic disorders often occur in chronic kidney diseases. We aim to investigate clinical features of metabolic indices in LN patients.

Methods: 194 patients with LN proven by renal biopsy were treated with steroid and immunosuppressants at China Medical University from 2007 to 2015. 24hr total urinary protein (uTP), hematuria (uRBC), estimated glomerular filtration rate (eGFR-EPI), systemic lupus erythematosus disease activity index (SLEDAI), compliments (C), immunoglobulin (Ig), and serum metabolic indices including uric acid (UA), low-density lipid cholesterol (LDL-C), and calcium (Ca) were observed up to 18 months. The correlations between pretreated metabolic indices and severity of LN before and after treatment were analyzed.

Results: After 18 months' treatment, uTP, uRBC, SLEDAI, and IgG decreased (uTP 4.3±0.3 vs 0.7±0.2 g/24hr, p<0.01; uRBC 50±10 vs 5±2/hp, p<0.01; SLEDAI 17.3±0.6 vs 5.3±0.9, p<0.01; IgG13.2±0.6 vs 9.9±0.4 g/L, p<0.01). sAlb, C3, and C4 increased (sAlb 24.7±0.6 vs 40.1±0.9 g/L, p<0.01; C3: 0.5±0.02 vs 0.9±0.04 g/L, p<0.01; C4: 0.11±0.01 vs 0.20±0.02 g/L, p<0.01). The pretreated metabolic indices significantly correlated with the activity of systemic and renal disease before and after treatment (table).

		Pretreated		
		UA	LDL	Ca

Post-treated	uRBC	r=0.4(p<0.05) n=42 (9m)		
	eGFR			r=0.4(p<0.05) n=40 (12m)
	SLEDAI	r=0.6(p<0.05) n=18(9m)		
	C4		r=0.6(p<0.01) n=31(18m)	
	IgG		r=−0.4(p<0.05) n=30(9m)	

Conclusions: The level of pretreated serum UA, LDL-C, and Ca correlated with the changing activity of lupus and LN. Our data suggest that the changes of pretreated metabolic indices might be additional biomarkers for the severity and management of LN. Thus, early correction of metabolic disorders might improve LN outcome.

Urinary Levels of TWEAK as a Biomarker of Lupus Nephritis in Hispanic Populations Fabiola Reyes,[1] Monserrat M. Perez-Navarro,[1] Adrian Rodriguez Matias,[1] Virgilia Soto,[2] Gabriela Gutierrez,[3] Zaira Medina,[3] Rafael Valdez-Ortiz.[1] *[1]Servicio de Nefrología, Hospital General de México, México, Mexico; [2]Dept of Pathology, Hospital General de México, México, Mexico; [3]Dept of Experimental Medicine, Univ Nacional Autónoma de México, México, Mexico.*

Background: Urinary levels of TWEAK (uTWEAK), may be correlated with the degree of lupus nephritis (LN) activity. Our objective was to determine the sensitivity and specificity of uTWEAK in Hispanic patients with active lupus nephritis.

Methods: A clinical study was performed. Four groups of patients were analyzed as follows: 1) patients with systemic lupus erythematosus (SLE) without renal activity (SLE-LN), 2) patients with SLE with renal activity (SLE+LN), 3) patients with other types of glomerulopathies (GMN), and healthy patients (controls).

Results: In all, 44 patients, with an average age of 35.9±11.5 years, were evaluated. uTWEAK levels were higher in patients with SLE+LN compared with patients in the other groups: SLE+LN 12.88±8.33, SLE-LN 3.12±2.31, GMN 4.36±2.31 and controls 2.41±1.94 pg/mgCr (p=0.007). A total of 72.7% of the cases had renal activity index scores above 12, and 90.9% of the cases had scores of chronicity below 6 points. Receiver Operating Characteristic (ROC) curve analysis revealed that uTWEAK levels above 2.0 pg/mgCr had a sensitivity of 90 % and a specificity of 60% for the diagnosis of renal activity due to lupus, with an area under the curve of 0.876 (IC 0.75 - 0.99). However, a significant correlation was not observed between the levels of uTWEAK and the histological findings specific to the activity and chronicity associated with SLE.

Conclusions: Our study revealed that uTWEAK can adequately distinguish renal activity due to lupus, but cannot predict the degree of histological activity in Hispanic patients with active lupus nephropathy.

FR-PO602

Using Hazard Functions to Predict Outcomes in Lupus Nephritis: A Novel Way to Assess New Therapies Brad H. Rovin,[1] Meggan Mackay,[2] Joanna Stein Fishbein,[2] Kenneth Kalunian,[4] Maria Dall'Era.[3] *[1]Ohio State Univ, Columbus; [2]Feinstein Inst; [3]UCSF; [4]UCSD.*

Background: The goal of therapy in lupus nephritis (LN) is long-term preservation of renal function. In clinical trials of drugs for LN, treatment success is evaluated by the proportion of patients achieving complete remission 6-12 months after starting therapy. However, short-term remission does not necessarily equate to sustained long-term kidney function. The present work was undertaken to establish novel endpoints for LN clinical trials that predict long-term kidney health.

Methods: A database of 944 patients with extended follow-up was established from 15 clinical centers/trials. This analysis sought predictors of new or worsening CKD, defined as a sustained decrease in eGFR ≥30%. Associations between CKD and clinical data at LN flare (baseline) through month 12 of treatment were determined using univariate Cox regression. Explanatory variables considered were: gender, age, race/ethnicity, ISN class, absolute levels of proteinuria, serum creatinine (SCr) and urine RBCs at baseline and 12 months, and % change in proteinuria and SCr from baseline through month 12. Variables significantly (p<0.10) associated with CKD were then tested by Cox proportional hazards regression, and using stepwise selection methods included in a final multivariable model if p<0.05.

Results: A total of 558 LN patients had all the required data and were included in the analysis. Variables significantly associated with CKD on univariate screen were race (binary variable, Black/non-Black), urine RBCs at baseline and 12 months, proteinuria at 12 months, SCr at baseline and 12 months, and %Δ in proteinuria and SCr from baseline to 12 months. The final multivariable model included log (%Δ proteinuria, p<0.0001), log (SCr at 12 months, p<0.0001) and race (p=0.04). The hazard ratios (HR) for CKD were 1.86 (95% CI: 1.52, 2.65) for log (%Δ proteinuria), 5.11 (3.04, 8.58) for log SCr and 1.65 (1.003, 2.70) for race. These variables were combined into a hazard function (HF) for CKD. HF=0.062*log(%Δ proteinuria)+1.63*log(SCr)+0.49*X_3, where X_3=1 if black, 0 if non-Black.

Conclusions: The HF can be used to evaluate new LN drugs for superiority in preventing future development of CKD.

Medication Adherence, Depression, and Disease Activity among Patients with Systemic Lupus Erythematous Abdulkareem Alsuwaida,[1] Nada S. Alsowaida,[2] Meshael M. Alrasheed,[2] Ahmed Y. Mayet,[3] Mohammed A. Omair.[1] *[1]Dept of Medicine, King Saud Univ, Riyadh, Saudi Arabia; [2]College of Medicine, King Saud Univ, Riyadh, Saudi Arabia; [3]Dept of Clinical Pharmacy, King Saud Univ, Riyadh, Saudi Arabia.*

Background: There are only a few studies that correlate adherence problems to disease progression among systemic lupus erythematosus (SLE) patients. The aim of this study is to assess the prevalence of medication adherence and depression among Saudi SLE patients, and to explore the impact of depressive symptoms on patient's adherence to the treatment regimen.

Methods: In a cross sectional study of 140 outpatients with SLE, we assessed the prevalence of medication non-adherence and severity of depression using paper questionnaires that contain a number of questions based on Morisky Medication Adherence Scale (MMAS-4) and Beck's Depression Inventory (BDI). The disease activity was assessed using the SLE Disease Activity Index (SLEDAI).

Results: None adherences were reported in 62.1 % and depression was noted 35% (49 patients). Moderate and severe depression were significantly associated with medium and high non adherence (p = 0.04) but not with disease activity. There is a significant correlation between disease activity and severity of depression (r=0.31, p=0.003). The logistic regression showed only moderate to severe depression is associated with non-adherence (OR 2.62; 1.02-6.71) and disease activity is the predictor of depression.

Conclusions: SLE patients should be routinely assessed for medication non-adherence and the factors behind that especially depression. Interventions aimed at alleviating depressive symptoms, which are quite common, could result in significant improvements in patient adherence and disease response in patients with SLE.

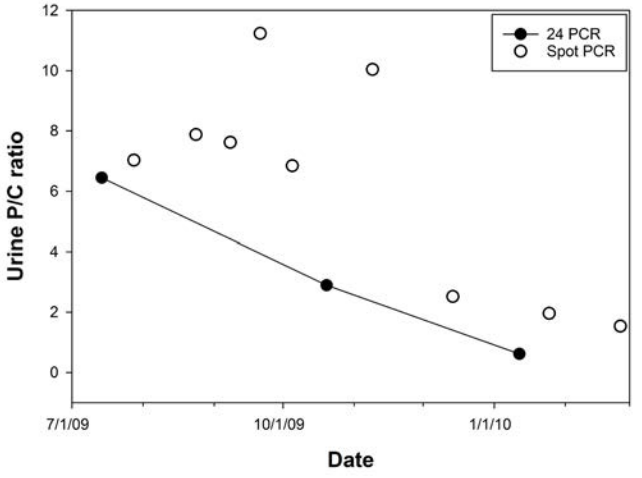
FR-PO604

24 Hour Protein:Creatinine Ratio (24 PCR), Not Spot PCR (Spot PCR), Should Be Used to Monitor the Treatment of Severe Lupus Nephritis (LN): The Experience of ACCESS Ganesh B. Shidham, Daniel J. Birmingham, Brad H. Rovin, Lee A. Hebert. *Nephrology, Ohio State Univ Wexner Medical Center, Columbus, OH.*

Background: It is well established that in proteinuric renal disease urine PCR varies greatly during any given 24 hour period. Spot urine (single void) PCR reveals this variability; 24 hour urine (24 PCR) conceals this variability because it represents the average of the PCRs during the urine collection. Here we estimated the extent to which using spot PCR, rather than 24 PCR, might lead to serious errors in management of LN because spot PCR are unreliable.

Methods: ACCESS (phase 2 trial of abatacept in severe LN) measured spot PCR monthly and 24 PCR each 3 months for up to 12 months in 103 patients. To assess the ability of spot PCR to correctly identify proteinuria trends during LN treatment, in each patient we displayed their spot PCRs in relationship to their proteinuria trend line (the line formed by the sequential 24 PCRs). Using a semiquantitative approach in each patient, spot PCR was adjudicated as either Reliable, Generally Reliable (problematic), or Unreliable in identifying proteinuria trend.

Results: The figure shows a representative patient in whom spot PCR was deemed Unreliable. Overall spot PCR was Unreliable in 35%, problematic in 24% and Reliable in only 41%. Baseline demographics and clinical measures did notdistinguish between Reliable/Unreliable. However, those with Unreliable PCRs were more likely to experience Treatment Failure and less likely to experience Complete Remission than those whose spot PCRs were Reliable (p = 0.024).



Conclusions: Compared to 24 PCR, spot PCR results are often highly and consistently misleading and likely would lead to management errors if relied upon for clinical decision making.

FR-PO605

Molecular Imaging of Treatment Naïve and Treatment-Experienced Kidneys in Lupus Nephritis Samir Parikh,[1] Ana Malvar,[2] Huijuan Song,[1] Valeria Gabriela Alberton,[2] Jianying Zhang,[1] Lianbo Yu,[1] Brad H. Rovin.[1] *[1]Nephrology, The Ohio State Univ Medical Center, Columbus, OH; [2]Nephrology, Hospital Fernandez, Buenos Aires, Argentina.*

Background: Lupus nephritis (LN) frequently relapses, and often shows the same histologic class at each flare. It is not clear whether the kidneys of patients who have LN flares after successful treatment show a similar molecular profile as kidneys from the first presentation of LN. This study was done to investigate the similarities and differences in LN flares at the molecular level.

Methods: Molecular profiling of the kidney was done on one SLE patient who had a biopsy at their first presentation of LN (Bx1, treatment naïve), and a second biopsy when the disease relapsed on maintenance immunosuppression after 1.5years of remission. Both biopsies showed class IV LN. RNA was extracted from each biopsy and the expression of 511 immune-response genes was compared using Nanostring technology.

Results: Bx1 and Bx2 showed significant differences in pro-inflammatory transcript profiles. Genes with increased expression at Bx2 compared to Bx1 included: *CD79a* (12.7-fold >Bx1), *CCL19* (10.3-fold), *CXCR6* (4.5-fold), *CXCL12* (3.6-fold), *IL17F* (3.1-fold), *CXCL11* (2.6-fold), *CCL13* (2.3-fold), and *CXCL10* (2.2-fold). Transcripts with increased expression at Bx1 compared to Bx2 included: *CCL23* (3.5-fold), *CCL16* (3-fold), *CCRL2* (2.7-fold), and *CCBP2* (2.7-fold).

Conclusions: These data show that LN flares of the same class and within the same patient can demonstrate different renal molecular profiles. Despite similar histology, the dominant inflammatory signature, especially among chemokine family member genes, is different in a treatment naïve flare compared to a flare that occurs on immunosuppression. These data suggest that relapses of LN may need to be treated differently than the first flare, and may explain why relapses often are more treatment resistant.

FR-PO606

Refractory Lupus Nephritis: Results of a Multi-Dimensional Survey on Real-Life Clinical Practice among International Lupus Experts Julia Maria Eder, Marc J. Weidenbusch, Hans J. Anders. *Nephrologisches Zentrum, Klinikum der Univ München, Munich, Bavaria, Germany.*

Background: Refractory lupus nephritis (RLN) is associated with poor long-term outcome in systemic lupus erythematosus (SLE). There is no consensus on how to define and manage RLN.

Methods: After review of international guidelines regarding LN and a literature search, a 27-item questionnaire was created in adherence to data privacy regulations by experts of the Lupus Nephritis Trials Network (LNTN). This survey was sent in March 2016 to LNTN members via email and given to attendees of two conferences (ISN Nexus Berlin 2016 and ERA-EDTA Vienna 2016). Statistical analyses were performed by means of the chi-square test (significance at $p<0.05$).

Results: The survey reached 293 nephrologists and rheumatologists, the response rate was 42.3%. 92.7% of the participants used persisting proteinuria as a diagnostic criterion for RLN, followed by serum creatinine (S-Cr) (71.7%) and an abnormal urine sediment (U-Sed) (61.2%). 60.4% of the participants performed re-biopsies when RLN is suspected. Experienced physicians (>20 yr practice) relied more on S-Cr (p=0.01). Nephrologists considered clinical SLE symptoms more relevant (p=0.002), while non-nephrologists outranked the U-Sed (p=0.004). RLN was believed to be due to persisting SLE disease activity (95.2%), drug non-compliance (77.4%) and renal scarring (56.5%). Non-compliance was addressed by asking the patient (80.6%) and usage of IV-medication (73.4%). 61.5% of all study participants administered a drug for at least 6 months before classifying LN as refractory, experienced physicians reassessed earlier (p=0.03). 1st line LN therapy is often MMF (61.6%), 2nd line therapy cyclophosphamide (total 42%, 36.8% Euro-Lupus, 5.2% NIH regimen). Rituximab is used as a 2nd and 3rd line treatment (23.1% and 13.3%, respectively).

Conclusions: There is a no consensus on when and how to assess treatment response in LN and a definition of RLN. Many causes can underly lack of efficacy, but often persistent disease activity is assumed and immunosuppressive therapy is escalated, while the awareness for other causes of RLN is limited. There is an unmet need for a consensus on definition and management of RLN.

FR-PO607

Lupus Podocytopathy: Comparison of Clinical Features and Renal Outcomes with Primary Forms Eduardo J.D. de Sa Carneiro Filho, Mariana Pigozzi Veloso, Marcella Martins Frediani, Lectícia Jorge, Cristiane B. Dias, Luis Yu, Viktoria Woronik. *Nephrology Div, Univ of São Paulo, Brazil.*

Background: Lupus podocytopathy (LP) is characterized by diffuse foot process effacement without peripheral capillary wall immune deposits and glomerular proliferation. It has been described in Systemic Lupus Erythematosus (SLE) patients with distinct features from classic proliferative nephritis, sharing similar characteristics with primary podocytopathies. This study aimed to compare clinical–morphologic features and renal outcomes between primary and lupus forms of Focal Segmental Glomerulosclerosis (LP/FSGS).

Methods: Retrospective unicentric analysis of 24 SLE patients who fulfilled the following 3 criteria were included as LP:[1] morphologic pattern resembling minimal change disease, mesangial proliferation or FSGS by light microscopy with negative immunofluorescence or only mesangial immune deposition;[2] absence of LN class III, IV or V; [3] presence of nephrotic syndrome. Sixteen LP/FSGS cases were randomly matched with 32 primary FSGS, NOS variant, according to age, gender and eGFR baseline clearance (MDRD simplified formula). Baseline, one year and final follow-up results were analyzed in both groups. Treatment proposed was based on KDIGO guidelines.

Results: At baseline LP global group showed an average age of 35 years, proteinuria 4.2±2 g/day, albumin 2.3±0.8 g/dL, Hb 11.8 g/L, C3 103 mg/dL, C4 20 mg/dL, creatinine 1.1±0.5 mg/dL and MDRD 84.9±38.8 mL/min/1,73 m2. FSGS subgroups clinical features and renal outcomes are summarized below.

	Primary FSGS (32)	LP/FSGS (16)
Baseline Features		
Age (y)	31± 14.9	34.8±11
Proteinuria (g/day)	8.31±0.98	4.6±0.79*
Cr (mg/dL)	1.28±0.9	1.28±0.93
Alb (g/dL)	2.08±0.9	2.1±0.9
Hb (g/L)	13.1±0.3	11.4±0.3*
Follow-up (months)	98	117
Remission		
Complete(%)	16(51)	8(57)
Parcial(%)	8(25)	2(14)
No response(%)	7(22)	4(28)
***p<0.05**		

Conclusions: Despite there was no difference regarding age, sex, fibrosis, albumin or treatment between subgroups, primary forms presented higher proteinuria (8.3g±0.9vs4.6g±0.7 p0.01), while LP subgroup lower Hb levels (11.4±0.3vs13.1±0.3 p0.004) with similar renal outcomes.

FR-PO608

Retinal Drusen in Patients with IgA Glomerulonephritis or SLE Judith A. Savige,[1] Peter D. Hughes,[3] Kathleen M. Nicholls,[3] Deb J. Colville.[1] *[1]Medicine and Nephrology, Univ of Melbourne, Melbourne, VIC, Australia; [2]Nephrology, Northern Health, Melbourne, VIC, Australia; [3]Nephrology, Royal Melbourne Hospital, Melbourne, VIC, Australia.*

Background: Drusen are deposits in the retina of immunoglobulins and Complement, that have an identical composition to glomerular deposits, and are associated with mutations in the Complement genes. Complement is implicated in the pathogenesis of IgA gn and SLE. We have found drusen in occasional patients with IgA gn or SLE and this study investigated how often they occurred in IgA gn and SLE, and any association with ESRD and common drusen-associated SNPs.

Methods: All subjects underwent non-mydriatic retinal imaging, and photographs were examined for drusen (more than 10 within 2 disc diameters of the macula). Control groups had FSGS or structural renal disease. Subjects also provided DNA for drusen-related SNP analysis, using the SEQUENOM iPLEX Assay at the Australian Genome Research Facility. SNPs included variants in genes in the Complement pathway (C2, C3, CFB, CFH, CFI and CD46), the purinergic system (P2RX4, P2RX7, PANX1) and other genes (TIMP3, APOE and ARMS). Statistical analysis was performed using SPSS.

Results: Thirty–nine subjects with IgA disease were studied including 32 with ESRD. Fifteen (38%) had central drusen. Thirty-two with SLE were studied including 17 (55%) with SLE nephritis and 6 (19%) with ESRD. Eighteen (58%) had drusen. Drusen were more common in subjects with IgA gn and SLE than with FSGS (3/38, 8%) or structural

renal disease (2/20, 10%) (p<0.0001). In IgA disease, drusen occurred more often in ESRD. One CFH SNP (p=0.03) and the CD46 S13F variants (p<0.01) were more common in IgA gn and ESRD than a normal cohort. In SLE the A353V variant in CD 46 was more common than in the normal cohort (p=0.03). There were trends for increased occurrence of the I272V variant in PANX1 (p=0.08) and the TIMP3 variants (rs9621532) (p=0.09) too.

Conclusions: Drusen are more common in IgA gn and SLE than in FSGS or structural renal disease. There is a possible increase with ESRD in IgA gn. GWAS suggest associations with Complement loci, and a CFH SNP was more common in patients with IgA disease and ESRD. Other drusen-associated SNPs may be important too.

FR-PO609

Genetic Markers to Predict Progression of IgA Nephropathy in Caucasians
Tarik Onur Tiryaki,[1] Ege Sinan Torun,[1] Sonay Temurhan,[2] Sebahat Akgul,[2] Serra Artan,[1] Yasar Caliskan,[1] Mehmet S. Sever.[1] *[1]Dept of Internal Medicine Div of Nephrology, Istanbul Univ Istanbul Faculty of Medicine, Istanbul, Turkey; [2]Dept of Medical Biology, Istanbul Univ Istanbul Faculty of Medicine, Istanbul, Turkey.*

Background: Genome–wide association studies indicate that IgA Nephropathy (IgAN) has a complex genetic architecture. In this study, we aimed to evaluate 4 tag single-nucleotide polymorphisms (tSNPs) in 129 patients with IgAN. Although these SNPs were found to be associated with risk of IgAN in Chinese cohort, the association signal has not been uniformly replicated in Turkish population.

Methods: A total of 129 IgAN patients (77 (59.7%) male, mean age: 36±13 years, median follow up of 25 months) were evaluated. The relationship between genetic markers (tSNPs; rs3803800, rs2738048, rs2412971, rs6677604) in 4 IgAN-associated genes (TNFSF13, DEFA, HORMAD2, CFH, respectively) and progression to kidney failure [category G5 chronic kidney disease (CKD)] were assessed.

Results: Kidney failure developed in 34 (26.4%) patients after a median follow up time of 25 months. Using the recessive model, we found that the genotype "AA" rs3803800 in TNFSF13 was associated with an increased risk of kidney failure in IgAN (OR = 2.52, 95% CI = 1.1-5.7, p = 0.018). Although not reaching statistically significance, the genotypes "GG" rs6677604 and "GG" rs2412971 were also associated with increased risk of kidney failure. The genotype "GG" rs6677604 was also found to be associated with higher T scores according to Oxford-MEST classification (p=0.04). The genotype "AA" rs3803800 was also found to be associated with higher S scores (p=0.04).

Conclusions: A new progression risk score for IgAN can be calculated based on these genetic markers including tSNPs in TNFSF13 and CFH genes to predict the risk of progression to kidney failure.

FR-PO610

Serum IgA/C3 Ratio: A Marker of Disease Activity in Patients with IgA Nephropathy
Kazuo Torikoshi,[1] Tomomi Endo,[1] Hiroyuki Suzuki,[1] Tatsuo Tsukamoto,[1] Eri Muso,[1] Takashi Yasuda,[2] Yoshinari Yasuda,[2] Tetsuya Kawamura,[2] Seiichi Matsuo.[2] *[1]Nephrology and Dialysis Center for Nephrology and Urology, Kitano Hospital, Tazuke Kofukai Medical Research Inst, Osaka, Japan; [2]Study Group of The Nationwide Retrospective Cohort Study in IgAN.*

Background: Serum levels of high IgA and low C3 through lectin and alternative pathway activation might relate the progression and exacerbation of IgA nephropathy (IgAN). The aim of this study were to examine 1) whether the serum IgA/C3 ratio serve as a marker of the progression in patients with IgAN and 2) the effect of tonsillectomy on the ratio.

Methods: 1) This nationwide multi-center retrospective study included 718 patients with biopsy-proven IgAN in Japan (mean follow-up of 6.5±2.9 years). The patients with doubling of serum creatinine at the time of renal biopsy were defined as progression. 2) After excluding those with insufficient serum IgA and C3 data at the end of observation period, 63 patients were subdivided either into 4 groups by therapy (control, tonsillectomy, steroid, and tonsillectomy and steroid pulse (TSP) group) or into 2 groups according to the change of IgA/C3 ratio from at the biopsy to the end of observation (6.1±2.8 years) (<15% decrease (non-improved) and ≥15% decrease (improved)).

Results: 1) Kaplan-Meir analysis of the patients with IgAN revealed that the group with high serum IgA/C3 (3.3 and above) had a significantly poorer renal outcome (p<0.05, log-rank test). In multivariate analysis of more than 4.45 years observation periods, renal end point of IgAN was significantly predicted by proteinuria≥1g/day (relative risk (RR)=2.11, 95% confidence interval (CI) 1.09-4.08), eGFR<60 (RR=7.30, 95% CI=3.40-15.6) and serum IgA/C3 ratio≥3.3 (RR=2.07. 95% CI=1.02-4.22). 2) Among the 4 groups divided by therapy, the serum IgA/C3 ratio and proteinuria were reduced only in the TSP group at the end of observation. The 2 groups divided along the change of ratio showed significantly higher percentage of complete remission of proteinuria in improved group than in non-improved (log rank=0.035).

Conclusions: The levels of serum IgA/C3 might reflect the disease activity and be a potent surrogate marker of the therapeutic efficacy in patients with IgAN.

Funding: Government Support - Non-U.S.

FR-PO611

IFI27/ ISG12A in Peripheral White Blood Cells Is a Useful Marker for IgA Nephropathy
Yasuyuki Nagasawa,[1] Ryohei Yamamoto,[2] Eri Muso,[3] Maki Shinzawa,[2] Kiyoko Yamamoto,[1] Tomoko Kimura,[1] Hirotsugu Iwatani,[2] Takahiro Kuragano,[1] Yoshitaka Isaka,[2] Takeshi Nakanishi.[1] *[1]Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan; [2]Dept of Nephrology, Osaka Univ, Suita, Japan; [3]Dept of Nephrology, Kitano Hospital, Osaka, Japan.*

Background: IgA Nephropathy is most common primary glomerular nephritis not only in Asian, but also in Caucasians. The methods to identify IgA nephropathy without hospitalization had been required. DNA microarray analysis is useful to comprehensively identify up- or down-regulated genes in PBMCs of patients. To identify a useful marker for IgA nephropathy, we explore the peripheral white blood cells by DNA microarray methods.

Methods: Sequential 137 patients who underwent kidney biopsy and blood samples were collected from Osaka University Hospital or Kitano Hospital. These patients had been diagnosed totally by kidney biopsy, medical history and blood examinations. Peripheral white blood cells samples from first fifteen IgAN and eight MN patients were provided for DNA microarray compared with healthy volunteers. And other samples were provided for extended qRT-PCR analysis. The study was reviewed and approved by the Research Ethics Committee of Osaka University and Kitano Hospital.Written informed consent was obtained from all participants.

Results: IFI27(interferon (IFN)-alpha-inducible protein 27 gene = interferon-stimulated gene 12a protein (ISG12A))gene was identified as the gene which decreased in all 15 IgA nephropathy patients along with 8 membranous nephropathy (See Figure1). Then, extended quantitative RT-PCR revealed the gene expression decreased in 44 IgA patients out of 48 IgA nephropathy patients. Median expression levels of IFI27 gene in IgA nephropathy patients (see Figure group 2) significantly reduced than those in immune disorder diseases (group 3) including myeloma kidneys(p=0.019). The expression levels in IgA nephropathy patients were marginally less than those in other primary glomerular nephritis patients (group 2) ($P = 0.079$). These results suggest that reduced IFI27 mRNA level is a useful gene marker that can be measured using RNA from PMBCs.

Conclusions: We propose that IFI27 may serve a useful genetic marker to diagnose IgA nephropath using peripheral blood.

FR-PO612

Successfull Rituximab Treatment for Adult Patients with Severe IgA Vasculitis - Henoch-Schoenlein Purpura Nephritis (HSPN)
Roberta Fenoglio, Dario Roccatello. *Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), San Giovanni Hospital, Turin, Italy.*

Background: Corticosteroids alone or in combination with Immunosuppressive agents has been suggested to be effective in IgA vasculitis (IgAV)- Henoch-Schoenlein Purpura Nephritis (HSPN). However, optimal treatment remains controversial. Due to the putative role of B lymphocytes in the pathogenesis of IgAV, Rituximab (RTX) appears a potential therapeutic tool. We report a monocentric experience on the use of RTX in severe adult IgA-vasculitis with biopsy-proven nephritis.

Methods: Our series includes 5 adult patients (3 males and 2 females), age 21-70 years.

Patients (n°)	Gender	Age at diagnosis	Organ involvement	Follow-up
1	F	70	S, K, J°	8 years
2	M	21	A, K, S*	33 months
3	M	43	A,K, S, J°	18 months
4	F	26	K, S*, J	7 months
5	M	55	K, A, J, S	3 months

CS=corticosteroids, MMF= mycophenolate mophetil, IGIV=intravenous Immunoglobulins, Cyp= cyclophosphamide, CyA=cyclosporine, AZA=azathioprine, S=skin with (*) necrotic ulcers, A=abdomen, K=kidney, J=joint involvement with (°) frank arthritis

The diagnosis was achieved according to EULAR criteria. RTX (lymphoma protocol) was administered as a rescue therapy in 3 patients, previously given a conventional immunosuppressive therapy without benefits. Two patients received RTX as a front-line treatment. All had a severe cutaneous and kidney involvement (diffuse intra and extracapillary proliferation with fibrinoid necrosis). Three patients had abdominal pain (in two cases associated with bleeding) and 2 severe arthritis.

Results: All patients achieved a complete renal remission. One needed a maintenance RTX therapy due to cutaneous relapses. The follow-up ranged from 6 months to 8 years. No clinically relevant adverse events have been observed.

Conclusions: This is the first case series describing successful RTX treatment of adult HSPN, and underlines the role of B lymphocytes in the pathogenesis of IgAV. This is consistent with previously reported benefits of RTX in other forms of vasculitis, and emphasized the role of B lymphocytes in the pathogenesis of IgAV.

FR-PO613

Can Serum Levels of Galactose-Deficient IgA1 and IgG Autoantibodies Predict the Course of Disease in Czech Patients with IgA Nephropathy? Dita Maixnerova,[1] Chunyan Ling,[2,3] Stacy D. Hall,[3] Colin Reily,[3] Rhubell T. Brown,[3] Michaela Neprasova,[1] Jelena Skibova,[4] Miloslav Suchanek,[5] Jan Novak,[3] Vladimir Tesar.[1] *[1]Dept of Nephrology, General Univ Hospital, 1st Faculty of Medicine, Charles Univ, Prague, Czech Republic; [2]Longhua Hospital, Shanghai Univ of Traditional Medicine, Shanghai, China; [3]Depts of Microbiology and Medicine, Univ of Alabama at Birmingham, Birminghan, AL; [4]Statistical Unit, Inst of Clinical and Experimental Medicine, Prague, Czech Republic; [5]Univ of Chemical Technology, Prague, Czech Republic.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis with serious prognosis leading to end-stage renal disease in 30-50% of patients. The diagnosis requires renal biopsy. Due to its inherent risks, non-invasive approaches are needed.

Methods: We examined 95 patients with biopsy-proven IgAN who were assessed at the time of diagnosis for renal function, proteinuria, microscopic hematuria, and hypertension, and followed-up clinically since then. Using serum samples collected the time of diagnosis, we determined levels of galactose-deficient IgA1 (Gd-IgA1) and IgG autoantibodies specific for Gd-IgA1 (IgGAb) using lectin and immunodetection methods. Spearman correlation coefficient was used for statistical analysis.

Results: Higher serum levels of Gd-IgA1 were associated with worse renal function (elevated serum creatinine) at the time of renal biopsy and during follow up ($r=0.223$ and $r=0.246$, respectively; $p<0.05$ for both). Higher serum levels of IgGAb correlated with higher degree of microscopic hematuria at the time of renal biopsy ($r=0.244$, $p<0.05$) and with worse renal function during the follow-up and at the end of the follow-up ($r=0.254$ and $r= 0.338$, respectively; $p<0.05$ for both).

Conclusions: Elevated serum levels of Gd-IgA1 and IgGAb may serve as markers of disease activity and/or decline of renal function and, thus, unfavorable prognosis in Czech patients with IgAN. Future tests in larger cohorts will determine whether these markers may provide diagnostic as well as prognostic information, enable monitoring of disease activity, and/or responses to treatment.

FR-PO614

IgA Nephropathy Is Associated with Elevated Levels of Renal BAFF and APRIL Deepak Kumar,[1] Rui Chang,[1] Chia Chi Sun,[1] Ivy A. Rosales,[2] A. Bernard Collins,[2] Rex Neal Smith,[2] Herbert Y. Lin,[2] Ravi I. Thadhani,[2] Julie Demartino.[2] *[1]TIP Immunology, EMD Serono Inc, Billerica, MA; [2]Div of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis, with up to 40% of patients progressing to end stage renal disease. Studies have shown that elevated levels of serum BAFF (B cell activating factor) and APRIL (A Proliferation Inducing Ligand) in IgAN are associated with severity of clinical and pathological disease features. Biologically, these cytokines also play a role in IgA class switch recombination in B cells. Further, a recent report showed that sera from IgAN patients can induce proliferation of renal mesangial cells, providing a mechanism for the pathogenesis of IgAN. However, the expression levels of BAFF and APRIL and their cognate receptors in the kidney during IgAN is not known.

Methods: Immunofluorescence (IF) staining was performed on kidney biopsies from 15 IgAN, 3 diabetic glomerulopathy (DG), 4 Minimal Change Disease (MCD) and 1 with no diagnostic abnormality (NDA).

Results: We report increased expression of APRIL by IF staining in both the glomerulus and tubular epithelial cells, and for BAFF in the glomerulus in kidney biopsies showing IgAN compared to biopsies showing DG, MCD and NDA. APRIL and BAFF staining in IgAN was also evident in interstitial CD68+ macrophages. Moreover, IF analysis of cognate receptors for BAFF and APRIL, such as B-cell maturation antigen (BCMA), transmembrane activator and CAML interactor (TACI) and BAFF-R, also showed increased expression in both tubular epithelial cells and glomerular parietal epithelial cells in IgAN compared to MCD. BCMA, TACI and BAFF-R staining was also evident in the interstitial CD20+ B cells.

Conclusions: Taken together, these data show increased tissue expression by immunohistochemical studies of BAFF, APRIL and their cognate receptors in kidney biopsies showing IgAN. Given the roles of BAFF and APRIL in autoantigen and/or autoantibody production in IgAN, this demonstrates the potential of BAFF and APRIL blockade in the treatment of IgAN.

Long Term Renal Survival in IgA Nephropathy with Crescents Kendral R. Knight, Dustin J. Little, Stephen W. Olson. *Walter Reed National Military Medical Center, Bethesda, MD.*

Background: The Oxford Classification (MEST criteria) established the impact of mesangial hypercellularity (M), endocapillary hypercellularity (E), segmental glomerulosclerosis (S), and tubular atrophy/interstitial fibrosis (T) histopathology on renal survival for IgA nephropathy (IgAN). Outcomes have been reported for Asian patients with >50% crescents, but the prognostic implications of glomerular crescents (including 1-50% crescents) in an ethnically diverse population have not been reported.

Methods: We performed a retrospective cohort study of 136 biopsy confirmed IgAN cases identified in the military electronic medical record system from 2000 - 2015. The renal survival, defined by the absence of renal replacement therapy (RRT), of IgAN with 1-50% crescents was compared to both IgAN with >50% crescents, and IgAN without crescents. For secondary analysis, the incidence of a >25% decline in eGFR and progression to stage IV CKD were compared between IgAN cases with 26%-50% crescents and IgAN cases with 1-25% crescents .

Results: Renal survival of IgAN with 1-50% crescents was superior to IgAN with >50% crescents (89%; 49/55 vs. 25%; 3/12, $p<0.001$), and equivalent to IgAN without crescents (89% vs. 87%; 60/69, $p=0.79$) over a median (IQR) follow up period of 61 (24,110) months. There was no statistically significant difference between these groups for any component of the MEST criteria. A greater proportion of subjects with 26-50% crescents experienced a ≥25% decline in eGFR (44%; 7/16 vs. 13%; 5/39, $p=0.02$) and progressed to stage IV CKD (50% vs. 13%, $p=0.006$) than those with 1-25% crescents.

Conclusions: In this comprehensive analysis of the prognostic value of crescents, independent of MEST criteria, for renal outcomes in IgAN patients followed for median 5 years, IgAN with1-50% crescents had a renal survival superior to IgAN with >50% crescents and similar to IgAN without crescents. The subgroup of IgAN with 26-50% crescents experienced a more rapid decline in GFR and more often reached stage IV CKD than IgAN with 1-25% crescents. Future prospective immunosuppression therapy trials could be considered for IgAN patients with 26-50% crescents.

Renal Outcomes in Patients with IgA Nephropathy (IgAN) Undergoing Liver Transplant (LT) Musab S. Hommos, Ziad El-Zoghby. *Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Liver cirrhosis is the most common cause of secondary IgAN. Renal IgA deposition is thought to be a consequence of impaired removal of IgA-containing immunocomplexes by Kupffer cells in the failing liver. If this hypothesis is correct, IgAN should have favorable renal outcomes following liver transplant.

Methods: Included are 11 patients (9 males) with biopsy proven IgAN. 6 patients underwent LT and 5 patients underwent combined liver-kidney transplant (CLKT) with a mean age of 50 at transplant time (Tx). We collected the level of proteinuria, hematuria, GFR at time of transplant, 12 and 60 months after Tx. We also reviewed any kidney biopsy done after Tx.

Results: Results are summarized in Figure 1. All patients had hematuria prior to Tx. Patient 2 progressed to end stage renal disease 5 years post Tx. Patient 9 had histological recurrence of IgAN found on protocol kidney allograft biopsy done 4 months post CLKT without clinical features of IgAN. Patient 10 had recurrent IgAN 2 months post CLKT associated with heavy proteinuria of 2640 mg/day, but that resolved with the addition of angiotensin-converting enzyme inhibitor (ACEi) and GFR remained stable at last follow up.

ID	Tx Type	GFR at Tx	Proteinuria (mg/day) prior to Tx	Hematuria at 1 year post TX	Proteinuria (mg/day) at 1 year post Tx	Hematuria at 5 years post Tx	Proteinuria (mg/day) at 5 years post Tx
1	LT	66	91	Yes	197	No	184
2	LT	110	95	No	3570	No	4343
3	LT	17	450	No	715	No	1096
4	LT	31	459	No	44	No	227
5	LT	35	855	No	422	N/A	N/A
6	LT	54	1147	No	356	No	58
7	CLKT	17	7784	No	44	No	35
8	CLKT	12	206	No	120	No	66
9	CLKT	19	558	No	94	N/A	N/A
10	CLKT	14	46	Yes	374	Yes	95
11	CLKT	21	217	No	211	No	143

Conclusions: Previous reports suggest that IgAN in liver cirrhosis patients has a benign course following LT. However, our data shows that IgAN can progress to end stage renal disease following LT and can have early recurrence in kidney allograft following CLKT. It is possible that some patients with progressive disease have primary rather than secondary IgAN. Persistent hematuria and/or proteinuria > 1000 mg/day post-transplant may indicate recurrent or persistent IgAN and may identify patients who would benefit from aggressive supportive therapy, including treatment with ACEi to prevent poor renal outcomes.

FR-PO617

Clinical Presentation of IgA Nephropathy Is Changing Toward More Aggressive Forms Affecting Older Patients: Data from the Spanish Registry of Glomerulonephritis Eduardo Gutierrez-Martinez,[1] Manuel Praga,[1] Francisco Rivera,[2] Juan Manuel Lopez Gomez.[3] *[1]Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain; [2]Nephrology, Hospital General de Ciudad Real, Ciudad Real, Spain; [3]Nephrology, Hospital Gregorio Marañón, on Behalf of All Members of the Spanish Registry of Glomerulonephritis, Madrid, Spain.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis in the world, but there are few epidemiological data about possible changes in its presentation over the years. Also, available infomation about the influence of age on the form of clinical presentation is scarce.

Methods: Aim of the study was to analyze all renal biopsies performed between 1994 and 2013 and recorded in the Spanish Registry of Glomerulonephritis with histological diagnosis of IgAN. The study was divided into five 4 year-periods (1994-97, 1998-2001, 2002-2005, 2006-2009 and 2010-2013) and patients were divided into 4 age groups: children (<17 years), adults: (17-45 years) and (46-65 years), and elderly (>65 years).

Results: From 20,974 renal biopsies recorded, 2961 (14.1%) corresponded to IgAN. The prevalence of IgAN remained stable, but a significant increase in age [from 37.6 (17.7) in 1994-97 to 44.9 (16.8) years in 2010-13; p0.001] and worse renal function at presentation from [1.9 (1.9) to 2.3 (2.1) mg/dl; p 0.001] was observed over the years. Nephrotic range proteinuria and acute kidney injury (AKI) as forms of presentation were significantly more commmon among elderly patients (17.7 and 35.3%) as compared to adult patients (12.7 and 9.5%) and children (11.3 and 4.9%). AKI in elderly patients correlated with a significant increase in the frequency of gross haematuria over time (54.5% in 1994-97 to 70.6% in 2010-13; p 0.001). Blood pressure, serum creatinine, proteinuria and the incidence of CKD were also significantly higher at presentation among elderly patients.

Conclusions: Although the prevalence of IgAN in Spain has remained stable over the years, patients are significantly older and present with a significantly worse renal function. Elderly patients with IgAN have a remarkable incidence of nephrotic range proteinuria (17.7%) and gross-haematuria-related AKI (70.6%).

FR-PO618

Association of Recurrent Proteinuria Related to IgA Nephropathy with the Mesangial Hypercellularity Score and Grade of Proteinuria at Diagnosis Takayuki Fujii, Satoshi Suzuki, Mizuki Shinozaki, Kaiji Saito, Mayu Morimoto, Noriko Terasaki, Tanaka Hiroaki. *Kidney Center, Seirei Sakura Citizen Hospital, Sakura City, Japan.*

Background: The grade of proteinuria is important for predicting the renal prognosis of patients with IgA nephropathy. The renal prognosis of those with the remission of proteinuria is favorable. However, even when treatment leads to the remission of proteinuria, recurrence is often observed. Currently, there are no global guidelines defining the remission or recurrence of IgA nephropathy. We examined recurrence-associated factors, regarding patients with a urinary protein level of <0.3 g/day as achieving remission and those in whom remission could not be maintained for 6 months or more as showing recurrence.

Methods: Of 313 patients who were diagnosed with IgA nephropathy based on kidney biopsy findings, with an eGFR of ≥30 mL/min/1.73 m^2 and a urinary protein level of ≥0.5 g/day, and could be followed-up for 2 years or more, we conducted a retrospective cohort study in 155 with the remission of proteinuria. Regarding recurrent proteinuria as an outcome, we examined recurrent proteinuria-associated clinical/histopathological data and treatment using Cox's proportional hazard model.

Results: The mean follow-up period was 16.5±8.7 years. The mean daily urinary protein level on kidney biopsy was 1.0±0.9 g. The mean eGFR was 78.1±23.2 mL/min/1.73 m^2. Of the 155 patients with remission of proteinuria, recurrent proteinuria was noted in 68. Recurrent proteinuria was associated with a urinary protein level of ≥1 g/day (HR: 2.78, 95%CI: 1.40-5.37) and mesangial hypercellularity score (M) =1 according to the Oxford classification (HR: 1.99, 95%CI: 1.06-3.58). On the other hand, steroid therapy was useful for maintaining the remission of proteinuria (HR: 0.37, 95%CI: 0.18-0.75).

Conclusions: Recurrent proteinuria in patients with IgA nephropathy was associated with a urinary protein level of ≥1 g/day at diagnosis and M1 according to the Oxford classification.

FR-PO619

The Clinical and Histopathological Difference of IgA Dominant Infection-Related Glomerulonephritis from Those of IgA Nephropathy: A Single Center Study Takaya Handa, Hiroyuki Suzuki, Eri Muso, Tatsuo Tsukamoto. *Nephrology, Kitano Hospital, The Tazuke Kofukai Medical Research Inst, Osaka, Japan.*

Background: IgA dominant infection-related glomerulonephritis (IgA-IRGN) is a unique form of IRGN histologically resemble to IgA nephropathy (IgAN). However, IgA-IRGN should be discriminated because of the difference of the clinical course. We compared both using a database of our hospital.

Methods: We extracted 15 patients with IgA-IRGN, whose clinical and pathological findings were matched the previous paper (Kidney Int2013;83,792-803), and 122 patients with IgAN as control from 1788 patients who underwent kidney biopsy from 2000 to 2015 in our hospital. To rise the characteristic surface of IgA-IRGN, we took several clinical and pathological parameters, including age, laboratory findings, and histological observation with light microscopy, immunofluorescence, and electron microscopy, and compared with those of IgAN. We further examined the prognosis of IgA-IRGN by the all-cause mortality and end stage renal disease.

Results: IgA-IRGN showed higher proportion of elderly (26.7vs 5%;p<0.05), lower eGFR (53.8±25.7 vs 74.7±24.9 ml/min/1.73m2;p<0.05), heavier proteinuria (5.1±6.0 vs 1.1±2.1 g/day;p<0.05),and lower serum albumin (3.1±0.7 vs 3.9±0.4 g/dl;p<0.05). Endocapillary proliferation was common(93%vs36%,p<0.05),and immunogloburines(IgG, IgA ,IgM) and complements(C3c,C1q and C4c) were detected along the glomerular capillary more frequently(p<0.05) consistent with the dense deposits at both subendtohelial and subepithelial sites more frequently (p<0.05) .IgA-IRGN patients were more susceptible to acute kidney injury (54% vs 4%; p<0.01).The prognosis of IgA-IRGN patients was poorer (p<0.05). Using univariate analysis, the risk factors of IgA-IRGN were past history of diabetic mellitus, heavy proteinuria (>3.0g/day), IgG and C1q deposition along the glomerular capillary.

Conclusions: IgA-IRGN and IgAN showed different clinical course and histological findings in immune complex deposition. Involvement of glomerular capillary lesion and activation of multiple complement pathway might influence on the prognosis in IgA-IRGN.

FR-PO620

Complement Factor H Gene Polymorphism rs6677604 and the Risk, Severity and Progression of IgA Nephropathy: A Systematic Review and Meta-Analysis See Cheng Yeo, Xinyang Liu, Adrian Liew. *Renal Medicine, Tan Tock Seng Hospital, Singapore.*

Background: Several studies reported an association between rs6677604 polymorphism and susceptibility to IgA nephropathy (IgAN), but attempts at validating this finding yielded inconsistent results.

Aim: We seek to clarify the association between complement factor H gene rs6677604 polymorphism and IgAN susceptibility, severity and progression.

Methods: Eligible studies were identified by a comprehensive database search. Meta-analyses were performed for rs6677604 allele frequency and the association with IgAN susceptibility. Subgroup analyses, publication bias, and sensitivity analyses were also conducted.

Results: 10 studies were included in the systematic review. Among them, four studies containing 10 datasets (15,617 IgAN-cases and 31,947 controls) were included in the quantitative meta-analysis. The pooled frequency of the minor allele (A) was significantly higher in Europeans than in Asians both in IgAN-cases (15.3% vs. 5.2%) and controls (21.3% vs. 6.4%), and the frequency in IgAN-cases was significantly lower than that in controls in both Europeans and Asians. Overall, a significant association was detected between rs6677604 and risk of IgAN – AA vs. GG: odds ratio (OR)=0.58, 95% confidence interval (CI) [0.48, 0.69]; AG vs. GG: OR=0.77, 95% CI [0.73,0.81]). In stratification by ethnicity, significant association between AA vs. GG and IgAN susceptibility was observed in Europeans (OR=0.56, 95%CI: 0.46-0.69) but not in Asians (OR=0.66, 95%CI: 0.46-1.04). No publication bias was observed. Systematic review did not reveal any association between rs6677604 polymorphism and IgAN severity/progression.

Conclusions: rs6677604-A allele was more prevalent in Europeans than in Asians. The presence of rs6677604-A allele significantly decreased IgAN susceptibility in Europeans, but this association was not confirmed in Asians. Not enough clinical evidence was found between rs6677604 polymorphism and IgAN severity/progression. Further functional studies are needed to validate the findings.

FR-PO621

First 1-Year GFR Decline Slope Can Identify High-Risk Patients in IgA Nephropathy Kyungho Lee, Eun Jeong Lee, Jung-Ho Shin, Hye Ryoun Jang, Jung Eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh. *Div of Nephrology, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

Background: IgA nephropathy (IgAN) is the most frequent primary glomerular disease and the leading cause of end-stage renal disease. This study investigated clinical and histologic predictors for renal survival in patients with IgAN with a focus on glomerular filtration rate (GFR) decline slope.

Methods: We screened all patients who diagnosed with primary IgAN between 1995 and 2012. Renal progression was defined as creatinine doubling. Using serial measurements of serum creatinine during the first 1 year, we calculated the GFR decline slopes. Then, we defined the patients with the steepest quartile of GFR slope as rapid decliner, those with the 2nd quartile of GFR slope as slow decliner and the others as non-decliner.

Results: Among 214 subjects, the age was 37 (28, 46), and baseline GFR was 81 (62, 100) mL/min/1.73 m^2. Both of them did not differ between the 3 groups. Rapid decliner and slow decliner had higher levels of protein/creatinine ratio (0.88, 0.89, and 0.58 g/g Cr respectively, P < 0.001) and higher score of tubular atrophy/interstitial fibrosis compared with non-decliner; 20.8%, 16.7 %, and 6.5 % in each groups showed score ≥1 (P = 0.007). Renal progression at 5 year was 76 % in rapid decliner, 91 % in slow decliner, and 100 % in non-decliner (P < 0.001, rapid or slow decliner vs non-decliner). After adjustment for sex, blood pressure, GFR, proteinuria, and histologic findings, slow decliner was associated with a 7.3-fold higher risk of progression (P = 0.017) and rapid decliner was associated with a 9.6-fold increased risk of progression (P = 0.006) compared with non-decliner. GFR slope value was also negatively associated with renal progression after adjustment for aforementioned covariates (P = 0.005).

Conclusions: First 1-year GFR slope was a predictor of renal progression, independently of proteinuria amounts and histologic findings. GFR slope can be incorporated to identify high-risk patients who need more aggressive treatment.

FR-PO622

Clinical Usefulness of the Oxford Classification in Determining Immunosuppressive Treatment in IgA Nephropathy Min-Uk Cha, Chang-Yun Yoon, Changhwan Seo, Hae-Ryong Yun, Seung Hyeok Han. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Although the Oxford classification has been widely used in IgA nephropathy, its clinical usefulness of determining immunosuppression is unknown. Here, we conducted an observational study to investigate whether the Oxford-MEST could predict the development of persistent proteinuria and worsening kidney function. We also evaluated the clinical effectiveness of corticosteroid treatment by the Oxford classification.

Methods: We studied 377 patients with early-stage IgA nephropathy who had proteinuria <1.0 g/g Cr and estimated glomerular filtration rate (eGFR) ≥50 ml/min/1.73m^2. The study endpoints were the development of a random urine protein-to-creatinine ratio of ≥1 g/g Cr and a 30% decline in eGFR during follow-up.

Results: The results showed that among the Oxford-MEST lesions, only M1 predicted the risk of the development of proteinuria ≥1.0 g/g Cr compared to other lesions in a

time-varying Cox model adjusted for multiple confounding factors. In addition, the risk of reaching a 30% decline in eGFR was significantly higher in patients with M1 than in those with M0. Furthermore, patients with M1 had a greater decline of eGFR than patients with M0. However, steroid treatment in M1 lesion was not associated with improving clinical outcomes in the unmatched and propensity score matched cohort.

Conclusions: The results showed that among the Oxford-MEST lesions, only M1 predicted the risk of the development of proteinuria ≥1.0 g/g Cr compared to other lesions in a time-varying Cox model adjusted for multiple confounding factors. In addition, the risk of reaching a 30% decline in eGFR was significantly higher in patients with M1 than in those with M0. Furthermore, patients with M1 had a greater decline of eGFR than patients with M0. However, steroid treatment in M1 lesion was not associated with improving clinical outcomes in the unmatched and propensity score matched cohort.

FR-PO623

Response of Patients with IgA Nephropathy to High Doses of Lisinopril and Omacor Ronald J. Hogg,[1] Ralph C. Bay,[2] Gerald B. Appel,[3] Daniel C. Cattran,[4] Fernando C. Fervenza,[5] Debbie S. Gipson,[6] Robert J. Wyatt.[7] *[1]Baylor, Scott & White Health, Temple, TX; [2]A.T. Still Univ, Mesa, AZ; [3]Columbia Univ, New York, NY; [4]Toronto General Hospital, Toronto, ON, Canada; [5]Mayo Clinic, Rochester, MN; [6]Univ of Michigan, Ann Arbor, MI; [7]Univ of Tennessee, Memphis, TN.*

Background: Treatment for patients (pts) with IgA nephropathy (IgAN) using angiotensin converting enzyme inhibitors (ACEi) or omega-3 fatty acids (O3FA) has been described previously, but there are limited data describing results obtained when the two are combined in high doses.

Methods: Lisinopril 10-80mg, as tolerated, and O3FA (Omacor®) 4gm (EPA 1.88 g., DHA 1.48 g.), were given daily to 79 IgAN pts with urine protein to creatinine ratios (UP/C) ≥0.6 (males) or ≥0.8 (females) who were enrolled in a multicenter prospective clinical trial. We evaluated the efficacy of the therapy after 3-6 months in 29 pts who were not receiving pre-study ACEi and/or O3FAs. Complete remission (CR) of proteinuria = UP/C ≤ 0.20 g/g. Partial remission (PR) = UP/C < 0.6 (males), < 0.8 (females).

Results: The UP/C fell from 1.94±1.13 to 0.88±0.75 in the 29 pts. The decrease in UP/C was correlated with decrease in systolic BP (r=.441, p=0.02) and diastolic BP (r=.483, p=0.01). Seventeen of the 29 pts had a CR (n=5) or PR (n=12) after 3 months; an additional 3 pts had a PR after 6 months. The UP/C fell from 1.91±1.26 to 0.42±0.15 in these 20 pts. Three of the pts who did not have a PR at 3 months were randomized to mycophenolate and subsequent UP/C results were censored. The overall rate of CR or PR after 3 or 6 months was therefore 76.9% (20/26 pts). The UP/C fell by at least 50% in 18 of the 20 pts, giving an adjusted CR/PR rate of 69.2% of pts who fulfilled both of the criteria for a PR.

Conclusions: Based on this small sample size, high doses of Omacor® and lisinopril for 3-6 months induced at least a PR in 69.2-76.9% of IgAN pts depending on how PR is defined. These results appear to be better than those described in other recent trials of non-immunosuppressive therapy and suggest that a further trial of the combination therapy described herein should be considered.

FR-PO624

Clinicopathological Features and Outcomes of IgA Nephropathy with Mild Proteinuria Xiang-Mei Chen. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing.*

Background: Information about the outcomes of IgA Nephropathy is mostly based on patients in whom proteinuria are higher than 1–2 g/d at renal biopsy time. The clinicopathological features and outcomes of IgAN patients presenting with mild proteinuria are not well described. Therefore we conducted a study to investigate the clinicopathological features and outcomes of IgAN patients with mild proteinuria.

Methods: Primary IgAN patients with proteinuria less than 1g/d in our hospital from January 1995 to December 2014 were retrospectively reviewed. The clinical and pathological data at renal biopsy and follow-up informations were collected and analyzed.

Results: 510 IgAN patients with mild proteinuria were enrolled in this study. At biopsy, 32.7% of the patients were found to have hypertention and 32.3% had a history of macroscopic hematuria.Lee's Grade III was observed in 73.1% of the patients. Lee's Grade IV-V was observed in 7.7% of the patients. Of the Oxford Classification, M1 was observed in 30.4% of the patients, E1 was observed in 5.1% of the patients, S1 was observed in 69.6% of the patients, T1 was observed in 14.9% of the patients, and T2 was observed in 1.6% of the patients. After a median follow-up of 50 months, 4(0.8%)patients developed ESRD, 22 (5.85%) presented proteinuria levels >1 g/24 h, 31(6.1%)patients had eGFR decline ≥30% of the basline(not including ESRD). 45(8.8%) patients presented proteinuria ≥1g/d, only 82(16.1%) patients had complete clinical remisssion. Logistic regression revealed that time average-proteinuria(TA-P)(RR31.85, P=0.000) was the risk factor of renal function dererioration and ESRD. Age(RR1.53, P=0.022) and proteinuria(RR11.61, P=0.001) were the risk factors of sustained proteinuria ≥1g/d after biopsy.

Conclusions: Severe renal pathological lesions may be observed in some IgAN patients with mild proteiunuria. Renal outcome is dismal in IgAN patients with mild proteinuria. Life-long follow-up with regular monitoring of proteinuria ,blood pressure and renal function is important especially for older patients with more proteinuria.

FR-PO625

Mycophenolate Mofetil Treatment for Henoch-Schonlein Purpura Nephritis with Nephrotic Range Proteinuria Dmitry V. Samsonov,[1] Anna Zolotnitskaya,[2] Praveen N. Chander,[3] Robyn G. Matloff,[1] Tanya E. Pereira.[1] *[1]Pediatrics, New York Medical College, Valhalla, NY; [2]Pediatric, The Children's Hospital at Montefiore, Bronx, NY; [3]Pathology, New York Medical College, Valhalla, NY.*

Background: We present our experience with Mycophenolate Mofetil (MMF) as an adjuvant agent for treatment of severe childhood HSP nephritis with nephrotic range proteinuria.

Methods: A retrospective chart review was performed on all patients (N=65) referred to our clinic for HSP Nephritis 01/01/2001 - 12/31/2015. Patients with confirmed nephrotic range proteinuria (> 3 mg/mg creatinine) who were treated with MMF (N=9) were included in analysis. Biopsies were classified according to Oxford MEST-scores. MMF mean dosage was 1251 mg/m^2/day, median follow up was 115 weeks.

Results: Demographic characteristics, treatment, and response to therapy are summarized below

N	Age/ Gender	Biopsy	Treatment	Up/c at onset	Laboratory findings prior to MMF initiation / at last visit		
	yr.mo/ gender	Oxford Class	1 Solumedrol pulse 2 Oral steroids 3 MMF 4 Cyclophosphamide	mg/ mg	Up/c mg/ mg	Albumin g/dl	eGFR by CKID Schwartz ml/min/1.73m2
1	4. 8/M	M1E1S0T0	2,3	10.7	4.2 / 0.12	3.5 / 3.6	> 75 / >75
2	6.5/M	M1E1S0T0	1,2,3	8.5	5.9 / 0.18	3.8 / 4.0	> 75 / >75
3	6.8/F	M1E1S0T0	1,2,3	27	8.6 / 0.26	2.9 / 3.9	> 75 / >75
4	8.0/M	M1E1S0T0	1,2,3	22.3	26 / 0.22	1.8 / 4.6	50.3 / 75
5	10.10/M	M1E1S0T0	1,2,3	8.4	8.7 / 0.14	2.6 / 4.5	> 75 / >75
6	5.10/M	M0E1S1T0	2,3	4.6	2.5 / 0.11	3.7 / 4.5	> 75 / >75
7	6.3/F	M1E1S1T0	2,3	3.8	2.1 / 0.19	3.7 / 4.4	> 75 / >75
8	5.6/M	M1E1S0T0	1,2,3,4	19.9	18.2 / 0.35	1.6 / 4.6	57 / >75
9	7.6/F	M1E1S0T0	1,2,3	13.2	3.9 / 0.13	2.7 / 4.4	> 75 / >75

All patients had normal eGFR and up/c at last follow up. Mean duration of MMF therapy was 36 weeks. MMF was successfully withdrawn in 7 out of 9 patients at last follow up. Degree of proteinuria on presentation was correlated with time needed to achieve remission.

Conclusions: Our results indicate that MMF may be an attractive adjunctive agent for treatment of HSP nephritis with nephrotic range proteinuria.

FR-PO626

A Global Platform for Prediction Modeling in 4915 Patients with IgA Nephropathy from Asia, Europe and the Americas Sean Barbour,[1,7] Gabriela Espino-Hernandez,[8] Heather N. Reich,[2,7] Yusuke Suzuki,[5,7] Zhihong Liu,[6,7] Rosanna Coppo,[4,7] Daniel C. Cattran.[2,7] *[1]Univ of BC; [2]Univ of Toronto; [3]Oxford Univ Hospital; [4]Torino Univ Hospital; [5]Juntendo Univ; [6]Nanjing Univ; [7]For the International IgAN Collaboration; [8]BC Renal Agency.*

Background: Predicting renal outcome in IgA nephropathy (IgAN) is very challenging. A comprehensive prediction model is needed to guide clinical management, facilitate trial design and test the prediction benefit of new biomarkers. The lack of a sufficiently large and diverse cohort with standardized data collection have limited previous efforts in this area, and no current prediction model has been validated for use in diverse ethnic and age groups worldwide.

Methods: We merged 10 datasets from collaborators worldwide to create a large international database designed to derive and validate a comprehensive prediction model in IgAN. All patients have biopsy-proven disease with Oxford MEST histology scores, and detailed baseline and longitudinal clinical, medication and laboratory data.

Results: The dataset includes 4915 patients from research groups in China, Japan, Europe and North/South America. This includes 1734 Caucasian, 1654 Chinese and 1338 Japanese patients. Across datasets, median follow-up time ranges from 3.3-7.2 years, mean baseline eGFR from 64-120 ml/min/1.73m^2, proteinuria from 0.9-2.6 g/d and age from 13-40 years. The frequency of MEST scores is: M1 12-94%, E1 11-58%, S1 31-83%, T1 6-30% and T2 1-12%. 870 patients experienced a 50% reduction in eGFR or ESRD.

Conclusions: We have created the largest and most diverse dataset in IgAN to date based on a collaboration of international researchers. The size and granularity of data captured in this dataset will enable development of the first ever prediction model in IgAN (similar to a Framingham score) that will be valid across different age and ethnic groups, and can be implemented in clinical practice worldwide. While each of the individual datasets will be governed locally, the merged database has been standardized for use by the collaborative group for multiple research purposes. This approach serves as a prototype for international collaboration and generation of merged datasets to study other types of glomerular diseases.

FR-PO627

Clinicopathological Characteristics and Prognosis of IgA Nephropathy Patients with Hepatitis B Virus Infection Hongrui Shi, Mengjun Liang, Jiafan Zhou, Ning Su, Jiang Zongpei. *Dept of Nephrology, The Six Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, China.*

Background: Some studies had found HBV played an important role in IgA nephropathy(IgAN).The aim of our study is to investigate clinicopathological characteristics and prognosis in IgAN patients with HBV infection.

Methods: We conducted a cohort study enrolling primary IgAN patients diagnosed by renal biopsy in our Hospital from Jan 2013 to Feb 2016.We compared clinicopathological characteristics between IgAN patients with or without HBV infection.Then the HBV-IgAN group was followed for a median of 14.2 months.Primary outcome was the decline of eGFR>25%.Secondary outcomes were remission of proteinuria and hematuria (defined as decline of proteinuria or hematuria>50%) and reactivation of HBV replication.

Results: There were146 patients eligible in our study,including 29 patients with HBsAg positive(19.9%).Patients in HBV-IgAN group were older (40.90±10.05yr vs.34.50±12.05yr, p=0.007),and had higher ALT level (26.38±14.72U/L vs.22.90±21.91U/L,p= 0.020),higher AST level (21.21±7.82U/L vs.18.64±9.90U/L, p=0.010),worse pathological grade (Lee IV+V,72.8% vs. 49.4%,p=0.040) and more thickness of vessel wall (100% vs. 81.9%,p=0.040).23 HBV-IgAN patients were followed up.10 patients (43.5%) had met the primary outcome,who had more serious renal injury (CKD4-5,50% vs. 0, p=0.007),more proteinuria in 24h(2.60±1.98g vs. 1.19±1.10g, p=0.017) and more interstitial infiltration (Oxford classification T2,66.7% vs.9.1%,p=0.028).Among 23 patients,9 of them got glucocorticoid or immunosuppressant therapy (GC group) and 14 of them received conservative therapy (CV group).In GC group,33.3% had met primary outcome;55.6% got remission of proteinuria;100% arrived remission of hematuria,while the ratio in CV group was 50.0%(p=0.67),30.8%(p=0.38) and 42.9%(p=0.018),respectively.The reactivation rate of HBV replication in GC group and CV group were 44.4% and 57.1% (p=0.68).

Conclusions: HBV-IgAN patients were 19.9% in our center.After follow-up,43.5% of the HBV-IgAN patients had met primary outcome.Glucocorticoid or immunosuppressant therapy may improve renal outcome of HBV-IgAN patients without obvious effect on reactivation of HBV replication.

FR-PO628

Long-Term Study of Cyclophosphamide, Leflunomide, Glucocorticoids and ACE-Inhibitors Treatment in IgA Nephropathy Shasha Chen, Li Wang, Guisen Li. *Renal Div and Inst of Nephrology, Sichuan Academy of Medical Sciences and Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Few studies are currently available about the efficiency and renal survival of IgA nephropathy (IgAN) treated with immunosuppressive agents.We retrospectively analyzed data from Chinese patients with IgAN to study long-term efficacy with different therapies, and explore the prognostic factors for recovery of renal function in patients with declining renal function.

Methods: 311 cases of biopsy-proven IgAN were retrospectively studied in this study. Outcome was renal function recovery (defined as improvement of creatinine by at least 30% or back to normal range). declining renal function.

Results: Cyclophosphamide group had a higher level of Scr (P<0.001), a lower level of eGFR(P<0.001), higher mesangial hypercellularity score (P<0.001), higher proportion of global and segmental glomerularsclerosis (P<0.001), more severe tubular atrophy/interstitial fibrosis lesions (P<0.001), severe interstitial lymphocyte and monocyte infiltration and most prominent vascular lesions (P<0.001) than other groups. Leflunomide group, Steroids+ACEI/ARB group and especially cyclophosphamide group had higher annual increase rate and value of eGFR, higher proportion of renal function recovery than ACEI/ARB group(P<0.001). 58.5%, 58.1%, 65.3% and 52.4% of cyclophosphamide group, leflunomide group, steroids+ACEI/ARB group and ACEI/ARB achieved renal function recovery. Multivariate regression analysis indicated that only eGFR (HR 1.094, P=0.027), gross hematuria (HR 0.045, P=0.016) and crescents (HR 0.677, P=0.049) were predictors for renal recovery.

Conclusions: Immunosuppressants (cyclophosphamide and leflunomide) played an important role in increasing renal recovery in IgA nephropathy patients with impaired renal function, especially in patients with crescents, vasculitic lesions on renal biopsy or massive proteinuria.

FR-PO629

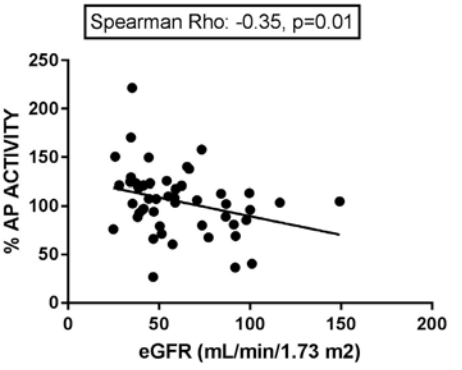
Alternative Pathway Activity in IgA Nephropathy Raad B. Chowdhury,[1] Magdalena Riedl,[5] Ping Lam,[1] Jennifer Gommerman,[1] Jan Novak,[2] Krzysztof Kiryluk,[3] Stuart Yang,[1] Sean Barbour,[4] Daniel C. Cattran,[1] Michelle A. Hladunewich,[1] Rulan S. Parekh,[5] Elisa Porfilio,[1] Bryan Coburn,[1] David Guttman,[1] Scott Gray-Owen,[1] Harindra Rajasekeran,[1] Christoph Licht,[5] Heather N. Reich.[1] *[1]UHN, Univ of Toronto; [2]Univ of Alabama; [3]Columbia Univ; [4]Univ of British Columbia; [5]Hospital for Sick Children.*

Background: A hallmark of IgA nephropathy (IgAN) is mesangial and circulating immune complexes containing aberrantly glycosylated IgA1 an anti-glycan antibody and C3. Recent GWAS suggest a common deletion of *CFHR1* and *CFHR3* as protective variant in IgAN. Deficiency of CFHRs results in functional surplus of CFH, a key regulator of the complement alternative pathway (AP), suggesting a functional role for the AP in IgAN pathogenesis. We evaluated functional differences in systemic AP activity in patients with IgAN hypothesizing that AP activity is increased in IgAN due to CFH dysfunction.

Methods: 52 IgAN and 38 healthy subjects were examined. AP activity was quantified via ELISA (Wieslab) detecting terminal C5b-9 generation after pathway-specific activation. CFH function was evaluated via hemolysis assay using sheep erythrocytes. Complement activity was correlated with clinical measures of disease activity including proteinuria and renal function.

Results: We did not observe an increase in systemic AP activity in IgAN compared with healthy controls with the Wieslab ELISA nor the hemolysis assay (p>0.05). In IgAN AP activity was inversely correlated with renal function (eGFR) (Spearman r=-0.35, p=0.01). There was no correlation with proteinuria.

Conclusions: We did not observe increased systemic AP activity in our IgAN cohort although we did find an inverse correlation with kidney function. If studies in a larger cohort confirm these results it is possible that AP dysregulation in IgAN is more important locally (at the cell surface) than systemically (fluid phase). Genotype and measures of AP proteins will be evaluated next.



Funding: Private Foundation Support, Government Support - Non-U.S.

FR-PO630

Altered Expression of *O*-Glycan Biosynthetic Enzymes in IgA1-Producing Cell Lines from Patients with IgA Nephropathy (IgAN) and Their Family Members Hiroyuki Ueda,[1,2] Yoshimi Ueda,[1,2] Colin Reily,[1] Zina Moldoveanu,[1] Stacy D. Hall,[1] Karen Hart,[1] Dana Rizk,[1] Krzysztof Kiryluk,[3] Ali G. Gharavi,[3] Takashi Yokoo,[2] Bruce A. Julian,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham; [2]The Jikei Univ School of Medicine, Japan; [3]Columbia Univ College of Physicians and Surgeons.*

Background: Familial (F) and sporadic (S) IgAN patients (IgANP) have elevated levels of serum galactose-deficient IgA1 (Gd-IgA1). Moreover, 50% of the first-degree relatives of F-IgANP have high serum Gd-IgA1 levels, ≥95th percentile of healthy controls (HC) without any clinical sign of IgAN. These serum Gd-IgA1 levels are longitudinally stable in most individuals. We have previously generated immortalized IgA1-producing cell lines (IgAPC) from S-IgANP and HC as a model system for analysis of IgA1 *O*-glycosylation pathways. Cells from IgANP secrete more Gd-IgA1 than do the cells from HC; this aberrant *O*-glycosylation is associated with aberrant expression of key glycosyltransferases (GTs) involved in the biosynthesis of *O*-glycans. Here, we generated IgAPC from a pedigree with F-IgAN and characterized their gene-expression patterns for C1GalT1 and *O*-glycan branching enzymes (GCNTs).

Methods: The pedigree includes 4 IgANP. We generated IgAPC from blood relatives with serum Gd-IgA1 levels >95th percentile of HC (high-Gd-IgA1 relatives; n=8), IgANP (n=2), and marry-ins (n=7). Expression levels of selected genes were determined by qRT-PCR.

Results: IgAPC from high-Gd-IgA1 relatives and IgANP secreted more Gd-IgA1 compared to those from marry-ins; Gd-IgA1 serum levels correlated with the degree of galactose deficiency of IgA1 secreted by the cell lines of corresponding donors. qRT-PCR analysis revealed that expression levels of *C1GALT1*, *COSMC*, and *GCNT1, 3,* and *4* in cells from high-Gd-IgA1 relatives and IgANP were lower compared to those in cells from marry-ins. Moreover, expression levels of *C1GALT1* and *GCNT1, 3,* and *4* negatively correlated with serum Gd-IgA1 levels.

Conclusions: Our studies revealed abnormal expression of multiple GT genes in IgAPC from IgANP and their relatives at risk of IgAN. These aberrancies affected *C1GALT1* as well as genes of *GCNT* family. Expression of these GTs correlated with the degree of IgA1 galactose deficiency.

FR-PO631

Clinical Significance of Histopathology in C3 Glomerulopathy (C3G) Pietro A. Canetta,[1] Dominick Santoriello,[2] Andrew S. Bomback,[1] Rupali S. Avasare,[1] Vivette D. D'Agati,[2] Glen S. Markowitz,[2] Gerald B. Appel.[1] *[1]Nephrology Div, Columbia Univ, New York, NY; [2]Renal Pathology Div, Columbia Univ, New York, NY.*

Background: C3G is defined by glomerular lesions containing C3 with little or no immunoglobulin (Ig). The relationship between histology, clinical features, and prognosis has not been studied in a large US series.

Methods: We examined histologic and clinical features of 66 patients (pts) with biopsy (bx) and followup data at our center. Each initial bx was re-scored for light microscopic

(LM) pattern of injury, immunofluorescent (IF) staining, and deposit location by electron microscopy (EM). A combined endpoint of 2x creatinine, GFR <15 or transplant was studied by logistic regression.

Results: Median GFR at bx was 62 ml/min (IQR, 39-135) and proteinuria was 2.8 g/gCr (1.2-5.4). LM patterns included membranoproliferative (MPGN, 55%), mesangioproliferative (MesGN, 23%), diffuse proliferative (12%), and diffuse sclerotic (11%). MPGN pts were youngest (22±16y); MesGN pts were older (45±25y, P<0.01) and had the least proteinuria (median 1.3 *vs* 3.2 g/gCr, P<0.01). By IF, C3 was the only immunoreactant in 47%; these pts were older than pts with any Ig (37±23 *vs* 23±14y, P=0.01) and had lower GFR (median 41 *vs* 106, P=0.01). By EM, 28% had dense deposit disease (DDD) and 72% had C3 glomerulonephritis (C3GN). DDD pts were older than C3GN (39±21 *vs* 26±18 y, P<0.01) and had a suggestion of lower GFR (P=0.07) but similar proteinuria. Rare variants of *C3*, *CFH*, *CFHR5*, or *CFI* were found in 11/48 and were not associated with LM/IF/EM pattern. A paraprotein was found in 12/25 and when present was associated with DDD (OR 6.7, P<0.05). Over a median 38 months (13-117), 35% reached the endpoint. Univariable outcome predictors included GFR at bx, global and segmental glomerulosclerosis, and IFTA. Achieving a 50% fall in proteinuria lowered risk of the endpoint (OR 0.11, P<0.01). MesGN had marginally significant lower risk (OR 0.22, P=0.07). In multivariable analysis, only GFR was significant.

Conclusions: C3G histology had important associations with age onset, disease severity, and other clinical features (such as DDD with paraproteins), but for predicting prognosis the effect of GFR dominated.

FR-PO632

Recurrent C3GN and Dense Deposit Disease (DDD) in the Renal Allograft Wooin Ahn, Renu Regunathan-Shenk, Rupali S. Avasare, Pietro A. Canetta, Andrew S. Bomback, Gerald B. Appel. *Internal Medicine, Columbia Univ Medical Center, New York, NY.*

Background: C3 glomerulopathy (C3G) is a GN associated with dysregulation of the alternative complement pathway, histologically categorized as either DDD or C3GN. There are few studies of transplantation in C3G, none comparing C3GN to DDD, and little data on the effect of eculizumab in recurrent C3G.

Methods: We retrospectively reviewed the charts of 19 patients (pts) with biopsy-diagnosed C3G evaluated at Columbia University Medical Center, who'd received a renal transplant (txp). We analyzed their clinical and laboratory presentation, and post-txp outcomes.

Results: Of the 19 pts receiving allografts 12 had C3GN and 7 DDD. There were 14 males and 5 females with a median age at diagnosis of 27(range 7-60) and at transplantation of 30 (range 17-70). Mean time from biopsy to ESRD was 64 months (range 5-191). 2/17 pts evaluated for genetic defects had variants in *MCP* or *CFHR5*. 3 had C3 nephritic factor and 3/7 tested had a monoclonal protein. 15 pts received allografts from live donors (10 related). Prior to txp 9 pts were on HD (mean 31 mo) and 2 on PD (mean 5 mo). Available HLA typing revealed 4/9 pts had DR17-DQ2, known to be associated with autoimmune disease. Pts were followed for a mean of 82 mo post txp. Total graft failure was 3/12 (25%) in C3GN and 6/7 (86%) in DDD. 1 DDD pt had immediate graft failure. For-cause biopsy revealed recurrence in all 6 remaining (100%) DDD pts by 15 mo (range 2-32) and in 10/12 (83%) C3GN pts by 42 mo (range 0-212).Graft failure occurred in 3/10 (30%) recurrent C3GN pts at a mean of 62 mo and 5/6 (83%) of recurrent DDD pts at a mean of 47 mo. Graft failure was attributed to recurrence in 67% of recurrent C3GN pts and 60% of the DDD pts. 5 pts with recurrence (4 C3GN and 1 DDD) were treated with eculizumab, of which 3 had graft failure attributed to recurrence.

Conclusions: Our data confirm the frequent post-txp recurrence of C3G, despite immunosuppression. We also show similar recurrence rates and graft failures rates due to recurrence in C3GN and DDD. Total graft failure rate was higher in DDD. The potential beneficial effects of eculizumab for recurrent C3G await larger studies.

FR-PO633

C3 Glomerulonephritis and Dense Deposit Disease Share Similar Clinical Features, Genetics, and Disease Course Rupali S. Avasare,[1] Andrew S. Bomback,[1] Pietro A. Canetta,[1] Maddalena Marasa,[1] Yifu Li,[1] Ali G. Gharavi,[1] Richard J. Smith,[2] Dominick Santoriello,[3] Vivette D. D'Agati,[3] Glen S. Markowitz,[3] Gerald B. Appel.[1] *[1]Div of Nephrology, Columbia Univ Medical Center; [2]Molecular Otolaryngology and Renal Research Laboratories, Univ of Iowa; [3]Div of Renal Pathology, Columbia Univ Medical Center.*

Background: C3 glomerulopathy (C3G) includes both dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). Few large series, and no large US study, have defined the course of these entities. We reviewed our center's experience with C3G to compare the clinical presentations, genetics, and outcomes of patients with DDD and C3GN.

Methods: We reviewed charts of 100 patients with a diagnosis of C3G followed at Columbia University. The primary outcome was doubling of creatinine, ESRD, or death. Patients with C3GN and DDD were compared by two-tailed T test or Mann-Whitney U test (continuous variables) and Fisher exact test (categorical variables).

Results: Of 100 patients, 78 had C3GN and 22 had DDD. There were 63 men and 37 women with 66 non-Latino whites, 20 Latinos, 8 Asians, 5 Blacks and 1 other. Median age was 24 yrs (15 – 43). Median creatinine was 1.27 mg/dl (0.8 – 2.0). Median proteinuria was 2.8 g/gCr (1.5 – 5.1). Of 74 patients with whole exome sequencing or complement-cascade specific testing, 14 (19%) had rare variants in *C3*, *CFH*, *MCP*, *CFHR5*, or *CFI* genes, although some variants were of unknown significance. Seven of 35 (20%) and two of 24 (8%) patients had C3 nephritic factor and CFH Ab, respectively. Nineteen of 32 (58%) patients had a monoclonal protein. Median follow-up time was 3.2 yrs (1.3 – 8.5). Therapies included steroids (n=65) and other immunosuppression (n=49). Forty-two patients reached the primary endpoint of doubling SCr, ESRD, or death: 32/78 (41%) in the C3GN group and 10/22 (45%) in the DDD group (p=0.6).

Conclusions: In 100 US patients, we found no major differences in clinical presentation, diagnostic workup, or outcomes between C3GN and DDD. Our detection rate for mutations and autoantibodies was lower than in previous reports. C3GN and DDD share not only a common pathogenesis but also a common course. The value of distinguishing between the two should be examined in future studies.

FR-PO634

Clinicopathological Features in Patients with Amyloidosis and Low Serum C3 Level Bernardo V. Reichert, Lectícia Jorge, Precil Diego Miranda de Menezes Neves, Cristiane B. Dias, Luis Yu, Viktoria Woronik. *Nephrology, Univ of São Paulo, São Paulo, SP, Brazil.*

Background: The complement system play an important role in the pathogenesis of different glomerulopathies. Recently, we have observed patients with amyloidosis and low serum C3 level. As far as we know, no study have specifically studied the complement levels in patients with amyloidosis. The aim of this study was to describe subjects with kidney amyloidosis and low serum C3 as well as compare them with those who present normal levels of C3.

Methods: We performed a retrospective study by reviewing clinical and histological data of amyloidosis patients submitted to renal biopsy at our center from 1999-2016. Decreased serum C3 levels (hypoC3) was defined as C3<90mg/dl. Of 47 patients, 9 were excluded by insufficient data.

Results: Of the patients, there were 9 patients with hypoC3(24%). In hypoC3, the type of amyloid was Ig amyloidosis in 6 patients(67%), AA amyloidosis (secondary b hepatitis) in 1(11%), familiar amyloidosis in 1(11%) and unclassified in 1(11%). In normalC3, the type of amyloid was Ig amyloidosis in 20 patients(69%), AA amyloidosis in 2(7%), familiar amyloidosis in 2(7%) and unclassified in 5(17%). The data are summarized in table 1.

Clinical and Histological Features		
	HypoC3(n=9)	NormalC3(n=29)
Age(y)	53.6±14.1	55.4±12.8
Male	5 (56%)	12 (42%)
Creat In(mg/dl)	4.1±2.9	1.6±0.7*
CKD EPI in	28±34	68±35*
Albumin(g/dl)	2.4±0.9	1.8±0.7
Proteinuria(g/day)	5.5±2.3	8.9±5.2*
C3 Level(mg/dl)	62±14	144±57*
Hemoglobin(g/dl)	10.4±0.5	12.6±2.3*
Hematuria n(%)	2(22%)	6(20%)
Mesangial C3 Deposition n(%)	6(75%)	7(25%)*
Follow up(y)	0.6±0.9	2.3±2.4*
ESRD	6(67%)	5(25%)*
*p<0.05		

Interestingly, hypoC3 was significantly associated with a lower CKD EPI, lower hemoglobin and a higher rate of mesangial C3 deposition, suggesting a more severe manifestation of the disease in hypoC3 subjects.

Conclusions: In our study, the presence of hypocomplementemia was associated with a worse renal prognosis and a greater mesangial deposits of C3 in renal biopsies in patients with amyloidosis. More studies are needed to clarify the role of the complement system in amyloidosis.

Funding: Government Support - Non-U.S.

FR-PO635

Mycophenolate Mofetil in C3 Glomerulopathy: Is It Really Effective? Ege Sinan Torun,[1] Tarik Onur Tiryaki,[1] Aysegul Oruc,[2] Yasemin Ozluk,[3] Halil Yazici,[1] Mehmet S. Sever,[1] Yasar Caliskan.[1] *[1]Dept of Internal Medicine Div of Nephrology, Istanbul Univ Istanbul Faculty of Medicine, Istanbul, Turkey; [2]Dept of Internal Medicine Div of Nephrology, Uludag Univ Faculty of Medicine, Bursa, Turkey; [3]Dept of Pathology, Istanbul Univ Istanbul Faculty of Medicine, Istanbul, Turkey.*

Background: This study aimed to evaluate the effect of immunosuppressive treatment on C3 glomerulopathy (C3G) progression.

Methods: A total of 68 patients [37 male, mean age:36±16 years] with C3G were enrolled. Patients with a baseline GFR value ≥30 mL/min and a minimum follow up of 6 months were assigned to mycophenolate mofetil (MMF) based (n=22) or non-MMF based (cyclophosphamide or azathioprine) (n=18) or conservative care (ACE inhibitors or ARBs) (n=12) treatment groups. The study groups were similar regarding age, gender, systolic blood pressure (BP), hemoglobin, serum albumin, proteinuria and eGFR at the time of biopsy. Patients in the MMF or non-MMF based groups received low-dose daily corticosteroids. The relationship between study groups and composite kidney failure events (defined as ESRD or a two-fold increase in serum creatinine level as compared to baseline) was assessed.

Results: Composite kidney failure events developed in 13 (25%) and ESRD developed in 10 (21.2%) patients after a median time of 40 months. The number of patients developing composite kidney failure events were similar among the study groups (MMF based group: 22.7%, non-MMF based group: 16.7%, conservative care group: 41.7%, p=0.29). In Cox

regression analysis, age (HR:0.863, p=0.003), proteinuria at the time of biopsy (HR:1.86, p=0.005) and eGFR (HR:0.923, p<0.001) at baseline were the clinical markers and the presence of crescents was the histopathological marker (HR 1.41, p=0.002) which predicted the composite kidney failure events.

Conclusions: In the present study, immunosuppressive treatment, particularly MMF based regimen was not found to be superior to conservative care in delaying the progression of C3G. Age, proteinuria and eGFR at the time of biopsy as clinical markers and the presence of crescents as a histopathological marker predicted the progression to ESRD.

FR-PO636

Progression of Chronic Kidney Disease in Alport Syndrome: Interim Data from the Athena Study Oliver Gross,[1] Gerald B. Appel,[2] James F. Simon,[3] Bertrand Knebelmann,[4] Paul C. Grint,[5] Jacqueline Blem,[5] Michael Huang,[5] Michelle N. Rheault.[8] *[1]Univ Medicine Goettingen, Goettingen, Germany; [2]Columbia Univ Med Center, NY; [3]Cleveland Clinic, Cleveland; [4]Hopital Necker, Univ Paris Descartes, Paris, France; [5]Regulus Therapeutics, San Diego; [6]Regulus Therapeutics, San Diego; [7]Regulus Therapeutics, San Diego; [8]Univ Minnesota Masonic Children's Hosp, Minneapolis.*

Background: Alport syndrome (AS) is a genetic kidney disorder resulting in capillary glomerular basement membrane defects, leading to end stage renal disease. The natural progression of chronic kidney disease (CKD) in AS is not well studied and biomarkers to predict CKD progression are lacking. The current study characterizes the natural decline in renal function in AS patients over 120 weeks.

Methods: ATHENA (NCT02136862) is a non-interventional, global, multicenter study enrolling 250 AS patients. Eligibility criteria include: age ≥12 years, confirmed diagnosis of AS, and glomerular filtration rate (GFR) between 30-90 ml/min/1.73m2. Patients with previous renal transplantation are excluded. Renal biomarkers and estimated GFR (eGFR) are assessed at baseline and every 12 weeks. mGFR is assessed at baseline and every 24 weeks.

Results: Interim analysis included 113 enrolled patients, with 69 and 33 patients through 24 and 48 weeks of follow-up, respectively. At baseline, mean age was 44.8 years (SD 15.2), 65% of patients were female, and 82% were white. Genetic analysis revealed 65% had X-linked AS. Baseline mean mGFR and eGFR (MDRD) were 55.2 and 58.5 ml/min/1.73m^2, respectively. At week 24 and 48, mean mGFR change from baseline was -0.61 and -2.19 ml/min/1.73m^2 and mean eGFR (MDRD) change from baseline was -1.27 and -2.83 ml/min/1.73m^2, respectively, compared to baseline. No clear trends in other blood or urine biomarkers were observed during 24 and 48 weeks of follow-up.

Conclusions: In this first prospectively designed natural history study of AS, interim data show a measurable decline in GFR by 24 and 48 weeks. With no currently approved therapies for AS, these data may have important implications for the design of future therapeutic clinical trials. Enrollment and analysis of ATHENA is ongoing.

FR-PO637

Rates of Kidney Transplantation across Glomerulonephritis Subtypes in the United States Michelle M. O'Shaughnessy,[1] Sai Liu,[1] Maria E. Montez-Rath,[1] Richard A. Lafayette,[1] Wolfgang C. Winkelmayer.[2] *[1]Stanford Univ, Palo Alto, CA; [2]Baylor College of Medicine, Houston, TX.*

Background: Whether access to kidney transplantation differs by cause of ESRD, and specifically by glomerulonephritis (GN) subtype, has rarely been explored.

Methods: Using the US Renal Data System, we identified all adult patients with ESRD attributed to 1 of 6 GN subtypes or 1 of 2 non-GN comparator groups (see table) who initiated dialysis in the US (1996-2011). Using Cox proportional hazards regression, with death as a competing risk and follow-up to end of 2011, we estimated hazard ratios [HRs (95% confidence intervals)] for first kidney transplantation (IgAN=reference). Models were adjusted for baseline demographics, comorbidities, and socioeconomic factors, as well as Organ Procurement Organization (OPO; actual or geographically most proximate).

Results: Among 632,908 patients, considerable heterogeneity in transplant rates across GN subtypes existed:

	Median f/u, yrs	Deceased Donor TX, %	Living Donor TX, %	Death before TX, %	Censored, %
FSGS, n=27,036	2.7	22.1	11.7	32.6	33.7
IgAN, n=9,828	2.8	26.9	24.2	17.3	31.6
MN, n=5,356	2.0	17.9	11.3	38.2	32.7
MPGN, n=3,977	2.7	19.3	12.7	39.6	28.4
LN, n=14,161	2.4	17.6	11.7	36.7	34.0
Vasculitis, n=5,277	2.4	10.7	8.8	47.2	33.4
DN, n=540,753	2.4	6.0	3.0	61.4	29.6
ADPKD, n=26,520	2.5	30.0	11.8	26.8	31.4

FSGS, focal segmental glomerulosclerosis; IgAN, IgA nephropathy; MN, membranous nephropathy; MPGN, membranoproliferative GN; LN, lupus nephritis; DN, diabetic nephropathy; ADPKD, autosomal dominant polycystic kidney disease; TX, transplant.

After adjusting for case-mix and OPO, patients with FSGS, LN, vasculitis, or DN had lower rates of kidney transplantation than those with IgAN [HRs 0.83 (0.76-0.90), 0.70 (0.63-0.78), 0.70 (0.59-0.82), and 0.48 (0.44-0.53), respectively], whereas those with MN, MPGN, or ADPKD had similar rates [HRs 1.07 (0.93-1.23), 0.88 (0.75-1.02), and 0.96 (0.87-1.04), respectively].

Conclusions: Identifying underlying reasons for these apparent disease-specific barriers to kidney transplantation may improve pre-transplant patient counseling, recipient selection procedures, and organ allocation policy.

FR-PO638

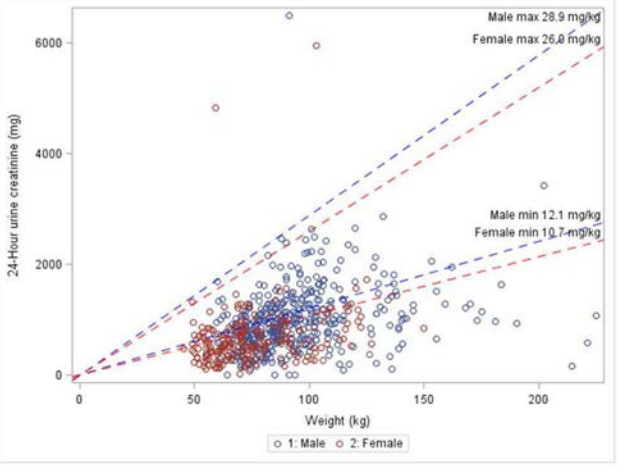
Unexpectedly Low 24-Hour Creatinine Excretion amongst Patients with Biopsy-Proven Glomerular Diseases Marie C. Hogan, Heather N. Reich, Peter J. Nelson, Sharon G. Adler, Daniel C. Cattran, Gerald B. Appel, Debbie S. Gipson, Matthias Kretzler, Jonathan P. Troost, John C. Lieske. *Nephrotic Syndrome Study Network Consortium (NEPTUNE).*

Background: Urine creatinine excretion (UCrE) is often used to assess accuracy of timed urine collections. Urinary analytes are also often normalized to UCr concentration.

Methods: Data from 666 unique 24 hr urine collections of 226 adults collected at protocol visits in the NEPTUNE cohort were available for analysis (minimal change 60, Focal sclerosis 91, membranous 60, other 91). UCr was analyzed in batches in a centralized laboratory by enzymatic creatinase assay.

Results: Total UCrE was systematically lower than typical reference ranges independent of weight (Figure). Overall among NEPTUNE adult patients, the measured UCrE was systematically 50% lower than predicted by a recently published equation (Ix and Wassel; CJASN 6:184-191,2011). A model using repeated measures ANOVA for 48 patients with 3 or more available values supported internal consistency of UCrE by subject (P=0.50). CKD stage influenced creatinine excretion with 37% at CKD stage 1 within the predicted UCrE range while only 24% were at CKD stage 4 (P<0.001). UCrE did not associate with serum albumin, but correlated with baseline steroid exposure (OR=1.5; p=0.02). However, when UCrE was stratified by exposure (on steroids one, both, or neither collection) intra-patient correlations did not vary.

Figure. Correlation of individual patients' 24-hour urine creatinine excretion (mg/ weight kg) for all adult NEPTUNE samples (n=226 patients/ 666 observations). Reference lines denote published 95% reference ranges for UCrE (Junge et al. Clin Chim ACTA 344: 137-148, 2004).



Conclusions: Patients with these biopsy proven glomerular diseases appear to have reduced creatinine generation. The reasons are unclear, but reduced muscle mass related to CKD likely plays some role. These results have implications for interpretation of both random and timed urine collections.

FR-PO639

Glomerular Disease Frequency Distributions by Continent - Results from the International Kidney Biopsy Survey Michelle M. O'Shaughnessy,[1,2] Susan L. Hogan,[2] Bawana Donna Thompson,[2] Rosanna Coppo,[3] Agnes B. Fogo,[4] J. Charles Jennette.[2] *[1]Stanford Univ, Palo Alto, CA; [2]Univ of North Carolina, Chapel Hill, NC; [3]Regina Margherita Hospital, Turin, Italy; [4]Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Large-scale studies comparing glomerular disease frequencies across continents are lacking.

Methods: We surveyed 29 nephropathology laboratories in 4 continents using a standardized form to obtain kidney biopsy diagnosis frequencies in recent consecutive years, along with population demographics for each diagnosis. If a specimen had multiple diagnoses, each was coded separately. This report focuses on glomerular disease frequencies by region and race/ethnicity. Cooperation was received from ASN-GDAG, RPS, and ERA-EDTA Immunonephrology Working Group.

Results: Diagnosis frequencies differed significantly by continent:

Glomerular disease frequencies by continent (n=41,527). Numbers represent %.				
	USA/Canada (10 centers) n=23,189	**Europe (14 centers) n=15,042**	**Asia (2 centers) n=1,609**	**Latin America (3 centers) n=1,687**
Focal Segmental GS[1]	19.2	14.9	6.9	21.8
IgA nephropathy[1]	11.7	22.1	39.5	6.8
Diabetic GS[1]	19.0	7.0	10.7	3.3
Membranous GP[1]	11.7	12.5	10.1	14.1
Lupus GN[1]	9.7	10.1	16.8	26.2
Pauci-immune GN[1]	5.2	8.0	2.5	2.5
Minimal change disease[1]	4.2	6.4	3.4	10.0
MPGN/C3GP[1]	2.6	3.7	1.1	3.1
Amyloidosis[1]	2.2	4.4	0.9	1.7
Thrombotic microangiopathy[1]	2.8	2.2	0.8	1.1
Thin basement membrane GP[1]	2.2	1.4	3.1	0.7
Other[1]	9.5	7.3	4.2	8.7
[1]Chi-square p<0.004 (0.05/12). GS, glomerulosclerosis; GP, glomerulopathy; GN, glomerulonephritis.				

After stratifying by race/ethnicity, diabetic GS was more (17% *vs* 2%, p<0.001) and lupus GN less (16% *vs* 28%, p<0.001) frequent among Latinos in USA/Canada *vs* Latin America, while focal segmental GS was more (13% *vs* 7%, p<0.001) and IgA nephropathy less (27% *vs* 41%, p<0.001) frequent among Asians in USA/Canada *vs* Asia.

Conclusions: Glomerular disease frequencies differed by continent, even among patients of similar race. Environmental factors or local biopsy policy may influence regional glomerular disease epidemiology independently from race.

FR-PO640

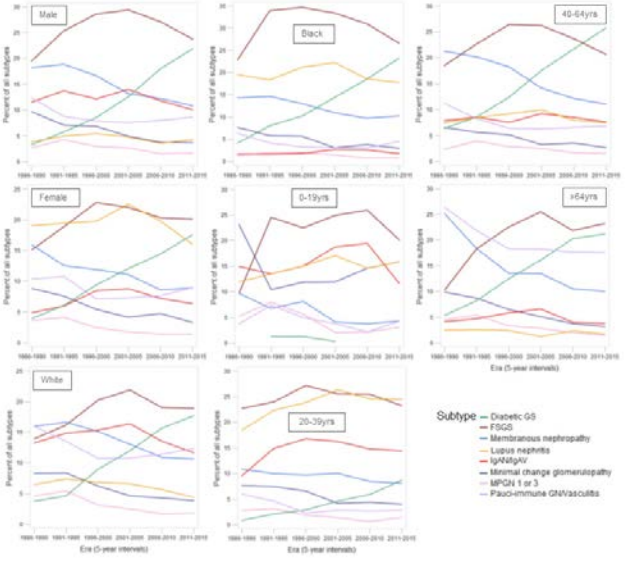
Temporal and Demographic Trends in Glomerular Disease Epidemiology in the United States, 1986-2015

Michelle M. O'Shaughnessy,[1,2] Susan L. Hogan,[2] Caroline J. Poulton,[2] Ronald J. Falk,[2] Harsharan Kaur Singh,[2] Volker Nickeleit,[2] J. Charles Jennette.[2] *[1]Stanford Univ, Palo Alto, CA; [2]Univ of North Carolina, Chapel Hill, NC.*

Background: Large-scale, contemporary, US studies exploring temporal trends in glomerular disease epidemiology by patient age, sex, and race are lacking.

Methods: In this cross-sectional, observational study, we examined glomerular disease subtype frequencies among all patients whose native kidney biopsy specimen was referred to the University of North Carolina (UNC), Chapel Hill, Nephropathology Laboratory (1986 to 2015), and who received a first biopsy confirmed diagnosis of a primary or secondary glomerular disease. Biopsy era (1986-1995, 1996-2005, 2006-2015) was the primary predictor. Patient age, sex, and race were secondary predictors. Relative biopsy frequencies were the primary outcomes.

Results: Among 23,959 cases of biopsy confirmed glomerular disease, the frequency of diabetic glomerulosclerosis increased dramatically over the 3 decades (4.4%, 10.0%, and 17.6% of cases, respectively, p<0.002). The frequency of FSGS increased initially but subsequently declined (18.0%, 23.8%, and 22.1%, respectively, p<0.002), whereas that of other common glomerular disease subtypes remained stable (IgA nephropathy, pauci-immune glomerulonephritis, lupus nephritis) or declined (minimal change disease, membranous nephropathy). These temporal trends were observed within all major sex, race, and age groups, with the exception of children, although substantial variation in glomerular disease subtype frequency distributions were observed across demographic groups cross-sectionally, **Figure 1**.



Conclusions: We identified significant changes in the relative frequencies of many glomerular disease subtypes over the past 30 years. We propose that exploration of behavioral and environmental exposures that likely underlie these findings should be the focus of future hypothesis-driven studies.

FR-PO641

B7.1 and suPAR Fail as Potential Biomarkers to Detect Podocyte Injury and Focal Segmental Glomerulosclerosis in Kidney Biopsies

Zoltan G. Laszik,[1] Flavio Vincenti.[2] *[1]Pathology, UCSF, San Francisco, CA; [2]Transplant Service, UCSF, San Francisco.*

Background: The mechanism of injury to podocytes in focal segmental glomerulosclerosis (FSGS) remains unclear. Both B7.1 (CD80) and suPAR have been proposed to cause FSGS but the findings have not been validated. To survey these markers as potential mediators of podocyte injury and as an aid to histologic diagnosis of FSGS we evaluated the expression of B7-1 and uPAR in native and transplant (Tx) kidney biopsies (Bx), and the expression of uPAR in mice injected with suPAR.

Methods: Study groups included Bx with FSGS (n=10), early post-Tx recurrent FSGS prior to (n=15) and post-plasmapheresis (n=7). Native Bx with membranous nephropathy (MN) (n=10) and minimal change disease (MCD (n=5), and normal 6 month post-Tx protocol Bx [n=10] served as controls. Immunostains were performed on formalin-fixed paraffin-embedded (FFPE) and frozen tissues for B7.1 and uPAR. B7.1 mRNA expression was also assessed by next generation *in situ* hybridization (ISH) on FFPE. Signal co-localization was evaluated via co-stain with the podocyte marker synaptopodin. In addition, uPAR immunohistochemical expression was also evaluated in the kidneys of wild type and uPAR -/- mice infused with recombinant suPAR. Electron microscopy was used in the mouse kidneys to assess foot process effacement in conjunction with renal functional studies.

Results: B7.1 protein and mRNA were not expressed in native kidneys with FSGS or MCD or in transplant kidneys with recurrent FSGS. In MN, B7.1 was localized only to the immune deposits. No apparent uPAR immunoreactivity was present in native kidneys or recurrent FSGS. suPAR infusion did not produce proteinuria or effacement of podocytes in wild type or uPAR deficient mice. uPAR was detected along the glomerular endothelial cells but not in podocytes in wild type mice while uPAR stain remained negative in uPAR deficient mice even after suPAR injection.

Conclusions: The data suggest that B7.1 and suPAR may not play a significant role in podocyte injury in native and transplant kidneys with FSGS. B7.1 and suPAR immunostains and ISH seem to have a limited value as diagnostic markers in kidney Bx with FSGS and recurrent FSGS post-transplant.

Urinary Monocyte Chemotactic Protein 1 as a Predictive Marker of Steroid Responsiveness in Children with Idiopathic Nephrotic Syndrome

Yuji Matsumoto, Yohei Ikezumi, Tomomi Kondo, Yoko Nakajima, Tetsuya Ito, Tetsushi Yoshikawa. *Pediatrics, Fujita Health Univ, Toyoake, Aichi, Japan.*

Background: We have previously reported that CD36 (low-density lipoprotein scavenger receptor)$^+$ macrophage (MQ) contributed in the pathogenesis of refractory nephrotic syndrome (NS). To elucidate the mechanism of MQ accumulation and to identify a predictive biomarker of steroid responsiveness, we compared differences in cytokine and chemokine levels in serum and urine between steroid-sensitive (SSNS) and steroid-resistant (SRNS) children.

Methods: In this study, 20 children with NS (7.1 ± 4.3 years; male-to-female ratio, 13:7) were enrolled. They were divided into a steroid-sensitive group (SSNS; n = 15) and a steroid-resistant group (SRNS; n = 5) according to their clinical course. Serum and urinary samples were collected at the time of onset and remission. Control serum and urine samples were also collected from age-matched healthy children (n = 15). Cytokines and chemokines were measured by using a cytometric bead array kit.

Results: The levels of several cytokines and chemokines in the urinary samples were significantly higher at onset than at remission (IP-10: p < 0.001, MCP-1: p < 0.001, MIG: p = 0.012, RANTES: p = 0.003) and those in the control samples (IL-6: p = 0.026, IP-10: p < 0.001, MCP-1: p = 0.032, MIG: p = 0.001, RANTES: p = 0.005). However, serum cytokine and chemokine levels did not significantly differ among the three groups. At onset, the urinary MCP-1 level was significantly higher in the SRNS group than in the SSNS group (p = 0.044).

Conclusions: The present study demonstrated that urinary cytokines and chemokines might be associated with the pathogenesis of NS. In particular, increased urinary excretion of MCP-1 in SRNS children was a potent predictive biomarker of steroid responsiveness in idiopathic NS. MCP-1, a chemokine recruiting macrophage, may play an important role in the pathogenesis of steroid resistance. Further histological studies warrant elucidation of the mechanisms of steroid resistance in refractory NS.

Biomarkers to Predict the Development of Glomerulosclerosis

Nina A. van de Lest,[1] Malu Zandbergen,[1] Ingeborg M. Bajema,[1] Jan A. Bruijn,[1] Reinhold Kreutz,[2] Marion Scharpfenecker.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Clinical Pharmacology and Toxicology, Charité Universitätsmedizin, Berlin, Germany.*

Background: Minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) are two common causes of the nephrotic syndrome. Some patients with biopsy-proven MCD have been shown to progress to FSGS. Early biomarkers indicating potential development of glomerulosclerosis before it becomes detectable by histology could help to discriminate between MCD patients that do or do not progress to FSGS. We previously described early changes in nephrin and segmental changes in desmin and podoplanin in a rat model for proteinuria and glomerulosclerosis (MWF rats). The aim of this study was to investigate whether changes in these markers are predictive for the development of glomerulosclerosis in MWF rats and patients with MCD.

Methods: 20 kidney sections of MWF rats and the non-proteinuric SHR strain were stained for desmin, podoplanin and nephrin at 4, 8 and 24 weeks of age. Quantification was performed using ImageJ. For a pilot study, renal biopsy samples of 10 MCD patients and 15 primary FSGS patients, diagnosed between 2001 and 2016, were stained for desmin, podoplanin and nephrin.

Results: In MWF rats, desmin expression in glomeruli was significantly increased at 8 and 24 weeks of age ($p<0.0001$), whereas it remained stable in SHR. Moreover, at 8 and 24 weeks, MWF rats showed segmental loss of podoplanin, which co-localized with *de novo* expression of desmin in podocytes. At 24 weeks of age, MWF rats developed segmental sclerosis. Glomeruli with segmental sclerosis displayed strong *de novo* desmin expression in podocytes and loss of podoplanin at the site of sclerosis. Confirming other studies, in biopsies of patients with MCD, the expression pattern of nephrin was granular and in FSGS, segmental loss of nephrin was observed. However, we also detected segmental loss of nephrin in patients with MCD.

Conclusions: Loss of podoplanin expression and *de novo* expression of desmin in podocytes predict development of segmental sclerosis in MWF rats. We also show segmental loss of nephrin in patients with MCD, which suggests that this marker may predict progression to FSGS.

FR-PO644

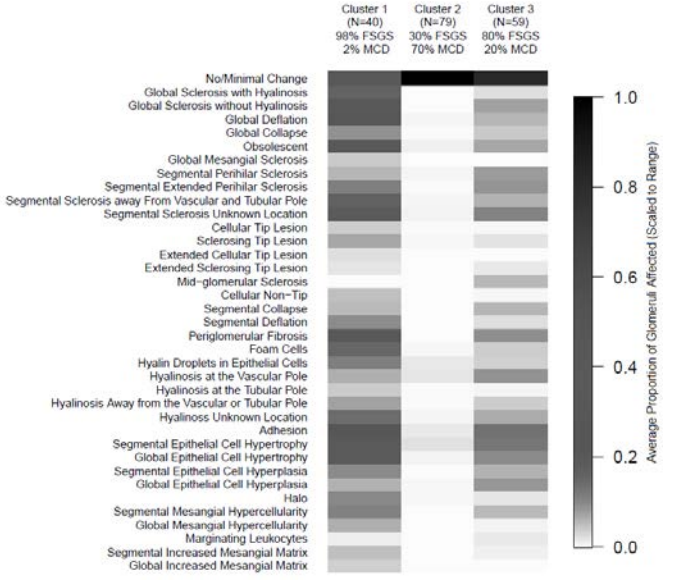
Minimal Change Disease and Focal Segmental Glomerulosclerosis Patient Subgroups Using Cluster Analysis of Morphologic Descriptors: Early Findings from the Nephrotic Syndrome Study Network

Laura H. Mariani,[1,2] Jarcy Zee,[2] Jeffrey B. Hodgin,[1] Matthias Kretzler,[1] Brenda W. Gillespie,[1] L. Barisoni,[3] Lawrence B. Holzman.[4] *[1]U. Michigan; [2]Arbor Research; [3]U. Miami; [4]U. Pennsylvania.*

Background: Conventional classification of minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) is based on qualitative interpretative pathology and does not capture disease heterogeneity. To overcome this problem, the descriptor-based NEPTUNE Digital Pathology Scoring System (NDPSS) was developed to assess multi-level, annotated whole slide images of renal biopsies.

Methods: To explore whether the NDPSS can identify patient subgroups, we used unsupervised cluster analysis of 68 MCD and 110 FSGS patients using the percent of glomeruli affected by 37 morphologic glomerular descriptors. We compared demographics, clinical characteristics, time to remission, and time to the composite of 40% reduction in estimated glomerular filtration rate (eGFR) or end-stage renal disease (ESRD) across the clusters.

Results:



3 clusters were found. Patients with a conventional diagnosis of MCD and FSGS were distributed across all 3 clusters, although FSGS patients represented the majority in Cluster 1. Cluster 1 patients had the highest rates of the composite outcome and lowest remission rates compared to the other two ($p<0.001$). Cluster 2 patients had higher rates of remission compared to Cluster 3. Cluster 2 patients were younger, had higher baseline eGFR, and lower baseline urine protein creatinine ratio ($p's<0.001$).

Conclusions: Clusters of patients with similar glomerular descriptor profiles had different clinical characteristics and outcomes. Therefore, given that the clusters do not match conventional morphologic classifications, there may exist previously undiscovered proteinuric disease subtypes that can now be identified using the NDPSS. The NDPSS is thus a useful methodology for diagnostic and prediction medicine.

Simple and Rapid Identification of Podocyte (Podo) Injury Using Anti-Podocalyxin (PCX) Antibody-Bound Latex Beads and Urine Sediments

Masanori Hara. *Dept of Pediatrics, Yoshida Hospital, Tsubame, Niigata, Japan.*

Background: The urine sediments from patients with Podo injury contain numerous PCX positive strucures as a form of granules trapped in the casts, in addition to Podo(es). In the current study we developed a simple and rapid light microscopic procedure to detect Podo injuries using latex beads bound with an anti-PCX antibody and urine sediments.

Methods: In order to get the antibody-bound latex we have newly developed monoclonal antibodies designing to trap the PCX positive granules or Podo(es). PCX expressing cell line (NCCIT) was used as positive control to search for the optimal reacting condition or requirements. Various approaches were tried and examined for requirements to get better discriminatory appearance of cells by light microscopic examination. The optimal conditions in the assay using NCCIT were checked also using human urine samples. Finally the new assay was applied to human urine samples with 34 diabetic patients (10 with microalbuminuric and 24 macroalbuminuric) and compared with the standard assay of conventional IF method.

Results: The optimal assay condition for the identification of PCX positive casts or Podo(es) in the sediments were as follows; 1) the mixture of 4 different antibodies (clones; 4A2, 4A7, 4D2 and 4E5) was required. 2) size and color of the latex should be 1.0 um and blue, 3) the sediments after centrifugation of starting urine volume of 1.5ml was mixed with 10 ul of 0.2 % antibody-bound latex and centrifuged using swing type at 1500 G for 15minutes and then the mixtures was gently suspended and served for light microscopic examination. The presence of latex-bound cells or casts was evaluated as positive for Podo injury in this assay. The time needed for entire procedures including microscopic examination was ~30 minutes. The good sensitivity (0.71) and specificity (0.96) was obtained.

Conclusions: We have developed a new method to detect podocyte injuries using antibody-bound latex beads and urine sediments that is simple and rapid without use of immunofluorescent microscope. This new approach might offer great advantages for the screening of podocyte injury in the practice of clinical nephrology.

FR-PO646

Proteomic Analysis Identifies Candidate Biomarkers of Steroid Resistance in Pediatric Glomerular Disease

Michael Merchant,[1] Shipra Agrawal,[2] William E. Smoyer,[2] Jon B. Klein.[1,3] *[1]Medicine, Univ of Louisville; [2]CCTR, The Research Inst at Nationwide Children's Hospital, Columbus, OH; [3]Pediatrics, The Ohio State Univ, Columbus, OH; [4]Robley Rex VAMC, Louisville, KY.*

Background: Glomerular disease is the third leading cause of ESRD in the US. Immunosuppressive drugs are the primary therapies for most glomerular diseases, but ~20-50% of patients fail to achieve a remission and can be deemed steroid resistant. No biomarkers exist to predict treatment responsiveness, leaving patients at high risk for both toxic side effects and disease progression. Prognostic biomarkers to prevent drug-induced toxicity, and to identify more targeted and effective treatments for glomerular disease represents an urgent need.

Methods: Paired plasma samples (n=30) were collected from 15 patients with nephrotic syndrome (NS) (steroid sensitive, SSNS; n=7 and steroid resistant, SRNS; n=8) and low abundant serum proteins were enriched by FPLC based immunodepletion of high abundant proteins. These paired samples were collected 6-8 weeks apart and corresponded to entry into the study (pre-steroid treatment) and a follow-up period at which time the clinical determination of steroid responsiveness was known. Samples were trypsinized, LCMS data (Orbitrap ELITE) collected and analyzed with Mascot/Sequest search strategy. Scaffold 4 was used for false discovery rate control, and ANOVA analysis was used to determine differences in protein abundances between SSNS and SRNS patient samples at pre- and follow-up time points.

Results: 45 of 223 protein clusters were differentially expressed (p-value <0.05) by ANOVA. 21 proteins remained significantly different following Benjamini-Hochberg multiple comparison correction (*p-value< 0.003). Unique protein abundance observations for SSNS were 4 increased pre-treatment and 3 increased post-treatment. 8 proteins decreased and 5 increased with steroid treatment in both SSNS and SRNS sample groups. One protein absent in SSNS pre-treatment was abundant in SSNS post-treatment and both SRNS pre-/post-treatment.

Conclusions: SSNS patients have plasma proteins that correlate with the response to steroid therapy. These proteins may have utility as prognostic biomarkers in pediatric patients.

Regulatory T-Cells Dynamics Predicts Clinical Response to Rituximab in Patients with Severe Primary Membranous Nephropathy
Michelle Rosenzwajg,[1,3,4] Eva Languille,[1,2] Hanna Debiec,[1,2] Joana Hygino,[3] Karine Dahan,[4] David Klatzmann,[1,3,4] Pierre M. Ronco.[1,2,4] *[1]Sorbonne Univs, UPMC Univ Paris 06, UPMC Univ Paris 06, Paris, France; [2]UMR_S 1155, F-75020, INSERM, Paris, France; [3]Biotherapy (CIC-BTi) and Inflammation-Immunopathology-Biotherapy Dept (I2B), AP-HP, Hôpital Pitié-Salpêtrière, Paris, France; [4]UMR_S 959, F-75005, INSERM, Paris, France; [5]Dept of Nephrology and Dialysis, AP-HP, Hôpital Tenon, Paris, France.*

Background: Little is known about cellular immune responses in primary membranous nephropathy (PMN). We aimed to characterize lymphocyte populations and cytokines/chemokines in patients with severe PMN at baseline and after rituximab infusion added to non-immune-suppressive anti-proteinuric treatment (NIAT) or under NIAT alone in the first rituximab-based RCT.

Methods: Twenty-five patients were enrolled in this study as well as 27 age-matched healthy donors. We investigated the dynamic changes of 33 lymphocyte subpopulations and 26 cytokines/chemokines in patients' peripheral blood.Twenty-one patients had PLA2R-related MN and one had anti-THSD7 antibodies.

Results: At baseline, the most significant changes between PMN patients and controls were (i) increased percentages of naive B-cells with decreased switched and non-switched memory B-cells; ii) overall decrease of NK cells percentage, contrasting with an increase of the $CD56^{bright}CD16^{-/lo}$ NK subset; (iii) decreased percentage of regulatory T cells (Tregs). This was associated with an increase of the plasma concentration of TNF-alpha, IL-5 and IL-2RA. After rituximab treatment, B-cell recovery was still incomplete at 6 months, with persistent alterations of B-cell subsets, overall increase of Treg and NK cell percentages and decrease of $CD56^{bright}CD16^{-/lo}$ NK subset and TNF-alpha levels. Noteworthy, the patients who responded to rituximab had the lower percentage of Tregs at baseline and a significant Treg increase at day 8 after rituximab. In contrast, Tregs remained unchanged in non-responders and in patients not treated with rituximab.

Conclusions: Altogether, Tregs delineate subgroups of PMN patients and is a potential predictive biomarker of rituximab efficacy.

Rituximab Residual Levels and Neutralizing Anti-Rituximab Antibodies (Ab) Are Associated with Response to Treatment in Patients with PLA2R-Related Membranous Nephropathy (MN)
Barbara Seitz-Polski,[1] Hanna Debiec,[2] Karine Dahan,[2] Sylvia Benzaken,[1] Pierre M. Ronco.[2] *[1]Nice Univ Hospital, France; [2]Tenon Univ Hospital, France.*

Background: The anti-CD20 monoclonal antibody rituximab can induce remission in patients with MN but apart from PLA2RAb titer, no predictor of clinical response has yet been identified.

Methods: In this pilot study, we measured residual rituximab serum levels and anti-rituximab antibodies at months 3 and 6 after each rituximab course, and searched for a neutralizing effect of anti-rituximab antibodies in 15 patients from Nice (1g at day 0 and day 14) and 27 patients from the French cohort GEMRITUX (375 mg/m^2 at day 0 and day 7; Dahan et al, JASN in press).

Results: Rituximab induced 10 remissions at month 6 in patients from Nice. Residual rituximab levels at month 3 were highly variable but significantly higher in patients who achieved remission at month 6 (p=0.003) while baseline proteinuria and PLA2RAb titer were not different (p=0.83 and p=0.09, respectively). Eight patients from the GEMRITUX trial were in remission at month 6. The rate of remission was higher in patients from Nice (p=0.03) and associated with higher residual rituximab level at month 3 (p=0.002) and lower CD19 count at month 6 (p<0.0001) while baseline proteinuria and PLA2RAb titer did not differ between the two cohorts (p=0.08 and p=0.53 respectively). Anti-rituximab antibodies were detected after 8 courses at month 6 in the two cohorts. Using competition assays, we showed that in 6 patients, rituximab antibodies could bind rituximab in the fluid phase and block in vitro rituximab cytotoxicity on B-cells whereas in the 2 other patients, antibodies were not neutralizing. The presence of neutralizing anti-rituximab antibodies in 6 among the 29 patients from the two cohorts in remission at month 12 (p=0.02) and PLA2RAb titers at month 6 (p=0.03) were both significantly associated with subsequent clinical relapses (n=6).

Conclusions: Monitoring of rituximab and neutralizing anti-rituximab antibodies may predict response and relapse in patients with MN associated with anti-PLA2R antibodies.

Circulating Antibodies against Thrombospondin Type I Domain-Containing 7A in Chinese Patients with Idiopathic Membranous Nephropathy
Zhao Cui, Jia Wang, Gang Liu, Minghui Zhao. *Renal Div, Dept of Medicine, Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: Prevalence of anti THSD7A antibodies in Chinese membranous nephropathy and its effect on prognosis were unknown. The present study is designed to assay the prevalence of anti THSD7A antibodies in Chinese idiopathic MN patients and explore its effects on prognosis.

Methods: 578 consecutive patients with biopsy-proven idiopathic MN diagnosed between years 2008 and 2016, and followed up at our center were enrolled. Anti PLA2R antibodies and anti THSD7A antibodies were assayed in circulation and in glomeruli. Clinical features and outcomes were compared between MN patients with and without anti THSD7A antibodies.

Results: Among 578 consecutive patients with idiopathic MN, 8 (1.4%) had anti THSD7A antibodies in circulation and in glomeruli. Among them, 2 patients had dual antibodies and two antibodies had no cross-reaction. Only one patient was female. Mean age of these patients was 58.4 ± 15.4 years. Patients with anti THSD7A antibodies had higher level of fibrinogen compared to anti PLA2R antibodies positive alone and dual antibodies negative patients (P=0.023, P=0.008). Other clinical features were comparable to MN patients without anti THSD7A antibodies (P>0.05). Patients with anti PLA2R antibodies positive had higher level of D-dimmer than those of dual antibodies negative (P=0.005). PLA2R and THSD7A expressed on the same position of podocyte by immunofluorescence. Patients received corticosteroids combined immunosuppressive therapy similar to that in patients without anti THSD7A antibodies (P>0.05). Clinical and renal prognosis among patients of anti THSD7A antibodies positive patients and antibodies negative patients had no significant differences (P>0.05).

Conclusions: MN patients with anti THSD7A antibodies had higher level of fibrinogen, which might be related with thrombogenesis. Patients with positive anti PLA2R antibodies seemed more likely to thrombus than patients with dual antibodies negative. Clinical and renal prognosis had no difference among patients with anti THSD7A antibodies positive and negative patients.

FR-PO650

Clinical and Pathological Spectrum of THSD7A Positive Membranous Glomerulopathy
Shree G. Sharma, Christopher Patrick Larsen. *Nephropathology, Arkana Laboratories, Little Rock, AR.*

Background: Thrombospondin type-1 domain containing 7A (THSD7A) is a recently described antigenic target in primary membranous glomerulopathy (MG). In the initial series, approximately 10% of the patients negative for PLA2R had antibodies against THSD7A.

Methods: All non-SLE associated MG cases (n=1070) were stained for PLA2R and THSD7A in our laboratory for a 30 month period. THSD7A-positive MG cases were selected for study. Serum samples were available from 18 THSD7A positive cases at the time of biopsy and tested by IFA for the presence of THSD7A antibodies (Euroimmun).

Results: The cohort consisted of 28 patients (17 males and 11 females). The mean age was 62 years (range 17 to 91 years). Twenty five (25) patients presented with full nephrotic syndrome and 3 patients with proteinuria with a mean proteinuria of 10 grams/day (range: 1.1-15 grams/day). The mean serum creatinine was 1.3 mg/dL(range: 0.6-3.3; n=25) and mean serum albumin was 2.0 g/dL(range: 1-3.2; n=18) . On renal biopsy, all the cases had positive THSD7A staining and two cases were also positive for PLA2R. Serum samples from all 18 patients available for study at the time of biopsy were positive (titer 1:10 to 1:500) for THSD7A antibodies. Follow up data was available in 18 patients. The mean proteinuria on follow up was 7.5 grams/day (range: 0.06 – 9.9; n=13), creatinine was 1.3 mg/dL (range 0.5-3.2; n= 17) and albumin was 2.5 g/dL (range 1.2-4.1; n=14).

Conclusions: We present the largest cohort to date of THSD7A-associated MG. In our patient population, THSD7A-associated MG accounts for 2.6%of non-SLE associated MG. Biopsy staining correlates well with the presence of serum antibodies at the time of diagnosis. Ongoing studies are underway examining the prognostic significance of serum antibody level.

FR-PO651

Analysis of PLA2R Sequence Variants in Japanese Patients with Idiopathic and Secondary Membranous Nephropathy
Hajime Kaga, Hideki Wakui, Atsushi Komatsuda, Naoto Takahashi. *Hematology, Nephrology, and Rheumatology, Akita Univ Hospital, Akita City, Japan.*

Background: Phospholipase A2 receptor (PLA2R) was found to be the major target antigen of autoantibodies in idiopathic membranous nephropathy (iMN) [N Engl J Med. 361: 11-21, 2009]. The prevalence of anti- PLA2R antibodies in Japanese patients with iMN is lower than those of any other countries [Clin Exp Nephrol. 19: 653-60, 2015]. Several reports showed PLA2R sequence variants are associated with iMN. However, genetic background of PLA2R in Japan has not been studied. Also genetic backgrounds of PLA2R in secondary MN (sMN) are unclear in Japan.

Methods: A total of 50 patients with iMN, 23 patients with sMN, and 50 patients with other renal diseases as a control admitted to our hospital and affiliated hospitals between 1990 and 2013 were enrolled in this study. Since Coenen et al. reported that single nucleotide polymorphisms (SNPs) in exon 1, 2, 5, 16 and 24 of PLA2R gene are significantly associated with iMN [J Am Soc Nephrol. 24: 677-83, 2013], we selected reported six SNPs, and then sequenced directly five exons of PLA2R, using genomic DNA prepared from peripheral lymphocytes in patients with iMN, sMN, and controls. The differences in these SNPs allele frequency among three groups were analyzed by Kruskal-Wallis test or χ^2 test. We also analyzed the relationship between clinical parameters (urinary protein, serum albumin, and serum creatinine) and genotypes of PLA2R by Kruskal-Wallis test.

Results: Four of six SNPs, rs3747119, rs3749117, rs35771982, and rs2715918 were significantly associated with iMN (p=0.0366, p<0.0001, p<0.0001, and p<0.0001, respectively). Only rs35771982 was significantly but weakly associated with sMN (p=0.0405). Between iMN and sMN, there were significant differences in allele frequency in rs3749117 and rs2715918 (p=0.0439 and p<0.0291, respectively). There were no correlations between PLA2R genotypes and clinical parameters.

Conclusions: This study showed for the first time the genetic background of PLA2R in Japanese iMN patients. The difference in these SNPs allele frequency may influence the lower prevalence of anti-PLA2R antibodies in Japan. We also showed that PLA2R sequence variants were not closely related with sMN.

FR-PO652

Changes of Lymphocytes Profile in Patients with Severe Systemic Lupus Erythematosus Treated with an Intensified B-Cell Depletion Therapy with Rituximab Dario Roccatello, Savino Sciascia. *Nephrology Dept, San Giovanni Bosco Hospital.*

Background: In this study we aim to prospectively investigate the differentiation and phenotypic changes of peripheral B cells and T regulatory lymphocytes (Treg) in patients with systemic lupus erythematosus (SLE) after an intensified B-Cell depletion therapy with Titiximab (RTX).

Methods: Ten patients with sever SLE [2males, mean age 41.6 yrs (25–57)] with severe multiorgan involvement have been prospectively treated with IBCDT protocol due to their resistance or intolerance to previous therapy. Protocol:RTX 375 mg/sm on days 1,8,15,22, and 2 more doses after 1 and 2 months, associated with 2 IV administrations of 10 mg/kg of cyclophosphamide and 3 methylprednisolone pulses (15mg/kg) followed by oral prednisone (0.8 mg/kg/day, rapidly tapered to 5mg/day by the end of the 3rd month after RTX). No further immunosuppressive maintenance therapy has been given. Circulating B cells and Treg in the peripheral blood were investigated by flow-cytometry (with monoclonal antibodies against CD45,CD3,CD4,CD19,CD20,CD25,FOXP3) at baseline, month 1, month 2, and every other month thereafter up to 1 year. Response was evaluated by assessing the changes in clinical/laboratory parameters and SLEDAI score.

Results: All patients had complete peripheral blood-B cell depletion after IBCDT and the CD20+B cells were not detectable in the circulation by the 12th month (detection limit of 0.005x109 /l). Upon detection of B cell depletion, we observed in 12 months a 4-fold increase in the circulating Treg (CD4+CD25+FOXP3+) (2% at baseline, 3% after 1 month, 4,5% at 6 month, 8% at 12 months). All patients achieved clinical remission after IBCTD and no flare were observed during the one-year follow-up. IBCDT resulted in a decrease of median global SLEDAI from 14.6 [11–23] to 4 [1–5] at 12 months ($p<0.01$).

Conclusions: Our results suggest a phenotypic change of peripheral T lymphocytes as a result of B cells depletion obtained with IBCTD. Treg considered being essential in the maintenance of peripheral self-tolerance, progressively increased after B cell depletion. Such immunological re-assessment was observed in association with clinical remission in the absence of further disease flare.

FR-PO653

Monocyte Chemotactic Protein-1, Fractalkine, and Receptor for Advanced Glycation End Products in Different Pathological Types of Lupus Nephritis and Their Value in Predicting the Treatment Prognosis Lan Lan, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

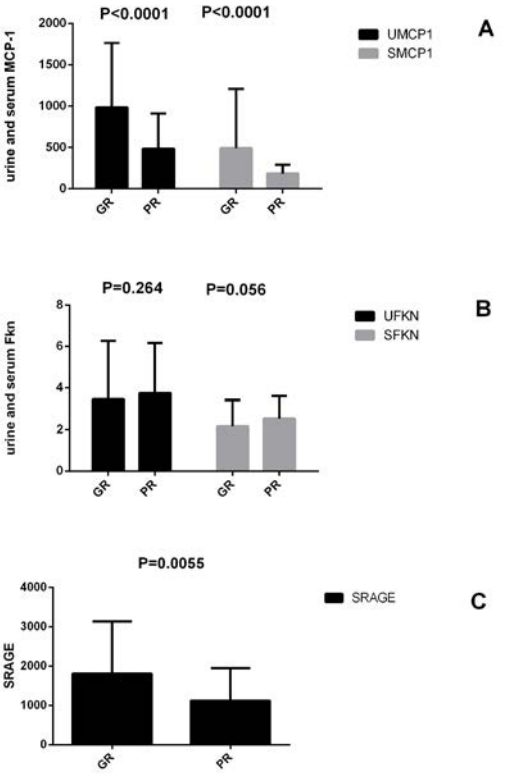
Background: Early diagnosis is important for the outcome of lupus nephritis (LN), and the pathological type of LN is closely related to the clinical manifestations and treatment prognosis.

Methods: In the patients included in this study, through renal biopsy, class III and class IV were defined as proliferative group, class V as nonproliferative group, class V+III and class V+IV as mixed group. During the follow-up, 40 of the 178 enrolled patients were found to have poor response to standard immunosuppressant therapy. The level of urine and serum MCP-1,Fractalkine, RAGE in the different groups was tested.

Results: The levels of urine and serum MCP-1, urine and serum Fkn, and serum RAGE were higher in the proliferative group, and lower in the nonproliferative group, and the difference was significant.

	Urine MCP-1 (pg/ml creatinine)	Serum MCP-1 (pg/ml creatinine)	Urine Fkn (ng/mmol creatinine)	Serum Fkn (ng/mmol creatinine)	Serum RAGE (pg/mL.)
proliferative group	1240.65 ±876.38	354.49 ±598.60	4.44 ±3.05	2.53 ±1.24	2020.74 ±1421.27
nonproliferative group	544.47 ±430.63	200.40 ±171.83	2.37 ±1.88	2.07 ±1.19	1257.94 ±862.83
mixed group	595.20 ±603.42	273.31 ±429.31	3.42 ±2.45	2.28 ±1.05	1707.85 ±1383.43

The levels of urine and serum MCP-1 and serum RAGE were lower in the poor response group; the difference was significant.



The relationship between urine MCP-1, urine and serum Fkn with the Systemic Lupus Erythematosus Disease Activity Index was proved.

Conclusions: The concentration of cytokines MCP-1, Fkn, and RAGE may be correlated with the nuclear factor-kappaB pathway. The cytokines may help in predicting the prognosis before standard immunosuppressant therapy.

FR-PO654

Zonal Cortical Scarring and Tubular Thyroidization in Biopsies of Patients with SLE - Indicator for Anti-Phospholipid Antibodies? Anjali A. Satoskar,[1] Robin Shah,[2] Sergey V. Brodsky,[1] Lee A. Hebert,[2] Brad H. Rovin,[2] Tibor Nadasdy.[1] *[1]Pathology, Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Internal Medicine Nephrology Div, Ohio State Univ Wexner Medical Center, Columbus, OH, United Kingdom.*

Background: Anti-phospholipid antibody syndrome (APS) can be primary or secondary to other autoimmune diseases, most commonly systemic lupus erythematosus (SLE). Among SLE patients, prevalence of anti-phospholipid antibodies (aPL) ranges from 30 to 40% and approximately 50% of these develop APS sometime during their disease course. Thrombotic microangiopathy (TMA) is a well-known complication of APS. We have encountered many kidney biopsies in SLE patients with zonal scarring and tubular thyroidization and positive aPL without evidence of ongoing TMA. Therefore we systematically studied the relevance of this association.

Methods: We searched our Pathology database for kidney biopsies from patients with SLE. Laboratory testing results for aPL were assessed based on a combination of tests (Staclot, dilute Russel viper venom test [DRVVT], and anti-cardiolipin antibodies). Biopsies were screened for presence/absence of zonal cortical scarring with tubular thyroidization.

Results: We identified 114 patients with SLE and kidney biopsy over a period of 9 years and 46 (40%) had at least one laboratory test indicating presence of aPL. Of the 46 patients with aPL, 15 (33%) had zonal scarring, 31(67%) did not. Of the 68 patients without aPL,only 5 (7.3%) had zonal scarring and 63 (92%) did not. Therefore, sensitivity was calculated to be 33%, specificity 92%, positive predictive value 75% and negative predictive value 67%. TMA-like changes were seen only in 7/15 biopsies with zonal cortical scarring and aPL.

Conclusions: Presence of zonal scarring and tubular thyroidization in kidney biopsies from patients with SLE, is a specific indicator for presence of aPL. Sensitivity of this feature is expectedly low because of its zonal nature and biopsy sampling issue. It may be the only morphologic indicator for the presence of aPL because TMA changes are frequently absent. The association of zonal renal cortical scarring with aPL isimportant to recognize because anti-coagulation therapy may be warranted.

FR-PO655

Proteome Analysis for Identification of Biomarkers for Accurate Diagnosis and Classification of Lupus Nephritis Patients in Saudi Arabia
Khaldoun Al-Romaih,[1] Zakia M.Anwar Shinwari,[1] Maram Alwahebi,[1] Basma Mohammed Alahideb,[1] Menah Allah Ahmed Sahraf,[2] Turki Al-Hussain,[3] Maged H. Hussein,[2] Ayodele Alaiya.[1] *[1]Stem Cell and Tissue Re-Generation Program; [2]Nephrology, Dept of Medicine; [3]Dept of Laboratory Medicine and Pathology, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia.*

Background: Lupus Nephritis (LN) is one of the most common causes of renal failure in Saudi Arabia. Treatment and prognosis in lupus nephritis are based mainly on the findings in renal histopathology obtained by renal biopsy, which is non-specific, invasive and does not account for disease mechanism. Most proteomic studies to date used either serum or urine samples in studying potential biomarker, making identifying potential biomarkers cumbersome and difficult to trace back to its site of origin.

Methods: Kidney tissue biopsy, urine and Peripheral Blood Plasma (PBP) samples from biopsy proven lupus nephritis patients were subjected to expression-proteomics using quantitative label-free liquid chromatography tandem mass-spectrometry (LC-MS/MS).

Results: Approximately 785 & 225 differentially expressed proteins were identified from kidney tissues & peripheral blood samples respectively. About 5% of the identified proteins from the plasma samples were also among the identified proteins from the tissue samples. Some of the differentially expressed proteins in kidney as well as peripheral blood are LGALS3BP, IGKC, FN1, IGHM, GHG1, and HBB". This indicates the likelihood to identify disease-associated biomarkers seen in kidney tissue as well as in plasma. This would subsequently allow monitoring of such biomarker proteins in peripheral blood, demanding less invasive procedures against kidney biopsy for objective classification and prognostic monitoring of LN patients.

Conclusions: The result demonstrates the potential of proteomics as a powerful tool for discovery of reliable diagnostic markers for lupus nephritis and other kidney diseases. The proteins with differential expression in both kidney tissues and corresponding plasma are potential targets for biomarker discovery in larger sample cohorts.

Clinical and Histopathologic Determinants of Renal Outcome in Lupus Nephritis - Starting from Scratch
Emilie Rijnink,[1] Yoe Kie Onno Teng,[1] Suzanne Wilhelmus,[1] Ron Wolterbeek,[1] Karlien Cransberg,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leiden Univ Medical Center; [2]Erasmus Univ Medical Center.*

Background: Controversy surrounds the prognostic significance of various lesions forming the basis of the ISN/RPS 2003 classification of lupus nephritis (LN). To improve evidence-based patient prognostication, we analyzed individual clinical and histopathologic parameters for their potential to predict renal outcome in LN outside the framework of the classification.

Methods: We included 105 patients with LN biopsied between 1987-2011. Fifty histopathologic and 10 clinical variables were determined as candidate predictors of outcome. We tested these baseline variables for their potential to predict eGFR trajectories during follow-up (registrations at 1, 5, and 10 years) in mixed and linear regression models, and progression to renal flare and end-stage renal disease (ESRD) in Cox regression models.

Results: The mean adjusted decline in eGFR was -0.75 (95% CI -1.46, -0.04) mL/min per year. A change in the level of eGFR decline was best predicted by %normal glomeruli (+2.67 mL/min/10%; 95% CI 0.52, 4.81), %cellular/fibrocellular crescents (-3.76 mL/min/10%; 95% CI -6.26, -1.25), %fibrous crescents (-13.47 mL/min/10%; 95% CI -24.20, -2.75), interstitial fibrosis/tubular atrophy (IF/TA) >25% (-39.26 mL/min; 95% CI -21.70, -56.82), age (-0.67 mL/min/y; 95% CI -0.26, -1.09) and non-Caucasian ethnicity (-13.85 mL/min; 95% CI -2.06, -25.63). Renal flare was best predicted by %fibrinoid necrosis (HR 1.48 per 10%; 95% CI 1.00, 2.16) and non-Caucasian ethnicity (HR 2.26; 95% CI 1.25-4.10). The end-point ESRD was predicted by %fibrinoid necrosis (HR 2.16 per 10%; 95% CI 1.34, 3.71) %fibrous crescents (HR 2.50 per 10%; 95% CI 1.20, 5.19), IF/TA >25% (HR 3.64; 95% CI 1.18, 11.25), eGFR at baseline (HR 0.98 per mL/min; 95% CI 0.96, 1.00); and non-Caucasian ethnicity (HR 7.21; 95% CI 2.33, 22.27).

Conclusions: Prognostication in LN may benefit from the assessment of specific lesions currently obscured in the classification. These prognosticators necessitate validation in future studies.

FR-PO657

Idiopathic Non-Lupus Full House Nephropathy Is Associated with Poor Renal Outcome
Emilie Rijnink,[1] Yoe Kie Onno Teng,[2] Tineke Kraaij,[2] Ron Wolterbeek,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center; [2]Nephrology, Leiden Univ Medical Center; [3]Statistics, Leiden Univ Medical Center.*

Background: Full house immunofluorescence in combination with various histopathologic lesions in the renal biopsies of patients without overt systemic lupus erythematosus (SLE) poses a diagnostic challenge. In this setting, the biopsy findings are sometimes termed non-lupus "full house nephropathy" (FHN). It is presently unknown whether non-lupus FHN is distinct from lupus FHN.

Methods: We included non-lupus FHN patients and controls with lupus FHN according to ≥4 ACR or SLICC criteria that were biopsied between 1968–2014 at the Leiden University Medical Center. The clinicopathologic characteristics and renal outcome of non-lupus FHN patients were compared to lupus FHN.

Results: Of 149 included patients, 32 had non-lupus FHN. Twenty of the non-lupus FHN patients had idiopathic non-lupus FHN, and the remainder had membranous nephropathy (anti-PLA2R-positive, n=1; paraneoplastic, n=3), IgA nephropathy (n=4), infection-related glomerulonephritis (n=2), and ANCA-associated vasculitis (n=2) with FHN. Idiopathic non-lupus FHN patients were more often male (P<0.001) than lupus FHN, and their renal biopsies more often showed a mesangial (P=0.04) or membranous pattern of injury (P=0.02), and less intense C1q staining (P=0.002). Clinically, they presented with significantly lower-range erythrocyturia (P=0.04), more proteinuria (P<0.01), and less complement consumption in the classical pathway (P<0.001) than lupus FHN patients. During the median follow-up of 20 years, no non-lupus FHN patients developed SLE. By multivariable Cox regression analysis of patients with a lupus nephritis class III/IV (±V) pattern of injury, idiopathic non-lupus FHN compared to lupus FHN was an independent risk factor for end-stage renal disease (hazard ratio 5.31, P=0.01).

Conclusions: Our results show that idiopathic non-lupus FHN is clinically and histopathologically distinct from lupus FHN. Importantly, idiopathic non-lupus FHN is associated with a poor renal outcome, warranting (early) recognition and urging future studies to elucidate therapeutic options.

FR-PO658

Validation of Systemic Lupus International Collaborating Clinics' Classification Criteria in a Cohort of Patients with Full House Glomerular Immune Deposits
Emilie Rijnink,[1] Yoe Kie Onno Teng,[2] Tineke Kraaij,[2] Olaf Dekkers,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center; [2]Nephrology, Leiden Univ Medical Center; [3]Epidemiology, Leiden Univ Medical Center.*

Background: In 2012, the Systemic Lupus International Collaborating Clinics (SLICC) presented a new classification for systemic lupus erythematosus (SLE). In this classification, biopsy-confirmed lupus nephritis with positive antinuclear or anti-double stranded DNA antibodies became a stand-alone criterion. In light of the increased weight of renal lupus in the classification, we aimed to test the validity of the SLICC classification as compared with the American College of Rheumatology (ACR) classification in patients with a lupus nephritis(-like) renal biopsy showing full house immunofluorescence.

Methods: All patients with a full house renal biopsy between 1968-2014 and clinical follow-up in our center were included. After independent review of clinical records and re-evaluation of biopsy findings, clinicians and a pathologist reached a consensus on the reference-standard clinical diagnosis of SLE. Fulfilment of ACR and SLICC criteria at the time of renal biopsy, diagnostic performance, and net reclassification improvement (NRI) were assessed.

Results: We included 149 patients with a renal biopsy showing full house immunofluorescence, 117 of whom had clinical SLE. Compared with the ACR classification, the SLICC classification had better sensitivity (100 vs. 94%); although, this was at the expense of specificity (91 vs. 100%; NRI= -0.034, P=0.563). Excluding the stand-alone renal criterion, the specificity of the SLICC classification reached 100%, with an NRI of 0.06 (P=0.008) compared with the ACR classification.

Conclusions: The SLICC classification proved to be useful with regard to diagnostic sensitivity among patients with a full house renal biopsy, whereas the stand-alone renal criterion had no additional value and compromised the specificity.

FR-PO659

PEARL: Pathway Exploration and Analysis in RenaL Disease in the Accelerating Medicine Partnership (AMP) Lupus Network
Celine C. Berthier,[1] Deepak Rao,[2] Arnon Arazi,[3] Edward P. Browne,[3] Thomas Eisenhaure,[3] Nir Hacohen,[3] David J. Lieb,[3] Betty Diamond,[4] Matthias Kretzler.[1] *[1]Univ of Michigan; [2]Brigham and Women's Hospital; [3]Broad Inst; [4]Feinstein Inst for Medical Research.*

Background: Despite treatments, a substantial proportion of lupus nephritis (LN) patients progress to end stage renal disease and death. Detailed transcriptomic analyses of LN kidneys may identify new therapeutic targets. Our goal is to demonstrate the feasibility of single cell and low-input transcriptomic analyses of LN kidney and urine cells.

Methods: Cells from urine and renal biopsies performed for clinical diagnosis from inform-consented patients (1 class III, 3 class IV+V, 1 class V) and 1 control (healthy part of tumor nephrectomy) were isolated, frozen into Cryostor solution, sorted and analyzed by RNAseq.

Results: Bulk flow sorted cell populations (CD45, epithelial) from kidney samples can separate LN from controls based on gene expression. Differential expression of IFN stimulated genes was detected in renal CD45 LN cells. Analysis of single cells sorted from 4 LN kidney biopsies revealed major differences in infiltrates composition, with 2 samples demonstrating a high percentage of B cells (average of 18% compared to no B cells in the other 2 samples) and CD4 T cells (18% vs 8%), and low percentage of CD8 T cells (9% vs 23%). A high transcriptomic lupus interferon signature was detected in urine CD45 cells. Distinct infiltrates and distinct expression profiles were detected across patients.

Conclusions: The PEARL-Phase 0 project shows the feasibility of single cell isolation and transcriptomic analysis from LN kidney and urine. Analyses at a bigger scale in the two next phases of the project will accelerate discovery of new therapeutic targets and identification of biomarkers to guide therapeutic decisions in lupus nephritis and integrate the treatment effect.

FR-PO660

Comprehensive Aptamer-Based Screening of 1,129 Proteins Reveals Novel Urinary Biomarkers of Lupus Nephritis Samantha Stanley,[1] Huihua Ding,[1] Claudia Pedroza,[2] Ramesh Saxena,[4] Michelle Petri,[3] Chandra Mohan.[1] *[1]Biomedical Engineering, Univ of Houston, Houston, TX; [2]Center for Clinical Research, UT Health Science Center, Houston, TX; [3]Rheumatology, John Hopkins Univ Medical School, Baltimore, MD; [4]Clinical Research and Evidence-Based Medicine, Univ of Texas Health Science Center, Houston, TX.*

Methods: An aptamer-based screen of 1129 proteins in 24 human urine samples (8 active lupus nephritis (LN), 8 inactive LN, 8 healthy controls (HC)) revealed 281 proteins were significantly elevated in both SLE patients relative to healthy controls and in active LN relative to inactive LN.

Results: Ingenuity Pathway Analysis revealed the upregulated proteins belong to known inflammatory, fibrosis and chemokine/cytokine networks. In an independent cohort of 93 subjects (16 active LN, 52 inactive LN, 25 HC), urine ALCAM, BFL1, calpastatin, hemopexin, PRX6, PF4, properdin, sE-selectin, TFPI and VCAM1 were ELISA-validated and shown to be once again significantly elevated in active LN compared to disease/HC (Fig 1); they also correlated strongly with many clinical/laboratory parameters, including renal-SLEDAI, PGA, eGFR, ESR and C3/C4. In ROC curve analysis, several proteins exhibited significant AUC in distinguishing active LN: ALCAM [0.89], calpastatin [0.82], FcgRIIBC [0.70], hemopexin [0.76], PRX6 [0.67], PF4 [0.77], properdin [0.71], TFPI [0.77], and VCAM1 [0.81]. Lasso logistic regression analysis identified a 4-marker-panel (PF4, TFPI, PRX6, VCAM1) as the best discriminator of active LN, with an AUC value of 0.93. A longitudinal cohort study of 18 LN patients with an average of 3 visits per patient showed these markers to vary substantially in their ability to track conventional disease indices.

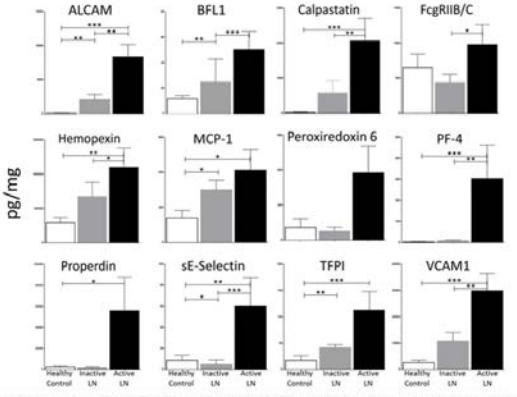

Fig 1: Creatinine-normalized ELISA units of 12 urine proteins in 93 subjects (16 active LN, 52 inactive LN, 25 healthy controls)

Conclusions: Urine ALCAM, BFL1, calpastatin, FcgRIIBC, hemopexin, MCP1, PRX6, PF4, properdin, sE-selectin, TFPI and VCAM1 arise as potential urinary biomarkers of LN; further studies are needed to establish their biomarker potential and pathogenic role.

FR-PO661

Cryofibrinogen Associated Glomerulonephritis Mariam P. Alexander,[1] Ralph Yachoui,[2] David L. Murray,[1] Jai Radhakrishnan,[3] Sanjeev Sethi.[1] *[1]Mayo Clinic, Rochester, MN; [2]Marshfield Clinic, Marshfield, WI; [3]Columbia Univ Medical Center, New York, NY.*

Background: Cryofibrinogen is a cryoprotein that precipitates after refrigeration of plasma, but not serum. While cryofibrinogenemia (CF) maybe asymptomatic it can manifest with thrombi, often involving skin. Renal involvement by CF is rarely reported. We present 2 cases of CF related membranoproliferative glomerulonephritis (CFGN)that were initially misdiagnosed as immunotactoid glomerulopathy (IG) and cryoglobulinemic GN (CGN).

Methods: The clinical presentation, lab results, renal biopsy (BX) morphology as assessed by light (LM), immunofluorescence (IF) and electron microscopy (EM) of 2 patients (pt) is presented. The cryoprecipitate (CRP) was isolated and studied ultrastructurally. The proteomic profile of the CRP was determined by mass spectrometry.

Results: Pt 1 was a 66yr old man who had cold induced skin eruptions. An initial BX due to hematuria & proteinuria was diagnosed as CGN. He was rxed with cyclophosphamide & high-dose steroids. A second BX a few yrs later for declining renal function was also diagnosed as CGN. Lab investigations: CF, present; CG, negative; normal complements, negative viral and autoimmune serology. Pt 2 was a 70yr old man with hematuria & proteinuria. He was a Hepatitis B carrier. He had no cutaneous eruptions. A BX was diagnosed as immunotactoid GN. Lab investigations: creatinine, 2.2mg/dL;24 hr urine protein, 8 g; SPEP, negative; CG, negative; CF, positive. Both biopsies showed a membranoproliferative GN (MPGN) with rare subendothelial & intraluminal deposits. IF showed no immunoglobulin deposition. EM showed intraluminal, subendothelial and rare subepithelial deposits which had a multilayered tubular structure. The mean luminal diameter was 158 nm. CRP isolated from the plasma showed identical ultrastructure. Mass spectrometry confirmed the peptide profile of the CRP was fibrinogen. Both BX diagnoses were revised as CFGN. Appropriate therapy was initiated.

Conclusions: Familiarity with the unique ultrastructural appearance of CFGN averts erroneous diagnosis, prompts appropriate evaluation for CF & permits accurate & timely initiation of therapy.

FR-PO662

Renal Dysfunction and Pathology Evaluation with Contrast-Enhanced Ultrasound Yao Xu,[1] Hongli Li,[2] Shan Mou.[1] *[1]Nephrology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China; [2]Ultrasound, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China.*

Background: The number of people with renal dysfunction due to CKD is increasing worldwide. The potential application of CEUS in nephrology has been proposed as a novel non-invasive imaging technique. We performed a prospective study to evaluate the predictive ability of contrast-enhanced ultrasound (CEUS) in chronic kidney disease (CKD) progression and its correlation with renal pathological changes.

Methods: CEUS was performed after an intravenous bolus injection of 1.5 ml SonoVue (BR1; Bracco Milan, Italy). Time-intensity curves (TICs) and quantitative indexes were created using QLAB quantification software. Risk factors related to kidney survival were investigated using a binary logistic regression model. All biopsies were analyzed with Masson's trichrome stain and α-SMA immunohistochemistry. Spearman correlation analysis was used to determine correlations.

Results: A total of 167 patients with CKD were enrolled in the study and followed for a mean period of 13.95 months. In total, seven (4%) patients exhibited composite kidney failure events (glomerular filtration rate (GFR) halving or end-stage renal disease (ESRD)). A significant difference in derived peak intensity (DPI) was noted among groups in different CKD stages. Multivariate logistic regression analysis revealed that the DPI was independently associated with progression of kidney disease. Patients with a DPI<9.63 db were less likely to recover from kidney disease progression. DPI levels were highly correlated with the degree of renal fibrosis. The area under the curve (AUC) for DPI and pathology combined was 0.874 (P<0.05), with a sensitivity of 75% and a specificity of 81%, which is greater than the AUC of pathology alone (0.829, P<0.05).

Conclusions: In patients with CKD, a high correlation exists between the DPI value and renal fibrosis. The DPI might be the most valuable CEUS parameter for the evaluation of renal function and fibrosis. It could be rapidly and continuously used for the diagnosis and prognosis of renal dysfunction.

Urinary miR-21 Abundance Increases with Decreasing Renal Function Markus Bitzer,[1] Klaas E.A. Max,[4] Jian Shi,[1] Iddo Z. Ben-Dov,[4] Beatrice Goilav,[3] The Neptune Consortium,[1] Thangamani Muthukumar.[2] *[1]Univ of Michigan; [2]Weill Cornell Medicine, Cornell Univ; [3]Albert Einstein College of Medicine; [4]The Rockefeller Univ.*

Background: MicroRNAs (miRs) are implicated as regulators and markers of kidney disease. We explored the role of urinary miRs as candidate markers for clinical outcomes in samples of two independent clinical studies.

Methods: Cell-free urine supernatant from 99 subjects with glomerular disease collected at time of enrollment into the Nephrotic Syndrome Study Network (NEPTUNE) was used to isolate RNA using a novel protease/nuclease-based isolation method which allows extraction of RNA tightly bound to proteins, including Argonautes. Small RNA-sequencing was performed using Illumina platform, sequence reads were mapped to the human genome and relative read-frequencies were associated with clinical, laboratory and structural parameters. 161 cell-free and equally processed urine samples of kidney transplant recipients enrolled in the Clinical trials in Organ Transplantation (CTOT) study were used for validation.

Results: Small-RNAs that were detected included microRNAs, tRNAs, ribosomal RNA, mRNA fragments and non-human RNAs. The 300 miRs with the highest mean abundance across all samples were used for further analysis. After correction for multiple testing, only miR-21 was significantly inversely associated with cross-sectional eGFR (r=-0.60; Bonferroni-adjusted p<0.01), and future development of ESRD (Bonferroni-adjusted p<0.05). Urinary miR-21 abundance was positively associated with scores for interstitial fibrosis (IF; r=-0.50; Bonferroni-adjusted p<0.01) and tubular atrophy (TA; r=-0.47; Bonferroni-adjusted p<0.01) but not with future eGFR decline in 77 samples for which these data were available. No association of urinary miR abundance with diagnosis, age, albuminuria or BMI was detected. In the independent CTOT cohort, miR-21 was also negatively correlated with cross-sectional eGFR (r=-0.42; Bonferroni-adjusted p<0.01), but not with other available parameters.

Conclusions: The association of higher urinary miR-21 abundance with increased IF/TA scores and lower renal function suggests that urinary miR-21 is a marker of renal fibrosis independent from disease category.

Negative Staining for COL4A5 Correlates with Worse Prognosis and More Severe Ultrastructural Alterations in Alport Syndrome Samar M. Said,[1] Mary E. Fidler,[1] Anthony M. Valeri,[2] Lynn D. Cornell,[1] Mariam P. Alexander,[1] Ahmed Mansour Alkhunaizi,[3] Anne S. Salyer,[4] Carl H. Cramer,[1] Marie C. Hogan,[1] Samih H. Nasr.[1] *[1]Mayo Clinic, Rochester, MN; [2]Columbia Univ, New York, NY; [3]Johns Hopkins Aramco Healthcare, Dhahran, MN, Saudi Arabia; [4]Permanente Medical Group, Oakland, CA.*

Background: Alport syndrome (AS) is a genetic disorder characterized by progressive hematuric nephropathy with or without sensorineural hearing loss and ocular lesions. Previous studies on AS included mostly children. In this renal biopsy-based study, we seek

to determine the prognostic value of loss of staining for COL4A5, its value in elucidating the mode of inheritance and its relationship with the ultrastructural glomerular basement membrane (GBM) alterations.

Methods: We performed direct immunofluorescence using a mixture of FITC-conjugated and Texas-red conjugated antibodies against COL4A5 and COL4A2, respectively, on renal biopsies of 58 patients with a pathologic diagnosis of AS (including 38 who were diagnosed in adulthood).

Results: The cohort consisted of 60% males and 40% females. All patients showed normal positive staining of GBM and tubular basement membranes for COL4A2. Of the 58 patients, 17 (29%) had loss of staining for COL4A5, with an expression pattern consistent with X-linked AS in 65% of cases and autosomal AS in 35% of cases. The remaining 41 (71%) had intact staining for COL4A5. Compared to patients with intact staining for COL4A5, those with loss of staining had more prominent ultrastructural GBM alterations, were younger at biopsy, were more likely to be males, and had a higher incidence of gross hematuria. By Kaplan-Meier survival analysis and Cox regression analysis, loss of staining for COL4A5 predicted earlier progression to overt proteinuria, CKD stage 2 or worse, and ESRD. By multivariate Cox regression analysis, loss of staining for COL4A5 and the severity of ultrastructural GBM alterations were independent predictors of the development of overt proteinuria and CKD stage 2 or worse.

Conclusions: COL4A5 expression pattern has an important prognostic value, it can unravel the mode of inheritance, and it correlates with the severity of ultrastructural GBM alterations.

FR-PO665

Podocyte Detachment Rate in Alport Syndrome Larysa T. Wickman,[1] Fangrui Ding,[2] Su Qing Wang,[1] Roger C. Wiggins,[1] Jie Ding.[2] *[1]Univ of Michigan, Ann Arbor, MI; [2]Peking Univ First Hospital, Beijing, China.*

Background: Alport Syndrome (AS) is an important cause of End Stage Kidney Disease recognized as a contributor to global disease burden. We previously reported that podocyte detachment rate measured in urine is increased and degree of podocyte depletion in renal biopsies is related to degree of proteinuria and glomerulosclerosis in AS. Podocyte detachment play a role in progressive loss of kidney function in AS. Podocyte detachment rate assay might therefore help guide treatment and assess novel therapies.

Methods: Alport Syndrome Prevention of Progression Project is an integration of a large well-characterized cohort of genetically-defined AS patients managed at Peiking University First Hospital in Beijing with novel podometric technology developed to identify and prevent progression of glomerular diseases at University of Michigan in Ann Arbor. Podocyte detachment rate was measured as the urine pellet podocin mRNA in ng/g creatinine using TaqMan assay.

Results: A total of 169 urine samples were collected for cross-sectional analysis, including from 132 AS patients with a clinical phenotype ranging from hematuria alone through hematuria with proteinuria with and without abnormal kidney function, and 37 age-matched controls. Control values from China and the US were not different. Urine samples from all AS patients contained an average 21-fold elevated amounts of podocin mRNA vs controls ($P<0.01$), comparable with 23-fold increase previously reported for AS patients in the US. AS patients with hematuria alone (without proteinuria) as a group had a 4.1-fold (range undetectable to 230-fold) increased rate of podocyte detachment vs controls ($P<0.01$), suggesting that individuals with high levels may be identifiable at an early stage as at risk for progression while those with normal levels may be identifiable as at low risk for progression.

Conclusions: Initial cross-sectional data in a large Chinese AS cohort are compatible with the concept that podocyte detachment rate measured non-invasively in urine might contribute useful information towards AS management. Further longitudinal studies are therefore warranted.

FR-PO666

Characteristics of Podocytes in the Urine in Pregnancy Using Flow Cytometry Bairbre A. McNicholas, Susan K. Anderson, Kimberly A. Muczynski. *Div of Nephrology, Univ of Washington, Seattle.*

Background: Podocyturia may be useful to predict high risk pregnancy. Detection of podocyturia is currently technically complex requiring a high level of expertise for interpretation. Flow cytometry is a sensitive technique that allows immediate study of cells shed into the urine. We describe the characteristics of podocytes detected in the urine of high-risk pregnancies using flow-cytometry and how they differ from non-pregnant individuals.

Methods: Urine cell pellets from 11 patients attending high-risk obstetric clinic and 2 healthy subjects at various stages of pregnancies was compared with 7 non-pregnant individuals (4F, 3M) using 7-color flow cytometry. Podocytes were identified as $DAPI^{-}$ $CD45^{-}$ cells positive for human Nephrin and/or podocalyxin. Appropriate isotype and fluorescence minus one was used for controls. Expression of CD80 and HLA-DR on podocytes was assessed. Immunofluorescence for nephrin and CD80 on urine cell pellets was used to confirm flow-cytometric findings.

Results: Podocytes were detected in the urine of all subjects. Podocytes per ml of urine was higher in high-risk pregnancy compared to healthy pregnancy and non-pregnant individuals (21.9±9 vs. 2.5±0.2 vs. 1.1±0.2 cell/ml urine, $p=0.05$ and $p<0.0001$ vs. high risk pregnancy). Two distinct population of podocytes were identified, $nephrin^{+}podocalyxin^{-}$ and $nephrin^{+}podocalyxin^{+}$. CD80 and HLA-DR was expressed only on $nephrin^{+}$ $podocalyxin^{-}$ cells. The proportion of $CD80^{+}nephrin^{+}podocalyxin^{-}$ cells was lower in high risk pregnancy compared to non-pregnant individuals (4.4±1.8 vs. 36.4±13 % of $nephrin^{+}podocalyxin^{-}$, $p=0.007$). The number of podocytes as a proportion of viable cells did not differ but number of viable cells was higher in high risk pregnancy compared to healthy controls (46101 vs 3745 cells/sample, $p=0.002$).

Conclusions: Podocytes can be detected in the urine using flow cytometry. Low levels of podocytes were detected in non-pregnant individuals suggesting turnover of podocytes occurs in healthy individuals. The number of $nephrin^{+}podocalyxin^{+}$ cells was higher and the proportion co-expressing CD80 was lower in high-risk pregnancy. Alteration in phenotype of detached podocytes may be a feature of high-risk pregnancies.

FR-PO667

Localization of Kidney Injury Markers TIMP-2 and IGFBP7 in Human Kidney Biopsies Martin Kimmel,[1] Moritz Schanz,[1] Mark Dominik Alscher,[1] Kerstin U. Amann,[2] Christoph Daniel.[2] *[1]Internal Medicine, Robert-Bosch Hospital, Stuttgart, Germany; [2]Nephropathology, FAU Erlangen-Nürnberg, Erlangen, Germany.*

Background: Tissue inhibitor of matrixmetalloproteases 2 (TIMP-2) and Insulin-like growth factor-binding protein 7(IGFBP7) are markers of cell cycle arrest and urinary [TIMP-2]*[IGFBP7] was recently cleared by the FDA for risk assessment of acute kidney injury. However, studies describing the localization or expression profiles of TIMP-2 and IGFBP7 in human renal tissue in patients with glomerular or tubular damage are lacking.

Methods: We analyzed n=38 kidney biopsies of patients with renal disease and n=10 control biopsies immunohistochemically. Changes in glomerular morphology were evaluated by a semi-quantitative glomerulosclerosis score (GSI) and tubular interstitial changes were graded by the tubular injury score (TSI) using PAS-stained paraffin sections and interstitial fibrosis and tubular atrophy (IF/TA) was graded according to BANFF classification. In addition, co-localization studies were performed using confocal laser scanning microscopy.

Results: In healthy control biopsies both TIMP-2 and IGFBP7 are rarely expressed within the tubular and glomerular compartment. However, compared to these controls both antigens are at least 2-fold significantly upregulated in biopsies from patients with kidney disease. TIMP2 is predominantly expressed in aquaporin 2 positive collecting ducts and to a lesser degree in the glomeruli. In contrast, IGFBP7 is expressed in both the glomerular and tubular compartment with comparable intensity. IGFBP7 expression could be detected in glomerular endothelial cells and podocytes as well as distal tubules and parts of the thick ascending limb. There were significant correlations for the tubular injury score (TSI) with tubular TIMP-2 ($r=0.403$; $p<0.005$) and IGFBP7 ($r=0.521$; $p<0.0002$). In addition, glomerular sclerosis score (GSI) correlated with glomerular TIMP-2 ($r=0.347$; $p<0.02$) and IGFBP7 ($r=0.341$; $p<0.03$).

Conclusions: The immunohistological examinations of TIMP-2 and IGFBP7 in human kidney biopsies underline the role of these markers especially in tubular damage.

FR-PO668

A New Therapeutic Strategy in IgA Nephropathy with CKD Using Methylprednisolone Pulse Therapy and Autologous Adipose Derived Stem Cells (Stromal Vscular Fraction) Byoung-Soo Cho,[1] Hyaejin Yun,[1] Sung Min Jung,[2] Kyung-Min Lee,[1] Wang Kwang Hong.[3] *[1]MIRAE ING Kidney Center, Seoul, Korea; [2]EWha Women's Medical College, Seoul, Korea; [3]ByulE Plastic Surgery, Seoul, Korea.*

Background: As yet there is no specific therapeutic means to treat IgAN especially when associated with CKD, but giving RAAS blocker etc., almost all cases of IgAN with CKD eventually progress to ESRD and need RRT.

Cell therapy is extensively evaluated as an alternative therapeutic modality for many kinds of diseases with no other options. Recently human MSCs prevent podocyte apotosis and injury and other reports have shown to reduce glomerulosclerosis and oxidative stress in animal model. We tried MP pulse therapy and autologous SVF in IgAN with CKD or with moderate degree glomerulosclerosis and followed up for 2 years.

Methods: Case 1: A 26-year-old male was diagnosed as IgAN with 24% glomerulosclerosis. Follow up renal biopsy showed markedly decreased immune deposits without lesions of glomerulosclerosis. Laboratory results showed BUN/Creatinine 6.9 mg/dl / 1.08 mg/dl, IgA 363 mg/dl, C3 159 mg/dl. urine protein/creatinine ratio 0.974, CCr 82 ml/mn. Follow up laboratory data showed BUN/creatinine 9.2 mg/dl/ 0.75 mg/dl, normal urinalysis, GFR, spot urine protein/creatinine ratio 0.090, GFR 131 ml/min. Case 2: A 44 years old female was diagnosed as IgAN stage IV(HSLee class.) with 61% glomerulosclerosis. Follow up renal biopsy showed 41% sclerosis with disappearance of IgA and C3 deposits. serum creatinine and GFR before therapy was 1.77 mg/dl and 35 ml/min, however follow up after 27 months was 0.99 mg/dl and 65 ml/min. Case 3: A 35 years old female was diagnosed as IgAN grade V with 67% glomerulosclerosis. Follow up renal biopsy showed IgAN stage IV with 33% glomerulosclerosis. Initial creatinine was 1.39 mg/dl and GFR was 43 ml/min. and follow up serum creatinine 1.21 mg/dl and GFR 53 ml/min.

Conclusions: Although further studies are needed, MP pulse therapy and autologous SVF therapy in intractable severe IgAN showed dramatic improvement not only laboratory data but also pathological findings. Therefore MP pulse therapy followed by autologous SVF therapy might be a promising new therapeutic strategy without noticeable side-effects or complications.

FR-PO669

Value of Biological Markers for Kidney Involvement and Outcome in Henoch Schonlein Purpura Nephritis: A Prospective Cohort Study
Evangeline Pillebout,[1,2] Laureline Berthelot,[1] Hamza Ayari,[2] Agnes Jamin,[1] Jonathan M. Chemouny,[1] Pierre Housset,[1] Virginia Sauvaget,[1] Denis Viglietti,[2] Margarita Hurtado-Nedelec,[1] Renato C. Monteiro.[1] *[1]INSERM1149, Paris, France; [2]Nephrology Unit, St. Louis APHP, Paris, France.*

Background: Henoch–Schönlein purpura (HSP) is a systemic vasculitis characterized by immunoglobulin A (IgA) deposits in skin, joints, kidneys and other organs. The current diagnosis and prognosis markers used in HSP assessment lack accuracy to estimate the risk of nephritis occurrence and its long-term outcome.

Methods: This French multicenter study prospectively enrolled 135 patients at the time of HSP diagnosis. All patients were evaluated for clinical and biological parameters: cytokines, immunoglobulins, Neutrophil Gelatinase Associated Lipocalin (NGAL), immune complexes and IgA glycosylation in serum and urine. They were followed 1 year for renal outcome. Poor renal outcome was defined as proteinuria/creatinine ratio >0.5g/g and/or decrease of eGFR or death.

Results: Among the 135 HSP patients, 93 had HSP-related nephritis (HSPN) and 42 did not. At the time of diagnosis, patients HSPN, compared to HSP without nephritis, exhibited higher serum levels of Galactose-deficient IgA1 and higher urinary concentrations of IgA, IgG, IgM, NGAL, IL-1β, IL-6, IL-8, IL-10, IgA-IgG and IgA-sCD89 complexes. Among those, urinary IgA had the highest AUC. After one year of follow-up, 23/93 patients showed a poor renal outcome. Clinical factors associated with poor renal outcome were age, diabetes, hypertension and eGFR decline. Among all biological parameters, determinants of poor renal outcome were urinary IgA, IgM, IgA-IgG and IgA-sCD89 complexes. They showed an accurate discrimination performance to identify patients with poor renal outcome.

Conclusions: This large prospective cohort study, with both adults and children, included at the onset of the disease, bring a better understanding of the pathophysiology of HSP. We defined new biomarkers able to segregate patients initially with or without nephritis, some of them provide an accurate discrimination of HSP-nephritis patients with poor 1-year renal outcome. This allowed us to define promising tools for clinicians that could be helpful in the diagnostic and follow-up of HSPN.

Antibody-Mediated Depletion of Galactose-Deficient IgA1 Secreted by Specific Subset of Tonsillar B Cells: A Novel Potential Pharmaceutical Concept for IgA Nephropathy
Junichi Yasutake,[1,2] Hitoshi Suzuki,[1] Naoko Hiura,[1,2] Kohei Yamasaki,[1,2] Yusuke Suzuki.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Nephrology Research Labs, Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) has been proposed as one of the important effector molecules in IgA nephropathy (IgAN). In IgAN multi-hit hypothesis, Gd-IgA1 secretion from tonsillar B cells is the primary step for pathogenesis of the disease. Serum Gd-IgA1 level is significantly high in patients with IgAN, approved by Gd-IgA1 ELISA. It might be possible that specific depletion of Gd-IgA1-producing tonsillar B cells enables descending serum Gd-IgA1 level and consequent IgAN treatment. Several reports have suggested the involvement of glycosylation enzymes such as galactosyltransferase and sialyltransferase in Gd-IgA1 secretion from mucosal B cells; we hypothesized that *O*-link glycans were broadly aberrant in various proteins expressed in tonsillar B cells of patients with IgAN due to dysfunction of those enzymes under pathophysiological condition.

Methods: CD27, which has *O*-link glycan sites, was chosen as a target membranous molecule in B cells. Anti galactose-deficient CD27 (Gd-CD27) monoclonal antibody (mAb) was established. Target cells of anti Gd-CD27 mAb were examined by flow cytometry using tonsillar cells and peripheral blood mononuclear cells (PBMCs) derived from patients with IgAN. Anti Gd-CD27 mAb was subjected to antibody dependent cytotoxicity (ADCC) assay against tonsillar Gd-CD27-positive cells under NK cells to evaluate their viability by flow cytometry and supernatant Gd-IgA1 level by enzyme-linked immunosorbent assay (Gd-IgA1 ELISA).

Results: Gd-CD27-positive cells were predominantly observed in tonsil derived from patients with IgAN. ADCC assay with NK cells revealed dose-dependent depletion of Gd-CD27-positive cells and consequent decrease of supernatant Gd-IgA1 level.

Conclusions: This study suggested the possibility to remedy IgAN by targeting tonsillar B cells that produce Gd-IgA1, based on the multi-hit hypothesis. Anti Gd-CD27 mAb may be one of the candidate therapeutic agents for IgAN.

Galactose-Deficient IgA1 Monoclonal Antibody Specifically Discriminate IgA Nephropathy and Henoch-Schönlein Purpura Nephritis
Hitoshi Suzuki,[1] Junichi Yasutake,[1,2] Yuko Makita,[1] Toshiki Kano,[1] Yusuke Suzuki.[1] *[1]Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Nephrology Research Labs, Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) has been proposed as an important effecter molecule in patients with IgA nephropathy (IgAN) and Henoch-Schönlein purpura nephritis (HSPN). Our previous study revealed that Gd-IgA1-specific monoclonal antibody KM55 (KM55 mAb) could be a new tool for detecting circulatory Gd-IgA1 in patients with IgAN, which enabled us to study molecular roles of Gd-IgA1. In this study, we further examined pathophysiological significance of Gd-IgA1 in glomerular deposits of patients with IgAN and HSPN by immunohistochemical analysis with KM55 mAb.

Methods: Renal biopsy specimens were obtained from 2013 to 2015 at Juntendo University Hospital with the informed consent from patients. Double Immunofluorescentstaining of Gd-IgA1 with KM55 mAb and anti-human IgA antibody was performed in paraffin embedded sections of renal biopsy specimens from patients with IgAN (n=45), and other renal diseases (n=30); such as lupus nephritis, HCV-related nephropathy and Henoch-Schönlein purpura nephritis (HSPN).

Results: Glomerular Gd-IgA1 was specifically detected in all patients with IgAN, but not in those with other renal diseases. Gd-IgA1 could not be detected even in patients with lupus nephritis accompanied by glomerular IgA deposition. In patients with IgAN, Gd-IgA1 was localized predominantly in the mesangial region as IgA deposition. Importantly, KM55 mAb was also positive in patient with HSPN as similar to those in IgAN.

Conclusions: This is the first observation to clearly indicate that Gd-IgA1 could be specifically deposited in glomeruli of IgAN and HSPN, strongly suggesting the pathophysiological function of Gd-IgA1 in those diseases. Further studies are necessary to clarify the underlying mechanisms of Gd-IgA1 deposition and induction of renal injuries in IgAN and HSPN. Novel monoclonal antibody KM55 mAb against Gd-IgA1 could be a powerful tool to detect nephritogenic IgA in patients with IgAN and HSPN.

FR-PO672

Production of Aberrantly-Glycosylated IgA1 and the Corresponding Autoantibodies Is Elevated in Patients with Henoch- Schönlein Purpura Nephritis
Hitoshi Suzuki,[1] Zina Moldoveanu,[2] Bruce A. Julian,[2] Robert J. Wyatt,[3] Jan Novak.[2] *[1]Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Univ of Alabama at Birmingham, Birmingham, AL; [3]Univ of Tennessee Health Sciences Center, Memphis, TN.*

Background: Patients with Henoch-Schöenlein purpura with nephritis (HSPN) and IgA nephropathy (IgAN), but not with Henoch-Schoenlein purpura without nephritis (HSP) have elevated serum levels of galactose-deficient IgA1 (Gd-IgA1). Gd-IgA1 is recognized by Gd-IgA1-specific IgG autoantibodies and, thus, forms immune complexes that are pathogenic, as they activate mesangial cells to proliferate of overproduce components of mesangial matrix. Mucosal infections are often associated with clinical presentation and exacerbation of HSPN and IgAN. In IgAN, some Gd-IgA1 and autoantibodies originate from tonsillar immunoglobulin-secreting cells; IL-6 may enhanceproduction of Gd-IgA1. Here, we assessed whether the common pathogenic features of IgAN are found also in patients with HSPN.

Methods: Serum and immunoglobulin-secreting cells from patients with HSPN and HSP and healthy controls were used for analysis of IgA1 glycosylation and Gd-IgA1-specific IgG. Serum Gd-IgA1 and Gd-IgA1-specific IgG were measured before and after tonsillectomy in adult HSPN patients.

Results: IgA1 secreted by cells from HSPN patients had Gal-deficient *O*-glycans, whereas IgA1 from HSP patients and healthy controls was normally galactosylated. This finding was consistent with lower expression of ß1,3-galactosyltransferase observed in cells from HSPN patients compared to cells from HSP patients. Levels of Gd-IgA1-specific IgG in sera and cell-culture supernatants of IgG-secreting cells were higher in HSPN than in HSP patients or healthy controls ($P<0.01$). Serum levels of Gd-IgA1 and Gd-IgA1-specific IgG were elevated in HSPN patients with active disease, manifested by hematuria/proteinuria ($P<0.01$). Tonsillectomy in HSPN patients reduced proteinuria and hematuria was accompanied by reduction of serum levels of Gd-IgA1 and Gd-IgA1-specific IgG ($P<0.001$).

Conclusions: Gd-IgA1 and Gd-IgA1-specific autoantibodies are elevated in patients with HSPN, supporting the hypothesis that HSPN and IgAN have common pathogenetic components.

FR-PO673

Regional Variations in the Clinical Characteristics at Diagnosis in Japanese Patients with IgA Nephropathy: An Analysis of the Japan Renal Biopsy Registry (J-RBR)
Yusuke Okabayashi,[1] Nobuo Tsuboi,[1] Yoichi Miyazaki,[1] Tetsuya Kawamura,[1] Makoto Ogura,[1] Ichiei Narita,[2] Toshiharu Ninomiya,[3] Hitoshi Yokoyama,[4] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences; [3]Center for Cohort Studies, Kyushu Univ; [4]Dept of Nephrology, Kanazawa Medical Univ School of Medicine.*

Background: Older age, hypertension, renal impairment, and heavy proteinuria at diagnosis are known to be poor prognostic indicators of immunoglobulin A nephropathy (IgAN). Previous studies have shown the remarkable regional differences in the incidence of ESRD within Japan, which has an ethnically homogeneous population (JAMA, 2000). This study examined the regional differences in these clinical features at biopsy and the relevant factors associated with such differences among Japanese IgAN patients.

Methods: The Japan Renal Biopsy Registry registration facilities were divided into 10 regions. The clinical features at biopsy were compared among the groups, which was divided based on the factors that may be associated with regional differences.

Results: A total 7177 patients were analyzed. In each region, the sex ratio was almost the same, but there were significant regional variations in age, eGFR, and urinary protein excretion. Distributions of clinical features were closely associated with the number of the Japanese Society of Nephrology (JSN) members per population, while, the regional variations in the clinical features did not correlate with the distributions of the elderly populations.

Variables	Category of JSN members ratio			P-value *
	Highest 3 areas (n=2458)	Intermediate 4 areas (n=1977)	Lowest 3 areas (n=2742)	
JSN members /10,000 populations	0.89	0.76	0.58	<0.001
Elderly IgAN patients (%)	9.4	8.7	10.4	0.127
Hypertension (%)	38.6	41.7	46.9	<0.001
eGFR (ml/min/1.73 m^2)	76.7±30.1	76.3±30.8	70.7±28.6	<0.001
UPE (g/day)	0.86±1.52	1.00±1.41	1.54±1.79	<0.001
Urinary RBC (%Grade3-4)	65.3	66.8	68.0	0.123
C-grade Ⅲ (%)	18.7	24.7	32.0	<0.001

UPE: urinary protein excretion, RBC: red blood cell,
Urinary RBC: Grade 1: 0-4/HPF, Grade 2: 5-10/HPF, Grade 3: 10-30/HPF, Grade 4: >30/HPF,
Continuous variables were expressed as mean±S.D. * : Kruskal-Wallis test

Conclusions: There are significant regional differences in the clinical features at diagnosis among Japanese IgAN patients. Social factors, such as an uneven distribution of nephrologists, may influence the timing of diagnosis and contribute to such differences.

FR-PO674

Prognostic Impact of Deleted Variants in Complement Factor H-Related Protein Genes, CFHR3 and CFHR1, in IgA Nephropathy on a Caucasian Population Perrine Jullien, Blandine Laurent, Christopher R. Mariat, Eric Alamartine, Nicolas Maillard. *Nephrology, Dialysis, Transplantation, CHU de Saint Etienne, Saint-Etienne, France.*

Background: Activation of complement through the alternative pathway plays a key role in the pathogenesis of IgA nephropathy. Large international genome–wide association studies have identified a deletion of complement factor H–related genes 1 and 3 (ΔCFHR1/3) associated with a lower risk of IgA nephropathy, but the prognosis value of these deletions in IgA nephropathy in Caucasian remains unknown. This study aims to compare the renal outcomes according to the ΔCFHR1/3 genotype.

Methods: This study was retrospective monocentric including only caucasian patients with biopsy proven primary IgA nephropathy since 1979, with available DNA samples and informed consent. Quantitative PCR was used to determine the presence of deletions of the genes CFHR1/3 (CFHR3-1Δ), standardized on the RNAse P gene. Clinical and biological data were collected by reviewing subject's medical records.

Results: A total of 727 patients were included, with an age of (median [IQR]) 38 [28-51] years at diagnosis and a follow up of 11,4 [5-18,1] years. So far, copy number analysis has been performed for 425 patients for CFHR1 gene only. Thirty-four percents of patients were heterozygous and 2% were homozygous for CFHR1Δ. Association between CFHR1Δ and age, eGFR, urinary protein excretion or pathologic measures at diagnosis was not significant (Welch t-test, p=0.99, p=0.1, p=0.35 and p=0.72 respectively). No significant association was found between CFHR1Δ and evolution toward stage III (167/425 patients) and stage V chronic kidney disease (CKD) (89/425 patients) (log rank test, p=0.62 and p=0.37 respectively).

Conclusions: There is no trend of association between CFHR1 gene deletion and renal outcomes in this intermediate analysis. Complete results concerning CFHR1/3 genotype of the whole cohort and evolution of renal function will be available for the ASN meeting.

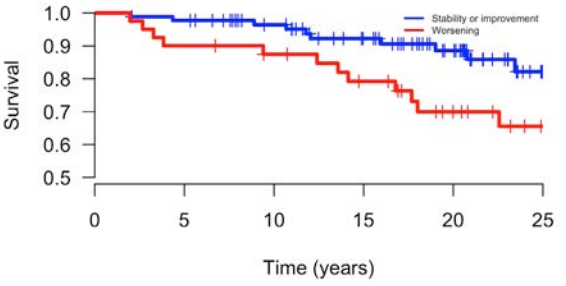
FR-PO675

Repeat Renal Biopsy Improves Oxford Classification-Based Prediction of IgA Nephropathy Outcomes Perrine Jullien, Blandine Laurent, Christopher R. Mariat, Eric Alamartine, Nicolas Maillard. *Dept of Nephrology, Dialysis, Transplantation, CHU Saint Etienne, Saint Etienne, France.*

Background: The prognosis of IgA nephropathy is heterogeneous, and its prediction is crucial to refine patient's treatment. It remains unknown whether a repeat pathological evaluation can be useful to refine renal death prediction. The aim of this study was to evaluate the prognostic impact of an Oxford classification-based repeat kidney tissue evaluation to predict end stage renal disease (ESRD).

Methods: Patients with biopsy-proven primary IgAN who underwent 2 renal biopsies in our center were analyzed retrospectively. Renal biopsies were scored blinded to the clinical data and according to the Oxford classification. Multivariable cox models were generated to evaluate the prognosis impact of the Oxford classification score progression on ESRD. This histological progression was defined as the difference in the sum of M,E,S,T variables between two biopsies (ΔMEST).

Results: A total of 131 patients were included, with an age of (median, [IQR]) 33 [23-45] years at diagnosis and a follow up of 19 [11-25] years. The second biopsy was performed after a time of 64 [59-78] months. ΔMEST was predictive of ESRD univariately (Cox, Hazard Ratio[IC95%] 1.38[1.06;1.81]).



This predictive capability remained significant after adjustment on clinical data at diagnosis and on initial Oxford classification score (M,E,S,T separately) (HR 2.37[1.55;3.62]). ΔMEST was still predictive of renal death after adjustment on previous variables and on evolution of proteinuria, evolution of hypertension and GFR slope between biopsies (HR 1.91[1.16 ;3.14]).

Conclusions: The evolution of Oxford classification, assessed by a second biopsy, is an efficient tool to predict ESRD in IgA Nephropathy. This prediction is independent from the histo-clinical evaluation at baseline and even from the clinical evolution between two biopsies.

FR-PO676

Comparison of Urinary Protein Levels in IgA Nephropathy Patients with or without Streptococcus Mutans Strains with cnm Gene Encoding Collagen-Binding Protein in the Oral Cavity Taro Misaki,[1] Shuhei Naka,[2] Rina Hatakeyama,[2] Akiko Fukunaga,[3] Ryota Nomura,[2] Taisuke Isozaki,[1] Kazuhiko Nakano.[2] *[1]Div of Nephrology, Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan; [2]Div of Oral Infections and Disease Control, Osaka Univ Graduate School of Dentistry, Suita, Osaka, Japan; [3]Dept of Dentistry, Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan.*

Background: Immunoglobulin (Ig)A nephropathy (IgAN) is the most common primary chronic glomerulonephritis, but the precise initiating pathogenesis remains unclear. *Streptococcus mutans* is a major pathogen for human dental caries, and *S. mutans* strains with the *cnm* gene encoding the Cnm collagen-binding protein reportedly contribute to the development of several systemic diseases. We have previously found that the rate of *cnm*-positive *S. mutans* strains harbored in the oral cavity was significantly higher in an IgAN patient group (32.1%) than in healthy controls (14.0%, p<0.05), as reported atASN Kidney Week 2014 and in *Clinical and Experimental Nephrology* in 2015. We therefore investigated the relationship between dental caries status and IgA nephropathy.

Methods: Saliva specimens from IgAN patients (n=109) were collected and *S. mutans* strains were isolated. The *cnm* gene was detected using PCR techniques. A total of 49 patients who agreed to dental visits were evaluated for dental caries status (DMFT score: decayed, missing, or filled teeth).

Results: The rate of *cnm*-positive *S. mutans*strains detected in IgAN patients was 27.5%. Mean (±standard error of the mean) DMFT score was significantly higher in the *cnm*-positive group (16.3±1.3) than in the *cnm*-negative group (11.9±1.2, p=0.04). Urinary protein levels were significantly higher in the *cnm*-positive group (1.6±0.5 g/gCr) than in the *cnm*-negative group (0.4±0.1 g/gCr, p=0.0021). Moreover, urinary protein levels were significantly higher in the high DMFT score group (score >15; 0.9 ± 0.3 g/gCr) than in the low DMFT score group (score <15; 0.3 ±0.05 g/gCr, p=0.0246).

Conclusions: The *cnm*-positive *S. mutans* strains could be associated with urinary protein levels as well as dental caries status in IgAN patients.

FR-PO677

Identification of Micro-RNAs Associated with IgAN Progression Izabella Z.A. Pawluczyk,[1] Robert H. Jenkins,[2] Karen Molyneux,[1] Donald Fraser,[2] Jonathan Barratt.[1] *[1]Infection, Immunity and Inflammation, Univ of Leicester, Leicester, Leicestershire, United Kingdom; [2]Inst of Molecular and Experimental Medicine, Univ of Cardiff, Cardiff, Wales, United Kingdom.*

Background: MicroRNAs (miRs) are small non-coding RNA molecules that post transcriptionally regulate gene expression and control many physiological and pathological processes. The aim of this study was to identify miRs associated with the risk of IgAN progression.

Methods: The miRnomes of renal biopsies from IgAN progressors (IgANp)(100% increase in serum creatinine post diagnosis) and non progressors (IgANnp) (<10% increase in serum creatinine over 10 years) were compared. To rule out differences due to generic proteinuric renal disease IgAN profiles were compared with those from membranous nephropathy (MN). Thin membrane nephropathy (TM) biopsies were used as 'normal' controls. Next Generation Sequencing was performed on RNA from 6 frozen biopsies from each of the 4 cohorts.

Results: 13 miRs were differentially expressed in IgANp compared to IgANnp, MN and TM and selected for validation by qPCR (20 biopsies per cohort). Validation identified 5 dysregulated miRs. Cortical localisation studies revealed that miR-150 exhibited a trend towards higher glomerular levels in IgANp (p=0.054), and significantly raised glomerular levels in MN (p=0.02). No differences in distribution were seen in IgANnp and TM. miR-155 expression was raised in the glomeruli of IgANp (P=0.025) and showed a similar trend

in IgANnp (p=0.057). Expression levels were comparable in the MN and TM. miR135a displayed higher interstitial expression in IgAnp (p=0.02) while IgANp, MN and TM showed no statistical difference in distribution.

Conclusions: These data suggest that a glomerular preference for miR-150 may indicate progressive disease, raised glomerular levels of miR155 may be associated with the IgAN phenotype and increased interstitial expression of miR135a may indicate a lower risk of progression. In conclusion these data provide us with a platform to robustly test miRs 150, 155 and 135a as potential biomarkers of IgAN progression and to investigate in vitro and in vivo the functional roles of these miRs in the pathogenesis and progression of IgAN nephropathy.

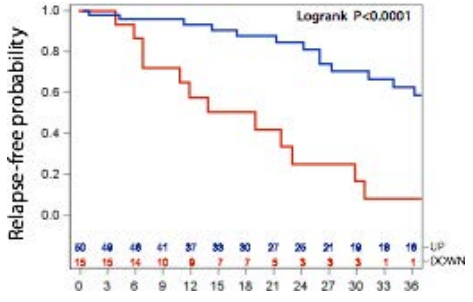
FR-PO678

Gene-Specific DNA Methylation Changes Predict Stable Remission in ANCA-Associated Vasculitis Patients Britta E. Jones,[1,2] Jia Jin Yang,[1] Akhil Muthigi,[1] Susan L. Hogan,[1] Yichun Hu,[1] Joshua Starmer,[1,3] Caroline J. Poulton,[1] William Franklin Pendergraft,[1] J. Charles Jennette,[1,2] Ronald J. Falk,[1] Dominic J. Ciavatta.[1,3] *[1]UNC Kidney Center, Dept of Medicine, UNC, Chapel Hill, NC; [2]Dept of Pathology and Laboratory Medicine, UNC, Chapel Hill, NC; [3]Dept of Genetics, UNC, Chapel Hill, NC.*

Background: Anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) is an autoimmune condition characterized by vascular inflammation and organ damage. Pharmacologically induced remission is complicated by relapses. Potential triggers of relapse are immunological challenges and environmental insults, both of which are associated with changes in epigenetic silencing modifications.

Methods: To establish a link between DNA methylation, a model epigenetic gene silencing modification, and autoantigen gene expression and disease status in AAV, we measured gene-specific DNA methylation of the autoantigen genes, myeloperoxidase (*MPO*) and proteinase 3 (*PRTN3*), in leukocytes of AAV patients followed longitudinally (n=82) and healthy controls (n=32).

Results: Patients with active disease demonstrated hypomethylation of *MPO* and *PRTN3* and increased expression of the autoantigens. Longitudinal analysis divided AAV patients into two groups based on DNA methylation change from active disease to remission. In patients with increased DNA methylation, *MPO* and *PRTN3* expression correlated with DNA methylation. Patients who increased DNA methylation at the *PRTN3* promoter had a significantly greater probability of a relapse-free period, independent of ANCA serotype; patients with decreased DNA methylation were more likely to relapse with a hazard ratio of 4.55 (95% CI, 2.09 to 9.91).



Conclusions: Changes in the DNA methylation status of the *PRTN3* promoter predict likelihood of stable remission and may explain autoantigen gene regulation.

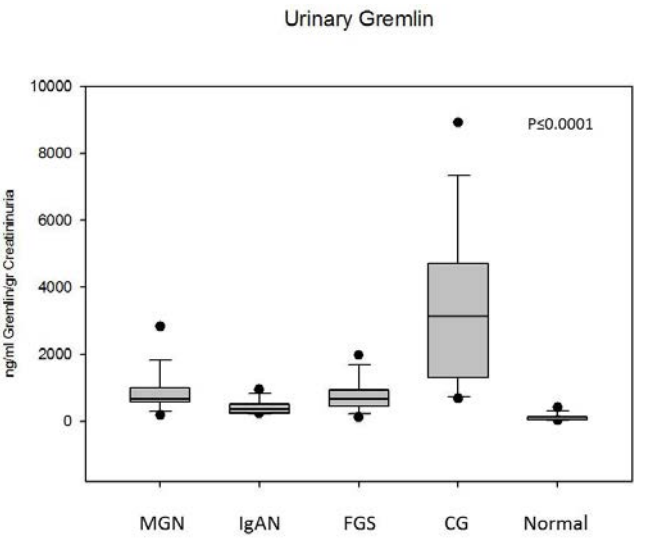
FR-PO679

Gremlin, a New Potential Urinary Biomarker of Crescentic Glomerulonephritis Alejandra Droguett,[1] Daniel Carpio,[1] Carolina Lavoz,[1] Maria Eugenia Burgos,[1] Graciela Valderrama,[1] Jesus Egido,[2] Marta Ruiz-Ortega,[2] Sergio A. Mezzano.[1] *[1]Nephrology, Univ Austral, Valdivia, Chile; [2]Fundación Jiménez Díaz, Univ Autónoma, Madrid, Spain.*

Background: Crescentic glomerulonephritis (CG) require immediate accurate diagnosis and appropriate therapeutic decisions. The pathogenesis of crescent formation still is debated. We have previously described that Gremlin, a BMP antagonist, is highly expressed both in cellular and fibrocellular crescents, corresponding to proliferating parietal epithelial cells (PECs) and monocytes and we proposed that Gremlin could act as a mediator of this damage and be a urinary biomarker of crescent formation.

Methods: We here studied urinary Gremlin by ELISA test in samples from 94 patients who simultaneously undergoing renal biopsy. 43 of them with CG (23 Pauci-immune, 17 Systemic Lupus and 3 IgA Nephropathy), 51 patients with other non crescentic GN and 16 healthy controls. CD163 and CCL18 have been recently described as monocytes-macrophages secreted proteins associate to crescent formation, therefore we also examined the potential colocalization of Gremlin with these proteins by immunohistochemistry and in situ hybridization.

Results: Urinary Gremlin levels were markedly augmented in patients with crescentic glomerulonephritis compared with healthy donors and with patients with other glomerular diseases (CG: 347.8 ug/grCr vs 91.6 in non-crescentic GN and 11.3 in healthy controls; P<0.001) (figure 1), and were correlated with the percentage of crescents (R= 0.5, P<0.004) and tubulointerstitial fibrosis (R=0.5, P<0.02).



Moreover, we confirmed a strong expression of Gremlin protein and mRNA in cellular glomerular crescents and this expression was co-located with CD163 and CCL18.

Conclusions: Overall, our results further extend the concept that Gremlin plays a role in the genesis of crescent formation and suggest that urinary Gremlin could be a non-invasive biomarker in CG. Fondecyt 1160465.

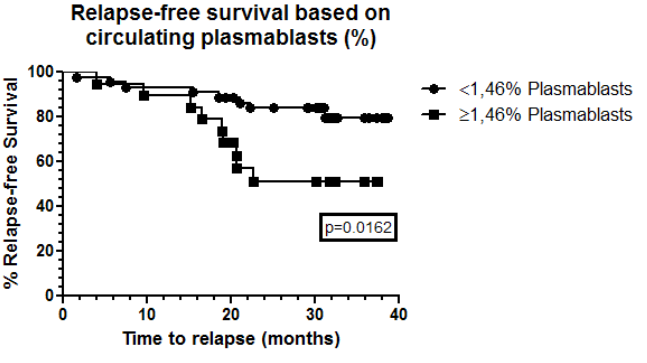
FR-PO680

Percentage of Circulating CD19+CD27+/hiCD38hi Plasmablasts in Granulomatosis with Polyangiitis Patients Predicts Relapse-Free Survival Anouk von Borstel,[1] Judith Land,[2] Abraham Rutgers,[2] Wayel H. Abdulahad,[2] Coen A. Stegeman,[1] Peter Heeringa,[3] Jan-Stephan Sanders.[1] *[1]Internal Medicine, Nephrology, UMCG, Groningen, Netherlands; [2]Rheumatology and Clinical Immunology, UMCG, Groningen, Netherlands; [3]Pathology and Medical Biology, UMCG, Groningen, Netherlands.*

Background: Granulomatosis with polyangiitis (GPA) is a small vessel vasculitis characterized by the presence of ANCA. Patients with GPA suffer from frequent disease relapses. Currently no reliable method to predict relapse in individual patients is available. B cells have both pro- and anti-inflammatory functions and are precursors of plasma cells that produce ANCA. We investigated the proportion of circulating plasmablasts (PB) in relation to relapse-free survival.

Methods: A cohort of 83 GPA patients was monitored for 19.4-38.8 months (median 32.7 months). By flow cytometry, the whole blood B cell phenotypes were determined from remission patients at time of inclusion. PB were defined as $CD27^{+/hi}CD38^{hi}$ within $CD19^{+}$ B cells. Patients with <2% B cells were excluded from analysis (n=20). Relapse-free survival was analyzed by Log-rank test and Cox proportional hazards analysis.

Results: During follow-up 17 patients relapsed 1.7-31.2 months (median 18.7) after inclusion. Relapsing patients had a significantly increased percentage of PB (median 1.46; range 0.73-3.88) compared to 46 non-relapsing patients (median 1.01; range 0.12-4.94; p=0.0436). Relapse-free survival during follow-up was significantly (p=0.0162) worse in patients with more than 1,46% PB (51.3%; n=44) in the circulation, 47.4% of these patients suffered from a relapse compared to 18.2% of patients with less than 1.46% PB (relapse-free survival 79.4%; n=19).



Conclusions: In conclusion, GPA patients that have a higher percentage of PB are at increased risk to experience a disease flare. The percentage of PB might be a potential biomarker for relapse and a novel monitoring and therapeutic target in AAV.

FR-PO681

International Validation Study for the Histopathological Classification of ANCA-Associated Glomerulonephritis (AAGN) Emma Van Daalen,[1] Laure-Helene Noel,[3] Kensuke Joh,[4] Yayoi Ogawa,[5] Suzanne Wilhelmus,[1] Andreas Kronbichler,[6] Renate Kain,[7] Steven Salvatore,[8] Xavier Puéchal,[9] Wladimir M. Szpirt,[10] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center; [2]Nephropathology, San Gerardo Hospital, Monza; [3]Pathology, Hôpital Necker, Paris; [4]Pathology, Tohoku Univ Sendai; [5]Renal Pathology Center, Hokkaido; [6]Internal Medicine, Medical Univ of Innsbruck; [7]Pathology, Medical Univ of Vienna; [8]Pathology and Laboratory Medicine, Weill Cornell Medical College, New York; [9]Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, Paris; [10]Nephrology, Rigshospitalet, Copenhagen.*

Background: In the original validation study for the histopathological classification of AAGN, the order of classes from focal to sclerotic corresponded to increasing severity of renal function loss. Subsequent validation studies (N=15) disagreed on outcomes in crescentic and mixed class. We here present an international validation study driven by the original investigators.

Methods: This interim analysis included 104 patients from centers in the U.S., Europe, and Asia. Each case was scored at a secured website by 2 pathologists from a group of 6; a 3rd pathologist gave the final conclusion in case of disagreement. Outcome at 1 and 5 years follow-up was based on KDOQI classification (eGFR>60/15-60/<15 or on dialysis/death). Renal survival was expressed as ESRD-free survival.

Results: The distribution of the histopathological classes was 41% focal, 18% crescentic, 27% mixed, 14% sclerotic. Mean $eGFR_{baseline}$ differed between classes (P<0.001), but was similar in crescentic and mixed class. The order of classes corresponded to outcome at 1 and 5 years (P<0.001, resp. P=0.016). Renal survival after 5 years was 95% in focal, 89% in crescentic, 96% in mixed, and 71% in sclerotic class. In the original study, renal survival after 5 years for respective classes was 93%, 76%, 61%, and 50%.

Conclusions: In this international validation study for the histopathological classification of AAGN, the classification predicted outcome at 1 and 5 years with crescentic and mixed class lumped together. Interestingly, in all classes renal survival was much higher than in the original report, possibly due to improvements in therapy.

FR-PO682

Measuring Complement Activation in ANCA-Associated Vasculitis Sonia Brigitte Boyer,[1] Eve Wu,[1] Elizabeth Alderman McInnis,[1] Lydia Aybar,[1] Carmen E. Mendoza,[1] Yichun Hu,[1] Susan L. Hogan,[1] Ronald J. Falk,[1] Patrick H. Nachman,[1] J. Charles Jennette,[2] Donna O. Bunch.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]Pathology, Univ of North Carolina, Chapel Hill, NC.*

Background: Investigating complement activation in ANCA-associated vasculitis (AAV) remains important. Cleavage of complement proteins *in vitro* despite using EDTA has been reported, thus accurate measurement of complement activation requires careful sample processing to avoid *in vitro* complement activation. We studied the effect of futhan (FU), a broad-specificity protease inhibitor, on measured complement activation in patients with AAV and healthy controls (HC).

Methods: 61 blood samples (15 active, 26 remission and 20 HC) were drawn into EDTA tubes and put on ice immediately. Paired samples were processed without or with 100mg/ml FU within 30 minutes and stored at -80°C until use. Plasma concentrations of properdin (Hycult), Bb, C3a, C5a and sC5b-9 (Quidel) were measured by ELISA. Differences in quantitative parameters between groups were assessed using a paired signed rank test. The relationship between two continuous variables was analyzed using Pearson's correlation.

Results: Bb plasma levels were higher in samples processed without FU than with FU (p<0.0001) for all sample groups (Table); however, the difference was systematic (r^2=0.83). Levels of sC5b9 also consistently trended higher (r^2=0.8) in samples processed without FU than with FU, but were different only in one group (p=0.02). C3a, C5a and properdin did not differ with or without FU (data not shown). C3a and C5a in samples with FU strongly correlated with those without FU (r^2 0.94 and 0.94 respectively).

Analyte	Group	No FU (median)	+FU (median)	P
Bb (µg/ml)	Act	0.88	0.69	<.0001
	Rem	0.85	0.69	<.0001
	HC	0.70	0.58	<.0001
sC5b9 (ng/ml)	Act	203.2	181.3	0.07
	Rem	134.7	126.5	0.02
	HC	123.6	114.5	0.29

Conclusions: Addition of FU may be required to accurately measure Bb and sC5b-9, but not properdin, C3a, or C5a. Further study is required, but our data suggests standardized processing methods including FU will improve measurement of complement activation.

Funding: NIDDK Support

FR-PO683

Significance of Immune Complex Deposition in Antineutrophil Cytoplasmic Antibody Associated Glomerulonephritis Ravi Agrawal,[1,2] James R. Taylor,[3] Pranay Kathuria.[1] *[1]Div of Nephrology, Univ of Oklahoma, School of Community Medicine, Tulsa, OK; [2]Northeast Pennsylvania Nephrology Associates, Scranton, PA; [3]Pathology Laboratory Associates, Tulsa, OK.*

Background: Antineutrophil Cytoplasmic Antibody(ANCA) associated glomerulonephritis is characterized by findings of a pauci-immune necrotizing and crescentic glomerulonephritis. In a small percentage of cases, immune complex deposition may be seen and in various studies have been associated with more severe disease.

Methods: A retrospective study of 43 ANCA positive patients with necrotizing/crescentic glomerulonephritis. Using data from the electron microscopy, patients were categorized into those with deposits and those without deposits. The presence and absence of deposits was correlated with age, ethnicity, clinical data, histologic (percentage of crescents and glomerular cellularity score) and immunofluorescence findings.

Results: Thirteen patients (30.2%) had immune deposits on electron microscopy. Immune deposits were seen significantly more in males (p=0.019) and in African-American ethnicity (p=0.023). The presence of immune deposits was associated with significantly more crescents (52.9±19.8 % Vs 31.9±27.4%, p=0.017) and more glomerular cellularity score (p=0.020). The mean serum creatinine but not the eGFR(calculated using Modification of Diet in Renal Disease equation) was significantly higher in the group with immune complex deposits. There was no significant difference between the two groups in terms of comorbid conditions and the amount of proteinuria. Immunoglobulins IgG and IgA were significantly more in patients with immune deposits (p=0.0004 and p=0.025, respectively).

Conclusions: Immune complex deposition in ANCA glomerulonephritis is seen significantly more in males and in African-American ethnicity. It is associated with significantly more crescents and higher glomerular cellularity score indicating more glomerular damage.

FR-PO684

Thrombotic Microangiopathy Associated with a Monoclonal Gammopathy Aishwarya Ravindran, Ronald Go, Fernando C. Fervenza, Sanjeev Sethi. *Mayo Clinic, Rochester, MN.*

Background: Thrombotic microangiopathies (TMA) comprise a heterogenous set of conditions linked by a common histopathologic finding of endothelial damage resulting in microvascular thrombosis. Monoclonal gammopathy may act as a potential trigger in the pathogenesis of TMA. We performed a retrospective, single institution study to determine the prevalence of monoclonal gammopathy in patients with TMA.

Methods: We included adults (≥18 years) from 2000-2016 with a clinical diagnosis of TMA who met the following criteria: i) microangiopathic hemolytic anemia and thrombocytopenia or histologic evidence of TMA ii) absence of a coagulopathy and a negative direct antiglobin test, iii) screened for monoclonal gammopathy. Monoclonal gammopathy was defined as the presence of monoclonal Ig in the serum/urine.

Results: 146 patients met the study criteria. Monoclonal Ig was detected in 20 patients (13.7%). The median age at diagnosis of TMA in patients with monoclonal Ig was 63 years (range: 19-80) and the majority were males (12; 57.1%). Among patients >50 years, the prevalence of monoclonal gammopathy was 19.7% (n=16), which is approximately 5-fold higher than the expected rate in this population (4.2%). Among the 20 patients with monoclonal gammopathy, 2 (10%) were classified as thrombotic thrombocytopenic purpura (ADAMTS13 activity <10%), 10 (50%) as atypical hemolytic uremic syndrome (clinicopathologic findings), and the remaining 8 (40%) could not be classified. The median serum creatinine at time of TMA diagnosis was 3.5 mg/dL (range: 0.7-14). Renal biopsy was performed in 15 cases, of which 8 showed glomerular thrombi, 11 showed mesangiolysis, and all 15 showed double contours along glomerular capillaries. Acute tubular injury was present in all biopsies. 8 biopsies also showed arterial thrombi. None of the biopsies showed monoclonal Ig on IF microscopy. 12 patients (60%) required dialysis during the course of the disease.

Conclusions: Similar to C3 glomerulopathy, our study shows an unexpectedly high prevalence of monoclonal gammopathy in patients with TMA suggesting a potential association of TMA with monoclonal gammopathy. Further studies are required to determine the underlying mechanisms of TMA associated with monoclonal gammopathy.

FR-PO685

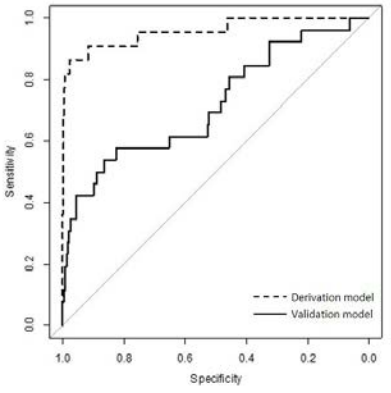
A Prediction Model for the Diagnosis of Thrombotic Microangiopathies at Hospital Admission Pietro Manuel Ferraro, Gianmarco Lombardi, Alessandro Naticchia, Antonio Sturniolo, Giovanni Gambaro. *Fondazione Policlinico Univ A. Gemelli, Rome.*

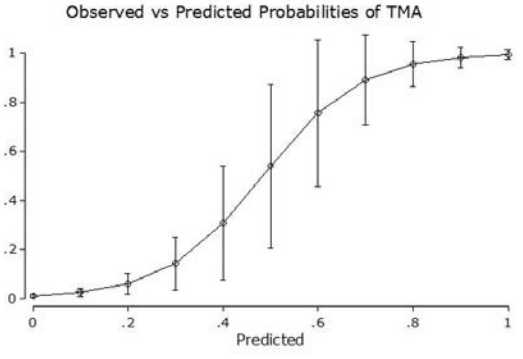
Background: Thrombotic microangiopathies (TMA) are a heterogeneous group of conditions characterized by microangiopathic hemolytic anemia, thrombocytopenia and several degrees of renal and other organs impairment. We developed a prediction model for the timely diagnosis of TMA in hospitalized patients based on easily obtained laboratory measurements.

Methods: We retrospectively collected data from all adult patients admitted at our Hospital from January 2010 to December 2014. ICD9 codes from primary diagnoses were used to determine whether a patient had TMA. Demographic and laboratory characteristics at admission of TMA patients were then compared with a sample of 476 patients who received other diagnoses. The model was externally validated in a cohort from another Hospital.

Results: Overall, 23 out of 696,438 patients received a primary diagnosis of TMA (prevalence rate 3.3 per 100,000). In univariate analyses, indirect bilirubin (odds ratio

[OR] for 1 mg/dL 2.68, 95% confidence interval [CI] 1.85, 4.02), lactate dehydrogenase (LDH) (OR for 100 IU/L 1.57, 95% CI 1.38, 1.85), hemoglobin (OR for 1 g/dL 0.56, 95% CI 0.45, 0.68), and platelet count (OR for 1,000 platelets/uL 0.97, 95% CI 0.96, 0.98) were significantly associated with TMA. In multivariate models, only LDH (OR 1.26, 95% CI 1.05, 1.63) and platelet count (OR 0.96, 95% CI 0.94, 0.98) were associated with TMA. The final regression model had an area under the ROC (AUROC) of 0.96 (95% CI 0.91, 1.00) and showed good calibration. External validation on 26 patients with and 500 without a diagnosis of TMA showed an AUROC of 0.72 (95% CI 0.60, 0.84).





Conclusions: We derived and externally validated a simple prediction model for the diagnosis of TMA in hospitalized patients. The model shows good performance and can help the clinician in identifying patients at high risk of TMA.

FR-PO686

Detection of Amyloidogenic Immunoglobulin Light Chain in AL Amyloidosis with Urinary Exosomes Nelson Leung,[1,2] David R. Barnidge,[3] Angela Dispenzieri,[2] Christopher J. Dick,[4] Shawna A. Cooper,[4] Samih H. Nasr,[3] Christopher J. Ward,[5] Marina Ramirez-Alvarado.[4,6] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Hematology, Mayo Clinic, Rochester, MN; [3]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [4]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN; [5]Nephrology and Hypertension, Kansas Univ Medical Center, Kansas City, KS; [6]Immunology, Mayo Clinic, Rochester, MN.*

Background: Immunoglobulin light chain (AL) amyloidosis is a fatal disease caused by the overproduction of monoclonal immunoglobulin light chain (LC). Diagnosis currently requires tissue biopsy. Urinary exosomes (UEX) are the smallest extracellular vesicles excreted by cells of the nephron. This study explores the use of UEX to assess for amyloidogenic LC.

Methods: A patient with no clinically detectable monoclonal LC in the serum or urine had UEX collected and evaluated by Western Blot. Identification of the monoclonal LC was performed by a combination of accurate molecular weight determination and topdown tandem mass spectrometry (MS) on the UEX and serum. Bottom-up proteomics was performed on a tryptic digest of amyloid deposits from the kidney isolated by laser dissection and then analyzed by tandem mass spectrometry (LSMS). cDNA was obtained from plasma cells clones from the bone marrow biopsy.

Results: Characteristic oligomeric LC bands were identified in the UEX. The same 2 monoclonal λ LC found in the UEX by MS were also found in the blood. LSMS identified tryptic peptides from a monoclonal LC in the IGLV6 gene family, same as the cDNA from the plasma cell clones which had the same amino acid sequences as the tryptic peptides. The molecular mass of the IGLV6 LC predicted by cDNA was identical to accurate molecular mass of the monoclonal λ LC observed in the serum and UEX. Finally, the relative abundance of the IGLV6 LC was conserved compared to the other non-amyloidogenic LC in the serum and UEX.

Conclusions: These results suggest that UEX can discriminate amyloidogenic LC from non-amyloidogenic LC. This could contribute significantly to the understanding of the pathogenicity of monoclonal LC.

FR-PO687

Assessment of Renal Response in Immunoglobulin Light Chain (AL) Amyloidosis by Urinary Exosomes Nelson Leung,[1,2] David R. Barnidge,[3] Angela Dispenzieri,[2] Christopher J. Dick,[4] Shawna A. Cooper,[4] Samih H. Nasr,[3] Christopher J. Ward,[5] Marina Ramirez-Alvarado.[4,6] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Hematology, Mayo Clinic, Rochester, MN; [3]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [4]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN; [5]Nephrology and Hypertension, Kansas Univ Medical Center, Kansas City, KS; [6]Immunology, Mayo Clinic, Rochester, MN.*

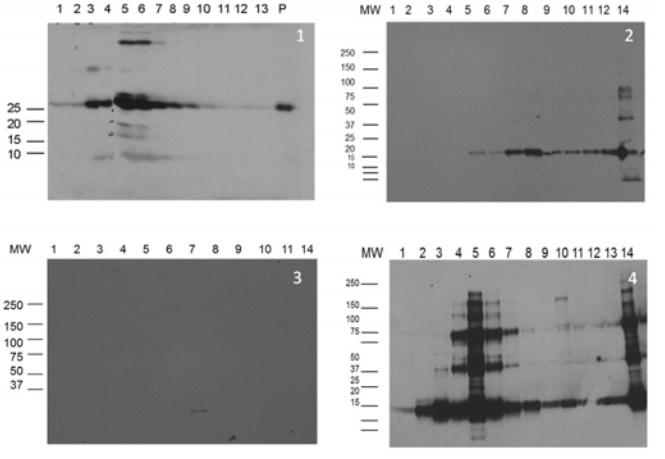
Background: Immunoglobulin light chain (AL) amyloidosis is a fatal disease caused by the overproduction of a monoclonal immunoglobulin light chain (LC). Accurate assessment of response is crucial for successful treatment. Urinary exosomes (UEX) have demonstrated different characteristics in AL amyloidosis vs multiple myeloma. This study explores the use of UEX to assess the renal response after treatment in AL amyloidosis.

Methods: Western blot was performed on the UEX of 4 patients with different hematologic status.

Patient	Hematologic status	Current proteinuria (g/d)	Proteinuria reduction	Renal outcome
1	ND	9.7	n/a	n/a
2	Treated to CR	0.7	91.6%	CR
3	Treated to CR	3.4	61.2%	CR
4	Treated to CR	3.4	76.5%	ESRD

From newly diagnosed (ND) patients to those treated to a hematologic complete response (CR).

Results:



The UEX of Patient 1 showed oligomeric LC bands > 25 kDa. Patient 2 and 3 had only monomeric LC bands (~25 kDa) often seen in multiple myeloma. Oligomeric (50 - 250 kDa) bands (similar to patient 1) were present in the UEX of patient 4 indicating active amyloid formation despite achieving a hematologic CR.

Conclusions: The oligomeric LC bands in UEX appear to be a good marker of renal response in AL amyloidosis. If confirmed, UEX may offer a great advantage over proteinuria in the assessment of renal response in AL amyloidosis.

Intra-Tubular Amyloid: A Significant Pathological Finding during Myeloma Cast Nephropathy Jean-Baptiste Gibier,[1] Viviane Gnemmi,[1] Marie-Christine Copin,[1] Francois Glowacki,[3] Raymond Azar,[4] Maxime Hoffmann,[7] Thomas Guincestre,[5] Xavier Leleu,[6] David Buob.[2] *[1]Pathology, CHRU Lille, Lille, France; [2]Pathology, Tenon Hospital, Paris, France; [3]Nephrology, CHRU Lille, Lille, France; [4]Nephrology, Dunkerque General Hospital, Dunkerque, France; [5]Nephrology, Hopital Victor Provo, Roubaix, France; [6]Hematology, CHU Poitiers, Poitiers, France; [7]Nephrology, La Louvière Hospital, Lille, France.*

Background: Cast nephropathy (CN) is the most common form of kidney disease in patients with multiple myeloma. Occasionally, casts may show amyloid staining properties i.e. green birefringence in Congo red. The frequency and signification of such intra tubular amyloid (ITAM) are poorly understood. In particular the link between ITAM and systemic amyloidosis has never been investigated.

Methods: A retrospective analysis with clinico-pathological correlation was performed of all cases of CN diagnosed at our institution between 2002 and 2012. Renal pathological findings and Congo red staining status were reviewed. Each patient was also screened for extra renal samples and if available a Congo red staining was performed. Treatment and clinical follow up data were obtained.

Results: Among 66 patients diagnosed with CN, 18 (27,2%) showed ITAM. There was no differences in clinical characteristics between patients with or without ITAM at time of biopsy. ITAM was associated with overrepresentation of λ light chain (14 out 18) whereas patients without ITAM showed balanced κ/λ ratio. Renal amyloid was found in 3 patients: 1 with ITAM and 2 without. Extra renal amyloid was found in 6 patients in the ITAM group and in only one patient in the "no ITAM" group. All in all, ITAM was significantly associated with systemic amyloidosis (7/18 vs 3/48 p=0,003).

Conclusions: This study reports for the first time an association between the existence of ITAM in kidney biopsies with CN and systemic amyloidosis. Our study highlights the importance of the systematic search of Congo red staining of casts in such context. Moreover it suggests that the detection of ITAM should lead to an exhaustive screening for other localizations of amyloidosis, as associated systemic amyloidosis is an adverse factor in myeloma patients.

FR-PO689

Beta Trace Protein Does Not Outperform Cystatin C or Creatinine in Estimating GFR in Older Adults

Natalie Ebert,[1] Peter Martus,[2] Camilla Koep,[1] Olga Jakob,[3] Elke Schaeffner.[1] *[1]Inst of Public Health, Charité, Berlin, Germany; [2]Inst for Med. Biometry, Eberhard Karls Univ Tübingen, Germany; [3]Clinical Epidemiology and Biostatistics, Charité.*

Background: Despite a lot of research the optimal endogenous biomarker for GFR estimation in the elderly has not been identified. We sought to analyse if beta trace protein (BTP) improved GFR estimation in older adults.

Methods: In 570 older adults with iohexol clearance measurement (BIS) creatinine, cystatin C, and BTP were measured. In a double logarithmic linear model prediction of mGFR by BTP was assessed. Analyses with BTP only and combined with serum creatinine and cystatin C were performed (all analyses adjusted for age and gender).

Results: Table 1 documents seven regression models including either single biomarkers or combinations.

	corrected R^2
Regression Modell (including age and gender)	
- BTP	0.671
- CysC - CysC + BTP	0.781 0.799
- Crea - Crea + BTP	0.739 0.787
- Crea + CysC - Crea + CysC + BTP	0.840 0.845

In terms of best r^2 the combination of all three biomarkers shows the best prediction of mGFR (r^2=0.828), although the combination of creatinine and cystatin C provided only a minimally diverging result (0.82). The single usage of BTP showed the worst prediction (r^2=0.671) within the models with one biomarker. In subgroup analysis (AHT, DM, BMI≤23 and BMI>30) there was no relevant additional benefit of including BTP into the prediction model (data not shown).

Conclusions: BTP alone or the addition of BTP does not outperform current biomarkers such as creatinine and cystatin C for GFR-estimation in older adults. Especially the use of cystatin C renders the addition of BTP unnecessary. Also, BTP did not show additional benefit in hypertensive, diabetic, lean or obese elderly patients.

FR-PO690

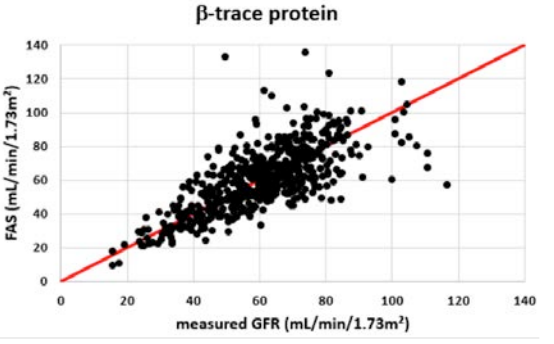
Diagnostic Value of Normalized Beta Trace Protein for Estimating GFR in Older Adults

Natalie Ebert,[1] Elke Schaeffner,[1] Hans Pottel.[2] *[1]Pub. Health, Charite, Germany; [2]Pub. Health, KU Leuven, Belgium.*

Background: BTP as a novel biomarker has emerged as alternative to creatinine (Scr) and cystatin C (Scys). The recently published Full Age Spectrum (FAS) eGFR equation has been developed by normalizing Scr with mean Scr of large healthy cohorts. We investigate whether this concept is also valid for BTP in elderly indiv. and compare it to Scr and Scys.

Methods: We used data from the Berlin Initiative Study (BIS), a pop-based cohort with mGFR (iohexol) examining KF in indiv. aged ≥70y. The fixed form of the FAS-equation was applied with normalized single (Scr, Scys, BTP) or combined (average of Scr and ScysC or Scr, Scys and BTP) biomarkers and performance statistics were calculated: constant bias (FAS - mGFR), proportional bias (FAS/mGFR), root mean square error of prediciton (rmse), Lin's concordance corr. coefficient, P10 and P30 (percentage of predictions within 10% or 30% of mGFR).

Results: Based on the distribution of BTP in n=566 BIS participants (mean age 78.5y), the peak-value is ±0.60 mg/L. Using the fixed form of the FAS equation and rephrasing it with BTP leads to: $FAS_{BTP} = 107.3 / [BTP/0.60] \times 0.988^{(Age-40)}$. Fig 1 shows FAS-prediction of single BTP versus mGFR.



BTP shows equivalent bias but less precision (P10, P30) as compared to Scr and Scys.

	Scr	Scys	BTP	Scr/sCys	Scr/Scys/BTP
bias	-0.4	0.6	0	-0.3	-0.6
prop	1.01	1.02	1.01	1.01	1.00
lin	0.826	0.832	0.728	0.873	0.863
rmse	9.5	9.6	11.1	8.0	8.4
P10	51	49	40	57	58
P30	94	94	87	96	97

The added value for the combination of three biomarkers (BTP/Scr/Scys) compared to Scr/Scys FAS is very small (Tab 1).

Conclusions: Normalizing renal biomarkers to make them independent of age and gender and building them into the FAS equation holds also true for BTP in our elderly cohort. Adding BTP to the combined Scr/Scys FAS equation has only limited effect on precision of GFR estimation.

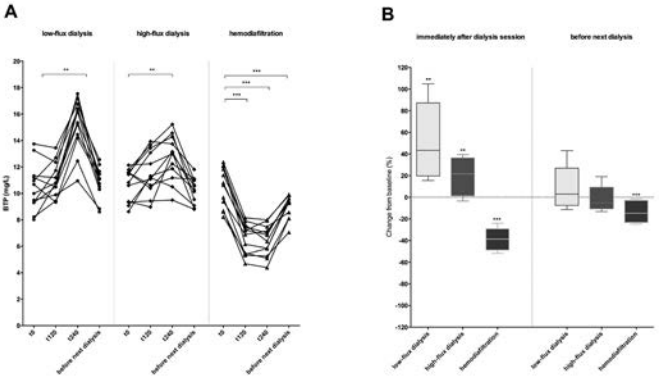
Plasma Beta-Trace Protein (BTP) as a Marker of Residual Renal Function (RRF): The Effect of Different Hemodialysis (HD) Modalities and Intraindividual Variability over Time

Amaryllis H. Van Craenenbroeck,[1,2] Ann-Christin Bragfors Helin,[1] Abdul Rashid Tony Qureshi,[1] Bengt Lindholm,[1] Björn Anderstam,[1] Peter Stenvinkel,[1] Peter F. Barany.[1] *[1]Divs of Renal Medicine and Baxter Novum, Dept of Clinical Science, Intervention and Technology, Karolinska Inst, Stockholm, Sweden; [2]Dept of Nephrology, Antwerp Univ Hospital, Antwerp, Belgium.*

Background: BTP is a low-molecular-weight molecule which may be used to assess RRF in dialysis patients (pts). Here we evaluated the influence of HD and hemodiafiltration (HDF) on plasma BTP, and analyzed the intra-individual variability of plasma BTP over time in HD and peritoneal dialysis (PD) pts.

Methods: In 12 prevalent HD pts, the effect of a single session of low-flux HD, high-flux HD and HDF on plasma BTP was studied. Blood samples were taken at baseline, after 120 and 240 minutes, and at the start of the next dialysis session. In 13 HD pts and 10 PD pts, intra-individual variability over three months was studied (monthly and weekly, respectively). Plasma BTP was measured using a nephelometric test (Siemens).

Results: No significant decrease in plasma BTP was seen following HD. HDF resulted in significant reduction of BTP levels already after the first half of dialysis time with a median reduction of 39% at the end of the session. A significant reduction of the molecule persisted and a significant decrease (-15%) was still found immediately before the start of the next dialysis session.



In both HD and PD pts, the reproducibility over time was excellent with intraclass correlation coefficient of 0.962 (0.928-0.995) and 0.923 (0.858-0.987) respectively.

Conclusions: BTP-based equations are a promising tool for estimations of RRF in pts on conventional HD or PD while in pts receiving HDF, plasma levels of BTP should be interpreted with care.

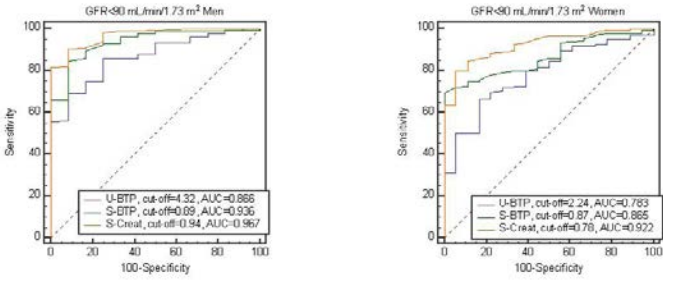
FR-PO692

Urinary β-Trace Protein – A Unique Biomarker to Screen Early Glomerular Filtration Rate Impairment Carlo Donadio. *Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.*

Background: The screening for chronic kidney disease (CKD) patients needs the measurement of serum markers. Our previous results indicated that urinary excretion of β-trace protein (BTP) (23-29 kDa), is increased in CKD patients from stage 2. **The aim of this study t**o assess the major determinants of urinary excretion of BTP and to evaluate its feasibility as non invasive marker of glomerular filtration rate (GFR) impairment.

Methods: We studied 355 CKD patients (198 males), 15-83 years, in stable clinical conditions, at the different stages of CKD on the basis of GFR (^{99m}Tc- DTPA). At the same time, we measured serum and urinary creatinine and BTP, and urinary albumin. Urinary excretion of BTP and albumin were expressed as mg/g creatinine. Fractional clearance of BTP was calculated as ratio of BTP clearance to creatinine clearance (%).

Results: Urinary excretion of BTP is mainly determined by its serum concentration and by the level of GFR, and to a lower extent by urinary albumin excretion. In fact, U-BTP and fractional clearance of BTP progressively and significantly increased along with the reduction of GFR and the concurrent rise in serum BTP. The relationship of U-BTP with GFR was very similar to that of S-BTP with GFR: urinary BTP mirrors serum BTP. The accuracy of U-BTP to screen patients with GFR<90 ml/min/1.73 m² was good (AUC 0.833), its sensitivity was 76.9%, specificity 80% and PPV 84.9%. Sensitivity of U-BTP was similar to that of S-BTP and S-Cr.



Conclusions: The major determinants of urinary excretion of BTP are S-BTP and GFR. U-BTP may be a suitable non invasive marker to screen the general population for detection of GFR<90 ml/min/1.73m².

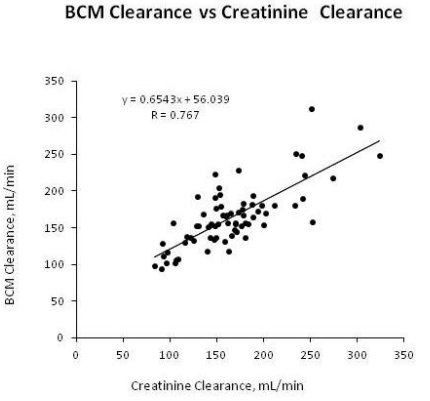
Urinary Creatinine Excretion and Creatinine Clearance Can Be Predicted in Severely Obese Patients by the Measurement of Body Cell Mass Carlo Donadio. *Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.*

Background: In obese patients the accuracy of prediction of renal function by formulas based on serum creatinine (PCr) and anthropometric data is quite low. The aim of this study was to evaluate if the value of body cell mass (BCM) allows to predict urinary creatinine excretion (UCr) and creatinine clearance (CCr).

Methods: Seventy-four patients (54 women), 19-66 years, BW 82.5-210 kg; BMI 35.2-73.6 kg/m², PCr (0.57-1.06 mg/dL). Measured parameters: PCr; UCr (urine collection 2 hrs); CCr measured (m-CCr) with the standard formula; CCr predicted by CG formula (CG-CCr) and by Salazar&Corcoran formula (S&C-CCr). GFR was predicted using MDRD formula (IDMS) and CKD-EPI formula. BCM was measured using a single frequency impedance analyzer. Renal dimensions were evaluated by bydimensional ultrasound scanning.

Results: 24h-UCr was 976-3684 mg, m 1809; BCM was 25-74 kg (m 49.3 kg men, 31.6 kg women). A strict linear correlation was found between 24h-UCr and BCM (r=0.79), closer than between 24h-UCr and BW (r=0.65). 24h-UCr and CCr were predicted from the individual values of BCM (BCM-CCr) (Donadio C. Kidney Int 63: S166-S168, 1997). Total renal volume was 425±103 mL; right kidney 211±63, left kidney 219.66 mL. The difference between BCM-CCr (165±41 mL/min) and m-CCr (167±44 mL/min) was insignificant. Quite different estimates were given by the other prediction formulas: C&G-CCr (199±72 mL/min), S&C-CCr (149±47mL/min), MDRD-GFR (122±34 mL/min), CKD-EPI-GFR (131±32 mL/min). BCM-CCr values showed also a good correlation with m-CCr (r=0.767, p<0.0001) and the concordance was similar for all values of renal function.



Correlation between predicted creatinine clearance (BCM Clearance) and measured Creatinine Clearance

Conclusions: In severely obese patients urinary creatinine excretion and creatinine clearance can be more accurately predicted from the measurement of body cell mass combined with serum creatinine, than with other formulas.

FR-PO694

Do Cystatin C Based Estimates of GFR Add Value in CKD Management in Primary Care? Adam Shardlow,[1,4] Natasha Juliette Mcintyre,[1] Simon D.S. Fraser,[2] Paul J. Roderick,[2] Richard J. Fluck,[1] Christopher W. McIntyre,[3] Maarten W. Taal.[1,4] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Univ of Southampton, Southampton, United Kingdom; [3]Univ of Western Ontario, London, ON, Canada; [4]Centre for Kidney Research and Innovation, Univ of Nottingham, Nottingham, United Kingdom.*

Background: Cystatin C has been proposed as a filtration marker and a risk factor in people with CKD. KDIGO guidelines suggest using a cystatin C based estimate of GFR ($eGFR_{cys}$) in defining those with disease. Cystatin C has not yet been widely adopted in clinical practice and to do so would require significant expense and education. We investigated the use of $eGFR_{cys}$ in 5 year follow-up of people with CKD stage 3 prospectively recruited from primary care.

Methods: 1741 people were recruited from primary care. All participants had an eGFR 30-60 ml/min on two occasions more than 90 days apart prior to study entry. Participants were assessed at baseline, 1 and 5 year follow-up visits. CKD EPI equations were used to calculate creatinine-based ($eGFR_{creat}$), cystatin C-based ($eGFR_{cys}$) and combined ($eGFR_{creat-cys}$) estimates of GFR. Multivariable regression models were used to predict CKD progression and mortality.

Results: At baseline, mean $eGFR_{creat}$ was 53.5, mean $eGFR_{cys}$ 45.1 and mean $eGFR_{creat-cys}$ was 48.3 ml/min (p<0.001 for all). Of 784 participants with $eGFR_{creat}$ 45-60ml/min, only 57 (7%) had $eGFR_{cys}$ >60 ml/min and 488 (62%) had $eGFR_{cys}$ <45ml/min. Greater difference between $eGFR_{creat}$ and $eGFR_{cys}$ was associated with higher eGFR, BMI, age, smoking and CRP. Over 5 years, correlation between the percentage change in $eGFR_{creat}$ and $eGFR_{cys}$ was moderate (r=0.49). Multivariable models to predict progression and mortality did not show significant difference using $eGFR_{creat}$, $eGFR_{cys}$ or $eGFR_{creat-cys}$.

Conclusions: In this cohort, use of $eGFR_{cys}$ resulted in minimal reclassification from CKD 3a to disease free. Baseline estimates of eGFR were significantly different and there was only moderate correlation in the change in renal function using $eGFR_{creat}$ and $eGFR_{cys}$. Whilst $eGFR_{cys}$ may have a place in selected patients with extremes of body habitus, these results do not show significant benefit to support its widespread application in primary care.

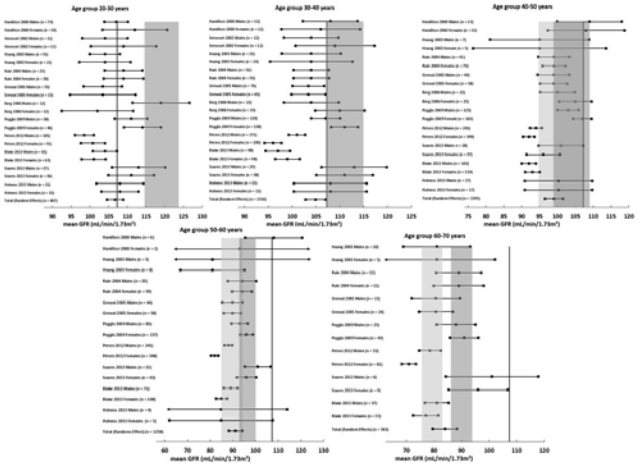
FR-PO695

Glomerular Filtration Rate in Healthy Living Potential Kidney Donors: A Meta-Analysis Hans Pottel,[2] Liesbeth Hoste,[2] Pierre Delanaye.[1] *[1]Nephrology, Univ of Liège, CHU Sart Tilman, Liege, Belgium; [2]Dept of Public Health and Primary Care, KU Leuven Campus Kulak, Kortrijk, Belgium.*

Background: Normal kidney function, or more specifically, normal glomerular filtration rate (GFR), in males and females, and its decline with age, is still much debated today. Most estimating GFR-equations have gender (and etnicity) multiplication factors, account for a decline that starts at very young age, and assume that GFR is as high as 120-130mL/min/1.73m² at young age, a reference value that dates back to the work of Homer Smith in the 1950s. The aim of this research study was to give more insight into 'normal' GFR-levels and the physiological decrease of kidney function with age and to test if the mathematical construction of eGFR-equations holds true in healthy kidney donors.

Methods: We conducted a meta-analysis of published GFR-measurements in healthy living potential kidney donors (n=5476, 46.7% males). Only publications dating from after the year 2000 were selected to avoid the possible influence of body surface area changes in the last decades on the indexed GFR, expressed in mL/min/1.73m², and involving only Caucasian subjects.

Results: We found that the mean GFR~107mL/min/1.73m² up to the age of 40 years, but beyond 40 years renal decline begins.



No evidence could be found for a difference between males and females in the separate age-groups.

Conclusions: A new mean GFR of 107mL/min/1.73m² can be set as opposed to the value of 120-130mL/min/1.73m² which was considered the reference value until now. It is advisable that the mathematical properties of estimating GFR-equations reflect the gender and age-independency (up to 40 years of age).

FR-PO696

Associations between Iohexol Clearance Measurement and Outcomes

Marlies Noordzij,[1] Kitty J. Jager,[1] Marie Evans.[2] *[1]ERA-EDTA Registry, Medical Informatics, AMC, Amsterdam, Netherlands; [2]Renal Medicine, CLINTEC, Karolinska Inst, Stockholm, Sweden.*

Background: In Sweden, the preferred method to determine GFR is measuring plasma iohexol clearance (IC). However, the safety of IC measurement has been questioned. We aimed (1) to evaluate which demographic and medical factors play a role in the decision to perform an IC measurement, and (2) to assess the associations between IC measurement and timing of start of RRT for ESRD, and all-cause mortality.

Methods: We included adult patients from the Swedish Renal Registry of Chronic Kidney Disease with a first visit between 2005-2011. By logistic regression we assessed which factors influenced the likelihood of IC measurement. To analyse time until start of RRT and death, Cox regression was performed. All multivariate models included age, sex, primary renal disease, and eGFR at inclusion in the registry. Propensity score matching was applied to control for confounding by indication in the comparison of patients with and without IC measurement.

Results: From a total of 13,570, there were 1,705 patients (12.6%) with IC measurement at least once during follow-up. The likelihood of receiving an IC measurement was significantly lower in patients aged ≥75 years (Odds Ratio [OR]: 0.79, 95% confidence interval [CI]: 0.69-0.91) when compared to those aged 45-64 years, in those with a higher eGFR (OR: 0.98, 95%CI: 0.97-0.98 for every ml/min/1.73m² increase) or with glomerulonephritis (OR: 0.64, 95% CI: 0.51-0.79) compared to those with diabetes as cause of renal failure. Cox regression based on the propensity matched cohort (N=2,966) showed that the risk of starting RRT was not different between patients with and without an IC measurement (Hazard Ratio [HR]: 0.90, 95%CI: 0.80-1.02). Also the risk of death was similar (HR: 1.04, 95%CI: 0.91-1.18).

Conclusions: We found that the oldest patients, those with higher eGFR and with glomerulonephritis were least likely to receive an IC measurement. Exposure to IC measurement was neither associated with higher risk of starting RRT for ESRD, nor with higher mortality risk. Based on these findings IC measurement seems to be safe for assessing GFR. Nevertheless, further research in other study populations is warranted to confirm our findings.

FR-PO697

Measurement of Glomerular Filtration Rate by Plasma Iohexol Clearance: Single versus Multiple Samples Method

Pierre Delanaye,[1] Etienne Cavalier.[2] *[1]Nephrology, Univ of Liège, Belgium; [2]Clincial Chemistry, Univ of Liège, Belgium.*

Background: Iohexol plasma clearance is considered as a reference method to measure glomerular filtration rate (GFR). However, different methodologies, have been developed regarding the number of plasma samples needed. In the current study, we tested the concordance between the simple single sample (SS) versus the multiple samples (MS) method.

Methods: We considered the patients referred to our university center for GFR measurement. In all patients, 5 mL of iohexol (Omnipaque™240; 240 mg/mL) are intravenously injected. Iohexol was measured by High Performance Liquid Chromatography. MS plasma clearance were obtained by calculating the clearance from slope calculated with four samples at 120, 180, 240 and 300 min. The result was then corrected by the Brochner-Mortensen equation. SS plasma clearance was calculated at every time with only one concentration and applying the Jacobsson equation. We studied the concordance within ±10%. We tested if the concordance was influenced by the timing of the SS method.

Results: One hundred and twelve patients have been included in the study (52 females): mean age 53±13 years, BMI 27±7 kg/m², GFR 84±29 mL/min (range from 17 to 158 mL/min). If the MS method is considered as the reference, results with SS method at 120, 180, 240 et 300 min had a concordance ±10% of 73, 91, 92 and 70%, respectively. For patients with GFR<50 mL/min (n=13), concordances were 15, 54, 77 and 92%, respectively. For patients with GFR>50 mL/min (n=99), concordances were 80, 96, 94 et 67%, respectively. If the timing of the SS method is chosen according to the expected GFR, i.e. SS at 180 min for patients with GFR>50 and SS at 300 min for patients with GFR<50 mL/min, the concordance will be of 96%.

Conclusions: We showed a good concordance between iohexol plasma clearance obtained with two methodologies, (MS and SS). This is especially concordant if the timing of the SS method is adapted to the expected GFR (180 min if normal GFR and 300 min if lower GFR). In large epidemiological studies, iohexol plasma clearance with SS is a validated and simplified alternative to measure GFR. The timing of this SS strongly influences the results and must be adapted to the GFR level.

FR-PO698

Systematic Renal Function Evaluation Using Iohexol or Inuline Clearance before Lung Transplantation in Adult Cystic Fibrosis Patients

Etienne Novel,[1] Solenne Pelletier,[1] Raphaële Nove-Josserand,[2] Quitterie Reynaud,[2] Stephane Durupt,[2] Laurence Dubourg,[3] Isabelle Durieu,[2] Maurice Laville,[1] Denis Fouque.[1] *[1]Nephrology, Univ Center Hospital – Lyon-Sud, Lyon - Pierre Benite, France; [2]Cystic Fibrosis Adult Center, Univ Center Hospital – Lyon-Sud, Lyon - Pierre Benite, France; [3]Nephrology, Univ Center Hospital – Edouard Herriot, Lyon, France.*

Background: Cystic fibrosis (CF) patients are at risk for kidney injury even before undergoing lung transplantation, because of prolonged exposure to aminoglycoside and complications of diabetes mellitus. The usual equations estimating the glomerular filtration rate (GFR) are not adapted in CF population due to patients low body weight. The aim of our study was to measure precisely the GFR of CF adult patients before lung transplantation.

Methods: Iohexol or Inuline clearance was realized in 21 adult CF patients, when they entered the lung transplant waiting list (n=17) or when the patient was considered by the clinician at high risk for renal disease (n=4). No patient was treated with aminoglycoside at the time of GFR measurement. BMI, history of diabetes mellitus were recorded. Exposure to IV aminoglycoside within the 5 years before GFR measurement was calculated. Urines samples were collected to check for proteinuria and albuminuria.

Results: 57% of CF patients were male, 43% were diabetic. Mean age at GFR measurement was 31 years old. Mean BMI was 19kg/m². 14% of patients had albuminuria of more than 30mg/L and none of them had proteinuria. Mean days of exposure to IV aminoglycoside therapy within the 5 years before GFR evaluation was 169 days (Ranging from 60 to 280 days). Tobramycin was the most used aminoglycoside at the mean posology of 7.6mg/kg/day. GFR was measured using iohexol for 15 patients and inuline was used for the remaining 6 patients. Mean measured GFR was 107mL/min/1.73m². Only 2 patients had a measured GFR between 60 and 90mL/min/1.73m². For these 2 patients, GFR estimation using CKD EPI was unable to detect the moderate decline in kidney function (estimated GFR >90mL/min/1.73m²).

Conclusions: Despite prolonged exposition to high dose of aminoglycoside associated with a high prevalence of diabetes mellitus, no major decline in GFR was observed in our cohort.

FR-PO699

Measurement of Glomerular Filtration Rate by Clearance of Non Radiocative Iothalamate

Yvonne El Kassis,[1] Joe M. El-Khoury,[2] Sihe Wang,[3] Emilio D. Poggio,[1] Georges Nakhoul.[1] *[1]Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH; [2]Laboratory Medicine, Yale Univ, New Haven, CT; [3]Laboratory Medicine, Cleveland Clinic Foundation.*

Background: Assessment of kidney function is best reflected by the Glomerular Filtration Rate (GFR). While GFR can be estimated using creatinine and cystatin-based equations, measurement using exogenous substances is more accurate and often necessary, particularly when precise assessment of renal function is desired (kidney donation). Radioactive iothalamate has commonly been used as a tracer for GFR measurement but the handling of radioactive material is cumbersome and challenging. The goal of our study is to compare the renal clearance (GFR measurement) of radioactive "hot" and non-radioactive "cold" iothalamate.

Methods: Patients received simultaneous sub-cutaneous injections of "hot" ^{125}I Sodium Iothalamate and "cold" Iothalamate Meglumin 60%. Analysis of the marker concentration in serum/urine samples was done by gamma counting (GAMC) of the ^{125}I and by liquid chromatography-tandem mass spectrometry (LCMS) of the "cold" iothalamate. GFR was measured as the renal clearance of "hot" and "cold" Iothalamate. We used scatter plots, regression analysis, correlation coefficient and bias.

Results: Between Oct 2011 and Jan 2013, 36 patients were enrolled. 18 were males (50%). Mean age was 50.9±15.8 years. GFR measurements ranged from 1.67-125.33 ml/min/1.73m² with a mean of 62.87±38.42 ml/min/1.73m² for the "hot" iothalamate and 1.45-122.96 ml/min/1.73m² with a mean of 61.07±37.85 ml/min/1.73m² for the "cold" iothalamate. The correlation coefficient of the 2 measurement methods was 0.99 with a bias of -1.81 ml/min/1.73m² (-2.9%) and an accuracy of 95%.

	Deming
Slope	0.985 (0.942 to 1.028)
Intercept	-0.854 (-4.023 to 2.315)
Std Err Est	4.755

Regression analysis - 95% Confidence Interval are shown in parenthesis

Conclusions: Renal clearance of "cold" iothalamate by LCMS is comparable to renal clearance of "hot" iothalamate by GAMC and offers a safer, less cumbersome option for GFR measurement.

FR-PO700

Creatinine-Based Renal Function Assessment Underestimates Chronic Kidney Disease (CKD) Prevalence: The Northern Manhattan Study (NOMAS) Syed Ali Husain,[1] Joshua Z. Willey,[1] Yeseon Park Moon,[1] Mitchell S.V. Elkind,[1] Ralph L. Sacco,[2] Myles S. Wolf,[3] Ken Cheung,[1] Clinton Wright,[2] Sumit Mohan.[1] *[1]Columbia Univ; [2]Univ of Miami; [3]Northwestern Univ.*

Background: Accurate glomerular filtration rate estimation (eGFR) informs drug dosing, risk stratification, and prognosis. Body composition heterogeneity influences creatinine production and the precision of creatinine-based eGFR ($eGFR_{cr}$) in the elderly. We compared CKD categorization using $eGFR_{cr}$ and cystatin C-based eGFR ($eGFR_{cys}$) in an elderly cohort.

Methods: NOMAS is a predominantly elderly, multi-ethnic cohort (n=3298) with a primary aim to determine stroke and vascular disease risk factors. We included participants with concurrent measured creatinine and cystatin C. $eGFR_{cr}$ was calculated using CKD-EPI 2009 and $eGFR_{cys}$ used CKD-EPI 2012 (cystatin). Logistic regression was used to estimate odds ratios (OR) for correlates of reclassification from $eGFR_{cr}$≥60 to $eGFR_{cys}$<60mL/min.

Results: Participants (n=2988, mean age 69±10yrs) were predominantly >65 years old (61%), Hispanic (53%), female (63%), former/current smokers (53%), and overweight/obese (BMI >25Kg/m^2: 69%). $eGFR_{cys}$ was lower than $eGFR_{cr}$ by mean 23 mL/min, and only 27.7% had a concordant CKD class by both measures.

Table 1: Reclassification of CKD Class by GFR-estimating Equation

$eGFR_{cr}$	$eGFR_{cys}$					Total
	<15	15-29	30-59	60-89	≥90	N
<15	11	1	0	0	0	12
15-29	19	14	0	1	0	34
30-59	10	172	385	41	1	609
60-89	2	48	1181	379	19	1629
≥90	0	8	256	402	38	704
Total	42	243	1822	823	58	2988

Most (78%) had $eGFR_{cr}$≥60 mL/min; of those, 64% had $eGFR_{cys}$<60 mL/min. Among participants with $eGFR_{cr}$ ≥60 mL/min, discordant cystatin C-based CKD diagnosis ($eGFR_{cys}$<60 mL/min) was more likely in those with age >65 (OR 5.68, 4.61-6.99), obesity (OR 2.06 vs BMI≤30, 1.64-2.59), current smokers (OR 1.87 vs non-smokers, 1.41-2.48) and females (OR 1.47, 1.19-1.92).

Conclusions: In a large, multiethnic, elderly cohort with a high BMI, we found a higher prevalence of CKD using $eGFR_{cys}$. Use of $eGFR_{cr}$ may underestimate CKD prevalence, particularly among the elderly, obese, smokers and women. Determining the best method to estimate renal function in elderly populations needs further study.

FR-PO701

Precise Estimation of GFR from Multiple Markers in Clinical Trials Lesley Inker,[1] Ronald D. Perrone,[1] Andrew S. Levey,[1] Hocine Tighiouart,[1] Frank S. Czerwiec,[2] Jaime Blais,[2] Sharin Roth,[2] Lucas Westcott-Baker,[2] Regis Perichon,[3] Josef Coresh.[4] *[1]Tufts Medical Center; [2]Otsuka Pharmaceuticals; [3]Metabolon; [4]Johns Hopkins Univ.*

Background: We showed that a panel of filtration markers (peGFR) can improve precision of estimated GFR compared to creatinine (eGFRcr). Improved ascertainment of endpoints can enhance conduct of clinical trials. As proof of concept, we evaluated the use of peGFR to detect treatment (Tx) effects of tolvaptan in a subset from the TEMPO3:4 pivotal trial (Torres NEJM 2012) compared to eGFRcr.

Methods: 42 (21 tolvaptan and 21 placebo) subjects matched by CKD stage, Mayo imaging classification, sex, age, race, region, hypertension status, and total kidney volume were included. Samples were assayed by Metabolon using LCMS methods for targeted metabolites. eGFRcr was computed using CKD-EPI equation. We examined treatment effects in acute phase after Tx initiation (baseline-week 3), chronic phase on Tx (week 3-month 36), and acute phase after Tx discontinuation (month 36-6 weeks post discontinuation). Tx effect was assessed as the difference in the slope of eGFR between Tx arms using a random effect mixed model with a three piece wise linear spline with knots at week 3 and month 36.

Results: The mean age was 39y and 48% were female. Mean baseline eGFRcr was 78 mL/min/1.73m^2. In the acute phases before or after Tx initiation, there were no differences between tolvaptan and placebo using peGFR or eGFRcr. In the chronic phase, tolvaptan slowed the decline in GFR compared to placebo using peGFR but not using eGFRcr.

	Treatment Effect (Change in GFR Tolvaptan – Change in GFR Placebo)					
	Acute phase on treatment (per month)		Chronic slopes (per year)		Acute phase off treatment (per month)	
	Tx effect (SE)	p	Tx effect (SE)	p	Tx effect (SE)	p
peGFR	-9.8 (3.4)	0.007	2.2 (0.9)	0.03	2.9 (2.5)	0.3
eGFRcr	-8.3 (2.6)	0.003	1.1 (1.1)	0.4	0.7 (2.0)	0.7

Conclusions: In a small subset of TEMPO trial, peGFR appears to enhance discrimination of the treatment effect seen in the overall population. This example provides preliminary support for test of the hypothesis that more precise estimates of GFR could increase efficiency of clinical trials.

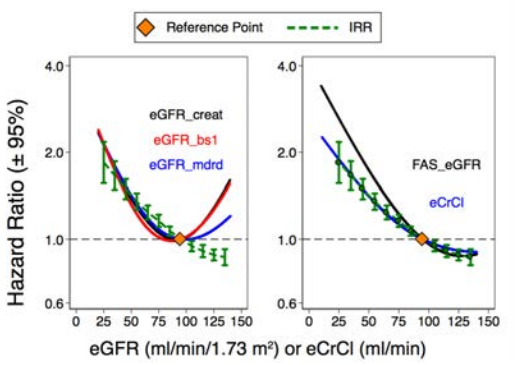
Comparisons of Estimated GFR and Cockcroft Gault Equations: Calibration against Relative Risk for All-Cause Mortality David G. Warnock,[1] Jan A.J.G. van den Brand,[5] Pierre Delanaye,[2] Richard J. Glassock,[3] Hans Pottel.[4] *[1]Medicine, UAB, Birmingham, AL; [2]Nephrology-Dialysis-Transplantation, Univ of Liege, Liege, Belgium; [3]Medicine, Geffen School of Medicine, Los Angeles, CA; [4]Public Health, KU Kulak, Kortrijk, Belgium; [5]Nephrology, Radboud Univ, Nijmegen, Netherlands.*

Background: The Cockcroft-Gault estimated creatinine clearance (eCrCl) equation has poorer precision and accuracy than the creatinine-based estimated GFR (eGFR), but still outperforms these equations in describing the risks of all-cause mortality. The full age spectrum equation (FAS_eGFR) has better accuracy than other creatinine-based eGFR equations, but its performance in assessing mortality risk has not yet been described.

Methods: Multivariable adjusted Cox analyses were done with the REGARDS cohort to assess the hazards for death using eGFR (CKD_EPI (eGFRcreat), MDRD (eGFRmdrd), Berlin Study Initiative (eGFRbs1), FAS_eGFR) and eCrCl as continuous variables. Hazard ratios were compared to Incident Rate Ratios mapped on to the eGFR scale, with a reference value set at 90 ml/min/1.73 m^2 or 90/ml/min.

Results:



The eGFRcreat, eGFRmdrd and eGFRbs1 equations had increased hazards for mortality above the reference eGFR ("J-curve"). This was not seen with eCrCl or FAS_eGFR equations, which were better calibrated with the Incident Rate Ratio curve above the reference eGFR, while eCrCl was better calibrated than FAS_eGFR below the reference eGFR value.

Conclusions: None of the current models optimize both estimation of measured GFR and risk assessment. The FAS_eGFR equation parallels the Relative Risk curves below the reference eGFR; a simple linear adjustment should improve its calibration. In contrast, the "J-curves" for the other eGFR equations cannot be resolved with simple linear adjustments of the hazard ratios above the reference eGFR value.

Formulas Do Not Reflect Renal Function Decline in CKD: The Nephrologist in the Mist

Ana Aldea Perona, Sergio Luis Lima, Natalia Negrín, Federico J. Gonzalez-Rinne, Armando Torres, Esteban Porrini, Victor Lorenzo. *Hospital Univ de Canarias, La Laguna, Spain.*

Background: The error of estimated GFR (eGFR) may jeopardize clinical trials designed to prevent CKD. However, the agreement between eGFR and measured (mGFR) decline has been seldom analyzed.

Methods: NEFROVID clinical trial (NCT01442272) evaluates the impact of calcifediol,paricalcitol or standard therapy in reducing proteinuria in CKD. mGFR was assessed in a subgroup of 13 patients by the clearance of iohexol and by 52 formulas every 3-m during 12 months. The agreement between mGFR and eGFR-derived declines was tested by the Concordance Correlation Coeficient (CCC).

Results: CCC ranged from 17 to 60 (~42%), indicating that 90% of eGFR showed an error of ±42% compared with mGFR. In some cases the error was severe for all formulas (case 12); indicated false slow (case 6) or faster decline (case 10) or improvement in GFR decline (case 8), (similar results were observed for all equations).

FR-PO704

When Creatinine Clearance and Estimated GFR Do Not Agree: The Use of a Gold Standard Method to Measure Renal Function in Clinical Practise

Esteban Porrini, Sara Estupiñan, Patricia Delgado Mallen, Marian Cobo, Aurelio Rodriguez, Rosa Miquel, Sergio Luis Lima, Natalia Negrín, Armando Torres. *Hospital Univ de Canarias, La Laguna, Spain.*

Background: Estimated GFR by formulas (eGFR) has a wide error in reflecting renal function in patients with diabetes, Chronic Kidney Disease (CKD), renal transplantation, polycystic disease and in healthy subjects. However, the impact of this error in day-to-day clinical practice has not been properly studied.

Methods: We studied 31 subjects who had a relevant dissociation between creatinine clearance (CrCl) and eGFR (MDRD), which limited the evaluation of renal function. We defined a relevant dissociation as a difference ≥20% between CrCl and eGFR. Also, GFR was measured (mGFR) in all patients by a gold standard, th iohexol plasma clearance. Subjects were divided in those with proven evidence of renal disease, from the outpatient clinic, and those without evidence of renal disease, referred from general practitioners.

Results: 20 subjects had no evidence of renal disease and 11 had CKD of diverse causes: unknown (n=1), CKD (n=5), lupus nephropathy (n=1), tubulointerstitial nephriis (n=1), diabetic nephropathy (n=3).

	No history of renal disease	History of CKD
N	20	11
Age	46.7±17.8	47.8±16.8
Gender (male)	20 (100%)	8 (73%)
Serum creatinine mg/dl	1.36±0.14	2±0.72*
eGFR-MDRD (ml/min)	66.3±13.2	46.1±21.8*
CrCl (ml/min)	108.3±23.2	73.8±32.9*
Diff. CrCl vs MDRD (%)	37.7±10.2	35.7±22.2*
mGFR (ml/min)	88.6±17.0	49.9±19.4*

The difference between eGFR and CrCL was about 40%, and CrCL was frequently higher than eGFR. Of note, mGFR showed values in between eGFR and CrCL. Renal ecography was normal in subjects with no history of renal disease.

Conclusions: mGFR is restricted to clinical research. However, the use of mGFR may be considered in especial clinical conditions, like these patients in whom standard methods do not allow an accurate and precise diagnosis of real renal function. The error of eGFR may have important consequences in clinical practice, which needs further study. *$p<0.05$.

Prevalence of Chronic Kidney Disease According to eGFR Derived from Standardized Serum Creatinine: A Population-Based Study

Arnar Jan Jonsson,[1,2] Sigrun Helga Lund,[2] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland; [2]Univ of Iceland, Reykjavik, Iceland.*

Background: Standardization of serum creatinine measurements (SCr) has improved the utility of SCr-based equations for estimating glomerular filtration rate (eGFR). The purpose of this study was to estimate the prevalence of chronic kidney disease (CKD) in Iceland based on eGFR derived from standardized SCr.

Methods: In this retrospective study, we obtained all SCr values from all clinical laboratories in Iceland for the years, 2008-2013. Information on age and sex was also obtained. Using computerized algorithms, we exclued SCr values during episodes of acute kidney injury. eGFR was calculated using the CKD-EPI equation. CKD was defined as eGFR <60 mL/min/1.73 m^2 for more than 3 months and staged according to the KDIGO classification system. Period prevalence of CKD stages 3-5 was calculated based on the population of individuals aged 18 years or above in Iceland, which numbered 245,631 on December 31, 2013.

Results: We retrieved 1,523,914 SCr values for 198,289 individuals aged 18 years and older. The median age was 60 years and 46% were male. The crude prevalence was in men and í women, The age-adjusted prevalence rate per 100,000 in men was 975 for CKD 3A, 269 for CKD 3B, 86 for CKD 4, and 33 for CKD 5. In women, the age-adjusted prevalence rate per 100,000 was 1314 for CKD 3A, 382 for CKD 3B, 86 for CKD 4, and 21 for CKD 5. The prevalence of CKD stages 3-5 increased with advancing age, from 31/100,000 in the age group 18-39 years, 261/100,000 in the age group 40-59 years, 1761/100,000 in the age group 60-69 years, 6003/100,000 in the age group 70-79 years and 12116/100,000 in those who were 80 years of age or older.

Conclusions: This nationwide study, which included standardized SCr measurements and comprises a large proportion of the Icelandic population, demonstrates lower prevalence of CKD stages 3-5 compared with previous studies in Iceland.

FR-PO706

Effect of Large Weight Reductions on Measured and Estimated Kidney Function Bernt Johan Illum von Scholten,[1] Frederik I. Persson,[1] Maria S. Svane,[2] Tine Hansen,[1] Sten Madsbad,[2] Peter Rossing.[1] *[1]Steno Diabetes Center; [2]Hvidovre Hospital.*

Background: In patients undergoing gastric bypass surgery and subsequently experiencing fast and large weight loss, muscle mass may be affected followed by changes in plasma creatinine (pCr). The MDRD and CKD-EPI equations for eGFR include creatinine. Serum cystatin C levels provide alternative GFR estimates not linked to muscle mass. We determined the effects of large weight loss after gastric bypass surgery on measured GFR and compared these changes with changes in eGFR.

Methods: Prospective, intervention study including 19 patients. All attended a baseline visit before gastric bypass surgery followed by a visit 6 months post-surgery. Renal function (mGFR) was assessed during four hours plasma ^{51}Cr-EDTA measurement by standard methods. PCr and cystatin C (cysC) were measured and GFR estimated by four different equations (MDRD, CKD-EPI-pCr, CKD-EPI-cysC and CKD-EPI-pCr-cysC) (ClinicalTrials.gov,NCT02138565).

Results: Patients were (mean±SD) 40.0±9.3 years, 14 (74%) were female and 5 (26%) had type 2 diabetes. Baseline weight was 127±21 kg, BMI 42±6 kg/m^2 and mGFR 88±17 ml/min/1.73m^2. At baseline, mGFR correlated with all estimates of GFR (R>0.50;$p\leq$0.025), except MDRD (p=0.093). Six months post-surgery weight loss was 27 (95% CI: 23; 31) kg, mGFR changed -9 (-17; -2) from 122 to 113 ml/min (p=0.024); adjusted for body surface area (BSA) mGFR was insignificantly changed +2 (-5; 9) ml/min/1.73m^2 (p=0.52). CKD-EPI-pCr eGFR increased by 12 (6; 17) (p<0.001) and MDRD eGFR by 13 (8; 18) (p<0.001), while CKD-EPI-cysC eGFR was changed by -2 (-8; 4) ml/min/1.73m^2 (p=0.51). Post-surgery mGFR correlated with all GFR estimates (R>0.60;$p\leq$0.008). Change in mGFR correlated with change in MDRD eGFR (R=0.50,p=0.030), but not with changes in other eGFR measures ($p\geq$0.08).

Conclusions: A weight loss of 27 kg achieved after gastric bypass surgery was associated with a reduction in mGFR of 9 ml/min but unchanged after adjustment for BSA. CKD-EPI-pCr and MDRD eGFR were increased, whereas CKD-EPI-cysC eGFR reflected the unchanged mGFR. eGFR equations based on creatinine should be carefully interpreted in patients experiencing large weight reductions, likely due to muscle mass change affecting creatinine.

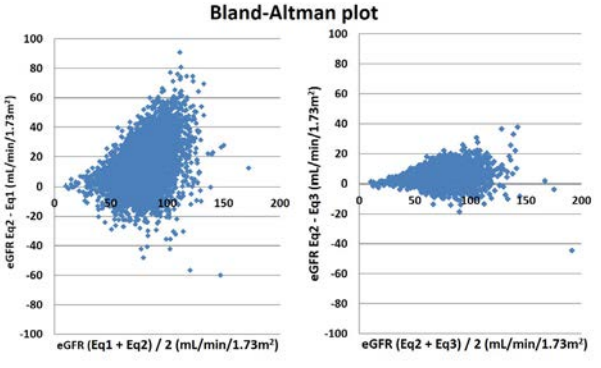
FR-PO707

Clinical Impact of Nutritious Status to Estimate GFR among Japanese Health-Check Subjects Yoshinari Yasuda, Shoichi Maruyama. *CKD Intiatives/ Nephrology, Nagoya Univ, Nagoya, Japan.*

Background: Accurate estimation of GFR is essential in diagnosis and severity classification of CKD. Utility of various GFR equations based on sCr and cystatin-C (Cys) were analyzed in this study.

Methods: The study subjects were 6,635 health-check subjects (3,234 females) in a single center in Aichi prefecture, Japan. IDMS-traceable sCr values were measured by enzymatic method and standardized Cys values were measured by immunonephelometry. Estimated GFR was calculated by Japanese GFR equations based on age, gender and sCr (Eq1) or Cys (Eq2), and by Eq3 based on age, gender, sCr, albumin and UN, eGFR=142×sCr$^{-0.923}$ ×Age$^{-0.185}$ ×Alb$^{0.414}$ ×UN$^{-0.233}$×0.772 (if female) (AJKD2009).

Results: Baseline characteristics (mean ± SD) of study subjects in male and female were 66.0 ± 11.5 and 63.4 ± 11.2 years old (yo), 166.4 ± 6.4 and 154.1 ± 6.1 cm, 63.7 ± 9.5 and 51.6 ± 7.8 kg, sCr: 0.91 ± 0.21 and 0.65 ± 0.13 mg/dL and Cys: 0.94 ± 0.23 and 0.81 ± 0.17 g/L. Both sCr and Cys increased as age developed, but exceeding upper-limit value rate was significantly high in Cys among elderly compared to sCr (male: 29.6 vs 7.3% in 60-69 yo, 50.5 vs 12.3% in 70-79 yo and 80.5 vs 16.7% in 80- yo, female: 21.3 vs1.5% in 60-69 yo, 43.5 vs 2.0% in 70-79 yo and 76.7 vs 21.1% in 80- yo), suggesting body muscle mass effect in sCr. CKD prevalence (GFR category 3a/3b and above) in Eq1 was significantly high compared to Eq2 and Eq3 (male: 23.3/3.9, 9.2/7.0, 14.7/2.5%, female: 16.5/1.5, 4.5/0.1, 8.7/0.9%). Bland-Altman plot revealed a systemic error between Eq1 and Eq2 especially in cases with high GFR values, but not between Eq2 and Eq3, suggesting considerable underestimation of GFR by Eq1.



Conclusions: Different GFR equations seriously affected CKD prevalence. Cys based equation and sCr based equation evaluating nutritious status would be more accurate among health-check subjects, probably because of high body muscle mass.

FR-PO708

Coronal Sectional Areas of the Kidney Components Measured by Noncontrast-Enhanced Steady-State Free Precession Magnetic Resonance Imaging with Spatially Selective Inversion Recovery Pulse and Their Association with Chronic Kidney Disease Tadashi Otsuka,[1] Ryohei Kaseda,[2] Yoshikatsu Kaneko,[2] Ryuzi Aoyagi,[1] Ichiei Narita.[2] *[1]Nephrology, Tachikawa General Hospital, Japan; [2]Nephrology, Niigata Univ, Japan.*

Background: Kidney imaging by magnetic resonance imaging (MRI) has been expected as a powerful tool to diagnose renal lesions. However, without contrast agents, it has been difficult to distinguish renal compartments clearly such as renal cortex or medulla region. Recently, noncontrast-enhanced steady-state free precession (SSFP) MRI with spatially selective inversion recovery (IR) pulse was reported to improve the visibility of renal corticomedullary differentiation in patients with renal insufficiency. Using this method, we investigated the correlations between renal function and segmental areas of the kidney compartments.

Methods: A total of 85 patients (aged 64±17 years) with CKD (mean estimated glomerular filtration rate [eGFR], 54.0 ± 24.5 ml/min/1.73 m^2) were recruited for this study. CKD patients were classified into four groups: The chronic glomerulonephritis group (CGN; n=34), the diabetic nephropathy group (DN; n=19), the nephrosclerosis group (BNS; n=15), and others (n=17). All patients underwent noncontrast-enhanced SSFP MRI with spatially selective IR pulse. The coronal sectional areas of kidney cortex, medulla and the maximum and minimum cortical thickness were measured.

Results: eGFR was positively correlated with coronal sectional areas of kidney cortex (R^2=0.53, P<0.001), medulla (R^2=0.28, P<0.001), and maximum cortical thickness (R^2=0.36, P<0.001) and minimum cortical thickness (R^2=0.47, P<0.001). Among DN and BNS, the correlation efficiency of eGFR with area of medulla (R^2=0.66, P<0.001; R2=0.63, P<0.001) was significantly higher than with other compartments. By contrast, in CGN, eGFR had no correlation with the area of medulla (R^2=0.06, P=0.07) and highest correlation was observed with the area of cortex (R^2=0.44, P<0.001).

Conclusions: Two-dimensional quantitative assessment of kidney compartments by noncontrast-enhanced SSFP MRI with spatially selective IR pulse significantly correlates with renal function and could provide specific information for differentiating the etiology of CKD.

FR-PO709

Surveillance of CKD Epidemiology in the U.S. – A Joint Analysis of NHANES and KEEP Orrin Myers, V. Shane Pankratz, Mark L. Unruh, Christos Argyropoulos. *Internal Medicine, Univ New Mexico, Albuquerque, NM.*

Background: Chronic kidney disease (CKD), although a growing public health issue, lacks a nationwide surveillance system. Large voluntary, community based detection programs (e.g. KEEP) have been used but have limitations due to self-selection. Surveillance with representative samples (e.g. NHANES) is limited because they do not capture sufficiently detailed data. We applied selection models to assess whether KEEP data can be adjusted to reflect trends in CKD prevalence from 2001-2012 as observed in NHANES.

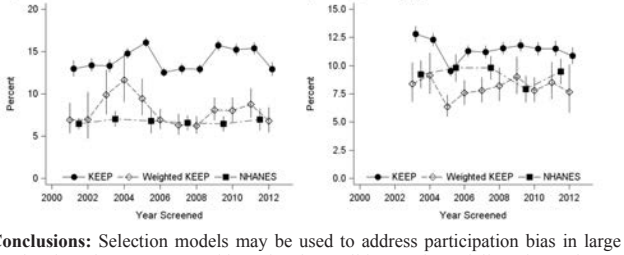
Methods: Selection models to predict KEEP participation were based on data collected 2001-2012 by KEEP and NHANES. Variables included demographic, socio-economic, and health-related indicators. Prevalence of CKD endpoints, eGFR<60 mL/min/1.73m^2, and ACR≥30 mg/g, were estimated by weighted logistic regression analyses that included random effects to account for state-level variation in recruitment practices.

Results: NHANES and KEEP samples included 27,565 and 127,149 participants, respectively. Participation bias was dramatically reduced after accounting for participation. KEEP (eGFR<60) estimates dropped from 14.3% to 8.0% when defining CKD as eGFR<60, and from 11.4% to 8.1% when defined as ACR≥30. NHANES estimates were 6.7% and 9.2%, respectively. Weighted CKD prevalence by year showed very good agreement with NHANES.

Table 1. Prevalence of eGFR<60 and ACR≥30.

	eGFR<60		ACR≥30	
Data and Model	**%**	**95% CI**	**%**	**95% CI**
NHANES	6.72	6.29 - 7.16	9.25	8.73 - 9.77
KEEP Unweighted	14.31	13.19 - 15.50	11.35	10.75 - 11.98
KEEP Weighted	8.01	7.02 - 9.12	8.07	7.25 - 897

Figure 1. Prevalence of eGFR < 60 ml/min/1.73 m^2 (A) and ACR ≥ 30 mg/g (B) by year for KEEP and NHANES.



Conclusions: Selection models may be used to address participation bias in large community detection programs. This makes it possible to substantially enhance inputs for future CKD surveillance systems that provide spatio-temporal maps of CKD hotspots in the US.

Funding: Private Foundation Support

FR-PO710

Secular Trends in Increase in the Prevalence of CKD in Diabetes Tracks the Secular Trends in Lower Systolic and Diastolic Blood Pressures in the U.S. Srini Beddhu,[1,2] Alfred K. Cheung,[1,2] Guo Wei,[1] R. E. Boucher,[1] Rabia Nadeem Kiani,[1] Tom Greene.[1] *[1]Univ of Utah, SLC, UT; [2]VA, SLC, UT.*

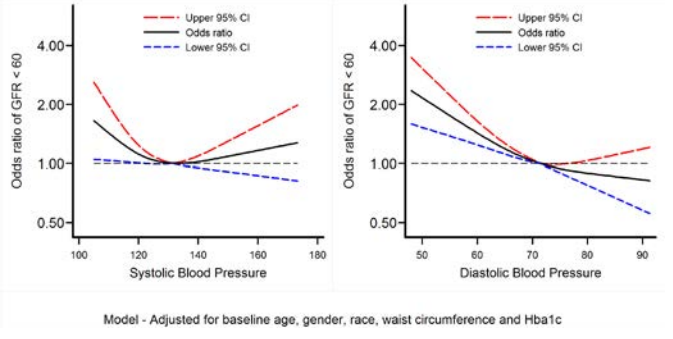
Background: Recent studies indicate intensive BP control might ↑ the incidence of CKD, yet ↓ the risk for mortality in those with established CKD. Hence, greater BP control might result in ↑ prevalence of CKD at the population level.

Methods: Using 1988-1994 (National Health And Nutrition Examination Survey) NHANES III as the reference, survey weight adjusted secular trends in prevalence of CKD (eGFR < 60 ml/min/1.73 m^2) in diabetics in 1999-2002, 2003-2006 and 2007-2010 NHANES were examined. Similarly, trends in SBP and DBP in diabetics with and without CKD were examined. Using median SBP or DBP as the reference, the odds of CKD in diabetics in the entire cohort were related to SBP or DBP in natural cubic spline regression models in svy suite using STATA 14.

Results: The prevalence of CKD in diabetics in the US has increased. In parallel, there has been a drop in SBP and DBP in diabetics without and with CKD but the drop has been more pronounced in CKD.

Diabetics in Survey	CKD prevalence in diabetics (%)	Non-CKD diabetics		CKD diabetics	
		SBP	DBP	SBP	DBP
NHANES III (N =1842)	13.3	133 ± 25	76 ± 13	146 ± 30	74 ± 16
1999-2002 (N=1078)	16.7	132 ± 18	73 ± 13	144 ± 25	61 ± 21
2003-2006 (N=1170)	18.1	131 ± 17	71 ± 12	139 ± 24	61 ± 18
2007-2010 (N=1793)	17.4	128 ± 19	70 ± 13	133 ± 24	60 ± 17

In spline regression analyses, lower SBP and DBP were associated with higher odds of CKD in diabetics.



Conclusions: Secular trends in increase in the prevalence of CKD in diabetics track the secular trends in drop in both SBP and DBP in the US population. This might reflect hemodynamic effects of intensive BP lowering that increases CKD incidence, practice patterns of more intensive BP lowering in CKD or decreased mortality with intensive BP lowering in CKD.

Prediction of Pathologic Proteinuria by Dipstick Albuminuria and the Specific Gravity Hajeong Lee,[1] Hee Gyung Kang.[2] *[1]Internal Medicine, Seoul National Univ Hospital, Korea; [2]Pediatrics, Seoul National Univ College of Medicine, Korea.*

Background: Proteinuria is essential to diagnose kidney disease. Urine dipstick test is easy to recognize pathologic proteinuria with lower cost, so usual health examination programs use it for screening of kidney diseases. However, spot urine dipstick albumin (DSA) is affect by urine specific gravity (USG). The impact of USG on estimation of proteinuria remains obscure.

Methods: We included patients who were tested DSA, spot urine protein to creatinine ratio (UPCR) and spot urine albumin to creatinine ratio (UACR) in the same day from 2010 to 2013. Pathologic proteinuria was defined as UPCR ≥0.2 g/g creatinine. Albuminuria was divided as microalbuminuria (UACR 0.03~0.30 g/g) and macroalbuminuria (UACR >0.30 g/g). A random 60% of the cohort was used to generate a development model, which was validated in the remaining 40%. Samples were stratified according to DSA and SG values. A DSA versus SG matrix was created, and each sample was allocated to a discrete DSA-SG category. Proportions of samples with pathologic proteinuria, microalbuminuria, macroalbuminuria were calculated for all 42 cells.

Results: A total of 86,874 cases of UPCR and 52,459 cases of UACR were collected. Associations between DSA and UPCR/UACR was different according to the USG. In the diluted urine with USG ≤1.010, more than 80% of patients with dipstick albumin 1+ had pathologic proteinuria. However, in the concentrated urine with USG ≥1.025, it was less than 5%. Using DSA-SG combination, we developed pathologic proteinuria, microalbuminuria, and macroalbuminuria prediction model. Optimum correlation between DSA-SG cells and UPCR/UACR were determined for development model. Accuracy for pathologic proteinuria, microalbuminuria, and macroalbuminuria were 90.1%, 84.0%, and 95.8%, respectively. Moreover, positive predictive values were 93.7%, 74.9%, and 89.2%.

Conclusions: A novel algorism to predict pathologic proteinuria and proteinuria quantitation using USG and DSA may be helpful to screening kidney disease more precisely.

FR-PO712

A Stochastic Model for the Waiting Time of Creatinine Rise to a Critical Level in Post Renal Transplant Period Chandra M. Pandey,[1] Sonam Bedi,[1] Raj K. Sharma,[2] Sada Nand Dwivedi.[3] *[1]Biostatistics and Health Informatics, Sanjay Gandhi Postgraduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, India; [2]Nephrology, Sanjay Gandhi Postgraduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, India; [3]Biostatistics, All India Inst of Medical Sciences, New Delhi, Delhi, India.*

Background: Elevated creatinine is a signal to poor functioning of allograft. There is a need to estimate the risk of rise in creatinine to a critical level, which is not observable directly.

Methods: A stochastic model with varied risk of creatinine rise is proposed to estimate the above risk. The underlying assumptions are: time to achieve the critical level in days was taken as random variable. Π and $(1-\Pi)$ is the proportion of transplant cases whose creatinine rise to critical level in a small length of time t to Δt is $\lambda_1\Delta t$ and $\lambda_2\Delta t$; where $\lambda_1<\lambda_2$. The probability density function of duration derived follows multinomial distribution with parameters λ_1, λ_2 and Π. The parameters are estimated using Maximum Likelihood Estimation method. The pilot values were given as an initial input. The estimates produced by previous iteration was given as input for subsequent iteration. The iteration process was repeated till the convergence was achieved and output at this level was taken as final estimate of these parameters. The variances and co-variances of the estimates are also obtained. The model was applied to 430 transplants performed at SGPGIMS during Jan 2008 to Dec 2013. The creatinine level within 20 days of discharge was considered as baseline. A rise of at least 30% to this baseline was considered as critical level of creatinine. The model has been applied to recipients within the first year of follow up.

Results: The model explained the data set ($\chi 2$=0.90). The estimate of parameters is: Π=0.5797, λ_1=0.0403 and λ_2=0.2427. About 40% of transplant cases belonged to high risk group, while 60% to low risk group.

Conclusions: The frequency and pattern of creatinine rise may help in formulating more precise and patient centric management strategy in post-transplant period.

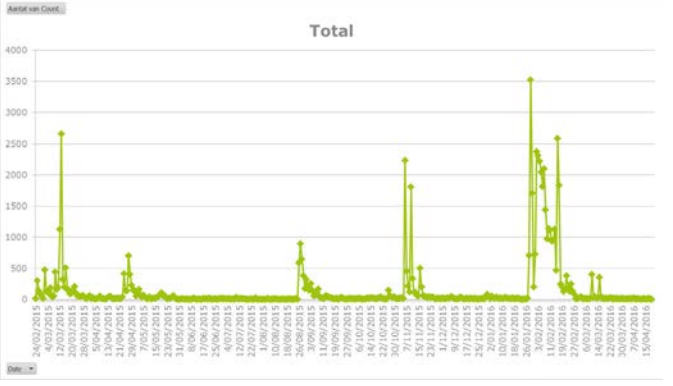
FR-PO713

Facebook® Can Be Used to Reach a Target Audience to Screen for CKD Risk Using the QKidney®-2014 Risk Calculator Eric E. Gheuens, Koenraad Peter Bouman, Ronald Daelemans. *ZNA Kidney Clinic, Ziekenhuis Netwerk Antwerpen, Antwerpen, Belgium.*

Background: On World Kidney Day (WKD) 2015 we launched the QKidney®-2014 risk calculator (www.Qkidney.org) to screen for CKD risk in the general population, aged between 35 and 75 years.

Methods: A webpage was created (wereldnierdag.zna.be) and launched on WKD 2015 using different traditional campaigns. In February 2016 we launched a Facebook® advertising campaign targeting users in the desired age group.

Results: The first weeks after the launch the risk calculator was used by about 5000 people. In the proceeding year a steady activity on the website created about 30.000 records. In February 2016, almost a year after the launch, the Facebook advertising campaign was active during two weeks. The website was viewed almost 600.000 times by about 350.000 unique users. 329.000 views were on desktops and 270.000 on mobile devices. Around 30.000 new records were created in this short time span.



There was a need to monitor the Facebook® page on a daily basis, since many messages were posted and discussions ensued that needed to be moderated. All in all the atmosphere on the page was very positive and very few negative reactions were posted.

Conclusions: Screening for CKD risk with an online risk calculator (QKidney®-2014) targeted to a specific audience via a Facebook® advertising campaign was highly effective. The use of social media in order to reach a specific target population to deliver a health related message should be explored more often.

FR-PO714

Chronic Kidney Disease(CKD) in HIV-Infected Patients: Relation to Viral Load Justine Johnson,[1] Eric Joseph Lai,[1] Wadi N. Suki,[1] Duc T.M. Nguyen,[2] Edward Graviss.[2] *[1]Dept of Medicine, Houston Methodist Hospital, Houston, TX; [2]Pathology, Houston Methodist Hospital, Houston, TX.*

Background: Since the advent of HAART, HIV-associated nephropathy has evolved from a disorder characterized by proteinuria and glomerulosclerosis to one with clinical characteristics more suggestive of tubulo-interstitial disease . The object of this study was to investigate the prevalence of CKD in a large HIV-infected population and viral load and CD4 counts as indices of effective HAART.

Methods: Electronic Medical Records of 3858 HIV-infected patients at a community health clinic were reviewed. Demographic characteristics and laboratory values for serum creatinine (SCr), CD4 count, and viral load were collected. Estimated GFR (eGFR) was calculated from the SCr by the CKD-Epi equation. CKD was considered as eGFR <60 ml/min/1.73m^2. Differences across kidney function stages were compared using Chi-square or Fisher's exact tests for categorical variables and Kruskal-Wallis test for continuous variables as appropriate. Univariate and multivariate ordinal logistic regression models were used to examine the relationship between kidney function stages and potential comorbidities. Representative comorbdities included hypertension, diabetes, cardiovascular disease. All analyses were performed on Stata version 13.1 (StataCorp LP, College Station, TX). A p-value of <0.05 was considered statistically significant.

Results: Patients with CKD represented 4.1% of the population; they were older, and had a higher representation of females. On ordinal logistic regression analysis, there was a highly significant association of CKD with viral load <50 copies/ml (OR+1.73, CI1.46 to 2.05, p<0.001), but not with the CD4 count.

Conclusions: Low or undetectable HIV viral load is generally indicative of a high degree of HAART medication compliance. The association of CKD with very low or undetectable viral load indicates that HAART medications are responsible for the high prevalence of CKD in these patients.

FR-PO715

Identification of Chronic Kidney Disease in the Veterans Affairs Healthcare System Rajiv Saran,[1] Anca Tilea,[1] Vahakn B. Shahinian,[1] Aaron Pearson,[1] Jennifer L. Bragg-Gresham,[1] Hal Morgenstern,[1] Brenda W. Gillespie,[1] Alan B. Leichtman,[1] Ann M. O'Hare,[2] John R. Hotchkiss,[2] Daniel F. Balkovetz,[2] Susan T. Crowley.[2] *[1]Univ of Michigan; [2]VA Healthcare System.*

Background: The strict application of the KDIGO definition for CKD surveillance in the VA HCS may miss cases; a more liberal case definition may improve sensitivity. We estimated VA CKD prevalence using two different definitions in existing operational data in the VA Renal Information System (VA REINS).

Methods: CKD prevalence was examined using laboratory data and ICD-9 codes from 2006-2014. Proteinuria was hierarchically categorized using any urine tests for albumin excretion rate (AER), albumin- creatinine ratio (ACR), protein excretion rate (PER), protein-creatinine ratio (PCR), or urine dipstick. GFR was estimated from outpatient serum creatinine. CKD prevalence was assessed using both strict KDIGO-specific criteria (evidence of persistent lab abnormality) and 'liberal' definitions of CKD. The denominator was defined operationally as the population of VA HCS 'users' (with ≥1 contact with VA in that or 2 previous yrs).

Results: Among 6,932,278 VA users in 2014, CKD prevalence using KDIGO criteria was 16.4%, whereas the liberal definition increased prevalence to 36.3% (Table). Only 3.2% had an ICD-9 diagnosis of CKD, while 74% had at least 2 eGFR measurements available and 74.5% had urinary protein assessment (29.4% with quantitative evaluation).

Liberal CKD Definition	N=6,932,278	%
Any eGFR <60ml/min/1.73m2	1,869,755	27
Proteinuria moderate or worse	1,342,435	19.4
CKD ICD-9 diagnosis	220,666	3.2
Total CKD	2,516,475	36.3
Strict CKD Definition		
Persistent eGFR <60 ml/min/1.73m2	713,068	10.2
ACR/PCR/AER/PER moderate or worse	555,778	8.0
CKD ICD-9 diagnosis	220,666	3.2
Total CKD	1,140,382	16.4

Conclusions: In the VAHCS there are substantial differences in CKD prevalence depending on the stringency of definition applied. The definition of CKD has implications for VA CKD population health management to ensure Veteran access to CKD care.

Funding: VA Support

FR-PO716

Prevalence of Chronic Renal Disease in Afro-Brazilian Isolated Communities in Brazilian Northeast Natalino Salgado Filho, Joyce S. Lages, Dyego José Araujo Brito, Laisson De Moura Feitoza, Francisco Monteiro Jr, Denizar Vianna, Gyl Barros-Silva, Elton Jonh Freitas Santos. *Federal Univ of Maranhão, Brazil.*

Background: In Brazil, *there are no consistent studies* investigating the prevalence of chronic renal disease in its Afro-descendant population. The objective was to investigate the prevalence of chronic renal disease (CRD) in 32 isolated Afro-descendant communities existing in the state of Maranhao, Northeast of Brazil.

Methods: This study included 1539 individuals living in rural areas. Epidemiological, clinical, and laboratory and anthropometric aspects were evaluated. The glomerular filtration rate (GFR) was estimated using CKD-EPI Creatinine (CKD-EPIcr), CKD-EPI Cystatin C (CKD-EPIcy), CKD-EPI Creatinine-Cystatin C (CKD-EPIcc) e MDRD. For the diagnosis and classification of CRD, the KDIGO (2012) criteria were applied.

Results: The gender most frequent was female (50,5%). The average age was 44,4 (±17,3) years, 616 (42,5%) without fixed income, 592(40,9%) have less than three years of study, 159 (10,98%) were smokers, 611 (42,2%) consumed alcohol regularly, diabetes was diagnosed in 91 (6,29%), hypertension in 427 (29,51%) and overweight and obesity in 653(45%). The evaluation of GFR for the stages 3A, 3B and V was respectively: 0.76, 0.14 and 0 (MDRD); 0.97, 0.14 and 0 (CKD-EPIcr); 3.32, 1.31 and 0.07 (CKD-EPIcy). It was not found individual with these stages when we used CKD-EPIcc equation.

Conclusions: The prevalence of CRD in Brazilian Afro-descendant communities, with low average age and socially vulnerable, was less than previously reported for others populations and presented wide variation of results according to the GFR measurement method used.

FR-PO717

Ovarian Reserve and Fertility Hormonal Profiles in Women with Chronic Kidney Disease Kate Bramham,[1,2] Aasmita Gautam,[1] Kate S. Wiles,[1] Lucy C. Chappell.[1] *[1]Div of Women's Health, King's College London, London, United Kingdom; [2]Dept of Renal Sciences, King's College London, London, United Kingdom.*

Background: Fertility is reported to be reduced in women with increasing severity of chronic kidney disease (CKD). Improved understanding of fertility assessment in women with impaired renal function will enable women with CKD to make informed choices about planning future pregnancy. Previous studies of reproductive hormones in women with CKD are small and the relationship between the novel biomarker of ovarian reserve, Anti-Mullerian Hormone (AMH) and renal function has not been explored. The objective of this study was to define the relationships between glomerular filtration rate (GFR) and i) reproductive hormones (follicle stimulating hormone (FSH), luteinising hormone (LH), oestradiol, progesterone and prolactin) ii) AMH, in women with CKD and healthy controls.

Methods: 94 women with CKD (Stage 1: 24 (23.1%); Stage 2: 23 (22.1%); Stage 3:35 (31.8%); Stage 4 and 5: 14 (13.5%) and 10(9.6%) healthy female controls were recruited. Participants provided a single blood sample for analysis. Fertility hormones were quantified by standard laboratory assays and their relationship with GFR assessed.

Results: AMH was not affected by GFR after adjustment for age. However there was a strong association between maternal age and AMH in women with CKD (R= -0.474, value p<0.005). No significant relationships were identified between GFR and FSH, oestradiol, progesterone after adjustment for age. However, there were significant negative correlations between LH and GFR despite correction for age (R= -0.231, p= 0.020), and between prolactin and GFR (R= -0.271, p= 0.005).

Conclusions: CKD does not appear to be associated with reduced ovarian reserve, thus AMH could be a useful tool in the assessment of ovarian reserve in women with CKD as its quantification is not affected by renal function. Serum prolactin increases with worsening GFR which is likely to reflect reduced excretion. Another novel finding was the increase in LH with reduced GFR and requires confirmation in a larger cohort.

Funding: Government Support - Non-U.S.

FR-PO718

Antiretroviral Treatment and Chronic Kidney Disease in Urban Zambia: Cohort Characteristics and Association with Chronic Kidney Disease Martin G. Zeier. *Div of Nephrology, Heidelberg Univ Hospital, Heidelberg, Germany.*

Background: The widespread use of antiretroviral-treatment (ART) increases life spans in Sub-Saharan-Africa (SSA). This goes along with an increase in non-communicable diseases, e.g. chronic kidney disease (CKD).

Methods: Study design Retrospective cohort study **Setting & Participants** Routine data of 1119 HIV patients were assessed for CKD in Lusaka/Zambia between 2011 and 2013 in a quasi-random sample. Inclusion criteria were at least one serum creatinine measurement and 90 days on ART. **Predictor OR Factor** HIV-infection, high blood pressure, ART-medication **Outcomes** We compared patients' conditions prior to ART initiation and at the last observation and applied multivariate models to assess the association between ART and eGFR. The CKD-EPI equation was used to estimate the glomerular filtration rate (eGFR) without the correction factor for African Americans.

Results: Ultimately, 28.2% of patients had eGFR category 2-5 (5.5% < 60 ml/min), compared to 24.8% (4.8%) prior to ART initiation. Hypertension was recorded in 26% of patients. 83% ever received Tenofovir (TDF). 12% of patients who later switched to TDF-free ART (TscART) had baseline eGFR categories3-5. eGFR deteriorated in 41% of

TscART patients, compared to 20% in the rest. Overall, 93% of patients with initial eGFR category 3-5 kept eGFR constant or improved. 20% newly developed high blood pressure, 40% of those with eGFR category 3-5 at baseline. Multivariate models revealed a negative effect of TDF on GFR. **Limitations** One creatinine measurement, 45% baseline creatinine values missing, no assessment of proteinuria.

Conclusions: Impaired renal function including CKD is a relevant health problem in HIV patients in SSA, growing with treatment duration. Patients with initially no/mild renal impairment experienced a loss of eGFR, in particular if receiving TDF. Baseline moderately/severely impaired patients retain or improve renal function on ART. Kidney monitoring is recommended, but should not delay access to ART.

FR-PO719

Glomerular Filtration Rate Is Low in the Inflammatory Arthritis Diseases Compared to Healthy Population: Essential Role of Inflammation

Suad Ma Hannawi,[1] Issa A.L. Salmi.[2] *[1]Internal Medicine, Ministry of Health, Dubai, United Arab Emirates; [2]The Renal Medicine Dept, The Royal Hospital, Muscat, Oman.*

Background: Inflammatory diseases are associated with subclinical renal impairment. **We** aimed at investigating the associations between estimated glomerular filtration rate(eGFR), traditional cardiovascular risk factors, and markers of inflammation and oxidative stress in inflammatory arthritis patients compared to healthy controls.

Methods: Participants were recruited from January 2013 to2016. Healthy subjects recruited from the community. MDRD formula was used to get eGFR. ttest was used to compare the laboratory values and renal function parameters between two groups. Linear regression analysis used to look for the correlation between GFR and each of traditional cardiovascular risk factors and inflammatory markers.

Results: Age mean(SD) was 49(13) yrs. Mean GFR of the inflammatory arthritis patients was 118 ± 30 ml/min (range 60 - 227) and 128 ±37 ml/min for the control. Inflammatory arthritis patients had lower GFR, albumin(P<0.001), and total protein (p=0.03), and higher ESR(P<0.001), CRP (P<0.001), and uric acid (p=0.01). Among patients and control groups, there was a negative linear relationship between GFR and age of the participants Controls (p=0.01,CI: -1.82,-0.26), patients (p<0.001,CI: -1.24,-0.40), SBP: controls (p= 0.04,CI: -0.61, -.00), patients(p=0.022 ,CI: -0.61, -0.05). Among the inflammatory arthritis group, GFR has a negative linear relationship with age of participants, age at disease onset (p=0.002,CI: -1.18, -0.29), DBP(p=-2.14, CI: -1.24, -0.05), ESR(p=0.04,CI:-0.24,-0.01), CRP(p=0.02, CI: -0.47, -0.04), uric acid(p<0.001,CI -0.18, -0.05), total protein (p= 0.01,CI: -0.91, -0.16). GFR positively associated with albumin level (p=0.03, p= 0.14, 2.35).

Conclusions: Untraditional risk factors such as oxidative stress and inflammation is associated with progression of renal injury. Study indicates that in inflammatory arthritis inflammation is involved in the early stages of impaired kidney function. Whether anti-inflammatory therapies are effective in slowing down the deterioration of kidney function in the arthritis diseases remain to be established.

FR-PO720

Chronic Kidney Disease of Unknown Origin-Possible Link to Mesoamerican Nephropathy in Guatemala

Pablo Garcia,[1] Jose Antonio Loaiza,[2] Violeta Chacon,[4] Joaquin Barnoya.[3] *[1]Medicine, Saint Peter's Univ Hospital, NJ; [2]Nephrology, Inst Guatemalteco de Seguridad Social, Guatemala; [3]Public Health Sciences, Washington Univ in St. Louis; [4]Research, Cardiovascular Unit of Guatemala, Guatemala.*

Background: Several epidemiological studies have described a high prevalence of Chronic Kidney Disease of unknown etiology (CKDu) along the Pacific Coast of Central America. This particular disease presentation is known as Mesoamerican Nephropathy (MeN). A definitive study has not been conducted to confirm the presence of MeN in Guatemala.

Methods: This cross sectional study was conducted in the largest referral center in Guatemala. All the patients who presented with ESRD during a period of 6 months were interviewed. We looked for "traditional" risk factors (diabetes and/or hypertension) and lack of "traditional" risk factors of CKD.

Results: A total of 249 patients were interviewed. 51% were males and 49% females, 54% of the patients lived in Guatemala City and 16.8% along the Pacific Coast. A total of 68% of the subjects had hypertension (HTN), 41% had diabetes mellitus (DM), and 25% did not present with DM or HTN. The subjects without DM and HTN were younger (35 ± 18.5) than the subjects with DM and/or HTN (50±17.3, p<0.001).

Table 1. Demographic Characteristics (n=249)

Gender	Frequency	Percentage %	
Male	128	51	
Female	121	49	
Origin	Frequency	Percentage %	
Guatemala	136	55	
Pacific Coast	42	19	

Table 2. Risk factors for ERSD (n=249)

Risk factor	Frequency	Percentage %	p
Diabetes	103	41	<0.001
Hypertension	170	68	
Diabetes and hypertension	85	34	
None	61	25	

Table 3. Age difference between those without traditional risk factors and those with traditional risk factors

	Without traditional risk factors	With traditional risk factors	p
Age,Mean±SD	35±18.5	50±17.3	<0.001

Conclusions: 25% of the subjects had neither DM nor HTN, a 16.8% came from three towns located on the Pacific Coast and the mean age was statistically significantly different between both groups, these findings may indicate evidence of MeN in Guatemala. Additional studies are recommended to establish the extent of MeN in Guatemala.

Funding: Private Foundation Support

FR-PO721

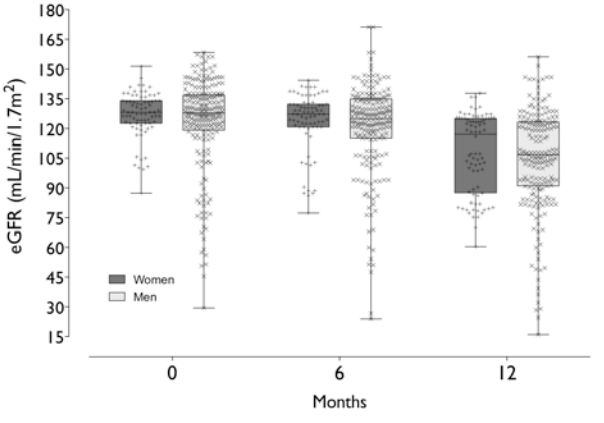
Rapid Loss of Kidney Function amongst Apparently Healthy Young Adults from Communities at Risk of Mesoamerican Nephropathy

Marvin Antonio Gonzalez,[1,2] Armando Benito Camacho,[1] Dorien Faber,[3] Jennifer S. Le Blond,[4] Catharina Wesseling,[5] Jason R. Glaser,[3] Dorothea Nitsch,[2] Aurora Aragon,[1] Neil Pearce,[2] Ben Caplin.[6] *[1]UNAN-Leon, Nicaragua; [2]London School of Hygiene and Tropical Medicine; [3]Fundacion Isla; [4]Imperial College London; [5]Karolinska Inst; [6]UCL Centre for Nephrology, United Kingdom.*

Background: Mesoamerican Nephropathy (MeN) is killing thousands of young adults across rural Central America, where intensive agricultural work is the dominant occupation. MeN is a form of chronic kidney disease (CKD) characterised by minimal proteinuria and interstitial scarring on biopsy. The aetiology and natural history of MeN are unknown.

Methods: In partnership with 9 affected communities in Leon and Chinandega regions, Nicaragua, we are (to our knowledge) undertaking the first community-based longitudinal study investigating MeN. We invited all men and a random sample of women (ratio 3:1), aged 18-30, without a history of CKD to take part. Questionnaire data and biosamples have been collected at baseline and at 6-monthly intervals. Estimated glomerular filtration rate (eGFR) was calculated by $CKD\text{-}EPI_{creat}$ and the slope estimated using a multilevel model. This abstract describes the eGFR decline to the halfway point of the 2-year study.

Results: 16 potential participants had a diagnosis of CKD and were not included. 350 of 360 eligible participants consented to take part and 94% have attended ≥2 of the 3 study visits to date. Mean baseline eGFR was 125mL/min/1.72m^2 and mean decline in eGFR was 19.0mL/min/1.73m^2 (95%CI: 16.5-21.5) over the first year with no difference between sexes (Figure).



Individual eGFR values with overlying box and whisker plot over the first year of follow-up (all communities). Boxes: interquartile range; Whisker: range.

Conclusions: The average annualised loss of >15% of kidney function in unselected, apparently healthy, young adults is consistent with the devastating effects of this disease that are reported. Questionnaire data and biosamples should allow us to go on to uncover associations between potential causal exposures and eGFR decline in MeN.

FR-PO722

A Comparision between the First-Degree Relatives of IgAN Patients and General Population: Prevalence, Risk Factors and Relative Risk of Chronic Kidney Disease Yi Bao, Xin Wei, Jing Zhou. *Nephrology, The First Affiliated Hospital of Nanchang Univ, Nanchang, China.*

Background: Primary IgA nephropathy (IgAN) is the commonest type of primary glomerulonephritis worldwide,which is a major cause of leading to ESRD in china. However,it is well unclear whether the first-degree relatives (FDRs)of IgAN patients underwent a higher risk with CKD or renal damage than the general population.The aim of our study was to investigate the familial clustering of IgAN in southern China, and estimated the relative risk of CKD comparing with mached controls.

Methods: A total of 634 FDRs of 295 IgAN patients were reviewed from November 2007 to March 2009 in southern China,and a random sample of 1167 age-, gender-, and region-matched controls without family history of CKD were included.Information on questionnaire,anthropometric measurements, laboratory examination results and health history were recorded. CKD risk factors, including age, gender, BMI, hypertension and etc were investigated.The odds ratio (OR) was used to estimate the relative risk of CKD between FDRs of IgAN patients and controls.

Results: There was a significant difference in prevalence of CKD (31.3% vs. 11.3%, P < 0.001)between the FDRs of IgAN patients and matched controls.After adjusting confounders, female gender (OR=2.02, P=0.008), hypertension (OR=2.14, P<0.001) and etc were independently associated with increased risk of CKD.The adjusted relative risk of 4.03 for CKD was obtained among the FDRs of IgAN patients and matched controls,and the adjusted relative risk for hematuria, albuminuria and reduced eGFR were 6.61 , 3.32 and 4.00, respectively.

Table1 The risk analysis of CKD, haematuria,albuminuria and reduced eGFR in IgAN patients' first-degree relatives comparing with controls

	Adjusted[a] OR	P	Adjusted[b] OR	P
CKD	3.71 (1.07, 1.84)	0.013	4.03 (3.08, 5.27)	<0.001
Haematuria	6.59 (4.60, 9.43)	<0.001	6.61 (4.59, 9.53)	<0.001
Albuminuria	3.05 (2.10, 4.43)	<0.001	3.32 (2.26, 4.88)	<0.001
Reduced eGFR	2.92 (1.65, 5.16)	<0.001	4.00 (2.17, 7.37)	<0.001

Table 2 Multivariate logistic regression analysis of associated risk factors of CKD in the first degree relatives with IgAN patients

Variable	Adjusted ORs	P
Age(years)		
20 – 39	1.00	
40 – 59	1.13 (0.73-1..73)	0.586
60 – 69	2.33 (1.07-5.05)	0.033
70 –	6.42 (2.26-18.26)	<0.001
Gender (female vs male)	2.02 (1.20-3.40)	0.008
BMI		
Nomal[a]	1.00	
Over weight[b]	1.30(0.81-2.10)	0.281
Obese [c]	1.91 (1.07-3.41)	0.028
Hipertrigliceridemia	1.81 (1.11-2.96)	0.018
Hypercholesterolemia	0.89 (0.52-1.52)	0.675
Hyperuricemia	0.91 (0.55-1.52)	0.721
Diabetes	1.84 (1.20-3.40)	0.159
Hypertension	2.14 (1.25-3.79)	0.006
Smoking	2.00 (1.11-3.60)	0.021

Conclusions: The study revealed the FDRs of IgAN patients experienced a higher risk with CKD than the general population.Furthermore, hypertension,female gender, hypertriglyceridemic and overweight are independent risk factors of CKD for this special population .

FR-PO723

Renal Interstitial Fibrosis: An Imperfect Prognostic Indicator in Chronic Kidney Disease Hanni Menn-Josephy,[1] Carol S. Lee,[1] Angela Nolin,[1] Marta Christov,[2] Denis Rybin,[1] Janice Weinberg,[1] Joel M. Henderson,[1] Ramon G. Bonegio,[1] Andrea Havasi.[1] *[1]Medicine- Renal Section, Boston Univ School of Medicine, Boston, MA; [2]Renal Div, New York Medical College, Valhalla, NY.*

Background: The extent of interstitial fibrosis on kidney biopsy is regarded as a prognostic indicator and guide to treatment. Patients with extensive fibrosis are assigned to supportive treatments with the expectation that they have advanced beyond the point at which immunosuppressive or other disease modifying therapies would be of benefit. Our study highlights some of the limitations of using interstitial fibrosis to predict who will develop ESRD.

Methods: Analysis of 434 consecutive renal biopsies performed between 2001-2012 at a single center. We assessed the influence of various clinical factors along with fibrosis as predictors of ESRD and dialysis free survival in various patient groups.

Results: Interstitial fibrosis performed well overall as a predictor of progression to dialysis and on average patients with >50% fibrosis progressed more rapidly than those with either 25-49% or 0-24% fibrosis with a median time to dialysis of 1.2 years, 6.5 and >10 years respectively. In contrast, interstitial fibrosis was of less value as a predictor of disease progression in a subset of cases that included patients over the age of 70 and those with diabetic nephropathy on biopsy. Surprisingly, 13.9% of patients with normal renal function had 25-49% fibrosis and 5% had more than 50% fibrosis on biopsy, and 5 years after undergoing biopsy 21% of patients with >50% fibrosis still remained dialysis free.

Conclusions: Renal fibrosis is an imperfect prognostic indicator for the development of ESRD and caution should be exercised in applying it too rigidly, especially in elderly or diabetic patients.

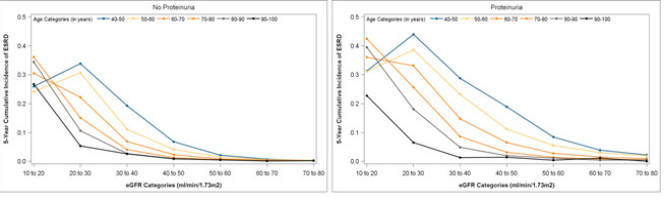
FR-PO724

Age-Dependent Thresholds of Kidney Function and Progression to End Stage Renal Disease in the Veterans Affairs Healthcare System Jennifer L. Bragg-Gresham,[1] Anca Tilea,[1] Hal Morgenstern,[1] Vahakn B. Shahinian,[1] Ann M. O'Hare,[2] Daniel F. Balkovetz,[2] Linda F. Fried,[2] Susan T. Crowley,[2] Rajiv Saran.[1] *[1]Univ of Michigan; [2]Veterans Affairs Healthcare System.*

Background: Normal aging has been linked to GFR decline; however, the definition of CKD does not take age into consideration. The VA Healthcare System (HCS) manages an aging population with many enrollees meeting CKD criteria using the standard fixed eGFR threshold. Whether age is a modifier of ESRD risk amongst Veterans with CKD has agency relevance for population health management, thus we examined existing data in the VA Renal Information System (REINS) to understand this issue.

Methods: 5,913,070 VA 'users' (defined by ≥1 contact with VA HCS in past 3 yrs) were identified in 2006 and followed through 2013. Cox regression estimated the effects of baseline eGFR by age and proteinuria [based on urine tests: Urine Albumin Excretion Rate (mg/24h), UACR (mg/g), Urine Protein Excretion Rate (mg/24h), UPCR (mg/g), Dipstick], on the 5-yr cumulative incidence of ESRD, adjusting for sex, race, BMI, blood pressure, and comorbidities at baseline. Patients were censored at death.

Results: The mean age of users was 61 yrs with 9.3% females. Veterans with eGFR <60 ml/min/1.73m^2 were older with more comorbidities. Adjusted 5-yr cumulative incidences of ESRD were higher for Veterans with albuminuria and for each incremental category of lower eGFR regardless of albuminuria, except for the youngest individuals at the lowest eGFR range. The risks of ESRD were highly dependent on age, with younger Veterans reaching a 5-yr ESRD risk of 10% at much higher levels of eGFR than older Veterans.



Conclusions: For Veterans with CKD, the risk of ESRD is highly dependent on age in addition to eGFR and albuminuria. When forecasting future VA operational and business needs related to ESRD, the VA HCS should consider age as a modifier of the current fixed eGFR definition of CKD.

FR-PO725

Low Serum Magnesium and Incident Chronic Kidney Disease in the Dallas Heart Study Javier A. Neyra, Silvia Ferrè, Xilong Li, Beverley Adams-Huet, Orson W. Moe. *UT Southwestern, Dallas, TX.*

Background: CKD is highly prevalent in the US adult population and carries increased mortality risk. Low magnesium has been associated with higher inflammatory cytokines in endothelial cells, which may contribute to kidney function decline. In this study, we aim to examine the association of serum magnesium (SMg) with incident CKD in the multiethnic population-based Dallas Heart Study (DHS) cohort.

Methods: DHS participants without prevalent CKD (eGFR-EPI ≥60 and absence of microalbuminuria) were included in the study (n =3146). The independent variable was SMg measured at the beginning of the study period, both as a continuous variable and divided into tertiles (low-medium-high). The primary outcome was incident CKD, defined as eGFR <60 and ≥25% reduction from baseline and/or de novo microalbuminuria (doubling of urinary albumin-to-creatinine ratio [ACR] from <10 mg/g to >10 mg/g). Multivariable Cox regression hazard models included demographics; comorbidity; anthropometric and biochemical parameters including albumin, phosphorus, and PTH; use of diuretics; and their interactions.

Results: Mean (SD) age was 44 (10) years, eGFR 102 (18) ml/min/1.73 m², and ACR 4.4 (4.4) mg/g. 44% were men; 52% African American, 29% Caucasian and 17% Hispanic. Mean SMg was 2.07 (0.18) mg/dl. Incident CKD occurred in 123/467 (26%) in the low, 177/884 (20%) in the medium, and 83/619 (13.4%) in the high SMg tertile groups, after a median follow-up of 7.1 years. SMg was independently associated with incident CKD: adjusted HR 1.5 (95% CI, 1.1–2.0) for low vs high tertile. Every 0.2 mg/dl increase in SMg reduced the adjusted hazard for incident CKD by 63%. There was a negative correlation between SMg and high-sensitivity C-reactive protein (hs-CRP) at the time of CKD diagnosis (r -0.11, p <0.001).

Conclusions: Low SMg was independently associated with incident CKD and had an inverse correlation with hs-CRP in the DHS cohort. Whether Mg deficiency contributes to CKD progression, and Mg supplementation attenuates inflammation and therefore retard the occurrence of CKD require further investigation.

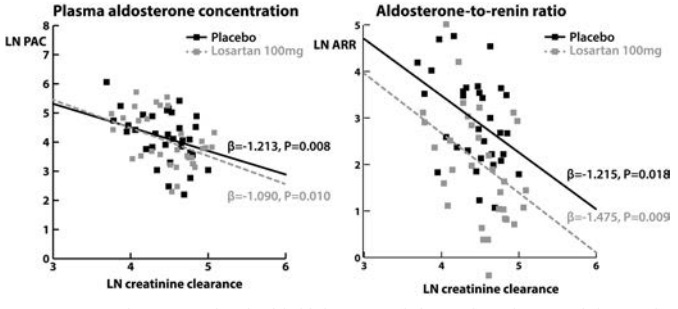
Lower Renal Function Is Associated with Higher Aldosterone and High Blood Pressure in Chronic Kidney Disease, Irrespective of RAAS Inhibition Christina M. Gant,[2,1] Gozewijn Dirk Laverman,[1] Liffert Vogt,[3] Hiddo Jan Lambers Heerspink,[4] Marc H. Hemmelder,[6] Gerjan Navis,[2] Femke Waanders.[5] *[1]Internal Medicine, ZGT Hospital, Almelo, Netherlands; [2]Nephrology, Univ Medical Centre Groningen, Groningen, Netherlands; [3]Nephrology, Academic Medical Centre Amsterdam, Amsterdam, Netherlands; [4]Clinical Pharmacy and Pharmacology, Univ Medical Centre Groningen, Groningen, Netherlands; [5]Internal Medicine, Isala Hospital, Zwolle, Netherlands; [6]Internal Medicine, Medical Centre Leeuwarden, Leeuwarden, Netherlands.*

Background: Aldosterone is elevated in chronic kidney disease (CKD) and may be involved in hypertension. The determinants of aldosterone and its association with blood pressure (BP) are not well studied in CKD patients. We studied the determinants of the plasma aldosterone concentration (PAC) and its association with BP in CKD, untreated and during renin-angiotensin-aldosterone system inhibition (RAASi).

Methods: We performed a post-hoc analysis on data from a randomized controlled cross-over trial in non-diabetic CKD patients (n=33, creatinine clearance (CrCl) 85 (75-95) ml/min, proteinuria 3.2 (2.5-4.0) g/d). The 6-week study periods were placebo, losartan 100mg (ARB) and ARB+hydrochlorothiazide 25mg (HCT), during both a normal (200±10 mmol Na+/d) and low (89±8 mmol Na+/d) dietary sodium intake (LS).

Results:



Lower CrCl was correlated with higher PAC (left panel) and ARR (right panel), similarly during placebo (black line) and during ARB (grey dotted line; ARR line shifted down). Patients with baseline PAC above the median had higher BP during most study periods. Only during maximal treatment with ARB+HCT+LS, BP was no longer different.

Conclusions: In CKD patients with mild renal function impairment, lower CrCl is associated with higher PAC, irrespective of RAASi. Also, high PAC is associated with higher BP. It is important to test the implications of our study on BP treatment in patients with renal function impairment.

Glomerular Filtration Rate Declines after Adrenalectomy in Patients with Primary Aldosteronism: Identification of Predictors for Decreased Renal Function Il Young Kim,[1] Jong Man Park,[2] Harin Rhee,[2] Sang Heon Song,[2] Eun Young Seong,[2] Dong Won Lee,[1] Soo Bong Lee,[1] Ihm Soo Kwak.[2] *[1]Dept of Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea; [2]Dept of Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Glomerular filtration rate (GFR) has been reported to decrease after unilateral adrenalectomy in patients with primary aldosteronism (PA). The aim of this study was to identify clinical predictors for decreased GFR after adrenalectomy in patients with PA.

Methods: The records of 187 patients (98 patients with PA and 89 patients with non-PA adrenal disease) who were followed for 6 months after unilateral adrenalectomy were retrospectively analyzed. Estimated GFR (eGFR) at 1, 3, and 6 month after operation were investigated. Preoperative predictors for eGFR % decrement at 1 month [(preoperative eGFR - eGFR at 1 month)/preoperative eGFR×100] were investigated.

Results: In baseline preoperative characteristics, PA group showed higher levels of systolic/diastolic blood pressure (SBP/DBP), aldosterone to renin ratio (ARR), and lower levels of potassium than non-PA group. There was no difference of baseline eGFR between two groups. The eGFR declined by 18.0 ± 22.1 ml/min/1.73 m² (16.8 ± 19.6% decline, P < 0.001) within 1 month of operation, then remained stable in PA group. However, there were no significant changes of eGFR in non-PA group throughout 6 months. In PA group, univariate analysis showed that SBP (r = 0.291, P = 0.004), DBP (r = 0.359, P < 0.001), ARR (r = 0.572, P < 0.001), and preoperative eGFR (r = 0.309, P = 0.002) correlated with eGFR % decrement at 1 month. Multiple linear regression analysis revealed that higher preoperative eGFR (β = 0.286, P = 0.001) and ARR (β = 0.464, P < 0.001) were independent predictors for eGFR % decrement at 1 month.

Conclusions: Renal function seems to deteriorate significantly after unilateral adrenalectomy in patients with PA. Clinicians need to pay attention to postoperative renal function in patients with PA, particularly who showed higher preoperative eGFR and ARR.

FR-PO728

Hyperuricemia as a Risk Factor for Proteinuria in Japanese General Population Tadashi Toyama, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

Background: Chronic kidney disease (CKD) is a risk factor for end-stage kidney disease and cardiovascular disease. Proteinuria consists the definition of CKD and is a known risk factor for progression of kidney dysfunction. Recent studies showed that hyperuricemia is one of the risk factors for loss of GFR and end-stage kidney disease; however, few studies have focused on the relationships of the development of proteinuria.

Methods: A historical Japanese cohort who underwent annual medical check-up between 1998 and 2007 and met the eligible criteria were included in the analysis. Participants aged ≥ 18 years and without CKD (eGFR was ≥60 ml/min/1.73 m² and urinary protein was minus or trace) were included in the analysis. Participants with CKD at baseline, without baseline status, or aged < 18 years were excluded from the analysis. Hyperuricemia was defined as uric acid ≥ 7 mg/dL for male and ≥ 6 mg/dL for female. Outcome was defined as development of dipstick proteinuria 1+ or more. Cox proportional hazards model was used to estimate risks for proteinuria.

Results: A total of 58,563 subjects were satisfied inclusion criteria. Mean follow-up period was 4.4 years. During the follow-up period, 2,285 (3.90%) subjects developed proteinuria. Compared with reference group, hyperuricemia was a significant risk factor for development of proteinuria (hazard ratio [HR] 1.64, 95% confidence interval [CI] 1.19 – 2.26) in female. These relationships were not found in male (HR 0.98, 95% CI 0.83 – 1.16). Analysis treating uric acid as a continuous variable showed the same trends (hazard ratio 1.16 [1.07 – 1.25], 95% CI 1.07 – 1.25 for female; HR 1.03, 95% CI 0.99 – 1.08 for male).

Conclusions: Stratified with male and female, hyperuricemia was a significant risk factor for development of proteinuria in females in the general Japanese population. Interventional studies are required to define the relationships.

Hyperuricemia out of Proportion to Renal Dysfunction in a Hotspot of Mesoamerican Nephropathy Joseph Kupferman,[1] Juan Jose Amador,[2] Katherine E. Lynch,[1] Rebecca L. Laws,[3] Damaris A. Lopez Pilarte,[2] Daniel R. Brooks,[2] David J. Friedman.[1] *[1]Dept of Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Dept of Epidemiology, Boston Univ School of Public Health, Boston, MA; [3]Dept of Environmental Health, Boston Univ School of Public Health, Boston, MA.*

Background: An epidemic of CKD of unknown etiology, termed Mesoamerican Nephropathy (MeN), is a major cause of morbidity and mortality in parts of Central America. Previous research has found hyperuricemia in some patients, and suggested that uric acid may play a role in disease pathogenesis. To probe deeper into this question, we compared the relationship between uric acid and kidney function in MeN cases to that in patients with CKD of traditional etiologies.

Methods: In a community in northwestern Nicaragua with very high CKD prevalence, we identified 24 families with multiple members affected by MeN. We also studied unrelated

former sugarcane workers with CKD of unknown cause. We compared the relationship of serum uric acid and eGFR between males with CKD from 3 NHANES cycles (n=253) and MeN patients from each of our two groups (n=99 and 237 for related and unrelated cases, respectively).

Results: Hyperuricemia, often severe, was common among MeN patients, whose uric acid levels were higher than those of NHANES participants despite more frequent use of uric acid-lowering medications in the Nicaraguan subjects (mean 9.8 and 9.6 mg/dL in unrelated and related patients, respectively, vs. 7.2 mg/dL in NHANES subjects). In multivariable linear mixed-effects regression analysis, uric acid levels were 2.0 mg/dL (95% CI, 1.0-3.0; p<0.001) higher in MeN cases with familial clustering compared to NHANES subjects, adjusting for age, eGFR, and hypouricemic therapies. Mean serum uric acid was higher in unrelated MeN cases than in the NHANES group by 1.8 mg/dL (1.0-2.6; p<0.001), after adjustment for age and eGFR.

Conclusions: In CKD patients from a MeN hotspot in Nicaragua, hyperuricemia out of proportion to the degree of renal dysfunction was common. Our results support the notion that, rather than being simply a consequence of impaired kidney function, hyperuricemia may be important in MeN pathogenesis.

FR-PO730

Heart Rate Variability and Its Relation to Renal Disease: Longitudinal Results from the PREVEND Study Chris H.L. Thio,[1] Arie M. Van Roon,[2] Ron T. Gansevoort,[3,4] Harold Snieder.[1] *[1]Epidemiology, Univ Medical Center Groningen (UMCG), Groningen, Netherlands; [2]Vascular Medicine, UMCG; [3]Nephrology, UMCG; [4]Prevention of REnal and Vascular ENdstage Disease (PREVEND) Cohort Study, Groningen, Netherlands.*

Background: In the general population, autonomic dysfunction (reflected by low heart rate variability, HRV) has been associated with cardiovascular disease. However, little is known about its relation to renal disease. We therefore examined the association between low HRV and renal outcomes.

Methods: In the population-based PREVEND Cohort Study, HRV measures (among which SDNN, standard deviation of normal-to-normal RR-intervals) were calculated from time-series of beat-to-beat blood pressure recordings at baseline. The lowest quartile was considered the risk group of interest and compared to the upper three quartiles combined. Cox-regression was performed to assess difference in incidence of chronic kidney disease (CKD de novo: eGFR<60ml/min/1.73m^2 and/or urinary albumin excretion, UAE≥30mg/24h). Using mixed effects modelling we examined the effect of SDNN on levels and slopes of eGFR and UAE in the total population and in CKD patients.

Results: Included were 4605 subjects (49% males, age range 33-80). During a median follow-up time of 7.3 years we identified 341 new cases of CKD. Low SDNN was associated with higher risk of CKD (unadjusted HR:1.66, 95%CI [1.30;2.12], p<0.001). After adjustment for age, sex, mean heart rate, and cardiovascular risk factors this association was no longer significant (fully adjusted HR:1.13, 95%CI [0.86;1.48], p=0.40). Association with de novo eGFR<60 or UAE≥30 was similarly non-significant. We found no effect of SDNN on levels and slopes of eGFR or UAE in the total population. In those with baseline CKD (N=939) low SDNN was related to lower level of eGFR (fully adjusted β=-3.73 ml/min/1.73m^2, 95%CI [-6.70;-0.75], p=0.014) but not to steeper eGFR decline.

Conclusions: In our study, low SDNN was not associated with de novo CKD. We found low SDNN to be associated with levels but not with steeper decline of eGFR in a subgroup of subjects with baseline CKD. Our findings suggest that autonomic dysfunction is a complication of CKD rather than a causal factor.

FR-PO731

Progression of Kidney Disease in Stage 3 and 4 Chronic Kidney Disease Elderly Patients Pradeep Arora,[1] Kabir Jalal,[2] Anu Gupta,[3] James W. Lohr.[3] *[1]Div of Nephrology, Richmond VA Medical Center, Richmond, VA; [2]Dept of Biostatistics, SUNY at Buffalo, Buffalo, NY; [3]Div of Nephrology, Buffalo VA Medical Center, Buffalo, NY.*

Background: The prevalence of chronic kidney disease is rising in the elderly population. We studied the rate of progression of CKD in this population and the factors associated with progression of CKD.

Methods: 4,562 patients > 65 years with 2 outpatient eGFRs <60 ml/min/1.73m^2, at least 90 days apart with no intervening eGFR > 60 ml/min/1.73m^2 (March 1, 2001 and March 31, 2008) in VISN2 network. Patients with eGFR<15 ml/min/1.73m^2 were excluded. Data obtained included demographics, comorbidities, and laboratory variables. Patients were stratified based on annual rate of decline of eGFR in 3 categories: < 1 ml/min/1.73 m^2, 1 to 4 ml/min/1.73 m^2, and > 4 ml/min/1.73 m^2 A mixed effects model with an unstructured covariance structure was used to model eGFR over time, measured quarterly. Two-way interactions of time by all comorbidities, time by lab scores, time by proteinuria status, as well as time by stage and time by age were included.

Results: Mean age was 77.2 years. 24.3% were diabetics. 4.3% had proteinuria. In univariate comparison of different rates of progression, 54.2% patients had an annual rate of progression < 1 ml/min/1.73 m^2. Multivariable Mixed Model analyses revealed that increasing age, BMI, presence of CVD, DM and proteinuria were associated with significantly increased rate of progression of CKD. Serum albumin and hemoglobin level were inversely associated with progression of CKD.

Model Effect	Estimate	P- Value
Time	0.086	0.054
Age	-0.119	<.001
Gender	1.087	0.041
BMI	-0.042	0.0267
Time * Albumin	0.101	<.001
Hemoglobin	0.436	<.001
Triglycerides	-0.005	<.001
CVD	-0.461	0.019
COPD	0.423	0.194
Time * Diabetes	-0.140	<.001
Stage 3a	24.159	<.001
Stage 3b	12.025	<.001
Time * Proteinuria	-0.7326	0.010
Systolic Pressure	-0.0135	0.001
Time * Systolic pressure * Proteinuria	0.004	0.047

Conclusions: CKD generally progresses at a slower rate in the elderly population.

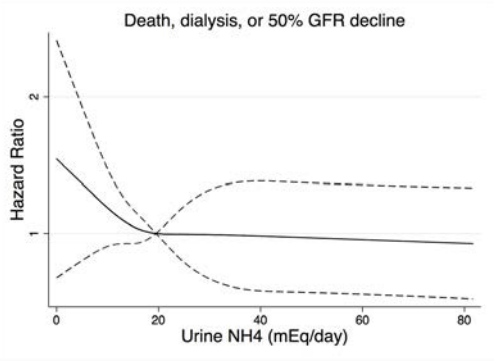
FR-PO732

Association of Urine Ammonium with Death and Kidney Outcomes in Hypertensive Chronic Kidney Disease Kalani L. Raphael,[1] David J. Carroll,[1] Jennifer L. Murray,[2] Thomas H. Hostetter,[3] John R. Asplin,[4] Srini Beddhu.[1] *[1]Univ of Utah; [2]Colorado College; [3]Case Western Reserve; [4]Litholink, Inc.*

Background: High renal NH_3 promotes tubulointerstitial fibrosis in animal models of chronic kidney disease (CKD), however, low NH_4^+ excretion was associated with CKD progression in a prior clinical study. We examined the association between urine NH_4^+ excretion, CKD progression, and death in the African American Study of Kidney Disease (AASK).

Methods: Baseline urine [NH_4^+] (mEq/L) was measured by the glutamate dehydrogenase method (n=1057). Participants were divided into tertiles of urine NH_4^+ excretion (mEq/day). Cox and spline regression models related baseline urine NH_4^+ excretion to the AASK primary composite outcome (death, dialysis or GFR reduction by 50%). Models were adjusted for demographics, randomized group, protein intake, urine potassium excretion, body mass index, measured GFR (mGFR), proteinuria, and [bicarbonate] at baseline. The lowest tertile served as the reference group in Cox model. The median NH_4^+ excretion value was the reference in the spline model.

Results: Baseline characteristics were: age 54 years, 61% male, mGFR 47 ml/min per 1.73m^2, median proteinuria 81 mg/gm, and urine NH_4^+ excretion rate 19.5 (95%, CI 6.5-44.3) mEq/day. After adjustment, the hazard ratios of the composite outcome were 0.93 (95% CI, 0.71-1.22) in the middle tertile and 0.89 (95% CI, 0.65-1.21) in the highest tertile compared to the lowest tertile of NH_4^+ excretion. The results were similar after including blood pressure, heart disease, and smoking status at baseline in the model. Adjusted spline regression models showed a trend towards higher risk of the composite outcome with urine NH_4^+ excretion below the median value.



Conclusions: Lower urine NH_4^+ excretion may associate with death and CKD progression among African Americans with hypertensive CKD, however, this did not reach statistical significance.

FR-PO733

Glycosuria and Renal Outcomes in Patients with Nondiabetic Chronic Kidney Disease - Is Glycosuria or Proximal Tubulopathy Renoprotective? Chi-Chih Hung, Shang-Jyh Hwang. *Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ.*

Background: Sodium glucose cotransporter 2 inhibitors have shown a potential for renoprotection beyond blood glucose lowering. Glycosuria in nondiabetic patients with chronic kidney disease (CKD) is sometimes noted. Whether glycosuria in CKD implies a

channelopathy or proximal tubulopathy is not known. Theoretically, proximal tubulopathy could prevent protein reabsorption and damage in proximal tubular cells. The consequence of glycosuria in CKD is also not studied.

Methods: We performed a cross-sectional study for the association between glycosuria and urine electrolyte excretion in 208 nondiabetic patients and a longitudinal study for the consequence of glycosuria, defined by dipstick, in 783 nondiabetic patients with stage 4-5 CKD and urine protein-to-creatinine ratio >500 mg/g.

Results: In the cross-sectional study, fractional excretion (FE) of glucose >4% was 3.4%, 6.3% and 62.5% in CKD stage 3, 4 and 5, respectively.Log-transformed FE glucose correlated with FE sodium, FE potassium, FE uric acid, and log-transformed eGFR in multivariate linear regression. In the longitudinal study, 279 (35.6%) patients had glycosuria. Glycosuria was associated with a decreased risk for end-stage renal disease (adjusted hazard ratio: 0.77; CI=0.62-0.97; *p=0.024*) and for rapid renal function decline (adjusted odds ratio: 0.63; CI=0.43-0.95; *p=0.032*); but glycosuria was not associated with all-cause mortality or cardiovascular events. The results were consistent in the propensity score matched cohort.

Conclusions: Glycosuria or proximal tubulopathy becomes frequent with renal function decline and is related to favorable renal outcomes in nondiabetic patients with stage 4-5 CKD.

FR-PO734

Health Literacy and Clinical Outcomes in Adults with Chronic Kidney Disease Claudia M. Lora, Ana C. Ricardo, Jesse Yenchih Hsu, Xue Wang, Eunice Carmona, Elisa J. Gordon, James H. Sondheimer, Jing Chen, Eva Lustigova, Edward J. Horwitz, Anne M. Slaven, Michael J. Fischer, James P. Lash. *The Chronic Renal Insufficiency (CRIC) Study Group.*

Background: In the general population, limited health literacy has been associated with increased risk for hospitalization and death. These associations have not been well evaluated in pre-dialysis chronic kidney disease.

Methods: We conducted a prospective study of 2,392 non-Hispanic white and black adults enrolled in the CRIC Study to examine the association between health literacy and clinical outcomes including incident end-stage renal disease (ESRD, dialysis, transplantation), atherosclerotic events (myocardial infarct, stroke, and peripheral arterial disease), hospitalizations, and all-cause death. Health literacy was measured once using the Short Test of Functional Health Literacy (STOFHLA) starting in 2008 (median: 4.7 years post-CRIC enrollment). Limited health literacy was defined as STOFHLA score ≤22.

Results: Five percent of non-Hispanic whites and 28% of non-Hispanic blacks had limited health literacy. Compared to participants with adequate health literacy, individuals with limited health literacy were more likely to be older (66 vs. 61 years), have income <$20,000 (51 vs. 19%), and less than high school education (44 vs. 7%). Over a median follow-up of 3.5 years, 229 developed ESRD, 206 experienced an atherosclerotic event, the overall hospitalization rate was 64 per 100 person-years, and 265 died. Table 1 summarizes multivariable analyses.

Table 1. Adjusted* Hazard Ratio or Rate Ratio for Participants with Limited vs. Adequate Health Literacy (N=2,392)

Outcome	HR or RR (95% CI)
Incident ESRD	1.09 (0.74, 1.60)
Atherosclerotic event	1.68 (1.10, 2.58)
Hospitalization rate	1.40 (1.28, 1.53)
Death from any cause	1.10 (0.72, 1.67)

*Adjusted for clinical center, age, gender, race, education, smoking, body mass index, systolic blood pressure, diabetes, HgA1c, baseline eGFR, urine protein, ACEi/ARB use

Conclusions: Limited health literacy was associated with higher risk of atherosclerotic events and hospitalization rates, but not with incident ESRD or death. Future work is needed to better understand these associations.

Funding: NIDDK Support

FR-PO735

T2* Values Are Better Than ADC Values for Functional MRI Evaluation to Accurately Predict CKD Progression Kei Sugiyama,[1] Tsutomu Inoue,[1] Eito Kozawa,[2] Masahiro Ishikawa,[3] Naoki Kobayashi,[3] Hirokazu Okada.[1] *[1]Nephrology, Saitama Medical Univ, Iruma-gun, Saitama, Japan; [2]Radiology, Saitama Medical Univ, Iruma-gun, Saitama, Japan; [3]Biomedical Engineering, Saitama Medical Univ, Hidaka, Saitama, Japan.*

Background: Blood oxygen level-dependent (BOLD) and diffusion-weighted (DW) magnetic resonance imaging (MRI), can non-invasively assess oxygen bioavailability and fibrosis in the kidney (Inoue T, et al. JASN 22: 1429, 2011). To extend their clinical utility, in this study, we investigated the relationships among the parameters from these two functional MRI modalities and the clinical course of chronic kidney disease (CKD).

Methods: This was a single center, retrospective observational study. Participants consisted of CKD stage G1-4 patients who had regularly visited our outpatient clinic. MRI was performed using a 1.5T imager. Age, gender, history of diabetes, proteinuria level, estimated glomerular filtration rate (eGFR), as well as T2* and apparent diffusion coefficient (ADC) values from both BOLD and DW MRI, were examined. Multiple regression analysis was performed to identify independent predictors of the annual rate of change in eGFR.

Results: Sixty-six cases (age 53.3 ± 16.4 years, eGFR 53.6 ± 28.8 mL/min/1.73 $m^{2)}$ were enrolled. Mean observation period was 5.5 ± 1.9 years. At the start point, ADC values, but not T2* values, were significantly correlated with eGFR ($p<0.05$; Spearmans). Univariate analyses, however, showed that T2* values, eGFR and proteinuria level, but not ADC values, were significantly correlated with annual decline in eGFR. These factors were still significant after adjustment for all independent variables in the multiple regression analysis (T2* values and eGFR $p<0.005$, proteinuria $p<0.001$).

Conclusions: ADC values, which are indices of tissue fibrosis, are significantly correlated with the current remaining renal function. On the other hand, T2* values, which are indices of tissue oxygenation, predict the future progression of CKD. In addition to traditional risk factors such as proteinuria and low GFR, we reconfirmed that hypoxia is another risk factor for CKD progression. Therefore, functional MRI can be a useful tool in assessing the pathophysiological and prognostic aspects of CKD.

FR-PO736

Optimization and Measurement of Urinary C3a Levels in the CRIC Cohort Venkata Sabbisetti,[1] Chi-Yuan Hsu,[2] Kathleen D. Liu,[2] Emily Christie,[1] Sushrut S. Waikar,[1] Joseph V. Bonventre.[1] *[1]Brigham & Women's Hospital, Harvard Medical School, Boston, MA; [2]Univ of California San Francisco School of Medicine, San Francisco, CA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Complement activation plays a vital role in the pathogenesis of renal fibrosis. We have found limitations of the available assays when performed on urine samples due to interference by urine proteins. We modified and validated a commercially available serum C3a assay (Quidel) to accurately measure urinary C3a (uC3a) levels and applied this method to measure uC3a from individuals in the Chronic Renal Insufficiency Cohort (CRIC) study.

Methods: We measured urinary C3a in 388 participants in the CRIC cohort in a nested, frequency matched case:control study design. Inclusion criteria for cases and controls included followup time of >3 years and baseline proteinuria <3.5 gm/d. We identified 194 randomly selected cases with eGFR slope <-3 ml/min/1.73m^2 per year and 194 randomly selected controls with eGFR slope of -1.5 to + 2.5 ml/min/1.73m^2 per year. C3a was measured using Quidel assay after urine protein was precipitated using acidified acetone followed by re-suspension of the pellet in sample diluent buffer. Unadjusted and multivariable-adjusted logistic regression models were fit to test the association of uC3a with subsequent CKD progression.

Results: Optimized protocol markedly improved assay performance with excellent linearity of dilution and spike recovery and eliminated the interference in urine matrix. Among 388 CRIC participants, uC3a was above the detection limit (0.026 ng/mL) in 45%. In logistic regression models adjusted for age, sex, race, clinical center, proteinuria, and eGFR, we detected no association between tertiles of uC3a and risk of CKD progression (tertile 2 vs tertile 1: odds ratio 0.96, 95% CI 0.55 – 1.66; tertile 3 vs tertile 1: odds ratio 1.24, 95% CI 0.64 – 2.40).

Conclusions: Readily implemented modifications of a commercial C3a assay eliminated analytical interference when implemented in urine. We found no evidence that uC3a levels can be used to identify CKD progression among CRIC Study participants.

The Ambulatory Arterial Stiffness Index Is an Independent Predictor of Accelerated Age-Related GFR Decline in the General Middle-Aged Population Bjorn Odvar Eriksen, Vidar T.N. Stefansson, Trond G. Jenssen, Ulla Dorte Mathisen, Jørgen Schei, Marit D. Solbu, Toralf Melsom. *Metabolic and Renal Research Group, UiT The Arctic Univ of Norway, Tromso, Troms, Norway.*

Background: Arterial stiffness measured as aortic pulse wave velocity predicts cardiovascular disease and incident chronic kidney disease. However, the role of arterial stiffness as a predictor of age-related GFR decline in the general population is unresolved due to the difficulty of measuring arterial stiffness and GFR with sufficient precision in population studies. The ambulatory arterial stiffness index (AASI) is a validated indicator of arterial stiffness easily calculated from ambulatory blood pressure measurements. We investigated whether AASI could predict iohexol clearance decline in a cohort representative of the general population.

Methods: We calculated the AASI from baseline ambulatory blood pressure measurements and measured iohexol clearance at baseline and follow-up in the Renal Iohexol Clearance Survey Follow-Up Study (RENIS-FU). The AASI was defined as 1 minus the regression slope of diastolic over systolic blood pressure. The RENIS cohort included a representative sample of the general middle-aged population without self-reported diabetes, cardiovascular, or kidney disease at baseline (n=1627). The age was 50 to 62 years at baseline, and the median observation time was 5.6 years.

Results: The mean (standard deviation) of the GFR decline rate was 0.95 (2.23) ml/min/year and of the AASI 0.38 (0.13). Baseline ambulatory or systolic blood pressure did not predict a steeper GFR decline. In multivariable adjusted linear mixed regression analysis, one standard deviation increase in baseline AASI was associated with a 0.12 (95% confidence interval 0.01 – 0.24) ml/min/year steeper GFR decline. This effect was independent of baseline ambulatory systolic and diastolic blood pressure and antihypertensive medication. The same finding was made in a subgroup without baseline hypertension ($p<0.05$).

Conclusions: We conclude that increased arterial stiffness, measured with the AASI, is an independent risk factor for accelerated age-related GFR decline in the general middle-aged population.

Serum FGF21 and FGF23 Are Associated with the Diastolic and Systolic Functions, Respectively, in Patients with Non-Diabetic Chronic Kidney Disease Masashi Kitagawa, Hitoshi Sugiyama, Akifumi Onishi, Keiko Tanaka, Toshio Yamanari, Tatsuyuki Inoue, Jun Wada. *Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Fibroblast growth factor (FGF) 19/21/23 is an endocrine FGF. Besides regulating mineral metabolism, FGF23, with the co-receptor Klotho, plays an important role in cardiovascular conditions including left ventricular hypertrophy. FGF21, a metabolic hormone that is crucial in glucose and lipid homeostasis, also has cardioprotective effects. The mechanisms by which FGF23, Klotho and FGF21 influence the systolic and diastolic functions in chronic kidney disease (CKD) patients remain unclear.

Methods: This cross-sectional study included 160 non-diabetic CKD patients. The serum levels of FGF23, Klotho and FGF21 were measured by a sandwich ELISA and the relationship between these biomarkers and the echocardiographic data was examined. Echocardiography was performed to measure the left ventricular mass index (LVMI), peak early diastolic mitral filling velocity (E), peak early diastolic mitral annular velocity (E'), and E/E' and ejection fraction (which represent the diastolic and systolic functions, respectively).

Results: The median or mean serum FGF23, Klotho and FGF21 levels were 48 (30-97), 617±236 and 356 (95-520) pg/mL, respectively. A univariate analysis showed that the natural logarithms of the FGF23 and FGF21 concentrations were negatively and positively correlated with E' and positively correlated with E/E' and LVMI. The serum FGF23 levels were associated with the EF. In a multivariate analysis, serum FGF21 and FGF23 were significant predictors of E' and EF, respectively (adjusted for age, gender, systolic blood pressure, HDL-cholesterol, hemoglobin, albumin, eGFR, proteinuria, phosphate, B-type natriuretic peptide, FGF21/23 and Klotho). Serum Klotho was significantly correlated with E', E/E' and LVMI in the univariate analysis but not in the multivariate analysis.

Conclusions: The serum FGF21 and FGF23 concentrations were independently associated with the diastolic and systolic functions, respectively in patients with non-diabetic chronic kidney disease.

FR-PO739

Predicting Treatment Response and Renal Survival in Crescentic ANCA Associated Glomerulonephritis Xia Liu, Ying-Hua Chen, Haitao Zhang, Zheng-Zhao Liu, Zhihong Liu, Weixin Hu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: Patients with crescentic ANCA associated glomerulonephritis (cre-AAGN) received intensive immunosuppressive therapy still have poor long-term renal survival. In this study, we analyze the factors, which may predict treatment response and long-term renal outcome in Chinese patients with cre-AAGN.

Methods: Sixty patients with biopsy-proven cre-AAGN were included and classified into renal replacement therapy (RRT, n=30) and non-RRT groups (n=30). Treatment response was recorded as good response (GR, the patients got rid of RRT in RRT group, or Scr declined ³25% of the baseline in non-RRT group) and non- response (NR, the patients needed maintenance RRT in RRT group, or Scr declined <25% of the baseline in non-RRT group) at three months of induction treatment.

Results: At three months treatment, GR was achieved in 53.3% and 80% of patients in RRT and non-RRT groups, respectively. In RRT group, renal disease duration, total crescent percentage, circumferential crescent ratio (circumferential/total crescents) and sclerotic glomeruli ($p<0.01$) were significantly lower in GR than that in NR cases. By multivariate Cox regression analysis, the circumferential crescent ratio was the only risk factor predicting not being GR, with the circumferential crescent ratio ³50% been the high risk for not being GR(HR 22.2, CI 2.17-200, P=0.002). In non-RRT group, the normal glomeruli percentage was markedly higher in GR patients than in NR patients (median: 20.4(12.3,29.0)% vs 5.3(2.3,11.5)%, p=0.022), with the normal glomeruli >7% being more likely to be GR (HR 13.3, CI 1.7-107.4, P=0.006). During a median follow-up of 19 (6- 58) months, 18 (30%) patients developed to ESRD, the five-year renal survival rate was 56.0%. The need of RRT(HR7.09, CI 2.32-21.65, P=0.006) and presence of nephrotic range proteinuria(HR5.9, CI 1.35-25.88, P=0.019) were the two independent risk factors for the development of ESRD.

Conclusions: In crescentic AAGN, the extent of circumferential crescent and normal glomeruli predicts treatment response, while the need for renal replacement therapy and proteinuria predict long-term renal survival.

FR-PO740

Urine Citrate Excretion Might Identify Eubicarbonatemic CKD Patients with Acid Retention and Assess Their Response to Therapy Nimrit Goraya,[1,2] Jan Simoni,[3] Jessica Pruszynski,[4] Nicolaos E. Madias,[5] Donald E. Wesson.[1,2,6] *[1]Internal Medicine, Baylor Scott and White Healthcare, Temple, TX; [2]Texas A&M HSC College of Medicine, Temple, TX; [3]Surgery, Texas Tech Univ HSC College of Medicine, Lubbock, TX; [4]Biostatistics, Baylor Scott and White Healthcare, Temple, TX; [5]Internal Medicine, St. Elizabeth's Medical Center and Tufts Univ School of Medicine, Boston, MA; [6]Diabetes Health and Wellness Inst, Dallas, TX.*

Background: Some CKD stage 2 (eGFR 60-89 ml/min/1.73 m^2) patients without metabolic acidosis nevertheless have acid retention and dietary acid reduction slows their eGFR decline. Urine excretion of citrate, a pH-sensitive metabolite, might identify eubicarbonatemic CKD patients with acid retention and assess response to therapy.

Methods: We measured acid retention and urine citrate excretion in CKD stage 2 (n=40) and stage 1 (eGFR >90 ml/min/1.73 m^2, n=26) eubicarbonatemic patients (TCO_2 ≥ 24.5 mM) before and after 30 days of dietary acid reduction with base-producing fruits and vegetables (F+V). Acid retention was measured by comparing observed to expected increase in plasma [TCO_2] in response to retained HCO_3 (dose - $U_{HCO3}V$) 8 hours after an oral $NaHCO_3$ bolus (0.5 meq/Kg bw), assuming 50% bw HCO_3 space distribution.

Results: Baseline acid retention was higher in CKD 2 than CKD 1 (28.1±9.4 vs. 5.2±12.0 mmol, respectively, $p<0.01$) but baseline 8 hour urine citrate excretion was lower in CKD 2 than CKD 1 (187±40 vs. 335±125 mg, $p<0.01$). Thirty days of F+V reduced acid retention in CKD 2 (to 18.4±17.4 mmol, $p<0.01$) but not in CKD 1 (to 4.7±15.6 mmol, p=0.88) and acid retention remained higher in CKD 2 than CKD 1 ($p<0.01$). By contrast, 30 days of F+V increased urine citrate excretion in both CKD 2 (to 245±70 mg, $p<0.01$ vs. baseline) and CKD 1 (to 369±125 mg, $p<0.02$, vs. baseline) yet urine citrate excretion remained lower in CKD 2 than CKD 1 ($p<0.01$).

Conclusions: Acid retention in eubicarbonatemic CKD patients was associated with low urine citrate excretion which increased after dietary acid reduction with F+V. Low urine citrate excretion might identify eubicarbonatemic CKD patients with acid retention and assess their response to therapy.

FR-PO741

Apolipoprotein L1 Genetic Variants Are Associated with Evidence of Early Kidney Injury in Sickle Cell Disease Divya G. Moodalbail, Joshua Zaritsky, Robert S. Mathias, Carlos E. Araya, Bonita E. Falkner. *Nemours.*

Background: Apolipoprotein L1 (APOL1) renal-risk variants prevalent in African-ancestry populations are associated with chronic kidney disease (CKD). CKD is a major cause of morbidity and mortality in sickle cell disease (SCD) in adults; yet the prevalence and significance of APOL1 renal-risk variants in this population remains unknown. Our objective was to determine expression of biomarkers of early kidney disease in African American youth with SCD, based on their APOL1 genotype.

Methods: We enrolled 40 African American subjects between 5 to 21 years of age with SCD (Hb SS or Hb S $ß^0$ thalassemia). Blood and concurrent urine samples were collected. All enrolled subjects underwent APOL1 genotyping by PCR analysis of DNA extracted from whole blood. Presence of two renal-risk variants qualified for APOL1 High Risk (HR) genotype, while presence of zero or one copy of renal-risk variants qualified for APOL1 Low Risk (LR) genotype. Only two subjects (both in APOL1 LR group) were on ACEi/ARB therapy at baseline.

Results:

Table 1. Characterization of Clinical Variables Based on APOL1 Genotype (total n=40)

Variables	APOL1 LR Group (n=30)	APOL1 HR Group (n=10)	p-value
Female Gender (%)	60	50	N/A
Age (Years)	12.0±4.28	11.1±4.63	0.596
BMI z-score	-0.18 (±1.19)	-0.53(±1.54)	0.466
Serum Cystatin C(mg/L)	0.71 (±0.114)	0.69 (±0.059)	0.633
BUN (mg/dL)	9.8 (±4.3)	10.6 (±3.9)	0.608
Serum Creatinine (mg/dL)	0.45 (±0.19)	0.42 (±0.08)	0.594
Bedside Schwartz eGFR (ml/min/1.73m^2)	150.67 (±46.8)	144.30 (±29.8)	0.690
Cystatin C eGFR (ml/min/1.73m^2)	102.36 (±17.0)	106.90 (±13.8)	0.474
Urine Osmolality (mOsm/Kg H_2O)	458.0 (426.0-514.0) *	417.0 (247.0-457.0) *	0.394
Urine Albumin Excretion Rate (mg/g creatinine)	**9.5 (8.0-16.0) ***	**19.5 (11.7-51.7) ***	**0.040**
ACEi/ARB Use (%)	6.7	0	N/A

*Median (IQR)

APOL1 HR genotype was expressed by 25% of our subjects; this is comparable to 23% reported prevalence of APOL1 HR genotype in African American adults with CKD (AASK study). Both groups were similar with respect to distribution of age, BMI z-scores, renal function and urine osmolality. Hyperfiltration was noted in both groups based on low serum creatinine for age, and elevated eGFR based on creatinine clearance. However, median urine albumin excretion rate was significantly higher in HR group vs. LR group.

Conclusions: Preliminary data in this cohort of 40 children and adolescents with SCD detected greater urine albumin excretion rate in the presence of APOL1 HR genotype. Screening SCD youth for heightened CKD risk may be an avenue to initiate targeted preventive interventions to preserve renal function and reduce progression of kidney disease.

Blood Monocyte Subsets and Neutrophils Increase with CKD Stage and Correlate with Both Renal Function and Inflammatory Cytokines

Serika D. Naicker,[1] William P. Martin,[1,2] Sarah Cormican,[1,2] Tomas P. Griffin,[1,2] Matthew D. Griffin.[1,2] *[1]School of Medicine, Regenerative Medicine Inst (REMEDI), National Univ of Ireland, Galway, Ireland; [2]Nephrology Services, Galway Univ Hospital, Saolta Univ Health Group, Galway, Ireland.*

Background: Chronic kidney disease (CKD) is associated with systemic inflammation which may contribute to cardiovascular complications and progression of renal injury. The aims of this study were to examine the relationships between specific circulating leukocyte populations and CKD stage/eGFR as well determine the correlations between circulating leukocytes and specific innate cytokines.

Methods: Blood samples were collected from outpatients with CKD stage 2-5 (n=188) and from healthy adult volunteers (Ctrl, n=42). Total lymphocyte, monocyte and neutrophil counts were quantified in whole blood aliquots by flow cytometry. Peripheral blood mononuclear cells were prepared and were analyzed immediately by 8-colour flow cytometry to quantify individual monocyte subsets. Serum cytokines levels were quantified by multi-plex assay. Statistical analyses were performed using GraphPad Prism© software.

Results: Total blood monocyte and neutrophil (but not lymphocyte) numbers increased progressively from Ctrl through CKD stages 2-5 and correlated strongly with serum creatinine, eGFR and blood urea nitrogen (BUN). Among the monocyte subsets, intermediate ($CD14^{++}/CD16^{+}$) monocytes demonstrated the strongest relationship with CKD stage, eGFR and BUN. Intermediate monocyte numbers also correlated strongly with neutrophil numbers. Among the serum cytokines analyzed, interferon gamma (IFNγ) and IL-18 were most significantly increased in a CKD stage-dependent manner and also correlated with intermediate monocyte numbers as well serum creatinine, eGFR, BUN and serum albumin levels. Serum concentrations of IFNγ and IL-18 correlated strongly with each other.

Conclusions: Our results demonstrate relationships between circulating innate immune cells (neutrophils/monocytes) and severity of CKD as determined by eGFR. Selective expansion of intermediate monocytes and increases in specific innate cytokines indicate that CKD-associated inflammation has distinct characteristics that may be amenable to intervention.

Implication of the White Blood Cell Count (WBC) in the Progression of IgA Nephropathy

Ricong Xu,[1] Qijun Wan,[2] Tong Li,[3] Yongcheng He.[4] *[1]Shenzhen Second People's Hospital; [2]Shenzhen Second People's Hospital; [3]Shenzhen Second People's Hospital.*

Background: Inflammatory markers such as serum or urinary interleukin-6 (IL-6) and serum albumin have been shown predicted effect for renal progression in patients with IgA nephropathy (IgAN)**,** however, there are limited data regarding on the relationship between the white blood cell count (WBC) and renal progression in IgAN patients.

Methods: We conducted a retrospective cohort study in 543 biopsy proven IgAN patients in our center to evaluate the association between the WBC and the clinical characteristics and the pathological features in IgAN patients, and analyzed the predictive effect of the WBC on long-term renal progression. The renal progression endpoint was defined as end stage renal disease (ESRD) or the doubling of the baseline serum creatinine concentration. Patients were divided into four groups according to the quartiles of the WBC. The Cox's proportional hazards regression models were used to assess the association of WBC with long-term renal progression.

Results: Compared to patients with lower quartiles of the WBC, those with higher quartiles of the WBC were with higher systolic blood pressure, diastolic blood pressure, and higher levels of neutrophils, lymphocytes, eosinophils, triglyceride, total cholesterol, low-density lipoprotein (LDL) cholesterol, 24 hours proteinuria, complement component 3 and complement component 4, as well as a lower level of estimated glomerular filtration rate (eGFR) ($P<0.05$). In addition, patients with higher quartiles of the WBC were with higher proportion of sclerosis in renal biopsy ($P<0.05$). During a median follow up of 50 months, 47 (8.7%) patients were found to achieve renal progression endpoint. The highest quartile of WBC was associated with higher risk of long-term renal progression (HR, 3.90; 95% CI, 1.23 – 12.4) after adjusting for potential confounding factors, and this result was still significant when using WBC as a continuous variable (HR, 1.13; 95% CI, 1.03 – 1.23).

Conclusions: Our results suggest that the higher baseline level of the WBC is associated with the long-term renal progression in IgAN patients.

FR-PO744

Urinary Activin A: A Novel Biomarker Reflecting the Severity of Tubular Damage in IgA Nephropathy

Yoshinori Takei, Akito Maeshima, Shunsuke Takahashi, Masao Nakasatomi, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: Activin A, a member of TGF-β superfamily, is known to regulate cell growth and differentiation in various tissues. It has been reported that activin A modulates ureteric bud branching in kidney development, inhibits tubular regeneration after renal ischemia, and acts as a potent inducer of renal fibrosis in rodents. However, the role of activin A in kidney diseases remains unknown in human. To address this issue, we analyzed renal biopsy specimens and urine from patients with IgA nephropathy (IgAN).

Methods: Ninety-two patients with biopsy-proven IgAN who were treated in our department from 2011 and 2015 were included in this study. Patients were categorized into 4 groups according to estimated GFR (≥60 versus <60 mL/min/1.73 m^2) and proteinuria (≥ 0.5 versus <0.5 g/gCr). Serum and urinary activin A were measured by ELISA. Correlation of urinary activin A with urinary N-gal, urinary KIM-1, renal functions and urinary protein levels were analyzed. The localization of activin A in renal biopsy specimens from IgAN patients was examined by immunostaining. Normal kidney specimens from patients who underwent nephrectomy were used as controls.

Results: Urinary activin A was almost undetectable in healthy volunteers, but was significantly increased in IgAN patients categorized into high-risk group (eGFR<60, U-P/Cr≥0.5 g/gCr) (9.6 ± 2.3 vs. 37.5 ± 9.6 pg/mgCr, $p<0.001$). There was a significant correlation of urinary activin A level with urinary N-gal and KIM-1. Urinary activin A level was negatively correlated with eGFR, but not with urinary protein level. Activin A was localized in the cytoplasm of distal tubules of normal kidneys. In contrast, activin A was present not only in distal tubules, but also in the apical lumen of proximal tubules in patients with IgAN.

Conclusions: These data suggest that urinary activin A is a new biomarker reflecting the severity of tubular damage in IgAN.

The Development and Progression of Renal Disease in Aboriginal People in a Remote Aboriginal Community: A Probable Model of Oligonephronia

Wendy E. Hoy. *CKD.CRE, Univ of Queensland, Brisbane, QLD, Australia; Menzies School of Health Research, Darwin, Northern Territory, Australia.*

Background: Kidney disease, marked by albuminuria, is very common in remote-living Australian Aboriginal people. Biopsy and autopsy findings are compatible with low nephron endowment. We describe renal profiles followed longitudinally in one high risk community, and interpret them in terms of disease "incidence" and "progression".

Methods: Urine ACR and EGFR were measured at a "baseline' community screen, (>80% participation), and measured or imputed (for renal failure) a mean 10.6 years later, in 1031 persons. Changes in ACR and EGF R over time were evaluated. Rates of two definitions of new onset or "incident" albuminuria (ACR>1 gm/mol, and ACR >3.4 gm/mol) developing over follow up were calculated for people with "normal" ACR levels at the first screen (ACR <1 or ACR <3.4).

Results: Birthweights were low (45% of older and 20% of younger subjects were low birthweight, <2.5 kg). On both screens high urine ACR and lower EGFR were common and were more marked at higher ages. Additionally, ACR rose and EGFR fell in many individuals over the follow up interval. Among 453 subjects with ACR <1 at the first screen, 55.9% developed ACR>1, and among 691 with ACR <3.4 at the first screen, 30.4% had developed ACR >3.4, by the second screen. From age >10+ years onwards, lower birthweight and lower baseline EGFR, independently, predicted new onset albuminuria by both incident expressions. Additional predictors included female sex, and, for those age>18+ years, the previous level of ACR (even those within the "normal" ranges). "Progression" (>25% loss of baseline EGFR) over the follow up in subjects age 18+ years was predicted by baseline ACR, age and diabetes.

Conclusions: The data support a model of nephron deficiency. Lower birthweight and lower previous EGFR are surrogates for relative nephron deficiency. Female sex is also constitutionally associated with lower nephron numbers. Once such a deficit is marked by high ACR, albuminuria is the most powerful predictor of further loss of GFR. Beyond continued attention to birthweights, interventions should target progression of albuminuria.

FR-PO746

Low White Blood Cell Count Is Independently Associated with the Progression of Chronic Kidney Disease in the Elderly: The CKD-ROUTE Study Yohei Arai,[1] Eiichiro Kanda,[2] Soichiro Iimori,[1] Shotaro Naito,[1] Yumi Noda,[3] Sei Sasaki,[1] Eisei Sohara,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Dept of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Kyosai Hospital, Tokyo, Japan; [3]Dept of Nephrology, Nitobe Memorial Nakano General Hospital, Tokyo, Japan.*

Background: Elevated white blood cell (WBC) count is a well-known predictor of the progression of chronic kidney disease (CKD). However, particularly in elderly patients, it is not uncommon for them to present with low WBC count rather than developing high WBC count in response to various morbidity states. Therefore, we hypothesized that not only high WBC count but also low WBC count may be associated with the progression of CKD in the elderly.

Methods: A prospective cohort derived from three-year follow-up data of the CKD Research of Outcomes in Treatment and Epidemiology (CKD-ROUTE) study was conducted. In thepresent study, participants aged over 60 years with pre-dialysis CKD stage G2-G5 were eligible. They were stratified into three groups based on WBC count using tertiles (T). The primary outcome was a composite of end-stage renal disease (ESRD) and 50% reduction in estimated glomerular filtration rate (eGFR). Data were analyzed using Cox proportional hazards model with adjustments for baseline characteristics.

Results: We enrolled 761 patients (males, 69%). Median WBC count was 6100 cells / high-power field (T1: <5400, n = [thinsp]248; T2: 5400-6900, n = [thinsp]250; T3: ≥6900, n = 263). During a median follow-up of 854 days, the primary outcome was observed in 181 patients (ESRD, 91; 50% reduction in eGFR, 90), whereas 61 patients died. Not only T3 but also T1 had significantly higher hazard ratios (HR) for the primary outcome than T2 (T1: HR 1.66, 95% confidence interval 1.12-2.45; T3: HR 1.78, 95% confidence interval 1.22-2.62). After adjusting for baseline characteristics, T1 had significantly higher adjusted hazard ratio (aHR) for the primary outcome than T2 (aHR 1.54, 95% confidence interval 1.02-2.33).

Conclusions: Low WBC count is independently associated with the progression of CKD in the elderly.

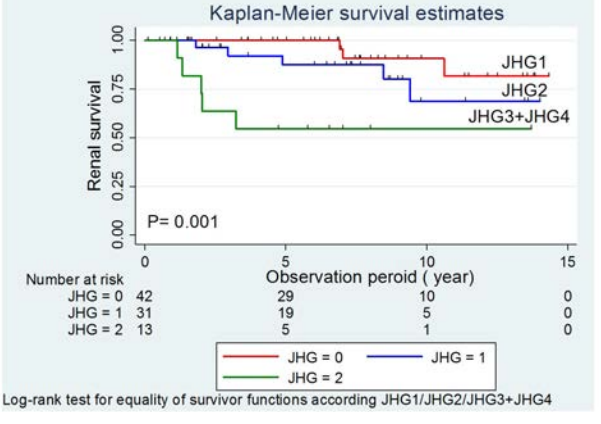
FR-PO747

Japanese Histologic Grade but the Oxford Classification Could Predict Renal Outcome in Japanese IgA Nephropathy Patients Ahmad Baseer Kaihan, Yoshinari Yasuda, Takayuki Katsuno, Shoichi Maruyama. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya City, Aichi Prefecture, Japan.*

Background: The Oxford classification (Oxford) is globally used, however it has not been fully validated among Japanese patients with IgA Nephropathy (IgAN). The aim of this study is to elucidate utility of Oxford and Japanese histologic grade (JHG), used in nationwide renal biopsy registry by Japanese Society of Nephrology, to predict renal outcome in Japanese IgAN patients.

Methods: This is a retrospective cohort study of 91 adult IgAN patients diagnosed in Nagoya University Hospital between 2001-2009 and followed up >1 year. Five cases with <8 glomeruli were excluded. Oxford and JHG were evaluated by 6 independent specialists. In JHG, glomerular lesions (cellular/fibrocellular/fibrous crescents, global/segmental sclerosis) percentage score in total obtained glomeruli was assessed and categorized into HG1 (<25%), HG2 (25-49%), HG3 (50-74%) and HG4 (≥75%). Renal outcome was 50% increase in sCr.

Results: Baseline characteristics (median, IQR) of study subjects were 36 (24-46) years old, 41 female, proteinuria: 1.2 (0.7-1.8) g/day and sCr: 0.9 (0.7-1.1) mg/dL. During a median follow-up period of 6.8 years, 15% of patients reached renal outcome. Pathological features were M0/1:79/21%, E0/1:59/41%, S0/1:33/67%, T0/1/T2:86/6/8% and crescent-/+:55/45% in Oxford and HG1:49%, HG2:36%, HG3:13% and HG4:2% in JHG. As compared to Oxford validation paper (KI2014) E1 and crescent were high and T1/2 was low in this study. Proteinuria, sCr, eGFR, UA, T score and JHG were significantly associated with renal outcome, but M/E/S scores nor crescent were not. In multivariate analysis, only JHG was a significant predictor for renal outcome.



Conclusions: JHG was superior to Oxford to predict renal outcome in Japanese IgAN patients, probably because Japanese patients are diagnosed at earlier and active phase.

FR-PO748

Clinico-Pathological Characterization and Outcome of IgAN with Crescent Dong-Rong Yu,[1] Qi-Ce Sun,[2] Yun-Qin Hu,[3] Fei Jiang,[4] Jun Wu,[5] Yong-Jun Wang.[6] *[1]Hangzhou Hospital of Traditional Chinese Medicine; [2]Zhejiang Chinese Medical Univ.*

Background: We examined the relations of crescent with clinic-pathological features and loss of renal function in IgAN.

Methods: 1054 patients with IgAN in Hangzhou hospital of traditional Chinese medicine between 2001 and 2007 were retrospectively studied. We divided 1054 patients who were diagnosed with IgAN into three groups based on their having mild (≤10%; n = 271),moderate (>10% and ≤25%, n = 182), or severe (>25%; n = 46) proportion of crescent lesion at diagnosis, compared with 555 cases without crescent formation as control group comparison.Ratios of decline in renal function was compared among the four groups during a median follow-up of 90.0 months(IQR=62.1-113.7).Loss of renal function was defined as ≥50% loss of GFR from baseline,doubling of serum creatinine,Dialysis or death. Multivariable associations between crescent and loss of renal function were examined by Cox proportional-hazards regression. Renal survival curves were generated with the Kaplan–Meier method.

Results: Of the 1054 subjects (59.3% women, mean age (33.4±9.94) years, mean proportion of crescent (13.2%±15.7%), mean GFR (98.0±35.5). Pathological indicators of activity indexes such as mesangial proliferation, glomerular sclerosis, tuft necrosis and chronic pathological changes such as tubular atrophy/interstitial fibrosis showed statistical difference in four groups,with the increasing of crescent proportion, degree of pathological further aggravate (P<0.05).(3)There were significant difference in the Lee's classification and the Oxford classification(P<0.05).Progression to renal failure was observed in 106(10.3%) patients.After multivariable adjustment, crescent(≥25%) was significantly associated with an increased risk of developing the loss of renal function (P=0.03), A Kaplan-Meier plot showed statistical difference in four groups in survival rate (P = 0.004) .

Conclusions: There is a certain correlation between the crescent lesion and the clinic-pathological features ,which can reflect the degree of disease progression to a certain extent. Higher proportion of crescent lesion (≥25%)is an independent risk factor for progression to Loss of renal function in IgAN.

FR-PO749

Associations of Echocardiographic Measures with Rapid Kidney Function Decline among African-Americans: The Jackson Heart Study Leila R. Zelnick,[1] Ronit Katz,[1] Bessie A. Young,[1] Adolfo Correa,[2] Bryan R. Kestenbaum,[1] Ian H. De Boer,[1] Nisha Bansal.[1] *[1]Univ of Washington; [2]Univ of Mississippi.*

Background: Heart failure (HF) is common in African-Americans. Structural cardiac abnormalities precede its clinical presentation, including greater left ventricular mass (LVM), greater pulmonary artery systolic pressures (PASP) and lower ejection fraction (LVEF). These subclinical measures, measured by echocardiogram, may also be associated with longitudinal kidney function decline.

Methods: We studied 2,405 African-American participants in the Jackson Heart Study (JHS) who had available echocardiograms at baseline and longitudinal measures of kidney function. LVM, LVEF and PASP were quantified from baseline echocardiograms. Estimated glomerular filtration rate (eGFR) was calculated from the creatinine-based CKD-EPI equation. Rapid kidney function decline (RKFD) was defined as >30% over a mean of 8 years, and incident CKD was defined as development of eGFR<60 mL/min/1.73m^2 and eGFR decline >1 mL/min/1.73m^2/year among CKD-free participants at baseline. Logistic regression models were adjusted for demographics, physical characteristics, comorbidities and medication use.

Results:

Associations of exposures with rapid kidney function decline (N = 2405)

	N at risk	N event	Unadjusted IR (per 1000 pys)	Adjusted odds ratio (95% CI)
Left ventricular hypertrophy				
No LVH	1846	78	5.3	1.0 (Ref)
LVH	559	57	12.5	1.31 (0.87, 1.97)
Per 25 g increment in LVM				1.18 (1.04, 1.34)
p-value				0.01
Left ventricular ejection fraction:				
LVEF < 60%	672	39	7.4	1.0 (Ref)
LVEF ≥ 60%	1720	96	6.9	0.83 (0.55, 1.25)
Per 5% increment				0.95 (0.83, 1.08)
p-value				0.40
Pulmonary artery systolic pressure:				
PASP < 30 mmHg	1146	52	5.6	1.0 (Ref)
PASP ≥ 30 mmHg	469	43	11.3	1.18 (0.75, 1.84)
Per 5 mmHg increment				0.97 (0.85, 1.10)
p-value				0.59

Left ventricular hypertrophy was defined as a left ventricular mass ≥ 150g for women and a left ventricular mass ≥ 200g for men. Rapid kidney function decline defined as >30% decline between exam 1 and exam 3. Adjusted model includes age, sex, education (HS/some college/college), height, weight, SBP, DBP, current smoking, history of diabetes, history of cardiovascular disease (MI and HF), and antihypertensive use

Mean (SD) age and eGFR were 52.2 (11.9) years and 87.4 (17.1); 37% of participants were male. Higher LVM was significantly associated with RKFD and incident CKD; a sex/LVM interaction was not significant in continuous models. The association with RKFD, but not incident CKD, remained statistically significant after multivariable adjustment. There was no association of LVEF or PASP with either RKFD or incident CKD in multivariable models.

Conclusions: Among African-Americans in a community-based cohort, greater LVM was significantly associated with RKFD. Further studies are needed to determine whether treating risk factors for left ventricular hypertrophy may also reduce risk of progression of kidney disease in this high-risk population.

Moderate Elevated Blood Selenium Is Associated with Reduced Risk of Renal Function Decline

Hao Zhang,[1,2,3] Yi Fang,[1,2,3] Xiaoyan Zhang.[1,2,3] *[1]Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Shanghai Inst of Kidney Disease and Dialysis, Shanghai, China; [3]Kidney and Blood Purification Laboratory of Shanghai, Shanghia, China.*

Background: Although the benefit of selenium (Se) supplement for patients with end-stage renal disease was supported by many studies, it is not clear whether elevated blood Se could or not improve renal function among general people. The purpose of this study is to examine the relationship between Se states and glomerular filtration rate (GFR) among general adults.

Methods: We conducted a cross-sectional analysis using 2011-2012 National Health and Nutrition Examination Survey (NHANES), and a total of 4885 persons 20 years or older were included. Whole blood Se were measured with inductively coupled plasma mass spectrometry. Renal function decline was defined as estimated GFR (CKD-EPI) <60 mL/min/1.73m^2. Logistic regression was applied to assess the association between blood Se levels and risk of renal function decline.

Results: The mean of blood Se of the all the 4885 participants was 193.3±27.5 μg/L, and all of them were above the criteria of Se deficiency, i.e. 98 μg/L. The mean Se concentrations for persons with eGFR≥90, 60-89, 30-59 and <30 mL/min/1.73m^2 were 193.8±28.1, 194.5±25.8, 186.8±28.5 and 177.3±24.0 μg/L, respectively. Compared to the lowest quintile of blood Se, the age-, gender- and race- adjusted odds ratios (ORs) were 0.88 (95% confidence interval 0.63-1.22) for the 2nd quintile, 0.61 (0.43-0.87) for the 3rd quintile, 0.60 (0.42-0.85) for the 4th quintile and 0.59 (0.41-0.85) for the highest quintile.

Blood Se (μg/L)	OR (95% CI)	*P*
Quintile 1 (105.39-172.96)	Reference	
Quintile 2 (172.98-185.64)	0.88 (0.63-1.22)	0.44
Quintile 3 (185.65-197.33)	0.61 (0.43-0.87)	<0.01
Quintile 4 (197.39-212.23)	0.60 (0.42-0.85)	<0.01
Quintile 5 (212.25-692.52)	0.59 (0.41-0.85)	<0.01

Conclusions: Even for the persons with relatively low but normal Se levels, moderate elevated blood Se was associated with reduced risk of renal function decline, but further elevated Se concentration, e.g. > 200 μg/L, may not have additional benefit for renal function.

FR-PO751

Elevated Bilirubin Level Is Associated with Better Renal Prognosis

Sehoon Park,[1] Jin Ho Hwang,[3] Jinhyuk Kim,[2] Seung Hee Yang,[1] Chun Soo Lim,[2] Yon Su Kim,[1] Jung Pyo Lee.[2] *[1]Dept of Internal Medicine, Seoul National Univ Hospital, Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Korea; [3]Dept of Internal Medicine, Chung-Ang Univ, Korea.*

Background: Protective effect of bilirubin on kidney injury was reported in patients with diabetes mellitus or Gilbert syndrome, and its role as an antioxidant was claimed as the reason. However, whether mildly elevated bilirubin is related to renal prognosis in more generalized population was scarcely described.

Methods: We assessed a cohort with reference range value of total bilirubin who visited for screening coronary artery CT scans. Patients who had major adverse cardiovascular events and follow-up duration less than 1 month were excluded from the study. The primary outcome was 30% reduction of eGFR from baseline, and the secondary outcome was a composition of doubling of serum creatinine, eGFR halving and a start of dialysis. Next, *in vivo* experiment with C57BL/6 mice was done to investigate the protective effect of intraperitoneal bilirubin treatment on kidney fibrosis by unilateral ureteral obstruction (UUO) model. The relationship between bilirubin treatment and activation of the HIF-1 pathway was also evaluated.

Results: A total number of 1,128 patients were included in our cohort. The study group who had relative hyperbilirubinemia (total bilirubin 0.8-1.2mg/dL) showed better renal prognosis in terms of the primary outcome (adjusted hazard ratio (HR) 0.332, 95% CI 0.162-0.679, *P*=0.003) and the secondary outcome (adjusted HR 0.114, 95% CI 0.026-0.791, *P*=0.026). Moreover, mice treated with bilirubin showed less fibrosis in UUO model (*P*<0.05) and decreased fibrosis markers such as TGF-β or FSP1 (*P*<0.01). Lastly, intraperitoneal bilirubin treatment led increment in HIF1a (*P*<0.01) and HIF1b (*P*<0.05).

Conclusions: Relative hyperbilirubinemia even within reference range level showed a protective effect on renal dysfunction progression. Intraperitoneal bilirubin treatment decreased kidney fibrosis and upregulated HIF-1 pathway in *in vivo* experiment. Therefore, bilirubin could be a potential therapeutic target to ameliorate kidney fibrosis by reducing oxidative stress injury.

FR-PO752

Differential Effects of Nicotine on the Cortical Production of Prostaglandins in Rats with Chronic Kidney Disease

Gabriel Rezonzew,[1] Phillip H. Chumley,[1] Helena Furberg-Barnes,[2] Irene Orlow,[2] Edgar A. Jaimes.[2] *[1]Div of Nephrology, Univ of Alabama at Birmingham; [2]Renal Service, Memorial Sloan Kettering Cancer Center.*

Background: Cigarette smoking is a risk factor in the progression of CKD. Nicotine (N), a major component of tobacco, worsens renal injury in 5/6 nephrectomy rats (Nx), a well-validated model of CKD (AJP'12). As we have shown, COX2 inhibition reduces renal injury in Nx rats on nicotine (ASN'13). In these studies we determined the effects of nicotine on the cortical production of prostaglandins (PGs) in normal rats and in rats with CKD.

Methods: Male SD rats were divided in five groups (n=7): Sham (S), S+N (0.1 gm/L, DW), S+N+COX-2 inhibitor (NS, 1.5 mg/Kg/day, SQ), Nx, Nx+N, Nx+N+NS, Nx+NS for 12 weeks. Rats were euthanized after 12 weeks and kidney cortex snap frozen and saved for PGs measurement by mass spectrometry (ng/g wet weight).

Results: Nicotine increased production of PGE_2 and PGI_2 in sham rats that was inhibited by NS. Nx resulted in increases in the cortical production of all PGs studied. Nicotine significantly reduced the production of PGE_2, PGI_2 and $PGF_{2\alpha}$ in Nx rats but not of TXB2 (Table). NS reduced the production of PGs in Nx groups suggesting COX2 as the is the main source of PGs in this model.

	S	S+N	S+N+NS	Nx	Nx+N	Nx+N+NS	Nx+NS
PGE_2	9.7±1.3	37.8±5*	20.3±3.2#	52.1±13.4*	29±4.6*,#	24.4±1.9#	18.5±3.6#
PGI_2	3.7±0.8	14.3±1.5*,#	5.5±0.7#	108.4±28.4*	40.6±10.7*,#	3.2±0.9#	2.4±0.5#
TXB_2	2.6±0.3	5.3±0.3	0.7±0.1#	9.4±2.8*	10.7±3.3*	1.4±0.3#	1.2±0.3#
PGF2α	5.3±0.9	10±1.2#	5±0.3#	26±6.8*	14.1±2.6*,#	6.6±0.5#	6.4±1#

* P < 0.05 vs Sham, # P < 0.05 vs Nx.

Conclusions: This study demonstrates that nicotine increases the production of PGs via COX2 in normal rats but reduces the production of all PGs studied except TXB_2 in rats with CKD. These findings suggest that differential effects on the production of specific PGs could explain at least in part the deleterious effects of nicotine in the progression of CKD, by downregulating some PGs (PGE_2, PGI_2 and $PGF_{2\alpha}$) while having no effect on others (TXB_2). Future studies will investigate the effects of nicotine on specific PG synthases.

Association between Gestational Diabetes and Maternal Chronic Kidney Disease

Elizabeth W. Dehmer,[1] Milind A. Phadnis,[2] Cora E. Lewis,[3] Holly J. Kramer,[4] Erica P. Gunderson.[5] *[1]Univ of North Carolina Gillings School of Global Public Health; [2]Univ of Kansas School of Medicine; [3]Univ of Alabama at Birmingham; [4]Loyola Univ Chicago; [5]Kaiser Permanente Northern California.*

Background: Gestational diabetes mellitus (GDM) is associated with subsequent type 2 diabetes mellitus, metabolic syndrome, and cardiovascular disease for affected women. We analyzed whether GDM is associated with incident chronic kidney disease (CKD), controlling for pre-pregnancy risk factors for both conditions.

Methods: A total of 820 women without diabetes enrolled in the Coronary Artery Risk Development in Young Adults (CARDIA) Study who were nulliparous at baseline in 1985-86 and reported at least one pregnancy during 25 years of follow-up were studied. GDM was self-reported. CKD was defined as development of estimated glomerular filtration rate < 60 ml/min/1.73m^2 or urine albumin to creatinine ratio ≥ 25 mg/g. Hazard ratios (HR) for developing CKD were compared between women with and without history of GDM using complementary log log models, beginning with first pregnancy and adjusting for pre-pregnancy age, systolic blood pressure, high density lipoprotein cholesterol, body mass index, smoking, education, kidney function, fasting glucose, and physical activity level as well as race and family history of diabetes. Interaction between race and GDM was also tested.

Results: Over mean follow-up of 20.8 years, N=101 women reported GDM and N=105 (58 black, 47 white) developed incident CKD, predominately manifested by increased albumin excretion in the urine. The unadjusted HR (95% confidence interval (CI)) for CKD was 1.46 (0.87, 2.45) for women with GDM compared to parous women who did not report a pregnancy with GDM. There was evidence of a GDM-race interaction (Wald interaction p=0.07 in the fully adjusted model). The HR (95% CI) for CKD in the fully adjusted model was 1.96 (1.04, 3.67) for black women with GDM compared to those without GDM. Among white women, the HR (95% CI) was 0.65 (0.23, 1.83).

Conclusions: GDM may be associated with subsequent development of CKD among black women.

FR-PO754

Advanced CKD Is Associated with Higher Use of Insulin, Independent of Hemoglobin (Hb) A1C Levels and Duration of Type 2 Diabetes Mellitus (T2DM) R. E. Boucher,[1] Debra Lynn Simmons,[1] Rabia Nadeem Kiani,[1] Guo Wei,[1] Tom Greene,[1] T. S. Bjordahl,[1] Linda F. Fried,[2] Srini Beddhu.[1] *[1]Univ of Utah; [2]VA Pittsburgh.*

Background: Need for insulin in T2DM might reflect decreased insulin secretion (beta cell dysfunction) and/ or insulin resistance. Longer duration of T2DM might also result in exhaustion of beta cell insulin secretion. We hypothesize that more advanced CKD reflects a state of ↓ insulin secretion and/or ↑ insulin resistance, so that need for use of insulin is higher in more advanced CKD after accounting for T2DM duration and HbA1C.

Methods: We examined a cohort of 592,491 veterans with a diagnosis for T2DM (defined by ICD9 codes) and outpatient serum creatinine measured between 1/1/2010 and 12/31/2013. Data on filled medications were obtained from outpatient pharmacy database. Laboratory data were obtained from routine clinical labs. DM duration was obtained by identifying the first instance of ICD9 codes for DM or HbA1c>6.5% or use of diabetes medications in the preceding 12 years. In a logistic regression model, eGFR stages, duration of DM and HbA1C levels were related to the use of insulin as the dependent variable adjusted for age, gender, race, CHF, lung disease, cancer, atherosclerotic conditions, SBP, DBP and BMI.

Results: Mean age was 67 ± 11 yrs. 96.6% were males and 16.9% were black. 28.0% were on insulin. Mean BMI was 32 ± 6 kg/m^2, mean eGFR was 74 ± 22 ml/min/1.73 m^2, mean HbA1c was 7.4 ± 1.7%, and mean diabetes duration was 5.8 ± 3.8 yrs.

Associations of eGFR groups, duration of diabetes and Hb1C with the use of insulin in veterans (N = 592,491)

	Adjusted Odds Ratio (95% CI)
eGFR groups	
≥90	Reference
60-89	1.21 (1.19, 1.23)
45-59	1.85 (1.81, 1.89)
30-44	2.84 (2.76, 2.92)
<30	4.26 (4.09, 4.45)
Diabetes Duration (yrs)	
<5	Reference
5-9	2.05 (2.02, 2.08)
≥10	4.00 (3.92, 4.07)
HbA1c (%)	
<7	Reference
7-8.4	3.49 (3.44, 3.55)
≥8.5	9.90 (9.73, 10.07)

Conclusions: Worsening renal function is associated with greater use of insulin. This is observed even at eGFR levels (> 45) at which metformin use is not contraindicated.

Funding: NIDDK Support

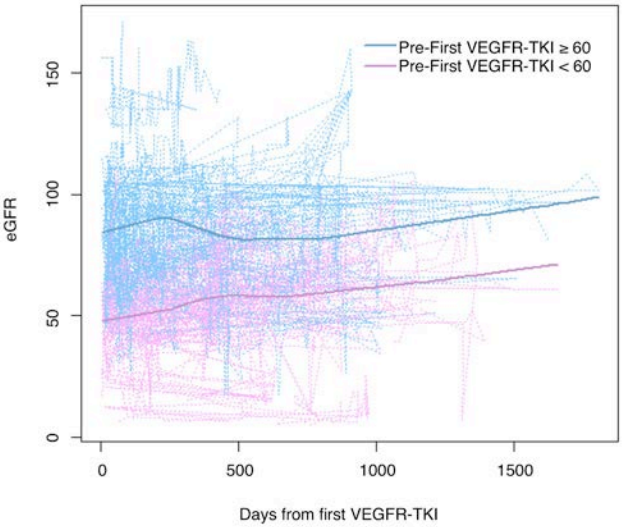
FR-PO755

Renal Function in Kidney Cancer Patients: Effects of Vascular Endothelial Growth Factor Receptor Tyrosine Kinase Inhibitors Brian Charles Boursiquot,[1] Emily C. Zabor,[2] Ilya Glezerman,[3,4] Edgar A. Jaimes.[3,4] *[1]Stanford Univ School of Medicine, Stanford, CA; [2]Dept of Epidemiology & Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY; [3]Dept of Medicine, Div of Nephrology & Hypertension, Weill Cornell Medical College, New York, NY; [4]Dept of Medicine, Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: VEGFR tyrosine kinase inhibitors (TKIs) have become first line therapy for metastatic renal cell carcinoma (mRCC). Their use leads to hypertension (HTN) in ~30% of patients, but their effects on long-term renal function are not known. In addition, it has been suggested that the development of HTN is linked to treatment efficacy. The main objective of this study was to determine whether TKIs affect long-term renal function and the role of HTN on these effects.

Methods: This is a retrospective study of 130 mRCC patients who were treated with TKIs at MSKCC. Longitudinal measurements of serum creatinine were used to calculate the eGFR for each patient over time, for a median of 1.5 years among survivors. New or worsening HTN was defined by documented start or addition of antihypertensives.

Results: Overall, the use of TKIs in patients with eGFR < 60 ml/min or eGFR ≥ 60 ml/min did not result in significant changes in long term renal function.



During follow up, 41 patients (31.5%) developed new/worsening HTN within 30 days from first TKI use and this was not linked to further reductions in eGFR. These patients appeared to survive longer than those who did not develop HTN within 30 days, although this was not statistically significant (P=0.07).

Conclusions: Our findings suggest that the use of TKIs does not adversely affect renal function even in the setting of new onset HTN or reduced eGFR at baseline. However prospective long-term studies will be needed to better assess the effects of TKIs on long-term renal function.

Histopathological Findings for Renal Progression Are More Pronounced in Upper Tract Urothelial Carcinoma Than in Renal Cell Carcinoma after Unilateral Nephrectomy Sheng-Wen Niu,[1] Peir-In Liang,[2] Ming-Yen Lin,[1] Wei-Ming Li,[3,4] Chun-Nung Huang,[3,4] Wen-Jeng Wu,[3,4] Li-Tzong Chen,[5] Shang-Jyh Hwang.[1,4] *[1]Nephrology, Kaohsiung Medical Univ Hospital; [2]Pathology, Kaohsiung Medical Univ Hospital; [3]Urology, Kaohsiung Medical Univ Hospital; [4]National Inst of Cancer Research; [5]Faculty of Medicine, Kaohsiung Medical Univ.*

Background: Patients with upper urinary tract urothelial carcinoma (UTUC) had high risk of chronic kidney disease or entering dialysis than renal cell carcinoma (RCC). We studied the pathological changes of renal tissue from nephrectomized kidney of UTUC and RCC, and compared the correlation between renal histopathology and progression to end-stage renal disease in these two groups of cancer patients.

Methods: This study included 132 cases of UTUC post ipsilateral nephrectomy and 61 cases of RCC post radical nephrectomy(RN). All of them were not yet on dialysis before surgery. The renal histopathology was read by 3 specialists: nephrologists or pathologist, independently. Clinical and laboratory data before surgery, whether entering into dialysis eventually, and dialysis-free days from surgery until December 31, 2014 were collected. We used logistic regression for tubulointerstitial (TI) nephropathy score and global glomerular sclerosis(GGS) rates respectively, and Cox regression to investigate which factors affect renal survival.

Results: There were significantly higher TI nephropathy scores and greater abnormal GGS rates from nephrectomized kidneys of UTUC than from RCC. Kaplan-Meier survival curve showed five-year dialysis-free survival rate was 0.863 in UTUC group and 0.967 in RCC group. There were two major pathological factors, hypertension [HR(95%CI): 3.03(1.02-9.02), p=0.046] and abnormal GGS rate [HR(95%CI):2.88(1.01-8.17), p=0.047], for dialysis-free survival in UTUC group; but no factor in RCC group.

Conclusions: There were two major pathological factors, hypertension and abnormal GGS rate, for dialysis-free survival within 5 years in UTUC patients post ipsilateral NUx; but no specific risk factor in RCC patients.

Funding: Government Support - Non-U.S.

FR-PO757

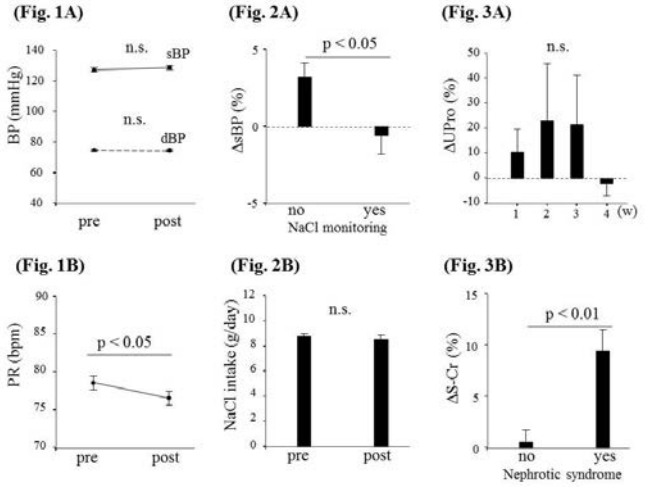
The Impact of the Kumamoto Earthquake on Renal Parameters in CKD Patients Yushi Nakayama, Masataka Adachi, Hideki Inoue, Takashige Kuwabara, Yuichiro Izumi, Yutaka Kakizoe, Masashi Mukoyama. *Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Disasters inevitably affect a number of diseases such as hypertension and kidney disease. A series of strong earthquakes attacked Kumamoto in central Kyushu, a southwest part of Japan, in April 2016. In this study, we evaluated the impact of the seismic disaster on CKD states during an early phase.

Methods: We analyzed blood and urine data from 225 out-patients with CKD (58±1.2 years), who visited our hospital during four weeks after the main shock. Systolic and diastolic blood pressures (sBP and dBP), pulse rate (PR), and body weight were also evaluated. These data were compared with preceding ones.

Results: Percentage of diabetic nephropathy (DN) was 12% and that of nephrotic syndrome was 14%. sBP and dBP did not change significantly (Fig. 1A). However, PR significantly reduced after the disaster (Fig. 1B). In sub-analyses evaluating the changes of each parameter between groups, sBP significantly increased only in patients whose daily NaCl intake was not monitored (Fig. 2A). For patients under monitoring, NaCl intake before and after the disaster was almost equivalent (Fig. 2B). dBP significantly reduced in DN (–9.5±3.0% vs non-DN; +1.2±1.1%, p<0.01). Urine protein excretion (U-Pro) tended to increase during three weeks (Fig. 3A). U-Pro also tended to increase in male (+22.5±12.3% vs female; -8.7±5.2%, p=0.086) or patients who experienced evacuation (+33.9±24.9% vs no; +5.7±5.2%, p=0.089). Serum creatinine significantly increased in patients with nephrotic syndrome (Fig. 3B).

Conclusions: Regular monitoring of urinary NaCl excretion might ameliorate the increase of BP during disaster. Sex, evacuation, and nephrotic syndrome could affect renal parameters after the earthquake. Further analyses are needed to evaluate the long-term impact of earthquake on CKD.



FR-PO758

Care of Chronic Kidney Disease Patients by General Practitioners Dunia Diaz, Ileana Farrada, Felix Hernandez, Rute C. Paixao. *Cleveland Clinic Florida.*

Background: The prevalence of patients with chronic kidney disease (CKD) in the United States has been steadily rising. While there is reasonable evidence that specific activities can be implemented to delay its progression and reduce mortality, CKD is under-recognized and undertreated in primary care offices.

Methods: We conducted a quality improvement (QI) project at Cleveland Clinic Florida by assessing the rate of recognition and proper staging of CKD and whether or not KDOQI guidelines for CKD care were being followed by general practitioners. The data was analyzed pre and post practitioner education (current CKD guidelines were taught at several conferences).

Results: A total of 99 patients were evaluated in the pre education (pre) and 107 in the post education (post). In the pre, no patients were followed by nephrology. In the post, 62/107 patients were established with a nephrologist. In terms of demographics there was no statistical difference for age, gender, or Caucasian ethnicity. Comorbidities such as DM and HLD were comparable but more patients in the post had HTN (82% vs 65%; p=0.007). General practitioners recognized and properly staged CKD more often in the post than in the pre (71% vs 23% for CKD recognition and 76% vs 22% for proper staging respectively; p<0.0001). There was no statistical difference for blood pressure control, ACEi/ARB, statin, and Metformin use among the groups. Better glucose control (HbA1c < 7.5) was achieved in the post when compared to the pre (84% vs 55%; p<0.05). Measurement of vitamin D also improved in the post (76% vs 25%; p<0.05). No statistical difference was noted in terms of NSAID use, anemia work up/treatment, and measurement of proteinuria, PTH, and phosphorus in the pre and the post unless the patient was followed by nephrology.

Conclusions: In this QI project, we found that education of general practitioners improved some but not all parameters. We also noted that patients followed by nephrologists were more likely to have measurement of proteinuria and bone mineral disease, anemia work up/treatment, and less NSAID use. No difference was noted for blood pressure control, ACEi/ARB, statin, or Metformin use. Further studies are needed to determine the long term significance of these differences.

FR-PO759

Haptoglobin Genotype among Patients with IgA Nephropathy: Impact on Disease Progression and Response to Treatment Zaher Armaly,[1] Nayef Mohamed Habbashe,[2] Kamal Hassan,[3] Rawi Ramadan,[4] Raymond Farah.[5] *[1]Nephrology, E.M.M.S. Hospital, Bar Ilan Univ, Nazareth, Israel; [2]Nephrology, HaEmeq Medical Center, Afula, Israel; [3]Nephrology, Western Galilee Hospital-Nahariya, Nahariya, Israel; [4]Nephrology, Rambam Health Campus, Haifa, Israel; [5]Internal Medicine, Ziv Medical Center, Safed, Israel.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis, may progress to ESRD. Although the pace of decline in kidney function in IgAN is affected by proteinuria, hypertension, and low eGFR at the time of the diagnosis, the exact mechanisms underlying the pace of deterioration is still largely unknown. Recently, the role of genetic risk factors in the pathogenesis of IgAN is being elucidated. However, the impact of haptoglobin (Hp) genotype on the progression of IgAN, was not studied yet. Therefore, the current study examines whether Hp genotype influences disease progression and response to treatment.

Methods: The present study included 28 patients with IgAN (42.5±2.5 years old), 26 non-IgAN chronic kidney disease (CKD), 54 patients on hemodialysis, and 150 healthy subjects. Blood and urine samples were collected at baseline and 6 months after initiation therapy. Serum creatinine (SCr) and total proteinuria, were determined in all IgAN patients. Blood analysis for Hp genotype was performed for all subjects.

Results: Twenty nine percent of IgAN patients were Hp 1-1, 36% Hp 2-1, and 36% Hp 2-2. In contrast, in patients with non-IgAN chronic kidney disease the prevalence of Hp 1-1, Hp 2-1, and Hp 2-2 was 8%, 19%, and 73%, respectively. In hemodialytic patients, prevalence of Hp 1-1, Hp 2-1, and Hp 2-2 was 19%, 28%, and 54%, respectively. In healthy subjects, the distribution of Hp 1-1, Hp 2-1, and Hp 2-2 was 7%, 39%, and 54%, respectively. Interestingly, IgAN Hp 2-2 patients were more stable and responded better to treatment with routine therapy (RAS inhibitors or steroid) than other Hp genotype, as was evident by the extent of proteinuria and SCr.

Conclusions: Hp 1-1 genotype is more common in IgAN patients as compared with general population in Israel, and even more than CKD patients or subjects on HD. Patients with Hp 2-2 responded better to appropriate therapy. The mechanisms underlying this phenomenon remain to be explored.

FR-PO760

Effects of Uric Acid and Inflammation on the Risk of Developing Chronic Kidney Disease in Female Rheumatoid Arthritis Patients Masako Kochi,[1] Kentaro Kohagura,[2] Yusuke Ohya.[1] *[1]Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus School of Medicine, Nishihara, Okinawa, Japan; [2]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara, Okinawa, Japan; [3]Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus School of Medicine, Nishihara, Okinawa, Japan.*

Background: Inflammation is a risk factor for progression of chronic kidney disease in the patients with in patients with rheumatoid arthritis as well as general population.Uric acid (UA) is suggested to promote inflammation. However, the combined effects of UA and inflammation on the risk of developing CKD are not known in RA. This study aims to examine the relationship between UA, C-reactive protein (CRP; a marker of inflammation), and the incidence of CKD in female RA patients.

Methods: We retrospectively examined a total of 284 female RA patients. The outcome of interest was incidence of CKD which was defined as an eGFR<60 mL/min/1.73 m^2 and/or positive dipstick testing for proteinuria for ≥3 months. High UA was defined >5.0 mg/dL, based on more than the highest quartile value at baseline and high CRP was defined as > 4.9 mg/L, based on more than median value for the baseline CRP.Patients were categorized into four subgroups by the presence of high UAand high CRP at baseline: lowUA and low CRP, lowUA and high CRP, highUA and low CRP, and high UA and high CRP.

Results: Mean baseline patient age was 57 years, and mean eGFR was 86 ml/minute/1.73 m^2. Over a median follow-up of 8 years, 41 (14%) patients developed CKD. High UA and high CRP were independently associated with the incidence of CKD, respectively. Subgroup analysis showed that the cumulative incidence of CKD was the highest in patients with high UA and high CRP group compared with all other groups (P = 0.002, log-rank test). In a multivariate analysis, high UA and high CRPwas significantly associated with increased risk for incident CKD (adjusted HR, 3.91; 95% confidence interval, 1.40–11.71; $p = 0.009$) independent of age, eGFR at baseline, classical risk factors and anti-RA drug uses.

Conclusions: Independent of confounding risk factors, high UA had an inflammation-augmented association with increased risk of CKD in female RA patients.

FR-PO761

Predictive Factors of Renal Outcome after Heart Transplantation Hee Jin Kwon, Subin Hwang, Jae Shin Choi, Jung Eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Hye Ryoun Jang. *Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

Background: Cardiorenal syndrome (CRS) frequently occurs in end-stage heart failure patients waiting for heart transplantation (HT) and combined heart kidney transplantation (HKT) is required in some patients. However, there have been few reports investigating predictive factors of renal outcome in patients receiving HT with no consensus for indication

of HKT. In this study, we investigated the factors predicting renal outcome after HT in end-stage heart failure patients, focusing on changes in renal function and chronic kidney disease (CKD) evaluated 1 year after HT.

Methods: A single–center retrospective cohort study of 182 patients receiving HT from 1996 to 2015 was conducted. A total of 160 patients were followed for at least 1 year after HT. Primary outcomes were eGFR, %ΔeGFR [100 X (post-HT eGFR - pre-HT eGFR)/ pre-HT eGFR], and CKD (eGFR < 60 ml/min/1.73m^2) prevalence at 1 year after HT. The results of pre-transplant kidney ultrasound (US) images were scored as follows: normal (0), increased echogenicity (1), findings suggestive underlying CKD (2).

Results: Perioperative renal replacement therapy (RRT) group (n=45) had more frequent proteinuria (p=.003) and mechanical circulating support (p<.001). Although mortality within 1 year was higher in RRT group than in non-RRT group (p<.001), there was no difference in CKD at post-HT 1 year. Higher eGFR at post-HT 1 year was associated with young age, high preoperative eGFR, and high ejection fraction (EF) at 1 year. High %ΔeGFR (significant improvement of renal function) at post-HT 1 year was associated with young age, preexisting CKD, preoperative RRT, low preoperative eGFR, and high preoperative EF. Old age, preexisting CKD, and high kidney US image score were identified as independent risk factors of CKD at post-HT 1 year.

Conclusions: Although RRT group showed higher mortality than non-RRT group, there was no difference in CKD at post-HT 1 year in survivors. Closer monitoring and careful management are required in HT patients with old age, preexisting CKD, high kidney US image score, and low postoperative EF for improving renal outcome.

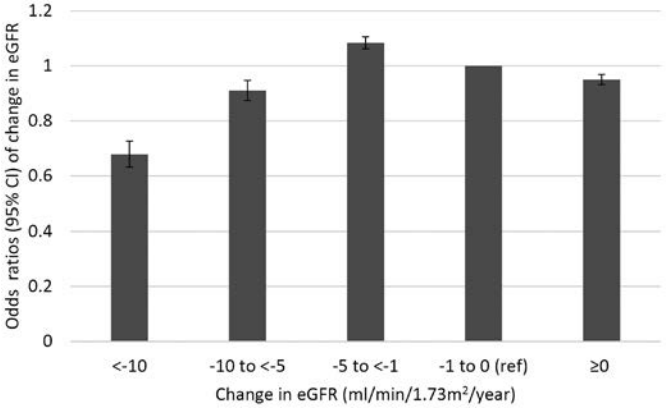
FR-PO762

Testosterone Replacement Therapy Is Associated with Less Progression of Chronic Kidney Disease Praveen Kumar Potukuchi,[1] Keiichi Sumida,[1] Miklos Zsolt Molnar,[1] Jun Ling Lu,[1] Fridtjof Thomas,[1] Connie Rhee,[2] Melissa Soohoo,[2] Elani Streja,[2] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]VA Medical Center, Memphis, TN.*

Background: Testosterone levels decrease with reduced renal function. Testosterone replacement therapy (TRT) has putative cardiovascular and metabolic benefits, but its effects on kidney function are unknown.

Methods: In a nationwide cohort of 827,582 U.S. male veterans with an eGFR ≥60 mL/ min/1.73 m^2 and available total testosterone level, we examined the association of incident TRT with kidney function changes (slopes of eGFR calculated from serum creatinine levels measured over 8-year follow up period) in five groups of chronic kidney disease (CKD) patients, using logistic and multinomial logistic regression models with adjustment for sociodemographics, comorbidities, medications, and clinical variables.

Results: The mean (SD) age of the cohort was 57.8 (11.3) years; 19% were African American and 27% were diabetic. Patients who received (vs. those who did not receive) TRT had experienced significantly lower risk of fast and very fast eGFR decline (logistic odds ratio[95% CI] for eGFR slope <-5 vs. >=-5 mL/min/1.73 m^2/year, 0.84 [0.81-0.87]) (multinomial odds ratios [95% CI] for eGFR slope <-10, -10 to <-5, -5 to <-1, and ≥ 0, vs. -1 to <0 mL/min/1.73 m^2/year, 0.68 [0.63-0.73], 0.91 [0.87-0.95], 1.08 [1.06-1.11] and 0.93 [0.93-0.97], respectively) (Figure).



Conclusions: TRT is associated with lower risk of rapid eGFR decline. Further studies are needed to elucidate the underlying mechanisms and to determine whether testosterone replacement therapy could indeed be renoprotective.

FR-PO763

Diuretic Use and Type on Progression in Chronic Kidney Disease Claudia S. Cabrera,[1] Jingrong Yang,[2] Thida Tan,[2] Bergur V. Stefansson,[1] Peter J. Greasley,[1] Alan S. Go.[2] *[1]AstraZeneca; [2]Kaiser Permanente Northern California.*

Background: Few studies have systematically evaluated medical therapies as potential risk factors for accelerated progression of CKD in "real world" populations. Conflicting data exist about the impact of diuretics outside clinical trials. In a large community-based Stage 3/4 CKD cohort, we evaluated the association between diuretic use and type with CKD progression and development of ESRD.

Methods: Within Kaiser Permanente Northern California, we identified adults with eGFR 15-59 min/1.73m^2 by CKD-EPI between 2008-2012 who had no prior diuretic use or ESRD. Through 2012, we calculated the rate (per 100 P-Y) of the composite outcome of ESRD, reaching eGFR <15 ml/min/1.73m^2, or >50% reduction from baseline eGFR. New initiation of diuretic therapy and type was identified from comprehensive pharmacy data. Demographics, clinical risk factors and longitudinal medical therapies were obtained from electronic medical records. We used marginal structural models (MSM) with inverse probability weighting (IPW) to evaluate the impact of loop or thiazide diuretics on CKD progression after adjusting for baseline and time-dependent confounders (including heart failure episodes). IPW's were calculated for treatment and censoring for each 30-day period of follow-up and integrated into pooled logistic regression models to estimate the effect of new use of loop or thiazide diuretics.

Results: In 117,728 eligible adults with eGFR 15-59 min/1.73m^2, mean age was 72 years, 57% women, 24% persons of color and 25% with diabetes. Over mean follow-up of 3.7±1.3 years, the overall rate of the renal composite outcome was 1.47 per 100 P-Y (95% CI: 1.43-1.50). In MSM models, initiation of diuretics was independently associated with higher rates of CKD progression even after accounting for use of other cardiovascular and renal-related medications and time-dependent confounders: thiazide diuretic (adjusted odds ratio [OR] 2.95, 95% CI:2.11-4.12) and loop diuretic (OR 1.47, 95% CI:1.23-1.74).

Conclusions: In a large, diverse, community-based Stage 3/4 CKD population, use of diuretics was independently associated with a higher risk of CKD progression, especially thiazide diuretics.

Long Term Kidney Outcomes among Proton Pump Inhibitors Users with and without Acute Kidney Injury Yan Xie,[1] Benjamin Charles Bowe,[1] Tingting Li,[1,2] Hong Xian,[1] Yan Yan,[1] Ziyad Al-Aly.[1,2,5] *[1]Clinical Epidemiology Center, VA Saint Louis Health Care System, Saint Louis, MO; [2]Dept of Medicine, Washington Univ School of Medicine, Saint Louis, MO; [3]Renal Section, Medicine Service, VA Saint Louis Health Care System, Saint Louis, MO.*

Background: Proton Pump Inhibitor (PPI) use is associated with increased risk of acute kidney injury (AKI), incident chronic kidney disease (CKD), CKD progression, and end stage renal disease (ESRD). PPI-associated CKD is presumed to be secondary to incomplete recovery of AKI. Whether long term adverse renal outcomes are mediated solely by occurrence of AKI is not known.

Methods: We used the Department of Veterans Affairs national databases to build a cohort of 158,574 incident users of acid suppression therapy: 137,310 PPI and 21,264 Histamine H2 receptor antagonists (H2 blockers) users with no history of AKI. Logistic regression models were built to examine the association of PPI exposure and odds of incident CKD, CKD progression, and ESRD within cohort participants with and without AKI during follow up.

Results: After a follow-up of 5 years, among those who developed AKI, and compared to new users of H2 blockers, new users of PPI had 1.29 (1.20, 1.38), 1.24 (1.17, 1.32), and 1.19 (1.03, 1.39) odds of having incident CKD, eGFR decline >30%, and 50% decline in eGFR or ESRD, respectively. Among cohort participants without AKI, and compared to new users of H2 blockers, new PPI users had 1.34 (1.25, 1.42), 1.30 (1.23, 1.37), and 1.31 (1.15, 1.50) odds of having incident CKD, eGFR decline >30%, and 50% decline in eGFR or ESRD, respectively.

Conclusions: Our results demonstrate that PPI use is associated with significant higher odds of adverse long term renal outcomes in incident users of acid suppression therapy with and without intervening AKI. The findings suggest that association of PPI use and long term renal outcomes may not be solely mediated by occurrence of AKI. Other possible pathways may include chronic indolent renal damage caused directly by PPI or mechanisms related to PPI-induced hypomagnesemia. Further investigation is necessary to elucidate the mechanisms linking PPI use and CKD.

FR-PO765

Red Cell Indices Are Not Indicative of Iron Deficiency in Children with Pre-Dialysis Chronic Kidney Disease Abdullahi Mudi,[1,2] Cecil S. Levy.[1] *[1]Div of Paediatric Nephrology, Univ of the Witwatersrand, Johannesburg, South Africa; [2]Dept of Paediatrics, Bayero Univ, Kano, Nigeria.*

Background: Iron deficiencyis common in children with chronic kidney disease (CKD). Clinicians in developing countries often rely on red cell indices (MCV, MCHC, RCDW) as a screening tool for iron deficiency because serum iron parameter tests are either expensive or not readily available. We aimed to evaluate the use of red cell indices in screening for iron deficiency in a group of children with pre-dialysis CKD.

Methods: Ninety-four children with CKD stage 1–4 were reviewed for age, sex and current medications. Each patient had blood samples sent for FBC and Iron Studies. CRP was simultaneously sent to exclude inflammation.

Results: Eleven of the children were on oral iron supplement and were excluded from the analysis. None of the children had received blood transfusion within the last four months. Median age 10 years (IQR:7-13 years); male to female ratio 1.96:1; 9/83 had low Hb (< 12g/dl); 43/83 had a low TSAT (<20%); 32/83 had a low ferritin (<30µg/l) and 20/83 had absolute iron deficiency (low TSAT and low ferritin); 23/83 had functional iron deficiency (low TSAT and normal ferritin). There was no statistically significant difference in the mean values of the haemoglobin and red cell indices between patients with deplete (low TSAT and/or low ferritin) and replete iron stores. CRP was not significantly associated with ferritin levels (p=0.093).

	Deplete Iron stores (n=55)	Replete Iron stores (n=28)	P value
Hb (g/dl)	13.41 ± 1.28	13.56 ± 1.33	0.619
MCV (Fl)	83.97 ± 5.55	83.78 ± 5.24	0.883
MCH (pg)	27.60 ± 2.19	27.69 ± 1.71	0.842
MCHC (g/dl)	32.81 ± 1.11	33.12 ± 0.93	0.211
RCDW (%)	14.13 ± 1.57	13.79 ± 0.95	0.297

Conclusions: A large number of children with CKD are iron deficient. The use of red cell indices to screen for iron deficiency among such patients may be misleading. We emphasise the use of serum iron parameters, rather than red cell indices to assess for iron deficiency in CKD as recommended by the KDIGO guidelines.

FR-PO766

Anemia Prevalence and Treatment in Patients with Non-Dialysis-Dependent Chronic Kidney Disease Wendy L. St. Peter,[1] Haifeng Guo,[1] Shaum Kabadi,[2] Sean Zhao,[2] David T. Gilbertson,[1] Louise Janice Sargent Heuer,[2] Yi Peng,[1] Trudy Pendergraft,[2] Suying Li.[1] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]AstraZeneca, Wilmington, DE.*

Background: Relatively little is known about the burden of anemia in stage 3-5 non-dialysis-dependent chronic kidney disease (NDD-CKD) patients. We evaluated anemia prevalence, treatment patterns, and cardiovascular (CV) outcomes in adults with stage 3-5 NDD-CKD.

Methods: We used Medicare and MarketScan® (commercial) claims data (10/1/2011 to 9/30/2012) to identify "older" (65+ yrs) and "younger" (18-64 yrs) CKD-NDD patients, respectively. During the baseline year from 10/1/2011-09/30/2012, anemia status (defined by diagnosis codes), patient demographics, and comorbidities were determined. We evaluated anemia treatment patterns [erythropoiesis-stimulating agents (ESAs), intravenous (IV) iron, and red blood cell (RBC) transfusions] after baseline anemia diagnosis. CV outcomes were identified during the 1-yr follow-up period.

Results: There were 148,550 (52%) older and 15,716 (28%) younger patients with anemia among stage 3-5 NDD-CKD patients in Medicare and MarketScan databases, respectively. Prevalence increased as CKD stage and age increased and was generally higher among women. The most common form of treatment (at least 1 administration) for anemia was RBC transfusions (22.2% older, 11.7% younger) followed by ESA (12.7% older, 10.8% younger) and IV iron (6.7% older, 9.4% younger). Treatment across all modalities increased by CKD stage and age. Comorbidity burden and inflammatory conditions were more commonly observed among older patients relative to younger patients. Major adverse cardiac events and thromboembolic events (unadjusted) increased by CKD stage and were higher among patients with anemia versus those without.

Conclusions: Approximately half of Medicare stage 3-5 NDD-CKD patients have anemia; RBC transfusion was commonly used to treat anemia. Anemia treatment patterns differ by age; older patients received twice as many RBC transfusions as younger patients and were also more likely to receive treatment with ESAs. Investigation into effects of anemia treatment patterns on CV outcomes is warranted in this population.

FR-PO767

Anemia Treatment Pattern Changes in Non-Dialysis-Dependent Chronic Kidney Disease Patients before and after Revised Food and Drug Administration Label and New Anemia Guidelines for Erythropoiesis-Stimulating Agents Wendy L. St. Peter,[1] Haifeng Guo,[1] Shaum Kabadi,[2] Sean Zhao,[2] David T. Gilbertson,[1] Louise Janice Sargent Heuer,[2] Yi Peng,[1] Trudy Pendergraft,[2] Suying Li.[1] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]AstraZeneca.*

Background: In June 2011, the US Food and Drug Administration (FDA) added more Black Box warnings to erythropoiesis stimulating agent (ESA) labels; in 2012, KDIGO released new anemia treatment guidelines. Our study aimed to examine changes in anemia treatment patterns from 2008 to 2012 in stage 3-5 non-dialysis-dependent chronic kidney disease (NDD-CKD) patients.

Methods: Stage 3-5 NDD-CKD patients with anemia (defined by diagnosis codes) were selected from a 20% Medicare random sample. Two study cohorts were created,"2008" and "2012", consisting of patients identified from 2007-2009 and 2011-2013 claims, respectively. ESA, intravenous (IV) iron, and red blood cell (RBC) transfusion use and time to use were evaluated after anemia diagnosis during baseline year. Consistent ESA treatment was defined as at least 1 ESA monthly administration in at least 80% of 12 follow-up months.

Results: There were 71,744 and 109,251 stage 3-5 NDD-CKD patients with anemia in 2008 and 2012 cohorts, respectively. Treatment with ESAs declined from 2008 to 2012, while IV iron use and RBC transfusions remained stable. Consistent ESA treatment was low among these NDD-CKD patients and declined further by 2012. Median time to ESA treatment increased by a week, remained stable for IV iron, but decreased for transfusions (59 to 34 days).

Anemia Treatment	2008 cohort (n=71,744) % Patients Treated	2012 cohort (n=109,251) % Patients Treated
ESA	29.4	12.7
IV iron	6.3	6.7
RBC transfusion	21.3	22.2
Any Anemia Treatment	45.1	34.0
ESA Treatment Patterns	**% Patients with ESA Treatment Pattern**	
Untreated	70.6	87.3
Not consistently treated	19.7	9.3
Consistently treated	9.7	3.4

Conclusions: ESA use decreased by 57% from 2008 to 2012; IV iron use and RBC transfusions remained stable. Patients received transfusions sooner, corresponding to decline in ESA use. This is the first study to report on the impact of FDA and KDIGO action on anemia treatment patterns in stage 3-5 NDD-CKD patients.

FR-PO768

Cost-Effectiveness Analysis of Intravenous Ferumoxytol for Treatment of Iron Deficiency Anemia in Adult Patients with Non-Dialysis Dependent Chronic Kidney Disease (ND-CKD) Naomi V. Dahl,[1] William Strauss,[1] Robert F. Kaper,[1] Frank A. Corvino,[2] Marko Zivkovic.[2] *[1]AMAG Pharmaceuticals, Inc., Waltham, MA; [2]Genesis Research, Hoboken, NJ.*

Background: Treatment of iron deficiency anemia (IDA) in CKD patients requires oral or IV iron replacement therapy, with or without simultaneous use of erythropoietin stimulating agents (ESAs). Ferumoxytol (FER) has demonstrated superior efficacy to oral iron in clinical trials.

Methods: This analysis studied the cost-effectiveness (CE) of treating IDA in ND-CKD patients with FER compared to oral iron, alone or in combination with ESA. A decision-analytic model was developed to compare health outcomes and costs associated with a 5-week outpatient treatment of IDA in ND-CKD patients with FER±ESA or oral iron±ESA in the US. Direct costs included: drug acquisition and administration, serious adverse events (AEs), and medical management. Treatment efficacy was determined as mean increase in g/dL hemoglobin (Hb) from baseline over a 5-week period. Clinical inputs were derived from patient-level data from 2 Phase 3 trials of FER vs oral iron in ND-CKD patients. Cost inputs were retrieved from RED BOOK and Centers for Medicare and Medicaid Services data. One-way sensitivity analysis to identify cost drivers and probabilistic sensitivity analysis utilizing Monte Carlo simulations to assess stability of results were performed.

Results: The cost of 5-week IDA treatments were $2,489, $5,216, $1,298, and $4,263 for FER, FER+ESA, oral iron, and oral iron+ESA patients, respectively. Over this period, increases in Hb were 0.76g/dL (FER), 1.42g/dL (FER+ESA), 0.19g/dL (oral iron), and 0.53g/dL (oral iron+ESA). Incremental cost per g/dL increase in Hb, compared to FER alone, was $398 for FER+ESA, $3,558 for oral iron, and $4,768 for oral iron+ESA. Efficacy was the main driver of CE for all treatments. AE and medical management costs were major components of oral iron monotherapy costs, as were drug acquisition costs for the other treatments.

Conclusions: FER was found to be the more cost-effective treatment strategy for IDA in ND-CKD patients over a 5-week study period compared to oral iron with or without ESA, and that FER as monotherapy was more cost-effective than in combination with ESA.

FR-PO769

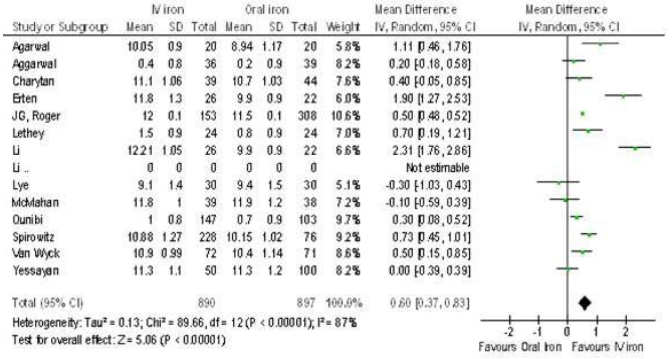
Intravenous versus Oral Iron Supplementation for the Treatment of Anemia in CKD: An Updated Systematic Review and Meta-Analysis Xavier Perez Hernandez,[1] Sumeet Munjal,[1] James W. Lohr,[1,2] Pradeep Arora,[3] Irfan Ahmed Moinuddin.[3] *[1]Medicine, SUNY at Buffalo, Buffalo, NY; [2]Nephrology, VA Medical Center, Buffalo, NY; [3]Nephrology, VA Medical Center, Richmond, VA.*

Background: Iron supplementation is essential for the treatment of patients with anemia of chronic kidney disease (CKD) not on dialysis. It is not clear which is the best method of iron administration. A previous meta-analysis which included studies through 12/2010 showed a significant improvement in transferrin saturation (Tsat), ferritin, and hemoglobin (Hgb) levels with the use of intravenous (IV) iron. However, further studies addressing this have been inconsistent in showing a benefit of IV iron over oral iron supplementation. In view of this, we performed an updated meta-analysis using the recent articles published after the original meta-analysis.

Methods: A search was performed from January 2011 of trials published in Medline. We included trials that included patients with CKD (stages III to V), were published in English, and the interventions were IV iron preparations versus oral iron supplementation. Primary outcomes assessed: percent of patients reaching their target Hgb, absolute Hgb level, ferritin level, and Tsat levels. Data was analyzed using Review Manager 5.1 using random effect modeling.

Results: 19 trials were identified (14 from prior trial and 5 from the updated search). Compared with oral iron, there was a significantly greater Hgb level in CKD patients treated with IV iron (weighted mean difference, 0.6 g/dL; 95% CI, 0.37 to 0.83), target

Hgb level (RR, 1.44; 95% CI, 1.13 to 1.82), ferritin level (weighted mean difference, 224.18 ng/dL; 95% CI, 157.24 to 291.12), and Tsat level (weighted mean difference, 2.99 %; 95% CI, 1.49 to 4.49).



Conclusions: Our review shows that CKD patients not on hemodialysis therapy have better Hgb level response when treated with IV iron.

FR-PO770

Serum Level of Soluble Fas Is a Predictor of Need for Red Blood Cells Transfusion in Patients with Chronic Kidney Disease Krissia K.S. Wallbach,[1] Luiza Pego Silva,[1] Marcos A. Meniconi,[1] Maria Dalboni,[1] Maria Eugenia F. Canziani,[1] Miguel A. Goes.[1,2] *[1]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Nephrology, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil.*

Background: Anemia related to chronic kidney disease (CKD) is associated with inflammation, impaired erythropoietin (Epo) production, iron status, soluble Fas (sFas) and PTH levels. Red blood cells (RBCs) transfusion as a consequence of severe anemia might be harmful, and predicting it remains a challenge.

Methods: We conducted a prospective study with 56 pre-dialysis patients for 144 months (Jan/2004-Dec/2015). Need for RBCs transfusion was the primary outcome. Serum sFas, IL-6, PTH, Epo level, EPI-CKD, Hb, Hct, iron status and use of rHuEPO were analyzed at baseline. Correlation between the variables and multivariate regression with Hb-dependent variable were performed on admission and binary logistic regression for RBCs transfusion was performed at the end of 144 months with sFas, EPI-CKD, transferrin saturation(Trs), IL-6 and Epo.

Results: Our population at baseline was 56+13 yo, 65,5% (35) males; diabetes and hypertension were the leading causes of kidney failure; Hb 12.5+2.3g/dL, Hct 37+7%, Trs 23+ 14%, ferritin 123+110ng/ml, EPI-CKD 34+14mL/min, sFas 3121+1249pg/ml, Epo 11+10pg/ml, IL-6 7.0 ± 6.4pg/mL, PTH 200 + 178pg/ml. There was a positive correlation between Hb and EPI-CKD (r=0.35; p=0.009), Hb and Trs (r=0.14; p=0.09) and a negative correlation between Hb and sFas (r=-0.35; p=0.008) and Hb and PTH (r=-0.32; p=0.03). Independent association between Hb and sFas (b=-0.378, p=0.02) was found. Four patients (7%) used rHuEPO and 8 (14%) required RBCs transfusion (3+1,5 units). We observed lower IL-6 (4.3+1.8, 7.4+6.8; p=0.08), EPI-CKD (22+9, 36+13; p=0.008) and Trs (18+7, 23+14; p=0.09) but higher sFas (5067+1015,2797+960, p<0.001), Epo (15.8+13.4, 10.6+9.7; p=0.08) and PTH (313+277,189+170; p=0.1) levels in the RBCs transfusion group. After binary logistic regression, sFas levels were independently associated to RBC transfusion (b=1.001 95% CI 1.000-1.001; p=0.01).

Conclusions: Serum sFas level is associated with anemia and is an independent predictor of need for RBC transfusion in CKD patients.

FR-PO771

Achieving Target Haemoglobin with Single High-Dose Iron Infusion: Predicting the Optimal Approach in Non-Dialysis Chronic Kidney Disease Christopher Brown, David Jackson, Reuben Morgan, Jennifer Williams, Ashraf I. Mikhail. *ABMU Health Board, United Kingdom.*

Background: The UK National Institute for Health and Care Excellence (NICE) have updated their guidelines for managing anaemia of CKD. These recommend a high-dose, low-frequency (HDLF) IV iron strategy for treating iron-deficiency for 1. patients receiving ESA and 2. patients not receiving ESA if intolerant of oral iron or Hb levels are not reached within 3 months. We analysed the Hb response in a non-dialysis CKD cohort to HDLF IV iron with a target Hb of 110g/L whose iron requirements were determined from the Ganzoni equation.

Methods: This retrospective analysis of 197 patients examined the Hb response to a single infusion of iron isomaltoside. Individual doses were calculated from the Ganzoni equation (with a target Hb set at 110g/L and iron stores set at 500mg) to a maximum single dose of 20mg/kg.

Results:

			Pre-treatment			Post-treatment		
			ESA group	Non-ESA group	Combined	ESA group	Non-ESA group	Combined

Treatment effect	Change in Hb (Min:Max)	g/L	*	*	*	10.2 (12.5%) (-9:55)	10.8 (12.7%) (-13:52)	10.5 (12.6%) (-13:55)
	Change in Hb per gram iron (Min:Max)	g/L/g	*	*	*	13 (15.1%) (-50:60)	12.2 (14.0%) (-35:56)	12.6 (14.6%) (-50:60)
Indicative	Additional dose needed to achieve target Hb	mg	*	*	*	424	570	494
	Additional dose needed to achieve target Hb	%				35%	48%	41%

Of the 197 patients analysed who received high-dose iron infusion between Oct 2012 and Apr 2016, one patient developed an adverse drug reaction (ADR); rash. Subsequent doses in this cohort resulted in 264 infusions with no further reported ADR. No patients had angioedema or required stopping the infusion, hospitalisation or medical intervention. Both ESA and non-ESA treated patients equally achieved aspirational Hb range. We calculated an indicative adjustment to the iron dose that may improve Hb target achievement to direct future dosing decisions. The higher indicative dose in the non-ESA group reflects the lower baseline iron stores (ferritin and TSAT).

Conclusions: A high-dose,low-frequency approach to IV iron can effectively achieve aspirational Hb levels in non-dialysis CKD patients. This is equally achievable in both ESA and non-ESA treated patients. Further analysis of dosing strategies are needed to predict the appropriate IV iron dose to achieve Hb levels and to evaluate the long-term safety of a HDLF approach.

FR-PO772

The Mortality Risk Associated with Functional Iron Deficiency in the U.S. Veterans with CKD Monique E. Cho, Jared Hansen, Celena B. Peters, Tao He, Brian C. Sauer. *Univ of Utah and George E. Wahlen Dept of Veterans Affairs Medical Center.*

Background: The clinical significance of functional iron deficiency (FID) has not been investigated in a large CKD population.

Methods: We performed a historical cohort study using the Veterans Affairs Informatics and Computing Infrastructure. We identified a CKD cohort (MDRD eGFR <60 mL/min/1.73m^2) with at least one set of iron indices between 2006-2015. The clinical characteristics were determined from the ICD-9 codes and laboratory data during the *baseline period*, defined as the year preceding the first available iron indices. Patients with baseline hematologic disorders, ESRD, organ transplantation, and cancer were excluded. The cohort was divided into 4 iron groups based on the joint quartiles (Q) of transferrin saturation (Tsat) and ferritin: FID, 1st Tsat Q + 3rd-4th ferritin Qs; Low Iron (LI), 1st Tsat+ferritin Qs; High Iron (HI), 4th Tsat+ferritin Qs; and Reference (R), 2nd-3rd Tsat+ferritin Qs. Mortality among iron groups was assessed using Cox proportional hazard models.

Results: Of the 1,126,184 Veterans with CKD, 249,705 met the inclusion criteria. The mean±SD for age and eGFR were 72±11 years and 47±19 mL/min/1.73 m^2, respectively. The median (IQR) Tsat and ferritin values were 21 (15, 28)% and 118 (56, 232)ng/mL. Of the study cohort, 43% could not be categorized. In the remaining 142,832 Veterans, the prevalence for FID, HI, LI, and R were 14%, 14%, 20%, and 52%, respectively. FID had the greatest baseline prevalence for arrhythmia (36%), diabetes (62%), heart failure (35%), hypertension (91%), stroke (18%), and peripheral arterial disease (20%). During the mean±SD follow-up period of 4.1±2.7 years, FID group exhibited the highest risk of all-cause mortality compared to R [hazard ratio, 95% CI: 1.46 (1.43, 1.50)], followed by HI [HR 1.23 (1.20, 1.26)], and LI [HR 1.17 (1.15,1.20)], after adjusting for age, sex, race, diabetes, cardiovascular (CV) risk factors, albumin, and hemoglobin.

Conclusions: FID is significantly more prevalent in patients with diabetes and CV disease and is strongly associated with all-cause mortality risk in CKD.

FR-PO773

Lowering Diastolic Blood Pressure Was Associated with Higher Incidence of Chronic Kidney Disease in General Population Only in Those Using Antihypertensive Medication Daisuke Uchida,[1] Ryo Kido,[2] Hiroo Kawarazaki,[1] Masaru Murasawa,[1] Shouichi Fujimoto,[3] Kunitoshi Iseki,[3] Toshiki Moriyama,[3] Kunihiro Yamagata,[3] Kazuhiko Tsuruya,[3] Tsuneo Konta,[3] Ichiei Narita,[3] Masahide Kondo,[3] Masato Kasahara,[3] Koichi Asahi,[3] Tsuyoshi Watanabe,[3] Yugo Shibagaki.[3] *[1]Dept of Nephrology, Inagi Municipal Hospital, Inagi, Tokyo, Japan; [2]Dept of Examination Center, Inagi Municipal Hospital, Inagi, Tokyo, Japan; [3]Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkup, Japan.*

Background: Whether diastolic blood pressure (DBP) is associated with developing chronic kidney disease (CKD) in the general population is not examined well.

Methods: Using national health check-up database from 2008 to 2011 in the general Japanese population aged 39 to 74 years, we evaluated the association between DBP and incidence of CKD 2 years later in 128,005 participants without CKD (proteinuria and/or eGFR <60, ml/min/1.73m2). DBP was categorized by every 5mmHg from the lowest

(<60mmHg) to the highest category (>100mmHg), and was further stratified into those with (meds+) and without antihypertensive medication (meds-). We calculated odds ratio (OR) for estimating adjusted risk of developing CKD using logistic regression model.

Results: Participants including 62% of female and 25.9% of med+ had mean age of 63 years, with mean eGFR of 78.2±13.4 and DBP of 76±11mmHg. Two years later, 12,379 (9.7%) developed CKD. Compared to meds- with DBP 60-64mmHg as reference, multivariate analysis showed no difference in risk of developing CKD among meds-, but significant difference in most DBP category of meds+, especially in the lowest category showing the highest risk (OR 1.51, 95%CI 1.14 to 1.99). The risk decreased as the DBP rose up to 90-94mmHg (p for trend 0.05). In subgroup analysis, meds+ similarly showed CKD risk reduction as DBP rose (p for trend 0.02), with significant difference among categories in part, but no difference was seen among any DBP in meds-.

Conclusions: Lower DBP was associated with higher risk of developing CKD in general population only in those taking antihypertensive medication.

FR-PO774

The Minimum Clinically Important Difference in the Incremental Shuttle Walk Test following a 12 Week Exercise Intervention in Chronic Kidney Disease

Thomas James Wilkinson,[1] Soteris Xenophontos,[1] Douglas W. Gould,[1] Emma L. Watson,[1] Alice C. Smith,[1] Joao L. Viana.[2] *[1]Leicester Kidney Exercise Team, Univ of Leicester, Leicester, Leicestershire, United Kingdom; [2]Univ Inst of Maia.*

Background: Chronic kidney disease (CKD) patients have poor cardiorespiratory capacity which limits physical performance and is strongly associated with outcome. The incremental shuttle walk test (ISWT) is a popular and well-defined field test to assess this but has not been validated in CKD. For clinical and research outcome measures, the minimum clinically important difference (MCID) is 'the smallest change important to patients' and is more relevant than 'statistically significant' changes which merely indicate that a change did not occur by chance. We aimed to establish the MCID in the ISWT after an exercise intervention in non-dialysis CKD.

Methods: 23 CKD patients (10 male, mean age 59 (27–80) years, eGFR 25 (8–41) mL/min/1.73m^2) undertook 30 minutes supervised aerobic and resistance exercise training thrice weekly for 12 weeks. Patients completed the ISWT at baseline and end of study. MCID was estimated using a patient centred *anchor*-based approach. Patient's perception of their ISWT change was assessed using the 36-Item Short Form Survey. After completing the exercise programme, patients were asked to identify, on a 5-point Likert scale, their perceived change in general health ('much better' to 'much worse').

Results: Mean baseline ISWT was 431 (SD: 232) m, which increased to 474 (SD: 227) m (+43m (CI: 17–68)) after the exercise intervention (P = .002). Using an *anchor*-based analysis, for participants who rated their general health as *'somewhat better'*, the mean improvement in the ISWT was 60m (CI: 27–93), or 14%. Conversely, in the participants who rated their general health as *'somewhat worse'*, the mean difference was -25m.

Conclusions: The MCID in the ISWT following an exercise intervention in CKD is 60m. This corresponds well with the ISWT MCID in patients completing cardiac (70m) and pulmonary rehabilitation (48m). This value will inform the design of clinical trials, and aid clinicians in the interpretation of meaningful ISWT changes in CKD after medical and lifestyle interventions in both clinical and research settings.

FR-PO775

Charlson Comorbidity Index - Impact on Hospitalization and Mortality in Chronic Renal Disease

Luisa H. Pereira,[1] Joao Santos,[2] Filipa B. Mendes,[1] Ana Paula Silva,[1,2] Ana Marreiros,[3] Pedro Neves.[1,2] *[1]Dept of Nephrology, Algarve Hospital Centre, Faro, Portugal; [2]Dept of Biomedical Sciences and Medicine, Algarve Univ, Faro, Portugal; [3]Algarve Univ, Faro, Portugal.*

Background: Chronic kidney disease (CKD) is a known risk factor for increased morbidity and mortality. Charlson comorbidity index (CCI) is the most extensively studied comorbidity index for predicting mortality and may help improving outcomes by identifying and treating patients earlier and more effectively. In this study we evaluated the correlation between CCI and hospital admissions in patients with chronic kidney disease and the influence of CCI on their mortality.

Methods: We included, in a retrospective observational study, 693 patients, with an eGFR< 30 ml/min/1.73m^2, followed in a pre-dialysis clinic between 2008-2012. Four groups were created, according to the CCI. G1 (n=172)-CCI ≤ 5.2; G2 (n=162)-CCI – 5.4-6.4; G3 (n=177)-CCI – 6.5-7.4 and G4 (n=182)-CCI ≥7.5. Descriptive statistics, ANOVA and chi-square tests were used for comparison between groups. *Bonferroni* test was used as a post-hoc test. *Kaplan-Meier* analysis was used to evaluate mortality in each group and *Log Rank* test for comparison between groups. To evaluate the relationship between CCI and the other variables we used a multivariate logistic regression.

Results: The mean age of our population was 70.09 years, 54% (371) male, with a mean eGFR (MDRD) of 20.2±9.2 ml/min. G1 patients were younger (p<0.001) and showed higher hemoglobin (p<0.001), eGFR (p=0.025), calcium (p=0.033) and albumin (p<0.001). In a multivariate logistic regression model ajusted to gender, age, haemoglobin, phosphorus, parathormone, eGFR, albumin and blood pressure, CCI is a risk factor of hospitalization (OR=1.362, Cl 95% 1.175-1.580, p<0,0001) and death (OR=1.243; CI 95% 1.053-1.467; p=0.010).Survival at 85 months was progressively shorter with higher CCI (G1= 86.7%, G2= 65.9%, G3=59.35 % and G4= 30.4%, log Rank =34.465, p=0.0001.

Conclusions: CCI provides a simple and valid method for classifying comorbidities and can be used as an instrument to predict patient's survival/mortality as their kidney disease progresses.

FR-PO776

Waist Circumference and LDL-Cholesterol and the Incidence of Chronic Kidney Disease in the Healthy Young- to Middle-Aged Working Men in Japan

Akihiro Kuma,[1] Bungo Uchino,[2] Masatoshi Kawashima,[1] Kazuhiko Enta,[1] Akihiko Kato.[3] *[1]Health Care Center, Central Japan Railway Co., Ltd.; [2]Health Promotion Center, Yamaha Motor Co., Ltd.; [3]Blood Purification Unit, Hamamatsu Univ Hospital.*

Background: Identifying modifiable risk factors is crucially important for reducing the burden of chronic kidney disease (CKD) in the working age population. We aimed to examine the association of lifestyle-related clinical parameters with kidney function decline over 5 years in a cohort of healthy young- to middle-aged men with preserved estimated glomerular filtration rate (eGFR).

Methods: We enrolled 10,668 adult Japanese men (<60 years) who had worked at the two companies in a retrospective fashion. We selected the subjects whose basal eGFR (mL/min/1.73m^2) range was from 60 to 90. We analyzed medical checkup data 5 years later, and examined changes of those data between the 2 time points. We defined the cut-off values of waist circumference (WC) as below 85 cm and serum LDL-cholesterol (LDL-C) as below 120 mg/dL according to the definition of the metabolic syndrome in JapanMinistry of Health, Labour and Welfare.

Results: Mean age and eGFR were 40.9±10.3 years and 76.2±7.8 at baseline. The 773 males (7.2 %) had developed newly to CKD at 5 years later. There was a significantly higher risk of CKD in men whose WC (OR=1.63, p<0.001) or LDL-C (OR=1.78, p<0.001) remained elevated at the two points. In addition, healthy men whose WC or LDL-C had become elevated over the cut-off value at 5 years later had a higher risk for CKD development (WC: OR=1.53, p=0.001, LDL-C: OR=1.38, p=0.008). There was also a significantly lower rate of eGFR decline in men whose WC and LDL-C levels had been concomitantly normalized at 5 years later than those whose levels had been still elevated (-1.1±7.1 vs. -3.6±6.5, p= 0.012).

Conclusions: These findings show that both WC over 85 cm and LDL-C over 120 mg/dL were risk factors for CKD development in adult men with 60-90 in eGFR. Because normalization of WC and LDL-C were related to a slower rate of eGFR decline, abdominal fatness and disturbed lipid profile could be a potentially modifiable risk factor in preventing CKD development in healthy young- to middle-aged working men.

FR-PO777

eGFR Agreement and Mortality Discrimination in Community Dwelling Obese Individuals

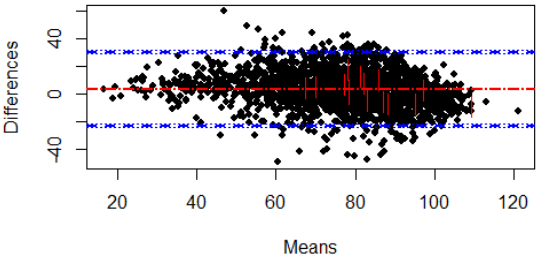
Donal J. Sexton,[1,2,3] Mark Canney,[1,2] Rose Anne M. Kenny,[1] Mark Alan Little,[2] Conall M. O'Seaghdha.[3] *[1]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin, Dublin, Ireland; [2]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [3]Dept of Renal Medicine, Beaumont Hospital, Dublin, Ireland.*

Background: Obesity is increasing worldwide and is a risk factor for chronic kidney disease. The relative performance of eGFR equations in obesity has not been fully characterised.

Methods: We analysed data from the first wave (2009-2011) of The Irish Longitudinal Study on Ageing with mortality follow up through wave 3 (2015). TILDA is a nationally representative prospective cohort study of community dwelling individuals in Ireland aged 50 years and over. Net Reclassification Improvement (NRI) and Integrated Discrimination Improvement (IDI) were used to compare the additive discrimination of each eGFR equation in comparison to MDRD within the obese subgroup.

Results: Mean (se) (Obese N=1805 vs 3554 non-obese individuals): SBP 138.6(0.49) mmHg vs 135.4(0.39) mmHg, Waist:hip ratio 0.95(0) vs 0.89(0), BMI 34(0.1) kg/m2 vs 26(0.04) kg/m2, all P<0.001. Mean difference 95% limits of agreement between eGFR equations included (ml/min/1.73m2): (vs MDRD) -3.53(-13.2 to 6.09) for CKD EPI Creatinine, -0.26 (-29.4 to 28.9) for CKD EPI Cystatin, and -1.82(-19.5 to 15.82) for CKD the combination equation. When comparing CKD EPI Creatinine to CKD EPI Cystatin we found 3.28 (-23.5 to 30.01) (**Bland-Altman plot Figure 1**).

Conclusions: eGFR equations do not appear to be interchangeable in obese community dwelling individuals, cystatin based eGFR equations may not provide improved mortality discrimination in this subgroup.



eGFR equation (vs MDRD)	Continuous NRI (se)	P value	IDI (se)	P value
Cystatin CKDEPI	0.0809 (0.06)	0.19	1083980 (0.0)	0.12
Creatinine CKDEPI	0.0099 (0.03)	0.77	0.000071 (0.0)	0.61
Combination Creatinine & Cystatin	0.0953 (0.06)	0.10	0.000585 (0.0)	0.24

FR-PO778

Association between Weight, Abdominal Obesity, and Albuminuria: Results from NHANES 2003-2014 Anawin Sanguankeo,[1] Sikarin Upala,[1] Eric L. Knight.[2] *[1]Internal Medicine, Bassett Medical Center, Cooperstown, NY; [2]Nephrology, Bassett Medical Center, Cooperstown, NY.*

Background: Many conditions are related to albuminuria. However, the relationship between obesity and albuminuria is controversial. We aim to determine the prevalence of albuminuria by obesity status based on multiple complementary measures of adiposity in U.S. adults and examine the association between weight, abdominal adiposity, and albuminuria.

Methods: We analyzed data from U.S. adults aged 18 years and older examined in the National Health and Nutrition Examination Survey (NHANES) from 2003–2014. We excluded participants who were pregnant or had estimated GFR<15 ml/min per 1.73 m^2. We determined the prevalence of albuminuria (urine albumin-to-creatinine ratio (UACR)≥30 mg/g) among the total sample, and separately within the two BMI classes: normal weight (18.5≤BMI<25) or obesity (BMI≥30), and abdominal obesity status: defined by gender criteria of waist circumference. Relationship between albuminuria, obesity, and abdominal obesity were evaluated using multivariate logistic regression.

Results: Among 28,468 adults who met inclusion criteria, 8.75% had UACR≥30 mg/g and 1.14% had UACR≥300 mg/g. Prevalence of having UACR≥30 mg/g in obesity, normal BMI, abdominal obesity, and normal waist are 11.43%, 7.32%, 8.75%, and 6.54%, respectively. In univariate model, obesity increases odds of having UACR≥30 mg/g (OR=1.63; 95%CI: 1.43-1.87), and UACR≥300 mg/g (OR=1.79; 95%CI: 1.38-2.31). Abdominal obesity also increases odds of having UACR≥30 mg/g (OR=1.72; 95%CI: 1.56-1.90), and UACR≥300 mg/g (OR=1.93; 95%CI: 1.53-2.45). After adjusting for age, gender, race, history of hypertension, history of diabetes mellitus, SBP, and DBP, being obese does not having UACR≥30 mg/g (OR=1.05; 95%CI: 0.91-1.20) or UACR≥300 mg/g (OR=0.87; 95%CI: 0.67-1.14). After adjusting for these factors and obesity, abdominal obesity increases odds of having UACR≥30 mg/g (OR=1.14; 95%CI: 1.01-1.28), but not UACR≥300 mg/g (OR=1.04; 95%CI: 0.73-1.47).

Conclusions: Abdominal obesity defined by waist circumference is an independent predictor of having UACR≥30 mg/g. Obesity defined by BMI is not associate with albuminuria after adjusting for confounders.

FR-PO779

Sedentary Time and Chronic Kidney Disease: A Cross Sectional Analysis of the Canadian Health Measures Study Tamara Glavinovic,[1] Thomas W. Ferguson,[1,2] Paul Komenda,[1,2] Claudio Rigatto,[1,2] Navdeep Tangri,[1,2] Clara Bohm.[1,2] *[1]Univ of Manitoba, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Winnipeg, MB, Canada.*

Background: Low physical activity (PA) levels are associated with adverse outcomes, including mortality in individuals with CKD. To determine the association between PA behavior and CKD using accelerometry data in a Canadian population, we conducted a cross-sectional analysis of data in the Canadian Health Measures Survey (CHMS). We hypothesized that lower kidney function would be associated with low PA levels and increased sedentary time.

Methods: The CHMS, a national survey, collects health information about Canadians. Data from adults (>18 years old) in the first three cycles (2007-2013) were analyzed (n=8444). PA monitoring was performed using Actical™ accelerometers. Primary outcome was proportion of sedentary time by activity quartiles (n=2111 per quartile). Multivariate logistic and linear regression incorporating key modifiers of PA behavior was used to assess the association between kidney function and sedentary time.

Results: Mean proportion of weekly sedentary time ranged from 81% (most sedentary quartile) to 58% (least sedentary quartile). CKD prevalence was highest in the most sedentary quartile (6.5%). CKD Stages 3b or higher had a 4.2-fold higher likelihood (95%CI 2.5-7.3) of being in a more sedentary quartile in comparison to eGFR>60ml/min/1.73m^2. CKD Stage 3a was associated with a 1.7-fold (95%CI 1.2-2.3) higher likelihood of being increasingly sedentary. Age, female sex, diabetes, heart disease and increased pulse pressure were significantly associated with increased sedentary time. Linear regression identified that the presence of CKD Stage 3b or higher was associated with an additional 5.41% (95%CI 3.8-7.0) of sedentary time vs. those with eGFR>60ml/min/1.73m^2. Stage 3b CKD was associated with an additional 3.58% (95%CI 1.6-5.6) of sedentary time compared with CKD 3a.

Conclusions: In this analysis more advanced CKD was strongly associated with increased sedentary time as measured by accelerometry. The effect of PA promotion and exercise programming on long-term improvement of sedentary behavior and associated adverse outcomes in this population warrants further investigation.

FR-PO780

Associations of Unintentional versus Intentional Weight Loss with Mortality in CKD in the U.S. Shweta Bansal,[1] Guo Wei,[2] R. E. Boucher,[2] Rabia Nadeem Kiani,[2] Tom Greene,[2] Srini Beddhu.[2] *[1]UTHSC at San Antonio, SA, TX; [2]Univ of Utah, SLC, UT.*

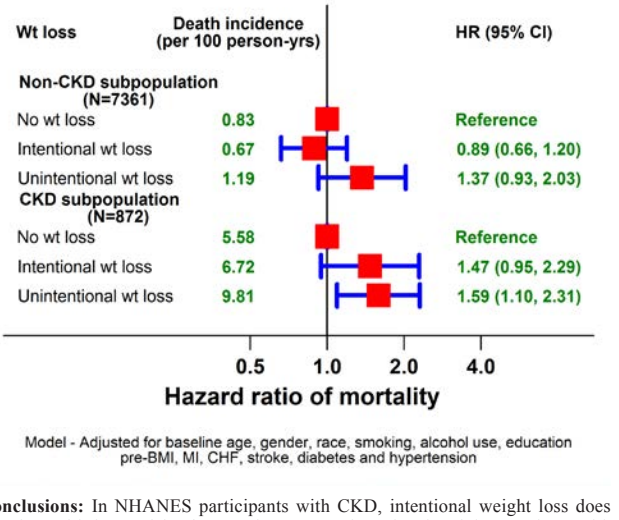
Background: Associations of weight (wt) loss with all-cause mortality (ACM) in moderate CKD is unclear. We hypothesize that intentional wt loss is associated with lower risk whereas unintentional wt loss is associated with increased risk of ACM in CKD.

Methods: We examined this hypothesis in 8233 participants with age>20yrs and BMI>25kg/m^2 in 1999-2004 NHANES. In this survey, subjects were asked about their current and 1yr prior wt; if the wt loss was >10lbs, whether it was intentional or unintentional. CKD was defined as CKD-EPI eGFR<60ml/min/m^2. Mortality until 2011 was obtained by probabilistic linkage to vital statistics by NHANES.

Results: Baseline characteristics are given in the table

	Non-CKD Subpopulation (N=7361)			CKD subpopulation (N=872)		
	No wt loss	Intent wt loss	Unintent wt loss	No wt loss	Intent wt loss	Unintent wt loss
	80.7%	14.2%	5.1%	82.8%	8.4%	8.8%
Wt loss(lb)	4.3±9	-26.9±14	-25.1±16	2.8±9	-25.7±14	-26.8±16
Age(yr)	47±12	44±11	44±14	71±11	67±10	73±10
Male(%)	55	48	53	44	33	35
AA race(%)	11	11	17	8	14	15
Smoking(%)	50	50	56	49.5	38	51
High School(%)	79.6	84	68.8	67	63.6	51
eGFR(ml/min)	95±14	97±13	97.8±16	47.8±10	46.8±10	44.7±14
CAD(%)	3.3	3	4.7	16.1	19.4	16
CHF(%)	2	1.4	2	12	24	18
Stroke(%)	2	2.7	3.3	10.7	20.8	10.8
DM(%)	10.4	15.5	14	25.6	38	30
HTN(%)	35	37	31	76	82	70
Wt 1yr ago(lb)	193±30	222±37	205.8±35	182.8±34	214.7±52	196.1±39
Current wt(lb)	197.2±31	195±33	180.6±33	185.5±36	189±50	169.4±36
PreBMI(kg/m^2)	30.3±4	34.8±5	32.3±5	30.2±4	35.7±7	32.5±6.0

There were 1253 ACM events over mean 8.3yrs of follow-up.



Conclusions: In NHANES participants with CKD, intentional weight loss does not associate with lower risk of ACM; however, unintentional weight associates with increased risk.

FR-PO781

Coffee, Tea, Caffeine and Risk of End Stage Renal Disease Quan Lan J. Lew,[1] Tazeen H. Jafar,[2] Jin Ai Zhen,[3] Khuan Yew Chow,[3] Woon-Puay Koh.[2] *[1]Singhealth Polyclinic, Singhealth Polyclinic, Asian, Singapore; [2]Duke-NUS Medical School; [3]Health Promotion Board, Singapore.*

Background: Previous studies have reported increased estimated glomerular filtration rate with coffee drinking, but no study has examined the relationship with end stage renal disease (ESRD) risk.

Methods: We examined the relationship between coffee, tea and caffeine consumption, and ESRD incidence in the Singapore Chinese Health study, a prospective cohort of 63,257 men and women aged 45-74 years during recruitment (1993-1998). Baseline information on consumption of caffeinated beverages, dietary and lifestyle factors were collected via in-person interviews. ESRD incidence was linked with the Singapore Renal Registry.

Results: After average 16.8 years, 1,143 incident ESRD cases were identified. Compared with <1 cup/day, regular coffee consumption reduced ESRD risk, the adjusted hazard ratio (HR) (95% CI) was 0.91 (0.79-1.05) for 1 cup/day and 0.82 (95% CI: 0.71-0.96) for >2 cups/day, P_{trend}=0.012. In men, the HR (95% CI) was 0.81 (0.66-1.00) for 1 cup/day and 0.71 (0.57-0.87) for >2 cups/day (P_{trend}=0.001). In contrast, in women, the results were 1.01 (0.83-1.21) for 1 cup/day and 0.97 (0.78-1.19) for >2 cups/day (P_{trend}=0.75); $P_{interaction}$=0.026. No association was observed with caffeinated tea or soda. The weak association between caffeine consumption and ESRD risk was nullified after adjusting for coffee. Results limited to participants with >4 years follow-up were similar.

Conclusions: Daily drinking of two or more cups of coffee may reduce ESRD risk, and this effect is not mediated by the caffeine content. The much stronger association in men suggests that the effect of coffee may be mediated via estrogen-receptors and is more apparent in estrogen deficiency.

FR-PO782

Prevalence of Medication Non-Adherence and Factors Affecting It in Patients of Chronic Kidney Disease at a Tertiary Care Public Teaching Hospital: A Cross Sectional Study Sanjay D'Cruz,[1] Rajiv Ahlawat,[2] Pramil Tiwari.[2] *[1]General Medicine, GMCH, Chandigarh, India; [2]Pharmacy Practice, NIPER, SAS Nagar, Punjab, India.*

Background: Medication non-adherence in CKD patients leads to adverse outcomes. The two important factors leading to non-adherence to medications are inability to afford the treatment and poor knowledge of the patient. The present study was carried out to study the prevalence of medication non-adherence and the factors influencing it in patients of CKD.

Methods: A cross sectional study was carried out in 600 CKD patients over a period of 20 months from Sept 2014 to April 2016 at our tertiary care hospital. CKD definition of the KDIGO was used. The proportion of days covered (PDC=total days all drug(s) available/days in follow-up period) algorithm was used to assess medication adherence in CKD patients. PDC varies between 0 and 1; and it can be converted to percentages. PDC value over 80% is considered adherent. Multivariate logistic regression was used to analyse factors affecting medication compliance.

Results: Out of 600 patients, 69% were non-adherent to prescription. Forgetfulness in 30% was found to be most common reason for non-adherence to drug therapy. It was followed by high cost of medications (21%), casual attitude (15%), lack of information (12%) and others in 22%. Medication non-adherence was found highest towards antihypertensive drugs (27%) followed by oral hypoglycemic drugs (21%), insulin (19%), iron injection (11%) and others in 23%. Non-adherence to drug therapy was found significantly higher with pill burden over 5 (OR 1.32,95% CI 0.84-3.12; P=0.043), medication by caregivers (OR 2.04, 95% CI 0.93-6.83; P=0.021), age > 60 (OR 2.17, 95% CI 1.06-3.21; P=0.047), illiteracy (OR 3.43, 95% CI 1.43-6.65; P=0.035) and lack of reimbursement (OR 2.17, 95% CI 1.31-3.26; P=0.012). Gender, dialysis, GFR, and duration of CKD did not have any influence on adherence.

Conclusions: 69%of patients were found non-adherent to drug therapy. Medication adherence was found to decrease with increased pill burden, drugs given by caregiver, increased age, lack of reimbursement and illiteracy.

FR-PO783

Effectiveness of Multifaceted Care Approach on Adverse Clinical Outcomes in Non-Diabetic CKD: A Systematic Review and Meta-Analysis Aminu K. Bello,[1] Bilal Qarni,[1] Arian Samimi,[1] Julius Oluoch Okel,[1] Trish Chatterley,[2] Branko Braam.[1] *[1]Medicine, Univ of Alberta; [2]Library Sciences, Univ of Alberta.*

Background: The impact of multifaceted interventions as compared to the usual care (ie. single risk factor control) in patients with non-diabetic CKD is unclear. We reviewed the evidence on the impact of multiple interventions on reducing adverse clinical outcomes in non-diabetic patients with CKD.

Methods: We searched MEDLINE, EMBASE, CINAHL and the Cochrane Library databases for published studies up to May 2016 on adult patients in a community or specialty care setting, with >2 CKD risk factors, treated with a combination of two or more interventions. We included randomized controlled trials (RCTs) and observational studies with at least 100 participants. The intervention of interest was treatment with a combination of two or more interventions compared to the usual care. The primary outcomes were reduction in the risk of adverse events (renal replacement therapy; RRT, all-cause hospitalizations, all-cause and cardiovascular mortality). Secondary outcomes were optimal risk factor control (blood pressure, proteinuria, smoking cessation).

Results: We identified 5 studies (2 RCTs and 3 cohort studies). In comparison to the usual care, multifaceted interventions were associated with a lower risk of all-cause mortality: (Risk ratio; [RR] 0.81, 95% confidence interval [CI] (0.63-1.03) and progression to kidney failure requiring dialysis- RR (95% CI): 0.57 (0.35-0.94). Multifaceted interventions did not impact risk of all-cause hospitalization- RR (95% CI): 0.93 (0.71-1.23) and blood pressure control- mean difference (95% CI): -0.48 (-2.5 to 1.55). Only a small number of studies met inclusion criteria. Heterogeneity, small sample sizes, and suboptimal study quality hampered the internal validity and generalizability.

Conclusions: Multifaceted interventions targeting multiple risk factors appeared to reduce the risk for major adverse clinical outcomes in patients with CKD. There is a need for high quality studies that can rigorously evaluate a set of interventions targeting multiple domains of CKD management in the population with non-diabetic CKD.

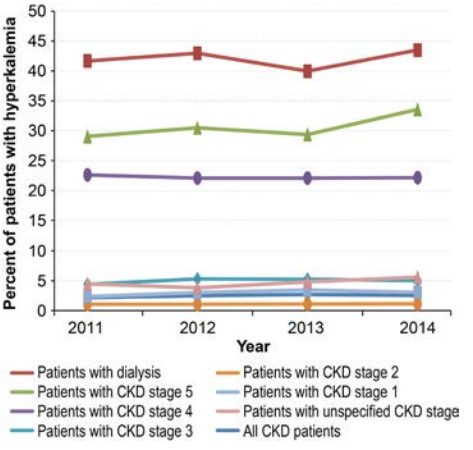
Prevalence of Hyperkalemia among Patients with Chronic Kidney Disease Keith Betts,[1] J. Michael Woolley,[2] Fan Mu,[1] Evangeline McDonald,[1] Wenxi Tang,[1] Eric Wu.[1] *[1]Analysis Group, Inc., Boston, MA; [2]ZS Pharma, San Mateo, CA.*

Background: There are limited published data on the epidemiology of hyperkalemia among patients with chronic kidney disease (CKD). This study estimated the prevalence of hyperkalemia among patients with CKD.

Methods: Adult patients with CKD were selected from a large US commercial claims database (01/01/2011-12/31/2014). CKD and CKD stage were identified by ICD-9 diagnosis codes or estimated by glomerular filtration rate. Dialysis was identified by procedure codes. Patients were required to have at least one calendar year of data with continuous enrollment throughout the year and at least one potassium lab result. Hyperkalemia was defined as having at least two serum potassium measurements >5.0 mEq/L or one diagnosis code of hyperkalemia (ICD-9, 276.7) or one prescription fill of a sodium polystyrene sulfonate. Prevalence of hyperkalemia for each calendar year (2011-2014) was calculated as the number of patients with hyperkalemia divided by the total number of eligible patients within the year.

Results: A total of 847,604 CKD patients were included in the analysis. Among all CKD patients, the prevalence of hyperkalemia ranged from 2.2% to 2.7% across calendar years (Figure 1). When stratified by CKD stage, the prevalence of hyperkalemia across calendar years ranged from 40.0% to 43.5% among patients on dialysis, 29.0% to 33.6% for stage 5, 22.1% to 22.6% for stage 4, 4.4% to 5.3% for stage 3, 1.0% to 1.1% for stage 2, 2.3% to 3.4% for stage 1. Among patients with unspecified CKD stage, the prevalence ranged from 3.8% to 5.6%. Figure 1. Prevalence of Hyperkalemia Among Patients with CKD.



Conclusions: The study provided estimates of prevalence of hyperkalemia among CKD patients, stratified by CKD stages across different calendar years. Hyperkalemia is common among CKD patients, and its prevalence generally increased at more advanced CKD stages.

FR-PO785

Cost of Hyperkalemia in Patients with Chronic Kidney Disease Keith Betts,[1] J. Michael Woolley,[2] Fan Mu,[1] Cheryl Q. Xiang,[1] Wenxi Tang,[1] Eric Wu.[1] *[1]Analysis Group, Inc.; [2]ZS Pharma.*

Background: Healthcare costs in patients with hyperkalemia (HK) have not been well characterized. This study estimated the healthcare costs of HK in patients with chronic kidney disease (CKD).

Methods: Adult patients with CKD, with or without HK (cases vs. controls), were selected from a large US commercial claims database (1/1/2010-12/31/2014). Patients were required to have serum potassium lab results. CKD was identified by ICD-9 diagnosis codes or estimated glomerular filtration rate. Dialysis was identified by procedure codes. HK was defined as having at least two serum potassium measurements >5.0 mEq/L or one diagnosis code of HK (ICD-9, 276.7) or one prescription of sodium polystyrene sulfonate. The index date was a randomly selected claim date indicating HK for cases and a randomly selected claim date for controls. Continuous enrollment of at least 6 months before the index date and 12 months after the index date was required. Controls were exactly matched one-to-one to cases on age group, CKD stage, heart failure, and Renin-Angiotensin-Aldosterone-System inhibitor use. 30-day and 1-year total healthcare costs (2015 USD) from the third-party perspective were compared between cases and controls.

Results: A total of 14,689 CKD patients with HK were matched to 14,689 CKD patients without HK. Among all CKD patients, cases had $4,379 higher 30-day costs ($7,241 vs. $2,862) and $19,589 higher 1-year costs than controls ($45,172 vs. $25,583) (both p<0.01). The 30-day cost difference was $6,983 between cases and controls in patients on dialysis, $9,685 for CKD stage 5, $3,730 for CKD stage 4, $3,880 for CKD stage 3, $3,113 for CKD stage 2, $3,075 for CKD stage 1 and $6,706 for unspecified CKD stage (all p<0.01, except for stage 1). The 1-year cost difference was $25,097 in patients on dialysis, $52,795 for CKD stage 5, $16,736 for CKD stage 4, $16,474 for CKD stage 3, $13,964 for CKD stage 2, $6,072 for CKD stage 1 and $27,459 for unspecified CKD stage (all p<0.01, except for stage 1).

Conclusions: Patients with HK had higher healthcare costs across all CKD stages, with generally higher costs in more advanced disease, supporting the hypothesis that HK imposes a large economic burden on US payers and the healthcare system.

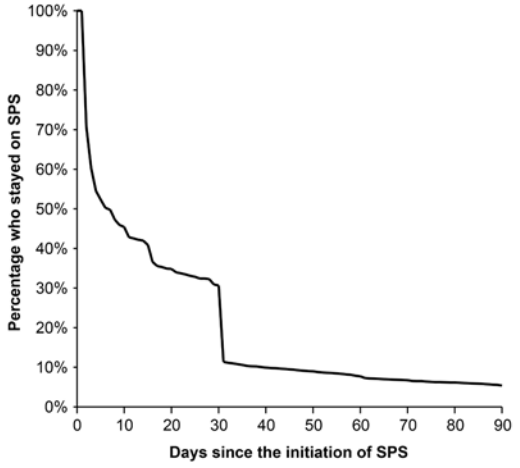
Real-World Treatment Discontinuation of Sodium Polystyrene Sulfonate

Keith Betts,[1] J. Michael Woolley,[2] Lihao Chu,[1] Fan Mu,[1] Wenxi Tang,[1] Eric Wu.[1]
[1]Analysis Group, Inc., Boston, MA; [2]ZS Pharma, San Mateo, CA.

Background: Sodium polystyrene sulfonate (SPS) has been studied in the context of clinical trials, but there is limited information regarding SPS treatment patterns in the real-world. This study describes the persistence of SPS treatment over time.

Methods: Adult patients who had at least one SPS prescription fill were identified from a large US commercial claims database (01/01/2010-12/31/2014). Patients were required to have at least 31 days of continuous enrollment post SPS prescription fill. SPS discontinuation was defined as having no subsequent SPS prescription refills within 30 days after the end of days of supply of their previous SPS prescription. Patients who did not discontinue SPS treatment were censored at the end of their continuous eligibility. SPS discontinuation was evaluated using the Kaplan-Meier estimator.

Results: A total of 4,559 patients initiated SPS therapy and met the eligibility criteria. Among these patients, the average number of SPS fills was 2.3 and the median time to discontinuation of SPS was 7 days (Figure 1). 49.8% of patients remained persistent with SPS through 7 days, 42.0% through 14 days, 30.7% through 30 days, 7.7% through 60 days, and 5.4% through 90 days, and 2.6% of patients were censored (not observed to discontinue). Figure 1. Kaplan-Meier curve of SPS persistence.



Conclusions: Patient persistence with SPS treatment was low, as the majority of patients discontinued treatment within 7 days and less than 10% remained persistent through 60 days.

FR-PO787

No Association of Serum Potassium Level with Mortality in Patients with Optimized Chronic Kidney Disease Care - The NephroTest Study

Sandra Wagner,[1,2] Marie Metzger,[1] Martin Flamant,[3] Pascal Houillier,[4,5] Jean-Philippe Haymann,[6] Francois Vrtovsnik,[3] Eric Thervet,[5,7] Jean-Jacques Boffa,[6] Ziad Massy,[1,2] Benedicte Stengel,[1,2] Patrick Rossignol.[2,8]
[1]INSERM U1018, Villejuif, France; [2]F-CRIN INI-CRCT; [3]Bichat APHP; [4]INSERM U1138; [5]HEGP APHP; [6]Tenon APHP; [7]INSERM UMRS970; [8]INSERM CIC 1433, Nancy, France.

Background: Low and high serum potassium (S_K) values are often associated with chronic kidney disease (CKD) or its treatments, and with poor outcomes, but their prognostic value in patients with optimized CKD care is uncertain.

Methods: We studied the prevalence of hypokalemia (hypoK) (<4 mmol/L) and hyperK (>5 mmol/L) in 1993 nondialysis patients with stage 1 to 5 CKD who underwent extensive renal tests during a 5-h in person visit (mean age: 59±15 yrs, 66% men). All had baseline S_K and GFR measurements (mGFR; ^{51}Cr-EDTA renal clearance) and 60% at least two. Cox models were used to estimate adjusted hazard ratios (HRs) of end-stage kidney disease (ESKD) and mortality prior to ESKD associated with baseline and time-dependent S_K levels.

Results: At baseline, median mGFR was 38.4 ml/min/1.73m² (IQR, 26.9-53.0); prevalence of hypoK was 26% (3.9% for Sk<3.5), and of hyperK, 6.4%; ACEi or ARBs was used in 77% of patients, thiazide or loop diuretics in 48%, potassium-sparing diuretics in 4%, K-binding resins in 6%, bicarbonates in 4%. At the initial and 2nd visits, 67.1% and 63.9% of the patients were normokalemic. After excluding 94 patients with stage 5 CKD at baseline, there were 376 ESKD events and 219 deaths prior to ESKD (36% from CV cause) over a median follow-up of 5 years. As compared to patients with S_K within [4-5] mmol/L, HRs [95%IC] of ESKD, all-cause and CV mortality prior to ESKD for those with hypoK were 1.32[0.99,1.76], 0.73[0.5,1.06] and 0.73[0.31,1.7], and for those with hyperK, 1.08[0.78,1.51], 0.70[0.39,1.27] and 1.59[0.63, 4.0], respectively. Considering time-varying S_K did not materially change these findings.

Conclusions: In this cohort of patients with optimized CKD care (per cohort protocol scheduled repeated measurements of S_K, GFR, treatment review after renal tests), mild hypoK was common and hyperK uncommon. Neither of them appeared to be associated with excess ESKD or mortality.

FR-PO788

Prevalence of Hyperkalemia among U.S. Adults

J. Michael Woolley,[1] Derek Weycker,[2] Mark Atwood,[2] Gerry Oster.[2] *[1]ZS Pharma; [2]Policy Analysis Inc.*

Background: While the underlying causes and clinical consequences of hyperkalemia (HK) are well understood, relatively little is known about the epidemiology of the condition among US adults, especially persons with comorbidities that may predispose them to high potassium (K) levels.

Methods: A retrospective study was undertaken using data from the National Health and Nutrition Examination Survey (NHANES), a large, multi-year, cross-sectional, nationally representative survey of the health and nutritional status of US adults and children based on both interview and physical exam. We identified all persons in NHANES, aged ≥18 years, with valid serum K values between 1999 and 2014; observations across years were pooled to increase precision of analyses. We estimated the point prevalence of HK (serum K level ≥5.0 mEq/L) on an overall basis and within subgroups defined on the basis of age, gender, comorbidity profile, and medication use. Multivariable logistic regression was employed to evaluate the relationship between the demographic and clinical characteristics of study participants and the presence of HK.

Results: We identified a total of 42,083 persons, aged ≥18 years, with valid serum K values between 1999 and 2014. Mean (SD) age of study subjects was 46 (17) years, 52% were women, 29% had hypertension, 10% had diabetes, 7% had chronic kidney disease (CKD), and 13% were taking a RAASi. Prevalence of HK increased approximately 9-fold with age, from 278 per 100,000 persons aged 35-49 years to 2394 per 100,000 persons aged ≥75 years; on an overall basis, the rate was 564 per 100,000 persons. In multivariable analyses, age, CKD, heart failure, and use of RAASi were important predictors of HK (Table).

Conclusions: Prevalence of hyperkalemia in the US increases substantially with age, and is especially high among persons with CKD or heart failure, and those taking RAASi.

Table. Prevalence of hyperkalemia among US adults aged ≥18 years in NHANES

	Prevalence of Hyperkalemia (≥5.0 mEq/L)

Higher Phosphorus Is Associated with Lower Hemoglobin in CKD Stages 3-5: Early Results from the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps)

Roberto Pecoits-Filho,[1] Charlotte Tu,[2] Lindsay Zepel,[2] Michelle M.Y. Wong,[2] Ronald L. Pisoni,[2] Friedrich K. Port,[2] Bruce M. Robinson,[2] Ziad Massy,[3,4] Francesca Tentori.[2,5] *[1]Pontifícia Univ Católica do Paraná, Brazil; [2]Arbor Research Collaborative for Health; [3]Ambroise Paré Univ Hospital, France; [4]CESP, UVSQ, INSERM U1018, France; [5]Vanderbilt Univ; [6]On Behalf of CKDopps and CKD REIN Investigators.*

Background: High phosphorus (P) and low vitamin D levels, typical manifestations of mineral and bone disorder (MBD), are common in patients with advanced CKD. MBD has been associated with increased inflammation, which may affect normal erythropoiesis. In order to better understand the link between phosphorus and hemoglobin (Hb) levels, we tested this association in the international CKDopps.

Methods: We evaluated early data from CKDopps, a prospective study of CKD patients with eGFR <60 mL/min/1.73m² from national samples of nephrology clinics in Brazil, France, Germany, and US. Linear mixed models were used to estimate the effect of P on hemoglobin (Hb), with different levels of adjustment for potential confounders and mechanistic variables.

Results: Data were available from 5,040 patients (mean age: 69 years; 40% female; median eGFR: 28.8 mL/min/1.73m²). eGFR was associated positively with Hb and inversely with P. Higher serum P was strongly associated with lower Hb even after adjustment for demographics, comorbidities, eGFR, labs, and vitamin D therapy (Table 1).

Table 1. Associations of serum phosphorus (per 1 mg/dL higher) with hemoglobin level, by level of adjustment

	Effect (95% CI) on Hb(g/dL) per 1 mg/dL higher serum P
Model 1	-0.64 (-0.70, -0.58)
Model 2	-0.39 (-0.45, -0.33)
Model 3	-0.36 (-0.42, -0.30)
Model 4	-0.36 (-0.42, -0.30)

Model 1 : adjust for age, gender, black, BMI, diabetes, hypertension, country
Model 2: Model 1 + eGFR
Model 3: Model 2 + albumin
Model 4: Model 3 + PTH + Vit D levels + Vit D therapy

Conclusions: In this multinational CKD cohort, higher P was associated with lower Hb, independent of kidney function and other MBD markers/treatments. Further studies will need to explore the possible mechanisms (inflammatory, endocrine) for this association and may generate important advances in the management of both anemia and MBD.

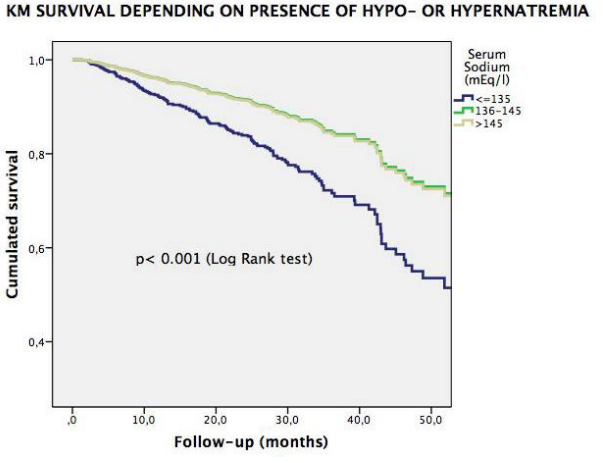
Prognostic Significance of Dysnatremia in the Survival of Chronic Kidney Disease Patients Not on Dialysis

Cristina Castro, Pablo Molina, Ana Avila, Veronica Escudero, Mercedes Gonzalez, Irina Sanchis, Jonay Pantoja Perez, Sandra Beltrán, Luis M. Pallardo, Jose L. Gorriz. *Nephrology, Hospital Univ Dr Peset, Valencia, Spain.*

Background: Patients with chronic kidney disease (CKD) show a high prevalence of comorbid conditions that could predispose to dysnatremias. The assessments of dysnatremias are scarce, being less in case of outpatients. In this study, we analyze the prevalence of dysnatremias in patients with CKD not on dialysis and its effect on survival and renal progression.

Methods: Post-hoc analysis of PECERA study(a 3-year follow-up prospective observational multicenter study, in Spanish Nephrology clinics), which included 882 patients, CKD stages 4-5 not on dialysis: 61,6% male, mean age:68±13 years. Baseline data: serum creatinine:3.1±1.1mg/dl; estimated glomerular filtration rate (eGFR) (MDRD):20±5ml/min/1.73m2. Mean follow-up:47±30 months.

Results: The prevalence of hyponatremia was 4.1% and hypernatremia 9.6% The univariate analysis found no differences in age, BMI, GFR, presence of liver disease or use of diuretic therapy among those with hyponatremia and normonatremia. The history of congestive heart failure (CHF)(p=0.034) and proteinuria (p=0.038) were more prevalent in patients with hyponatremia. After adjustment for age, sex, eGFR, CHF, diuretics, phosphatemia and serum albumin, the presence of hyponatremia was independently associated with worse survival (HR 1.97,95% CI:1.06-3.67;p=0.033)



Hypernatremia was not associated with increased mortality rate (p=0.862). In the multivariate analysis, dysnatremia was not associated with renal progression (p=0.219) nor hospitalization (p=0.739).

Conclusions: In patients with CKD not on dialysis, abnormalities water homeostasis, manifested as hypo- or hypernatremia, are common clinical findings. Hyponatremia was independently associated with an increased mortality, whereas hypernatremia is not associated with poor prognosis.

FR-PO791

Impact of Pill Burden on Adherence and Patient-Reported Quality of Life - An Analysis of a Real-World Non-Dialysis Chronic Kidney Disease Patient Population

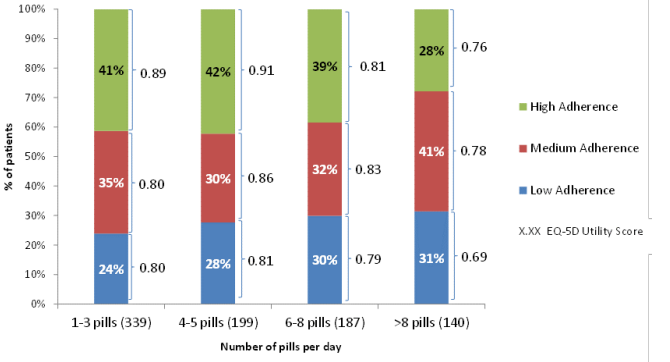
James Jackson, Anna Hadfield, Rebecca Moon. *Adelphi Real World.*

Background: Pill burden is a common problem facing Chronic Kidney Disease (CKD) patients trying to manage complications caused by their CKD. The objective of this analysis is to determine if there is a link between increased pill burden and poorer adherence and whether this has an additional impact on patient quality of life (QoL).

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme (DSP), a real-world, cross-sectional survey of consulting CKD patients conducted between July-October 2015 in the US and 5EU. Patients were grouped into those reporting to take 1-3, 4-5, 6-8 and >8 pills per day in total and descriptively analysed. Adherence was assessed using the Morisky Medication Adherence scale (MMAS-8) and QoL was a measured using the EuroQol-5D-3L (EQ-5D).

Results: Results from 865 non-dialysis CKD (stage 3-4) patient-completed questionnaires showed an increase in polypharmacy was associated with an increase in the proportion of patients with low adherence (24% among patients taking 1-3 pills rising to 31% among those taking >8 pills per day (figure 1). A clinically significant reduction was observed in the mean EQ-5D score for patients taking >8 pills per day compared with those taking 1-3,4-5 or 6-8 pills per day (figure 1). Patients with high adherence consistently reported higher EQ-5D scores, regardless of pill burden (figure 1).

Figure 1. MMAS-8 and associated EQ-5D scores for non-dialysis CKD patients receiving daily oral therapy



Conclusions: Increased polypharmacy has a negative impact on patient adherence. Low adherence is associated with a poorer quality of life compared with patients who have high adherence. Physicians should therefore aim to prescribe drug regimens with a lower pill count as this could lead to an increase in patient adherence and improved patient outcomes.

FR-PO792

Barriers to Dietary Adherence in Chronic Kidney Disease

Maya K. Rao,[1] Maria Berenice Nava,[1] Natalia Cortez,[1] Lara Zakaria,[2] Mariana C. Chiles,[1] Wahida Karmally,[2] Jai Radhakrishnan,[1] Sumit Mohan.[1] *[1]Div of Nephrology, Columbia Univ, New York, NY; [2]Irving Inst for Clinical and Translational Research, Columbia Univ, New York, NY.*

Background: Dietary restriction is essential to multidisciplinary chronic kidney disease (CKD) care. Barriers to dietary adherence are poorly understood.

Methods: English and Spanish speaking patients with Stage 4 and 5 CKD were enrolled in a cross sectional study and completed 1) a Short Assessment of Health Literacy (SAHL) screen, 2) Newest Vital Sign (NVS), a numeracy screen, 3) a survey evaluating barriers to adherence, 4) a food frequency questionnaire (FFQ), and 5) a knowledge assessment of high potassium and phosphorus foods.

Results: The majority of patients (37/52, 71%) had limited health literacy and numeracy defined as a SAHL score of ≤ 8 or a NVS score ≤ 3. These patients were more likely to be older (p=.006), Hispanic (p=.014), have lower educational attainment (p=.003), and primarily Spanish speaking (p=.009). Most patients (81%) reported receiving dietary counseling. Patients who received counseling were more likely to report changing their diet since CKD diagnosis (p=.024) and improved compliance with kidney dietary restrictions (p=.002). Dietary sodium, potassium, phosphorus and protein intake as measured by the FFQ was not different among patients with and without limited literacy and numeracy, or patients who did and did not receive dietary counseling. In the total cohort, the mean number of correct answers in identifying the four high potassium and four high phosphorus foods was 2.4 and 1.5, respectively. These numbers were not different among patients with and without limited literacy and numeracy, or patients who did and did not receive dietary counseling.

Conclusions: Limited health literacy and numeracy is common among patients with CKD 4 and 5 but there was no difference in dietary intake of restricted nutrients, or knowledge of restricted foods in subjects with and without limited literacy and numeracy. Dietary counseling did not result in better knowledge of restricted foods or differences in intake of restricted nutrients. Methods to improve the efficacy of dietary counseling need to be explored further.

Pharmacological Treatment for Chronic Kidney Disease (CKD) and Associated Outcomes in Medicare Part D Enrollees

Yun Han,[1] Steven Erickson,[1] R. Hirth,[1] Rajiv Saran,[1] Rajesh Balkrishnan.[2] *[1]U of Michigan; [2]U of Virginia.*

Background: Few studies have assessed the effects of different pharmacological treatment regimens in hypertensive CKD patients. This study aimed to assess the effects of monotherapy with ACEIs/ARBs versus the combination therapies of ACEIs/ARBs plus other blood pressure/ lipid lowering agents among Medicare Part D enrollees with hypertension and CKD in the United States.

Methods: We used the Medicare 5% sample claim data (2006-2013) in this retrospective cohort study. Eligible cases were hypertensive patients newly diagnosed with CKD and continuously enrolled in Medicare Part D from 2008-2013. Pharmacologic therapies were assessed using a 3-month period after the date of the first CKD diagnosis. Multivariate Cox proportional hazards regression was used to assess effects of different pharmacologic therapies on progression to end stage renal disease (ESRD) and death.

Results: About 44% of CKD patients used ACEIs/ARBs within three months after the diagnosis of CKD. Compared to therapies without ACEIs/ARBs, combination therapy of ACEIs/ARBs plus statins showed the largest beneficial effect on reducing the risk for ESRD (HR: 0.53, p<0.0001). Combination of statins, ACEIs/ARBs, and other concomitant antihypertensive agents was most significantly associated with reducing the risk for all-cause mortality (HR: 0.45, p<0.0001).

Medication use was defined as having at least one pharmacy claim within each pharmacologic therapy during a three-month period after the date of first diagnosis of CKD

* Continuously enrolled in Medicare A&B from 2006/1/1 and continuously enrolled in Medicare Part D from 2007 to end of 2013/date of death were required. A two-year look-back period was applied (2006-2007) to evaluate baseline characteristics, and a one-year look-back period (2007) was used to examine medication use history.

$ Adapted Charlson comorbidity index was calculated by excluding diabetes, kidney diseases and cardiovascular diseases

^ Abbreviations: ASHD, atherosclerotic heart disease; AMI, acute myocardial infarction; CHF, congestive heart failure; CVA/TIA, cerebrovascular accident/transient ischemic attack; PAD, peripheral arterial disease; AFIB, atrial fibrillation; SCA/VA, sudden cardiac arrest and ventricular arrhythmias; PCI, percutaneous coronary interventions; CABG, coronary artery bypass grafting; ICD/CRT-D, implantable cardioverter defibrillators/cardiac resynchronization therapy with defibrillator devices.

& ACEIS/ARBs window is defined as time distance between first observed date of refilling ACEIs/ARBs and first observed date of CKD diagnosis. Anti-hypertension agents user defined as having any pharmacy claim of calcium channel blockers, beta blockers or diuretics.

Conclusions: Therapies including ACEIs/ARBs were preferred as initiation therapy in hypertensive CKD Medicare patients more than non-ACEIs/ARBs therapies. Combination therapies of ACEIs/ARBs and statins were associated with reduced risk of ESRD, while treatment regimens including ACEIs/ARBs plus statins and other antihypertensive agents were associated with decreased risk of death. These findings may provide additional evidence for the effectiveness of treatment regimens including ACEIs/ARBs in treating elderly patients with hypertension and CKD.

Intake of Proton Pump Inhibitors Is a Significant Risk Factor for Bacterial Pneumonia in CKD Patients

Takeru Seto,[1] Tsutomu Inoue,[1] Hiroaki Amano,[1] Takeru Kusano,[2] Kei Sugiyama,[1] Hirokazu Okada.[1] *[1]Nephrology, Saitama Mecial Univ, Iruma-gun, Saitama, Japan; [2]General Medicine, Saitama Mecial Univ, Iruma-gun, Saitama, Japan.*

Background: CKD is a well-known risk factor for cardio- and cerebrovascular diseases, thus many of CKD patients are treated with oral antiplatelet agents together with proton pump inhibitors (PPIs). Recently, an association between the intake of PPIs and pneumonia has received a good deal of attention, particularly among the elderly. In this study, therefore, we investigated whether PPI intake increases the incidence of pneumonia in CKD patients.

Methods: The study was designed as a single center, observational and longitudinal study. Subjects consisted of patients with renal insufficiency equal to or more than CKD stage G3a, who had visited our outpatient clinic. Multivariable logistic-regression models were employed to estimate the risk of hospitalization due to bacterial pneumonia. Independent variables included age, gender, serum albumin, the presence of diabetes mellitus, and the administration of immunosuppressants, statins, PPIs, and H2-receptor blockers (H2RB).

Results: A total of 410 CKD patients were enrolled. Mean age was 60.0 ± 13.1 years, mean estimated GFR was 34.1 ± 16.0 ml/min/1.73^2, and rates of PPI and H2RB intake were 18.0% and 17.8%, respectively. Adjusted odds ratio (aOR) of PPI and H2RB were 7.81 (p<0.01) and 1.01 (p=0.99), respectively. Intake of PPIs was found to be a significant risk factor for hospitalization due to bacterial pneumonia. Additionally, lower serum albumin, the presence of diabetes mellitus, and the administration of immunosuppressants were also significant risk factors, while intake of statin decreased the incidence of pneumonia (aOR 0.28, p=0.04).

Conclusions: Intake of PPIs was a marked risk factor for pneumonia. Since there was a significant difference in the incidence of pneumonia between patients receiving PPIs and those receiving H2RBs, mechanisms unique to PPIs, such as their effect on the pH of respiratory secretions, likely contribute to the episodes of pneumonia. We should, therefore, pay attention to the deterioration of defense mechanisms against bacterial infection in CKD patients when we prescribe PPIs with or without antiplatelet agents.

FR-PO795

Increased Urinary Angiotensinogen in CKD Patients with High Salt Diet and Hypertension

Ha Yeon Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [2]Dept of Internal Medicine, Seoul National Univ, Seoul, Korea.*

Background: Urinary angiotensinogen is known to be related with intra-renal renin-angiotensin system (RAS) activity. High sodium diet is associated with volume expansion and hypertension. Increased RAS activity is suggested as its common pathomechanism of hypertension. We investigate the clinical determinant of urine angiotensinogen and determine the relationship between high salt intake and increased urinary angiotensinogen in patients with high blood pressure.

Methods: In total, 969 CKD patients were included and divided into four groups according to quartile of their 24hr - urine sodium excretion to creatinine ratio and 24-hr urine sodium-to-creatinine ratio (24HUNa/Cr): The urine angiotensinogen-to-creatinine ratio (UAGT/Cr) was specifically assayed with a commercially available enzyme-linked immunosorbent assay kit.

Results: Urine angiotensinogen was significantly higher in patients with increased 24hr - urine sodium excretion to creatinine ratio. Univariate linear regression analysis showed that the urine angiotensinogen concentrations were correlated with systolic blood pressure, the albumin-to-creatinine ratio, and 24-hr urine sodium-to-creatinine ratio. Whereas they were negatively correlated with waist hip ratio, the estimated glomerular filtration rate, serum albumin and hemoglobin levels and 24-hr urine potassium-to-creatinine ratio. Multiple regression analysis revealed that 24-hr urine sodium-to-creatinine ratio, the estimated glomerular filtration rate and waist hip ratio were independently associated with the logarithm of urine angiotensinogen levels (r = 0.35, p =0.021).

Conclusions: Urine angiotensinogen concentrations are higher in patients with increasing 24hr - urine sodium excretion to creatinine ratio. In a group of 4th quartile systolic blood pressure and 4th quartile 24h urine-sodium excretion to creatinine ratio, the level of urine angiotensinogen was highest in a total cohort study. Urine angiotensinogen was significantly independent determinant in high blood pressure concomitant with high salt diet after adjusting other clinical factors in CKD patients.

FR-PO796

Detection of Early Nephropathy and Risk Factors in Patients with Essential Hypertension in the Primary Health Care Jorge Lopez-Leal, Laura Cortes-Sanabria, Edgar U. Tellez-Agraz, Roxana Marquez-Herrera, Maria Alejandra Guzman, Alfonso M. Cueto-Manzano. *Unidad Investigacion Medica en Enfermedades Renales, IMSS, Guadalajara, Mexico.*

Background: Hypertension (HTN) is the second most common cause of ESRD. There is scarce information about prevalence of early nephropathy (EN) in patients with essential HTN. **Aim:** To determine the prevalence of EN and associated risk factors in patients with essential HTN of 9 primary health care units (PHC) in Guadalajara.

Methods: Cross-sectional study in patients with essential HTN, ≥18 yrs, any HTN vintage. Patients with transient albuminuria, diabetes, secondary HTN, other CKD causes and previously known CKD were excluded. Sociodemographic, clinical and biochemical data were collected. Albuminuria/Creatinuria ratio (ACR) in a first void urine sample and eGFR (CKD-EPI) were determined. Kidney function was classified (KDIGO) as normal (NF): eGFR ≥90mL/min/1.73m^2 and ACR <30mg/g; EN: CKD stages 1 and 2, and overt nephropathy (ON) stage ≥3.

Results: Prevalence of CKD was 18% (6% EN and 12% ON). Main results are shown in the table.

Variable	NF (N871)	EN (N66)	ON (N125)
Age *yrs*	59±11	62±14	69±11[ab]
Male sex *N(%)*	267(31)	29(44)[a]	56(45)[a]
Smoking *N(%)*	222(25)	20(30)	43(34)
<6 school yrs *N(%)*	503(58)	43(65)[a]	90(72)[a]
Systolic blood pressure *mmHg*	131±16	135±17	137±20[a]
HTN vintage *yrs*	7(3-14)	9(4-12)	10(5-17)
>140/90 mmHg *N(%)*	330(38)	34(51)[a]	63(50)[a]
Body mass index *kg/m^2*	30±5	30±6	29±5
Antihypertensives *N(%)*	1.5±0.7	1.5±0.7	1.7±0.7[ab]
ACE inhibitors *N(%)*	488(56)	40 (61)	66(53)
Uric acid *mg/dL*	5.4±1.1	5.6±1.4	6.4±1.3[ab]
Creatinine *mg/dL*	0.80±0.16	0.82±0.20	1.32±0.49[ab]
eGFR *mL/min/1.73m^2*	88±14	88±14	47±10[ab]
ACR *mg/g*	7(3-12)	51(34-117)[a]	8(1-20)
[a]p<0.05 vs NF, [b]p<0.05 vs EN			

Older age (≥60 yrs) (OR 2.5, p<0.001), hyperuricemia (OR 2.1, p=0.001), uncontrolled HTN (OR 1.8, p=0.001), male (OR 1.6, p=0.007), <6 school yrs (OR 1.4, p=0.032) predicted the presence of nephropathy.

Conclusions: Overall prevalence of CKD was 18% in patients with essential HTN of the PHC. Modifiable and non-modifiable risk factors associated to nephropathy are very common in this population.

FR-PO797

The Association of Midlife Uric Acid with Kidney Function in the General Population after 26 Years of Follow-Up Anny Ros Gudmundsdottir,[1] Thor Aspelund,[2,3] Bjorn Odvar Eriksen,[4] Rafn Benediktsson,[1,5] Margret B. Andresdottir.[1,5] *[1]Faculty of Medicine, Univ of Iceland; [2]The Icelandic Heart Association, Iceland; [3]Puplic Health Sciences, Univ of Iceland; [4]Metabolic and Renal Research Group, The Arctic Univ of Norway; [5]Div of Endocrinolgy, The National Univ Hospital of Iceland; [6]Div of Nephrology, The National Univ Hospital of Iceland.*

Background: Hyperuricemia has been associated with decline in kidney function. Proving causation is a challenge because of the renal elimination of serum uric acid (SUA) in addition to the association between SUA and other metabolic factors. In this study we used inverse probability of treatment weighting (IPTW) as an approach to limit confounding.

Methods: Data from 5141 volunteers in the AGES/Reykjavik study who had been followed prospectively for a median of 26 years, were analyzed to examine the association between SUA in midlife and GFR in late life. Estimated GFR (eGFR) was calculated with CKD-EPI creatinine equation. First, a multivariable linear regression model was conducted with SUA as exposure of interest and eGFR as outcome. We adjusted for age, hypertension, erythrocyte sedimentation rate, triglycerides, glucose, BMI and $eGFR_{midlife}$. Second, a propensity score was calculated based on the variables above. IPTW was used which is based on the propensity scores. The effect on eGFR was then studied with linear regression analysis, with hyperuricemia as exposure.

Results: Average eGFR in late life was 64.6 ml/min per 1.73m^2 in men and 63.2 ml/min per 1.73m^2 in women with mean age 76.5 (±5.1) and 76.1 (±5.1), respectively. Patients with hyperuricemia were 364 in total. Results of the statistical models are shown in table:

Multiple linear regression				
	Coef. of interest	β	95% CI	P-value
Men	SUA (per 100 µmol/L)	-0.30	-1.3 to 0.71	0.6
Women	SUA (per 100 µmol/L)	-1.61	-2.6 to -0.60	0.002
IPTW				
Men	Hyperuricemia	-3.54	-4.87 to -2.22	<0.0001
Women	Hyperuricemia	-7.62	-8.77 to -6.48	<0.0001

Conclusions: Higher SUA in midlife was independently associated with lower eGFR in late life especially in women.The association was confirmed with IPTW which supports causal effect of SUA.

FR-PO798

The Effect of Early Urate Lowering Therapy on Renal Disease Progression in Hyperuricemic Patients with Chronic Kidney Disease Sung Joon Shin,[1] Kwanghoon Lee.[2] *[1]Nephrology, Dongguk Univ Ilsan Hospital, Goyang-si, Gyeonggi-do, Korea; [2]Rheumatology, Dongguk Univ Ilsan Hospital, Goyang-si, Gyeonggi-do, Korea.*

Background: This study aimed to determine whether urate lowering therapy (ULT) could delay renal disease progression in hyperuricemic patients with chronic kidney disease (CKD) according to the baseline stage of CKD.

Methods: We retrospectively reviewed the medical records of patients who were diagnosed as stage 3 and 4 CKD and concurrent hyperuricemia (> 7.0 mg/dL for males and > 5.7 mg/dL for females) from September 2005 to October 2015. The duration of follow-up should be longer than 6 months and the duration of treatment longer than 6 months for ULT group. We defined renal disease progression as follows; decline of eGFR greater than 30% compared to the baseline value, initiation of dialysis or eGFR < 15 mL/min/1.73m^2. To determine whether the baseline stage of CKD has an impact on the effect of ULT on renal disease progression, we analyzed the association of baseline stage of CKD with renal disease progression by binary logistic regression analysis.

Results: The uric acid levels markedly decreased from baseline (from 9.2±1.9mg/dL to 7.5±3.0mg/dL, p=0.028) and the degree of decrease was significantly greater in the ULT group (-1.9±4.2 mg/dL vs. -0.6±1.8 mg/dL, p=0.037). The mean decrease of eGFR from baseline tended to be smaller in the group that achieved target uric acid level (-2.81±9.4 mL/min/1.73m^2 vs. -8.57±10.0 mL/min/1.73m^2) and the rate of renal disease progression tended to be lower in the ULT group (33.9% vs. 44.1%). Subgroup analysis showed that the benefit of ULT was most apparent in CKD patients with stage 3a. In the multivariate analysis, the baseline stage of CKD was significantly associated with renal disease progression (p for trend <0.001) and the adjusted odds ratio for renal disease progression with stage 3a as a reference was 6.5 (95% confidence interval (CI) 3.419 ~ 12.357).

Conclusions: The ULT delayed renal disease progression significantly in hyperuricemic patients with CKD. The baseline stage of CKD was an independent risk factor for renal outcomes in ULT group. So, patients with early CKD stage might gain more benefit from ULT than those with late stage.

FR-PO799

Uric Acid in Chronic Kidney Disease Patients: The Role of Villain on Inflammation Denise Mafra, Juliana Saraiva Anjos, Ana Paula Black Dreux, Ludmila F.M.F. Cardozo, José Carlos Carraro-Eduardo. *Federal Univ Fluminense.*

Background: Hyperuricemia has been suggested to be involved in progression of chronic kidney disease (CKD), inflammation and developing cardiovascular disease. However, the mechanisms by which uric acid acts have not yet been fully elucidated. Researchers have shown that uric acid induces renal inflammation via activation of NF-κB signaling. Then, uric acid might be the new mechanism that activates the NF-κB and consequently, inflammation.The aim of this study was to evaluate a possible association between uric acid plasma levels and NF-κB mRNA expression in non-dialysis CKD patients.

Methods: Thirty-seven non-dialysis CKD patients (20 men, 58.0 ± 12.3 yr, BMI 29.0 ± 6.2 kg/m^2, glomerular filtration rate 34.8±13.6mL/min/1.73m^2) were evaluated. The peripheral blood mononuclear cells (PBMC) were isolated and Quantitative Real-Time PCR analysis were performed to evaluate the expression levels of mRNA encoding NF-κB (*7500 Real-Time PCR* System, *Applied Biosystems*). Routine laboratory parameters were measured by standard techniques and body mass index (BMI) was calculated.

Results: The biochemical parameters are shown in Table 1.

Parameters	Values
Creatinine (mg/dL)	2.2 ± 0.9
Blood urea nitrogen (mg/dL)	73.9 ± 30.8
C-Reactive Protein (mg/dL)	4.9 (1.1-5.8)
Potassium (mEq/L)	4.4 ± 0.5
Albumin (mg/dL)	3.7 ± 0.4
Uric acid (mg/dL)	6.3 ± 1.3
Cholesterol (mg/dL)	170 ± 48
Triglycerides (mg/dL)	129 ± 58
LDL (mg/dL)	91.4 ± 41.9
HDL (mg/dL)	53.1 ± 17.3
NF-κB mRNA expression	0.83 (0.66 – 1.5)

Only 33% of patients presented high uric acid levels. Linear regression showed that uric acid was an independent predictor for NF-κBmRNA expression (β = 0.35, p= 0.04) after adjustment on age, gender, BMI, GFR and CPR levels.

Conclusions: The results suggest that uric acid levels, even in the normal range, are associated with increased NF-κB expression in CKD patients.

FR-PO800

Uric Acid and Disease Progression and Mortality in CKD

Hernan Rincon-Choles,[1] Stacey Jolly,[2] Susana Arrigain,[3] Victoria Konig,[3] Michael Rothberg,[2] Jesse D. Schold,[3] Sankar D. Navaneethan,[4,5] Joseph V. Nally.[1]
[1]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [2]General Internal Medicine, Cleveland Clinic, Cleveland, OH; [3]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [4]Nephrology, Baylor College of Medicine, Houston, TX; [5]Nephrology, Houston Veterans Affairs Medical Center, Houston, TX.

Background: Various observations associate hyperuricemia (HU) with progression of CKD and mortality. We examined the association of HU with ESRD and mortality in the Cleveland Clinic CKD Registry.

Methods: We included 1,676 patients with CKD stages 3 and 4 from Ohio, without malignancy who had uric acid (UA) measurements a year prior to second eGFR<60ml/min per 1.73 m^2, and some follow up eGFR, between 2005 and 9/15/2009. We ascertained ESRD from the USRDS and mortality from the State Department of Health mortality files. We fitted Cox models of pre-ESRD mortality and competing risks model of ESRD with death as a competing risk adjusted for demographics, comorbidities, and laboratory measures including eGFR. Time-dependent uric acid lowering therapy (UALT) was adjusted on mortality models, and baseline UALT on ESRD models.

Results: 95 patients reached ESRD and 201 reached pre-ESRD death during a median follow up of 2.8 years. In the adjusted models, neither UA level nor UALT were significantly associated with mortality or ESRD.

Table 1. Associations between uric acid and UALT and pre-ESRD mortality and ESRD

	Pre-ESRD Mortality*** HR (95% CI)	ESRD* SHR (95% CI)
Model 1 (high/low UA)		
High UA (M>8, F>7) vs. low	1.15 (0.85, 1.55)	1.25 (0.76, 2.04)
UALT vs. No	0.81 (0.60, 1.09)	1.41 (0.92, 2.16)
Model 2 (Quartiles of UA)		
Q1 (1.1-5.9)	Ref	Ref
Q2 (6.0-7.3)	1.07 (0.68, 1.67)	0.52 (0.19, 1.42)
Q3 (7.4-8.8)	1.24 (0.80, 1.93)	1.59 (0.72, 3.50)
Q4 (8.9-16.6)	1.28 (0.84, 1.95)	1.43 (0.65, 3.14)
UALT vs. No	0.82 (0.61, 1.11)	1.48 (0.97, 2.24)
Model 3 (continuous UA)		
Uric Acid (per 1 mg/dL higher)	1.05 (0.98, 1.12)	1.06 (0.97, 1.16)
UALT vs. No	0.81 (0.60, 1.10)	1.39 (0.91, 2.13)

*Adjusted for age, sex, race, BMI, SBP quartiles, DM, ACEI/ARB, diuretics, eGFR
**Above variables plus log triglycerides, log cholesterol, CAD

Conclusions: In contrast to some prior reports we found no evidence that hyperuricemia is associated with increased risk of mortality or CKD progression to ESRD in patients with CKD stages 3 and 4, in the adjusted models.

Funding: Pharmaceutical Company Support - Pharmaceutical Company Support-CCF CKD Registry creation was supported by an unrestricted grant from Amgen to the Department of Nephrology and Hypertension at the Cleveland Clinic

FR-PO801

Urinary Calcium Excretion and Risk of Chronic Kidney Disease in the General Population

Jacob M. Taylor,[1] Lyanne M. Kieneker,[1] Martin H. De Borst,[1] Sipke T. Visser,[2] Ido Peter Kema,[3] Stephan J.L. Bakker,[1] Ron T. Gansevoort.[1]
[1]Internal Medicine, Univ of Groningen, UMCG, Netherlands; [2]Pharmacoepidemiology and Pharmacoeconomics, Univ of Groningen, UMCG, Netherlands; [3]Laboratory Medicine, Univ of Groningen, UMCG, Netherlands.

Background: Calcium and vitamin D are essential nutrients for human health, and are recommended as part of a healthy diet. However, high urinary calcium excretion (UCaE) has been shown to lead to accelerated renal function decline in individuals with renal tubular diseases. It is not known whether this association also exists in the general population. Therefore, we investigated whether high UCaE is associated with risk of developing chronic kidney disease (CKD) in community dwelling subjects.

Methods: Urine samples of 5,491 subjects who were free of CKD at baseline and participated in the PREVEND study (a prospective, observational, general population based cohort of Dutch men and women aged 28-75 years), were examined for UCaE. UCa concentration was measured in two 24h urine samples at baseline (1997-1998) by indirect potentiometry. UCaE was treated both as a continuous variable and as a categorical variable grouped according to sex-specific quintiles for UCaE. UCaE was compared to *de novo* development of eGFR <60 ml/min/1.73m^2 and/or albuminuria >30 mg/24h.

Results: Baseline median UCaE was 166 mg/24h for men (interquartile range [IQR]: 117-220 mg/24h), and 141 mg/24h for women (IQR: 96-193 mg/24h). During a median follow-up of 10.3 years (IQR: 6.2-11.4 yrs), 899 subjects developed CKD. After multivariable adjustment for non-modifiable and modifiable covariates, every 40 mg/24h higher baseline UCaE was associated with a 6% lower risk for incident CKD during follow-up (HR: 0.94 [0.88-0.99], p=0.02). The association showed to be significantly non-linear, with highest risk of CKD in the lowest quintile for UCaE (HR: 1.28 [0.97-1.68], p=0.09). There was no association between UCaE and mortality or cardiovascular health during follow-up, indicating that this association was not a reflection poor nutritional intake due to bad health.

Conclusions: These findings indicate that high levels of UCaE do not increase risk of CKD, but rather that low levels of UCaE may be harmful.

FR-PO802

Optimal End Stage Renal Disease Starts Are Associated with Less Sepsis, Lower Mortality and Fewer Inpatient Days

Peter W. Crooks,[1] Christopher O. Thomas,[2] Linda K. Radler.[1]
[1]The Permanente Federation, LLC, Oakland, CA; [2]Kaiser Permanente Northwest, Portland, OR.

Background: Endorsed by the National Quality Forum, the Optimal End Stage Renal Disease (ESRD) Starts measure assesses the proportion of patients who receive a preemptive kidney transplant or initiate maintenance outpatient therapy on peritoneal dialysis or hemodialysis [HD] via arteriovenous fistula or arteriovenous graft. Six Kaiser Permanente Regions have tracked the measure since 2011; this study compares outcomes for patients with and without an optimal ESRD start.

Methods: 2089 patients with an optimal ESRD start were propensity score-matched by demographics, comorbidities, BMI, eGFR before ESRD, and alcohol and tobacco use to 2089 patients starting outpatient HD with a central venous HD catheter. Outcomes included sepsis, mortality and inpatient days for the first 12 months after starting renal replacement therapy. Logistic regression and Cox proportional hazard regression, adjusted for propensity score, were used to calculate odds ratios for sepsis and mortality and the hazard ratio for mortality. The rate ratio for inpatient days was adjusted for prior inpatient use and propensity score.

Results: Among patients with optimal ESRD starts, mean sepsis and mortality rates per person-year were 0.14 and 0.09; mean annual inpatient days were 9.8. Comparable rates and days for patients with nonoptimal starts were 0.49, 0.31, and 25.8, respectively. Odds ratios for sepsis and mortality were 0.29 (95% confidence interval [CI], 0.24 to 0.34) and 0.28 (95% CI, 0.23 to 0.35), respectively, compared to patients with nonoptimal starts; the mortality hazard ratio was 0.36 (95% CI, 0.30 to 0.43). Patients with optimal ESRD starts had 62% fewer inpatient days (rate ratio 0.38, 95% CI 0.31 to 0.46). All ratios were significant at $p < 0.001$.

Conclusions: Optimal ESRD Starts were associated with substantial reductions in morbidity, mortality, and inpatient days. While it was not possible to match for all patient characteristics, this study supports the use of the Optimal ESRD Starts measure within the U.S. health care system to evolve a more systematic approach to identifying, educating and supporting patients at high risk for ESRD.

Background: CKD patients have an increased risk of death. A simple prediction model of CKD patient mortality would be useful. To improve the accuracy and streamline such predictions, we used the Woodpecker™ approach to construct models from reported risks in the literature. The goal of this project was to develop a risk scoring system and prediction model of two-year mortality of patients with CKD of stage 2 and greater.

Methods: A risk indicator (*R*) was calculated by starting with 0, add 0.039 for every year of age, add 0.4 for male sex, add 0.4 for every stage of CKD over stage 2, add 0.9 for presence of proteinuria, add 0.6 for smoking history, and add 0.3 for each significant comorbidity up to 5. The result is multiplied by 1.257 to scale *R* from 0 to 10. We developed 4 different equations (one linear, two exponential, and a combined one) to estimate the probability of two-year mortality. We used NHANES 1999-2004 data for validation (n=6,057 subjects with CKD stage 2 or above).

Results: The predictions were compared to actual NHANES mortality outcomes by R alone and in patient groups divided by R (0-2, >2-3, >3-4, >4-5, >5-6, >6). This prediction yielded a satisfactory area under an ROC curve of 0.84. We compared the predicted probability of death based on R with the actual two-year mortality using each of the prediction formulae. The combined expression offered predictive results closest to the actual outcomes, particularly in the higher risk groups (R>4).

Conclusions: We propose a practical prediction model that allows estimation of a CKD patient's relative risk of two-year mortality on a 1 to 10 scale, and a probability of death. This equation can be used in clinical practice to target subjects at risk as well as in clinical research, e.g., to help designing clinical trials.

eGFR Decline of 40% as an Alternative Endpoint in Clinical Trials: Experience from EMPA-REG OUTCOME

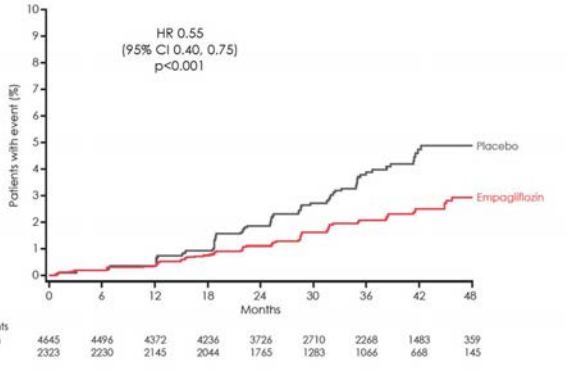
Christoph Wanner,[1] Hiddo Jan Lambers Heerspink,[2] Egon Pfarr,[3] Mario Maldonado-Lutomirsky,[3] Audrey Koitka-Weber,[3] Hans-Juergen Woerle,[3] Maximilian von Eynatten,[3] Vlado Perkovic.[4] *[1]Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; [2]Dept of Clinical Pharmacy and Pharmacology, Univ of Groningen, Groningen, Netherlands; [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [4]George Inst for Global Health, Sydney Univ, Sydney, Australia.*

Background: Doubling of serum creatinine (DSC) is highly predictive of ESRD but its use as an endpoint in clinical trials requires long duration of follow-up and large sample sizes. The National Kidney Foundation and FDA have proposed the utility of lower thresholds in eGFR decline as alternative renal endpoints.

Methods: In EMPA-REG OUTCOME, 7020 patients with type 2 diabetes and high cardiovascular risk were randomized 1:1:1 to receive empagliflozin (EMPA) 10 mg, 25 mg, or placebo in addition to standard of care. Treatment group differences in the time to first DSC (accompanied by eGFR [MDRD] of ≤45 mL/min/1.73m^2) and sustained (defined as 2 consecutive measurements ≥4 weeks apart) eGFR decline of 40% from baseline were assessed for EMPA pooled vs placebo using a Cox proportional hazards model.

Results: Incidence rates of DSC were 9.7 and 5.5 events per 1000 person-years with placebo and EMPA, respectively. EMPA reduced DSC risk by 44% *vs* placebo (p<0.001). Incidence rates of sustained eGFR decline of 40% were 12.4 and 7.0 events per 1000 person-years with placebo and EMPA, respectively. The risk of sustained eGFR decline of 40% was reduced by 45% with EMPA *vs* placebo (p<0.001, Figure).

Figure. Time to first sustained decline in eGFR of 40% from baseline



Data from patients treated with ≥1 dose of study drug.
Sustained decline in eGFR of 40% from baseline: defined as 2 consecutive measurements with decline in eGFR of 40% from baseline that were ≥4 weeks apart.

Conclusions: EMPA significantly lowered the risk of sustained eGFR decline of 40% and the overall effect size was consistent with the harder endpoint of DSC. Our data support the consideration of a lower threshold in eGFR decline as an alternative renal endpoint for assessing CKD progression in clinical trials.

Effect of Empagliflozin on Albuminuria in Patients with Type 2 Diabetes and High Cardiovascular Risk

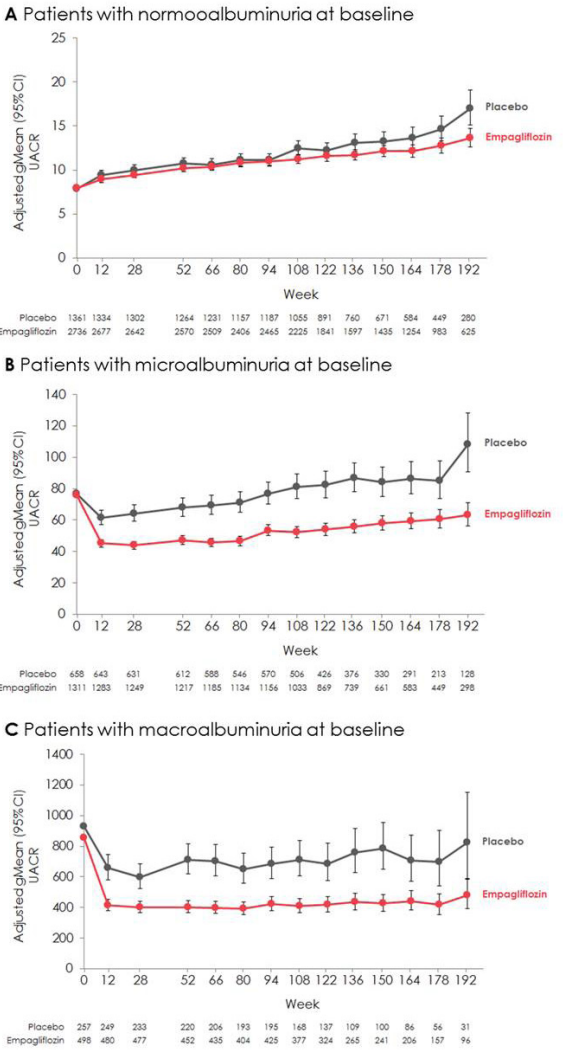
Christoph Wanner,[1] Bernard Zinman,[2] Silvio E. Inzucchi,[3] Egon Pfarr,[4] Audrey Koitka-Weber,[4] Maximilian von Eynatten,[4] Hiddo Jan Lambers Heerspink,[5] David Cherney.[6] *[1]Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; [2]Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, Canada; [3]Section of Endocrinology, Yale Univ, New Haven, CT; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [5]Dept of Clinical Pharmacy and Pharmacology, Univ of Groningen, Groningen, Netherlands; [6]Toronto General Hospital, Univ of Toronto, Canada.*

Background: Short-term treatment with empagliflozin (EMPA) reduced albuminuria in patients with type 2 diabetes (T2D). The present analysis aimed to explore short- and long-term effects of EMPA on albuminuria in EMPA-REG OUTCOME.

Methods: Patients with T2D and high cardiovascular (CV) risk were randomized (1:1:1) to EMPA 10 mg, 25 mg or placebo in addition to standard of care. Changes in urinary albumin-to-creatinine ratio (UACR, log-transformed) from baseline were analyzed for EMPA pooled vs placebo using a mixed model repeated measures analysis.

Results: 7020 patients were treated. At baseline, 59.4%, 28.7% and 11.0% had normo-, micro- and macroalbuminuria, respectively. At Week 12, placebo-adjusted geometric mean ratio of UACR change from baseline with EMPA pooled was -7% (95%CI -12 to -2; p=0.01), -25% (95%CI -31 to -19; p<0.001) and -32% (95%CI -41 to -23; p<0.001) in patients with normo-, micro- or macroalbuminuria at baseline, respectively. At Week 192, placebo-adjusted geometric mean ratio of UACR change from baseline with EMPA pooled was -21% (95%CI -31 to -9; p=0.001), -40% (95%CI -51 to -27; p<0.001) and -38% (95%CI -58 to -9; p<0.05) in these subgroups, respectively (Figure).

Figure. UACR over time.



Mixed model repeated measures analysis using all data up to individual trial completion in treated patients who had a baseline and post-baseline measurement.
Normoalbuminuria defined as UACR <30 mg/g.
Microalbuminuria defined as UACR ≤300 mg/g
Macroalbuminuria defined as UACR >300 mg/g.

Conclusions: In patients with T2D and high CV risk, EMPA led to sustained reductions in UACR from as early as Week 12, regardless of baseline albuminuria status. These results support both short- and long-term renal effects of EMPA on UACR.

FR-PO806

Rapid Onset of Renal Effects with Empagliflozin in Type 2 Diabetes: A Cumulative Renal Event Analysis over Time in EMPA-REG OUTCOME

Christoph Wanner,[1] Guntram D. Schernthaner,[2] Audrey Koitka-Weber,[3] Michaela Mattheus,[3] Maximilian von Eynatten,[3] Mark E. Cooper.[4] *[1]Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; [2]Dept of Internal Medicine, Rudolfstiftung Hospital, Vienna, Austria; [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [4]Baker IDI Heart and Diabetes Inst, Melbourne, Australia.*

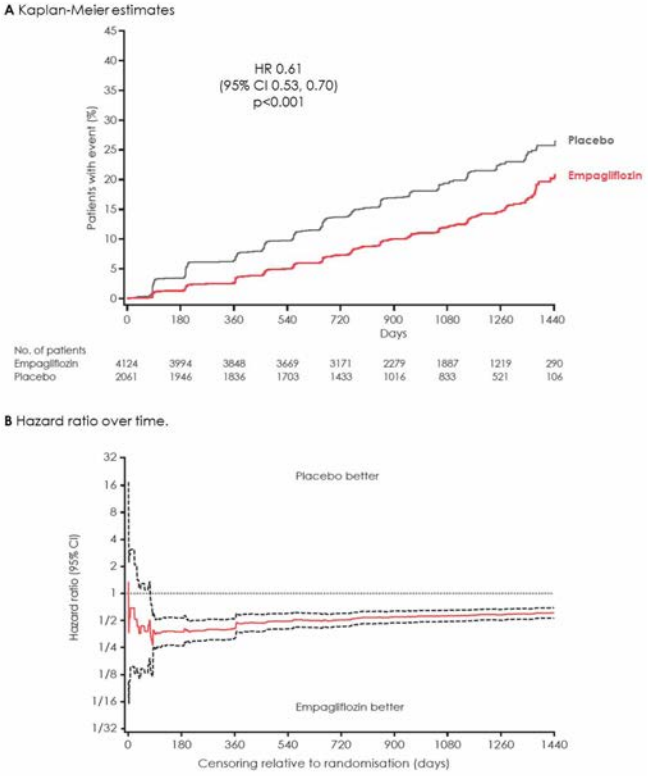
Background: Patients with diabetes are at high risk of developing CKD. In EMPA-REG OUTCOME, empagliflozin (EMPA) significantly slowed CKD progression in patients with type 2 diabetes and high cardiovascular risk. To further explore the onset of the observed renal effects with EMPA we investigated hazard ratios (HRs) over time for the composite outcome of incident or worsening nephropathy.

Methods: Patients were randomized to receive EMPA 10mg, 25mg or placebo in addition to standard of care. The cumulative probabilities of experiencing incident or worsening nephropathy (i.e. progression to macroalbuminuria, doubling of serum creatinine

accompanied by eGFR [MDRD] ≤45 mL/min/1.73m^2, initiation of renal replacement therapy or death due to renal disease) were analyzed for pooled EMPA *vs* placeboin patients treated with ≥1 dose of study drug. HRs and 95% CIs (obtained from Cox regression analyses) were derived at each time point following randomization until the last observation of the last patient. All events until the respective cut-off day were considered and patients without events were censored at that day.

Results: A significantly lower risk for the composite renal outcome with EMPA *vs* placebo was observed within the first 3 months and this effect was maintained throughout the trial (Figure). HRs stabilized as the number of patients with events increased over time.

Figure. Incident or worsening nephropathy. (**A**) Kaplan-Meier estimates (**B**) Hazard ratio over time.



Conclusions: Renal effects of EMPA occurred within the first 3 months of treatment. This rapid onset of action may reflect renal hemodynamic changes and reduction of glomerular hypertension.

FR-PO807

Effects of Canagliflozin versus Glimepiride on eGFR Based on Serum Creatinine and Cystatin C in Patients with Type 2 Diabetes

Matthew R. Weir,[1] Christian W. Mende,[2] Ujjwala Vijapurkar,[3] Robert Cuddihy,[3] Jimmy Ren,[3] Michael J. Davies.[3] *[1]Univ of Maryland School of Medicine, Baltimore, MD; [2]Univ of California, San Diego, La Jolla, CA; [3]Janssen Scientific Affairs, LLC, Raritan, NJ.*

Background: Canagliflozin (CANA), an SGLT2 inhibitor, has shown durable glycemic improvement and weight loss versus glimepiride (GLIM) over 104 weeks in patients with type 2 diabetes mellitus (T2DM) on background metformin; CANA showed a transient estimated glomerular filtration rate (eGFR) reduction that stabilized over time versus a progressive decline with GLIM. Accurate assessment of eGFR (typically calculated using serum creatinine [Cr]) is important as efficacy of SGLT2 inhibitors is impacted by renal function, and cystatin C (CysC)-based equations have been proposed but not confirmed as an alternative, less variable measure of eGFR. We assessed the effects of CANA 300 mg versus GLIM on eGFR based on serum Cr and combined Cr/CysC.

Methods: This post hoc analysis used data for CANA 300 mg (n=252) and GLIM (n=215) from patients in the overall study who completed 104 weeks of treatment without rescue therapy. Correlation in baseline (BL) eGFR using Cr and Cr/CysC equations was measured, and mean change from BL in eGFR at Week 104 was evaluated for CANA 300 mg versus GLIM.

Results: There was a modest correlation in BL eGFR calculated using Cr and Cr/CysC equations (R^2=0.38). Similar eGFR reductions were seen with CANA 300 mg and GLIM after 104 weeks using the Cr/CysC equation, whereas eGFR reduction was larger with GLIM compared to CANA 300 mg using the Cr-based equation (**Table**).

Conclusions: Differences in eGFR over 2 years were seen with CANA and GLIM when assessed based on serum Cr but not Cr/CysC. SGLT2 inhibitors are a newer class of antihyperglycemic agents with hemodynamic effects and ongoing, long-term, renal outcome trials will determine the potential for renoprotection in patients with T2DM.

Table. Change in eGFR at Week 104 Using Cr- and Cr/CysC-based Equations

	eGFR (Cr)*		eGFR (Cr/CysC)	
	GLIM (n = 215)	CANA 300 mg (n = 252)	GLIM (n = 215)	CANA 300 mg (n = 252)
Mean (SD) baseline, mL/min/1.73 m^2	87.5 (16.7)	91.7 (18.1)	88.7 (18.6)	92.2 (17.9)
LS mean change (SE) at Week 104	–6.2 (1.0)	–2.7 (0.9)	–4.4 (1.0)	–4.5 (1.0)
Difference (95% CI) vs GLIM		3.5 (1.3, 5.8)		–0.1 (–2.4, 2.3)

SD, standard deviation; LS, least squares; SE, standard error; CI, confidence interval; MDRD, Modification of Diet in Renal Disease.
*MDRD equation.

Effects on Renal Function, Renal Protection and Glucose Metabolism of Sitagliptin to Type 2 Diabetes with Moderate or Severe Renal Dysfunction

Renal Effect and Safety of Sitagliptin (REAL) Trial Koichi Kanozawa,[1] Shigehiro Katayama,[2] Satoko Nakamura,[1] Rika Kono,[1] Yuichi Noguchi,[2] Yuta Kogure,[1] Hiroaki Hara,[1] Minoru Hatano,[1] Tomonari Ogawa,[1] Hajime Hasegawa.[1] *[1]Div of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan; [2]Dept of Endocrinology and Diabetes, Saitama Medical Univ, Moroyama, Saitama, Japan.*

Background: Recently, many studies suggested renoprotective effects by the DPP-4 inhibitor (DPP-4i). Clinically, while maintaining renal function, and performing the medical economically efficient glycemic control is important. A multicenter study aimed to investigate the maintenance and protection of renal function, and an efficient glycemic control by the DPP-4i, sitagliptin for the patients with type 2 diabetes (T2DM) with moderate or severe renal impairment.

Methods: Objects: Japanese adult patients with T2DM, have renal dysfunction less than eGFR 60mL / min / 1.73m2, and treat with different characteristic DPP-4i (one of the vilda-, alo- or linagliptin) more than two months. Study Design: Patients have been switched administration a dose of sitagliptin according to renal function (group A: 25-50mg in 30 <eGFR ≤ 60 mL / min / 1.73 m2, group B: 12.5-25mg in eGFR ≤ 30 mL / min / 1.73m2) from the other DPP-4i, and follow after three and six months. The primary endpoints are, eGFRcreat, eGFRcys, urinary liver type fatty acid binding protein, urinary albumin to creatinine ratio, urinary type IV collagen, urinary β2-microglobulin, and urinary 8-isoprostane. Secondary endpoints are HbA1c, postprandial blood glucose, postprandial c- peptide, and postprandial active GLP-1. In addition, it was also examined drug prices.

Results: 49 patients of seven centers (group A: 26 , group B: 23 patients) were analyzed. By changes to sitagliptin from other DPP-4i, there was no change in any of the primary endpoints also to secondary endpoints. On the other hand, drug prices per day had been reduced even 76.7 Japanese yen.

Conclusions: Switching from other DPP-4i to sitagliptin had maintained good glycemic control, renal function or renoprotection, and it was considered to be beneficial in terms of cost-effectiveness for patients with T2DM, had moderate or severe renal impairment.

Clinical Characteristics of Patients with Bullous Pemphigoid Associated with Dipeptidyl Peptidase-4 Inhibitors: Is Chronic Kidney Disease a Risk Factor?

Hideaki Oka,[1] Shunsuke Yamada,[2] Taro Kamimura,[1] Yutaro Hirashima,[1] Tomoya Shukuri,[1] Seishi Aihara,[1] Atsumi Harada,[1] Kazuhiko Tsuruya.[2,3] *[1]Matsuyama Red Cross Hospital, Div of Kidney Center, Matsuyama, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Bullous pemphigoid (BP) is the most commonly acquired autoimmune blistering dermatosis. Its etiology is usually idiopathic but may occasionally be drug-induced. This study assessed the incidence of BP induced by dipeptidyl peptidase 4 inhibitors (DPP4Is) and the factors associated with DPP4Is-induced BP.

Methods: The present study was a single-center retrospective cohort studythat reviewed and examined all patients who were histologically diagnosed with BP at our hospital between 2005 and 2015. We analyzed the incidence of DPP4Is-associated BP and compared the characteristics of BP patients who were and were not treated with DPP4Is.

Results: Of the 66 patients diagnosed with BP during the study period, 19 were diagnosed during the 5 years before the introduction of DPP4Is and 47 during the 6 years after the introduction of DPP4Is. Of the latter, nine had been taking DPP4Is at diagnosis. There were no significant differences in age, sex, prevalence of anti-BP180 antibody, and BP treatment and outcomes between patients who were and were not treated with DPP4Is. In contrast, the prevalence of chronic kidney disease (CKD) was higher in patients who were than were not treated with DPP4Is, with rates of stage 5 CKD being 44% (4 of 9) and 4% (2 of 57), respectively.

Conclusions: The incidence of DPP4Is-associated BP appears to be increasing. CKD may increase the risk of DDP4Is-associated BP. Further large cohort studies and case-control studies are required to identify the interactions between CKD and DPP4Is-associated BP.

FR-PO810

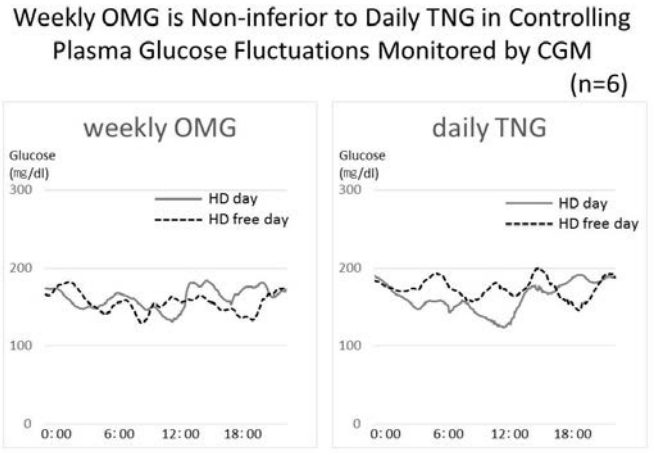
Omarigliptin, a Novel Once-Weekly Oral Dipeptidyl Peptidase-4 Iinhibitor, Is Non-Inferior to Daily Teneligliptin in Controlling Plasma Glucose Fluctuations and Exerts Better Medication Adherence in Hemodialysis Patients with Type 2 Diabetes in a Crossover Study: An Assessment by Continuous Glucose Monitoring

Sayuri Watanabe,[1] Rei Moriyama,[1] Chigusa Fukagawa,[1] Kenta Tsukuda,[1] Jyunichiro Hashiguchi,[1] Satoshi Funakoshi,[1] Takashi Harada,[1] Yoko Obata,[2] Tomoya Nishino.[2] *[1]Nagasaki Kidney Center, Japan; [2]Nagasaki Univ Hospital, Japan.*

Background: During hemodialysis (HD), plasma glucose (PG) level drops due to various factors including clearance gap between glucose and insulin, and then rebounds to hyperglycemic state after HD. These PG fluctuations can induce cardiovascular events in HD patients with type 2 diabetes mellitus (T2D). Omarigliptin (OMG) is a novel long-acting oral dipeptidyl peptidase-4 inhibitor (DPP-4I)used in the treatment of T2D patients with or without renal impairment.

Methods: In this study we compared once-weekly OMG to once-daily teneligliptin (TNG) on PG control in a crossover study assessed by continuous glucose monitoring (CGM) in a crossover study. Six adult HD patients with T2D who had been treated with 40mg of daily TNG were switched to once-weekly 12.5mg of OMG for 8 weeks, then to previous dose of daily TNG. All patients were monitored for PG control by 5-day CGM, and the mean amplitude of glycaemic excursions (MAGE) calculated before and after switching. OMG was given right after HD treatment in the presence of HD staff, and the medication adherence (total actual number of tablets taken during a period / number of tablet expected to be taken during a period x 100) was calculated at the end time point of each arm.

Results:



As shown in figure 1, there was no significant difference between once-daily TNG and once-weekly OMG in PG at the start of HD or MAGE. The medication adherence was 100% in OMG and 87% in TNG, respectively.

Conclusions: Our results indicate the effects of OMG are non-inferior to TNG, and OMG exerts better medication adherence.

FR-PO811

Linagliptin and Changes in Novel Urinary Biomarker Panels in Type 2 Diabetes: A Predefined Substudy from the MARLINA-T2D™ Trial

Tzu-Ling Tseng,[1] Wei-Ya Lin,[1] Hsiang-Chi Wang,[1] Chi-Hsuan Huang,[1] Sandra Thiemann,[2] Maximilian von Eynatten,[2] Lee-Ming Chuang.[3] *[1]Bio Preventive Medicine Corp., Taiwan; [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Germany; [3]National Taiwan Univ Hospital, Taiwan.*

Background: The DN_Score is a composite score derived from DNlite, a novel urinary biomarker panel composed of alpha2-HS-glycoprotein precursor, alpha-1-antitrypsin and acid-1-glycoprotein. Previous evidence showed that the DN_Score significantly correlated with stages of kidney disease in both, type 1 diabetes (T1DM) and type 2 diabetes (T2DM). In this predefined substudy from MARLINA-T2D™, we applied the DN_Score to evaluate the renal effects of linagliptin in patients with T2DM and prevalent albuminuria.

Methods: MARLINA-T2D™ is a Phase IIIb, multicenter, multinational, randomized, double-blind, placebo (PBO) controlled, parallel group study to evaluate the glycemic and renal efficacy of linagliptin 5 mg QD for 24 weeks in T2DM patients, with micro- (30-300 mg/g creatinine) or macroalbuminuria on top of current treatment with ACE inhibitor or ARB. The percent change from baseline in the DN_Score at Week 24 was analyzed by an analysis of covariance (ANCOVA) based on the full analysis set, with baseline DN_Score as the prespecified covariate.

Results: Out of 360 patients in MARLINA-T2D™, urine samples for this biomarker study were available for 157 and 161 individuals receiving PBO and linagliptin, respectively. Linagliptin significantly reduced the DN_Score (%) from baseline to Week 24 vs PBO ($p<0.05$). Moreover, adjusted mean changes in the DN_Score (%) were consistently reduced with linagliptin in subgroups of patients with baseline UACR<300, eGFR-C ≥median, HbA1C <8.5%, and age <65 (all $p<0.05$).

Conclusions: Linagliptin significantly improved the DN_Score in T2DM patients and this effect was mainly driven by the early renal damage subgroup. The potential of linagliptin in diabetic kidney disease with concomitant albuminuria warrants further research, including longer-term observation and studies of linagliptin in T2DM patients with more advanced CKD.

Non-Insulin Glycemia-Lowering Strategies and Mortality in Patients on Chronic Hemodialysis-A EURODOPPS Study

Ionut Nistor,[1,2] Ayesha Sajjad,[3] Dimitrie Cristian Siriopol,[2] Adrian Covic,[2] Anneke Kramer,[3] Brian Bieber,[4] Vianda S. Stel,[3] Francesca Tentori,[4] Werner Kleophas,[5] Ziad Massy,[6] Bruce M. Robinson,[4] Kitty J. Jager,[3] Wim Van Biesen.[1] *[1]ERBP, Ghent Univ Hospital, Ghent, Belgium; [2]Gr. T. Popa Univ of Medicine and Pharmacy, Iasi, Romania; [3]ERA-EDTA Registry, AMC, Amsterdam, Netherlands; [4]Arbor Research Collaborative for Health, Ann Arbor; [5]DaVita Renal Center Düsseldorf, Düsseldorf, Germany; [6]Ambroise Paré Univ Hospital and Inserm U1018, Paris, France.*

Background: Patients with type 2 diabetes mellitus on chronic hemodialysis may be at an increased risk for hypoglycemia associated mortality. We hypothesized that in this patient group, this risk may be higher with insulin vs non-insulin glycemia-lowering treatment strategies and that a strategy of maximal oral therapy is better than that of starting/adding insulin.

Methods: Clinical data were obtained from the European Dialysis Outcomes and Practice Patterns Study (EURODOPPS) phases 1-4 (1998-2011) for 5437 diabetic patients (age 40-104 years) on hemodialysis from 7 European countries (Belgium, France, Germany, Italy, Spain, Sweden, and United Kingdom). Patients on non-insulin glycemia-lowering strategies (all classes) were compared with those on insulin containing strategies (all types) for all-cause and cardiovascular mortality. Multivariate Cox regression analysis was conducted in the total sample.

Results: After adjusting forage, gender, dialysis vintage, comorbidities, country, DOPPS phase, body mass index, albumin, glycated hemoglobin (HbA1c), smoking, Kt/V, residual renal function, and diabetes as a cause or as a comorbidity, patients on non-insulin vs insulin containing glycemia-lowering strategies had a reduced risk of all-cause mortality (HR:0.74;95%CI:0.57-0.96) but not of cardiovascular mortality.

Conclusions: Our results suggest a reduced risk of death in patients with diabetes on hemodialysis when on non-insulin vs insulin based glycemia-lowering strategies. However, these findings may be subject to residual confounding and require further investigation.

FR-PO813

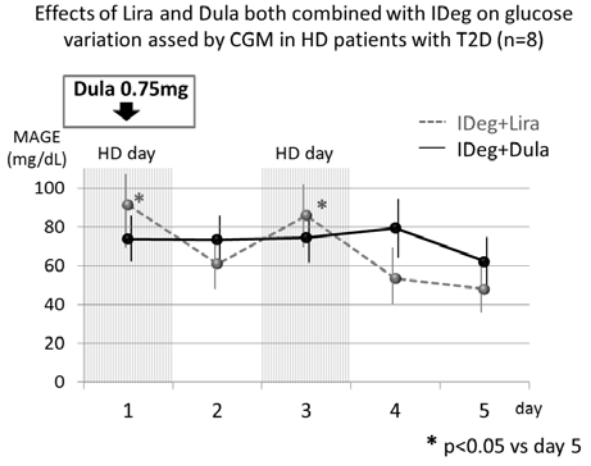
Dulaglutide, a Once-Weekly Glucagon-Like Peptide Receptor-Antagonist, Is Superior to Daily Liraglutide in Reducing Plasma Glucose Fluctuations in Hemodialysis Patients with Type 2 Diabetes Receiving Insulin Degludec: An Assessment by Continuous Glucose Monitoring

Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Takashi Harada,[1] Kenji Sawase,[1] Hiroshi Ichinose,[1] Osamu Sasaki,[1] Chigusa Fukagawa,[1] Rei Moriyama,[1] Kenta Tsukuda,[1] Yoko Obata,[2] Tomoya Nishino.[2] *[1]Nagasaki Kidney Center, Japan; [2]Nagasaki Univ Hospital, Japan.*

Background: Plasma glucose (PG) levels are shown to drop during the course of hemodialysis (HD) but to rebound to a hyperglycemic state following HD. These PG fluctuations place HD patients with type 2 diabetes (T2D) at risk of cardiovascular events. Dulaglutide (Dula) is a novel, long-acting glucagon-like peptide receptor antagonist (GLP-1RA) used in the treatment of T2D patients with or without renal impairment. We previously reported the superiority of liraglutide (Lira) + insulin degludec (IDeg) to basal-bolus insulin therapy in controlling PG fluctuations in HD patients with T2D. In this study we compared by using CGM once-daily Lira and once-weekly Dula, each combined with daily IDeg.

Methods: Eight adult HD patients with T2D who had been treated with once-daily Lira (0.6-0.9 mg) combined with daily IDeg (5-74 units) (Lira + IDeg) were switched to once-weekly Dula 0.75 mg combined with daily IDeg (Dula + IDeg), where Dula was injected on Wednesday or Thursday (day 1 in Figure). All patients were monitored for PG control by CGM for 5 days, and the mean amplitude of glycaemic excursions (MAGE) calculated before and after switching.

Results:



As shown in figure 1, a significant difference was observed in MAGE between on-HD and off-HD days with IDeg + Lira, whereas this difference was cancelled out 2 to 4 weeks after switching to IDeg + Dula. Four out of 8 patients reported mild gastrointestinal adverse events with IDeg + Dula, which, however, were thought to be transient.

Conclusions: Thus, Dula appears to be potentially superior to Lira in reducing PG fluctuations in HD patients with T2D receiving IDeg.

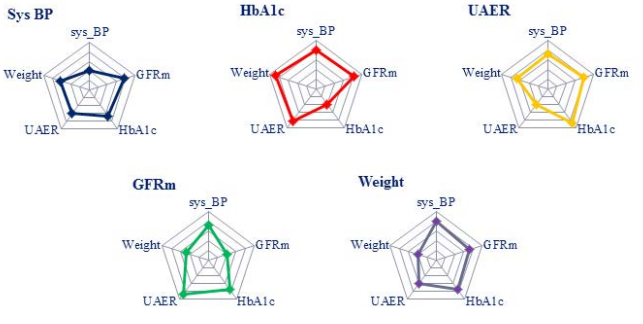
FR-PO814

Pleiotropic Effects of GLP-1 Treatment on Renal Risk Factors in Type 2 Diabetes: Individual Effects of Treatment Emilie Hein Zobel, Bernt Johan Illum von Scholten, Morten Lindhardt, Frederik I. Persson, Tine Hansen, Peter Rossing. *Steno Diabetes Center.*

Background: Management of diabetic nephropathy includes reduction of albuminuria, blood pressure, glucose and weight. The GLP-1 receptor agonist liraglutide may possess these pleiotropic effects. We aimed to elucidate the individual treatment response on multiple renal risk factors and determined if high responders (highest reduction) in each risk factor also had the highest response in other renal risk factors (cross-dependency).

Methods: We treated 31 type 2 diabetics with liraglutide for 7 weeks followed by 3 weeks washout. 23 re-started treatment and were followed for 1 year. We evaluated changes in HbA_{1c}, weight, SBP, UAER and mGFR (^{51}Cr-EDTA). Changes in high (Q4) vs. low responders (Q1-Q3) were compared for each outcome measure. The effects of treatment/off treatment/re-treatment (the off-on/off-on effect) was evaluated to account for random effects.

Results: After 7 weeks HbA_{1c} was reduced by 6 (95%CI: 3;9) mmol/mol, weight 2.5 (1.8;3.2) kg, SBP 4 (-1;9) mmHg and UAER 30 (12;44) %. mGFR was reduced 11 (7;14) ml/min/1.73m^2, previously shown reversible and considered haemodynamic. High responders in mGFR had a reduction in weight compared to low responders (4.3 *vs.* 1.9 kg; p=0.002). High responders in weight and SBP had a tendency of higher reduction in UAER compared to low responders (47 *vs.* 23%, p=0.14). No cross-dependency was observed in the other outcome measures (p≥0.16). The treatment response (the off-on/off-on effect) did not differ after 7 weeks and 1 year of liraglutide treatment (p≥0.12).



Conclusions: Liraglutide possesses pleiotropic effects on renal risk factors. On the patient-level, the effect on the individual risk factor cannot be anticipated based on response in other risk factors. The patients experienced same response when re-starting treatment, indicating that our primary findings are not caused by random effects.

FR-PO815

Renal Effects of Liraglutide in Type 2 Diabetic Patients with Albuminuria: A Randomized Clinical Trial Bernt Johan Illum von Scholten,[1] Frederik I. Persson,[1] Signe Rosenlund,[1] Tine Hansen,[1] Peter Rossing.[1,2,3] *[1]Steno Diabetes Center; [2]Univ of Copenhagen; [3]Aarhus Univ.*

Background: Patients with type 2 diabetes and albuminuria have high cardiorenal morbidity and mortality despite multifactorial treatment. We evaluated the renoprotective effect of glucagon-like peptide-1 (GLP-1) receptor agonist liraglutide on top of multifactorial care, including renin angiotensin system (RAS) inhibition.

Methods: Randomized, double-blind, placebo-controlled, cross-over trial including patients with type 2 diabetes and persistent albuminuria (urinary albumin to creatinine ratio [UACR] > 30 mg/g in at least two of three consecutive morning spot urine samples), estimated glomerular filtration rate (eGFR) ≥30 mL/min/1.73 m^2, and prescribed stable antidiabetic treatment and RAS inhibition > 4 weeks before inclusion. Patients received liraglutide (1.8 mg/day) and matched placebo for 12 weeks in random order. Primary endpoint was change in 24-h urinary albumin excretion rate (UAER) (ClinicalTrials.gov, NCT02545738).

Results: We screened 40 patients, 32 were randomized and 27 completed the study. After placebo treatment, geometric mean (IQR) UAER was 199 (81-531) mg/24-h, mean (SD) measured GFR (^{51}Cr-EDTA) was 75 (36) mL/min per 1.73 m^2, 24-h blood pressure 145/80 (15/8) mmHg and HbA_{1c} 61 (11) mmol/mol. Liraglutide treatment reduced HbA_{1c} by 8 (95% CI: 5; 11) mmol/mol (p<0.001) and weight by 1.8 (95% CI: 0.2; 3.4) kg (p=0.032) when compared to placebo. In addition liraglutide treatment reduced UAER by 32 (95% CI: 7; 50) % (p[thinsp]=[thinsp]0.017) compared with placebo. Seven patients (26%) had a reduction in UAER > 50%. Change in GFR (^{51}Cr-EDTA) was -5 (95% CI: -11; 2) mL/min/1.73 m^2 (p=0.15), and change in 24-h systolic blood pressure was -4 (95% CI: -9; 2) mmHg (p=0.16). Change in UAER was associated with change in 24-h systolic blood pressure (p=0.006) but not with change in HbA_{1c}, weight or GFR (p>0.06), overall model R^2=0.54.

Conclusions: Our placebo-controlled randomized trial suggests that liraglutide treatment has renoprotective effects on top of multifactorial treatment, including RAS inhibition, in patients with type 2 diabetes and albuminuria.

Delayed-Release Metformin Targeting the Lower Small Intestine Elicits Minimal Systemic Exposure in Patients with Severe Renal Impairment: Results of Pharmacokinetic Simulation George L. Bakris,[1] Adekemi Taylor,[2] Brandon Walsh,[3] Colleen Burns,[3] Ralph A. DeFronzo,[4] Mark Fineman.[3] *[1]Univ of Chicago; [2]Certara Strategic Consulting; [3]Elcelyx Therapeutics; [4]Univ of Texas.*

Background: Initiation of metformin is not recommended in patients with chronic kidney disease (CKD) Stage 3B or greater due to lactic acidosis risk secondary to increased systemic metformin exposure. A delayed-release metformin (Met DR) that targets the L-cell in the lower bowel is in development and results in improved potency (e.g., equivalent fasting glucose reduction at daily doses of 600 mg Met DR vs. 1000 mg current metformin), with ~50% less systemic exposure at identical daily doses. Thus, Met DR may provide an alternative to current metformin in subjects with CKD Stage 3B/4. To select appropriate Met DR doses in various CKD stages, we developed a population PK model capable of predicting metformin plasma exposure based on formulation, dose, and CKD stage.

Methods: Metformin exposure predictions from simulations of 3 doses of Met DR (600, 900, 1200 mg) were compared to 1000 and 2000 mg metformin immediate-release (Met IR) in patients with CKD Stage 3A, 3B, or 4. Each simulation consisted of 1000 subjects with varying body weight and eGFR values.

Results: Across CKD Stages 3 and 4, all Met DR doses elicited lower systemic exposure than 2000 mg daily Met IR in Stage 3A patients. In Stage 3B CKD, 1200 mg of Met DR (a dose predicted to elicit similar glycemic effects to 2000 mg Met IR) elicits 40% lower mean exposure than the suboptimal, but recommended, 1000 mg daily Met IR dose.

Conclusions: We conclude that Met DR at doses up to 1200 mg daily may provide a useful alternative for subjects receiving ≤1000 mg Met IR with CKD Stage 3B, or as an option to initiate metformin for patients with CKD Stage 3B/4.

	Plasma Metformin Steady State $AUC_{0\text{-}24}$ (µg•h/mL; mean [CI: 5%-95%])

Metformin Misuse in Chronic Kidney Disease: A Cohort Study Vladimir Coliche, Laetitia Koppe, Louis De Laforcade, Maurice Laville, Solenne Pelletier, Pierre Trolliet, Denis Fouque. *Nephrology, Centre Hospitalier Lyon Sud, Lyon, France.*

Background: Metformin is the most widely prescribed oral antidiabetic treatment, and the only one that showed a survival benefit including in chronic kidney disease (CKD) patients. However, metformin has side effects, particularly in these patients. Yet, there is no consensus on metformin optimal dose and withdrawal necessity in severe CKD stages. The aim of our study is to describe the use of metformin in routine practice in patients with CKD.

Methods: We followed 581 patients with type 2 diabetes in the Departement of Nephrology at the University Hospital between March 2014 and March 2016. Pts were classified into 6 CKD stages: 45 pts (eGFR-CKD EPI > 90 ml/min, stage 1), 72 (stage 2), 117 (stage 3a), 187 (stage 3b), 124 (stage 4), and 36 (stage 5ND). All antidiabetic treatments were gathered. Glycated hemoglobin (HbA1c) was recorded in 376 patients. Comparisons were performed by Student's T test.

Results: Results are shown in Table 1. There was no statistical difference between Met+/- groups for HbA1c. One lactic acidosis episode was recorded over 2 yrs.

CKD Stage	1	2	3a	3b	4	5
Metformin+: patients (%), HbA1c	40(89%), 7.3 ±1.5%	42(58%), 7.6 ±1.5	61(52%), 7.2 ±1.5	39(21%), 7.3 ±1.2	9(7%), 8.4 ±1.8	0
Metformin-: patients (%), HbA1c	5(11%), 7.2 ±0.3	30(42%), 7.6 ±2.0	56(48%), 7.4 ±1.3	148(79%), 7.5 ±1.4	115(93%), 7.4 ±1.8	36(100%), 6.8±1.8
Daily dose (mg)	1907 ±574	1786 ±705	1535 ±602	1423 ±649	1400 ±555	0

Conclusions: Except in stage 5, there was a gradual increase in HbA1c with the severity of CKD, whereas metformin use was limited (50% pts only, stages 2 and 3a) and dosage low (stages 2 and 3a). By contrast, metformin dose was above recommendation in stage 3b, and still prescribed in few patients in stage 4 despite theoretical contraindication. The better diabetes control in stage 5 is probably explained by the concomitant insulin treatment (75% pts). Thus, the use of metformin in CKD seems to be inadequate both in terms of dose adjustment and metabolic control. Dosage should be better adapted to the CKD stage. There is an urgent need for randomized studies of metfomin use on survival in stages 4 and 5 CKD.

FR-PO818

HbA1C, ESRD and Death in Chronic Kidney Disease Sankar D. Navaneethan,[1] Stacey Jolly,[2] Jesse D. Schold,[2] Susana Arrigain,[2] Wolfgang C. Winkelmayer,[1] Joseph V. Nally.[2] *[1]Baylor College of Medicine; [2]Cleveland Clinic.*

Background: Diabetic nephropathy is the leading cause of end stage of renal disease and contributes to mortality in chronic kidney disease (CKD). Ideal HbA1C level in CKD is unclear. We studied the associations of HbA1C with ESRD and death among non-dialysis dependent CKD patients.

Methods: We included 6,165 diabetic patients with eGFR <60 ml/min/1.73 m^2 and/or having CKD diagnosis, and on oral hypoglycemic agents and/or insulin in this analysis. Time dependent Cox proportional hazards models and competing risk analyses were used to study the associations between HbA1C, and all-cause mortality and ESRD while adjusting for demographics, comorbid conditions, use of relevant medications and kidney function measures.

Results: During a median follow-up of 2.4 years, 957 patients died (887 pre-ESRD deaths) and 205 patients reached ESRD. In the Cox proportional hazards model with time dependent repeated measures, after covariate adjustment, lower HbA1C level (<6% vs 6-6.9%) was associated with higher risk of death (HR 1.41, 95% CI 1.16, 1.71).

Outcome	<6%	6-6.9%	7-7.9%	8-8.9%	>9%
Mortality [HR, 95% CI)	**1.41(1.16, 1.71)**	Ref	0.89(0.74,1.06)	0.94(0.76, 1.19)	1.22(0.96, 1.55)
ESRD [SHR, 95% CI)	0.56(0.31, 1.01)	Ref	0.85(0.57,1.27)	0.59(0.35, 1.01)	1.20(0.78, 1.84)

Even though there was a trend, higher levels of HbA1C were not associated with death. When examining HbA1c as a continuous variable, the relationship was non-linear, with very low levels of HbA1c having the highest risk of mortality, and risk being lowest at about HbA1c 7-8%. In the competing risk models, both lower and higher HbA1C levels were not associated with ESRD when compared to HbA1c 6-6.9%. Sensitivity analyses by excluding those with malignancy and type 1 diabetes yielded qualitatively similar results.

Conclusions: Among non-dialysis dependent CKD population, HbA1C <6% was associated with higher risk of death. Associations between HbA1C and ESRD appears to be non-linear with lowest risk at 7-8%. Further studies examining causes of death in those with lower HbA1C are needed.

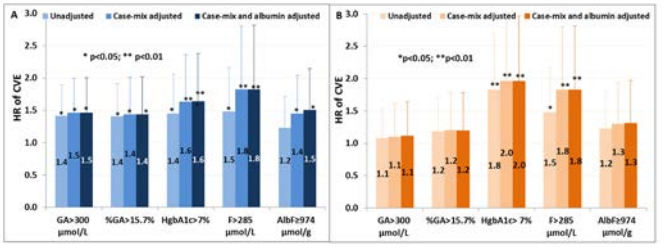
Glycemic Markers and Cardiovascular Events in Hemodialysis Patients from the GIDE Study Mark E. Williams,[1] Neal Mittman,[2] Lin Ma,[3] Julia I. Brennan,[4] Ann Mooney,[3] Chinu M. Jani,[4] Curtis D. Johnson,[4] Eduardo K. Lacson,[5] Norma J. Ofsthun,[3] Franklin W. Maddux.[3] *[1]Joslin Diabetes Center, Boston, MA; [2]Kidney Care of Brooklyn and Queens, Brooklyn, NY; [3]Fresenius Medical Care North America, Watham, MA; [4]Spectra Laboratories, Rockleigh, NJ; [5]Tufts Univ School of Medicine, Boston, MA.*

Background: The GIDE (Glycemic Indices in Dialysis Evaluation) study is evaluating several glycemic indices including HgbA1c, albumin-adjusted and unadjusted fructosamine (AlbF; F), and glycated albumin (GA) or percent GA (%GA) in hemodialysis (HD) cohorts with and without diabetes. Since cardiovascular events (CVE) are associated with diabetes, we examined the associations between each glycemic indices and CVE risks.

Methods: A combined cohort of 2,501 active HD patients (1,478 with diabetes, 1023 without) from 26 FMCNA facilities had baseline indices measured Jan-Mar 2013 and monthly until March 2016. Poor glycemic controls were based on: HgbA1c >7%, F>285µmol/L, AlbF≥974µmol/g, GA>300µmol/L, and %GA>15.7%. CVE included acute myocardial infarction (AMI), cerebrovascular accident (CVA), and peripheral vascular disease (PVD) which were diagnosed from hospital discharges in 3-years follow up. Times to the first CVE were used for the survival analysis. Standard and time-dependent (TD) Cox models with adjustments for case-mix and albumin level at baseline were utilized to determine associations between each glycemic indices and CVE risks.

Results: In 2,501 HD patients, 179 (7.1%) had at least one CVE during the 3-years follow-up periods; 125 (8.5%) in diabetes and 54 (5.3%) in non-diabetes. The hazard ratios of CVE from standard and time-dependent Cox models were shown in Figure 1.

Figure 1. Hazard Ratios (HR) of Cardiovascular Events (CVE) from Standard (A) and Time-dependent (B) Cox Models



Conclusions: While most studies in ESRD evaluated for a relationship between poor glycemic control and mortality, the GIDE study also demonstrates an increased risk for CVE associated with elevated levels of multiple glycemic indices.

FR-PO820

Glycemic Control and All-Cause Hospitalization in an Urban Hemodialysis Population Jeffrey I. Silberzweig,[1,2] Thomas Parker,[1] Daniel Levine.[1] *[1]The Rogosin Inst, New York, NY; [2]Nephrology and Hypertension, Weill Cornell Medicine, New York, NY.*

Background: Data suggests a U-shaped association of mortality with glycemic control in patients with diabetes mellitus treated by hemodialysis (Ricks[1], Ramirez[2], Rhee[3]) but limited published data suggest that poor glycemic control is associated with increased risk of hospital admission (Toida[4]).

Methods: We evaluated time-averaged glycemic control in a population of 346 in-center hemodialysis patients and assessed its relationship with all-cause hospitalization between January 1, 2014 and July 30, 2015. Data were analyzed using t tests and a multifactorial model of the number of hospitalizations per patient.

Results: We observed close fits between time-averaged serum glucose levels and hemoglobin A1c (r^2=0.56). While the risk of hospital admission associated with the diagnosis of diabetes ($p < 0.05$), it did not associate with either measure of glycemic control (p=0.4 for serum glucose, p=0.7 for mean hgbA1c). These relationships were not changed by inclusion of race, gender, age, duration of dialysis or tobacco use. Both serum albumin ($p<0.05$) and ferritin ($p<0.05$) were associated with increased risk of hospital admission.

Conclusions: Glycemic control does not associate with increased risk of hospital admission despite an association with the presence of diabetes. The relationships with markers of inflammation and nutrition suggest that improved glycemic control may associate with poor nutrition, a known risk factor for poor outcomes among patients treated by hemodialysis.

FR-PO821

Associations between Mortality and Glycemic Control with Glycated Albumin and Hemoglobin A1c in Diabetic Patients on Hemodialysis
Junichi Hoshino,[1,2] Masanori Abe,[1,3] Takeshi Hasegawa,[1,4] Takayuki Hamano,[1,5] Atsushi Wada,[1,6] Yoshifumi Ubara,[2] Kenmei Takaichi,[2] Shigeru Nakai,[1,7] Masaaki Inaba,[8] Ikuto Masakane.[1,9] *[1]The Committee of Renal Data Registry, The Japanese Society for Dialysis Therapy, Tokyo, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [3]Nihon Univ School of Medicine, Tokyo, Japan; [4]Showa Univ Fujigaoka Hospital, Kanagawa, Japan; [5]Osaka Univ Graduate School of Medicine, Osaka, Japan; [6]Kitasaito Hospital, Asahikawa, Japan; [7]Fujita Health Univ, Aichi, Japan; [8]Osaka City Univ Graduate School of Medicine, Osaka, Japan; [9]Yabuki Hospital, Yamagata, Japan.*

Background: For glycemic control in diabetic HD patients, it remains unclear what level of glycated albumin (GA) was associated with lower mortality. Here we examined the difference in association between GA and hemoglobin A1c (HbA1c) with 1-year mortality in a cohort of the Japanese Society for Dialysis Therapy.

Methods: We followed 84,282 diabetic patients on maintenance hemodialysis (mean age 67.3±11.2 years; mean dialysis vintage, 6.4±4.5 years) for a year, 2013-2014, using Cox regression to calculate adjusted hazard ratios (HRs) and 95% confidence intervals (95% CI) for 1-year mortality after adjusting for all such potential confounders as age, sex, smoking, diabetes type, etc.

Results: The adjusted HRs of mortality with baseline GA <12.5, 12.5-<15, 15.0-<17.5, 17.5-<20.0, 20.0-<22.5, 22.5-<25.0, 25.0-<27.5, 27.5-<30.0, and ≥30.0% were, respectively, 2.53 (95% CI, 1.10-5.80), 1.06 (0.68-1.66), 1.00 (reference), 1.22 (0.93-1.58), 1.09 (0.84-1.43), 1.40 (1.07-1.85), 1.31 (0.96-1.79), 1.77 (1.26-2.49), and 1.64 (1.20-2.23); and with A1c <4.5, 4.5-<5.0, 5.0-<5.5, 5.5-<6.0, 6.0-<6.5, 6.5-<7.0, 7.0-<7.5, 7.5-<8.0, and ≥8.0%, respectively, 1.57 (1.03-2.37), 1.34 (0.97-1.84), 1.16 (0.87-1.55), 1.11 (0.83-1.47), 1.09 (0.82-1.45), 1.14 (0.84-1.54), 1.00 (reference), 1.30 (0.89-1.88), and 1.55 (1.11-2.18). Lowest mortality**:** 12.5-22.5% for GA, 5.0-7.5% for HbA1c. U-shape association of both GA and HbA1c was consistent regardless of albumin level, although weakened in cardiovascular patients.

Conclusions: Both GA and Hb1c levels showed U-shape associations with 1-year mortality in diabetic HD patients, lower mortality with GA 12.5-22.5% and HbA1c 5.0-7.5%.

FR-PO822

Associations between Glycemic Control and Infections among U.S. Hemodialysis Patients with Diabetes Mellitus
Jinnie J. Rhee,[1] Yuanchao Zheng,[1] Maria E. Montez-Rath,[1] Wolfgang C. Winkelmayer.[2] *[1]Div of Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [2]Section of Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Little is known about any associations between glycemic control and hospitalized or fatal infections in hemodialysis (HD) patients with diabetes mellitus (DM).

Methods: We used data from the US Renal Data System and electronic health records data from a large US dialysis provider merged at the patient level. Socioeconomic status was estimated using area-level US census data. Adult Medicare-insured patients with DM aged ≥18 years who initiated in-center maintenance HD treatment from 2006 to 2011 and survived >90 days were included. The exposure was time-averaged HbA1c and quarterly mean HbA1c values were categorized as follows: <6.5% (reference), 6.5-<7.5%, 7.5-<8.5%, and ≥8.5%. We used Medicare claims to ascertain infection-related hospitalizations and the ESRD Death Notification (CMS-2746) to identify death from infectious cause as study outcomes. We used Cox proportional hazards models to estimate multivariable-adjusted hazard ratios (HR) and 95% CI for the associations between time-averaged HbA1c category and these infectious events, adjusting for baseline demographics, updated comorbidities from claims, and time-averaged vital signs and laboratory results.

Results: Among 16,387 eligible patients, 6585 infection-related hospitalizations occurred and 887 deaths were linked to infection. Compared with patients with HbA1c <6.5%, the HRs for infection-related hospitalization were 0.99 (CI, 0.93, 1.06), 1.03 (CI, 0.95, 1.13), and 1.12 (CI, 1.02, 1.22) for patients with HbA1c 6.5-<7.5%, 7.5-<8.5%, and ≥8.5%, respectively (*P*-trend=0.02). The corresponding HRs for death from infection were 0.88 (CI, 0.70, 1.10), 0.82 (CI, 0.61, 1.09), and 0.74 (0.52, 1.04) for patients with HbA1c 6.5-<7.5%, 7.5-<8.5%, and ≥8.5%, respectively, compared with those with HbA1c <6.5% (*P*-trend=0.08).

Conclusions: In summary, while time-averaged HbA1c was not clearly associated with the risk of infection-related mortality, there was a significant trend toward higher rates of infection-related hospitalizations with increasing HbA1c levels.

FR-PO823

Changes in Health-Related Quality of Life over Time and Effect of Losartan Treatment in Patients with Type 2 Diabetes Mellitus and Nephropathy
Michelle Pena, Dick de Zeeuw, Bauke Schievink, Petra Denig, Hiddo Jan Lambers Heerspink. *Clinical Pharmacy and Pharmacology, Univ Medical Center Groningen, Netherlands.*

Background: Patients with chronic kidney disease have low health-related quality of life (HRQOL), and in general females report lower HRQOL than males. However, there is limited data about longitudinal changes in HRQOL in these patients. Additionally, the effect of angiotensin receptor blockers on HRQOL is unknown. We explored these issues in patients with type 2 diabetes mellitus (T2DM) and nephropathy who participated in the RENAAL trial.

Methods: The RENAAL trial assessed the effect of losartan versus placebo on renal outcomes in 1513 patients with T2DM and nephropathy. Analysis of HRQOL was pre-specified for the 635 U.S. participants (42% of total cohort). HRQOL was assessed with the Short Form-36 survey and is reported as the mental health component summary (MCS) and physical health component summary (PCS). The general population reference values for both MCS and PCS are 50.0 (SD 10.0). HRQOL was measured at baseline and every 3 months until end of follow-up. Mixed-effects models were used to assess changes in MCS and PCS over time and to determine the effect of losartan on MCS and PCS.

Results: Participants (mean age 59.7 (SD 7.8) years; 64.3% males; mean eGFR 42.0 (SD 12.5) mL/min/1.73m^2; median UACR 1060 [Q1–Q3 502–2259] mg/g) were followed for a median of 3.3 [Q1–Q3 2.7-3.8] years. Mean baseline MCS was 51.4 (SD 10.1) and PCS was 38.6 (SD 10.8). In the placebo arm, MCS and PCS decreased by 0.8 (95%CI -1.04, 0.46; p<0.01) and 1.1 (95%CI -1.74, 0.83; p<0.01) per year, respectively. Losartan compared to placebo did not change MCS (-0.96 (95%CI -3.00, 1.09; p=0.36) or PCS -0.80 (95%CI -2.81, 1.22; p=0.44). At baseline, males reported higher MCS and PCS compared to females, but there were no gender differences in changes in MCS and PCS over time.

Conclusions: MCS and PCS decreased over time in patients with T2DM and nephropathy. Furthermore, losartan did not appear to have an effect on MCS and PCS, although it previously showed effect on other clinical parameters in this group of patients. Both men and women reported similar declines in MCS and PCS over time.

FR-PO824

Urinary Metabolomics Predict Albuminuria Response to Spironolactone Therapy in Type 2 Diabetes
Michelle Pena,[1] Skander Mulder,[1] Paul Perco,[2] Christina Stolzenburg Oxlund,[3] Ib A. Jacobsen,[3] Morten Lindhardt,[4] Peter Rossing,[4] Hiddo Jan Lambers Heerspink.[1] *[1]Univ Medical Center Groningen; [2]Emergentec Biodevelopment GmbH; [3]Odense Univ Hospital; [4]Steno Diabetes Center.*

Background: Spironolactone, a mineralocorticoid blocker, significantly reduces albuminuria (UACR) in patients with type 2 diabetes (T2DM) albeit with a large betweeen-individual variability in response. Finding new biomarkers that predict UACR response to spironolactone may tailor optimal therapy. We tested an *a priori* defined set of metabolites to predict UACR response to spironolactone.

Methods: Samples were used from a randomized placebo controlled double blind trial of patients with T2DM and resistant hypertension assigned to spironolactone 25-50mg/day (n=50) or placebo (n=50) for 16 weeks adjunct to RAS inhibition. We used a systems medicine approach to select *a priori* 14 plasma metabolites (oxidative stress, biogenic amines) and 18 urine metabolites (biogenic amines, organic acids) to predict UACR response to spironolactone. Metabolites were chosen by matching a diabetic kidney disease molecular model with a spironolactone mechanism of action molecular model. We performed plasma and urinary metabolomics by LC-MS at baseline. We used linear regression to develop separate baseline plasma and urine metabolite scores and tested if these scores could predict UACR response to spironolactone by analysis of covariance.

Results: Spironolactone reduced UACR relative to placebo by median -42% with large variability (5th–95th percentile -93 – +212). The urine metabolite score was inversely correlated with baseline UACR (Pearson's r -0.37 p<0.01). The plasma metabolite score was not correlated with baseline UACR. The urine metabolite score predicted UACR response to spironolactone (p=0.03 urine score*treatment interaction). The plasma score*treatment interaction was not significant. Analyzed by tertiles of urine metabolite score, placebo-adjusted UACR reduction was significant only in the lowest tertile (-61% (95%CI -86 – -36) p<0.01).

Conclusions: An *a priori* defined set of 18 urinary biogenic amines and organic acids predicts UACR response to spironolactone, suggesting that this urine metabolite score may be a tool to tailor optimal therapy in T2DM.

Angiotensin Converting Enzyme Inhibitors versus Angiotensin Receptor Blockers for Control of Moderately Increased Albuminuria in Hypertensive Type 2 Diabetic Patients
Prabhakar Doddi,[1] N. Sireesha,[2] J. Rani,[2] Vivekanand Jha.[3] *[1]Nephrology, Andhra Medical College, Visakhapatnam, Andhra Pradesh, India; [2]Pharmacology, Andhra Medical College, Visakhapatnam, Andhra Pradesh, India; [3]Nephrology, PGIMER, Chandigarh, India.*

Background: Studies on head to head comparison of angiotensin-converting enzyme inhibitors(ACEi) or angiotensin receptor blockers (ARBs) with reduction of albuminuria as a primary outcome in patients with type 2 diabetes mellitus (DM) and hypertension are limited.

Methods: This was a single centre, prospective, randomized, open label, active controlled study carried out in patients with well controlled type 2 DM with hypertension and urinary albumin excretion rate (UAER) of 20-200µg/min. Exclusion criteria included pregnancy, renal artery stenosis, serum creatinine>1.5 mg/dl , blood pressure more than 180/110 mm Hg, coronary artery disease, congestive heart failure, cerebrovascular accident. Sixty patients were recruited from January 2013 to December 2014 and followed for 52 weeks. Patients were randomized to receive enalapril (n=30, group A) or losartan (n =30, group B) which were titrated to the maximum of 20 mg and 100 mg respectively. Patients with blood pressure of >150/95 mm of hg at the end of 8 weeks, were started on other antihypertensive drugs. Albumin excretion rate was calculated in a 24 hr sample using EIA.

Results: The mean age(years) was 56±11.2 in group A and 54.10.8 in group B . Ratio of male to female was 16:14 in group A and it was 15:15 in group B. The mean SBP(mm of hg) , DBP(mm of hg) and UAER (µg/min)in group A were 167.73±10.58, 99.20±4.16 and 133.33±45.79 respectively and in group B were 159.13±10.49, 100.33±6.33 and 117.80±34.0 respectively. After 52 weeks of follow up there was significant decrease in mean SBP, DBP and UAER in both groups (p<0.0001, <0.0001 and 0.001 respectively for group A and P<0.0001, <0.0001 and <0.0001 respectively for group B).On comparison there was no significant difference between enalapril and losartan on control of hypertension and UAER (p- 0.32 , 0.28 and 0.06 for SBP and DBP and UAER respectively).

Conclusions: In patients with type 2 DM and hypertension, treatment with ACEi or ARBs is equally effective in reducing blood pressure and albuminuria.

FR-PO826

High Salt Intake Is an Independent Predictor for Diabetes Mellitus in Japanese Adults: 5 Year Cohort Study Masanari Kuwabara,[1,2,3] Miguel A. Lanaspa,[1] Thomas Jensen,[1] Ana Andres-Hernando,[1] Carlos Alberto Roncal-Jimenez,[1] Tamara Milagres,[1] Christina Cicerchi,[1] Richard J. Johnson.[1] *[1]Div of Renal Diseases and Hypertension, Univ of Colorado Denver; [2]Toranomon Hospital, Tokyo, Japan; [3]St. Luke's International Hospital, Tokyo, Japan.*

Background: Diabetes mellitus (DM) is a strong risk factor for cardiovascular disease. Type 2 DM develops in the setting of excess caloric intake. This clinical study was conducted to clarify whether high salt intake may be independent of caloric intake as a risk factor for developing DM.

Methods: This was a large-scale retrospective cohort study using Japanese medical check-up data in St. Luke's international hospital, Tokyo, Japan between 2004 and 2009. We analyzed 12,456 subjects without DM between 30 and 85 years old in 2004. We evaluated risk factors for developing DM in 2009 by adjusted logistic analysis and propensity score matching analysis by age, gender, body mass index, smoking habit, hypertension, dyslipidemia, hyperuricemia, chronic kidney disease, total calorie and salt intake. This study divided the two groups as total calories (cutoff level: 2150 kcal/day) and salt intake (cutoff level: 11g/day) and compared with two-by-two groups.

Results: The group with high calorie and high salt intake had a significantly higher risk for developing DM compared with low calories and low salt intake group (p=0.001) and high calories and low salt intake group (p=0.013). After multiple adjustment, salt intake of >11g/day was an independent risk factor for developing DM [odds ratio (OR) per 1 year increased: 1.330, 95% confidence interval (CI): 1.023-1.730], as was aging (p<0.001), higher body mass index (p<0.001), smoking habit (p=0.029), and dyslipidemia (p=0.002). Gender, hypertension, hyperuricemia, chronic kidney disease and high calorie intake (>2150 kcal/day) did not predict development of DM. After adjustments for propensity score, salt intake of > 11g/day was an independent risk factor for developing DM as compared with salt intake of ≤ 11 g/day (OR: 1.35, 95% CI: 1.017-1.795).

Conclusions: Salt intake of > 11 g/day is an independent predictor of DM. Restricting salt intake in addition to other life style modifications may be important in preventing the development of DM.

Renal Effects of Intravitreal Bevacizumab Injection for Diabetic Retinopathy Jiahua Li,[1] Min Zhuo,[1] Christine Joy C. Junia,[1] Ferah Diba Ciftci,[1] Carolyn S. Brecklin.[2] *[1]Internal Medicine, John H. Stroger Jr. Hospital of Cook County, Chicago, IL; [2]Nephrology, John H. Stroger Jr. Hospital of Cook County, Chicago, IL.*

Background: Vascular endothelial growth factor (VEGF) inhibitors, including the humanized monoclonal antibody bevacizumab, are widely used to treat forms of pathologic angiogenesis, such as metastatic carcinomas and proliferative diabetic retinopathy. Patients who receive systemic bevacizumab for malignancy may develop renal insufficiency, hypertension, and proteinuria. However, the renal effects of intravitreal bevacizumab injection among diabetic patients are unclear.

Methods: In this single-center retrospective study, patients who received intravitreal bevacizumab injection for diabetic retinopathy from September 2014 to October 2015 were identified. Patients were selected by the following criteria: received ≥2 standard doses (2.5mg) of intravitreal injection; had a basic metabolic panel, spot urinary protein/creatinine ratio (UPCR), hemoglobin A1c, and blood pressure records before the first injection and after the last injection within a defined period. The comparisons of serum creatinine (SCr), estimated GFR (eGFR), UPCR, blood pressure were performed with the use of paired t-test and multivariate regression.

Results: 75 out of 472 patients were included. On average, patients received 3.1 (95% confidence interval [CI], 2.9 to 3.5) intravitreal bevacizumab injections. The changes of SCr (mg/dl) and eGFR (ml/min/1.73m^2) were insignificant (1.19 to 1.38 and 67.4 to 66.4 respectively). The diastolic blood pressure (DBP) (mmHg) significantly increased from 72.6 to 75.2 (p=0.05) while the systolic blood pressure (SBP) and mean arterial pressure (MAP) did not change significantly. The UPCR (mg/mg) significantly increased from 545 to 720 (p=0.05). The change of proteinuria is positively correlated with the number of injections (R^2=0.214, p=0.019) after adjusting for age, black race, baseline eGFR, change of MAP, change of HbA1c, and use of ACEi/ARBs.

Conclusions: Our study shows that intravitreal bevacizumab injection associated with an increase of proteinuria in a dose-dependent fashion.

FR-PO828

The Renoprotective Role of Paracalcitol on Type 2 Diabetic Chronic Kidney Disease Filipa B. Mendes,[1] Isabel Almeida,[2] Luisa H. Pereira,[1] Ana Paula Silva,[1,2] Ana Marreiros,[3] Pedro Neves.[1,2] *[1]Dept of Nephrology, Algarve Hospital Centre; [2]Dept of Biomedical Science, Algarve Univ; [3]Algarve Univ.*

Background: Chronic kidney disease (CKD) is a public health problem and Diabetes is the number one causing it, worldwide. Albuminuria is an important sign of CKD progression, cardiovascular disease and death. Therefore, many drugs have been tested in order to reduce the albuminuria. One of those drugs have been the vitamin D analogues. In this study we analyzed the role of paricalcitol in the reduction of the urinary albumin-to-creatinine ratio (UACR) in patients with type 2 diabetes and CKD. We also verified the impact of baseline vitamin D in that ratio.

Methods: In an observational retrospective study, 42 patients with CKD secondary to type 2 diabetes were treated with paricalcitol, 1 µ daily during at least 3 months. We analysed patients data and laboratorial parameters at baseline (T0) and 12 weeks after treatment with paricalcitol (T1). We also divided our population in 2 groups accordingly the vitamin D level (G 1 – vitamin D <10 ng/mL and G 2 - vitamin D ≥ 10 ng/mL). We used descriptive statistics, *Wilcoxon* test, Sign test, *Student's t* test and the geometric average growth rate.

Results: After paracalcitol treatment (T1) we found a reduction of UACR (p=0.001) and PTH (p=0.001), whereas the vitamin D level increased (p < 0,0001). G1 showed higher levels of UACR (p=0,002) at baseline. After 12 weeks (T1) of paricalcitol treatment, according to the geometric average growth rate, it was found a reduction of in the UACR (1.78 %) and in the PTH (3,85%). On the other hand, Vitamin D and eGFR showed an increase of 3,38% and 0,10%, respectively.

Conclusions: In our study paricalcitol showed renoprotective effects in type 2 diabetes, promoting a reduction in the urinary albumin-to-creatinine ratio. Moreover, there is an inversely proportional association between vitamin D and UACR at baseline.

FR-PO829

PBI-4050 Reduces Cardiovascular and Renal Biomarkers in Type II Diabetic Patients with Metabolic Syndrome Pierre Laurin, Brigitte Grouix, Alexandre Laverdure, Boulos Zacharie, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050 is an orally active drug candidate with anti-fibrotic efficacy in multiple preclinical models of fibrosis in kidney, liver, lung, heart and pancreas. PBI-4050 has been shown to protect against pancreatic fibrosis in db/db and db/db eNOS-/- mice by reducing macrophage and lymphocyte infiltration, ER stress and increasing autophagy.

Methods: A phase II, open label, single center, single arm study in twenty type 2 diabetes patients with metabolic syndrome was undertaken. The objectives were to evaluate the efficacy safety and tolerability of PBI-4050 following oral administration of 800 mg doses once daily for 12 weeks; and to demonstrate pharmacological activity and translation of efficacy from preclinical studies to humans by monitoring early evidence of changes in cardiorenal disorders biomarkers.

Results: PBI-4050 was demonstrated to be safe and well tolerated without SAEs. PBI-4050 treatment reduced HbA1c (average ΔHbA1c of -0.80, p=0.003 with HbA1c baseline of >7.5%, average ΔHbA1c of -1%, p=0.003 with HbA1c baseline of >7.5%,) in twenty patients. In same patients IL-18 was reduced in the urine (p<0.05). Pentraxine-3 and resistin were reduced in blood (p<0.01).

Conclusions: PBI-4050 was safe and well tolerated in type II diabetic patients with metabolic syndrome. PBI-4050 was efficacious in reducing HbA1c, waist circumference, BMI and weigh, and reduced cardio renal biomarkers Il-18, Pentaxine-3 and resistin. These results demonstrated that PBI-4050 may be an efficacious therapy for chronic kidney disease patients with type II diabetes.

FR-PO830

Structured Exercise in Obese Diabetic Patients with Chronic Kidney Disease: A Randomized Controlled Trial David J. Leehey,[1,2] Eileen Collins,[1] Holly J. Kramer,[1,2] Cheryl Cooper,[1] Jolene Butler,[1] Conor Mcburney,[1] Christine Jelinek,[1] Domenic Reda,[1] Lonnie Edwards,[1] Anne Garabedian,[1] Susan Oconnell.[1] *[1]Medicine and Research, Hines VA Hospital, Hines, IL; [2]Medicine, Loyola Univ Medical Center, Maywood, IL.*

Background: Patients with type 2 diabetes mellitus (DM), obesity, and chronic kidney disease (CKD) are generally physically inactive and may benefit from exercise. Our objective was to determine the effects of structured exercise on physical fitness, kidney function, endothelial function, inflammation, and body composition in such patients.

Methods: In this randomized, controlled trial, 36 male patients (age 49-81) were randomly assigned to exercise + diet management (n=18) or diet alone (n=18). Participants were eligible if they had type 2 DM, body mass index (BMI) > 30 kg/m^2, CKD stage 2-4, and persistent proteinuria (> 200 mg/g creatinine for > 3 months). The exercise intervention was a 12-week (3 days per week) program of aerobic and resistance training followed by 40 weeks of home exercise. The primary outcome measure was change from baseline in urine protein to creatinine ratio (UPCR) at 12 weeks and 52 weeks.

Results: 32 participants completed the study (14 exercise + diet, 18 diet alone group). Change from baseline in UPCR was slightly greater in the diet alone group at 12 weeks but not at 52 weeks. Changes in both symptom-limited and constant-workrate treadmill times were significantly higher in the exercise + diet group at 12 weeks but not at 52

weeks. There were no significant differences in urine albumin to creatinine ratio (UACR), estimated glomerular filtration rate (eGFR), endothelial function, inflammation, or body composition between the groups.

Conclusions: In obese diabetic subjects with CKD, structured exercise improved exercise capacity but not body composition or renal function.

Renal Sympathetic Activity Assessed by 123I-MIBG Scintigraphy Is Associated with Clinical Measures of Cardiac Autonomic Function

Tine Hansen,[1] Bernt Johan Illum von Scholten,[1] Christian Stevns Hansen,[1] Philip Hasbak,[2] Andreas Kjaer,[2] Peter Rossing.[1,3] *[1]Steno Diabetes Center, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Univ of Copenhagen, Denmark.*

Background: Scintigraphy with ^{123}I-metaiodobenzylguanidine (MIBG) can assess functional sympathetic innervation in organs. The relation between renal ^{123}I-MIBG uptake and measures of cardiac autonomic function has never been investigated.

Methods: In 25 patients with type 2 diabetes and 14 non-diabetic controls we performed three cardiac autonomic reflex tests (CARTs) and five time- and frequency domain heart rate variability (HRV) indices. We quantified functional renal sympathetic innervation by planar scintigraphy performed 15 min (early) and 4 hours (late) after administration of ^{123}I-MIBG. Regions of interest (ROI) were drawn over left kidney (avoiding the pelvis) and the upper mediastinum (avoiding the thyroid gland) in the planar posterior view, andlate kidney/mediastinum-ratio was calculated from mean counts per pixel within each ROI.

Results: Late kidney/mediastinum ratio correlated positively with all time- and frequency domain HRV indices ($p \leq 0.02$). For the CARTs, the late kidney/mediastinum ratio correlated positively with the deep breathing test (a measure of parasympathetic function) ($p=0.04$), but not with response to standing or the Valsalva test ($p \geq 0.70$). All significant associations persisted after adjustment for age and heart rate ($p \leq 0.02$). After further adjustment for sex, HbA1c and urinary albumin excretion rate one of the HRV indices, low frequency power, reflecting a combination of sympathetic and parasympathetic tone remained significantly correlated to late kidney/mediastinum ratio ($p=0.02$). Late kidney/mediastinum ratio did not correlate with urinary albumin excretion rate, eGFR or systolic blood pressure ($p \geq 0.19$).

Conclusions: We demonstrate a relationship between renal ^{123}I-MIBG uptake and cardiac autonomic function. This indicates that ^{123}I-MIBG scintigraphy of renal sympathetic tissue could be a valid measure of autonomic function in the kidneys and warrants further research in larger study populations.

FR-PO832

Comparative Effectiveness of a Multifactorial Patient-Centered Intervention in Type 2 Diabetes (T2D)

Clarissa Jonas Diamantidis,[1] Hayden Bosworth,[1] Uptal D. Patel,[1,2] Megan M. Oakes,[1] Shelby D. Reed.[1] *[1]Duke Univ School of Medicine; [2]Gilead Sciences, Inc.*

Background: The STOP-DKD study is an ongoing clinical trial evaluating the impact of a multifactorial pharmacist telehealth intervention on renal complications of T2D. We sought to explore expected costs, improvements in quality-adjusted survival and cost-effectiveness of implementing such an intervention on a population level in T2D when varying program costs and age eligibility.

Methods: The Archimedes Model is a mathematical simulation model which represents physiological processes using data incorporated from the National Health and Nutrition Survey (NHANES) to generate population-level estimates. We used Archimedes modeling to simulate and compare costs and outcomes over a 20-year (yr) period amongst individuals with T2D receiving usual care and a multifactorial intervention consisting of statin therapy, smoking cessation, blood pressure reduction (systolic blood pressure 139 mmHg if > 140), weight reduction (5% if BMI >30 and <35; 10% if BMI ≥35) and HbA1c reduction (target 8% if >8%), each modeled at 50% effectiveness. We varied annual program costs from $200 to $800 per individual and assessed four age-based subgroups (45-64, <65, 65-74 and ≥65 yrs).

Results: Among individuals ages 20 to 80 yrs, 9.4% are diagnosed with T2D (mean age 60.2yr). Simulated, undiscounted quality-adjusted life-years (QALYs) with usual care and QALY gains expected with the multifactorial intervention were estimated at 3.93+ 0.02 at 5yr, 7.26+ 0.06 at 10yr and 12.09+ 0.22 at 20yr. At 20yr, all programs ranging from $200 to $800 per yr per individual demonstrated good value: $200/yr, cost-saving; $400/yr, $7025 per QALY; $600/yr, $18,461 per QALY; and $800/yr, $33,784 per QALY. The program was more economically-attractive when targeting older individuals with incremental cost-effectiveness ratios of $23,299 per QALY in ages 65-74 and $23,362 per QALY in ages ≥65.

Conclusions: Dissemination of a population-based, moderately-effective, low-cost, patient-centered intervention in T2D could increase quality-adjusted life expectancy more efficiently than standard medical therapies used to treat complications of T2D, particularly among older individuals.

Funding: NIDDK Support

FR-PO833

Referral to a Multi-Disciplinary Diabetic Renal Clinic Is Associated with Improved Renal Functional Course in Type 2 but Not Type 1 Diabetics with Chronic Kidney Disease

William P. Martin,[1] Tomas P. Griffin,[1] David W. Lappin,[2] Damian Gerard Griffin,[2] Timothy O'Brien,[1,2] Matthew D. Griffin.[1,2] *[1]Regenerative Medicine Inst (REMEDI), National Univ of Ireland, Galway, Ireland; [2]Endocrinology and Nephrology Services, Saolta Univ Health Care Group, Galway, Ireland.*

Background: Diabetic patients with chronic kidney disease (CKD) may benefit from combined Diabetology and Nephrology care. The study aim was to examine the impact of a multi-disciplinary Diabetic Renal Clinic (DRC) on slope of MDRD eGFR and metabolic indices of type 1 (T1D) and type 2 (T2D) diabetics with CKD.

Methods: Patients attending a DRC at a tertiary referral center from 2008 to 2012 were identified. Serial renal and metabolic indices were recorded from 2004 to 2014, and compared pre- and post-first DRC attendance using SPSS v22.

Results: 200 subjects were identified (44 (22.0%) T1Ds and 156 (78.0%) T2Ds). Median [IQR] number of eGFR measurements was 31 [18, 56] per subject over 8.70 [6.34, 10.31] years. Age, n (%) female, eGFR, and urinary albumin:creatinine ratio of the two subgroups at the time of first DRC attendance were: 44.71 ± 15.71 vs. 68.94 ± 10.53 years ($p < 0.001$); 19 (43.2%) vs. 46 (29.5%) ($p = 0.126$); 57.98 ± 29.92 vs. 46.10 ± 20.57 mL/min/SA/year ($p = 0.018$); and 33.30 [4.00, 147.50] vs. 13.20 [3.20, 91.10] mg/mmol ($p = 0.321$). An additional etiology for CKD was found in 2 (4.5%) T1D and 34 (21.8%) T2D subjects. Results for eGFR decline are shown in the Table.

	T1D (n = 44)				T2D (n = 156)			
	Pre-DRC Attendance	Post-DRC Attendance	n (%)	p	Pre-DRC Attendance	Post-DRC Attendance	n (%)	p
Rate of eGFR decline (mean ± SD; mL/min/SA/yr)	-2.06 ± 4.37	-2.77 ± 3.33	28 (63.6%)	0.476	-3.22 ± 4.52	-2.21 ± 3.14	105 (67.3%)	0.049
Mean $HbA1_c$ (mean ± SD; mmol/mol)	79.22 ± 19.82	71.81 ± 17.73	42 (95.4%)	0.001	62.23 ± 14.37	60.73 ± 13.13	143 (91.7%)	0.171
Mean total cholesterol (mean ± SD; mg/dL)	197.22 ± 50.27	180.59 ± 41.38	40 (90.9%)	0.012	157.77 ± 35.19	152.36 ± 36.74	127 (81.4%)	0.065

Conclusions: Referral to a combined care DRC resulted in slower eGFR decline in T2D but not T1D subjects with CKD.

Funding: Government Support - Non-U.S.

FR-PO834

Impact of the Medical Care by Diabetologists, Non-Diabetlogists and Home Doctors before Nephrology Referral on Renal Prognosis in Patients with Diabetic Nephropathy

Yukimasa Iwata, Rei Iio, Terumasa Hayashi, Hiroki Okushima. *Nephrology, Osaka General Medical Center, Osaka, Japan.*

Background: Although it has been recognized that early referral to nephrologists is crucial for the protection of kidney function, it is hard to say that in the current clinical practice in Japan, nephrology referral (NR) is early enough for nephrologists to offer specialized care to patients with diabetic nephropathy (DN). Thus, we conducted single center retrospective study to compare the impact of the medical care by diabetologists, non-diabetologists and home doctors before NR on clinical status at NR and renal outcome.

Methods: We enrolled 469 patients with DN referred to our nephrology division from October 2010 to September 2014. Clinical status at NR were compared among the three groups and the impact of the medical care by the different specialties before NR on renal outcome (initiation of renal replacement therapy; RRT) was analyzed by multivariate Cox proportional hazards model.

Results: Mean age and eGFR at NR were 67.1±12.3 years and 31.2±19.6 ml/min/1.73m^2, respectively and 70.5% were male. The number of patients referred from diabetologists (Group A), non-diabetologists (Group B) and home doctors (Group C) were 140, 184, and 145, respectively. A total of 105 patients started RRT: 33, 45 and 27 in Group A, B and C, respectively ($P = 0.416$). The cumulative incidence of renal outcome was not significantly different between the groups ($P = 0.392$). The median duration from NR to the renal outcome was 16.7 months (IQR : 6-25.3). Multivariate Cox proportional hazards model showed that eGFR (HR 0.90; 95%CI 0.86-0.94), proteinuria (HR 1.03; 95%CI 1.01-1.05), and systolic blood pressure (HR 1.01; 95%CI 1.00-1.03) were independently associated with renal outcome; however, pre-nephrology care by non-nephrologists including diabetologists did not have any impact on renal outcome.

Conclusions: In the current clinical practice in Japan, NR may be too late to offer specialized care by nephrologists to protect kidney function in patients with DN.

FR-PO835

Patients' Perspectives of Diabetes Management in the Haemodialysis Unit Katey Atkins, Adam Kirk. *Wessex Kidney Centre, Queen Alexandra Hospital, Portsmouth, United Kingdom.*

Background: Patients with diabetes and established renal failure on haemodialysis pose unique challenges for the nephrologist. Individualised care is recommended with the aim to improve outcomes without added hypoglycaemic risk. Patient understanding will underpin this process. We performed a survey to establish the current practices and opinions of our haemodialysis patients managing diabetes.

Methods: A questionnaire was distributed to all patients with diabetes that are on regular maintenance haemodialysis.

Results: 110 returned questionnaires, 101 in-centre HDF and 9 from the Home HD programme. Of these 20% report having Type 1 diabetes, 73% Type 2 diabetes and 7% were unclear. 97/110 (88%) have had diabetes for over 5 years. 93/110 (84%) of all respondents considered themselves to be either very or quite confident in managing their diabetes. Surprisingly 52/110 (47%) were unaware of the HbA1c test. 85/110 (77%) were on insulin therapy. One person reported having no home monitor. In the 84 remaining 6% did not check their blood sugars, a further 5% did not check on a daily basis. 6/110 respondents had either no access to a home monitor or did not have blood sugar levels checked at dialysis. The remaining 104 provided opinions on glucose control and corrective actions. For some answers more than one response was given, this was reflected in the totals. 29/104 (28%) considered only a reading of ≤ 3 to be low, 8 (8%) did not know what a low reading was. On having a low reading 7/108 (6%) did nothing or did not know what to do, only 2 commented on adjusting medication and 1 on re-checking. 17/104 (16%) did not consider a reading to be high until it was ≥20, 9/104 (9%) did not know what a high reading was. Following a high level 22/110 (20%) of all answers stated they either did nothing or did not know what to do. Of those on insulin 49/85 (58%) adjust insulin dose in their actions. 10/110 (9%) managed hyperglycaemia with water or exercise.

Conclusions: There is significant variation in practices and opinions within the cohort of patients that responded. Despite the high level of perceived confidence many issues with understanding and safety has been highlighted. To address this we propose targeted education programme.

FR-PO836

Timing of Renal Replacement Therapy in Acute Kidney Injury: A Systematic Review and Meta-Analysis Rhea Bhargava,[1] Saiprasad Narsingam,[1] Himmat Grewal,[3] Mohamed A. Omer,[1] Reem Mustafa.[2] *[1]Internal Medicine, Univ of Missouri - Kansas City School of Medicine, Kansas City, MO; [2]Nephrology, Univ of Missouri - Kansas City School of Medicine, Kansas City, MO; [3]Internal Medicine, Saint Vincent Hospital, Worcester, MA.*

Background: Acute Kidney Injury (AKI) is common in critically ill patients and has been associated with increased mortality. The timing of initiation of renal replacement therapy (RRT) has been controversial in patients with AKI.

Methods: We searched the Cochrane Central Register, OVID MEDLINE, EMBASE and PubMed until May 15th 2016. We reviewed the reference lists of relevant reviews, registered trials, as well as relevant conference proceedings. We included all randomized controlled trials that evaluated the effect of timing of initiation of renal replacement therapy in adult patients with AKI. We followed the GRADE approach to assess confidence in the estimates of effect (i.e. the quality of evidence). We conducted meta-analyses using random effects models on review Manager Version 5.3.

Results: Nine randomized control trials were included consisting of a total of xxx pts. Compared to "Late RRT", "early RRT" had a non-significant decrease in mortality with a Risk Ratio (RR) of 0.92 (95% confidence interval (CI) 0.82-1.04, p=0.18, I^2=51%). However, "early RRT" significantly decreased the number of patients who were dialysis dependent with a RR of 0.55 (95% CI 0.32-0.95,I^2=0%). Intensive care unit length of stay (LOS) decreased with a mean difference (MD) of 1.41 days (95% CI 0.24-2.59 ,I^2=0%) and hospital LOS also decreased with a MD of 5.15 days (95% CI 3.0-7.3 ,I^2=87%) in the early versus late RRT group. There was no difference in the adverse events between the two groups.

Conclusions: In critically ill patients with AKI, early initiation of RRT may decrease dependence on long-term dialysis. It may also shorten the ICU and hospital LOS. Additional studies are needed to determine the true effect on mortality although it appears to be decreased.

FR-PO837

Implementation of a Decision Making Algorithm for Acute Kidney Injury Requiring Renal Replacement Therapy Mallika L. Mendu, David M. Charytan, Joseph V. Bonventre, Sushrut S. Waikar. *Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Acute kidney injury (AKI) is a common and devastating complication in hospitalized patients. AKI requiring renal replacement therapy (RRT) is associated with in-hospital mortality rates exceeding 40%. Clinical decision tools related to RRT initiation for AKI patients in the ICU have yet to be elucidated.

Methods: We conducted a 1-year prospective cohort study in a medical ICU of an academic medical center involving the implementation of an AKI Standardized Clinical Assessment and Management Program (SCAMP), a decision making algorithm. The SCAMP algorithm provided recommendations about optimal indications for initiating and discontinuing RRT based on various clinical parameters. We collected information on clinicians' adherence or non-adherence to the SCAMP recommendations as well as clinical outcomes.

Results: Patients whose providers adhered to the SCAMP recommendation to start RRT had lower in-hospital mortality (42% vs. 63%, p<0.01) than those whose providers did not. The difference in mortality persisted after multivariable logistic regression analysis adjusting for age, albumin and severity of disease. In pre-specified subgroup analyses, adherence was associated with lower risk of death only in patients with severity of disease scores below the median (adjusted odds ratio 0.21, 95% CI 0.08 – 0.54).

-	Univariable OR (95%)	p-value	Multivariable OR (95% CI)	p-value
Adhered to recommendation to start RRT	0.42(0.22, 0.81)	0.01	0.43 (0.21, 0.85[a]	0.02
By Risk Group				
High risk[c]	1.09(0.40, 2.95)	0.86	1.06 (0.38, 2.95)[b]	0.91
Low risk[d]	0.22(0.09, 0.55)	<0.01	0.21 (0.08, 0.54)[b]	<0.01
Age at enrollment	1.02 (1.00,1.04)	0.12	1.02 (1.00, 1.04)	0.1
Albumin at enrollment	0.49 (0.29,0.82)	<0.01	0.49 (0.27, 0.89)	0.02

a. Main effects for risk group and adherence b. Incorporates interaction term between risk group and adherence, p-value= 0.02 c. High ATN risk- >50% predicted mortality risk d. Low ATN risk- <50% predicted mortality risk.

Conclusions: Algorithms like the AKI SCAMP may assist in complex clinical decision making and potentially improve outcomes.

FR-PO838

Analysis of Mortality Predictors in Acute Kidney Injury Requiring Continuous Renal Replacement Therapy after Cardiac Surgery Young Lee Jung,[1] Jae Young Kang,[2] Soo Youn Lee,[3] Dong Jin Kim.[4] *[1]Dept of Internal Medicine, ; [2]Div of Nephrology, ; [3]Div of Cardiology, ; [4]Dept of Cardiothoracic Surgery, Sejong Hospital, Korea.*

Background: Since the postoperative AKI contributes to high mortality,several risk factors have been reported to be associated with AKI after cardiac surgery.Despite the advances of CRRT and surgery techniques using cardiopulmonary bypass as the management of AKI,the mortality of postoperative AKI requiring CRRT increased.The purpose of this study was to determine the predictors of mortality in AKI requiring CRRT after cardiac surgery,and to contribute to reducing mortality through correction of the determined risk factors.

Methods: The retrospective analysis included a total of 3623 patients underwent cardiac surgery;CRRT was required in 125patients between March 2011 and March 2016. Variables predicting mortality were selected from those proven as available risk factors of postoperative AKI in the previous studies.The variables were analyzed in two groups:non-survivor group who died within 30days,and survivor group.We used a logistic regression model to assess the relationship between predictors and mortality,while adjusting for other risk factors.

Results: The mortality rate was 44.1% for 125 patients with postoperative AKI requiring CRRT.Univariate analysis identified the following as significant risk factors:Extracardiac vascular disease,eGFR,EuroSCORE,IABP before surgery,Combined operation,Operation time,Time of bypass,Aortic cross clamp time,CRP level at CRRT,the use of ECMO(P<0.05). In multivariate analysis,mortality was significantly correlated with extracardiac vascular disease,eGFR,combined operation,CRP level at CRRT,the use of ECMO(P<0.05).

Conclusions: These findings demonstrated that the statistically strong predictors of the mortality following cardiac surgery were proved to be the presence of extracardiac vascular disease,preoperative renal dysfunction,concomitant surgery,the use of ECMO,and high CRP level at CRRT initiation.The identification of predictors associated with mortality would help to better manage such patients with AKI requiring CRRT after cardiac surgery. Also,preventive strategy using these predictors remains the mainstay to reduce the mortality.

FR-PO839

Predictors of AKI and Renal Outcome in Adult Patients on Extra Corporeal Membrane Oxygenation (ECMO) Venkata Buddharaju, Maureen E. Brogan, Rudrick V. Ledesma, Savneek S. Chugh. *Nephrology, New York Medical College, Valhalla, NY.*

Background: ECMO is increasingly being used in critical care units for patients with cardiogenic shock or respiratory failure. In spite of advances, mortality associated with it is very high. Acute Kidney injury (AKI) requiring renal replacement therapy (RRT) is very common and is associated with increased mortality. There is paucity of data about the predictors of AKI needing RRT and of poor outcome among these patients. Previous studies have been mostly in pediatric population and data is lacking in adults.

Methods: We performed a chart based retrospective study analyzing all the adult patients admitted to our hospital receiving ECMO.

Results: Charts on 40 patients reviewed which showed high in-hospital mortality (45% or 18/40) and the incidence of AKI was 50% (20/40). The Etiology of AKI was documented to be from Acute Tubular Necrosis (ATN). Out of 20 patients with AKI, 18 patients required RRT with 16 patients requiring CVVHD (Continuous Veno-venous hemodialysis) and 2 required Hemodialysis (HD) as the initial modality of renal support. Out of 18 patients who died, 10 patients had AKI requiring RRT. The data also showed that 16 patients had new onset proteinuria on dipstick and was associated with the development of AKI. We found an interesting relationship between the flow on ECMO and development of AKI. Low flow less than 2-2.5L and high flow more than 4-4.5L are associated with more AKI. This relationship has to be studied using statistical analysis at the conclusion of the data

collection. Out of 20 patients who developed AKI, 10 patients died, another 4 went on to End Stage requiring HD at the time of discharge and the remaining 6 patients left with significant renal injury and progressed to chronic kidney disease.

Conclusions: What is clear from our study so far is that patients, who require ECMO, regardless of the indication, have a higher mortality and AKI requiring RRT. The flow parameters are also very interesting as very low (less than 2.5L/min) and higher flows (more than 4-4.5L) are associated with kidney injury which supports the hypothesis that AKI in these patients are mainly due to ischemic ATN.

FR-PO840

Intraoperative Hemodialysis during Liver Transplantation Cary H. Paine,[1] Terra Pearson,[2] James D. Perkins,[2] Raghu V. Durvasula.[1] *[1]Dept of Medicine, Div of Nephrology, Univ of Washington, Seattle, WA; [2]Dept of Surgery, Div of Transplant Surgery, Univ of Washington, Seattle, WA.*

Background: With the introduction of the Model for End-Stage Liver Disease (MELD) in 2002 the percentage of liver transplant recipients (LTRs) with acute kidney injury (AKI) has increased. Intraoperative hemodialysis (IHD) during liver transplantation has been shown to be safe, but it is unknown whether this procedure improves perioperative outcomes.

Methods: We conducted a retrospective analysis of all LTRs at the University of Washington between 2003 and 2014. We compared all LTRs that received IHD with LTRs that had preoperative AKI but did not undergo IHD. AKI was defined as serum creatinine ≥1.5mg/dL. Outcomes included postoperative serum potassium, arterial base deficit, alanine aminotransferase (ALT) (a marker of early graft function), ventilator days, ICU length of stay (LOS), and hospital LOS.

Results: Among 1,191 LTRs, 146 received IHD (12.3%) compared to 164 patients who had AKI but did not receive IHD (13.8%). IHD patients had higher MELD scores (mean 34.6 vs. 24.9) and were more likely to require mechanical ventilation and vasoactive medications preoperatively. ALT and arterial base deficit were lower in the IHD group, and there was no difference in serum potassium, ventilator days, or ICU LOS. Hospital LOS was longer in the IHD group (Table 1).

Table 1: Postoperative Outcomes

	IHD [n=146]	non-IHD [n=164]	P
Mean (SD) Potassium (mEq/L)	4.5 ± 0.7	4.6 ± 0.8	0.11
Mean (SD) Arterial Base Deficit (mEq/L)	6.98 ± 4.2	9.9 ± 3.8	<0.0001
Mean (SD) ALT (units/L)	799 ± 1044	1061 ± 1012	0.02
Mean (SD) Ventilator days	1.86 ± 3.67	1.78 ± 5.37	0.9
Mean (SD) ICU LOS (days)	4.35 ± 5.2	3.28 ± 6.2	0.17
Mean (SD) Hospital LOS (days)	37 ± 33.6	19 ± 16	<0.0001

Conclusions: Our data indicate that, despite an overall higher level of acuity among LTRs who received IHD, there was no difference in postoperative electrolyte concentrations, ventilator days or ICU LOS when compared to LTRs with AKI who did not receive IHD. However, LTRs who received IHD had lower ALT levels, which may suggest better early graft function. Clinical trials are needed to further determine the efficacy of IHD in LTRs to improve perioperative and long-term outcomes.

FR-PO841

Use of Novel Phosphate-Containing Replacement Solution for Treating Hypophosphatemia in Continuous Renal Replacement Therapy (CRRT): Predictions from a Mass Balance Model Farah N. Ali,[1,2] Mary Gellens,[1] Baris U. Agar,[1] J. Ken Leypoldt.[1] *[1]Baxter Healthcare; [2]Northwestern Univ.*

Background: Hypophosphatemia is a common consequence of CRRT that often requires treatment with intravenous infusion of phosphate-containing solutions. Conventional replacement solutions (RS) do not contain any phosphate, but phosphate-containing replacement solutions (RS+P) now exist; however, there is limited data on optimal use of such solutions. Our objective was to predict the changes in serum phosphate concentration for hypophosphatemic patients when using RS+P in various CRRT prescriptions.

Methods: A mass balance model was used to predict increases in serum phosphate concentration for patients treated with CRRT when using varying ratios of conventional dialysate/replacement fluid with zero phosphate concentration and RS+P (1 mmol/L or 3.097 mg/dL phosphate). CRRT assumptions included: solution rates of 20-40 mL/min, starting serum phosphate concentrations of 1.5, 2.0, or 2.5 mg/dL, and CVVHDF modality.

Results: Use of RS+P alone or as both replacement fluid and dialysate increased serum phosphate concentrations in all 3 starting concentration groups; increases in serum phosphate concentrations ranged from 1.24 to 2.95 mg/dL. For starting phosphate values of 1.5 mg/dL, any studied combination of fluids normalized the serum phosphate (normal range 2.5-4.5 mg/dL). For starting phosphate values of 2.5 mg/dL, only use of RS+P as both replacement and dialysate resulted in values of serum phosphate higher than 5.0 mg/dL. Use of RS+P post-filter resulted in modestly higher values than pre-filter infusion.

Conclusions: Normalization of serum phosphate using RS+P in CRRT may be achieved through a variety of prescription techniques. High phosphate levels only occurred with higher baseline serum phosphate values when RS+P was used as both replacement and dialysate. Varying the proportion of RS+P as replacement fluid and dialysate during CVVHDF may allow individualization of therapy to normalize serum phosphate, while maintaining CRRT dose.

FR-PO842

A Comparison of Two Different Dialysate Phosphate Supplementation Approaches for Continuous Renal Replacement Therapy Michael Heung,[1] Alex Ryan Shaw,[2] Weerachai Chaijamorn,[2] Bruce A. Mueller.[2] *[1]Internal Medicine-Nephrology, Univ of Michigan, Ann Arbor, MI; [2]College of Pharmacy, Univ of Michigan, Ann Arbor, MI.*

Background: Hypophosphatemia is a common and clinically significant complication of continuous renal replacement therapy (CRRT). To decrease risk of hypophosphatemia, we routinely supplement CRRT solutions with phosphate (1.5mmol/L). Recently, a commercially-available phosphate-containing (P-C) CRRT solution (1.0mmol/L) has become available in the US.

Methods: We performed a time-limited substitution trial of P-C CRRT solution and compared biochemical parameters to our baseline standard approach of phosphate-added (P-A) solutions. CRRT was otherwise prescribed at discretion of treating team. Outcomes were daily serum phosphate and bicarbonate concentrations, incidence of hypophosphatemia and acidosis, and need for phosphate supplementation.

Results: We analyzed data from 127 patient CRRT-days using P-C solutions and compared to baseline experience with 256 CRRT-days using P-A solutions (Table). Mean daily phosphorus levels were in the normal range for both groups, but lower in the P-C compared to P-A groups; there was no difference in incidence of hypophosphatemia. The P-C group did receive more exogenous phosphate administration but at a low overall rate. No CRRT solution-related complications occurred during either period of the pilot.

Variables	Phosphate Containing Dialysate (4 K/1 Phos/22 HCO_3)	Phosphate Added Dialysate (4 K/1.5 Phos/25 HCO_3)	P-Value
Minimum daily phosphorus, mean (SD)	3.41 (0.87)	3.78 (0.98)	<0.05
Maximum daily phosphorus, mean (SD)	4.27 (1.34)	4.61 (1.11)	<0.05
Phosphorus <2.7mg/dL (% of days)	14.29	13.67	0.87
Phosphate supplementation (% of days)	5.51	1.56	<0.05
Daily serum bicarbonate, mean (SD)	28.56 (6.32)	29.60 (6.06)	0.16
Serum bicarbonate <22mEq/L (% of days)	12.60	8.59	0.22
Daily pH, mean (SD)	7.39 (0.06)	7.36 (0.06)	<0.05

Conclusions: Overall, hypophosphatemia was uncommon when using phosphate-enriched CRRT solutions, and occurred at a similar rate between the P-A and P-C groups. Commercially available P-C dialysate has the potential advantage of eliminating the risks associated with compounding errors, such as contamination or incorrect additives. Additional analyses examining clinical outcomes and cost effectiveness are needed.

FR-PO843

Cost Savings and Quality Improvement in an Independent Pediatric CRRT Program Katherine Twombley. *Pediatrics, Medical Univ of South Carolina.*

Background: CRRT is a complex method of providing dialysis to critically ill patients. Lack of education and hands on training specific to pediatric patients can lead to inadequate therapy. The goal of this project was to implement a pediatric specific CRRT education program for nurses and ICU physicians.

Methods: Pediatric specific education, protocols, clinical algorithms, and policies were developed. Direct care nurses completed an 8 hour learning session that included hands on practice using high fidelity simulation. Additionally, a core pediatric CRRT resource team comprised of nurses with advanced training in CRRT was formed to provide additional support for therapy initiation, sophisticated pump management, and additional staff needs. We also developed a pediatric ICU physician class that focused on the importance of starting CRRT before a patient is fluid overloaded to decrease treatment time. Pre and post education tests were given to asses comprehension. After one year, we compared filter life and dose of CRRT received.

Results: Pre education CRRT knowledge for RN and MD/DOs was 73% and post was 93%. Our average Filter life before training was 8.9 hours. Our average filter life post is 55.81 hrs. Pre-education we did 7272 hours of CRRT=17.8days/pt=427hrs/pt. At 8.9hrs/filter=817 filters X $210/filter=$171,586 .Assume 4 bags of fluid/day @$28.21/bag=$34,190.52 **Total=$239,967.04** Post-education we did 2352 hour of CRRT=7days/pt=168hrs/pt. At 55.81hrs/filter=42 filters X $210/filter=$8850 Assume 4 bags of fluid/day @$28.21/bag=$11,058.32 **Total=$19,908.32 Total Savings since new education initiative=$220,028.72** on filters and fluids alone. Pre education, the unintended time off therapy was 9 hrs, and the patients received only 81% of prescribed dose. Post education, the unintended time off therapy was 0.9hrs, the patients received 98% of the prescribed dose.

Conclusions: An independent pediatric CRRT education program and resource team were instrumental in creating a baseline for all caregivers. Pediatric CRRT algorithms established a standard of care for all patients. In addition, interactive education and ongoing support improved delivery of therapy and reduced time off therapy overall. This resulted in a huge cost savings in just one year.

FR-PO844

Effect of Continuous Renal Replacement Therapy on Carnitine Levels and Acyl to Free Carnitine Ratio in Children Kl Sgambat, Asha Moudgil. *Children's National, Washington DC.*

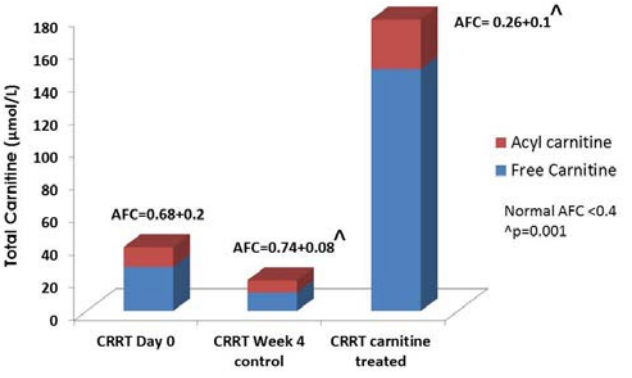
Background: Carnitine is essential for energy production in myocardium and removal of toxic acylcarnitines. We recently showed carnitine is rapidly depleted by continuous renal replacement therapy(CRRT), however effect of CRRT on acylcarnitine and response to therapy have not been investigated. We report effect of CRRT and carnitine therapy on carnitine homeostasis in critically ill children with acute kidney injury(AKI).

Methods: We conducted a retrospective study of children(0-26 years) who underwent CRRT at Children's National between 2011-2015. Patients with serial total(TC) and free carnitine(FC) levels were included and acyl to free carnitine ratio(AFC) calculated. TC, FC, and AFC of patients who received intravenous carnitine during CRRT were compared with unsupplemented controls by Student's t-test, prevalence of abnormal TC, FC, and AFC(≥0.4) by Chi-squared.

Results: The study group comprised of 49 children(9.2± 0.9 years); 6 received carnitine supplementation, 43 controls did not. At initiation of CRRT, 41.1% were TC and FC deficient, and 64.7% had elevated AFC. Prevalence of abnormal TC, FC, and AFC increased to 100% by week 4 of CRRT in controls. In comparison, 100% of those treated with carnitine while on CRRT became TC and FC replete, and only 16.6% had abnormal AFC(p=0.003). TC and FC of treated patients(179+108 and 148.5+93.1 µmol/L) were higher vs. controls(27.1+2.3 and 18.7+1.8 µmol/L), p=0.0001. Mean AFC at CRRT initiation was elevated (0.68±0.16), and increased to 0.74±0.08 within 4 weeks in controls; FC negatively correlated with AFC(r= -0.4,p=0.003). In those treated with carnitine, AFC normalized to 0.26+0.06 at 4 weeks of CRRT(p=0.001),see Figure.

Conclusions: CRRT is associated with disturbed carnitine homeostasis, resulting in TC and FC deficiency with concurrent elevation of AFC. This is the first study to show TC, FC, and AFC normalize in children on CRRT who receive carnitine supplementation.

Figure. Mean total and free carnitine levels decrease while Acyl:free carnitine ratio (AFC) increases with time on CRRT in controls. Mean AFC is normal in those receiving carnitine supplementation on CRRT.



FR-PO845

High Cut-Off Dialysis Is Efficient with HCO Membrane Markus Storr, Ulrike Haug, Adriana Boschetti-de-Fierro, Bernd Krause. *Research & Development, Gambro Dialysatoren GmbH, Hechingen, Germany.*

Background: High cut-off (HCO) membranes are indicated for enhanced removal of 20-50kDa toxins [Gondouin, Adv Chronic Kidney Dis 2011]. Applications include myeloma kidney treatment, sepsis and rhabdomyolysis. Though a classification for HCO membranes is available [Boschetti-de-Fierro, Int J Artif Organs 2013], some high-flux dialyzers are used for high cut-off dialysis. We compare the performance of two dialyzers offered for high cut-off treatment of myeloma kidney, and which, according to the mentioned classification, are categorized as high cut-off dialyzer (Theralite) and as high-flux dialyzer (APS-21EH).

Methods: High cut-off treatments were simulated with Q_B=250ml/min, Q_D=500ml/min and Q_{UF}=10ml/min for Theralite (HCO, Gambro) and APS-21EH (APS, Asahi). In each experiment (HCO n=7, APS n=2), 1L of human plasma (octaplasLG, protein conc. 60g/L) was recirculated for 60min followed by 60min treatment. Markers were spiked into the plasma at 55min of recirculation: β2-m (5 mg), myoglobin (500 µg), λ-FLC (150 mg), interleukin 6 was comprised in plasma. Samples were taken from plasma pool and dialysate at various times. Clearances were calculated from first order kinetics of pool concentration (measured by nephelometry) over time.

Results:

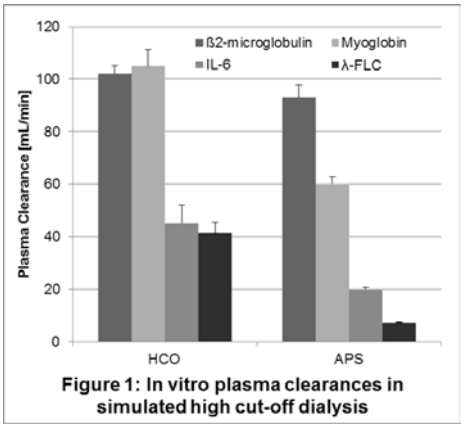


Figure 1: In vitro plasma clearances in simulated high cut-off dialysis

The HCO membrane showed higher clearances than the APS high-flux membrane for the middle molecules investigated. High differences were found for myoglobin (105 vs. 60ml/min), relevant when treating rhabdomyolysis, and for λ-FLC (41 vs. 7ml/min), which is relevant in the myeloma treatment.

Conclusions: Based on the plasma clearances observed, an efficient high cut-off dialysis treatment with the expected removal of middle molecules is only possible with dialyzers comprising a membrane categorized as high cut-off (HCO) membrane. Results indicate that a high-flux membrane does not offer the efficient removal required in acute cases.

Funding: Pharmaceutical Company Support - All authors are employees of the Gambro Dialysatoren GmbH, Hechingen (Germany). Gambro AB (including all direct and indirect subsidiaries) is now part of Baxter International Inc. Baxter is a manufacturer of dialysis devices. None of the authors has proprietary interest. All experimental information is given in great detail to exclude any bias on the results

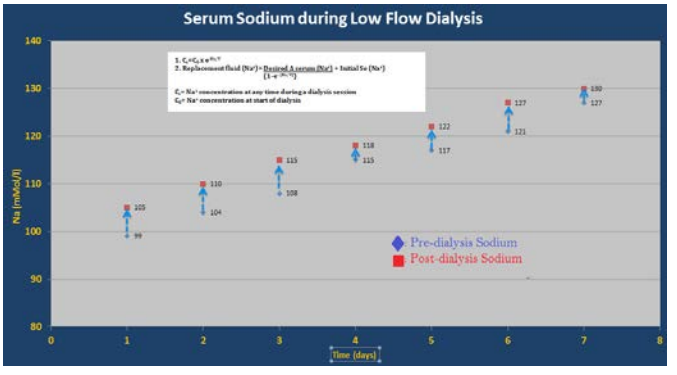
FR-PO846

Use of Logarithmic Constant of Exponential Decay to Control Sodium Conductivity and Kinetics in a Patient with End Stage Renal Disease and Severe Hyponatremia Hormaz Dara Dastoor,[1] Chandra Mauli Jha,[2] Ken J. Donaldson,[3] Thalakunte Muniraju,[3] Samra Abouchacra,[1] Hatem Mohyeldin Ebeid.[4] *[1]Div of Nephrology, Rahba Hospital- Johns Hopkins International, United Arab Emirates; [2]Div of Nephrology, Burjeel Hospital, United Arab Emirates; [3]Div of Nephrology, Dumfries and Galloway Royal Infirmary, United Kingdom; [4]Div of Nephrology, Al Noor Hospital, United Arab Emirates; [5]Div of Nephrology, Tawam Hospital, United Arab Emirates.*

Background: We present a case of a patient with severe renal failure and Hyponatremia who was treated by Renal Replacement Therapy. Sodium (Na^+) Kinetics and Conductivity were regulated using a complex algorithm created using a logarithmic constant "*e*" as measure of Exponential Decay of Na^+ transfer, resulting in a controlled and predictive rise in Plasma Sodium (PNa^+).

Methods: A 25-year-old male presented with renal failure and PNa^+ 99 mmol/l, urea 58 mmol/l, Creatinine 1551 umol/l with altered mental status and seizures.The patient was initially placed on CVVHD followed by conventional HD. Over the next few days his PNa^+ had a gradual and steady rise and had a complete recovery without any neurological sequelae .

Results: Using the below formulas we can predict expected post dialysis Serum Na concentration and determine Na concentration of Replacement fluid required to achieve desired post dialysis Na concentration.



Conclusions: Understanding the principles of Sodium Transfer, Conductivity and Kinetics in renal failure, allows for use of complex Logarithmic equations using Mathematical constant of Logarithmic Decay "e" as measure of exponential transfer of Sodium and Urea.By controlling the transfer of Sodium during a Hemodialysis session we can control the rate of rise in Plasma Na^+ for patients with severe Hyponatremia and renal failure. This can result in a steady rise in PNa^+ concentrations and avoid potentially fatal ODS.

FR-PO847

OPTIMAL Selection for and Timing to Start Renal Replacement in Critically Ill Older Patients with Acute Kidney Injury (OPTIMAL-AKI): A Prospective Observational Cohort Study

Ron Wald,[1] Josee Bouchard,[2] Jean-Francois Cailhier,[2] James William Barton,[3] Sean M. Bagshaw.[4] *[1]St. Michael's Hospital, Canada; [2]Univ de Montreal, Canada; [3]Univ of Saskatchewan, Canada; [4]Univ of Alberta, Canada.*

Background: Older patients represent approximately half of those who receive renal replacement therapy (RRT) in intensive care unit (ICU) settings. We have limited information on the optimal circumstances for starting or withholding RRT in older patients with AKI.

Methods: Prospective observational cohort study performed at 16 centers from across Canada, September 2013 and July 2015. Inclusion criteria: 1) >= 65 y, 2) admitted to ICU, and 3) KDIGO Stage 2-3 AKI. Exclusions: 1) received urgent RRT for drug overdose and 2) receiving any RRT in preceding 4 weeks. Primary exposure was receipt of RRT. Primary outcome was 90-day mortality. Secondary outcomes included reasons for not receiving RRT and changes to goals-of-care (GOC).

Results: 499 patients were enrolled. Mean age was 75 (SD 7.2) y, 204 (41%) were female, and mean Charlson comorbidity score was 3.0 (SD 2.3). Median Clinical Frailty Score (CFS) was 4.0 (IQR 3.0-5.0), 95 (20%) had cognitive impairment and 192 (39%) and has been hospitalized in the preceding 6 months. Mean APACHE II score was 28.0 (SD 8.8). Of the cohort, 361 (72%) of patients would have been offered RRT if indicated while 229 (46%) actually received RRT. Leading indications for RRT included oligo-anuria (74%), fluid overload (35%) and acidemia (33%). Reasons for not starting RRT included: kidney recovery (67%), not aligned with goals-of-care (25%) and active limitation-of-medical-therapy (11%). Factors independently associated with not receiving RRT included: age, CFS, peak serum creatinine at admission, vasoactive support and APACHE II score. 90-day mortality was 45% (n=113) for those receiving RRT and 56% (n=141) for those not receiving RRT (OR 0.91; 95% CI, 0.64-1.31). In total, 201 patients (42%) had a change in GOC; change in GOC was not associated with the receipt of RRT.

Conclusions: The majority of older adults in the ICU with AKI would be offered RRT and approximately half received RRT. Clinical need, as well as underlying frailty and severity of illness, influence decision-making regarding RRT.

Funding: Government Support - Non-U.S.

FR-PO848

Temporal Trends of Dialysis Requiring Acute Kidney Injury after Orthotopic Cardiac and Liver Transplant Hospitalizations

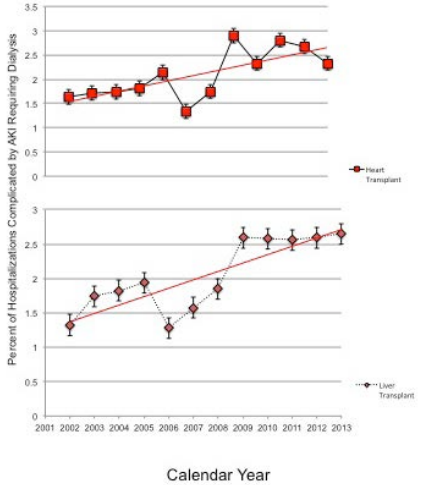
Girish N. Nadkarni,[1] Kinsuk Chauhan,[1] Ioannis Konstantinidis,[1] Pranav S. Garimella,[2] Madhav C. Menon,[1] Charuhas V. Thakar.[3] *[1]Icahn School of Medicine at Mount Sinai; [2]Tufts Univ School of Medicine; [3]Univ of Cincinnati, and Renal Section, Cincinnati VA Medical Center.*

Background: We sought to assess the national epidemiology of acute kidney injury requiring dialysis (AKI-D) in stable orthotopic cardiac and liver transplant.

Methods: We used the Nationwide Inpatient Sample to evaluate the yearly trends (2002 to 2013) of AKI requiring dialysis (AKI-D) in cardiac and liver transplant. We excluded the postoperative period. We defined AKI by ICD9 code 584.xx and dialysis procedure by presence of procedure code of 39.95 or diagnosis code of v45.11, v56.0 or v56.1. We used survey logistic regression to assess AKI-D impact on hospital mortality and adverse discharge and calculated adjusted odds ratios (aOR).

Results: We identified 130,143 hospitalizations with cardiac transplant of which 2776 (2.13%) had AKI-D and 266,987 hospitalizations with liver transplant of which 5689 (2.14%) had AKI-D. There was 45% increase in AKI-D in cardiac transplant, from 1.63% in 2002 to 2.33% hospitalizations in 2013; p<0.01 and a two-fold increase in AKI-D in liver transplant admissions, from 1.32% in 2002 to 2.65% hospitalizations in 2013; p<0.01.

Figure 1. Temporal Trends of Orthotopic Heart and Liver Transplant Hospitalizations Complicated by Acute Kidney Injury Requiring Dialysis



This increase was attenuated after adjustment for temporal changes in demographics, comorbidities and procedures. AKI-D in cardiac transplant recipients was associated with three-fold mortality (aOR 2.85; 95% CI 2.11-3.80) and two-fold adverse discharge (aOR 1.97; 95% CI 1.53-2.55). Similarly, AKI-D in liver transplant recipients was associated with two fold mortality (aOR 1.95; 95% CI 1.53-2.55) and adverse discharge (aOR 1.91; 95% CO 1.57-2.30).

Conclusions: This study highlights the growing burden of AKI-D in non-renal solid organ transplant recipients and its impact, and emphasizes the need to develop strategies to reduce the risk of AKI.

FR-PO849

Timing of Renal Replacement Therapy and Risk of Death: A Pooled Observational Analysis of 5 Randomized Trials

Min Jun,[1,6] Ying Wang,[1,6] Paul M. Palevsky,[3,6] Alan Cass,[4,6] Robert Faulhaber-Walter,[5,6] John A. Kellum,[3,6] Martin P. Gallagher.[1,6] *[1]George Inst, Australia; [2]Austin Health, Australia; [3]U of Pittsburgh; [4]Menzies S. of Health Research; [5]Hannover Medical School; [6]On Behalf of the IMPROVE-AKI Investigators.*

Background: There is uncertainty regarding the effect of timing of RRT initiation on patient outcomes in AKI. We sought to assess the relationship, in acute kidney injury (AKI) patients, between the timing of initiation of renal replacement therapy (RRT) and death at 28 days.

Methods: We collected data on timing of RRT initiation from 5 randomized trials (originally assessing dialysis intensity) defined as the time from intensive care unit (ICU) admission to RRT initiation (or trial randomization as a proxy to RRT initiation). We used Cox regression, stratified by study, using baseline demographic, disease-severity, and laboratory information. Follow up for death started at RRT initiation (or proxy).

Results: 3150 patients were included. The median time between ICU admission and RRT initiation (or proxy) was 2 days. Patients were grouped into 4 categories of increasing time from ICU admission to RRT initiation (quartiles: ≤0.62 [reference], 0.63-2, 2.1-4.25, ≥4.26 days). The effect of the timing of RRT initiation was not constant over time (i.e. proportional hazards violation) and thus the association between timing of RRT initiation and death was assessed across 2 time-bands (0-7 and 8-28 days). Patients in the first time-band (who did not survive to be included in the second) had higher APACHE2 scores, which indicated greater disease severity (31.9 vs 27.2). The timing of RRT initiation was not associated with the risk of death at 7 days during the first week of follow-up (HR[95% CI] for groups 0.63-2, 2.1-4.25, ≥4.26 days: 0.93[0.74-1.16], 1.01[0.78-1.30], and 0.94[0.72-1.24], respectively. For those who survived to 8 days, delayed RRT initiation was associated with an increased 28-day death risk (1.19;[0.90-1.57], 1.41;[1.04-1.90], 1.55;[1.15-2.09], respectively).

Conclusions: In our pooled analysis, the effect of RRT initiation timing varied with the duration of follow up. Delayed RRT initiation was associated with an increased risk of death among patients who survived more than 7 days.

FR-PO850

TORCH: How a Small Charity Can Effect Significant Improvement in Kidney Care in Haiti

Robert S. Brown,[1] Philip C. Cleophat,[2] Brian D. Remillard.[3] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Hôpital Univ de Mirebalais, Mirebalais, Haiti; [3]Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Background: Though the ISN 0 by 25 initiative to avoid preventable deaths from AKI by 2025 is desirable, kidney disease care in Haiti was almost non-existent. Renal replacement therapy (RRT) was available to only a few patients in Port-au-Prince. In a World Kidney Forum (AJKD Mar 2016), Haiti was not even mentioned with the 20 Latin American countries providing some RRT.

Methods: In 2014, The Organization for Renal Care in Haiti, TORCH, Inc, a 501(c)(3) tax exempt Massachusetts charity, was formed with the mission to 'provide education, medical equipment, training and other resources to medical professionals and facilities in Haiti so that they can provide treatments to individuals with kidney disease who would otherwise not receive such treatments'. We realized that TORCH could not obtain enough monetary support to accomplish such a task by itself.

Results: TORCH served as a focus to obtain help from multiple partners. TORCH brought medical residents and nurses from the Partners in Health/Zanmi Lasante hospital in Mirebalais (HUM) to Hanover and Boston for training to perform hemodialysis (HD). Then, using equipment and supplies donated by NxStage, Bridge of Life and Sustainable Kidney Care Foundation, HUM initiated HD treatments for patients with AKI. To date, 26 patients have undergone a total of 70 HD treatments with 12 complete recoveries, 2 improved, 2 ongoing treatments, 1 CKD and 9 deaths. TORCH has sent 2 advanced practice nurses from the USA to Port-au-Prince to teach peritoneal dialysis techniques to 30 professionals. With Bridge of Life, we plan a prevention program to diagnose Haitians with undetected hypertension, diabetes and proteinuria. TORCH will provide expenses to train Haitian professionals in the USA in basic nephrology care and later in kidney transplantation.

Conclusions: With dedicated volunteers, a group of charitable partners, and only limited funds, a small charity can effect large improvements in kidney care in Haiti. The success of this effort to save lives may engender future support from government and other deep pockets.

FR-PO851

A Single-Center Retrospective Study of the Effect of Residual Renal Function plus Continuous Renal Replacement Therapy (CRRT) Dose on the Prognosis of Patients with Acute Kidney Injury (AKI) Xiang-Mei Chen. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing.*

Background: Pre-CRRT residual renal function differs among patients with AKI, and "uninjured healthy nephrons" still work. "Exogenous" replacement function provided by CRRT and residual renal function were considered total renal function, whose levels may affect the prognosis and renal function recovery of AKI patients.

Methods: We conducted a retrospective analysis of patients treated at our hospital between January 2010 and December 2014. A total of 215 AKI patients who received CRRT met the inclusion and exclusion criteria and were included in this study. Pre-CRRT residual renal function, CRRT dose, and pre-CRRT residual renal function plus CRRT dose were calculated. Moreover, the patients were divided into "high" groups and "low" groups based on the mean values of pre-CRRT residual renal function plus CRRT dose, and inpatient mortality and the 90-day renal recovery rate were compared between the two groups.

Results: Residual renal function and CRRT dose were calculated for 215 patients, and the patients were divided into a high group (55.72 ± 6.53 mL/h/kg, n = 104) and a low group (30.89 ± 7.69 mL/h/kg, n = 111) on the basis of their total renal function (pre-CRRT residual renal function plus CRRT dose). whereas inpatient mortality was significantly higher in the low group than in the high group (53.15% vs 39.39%, P = 0.021). Moreover, the 90-day renal recovery rate was higher in the high group than in the low group (67.21% vs 50.00%, P = 0.044). A multivariate regression analysis that controlled for confounding factors showed that renal function was an independent factor for inpatient mortality (HR 0.802; 95% CI 0.570-0.983; P = 0.013) and renal recovery rate (OR 0.817; 95% CI 0.556-0.984; P = 0.017).

Conclusions: Exogenous "renal function" with CRRT provided on the basis of pre-CRRT residual renal function may have improved the survival and renal recovery of AKI patients and was more effective in the high group than in the low group.

FR-PO852

Early Continuous Renal Replacement Therapy in Septic Acute Kidney Injury Could Be Defined by Its Initiation within 24 Hours of Vasopressor Infusion Seung Don Baek,[1] Eun Kyoung Lee,[2] Jai Won Chang.[1] *[1]Dept of Internal Medicine, Asan Medical Center, Seoul, Korea; [2]Dept of Internal Medicine, Dankook Univ College of Medicine, Cheonan-si, Korea.*

Background: Although institution of early continuous renal replacement therapy (CRRT) reduces morbidity and improves outcomes in patients with septic acute kidney injury (AKI) by removing inflammatory cytokines, the optimal timing for the initiation of early CRRT is uncertain and requires a practically feasible definition with acceptable evidence.

Methods: We investigated the clinical impacts of three time interval parameters on the morbidity and mortality of 177 patients with septic AKI: (1) time from vasopressor initiation to CRRT initiation ($T_{vaso\text{-}CRRT}$), (2) time from ICU admission to CRRT initation ($T_{ICU\text{-}CRRT}$), and (3) time from endotracheal intubation to CRRT initiation ($T_{endo\text{-}CRRT}$).

Results: The proportion of the patients with $T_{vaso\text{-}CRRT}$ less than 24 hours (median 14 hours, interquartile range [IQR] 5–30 hours) was significantly higher in the survival group than in the non-survival group (84.3% vs. 58.5%, $p < 0.001$). $T_{vaso\text{-}CRRT}$ less than 24 hours and SOFA score were independent factors associated with 28-day mortality (hazard ratio [HR], 0.449; 95% confidence interval [CI], 0.211–0.956; $p = 0.038$; and HR, 1.587; 95% CI 1.339–1.880; $p < 0.001$, respectively) and 90-day mortality (HR, 0.369; 95% CI, 0.165–0.825; $p = 0.015$; and HR, 1.566; 95% CI, 1.320–1.858; $p < 0.001$, respectively). $T_{ICU\text{-}CRRT}$ (median 17 hours, IQR 5–72 hours) and $T_{endo\text{-}CRRT}$ (median 13 hours, IQR 4–48 hours) were significantly correlated with both the length of ICU stay ($p < 0.001$) and mechanical ventilation duration ($p < 0.001$).

Conclusions: Considering the possible therapeutic measurement by physician on the basis of the results in this study, early CRRT could be defined by a $T_{vaso\text{-}CRRT}$ less than 24 hours. The $T_{ICU\text{-}CRRT}$ and $T_{endo\text{-}CRRT}$ are associated with morbidity and not mortality.

FR-PO853

Early Mortality on Continuous Renal Replacement Therapy (CRRT): The Prairie CRRT Study Bhanu Prasad. *Nephrology, Regina Qu Appelle Health Region, Regina, SK, Canada.*

Background: Patients with acute kidney injury (AKI) requiring renal replacement therapy (RRT) have an increased short-term and long-term risk of mortality. In most north american intensive care units (ICU), these patients receive continuous renal replacement therapy (CRRT). Some patients once initiated on CRRT may not survive more than 24 hours. For these patients the rationale for the use of this invasive and cost intensive therapy and its appropriateness has been debated. We were interested in identification of risk factors for early mortality.

Methods: We conducted a prospective cohort study of patients undergoing CRRT for AKI in three ICUs of the Regina Qu'Appelle Health Region (RQHR) from April 2013 to September 2014. We collected data on demographic, laboratory and clinical measures and followed patients from admission to 9 months post discharge. The primary outcome was: <24 hour mortality after CRRT initiation. Other secondary outcomes included mortality, and renal outcomes post discharge for 90 days. A stepwise multiple variable logistic regression model was created using death within 24 hours of starting CRRT as the dependent variable, with significant variables derived from univariate analysis as covariates.

Results: 269/2634 patients admitted to the ICUs in the study period had stage III AKI. 106/269 were started on CRRT. 66/106 died in ICU whilst on CRRT. 17/66 (26%) died within 24 hours of initiating therapy. Patients who died within 24 hours had a higher FiO2 (0.8 ± 0.2 vs. 0.6 ±0.2, p= 0.011); higher epinephrine (32.0 ± 29.9 vs. 6.5 ± 9.3, p= 0.005); higher norepinephrine levels (39.4 ± 23.5 vs. 19.6 ± 14.2, p=0. 005); lower pH (7.1 ± 0.2 vs. 7.3 ± 0.1, p= 0.005) when compared to those who survived the first 24 hours of admission.

Conclusions: 26% of the patients died within the first 24 hours of starting CRRT. In stepwise multivariate logistic regression analysis, patients appear to be at high risk of early mortality if they have a high FiO2 (>0.7) and high norepinephrine > 20 ug. However, we were unfortunately unable to identify any specific clinical and biochemical indicators that suggested early mortality with a high degree of statistical confidence.

FR-PO854

Pre-Emptive CRRT Is Associated with Improved Outcome of Dialysis-Requiring Severe Acute Kidney Injury: Multicenter Prospective Study Tetsushi Yamashita,[1] Eisei Noiri,[1] Daisuke Sanada,[2] Takayuki Tsuji,[3] Hideo Yasuda,[3] Masaomi Nangaku,[1] Kent Doi.[1] *[1]The Univ of Tokyo, Tokyo, Japan; [2]Showa Univ, Tokyo, Japan; [3]Hamamatsu Univ School of Medicine, Hamamatsu, Japan.*

Background: It is controversial when to start RRT for AKI patients without life-threatening complications and pre-emptive RRT is frequently considered especially in ICUs. This study was conducted to reveal the characteristics of patients with pre-emptive CRRT compared with classic CRRT.

Methods: This study enrolled 146 patients who needed CRRT as the initial method of RRT in the adult mixed ICUs of 3 university hospitals. CRRT initiation was determined by the attending physicians based on each patient condition. We considered the following factors as conventional indications for RRT according to the previous study (CJASN 2014;9:1577): hyperkalemia, severe acidosis, severe azotemia, oliguria, and fluid overload with pulmonary edema. CRRT without conventional indications was defined as pre-emptive CRRT and CRRT with one or more conventional indications was defined as classic CRRT.

Results: Fifty-nine patients (40%) fulfilled at least one conventional indication before initiation of CRRT (classic CRRT). Patients with pre-emptive CRRT had similar baseline conditions evaluated by eGFR, SOFA score on ICU admission, SOFA score at CRRT initiation. However, they had lower serum creatinine (p<0.001) and plasma NGAL (p=0.03) at CRRT initiation, less in-hospital mortality (p=0.04), and more often renal recovery (p=0.006) which was defined as being alive and independent from dialysis on discharge with a less than 50% decrease in eGFR than patients with classic CRRT.

	Pre-emptive	Classic	*p* value
Age	69	72	0.27
Baseline eGFR	74.5	66.8	0.17
Cre	2.47	3.53	<0.01
Plasma NGAL	449	609	0.03
SOFA score on ICU admission	8	8	0.97
SOFA score at CRRT initiation	10	10	0.71
ICU mortality	29%	32%	0.71
In-hospital mortality	37%	54%	0.04
Renal recovery	54%	31%	<0.01

Conclusions: This observational study suggests pre-emptive CRRT could provide better outcomes of in-hospital mortality and renal recovery. Measures to distinguish the patients for whom RRT is beneficial is necessary to improve the performance of CRRT on AKI treatment.

FR-PO855

Initiation Time of Renal Replacement Therapy on Patients with Acute Kidney Injury: A Systematic Review and Meta-Analysis of 7746 Participants Caixia Wang,[1] Linsheng Lv,[2] Xun Liu,[1] Shaomin Li,[1] Yanni Wang,[1] Tan-Qi Lou.[1] *[1]Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sun Univ, Gaungzhou, China; [2]Operation Room, The Third Affiliated Hospital of Sun Yat-sun Univ, Guangzhou, China.*

Background: Early initiation of renal replacement therapy (RRT) is recommended to improve clinical outcomes in patients with acute renal failure (ARF) in some studies, but its effects on mortality and renal recovery are unknown.

Methods: Randomized controlled trials (RCTs) and cohort comparative studies comparing early RRT with late RRT in patients with AKI were identified through PubMed, Embase, the Cochrane library and references of related papers. The primary outcome was all-cause mortality. Secondary outcomes were renal recovery, hospital mortality, duration of hospitalization and mechanical ventilation. Data were analyzed by Random effects model.

Results: We evaluated 52 studies (including nine RCTs) with 7746 patients with AKI. Analysis of the trials included showed that patients receiving early RRT had a 25% reduction in all-cause mortality compared to those receiving late RRT (risk ratio [RR] 0.75, 95% CI [0.69, 0.81]). We noted a 22% increase in renal recovery (RR 0.75, 95% CI [1.02, 1.45]) and 4.26 days (mean difference [MD], 95% CI [-7.99, -0.53]) reduction in duration of hospitalization and 2.33 days (MD, 95% CI [-3.40, -1.26]) reduction in duration of mechanical ventilationin patients assigned to early RRT.

Conclusions: Early initiation of RRT was associated with a decreased risk of all-cause mortality compared with late initiation of RRT in patients with AKI. The findings need to be interpreted with caution given the heterogeneity between studies. Further studies are needed to identify the causes of mortality and to assess whether mortality differs by dose of dialysis.

Phase Angle Is Associated with Hospital Mortality Risk in Acute Kidney Injury Patientes Irrespective of Clinical Severity Francisco Javier Lavilla,[1] Maria Jose Molina Higueras,[1] Pelayo Moiron Fdez-Felechosa,[1] Nuria Garcia-Fernandez,[1] Paloma L. Martin Moreno,[1] Pedro Errasti,[1] Jorge M. Nunez-Cordoba.[2] *[1]Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain; [2]Research Support Service, Central Clinical Trials Unit, Clinica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: The phase angle (PA) is a novel marker of functional status that is determined by bioelectrical impedance analysis (BIA). A low PA has been suggested to be an adverse prognostic marker of survival, although no study has evaluated its prognostic influence on acute kidney injury (AKI) patients, independently of clinical severity. We evaluated the association between PA and hospital death in AKI patients adjusting for individual severity index (ISI), which is a validated proxy of clinical severity.

Methods: Clinical and analytical factors, PA, and hospital death were prospectively registered in 97 AKI patients. ISI formula includes age decade, sex, nephrotoxic, oliguria, hypotension, jaundice, coma, consciousness, and assisted respiration. We evaluated c-reactive protein (CRP- mg/dL) and albumin (mg/dL) levels. Also we evaluated ECOG and Karnofsky index. Clinical and analytical variables were assessed when the nephrologist saw the patient the first time.

Results: Patients characteristics: mean age, 67.4 (SD: 14.9) years; men (72.2%); AKI etiology (Prerenal 67.6%, Renal 9.5%, Pre-renal 14.3%, Postrenal 3.8%, others 4.8%); mean ISI, 0.24 (SD: 0.12); and mean PA, 3.99 (SD: 1.35). Hospital deaths: 10 (10.31%). We evaluate association of PA with ISI (r=-0.210 p=0.031), CRP (r=-0.209 p=0.039), Albumin (r=0.362 p=0.003), ECOG (r=-0.374, p=0.003) and Karnofsky index (r=0.456, p<0.001). The OR (95% CI) for PA (per degree increase) was 0.33 (0.14; 0.78) after adjusting for age, sex, and clinical severity.

Conclusions: PA was associated with protein metabolism and chronic health status The PA appears to be a prognosis index of hospital mortality in AKI patients irrespective of clinical severity.

FR-PO857

Extracellular Hypervolemia Evaluated with Bioimpedance, as a Prognostic Marker in Acute Kidney Injury Francisco Javier Lavilla, Maria Jose Molina Higueras, Pelayo Moiron Fdez-Felechosa, Paloma L. Martin Moreno, Nuria Garcia-Fernandez, Pedro Errasti. *Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: The bioelectrical impedance analysis (BIA) is a noninvasive and painless technique is easy to perform, which is used for determining body composition . Can offer information about membrane cell integrity, volemia and clinical status. We evaluate use of BIA to measure extracellular watter with extracelular/intracelular watter ratio –ECW/ICW- and extracelular/total body watter –ECW/TBW-) as a prognostics markers in acute kidney injury (AKI).

Methods: We include a cohort of 159 patients (médium age 66 years SD 1.8, and male 73 % with AKI, and BIA. We evaluate clinical prognostic index (individual severity index –ISI-), analitical inflammatory parameters (C-reactive protein –mg/dL-) and chronic health index (Karnofsky –K-). We use SPSS 20.0.

Results: Exitus 9.4%. ECW/ICW p=0.004, OR 2.247 CI 95%1.266-3.98 was associated with risk mortality better than ECW/TBW p= 0.018 OR 5.539 CI 95% 1.33-23.0. The AUC to mortality with ECW/TBW was 0.734 (p=0.003, CI 95% 0.625-0.844) and with ECW/ICW was 0.778 (p=0.001, CI 95% 0.678- 0.879). ECW/ICW was associated with prognosis, inflammatory and chronic health state in AKI, better than ECW/TBW. ECW/ICW with ISI (r=-0.271, p=0.001), CRP (r=0.248, p=0.004) and Karnofsky (r=-0.253, p=0.003) and ECW/TBW with ISI (r=-0.115, p=0.148), CRP (r=0.124, p=0.131) and Karnofsky (r=0.242, p<0.002). ECW/ICW is also better associated (p=0.014) with respiratoy failure (No failure 1.45 EE 0.05, moderate 1.57 EE 0.16, severe 2.33 EE 1.17) than ECW/TBW (p=0.082).

Conclusions: Higher ECW are associated with prognosis in AKI. ECW/ICW was associated better with mortality than ECW/TBW. ECW/ICW is associated better with prognostic index, c-reactive protein levels, Karnofsky index and respiratory failure.

FR-PO858

Bioimpedance Analysis Guided Volume Expansion for the Prevention of Contrast Induced-Acute Kidney Injury Sarassawan Kananuraks, Arkom Nongnuch. *Renal Unit, Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.*

Background: Periprocedure fluid administration is a cornerstone for prophylaxis of contrast-induced acute kidney injury (CI-AKI). Recent trials showed the benefit of personalized larger amount of fluid administration categorized by fluid status accessed by left ventricular end diastolic pressure (LVEDP) compared with conventional protocol. However, the LVEDP is invasive procedure leading to limited clinical application. Bioimpedance analysis (BIA) is non-invasive tool for determining fluid status in CKD. This study aim to prove personalized fluid administration categorized by BIA may lower incidence of CI-AKI comparing with conventional protocol (NCT02449317).

Methods: In this randomized controlled trial, we personalized isotonic bicarbonate administration categorized by total body water/extra cellular water (ECW/TBW) comparing with conventional bicarbonate protocol for preventing CI-AKI in 56 CKD patients undergoing coronary angiography (CAG). For the BIA group, patients would receive fluid rate 3 ml/kg for 1 hour before CAG and 1ml/kg/h, 2 ml/kg/h and 4 ml/kg/h for 6 hours after CAG if ECW/TBW was >0.4, 0.36-0.4 and <0.36 respectively. In the conventional group, they received fluid rate 3 ml/kg for 1 hour before CAG and 1 ml/kg/h for 6 hours after CAG. CI-AKI was defined as an increased in serum creatinine more than 0.3 mg/dL with in 48-72 hours after CAG.

Results: Baseline characteristics were comparable between two groups except periprocedure volume, which was significantly greater in BIA group.

Fluid Overload Masks AKI Diagnosis and Associated Outcomes in Critically Ill Children David T. Selewski,[1] Katja M. Gist,[2] Erin K. Stenson,[3] Shina Menon,[4] Stuart Goldstein,[3] Rajit K. Basu.[3] *[1]Univ of Michigan, Ann Arbor, MI; [2]Univ of Colorado, Aurora, CO; [3]Cincinnati Children's Hospital, Cincinnati, OH; [4]Univ of Washington, Seattle, WA.*

Background: Acute kidney injury (AKI) occurs commonly in critically ill children and is associated with adverse outcomes. Fluid overload (FO) has been shown to mask the diagnosis of AKI in select populations (adults, congenital cardiac surgery). This study aims to evaluate the impact FO has on the diagnosis of AKI in a general pediatric intensive care unit (PICU) population.

Methods: Secondary analysis of The Acute Kidney Injury in Children Expected by Renal angina and Urinary Biomarkers (AKI-CHERUB) study, a single center prospective observational study conducted in a tertiary care PICU. The primary outcome was severe AKI at 48 hrs, utilizing the SCr based KDIGO definition Stage 2-3 AKI. AKI was also recalculated using SCr corrected for FO (Cr_{corr} = SCr x [1 + (net fluid balance/total body water)]). FO was calculated daily by fluid balance from PICU admission. Secondary outcomes: length of mechanical ventilation (MV), PICU LOS, hospital LOS.

Results: 181 patients were in the cohort (166 with complete outcome data). Mortality was 5%. 57 patients (31%) had 10-20% FO and 28(15%) ≥20% FO at 48 hrs. The incidence of all AKI was 14.9%(n=29) and increased to 27.7%(n=50) with Cr_{corr}. Using Cr_{corr}, 34.5%(N=10) had an increased AKI stage, with 5 additional cases of severe AKI diagnosed. Severe AKI by Cr_{corr} was associated with adverse outcomes (Table).

	Severe AKI by Cr(N=163)		p	Severe AKI by Cr_{corr}(N=166)		p
	Yes(N=12)	No(N=151)		Yes(N=17)	No(N=149)	
Length of MV*	3(0.5,8)	1(0,5)	0.16	3(0.5,8)	1(0,5.5)	0.18
ICU LOS*	8(3.8,15)	4(3,11)	0.15	10(6,16)	4(3,11)	0.02
Hospital LOS*	16(10,56)	14(8,29)	0.37	18(10,55)	14(8,25)	0.06
Organ Failure*	8.5(3.3,14.8)	2(0,6)	0.002	7(2.5,10.5)	2(0,6)	0.008
*days, Med(IQR)						

Conclusions: We show FO masks the diagnosis of over 40% of patients with AKI and should be accounted for when monitoring for AKI. Furthermore the failure to correct SCr measure for FO dilutes the impact of AKI on outcomes.

FR-PO860

Nesiritide Modulates Inflammatory Response during Cardiac Surgery Thomas M. Beaver,[1] Jessica A. Cobb,[1] Abhilash Koratala,[2] A. Ahsan Ejaz.[2] *[1]Div of Thoracic and Cardiovascular Surgery, Univ of Florida; [2]Div of Nephrology, Hypertension & Renal Transplantation, Univ of Florida.*

Background: The study was performed to investigate the effects of NES on inflammatory response during cardiac surgery.

Methods: N=29 cardiac surgery patients were randomized to an infusion of NES versus placebo (Ctrl). The effect of NES on inflammatory response was investigated by measuring a panel of candidate biomarkers and clinical parameters at predetermined time points.

Results: There were no significant differences between the groups with regards to the early biomarkers of AKI: urine NGAL (NES 230.3+71.5ng/mL vs. Ctrl 554.4+263.3ng/mL, p=0.253) and urine IL-18 (NES 29.9+4.8pg/mL vs. 254.5+118.3pg/mL, p=0.090). A concerted biomarker kinetic pattern of time-differentiated peak concentrations was observed. IL-10, IP-10, IL-6, IL-10, IP-10, MIP-1a, INF-a, INF-g, IL-1a, IL-3 and IL-7 reached peak concentration at 0hr following end of CPB; TNF-a, EGF, GM-CSF, IL-12p40, IL-17, MIP-1b and MCP-1 at 1hr; IL-18, VEGF, IL-13 and IL-1ra at 2hrs, TNF-b, G-CSF, IL-1b, IL-2, IL-4, IL-5 and IL-15 at 2hrs; and ET-1 and IL-18 at 6hrs. A generalized trend towards lower levels of biomarker concentration in the NES group compared to the Ctrl group could be observed. At 0hr, the NES group exhibited significant reduction of peak concentrations of IL-6 (p=0.009), IL-10 (p=0.009), IL-1a (p= 0.020), IP-10 (p= 0.001) and IFN-a (p=0.032) compared to the Ctrl group. Significant reduction in peak concentrations of TNF-a (p=0.007) and MIP-b (p=0.027) at 1hr and ET-1 (p=0.020) at 6hrs were observed in the NES group compared to the Ctrl group.

Conclusions: Our study demonstrated a concerted inflammatory response in cardiac surgery that was modulated by nesiritide. Furthermore nesiritide attenuated ET-1 response thus suggesting that previously observed favorable renal effect may be linked to attenuated renal vasoconstriction.

FR-PO861

Pulsatile Portal Flow and Acute Kidney Injury after Cardiac Aurgery William Beaubien-Souligny,[1] Josee Bouchard,[2] Yoan Lamarche,[1] Jean-Francois Cailhier,[3] André Denault.[1] *[1]Intensive Care, Montreal Heart Inst, Montreal, QC, Canada; [2]Nephrology, Hôpital Sacré-Coeur de Montréal, Montreal, QC, Canada; [3]Nephrology, Chum, Montreal, QC, Canada.*

Background: Acute kidney injury (AKI) is frequent following cardiac surgery and venous congestion of the kidneys may play a role in the development of AKI. We assessed whether portal flow pulsatility (PP), a sign of portal hypertension from congestive heart failure which could reflect elevated venous pressure in kidneys, may independently predict AKI, as well as risk factors for PP.

Methods: We conducted a retrospective cohort study including patients who had at least one assessment of portal flow during the week following cardiac surgery between May 2015 and February 2016 at our institution. We excluded patients with stage V CKD, AKI before surgery or liver cirrhosis. PP was defined as a pulsatility fraction ≥ 50%. We assessed AKI over the week after surgery according to the KDIGO serum creatinine criteria and performed logistic regression analyses to identify independent risk factors of AKI and PP.

Results: We screened 136 patients and included 102 patients with a mean age of 69. 37.3% of patients underwent CABG while 58.8% had valvular or complex surgeries. 21.6% had stage III CKD and 2% had stage IV CKD. PP was detected in 35% of patients. AKI developed in 60.8% of patients with 13.7% progressing to severe AKI (stage 2 or higher). The detection of PP was associated with a significant increase in the risk of AKI (OR: 6.0 CI: 2.2-16.4) and severe AKI (OR: 5.4 CI: 1.5–18.6).The association with AKI was significant in a multivariate model including baseline creatinine and the SOFA cardiovascular score during the first two days after surgery (OR: 5.7 CI: 1.9-16.8). Maximal pulmonary artery pressure (44 vs 39 mmHg p = 0.03) and percentage of cumulative fluid balance over body weight (4.9% vs 3.6% p = 0.04) were associated with PP.

Conclusions: In our study, the detection of PP during the first week after cardiac surgery was independently associated with an increased risk of AKI after adjustment for baseline serum creatinine and SOFA cardiovascular score after surgery. Further studies are required on the role of PP as a marker of venous congestion of the kidneys to predict AKI.

The Timing of Eculizumab Therapy Predicts Renal Survival in Atypical Hemolytic Uremic Syndrome Salem Almaani, Udayan Y. Bhatt, Jason Prosek, Brad H. Rovin, Samir Parikh. *Ohio State Univ, Columbus, OH.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a life threatening disease instigated by alternative complement pathway dysregulation and often results in acute renal failure from thrombotic microangiopathy. Treatment with eculizumab, a terminal complement blocker, is effective, but some patients are still left with significant renal impairment. This work aims to determine whether the timing of eculizumab treatment predicts renal survival in patients with aHUS.

Methods: We conducted a retrospective analysis of clinical data from 22 aHUS patients treated with eculizumab. Demographics are summarized in the table. Median follow up time was 22 months (IQR 13-43.75). The time to treatment initiation was tested as a predictor of adverse renal outcomes by univariate and multivariate analysis. Outcomes were defined as a ≥50% increase in serum creatinine (SCr), end-stage renal disease, or a composite endpoint of either. Other variables were tested but only age and sex met inclusion criteria for multivariate analysis.

Age at presentation (Avg ±SD)	41.7±17.2
Sex (men/women)	5(20.8%) / 19 (79.2%)
Race (White/Black/Other)	19(79.2%) / 4 (16.6) / 1 (4.2%)
Patients requiring dialysis	15 (62.5%)
Time on dialysis (months, Median, IQR)	2 (0.6-12)
Time to Eculizumab (days, Median, IQR)	9 (6-34)
Baseline Creatinine (mg/dl, Avg±SD))	1.31±0.54
Patients with identified mutation	13 (59%)

Results: A delay in eculizumab initiation >10 days after clinical presentation was predictive of a ≥50% increase in SCr (OR=10.5, 95% CI: 1.11 to 98.91, p=0.040), and was 100% predictive of dialysis dependence by univariate analysis. Time to treatment was a significant predictor of the composite outcome by univariate analysis (OR=22.5, 95% CI: 2.60 to 194.51, p=0.005) and multivariate analysis (OR=50.14, 95% CI: 2.67 to 942.29, p=0.005).

Conclusions: The delayed administration of eculizumab is associated with an increased risk of poor renal outcomes in aHUS. Initiation of terminal complement blockade within 10 days of clinical presentation is essential for long-term preservation of renal function in patients with aHUS.

FR-PO863

Free Hepatic Venous Pressure as a Marker of Renal Venous Congestion: Is There a Correlation with Hemodynamic Renal Dysfunction in Patients with Cirrhosis? Neel Desai, Ladan Golestaneh. *Nephrology, Albert Einstein College of Medicine - Montefiore Medical Center, Bronx, NY.*

Background: Intra-abdominal hypertension (IAH, abdominal cavity pressure >/= 12 mmHg) correlates with renal disease. The pathophysiology of this relationship is not clearly understood - IAH is thought to cause renal venous congestion by increasing venous pressure and impairing venous drainage. We hypothesize that in patients with cirrhosis elevated abdominal venous pressure, as represented by an elevated Free hepatic venous pressure (FHVP, routinely measured during Transjugular Intrahepatic Portosystemic Shunt or TIPS procedures), correlates with hemodynamic renal dysfunction when adjusted for other pertinent clinical factors.

Methods: We used our institution's electronic health record based database to search for patients who underwent TIPS procedures between 2008-2015. Information collected included demographics, FHVP, other co-morbidities and markers of parenchymal renal disease. Patients with End Stage Renal Disease (ESRD) +/- missing race information were excluded. Calculated GFR using the MDRD formula was used in all data analyses which was done using the STATA 14.0 software.

Results: A total of 122 patients were included in the study based on the criteria listed above. The mean FHVP was 13.9mmHg and mean EF was 65%. 16.8% of the patients had evidence of parenchymal renal disease on the renal sonogram which correlated with a 19.2cc/min decrease in baseline GFR (P=0.02). 12.4% of the patients had proteinuria which correlated with a 19.4cc/min decrease in baseline GFR (P=0.04). Every 1mmHg increase in the FHVP was associated with a 0.49cc/min decrease in baseline GFR which was not statistically significant (P=0.35).

Conclusions: Our data suggests that in patients with cirrhosis an increase in FHVP is not associated with a statistically significant decrease in baseline GFR. It is possible that the presence of hyper-dynamic cardiac function is compensating to maintain GFR in this sample by increasing cardiac output and renal perfusion. Our study is also not adequately powered. The association of elevated venous pressure and hemodynamic renal dysfunction needs to be explored further in patients with cirrhosis.

FR-PO864

Efficacy of Eculizumab in Gemcitabine-Induced Thrombotic Microangiopathy: Analysis of a Retrospective Study Cohort Steven Grange,[1,7] Maximilien Grall,[1,7] Francois Provot,[2,7] Coindre Jean-Philippe,[3,7] Claire Pouteil-Noble,[4,7] Dominique Guerrot,[5,7] Paul Coppo.[6,7] *[1]Medical Intensive Care Unit, Rouen Univ Hospital, France; [2]Nephrology, Lille Univ Hospital, France; [3]Nephrology, Le Mans General Hospital, France; [4]Nephrology, E.Herriot Hospital, Lyon I Univ, France; [5]Nephrology, Rouen Univ Hospital, France; [6]Hematology, St. Antoine Univ Hospital, AP-HP, Paris, France; [7]French TMA Reference Center, St. Antoine Univ Hospital, AP-HP, Paris, France.*

Background: Gemcitabine is a broadly prescribed chemotherapy with renal adverse events, including thrombotic microangiopathy (TMA). This study evaluated the efficacity of eculizumab in patients with gemcitabine-induced TMA.

Methods: We conducted an observational, retrospective, multicentric study including all patients with gemcitabine-induced TMA treated by eculizumab in 4 French centers, between 2011 and 2014. Patients with TMA attributed to cancer and to allogenic stem cell transplant were excluded.

Results: 7 patients were included (6 women, 1 man). Gemcitabine was prescribed for pancreatic (n=3, 43%), ovarian (n=3, 43%) and pulmonary (n=1, 14%) cancer. TMA occured after a median of 5 months (range 1.7-8.4) and a median cumulative dose of 23.7g (range 0.9-48.0). The main characteristics were hemolytic anemia (100%), acute renal failure (100%, including 57% stage 3 AKI and 28% renal replacement therapy), hypertension (71%) and diffuse edema (57%). Eculizumab was started after a median of 27 days (range 7-44) following TMA diagnosis. A median of 4.5 injections of eculizumab was performed (range 3-22). Hematological remission was achieved in 5 patients (71%) and blood transfusion significantly decreased after one injection of eculizumab (median of 2 packed red blood cells (range 0-10) vs 0 (range 0-1), p=0.047). Complete nephrologic remission was achieved in 1 patient (14%), and partial remission in 4 patients (57%). Three patients (42%) died during follow up, 1 from a septic and hemorrhagic shock, 2 from cancer evolution (3 and 13 months after eculizumab initiation).

Conclusions: This study suggests that eculizumab is efficient on hemolysis and reduces transfusion requirement in gemcitabine-induced TMA. The benefit of eculizumab on the revovery of kidney function remains uncertain.

FR-PO865

Design of the STOP-AKI Trial: Safety, Tolerability, Efficacy and Quality of Life of Human Recombinant Alkaline Phosphatase in Patients with Sepsis-Associated Acute Kidney Injury Jacques Arend,[1] Esther Peters,[2] Ravindra L. Mehta,[3] Patrick T. Murray,[4] Jurgen Hummel,[5] Michael Joannidis,[6] John A. Kellum,[7] Peter Pickkers.[2] *[1]AM-Pharma, Bunnik, Netherlands; [2]Dept of Int Care Med, Radboudumc, Nijmegen, Netherlands; [3]Div of Nephrol, Dept of Med, Univ of California, San Diego, CA; [4]School of Med, Univ Coll Dublin, Dublin, Ireland; [5]PPD, Bellshill, United Kingdom; [6]Div of Int Care and Emerg Med, Dept of Int Med, Medical Univ Innsbruck, Innsbruck, Austria; [7]Ctr for Crit Care Neph, Dept of Crit Care Med, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Acute Kidney Injury (AKI) occurs in ~60% of critically ill patients, and sepsis is the most common underlying cause. No pharmacological treatment options are licensed to treat sepsis-associated AKI (SA-AKI). Administration of *bovine* intestinal alkaline phosphatase (AP) improved renal function in critically ill sepsis patients. To build on these observations, a *human recombinant* AP (recAP) was developed and is currently tested for safety and efficacy in patients with SA-AKI.

Methods: This is a randomized, double-blind, placebo-controlled, dose-finding adaptive phase IIa/IIb study, conducted in critically ill patients with SA-AKI (NCT02182440). A minimum of 290 patients will be enrolled at ~50 sites in the European Union and North America. The study involves 2 parts. Patients enrolled during Part 1 will be randomly assigned to receive placebo (n=30) or 1 of 3 different doses of recAP (n=30 per group) once daily for 3 days (0.4 mg/kg, 0.8 mg/kg, or 1.6 mg/kg). In Part 2, patients will be randomly assigned to receive the most efficacious dose of recAP (n=85), selected by an independent data safety monitoring board during an interim analysis, or placebo (n=85). Treatment must be administered within 24 h after SA-AKI is first diagnosed and within 96 h from first diagnosis of sepsis. The primary endpoint is the area under the time-corrected endogenous creatinine clearance curve from days 1-7. The key secondary endpoint is the incidence of renal replacement therapy during day 1-28.

Results: The estimated study enrollment completion date is February 2017.

Conclusions: Results of this study will reveal the safety and efficacy of recAP to treat SA-AKI in critically ill patients.

FR-PO866

How Is Acute Kidney Injury Defined and Represented in Critically Ill Patients in Randomized Controlled Trials? Rogerio Passos, Zilma Regia de Sousa Barreto, Roseanne Ferreira de Freitas Euzebio, Luis Miranda Conceição, Ana Carolina E. Cattony, Camila Magalhães Brandão, Fabiana Gois Sousa, Gerlane Araujo Luz, Laryssa Passos Santos, Paulo Benigno Pena Batista. *Intensive Care Unit, São Rafael Hospital, Salvador, Bahia, Brazil.*

Background: Acute kidney injury (AKI) is a prevalent condition in critically ill patients and it is associated with increased mortality in this population. Targeted analysis of this subgroup in randomized clinical trials is essential to guide an accurate conduct and lead to better outcomes. The primary goal of the present study was to quantify the representation of patients with AKI and to assess the criteria used to define it in multicenter randomized clinical trials.

Methods: A sensitive search strategy for randomized controlled trials published from 2006 to 2016 was conducted in MEDLINE using the PubMed interface selecting the keywords "sepsis", "mechanical ventilation", "ARDS" and "critically ill patients". All publications of adult, randomized controlled trials carried out in the intensive care unit, with mortality as primary outcome were included and reviewed independently.

Results: A total of 379 articles were reviewed. We identified 60 elegible studies, 41 (68%) were multicenter, 51 (85%) included patients with renal dysfunction at baseline and in 14 (23%) the population with renal impairment underwent a subgroup analysis. None of studies reported the proportion of enrolled patients with acute kidney injury. In the follow up of the patients during these studies, generic scores as APACHE II, SAPS II and SOFA were used in 44 (73%) of studies to define AKI, specific AKI scores as RIFLE and the Brussels score were used in 6% and 3% respectively, and 18% of the studies did not describe any criteria to define AKI.

Conclusions: In multicenter randomized clinical trials assessing mortality as primary outcome there is an underrepresentation of AKI patients in the enrollment of the patients and no consensus in AKI definition during the follow up of the patients during studies. The consequence is that we lack evidence on interventions for this growing high-risk population.

FR-PO867

Serum Free Light Chain Level at Diagnosis and Patient Outcomes in Myeloma Cast Nephropathy-A Multicentre Study Punit Yadav,[1] Insara Jaffer Sathick,[2] Nelson Leung,[2] Elizabeth E. Brown,[3] Mark Cook,[1] Paul W. Sanders,[3] Paul Cockwell.[1] *[1]Queen Elizabeth Hospital, Birmingham, United Kingdom; [2]Mayo Clinic, Rochester; [3]Univ of Alabama at Birmingham.*

Background: Myeloma cast nephropathy (MCN), a consequence of excess monoclonal immunoglobulin free light chain (FLC) production, is a common cause of severe renal impairment in multiple myeloma (MM). However, the threshold of FLC level in serum that is associated with the development of MCN is uncertain.

Methods: In a multicentre cohort of MM patients presenting with biopsy-confirmed MCN between 2002-2014, we evaluated prospectively measured serum FLC levels obtained using a single nephelometric assay. We report renal outcome and overall survival (OS) relative to serum FLC level at diagnosis controlling for demographic factors.

Results: 103 patients were enrolled from 3 tertiary centres. Median age at diagnosis was 63 years (IQR 57-69). The majority were male (58.2%) and of white race (88.3%). Light chain only MM was the predominant paraprotein type (47.6%). The median involved FLC level at diagnosis was 753 mg/L (range 107-114600). Serum creatinine was 6.0 mg/dL (IQR 4.6-9.8), eGFR 7 ml/min (IQR 5-11), calcium 9.4 mg/dL (IQR 9.0-10.8) and haemoglobin 9.0 g/dL (IQR 7.8-10.1). 67% of patients received dialysis treatment, of which 52.1% recovered independent renal function. Median duration on dialysis for those who recovered renal function was 36 days (IQR 22.7-89.7). 2 patients had a monoclonal FLC level <500 mg/L; one was hypercalcaemic, while the other patient had high-normal serum calcium level and received NSAIDs. 67.3% died with a median OS of 515 days (95% CI 293-736). In a multivariable analysis, age, serum calcium level and high cut-off haemodialysis treatment were associated with recovery of independent renal function. Age at diagnosis and serum calcium level were inversely correlated with OS.

Conclusions: This is the largest reported cohort of patients with biopsy-confirmed MCN and serum FLC levels. Only 2 patients had a serum FLC level <500 mg/L at diagnosis; both of whom had risk factors known to promote the development of MCN. Elevated serum calcium level at diagnosis was associated with lower rates of renal function recovery and poor OS.

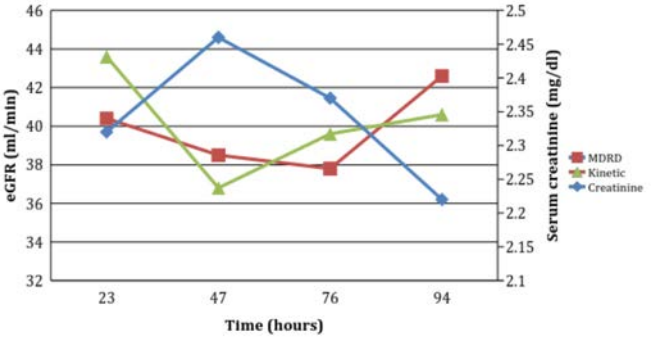
FR-PO868

Renal Function Assessment in the Setting of Acute Kidney Injury Applying the Kinetic GFR Formula Jose S. Lopez Gil,[2] Luis Antonio Garcia,[2] Javier Zúñiga-Varga,[1] Juan Pablo Herrera Felix.[1] *[1]Nephrology Dept, American British Cowdray, Mexico, Mexico City, Mexico; [2]Postgraduate, UNAM, Mexico, Mexico City, Mexico.*

Background: There is no reliable method to estimate or asses kidney function in acute kidney injury (AKI), therefore, we applied the kinetic GFR formula proposed by Chen (JASN 24:2013) to estimate changes in GFR, evaluate renal outcomes and value the accuracy of this formula.

Methods: This is a retrospective study. 30 patients with AKI were randomly selected from 763 admissions between 2010 and 2016. Serum creatinine (SCr) values from previous years to admission were collected to establish baseline SCr. Admission SCr and the four subsequent SCr were collected. GFR was estimated by Kinetic (kGFR) and MDRD formulas.

Results: Mean age was 70.6 ± 15.9 years. Males represented 56.6% (17). Admission diagnosis was infectious disease in 26.6% (8), heart disease in 13.3% (4) and neoplasms in 10% (3). Mean baseline SCr was 1.15±0.44mg/dl and the admission SCr was 2.46 ± 1.9mg/dl. The mean SCr in the first sample was 2.32±1.8mg/dl, eGFR MDRD 40.4±25.1ml/min and kGFR 43.6±22.5ml/min. In sample 2, mean SCr was 2.46±2.1mg/dl, MDRD 38.5±24.4ml/min and kGFR 36.8±25.5ml min. In sample 3, SCr was 2.37±1.9mg/dl, MDRD 37.8 ± 21.3ml/min and kGFR 39.6± 25.5ml/min. In sample 4, SCr was 2.22±1.9mg/dl, MDRD 42.6 ± 30.7ml/min and kGFR 40.6±27.4ml/min. Mean SCr increased 6% from sample 1 to sample 2 and MDRD GFR decreased only 4.7% while kGFR decreased by 15.6%. From sample 2 to sample 3 mean SCr decreased 3.7% and MDRD GFR declined by 1.8%, while the kGFR improved by 7.6%. Even when the SCr remains constant between samples, the kGFR formula demonstrates a recovery of GFR of 2.3 ml/min while the MDRD remains unchanged.



Conclusions: The kGFR formula seems to be more reliable than MDRD to accurately estimate kidney function in AKI. Renal function recovery is identified earlier by kGFR.

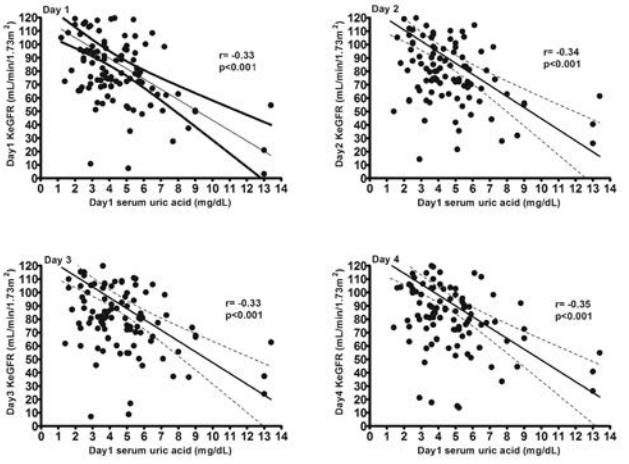
FR-PO869

Relationship of Serum Uric acid and Kinetic Estimated Glomerular Filtration Rate in Acute Myeloid Leukemia Patients Abhilash Koratala,[1] Kawther Farouk Alquadan,[1] Girish Singhania,[2] Michiko Shimada,[3] Richard J. Johnson,[4] A. Ahsan Ejaz.[1] *[1]Univ of Florida; [2]Univ of Utah; [3]Hirosaki Univ, Japan; [4]Univ of Colorado.*

Background: We investigated the relationship between SUA and renal function using kinetic eGFR (KeGFR) in a unique patient cohort wherein SUA levels fluctuate during the course of standard care.

Methods: Data from patients undergoing treatment for acute myeloid leukemia (AML) were analyzed retrospectively. Correlations between SUA and serum creatinine (SCr) and KeGFR were investigated. Statistically significant and clinically relevant determinants were studied in multivariate regression models.

Results: N=126 patients. Baseline SUA was associated with an increased risk for AKI (OR 1.27, 1.1-1.5, p=0.003) and tumor lysis syndrome (OR 1.26, 1.1-1.5, p=0.005). Prophylactic uric acid-lowering therapy and hydration resulted in lower SUA values from baseline in 88.1% of the patients, 20.4% reduction was observed on post-induction day 1. Significant linear correlations were observed between SUA and SCr (r=0.35, p<0.001) and inverse correlation was also observed between SUA and KeGFR on day 1 (r= -0.33, p<0.001) that persisted through day 4. By subgroup analysis, patients with primary AML (r= -0.49, p<0.001), baseline SUA >5.5mg/dL (r= -0.41, p=0.002) and baseline eGFR >60mL/min/1.73m2 (r= -0.51, p<0.001) demonstrated robust relationships between SUA and KeGFR. The relationship was more robust when the groups were combined (primary AML + baseline SUA>5.5mg/dL + baseline eGFR >60mL/min/1.73m2, r= -0.52, p<0.001).



Conclusions: The study demonstrated a linear relationship between SUA and SCr and an inverse relationship between SUA and KeGFR in a dynamic clinical situation.

FR-PO870

Subarachnoid Hemorrhage Induces Neuro-Cardio-Renal Interactions in the Acute Phase Naoki Ikegaya,[1] Kiyoshi Mori,[2] Takuya Yoshida,[5] Hiromichi Kumagai,[5] Yasuhiro Yamamura,[4] Mamoru Tomida,[4] Seiya Takehara,[4] George Seki,[3] Akira Hishida.[3] *[1]Dept of Medicine, Yaizu City Hospital, Yaizu, Japan; [2]School of Pharmaceut Sci, Univ of Shizuoka, Shizuoka, Japan; [3]Dept of Nephrology, Yaizu City Hospital, Yaizu, Japan; [4]Dept of of Neurosurgery, Yaizu City Hospital, Yaizu, Japan; [5]Dept of Clin Nutrition, School of Food and Nutritional Sci, Univ of Shizuoka, Shizuoka, Japan.*

Background: Subarachnoid hemorrhage (SAH) is known to induce acute cardiovascular stress as reflected by ECG changes, and renal dysfunction is associated with poor prognosis in SAH. However, the precise mechanisms of extra-brain injury in SAH have not been fully understood.

Methods: We prospectively analyzed ECG, urinary albumin, and NGAL, and serum NT-proBNP, endothelin and inflammatory cytokines such as IL-6 and TNF-alpha in 24 consecutive SAH patients without known kidney disease on day1, 2, and 14.

Results: ECG abnormalities were observed in 13 out of 24 patients with SAH at baseline. SAH patients with ECG abnormalities showed increased levels of albuminuria (Mean±SD, 627.9±1441.5 vs. 88.0±88.6 mg/g Cr), NT-proBNP (1033.8±2121.2 vs. 95.1±111.6 pg/ml) and endothelin (2.21±0.80 vs. 1.88±0.5 pg/ml), but no differences in IL-6 and TNF-alpha compared to patients without ECG abnormalities at baseline. Urinary NGAL significantly increased in patients with ECG abnormalities on day 2. Serum endothelin decreased towards normal values on day 2 and 14, and IL-6 and TNF-alpha increased on day 2 and 14 in both groups.

Conclusions: ECG abnormalities were associated with elevated levels of endothelin and albuminuria early after SAH, suggesting interactions among heart, brain and kidneys through increased endothelin in the acute phase.

FR-PO871

Inverse Interaction between Diuretics and Renin-Angiotensin Blockers in Contrast-Induced Nephropathy after Coronariography Lucero Salgado Ambrosio, Armando Vazquez-Rangel. *Nephrology, Inst Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico City, Mexico.*

Background: Prevention of contrast-induced nephropathy(CIN)is limited mostly to hydration, while some other interventions as diuretics and renin-angiotensin blockers seem to be counter intuitive. Nevertheless, patients with cardiovascular disease are usually under these drugs,and sometimes hydration is difficult to implement if heart failure or chronic fluid overload is present.

Methods: A retrospective cohort of patients undergoing coronary angiography in our National Institute of Cardiology in Mexico City from January 2011 to December 2011. Patients with ambulatory or short-stay procedures were excluded. Clinical and biochemical characteristics were obtained through medical records. Specifically, the use of loop diuretics, angiotensin converting enzyme inhibitors(ACEI) or angiotensin receptor blockers (ARB) was assessed from 24 hours before to 24 hours after coronariography. CIN was defined by KDIGO criteria by serum creatinine.

Results: 515 patients were analyzed. Baseline characteristics included:male 398 (77.3%), diabetes 201 (39.0%),hypertension 273 (53.0%), cardiogenic shock 2 (4.3%), chronic heart failure 72 (14.0%), previous myocardial infarction 60 (11.6%), acute coronary syndrome 460 (89.3%), emergency procedure 178 (34.5%). Of the total, 168 (32.6%) received loop diuretics, and 420 (81.5%) received ACEI/ARB peri-procedure.CIN was present in 61 (11.8%) patients. There was a significant difference between patients receiving loop diuretics for CIN (34 [20.2%]) vs patients without loop diuretics (27 [7.8%]) (p<0.05). Within patients receiving loop diuretics, the incidence of CIN for those receiving ACEI/ARB was 21 (16.7%) vs 13 (30.9%) without ACEI/ARB.Multivariate analysis confirmed this observation adjusted for fluid balance.

Conclusions: For high risk cardiovascular population, mostly with acute coronary síndrome, the use of diuretics increased the incidence of CIN, nevertheless, the concomitant use of ACEI/ARB protected partially from this risk. In patients with adequate fluid status or fluid overload because of heart failure, with the need of loop diuretics, reducing local vasoconstriction with ACEI/ARB could reduce the risk of CIN.

FR-PO872

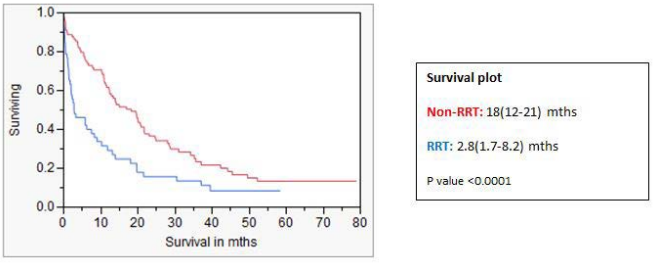
Renal Replacement Therapy after Ventricular Assist Device Implantation, a Single-Center Study Insara Jaffer Sathick,[1] M. Lourdes Gonzalez Suarez,[1] Kianoush Banaei-Kashani,[1,3] Karl A. Nath.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Critical Care, Mayo Clinic, Rochester, MN; [3]Mayo Medical School, Rochester, MN.*

Background: We evaluated heart failure patients receiving ventricular assist device(VAD)implantation who developed severe acute kidney injury(AKI) requiring renal replacement therapy(RRT).

Methods: We included patients≥18 years undergoing VAD implantation at Mayo Clinic between 2007 to 2015. We assessed overall survival in patients with or without AKI requiring RRT.

Results: 326 patients underwent VAD implantation. 71/326 patients required RRT after implantation.Serum creatinine at implantation,pulsatile device, duration of surgery,higher APACHE and SOFA scores,blood transfusion,positive fluid balance were associated with AKI requiring RRT. RRT group had worse survival (Odds ratio (CI) = 4.5 (2.5-8.2) p value <0.0001) and less likelihood of receiving cardiac transplant (Odds ratio (CI)= 0.47 (0.2-0.98), p value 0.03). At 2year follow up, median survival was 2.8 months in the RRT group vs 18 months in the nonRRT group.

N=326	RRT N=71	Non RRT N=255	p value
Median age	59	62	0.05
Pre-existing CKD %	60	56	0.4
Creatinine at implantation, mg/dl	1.8 (1.3-2.3)	1.3 (1.1-1.7)	0.0003
Continuous vs pulsatile device(%)	83:17	96:4	<0.0001
Median duration of surgery, mins	368	288	0.0002
Median RBC transfusion, units	36	12	<0.0001
Fluid balance on day 1, liter	+1.9	+1.4	0.01
Median follow up, days	180	680	<0.0001
Median survival, mths	2.8(1.7-8.2)	18(12-21)	<0.0001
Cardiac transplant	14%	25%	0.03



Conclusions: Patients who sustain severe AKI requiring RRT after VAD implantation have worse outcomes. Blood transfusion and positive fluid balance are predictors of severe AKI in addition to kidney function at implantation and severity of illness.

FR-PO873

Comparing Left Ventricular Assist Device Implantation and Inotropes for Renal Function and Outcomes Sean Verma,[1] Emmanuel Bassily,[1] Shane Leighton,[1] Igor Sunjic,[1] Angel Iran Martin,[1] Tambi Jarmi,[2] Claude Bassil.[2] *[1]Internal Medicine, Univ of South Florida; [2]Nephrology, Univ of South Florida.*

Background: Left Ventricular Assist Device (LVAD) implantation and inotropes serve as a bridge to heart transplantation or as destination therapy in those who aren't heart transplant candidates. Little is known about renal function and outcomes with LVAD placement, and a study comparing LVAD recipients versus solely inotrope treatment has not been previously performed.

Methods: 169 patients with continuous flow LVAD implantations and 20 patients with solely inotrope therapy with dobutamine or milrinone were analyzed. Mann-Whitney U Testing and chi-squared analysis compared the groups for long term renal outcomes after LVAD or continuous inotrope therapy was started (baseline), 3, and 6 months later. We also compared incidence of AKI, defined as an increase in creatinine of 0.3 mg/dL in 48 hours or 1.5 times the baseline in the last 7 days, need for renal replacement therapy (RRT), brain natriuretic peptide (BNP), and death during 6 months following LVAD or inotrope implementation.

Results: The groups had the same age, race, gender, BMI, tobacco use, diabetes, CKD, and hypertension distribution. The median creatinine in the groups was not statistically different (p-values 0.552, 0.081 and 0.469 at baseline, 3, and 6 months respectively). The median estimated glomerular filtration rate, calculated with the modified diet renal disease equation, was not statistically different between the groups (p-values 0.822, 0.644, and 0.507 at baseline, 3 and 6 months respectively). The incidence of AKI, RRT, and mortality in the groups over 6 month follow up after treatment were not significantly different. The median BNP at 6 months in the LVAD and inotrope groups was 216 pg/dL (range 14 to 2995 pg/dL) and 497 pg/dL (range 147 to 1242 pg/dL), with p-value statistically significant at 0.005.

Conclusions: The sole use of inotropes in patients with end-stage heart failure is non-inferior for outcomes in survival, incidence of AKI, need for RRT, and renal function within 6 months when compared to LVAD placement. More studies are needed to compare inotropes and LVAD implantation on renal function and outcomes over a longer time period.

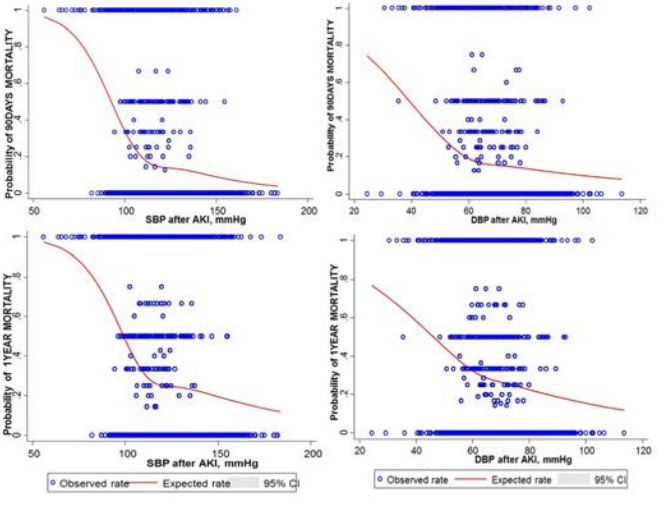
FR-PO874

Optimal Blood Pressure in Acute Kidney Injury: What and When? Seon Ha Baek, Ki Young Na, Sejoong Kim. *Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam, Republic of Korea.*

Background: Blood pressure (BP) is an important target for kidney injury, but few data showed optimal BP in patients with acute kidney injury (AKI) relative to mortality.

Methods: We performed a retrospective cohort study of 2304 patients who had their creatinine levels measured (≥ 1 measurement) during admission for a period of 1 year (January 1, 2013 through December 31, 2013) at tertiary hospital and were diagnosed with AKI by Kidney Disease Improving Global Outcomes (KDIGO) definition based on serum creatinine criteria. Average BP (systolic [SBP] and diastolic [DBP]) was categorized into 10-mmHg increments (at early period of admission within 48hr and at 48hr after development of AKI).

Results: The overall 90-day and 1-year mortality for patients were 17.6 % (405/2304) and 29.0% (669/2304). The relationship between BP (SBP and DBP) followed a J-shaped curve association with increased 90-day and 1-year mortality at low BP value in univariable analysis (SBP <120mmHg and DBP <60mmHg at admission and after AKI).



However, SBP at 48hr after AKI was only a predictor for 90-day mortality after adjustment for baseline variables (reference systolic BP ≥ 140mmHg, <100mmHg, Hazard ratio [HR] 4.528, P <0.001; 100-110mmHg, HR 2.177, P = 0.005; 110-120mmHg, HR 1.764, P = 0.033; 120-130mmHg, HR 1.415, P = 0.215; 130-140mmHg, HR 1.656, P = 0.088). This trend also remained in the relationship between average SBP after AKI and 1-year mortality.

Conclusions: After AKI, a J-shaped curve association existed between SBP at 48hr after AKI and 90-day/1-year mortality, which suggests that too low of a pressure (especially <120mmHg) may be dangerous. SBP after AKI was only a predictor for mortality rather than SBP/DBP at admission or DBP after AKI.

FR-PO875

Identification of Acute Kidney Injury Using a Novel Electronic Urine Flow-Rate Device Mor Grinstein,[1] Aliza D. Goldman,[2] Hagar Azran,[2] Dafna Willner.[2] *[1]Massachusetts General Hospital; [2]Anesthesiology and CCM, Hadassah-Hebrew Univ Hospital, Israel.*

Background: Criteria for identifying acute kidney injury (AKI) include measurements of serum creatinine (SCr) and urine output (UO). Current clinical practice for UO measurement involves manual recording of data, subject to human errors, including time errors and inaccurate urine drainage bags. A novel electronic device used in this study provided timely and accurate data for hourly urine output. We validated this device and analyzed it for the ability to identify AKI according to the AKIN (Acute Kidney Injury Network) criteria. We compared UO measured electronically to manual nursing staff records, as well as to SCr values.

Methods: Study Population: 40 hospitalized patients in the General ICU at Hadassah Hospital, Jerusalem, Israel with a urinary catheter Materials: The RenalSense *Clarity RMS™ sterile sensor kit* for electronic monitoring of UO. For this study, the RenalSense drainage bag included a standard urinometer for the nursing staff to record UO as per standard practice. The drainage bag was placed on a scientific scale (gold standard) to validate the sensor measurements. Sensor data and nursing staff manual records of UO were compared to the scale data. Daily SCr, urea, and creatinine clearance were collected from patient records up to 7 days following the drainage bag removal. Relevant fluids and medication were recorded.

Results: Our observations have shown that electronically recorded data of UO is more consistent, reliable and accurate than nursing records. Moreover, our study has highlighted the weakness of SCr as an accurate measurement of kidney function. Most patients showed a steady decrease to very low levels of SCr, even below normal range, possibly due to fluid overload. We found an average length of stay in the ICU of 14 days in patients with low UO as defined by the AKIN criteria versus 10 days in patients that had normal UO.

Conclusions: Close urine monitoring during this study has provided observation of diuretic response in real-time. This study has highlighted applications of a novel electronic device for measuring UO such as identifying AKI, decisions as to timely fluid and diuretic administration, and dose response.

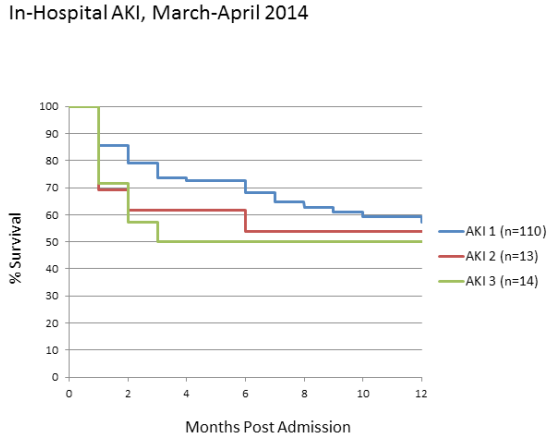
FR-PO876

Poor Survival 12 Months after In-Hospital AKI e-Alert Regardless of Stage Nina Gerdes, Clare Morlidge, Kate Berresford, Catherine J. Marshall, Suresh Mathavakkannan, Andrew Findlay. *Dept of Nephrology, Lister Hospital, East & North Hertfordshire NHS Trust, Stevenage, Hertfordshire, United Kingdom.*

Background: Acute kidney injury (AKI) is an emerging national and global health imperative. Here we review 12 month survival amongst patients following in-hospital AKI e-alert.

Methods: Data was retrospectively evaluated from secondary care hospital AKI e-alerts between 28/03-28/04/2014. Patient contact episodes (PCE) over the same period were recorded to calculate incidence. PCE were defined as adult elective and emergency attendances to the hospital. AKI e-alerts were staged by a nephrologist for accuracy along KDIGO guidelines. In-hospital AKI was defined as an e-alert generated >24 hrs after admission. Age adjusted co-morbidity was obtained from electronic patient record. Patients were followed up for one year.

Results: There were 412 AKI e-alerts generated from 19,530 patient contact episodes (PCE). On nephrologist review 299 (72.5%) were genuine AKI. 137 AKI e-alerts were in-hospital AKI with 110 AKI 1; 13 AKI 2 and 14 AKI 3. This gave AKI event rates of 7.01/1000 PCE for total in-hospital AKI, 5.63/1000 PCE for AKI 1, 0.67/1000 PCE for AKI 2 and 0.72/1000 PCE for AKI 3. Patient survival 12 months after AKI e-alert for in-hospital AKI was 57.27% for AKI 1, 53.85% for AKI 2 and 50% for AKI 3. Timing of death differed between AKI stages with 37.8% of AKI 1, 67.74% of AKI 2 and 81.82% of AKI 3 in-hospital AKI dying whilst inpatients.



Mean age adjusted Charlson co-morbidity scores of all in hospital AKI, Stage 1, 2 and 3 were high (5.71, 5.51, 6.85, 6.51 respectively).

Conclusions: In-hospital AKI, regardless of stage, is associated with poor survival at 12 months. High age-adjusted co-morbidity scores for AKI 1 may explain why a relatively minor AKI is associated with poor 12 month survival. Minor AKI may be a marker of underlying physiological frailty and increased risk of death.

FR-PO877

Reduction of In-Hospital AKI Incidence Using a Multidisciplinary Model and Intelligent Data Analysis Nina Gerdes, Clare Morlidge, Kate Berresford, Catherine J. Marshall, Suresh Mathavakkannan, Andrew Findlay. *Nephrology, Lister Hospital, East & North Herts NHS Trust, Stevenage, Hertfordshire, United Kingdom.*

Background: In-hospital acute kidney injury (AKI) is associated with poor survival at 1 year regardless of stage. A multidisciplinary AKI service was developed to reduce in-hospital AKI incidence.

Methods: A specialist nurse interrogated daily AKI e-alerts and prioritized deteriorating AKI above severity. A daily working week ward round consisting of Nephrology consultant, Renal pharmacist and AKI specialist nurse started in February 2016 to review patients with deteriorating AKI. AKI incidence was measured retrospectively 2 months prior to the introduction of AKI team and 2 months afterwards. All AKI e-alerts from December 2015-March 2016 were staged along KDIGO guidelines. In-hospital AKI was defined as an e-alert generated >24hrs post admission. To measure incidence the number of patient contact episodes (PCE) defined as adult emergency and elective attendance to a secondary care hospital was calculated per week. The number of AKI alerts over a week was divided by the number of PCE and multiplied by 1000 to give number of AKI events per 1000 PCE per week.

Results: There was a significant reduction in total in-hospital AKI, AKI 1 and AKI 2 but not AKI 3 incidence following the introduction of the AKI team (February+March 2016) compared to the 2 months prior to introduction.

	Pre-AKI team	Post AKI team	P - value
Total in-hospital AKI	7.07* (1.14)	5.25 (1.31)	0.015
In-hospital AKI 1	5.56 (0.84)	4.25 (1.24)	0.034
In-hospital AKI 2	0.87 (0.33)	0.21 (0.14)	0.0016
In-hospital AKI 3	0.44 (0.49)	0.51 (0.26)	0.92
* Incidence - No of AKI events / 1000 PCE / Week			
Data not normally distributed - Median (SD) shown, P value refers to Mann-Whitney U-test.			

Conclusions: A model of daily AKI e-alert review, data analysis and prioritization of declining AKI over severity followed by targeted clinical multidisciplinary review of the patients with AKI has been associated with a significant reduction of in-hospital total AKI, AKI 1 and 2 incidence reduction. A preventative approach targeting early deteriorating AKI rather than severe established AKI may reduce in-hospital AKI.

FR-PO878

Telenephrology: A 2 Year (1978 Visits) Experience Caring for Hospitalized Patients in a Rural Community Hospital Brenda R.C. Kurnik, Jerome S. Tannenbaum. *Sanderling Renal Services, Nashville, TN.*

Background: Telemedicine has been utilized for over 30 years. Early applications included "store and forward" technology and tele-monitoring. The limited literature in telenephrology is primarily focused on outpatients. We report a two year experience using real-time audio video technology to perform nephrology consultations, follow up visits and dialysis on in-patients in a rural hospital.

Methods: A retrospective study of inpatients requiring nephrology care between April 2014 and April 2016. Consultations were requested by the on-site physicians and were performed by reviewing the patient's hospital EMR and performing a real-time history and physical exam with audio-video technology and Littman electronic stethoscope.Notes were typed into the hospital EMR and local physicians were contacted by phone as needed.

Results: A total of 427 consults and 1551 follow up visits were performed. Population characteristics: 213 females, 214 males; age range 25-99 yrs. old. Patient location: ICU 154, PCU 36, floor 237. Average LOS of 6.8 days. Disposition: home/rehab 360, transferred to tertiary care hospital 28, hospice 21, and deceased 18. Consults were performed on 186 patients with ESRD (165 HD/21 PD) and 241 pts for: ARF (193) Overdose (2) CKD (26) and electrolyte disorders (20). The pts with ESRD received 405 hemodialysis treatments and 70 peritoneal dialysis treatments. We did 123 acute dialysis treatments in 31 pts. (15 pts received 45 HD for ARF, 15 pts received 77 HD for CKD which progressed to ESRD, and one pt/ 1 HD for an overdose. Dialysis complications were few, 5 pts had shortened HD for hypotension and 2 treated for hypertension. There were no access issues. Disposition for ESRD pts: home/rehab 171, transfer 7, hospice 3, deceased 5. Disposition for Non-ESRD pts: home/rehab 189, transfer 21, hospice 18, deceased 13. Of the 15 pts requiring HD for ARF, 12 regained renal function, 1 was made hospice and 2 were transferred on HD.

Conclusions: Telenephrology for the co-management of patients in a rural hospital is both feasible and safe. Our care included pts with both ESRD and ARF requiring dialysis.

FR-PO879

A Bedside Clinical Tool Using Creatinine Kinetics to Predict Additional Renal Injury and Early Recovery Maurice I. Khayat,[1] Jonathan Deeth,[2] Jonathan Sosnov.[3] *[1]Internal Medicine, San Antonio Military Medical Center, Fort Sam Houston, TX; [2]Anesthesiology, Evans Army Community Hospital, Fort Carson, CO; [3]Nephrology, San Antonio Military Medical Center, Fort Sam Houston, TX.*

Background: The characteristics of changing creatinine concentrations during acute renal failure are often confusing to clinicians and can cloud the patient's true current state of renal injury. By modifying the formula for kinetic estimate of glomerular filtration rate, a simple bedside clinical tool can be used to identify subtle changes in renal function.

Methods: The kinetic estimate of glomerular filtration rate was rewritten to instead calculate a predicted peak creatinine after each assumed renal injury. By comparing the changes in predicted peak creatinine at two or more subsequent time intervals, the patient's current state of renal injury can be determined: early recovery, a single ongoing renal insult, or multiple simultaneous renal injuries.

Results: Three case examples are provided using the equation for predicted peak creatinine. In each case, the creatinine concentration has continued to rise at three sequentially-measured times. However, the change in predicted peak creatinine is analyzed for each case, demonstrating scenarios involving (a) multiple simultaneous renal injuries, (b) a single, ongoing renal injury, and (c) a renal process with early intervention and recovery.

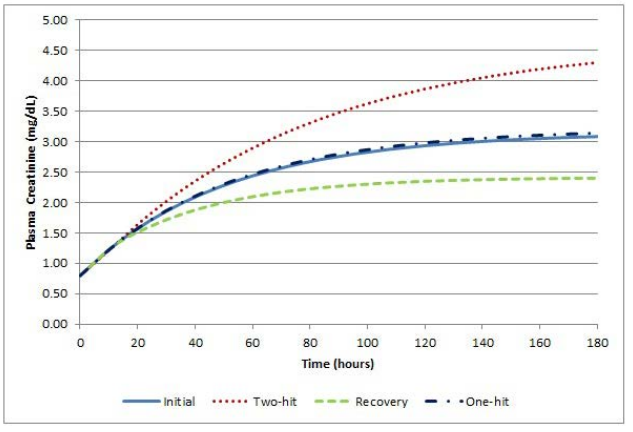


Figure 1 – Plot of the projected plasma creatinine versus time describing three different clinical case scenarios. The initial projected creatinine based on the plasma creatinine values at t1 and t2 (common to all example cases) is demarcated by the solid line above. The projected creatinine curves based on the amended peak creatinine after recalculation at t3 for each case (two injuries, one injury and early recovery) are superimposed as marked.

Conclusions: The use of this model may provide the clinician with an easy bedside tool to assess a patient's state of acute kidney injury. Reassessment of how the creatinine is changing is already a non-quantitative part of a nephrologist's approach to acute kidney injury. Providing an assessment of the patient's changing renal function would be a useful addition to detect early renal recovery or additional renal injuries in order to appropriately adjust treatment strategies.

Computerized Algorithms Compared to a Nephrologists Diagnosis of Acute Kidney Injury Arnar Jan Jonsson,[1,2] Sigrun Helga Lund,[2] Runolfur Palsson,[1,2] Olafur S. Indridason,[2] Ingibjorg Kristjansdottir.[2] *[1]Univ of Iceland; [2]Landspitali - the National Univ Hospital of Iceland, Reykjavik, Iceland.*

Background: Although the recent consensus criteria for acute kidney injury (AKI) is a step forward, the lack of reliable baseline serum creatinine (SCr) still hampers epidemiological studies. The aim of this study was to examine AKI diagnosis based on different computerized algorithms compared to AKI determined by a nephrologist in patients visiting an emergency department (ED) of a university hospital.

Methods: In this retrospective study, we used electronic medical records at the University Hospital in Reykjavik to identify all patients aged ≥18 years, who upon arrival to the ED in the year 2010 had an elevated SCr level. All available SCr values were reviewed and a nephrologist determined whether AKI was present using the KDIGO criteria, together with clinical data. Computerized algorithms based on the KDIGO SCr criteria, accounting for various time intervals for baseline SCr and changes in follow-up SCr were constructed in R.

Results: At 47,558 ED visits, SCr was measured in 15,623 patients for a total of 24,594 measurements. An elevated SCr was observed in 2,878 (18.4%) patients. Strict adherence to the KDIGO criteria (SCr increase of 0.3 mg/dl over 48 hrs or 50% increase over 7 days) yielded a 63% sensitivity, 94% specificity, 96% positive predictive value (PPV) and 49% negative predictive value (NPV) for the diagnosis of AKI. Allowing for longer time frame (365 days) for baseline SCr, yielded 75% sensitivity, 89% specificity, 94% PPV and 58% NPV. The algorithm with the highest sensitivity consisted of strict adherence to the KDIGO criteria together with the addition of 50% increase from baseline SCr from the previous year or 33% decrease in SCr within 7 days of the index SCr. This algorithm yielded a sensitivity of 86% but only 46% specificity. PPV and NPV were 81% and 57%, respectively.

Conclusions: Computerized algorithms for detection of AKI in patients visiting the ED, perform variably compared to a nephrologists (gold standard). Incorporating a measure of reduction in SCr following the visit may confer benefit at the risk of decreased specificity.

Funding: Government Support - Non-U.S.

FR-PO881

Acute Kidney Injury Electronic Alert Triggered Intervention Improves Length of Stay Rhodri Pyart, Craig D. Beaton, Afza L. Sadiq, Harsha P. Reddy, Benjamin J. Thomas, Chris P. Subbe, Vijaya Bharath P. Ramasamy. *Nephrology, BCUHB, Wrexham, United Kingdom.*

Background: Acute kidney injury (AKI) in hospital can be alerted electronically (e-alert) to clinicians using software that tracks creatinine changes. It is unclear however if any clinical intervention at this stage has a beneficial outcome. The aim of this study was to establish whether nephrology or critical care outreach team (CCOT) review of patients identified with AKI by e-alerts resulted in improved clinical outcomes and length of hospital stay.

Methods: Patients with AKI e-alerts were reviewed by nephrologists (grade 2 and 3 AKIs) and CCOT (grade 1 AKIs) on the same day. This was carried out for 30 consecutive days. Information on outcomes was prospectively collected for a follow up period of 80 days. A comparator group was formed 6 months earlier, made up of patients with an AKI e-alert generated over 60 consecutive days who were followed up with no intervention.

Results: 398 genuine AKIs were identified from all generated AKI e-alerts, 273 patients had no intervention while 125 patients were reviewed based on grade of AKI as above. There were no differences between the groups in mean age (75.0 ±14.9 vs 75.2 ±14.4 years, p = 0.909) and baseline creatinine (97.0 ±52.6 vs 99.7 ± 57.7 µmol/L, p = 0.467). The proportion of patients discharged home by 30 days post AKI was significantly higher in the intervention group (56.0% vs 44.7%, p = 0.018). The death censored median length of hospital stay was also significantly lower in the intervention group (13 vs 8 days, p = 0.034). The mortality rate trended towards being lower in the intervention group as compared to the comparator group at 80 days (32.0 % vs 38.5%, p = 0.108). The rate of progression of grade 1 and 2 to grade 3 AKIs also trended towards being lower in the intervention group (10.3% vs 6.3%, p = 0.115). There were no statistically significant differences in the need for renal replacement therapy, use of ICU beds and renal recovery at 80 days.

Conclusions: Our study supports the use of intervention in patients triggered with AKI e-alert. In particular it suggests that there is significant benefit in terms of shorter length of hospital stay. Larger studies are needed to support these findings.

FR-PO882

Irisin and Inflammatory Biomarkers in End Stage Renal Disease Patients Submitted to Remote Ischemic Pre Conditioning Marcelo Rodrigues Bacci, Mariana Carvalho Gouveia, Fernando Luiz Affonso Fonseca. *General Practice, ABC Medical School, Santo Andre, São Paulo, Brazil.*

Background: Irisin is a muscle-secreted protein released into the circulation by cleavage of fibronectin type III domain containing protein 5.It has been studied as a biomarker of myocardial injury. Areas submitted to remote ischemic cardiac preconditioning in experimental models have less occurrence of necrosis.The purpose of this study is to determine serum irisin levels and its association with troponin in patients with chronic kidney disease undergoing hemodyalisis submitted to RIPC.

Methods: It is a double blind randomised trial with two groups:intervention;submitted to RIPC in the right arm with sphygmomanometer with 200mm/Hg of pressure with three-5 minute rounds alternating with deflation totalling 30 minutes and control group;without RIPC.Intervention group received RIPC in three consecutive hemodialysis sessions.Blood samples were taken before the first session and after the third consecutive dialysis session. BUN for calculation of single pool Kt/v, ultra sensitive I troponin and irisin were measured to evaluate dialysis adequacy and myocardial injury.To evaluate inflammatory profile were measured TNF, selenoprotein, tioredoxin, NF kB.

Results: A total of 14 patients were selected with 50% of men. About 64.3% had diabetes. Troponin levels were not affected by the RIPC intervention with a p=0.281. The difference between the moments of blood collection of each biomarker was not affected by the RIPC . Spearman's correlation test showed a p value of 0.558 between irisin and troponin.

Inflammatory biomarkers did not have statistical difference between the time of collection of the sample and neither between RIPC and control group. Only interleukin 6 showed a p= 0.039 analysing the moments of collection and the occurrence or not of RIPC.

Conclusions: In conclusion despite being a promising myocardial injury biomarker, irisin was not affected by hemodialisys in end stage renal disease. Moreover, RIPC did not affect its levels independently of the moment of the collection (before or after).

FR-PO883

Prognostic Significance of Hemodynamic Parameters in Hemodialysis Patients Ferruh Artunc,[1] Bjoern Friedrich,[2] Nils Heyne,[1] Stefanie Haag.[1] *[1]Internal Medicine, Div of Nephrology, Univ Hospital, Tuebingen, Germany; [2]Nephrology Center, Leonberg, Germany.*

Background: Hemodialysis (HD) patients have a high mortality that mainly results from cardiac impairment. Using an ultrasound dilution device various hemodynamic parameters can be measured during a HD session. So far, there is no data regarding the prognostic significance of these parameters.

Methods: We conducted a prospective cross-sectional study in 185 stable HD patients and measured cardiac index (CI), access flow (AF) and central blood volume

index (CBVI) using the Transonic HD03 monitor at the beginning and end of a single HD session. In addition, we calculated systemic CI (SCI=CI-AF) and oxygen delivery index (DO_2I=SCI*hemoglobin*1.34). Survival analysis was performed after a median follow-up of 606 (interquartile range 593;621).

Results: During follow-up 33 patients (18%) died. Compared to the survivors, deceased patients tended to have a lower CI (P=0.09) and had a significantly reduced SCI and DO_2I (P=0.02 and 0.002, resp.). Drop in CI, SCI and DO_2I at the end of HD (ΔCI, ΔSCI und ΔDO_2I) was significantly higher in deceased patients. In contrast, AF, CVBI and hemoglobin was not different between survivors and deceased patients. Receiver-operator-characteristic (ROC) analysis revealed area-under-the-curve (AUC) values for the endpoint death of 0.68 for DO_2I (P=0.001) and 0.65 for SCI (P=0.013). AUC for ΔCI, ΔSCI and ΔDO_2I ranged between 0.62 and 0.63 (P=0.02-0.03). The combination of two parameters such as CI with ΔCI or SCI with ΔSCI or DO_2I with ΔDO_2I increased AUC values substantially (0.71-0.75). In addition, cox regression confirmed significant survival benefit at higher DO_2I and lower ΔCI, ΔSCI and ΔDO_2I.

Conclusions: This study is the first to show a prognostic significance of hemodynamic parameters in HD patients. Systemic CI and oxygen delivery index at rest as well as drop of these parameters at the end of HD were associated with increased mortality. The results underscore the prognostic relevance of cardiac function for the survival of HD patients.

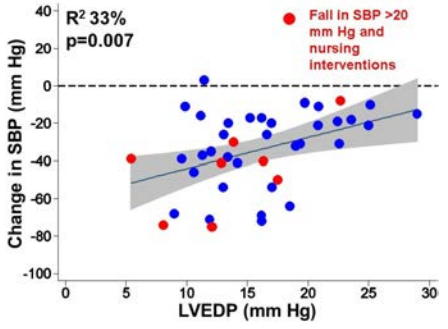
FR-PO884

Non-Invasive Left Ventricular End-Diastolic Pressure Measurement in Hemodialysis Patients and Intradialytic Hypotension Tariq Shafi, Bernard G. Jaar, Luis F. Gimenez, Chloe F. Knight, Seungyoung Hwang, Naya El Hage, Surekha Uma Mullangi, Josef Coresh, Harry A. Silber. *Johns Hopkins Univ.*

Background: Assessment of volume status remains highly subjective and is a major challenge in managing dialysis patients. We tested a novel hand-held device that provides non-invasive assessment of left ventricular end-diastolic pressures (LVEDP), an important indicator of left ventricular volume/pressure overload. We hypothesized that a low LVEDP at the start of hemodialysis (HD) will be associated with intradialytic hypotension.

Methods: We recruited HD patients from 4 Baltimore area dialysis units. Baseline data collected includes demographics, medical history, KDQOL-36, NYHA dyspnea scale, intra/post dialysis symptoms, predialysis metrics [LVEDP, bioimpedance, blood pressure (BP)] and echocardiogram. We assessed the association of predialysis LVEDP with change in systolic BP (SBP) during dialysis (lowest SBP – predialysis SBP) and hypotension episodes requiring nursing interventions.

Results: In the first 45 participants (mean age 60 years, 58% male, 87% Black), median [25th, 75th percentiles] for predialysis LVEDP was 16 mmHg [2, 20], interdialytic weight gain (IDWG) was 1.8 kg (1.1, 2.7) and SBP was 147 mmHg [134, 162]. Significant fall in SBP (≥20 mmHg) was common and occurred in 32 (71%) patients of whom 7 (16%) also required nursing interventions. Predialysis LVEDP was associated with fall in SBP during dialysis (p=0.007) and intradialytic hypotension requiring nursing interventions (p=0.04). Predialysis SBP (p=0.3), IDWG (p=0.4) or bioimpedance water measurement (p=0.5) were not associated with intervention requiring intradialytic hypotension.



Conclusions: Our findings suggest that non-invasive LVEDP measurement can provide an objective assessment of volume status and identify HD patients at risk of intradialytic hypotension.

Funding: NIDDK Support

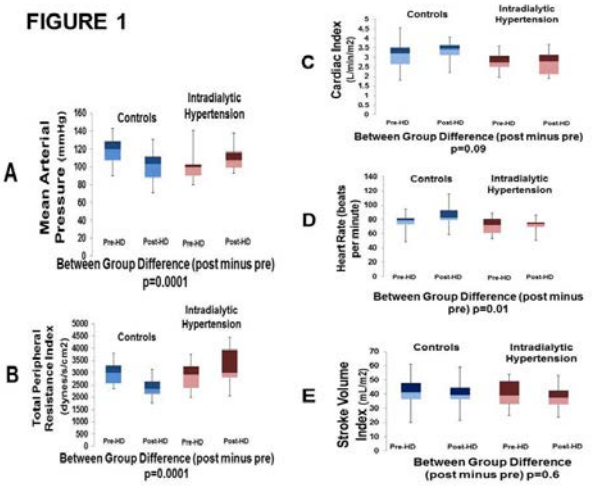
FR-PO885

Measurements of Extracellular Volume and Cardiovascular Hemodynamics in Patients with Recurrent Intradialytic Hypertension Peter N. Van Buren, Javier A. Neyra, Robert D. Toto. *UT Southwestern.*

Background: Intradialytic hypertension (IH) is a recurrent phenomenon in some hemodialysis (HD) patients and is associated with increased mortality. Both extracellular volume overload and vascular resistance surges have been separately observed in patients with intradialytic blood pressure (BP) increases. We simultaneously compared pre-HD, post-HD, and changes in body fluid and hemodynamics in patients with recurrent IH and HD controls.

Methods: We used whole-body bioimpedance spectroscopy and impedance cardiography to compare pre-HD, post-HD, and intradialytic changes in total body water (TBW) and extracellular water (ECW), as well as cardiac index (CI) and total peripheral resistance index (TPRI) in 18 patients with recurrent IH and 18 hypertensive HD controls with intradialytic BP decreases.

Results: During screening, the mean systolic BP before and after HD was 165 (18) and 138 (2.1) mmHg in controls and 141 (17) and 162 (16.2) mmHg in IH patients. During the study, there were between group differences in the change in MAP, TPRI and heart rate from pre to post dialysis, but not in CI or stroke volume index.



The ECW/TBW ratio was higher in IH patients before and after dialysis.

	Controls (n=18)	IH (n=18)	p-value
PRE-HD			
TBW (L)	48.2 (11)	46.5 (10)	0.6
ECW (L)	21.6 (5)	22.0 (5)	0.8
ECW/TBW	0.453 (0.05)	0.478 (0.03)	0.05
POST-HD			
TBW (L)	45.2 (11)	43.6 (9)	0.7
ECW (L)	19.1 (4)	20.1 (5)	0.5
ECW/TBW	0.427 (0.04)	0.461 (0.03)	0.01

There was a trend for changes in ECW and ECW/TBW from pre- to post-dialysis to be smaller in IH patients than controls (p= 0.06 and 0.1, respectively).

Conclusions: Recurrent IH is associated with higher post-HD extracellular volume and TPRI. Intradialytic TPRI surges likely account for the vasoconstrictive state post-HD, but intradialytic fluid shifts may contribute to the volume expanded state post-HD.

Funding: NIDDK Support

FR-PO886

Adrenal Insufficiency (AI) Is Highly Prevalent and May Be Associated with Intradialytic Hypotension(IDH) in Hemodialysis(HD) Patients Eunjung Kim,[1] Myung Jin Choi,[2] Jung-Woo Noh,[3] Dong Ho Shin,[4] Ja-Ryong Koo.[1] *[1]Hallym Univ, Dongtan; [2]Chuncheon; [3]Kangnam; [4]Gangdong.*

Background: Many maintenance HD patients had been chronically exposed to pharmacologic dose of steroid for the underlying kidney disease or various coexisting disease. We evaluated prevalence, risk factor and clinical impact of AI as a possible cause of IDH in HD patients.

Methods: Among 106 HD patients, 10 patients on current steroid treatment were excluded and remaining 96 patients were studied. Adrenal function was evaluated during HD by high dose ACTH stimulation test. AI was defined by baseline serum cortisol<10 μg/dL and ACTH stimulated maximal serum cortisol<18 μg/dL. Status of previous steroid exposure was identified through the evaluation of medical record and history about underlying, coexisting disease, medications and injections. IDH was defined by symptomatic decrease in systolic BP≥20 mmHg and the mean IDH event during 6 consecutive HD sessions was calculated. In selected patients with IDH and AI who agreed to steroid replacement, change in the incidence of IDH before and after steroid treatment was ascertained.

Results: The prevalence of AI was 36.5% (73.5% in 34 patients with previous steroid exposure vs 16.1% in 62 patients without steroid exposure). There was no difference in the prevalence of AI according to the type of underlying kidney disease (diabetes 32.0%, glomerulonephritis 40.5%). However, the patients with coexisting disease (gout, osteoarthritis, connective tissue disease)had significantly higher prevalence of AI as compared with the patients without coexisting disease (81.3% vs 20.6%). 33 (34.4%) patients had one or more(mean 2.30±1.13) IDH events during 6 consecutive HD sessions. The proportion of patient with IDH event was significantly higher in the patients with AI as compared with the patients without AI(48.6% vs26.2%). Moreover,in 10 IDH patients with AI who treated by steroid, IDH occurred in only 3 patients after 4weeks of steroid replacement(mean 1.90±0.74vs0.30±0.48).

Conclusions: In HD patients, careful evaluation of medical record and history about coexisting disease, medications, and injections is required to find out underlying AI. Steroid replacement may be a therapeutic option in IDH patient with AI.

FR-PO887

Pneumatic Compression during Hemodialysis May Avoid Hypotension
Valeria Regina C. Alvares,[1] Camila Dosse,[1] Bruno Gualano,[2] Ana Lucia S. Pinto,[2] Benedito J. Pereira,[1] Rosa M.A. Moyses,[1,3] Rosilene M. Elias.[1] *[1]Nephrology, Univ de Sao Paulo, São Paulo, Brazil; [2]Rheumatology, Univ de São Paulo, Brazil; [3]Univ Nove de Julho (UNINOVE), Brazil.*

Background: Intradialytic hypotension (IDH) is still the most common complication during chronic hemodialysis (HD), and is associated with increased mortality. As the main source of extracellular fluid removed during HD is the legs, we hypothesized that exercise and pneumatic compression during the first hour of HD would reduce IDH, by providing higher venous return and preserving central blood flow.

Methods: We prospectively studied 21 patients (13 men) who were submitted to a baseline cicloergoespirometry and undergone three consecutive random first-week HD session: control, pneumatic compression and intradialytic exercise (cicloergometry). Data from segmental bioelectrical impedance and blood pressure measurement each hour during HD were assessed. IDH was defined as a drop in mean arterial pressure (MAP) ≥20 mmHg with symptoms.

Results: When comparing control, exercise and pneumatic compression, we found no difference in ultrafiltration rate (p=0.628), delta of weight (p=0.415), and percentage of urea reduction (p=0.941). Maximum oxygen uptake (VO_2 peak) was 23.0 ± 6.2mL/kg/min. MAP pre dialysis was similar in the three conditions (p=0.245). The delta of total body water, intra and extracellular volume was similar in control, exercise and pneumatic compression (p=0.209, p=0.348 and p=0.467, respectively). The delta of legs and trunk water content was also similar among conditions (p=0.235 and p=0.817, respectively). The delta of MAP was -5.9 ± 17.2, -9.6 ± 18.0 and -0.2 ± 13.7 mmHg in control, exercise and pneumatic compression, respectively (p=0.152). IDH occurred in 9 (43%), 8 (38%) and 5 (24%) patients in control, exercise and pneumatic compression, respectively (p=0.014);post test revealed that pneumatic compression presented less IDH than control and exercise.

Conclusions: Pneumatic compression during the first hour of dialysis was associated with less IDH, albeit no effect on fluid parameters, including preservation of central fluid was observed. Further studies are required to better understand physiological and hemodynamic changes in patients during HD.

FR-PO888

The Effects of Intradialytic Volume Changes on Cardiovascular Hemodynamics
Nathan W. Levin,[1] Marcia H.F. Goulart de Abreu,[2] Lucas Espíndola Borges,[2] Helcio Antonio Tavares Filho,[2] Rabia Sarwar,[3] Surendra K. Gupta,[3] Shaul Lev,[4] Caroline Williams.[3] *[1]Mt Sinai School of Medicine, NY; [2]Biocor Hospital Belo Horizonte MG, Brazil; [3]Queens Artificial Kidney, NY; [4]Rabin Medical Center, Israel.*

Background: Intradialytic hypotension (IDH) is a major clinical problem in chronic hemodialysis. A novel noninvasive regional impedance cardiography device was used to evaluate IDH in a quality improvement project.

Methods: The device (NICaS, NI Medical, Israel) provided repeated cardiac power index (CPI) and total peripheral resistance index (TPRI) measurements over 4-5 treatments.

Results: N=52 patients. In 184 non-IDH treatments/ 237, SBP decreased from 141±24 to 130±20 mmHg. CPI and TPRI decreased by 18±19% and 2±27% respectively. IDH occurred in 53 (22%) treatments with mean SBP decreasing from 134±20 to 92±11 (P>0.001). IDH treatments were divided into 3 subgroups according to hemodynamic trends: **1)** ***Solitary cardiac power reduction*** (n=26, 49% of treatments): CPI decreased 42±11%, (0.64±0.14 to 0.37±0.07 [w/m^2]) (P>0.001) with insignificant TPRI reduction. SBP decreased from 130±23 to 89±12 (P>0.001). **2)** ***Solitary vasodilatation*** (n=11, 21% of treatments): TPRI decreased 31±6% (3,155±962 to 2,168±639) [dyn*sec/cm^5/m^2]) (P>0.001 with insignificant change in CPI. SBP decreased from 134±16 to 102±7 (P>0.001). **3)** ***Mixed hemodynamics*** (n=16, 30% of treatments): CPI decreased 34±9% (0.66±0.13 to 0.44±0.10 (P>0.001) and TPRI decreased 32±7% (2,431±547 to 1,645±306 (P>0.001). SBP decreased from 140±17 to 90±10 (P>0.001). The proportion of diabetic patient treatments was greater in the low TPRI than in the low CPI groups (81% vs 42%, P<0.005).

Conclusions: 1) This technology provides quantitative insights into the major proximate causes of IDH, which are reductions in CPI and/or in TPRI**. 2)** *Potential actions*before onset of hypotension include lowering UFR to maintain falling cardiac preload and CPI, and using vasopressors (e.g.midodrine) or cooling, to increase TPRI. These approaches could prevent occurrence of IDH. **3)** The apparent effect of diabetes with presumed autonomic dysfunction, in the low TPRI subgroups (2 and 3), warrants the investigative use of prophylactic vasoconstriction.

FR-PO889

Oxygen Extraction Ratio (OER): A Marker of Haemodynamic Stress in Haemodialysis (HD)?
Sandro Mazzaferro,[1] Silverio Rotondi,[2] Maria Luisa Muci,[2] Lida Tartaglione,[1] Luciano Carbone,[2] Marzia Pasquali.[3] *[1]Scienze Cardiovascolari, Respiratorie, Nefrologiche, Anestesiologiche e Geriatriche, Sapienza Univ, Rome, Italy; [2]Nephrology and Dialysis Unit, ICOT Hospital, Latina, Italy; [3]Nephrology and Dialysis Unit, Policlinico Umberto I, Rome, Italy.*

Background: Cardiovascular stress and symptoms occurr in HD sessions. Monitoring Blood Volume (BV) allows prevention but does not measure the stress entity. The OER (n.v.25-30%), used to estimate tissue oxygenation, mirrors adaptation to hypoxia/hypoperfusion. We hypothesized that, if detectable, its changes during HD could reflect hemodynamic stress.

Methods: OER (periferal O_2 saturation (SO2)/central venous SO_2, respectively measured with an oxymeter and a gas analyser) was measured in patients with CVC. We sampled OER before, 15', 30', 60', 120' and at the end of HD in each patient in three consecutive HD (long and short intervals) with an UF rate <10 ml/kg/h. We recorded BP, HR, UF, BV and symptoms.

Results: In the 10 patients enrolled (age 72±14 y, M/F=2/8, HD since 38±41 months) we observed overlapping changes in OER (p=n.s.) in the 3 consecutive sessions and thus averaged the values. OER increased progressively from 35±7% to 47±8% (p<.0002), in front of UF (-2,2±0,79 Kg, BV reduction (-8±4%, p<.0001), no change in BP or HR (table 1), no symptoms.

	Basal (M±SD)	15' (M±SD)	30 '(M±SD)	60' (M±SD)	120' (M±SD)	End of HD(M±SD)	ANOVA
O.E.R., %	35±7	40±9	42±7	42±7	43±9	47±8	.0002
SBP, mmHg	121±16	126±21	126±19	128±18	121±16	122±22	n.s.
DBP, mmHg	69±13	68±12	73±16	73±15	70±13	71±14	n.s.
HR, bpm	67±10	65±10	65±15	66±11	67±10	70±10	n.s.
BV, %	0	-2±1	-3±2	-5±2	-6±3	-8±4	.0001
UF, Kg	0	0.2±0.08	0.3±0.12	0.6±0.21	1.2±0.4	2.2±0.79	.0001
OER= Oxygen extration ratio; SBP= Systolic blood pressure; DBP= Dyastolic blood pressure; HR= Heart rate; BV= Blood volume; UF= Ultrafiltration							

Conclusions: OER, already increased before HD, showed a progressive increment during session, reflecting haemodynamic adaptation. With stable BP and no symptoms, OER significantly increases during HD and could represent a useful tool to monitor hemodynamic stress.

Pre-Dialysis IVC Diameter Predicts Ultrafiltration Goal in Hospitalized ESRD Patients
Azeem Mohammed,[1,3] Michael Ibe,[1,3] Jennifer L. Waller,[2] Pascha Schafer,[1,3] Matthew J. Diamond,[1,3] John Jason White,[1,3] Lu Y. Huber,[1,3] N. Stanley Nahman.[1,3] *[1]Dept of Medicine, Augusta Univ, Augusta, GA; [2]Dept of Biostatistics and Epidemiology, Augusta Univ, Augusta, GA; [3]Dept of Medicine, Charlie Norwood VAMC, Augusta, GA.*

Background: Estimates of hemodialysis(HD) ultrafiltration(UF) goals are based on volume status. Usually UF goals are empiric, with hypotension on HD indicating "dry weight." Bedside ultrasonography can determine inferior vena caval diameter(IVCD) which may predict right ventricular (RV) pre-load. We theorized that IVCD may enhance assessment of volume status and help guide UF goals for HD.

Methods: ESRD inpatients without known RV failure were studied. Prior to HD, hypertension(HTN) (BP> 140mmHg) and presence of edema were recorded and UF goal assigned. A nephrology fellow, trained to assess IVCD using a GE Sonosite machine, measured IVCD at its entry into the right atrium prior to and following HD. Linear regression(LR) was used to examine the association between pre-IVCD and volume removal.

Results: 20 patients were studied from Jan-May 2016. Physical findings:edema(65%), HTN(70%) and both(45%). Groups were defined as euvolemic (no edema, no HTN N=3) or hypervolemic(edema and HTN N=10).

Group	Pre SBP	Post SBP	Pre IVCD	Post IVCD	Change in IVCD	UF removed
Euvolemic	113±13	114±9	1.47±0.3	1.33±0.4	0.1±0.1	0.3±0.6
Hypervolemic	168±23	142±16*	2.44±0.4	2.01±0.4*	0.4±0.2	2.07±0.5
All patients	152±27	133±17*	1.74±0.4	2.07±0.5*	0.3±0.2	3.75±0.98
*p < 0.05 when compared to pre-dialysis levels						

Table 1 shows pre and post-dialysis SBP(mmHg), IVCD (cm), change in IVCD (cm) and UF removed (L). For all patients, a correlation between pre-SBP and IVCD (r=0.7801) and pre-SBP and volume removed (r=0.7719) was found. In edematous patients LR showed for every 1 cm change in pre IVCD the amount of volume removed increased by 1.43 kg controlling for edema and pre-SBP.

Conclusions: IVCD is a non-invasive, objective marker of pre-load in hypervolemic HD inpatients, is well tolerated, and correlates with UF removal. IVCD augments volume assessment and may help guide determination of UF goals in HD.

FR-PO891

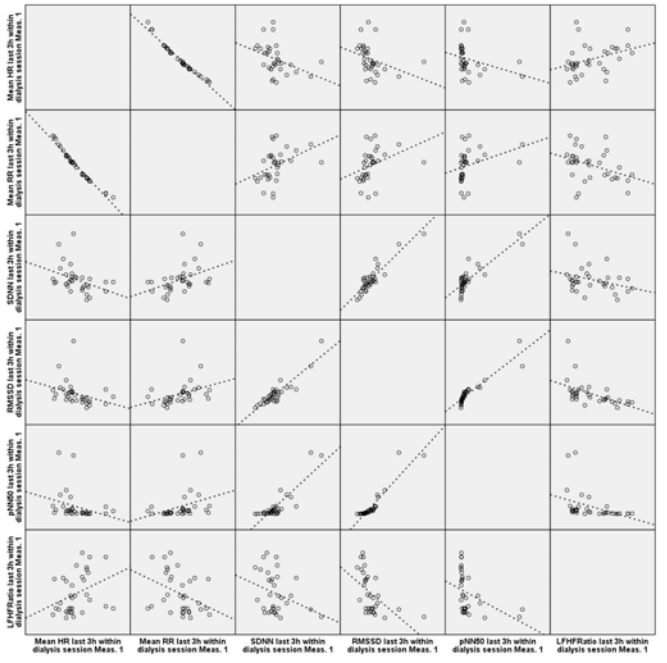
Heart-Rate-Variability in Haemodialysis
Joachim H. Beige. *Nephrology and Dialysis, Hospital St. Georg, Leipzig, Germany.*

Background: Heart rate variability (HRV) is a measure of time intervalls between heartbeats and characterizes the ability to adapt to (patho)physiological conditions. It can be used hypothetically to assess the sympathetic acitivity during haemodialysis (HD). Because only sparse infomation about HRV during HD is available we investigated the course of HRV during and after HD and it´s correlation to anthropometrical and HD data.

Methods: Continous measurement of five recognized HRV measures (meanRR-dist., SDNN, RMSSD, pNN50, LF/HF Ratio) in time slots of 3 hours during and immediately after HD at 2 consecutive HD sessions of 34 patients by long-term ECG including artifact flattening. During these 68 sessions, no intradialytic morbid events (IME) appeared.

Computation of descriptive statistical analyses (ANOVA, linear regression, population discrimation) was done by SPSS vs. 21 package including analysis of HRV precision by repeated measures by paired t-test.

Results: The highest correlation between HRV markers (all p<0.0001) in consecutive HD sessions (i.e. the best precision) was found for RMSSD during HD (T=0,856) and PNN50 after HD (T=0,929). Correlation of HRV Marker with each other was highest for pNN50 and RMSSD.



Linear regression analyses of pNN50 und RMSSD with age, gender, dialysis vintage, comorbidities, ESA index, PO4, Hbg, KtV, ultrafiltration (UF), dry weight and blood pressure yielded only one weak association between UF and pNN50 during HD (T=2,72, p=0,035).

Conclusions: All HRV markers showed high measurement precision and no interdependency with anthropometrical data. Dialysis-related HRV showed similarity to data from 695 healthy individuals (Sammito et al.). Relationship with (not appeared) IME was not studied and no conclusion about predictibility of HRV against IME can be drawn. However, the relationship with UF points to a thinkable usefullness of HRV as HD biofeedback measure. Further investigations of time courses and patterns will be conducted.

FR-PO892

On-line Hemodiafiltration: Which Mode for Better Cost Effectiveness

Panagiota E. Giannou, Athanasia Kapota, Aikaterini Damianaki, Aglaia Chalkia, Dimitrios Petras. *Nephrology Dept, Hippokration General Hospital, Athens, Greece.*

Background: According to the latest studies there are benefits from the use of on line hemodiafiltration (olHDF), especially in the postdilution mode. Generally, this advantage is due to the fact that postdilution olHDF results in better removing of low and medium molecular weight substances. However for successful and uncomplicated postdilution olHDF, high blood flow rates (typically >350 mL/min) are needed. This study aimed to assess the efficacy of removal of low and medium molecular weight substances when blood flow rates<350 ml/min are used, combining various modes of online hemodiafiltration / hemofiltration (olHF).

Methods: We studied 30 patients who were subjected to 4 different dialysis modes. The duration of all dialysis sessions was 4 hours and a high flux filter (PEPA membrane, surface 2,1m^2) was used with blood flow rates from 320 to 350 ml/min. The blood flow rates were the same in each mode for each patient. The 4 groups were: A) a combination of predilution olHDF (2 hours) and predilution olHF (2hours) by giving replacement fluid (RF) at a replacement rate (RR) of 80%, B) predilution olHDF by giving RF at RR of 80%, C) a combination of postdilution olHDF (2 hours) and postilution olHF (2 hours) by giving RF at a RR of 20%, D) postdilution olHDF by giving RF at a RR of 20%. The percentage of change of β2 microglobulin and urea during every session was measured.

Results: No statistical significance in β2 microglobulin for all methods (percentage of change per method A: 75% B: 70% C: 72.5%; D: 78.7%) was found. Instead the percentage of change of urea was statistically significant lower (p <0.01) in method A and C relatively to others. No statistically significant difference for urea in method B and D was found.

Conclusions: Thus, for patients with blood rate <350 ml/min, the use of predilution olHDF by giving RF at a RR of 80% is effective, providing sufficient removal of uremic toxins (low and medium molecular weight substances) without the disadvantage of filter malfunction (increased transmembrane pressure, filter clotting etc.),as seen usually in olHDF postdilution in these blood flow rates.

FR-PO893

Clinical Effectiveness of Intermittent Infusion Hemodiafiltration Using Backfiltration of Ultrapure Dialysis Fluid Compared with Predilution On-Line Hemodiafiltration: A Prospective, Multicenter, and Controlled Trial

Michio Mineshima, Kei Eguchi. *Clinical Engineering, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Intermittent Infusion Hemodiafiltration (I-HDF) has been introduced to improve the peripheral circulation of dialysis patients and to reduce the occurrence of hypotension during a hemodialysis treatment. The clinical effectiveness of I-HDF, however, has not been clarified in comparison with those in other on-line HDF therapies.

Methods: A prospective, multicenter, parallel group comparative trial was carried out to reveal the clinical effectiveness of I-HDF compared with predilution on-line HDF (Pre-HDF) that is the most popular on-line HDF therapy in Japan at present. Patients were allocated to two groups after matching for age(±5y.o.), dry weight(±5kg) and with/without diabetes. After obtained informed consent, 36 patients, namely 18 pairs, participated in this clinical trial. During the trial, we evaluated the clinical condition and quality of life (QOL) of the patients and solute removal characteristics.

Results: The results showed no difference in clinical condition and QOL scores between two groups. Reduction ratio of the systolic blood pressure originally showed no difference between two groups but it decreased slightly as the trial proceeded after changing from hemodialysis therapy. There was also no difference in the number of treatments by medical staff, but this also significantly decreased as the trial proceeded in both groups. On the other hand, the Pre-HDF group demonstrated significantly higher removal rates of β2-microglobulin and α1-microglobulin than in the I-HDF group. As the same time, albumin leakage amount in a treatment was also significantly larger in Pre-HDF than that in I-HDF.

Conclusions: In conclusion, the clinical condition and QOL of the patients undergoing I-HDF was not inferior to those having Pre-HDF. Furthermore, Pre-HDF demonstrated a significantly higher removal rate in the middle and larger solutes and larger albumin leakage in comparison with I-HDF.

FR-PO894

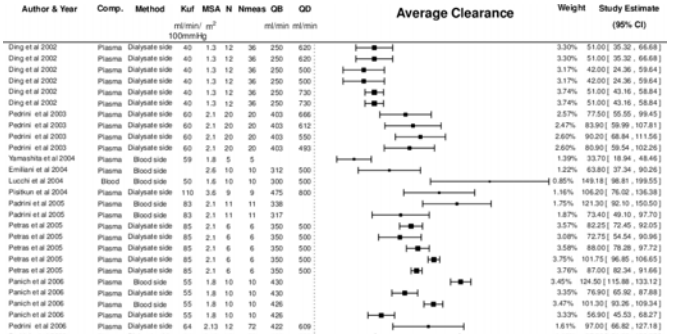
Beta-2 Microglobulin Removal by Convective Dialysis: A Meta-Analysis

Ahmed H. Alaini,[1] Maria-Eleni Roumelioti,[1] Gregory S. Trietley,[2] Thomas D. Nolin,[2] Yue-Harn Ng,[1] Zhi Xu,[1] Mark L. Unruh,[1] Christos Argyropoulos.[1] *[1]Internal Medicine-Nephrology, UNMHSC, Albuquerque; [2]Pharmacy and Therapeutics, Univ of Pittsburgh, Pittsburgh.*

Background: Accumulation of Beta-2 Microglobulin (B2M) in ESRD patients is associated with cardiovascular and infectious mortality. We conducted a meta-analysis of data about the efficacy of convective dialysis therapies (CDT) i.e. (hemodiafiltration, HDF or hemofiltration, HF) in removing B2M.

Methods: We used ProQuest to search EMBASE and MEDLINE, for randomized controlled trials and observational studies in CDT between 2001-2013. Clearance measurements at blood side and/or dialysate side were included and reported via random effects meta-analysis.

Results: We identified 36 HDF and 4 HF studies. Average clearance was 90 ml/min with substantial heterogeneity among studies.



In meta-regression (table 1) we found that whole blood and dialysate side clearances were higher and lower respectively compared to plasma clearance. Higher blood and substitution flow rates were significantly associated with higher clearance of B2M.

	estimate	se	p-value
Intercept	26.2	26.7	0.3
Membrane Kuf (ml/min/100mmHg)	0.3	0.2	0.1
Clearance Type (ref=blood side)			
Average Dialysate+Blood Side	34.2	27.3	0.2
Dialysate	-36.9	6.9	**<0.001**
Blood vs. plasma clearance	57.7	8.2	**<0.001**
Blood flow (ml/min)	0.2	0.1	**0.02**
Treatment Duration (min)	-0.05	0.03	0.1
Substitution fluid rate (ml/min)	0.1	0.04	**<0.001**
Secular trend (year)	-0.2	2.04	0.9

Conclusions: There is substantial heterogeneity in the middle molecule clearance by CDT related to both methodological (type of measurement) and operational characteristics (flow rates). Future studies should standardize methodology for these measurements to highlight clinically important differences related to the dialysis technique.

FR-PO895

The Standardization of Convective Volume to Body Water Predicts the Efficacy of Convective Transport in On-Line Hemodiafiltration

Nicolás Macías, Alba Santos, Almudena Vega, Soraya Abad, Ines Aragoncillo, Santiago Cedeno Mora, Ana M. Garcia Prieto, Tania Linares, Juan Manuel Lopez Gomez, Marian Goicoechea. *Nephrology, Hospital Gregorio Marañón, Madrid, Spain.*

Background: Online hemodiafiltration(OL-HDF) with high convective volumes(CV) has been associated with improved patient survival compared to conventional hemodialysis, explained by better removal of middle-sized uremic toxins. The purpose of this study was to determine the corporal composition parameters influencing the efficacy of CV in the removal of different molecular weight(MW) molecules.

Methods: Demographic data, corporal composition with bioimpedance, dialysis features and reduction rates of different MW-molecules (urea–60Da–, beta-2microglobulin(B2M)–11.8KDa–, cystatin C–13KDa–, myoglobin–17.2KDa–, prolactin–23KDa– and alpha-2macroglobulin–725KDa–) in a 4-hour postdilution OL-HDF session were collected in 61 patients.

Results: The mean of CV was 30.6 ± 4.7 L/session. We observed a significant negative correlation of B2M, cystatin-C, myoglobin and prolactin reduction rates with body surface area, weight, total body, extracellular(ECW) and intracellular water (ICW), lean tissue mass and body cellular mass. The multivariable regression analysis identified ECW and ICW as the only corporal composition factors independently associated to the relative elimination of B2M (Beta:-.801, p0.002 for ECW and Beta:-1.710, p0.001 for ICW), cystatin-C (Beta:-.656, p0.010 for ECW and Beta:-1.511, p0.004 for ICW) and myoglobin (Beta:-.745, p0.014 for ECW and Beta:-2.103, p0.001 for ICW), in addition to CV. Only the ratio CV/ECW was an independent predictor for higher elimination of B2M (Beta:.866, p<0.001), cystatin-C (Beta:.745, p0.001) and myoglobin (Beta:.662, p0.008). The standardization with total body water(TBW) as the ratio CV/TBW showed similar significant results with weaker association.

Conclusions: Extracellular and intracellular water are independently associated to the reduction of medium-sized molecules. The ratio "convective volume/extracellular water" predicts higher efficacy of convective transport. Adjust the convective volume to patient features could be useful to monitor the efficacy of OL-HDF and to prescribe individualized therapies.

FR-PO896

Impact of Different Low Molecular Weight Heparin Administration Routes in High-Flux Hemodialysis and Online Hemodiafiltration

Amir Shabaka, Jose A. Herrero, Marisol Poma Tapia, Fernando Tornero. *Nephrology, Hospital Clinico San Carlos, Madrid, Spain.*

Background: Pre-filter administration of low molecular weight heparin(LMWH) in the arterial line of hemodialysis(HD) circuits during high-flux HD(HF-HD) and online hemodiafiltration(OL-HDF) can lead to clearance of LMWH. The aim of this study was to evaluate whether different administration routes of enoxaparin can affect its efficacy.

Methods: 15 patients, 13 on OL-HDF and 2 on HF-HD. All sessions were done with 1.8 m2 helixone dialyzer and each session lasted 4 hours. Baseline dialyzer and venous chamber clotting were evaluated by administration of enoxaparin through the arterial line(AL) at the start of HD, and for 3 consecutive weeks by administration of enoxaparin through the venous line 2 minutes before connection with the following dosing schedule: Week 1 with 100% of the AL dose(V100), week 2 with 75% of the AL dose(V75), week 3 with 50% of the AL dose(V50). In each session filter clotting was assessed with a semiquantitative visual scale (0= no clotted capillaries, 1= <5% clotted capillaries, 2= 5-25% clotted capillaries, 3= >25% clotted capillaries). Anti-Xa levels were measured at 0, after 60 and 240 minutes of HD. In each session we determined KT, processed blood volume(PBV), and infusion volume in patients with OL-HDF.

Results: There were no significant differences in dialyzer clotting between AL (0=46.7%, 1=40%, 2=13.3%, 3=0%), V100 (0=73.3%, 1=20%, 2=6.7%, 3=0%)(p=0.155) and V75 (0=66.7%, 1=20%, 2=6.7%, 3=6.7%)(p=0.388). Dialyzer clotting was significantly higher with V50 than with AL, V75 and V100 (0=0% 1=26.7%, 2=53.3%, 3=20%) (p<0.001). Similar differences were observed regarding venous chamber clotting. Anti-Xa levels were significantly higher with V100 (60 min=0,525, 240 min= 0,262 IU/mL) than with AL (60 min=0,784, 240 min=0,428 IU/mL)(p=0,02). There were no differences in Anti-Xa levels between AL and V75 or V50. There were no differences in KT, PBV and infusion volume in OL-HDF between the different forms of LMWH administration.

Conclusions: Administration of LMWH through the venous line before the start of hemodialysis allows for a 25% reduction in the dose compared to administration through the arterial line, both in HF-HD and OL-HDF.

FR-PO897

Protein-Bound Toxin Removal with Novel High Cut-Off Membrane Dialyzer in Limited Blood Flow Online Hemodiafiltration (OL-HDF) versus High-Efficiency OL-HDF with High-Flux Dialyzer

Wanjak Pongsittisak,[1] Khajohn Tiranathanagul,[1] Maneerut Limjariyakul,[2] Supeecha Wittayalertpanya,[2] Paweena Susantitaphong,[1] Nattachai Srisawat,[1] Somchai Eiam-Ong,[1] Kearkiat Praditpornsilpa.[1] *[1]Medicine-Nephrology, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; [2]Pharmacology, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Protein-bound toxins especially p-cresol (pCS) which could not be removed by hemodialysis (HD) are obviously correlated with high mortality in HD patients. High-efficiency post-dilution online hemodiafiltration (OL-HDF) using high-flux dialyzer which requiring high blood flow rate has been reported to enhance pCS removal and improve patient survival. Unfortunately, the majority of patients could not reach that high blood flow because of the limitation of their arteriovenous access. Herein, we innovated the effective OL-HDF modality for this situation by integrating the novel high cut-off membrane dialyzer (HCM) into pre-dilution OL-HDF.

Methods: This randomized crossover control study was conducted in 9 OL-HDF patients to compare the two week periods between the new modality (limited blood flow OL-HDF with HCM) and the control (high-efficiency OL-HDF). The removals of small and middle molecular weight uremic toxins as well as protein-bound uremic toxin were determined and compared. The pCS was measured by high performance liquid chromatography. The dialysate albumin loss and patient safety were also monitored.

Results: This new modality, OL-HDF with HCM, was safe and no adverse event was recorded. Its pCS removal in term of pCS reduction ratio (RR) was comparable with high efficiency OL-HDF [59.5 (IQR; 49.1, 62.6) vs. 54.7 (IQR; 48.6, 58.2) %, p=0.441]. The β2-microglobulin removal was significant higher in this new modality. Two techniques provided adequate and comparable small molecule removal. No patients developed hypoalbuminemia despite the higher dialysate albumin loss in the new modality.

Conclusions: This new OL-HDF with HCM which could apply to every dialysis patients provided effectively protein-bound uremic toxin removal comparable with high efficiency OL-HDF and could potentially provide the comparable good long-term survival.

FR-PO898

Immersion Can Enhance Fluid Redistribution and Prevent Intradialytic Hypotension- A Prospective, Randomized, Crossover Clinical Trial

Keren Doenyas-Barak, Ilia Beberashvili, Nedal Garra Garra, Shai Efrati. *Dept of Nephrology and Hypertension, Asaf Harofeh Medical Center, Zerifin, Israel.*

Background: Intradialytic hypotension (IDH) is an important cause for morbidity among hemodialysis (HD) patients. IDH occurs mainly when the ultrafiltration (UF) rate exceeds fluid redistribution from the extravascular to the vascular bed. Water immersion can be an effective method for hydrostatic pressure induced transfer of volume from the interstitium to the intravascular space. This randomized, crossover study evaluated the physiological and clinical effects of immersion on the occurrence of IDH.

Methods: Ten male HD patients, who had frequent IDH, defined as symptomatic hypotension occurring in more than 20% of the sessions were randomized to a 3 hour mid-week "wet" and "dry" HD session, in a crossover manner. The wet session was performed while immersed up to the neck in a 34ºC-35ºC bath, and the dry session was standard HD. UF goals were determined as the mean UF during the 10 sessions preceding the study ±10% according to body weight at admission, and the dialysis time was shortened to 3 hours instead of the usual 4. Symptoms, blood pressure (BP), atrial natriuretic peptide (ANP) and aldosterone blood levels were measured during the sessions. .

Results: Mean UF did not differ between the two sessions (2.99±0.64kg vs. 2.96±0.74kg in wet and dry sessions respectively). Symptomatic hypotension did not develop in any of the patients during the wet session, compared to 4 (40%) during the dry session. Systolic BP adjusted to UF was stable during the wet session, 0.22 (95% CI -0.27 to 0.70), P=0.38, but significantly decreased during the dry session, -0.68 (95%CI -1.24 to-0.11), P=0.02. Diastolic BP did not change during the sessions. Mean ANP significantly increased in the wet session, by 31.36 (95%CI 8.73 to 53.99), P=0.07, and slightly and insignificantly decreased in the dry session, by -21.66 (95% CI -52.59 to 9.25), P=0.167. Aldosterone blood levels did not change.

Conclusions: Delayed fluid redistribution during HD can be effectively reversed by immersion, with improved blood pressure stability and symptoms.

FR-PO899

Utility of Plasma b2-Microglobulin Levels for Estimating Residual Kidney Function without Urine Collection Yoshihiro Matsumoto, Kimitoshi Shiratori, Youichi Nojima, Yasushi Shimada. *Dept of Nephrology and Dialysis, Shizuoka City Hospital, Japan.*

Background: Residual kidney function (RKF) is associated with survival benefits in hemodialysis (HD) patients but cannot be assessed without urine collection. Plasma β2-microglobulin and cystatin C levels have been used to estimate kidney function in patients with renal insufficiency before dialysis therapy. We investigated the ability of these markers to estimate RKF in patients on HD.

Methods: Seventy-one patients undergoing incremental low-flux HD in a single center during 2008–2015 were enrolled. Blood was sampled before the first HD session of the week to estimate β2-microglobulin and cystatin C. Urine was collected 24 hours before the first HD session of the week. We assumed that creatinine and urea secretion per day divided by body weight before HD (Ucr and Uurea, respectively) corresponded to RKF regardless of their plasma levels, which are known to change significantly during urine collection. The relationships between plasma β2-microglobulin/cystatin C levels and Ucr/Uurea were explored.

Results: The average HD duration and urine volume were 17 (1–58) months and 1280 (350–3000) mL, respectively. Ucr and Uurea were closely correlated (r = 0.84). Ucr was more closely correlated with plasma β2-microglobulin levels (r = -0.74) than with cystatin C levels (r = -0.61) and urine volume (r = 0.62). Urea was also correlated with β2-microglobulin levels (r = -0.69), cystatin C levels (r = -0.51) and urine volume (r = 0.73).

Conclusions: Plasma β2-microglobulin levels before HD may provide better estimates of RKF than cystatin C. β2-microglobulin may be clinically useful for determining individual dialysis doses without the need for frequent urine collection in HD patients with RKF.

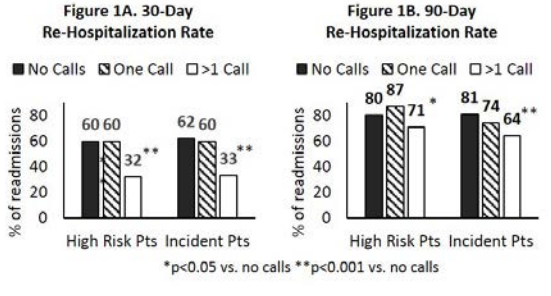
FR-PO900

Post-Hospital Case Management of Incident and High Risk Prevalent Hemodialysis Pts Reduces 30- and 90-Day Readmission Rates Rebecca L. Wingard,[1] Kathryn A. McDougall,[1] Billie Axley,[1] Andrew D. Howard,[2] Joelle Heilemann,[1] Sharon Deluca,[1] Sheetal Chaudhuri,[1] Hao Han,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Metropolitan Nephrology Associates, Clinton, MD.*

Background: 30-day readmission rates for West Virginia (WV) Fresenius HD incident pts (IPs, n=384, 1st 120 days of HD) and high risk prevalent pts (HRPPs, n=159, >=6 hospitalizations/yr) were high in 2014 at 55% and 60%, respectively. 90-day readmission rates were 80% for IPs and 85% for HRPPs. The Right TraC™ (RT) Program used post-hospital case management to reduce readmissions for IPs and HRPPs.

Methods: 26 Fresenius WV HD clinics were in RT 2/1/15 to 2/29/16. IPs, and HRPPs with high likelihood of >=6 hospitalizations/year (identified by an internally validated predictive model) were included. A telephonic RT case manager (RTCM) attempted contact with pt or caregiver weekly during 30 days post-hospital discharge (DC) to discuss DC instructions, facilitate follow-up appointments, and review strategies to manage medications, nutrition, dry weight, access issues, and anemia. For pts alive for 90 days post-hospital (n=205 IPs, 369 DCs; 310 HRPPs, 605 DCs), 30- and 90-day readmission rates were compared for pts who received no RTCM calls (29% for IPs; 27% for HRPPs) vs. one call (13% for IPs; 18% for HRPPs) or >1 call (58% for IPs; 55% for HRPPs) using two sample t-test.

Results: 30-day readmission rates for pts with no calls vs. >1 call were 60% vs. 32% for HRPPs (p<0.001) and 62% vs 33% for IPs (p<0.001) (Figure 1A). 90-day readmission rates for pts with no calls vs. >1 call were 80% vs. 71% for HRPPs (p<0.05) and 81% vs 64% for IPs (p<0.001) (Figure 1B). 30- and 90-day readmission rates for no calls vs 1 call were not significantly different.



Conclusions: Post-hospital telephonic case management was associated with fewer readmissions for IPs and HRPPs who received >1 phone call in the 30-day post-hospital period.

FR-PO901

Effect of Dialysis Potassium Bath on QT Interval during Hemodialysis Aamir Zuberi, Hafsa Z. Zuberi, Hassaan Patel, Maggie Dickens, Fatima Zuberi. *Nephrology, Wise Health System, Decatur, TX.*

Background: Sudden death accounts for nearly half of all cardiac deaths in dialysis patients.QT prolongation has been associated with cardiac arrhythmias that could lead to sudden cardiac death. Of interest is the question of effect of potassium concentration in dialysis solution on QT interval. This study was conducted to assess the effects of 2K and 3K dialysis baths on QT interval in stable hemodialysis patients in an outpatient dialysis facility.

Methods: Study was approved by the Institutional Review Board. Funding was provided by the dialysis provider, Wise Health System. EKGs were checked at the beginning and end of dialysis sessions. The following parameters were noted: age, gender, presence or absence of comorbidities including coronary artery disease and diabetes , dialysis treatment time, dialysis K concentration, pre-dialysis plasma K concentration, pre & post-dialysis corrected QT intervals (QTc), and pre- and post-dialysis change in QTc.

Results: We enrolled 79 patients, with a mean age of 62 years (range: 21-88 years). Male gender dominated the cohort 46/79 (58%). 50 (63%) patients had CAD. 48 (61%) had DM. Dialysis treatment time ranged from 2.75-4.5 hours with an average of 3.7 hours. Pre-dialysis QTc ranged from 408-574 milliseconds. Post- dialysis QTc ranged from 413-665 milliseconds. Pre-dialysis mean K was 4.7 mmol/L (range: 3.1 to 7.5 mmol/L). Of the 31 patients dialyzed with a 2K dialysis solution, mean QTc change was 202 milliseconds as opposed to 160 milliseconds in the 48 patients dialyzed with a 3K dialysis solution (p=NS). Subgroup analyses for duration of dialysis (>3.5 hours), pre-dialysis K (>4.5 mmol/L), CAD, DM and age>60 did not reveal any significant trends. Men were more likely to have a prolonged QTc (p=0.03). We observed an inverse relationship between pre-dialysis K and QTc (p=0.04).

Conclusions: Patients dialyzed with a 2K dialysis solution had longer QTc compared to patients dialyzed with a 3K dialysis solution. Men were more likely to have a longer QTc compared to women. Patients with lower pre-dialysis K were more likely to have longer QTc. Adjustments in dialysis solution K concentration could limit risk of life threatening arrhythmia in patients at risk of sudden cardiac death.

FR-PO902

Aiming for the Optimal Bicarbonate Prescription for Maintenance Hemodialysis Therapy in End-Stage Renal Disease Andreas Bozikas, Iliana Kiriakoutzik, Ioannis Petrou, Pinelopi Pisanidou, Theodoros Tourountzis, Nikolaos Georgilas, Panagiotis Pangidis, Sofia Spaia. *Nephrology, General Hospital, Thessaloniki, Greece.*

Background: Due to the gradual depletion of the body's buffers and rapid repletion during hemodialysis, many problems arise as a result of current treatment routine since both acidemia and alkalemia can be associated with adverse consequences. We compared the effect of higher doses of [HCO3] based dialysate to standard [HCO3] bath plus oral bicarbonate therapy.

Methods: 60 HD patients were evaluated according to their predialysis acid-base status before the 1st and the 2nd session of the week with a standard [HCO3] based dialysate of 35 mEq/l. Those with predialysis[HCO3]< 22 mEq/l were assigned against dialysis bath with[HCO3] levels (+2 mEq/l) for 2weeks (period A) and subsequently to the standard dialysate bath plus oral sodium bicarbonate (5gr/t.i.d) for 2 more weeks (period B). Records of pre/post dialysis acid base status after each period,with evaluation of different parameters were recorded.

Results: Predialysis acid base didn't present significant differences, between the 1st and 2nd dialysis session. 25 patients predialysis pH was <7.35, while 42 presented predialysis HCO3 <22 mEq/L. 18 patients had pH >7,45 after HD session.Comparing the 2 study periods, patients appeared with predialysis [HCO3] in accordance with quidelines, after 2 weeks of oral bicarbonate, while post dialysis HCO3 were increased during the 1st study period.

	Period A	Period B	p
$HCO3^-$ predialysis	21.51 ± 2.5	23.02 ± 2.8	0.03
$HCO3^-$ post dialysis	27.6 ± 1.7	26.4 ± 1	0.03
pH predialysis	7.36 ± 0.05	7.36 ± 0.05	ns

Conclusions: This study shows that conventional dialysate [HCO3] concentrations of 35 mEq/l results in a considerable degree of predialysis acidemia. Increasing [HCO3] dialysis bath results in more prominent postdialysis alkalemia, but it is not sufficient to maintain acid base balance in the interdialytic period. On the contrary, oral bicarbonate therapy at a dose of 5gr/d results in more balanced acid base status, avoiding post dialysis alkalemia.Potential solutions include a multifaceted approach of oral and individualized delivery of HCO3.

FR-PO903

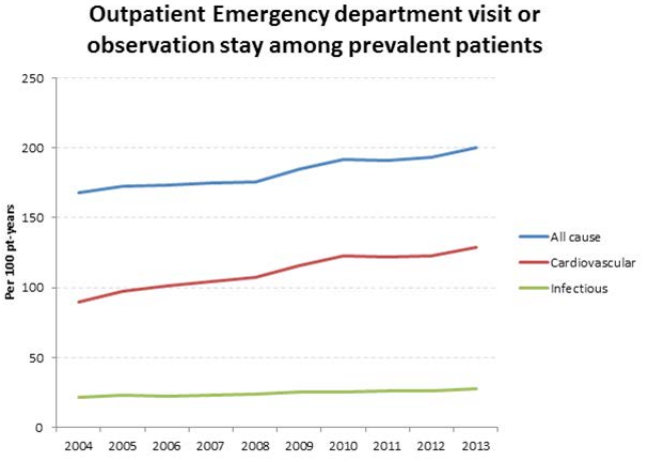
Growth of Cardiovascular and Infection Emergency Room and Observation Stays in the Dialysis Population Allan J. Collins,[1] Peer Kidney Care Initiative Investigators.[2] *[1]Chronic Disease Research Group, MMRF, Minneapolis, MN; [2]Peer Kidney Care Initiative.*

Background: Recent efforts by CMS to incentivize hospitals to reduce readmissions have focused on acute myocardial infarction, congestive heart failure, and pneumonia. While traditional readmissions of dialysis patients have declined, little is known about changes in the use of alternative forms of acute care, namely emergency department encounters (EDE) and observational stays (OBS), following an index hospitalization.

Methods: We studied prevalent (>1 year on dialysis) and incident (<1 year on dialysis) Medicare patients dialyzing in freestanding US units for the cohort years 2004-2013. EDE and OBS (occurrence and hours) were identified from revenue codes and the place of service on Part A hospital claims. Because clinical symptoms commonly occupy the first position, we used the first 5 diagnosis codes to define disease areas by organ system.

Results: Overall, EDE or OBS increased 19.2% 2004-2013. The increase in EDE (alone) was 3.8% and in OBS (alone) 58.5%. The combination of EDE or OBS for cardiovascular disease (CVD) causes increased 43% and for infections 29.3%, 2004-2013. After stabilizing from 2010 to 2012, EDE or OBS increased 3.4% overall, 4.6% for CVD and 6.8% for infection, 2012-2013.

Conclusions: While EDEs have changed only modestly in the past 10 years, there is evidence of marked increases in the use of OBS. Data suggest that hospitals are shifting the site of care away from traditional inpatient admissions, but how this affects morbidity and mortality is unknown.



Funding: Pharmaceutical Company Support - Financial support for the Peer Kidney Care Initiative is provided by the following participating provider organizations: American Renal Associates, Atlantic Dialysis Management Services, DaVita HealthCare Partners, Dialysis Clinic, Inc., Fresenius Medical Care, Independent Dialysis Foundation, Northwest Kidney Centers, Satellite Healthcare, The Rogosin Institute, U.S. Renal Care, and Wake Forest University, Private Foundation Support

FR-PO904

Low Vitamin D as a Modifying Factor in the Relationship between Obesity and Vascular Calcification in Hemodialysis Patients Jwa-Kyung Kim,[1] Sun Ryoung Choi,[2] Jae-Won Lee,[3] Sung Gyun Kim.[1] *[1]Internal Medicine, Kidney Research Inst, Hallym Univ Sacred Heart Hospital, Anyang, Korea; [2]Internal Medicine, Sahmyook Medical Center, Seoul, Korea; [3]Internal Medicine, G Sam Heart Hospital, Anyang, Korea.*

Background: Obesity is a risk factor for increased cardiovascular disease. Whether vitamin D deficiency modifies this association is unclear. Here, we examined the association of obesity and vitamin D deficiency with vascular calcification score (VCS) in incident end-stage renal disease (ESRD) patients.

Methods: A cross-sectional study was conducted with 213 ESRD patients who newly started hemodialysis. Vitamin D deficiency was defined as serum 25-hydroxyvitamin D (25(OH)D) levels below 10 ng/mL, and levels below 3 ng/mL was considered very low. Obesity was defined as a percentage of body fat (PBF) higher than the sex-specific median value in the cohort (>26.8% for men, >36.2% for women). VCS was measured by plain radiographic film of the lateral abdomen in the standing position.

Results: Mean age was 63.7±13.4 years and 31.9% were women. Most ESRD patients (76.6%) had 25(OH)D deficiency at the start of dialysis, and 44.7% of them had very low levels of 25(OH)D. The prevalence of 25(OH)D deficiency was much higher in obese patients than non-obese patients, and it had significant inverse association with PBF (r=-0.315, p< 0.001). Abdominal aortic calcification was identified in 104 (48.9%) patients. VCS was significantly higher in obese population; 2.6 (0-23) for all patients, 4.2 (0-23) for obese and 1.0 (0-12) for non-obese patients (p<0.001). Interestingly, serum 25(OH)D affected the relationship between obesity and the risk of vascular calcification, such that vitamin D deficiency was associated with greater risk of a high VCS, especially in obese population [odds ratio (OR) 3.02, 95% confidence interval (CI) 1.09-9.38)], but not with non-obese patients (OR 1.82, 95% CI 0.56-5.60).

Conclusions: The magnitude and direction of the association between obesity and the risk of vascular calcification may depends on an individual's 25(OH)D level, a possible representative marker of cardiometabolic disturbance in ESRD patients.

FR-PO905

Association of Vitamin K and Matrix Gla Protein with Subclinical Cardiovascular Disease in Incident Hemodialysis: Predictors of Arrhythmic and Cardiovascular Risk in End-Stage Renal Disease (PACE) Study Esther D. Kim,[1] Stephen M. Sozio,[2] Michelle M. Estrella,[2] Bernard G. Jaar,[2] Lucy A. Meoni,[2] Joao A.C. Lima,[2] Rulan S. Parekh.[1,2] *[1]U of Toronto; [2]Johns Hopkins U.*

Background: Recent studies suggest repletion of low vitamin K levels in HD patients may have a beneficial effect in reduction of circulating inactive desphosphorylated-uncarboxylated matrix Gla protein (dp-ucMGP) and vascular calcification; however, the independent associations of vitamin K and dp-ucMGP with subclinical measures of cardiovascular disease are unknown.

Methods: In a prospective study of 231 incident HD patients in the PACE study with available biomarker data, we examined the association of dietary vitamin K and baseline dp-ucMGP with total coronary artery calcium (CAC) score and longitudinal measures of pulse wave velocity (PWV). Vitamin K status was estimated using self-reported phylloquinone intake from 24-hour dietary recall. Baseline and longitudinal associations were examined using modified Poisson regression and mixed-effects model, respectively.

Results: The mean age of the cohort was 55±13 years, and the majority were African-American (68%), had diabetes (57%), and coronary artery disease (39%). Compared to lower vitamin K (<31mcg) intake, moderate intake was associated with lower prevalence of CAC at baseline and higher intake was associated PWV longitudinally independent of dp-ucMGP and potential confounders. Dp-ucMGP was not associated with CAC or PWV.

Association of vitamin K and dp-ucMGP with subclinical cardiovascular outcomes

	CAC score >0 (reference score=0) (n=231)	Longitudinal PWV* (n=108)
	Prevalence ratio (95% CI)	Difference (95% CI), log-m/s
Dietary vitamin K in tertiles		
Low (<31 mcg)	*ref*	*ref*
Moderate (31-74 mcg)	**0.78 (0.63, 0.97)**	-0.01 (-0.11, 0.09)
High (>74 mcg)	0.91 (0.74, 1.11)	**-0.10 (-0.20, -0.01)**
dp-ucMGP, per 1 log-pm	0.98 (0.86, 1.11)	-0.01 (-0.06, 0.05)

Adjusted for dietary vitamin K, dp-ucMGP, age, sex, race, Charlson comorbidity index, C-reactive protein, warfarin use
* p- trend<0.05

Conclusions: Higher dietary vitamin K intake is not consistently associated with lower prevalence of coronary calcification but is associated longitudinally with less arterial stiffness. This suggests that dietary vitamin K supplementation may be beneficial in reducing vascular stiffness but requires further study.

Funding: NIDDK Support

FR-PO906

FGF-23 and IL-6 Are Associated with Progression of Coronary Arterial Calcification (CAC) in Patients New to Dialysis Qijun Wan,[1,2] Sylvia E. Rosas.[2] *[1]Nephrology Dept, The First Affiliated Hospital of Shenzhen Univ, Shenzhen, China; [2]Kidney and Hypertention, Joslin Diabetes Center, Boston, MA.*

Background: Inflammation stimulates production of fibroblast growth factor 23 (FGF23). We have shown that elevated FGF23 levels are associated with CAC progression in individuals initiating dialysis. Our aim was to determine if inflammation was responsible for the association of FGF23 with CAC progression.

Methods: One hundred initial dialysis patients were enrolled. CAC were measured by multi-slice computed tomography. CAC was calculated using Agatston score (AS) and calcium volume score (VS). CAC progression was measured by the annualized difference in score AS and by the square root volume difference. Sixty-seven study participants had repeat CAC measures at one year. Linear regression was used to assess the association of IL-6 and FGF23 with CAC progression adjusting for potential confounders. The participants were also divided into 3 groups (mild, moderate and high) based on their IL-6 and FGF23 levels.

Results: The mean age of participants was 50.6 ± 12.8 years. 33 % were women, and 64.7 % were black. The baseline median IL-6 level was 3.07 mg/L [interquartile range (IQR), 1.98-5.75] and was associated with the baseline CAC [coefficient (standard error), 0.57 (0.24), $p = 0.02$] after adjustment for known risk factors for CAC. IL-6 was associated with CAC progression both by AS [158.1 (68.99), $p = 0.03$]. When FGF23 was included in the model there was only mild change of the coefficient [135.42 (66.67), $p = 0.047$]. FGF remained significant in this model [171.12 (70.1), $p = 0.02$]. Similar results were found using the VS. Participants in the high group had increased CAC progression [AS 122.41 (9.40-447.69) and VS 3.62 (1.87-14.73)] compared to mild [AS 5.64 (0-70.89) and VS 0.97 (0-2.58)] and moderate groups [AS 18.75 (0-125.21) and VS 1.66 (0-3.11)]. This association persisted in multivariate models [AS 497.19 (168.21), $p = 0.005$ and VS 6.93 (1.72), $p < 0.001$].

Conclusions: IL-6 is strongly associated with CAC presence. Both serum IL-6 and FGF23 are independently associated with CAC progression. Individuals new to dialysis with both elevated IL-6 and FGF23 are at highest risk for CAC progression.

FR-PO907

Vascular Calcification and Left Ventricular Hypertrophy in Hemodialysis Patients: Interrelationship and Clinical Impact Yu Ah Hong, Hye Eun Yoon, Yoon-Kyung Chang, Chul Woo Yang, Suk Young Kim, Hyeon Seok Hwang. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Korea.*

Background: Vascular calcification (VC) and left ventricular hypertrophy (LVH) is a morphological marker of vascular disorders and a significant indicator of cardiac pathology in hemodialysis (HD) patients. However, their relationship and combined effects on clinical outcomes remain undetermined.

Methods: We included 341 HD patients, who were examined with plain chest radiographs for aortic arch VC and with echocardiography for LVH.We investigated the relationship between VC and LVH, and their clinical significance for cardiovascular events (CVE) and death.

Results: VC was found in 100 HD patients (29.3%). LVH was more prevalent in patients with VC compared with those without VC (70.0% vs. 50.2%; $P = 0.001$). VC was independently associated with a 2.42-fold increase in the incidence of LVH (95% confidence interval [CI], 1.26–4.65).In multivariate analysis, compared with patients with neither VC nor LVH, the coexistence of VC and LVH was independently associated with CVE (hazard ratio [HR], 2.01; 95% CI, 1.09–3.72), whereas VC or LVH alone was not. Patients with both VC and LVH had the highest risk for a composite event of death and CVE (HR, 1.88; 95% CI, 1.15–3.06). Significant synergistic interaction was observed between VC and LVH (P for interaction = 0.039).

Conclusions: VC was independently associated with LVH. Coexistence of VC and LVH was associated with higher risk of CVE and composite event than either factor alone. There was a synergistic interaction between VC and LVH for the risk of a composite event.

FR-PO908

Factors Affecting Vascular Calcifications in Peritoneal Dialysis Sofia H. Marques, Rute Carmo, Luís Mendonça, Ana Teresa Nunes, Ana Beco, Ana Oliveira, Manuel Pestana. *Nephrology, Centro Hospitalar São João, Porto, Portugal.*

Background: Vascular calcifications are associated with mortality in dialysis patients. Correlations with serum markers, therapy and dialysis modalities are not constant across the studies. We aimed to study clinical and laboratory data to determine factors influential to a higher vascular calcification index (VCI) in peritoneal dialysis (PD) patients.

Methods: 109 patients in our PD unit in December 2015 entered this retrospective analysis. VCI was determined using the Adragao score, counting the presence of vascular calcifications in a plain X-ray of the pelvis and hands (0 to 8) dating from the last 12 months. Current clinical and analytical data were collected.

Results: Mean age was 53.8 (±14.0) and 52.3% were men. Concerning the VCI, 51 patients had 0; 20 had 1-2; 14 had 3-4 and 24 had > 4. Compared to 71 patients with score ≤2, patients with VCI >2 (n=38) were significantly older (60.2±13.0 vs. 50.3±13.4; p=0.00), more often men (73.7% vs. 42.3%; p=0.00), diabetic (60.5% vs. 14.3%; p=0.00), hypertensive (55.6% vs. 34.8%; p=0.04), with higher extracellular/intracellular water ratio (0.65±0.03 vs. 0.60±0.04; p=0.00) by bioimpedance and higher BMI (27.5±4.6 vs. 25.4±4.3; p=0.04). They had more often a weekly Kt/V < 1.7 (29.7% vs. 10.1%; p=0.01) and were more often on automatic peritoneal dialysis (APD) vs. continuous ambulatory peritoneal dialysis (57.9% vs. 35.3%; p=0.02). In addition, they had lower albumin (3.4±0.47 vs. 3.8±0.50 g/dL; p=0.00), lower potassium (4.0±0.68 vs. 4.4±0.68 mEq/L; p=0.01) and higher protein losses (24.5±12.7 vs.17.5±9.8 g/day; p=0.00). No differences were found in dialysis vintage, residual renal function, icodextrin use, serum calcium, phosphate, parathyroid hormone, hemoglobin or current use of phosphate-binder, vitamin D analogs, cinacalcet, erythropoiesis-stimulating agent, renin-angiotensin system blockers or statins.

Conclusions: In PD patients, VCI was associated with traditional biomarkers such as increased age, masculine gender, diabetes and hypertension as well as with other non-traditional factors such as less efficient dialysis, APD, higher extracellular water content and serum parameters suggestive of malnutrition.

FR-PO909

Serum Fibroblast Growth Factor 21 Predicts All-Cause Mortality in End-Stage Renal Disease Marina Kohara,[1] Takahiro Masuda,[1] Kazuhiro Shiizaki,[2] Tetsu Akimoto,[1] Yuko Watanabe,[1] Sumiko Honma,[3] Chuji Sekiguchi,[4] Yasuharu Miyazawa,[4] Eiji Kusano,[5] Yasushi Asano,[3] Makoto Kuro-o,[2] Daisuke Nagata.[1] *[1]Div of Nephrology, Dept of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [2]Center for Molecular Biology, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [3]Japanese Red Cross Koga Hospital, Koga, Ibaraki, Japan; [4]Nasu-Minami Hospital, Nasukarasuyama, Tochigi, Japan; [5]JCHO Utsunomiya Hospital, Utsunomiya, Tochigi, Japan.*

Background: Fibroblast growth factor (FGF) 21 is an anti-aging hormone which is secreted from liver in response to fasting. Circulating FGF21 concentration is increased in end-stage renal disease (ESRD) that may be survival response to accelerated aging. However, the impact of an increase in circulating FGF21 levels on prognosis remains unknown.

Methods: ESRD patients receiving chronic hemodialysis (HD) were included in this study. Serum FGF21 levels were measured by a sandwich ELISA. The patients were grouped into the high and low FGF21 groups by the median value. The primary outcome was cardiovascular events and all-cause death. The Kaplan–Meier method and Cox proportional hazard model were used for survival analyses.

Results: Of 107 participants (age 65.3±13.0 years, male 59.8%, HD duration 5.7±5.3 years, diabetes mellitus [DM] 41.1%), 17 (15.9%) patients died during a median follow-up of 44 months (interquartile range [IQR] 21–66 months). Median serum FGF21 levels were 1701 pg/mL (IQR 867–2957 pg/mL). Smoking rates and serum uric acid (UA) in the high FGF21 group were significantly higher than in the low FGF21 group. Kaplan–Meier analysis with log-rank test revealed that the high FGF21 group had a higher rate of all-cause mortality (P=0.040) than the low-FGF21 group, but the association between FGF21 levels and cardiovascular events was not found (P=0.795). In the multivariate Cox regression model including age, gender, DM, smoking and serum UA, high serum FGF21 remained an independent predictor for increased mortality (hazard ratio, 4.05; 95% confidence interval, 1.34 to 15.27; P=0.012).

Conclusions: These results suggest that high serum FGF21 levels are associated with increased mortality in ESRD patients. Further studies are required to evaluate a mechanistic link between FGF21 elevation and poor outcome.

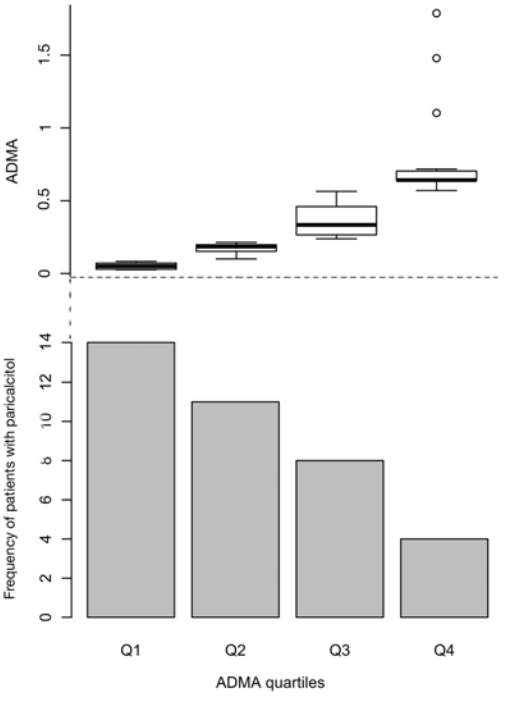
FR-PO910

Asymmetric Dimethylarginine Levels Are Lower in Hemodialysis Patients Treated with Paricalcitol Nestor Oliva-Damaso,[1,4] Elena Oliva-Damaso,[2] Francisco Javier Rodriguez-Esparragon,[3] Juan Payan Lopez,[1] Alberto Maranes,[4] Eduardo Baamonde,[2] Yanet Parodis Lopez,[2] Nicanor Vega-Diaz,[2] Jose C. Rodriguez-Perez.[2] *[1]Nephrology, Hospital Costa del Sol, Marbella, Malaga, Spain; [2]Nephrology, Hospital Univ de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Las Palmas, Spain; [3]Unidad de Investigación, Hospital Univ de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Las Palmas, Spain; [4]Nephrology, Hospital Quirón, Marbella, Malaga, Spain.*

Background: Chronic Kidney Disease (CKD) is associated with an inflammatory condition involving an increased risk of cardiovascular (CV) morbimortality. Asymmetric dimethylarginine (ADMA) is an endogenous inhibitor of nitric oxide synthase and may be an independent risk factor for CV disease in HD patients.

Methods: We performed a cross sectional observational study in 93 randomly selected patients on chronic HD to evaluate the association between ADMA levels and CV medication.

Results: Patients (62.4% male) had an average age of 64.7±13.1 years. 45.2% were diabetic with a median of 53.1 months (IQR 31.8-89.7) in HD. Patients treated with paricalcitol had significantly lower ADMA levels (0.21±0.19 µmol/L) than the rest (0.42±0.35 µmol/L) (**p=0.00027**).



Patients treated with paricalcitol were less likely to have very high ADMA levels (**p=0.014**) with no significant differences with other medications. Higher dose of paricalcitol was related with lower levels of ADMA showing a significant negative dose-response relationship (–0.46; **p=0.001**).

Conclusions: HD patients treated with paricalcitol presented significantly lower ADMA levels. Beneficial effects in terms of CV morbidity and mortality have been demonstrated by paricalcitol in HD patients but its association with ADMA has not been reported. Studies to confirm this effect and determine the underlying pathophysiological mechanism are necessary.

FR-PO911

Oral Calcitriol and Cardiovascular Events in Hemodialysis Patients Lin Ma,[1] Ravi I. Thadhani,[2] Norma J. Ofsthun,[1] Amanda Stennett,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: A large clinical pilot began at Fresenius Medical Care North America (FMCNA) in December of 2013 to examine the feasibility of administering oral calcitriol (OC) rather than intravenous Vitamin D (IVD) for in-center hemodialysis (IHD) patients. We conducted a retrospective cohort study to compare the survival and hospitalization risks associated with OC and IVD treatments.

Methods: Among FMCNA IHD adult patients, 6,689 who started OC and 128,890 who received only IVD between December 1, 2013 and June 30, 2014 were followed up to 1 year. The index date was set to the OC start date or a random date within the study period for those patients receiving IVD. Cardiovascular events (CVE) including acute myocardial infarction (AMI), congestive heart failure (CHF), cerebrovascular accident (CVA), peripheral vascular disease (PVD), and cardiorespiratory arrest (CPA) were examined. These were all newly diagnosed from hospital discharges in the first year following the start date. Months from the index date to the first CVE were used for the survival analysis. Kaplan-Meier and Cox proportional hazards regression models were used to compare the CVE risks.

Results: Baseline characteristics between 2 groups were clinically comparable. Incident rates were: AMI 1.2% in OC vs. 1.4% in IVD, p=0.2; CHF 1.8% in OC vs. 2.3% in IVD, p=0.004; CVA 0.3% in OC vs. 0.9% in IVD, p<0.0001; PVD 0.9% in OC vs. 1.2% in IVD, p=0.03; CPA 1.3% in OC vs. 1.6% in IVD, p=0.05. Compared with IVD, crude CVE risk for OC was 26.3% lower (2.1% vs. 2.8%, p=0.0003); unadjusted hazard ratio (HR) was 0.73 (95% CI: 0.62, 0.87), p=0.0004; case-mix adjusted HR was 0.80 (95% CI: 0.67, 0.95), p=0.009; and case-mix & lab adjusted HR was 0.78 (95% CI: 0.66, 0.93), p=0.005.

Conclusions: There was no overall increase cardiovascular events seen in the oral calcitriol group at 1 year, and outcomes may have been slightly better compared with intravenous vitamin D group.

FR-PO912

Outcome Predictors in Maintenance Hemodialysis Patients with Cerebral Hemorrhage Mineaki Kitamura,[1,2] Tadashi Uramatsu,[2] Yoko Obata,[2] Yohei Tateishi,[3] Masaharu Nishikido,[1] Takayuki Matsuo,[4] Akira Tsujino,[3] Tomoya Nishino.[2] *[1]Div of Blood Purification, Nagasaki Univ Hospital, Nagasaki, Japan; [2]Dept of Nephrology, Nagasaki Univ Hospital, Nagasaki, Japan; [3]Dept of Neurology, Nagasaki Univ Hospital, Nagasaki, Japan; [4]Dept of Neurosurgery, Nagasaki Univ Hospital, Nagasaki, Japan.*

Background: Cerebral hemorrhage is life-threatening and adversely affects activities of daily living (ADLs). However, factors contributing to poor outcomes in maintenance hemodialysis patients with cerebral hemorrhage remain unknown. Accordingly, we retrospectively studied hemodialysis patients with cerebral hemorrhage.

Methods: After excluding traumatic and subarachnoid hemorrhage, 91 hemodialysis patients with cerebral hemorrhage admitted to Nagasaki University Hospital during 2007-2015 were enrolled. We collected data on hemodialysis status, laboratory data, and medication from medical referral letter. We also evaluated hematoma volume, National Institutes of Health Stroke Scale (NIHSS) score on admission, and ADLs on discharge from the hospital.

Results: The patients were aged 65±11 years old, and male:female = 60:31. Hemorrhage area: putamen, 31; subcortical, 24; thalamus, 20; cerebellum, 10; pons, 3; and others, 2. Severe outcomes: 29 died and 31 were severely disabled. Large volume of hematoma and high NIHSS score predicted poor prognoses. Antiplatelet use was an independent risk factor for death and severe disability by multivariate analysis. Pre-onset low serum albumin was also an independent risk factor for death. Age, dialysis duration, sex, anticoagulant use, pre-onset blood pressure, and diabetes history did not influence the prognosis. The relationship between prognosis and amount of fluid removal per unit body weight in pre-onset hemodialysis showed a U shape, e.g., Quintile 1 (lowest) and Quintile 5 (highest) for the fluid removal rate in pre-onset hemodialysis had a significantly higher risk for death (odds ratio 11.9; p<0.01 and 10.8; p=0.012, respectively; reference = Quintile 3).

Conclusions: To prevent the progression of cerebral hemorrhage, we should be aware of the use of antiplatelet drugs and weight gain caused by malnutrition or dietary noncompliance.

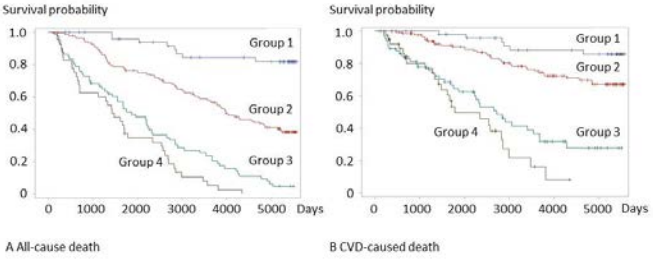
FR-PO913

A New Risk Scoring System for Prediction of Long-Term Mortality in Patients on Maintenance Hemodialysis Eiichiro Kanda,[1] Hiroshi Kawaguchi,[2] Yoichiro Tabata,[3] Noriyoshi Murotani,[4] Tomoko Maeda,[5] Hidetaka Itoh,[6] Haruki Itoh.[7] *[1]Tokyo Kyosai Hospital; [2]Tokiwa-kai Medical Corporation; [3]Meysey-kai Medical Corporation; [4]Japan Community Health Care Organization Chiba Hospital; [5]Sakakibara Heart Inst Clinic; [6]Toranomon Mutual Aid General Hospital; [7]Sakakibara Heart Inst.*

Background: It has been reported that the survival of hemodialysis (HD) patients is poor, and the leading cause of death is cardiovascular disease. To identify high-risk patients and treat them carefully, we developed a scoring system to evaluate their 15-year prognosis in a prospective cohort study.

Methods: We analyzed data from 312 and 310 patients to develop and validate the prediction model, respectively. The association of potential risk factors with death was tested by Cox proportional-hazards analysis, and a risk scoring model was developed. Then, the model was validated.

Results: Two hundred patients (64.1%) in the cohort for model development died. Six independent prognostic factors were retained in the final model, and each was assigned a score proportional to its regression coefficient: 65 years or older, 3; diabetic nephropathy, 3; hypotension, 1; pre-HD cardiothoracic ratio ≥50%, 1; pre-HD BNP ≥250 pg/mL, 1; and pre-HD numbers of abnormal findings on electrocardiograms=0, 1, 2 or larger, 0, 1, 5. The patients were categorized as follows with their scores: Group 1 (low risk), 0; Group 2, 1 to 3; Group 3, 4 to 5; and Group 4 (high risk), 6 and higher. In the cohort for model validation, Groups 2 to 4 showed a higher risk than Group 1: Group 2, hazard ratio 4.66 (95% confidence interval 2.25, 9.64); Group 3, 13.62 (6.48, 28.63); and Group 4, 20.86 (9.60, 45.31).



Conclusions: A new risk scoring system for predicting 15-year mortality was developed. This system may be useful for evaluating HD patients' prognosis.

FR-PO914

High Interleg Systolic Blood Pressure Difference and Protein-Energy Wasting (PEW) Increase Risk of Cardiovascular Events and Mortality in Incident Dialysis Patients Sawako Kato,[1] Bengt Lindholm,[2] Shoichi Maruyama,[1] Yukio Yuzawa,[3] Yoshinari Tsuruta,[4] Kaoru Yasuda.[5] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Baxter Novum & Renal Medicine, Karolinska Inst, Stockholm, Sweden; [3]Nephrology, Fujita Health Univ Hospital, Toyoake, Japan; [4]Meiyo Clinic, Toyohashi, Japan; [5]Masuko Memorial Hospital, Nagoya, Japan.*

Background: While high interarm blood pressure (BP) difference is a marker of arterial stiffness, PEW is linked to atherosclerosis. Here we analyzed if high interleg systolic BP difference (ISBPD) used instead of interarm BP difference (as most hemodialysis patients had arm AV fistula), and concomitant PEW associates with cardiovascular (CV) events and mortality in dialysis patients.

Methods: In 125 incident Japanese dialysis pts (aged 59 ± 11 years; 84 men), ISBPD and subjective global assessment (SGA) as a marker of PEW were measured. Pts were divided into 4 groups according to median ISBPD, 6 (range, 0-98) mmHg, and if they were well-nourished (SGA A; n=28) or malnourished (SGA B; n= 79, and SGA C; n=18). During follow-up for median 46.4 (range, 1–95) months, 20 deaths and 76 CV events occurred and their corresponding relative risks (RRs) were analyzed.

Results: In Kaplan-Meier, high ISBPD and malnutrition associated with the highest mortality (Log rank 8.65, P = 0.034), while there was no difference between high ISBPD/well-nourished pts and low ISBPD/malnutrition pts. In Cox, pts with high ISBPD and malnutrition had increased RR of death (RR of high vs low ISBPD, 3.14, 95% CI; 1.21-9.15; RR of SGA category B and C vs A, 2.94, 95% CI; 0.71-20.8 and 12.3, 95% CI; 1.81-120.7, respectively) after adjustments for age and diabetes. For SGA categories A, B, and C, the cumulative number of CV events per 100 pts year in high-ISBPD pts were 4.6, 29.1, and 91.9, and in low-ISBPD pts 3.0, 5.7, and 0, respectively.

Conclusions: In incident dialysis pts, higher ISBPD associated with increased risk of mortality, and with CV events which however occurred almost exclusively in pts with higher ISBPD and severe PEW, suggesting that pts with arterial stiffness have increased susceptibility to onset of CV events especially in presence of severe PEW.

FR-PO915

Periodontitis and Early Mortality among Adults Treated with Hemodialysis: A Multinational Propensity-Matched Cohort Study Marinella Ruospo,[1,2] Suetonia Palmer,[3] Giovanni F.M. Strippoli.[1,4,5] *[1]Diaverum Medical Scientific Office; [2]Amedeo Avogadro Univ of Eastern Piedmont; [3]Univ of Otago Christchurch; [4]Univ of Sydney; [5]Univ of Bari, on behalf of the ORALD Investigators.*

Background: Periodontitis, a multifactorial disease that involves inflammation of the structures supporting teeth, is common, treatable, and may be associated with mortality in the general population and adults with chronic diseases. However, it is unclear whether periodontitis is associated with survival in the setting of kidney failure.

Methods: ORAL-D was a multinational cohort study involving 3338 dentate adults with end-stage kidney disease treated in a hemodialysis network in Europe and South America. ORAL-D was designed to examine the associations between oral health and all-cause and cardiovascular-related mortality in people on long-term hemodialysis. Propensity score methods were used to assemble a matched cohort of participants with moderate to severe periodontitis with characteristics similar to patients with no or mild periodontitis. Periodontal disease was assessed using the World Health Organization Community Periodontal Index. A random-effects Cox proportional hazards model was fitted with shared frailty to account for clustering of mortality risk within countries.

Results: Among the 3338 dentate participants, 1355 (40.6%) had moderate to severe periodontitis at baseline. Moderate to severe periodontitis was associated with a lower risk of all-cause (9.1 versus 13.0 per 100 person years, hazard ratio 0.74, 95% confidence interval 0.61 to 0.90) and cardiovascular (4.3 versus 6.9 per 100 person years, hazard ratio 0.67, 0.51 to 0.88) mortality. These associations were not changed substantially in sensitivity analyses restricted to participants with 12 or more natural teeth or when analyses accounted for competing causes of cardiovascular death.

Conclusions: Periodontitis does not appear to be associated with an increased risk of all-cause and cardiovascular mortality in adults treated with hemodialysis.

FR-PO916

Accelerated Aging-Associated Immune Changes Are Associated with Cardiovascular Disease in End-Stage Renal Disease Patients

Tzu-Ying Chou,[1] Kai-Hsiang Shu,[1,2] Fang-Yun Lay,[1] Yi-Fang Chuang,[3] Jean-San Chia,[4] Yen-Ling Chiu.[1,2] *[1]Nephrology, Far Eastern Memorial Hospital, Taiwan; [2]Medicine, National Taiwan Univ Hospital, Taiwan; [3]Epidemiology, National Yang Ming Univ, Taiwan; [4]Graduate School of Immunology, National Taiwan Univ, Taiwan.*

Background: Patients with end-stage renal disease (ESRD) exhibit accelerated aging of the immune system and increased risk for cardiovascular diseases, but the contribution of "immune system aging", or "immunosenescence" to cardiovascular disease is not clear.

Methods: We performed comprehensive lymphocyte and monocyte immunophenotyping in 199 ESRD patients on maintenance hemodialysis and age-matched 57 healthy individuals. Peripheral blood were sampled before hemodialysis session and processed immediately for mononuclear cell isolation and staining. Using multicolor flow cytometry, lymphocytes were separated into subpopulations including naive T cells (CCR7+CD45RA+), central memory (CCR7+CD45RA-), effector memory (CCR7-CD45RA-), terminal effector (CCR7-CD45RA+) and memory stem cells (naive cells with high CD28 and CD95). Monocytes were separated into classical (CD14++CD16-), intermediate (CD14++CD16+) and non-classical monocytes (CD14+CD16+).

Results: Compared to healthy individuals, ESRD patients showed decreased numbers of naïve CD4+ and CD8+ T cells and increased numbers of intermediate monocytes (CD14++CD16+), and these changes significantly correlated with age. Lymphocyte and monocyte aging also correlated with other established cardiovascular risk factors, including hemoglobin and high-sensitivity C-reactive protein. In a multivariate-adjusted logistic regression model, a low naïve CD8+ T cell level in combination with a high intermediate monocyte level was independently associated with the existence of coronary artery disease (OR=3.58, 95% CI=1.2~10.4, p=0.019) as well as cardiovascular diseases including stroke and peripheral arterial occlusive disease (OR=3.98, 95% CI=1.5~10.8, p=0.007).

Conclusions: These results indicate that cardiovascular disease burden in the ESRD population might be enhanced by the presence of accelerated immunosenescence, or aging-related immune changes.

FR-PO917

Serum Magnesium Level Can Predict Mortality in Chinese Hemodialysis Patients: A Cohort Study and 3-Year Follow-Up

Zijin Chen, Zuanhong Jiang, Xiaobo Ma, Haijin Yu, Xiaonong Chen. *Dapartment of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

Background: To analysis serum magnesium level and its risk factors in Chinese hemodialysis.and whether serum magnesium level is associated with mortality.

Methods: MHD patients were treated in Ruijin Hospital affiliated to Shanghai Jiaotong University School of Medicine in July 1,2012. All patients were consistently treated by 4-hour hemodialysis three times per week, with dialyzer magnesium concentration 0.5 mmol/L. All clinical data, biochemical data and medication were collected at baseline. 3 years follow up and record with the combination of death or withdrawal from dialysis therapy leading to death as the primary outcome. Reference range of magnesium in our laboratory is 0.74-1.03mmol/L.

Results: 230 MHD patients were enrolled, with 63.0% male, 11.3% diabetes. Mean age was 56.67±14.48yrs-old and median dialysis vintage 41(IQR 20.75-72.25) months. Mean magnesium was 1.12±0.16mmol/L. 34.8% patients was in normal range and 65.2% with hypermagnesemia, no one was hypomagnesemia. Pearson correlation showed that age, weight, spKt/V, RBC, Hb, Hct, pre-ALB, pre-dialysis BUN, SCR,UA,Na, K,P, ALB, LDL, 25(OH)D is associated with serum magnesium level(Fig 1). In multiple stepwise liner regression,BUN, Hct, Ca, spKt/V, SCR, K, Na and weight are independent factors of magnesium(Table 1). Follow 36 months, totally 54 patients died. 15 patients died of heart disease, 13 cerebral disease. Kaplan-Meier analysis showed lower magnesium level is associated with higher all-cause mortality and cardiovascular motality (Fig 2).Cox regression hazard analysis identified hypomagnesemia as a significant predictor for all-cause mortality in MHD patients(Table 2).

Table 1. Independent factors of Mg in multiple stepwise liner regression

	beta	P	95.0% CI	
Constant		0.115	-1.578	0.172

Mg>1.37mmol/L(Ref)	-	1	-	-	-	1	-	-	-	1	-	-	-	1	-	-

Model 1:Unadjusted Model 2:age, sex, dialysis vintage adjused Model 3:Model 2+kt/V, Hb, ALB, Ca, P, iPTH
Model 4:Model 3+TG, TC, HDL,LDL

Conclusions: A high prevalence of hypermagnesemia is in MHD patients. Serum magnesium level can predict the mortality in Chinese dialysis patients.

FR-PO918

High suPAR Is Strongly Associated with Adverse Outcomes in Patients with End-Stage Renal Disease on Dialysis

Christiane Drechsler,[1,8] Salim Hayek,[2] David Changli Wei,[3] Sanja Sever,[4] Vera Krane,[1,8] Winfried März,[5,6,7] Christoph Wanner,[1,8] Jochen Reiser.[3] *[1]Div of Nephrology, Univ Hospital Wuerzburg, Wuerzburg, Germany; [2]Div of Cardiology, Emory Univ School of Medicine, Atlanta; [3]Dept of Medicine, Rush Univ, Chicago; [4]Div of Nephrology, Massachusetts General Hospital, Charlestown; [5]Med. Clinic V, Univ of Heidelberg, Mannheim, Germany; [6]Medical Univ Graz, Austria; [7]Synlab Academy, Germany; [8]Comprehensive Heart Failure Center, Wuerzburg, Germany.*

Background: Soluble urokinase plasminogen activator receptor (suPAR) is associated with adverse outcomes in various populations, and is implicated in the pathogenesis of kidney disease. SuPAR concentrations often increase as eGFR decreases, and it is unclear whether they remain predictive of outcomes in patients with end-stage renal disease (ESRD).

Methods: We measured serum suPAR at enrolment in 1175 hemodialysis patients with type 2 diabetes mellitus (54% male, mean age 66±8 years old), participating in the German Diabetes and Dialysis Study (4D Study). Patients were followed for 4 years for death and cardiovascular events. We examined the association between suPAR tertiles and outcomes using Cox regression analyses, adjusting for clinical characteristics.

Results: Median suPAR was 10521 pg/ml (IQR 9105–12543 pg/ml). Patients with suPAR > 11633 pg/ml (third tertile) had an almost 2-fold higher mortality compared to those with suPAR < 9599 pg/ml (first tertile) (adjusted HR 1.9; 95% CI 1.5-2.3). The risks of sudden death and stroke were strongly increased (adjusted HR_{SD} 2.2; 95% CI 1.4-3.5, and adjusted HR_{stroke} 2.2; 95% CI 1.3-3.6, respectively, third versus first tertile), together accounting for the higher incidence of cardiovascular events combined (adjusted HR 1.7; 95% CI 1.4-2.2). In contrast, there was no association between suPAR and the risk of non-fatal myocardial infarction.

Conclusions: SuPAR is strongly associated with poor cardiovascular outcomes in patients with ESRD which may reflect pathologic processes beyond decreased renal function. Further studies are needed to determine whether suPAR is a modifiable risk factor and a potential therapeutic target.

FR-PO919

Plasma Betaine and Cardiovascular Outcomes in Hemodialysis Patients

Tariq Shafi,[1] Neil R. Powe,[2] Timothy W. Meyer,[3] Tanushree Banerjee,[2] Seungyoung Hwang,[1] Michal L. Melamed,[4] Josef Coresh,[1] Thomas H. Hostetter.[5] *[1]Johns Hopkins Univ; [2]Univ of California, San Francisco; [3]Stanford Univ; [4]Albert Einstein Medical College; [5]Case Western Reserve Univ.*

Background: Betaine (trimethylglycine) is a precursor for gut microbiome-derived trimethylamine-N-oxide (TMAO), a uremic toxin, but is also biochemically active, enhancing very-low-density lipoprotein (VLDL) activity and affecting serum homocysteine concentration.

Methods: We measured plasma betaine levels in 1276 patients of the NIDDK sponsored, Hemodialysis (HEMO) Trial and analyzed their relation over time to CV death, sudden cardiac death (SCD) and first CV event adjudicated by an outcomes committee. We used Cox proportional hazards models adjusted for potential confounders (demographics, clinical characteristics, comorbidities, residual kidney function, albumin and TMAO). We also examined interactions by race and dialysis interventions (high flux or dose).

Results: Mean age of the patients was 58 years, 63% were Black and 42% were male. Median (interquartile range) betaine concentration was 53 μM (41, 65). Median follow-up

was 2.3 years. In unadjusted and full adjusted models (including adjustment for TMAO), higher betaine concentrations were associated with a higher risk of CV outcomes. Subgroup analyses did not show significant interactions with race or dialysis intervention.

Association of Betaine with Cardiovascular Outcomes in 1276 Patients of HEMO Study**			
Outcomes	Events	HR (95% CI)	*P*
CV Mortality	220	1.52 (1.15-2.02)	0.003
Sudden Cardiac Death	126	1.55 (1.17-2.05)	0.002
First CV Event	644	1.15 (0.98-1.35)	0.09
**Adjusted HR per 2-fold increase in solute			

Conclusions: Plasma betaine is a risk factor for CV outcomes in hemodialysis patients and this association appears to be statistically independent of serum TMAO concentrations.

Funding: NIDDK Support

FR-PO920

P-Cresol Sulfate, Indoxyl Sulfate, Hippurate and Phenylacetylglutamine and Cardiovascular Outcomes in Hemodialysis Patients

Tariq Shafi,[1] Tammy L. Sirich,[2] Timothy W. Meyer,[2] Seungyoung Hwang,[1] Michal L. Melamed,[3] Tanushree Banerjee,[4] Josef Coresh,[1] Thomas H. Hostetter,[5] Neil R. Powe.[4] *[1]Johns Hopkins Univ; [2]Stanford Univ; [3]Albert Einstein College of Medicine; [4]Univ of California, San Francisco; [5]Case Western Reserve Univ.*

Background: We recently reported that a large increase in Kt/Vurea in the Hemodialysis (HEMO) Study failed to achieve significant reduction in p-cresol Sulfate (PCS), indoxyl sulfate (IS), hippurate (HIPP) and phenylacetylglutamine (PAG). The goal of this study was to determine the association of these solutes with cardiovascular (CV) outcomes.

Methods: We measured PCS, IS, HIPP and PAG in HEMO Study samples (N=1276) and analyzed their association with CV death, sudden cardiac death (SCD) and first CV event, using Cox model adjusted for potential confounders [demographics, clinical characteristics, comorbidities, albumin, residual kidney function (RKF)].

Results: Mean age of the patients was 58 years, 63% were Black and 42% were male. None of the solutes were associated with any CV outcomes (Table 1). Trial interventions (which did not reduce solute concentration) did not modify the association between the solutes and CV outcomes. In pre-specified subgroup analyses, total HIPP and PAG were associated with CV death only in patients with RKF (n=433; p-interaction <0.05).

Association of Solutes with CV Outcomes in 1276 Patients of HEMO Study**						
	CV Death (n=220)		**SCD (n=126)**		**First CV Event (n=644)**	
	HR	P	HR	P	HR	P
PCS	0.98 (0.90-1.07)	0.7	0.98 (0.88-1.10)	0.8	0.98 (0.94-1.01)	0.1
IS	0.96 (0.81-1.14)	0.6	0.94 (0.75-1.18)	0.6	0.99 (0.92-1.07)	0.8
HIPP	1.09 (0.98-1.21)	0.1	1.03 (0.91-1.17)	0.6	0.98 (0.94-1.03)	0.5
PAG	1.09 (0.94-1.26)	0.2	1.08 (0.90-1.30)	0.4	0.99 (0.92-1.05)	0.6
** Adjusted HR per 2-fold increase in solute						

Conclusions: In prevalent hemodialysis patients participating in a large U.S. hemodialysis trial, PCS, IS, HIPP and PAG were not associated with CV outcomes. Dialysis interventions to reduce the burden of CV disease are unlikely to be successful without better knowledge of solute toxicity.

Funding: NIDDK Support

FR-PO921

Adipokines, Blood Pressure and Arterial Elasticity in Dialysis Patients

Wenjin Liu, Meijuan Meng, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Previous studies have suggested that adipokines, a group of hormones and cytokines released by white adipose tissue, may exert potent and inconsistent effects on cardiovascular (CV) system. There remains a paucity of data regarding theirs associations with CV parameters in patients on maintenance hemodialysis.

Methods: This is a cross-sectional analysis of midterm baseline data from a cohort study. Two-hundred and twenty eight dialysis patients from dialysis centers of four tertiary hospitals in East China were recruited. Blood pressure level and arterial elasticity were evaluated by ambulatory blood pressure monitoring and pulse wave velocity measurement on a nondialysis day, respectively. Adipokines (adiponectin, resistin, PAI-1, Leptin, MCP-1, adipsin) were detected using pre-dialysis plasma samples by multiplex assays. Associations of adipokines with ambulatory systolic blood pressure (A-SBP) and carotid-to-femoral pulse wave velocity (cfPWV) were determined using generalized linear models.

Results: For blood pressure, in a basic age- and sex-adjusted model, adiponectin is positively associated with A-SBP (p=0.004) while resistin, PAI-1, leptin and adipsin are inversely associated with A-SBP (p≤0.001 for resistin, PAI-1 and leptin; p=0.021 for adipsin).In more extensive adjusted models, adiponectin is still positively associated with A-SBP while resistin, PAI-1, leptin are inversely associated with A-SBP (p<0.01 for all). For arterial elasticity, only adiponectin is inversely associated with cfPWV (p<0.01 for all models).

Conclusions: Circulating adipokines are associated with blood pressure and arterial elasticity in dialysis patients, suggesting their diverse effect on cardiovascular system in these patients.

FR-PO922

Additive Prognostic Utility of Serum ST2 Level as a Predictor of Cardiovascular Outcomes in Incidental Hemodialysis Patients

Seok Joon Shin, Soojeong Kim, Hye Eun Yoon. *Nephrology, The Catholic Univ of Korea, Seoul, Korea.*

Background: ST-2 concentration is known to be a predictor for cardiovascular (CV) mortality and hospitalization due to CV disease in patients with heart failure. This study was to evaluate the prognostic value of serum ST-2 level in incident dialysis patients, in terms of mortality and CV events.

Methods: A total 182 ESRD patients starting maintenance dialysis were enrolled. We measured the pre-dialysis serum ST-2 level at the start of dialysis. Patients were divided into two groups according to the median ST-2 level. Factors associated with serum ST-2 level were analyzed. The associations between serum ST-2 level and mortality and CV events were investigated.

Results: Median follow up duration was 628 days (interquartile range 382 to 1,052 days). There was no significant difference in baseline demographic characteristics and comorbidity between the two groups. The high ST-2 group showed higher levels of C-reactive protein (CRP), phosphorus, and calcium-phosphorus product, and lower albumin and calcium levels than those of the low ST-2 group. Serum ST-2 level showed significantly positive correlations with levels of phosphorus, calcium-phosphorus product, and CRP, and the ratio of peak early to late diastolic filling, while it showed significantly negative correlations with serum albumin level and ejection fraction, after age- and sex-adjustment. The patient survival rate was significantly lower in the high ST-2 group compared with that of the low ST-2 group after 3 years follow up (69.2% vs. 86.9%, P= 0.023). The event free survival rate for death and non-fatal CV event was significantly lower in the high ST-2 group compared with the low ST-2 group (59.4% vs. 80.3%, P =0.008). In multivariate Cox regression analysis, the ST-2 level was also a significant predictor for composite of end-points after adjustments for traditional CV risk factors and laboratory parameters (HR = 1.011, P = 0.003).

Conclusions: This study showed that serum ST-2 level independently predicted mortality and non-fatal CV events in ESRD patients. High ST-2 concentration could be an additive predictor for adverse CV outcomes in incident dialysis patients.

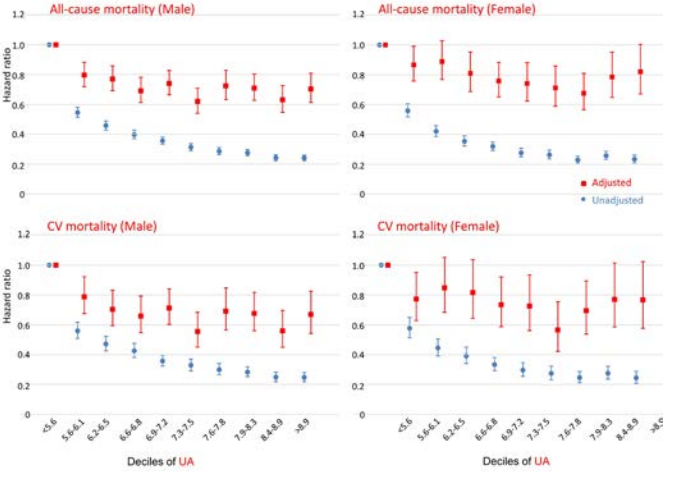
A Lower Serum Uric Acid Is Associated Not Only with All-Cause Mortality but also Cardiovascular Mortality among Patients Receiving Hemodialysis in Japan

Naoki Sugano,[1] Yukio Maruyama,[1] Takashi Yokoo,[1] Atsushi Wada,[2] Takashi Shigematsu,[2] Ikuto Masakane.[2] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: High level of serum uric acid is prevalent in chronic kidney disease (CKD), however it has a controversy whether high or low serum uric acid level appears to be a risk factor of cardiovascular event and mortality in the patients of receiving renal replacement therapy.

Methods: We collected the baseline data of 222,434 patients receiving HD thrice weekly (males: 63.0%, 66 ±12 years, median HD vintage of 60 months, females: 68 ±13 years, median HD vintage of 72months) extracted from a nationwide dialysis registry at the end of 2011 in Japan. Then we evaluated the patient survival and development of complication using the registry at the end of 2012.

Results: During one-year follow-up, 18775 (8.4%) died of all causes including 8094 (3.6%) cardiovascular death. All-cause mortality, and cardiovascular mortality were lower in line with the increase of baseline uric acid. In a multivariable logistic regression analysis (figure 1), patients of the highest quartile of uric acid had lower all-cause, and cardiovascular mortality compared with those of the lowest quartile (males: OR, 0.745; 95% CI, 0.6753 to 0.8207, females: OR, 0.8333; 95% CI, 0.7206 to 0.9636, and males: OR, 0.7202; 95% CI, 0.6266 to 0.8278, females: OR, 0.8575; 95% CI, 0.7029 to 1.0462, respectively).



Conclusions: In this large observational cohort study, lower levels of serum uric acid were independently associated not only with all-cause mortality but also cardiovascular mortality among Japanese HD patients. Close monitoring of serum uric acid is thought to be necessary for the management of HD patients.

Menopause Status Is Associated with Mortality in Women on Hemodialysis Sharanya Ramesh,[1] Matthew T. James,[1,2,3,4] Stephen B. Wilton,[1,2] Jayna M. Holroyd-Leduc,[1,3] Marcello Tonelli,[1,2,3,4] Brenda Hemmelgarn,[1,2,3,4] Sofia B. Ahmed.[1,2,4] *[1]Cumming School of Medicine, Univ of Calgary; [2]Libin Cardiovascular Inst of Alberta; [3]Dept of Community of Health Sciences, Univ of Calgary; [4]Alberta Kidney Disease Network; [5]Brigham and Women's Hospital, Harvard Univ.*

Background: Young women with end-stage kidney disease (ESKD) have low survival compared to age-matched men. Women with ESKD have an abnormal hypothalamic pituitary gonadal axis, characterized by low estradiol. We hypothesized that premature menopause is associated with death in women with ESKD.

Methods: Women who initiated hemodialysis (HD) between Feb 2005 and Nov 2012 in 3 centers were classified as premenopausal, perimenopausal and postmenopausal using the Women's Ischemia Syndrome Evaluation (WISE) criteria based on serum estradiol, follicle stimulating hormone levels and age. The associations between menopausal status and all cause, cardiovascular(CV) and non-cardiovascular(non-CV) mortality were determined by survival curves and Cox regression.

Results: Four hundred eighty-two women (60±16years, 53% diabetic) were followed for 2.9 years (IQR=3.47 years) with 241 deaths (31% CV). Thirty percent of women had a premenopausal sex hormone profile (estradiol: 196±187 pmol/L), while 7% and 58% had a perimenopausal (estradiol: 230±335 pmol/L) and postmenopausal (estradiol: 55±38 pmol/L) sex hormone profile respectively. In comparison to postmenopausal women, peri- and premenopausal women had higher all-cause mortality after adjustment for covariates (hazard ratio(HR)[95% confidence interval (CI)]:1.87[1.17-2.99] and 1.8[1.32-2.46] respectively), and higher CV mortality after adjustment (HR: 2.72[1.30-5.70] and 1.81[1.03-3.17], respectively). In comparison to postmenopausal women, premenopausal women had higher non-CV mortality after adjustment (HR: 1.71[1.07-2.73]).

Conclusions: Using the WISE classification,peri- and premenopausal women with ESKD on HD have a higher risk of all-cause and CV mortality compared to postmenopausal, and premenopausal women have a higher non CV mortality compared to postmenopausal women. Further studies are required to determine the pathophysiology leading to increased mortality risk in young women with ESKD.

Long-term Serial Measurements of High-Sensitivity Troponin T in Stable Hemodialysis Patients: The Effect of Angiotensin II Blockade and Associations with Clinical Variables The Safir Study Group. *Depts of Renal Medicine and Cardiology, Aarhus Univ Hospital, Aarhus, Denmark.*

Background: For the interpretation of high-sensitivity troponin T (TnT) levels in hemodialysis (HD) patients, it is important to know the expected range, variation over time, and the impact of clinical and HD specific factors.

Aim To study the effect of angiotensin II receptor blockade (ARB), short and long-term variation in TnT, and associations with cardiac status in stable HD patients.

Methods: 81 HD patients (urine output >300 mL/day, HD-vintage <1 year, and left ventricular (LV) ejection fraction (EF) >30%) were randomized double-blind for placebo (n=40) or ARB treatment (n=41) with irbesartan (150-300 mg) and followed for 12 months with serial measurements of TnT using Roche (Elecsys STAT) high-sensitivity assay.

Results: Baseline TnT medians with ranges (placebo/ARB) were: 45(14-295)/46(10-343)ng/L. ARB treatment did not significantly affect mean TnT levels over the 12-month study period ($P \geq 0.19$ in all tests for parallel curves, equal levels, and constant levels). Week-to week individual variation was median(95% range) 0(-24-19)ng/L corresponding to a median (95% ref. range) TnT-ratio (1 week/baseline) of 1.0(0.7-1.4); $P=0.9$. Individual amplitude (max-min) over 12 months was median 13(0-114)ng/L corresponding to range/median 29(0-208)%. In univariate analysis, baseline TnT was positively correlated with diabetes, ultrafiltration, arterial stiffness, and N-terminal brain natriuretic prohormone (NT-proBNP) and negatively correlated with hematocrit and residual renal function. Higher TnT levels at baseline were associated with a higher risk of admission and cardiovascular events during follow-up with natural log-transformed TnT odds-ratios (95% CI): 2.62(1.22-5.64) and 2.25(1.04-4.86). Increase in TnT over time was significantly associated with increase in LV mass and NT-proBNP and decrease in LV EF and late intradialytic stroke volume (30 minutes before end of HD).

Conclusions: There was no significant effect of ARB treatment. Week-to-week variation was low, yet over 12 months individual patients had considerable TnT fluctuations. Rise in TnT over time was significantly correlated with deterioration of cardiac status.

High-Sensitivity Troponins in Clinically Stable Dialysis Patients: Variation and Prognostic Value Sunna Snaedal,[1,2] Peter F. Barany,[1] Sigrun Helga Lund,[3] Abdul Rashid Tony Qureshi,[4] Olof Heimburger,[1] Peter Stenvinkel,[1] Christian Löwbeer,[5,6] Karolina Szummer.[7] *[1]Dpt of Clinical Science, Intervention and Technology, Karolinska Inst, Stockholm, Sweden; [2]Nephrology Dpt, Landspitali Univ Hospital, Reykjavik, Iceland; [3]Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland; [4]Dept of Baxter Novum, Karolinska Inst, Stockholm, Sweden; [5]Dept of Laboratory Medicine, Karolinska Inst, Stockholm, Sweden; [6]Dept of Clinical Chemistry, Aleris Medilab, Täby, Sweden; [7]Dept of Cardiology, Karolinska Inst, Stockholm, Sweden.*

Background: Cardiac troponins are elevated in dialysis patients even without signs of cardiac ischemia.The study aim was to assess variation and prognostic value of serial high sensitivity cardiac Troponin I (hs-cTnI) and T (hs-cTnT) in prevalent, stable dialysis patients.

Methods: In 198 prevalent hemodialysis (HD) and 78 peritoneal dialysis (PD) patients 4 monthly hs-cTnI and hs-cTnT measurements were obtained. Variability was assessed with reference change values and mixed models. Cox regression models were used for survival analyses, maximal follow-up 50 months.

Results: Troponin levels were similar in HD and PD patients (median [IQR] hs-cTnI; 25ngL [14–43] vs 21ng/L [11–37], hs-cTnT; 70ng/L [44–129] vs 67ng/L [43–123]). 42% of hs-cTnI and 98% of hs-cTnT were above the decision limit of myocardial infarction (MI). Variability of troponins associated with age, male sex, protein-energy wasting and congestive heart failure, not with ischemic heart disease or dialysis form. The reference change values were +68/-41% (hs-cTnI) and +29/-23% (hs-cTnT), index of individuality 0.07 for both. Constantly high hs-cTnT (above 108 ng/L) predicted death [HR 2.09 95% CI 1.03-4.26] while hs-cTnI did not.

Conclusions: A large proportion of stable dialysis patients have troponins levels above the decision limit for MI. Large intra-individual differences support the use of reference change values when assessing dialysis patients with possible acute cardiac events. A constantly high level of hs-cTnT and not hs-TnI predicted a doubled risk of death.

FR-PO927

High Sensitive Troponin-I Level and Hemodialysis-Induced Myocardial Injury in Chronic Hemodialysis Patients Khajohn Tiranathanagul,[1] Tanawat Tarapan,[2] Khrongwong Musikatavorn,[2] Piyarat Phairatwet,[3] Paweena Susantitaphong,[1] Kriang Tungsanga,[1] Somchai Eiam-Ong.[1] *[1]Medicine-Nephrology, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; [2]Emergency Medicine, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [3]Nephrology, Bhumirajanakarindra Kidney Inst Hospital, Bangkok, Thailand.*

Background: High-sensitivity Troponin I (hsTnI) is the best biomarker for myocardial injury. The current cut-off point for diagnosis of acute myocardial infarction (MI) was derived from general population. The reduction in renal clearance and the removal by hemodialysis (HD) affected the level and utility of this marker in HD ESRD patients. Unfortunately, there was unavailable well-designed study that determined the appropriated level of hsTnI in this specific population. Moreover, the HD process itself might cause undesirable myocardial injury and enhance post HD hsTnI level.

Methods: This comparative study was conducted to compare the hsTnI level between 100 HD ESRD patients (age 64.5 ± 13.8 years) and their 107 matched population with good renal function (age 63.8 ± 9.97 years). Moreover, the pre- and post-HD hsTnI levels were also compared to determine the effect of HD on hsTnI.

Results: The hsTnI levels in the HD ESRD group were higher than in the control group [median (IQR): 54.3(20.6-152.7) vs. 18 (6.2-66.1) ng/L, p< 0.001).The hsTnI levels reduced after HD process from 54.3 (20.6-152.7) ng/L in pre-HD to 27.1(12.3-91.4) ng/L in post-HD (p=0.015). Of interest, 25% of HD ESRD patients had increment of hsTnI after HD and represented HD-induced myocardial injury. The significant risk factors were high HbA1C, high blood flow rate, and high dialysate flow rate.

Conclusions: In HD ESRD patients, the baseline hsTnI levels are approximately three times significantly higher than in general population. As such, the cut point for acute MI diagnosis in HD ESRD patients should be three times of reference level in general population. However, the dynamic change of hsTnI overtime was still recommended for the final acute MI diagnosis. Hemodialysis could reduce hsTnI level. Certain numbers of HD ESRD patients had HD-induced silent myocardial injury and should be aggressively investigated to prevent further cardiovascular mortality.

Native T1 Mapping Is a Highly Reproducible Measure of Myocardial Fibrosis in Hemodialysis Patients Independent of Hydration Status
Matthew P.M. Graham-Brown,[1,2,3] Darren R. Churchward,[1,2] Daniel Scott March,[1,2] David J. Stensel,[3] Gerry Patrick Mccann,[2] James Burton.[1,2] *[1]John Walls Renal Unit, Leicester General; [2]Depts of Infection, Immunity & Inflammation & Cardiovascular Sciences, Univ of Leicester, United Kingdom; [3]4 National Centre for Sport & Exercise Medicine, Loughborough Univ, United Kingdom.*

Background: Myocardial fibrosis occurs frequently in hemodialysis (HD) patients and is associated with poor prognosis. Native T1 mapping is a novel cardiac MRI (CMR) technique that measures longitudinal proton relaxation to characterize tissue with great specificity. Native T1 mapping correlates well with myocardial fibrosis in many diseases, but concerns remain about its use in HD patients due to the potential impact of changes in hydration status on T1 time. We examined the inter-study reproducibility of native T1 mapping in HD patients and the effects of hydration on native T1 time.

Methods: 3T CMR was performed twice on non-dialysis days for 10 patients (median interval 7 days) to assess reproducibility of native T1 mapping. Changes in left ventricular end-diastolic volume (ΔLVEDV) and changes in weight (Δweight) between scans were used as surrogates of hydration status and the effects these on change in native T1 (ΔT1) between scans was assessed.

Results: There was no interval difference between mean native T1times (1267.8ms±35.4 vs 1270.7ms±30.5, P=0.6) with an inter-study co-efficient of variation of 0.7%. Bland-Altman analysis showed narrow limits of agreement with no systematic bias. LVEDV and weight were different between scans (mean change LVEDV 11.7ml±8.7, mean change weight 0.5kg±0.5) and there was a significant correlation between ΔLVEDV and Δweight (r=0.682, P=0.03). There were no correlations between ΔT1 and ΔLVEDV or Δweight (r=-0.14, P=0.7 and r=0.2, P=0.6). Linear regression confirmed ΔT1was unaffected by ΔLVEDV and Δweight (F(1,8)=0.15, adj R^2=0.1, P=0.71 and F(1,8)=0.31, adj R^2=0.08, P=0.59).

Conclusions: These results show for the first time that native T1 time is unaffected by hydration status. The outstanding test-retest, inter-study, reproducibility demonstrated for native T1 mapping make it an attractive imaging biomarker for clinical trials to assess changes in myocardial fibrosis.

FR-PO929

Insights from Speckle Tracking Echo in Detecting Differences in Myocardial Function in End-Stage Renal Disease
Panagiota E. Giannou,[1] Vasiliki Kakiouzi,[2] Athanasia Kapota,[1] Aikaterini Damianaki,[1] Constantina Aggeli,[2] Dimitrios Petras.[1] *[1]Nephrology Dept, Hippokration General Hospital, Athens, Greece; [2]1st Cardiology Clinic, Univ of Athens, Hippokration General Hospital, Athens, Greece.*

Background: Hemodialysis (HD) is capable of inducing subclinical myocardial dysfunction and this phenomenon is primarily related to hemodynamic instability. In contrast, peritoneal dialysis (PD) has until recently been considered to exert little, if any, significant hemodynamic effects. The aim of the current study was to assess whether speckle tracking echocardiography, by measuring global longitudinal strain (GLS), could assess differences in early myocardial dysfunction between patients with end stage renal disease (ESRD) who have undergone PD and those who are treated with HD.

Methods: Thirty-nine patients with ESRD and with no known coronary artery disease were enrolled. Patients were stratified into two groups according to the dialysis modality (i.e. 23 on HD and 16 on PD). All patients underwent comprehensive 2D echocardiographic study. Apart from standard 2D and Doppler measurements, GLS was measured using the obtained apical views. Cross-sectional comparisons of the derived parameters were made between the two groups.

Results: There was no difference in mean age (65.5 ± 9.9 vs. 57.7 ± 7.9, p= 0.07) and dialysis duration (mean 85 ± 106.7 vs 50.63 ± 57.2 months, p=0.4) between the two groups. Moreover, mean left atrial (40.1 ± 6.4 vs 41.6 ± 8.9mm, p=0.5), intra-ventricular septum (10.7 ± 1.8 vs. 9.9 ±1.9mm, p=0.4), EF (48.5 ± 12.3 vs. 45,6 ± 8.7%, p= 0.4) and E/Em (9.7 ± 4.5 vs. 10.1 ± 4.8, p=0.7) measurements were not statistically different. However, GLS was less negative in the HD group (-11.6± 3.8 vs. -15.4 ± 4.5, p=0.04).

Conclusions: Patients, in HD, exhibit less negative GLS values, in comparison to those in PD. It must be mentioned that less negative GLS is proven to be associated with an early myocardial dysfunction and an increased cardiovascular mortality. This could be attributed to different hemodynamic effects of each dialysis modality on myocardial function.

FR-PO930

Impact of Left Ventricular Hypertrophy Regression after Initiation of Intensive Hemodialysis on Clinical Outcomes
Emilie Trinh, Christopher T. Chan. *Nephrology, Univ Health Network, Toronto, ON, Canada.*

Background: Left ventricular hypertrophy (LVH) is an independent risk factor for mortality and cardiovascular events in patients with end-stage renal disease. Multiple studies have shown that frequent hemodialysis leads to LVH regression. However, the impact of left ventricular mass (LVM) regression on clinical outcomes in the setting of intensive hemodialysis remains unknown.

Methods: This observational cohort study assessed the impact of LVH regression on the composite outcome of time to all-cause mortality, technique failure or cardiovascular hospitalization. LVH regression was defined as either a reduction of more than 10% in LVM in patients with LVH at baseline or prevention of LVH in those without LVH at baseline. Risk factors associated with regression or progression of LVM were also examined.
